1 | MASH RESOLUTION WITHOUT FIBROSIS WORSENING AFTER BARIATRIC SURGERY IMPROVES LONG-TERM SURVIVAL

Guillaume Lassailly, Robert Caiazzo, Viviane Gnemmi, Helene Verkindt, Line-Carolle Ntandja-Wandji, Massih Ningarhari, Emmanuelle Leteurtre, Violetta Raverdy, Sebastien Dharancy, Alexandre Louvet, François Pattou and Philippe Mathurin, CHU De Lille

Background: Health agencies are waiting for studies with an extended follow-up evaluating whether *resolution of MASH without worsening of fibrosis* is associated with reduced risk of mortality. This study assessed the impact of histological evolution on long-term survival in MASH patients treated with bariatric surgery. **Methods:** From 1994 to 2022, 2940 bariatric surgery candidates at CHU de Lille were prospectively included. Liver biopsy was performed systematically at baseline and a consecutive biopsy was proposed at one year for MASH patients. We studied in univariate and multivariate analysis the 15-year survival of baseline MASH and fibrosis as well as MASH resolution without worsening of fibrosis after surgery. **Results:** At baseline, liver biopsy was available in 2687 (91%) patients, in whom 232 (8.6%) had biopsy-proven MASH. Paired biopsies before and 1 year after surgery were available in 146/232. Median follow-up of patients with biopsies was 14.7 years. At baseline, MASH patients were different than no-MASH patients for: age 47 vs 42 y, AST 37 vs 22 IU/L, GGT 56 vs 29 IU/L, glucose 133 vs 98 mg/dL, steatosis 60% vs 20% and fibrosis 2 vs 0 ($p < 0.001$ for all), but not for BMI 45.8 vs 46.2 kg/m². At baseline, patients with MASH and patients with significant fibrosis (≥ F2) had lower 15-year survival: 83.9% vs 92.7% $p < 0.001$; 79.8% vs 94.0% $p < 0.001$ respectively. After surgery, MASH resolution without worsening of fibrosis was associated with better biological and histological improvement in terms of steatosis 5% (1-20) vs 20% (10-40), fibrosis 1(0-2) vs 3(2-3), AST 21(18-27) vs 29(17-38) IU/L, GGT 22(14-33) vs 32(17-80) IU/L, glucose 93(86-108) vs 104(86-117) mg/dL ($p < 0.001$ for all). MASH resolution was associated with a better 15-year survival in univariate analysis (88.4% vs. 70.8%, $p = 0.009$) and multivariate analysis (HR 0.37, $p = 0.02$) adjusted for age, gender, BMI, diabetes, arterial hypertension, dyslipidemia, and baseline fibrosis. Interestingly, 15-year survival of patients with MASH resolution became similar than those without baseline MASH: 88.4% vs 92.4%, $p = 0.4$ (Figure). 95% of patient with fibrosis regression had MASH resolution. Those achieving a fibrosis regression to F0-F1 at 1 year had a better survival (87.5% vs 69.7% $p < 0.01$); however, it remained lower compared to baseline F0-F1 patients 95.2% vs 87.5% $p = 0.03$. **Conclusion:** Resolution of MASH without worsening of fibrosis is a predictive factor of long-term survival. Fibrosis regression was observed mainly after MASH resolution.

Michael Fuchs[6], Brian C. Davis[7], Vishwadeep Ahluwalia[5], Robert Cadrain[5], Masoumeh Sikaroodi[8] and Patrick M Gillevet[8], (1)Virginia Commonwealth University and Central Virginia Veterans Healthcare System, (2)Virginia Commonwealth University and Richmond VA Medical Center, (3)Richmond VA Medical Center, (4)McGuire Veterans Affairs Medical Center, (5) Virginia Commonwealth University, (6)Mcguire Veterans Affairs Medical Center, Moseley, VA, (7)Hunter Holmes McGuire VA Medical Center, (8)George Mason University

Background: Minimal hepatic encephalopathy (MHE) is associated with poor outcomes but treatment strategies are limited. Rifamycin SV MMX (RiVM) is a novel rifampin derivative which a non-absorbable antibiotic with maximal impact in the colon. Aim: Evaluate impact of RiVM on microbiome, safety & gut-brain axis in an RCT. **Methods:** We performed a phase 2 placebo-controlled, double-blind RCT under FDA IND. We randomized cirrhosis outpts with MHE (PHES or Stroop) 1:1 into RiVM or placebo 600 mg BID (1200 mg) BID for 30 days with 7 day post-drug f/u. There were 4 visits; baseline, day 7, 15 & 30. *Primary outcome* was stool microbial change (cirrhosis dysbiosis ratio CDR, high = good) in rifamycin vs placebo through 16SrRNA sequencing from baseline to day 30 (end). CDR is the ratio of *Lachnospiraceae* + *Ruminococcaceae* + *Veillonellaceae* to *Enterobacteriaceae* + *Bacteroidaceae*. Secondary outcomes were gut-brain (cognition, serum ammonia, optional brain MR spectroscopy, MRS), inflammatory (stool calprotectin), PROs (SIP: total, physical, psychosocial, high = worse) and handgrip strength. Comparisons between/within gps & delta (Δ Post minus Pre) values were compared. **Results:** 58 pts were screened; 8 had overt HE, 11 screen failed due to no MHE on testing, 9 were not interested. Ultimately 30 pts were enrolled (15/gp), who completed the study without any safety concerns, including the post-drug visit with good adherence. Groups were largely equivalent on baseline but ammonia & SIP scores were higher in RiVM vs placebo (Fig B). 7 RiVM and 11 placebo-assigned pts agreed & were eligible for the optional brain MRS. Microbiota: CDR decreased in RiVM pts due to ↓*Lachnospiraceae* & *Ruminococcaceae*, although *Bacteroidaceae*↑. There was ↓±diversity & significant β-diversity change with clustering of post-RiVM vs pre & post-RiVM vs post-placebo (Fig D/E). Labs: No change in MELD-Na but ammonia & calprotectin decreased in RiVM vs baseline and Δ ammonia was higher in RiVM (Fig B); no change in placebo. Cognition and Brain MRS: Although serial dotting, which tests for psychomotor speed improved in RiVM, no other changes were seen within/between gps. Brain Glutathione ↑with RiVM & decreased in placebo ($p = 0.03$) on brain MRS but remaining metabolites (choline, myoinositol, glutamate/glutamine) remained similar. PROs: ΔPhysical SIP and handgrip were higher indicating improved strength & better physical QOL with RiVM vs placebo. **Conclusion**: In this phase 2 double-blind, placebo-controlled RCT of rifamycin SVMMX in patients with cirrhosis and MHE, we found no safety concerns. RiVM Rx resulted in lowered gut microbial ± diversity and cirrhosis dysbiosis ratio. RiVM therapy was associated with reduction in blood ammonia and improved physical function and handgrip. There was also a reduction in brain oxidative stress with RiVM but no change in cognitive testing. RiVM, with predominant colonic action, may have important gut-brain axis modulatory impact in cirrhosis and MHE.

3 | SERIAL ENDOSCOPIC INJECTION SCLEROTHERAPY WITH N BUTYL CYANOACRYLATE GLUE VERSUS RADIOLOGICAL INTERVENTION FOR SECONDARY PROPHYLAXIS OF GASTRIC VARICEAL HEMORRHAGE IN PATIENTS WITH LIVER CIRRHOSIS (CRISP-GV): A RANDOMIZED CONTROLLED TRIAL★

Sagnik Biswas, Manas Vaishnav, Shekhar Swaroop, Umang Arora, Arnav Aggarwal, Piyush Pathak, Abhinav Anand, Anshuman Elhence, Deepak Gunjan, Saurabh Kedia, Soumya Jagannath Mahapatra, Shivanand Gamanagatti and Dr Shalimar, All India Institute of Medical Sciences, New Delhi

Background: Acute variceal bleed (AVB) from cardiofundal varices (GOV-2/IGV-1) is associated with high mortality rates in patients with liver cirrhosis. No consensus exists on the best modality to prevent rebleeding after an index episode of bleeding. **Methods:** Consecutive cirrhosis patients with AVB from cardiofundal varices, after primary hemostasis by endoscopic obturation with cyanoacrylate glue (CYA), were randomized into two arms. In the 'endoscopic intervention' (EI) arm, endoscopic obturation with CYA was repeated at regular intervals (1, 3, 6 and 12 mo); while in the 'radiological intervention' (RI) arm, patients underwent transjugular intrahepatic portosystemic shunt (TIPS) or balloon-occluded retrograde transvenous obliteration (BRTO); preferably BRTO, if a shunt vessel was present. Hepatic venous pressure gradient (HVPG) was measured at baseline and 1 month. Primary outcome measures included rebleed rates and all-cause mortality at 1 year. **Results:** We randomized 90 patients (n = 45 in each arm), median age 46 (35-55) years with mean (±SD) Child and MELD scores at baseline 7.4 ± 1.8 and 12.3 ± 3.2, respectively. Alcohol was the predominant etiology of cirrhosis in 33 (36.7%) patients. There were no differences in baseline characteristics between the two arms. In the RI arm, 25 patients underwent BRTO and 20 underwent TIPS. Median follow-up was 17.9 and 16.4 months, for EI and RI arms, respectively. Rebleed rates at 1 year were significantly higher in the EI arm compared to RI arm: 13 (28.9%) vs 3 (6.7%); $p = 0.010$ (Figure 1a). Mortality at 1 year was 12 (26.7%) in the EI arm versus 7 (15.6%) in the RI arm ($p = 0.108$) (Figure 1b). Technical success for glue injection, TIPS and BRTO was 100%, 100% and 96.2% respectively. Worsening of ascites after radiological intervention was reported by 12 (26.7%) patients versus 2 (4.4%) in EI arm; $p = 0.007$. On sub-group analysis, patients undergoing BRTO had a statistically insignificant median rise in HVPG (2 mm versus 1 mm of Hg; $p = 0.715$) and aggravation of esophageal varices on follow-up (24% versus 11%; $p = 0.150$) compared to the EI arm. There was no significant difference in complications, rebleeding rates and overall mortality at 1 year between those undergoing TIPS as compared to BRTO. The probability of remaining free from all-cause rebleeding at 1 and 2 years was 70.7% versus 93%, and 52.3% versus 93% for the EI and RI arms, respectively (Figure 1a). **Conclusion:** Radiological intervention for secondary prophylaxis significantly reduces rebleeding in patients with liver cirrhosis with GV hemorrhage but does not provide any survival benefit. TIPS and BRTO have comparable complications, rebleeding and mortality rates on follow-up.

Ocala GI Research, (11)89bio, CA, (12)Mayo Clinic, Rochester, MN

Background: Metabolic dysfunction-associated steatohepatitis (MASH) patients who have developed stage F4 fibrosis (cirrhosis) are at risk of hepatic decompensation, hepatocellular carcinoma, liver transplant, cardiovascular events, liver and all-cause mortality. There are currently no approved therapies for non-cirrhotic or cirrhotic MASH. **Methods:** The ENLIVEN Phase 2b study assessed the effect of treatment for 24 weeks with one of three doses of pegozafermin or placebo on liver histology endpoints in 222 subjects with biopsy confirmed MASH (fibrosis F2 or F3, NAS ≥ 4 points). Initially, biopsies were assessed by one of two central pathologists; during the study, a novel 3-panel consensus scoring method was introduced to increase objectivity in biopsy reading. Baseline biopsies of subjects enrolled prior to this change were re-read by the panel. Fourteen subjects who met the study histological inclusion criteria based on the original read were re-classified as having stage F4 fibrosis by the consensus panel. All subjects had well compensated cirrhosis. We present post-hoc descriptive data for these subjects. **Results:** Baseline characteristics included: female 57%, mean age 56, average BMI 36.8, mean MRI-PDFF 15%, mean ProC3 65ng/mL, and 86% with a history of diabetes. Treatment assignment of the 14 subjects was: Placebo n = 2; Pooled pegozafermin (PGZ) n = 12. Follow-up biopsies at week 24 were available for 12 of the 14 subjects (PBO n = 1; PGZ pooled n = 11). PGZ led to ≥ 1 stage fibrosis improvement in 9 of the 11 treated patients (82%), and to ≥ 1 stage fibrosis improvement without worsening of MASH in 5/11 (45%) subjects. No fibrosis improvement was observed in the placebo group. There was concurrent improvement compared to baseline in the non-invasive fibrosis biomarkers ProC3 and FAST (LS means difference -24% and -53%, respectively). Treatment with PGZ also reduced ALT at week 24 compared to baseline (LS mean -53%). Pegozafermin was well tolerated in these subjects with the most common treatment-emergent adverse events being GI side effects and injection site reactions. No severe adverse events, discontinuations, or deaths were reported. **Conclusion:** These data demonstrate robust fibrosis improvement at 24 weeks in patients with MASH-related cirrhosis who were treated with PGZ. In addition to regression of fibrosis, reductions were observed in liver specific biomarkers of fibrogenesis/fibrosis (ProC3 and FAST) and inflammation (ALT). Pegozafermin appears to maintain a safety and tolerability profile in patients with compensated cirrhosis comparable to those with less advanced disease (MASH with F2/F3 fibrosis). Although this small subset precludes statistical analysis, the numerical improvement observed across both histology and biomarkers is encouraging and supports further evaluation of PGZ as a treatment for subjects with compensated MASH cirrhosis.

f 5 | ANALYZING NEW ONSET HEPATIC DECOMPENSATION AND LONG TERM ABSTINENCE/CRAVING IN PATIENTS WITH ALCOHOL ASSOCIATED LIVER DISEASES (AALD): A DOUBLE BLIND RANDOMIZED CONTROL TRIAL (RCT) FOR EFFECTIVENESS OF SELF ADMINISTERED 12 WEEKS 50 MG ORAL NALTREXONE VERSUS PLACEBO; ALONG WITH STANDARD COUNSELLING★

Hospitals, Hyderabad, India, (3)Institute of Liver and Biliary Sciences, New Delhi, India, (4)Ilbs

Background: Long term reduction and alcohol abstinence have been known to reduce both short and long term mortality in patients with Alcohol associated Liver diseases (AaLD). Naltrexone, despite being known efficacy in Alcohol dependence, has not been tested in liver disease patients. We aimed to evaluate six and twelve month abstinence rates (and new onset decompensation events over 12 mo) after 12 weeks of Naltrexone (50 mg) compared with placebo in patients with underlying AaLD. **Methods:** 6 and 12 month abstinence rates were analyzed in AaLD patients given take home oral Naltrexone versus placebo; as part of 12 weeks double blind RCT at ILBS hospital, (NCT04391764). Consecutive AaLD patients with no recent decompensation (last 60 d) were given Naltrexone or placebo tablets if they fulfil DSM-5 criteria for AUD. Cirrhosis was confirmed with histology and imaging findings. Self report, family member's corroboration and blood Ethyl glucoronide testing were done to ascertain abstinence and lapses. Obsessive compulsive drinking scores (OCDS) and self reports of craving (Visual analogue scale-VAS) were used to measure craving at 6 and 12 months. All patients discontinued use of Naltrexone and placebo after the 12 weeks study period; as well as counselling as part of the study. Number of episodes of new onset decompensation was noted. As routine clinical practice all patients received Brief intervention counselling for AUD. **Results:** A total of 147 AaLD patients were screened for inclusion in the study, out of which 100 were included and 56 patients completed 12 months follow up and were analysed (28 in each group). Baseline clinical and alcohol use related parameters were comparable between the two groups. At 12 months, 7.1% (2/28) had new onset hepatic decompensation vs 14.2% (4/28) in the placebo group (aOR = 2.34,$p = 0.04$). There was significant improvement in CTP (t = -3.94, $p < 0.01$) and MELD scores (t = -4.07, $p < 0.01$) at 12 months; along with significant reduction in total Bilirubin (t = 4.47, $p < 0.01$), INR (t = 0.37, $p < 0.01$) and serum GGT levels (t = 2.28, $p = 0.03$). Among alcohol use related parameters proportion of patients abstinent at 12 months were higher in Naltrexone as compared to placebo ($x^2 = 0.37$, $p = 0.04$). There was reduction in number of lapses in the Naltrexone group ($p = 0.74$) at 12 months. Moreover craving measures including OCDS and VAS were also significantly lower in drug group as compared to placebo. Naltrexone group had lesser number of lapses per month at one year as compared to placebo (3.93 vs 6.50; $p = 0.26$). Both patients with new onset decompensation in Naltrexone continued alcohol consumption. Adverse events were comparable in both the groups (41.4 % vs 26 %; $p = 0.59$) and none required discontinuation of drug. **Conclusion:** This is the first placebo controlled RCT using Naltrexone in AaLD patients. It showed that it is a safe and effective drug for improving alcohol use related parameters and new onset decompensation at 6 and 12 months.

Background: The emergence of direct-acting anti-HCV agents has led to a significant increase of patients who achieve sustained virologic response (SVR) but remain at risk of HCC development over a decade. HCC risk stratification post SVR is urgently needed. **Methods:** A hepatic transcriptome-based Prognostic Liver Signature for SVR (PLS-SVR) was identified in 85 patients who

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

had curative resection/ablation for post-SVR HCC (derivation set), and independently validated in 39 HCC-naïve post-SVR patients (tissue validation set). Subsequently, a blood-based surrogate of PLS-SVR, Prognostic Liver Secretome signature for SVR (PLSec-SVR), was defined using our computational pipeline (TexSEC) for non-invasive HCC risk assessment. PLSec-SVR was validated in two independent cohorts of HCC-naïve (serum validation set 1; matched 41 cases and 123 controls) and HCC-experienced (serum validation set 2; cohort of 146 subjects) patients. In the serum validation sets, we assessed clinical utility of PLSec-SVR as an etiology-specific "plug-in" to refine HCC risk prediction with our previously reported etiology-agnostic PLSec-AFP score. **Results:** We defined a 170-gene PLS-SVR, including 133 high- and 37 low-risk genes, in the derivation set, where the 5-year de novo HCC recurrence rates were 66.1% and 6.3% in high- and low-risk patients, respectively (adjusted hazard ratio [aHR], 48.9; 95% confidence interval [CI], 11.3-194.8). In the tissue validation set, 25 (64%) patients were classified as high risk, which was significantly associated with incident HCC (aHR, 9.99; 95% CI, 1.11-1319.4). PLS-SVR was converted to a 6-protein PLSec-SVR. In serum validation set 1 and 2, PLSec-SVR identified 59 (36%) and 43 (29%) high-risk patients, respectively, and was independently associated with HCC risk (adjusted OR [aOR], 3.08; 95% CI 1.42-6.65 and aHR, 2.59; 95% CI, 1.55-4.32 in serum validation sets 1 and 2, respectively). Integration of PLSec-SVR with the etiology-agnostic PLSec-AFP improved prognostic capability as a "plug-in" module (aOR, 13.9; 95% CI, 3.82-50.5 and aHR, 14.2; 95% CI, 6.17-32.6 in serum validation sets 1 and 2, respectively). **Conclusion:** PLSec-SVR enables prediction of long-term risk of post-SVR HCC development and substantially improves the performance of the etiology-agnostic PLSec-AFP score to inform necessity of regular HCC screening.

Grover[7], Pankaj Gupta[4], Sahaj Rathi[4], Nipun Verma[3], Sreedhara B Chaluvashetty[4], Harish Bhujade[4], Naveen Kalra[4], Jasvinder Nain[4], Vishesh Kumar[4], Prerna Sharma[4] and Surender Singh[4], (1)Postgraduate Institute of Medical Education & Research, Chandigarh, India, (2)Sanjay Gandhi Postgraduate Institute of Medical Sciences, (3)Post Graduate Institute of Medical Education and Research, Chandigarh, India, (4)Post Graduate Institute of Medical Education and Research, (5)Institute of Liver and Biliary Sciences, (6)Institute of Microbial Technology (CSIR-IMTECH), (7)Punjab Government

Background: Decentralized care, using free-of-charge generic direct-acting antiviral agents (DAAs) in patients with chronic hepatitis C (CHC) infection has resulted in cure rates of 91.6% in a large prospective multicentric population-based cohort from the state of Punjab, India. The rate of recompensation, as per BAVENO-VII criteria, in patients with decompensated CHC-related cirrhosis following DAAs, needs evaluation as part of public health policy to eliminate chronic hepatitis C in India. **Methods:** We evaluated patients with decompensated CHC-related cirrhosis treated at the PGIMER, Chandigarh and followed them up q6months for clinical events, viral, biochemical, endoscopic surveillance & imaging tests, and new evidence hepatocellular carcinoma (HCC). The diagnosis of cirrhosis was based on clinical evidence including AST-to-platelet ratio index (APRI ≥ 2.0) and FIB-4 score (> 3.25) or on liver stiffness measurement (LSM) ≥ 12.5 kPa on Fibroscan. The rate of recompensation was noted. Progression of portal hypertension (PHT) was defined as the onset of varices needing treatment or PHT-related bleeding. Patients with HIV or HBV coinfection and HCC at presentation were excluded from analysis. **Results:** Between April 2018 and December 2022, of 6516 patients with cirrhosis who reported to the nodal centre, we enrolled 1152 with decompensated cirrhosis (mean age:53.2 ± 11.5 y, 62.9% men, median MELDNa 18.5,73.5%-unsafe injection related,77.9% urban). The decompensation events included ascites (1098, 95.3%), hepatic encephalopathy (191,16.6%), and history of variceal bleeding (284, 24.7%) at enrolment. SVR-12 was 81.8%, due to referral of difficult-to-treat cases to PGIMER. Resolution of ascites was noted in 993(86.2%), but diuretic withdrawal achieved in 280 (24.3%). Recompensation was documented in 284 (24.7%). On multivariate logistic regression only higher age (aHR 1.013 ,95%CI:1.003-1.048,$p = 0.042$) and higher MELDNa (aHR 1.213,95%CI: 1.003-1.028, $p = 0.033$) predicted failure to recompensate. Progression of PHT was noted in 158 patients: with rebleed in 45 (3.9%) during a follow-up period of 52 months (interquartile range, 18-68.5 mo). Treatment failure (OR 1.8, 95%CI:1.3-4.9, $p = 0.002$) and presence of HE (OR4.4, 95%CI:1.3-5.6, $p = 0.044$) were associated with progression of PHT. Of 145 patients who died, and 6 underwent liver transplantation. In follow up at 2 years. A decrease in MELDNa of ≥ 3 occurred in 409(35.5%) and a final MELD score of < 10 was achieved in 31.7%. On surveillance, 29(0.45%) new cases of HCC were diagnosed during follow up. **Conclusion:** The Punjab HCV Model demonstrates that recompensation of cirrhosis is achievable in 24% of decompensated cirrhosis, but these patients should remain on HCC surveillance. Patients with cirrhosis should be followed up following virological cure for new decompensations and HCC, which should be integrated in public health-care policy for HCV elimination.

Background: Patients with cirrhosis are at increased risk of liver decompensation and HCC which can result in liver transplant or death. There is no available therapy and previous clinical trials have failed to show a benefit in patients with NASH and cirrhosis. Aldafermin, an engineered analog of the human hormone FGF19, improved liver histology in previous non-cirrhotic, phase 2 trials. We report results from ALPINE 4, a 48-week, phase 2b paired liver biopsy study in patients with compensated cirrhosis due to NASH (NCT04210245). **Methods:** 160 patients were randomized to receive placebo (PBO, n = 56), aldafermin 0.3mg (n = 7; enrollment in the 0.3mg arm was discontinued during trial to allow patients exposure to higher doses), 1mg (n = 42), or 3 mg (n = 55) SC QD at 48 sites in 8 countries. Key inclusion criteria included compensated cirrhosis (CTP-A) with biopsy-proven NASH (NASH CRN criteria). Patients underwent liver biopsy at baseline and week 48. The primary endpoint was the change in Enhanced Liver Fibrosis (ELF) score from baseline to week 48 vs. PBO. Secondary endpoints included fibrosis improvement of ≥ 1-stage, C4, serum bile acids, Pro-C3, ALT and AST. Primary analysis was performed in the ITT population using MMRM method. **Results:** Demographic and baseline characteristics were similar across the trial groups. The mean age was 59.6 (8.2) years and 76% of patients had T2D at baseline. The primary endpoint was achieved with aldafermin 3mg. At week 48, the least-squares (LS) mean difference between aldafermin and PBO in ELF was −0.1 for 1mg and −0.5 for 3mg ($p < 0.001$) (Table 1). Fibrosis improvement of ≥ 1-stage was achieved in 15%, 21% and 23% patients in the PBO, 1mg and 3mg groups, respectively. Dose-dependent reductions in C4 (LS mean difference vs. PBO: −65% and −72% in 1mg and 3 mg groups), total bile acids (−67%, −82%), the fibrogenesis biomarker Pro-C3 (−54%, −60%), ALT (−30%, −35%), and AST (−19%, −28%) were observed. Adverse events were mostly mild and moderate in severity. Six (6%) patients on aldafermin discontinued treatment due to drug-related adverse events. Serious adverse events occurred in 19 (12%) patients, all deemed unrelated to drug. No DILI or HCC was reported in the study. **Conclusion:** We herein report positive primary endpoint results in a randomized controlled trial of aldafermin in patients with NASH and compensated cirrhosis. Aldafermin achieved dose-dependent benefits in ELF and other non-invasive markers of both inflammation and fibrosis.

Baseline values are mean (SD); least-squares means difference *vs.* placebo (PBO) or percentage of patients are shown. Enrollment in the 0.3mg dose group was discontinued early during trial to allow patients exposure to higher doses, thus not included in the analysis due to small N numbers.

Primary analysis was performed in the intention-to-treat (ITT) population using mixed-model repeated measures (MMRM) method. Fibrosis improvement was analyzed using Cochran-Mantel-Haenszel (CMH) test stratified by baseline T2D status and randomization ratio.

ALT, alanine aminotransferase; AST, aspartate aminotransferase; C4, 7alpha-hydroxy-4-cholesten-3-one; ELF, enhanced liver fibrosis; LSM, liver stiffness measure by Fibroscan; Pro-C3, neoepitope-specific N-terminal propeptide of type III collagen; TBA, serum total bile acids.

9 | VALIDATION OF THE R3-AFP MODEL FOR RISK PREDICTION OF HCC RECURRENCE AFTER LIVER TRANSPLANTATION IN THE SILVER CLINICAL TRIAL

Charlotte Laurent Costentin, Grenoble Alpes University; Institute for Advanced Biosciences, Research Center UGA/Inserm U 1209/Cnrs 5309; Gastroenterology, Hepatology and GI Oncology Department, Grenoble Alpes University Hospital, Federico Pinero, Hospital Universitario Austral, Austral University, Argentina, Quirino Lai, Sapienza University of Rome, Helena Degroote, Ghent University Hospital, Andreas A Schnitzbauer, University Hospital Frankfurt, Edward Geissler, University Hospital Regensburg and Christophe Duvoux, Hospital Henri Mondor AP-HP, University of Paris-Est Créteil (UPEC).

Background: Hepatocellular carcinoma (HCC) recurrence risk after liver transplantation (LT) has been evaluated with different prediction models following pathology explant analysis. The inclusion of alpha-feto protein (AFP) in these models, such as the novel R3-AFP score (1), have significantly improved risk stratification of HCC recurrence post-LT. The SiLVER trial (NCT00355862) evaluated the efficacy of mTOR inhibitors (Sirolimus-Group B) compared to mTOR-free based immunosuppression (Group A) to reduce post-LT HCC recurrence (2). Here, we aimed to validate the prognostic and predictive discrimination power of R3-AFP scoring on the intention-to-treat population (ITT) included in the SiLVER trial (NCT00355862). **Methods:** We included the intention-to-treat (ITT) patient population from the SiLVER Study. Cox proportional hazard survival analysis was performed, estimating hazard ratios (HR) and 95% confidence intervals (95% CI). Discriminant function was evaluated using the Harrell's c-index. A competing risk regression analysis was also conducted estimating sub-HR. Calibration was conducted through expected versus observed events estimating the baseline hazard. **Results:** Overall, 528 patients signed written informed consent of which 20 were excluded for the intention-to-treat analysis (Group A, n = 256 ; Group B, n = 252). The 5-year recurrence rate in the ITT population was 18.7% (95% CI

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

15.3-22.6; n = 88 recurrences). The frequency distribution of the R3-AFP score was 42.6% low risk group (n = 216), 35.7% (n = 181) intermediate risk, 19.5% high risk group (n = 99), and 2.2% very high risk group (n = 11). The R3-AFP score correctly stratified HCC recurrence risk (Figure 1) (reference: low risk group): intermediate risk group SHR 1.80 (95% CI 1.02;3.18), high risk group SHR 4.20 (2.41;7.31), and very high risk group SHR 9.55 (3.66;24.92). Discrimination power for the R3_AFP model was 0.75 (95% CI 0.69;0.81) in the ITT population; lower in the mTOR group [Group A 0.75 (CI 0.69-0.81) when compared to Group B 0.67 (0.59-0.75); $p = 0.048$]. No significant differences were observed between expected and observed events across R3-AFP strata. **Conclusion:** The R3-AFP score has been validated in the ITT population of the SiLVER trial, a high-quality evidenced-based data, showing good performance. The model had lower discrimination of the risk of recurrence in exposed subjects with mTOR immunosuppression. This should lead to further hypothesis testing.

10 | DISPARITIES IN ACCESS TO LIVER TRANSPLANTATION FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS-ASSOCIATED HEPATOCELLULAR CARCINOMA

David W. Victor III[1], Elizabeth W. Brombosz[1], Sudha Kodali[1], Mazen Noureddin[2], Tamneet Basra[1], Robert S. McFadden[1], Edward Graviss[1], Duc Nguyen[1], Constance Mobley[1] and R. Mark Ghobrial[1], (1)Houston Methodist Hospital, Houston, TX, (2)Houston Research Institute, Houston, TX

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is the fastest-growing etiology of liver disease for patients with hepatocellular carcinoma (HCC) added to the liver transplantation (LT) waitlist in the US. Patients with MASH-HCC are disproportionately of Hispanic ethnicity, who have historically had poorer access to LT than non-Hispanic (NH) whites. However, it is unclear whether racial and ethnic minorities are waitlisted and transplanted for MASH-HCC at lower-than-expected rates. **Methods:** Adults with HCC waitlisted for LT between 1/2015 and 12/2021 were identified in the US Scientific Registry of Transplant Recipients standard analysis file. Patients were included if they (1) had a MASH diagnosis, or (2) had a diagnosis of cryptogenic/idiopathic cirrhosis and body mass index > 30 kg/m^2. Differences between groups were compared using Chi-square, Fisher's exact, or Kruskal Wallis tests as appropriate. Cox regression modeling was used to determine characteristics associated with having liver transplantation. A p value of < 0.05 was considered statistically significant. **Results:** Of the 3810 LT candidates, the majority (2713, 71.2%) were NH white. Only 49 (1.1%) were Black, 891 (23.4%) were Hispanic, and 115 (3.0%) were Asian. Most candidates went on to undergo LT, although the proportions of patients receiving LT were significantly different ($p = 0.001$; Figure 1). In pairwise comparisons, Hispanics underwent LT at significantly lower rates than NH whites ($p < 0.001$). Waitlist mortality rates were not significantly different among races/ethnicities ($p = 0.06$). Hispanics received LT at a significantly higher rates in the post-Median MELD at Transplant (MMAT) era (after 6/1/2019) than in the pre-MMAT era ($p = 0.02$). MMAT era did not impact the proportion of patients undergoing LT for other races/ethnicities (all $p > 0.05$). In multivariable Cox regression analysis, Hispanic (HR, 0.85; 95% CI, 0.77-0.95; $p = 0.002$) and Asian (HR, 0.79; 95% CI, 0.63-0.98; $p = 0.04$) patients were significantly less likely to receive LT than NH white patients. **Conclusion:** Hispanics and

Asians are less likely to receive LT for MASH-HCC than other races/ethnicities. A significantly greater proportion of Hispanic patients had LT in the post-MMAT era, likely reflecting efforts across the country to mitigate access disparities. The proportion of Black patients waitlisted for LT was also surprisingly low. Although there are encouraging trends, work is still needed to address disparities in access to LT for MASH-HCC.

11 | IMPACT OF ACUTE KIDNEY INJURY RESPONSE ON SURVIVAL AND LIVER TRANSPLANT RATES IN HOSPITALIZED PATIENTS WITH CIRRHOSIS AWAITING LIVER TRANSPLANTATION: RESULTS FROM THE HRS-HARMONY CONSORTIUM

Xing Li[1], Tianqi Ouyang[2], Giuseppe Cullaro[3], Kavish R. Patidar[4], Eric Przybyszewski[2], Robert M Wilechansky[2], Douglas A. Simonetto[5], Pratima Sharma[6], Justin M. Belcher[7], Kevin R. Regner[8], Nneka Ufere[2], Andres Duarte-Rojo[9], Nabeel Wahid[10], Sumeet Asrani[11], Shelsea A. St. Hillien[2], Jevon Robinson[2], Raymond T. Chung[12] and Andrew Allegretti[2], (1)Massachusetts General Hospital, Cambridge, MA, (2)Massachusetts General Hospital, (3)Columbia University Medical Center, New York, NY, (4)Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center, (5) Mayo Clinic, Rochester, Rochester, MN, (6)University of Michigan, Ann Arbor, MI, (7)Yale University, New Haven, CT, (8)Medical College of Wisconsin, (9)University of Pittsburgh, (10)Northwestern University, Chicago, IL, (11) Baylor University Medical Center, Dallas, TX, (12) Massachusetts General Hospital, Harvard Medical School

Background: Acute kidney injury (AKI) frequently complicates the course of hospitalized patients with cirrhosis and negatively impacts prognosis. Response to medical management in AKI is variable, depending on the etiology and severity of the injury. How AKI improvement or response affects liver transplant timing is less clear. We sought to assess the impact of AKI response to treatment on survival and liver transplantation (LT) for patients with cirrhosis waitlisted for LT. **Methods:** Retrospective study of consecutive patients with cirrhosis waitlisted for LT who had been hospitalized with AKI in 2019 at 11 U.S. transplant centers. The exposure of interest was AKI response to medical management (defined as a decrease in serum creatinine to within 0.3 mg/dL of baseline or regression of AKI stage) versus no response during hospitalization. The outcomes were 90-day rates of overall survival (with LT as a competing risk), transplant-free survival, and rates of LT with associated time to transplant, as well as resource utilization during hospitalization. We adjusted for confounders including age, sex, race, etiology of cirrhosis, study site and MELD-Na score at the time of admission. A sensitivity analysis was performed on the sub-population who received HRS vasoconstrictor therapy. **Results:** Of 2057 patients with AKI, 317 were waitlisted for LT and included in the study. 170 had AKI response to medical management (53.6%) and 147 with no response (46.4%). Compared to non-responders, responders had better 90-day overall survival (89.4% vs. 76.2%, aHR for 90-day mortality 0.34 [95% CI 0.18, 0.65, $p = 0.001$]), and better 90-day transplant-free survival (63.5% vs. 25.2%, aHR for 90-day risk of death or transplant 0.35 [95% CI 0.25, 0.50, $p < 0.001$]). The rate of LT was lower for responders compared to non-responders (45.9% vs. 61.2%, aHR 0.55 [95% CI 0.37, 0.84, $p = 0.005$]). The majority (79%) of LT in responders occurred after discharge, at a median of 103 days, while the majority (62%) of transplants in non-responders occurred during the same hospitalization, with the remainder occurring post-discharge at a median of 58 days. Compared to non-responders, responders had shorter hospital and ICU lengths-of-stay by a median of 10 and 6 days respectively, and smaller percentages of patients needing ICU, intubation, renal replacement therapy and pressor use. Sensitivity analysis within the sub-population that received HRS vasoconstrictor therapy (n = 180) yielded similar results. **Conclusion:** In patients with cirrhosis waitlisted for LT who are hospitalized with AKI, AKI response to therapy is associated with improved 90-day survival, despite a reduced LT rate and longer time to LT. As the newly approved vasoconstrictor terlipressin becomes more widely available in the U.S. for treatment of HRS-AKI, further research on how this therapy, which affects AKI response rates, impacts LT rate and timing, and potentially LT allocation, is warranted.

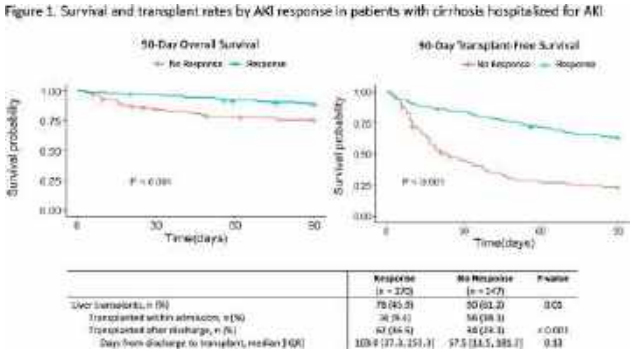

Figure 1. Survival and transplant rates by AKI response in patients with cirrhosis hospitalized for AKI

Background: Alagille syndrome (ALGS) is an inherited liver disorder dominated by high γ-glutamyltransferase (GGT) cholestasis. Previous studies have demonstrated limited efficacy of surgical interruption of the enterohepatic circulation in ALGS, with varying degrees of improvement in pruritus and xanthomas. Utilizing the GALA database, we sought to evaluate whether surgical biliary diversion (SBD) alters the natural history of liver disease. **Methods:** Multicenter retrospective analysis of children with clinically and/or genetically confirmed ALGS. Laboratory data were collected preoperatively (−6 to 0 mo) and postoperatively (3 to 12 mo). Paired

sample t-tests were used to compare continuous variables, and McNemar's tests were used to compare binominal variables pre-and postoperatively. Receiver operating characteristic (ROC) curves were used to determine the optimal laboratory threshold for predicting native liver survival (NLS) following SBD. Cox proportional hazards models were constructed to determine NLS in ALGS-SBD patients. **Results:** Of 1673 ALGS patients, 3.7% (n = 62; 54.8% male) underwent SBD from 26 centers. The median age of SBD was 2.5 years (IQR 1.8 – 4.4). Most ALGS patients underwent a partial external biliary diversion (54.8%, n = 34), followed by a partial internal biliary diversion in 19.4% (n = 12) and ileal exclusion in 12.9% (n = 8). 100% (n = 62) of patients reported pruritus at the time of SBD, and 51.4% (n = 18/35) reported xanthomas. ALGS-SBD patients had a 2.5-fold greater risk of liver transplantation (LT) or death (95% CI 1.6 – 3.9; $p < 0.01$). Following SBD, there were no significant differences in total bilirubin (TB) (8.8 vs. 9.1 mg/dL, $p = 0.51$), ALT (159.5 vs. 189.7 U/L, $p = 0.38$), GGT (495.0 vs. 459.5 U/L, $p = 0.21$) or cholesterol (493.0 vs. 414.6 mg/dL, $p = 0.21$). Availability of serum bile acids (SBA) was limited; however, in 10 patients with SBAs pre- and postoperatively, there was a significant reduction following SBD (257.2 vs. 97.7 μmol, $p = 0.05$). Among these patients, 80% achieved NLS. TB levels < 4.0 mg/dL following SBD were significantly associated with longer NLS ($p = 0.05$; AUC TB, 0.784; sensitivity, 94%; specificity, 52%). There were no significant improvements in pruritus (100% vs. 91.7%, $p = 0.25$) or xanthomas (51.4% vs. 45.1%, $p = 0.67$) after SBD. **Conclusion:** SBD in ALGS was associated with an increased risk of LT or death. SBD may be a marker for severe hepatic phenotype in ALGS. In contrast to PFIC, SBD does not appear to improve NLS in ALGS. However, in a subset of ALGS-SBD patients with SBA, higher rates of NLS were noted in those who experienced a substantial decrease in post-operative SBA levels. These findings also indicate that post-SBD TB levels can be used as a biomarker for NLS. In an era of ileal bile acid transporter (IBAT) inhibitors, SBD may become obsolete in ALGS.

Background: The mechanisms of alcoholic hepatitis (AH) are complex and involve the cross talk between organ systems. MiR150, one of the most abundant microRNAs in immune cells, has been implicated in various liver diseases, but its role in AH pathogenesis remains unclear. We aimed to determine the role of the miR150-mediated immune cells-liver axis in AH pathogenesis. **Methods:** MiR150 levels were measured in serum (S) and liver (L) samples from healthy controls (HC, N = 15 for S, 5 for L), heavy drinkers (HD, N = 17 for S), and AH (N = 65 for S, 5 for L) patients. Correlations between miR150 levels, MELD scores, and serum transaminases were analyzed. Global *miR150* knockout mice (*miR150*$^{-/-}$) and myeloid cell-specific miR150 knockout mice (*miR150*$^{Lyz-/-}$) were generated to assess the function of *miR150* in a chronic plus binge alcohol feeding model. **Results:** Serum and hepatic miR150 level were significantly reduced in AH patients compared to HC. Serum miR150 level negatively correlated with serum AST, but not with MELD score. The level of hepatic miR150 was markedly reduced in mice fed with chronic plus binge alcohol model. Genetic deletion of *miR150* attenuated ethanol-induced liver injury and steatosis, as evidenced by the reduction of ALT, and hepatic triglyceride level. Fatty acid β-oxidation-associated proteins, including PPAR±, PGC1±, UCP2, CPT1A, and hormone sensitive lipase, were highly upregulated in both liver and WAT of ethanol-fed *miR150*$^{-/-}$ mice compared to WT mice. To understand how miR150 is involved in alcohol-induced steatosis, we observed a significant increase in the expression of the miR150 target gene, thyroid hormone receptor β (THRB), in the liver, WAT, and circulating extracellular vesicles (EVs). MiR150 deletion contributed to a significant increase in THRB in macrophages and macrophage-derived EVs. Ethanol fed myeloid cell-specific miR150 knockout mice also exhibited elevated THRB levels in the liver, WAT, and circulating EVs. The level of THRB was also increased in the serum EVs of AH patients compared with HC. Deletion of *miR150* in myeloid cells ameliorated ethanol-induced liver steatosis, with upregulated expression of PPAR±, UCP2, and CPT1A observed in both the liver and WAT. For the translational aspect of our results, we found that mice treated with THRB agonist, Resmetirom, significantly reduced ethanol-induced hepatic steatosis. The role of miR-150 and ALD pathogenesis is illustrated in the Figure. **Conclusion:** Macrophage-derived miR150 plays a crucial role in controlling the progression of steatosis through the release of THRB-containing EVs. MiR-150 and its target (THRB) may represent potential therapeutic targets for ALD.

MIR150 deletion in myeloid cells contributes to elevation in the release of THRB containing EVs from macrophages; which can be taken up by adipocytes. THRB leads to the promotion of FFA β-oxidation, reduction in circulation FFA level and a consequent improvement in hepatic steatosis. Macrophages derived THRB enriched EVs can also be internalized by hepatocytes, thereby promoting FFA β-oxidation, downregulating of hepatic lipogenesis, and amelioration of steatosis. MiR-150, notably its target, THRB, represent a potential therapeutic target for ALD.

14 | HEPATITIS B VIRUS INFECTION OF PRIMARY AND PLURIPOTENT STEM CELL DERIVED MULTICELLULAR HEPATIC SPHEROIDS REVEALS COMPLEX INTRACELLULAR AND INTERCELLULAR INTERACTIONS AND HOST RESPONSES

Yaron Bram, Vasuretha Chandar and Robert E. Schwartz, Weill Cornell Medicine, NY

Background: Human pluripotent stem cell (PSC) derived hepatocyte-like cells and primary human hepatocytes applications for clinical or research uses is dependent on the ability to generate phenotypically and functionally relevant hepatocytes or hepatocyte-containing constructs. We have developed a scalable multi-well platform that enables the rapid generation of three-dimensional (3D) multicellular spheroids composed of primary and stem cell derived human liver parenchymal cell types including hepatocytes, liver sinusoidal endothelial cells (LSEC), stellate cells (HSC), and Kupffer cells. This 3D system is able to maintain hepatocellular function long-term and can be used to model the complex interactions and host responses between hepatocytes and nonparenchymal cells (LSEC, HSC, and Kupffer cells) during HBV Infection. **Methods:** Multicellular spheroids containing hepatocytes and nonparenchymal cells alone were generated from primary human liver tissue or from human PSCs. This robust human multicellular platform maintains hepatocellular and non-parenchymal cell differentiated function for greater that 6 weeks and allows for extended experiments. Given the longevity and stability of the platform we examined whether such a platform could be used to model the complex interactions and host responses between hepatocytes, LSEC, HSC, and Kupffer cells in vitro during HBV infection. **Results:** We generated multicellular spheroids and examined the acute and chronic changes due to HBV infection in multicellular spheroids. We found that multicellular spheroids maintain long-term infection in contrast to traditional hepatocyte-culture systems. Moreover, we found that metabolic perturbations led to impaired higher viral loads, hepatocyte injury, and macrophage and stellate cell activation. We evaluated the cross-talk between these different cell types early and late after HBV infection and found that in unexpectedly the presence of macrophages led to higher viral loads than when they were not present in the multicellular spheroids. We identified that Kupffer cell cytokine production is responsible for increased viral loads and neutralizing antibodies against IL-6 were able to mitigate this effect. **Conclusion:** Our work demonstrates that multicellular spheroids composed of primary and stem cell derived human liver parenchymal cell types including hepatocytes, LSEC, stellate cells, and Kupffer cells have stable function and can model complex disease phenotypes in vitro. Leveraging these technologies focused on HBV enabled studies of viral infection and can be leveraged in mechanistic studies of infection.

f 15 | INHIBITION OF GUT BACTERIAL BILE SALT HYDROLASES (BSHS) ATTENUATES EARLY NON-ALCOHOLIC STEATOHEPATITIS (NASH) AND NASH WITH FIBROSIS

Yongtao Wang[1], Liz Jones[2], Yoojin Lee[1], Snehal Chaudhari[2], James C. Reed[3], Lawrence Zukerberg[4], Mozhdeh Sojoodi[5], Wenyu Lin[3], Min Xu[3], Eliana T. Epstein[3], Jonathan Eddy[1], Oizoshimoshiofu Dimowo[1], Alan C. Mullen[1], Georg M. Lauer[3], Kenneth K. Tanabe[5], A. Sloan Devlin[2] and Raymond T. Chung[3], (1)Division of Gastroenterology, Massachusetts General Hospital

and Harvard Medical School, (2)Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, (3)Massachusetts General Hospital and Harvard Medical School, (4)Department of Pathology, Massachusetts General Hospital and Harvard Medical School, (5)Division of Gastrointestinal and Oncologic Surgery, Massachusetts General Hospital and Harvard Medical School

Background: Increased intestinal permeability is one of the multiple hits in the pathogenesis of non-alcoholic steatohepatitis (NASH). Bile salt hydrolase (BSH) is a gut bacterial enzyme that hydrolyzes conjugated bile acids (BAs) into unconjugated BAs. Our previous study reported that inhibition of BSH with a gut-restricted small molecule inhibitor, AAA-10, increased conjugated BAs and prevented the development of intestinal permeability and liver steatosis in an early onset, diet-induced rat steatosis model. This study sought to evaluate whether AAA-10 could treat pathogenic intestinal permeability and liver damage in models of early NASH and NASH with fibrosis. **Methods:** 8-week-old Wistar rats were fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for either 3 or 6 weeks to develop early NASH or NASH with fibrosis, respectively. Rats were randomly assigned into two groups and gavaged twice daily with either 10 mg/kg of AAA-10 or control vehicle for 1 or 2 weeks. Molecular and histologic assessments on ileum and liver tissue were performed. RNA sequencing was performed to assess alteration of the global transcriptomic landscape of ileum and liver. *In vitro* human hepatic stellate cells (HSCs) and *ex vivo* human precision-cut liver slices (PCLS) were used to assess the effect of treatment with conjugated and/or unconjugated BAs. **Results:** Increased BSH activity and gut permeability were observed with liver fibrosis. After AAA-10 treatment, liver chemistry indices including ALT and AST improved. In both early NASH and NASH with fibrosis models, BSH inhibition reduced gut permeability by decreasing translocation of FITC-dextran and ileal expression of *occludin*, a tight junction protein upregulated and translocated to the membrane to compensate for disrupted tight junctions in NASH. BSH inhibition was associated with lowered liver collagen deposition, improved fibrosis score and reduced expression of pro-fibrogenic genes. Consistently, RNAseq analysis showed that the global transcriptomic signatures of intestinal function including absorption ability were restored after BSH inhibition, suggesting reduced intestinal permeability. Liver inflammatory and fibrogenic signatures were inhibited after AAA-10 treatment. BSH inhibition also enhanced 113 good prognosis genes and reduced 73 poor prognosis genes in the liver previously shown to be associated with progressive liver disease and HCC. Conjugated BA treatment attenuated TGF-β induced fibrogenic genes in *in vitro* human primary HSCs and TWNT4 cells and in *ex vivo* human PCLS; these changes were reversed by unconjugated BA treatment. **Conclusion:** BSH inhibition with AAA-10 treatment reduced gut permeability and alleviated liver fibrosis in rats with early NASH and NASH with fibrosis. These data suggest that inhibitors of gut bacterial BSHs could be developed as treatments for NASH and other diseases characterized by pathogenic intestinal permeability.

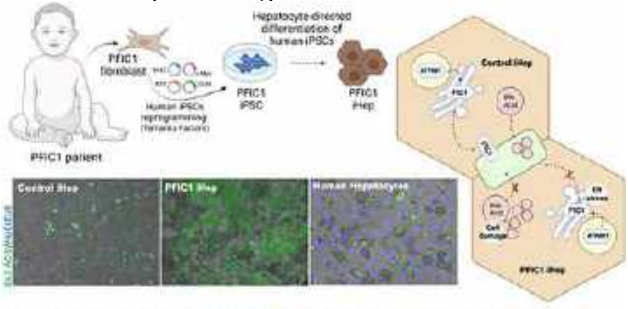
by the inability to appropriately excrete bile salts (BS) from hepatocytes. PFIC1 results from mutations in *ATP8B1* encoding FIC1, an apical membrane aminophospholipid translocase. FIC1 dysfunction is hypothesized to lead to BS retention via decreased farnesoid X receptor (FXR) activation. Unfortunately, a lack of reliable disease models has impeded scientific discovery and clinical advancement. We aim to explore how human induced pluripotent stem cells (hiPSCs) may be used to generate patient-specific liver tissue to model PFIC. **Methods:** Fibroblasts of 3 PFIC1 patients were reprogrammed into hiPSCs via nucleofection. hiPSC stemness was determined by qPCR and staining for pluripotency markers. Human induced hepatocytes (hiHeps) were then generated, carrying *ATP8B1* mutations. Hepatic differentiation was validated by comparison to primary human hepatocytes (hAH). Staining and Western Blot assessed FIC1 expression and localization. BA assays measured concentrations and investigated BA export. A luciferase assay enabled assessment of FXR activity, and a microarray was run to identify pathway specific alterations in gene expression. **Results:** We successfully generated PFIC1-hiPSCs, their stemness status comparable with commercially available hiPSC (OCT3/4 and Nanog positive nucleus > 95%) and differentiate these cells into hepatocyte-like cells. All generated hiHeps showed the expression of adult isoform of the HNF4a (> 90%positive nucleus) and albumin (> 70% positive cells) and no expression of the alpha fetoprotein. Additional mRNA levels of hepatocyte specific markers were comparable with hAH. Functionally, patient specific PFIC1 hiHeps exported less BA than healthy hiHeps and hAH hepatocytes (basal FXR activity: hiHeps control: 0.96 ± 0.06, PFIC1 hiHeps #1: 0.09 ± 0.05 and hAH: 1.37 ± 0.15). The luciferase assay demonstrated a reduction in FXR. Microarray showed increases in expression of ER stress related genes in the PFIC1 hiHeps, suggesting that the cells are compensating for the mutant FIC1 protein. **Conclusion:** PFIC1-specific hiHeps can recapitulate the dysfunctional activity of FIC1 and support the hypothesis that dysregulated FXR contributes to the PFIC1 phenotype. These findings represent a novel model for further interrogation to unlock a deeper understanding of PFIC1 pathophysiology and possible therapeutic targets.



Graphical abstract: Fibroblast from PFIC1 patient were reprogrammed to induced pluripotent stem cells (PFIC1 iPSC) and then differentiated into hepatocyte-like cells (PFIC1 iHep). Our analysis revealed an increase in the endoplasmic reticulum (ER) stress due the retention of the FIC1 protein in the ER and an inefficient exportation of bile acid into the biliary canaliculus leading to cellular damage.

17 | INTERACTION OF INNATE AND ADAPTIVE IMMUNITY DRIVES NLRP3 INFLAMMASOME ACTIVATION AND HEPATOCYTE APOPTOSIS IN MURINE LIVER INJURY FROM IMMUNE CHECKPOINT INHIBITORS

Layla Shojaie[1], Jacob Bogdanov[1], Helia Alavifard[1], Myra Ali[1], Simeon Mahov[2], Sue Murray[3], Gary C. Kanel[1], Zhang-Xu Liu[1], Akil Merchant[2], William Stohl[1] and Lily Dara[1], (1)Keck School of Medicine of USC, (2) Cedars-Sinai Medical Center, Los Angeles, CA, (3)Ionis Pharmaceuticals, Inc.

Background: Immune checkpoints (CTLA4 & PD1) are inhibitory pathways that block aberrant immune activity and maintain self-tolerance. Tumors co-opt these checkpoints to avoid immune destruction. Immune Checkpoint Inhibitors (ICIs) activate immune cells and restore their tumoricidal potential, making them highly efficacious cancer therapies. However, immunotolerant organs such as the liver depend on these tolerogenic mechanisms, and their disruption with ICI use can trigger the unintended side effect of hepatotoxicity termed immune mediated liver injury from checkpoint inhibitors (ILICI). Patients with severe ILICI discontinue ICIs and start steroids, to the detriment of their cancer. How liver cells are dying, and which cell death pathways are involved in ILICI is not known. Understanding how to uncouple ILICI from ICI anti-tumor activity is of paramount clinical importance. **Methods:** We developed a murine model to recapitulate human ILICI. $CTLA4^{+/-}$ mice were treated with combined anti-CTLA4 + anti-PDL1 or IgG1 + IgG2 for 14 days. We probed cell death subroutines: apoptosis, necroptosis, and pyroptosis. We tested two forms of antisense oligonucleotides to knockdown (KD) caspase-3 (C3) in a total liver (hepatocytes and NPCs) or in a hepatocyte-specific manner. We employed imaging mass cytometry (IMC), a powerful multiplex platform for immunophenotyping and spatial cell interaction analysis to study immune cross-talk in our model. **Results:** ICI treated mice had significant evidence of liver injury. We

detected cleaved caspase-3 (cC3), indicating apoptosis was occurring, as well as NLRP3 inflammasome activation, but no necroptosis. Total liver KD of C3 worsened liver injury, increased inflammasome activation, and triggered GSDMD-mediated pyroptosis. In contrast, hepatocyte-specific KD of C3 reduced liver injury and NLRP3 inflammasome activation. IMC-generated single-cell data for 77,692 cells was used to identify 22 unique phenotypic clusters. Spatial analysis revealed cC3+ hepatocytes highly interacted with macrophages and NLRP3^{hi} myeloid cells. We also observed zones of three-way interaction between cC3+ hepatocytes, CD8^{+} T-cells and macrophages. **Conclusion:** Our work is the first to identify hepatocyte apoptosis and NLRP3 inflammasome activation as drivers of ILICI. Our single-cell IMC data demonstrates macrophages and NLRP3^{hi} myeloid cells are among the nearest neighbors of cC3+ hepatocytes and contribute to injury. We report that the interplay between adaptive and innate immune cells is critical to hepatocyte apoptosis and ILICI.

18 | RGS rs35197737 IN CHROMOSOME 1 IS ASSOCIATED WITH RISK OF STATIN INDUCED LIVER INJURY: RESULTS FROM THE DRUG INDUCED LIVER INJURY NETWORK (DILIN)

Tae-Hwi Schwantes-An[1], Marco A Abreu[1], Yi-Ju Li[2], Andrew Dellinger[2], Paola Nicoletti[3], Lily Dara[4], Victor J. Navarro, Md[5] and Naga P. Chalasani[6], (1)Indiana University School of Medicine, (2)Duke University, Durham, NC, (3)Mount Sinai, (4)University of Southern California, Los Angeles, CA, (5)Albert Einstein Medical Center, Doylestown, PA, (6)Indiana University Medical Center, Indianapolis, IN

Background: Statins may very rarely cause drug induced liver injury (DILI) but its pathogenesis is not well understood. Genetic factors may play a role in the pathogenesis of liver injury due to selected agents. In this study, we investigated genetic factors associated with statin DILI through a genome wide association study (GWAS). **Methods:** We conducted a GWAS of statin DILI. Statin DILI cases with definite, highly likely or probable causality scores were identified from Drug Induced Liver Injury Network (DILIN) studies between 2004 and 2022. Controls were statin treated patients with no DILI (statin controls) identified from Indiana Biobank (IB). Statin controls were defined as having ALT < 45 U/L and Alk p < 125 U/L during the 12 months preceding and 6 months following statin prescription and absence of ICD code 573.8 and K71. Imputed, QC passing variants from the cases and controls were combined then re-cleaned to adjust for any potential batch effects. We compared statin DILI cases to statin controls as primary GWAS then compared top three suggestive hits in 1) non-statin DILI from DILIN studies (DILI controls) and 2) not statin exposed individual's with no evidence for liver injury from Indiana Biobank (IB Controls). Association tests were conducted in cross ancestry group and EUR ancestry specific fashion while adjusting for age, sex, and several principal components. Logistic regression model with Firth correction was used. **Results:** There were 71 statin-DILI cases with definite, highly likely or probable causality and 552 statin controls. After QC, there were 5,483,580 variants available for GWAS. In both cross-ancestry and EUR ancestry specific analysis we observed 3 suggestive ($p < 5e^{-06}$) associations (Table 1). These associations were more prominent in EUR ancestry specific analyses. In the EUR comparison, rs35197737, variant in *RGS1* (regulator of G Protein signaling 1), showed a strong association with statin-DILI (OR = 5.03, (95% C. I. = 2.77- 9.13), $p = 1.14x10^{-07}$). On chromosome 10, rs75629598 in *FRMD4A* (FERM domain containing 4A) showed significant association with statin DILI (OR = 4.35 (95% CI: 2.33-8.12), $p = 3.97\ x10^{-06}$). Lastly, rs7658630, intergenic variant, was associated with an increased risk (p-value = 2.68 $x10^{-07,}$ OR = 4.85, 95% CI: 2.66-8.85) for statin-DILI. The comparisons between statin DILI and DILI controls and between statin DILI and IB controls are also shown in Table 1. *RGS* rs35197737 showed genome-wide significant association with statin DILI in comparison to IB controls (OR: 5.74, 95% C.I. 3.29-10.00, $p = 7.22\ x10^{-10}$) and strong association in comparison to DILI controls (OR:

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

4.11, 95%: 2.42-7.00, $p = 1.88x10^{-07}$). **Conclusion:** rs35197737 in *RGS1* (Chr 1) appears to be a significant risk factor for statin DILI. Further studies to confirm this observation and to understand the mechanisms by which it contributes to statin DILI are warranted.

Table 1: Variants associated with liver injury due to statins in European Caucasians

19 | EFFECTS OF MICROPLASTICS ON THE HEPATIC TRANSCRIPTOME

Ngozi Victoria Adiele[1], Frederick Ekuban[1], Abigail Ekuban[2], Jianzhu Luo[1], Jingjing Zhao[1], Julia Chariker[1], Eric C Rouchka[1], Timothy O'Toole[1] and Matthew Cave[1], (1)University of Louisville, Louisville, KY, (2) University of Louisville

Background: Pollution from plastics is an increasing health threat. Microplastics are small plastic pieces, which are formed by direct synthesis for industrial or consumer applications as well as by environmental plastic degradation. As plastic degradation is increased by UV light and "weathering", global warming has increased environmental microplastics. Polystyrene (PS) microplastics are ingested endocrine and metabolism disrupting chemicals, which have previously been associated with diabetes, obesity, NAFLD, gut dysbiosis, and increased intestinal permeability. PS in combination with polyethylene and polypropylene, makes up over 50% of environmental microplastics. Here, in order to better understand the hepatic effects of PS exposures, we performed mRNA-Seq in livers from a mouse PS exposure model. **Methods:** Chow diet-fed male C57Bl/6j were exposed to either 0.5 µm or 5 µm PS beads in water at 1µg/ml and controls were given water without PS beads for 12 weeks. Lipid analysis and mRNA-Seq was performed in whole liver abstracts and pathway enrichment analyses were performed using Ingenuity pathway analysis software (IPA). **Results:** Hepatic cholesterol was significantly increased by PS. Transcriptomics analysis revealed a size-dependent effect of PS bead exposures. The 0.5 µm exposures were associated with 278 unique differentially expressed genes (DEGs) in liver. Of these, *Steap4*, *Tnfaip3, and Ccl2* were the most up-regulated, while *Tpm2* and *Trib3* were the most down-regulated. 5 µm PS was associated with 44 unique DEGs. *Firre* was the most up-regulated gene, while *Slpi* and *Ctgf* were the most down-regulated. 5 DEGs (e.g., *Rev1*, *Brpf1*, *Ccnt2*, *Cavin2*, and *Pea15a*) were common to both exposure groups. 60 processes were enriched by 0.5 µm PS, and 6 were enriched by 5 µm PS. These processes included FXR/RXR Activation, Aryl Hydrocarbon Receptor Signaling, and LPS/IL-1 mediated inhibition of RXR. **Conclusion:** PS disrupted hepatic cholesterol metabolism. It was associated with hepatic transcriptional reprogramming in a PS bead size-dependent manner. Pathway enrichment analyses demonstrated a potential role for gut-derived signaling molecules (e.g., bile acids impacting FXR, indoles impacting AhR, and endotoxin impacting TLR4) in the metabolic toxicities associated with PS exposures. A confirmatory fecal/liver metabolomics analysis is currently ongoing.

20 | ACTIVATION OF TFEB PROTECTS AGAINST ACETAMINOPHEN-INDUCED LIVER INJURY IN MICE

Mengwei Niu, Xiaojuan Chao, Shaogui Wang, Hartmut Jaeschke, Hong-Min Ni and Wen-Xing Ding, University of Kansas Medical Center, Kansas City, KS

Background: Macroautophagy (referred to as autophagy hereafter) is a major intracellular lysosomal degradation pathway that is responsible for the degradation of misfolded/damaged proteins and organelles. Previous studies showed that autophagy protects against acetaminophen (APAP)-induced injury (AILI) via selective removal of damaged mitochondria and APAP protein adducts. The lysosome is a critical organelle sitting at the end stage of autophagy for autophagic degradation via fusion with autophagosomes.The goal of this study was to investigate the role and mechanisms of transcription factor EB (TFEB)-mediated lysosomal and mitochondria biogenesis in AILI. **Methods:** Wildtype mice, liver-specific TFEB knockout mice or mice with hepatic overexpression of TFEB using Adenovirus-Tfeb were treated with APAP for various time points. Serum alanine aminotransferase (ALT) levels, liver histology and TUNEL staining as well as RNA sequencing and western blot analysis were performed. A cell-based imaging high-throughput chemical screening for TFEB agonists using a stable GFP-TFEB AML12 cell line was also performed. **Results:** We showed that TFEB was impaired by APAP resulting in decreased lysosomal biogenesis in mouse livers, which was associated with levels of APAP-adducts and liver injury. Genetic loss-of and gain-of function of hepatic TFEB exacerbated or protected against AILI, respectively. Mechanistically, overexpression of TFEB increased clearance of APAP protein adducts and mitochondria biogenesis as well as SQSTM1/p62-dependent non-canonical nuclear factor erythroid 2-related factor 2 (NRF2) activation and hepatic glutathione biosynthesis to protect against AILI. Cell-based imaging high-throughput chemical screening identified a group of TFEB agonists. Among these agonists, salinomycin, an anticoccidial and antibacterial agent, activated TFEB and protected against AILI in mice. **Conclusion:** In conclusion, genetic and pharmacological activating TFEB promotes removal of APAP-adducts and damaged mitochondria with concurrent increased mitochondrial biogenesis, which may be a promising approach for improving recovery of AILI.

21 | MITOCHONDRIAL Ca2+ UNIPORTER (MCU) IN HEPATOCYTES BUT NOT IN KUPFFER CELLS PROMOTES LIVER INJURY INDUCED BY ACETAMINOPHEN (APAP)

Jiangting Hu, Anna-Liisa Nieminen, Judith A. Dent and John J. Lemasters, Medical University of South Carolina

Background: Iron-catalyzed formation of reactive oxygen species (ROS) increases after APAP overdose and triggers the mitochondrial permeability transition (MPT). Previous studies show that iron translocation from lysosomes into mitochondria by MCU in hepatocytes promotes the MPT after APAP. Kupffer cells are liver resident macrophages that are involved in uptake, processing, and export of iron. Here, our Aim was to investigate and compare the roles of MCU in hepatocytes and Kupffer cells in APAP hepatotoxicity. **Methods:** Hepatocyte specific MCU knockout mice (hsMCU KO) and Kupffer cell specific MCU knockout mice (ksMCU KO) were created by individual crosses of floxed MCU mice with Alb-Cre mice and Clec4f-Cre-tdTomato mice, respectively. MCU deficiency in hepatocytes and Kupffer cells was confirmed by Western blot or immunocytochemistry. hsMCU KO, ksMCU KO, and widetype (WT) mice were treated with 300 mg/kg APAP or vehicle. Liver injury was assessed by histology and serum ALT at 24 h. **Results:** Western blots confirmed the absence of MCU protein expression in isolated hepatocytes from hsMCU KO mice. MCU protein remained expressed in the kidneys of hsMCU KO mice. The absence of MCU protein expression in Kupffer cells of ksMCU KO mice was confirmed by immunocytochemistry. In hsMCU WT mice, overdose of APAP increased serum ALT (9398 U/L) and centrilobular necrosis (55%) at 24 h, indicating severe liver injury. By contrast in hsMCU KO mice, ALT and hepatic necrosis were decreased to 4104 U/L and 24%, respectively. However, ALT and hepatic necrosis between ksMCU KO and the corresponding WT mice at 24 h after overdose APAP were not significantly different. CYP2E1 expression in hsMCU KO mice was similar to WT mice, indicating the protection against APAP-induced hepatic injury in MCU deficient hepatocytes was not the result of decreased APAP metabolism by CYP2E1. **Conclusion:** The core protein of the mitochondrial calcium uniporter complex, MCU, specifically located in hepatocytes, but not in Kupffer cells, plays a central role in APAP-induced hepatotoxicity.

22 | IDENTIFICATION OF A REGULATORY VARIANT IN A LONG NONCODING RNA THAT INFLUENCES EXPRESSION OF EXOC3L4 AS A RISK FACTOR FOR CHOLESTATIC-MIXED DRUG-INDUCED LIVER INJURY

Paola Nicoletti[1], Song Zhenwei[2], Samreen Zafer[1], Andrew Dellinger[3], Yi-Ju Li[3], Huiman Barnhart[3], Naga P. Chalasani[4], Robert J. Fontana[5], Joseph Odin[1], Jose Serrano[6], Tae-Hwi Schwantes-An[7], Andrew Stolz[8], Guruprasad P. Aithal[9], Raul J. Andrade[10], Einar Stefan Bjornsson[11], Ann Daly[12], M I Lucena[13] and Paul B. Watkins[14], (1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)University University of North Carolina at Chapel Hill, Research Triangle Park, NC, (3)Duke University, Durham, NC, (4)Indiana University Medical Center, Indianapolis, IN, (5)University of Michigan Medical Center, Ann Arbor, MI, (6)National Institute of Diabetes, Bethesda, MD, United States, (7)Indiana University School of Medicine, (8)University of Southern California, Los Angeles, CA, (9)Nottingham University Hospital NHS Trust and University of Nottingham, Nottingham, UK, (10)Universidad De Málaga,Málaga, Spain, (11)Landspitali University Hospital, Reykjavik, Iceland, (12)Newcastle University, Newcastle upon Tyne, UK, (13)Universidad De Málaga, Málaga, Spain, (14)University of North Carolina at Chapel Hill, Research Triangle Park, NC

Background: Genetic factors associated with DILI susceptibility have been observed to be largely drug specific. The aim of this study was to identify novel risk factors for Cholestatic-Mixed Drug Induced Liver Injury (CM-DILI). **Methods**: Genome-Wide Association (GWAS) and Transcriptome-Wide Association (TWAS) analyses were performed on 927 CM-DILI cases (R value < 5.0) and 10,397 population-based controls of European descent. Associations were confirmed in a validation cohort of 274 CM-DILI cases and 17,836 population-based controls. TWAS analysis was conducted by Fusion using summary statistics from the discovery European GWAS and multi tissues references designed by Context algorithm. CM-DILI cases were also compared to hepatocellular DILI cases. RNA knockdown and analysis of subsequent expression of candidate target genes were performed in three human liver cell lines (HepG2, Huh7, and PH5CH8). **Results**: A single nucleotide variant, rs11624069 (C) on chromosome 14, demonstrated a genome-wide significant association with CM-DILI risk in the discovery cohort (OR [95%CI] = 1.33 [1.20-1.46] $p = 9.3x10^{-9}$). The association was confirmed in the validation cohort (OR [95%CI] = 1.25 [1.06-1.48] $p = 0.009$). In contrast, hepatocellular DILI cases showed similar allele frequency as population controls. rs11624069 (C) was also over-represented in Hispanic and African American CM-DILI cases compared to ethnically matched controls. Interestingly, rs11624069 has been associated with risk of Primary Biliary Cholangitis and elevation in serum cholestatic biomarkers in healthy populations. TWAS identified that rs11624069 (C) was colocalized with a cis eQTL signal conserved across tissues, increasing the expression of *RP11-736N17.8*, a long noncoding RNA ($p = 2.3x10^{-6}$). In the liver, rs11624069 (C) was associated with increased expression of *RP11-736N17.8* ($p = 7.0x10^{-10}$) and also, less strongly, of *EXOC3L4* ($p = 0.002$), a nearby gene selectively expressed in hepatocytes. Knockdown of *RP11-736N17.8* expression in the three liver cell lines was found to markedly reduce expression of *EXOC3L4*. **Conclusion**: GWAS identified a regulatory variant for *RP11-736N17.8,* a long noncoding RNA, which modulates expression of *EXOC3L4,* as a novel risk factor for CM-DILI due to multiple drugs. Since *EXOC3L4* is a component of the exocyst complex, which is involved in tracking of proteins to apical versus basolateral membranes, the association of rs11624069 (C) with CM-DILI may relate to altered membrane trafficking of transporters for bile constituents.

23 | HEPATIC STELLATE CELL-SPECIFIC GLYCOLYSIS REGULATES SPATIAL GENE ZONATION AND CELLULAR INTERACTIONS TO PROMOTE IN VIVO LIVER FIBROSIS

Leo Liu[1], Shalil Khanal[1] and Enis Kostallari[2], (1)Mayo Clinic, (2)Mayo Clinic, Rochester, MN

Background: Hepatic stellate cells (HSCs) are the main drivers of liver fibrosis. During The Liver Meeting 2022,

we demonstrated that glycolysis deficiency selectively in HSCs attenuated liver fibrosis *in vivo*. The aim of the present study is to understand how HSC-specific glycolysis promotes liver fibrosis by altering signaling pathways and HSC interactions with the surrounding cell types in a spatial manner. **Methods:** Liver fibrosis was induced by carbon tetrachloride (CCl_4) administration in glycolysis-deficient mice, where hexokinase 2 (HK2) was deleted selectively in PDGFRβ$^+$ HSCs ($HK2^{\Delta HSC}$), and their $HK2^{fl/fl}$ littermate controls. 10X Genomics Visium platform was employed to examine spatial gene expression. Data were normalized using SCTransform and integrated using Harmony algorithm. Unsupervised clustering was performed using Louvain algorithm. In-house and public single cell RNA-seq data (GSE175939, GSE108097) were integrated for cell type deconvolution using RCTD algorithm. Differential co-localization analysis between cell types was performed using *Fisher's z* test. **Results:** RNA was collected and sequenced from each of the 55-μm spatial spots, each spot including several cells. Based on conserved gene expression, the spots were classified into 4 clusters (0-3) across the conditions. Clusters 0 and 3 expressed the peri-portal marker Cyp2f2, while clusters 1 and 2 expressed the peri-central marker Cyp2e1 as well as collagen 1±1 and 3±1 (adj. $p < 0.05$). Gene ontology analysis (Panther 2023) of differential gene expression showed that HSC-specific glycolysis regulated distinct pathways during liver fibrosis, such as amino acid metabolism in the peri-portal clusters and extracellular matrix, vitamine A and glucosaminoglycan-related pathways in the peri-central clusters (FDR < 0.02). These results suggest that glucosaminoglycan metabolism closely correlates to HSC activation and matrix deposition in the pericentral areas. In addition, a neighborhood analysis was performed to study how HSC-specific glycolysis regulates cell-to-cell interactions. CCl_4-mediated fibrosis was accompanied by an increased colocalization between HSCs and macrophages, T cells and dendritic cells ($p < 0.05$), which were significantly reduced when HK2 was selectively deleted in HSCs ($p < 0.05$). **Conclusion:** Our results suggest that HSC-specific glycolysis promotes liver fibrosis by regulating distinct metabolic pathways in peri-central versus peri-portal zones and facilitating the interaction between HSCs and immune cells *in vivo*.

24 | EXTRACELLULAR MATRIX PROTEIN 1 ATTENUATES HEPATIC FIBROSIS BY INHIBITING PROTEASE-MEDIATED LATENT TGF-² 1 ACTIVATION

Frederik Link[1], Yujia Li[2], Stefan Munker[3,4], Weiguo Fan[5], Zeribe Nwosu[1,6], Matthias Ebert[1,2], Honglei Weng[2], Sai Wang[2] and Steven Dooley[1], (1)Medical Faculty Mannheim, Heidelberg University, (2) Department of Medicine II, Section Molecular Hepatology, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, (3)University Hospital, Lmu Munich, (4)Department of Medicine II, University Hospital, Ludwig-Maximilians-University Munich, Munich, Germany, (5)Stanford University, (6)Rogel Cancer Center, University of Michigan

Background: ECM1 depletion results in excessive latent TGF-β1 activation and lethal liver fibrosis in mice. In patients suffering from chronic liver diseases, ECM1 expression gradually decreases with increasing severity of fibrosis. We investigated the underlying mechanisms of how ECM1 contributes to tissue homeostasis in healthy livers and what changes occur during CLD progression. **Methods:** RNAseq of WT and ECM1-KO murine livers was performed to detect ECM1-KO-related changes in gene expression. Functional assays were performed using immortalised and primary hepatic stellate cells, WT and ECM1-KO mice, and liver tissue from patients suffering from CLD. **Results:** DESeq shows that expression of thrombospondins (TSPs), including TSP-1, matrix metalloproteinases, ADAMTS proteases, increased concomitantly with LTGF-β1 activation and fibrosis following ECM1-KO. In the LX-2 and phHSCs, ECM1 prevented TSP-1-, ADAMTS1-, MMP-2- and -9-mediated LTGF-β1 activation, as assessed by the concentration of active TGF-β in conditioned media through using the MFB-F11 TGF-β reporter cell line and the expression changes of hepatic fibrosis markers. IF staining for TGF-β1 LAP-D (R58) further demonstrated that protease-mediated LTGF-β1 activation is inhibited by the ECM1 in LX-2 HSCs. Co-IP analyses revealed that ECM1 interacts with all four of the tested LTGF-β1-activating proteases and, for MMP-2 and -9, binding occurred preferentially to their respective activated state. Next, in vitro interaction assays showed that ECM1 abrogates TSP-1- and ADAMTS1-mediated LTGF-β1 activation through an interaction with their respective KRFK or KTFR sequence. Further, ECM1

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

abolishes MMP-2/9-mediated LTGF-β1 activation through inhibiting their proteolytic activity. *In mice*, AAV-mediated overexpression of ECM1 in hepatocytes protected from KRFK-mediated LTGF-β1 activation and subsequent hepatic fibrosis. Importantly, KTFR injection was able to rescue the ECM1-KO phenotype and thus revert liver injury in mice affected by ECM1 depletion. We also found that in patients suffering from CLD, a loss ECM1 expression was accompanied by induction of TSP-1, ADAMTS1, MMP-2, and MMP-9, all of which mediate LTGF-β1 activation. **Conclusion:** ECM1 exerts its hepatoprotective effect through an inhibition of protease-mediated excessive LTGF-β1 activation by interacting with activating motifs and directly reducing proteolytic activity. During progression of CLD, ECM1 expression decreases and therewith liver tissue homeostasis is disturbed as protease-mediated LTGF-β1 activation becomes unhinged, resulting in increased active TGF-β1 bioavailability, elevated fibrogenic signaling, and ultimately the worsening of hepatic fibrosis. Our findings indicate that delivering ECM1 (or respective phenocopying peptides) to the liver when it is lost can serve as a novel yet safer TGF-β1 directed therapy.

25 | ER-ASSOCIATED PROTEIN DEGRADATION AS A POTENTIAL ANTI-FIBROTIC TARGET IN HEPATIC STELLATE CELLS

Jessica Maiers, Alexander Jackson, Reese A Baxter and Avishek Paul, Indiana University School of Medicine

Background: Liver injury activates hepatic stellate cells (HSCs) which drive fibrosis through secreting extracellular matrix proteins. Proteins destined for secretion are cotranslationally translocated into the endoplasmic reticulum (ER), folded, and exported for secretion. Activated HSCs exhibit increased protein translation leading to ER stress, which is sensed by ER membrane proteins Activating transcription factor 6 (ATF6±), Inositol-requiring enzyme 1 (IRE1±), and Protein kinase R-like ER kinase (PERK). These sensors initiate the Unfolded Protein Response (UPR) to relieve stress through processes including ER-associated degradation (ERAD): where misfolded proteins are targeted for proteasome degradation. The UPR is critical for HSC activation and fibrogenesis, but whether ERAD plays a key pro-fibrotic role is unknown. Publicly available RNAseq data revealed upregulation of ERAD components in cirrhotic livers, thus we hypothesized that ERAD is crucial for HSC activation and fibrogenesis. **Methods:** Primary human HSCs (hHSCs) were activated with TGFβ in combination with UPR inhibitors (Ceapin A7, 4μ8C, or GSK2656157 to inhibit ATF6±, IRE1±, or PERK respectively), or ERAD inhibitor Eeyarestatin 1 (EER1). ERAD components and HSC activation were analyzed by Western blot, qPCR, and microscopy. Immortalized hHSC (LX-2) cells were transfected with an siRNA targeting ERAD component SEL1L and analyzed for HSC activation. *In vivo*, C57BL/6J mice were fed a high fat diet for 8 weeks (D12102Ci) or control diet with biweekly injections of 2mg/kg EER1 or vehicle. Liver sections were analyzed for fibrosis by Western blot and Sirius red staining. **Results:** TGFβ increased ERAD components *ERdj4*, *ERdj5*, *HERPUD1*, and *HRD1*, while decreasing protein levels of ERAD substrate OS-9, indicative of increased ERAD activity ($p < 0.05$). IRE1± inhibition limited TGFβ induction of *ERdj4* and collagen deposition ($p < 0.05$), while PERK inhibition increased *HRD1*, *ERdj4*, and *ERdj5* levels, and TGFβ-induction of collagen deposition ($p < 0.05$), linking ERAD and HSC activation. ERAD inhibition decreased ±SMA and Collagen 1 protein levels in hHSCs treated with TGFβ, and knockdown of *SEL1L* decreased collagen I levels at 24h. Unexpectedly, disrupting ERAD increased collagen deposition at 48h in both hHSCs and LX-2 cells. Finally, *in vivo* studies revealed that ERAD inhibition limited diet induced fibrogenesis and HSC activation. **Conclusion:** ERAD components increased in activated HSCs, and ERAD inhibition limited fibrogenesis *in vivo*. *In vitro*, ERAD disruption limited HSC activation at earlier time points (24h), but increased fibrogenesis at later time points (48h). We hypothesize that prolonged ERAD inhibition induces protein trafficking and secretion to remove misfolded proteins from the ER *in vitro*, but that long term ERAD inhibition limits fibrogenesis *in vivo*. This work identifies ERAD as a possible therapeutic target for fibrosis and fibrogenesis.

26 | HEPATIC STELLATE CELL-DERIVED 12-HHTRE AUTOINDUCES LTB4R2 FOR CTNNB1-YAP1 HCC PROMOTION PATHWAY

Sonal Sinha[1], Keigo Machida[1], Meng Li[2], Audrey Kapelanski-Lamoureux[3], Alexander Rialdi[4], Ernesto Guccione[5] and Hidekatzu Tsukamoto[1], (1)University of Southern California, (2)USC Libraries Bioinformatics Service, University of Southern California, (3)Mcgill University, (4)Icahn School of Medicine at Mount Sinai

(ISMMS), (5)Icahn School of Medicine at Mount Sinai Hess Center for Science and Medicine

Background: A subpopulation of tumor-associated activated hepatic stellate cells (aHSC) is implicated in releasing an oxylipin, 12-hydroxyheptadecatrienoic acid (12-HHTrE) to render HCC promotion via its high-affinity receptor LTB4R2 and downstream activation of CTNNB1 and YAP1/TAZ in HCC cells, highlighting the novel tumor promoter role of LTB4R2 (Nature Comm 2023. PMID: 37156770). However, if or how aHSC regulate LTB4R2 expression in HCC is unknown. Aim: We aimed to test a hypothesis that LTB4R2 expression is auto-induced by aHSC-derived 12-HHTrE to provide a spatially-directed, positive forward loop for tumor promotion. **Methods:** *Scd2$^{f/f}$;Col1Cre* vs. *Scd2$^{f/f}$* mice were injected with DEN and fed Western alcohol diet for 4-5 months to induce liver tumorigenesis. Huh7 cells were treated with conditioned media (CM) from LX2 cells with or without *SCD* or *CYP1B1* KD, 12-HHTrE or appropriate vehicle. Human *LTB4R2* promoter-first intron (-1517/+344) was cloned and its deletion-luciferase reporter constructs were generated for transfection analysis in Huh7 cells. Patient HCC tissues were analyzed by IHC and the LTB4R2 dependence of patient HCC organoid growth was examined by pharmacologic and genetic manipulations. **Results:** Liver tumorigenesis in *Scd2$^{f/f}$* mice was associated with upregulation of LTB4R2 mRNA and protein, which were largely abrogated by conditional ablation of *Scd2* in aHSC in *Scd2$^{f/f}$;Col1Cre* mice with reduced liver concentration of 12-HHTrE and tumor burden, suggesting aHSC-SCD2-12-HHTrE regulation of LTB4R2. LX2 cells released 12-HHTrE in a manner dependent on SCD or CYP1B1 and CM from such cells induced LTB4R2 expression and LTB4R2-dependent CTNNB1/YAP1 activation in Huh7 cells. Direct 12-HHTrE treatment of Huh7 cells also caused LTB4R2 upregulation which was prevented by CTNNB1 KD. Using *LTB4R2* proximal promoter-first intron deletion-reporter constructs, 12-HHTrE-mediated stimulation was mapped to -492/-244 promoter and +258/+344 intronic regions and these activities were blunted by CTNNB1 KD. Bioinformatic analysis revealed CTNNB1 enrichment and multiple TCF sites within the first intron segment. Spatially directed LTB4R2 induction by CYP1B1-generated 12-HHTrE by aHSC was supported by the presence of CYP1B1+ aHSC surrounding LTB4R2+ HCC cells in patient HCC. Lastly, pharmacologic or genetic inhibition of LTB4R2 in patient HCC organoids significantly attenuated their growth. **Conclusion:** Our results suggest that 12-HHTrE released by aHSC in tumor microenvironment causes a CTNNB1-dependent, transcriptional upregulation of LTB4R2 in HCC to allow the 12-HHTrE-LTB4R2-CTNNB1-YAP1/TAZ tumor promotion pathway. CYP1B1-dependent 12-HHTrE release by aHSC may be considered as an upstream therapeutic target for HCC in this pathway.

27 | IDENTIFICATION OF ANTI-FIBROTIC microRNAs ENRICHED IN EXTRACELLULAR VESICLES DERIVED FROM BONE MARROW MESENCHYMAL STEM CELLS IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS

Daiki Kawamoto[1], Toshihiko Matsumoto[2], Naoki Yamamoto[2] and Taro Takami[1], (1)Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan, (2)Yamaguchi University Graduate School of Medicine

Background: We have been developing a liver regeneration therapy for decompensated liver cirrhosis (DLC) using cultured autologous bone marrow mesenchymal stem cells (BMSCs). Currently, we are conducting a clinical trial called "Self-contained liver cirrhosis regeneration therapy (jRCT2063200014)". In our clinical trial, hepatic arterial infusion of cultured autologous BMSCs has ameliorated liver function and fibrosis in patients with DLC. However, the mechanism of anti-fibrotic action of BMSCs remain to be fully determined. It was recently reported that extracellular vesicles derived from MSCs (MSC-EVs) exhibited antifibrotic properties. We therefore examined the effect of MSC-EVs on extracellular matrix (ECM) production by hepatic stellate cells, and identified anti-fibrotic microRNAs (miRNAs) enriched in MSC-EVs using BMSCs derived from patients with DLC in our clinical trial with aim of developing adequate quality standards for MSCs in liver regeneration therapy. **Methods:** Human hepatic stellate cells (HHSteCs) were treated with TGFβ for activation and subsequently treated with EVs isolated from the culture media of human BMSCs and ECM gene expression determined. We used a microarray to perform a comprehensive analysis of miRNA expression profiles and compared miRNA expression profiles in MSC-EVs derived from healthy individual's or patients with DLC in our clinical trial and HHSteCs. To identify the antifibrotic miRNAs enriched in MSC-EVs, each mimic of miRNAs that highly expressed in MSC-EVs and lowly expressed in HHSteCs was transfected into HHSteCs and ECM gene expression determined. **Results:** MSC-EVs inhibited expression of ECM genes (COL1A1, COL1A2, COL3A1 and ELN) by activated HHSteC ($p < 0.05$). Thirty-six miRNAs were extracted from the microarray data that showed normalized

intensity of > 1,000 in both MSC-EVs of healthy individual's and that of patients with DLC in our clinical trial. Among these miRNAs, ten miRNAs highly expressed in MSC-EVs and lowly expressed in HHSteCs. Each miRNA mimic of the ten miRNAs was transfected into activated HHSteCs and we identified five miRNAs which suppress expression of any of ECM genes ($p < 0.05$). Furthermore, transfection of a combination of the five miRNAs into activated HHSteC resulted in a significant decrease in expression of COL1A1, COL1A2, COL3A1, and ELN ($p < 0.05$). **Conclusion:** This study identified five anti-fibrotic miRNAs enriched in MSC-EVs and provided insight into mechanisms of action of MSC-EVs in fibrosis regression. Hence, miRNAs in MSC-EVs may be potential biomarkers for functional assessment of MSCs in liver regeneration therapy.

28 | MACROPHAGE HETEROGENEITY DURING MASH REGRESSION UNVEILS MULTIFACETED TREM2 DEPENDENT MECHANISMS THAT FACILITATE MASH AND FIBROSIS RESOLUTION

Souradipta Ganguly[1], Kei Ishizuka[1], Brin Rosenthal[1], Nathalia Castorena[1], Aryaman Bhattacharya[1], Tatiana Kisseleva[1], David A. Brenner[1,2] and Debanjan Dhar[1], (1)University of California, San Diego School of Medicine, (2)Sanford Burnham Prebys Medical Discovery Institute

Background: Macrophage (MF) are recruited to the liver during MASH progression, including fibrogenic TREM2+ hepatic lipid associated MF (LAMs). However, the TREM2 receptor itself is anti-fibrotic, in that *Trem2*$^{-/-}$ mice have more severe MASH than WT mice. Despite these recent studies, little is known about mechanisms that regulate MF function during MASH regression. We studied Trem2 expression in MF across the MF clusters during MASH regression, identified MF sub-populations that aid in MASH resolution, and investigated whether Trem2 is required for efficient MASH regression and the underlying mechanisms. **Methods:** Foz (*Alms1*$^{-/-}$)[1] and Foz::*Trem2*$^{-/-}$ mice on Western Diet (WD) developed MASH by 12w[1]. Foz mice are hyperphagic and develop MASH on a WD. Regression was studied by switching MASH mice to normal chow for an additional 4-8w. scRNAseq elucidated MF gene signatures and pathways. In vitro experiments were performed with bone marrow derived MF (BMDM) from WT and *Trem2*$^{-/-}$ mice. **Results:** Absence of Trem2 impaired fibrosis, inflammation and steatosis resolution during MASH regression. scRNAseq revealed two Trem2-expressing MF sub-populations during MASH progression and regression in Foz+WD mice: (i) Monocyte derived MF that occupy the Kupffer cell niche (MoKC), and (ii) hepatic lipid associated MF (LAM). While MoKC was the major MF sub-population during MASH progression, it decreased during regression with reduced Trem2 expression. LAMs maintained Trem2 expression and expanded, becoming the dominant MF sub-population during regression. Within the regression livers, scRNA-seq revealed that Trem2-hi MF were highly enriched in MASH-resolving pathways (extracellular matrix degradation, phagocytosis and lipid handling). Trem2-low MF, on the other hand, expressed disease worsening pathways (inflammation, cell death). While hepatic LAMs have mostly been studied in the context of MASH progression, our findings demonstrate that during regression they resemble restorative MF, with increased expression of MMPs and phagocytosis-related genes. *In vitro* experiments demonstrated superior collagen degradation ability by Trem2+ BMDMs compared to their Trem2- counterparts. **Conclusion:** This study expands our understanding of MF heterogeneity in MASH by uncovering distinct sub-populations during regression. We highlight the significance of Trem2 in mediating MASH regression and delve into the multiple probable mechanisms through which Trem2 achieves this effect. Animals studies: All animals received humane care according to the "Guide for the Care and Use of Laboratory Animals". Experiments were performed in accordance with the UCSD IACUC and NIH guidelines. Human samples: Publicly available human database were mined. Reference:[1]PMID: 34062281

and Jasmohan S. Bajaj[2,3], (1)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, (2) Virginia Commonwealth University and Richmond VA Medical Center, (3)Stravitz-Sanyal Institute for Liver Disease & Metabolic Health, School of Medicine, Virginia Commonwealth University, Richmond, VA, USA

Background: Oxygen and inflammation levels in the gut have emerged as important factors in liver disease progression. Intestinal hypoxia, caused by altered blood flow and impaired oxygen delivery, triggers inflammation, and disrupts the intestinal barrier, leading to bacterial translocation and could encourage dysbiosis with facultative anaerobes. Bacterial translocation and their products reach the liver, promoting inflammation, oxidative stress, and liver damage. However, the relationship between oxygen response, gut inflammation, and liver disease progression in cirrhosis patients remains largely unknown and are the focus of this study. **Methods:** Twelve age-balanced men, including healthy control (54 ± 3 yrs), compensated (55 ± 4 yrs, MELD 7) , and decompensated cirrhosis (56 ± 5 yrs, MELD 11, prior HE on lactulose) underwent EGD & prepped colonoscopy on the same day with pinch biopsies taken from the duodenum (DUOD) and ascending colon (ASCEND). Total RNA was isolated using Trizol. Gene profiles were analyzed with the NanoString nCounter®. Differentially expressed genes (DEGs) between groups were identified using Rosalind. Gene Ontology (GO) function and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses were performed. **Results:** Bioinformatic analysis revealed significantly upregulated expression of key inflammation-related genes [mitogen-activated protein kinase kinase 2 (MAP2K2), signal transducer and activator of transcription 3 (STAT3) and thioredoxin (TXN)], along with downregulated expression of genes associated with reactive oxygen response (ROS) [Ferredoxin 1 (FDX1), Metal Regulatory Transcription Factor 1 (MTF1)] in both DUOD and ASCEND of cirrhosis subjects compared to healthy controls. Furthermore, decompensated patients exhibited increased expression of inflammation-related genes [MAP2K1, Nuclear Factor Kappa B Subunit 1 (NFKB1) and Interleukin 6 (IL6)] and decreased ROS-related genes [Epidermal Growth Factor Receptor (EGFR) and NADH: Ubiquinone Oxidoreductase Subunit A12 (NDUFA12)] compared to compensated patients. The GO and KEGG analysis highlighted that, in compensated patients, DEGs were most associated with increase in 'aerobic respiration', 'response to hypoxia', 'oxidative phosphorylation', 'chemical carcinogenesis - reactive oxygen species' and decrease in 'response to oxidative stress', 'cellular respiration', 'inflammatory response'. Similar trends were observed in decompensated patients, with more significant changes. **Conclusion:** We found alteration in oxygen consumption-related gene expression across small and large intestine in humans with cirrhosis, which increases with progression of disease. This could promote the growth of potential anaerobic pathobionts in the gut and could be relevant in understanding the interplay between gut oxygen levels, inflammation, and liver disease in liver cirrhosis.

Table. Genes and pathways related to oxygen consumption and Inflammation in patients with cirrhosis.

Genes list	Expression in samples	Pathway included
MAP2K2, AKT1, STAT3, TXN	Upregulated significantly in cirrhosis vs controls (Duodenum part)	Inflammation including IL-1, IL-6 and TNF signaling
MAP2K2, TXN	Upregulated significantly in cirrhosis vs controls (Ascending colon part)	Inflammation including IL-1, IL-6 and TNF signaling
MAP2K1, RELA, NFKB1, IL6, RELA, NFKB1	Upregulated significantly in decompensated vs compensated (Ascending colon part)	Inflammation including IL-1, IL-6 and TNF signaling
WRN, MTF1, FDX1	Downregulated significantly in compensated vs controls (Duodenum part) Downregulated significantly in compensated vs controls (Ascending colon part)	Reactive Oxygen Response
EGFR, NDUFA12	Downregulated significantly in decompensated vs compensated (Duodenum part) Downregulated significantly in decompensated vs compensated (Ascending colon part)	Reactive Oxygen Response
NDUFA12, NDUFS7, IDH3G, NDUFA1, SDHB, SOD2, FAHD1, COX5B, SLC16A3	Upregulated significantly in cirrhosis vs controls (Duodenum part) Upregulated significantly in cirrhosis vs controls (Ascending colon part)	Mitochondrial Respiration

f 30 | ETHANOL-INDUCED REDUCTION IN THE INTESTINAL METHYLATION POTENTIAL PROMOTES TIGHT JUNCTION DISRUPTION: PROTECTION BY BETAINE TREATMENT

Sathish Kumar Perumal[1,2], Madan Kumar Arumugam[1,2], Murali Ganesan[1,2], Natalia Osna[1], Karuna Rasineni[1,2] and Kusum K. Kharbanda[1,2], (1) Veterans Affairs Nebraska-Western Iowa Health Care System, (2)University of Nebraska Medical Center

Background: The gut-liver interaction has emerged as a critical component in alcohol-associated liver disease (ALD) pathogenesis. The central mediators are the gut

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

luminal antigens, especially endotoxins that translocate to the liver. This occurs because of (i) compromised gut barrier integrity due to epithelial tight junction (TJ) disruption; and (ii) qualitative/quantitative gut microbiota changes and increased production of pathogenic antigens. We have previously shown that ethanol consumption alters the liver methionine metabolic pathway causing a rise in intracellular S-adenosylhomocysteine (SAH) levels. While the levels of the key methyl donor, S-adenosylmethionine (SAM), is unchanged, the lowering of the SAM:SAH ratio impairs several methylation reactions leading to the generation of hallmark features of early alcohol-associated liver injury. We have further shown that treatment with betaine preserves the liver methylation potential to thereby prevent alcohol-induced liver damage. This study was undertaken to examine the effect of alcohol on intestinal methionine metabolic pathway and explore whether any functional detriment of these alterations could be prevented by betaine treatment. **Methods:** Adult male C57Bl/6 mice were fed the Lieber DeCarli control or ethanol diet for 6 weeks. At the end of the feeding regimen, blood, liver, cecal content and ileal segments were removed and analyzed. **Results:** We observed that while SAM levels were maintained in the ileal mucosa of the ethanol-fed mice, there was a significant rise in SAH levels which decreased the SAM:SAH ratio by ~2-fold ($p < 0.02$) compared with controls. All these changes were like those previously reported in the livers of ethanol-fed mice. Concomitant with the alterations in the crucial components of ileal methionine metabolic pathway that controls the cellular methylation potential, we observed disorganized localization of key members (occludin, claudin-1) of the multiprotein TJ complex by confocal microscopic analysis. Western blotting of the detergent insoluble fraction confirmed their loss in the ileal membrane fraction (where TJs are localized) of ethanol-fed mice compared with controls. The ethanol-induced TJ disruption was accompanied by systemic endotoxemia and ~2-, 8- and 3-fold enhanced hepatic expression of the respective mRNAs encoding the pro-inflammatory cytokines, TNF±, CCL2 and IL1β, respectively. Betaine supplementation not only prevented ethanol-induced TJ disruption and microbiota changes, but also mitigated systemic endotoxemia and liver inflammation. **Conclusion:** Taken together, our results indicate that alcohol-induced alterations in the intestinal epithelial methionine metabolic pathway and the resulting impairments in methylation reaction promotes gut leakiness and progressive liver injury. Betaine by preventing intestinal methylation defects and microbiota changes prevents the development of ALD.

31 | NOVEL MECHANISMS UNDERLYING GUT LEAKINESS AND SYSTEMIC ENDOTOXEMIA IN PROMOTING LIVER FIBROSIS VIA THE GUT-LIVER AXIS AND THE MECHANISTIC PROTECTION OF MELATONIN

Wiramon Rungratanawanich, Karli LeFort and Byoung-Joon (B.J.) Song, Nih (NIAAA)

Background: Liver fibrosis is the consequence of chronic liver diseases that can progress to cirrhosis and liver failure. However, the role and mechanism of gut leakiness in liver fibrosis are poorly understood, and there is no FDA-approved drug to treat liver fibrosis. In this study, we aimed to investigate the causal role of protein acetylation and gut dysbiosis in promoting gut leakiness, endotoxemia, and liver fibrosis and the protection by melatonin (MT), a safe agent recognized by FDA, through the gut-liver axis. **Methods:** Young male Sprague-Dawley rats were divided into 12 groups (4 groups x 3 timepoints): Control (vehicle), MT (10 mg/kg/day, oral), TAA (200 mg/kg/dose twice a week, i.p.), and MT+TAA for 1, 2, or 4 weeks (n = 6-8/group). Histological analyses were determined by Picrosirius red, H&E, and TUNEL staining. Liver injury was evaluated by serum transaminases (ALT, AST) and markers for apoptosis and fibrosis. Gut dysbiosis was measured via 16S metagenomic sequencing and metabolomic analyses of cecum samples. Gut leakiness was assessed by serum endotoxin (LPS), while immunoblots and immunoprecipitation were performed to detect protein alterations. For additional mechanistic studies, similar experiments were performed in wild-type (WT) and gut- or liver-specific *Sirt1*-KO mice using TAA (200 mg/kg/dose twice a week, i.p.) for 5 weeks (n = 6-8/group). **Results:** TAA caused hyperacetylation (Ac-Lys) of gut and liver proteins via selective suppression of Sirtuin 1 (SIRT1) deacetylase along with gut dysbiosis, leading to gut leakiness, endotoxemia, and liver fibrosis, all of which were improved by MT. Gut tight and adherent junction proteins (TJ/AJs) were acetylated and degraded via ubiquitin-dependent proteolysis. Decreased TJ/AJs with increased intestinal deformation, enterocyte apoptosis, and serum endotoxin were observed as early as 1 week, while liver fibrosis and injury markers, hepatocyte apoptosis, and serum ALT and AST were markedly elevated 2 and 4 weeks after TAA exposure. TAA increased the abundance of pathogenic bacteria (Proteobacteria, Ruminococcaceae, etc.) but decreased the levels of short-chain fatty acids (Butyric, Propionic acids, etc.). Interestingly, TAA decreased only SIRT1 activity and protein levels, but not other six SIRT isoforms, and caused hyperacetylation of liver proteins related to inflammation (Ac-NFκB) and apoptosis (Ac-FOXO1). Pretreatment with

MT ameliorated all these changes at 1, 2, and 4 weeks. TAA-exposed gut- or liver-specific *Sirt1*-KO mice also showed markedly decreased gut TJ/AJs with greater enterocyte apoptosis, endotoxemia, liver fibrosis, and hyperacetylation of gut and liver proteins than those of WT mice. **Conclusion:** This study showed the novel mechanisms of the decreased SIRT1-mediated protein hyperacetylation along with gut dysbiosis in promoting gut leakiness and liver fibrosis and the protective role of melatonin through the gut-liver axis.

32 | MICROBIAL MONOTHERAPY WITH LEUCONOSTOC SP. LB-P8 IMPROVES INFLAMMATION AND FIBROSIS IN MOUSE MODELS OF PRIMARY SCLEROSING CHOLANGITIS

Steven P. O'Hara[1], Kyoungsub Song[2], Seunghwan Choi[2], Carys A. Turner[1], Nicholas E. Pirius[1] and Nicholas F. LaRusso[3], (1)Mayo Clinic, (2)Liscure Bioscience, (3)Mayo Clinic, Rochester, MN

Background: PSC is an archetypical example of a disease with an impaired gut-liver axis and PSC patients with or without inflammatory bowel disease exhibit enteric microbial dysbiosis. Gut microbiota produce diverse metabolic products but how microbes influence PSC disease progression is unclear. By screening bacterial species (sp.) in a transwell gut-liver axis model, we identified novel *Leuconostoc sp*. (LB-P8) that may have anti-fibrotic properties via inhibition of TGF-β/SMAD signaling. Here we investigated whether oral dosing of LB-P8 improved inflammation and fibrosis in mouse models of PSC. **Methods:** We used two models: chronic feeding (7 weeks) of 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) and the Mdr2-/- mouse. Live culture or freeze-dried preparations of LB-P8 were orally gavaged daily for 4 weeks following disease onset. Peribiliary injury, inflammation, fibrosis, and cholangiocyte senescence were measured biochemically (ALT & ALP), and by histology, immunofluorescence, picrosirius red staining, hydroxyproline content, and qPCR. LB-P8-derived metabolites were analyzed using untargeted UPLC-MS/MS. Finally, RNA-seq was performed on hepatic stellate cells (HSCs) cultured in the presence or absence of LB-P8. **Results:** LB-P8 reduced DDC-fed and Mdr2-/- mouse model-induced elevations of serum ALT (~50 %), and ALP (20-50%). Fibrosis was reduced in live culture LB-P8 treated mice as evident by reduced picrosirius red staining (~50%), and hepatic hydroxyproline content. In Mdr2-/- mice, live culture LB-P8 treatment reduced hepatic mRNA expression of the fibrosis marker, Col1a1 (>50%), inflammatory markers, Tnf-± and Mcp-1 (~50%), and senescence markers, p16 and p21 (~80%). In DDC-fed mice, LB-P8 reduced macrophage number (F4/80; ~30%) and senescent cholangiocytes (p21 immunofluorescence) (~40%). Metabolomic profiling of LB-P8 cultures revealed increased detection of 38 metabolites involved in anti-fibrosis/inflammation compared to control and negative strains. RNA seq analysis of HSC further showed that LB-P8 decreased TGF-β, EMT, and integrin signaling pathways. **Conclusion:** LB-P8 ameliorates cholestatic liver disease progression likely by reducing cholangiocyte senescence, TGF-β-mediated fibroblast activation, and periportal accumulation of macrophages. These data suggest that LB-P8 targeting of the gut-liver axis is a potential novel therapeutic strategy for the treatment of PSC.

Department of Gastroenterology and Hepatology, Zhongshan Hospital, Shanghai, China, (3)Shanghai Institute of Liver Diseases, Fudan University Shanghai Medical College, Shanghai 200032, China, (4)Dept. of Medical Microbiology, Fudan University School of Basic Medical Sciences, Shanghai 200032, China

Background: Emerging evidence demonstrates microbial metabolites play pivotal roles in onset and progression of liver fibrosis and imidazole propionate (ImP) as a microbially produced histidine-derived metabolite was significantly increased in patients with chronic hepatitis B/cirrhosis compared to healthy controls. However, whether ImP is involved in hepatic fibrosis remains unclear. The present study aimed to explore the effects of ImP on hepatic fibrosis and its potential mechanisms. **Methods:** ImP (100μg) was administered i.p. twice daily for late 3 weeks in CCl_4-induced model (i.p. 9 weeks, twice weekly). Phosphorylated H2AX (γH2AX) DNA damage was detected by Western blot. M1 macrophage polarization was determined by gene expression of inducible nitric oxide synthase (iNOS), IL1β and IL6. **Results:** Although ImP administration alone did not cause liver fibrosis compared to controls, but it significantly exacerbated the progression of CCl_4-induced hepatic injury as documented by serum levels of ALT (452.5 ± 103.7 vs. 170.0 ± 27.5U/L, $p < 0.05$), AST (545.8 ± 102 vs. 237.0 ± 39.8U/L, $p < 0.05$). Collagen deposition was dramatically increased in CCl_4+ImP-treated compared to CCl_4-treated mice as indicated by Masson's staining and Sirius red staining. Gene expression of smooth muscle ±actin (±SMA) (3.35 ± 0.86 vs. 0.90 ± 0.09), procollagen 1±1 (COL1±1) (2.72 ± 0.58 vs. 1.00 ± 0.16) and procollagen 3±1 (COL3±1) (2.94 ± 0.78 vs. 0.98 ± 0.013, $p < 0.05$) was upregulated in CCl_4+ImP-treated mice. Additionally, liver showed more inflammation in CCl_4+ImP-treated mice, as demonstrated by enhanced infiltration of macrophages with CD11b immunofluorescence. To further analyze how ImP regulates macrophages *in vitro*, bone marrow-derived macrophages (BMDMs) were differentiated from WT mice. ImP increased expression of M1 polarization markers, iNOS (3.06 ± 0.45 vs. 1.03 ± 0.17, $p < 0.05$), IL1β (1.82 ± 0.09 vs. 0.98 ± 0.04, $p < 0.005$) and IL6 (3.17 ± 0.67 vs. 1.03 ± 0.19, $p < 0.05$) in BMDMs following LPS treatment. Furthermore, ImP elevated γH2AX protein in CCl_4-induced mouse liver and mRNA expression of iNOS in LPS-stimulated primary hepatocytes. Based on Hoechst staining, percentage of apoptotic primary hepatocytes in the LPS+ImP group was increased compared to LPS control. The supernatant of hepatocytes treated with LPS+ImP further potentiated proinflammatory polarization in BMDM than only LPS-stimulated hepatocytes, as evidenced by increased mRNA levels of iNOS. The supernatant of BMDM derived from hepatocytes treated by LPS+ImP further facilitated hepatic stellate cell (HSC) activation. **Conclusion:** Gut microbe-generated ImP potentiated fibrotic progression induced by CCl_4 intoxication in mice. Pronounced hepatocellular apoptosis, recruitment of inflammatory cells to damaged liver, release of pro-inflammatory cytokines (IL1β, IL6) may account for enhanced activation of HSCs into collagen type I-producing myofibroblast-like cells.

34 | INTESTINAL EPITHELIAL CELL OSTEOPONTIN PROTECTS FROM MASH BY CHANGING THE COMPOSITION OF THE GUT MICROBIOME AND BILE ACIDS

Hui Han[1], Sukanta Das[1], Xiaodong Ge[1], Zhuolun Song[1], Sai Santosh Babu Komakula[1,2], Ines Barahona[1], Romain Desert[1], Dipti Athavale[1], Wei Chen[1], Daniel Lantvit[1], Grace Guzman[1] and Natalia Nieto[1], (1)University of Illinois at Chicago, (2)University of Illinois at Chicago, Chicago, IL, United States

Background: osteopontin (OPN, encoded by *SPP1*) is involved in chronic liver disease. Previous studies reported that intestinal OPN regulates the gut microbiota, however the role of intestinal epithelial cell (IEC)-derived OPN in metabolic dysfunction-associated steatohepatitis (MASH) is unknown. **Methods:** we generated *Spp1* knock-in ($Spp1^{KI\ IEC}$) and knock-out ($Spp1^{\Delta IEC}$) mice in IECs and fed both genders with high fat, fructose, and cholesterol diet to induce MASH, or with isocaloric control diet, for 6 months. **Results:** immunohistochemistry revealed decreased OPN expression in IECs in WT mice with MASH compared to control diet. $Spp1^{\Delta IEC}$ showed worse hepatic inflammation (increased $CD11b^+$ cell infiltration and up-regulation of pro-inflammatory cytokines) than WT mice regardless of diet but developed more liver fibrosis and increased serum ALT than WT mice, when fed MASH-inducing diet. $Spp1^{\Delta IEC}$ mice displayed clutched IECs with condensed cytoplasm and pyknotic nuclei, increased $TUNEL^+$ IECs, downregulation of tight junction proteins, increased serum LPS and hepatic bacterial load, compared to WT mice, regardless of diet. Metagenomic analysis of gut microbiota revealed that $Spp1^{\Delta IEC}$ mice had enhanced β-diversity due to increased Deferribacteres and Verrucomicrobiota phyla. Multi-factor analysis revealed that 11 genera and 27 species were differentially upregulated in $Spp1^{\Delta IEC}$ mice,

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

regardless of diet. Among them, Clostridium_XlVa, Parabacteroides and Dora regulate bile acid (BA) deconjugation and 7-dehydroxylation. Total BAs increased in portal serum and decreased in feces from *Spp1*$^{\Delta IEC}$ compared to WT mice with MASH, indicating less BA excretion. Both the MASH diet and the *Spp1*$^{\Delta IEC}$ genotype independently increased conjugated primary BAs, particularly taurocholic acid (TCA), in both genders. Unconjugated primary BAs decreased in MASH but were less affected in *Spp1*$^{\Delta IEC}$ mice. Secondary BAs were lower in serum, however taurodeoxycholic acid (TDCA) significantly increased in *Spp1*$^{\Delta IEC}$ mice, regardless of diet. The hepato-protective BA tauroursodeoxycholic acid (TUDCA), mildly increased in both genders, regardless of diet, but was less abundant than TCA and TDCA. Compared to WT mice, *Spp1*$^{KI\ IEC}$ mice were protected from MASH shown by reduced gut permeability, liver inflammation, and fibrosis. **Conclusion:** IEC-derived OPN protects against MASH by preserving gut permeability, changing the composition of the gut microbiome, and bile acids.

35 | LIPID INDUCED ENDOTHELIAL INTERCELLULAR ADHESION MOLECULE 1 (ICAM1) PROMOTES METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Qianqian Guo[1], Mireille Khoury[1], Feda H Hamdan[2], Alexander Q. Wixom[2], Jose C. Villasboas[2] and Samar H. Ibrahim[2], (1)Mayo Clinic Rochester, Rochester, MN, (2)Mayo Clinic

Background: During metabolic dysfunction-associated steatohepatitis (MASH), liver sinusoidal endothelial cells (LSECs) acquire a pro-inflammatory phenotype characterized by increased adhesion molecules expression and myeloid cells-associated liver inflammation culminating in disease progression. However, the exact molecular mediators of this phenomenon are unclear. Herein, we aim to uncover the pathogenic role and the transcriptional regulation of intercellular adhesion molecule (ICAM1), an upregulated LSEC adhesion molecule in MASH and lipotoxicity. **Methods:** Chromatin immunoprecipitation (ChIP) assay was used to evaluate the enrichment at the *ICAM1* promoter of the active epigenetic mark, H3K27ac in primary human hepatic sinusoidal endothelial cells (HHSECs). HHSECs were seeded in a flow chamber, and primary human neutrophils were infused using a flow-based adhesion assay. Wild-type C57BL/6J mice were fed fat, fructose, and cholesterol (FFC) diet or choline-deficient high-fat diet (CDHFD) to induce MASH. Paraffin embedded liver sections from MASH patients or normal subjects were subjected to immunostaining and multiplex imaging using the CODEX (Co-detection by indexing) system. **Results:** Data mining of Assay for Transposase-Accessible Chromatin with sequencing (ATAC-seq) in LSECs from MASH and control mice identified open chromatin regions at the promoter region of *Icam1* that are significantly enriched in MASH mice. We validated the upregulation of ICAM1 expression in HHSECs with palmitate (PA) treatment. ChIP assay for H3K27ac showed H3K27ac enrichment is significantly induced by PA treatment at the ICAM1 promoter region. Using pharmacological and genetic inhibition approaches, we identified that ICAM1 upregulation in lipotoxicity is induced by glycogen synthase kinase 3 activation, and its downstream signaling pathway (JNK and c-Jun). Flow-based adhesion assay showed reduced neutrophil adhesion to PA treated HHSECs in the presence of ICAM1 Antibody (Ab). ICAM1 Ab-treated mice in both MASH models had reduced liver inflammation and fibrosis compared to controls, as assessed by decreased mRNA expressions of *Mcp1* and *Pdgfrb,* reduced immunostaining of the neutrophil marker myeloperoxidase (MPO), and reduction of infiltrated proinflammatory monocytes and neutrophils by flowcytometry. ICAM1 liver immunostaining was increased in patients with MASH and correlated with disease severity (Figure 1A). Bioinformatic analysis of the CODEX multiplexed liver tissue showed distinct zonal distribution of 7 myeloid cells in steatosis versus MASH with adherent myeloid cells to the sinusoidal endothelium (Figure 1B). **Conclusion:** Lipotoxic stress enhances the expression of LSECs ICAM1 via a c-Jun-associated histone modification. Inhibition of ICAM1 was salutary in murine MASH mainly secondary to reduced hepatic recruitment of proinflammatory myeloid cells and might serve as a potential therapeutic target for human MASH.

f 36 | GENETIC ABLATION OF CD4 T CELLS IN MICE ATTENUATES LIVER INJURY, INFLAMMATION, AND FIBROSIS IN NONALCOHOLIC STEATOHEPATITIS★

Hyun Se Kim Lee, Lucia Valenzuela Perez, Rachel L. Bayer, Ivone Igreja E Sá, Ester Dohnalkova, Ece Janet Dinc, Qianqian Guo, Samar H. Ibrahim, Adebowale O. Bamidele and Petra Hirsova, Mayo Clinic

Background: Nonalcoholic steatohepatitis (NASH) is a progressive condition characterized by excessive inflammation, which may lead to fibrosis. To date, the contribution of T cells to NASH remains largely unexplored. Our unpublished data suggest that CD4 T cells with pathogenic Th1 phenotype accumulate in murine NASH livers. Therefore, we investigated the role of CD4 T lymphocytes in NASH development. **Methods:** Whole-body CD4 knockout ($CD4^{-/-}$) and wild-type (WT) mice were fed chow or NASH-inducing diet high in fat, fructose, and cholesterol (FFC) for 24 weeks. Insulin resistance and metabolic phenotype were evaluated at weeks 16 and 18, respectively. Liver injury, inflammation, and fibrosis, along with gut microbiome were evaluated after 24 weeks of feeding. **Results:** CD4 deletion in FFC-fed mice did not affect food intake, weight gain, lean and fat mass, insulin resistance, and metabolic profile (e.g., metabolic rate, energy expenditure) as assessed by CLAMS (Comprehensive Lab Animal Monitoring System). However, liver weight and liver injury (assessed by plasma alanine aminotransferase) were significantly reduced in FFC-fed $CD4^{-/-}$ mice compared to WT, despite no changes in liver steatosis (measured by triglyceride levels). Mouse intrahepatic leukocytes were isolated and subjected to immunoprofiling by mass cytometry (CyTOF) and flow sorting of monocyte-derived macrophages (MoMF). Transcriptomic analysis in isolated MoMF using NanoString technology revealed that scar-associated macrophage markers (Trem2 and CD9) were less abundant in FFC-fed $CD4^{-/-}$ mice. Concordantly, liver hydroxyproline assay and Sirius red staining demonstrated a striking reduction in hepatic collagen deposition in FFC-fed $CD4^{-/-}$ mice, suggesting that CD4 T cells are required for liver fibrogenesis in NASH. The decrease in inflammatory and fibrogenic response was further validated by IHC for galectin-3 (macrophage marker) and ±SMA (a marker for activated hepatic stellate cells). Finally, FFC-associated microbiota alterations, such as increases in bacterial genes linked with glycolysis, glucogenesis, and lysine biosynthesis, were not observed in FFC-fed $CD4^{-/-}$ mice. Also, the gut microbiota alpha diversity in FFC-fed $CD4^{-/-}$ mice resembled that of chow-fed controls, exhibiting similar Firmicutes/Bacteroidetes ratios. **Conclusion:** Genetic loss of CD4 T cells in a murine NASH model results in a reduction in liver injury, inflammation, and fibrosis, independent of the metabolic syndrome. Together, we allude that CD4 T cells contribute to NASH pathogenesis.

37 | INTESTINE SPECIFIC HIF-1α OVEREXPRESSION AMELIORATES WESTERN DIET-INDUCED MASLD AND METABOLIC PHENOTYPES

Ming Song[1], Manman Xu[1] and Craig J. McClain[1,2], (1) University of Louisville, Louisville, KY, (2)Robley Rex VAMC

Background: Intestine epithelial HIF-1± plays a critical role in the maintaining of gut barrier function. Disrupted gut barrier function contributes to the development of metabolic syndrome. The aim of this study is to determine whether pharmacological or genetic activation of intestinal HIF-1± ameliorates western diet-induced MASLD and metabolic syndrome. **Methods:** *Hif1α*$^{LSL/LSL;VilERcre}$ and *Hif1α*$^{LSL/LSL}$ mice were generated by crossing LSL-HIF1 dPA mice with villin-cre-ERT2 mice. The intestine *Hif1α* activation was induced by tamoxifen administration. Male adult *Hif1α*$^{LSL/LSL}$ and *Hif1α*$^{LSL/LSL;VilERcre}$ mice were fed with regular chow diet, high fructose (HFr) or high-fat (60%

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

Kcal) high-fructose diet (HFHFr) for 8 weeks. High fructose diet was given via 30% fructose (w/v) in the drinking water *ad lib* for 8 weeks. Glucose and insulin tolerance test, and liver histology were evaluated. Ileum transcriptome was assessed by bulk RNA-seq. 8- to 10-week-old male HIF-1± luciferase reporter (ODD-luc) mice were fed with chow with or without 30% fructose (w/v) in the drinking water *ad lib* for 2 weeks and treated with dimethyloxalylglycine (DMOG), a pharmacological activator of HIF-1, at the dose of 8mg/mouse via IP injection every second day for 2 weeks. At the end of experiment, the luciferase activities of the entire GI tract were evaluated by bioluminescence imaging (BLI). Blood glucose level and cecal stool 16S rRNA sequencing were evaluated. **Results:** *Hif1α*$^{LSL/LSL;VilERcre}$ mice exhibited markedly improved glucose tolerance compared to *Hif1α*$^{LSL/LSL}$ mice in response to HFr diet. Intestine-specific *Hif1α*-overexpression led to markedly improved hepatic steatosis and a trend of decreased liver/body weight ratio without obvious alteration in the body weight when exposed to HFHFr diet. Of note, intestine-specific *Hif1α*-overexpression led to increased white adipose tissue (eWAT) weight and a trend of increased cecum/body weight ratio. DMOG treatment led to increased intestine HIF luciferase activity as shown by BLI and decreased blood glucose level associated with a remarkable alterations of gut microbiota composition in HFr diet fed ODD-luc mice. Ileum RNA-seq data analysis revealed that GO terms, including glycolytic process, pyruvate metabolic process, ATP generation from ADP were upregulated in *Hif1α*$^{LSL/LSL;VilERcre}$ mice. KEGG enrichment analysis further showed that glycolysis/gluconeogenesis was up in *Hif1α*$^{LSL/LSL;VilERcre}$ mice. **Conclusion:** Our data provide evidence that pharmacological or genetic activation of intestinal HIF-1± markedly ameliorate western diet-induced MASLD and metabolic phenotypes. RNA-seq data suggest that intestinal HIF-1± activation upregulates glycolysis, presumably leading to enhanced cell proliferation. Intestinal HIF-1± could be a promising therapeutic target for the treatment of MASLD and metabolic syndrome.

38 | HEPATOCYTE-SPECIFIC HIF-1α DELETION ACCELERATES NON-ALCOHOLIC STEATOHEPATITIS PROGRESSION TO LIVER FIBROSIS

Ziyong Zhang[1], Wenwen Li[1], Jialin Liao[2], Dongyan Zhang[2], Yang Song[2], Lushan Xiao[1], Li Liu[3] and Xuejing Zou[1], (1)Hepatology Unit and Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China, (2)Department of Radiation Oncology, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China, (3)Big Data Center, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China;hepatology Unit and Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China

Background: Non-alcoholic steatohepatitis (NASH) is prevalent, yet lacks for effective treatments to hinder rapid fibrosis progression, which is the main factor that limits patient prognosis. The role of Hypoxia-inducible factor 1± (HIF-1±) in NASH progression remains unclear. This study investigates the impact and mechanism of hepatocyte-specific HIF-1± deletion on NASH fibrosis, aiming to uncover a novel therapeutic target. **Methods:** Hepatocyte-specific HIF-1±knockout mice were generated using the Cre-Lox system and non-alcoholic steatohepatitis (NASH) models were established via a methionine choline-deficient (MCD) diet or Gubra-Amylin NASH (GAN) diet. During the study, mouse food intake and weight changes were monitored, and biochemical indices were evaluated. Liver specimens were obtained for weighing, quantitative measurements of TC and TG, histopathological examination via H&E staining, Oil Red O staining, Sirius Red staining, and immunohistochemical staining. RNA-seq, histological techniques, flow cytometry, and co-culture experiments were employed to screen for and characterize the expression and functionality of GPMNB-positive macrophages. **Results:** Hepatocyte-specific HIF-1± knockout mice, compared with the Flox control group, demonstrated significantly exacerbated hepatic steatosis and increased formation of fatty granulomas when subjected to MCD and GAN diet-induced NASH models. However, knockout mice exhibited no significant difference in physiological parameters such as weight change and serum biochemistry under normal dietary conditions, compared to wild-type mice. HIF-1±knockout mice characterized an earlier onset of hepatic fibrosis, accompanied by significantly upregulated mRNA expression of fibrosis-related genes. Recruitment of GPNMB^{+} macrophages was observed in the HIF-1±depleted liver. Single-cell sequencing data of the liver tissues indicated that GPNMB was predominantly expressed in macrophages. Furthermore, the GPNMB protein stimulated hepatic stellate cell activation, suggesting that GPNMB^{+} macrophages might hasten the progression of NASH to liver fibrosis. **Conclusion:** Hepatocyte-specific HIF-1± deficiency accelerates NASH progression to liver fibrosis through the recruitment of GPNMB^{+} macrophages. Targeting GPNMB might provide a promising strategy to curb fibrosis progression and benefit NASH prognosis.

39 | ROLE OF AUTOPHAGY IN HEPATIC ACETYLOME REGULATION

Kamal Baral, Arissa Mercer, Adriana Lopez, Gang Liu, Xiao-Ming Yin and Bilon Khambu, Tulane University School of Medicine, New Orleans, LA

Background: Liver acetylome is a set of protein acetylation's whose level reflects cellular metabolic health and is directly linked to intracellular pathways. However, to date, little is known about the cellular pathways that maintain the hepatic acetylome levels. Here, we show that macroautophagy hereafter referred to as autophagy, an intracellular lysosomal degradative pathway, regulates the hepatic acetylome. **Methods:** Various mouse models of autophagy deficient and autophagy activated conditions were used to dissect the role of autophagy in hepatic acetylome regulation. Wild type (WT) mice were injected with chloroquine (60mg/Kg, i.p) for 6 consecutive days to inhibit autophagy. Total liver lysate and subcellular fractions were analyzed by immunoblotting for acetylated lysine. Liver sections were immunostained for acetyl-Lysine. Hepatic level of acetyl-CoA, CoA and Histone H3 acetylation, and quantitative PCR of various enzymes involved in acetyl-CoA regulation were examined. For rescue experiments, acetyl-CoA was administered intraperitoneally (10mg/kg body weight) for eight consecutive days. Liver sections were subjected to H&E staining and serum ALT was examined as a measure of liver injury. **Results:** Examination of total acetylome (nuclear, cytosolic, mitochondrial, membrane) in autophagy-deficient or autophagy-defective liver exhibited remarkably lower levels compared to normal liver. The lower hepatic acetylome was independent of the cellular injury that is commonly seen in autophagy-deficient conditions. In contrast, autophagy activation by fasting or rapamycin treatment increased the level of hepatic acetylome. Moreover, mechanistic studies showed that hepatic autophagy function is essential to maintaining levels of acetyl-CoA, a central intermediate metabolite needed for acetylation of proteins. Autophagy impairment significantly reduced hepatic acetyl-CoA production through transcriptional downregulation of key enzymes involved in the acetyl-CoA synthesis, including *Acly, AceCS1, AceCS2, Mcd,* and *Pdha1*. Notably, replenishing hepatic acetyl-CoA rescued the lowered hepatic acetylome and, interestingly, protected against liver injury in the autophagy-deficient liver. **Conclusion:** In conclusion, autophagy regulates the hepatic acetylome as an important mechanism for protecting liver against injury and causing liver damage.

Background: Nonalcoholic steatohepatitis (NASH) is a progressive disease characterized by liver inflammation. Emerging evidence implicates T cells in the disease pathogenesis. Our unpublished data show that CD4 T cells contribute to NASH development; however, hepatic CD4 T cell phenotypes and functions in NASH have not yet been systematically examined. **Methods:** C57BL/6J mice were fed with a chow or NASH-inducing diet high in fat, fructose, and cholesterol (FFC) for 24 weeks. Purified intrahepatic CD4 T cells were characterized by the cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq, which combines scRNA-seq with analysis of cell surface proteins), immunophenotyping by mass cytometry (CyTOF), NanoString targeted mRNA analysis (nCounter), and analyses of effector cytokines using flow cytometry following *ex vivo* stimulation (anti-CD3/CD28 with or without PMA/Ionomycin). **Results:** To better understand the role of CD4 T cell subsets in murine NASH, we leveraged two complementary approaches: an unbiased approach by CITE-seq and CyTOF with 44 well-established T cell markers. These two single-cell analyses revealed that hepatic CD4 T cells from chow and FFC diet-fed mice are highly heterogeneous as they separated into 15 and 18 unique clusters by CITE-seq and CyTOF, respectively. Livers from chow-fed mice had a distinct population of naïve T cells, while NASH livers were significantly enriched in T-bet^{+} cells in various stages of activation, suggesting enrichment of Th1 cells. Interestingly, NASH livers were also enriched in Foxp3^{+} cells as well as regulatory T cells (defined as Foxp3^{+} CD25^{+}). To compensate for the depth of sequencing in CITE-seq, we profiled mRNA expression of select 750 immune-related genes in hepatic CD4 T using NanoString technology. A total of 207 genes were differentially expressed between chow liver and NASH-derived CD4 T cells. Top upregulated genes in NASH CD4 T cells included Ifng, Havcr2 (Tim3), and Pard3, confirming the enrichment of Th1 cells in NASH livers. To further validate the Th1 effector phenotype in NASH, hepatic CD4 T cells from chow and FFC-fed mice were re-stimulated *ex vivo*. Upon stimulation, NASH-derived CD4 T showed markedly increased expression of IFNγ, with minimal changes in IL17a, compared to chow liver CD4 T cells. Also, frequencies of TNF±$^{+}$ IFNγ^{+} cells were significantly increased in NASH-derived CD4 T cells. **Conclusion:** These results indicate that IFNγ- and TNF±producing Th1 cells are enriched in diet-induced murine NASH, likely promoting NASH pathogenesis.

41 | INTESTINAL ENDOGENOUS RETROVIRUSES PROMOTE ETHANOL-INDUCED LIVER DISEASE IN MICE★

Noemi Cabre[1], Marcos F. Fondevila[1], Xinlian Zhang[2], Yanhan Wang[1], Cristina Llorente[1] and Bernd Schnabl[3,4], (1)Department of Medicine, University of California San Diego, San Diego, CA, (2)Division of Biostatistics and Bioinformatics, Department of Family Medicine and Public Health, University of California San Diego, (3)University of California San Diego, (4)VA San Diego Healthcare System

Background: Alcohol-associated liver disease (ALD) is a major public health problem worldwide, and gut microbial dysbiosis is an important contributor to ALD pathogenesis. Our previous study showed that patients with alcohol-associated hepatitis (AH) have increased proportions of mammalian viruses including retroviruses in the fecal virome. However, the role of the gut virome and in particular of endogenous retroviruses (ERVs) for ALD development is unknown. The aim of this study was to evaluate the contributions of ERVs to ALD onset and progression. **Methods:** We used transcriptomics for human duodenal biopsies. Gnotobiotic and genetically modified C57BL/6 mice were subjected to the chronic plus binge ethanol feeding model (NIAAA). **Results:** Three specific ERVs were upregulated in duodenal biopsies of patients with alcohol use disorder and ALD (n = 45) as compared with non-alcoholic

controls (n = 15) as analyzed by RNAseq. Using the NIAAA model, we confirmed that chronic ethanol feeding of mice resulted in an increased abundance of ERVs in intestinal epithelial cells (IECs) of the small intestine and colon, but not in the liver. Ethanol treatment (50mM) induced the expression of ERVs in cultured small intestinal mouse organoids, which was blocked with the histone acetylation inhibitor A485, indicating that ethanol-mediated histone acetylation is involved in upregulation of ERVs. To further define the importance of ERVs in ethanol-induced liver disease, we colonized germ-free mice with stool from fecal retrovirus-positive and -negative AH patients. All patients were HIV negative. Germ-free mice transplanted with stool from fecal retrovirus-positive patients showed exacerbated ethanol-induced liver injury, steatosis, and inflammation. Oral treatment with antiretroviral medications (Emtricitabine, Tenofovir, Nevirapine) reduced ethanol-induced liver disease and intestinal ERV abundance in gnotobiotic mice colonized with stool from retrovirus-positive patients. Z- nucleic -binding protein 1 (*Zbp1*) is a sensor of ERVs and is known to trigger cell death in IECs and to induce gut barrier dysfunction. *Zbp1* was upregulated in the intestine of ethanol-fed mice and reduced following antiretroviral medications. To demonstrate that Zbp1 mediates the effect of ERVs in the intestine, we generated mice with an IEC specific deletion of Zbp1 ($Zbp1^{\Delta IEC}$). $Zbp1^{\Delta IEC}$ showed reduced ethanol-induced steatohepatitis as compared with floxed wildtype littermates. Deletion of *Zbp1* in hepatocytes or Kupffer cells did not affect ethanol-induced liver disease. **Conclusion:** Our results indicate that alcohol upregulates endogenous retroviral elements in the intestine of mice and humans. Reducing gut ERVs or deletion of intestinal *Zbp1* in mice protects against ethanol-induced liver disease, indicating that the ERV-Zbp1 axis could be a potential therapeutic strategy for ALD.

f 42 | EXPLORING THE ROLE OF X-BINDING PROTEIN-1 (XBP1) IN THE GUT- LIVER AXIS DURING ALCOHOL-RELATED LIVER DISEASE (ARLD)

Carlos Sanz-García[1,2], Raquel Benedé-Ubieto[3], Marina S Mazariegos[3], Kang Zheng[3], Alejandro H. Gutierrez[1], Javier Vaquero[4], Rafael Bañares[5], Eduardo Martinez-Naves[3], Rubén Francés[6], Esther Caparrós[6,7], Santiago Canals[6], Yulia Nevzorova[8] and Francisco Javier Cubero[8], (1)Complutense University School of Medicine, (2)Complutense School of Medicine, Madrid, Spain, (3)Ucm, (4)Centro De Investigación Biomédica En Red De Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain, (5)Centro De Investigación Biomédica En Red De Enfermedades Hepáticas y Digestivas (CIBEREHD), (6)Umh, (7) Miguel Hernández University, Spain, (8)Instituto De Investigación Sanitaria Gregorio Marañón (IiSGM)

Background: In the context of alcohol-related liver disease (ArLD), changes in the homeostasis of the gut-liver axis have become a focus of major attention in the past few years. The transcription factor X-Binding protein-1 (XBP1) is a major regulator of UPR, mediating adaptation to ER stress. In the present study, we aimed to analyze the function of XBP1 in the gut (intestinal epithelial cells, IECs), and in the liver (hepatocytes) in promoting ArLD. **Methods:** Eight- to 13-week-old female and male mice with specific deletion of XBP1 in IECs ($XBP1^{\Delta IEC}$), XBP1 in Hepatocytes ($XBP1^{\Delta HEPA}$), and XBP1-floxed wildtype ($XBP1^{f/f}$) mice were subjected different experimental models of ArLD: (i) Lieber-DeCarli control and ethanol diet for 8 weeks plus a multiple PBS or EtOH gavage, respectively, and (ii) DUAL diet, a preclinical model of non-alcoholic fatty fatty liver disease/non-alcoholic steatohepatitis (NAFLD/NASH) characterized by the development of metabolic syndrome. Upon sacrifice, organs were extracted, and markers of liver damage, histopathological examination and techniques of Biochemistry and Molecular Biology were performed. Finally, antibiotic treatment (Abx) was performed as a therapeutic approach. **Results:** Serum markers of liver damage (e.g.: AST, ALT) were statistically increased in $XBP1^{\Delta IEC}$ compared with $XBP1^{f/f}$ after both preclinical models, and associated with significantly higher cell death. Concomitantly, H&E staining of $XBP1^{\Delta IEC}$ livers displayed macrovesicular ballooning accompanied by significantly elevated markers of inflammation including TNFa, IL-6, MCP-1, TLR2/4, liver fibrosis (Sirius red and collagen I deposition), and signs of bacterial translocation into the liver (LPS, LTA and bacterial DNA). Furthermore, the content of intrahepatic triglycerides revealed significantly increased lipid deposition in $XBP1^{\Delta IEC}$ compared with $XBP1^{f/f}$ after both types of

preclinical models. Presence of autophagic vacuoles, decreased lysozyme granules and dilation of the Golgi cisterns associated with loss of Paneth cells and increased gut permeability (Mucin-2, ZO-1) was characteristic of XBP1$^{\Delta IEC}$ compared with XBP1$^{f/f}$ ilea, after both models of ArLD. Microbiota analysis revealed significantly increased abundance of *Lachnospiraceae*, *Muribaculaceae* and *Romboutsia* in in XBP1$^{\Delta IEC}$ mice. Abx therapeutics reversed the inflammatory phenotype of DUAL-ArLD with reduced liver injury, steatosis and fibrosis. **Conclusion:** Our results clearly suggest that loss of XBP1 in IECs trigger significant inflammation in the gut-liver axis, opening a novel therapeutic avenue for research in the context of ER stress and ArLD.

43 | TARGETING IL-17RA IN HEPATOCYTES AS A NOVEL THERAPEUTICAL APPROACH FOR AALD USING GALNAC DELIVERY SYSTEM

Raquel Weber[1], Vivian Zhang[1], Leon Lin[2], Alvaro Eguileor Gine[3], Sadatsugu Sakane[3,4], Souradipta Ganguly[3], Debanjan Dhar[3], Meghna Pulacode[1], Mira Sadek[2], David A. Brenner[3] and Tatiana Kisseleva[3], (1) University of California San Diego, (2)UCSD, (3) University of California, San Diego School of Medicine, (4)University of California, San Diego

Background: IL-17 signaling is implicated in the pathogenesis of alcohol-associated liver disease (AALD) leading to steatosis, fibrosis and hepatocellular carcinoma (HCC). We recently demonstrated that the specific deletion of IL-17RA in hepatocytes protects from steatosis, fibrosis and HCC in high fat diet plus ethanol (HFD+EtOH)-fed in MUP uPA mice (model that express urokinase-type plasminogen activator driven by a hepatocyte promoter for major urinary protein). As an alternative approach, the conjugation of antisense oligonucleotides to N-acetylgalactosamine (GalNAc) has been shown to efficiently target the liver via high-affinity binding to the asialoglycoprotein receptor expressed at the surface of hepatocytes. We hypothesize that the suppression of IL-17RA with GalNAc-IL-17RA siRNA therapeutical dosing in hepatocytes is sufficient to ameliorate AALD-induced steatosis, fibrosis, and HCC in mice. As a novel therapeutic approach, here we aim to treat AALD by selectively blocking IL-17RA in hepatocytes using GalNAc siRNA delivery system. **Methods:** MUP uPA mice were fed with HFD +EtOH or HFD only (Pair-fed) for 18 weeks. From week 9 to week 18, the mice were weekly treated, subcutaneously, with 10mg/kg of GalNAc siRNA IL17-RA or Control. The liver function, and the extent of steatosis, fibrosis and HCC were measured after 18 weeks. **Results:** The therapeutical dosing of GalNAc siRNA decreased the mRNA levels of IL-17RA by 60% in total liver, the downregulation of IL17-RA protein levels was also confirmed by western blot. Despite the number of tumors were not changed between groups, the tumors sizes were remarkably reduced (5x) in mice treated with GalNAc siIL-17RA. Interestingly, the therapeutically treatment in AALD mice also suppressed steatosis and fibrosis by 50%. In corroboration with our previous findings using an IL-17RA hepatocyte specific KO mice, we saw downregulation of target genes involved in ER stress-related and *de novo lipogenesis* (*Caspase 2, Srepb1, Srebp2, Dhcr7, Acca, Fasn*). In addition to these, the serum levels of ALT were decreased by 50% on GalNAc siIL-17RA treated mice in comparison to control, indicating an improvement of the liver function. **Conclusion:** Downregulation of IL-17RA in hepatocytes using GalNAc siRNA therapeutical approach, suppressed steatosis, fibrosis and remarkably reduced HCC growth in AALD mouse model. Targeting IL-17RA therapeutically using GalNAc, delivery system may become an efficient alternative to treat AALD.

44 | ALCOHOL CONSUMPTION ACCELERATES HEPATIC MICROPLASTIC ACCUMULATION VIA IMPAIRED INTESTINAL MUCOSAL BARRIER

Su-Min Baek, Tae-Un Kim, Jae-Hyuk Yim, Woo Jun Kim and Jin-Kyu Park, Kyungpook National University

Background: Microplastic (MP) is defined as the plastics size less than < 5mm. MP accumulates in humans via ingestion. Therefore, the gut-liver axis may be a important to prevent MP accumulation. However, many of the studies focus on the marine organisms and its biological effect and distribution pattern remain to be elucidated in mammals. Therefore,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the present study investigates the role of gut-liver axis in protection of hepatic MP accumulation. **Methods:** During the experiment, mice were divided into control, control + MP, EtOH, and EtOH + MP groups. EtOH groups were ingested Lieber-deCarli ethanol diet for 5 weeks. Polystyrene (PS)-MP groups were orally administered at a dose of 0.1mg/kg 5 times a week. Since PS-MPs were tagged with immunofluorescent dye, the distribution pattern of MPs was analyzed with immunofluorescence assay. Liver injury was assessed with histopathology, serum ALT, AST, and TG assay, Oil-Red-O staining, and hepatic TG assay. Caco-2 was also used to analyze the MP distribution pattern under the similar condition as *in vivo*. **Results:** EtOH + MP group showed the higher hepatic steatosis and inflammatory lesions than other groups. Moreover, EtOH + MP group showed significant higher MP accumulation than control + MP group, indicating that MP accumulation was affected by hepatic damage. To explore the mechanism, MP accumulation pattern in the intestines was next investigated since gut-liver axis is one of the key mechanisms in alcoholic liver disease. EtOH + MP group exhibited significant intestinal damages such as epithelial necrosis, vacuolar degeneration, disintegration and detachment, and fusion of villi. However, control + MP group showed intact intestinal structure. Similar with the histopathological patterns, EtOH + MP group showed a remarkably higher MPs accumulation pattern in the intestines than in control + MP group. In confocal images, MPs penetrated into the lamina propria through the damaged intestinal epithelium in EtOH + MP group while only few MPs penetrated in control + MP group, which was characterized by intact intestinal epithelial structure. Ethanol ingestion disrupted the intestinal mucosal barrier, and the PS-MP accumulation was remarkably increased. **Conclusion:** The result suggests that ethanol aggravates PS-MPs accumulation in the liver via disrupted intestinal mucosal barrier, and the gut-liver axis could be a novel therapeutic target in prevention of PS-MPs accumulation in the body.

f 45 | CHRONIC ETHANOL INSULT INCREASES HSD17beta13 ON HEPATOCELLULAR LIPID DROPLETS VIA A LOSS OF AN ASSOCIATED SEGREGASE p97/VCP TO PROMOTE HEPATIC STEATOSIS

Shaun Weller[1], Ryan Schulze[1], Sandhya Sen[1], Donglin Ding[1], Carol A. Casey[2], Paul Thomes[2], Conrad Weihl[3] and Mark A. McNiven[1], (1)Mayo Clinic, (2)University of Nebraska Medical Center, (3)Washington University School of Medicine in St. Louis

Background: Chronic EtOH insult is known to lead to an accumulation of lipid droplets (LDs) in hepatocytes resulting in hepatic steatosis. Our previous study reported that EtOH resulted in a 10-fold reduction of the LD-associated segregase VCP/p97, a protein implicated in LD protein clearance. Concomitant with this decrease was a 6-fold increase in the association of the hydroxysteroid enzyme HSD17β13 known to play an important role in hepatic steatosis. From these findings we predict that this alteration in the LD-proteome can lead to a disruption of LD catabolism and hepatocellular steatosis in vivo. The GOAL of this current study was to experimentally reduce hepatocellular VCP levels via a targeted knock out in mice to test the effects on LD-associated HSD17β13 levels and hepatic steatosis. **Methods:** A hepatocyte specific knockout of VCP was used along with histology, immunofluorescence microscopy, western blot analysis in combination with transient knockdown and manipulation of cultured hepatocytes. **Results:** The liver-specific knockout of VCP resulted in a dramatic > 10-fold increase in liver triglycerides and hepatic LDs in just 7days on a normal chow diet. Importantly, 13-day KO mice displayed livers with a 5-fold increase in HSD17β13. Parallel studies using primary isolated mouse hepatocytes showed that acute inhibition of VCP activity with either the drug DBeQ, or siRNA mediated knockdown, resulted in an elevation of HSD17β13 levels and a 5-fold increase in LD content. We have found that HSD17β13 is a mono-ubiquitinated protein predicted to be removed from the LD surface to the proteosome by VCP. Surprisingly, treatment of hepatoctyes with the proteasome inhibitor MG132 had no effect on HSD17β13 levels while inhibition of lysosome function with chloroquine resulted in a 6-fold increase of HSD17β13. In support of this finding IF

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

staining of these hepatocytes shows a marked colocalization of lysosomes with HSD17β13-associated LDs. **Conclusion:** This study suggests that a reduction in the levels of the VCP segregase by EtOH insult, or targeted KO, results in a substantial increase in the hepatocellular levels, and LD association of HSD17β13. Hepatocytes without VCP are unable to target ubiquitylated HSD17β13 to the lysosome for degradation leading to hepatic steatosis. These findings provide new insights into the cellular mechanisms by which EtOH exposure disrupts normal hepatic lipid catabolism. Supported by R01AA020735 (to M.A.M. and C.A.C.).

46 | GENERATION AND CHARACTERIZATION OF A HUMANIZED MOUSE MODEL OF ALCOHOL INDUCED STEATOSIS, INFLAMMATION AND FIBROSIS

Eleanna Kaffe and Wajahat Z. Mehal, Yale University, New Haven, CT

Background: Alcoholic associated liver disease (AALD) is a poorly characterized pathology characterized by steatosis, inflammation and fibrosis. The lack of an animal model which recapitulates key features of AALD has been a major limitation in understanding its etiology and in the development of effective therapies. To identify the cellular differences between the mouse and human liver responsible for the different injury response to alcohol we have generated humanized mice that can support human liver cells (parenchymal and non-parenchymal cells) along with human hematopoiesis [1]. **Methods:** In humanized and non-humanized mice (control mice having mouse liver and mouse hematopoiesis), we applied the NIAAA model of chronic and binge ethanol feeding (10-days ad libitum oral feeding with the Lieber-DeCarli ethanol liquid diet plus a single binge ethanol feeding 9 hours before the end of the experiment). This model was evaluated by: i) Serum ALT and bilirubin, ii) flow cytometry to define the immune cell composition in the liver and blood iii) H&E staining to assess steatosis, inflammation and ballooning iv) human/mouse aSMA and human Collagen-3 to asses mouse and human hepatic stellate cells activation and v) human CK8/18 to asses Mallory bodies formation. **Results:** We have seen that humanized mice had higher degree of steatosis, inflammation and ALT levels than non-humanized. In particular, the humanized mice had severe macrovesicular steatosis with Mallory bodies and ballooning whereas non humanized mice have minimal microvesicular steatosis. Also, humanized mice only have abnormal levels of bilirubin, mild to moderate fibrosis, severe peripheral lymphopenia. Of note, in the high degree steatotic areas of humanized mice, we observed human hepatic stellate cell activation between steatotic human hepatocytes, and human collagen. **Conclusion:** We have demonstrated that by fully humanizing mouse livers key features of AALD can be reproduced to a greater degree than they can in mouse only livers. This will be the first mouse alcohol model having high degree of macrovesicular steatosis in human hepatocytes, alcohol-driven fibrosis mediated by human hepatic stellate cells, and pathological immune responses driven by human Immune cells. This model will be a unique tool to study pathways leading to severe steatotic, fibrotic and inflammatory responses of ALD.

Background: This open-label study assessed the safety and efficacy of vebicorvir (VBR)+AB-729+nucleos(t)ide reverse transcriptase inhibitor (NrtI) in virologically suppressed (VS) patients (pts) with hepatitis B e antigen (eAg) negative chronic hepatitis B infection (NCT04820686). VBR is a 1st-generation core inhibitor and AB-729 is a single trigger GalNAc-siRNA targeting all HBV RNA transcripts. Initial end of treatment (EOT) responses were previously described. Here, we report additional EOT data and preliminary off-treatment responses. **Methods:** Sixty-five VS eAg negative pts were randomized to receive VBR+AB-729+NrtI (n = 32), VBR+NrtI (n = 16), or AB-729+NrtI (n = 17) for 48 weeks (wks). VBR 300 mg was given orally once daily and AB-729 as a 60 mg subcutaneous injection every 8 wks. Based on Wk 48 lab results, pts with ALT < 2x upper limit of normal + HBV DNA < lower limit of quantification (LLOQ) + hepatitis B surface antigen (sAg) < 100 IU/mL could discontinue all treatment and enter follow-up. Patients not meeting this criterion continued NrtI alone during follow-up. Virologic markers included sAg (Abbott Architect; LLOQ = 0.05 IU/mL) and HBV DNA (Cobas TaqMan; LLOQ = 20 IU/mL). Safety was assessed by adverse events (AEs) and lab parameters. **Results:** Baseline characteristics were similar across treatments. Treatments were well tolerated with 9% (3/32), 6% (1/16), and 6% (1/17) of pts discontinuing treatment due to an AE in the VBR+AB-729+NrtI, VBR+NrtI, and AB-729+NrtI arms, respectively. AEs on treatment were generally Grade 1/2 and reported in 81% (26/32), 75% (12/16), and 71% (12/17) of pts in the VBR+AB-729+NrtI, VBR+NrtI, and AB-729+NrtI arms, respectively. There was a single serious AE (COVID-19 pneumonia in a VBR+AB-729+NrtI recipient). At time of analysis, while no pts had HBsAg seroconversion, 16/26, 0/15, and 8/10 pts with available Wk 48 data met criteria to stop all treatment in the VBR+AB-729+NrtI, VBR+NrtI, and AB-729+NrtI arms, respectively. Of these, 12 pts who received VBR+AB-729+NrtI and 7 who received AB-729+NrtI discontinued all treatment. 8 wks after discontinuing all treatment, continued suppression of sAg < 100 IU/mL was observed in 89% (8/9) and 83% (5/6) of pts with available data receiving VBR+AB-729+NrtI and AB-729+NrtI, respectively (Table). **Conclusion:** Treatments were well tolerated. Available data indicate that adding VBR to AB-729+NrtI does not result in significantly greater on- or post-treatment improvements in markers of active HBV infection vs AB-729+NrtI.

Table. sAg Response by Time Point

Time Point	Parameter	VBR+AB-729 +NrtI (N=32)	VBR+NrtI (N=16)	AB-729+NrtI (N=17)
Baseline	sAg (log_{10} IU/mL); mean (SD)	3.4 (0.57)	3.3 (0.62)	3.3 (0.58)
	sAg <100 IU/mL; n/N (%)	0/32	0/16	0/17
Wk 48 End of Rx	sAg change from baseline (log_{10} IU/mL); mean (SD)	−1.9 (0.92)	0.0 (0.12)	−1.9 (0.91)
	sAg <100 IU/mL; n/N (%)	17/26 (65.4)	0/15 (0)	9/10 (90.0)
	sAg <10 IU/mL; n/N (%)	6/26 (23.1)	0/15 (0)	2/10 (20.0)
	Pts meeting stopping criteria; n/N (%)[a]	16/26 (61.5)	0/15 (0)	8/10 (80.0)
	Pts stopping all treatment; n/N (%)	12/26 (46.2)	0/15 (0)	7/10 (70.0)
4 Wks Post Rx[b]	sAg change from baseline (log_{10} IU/mL); mean (SD)	−1.9 (0.51)	NA	−1.8 (0.75)
	sAg <100 IU/mL; n/N (%)	12/12 (100.0)	0	6/7 (85.7)
	sAg <10 IU/mL; n/N (%)	4/12 (33.3)	0	1/7 (14.3)
8 Wks Post Rx[b]	sAg change from baseline (log_{10} IU/mL); mean (SD)	−1.9 (0.54)	NA	−1.8 (0.70)
	sAg <100 IU/mL; n/N (%)	8/9 (88.9)	0	5/6 (83.3)
	sAg <10 IU/mL; n/N (%)	2/9 (22.2)	0	1/6 (16.7)

Reported numbers reflect those at the time of the analysis.
[a]Wk 48 stopping criteria: ALT <2x ULN + HBV DNA <LLOQ + sAg <100 IU/mL.
[b]For pts discontinuing all treatment only; N reflects the number of patients with available sAg data at the specified analysis visit.
ALT, alanine aminotransferase; HBV, hepatitis B virus; LLOQ, lower limit of quantification; NA, not applicable; NrtI, nucleos(t)ide reverse transcriptase inhibitor; pt, patient; Rx, treatment; sAg, hepatitis B surface antigen; SD, standard deviation; ULN, upper limit of normal; VBR, vebicorvir; wk, week.

48 | PERIPHERAL SINGLE CELL GENE EXPRESSION CHANGES IN RESPONSE TO TOLL-LIKE RECEPTOR 8 AGONIST TREATMENT IN CHRONIC HEPATITIS B PATIENTS

Jeffrey Wallin[1], Circe McDonald[1], Bryan Downie[1], Leonard Anang Sowah[1], Mario Cortese[1] and Florian Wimmers[2], (1)Gilead Sciences, Inc., (2)University of Tuebingen

Background: Selgantolimod (SLGN) is an oral selective small molecule TLR8 agonist with antiviral potential that has been shown to be safe and well-tolerated in individual's with chronic hepatitis B (CHB). SLGN stimulates a robust pharmacodynamic response as measured by the detection of TLR8 pathway cytokines such as interleukin (IL)-12p40 and IL-1RA. We further characterized the molecular impact of SLGN treatment in peripheral blood mononuclear cells (PBMCs) using single cell profiling technologies. **Methods**: Viremic chronic hepatitis B (CHB) patients received once weekly 3 mg SLGN for 24 weeks. Blood samples were collected before and 4 hours post dosing at baseline, week 11 and week 23 for four participants. PBMCs were isolated and gene expression was evaluated using the 10X single cell RNA-seq protocol. Analysis was performed using the Seurat R package with cell type identification performed with SingleR. Differences in gene expression between baseline and on- treatment timepoints were determined by a non-parametric Wilcoxon rank sum text. **Results**: Seventeen cell clusters were identified by single cell gene expression analysis. Pathway-level analysis using blood transcriptional modules (BTM) indicated type I interferon modulation at on treatment time-points across multiple cell types (FDR < 0.01). Particularly, interferon stimulated genes, such as *IFI144L, STAT1, and MX1* were upregulated after SLGN treatment in several clusters, including those annotated as B, T, and NK cells. Furthermore, we observed modulation of TLR and inflammatory signaling associated with classical and non-classical monocytes. Of the many differentially expressed genes (DEGs) identified in the classical monocyte cluster (FDR < 0.05), *MECP2* and *FKBP5*, among others, were upregulated at all 4 hr postdose timepoints. Their gene products have been reported to act as regulator of chromatin structure and gene expression in immune cells (MECP2), and to be involved in the downregulation of excess interferon responses (FKBP5). Further, in the non-classical monocyte cluster, we observed DEGs at the same on-treatment timepoints, with overall lower fold change differences as compared to classical monocytes (mean log2 fold change 0.66 compared to 0.49). Of interest, different kinetics for DEGs were observed for naïve T cells in comparison to baseline. While several hundred DEGs were observed at 4hr post first administration of SLGN in the naïve T-cell cluster, including *STAT3* and NFkB pathway-related genes, subsequent on-treatment timepoints demonstrated overall fewer DEGs. **Conclusion**: Single cell PBMC analysis from SLGN-treated CHB viremic patients identified substantive changes in gene expression in multiple cell types. These findings provide greater insight into the cellular changes following SLGN treatment, and may inform complementary mechanisms for a HBV cure combination strategy.

Background: In the Phase 2b B-Clear study (209668), bepirovirsen (BPV; an antisense oligonucleotide) 300 mg for 24 weeks (wks) achieved sustained HBsAg and HBV DNA loss (< lower limit of quantification [LLOQ] for 24 wks off BPV therapy) in 9% of participants (pts) who remained on nucleos[t]ide analogs (NA); end of BPV response rates were higher (26%), but some pts relapsed during follow-up. Response was higher in pts with lower baseline HBsAg (d 3000 vs d 1000 IU/mL: 12% vs 16%). The B-Together study assessed if sequential therapy with BPV and pegylated interferon (PegIFN) can improve on the BPV efficacy rates observed in B-Clear. **Methods:** B-Together was a Phase 2b, multicenter, randomized, open-label study. Patients on stable NA therapy were eligible if they had HBsAg > 100 IU/mL, HBV DNA < 90 IU/mL, ALT d 2x upper limit of normal and no contraindication to receive PegIFN. Pts were randomized 1:1 to receive BPV 300 mg once weekly (QW; plus loading dose on Days 4 and 11) for 24 (Arm 1) or 12 (Arm 2) wks. Post BPV end, eligibility was assessed to receive up to 24 wks of PegIFN 180 mcg QW, with 24 (Arm 1) or 36 (Arm 2) wks follow-up post PegIFN end. Pts continued NA therapy throughout the study. Primary endpoint: proportion of pts with HBsAg and HBV DNA < LLOQ for 24 wks after planned end of sequential treatment, in the absence of newly initiated antiviral therapy (rescue therapy). Safety was assessed by adverse event (AE) monitoring. **Results:** The study enrolled 108 pts (n: Arm 1 = 55; Arm 2 = 53). Baseline characteristics were similar between arms and to those in B-Clear. The primary endpoint was achieved by 5 (9%) pts in Arm 1 and 8 (15%) pts in Arm 2 (Figure); all responders had baseline HBsAg d 3000 IU/mL. Only BPV responders benefited from Peg-IFN treatment, through prevention of relapse off-treatment (relapse rate B-Together vs B-Clear: Arm 1: 58% vs 63%; Arm 2: 0% vs 75%). The proportion of pts experiencing AEs was similar in both arms (Arm 1: 52 [95%]; Arm 2: 52 [98%]). Serious AEs were reported in 8 (7%) of pts (during BPV: 5 [5%]; during PegIFN: 0; follow-up period: 3 [3%]). BPV did not appear to adversely influence the safety profile of subsequent PegIFN. **Conclusion:** Sequential therapy with BPV and PegIFN results in an improved off-treatment response vs BPV alone (B-Clear), which appears to be driven by prevention of relapse in BPV responders. There were no new safety signals of concern. Funding: GSK (study 209348).

50 | A PHASE 2b, OPEN-LABEL STUDY TO EVALUATE THE EFFICACY, SAFETY, TOLERABILITY, IMMUNOGENICITY AND TREATMENT REGIMENS OF VTP-300 COMBINED WITH LOW-DOSE NIVOLUMAB IN CHRONIC HEPATITIS B INFECTION

Henrik Sorensen[1], Tom Evans[1], Dereck Tait[1], Louise Bussey[1], Radka Kolenovska[1], Debalina Mukherjee[2], Sazlyna Lim[2], Wan Long Chuang[3], Man-Fung Yuen[4] and Anchalee Avihingsanon[5], (1)Vaccitech Plc, (2) Novotech, (3)Kaohsiung Medical University Hospital, Kaohsiung Medical University, (4)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong, Hong Kong, China, (5)Chulalongkorn University

Background: New treatment concepts focus on enhancing rates of functional cure of chronic hepatitis B (HBV) with the aims of stopping nucleos(t)ide treatment (NA) with no risk of virological relapse or liver disease progression and further decreasing the risk of hepatocellular carcinoma (HCC). Induction of a CD8+ T cell response to HBV is likely a required mechanism to achieve a functional cure. VTP-300 is an antigen-specific investigational immunotherapy consisting of a Chimpanzee Adenovirus (ChAdOx1) prime and Modified Vaccinia Ankara virus (MVA) boost delivering antigens associated with hepatitis B infection. A Phase 1b/2a study in 54 patients previously showed VTP-300 had meaningful and durable hepatitis B surface antigen (HBsAg) responses as a monotherapy and in combination with low dose nivolumab (LDN). This study will examine different dose timing and boosting regimens to further optimize HBsAg level reductions. **Methods:** A Phase 2b trial is enrolling up to 120 patients (40 patients in each of 3 groups) with CHB, on antivirals for at least six months before screening with a HBV-DNA viral load of ≥ 1000 IU/mL and HBsAg ≤ 10 IU/mL and ≥ 4,000 IU/mL). Group 1, ChAdOx1-HBV (2 x 10*10 viral particles) followed by MVA-HBV (1 x 10*8 pfu) and LDN (0.3 mg/kg IV) at D29; Group 2, ChAdOx1-HBV (2 x 10*10 viral particles) followed by MVA-HBV (1 x 10*8 pfu) and LDN (0.3 mg/kg IV) at D29 followed by MVA-HBV (1 x 10*8 pfu) and LDN at D85; Group 3, ChAdOx1-HBV (2 x 10*10 viral particles) followed by MVA-HBV (1 x 10*8 pfu) at D29 followed by LDN at D36 followed by MVA-HBV (1 x 10*8 pfu) at D85 (only if HBsAg is ≤ 10IU/mL. The primary endpoint is the percentage of participants with a greater than 1 log HBsAg reduction at 6 months after initiation of therapy. HBV specific T cell responses are assessed using genotype C and D HBV peptides spanning the HBV immunogen in an IFNg ELISpot assay during the one-year follow-up period. **Results:** As of 22 May 2023, 51 participants have been enrolled in HBV003 and efficacy and safety data continue to accrue. At the 2023 AASLD meeting, we expect to report on at least 50 participants who will have reached D113, showing the effects of a second MVA-HBV booster on HBsAg levels and the impact of a LDN administration at D36 rather than at the time of MVA-HBV administration. In addition, at least 40 participants are expected to have reached the D169 timepoint when they will be evaluated for NA discontinuation. We expect recruitment to be complete by December 2023 with final results available early 2025. **Conclusion:** VTP-300 is a novel antigen-specific investigational immunotherapy which has shown (in a Phase 1b/2a study) meaningful and durable HBsAg reductions in patients with HBV as a monotherapy and in combination with LDN. Evaluating the addition and

timing of PD-1 inhibitor administration and a second boost of MVA-HBV is critical to optimizing the regimen of VTP-300 which may be a critical component of a functional cure regimen.

Background: Treatment of CHB with JNJ-3989 and NA ± JNJ-6379 has shown profound reductions in serum hepatitis B viral (HBV) markers. The INSIGHT study aims to assess intrahepatic changes in virological and immunological markers with JNJ-3989 based treatment in CHB patients. **Methods:** INSIGHT is a phase 2 multicenter study in CHB patients who are hepatitis B e-antigen positive (HBeAg+) and not currently treated (NCT; Group 1) or HBeAg-negative (HBeAg-) and virologically suppressed (VS) by NA (Group 2). Patients received 48 weeks of JNJ-3989 + NA (± JNJ-6379 withdrawn from study). Paired percutaneous core liver biopsies and fine needle aspiration biopsies (FNABs) were collected using standardized procedures at baseline and week 40 to investigate changes in intrahepatic viral and immune markers. **Results:** Levels of viral serum markers were higher for participants in Group 1 versus Group 2 at BL. JNJ-3989 treatment resulted in a mean (SE) hepatitis B surface antigen (HBsAg) change from BL of -3.78 (0.481) $\log_{10}$ IU/mL for Group 1 and -2.40 (0.160) for Group 2 at Week 40. One out of nine (11.1%) patients in Group 1 reached HBsAg seroclearance at W40. The estimated mean percentage of HBsAg positive hepatocytes decreased by W40 in both groups while the mean percentage of HBcAg+ cells decreased only in Group 1 (Table). In Group 1, the percentage of HBV RNA+ hepatocytes declined from min 90.2 to max 100% at BL to 4.4-28.4% at W40 (n = 4 patients in each group with samples profiled at BL and W40) and in Group 2 from 8.6-31.6% at BL to 5.6-15% at W40 (n = 4 pairs). The percentage of cccDNA–/HBV RNA– cells increased during JNJ-3989 treatment in both groups, from 0-1.2% at BL in Group 1 and 31.3-64.8% in Group 2; to 48.1-68.9% in Group 1 (n = 4 pairs) and 51.1-66.7% in Group 2 (n = 4 pairs) at W40. Profiling of FNABs identified enrichment in early activated CD8+ T cells by W40 in Group 1 and depletion of CD8+ exhausted T cells, CD8 + effector memory T cells, and CD8+ memory stem cells in Group 2. **Conclusion:** Treatment of CHB patients with JNJ-3989 resulted in reduction of HBsAg + hepatocytes at week 40 with an increased fraction of non- infected hepatocytes. Changes during treatment were seen in intrahepatic CD8+ T cells (increase of early activated CD8+ T cells in Group1 and depletion of exhausted T cells in Group 2), suggesting that JNJ-3989 + NA treatment combination leads to activation of intrahepatic adaptive immunity.

Table. Changes From BL Over Time in HBsAg+ and HBcAg+ Hepatocytes

Assay	Group	Number of samples with both baseline and week 40 data	Estimated percentage at Baseline (80% CI)*	Estimated percentage at Week 40 (80% CI)*
HBsAg	Group 1 (Baseline N=7)	6	78.48 (45.715, 94.047)	0.03 (0.003, 0.233)
	Group 2 (Baseline N=9)	9	6.67 (2.104, 19.198)	0.09 (0.191, 4.955)
HBcAg	Group 1 (Baseline N=7)	6	83.67 (70.661, 91.596)	4.46 (1.069, 16.773)
	Group 2 (Baseline N=9)	9	0.03 (0.016, 0.064)	0.10 (0.030, 0.325)

*The estimated percentage of HBsAg+ hepatocytes at baseline and Week 40, and the change from baseline in proportion of HBsAg+ hepatocytes at Week 40 were estimated by modelling the proportion of HBsAg+ hepatocytes using a binomial mixed model with normal random effects to account for potential overdispersion.

52 | LONG TERM HBsAg REDUCTION BY A NASAL ADMINISTRATIVE THERAPEUTIC VACCINE CONTAINING HBsAg AND HBCAG MIXED WITH MUCOADHESIVE CVP IN PATIENTS WITH CHRONIC HBV INFECTION: THE RESULTS OF 48 MONTHS FOLLOW UP

Osamu Yoshida[1], Kana Shiraishi[1], Yusuke Imai[1], Takahiro Sanada[2], Kyoko Tsukiyama-Kohara[3], Takashi Miyazaki[4], Taizo Kamishita[4], Teruki Miyake[1], Yoshio Tokumoto[1], Julio Cesar Aguilar[5], Gerardo Enrique Guillen[5], Michinori Kohara[2] and Yoichi Hiasa[1], (1)Ehime University, (2)Tokyo Metropolitan Institute of Medical Science, (3)Kagoshima University, (4)Toko Yakuhin Kogyo CO., Ltd., (5)Cigb

Background: We reported the HBsAg reduction by a nasal administrative therapeutic vaccine containing HBsAg/HBcAg mixed with mucoadhesive excipient carboxy-vinyl polymer (CVP-NASVAC) in chronically HBV infected patients. This study was aimed to assess the long-term efficacy of CVP-NASVAC at 48 months after the first 10 doses. **Methods:** CHB patients were enrolled in an open-label clinical trial at Ehime University Hospital, Japan, after receiving written consent, and permission from institutional review board (CRB#18EC003), and registration to the clinical trial authority of Japan jRCT (#jRCTs061180100). CVP-NASVAC was administrated for 10 times, once in every 2 weeks, some patients received additional 10 doses at least 12 months interval. We analyzed the data at 48 months after the first 10 doses of CVP-NASVAC. **Results:** Seventy-two patients enrolled in this study, and sixty-one participants completed 48 months follow-up and analyzed data. Twenty-five participants continued NAs during the study. Forty participants received additional 10 doses of CVP-NASVAC. At 48 months after the first 10 doses, 85.2% (n = 52/61) patients showed HBsAg reduction from the baseline, and the mean HBsAg reduction was -40.3% (-0.4352 Log IU/mL). Notably, eight participants lost HBsAg. CVP-NASVAC induced anti-HBs in 70.5% (43/61) patients. HBcAg specific CTL were increased after the CVP-NASVAC treatment. Three out of nine patients lost HBeAg during 48 months follow-up. HBcrAg reduction was observed all the twenty-four participants who were

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

detected HBcrAg at the baseline. **Conclusion:** CVP-NASVAC displayed a long term HBsAg reduction and loss. CVP-NASVAC could be a novel immune therapy for HBsAg reduction and elimination in HBV infected patients.

53 | HEALTHCARE ACCESS THROUGH FACILITATED TELEMEDICINE FOR UNDERSERVED POPULATIONS: A STEPPED WEDGE CLUSTER RANDOMIZED CONTROLLED TRIAL OF HEPATITIS C VIRUS TREATMENT AMONG PERSONS WITH OPIOID USE DISORDER

Andrew Talal[1], Marianthi Markatou[1], Anran Liu[1], Ponni V. Perumalswami[2,3], Amreen Dinani[3,4], Jonathan Tobin[5,6] and Lawrence Brown[7,8], (1)University at Buffalo, State University of New York, (2)University of Michigan Medical Center, (3)Icahn School of Medicine at Mount Sinai, (4)Duke University School of Medicine, Chapel Hill, NC, (5)Clinical Directors Network, (6) Rockefeller University, (7)START Treatment and Recovery Centers, (8)Weill Cornell Medicine, NY

Background: Telemedicine removes geographic and temporal obstacles to healthcare access. Few randomized trials have evaluated telemedicine effectiveness for underserved populations. We compared sustained virological response (SVR12) rates for hepatitis C virus (HCV) infection among persons with opioid use disorder through facilitated telemedicine (FTM) versus offsite liver specialist referral (usual care or UC). **Methods:** We conducted a prospective, cluster randomized trial utilizing the stepped wedge design to compare SVR12 rates between FTM onsite in opioid treatment programs (OTPs) to UC. Between 3/1/17 and 2/29/20, we enrolled 602 participants at 12 OTPs throughout New York State. All OTPs began with UC and every 9 months, 4 sites, randomly selected, transited from UC to FTM during 3 steps. We followed participants for two years to assess for reinfection. Participant inclusion criteria required six months enrollment in the OTP and active insurance. Multiple imputation was used to handle missing data (5.8% missingness). To estimate the intervention effect, we used a robust, non-parametric, within-period, cluster-level method. To assess for heterogeneity of treatment effects, we utilized generalized linear mixed effects models. **Results:** A total of 602 participants (FTM [n = 290] and UC [n = 312]) with mean age of 48.1 ± 13.0 years, 61.3% male, 30.7% Hispanic, 49.2% African American or other races, 28.1% with anxiety/depression, and 23% with cirrhosis. In FTM, 268/290 (92.4%) participants initiated treatment while 126/312 (40.4%) UC participants initiated treatment. The overall SVR12 was 90.7% in FTM compared to 35.2% in referral. The period specific intervention effect, computed as the difference between the SVR12 rate cluster-period summaries for FTM and UC is 0.596 ($p < 0.0001$, 95% CI: (.237, .955)). We did not identify heterogeneity of treatment for fibrosis, urban/rural, or mental health (anxiety/depression) conditions. We found that drug use decreased significantly ($p = < 0.0001$) among cured participants, regardless of intervention arm between the first and SVR12 visits. Minimal (n = 13) reinfections occurred, resulting in an HCV reinfection incidence of 2.42 per 100 person-years of observation. Participants reported very high healthcare delivery satisfaction, equivalent between arms. **Conclusion:** HCV treatment through FTM integrated into OTPs results in significantly higher SVR12 compared with offsite referral. Drug use also declined significantly, and the response was durable with minimal HCV reinfections over two years. FTM integrates HCV management into OTPs, increasing access of underserved populations to high-quality HCV care with high patient satisfaction. FTM should be considered an approach to expand healthcare access as part of HCV elimination approaches.

54 | LONG-TERM RISK OF LIVER-RELATED AND NON-LIVER-RELATED DEATH AFTER DIRECT-ACTING ANTIVIRAL-MEDIATED SUSTAINED VIROLOGIC RESPONSE IN HEPATITIS C VIRUS PATIENTS

Yuki Tahata[1], Hayato Hikita[1], Yasutoshi Nozaki[2], Hisashi Ishida[3], Naoki Hiramatsu[4], Masanori Miyazaki[5], Ryotaro Sakamori[6], Naoki Morishita[7], Kazuyoshi Ohkawa[8], Akira Kaneko[9], Fumihiko Nakanishi[10], Yoshinobu Doi[11], Takayuki Yakushijin[12], Mitsuru Sakakibara[13], Kazuho Imanaka[14], Naruyasu Kakita[15], Akira Doi[16], Akira Nishio[1], Takahiro Kodama[16], Tomohide Tatsumi[1] and Tetsuo Takehara[16], (1)Osaka University, Graduate School of Medicine, (2)Kansai Rosai Hospital, (3)Ikeda Municipal Hospital, (4)Osaka Rosai Hospital, (5)Osaka Police Hospital, (6)National Hospital Organization Osaka National Hospital, (7)Minoh City Hospital, (8)Osaka International Cancer Institute, (9) Japan Community Healthcare Organization Osaka Hospital, (10)National Hospital Organization Osaka Minami Medical Center, (11)Otemae Hospital, (12)Osaka General Medical Center, (13)Yao Municipal Hospital, (14) Itami City Hospital, (15)Kaizuka City Hospital, (16)Osaka University Graduate School of Medicine

Background: Direct-acting antiviral (DAA) treatment enables almost all patients with hepatitis C virus (HCV), including those with decompensated cirrhosis to achieve sustained virologic response (SVR), and improves prognosis in SVR patients. However, factors associated with long-term prognosis after SVR are unclear. The aim of this study is to clarify the risk factors for long-term prognosis according to liver-related and non-liver-related death. **Methods:** This prospective study included 3,238 HCV patients who started DAA treatment between September 2014 and June 2021 and achieved SVR in Japanese hospitals. Patients who developed hepatocellular carcinoma (HCC) before SVR were excluded. SVR was defined as serum HCV-RNA undetectable at 24 weeks after the end of treatment. The start of the observation period was the time of SVR confirmation. Factors associated with liver-related and non-liver related death after SVR were examined by Cox proportional hazard analysis. Liver-related death was defined as death from HCC, liver failure and varix rupture. **Results:** The median age was 69 years, 43% of patients were male, 9% of patients had a history of HCC and 18% of patients had liver cirrhosis. During the median follow-up of 50.4 months from SVR, 24 patients died of liver-related causes, and 103 patients died of non-liver-related causes. Among the 24 patients who died of liver-related causes, 20 patients died of HCC, three died of liver failure and one died of varix rapture. Among the 103 patients who died of non-liver-related causes, the most common causes of death were malignant tumors other than HCC (20 patients), cerebrovascular and cardiovascular events (14 patients) and infections (12 patients). The proportion of patients who died of liver-related causes was significantly higher in patients with a history of HCC than in those without (46% vs. 11%, $p < 0.001$). Annual liver-related mortality at 3/4/5 years after SVR was 1.5/1.3/3.6% in patients with a history of HCC. Liver-related and non-liver-related mortality at 5 years were 1.1% and 4.4%, respectively. In the multivariate analysis, older age ($p = 0.008$), history of HCC ($p = 0.002$) and lower albumin level at SVR ($p = 0.014$) were significantly associated with liver-related mortality after SVR, and older age ($p < 0.001$), male sex ($p = 0.006$) and lower albumin level at SVR ($p < 0.001$) were significantly associated with non-liver-related mortality after SVR. **Conclusion:** Approximately 80% of deaths in SVR patients were non-liver-related cause, and older age, male sex and lower albumin level at SVR were significantly associated with non-liver-related death. In patients with a history of HCC, the risk of liver-related death persists over the long term after SVR.

55 | CHARACTERIZING LINKAGE TO HEPATITIS C VIRUS CARE DURING AND FOLLOWING PREGNANCY: IDENTIFYING MISSED OPPORTUNITIES FOR TESTING AND TREATMENT

Andrew Bryan Mendlowitz[1,2,3], Jennifer A. Flemming[2,4], Tatyana Kushner[5], William W. L. Wong[2,3,6], Zoe R Greenwald[2,7,8], Jeff Kwong[2,7,9], Camelia Capraru[1], Jordan J. Feld[1] and Mia Biondi[1,10], (1)Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, Toronto, Canada, (2)Ices, (3)University Health Network, (4)Queen's University, (5)Icahn School of Medicine at Mount Sinai, New York, NY, (6)University of Waterloo, Waterloo, Canada, (7)University of Toronto, (8)St. Michael's Hospital, (9)Public Health Ontario, (10)School of Nursing, York University, Toronto, Canada

Background: With the ongoing opioid epidemic, hepatitis C virus (HCV) prevalence in women of childbearing potential has increased in North America.

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

As pregnancy may be the only time many women interact with the healthcare system, it presents an opportune time for HCV screening and linkage to care. Poor postpartum follow-up may justify treatment in pregnancy, but there is currently little known about the cascade of care for women of childbearing potential with HCV in pregnancy or postpartum. **Methods:** We performed a population-based retrospective cohort study linking pregnancies between 2008 and 2020 to HCV testing records (spanning 1999 to 2020) and health administrative data in Ontario, Canada. Pregnancies were identified using algorithms that detected pregnancy loss < 20 weeks, induced abortion, prenatal ultrasound, livebirths, and stillbirths ≥ 20 weeks. We determined whether individual's tested positive for HCV antibody (Ab+), were RNA tested, RNA+, and/or initiated treatment. Kaplan Meier methods were used to model time from Ab+ to subsequent RNA test, and from first RNA+ record to treatment. Missed opportunities for engagement in HCV care were defined as pregnancies that occurred following Ab+ prior to subsequent RNA test, and following first RNA+ record prior to treatment initiation. **Results:** We identified 13,432 individual's with HCV Ab+ and/or RNA test(s) and ≥ 1 pregnancy record (corresponding to 28,761 pregnancies). Of these, 2,868 (21.4%) had their earliest Ab+ test record during a pregnancy. Of individual's ever Ab+,11,668 (86.9%) received RNA testing and 2,668 (22.9%) had their earliest RNA test during a pregnancy. Of the 4,945 individual's ever RNA+ without spontaneous clearance, 2,057 (41.6%) initiated treatment. Time to RNA test from Ab+ record improved from 47.5 (95% CI:41.7-53.7) weeks prior to 2012 to 5.7 (95% CI:5.2-6.8) weeks after 2018. Time to treatment from RNA+ improved from 15.1 (95% CI:14.1-16.2) years prior to 2012 to 1.9 (95% CI:1.6-2.2) years after 2018. Of those with their earliest Ab+ test (N = 9,527), 1,956 (20.1%) had ≥ 1 pregnancy before a subsequent RNA test. Treatment occurred in the minority with a RNA+ record. Following those from their first RNA+ (N = 4,936), 2,266 (45.9%) had ≥ 1 pregnancy before initiating treatment (Figure). There were 1,767 individual's never linked to an RNA test corresponding to an average of 1.6 missed pregnancies per person. Considering the 2,212 missed pregnancies among those RNA+ with no treatment record (assuming clearance of 40% and 5% vertical transmission rates), we estimate 195 infected infants may have been a consequence of these missed opportunities for engagement. **Conclusion:** We observed significant gaps in follow-up testing after initial Ab+ test, and in treatment following an RNA+ result. It will be critical to enhance linkage after HCV diagnosis during or before pregnancy to reduce transmission, particularly following adoption of universal HCV screening in pregnancy.

56 | ONGOING EXPERIENCE OF IMPLEMENTING "THE TORONTO PROTOCOL": AN ULTRA-SHORT COURSE GLECAPRIVER/ PIBRENTASVIR WITH EZETIMIBE FOR SOLID ORGAN TRANSPLANTATION FROM HCV-INFECTED DONORS TO HCV-UNINFECTED RECIPIENTS

Wesam Aleyadeh[1,2], Marcelo Cypel[1], Rhonda Allan[1], June Wang[1], Dipika Munyal[1], Atul Humar[1] and Jordan J. Feld[3], (1)University Health Network, (2)Cleveland Clinic Akron General, (3)Toronto General Hospital Research Institute

Background: The ongoing overdose crisis has led to an increase in transplantation of organs from HCV-infected donors (D+) to uninfected recipients (R-). We previously showed that an ultra-short course (1 d pre and 7 d post) of glecaprevir/pibrentasvir (G/P) combined with ezetimibe (E) prevented chronic infection in non-liver solid organ recipients. We report our results for 2 cohorts: extended follow-up for patients in the original study (n = 30), as well as outcomes since adoption of the "Toronto Protocol" as standard of care (SOC) (n = 58). **Methods**: All D+/R- organ recipients who received the Toronto Protocol with G/P+E x1 dose pre- and daily for 7 days post-transplant were followed to last HCV RNA result or patient death. The primary endpoint was establishment of chronic HCV infection, defined as positive HCV RNA 12 weeks post-transplant or need for retreatment. Additional outcomes include graft rejection and patient survival. **Results**: Since adoption of the protocol as standard of care, 58 patients received D+/R- organ transplants from 42 donors. The SOC cohort included 34 (59%) males and 24 (41%) females. The mean age was 57 years (range 22-80), with 32 kidney, 14 lung, 6 heart, 3 pancreas, and 3 kidney-pancreas organ transplants. All non-kidney and 26 (81%) of kidney transplants completed the full treatment regimen before hospital discharge with no dose reductions or treatment discontinuation. All patients had undetectable HCV RNA 2 weeks post-transplant and at last follow-up; median 65 weeks (range 2-171 weeks). 27 (46%) patients developed HCV antibodies that persisted post-treatment. There were 3 deaths unrelated to HCV treatment reported at 11, 188, and 286 days post-transplant and 10 episodes of biopsy-proven rejection, all after completion of HCV therapy. The initial trial included 30 recipients from 18 donors. With extended follow-up to 220 weeks (median 186 weeks; IQR 56-317), no patients developed chronic HCV infection or relapsed. The 6- month patient survival rate was 93%. There was no graft loss, but 14 (24%) patients died from 7 to 178 weeks post-transplant with no HCV-related deaths. In total, 88 organ recipients have completed the G/P+E protocol with no virological breakthrough or need for retreatment and no HCV-related complications. **Conclusion**: An ultra-short regimen of G/P+E prevented chronic HCV infection in all D +/R- transplant recipients and was well tolerated, allowing the majority to complete treatment before hospital discharge. These results support the current AASLD/IDSA guidance recommendation to initiate treatment promptly after transplantation.

	Initial Trial (n=30)	Standard of care (n=58)
Mean age (range)	61 (27-76)	57 (22-80)
Sex		
Male	23 (77%)	34 (59%)
Female	7 (23%)	24 (41%)
Transplanted organ		
Lung	13 (43%)	14 (24%)
Kidney	10 (33%)	32 (55%)
Heart	6 (20%)	6 (10%)
Kidney/Pancreas	1 (3%)	3 (5%)
Pancreas	0	3 (5%)
Undetectable HCV RNA at 12 weeks		
	30 (100%)	58 (100%)
Episodes of rejection requiring treatment		
	3 (10%)	9 (16%)
Graft survival* at 6-months		
	28 (93%)	57 (98%)
Patient survival at 6-months		
	28 (93%)	57 (98%)
AEs related to treatment		
	1 (3%)	1 (3%)
HCV-related complications

57 | ESTABLISHING A PHARMACIST-LED HEPATITIS C TREATMENT CLINIC WITHIN A LARGE HEALTHCARE SYSTEM

Kenneth John Barga[1], Anthony Michaels[1,2], Adam Hanje[1,2], Ruchi Bhatia[1,2], Pamella Kibbe[1,2] and Gretchen Calhoun[1,2], (1)Ohiohealth Comprehensive Liver Program, (2)Ohio Gastroenterology Group

Background: Hepatitis C Virus (HCV) is a blood-borne viral pathogen resulting in hepatic inflammation that – if left untreated – may lead to advanced liver disease, hepatocellular carcinoma, and death. With the advent of improved treatment modalities, several national, state, and local governing bodies have called for HCV eradication. In March of 2023, the United States Presidential Administration announced plans to start a National Hepatitis C Elimination Program. This five-year plan, budgeted to start in the Fiscal Year 2024, will focus on access to diagnostic testing and HCV treatment along with comprehensive public health efforts. From a state level, HCV remains prevalent in Ohio with the ongoing opioid epidemic. To help improve access to HCV treatment, the Ohio Department of Health created the Hepatitis Surveillance Program and Hepatitis Prevention Initiative. Despite this, OhioHealth – a large healthcare system of 15 hospitals and affiliate organizations in Central Ohio – did not have ambulatory hepatology services until January of 2023. During the inception of the OhioHealth Comprehensive Liver Program, clinicians developed a pharmacist-led, referral-based viral hepatitis clinic to expand access to HCV treatment throughout Ohio. This quality improvement project under a collaborative practice agreement looks to evaluate the program's success while also spreading best practices. **Methods:** This project assessed all patients referred to the OhioHealth Viral Hepatitis Clinic since the program's inception in January 2023. Data was collected via manual, retrospective chart review. Descriptive statistics were performed to assess the data. **Results:** Since January of 2023, 70 adult (average age: 46.8 y), HCV-infected patients have followed with the program. Of these 70 patients, 81.4% were white and 57.1% were female. The most common means of viral acquisition was intravenous drug exposure (62.9%). Most were treatment-naïve (91.4%), genotype 1a (48.6%) and non-cirrhotic (74.3%). Two patients (2.9%) had HBV coinfections while none had concurrent HIV. Most patients received either an 8- or 12-week course of treatment (85.7%). Patients initiated treatment within an average of 8.9 days of their first pharmacist visit. Patients were not required to visit with the pharmacist while on-treatment; however, they will complete 12-week post-treatment assessments. **Conclusion:** This pharmacist-led, referral-based viral hepatitis clinic has been very successful and well received thus far in our large healthcare network with the goal of achieving HCV elimination. All outcomes data will be available and presented at AASLD's Liver Meeting in November of 2023.

Table 1. Demographic Characteristics and Treatment of HCV (n=70)

Age – avg. (years)	46.8	**Gender** – no. (%)	
		Male	30 (42.9)
		Female	40 (57.1)
Race or ethnic group – no. (%)		**History of IVDM** – no. (%)	
White	57 (81.4)	Yes	44 (62.9)
Black or African American	9 (12.9)	No	26 (37.1)
Hispanic or Latino	2 (2.9)	If yes, former vs. current use – no. (%)	
Other	2 (2.9)	Current	0 (0)
		Former	44 (100)
Antacid use while on HCV treatment – no. (%)		**HCV genotype** – no. (%)	
PPI	12 (17.1)	1a or 1b	34 (48.6) or 3 (4.3)
Alternative Antacid	13 (18.6)	2	7 (10)
None	46 (65.7)	3	18 (25.7)
		4 – 6	0 (0)
		Mixed	3 (4.3)
		Unknown / inconclusive	5 (7.1)
Fibrotic stage – no. (%)		**History of cirrhosis** – no. (%)	
F0 – F1	30 (42.9)	Yes	18 (25.7)
F2	5 (7.1)	No	52 (74.3)
F3	4 (5.7)	If cirrhotic, compensated vs. decompensated – no. (%)	
F4	18 (25.7)	Compensated	12 (66.7)
Unknown	13 (18.6)	Decompensated	6 (33.3)
HBV coinfection – no. (%)		**HIV coinfection** – no. (%)	
Yes	2 (2.9)	Yes	0 (0)
No	68 (97.1)	No	70 (100)
History of liver transplant – no. (%)		**History of HCV treatment** – no. (%)	
Yes	0 (0)	Treatment-naive	64 (91.4)
No	70 (100)	Treatment-experienced	6 (8.6)
		If treatment-experienced, which regimens were used – no. (%)	
		Interferon- or ribavirin-based	4 (66.7)
		DAA-based	2 (33.3)

HCV treatment – no. (%)	
Glecaprevir-pibrentasvir 300-120mg daily x8 weeks	10 (14.3)
Sofosbuvir-velpatasvir 400-100mg daily x12 weeks	50 (71.4)
Sofosbuvir-velpatasvir 400-100mg daily x24 weeks	5 (7.1)
Sofosbuvir-velpatasvir 400-100mg daily + weight-based ribavirin daily x12 weeks	1 (1.4)
Sofosbuvir-velpatasvir-voxilaprevir 400-100-100mg daily x12 weeks	2 (2.9)
Treatment not required	2 (2.9)
Average time elapsed between initial visit and treatment initiation – avg. (days)*	8.9
SVR achieved – no. (%)	Data will be available for and presented at AASLD 11/2023.

*Six total patients were excluded from this average as two did not require treatment, one had an unknown start date, one is waiting for Ohio Medicaid benefits, one is waiting on home medication delivery, and one is waiting on NS5A resistance testing.

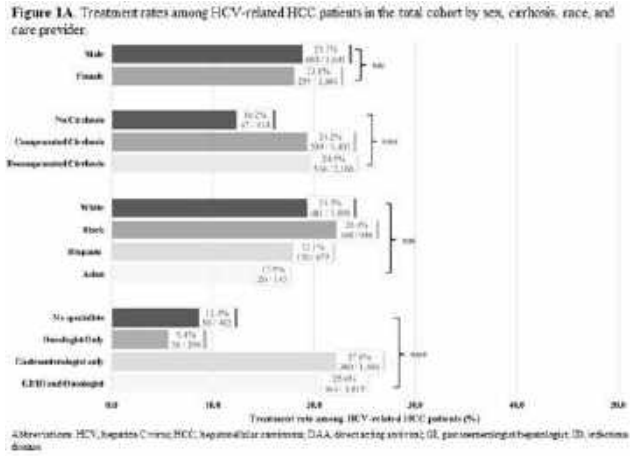
58 | LOW ANTIVIRAL TREATMENT RATE FOR PATIENTS WITH HEPATITIS C (HCV)-RELATED HEPATOCELLULAR CARCINOMA (HCC)– A REAL-WORLD NATIONWIDE U.S. STUDY

Leslie Yeeman Kam[1], Yee Hui Yeo[2], Fanpu Ji[3], Linda Henry[1], Ramsey Cheung[1,4] and Mindie H. Nguyen[1], (1) Stanford University Medical Center, Palo Alto, CA, (2) Cedars-Sinai Medical Center, Culver City, CA, (3)The Second Affiliated Hospital of Xi'an Jiaotong University, (4)Veterans Affairs Palo Alto Health Care System

Background: All-oral interferon-free direct-acting antiviral agents (DAAs) for treatment and cure of hepatitis C virus (HCV) became available in 2013-2014. Our primary objective is to determine the proportion of patients with HCV-related HCC who received DAA after 2014 and factors associated with treatment receipt. We also evaluated DAA treatment impact on the overall survival in this population as a secondary outcome. **Methods:** This retrospective study identified patients with HCV-related HCC from 2015-2021 using Optum's Clinformatics® Data Mart (CDM) Database – a large, national, de-identified, adjudicated claims database of medically insured patients. Adults with HCV-related HCC and at least 6 months of insurance coverage, but without prior liver transplant, hepatitis B, D or HIV co-infection were included. **Results:** We identified and analyzed 3,922 patients with HCV-related HCC. Of these, 922 (23.5%) received DAA. Treatment rates were higher for patients with cirrhosis (both compensated and decompensated), those who received care from gastroenterology (GI) or infectious disease (ID) with or without oncology specialists (Figure 1A). Compared to untreated patients, the DAA-treated group was also younger (65.2 ± 7.5 vs. 66.4 ± 7.5 y, $p < 0.001$). In multivariable logistic regression, younger age (aHR 0.98, 95%CI: 0.97-0.99, $p < 0.001$), being seen by a GI/ID physician (aHR 3.06, 95%CI: 2.13-4.51, $p < 0.001$), having cirrhosis (compensated: aHR 1.60, 95%CI 1.18-2.21; $p = 0.003$; decompensated: aHR 1.45, 95%CI 1.07-1.98, $p = 0.02$) were associated with higher odds of receiving DAA treatment, but not sex or race/ethnicity. DAA treated patients had significantly higher 5-year survival compared to untreated patients (47.2% vs. 35.2%, $p < 0.001$, Figure 1B). Following adjustment for age, sex, race/ethnicity, Charlson Comorbidity Index, HCC treatment, receiving DAA treatment remained significantly associated with lower mortality (aHR:0.61, 95%CI: 0.53-0.69, $p < 0.001$). **Conclusion:** Although those who received DAA treatment had a significantly better 5-year survival, DAA treatment remains underutilized even in the sickest of patients with HCV who are insured as less than one in four patients were treated. Seeing GI/ID specialist was associated with 3 times higher odds of receiving DAA therapy in patients with HCV-related HCC, highlighting the needs for a multidisciplinary approach to care for this population.



Disclosures: The following people have nothing to disclose: Leslie Yeeman Kam, Yee Hui Yeo, Fanpu Ji, Linda Henry, Ramsey Cheung, Mindie H. Nguyen

59 | IMMEDIATE POSTPARTUM CESSATION OF TENOFOVIR IN HIGHLY VIREMIC PREGNANT MOTHERS WITH CHRONIC HEPATITIS B INFECTION: MATERNAL AND INFANT OUTCOMES

Chen Yu[1], Lung Yi Mak[2], Mary Tang[3], Jingyi Yang[1], Chen Bang Chow[1], Om Tang[1], Tao Lyu[1], Juan Wu[1], Qingjuan Huang[1], Haibo Huang[1], Ka Shing Cheung[3], Man-Fung Yuen[4] and Wai-Kay Seto[5], (1)Hku-Shenzhen Hospital, (2)Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, (3)The University of Hong Kong, (4)State Key Laboratory of Liver Research, the University of Hong

Kong, Hong Kong SAR, (5)Department of Medicine, School of Clinical Medicine, the University of Hong Kong

Background: Antiviral prophylaxis with tenofovir disoproxil fumarate (TDF) during pregnancy is the current standard of care to prevent mother-to-child transmission (MTCT) of chronic hepatitis B (CHB) infection in highly viremic mothers. We investigated the maternal and fetal outcomes in a large Chinese cohort of TDF-treated CHB pregnant subjects. **Methods:** In this prospective study, consecutive treatment-naïve non-cirrhotic highly viremic (defined as hepatitis B virus [HBV] DNA e 200,000 IU/mL) CHB mothers were treated with TDF at 24-28 weeks of pregnancy. In accordance with Chinese CHB guidelines, TDF was stopped right after delivery, or e 4 weeks postpartum. Serum HBV DNA and alanine aminotransferase (ALT) were monitored every 6-8 weeks to determine virological relapse (VR, defined as HBV DNA e 2 log increase from treatment cessation). Retreatment was indicated for VR + ALT above upper limit of normal. Infants were given HBV vaccine within 12 hours of birth, 1 and 6 months, in addition to HBV immunoglobulins. Serum hepatitis B surface antigen (HBsAg), antibody to HBV core (anti-HBc) and antibody to HBsAg (anti-HBs, lower limit of detection 10 IU/L) were checked in infants at 6 months. **Results:** A total of 330 eligible subjects were recruited (median age 30 [interquartile range IQR 28-32], 81.8% HBeAg+). At baseline, the median ALT was 17 (13-24) U/L and median HBV DNA was 7.82 (6.91-8.20) log IU/mL. At delivery, 6.2% remained highly viremic. TDF was stopped right after delivery in 66.4%, and e 1 month in 33.6%. Among 293 with full follow-up data, VR was observed in 98.3% and 11.8% were retreated. Timing of TDF cessation, HBeAg status and DNA levels at delivery did not alter the risk of VR (Figure A) or retreatment (Figure B). Among 299 livebirths who had full serological profile at 6 months, 0% were HBsAg+, 23.1% were anti-HBc+, and 98.7% were anti-HBs+ (32.8% > 1000 IU/L). On multivariate analysis, age (odds ratio [OR] 0.884, 95% CI 0.792-0.988), baseline ALT (OR 1.071, 95% CI 1.026-1.119), and infant anti-HBs > 1000 IU/L (OR 0.364, 95% CI 0.133-0.996) were independently associated with retreatment. Infant anti-HBs > 1000 IU/L (OR 7.203, 95% CI 3.913-13.200) and birth weight (OR 0.422, 95% CI 0.195-0.912) were independently associated with infant anti-HBc+. **Conclusion:** Prophylactic TDF and neonatal immunization were highly effective to prevent MTCT of HBV in highly viremic mothers. Cessation of prophylactic TDF right after delivery showed similar rates of VR or retreatment compared to stopping TDF e 4 weeks postpartum. Figure legend: Risk of A) VR and B) retreatment stratified by clinical parameters with respect to whether they were highly viremic at delivery, HBeAg status, and whether tenofovir was stopped at delivery vs stopped e 4 weeks postpartum.

60 | LIVER STIFFNESS MEASUREMENT TO DETECT SEVERE FIBROSIS AND CIRRHOSIS IN PATIENTS WITH CHRONIC HEPATITIS D INFECTION

Dominique M Roulot[1,2], Segolene Brichler[3], Richard Layese[4], Louis D'Alteroche[5], Nathalie Ganne-Carrié[6], Christiane Stern[7], Antonio Saviano[8], Vincent Leroy[9], Francoise Roudot-Thoraval[4] and Victor De Ledinghen[10], (1)Unité D'hépatologie, Assistance Publique-Hôpitaux De Paris, Hôpital Avicenne, (2) Université Sorbonne Paris Nord, (3)CHU Avicenne, (4) Aphp-Hopital Henri Mondor, (5)CHU Tours, (6) Hepatology Department, Avicenne Hospital, AP-HP, France, (7)Service d'Hépatologie, Hôpital Beaujon, (8) University of Strasbourg, France, (9)Aphp, (10)Centre D'investigation De La Fibrose Hépatique, Bordeaux University Hospital, Pessac, France; Inserm U1053, Bordeaux University, Bordeaux, France

Background: Hepatitis D virus (HDV) infection is associated with accelerated progression of liver disease to cirrhosis. Liver biopsy (LB) remains the gold standard procedure for fibrosis staging in HDV chronic hepatitis. Transient elastography (TE), which has transformed the management of hepatitis B and C infection has not been evaluated in large populations of HDV-infected patients. We investigated TE (FibroScan) performance for the diagnosis of HDV-induced liver fibrosis. **Methods:** HDV RNA-positive patients from a national cohort were investigated by TE, performed within 6 months from LB. Hepatic fibrosis stages were assessed using the Metavir score (F0-4). TE diagnostic performance in identifying cirrhosis (F4), severe fibrosis (F3) and significant fibrosis (F2) was compared to that of non-invasive fibrosis tests, such as the AST to platelet ratio index (APRI), the fibrosis-4 score (FIB-4) and the Delta-4 fibrosis score (D4FS). AUROC and Youden indexes were used to establish optimal cut-offs values. **Results:** Valid liver stiffness measurements (LSM) from 230 patients were analyzed (median age 36 [30-44] yrs, median BMI 24.0 [21.6-27.5] kg/m^2). Histologic fibrosis stage prevalence was 20.4% for F0F1, 27.0% for F2, 18.7% for F3 and 33.9% for F4. TE displayed excellent diagnostic accuracy for the detection of cirrhosis (AUROC of 0.88), superior to that of APRI (0.76), FIB-4 (0.79) and D4FS (0.86) ($p = 0.007$). TE was also superior for detecting severe fibrosis: AUROC of 0.85, compared to 0.72 for

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

APRI and 0.76 for FIB-4 ($p = 0.003$). Its performance was not better for detecting significant fibrosis (AUROC of 0.81 compared to 0.72 for APRI and 0.72 for FIB-4, $p = 0.39$). At the optimized cut-off value of 11.1 kPa for cirrhosis diagnosis, TE showed 81% sensitivity, 81% specificity, PPV of 68.5% and a NPV of 89%; 81% of the patients being correctly classified. At the optimized cut-off value of 10.4 kPa for determining severe fibrosis, TE sensitivity was 70.2%, specificity 83.5%, PPV 82.5% and NPV 71.7%, with 76.5% of correctly classified patients. At both cut-off values, PPV remained unchanged after exclusion of patients with ALT > 5N. **Conclusion:** In this large real-life cohort of HDV-patients, TE showed good diagnostic performance for determining severe fibrosis and cirrhosis, superior to that of APRI, FIB-4 and D4FS. The high probability of severe fibrosis, when LSM > 10.4 kPa, and cirrhosis, when LSM ≥ 11.1 kPa, justifies rapid treatment. In case of LSM ≤ 10.4kPa, LB is still recommended.

f 61 | AN OPEN-LABEL ROLLOVER STUDY FOLLOWING A RANDOMIZED TRIAL FOR CHRONIC HEPATITIS B WITH HIGH SERUM VIRAL LOAD BUT MILD ELEVATED AMINOTRANSFERASE

Yao-Chun Hsu[1], Chi-Yi Chen[2], Cheng-Hao Tseng[3], Chieh-Chang Chen[4], Teng-Yu Lee[5], Ming-Jong Bair[6], Jyh-Jou Chen[7], I-Wei Chang[8], CHi-Yang Chang[9], Ming-Shiang Wu[10] and Jaw-Town Lin[1], (1)E-Da Hospital, (2) Ditmanson Medical Foundation Chiayi Christian Hospital, Chia Yi, Taiwan, (3)E-Da Cancer Hospital, I-Shou University, (4)National Taiwan University Hospital, (5)Taichung Veterans General Hospital, (6) Mackay Memorial Hospital-Taitung, (7)Department of Internal Medicine, Chi Mei Medical Center, Liouying, Tainan, Taiwan, (8)Taipei Medical Universtiy, (9)Fu-Jen Catholic University, (10)Tainan Municipal Hospital*

Background: This study extends the follow-up of participants who completed a randomized placebo-controlled trial evaluating the safety and efficacy of tenofovir disoproxil fumarate (TDF) in reducing the risk of histological progression in patients with chronic hepatitis B (CHB) characterized by high viral load and minimally raised serum alanine aminotransferase (ALT) levels. We report herein the outcomes of patients who received three years of open-label TDF treatment after completing a randomized trial **Methods:** This open-label study enrolled participants who had completed a three-year trial of TDF vs. placebo for CHB patients with serum HBV DNA exceeding 2000 IU/mL and ALT levels between one to two times the upper limit of normal (ULN). Exclusion criteria included malignancy, cirrhosis, hepatic insufficiency, renal failure, pregnancy, or viral coinfections. Upon completing the randomized trial, eligible patients were all rolled over to receive three years of open-label TDF treatment, followed by a liver biopsy to evaluate histological changes. The severity of fibrosis was evaluated using the Ishak scoring system, and necroinflammation was assessed using the Knodell system (ClinicalTrials.gov Identifier: NCT02463019). **Results:** A total of 146 patients (median age of 47 y, IQR: 41-57 y, 80.8% male) were enrolled in the study. At baseline, 18.5% (n = 27) of patients were HBeAg-positive, and 47.9% (n = 70) had undetectable HBV DNA. Moderate to severe liver fibrosis or cirrhosis (Ishak ≥ 3 points) was present in 33.3% (n = 42) of patients. During the 3-year period, 23 patients withdrew from the study, including 5 who developed hepatocellular carcinoma (3 initially assigned to placebo, 2 to TDF). Among the remaining 123 patients with paired liver biopsies, severity of liver fibrosis significantly improved after 3 years of open-label TDF treatment ($p < 0.0001$, Stuart-Maxwell test), with the proportion of patients with an Ishak score of liver fibrosis ≥ 3 points

decreasing to 9.8% (12 patients, Figure 1). Furthermore, viral remission (defined as undetectable HBV DNA) and ALT normalization were achieved in 82.2% and 69.0% of patients, respectively. There were no serious adverse events attributable to the study medication. **Conclusion:** In this open-label rollover study following a three-year randomized trial, we found that continued use of TDF in CHB patients with high viral load and mild ALT elevation led to significant improvement in liver fibrosis.

62 | HEPATOCELLULAR CARCINOMA RISK IN SUB-SAHARAN AFRICAN AND AFRO-SURINAMESE INDIVIDUALS LIVING WITH CHRONIC HEPATITIS B IN EUROPE: AN INTERNATIONAL MULTICENTER RETROSPECTIVE COHORT STUDY

Lesley Ann Patmore[1], Kirsi Van Eekhout[2], Maria Buti[3], Ozgur Mustafa Koc[4], K Agarwal[5], Rob J. De Knegt[1], Harry L. A. Janssen[6,7], Marc Van Der Valk[2], Faydra Ione Lieveld[8], Matthijs Kramer[4], Joep De Bruijne[8], Mark Claassen[9], Colette Smit[10], Robert A. De Man[11], Bart Takkenberg[2], Ivana Carey[12] and Milan J. Sonneveld[1], (1)Erasmus MC, University Medical Center, (2) Amsterdam University Medical Center, Amsterdam, Netherlands, (3)Hospital Universitari Vall d'Hebron, Department of Medicine of the UAB (Universitat Autònoma de Barcelona), Spain, (4)Maastricht University Medical Center, (5)King's College Hospital, (6)Erasmus MC, University Medical Center Rotterdam, (7)Toronto General Hospital Research Institute, (8) Utrecht Umc, (9)Rijnstate Hospital Arnhem, (10)HIV Monitoring Foundation, (11)Erasmus MC, University Medical Center, Rotterdam, Netherlands, (12)Institute of Liver Studies, Kings College Hospital, London, United Kingdom

Background: Cross-sectional studies have identified individual's from sub-Saharan Africa with (SSA) chronic hepatitis B (CHB) as a potential risk group for hepatocellular carcinoma (HCC) and advocate enrolment in an HCC surveillance program even in the absence of cirrhosis. However, the incidence of HCC and performance of HCC risk scores in this population are unknown. **Methods:** We conducted an international multicenter retrospective cohort study of all consecutive hepatitis B virus (HBV) mono-infected individual's with SSA or Afro-Surinamese (AS) ethnicity managed at sites in the Netherlands, the United Kingdom and Spain. We assessed the 5 and 10 year cumulative incidence of HCC in the overall study population and according to baseline fibrosis grade and HBV DNA levels. We also studied potential other predictors of HCC development using Cox regression. Finally, we assessed the performance of the (m)PAGE-B score for stratifying HCC risk. **Results:** We analyzed 1473 individual's; the majority of whom were male (59.7%) with a median age of 38 years (interquartile range [IQR] 29-46) at enrolment. At baseline 12.7% had advanced fibrosis (METAVIR e F3 based on biopsy or FibroScan). During a median follow-up of 8 years (IQR 3.9 – 11.4) 34 individual's developed HCC. The 5 and 10 year cumulative incidence of HCC was 1% (95% confidence interval [CI] 0.99 – 1.01) and 2.5% (95% CI 2.39–2.41), with no difference observed across ethnicities ($p = 0.238$). Among individual's without advanced fibrosis at baseline, the 5 and 10 year cumulative incidence of HCC was 0% and 0.7%, compared to 7.1% and 12.1% among individual's with advanced fibrosis ($p < 0.001$). The 5 and 10 year cumulative HCC incidence was 0.7% and 1% for individual's with a baseline HBV DNA < 2,000 IU/mL compared to 1.3% and 3.6% among individual's with HBV DNA at baseline > 2,000 IU/mL ($p = 0.031$). In addition to baseline fibrosis grade and HBV DNA levels, univariate analysis revealed that older age (hazard ratio [HR] 1.07, 95% CI 1.04–1.10 $p < 0.001$), male sex (HR 2.59, 95% CI 1.13–5.94 $p = 0.025$), platelet count (HR 0.98, 95% CI 0.97–0.98 $p < 0.001$), and albumin (HR 0.89, 95% CI

0.83–0.94 $p < 0.001$) were significantly associated with HCC development. The 10 year cumulative incidence of HCC was 0.5% among individual's with a low PAGE-B score (n = 771, 52.3% of cohort), compared to 2.9% in the intermediate risk group (n = 569, 38.6% of cohort) and 15.9% in the high risk group (n = 85, 5.8% of cohort; $p < 0.001$). Similar results were obtained for the modified PAGE-B score. **Conclusion:** This unique international multicenter cohort of SSA and AS individual's with CHB shows a limited 5 and 10 year cumulative risk of HCC. The risk of HCC was negligible for individual's without advanced fibrosis at baseline, and among individual's with low baseline (m)PAGE-B scores. Based on these findings, the majority of these patients can potentially be excluded from HCC surveillance based on absence of advanced fibrosis and/or low HCC risk scores.

Background: Bulevirtide (BLV), a novel hepatitis delta virus (HDV) entry inhibitor, is approved in Europe for treatment of chronic hepatitis D (CHD). In clinical studies, virologic response (VR) was defined as undetectable HDV RNA or ≥ 2-$\log_{10}$ IU/mL decline from baseline (BL). Optimal BLV monotherapy duration for CHD is unknown; it is also unclear whether continued therapy will benefit patients (pts) with early virologic nonresponse (NR) or partial response (PR). This integrated analysis evaluated continued BLV monotherapy in pts without VR after 24W. **Methods:** Results from pts who completed BLV monotherapy for 96W in the Phase 3 (MYR301; NCT03852719) and Phase 2 (MYR204; NCT03852433) studies were included. NR and PR were defined as HDV RNA declines of < 1 $\log_{10}$ IU/mL and ≥ 1 but < 2 $\log_{10}$ IU/mL, respectively. Rates of biochemical response (alanine aminotransferase [ALT] within normal limits [WNL]) were compared. **Results:** 141 CHD pts (47 BLV 2mg; 94 BLV 10mg) were evaluated. At BL 67% were male, 87% White, 43% had cirrhosis, 40% received concomitant nucleos(t)ide analogues, and 50% had prior interferon exposure. Mean (SD) HDV RNA was 5.2 (1.3) $\log_{10}$ IU/mL; median (Q1, Q3) ALT was 94 (64, 136) U/L. At W24, 92/141 (65%) pts had VR (53 [58%] with ALT WNL), 34/141 (24%) had PR (19 [56%] with ALT WNL), and 15/141 (11%) had NR (2 [13%] with ALT WNL) (Table). 49 pts had NR or PR at W24. Of the 34 PR pts at W24, 25 (74%) had VR, and 24 (71%) had ALT WNL by W96. Of the 15 NR pts at W24, 7 (47%) had VR and 3 (20%) had PR by W96. A higher proportion of NR at W24 achieved VR at W96 among those receiving BLV 10mg (4/5, 80%) vs BLV 2mg (3/10, 30%). Among W24 NR or PR, the mean BL HDV RNA did not predict viral response at W96. Median (Q1, Q3) BL U/L ALT was higher in pts with NR (138 [112, 196]) vs VR (79 [53, 113]) and PR (95 [56, 150]) at W96. The mean (SD) $\log_{10}$ IU/mL HDV RNA change at W96 among VR/PR/NR was −3.6 (1.1), −1.4 (0.3), and −0.2 (0.7) for VR, PR, and NR at W96. Median (Q1, Q3) U/L ALT change at W96 among VR/PR/NR was −48 (−73, −12), −42 (−83, −6), and −67 (−102, −33), respectively. Among all NR at W96, ALT declined > 50% from BL in 7/11 (3/11 achieved ALT WNL). **Conclusion:** Of 49 pts without VR at W24, the majority with PR and nearly half with NR were able to achieve VR at W96. ALT improved in all viral-response groups including those with NR. These results provide evidence for continuing BLV therapy despite early (24W) suboptimal virologic responses.

64 | TENOFOVIR VERSUS ENTECAVIR IN PREVENTING HCC AND DEATH: ANSWER FROM A LARGE INTEGRATED HEALTH PLAN POPULATION

Varun Saxena[1], Douglas A. Stram[2], Krisna P. Chai[1], Brock AW Macdonald[1], Sripriya Balasubramanian[1], Nizar Mukhtar[3] and Suk Seo[1], (1)Kaiser Permanente Northern California, (2)Kaiser Permanente Northern California Division of Research, (3)Kaiser Permanente San Francisco Medical Center

Background: Chronic hepatitis B (CHB) suppressive therapy with tenofovir disoproxil (TDF) or entecavir (ETV) has been shown to reduce the risk of hepatocellular carcinoma (HCC) and mortality. However, controversy exists regarding if one treatment is better than the other. **Methods:** All Kaiser Permanente Northern California adult (age > 17 y) patients with CHB undergoing suppressive treatment with either TDF or ETV for at least 1 year at any time between 1/1/2006 and 12/31/2021 and with > 90% adherence by prescription refill data were included. TDF treated patients were 1:1 propensity score (PS) matched to ETV treated patients on baseline age, sex, race/ethnicity, body-mass index (BMI), diabetes, hyperlipidemia, hypertension, alcohol abuse, HIV, cirrhosis, prior lamivudine treatment, creatinine, hepatitis B DNA and hepatitis B envelope antigen/antibody status. Outcomes of interest included HCC development and mortality and were compared in the overall TDF and ETV cohorts as well as in the PS matched cohorts **Results:** A total of 3384 treated HBV patients were included, 1031 (30%) TDF and 2353 (70%) ETV. Compared to ETV, TDF treated patients were younger (mean 48 vs. 52 y), more likely female (39% vs. 34%), thinner (BMI 24 vs. 25 kg/m^2), have less diabetes (10% vs. 14%), less hyperlipidemia (21% vs. 32%), less hypertension (21% vs. 31%), more HIV co-infection (4% vs. 0%), less cirrhosis (8% vs. 12%), more prior lamivudine treatment (16% vs. 7%), lower creatinine (0.88 vs. 0.96 mg/dL), lower DNA (6.0 vs. 6.3 million IU/mL) and more envelope antigen positivity (38% vs. 33%). 978 TDF patients were successfully PS matched to ETV patients and differences between groups resolved. Overall and compared to ETV, TDF was associated with reduced HCC (HR: 0.60, 95% CI: 0.4-0.9, $p = 0.02$; Figure 1A) and with reduced mortality (HR: 0.60, 95% CI: 0.4-0.9, $p < 0.01$). In PS matched and compared to ETV, TDF was *not* associated with reduced HCC (HR: 0.93, 95% CI: 0.4-2.0; $p = 0.85$; Figure 1B) *nor* with reduced mortality (HR: 0.71, 95% CI: 0.4-1.2, $p = 0.22$). **Conclusion:** When comparing overall TDF and ETV treated populations, TDF is better than ETV in HCC and mortality risk reduction. However, this result is likely related to provider treatment patterns where patients with additional risk factors for HCC and mortality are selected to receive ETV over TDF. When these additional risk factors are controlled for in PS matched cohorts, the advantage of TDF over ETV is not distinguishable.

65 | AN ADVANCED PRACTICE PROVIDER (APP) DRIVEN, WEIGHT INTERVENTION IN LIVER DISEASE (WILD) CLINICAL PATHWAY ACHIEVES MORE MEANING WEIGHT LOSS IN PATIENTS WITH MASLD COMPARED TO STANDARD OR CARE

Vicki Shah, Sarah Repking, Colleen Folkers, Laura Ritchie, Lelani C. Fetrow and Sujit V. Janardhan, Rush University Medical Center

Background: As the prevalence of obesity and MASH continues to grow, novel treatment options are needed to prevent progression as there are currently no medications approved to treat MASH. Weight loss has been shown to be an effective treatment with a 5% weight loss reversing steatosis and a 10% weight loss reversing liver fibrosis. Clinical trials using lifestyle-based weight loss interventions in MASH have been shown to achieve > 5% total body weight loss (TBWL) in 30% of patients and > 10% TBWL in 10% of patients. It is unclear if the standard of care hepatology practice is sufficient to achieve these recommendations in the clinical setting or if a more dedicated intervention is needed. **Methods:** In 2018, our department developed the Weight Intervention in Liver Disease (WILD) clinical pathway, an intensive weight loss program embedded into our hepatology clinic. The program was supervised by a hepatologist board certified in obesity medicine and executed by three advanced practice providers (APP) with obesity certification. WILD provided lifestyle interventions for those with (1) MASLD (2) body mass index (BMI) > 27 with comorbidity or > 30 with or without comorbidity and (3) the willingness to participate. The patients were seen monthly to evaluate progress with nutrition, exercise, behavioral modifications, and weight loss medications. A retrospective chart review was completed to compare percent weight changes of WILD patients managed by APPs to those receiving standard of care in the APP hepatology practice. Patients were included if they had either participated in the WILD program for at least 6 months with a minimum of 2 visits or if they had achieved 10% body weight loss goal prior to the 6-month mark. Using electronic medical records, data collected included demographics, starting weight, maximum achieved weight loss and final recorded weight in the program. **Results:** Between October 2018 and May 2023, 72 patients participated in the WILD pathway and met criteria for the study. This was compared to 30 patients who received standard of care from October 2018 to June 2021. Of the 72 patients seen in the WILD pathway, 56 patients (77.8%) achieved weight loss with a median TBWL of 7.42%. Only 12 patients (40%) in the standard of care cohort achieved weight loss with a median TBWL of 2.95%. Of the 56 patients that lost weight in the WILD pathway, a total of 30 patients (53.6%) lost ≥ 5-10% with 16 (28.5%) losing ≥ 10%. In the standard of care cohort, only 4 patients (0.14%) lost ≥ 5% TBWL and no patients with ≥ 10% TBWL. **Conclusion:** A dedicated, intensive APP-directed weight intervention pathway embedded within a standard hepatology practice was more successful in helping patients achieve meaningful weight loss than standard hepatology APP-based care and published clinical trials for MASH. This data supports the development of APP driven weight loss interventions in GI and hepatology specialties to most effectively manage the massive clinical burden of MASH.

Figure 1. Comparison of TBWL between WILD pathway and routine APP care

66 | INCORPORATING ADVANCE CARE PLANNING IN ADULTS WITH DECOMPENSATED CIRRHOSIS AT LIVER TRANSPLANT CENTERS: A NURSING-LED EDUCATIONAL INITIATIVE

Janet Gripshover[1,2], Rita D'Aoust[1], Deborah Baker[1] and Arpan Arun Patel[3], (1)Johns Hopkins University, (2) University of California Los Angeles, (3)Greater Los Angeles VA Healthcare System

Background: Clinician inexperience with advanced care planning (ACP) is a barrier to patient-centered care for adults with decompensated cirrhosis (DC) at liver transplant centers. Because transplant nurse coordinators are well-versed in DC prognoses and often develop marked therapeutic relationships with patients, these health care team members may be uniquely poised to promote ACP in the DC population.

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Our aim was to pilot test an ACP educational program for transplant nurse coordinators. **Methods:** An ACP expert familiar with the liver transplant population (N.W.) conducted a 1-hour educational seminar, attended by liver transplant nurse coordinators (n = 8). Subject matter included the importance of ACP in the DC population as well as practical requirements for completing and documenting advanced directives (AD) at our medical center. Following the seminar, transplant coordinators were encouraged to bring up AD completion during intake appointments with pre-liver transplant patients. Three follow-up check-in meetings occurred at various intervals to help address barriers to workflow incorporation. Documentation of ACP conversations and AD completion rates in the 12 weeks before and after the intervention were compared using paired t-tests. A post- intervention survey was conducted to assess nurse coordinator engagement and perceptions on feasibility, applicability, and appropriateness of the intervention. **Results:** Prior to the intervention, 10 of 108 patients (9.3%) had any ACP documentation and 5 (4.6%) had a completed AD. After the intervention, 5 of 107 (4.7%) had any ACP documentation and 5 (4.7%) patients completed an AD, demonstrating no significant differences pre- and post- intervention (Δ ACP documentation: $p = 0.187$, Δ AD completion: $p = 0.998$). The most cited barrier by the transplant nurse coordinators was other responsibilities taking precedence (N = 3), as well as a perception that transplant social workers are better suited to perform this task (N = 5, open-ended responses). Regarding nurse coordinator engagement, acceptability scores received the highest mean scores of 4.0 out of 5.0 (SD 0.82), followed by feasibility (3.5, SD 0.65) and applicability (3.42, SD 0.57). **Conclusion:** This project demonstrates that an education intervention for health care providers alone may not be sufficient in improving ACP amongst patients with DC, and further work to reduce other ACP barriers such as operational constraints may be required.

67 | HEPATITIS C MEDICATION ADHERENCE OUTCOMES FOR THE LOUISIANA MEDICAID SUBSCRIPTION-BASED MODEL AT SPECIALTY PHARMACY

Amanda Mooney and Claire Ozoral, Ochsner Health

Background: Prior to July 2019, Hepatitis C (HCV) treatment was limited in the state of Louisiana due to restrictive prior authorization (PA) criterion for Medicaid patients. Ochsner Specialty Pharmacy (OSP), a health-system integrated pharmacy within the largest non-profit health system in the state was unable to fill most Medicaid HCV prescriptions and instead had to assist most patients with enrollment in the manufacturer assistance program with an uncertain amount of refill follow-up and pharmacist contact. In July 2019, Louisiana entered a subscription-based contract which allowed Medicaid patients unrestricted access to authorized generic sofosbuvir-velpatasvir. Medicaid patients were now able fill their HCV treatment at OSP with close pharmacist follow up and contact. The primary outcome of this study was to determine the impact of specialty pharmacy on HCV medication adherence rates as determined by the proportion of days covered (PDC). Secondary outcome include the proportion of patients who achieve sustained virologic response (SVR), and time to treatment initiation. **Methods:** This retrospective review of Medicaid patients with a diagnosis of HCV was collected from the electronic medical record between the dates of January 1, 2019 through December 31, 2019. Medicaid patients were included in the study if they were prescribed a direct-acting antiviral (DAA) by an Ochsner provider and were DAA treatment naïve. Patients were excluded if they had advanced levels of fibrosis, a history of transplantation, and did not complete or were deceased prior to the end of treatment. **Results:** A total of 391 patients met all inclusion criteria (321 patients in the OSP group and 70 patients in the manufacturer group). For the primary outcome, patients in the OSP group saw a statistically significant increase in medication adherence as measured by PDC from 80.3% to 94% ($p < 0.05$). In addition, time to treatment initiation decreased from 94 days in the manufacturer group to only 20 days in the OSP group ($p < 0.05$). No significant difference was observed in SVR rates. **Conclusion:** The close follow up and clinical services provided by OSP led to increased rates of HCV medication adherence. In addition, the unrestricted access to HCV treatment led to much shorter times to treatment. This study demonstrates the importance the additional clinical services provided by health-system integrated specialty pharmacists have on HCV medication adherence.

Southern California Liver Centers, (2)Gateway Comprehensive Medical Group, APC

Background: The prevalence of obesity and metabolic syndrome is on the rise in the US particularly in Hispanic patients. Individual's with Nonalcoholic Fatty Liver Disease (NAFLD) are prone to progress to Nonalcoholic Steatohepatitis (NASH), which could lead to cirrhosis and liver cancer. Early identification of individual's at risk for developing NASH is critical. In 2017 we initiated and reported on a screening program for fatty liver and liver fibrosis using FibroScan® in a primary care practice (PCP) with predominantly Hispanic patients in Southern California "South Bay fatty liver cohort". This is a 6-year report on the disposition of the patients and follow-up in the primary care setting in contrast to those referred to a Hepatology practice. **Methods:** Between March, 2017 and June, 2017 958 adults (18 y and older) attending a primary care clinic, who had no known history of liver disease agreed to be screened and had an evaluable Fibroscan®. Pts were followed and managed per standard of care in the primary care setting including annual check-ups, FibroScan® assessments and referral to specialists if needed. **Results:** Of the 958 pts, 622 pts (64.9%) changed their health insurance carrier and had a change in their Primary Care practice during the COVID-19 pandemic, 6 pts (0.6%) were deceased, 109 pts (16.6%) were not able to be reached. The subjects of this analysis are 221 pts who returned for a 6-year follow-up. 68.2% were females; mean age was 56.0 $\pm$15.4 years and 86.4% Hispanic. ALT, AST, and Albumin were within normal range at baseline and 6-year follow-up. APRI was not applicable in this population and all had a score $<=0.1$ at baseline and follow-up. Similarly, all had a Fib-4 Index <1 at baseline and follow-up. Refer to table 1 for the 6-year change in BMI, FibroScan®, Hemoglobin A1C, and metabolic syndrome. **Conclusion:** In a pre-dominantly Hispanic community patient population with no known history of fatty liver disease attending a primary care clinic at baseline, 23% of patients continued to be followed up regularly. Over 6 years with annual follow-up visits, there was 1) a slight change in the fat infiltration and minimal change in liver stiffness measure by FibroScan®, 2) significant progression in the metabolic syndrome presentation and risk factors, and 3) significant changes in health insurance status and routine follow-up. This underscores the importance of implementing incentive programs for PCP based on patients outcomes in respect to the management of patients with NAFLD. In addition, these findings re-emphasize the need for educational programs to PCP on the non-alcoholic fatty liver disease spectrum, its consequences as well as the importance of close follow-up of patients at risk for metabolic syndrome and when to refer to liver specialists.

Table 1		Baseline	6-year follow-up
# of pts		221	221
BMI	Normal (18.5 to <25)	15.0%	4.1%
	Overweight (25 to <30)	35.7%	38.8%
	Obese (>=30)	49.3%	57.1%
FibroScan®	CAP > 290	41.6%	47.0%
	LSM > 7 kPa	25.8%	33.3%
Hemoglobin A1C	Mean $\pm$ Standard Deviation	6.19 $\pm$ 1.43	6.20 $\pm$ 1.31
	A1C > 6.5%	16.8%	24.4%
Metabolic Syndrome	1 risk factor	24.9%	26.8%
	2 risk factors or more	7.2%	21.2%

Massachusetts General Hospital, Massachusetts Institute of Technology and Harvard University, (5) National Taiwan University Hospital

Background: Approximately 4 million people worldwide are co-infected with chronic HBV (CHBV) and HIV due to shared transmission routes. The progression of CHBV to cirrhosis and hepatocellular carcinoma is accelerated by HIV coinfection compared to HBV mono-infection. The mechanisms underlying this accelerated natural history are not well characterized. HIV and its proteins, such as gp120, signal through CCR5 and CXCR4 on hepatocytes and hepatic stellate cells to promote cell growth and proliferation through hypoxia-inducible factor-1± (HIF-1±). We hypothesize that HIV and its proteins promote HBV-induced liver fibrosis in HIV/HBV coinfected cell culture models through HIF-1± and TGF-β1 signaling. **Methods:** Infectious HBV viral particles (HBVvp) were purified from the HBV supernatant (HBVsup) of HepAD38 cells. HIV NL4-3 strains viral particles (HIVvp) were isolated from HIV-infected U937 macrophage supernatant (HIVsup). The HBVvp, HBVsup, HIVvp or HIVsup were directly incubated (or infected) with LX-2 stellate cells, U937, and HBV-infected NTCP-HepG2 cells in mono or 3D spheroid coculture models. Cells were incubated with recombinant HIV proteins including gp120. HBV subgenomic constructs were transfected into NTCP HepG2 cells. We also evaluated the effects of inhibitors of HIF-1± and HIV gp120 in the HBV carrier mouse that were generated by hydrodynamic injection of pAAV/HBV1.2 plasmid though the tail vein into wild-type C57BL/6. The HIV/HBV replication, HIF-1±, and fibrotic gene expressions were monitored by qRT-PCR, ELISA, Western blot, and immunostaining. **Results:** HIV and HIV gp120, through engagement with CCR5 and CXCR4 coreceptors, activate AKT and ERK signaling and subsequently upregulate HIF-1± to increase HBV-induced TGF-β1 and profibrogenic gene expression in hepatocytes, HSCs and in the HBV carrier mouse. HIV gp120 exacerbates HBV X protein overexpression-induced HIF-1± expression and liver fibrogenesis through the TGF-β1 induced SMAD signaling pathway. Of note, HIF-1± siRNA transfection or the small molecule HIF-1a inhibitor acriflavine blocked HIV, HBV and the TGF-β1-induced fibrogenic response. HIV-induced upregulation of HIF-1± and profibrotic genes was abrogated by CCR5/CXCR4 inhibition. **Conclusion:** HIV and gp120 exacerbate HBV-induced liver fibrogenesis through upregulation of the HIF-1± and TGF-β1 pathway through CCR5/CXCR4. HIF-1± may be a novel target for antifibrotic therapeutic development in HBV/HIV coinfection.

liver compartment. In the context of a unique HBV clinical cohort in Zambia, where 20% of people with chronic HBV infection have HIV coinfection, we collected liver cells with fine needle aspiration (FNA) and compared cell milieu and expression patterns by HIV infection status. **Methods:** Treatment-naïve adults with either HBV/HIV coinfection or antiviral treatment-eligible chronic HBV monoinfection were enrolled in an observational cohort in Lusaka, Zambia, and underwent liver FNAs. Liver cells were loaded into the HIVE device (Honeycomb Biotechnologies), which permits a field site to capture and stabilize the full spectrum of intrahepatic cells for subsequent analysis at a distant site via single-cell RNA sequencing. We analyzed the intrahepatic gene expression (in a total of 7,992 high-quality cells) in 12 participants, including 6 with HBV/HIV coinfection. **Results:** The median age of analyzed participants was 31 years (range: 20-45), 4 (33.3%) were female (2 in each group), and half had HIV coinfection. Participants with coinfection had a median peripheral CD4 count of 225 cells/mm^3 (range: 69-999). Overall, HBV/HIV coinfection was associated with increased frequencies of CD8+ T cells and decreased frequencies of neutrophils and B cells. S100, MHC-II, and interferon-stimulated genes (ISG) were recurring gene programs in the myeloid compartment, with distinct expression patterns in each cell type. Significant differences in gene expression by HIV status were seen across a range of immune cell types, and distinct expression patterns were detected within subpopulations. HBV/HIV coinfection was associated with increased expression of ISG and higher signaling of PD-1/PD-L1 in neutrophils, which was paralleled by increased PD-1 expression in CD8+ T cells. **Conclusion:** Through single-cell analysis of liver FNAs, we observed pre-treatment differences in the intrahepatic milieu between adults with HBV/HIV coinfection and HBV monoinfection. A higher basal level of innate immune ISG and PD-1/PD-L1 signaling suggests possible unique mechanisms by which HIV coinfection accelerates HBV-related liver disease. This work also demonstrates the feasibility of FNA-based single-cell sequencing from remote sites.

71 | A RHESUS MACAQUE MODEL OF HIV/HBV CO-INFECTION

Sreya Biswas, Savannah Lutz, Lauren N Rust, Conor McMahon, Sofiya Yusova, Spandana Naldiga, Miranda Fischer, Jeremy Smedley, Jonah B. Sacha and Benjamin J. Burwitz, Oregon Health & Science University

Background: HBV and HIV are both major global health concerns as HBV infects 296 million people while HIV infects 38 million individual's worldwide. HIV/HBV co-infection is common due to similar routes of transmission, with an estimated 10% of HIV-infected individual's also infected with HBV. HIV/HBV co-infected individual's progress to chronic HBV infection more frequently and exhibit reduced HBV-specific T cell responses, with a higher probability of extensive liver fibrosis and hepatocellular carcinomas. Thus, a greater understanding of the interplay between HIV and HBV infections is urgently needed to design strategies to prevent accelerated liver disease. Rhesus macaques (RM) are a well-established non-human primate model for HIV research, and we discovered recently that antibody-mediated CD4$^+$ T cell depletion in RM leads to long-term, high-titer HBV replication. In this study, we investigated the potential of inducing natural CD4$^+$ T cell depletion via SHIV$_{DH12\ Clone\ 7}$ infection and using it to establish HIV/HBV co-infection in RM. **Methods:** Animals were intravenously infected with SHIV$_{DH12\ Clone\ 7}$ (5x10^3 TCID$_{50}$) and then three weeks later challenged

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with HBV (genotype D, 1x10^9 virions, i.v). Weekly blood draws were taken to monitor HBV and SHIV infection, and track CD4$^+$ T cells and HBV surface antigens (HBsAg). Liver biopsies were obtained every four weeks to quantify HBV replication in the liver by quantitative PCR. Serum chemistries were run weekly to monitor metabolic changes in the liver associated with co-infection. **Results:** Preliminary studies showed successful CD4$^+$ T cell depletion in two RM following SHIV infection. However, one RM controlled SHIV infection (Mamu-B*08$^+$) and CD4$^+$ T cells returned concurrent with clearance of HBV. The second RM exhibited SHIV ($>10^5$ copies/ml) and HBV ($>10^4$ copies/ml) chronic co-infection (>24 weeks). HBV infection was validated by the presence of HBsAg and HBV DNA in the serum and HBV RNA in the liver. Based on the preliminary results, we repeated the study with nine additional animals and found that four exhibited a similar trend of co-infection. **Conclusion:** These results indicate that SHIV-mediated CD4$^+$ T cell depletion helps sustain HBV infection. Thus, we show for the first time an HIV/HBV co-infection model in RM that can be beneficial for studies investigating pathogenesis associated with co-infection; which will be critical for the further development of this model.

72 | TP53BP2 IS ASSOCIATED WITH HBsAg CLEARANCE IN PEGINTERFERON-ALFA-TREATED CHRONIC HEPATITIS B

Guiwen Guan[1], Xiangmei Chen[1] and Fengmin Lu[1,2], (1) Peking University, (2)Peking University People's Hospital

Background: Hepatitis B surface Antigen (HBsAg) loss occurs in a minor fraction of patients with Chronic Hepatitis B (CHB) under interferon therapy. Identifying the host factors critical for CHB cure can help recognize those who would benefit from interferon therapy. **Methods:** This study enrolled a total of 95 CHB patients, 48 achieved HBsAg loss under Peginterferon-alpha (Peg-IFN±) therapy while 47 did not. A Genome-Wide Association Study (GWAS) was conducted on these patients to pinpoint the host gene(s) contributing to HBsAg loss. We then validated the results in an additional cohort of 207 patients, 81 of whom achieved HBsAg loss. Expression Quantitative Trait Loci (eQTL) analyses, RNAseq analysis of liver biopsies from interferon-treated patients, and a series of in vivo and in vitro experiments using interferon treatment were then used to verify the functional involvement of the identified candidate gene. **Results:** The Single Nucleotide Polymorphism (SNP) rs7519753-C allele was found significantly associated with serum HBsAg loss in CHB patients undergoing Peg-IFN± treatment ($p = 4.85$ * 10-8, OR = 14.47). This association was consistently observed in the validation cohort, where the frequency of rs7519753-C genotype was significantly higher in the HBsAg loss group ($p = 0.008312$, OR = 1.64). RNA-seq analysis of liver biopsies from interferon-treated patients showed that the expression of TP53BP2 was significantly higher in the HBsAg loss group ($p < 0.05$). The population carrying the rs7519753 C allele had higher TP53BP2 expression in the liver ($p = 2.9$ * 10-6). Additional experiments demonstrated that TP53BP2 amplified the expression of Interferon-Stimulated Genes (ISGs) in the presence of interferon. Mechanistically, TP53BP2 could post-transcriptionally downregulate the expression of SOCS2, thus enhancing the antiviral activity of the JAK/STAT signaling pathway activated by interferon therapy. **Conclusion:** The SNP rs7519753-C allele correlates with a higher probability of serum HBsAg loss in CHB patients undergoing Peg-IFN± treatment and higher hepatic TP53BP2 expression. TP53BP2 can potentiate the hepatocyte response to IFN-± by inhibiting SOCS family gene expression. This suggests a pivotal role of TP53BP2 in predicting and enhancing interferon response in CHB patients.

73 | CIRCULATING CLASSICAL MONOCYTE-DERIVED IL-1² PRODUCTION IS ASSOCIATED WITH THE REDUCTION OF SERUM HBsAg LEVELS IN CHRONIC HEPATITIS B

Satoshi Shigeno[1], Takahiro Kodama[2], Kazuhiro Murai[1], Akira Nishio[1], Hayato Hikita[1], Tomohide Tatsumi[1] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2)Osaka University Graduate School of Medicine

Background: Although nucleotide analogs (NA) prevent viral replication in chronic hepatitis B (CHB) patients, it rarely achieve HBsAg seroclearance. While the reduction of HBsAg levels is associated with HBsAg seroclearance, the factors regulating HBsAg levels are not well understood. To aim for "Functional Cure", we explored the host immunodynamics involved in the reduction of HBsAg levels. **Methods**: Among CHB patients (HBsAg > 1000 IU/mL before the NA treatment) treated with more than five years of NA treatment, we selected four patients whose HBsAg levels decreased below 100 IU/mL (declining group) and four patients whose HBsAg levels maintained above 1000 IU/mL (prolonged group). The peripheral blood mononuclear cells (PBMCs) from these patients, as well as three healthy controls, were sent for single-cell RNA sequencing (scRNAseq) targeting the 400 immune-related genes. PBMCs from additional 32 CHB patients (declining group: n = 24, prolonged group: n = 8) were used for the validation study. In vitro analysis was performed with HBV-expressing cell line HepG2/2.2.15. **Results**: The average duration of NA treatment for the eight CHB patients was 9.5 years, and there were no differences in clinical backgrounds including age, gender, type of NA treatment, or duration of treatment between the declining and prolonged groups. A total of 82,000 PBMCs were evaluated through scRNAseq and categorized into 10 immune cell clusters including $CD8^+$T cells, $CD4^+$T cells, NK cells, B cells, monocytes, and dendritic cells. Although the frequency of each cell population was not different between the declining and prolonged groups, analysis of the differentially expressed gene of each cluster revealed that the IL-1β expression levels of the $CD14^+CD16^-$ classical monocyte cluster were significantly higher in the declining group than those in the prolonged group. In the validation cohort, the IL-1β expression levels of the isolated circulating $CD14^+$ classical monocytes of the declining group were also significantly higher than those of the prolonged group. In vitro analysis, recombinant IL-1β treatment significantly decreased the HBsAg levels in the supernatant of HepG2/2.2.15 in a dose-dependent manner. **Conclusion**: In CHB patients, the differences in IL-1β production capacity in peripheral blood classical monocytes might be involved in the reduction of serum HBsAg levels during NA treatment.

74 | DYNAMIC CHANGES OF T-CELL IMMUNITY IN WOMEN WITH CHRONIC HBV INFECTION DURING PREGNANCY AND POSTPARTUM AND ITS RELATIONSHIP WITH HBV INFECTION STATUS

Jinlin Hou[1], Yaohua Hao[1], Yunfei Gao[2], Yongyin Li[3], Yanchen Ma[1], Xiaoyi Liu[1], Meiting Huang[4], Xueru Yin[1] and Xuelian Zhang[1], (1)Nanfang Hospital, Southern Medical University, (2)Zengcheng Branch of Nanfang Hospital, Southern Medical University, (3)State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, (4)Huizhou Third People's Hospital

Background: The natural history and disease progression of hepatitis B virus (HBV) infection depend on the interaction between the immune system and the virus. Pregnancy, a special physiological process, can change the maternal immune status. For pregnant women with chronic HBV infection, it is still unclear how the maternal immune system changes during pregnancy and postpartum, and whether this change will lead to changes in HBV infection status and disease progression. In this study, we explored the dynamic changes of T-cell immunity in women with chronic HBV infection from pregnancy to postpartum and their correlation with virological markers and liver biochemical parameters. **Methods:** In this study, 24 HBeAg+ pregnant women with chronic HBV infection were enrolled and followed up from pregnancy to postpartum, and 12 HBeAg+ non-pregnant women in the stage of immunotolerance (IT) were included as control. We observed the dynamic changes of T cell phenotype and function, liver function, and virological markers during follow-up, and analyzed the correlation between parameters of T cell immunity and clinical laboratory. **Results:** By analyzing the dynamic change of T lymphocyte phenotype and function, we found that the frequency of Th1($CD4^+CXCR3^+CCR6^-$) subset was significantly lower during pregnancy than that after delivery($p = 0.000$). Conversely, the frequency of Th2 subset ($CD4^+CCR6^-CXCR3^-$) was significantly higher

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

during pregnancy than that after delivery($p = 0.000$). However, Th17 ($CD4^+CXCR3^-CCR6^+$) frequency remained stable during pregnancy and postpartum ($p = 0.341$). In the analysis of differentiation stages of Th1 memory cells, we found that the central memory T cells (TCM) were dominant during pregnancy and effector memory T cells (TEM) were dominant after delivery. At 32-40 weeks of gestation, the ability of $CD4^+$T cells to secrete IL-17 was significantly higher than that of 40 days and 4-6 months after delivery ($p = 0.008$, $p = 0.009$). In addition, we found that Th1 frequency was negatively correlated with the level of HBeAg ($p = 0.045$, r = -0.442), and IL-17 was positively correlated with the level of ALT ($p = 0.043$, r = 0.647). **Conclusion:** T cell immunity experiences dynamic change from pregnancy to postpartum, with domination of anti-inflammatory reaction during pregnancy and domination of the pro-inflammatory reaction after delivery. Th1 subset is associated with immune clearance of HBV infection and liver inflammation.

75 | THE CIRRHOSIS MEDICAL HOME: A PILOT RANDOMIZED TRIAL OF A COLLABORATIVE CARE MODEL FOR PATIENTS WITH DECOMPENSATED CIRRHOSIS

Eric S. Orman[1], Archita Parikh Desai[1], Noll Campbell[2], Nicole Fowler[1], Jake McCarty[1], Francis Pike[1], Naga P. Chalasani[3] and Malaz Boustani[1], (1)Indiana University, (2)Purdue University, (3)Indiana University Medical Center, Indianapolis, IN

Background: Patients with decompensated cirrhosis have poor quality of life and complex care needs that could be addressed with existing services; but the fragmented healthcare system does not provide the necessary coordination to best care for this population. Collaborative care models (CCM) can bridge this gap by providing coordinated, personalized care using care coordinators. In this pilot randomized trial, we developed and tested a CCM for cirrhosis: The Cirrhosis Medical Home (CMH). **Methods:** We randomized 40 hospitalized patients with decompensated cirrhosis and poor quality of life (SF-36 physical and/or mental component score < 40) to receive care through the CMH or usual care in a 1:1 ratio for 6 months following hospital discharge. In the CMH, a nurse coordinator, supported by an interdisciplinary clinical team, provides personalized protocol-driven care guided by dynamic feedback measures. Quality of life (SF-36) and mortality were compared at 3 and 6 months after enrollment. **Results:** The median age was 58, 70% were female, and 95% were White. 74% had Medicare or Medicaid insurance, 21% were employed, and 20% were discharged to a healthcare facility. The median MELD-Na was 24. Median baseline SF-36 domains ranged from 0 (role limitations) to 56 (emotional wellbeing), and median physical and mental component scores were 25.9 and 40, respectively. After 3 months, 13 patients (32.5%) died or enrolled in hospice (7 usual care and 6 CMH; p = 0.74), 4 (10%) underwent liver transplant (2 each), and 12 (30%) provided follow-up patient-reported outcomes (PROs). At 3 months, patients in the CMH had increases in all but one SF-36 domain; patients in usual care had decreases in all but two (Table). None of the differences were statistically significant. After 6 months, an additional 5 patients died (total 11 usual care and 7 CMH; 45% overall, $p = 0.20$), and 8 (20%) provided PROs. At 6 months, physical functioning increased in the usual care arm and decreased in the CMH arm ($p = 0.02$, Table). The remaining differences were not significant. **Conclusion:** Hospitalized patients with decompensated cirrhosis and poor quality of life have high short-term mortality, which may limit the impact of collaborative care interventions focused on improving PROs. Future transitional care interventions may have more impact by triaging those at lower risk of short-term mortality to interventions like the CMH while linking those at higher risk to high quality palliative care services.

Change in SF-36 from Baseline*

	3-month follow-up			6-month follow-up

76 | THE LIVER TOOLKIT – AN INNOVATIVE INFORMATION TECHONOLOGY SOLUTION TO SCREEN PATIENTS IN GENERAL PRACTICE FOR UNDIAGNOSED CIRRHOSIS★

David S. Prince[1,2,3], Shakira Hoque[4], Christy Kim[4], Salim Maher[1,4], Nathan McGarry[4], Jane Miller[5], Phoebe Chomely[5], Janice Pritchard-Jones[1], Sally Spruce[1], Ken Liu[1,2], Simone I. Strasser[1], Brendan Goodger[5], Amany Zekry[4] and Geoffrey McCaughan[1,2], (1)Royal Prince Alfred Hospital, (2)Centenary Institute, (3)Liverpool Hospital, (4)St George Hospital, (5)Central and Eastern Sydney Primary Health Network

Background: Detecting patients with undiagnosed chronic liver disease is a public health challenge. Patients with advanced fibrosis or compensated cirrhosis have much better outcomes than those with decompensated disease and may be eligible for interventions to prevent disease progression **Methods:** A cloud-based software solution ('the liver toolkit') was developed to access primary care practice software to identify patients at risk of advanced chronic liver disease (ACLD). Clinical history and pathology results were extracted to calculate Aspartate aminotransferase to Platelet Ratio (APRI) and Fibrosis 4 (FIB-4) scores. Patients with elevated scores (APRI ≥ 1.0 and FIB-4 ≥ 3.25) or other risk factors of liver disease were recalled for assessment including transient elastography (TE) **Results:** Existing pathology results of more than 32,000 adults across nine general practices were assessed to identified 703 patients at high risk of ACLD (2.2% of the cohort). Patients with an existing diagnosis of cirrhosis were excluded. 179 patients (26%) were successfully recalled and 23 (13%) were identified to have advanced fibrosis or cirrhosis (Liver stiffness measure (LSM) ≥ 10.0 kPa)(10% indeterminate results, 25% early fibrosis, 52% normal). In almost all cases the diagnosis of liver disease was new with the most common aetiology being non-alcoholic fatty liver disease (n = 20, 83%). The liver toolkit was better at detecting patients who required further assessment in secondary care than direct general practitioner referral to the team (22.9% vs 3.6%, $p = 0.021$). APRI ≥ 1.0 and FIB-4 ≥ 3.25 had a positive predictive value for detecting advanced fibrosis or cirrhosis of 20% and 24% respectively. Patients who did not attend recall had markers of more severe disease with a higher median APRI score (0.46 vs 0.57, $p = 0.041$). **Conclusion:** This novel information technology system successfully screened a large primary care cohort using existing pathology results to identity patients at increased risk of advanced chronic liver disease. More than one in five patients recalled were found to have liver disease needing ongoing specialist follow up.

77 | HEAR-MHE: POINT-OF-CARE ANALYSIS OF RECORDED SPEECH AS A NOVEL METHOD TO DETECT HEPATIC ENCEPHALOPATHY

Patricia Pringle Bloom[1], Caitlyn Fisher[1], Nazokat Otajonova[2], Luis Garrido-Treviño[3], Aran Farrell[2], Jessica Robin[4], Sumeet Asrani[3] and Anna Lok[5], (1) University of Michigan, (2)Baylor, (3)Baylor University Medical Center, Dallas, TX, (4)Winterlight Labs, (5) University of Michigan Medical Center

Background: Variation in speech may be an early sign of minimal hepatic encephalopathy (MHE) or future overt HE (OHE). Though a battery of tests is available for MHE assessment, these are cumbersome and rarely used in clinical practice. In a prospective study, we evaluated the ability of speech recorded at home or in the office to correlate with validated HE assessments in patients of diverse backgrounds. **Methods**: In a prospective study ("HE Audio Recording to Detect MHE" or HEAR-MHE), we enrolled 212 patients (169 cirrhosis and 43 non-cirrhosis controls) from two geographically disparate centers. Patients underwent psychometric HE score (PHES; validated test to diagnose MHE), animal naming test, and audio recording while reading a paragraph. Speech variables (acoustic, lexical, and syntactic) were automatically extracted from recordings via the Winterlight Labs Smartphone analysis platform, an app initially designed to characterize speech in dementia, and immediately transmitted data to the research team via a secure server. Patients with cirrhosis were in 3 non-overlapping categories: (1) prior OHE + HE treatment, (2) MHE with no prior OHE (diagnosed by PHES ≤ -4), (3) no MHE or prior OHE. T-tests compared continuous

Symbols: ƒ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

variables, Pearson correlation correlated continuous variables, and Vuong's test compared AUCs of different models. **Results:** Cirrhosis: median 63 years (IQR 55, 68), 52% male, median MELD 9 (IQR 7, 12), 39% alcohol and 33% fatty liver. Controls: median 55 years (IQR 42, 62), 56% male, and 58% had fatty liver disease and 16% viral hepatitis. Office Audio: Audio recordings were median 36 seconds (IQR 33, 41). Speech rate was significantly slower in patients with MHE (152 words/min) and history of OHE (155 words/min) as compared to either no MHE or controls (169 and 172 words/min; Figure). Prediction of MHE using speech rate was comparable to the animal naming test (AUC 0.73 vs 0.66, $p = 0.12$) Home Audio: Patients performed 43 audio recordings with personal Smartphone apps. 23/225 (10%) speech variables were significantly correlated (< 0.05) between home and office recordings, despite recordings on different days. Speech rate at home was highly correlated to that in the office ($r = 0.53$, $p < 0.01$) and PHES score in office ($r = 0.71$, $p < 0.01$). Speech rate findings were similar regardless of site ($p = 0.44$) or patient region of origin ($p = 0.30$), in the whole cohort or within patient sub-groups. **Conclusion:** Brief audio recordings through a Smartphone app either at home or office may help identify patients with MHE and perform as well as traditional HE tests. Speech data can be reliably obtained at home or in the office and is not adversely impacted by accent. Automated speech analysis through Smartphone apps is a promising novel method to identify high risk patients at risk for future complications of decompensated cirrhosis.

78 | PREOPERATIVE HEPATOLOGY AND PRIMARY CARE VISITS ARE ASSOCIATED WITH REDUCED POSTOPERATIVE MORTALITY IN PATIENTS WITH CIRRHOSIS UNDERGOING SURGERY: A VETERANS AFFAIRS PROPENSITY MATCHED STUDY

Bachir Ghandour[1], Elliot B. Tapper[2], Marina Serper[1,3,4,5] and Nadim Mahmud[1,4,5,6], (1)Hospital of the University of Pennsylvania, (2)University of Michigan, (3)University of Pennsylvania, Philadelphia, PA, United States, (4)Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, (5)University of Pennsylvania Perelman School of Medicine, (6) University of Pennsylvania

Background: Patients with cirrhosis have increased surgical risk compared to the general population. Preoperative optimization by nonsurgical clinicians improves postoperative outcomes after colectomy in studies of patients with major comorbidities, however, data specific to patients with cirrhosis and addressing more diverse surgeries are limited. This study aimed to assess the impact of preoperative primary care provider (PCP) and/or gastroenterology/hepatology (GI/Hep) visits on postoperative mortality in patients with cirrhosis undergoing surgery. **Methods:** This was a retrospective cohort study of patients with cirrhosis in the Veterans Health Administration who underwent surgery between 1/2008 and 12/2022. We compared patients with preoperative PCP and/or GI/Hep appointments in the 60 days prior to the surgery with a propensity score (PS) matched group without preoperative appointments. Groups were matched for baseline age, sex, race/ethnicity, liver disease etiology, surgery type (e.g. abdominal wall, major abdominal, orthopedic, etc.), Child-Turcotte-Pugh Score, MELD-Na, and medical comorbidities. We then used Cox regression (CR) and Fine and Gray competing risk (FGCR, transplant as competing event) regression to evaluate the association between preoperative outpatient visit type and postoperative mortality at 6 months. **Results:** We compared 1992 patients with cirrhosis who had preoperative PCP/

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

GI/Hep appointments with 1839 PS matched patients with no preoperative appointments, with covariate balance being achieved for all key covariates listed above ($p > 0.05$). Using CR, the hazard of postoperative mortality at 6 months was significantly reduced among patients who had preoperative appointments with GI/Hep + PCP (hazard ratio [HR], 0.56; 95% confidence interval [CI], 0.36-0.88; $p = 0.01$), GI/Hep only (HR, 0.67; 95% CI, 0.46-0.96; $p = 0.02$), or PCP only (HR, 0.72; 95% CI, 0.54-0.96; $p = 0.02$) compared to those with no preoperative appointments. Similar results were obtained using FGCR analysis (Figure 1). **Conclusion:** Preoperative visits were associated with reduced risk of postoperative mortality in patients with cirrhosis, and greatest risk reduction was observed in patients with both PCP + GI/Hep visits. This suggests that these clinics may contribute to different elements of preoperative optimization that are synergistic. Future studies are needed to identify mechanisms underlying these differences to standardize preoperative optimization strategies.

Background: An assessment of varices is required prior to systemic therapy in patients with HCC. However, current non-invasive criteria, including the Baveno criteria, have not been validated in patients with HCC, and performing an EGD can delay HCC treatment initiation. We aimed to develop a noninvasive algorithm for assessing varices in patients with unresectable HCC. **Methods:** We performed a multicenter

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

retrospective study from 20 centers in the US, including adult patients with BCLC stage B/C HCC from 2007-2019. We included those with Child Pugh A5-B7 cirrhosis with an EGD within 12 months of index imaging without intervening HCC treatment. We excluded patients with history of variceal bleeding or uncontrolled ascites or hepatic encephalopathy. We collected demographics, laboratory data, and CT/MRI imaging findings extracted by an abdominal radiologist including presence of abdominal varices, spleen diameter/volume, and portal vein diameter. High-risk varices per EGD were defined as large varices, those requiring banding, presence of white nipple, or presence of red wale. We used elastic net for variable selection and model building. We divided the cohort into a 70:30 training set and validation set, with the goal of maximizing negative predictive value to avoid EGD in low-risk patients. **Results:** We included 707 patients, with a median age 64.6 years, 80.6% male and 59.8% White, 15.0% Black, 8.2% Asian, and 23.2% Hispanic. The most common liver disease etiologies were hepatitis C (43.6%), alcohol (39.9%), hepatitis B (6.5%), and NASH (4.7%). Patients were evenly distributed between BCLC B (54.0%) and C stage (46.0%) disease. Median time from HCC diagnosis to EGD was 47.4 (IQR: 114) days, with 24.4% of patients having high-risk varices. Our clinical model (Table) achieved an NPV of 87.0% in the validation cohort. Our model including imaging variables (Table) increased NPV to 93.0% in the validation cohort. The model would avoid conducting EGDs in 49 out of every 100 patients without significant varices. In a sensitivity analysis including other high risk bleeding diatheses (gastric varices and portal hypertensive gastropathy), the model had an NPV of 89%. **Conclusion:** A model using clinical and imaging data can accurately predict absence of high-risk varices in patients with HCC and avoid EGD in many patients prior to initiation of systemic therapy, thereby expediting care for patients with unresectable HCC.

Table: Predictor variables for presence of high-risk varices in patients with unresectable HCC

Model	Components	Negative Predictive Value	EGDs Avoided per 100 low risk patients	EGDs not conducted per 100 high risk patients
Clinical/Demographic Variable Model	Age, Sex, Child Pugh score, platelet count, albumin	87%	56	30

80 | DECISION-ANALYTIC MODEL TO PROJECT THE BENEFIT OF TERLIPRESSIN TREATMENT AMONG PATIENTS WITH ALCOHOL-RELATED CIRRHOSIS AND HRS

Khalid Mumtaz[1], Nikolaos T. Pyrsopoulos[2], Thomas M. Leventhal[3], Nyingi Kemmer[4], K. Gautham Reddy[5], Xingyue Huang[6] and Khurram Jamil[6], (1)The Ohio State University, Wexner Medical Center, (2)Rutgers University, Newark, NJ, (3)University of Minnesota, (4) Tampa General Hospital, (5)University of Chicago Medical Center, (6)Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Alcohol-related liver disease is a major cause of liver cirrhosis and has recently emerged as the most common indication for liver transplantation. Hepatorenal syndrome (HRS)—a rapidly progressive renal failure—is a fatal complication of decompensated cirrhosis with ascites. The FDA-approved vasopressin analogue, terlipressin (terli)—in combination with albumin—is recommended to treat patients (pts) with HRS-acute kidney injury (AKI). Terli also demonstrated efficacy in the subpopulation of pts with alcohol-related hepatitis. Based on the Premier Healthcare Database, the annualized estimate of HRS cases in 2021 was over 60,000 pts; approximately 60% of HRS cases were alcohol-related. In the pooled population of 3 Phase III North American, randomized, placebo (pbo)-controlled trials (NA RCTs) of terli in pts with HRS, cirrhosis had an alcohol-related etiology in 59.5% of pts. This study estimated the benefits of terli in adult pts with HRS and alcohol-related cirrhosis (AC) in real-world practice. **Methods:** A decision-analytic approach was used to create a model based on the US annual projection for HRS and AKI using data from the Premier Healthcare Database on the prevalence of an alcohol-related HRS diagnosis among hospitalized pts and the efficacy of terli vs pbo—including HRS reversal—reported in the 3 NA RCTs (OT-0401, REVERSE, and CONFIRM). Under the assumption that 80% of pts with HRS and AC would meet the FDA label criteria for terli (ie, pts with serum creatinine < 5 mg/dL, acute-on-chronic liver failure grade 0–2), the model projected additional responses (ie, HRS reversal), reduction in intensive care unit (ICU) stay duration, reduction in the need for renal replacement therapy (RRT), and an increase in transplant-free survival. **Results:** Using the estimate of 50,000 cases of HRS-AKI per year in the US, 60% of HRS-AKI cases with AC, and 80% of those pts meeting the label criteria, the model resulted in 24,000 pts with HRS-AKI and AC who would be eligible for terli treatment. The estimated outcomes are summarized in Table. **Conclusion:** Model estimates using terli (vs pbo) in pts with HRS and AC projected a substantial annual improvement in HRS reversal and remaining alive and transplant-free, and a reduction in RRT and duration of ICU stay. These projected benefits may result in improved outcomes and decreased cost of care among pts with HRS and AC who are treated with terli.

Table. Model estimates and predicted incremental annual outcomes for patients with alcohol-related HRS, SCr <5 mg/dL, and ACLF grade 0–2 (N=24,000)

	Estimates		Incremental outcomes
Outcomes	Terli (plus albumin)	Pbo (plus albumin)	Terli vs pbo
HRS reversal rate	45.8%	11.9%	8143 pts
RRT rate during hospital stay (up to 14 days)	28.2%	38.8%	−2542 pts
Alive and transplant-free rate (up to 90 days)	41.7%	28.3%	3216 pts
Average ICU stay	1.1 days	1.5 days	−8570 days

ACLF, acute-on-chronic liver failure; HRS, hepatorenal syndrome; ICU, intensive care unit; pbo, placebo; pts, patients; RRT, renal replacement therapy; SCr, serum creatinine; terli, terlipressin.

Nathan Alhalel[5], Nancy Mason[1], Michaela Rowland[1], Kirsten Engel[1], Jennifer C. Lai[6], Maria Edelen[7], Chengbo Zeng[7], Kedie Pintro[1], Nora Horick[1] and Areej El-Jawahri[1], (1)Massachusetts General Hospital, (2)Harvard Medical School, (3)New York-Presbyterian/Weill Cornell Medical Center, (4)University of Pittsburgh Medical Center, (5)University of California, San Francisco, (6)University of California-San Francisco, San Francisco, CA, (7)Brigham and Women's Hospital

Background: Patients with decompensated cirrhosis (DC) often experience high psychological symptom burden. Family caregivers of patients with DC are at risk for psychological distress. **Methods:** We conducted a cross-sectional study in which outpatients with DC and their caregivers completed assessments of depression severity (Patient Health Questionnaire 9, (PHQ-9) e 10 indicate moderate-to-severe depression; Hospital Anxiety and Depression Scale (HADS-D)), and anxiety symptoms (Hospital Anxiety and Depression Scale, HADS-A). Scores > 7 on HADS-A and HADS-D indicate clinically significant anxiety and depressive symptoms, respectively. Caregivers also completed the Zarit Burden Index 12 (ZBI-12 e 12 indicate caregiving burden and > 20 indicate high burden). To analyze patient-caregiver dyads, we used paired sample *t* tests and McNemar's tests for continuous and categorical variables, respectively. **Results:** Between July 2018 and September 2022 we prospectively enrolled 218 out of 330 (66%) patients with DC (mean age 57.5 [SD 10.2], median MELD-Na 16 [IQR 11-22]) and 127 caregivers (mean age 57.1 [SD 13.3], 63% spouses). Among patients, 42% had moderate-to-severe depression severity based on PHQ-9, and 39% and 44% had clinically significant depressive and anxiety symptoms based on HADS-D and HADS-A, respectively. Among caregivers, 67% screened positive for caregiving burden and 28% reported high caregiving burden. 24% had moderate-to-severe depression severity, and 35% and 53% had clinically significant depressive and anxiety symptoms, respectively. Among the 127 patient-caregiver dyads, patients reported significantly higher PHQ-9 ($M_{diff} = 3.0$, $p < 0.001$) and HADS-D ($M_{diff} = 1.3$, $p = 0.002$) scores compared to their caregivers. There was no difference between patients and caregivers on HADS-A ($M_{diff} = -0.7$, $p = 0.16$). Among patient-caregiver dyads, both patients and caregivers reported moderate-to-severe depression and clinically significant depressive and anxiety symptoms in 15%, 18%, and 28% of dyads, respectively. **Conclusion:** In this cohort study, patients with DC and their caregivers reported high rates of psychological distress and caregiving burden. Among patient-caregiver dyads, nearly 1 in 6 reported moderate-to-severe depression and over 1 in 4 reported clinically significant anxiety symptoms. These results underscore the critical need to develop supportive care interventions to reduce psychological distress in both patients with DC and their caregivers.

82 | CRITICAL GAPS AND DISPARITIES IN GUIDELINE-RECOMMENDED ALBUMIN USE FOR SPONTANEOUS BACTERIAL PERITONITIS: A NATIONAL COHORT STUDY

Marina Serper[1], Marya Pulaski[1] and Nadim Mahmud[2], (1)University of Pennsylvania, (2)Hospital of the University of Pennsylvania

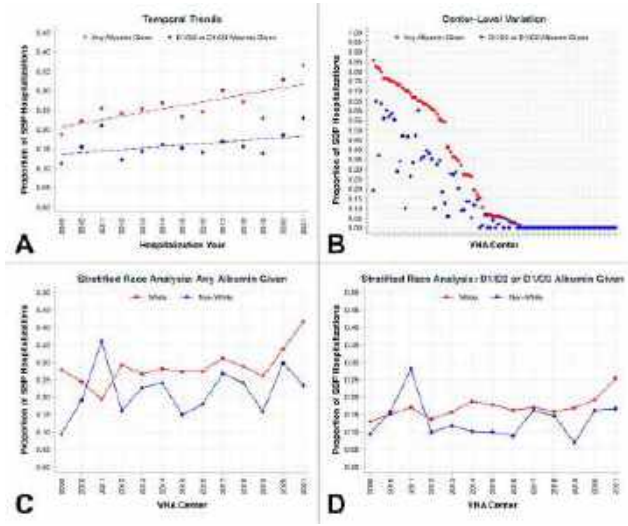
© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Albumin reduces mortality in spontaneous bacterial peritonitis (SBP) and is recommended by national guidelines. However, gaps and potential disparities in standard of care are not well-studied in large cohorts. We investigated temporal trends, center-level variation, and racial disparities in guideline-recommended albumin use for patients hospitalized with SBP in a large national cohort of Veterans with cirrhosis (VOCAL). **Methods:** This was a retrospective cohort study of SBP hospitalizations from 2009-2021. SBP admission diagnosis was manually validated and defined as: an inpatient SBP diagnosis code in the presence of e 1 paracentesis and hospital stay > 2 days (positive predictive value 91%). Demographic and clinical variables including comorbidities, laboratory data, and liver disease severity were abstracted. Albumin administration was collected from inpatient (BCMA) tables; hospitalizations were classified as any albumin, guideline-recommended albumin (day 1+2 or day 1+3), no albumin. Temporal trends were evaluated using linear regression. Center-level variation was explored among the 92 centers with at least 10 SBP hospitalizations. Stratified analysis was performed by white vs. non-white race. **Results:** We identified 3742 SBP hospitalizations; 35% had Child Turcotte Pugh (CTP)-A cirrhosis, 57% CTP-B, and 8.6% CTP-C. The median MELD-Na on admission was 18 (IQR 23-33). Only 988 (26%) received any albumin; of whom 588 (60%) received guideline-recommended albumin. The proportion of patients receiving any albumin increased over time (beta 0.009, $p = 0.003$; Figure 1A); guideline-recommended albumin use numerically increased but was not statistically significant (beta 0.004, $p = 0.12$). There was substantial center-level variability in albumin administration (Figure 1B); 36 centers (39%) did not administer any albumin for patients hospitalized with SBP. Finally, we identified racial differences in albumin use (Figure 1C/D); white patients had a 7% higher probability of receiving any albumin versus non-white patients (beta 0.070, $p = 0.005$). **Conclusion:** A large proportion of VA patients hospitalized with SBP did not receive albumin. While utilization has increased over time, there is substantial center-level variability. Furthermore, white patients were consistently more likely than non-white patients to receive albumin. Additional research is needed to elucidate drivers of these observed disparities, and quality improvement efforts such as clinical decision support should prompt albumin use once SBP is diagnosed.



Disclosures: Nadim Mahmud – Grifols: Grant/Research Support (research funding from ineligible companies should be disclosed by the principal or named investigator even if that individual's institution receives the research grant and manages the funds), No, No; The following people have nothing to disclose: Marina Serper, Marya Pulaski

83 | NURSE CARE COORDINATION IN CHRONIC LIVER FAILURE REDUCES READMISSIONS FROM HEPATIC ENCEPHALOPATHY AND IMPROVES QUALITY OF CARE; RESULTS FROM THE MULTICENTRE RANDOMIZED CONTROLLED ALFIE TRIAL

Alan J Wigg[1,2], Sumudu Narayana[1], Peter D Rose[1], Richard J Woodman[2] and ALFIE investigator group, (1) Southern Adelaide Local Health Network, (2)Flinders University

Background: Emergency admissions related to chronic liver failure (CLF) are common, expensive and associated with frequent readmission. There are no multicenter randomized controlled trials (RCT) investigating models to reduce liver-related emergency admissions (LREA). The primary aim of the Australian Liver Failure (ALFIE) trial was, therefore, to assess the efficacy of a nurse coordination model of care to reduce LREAs. **Methods:** The study was a multicenter RCT occurring between 2018 and 2022. Patients were recruited following an inpatient admission with a CLF complication. The intervention at each site was a multifaceted care

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

coordination model involving a nurse. Key components included intensive post-discharge monitoring (weekly phone calls for a minimum of 3 mo), rapid access to care pathway, enhanced patient and carer education and self-management support. The intervention was applied continuously for the duration of the trial. Secondary aims were to assess the effects of this model on other measures of hospital usage, mortality, patient-reported outcomes and quality of care. **Results:** 146 patients (75 Intervention group, 71 Control group) were recruited. The combined cohort had the following characteristics: mean age 54.9 years, 68% male, median MELD score 19.0 and median Child-Pugh score 9.0. The main causes of CLF were alcohol (68%), MAFLD (16%) and HCV (11%). The median (IQR) follow-up time for individual's in the Intervention and Control groups was 2.0 years. For the primary endpoint, LREA, there was a non-significant 11% reduction in LREA for the Intervention group vs. Control group (IRR 0.89, 95% CI 0.53-1.50, $p = 0.666$). Improvement trends were also seen for the Intervention group for ICU admissions (IRR = 0.62 $p = 0.491$), 7-day readmissions (IRR = 0.72, $p = 0.62$), and length of stay (IRR = 0.86, $p = 0.56$). The leading causes of LREAs were ascites (43%), encephalopathy (22%) and variceal bleeding (11%). There was an increased risk of LREA due to encephalopathy in the Control vs. Intervention group (Hazard ratio = 1.87, 95% CI = 1.18-2.96, $p = 0.007$); see Figure. There were no significant differences observed between groups for actuarial survival, or quality-of-life measures (CLDQ, EQ5D-5L utility, EQ-5D-VAS, QALY gains). All quality-of-care measures were improved in the Intervention group with significant improvement for HCC surveillance adherence ($p = 0.05$), performance of bone density ($p = < 0.001$) and vitamin D testing ($p = < 0.001$). **Conclusion:** This care coordination model showed benefits for CLF patients, particularly for reductions in LREA due to encephalopathy and improved quality of care. Further studies are needed to define this intervention model's optimal components, patient groups and settings. Further studies examining model cost-effectiveness and qualitative experiences of patients and care providers are in progress.

84 | LIVER CANCER SURVEILLANCE IN THE VA: IMPLEMENTATION-EFFECTIVENESS STEPPED-WEDGE CLUSTER-RANDOMIZED TRIAL

Vera Yakovchenko[1], Patrick Spoutz[2], Brittney Neely[1], Carolyn Lamorte[1], Dawn Scott[3], Heather McCurdy[4], Anna Marie Nobbe[5], Nsikak Richard Ekanem[6], Gwen Robins[7], Jasmohan S. Bajaj[8], Monica Merante[1], Sandra Gibson[1], Chaeryon Kang[9], Tamar H. Taddei[10,11], Timothy R. Morgan[12] and Shari S. Rogal[1,9], (1)VA Pittsburgh Healthcare System, (2)Veterans Integrated Service Network 20, (3)Central Texas VA Healthcare System, (4)VA Ann Arbor Healthcare System, (5) Cincinnati VA Medical Center, (6)VA Northern Indiana Healthcare System, (7)Martinsburg VA Medical Center, (8)Virginia Commonwealth University and Central Virginia Veterans Healthcare System, (9)University of Pittsburgh, (10)Yale University, New Haven, CT, (11) West Haven VA Medical Center, (12)VA Long Beach Healthcare System

Background: AASLD and EASL guidelines recommend all people with cirrhosis undergo twice yearly screening for hepatocellular carcinoma (HCC) with hepatic imaging. However, patient, provider, and system level barriers impede ongoing surveillance efforts. This stepped-wedge hybrid effectiveness-implementation trial assessed the impacts of using a quality improvement playbook called Getting to Implementation (GTI) to support VA facilities to select, implement, and evaluate data-driven strategies to improve HCC surveillance. **Methods:** This hybrid type III (implementation-effectiveness) stepped-wedge cluster randomized design was conducted at 12 VA sites between October 2020 and April 2023. We used a multi-faceted facilitation strategy consisting of manualized GTI during a 12-month active implementation and six-month sustainment period. The primary implementation outcome was GTI completion and strategy implementation. The secondary clinical outcome was receipt of guideline-concordant HCC surveillance at baseline, post-intervention, and sustainment. Analysis involved a three-level, generalized linear mixed model. **Results:** Of 12 VA facilities, selected based on having low baseline HCC surveillance rates, 10 completed GTI with high fidelity. These 10 sites implemented a median of four implementation strategies while receiving an average of 19 ± 5 facilitation hours. HCC surveillance improved from 21% at baseline to 30% during

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

intervention and remained elevated at 32% during sustainment. Sites receiving more facilitation ($r = 0.59$, $p = 0.048$) and sites implementing a greater variety of strategies had higher HCC surveillance improvement. Generalized linear mixed models indicated significant changes in HCC surveillance during both implementation (aOR = 1.306; 95% CI: [1.159, 1.472], $p < 0.0001$) and sustainment (aOR versus control = 1.511; 95% CI: [1.315, 1.73], p-value < 0.0001). Sustainment, a challenge for implementation trials, was significantly associated with improvement in HCC surveillance compared with active implementation (aOR = 1.168; 95% CI: [1.018, 1.340], p-value 0.0271). **Conclusion:** Data-driven strategies with facilitated quality improvement sustainably improved HCC surveillance in Veterans with cirrhosis receiving care in the lowest-performing VA facilities. Further research is needed to understand the heterogenous effects across sites, which may have been driven by differences in site baseline characteristics and facilitation and strategy implementation nuances.

85 | FEASIBILITY AND RESULTS OF AN INPATIENT TELEHEPATOLOGY CONSULT SERVICE IN AN INTEGRATED HEALTH SYSTEM

Haleigh Hanson[1], Loren Cihlar[1], Amber Rutues[1], Hollie Mayes[1], Niharika R. Samala[2], Samer Gawrieh[3], Craig Lammert[4], Howard C. Masuoka[5], Naga P. Chalasani[6] and Raj Vuppalanchi[4], (1)Indiana University Health, (2) Indiana University, Indianapolis, IN, (3)Indiana University School of Medicine, Indianapolis, IN, (4)Indiana University School of Medicine, (5)Indiana University, (6) Indiana University Medical Center, Indianapolis, IN

Background: Providers at community hospitals often seek to transfer hospitalized patients with advanced liver disease to tertiary/quaternary care hospitals for further management due to lack of expertise in caring for these patients. However, it is possible to co-manage such patients at local hospitals by providing virtual consultation by tertiary care hepatologists via inpatient telehepatology (INP-TH) consultation. We aimed to describe demographics, liver disease severity, and related outcomes such as transfer rate, subsequent outpatient follow-up, readmission rate, and 30-day mortality. **Methods:** Indiana University Health (IUH) is a 16-hospital integrated health system with a single adult academic health center (AAHC) with concentrated hepatology expertise and a liver transplant program. We established a pilot INP-TH team led by a Hepatologist, an Advanced Practice Provider, and a Medical Assistant in July 2022 to co-manage hospitalized patients with advanced liver disease at an affiliated IUH community hospital. In this model, providers caring at the community IUH hospital request a telemedicine consultation from INP-TH team in lieu of a hospital transfer. American Well platform embedded with Cerner's electronic health record (EHR) with a patient facing Apple iPad was utilized for the current study. **Results:** A total of 81 INP-TH consultations were provided, with only 9 (11%) patients requiring a transfer to the AAHC. Of these 81 consultations, 66 consultations on 61 unique patients had outcomes data with greater than 30-day follow-up. The median age was 60 (range: 19-80) years with 65% having a diagnosis of cirrhosis. At the time of INP-TH consult, 80% had signs of liver decompensation with MELD 21 $\pm$ 7; 83% had MELD $\geq$ 15. The more common etiologies of liver disease included alcohol associated liver disease (30%) and non-alcoholic fatty liver disease (29%). The duration of hospitalization was 9.2 $\pm$ 8.3 days with duration of stay 3.2 $\pm$ 3.9 days prior to INP-TH consultation. There were 20 (30%) patients requiring readmission. Thirty (45%) patients who were not transferred were seen in the outpatient setting at AAHC within 30 days. In 61 patients

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with 30-day post-discharge follow-up, there were 7 (11%) deaths (1 transferred and 6 non-transferred) with 61% deaths occurring inpatient. **Conclusion:** This proof-of-principle study shows that a telemedicine consultation service by tertiary care hepatologists is feasible to co-manage patients with advanced liver disease hospitalized to a community hospital within an integrated healthcare system. Hospital to hospital transfers can be dramatically minimized but a comprehensive evaluation of provider, patient, and caregiver with satisfaction surveys along with patient outcomes is necessary.

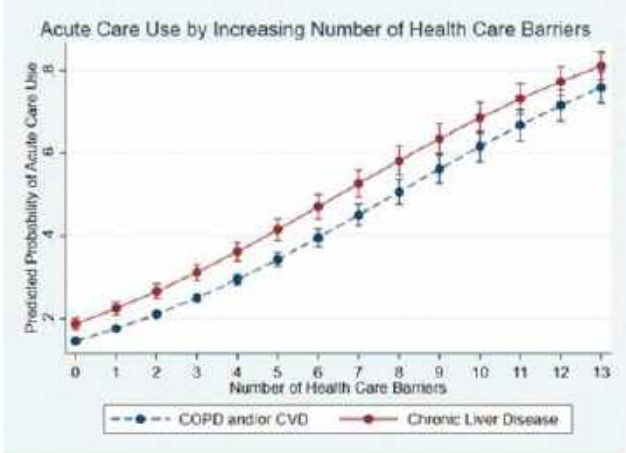
86 | ASSOCIATION OF HEALTH CARE BARRIERS AND ACUTE CARE USE AMONG ADULTS WITH CHRONIC LIVER DISEASE VS. OTHER CHRONIC DISEASES IN THE UNITED STATES

Carrie Wong and James Macinko, University of California, Los Angeles

Background: The relative prevalence of health care barriers for patients with CLD vs. those with non-CLD chronic diseases and the cumulative effect of these barriers on recurrent acute care use remains unknown. We aimed to assess the number of health care barriers and their association with acute care use by CLD vs. chronic obstructive pulmonary disease (COPD) and/or cardiovascular disease (CVD). **Methods:** We performed a pooled cross-sectional study using data from the National Health Interview Survey from 2011 to 2017 and applied weight adjustments to yield nationally representative estimates. In-person surveys provided self-reports on sociodemographic, health, and health care characteristics. Health care barriers (from organizational, financial, transportation domains) were measured as a count of all reported barriers (ranging from 0 to 13). Acute care use was defined as ≥ 2 hospitalizations and/or emergency department visits in the past year. We performed descriptive statistics (χ^2, Wald test), multivariable regression analyses (negative binomial, logistic regression), and estimated predicted probabilities from these models. **Results:** The sample included 47,037 adults (5,062 CLD vs. 41,975 COPD/CVD) which provided weighted estimates for 43,264,685 persons (4,742,444 CLD vs. 38,522,241 COPD/CVD). The CLD group was younger (median age 55 vs. 62 years), had more Hispanics (17.5% vs. 8.6%), fair/poor health (41.4% vs. 33.3%), less than high school education (7.2% vs. 6.5%), poverty (20.1 vs. 15.3%), material hardship (29.5% vs. 21.5%), and public insurance (23.6% vs. 15.7%) than the COPD/CVD group ($p < 0.001$). The prevalence of health care barriers for CLD was 1.29 times greater compared to COPD/CVD after adjusting for age, sex, region, and year (incident rate ratio 1.29, 95% CI 1.22-1.37, $p < 0.001$). Adjusted odds of acute care use were 1.36 (95% CI 1.23-1.50, $p < 0.001$) times greater for CLD vs. COPD/CVD. Probability of acute care use increased with greater health care barriers (0.19-0.81 for CLD, 0.15-0.76 for COPD/CVD) and the differences between CLD and COPD/CVD were consistent across the distribution (Figure). **Conclusion:** Our findings from a national sample representative of over 43 million US adults revealed that those with CLD (vs. other common chronic conditions COPD/CVD) have a higher prevalence of health care barriers, which was in turn associated with increased probability of acute care use. These disparities in health care accessibility and utilization are attributable to both characteristics of US adults with CLD and their ability to access appropriate and timely medical care.



Data source: NHIS, 2011-2017. COPD, chronic obstructive pulmonary disease; CVD, cardiovascular disease. Predicted probabilities of acute care use were derived from a multivariable logistic regression model to predict acute care use by disease group (CLD vs. COPD/CVD) and included number of health care barriers, age, sex, US Census region, and year (n=47,023; population size=43,255,608).

Background: In the primary analysis (data cut-off: 27 August 2021) of the phase 3 HIMALAYA study (NCT03298451) in unresectable hepatocellular carcinoma (uHCC), STRIDE (Single Tremelimumab Regular Interval Durvalumab) significantly improved overall survival (OS) and demonstrated a durable long-term survival benefit versus sorafenib; durvalumab monotherapy was noninferior to sorafenib (Abou-Alfa et al. *NEJM Evid* 2022). Here, we report an updated 4-year OS analysis of HIMALAYA. **Methods:** Participants with uHCC and no previous systemic treatment were randomized to STRIDE (tremelimumab 300 mg for one dose plus durvalumab 1500 mg every 4 weeks [Q4W]), durvalumab (1500 mg Q4W) or sorafenib (400 mg twice daily). Data-cut off was 23 January 2023 (STRIDE OS data maturity, 78%). OS and serious treatment-related adverse events (TRAEs) were assessed. In addition, baseline demographics and disease characteristics were assessed in long-term survivors (LTS; participants surviving ≥ 36 mo beyond randomization). **Results:** Follow-up duration was approximately 4 years across treatment arms (Table). The OS HR versus sorafenib (0.78; 95% CI, 0.67–0.92) and estimated 36-month OS rate (30.7%) for STRIDE were consistent with the primary analysis. The 48-month OS rate remained higher for STRIDE (25.2%) versus sorafenib (15.1%). No new serious TRAEs occurred after the primary analysis for STRIDE (17.5%). Durvalumab OS noninferiority to sorafenib and safety was consistent with the primary analysis. Baseline demographics, clinical characteristics and subsequent therapies, including tremelimumab rechallenge, for LTS in the STRIDE arm were generally consistent with the full analysis set, suggesting that LTS were not from any particular subgroup. **Conclusion:** These data reinforce the sustained, long-term OS benefit of STRIDE versus sorafenib in a diverse uHCC population, demonstrating unprecedented 3- and 4-year OS rates and longest follow-up to date in phase 3 uHCC studies. STRIDE maintained a tolerable safety profile, with no new serious safety events. This abstract was originally presented at the 2023 World Congress on Gastrointestinal Cancer.

Table: Updated analysis of HIMALAYA with 4 years of follow-up (data cut-off: 23 January 2023)

	STRIDE (n=393)	Sorafenib (n=389)
Median follow-up duration (95% CI)	49.12 (46.95–50.17)	47.31 (45.08–49.15)
OS HR (95% CI)*	0.78 (0.67–0.92)	
OS rates, % (95% CI)		
36 months	30.7 (26.1–35.3)	19.8 (15.9–24.1)
48 months	25.2 (20.8–29.7)	15.1 (11.5–19.2)
Serious TRAEs (including death), n/N (%)	68/388 (17.5)	36/374 (9.6)

*OS HRs and CIs were calculated using a Cox proportional hazards model.

88 | ANTICANCER EFFECTS OF VITAMIN K COMBINED WITH TRANSARTERIAL CHEMOEMBOLIZATION IN HEPATOCELLULAR CARCINOMA; A PROSPECTIVE, RANDOMIZED TRIAL.

Yoshimichi Haruna and Takayuki Yakushijin, Osaka General Medical Center

Background: We have previously reported that vitamin K dosing augments the anticancer effects of sorafenib by suppressing levels of des-γ-carboxy prothrombin (DCP), a known tumor growth and angiogenesis factor produced in HCC under sorafenib-induced ischemia. Herein, we aimed to establish whether vitamin K dosing could afford a similar anticancer effect when combined with transarterial chemoembolization (TACE), known to induce ischemic tumor necrosis in HCC. **Methods:** We performed a prospective, randomized, open-label trial, randomly assigning patients with unresectable HCC (1:1) to TACE + vitamin K or TACE alone groups. In the TACE + vitamin K group, patients received 45 mg of oral vitamin K2 daily from the day of TACE until day 28. Co-primary endpoints were objective response rate and progression-free survival (PFS); the secondary endpoint was safety. **Results:** No significant differences in baseline characteristics were observed between the TACE + vitamin K group (n = 50) and TACE alone group (n = 51). The TACE + vitamin K group exhibited a significantly higher objective response rate than the TACE alone group (96.0% *vs*. 82.4%, $p = 0.028$). The PFS was significantly longer in the TACE + vitamin K group than that in the TACE alone group (median time: 262 days [95% confidence interval (CI), 35.8–488.2 d] *vs*. 146 days [95% CI, 111.6–180.4 d]; $p = 0.013$, hazard ratio (HR): 0.55 [95% CI, 0.34–0.89]). Subgroup analysis revealed that vitamin K dosing prolonged PFS, particularly in females (HR of female and male: 0.25 *vs.* 0.72), patients within up-to-7 criteria (HR of within up-to-7 criteria and beyond: 0.44 *vs.* 1.21), or those with high baseline serum DCP levels (HR of DCPg 100 and < 100 mAU/mL: 0.38 *vs.* 0.65). The PFS was markedly prolonged in patients; male with their baseline DCPg 100 mAU/mL or female, and within up-to-7 criteria; who seem to be most favorable for TACE + vitamin K (median [95% CI] days: 712 [290.1–1133.9]

vs. 141 [89.3–192.7], HR 0.11 [0.04–0.30], $p < 0.001$). Furthermore, we focused on the incidence of rapid and crucial recurrence defined as emergence of macroscopic vascular invasion (Vp4 or Vp3), multicentric intrahepatic recurrence (an increase > 10 nodules compared with the latest radiological image), massive infiltrative tumor growth, extrahepatic spread, or abrupt death due to rapid tumor progression, within 120 days after TACE. In the TACE + vitamin K group, 4 patients (8%) had 4 events of rapid and crucial recurrence, whereas 11 patients (22%) of the TACE alone group experienced 14 events of rapid and crucial recurrence. The rapid and crucial recurrence was observed more frequently in the TACE alone group than in the TACE + vitamin K group ($p = 0.049$). Regarding safety, there were no significant differences in the incidence of adverse events between the two groups. **Conclusion:** Compared with TACE alone, vitamin K dosing combined with TACE improved anticancer outcomes.

89 | COMPARISON OF RECURRENCE PREDICTION MODELS AND IMBRAVE 050 CRITERIA TO SELECT PATIENTS FOR ADJUVANT IMMUNOTHERAPY AFTER CURATIVE RESECTION OF HEPATOCELLULAR CARCINOMA

I-Cheng Lee[1,2], Hao-Cyuan Chu[2], Shinn-Ying Ho[2], Gar-Yang Chau[3], Ming-Chih Hou[1] and Yi-Hsiang Huang[1,2], (1)Taipei Veterans General Hospital, (2)National Yang Ming Chiao Tung University, (3)Taipei Veterans General Hospital Department Surgery

Background: The IMbrave 050 trial recently demonstrated positive results of the adjuvant atezolizumab plus bevacizumab therapy for hepatocellular carcinoma (HCC) patients at high-risk of recurrence after curative treatment. However, the IMbrave 050 criteria to define high-risk of recurrence might be suboptimal. The aim of this study was to compare the performance of current prediction models and IMbrave 050 criteria in predicting recurrence after curative resection for HCC. **Methods:** Consecutive 1444 HCC patients receiving curative resection were retrospectively enrolled, including 984 (68.1%) patients fulfilling IMbrave 050 high risk criteria. In the high risk group, patients were classified as group 1 (up to three tumors, with largest tumor > 5, n = 458), 2 (four or more tumors, with largest tumor ≤ 5 cm, n = 15) and 3 (up to three tumors, with largest tumor ≤ 5 cm with vascular invasion and/or poor tumor differentiation, n = 511) by IMbrave 050 definition. The performance of ERASL-post and an artificial intelligence (AI)-derived clinical-radiomic GARSL postoperative model were compared with IMbrave 050 criteria in predicting recurrence after resection. **Results:** Besides tumor size, tumor number and microvascular invasion, AFP level, ALBI grade and FIB-4 score were also independent predictors of early recurrence by multivariate analysis. The median RFS in patients with IMbrave low risk, and high risk groups 1, 2 and 3 were 80.0, 22.0, 16.2 and 49.6 months, respectively ($p < 0.001$). The median RFS in patients with ERASL low-, intermediate-, high-risk groups, and GARSL low-, high-risk groups were 69.1, 21.5, 5.0, 96.6 and 10 months, respectively. The area under the receiver operating characteristic curves (AUCs) of IMbrave 050 criteria, ERASL and GARSL models for predicting early recurrence of HCC within 2 years were 0.614, 0.674 and 0.857, respectively. In the IMbrave high risk group, 46.9% and 56.2% of patients were classified as low risk by ERASL and GARSL models, respectively. In the IMbrave low risk group, 0% and 25.3% of patients were classified as high risk by ERASL and GARSL models, respectively. **Conclusion:** The high risk patients defined by the IMbrave 050 criteria were heterogeneous and outcomes varied widely. Prediction models using more comprehensive prognostic factors, especially the AI-derived GARSL model, performed better to select high-risk candidates for adjuvant immunotherapy.

Background: Recurrence can occur in over 70% of hepatocellular carcinoma (HCC) patients within 5 years after curative resection. While histological microvascular invasion (MVI) predicts recurrence, it is ascertained from resected specimens and cannot provide pre-operative prognostication. We developed an artificial intelligence deep learning-based model using pre-operative computed tomography (CT) for predicting HCC recurrence. **Methods:** Chinese patients with resected histology-confirmed HCC were recruited from four centers in Hong Kong, and were randomly divided in an 8:2 ratio into training and internal validation groups. We developed Recurr-Net, a multi-phasic residual-network random survival forest deep learning model, incorporating pre-operative triphasic contrast CT images and clinical data (sex, age, comorbidities, blood tests) to predict HCC recurrence. The model was externally tested in an independent cohort from Taiwan. The area-under-curve (AUC), positive- and negative-predictive values (PPV/NPV) of the model was compared against MVI. Survival analysis was also performed. **Results:** This analysis included 1,254 patients (82.9% male, age at CT 62.2 +/- 10.8 years, median follow-up 7.8 [5.8-10.0] years). 551 (43.9%), 140 (11.2%) and 563 (44.9%) patients were in the training, internal validation, and external testing cohorts respectively. The cumulative HCC recurrence rate at years 2 and 5 were 42.1% and 56.6% respectively. The model was trained for 42 epochs. In the internal validation cohort, Recurr-NET achieved an AUC of 0.823 (95%CI 0.684-0.842, PPV 0.778, NPV 0.753) and 0.801 (95%CI 0.632-0.815, PPV 0.857, NPV 0.547) for predicting recurrence at years 2 and 5, significantly outperforming the predictive value of MVI (year 2 AUC 0.564 [95%CI 0.484-0.653], PPV 0.591, NPV 0.554; year 5 AUC 0.527 [95%CI 0.437-0.624], PPV 0.690, NPV 0.365) (Both $p < 0.01$). In the external testing cohort, Recurr-NET achieved an AUC of 0.787 (95%CI 0.647-0.801, PPV 0.743, NPV 0.755) and 0.753 (95%CI 0.607-0.765, PPV 0.847, NPV 0.507) for predicting recurrence at years 2 and 5, significantly outperforming MVI (year 2 AUC 0.609, 95%CI 0.535-0.682, PPV 0.478, NPV 0.774; year 5 AUC 0.560, 95%CI 0.483-0.642, PPV 0.679, NPV 0.464) (Both $p < 0.05$). In both internal validation and external testing cohorts, Recurr-NET had significantly better discriminative ability than MVI for 2-year (Figures 1A & 1C; Validation: 77.8% vs 59.1%; External testing: 74.3% vs 47.8%) and 5-year recurrence risks (Figures 1B & 1D; Validation 85.7% vs 69.0%; External testing: 84.7% vs 67.9%) (Both $p < 0.001$). **Conclusion:** Recurr-NET was superior to MVI in predicting early and late HCC recurrence, and has potential to emerge as a novel tool for pre-operative prognostication of HCC outcomes. 91 | ANALYSIS OF IMMUNE-RELATED ADVERSE EVENTS AND TIME-TO-TREATMENT DISCONTINUATION OF ATEZOLIZUMAB AND BEVACIZUMAB IN PATIENTS WITH HEPATOCELLULAR CARCINOMA: A MULTICENTER COHORT STUDY

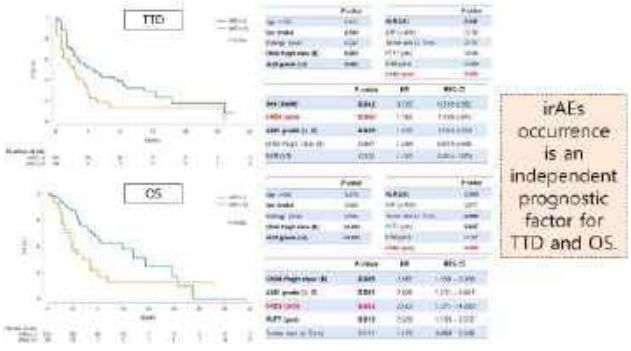
Heechul Nam[1], Ji Won Han[2], Soon Kyu Lee[1], Hyun Yang[1], Haelim Lee[1], Pil Soo Sung[3], Hee Yeon Kim[1], Myeong Jun Song[1], Jung Hyun Kwon[1], Chang Wook Kim[1], Si Hyun Bae[1], Jong Choi[3], Seung Kew Yoon[3] and Jeong Won Jang[3], (1)The Catholic University of Korea, (2)The Catholic University of Korea, Seoul, Korea, (3) Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, Republic of Korea

Background: Pragmatic endpoints, such as time-to-treatment discontinuation (TTD), defined as the duration from starting a medication to the date of treatment discontinuation or death, have been proposed as a potential efficacy endpoint for real-world practice. This study aims to analyze the frequency and severity of immune-related adverse events (irAEs) and TTD in patients with hepatocellular carcinoma (HCC) receiving Atezolizumab and Bevacizumab (A+B) treatment. **Methods:** This retrospective, multi-center study included

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

consecutive HCC patients who received A+B treatment from September 2020 to December 2022. The primary endpoint of the study was the assessment of TTD and overall survival (OS). The associations of factors on outcomes were analyzed using Cox proportional hazards regression and multivariable logistic regression models. **Results:** The study included 150 HCC patients with a median age of 64 years. 85.3% were male, and 69.3% had viral hepatitis etiology. 52% had portal vein tumor thrombus (PVTT). Overall, 34.0% patients experienced grade 3 or higher treatment-related adverse events, with 20.0% reported irAEs. The incidence rates of irAEs were hepatitis (9.3%), colitis (3.3%), severe fatigue (2.0%), pneumonitis (2.0%), cholangitis (1.3%), skin rash (1.3%), myositis (0.7%), asthma (0.7%), and anaphylactic shock (0.7%). The median OS was 13.6 months (95% CI, 8.0-20.6) and the median progression-free survival was 5.7 months (95% CI, 4.0-12.5), while the median TTD was 3.6 months (95% CI, 2.6-5.1). Occurrence of irAEs, female gender, ALBI grade e 2, Child-Pugh class B, and neutrophil-to-lymphocyte ratio (NLR) e 3 and were found to be significantly associated with poor TTD in the univariate analysis. In the multivariate analysis, occurrence of irAEs (HR, 1.765; 95% CI, 1.108-2.813, $p = 0.004$), ALBI grade e 2 (HR, 1.639; 95% CI, 1.054-2.550, $p = 0.028$) and female gender (HR, 1.687; 95% CI, 1.018-2.795, $p = 0.042$) were identified as the independent predictor of TTD. For OS, the univariate analysis showed that irAEs, ALBI grade e 2, Child-Pugh class B, NLR e 3, PVTT and tumor size (e 7cm) were found to be significant. The occurrence of irAEs (HR, 2.423; 95% CI, 1.371-4.280, $p = 0.002$), ALBI grade e 2 (HR, 2.926; 95% CI, 1.511-5.667, $p = 0.001$), Child-Pugh class B (HR, 2.685; 95% CI, 1.258-5.308, $p = 0.005$), and PVTT (HR, 2.029; 95% CI, 1.159-3.552, $p = 0.013$) were identified as the independent predictor of OS. **Conclusion:** In our multicenter retrospective cohort study, the combination therapy of A+B demonstrated significant efficacy. Our results highlight the importance of TTD as an important outcome measure, encompassing both disease progression and treatment discontinuation. We identified irAEs as an independent prognostic factor for A+B treatment. Thus, it is crucial to actively monitor and manage irAEs to optimize treatment outcomes.



Disclosures: The following people have nothing to disclose: Heechul Nam, Ji Won Han, Soon Kyu Lee, Hyun Yang, Haelim Lee, Pil Soo Sung, Hee Yeon Kim, Myeong Jun Song, Jung Hyun Kwon, Chang Wook Kim, Si Hyun Bae, Jong Choi, Seung Kew Yoon, Jeong Won Jang

92 | MOLECULAR SIGNATURE OF PERIPHERAL CIRCULATING TUMOR CELLS IN CANCER PROGRESSION OF HEPATOCELLULAR CARCINOMA PATIENTS TREATED BY ATEZOLIZUMAB PLUS BEVACIZUMAB

Yosuke Murata[1,2], Takuto Nosaka[1], Tatsushi Naito[1], Kazuto Takahashi[1], Yu Akazawa[1], Hidetaka Matsuda[1], Masahiro Ohtani[1] and Yasunari Nakamoto[1], (1) University of Fukui, (2)Sugita Genpaku Memorial Obama Municipal Hospital

Background: The mechanisms leading to cancer progression of hepatocellular carcinoma (HCC) such as acquired resistance to immunotherapies and metastatic progression are not clear. Circulating tumor cells (CTCs) have been defined as cancer cells released into the blood circulation from primary tumor. CTCs have notable advantages in that they are noninvasive and real-time biomarker that provide information about metastatic process. CTC analysis has the potential to reveal the mechanism of disease progression and is expected to be applied clinical use such as treatment decision. We investigated the changes in CTC counts and gene expression related to cancer progression in patients with unresectable HCC treated by Atezolizumab plus Bevacizumab. **Methods:** We obtained 5mL of peripheral blood from 15 HCC patients treated with Atezolizumab plus Bevacizumab at baseline and response evaluation. Treatment response was assessed by modified RECIST. CTCs were isolated with RosetteSep™ Human CD45 Depletion Cocktail and enriched cells were stained with monoclonal antibodies targeting the cell surface antigens including CD45, CD90, CD133, Pan-CK, EpCAM, and Vimentin. The cells were counted by flow cytometry using a FACSAria II. CD45 negative and Pan-CK positive cells were defined as CTCs. RNA was extracted from enriched cells and 373 genes related to cancer progression were investigated by next-generation sequencing (NGS) on Illumina Miseq and gene set enrichment analysis (GSEA) was performed. **Results:** Median CTC counts of PR/SD group decreased at response evaluation, compared with baseline (127 ± 43 vs. 58 ± 6, $p < 0.05$) and is lower compared with PD group at response evaluation (58 ± 6 vs. 153 ± 12, $p < 0.05$). In NGS analysis of 373 genes, 99 genes

showed significant expression changes in clinical course. Unsupervised hierarchical clustering analysis with the changes of 99 genes expression levels classified into two clusters A and B. Patients in cluster A were responder with Atezolizumab plus Bevacizumab and showed 100.0% survival rate at 1-year, which was better than 50.0% survival rate in cluster B ($p = 0.06$). GSEA showed that the genes expression of apoptosis signaling pathway (FAS, BCL2) were significantly upregulated in responder group (cluster A). TGF-beta signaling pathway-related genes (TGF-β1, SMAD2) were upregulated in non-responder group (cluster B) in clinical course of Atezolizumab plus Bevacizumab ($p < 0.05$). **Conclusion:** In HCC patients treated by Atezolizumab plus Bevacizumab, the change of CTC counts was related to therapeutic effect. The gene expression analysis of CTCs showed that apoptosis signaling pathway-related genes were upregulated in responder group and the activation of TGF-beta signaling pathway may play an important role in resistance to Atezolizumab plus Bevacizumab. CTC in HCC patients treated by immunotherapy may be a notable biomarker that reveal molecular signature of cancer progression.

93 | CLINICAL IMPACT OF CEUS ON INDETERMINATE LIVER NODULES ON MRI: SUB-ANALYSIS FROM A PROSPECTIVE MULTICENTER TRIAL

Yuko Kono[1], Fabio Piscaglia[2], Stephanie R Wilson[3], Alexandra Medellin[3], Shuchi K Rodgers[4], Paul S Sidhu[5], Aya Kamaya[6], David Fetzer[7], Virginia Planz[8], Annalisa Berzigotti[9], Lisa Finch[10], Corinne Wessner[11], Kristin Bradigan[11], John Eisenbrey[11], Flemming Forsberg[11] and Andrej Lyshchik[11], (1)University of California, San Diego, (2)University of Bologna, (3) University of Calgary, (4)Einstein Medical Center, (5) King's College Hospital, (6)Stanford University, (7) University of Texas, Southwestern Medical Center, (8) Vanderbilt University, (9)University of Bern, (10) Swedish Medical Center, (11)Thomas Jefferson University

Background: Contrast-enhanced ultrasound (CEUS) is a promising diagnostic technique for hepatocellular carcinoma (HCC) diagnosis. While EASL HCC guidelines endorse its use in cases of inconclusive CT or MRI based on non-focused studies, the diagnostic potential of CEUS for HCC is not currently recognized by AASLD guidelines. This study aimed to assess the clinical impact of CEUS specifically in cases where liver lesions were indeterminate on MRI. **Methods:** A prospective international multicenter validation study for CEUS LI-RADS (Liver Imaging Reporting And Data System) was conducted between January 2018 and August 2021. A total of 594 patients at risk for HCC were enrolled. CEUS was performed using intravenous administration of Lumason (Bracco Diagnostic) within 4 weeks of MRI, and the liver nodules were classified based on CEUS and MRI LI-RADS criteria. Tissue histology and CT/MRI imaging follow-up were used as the reference standard. **Results:** A total of 545 nodules reached a final diagnosis based on the reference standard. Among them, 75 nodules with indeterminate MRI characterization (LR-NC: non categorizable, and LR-3: intermediate probability of HCC) were selected for analysis. Reference standard used was follow up CT/MRI (54, 72%), biopsy (14, 18.7%), and explant histology (7, 9.3%). Among the nodules categorized as LR-NC on MRI (n = 21), one was CEUS LR-1, was determined to be benign, all 6 CEUS LR-5 were confirmed to be HCC and 2 LR-M were malignant resulting in a clinical impact in 42.9% (9/21). In the case of LR-3 on MRI (n = 54), there were a total of 14 HCCs, with 7 CEUS LR-4 (probable HCC) and 7 CEUS LR-5. CEUS LR-1 (n = 1) and LR-2 (n = 6), were all benign (100% NPV). PPV of CEUS LR-5 for HCC was 100%. There was one CEUS LR-TIV, and biopsy confirmed poorly differentiated HCC. However, in the case of one CEUS LR-M, the follow-up MRI revealed LR-2, suggesting a false positive CEUS result. When LR-NC and LR-3 lesions on MRI (n = 75) were combined, CEUS LR-1 (n = 2) and LR-2 (n = 6), nodules were all benign, CEUS LR-5 (n = 13) were all HCC. Two CEUS LR-M from LR-NC and one CEUS LR-TIV from LR-2 were malignant, resulting in a clinical impact in 32% (24/75). CEUS had one false positive LR-M case, which was benign on follow up MRI. **Conclusion:** CEUS LI-RADS demonstrated high clinical impact in liver nodules with indeterminate MRI characterization accurately, identifying both non-malignant lesions, HCC and other malignancy in 32% of patients. These findings highlight the significant clinical value of CEUS in the characterization and diagnosis of liver lesions, particularly in cases where MRI findings are inconclusive or indeterminate.

94 | CT-BASED DEEP LEARNING MODEL OF HEPATIC VENOUS PRESSURE GRADIENT FOR PREDICTING THE PROGNOSIS OF HEPATOCELLULAR CARCINOMA WITH TRANSARTERIAL CHEMOEMBOLIZATION (CHANCE-CHESS): A MULTICENTER COHORT STUDY

Yuqing Wang[1], Zhi-Cheng Jin[1], Qian Yu[1], Biao Luo[1], Chuan Liu[1], Jianjian Chen[1], Tao Pan[1], Li Chen[1], Haidong Zhu[1], Shenghong Ju[1], Xiaolong Qi[2] and Gaojun Teng[1], (1)Zhongda Hospital, Medical School, Southeast University, (2)Zhongda Hospital, Medical School, Nanjing, Jiangsu, China

Background: To evaluate the impact of CT-based deep learning model of hepatic venous pressure gradient (HVPG) on prognosis of hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolization (TACE) and systemic therapy. **Methods:** A total of 261 consecutive HCC patients treated with TACE and systemic therapy, and had a contrast-enhanced abdominal CT as part of their pre-surgical work-up, were retrospectively collected between January 2010 and December 2021. A CT-based HVPG Score, whose computed formula was: 17.37-4.91*ln(Liver/Spleen volume ratio) +3.8[If presence of peri-hepatic ascites],was used to diagnose portal hypertension (image-based CSPH, iCSPH for short) with a cut-off value 11.606. The 3D liver and spleen volume were automate calculated by a deep learning segmentation model, and the presence of peri-hepatic ascites was diagnosed by two independent investigators in portal-venous phase CT. Overall survival (OS) as study endpoint was analyzed by Kaplan-Meier and Cox regression. **Results:** Among 261 patients, 80(30.7%) were diagnosed with iCSPH by CT-based HVPG Score. The median OS in iCSPH group was significantly shorter than non-iCSPH group (16.9 mo vs. 20.7 mo, $p = 0.022$). Multivariable analysis indicated that the presence of iCSPH was a negative prognostic factor for OS (adjusted hazard ratio [HR], 1.423, $p = 0.045$). **Conclusion:** The segmentation model shows good performance in liver and spleen segmentation in HCC patients, which may help non-invasive HVPG assessment and other CT imaging studies in HCC patients. CT-based HVPG Score was significantly associated with poor outcome and should be taken into consideration when managing HCC patients underwent TACE and systemic therapy.

Background: The existing hepatocellular carcinoma (HCC) risk scores have modest accuracy and most are specific to chronic hepatitis B. In this study, we developed and validated a liver stiffness-based machine learning algorithm (ML) for prediction and risk stratification of HCC in various chronic liver diseases (CLDs). **Methods:** MLs were trained for prediction of HCC in 5155 adult patients with various CLDs in Korea and further tested in two prospective cohorts from Hong Kong (HK, N = 2732) and Europe (N = 2384). Model performance was assessed according to Harrell's C-index and time-dependent receiver operating characteristic (ROC) curve. **Results:** We developed the LSM-XGB HCC score, a liver stiffness-based ML HCC risk score, with liver stiffness measurement ranked as the most important among 9 clinical features (Figure). The Harrell's C-index of the LSM-XGB HCC score in HK and Europe validation cohorts were 0.89 (95% confidence interval [CI] 0.85-0.92) and 0.91 (95%CI 0.87-0.95), respectively. The area under ROC curves of the LSM-XGB HCC score for HCC in 5 years were ≥ 0.89 in both validation cohorts. The performance of LSM-XGB HCC score was significantly better than existing HCC risk scores including aMAP score, Toronto HCC risk index, and seven hepatitis B related risk scores. Using a cutoff of 0.045, 82.7% and 89.0% of patients in HK and Europe validation cohorts were classified as low-risk for a possible exemption from HCC surveillance, respectively; the annual HCC incidence for low-risk group was 0.10%-0.19%. The high-risk group had an annual HCC incidence of 1.91% and 2.63% in the HK and Europe validation cohorts, respectively. **Conclusion:** The LSM-XGB HCC score is a useful machine learning-based tool for clinicians to stratify HCC risk in patients with CLDs.

96 | A DEEP LEARNING-BASED HEPATOCELLULAR CARCINOMA STAGING SYSTEM BY MULTI-PHASE COMPUTED TOMOGRAPHY

Chia-Shin Wei[1], Po-Chuan Wang[1], Hsinhan Tsai[1], Weichung Wang[1], Che Lin[1] and Tung-Hung Su[2], (1) National Taiwan University, (2)National Taiwan University Hospital

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer. The Barcelona Clinic Liver Cancer (BCLC) staging system is widely used to diagnose and manage HCC. However, currently, automated image-based staging algorithms are lacking. This study aims to automate the BCLC staging process

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

using deep learning techniques on multi-phase abdominal computed tomography (CT) images to enhance efficiency with good accuracy. **Methods:** This study utilizes two open datasets: Multimodality annotated HCC cases with and without advanced imaging segmentation (HCC-TACE-Seg) dataset and The Medical Segmentation Decathlon (MSD) Liver dataset. A novel two-stage deep learning pipeline for automatic BCLC staging was generated. We employ an automatic segmentation model in the proposed pipeline to locate the liver and possible lesions. Then, a 3D image classification model is applied to the liver to identify the lesions for BCLC staging. We adopt the nnU-Net as our segmentation model backbone. The segmentation model is trained and evaluated on the combined HCC-TACE-Seg and MSD datasets. For the BCLC staging model, we adopt the 3D ResNet as our model backbone and train on the HCC-TACE-Seg dataset. Furthermore, we proposed three inter-phase fusion techniques (early fusion, intermediate fusion, and late fusion) to utilize the information from the multi-phase CT images. **Results:** Our liver segmentation results were consistent with existing algorithms in accurately delineating the liver region (dice score 0.95), while liver tumor segmentation ranked above average among evaluated methods (dice score 0.64 vs. 0.54). We compared the multi-phase models with single-phase imaging for BCLC staging. Among the proposed multi-phase models, late fusion performed the best, and outperformed single-phase ones with an overall accuracy of 77.78% (vs. 68.89% in the pre-contrast phase and PV phase, 73.33% in A phase), demonstrating the importance of inclusion of different phases of CT images for accurate staging. The best prediction accuracy for BCLC stages A, B, and C were 93.33%, 73.33%, and 66.67% respectively. **Conclusion:** Our numerical experiments demonstrate that the multi-phase staging models outperform the single-phase one and image processing-based method with an accuracy of 77.78%. Overall, the proposed pipeline can aid the radiologist for the BCLC staging process in the future.

97 | DETECTION OF CHOLANGIOCARCINOMA WITH PROTEASE ACTIVITY PROBES

Jesse Kirkpatrick[1,2], Janvi Huria[3], Pinzhu Huang[4], Daniela Sia[5], Yury V. Popov[4] and Sangeeta Bhatia[3,6], (1)MIT, (2)Harvard-MIT, (3)Massachusetts Institute of Technology, (4)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (5)Icahn School of Medicine at Mount Sinai, New York, NY, (6)Howard Hughes Medical Institute

Background: Patients with primary sclerosing cholangitis (PSC) are at a 400-fold increased risk of cholangiocarcinoma (CCA), and are thus recommended to undergo annual screening with magnetic resonance cholangiopancreatography (MRCP). Unfortunately, MRCP findings are nonspecific for CCA in the setting of biliary fibrosis and screening may not confer a survival benefit. We have previously developed a new class of diagnostic tools that detect dysregulated protease activity in the tumor microenvironment. In this work, we sought to leverage one such tool, activatable zymography probes (AZPs), which enable visualization of tumor-associated protease dysregulation *ex vivo* and *in vivo*. Because proteases have been shown to be dysregulated in CCA, we set out to develop a protease activity-based diagnostic for PSC-associated CCA. **Methods:** We induced CCA tumor formation in the *Mdr2*$^{-/-}$ mouse model of biliary fibrosis via hydrodynamic injection of plasmids encoding for AKT and YAP1, and the Sleeping Beauty (SB) transposase (Fig. 1A). We then synthesized a panel of 26 AZPs and applied them to fresh frozen liver tissue sections from tumor-bearing and *Mdr2*$^{-/-}$ mice (Fig. 1B). Finally, we administered PEGylated AZPs into tumor-bearing and *Mdr2*$^{-/-}$ mice and performed IVIS imaging to assess tumor uptake *in vivo* (Fig. 1E). **Results:** We found that 14 AZPs, most notably AZP6, exhibited significantly increased binding to CCA tumors ($p_{adj} < 0.05$, fold change > 1.5) relative to fibrotic bile ducts (Fig. 1C), which was abrogated by protease inhibitors (Fig. 1D, "INH"). We found that AZP6 bound significantly more strongly to cells with high expression of vimentin ($p < 0.01$) and low expression of cytokeratin 7 ($p < 0.001$), suggesting that AZP6 is cleaved by mesenchymal cells (not shown). To assess the generalizability of AZP6 across CCA models, we tested it on tissue sections from an FBXW7/AKT-mutant CCA model and found that it specifically labeled tumors in a pattern similar to that seen in the YAP1/AKT model (not shown). Finally, we found significantly increased fluorescence in explanted livers from mice with CCA after *in vivo* administration of AZP6 ($p < 0.01$) (Fig. 1F, G). **Conclusion:** AZPs detect and localize dysregulated protease activity *ex vivo* and *in vivo* in mouse models of CCA, without false positives from benign biliary fibrosis. Protease-activated diagnostics like AZPs, when used in

98 | A NOVEL 5-POINT SCORING SYSTEM FOR THE DIFFERENTIATION OF HCC FROM INTRAHEPATIC CCA IN LR-M PATIENTS

Rebekka J.S. Salzmann[1], Tudor Mocan[2,3], Cristiana Grapa[3], Lavinia Patricia Mocan[3], Bingduo Wang[1], Rares Craciun[3], Zeno Sparchez[3], Ingo G. Schmidt-Wolf[1], Christian P. Strassburg[1], Arnulf G. Willms[4], Veronika Lukacs-Kornek[1] and Miroslaw T. Kornek[1], (1) University Hospital Bonn, (2)Babes-Bolyai University, (3)Iuliu Haţieganu University of Medicine and Pharmacy, (4)German Armed Forces Central Hospital Hamburg

Background: Despite recent developments, it is still very difficult to differentiate hepatocellular carcinoma (HCC) from intrahepatic cholangiocarcinoma (iCCA). Clinically available methods such as CT, MRI, and contrast-enhanced ultrasound require the highest level of investigator experience to reliably differentiate between HCC and iCCA. Here, we used the surface analysis interferometric and fluorescence imaging methodology for small extracellular vesicles (small EVs) analysis in liver cancer category (LI-RADS) M (LR-M) patients. We evaluated their clinical performance and proposed a 5-point system using serological markers to distinguish HCC from iCCA. **Methods:** Small EVs from 24 patients' sera were isolated by size exclusion chromatography (SEC). Particle counts were measured by nanoparticle tracking analysis (NTA). Small EVs were captured on a microarray chip coated with CD9, CD63 and CD81 and surface stained with fluorescent labelled anti-CD133/2 antibody. Surface analysis of small EVs on a single particle level was performed with ExoView® R100 (NanoView Biosciences, Boston, USA). Data analysis was performed using ExoView® Analyzer 3.2. Additionally, thrombocytes, ALP, CRP were assessed. **Results:** 1) Whole sera particle concentrations isolated from iCCA and HCC differ significantly ($p = 0.0364$) with a mean particle concentration/mL ± SD of $1.8x10^{15}$ ± $1.4x10^{15}$in iCCA and $8.2x10^{14}$ ± $5.3x10^{14}$ in HCC (AUROC 0.74, sensitivity and specificity 75% and 58.3%, respectively. 2) Individual small EV subpopulations as characterized by $CD9^+CD133/2^+$ and $CD81^+CD133/2^+$ were significantly elevated in iCCA ($CD9^+C133/2^+$: $p = 0.0315$, AUROC 0.74 and $CD81^+CD133/2^+$: $p = 0.0244$, AUROC 0.826). 3) Thrombocytes, ALP and CRP were elevated in iCCA compared to HCC. ($p = 0.0238$ and AUROC 0.76; $p = 0.0023$ and AUROC 0.85; $p = 0.0092$ and AUROC 0.88, respectively). 4) On an individual basis, each biomarker such as particles, small EVs, thrombocytes, ALP, and CRP did not achieve sensitivity or specificity greater than 80%. However, when each biomarker was converted into a binary categorical variable and a final score was calculated by assigning a point for each factor to the biomarker's cut-off value below it, samples could be scored from 0 to 5. Samples with a score of 3 to 5 were categorized as HCC and 0 to 2 points as iCCA, resulting in a diagnostic performance with a sensitivity of 100% and a specificity of 83.3%. **Conclusion:** Regarding the heterogeneity among liver cancer entities it was found that a combined consideration of biomarkers exceeds the diagnostic value of a single marker. Using a 5-point scoring system we were able to differentially diagnose 24 LR-M patients with HCC or iCCA with a sensitivity of 100 % and specificity of 83.3%. Our findings suppose that combining small EVs with serological biomarkers could improve the diagnostic performance of liquid biopsy markers in a clinical context.

Background: Hepatocellular carcinoma (HCC) is a major cause of mortality worldwide. Providing precision medicine to patients is a key unmet need. Preclinical models, when accurately reflecting human disease, offer an opportunity to understand varying therapeutic responses between different patient groups. We aimed to develop a suite of genetically engineered mouse models (GEMMs), link them to human subtypes of HCC and integrate this with a cross-species organoid platform, to ultimately identify and test new therapies in human-relevant pre-clinical models. **Methods:** We developed a suite of 25 new GEMMs, modelled upon HCC-relevant mutations. We characterised these transcriptionally alongside classic non-genetic mouse models of HCC and used computational approaches to positionally align the mice to human HCC data. Integration of this data permitted the development of new cross-species molecular subclasses of HCC. We validated the subclasses histologically, performed organoid-based screening, and tested numerous therapeutic responses *in vivo*. **Results:** Our GEMMs exhibited many of the typical features of human HCC, including clonal origin, heterogeneity, histopathology, and disease progression, including metastasis. We classified four cross-species clusters (HuMo clusters) in the transcriptomic alignment using our specific algorithm. These HuMo clusters showed distinct characteristics including differentiation grade, degree of steatosis, and inflammatory profile. As proof of concept, we showed subtype specific responses to standard of care treatments within, and differing between, murine representative models of the clusters. Furthermore, the linked *in vivo – in vitro* approach identified a novel therapeutic candidate capable of priming immune-checkpoint inhibition (ICI) responses in previously ICI-resistant tumors. **Conclusion:** Our newly developed GEMMs show distinct subclass-specific features of human HCC. They present a platform for informing translational research and performing more in-depth mechanistical studies of HCC. We show that, by using multiple integrated resources, linking patient data with suitable preclinical *in vivo* and *in vitro* organoid models, we are able to propel therapeutic options forward towards precision medicine for HCC.

100 | A POSITIVE FEEDBACK BETWEEN CHOLESTEROL SYNTHESIS AND THE PENTOSE PHOSPHATE PATHWAY RATHER THAN GLYCOLYSIS PROMOTES HEPATOCELLULAR CARCINOMA

Ningning Liu, Chinese Academy of Sciences and Guisheng Song, University of Minnesota

Background: Hepatic cholesterol accumulation and hypercholesterolemia are considered as the risk factors of hepatocellular carcinoma (HCC). However, the therapeutic effects of cholesterol lowering drugs for the treatment of HCC are controversial, indicating that the relationship between cholesterol metabolism and HCC is more complex than anticipated. **Methods:** FVB/NJ mice were hydrodynamically injected with c-Myc and *Sleeping Beauty* to induce HCC. UPLC-MS/MS was used to analyze metabolites of glycolysis and the pentose phosphate pathway (PPP). ^{14}C-acetate sodium and ^{3}H-thymidine were used to measure cholesterol synthesis and DNA synthesis, respectively. A dual-AAV8-based CRISPR/Cas9 was used to ablate the binding site of miR-206 within the 3'UTR (untranslated region) of its target genes. **Results:** Activation of cholesterol synthesis, glycolysis and the pentose phosphate pathway (PPP) was observed in HCC patients and c-Myc HCC mouse model. A positive feedback between cholesterol synthesis and the PPP was formed in tumors of c-Myc mice. Blocking the PPP prevented cholesterol synthesis and thereby development of HCC in c-Myc mice, while ablation of glycolysis did not affect cholesterol synthesis and failed to prevent c-Myc-induced HCC. Unexpectedly, *HMGCR* (3-hydroxy-3-methylglutaryl-CoA reductase) and *G6PD* (glucose-6-phosphate dehydrogenase), the rate-limiting enzymes of cholesterol synthesis and the PPP, were identified as direct targets of microRNA-206. By targeting *Hmgcr* and *G6pd*, microRNA-206 disrupted the positive feedback between cholesterol synthesis and the PPP, thereby inhibiting DNA synthesis and hepatocyte proliferation. Hydrodynamic injection (HDI) of microRNA-206 fully prevented HCC in c-Myc mice, while 100% of control mice dies of HCC. Disrupting the interaction of microRNA-206 with *Hmgcr* and *G6pd* restored cholesterol synthesis, the PPP and HCC growth in microRNA-206-treated c-Myc mice. **Conclusion:** This study identified a previously undescribed positive feedback loop between cholesterol synthesis and the PPP, which drives HCC development by providing substrate of DNA synthesis and energy for hepatocyte proliferation, while microRNA-206 prevents HCC by disrupting this loop. Cholesterol synthesis as a process rather than cholesterol itself is the major contributor of HCC, which at least in part explains the controversial findings of cholesterol-lowering drugs for the treatment of HCC.

Background: Active HCV infection has decreased with the introduction of direct-acting antivirals (DAAs). However, a subset of patients remains at risk for HCC development even after achieving a sustained virologic response (SVR). Chemopreventive measures post SVR are urgently needed to reduce incident HCC. **Methods:** We first validated our previously reported Prognostic Liver Signature (PLS) for association with post-SVR HCC risk in two independent cohorts of HCC-naïve (n = 41) and HCC-experienced (n = 85) patients with longitudinal observation up to 20 years. Post-SVR HCC risk driver genes were determined using multiscale embedded gene co-expression network analysis and based on association with time to HCC development. Candidate compounds targeting the HCC risk driver genes were tested for PLS modulation in a PLS-inducible cell culture system (cPLS) and ex vivo culture of clinical precision-cut liver slice (PCLS) for PLS modulation. HCC-preventive effect of the compound was assessed in two mouse models of HCC development: fibrosis/HCC induced by DEN + CCl4 and NASH HCC induced by genetic knockout of Pten and Scap genes (Pten/Scap-ko). **Results:** PLS was associated with long-term post-SVR HCC incidence in the HCC-naïve (adjusted hazard ratios [aHR], 5.02; 95% CI, 1.26-19.9) and HCC-experienced (aHR, 2.28; 95% CI, 1.01-5.15) patient cohorts. Among the PLS member genes, 19 putative key HCC risk driver genes were identified, including DDR1 as the most strongly associated with time to HCC development in multiple independent clinical cohorts. A comprehensive computational compound screening suggested a small molecule DDR inhibitor as a top candidate for reversal of high-risk PLS. A clinically developed DDR1 inhibitor, 7rh, significantly reversed high-risk PLS in the in vitro cPLS system and ex vivo PCLS culture. Further, 7rh diminished HCC development in the DEN + CCl4 mouse model accompanied by reversal of the high-risk pattern of PLS, whereas this effect was not observed in the Pten/Scap-ko mouse model. No notable toxicity was observed. **Conclusion:** Our pre-clinical study suggests that 7rh is a candidate post-SVR HCC chemoprevention agent with PLS as a companion biomarker to guide its indication and monitor the effect.

102 | EZURPIMTROSTAT AUTOPHAGY BLOCKER, A PALMITOYL-PROTEIN THIOESTERASE 1 (PPT1) INHIBITOR, AND ATEZOLIZUMAB/ BEVACIZUMAB TRIPLE COMBINATION REGIMEN ENHANCES ANTITUMOR EFFICACY IN HEPATOCELLULAR CARCINOMA

Eloine Bestion[1], Soraya Mezouar[1], Antoine Rivière[1], Yan Wang[2], Arnaud Peyronnier[2], Christelle Ansaldi[1], Thomas Decaens[3], Gael Roth[3], Eric Raymond[1] and Philippe Halfon[1], (1)Genoscience Pharma, (2)Inovotion SAS, (3) Univ. Grenoble Alpes, Institute for Advanced Biosciences-Inserm U1209/ Cnrs Umr 5309, Clinique Universitaire d'Hépato-Gastroentérologie, CHU Grenoble Alpes

Background: Immune checkpoint therapies combination with anti-VEGF is the standard-of-care in first-line of hepatocellular carcinoma (HCC). However, only 30 % of patients present a response to first line therapy. Autophagy inhibitors were recently spotted out as a potential robust strategy to promote antigen presentation and therefore reinforce immune checkpoint inhibitors (ICIs) potency conducting to strong anti-tumoral response. Hereafter, we aimed to assess the efficacy of GNS561 (Ezurpimtrostat), an autophagy inhibitor targeting palmitoyl-protein thioesterase-1 (PPT-1) lysosomal enzyme, in combination with atezolizumab/bevacizumab in HCC in a chicken embryos model. **Methods:** Chorioallantoic membrane (CAM assay) model was used, inoculated with liver adenocarcinoma Hep3B cell line at day 9 (D9). Between D9 and D18, eggs were treated every two day with GNS561 alone (0.92 mg/kg), or in combination with atezolizumab/bevacizumab (at 1 mg/kg/1mg/kg (R1), or 2 mg/kg/2mg/kg (R2)). At D18, the upper portion of the CAM containing tumor is removed. The tumors are cut away from normal CAM tissue and weighed, and the number of dead embryos is counted. A one-way analysis of variance with post-tests is done. No cytotoxicity was reported. **Results:** All regimens induced a significant tumor growth regression compared to the control group, GNS561 alone having a more potent anti-tumoral effect ($p < 0.0004$) compared to both atezolizumab/bevacizumab regimens (R1, $p < 0.0147$; R2, $p < 0.0071$). Interestingly, atezolizumab/bevacizumab combination regimens exhibited no significant difference between the two tested dose-regimens. A triple combination regimen led to significantly improved anti-tumoral efficacy compared to the two atezolizumab/bevacizumab groups, for comparable dosing (R1, $p < 0.0076$, R2, $p < 0.0001$), spotlighting triple combination superior benefit. Results further pointed out GNS561 combination with atezolizumab/bevacizumab significant superior anti-tumor effect at the highest dose in comparison with GNS561 alone, reinforcing the interest of triple therapy ($p < 0.0030$). **Conclusion:** This study reports that GNS561 potentiates the anti-tumor effect of atezolizumab/bevacizumab combination emphasizing PPT1 inhibitors' therapeutic interest in combination with immunotherapy in HCC. This triple therapy is currently tested in the randomized phase 2 clinical trial ABE-LIVER, in first line setting in advanced HCC (NCT05448677).

103 | PSMP INHIBITS HCC PROGRESSION BY REGULATING THE POLARIZATION OF TUMOR-ASSOCIATED MACROPHAGES THROUGH THE PI3K/AKT PATHWAY

Shaoping She[1], Liying Ren[1], Dongbo Chen[1] and Hongsong Chen[2], (1)Peking University People's Hospital, (2)Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease

Background: Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver and represents a major global health-care challenge. PC3

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

secreted microprotein (PSMP) is a novel chemotactic cytokine that can recruit peripheral blood monocytes and lymphocytes through its chemokine receptor CCR2. Our previous study found that PSMP is significantly highly expressed in human and mouse liver fibrosis/cirrhosis. PSMP promotes the progression of liver fibrosis by regulating the infiltration, activation and polarization of macrophages. However, the relationship between PSMP and the development and prognosis of HCC remains unclear. **Methods:** The expression of PSMP was detected in two independent HCC patients cohorts and its correlation with patients' prognosis was analyzed. *In vivo*: In PSMP knockout (*Psmp*$^{-/-}$) and wild-type (WT) mice, subcutaneous tumorigenesis models and liver orthotopic tumorigenesis models were established using two mouse HCC cell lines (Hepa1-6, H22); In nude mice, subcutaneous tumorigenesis models were established using two human HCC cell lines (Huh7, HepG2). The direct effects of PSMP on the polarization of macrophages (human THP-1 cell line and mouse bone marrow-derived macrophages (BMDMs) were studied *in vitro*. In addition, we performed RNA sequencing of BMDMs from *Psmp*$^{-/-}$ and WT mice. **Results:** Through the detection of clinical HCC patient samples, we found that PSMP is downregulated in human HCC tissues, and its expression level is positively correlated with the prognosis of HCC patients. *In vivo*, we found that genetic deletion of PSMP promotes subcutaneous and liver orthotopic tumor growth and metastasis in mice; Overexpression of PSMP inhibits the formation of subcutaneous tumors in nude mice. Mechanistically, the deletion of PSMP substantially suppresses the infiltration of CD8+ tumor-infiltrating lymphocytes (TILs) while promoting the infiltration and polarization of M2 tumor-associated macrophages (TAMs) within the liver. *In vitro,* we observed that PSMP possesses the capacity to induce M1-polarization and suppress M2-polarization of mouse BMDMs and human THP-1 cells. In addition, analysis of RNA sequencing results showed that PSMP may mediate the polarization of macrophages by regulating the PI3K/Akt signaling pathway. Then, we verified that PSMP mediates its inhibitory effect on M2-polarization of macrophages by suppressing the PI3K/Akt pathway through the inhibition of p85 and Akt phosphorylation. **Conclusion:** Collectively, PSMP may inhibit the M2 polarization of TAMs by downregulating PI3K/Akt pathway, and then promote the anti-tumor immune response of CD8+ T cells, and ultimately inhibit the progression of HCC. The results are expected to clarify the role and mechanism of PSMP in the liver tumor microenvironment for the first time, which has important theoretical significance, and may also provide new targets for the treatment of HCC, with potential application value.

104 | SLC1A5 REGULATES LIPID METABOLISM AND FORMS AN IMMUNOSUPPRESSIVE TME IN HCC★

Jialin Liao[1], Wenwen Li[2], Ziyong Zhang[2], Xuejing Zou[2], Dehua Wu[1] and Dongyan Zhang[1], (1)Department of Radiation Oncology, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China, (2) Hepatology Unit and Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China

Background: Tumor microenvironment(TME) reflects the intertwined crosstalk between cancer cells and tumor-infiltrating immune cells, affecting the efficiency of immunotherapy. Metabolic reprogramming, one of the major hallmarks of hepatocellular carcinoma(HCC), is unclear in the aspect of reshaping TME. In this study, we report the vital role of SLC1A5, the major glutamine transporter of tumor cells, in HCC progression and the formation of immunosuppressive TME. **Methods:** TCGA-LIHC cohort was obtained to analyze the expression level of SLC1A5 and its correlation with overall survival(OS) and SLC1A5 expression was further detected in our HCC cohort(metastatic vs non-metastatic patients) by qRT-PCR. The functions of SLC1A5 on HCC were investigated by gain-of-function and loss-of-function assays both *in vitro* and *in vivo*. Flow cytometry analysis, bioinformatics analysis, co-immunoprecipitation, qRT-PCR, Western blotting, and Oil Red O staining were

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

performed to explore the mechanisms of SLC1A5 on HCC progression. **Results:** We found that the expression of SLC1A5 was significantly upregulated in HCC compared with non-tumor tissues among 2 cohorts. Metastatic patients in our cohort markedly upregulated SLC1A5 in the tumor than in the paired non-tumor tissues, while the paired specimens of non-metastatic patients presented identical levels of SLC1A5 expression. And high expression of SLC1A5 predicted poor OS. SLC1A5 overexpression potentiated cellular proliferation and migration, whereas its knock-down significantly attenuated them both *in vitro* and *in vivo.* Besides, SLC1A5-overexpression enhanced the infiltration of Tregs, drove $CD8^+$ T cells exhaustion and macrophage M2 polarization. Mechanistically, we found that SLC1A5 directly binds to lipid synthesis enzymes that engage in fatty acid elongation. SLC1A5 knockdown not only reduced lipid droplets but also decreased the expression of lipid synthesis and elongation-related genes, which is associated with poor survival. Finally, blocking SLC1A5 by GPNA effectively inhibits tumor growth and reduces Tregs infiltration. **Conclusion:** Our results reveal that SLC1A5 plays a pivotal role in the development of HCC by directly interacting with lipid metabolic enzymes to facilitate tumor cell proliferation and migration, thereby constructing an immunosuppressive TME. Hence, SLC1A5 may serve as a novel prognostic biomarker and therapeutic target in HCC, and SLC1A5 blockade holds the promise to counteract immunotherapy resistance.

105 | REPROGRAMMING THE INTRAHEPATIC CHOLANGIOCARCINOMA IMMUNE MICROENVIRONMENT BY CHEMOTHERAPY AND CTLA-4 BLOCKADE ENHANCES ANTI-PD1 THERAPY

Jiang Chen[1,2], Zohreh Amoozgar[1], Xin Liu[1], Shuichi Aoki[1], Zelong Liu[1], Aya Matsui[1], Zhangya Pu[1], Stefan Halvorsen[1], Pin-Ji Lei[1], Won Jin Ho[3], Peigen Huang[1], Rakesh Jain[1], Nabeel M. Bardeesy[4] and Dan G. Duda[5], (1)Massachusetts General Hospital and Harvard Medical School, Boston, USA, (2)Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou, China, (3) Johns Hopkins School of Medicine, Baltimore, USA, (4) Department of Medicine, Division of Oncology, Massachusetts General Hospital, Boston, Harvard Medical School, Boston, USA, (5)Massachusetts General Hospital

Background: Intrahepatic cholangiocarcinoma (ICC) has limited therapeutic options and dismal prognosis. Anti-PD-L1 immunotherapy combined with gemcitabine/cisplatin chemotherapy has recently shown efficacy in biliary tract cancers, but responses are seen only in a minority of patients. Here, we studied the roles of anti-PD1 and anti-CTLA-4 immune checkpoint blockade (ICB) therapies when combined with gemcitabine/cisplatin and the mechanisms of treatment benefit in orthotopic murine ICC models. **Methods:** We evaluated the effects of the combined treatments on ICC vasculature and immune microenvironment using flow cytometry analysis, immunofluorescence, imaging mass cytometry, RNA-sequencing, qPCR, and in vivo T-cell depletion and CD8 + T-cell transfer using orthotopic ICC models and transgenic mice. **Results:** Combining gemcitabine/cisplatin with anti-PD1 and anti-CTLA-4 antibodies led to substantial survival benefits and reduction of morbidity in two aggressive ICC models, which were ICB-resistant. Gemcitabine/cisplatin treatment increased the frequency of tumor-infiltrating lymphocytes and normalized the ICC vessels, and when combined with dual CTLA-4/PD1 blockade, increased the number of activated CD8 + Cxcr3 + IFN-γ + T-cells. Depletion of CD8 + but not CD4 + T-cells compromised efficacy. Conversely, CD8 + T-cell transfer from Cxcr3 –/– versus Cxcr3 +/+ mice into Rag1 –/– immunodeficient mice restored the anti-tumor effect of gemcitabine/cisplatin/ICB combination therapy. Finally, rational scheduling of the ICBs using anti-CTLA-4 “priming” with chemotherapy followed by anti-PD1

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

therapy achieved equivalent efficacy with continuous dosing while reducing overall drug exposure. **Conclusion:** Gemcitabine/cisplatin chemotherapy normalizes vessel structure, increases activated T-cell infiltration, and enhances anti-PD1/CTLA-4 immunotherapy efficacy in aggressive murine ICC. This combination approach should be clinically tested to overcome resistance to current therapies in ICC patients.

106 | HEPATOCYTE DELETION OF REGULATORY T CELLS BY ENCLYSIS IS INCREASED IN AUTOIMMUNE HEPATITIS COMPARED TO MASH AND CAN BE TOGGLED BY PPARA AGONISTS AND ANTAGONISTS★

Yiyu Fan[1], Zania Stamataki[1], Aekkachai Tuekprakhon[1], Rebecca Sinclair[1], Federica Pandolfini[2], Robert Bryce[1], Harriet Hill[1], Kulvinder Jennifer Gill[3], Gary Reynolds[3], Nicholas Barnes[4] and Omar Qureshi[5], (1)Institute of Immunology and Immunotherapy, University of Birmingham, (2)Cancer Research Horizons, UK, (3) Centre for Liver and Gastrointestinal Research, Nihr Birmingham Liver Biomedical Research Unit, University of Birmingham, (4)Institute of Clinical Sciences, College of Medical and Dental Sciences, University of Birmingham, (5)Celentyx Ltd, UK

Background: The liver is a tolerising organ, to prevent continuous immune activation following the portal influx of antigens from the gut. Regulatory T cells (Treg) dampen inflammation and are important to prevent liver injury. We discovered that hepatocytes engulf and delete live Treg cells by *enclysis*, which was distinct from known cell-in-cell structure processes and thus can be targeted specifically (PMID: 31693899). Understanding how enclysis is modulated will enable us to toggle Treg cell frequencies in the liver and dampen inflammation or boost immunity as required. We investigated the role of Peroxisome proliferator-activated receptor alpha (PPAR±) in the modulation of enclysis. **Methods:** FoxP3, Tbet and PPAR± were assessed in non-cirrhotic livers, AIH and MASH (n = 30) by immunohistochemistry (IHC). To test pharmacological inhibitors of enclysis in vitro, we set up a fluorescence-based high content assay using Huh-7 cells and Jurkat cells as models for hepatic epithelia and CD4+ T cells respectively, and tested titrations of Clofibric Acid, Fenofibrate, and GW6471. Cell-in-cell structures were quantified using custom rule-based algorithms in collaboration with Celentyx Ltd. Hits were validated in concentration-response assays using confocal microscopy. **Results:** Enclysis for Treg cells, but not Th1 cells, was reduced in AIH compared to MASH livers ($p = 0.0019$). PPAR± agonists Clofibric Acid ($p = 0.0156$) and Fenofibrate ($p = 0.0156$) reduced enclysis, and PPAR± antagonist GW6471 increased enclysis in vitro ($p = 0.02$). In non-cirrhotic livers, PPAR± was expressed in periportal hepatocytes and less in mid-lobular hepatocytes. MASH was similar, with high PPAR± in peri-fibrous regions and low in mid-lobular hepatocytes. Conversely, AIH liver explants showed reduced PPAR± in all hepatocytes, consistent with increased enclysis (Fig.1). **Conclusion:** The natural deletion of Treg cells by hepatocytes was increased in AIH compared to MASH, revealing enclysis as a new target for therapeutic intervention to dampen inflammation. The robust modulation of enclysis by PPAR± agonist and antagonist compounds suggests that enclysis can be toggled pharmacologically to control Treg cell frequencies specifically in the liver. The reduction of hepatocyte PPAR± expression in AIH compared to healthy livers and to MASH, proposes a role for aberrant PPAR± expression in the pathogenesis of AIH, which needs further investigation. Keywords: Enclysis, inflammation, regulatory T cells, fibrates, PPARalpha, fenofibrate, clofibrate, AIH, MASH

107 | CHOLANGIOCYTE-MEDIATED INFILTRATION OF NEUTROPHILS IN THE PERI-PORTAL REGION INDUCES OXIDATIVE STRESS IN PRIMARY SCLEROSING CHOLANGITIS

Abid Anwar[1,2], Jordan Young[3], Usman Yaqoob[4], Sofia Jerez[1], Robert C. Huebert[4] and Nidhi Jalan-Sakrikar[3], (1)Mayo Clinic, Rochester, MN, (2)University of Illinois College of Medicine, (3)Mayo Clinic, (4)Mayo Clinic Rochester, Rochester, MN

Background: Primary Sclerosing Cholangitis (PSC) manifests with fibrotic scarring of the intrahepatic and extrahepatic bile ducts due to an immune-mediated inflammatory response. The cyclic GMP–AMP synthase –stimulator of interferon genes (cGAS-STING) signaling pathway is a key mediator of inflammatory gene expression and cytokine release in response to cellular stress. The inflammatory milieu observed in PSC recruits immune cells, including neutrophils, to infiltrate the peri-portal region. Our goal is to investigate the mechanism of neutrophil homing to the biliary tree and the crosstalk between neutrophils and cholangiocytes. **Methods:** Immunofluorescence (IF) was performed on liver tissues from PSC patients and mouse models of PSC (3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC)-fed mice and Mdr2-/- mice) for markers of bile ducts and neutrophils (KRT19 and MPO). RT-PCR was employed on whole liver tissue for the neutrophil marker, MPO. Immunohistochemistry (IHC) for 8-hydroxy-2' -deoxyguanosine (8-OHDG) was used to mark oxidative damage in liver tissues. Cholangiocyte-derived organoids (cholangioids) from wildtype and Mdr2-/- mice were analyzed for DNA damage using RT-PCR, western blotting, and immunostaining. cGAS-STING activation was evaluated by immunoblotting and IF. The NanoString NCounter assay was performed on mice liver tissues to investigate chemoattractants for neutrophils. Cholangiocytes isolated from mice injected with lipopolysaccharide (LPS) and H69 cells treated with LPS (to induce an inflammatory response) were analyzed for proinflammatory cytokines and components of the cGAS-STING pathway. **Results:** Increased presence of peri-portal neutrophils was observed from PSC patient and mouse liver tissues compared to controls (6.7 ± 1.74-fold, $p < 0.0005$, $n = 5$). RT-PCR analysis from Mdr2-/- and DDC-fed mice tissues revealed increased gene expression of the neutrophil marker, MPO, compared to chow-fed mice (5-fold and 4.5-fold respectively, $p < 0.05$). Congruently, oxidative stress was significantly increased in these liver tissues as shown by 8-OHDG staining. Immunostaining of Mdr2-/- cholangioids confirmed an increase in the DNA damage marker, 53BP1, compared to WT cholangioids. Downstream of DNA damage, we observe activation of the cGAS-STING pathway by immunoblotting for STING and IF for Phospho-STING in mouse models. Ncounter analysis revealed a ~30-fold upregulation of the chemokine, CCL2, in DDC-fed and Mdr2-/- mice liver tissues. This was further confirmed in primary cholangiocytes isolated from LPS-treated mice and H69 cells treated with LPS. **Conclusion:** Our findings suggest that activation of the cGAS-STING pathway in cholestatic liver disease triggers an immune response including peri-portal neutrophil infiltration. This infiltration propagates oxidative stress and perpetuates the biliary fibrosis and inflammation characteristics of PSC.

108 | TARGETING OF INFLAMMATORY MONOCYTES VIA CCL2/CCR2 SIGNALING AS A THERAPEUTIC STRATEGY AGAINST AUTOIMMUNE HEPATITIS BY USING MACROPHAGE-DERIVED EXTRACELLULAR VESICLES

Xiaoli Fan[1], Ruiqi Wu[2], Xiaoze Wang[3] and Li Yang[1], (1) West China Hospital, Sichuan University, (2)West China Hospital, Sichuan University, Chengdu, Sichuan, China., (3)West China Hospital

Background: Autoimmune hepatitis is a serious chronic liver disease with immune disorders, histological lesions and liver dysfunction, with a gradually increasing prevalence. Yet the cellular and molecular mechanisms of immune dysregulation in AIH are poorly understood. **Methods:** Using proteomic analysis, we comprehensively profiled the differentially expressed proteins and signaling pathways of liver during human AIH. Then, monocytes and macrophage from blood and livers of AIH patients and controls were analyzed. The recruitment and polarization of monocyte-derived macrophages in AIH and the mechanism of CCL2/CCR2 axis activation were investigated by Concanavalin induced experimental AIH (EAH). The CCL2/CCR2 axis was blocked by CCL2 neutralizing antibody and CCR2 antagonist to determine its effect on AIH mice. Finally, M2 macrophage-derived extracellular vesicles (M2-EVs) were isolated and extracted as drug delivery tool of CCR2 antagonist, and its therapeutic effect on AIH mice was determined. **Results:** Proteomic analysis took expression ratio (FC) > 1.5 times and $p < 0.05$ as screening criteria, and a total of 1028 proteins were identified as increased or decreased. KEEG analysis suggested that differential expressed proteins were mainly associated with metabolic processes. The expression of mononuclear macrophage system marker proteins were increased in the liver tissue of AIH patients as revealed by proteomic analysis and immunohistochemistry. The proportion of classical monocytes in peripheral blood of AIH was increased, which was positively correlated with the levels of ALT and AST of AIH patients. The co-localization analysis of liver tissue suggested that CCL2 originated from Kupffer cells (KC), and the expression of CCR2 increased after circulating monocytes infiltrated liver. The expression of M1 marker in AIH liver tissue increased. AIH mouse models suggest mobilization of inflammatory monocytes on the bone marrow-liver axis and spleen-liver axis. Blocking-up of CCL2/CCR2 axis with CCL2 neutralizing antibody or CCR2 antagonist, respectively, alleviated liver injury in AIH mice, while recombinant CCL2 injection increased recruitment of inflammatory monocytes with bone marrow-liver axis and spleen-liver axis to liver, aggravating liver injury. CCR2 antagonist-M2-EV can target circulating mononuclear cells and activated mononuclear macrophages in the liver, respectively, to reduce liver injury in AIH mice. **Conclusion:** AIH mediates the recruitment of inflammatory monocytes from bone marrow and spleen to liver through the CCL2/CCR2 axis, which can be inhibited by different methods to reduce liver inflammatory injury in AIH mice. M2- EVs delivers CCR2 antagonists targeting activated pro-inflammatory monocytes and hepato-splenic mononuclear macrophage system in the circulating pool, indicating that CCR2 antagonists-EVs could be a potential agent for liver and monocyte targeted therapy for AIH.

109 | IMMUNOLOGICAL PROFILE ASSOCIATED WITH SEX DISPARITY OF CHOLESTATIC LIVER INJURY IN Mdr2-/- MICE

Grayson Way[1], Jing Zeng[2], Yun-Ling Tai[3], Derrick Zhao[3], Xixian Jiang[3], Xuan Wang[3], Rebecca Martin[1], Phillip B. Hylemon[3] and Huiping Zhou[1,3,4,5], (1)Virginia Commonwealth University, (2)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, United States, (3)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, (4)Stravitz-Sanyal Institute for Liver Disease & Metabolic Health, School of Medicine, Virginia Commonwealth University, Richmond, VA, USA, (5)Central Virginia VA Health Care System

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by inflammation, bile duct proliferation, and hepatic fibrosis, with a high risk for liver cancer. Multi-drug resistance 2-deficient ($Mdr2^{-/-}$) mice have been widely used as a PSC model. These mice spontaneously develop fibrosis as early as 6-8 weeks and liver tumors at 10-12 months. Previous studies from our lab, and others, have shown that female $Mdr2^{-/-}$ mice have worse disease progression with increased tumor burden compared to male $Mdr2^{-/-}$ mice. However, the specific immunological landscape underlying sex differences in disease progression in $Mdr2^{-/-}$ mice remains unclear and is the focus of this study. **Methods:** Age and sex-matched wild type (WT) and $Mdr2^{-/-}$ mice (FVB, 3-12 mo, n = 6-12) were used. Brefeldin A was injected via the tail vein 3-6 hours prior to liver perfusion. The livers were then isolated, digested, and processed into a single-cell suspension. After removing the hepatocytes, the immune cells were fixed, incubated with Fc blocker and stained with cell-type-specific antibodies, and run on a Cytek Aurora spectral flow cytometer. All cells are pre-gated on live-dead gating by Zombie-UV, singlet gating, and CD45+ gating. The mRNA expression levels of key genes involved in inflammation and fibrosis were measured by qPCR. Liver injury was assessed by histology. **Results:** Total macrophages and Kupffer cells (KCs) were significantly reduced, while T cells and PMN-MDSCs were increased in $Mdr2^{-/-}$ mice compared to WT in both genders at 3-5 months old. At both 6 and 12 months old, male $Mdr2^{-/-}$mice have stronger macrophage-focused immune responses, with more total macrophages and monocyte-derived macrophages (Md-MQs) than females, while female $Mdr2^{-/-}$ mice have higher lymphocyte response than male mice with more CD4s, CD4Tes, Th1s, Th2s, Tregs, CD8Tes cells. However, the sex difference in NK and NKT cells was only identified in 6-month-old $Mdr2^{-/-}$ mice; females have higher NKs, NKTs, mature NKs, and IFNy-positive NK cells. qPCR analysis revealed that 12-month old female $Mdr2^{-/-}$mice have significantly higher expression of Cxcl16, Cxcl10, Cxcl12, Cxcr4, Cxcr6, Ck19, Col1a1 and Col4a1, etc. **Conclusion:** Identification of the specific immunological landscape associated with the sex disparity of $Mdr2^{-/-}$ mice in cholestatic liver injury and tumorigenesis will provide valuable insights into the pathogenesis of PSC and develop sex-specific therapeutics.

110 | B CELL ACTIVATION IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: METABOLIC SHIFTS AND IMPLICATIONS FOR ANTIGEN-SPECIFIC RESPONSES

Fanta Barrow, University of Minnesota

Background: Metabolic dysfunction associated steatohepatitis (MASH) involves immune mechanisms and the contribution of adaptive immunity to disease progression has been increasingly recognized. B cells, with their ability to modulate inflammation, are key players in inflammatory diseases. However, their precise role and underlying mechanisms in MASH pathogenesis remain unclear. Therefore, our research aims to investigate the mechanisms driving B cell activation and their pro-inflammatory activity in MASH. **Methods:** We established a mouse model of MASH by feeding mice a high-fat, high-carbohydrate diet to closely resemble human MASH. We focused on studying the secretome of B cells by employing Isoplexis single-cell B cell secretome analysis specifically on intrahepatic B cells from mice with MASH and healthy controls. To understand the phenotypic landscape of liver B cells during MASH, single-cell RNA sequencing was used to characterize their transcriptional profiles. Metabolic adaptations of B cells during MASH were explored using Seahorse XF assays and targeted metabolomics. To investigate the role of B cell antigen-specific responses in MASH, B cell receptor restricted mice fed the MASH-inducing diet were utilized. **Results:** Our investigation revealed a notable accumulation of pro-inflammatory B cells in the livers of MASH patients and mice fed a high-fat, high-carbohydrate diet. Single-cell B cell secretome analysis uncovered a proteomic landscape reflecting their pro-inflammatory function. Additionally, single-cell RNA sequencing identified a population of immature B cells that diminished during MASH, indicating altered maturation. We hypothesized that metabolic regulation might be involved due to these changes. Seahorse XF assays showed that B cells in MASH rely on increased oxidative phosphorylation (OXPHOS) rather than glycolysis for energy during immune activation. Importantly, we found that OXPHOS-dependent ATP production is fueled by pyruvate oxidation. Inhibiting pyruvate oxidation in MASH B cells completely abolished their pro-inflammatory potential, dependent on B cell receptor signaling. B cell receptor-restricted mice, recognizing an irrelevant antigen, displayed improved disease outcomes with enhanced fatty acid β-oxidation, decreased steatosis, and reduced fibrosis. Additionally, disease amelioration was accompanied by systemic decreases in IgG antibody isotypes, previously correlated with MASH severity in humans. **Conclusion:** Our study highlights the pro-inflammatory role of B cells in MASH, driven by metabolic adaptations and antigen-specific responses. Understanding the factors regulating B cell metabolism during inflammation could open avenues for selectively targeting their pathogenic activity in MASH.

111 | SERUM PROTEOMICS REVEALS UNIQUE ASSOCIATION OF CCL24 WITH DISEASE-RELATED PATHWAYS AND SIGNATURES IN PRIMARY SCLEROSING CHOLANGITIS

Ilan Vaknin[1], Tom Snir[1], Raanan Greenman[1], Revital Aricha[1], John Lawler[1], Francesca Saffioti[2,3], Douglas Thorburn[2], Massimo Pinzani[2] and Adi Mor[1], (1) Chemomab Ltd., (2)UCL Institute for Liver and Digestive Health, University College of London, (3) Oxford University Hospitals NHS Foundation Trust

Background: Primary sclerosing cholangitis (PSC) is a chronic liver disease characterized by inflammation and fibrosis of the bile ducts. CCL24 (Eotaxin-2) is a chemokine that promotes inflammation and fibrosis and is overexpressed in the liver of patients with PSC, particularly in areas with biliary injury. Previous studies showed that blocking CCL24 interferes with core pathways that contribute to PSC pathophysiology in preclinical models. These properties are unique to CCL24 and are not shared with other ligands of its cognate receptor, CCR3, like Eotaxin-1 (CCL11) and Eotaxin-3 (CCL26). In this study, we aim to further investigate the unique role of CCL24 in the pathophysiology of PSC and its association with disease-related pathways. **Methods:** Sera from patients with PSC (n = 45) and healthy controls (n = 30) were analyzed using the Olink proximity extension assay (PEA) of 3072 proteins. Subjects' demographics and enhanced liver fibrosis (ELF) score were documented. Serum proteomics data were analyzed according to three comparisons: (1) healthy controls vs. patients with

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

PSC, (2) fibrosis severity in PSC patients, defined by ELF score (9.8 cutoff, defining advanced fibrosis), and (3) serum levels of CCL24 in PSC patients. Differentially expressed proteins (DEPs) were subjected to Ingenuity Pathway Analysis. Expression of protein lists was compared between healthy controls and patients with PSC, then further analyzed among patients with PSC, stratified by serum levels of CCL24, CCL11 or CCL26. **Results:** Serum proteomics analysis revealed canonical pathways (such as hepatic stellate cell activation) and upstream regulators (such as IL1β) which are activated in patients with PSC, in patients with advanced fibrosis and in patients with high CCL24 levels. Additionally, protein lists related to multiple hepatotoxicity functions, such as liver fibrosis, were upregulated in patients with high CCL24 levels. Furthermore, expression of these protein lists was found to be uniquely associated with serum levels of CCL24, but not associated with CCL11 or CCL26. **Conclusion:** This study provides further evidence of the critical role of CCL24 in the pathogenesis of PSC, highlighting its unique association with disease-related pathways not shared by other eotaxins. Targeting CCL24 could be a promising therapeutic strategy for the treatment of PSC, which supports the ongoing phase 2 study of CM-101, a CCL24 neutralizing antibody, in patients with PSC.

112 | RUNX1 TRANSCRIPTION FACTOR MEDIATES THE TGF² - STIMULATED INFLAMMATORY RESPONSE BY CHOLANGIOCYTES IN PRIMARY SCLEROSING CHOLANGITIS

Sayed Obaidullah Aseem[1], Jing Wang[2], Jing Zeng[3], Yunling Tai[4], Derrick Zhao[4], Grayson Way[2], Xuan Wang[4], Emily Gurley[4], Robert C. Huebert[5], Arun Sanyal[6], Phillip B. Hylemon[4] and Huiping Zhou[2], (1)Department of Internal Medicine and GI Division, Medical College of Virginia, Virginia Commonwealth University, Midlothian, VA, (2)Virginia Commonwealth University, (3)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, United States, (4)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, (5)Mayo Clinic Rochester, Rochester, MN, (6)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA

Background: Primary sclerosing cholangitis (PSC) is marked by inflammation and progressive biliary fibrosis, which can lead to cirrhosis and its complications. Cholangiocytes activated by transforming growth factor-β (TGFβ) signal to immune cells and activate hepatic myofibroblasts to deposit the extracellular matrix. Our previous data suggest that TGFβ-mediated transcriptomic changes in cholangiocytes may occur through runt-related transcription factors (RUNX). However, studies of RUNX1 in hepatobiliary fibrosis have revealed conflicting findings because of unexplored mechanistic understanding in cholangiocytes, which is the focus of this study. **Methods:** Mouse large biliary epithelial cells (MLE) and PSC-derived cholangiocytes (PSC-C) were used to test the effects of RUNX inhibitors (Ro5-3335 and AI-10-104) and siRNA knockdown on TGFβ-mediated signaling. Multidrug resistance 2 deleted ($Mdr2^{-/-}$) mice (12 weeks, male and female) were treated with the RUNX inhibitor Ro5-3335 intraperitoneally at 50 mg/kg every other day for 3 weeks. **Results:** RUNX1 mRNA is significantly increased in TGFβ-treated cholangiocytes, $Mdr2^{-/-}$ mouse cholangiocytes and RNA-seq of PSC tissue (Log Fc 1.63) (GEO data set: GSE159676). RUNX inhibitors significantly reduced the expression of fibroinflammatory markers such as platelet-derived growth factor B (PDGFB) and interleukin 6 (IL-6) in TGFβ treated MLE. Ro5-3335, also reduced the basal expression of PDGFB and IL-6

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

in PSC-C. RUNX1 specific siRNA knockdown in PSC-C reduced the basal expression of IL-6. Conversely, the expression of anti-inflammatory and anti-fibrotic, peroxisome proliferator-activated receptor γ (PPARγ) was increased. Mdr2$^{-/-}$ mice treated with Ro5-3335 showed significant reductions in serum alanine transaminase and hepatic expression of inflammatory markers (Il-6, Tnfa, Il-1b, Nfkb) by 40-75% but not the anti-inflammatory cytokine, Il-10. In contrast, mRNA markers (Collagen, ±Smooth muscle actin) and picrosirius red histological staining of fibrosis did not show a significant reduction. **Conclusion:** RUNX1 has an essential role in TGFβ-mediated activation of the inflammatory response in cholangiocytes and Mdr2$^{-/-}$ mice. We are conducting longer *in vivo* experiments of RUNX inhibition to determine the effects on biliary fibrosis. Cholangiocyte-selective RUNX1 knockout mice will also be used for further investigation. Targeting RUNX1 may represent a novel therapeutic strategy in cholestatic liver disease.

Research Center, Tokyo Medical University Ibaraki Medical Center

Background: Progressive familial intrahepatic cholestasis (PFIC) 3 is a life-threatening hereditary disease caused by adenosine triphosphate-binding cassette subfamily B member 4 (ABCB4) gene mutations. The murine bile acid composition is different from that of humans. Mice are less likely to develop cholestasis due to the predominance of hydrophilic bile acids such as muricholic acids, which are synthesized by enzymes including Cyp2c70. In this study we utilized Cyp2a12/Cyp2c70 double-knockout (DKO) mice which have human-like hydrophobic bile acid composition. We induced liver-specific Abcb4 deletion using adeno-associated virus (AAV)-mediated Cas9 and gRNA expression vectors in the DKO mice and investigated whether this mouse model would represent human PFIC3. **Methods:** We constructed an AAV vector containing SaCas9 under a liver-specific promoter. The DKO and wild type (WT) mice were infected with AAV containing SaCas9 and gRNAs against Abcb4. Liver injury, bile acid metabolism and gene expression were analyzed in 5 weeks after infection. **Results:** Abcb4 deficient DKO mice (Abcb4-DKO) showed a significant increase in the body-liver weight ratio compared with Abcb4 deficient WT mice (Abcb4-WT). Liver enzymes were significantly elevated in Abcb4-DKO compared with WT and Abcb4-WT; AST: 35.3 ± 31.5, 323.5 ± 173.7 and 740.2 ± 358.1, ALT: 33.5 ± 51.2, 393 ± 65.9 and 1284.8 ± 416.4, and ALP: 129.0 ± 53.2, 260 ± 63.3 and 614.8 ± 342.5 IU/L (mean ± SD), in WT, Abcb4-WT and Abcb4-DKO, respectively, suggesting the presence of severe liver injury in Abcb4-DKO. Serum total bile acid levels in Abcb4-DKO were also higher than Abcb4-WT (9.1 ± 6.1 vs. 5.8 ± 0.9 μmol/L). Abcb4-DKO showed more intense inflammatory cell infiltration in the portal region and scattered CK19 positive cells representing ductal reaction than Abcb4-WT. The mRNA expressions of mCol1a1 and mTimp-1 were significantly increased in Abcb4-DKO, indicating the progression of liver fibrosis. Analysis of bile acid composition in the liver demonstrated increase of TCDCA and decrease of TDCA in Abcb4-DKO. **Conclusion:** Abcb4 deficient mice with human-like bile acid composition showed severe liver inflammation compared with Abcb4 deficient WT mice, suggesting the importance of hydrophobic bile acid composition to induce liver injury. This mouse could be a useful tool for cholestasis research as a PFIC3 animal model.

114 | LOSS OF TAZ AFTER YAP DELETION SEVERELY IMPAIRS FOREGUT DEVELOPMENT AND WORSENS CHOLESTATIC HEPATOCELLULAR INJURY

Laura Molina[1], Adelya Gabdulkhakova[2], Yekaterina Krutsenko[3], Junjie Zhu[4], Silvia Liu[3], Minakshi Poddar[5], Sucha Singh[5], Xiaochao Ma[4] and Satdarshan (Paul) Monga[1,3], (1)University of Pittsburgh Medical Center, (2) University Hospital Heidelberg, (3)University of Pittsburgh School of Medicine, (4)University of Pittsburgh School of Pharmacy, (5)University of Pittsburgh

Background: We previously showed that loss of Yes-associated protein 1 (YAP) in early liver development (YAP^{KO}) leads to an Alagille syndrome-like phenotype, with failure of intrahepatic bile duct development, severe cholestasis, and chronic hepatocyte adaptations to reduce liver injury. TAZ, a paralog of YAP, was significantly upregulated in YAP^{KO} hepatocytes and interacted with TEAD transcription factors, suggesting possible compensatory activity. **Methods:** We deleted both *Yap1* and *Wwtr1* (which encodes TAZ) during early liver development using the *Foxa3* promoter to drive Cre expression, similar to YAP^{KO} mice, resulting in YAP/TAZ double knock out (DKO) and YAP^{KO} with TAZ heterozygosity (YAP^{KO} TAZ^{HET}). We evaluated these mice using immunohistochemistry, serum biochemistry, bile acid profiling, and RNA-sequencing. **Results:** DKO mice were embryonic lethal, but their livers were similar to YAP^{KO}, suggesting an extrahepatic cause of death. Male YAP^{KO} TAZ^{HET} mice were also embryonic lethal, with insufficient samples to determine the cause. However, YAP^{KO} TAZ^{HET}females survived and were phenotypically similar to YAP^{KO} mice, with increased bile acid hydrophilicity and similar global gene expression adaptations but worsened hepatocellular injury. TAZ heterozygosity in YAP^{KO} impacted expression of canonical YAP targets *Ctgf* and *Cyr61*, and we found changes in pathways regulating cell division and inflammatory signaling correlating with an increase in hepatocyte cell death, cell cycling, and macrophage recruitment. **Conclusion:** YAP loss (with or without TAZ loss) aborts biliary development. YAP and TAZ play a co-dependent critical role in foregut endoderm development outside the liver, but they are not essential for hepatocyte development. TAZ heterozygosity in YAP^{KO} had a subtle impact on cell cycling and inflammatory signaling in the setting of chronic injury, highlighting genes that are especially sensitive to TAZ regulation, and may exacerbate cholestatic liver injury.

115 | ELUCIDATING THE MECHANISMS OF KIF12-MEDIATED HIGH GGT CHOLESTASIS★

Joseph Brancale, Nina Dashti-Gibson, Anubha Seth, Chigoziri Konkwo and Silvia M. Vilarinho, Yale School of Medicine, New Haven, CT

Background: We and others have shown that rare bi-allelic loss-of-function mutations in Kinesin family member 12 (*KIF12*) cause pediatric high-GGT cholestasis as well as fibrosis, ductular reaction, and bile duct loss. KIF12 has putatively been defined as a microtubule-associated motor protein, but little is known about its function and even less about its role in the pathogenesis of cholestasis. **Methods:** We used Crispr-Cas9 technology to introduce a homozygous Arg219 premature termination mutation (Arg219*) reported in 6 patients into a human induced pluripotent stem cell (hiPSC) line. Wild-type and Arg219* hiPSCs were differentiated into cholangiocyte-like cells (iCCs) using a protocol that

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

induces definitive endoderm followed by hepatic endoderm, hepatoblast, and finally iCCs. These iCCs were plated as monolayers, polarized on transwells, and cultured as 3D basolateral-out and apical-out organoids. Confocal microscopy was used to visualize protein markers and organelle localization. GGT activity and secretin response were performed. qPCR and bulk RNA sequencing were used to identify transcriptomic signatures. **Results:** iPSC differentiated cholangiocytes display stage specific markers in both wild-type and Arg219* cells. Arg219* cells showed no detectable defects in growth rate, actin cytoskeleton or iCCs maturation markers but demonstrated increased GGT activity. RNA sequencing between KIF12 mutant and wild-type iCCs identified differential expression in ~100 genes with gene ontology suggesting underrepresentation of proteins with extracellular signaling domains ($p = 2.5*10^{-8}$) in KIF12 mutant iCCs. Confocal microscopy demonstrated gross organelle localization defects with decreased mitochondrial footprint ($p = 1.8*10^{-5}$), decreased lysosomal distance to nucleus ($p < 2.2*10^{-16}$), and defects in cilia positioning in KIF12 mutant iCCs as compared to wild-type iCCs controls. To better understand cilia defects we performed 3D organoid culturing. Organoids also demonstrated mature cholangiocyte markers such as CK7 and CK19 as well as functional capability as demonstrated by secretin swelling protocol. Cilia were present on organoids but exhibited mislocalization to the basolateral membrane in Arg219* iCCs, independently of membrane polarization. **Conclusion:** Using iPSC differentiated cholangiocytes we have demonstrated that *KIF12* deficiency leads to increased GGT, transcriptional alterations with decreased extracellular signaling, and pronounced organelle mislocalization, possibly due to an impairment in organelle trafficking. This evidence implicates kinesins as critical mediators of cell homeostasis and provides new cellular and molecular insights into human cholestatic liver disease pathogenesis.

Background: About 30% of patients with PBC have a suboptimal response to ursodeoxycholic acid (UDCA), leading to a worse prognosis. In the phase III POISE trial, response to obeticholic acid (OCA) was assessed by using the POISE score. Recently, complete biochemical normalization (normal ALP and bilirubin d 0.6 ULN) has been proposed as a new therapeutic aim in PBC, as it significantly improves liver-related and overall survival, but the effectiveness of second-line therapy for this new therapeutic target has not been evaluated. **Methods:** Prospective, multicentre real-world clinical practice study including PBC patients non-responders to UDCA according to Paris II criteria, from 25 hospitals from Spain and Portugal. All patients received OCA or OCA plus fibrates (19.25%), and the study evaluated the safety and effectiveness of treatment on biochemical and liver function scores, GLOBE-

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

PBC and UK-PBC at 5 years. POISE response rates, biochemical complete response, incidence of decompensation, liver-related survival and safety were also assessed. **Results:** The study included 316 patients, with a median follow-up of 26.3 months (IQR: 13.3-43.3). ALP, GGT and aminotransferases decreased ($p < 0.01$), while serum albumin increased ($p < 0.01$) and bilirubin also decreased ($p = 0.013$). Globe-PBC and UK-PBC scores at 5 years improved ($p < 0.01$). At 12 months, 41.7% achieved a POISE response by intention-to-treat (ITT) analysis. Factors associated with POISE response in the univariate analysis were absence of cirrhosis, lower serum bilirubin and lower values of FIB-4, APRI, CPT, Globe and UK-PBC scores, as well as higher serum albumin, higher platelet count and triple therapy. After adjusting for sex, age, cirrhosis, albumin levels, bilirubin, platelet count and baseline OCA dose, triple therapy, serum albumin and bilirubin remained associated with POISE response. Triple therapy was more likely to achieve a complete biochemical response compared to dual therapy (fig. 1). Liver-related survival at 36 months was 97.3% (95% CI 94-98.8). OCA discontinuation occurred in 18.2% of patients. Decompensation, death and liver transplantation occurred in 19, 3 and 4 patients, respectively. Of the 72 patients with cirrhosis, 16 experienced decompensation, all of them with APRI ≥ 0.75 (AUROC: 0.77, CI: 0.65-0.89). **Conclusion:** Second-line therapy with OCA or OCA plus fibrates showed long-term positive effects on liver biochemistry and liver function in patients with PBC non-responders to UDCA. Triple therapy was more effective than dual therapy in achieving a POISE response and a complete biochemical response. The treatment appears safe in the early stages of cirrhosis.

117 | A-LINK: UTILIZING A LEARNING HEALTH NETWORK MODEL FOR IMPROVING OUTCOMES IN AUTOIMMUNE HEPATITIS

Amy E. Taylor[1], Cyd Castro-Rojas[1], Rebekah Karns[1], Karan Mudaliar[1], Mallory Moor[1], Mosab Alquraish[1], Sakil Kulkarni[2], Nitika Arora Gupta[3], Leina Alrabadi[4], Jennifer Halma[4], Heli Bhatt[5], Katelyn Saarela[6], Mary Ayers[7], Shehzad Saeed[8], James E. Squires[7] and Alexander G. Miethke[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Washington University in St. Louis, (3)Emory University School of Medicine, (4)Lucile Packard Children's Hospital Stanford, (5)University of Minnesota, (6)Seattle Children's Hospital, (7)UPMC Children's Hospital of Pittsburgh, (8)Dayton Children's Hospital

Background: A-LiNK (Autoimmune Liver disease Network for Kids) is a collaborative, multi-center learning health network uniting patients, parents, clinicians, researchers, and stakeholders to address gaps in care for children with Autoimmune Liver Disease. We seek to define predictors of optimal outcomes and determine current practices in Autoimmune Hepatitis (AIH). **Methods:** Patients aged 1-21 years old with AIH and ≥ 1 year of follow-up were included in a retrospective registry, with clinical data collected at diagnosis and every 3 months for 1 year. The primary endpoints were biochemical remission rate (defined as normal serum AST and ALT based on

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

age/sex) 6 months after diagnosis and predictors of non-remission. In an accompanying prospective cohort, patients with AIH had laboratory values, clinical findings, and patient-reported outcomes documented. Key outcomes were rates of biochemical and steroid-free remission. Statistical analysis for significance utilized Fischer's p test for dichotomous variables and Wilcoxon rank sum for continuous variables. **Results:** Seven A-LiNK centers included 116 patients with AIH in a retrospective cohort: 64% female, 71% white, and 17% African American. Within 1.5 months of diagnosis, 98% were treated with IV/oral corticosteroids, 14% budesonide, and 54% immunomodulators. Of 72 patients with 6-month biochemistries, 65% were in biochemical remission. Non-remission at 6 months was associated with being female; African American; low serum albumin and hematocrit; and elevated IgG, white blood cell count, and INR (all $p < 0.05$). Type of immunosuppression at induction was not associated with remission at 6 months. Prospectively, 4 A-LiNK centers enrolled 36 patients with AIH from March 2022-May 2023 with 61 visits. Participants had similar demographics as the retrospective cohort. The median age at enrollment was 16.4 years, with a median 3.8 years since diagnosis. Most patients were on immunosuppression: 42% prednisone, 25% budesonide, 61% azathioprine, 19% mycophenolate mofetil, and 6% tacrolimus. Only 3 patients were off immunosuppression. At initial visit, 11 (31%) endorsed fatigue and/or abdominal pain; 5 had steroid-associated complications, and 2 experienced complications of portal hypertension. Key outcomes of biochemical and steroid-free remission rates were reported monthly, shown in Figure 1. **Conclusion:** In a multi-center retrospective cohort, only 65% of patients with AIH achieved remission 6 months after diagnosis, with female and African American children less likely to enter remission. In a prospective prevalence study, only 61% were in remission and 33% were in steroid-free remission at a median of 3.8 years after diagnosis. These findings highlight the ongoing need for better pharmacological therapy and application of guideline-based care and is foundational for future implementation trials to improve biochemical and steroid-free remission rates in AIH.

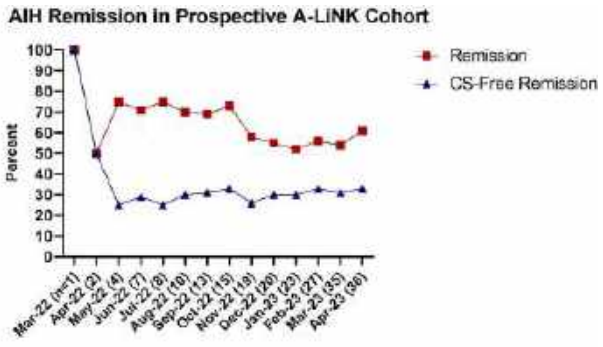

Figure 1: Remission rates in AIH. Enrollment began in March 2022 with patients of any age with a clinical diagnosis of AIH. Patients received care per provider/center practice. Running totals of patients enrolled were documented monthly, with biochemical remission and corticosteroid-free remission rates plotted for new and subsequent visits. For patients with multiple visits, monthly percentages were updated to reflect changes in remission status.

118 | SPLEEN STIFFNESS MEASUREMENT BY TRANSIENT ELASTOGRAPHY WITH A SPLEEN-DEDICATED MODULE: A PROSPECTIVE PILOT FEASIBILITY STUDY IN A PEDIATRIC COHORT

Silvia Nastasio, Enju Liu, Cosette Scott, Sakinah Master, Scott Elisofon, Andrew Wehrman, Katherine Sweeny and Christine K. Lee, Boston Children's Hospital and Harvard Medical School, Boston, MA

Background: Several studies in adults showed that spleen stiffness measurement (SSM) by vibration-controlled transient elastography (VCTE) can accurately assess clinically significant portal hypertension (HTN) and predict presence of esophageal varices. However, pediatric studies on SSM published thus far have used a liver-specific probe to measure the spleen making them difficult to interpret and possibly overestimating SSM, as the spleen is inherently a stiffer organ than the liver. The new dedicated spleen stiffness examination of the FibroScan® 630 uses a higher shear wave frequency (100 Hz v. 50 Hz) and can measure to a higher SSM (100 kPa v 75 kPa) compared to the liver-specific one. Given unique measurement challenges in children and lack of pediatric data, we aimed to conduct a feasibility study to assess SSM with the new spleen-dedicated examination in a cohort of pediatric patients. **Methods:** We conducted a prospective pilot study enrolling patients with chronic liver disease aged 5-30 years followed at Boston Children's Hospital. Subjects underwent SSM by VCTE with the spleen-dedicated examination on the M probe (FibroScan® 630) and liver stiffness measurement (LSM) by conventional VCTE. Laboratory data were collected if obtained within 1 month of SSM. **Results:** 152 patients (67% male) with median age 15 years [IQR 11, 18] were enrolled. Most common liver disorders were NAFLD (44%), viral hepatitis (10%), and biliary atresia (6%). Median weight was 68.8 kg [IQR 50, 88]. Laboratory data showed median [IQR] ALT 39 IU/L [20, 69], GGT 27 IU/L [17, 45], albumin 4.6 g/dL [20, 69], direct bilirubin 0.2 mg/dL [0.2, 0.2], INR 1.02 [0.94, 1.07], and platelet count 268 x10^9/L [211, 312, 13% < 150]. Thirteen percent of patients had a palpable spleen on exam. LSM was successfully obtained in 142 patients

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

using a S1 (1%), M (77%) and XL probe (22%). Median LSM value was 5.5 kPa [IQR 4.7, 7.4] (15.5% LSM > 8.6 kPa); median CAP score was 239 [IQR 191, 291]. SSM was successfully obtained in 146 (96%) patients with an overall failure rate of 4% due to a high skin-to-capsule distance. Median SSM was 18.5 kPa [IQR 13.7, 25] and 11 (7.5%) patients had a SSM ≥ 40. SSM significantly correlated with LSM ($p < 0.001$; Pearson coefficient 0.3) [Fig.], AST ($p < 0.001$), ALT ($p < 0.001$) and GGT ($p = 0.001$). **Conclusion:** This is the first study to show feasibility and extremely high success rate of the novel spleen-dedicated examination to measure SSM in children. With such spleen specific acquisition settings, feasibility and correlation to LSM, the novel spleen-dedicated SSM examination is a promising, more accurate tool to monitor for the evolution of portal HTN and its complications in children with liver disease.

Fig. Correlation between spleen stiffness measurement and liver stiffness measurement measured by vibration-controlled transient elastography with the new spleen-dedicated examination on the M probe (FibroScan® 630).

119 | A PILOT STUDY OF MULTIPLEXED PROTEOMIC NEWBORN SCREENING FOR WILSON DISEASE IN WA STATE

Sihoun Hahn[1], Phi Duong[2], Aranjeet Singh[3], Santosh Shanunak[3], Jonathan Hill[3], Brandon Officer[3], Tareq Shahbal[3], Allison Feise[3], Joseph Uchytil[3], John Thompson[3], Sean Sandin[4], Claire Klippel[4] and Chris Collins[4], (1)University of Washington/Seattle Children's Hospital, (2)Seattle Children's Research Institute, (3) WA State, (4)Key Proteo

Background: Newborn Screening (NBS) is successful in identifying infants with fatal but treatable disorders enabling early intervention with favorable outcomes. Unfortunately, many congenital disorders in particular Wilson disease do not feature specific metabolic biomarkers nor analytical methods suitable for NBS even where highly effective preemptive treatments are available. In our recent study, we demonstrated that direct measurements of the ATP7B itself using multiplexed proteomic methods from dried blood spots can be highly diagnostic and utilized in population screening for Wilson disease. Through quantification of the extremely low abundance intracellular proteins in dried blood spots, patients with Wilson Disease are readily detected. **Methods:** A first-in-class proteomic-based in vitro diagnostic (IVD) reagent kit has been manufactured under the GMP facility for identification of the four new conditions (Wilson disease, X-linked agammaglobulinemia, Wiskott-Aldrich syndrome, and Adenosine Deaminase deficiency (ADAD) in a single-run multiplex assay from DBS by LC-MS/MS. Within the assay range, linearity, accuracy, and precision were acceptable. A pilot study screening newborns in WA state for targeted conditions was initiated after IRB approval. Genetic sequencing of samples with peptide concentrations below tentative cutoffs is used for confirmation. **Results:** Kit validation shows consistent performance and inject-to-inject time is < 3 minutes. 19,100 newborns have been screened to date. Gender, ethnicity, birthweight and time of collections were included in the analysis. No differences in gender, ethnicity or birthweight are observed for ATP7B peptides. Two potential cases (one likely carrier and one uncertain) have been identified for Wilson disease to date. The first case carried one pathogenic variant, p.Gly626Ala and one likely benign variant, pLeu1015 = . ATP7B peptides were marginally below the cutoffs. The second case

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

presented with two variants of uncertain significance, p. Pro610Leu and p.Arg1224Leu. ATP7P887 peptide was marginally below the cut off (71.0 pmol/L, cutoff = 75.7) while ATP7B1056 peptide was in the normal range. The overall rates of false positive were very low for all four conditions. **Conclusion:** This study highlights the use of novel IVD assay demonstrating the feasibility of LC-MS/MS proteomics for NBS of Wilson disease and other inborn errors of immunity.

120 | THE SIGNIFICANT ASSOCIATION BETWEEN PNPLA3 G ALLELE AND ADVANCED FIBROSIS IN CHILDREN WITH NAFLD IS FURTHER INFLUENCED BY BMI AND type2 DIABETES★

Chaowapong Jarasvaraparn[1], Jean P Molleston[1], Eduardo Vilar-Gomez II[2], Katherine Yates[3], Cynthia A. Behling[4], Nidhi P. Goyal[5], Kimberly P Newton[6], Miriam B. Vos[7], Stavra Xanthakos[8], Jeffrey Schwimmer[9] and Naga P. Chalasani[2], (1)Indiana University, (2)Indiana University School of Medicine, (3)Johns Hopkins School of Public Health, (4)Pacific Rim Pathology, (5) University of California, San Diego, (6)University of California, San Diego School of Medicine, (7)Division of Gastroenterology, Hepatology, and Nutrition, Department of Pediatrics and Nutrition and Health Sciences Graduate Program, Emory University, (8) Division of Gastroenterology, Hepatology and Nutrition, Cincinnati Children's Hospital Medical Center, (9)UC San Diego

Background: *PNPLA3* rs738409 polymorphism, obesity, and type 2 diabetes mellitus (T2DM) are strongly associated with non-alcoholic fatty liver disease (NAFLD) and its severity in children. Whether *PNPLA3* rs738409-related predisposition to NAFLD severity is influenced by obesity and T2DM in children with NAFLD is not known. Therefore, we examined the relationship between *PNPLA3* rs738409, body mass index (BMI), T2DM, and the risk of advanced fibrosis in children with biopsy-proven NAFLD. **Methods:** 1,047 children between 2 and 18 years of age with biopsy-proven NAFLD enrolled into Non-Alcoholic Steatohepatitis Research Network prospective studies were analyzed. The primary study outcome was biopsy-confirmed advanced fibrosis (fibrosis stage ≥ 3,). T2DM was defined as self-reported, or HbA1c levels ≥ 6.5%, or fasting plasma glucose of ≥ 126 mg/dl, or current use of glucose-lowering medications. Logistic regression models were used to examine associations of rs738409 (additive model of inheritance; CC, CG, or GG), T2DM, and BMI with advanced fibrosis, while controlling for race/ethnicity, sex, and hypertension. Multiplicative interaction terms between rs738409, T2DM, BMI, and age were included in all models. **Results:** The cohort consisted of 724 Hispanics (69%) and 261 non-Hispanic Whites (25%).The *PNPLA3* rs738409 variant was present at a frequency of 0.76. Among all children, rs738409 genotypes were distributed as follows: CC (n = 149, 14.3%), CG (n = 363, 34.6%), and GG (n = 535, 51.1%). The prevalence of advanced fibrosis was 13%. Out of 140 children with advanced fibrosis, 130 (93%) carried at least one *PNPLA3* G allele (CG; 44/130 (33.8%) or GG; 86/130 (66.2%)). The *PNPLA3* G allele was independently associated with a high risk of advanced fibrosis (OR: 1.55, 95% CI: 1.16-2.09). Compared with individual's with *PNPLA3* CC genotype, the risk of advanced fibrosis increased by 2.1-fold (95% CI: 1.0-4.3) for children with CG genotype and 2.8-fold (95% CI: 1.4-5.8) for children with GG genotype. BMI was independently associated with advanced fibrosis, with stronger effects seen in children with *PNPLA3* CG (OR: 1.03, 95% CI: 1.004-1.05) and GG (OR: 1.04, 95% CI: 1.014-1.06), compared with CC (OR: 0.99, 95% CI: 0.95-1.03) genotypes (*Figure 1A*), p for interaction < 0.01. T2DM was positively associated with the risk of advanced fibrosis, with stronger effects among children with CG (OR: 3.6, 95% CI: 1.0-16.6) and GG (OR: 6.2, 95% CI: 1.4-28.0) compared with CC (OR: 2.9, 95% CI: 0.5-15.8) genotypes (*Figure 1B*), p for an interaction < 0.01. **Conclusion:** *PNPLA3* G-allele, higher BMI and T2 DM are significantly associated with advanced fibrosis in children with NAFLD, The adverse relationship between *PNPLA3* G allele and advanced fibrosis is significantly worsened by higher BMI and type2 diabetes. This indicates aggressive attention to BMI and T2DM is particularly important in children with NAFLD carrying *PNPLA3* G-allele.

Background: Alagille syndrome (ALGS) is a rare, autosomal dominant multisystem disorder characterized by cholestasis and extrahepatic manifestations. Given the current era of ileal bile acid transporter (IBAT) inhibitor therapies that reduce serum bile acid (SBA) levels, the aim of this study was to determine whether SBA are a predictor of clinical outcomes in ALGS. **Methods:** Patients were ascertained from the GALA cohort, an international multicentre study including clinically and/or genetically diagnosed children with ALGS. Those with neonatal cholestasis and at least one SBA measurement during follow-up were eligible for inclusion. An established SBA threshold in progressive familial intrahepatic cholestasis (PFIC) (102 umol/L) was assessed as a time-dependent covariate in Cox regression analyses for native liver survival (NLS); liver transplantation and death as endpoints, overall and while adjusting for total bilirubin (TB) levels and stratified by geographical region. The association between median SBA in the first 3 years according to the PFIC threshold and NLS was also assessed. Patients who did not meet one of these endpoints were truncated at the time of biliary diversion, Kasai procedure, trial enrollment, or their last follow-up, up to a maximum of 18 years of age. **Results:** 570 patients from GALA were included, of whom 348 (61.1%) were male with a median year of birth of 2012 (IQR 2007-2015). Rates of NLS at 1, 5 and 18 years were 97.2%, 81.8%, and 53.6%, respectively. There is a moderate positive correlation between SBA and total bilirubin (Pearson correlation = 0.47, $p < 0.001$). The was a significant predictor of outcome (HR = 3.78, 95% CI 2.39-5.99, $p < 0.001$) and there was no significant difference in the impact of SBA between the first ($p = 0.32$). SBA remained a significant factor for NLS while adjusting for TB clearance at 1 year (HR = 2.00, 95% CI 1.10-3.65, $p = 0.02$), where clearance is defined as TB < 2 mg/dL. There was no significant interaction between the SBA threshold and clearance of TB. Furthermore, if median SBA in the first 3 years was above 102 umol/L, patients had lower NLS at 8 years of age (Figure, $p = 0.005$), including in those with favourable bilirubin trends (90.9% vs. 95.9, $p = 0.04$). **Conclusion:** SBA is an independent predictive factor for NLS in children with ALGS and neonatal cholestasis. Of note, SBA is also associated with NLS in children with ALGS who clear their bilirubin i.e. those with anicteric cholestasis. This is relevant in the context of IBAT inhibitors that promote a reduction in SBA and are currently indicated for pruritus but may also impact

Background: Alagille syndrome (ALGS) is a rare, genetic, multisystem disorder in which cholestatic liver disease is common and that may include clinical manifestations of severe pruritus and elevated bile acids (BAs). The efficacy and safety of odevixibat, an ileal bile acid transporter inhibitor, were assessed in patients with ALGS in the phase 3 ASSERT and ASSERT-EXT trials. Using data from these studies, we analyzed the effects of odevixibat on pruritus and BAs over time. **Methods:** ASSERT (NCT04674761) was a randomized, placebo-controlled study that enrolled patients with ALGS who had a history of significant pruritus and elevated serum BAs. Patients were randomized 2:1 to odevixibat 120 μg/kg/day or placebo, respectively, and received treatment for 24 weeks. Patients who completed ASSERT could enter ASSERT-EXT (NCT05035030), an ongoing, 72-week open-label extension study in which all patients receive odevixibat 120 μg/kg/day. The primary endpoint in these studies was related to change in pruritus scores, evaluated using the PRUCISION observer-reported instrument (range, 0−4, with higher scores indicating worse symptoms). A secondary endpoint in both studies was change in serum BAs. Changes over time in scratching scores and BAs were analyzed in odevixibat-treated patients from ASSERT and/or ASSERT-EXT in a pooled analysis of data that spans from patients' first dose of odevixibat to a data cutoff date of September 9, 2022; data from patients who received placebo in ASSERT are presented for comparison. **Results:** At the data cutoff, 52 odevixibat-treated patients comprised the pooled population; 17 patients who received placebo in ASSERT subsequently received odevixibat in ASSERT-EXT. Odevixibat-treated patients had rapid reductions in mean scratching scores and BA levels that

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were sustained over time; responses in individual patients are shown in the Figure. At the data cutoff date, treatment-emergent adverse events (TEAEs) were reported in 83% (43 of 52) of odevixibat-treated patients and in 71% (12 of 17) of placebo-treated patients. The most common TEAEs during odevixibat treatment were diarrhea (29%; 6% with placebo) and pyrexia (21%; 24% with placebo). Drug-related TEAEs occurred in 29% of odevixibat-treated patients (15 of 52) and in 18% of placebo-treated patients (3 of 17). In the odevixibat-treated group, the only drug-related TEAEs occurring in > 1 patient were diarrhea (6 patients, 12%) and abdominal pain, upper abdominal pain, and vomiting (each in 2 patients, 4% each). No odevixibat-treated patients had TEAEs leading to treatment discontinuation as of the data cutoff date. **Conclusion:** In patients with ALGS, odevixibat treatment for up to 36 weeks resulted in improvements in pruritus and reduced BA levels; these changes occurred rapidly, with effects sustained over time. Most TEAEs with odevixibat were related to diarrhea and were mild or moderate in severity.

123 | SPATIAL TRANSCRIPTOMICS IDENTIFIES IMMUNE EXPANSION OF SCAR REGIONS AND REDUCED HEPATOCYTE ZONATION IN LIVERS FROM PATIENTS WITH BILIARY ATRESIA

Sarah A. Taylor[1], Kyle D. Gromer[2], Padmini Malladi[2] and Tallulah Andrews[3], (1)Children's Hospital Colorado, University of Colorado School of Medicine, (2)Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (3)University of Western Ontario

Background: Multiple metabolic and inflammatory pathways have been associated with patient outcome in biliary atresia (BA), however, the spatial relevance of these pathways among BA and non-BA disease controls has not been well defined. In the present study, we overcome this gap in knowledge and define the hepatic spatial transcriptome in pediatric cholestasis. **Methods:** VISIUM Spatial transcriptomics was performed on frozen liver tissue obtained at the time of pediatric liver transplantation from 4 groups: 1) BA patients < 2 years of age (BA1, n = 3), 2) BA patients > 2 years of age (BA2, n = 4), 3) non-BA cholestatic patients (nonBA, n = 4), and 4) non-diseased pediatric donor liver (NL, n = 3). Published single-cell datasets were used to infer cell-type composition of hepatocyte and scar regions. Standard statistical tools were used to integrate and identify differential gene expression (DE), and tissue composition within and between samples. Metabolic pathways were modeled from gene expression using the compass algorithm. **Results:** BA1 patients had higher direct bilirubin level at the time of sample collection with median of 20.4 mg/dL (IQR 11.7-NA) compared to BA2 and nonBA groups with medians of 2.0 mg/dL (IQR 0.6-2.2) and 4.8 mg/dL (IQR 1.3-11.7) respectively ($p = 0.004$). This was associated with an increase in bile acid synthesis pathways and a trend towards greater cholangiocyte signature (Figure 1) in BA1 compared to BA2. In contrast, BA2 had higher immune infiltration in scar regions (Figure 1A) and arginine and proline metabolism. BA1 scars were most unique with 662 DE genes, whereas BA2 and nonBA scars had fewer than 50 DE genes. More specific comparison among the scar signatures of BA patients demonstrated distinct scar-associated clusters involved in angiogenesis and T cell activation in BA1 versus enriched processes of translation and peptide metabolic processes in BA2. Both BA groups showed reduced hepatocyte zonation as demonstrated by lower portal hepatocyte gene signature than nonBA and NL groups (Figure 1B). **Conclusion:** We identify distinct spatial transcriptomes in children with cholestatic liver disease that differ by etiology and disease severity. BA patients requiring earlier transplant (BA1) exhibited a higher bile acid metabolic signature and greater heterogeneity within the scar region than older BA patients (BA2). These findings help identify aberrant immune-metabolic patterns that may contribute to disease progression in BA.

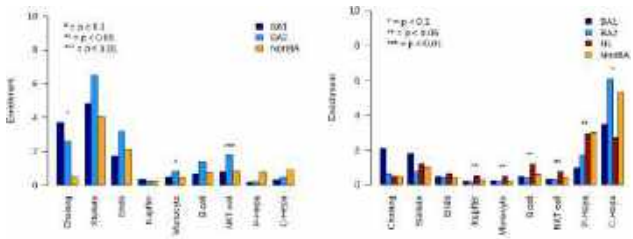

Figure 1. A. Enrichment for cell types in the scar region of diseased groups shows significantly increased NKT cell signature in BA2. **B.** Analysis within hepatocyte regions identified reduced peri-portal hepatocyte signature in BA groups whereas NL hepatocyte regions had increased expression of immune cell signatures.
C-Hepa – peri-central hepatocyte; Cholang – cholangiocyte; Endo – endothelial cell; NKT – natural killer T cells; P-Hepa – peri-portal hepatocyte.

Disclosures: Sarah A. Taylor – Albireo: Advisor, No, No; Disclosure information not available at the time of publication: Kyle D. Gromer, Padmini Malladi, Tallulah Andrews

124 | STAT3 SIGNALING MEDIATES FXR AGONIST PROTECTION IN ACUTE CHOLANGIOPATHY MOUSE MODEL

Swati Ghosh[1], Michael W Devereaux[1], Aimee Anderson[1], David J Orlicky[2] and Ronald J. Sokol[1,3], (1) Department of Pediatrics, University of Colorado School of Medicine, (2)Department of Pathology, University of Colorado, (3)Digestive Health Institute, Children's Hospital Colorado

Background: Primary sclerosing cholangitis (PSC), a chronic cholangiopathy, results in cholestasis, inflammation, and stricturing of intrahepatic and extrahepatic bile ducts. Recently, we have shown that the transcription factor STAT3 mediated, in part, the protective role of the FXR agonist, GW4064, in parenteral nutrition

(PN)-associated cholestasis *(Ghosh* et al*., Hep comm 2023)*. The objective of this study is to determine the interaction of STAT3 and FXR agonists (IV GW4064 and obeticholic acid [OCA]) in a mouse model of acute cholangiopathy and *in vitro*. **Methods:** Acute DDC dietary mouse model (diethyl1,4-dihydro-2,4,6-trimethyl-3,5-pyridinedicarboxylate diet feeding x1 d) and cell culture were used. **Results:** DDC mice had increased AST, ALT, bilirubin, bile acids, ductular reaction and macrophage infiltration and reduced hepatocyte mRNA expression of *Abcb11, Abcg8, Nr0b2* (SHP), *Nr5a2* and *Abcc2* mRNA relative to chow fed mice; all of these were normalized by either FXR agonist treatment. Macrophage mRNA expression of pro-inflammatory (M1) and anti-inflammatory (M2) genes showed that FXR agonists led to upregulation of M2 (*Clec10a1*, *Msr1*, *Klf4*) and down regulation of M1 genes (*Cd68*, *Il-1b*, *Itgam, Cox1*) in DDC mice vs. controls. A significant increase in hepatic STAT3 phosphorylation and acetylation and binding of FXR to *Stat3* promoter, as well as decreased apoptosis markers by flow cytometry (FAS, caspase 8 and caspase 3), were present in FXR agonist/DDC mice compared to DDC mice. DDC mice showed elevated hepatic arachidonic acid (AA) levels (mass-spec) associated with apoptosis, both of which were ameliorated by FXR agonist treatment. AA incubation with Huh7 cells caused increased apoptosis (by Annexin V flow cytometry). In THP1 cells that were exposed to AA cocultured with Huh7 cells, treatment with GW4064 or OCA increased anti-inflammatory *Il-10* and *PPARA* mRNA in THP1 and *ABCB11*/BSEP mRNA in Huh7. In Huh7, AA suppressed the protective upregulation by OCA or GW4064 of BSEP and SHP, and when *STAT3* was knocked down by siRNA ,then the expression was further suppressed. Finally, in DDC mouse liver, increased binding of STAT3 to *Cpt1b* promoter with its increased expression (likely enhanced fatty acid oxidation) was induced by GW4064. **Conclusion:** In the DDC acute cholangiopathy model, FXR agonists are protective through STAT3 signaling, M1 to M2 macrophage polarization, and by inducing fatty acid oxidation, suggesting STAT3 as a potential therapeutic target in PSC.

125 | SPATIALLY RESOLVED EXPANSION OF REGULATORY IMMUNE CELLS MAY PREDICT CLINICAL OUTCOMES IN PEDIATRIC ACUTE LIVER FAILURE

Johanna Ascher Bartlett[1], Brittany Rocque[2], Sarah Bangerth[2], Carly Weaver[3], Arianna Barbetta[2], Tricia Saputera[2], Kambiz Etesami[2], George S. Yanni[3], Rohit Kohli[4] and Juliet Emamaullee[5], (1)Children's Hospital Los Angeles, Los Angeles, CA, (2)University of Southern California, (3)Children's Hospital Los Angeles, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)University of Southern California, Los Angeles, CA

Background: Pediatric acute liver failure (PALF) remains a poorly-characterized disease entity that affects children of all ages. Emerging data supports an underlying immune-mediated process driving progression and severity. Up to 25% of patients will require liver transplantation (LT), yet there are no reliable indicators of disease trajectory to guide clinicians. **Methods:** A single center, retrospective cohort of 58 children was identified: 38 with PALF (25 who recovered (SR) and 13 who underwent LT) and 20 patients who underwent surveillance liver biopsy following LT, whose histologically normal liver tissue is indistinguishable from otherwise healthy liver biopsies. Imaging Mass Cytometry was performed on these specimens using a 25-marker panel. Post-processing using our informatics pipeline generated a spatially resolved, single-cell dataset. Results were stratified by disease, and sub-analyzed by PALF outcome (SR vs LT). **Results:** The study population resulted in 337,823 cells including 120,387 immune cells, which were identified based on lineage marker expression, making up 23 immune subpopulations. When comparing normal liver tissue and PALF, PALF patients had more immune cells overall ($p < 0.01$) – specifically macrophages ($p < 0.01$), monocytes ($p < 0.01$) and CD8+ T-cells ($p = 0.01$) (Fig 1A). No difference was observed between overall populations of CD4+ T-cells. When comparing immune populations between PALF and normal liver tissue, PALF demonstrated more proliferating CD8+T-cells ($p = 0.02$) and HLADR+CD4+T-cells ($p = 0.03$) than normal tissue (Fig 1B). In the CD4+ compartment, PD1+HLADR-CD4+Tregs were present in the PALF cohort that were absent in normal tissue. Within PALF, patients with SR demonstrated more CD4+ Tregs compared to LT ($p = 0.04$), specifically, PD1+HLADR-Tregs, as well as PD1+C8+T-cells (Fig 1C/D). When evaluating non-immune populations, PALF tissue demonstrated increased Ki67 and HLADR+ hepatocytes when compared to normal tissue ($p < 0.01$) (Fig 1E). **Conclusion:** Our spatially resolved single cell atlas of PALF has determined that PALF is associated with greater proliferative cell populations than normal liver tissue, and PD1+HLADR-CD4+Tregs and are unique to this disease entity. Hepatocyte proliferation as indicated by Ki67 and HLADR predominates PALF. Further, we have determined that favorable clinical outcomes are associated with expansion of regulatory cell populations. Our preliminary analysis has determined that a subset of regulatory and PD1+T cells are

characteristic of patients who experience recovery, suggesting an important role for immune exhaustion mediating liver inflammation and injury in PALF. Future studies are needed to evaluate these cell populations as potential biomarkers and therapeutic targets.

f 126 | DEVELOPING A THERAPEUTIC MODEL FOR INTRAHEPATIC CHOLESTASIS BY MODULATING THE INTESTINAL MICROBIOME

Huey-Huey Chua[1], Shu-Hao Hsu[1], Yen-Hsuan Ni[1], Bang-Yu Liou[1], Ray Lin[1], Mei-Hwei Chang[2] and Huey-Ling Chen[1], (1)National Taiwan University College of Medicine, (2)National Taiwan University, College of Medicine

Background: The homeostasis of gut microbiota is pivotal to maintaining the physiological liver-gut axis. In cholestatic diseases, impaired bile flow changes the composition of gut bacteria and subsequently dysregulates the bile acids metabolisms. Beneficial roles of vancomycin (VCM) in treating patients with sclerosing cholangitis have been reported; yet the mechanism is not clear. The therapeutic values of the intestinal microbiome restoration in cholestatic disease are less explored. **Methods:** Adult male *Bsep (abcb11)* knockout mice with genetic variants in Plec demonstrated a more severe jaundiced phenotype named *Bsep-ko-JD (*KO). This intrahepatic cholestatic model treated with vancomycin (VCM) exhibited decreased serum bilirubin levels, improved liver bile acid profiles, and ameliorated damages in the biliary ductal structures. This study aims to explore the potential therapeutic gut microbe of the cholestatic liver disease model. **Results:** Using next generation sequencing to profile the intestinal microbiota, the weighted UniFrac principal co-ordinates analysis (PCoA) showed that VCM largely changed gut microbiota in the wild type (WT)-VCM and the KO mice compared to control (Ctrl). (Figure) Parabacteroides goldsteinii (PG) was the most abundant species in this intrahepatic cholestasis model. We treated the KO mice with 1*10^9 PG or phosphate buffered saline by intragastric gavage 3 times per week for a total of 4 weeks. Significant improvement in the PG-treated mice was noted as evidenced by decreased levels of serum bile acids, direct-bilirubin, alkaline phosphatase, as well as reduced levels of hepatic chenodeoxycholic acid, lithocholic acid, and lymphocyte infiltration in the liver. **Conclusion:** Our results suggested that the PG identified from a therapeutic model of intrahepatic cholestasis may modulate bile flow and/or bile acid metabolisms, and may direct future investigations of the treatment of cholestatic liver diseases.

127 | BILIARY ATRESIA CANDIDATE GENE Pkd1l1 IS ESSENTIAL FOR MAINTENANCE OF BILIARY EPITHELIAL CELL INTERACTION AND INFLAMMATORY RESPONSE

Caroline Klindt-Morgan[1,2,3], David Lee[1], Dominick Hellen[1], Ashley Bennett[1], Kimberly Pachura[1], Paul A. Dawson[1] and Saul Karpen[1], (1)Children's Healthcare of Atlanta & Emory University School of Medicine, Atlanta, GA, (2)Emory University School of Medicine, (3) Heinrich Heine University Dusseldorf

Background: Biliary atresia (BA) is the most common reason for liver transplantation in infants, but its etiopathology is still not completely understood. A nationwide genomic study identified mutations in *PKD1L1* as a BA candidate gene. Liver-specific deletion of *Pkd1l1* in mice results in liver pathology analogous to changes seen in BA, but how *Pkd1l1*-deficient cholangiocytes differ from wild type cells is unknown. The aim of this study was to elucidate the role of Pkd1l1 in cell homeostasis using isolated biliary epithelial cells (BECs) and intrahepatic biliary organoids (ICOs). **Methods:** Intrahepatic BECs were isolated from 6–8-week-old male *Pkd1l1*$^{Fl/Fl}$ (control) and *Pkd1l1*-deficient *(KO)* mice by fluorescence-activated cell sorting. Two models were used: BEC Transwell cultures grown to polarized monolayers; and isolated BECs to generate ICOs in 3-D cultures. Cells were incubated with DMSO, CDCA (Chenodeoxycholic Acid, 100mM), UDCA (Ursodeoxycholic Acid, 100mM) and Lipopolysaccharides (LPS, 100 IU/ml) from 1 to 24 hours. Organoid formation was visualized using light microscopy. BECs and organoids were characterized by RT-qPCR for known reactive ductular genes and immunofluorescence (IF) to explore cell structure and tight junction integrity. **Results:** ICOs derived from KO mice were significantly smaller in size compared to control (average size 60204 mm^2 vs 2912 mm^2, 20-fold decrease; $p < 0.0001$). Tight junctions, as indicated by IF of markers such as beta-catenin, were disorganized in KO compared to control cells in both systems. After challenge with CDCA and LPS to induce a reactive biliary phenotype, ICOs demonstrated aberrant mRNA expression of several proinflammatory cytokines in KO versus control (e.g., *Ccl5 and Cxcl2* with 5-fold and 4-fold higher expression in KO compared to control cells respectively). A similar, pro-inflammatory phenotype has been observed in Transwell cultures with a basal increase of several markers (e.g, *Cxcl1*, with 9-fold increase in KO as compared to control). **Conclusion:** Our studies demonstrate that *Pkd1l1* is essential for the maintenance of normal BEC epithelial tight junctional structure and regulation of inflammatory response. This enhanced reactive ductular phenotype of KO cells mirrors features of human BA livers. These findings support the relevance of *Pkd1l1* KO as a mouse model of the cholangiopathy leading to the BA phenotype and a valuable tool for evaluation of possible therapies of this devastating disease.

Background: Biliary atresia (BA) is the principal indication for liver transplantation in children, yet there is little information regarding its underlying etiology. Recent data strongly places BA as a developmental cholangiopathy suggesting that there are gene variant contributions that can be discovered using modern gene sequencing and analytical technologies. Exome analysis of a subset of BA patients with laterality features (BASM) identified causative variants in a ciliary gene, *PKD1L1*, supporting this approach; however, a larger dataset with multiple analytical approaches is needed to explore the likely multiple genetic contributors to BA. **Methods:** DNA was obtained from participants with BA enrolled in the NIH-supported NIDDK ChiLDReN consortium, a prospective study of cholestatic infants from 14 sites in North America. Exome sequencing and SNP microarray (Illumina 654k) were performed on participant DNA. Analyses were performed using heuristic filtering and artificial intelligence approaches that rely on evolutionary conservation, allele frequency, inheritance patterns, predicted protein impact and ClinVar annotation. Rare, protein-altering variants in genes identified by Gene Ontology (GO) pathway analyses were investigated. **Results:** 1751 BA participants (1564 BA and 187 BASM) underwent both exome and SNP array analysis. In both BA and BASM cases, rare protein-coding variants in several genes including *DNAH11*, *DNAH5*, *CCDC40*, *KMT2D* as well as *PKD1L1* were identified in expected inheritance patterns as previously reported to cause Mendelian human disease. Employing GO analytics for both BA and BASM subsets yielded several significant pathways (multiple test corrected p-values < 0.05) with variants in genes participating in crucial functions including: cell adhesion processes, microtubule processes and transport, ciliary assembly and structure. **Conclusion:** A combination of a large multi-center dataset and multiple methodologies has identified rare, presumably functionally relevant mutations in a number of genes known to cause human disease. Pathway approaches have identified a greater-than-expected number of variants in genes implicated in in ciliary, microtubule, and cell structural pathways. Taken together, these results provide a number of attractive BA candidate genes and pathways that can be explored and validated in suitable cell, organoid and animal-based models to better understand the genetic and mechanistic landscape of BA.

129 | FAVOURABLE OUTCOMES OF PEDIATRIC LIVER TRANSPLANTATION FOR PRIMARY LIVER TUMORS- RETROSPECTIVE ANALYSIS OF A LARGE CANADIAN COHORT

Sagar Mehta[1], Eveline Lapidus-Krol[2], Jennifer Stunguris[1,3], Maria DeAngelis[1,3], Krista Van Roestel[4], Julia Hensleyab[1,3], Yaron Avitzur[1,3], Robert H.J. Bandsma[1,3], Nicola Jones[1,3], Binita M. Kamath[1,3], Simon C. Ling[1,3], Mar Miserachs[1,3], Anand Ghanekar[2,3,5], Mark Cattral[2,3,5], Furqan Shaikh[6], Vicky Lee Ng[1,3] and Blayne Sayed[2,3,5], (1)Division of Gastroenterology, Hepatology and Nutrition, the Hospital for Sick Children, Toronto, ON, Canada, (2) Division of General and Thoracic Surgery, the Hospital for Sick Children, (3)Transplant and Regenerative Medicine Centre, the Hospital for Sick Children, University of Toronto, (4)The Hospital for Sick Children, (5)Ajmera Transplant Center, University of Toronto, Toronto, ON, Canada, (6)Department of Hematology/Oncology, the Hospital for Sick Children

Background: Multimodal treatment for pediatric liver tumors, including indications for transplantation, has evolved over the last several decades. The main objective of this study was to describe the outcomes following liver transplantation (LT) for children with primary hepatic malignancies over 30 years at our center which has the largest pediatric LT program in Canada. **Methods:** Charts of patients transplanted at our center for primary hepatic tumors between January 1990 and December 2021 were included in our retrospective review. Demographic, operative, and outcome data were collected. Chi-square tests and univariate analyses were performed for survived vs non survived patients with hepatoblastoma. A p value of d 0.05 was considered significant. **Results:** A total of 37 patients underwent LT for primary hepatic malignancies during the study period: 31 hepatoblastoma (HB) and 6 non-HB (2 hepatocellular carcinoma (HCC), 2 undifferentiated embryonal sarcoma, 1 angiosarcoma and 1 multifocal infantile hemangioma). In HB patients with available data (14 females, median age at diagnosis 29.5 months; range 1-158), 2 (7.4%) were PRETEXT II, 8 (29.6%) and 16 (59.3%) were PRETEXT III and IV, respectively. Metastases at diagnosis were detected in 4 (13.3%) patients, all in the lungs. Of these, 1 patient had a residual lesion which was decreasing rapidly in size. All the patients received neo-adjuvant chemotherapy (median cycles- 6; range 2-10), while 14/25 had adjuvant chemotherapy. The median age at transplant was 34 months (range 6-160). One (3.2%) patient had salvage transplant secondary to incomplete tumor resection. Overall survival was 74.2% (23/31) with a median follow-up of 132 months (range 1-355). All deaths were secondary to disease recurrence (median 15 months after LT; range 1-78). The most common site of recurrence was lungs (62.5%). Higher median alpha-fetoprotein (AFP) prior to LT was associated with worse survival (160296 vs 848 μg/L; p 0.003). AFP decrease of > 95% from presentation was significantly associated with improved survival (p 0.024). Other factors such as tumor histology, AFP at diagnosis, PRETEXT/POSTEXT stage, metastasis at diagnosis, liver donor type and era of LT, or positive resection margin (R1) were not associated with differences in survival in our cohort. All the non-HB recipients were alive following LT at the last visit (median 9.5 months, range 1-51). None had extrahepatic disease at presentation. Recurrence of disease was noted in 2 patients (1 HCC and 1 angiosarcoma), each treated with surgical resection. **Conclusion:** The overall survival rate following liver transplant in HB patient is 74.2%, with tumor recurrence as the most important

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

contributor of mortality. Lower AFP levels before LT and > 95% AFP decrease from presentation are associated with survival. LT in non-HB tumor has favorable outcomes in selected patients, even with post-transplant recurrence.

130 | SIMULTANEOUS LIVER TRANSPLANT AND SLEEVE GASTRECTOMY IS A SAFE SURGICAL OPTION THAT IMPROVES METABOLIC SYNDROME AND REDUCES ALLOGRAFT STEATOSIS

Ellen Larson[1], Samia Ellias[2], Nickie Francisco-Ziller[1], Michael D. Leise[1], Kymberly Watt[3], Dana Perry[1], Tayyab Diwan[1], Timucin Taner[1], Charles B. Rosen[1], Enrique F Elli[1], Caroline C Jadlowiec[4], Shennen A. Mao[1], Todd Kellogg[1] and Julie Heimbach[1], (1)Mayo Clinic, (2)Johns Hopkins, (3)Mayo Clinic, Rochester, MN, (4)Mayo Clinic Arizona, Phoenix, AZ

Background: The prevalence of obesity and metabolic syndrome (MS) is rising dramatically among liver transplant (LT) candidates, many of whom have NASH. Following LT, untreated MS often causes recurrent NAFLD and NASH. Several small case series describe bariatric surgery pre-, post-, or concurrently with LT as a treatment for MS. We reviewed our experience with LT and concurrent sleeve gastrectomy (LTSG) with aims to determine long-term safety, efficacy, and impact on progression of MS and liver disease after transplantation. **Methods:** A multi-center retrospective analysis of all patients undergoing LTSG using a single clinical protocol (n = 73) was performed. Follow-up duration was 4 to 153 months. Outcomes assessed included morbidity and mortality, graft loss, BMI, evolution of MS, and development of allograft steatosis on ultrasound and fibrosis on magnetic resonance elastography. A comparison cohort included all 185 patients with BMI > 30 who underwent LT-only for NASH transplanted during the same time period. **Results:** There was no significant difference in all-cause mortality or graft loss between LT and LTSG patients (Figure A, B). At last follow up, 20.3% and 23.4% of LTSG patients had steatosis and fibrosis, respectively, versus 40.4% and 37.3% of LT-only patients with steatosis and fibrosis respectively ($p = 0.01$ steatosis, $p = 0.12$ fibrosis). The prevalence of diabetes in LTSG patients decreased significantly from 42.2% at transplant to 20.3% at last follow up ($p = 0.01$), versus no significant change in diabetes prevalence in LT-only patients. The prevalence of hypertension in LTSG patients decreased from 61.1% to 35.8% ($p < 0.01$) and hyperlipidemia was not significantly changed (Figure C). LTSG patients, starting with an average BMI of 45.5, had significantly reduced BMI for at least 9 years following surgery (all $p < 0.001$). LT-only patients, with an average BMI of 34.0, had no significant change in BMI (Figure D). One LTSG patient (1.4%) had a gastric sleeve leak and one required hiatal hernia repair. None required revision. Severe gastric reflux occurred in 11.1% of LTSG patients; risk factors included male sex, pre-existing diabetes, and pre-existing GERD. **Conclusion:** LTSG is an excellent option for those with BMI > 40; it confers no increase in mortality or graft loss even when compared to a less obese cohort. LTSG reduces recurrence of steatosis and trends toward less fibrosis when compared to LT alone, and leads to sustained weight loss and resolution of diabetes and hypertension.

131 | SINGLE CELL TRANSCRIPTIONAL T CELL DYNAMICS OF PEDIATRIC LIVER TRANSPLANT REJECTION

Anna L. Peters[1,2], Erica DePasquale[1], Gousia Begum[1], Krishna Roskin[1,2], E. Steve Woodle[2] and David Hildeman[1,2], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Cincinnati

Background: Conventional therapy for late T cell mediated acute cellular rejection (ACR) in liver transplant includes corticosteroids and anti-thymocyte globulin, has remained unchanged for six decades, and is not infrequently met with treatment failure. Here, we used single cell RNAseq with TCR V(D)J profiling to identify expanded (ie, alloreactive) T cell clones and their gene expression profiles in response to anti-rejection treatment. **Methods:** Single cell suspensions were generated from cryopreserved 16G liver biopsy tissue using cold active proteases. Whole cell and TCR libraries were constructed using 10X Chromium 5'v1.1 and 5'V(D)J TCR sequencing kits. Cells were clustered based on cell type specific gene expression profiles by unsupervised analysis in Seurat and TCR libraries were superimposed into the cell clusters. TCR clonotypes were defined as expanded if the CDR3±/ß sequences were expressed in > 2 cells. Cellular communication between Kupffer cell (KC) and T cell populations was analyzed using CellPhoneDB. **Results:** Overall, 10,896 cells isolated from 30 biopsies obtained from 14 patients (5 normal or non-ACR allograft dysfunction, 9 ACR) were analyzed. Consistent with their role in mediating ACR, all expanded T cell clones were $CD8^+$ ($CD8_{EXP}$) according to transcriptional analysis and were significantly expanded in ACR biopsies ($p < 0.05$, Student's t-test). $CD8_{EXP}$ bore markers of activated tissue resident memory cells (Trm; *CD69*, *CXCR6*, *HLA-DR*, *GZMB*), and retained their clonotype identity and phenotype in subsequent biopsies from the same patients despite histologic ACR resolution. In contrast, $CD4^+$ T cells were only found in the unexpanded T cell pool and had a gene expression profile consistent with naïve T cells (*TCF7*, *CCR7*, *SELL*). CellPhoneDB analysis revealed differential crosstalk between KC and $CD8_{EXP}$ T cell populations, with activation of the CD2-CD58 proliferative pathway and downregulation of TGFß signaling. **Conclusion:** Despite 6-antigen HLA mismatches corresponding to a massive number of potential allogeneic epitopes, we uncovered a remarkably limited number of $CD8_{EXP}$ clones. Sequential biopsies demonstrated persistence of these clones up to several months, suggesting that the restricted clonal expansion is not due to sampling bias, but rather to a consistently focused allo-response. Transcriptomic analysis revealed differential gene expression and crosstalk between KC-T cell populations which may facilitate T cell retention in allograft liver tissue.

Background: Since our first pediatric anonymous non-directed live donor liver transplant (Anon-LDLT) performed in April 2005, 62 children have undergone live donor liver transplant (LDLT) with an anonymous non-directed graft. Anon-LDLT organs being allocated as per our deceased donor liver transplant wait list. The objective of this study was to evaluate clinical outcomes, recipient characteristics and social determinants of health of pediatric recipients of Anon-LDLT in comparison to those who received a directed LDLT (Dir-LDLT). **Methods:** Retrospective analysis of all recipients of LDLT performed between January 2005 and March 2023. Demographic and clinical data included age, sex, race, ethnicity, single-parent households, primary diagnosis, recipient blood type, time on waiting list, post-LT intensive care unit (ICU) length of stay (LOS), time to extubation, and post-transplant comorbidities were assessed as covariates. A comparative analysis was conducted between children receiving Anon-LDLT versus Dir-LDLT. A p value of d 0.05 was considered significant. **Results:** A total of 236 (51% male, 62% white, 19.5% Asian, 7% Black, 3% indigenous) children (median age 11 mo) underwent LDLT. Biliary atresia (44%) and metabolic diseases (31%) were the commonest primary indications. Anon-LDLT was performed in 62 (26.2%) children, none of whom had any directed live liver donor options. Recipients of Anon-LDLT were more often non-white (55% vs 32%, $p = 0.001$), Black (13% vs 5%, $p = 0.043$) and Indigenous (8% vs 2%, $p = 0.018$) recipients in comparison to Dir-LDLT recipients. Anon-LDLT recipients were more frequently living in single parent households (18% vs 3%, $p < 0.001$) and to require interpreter assistance (11% vs 3%, $p = 0.010$) (Table), compared to children who received a Dir-LDLT. Out-of-province children were more likely to undergo Anon-LDLT (19/62, 31%) compared to Dir-LDLT (31/174, 18%, $p = 0.034$). Median time on the wait list was longer for Anon-LDLT (92 d) compared to Dir-LDLT (62 d) recipients ($p = 0.004$). Post-LT ICU LOS, time to extubation or other post-LT complications were not statistically different between groups. There were no cases of graft failure or re-transplantation in the Anon-LDLT recipients. **Conclusion**: This retrospective analysis of 62 children undergoing Anon-LDLT at a single institution confirms excellent patient and graft survival. Patients from Indigenous and Black communities, single parent and households where English is a second language, are more frequently the beneficiaries of Anon-LDLT grafts. Anon-LDLT, as utilized in this single center analysis, benefits medically underserved pediatric patients who otherwise have limited access to the advantages of LDLT.

Table. Characteristics of pediatric living-donor liver transplants by donor type

	Anon-LDLT N = 62	Dir-LDLT N= 174	p-values
Age, months (IQR)	13 (8, 35)	11 (7, 48)	0.753
Gender, Male n (%)	31 (50%)	90 (52%)	0.816
Body weight, z-score	-0.16 (-1.25, 0.82)	-0.28 (-1.26, 0.45)	0.640
Race/Ethnicity			**0.006**
Asian	14 (22.5%)	32 (18%)	
Black	8 (13%)	9 (5%)	
Caucasian	28 (45%)	119 (68.5%)	
Hispanic	1 (1.5%)	4 (2.5%)	
Indigenous	5 (8%)	3 (2%)	
Multi-racial and others	6 (10%)	7 (4%)	
Primary diagnosis			**0.001**
Alagille syndrome	3 (5%)	6 (3%)	
Biliary atresia	27 (43.5%)	95 (55%)	
Metabolic disorder	19 (30.5%)	16 (9%)	
Acute liver failure	0 (0%)	10 (6%)	
malignancy	3 (5%)	8 (5%)	
Others	10 (16%)	39 (22%)	
Single parent	11 (18%)	6 (3%)	**<0.001**
English as Second Language	7 (11%)	5 (3%)	**0.010**
Recipient blood type			0.957
A	23 (37%)	60 (35%)	
B	10 (16%)	25 (14%)	
AB	3 (5%)	9 (5%)	
O	26 (42%)	79 (46%)	
Time on waiting list, days	92 (57, 135)	62 (36, 126)	**0.004**
ICU stay, days	3 (2, 8)	3 (2, 7)	0.321
Time to extubation, days	1 (1, 3)	1 (1, 4)	0.183
Posttransplant length of hospitalization	25.5 (17, 36)	21 (15, 35.5)	0.182
Hepatic artery thrombosis	1/55 (2%)	5/166 (3%)	0.637
Portal vein thrombosis	2/55 (4%)	9/166 (5%)	0.598
Biliary stricture	4/55 (7%)	13/166 (8%)	0.893
Re-transplant	0 (0%)	4 (2%)	0.229
Graft survival rate (post 1yr)	62 (100%)	173 (99%)	0.550
Death	0 (0%)	5 (3%)	0.177
Survival rate (post 1 year)	62 (100%)	172 (99%)	0.397

Data are presented as medians and interquartile ranges or N (%).

Anon-LDLT: anonymous non-directed live donor liver transplant
Dir-LDLT: directed live donor liver transplant

Background: Peripheral blood (PB) regulatory T cells (Tregs) in post-transplant alloimmune hepatitis (DAIH) & autoimmune hepatitis (AIH) have poor regulatory function, however little is known about intrahepatic (IH) Tregs in both diseases. As the human Treg compartment encompasses multiple subsets that delineate different developmental stages & their associated regulatory function, we used mass cytometry & unsupervised clustering algorithm Flow self-organizing map (FlowSOM) to interrogate the distribution of subsets within *ex-vivo* $CD25^{hi}CD127^{lo/neg}FoxP3^{+}$ Treg in PB & liver (IH) of children with DAIH & non-transplanted children with AIH. **Methods:** Enriched $CD4^{+}$ T cells from peripheral blood mononuclear cells (PBMC) and intrahepatic lymphocytes (IHL) of children with DAIH (n = 5), AIH (n = 5), biopsy proven acute rejection (AR) (n = 3), liver transplanted children with graft dysfunction (n = 6), & liver transplanted children with normal graft function (LTC) (n = 14) were expanded in culture with Dyna beads CD3/CD28, rIL-2 & TGF-b for 5-days prior to FACS sorting of Tregs. For FACS sorting, Tregs were identified by high expression of CD25 & low expression of CD127. *Ex-vivo* sorted PB & IH Tregs were then stained for mass cytometry with metal-conjugated monoclonal antibodies (CD49D, CD4, CCR4, CD45RA, CD3, CD39, FoxP3, CD95, CD45RO, CD25, CD152, HLA-DR, CD127, CD73, NRP1, Helios, LAP, CD45). Cells were acquired using a CyTOF Helios mass cytometer. CyTOF data was time-based bead normalized using standard procedures. The data were then uploaded to OMIQ (Omiq.ai), manually gated using Gaussian parameters to resolve live, intact, single cells for further analysis. Expression levels were arcsinh transformed with a cofactor of 5 and compared across disease groups within the Treg population. Clustering was performed using FlowSOM & visualized using dimensionality reduction using UMAP. All statistical analyses were performed in GraphPad Prism v9 (Dotmatics). **Results:** Demographics reported in Table 1 below. 10 phenotypically distinct clusters were identified based on15 analyzed parameters within PB & IH Tregs of DAIH, AIH patients, as well as LTC subjects. IH Tregs of AIH patients were characterized by a higher CD45RA, & lower CCR4, Helios, FoxP3, CD25, CD73, CD39, CD45RO, & CD95 expression when compared with PB Tregs ($p < 0.001$). IH Tregs of DAIH patients were characterized by a higher expression of CD45RA, CCR4, CD25, CD73, CD95, & lower expression of FoxP3, Helios, CD39 compared to PB Tregs ($p < 0.001$). An important suppressive mechanism mediated by Treg involves the CD39/CD73 adenosine pathway. In humans, $CD39^{+}$ Tregs are implicated in the suppression of Th17 responses & the control of autoimmunity. **Conclusion:** The lower expression of FoxP3 & Helios in IH Tregs of patients with DAIH & AIH could suggest Treg destabilization. Further work is needed to determine if these IH Tregs have the potential to transdifferentiate into effector T cells.

	Post-transplant alloimmune hepatitis (n=5)	Autoimmune Hepatitis (n=5)	LT Control (n=14)	Acute Rejection (n=3)	Graft Dysfunction (n=6)

Lurie Children's Hospital of Chicago, Chicago, IL, (30)Bern University Hospital, University of Bern, (31)University of Milan, (32)Texas Children's Hospital

Background: There are very limited high-quality data from which to derive therapeutic approaches to portal hypertension (PHT) in children. Management of varices, in particular, is quite controversial in pediatrics. IMPPHR was developed to derive large-scale international data, thereby enhancing our knowledge of PHT. The three major foci of data collection in IMPPHR are, 1) morbidity and mortality of first variceal hemorrhage, 2) feasibility and safety of primary prophylaxis of varices, 3) approaches to secondary prophylaxis of variceal hemorrhage. Subject level data collection is ongoing in IMPPHR (n = 241 cases as of 4.27.23) and will be reported in the future. This report provides center-specific data relevant to the management of varices. **Methods:** Each site submitted institutional resources and clinical activity accrued over 2 years between January 1, 2018 and December 31, 2019 to present a snapshot of resources and approaches available in clinical practice. **Results:** 23 centers (11 countries, 4 continents) serving an aggregate population of > 100,000,000 with 5970 hospital beds and 1024 ICU beds provided site specific data. Overall 600 liver transplants were performed at the sites for indications that included but were not limited to PHT ([median per center] 19: [25-75%ile] 6-34) of which 112 (1: 0-6) were living donor and 222 (5: 0-10) were technical variant grafts. In aggregate, 885 (23: 15-38) endoscopic variceal ligations were performed by 99 (4:2-6) individual's, while 266 (3:0–10) endoscopic sclerotherapy sessions were performed by 46 (2: 0-3) individual's. Potential two year endoscopic practitioner caseload varied significantly by site (variceal ligation 7: 2.8-13.8, sclerotherapy 1.5: 0.0-5.0). Nontransplant nonendoscopic interventions for PHT included 55 (range per center 1–20) portosystemic shunts (12/23 centers), 21 (range 1–5) TIPS (8/23 centers) and 30 (range 1–8) MesoRex bypass procedures (11/23 centers). 8 centers, Group A, performed at least 3 of at least one of these nontransplant nonendoscopic procedures; their center characteristics differed from the remaining 15 centers, Group B (Table). **Conclusion:** A multi-center registry focused on pediatric esophageal varices, has been developed with ongoing patient data entry. Site specific data reveals marked variability in approaches. Many pediatric centers perform only small numbers of endoscopic procedures for PHT, often divided among several proceduralists. There is also variable and limited use of nonendoscopic nontransplant interventions for PHT. IMPPHR will permit analysis of the impact of differences in approach on outcomes, helping to inform optimal treatment decisions and program planning. Supported by the Spain Family and an ESPGHAN Networking Grant.

Characteristic ->	Population of area (M)	Hospital Beds	OLT	LRD	Tech Variant	EVL	EST

Tonascia[2], (1)Indiana University School of Medicine, (2) Johns Hopkins School of Public Health, (3)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, (4)University of California, San Diego, San Diego, CA, (5)Saint Louis University, (6)Washington State University, (7)Duke University, (8)Cleveland Clinic Foundation, (9)University of Southern California

Background: The effect of *PNPLA3* rs738409 I148M variant (G allele) on the clinical course of adults with biopsy-proven nonalcoholic fatty liver disease (NAFLD) has not been prospectively investigated. We examined (1) the association between *PNPLA3* G allele and clinical outcomes and (2) how relationships among *PNPLA3* G allele, age, and type 2 diabetes mellitus (T2DM) impact clinical outcomes in patients with biopsy-proven NAFLD. **Methods:** A total of 2,075 adults with biopsy-proven NAFLD were enrolled in the NASH CRN studies between October 2004 and May 2019, and prospectively followed until September 2020, death, or transplant. Cox proportional and competing risk models were used to examine associations between *PNPLA3* G allele and all-cause mortality (death of any cause) or composite liver (liver-specific deaths or new-onset varices, hepatic decompensation, HCC, or liver transplant)-, cardiovascular (cardiovascular or cerebrovascular-specific events or deaths)-, non-HCC malignancies (cancers-specific events, and mortality, excluding HCC)-, and chronic kidney disease (CKD) (new onset glomerular filtration rate < 60 mL/min/1.73 m^2, or CKD-related death)-related outcomes. All analyses were adjusted by race/ethnicity, age, sex, T2DM, body mass index (kg/m^2), hypertension, and smoking status. **Results:** The *PNPLA3* genotypes were CC: 32%; CG: 44%; and GG: 24%. During a median follow-up of 3.4 years, there were 53 (3%) deaths of any cause. *PNPLA3* G allele was not associated with all-cause mortality (Adj. HR: 0.85, 95% CI: 0.57-1.27), but it was significantly associated with an increased risk of the composite liver outcome (CLO) (Adj. sHR: 1.39, 95% CI: 1.06-1.81). *PNPLA3* G allele was also not associated with cardiovascular events (Adj. sHR: 1.09, 95% CI: 0.86-1.39), non-HCC malignancies (Adj. sHR: 1.00, 95% CI: 0.72-1.40) or CKD (Adj. sHR: 1.25, 95% CI: 0.90-1.74). The effect of *PNPLA3* G allele on the risk of CLO increased positively and exponentially among those aged > 60 years or with T2DM (p values for interactions < 0.01). Adults 60 or older with CG (Adj. sHR: 3.3, 95% CI: 1.0-14.8) and GG (Adj. sHR; 5.8, 95% CI: 1.3-26.5) genotypes showed the highest risk of CLO as compared to those with CG/GG genotypes and aged < 60 (Figure 1A). Similarly, T2DM patients with *PNPLA3* CG (Adj. sHR: 3.2, 95% CI: 1.5-7.0) and GG (Adj. sHR: 7.8, 95% CI: 3.5-17.4) exhibited the highest risk of CLO compared to non-T2DM people with CG/GG genotypes (Figure 1B). **Conclusion:** The carriage of *PNPLA3* G allele is associated with worse liver outcomes in patients with biopsy-proven NAFLD. Increasing age and type 2 diabetes amplify this relationship. Routine genotyping of PNPLA3 in patients with NAFLD is warranted.

136 | ADIPOSE TISSUE INSULIN RESISTANCE AFFECTS LIVER MITOCHONDRIAL FUNCTION INDEPENDENTLY OF LIVER FAT ACCUMULATION★

Fernando Bril[1], Srilaxmi Kalavalapalli[2], Kenneth Cusi[2] and Meagan Gray[1], (1)University of Alabama at Birmingham, (2)University of Florida

Background: The mechanisms contributing to the progression to NASH in patients with NAFLD are unclear. Our central hypothesis is that the inability of hepatic mitochondria to enhance nutrient oxidation in the setting of nutrient oversupply plays a key role in the progression of liver disease in NAFLD. The aim of this study was to explore the relationship between adipose tissue insulin resistance (IR), liver fat, and *in vivo* hepatic mitochondrial function. **Methods:** Patients with BMI ≥ 25kg/m^2, without diabetes were included in the study. Patients underwent a 2-hour oral glucose tolerance test (OGTT) and a liver proton magnetic resonance spectroscopy (^{1}H-MRS) to measure liver fat. Adipose tissue IR was estimated during a fasting period as AdipoIR: fasting insulin x free fatty acids (FFA) and in the postprandial period as insulin-mediated suppression of FFA during an OGTT. *In vivo* hepatic mitochondrial ATP levels were measured by phosphorus (^{31}P)-MRS at baseline and every 30 minutes during a 2-hour oral fructose (75 grams) challenge (OFC). Due to unregulated phosphorylation of fructose upon entering hepatocytes, the OFC

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

provides a dynamic measurement of hepatic ATP consumption and re-synthesis as a surrogate marker of mitochondrial function. Hepatic ATP levels were estimated as β-ATP/total phosphorus. **Results:** A total of 37 patients were recruited (54 ± 11 years; 43% male/57% female; BMI: 34.4 ± 6.3 kg/m^2; NAFLD: 51%). No differences were found in basal hepatic ATP levels in patients with or without NAFLD ($p = 0.44$). Similarly, we did not observe any difference in basal hepatic ATP levels with increasing levels of adipose tissue IR ($p = 0.42$). After the OFC, no differences were observed in changes in hepatic ATP levels in patients with vs. without NAFLD ($p = 0.67$) or based on quartiles of liver fat (Figure 1A). However, changes in hepatic ATP levels after the OFC were significantly different among groups defined by quartiles of adipose tissue IR (Figure 1B-C). These differences were more pronounced when adipose tissue IR was measured during fasting (i.e., Adipo-IR) than the postprandial state. Patients on the highest quartile of adipose tissue IR showed no consumption of ATP after the OFC, but rather an overall increase in ATP levels over time. Adipo-IR significantly correlated with changes of hepatic ATP after the OFC (-0.52, $p = 0.001$). **Conclusion:** Patients with increased adipose tissue IR, particularly in the fasting state, showed an over-compensatory hepatic mitochondrial response, characterized by an increase in hepatic ATP levels after fructose consumption. This suggests that chronic elevated of fasting FFA lead a compensatory increase of hepatic mitochondrial oxidation capacity. At what point this compensation is overwhelmed leading to inflammation and lipotoxicity remains to be determined.

137 | HEPATIC STEATOSIS IS ASSOCIATED WITH INCREASED CARDIOVASCULAR EVENT RATE AMONG PEOPLE AT LOW 10-YEAR ATHEROSCLEROTIC CARDIOVASCULAR DISEASE RISK

Julia Karady[1], Thomas Mayrhofer[1], Borek Foldyna[1], Michael T Lu[1], Nandini Mehyerson[1], Udo Hoffmann[1], Neha Pagidipati[2], Svati Shah[2], Pamela S Douglas[2], Maros Ferencik[1] and Kathleen E. Corey[3], (1) Massachusetts General Hospital, (2)Duke Clinical Research Institute, (3)Massachusetts General Hospital, Somerville, MA

Background: Hepatic steatosis (HS) and a 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥ 7.5% are associated with increased risk for future cardiovascular events. However, cardiovascular risk of patients with HS at ASCVD < 7.5% is not clearly understood. **Methods:** We studied adults with suspected stable angina and no history of coronary artery disease (CAD) who underwent coronary CT imaging in the PROMISE trial. HS, coronary artery calcium (CAC) score, obstructive CAD (stenosis ≥ 50%) and vulnerable plaques (plaques with low attenuation, positive remodeling, and napkin-ring sign) were defined by using coronary CT datasets. Major adverse cardiovascular event (MACE) was defined as hospitalization for unstable angina, non-fatal myocardial infarction, and all-cause death. Multivariable Cox regression analysis adjusting for CAC, obstructive CAD and vulnerable plaques assessed whether HS independently predicts MACE among patients at < 7.5% ASCVD risk. **Results:** Among ASCVD < 7.5% risk patients, individual's with HS were younger (54.3 ± 5.2 vs 55.8 ± 5.2; $p < 0.001$), more likely to be males (40.2% [98/244] vs 27.1% [260/960]; $p < 0.001$), had more risk factors (mean number of risk factors: 2.06 ± 0.89 vs 1.93 ± 0.91; $p = 0.047$) and had higher triglycerides (138.0 vs 115.0 mg/dL, $p = 0.014$) and alanine transaminase (30.0 vs 19.0 mg/dL; $p < 0.001$) than those without HS. These features similarly differed among patients with ASCVD ≥ 7.5% risk with and without HS. CAD characteristics, (CAC, obstructive CAD, vulnerable plaques) did not differ between HS vs no HS patients independent of ASCVD risk (all $p > 0.05$). Patients with HS had higher MACE rate in the ASCVD < 7.5% (1.5% [14/960] vs 3.75 [9/244]; $p = 0.027$) and ASCVD ≥ 7.5% groups (3.1% [56/1,802] vs 4.7% [33/696]; $p = 0.043$) compared to patients without HS. Among patients without HS ASCVD ≥ 7.5% had higher MACE rate compared to ASCVD < 7.5% (3.1% [56/1,802] vs 1.5% [14/960]; $p = 0.011$). In patients with HS MACE rates were similar (ASCVD ≥ 7.5% vs < 7.5%: 4.7% [33/696] vs 3.7% [9/244], $p = 0.484$). The cumulative event rate was significantly lower for patients without HS and ASCVD <

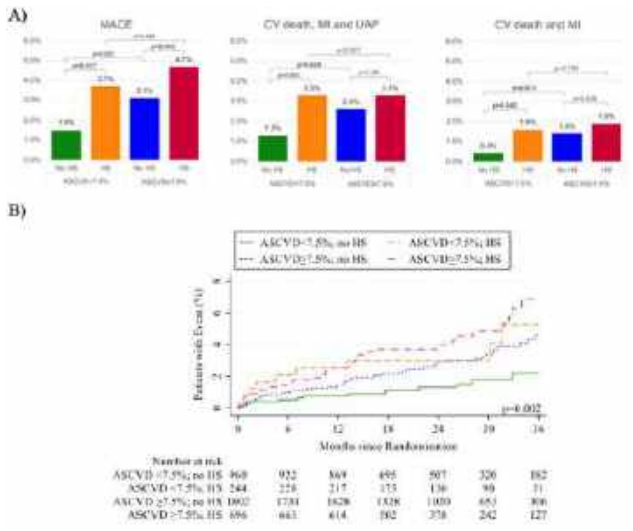
7.5% compared to the other groups (*figure*). In patients with ASCVD < 7.5%, HS predicted MACE (aHR:2.34, 95%CI:1.01-5.43; $p = 0.048$), independent of CAD characteristics. **Conclusion:** Individual's with radiographic HS and < 7.5% ASCVD risk have similar CAD severity and burden as patients without HS at < 7.5% ASCVD but experience similar MACE rates as individual's at e 7.5% ASCVD risk.



A) Event rates across the four strata of patients with and without Hepatic Steatosis and ASCVD <7.5% vs ≥7.5%. **B)** Cumulative major adverse cardiovascular event rates across the four strata of patients with and without Hepatic Steatosis and ASCVD <7.5% vs ≥7.5%. ASCVD: Atherosclerotic cardiovascular disease; CV: Cardiovascular; HS: Hepatic steatosis; MI: Myocardial infarction; UAP: Unstable angina pectoris.

138 | IDENTIFICATION OF THE ENVIRONMENTAL POLLUTANTS AND METABOLIC PATHWAYS ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE SEVERITY

Niharika R. Samala[1], Matthew Ryan Smith[2], Christina Pinkston[3], Shesh N Rai[3], Young-Mi Go[2], Dean P. Jones[4], Naga P. Chalasani[5] and Matthew Cave[6], (1) Indiana University, Indianapolis, IN, (2)Emory University, (3)University of Cincinnati, (4)Emory University, Children's Healthcare of Atlanta, (5)Indiana University Medical Center, Indianapolis, IN, (6) University of Louisville, Louisville, KY

Background: Environmental pollutants are associated with disrupted hepatic metabolism and NAFLD. A pilot study (n = 140) presented at AASLD elucidated exposures and metabolic pathways associated with NAFLD severity. To confirm these findings, a larger cross-sectional multi-'omics study was performed in subjects with NAFLD. **Methods:** Exposomics and metabolomics (LC-MS^2 using HILIC & C18 columns & GC-MS^2) were performed in plasma samples from 341 prospectively enrolled NAFLD patients diagnosed by AASLD guidelines. Fibrosis severity was determined by liver stiffness measurement (LSM) and steatosis by controlled attenuation parameter (CAP). LSM > 8.6kPa was considered to be clinically significant fibrosis (CSF). Exposome- and metabolome-wide association studies (EWAS & MWAS) were performed using the R package xMSPanda. Pathway enrichment analyses were performed using mummichog. **Results:** The NAFLD cohort (mean age = 53 ± 14 y, mean BMI = 35 ± 7 kg/m^2) was 60% female and 95% White. 48% had diabetes-2, 53% had dyslipidemia, and 60% had hypertension. Four environmental pollutants (ethyl-decanoate, ethyl-undecanoate, diethylthiophosphoric acid, and hydroxycitronellal) were significantly associated with CSF ($p < 0.05$, FDR < 0.20). At a less stringent threshold ($p < 0.05$, FDR > 0.20), 42 exposures were associated with CSF. These included environmental phenols confirming results from the pilot study. The MWAS of LSM revealed significant associations with 271 (HILIC) and 314 (C18) metabolic features ($p < 0.05$, FDR < 0.05). Thirty metabolic pathways were associated with fibrosis including: bile acids; glycosphingolipids; vitamin D3; hexose-phosphorylation; keratan-sulfate; N-glycan; pyrimidine, arginine-proline; and linoleate, confirming results from the pilot study. CAP was significantly associated with 35 (HILIC) and 17 (C18) metabolic features. Fifteen pathways were associated with hepatic steatosis, 8 of which were previously identified in the pilot study. **Conclusion:** Multiple environmental pollutants were associated with CSF, with several previously identified in the pilot cohort. Bile acid metabolism was the most significantly enriched pathway associated with liver fibrosis, and seven pathways were perturbed by both steatosis and fibrosis recapitulating results from the pilot study in this larger cohort. Reverse causality cannot be excluded. These findings suggests that pollutants have a significant impact on liver fibrosis in NALFD and warrant additional investigation.

139 | HEPATIC LOBULAR INFLAMMATION IS THE MOST IMPACTED PROGNOSTIC FACTOR RATHER THAN FIBROSIS IN PATIENTS WITH BIOPSY-PROVEN MASLD: MULTI-CENTER STUDY★

Tsubasa Tsutsumi[1], Takumi Kawaguchi[1], Hideki Fujii[2], Hideki Hayashi[3], Michihiro Iwaki[4], Hirokazu Takahashi[5], Satoshi Oeda[6], Hideyuki Hyogo[7], Yoshihiro Kamada[8], Miwa Kawanaka[9], Hidenori Toyoda[10], Yoshio Sumida[11], Masato Yoneda[4], Shinichi Aishima[6], Atsushi Nakajima[12] and JSG-NAFLD, (1)Kurume University School of Medicine, (2)Osaka Metropolitan University, Osaka, Japan, (3)Gifu Municipal Hospital, (4)Yokohama City University Graduate School of Medicine, (5) Division of Metabolism and Endocrinology, Faculty of Medicine, (6)Saga University, (7)Life Care Clinic Hiroshima, (8)Osaka University Graduate School of Medicine, (9)Kawasaki Medical School, (10)Ogaki Municipal Hospital, (11)Aichi Medical University, (12) Yokohama City University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) captures patients at high risk of hepatic fibrosis and cardiovascular disease. However, limited information is available on the prognosis of MASLD. This study aimed to investigate the prognosis of patients with biopsy-proven MASLD and validate a group of fatty liver patients excluded from MASLD because of no metabolic abnormalities by a multi-center longitudinal cohort. We also investigate the most important histological finding associated with the prognosis of patients with MASLD. **Methods:** We enrolled 1,444 patients with fatty liver who underwent liver biopsy (age 57, female 55.1%, BMI 27.4). Patients were classified into the following three groups: the MASLD group (steatosis with metabolic abnormalities), the non-MASLD group (steatosis without metabolic abnormalities), or the Burnt-out group (no steatosis on biopsy). Cox proportional hazard analysis and Kaplan-Meier analysis were performed to identify the factor associated with the prognosis. Furthermore, decision-tree analysis was demonstrated to determine the most affected histological finding related to the prognosis of each group. **Results:** The prevalence of patients with MASLD, non-MASLD, and Burnt-out group was 92.1% (1,330/1,444) and 3.1% (45/1,444), 4.8% (69/1,444), respectively. During the 9,083 person-years of observation, 4.3 person-years of deaths occurred in all patients, and 84.2% (32/38) of the deceased patients were in the MASLD group in this study. As for the histopathological features, the MASLD group showed the highest prevalence of inflammation in grades 1-3 (95.2%). Whereas the Burnt-out group showed the highest prevalence of fibrosis stages 3 and 4 (35.3%). Compared to the MASLD group, the Burnt-out group was identified as an independent factor associated with prognosis in Cox proportional hazard analysis (RR 5.91, $p = 0.0001$). On the other hand, it could not compare the statistical analysis with the other groups because of the absence of deaths in the non-MASLD group. Kaplan-Meier analysis revealed significant differences in prognosis among the three groups (Log-rank $p = 0.0009$). Ten-year survival rate was 95.6% in MASLD, while no patient died in the non-MASLD group until the end of the follow-up period. Decision-tree analysis revealed hepatic fibrosis was the most affected histological finding associated with the prognosis in the Burnt-out group. In contrast, we identified hepatic inflammation as the most affected prognostic finding in the MASLD group. **Conclusion:** We showed MASLD was a major pathological condition related to the deaths and the prognosis of MASLD was worse than non-MASLD. Hepatic inflammation rather than fibrosis was the most affected prognostic histological finding in patients with MASLD. Thus, metabolic abnormalities may worsen the prognosis of patients with fatty liver. Inflammation may be responsible factor for the poor prognosis of MASLD.

140 | ARTIFICIAL INTELLIGENCE TO MEASURE FIBROSIS CHANGE ON LIVER BIOPSY IN MAESTRO-MASH: A PHASE 3 SERIAL LIVER BIOPSY STUDY IN 966 PATIENTS WITH MASH TREATED WITH RESMETIROM OR PLACEBO

Stephen A Harrison[1], Rebecca A. Taub[2], Ya-Yun Ren[3], Elaine Lay Khim Chng[4] and Dean Tai[4], (1)Pinnacle Clinical Research Center, San Antonio, TX, (2)Madrigal Pharmaceuticals, (3)Histoindex Pte Ltd, (4)Histoindex Pte Ltd, Singapore

Background: MAESTRO-MASH (NCT03900429), an ongoing, randomized, double-blind, placebo-controlled Phase 3 serial liver biopsy study, achieved both primary endpoints on liver biopsy (MASH resolution and fibrosis reduction) at Week 52 with both resmetirom doses, including a e 1-stage reduction in fibrosis without worsening of MASH of 24%, 26% (mITT) at 80 and 100 mg resmetirom compared with placebo (14%). As an exploratory endpoint, artificial intelligence slide reading technologies were employed to measure the effect of resmetirom on fibrosis on serial liver biopsy using both continuous and quantitative scoring. **Methods:** Fibrosis was estimated as a continuous and categorical score using second harmonic generation (qFibrosis)/two photon excited fluorescence of 768 paired biopsy samples from MAESTRO-MASH. A separate unstained slide was analyzed for qFibrosis (normalized by tissue area and then corrected for qSteatosis (tissue area-steatosis area)). Relative changes in 184 fibrosis parameters were determined. **Results:** The analyses were based on a total of 768 slide pairs including a baseline and Week 52 slide that were received and met criteria for quality ($< 10\%$ missing pairs; $< 3\%$ excluded for quality). Based on a continuous qSteatosis score, the percent change from baseline in steatosis was 80 mg resmetirom, -36%; 100 mg resmetirom, -46%; placebo, -10%; $p < 0.0001$ for both resmetirom doses. The continuous change from baseline in corrected qFibrosis score was 80 mg resmetirom, -22%; 100 mg resmetirom, -20%; placebo,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

3%; $p < 0.0001$ for both resmetirom doses. The categorical qFibrosis stage aligned with the stage assigned by the central pathologists (F1, F2, F3) with the exception that qFibrosis estimated a high fraction (~20%) as F4 at baseline (F4 scored at baseline by the central pathologists were excluded from this study). Based on categorical change in qFibrosis score, there was a significant improvement in fibrosis stage (1-stage or 2-stage improvement) at 80 and 100 mg resmetirom relative to placebo, and less worsening of fibrosis in the resmetirom groups compared with placebo (Table). The percentage showing improvement in qFibrosis (≥ 1-stage) was higher than scored by the central pathologists and identified 90% of resmetirom responders determined by the central pathologists. Significant correlations were observed between reduction in qFibrosis and reduction in PDFF, ALT, AST, and ELF. **Conclusion:** Measurements of fibrosis change using qFibrosis on either a continuous or categorical scale demonstrated a clear improvement and less worsening in fibrosis among resmetirom-treated patients with MASH as compared with placebo-treated patients after 52 weeks.

Table. Categorical change in qFibrosis stage

	≥1-stage improvement	p-value	≥2-stage improvement	p-value	Worsened	p-value
80 mg resmetirom	58%	<0.0001	19%	<0.0001	11%	<0.0001
100 mg resmetirom	56%	<0.0001	25%	<0.0001	11%	<0.0001
Placebo	34%		7%		35%

141 | TITLE: MAXIMIZING THE BENEFITS OF STATIN THERAPY FOR LIVER DISEASE PREVENTION: TARGETING PATIENTS WITH UNMET STATIN THERAPY NEEDS★

Mara Sophie Vell[1], Arunkumar Krishnan[2], Kirk J. Wangensteen[3], Kate Townsend[4], Jonel Trebicka[5], Eleonora Scorletti[4], Inuk Zandvakili[4], Marijana Vujkovic[6], Christian Trautwein[7], Rohit Loomba[8], Saleh A Alqahtani[9], Daniel J. Rader[4], Kai M. Schneider[1] and Carolin Victoria Schneider[1], (1)University Hospital Rwth Aachen, (2)West Virginia University School of Medicine, Morgantown, (3)Division of Gastroenterology and Hepatology, Department of Medicine, Mayo Clinic, Rochester, MN, (4)University of Pennsylvania, (5) University Hospital Münster, (6)Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (7)Department of Internal Medicine III, University Hospital, Rwth Aachen, Germany, (8)University of California, San Diego, San Diego, CA, (9)King Faisal Specialist Hospital and Research Center

Background: Chronic liver diseases, such as non-alcoholic fatty liver disease (NAFLD) and viral hepatitis, contribute significantly to liver-related morbidity and mortality. Statins, commonly prescribed for dyslipidemia, have been suggested to possess hepatoprotective effects beyond their lipid-lowering properties. This study aims to assess the association between statin use and liver-related outcomes, including hepatocellular carcinoma incidence and liver-related mortality, utilizing data from the UK Biobank. **Methods:** Propensity score matching was employed to match patients without prior liver disease. Patients were matched according to the following criteria: Age, sex, BMI, ethnicity, diabetes mellitus with or without insulin or biguanide use, hypertension, ischemic heart disease, dyslipidemia, aspirin use, and number of medications taken. The study compared primary outcomes between 205,057 statin-users and non-users after matching using cox regression models as well as Fine and Grey models in R. We defined incident liver disease as the occurrence of any new diagnosis of K70-K77 after baseline. Hepatocellular carcinoma was identified using ICD-10 code C22.0, and liver-related death was determined based on deaths attributed to either K70-K77 or C22.0. **Results:** In the UK Biobank (n = 205,057), statin-users exhibited a 15.4% reduced risk of developing new liver disease ($HR_{UKB} = 0.846$, 95% CI, 0.782-0.915; $p = < 0.001$), a 28.0% lower risk of liver-associated death ($HR_{UKB} = 0.720$, 95% CI, 0.588-0.880; $p = 0.001$) and a 42% lower risk of hepatocellular carcinoma development ($HR_{UKB} = 0.580$, 95% CI, 0.350-0.963; $p = 0.04$). When comparing statin-users to non-users with an indication for statin therapy but without a statin prescription, the risk reduction for new liver disease increased to 23.6% ($HR_{UKB} = 0.764$, 95% CI, 0.693-0.842; $p = < 0.001$). **Conclusion:** Our findings strongly suggest that the utilization of statins is linked to a notable reduction in liver-related outcomes, such as the incidence of hepatocellular carcinoma and liver-related mortality. Notably, these findings were even more pronounced when comparing individual's who were prescribed statins to non-users who were likely candidates for statin treatment. Our comprehensive analysis provides robust evidence that underscores the potential preventive benefits of statins on liver disease.

Table

Table: Statin use compared with non-users with indication for statin intake at baseline and the development of liver disease, hepatocellular carcinoma, and liver-related mortality in UKB

Event and Treatment Group	No. with Event/ Total No.	Hazard Ratio (95% CI)	P-value
New Liver Disease[a]			
No Statin intake	801/43,114	1.00 (reference)	-
Statin intake	902/56,109	0.764 (0.693 to 0.842)	<.001[c]
Subdiagnoses[b]			
Alcohol-associated liver disease (K70)	95/56,109	0.690 (0.509 to 0.936)	.02[c]
Fatty liver (K76.0)	392/56,109	0.701 (0.608 to 0.808)	<.001[c]
Liver cell carcinoma (C22.0)	21/56,109	0.57 (0.30 to 1.07)	.08
Liver-related Death			
No Statin intake	126/43,114	1.00 (reference)	-
Statin intake	138/56,109	0.728 (0.564 to 0.939)	.02[c]

[a] Incident Liver Disease is defined as new onset Liver Disease K70-K77 or C22.0 after Baseline examination.
[b] For subdiagnoses, only patients taking statins were referred to, with hazard ratios and P-values calculated consistently compared to patients not taking statins.
[c] Significant P-value.
[d] We compared statin-users with non-users who met the criteria for statin use and did not receive a statin prescription. We selected controls with at least one of total triglycerides >2.3mmol/L, LDL-cholesterol >4.9mmol/L, and total cholesterol >8mmol/L as simplified criteria for a statin indication at baseline.

142 | SINGLE ANASTOMOSIS DOUDENO-ILEAL BYPASS WITH SLEEVE GASTRECTOMY ALLEVIATES LIVER STIFFNESS AND CONTROLLED ATTENUATION PARAMETER IN OBESE PATIENTS – COMPARISON OF 4 MODALITIES

Lukas Hartl[1], Larissa Nixdorf[2], Stefanie Ströhl[1], Moritz Felsenreich[2], Magdalena Mairinger[2], Julia Jedamzik[2], Paula Richwien[2], Mathias Jachs[1], Georg Semmler[1], Lorenz Balcar[1], Michael Schwarz[3], Christoph Bichler[2], Michael Trauner[4], Mattias Mandorfer[1], Thomas Reiberger[4], David Josef Maria Bauer[1,5] and Gerhard Prager[2], (1)Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, (2)Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Vienna, Austria, (3)Medical University of Vienna, (4)Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, (5)Department of Medicine IV – Gastroenterology and Hepatology, Klinik Ottakring, Vienna, Austria

Background: Obesity, metabolic syndrome, and non-alcoholic fatty liver disease (NAFLD) are becoming increasingly prevalent. Bariatric surgery, combining weight loss with metabolic improvements, may represent an effective treatment for these disease entities in obese patients with single anastomosis doudeno-ileal bypass with sleeve gastrectomy (SADI-S) representing a novel bariatric procedure. According to the recent guidance on non-invasive tests, liver stiffness measurement (LSM) assessed by vibration-controlled transient elastography (VCTE) or shear wave elastography (SWE) is recommended for risk stratification. **Methods:** Patients who underwent bariatric surgery at the Vienna General Hospital between 01/2021-12/2022 were included in this prospective study. LSM (via VCTE, as well as point SWE [pSWE] and 2D-SWE using the Siemens Sequoia Acuson system) and controlled attenuation parameter (CAP) assessment were performed before (baseline; BL) and three months after surgery (3M). Patients were stratified for the type of bariatric surgery. **Results:** Overall, 93 patients (SADI-S: 30.1% [n = 28], one anastomosis gastric bypass [OAGB]: 28.0% [n = 26]; Roux-en-Y gastric bypass [RYGB]: 29.0% [n = 27]; sleeve gastrectomy [SG]: 12.9% [n = 12]) with female predominance (68.8%) and a median age of 40.9 years were included. Patients with SADI-S had the highest median body mass index (BMI; 53.3 kg/m2). The median excess weight loss (EWL) after 3 months among all patients was 46.8% and did not differ between the different bariatric procedures. VCTE and CAP paired success rates were 76.8% (n = 43/56) and 83.9% (n = 47/56), while it was 98.2% (n = 55/56) for pSWE and 2D-SWE, respectively. After SADI-S and RYGB, VCTE significantly decreased (SADI-S: BL: 7.3 kPa vs. 3M: 4.8 kPa; $p < 0.001$/RYGB: BL: 5.5 kPa vs. 3M: 4.1 kPa; $p = 0.028$), while it remained unchanged after OAGB ($p = 0.391$) and SG ($p = 0.999$). Moreover, pSWE and 2D SWE LSM dropped significantly after SADI-S (pSWE: BL: 3.9 kPa vs. 3M: 2.7 kPa; $p = 0.002$/2D SWE: BL: 4.9 kPa vs. 3M: 3.2 kPa; $p < 0.001$), but not after other bariatric procedures. Interestingly, 19 patients (44.2%) showed no relevant decrease in LSM after bariatric surgery (< 10% decrease). Finally, there was a marked decline in CAP after SADI-S (BL: 367.5 dB/m vs. 3M: 286.0 dB/m; $p = 0.020$), OAGB (BL: 303.0 dB/m vs. 3M: 4.1 dB/m; $p = 0.019$) and RYGB (BL: 343.0 kPa vs. 3M: 277.0 dB/m; $p < 0.001$). **Conclusion:** LSM - as assessed by both VCTE and SWE - significantly decreased 3 months after bariatric surgery, particularly in patients undergoing SADI-S. We will continue to evaluate if the

decrease in LSM and CAP are 'just' due to EWL or will translate into improved clinical outcomes.

143 | DIGITAL IMAGE QUANTIFICATION OF THE ANTIFIBROTIC EFFECT OF SEMAGLUTIDE AND THE IMPACT OF LIVER FAT IN NONALCOHOLIC STEATOHEPATITIS

Vlad Ratziu[1], Ashan Shoeb Patel[2], Niels Moctezuma Krarup[2], Sharat Varma[2], Mazen Noureddin[3] and Arun Sanyal[4], (1)Sorbonne Université, Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Institute of Cardiometabolism and Nutrition (ICAN), (2)Novo Nordisk a/S, (3)Houston Methodist Hospital, Houston Research Institute, Houston, TX, (4)Division of Gastroenterology, Hepatology and Nutrition, Department of Internal Medicine, Virginia Commonwealth University

Background: Following reductions in steatosis and body weight with glucagon-like peptide-1 receptor agonist treatment for nonalcoholic steatohepatitis (NASH), decreases in liver volume can cause collagen condensation resulting in an over estimation of fibrosis burden when measured by pathologist-reported histology evaluation. Thus, improved methods to objectively evaluate histological changes are needed. Here, digital quantification of the collagen proportionate area (CPA) was compared in the total biopsy area and non-steatotic liver tissue (fat-free CPA) following semaglutide treatment for NASH. **Methods:** This was a post-hoc exploratory analysis of a phase 2 randomized trial of subcutaneous semaglutide 0.1, 0.2, or 0.4 mg once daily versus placebo (NCT02970942). Patients had biopsy-confirmed NASH and fibrosis stage F1–F3. Liver biopsies were obtained up to 21 weeks before screening

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

or at baseline and at week 72; digitized biopsy slides were evaluated. CPA was quantified by measuring collagen deposition as a proportion of either: 1) the total biopsy area (standard CPA) or 2) the non-steatotic biopsy area (i.e. normalized for fat: fat-free CPA = collagen area / [biopsy area – steatosis area]). Changes from baseline to week 72 were analyzed by analysis of covariance for both methods. **Results:** Digitized slides were available for 249 patients for the standard CPA analysis, and 246 patients for the fat-free CPA analysis. A dose-dependent semaglutide treatment effect was seen with both methods (Figure). Standard CPA was numerically reduced with semaglutide 0.4 mg vs placebo (estimated treatment difference [ETD]: –1.68 [95% confidence interval: –4.62, 1.26]; $p = 0.26$). For fat-free CPA, the semaglutide 0.4 mg ETD increased to –2.99 (95% confidence interval: –6.39, 0.41), and the *p*-value approached statistical significance ($p = 0.08$). An enhanced reduction of CPA was seen across all semaglutide doses when measured by fat-free versus standard CPA (Figure). **Conclusion:** When measuring CPA before and after semaglutide treatment, the removal of the confounding effect of the fat area results in numerically greater improvements in fibrosis. The fat-free adjustment analysis for CPA increases the accuracy of fibrosis resolution assessment when using drugs with strong anti-steatogenic effects.

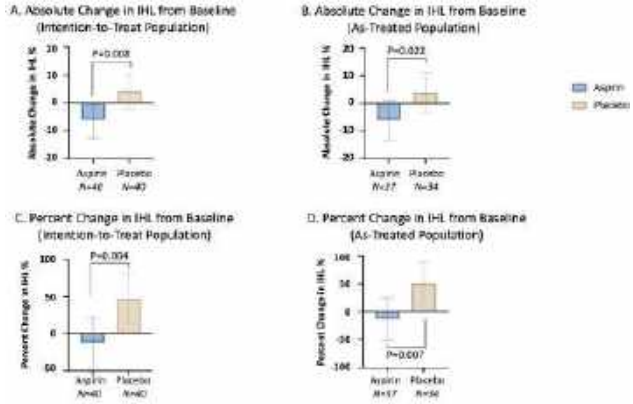
144 | DAILY ASPIRIN THERAPY FOR THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A RANDOMIZED CONTROLLED TRIAL

Robert M Wilechansky[1], Stefania Stoyanova[1], Alessandra Grossman[1], Laura E. Dichtel[1], Charles N. Serhan[2], Karen K. Miller[1], Kathleen E. Corey[1], Raymond T. Chung[3], Andrew T. Chan[1] and Tracey G. Simon[1], (1)Massachusetts General Hospital, (2) Brigham and Women's Hospital, (3)Massachusetts General Hospital, Boston, MA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a chronic, progressive disease with substantial morbidity and mortality and no approved treatments. Observational studies have linked aspirin use to reduced prevalence and progression of MASLD. However, the efficacy and safety of aspirin for reducing hepatic steatosis, inflammation, and fibrosis in patients with MASLD are unknown. **Methods:** In a 6-month, randomized, double-blind, placebo-controlled trial, we assigned 80 adults aged 18-70 years with established MASLD (without cirrhosis) to receive daily aspirin 81mg daily or placebo in a 1:1 ratio. The primary endpoint was mean change in intrahepatic lipid content (IHL) by proton magnetic resonance spectroscopy (1H-MRS); secondary endpoints included mean changes in alanine aminotransferase (ALT), IHL by MRI proton density fat fraction (MRI-PDFF), and the combined inflammation and fibrosis cT1 score. Treatment effects were assessed from the intention-to-treat population. **Results:** Between September 2019 and November 2022, 80 participants were randomized, and 71 completed the trial. At baseline, mean age (47.9 ± 12.1), BMI (33.7 ± 6.0 kg/m^2), sex distribution (56.3% female), and IHL (37.6 ± 18.4%) did not differ between groups. Absolute IHL change at month 6 was -7.3% (95% CI: -14.3 to -0.3) with aspirin and 3.0% (95% CI: -4.4 to 10.5) with placebo ($p = 0.009$), yielding a relative IHL reduction of 10.3% with aspirin compared to placebo (95% CI: -17.9 to -2.8; $p = 0.011$). The percent change in IHL was -17.3% (95% CI: -30.3 to -3.7) with aspirin and 30.3% (95% CI: 5.4 to 56.1) with placebo ($p = 0.007$). Improvements in all prespecified secondary hepatic endpoints were observed in the aspirin group, including a reduction in mean cT1 score (-18.8, 95% CI: -50.7 to 13.0) vs. placebo (29.2, 95% CI: -2.3 to 60.7, $p = 0.011$). The mean absolute weight change did not differ between groups (0.1kg for aspirin vs. 0.4kg for placebo, $p = 0.80$), nor did the proportion of patients with ≥ 3% weight loss (12.5% for aspirin vs. 10% for placebo, $p = 0.66$). The only drug-related adverse event in the aspirin group was heartburn in 1 participant. Adverse events led to discontinuation in 1 participant per group. **Conclusion:** In this 6-month trial in adults with MASLD, aspirin 81mg daily substantially reduced hepatic steatosis and markers of hepatic inflammation and fibrosis. These findings support larger, long-term trials assessing the effects of aspirin on MASLD histological and clinical endpoints.

Figure 1: Effect of Daily Aspirin versus Placebo on Intrahepatic Lipid (IHL) Content



Least-squares means are presented. Panels A and B show the absolute change in IHL percentage from baseline to month 6, derived from analysis of covariance models for the Intention-to-Treat (ITT) population (Panel A) and the As-Treated (AT) population (Panel B), as per the Methods. Panels C and D show the 6-month percent change in IHL percentage, derived from an analysis of covariance model for the ITT population (Panel C) and the AT population (Panel D). For Panels A and C, missing values at month 6 were imputed with multiple imputation. I-bars indicate 95% confidence intervals. IHL: Intrahepatic lipids.

145 | LUBIPROSTONE REDUCES FAT CONTENT ON MRI-PDFF IN PATIENTS WITH MASLD

Mohamed El-Kassas, Endemic Medicine Department, Faculty of Medicine, Helwan University, Cairo, Egypt, Hongqun Liu, University of Calgary Cumming School of Medicine and Samuel S. Lee, University of Calgary

Background: Lubiprostone has been shown to improve intestinal permeability. We aimed to assess the safety and efficacy of lubiprostone in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** This randomised placebo-controlled trial was conducted in a specialized MASLD outpatient clinic at the National Hepatology and Tropical Medicine Research Institute, Cairo, Egypt, and recruited patients with radiological evidence of MASLD. Eligible patients were randomly assigned to either lubiprostone 24 µg or placebo orally twice daily for 48 weeks. The primary endpoint was a change from baseline in fat quantification by MRI-PDFF. Safety was assessed clinically and by laboratory testing. This trial was registered at Clincaltrials.gov (NCT05768334). **Results:** Between November 2020 and February 2023, we screened 176 patients of whom 116 were eligible. 57 patients received lubiprostone (group 1) while 59 patients received placebo (group 2). In groups 1 and 2, MRI-PDFF was technically unfeasible in 3 and 1 patient; 12 and 18 subjects were lost to followup, respectively, and 4 patients discontinued lubiprostone, leaving 40 in each group for final analysis. A greater reduction in fat quantity by MRI-PDFF from baseline to 48 weeks was seen in the lubiprostone group vs. placebo group ($p = 0.04$; table 1) despite a statistically significant reduction in body weight in the control group compared to the lubiprostone group. However, no significant difference was found between both groups regarding liver stiffness measurement by Fibroscan or ALT levels. Severe diarrhea requiring treatment stoppage was encountered in one patient in the lubiprostone group. No other serious adverse events or mortality occurred. **Conclusion:** Lubiprostone was well tolerated and reduced liver MRI-PDFF fat content in patients with MASLD over 48 weeks. Lubiprostone appears promising to treat MASLD, and warrants larger studies to confirm efficacy.

Changes from baseline to week 48 in the two groups

Parameter		Group I (Lubiprostone) N = 40	Group II (Control) N = 40	P-value
CAP	Median (IQR)	-36.5 (-59 - -40)	-33 (-50 - -7)	0.956
	Range	-116 - 88	-93 - 78	
LSM kPa	Median (IQR)	0.3 (-0.8 - 1.1)	0.1 (-0.9 - 0.5)	0.718
	Range	-2.9 - 1.9	-3.6 - 4.7	
MRI-PDFF	Median (IQR)	-4.17 (-7.1 - -0.98)	-2.32 (-3.47 - 1.03)	0.044
	Range	-27.3 - 8.57	-15.5 - 3.73	

CAP, controlled attenuation parameter. LSM, liver stiffness measurement. IQR, inter-quartile range. Differences between the two groups analyzed by Mann-Whitney test.

146 | RISK OF ADVERSE LIVER AND RENAL OUTCOMES AFTER INITIATION OF A SODIUM-GLUCOSE COTRANSPORTER 2 INHIBITOR VS. GLP-1 RECEPTOR AGONISTS AND DIPEPTIDYL PEPTIDASE-4 INHIBITORS AMONG US ADULT PATIENTS WITH TYPE 2 DIABETES AND MASLD

Arunkumar Krishnan[1], Tinsay A. Woreta[2], Dipatsree Mukherjee[3], Shyam Thakkar[4], Shailendra Singh[4], William R. Hutson[4] and Saleh A Alqahtani[5,6], (1)Atrium Health Levine Cancer Institute, (2)Johns Hopkins Medicine, Baltimore, MD, (3)Apex Institute of Medical Sciences, (4)West Virginia University School of Medicine, (5)Johns Hopkins University School of Medicine, (6)King Faisal Specialist Hospital and Research Center

Background: The effects of sodium-glucose cotransporter-2 inhibitors (SGLT-2i) on liver and renal outcomes in patients with type 2 diabetes mellitus (T2DM) were demonstrated in recent trials. However, the magnitude of benefits associated with underlying metabolic dysfunction-associated steatotic liver disease (MASLD) remains unclear. We aimed to explore the risk of adverse liver and renal outcomes in patients with MASLD and T2DM taking SGLT-2i vs. dipeptidyl peptidase-4 inhibitors (DPP-4i) and glucagon-like peptide-1 receptor agonists (GLP-1RA). **Methods:** We conducted a population-based, multicenter cohort study with consecutive patients diagnosed with MASLD (without cirrhosis) and T2DM using the TriNeTx dataset. Cohort entry was defined as the date of the first-ever prescription for one of the drugs of interest (SGLT-2i, GLP-1RA, or DPP-4i) during the study period. We used a lag of 6 months for all exposures to minimize protopathic bias. We performed a 1:1 propensity score matching (PSM) to reduce confounding effects. The primary outcomes were defined as the first incidence of cirrhosis, the composite outcome of hepatic decompensation events, and hepatocellular carcinoma (HCC). Secondary outcomes included composite outcome of chronic kidney disease (CKD), composite endpoint of a severe stage of CKD (stages 4-5), and need for hemodialysis. We conducted secondary mad sensitivity analyses to assess the robustness of our findings. The outcomes were estimated using a Cox proportional hazards model with hazard ratios (HR) and 95% confidence intervals (CI). **Results:** In this cohort, 47890 patients received SGLT-2i, and 45160 patients receiving DPP4i were included as controls. After PSM,

43758 patients were followed for a median of 1.9 years. For sensitivity analysis, 59205 were included in the GLP-1RA group. Compared with DPP4i use, SGLT-2i use was associated with a lower risk of incident cirrhosis (HR, 1.01), hepatic decompensation (HR 1.03), and HCC (HR 1.07). Similarly, secondary outcomes composite CKD, severe stages of CKD, and need for hemodialysis. The SGLT2i group was non-inferior to the GLP-1RA group in terms of liver outcomes: the incidence of cirrhosis (HR 1.0), hepatic decompensation (HR 0.99) and HCC(HR 0.89) was similar compared with the SGLT-2i group. Sensitivity analysis showed a similar magnitude to the primary and secondary analyses. **Conclusion:** In patients with MASLD and T2DM, SGLT-2i use was associated with significantly reduced risks of adverse liver and renal outcomes compared with DPP4i. SGLT-2i was not inferior to GLP1-RA for adverse liver outcomes but showed a significantly lower incidence.

Table 1. Adverse liver and renal outcomes between the Users of SGLT2 vs. DPP4i in patients with NAFLD and type 2 diabetes

Outcomes	SGLT2 (N=43738), n	DPP4i (N=43738), n	HR (95% CI)
Primary outcome			
Cirrhosis	2912	3215	0.92 (0.89-0.99)
Events of hepatic decompensations	2107	2547	0.90 (0.87-0.95)
Hepatocellular carcinoma	265	379	0.89 (0.78-0.85)
Secondary outcome			
Composite outcome of CKD *	5565	5943	0.98 (0.94-0.98)
Severe stage of CKD[$]	781	1079	0.72 (0.6 – 0.79)
Need for hemodialysis	166	275	0.60 (0.50-0.73)

Abbreviations: SGLT-2i, sodium-glucose cotransporter 2 inhibitors; DPP-4i, dipeptidyl peptidase-4 Inhibitors; CKD, chronic kidney diseases.
*Composite endpoint of CKD was defined as CKD progression from five stages (stages 1-5);
[$]Severe stage of chronic kidney disease was defined as CKD progression stages 4-5.

147 | DEEP PHENOTYPING OF TM6SF2 TO CHARACTERIZE HEPATIC STEATOSIS, PLASMA LIPID TRAITS, AND METABOLIC RISK FACTORS USING A GENOME-FIRST APPROACH★

Helen Huang[1], Cecilia Vitali[1], Michael C Phillips[1], Kate Townsend[2], David Zhang[1], Eleonora Scorletti[2], Nicholas J. Hand[2], Joseph Park[1], Kai M. Schneider[3], Daniel J. Rader[2], Carolin V. Schneider[1] and Regeneron Centre, (1)Perelman School of Medicine, University of Pennsylvania, (2)University of Pennsylvania, (3) University Hospital Rwth Aachen

Background: An unbiased 'genome-first' approach has the potential to expand the understanding of common coding and predicted loss-of-function (pLOF) variants associated with non-alcoholic fatty liver disease (NAFLD). Utilizing this approach, we aimed to uncover the functionality of pathogenic variants in *TM6SF2*. **Methods:** We leveraged exome sequencing data from 44,297 patients in the Penn Medicine Biobank and interrogated 121 non-synonymous missense variants and 12 pLOF variants for associations with ICD-10 coded NAFLD, non-alcoholic steatohepatitis (NASH), and hepatocellular carcinoma (HCC). Significant variants were further analysed with serum parameters, liver fat scores, and imaging adjusted for age, sex, body mass index, principal components of ancestry, and carriage of *PNPLA3* rs738409:G. We replicated findings in the UK Biobank (UKB) and differences were statistically significant when $p < 0.05$. *In silico* prediction of the structure of *TM6SF2* was generated using ColabFold Alphfold2 notebook with MMseqs2. **Results:** E167K homozygotes are at an increased risk of ICD-diagnosed NAFLD ($p < 0.0001$, OR:4.8), NASH ($p < 0.0001$, OR:5.1), and HCC ($p = 0.001$, OR:1.77). Similarly, E167K heterozygotes exhibited a similar trend with NAFLD and NASH only. Additionally, L156P heterozygotes were at an increased risk of physician-diagnosed NAFLD ($p < 0.001$, OR:2.16) and NASH ($p < 0.0001$, OR:2.10). Only L156P homozygotes were at an increased risk for HCC (N = 2, $p < 0.0001$, OR:532.0). We successfully replicated associations with ICD-diagnosed NAFLD, NASH, and HCC in the UKB for both variants. Additional diagnoses on imaging, coupled with evidence of elevated CT-derived hepatic fat scores, in the PMBB strengthened these associations in E167K and L156P carriers ($p < 0.01$). Metabolomic analyses reveals lower circulating total cholesterol, triglycerides, fatty acids, and total choline in E167K and L156P carriers (Bonferroni-corrected, $p < 0.0001$). *In silico* predictions validate both mutations to cause structural disruptions on the EXPERA domain leading to loss of *TM6SF2* protein function. This hypothesis was strengthened when we interrogated pLOF variants and discovered a stop-gain truncation codon (W35X) associated with an increased risk of physician-diagnosed NAFLD ($p = 0.03$, OR:15.9), NASH ($p = 0.01$, OR:23.4) and elevated liver fat scores ($p < 0.001$) in the same directionality as E167K and L156P. **Conclusion:** We confirm that E167K and L156P induces a loss-of-function effect on the protein structure, thus leading to liver disease, and identified a stop-gain codon of potential therapeutic utility towards NAFLD.

148 | TRIPLE HORMONE RECEPTOR AGONIST RETATRUTIDE RESOLVES STEATOSIS IN > 85 % OF SUBJECTS WITH MASLD AND OBESITY IN ASSOCIATION WITH IMPROVED METABOLIC HEALTH

Arun Sanyal[1], Juan Pablo Frias[2], Melissa K Thomas[3], Kieren J. Mather[3], Qiwei Wu[3], Yu Du[3], Bram Brouwers[3], Axel Haupt[3] and Mark L. Hartman[3], (1)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, (2)Velocity Clinical Research, (3)Eli Lilly and Company

Background: Retatrutide (RETA; LY3437943) is a novel triple agonist of the GIP, GLP-1 and glucagon receptors under investigation for obesity treatment. A 48-week phase 2 obesity study demonstrated weight loss of −22.8% and −24.2% with RETA 8 and 12 mg. We report effects of RETA on liver fat (LF) and correlations with metabolic measures in subjects with MASLD included in this trial. **Methods:** Adults aged 18-75 yr with BMI ≥ 30 or ≥ 27 kg/m^2 and ≥ 1 weight-related condition (T2D excluded) were randomly assigned to 48 wk of QW sc RETA (1, 4, 8 or 12 mg) or PBO. The MASLD substudy included subjects with ≥ 10% LF (MRI-PDFF). The primary outcome was relative LF change from baseline (CFB) at 24 wks. Additional outcomes included relative LF CFB at 48 wks and proportion of subjects achieving LF < 5%. Relationships between relative LF CFB and changes in body weight (BW), waist circumference (WC) and fasting metabolic biomarkers were explored. **Results:** Of 338 subjects enrolled in the trial, 98 (46.9% female) participated in the substudy with mean age 46.6 yrs, BMI 38.4 kg/m^2, WC 118.3 cm, ALT 35.9 IU/L, AST 25.4 IU/L, FIB4 0.79 and ELF 8.1. Mean LF at baseline ranged from 15.6 to 21.0% across treatment groups. The mean relative LF CFB (%) at 24 wks was −42.9 (RETA 1 mg), −57.0 (4 mg), −81.4 (8 mg), -82.4 (12 mg) and +0.3 (PBO), and at 48 wks was −51.3 (1 mg), −59.0 (4 mg), −81.7 (8 mg), −86.0 (12 mg) and −4.6 (PBO) (all $p < 0.001$ vs PBO). At 48 wks, LF < 5% was achieved by 57% (1 mg), 29% (4 mg), 89% (8 mg), 93% (12 mg) and 0% (PBO) of subjects (all $p < 0.001$ vs PBO). ALT and AST did not change consistently versus PBO. At 48 wks, relative LF reduction was significantly correlated with %CFB in BW and WC (r = 0.774 and 0.588, respectively; both $p < 0.001$); a nonlinear relationship with BW %CFB was demonstrated, with near-maximal LF reduction achieved at ~20% BW loss ($p = 0.002$; Figure). RETA doses ≥ 4mg improved insulin sensitivity, reflected by significant reductions vs PBO for fasting insulin (range -37.3 to -70.9%), HOMA2-IR (insulin; -35.8 to -69.3%), and increases vs PBO for adiponectin (29.8 to 99.3%) at 24 and 48 wks (all $p < 0.05$). By 24 wks, RETA doses ≥ 4mg significantly changed biomarkers of lipid storage and metabolism vs PBO ($p < 0.05$), including reducing triglycerides (TG; range -35.4 to -40.0%), leptin (-29.0 to -55.8%), and FGF-21 (-52.2 to -65.7%), and increasing beta-hydroxybutyrate (BOHB; 78.0 to 181.2%), a marker of fatty acid oxidation. At 24 and 48 wks, significant ($p < 0.05$) linear correlations were observed between relative LF reduction and % CFB in liver volume, TG, insulin, HOMA2-IR, adiponectin, leptin and FGF-21, but not BOHB. **Conclusion:** In subjects with MASLD, RETA 8 and 12 mg resolved steatosis in > 85% of subjects. Near-maximal LF reductions were achieved at ~20% reductions in BW. LF reductions were linearly related with metabolic measures associated with improved insulin sensitivity and lipid metabolism.

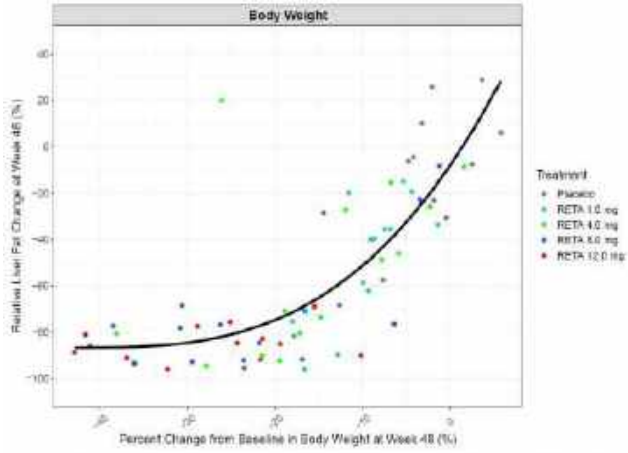

Figure 1 - Scatterplot and fitted power model curve between the relative liver fat reduction vs. percent changes in body weight at Week 48.

149 | RELATIONSHIP OF NON-INVASIVE MEASURES WITH HISTOLOGICAL RESPONSE IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS AND FIBROSIS: 52-WEEK DATA FROM THE PHASE 3 MAESTRO-NASH TRIAL

Rohit Loomba[1], Jörn M. Schattenberg[2], Rebecca A. Taub[3], Dominic Labriola[3], Mazen Noureddin[4], Vlad Ratziu[5] and Stephen A Harrison[6], (1)University of California, San Diego, San Diego, CA, (2)I. Department of Medicine, University Medical Centre Mainz, Mainz, Germany, (3)Madrigal Pharmaceuticals, (4)Houston Research Institute, Houston, TX, (5)Sorbonne Université, Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Institute of Cardiometabolism and Nutrition (ICAN), (6)Pinnacle Clinical Research Center, San Antonio, TX

Background: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80mg, resmetirom 100mg, or placebo administered once daily. Histologic endpoints were assessed after 52 weeks. Dual primary endpoints at Week 52 were achieved with both resmetirom 80mg and 100mg: NASH resolution with no worsening of fibrosis (NR) or ≥ 1-stage reduction in fibrosis with no worsening of NAS (FR). **Methods:** Adults with ≥ 3 metabolic risk factors, liver stiffness ≥ 8.5 kPa, hepatic fat ≥ 8%, biopsy-confirmed NASH with F1B-F3 fibrosis, and NAS ≥ 4 were eligible to participate in MAESTRO-NASH. The relationship of non-invasive measures with histological response (NR and/or FR) in the resmetirom 80mg, resmetirom 100mg, and placebo groups was assessed. **Results:** Patients with biopsy-confirmed NASH with fibrosis had high metabolic risk including obesity (mean BMI = 36), type 2 diabetes (70%), hypertension (78%), and 10-year ASCVD risk score > 14. Baseline mean (SD) FibroScan VCTE was 13.3 (6.8), 13.6 (7.1), and 12.9 (5.6) kPa for the resmetirom 80mg, resmetirom 100mg, and placebo groups. Baseline ELF across all fibrosis groups was 9.8 (0.87). FIB-4 across all dose groups was 1.3. Median reduction in MRI-PDFF was 42% and 52% in the paired biopsy population at resmetirom 80mg and 100mg. Among patients treated with resmetirom 80mg or 100mg who

achieved a ≥ 30% reduction from baseline in MRI-PDFF, NR was observed in 28% and 38% and FR in 17% and 18% more patients than placebo. Among resmetirom-treated patients with a ≥ 120% increase in SHBG (marker of drug exposure), NR was seen in 34% and 37% and FR in 22% and 20% more resmetirom 80mg and 100mg patients than placebo. A ≥ 30% PDFF response was observed in 96%, 88%, and 92% of resmetirom 100mg NR, FR, and NR and/or FR responders. Half of the resmetirom ≥ 30% PDFF responders without NR or FR showed ≥ 2-point NAS reduction. On biopsy, NR correlated with FR ($r^2 = 0.30$). Additional correlates of NR and FR at resmetirom 100mg included reduction in PDFF ($r^2 = 0.39$, 0.23); ALT ($r^2 = 0.20$, 0.24); and liver volume ($r^2 = 0.25$, 0.18). Weaker correlations were observed with AST and FibroScan CAP. Correlations at resmetirom 80mg were similar. LDL-C lowering did not correlate with either NR or FR. Although MRE (kPa), Fibroscan VCTE, and ELF were reduced with resmetirom treatment, the reduction in these non-invasive measures did not correlate with NR or FR. **Conclusion:** Achievement of NASH resolution and fibrosis reduction was associated with a ≥ 30% reduction from baseline in MRI-PDFF and ≥ 120% increase in SHBG at both resmetirom doses (80 and 100mg). Additional analyses, including artificial intelligence (AI)-based assessments of histological response, are ongoing.

150 | Itfg1: A PROMISING TARGET FOR ENHANCED LIVER REGENERATION AND CHRONIC LIVER DISEASE TREATMENT

Viktoriia Iakovleva[1], Anna Potapova[1], Agnes Ong[1], Gao Rong[1], Yock Young Dan[2] and Torsten Wuestefeld[1,3], (1) Genome Institute of Singapore, (2)National University Health System (NUHS), (3)Nanyang Technological University

Background: The liver has a remarkable regenerative capacity. Nevertheless, under chronic liver-damaging conditions, this capacity becomes exhausted, allowing the accumulation of fibrotic tissue and leading to end-stage liver disease. Enhancing the endogenous regenerative capacity by targeting regeneration breaks is a novel therapeutic approach. We set up an in vivo functional genetic screen to identify such regeneration breaks. Integrin Alpha FG-GAP Repeat Containing 1 (ITFG1) was one of the top hits. We proofed that hepatocyte specific knockdown of Itfg1 enhances the endogenous regenerative capacity of the liver and counteracts chronic liver disease. **Methods:** We conducted an in vivo functional genetic RNAi screen in the thioacetamide (TAA) driven chronic liver disease model. Two independent shRNAs targeting Itfg1 were significantly enriched. We then tested the effect of Itfg1 knockdown on mouse and human hepatocyte proliferation in vitro. Furthermore, taking advantage of the FAH knockout mouse model, we tested for Itfg1 knockdown driven faster liver repopulation, enhanced regeneration after partial hepatectomy and fibrosis reduction in chronic liver damaging conditions, including "Western Diet" driven NAFLD. For unraveling the mechanism of Itfg1 inhibition driven accelerated liver regeneration we did in depth transcriptomic and proteomic analysis. **Results:** Knockdown of Itfg1 in immortalized mouse as well as human hepatocytes accelerates their proliferation and wound healing in vitro. In vivo knockdown of Itfg1 in hepatocytes, accelerates their ability to repopulate the liver of FAH deficient mice. Furthermore, in fully repopulated mice, where every hepatocyte expresses the shRNA targeting Itfg1, liver regeneration upon partial hepatectomy is accelerated. The enhanced regenerative capacity also attenuated TAA and "Western Diet" induced chronic damage. Itfg1 knockdown not only reduced fibrosis but also reduced steatosis in the NAFLD model. Our transcriptomic and proteomic analysis showed that Itfg1 knockdown affects fatty acid metabolism, the MAPK and AKT pathways. **Conclusion:** We identified and validated Itfg1 as a target for enhancing the endogenous regenerative capacity of the liver. Enhancing the endogenous regenerative capacity attenuates chronic liver disease. We are currently in the process to translate our results into RNAi therapeutics.

151 | EMPAGLIFLOZIN IS EQUALLY EFFECTIVE IN REDUCING LIVER FAT CONTENT IN T2DM PATIENTS AND IN NON-DIABETIC INDIVIDUALS, A RANDOMIZED TRIAL

Siham Abdelgani, Uth San Antonio

Background: This study was performed to examine the effect of empagliflozin on liver fat content in T2DM patients and in nondiabetic individual's, and the relationship between the decrease in liver fat and other metabolic actions of empagliflozin. **Methods:** 30 T2DM and 27 nondiabetic individual's were randomized to receive in a double blind fashion in 2:1 ratio treatment with empagliflozin or matching placebo. Patients received 75-grams OGTT, liver fat content with MRI spectroscopy before and at the end of therapy. Hepatic glucose production at the start of therapy was measured with 3H-glucose infusion. **Results:** empagliflozin caused -2.75% and -1.93% absolute reduction in liver fat content in T2DM and nondiabetic individual's, respectively, compared to +0.9% and +0.8% increase, respectively, in subjects receiving placebo, ($p < 0.05$ for both groups). The decrease in hepatic fat content was strongly influenced by baseline liver fat content and was strongly related to the decrease in body weight ($r = 0.53$, $p < 0.001$) and improvement in insulin sensitivity caused by empagliflozin ($r = -0.51$, $p < 0.001$), but was not influenced by the decrease in fasting plasma glucose, HbA1c or the increase in hepatic glucose production. **Conclusion:** empagliflozin is equally effective in reducing liver fat content in T2DM patients and in nondiabetic individual's. The decrease in liver fat content is independent of the decrease in plasma glucose concentration but is strongly related to the decrease in body weight and improvement in insulin sensitivity.

Disclosures: The following people have nothing to disclose: Siham Abdelgani

152 | SAROGLITAZAAR IS EFFECTIVE IN IMPROVING LIVER STIFFNESS MEASUREMENT AND LIVER ENZYMES IN NONALCOHOLIC STEATOHEPATITIS

Tarana Gupta[1], Pankaj Kaushik Jr.[2] and Rakesh Mittal[2], (1)Pandit Bhagwat Dayal Sharma Institute of Medical Sciences, Rohtak, (2)Pt Bds Pgims, Rohtak

Background: Despite advances in understanding the pathophysiology of nonalcoholic steatohepatitis (NASH), no pharmacotherapy has been proven effective in improving outcome. Peroxisome proliferator-activated receptors (PPAR) are nuclear receptors with key role in metabolic homeostasis and inflammation and PPAR knockout mice are susceptible to development of NASH. Studies have shown protective role of PPAR-± in hepatic steatosis and inflammation and PPAR-γ as insulin sensitizers. Saroglitazaar is dual PPAR ± and γ agonist approved for diabetic dyslipidemia Though the drug is approved in India for use in patients with NASH, data regarding improvement in liver fibrosis is still awaited. We compared saroglitazaar alone versus its combination with vitamin E in patients with NASH. **Methods:** This was a prospective, randomized, open label clinical trial conducted from July 2021 to December 2022 in a tertiary care center. The study was approved by institutional ethics committee and registered on CTRI vide registration no CTRI/2021/07/034946. All patients of biopsy proven NASH were randomized in 1:1 allocation ratio to receive saroglitazaar 4 mg OD (Group I) or saroglitazaar 4 mg OD with Vitamin E 400 IU OD (Group II) for a period of 6 months. The primary end points were improvement in NAS score, liver stiffness measurement (LSM) values by transient elastography and liver enzymes (SGPT). The secondary end points were improvement in BMI and serum triglycerides (TG) and cholesterol (Chol) levels. **Results:** Total 53 patients were enrolled, two patients in Group I were lost to follow up and finally, Group I ($n = 25$) and Group II ($n = 26$) were analysed. All baseline characteristics were comparable between two groups. In primary end points, LSM values improved in group I (9.1 to 7.0 kPa, $p = 0.03$), Group II (7.9 to 7.1 kPa, $p = 0.04$), SGPT values improved in Group I (101 to 81 U/L, $p = 0.02$), Group II (98 to 75 U/L, $p = 0.04$) significantly with no change in NAS score in both the groups from baseline to 24 weeks respectively. In secondary end points, significant reduction in TG and Chol in Group I (234 to 167 mg/dL, $p = 0.003$; 234 to 199 mg/dL, $p = 0.04$), Group II (223 to 188 mg/dL, $p = 0.04$; 229 to 189 mg/dL, $p = 0.007$) respectively with no change in BMI. **Conclusion:** Saroglitazaar alone was effective in improving LSM and SGPT values in NASH. However, no improvement in NAS score could be observed over a period of 24 weeks.

153 | AN AGE-STATIN INTERPLAY IN PREVENTING THE DEVELOPMENT OF CIRRHOSIS IN A 10-YEAR COHORT OF PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)★

Georgia Sofia Karachaliou[1], Amy M Perkins[2], Chad Dorn[2], Qingyi Wei[1], Xiaoming Xu[3], Sheng Luo[3], Glenn Temple Gobbel[2], Ruth Reeves[2], Mustafa Bashir[4], Manal F. Abdelmalek[5], Anna Mae Diehl[3] and Ayako Suzuki[6,7], (1)Duke University Medical Center, (2) Vanderbilt University Medical Center, (3)Duke University, (4)Duke University, Durham, NC, (5)Mayo Clinic, Rochester, MN, (6)Durham VA Medical Center, Durham, NC, (7)Duke University, NC

Background: Statins reduce the risk of hepatic fibrosis in patients with chronic liver diseases. Since age, sex, and menopausal status modulate NAFLD pathogenesis and fibrosis risk, the effects of statins on hepatic fibrosis may vary by age and sex. We aimed to assess age-/sex-disparities in the association between statin use and the incidence of cirrhosis in patients with NAFLD. **Methods:** We developed a cohort of NAFLD patients between 2007 and 2009 (baseline period), applying the validated algorithm (PMID: 30144434) to the VA electronic health records. We created baseline variables including demographics, BMI, statin use, comorbidities, relevant co-medications, such as beta-blockers and metformin, and FIB-4 scores. The cohort was then followed for incident cirrhosis defined by ICD codes for up to ten years. We also captured cumulative standardized dose and duration of statins, BMI, and co-medication use during the follow-up and analyzed them as time-dependent covariates. Patients were censored at the diagnosis of other chronic liver diseases, alcohol use disorder, death unrelated to cirrhosis, or loss to follow-up. Cox proportional hazards regression models without and with time-dependent covariates were used to associate incident cirrhosis with statin use at baseline and during follow-up, respectively. Disparities were assessed in subgroup analyses by age (using a cut-off of 51 years, the average age at menopause in the US) and sex as well as in a model with an interaction term. **Results:** A total of 335,991 patients (median age of 62 years, male 91%, White 78%, median BMI of 31 kg/m2, DM 39%, and statin use 65% at baseline) were analyzed after excluding prevalent cirrhosis, incident cirrhosis within one-year follow-up, and no follow-up data after the index date from 346,818 NAFLD patients identified at the baseline. Cumulative incidence of cirrhosis was 2.96% (median follow-up of 117 [50, 121] months), which differed by sex and age group (d or > 50 y). After adjusting for potential confounders and baseline FIB-4 score, baseline statin use was associated with a reduced risk of developing cirrhosis (HR and 95% CI = 0.77 [0.65, 0.91]). In the models with time-dependent covariates, both cumulative standardized dose and duration during follow-up showed significant protective effects against cirrhosis development (HR and 95%CI = 0.72 [0.68, 0.76]) and 0.67 [0.63, 0.72], respectively). The effect of cumulative standardized statin dose and duration showed a significant interaction with age (interaction: $p = 0.0005$ and $p < 0.0001$, respectively), associated with stronger protection from cirrhosis development in older vs. younger subjects. **Conclusion:** Statins are more protective against cirrhosis in older subjects, and this effect is not influenced by sex.

154 | MACHINE LEARNING SCORES ACCURATELY CLASSIFY INDIVIDUALS AT INDETERMINATE RISK OF INCIDENT CIRRHOSIS INTO LOW AND HIGH RISK GROUPS

Vincent Chen[1], Chinmay Raut[2], Antonino Oliveri[3], Yanhua Chen[2], Majd Aboona[4], Claire Faulkner[4], Wei Xuan Tay[5], Nicole Xinrong Han[5], Karn Wijarnpreecha[6], Yu JUN Wong[5] and Elizabeth K. Speliotes[7], (1) University of Michigan Medical Center, (2)University of Michigan, (3)University of Michigan, Ann Arbor, MI, (4) University of Arizona College of Medicine, Phoenix, AZ, (5)Changi General Hospital, (6)University of Arizona College of Medicine Phoenix, Phoenix, AZ, (7) University of Michigan Medical School, Ann Arbor, Michigan, USA

Background: Risk stratification in non-alcoholic fatty liver disease (NAFLD) using non-invasive scores including Fibrosis-4 (FIB4) and NAFLD fibrosis score (NFS) is recommended by clinical guidelines. However, FIB4 and NFS values are indeterminate in 20-50% of patients with NAFLD. We aimed to develop machine learning models to improve upon FIB4 and NFS, especially in the indeterminate-risk range. **Methods:** We included two cohorts, Michigan Medicine (MM) patients with NAFLD, and UK Biobank (UKBB) participants without excess alcohol intake or chronic liver diseases other than NAFLD. We adopted a two-stage approach to train in MM a model to identify incident cirrhosis. First, we used a least absolute shrinkage and selection operator (LASSO) model to select features. Second, we generated using those features a random forest (RF) model based on downsampling. We externally validated this model in UKBB and compared it to FIB4 and NFS based on time-dependent area under the curve (tAUC) models for risk of incident cirrhosis at 10 years. We compared incidence rates based on quintile of predicted risk by the RF model. **Results:** The MM and UKBB cohorts included 28,684 and 480,651 participants, respectively. LASSO regression identified six predictors of incident cirrhosis in MM which were included in the RF model: age, AST, ALP, platelets, diabetes, and hypertension. In the UKBB, the RF model had 10-year tAUC of 0.84 (0.82-0.86) which outperformed FIB4 [0.81 (0.79-0.83)] and NFS [0.76 (0.73-0.78)], $p < 0.05$ for both. The RF model identified considerable heterogeneity in risk of incident cirrhosis in patients with indeterminate FIB4 (1.3-2.67) or NFS (-1.455 to 0.675) with > 10-fold variation of cirrhosis incidence between the bottom quintiles (1-2) and top quintile (5) of RF model risk (Table). Patients with indeterminate FIB4/NFS and the lowest 40% of RF model risk had incidence of cirrhosis similar to those with low FIB4 (< 1.3) or NFS (< -1.455), and those in the top 20% had similar incidence to that of high NFS (> 0.675) or FIB4 (> 2.67). The RF model reclassified 30-40% of indeterminate-risk patients into high or low risk categories. These findings were consistent in subgroups including diabetes or elevated transaminases. **Conclusion:** We trained and externally validated a simple RF model that identified heterogeneity among indeterminate-risk patients. This model accurately risk stratifies 30-40% of indeterminate-risk individual's using commonly-available predictors, thus providing a scalable pathway to optimize tertiary care referrals.

Conventional score	Quintile of random forest risk score	% overall population	Incidence rate of cirrhosis (per 1000 person-years)
NAFLD fibrosis score			
< -1.455		64%	0.06 (0.05-0.07)
-1.455 to 0.675	1-2	10%	0.09 (0.06-0.14)
	3-4	20%	0.18 (0.15-0.22)
	5	3%	1.27 (1.03-1.55)
>0.675		3%	1.51 (1.25-1.81)
Fibrosis-4			
<1.3		68%	0.05 (0.04-0.06)
1.3-2.67	1-2	6%	0.08 (0.04-0.13)
	3-4	22%	0.19 (0.15-0.22)
	5	3%	1.25 (1.03-1.51)
>2.67		1%	3.88 (3.20-4.67)

Background: *PNPLA3* rs738409 C > G is strongly associated with NAFLD and its severity. *PNPLA3* expression is highly regulated by changes in energy balance; however, little is known about the interplay between *PNPLA3*, dietary factors, alcohol intake, and risk of liver-related death (LRD). We examined the effect of interactions between *PNPLA3* rs738409 and dietary factors (macronutrients/coffee-tea intake) and alcohol consumption on the risk of LRD in a population-based US cohort. **Methods:** 14,797 adults enrolled in NHANES III (1991–1994) were investigated. Participants with lack of *PNPLA3* rs738409, dietary nutrients, and heavy alcohol intake (> 2 or > 3 drinks per day in women and men) were excluded. The remaining 4361 participants (study cohort) were linked to the National Death Index mortality data through December 2019. LRD was the study outcome. Associations between *PNPLA3*, dietary nutrients (% daily calories from fat, protein, carb, monounsaturated fatty acids [MUFAs], polyunsaturated fatty acids [PUFAs] and saturated fats, fiber, and cholesterol), non-heavy alcohol intake, and LRD were examined using weighted multivariable competing risk regression models, adjusted for age, sex, race/ethnicity, calorie intake, BMI, and physical activity. Multiplicative interaction terms between *PNPLA3* and variables of interest were included in all models. **Results:** The *PNPLA3* CC, CG, and GG genotypes frequencies were 55%, 36%, and 9%. There were 28 LRD (0.6%) over a mean 23.1 years follow-up. *PNPLA3* G allele was associated with LRD (sHR: 2.8, 95% CI: 1.4-5.6). Non-heavy alcohol intake (sHR: 2.2, 95% CI: 1.07-4.5), % MUFAs (sHR: 0.94, 95% CI: 0.88-0.99), cholesterol intake (mg) (sHR: 1.001, 95% CI: 1.0004-1.002), and coffee-tea intake ≥ 3 cups/day (sHR: 0.38, 95% CI: 0.04-0.99) were also associated with risk of LRD. Compared to wild-type *PNPLA3* and non-drinkers, G allele carriage significantly increased the risk of LRD among drinkers (sHR: 3.5, 95% CI: 1.9-6.4) vs non-drinkers (sHR: 1.9, 95% CI: 0.7-5.1). Compared to wild-type *PNPLA3*, a higher risk of LRD was observed among G-allele carriers and higher consumption (top quartile) of saturated fat (sHR: 3.5, 95% CI: 1.2-9.7), and cholesterol (sHR: 3.0, 95% CI: 1.7-6.2). However, compared to wild-type *PNPLA3*, effects of the G-allele on the risk of LRD were significantly attenuated in those with higher consumption (top quartile) of coffee/tea (sHR: 0.06, 95% CI: 0.007-0.55) and MUFAs (sHR: 0.5, 95% CI: 0.1-0.9). The interactions between other macronutrients and *PNPLA3* variation did not significantly impact the risk of LRD (Table 1). **Conclusion:** Non-heavy alcohol consumption and high intake of saturated fat and cholesterol adversely whereas higher caffeine/tea drinking favorably modify the risk of liver-related death associated with *PNPLA3* rs738409. If supported by other studies, these observations will assist in the personalized management of NAFLD.

Table 1. Joint effects of *PNPLA3* (additive model) and non-heavy alcohol intake and selected dietary factors on risk of liver-related mortality.

Pennsylvania, Philadelphia, PA, USA, (5)Hospital of the University of Pennsylvania

Background: Studies on incident liver and cardiovascular outcomes in lean (body mass index: BMI < 25 kg/m^2, or < 23 kg/m^2 for Asians) vs. non-lean individual's with metabolic dysfunction-associated steatohepatitis (MASH) have reported mixed results. We aimed to compare incident clinical outcomes and mortality between lean and non-lean individual's with compensated MASH cirrhosis in a large national cohort. **Methods:** This was a retrospective cohort study of patients with newly diagnosed compensated MASH cirrhosis from 1/2008-5/2021 in the Veterans Health Administration. Average BMI in the 12 months prior to cirrhosis diagnosis was used to classify lean vs. non-lean MASH, and alternate etiologies of liver disease were excluded using validated algorithms. Our primary outcome was incident hepatic decompensation. Secondary outcomes were incident major adverse cardiovascular events (MACE- a composite of myocardial infarction, cardiac arrest, stroke, heart failure, atrial fibrillation) and all-cause mortality. Multivariable Cox proportional hazard models were constructed to assess the effects of lean status on clinical outcomes and survival. Fine and Gray competing risk regression was used where applicable. **Results:** We included 15,974 MASH patients in our analytic sample: 1,731 lean and 14,243 non-lean patients. Included patients were mostly male (95%), median age was 68 years, and 67% were non-Hispanic white. At baseline, prevalence of diabetes was lower in lean vs. non-lean individual's (44.8% vs. 72.9%, $p < 0.001$). Lean individual's also had fewer cardiometabolic risk factors at baseline. In multivariable models (Figure 1), with adjustments for age, sex, race, smoking status, diabetes, MELD-Na, and alcohol use per AUDIT-C, lean status was associated with a 92% increased risk of all-cause mortality (aHR = 1.92; 95% CI: 1.77–2.08). Paradoxically, lean status was associated with a 39% decreased risk of incident hepatic decompensation (aSHR = 0.67; 95% CI: 0.58–0.77). There was no significant association between lean status and major adverse cardiovascular events (aSHR = 0.84, [95% CI: 0.70–1.01], $p = 0.07$). **Conclusion:** In patients with compensated MASH cirrhosis, lean status was associated with increased all-cause mortality and decreased risk of hepatic decompensation. Despite low prevalence of diabetes and better cardiometabolic profile, lean individual's were at equally high risk of MACE. Future studies should evaluate other drivers (e.g., extrahepatic cancer, renal disease, and genetics) of mortality in lean MASH patients.

157 | MACHINE LEARNING PREDICTS DIETARY PATTERNS ASSOCIATED WITH FATTY LIVER DISEASE PROTECTION★

Simon Schophaus[1], Kate Townsend[2], Jan Niklas Clusman[1], Alexander Koch[1], Christian Trautwein[3], Kai M. Schneider[4] and Carolin Victoria Schneider[5], (1) University Hospital Rwth Aachen, Aachen, Germany, (2)University of Pennsylvania, (3)University Hospital, Rwth Aachen, (4)Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, University Hospital Rwth Aachen, Aachen, Germany, (5)University Hospital Rwth Aachen

Background: Non-alcoholic fatty liver disease (NAFLD) affects a substantial proportion of the general population, but little is known about the impact of specific nutrients on its prevention. Utilizing unbiased machine learning, we aimed to investigate the association between dietary nutrients and the development of NAFLD in the large UK Biobank dataset. **Methods:** We analyzed data from the UK Biobank, focusing on individual's with dietary assessments (up to five dietary questionnaires per person) and excluding those with pre-existing liver disease. Comprehensive benchmarking revealed superiority of a random forest classifier to examine the association between dietary questionnaire nutrients and steatosis development over 11 years of follow-up. A cohort study of more than 200,000 participants was then conducted to assess the association between manganese intake and liver outcomes (ICD10 codes). All analyses were adjusted for age, sex, BMI, Townsend index of socioeconomic status, kcal, alcohol intake, protein intake, fat intake, carbohydrate intake, and multiple testing. **Results:** A random forest classifier was used to analyze the feature importance of 63 nutrients and imaging-proven steatosis in a cohort of over 35,000 UK Biobank participants. Our results showed that participants with higher dietary manganese intake were less likely to have imaging-proven steatosis, suggesting a potential protective effect of manganese against NAFLD (Figure 1 A). We then validated the importance of manganese in a cohort study of over 200,000 UK Biobank participants to examine the relationship between manganese intake and liver outcomes and found that higher manganese intake was associated with a lower risk of ICD-10 coded fatty liver (OR = 0.851 (0.804-0.900), $p < 0.001$), independent of other potential confounders. In addition, there was a significant effect of manganese on metabolomics available in > 49,000 individual's (Figure 1B) and showed an association with reduced VLDL secretion. **Conclusion:** Our study provides evidence that higher manganese intake may be associated with lower odds of steatosis in a large population-based sample. These findings highlight a potential role for manganese in the prevention of NAFLD, but further research is needed to confirm these findings and to investigate the underlying mechanisms. Finally, our study elucidates a comprehensive workflow that leverages the potential of machine learning techniques and vast datasets to facilitate precision nutrition strategies for the prevention of liver disease. A)Feature Importance for Predicting imaging-diagnosed steatosis using a Random Forest Model: For each input feature, we calculated %IncMSE by permuting the feature's values and measuring increase in the Mean Squared Error. B)Associations of metabolic biomarkers with manganese intake among > 49,000 participants: Hazard ratios (with 95% confidence intervals) presented per 1-SD higher metabolic biomarker.

158 | WE ARE GOING DOWN THE WRONG PATH! THE CURRENT AASLD GUIDANCE MISCLASSIFIES MAJORITY OF PATIENTS WITH MASLD AND SIGNIFICANT FIBROSIS

W. Ray Kim, Nakia L Chung, Ajitha Mannalithara, Vivek Charu, Natalie J. Torok, Paul Yien Kwo, Allison J. Kwong and Sun H Kim, Stanford University School of Medicine

Background: Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) has extremely high prevalence in the US and globally with increasing incidence of morbidity and mortality in the population. Effective strategies to identify patients at risk of future complications, namely those with stage 2 (F2) or more advanced fibrosis represent the critically important first step in mitigating the public health impact of MASLD. Essentially all of the society guidelines, including the latest guidance from AASLD, recommend using FIB-4 < 1.3 to define low risk subjects not requiring further evaluation. We evaluate the diagnostic performance of FIB-4 in detecting F2 and F3 in the US general population, in comparison to the SAFE (Steatosis-Associated Fibrosis Estimator, Hepatology 2023;77:256) score, recently developed to detect F2 in primary care. **Methods:** We queried the most recent (2017-2020) National Health and Nutrition Examination Survey (NHANES) data, which included transient elastography. We selected adult (≥ 18 y) examinees with a controlled attenuation parameter (CAP) score ≥ 274 dB/m and without viral hepatitis or significant alcohol use. Individual's with incomplete elastography results or other missing data were excluded. Liver stiffness (LSM) of 8 kPa was taken as the threshold for F2 and 12 kPa for F3. The FIB-4 and SAFE scores were calculated using the published formulae. **Results:** The NHANES data projected to 73 million (M) US civilian adults with MASLD, of whom 12.2M (16.6%) had LSM ≥ 8kPa and 4.3M (5.9%) had LSM ≥ 12kPa. As seen in the Table, FIB-4 classified 55.5M, 16.7M and 1.2M US adults as low- (< 1.3), intermediate-, and high-risk (> 2.67), respectively. Of those, 15.7%, 17.8% and 44.5% had LSM ≥ 8kPa and 4.9%, 7.5%, and 30.4% had LSM ≥ 12kPa, respectively. More strikingly, of subjects with LSM ≥ 8kPa, 8.7M (71%) subjects would have FIB-4 < 1.3 and thus be excluded from further assessment. Similarly, of subjects with LSM ≥ 12 kPa, 2.7M (63%) would have FIB-4 < 1.3. The SAFE score classified 34.4M, 26.0M and 13.0M subjects as low-(< 0), intermediate-, and high-risk (≥ 100), respectively. Of those, 8.2%, 17.7% and 36.7% had LSM ≥ 8kPa and 1.8%, 5.2%, and 18.2% LSM ≥ 12kPa, respectively. SAFE performed better than FIB-4 in excluding fibrosis in the low-risk category. Of subjects with LSM ≥ 8kPa, 23% would have SAFE < 0 and of those with LSM ≥ 12 kPa, 14% would have SAFE < 0. As in other validation studies, SAFE had higher Area Under the Receiver Operating Characteristic curve in detecting F2 than FIB-4 (0.70 versus 0.58). **Conclusion:** When applied to population-based data representative of the US, the current guidance recommendation based on the FIB-4 score would miss the majority of patients with F2 and even F3. On the other hand, the SAFE score, designed to detect F2 in primary care, more accurately risk-stratify subjects with MASLD in the population.

159 | NON SELECTIVE BETA BLOCKER REDUCES MORTALITY OF CIRRHOSIS PATIENTS ADMITTED TO INTENSIVE CARE UNIT WITH ACUTE DECOMPENSATION

Rahul Kumar[1,2], Su Lin[2], Gautam Mehta[2], Banwari Agarwal[3], Rajeshwar P. Mookerjee[4] and Rajiv Jalan[5,6], (1)Changi General Hospital, (2)UCL, London, (3)Royal Free Hospital, (4)Aarhus University, (5)UCL, (6) University College London Medical School

Background: Non-selective-beta-blockers (NSBB) are main stay of therapy in portal hypertension management. Apart from direct portal pressure reduction, NSBB's modulate inflammatory cascade, which could be beneficial in patients with acute decompensation (AD). We therefore aimed to evaluate effect of NSBB on 28-day mortality and markers of systemic inflammation in a propensity score matched (PSM) cohort of AD patients

requiring intensive care unit(ICU) admission. **Methods:** Patients were recruited from registry of AD patients requiring ICU admission. Out of the total 445 patients, 109 patients were on NSBB before admission (NSBB-group) who were PSM for pre-admission Childs-Turcotte-Pugh(CTP) score. 106 patients not on NSBB, served as the control-group. The on-admission to ICU parameters, markers of systemic inflammation; white cell count (WCC), neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR), C-reactive protein (CRP) and 28-days mortality were compared by standard statistical tests. **Results:** After PSM, no difference was observed in aetiology of cirrhosis, or precipitating event for AD. Pre-admission creatinine, bilirubin, INR and haemoglobin were similar between the groups. Pre-admission WCC and NLR was lower in NSBB-group, whereas CTP(median;7) and MELD(median:12) were similar. On admission to ICU, NSBB-group had lower heart rate($p < 0.001$), platelets($p = 0.010$), WCC ($p = 0.018$), NLR($p = 0.008$) and CRP($p = 0.013$). Significantly more community acquired bacterial infections ($p = 0.004$), renal($p = 0.003$) and liver($p = 0.034$) failure and higher grades of acute-on-chronic-liver-failure (ACLF)($p = 0.005$) were seen in non-NSBB-group. Significantly lower 28-day($p = 0.001$) and 90-day($p < 0.001$) mortality was seen in NSBB-group (Figure 1). Univariate and multivariable analysis for 28-days mortality showed that while ACLF at presentation and community acquired bacterial infection were independent negative predictors, prior-NSBB use was positive predictors of survival. **Conclusion:** Prior-NSBB use blunts inflammatory response favourably and is associated with improved 28 and 90-day mortality in critically-ill patients with acute decompensation (Figure 2).

160 | AN OPEN-LABEL PARALLEL-GROUP, PHASE II RANDOMISED CONTROLLED TRIAL OF AUTOLOGOUS MONOCYTE DERIVED MACROPHAGE INFUSION IN COMPENSATED CIRRHOSIS

Paul N Brennan[1], Debbie Troland[1], Mark MacMillan[1], Thomas Manship[1], Francesca Moroni[1], Alison Glover[2], Catriona Graham[1], Scott Semple[1], David M Morris[1], Alasdair R Fraser[2], Chloe Pass[2], Lisa Ritchie[2], Donna Mitchell[2], Neil McGowan[2], Marc Turner[2], Neil Lachlan[3], John Dillon[4], Jonathan Andrew Fallowfield[1], John D Campbell[5] and Stuart J Forbes[1], (1)University of Edinburgh, (2)Scottish National Blood Transfusion Service, (3)Glasgow Royal Infirmary, (4)University of Dundee, (5)Glasgow University

Background: Cirrhosis is characterised by severe liver fibrosis, organ dysfunction and liver-related complications. Presently, there are no approved anti-fibrotic or pro-regenerative therapies for cirrhosis. Preclinical studies have shown bone marrow-derived macrophage injections can resolve hepatic fibrosis, stimulate regeneration and reduce inflammation. We previously demonstrated the safety of peripheral infusion of *ex vivo*-matured autologous monocyte-derived macrophages in patients with compensated cirrhosis in a Phase 1 trial. **Methods:** In a multicentre, open-label, parallel-group, Phase 2, randomised controlled trial (ISRCTN10368050), we evaluated the efficacy of autologous monocyte-derived macrophage therapy, compared with standard medical care, in a cohort of adult patients with compensated cirrhosis and MELD score e 10 and d 17. Participants were randomised 1:1, based on a minimisation algorithm using the key variable aetiology of disease (alcohol-related liver disease, non-alcoholic fatty liver disease, other). Treatment was of either three cycles of apheresis and macrophage infusion (n = 3) or a single apharesis and macrophage infusion (n = 23) of up to 10^9 macrophages; n = 24 participants received standard of care. Initially, the trial was designed to administer three infusions in the treatment arm, but due to the challenge of undergoing three apheresis sessions, and completing the trial within the proposed time frame, a single infusion protocol was adopted. The primary outcome was the difference in baseline to day 90 change in MELD score (ΔMELD) between treatment and control groups (ΔΔMELD). Secondary outcomes included: adverse clinical outcomes; non-invasive fibrosis markers (Liver Stiffness Measurement (LSM), serum enhanced liver fibrosis test (ELF) and Pro-C3/C3M, corrected T1 (cT1)

MRI); and health-related quality of life (HRQoL) at 90, 180, 360 days. **Results:** The ΔΔMELD between day 0 and day 90 in the treated group compared with the standard of care group was -0.87 (95% CI 1.79, 0.0; $p = 0.06$). The treatment group had less variable MELD scores than the control group (see Figure). Within the 360 days follow-up there were: 5/24 participants in the control group developed a total of 10 liver-related severe adverse events including 2 deaths, whilst no liver-related severe adverse events or deaths occurred in the treated group. There were no statistically significant differences in non-invasive fibrosis markers or HRQoL on per protocol analysis; exploratory analyses are awaited. **Conclusion:** This study reinforces the safety of macrophage cell therapy in patients with compensated cirrhosis, suggests their therapeutic potential and supports further development of macrophage therapy for liver disease.

161 | MAPPING IMMUNOLOGICAL LANDSCAPE IN DECOMPENSATED CIRRHOSIS PROGRESSION THROUGH MULTINOMIAL AND ORDINAL REGRESSION ANALYSIS

Zhujun Cao[1], Minghao Cai[1], Yujing Yao[2], Yuhan Liu[1], Chenxi Zhang[1], Yaoxing Chen[1], Yan Huang[1], Yide Lu[3], Ruokun Li[4], Zhuping Qian[5], Yi Zhou[6], Li Ziqiang[7], Baoyan An[1], Haiguang Xin[1], Hui Wang[1], Xiaogang Xiang[1], Richard Moreau[8,9] and Qing Xie[7], (1) Department of Infectious Disease, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (2) Department of Biostatistics, Mailman School of Public Health, Columbia University, (3)Department of Laboratory Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, (4)Department of Radiology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (5)Department of Nursing, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (6)Department of Emergency, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (7)Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (8) European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain, (9)Institut National De La Santé Et De La Recherche Médicale (INSERM)

Background: Systemic inflammation is known as a major role in pathogenesis of acute-on-chronic liver failure (ACLF) from cross-sectional studies, but its detailed impacts on the dynamic trajectory of this disease from the absence of organ dysfunction (OD) to onset of OD, organ failure (OF) and eventual ACLF remains poorly understood due to challenges in collecting data and samples from individual's. Multinomial and ordinal regression analyses are useful tools to circumvent the limitation intrinsic to cross-sectional studies in cirrhosis. They identify significant predictors of different outcome categories and provide insights into the transition between stages towards ACLF. **Methods:** We investigated inflammatory signals, including blood cell counts and 21 serum biomarkers in 238 inpts with cirrhosis assigned to one of the following four stages: no OD (n = 110), OD (n = 40), OF without ACLF (n = 54), and ACLF (n = 34). The association of signals with each stage was assessed with multivariable models using multi-category outcomes without (Softmax regression) and with order (adjacent-category logit model). Prognostic ability of the signals was assessed with competing risk analysis followed by the evaluation of integrated discrimination improvement (IDI) and net reclassification improvement (NRI) of these signals to the exiting prognostic models. Another 156 cirrhosis inpts were used for validation. **Results:** Descriptive analysis: The progression of cirrhosis towards ACLF is characterized by an increasingly maladapted immune response as indicated by: 1) blunted type 1 immunity (type 1 effector IFN-γ did not change across stages); 2) abortion of type 2 immunity (production blocked between first-line cytokine, IL-25 and IL-33 second-line cytokines IL-4, IL-13); 3) imbalance of type 3 immunity (IL-22 dominant phenotype) ; 4) enhanced immunosuppression (continuous increases of anti–inflammatory markers (IL-10, sCD163), decreases in chemokines [*e.g.*, IL-8, IP-10], and a reduction in lymphocyte count) Multivariable analyses: Higher levels of IL-6, IL-10, sCD163, MCP-1, IL-25, IL-33, IL-22, or higher white-cell or neutrophil counts were associated with increased risk of getting more severe from OD towards ACLF at any disease stage (Figure 1). Prognostic analysis: The 28–day all–cause mortality can be independently predicted by the baseline levels of IL–6, sCD163, and MIP–3±, which together with blood

immune cell, significantly enhanced the prognostic accuracy of CLIF-C OF (C-index [95%CI], 0.88 [0.82-0.94] vs. 0.84 [0.77-0.92], both $p = < 0.01$ by IDI and NRI). The results were validated in an independent cohort with 156 patients. **Conclusion:** Future therapies targeting the activation of type 1 immunity, restoration of type 2 immunity and balance of type 3 immunity would be important to prevent ACLF. Markers identified in this study are potential targets for developing new or improving prognostic scores currently available.

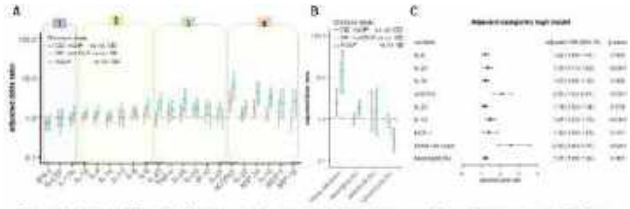

Figure 1. Adjusted effect of inflammatory markers and circulating immune cells on disease stages by Softmax regression analysis and adjacent logit model

(A, B) Multivariable Softmax regression analysis of OD vs no OD, OF vs no OD, ACLF vs no OD for inflammatory markers (A) and circulating immune cells (B) by adjusting age, sex, previous decompensation, overt ascites, gastroesophageal variceal bleeding, antibiotics within the last week, diuretics within the last week, and transfers from other hospitals. (C) By adjusting the same covariates used in panel A and B, the multivariable adjacent logit model for identification of the parallel effect of inflammatory markers associated with the disease stages considering as an ordinal outcome. Adjusted odds ratios in all the panels and/or each unit increase in the natural logarithm (ln) each inflammatory marker level.

Only the markers with a significant parallel effect in the adjacent category logit model without violating the parallel assumption are presented in Panel C and F. This multivariable analysis identified markers that were significantly associated with the odds of progression to a more severe stage towards ACLF at any disease stage. For example, per unit increase in the natural logarithm of the IL-6 level in pg/mL is associated with an adjusted odds ratio of 1.22 (95%CI: 1.06–1.41, p = 0.006) or an 22% increase in the risk of progression to a more severe stage towards ACLF at any disease stage (e.g., OD to OF or OF to ACLF).

Abbreviation: OD, organ dysfunction; OF, organ failure; ACLF, acute-on-chronic liver failure; MCP–1, monocyte chemotactic protein; MIP–1β, macrophage inflammatory protein–1β; MIP–3α, macrophage inflammatory protein–3α; IL, interleukin; IP–10, interferon-inducible protein 10; TNF–α, tumor necrosis factor; IFN–γ, interferon gamma; G–CSF, granulocyte colony–stimulating factor; sCD163, soluble CD163; OR, odds ratio.

162 | EARLY LACTATE-GUIDED TREATMENT STRATEGIES IN CRITICALLY ILL PATIENTS WITH CIRRHOSIS AND SEPSIS

Rehma Shabbir[1], Luis Garrido-Treviño[2], Lauren Hall[1], Gerald Ogola[1] and Sumeet Asrani[2], (1)Baylor Scott & White Research Institute, (2)Baylor University Medical Center, Dallas, TX

Background: Inpatient mortality among cirrhosis patients requiring Intensive Care Unit (ICU) admission for sepsis is high especially in those with Acute on Chronic Liver Failure. Endpoints of early goal directed therapy within 24 hours of admission are poorly defined in cirrhosis patients. Specifically, lactate (LA) clearance is impaired in cirrhosis, but early LA-guided resuscitation strategies are part of sepsis protocols in non-liver population. Recently, Model for End-stage Liver Disease-lactate (MELD-LA) was developed and independently validated as a simple, objective marker for short term prognosis in critically ill patients with cirrhosis as compared to MELD, MELD-Sodium and ICU specific scores in multiple global populations (n = 8,640). Among cirrhosis patients with sepsis, we sought to identify MELD-LA cutoffs for 30-day mortality as well as assess early LA clearance as potential surrogate of effective goal directed therapy. **Methods:** We reviewed all patients with cirrhosis admitted to the ICU (n = 9,557, 2014-July 2022) in a large, integrated healthcare system. We examined a subset of patients with sepsis and evaluated initial MELD-LA and LA clearance within the first 24 hours. **Results:** Overall, there were 3,879 cirrhosis patients admitted with sepsis in the ICU (43.2% female, 20.5% Hispanic, 13.9% dialysis, MELD score 20.8 (8.6) and MELD-LA 17.6 (5.7). Mean initial LA was 4.5 mg/dL. At 30-day mortality was 41.1%. On adjusted analysis, MELD-LA was an independent predictor of 30-day mortality (HR 1.06 , 1.05-1.07). In patients with serial LA (n = 868), after adjusting for demographics and MELD, both initial LA (HR 1.17, 1.14-1.20) and delta LA within 24 hours (HR 1.17, 1.15-1.19) were associated with 30-day mortality. Similar findings were noted for inpatient and 1 year mortality. Survivors versus non-survivors: For survivors, the mean initial LA was lower (3.7 vs 5.5 mg/dL) with higher change in LA -1.04 mg/dL(35.2% lactate clearance) vs -0.4 mg/dL (12.0% lactate clearance) respectively (Table). The impact of LA clearance varied by presenting MELD-LA. Achieving a LA clearance of 35% over 24 hours was associated with a decline in 30-day mortality of 25% (MELD-LA < 15), 18% (MELD-LA 15-24) and 9% (MELD-LA 25+) (Figure). **Conclusion:** Mean LA at presentation for patients with cirrhosis is high at admission for those with sepsis. A goal reduction of initial LA by one-third over 24 hours may suggest response to early goal directed therapy. A combination of MELD-LA at presentation along with LA clearance within 24 hours may allow for earlier risk stratification in critically ill ICU patients with cirrhosis.

Association of lactate parameters with survivors and non-survivors at 30-day post ICU admission

	Non-survivors	Survivors
MELD	23.7	16.7
MELD-LA	19.6	16.1
Initial lactate (mg/dL)	5.5	3.7
Delta lactate (median, IQR)	-0.4 (-2.7, 1.6)	-1.04 (-3.1, 0.0)
Percent clearance (median, IQR)	12.0% (-41.8%, 47.9%)	35.2% (0.0%, 68.0%)

163 | UNMASKING THE HIDDEN PATTERNS: MACHINE LEARNING IDENTIFIES AND PREDICTS CLUSTERS WITH DISTINCT PROFILES AND OUTCOMES IN ACUTE-ON-CHRONIC LIVER FAILURE (CLUSTER-ACLF)

Nipun Verma[1], Pratibha Garg[2], Arun Valsan[3], Akash Roy[4], Saurabh Mishra[5], Parminder Kaur[5], Sahaj Rathi[6], Arka De[6], Madhumita Premkumar[7], Sunil Taneja[1], Ajay K. Duseja[1], Virendra Singh[8] and Radha K. Dhiman[9], (1) Post Graduate Institute of Medical Education and Research, Chandigarh, India, (2)Postgraduate Institute of Medical Education & Research, (3)Amrita Institute of Medical Sciences, Kochi, India, (4)Sanjay Gandhi Postgraduate Institute of Medical Research, (5) Postgraduate Institute of Medical Education and Research, Chandigarh, (6)Post Graduate Institute of Medical Education and Research, (7)Postgraduate Institute of Medical Education & Research, Chandigarh, India, (8)Punjab Institute of Liver and Biliary Sciences, Mohali, India, Chandigarh, CH, India, (9)Sanjay Gandhi Postgraduate Institute of Medical Sciences

Background: Heterogeneity among patients with acute-on-chronic liver failure (ACLF) confer variable outcomes (mortality-range: 0-100%). While prognostic scores capture the known associations, machine learning (ML) can identify the intricate hidden patterns between patient characteristics without any explicit hypothesis or labelling that remain unexplored in ACLF. We employed ML to explore, describe, and predict unknown clusters in ACLF patients. **Methods:** We applied unsupervised ML on the data of 1568 ACLF patients defined by APASL or EASL criteria, recruited ambispectively over 2015-2023 with a 90-day follow-up at a tertiary care centre. After initial processing and evaluation of cluster tendency, the data, including clinical details, investigations, and organ failures at day-0, 3, and 7 of admission, were subjected to distance, density, and model-based clustering. We interpreted a final model with least BIC and identified clusters through inferential statistics. Then, we explored the cluster associations with disease evolution and mortality. Finally, we employed supervised ML in 70% of data to train the models and 30% of remaining data to predict and interpret the clusters. **Results:** We enrolled ACLF patients aged 44.3 (11.3) years, 87% males, 62.9% with alcoholic hepatitis, 29.6% with APASL, 15.5% with EASL, 54.9% with both APASL and EASL criteria, and a MELD of 29(7) with survival of 50.5%. Nonsurvivors were likely to have both EASL+APASL or EASL-ACLF, > 1 acute precipitant, tense ascites, grade III-IV HE, infection, organ failures, and poor severity scores ($p < 0.001$, each). Of nine algorithms, the latent class model identified four distinct clusters. Cluster 1 vs. 2 (HR: 1.94), 1 vs.3 (HR: 2.23), and 1 vs.4 (HR: 4.12) were associated with mortality (Fig.1A), that remained significant after adjustment for CLIF-C ACLF or MELD or AARC score ($p < 0.001$, each). Patient's stratification into clusters could increase the discriminative ability of CLIF-C ACLF for mortality prediction by 11%. Distinct clinical profiles, organ failures, and severity scores were attributed to the clusters. APASL-ACLFs were frequently noted (70%) in cluster1. Females, acute or chronic viral hepatitis was common and alcoholic hepatitis, infections, and tense ascites were less prevalent in cluster2. Clusters 1 to 4 had an increasing gradient of severity, organ failures, mortality, EASL+APASL ACLF, infections, > 1 acute precipitant, alcoholic hepatitis, tense ascites, and grade III-IV HE ($p < 0.001$). While extreme gradient boost was best (AUC: 0.989), an interpretable decision tree could also predict clusters with very good AUC of 0.875 (Fig.1B). **Conclusion:** ML for the first time could identify and precisely predict hidden clusters with distinct phenotypes and outcomes in ACLF. Stratification of patients into clusters can guide their prognosis, resource allocation, intensive care management, and liver transplant discussions in ACLF.

Background: Regional differences in environment, health-care system, microbiology lab capabilities, countermeasures of drug resistance may greatly impact the occurrence and evolution of infection in cirrhosis. We aimed to assess the prevalence, characteristics, clinical impact, and variations in infection on admission (AdI) across a global population of cirrhosis inpatients. **Methods:** CLEARED Consortium prospectively recruited inpts with cirrhosis from 6 continents. Data were collected at baseline and followed during admission. Infections diagnosed empirically or by culture using prespecified criteria within 48 hrs of admission were defined as AdI. Comparisons were made between pts w/wo AdI & between regions. Multivariable (MV) analysis for in-hospital mortality was performed using admission variables. **Results:** AdI was identified in 1351 pts (32%) among 4238 pts from 27 countries. Major site was SBP (28.9%), respiratory (RTI, 17.3%) & UTI (14.3%). No organism was isolated in 48%, then G- (25%), G+(11%) & fungal (3%). Among 580 AdI pts with isolated organisms, 20% had drug-resistant organisms (DRO). AdI vs No-AdI admission variables AdI and No-AdI pts had similar demographics and etiology of cirrhosis but ↑ MELD-Na (24 vs 19, $p < 0.001$), prior infections (33 vs 13%), ascites (69 vs 61%), overt HE (32 vs 24%), AKI (20 vs 14%) and transplant listing (11 vs 9%), all $p < 0.01$. AdI pts had ↑ use of lactulose (49 vs 39%), rifaximin (30 vs 21%), diuretics (57 vs 52%) and SBP Prophylaxis (16 vs 12%), all $p < 0.001$. AdI pts had ↑ HE (42 vs 32%), AKI (37 vs 17%), anasarca (43 vs 35%), & lower GI bleed (18 vs 28%) as causes of admission, all $p < 0.01$. Outcomes: AdI pts developed ↑ nosocomial infections (17 vs 11%), AKI (47 vs 28%), brain (19 vs 9%), respiratory (15 vs 6%) and circulatory failures (19 vs 7%), ICU transfers (25 vs 15%) and in-hospital (21 vs 7%), all $p < 0.001$. MV analysis identified AdI as a significant risk factor for in-hospital mortality (OR 2.78, $p < 0.0001$) independent of age (OR, 1.02, $p < 0.001$) baseline MELD-Na (OR 1.15, $p < 0.001$), prior GI bleed (OR 1.3 $p = 0.03$) and prior HCC (OR 2.00, $p = 0.002$), *etc*. Regional variations African sites

had the highest prevalence of AdI but lowest culture positivity (Fig A, C). SBP was highest in Africa while UTIs were highest in Nth Am (Fig B). RTI was higher in EU, Asia and Australia while skin and soft tissue infection was higher in Sth and Nth Am. The rest were similar. G- were higher in Nth Am & Australia while G+ were similar. Fungi were higher in Asia and America (Fig C). DRO varied across the continents and was influenced by insufficient culture positive isolates (Fig D). **Conclusion:** In this global cohort, one-third of the inpts with cirrhosis had AdI which increases risk of in-hospital mortality by ~3 fold. Tailored strategies should be developed for different regions due to the substantially different characteristics in terms of types, culture positivity rates, isolated causative organism(s) and DROs across regions.

f 165 | AMONG YOUNG ADULTS SURVIVING A FIRST PRESENTATION OF ACUTE ALCOHOLIC HEPATITIS, FEMALES ARE AT 50% HIGHER RISK OF PROGRESSION TO CIRRHOSIS AND DECOMPENSATION

Jennifer A. Flemming, Queen's University, Maya Djerboua, Ices and Norah Terrault, University of Southern California, Los Angeles, CA

Background: Alcohol related harms to adolescents and young adults (AYAs) are on the rise and a priority group for identification and treatment to prevent progression of alcohol-associated liver disease

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(ALD). Females are at higher risk of developing ALD compared to males secondary to biologic and social-cultural factors. However, whether this sex difference persists after an episode of acute alcoholic hepatitis (AH) is unknown. This study aimed to evaluate the association between female sex and incident cirrhosis after first presentation of AH in the general population. **Methods:** Retrospective population-based cohort study of routinely collected healthcare data from Ontario, Canada. AYAs (aged 13-39) with a first presentation of AH as the most responsible diagnosis at emergency room (ER) or hospital admission were identified from 2002 to 2021 and followed to 2022. Incident cirrhosis was defined based on validated coding. The association between female sex and incident cirrhosis from 6 months post-discharge onward was evaluated using competing risks regression where liver transplant (LT) and death were competing events to cirrhosis with adjustment for age, income quintile, rurality, co-morbid illness, immigration status, and disease severity (ER vs. inpatient). **Results:** Overall n = 3,340 AYAs with first presentation of AH were identified; median age at presentation was 33 years (IQR 28-36), n = 1,190 (36%) were female, n = 4,717 (70%) had healthcare encounters related to alcohol within the 2-years prior to AH presentation, n = 2,801 (70%) required hospital admission, and n = 624 (19%) had cirrhosis and/or decompensation at index. Of those requiring hospital admission, the median length of stay was 5 days (IQR 3-8), n = 465 (17%) required ICU level care, n = 76 (2%) required hemodialysis and n = 91 (3%) died before discharge. After a median follow-up of 4 years (IQR 2-9 y), n = 603 (22%) died and n = 7 (< 1%) received LT. In total n = 2,690 (81%) were alive and without cirrhosis at 6 months post discharge of which n = 789 (29%) were diagnosed with cirrhosis during follow-up (n = 325 [35%] in females; n = 464 [26%] in males, $p < 0.001$), and of those, n = 320 (41%) were decompensated. After adjusted competing risks regression, female sex was associated with a 47% higher subhazard of cirrhosis compared to male sex (sHR 1.47, 95% CI 1.23-1.76, $p < 0.001$) in addition to older age (sHR 1.05, 95% CI 1.03-1.06) and higher co-morbidity (sHR 1.36, 95% CI 1.01-1.82; Table). The cumulative incidence of death at 1-, 5-, and 10-years was 9%, 22%, and 31% respectively without difference between sexes ($p = 0.06$). **Conclusion:** Almost 1/3rd of young adults with first presentation of AH develop cirrhosis after a median of 4 years and this risk is 50% higher for females vs. males. Whether this is secondary to differences in biologic or sociocultural factors such as ongoing alcohol use or engagement in medical care or alcohol use disorder treatment requires further investigation.

Table: Fine Grey competing risks regression for the association between sex and incident cirrhosis in young adults surviving a first presentation of acute alcoholic hepatitis.

	Univariate			Multivariate

166 | SPIRONOLACTONE THERAPY ASSOCIATES WITH REDUCED INCIDENT ALCOHOL-ASSOCIATED LIVER DISEASE IN HIGH RISK PATIENTS: A RETROSPECTIVE COHORT STUDY

Jay Luther[1], Augustin Vannier[2], Wei Zhang[1], Rachael Mahle[1], Russell P. Goodman[3] and Esperance Schaefer[3], (1)MGH, (2)University of Chicago, (3) Massachusetts General Hospital

Background: Effective treatment for alcohol use disorder (AUD) is the cornerstone of preventing the development of alcohol-associated liver disease (ALD). Recent preclinical and epidemiological data suggest spironolactone, a mineralocorticoid receptor antagonist, reduces alcohol consumption (PMID: 36123420) and may be a promising option to treat AUD. However, its impact on the development of ALD in high risk patients is unknown. **Methods:** This retrospective cohort study used the Mass General Brigham Biobank, an ongoing research initiative that had recruited 127 480 patients at the time of this study. International Statistical Classification of Diseases and Related Health Problems, Ninth and Tenth Revision diagnosis codes were used to identify patients with AUD and no ALD at study entry, as well as the primary outcome of incident ALD during study follow-up. Patients with ascites were excluded from study

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

enrollment. Treatment with spironolactone was defined by documentation of > 3 prescriptions. Patients were considered to be treated if they initiated spironolactone before the relevant outcome. Alcohol use was assessed through a one-time questionnaire that included a linear scale of standard drink consumption, with higher scores correlating with more alcohol use. Cox proportional hazards models adjusting for potential confounders were used to calculate hazard ratios (HR) and 95% confidence intervals (CIs). **Results:** The cohort comprised 9635 patients with AUD, of whom 566 (5.9%) were treated with spironolactone before a diagnosis of ALD. In total, 1135 patients (11.8%) developed ALD over a median follow-up time of 9.7 years. Patients treated with spironolactone were more likely to be older, obese, and receive concurrent medical addiction therapy and less likely to receive psychotherapy and have a concurrent substance use disorder compared to patients never receiving therapy. Treatment groups were similar in viral hepatitis status, homelessness, ethnicity, and sex. In a multivariable analysis accounting for age, sex, ethnicity, BMI, viral hepatitis status, receipt of alcohol therapy, concurrent substance disorder, psychiatric disease, congestive heart failure, and hypertension, spironolactone therapy was associated with a decreased incidence of ALD (HR: 0.68; 95% CI, 0.38-0.93; $p = 0.02$). We did not observe a dose-dependent association between spironolactone and likelihood of ALD (HR: 0.99; 95% CI: 0.98-1.00; $p = 0.27$). Notably, AUD patients treated with spironolactone reported less alcohol use compared to those not receiving treatment (linear drinking score of 3.2 in treated group versus 3.9 in the untreated group, $p = 0.02$). **Conclusion:** Spironolactone therapy is associated with reduced alcohol use and incident ALD in patients with AUD and may offer a novel therapeutic strategy in limiting the development of ALD in high-risk patients.

167 | PHOSPHATIDYLETHANOL MONITORING OF POST-TRANSPLANT ALCOHOL CONSUMPTION AMONG ALCOHOL AND NON-ALCOHOL-RELATED LIVER TRANSPLANT RECIPIENTS

Mayan Teles[1], Fnu Baimaji[1], Sarah Andrews[1], Mandana Khalili[2], Hannah C. Sung[1], Andrew M. Cameron[1], Oluwaseun Falade-Nwulia[1], Geetanjali Chander[3], Mary E. McCaul[1] and Po-Hung (Victor) Chen[1], (1)Johns Hopkins University, (2)University of California, San Francisco, (3)University of Washington

Background: Accurate alcohol assessments after liver transplants (LT) are crucial for understanding alcohol use and guiding treatment, particularly among LT recipients with prior alcohol-related liver disease (ALD). Biomarkers offer objective measures of alcohol exposure, but LT centers have not universally implemented routine biomarker use. Phosphatidylethanol (PEth) is a blood biomarker capable of detecting alcohol use during the prior 3-4 weeks. We assessed universal PEth testing for quantifying post-LT alcohol use in ALD and non-ALD LT recipients. **Methods:** We identified consecutive LT recipients with routine clinical PEth testing from a single LT center and compared three groups: standard LT (SLT; ≥ 6 months alcohol-free at LT), early LT (ELT; < 6 months alcohol-free at LT), and non-ALD. The primary outcome was post-LT alcohol use, defined by positive PEth tests (i.e., > 20 ng/mL). We used the Kruskal-Wallis test for between-group comparisons of continuous variables. Kaplan-Meier estimates analyzed times to the earliest positive PEth test, stratified by LT recipient group and compared by the log-rank test. We also created a multivariable Cox model to estimate hazard ratios for post-LT alcohol use, adjusting for age (using a five-knot restricted cubic spline), gender, and race/ethnicity. Our alpha was 0.05. **Results:** We included 159 LT recipients: 56 (35%) SLT, 42 (26%) ELT, and 61 (39%) non-ALD. Among the subjects, 64 (40%) were women, 123 (77%) identified as white, and the median age was 55 (IQR 45-62) years. The median follow-up time was 172 (IQR 69-288) days, and each LT recipient had a median of 8 (IQR 4-13) PEth tests. Overall, 26 (16%) LT recipients had at least one positive PEth test: 14 (25%) SLT, 9 (21%) ELT, and 3 (5%) non-ALD. Among those with positive PEth tests, the median time to the first positive test was 81 (IQR 57-120) days after hospital discharge from LT. Kaplan-Meier curves depicted significantly different times to the first positive PEth test between the groups ($p = 0.05$) (Figure). Relative to SLT recipients, ELT recipients had similar risks of post-LT alcohol use (aHR 0.81; 95% CI 0.32-2.1), but non-ALD recipients had significantly lower risks (aHR 0.11; 95% CI 0.03-0.45). **Conclusion:** Our analysis of PEth results depicted different timing and risks of post-LT alcohol use between the three LT recipient groups. Prior studies suggested that self-reporting may underestimate actual alcohol use. Therefore, routine PEth testing, especially during the first 180 days post-LT, may help delineate alcohol use patterns to guide targeted addiction care.

168 | SATURATED FAT FAVORABLY ALTERS THE GUT MICROBIOTA AND IMPROVES SURVIVAL IN PATIENTS WITH SEVERE ALCOHOLIC HEPATITIS: A RANDOMIZED CONTROLLED TRIAL★

Harshita Tripathi[1], Jaya Benjamin[2], Shvetank Sharma[1], Rakhi Maiwall[2], Vinod Arora[1], Chhagan Bihari[3], Guresh Kumar[1], Yogendra Kumar Joshi[2] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, New Delhi, India, (2)Institute of Liver and Biliary Sciences, New Delhi, (3)Institute of Liver and Biliary Sciences

Background: Severe alcoholic hepatitis (SAH) is associated with malnutrition, dysbiosis and inflammatory cytokines augmenting liver injury resulting in high mortality. Experimental studies have reported that in comparison to unsaturated fat (UF), saturated fat (SF) improves dysbiosis, inflammation, liver enzymes and protects against alcoholic liver injury, but effect on clinical outcome and gut microbiota (GM) in SAH patients is lacking. Aim: Primary aim was to compare the effects of diet rich in SF versus UF on 60-day mortality. Secondary aims included effects on clinical outcomes, inflammatory markers and GM profile. **Methods:** Of 169 SAH patients screened, 67 with mDF between 32-100, without sepsis, acute kidney injury (AKI), or malignancy were randomized into SF (Ghee i.e., clarified butter; n = 34) or UF (Soyabean Oil; n = 33) arm. Patients in both arms received 35 kcal and 1.2-1.5g protein/ kg /day (55-60% carbohydrate, 20% protein, 30-35% fat) for 60 days. GM was assessed using 16S V3-V4 region analysis by Novaseq. Changes in the clinical [MELD, CTP, mDF, FIB-4], biochemical, pro-inflammatory [TNF-±, NF-κB] and anti-inflammatory [IL-10, adiponectin] parameters, at 60-days were assessed. **Results:** Baseline parameters [age 40 ± 7.37 yrs; ascites 47 (84%); BMI 21.3 ± 3.8 kg/m^2; mDF 62.4 ± 21.4; MELD 28 ± 9.3; CTP 10.6 ± 1.4], GM phyla and species were comparable between groups. SF and UF were well tolerated. 60 day mortality was significantly lower in SF (12.2%) vs. UF (33%) arm; $p = 0.014$ (Fig.1 C) as per ITT analysis. Five patients from each arm were lost to follow-up. A significant improvement in AST, ALT, IL-10 levels and a trend towards reduction in TNF-± levels was seen in SF compared to UF (Fig.1-B). In the GM, commensal taxa like *Bacteriodes plebius*, *B. coprocoia*, Denoccota, Fusobacteria and Bacterium NLAE-z1-H40 increased significantly only in SF group ($p < 0.05$). But, pathogenic taxa, Protobacteria, Deferribacterota, Aquificota, Bdellovibrionota, Camplylobacteria, Acidobacteria, Verrucomicrobiota, Desulfobacteriota, *Klebisella pneumonia*, *Escherichia coli*, *Haeomophilus pittmaniae*, increased in the UF group. ($p < 0.05$) (Fig. 1-A). **Conclusion:** Two months of saturated fat as a therapeutic intervention, improved survival in SAH patients compared with unsaturated fat. This could be related to promotion of the growth of commensal bacteria which attenuated inflammation, disease severity and improved liver disease indices.

Abraldes[8], Guadalupe Garcia-Tsao[9], Debbie L. Shawcross[10], Yunpeng Yu[11], Qing Tang[11], Victor Vargas[12], Elizabeth Verna[13], Bruce Barton[14], Gyongyi Szabo[15], Laura E. Nagy[4], Patrick S. Kamath[16], Robert S. Brown Jr[17], Bernd Schnabl[18], Michael R. Lucey[19], Arun Sanyal[20], Mack C. Mitchell[21], Svetlana Radaeva[22], Naga P. Chalasani[23], Vijay Shah[6], Craig J. McClain[5] and Ramon Bataller[24], (1)Department of Biostatistics and Health Data, Indiana University School of Medicine, Indianapolis, in, (2)Indiana University School of Medicine, Indianapolis, IN, (3)University of Pennsylvania, Indianapolis, IN, (4)Cleveland Clinic Foundation, (5)University of Louisville, Louisville, KY, (6)Mayo Clinic Rochester, Rochester, MN, (7)University Hospital of Lille, (8)University of Alberta, AB, Canada, (9)Department of Digestive Diseases, VA - CT Healthcare System, (10)King's College London, (11) Indiana University, (12)University of Barcelona, (13) Columbia University Medical Center, New York, NY, (14)University of Massachusetts Memorial Health Care, (15)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (16)Mayo Clinic, Rochester, MN, (17)Cornell University, (18)University of California San Diego, (19)University of Wisconsin School of Medicine and Public Health, Madison, WI, (20)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, (21)University of Texas Southwestern Medical Center, (22)National Institutes of Health, Bethesda, MD, (23)Indiana University Medical Center, Indianapolis, IN, (24)Barcelona Clinic, Barcelona, Spain

Background: Corticosteroids are the standard of care for SAH in the absence of contraindications. Survival benefits conferred by steroids are often gained at the expense of increased infection risk. We investigated the co-incidental impact of infection mitigation measures during the COVID pandemic on mortality in SAH patients treated with corticosteroids. **Methods:** Data from 5 recent clinical studies were combined, 3 of which were conducted before the COVID outbreak, one during the pandemic, and one included a time-frame before and during the COVID. April 1, 2020 was defined as the start of COVID-19 outbreak period because the ongoing studies stopped recruitment in the early months of the pandemic. Mortality rates at 28, 90, and 180 days were compared between the pre and during-COVID pandemic periods in patients treated with corticosteroids. Cox regression analyses were performed to compare the survival while controlling for patient characteristics. **Results:** Data from 575 patients (415 from pre-COVID and 160 during COVID) were analyzed. Patients recruited during the COVID pandemic were slightly younger (43.7 vs. 46.5 in the pre-COVID period). Mean MELD scores were similar (25.7 for pre-and 24.8 for during-COVID periods). Mortality rates at 28 (11.6% vs 2.5%), 90 (22.4% vs 10%), and 180 (26.5% vs 15%) days were consistently higher for the pre-pandemic period (Figure 1A). Estimated survival probabilities were significantly higher during the pandemic (Figure 1B). After controlling for MELD and patient characteristics, the adjusted hazard ratios of the during-COVID period for 28, 90, and 180-days survival were 0.28 (95%CI [0.1,0.79]), 0.51 ([0.3,0.87]), and 0.57 ([0.36,0.89]), respectively (all $p < 0.05$). **Conclusion:** The markedly lower mortality rates in SAH patients treated with steroids after the COVID outbreak raise the possibility that infection mitigation measures enacted during the pandemic may have collaterally benefited patients on corticosteroid therapy.

170 | PRE-TREATMENT GUT MICROBIOTA PREDICTS SURVIVAL AFTER FECAL MICROBIOTA TRANSPLANTATION IN SEVERE ALCOHOLIC HEPATITIS

*Lubomir Skladaný[1], Katarina Soltys[2], Natalia Bystrianska[3], Daniela Žilinčanová[1], Svetlana Adamcova Selcanova[4], Peter Bánovčin[5], Jan Bure**a**[6], Tomas Koller[7] and Juan Pablo Arab[8], (1)F. D. Roosevelt Teaching Hospital, (2)Comenius University, (3)F. D. Roosevelt Teaching Hospital, Badín, Slovakia, (4) University Hospital of F. D. Roosevelt, (5)Comenius University Jesenius Faculty of Medicine, (6)Charles University Faculty of Medicine, Central Military Hospital, (7)Comenius University Faculty of Medicine, (8)University of Western Ontario, London, ON, Canada*

Background: New therapeutic alternatives to corticosteroids in severe alcohol-associated hepatitis (SAH) is unmet need. Fecal microbiota transplantation (FMT) has been proposed as it targets well-established pathophysiological pathway but, data is scarce and many unanswered questions remain. One of the principal tools for personalized management of SAH is selection of patients whose potential to benefit from FMT is increased based on their pre-FMT gut-microbiome analysis. Aim: To search for patterns in the pre-FMT gut microbiome of patients with SAH which are associated with increased probability of response to FMT (survival). **Methods:** We enrolled 36 adult consenting patients with SAH and 20 healthy controls; fecal samples were collected at time of SAH diagnosis at HEGITO and from healthy controls at the Faculty of Chemical and Food Technology. After DNA isolation using QIAamp PowerFecal Pro DNA Kit (Qiagen), microbial profiling was performed using 16S ribosomal RNA amplicon sequencing. The libraries were prepared using the (PCR) products according to the MiSeq System guidelines (Illumina), obtained data were analyzed with QIIME 2. **Results:** Dysbalanced gut microbiota of SAH patients was typical for elevated levels of pathogens and opportunistic pathogens including Enterococcus, Eggerthella, Fusobacterium and decrease of beneficial bacteria like Faecalibacterium, Eubacterium, Coprococcus, Barnesiella and Roseburia. Antibiotic treatment of infections preceding FMT (ATB) affected microbiota community with significantly prevailing Enterococcus spp., hence compromising the informativeness of its composition. On the other hand, microbiome of patients without ATB was enriched in Streptococcus sp., Actinomyces sp. or Escherichia/Shigella sp., ($p < 0.05$), and we were able to determine a predictive potential of gut microbiome for survival after FMT. Survivors possessed higher relative abundance of short-chain-fatty acids (SCFA) producers Faecalibacterium, Subdligranulum or unspecified Ruminococcaceae. **Conclusion:** Pre-FMT abundance of certain SCFA producing taxa is associated with better survival after FMT for SAH which might prove to be of predictive and therapeutic potential, respectively; ATB for infections erase predictive potential.

171 | THE RISK OF LIVER FIBROSIS IS GREATEST IN AREAS OF HIGHER SOCIOECONOMIC DEPRIVATION: A RISK-FACTOR BASED POPULATION SCREENING STUDY

Huw Purssell[1,2], Lucy Bennett[3], Oliver Street[2], Jennifer Scott[2], Karen Piper Hanley[2], Indra Neil Guha[3], Neil A Hanley[1,2], Varinder Singh Athwal[1,2] and ID LIVER consortium, (1)Manchester University NHS Foundation Trust, (2)University of Manchester, (3)Nihr Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, UK

Background: Early detection of liver disease has been identified as a public health priority in the UK. Symptoms are rare before advanced stages and case finding using risk factors improves identification. In financially constrained health systems, case finding in areas with greater disease burden is prudent. Socioeconomic deprivation is associated with advanced liver disease. We assessed the incidence of liver disease by population deprivation using a community case finding pathway. **Methods:** 6 primary care practices (PCP) were selected from different socioeconomic areas of Manchester, UK. A mean Index of Multiple Deprivation (IMD) score was calculated for each PCP based on its catchment area. PCPs were grouped into low (n = 3), medium (n = 1) and high deprivation (n = 2). Patients were identified using SNOMED codes for risk factors, including Type 2 diabetes, Body Mass Index > 30kg/m^2, harmful alcohol consumption (> 280/ > 400 grams ethanol in females/males per week), abnormal ALT or hepatic steatosis. Patients with ≥ 2 risk factors were invited to a one stop community assessment. A sub-group of patients with 1 risk factor were invited depending on capacity. Patients underwent a clinical history, full liver blood based aetiological screen and transient elastography (TE). Fibrosis was assessed with FIB-4 score and TE. Fibrosis risk was determined by a liver stiffness measurement (LSM) > 8.0kPa and FIB-4 > 1.30. **Results:** A total population of 63,143 patients were investigated, of which 7813 (12.4%) had ≥ 1 risk factor. 5839 (74.7%) and 1974 (25.3%) patients had 1 and ≥ 2 risk factors respectively. 1907 (1557x ≥ 2 risk factors, 350x 1 risk factor) patients were invited for assessment of which 430 (22.5%) patients attended. 300 (69.8%) patients were diagnosed with NAFLD. 38 (8.8%) patients were identified with alcohol related liver disease and 53 (12.3%) patients had mixed alcohol and metabolic disease. 59 (13.7%) patients had a LSM > 8.0 kPa. More patients from areas of high deprivation (26 (21.9%) patients) had risk of liver fibrosis compared to areas of medium (14/89 (15.7%) patients) and low deprivation (21/222 (9.5%) patients) (X^2 (2, N = 430) = 9.99, p = 0.0068)(Figure 1). Adjusting for age and gender, patients from areas of high deprivation were significantly more likely to have fibrosis risk than those from areas of low deprivation (adjusted OR 1.02, p = 0.012, 95% CI 1.004-1.035). **Conclusion:** Proactive community-based case finding for liver disease is best targeted in areas of high deprivation to improve diagnostic yields.

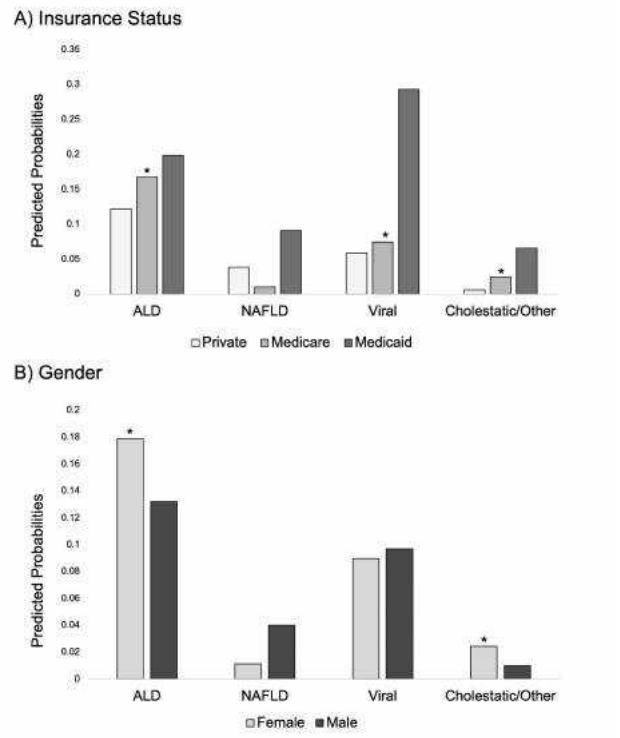
172 | PSYCHOSOCIAL AND DEMOGRAPHIC DISPARITIES IN ACCESS TO LIVER TRANSPLANTATION ACROSS ETIOLOGY OF LIVER DISEASE: AN ANALYSIS OF 2,391 TRANSPLANT EVALUATIONS

Sasha Deutsch-Link[1], Andrew M Moon[2], Robert S Sandler[1] and Marina Serper[3], (1)University of North Carolina, (2)University of North Carolina, Durham, NC, (3)University of Pennsylvania, Philadelphia, PA, United States

Background: The rising prevalence of alcohol-associated liver disease (ALD) and non-alcoholic fatty liver disease (NAFLD) has led to increases in the need for liver transplantation (LT). The purpose of our study was to investigate disparities in access to LT, and whether those disparities were consistent across etiology of liver disease. **Methods:** We performed a retrospective study of 2,391 LT evaluations at a single tertiary transplant center. Multivariable logistic regression analysis adjusting for race and ethnicity, gender, age, evaluation MELD-Na, insurance, Community Health Score, and the Stanford Integrated Psychosocial Assessment for Transplant (SIPAT) score was used to assess disparities in overall transplant waitlisting and in being declined for waitlisting due to psychosocial reasons. We also performed interaction analyses to investigate whether these disparities were differential across etiology of liver disease. **Results:** The cohort included 2,391 patients evaluated for transplant. In multivariable models the following factors were associated with increased risk of declining for LT waitlist: Medicaid insurance (OR 2.44, 95% CI 1.76-3.37), Medicare insurance (OR 1.71, 95% CI 1.39-2.11), a high-risk SIPAT score (OR 1.77, 95% CI 1.42-2.21), Black race (OR 1.41, 95% CI 1.06-1.87) and older age (OR 1.03, 95% CI 1.02-1.04). The following variables were associated with declining for waitlisting due to psychosocial reasons: ALD (OR 2.43, 95% CI 1.20-4.93), Black race (1.76, 95% CI 1.10-2.82), Medicaid insurance (OR 2.09, 95% CI 1.31-3.31), and a high risk SIPAT score (OR 6.21, 95% CI 4.08-9.45). The risk of being declined for waitlisting due to psychosocial reasons was differentially higher in patients with Medicare insurance with ALD compared to private insurance and in women with ALD (Figure 1). **Conclusion:** Several sociodemographic factors contribute to disparities in transplant access. Among patients with ALD, female patients and patients on public insurance experience even more pronounced barriers to transplant waitlisting. This may reflect a combination of stigma, bias in transplant provider perception, and increased psychosocial barriers in this population. Future directions should include interventions to address bias in the transplant evaluation process and on improving psychosocial resources in higher-risk populations.

Figure 1. Predicted Probability of Not Being Waitlisted for Psychosocial Reasons Across Etiology of Liver Disease



*Significant at p < 0.10; cutoff chosen due to interaction analysis, which often uses significance at p< 0.10-0.20. ALD; alcohol-associated liver disease. NAFLD; non-alcoholic fatty liver disease. A) Reference group: private insurance. B) Reference group: male. All interaction analysis adjusted for age, MELD-Na, and evaluation year.

173 | IMPACT OF SOCIAL DETERMINANTS OF HEALTH ON TIME TO TREATMENT INITIATION AND PROGRESSION OF HEPATOCELLULAR CANCER

Danielle Garfunkel[1], Christina Tsai[1], Arielle Greenberg[1], Zoe Verzani[2], Brett Fortune[1] and Clara Tow[1], (1) Montefiore Medical Center, (2)Weill Cornell Medical Center

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: While studies have associated social determinants of health (SDOH) with hepatocellular carcinoma (HCC) treatment delay of > 3 months, there is limited data on SDOH impacting expedited treatment and subsequent outcomes. This study investigates whether components of SDOH are associated with progression-free survival for HCC within Milan criteria and their effect on time to initiate HCC treatment. **Methods:** We conducted a retrospective cohort study of adults diagnosed with HCC within Milan criteria from 2010 to 2021 at an urban liver transplant center. Patients who were not treated or received initial curative surgery (transplant or resection) were excluded. Patients with expedited therapy (< 45 d from diagnosis) were compared to those with non-expedited therapy (e 45 d). Demographic data was gathered via chart review. Patients were geospatially mapped by address and linked to a Federal Information Processing Standards (FIPS) code and SDOH data from the 2020 U.S. Census. Our primary outcome was progression free survival. Secondary outcomes included time from diagnosis to treatment. T-tests, chi-square tests, logistic and cox univariate regression analyses were performed. **Results:** Of 1401 patients with HCC, 235 (17%) were included. Our sample had an average age of 63 years and consisted of 64% males, 52% Hispanics, and 85% T1 tumors by TNM staging (Table 1). There was a notable trend towards increased progression free survival for those treated in < 45 days ($p = 0.094$). A smaller proportion of non-White patients received expedited treatment compared to White patients (37% vs 58%, $p = 0.01$). SDOH associated with delayed therapy included higher social vulnerability index ($p = 0.013$), minority status ($p = 0.03$), income below 150% poverty line ($p = 0.007$), vulnerable housing/transportation ($p = 0.032$), vulnerable socioeconomic status ($p = 0.027$), educational level below high school ($p = 0.003$), and limited English ($p = 0.033$). Though larger tumors received more expedited therapy ($p = 0.019$), tumor size e 2 cm was associated with rapid disease progression ($p = 0.015$). **Conclusion:** SDOH clearly impact time to HCC treatment initiation and cancer progression. Despite the expedited group's larger tumor size and the faster progression of larger tumors, there was a trend towards improved progression-free survival for patients receiving expedited treatment before 45 days. These findings underscore the importance of early treatment and implementing interventions to mitigate SDOH disparities in care of patients burdened by HCC.

Table 1 Baseline characteristics and social determinants of health for locally treated hepatocellular carcinoma, stratified by time from diagnosis to treatment.

174 | THE SOCIAL DETERMINANTS OF ACCESS TO CURATIVE THERAPIES FOR HEPATOCELLULAR CARCINOMA: A PROSPECTIVE COHORT STUDY

Lauren D. Nephew[1], Susan Rawl[1], Allie Carter[1], Eric S. Orman[1], Archita Parikh Desai[1], John Holden[2], Marwan S. Ghabril[1], Kavish R. Patidar[3], Nicole Garcia[1], Meera Farzana Iyengar[1], Gabriella Aitcheson[1], Eleazar Montalvan[1] and Naga P. Chalasani[4], (1)Indiana University, (2)Indiana University School of Medicine, (3) Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center, (4)Indiana University Medical Center, Indianapolis, IN

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death, with high morbidity and mortality among vulnerable populations. We hypothesized the social determinants of health (SDOH), downstream social risks, and health behaviors impact access to curative therapies. **Methods:** Adult patients were prospectively enrolled from three hospitals in the Indianapolis area from 6/2019-11/2021. Sixteen individual and area-level SDOH within three access to care domains were collected using structured interviews and validated questionnaires (Panel A). Multinominal multivariable logistic regression was used to explore the associations between these SDOH and the outcomes of being alive without curative therapy, and having been transplanted/resected, or deceased at one year. Multivariable Cox survival analysis was used to explore time to death. **Results:** Of 139 patients with well characterized HCC 14.4% were Black and 7.9% were Hispanic. Most were Childs Pugh Category A (61.9%) and hepatitis-C virus was the most common underlying liver disease (46.5%). Annual household incomes of < $15,000 were reported by 21.6% of participants, and 7.9% reported trouble with transportation to medical appointments. 47.1% of patients lacked knowledge of their underlying liver disease. Brief Health literacy (BRIEF) scores were significantly lower, indicating worse health literacy, among those who died during the study period compared to those who were transplanted ((8.3 ± 3.8 vs. 10.5 ± 3.4) or still alive (10.7 ± 3.7) ($p = 0.013$) (Panel B). On average the cohort was followed 483 days; 31.6% (n = 44) underwent transplant/resection and 19.4% (n-27) were deceased at follow-up. Multivariable multinomial logistic regression analysis showed that higher health literacy was associated with a greater odds of being transplanted/resected compared to deceased (OR 1.206 95% CI 1.047-1.389, $p = 0.009$) and higher odds of being alive without transplant compared to deceased (OR 1.213 95% CI 1.065-1.381, $p = 0.004$). Recent alcohol use was associated with lower odds of being transplanted/resected compared to being alive (OR 0.243 95% CI 0.076-0.779, $p = 0.017$). On multivariable survival analysis health literacy scores were associated with survival (HR 0.87, 95% CI 0.80-0.96). **Conclusion:** Low health literacy and recent alcohol are strong determinants of receiving curative therapies for HCC and survival. These social risks are modifiable from within the health care system.

Figure. Social determinants of health, social risks, and health behaviors in patients with HCC by outcome status

A. Access to care domains, SDOH, social risks, and health behaviors evaluated

Ability to Perceive	Ability to Pay and Reach		Ability to Engage
Health Literacy	Income	Insurance	Social Support

175 | PSYCHOSOCIAL NOT CLINICAL FACTORS PREDICT LIVER TRANSPLANT LISTING AMONG SAFETY-NET REFERRALS

Mark Chang Wang[1], Saroja Bangaru[1], Matt Sumethasorn[1], Sarah Wang[1], Jihane N. Benhammou[2], Christopher Wong[1] and Kali Zhou[3], (1)University of Southern California, (2)University of California, Los Angeles, Los Angeles, CA, (3)University of Southern California, Los Angeles, CA

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Due to socioeconomic and healthcare access challenges, safety-net patients with liver disease face substantial disadvantages. Little is known about which factors – including psychosocial factors – impact listing for liver transplantation (LT) among the safety-net population. **Methods:** This was a multi-site retrospective study of adult patients who received outpatient hepatology care and were referred for LT between 2016 and 2022 from LA General Medical Center, which is one of the largest municipal safety-net hospitals and serves as the referring center to two transplant centers (Keck USC or UCLA). Demographics, clinical data, and LT evaluation outcomes were collected from the medical record. Among those who completed LT evaluation, detailed psychosocial data from the initial LT social work assessment were collected. Univariate and multivariate analyses were performed to determine clinical and psychosocial predictors of LT listing. **Results:** Out of 318 referred safety-net patients, 238 were evaluated for LT, with 233 having received a listing decision (135 listed, 98 declined). 80.0% had Medi-Cal insurance, 34.3% were primarily English-speaking, 53.1% were unemployed, and 44.3% had less than a high school education. Patients were similar in age, race/ethnicity, sex, disease etiology, and clinical decompensation by listing status. Per univariate analysis, listed patients were more likely to be legal residents than undocumented, live in a house, have ample social support, be married, be foreign-born, and have NASH. They were less likely to have transportation and financial barriers, unstable housing, and limited sobriety. After adjusting for age, evaluation site, and race/ethnicity, multivariable analysis identified legal status (OR 0.37, 95% CI 0.14-0.96), social support (OR 4.21, 95% CI 1.69-10.51), and living in a house (OR 3.25, 95% CI 1.58-6.68) as independent predictors of listing (Table). There was a non-significant trend towards higher odds of listing if foreign-born and no transportation barriers. Among 98 declined patients, the most common reasons for denial were lack of social support (23), being too early for LT (22), limited sobriety (19), HCC tumor burden (15), adherence concerns (14), and comorbidity (11). **Conclusion:** Among safety-net patients, psychosocial rather than clinical factors were predictive of LT listing. Targeted efforts to modify these factors may mitigate disparities in the LT listing process for underserved populations.

Church, VA, (3)The Global Nash Council, Washington, DC, (4)School of Public Health, University of Haifa, Haifa, Israel; Department of Gastroenterology, Tel-Aviv Medical Center, Tel-Aviv, Israel, (5)Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain, (6)Center for Outcomes Research in Liver Diseases, Washington, DC, (7)Inova Medicine, Inova Health System, Falls Church, VA

Background: Food insecurity can increase the risk for NAFLD. We assessed the association between food insecurity and NAFLD among adolescents in the United States. **Methods:** Data for adolescents (aged 12-18) from the National Health and Nutrition Examination Survey (2017-2018) were analyzed. Food insecurity was assessed using the U.S. Department of Agriculture (USDA) Child Food Security Survey Module, including 8 food security questions. Adolescents with 2 or more affirmative responses are classified as having food Insecurity according to USDA guidelines. Participation in Supplemental Nutrition Assistance Program (SNAP) was defined as anyone in household participating in the past 12 months. Low household (HH) income level was defined as household income < 138% federal poverty level [FPL]). NAFLD was defined by transient elastography (TE) with a controlled attenuation parameter (CAP) of e 285 dB/m without other causes of liver disease. Significant fibrosis (SF) and advanced fibrosis (AF) was defined by TE liver stiffness > 8.0 kPa and 13.1 kPa, respectively. **Results:** Among 771 adolescents included in NHANES 2017-2018 [mean age 14.7 years; 52.5% male; 50.9% white, 12.7% Black, and 16.7% Mexican American, 7.7% Hispanic and 4.5% Asian], 9.8% reported food insecurity and 10.8% had NAFLD; 22.5% obesity; 45.4% central obesity; 1.0% diabetes; 20.9% Pre-diabetes; 4.5% hypertension, 41.6% hyperlipidemia, 17.3% high C-reactive; 2.5% SF; and 0.5% AF. Of the adolescents who were considered food insecure, 98.9% relied on low-cost food, 93.2% couldn't get balanced meal and 51.5% did not eat enough food. Compared to the food-secure adolescents, food-insecure adolescents had higher rates of NAFLD (18.7% vs. 9.9%) and higher rates of advanced hepatic fibrosis (2.8% vs. 0.3%). Furthermore, they were more likely to be non-US citizens (88.8% vs. 95.6%), live with lower HH income (70.4% vs. 25.7%) and lower head of HH education (29.2% vs. 17.0%) and higher rates of SNAP participation (62.4% vs. 25.1%). There were no differences in metabolic diseases (T2D etc.) according to food insecurity. A model adjusted for demographic, metabolic diseases and SNAP participation showed that food insecurity (Odds ratio [OR] = 2.62, 95% confidence interval [1.07-6.41]), obesity (OR = 15.56 [7.71-31.50]), and hypertension (OR = 4.93 [2.67-9.14]) were independently associated with NAFLD. An additional multivariable model showed that living in a food-insecure adolescents living in lower HH income was associated with an even higher risk of NAFLD (OR = 4.79 [1.44-15.86]) versus adolescents living in higher HH income. **Conclusion:** Food insufficiency and low household income drive NAFLD risk for adolescents.

177 | CHARACTERISTICS AND OUTCOMES OF TRANSGENDER PATIENTS WITH CIRRHOSIS: A NATIONAL COHORT STUDY★

Hirsh Elhence[1], Norah Terrault[2], Jeffrey A Kahn[2] and Brian P. Lee[2], (1)Keck School of Medicine of USC, (2) University of Southern California

Background: The American Association for the Study of Liver Diseases has stated that fostering a "supportive environment for transsexual individual's seeking hepatology care" is an important goal. However, the landscape of transgender patients with cirrhosis is largely unknown. We aimed to assess the clinical characteristics of transgender patients with cirrhosis and quantify their outcomes. **Methods**: We retrospectively analyzed a large national insurance registry (Optum) between 2008-2021, including

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

adults with cirrhosis identified by validated ICD-9/10 codes. Liver transplant recipients were censored at transplant. Transgender patients were identified using a billing code definition validated in a large national insurance registry (89% true-positive rate and 0.05% false-negative rate). Inverse-probability treatment weighting (IPTW) was used to balance trans- and cis-gender populations on individual level characteristics, such as age, reported gender, Charlson comorbidity index, cirrhosis etiology and decompensation status. The outcome was all-cause mortality. Patients were censored at 3-years of follow-up. **Results**: Among 55,741,658 adults in Optum, 28,672 (0.05%) were transgender. Among 282,106 adults with cirrhosis, 175 (0.06%) were transgender, with median follow-up of 2.4 years (IQR 0.9-4.2). Among patients with cirrhosis, trans- (vs. cis-) gender patients were younger (median age [IQR]: 62 [50-69] vs. 65 [57-72], $p < 0.001$), more likely to have alcohol (105 [60%] vs. 143,175 [51%], $p = 0.02$) or viral (65 [37%] vs. 79,406 [28%], $p = 0.01$) as cirrhosis etiologies, diagnoses of anxiety (111 [63%] vs.106,031 [38%], $p < 0.001$), depression (113 [65%] vs. 107,755 [38%], $p < 0.001$), and HIV (14 [8%] vs. 3,971 [1%], $p = 0.001$). Trans- (vs. cis-) gender patients had a similar likelihood of liver decompensation during follow-up (86 [51%] vs. 139,265 [49%], $p = 0.70$), and undergoing liver transplantation (4 [2%] vs. 4,763 [2%], $p = 0.54$). In IPTW-weighted survival analysis, probability of 3-year survival (72% vs. 70%, $p = 0.54$) (Figure 1), and 3-year liver decompensation (33% vs. 40%, $p = 0.94$) were similar. Trans- (vs. cis-) gender patients with cirrhosis spent more time receiving healthcare outside the home (median utilization per 100 days [IQR]: 3.1 days [0.9-9.9] vs. 1.5 days [0.3-5.1], $p < 0.001$). **Conclusion**: In this national study of insured persons with cirrhosis, the proportion of transgender patients was similar to the overall Optum population. We found that trans- (vs. cis-) gender patients have different clinical characteristics and greater healthcare utilization, but have similar liver decompensation, transplant, and mortality rates. These findings may help inform gender-inclusive hepatology care.

178 | RACIAL AND ETHNIC DISPARITIES IN WAITLIST MAINTENANCE: UPDATING LABS AND REMAINING ACTIVE

Alexandra Strauss[1], Vedant S. Jain[2], Jennifer Motter[3], Tanjala S. Purnell[1], Dorry L. Segev[4] and Allan B. Massie[4], (1)Johns Hopkins University, (2)Carle Illinois College of Medicine, (3)New York University, (4)NYU Langone Health

Background: Despite liver transplant (LT) waitlist prioritization being based on model for end stage liver disease (MELD) score, situations arise when patients are not optimally represented: 1) "inactive" and 2) lower MELD due to missing MELD "recertification". LT candidates are required to update, or "recertify", their labs within a certain amount of time based on their MELD (e.g., MELD ≥ 25 requires recertification by 7 days or MELD decreases to last lower value and then to 6 if missed again). Also, patients become inactive for many reasons, some related to waitlist maintenance, and inactive status is associated with higher waitlist mortality. Social determinants of health may disproportionally impact patients leading to racial disparities in recertifying MELD and remaining active. We aimed to examine the association between race/ethnicity and these sub-optimal states. **Methods:** We studied national registry data (SRTR) on adult, first-time LT waitlist registrants 1/2017-9/2022. Patients who ever received MELD exception points or were classified as Status 1 were excluded. For Model 1, the outcome event was defined as ever missing lab recertification or being inactive due to "candidate cannot be contacted", "candidate work-up not complete", "insurance issues", or "medical non-compliance". Model 2 was only ever missing recertification, and Model 3 was any of the above inactive reasons. We performed multivariable modified Poisson regression with robust variance estimator to examine race/ethnicity disparities in the outcome. Models were adjusted for gender and age. **Results:** Of the 44,073 candidates, 6.4% were Black and 16.6% were Hispanic. There were 12,940 (29.4%) candidates that

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

did not recertify MELD labs on schedule and 3,173 candidates (7.2%) that were inactive for any of the specified reasons as listed above. In adjusted analysis Model 1, Black candidates were at 11% higher risk (aRR 1.11, 95%CI 1.05-1.17, $p < 0.001$), and Hispanic candidates were at 24% higher risk (aRR 1.24, 95%CI 1.20-1.28), $p < 0.001$). For Model 2, effect sizes were similar. For Model 3, Black candidates were at 21% higher risk (aRR 1.21, $p = 0.004$) and Hispanic candidates were 12% higher risk (aRR 1.12, $p = 0.01$). **Conclusion:** Black and Hispanic LT candidates are at higher risk of not recertifying their MELD labs or becoming inactive, which may lead to worse waitlist outcomes. Further research and interventions to support waitlist maintenance at the patient and transplant center level are needed for personalized approaches.

f 179 | HIGH BLOOD LEVELS OF LEAD ARE ASSOCIATED WITH LIVER FIBROSIS AND SHORTENED TELOMERES IN AFRICAN AMERICANS IN A U.S. NATIONAL COHORT

Ning Ma[1], Rowena Yip[1], Sara Lewis[1], Michael Crane[1], Artit Jirapatnakul[1], Costica Aloman[2], Meena B. Bansal[1], Douglas T. Dieterich[1], David F. Yankelevitz[1], Claudia Henschke[1] and Andrea D. Branch[1], (1)Icahn School of Medicine at Mount Sinai, (2)Rush University Medical Center, Chicago, IL

Background: Environmental pollutants cause liver damage and telomere shortening. Effects may vary by race/ethnicity. This study examined interactions among liver-related outcomes, telomere length, and environmental pollutants by race/ethnicity. **Methods:** The study included 36,092 adults (age ≥ 20 y old) in the National Health and Nutrition Examination Survey (NHANES, 1999-2018) with data on blood levels of cadmium (Cd), lead (Pb) and mercury (Hg); 1,242 had data on 34 polychlorinated biphenyls (PCBs); and 7,360 had data on telomere length. Advanced liver fibrosis (LF) was defined as ALT elevation (≥ 40 IU/L, men; ≥ 31 IU/L, women) and FIB-4 ≥ 2.67 and/or Forns ≥ 6.9 and/or APRI ≥ 1.5. Shortened telomeres were in the 1st quartile (Q1) of length. Associations between advanced LF and pollutants were analyzed by multivariable logistic regression (MVL); mixtures were analyzed by weighted quantile sums (WQS) models. **Results:** High (Q4) blood levels of Pb were significantly associated with advanced LF in non-Hispanic (NH)-Blacks, but not in any other racial/ethnic group in MVL models adjusted for survey cycle, age, sex, BMI, smoking status, alcohol use, diabetes, and poverty: Odds ratio = 2.35, (95%CI, 1.43-3.85) (Fig 1A). Cd was associated with advanced LF in all racial/ethnic groups (Fig 1A). In WQS mixture analysis of three metals, Pb was the most significant contributor to the association between toxic exposure and advanced LF in NH-Blacks, while Cd was the most significant contributor in other groups. High (Q4) blood levels of Pb were associated with shortened telomeres in NH-Blacks and Mexican Americans (Fig 1B); Q4 blood levels of Cd were associated with shortened telomeres in NH-Whites (Fig 1B). Shorter telomeres were associated with higher risk of advanced LF (Fig 1C). In WQS mixture analysis of metals and PCBs, Cd and PCB199 were the most significant contributors to the significant association between toxic exposures and advanced LF (Fig 1D), while PCB126, Cd, and Pb were the most significant contributors to the significant association between toxic exposures and ALT elevation (Fig 1E). **Conclusion:** Innovations in statistics allow mixtures to be analyzed. WQS mixture analysis of common pollutants revealed that Pb is associated with advanced LF in NH-Blacks. This hepatotoxic effect may be mediated by telomere shortening, which was associated with Pb exposure in NH-Blacks and Mexican Americans. Pollution may be contributing to liver-related healthcare disparities.

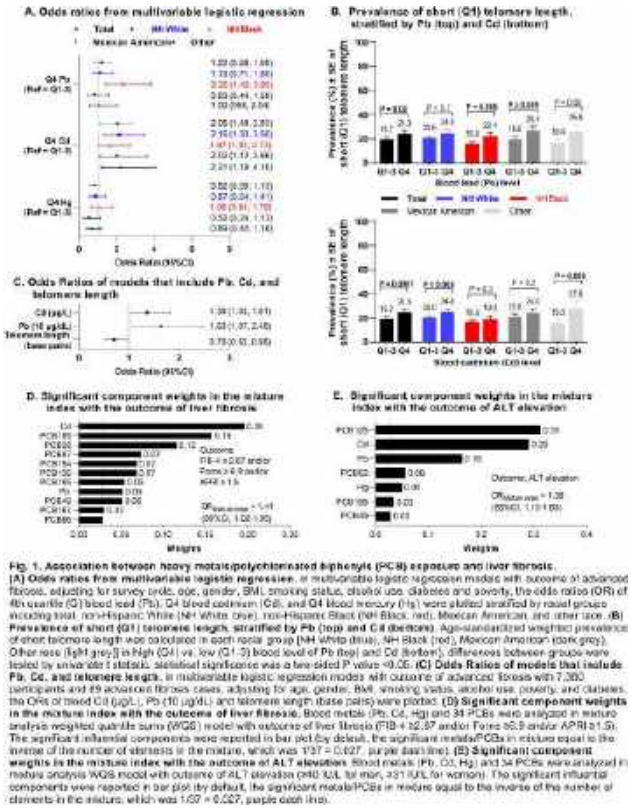

Fig. 1. Association between heavy metals/polychlorinated biphenyls (PCB) exposure and liver fibrosis. **(A) Odds ratios from multivariable logistic regression**, a multivariable logistic regression models with outcome of advanced fibrosis, adjusting for survey cycle, age, gender, BMI, smoking status, alcohol use, diabetes and poverty, the odds ratios (OR) of 4th quartile (Q4) blood lead (Pb), Q4 blood cadmium (Cd), and Q4 blood mercury (Hg) were plotted stratified by racial groups including total, non-Hispanic White (NH White, blue), non-Hispanic Black (NH Black, red), Mexican American, and other race. **(B) Prevalence of short (Q1) telomere length, stratified by Pb (top) and Cd (bottom).** Age-standardized weighted prevalence of short telomere length was calculated in each racial group (NH White (blue), NH Black (red), Mexican American (dark grey), Other race (light grey)) in high (Q4) vs. low (Q1-3) blood level of Pb (top) and Cd (bottom); differences between groups were tested by univariate t statistic, statistical significance was a two-sided P value <0.05. **(C) Odds Ratios of models that include Pb, Cd, and telomere length**, in multivariable logistic regression models with outcome of advanced fibrosis with 7,380 participants and 89 advanced fibrosis cases, adjusting for age, gender, BMI, smoking status, alcohol use, poverty, and diabetes, the Q4s of blood Cd (µg/dL), Pb (10 µg/dL) and telomere length (base pairs) were plotted. **(D) Significant component weights in the mixture index with the outcome of liver fibrosis.** Blood metals (Pb, Cd, Hg) and 34 PCBs were analyzed in mixture analysis weighted quantile sums (WQS) model with outcome of liver fibrosis (FIB-4 ≥2.67 and/or Forns ≥6.9 and/or APRI ≥1.5). The significant influential components were reported in bar plot (by default, the significant metals/PCBs in mixture equal to the inverse of the number of elements in the mixture, which was 1/37 = 0.027, purple dash line). **(E) Significant component weights in the mixture index with the outcome of ALT elevation.** Blood metals (Pb, Cd, Hg) and 34 PCBs were analyzed in mixture analysis WQS model with outcome of ALT elevation (>40 IU/L for men, >31 IU/L for women). The significant influential components were reported in bar plot (by default, the significant metals/PCBs in mixture equal to the inverse of the number of elements in the mixture, which was 1/37 = 0.027, purple dash line).

180 | STAKEHOLDER ENGAGEMENT TO IDENTIFY KEY DETERMINANTS OF VIRAL HEPATITIS AND LIVER CANCER SCREENING AND CARE IN ASIAN AMERICAN COMMUNITIES

Ponni Perumalswami[1], Yi-Chun Wang[1], Ariana Chen[1], Szu Hsien Chen[2], Tsu-Yin Wu[2] and Neehar Dilip Parikh[1], (1)University of Michigan, (2)Eastern Michigan University

Background: Viral hepatitis screening and link to care is a key cancer control strategy to prevent development of liver cancer, especially in underserved populations. We lack data on determinants for viral hepatitis and liver cancer screening and care particularly in geographically spread Asian American (AA) populations. **Methods:** We engaged: 1) external stakeholders across Michigan and 2) leaders from 3 Michigan AA communities (Bangladesh, Burmese, Chinese) to identify determinants of viral hepatitis and cancer screening. External stakeholders organizations from state government, community partners, and the Rogel Michigan Medicine Cancer center participated in a focus group to identify broad viral hepatitis and cancer screening and care determinants for Michigan AA communities. We conducted 1:1 semi-structured interviews with 2-5 leaders from each AA community. The interviews assessed 1) general cancer screening, 2) viral hepatitis and liver cancer knowledge and beliefs, 3) health concerns/access. The focus group and interviews were conducted in English, audiotaped and transcribed. A rapid data analysis approach was used to identify key determinants and then grouped by themes informed by the National Institute of Minority Health and Health Disparities Framework. **Results:** Eight representatives from external stakeholders participated in the focus group and 11 community leaders from the 3 AA groups participated in interviews. A summary of determinants (barriers [B] and facilitators [F]) is included in the Table grouped by themes. According to AA community leaders, top health concerns included diabetes, hypertension, mental health and chronic diseases. Shared barriers included non-English language, lack of education, misinformation, transportation, lack of insurance, costs of care with insurance, stigma, fear of lost wages and lack of funding for outreach activities. Shared facilitators included trust in community leaders, bilingual services, health education programs and community partnership. Unique determinants within communities included: 1. Burmese: experiencing racism when seeking healthcare (B), multiple dialects within community (B), multiple religious affiliations that further silo communities based on dialects (B), 2. Bangladesh: prior hepatitis outreach activities (F), multisite community organizations (F) and 3. Chinese: positive health messaging (F), reassuring community about treatment options (F), trust

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in healthcare providers (F). External stakeholders did not identify many determinants raised by AA community leaders representing a learning opportunity. **Conclusion:** While many determinants of viral hepatitis and liver cancer outreach efforts are shared across in Michigan AA communities, some barriers and facilitators vary by communities. To adapt or develop viral hepatitis and cancer outreach, tailored interventions to address community specific determinants are needed.

181 | SOCIAL DETERMINANTS OF HEALTH ARE ASSOCIATED WITH ADHERENCE TO MONITORING AMONG IMMIGRANTS WITH CHRONIC HEPATITIS B: A MULTICENTER STUDY

Kali Zhou[1], Christine C Hsu[2], Christopher Wong[1], Andrea Lynn Keller[3], Coleman I. Smith[4], Amol S. Rangnekar[5], Ariana Chen[6], James Ajokubi[7] and Norah Terrault[8], (1)University of Southern California, (2) National Institute of Health, (3)Medstar Health, (4) Georgetown University Hospital, (5)Medstar Georgetown University Hospital, (6)University of Michigan, (7)Georgetown University, (8)University of Southern California, Los Angeles, CA

Background: Immigrants are the largest subgroup living with chronic hepatitis B (HBV) infection in the United States (US). Close monitoring is recommended for all patients with chronic HBV regardless of disease activity. It is not well understood how immigration factors and social determinants of health (SDOH) impact downstream adherence to HBV monitoring among immigrants. **Methods:** We conducted a multicenter multilingual survey study among foreign-born adults with chronic HBV at three sites in California and Washington D.C. between 7/2021-2/2023. Participants were surveyed regarding 1) immigration factors such as birth country, time in the US, and citizenship status 2) acculturation including the Vancouver Index of Acculturation and language preferences 3) SDOH such as education, income, employment, and insurance and 4) clinical factors such as specialty care, treatment status, and evidence of end-stage liver disease. Primary outcome was optimal adherence to monitoring, defined as % of time with at least annual testing of HBV DNA, ALT, and ultrasound (if indicated for cancer surveillance per AASLD guidelines) while under care. Outcomes data were retrospectively collected through electronic medical records. Stepwise backwards logistic regression was used to examine factors associated with outcome. **Results:** 217 participants (median 57 y, 55% male) completed the survey from 27 birth countries, with highest representation from China (30%), Vietnam (16%), and South Korea (10%). 6% were from Latin America. A minority (29%) were recently immigrated within the past 20 years and 63% were US citizens. Nearly all participants (92%) reported seeing a specialist for HBV, with 74% currently on treatment. 119 participants (55%) had optimal adherence to monitoring over median 4 years (2-7) under care. Immigration factors, degree of acculturation and language were not associated with adherence. Factors associated with more optimal adherence on multivariate testing included younger age (OR 0.96, 95% CI 0.93-0.99), on treatment (vs not: OR 2.7, 1.2-5.9), currently employed (vs not; OR 2.2, 1.0-5.0), and higher education (college vs high school; OR 3.6, 1.4-9.0; graduate degree vs high school: OR 3.2, 1.1-9.6). **Conclusion:** SDOH rather than immigration-related factors influenced likelihood of adherence to guideline-recommended monitoring of chronic HBV infection among immigrants. Efforts to improve monitoring should target socially disadvantaged foreign-born.

182 | UNVEILING THE TOTAL BURDEN OF LIVER CANCER IN LOW SOCIO-DEMOGRAPHIC INDEX COUNTRIES FROM 2010-2019: EPIDEMIOLOGICAL TRENDS, ETIOLOGY, AND GENDER SPECIFIC PATTERNS

Gautam Maddineni[1], Silpa Choday[2], Kelsey Theriault[1], Abraham Bell[3], Dustin Paul Begosh[1], Magdy El-Din[1] and Karn Wijarnpreecha[4], (1)Florida State University, (2)Creighton University, (3)Florida State University, Cape Coral, FL, (4)University of Arizona College of Medicine Phoenix, Phoenix, AZ

Background: Liver cancer poses a significant health challenge worldwide, but its burden in low Socio-Demographic Index (SDI) countries remains understudied. These countries face unique obstacles, including limited healthcare resources, inadequate screening programs, and a higher prevalence of risk factors like hepatitis B and C. Liver cancer has become a pressing public health issue, impacting individual's, communities, and healthcare systems in low SDI countries. This abstract explores the total burden of liver cancer in these regions, focusing on epidemiological trends, etiology, and the disease's impact on morbidity, mortality, and socioeconomic factors. Understanding these challenges can guide interventions, prevention efforts, and resource allocation to alleviate the burden of liver cancer and improve health outcomes in vulnerable populations. **Methods:** This study utilized data from the Global Burden of Disease Study 2019 (GBD 2019), which assesses disease burden and risk factors across 204 countries and territories. We extracted data on liver cancer incidence, deaths, and disability-adjusted life years (DALYs) from low SDI countries between 2010 and 2019. Various statistical techniques were employed to address data heterogeneity, and a Bayesian geospatial regression analysis was used to estimate liver cancer-related mortality. The study included comprehensive stratification by country, sex, and year, and proportional models were applied to determine the contribution of different etiologies to liver cancer cases. **Results:** The burden of liver cancer in low SDI countries increased in incidence and DALYs from 2010 to 2019, with a higher prevalence observed among males. Alcohol-related liver cancer cases continued to rise, predominantly affecting males. The incidence rate remained stable in females, but DALYs increased. Hepatitis B-related liver cancer showed a declining trend, with decreasing rates in both incidence and deaths. Hepatitis C-related liver cancer also decreased, but males had a higher frequency of deaths despite females being the most affected. Non-alcoholic steatohepatitis (NASH)-related liver cancer cases increased significantly, particularly among females. Other causes of liver cancer demonstrated an upward trend in frequency (Image). **Conclusion:** This study provides insights into the burden of liver cancer in low SDI countries, highlighting different etiologies. The overall burden of liver cancer is decreasing, particularly for hepatitis B and C cases. However, viral hepatitis cases still lack adequate treatment, emphasizing the importance of early detection and treatment to prevent liver cirrhosis and cancer. Metabolic-related liver cancer, including NASH, is a growing concern globally and in low SDI countries. Prevention and control strategies specific to these regions are crucial to reducing the burden of liver cancer. Ref: https://vizhub.healthdata.org/gbd-results/.

DeLemos, Carolinas Healthcare System, Arpan Mohanty, Boston University School of Medicine, Melisa Melisa Dirchwolf, Hospital Privado De Rosario, Brett Fortune, Montefiore Medical Center, Patrick Grant Northup, NYU Langone Health, Saint Petersburg, FL, James Patrie, University of Virginia School of Medicine, Department of Biostatistics, VA and Stephen H. Caldwell, University of Virginia, Charlottesville, VA

Background: Patients with decompensated cirrhosis are frequently hospitalized and often undergo multiple invasive procedures. We aimed to define the incidence of procedural-related bleeding in patients with acute on chronic liver failure (ACLF) and to compare it with that of patients without ACLF. **Methods:** Prospective, multicenter, international cohort study of hospitalized patients with cirrhosis undergoing non-surgical procedures. Patients were followed until 28 days from admission, death, liver transplantation, and/or undergoing surgery. Procedural bleeding was defined according to ISTH definitions and defined as major, clinically relevant non-major (CRNMB), and other. The risk of the procedure was judged to be low or high risk based on recent AASLD guidelines. ACLF at admission was defined according to European Foundation for the Study of Chronic Liver Failure. **Results:** A total of 1,051 patients undergoing 2,688 non-surgical procedures were enrolled from 20 centers in North and South America. 224 (21.3%) of the patients enrolled had ACLF on admission versus 827 patients without ACLF on admission. At admission patients with ACLF more commonly had ascites, AKI and infection. Length of stay was longer in patients with ACLF (mean 17.4 d ACLF vs. 11.9 d non-ACLF) and they underwent more procedures while hospitalized (mean 3.3 ACLF vs. 2.3 non-ACLF). Proportion of high risk procedures in patients with ACLF was lower compared to patients without ACLF (4.9% ACLF vs. 10.5% non-ACLF, $p < 0.001$). Prior to procedures coagulation parameters were significantly different in patients with ACLF ((platelets (k/uL) 100 ACLF vs. 116 non-ACLF $p < 0.001$; INR 2.1 ACLF vs. 1.7 non-ACLF, $p < 0.001$; fibrinogen (mg/dL) 181 ACLF vs 201 non-ACLF, $p = 0.005$). Patients with ACLF were more likely to receive pre-procedure prophylaxis with platelet and plasma transfusion. A total of 76 procedural related bleeding events were identified in this cohort (25 major, 30 clinically relevant non-major, and 21 other bleeds). Bleeding was more prevalent in patients with ACLF compared to patients without ACLF (14.2% ACLF vs. 5.3%, $p < 0.001$) with a relative risk of bleeding for patients of 2.69 [95% CI 1.74, 4.13] (See Table). Non-procedural related bleeding while hospitalized occurred more frequently in patients with ACLF (21% ACLF vs. 15% non-ACLF, $p = 0.035$). Patients with ACLF had higher mortality and more commonly underwent liver transplantation during 28-day follow up. **Conclusion:** Prior studies have demonstrated patients with ACLF have unique hemostatic profiles compared to patients with decompensated cirrhosis. Patients with ACLF are more likely to develop procedural related bleeding despite undergoing lower risk procedures more commonly compared to patients with decompensated cirrhosis without ACLF. Factors which may explain this observation include increased number of procedures, comorbidities, and severity of liver disease.

Table: Patient related procedural bleeding events

Procedural bleed type	All (1051)	No ACLF (827)	ACLF (224)	
No Bleeding	975 (92.5)	783 (94.7)	192 (85.7)	<0.001
Bleeding events				
Major Bleeding	25 (2.4)	16 (1.9)	9 (4.0)	0.031
CRNMB	30 (2.9)	17 (2.1)	13 (5.8)	0.008
Other Bleeding	21 (2.0)	11 (1.3)	10 (4.5)	0.003

*n(%); CRNMB: Clinically relevant non-major bleeding; ACLF: acute on chronic liver failure.

184 | REDUCE DOSE SAFETY OF DIRECT ORAL ANTICOAGULANTS IN CIRRHOTIC PATIENTS AND PORTAL VEIN THROMBOSIS WITH COEXISTENT SIGNIFICANT THROMBOCYTOPENIA: A MULTI-COUNTRY STUDY

Julton Tomanguillo Chumbe[1], Mark Ayoub[2], Lauren Searls[2], Frank Annie[2], Harleen Chela[2], Nadeem Anwar[1] and Ebubekir Daglilar[1], (1)West Virginia University - Charleston Area Medical Center, Charleston, WV, (2)Charleston Area Medical Center/WVU Charleston Division

Background: Treating portal vein thrombosis in patients with cirrhosis becomes increasingly challenging when there is also significant thrombocytopenia ($< 50*10^3$/uL). As suggested by various international medical societies, a 50% reduction in the standard anticoagulation dosage has been recommended for individual's with significant thrombocytopenia. In this study, our goal was to evaluate the safety of using

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

reduced doses of direct oral anticoagulants (DOAC) among cirrhotic patients who have PVT and coexisting significant thrombocytopenia. **Methods:** Adult patients 18 years and old with the diagnosis of cirrhosis and significant thrombocytopenia, as defined by platelet count between 30 and 49*10^3/uL, were identified using TriNetX between 2007 and 2020. TriNetx includes a total of 106 different health care organizations from 14 different countries. Patients with cirrhosis with significant thrombocytopenia were divided into two cohorts; the first cohort comprised patient receiving 50% reduced-dose DOAC (Apixaban or Rivaroxaban), and a second cohort did not receive any anticoagulation therapy. We compared the rate of mortality and significant bleeding such as intracranial bleeding and gastrointestinal bleeding between propensity matched (PSM) pairs of patients. **Results:** A total of 2,245 patients with cirrhosis and significant thrombocytopenia were included in this analysis. Of these 16% (n = 350) were on DOAC, and 84% (n = 1,890) were not on anticoagulation. The raw data showed a higher rate of key comorbidities in the DOAC group, such as chronic heart failure (21.7% vs 7.1%, $p < 0.001$), diabetes mellitus (51.0% vs 29.9%, $p < 0.001$), and CKD (35.8% vs 13.9%, $p < 0.001$). Subsequently, two well-matched cohorts were created using a 1:1 propensity-scored matching model (329/329). No significant difference was noted between the two groups in the rate major bleedings at 6 or 12 months. At 6-months intracranial hemorrhage (3.04% vs 3.04%, $p = 1.00$), gastrointestinal bleeding (16.41% vs 12.15%, $p = 0.475$), and over-all mortality (20.97% vs 21.58%, $p = 0.84$). At 12-months intracranial hemorrhage (3.04% vs 3.04%, $p = 1.00$), gastrointestinal bleeding (19.14% vs 14.28%, $p = 0.09$), and over-all mortality (24.62% vs 24.62%, $p = 1.00$). **Conclusion:** In a large multi-country study, the use of reduced dosed DOAC in patient with cirrhosis and significant thrombocytopenia was not significantly associated with major bleedings such as intracranial hemorrhage or gastrointestinal bleeding up to 12-months when compared with patient not on anticoagulation.

185 | LIVER LYMPHANGIOGENESIS MITIGATES THE PROGRESSION OF FIBROSIS★

Jain Jeong[1], Yilin Yang[2], Teruo Utsumi[3], Matthew McConnell[2], Rolando Garcia-Milian[1], Xuchen Zhang[2], Shi-Ying Cai[2], James L. Boyer[1] and Yasuko Iwakiri[1], (1) Yale School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT, (3)VA Connecticut Health Care

Background: Chronic inflammation due to various etiologies leads to liver fibrosis and subsequently cirrhosis. The liver lymphatic system helps to reduce inflammation. We hypothesized that the liver lymphatic system ameliorates liver fibrosis/cirrhosis. **Methods:** Mice with different stages of liver fibrosis were generated using bile duct ligation (BDL) surgery. Liver lymphatic endothelial cells (LECs) from different stages of liver fibrosis were isolated for RNA sequencing. Liver samples from control and primary sclerotic cholangitis (PSC) patients were analyzed. **Results:** Hepatic lymphatic vessel (LV) numbers were significantly increased until 2 weeks after BDL (fibrosis stage), but decreased by 4 weeks (cirrhosis stage). To determine whether this drop in LV numbers further promotes liver fibrosis, we blocked new LV formation in BDL mice using MAZ51, an inhibitor of VEGFR3 and found aggravated liver fibrosis by increased Sirius Red (1.4-fold, $p < 0.05$), hydroxyproline (1.9-fold, $p < 0.05$), increased MPO-positive neutrophil number (2.8-fold, $p < 0.05$), and decreased lymphatic drainage (2.5-fold, $p < 0.05$). These results suggest that decreased lymphatic drainage promotes liver fibrosis progression. In contrast, administration of VEGF-C, the most potent factor promoting new LV formation, via AAV8-VEGF-C significantly increased LV numbers and inhibited liver fibrosis as indicated by decreased Sirius Red (1.4-fold, $p < 0.05$), hydroxyproline (1.4-fold, $p < 0.05$), and CD68-positive macrophage number (1.7-fold, $p < 0.05$). Transcriptomic analysis of LECs revealed increased TGFβ signaling, which is known to inhibit lymphangiogenesis in cirrhotic mouse livers. Blocking TGFβ signaling via LY364947 significantly increased LV numbers (2.0-fold, $p < 0.001$) and area (1.8-fold, $p < 0.01$) in cirrhotic mouse livers. In livers from PSC patients, we found increased LV number in compensated (3.5-fold, $p < 0.001$, n = 7) and decompensated (2.5-fold, $p < 0.05$, n = 6) cirrhosis. Importantly, hepatic LV number decreased in decompensated cirrhotic liver (1.4-fold, $p < 0.05$) compared to compensated cirrhotic patients. Histological analysis showed co-localized pSMAD2 expression increased in liver LECs in decompensated liver cirrhosis, indicating TGFβ-driven lymphatic dysfunction may contribute to the decompensation of liver cirrhosis. **Conclusion:** The liver lymphatic system inhibits liver fibrosis and progression to liver cirrhosis. VEGF-C-driven lymphangiogenesis and lymphatic drainage could be a novel therapy for liver fibrosis/cirrhosis.

186 | A COMPARATIVE ANALYSIS OF OUTCOMES BETWEEN DIRECT ORAL ANTICOAGULANTS AND LOW-MOLECULAR-WEIGHT HEPARIN OR VITAMIN K ANTAGONISTS IN BUDD-CHIARI SYNDROME: A GLOBAL MULTICENTER PROPENSITY-MATCHED STUDY

Abdullah Sohail, University of Iowa, Khadija Naseem, Cleveland Clinic Foundation, Muhammad Mujtaba Bhinder, Charleston Area Medical Center and Ahmad Khan, Case Western Reserve University

Background: In patients with Budd Chiari syndrome (BCS), the current treatment guidelines recommend a step-up approach starting with lifelong anticoagulation with low-molecular-weight heparin (LMWH) or vitamin K antagonists (VKA). Although direct oral anticoagulants (DOAC) may simplify patient management, there is limited data on the safety and efficacy of DOAC in patients with BCS. This study used a large research network to compare the outcomes of patients with BCS treated with DOACs, LMWH, and VKAs. **Methods:** In this retrospective cohort study and time-to-event analysis, we utilized the TriNetX electronic health records network, which encompasses over 100 million patients, from January 1st, 2015, to December 31st, 2020. The primary cohort included patients aged 18 years or older diagnosed with BCS. We performed (1:1) propensity score matching age, gender, race, and comorbidities, including Liver Cirrhosis, Diabetes Mellitus, Hypertension, Chronic kidney disease, and malignancy. Two matched control cohorts were created: one consisting of patients with BCS treated with LMWH or VKAs, and the other comprising patients treated with DOACs (including dabigatran, rivaroxaban, apixaban, and edoxaban). Using a Cox model, we estimated the incidence of gastrointestinal bleeding, retroperitoneal hemorrhage, Intracranial hemorrhage, and acute liver failure between propensity score-matched pairs of patients. **Results:** We identified 2,841 patients with BCS who met the inclusion criteria. Among them, 1,997 patients were treated with LMWH or VKAs, while 844 patients were treated with DOACs. Both groups had a majority of female and Caucasian patients, and there were no statistically significant differences in comorbid conditions before and after propensity matching (Table 1). Although there was a higher incidence of acute liver failure in the LMWH/VKA group before propensity matching, this difference did not remain statistically significant after matching. Additionally, there were no significant differences in the incidence of gastrointestinal bleeding, retroperitoneal hemorrhage, and intracranial hemorrhage between the two groups, both before and after propensity matching. **Conclusion:** Based on a large nationwide study, BCS patients treated with DOACs showed comparable rates of gastrointestinal bleeding, retroperitoneal hemorrhage, intracranial hemorrhage, and acute liver failure to those treated with LMWH or VKAs. LMWH or VKA treatment requires continuous monitoring, which may affect patient compliance. Our study suggests that DOACs could serve as an effective and safe long-term anticoagulation alternative for these patients. However, further confirmation through larger prospective studies is necessary.

187 | BAR501, A SELECTIVE GPBAR1 AGONIST, REDUCES VASCULAR INFLAMMATION AND ATHEROSCLEROSIS IN A MOUSE MODEL OF MASLD

Michele Biagioli[1], Silvia Marchianò[1], Cristina Di Giorgio[1], Martina Bordoni[1], Rosalinda Roselli[2], Rachele Bellini[1], Ginevra Urbani[1], Carmen Massa[1], Eleonora Distrutti[3], Angela Zampella[2] and Stefano Fiorucci[1], (1) University of Perugia, (2)University of Naples, Federico II, (3)Azienda Ospedaliera Di Perugia

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), represent the most common cause of chronic liver disease in Western countries. MASLD patients are at increased risk for developing clinically meaningful cardiovascular diseases (CVD), including stroke and coronary artery disease and its fatal and nonfatal ischemic complications. It is widely established that the CV component dictates the patient outcomes more frequently and to a greater extent than does the progression of the liver component and it is the most common cause of death for MASLD patients. There are no drugs specifically approved for the treatment of CVD and liver components of MASLD. In this scenario, there is therefore a constant search for new therapeutic targets and new therapies for the treatment of CVD in patients with MASLD. GPBAR1is a receptor, belonging to the family of bile acid receptors (BARs), activated by secondary

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

bile acids and their derivatives. Activation of GPBAR1 increases energy expenditure in the adipose tissue and promotes the release of Glucagon-like peptide (GLP)-1 and FGF15. Furthermore, GPBAR1 is expressed by cells of innate immunity and endothelial cells and their systemic activation counter-regulates leukocytes/endothelial cells adhesion and contribute to the vasodilatory properties of bile acids. The purpose of this study was to evaluate the effect of GPBAR1 activation in a mouse model of atherosclerosis. **Methods:** Apolipoprotein E deficient mice ($ApoE^{-/-}$), a standard model of atherosclerosis, were fed with HFD-F alone or with BAR501 for 14 weeks and then sacrificed. The aortic rings, aorta and liver were isolated and analyzed. **Results:** The GPBAR1 expression in the atherosclerotic plaques in rodent and patient's aorta, highlighted by IF staining, confirmed the involvement of the receptor in the atherosclerotic process. BAR501 in $ApoE^{-/-}$ mice exposed to HFD-F decreased body weight gain and increased insulin sensitivity. Furthermore, the administration of BAR501 induced an increase in the plasma concentration of GLP-1 and FGF15. Activation of GPBAR1 also resulted in the reduction of thickness and atheroma area in the aorta with a decrease in infiltrating $GPBAR1^{+}$ immune cells. The transcriptome analysis of the aorta showed a anti-inflammatory activity of BAR501 that down-regulated the expression of many genes belonging to inflammatory pathways. Macrophages represent the main actors of the atherosclerosis process; the analysis of macrophage subpopulations extracted from the spleen of mice from the different experimental groups showed a systemic anti-inflammatory activity exerted by BAR501, with an increase of $IL10^{+}/IL6^{+}$ macrophages ratio. **Conclusion:** GPBAR1 activation reduces systemic inflammation induced by a high-fat diet thereby reducing atherosclerotic lesions in the aorta, suggesting that BAR501 therapy may represent a potent new treatment for MASLD-related CVD.

188 | SAFETY OF DOACS IN PATIENTS WITH CHILD-PUGH CLASS C CIRRHOSIS AND ATRIAL FIBRILLATION

Mark Ayoub[1], Julton Tomanguillo Chumbe[1], Morgan Koontz[2], Ebubekir Daglilar[1], Nadeem Anwar[1] and Vishnu Naravadi[1], (1)West Virginia University - Charleston Area Medical Center, Charleston, WV, (2) Health Services & Outcomes Research, Charleston Area Medical Center

Background: Anticoagulation (AC) is the mainstay of thromboprophylaxis for stroke prevention in atrial fibrillation (AF) and is recommended. Cirrhosis is a risk factor for AF development; hence, AF is common in patients with cirrhosis. The hemostatic pathways in cirrhosis are imbalanced which makes their response to anticoagulation unpredictable. While Direct-Oral Anticoagulants (DOACs) are shown to be safe and effective in patients with AF without cirrhosis, they are hardly studied in patients with cirrhosis. Therefore, this study aims at comparing safety and evaluating different outcomes in patients with Child C cirrhosis receiving anticoagulation for AF. **Methods:** We queried the Global Collaborative Network TriNetX- a de-identified database of healthcare organizations from four different countries. Patients with Child-Pugh class C cirrhosis and atrial fibrillation were divided into three cohorts; the first cohort included patients on DOACs (apixaban or rivaroxaban), second cohort included patients not on any anticoagulation, third cohort included patients on warfarin. Two well-matched cohorts were created using 1:1 propensity-scored matching model between cohorts. Three study arms were created after propensity matching. We compared the rates of intracranial hemorrhage, embolic stroke, gastrointestinal (GI) bleed, mortality, and transplant status. **Results:** A total of 16,029 patients met the inclusion criteria. Of those, 20.2% (n = 3,235) were on DOACs, 47.1% (n = 7,552) were not on any anticoagulation, and 32.7% (n = 5,242) were on warfarin. In the first study arm comparing patients on AC vs no AC, a statistically significant benefit was identified in terms of 3-year mortality risk (47% vs 71%, $p < 0.0001$) and the transplant status (17% vs 5%, $p < 0.0001$) among patients on AC.

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

However, no significant difference was identified regarding intracranial hemorrhage (3.1% vs 2.7%, $p = 0.19$) and GI bleeding risk 18.8% vs 19.5 %, $p = 0.3$). In the second arm we compared patients on DOACs vs no AC, there was again identified a mortality benefit (40% vs 72%, $p < 0.0001$) and a higher transplant rate (9% vs 3.2%, $p < 0.0001$) with DOACs. The rates of intracranial hemorrhage (6% vs 4%, $p = 0.03$) were higher in patients on DOACs compared to no AC. In the third arm we compared patients on DOAC's vs Warfarin, a statistically significant lower risk of intracranial hemorrhage (6.6% vs 8.7%, $p = 0.004$) and GI bleed (2% vs 2.4%, $p < 0.0001$) was identified in patients on DOACs with no difference in the mortality rate (42% vs 43.7%, $p = 0.2$) or the transplant status (8.3% vs 7.1%, $p = 0.9$) (Please see table). **Conclusion:** Anticoagulation is safe in patients with Child-Pugh class C cirrhosis with atrial fibrillation and may provide a mortality benefit. DOACs are a safer alternative to warfarin with a lower risk of intracranial hemorrhage and GI bleed. The higher rates of embolic stroke in patients on AC is likely a selection bias as patients with stroke are more likely to be placed on AC.

	AC	No AC	P value	DOAC	No AC	P value	DOAC	Warfarin	P value
Intracranial Hemorrhage	3%	2.7%	0.19	6.2%	4.9%	0.03	6.6%	8.7%	0.004
Embolic Stroke	0.9%	0.5%	0.03	1.1%	0.5%	0.009	1.2%	1.4%	0.63
GI bleed	18.8%	19.5%	0.3	19.4%	21.5%	0.065	2%	2.4%	0.0001
Mortality in 3 years	47.4%	71.2%	0.00001	40.1%	72.4%	0.00001	42%	43.7%	0.2

189 | HBV VIRUS-HOST CHIMERA DNA SERVES AS A PERSONALIZED CIRCULATING BIOMARKER FOR RESIDUAL TUMORS AFTER SURGICAL RESECTION OF HEPATOCELLULAR CARCINOMA

Gar-Yang Chau[1], Wei-Chen Lee[2], Ming-Chih Ho[3], Teng-Wei Chen[4], Rey-Heng Hu[3], Tsung-Han Wu[2], Hao-Jan Lei[1], Shu-Cheng Chou[1], Hsiu-Lung Fan[4], Ting-Jung Wu[2], Cheng-Maw Ho[3], Hong-Shiue Chou[2], Sheng-Tai Tzeng[5], Ya-Chun Wang[5], Shiou-Hwei Yeh[6] and Pei-Jer Chen[3], (1)Taipei Veterans General Hospital Department Surgery, (2)Linkou Chang Gung Memorial Hospital, (3)National Taiwan University Hospital, (4)Tri-Service General Hospital, (5)TCM Biotech International Corp., (6)College of Medicine, National Taiwan University

Background: Early recurrence of hepatocellular carcinoma (HCC) after surgical resection compromises patient survival. Timely detection of minimal residual tumor is helpful in recurrence monitoring and evaluating treatment strategies. This study examined the feasibility of virus-host chimera DNA (vh-DNA) generated from integration sites of hepatitis B virus (HBV) in the HCC chromosome as a personalized circulating biomarker for residual tumors after surgery. **Methods:** The tumor-specific vh-DNA integration sites were determined in 148 HBV-related HCC patients by capture-based next-generation sequencing (NGS). For each individual HCC, vh-DNA was quantified using a customized droplet digital PCR (ddPCR) assay in plasma samples collected pre-operation and within 14 months after surgery, and the results were compared with the clinical outcomes. **Results:** HBV integrations were identified in 132 out of 148 patients with HBV-related HCC (89.2%). The preoperative blood vh-DNA concentration was correlated with tumor size ($r = 0.73$, detection limit at 1.5 cm). Among the 113 patients who completed the postoperative follow-up, the positive predictive value (PPV) of vh-DNA for tumor recurrence was 71% (17/24), and the negative predictive value (NPV) was 92% (82/89). The smallest recurrent HCC with detectable circulating vh-DNA was 0.8 cm, and the average leading time of vh-DNA detection was 158 days earlier than computed tomography scanning. A total of 78% (18/23) of recurrences originated from the same HCC clones sharing the same vh-DNA, suggesting that most of the early recurrence came from residual tumor cells. Moreover, logistic regression analysis showed that vh-DNA was an independent risk factor for predicting early recurrence ($p < 0.0001$). When vh-DNA combined with the serum markers AFP and PIVKA-II, the sensitivity and specificity of recurrent HCC were 95.8% (23/24) and 95.5% (85/89), respectively. **Conclusion:** This study demonstrates that vh-DNA can serve as a personalized circulating tumor marker for HBV-related HCC patients. Utilizing vh-DNA to monitor the presence of residual tumors after surgery could be a promising solution for prognosis assessment, recurrence monitoring, and guiding adjuvant therapies in the future.

190 | MULTI-ANCESTRY WHOLE GENOME SEQUENCING (WGS) AND META-ANALYSIS TO IDENTIFY LOCI ASSOCIATED WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)★

Chinmay Raut[1], Yanhua Chen[1], Antonino Oliveri[1], Mary F Feitosa[2], Jeffrey R O'Connell[3], Kathleen A Ryan[3], Jerome I Rotter[4], Stephen S Rich[5], Kendra A Young[6], Aaron Hakim[7], Patricia A Peyser[1], Lawrence F Bielak[1], Michelle T Long[8,9], Ching-Ti Liu[10], Elizabeth K. Speliotes[11], Nicholette D Palmer[12] and NHLBI Trans-Omics for Precision Medicine (TOPMed) Consortium and the GOLD Consortium, (1)University of Michigan, (2)Washington University School of Medicine in St. Louis, (3)University of Maryland-Baltimore, (4)The Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, (5)University of Virginia, (6) University of Colorado Anschutz, (7)Brigham and Women's Hospital, Harvard Medical School, (8)Boston University School of Medicine, (9)Novo Nordisk a/S, (10)Boston University School of Public Health, (11) University of Michigan Medical School, (12)Wake Forest School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common cause of chronic liver disease in the US. Notably, disease prevalence differs greatly by race/ethnicity, with the highest prevalence in those of Hispanic and Asian ancestry, and the lowest prevalence in those of African ancestry. To date, studies have identified common variants associated with MASLD in predominantly European or American populations. We have conducted the largest-to-date multi-ancestry whole genome sequencing (WGS) association study to identify rare variants that promote MASLD in the NHLBI Trans-Omics for Precision Medicine (TOPMed) Consortium. **Methods:** Study- and ethnic/race-stratified association analyses were conducted in six cohorts with imaging-measured hepatic steatosis using SAIGEgds adjusted for age, sex, alcoholic drinks per week, and principal component estimates of admixture. Stratified results were meta-analyzed for Hispanic Ancestry, non-Hispanic European Ancestry, non-Hispanic African Ancestry, and non-Hispanic Chinese Ancestry individual's and for an overall analysis using a fixed-effects meta-analysis in METAL. Cochran's Q test and the I2 metric were used to identify and quantify heterogeneity. **Results:** The meta-analysis included 16,664 individual's with imaging-measured hepatic steatosis. Of these, 9,443 were of European Ancestry, 5,918 were of African Ancestry, 937 were of Hispanic Ancestry and 366 were of Chinese Ancestry. The ethnic/race-stratified meta-analysis identified six variants significantly associated ($p <= 5E-08$) with MASLD, i.e. European Ancestry (n = 2), African Ancestry (n = 4), including variants in/near PNPLA3, TM6SF2, PPP1R3B, LINC01684, and SLC2A1. An additional 15 variants trended toward association ($p <= 5E-07$) i.e. European Ancestry (n = 1), African Ancestry (n = 11), Hispanic Ancestry (n = 2), and Chinese Ancestry (n = 1) with MASLD. **Conclusion:** In a large, multiethnic analysis of imaging-measured hepatic steatosis, we replicated loci previously associated with MASLD and identified possible new race-specific loci. Several variants were trending toward association and will benefit from ongoing analyses to include 6,492 additional samples.

191 | NOVEL SERUM METABOLOMIC SIGNATURE OF PNPLA3 HOMOZYGOSITY IN HUMAN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Carolin Victoria Schneider[1], Yazhou Chen[1], Kai M. Schneider[2] and Rohit Loomba[3], (1)Rwth Aachen, (2) Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, University Hospital Rwth Aachen, Aachen, Germany, (3)University of California, San Diego, San Diego, CA

Background: The patatin-like phospholipase domain-containing protein 3 (PNPLA3) gene is strongly implicated in the development of metabolic dysfunction-associated steatohepatitis (MASH). Gene silencing approaches are being considered for treatment of MASH but there are limited blood-based biomarkers of PNPLA3 homozygosity. There's an unmet need to develop a serum-based biomarker panel that is specific for PNPLA3 homozygosity and could then be used to assess the pharmacodynamics response to PNPLA3 targeted therapies. **Methods:** We examined an extensive lipidomic and metabolomic dataset derived from the UK Biobank (Access number 71300). First, we selected the 4018 homozygous carriers of PNPLA3 rs738409_G. We then performed a 1:1 propensity score matching of non-carriers based on age, sex and BMI. Liver fat content was evaluated by proton density fat fraction on MRI in a subset of UKB participants (n = 323 homozygous and 347 non-carriers). The resulting dataset was split into an

85% training set and a 15% test set. After benchmarking, a random forest machine learning algorithm was chosen as the predictive model, **Results:** The mean liver fat content of PNPLA3 homozygotes versus non-carriers was 8.1% versus 4.3%. The PNPLA3 rs738409_G homozygotes exhibited a distinct metabolic profile compared to non-carriers (Figure 1). In the training cohort, a panel consisting of 9 metabolites and 1 routine hepatic screening parameter including saturated fatty acids to total fatty acids percentage, phospholipids to total lipids in IDL percentage, glutamine, glycine, phospholipids to total lipids in chylomicrons and extremely large VLDL percentage, average diameter for LDL particles, tyrosine, phospholipids to total lipids in very small VLDL percentage, cholesteryl esters to total lipids in small LDL percentage and alanine aminotransferase (ALT) was able to differentiate between PNPLA3 homozygotes versus non-carriers with an AUROC of .90 (95%CI: 0.89-0.90, p-value < 0.001), while ALT alone only received an AUROC of **.71** (95%CI: 0.71-0.71, p-value < 0.001). The results remained consistent in the validation cohort with a statistically significant AUROC of **.63** (95%CI: 0.63-0.63, p-value < 0.001). Among these top 9 differentially expressed metabolites, we examined which increased with liver fat content among participants with PNPLA3 homozygosity and observed that phospholipids to total lipids in IDL percentage, glutamine, average diameter for LDL particles and glycine decreased as the liver fat content increased, while all others increased. **Conclusion:** Here, we demonstrate a novel metabolomics signature of PNPLA3 homozygosity, and a set of metabolites that change with changes in liver fat content among those with PNPLA3 homozygosity. These data have major clinical implications in clinical drug development and companion diagnostics for PNPLA3 targeted therapies. Figure 1: Metabolic profile of PNPLA3 rs738409_G homozygotes compared to non-carriers.

192 | DYNAMIC EVOLUTION OF CIRCULATING TUMOR DNA IN PATIENTS WITH HEPATOCELLULAR CARCINOMA ACROSS TUMOR STAGES AND TREATMENTS

Claudia Campani[1,2], Sandrine Imbeaud[1], Marianne Ziol[1,3], Pierre Nahon[4,5], Sabrina Sidali[1,6], Alix Demory[1,7], Olivier Seror[8], Valerie Taly[9], Pierre Laurent-Puig[10], Nathalie Ganne-Carrié[1,7], Jessica Zucman-Rossi[4] and Jean-Charles Nault[1,7], (1)Cordeliers Research Center, Inserm 1138, "Functional Genomics of Solid Tumors" Lab, Paris, France, (2)Internal Medicine and Hepatology Unit, Department of Experimental and Clinical Medicine, University of Florence, (3)Anatomopathology Department, Avicenne Hospital, AP-HP, France, (4)Cordeliers Research Center, Functional Genomics of Solid Tumors Team, (5) Avicenne Hospital, Hepatology, (6)Beaujon Hospital, Hepatology, (7)Hepatology Department, Avicenne Hospital, AP-HP, France, (8)Avicenne Hospital, Interventional Radiology, (9)Centre De Recherche Des Cordeliers, Paris, France, (10)Department of Genomic Medicine of Tumours and Cancers, European Hospital George-Pompidou

Background: Circulating tumor DNA (ctDNA) is a promising non-invasive biomarker in cancer management. We aimed to assess the dynamic evolution of ctDNA in patients with hepatocellular carcinoma (HCC). **Methods:** A total of 832 plasmas collected in 173 patients with HCC and 56 patients with chronic liver diseases without HCC were studied. We evaluated the quantity of cell free DNA (cfDNA) and search for mutations in *TERT* promoter (*TERT*p.), *CTNNB1*, *TP53*, *PIK3CA* and *NFE2L2* by ultra-deep next generation sequencing and for *TERT*p. by digital droplet PCR. 250 tumor samples from the same patients were sequenced for 39 driver genes. **Results:** Among the 173 HCC patients, 82% were male (median age 63), 73% had cirrhosis. The etiologies of the underlying liver diseases were hepatitis B (28%), hepatitis C (42%), NAFLD (26%) and chronic alcohol intake (40%). Tumors were classified BCLC 0 (23%), BCLC A (44%), BCLC B (21%) and BCLC C (12%). Tumor sequencing identified mutations in *TERT*p. (71%), *TP53* (28%), *CTNNB1* (27%), *ATM* (15%), *ARID1A*(13%), *ARID2* (8%), *NFE2L2* (2%) and *PIK3CA* (2%). Among

the 776 plasmas of patients with HCC, 502 were collected in patients with an active HCC (aHCC), 158 24 hours after a locoregional treatment and 116 in patients with a past history of HCC but without active HCC at sampling (iHCC). Median cfDNA quantity was higher in aHCC than iHCC (0.27 vs 0.16 ng/μL, $p < 0.001$). Within the 502 plasmas of patients with an aHCC we identified the following mutations in 46% of them (24% patients had normal serum AFP): *TP53* (29%), *TERT*p. (27%), *CTNNB1* (13%), *PIK3CA* (0.4%) and *NFE2L2*(0.2%). CfDNA mutation rate increased across tumor stages (16% BCLC 0, 25% BCLC A, 42% BCLC B and 58% BCLC C; $p < 0.001$). The presence of mutations, particularly in the *TERT*p. and *TP53*, was associated with overall survival and recurrence/progression-free survival, both when considering all plasma samples and in the analysis of various treatment subgroups. Among 116 iHCC plasmas, 26 (22%) had mutations; in 21 cases mutations were concordant with those observed in a previous plasma sample or in a tumor from the same patient. Regarding plasmas obtained before and 24 hours after locoregional treatments an increase in cfDNA level (0.19 before vs 0.63 after, $p < 0.001$) and in mutation rate (31% vs 44%, $p < 0.001$) was observed at H24. Finally, a total of 179 plasmas in 50 patients with unresectable HCC treated by atezolizumab/bevacizumab were analyzed. Baseline cfDNA mutations were observed in 49% of cases; serum AFP was normal in 24% of these patients. Mutations in cfDNA observed at baseline disappeared in all patients with a radiological response at 12 weeks. In contrast, persistence of mutations under treatment was significantly associated with radiological progression ($p = 0.005$). **Conclusion**: Circulating tumor DNA offers dynamic information about tumor biology representing a non-invasive tool potentially useful to guide HCC clinical management.

193 | SINGLE-NUCLEI TARGETED DNA SEQUENCING REVEALS PATTERNS OF SELECTIVE CLONAL EVOLUTION DURING HEPATOCELLULAR CARCINOMA (HCC) PROGRESSION★

Josephine Zhang[1], Akanksha Suresh[1], Lea Lemaitre[1], Rachel Agoglia[2], Brittney Otero[2], Reshma Reguram[1], Vivek Charu[3], Brendan Visser[1], Andrew Bonham[1] and Renumathy Dhanasekaran[1], (1)Stanford University, (2) Mission Bio, (3)Stanford University School of Medicine

Background: Single-cell technologies address the critical issue of tumor heterogeneity in hepatocellular carcinoma (HCC), but face challenges such as complex cell isolation, need for fresh samples, and limited genomic coverage from low DNA content. To overcome these obstacles, we developed a robust workflow for single-nucleus DNA sequencing from frozen HCC tissue, utilizing a custom amplicon panel to elucidate genetic events in HCC clonal evolution. **Methods:** Under IRB approval, we collected eight paired frozen HCC tissue samples from the tumor core and edge of four treatment-naive patients. Enzymatic nuclei extraction generated single-nuclei droplet suspensions, followed by Tapestri platform barcoding, amplicon library creation, and Illumina sequencing (Fig 1A). We curated a consensus panel of HCC-specific genes from five public databases and designed 146 amplicons to target 204 mutations in 44 frequently mutated genes. Our analysis was augmented with bulk DNA sequencing data from six external studies comprising 1122 samples. **Results:** We isolated and genotyped 13,718 nuclei through single-nuclei targeted DNA sequencing, identifying 23 total single-nucleotide variants (SNVs), insertions, and deletions. *TP53, PIK3CA,* and *TRMT9B* were the most frequently mutated and 12 mutations (52%) occurred on chromosome 8. Using the variants identified in each patient, we compared the subclone architecture between the tumor core and edge. The dominant clone in the edge showed a 10.8-fold enrichment (SEM = 3.5) versus the core (Fig 1B). We also examined copy number variations (CNVs) relative to the least mutated clone in each sample and found 10 total CNVs in chromosomes 1, 4, 8, 13, 16, and 17. In five samples, there was a loss in chromosome 17 that corresponded to decreased ploidy of *TP53*. Chromosome 8 was frequently affected by copy number alterations, where *ZFHX4*, *XKR9*, and *ZFAT* were amplified while *ERI1*, *PDGFRL*, and *XPO7* were deleted. These genes are clustered on either chromosome arm, suggesting that partial chromosome deletion contributes to tumor progression (Fig 1C). Our workflow achieved comprehensive coverage of HCC-specific genetic events, as the alterations we identified were present in 50% of patients in the external HCC cohort (n = 1122) (Fig 1D). Moreover, patients with alterations in genes found in the tumor edge had significantly poorer survival rates (median 70.1 vs 83.6 mo, $p = 0.04$). **Conclusion:** In summary, we optimized a novel workflow that enabled in-depth study of intratumoral clonal evolution in HCC through targeted sequencing of 13,718 single nuclei isolated from frozen tissue. We revealed a higher frequency of genetic alterations in the tumor core than edge, indicating the selection of invasive subclones during tumor

progression. Our workflow overcomes the obstacles of traditional single-cell studies while achieving high-resolution insights that reflect true genetic alterations driving clonal evolution in HCC.

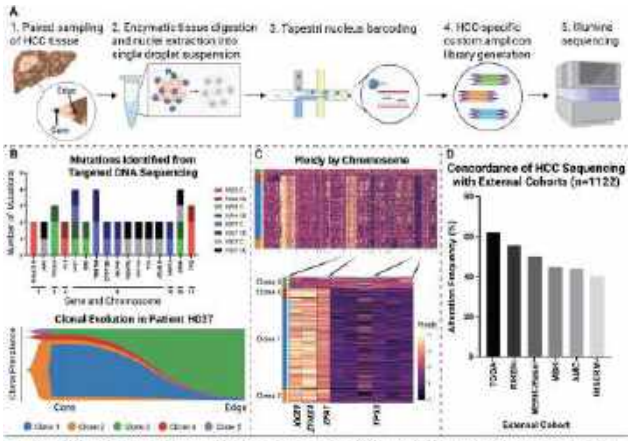

Figure 1. A) Study design: Paired sampling of tumor core and edge from HCC tissue followed by enzymatic tissue digestion and nuclei extraction, Tapestri barcoding, HCC-specific custom amplicon library generation, and Illumina sequencing. B) Mutations (SNVs and indels) were identified in 16 genes and were most prevalent in chromosome 8. Across patients, we observed selection of an invasive clone in the edge, as seen in the representative patient H037. C) CNVs were observed across the genome, primarily as copy number losses. In 5 of 9 samples, there was a copy number loss of *TP53*. Copy number alterations were also prevalent in genes on chromosome 8, including *XKR9*, *ZFHX4*, and *ZHX1*. D) We validated the concordance of our sequencing results with six public bulk sequencing databases and found that 50% of patients in the external cohorts had at least one genetic alteration identified in edge samples.

194 | TARGETED THERAPY ADAPTED TO TUMOR BIOLOGY IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA OR HEPATOCHOLANGIOCARCINOMA REFRACTORY TO ATEZOLIZUMAB/BEVACIZUMAB

Wendy Limousin[1], Pierre Laurent-Puig[2,3,4], Marianne Ziol[1,5,6], Nathalie Ganne-Carrié[1,7], Pierre Nahon[1,7], Amal Ait-Omar[8], Olivier Seror[1,9], Sabrina Sidali[10], Claudia Campani[1,11], Pierre Blanc[12], Alban Lermine[12], Laetitia Marisa[12], Jessica Zucman-Rossi[1] and Jean-Charles Nault[1,7], (1)Cordeliers Research Center, Functional Genomics of Solid Tumors Team, (2) Cordeliers Research Center, Inserm, Cnrs Snc 5096, (3)Medical Biology Laboratory Seqoia, (4)Department of Genomic Medicine of Tumours and Cancers, European Hospital George-Pompidou, (5)Avicenne Hospital, Pathology, (6)Avicenne Hospital, Centre De Ressources Biologiques, (7)Avicenne Hospital, Hepatology, (8)Avicenne Hospital, Gastroenterology, (9) Avicenne Hospital, Interventional Radiology, (10) Beaujon Hospital, Hepatology, (11)University of Florence, Italy, (12)Medical Biology Labratory Seqoia

Background: The "French Medicine Genomic program 2025" is an academic research program that allows to perform whole-genome/exome/RNA sequencing in advanced cancer refractory to systemic treatments to give access to off-labeled therapies adapted to genomic alterations in clinical practice. We reported results in intermediate and advanced hepatocellular carcinoma (HCC) and hepato-cholangiocarcinoma (H-CCK). **Methods:** In one center, all patients with HCC or H-CCK who progressed under or did not respond to Atezolizumab/Bevacizumab with available tumor frozen samples benefited from whole-genome/exome and RNA sequencing. Targeted therapies were matched to the genomic alterations following recommendation of a molecular tumor board. Subsequent radiological response and overall survival were assessed. **Results:** Between September 2020 and January 2023, among 135 patients with primary liver cancer treated by Atezolizumab/Bevacizumab, twenty patients benefited from genomic analysis after progression (16 HCC; 4 H-CCK). 19 patients had analyzable data, 70% were male, median age was 57 years, 65% had metastatic disease and 45% had vascular invasion. The main driver genes altered in these 19 HCC/HCC-K were *TP53* (47%), *RB1* (37%), *TERT* promoter (32%), *PTEN* (21%), *CCND1/FGF19* amplification (21%), *CTNNB1* (16%), *ARID1A* (16%), *PIK3CA* (16%), *ALB* (16%), *CDKN2A* (11%) and *TSC1* (11%). Mutational signatures of exposure to aflatoxin B1 were identified in 5 patients and of aristolochic acid in1 patient. A high homologous recombination score (defined by a score > 42) in 1 patient. One constitutional variant in *TMEM127* predisposing to pheochromocytoma triggered family screening Among these 19 patients, 14 patients (76%) harbored at least one actionable genomic alteration among whom 9/14 received an adapted targeted therapy (45%). One patient with H-CCK showing *CDK4* amplification was treated by Palbociclib, he experienced a partial radiological response during 16 months. Another patient with H-CCK and high *HER2* overexpression and a high homologous recombination score was treated by Trastuzumab/Olaparib with had a stable disease at the first imaging evaluation. One patient with an HCC and biallelic inactivation of *TSC2* silencing its gene expression, harbored a complete radiological response under Everolimus. The remaining six treated patients (6 HCC) harbored a progressive disease including three patients treated by Trametinib, two by Everolimus and one by Olaparib. **Conclusion:** Molecular based guided therapy is feasible in patients with HCC and H-CCK and progressing under atezolizumab/bevacizumab. Forty-

195 | LONG-TERM IMPROVEMENTS IN LIVER AND LIPID OUTCOMES IN ADULTS AND CHILDREN WITH ACID SPHINGOMYELINASE DEFICIENCY TREATED WITH OLIPUDASE ALFA ENZYME REPLACEMENT THERAPY

Beth Linda Thurberg[1], Jaya Ganesh[2], Roberto Guigliani[3], Nathalie Guffon[4], Robin Lachmann[5], Eugen Mengel[6], Maurizio Scarpa[7], Melissa P Wasserstein[8], Mario Aguiar[9], Nicole Armstrong[9] and Monica Kumar[9], (1)Beth Thurberg Orphan Science Consulting, LLC, (2) Mount Sinai School of Medicine, (3)Ufrgs, HCPA, Inagemp, DASA and Casa Dos Raros, (4)Centre De Référence Des Maladies Héréditaires Du Métabolisme, Hôpital Femme Mère Enfant- Hospices Civils De Lyon, (5)Charles Dent Metabolic Unit, National Hospital for Neurology and Neurosurgery, (6)Sphincs Gmbh, Institute of Clinical Science for Lysosomal Storage, (7) Regional Coordinator Centre for Rare Diseases, University Hospital of Udine, (8)Children's Hospital at Montefiore, Albert Einstein College of Medicine, (9) Sanofi

Background: Acid sphingomyelinase deficiency (ASMD) is a progressive, multisystemic, and debilitating lysosomal storage disease. Sphingomyelin accumulation in liver, lungs, and other tissues leads to hepatosplenomegaly, pulmonary disease, liver dysfunction, and dyslipidemia in most patients. Liver disease is a primary cause of death. Olipudase alfa, IV recombinant human ASM (Sanofi), is approved in > 35 countries for non-CNS manifestations of ASMD in adults and children. **Methods:** We report liver and lipid values at baseline and after 2Y of olipudase alfa treatment in ongoing clinical trials and extensions (NCT02004691, NCT02292654 NCT02004704, NCT01722526): ASCEND (35 adults); ASCEND-Peds (20 children); Phase 1b (5 adults, for whom 6.5Y data are also available). We also report Spearman correlations between baseline liver volume and percent liver tissue area occupied by sphingomyelin in all adult patients (Phase 1b and ASCEND). **Results:** Table 1 shows values at baseline and after 1, 2, and 6.5 years of treatment. Liver biopsy data showed ~30% tissue area occupied by sphingomyelin at baseline, with ~90% clearance after 0.5-1Y of olipudase alfa. Percent liver tissue area occupied by sphingomyelin correlated with liver volume in multiples of normal ($r = 0.48$, $p = 0.0017$). Mean baseline plasma lyso-sphingomyelin was > 40x normal in all three cohorts, with 6mo decreases of ɛ 65% sustained over time. At baseline, most patients had hepatomegaly, low HDL cholesterol, high LDL cholesterol, and high triglycerides; approximately half had elevated liver transaminases. After 2Y of treatment, liver volumes in most patients were d 1.25 multiples of normal (mean reductions: 30% in ASCEND, 49% in ASCEND-Peds, 30% reduction in Phase 1b with 44% reduction after 6.5Y) and mean HDL cholesterol had increased 65% in ASCEND, 137% in ASCEND-Peds, and 115% in Phase 1b (171% increase at 6.5Y). Mean LDL cholesterol, triglycerides, and liver transaminases decreased in all cohorts within 1Y to normal/near-normal values and were maintained over time. Spleen volume, respiratory function, disease biomarkers, and in children, height Z-scores, also improved with olipudase alfa treatment. Olipudase alfa was generally safe and well tolerated; most adverse events (AEs) were mild or moderate with no trial withdrawals due to drug-related AEs. **Conclusion:** Olipudase alfa treatment resulted in sustained improvements or normalization in liver and lipid parameters in adults and children with ASMD.

Table 1. Liver and lipid values in clinical trials of olipudase alfa

	Time on olipudase alfa	Phase 1b/LTS (5 adults)	ASCEND (35 adults)	ASCEND-Peds (20 children)

196 | SERUM Z POLYMER LEVELS AND FACTORS AFFECTING INCREASED LIVER FIBROSIS ARE ASSOCIATED WITH FUTURE SEVERE LIVER DISEASE OUTCOMES IN A PROSPECTIVE COHORT OF ADULTS WITH ALPHA-1-ANTITRYPSIN DEFICIENCY★

Anandini Suri[1], Zidong Zhang[1], Brent Neuschwander-Tetri[1], Rohit Loomba[2], David A. Brenner[3], Andrew Wilson[4], Danielle Carpenter[1], Rosemary Negy[1] and Jeff Teckman[1], (1)Saint Louis University, (2)University of California, San Diego, San Diego, CA, (3)Sanford Burnham Prebys Medical Discovery Institute, (4)Boston University

Background: Outcomes of adults with ZZ alpha-1-antitrypsin deficiency (AATD) liver disease is variable and unpredictable. There is a lack of prospective data,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

including on the utility of liver biopsy. Hypothesis: Prospective clinical and biopsy data will identify factors associated with severe liver disease outcomes in AATD. Objective: Use data from a prospective, multi-center adult cohort of AATD ZZ subjects with protocol enrollment liver biopsies to identify the prognostic value of clinical markers and biopsy for the development of severe liver disease outcomes. **Methods:** Homozygous ZZ AATD adults enrolled prospectively at 3 US sites with standardized clinical evaluations, followed annually with standardized data collection and outcomes recorded. Liver biopsy obtained at enrollment, unless previous biopsy confirmed cirrhosis (grouped as Ishak >4). Fibrosis scored using Ishak score (stage 0 – stage 6). Minimal fibrosis defined as Ishak 0-1, increased fibrosis as Ishak $\geq$ 2. Severe liver disease outcomes defined as death related to liver disease, liver transplantation or listing. **Results:** 96 subjects enrolled; 51% had increased fibrosis at enrollment (49% Ishak 0-1, 36% Ishak 2-3, and 15% cirrhotic at enrollment). 62% had normal FEV1 ($>80\%$ predicted), 37% on AAT protein replacement. Serum Z polymer levels were associated with increased fibrosis. Mean serum Z polymer levels increased with the degree of fibrosis (9.7 $\pm$6.8 Ishak 0-1, vs 12.1 $\pm$ 4.3 Ishak 2-3, vs 16.1 $\pm$ 8.1 for Ishak $\geq$ 4 ; $p=0.0194$). Mean BMI and prevalence of obesity increased with degree of fibrosis (Table 1).Clinical signs of advanced liver disease, and relevant elevations in ALT, AST, and GGT were evident with cirrhosis only. 8 severe liver disease related outcomes were reported in median 3.8 years of follow up; 3 liver disease related deaths, 3 liver transplants and 2 on transplant waiting list. All those with significant events had increased fibrosis on enrollment biopsy (100% with severe outcome, vs 46.9% without severe outcome, $p<0.001$). Increased BMI and obesity were associated with increased fibrosis and liver related events. Serum Z polymer levels were higher in those with future adverse events (18.2 $\pm$ 9.2 vs 11 $\pm$ 6.3; $p=0.011$). Low APRI score (<0.5) and FIB –4 score (<1.3) had a NPV of 98% in predicting future severe liver disease related events. Elastography scores, FEV1, smoking and alcohol consumption patterns were not associated with significant fibrosis or adverse liver outcomes. **Conclusion:** Significant fibrosis is prevalent in adults with ZZ AATD. Clinical signs of liver disease and elevations of liver enzymes are often delayed until cirrhosis develops. Serum Z polymer levels could be a biomarker to detect fibrosis early and predict outcomes. High BMI and obesity are associated with increased fibrosis and adverse liver disease outcomes. Increased fibrosis at enrollment biopsy is a strong predictor of future severe liver disease outcomes in this cohort.

Table 1 : Factors affecting fibrosis on liver biopsy in adults with ZZ alpha 1 antitrypsin liver disease

Parameter	Overall (N=96)	Ishak Score 0-1 (N=47)	Ishak Score 2-3 (N=29)	Ishak Score ≥4 or Known severe (N=20)	p value

197 | ARBM-101 AS A SAFE AND POTENT THERAPEUTIC OPTION FOR WILSON DISEASE

Eun-Jung Kim[1], Dasol Kim[1], Banu Akdogan[2], Noreene M Shibata[3], Judith Sailer[4], Adriana Fontes[2], Dongsik Park[1], Hongjae Lee[1], Chunwon Jung[1], Byongkeol Min[1], Eok Park[1], TaeWon Kim[1], Seoyoung Choi[1], Alan DiSpirito[5], Bernhard Michalke[2], Weonbin Im[1], So-Young Eun[1], Hans Zischka[2] and Valentina Medici[3], (1) Arbormed Co., Ltd., (2)Helmholtz Center Munich, German Research Center for Environmental Health, (3) University of California Davis, Sacramento, CA, (4) Technical University of Munich, School of Medicine, (5) Iowa State University

Background: Wilson disease (WD) is a rare genetic disorder that can progress to either acute or chronic liver diseases due to excess copper accumulation in the liver derived from disruptive mutations affecting the

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ATP7B gene with consequent copper metabolism and trafficking disturbances. In current clinical practice, reduction of excess liver copper and amelioration of the subsequent liver pathology by the approved copper chelators is often inadequate. Our recent reports showed the potential of ARBM-101 as a drug candidate that promptly removes excess copper by increasing its fecal excretion through the bile in a WD rat model of severe (acute) liver damage. Here, we extend our studies on the effects of ARBM-101 to a mouse model of chronic liver damage due to spontaneous hepatic copper accumulation. Moreover, we present our evaluation of the ARBM-101 *in vitro* safety profile and further understanding of its mode of action have strengthened its therapeutic potential. **Methods:** To test whether ARBM-101 can protect mice from developing advanced liver damage, a genetic mouse model of WD, the *Atp7b*$^{-/-}$mouse, was treated i.p. every other day for two weeks followed by maintenance injections every two weeks over 3 months. To test whether ARBM-101 protects animals from acute liver failure and death, LPP rats were treated with ARBM-101 at different disease stages, using several parameters including body weight loss and elevation of liver enzymes to determine disease severity. *In vitro* inhibitor assays were performed to understand entry/exit mechanisms of ARBM-101 in HepG2 cells in the presence or absence of copper. Ceruloplasmin activity assays were also performed using human serum samples. **Results:** Similar to WD rats, the *Atp7b*$^{-/-}$ mice treated with ARBM-101 showed a pattern of predominant fecal copper excretion with improved parameters of liver damage. Further, we report the rescue of male WD rats, from severe disease stages by ARBM-101, showing normalization of liver enzymes and stabilization of body weight. Ceruloplasmin activity in human sera was not significantly affected by addition of excess ARBM-101 *in vitro*. Potential mechanisms of ARBM-101-mediated copper excretion have been unraveled with involved transporters, including MRP2, as organic anion transporters. **Conclusion:** Our data highlight the excellent therapeutic potential and safety profile of ARBM-101 for acute and chronic liver diseases in WD.

198 | EVALUATION OF NON-CERULOPLASMIN COPPER BY PROTEIN SPECIATION (NCC-SP) AND 24-HOUR URINARY COPPER EXCRETION (UCE) FOR MONITORING CHELATOR TREATMENT IN PATIENTS WITH WILSON DISEASE.

Peter Ott[1], Thomas Damgaard Sandahl[1], Omar F Kamlin[2], Michael L. Schilsky[3] and On Behalf of The CHELATE Trial Investigators, (1)Aarhus University, (2) Orphalan, (3)Yale University

Background: NCC and UCE are recommended for treatment monitoring in Wilson Disease (WD)(1). NCC is assumed to reflect the bioavailable copper (Cu) in plasma and is in equilibrium with the pool of stored Cu. UCE reflects body stores of Cu and is also influenced by the cupriuretic effect of therapy. Current methods to estimate NCC are flawed. The novel assay, NCC-Sp, is an accurate and reproducible method for NCC determination, and therefore was used as the primary endpoint in the CHELATE trial (NCT03539952, sponsor, Orphalan, France) (2). Our aim was to compare NCC-Sp and UCE in the study population. **Methods:** We performed a secondary analysis on measurements from all specimens from 53 adults with stable WD on d-penicillamine (DPA). Samples were collected for NCC every 4 weeks after screening until the primary endpoint (24w post-randomization) and end of the extension period (48w). UCE was collected at -12w, -8w, -4w, randomization (0w), 4w, 24w and 48w. After a 12-week run-in period, patients were randomized to continue DPA (N = 27) or switched to trientine tetrahydrochloride (TETA4; N = 26) mg-for-mg and followed for 24 weeks. Cu was measured by ICP mass spectrometry. NCC-Sp is the total serum Cu minus ceruloplasmin-Cu as separated by anion exchange chromatography (2). **Results:** Data from 496 NCC-Sp and 296 UCE measurements were analyzed. A large fraction of NCC-Sp (27%) and UCE (58%) values (Figure) were outside recommended target ranges for stable patients (1). Following randomization NCC-Sp declined from 84.4 ± 22.3 to 53.4 ± 18.3 μg/L in the DPA arm and from 67.0 ± 33.1 to $57\text{-}6 \pm 29.8$ μg/L in the TETA4 arm, likely due to further de-coppering, but without correlation between UCE and change in NCC-Sp. UCE and NCC-Sp were weakly correlated, but the correlation was statistically significant (DPA arm: $r^2 = 0.04$, $p = 0.001$; TETA4: $r^2 = 0.12$, $p = 0.0001$). UCE did not correlate with dose (mg/kg) overall; however, UCE/mg dose was higher with DPA (mean ± SD 0.66 ± 0.35 μg/24H/mg dose) compared with TETA4 (0.33 ± 0.18; $p < 0.001$). Following randomization there was no correlation with either NCC-Sp or change in NCC-Sp to dose prescribed. NCC-Sp and not UCE correlated positively to

AST (Figure). The relationship to ALT was similar but weaker (UCE: DPA $r^2 = 0.008$, NS; TETA4 $r^2 = 0.17$, $p = 0.04$. NCC-Sp: DPA: $r^2 = 0.017$, $p = 0.04$; TETA4 $r^2 = 0.023$, $p = 0.02$). **Conclusion:** Though different cupriuretic effects of TETA4 and DPA were observed in the study, a similar overall effect on NCC-Sp indicated copper balance was maintained. NCC-Sp but not UCE correlated with ALT and AST, suggesting its greater utility for monitoring chelator therapy. The large fraction of treated patients outside recommended target ranges for UCE and NCC suggests re-evaluation of target ranges is necessary including correlation with clinical and biochemical outcomes. 1. Schilsky ML et al. Hepatology 2022. 2. Schilsky ML et al. Lancet Gastroenterol Hepatol 2022.

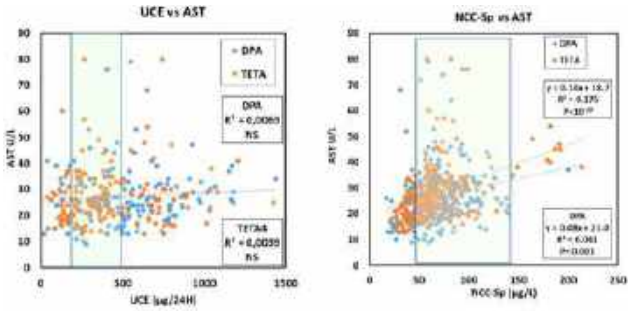

Figure. Panel A: UCE versus ASL. Panel B. NCC-Sp versus AST. In both panels, the currenly recommended (1) ranges for UCE and NCC are marked in shaded green.

199 | DECREASED PREGNANE X RECEPTOR (PXR) EXPRESSION PROMOTES LIVER NODULE DEVELOPMENT IN Atp7b-/- MICE

Clavia R. Wooton-Kee, Baylor College of Medicine, Houston, TX, Hari Yalamanchili, Baylor College of Medicine and David D. Moore, University of California, Berkeley

Background: Wilson's disease (WD) is an autosomal recessive disorder caused by inactivating mutations in the copper (Cu^{++}) transporting P-type ATPase. Loss of Atp7b function prevents translocation of Cu^{++} into the trans-Golgi network and excretion into bile. Cu^{++} exposure results in oxidative stress, inflammation, and mitochondrial dysfunction and fibrosis, cirrhosis, and liver failure. WD patients and *Atp7b*$^{-/-}$ mice have a progressive course of hepatocellular pathology, which includes regenerative hepatic nodule growth. An abundance of pregnane X receptor (PXR) response elements were recently identified in down-regulated gene sets identified by microarray analysis in pre-symptomatic *Atp7b*$^{-/-}$ mice, suggesting a link between xenobiotic and metabolic pathways in WD. Further, PXR mRNA expression was decreased in *Atp7b*$^{-/-}$ mice. We tested the hypothesis that decreased PXR activity exacerbates the progressive hepatic pathology in *Atp7b*$^{-/-}$ mice. **Methods:** H&E, Ki-67, and CK-19 staining was performed on liver sections of *Atp7b*$^{-/-}$, DKO$^{Atp7b/PXR}$, and

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

wild-type mice. RNA-Sequencing analysis was performed with 3-, 6-, and 12-month-old liver tissues from *Atp7b*$^{-/-}$, DKO$^{Atp7b/PXR}$, and wild-type mice. **Results:** Hepatocellular pathology and liver nodule development was more advanced in DKO$^{7b:PXR}$ mice vs. *Atp7b*$^{-/-}$ mice. At 12 months of age DKO$^{Atp7b:PXR}$ and *Atp7b*$^{-/-}$ livers displayed prominent histologic abnormalities including mild microsteatosis, hepatocellular ballooning, apoptosis, and mild lobular inflammation. H&E staining revealed clear demarcation between nodules and normal tissue. Nodules of *Atp7b*$^{-/-}$ mice displayed more Ki-67 staining than the adjacent normal tissue (Ki-67 index 5.5% normal tissue vs. 28% nodule). Ki-67 staining in nodules of DKO$^{Atp7b:PXR}$ livers was less than *Atp7b*$^{-/-}$ mice, which is suggestive of dynamic molecular shifts to limit further cell proliferation. Normal tissue areas in the *Atp7b*$^{-/-}$ and DKO$^{Atp7b:PXR}$ livers displayed increased and diffuse glutamine synthetase (GS) staining, which is characteristic of hepatocellular stress; however, normalized GS staining around the central vein was displayed in adjacent nodular sections. *Atp7b*$^{-/-}$ and DKO$^{Atp7b:PXR}$ livers displayed increased CK-19 staining and ductular reaction with bile duct proliferation and inflammation. Chemical Carcinogenesis, Metabolic, PPAR Signaling, and Cell Signaling pathways were enriched in 3-, 6-, and 12-month-old *Atp7b*$^{-/-}$ mice. We found unique and abundant enrichment of pathways related to protein metabolism and cytoskeleton regulation in DKO$^{Atp7b:PXR}$ relative with *Atp7b*$^{-/-}$ mice. Pathway analysis of nodules revealed an abundance of immune function and cell adhesion pathways in nodules of DKO$^{Atp7b:PXR}$ relative to nodules of *Atp7b*$^{-/-}$ mice. **Conclusion:** Impaired PXR activity increases copper-induced hepatocellular pathology. These findings reveal a new target in the development of hepatic pathology in WD.

200 | METABOLIC SYNDROME ASSOCIATED FATTY LIVER DISEASE IS A SIGNIFICANT RISK FACTOR FOR THE DEVELOPMENT OF HEPATIC EVENTS IN ALPHA-1-ANTITRYPSIN PI*ZZ INDIVIDUALS

Aron Zachary Evans[1], Sameer Prakash[1] and Arvind R. Murali[1,2], (1)University of Iowa Hospitals and Clinics, (2) Orlando Health

Background: Patients with Alpha-1-antitrypsin Pi*ZZ homozygotes are at risk for developing liver cirrhosis and hepatocellular carcinoma. However, there is a high degree of variability in the clinical manifestations of patients with A1AT Pi*ZZ suggesting that genetic and environmental disease modifiers play an important role in the disease process. The prevalence of nonalcoholic fatty liver disease (NAFLD) has been rising worldwide. We aimed to determine the impact of NAFLD in the development of hepatic events in patients with A1AT Pi*ZZ homozygotes. **Methods:** All patients with A1AT Pi*ZZ homozygous state seen at a large tertiary care academic institution were identified using the data pooling technique by the information and technology department at University of Iowa Hospitals and Clinics. Patients with NAFLD were identified using ICD codes. Clinical and demographic data as well as hepatic events (ascites, hepatic encephalopathy, esophageal varices, or hepatocellular carcinoma), if any, were also extracted. Logistic regression analysis was performed to determine the impact of NAFLD in the development of hepatic events in patients with A1AT ZZ. Odds ratio (OR) with 95% confidence intervals were calculated. **Results:** We identified 53 patients with A1AT ZZ phenotype, 29 (55%) were males. Twenty (38%) of the 53 A1AT ZZ patients had a diagnosis of NAFLD. Of the 53 patients, 14 (26%) developed hepatic events. Eleven (55%) of the 20 patients with A1ATD and NAFLD developed hepatic events, while only 3 (9%) of the 33 patients with A1ATD and without NAFLD developed hepatic events ($p < 0.001$). On logistic regression analysis, NAFLD was significantly associated with the development of hepatic events in patients with A1AT Pi*ZZ, unadjusted OR 12.2 (CI: 2.78-53.6), $p < 0.001$). When adjusted for age, sex, and BMI, NAFLD remained a significant risk factor for the development of hepatic events in patients with Pi*ZZ with an adjusted OR 15.2, (CI: 2.5-94.4), $p = 0.003$. **Conclusion:** A1AT ZZ homozygous individual's who also develop NAFLD have a higher risk for the development of hepatic events as compared to those who do not have NAFLD. A1AT ZZ patients should thus be screened for the presence of fatty liver disease and aggressive control of metabolic risk factors should be initiated. A1AT ZZ patients should be strongly advised to avoid weight gain and follow a healthy lifestyle as early in life as possible. Larger studies are needed to confirm our findings.

Table 1: Predictors of development of hepatic events in patients with A1AT ZZ phenotype

Variable	Odds Ratio	95% Confidence Interval		P value
NAFLD	15.2	2.46	94.4	0.003
Sex	0.73	0.13	3.96	0.715
Age	1.02	0.98	1.06	0.380
BMI	1.03	0.93	1.15	0.529

201 | THREE-DIMENSIONAL MR ELASTOGRAPHY IDENTIFIES PORTAL HYPERTENSION IN CIRRHOSIS: A PROSPECTIVE MULTICENTER STUDY

Zhiying Wang[1], Yu Shi[1], He Zhu[2], Meng Niu[3], Zhenghan Yang[4], Shenghong Ju[5] and Xiaolong Qi[6], (1) Shengjing Hospital of China Medical University, (2)The Sixth People's Hospital of Shenyang, (3)The First Affiliated Hospital of China Medical University, (4) Capital Medical University Affiliated Beijing Friendship Hospital, (5)Jiangsu Key Laboratory of Molecular and Functional Imaging, (6)Zhongda Hospital, Medical School, Southeast University, Nanjing, Jiangsu, China, Lanzhou, China

Background: To develop a non-invasive multivariate models based on Three-dimensional MR elastography (3D-MRE) to determine portal hypertension (PH), particularly to diagnose clinically significant portal hypertension (CSPH, HVPG > 10mmHg) and severe portal hypertension (SPH, HVPG > 12mmHg), using HVPG as the gold standard. **Methods:** This prospective, multicenter study enrolled patients with cirrhosis scheduled for HVPG, and who intended to undergo MR imaging (including 3D-MRE and diffusion-, T1-, and T2-weighted imaging) before the HVPG procedure. A total of 57 patients were recruited from five institutions. Multiple viscoelastic parameters of the liver and spleen, as well as shear stiffness (SS) ratios and subtraction values, were evaluated independently by two radiologists. Univariable and multivariable linear regression analyses were conducted to assess the associations between mechanical parameters and HVPG. Univariable and multivariable logistic regression analyses were used to predict CSPH and SPH, respectively. **Results:** HVPG showed the strongest positive correlation with splenic SS at 60Hz ($r = 0.785$; $p < 0.001$), followed by hepatic SS at 30Hz ($r = 0.631$; $p < 0.001$), splenic SS at 30Hz ($r = 0.612$; $p < 0.001$), hepatic SS at 60Hz ($r = 0.547$; $p < 0.001$). Multivariable linear regression analysis showed splenic SS at 60Hz ($\beta = 1.017$; 95% CI: 0.71, 1.325; $p < 0.001$), liver SS ratio ($\beta = -2.359$; 95% CI: -4.477, -0.241; $p = 0.03$), and liver stiffness difference ($\beta = 1.169$; 95% CI:0.251,2.087; $p = 0.001$) was the independent factors determining HVPG. Approximately 56.5% of the total variability in HVPG was explained by these 3 variables (adjusted $R^2 = 0.565$). Logistic regression analysis showed splenic SS at 60Hz (OR = 2.217 [95% CI:1.292, 3.803]; $p = 0.004$) and liver SS at 30Hz (OR = 6.211 [95% CI: 1.218, 31.669]; $p = 0.028$) were independently associated with CSPH, establishing a model with excellent performance in diagnosing CSPH(area under the receiver operating characteristic curve [AUC], 0.975 [95% CI: 0.79, 0.99]). As for SPH, it showed splenic SS at 60Hz (OR = 1.65 [95% CI:1.25,2.16]; $p = 0.001$) were independently associated with HVPG, also with better performance (AUC, 0.969 [95% CI: 0.81, 0.98]). **Conclusion:** 3D-MRE with dual frequencies is a very promising method in both predicting HVPG and diagnosing the presence CSPH and SPH. Splenic stiffness at 60Hz, combining liver stiffness ratio (60Hz/30Hz) and differences (60Hz-30Hz), was the independent parameters associating HVPG.

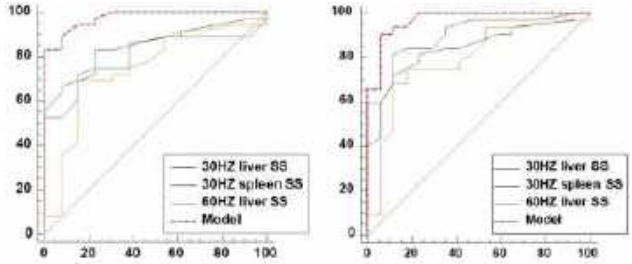

Figure 1 (A-B) ROC analysis for diagnosing clinically significant portal hypertension (A) and severe portal hypertension (B)

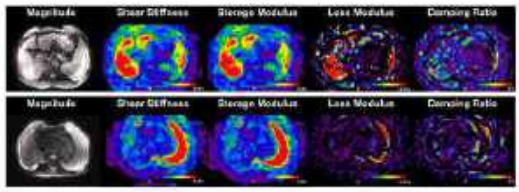

Figure 2 (A-B) Representative Magnetic Resonance Elastography (MRE) images at 60Hz for two patients. The top row shows MRE images for a patient with hepatic shear stiffness of 6.5 kPa and splenic shear stiffness of 6.1 kPa, with a HVPG measurement of 11 mmHg. The bottom row shows MRE images for a patient with hepatic shear stiffness of 3.5 kPa (mildly elevated) and splenic shear stiffness of 12.6 kPa, with a HVPG measurement of 18 mmHg. The HVPG result is more strongly correlated with the splenic shear stiffness than that of the liver stiffness.

Background: Non-invasive diagnostic tools for clinically significant portal hypertension (CSPH) have been developed in the ANTICIPATE study/subsequent work (liver stiffness measurement (LSM) and platelet count (PLT) ± BMI) and endorsed by the Baveno VII consensus. A dedicated 100Hz probe for spleen stiffness measurement (SSM) substantially increased its clinical applicability, but limited data exists on the diagnostic performance of SSM (100Hz) for CSPH as well as its ability to improve the ANTICIPATE ± NASH models. **Methods:** Twelve specialized, high-volume European centers contributed data from prospectively characterized compensated advanced chronic liver disease (cACLD, defined by LSM ≥ 10kPa or F3/4 fibrosis) patients who underwent paired assessment of the hepatic venous pressure gradient (HVPG), LSM, and SSM from 2021-2023. The goal was to refine the non-invasive diagnosis of CSPH by adding SSM to LSM/PLT ± BMI, and to compare the algorithm's diagnostic performance to the ANTICIPATE ± NASH models. In line with previous work, the analysis was restricted to patients with Child-Turcotte-Pugh A stage disease. All area under the receiver operating characteristics curve (AUC) analyses were derived from bootstrapping (n = 2000). **Results:** Overall, 244 cACLD patients were included. Most had NAFLD (40.2%) or ALD (36.1%), followed by viral (14.8%) and other (8.9%) etiologies. The median BMI was 28.9 (IQR: 24.8; 33.6) kg/m^2, and 43.0% were obese (BMI ≥ 30). The median HVPG was 11 (8; 15) mmHg (CSPH prevalence: 64.8%), and the median LSM, SSM and PLT were 22.5 (14.8; 33.2)kPa, 45.6 (33.0; 66.5)kPa, and 129 (92; 183)G/L, respectively. SSM and LSM yielded a comparable AUC for CSPH (SSM: 0.778, LSM: 0.755, DeLong-test: $p = 0.546$). In logistic regression analysis, SSM, LSM, PLT and obesity (BMI ≥ 30) were independently associated with CSPH. The combined model had an AUC for CSPH diagnosis of 0.864. Notably, its diagnostic performance was superior to the ANTICIPATE ± NASH model (AUC: 0.814, DeLong test: $p = 0.008$). A nomogram was developed to facilitate point-of-care risk stratification (Figure). Results were confirmed by cross-validation after randomly splitting the data into a 1:1 train/test cohort matched by CSPH prevalence (data not shown) **Conclusion:** SSM by the novel, dedicated 100Hz module improves the non-invasive diagnosis of CSPH vs. established tools, which tend to be slightly less accurate in the context of contemporary (predominantly NAFLD/ALD) cohorts.

203 | PLACEMENT OF A TRANS-JUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT (TIPS) MODIFIES THE EXPRESSION OF PROINFLAMMATORY CYTOKINES IN CIRCULATING MONOCYTES EXPOSED TO LIPOPOLYSACCARIDE

Mirella Pastore, Francesco Vizzutti, Nadia Navari, Davide Roccarina, Martina Rosi, Valentina Adotti and Fabio Marra, University of Florence

Background: Recent data have indicated that decompensated cirrhosis is characterized by an imbalance in the innate immune system, leading to low-grade systemic inflammation. In particular, inflammatory cytokines secreted by monocytes and macrophages have been implicated in the pathogenesis of portal hypertension and its complications. Additionally, MerTK-expressing monocytes participate in the determination of severity of acute liver failure. Trans-jugular intrahepatic portosystemic shunt (TIPS) is currently used for the treatment of complications of portal hypertension, but whether portosystemic derivation results in changes in the biology of inflammatory cell is currently unknown. **Methods:** Fifteen patients with severe portal hypertension referred for TIPS placement were enrolled. During the TIPS procedure, blood from the portal and jugular vein was drawn, and at 4 weeks after TIPS placement a sample from a peripheral vein was repeated. Monocytes were isolated from peripheral blood mononuclear cells by adherence after Ficoll-Hypaque purification, and stimulated with LPS (1 μg/ml) for 2, 8 and 24 hours. Gene expression was evaluated by real-time PCR. **Results:** Upon exposure to LPS, a significant increase in gene expression of IL-1beta, IL-6, TLR4 and MERTK was observed in monocytes isolated from either the portal or the jugular vein. Basal and LPS-stimulated mRNA levels of these molecules were markedly lower in the post-TIPS compared to pre-TIPS, in particular after exposure to LPS. Expression of the anti-inflammatory cytokine, IL-10, was significantly increased after LPS stimulation for 2 and 8 hours. After TIPS, mRNA levels of IL-10 were reduced in unstimulated conditions but increased after LPS stimulation for 2 hours. **Conclusion:** Reduction of portal pressure through TIPS placement is associated with reduced expression of pro-inflammatory mediators and modulation of anti-inflammatory IL-10. Increased portal pressure in cirrhotic patients may be a direct modulator of the complex changes in the inflammatory balance observed in these patients.

Veterans Affairs Puget Sound Healthcare System, (3) University of Washington, Seattle, WA, (4)Veterans Affairs Puget Sound Health Care System, (5)VA Puget Sound Healthcare System, (6)University of Washington Medical Center

Background: FibroScan®-derived liver stiffness (LS) values above a threshold of 20 kilopascals (kPa) has been used to guide endoscopic screening for gastro-esophageal varices. However, there is limited data on the clinical significance of LS values above this threshold. We aimed to assess whether LS values ≥ 20 kPa are associated with death, decompensation, and hepatocellular carcinoma (HCC). **Methods:** We identified 20,776 patients who underwent Fibroscan LS measurement since 1/2014 at the Veterans Affairs Healthcare System and after excluding those with HCC, decompensation (ascites, hepatic encephalopathy, or gastro-esophageal variceal bleeding), or liver transplantation prior to LS measurement. Baseline characteristics were ascertained within 1 year prior to LS date. Patients were followed from LS date until 1/2022 for death, hepatic decompensation, variceal bleeding alone, and HCC. We used multivariable Cox proportional hazards regression to determine the association between LS measurements and these outcomes. **Results:** Among the 20,776 patients, 95.5% were male and mean age was 63.8 ± 9.6 years. LS values were < 20 kPa in 17,175 (82.7%), 20 to < 40 kPa in 2,724 (13.1%), 40 to < 60 kPa in 470 (2.3%) and 60 to 75 kPa in 407 (2%). The etiology of liver disease was due to chronic hepatitis C infection in 50.2%, non-alcoholic fatty liver disease in 22.2%, and alcohol-related liver disease in 10.6%. Over a mean follow-up of 2.6 ± 1.8 years after LS date, 2,635 patients died, 1,106 had hepatic decompensation (of whom 211 had variceal bleeding), and 815 were diagnosed with HCC. Compared to those with LS values 20 to < 40 kPa, risk of mortality, decompensation, and variceal bleeding was lower for those with LS < 20 kPa and higher across increasing LS groups (Table). With regards to HCC incidence, compared to those with LS 20 to < 40 kPa (2.6 per 100 Person-Years [P-Ys]), the incidence was higher for those with 40 < 60 kPa (3.9 per 100 P-Ys) but not 60 to 75 kPa (2.3 per 100 P-Ys). On multivariable analysis, compared to the referent LS group 20 to < 40 kPa, those in the 40 to < 60 kPa and 60 to 75 kPa groups had significantly higher risks of death (aHRs 1.46 [95% CI 1.10-1.94] and 2.04 [95% CI 1.50-2.77]), decompensation (aHRs 2.04 [95% CI 1.46-2.87] and 3.80 [95% CI 2.82-5.11]), variceal bleeding (aHRs 3.43 [95% CI 1.96-5.97] and 2.94 [95% CI 1.66-5.21]), but not HCC (aHRs 1.23 [95% CI 0.82-1.84] and 0.87 [95% CI 0.51-1.47]). Compared to those with LS 20 to < 40 kPa, those with LS < 20 kPa had significantly lower risks of mortality (aHR 0.62 [95% CI 0.54-0.71]), decompensation (aHR 0.40 [95% CI 0.33-0.49]) and HCC (aHR 0.44 [95% CI 0.35-0.55]). **Conclusion:** Compared to a referent group of 20-40 kPa, higher LS values are associated with increased risk of death, decompensation, and variceal bleeding. Higher LS values beyond this referent group are not associated with an increased risk of HCC. Lower LS (< 20 kPa) is associated with lower risk of all outcomes.

Table. Association of liver stiffness with mortality and liver-related outcomes

Liver stiffness (kPa)	Number of patients (%)	Patient-years (P-Y)	Number w/outcome (%)	Incidence (per 100 P-Y)	Hazard ratio (95% CI)	Adjusted hazard ratio* (95% CI)	Hazard ratio per 1 kPa increase beyond 20 kPa (95% CI)
A. Mortality							1.014 (1.01-1.02)
<20	17,175	43,244.4	1,873 (10.9%)	4.3	0.67 (0.6-0.73)	0.62 (0.54-0.71)	
20 to <40	2,724	7,706.8	508 (18.6%)	6.6	1	1	
40 to <60	470	1,383.2	136 (28.3%)	9.8	1.49 (1.23-1.8)	1.46 (1.10-1.94)	
60 to 75	407	1,077.2	117 (27.2%)	10.9	1.67 (1.37-2.04)	2.04 (1.5-2.77)	
B. Decompensation (ascites, gastro-esophageal variceal bleeding, or hepatic encephalopathy)							1.031 (1.026-1.036)
<20	17,175	42,235	619 (3.6%)	1.5	0.39 (0.34-0.46)	0.40 (0.33-0.49)	
20 to <40	2,724	7,250.6	267 (9.8%)	3.7	1	1	
40 to <60	470	1,224.8	96 (20.4%)	7.8	2.12 (1.68-2.68)	2.04 (1.46-2.87)	
60 to 75	407	883.36	124 (30.5%)	14.0	3.74 (3.03-4.63)	3.8 (2.82-5.11)	
C. Gastro-esophageal variceal bleeding							1.03 (1.02-1.04)
<20	17,175	43,093.5	87 (0.5%)	0.2	0.24 (0.17-0.33)	0.36 (0.24-0.54)

205 | ALCOHOL-RELATED CIRRHOSIS EXPERIENCES LOWER 6-WEEK MORTALITY AFTER ACUTE VARICEAL BLEEDING COMPARED TO OTHER ETIOLOGIES USING A LARGE PROPENSITY SCORE MATCHED INTERNATIONAL COHORT

Adam Buckholz[1], Yu JUN Wong[2], Rochelle Wong[3], Michael P. Curry[4], Gyorgy Baffy[5], Erik Chak[6], Tarun Rustagi[7], Le Shaun Ang[8], Wen Hui Leia Teo[8], Arpan Mohanty[9] and Brett Fortune[10], (1)New York Presbyterian Hospital Program, (2)Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, (3)Weill Cornell Medicine, NY, (4) Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (5)VA Boston Healthcare System, (6)Univ of California Davis School of Medicine, (7)California Pacific Medical Center, (8)Changi General Hospital, (9)Boston University School of Medicine, (10) Montefiore Medical Center

Background: Acute variceal bleeding (AVB) is a cause of serious morbidity and mortality in cirrhosis. While more severe disease (e.g. higher Child-Turcotte-Pugh [CTP] score) has been shown to correlate

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with worse outcomes after AVB, it is unclear if this correlation remains universal across all cirrhosis etiologies. Using a large multinational cohort of AVB patients, this study aims to compare the 6-week mortality after AVB between alcohol-related (AR) and non-alcohol-related (NAR) cirrhosis patients, adjusting for CTP score. **Methods:** Patients with cirrhosis hospitalized for AVB from 2012-2020 were retrospectively identified from 7 hospitals in the US and Singapore. Those receiving pre-emptive TIPS or liver transplant were excluded. AR cirrhosis was defined based on significant alcohol history during medical chart review. All patients were managed with endoscopy, antibiotics, and vasoactive therapy. The primary outcome was 6-week mortality (Baveno 6). A quasi-experimental method, using propensity score matching with the nearest 3 neighbors and maximum caliper distance of 0.1, was performed in a logit model, adjusting for age, gender, and CTP score. This was iteratively performed to evaluate the average treatment effect on the treated (ATET: the estimated causal effect of a variable [AR cirrhosis] on the observed difference in outcomes) in all patients, those with advanced disease (CTP > 7), and those with CTP C 10-13 or CTP B with active hemorrhage on endoscopy, where a negative ATET value represents 6-week mortality benefit. **Results:** A total of 469 patients (204 [44%] with AR disease) were included. The baseline characteristics were similar across sites with the exception that the Singapore cohort was older, had less alcohol use, and had more HBV-related cirrhosis. The AR cirrhosis cohort had more men, lower age, and higher admission MELD/CTP/MELD 3.0 scores. Overall 6-week mortality was 15% with no differences between AR and NAR cirrhosis ($p = 0.77$, [Fig A]). Adjusting for CTP score, AR cirrhosis was associated with lower 6-week mortality risk (OR 0.49, 95% CI 0.27-0.90, $p = 0.02$) [Fig B]. After propensity matching with age, gender and CTP score, there was a significant mortality reduction from AR cirrhosis etiology among those with CTP B and active bleeding or CTP C (n = 199, ATET -0.23, 95% CI -0.35, -0.10, $p < 0.01$) as well as those with CTP > 7 (n = 272, ATET -0.16, 95% CI -0.31, -0.01, $p = 0.04$). The overall beneficial effect from having AR cirrhosis compared to other etiologies neared significance (n = 469, ATET -0.09, 95% CI -0.20, +0.02, $p = 0.10$). **Conclusion:** In a large multinational cohort of patients with AVB who did not undergo TIPS, we found that patients with AR cirrhosis have lower 6-week mortality than those with other etiologies, particularly at higher CTP scores. This highlights the importance of underlying disease etiology on AVB outcomes and warrants further investigation to elucidate the impact of therapeutics on these subgroups.

A

	Alcohol (n=204)	Non-alcohol (n=265)	Total (n=469)	P value
Gender, M (%)	160 (78%)	175 (66%)	335 (71%)	<0.01
Age, mean (SD)	52.4 (11.0)	61.0 (11.1)	57.3 (11.9)	<0.01
Admission MELD	18.1	13.8	15.7	<0.01
Admission CTP	9.12	7.80	8.37	<0.01
Admission MELD 3.0	19.5	15.9	17.5	<0.01
6-week Mortality, n (%)	32 (15.7%)	39 (14.7%)	71 (15.1%)	0.77

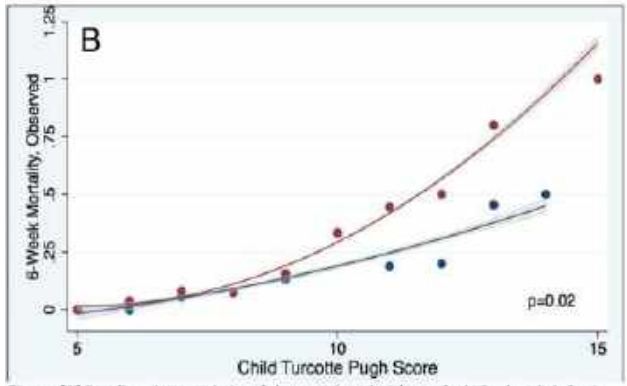

Figure: [A] Baseline characteristics of those with and without alcohol-related cirrhosis. [B] Scatter plot demonstrating observed 6-week mortality at each CTP Score. At higher CTP score, those with alcohol-related cirrhosis (BLUE) have significantly lower rate of 6-week mortality when compared to non-alcohol etiologies (RED, p-value = 0.02).

206 | CARVEDILOL PLUS NUCS TO PREVENT THE PROGRESSION OF ESOPHAGEAL VARICES IN VIROLOGICAL SUPPRESSED HBV-CIRRHOSIS PATIENTS: A RANDOMISED, OPEN-LABEL TRIAL

Bingqiong Wang[1], Jialing Zhou[1], Xiaoning Wu[2], Yameng Sun[2], Lei Li[3], Ping Li[4], Minghui Li[5], Wei Jiang[6], Mingyi Xu[7], Bo Feng[8], Xiaoyuan Xu[9], Jilin Cheng[10], Wen Xie[11], Tao Han[12], Xiaozhong Wang[13], Hai Li[14], Hongxin Piao[15], Xinyu Zhao[16], Shuyan Chen[5], Tongtong Meng[2], Qiushuang Guan[1], Fandong Meng[17], Yuanyuan Kong[18], Xiaojuan Ou[2], Jidong Jia[2] and Hong You[5], (1)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing Key Laboratory of Translational Medicine on Liver Cirrhosis, National Clinical Research Center for Digestive Diseases, Beijing, China;, (2)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (3)Department of Gastroenterology and Hepatology, Beijing Youan Hospital, Capital Medical University, Beijing, China, (4) Department of Hepatology, Tianjin Second People's Hospital, Tianjin, China, (5)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, (6)Department of Gastroenterology, Zhongshan Hospital (Xiamen), Fudan University, Xiamen 361015, China, (7)Department of Gastroenterology and Hepatology, Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, (8)Peking University People's Hospital, (9)Peking University First Hospital, (10)Department of Gastroenterology, Shanghai Public Health Clinical Center, (11)Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (12)Department of Hepatology, Tianjin Third Central Hospital, Tianjin Medical University, (13)The Fourth Affiliated Hospital of Xinjiang Medical University (Xinjiang Hospital of Traditional Chinese Medicine), (14)Department of Gastroenterology, Tianjin Xiqing Hospital, (15) Department of Infectious Diseases, Affiliated Hospital of Yanbian University, (16)Department of Clinical Epidemiology and EBM Unit, National Clinical Research Center for Digestive Diseases, Beijing, China; Beijing Friendship Hospital, Capital Medical University., (17) Department of Gastroenterology, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center for Digestive Diseases, Beijing, China;, (18)Clinical Epidemiology and EBM Unit, Beijing Friendship Hospital, Capital Medical University, Beijing Clinical Research Institute, Beijing, China

Background: Portal hypertension progression can be relieved after controlling the etiology of liver cirrhosis. Whether beta-blockers could additionally enhance the effects during treatment, particularly for mild esophageal varices (EVs), was unclear. This study aims to assess the efficacy of add-on carvedilol to delay EVs progression during anti-HBV treatment in HBV-related cirrhosis. **Methods:** This randomised controlled trial enrolled patients with HBV-related cirrhosis and mild/moderate EVs. The participants were randomly assigned to receive NUCs or carvedilol 12.5 mg plus NUCs (1:1 allocation ratio). The primary endpoint was the progression rate of EVs at 2 years of follow-up (NCT 03736265). **Results:** Totals of 238 patients (mild EVs, 77.3%) were randomised into 119 NUCs and 119 carvedilol plus NUCs (CARV combination group). Among them, 205 patients (86.1%) completed paired endoscopies. EVs progression rate was 15.5% (16/103) in NUCs group and 12.7% (13/102) in CARV combination group (RR = 0.80, 95%CI 0.36-1.77, $p = 0.59$). Subgroup analysis on moderate EVs showed CARV combination group had a more favorable effect in promoting EVs regression (43.5% vs. 13.1%, $p = 0.03$) than NUCs alone, but not in mild cases ($p = 0.50$). The incidence of liver-related events (decompensation, hepatocellular carcinoma, or death/liver transplantation) within 2 years was similar between the two groups (11.2% vs. 10.4%, $p = 0.88$). **Conclusion:** In virological suppressed HBV-cirrhosis patients, the added carvedilol strategy was non-inferior to NUCs monotherapy to prevent progression in esophageal varices. However, the carvedilol-added approach might improve the outcome for patients with moderate varices.

207 | A RANDOMIZED CONTROLLED TRIAL COMPARING SUSTAINED LOW EFFICIENCY DIALYSIS WITH CONTINUOUS RENAL REPLACEMENT THERAPY FOR SEPSIS-ASSOCIATED ACUTE KIDNEY INJURY IN CRITICALLY ILL PATIENTS WITH CIRRHOSIS (NCT04494542)

Rakhi Maiwall[1], Neha Chauhan[2], Ashinikumar Kumar Hidam[2], Sherin Thomas[2], Chandani Bhagat[2], Prashant Aggarwal[2], Shivali Panwar[2], Harsh Vardhan Tevethia[1] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, New Delhi, (2)Institute of Liver and Biliary Sciences, (3)Ilbs

Background: Continuous renal replacement therapy (CRRT) is the preferred mode of dialysis in critically ill hemodynamically unstable patients and in addition removes the inflammatory cytokines that accumulate in sepsis. Sustained low-efficiency dialysis (SLED) is a hybrid modality of intermittent dialysis with the advantage of metabolic control, hemodynamic stability, at a reduced cost. We aimed to compare CRRT versus SLED in patients with cirrhosis and sepsis-associated AKI(SA-AKI) in preventing the incidence of intradialytic hypotension (IDH). **Methods:** Prospective single-center open-label randomized controlled trial wherein critically ill patients with cirrhosis (CICs) with SA-AKI and norepinephrine dose < 0.10 ug/kg/min) were randomized to CRRT versus SLED. Pre and post (8 hours) rotational thromboelastometry (ROTEM, $n = 62$) and inflammatory cytokines was performed in 20 patients (10-CRRT, 10-SLED). **Results:** A total of 62 patients were randomized to SLED ($n = 31$) vs. CRRT ($n = 31$). The baseline characteristics were comparable. The mean age was 45.7 ± 10.8 years, 95% males, 81% alcohol-related, with arterial lactate 2.3 ± 1.9 umol/L ,serum creatinine 3.1 ± 2.1 mg/dl, MELD 53.4 ± 9.7 and SOFA score 12.6 ± 2.9. The indication for dialysis was metabolic acidosis in 90%. The norepinephrine (NE) dose was comparable at baseline [(0.06 ± 103) vs (0.7 ± 10.3) ug/kg/min; $p = 0.13$). On intention-to-treat analysis, the development of IDH was lower in CRRT [11(35.5%) vs. 22 (71%);$p = 0.01$). There was no difference in 28-day mortality [(12(38.7%) vs.14(45.2%); $p = 0.19$], the recovery of AKI at day 14 [11 (35.5%) vs. 7 (22.6%); $p = 0.40$] but reduction in SOFA score by 2 points was higher in CRRT[13 (41.9%)vs.4(12.9%); $p = 0.02$] with a significant lower NE dose at day 2 [(0.9 ± 0.16) vs. (0.17 ± 0.11) ug/kg/min ;$p = 0.03$) vs. SLED respectively. A significant reduction in arterial lactate from baseline [$(2.1 \pm 1.9$ to 1.9 ± 1.1; $p = 0.047$) was noted in CRRT vs. SLED (2.0 ± 1.9 to 2.2 ± 1.8; $p = 0.33$)]. The days of mechanical ventilation and ICU stay were not different. There were 7(22.5%) patients with protocol violation in SLED group who required CRRT due to IDH. The median duration of CRRT was 48 (IQR 15-116 hours) while the mean number of SLED sessions were 3 ± 2.1. A significant derangement in coagulation by ROTEM was noted more with SLED. Inflammatory cytokines (serum ferritin, c-reactive protein) showed significant reduction with CRRT vs. SLED while levels of interleukin-6 increased after CRRT. (Figure) **Conclusion:** CRRT compared to SLED is a better modality which lowers the incidence of IDH achieves better lactate clearance and reduction in SOFA scores in cirrhosis patients with SA-AKI but does not confer any survival benefit. CRRT is possibly more effective in clearing inflammatory cytokines and causes lesser impairment in coagulation compared to SLED. Large controlled trials are required for exploring the observed benefits of CRRT in CICs.

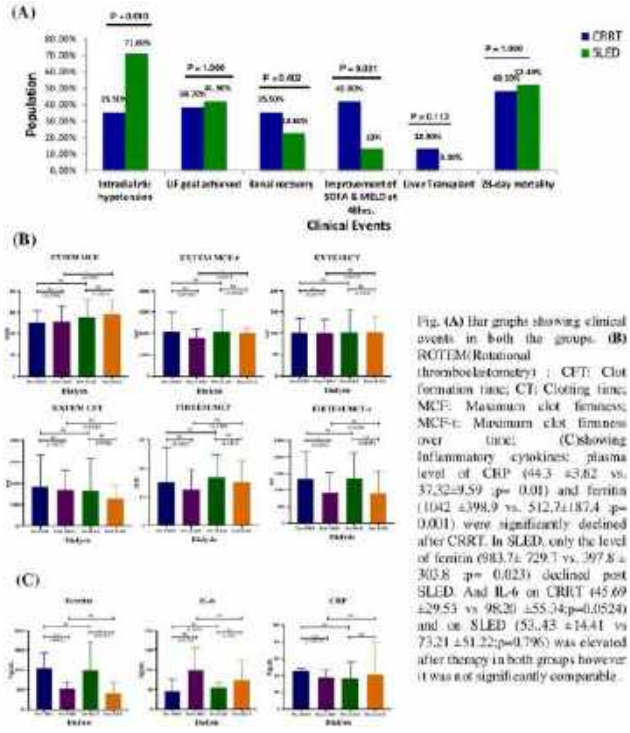

Fig. (A) Bar graphs showing clinical events in both the groups. (B) ROTEM(Rotational thromboelastometry) : CFT: Clot formation time; CT: Clotting time; MCF: Maximum clot firmness; MCF-t: Maximum clot firmness over time; (C)showing Inflammatory cytokines: plasma level of CRP (44.3 ±3.82 vs. 37.32±9.59 ;p= 0.01) and ferritin (1042 ±398.9 vs. 512.7±187.4 ;p= 0.001) were significantly declined after CRRT. In SLED, only the level of ferritin (983.7± 729.7 vs. 397.8± 303.8 ;p= 0.023) declined post SLED. And IL-6 on CRRT (45.69 ±29.53 vs 98.20 ±55.34;p=0.0524) and on SLED (53.43 ±14.41 vs 73.21 ±51.22;p=0.796) was elevated after therapy in both groups however it was not significantly comparable.

208 | ALBUMIN IS INTERNALIZED BY PRIMARY MONOCYTES USING CLATHRIN-INDEPENDENT ENDOCYTOSIS WHICH IS REQUIRED FOR ITS ANTI-INFLAMMATORY EFFECT

Mireia Casulleras[1,2], Irini Evnouchidou[3], Eva Boisel[3], Marta Duran-Güell[1], Berta Romero-Grimaldo[4], Bryan J. Contreras[4], Cristina López-Vicario[1], Richard Moreau[5], Vicente Arroyo[6], Loredana Saveanu[3] and Joan Claria[1,2], (1)Hospital Clínic-Idibaps, Barcelona, Spain, (2)European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain, (3)University of Paris, Center of Research on Inflammation, Inserm U1149, Cnrs ERL8252, Hôpital Beaujon, Assistance Publique-Hôpitaux De Paris, (4)Hospital Clínic-Idibaps, (5) European Foundation for the Study of Chronic Liver Failure, Paris, France, (6)European Foundation for the Study of Chronic Liver Failure and Grifols Chair, Barcelona, Spain

Background: Albumin has been shown to modulate systemic inflammation in patients with decompensated liver cirrhosis receiving infusions of this protein as therapy. Although the anti-inflammatory effect of albumin has been described to be secondary to its internalization into mononuclear leukocytes, the cell type and the mechanism by which albumin is internalized by these immune cells are at present unknown. **Methods:** The internalization of tetramethylrhodamine isothiocyanate (TRITC)-labelled albumin by B and T lymphocytes and different subsets of monocytes and dendritic cells was scrutinized by flow cytometry using the expression of distinct surface markers. The albumin-binding receptor(s) was identified by albumin immunoprecipitation and untargeted proteomics. Albumin uptake and intracellular trafficking in primary monocytes was examined by confocal microscopy and the endocytic routes involved in the internalization of TRITC-albumin were screened in THP-1 cells transduced with shRNA lentivirus blocking different key cellular endocytic pathways. **Results:** Albumin was predominantly endocytosed and intracellularly accumulated by classical monocytes, which are highly phagocytic. In these cells and during the first 30 min after incubation, albumin was mainly located in early EEA1-positive endosomes whereas at later time points the albumin signal was also located in LAMP1-positive lysosomes. The shRNA lentivirus screening showed that albumin internalization was dependent on dynamin 2, ARF6 and ARF1, which are clathrin-independent routes. Untargeted proteomics of immunoprecipitated albumin identified two transmembrane proteins, the neonatal Fc receptor (FcRn) and CD44, as potential albumin receptor candidates. Of note, unlike THP-1 cells, classical monocytes freshly isolated from blood donors tested positive for intracellular albumin signal, indicating that the internalization of albumin by immune cells is a common occurrence in humans. **Conclusion:** These findings offer new perspectives for the understanding of the mechanisms involved in the interaction of the albumin molecule with the immune system in those conditions where this protein is therapeutically used, as is the case of decompensated cirrhosis liver patients.

209 | ROLE OF LONG TERM ALBUMIN THERAPY IN TREATMENT OF DECOMPENSATED CIRRHOSIS

Deepanshu Khanna and Premashis Kar, Max Superspeciality Hospital, Vaishali

Background: Cirrhosis now has the 10th highest mortality rate worldwide. Most cirrhosis deaths are caused by the emergence of clinical decompensation, and 4%–12% of those who have the disease, experience at least one episode of decompensation per year. These patients are highly susceptible to infections due to increased systemic inflammation leading to kidney failure and death. Aim was to study the efficacy of albumin in reducing episodes of decompensation, preventing bacterial infection, kidney dysfunction and mortality. **Methods:** Study involved patients with Child B or C cirrhosis with albumin level below 30 g per litre, who were administered 20% human albumin weekly with standard medical treatment for 3 months or or till serum albumin levels are 4.0 g/dL (whichever is earlier) and compared with age and sex matched controls who received only standard medical treatment. The primary end-point was 6 month mortality, and the secondary end-points were reduction in infections, kidney dysfunction, ascites recurrence, hepatic encephalopathy, gastrointestinal bleed and complications of cirrhosis. **Results:** From September 2021 to January 2023, 88 cases and 86 controls were taken and followed up for 6 months. Overall 6-month survival was not statistically significant between groups (95.1% vs 91.9%; $p = 0{\cdot}330$). Incidence of Recurrence of ascites (34.09% v/s 59.3%, $p < 0.001$), Kidney dysfunction (6.8% v/s 24.4%, $p < 0.001$), hepatic encephalopathy (15.9% vs 37.2%, $p = 0.015$), Spontaneous bacterial peritonitis (7.9% vs 18.6%, $p = 0.002$), Non SBP infections (7.9% vs 18.6%, $p = 0.038$) were significantly less in cases as compared with controls, however Gastrointestinal bleed (14.8% vs 17.4%, $p = 0.632$) was

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

not statistically significant. **Conclusion:** Long-term Human albumin acts as a disease modifying treatment in patients with decompensated cirrhosis.

210 | HIGH DOSES OF ALBUMIN INCREASES MORTALITY AND COMPLICATIONS IN TERLIPRESSIN TREATED PATIENTS WITH CIRRHOSIS: INSIGHTS FROM THE ATTIRE TRIAL★

Nikolaj Torp[1,2], Louise China[3], Mads Israelsen[4], Aleksander Krag[2,5] and Alastair O'Brien[3], (1)Odense University Hospital, (2)University of Southern Denmark, Odense, Denmark, (3)University College London, (4) Liver Research Centre, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark, (5)Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark

Background: The CONFIRM trial revealed potential harm with terlipressin in a subset of patients, who developed respiratory failure. It remains unclear to what degree concomitant albumin contributes to the undesirable outcomes of terlipressin treatment. Using ATTIRE trial data, we compared safety of serum targeted albumin infusions to standard-of-care in patients with cirrhosis receiving terlipressin. **Methods:** ATTIRE was a randomized controlled trial of albumin infusions in 777 patients hospitalized with cirrhosis and hypoalbuminemia (< 3.0 g/dL). Patients were randomized to serum targeted albumin (STA) infusions, aiming for a serum albumin level > 3.0 g/dL, or standard-of-care (SoC), where albumin infusions was allowed as per clinical guidelines. At trial enrollment, 42 patients received terlipressin in the STA group (STA+TP) and 41 in SoC group (SoC+TP). Patients not receiving terlipressin at enrollment, served as controls (STA-TP, n = 338 and SoC-TP, n = 356). We studied mortality at day 15 and complications from trial SAE reporting. The primary outcome was a composite of 15-day complication-free survival (15-day mortality, respiratory failure, pulmonary edema and fluid overload). **Results:** Terlipressin indications were variceal bleed (74%), hepatorenal syndrome (23%) and hypotension (3%). Patients in the STA+TP group received higher albumin doses compared to the SoC+TP group (mean±SD: 209 ±125 grams vs. 96±162 grams, $p < 0.001$). Baseline disease severity was similar between the two groups (median MELD: STA+TP = 19 [15-23] vs. SoC+TP = 18 [14-24], $p = 0.520$). The STA+TP group had a significantly lower 15-day complication-free survival than the SoC+TP group (Figure, $p = 0.006$). Compared to patients without terlipressin use at enrollment, the prognosis was also worse for STA+TP vs. STA-TP ($p < 0.001$), but similar between SoC+TP and SoC-TP ($p = 0.809$). Mortality rate during the 15-day follow-up was 21% in STA+TP and 7% in SoC+TP. The risk of respiratory failure was 7% (STA+TP) and 2% (SoC +TP), despite similar renal function at baseline (median creatinine: STA+TP = 1.0 mg/dL [0.7-1.6] vs. SoC+TP = 0.9 mg/dL [0.7-1.5], $p = 0.752$). Adjusting for disease severity, the increased risk of 15-day mortality and complications persisted in the STA+TP group (sHR = 5.63, 95% CI: 1.60; 19.86, $p = 0.007$), independently of baseline MELD (HR = 1.05, 95% CI: 1.02; 1.08, $p = 0.002$). A subgroup analysis of variceal bleed patients treated with terlipressin, showed a markedly higher risk of 15-day mortality and complications in the STA+TP group (19%) compared to the SoC+TP group (0%, $p = 0.011$). **Conclusion:** High albumin doses, due to serum targeted albumin infusions, is associated with an increased risk of mortality and complications in patients with cirrhosis receiving terlipressin, independently of disease severity. These findings suggest a cautious use of concomitant albumin to terlipressin, outside current dosing recommendations and indications.

211 | ALBUMIN DOSING WITH TERLIPRESSIN FOR THE TREATMENT OF HRS-AKI: A DOUBLE-EDGED SWORD

Florence Wong, Toronto General Hospital, Toronto, ON, Canada, S. Chris Pappas, Orphan Therapeutics, Michael P. Curry, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Pratima Sharma, University of Michigan, Ann Arbor, MI and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Current guidelines for the diagnosis of HRS-AKI require the use of albumin as volume expander to exclude pre-renal azotemia. The treatment of HRS-AKI (hepatorenal syndrome) also recommends the use of terlipressin with albumin at a dose of 20-40g per day. However, the optimal dose of albumin to be given in the pre- and during treatment remains unclear. We evaluated total albumin use in the two largest placebo-controlled, randomized trials of terlipressin plus albumin versus placebo in patients with HRS-AKI. **Methods:** Pooled data from the two trials (CONFIRM-NCT02770716 and REVERSE-NCT01143246) were used to determine transplant-free survival (TFS) and HRS reversal by total albumin quartiles; total albumin included albumin given up to 14 days prior to randomization and concomitant albumin given during study treatment. TFS was analyzed using a Kaplan-Meier product limit method; HRS reversal was defined as serum creatinine d 1.5 mg/dL by day 14 or discharge. **Results:** The 4 quartiles of total albumin dose given were d 325g (Gp A), > 325 to d 456.25g (Gp B), > 456.25 to d 655g (Gp C), and > 655g (Gp D). HRS reversal rates for the terlipressin patients were 33.7%, 31.9%, 27.8% and 38.2% for Gp A to D respectively. Similarly, the placebo group had comparable proportions of patients who achieved HRS reversal, being 12.7%, 24.3%, 15.4% and 18.4% for Gp A to D respectively. Therefore, there was no dose-response relationship between total albumin use and HRS reversal for either treatment group. The TFS by day 90 for the terlipressin patients were 25.6%, 29.0%, 27.8% and 27.9% for Gp A to D respectively. The corresponding TFS by Day 90 for the placebo patients were 14.5%, 18.9%, 28.8% and 45.4%. Therefore, once again, there was no relationship between total albumin use and TFS by Day 90 in the terlipressin group. In contrast, TFS by Day 90 increased in the placebo group with increasing albumin dose used, being 14.5%, 18.9%, 28.8% and 45.4%. for Gp A to D respectively. Importantly, there was a significant difference in placebo versus terlipressin TFS at Day 90 in the > 655 g albumin quartile (terlipressin 27.9% vs. placebo 45.5%, $p = 0.044$). The lower TFS by Day 90 amongst terlipressin patients who received more than655g of albumin appears to be related in part to death from respiratory failure/sepsis/septic shock (terlipressin 12.6% vs placebo 3.0%). **Conclusion:** These results demonstrate that there does not appear to be an easily identifiable optimal dose of albumin during terlipressin therapy. The relationship between albumin use and the balance between efficacy and safety is complex; this "double-edged sword" underscores the need for careful patient selection and monitoring of albumin use to avoid volume overload.

212 | SAFETY AND EFFICACY OF DAPAGLIFLOZIN IN RECURRENT ASCITES: A PILOT STUDY

Virendra Singh[1], Arka De[2], Rishav Aggarwal[1], Shivani Chandel[1], Akash Gandotra[2] and Naveen Dandia[1], (1) Postgraduate Institute of Medical Education and Research, (2)Post Graduate Institute of Medical Education and Research

Background: The pathophysiology of ascites in cirrhosis entails vasodilatation with the consequential activation of sympathetic nervous system and renin-angiotensin-aldosterone system, leading to retention of sodium and water. Dapagliflozin, a sodium glucose linked transporter-2 inhibitor, induces natriuresis and is beneficial in patients with heart failure. We hypothesised that a similar natriuretic effect may improve mobilization of ascites in patients with cirrhosis. In this pilot study, we evaluated the efficacy and safety of dapagliflozin in patients with cirrhosis with recurrent ascites. **Methods:** Forty patients with recurrent ascites and cirrhosis were randomized 1:1 in a double blinded fashion to receive either dapagliflozin (10 mg/day) with standard medical therapy (Group A) or placebo with standard medical therapy (Group B). The primary outcome was control of ascites at 6-months. Secondary outcomes were urine output, 24-hour urinary sodium, estimated glomerular filtration rate, HbA1c, mean arterial pressure, Child Turcotte Pugh (CTP), model for end stage liver disease (MELD) scores and survival at 6-months, incidence of acute kidney injury (AKI), infections, hepatic encephalopathy, hyponatremia, hypokalemia, hepatocellular carcinoma, diabetic ketoacidosis and hyperglycemic hyperosmolar nonketotic coma. **Results:** The 2 groups were comparable at baseline. Complete and partial control of ascites at 6-months were seen in 3 (15%) and 11 (55%) patients in Group A which was significantly better than that in Group B (complete control: 0, partial resolution: 7 (35%), $p = 0.01$). Change in urinary sodium was significantly higher in Group A [13.3 (-10.9 to 30.1) vs -4.4 (-16.4 to 5.6), $p < 0.001$]. However, there was no difference in change in urine output, estimated glomerular filtration rate, HbA1c, mean arterial pressure, CTP or MELD scores between the groups at 6-months. Incidence of AKI (50% vs 15%, $p = 0.04$) and infections (55% vs 20%, $p = 0.04$) were significantly higher in Group A but there was no difference in hepatic encephalopathy, hyponatremia, hypokalemia, hepatocellular carcinoma, diabetic ketoacidosis and hyperglycemic hyperosmolar nonketotic coma. Survival at 6-months was similar in the 2 groups (65% vs 68.2%, $p = 0.75$). **Conclusion:** Significantly better control of ascites and higher natriuresis are observed with dapagliflozin. However, it does not improve disease severity scores or survival, and is associated with increased AKI and infections (NCT05014594).

213 | ADDITION OF RIFAXIMIN TO BROAD-SPECTRUM ANTIBIOTICS HAS NO BENEFICIAL ROLE IN CRITICALLY ILL CIRRHOSIS PATIENTS WITH ACUTE OVERT HEPATIC ENCEPHALOPATHY- A DOUBLE-BLIND, RANDOMIZED CONTROLLED TRIAL

Anand V. Kulkarni, Mahathi Avadhanam, Pooja Karandikar, Anand Gupta, Asim Ahmed Zuberi, Venu

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Simhadri, Sowmya T R, Manasa Alla, Shantan Venishetty, Mithun Sharma, Nageshwar D Reddy and Padaki Nagaraja Rao, Aig Hospitals, Hyderabad, India

Background: Critically ill cirrhosis (CIC) patients admitted to the intensive care unit (ICU) are usually on broad-spectrum intravenous antibiotics due to suspected infection or as a protocol. Few reports have suggested rifaximin to be beneficial in acute overt hepatic encephalopathy (OHE). However, the role of rifaximin in patients on broad-spectrum antibiotics admitted to ICU is still unclear. Therefore, we aimed to assess the efficacy of addition of rifaximin to broad-spectrum antibiotics for CIC patients admitted to ICU for OHE. **Methods:** In this double-blind trial, patients with OHE admitted to ICU were randomized to receive antibiotics alone (Gr. A) or antibiotics with rifaximin (Gr. B). All patients received lactulose. The primary objective was to compare the resolution of HE (defined as 2-grade reduction and/or complete resolution of HE by West-Haven criteria) among the two groups. The secondary objective was to compare the time taken for the resolution of HE, in-hospital mortality, nosocomial infection, endotoxin levels, and predictors of HE resolution. **Results:** 184 patients (age-47.8 ± 11.7 y; females-11.4%; alcohol-66.3%; MELD-29.4 ± 9.4; 92 patients in each group) were included. Baseline characteristics, including age, sex distribution, and severity scores, were similar among both groups. The most common precipitant of OHE was constipation with dyselectrolytemia in both groups (41%). The median number of stools passed per day in both groups was similar (4 [0-6] vs. 4 [2-6] in Gr.B; $p = 0.86$). Forty-one percent in Gr. A and 50% in Gr. B received L-ornithine L-aspartate infusion concomitantly ($p = 0.3$). The most common antibiotic used was carbapenems, followed by cephalosporin with beta-lactamase inhibitor in both groups. The proportion of patients achieving HE resolution was similar in both groups (44.6% [95%CI, 32-70.5] in Gr. A vs. 46.7% [95%CI, 33.8-63] in Gr. B; $p = 0.88$) (Fig. a). Time to achieve the primary objective was 3.65 ± 1.82 days and 4.11 ± 2.01 days in Gr. A and B, respectively ($p = 0.27$). In-hospital mortality was similar among both groups (62% vs. 50% in Gr. B; $p = 0.13$). Seven percent and 13% in Gr. A and B developed nosocomial infections ($p = 0.21$). 12% and 14.1% in Gr. A and B ($p = 0.82$) needed the addition of another antibiotic or upgradation to carbapenems. Baseline endotoxin levels (1.22 ± 0.72 vs. 1.3 ± 0.86 EU/ml; $p = 0.8$) and the delta change in levels of endotoxin at the resolution of HE were similar among both groups (Fig. b). On multivariate Cox regression analysis, a higher SOFA score predicted a lesser chance of OHE resolution (hazard ratio [HR], 0.85 [0.79-0.92];$p < 0.001$), while higher albumin levels increased the chance of OHE resolution (HR, 1.6 [1.06-2.4]; $p = 0.02$). **Conclusion:** The addition of rifaximin to broad-spectrum antibiotics has no beneficial role in critically ill cirrhosis patients with acute OHE admitted to ICU.

214 | MUSCLE FAT INFILTRATION IS ELEVATED IN PREFRAIL AND MODERATELY PHYSICALLY IMPAIRED PATIENTS – INTERIM RESULTS FROM THE PROSPECTIVE MULTI-CENTER CIRRHOSIS COHORT STUDY ACCESS-ESLD

Mikael Fredrik Forsgren[1,2], Wile Balkhed[1], Patrik Nasr[1], Daniel Sjögren[3], Jennifer Linge[1,2], Anna Cederborg[1], Markus Holmberg[1], Nils Dahlström[1], Henrik Stjernman[3], Martin Rejler[3], Stergios Kechagias[4], Olof Dahlqvist Leinhard[1,2] and Mattias Ekstedt[4], (1)Linköping University, (2)Amra Medical AB, (3)County Hospital Jönköping, (4)Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden

Background: Physical frailty and sarcopenia are related but not fully overlapping, and links to outcomes and health care utilization in liver cirrhosis. Physical frailty may be assessed with Liver Frailty Index (LFI) or Short Performance Physical Battery (SPPB), and sarcopenia is typically assessed by measuring muscle size using imaging. A magnetic resonance imaging (MRI) based assessment (Muscle Assessment Score [MAsS]) combining sex-adjusted thigh muscle fat infiltration (MFI) and muscle volume z-score (MVZ), has been developed to describe muscle health. Large population studies have shown that MAsS better predicts physical function and hospitalization than its individual components. MAsS can be used to detect muscle composition (MC) phenotypes, of which adverse MC (high MFI & low MVZ) independently predicts all-cause mortality. The aim was to assess the association of MAsS and L3 skeletal muscle index (L3-SMI) with physical frailty tests (SPPB & LFI) and assess

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

MC phenotypes in ACCESS-ESLD – a prospective longitudinal multi-center cohort study of patients with liver cirrhosis. **Methods:** MAsS and L3-SMI were measured using AMRA® Researcher based on an 8 min MRI acquired on the same day as SPPB and LFI. SPPB was grouped as very low-to-low (<7), moderate (7-9), and high (10-12) physical performance. LFI was grouped as frail (>4.5), prefrail (3.8-4.4), less robust (3.2-3.7), and robust (<3.2). MC phenotypes were defined according to literature. T-tests were used for statistical testing. **Results:** The first 76 patients (46 males; BMI 29.5 ± 6.3 kg/m^2; Age 66 ± 10 yrs; mainly alcohol related cirrhosis and NAFLD, but also hepatitis B and C, and autoimmune diseases) were included. Patients with moderate (compared to high) physical performance had increased MFI from baseline (+1.77 pp, $p=0.020$). There was no difference in MVZ nor L3-SMI. Only 3 patients had very low-to-low physical performance. MFI was higher in frail (+3.70 pp, $p=0.035$) and prefrail (+1.16 pp, $p=0.040$) compared to robust, and in frail (+2.98 pp, $p=0.035$) compared to less robust. MVZ was lower in prefrail (-0.72 SD, $p=0.049$) and less robust (-0.86 SD, $p=0.029$) compared to robust. There was no difference for L3-SMI. Patients with adverse MC (n=15) had higher LFI (3.98 v 3.49, $p=0.040$), lower SPPB (8.93 v 10.26, $p=0.020$), and lower L3-SMI (42.5 v 49.3, $p=0.035$) compared to all other MC phenotypes (see MC prevalences in Fig) without differences in BMI or age. **Conclusion:** Results suggest that 20% of patients with cirrhosis have adverse MC, a large group (53%) low muscle volume, and few (5%) only high fat (see Fig). MFI was significantly higher with reduced physical function and by increasing frailty index. Adverse MC, as detected by MAsS, showed significantly higher frailty and lower physical performance, unrelated to age and BMI. These results indicates that MFI could be used as a frailty marker and that MAsS describes both frailty and sarcopenia in patients with liver cirrhosis.

215 | CL-ART: A NOVEL SMARTPHONE APPLICATION THAT CAN HELP PREDICT FUTURE HOSPITALISATION SECONDARY TO CIRRHOSIS ACUTE DECOMPENSATION

Kohilan Gananandan[1], Ann-Sophie Frees Wietz[2], Ahmed El Shabrawi[1], Ann Catrine Daugaard Mikkelsen[2], Maria Pilar Ballester[1], Konstantin Kazankov[2], Anu Balaji[3], Ravan Boddu[3], Ravi Kumar[3], Karen Louise Thomsen[1,2] and Rajeshwar P. Mookerjee[1,2], (1)University College London, (2)Aarhus University, (3)Cyberliver Limited

Background: Hepatic encephalopathy (HE) is the most frequent cirrhosis complication leading to hospital admissions and is associated with significant mortality. The aim of this study was to determine the ability of the CyberLiver-Animal Recognition Test (CL-ART) to predict future hospitalisation due to decompensation, especially through HE, comparing its performance to established HE tests. **Methods:** A prospective study of cirrhosis patients applying three different cognitive tests at two tertiary hepatology centres was performed. The CL-ART involved a timed (usually <30 seconds) recognition of animals using a smartphone app (Figure 1). EncephalApp Stroop Test and Psychometric Hepatic Encephalopathy Score (PHES) were chosen as test comparisons. Follow-up clinical data was collected for a 6-month period. **Results:** 43 healthy controls and 103 cirrhosis patients were included (median CL-ART time 15.7s vs 24.0s). The baseline characteristics of the cirrhosis patients were 65% male, median age 58, Child-Pugh Score 8 [IQR 7-10], MELDNa 15 [IQR 11-19], CLIF-C AD 48 [IQR 44-52]. CL-ART demonstrated a good correlation with EncephalApp (r=0.81, $p<0.001$) and PHES (r=-0.63, $p<0.001$). When analysing patients admitted due to HE during their follow-up, baseline CL-ART was significantly higher compared to participants who were not hospitalised (31.5 vs 22.6s, $p<0.001$) with an AUROC of 0.85 (95% CI 0.77-0.93) for predicting future HE admissions. This was comparable to EncephalApp (AUROC 0.83, 95% CI 0.74-0.92) and

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ammonia (AUROC 0.81, 95% CI 0.71-0.91). In multiple logistic regression analysis, CL-ART remained an independent predictor of future HE admissions (OR 1.15, $p = 0.049$). Using the Youden index, the optimal CL-ART cut-off to predict HE-related admissions is 26s (sensitivity 91.7%, specificity 71.4%). When analysing all subsequent admissions due to any decompensation event, baseline CL-ART scores were significantly higher in those subsequently hospitalised (27.0 vs 21.3s, $p < 0.001$) with an AUROC of 0.76 (95% CI 0.66-0.85). Finally, the CL-ART also demonstrated superior participant useability (Figure 1). **Conclusion:** This study demonstrates that CL-ART can help predict hospitalisation due to all decompensation, with highest sensitivity and specificity for HE-related admissions. Its rapid testing, smartphone application and high useability mean it can be used remotely, and therefore, play a crucial role in predicting decompensation, enabling early community intervention.

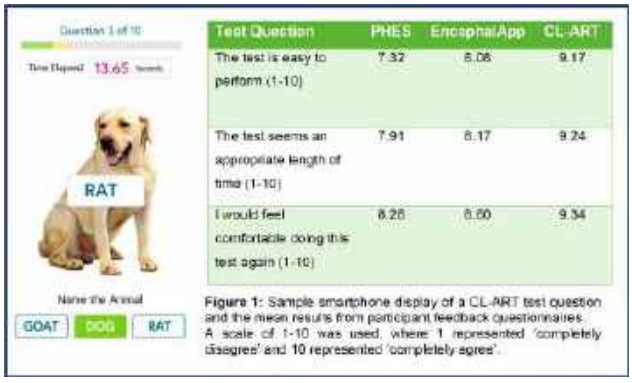

Figure 1: Sample smartphone display of a CL-ART test question and the mean results from participant feedback questionnaires. A scale of 1-10 was used, where 1 represented 'completely disagree' and 10 represented 'completely agree'.

Disclosure information not available at the time of publication: Ann-Sophie Frees Wietz, Ahmed El Shabrawi, Ann Catrine Daugaard Mikkelsen, Maria Pilar Ballester, Konstantin Kazankov, Anu Balaji, Ravan Boddu, Ravi Kumar, Karen Louise Thomsen, Rajeshwar P. Mookerjee

216 | LINKAGE OF LIVER STIFFNESS WITH COGNITIVE PERFORMANCE ACROSS THE SPECTRUM OF CHRONIC LIVER DISEASE AND IMPACT ON QOL: A MULTI-NATIONAL STUDY

Lea Ladegaard Gronkjaer[1], Kevin Houston[2,3], Chathur Acharya[4], Mette Lauridsen[1] and Jasmohan S. Bajaj[2], (1)Hospital of South West Jutland, (2)Virginia Commonwealth University, (3)Virginia Commonwealth University, Richmond, VA, United States, (4)Ohio State University Wexner Medical Center

Background: Quality of life and symptom management are important for patients with chronic liver disease (CLD), which can precede cirrhosis development. CLD patients with/without cirrhosis have mood disorders which affect cognition. Cognitive impairment is testing using simple (Animal naming, ANT) or more complicated [Stroop and Psychometric hepatic encephalopathy score (PHES)] but their impact on QOL across the spectrum of CLD is unclear. Aim: Evaluate determinants of poor QOL across the CLD spectrum in a multi-center study. **Methods:** Outpatients with compensated cirrhosis and with pre-cirrhotic liver disease (F1-F3) were enrolled prospectively in 2 centers. Demographics, disease etiology, and co-morbid conditions were recorded. Fibroscan was performed. We evaluated depression & anxiety (Beck inventories BDI/BAI), PTSD, medications (psychoactive, PPI, diabetes), and alcohol use (AUDIT) and performed cognitive testing using ANT, PHES, and EncephalApp Stroop (has Off and OnTimes). Finally, the Sickness Impact Profile (SIP, generic QOL instrument with psychosocial and cognitive domains) was administered. Comparisons of those with/without cirrhosis were performed and Fibroscan kPa were correlated with cognition & QOL. Linear regression for prediction of physical & psychosocial SIP was performed for all pts using cirrhosis/not as a covariate. **Results:** We included 116 outpatients (11 F2, 34 F3 and 72 F4) from USA & Denmark. As shown in table 1, pts with cirrhosis were older, more likely to have alcohol, and lower likelihood of NAFLD (FigA). Other demographic measures, BMI, & co-morbid conditions/medications were similar. Cirrhosis pts as expected had higher Fibroscan kPa & creatinine/bilirubin. PROs: Beck inventories were worse in non-cirrhotic patients while frailty & alcohol intake were similar. QOL: SIP was higher (worse) in patients without cirrhosis, especially related to physical score. Cognitive testing: EncephalApp Off Time was higher in cirrhosis while other tests were statistically similar. Correlation with Fibroscan: EncephalApp OffTime ($r = 0.4$, $p < 0.0001$) and PHES Score ($r = -0.4$, $p = 0.003$) were linked with kPa (Fig B/C). No correlation of kPa with SIP was seen. Regression: *SIP physical*: higher BDI (T-value 2.32, $p = 0.02$), EncephalApp Offtime (2.80 $p = 0.006$) and lower age (-2.59, $p = 0.01$) were linked. *SIP psychosocial*: BDI (2.88, $p = 0.005$) & EncephalApp Offtime (2.25, $p = 0.03$) and BAI (4.09, $p < 0.0001$) were linked. Cirrhosis status was not significant. **Conclusion:** In a multi-center cohort of outpatients across the spectrum of CLD from F2 through compensated cirrhosis, we found that QOL was worse in pre-cirrhotic vs cirrhosis stages. Liver stiffness was linked with cognition, while QOL was correlated with mood disorders, which were higher in pre-cirrhotic stages. Mood disorders and impaired cognitive performance are independent determinants of QOL in a

217 | EFFICACY OF VITAMIN C ON AKI OUTCOMES IN CRITICALLY ILL PATIENTS WITH CIRRHOSIS AND MULTIDRUG-RESISTANT BACTERIAL INFECTIONS- A RANDOMIZED CONTROLLED TRIAL [NCT04494451

Rakhi Maiwall[1], Ashinikumar Kumar Hidam[2], Neha Chauhan[2], Samba Siva Rao Pasupuleti[3], Vikas Khillan[2], Harsh Vardhan Tevethia[1], Rajan Vijayaraghavan[2], Anupam Kumar[2], Sherin Thomas[2] and Shiv Kumar Sarin[4], (1)Institute of Liver and Biliary Sciences, New Delhi, (2)Institute of Liver and Biliary Sciences, (3)Mizoram University (A Central University), Pachhunga University College Campus, (4)Ilbs

Background: Infections with multidrug-resistant organisms (MDR) are a common cause of organ failures and increased fatality in patients with cirrhosis. Sepsis is associated with increased oxidative stress with widespread endothelial, cellular injury and acute deficiency of vitamin C. Polymyxins used for MDR infections have increased incidence of nephrotoxicity. We aimed to evaluate the impact of vitamin C on outcomes of sepsis-associated acute kidney injury (SA-AKI). **Methods:** Patients with nosocomial acquisition or proven MDR infections underwent open-label randomization into two groups. Group 1-received iv vitamin C (25 mg/kg or 1.5 gram maximum every 6 hourly) for 5 days along with polymyxin antibiotics while group 2 (SMT) received iv antibiotics alone. Primary end-point was AKI progression at day 5. Intention-to-treat analysis was performed. In a subset of patients ($n = 20$), we performed ELISA of plasma levels of vitamin-c, syndecan-1- a marker of endothelial glycocalyx degradation, von willebrand factor (vWF), and ADAMTS13 (a disintegrin and metalloproteinase thrombospondin motif) as markers of endothelial injury and microcirculation. **Results:** A total of 100 patients, 50 in each group, with mean age 48.7 ± 9.8 years, lactate 2.67 ± 2.27 μmol/L, SOFA scores 11.1 ± 3.6, 91% males, 60% alcohol-related were randomized. The KDIGO stage at enrolment was comparable 1:2:3 (68%:14%:18% vs. 64%:16%:20%; $p = 0.91$). Pneumonia was the commonest infection in 61%. Culture-proven MDR infections were seen in 51% patients, commonest being Acinetobacter baumannii (45.1%) and Klebsiella pneumoniae (27.4%). On intention-to-treat analysis, at day 5, AKI progression was significantly lower in Vit-C+SMT (18% vs. 54%; $p < 0.001$) with higher reversal of shock (56% vs. 22%; $p = 0.001$), lactate clearance at 12 hrs. (60% vs. 32%; $p = 0.009$) and 24 hrs. (56% vs. 34%; $p = 0.044$), reduction in SOFA score at 48 hrs. (52% vs. 26%; $p = 0.013$), and higher AKI recovery at day 14 compared to SMT (61.2% vs. 32%; $p < 0.001$) respectively. The 28-day mortality, need of dialysis, duration of ICU stay and mechanical ventilation were not different. There were no major adverse events requiring Vitamin C discontinuation, 20% patients developed thrombocytopenia. At day 5, a significant reduction in ADAMTS13, syndecan-1 and elevation in vWF levels and Vitamin-c levels were observed in Vit-C+SMT vs. SMT group.(Figure) **Conclusion:** Vitamin C improves outcomes of SA-AKI in cirrhosis patients with MDR infections. Reduction in endothelial injury, stabilization of endothelial glycocalyx with improvement in microcirculation, and possible reduction in nephrotoxicity of polymyxin antibiotics could be potential mechanisms of the observed benefit.

218 | COMPARISON OF BOLUS VERSUS CONTINUOUS INFUSION OF TERLIPRESSIN IN CIRRHOTIC PATIENTS WITH SEPTIC SHOCK: A RANDOMIZED CONTROLLED TRIAL (NCT 04819568)★

Priti Jain, Rakhi Maiwall, Shiv Kumar Sarin and Manoj Kumar Sharma, Institute of Liver and Biliary Sciences

Background: In-hospital mortality of cirrhosis patients with septic shock is higher than in other patients and exceeds 70%. These patients have high output cardiac failure secondary to severe systemic vasodilatation which is refractory to catecholamines. Terlipressin, as a second vasopressor, can provide the severe systemic vasodilation and improve macro and microcirculation. Terlipressin has been used either as continuous infusion or boluses in hepatorenal syndrome. However, at present none of studies reveal which would be a better mode of administration considering the reversal of hemodynamic and safety of patients. We aimed to study the efficacy of continuous infusion of terlipressin (T-CON) versus intermittent boluses (T-BOL) in reversal of septic shock in cirrhosis patients. **Methods:** In this study, 115 patients requiring noradrenaline more than 0.5 ug/kg/min to maintain mean arterial pressure (MAP) of more than 65 mm Hg were randomized into T-CON (n = 55) at 2mg/24`hour continuous infusion and T-BOL (n = 57) at intermittent boluses of same dosage. The dose was increased to maximum 4 mg. Primary end-point was reversal of shock over 72 hours. Secondary end-points included rebound hypotension, treatment-related adverse effects, effect on hemodynamic and mortality at 28 days. **Results:** Baseline parameters [aged (years) 47.41 ± 9.91 vs. 47.41 ± 9.95; $p = 0.44$, males (%) 93.1 vs. 96.4; $p = 0.68$, alcohol (%) 70.4 vs. 73.9; $p = 0.73$] were comparable in two groups; including serum lactate (μmol/L) [2.32 ± 0.95 vs. 2.55 ± 1.12; $p = 0.24$], SOFA scores [12.43 ± 3.62 vs. 12.48 ± 3.50; $p = 0.94$], MELD Na [33.13 ± 5.27 vs. 31.25 ± 8.01; $p = 0.16$] and MAP [73.88 ± 6.21 vs. 73.35 ± 6.18; $p = 0.65$]. Pneumonia is most common source of sepsis [89.7% vs. 77.2%; $p = 0.08$] in both the groups. On intent to treat analysis, reversal of shock at 72 hours [65.5% vs. 42.1%; $p = 0.02$] was significantly better in T-CON. Better improvement in hemodynamics, systemic vascular resistance [47.8% vs. 23.8%; $p = 0.04$], cardiac index [47.6% vs. 23.5%; $p = 0.06$] and lactate improvement [48.1% vs. 44.7%; $p = 0.84$] was achieved in T-CON. Significantly fewer incidences of rebound hypotension [43.1% vs. 78.9%; $p = 0.03$] and adverse effects of terlipressin [51.7% vs. 75.4%; $p = 0.01$] were noted in T-CON group. Common terminology criteria for adverse events (CTCAE) grading showed more incidence of Grade 3 [20% vs. 25.6%] and Grade 4 [46.6% vs. 44.2%]. Adverse events causing protocol violation (CTCAE 2-5) [37.9% vs. 57.9%; $p = 0.04$] were significantly higher in the T-BOL. Even on per-protocol analysis, reversal of shock was better in T-CON [69.4% vs. 41.7%; $p = 0.03$]. The duration of ICU stay, mechanical ventilation and 28 days mortality were not different between groups. **Conclusion:** Continuous infusion of terlipressin is superior to intermittent boluses as a second vasopressor in cirrhosis patients with septic shock by better improvement of hemodynamic and sustained reversal of shock.

Lee[4], Sherlot Song[1], Henry Lik Yuen Chan[6], Vincent Wai-Sun Wong[1], Victor De Ledinghen[7], Seung Up Kim[5] and Terry Cheuk-Fung Yip[8], (1)The Chinese University of Hong Kong, (2)Medical Data Analytics Centre (MDAC), the Chinese University of Hong Kong, (3) Ordeaux, (4)Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, South Korea, (5) Yonsei University College of Medicine, Seoul, Republic of Korea, (6)Chinese University of Hong Kong, Hong Kong, China, (7)University Hospital Bordeaux, (8)The Chinese University of Hong Kong, Hong Kong, 91, China

Background: Baveno VII was proposed for non-invasive identification of clinically significant portal hypertension. However, a substantial proportion of patients is classified in the grey zone (i.e., liver stiffness 15-24.9 kPa and/or platelet count $< 150 \times 10^9$/L). We aimed to evaluate the risk and predictors of hepatic decompensation in grey zone patients and determine the prognostic role of spleen stiffness measurement (SSM). **Methods:** Prospective cohorts (from Hong Kong, Korea and France) of patients who had undergone transient elastography examination for chronic liver disease were included. The risk of hepatic decompensation was estimated using competing risk regression with hepatocellular carcinoma and non-liver related death as competing events. **Results:** We identified 2763 compensated advanced chronic liver disease (cACLD) patients. There were 1243 (44.9%) and 536 (19.4%) patients in the Baveno VII grey zone and high-risk groups, respectively. The cumulative incidence of decompensation at 5 years was significantly different among the low-risk (0.6% [95% CI, 0.2-1.3%]), grey zone 4.2% (95% CI, 3.1-5.4%) and the high-risk groups (11.4% [95% CI, 8.7-14.6%]). By competing risk analysis, aetiology of liver disease (non-viral hepatitis), albumin-bilirubin score and alkaline phosphatase level were independently associated with decompensation in grey zone patients (Figure). The combination of Baveno-VII and spleen stiffness significantly reduced patients classified into the grey zone (12.8% in cACLD patients), while maintaining high discrimination of decompensation in the low- and high-risk groups. **Conclusion:** Patients in the grey zone of the Baveno VII criteria remain at high risk of hepatic decompensation. Clinical risk factors and spleen stiffness can further stratify the risk in such patients.

Background: Liver cells paracrinally affect neighboring cells through the release of extracellular vesicles (EVs), which may contain microRNAs (miRNAs). Our aim was to investigate the role of miRNAs enclosed in hepatocyte-derived EVs as modulators of endothelial dedifferentiation in chronic liver disease (CLD). **Methods:** EVs were purified from the supernatant of healthy (CT) or cirrhotic (CH) primary hepatocytes (hepEVs) from human and rat livers. *In vivo*: Healthy rats were intravenously treated with fluorescence-labelled hepEVs-CT, hepEVs-CH or vehicle (n = 10) to evaluate their biodistribution, sinusoidal endothelial uptake, and

LSEC phenotype through transcriptomic analysis and vWF and eNOS protein expression (n = 6). *In vitro*: Human hepEVs miRNAs profile was analyzed and those significantly deregulated in CH were validated in rat hepEVs by qPCR (n = 3 & 9, respectively). Exogenous over-expression of deregulated miRNAs was performed in CT-LSECs, followed by RNAseq and data analysis using Ingenuity Pathway Analysis (IPA) (n = 5). Endothelial deregulations due to miRNAs overexpression was compared to primary cirrhotic rat LSECs (n = 6) and human cirrhotic liver tissue (ethanol etiology, n = 12). **Results:** Upon in vivo administration, hepEVs-CH mostly accumulated in the liver, inducing endothelial dysfunction as suggested by the deregulation of 144 genes involved in pro-fibrogenic and inflammatory pathways, together with vWF upregulation and eNOS reduction. Characterization of human hepEVs-CH showed 37 miRNAs significantly deregulated in comparison to hepEVs-CT, being miR-A and miR-B validated in rat hepEVs-CH. Interestingly, miR-B target genes were significantly downregulated in CH-LSECs. Transcriptome analysis of LSECs transfected with miR-A or miR-B revealed 868 and 771 genes significantly deregulated vs miR-control. Moreover, the transcriptome of miR-B transfected cells showed 51% homology with CH-LSECs supporting the key role of miR-B in LSEC dedifferentiation. Indeed, IPA confirmed miR-B detrimental effects promoting deregulation in molecular processes involved in fibrogenesis, inflammation and cell death. Differential expression of specific genes of such pathways was confirmed in CH-LSECs and in endothelial population of human liver tissues, suggesting new potential targets for LSEC amelioration in CLD. **Conclusion:** miRNAs embedded in hepatocytes' EVs actively contribute to endothelial dedifferentiation in CLD. We propose this paracrine route as a novel therapeutic approach for endothelial dysfunction and portal hypertension in cirrhosis.

Modena, (28)Zhongda Hospital, Medical School, Southeast University, Nanjing, Jiangsu, China, Lanzhou, China

Background: The non-invasive models stratifying clinically significant portal hypertension (CSPH) are limited. We aim to develop a novel non-invasive model for predicting CSPH in patients with compensated advanced chronic liver disease, and investigate whether carvedilol could prevent hepatic decompensation in high-risk CSPH patients stratified by the novel model. **Methods:** In this study, the derivation cohort (n = 819) from a meta-analysis of 6 studies was used to identify risk factors and develop a novel noninvasive model for predicting CSPH. The novel model was validated in hepatic venous pressure gradient (HVPG) cohort (n = 151) and was further assessed for the ability of predicting hepatic decompensation in follow-up cohort (n = 1,102). The carvedilol-treating cohort (n = 51) was included to prove that carvedilol could prevent hepatic decompensation in high-risk CSPH patients stratified by the novel model. **Results:** In derivation cohort, liver stiffness measurement and platelets were identified as independent risk factors of CSPH and fitted to develop the novel CSPH risk model. A novel CSPH model was established as follows: 0.093510*LSM (kPa) - 0.01005*PLT (×10^9/L)-0.11. The novel model performed significantly better (all $p < 0.05$) than other methods in HVPG cohort (Figure 1A). The risk of CSPH was stratified by the cut-off values at -0.68 and 0. The cumulative incidences (1.7% vs 2.5% vs 15.8%) of decompensation were significantly different in the low-, middle- and high-risk ($p < 0.001$, Figure 1B) groups in follow-up cohort. The high-risk CSPH patients stratified by the novel model from carvedilol-treating cohort had significantly lower rates of decompensation than those of non-selective beta-blockers untreated high-risk CSPH patients from follow-up cohort ($p < 0.05$, Figure 1 C&D). **Conclusion:** Treatment with carvedilol among high-risk CSPH patients stratified by the novel model significantly reduces the risk of hepatic decompensation.

Background: Point-of-care echocardiography (POC-Echo) can be used to evaluate Cirrhotic Cardiomyopathy (CCM) and inferior vena cava (IVC) dynamics. The impact of cardiac function and IVC dynamics

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

on cirrhosis progression towards refractory ascites and HRS-AKI is yet to be defined. This study aims to evaluate the utility of CCM markers and IVC changes, assessed by POC-Echo, in predicting adverse outcomes in patients with cirrhosis and ascites. **Methods:** Serial POC-Echo was done at presentation, at 1 week following 1st paracentesis, and subsequently at 3 & 6 months from 1st assessment in decompensated patients with ascites. Clinical data, diuretic response, cardiac & renal biomarkers were prospectively collected at presentation, and at 6 & 12 months. CCM was defined as per CCM consortium 2020 criteria. Refractory ascites and HRS-AKI were diagnosed as per International Ascites Club 2015 criteria. Patients with coronary artery disease, valvular heart disease, those on dialysis, uncontrolled thyroid disease, portopulmonary hypertension, dilated cardiomyopathy, and hepatocellular carcinoma were excluded. (Figure 1) **Results:** We enrolled 130 cirrhotic patients with ascites at presentation [(62% men, aged 50 ± 12years, 61.5% alcohol-related, median MELD-Na 18.8 (16.3- 24.3)]. There were 34(28.3%) patients with CCM at presentation. Twenty-four patients subsequently developed refractory ascites (18.4%), and 22 (16.9%) patients developed at least 1 episode of HRS-AKI on 1-yr follow up. Overall mortality was 22(17%) at 1 year. When adjusted for age, gender, presence of diabetes, and etiology of liver disease, MELD-Na (aHR 1.3,95%CI: 1.2-2.4, $p < 0.001$), NT-proBNP (aHR 1.1, 95% CI: 1.01-1.31, $p = 0.032$), low Cardiac index at presentation (aHR 0.9, 95%CI:0.7-0.9, $p = 0.022$) and Cystatin C (aHR 1.2, 95%CI: 1.1-3.2, $p < 0.001$) predicted 1-year mortality. IVC dynamics showed poor association with diuretic response or HRS-AKI. CCM markers, namely, septal E/e' representing filling pressures (aHR 1.3, 95%CI: 1.3-4.3, $p = 0.033$) and e' representing myocardial relaxation (aHR 0.98, 95% CI 0.7-0.9, $p = 0.045$) were predictive of development of HRS-AKI on follow up. A reduction in cardiac index by 24% at 7 days predicted poor diuretic response, and preceded fall in mean arterial pressure. On adjustment for MELDNa, presence of CCM at baseline was associated with subsequent HRS-AKI [OR 3.2, 95%CI: 1.9-6.8, $p < 0.001$) and mortality [OR 4.1, 95% CI: 1.4-9.6, $p = 0.012$), but did not predict risk of refractory ascites. **Conclusion:** Cirrhotic cardiomyopathy is independently associated with HRS-AKI and 1-year mortality in patients with cirrhosis and ascites. Impaired cardiac index, which can represent undiagnosed CCM, may limit the potential for resolution of ascites. POC-Echo can predict prognosis and may inform therapeutic strategies in cirrhosis with ascites.

223 | MEAN ARTERIAL PRESSURE: A TARGET FOR ACUTE KIDNEY INJURY RESPONSE REGARDLESS OF ACUTE KIDNEY INJURY TYPE

Giuseppe Cullaro[1], Arjun Sharma[2], Jessica Beth Rubin[1], Jin Ge[1], Andrew Allegretti[3], Kavish R. Patidar[4] and Jennifer C. Lai[2], (1)University of California, San Francisco, (2)University of California-San Francisco, (3) Massachusetts General Hospital, (4)Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center

Background: Acute kidney injury (AKI) is a deadly complication of cirrhosis, and treatments are limited. Vasoconstrictors have been used to treat hepatorenal syndrome AKI (HRS-AKI), but the impact of augmenting mean arterial pressure (MAP) on all AKI types has not been studied, limiting the application of clinically-proven treatments for HRS-AKI to non-HRS-AKI. Herein, we precisely characterize the impact of MAP on AKI reversal, independent of subtype. **Methods:** Among decompensated cirrhosis patients in our ongoing, prospective cohort, we identified incident AKI episodes AKI was defined as a ≥ 50% increase in creatinine (sCr) from an outpatient baseline, a minimum of 7 days prior, that required hospitalization and lasted > 48 hours. AKI was staged according to guidelines using the peak hospitalization sCr.

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

AKI type was defined per guidelines and independently validated by 3 investigators. AKI reversal was defined as a return in sCr to within 0.3mg/dL of baseline. To determine the impact of MAP on AKI reversal, we completed time-dependent Cox-regression models with time beginning at the time of peak sCr and ending at death, discharge, or AKI reversal. We determined the optimal MAP cut-off for AKI reversal by comparing log-rank statistics. To investigate if the initial MAP or MAP trajectories were associated with AKI reversal, we calculated time-dependent MAP intercepts and slopes over time. **Results:** Among 1,626 participants (43% Female, 21% NAFL, 88% White) with a median MELDNa of 16 (14-20) followed for a median 1.5 years (0.6 – 3.5), we identified 306 episodes of AKI that lasted at least 48 hours and required hospitalization. Of these 306 episodes of AKI, 140 (46%) were HRS-AKI. As compared to those with non-HRS-AKI, those with HRS-AKI had significantly lower MAPs (73 v. 78), more severe AKI episodes (e Stage 2 AKI: 85% v. 72%), and less AKI reversal (16% v. 30%)(*p* d 0.004 for all). In time-dependent Cox models accounting for baseline sCr and AKI stage, each 5 mmHg increase in MAP was associated with 1.18x (1.07–1.31) the hazard of AKI reversal. AKI type (e.g., HRS-AKI) was not associated with AKI reversal in uni- or multivariable analyses ($p > 0.05$ for both). There was no interaction between AKI type and MAP ($p > 0.05$). In univariable, time-dependent Cox models, the optimal MAP cutoff most associated with AKI reversal was e 84mmHg ($p = 0.005$) (Figure 1). In time-dependent Cox models accounting for baseline sCr and AKI stage, both MAP slope (aHR 2.2 (1.3 – 3.6) per 1 mmHg increase per minute) and MAP intercept (1.01 per 1 mmHg increase (1.01 – 1.02)) were significantly associated with AKI reversal. **Conclusion:** Our analysis highlights that MAP, specifically e 84 mmHg, is associated with AKI reversal, independent of AKI type. This was true for both initial MAP (intercept) and the change in MAP over time (slope). Our data support the investigation of strategies to maintain a MAP e 84 mmHg among all cirrhosis patients with AKI, regardless of AKI type.

Figure 1. Survival Plot for Full AKI Reversal

224 | IMPROVED MEAN ARTERIAL PRESSURE FROM BASELINE TO THE END OF TREATMENT WITH TERLIPRESSIN IS ASSOCIATED WITH HEPATORENAL SYNDROME REVERSAL: A POOLED ANALYSIS OF 3 PHASE III STUDIES

Zachary Fricker[1], Antonio J. J. Sanchez[2], Marlyn J. Mayo[3], Khurram Jamil[4] and Michael P. Curry[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)University of Iowa Hospitals and Clinics, (3)University of Texas Southwestern Medical Center, (4)Mallinckrodt Pharmaceuticals, Bridgewater, NJ

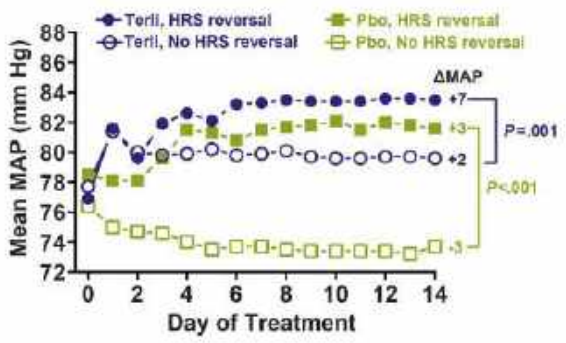
Background: Hepatorenal syndrome type 1 (HRS-1) is a rapidly progressive form of renal failure associated with high mortality in patients (pts) with decompensated cirrhosis and ascites. The FDA-approved vasopressin analogue, terlipressin (terli), improves renal function in pts with HRS-1 by reducing portal hypertension and increasing effective arterial volume and mean arterial pressure (MAP)—a marker of the hemodynamic response to treatment. Using the largest-to-date, prospective database of terli for the treatment of HRS, this subgroup analysis compared the change in MAP (ΔMAP) from baseline (BL) to the end of treatment (EOT) based on HRS reversal status and treatment group. **Methods:** Pooled data from the safety population (ie, treated pts) from 3 Phase III studies (OT-0401, REVERSE, and CONFIRM) were used to compare HRS reversal (defined as a serum creatinine d 1.5 mg/dL while on treatment, by EOT or discharge), and ΔMAP from BL to EOT (Day 0 to Day 14) by HRS reversal status and treatment group. MAP was averaged daily, before and 2 hours post-injection (4 per day) of terli or placebo (pbo); if data were missing, the last observation was

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

used. Associated p values were determined via a chi-square test (HRS reversal), ANOVA and Kruskal-Wallis test (ΔMAP by HRS reversal status), or a Wald test (odds ratio determined via logistic regression analysis). **Results:** In the pooled population (N = 598), 349 pts received terli and 249 pts received pbo. HRS reversal was achieved by more pts treated with terli than pbo (34% [117/349] vs 17% [42/249], $p < 0.001$). Mean MAP (± SD, mm Hg) at BL was similar between pts who achieved HRS reversal and those who did not, regardless of treatment (terli, 77 ± 11 vs 78 ± 13; pbo, 79 ± 10 vs 76 ± 11; Figure); whereas, pts who achieved HRS reversal had a significant ΔMAP (mean ± SD, mm Hg) from BL to EOT versus those with no HRS reversal (terli, +7 ± 11 vs +2 ± 13, $p = 0.001$; pbo, +3 ± 9 vs -3 ± 11, $p < 0.001$; Figure). A ΔMAP of ≥ 5 mm Hg was significantly associated with HRS reversal (odds ratio [95% confidence interval]: terli, 2.427 [1.531–3.846] $p < 0.001$; pbo, 2.545 [1.282–5.051] $p = 0.008$), regardless of treatment. **Conclusion:** In this analysis, significantly more terli-treated pts than pbo-treated pts achieved HRS reversal. A greater increase in MAP from BL to EOT was noted among those pts who achieved HRS reversal, with an increase in MAP of ≥ 5 mm Hg significantly associated with the odds of achieving HRS reversal, regardless of treatment.

Figure. Daily MAP in Patients Treated with Terlipressin or Placebo by HRS Reversal Status, Pooled Safety Population



HRS, hepatorenal syndrome; MAP, mean arterial pressure; ΔMAP, change in mean arterial pressure from baseline (ie, Day 0) to Day 14; Pbo, placebo; Terli, terlipressin.

225 | TRENDS IN UTILIZATION AND POST-TRANSPLANT OUTCOMES IN COVID-19 POSITIVE DECEASED DONOR LIVER TRANSPLANTATION★

Roy X Wang, Samir Abu-Gazala and Nadim Mahmud, Hospital of the University of Pennsylvania

Background: Initial recommendations from scientific societies cautioned against procurement of livers from COVID-19(+) donors. Growing evidence supports the short-term safety of liver transplantation from COVID-19 (+) donors. We described usage of liver transplants from COVID-19(+) donors during the COVID-19 pandemic and characterized associated transplant outcomes using data from the United Network for Organ Sharing registry. **Methods:** Liver transplant recipients from 7/2020-7/2022 were included in our retrospective cohort study. COVID-19(+) donors were identified by nucleic acid test or antigen positive testing. Trends in procurement of COVID-19(+) livers were compared against incident COVID-19 cases in the United States. Propensity score matching was used to account for differences between patient groups and to generate a 3:1 controls:cases matched cohort. Kaplan-Meier analysis was performed to plot survival distributions between donor COVID-19 status and transplant outcomes in the matched cohort. Fine and Gray competing risks regression (competing event = retransplantation) and standard Cox regression were performed to evaluate the association between donor status and patient and allograft survival, respectively. **Results:** The analytic cohort included liver transplants from 13,096 COVID-19(-) and 299 COVID-19(+) donors. Increased utilization of COVID-19(+) organs was observed after peaks in COVID-19 cases in the US (Figure A). COVID-19(+) donors were younger (median age 38 vs 41, $p < 0.001$), more likely to be donors after brain death (94.0% vs 88.8%, $p = 0.005$), and more likely to be in certain UNOS regions ($p < 0.001$). No significant differences in demographic data were observed between recipients of COVID-19(-) vs COVID-19(+) livers. After one year of post-transplant follow-up, no differences in patient survival (log-rank $p = 0.70$; subhazard ratio [sHR]: 1.11, 95% confidence interval [CI]: 0.61-2.00, $p = 0.74$; Figure B) or allograft survival (log-rank $p = 0.14$; hazard ratio [HR]: 1.44, 95% CI: 0.88-2.36, $p = 0.14$; Figure C) were noted between transplant from COVID-19(+) and COVID-19(-) donors. **Conclusion:** Patient and allograft survival were similar at one year post-transplant in a large cohort comparing COVID-19(-) and COVID-19(+) donors. Utilization of livers from COVID-19(+) donors paralleled disease incidence in the US and varied across UNOS region. Liver transplant from COVID-19(+) donors has acceptable short-term outcomes and may represent an opportunity to expand organ access.

226 | PREDICTORS OF HOSPITAL-RELATED OUTCOMES OF COVID-19 INFECTION IN LIVER TRANSPLANT RECIPIENTS IN UNITED STATES: A NATIONWIDE INPATIENT STUDY

Abdullah Sohail, The University of Iowa Hospitals and Clinics, Khadija Naseem, Cleveland Clinic Foundation, Ahmad Khan, Case Western Reserve University and Kyle E. Brown, University of Iowa Carver College of Medicine, Iowa City, IA

Background: Liver Transplant (LT) recipients are vulnerable to severe infections because of their immunocompromised status. Previous studies had conflicting results regarding the impact of COVID-19 infection on LT recipients. However, most of these studies were single-centered, had a small sample size, or lacked national-level data. In this study, we utilized a large inpatient database to investigate hospital-related outcomes in LT recipients with concurrent COVID-19 infection. **Methods:** We queried the 2020 National Inpatient Sample database to identify LT recipients with COVID-19 hospitalizations who underwent LT in the index hospitalization or had a history of LT. We excluded patients aged < 18 years and trauma-related hospitalizations. Our primary outcomes included comparing all-cause inpatient mortality, mechanical ventilation (MV), and intensive care unit (ICU) utilization between COVID and non-COVID groups. Secondary outcomes included resource utilization, including length of stay (LOS) and total hospitalization charges in both groups. We conducted univariate and multivariate regression analyses to identify the independent predictors of mortality. **Results:** A total of 2,259 adult LT recipients hospitalizations with concurrent COVID-19 infection were identified. The mean age of these patients was 62.42 vs. 59.60 years for the LT without COVID-19 group; the majority were male (59.3% vs. 52%) and Caucasian (56.5% vs. 50.6%) in both groups. Patients with LT and COVID-19 infection had higher mortality (13.70% vs. 2.47%, $p = 0.01$) and developed more septic shock (10.6% vs. 7.2%; $p = 0.01$) but had no increase in ICU utilization (11.3% vs.12.3%; $p = 0.06$) or MV requirement (13.9% vs. 11.9%; $p = 0.16$) as compared to the non-COVID group. Regarding resource utilization, mean LOS (8.96 d vs. 8.17 d; $p = 0.12$) was similar, but mean hospitalization charges were higher in the non-COVID group ($125,961 vs. $177,058; $p = 0.00$). On univariate and multivariate logistic regression analyses, COVID-19 infection, septic shock, MV, and ICU were independent predictors for mortality. **Conclusion:** We found that COVID-19 infection is an independent predictor of mortality in LT recipients, with a 5-fold increase in mortality compared to LT patients without COVID-19. This data (2020) predates the availability of COVID vaccines, and many LT recipients have since been vaccinated. It will be interesting to see if these trends are present for subsequent years of the pandemic. Moreover, when these patients acquire infection, they should be treated promptly with the latest therapies to improve their clinical outcomes.

227 | REAL-TIME MEASUREMENTS OF BIOMARKERS FOR GRAFT ASSESSMENT AND PATIENT MONITORING

Florian Huwyler[1], Janina Eden[2], Jonas Binz[1], Leslie Cunningham[1], Richard Sousa Da Silva[2], Max Hefti[1], Pierre A. Clavien[3], Philipp Dutkowski[2] and Mark William Tibbitt[1], (1)ETH Zurich, (2)University Hospital Zurich, (3)University of Zürich

Background: Due to a global shortage of liver grafts, transplant surgeons increasingly resort to transplanting DCD (donated after circulatory death) organs. However, these organs are more susceptible to complications as a result of increased ischemic reperfusion injury. The worst of which is primary non-function, requiring an urgent re-transplantation. To date, there is no reliable metric to estimate the amount of reperfusion injury prior to transplantation. Clinical studies have demonstrated a correlation between flavin mononucleotide (FMN) in the perfusate of hypothermically perfused (HOPE) liver grafts and the risk of post-operative complications, related to mitochondrial damage. These findings indicate that FMN can be used as a biomarker for liver graft quality and motivate the need for robust real-time measurement of FMN. **Methods:** We developed a portable spectrofluorometric device, that can be used directly in the operating room during HOPE, which measures FMN concentration in the perfusate in real-time. Continuous FMN measurements were collected for 26 extended criteria DCD liver grafts prior to being transplanted or discarded. **Results:** Our real-time measurements show that FMN concentration in the perfusate not only indicates severe risk of complications, but also correlates with patient recovery after transplantation. Specifically, post-transplant transaminase expression and coagulation factor synthesis correlated with released FMN. This demonstrates how our technology can be used to assess DCD grafts prior to transplantation, mitigating the risk of non-anastomotic complications and primary non-function. The same approach can be used to also measure other biomarkers non-invasively in perfusate, or even dialysate of dialysis patients. **Conclusion:** Here, we show how liver specific biomarkers that previously were only used in research, could be successfully translated to clinical practice. Further, unprecedented continuous real-time data provides better data sets for research and improved patient diagnosis.

228 | EARLY GRAFT FAILURE AFTER LIVING DONOR LIVER TRANSPLANT

Ahmad Anouti[1], Moustafa Al Hariri[2], Lisa B. VanWagner[3], William M. Lee[3], Arjmand R. Mufti[3], Mark Pedersen[4], Jigesh Shah[1], Steven Hanish[1], Parsia A. Vagefi[5], Thomas G. Cotter[4] and Madhukar Patel[3], (1) University of Texas Southwestern, (2)Qatar University, (3)University of Texas Southwestern Medical Center, (4) University of Texas Southwestern Medical Center, Dallas, TX, (5)UT Southwestern Medical Center

Background: Living donor liver transplantation (LDLT) has been increasing in the United States (US). While data exists on longer-term patient and graft outcomes, a contemporary analysis of short-term outcomes is needed to better understand risk factors and opportunities for improvement. **Methods:** Adult (≥ 18 y) LDLT recipients from January 2004 to December 2021 were analyzed from the United States Scientific Registry of Transplant Recipients (SRTR). Graft status at 30 days was assessed with graft failure defined as retransplantation or death. Bivariate analysis of continuous and categorical variables was performed, and a multivariable logistic regression was used to identify risk factors of early graft failure. **Results:** During the study period, 4,544 LDLTs were performed with a graft failure rate of 3.4% (155/4544) at 30 days. Grafts from male donors (aOR: 0.63, CI: 0.45-0.89, $p = 0.009$), right lobe grafts (aOR: 0.41, CI: 0.27-0.62, $p < 0.001$), older recipient age (aOR: 0.99, CI: 0.97-0.99, $p = 0.015$), and higher recipient albumin (aOR: 0.73, CI: 0.57-0.93, $p = 0.011$) were associated with superior early graft outcomes, whereas, Asian recipient race (vs. White;

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

aOR: 3.37, CI: 1.98-7.07, $p < 0.001$) and a history of recipient PVT (aOR: 2.7, CI: 1.52-4.77, $p = 0.001$) were associated with inferior outcomes. LDLTs performed during the most recent 2016-2021 period (compared to 2004-2009 and 2010-2015) resulted in significantly superior outcomes (aOR: 0.45, $p < 0.001$, CI: 0.23-0.69) (Table 1). **Conclusion:** Our study demonstrates that while short-term adult LDLT graft failure is uncommon, there are opportunities for optimizing outcomes by prioritizing right lobe donation, improving candidate nutritional status, and careful pretransplant risk assessment of candidates with known PVT. Notably, a period effect exists whereby increased LDLT experience in the most recent era correlated with improved outcomes.

Table 1: Multivariable analysis of early graft failure in LDLT recipients.

Variables	aOR	CI	Multivariable P-Value

229 | PHENOTYPIC CLUSTERING IDENTIFIES HIGH-RISK PROFILES FOR SARCOPENIA & 1-YEAR POST-TRANSPLANT MORTALITY IN PATIENTS WITH END-STAGE LIVER DISEASE

Hiteshi Dhami- Shah[1], Gautham Pranesh[2], Disha Mogre[3], Ameet Mandot[1], Rashmi Badhe[1], Parul Garde[1], Madhuri Nigudkar[3], Anuradha Ramesh[3], Jagmeet Madan[3] and Samir Ramnik Shah[1], (1)Global Hospitals, Mumbai, (2)Mitopower LLC, (3)SVT College of Home Science

Background: Sarcopenia in end-stage liver disease (ESLD) has been identified as a risk factor for increased mortality. Radiological parameters; psoas muscle area index (PMAI) & transverse psoas muscle thickness index (TPMTI) assess muscle quantity. While psoas muscle density index (PMDI) assesses muscle quality. Both identify muscle wasting, atrophy & myosteatosis. Aim: The study evaluated ESLD phenotypes & their association with 1-year post-transplant mortality. The relationship between high PMAI/TPMTI & low PMDI, suggesting a possibility of larger but weaker muscles due to myosteatosis was investigated. **Methods:** A total of 101 ESLD subjects were included. A retrospective analysis was conducted on 86 subjects with complete data. Clinical characteristics (age, PMAI, TPMTI, PMDI, CTP score, MELD score, BMI) were normalized using z-scores. Hierarchical & k-means clustering identified distinct phenotypes. Mortality rates across clusters were analyzed to identify high-risk groups. **Results:** Five distinct phenotypes were identified. Cluster 1 represented individual's with an average age & high PMAI, TPMTI, BMI & low PMDI. CTP & MELD scores were close to average. Cluster 2 comprised young subjects with low PMAI, BMI, CTP, MELD & high PMDI. Cluster 3 was similar to Cluster 2, with younger subjects & baseline PMAI, PMDI, BMI & low TPMTI. CTP & MELD scores were high. Cluster 4 consisted of older individual's with high PMDI & low PMAI, TPMTI, BMI, CTP & MELD. Cluster 5 represented a baseline age group with baseline PMAI, high BMI & low PMDI, TPMTI, CTP & MELD. Cluster 1 had the highest mortality rate 41.7% & Cluster 2 had the lowest mortality rate (0%) compared to the overall mortality rate of 19.8%. Clusters 3, 4, & 5 had similar mortality rates of 17.4%, 17.9%, & 15.8%, respectively. **Conclusion:** Clustering effectively identified high-risk phenotypes for sarcopenia & 1-year mortality in ESLD patients. Cluster 1, despite average age & baseline MELD, exhibited the highest mortality rate with low PMDI & high PMAI, TPMTI, & BMI. This suggests the possibility of myosteatosis contributing to mortality. Cluster 2 represented the lowest-risk group with younger patients having low BMI, MELD & high PMDI. These findings have implications for risk stratification & potential interventions to improve outcomes in this vulnerable patient population post-transplant.

230 | PREHABILITATION IN LIVER TRANSPLANT CANDIDATES IMPROVES FRAILTY METRICS LEADING TO IMPROVED SURVIVAL

Fei-Pi Lin[1], Pamela M Bloomer[1], Michele Molinari[1], Christopher Hughes[1], Gavin E. Arteel[2], Michael A. Dunn[3] and Andres Duarte-Rojo[4], (1)University of Pittsburgh Medical Center, (2)University of Pittsburgh, (3)University of Pittsburgh, Ossian, IN, (4)Northwestern University Feinberg Scho

Background: An outpatient prehabilitation strategy is feasible and effective in improving frailty in liver transplant (LT) candidates. We previously showed that attendance to physical therapy (PT) sessions results in a significant reduction in mortality, but were unable identify the frailty change threshold that yields such benefit. The aim of this study was to determine the impact of variation of frailty metrics on mortality and to identify a minimum clinically important difference that could provide a survival advantage to LT candidates with frailty. **Methods:** LT candidates who attended PT consultation at our center between 2018 and 2022 were prospectively included. All patients received a personalized prehabilitation prescription and regular follow-up visits with a dedicated LT PT. Physical fitness assessment included the LFI and 6-min walk test (6MWT). Changes in LFI and 6MWT between PT visits were averaged and used as a measure of prehabilitation engagement/success. Multivariable survival models, including competing risks models against LT, were fit to investigate the impact of frailty metrics and prehabilitation engagement on mortality. **Results:** A total of 1275 patients were prospectively included (59% male, age 57 ± 11, BMI 30 ± 7, MELD 14 ± 6) and their data collected during 1973 PT visits (193 attended two visits, 162 attended three or more). Main indications for LT were alcohol (31%) and NAFLD (29%). Median LFI was 3.79 (3.21-4.41) and 23% were frail, whereas median 6MWT was 336 m (243-404) and 26% were frail; between-metrics agreement was 83%. In subjects who improved their LFI score (n = 227/351), the absolute change was -0.38 (-0.17 to -0.84), whereas for 6MWT (n = 209/332), the absolute change was 54 m (25-105). A total of 677 (55%) patients were waitlisted, LT occurred in 462 (37%) and death in 335 (26%). LFI improvement by 0.4 was associated with lower pre-transplant mortality (Table 1 and Figure 1). Sensitivity analyses restricted to patients with two or more LT PT visits did not change the findings. Surprisingly, improvement in 6MWT was not associated with a survival advantage. **Conclusion:** Prehabilitation in LT candidates was associated with significant improvement in LFI and 6MWT. A minimum improvement in LFI by 0.4 was associated with better survival, independently of frailty status, and it could be used as an objective and clinically relevant on-training endpoint for frailty intervention.

Table 1: Cox proportional hazards multivariable survival analysis; Competing risks model including liver transplantation as a competing risk.

	Proportional Hazards Survival Analysis			Competing Risks Survival Analysis		
	HR	95% CI	p-value	sHR	95% CI	p-value
Age (year)	1.01	1.00-1.02	0.014	1.01	0.99-1.02	0.056
Alcohol etiology	0.71	0.54-0.92	0.013	Excluded (stepwise backward)		
Albumin (g/dL)	0.58	0.47-0.72	<0.001	0.66	0.52-0.83	0.001
MELD (point)	1.05	1.03-1.08	<0.001	1.04	1.02-1.07	<0.001
Frailty by LFI (point)	1.85	1.52-2.51	<0.001	2.87	2.20-3.74	<0.001
LFI improved by ≥0.4	0.46	0.28-0.75	0.002	0.46	0.27-0.78	0.004

All models adjusted by sex and number of PT visits

Figure 1: Competing-risks regression curve. LFI improvement by at least 0.4 was associated with improved mortality.

De Cruces, (12)CH Canarias, (13)H Val D'hebron, (14)Complexo Hospitalario Universitario De Santiago, Coruña, (15)HU La Fe, (16)University of Navarra, (17)CNIO, (18) Itainnova, (19)Universidad De Zaragoza, (20)Servicio De Aparato Digestivo. Hospital General Universitario Gregorio Marañón

Background: Comorbidity plays an important role in the mortality of patients both on the waiting list and after liver transplantation (LT). To analyze the impact of comorbidities on LT, a prospective and multicentre study (HEPA_TIC) has been launched. **Methods:** Analysis of 1440 consecutive patients included in LT waiting list, in 18 Spanish hospitals, from October 2019 to October 2022. Retransplantation, multivisceral transplantation and patients younger than 16 years were excluded. Comorbidities at the time of listing, and follow-up variables were collected. The analysis of comorbidities was disaggregated by sex. To group comorbidities, three types of unsupervised algorithms were applied using matching-learning: agglomerative clustering, Kmodes, and spectral clustering. Groups were compared by the log Rank test in their evolution. **Results:** Patients were predominantly male (76.6%) with a median age of 61.7 years IQR (56-66); 60.7 years in females IQR (54-67) and 61.8 in males (57-66) ($p < 0.05$). Decompensated cirrhosis was the most frequent indication with no differences in both sexes. Hepatocellular carcinoma was significantly more frequent in males (45.9% vs. 24.6%; $p < 0.001$). The most frequent comorbidities were diabetes and arterial hypertension. Diabetes, COPD and cardiovascular disease were significantly higher in men ($p < 0.05$), while chronic kidney disease was higher in women ($p < 0.05$). Only 8.1% of the listed patients had no comorbidities. The number of comorbidities was higher in males than in females ($p < 0.001$). 34% of the listed men and 19.8% of the women had more than three comorbidities. The number of comorbidities was associated with lower survival after liver transplantation ($p = 0.04$). The three types of algorithms grouped patients into clusters that differed in the prevalence of various comorbidities. Follow-up analyses found significant differences ($p > 0.05$) in survival after transplantation among the clusters defined by the algorithms. Metabolic syndrome represented the greatest difference between the groups. Groups with a higher prevalence of this syndrome had a lower survival rate after transplantation. **Conclusion:** Comorbidities are highly prevalent in patients with liver disease on the transplant waiting list, and they differ between men and women. A higher number of comorbidities is associated with lower survival after transplantation. There are patterns of patients with different comorbidities that exhibit differences in survival after LT.

232 | NON-ALCOHOLIC STEATOHEPATITIS (NASH) HAS BECOME THE MOST COMMON INDICATION FOR LIVER TRANSPLANTATION AMONG CANDIDATES WITH HEPATOCELLULAR CARCINOMA IN THE UNITED STATES

Zobair M. Younossi[1,2,3], Reem Al Shabeeb[4], Katherine Elizabeth Eberly[4], Dipam Shah[4], Veronica Nguyen[1], Janus Ong[5], Saleh A Alqahtani[6], Linda Henry[1,4,7] and Maria Stepanova[7], (1)Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, (2)Center for Liver Disease, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, VA, (3)Inova Medicine, Inova Health System, Falls Church, VA, (4)Inova Health Systems Medicine Service Line, Falls Church, VA, (5)College of Medicine, University of the Philippines, Manila, Philippines, (6) Johns Hopkins University School of Medicine, (7)Center for Outcomes Research in Liver Diseases, Washington, DC

Background: High prevalence of obesity in the U.S. is driving the burden of non-alcoholic steatohepatitis (NASH) and associated adverse clinical outcomes including NASH-related end-stage liver disease and hepatocellular carcinoma (HCC). Our aim was to assess the most recent trends in patients with chronic liver disease (CLD) listed for liver transplantation (LT) in the U.S. using a national registry. **Methods:** The Scientific Registry of Transplant Recipients (SRTR) was used to select adult (≥ 18 y at listing) LT candidates included between 2013-2022. Primary and secondary listing etiologies were used to identify patients with the most common etiologies of CLD. **Results:** There were 116,292 LT candidates with a known etiology of CLD. In candidates without HCC, the most common CLD etiology was alcoholic liver disease (ALD) which increased from 23% (2013) to 48% (2022); the most rapid increase happened

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

between 2019-2022 (from 38% to 48%). The second most common indication for non-HCC LT was NASH, the proportion of which increased from 19% (2013) to 27% (2022). In contrast, rates of chronic hepatitis C (CHC) decreased from 28% (2013) to 4% (2022) and chronic hepatitis B (CHB) declined from 1.8% (2013) to 1.1% (2022) (all trend $p < 0.01$). Cumulatively, 21% (n = 24,657) of candidates listed for LT had HCC. However, the proportion of HCC decreased from 24-25% (2013-2016) to 17% (2021-2022). Among candidates with HCC, the proportion of CHC decreased from 60% (2013) to 27% (2022) while NASH increased from 10% to 31% and ALD from 9% to 24%, respectively (all trend $p < 0.0001$) (Figure). On the other hand, the proportion of CHB remained stable between 5 to 7% (trend $p = 0.62$). Among candidates with HCC, the rapid increase in the proportion of NASH continued during the most recent study years: 20% (2018) to 28% (2020) to 31% (2022), and the increasing trend remained significant overtime after adjustment for candidates' age, sex, ethnicity, obesity, and type 2 diabetes. The average magnitude of increase in the proportion of NASH in candidates with HCC in 2018-2022 was +2.8 percentage points per year ($p < 0.0001$). **Conclusion:** The impact of different etiologies of CLD to LT burden in the U.S. has been changing over the last decade. ALD and NASH remain the two most common indications for non-HCC-LT, while NASH is currently the most common indication for HCC-LT.

233 | PREDICTORS OF RENAL RECOVERY AND SURVIVAL OUTCOMES IN LIVER TRANSPLANT RECIPIENTS MEETING SLK ELIGIBILITY CRITERIA

Richie Manikat, Allison J. Kwong, Xingxing Cheng, Bonnie Chow, Meera Bhargava, Sudharshan Achalu, Thomas Pham, W. Ray Kim and Paul Yien Kwo, Stanford University School of Medicine

Background: The 2017 UNOS simultaneous liver-kidney transplant (SLK) policy establishes the minimum eligibility criteria for SLK listing and a mechanism to expedite kidney after liver transplantation (Safety Net). Candidate selection for SLK versus Safety Net requires further refinement. Our AIMS were two-fold: 1) to analyze the pre- and post-liver transplant progress of patients eligible for SLK, who instead underwent liver transplant (LT); 2) to compare the outcomes of these patients with a historical cohort of SLK patients. **Methods:** Single center retrospective chart review was completed for LT recipients with eGFR (estimated glomerular filtration rate) < 35 ml/min at time of LT or had a kidney transplant evaluation episode opened prior to LT from 2017-2022. These patients were compared to patients that received SLK from 2007-2016, prior to the 2017 policy change. Demographic data and clinical data, length of hospital stay, number of hospital days post-transplant, and survival data were collected. Renal recovery was defined as recovery of eGFR to > 20ml/min post LT. **Results:** 45 LT recipients who qualified for potential SLK from 2017-2022 and 55 patients who received SLK from 2007-2016 were compared. Of these 45 patients (Safety Net group), 17 patients received a kidney transplant after a liver transplant (KALT), and 28 patients received a liver transplant alone (LTA). Median follow-up time was 6.4 years in the SLK group and 2.2 years in the safety net group. No difference was found in overall three-year post-LT survival between patients who did or did not receive SLK ($p = 0.14$) (Table). Among the 28 patients that received LTA, 19 achieved renal recovery within 12 months, 7 were declined for KALT (4 for frailty and 3 for other causes) and 2 died. Five of these patients remain on dialysis. In the patients with renal recovery, average eGFR 1-year post-transplant was 35 ml/min. In a multivariable logistic regression model adjusted for age and sex, predictors of renal recovery included male sex ($p = 0.02$) and absence of diabetes ($p = 0.04$). Between the KALT and LTA groups, there were no significant differences in days in hospital after transplant, length of ICU stays, number of hospitalizations, or episodes of rejection. **Conclusion:** Safety Net protocol provides similar survival in patients that receive a liver transplant alone compared to a historical SLK cohort. In our cohort, 19 out of 28 potential SLK candidates

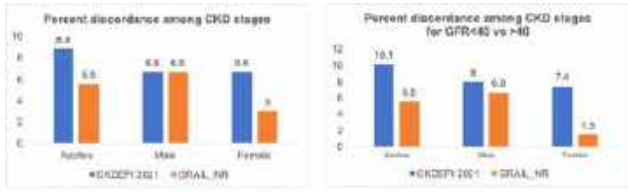
234 | ESTIMATING GFR IN PATIENTS WITH DECOMPENSATED CIRRHOSIS AWAITING TRANSPLANT: UPDATED GRAIL WITHOUT RACE PERFORMS BETTER THAN CKD EPI 2021

Luis Garrido-Treviño, Mohammad Amin Fallahzadeh, Giovanna Saracino and Sumeet Asrani, Baylor University Medical Center, Dallas, TX

Background: Accurate estimation of glomerular filtration rate (GFR) is important for decisions regarding dual organ transplantation and patient management on the waitlist. Currently, a novel race free equation (CKD-EPI AS, Inker et al. NEJM 2021) is the reference standard for estimating GFR across the US. However, its performance in patients with cirrhosis was never validated. Further, performance of CKD EPI AS 2021 may be suboptimal in cirrhosis patients with low GFR, ascites and frail patients (AASLD 2022). We have shown that liver specific equations (GFR assessment in liver disease, GRAIL, Asrani et al. Hepatology 2019) have better performance as compared to other GFR equations. We sought to develop and validate an updated GRAIL without race (GRAIL_NR). **Methods:** We examined all cirrhosis patients with protocol measured GFR between 1985-2015 using iothalamate clearance. We estimated GFR using novel non-race equations: CKD-EPI 2021, CKD-EPI refit to liver population, as well as GRAIL_NR. Model was developed using cumulative probability models, associations between variables and mGFR were examined via linear association and restricted cubic spline and validated using split sample. The final components were age, sex, albumin, creatinine, and BUN. Addition of interactions or other variables (BSA, serum sodium) did not appreciably improve performance. We compared Concordance Correlation Coefficient, bias, precision, % agreement CKD stages and measurements within 30% of mGFR (p30). We further examined performance in relevant subsets: ascites, sex and low GFR (GFR < 40 vs > 40 ml/min/1.73m^2). **Results:** Updated GRAIL_NR was more precise and had higher concordance (0.82, 0.79-0.85) as compared to CKD-EPI 2021 (0.78, 0.74-0.81) as well as refit CKD-EPI AS_Liver (0.77, 0.73-0.81). As compared to CKD-EPI 2021, updated GRAIL_NR had lower bias (-0.8 vs. +1.56, mGFR-eGFR), higher percent agreement for CKD staging (95.4% vs. 93.3%), higher agreement for low GFR vs high GFR (cutoff 40, 95.4% vs. 93.7%) and higher measurements within 30% of mGFR (78.7% vs. 74.3%). We examined differences in relevant subsets. Percent discordance between estimated CKD stage and actual CKD stage was lower with GRAIL_NR in patients with ascites and females. (Figure) This was especially pronounced when limited to patients with GFR < 40ml/min/1.73m^2 **Conclusion:** A race-free eGFR equation developed and validated in patients with may help guide decision making in patients with decompensated cirrhosis listed for transplantation, especially in subsets where prediction of renal function is suboptimal.



Percent discordance between estimated CKD stage and actual CKD stage was lower with GRAIL_NR in patients with ascites and females. This was especially pronounced when limited to patients with GFR<40ml/min/1.73m^2

(2)Histoindex Pte Ltd, Singapore, (3)Bristol Myers Squibb

Background: FDA recommended histopathological end-points for NASH clinical trials may not be fully evaluated by conventional histological staging. Shorter time frames in NASH trials make it difficult to assess changes in treatment-induced fibrosis with current classification systems. Assessment of specific morphological fibrosis parameters and their quantification in specific zones of NASH-CRN classification, can be done by SHG/TPE-based AI platforms. NASH-CRN parameters may map overall fibrosis changes, but any specific drug-induced changes may not be fully quantified by these alone. This detailed analysis helps overcome limitations of conventional histological examination and describe fibrosis changes and drug-induced effects. **Methods:** Biopsy slides were obtained from FALCON-1 clinical trial (24-week randomized double-blind, placebo-controlled phase 2 study of 10, 20, and 40 mg pegbelfermin in NASH patients, NCT03486899). SHG/TPE microscopy and AI analysis were used to estimate NASH-CRN fibrosis parameters as continuous variables for 176 paired biopsy slides. Additional Zone 2 fibrosis parameters were evaluated to measure drug-induced effects. Based on pathologist classification of changes in fibrosis stage of biopsies comparing baseline and post-treatment slides, they were divided into three groups: Progressive (1-stage or more increase in fibrosis), Regressive (1-stage or more decrease in fibrosis), and No-change (no change in fibrosis stage). These changes were depicted using radar maps with normalized values. **Results:** In regressive group, there was reduction of fibrosis as per NASH-CRN parameters in both treatment and placebo cohort, measured by SHG/TPE microscopy and AI analysis. Reductions in placebo cohort were statistically insignificant; in treatment cohort (which included patients of all drug doses combined), reduction in fibrosis of periportal and perisinusoidal regions were statistically significant (Figure 1A). Fibrosis measurements in No-change group follow similar pattern of reduction as in Regressive group (Figure 1B). Specific Zone 2 fibrosis parameters (S1-S3) for treatment-cohort of all 3 groups are shown in Figure 1C. These show statistically significant reductions in fibrosis parameters post-treatment, despite being labelled as regressive, no-change and progressive by pathologist classifications. Parameters S1-S3 in placebo-cohort also show reductions, but were statistically insignificant. **Conclusion:** SHG/TPE-based AI platforms allowed for quantification and mapping of specific parameters revealing improvement in both NASH-CRN and Zone 2 fibrosis parameters not seen in manual NASH-CRN staging. They may be able provide quantitative drug-induced specific changes in fibrosis which can be more sensitive than manual staging. This may be ideal for phase 2 clinical trials which have short time frames, and help better design and strategize phase 3 trials.

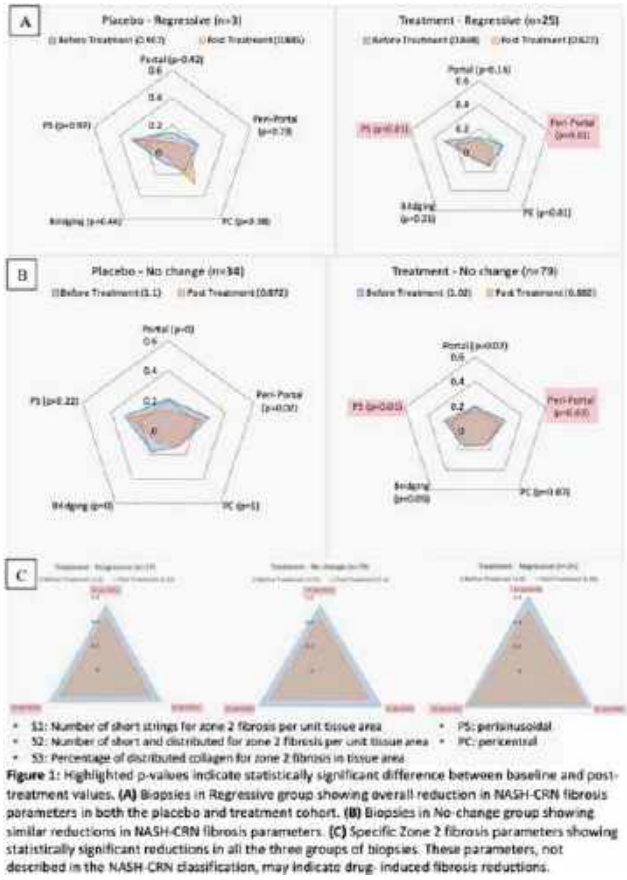

Figure 1: Highlighted p-values indicate statistically significant difference between baseline and post-treatment values. **(A)** Biopsies in Regressive group showing overall reduction in NASH-CRN fibrosis parameters in both the placebo and treatment cohort. **(B)** Biopsies in No-change group showing similar reductions in NASH-CRN fibrosis parameters. **(C)** Specific Zone 2 fibrosis parameters showing statistically significant reductions in all the three groups of biopsies. These parameters, not described in the NASH-CRN classification, may indicate drug- induced fibrosis reductions.

Helena Isoniemi[2], Hannele Yki-Järvinen[2] and Rohit Loomba[4], (1)National University of Singapore, (2) University of Heslinki, (3)University of California, San Diego, (4)University of California San Diego

Background: Nonalcoholic fatty liver disease (NAFLD)-related fibrosis is heritable, but it is unclear how family history may be used to identify first-degree relatives with advanced fibrosis. We aimed to develop and validate a simple risk score to identify first-degree relatives of probands who have undergone assessment of liver fibrosis who are at higher risk of NAFLD with advanced fibrosis. **Methods:** This prospective, cross-sectional, familial study consisted of a derivation cohort from San Diego,USA, and a validation cohort from Helsinki, Finland. This study included consecutive adult probands (n = 242) with NAFLD and advanced fibrosis, NAFLD without advanced fibrosis, and non-NAFLD, with at least one of their first-degree relatives. All included probands and first-degree relatives underwent evaluation of liver fibrosis, the majority by magnetic resonance elastography.Models were derived utilizing the UCSD (derivation) cohort to detect the presence of NAFLD with advanced fibrosis. Univariable and multivariable logistic regression analyses were performed in the UCSD (derivation) cohort for factors associated with NAFLD and advanced fibrosis. To develop a simple risk score based on a points system, regression coefficients from the logistic regression model were transformed into scores by rounding to an integer. The score was then externally validated in the Helsinki (validation) cohort. **Results:** A total of 396 first-degree relatives (64% male) were included. The median (IQR) age and BMI were 47 (32-62) years and 27.6 (24.1-32.5) kg/m^2, respectively. Age (1-point), type 2 diabetes (1-point), obesity (2-points) and proband with NAFLD and advanced fibrosis (2-points) were predictors of advanced fibrosis among first-degree relatives in the derivation cohort (n = 220) and formed the NAFLD Familial Risk score. The area under the receiver operator characteristic curve (AUC) of the NAFLD Familial Risk score for detecting advanced fibrosis was 0.94 in the validation cohort (n = 176). The NAFLD Familial Risk score outperformed the Fibrosis-4 index in the validation cohort (AUC 0.94 versus 0.70, $p = 0.02$). **Conclusion:** The NAFLD Familial Risk Score accurately identifies NAFLD with advanced fibrosis in first-degree relatives of probands who have undergone an assessment of liver fibrosis. It is simple, does not require a calculator or extensive laboratory investigations, and may be a helpful alternative to FIB-4 for screening first-degree relatives. These data may have implications for surveillance in NAFLD.

237 | THE IMPACT OF GENETIC RISK ON THE PREVALENCE OF ADVANCED FIBROSIS AND CIRRHOSIS IN PROSPECTIVELY ASSESSED PATIENTS WITH TYPE 2 DIABETES

Lana Bridi[1], Saaket Agrawal[2,3,4], Erick Sandoval[1], Kaleb Tesfai[1], Egbert Madamba[1], Ricki Bettencourt[1], Lisa M. Richards[1], Amit V. Khera[3,4,5], Rohit Loomba[6] and Veeral Ajmera[1], (1)University of California, San Diego, (2)Broad Institute of MIT and Harvard, (3) Brigham and Women's Hospital, (4)Harvard Medical School, (5)Verve Therapeutics, (6)University of California, San Diego, San Diego, CA

Background: Genetic factors contribute to the risk and severity of NAFLD and fibrosis, however, the utility of genetic testing to stratify the risk for advanced fibrosis and cirrhosis among patients with type 2 diabetes mellitus (T2DM) remains poorly characterized. **Methods:** This prospective study enrolled adults age ≥ 50 years with T2DM recruited from primary care or endocrinology clinics. Participants underwent a standardized clinical research visit with fasting labs and detailed assessment for other causes of liver disease. Polygenic risk score (PRS) was the sum of established risk alleles in *PNPLA3*, *TM6SF2* and *SERPINA1* minus the protective variant in *HSD17B13* and dichotomized into low and high risk according to the median. Magnetic resonance elastography (MRE), vibration controlled transient elastography (VCTE) and controlled attenuation parameter (CAP) were

performed. Advanced fibrosis was defined as MRE ≥ 3.63 kPa, or VCTE ≥ 8.8 kPa if MRE was not available. Cirrhosis was defined as MRE ≥ 4.67 kPa or VCTE ≥ 15 kPa if MRE was not available. **Results:** Of 382 included patients the mean age and BMI were 64.8 (± 8.4) years and 31.7 (± 6.2) kg/m^2, respectively. The cohort was 61.5% female, and 40.9% Hispanic. The prevalence advanced fibrosis and cirrhosis was 12.3% and 5.24%, respectively and higher PRS was associated with higher risk of cirrhosis (2.7% vs. 7.5%, $p = 0.037$) (Fig. 1a). Evaluating *PNPLA3* alone revealed that patients with CG or GG vs. CC were associated with higher risk of both advanced fibrosis (15.2% vs. 8.2%, $p = 0.042$) and cirrhosis (7.1% vs. 2.5%, $p = 0.046$) (Fig. 1b). The prevalence of advanced fibrosis and cirrhosis by PRS was further stratified by the Fibrosis-4 (FIB-4) index categories; < 1.3, 1.3-2.67 and > 2.67. High PRS was associated with an increased risk of advanced fibrosis among those with low FIB-4 index (FIB-4 < 1.3) (9.6% vs 2.3%, $p = 0.036$) but was not significantly different in other FIB-4 categories. **Conclusion:** Utilizing a well-phenotyped, prospective cohort of adults with T2DM we found that genetic risk amplifies the prevalence of advanced fibrosis and cirrhosis, and evaluating *PNPLA3* alone stratifies patients well. Adding an assessment of genetic risk to recent recommendations to screen at risk populations, including T2DM, may add precision to identifying patients at the greatest risk of liver related morbidity and mortality and identify patients with low FIB-4 who are still at risk for liver related morbidity and mortality.

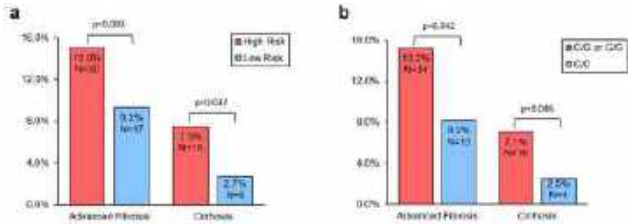

Figure 1. Prevalence of advanced fibrosis and cirrhosis in adults 50 years or older with type 2 diabetes. Prevalence was stratified by (a) overall polygenic risk score and (b) PNPLA3 allele genetic risk alone (C/G or G/G confer risk).

238 | IMPACT OF BMI ON NIS2+TM AND ESTABLISHED NON-INVASIVE TESTS FOR THE EVALUATION OF NON-ALCOHOLIC LIVER DISEASE

Sven Francque[1], Stephen A Harrison[2], Jorn Schattenberg[3], Bérénice Alard[4], Jérémy Magnanensi[4], Zouher Majd[4], Dean W Hum[4], Bart Staels[5], Quentin M. Anstee[6], Vlad Ratziu[7] and Arun Sanyal[8], (1)University of Antwerp, Edegem, Belgium, (2)Summit Clinical Research; Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, San Antonio, TX, (3)I. Department of Medicine, University Medical Centre Mainz, Germany, (4)Genfit S.a., Loos, France, (5) Université De Lille, Inserm, CHU Lille, Institut Pasteur De Lille, Lille, France, (6)Newcastle Nihr Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK, (7) Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hôpital Pitié-Salpêtrière, Paris, France, (8)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA

Background: While obesity is a risk factor for NAFLD, patients across the BMI spectrum are affected by the disease, creating a need for reliable non-invasive tests (NITs) with performances that are not affected by BMI. While most of standard NITs are designed to detect advanced fibrosis, NIS2+™, an optimization of the blood-based NIS4® technology, is specifically designed to detect at-risk NASH (NAS e 4; F e 2). We aimed to isolate the effect of BMI on NITs and assess their clinical reliability across the BMI spectrum. **Methods:** Among all non-cirrhotic NASH patients enrolled in the RESOLVE-IT Phase 3 trial (NCT02704403), those with data for NIS2+™, APRI, NFS, FIB-4, ELF™ and FibroScan (FS) were selected (n = 898). This cohort was split in 4 BMI-based subgroups: non-obese, Class 1, 2 and 3 obesity. To isolate the effect of BMI from confounding factors, we matched the 4 groups for the histology and other comorbidities using a propensity score matching algorithm, resulting in 4 groups of n = 113 patients. One-way ANOVA tests were used to evaluate the BMI impact on NITs and biomarkers distribution. Impact on clinical performances (sensitivity, specificity) was also analyzed using fixed cutoffs. **Results:** NFS was impacted by BMI ($p < 0.0001$), with scores increasing along with BMI. The significant decrease in albumin concentration with BMI ($p < 0.0001$) and the presence of BMI in the NFS equation explain the NFS results. FS distribution was significantly impacted by BMI ($p < 0.0001$), displaying increased mean scores in Class 3 obesity compared to other groups (14.3 kPa vs 10.1-11.0kPa). The BMI impact on NFS and FS distributions resulted in a decrease in specificity with increasing BMI when ruling-out (NFS: 76% to 20%; FS: 49% to 33%) and ruling-in (NFS:100% to 83%; FS 76% to 48%) F e 3. While NFS sensitivity progressively increased with BMI when ruling-out (NFS: 52% to 90%) and ruling-in (NFS:2% to 33%) F e 3, FS achieved the highest sensitivity in class 3 obese patients compared to other groups (rule-out: 94% vs 76-88%; rule-in: 82% vs 60-68%). NIS2

+™, APRI, ELF™ and FIB-4 were not significantly impacted by BMI, resulting in stable clinical performance. **Conclusion:** NIS2+™, FIB-4, APRI and ELF™ were not significantly impacted by BMI. NFS was, however, significantly impacted by BMI, notably due to BMI-associated differences in albumin levels. Liver stiffness by FS was also significantly impacted in Class 3 obesity. This suggests a need for BMI-adapted cutoffs for these particular NITs.

239 | CLINICAL, BIOLOGICAL AND IMAGING PREDICTORS OF AT-RISK METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH): COMBINED DATA FROM MULTIPLE THERAPEUTIC TRIALS INCLUDING MORE THAN 6,000 PATIENTS (IN COLLABORATION WITH NAIL-NIT CONSORTIUM)

Stephen A Harrison[1], Julie Dubourg[2], Naim Alkhouri[3], Mazen Noureddin[4], Jörn M. Schattenberg[5] and Sophie Jeannin[2], (1)Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, (2) Summit Clinical Research, San Antonio, TX, (3)Arizona Liver Health, Phoenix, AZ, (4)Houston Research Institute, Houston, TX, (5)I. Department of Medicine, University Medical Centre Mainz, Johannes Gutenberg University, Mainz, Germany, Mainz, Germany

Background: The identification of at-risk metabolic dysfunction-associated steatohepatitis (MASH) patients remains a main challenge in both clinical practice and clinical trial settings. Several non-invasive biomarkers have been developed to identify those at-risk MASH patients who would benefit from pharmacological therapy. We aimed to describe the main predictors of at-risk MASH across multiple therapeutic clinical trials. **Methods:** We combined screening data from 7 MASH non-cirrhotic phase 2 trials. Predictors of at risk-MASH were examined using logistic regression and excluding patients with cirrhosis **Results:** Out of the 6,558 patients, 2,173 with centrally assessed liver biopsy were included. Among them, 912 (42%) met the histopathological criteria for at-risk MASH. The predictors of at-risk MASH are shown in Table 1. The proportion of at risk-MASH patients was 12%, 26%, 42% and 61% in patients with AST < 20, AST 20-30, AST 30-40, and AST ≥ 40, respectively. This rises to 54% in patients with AST ≥ 30 versus 23% in patients with AST < 30. In patients with FAST < 0.35, FAST 0.35-0.67, and FAST ≥ 0.67, 34%, 58%, and 74% were "at-risk MASH", respectively. This rises to 69% for patients with FAST ≥ 0.5 versus 40% in patients with FAST < 0.5. When focusing on Fib-4 categories (< 1.3, 1.3-

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

2.67, e 2.67), the at-risk MASH population represented 31%, 56%, and 75% of the patients, respectively. The proportion of at-risk MASH patients was 35% in patients with HbA1c < 6.5% compared to 53% in patients with HbA1c e 6.5%. In the population with FAST e 0.50, 76% of patients with HbA1c e 6.5% were "at-risk MASH" compared to 64% with HbA1c < 6.5%. Similarly, in the subgroup with FAST e 0.67, patients with HbA1c e 6.5% had a higher probability of at-risk MASH (78%) compared to those with HbA1c < 6.5% (70%). **Conclusion:** Simple non-invasive biomarkers can help stratify at-risk MASH patients. We recommend using the FAST-score as a simple tool to target at-risk MASH patients with a cutoff point of 0.5 for patients with HbA1c e 6.5% and 0.67 for patients with HbA1c < 6.5%.

240 | DEVELOPMENT OF A NON-INVASIVE CLASSIFIER (FAST-3) TO PREDICT ADVANCED FIBROSIS IN MASH IN LIEU OF LIVER BIOPSIES IN U.S. ADULTS WITH MASLD

Pankil Shah[1], Phillip Leff[2], Rida Nadeem[3], Ria Kundu[3] and Naim Alkhouri[3], (1)Uthealth San Antonio, (2)TBA, (3)Arizona Liver Health, Phoenix, AZ

Background: Metabolic dysfunction-associated steatohepatitis (MASH) diagnosis and scoring depend on invasive liver biopsies by measuring metabolic dysfunction-associated steatotic liver disease (MASLD) activity score (NAS) and fibrosis score. However, a quantitative estimation of the combined effect of clinically available laboratory measures and transient elastography parameters (controlled attenuation parameter [CAP] and liver stiffness score [LSM]) as a screening / diagnostic test for advanced MASH has been suggested. In this study, we aimed to develop such a non-invasive classifier for MASH (NAS > 4 and fibrosis stage > 3 [F3]) in lieu of histological assessment by liver biopsies in adult patients with MASLD. **Methods:** We used a retrospective cohort study of 258 adult patients with MASLD who had undergone biopsy and transient elastography (FibroScan®) assessment. A predictive logistic regression-based algorithm utilizing clinical and controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) measured by FibroScan® devices was developed and internally validated to predict MASH(NAS4/F3) (confirmed with liver biopsy). Fractional polynomial forms of the predictors were evaluated, and the final model was built with L1 penalization (LASSO) using 10-fold cross-validation to obtain the optimum penalty factor. The developed model was examined for calibration (calibration plot), discrimination (AUROC), and performance (Brier score, Sensitivity, Specificity, positive predictive value [PPV], negative predictive value [NPV]). Optimal Cutpoints for 'rule-in' and 'rule-out' criteria were developed. Optimism and unbiased estimates from internal validation were obtained using 2000 bootstrapped samples. All tests were two-sided with a significant *p*-value set at 0.05. **Results:** Our predictive algorithm (FAST-3) utilized five clinical variables (sex, body mass index (BMI), aspartate aminotransferase (AST), bilirubin, and platelet count), controlled attenuation parameter (CAP), and liver stiffness measurement (LSM). The classifier demonstrated good calibration (calibration plot), discrimination (AUROC: 0.77 (0.71 – 0.83), and performance (Brier score 0.13 (0.11 – 0.16)). Optimal cutpoints for 'rule-in' and 'rule-out' criteria were evaluated and showed excellent PPV and NPV (PPV: 45% and NPV: 95%). **Conclusion:** The potential utility for a non-invasive classifier (FAST-3) as a replacement for invasive liver biopsies to identify patients with advanced fibrosis in MASH (NAS4/F3) is enormous. We demonstrate excellent performance and internal validity for this index. The results from this study should be validated in a multi-center prospective cohort study, especially with high representation from Hispanic and other at-risk minority groups.

Table 3: Comparing the point estimates of sensitivity, specificity, PPV, and NPV for FAST with the unbiased estimates for the current algorithm in relation to their Rule-in and Rule-out cutoffs to predict NASH(NAS4/F3).

	Rule in		Rule out	
	FAST	FAST3	FAST	FAST3
Specificity	0.71	0.89 (0.85, 0.94)		
PPV	0.33	0.46 (0.31, 0.62)		
Sensitivity			0.59	0. 0.88 (0.79, 0.97)
NPV			0.88	0.95 (0.92, 0.99)

Figure 3: Calibration plot showing agreement between prediction and observed risk of NASH(NAS4/F3)

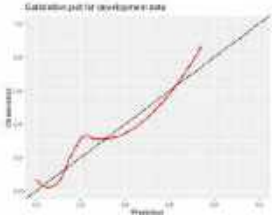

Figure 4: Calibration plot for development data showing the agreement by decile of predicted risk for NASH(NAS4/F3)

1000-A | EXTENDED STATIC STORAGE AT 10°C DEMONSTRATES SUPERIOR LIVER FUNCTION COMPARED TO STANDARD STORAGE ON ICE OR AT 18°C

Kaitlyn M. Tracy[1], Timothy R. Harris[1], Michael Cortelli[1], Sean A. Francois[1], William D. Tucker[1], Yutaka Shishido[1], Carl A. Johnson Jr.[1], Alexandra DeBose-Scarlett[1], Kimya Raietparvar[2], Tioluwanimi Adesanya[2], Nancy Cardwell[1], Caitlin T. Demarest[1], Rei Ukita[1], Chetan Pasrija[1], Muhammad Ameen Rauf[1] and Matthew Bacchetta[1,2], (1)Vanderbilt University Medical Center, (2)Vanderbilt University

Background: While the use of donation after cardiac death (DCD) allografts is one mechanism to expand the liver donor pool, these organs are at substantially higher risk of ischemic cholangiopathy. Recent innovations in normothermic and hypothermic machine perfusion are promising to decrease the risk of long-term biliary complications, however, these techniques may be cost prohibitive for widespread adoption at present. Due to these limitations, there is a need to re-evaluate and optimize conventional static cold storage. **Methods:** A porcine DCD model was developed using hypoxia-induced cardiac arrest to mimic human DCD. Livers were procured in standard fashion. During back bench preparation, cannulae were placed in the inferior vena cava, hepatic artery, portal vein, and common bile duct. The organ was placed in static storage for 18 hours either on ice (standard practice), at 10°C, or at 18°C with $n = 1$ per experimental group. After static storage, hepatic function was evaluated on a normothermic machine perfusion (NMP) platform with autologous porcine blood over 4 hours. Livers were assessed using markers of hepatocellular injury, metabolic performance, and biliary viability. **Results:** Mean warm ischemia and cold ischemia times were 23±2.6 minutes and 18±0.16 hours, respectively. At completion of NMP, AST and ALT were lowest in the 10°C group (2673 U/L and 100 U/L, respectively) compared to ice (5870 U/L, 184 U/L) or 18°C (6615 U/L, 436 U/L). Lactate normalized during NMP of the 10°C liver (0.41 mmol/L) but remained elevated for livers stored on ice (4.08 mmol/L) and at 18°C (5.68 mmol/L). At conclusion of NMP, pH was 7.40 and 7.28 for ice and 10°C groups, respectively, with greater bicarbonate required for the liver stored on ice (78mEq and 15mEq, respectively). The liver stored at 18°C demonstrated persistent acidosis (pH 7.1) despite 53mEq bicarbonate administered. The liver stored at 10°C produced 10.7mL of bile with a favorable bile glucose to perfusate glucose ratio (0.07) whereas livers stored on ice and 18°C made no bile and 1.0mL of bile, respectively, with an unfavorable ratio of 0.79 at 18°C. **Conclusion:** After extended static storage, the liver stored at 10°C demonstrated decreased hepatocellular injury, superior metabolic function, and preserved biliary viability compared to livers stored either on ice or at 18°C. These findings suggest that static storage at 10°C, compared to conventional storage on ice, may improve DCD allograft function and extend permissible preservation time.

1001-A | G-CSF-MOBILIZED AUTOLOGOUS PERIPHERAL BLOOD CD34-POSITIVE CELL INFUSION THERAPY FOR HCV-RELATED DECOMPENSATED CIRRHOSIS

Toru Nakamura[1,2], Atsutaka Masuda[1,2], Makoto Kako[3], Hirayuiki Enomoto[4], Masaki Kaibori[5], Yasuyuki Fujita[6], Kyoko Tanizawa[6], Tetsuya Ioji[6], Hideki Iwamoto[1,2], Hironori Koga[1,2], Hiroyuki Suzuki[1,2], Tomoyuki Takashima[4], Haruki Uojima[3,7], Hidekazu Yamamoto[5], Kazunori Yoh[4,8], Atsuhiko Kawamoto[6], Shuhei Nishiguchi[4,9], Takuji Torimura[1,10] and Takumi Kawaguchi[1], (1)Kurume University School of Medicine, (2)Research Center for Innovative Cancer Therapy, Kurume University, (3)Shonan Kamakura General Hospital, (4)Hyogo Medical University, (5)Kansai Medical University, (6)Foundation for Biomedical Research and Innovation at Kobe, (7)Research Institute, National Center for Global Health and Medicine, (8)Yoh Digestive Clinic, (9)Kano General Hospital, (10)Omuta City Hospital

Background: Preclinical studies have shown that peripheral blood (PB)-CD34$^+$ cell transplantation reduced established liver fibrosis and promote hepatic regeneration. Based on many basic animal studies, we have done a prospective clinical trial for patients with decompensated cirrhosis and demonstrated that autologous G-CSF-mobilized PB-CD34$^+$ cell therapy is feasible, safe, and effective in slowing the decline of hepatic residual function. The aim of the study is to investigate the efficacy and safety of G-CSF-mobilized autologous PB-CD34$^+$ cells cell infusion therapy compared with standard medical therapy for HCV-related decompensated cirrhosis. **Methods:** We did a multicenter, open-label, randomized control trial. Patients were randomly assigned (2:1) to the CD34$^+$ cell transplant (cell transplant) or standard medical therapy (standard treatment) group and followed up for 52 weeks. The primary endpoints were the non-progression rate in Child-Pugh (CP) score at 24 weeks post-enrollment and the safety of the protocol treatment. Patients in the cell transplant group were admitted to the hospital and received G-CSF injections for 5 days to mobilize CD34$^+$ cells from bone marrow. On Day 4-5, leukapheresis was done and CD34$^+$ cells were isolated using CliniMACS magnetic cell sorter. On Day 5, the isolated CD34$^+$ cells were then infused through the hepatic artery. Patients assigned to the standard treatment group continued treatment that had been initiated prior to enrollment. **Results:** Fourteen patients were enrolled (cell transplant group: 10, standard treatment group: 4). The primary endpoint was 90% in the cell transplant group and 100% in the standard treatment group, with no significant differences between groups. When the evaluation method was changed from the non-progression rate in CP score to the improvement rate in CP score by one or more points, the cell transplant group was superior, with 50% of patients in the cell transplant group compared to 25% in the standard treatment group. In addition, 40% of patients in the cell transplant group improved from decompensated to compensated cirrhosis. In the secondary endpoints, serum albumin levels tended to increase in the cell transplant group. Significant intergroup differences were also observed in the MELD score (change at 8, 12, and 36 weeks post-enrollment), total bilirubin level (change at 12 weeks post-enrollment), and QOL endpoints (change in physical function and body pain at 52 weeks post-enrollment). For safety evaluation, 3 serious adverse events occurred in the cell transplant group and 1 in the standard treatment group. There were no deaths due to cirrhosis, no all-cause mortality, and no occurrence of hepatocellular carcinoma in all patients. **Conclusion:** Autologous PB-CD34$^+$ cell infusion therapy is a beneficial treatment for decompensated cirrhosis. This therapy may have the potential to escape decompensated cirrhosis, resulting in avoiding liver transplantation.

Background: Liver is an immune regulatory organ. Operational tolerance to liver transplants (Tx) occurs in some patients with stable liver function for several years, while it is not generally seen in other Tx. To obtain a better understanding of the mechanisms involved in T cell reactivity in the liver allograft and enable the discovery of therapeutic targets for rejection (Rej) and tolerance, we profiled the transcriptomes of more than 125,000 single cells isolated from 17 livers and 4 peripheral blood samples and analyzed bulk mRNA from 48 liver biopsies in the monkey liver Tx model. **Methods:** Cynomolgus recipients received orthotopic liver allograft Tx with tacrolimus-based immunosuppression. Graft immune status, stable or Rej were defined based on liver function tests and pathology. Graft wedge biopsies were done at stable or Rej phases. Naïve control livers were obtained from naïve cynomolgus monkeys. Single cell RNA sequences were done by 10x genomics. Bulk mRNA were analyzed by nanoString. **Results:** The transcriptional profiles of individual cells in the liver enabled us to identify 9 T cell subsets based on their molecular and functional properties and delineate their developmental trajectory. 4 subsets (1,2,6 and 8) of T cells in the Rej livers, 3 subsets (3,4 and 7) in the naïve livers and 1 subset (9) in the stable liver were identified (Fig A). Specific subsets such as exhausted CD8 T cells and Tregs are preferentially enriched in the Rej liver grafts. Genes related to cytotoxicity were expressed on both Rej and naïve subsets with no noticeable differences, while exhaustion markers were preferentially expressed on Rej liver(Fig B). The expression of exhaustion markers did not correlate with cytotoxic markers, indicating they are not upregulated by cytotoxic cell activities. Trajectory analyses identified the cell development from naïve to the end of cell activation, exhaustion, and senescence/apoptosis subsets (8 and 6) in the Rej livers (Fig C). Circulating T cells showed different properties from T cells in the liver graft: cytotoxicity markers on the circulating T cells were slightly upregulated at Rej phase compared to naïve liver, while exhaustion markers showed low expression with no difference between naïve and Rej phase(Fig D). When T cells in the liver and in the circulation at the same time of Rej were compared, exhaustion markers were preferentially expressed on liver T cells, whereas cytotoxic markers were more upregulated on circulating T cells (Fig E). Kupffer cells and DC, but not B cells in the Rej liver, upregulated PD-L1, PD-L2 and TREM2, a marker of immunosuppressive myeloid cells (Fig F). Consistent findings were seen in the bulk mRNA analyses for 48 liver samples. **Conclusion:** Liver allograft microenvironment may modulate T cell activation by immune checkpoint where antigen presenting cells such as Kupffer cells and DC may contribute, suggesting the spontaneous resolution of Rej inducing operational tolerance.

Background: Endothelial cells (ECs) display a myriad of protective roles that contribute to tissue homeostasis (i.e. modulation of the immune system and secretion of growth factors). Embedding healthy ECs in a 3D collagen-based scaffold shields their immunogenicity and maximizes their protective roles. Indeed, matrix-embedded endothelial cells (MEECs) protect the healthy liver against acute ischemic injury. Here, we explore the impact of MEECs on injury and inflammation in the setting of pre-existing fibrotic liver disease and cirrhosis. **Methods:** Liver slices from cirrhotic patients ($n = 6$) were co-cultured in direct contact with acellular matrices or MEECs. Viability was examined after 24 hours by measuring ATP levels in human hepatic homogenates. The expression of genes associated with hepatic injury, inflammation, and regeneration was quantified by Real-time PCR in human samples. Experimental fibrosis was induced in BALB/c mice ($n = 12$) by i.p. injection of CCl_4 for 8 weeks, after which acellular matrices or MEECs were placed in the perihepatic space between the median and right lobes, or subcutaneously. Liver integrity, inflammation, fibrosis, and regeneration were evaluated one week later. *In vitro*, MEECs and 2D-ECs gene expression patterns were compared to decipher potential drivers of immunomodulation, extracellular matrix remodeling, and regeneration. **Results:** Human liver slices in contact with MEECs exhibited greater viability than slices exposed to acellular matrices (ATP/Protein, 1.4 ± 0.5 pmol/μg vs 1.9 ± 0.5, $p < 0.05$). This viability improvement was accompanied by an identical magnitude of induction of hepatic expression of the metabolic enzyme CYP2B6 (3.8 ± 3.0 vs 5.1 ± 3.4 fold change (fc), $p < 0.05$) and an even greater increase in hepatocyte growth factor expression (HGF, 1.0 ± 0.2 vs 2.2 ± 0.6 fc, $p < 0.05$). These effects were associated with an increase in the expression of anti-inflammatory genes (Arg1, MRC1, MMP9) and a reduction in NOS2 expression in human liver slices treated with MEECs. Fibrotic livers of mice treated with perihepatic implants of MEECs also showed a decrease in inflammation and liver damage that was accompanied by a decrease in fibrosis, and an increase in hepatic regeneration. In contrast, subcutaneous implants of MEECs did not exert any effect on inflammation, liver damage, fibrosis, or regeneration. Mechanistically, MEECs expressed higher levels of anti-inflammatory chemokines (CXCL16 and CX3CL1), extracellular matrix modulators (matrix metalloproteinase 2 and fibronectin 1), and growth factors (HGF and fibroblast growth factor 2) than 2D-ECs. **Conclusion:** 3D-engineered ECs matrices protect human cirrhotic liver from injury and inflammation in short-term treatment, and boost regeneration, reduce inflammation, injury, and fibrosis in long-term therapy in fibrotic livers. This study highlights the potential therapeutic utility of MEECs for chronic liver disease.

f 1004-A | SINGLE CELL ATLAS OF LIVING DONOR LIVER BIOPSIES REVEALS HEPATO-INFLAMMATORY GENE ACTIVATION AND T CELL RECRUITMENT IN THE NEUROLOGICALLY DECEASED DONOR LIVER★

Diana Nakib[1,2], Catia Perciani[1], Sai Chung[1,2], Damra Camat[1,2], Lewis Liu[1,2], Xue Zhong Ma[1], Justin Manuel[1], Blayne Sayed[1,3], Mark Cattral[1], Gonzalo Sapisochin[1], Anand Ghanekar[1,3], Markus Selzner[1], Nazia Selzner[1,2], Sonya A MacParland[1,2] and Ian McGilvray[1], (1) University Health Network, (2)University of Toronto, (3) The Hospital for Sick Children

Background: Living donor (LD) liver transplantation represents 1 in 8 liver transplantations in Canada and has led to successful outcomes for patients on waitlists for neurologically-deceased donor (NDD) livers. Although short term recipient outcomes are similar between LD and NDD liver transplantations, it is unclear if there are fundamental differences in the donor tissue types. For example, hepatocyte stress, immune infiltration, and inflammation may differ. Studies have demonstrated an upregulation of inflammatory genes during the preparation, preservation and reperfusion of LD and NDD transplanted livers, which could have important impacts on transplant success. Here we used single cell transcriptomics to build an atlas of the cellular landscapes of LD and NDD livers, and have uncovered

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

pathways of cellular stress and inflammation unique to NDD livers. **Methods:** We employed 10x Genomics 5' single-cell RNA sequencing with T cell receptor (TCR) and B cell receptor (BCR) sequencing to examine the cellular landscapes of NDD liver caudates (n = 10) and LD liver biopsies (n = 10) collected immediately after laparotomy. In addition to LD liver biopsies, we collected matched blood (n = 10). **Results:** Our atlas demonstrates the presence of expected human hepatic cell populations in both the NDD and LD liver. We confirm the increased expression of pro-inflammatory genes in NDD-specific hepatocyte populations, examples include *TGM2*, *NAMPT* and *SERPINE1*, which are involved in myeloid polarization, recruitment and activation. We observe several NDD-specific myeloid populations. These include a recently-recruited neutrophil population enriched in inflammatory genes (*S100A8/9*), chemokine receptors (*CXCR1/2*), and *CXCL8*, a gene involved in T cell and myeloid recruitment to the liver. Through gene set enrichment analysis, we observe that the NDD-specific myeloid populations, as well as NDD-specific neutrophils, are enriched in pathways related to leukocyte activation, responses to inflammation and stress, in addition to the regulation and activation of T cells. After excluding any lymphocytes sharing gene expression profiles with circulating PBMCs, TCR sequencing reveals a significant increase in the clonotypic diversity of both naive CD4+ and effector memory CD8+ T cells in NDD livers in comparison to LD livers. However, BCR sequencing reveals similar clonotypic diversity of mature and antibody-secreting B cells in the NDD and LD liver. This suggests increased T cell-specific recruitment and infiltration of the NDD liver that is not observed in the LD liver. **Conclusion:** Our results reveal that the NDD liver experiences an upregulation of hepato-inflammatory genes across cell types that is associated with the recruitment of a neutrophil-T-cell axis not observed in the LD liver.

1005-A | A NOVEL PROTOCOL OF LIVING DONOR LIVER TRANSPLANTATION FOR NON-RESECTABLE PERIHILAR CHOLANGIOCARCINOMA

Ken Fukumitsu, Kojiro Taura, Takashi Ito, Takayuki Anazawa, Kazuyuki Nagai, Yoichiro Uchida, Takamichi Ishii and Etsuro Hatano, Kyoto University

Background: Liver transplantation for unresectable perihilar cholangiocarcinoma has been widely performed depending on Mayo protocol. This protocol, however, is based on the condition of deceased donor liver transplantation (DDLT), and since nobody knows the timing of the donor's allocation in advance, patients should wait with an administration of anticancer drugs until transplantation. On the other hand, in Japan, liver transplantation for perihilar cholangiocarcinoma is limited to living donor liver transplantation (LDLT). Adding to this, the resume of chemotherapy has been advanced recently, and a novel resume for cholangiocarcinoma has been approved. **Methods:** The following two improvements were adjusted in LDLT for perihilar cholangiocarcinoma. 1. Change in the order of induction of radiotherapy and chemotherapy. LDLT has the advantage that the schedule of the operation date can be decided in advance. Therefore, the date of liver transplantation was set when donor eligibility and response to treatment were confirmed, and then radiotherapy was added retroactively from the date of the transplantation. 2. Change the resume of chemotherapy. The chemotherapy regimen was changed from 5-FU and Capecitabin to combination of Gemcitabine, Cisplatin and S-1(GCS), has been proven to be effective to cholangiocarcinoma. **Results:** Three patients underwent LDLT, one of whom underwent pancreatoduodenectomy (PD) with liver transplantation simultaneously. The first patient had hilar cholangiocarcinoma with primary sclerosing cholangitis (PSC) and still alive without recurrence. The second patient had hilar cholangiocarcinoma with hepatic hilum lymph node metastasis, which turned out to be negative after chemotherapy. Presently this patient has recurrence in bone and performing chemotherapy. The third patient was a hilar cholangiocarcinoma with PSC that had extended to the pancreas, so PD was performed simultaneously, who is still alive without recurrence. **Conclusion:** The protocol of LDLT for perihilar cholangiocarcinoma was improved depending on the advantages to DDLT. Our protocol for LDLT can be performed safely, and further investigation will be necessary.

1006-A | ACCURATE PREDICTION OF LIVER WAITLIST MORTALITY AND 1-YEAR POST-TRANSPLANT SURVIVAL WITH MACHINE LEARNING

Rowland Pettit[1,2], Britton Marlatt[3], Selim Uzgoren[3], Jim Havelka[3], Anil Shetty[3], George Cholankeril[2] and Abbas Rana[2], (1)Mass General Brigham, (2)Baylor College of Medicine, (3)Informai

Background: The UNOS database provides valuable data for studying transplantation outcomes, while the application of machine learning (ML) algorithms has gained attention in this field. This study aims to utilize XGBoost, a powerful ML algorithm, to predict transplantation outcomes using the UNOS database and compare its performance to the SRTR models. By leveraging ML techniques and the comprehensive data from UNOS, we aim to enhance our predictive capabilities and decision-making in transplantation. **Methods:** We conducted a retrospective analysis of 139,323 adult liver transplant (LT) recipients from the UNOS database. Using XGBoost, we predicted waitlist mortality and one-year post-transplant survival. The XGBoost model was trained through 60 iterations using Bayesian Search Cross Validation and its performance was evaluated using AUCROC. We identified the top 10 features for waitlist mortality prediction based on XGBoost's importance scores, which were validated using 4-fold cross-validation. Additionally, we performed statistical bootstrapped comparisons with Cox proportional hazards and SRTR models to assess the accuracy and reliability of XGBoost in predicting long-term post-transplant outcomes. **Results:** Our study showed that XGBoost outperformed SRTR models in predicting 1-year survival after liver transplant (LT), with a significantly higher discriminative ability (c-statistic: XGBoost 0.73 vs. SRTR 0.62, $p < 0.001$). For 90-day waitlist mortality, our top-performing XGBoost model achieved strong predictive metrics: AUC-ROC 0.8027, AUC-PR 0.8147, and F1-Score 0.7711. The XGBoost algorithm identified the top 10 important features for waitlist mortality, including variables related to life support, previous transplant, MELD/PELD score, listing center code, diagnosis codes, UNOS/OPTN region, ABO blood group, VAD/TAH, and ascites. These features significantly improved the accuracy of identifying patients at higher risk of waitlist mortality. **Conclusion:** XGBoost demonstrated superior performance over Cox proportional hazard models in predicting 1-year survival after liver transplant. We successfully developed a clinically relevant XGBoost model for 90-day waitlist mortality, achieving high clinical utility (AUC-ROC > 0.8). These findings suggest the potential of AI-based models, such as XGBoost, to improve transplant decision-making and should be considered for integration into the workflow.

1007-A | ACUITY CIRCLES IMPROVED DISPARITY IN ACCESS TO LIVER TRANSPLANT FOR HISPANICS AND ASIANS BUT NOT AFRICAN AMERICANS

Ahmed Elkafrawy[1], David Axelrod[1] and Tomohiro Tanaka[2], (1)University of Iowa Hospitals and Clinics, (2)University of Iowa Hospitals and Clinics, Iowa City, IA

Background: The Organ Procurement and Transplantation Network (OPTN) adopted a new liver allocation system based on acuity circles (AC) in February 2020. Understanding the impact of the AC on existing racial and ethnic disparities in waitlisted liver transplant (LT) candidates is vital to inform further policy development. **Methods:** OPTN data were queried to identify eligible adult patients (age ≥ 18 y) on the LT waitlist before and after implementing the AC (pre-AC, 1/1/2017 – 2/3/2020, post-AC, 2/4/2020 – 12/31/2022). Cox proportional hazard model with Model of End-Stage Liver Disease score (MELD) and recipient age as a time-dependent covariate (TDC), and Fine-Gray regression model with LT and death/drop-out (D/D) as competing risks were used to assess probability of receiving LT in different racial/ethnic minorities compared to Caucasians. Fine-Gray model was performed by censoring candidates who were on the waiting list before the implementation of the AC and remained on the list thereafter. The two models were employed to address the limitations of the Fine-Gray model, which does not adequately incorporate the TDC, and the Cox model, which does not account for competing risks. Other confounders included candidates' sex, age, etiology of liver disease, presence of HCC, body mass index (BMI) and MELD score, at listing. **Results:** This analysis included a total of 39,227 patients pre-AC and 38,443 patients post-AC. Despite overall improvements post-AC, racial/ethnic disparities persist in LT and D/D rates

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

compared to Caucasians (LT: 64% to 67%, D/D: 17% to 16%): African Americans (LT: 63% to 66%, D/D: 20% to 17%), Hispanics (LT: 60% to 65%, D/D: 23% to 20%), Asians (LT: 59% to 64%, D/D: 20% to 16%), pre- and post-AC, respectively ($p < 0.001$). Cox model with TDC (Figure A) showed adjusted hazard ratio (aHR) of receiving LT in African Americans compared to Caucasians pre- and post-AC was 0.90 (95% confidence interval [CI] 0.85-0.94) in both groups. In comparison, among Hispanics, HR of receiving LT was 0.67 (95% CI 0.65-0.70) pre-AC which improved to 0.75 (0.73-0.78) post-AC. While aHR for Asians pre-AC was 0.73 (95% CI 0.68-0.78), it increased to 0.85 post AC (0.80-0.91). Fine-Gray competing risk regression model showed similar outcomes (Figure B): transplant probability of African Americans compared to Caucasians pre-AC was 0.96 (95% CI 0.94-0.99) and post-AC it remained unchanged (aHR of 0.95, 95% CI 0.93-0.98). In Hispanics, pre-AC aHR was 0.91 (95% CI 0.89-0.93) vs. 0.95 (0.93-0.97) post-AC. The aHR for Asians was 0.90 (95% CI 0.87-0.94) pre-AC vs. 0.96 (0.82-0.99) post-AC. **Conclusion:** Racial and ethnic disparities still exist among all LT candidates with non-Caucasian races/ethnicities after implementing the AC. In both of our censored regression models, the AC allocation system has improved access to LT in Hispanics and Asians but not for African Americans.

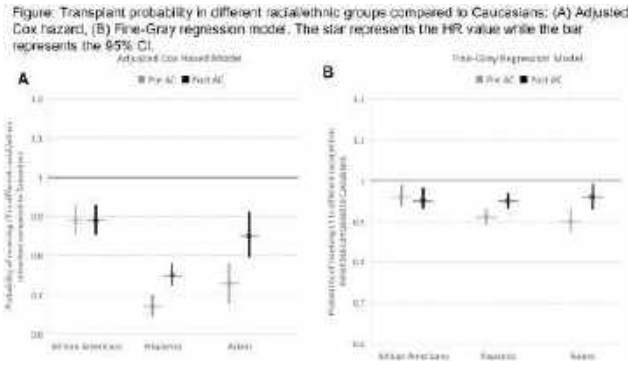

Figure: Transplant probability in different racial/ethnic groups compared to Caucasians: (A) Adjusted Cox hazard, (B) Fine-Gray regression model. The star represents the HR value while the bar represents the 95% CI.

1008-A | ASSESSING NEIGHBORHOOD LEVEL SOCIAL VULNERABILITY AMONG EARLY LIVER TRANSPLANT RECIPIENTS AT FOUR CENTERS

James Flanary[1], Po-Hung (Victor) Chen[1], Alexandra Strauss[1], Nicole M. Welch[2], Annette Bellar[2], Courtney B. Sherman[3], Bilal Hameed[4], Mandana Khalili[3], Srinivasan Dasarathy[5], Elizabeth King[1] and Andrew M. Cameron[1], (1)Johns Hopkins University, (2) Cleveland Clinic, (3)University of California, San Francisco, (4)University of California San Francisco, San Francisco, CA, (5)Cleveland Clinic Foundation

Background: Some liver transplant centers have adopted the practice of early liver transplants (ELT) for candidates with alcohol-related liver disease and less than six months of abstinence at listing. As this practice has gradually become more common, we sought to evaluate whether the population undergoing ELT is representative of the population in need. Our study quantified sociodemographic characteristics for the ZIP codes in which ELT recipients resided and compared those with sociodemographic characteristics of all other ZIP codes in the referral region. **Methods:** All ZIP code tabulated areas within a 150 nautical mile (Nmi) radius of the four participating transplant centers were included. Geographically, these centers represent the mid-Atlantic (Johns Hopkins), south (Cleveland Clinic-Florida), midwest (Cleveland Clinic-Ohio), and west (University of California-San Francisco) regions of the United States. Recipients of ELT underwent transplant between 2019 and 2023. Sociodemographic variables were obtained from the 2020 American Community Survey data and the social vulnerability metric (SVM). The SVM is an ecologic measure of social determinants of health for each ZIP code. We stratified ZIP codes according to whether or not any patient who underwent ELT resided within that ZIP code. For each transplant center, chi-squared tests compared sociodemographic characteristics between ZIP codes with ELT patients to ZIP codes without ELT patients. **Results:** Each center had between 14 and 71 ZIP codes in which ELT recipients resided. The most common racial category of ZIP codes with ELT recipients was either predominantly white or racially integrated. At each center, over 60% of ZIP codes with ELT recipients were within 50Nmi of the transplant center. At one center, ZIP codes with ELT recipients had lower vulnerability ($p < 0.001$), less poverty (17% vs. 34%, $p = 0.005$), and higher MHI (20% vs. 53%, $p < 0.001$) than other ZIP codes in the referral region. However, these differences did not persist when we restricted ZIP codes to within the state of the center. The remaining three centers did not have significant differences in these characteristics (Table). **Conclusion:** The majority of ELT recipients come from ZIP codes in relative proximity to a center that is currently offering ELT. Within these ZIP codes, there is a trend toward ELT recipients residing in ZIP codes with less social vulnerability, or in other words, more favorable sociodemographic characteristics. Further analysis is necessary to define the population that could benefit from ELT and whether there are individual's within socially vulnerable neighborhoods that lack access.

Predominant racial category was designated if >60% of the ZIP code was of a particular race/ethnicity. Racially integrated indicated that no race/ethnicity was greater than 60% of the total population. Social vulnerability metric (SVM) is grouped according to quartiles based on national percentile rankings. Each of the four income & insurance variables are split according to the median across ZIP codes in the US. MHI = median household income.

1009-A | COMBINED HEART-LIVER TRANSPLANT VS HEART TRANSPLANT ALONE: A SINGLE CENTER EXPERIENCE

Ritika M. Mazumder, Andrew Ford, Omar T. Sims and Jamak Modaresi Esfeh, Cleveland Clinic

Background: Combined heart-liver transplantation (CHLT) is a viable option for treating concomitant heart and liver failure. Indications for CHLT, however, are not well defined. The objectives of this study were to describe pre-transplant characteristics and post-transplant survival among patients with liver fibrosis who underwent CHLT versus heart transplantation (HT) alone. The incidence of decompensated cirrhosis after HT was also investigated. **Methods:** All adult heart transplants with liver fibrosis at our center from January 2009 to August 2022 were included in the analysis. **Results:** A total of 52 patients (HT = 42; CHLT = 10) met inclusion criteria. Heart failure etiology in the HT group included 9 ischemic cardiomyopathy (21%), 23 non-ischemic cardiomyopathy (55%), and 10 congenital heart diseases (24%). The CHLT group included 1 (10%), 5 (50%), and 4 (40%), respectively. The HT group had 9 (21%) cases of primary liver disease and 33 (79%) cases of congestive hepatopathy, while the CHLT group had 5 (50%) cases of primary liver disease and 5 (50%) cases of congestive hepatopathy. The preoperative LV ejection fraction for HT and CHLT averaged 29+20% and 38+14%. The pre-transplant MELD-Xi for HT and CHLT was 11.2 +6.5 and 9.16+5.0. F1 fibrosis (52%) was more common in the HT group and F4 fibrosis (80%) was more common in the CHLT group. Portal hypertension (PHTN) was present in 40% of HT patients and 90% of CHLT patients. Over the median follow-up of 3.7 (IQR 1.2-9.1) years, none of the CHLT patients and 14

(33%) HT patients died; the crude mortality rate between HT and CHLT did not differ statistically ($p = 0.6$, Figure 1). None of the HT patients progressed to decompensation (e.g., new ascites, variceal bleed, jaundice or hepatic encephalopathy) within 6 months of transplantation. **Conclusion:** Despite preexisting liver disease and PHTN, HT and CHLT patients had similar survival outcomes. Furthermore, HT patients with compensated liver disease did not progress to decompensation after transplantation. Further research is needed to determine selection criteria for patients undergoing CHLT and ensure efficient utility of limited organs.

1010-A | CORRELATION OF TUMOR RESPONSE FOLLOWING LIVER DIRECTED THERAPY FOR HEPATOCELLULAR CARCINOMA : A RADIOLOGICAL / PATHOLOGICAL CORRELATION

Mohammad Bourmaf[1], Kabir Chhabra[1], Mohammed Rifat Shaik[2], Dabin Choi[1], David Lee[1], Hyun S. Kim[1] and Kirti Shetty[3], (1)University of Maryland Medical Center, (2)University of Maryland Medical Center Midtown Campus, (3)Department of Hepatology and Liver Transplantation, the University of Maryland, School of Medicine, Baltimore, MD, USA

Background: Liver directed therapy (LDT) for HCC is essential to "bridge" patients to liver transplantation (LT). The Liver Reporting and Data System Treatment Response Algorithm (LR-TR) categorizes tumor response to LDT but questions persist regarding its generalizability. We therefore undertook this study in a HCC population undergoing LT after LDT to (1) correlate LR-TR findings to pathological tumor necrosis on explant (2) correlate degree of tumor necrosis to HCC recurrence post LT. **Methods:** A pathological database identifying all patients who underwent LT for HCC between January 2019 and June 2022 was utilized and clinical variables were extracted from the electronic medical record. Pre-LT imaging study for LIRADS-TR assessment was required to be within 90 days of LT and explant sectioning at 5 mm intervals described HCC characteristics. The following LIRADS-TR classifications were used – viable, equivocal, and non-viable. The corresponding percentage of explant necrosis was as follows: > 90%, 50-89%, < 50%. For continuous variables, means and standard deviations were calculated if normally distributed and medians (interquartile ranges IQR) were calculated if non normally distributed. Chi-square tests and Fisher exact tests were used to test between group differences for categorical variables. All *p*-values were reported as two-sided and a p-value < 0.05 was considered statistically significant. Institutional Review Board approval was obtained. **Results**: 50 patients underwent a total of 83 LDT sessions (median 2, range 1 – 5 sessions / patient) – details in table 1. Radiological - pathologic correlation of 48 paired HCCs are summarized in table 2. Of note, 90% of tumors that were non-viable by LR-TR criteria showed > 90% necrosis on explant pathology (correlation coefficient: $p = 0.05$,) However, LR– equivocal and LR-viable lesions showed inconsistent correlation. HCC recurrence was noted in 9 patients (18%) at a median of 382 days post LT (range 78 – 790 d). Of these, 2 patients had 100 % necrosis, 3 had < 50% necrosis, and 4 had 50 -89 % necrosis on explant. **Conclusion:** The LI-RADS TR algorithm for assessing HCC response to liver directed therapy performed well in our study cohort for predicting non-viable tumor on explant analysis. However, there was a lack of correlation for equivocal and viable lesions. This observation is consistent with known tumor biology, as lack of enhancement on imaging shows imperfect correlation to pathological tumor necrosis. Additionally, different forms of liver directed therapy may produce sequelae that are not well-captured by the LR-TR classification system. It is therefore crucial for the liver imaging community to continue its refinement of diagnostic techniques to capture tumor response to therapy. This will enable optimization of pre-transplant therapies to minimize HCC recurrence rates.

f 1011-A | CYSTATIN C: A BETTER MARKER THAN SERUM CREATININE FOR e STAGE 2 ACUTE KIDNEY INJURY (AKI) AND WAITLIST MORTALITY (WLM) AMONG DECOMPENSATED CIRRHOSIS PATIENTS

Giuseppe Cullaro, University of California, San Francisco, Kavish R. Patidar, Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center, Andrew Allegretti, Massachusetts General Hospital and Jennifer C. Lai, University of California-San Francisco

Background: Serum creatinine (sCr) is known to be an inaccurate metric, varying by sex, race, and functional status. Cystatin C (cysC) is an affordable, widely available metric that decreases these inaccuracies and is recommended by the National Kidney Foundation. Herein, we compare the association between sCR and cysC with Stage 2 AKI and WLM occurrence. **Methods**: In our ongoing, prospective cohort, we measured sCr and cysC levels at outpatient "Phase 1" visits. To quantify the variation in cysC and sCr, we calculated cysC to sCr ratios (CYS/CR), categorizing patients by the median value of < or e 1.46. We utilized linear regression to determine the factors most associated with CYS/CR. To determine if cysC was more strongly associated with key outcomes (e Stage 2 AKI – a e 200% increase in sCr from baseline; WLM – death or delisting for sickness) than sCr, we compared univariable Cox-regression models using the Likelihood Ratio Test. We repeated these comparisons in populations most impacted by inaccuracies in sCr — women, frail patients (Liver Frailty Index [LFI] e 4.2), and Childs C patients. **Results**: Among 528 participants, those with a high vs. low CYS/CR were more likely to be female (59 v. 31%), frail (38 v. 26%), have Child C cirrhosis (62 v. 50%), and experience WLM (27 v. 17%) (p d 0.01 for all, Table 1). In multivariable linear regression, the factors associated with CYS/CR were: LFI per 1 point (B 0.07, 95CI 0.03 – 0.12); female sex (B 0.20, 95CI 0.20 – 0.35); Child C cirrhosis (B 0.13, 95CI 0.06 – 0.20). In univariable Cox regression, only cysC was associated with WLM (cysC: HR1.3 $p < 0.001$; sCr: HR 1.2, $p = 0.1$). cysC (vs. sCr) was more strongly associated with WLM (Log-Likelihood Difference [LLD] 5.4, $p < 0.001$). This was observed in women (LLD 1.9), frail patients (LLD 1.5), and Child C patients (LLD 1.4) ($p < 0.001$ for each). In univariable Cox regression, only cysC was associated with Stage 2 AKI (cysC: HR1.3, $p = 0.04$; sCr: HR 1.1, $p = 0.4$). cysC (vs. sCr) was more strongly associated with Stage 2 (LLD 2.7, $p < 0.001$). This was also seen in women (LLD 0.1), frail patients (LLD 0.2), and Child C patients (LLD 0.9) ($p < 0.001$ for all). **Conclusion:** CysC is more strongly associated with AKI and WLM than sCr. CYS/CR varies substantially by sex, frailty, and Child class, suggesting an underestimation of kidney dysfunction in these groups. Our data support the routine measurement of cysC among decompensated cirrhosis patients.

1012-A | DISPARITIES IN LIVER TRANSPLANT EVALUATION (LTE): PREDICTORS OF LTE CLOSURE AT A LARGE U.S. TRANSPLANT CENTER

Caroline McLeod[1], Alex R. Jones[2], Olgert Bardhi[1], Prajwal Gowda[3], Dyanna Gregory[1], Alvaro Noriega Ramirez[2], Haley Holderness[3], Jeremy Louissaint[2], Thomas G. Cotter[2], Nicole E. Rich[2], Madhukar Patel[2], Arjmand R. Mufti[2], Lisa B. VanWagner[2], Amit G. Singal[2] and Sarah Rosanna Lieber[2], (1)UT Southwestern Medical Center, (2)University of Texas Southwestern Medical Center, (3)UT Southwestern School of Medicine

Background: Liver transplantation (LT) is a lifesaving surgery for patients with end stage liver disease; however, access is fraught with inequities. Race, sex, and socioeconomic disparities have been described among listed and transplanted individual's. However, upstream factors have been understudied in the LT evaluation (LTE) process. Therefore, we aimed to provide an in-depth analysis of sociodemographic and psychosocial factors associated with LTE closure. **Methods:** A retrospective chart review of a random selection of adult LT candidates evaluated between 2015-2020 was performed and stratified by evaluation outcome: closed, waitlisted, or transplanted. Bivariate and multivariable logistic regression assessed for associations between psychosocial and medical factors and LTE closure. **Results:** A total of 161 LTE closures were compared to 127 waitlisted or transplanted individual's (Table 1). The most common reasons for LTE closure were medical (62.7%), followed by psychosocial (30.4%) and personal choice (6.8%). The most common medical reasons for LTE closure were non-liver related comorbidities (47.5%) and improvement in health no longer requiring LT (35.6%). The most common psychosocial reasons were ongoing substance use (30%) and failure to identify social support (30%). Among LTE closures, 37% had an incomplete evaluation— the most frequent components not completed were cardiac (76%), preventive health testing (66%), radiology (64%), and social work (62%) visits. Compared to those waitlisted/transplanted, LTE closures occurred in patients who were older, had lower income levels, less reliable access to transportation, pre-existing psychiatric comorbidity, higher SIPAT scores, and needed simultaneous liver-kidney transplant (SLK) (Table 1). In multivariable analysis, factors significantly associated with LTE closure included older age (aOR 3.03 [95% CI 1.31, 7.00]), need for SLK (aOR 5.62 [1.70, 18.53]), psychiatric history (aOR 2.25 [1.03, 4.92]), and substance use history (aOR 2.95 [1.26, 6.91]) adjusting for sex, education, income level, race, ethnicity, insurance type, transplant indication, and being seen in a satellite clinic. **Conclusion:** Older patients, SLK candidates, or individual's with prior psychiatric or substance use histories are more likely to have an LTE closed independent of important social determinants of health. A complex interplay of factors including socioeconomic status, race/ethnicity, and psychosocial history likely exists and needs to be investigated to overcome inequities in LT access.

1013-A | DO WE STILL NEED MICROSCOPE SURGERY IN HEPATIC ARTERY ANASTOMOSIS TO DECREASE THE INCIDENCE OF COMPLICATIONS IN LIVING DONOR LIVER TRANSPLANTATION? SYSTEMATIC REVIEW AND META-ANALYSIS

Beshoy Effat Elkomos, General Surgery Department - Ain Shams University, Philopateer Effat Alkomos, Faculty of Medicine - Ain Shams University, Mina Effat Alkomos, Gastroentrology Department, St. Joseph's University, Paterson, NJ, USA and Amr Abdelaal, General Surgery Department- Ain Shams University Hospital

Background: Hepatic artery thrombosis (HAT) is the most serious vascular complication after LT. Moreover, in comparison to DDLT, HA anastomosis is more challenging in LDLT With a lot of controversial topics about the use of microscopic surgery in LDLT. We aimed to Compare the use of microscopic and loupe surgery in hepatic artery anastomosis in adult and pediatric LDLT to decrease the incidence of vascular complications **Methods:** PubMed, Scopes, Web of Science, and Cochrane Library were searched for eligible studies from inception to April 2023 and a systematic review and a meta-analysis were done **Results:** According to our eligibility criteria, 10 studies with a total of 1939 patients were included. In comparison to microscopic surgery, loupe anastomosis has a similar incidence of Hepatic artery thrombosis. (Thrombosis, RR = 0.96, 95% CI = 0.26-3.48, $p = 0.95$). In addition to that, no significant difference was detected between the two types in terms of stenosis, decreased blood flow and hospital stay. (Decreased blood flow, RR = 0.68, 95% CI = 0.01-86.65, $p = 0.88$), (Stenosis, RR = 1.81, 95% CI = 0.19-17.21, $p = 0.60$) and (Hospital stay, MD = 1.16, 95% CI = -3.79-6.11, $p = 0.65$). However, the operative time was longer in the case of microscopic surgery (Anastomotic time, MD = 24.09, 95% CI = 7.79-40.39 $p = 0.004$) **Conclusion:** With an equal incidence of complications and shorter operative time, Loupe anastomosis offers a great alternative to microscopic surgery in HA anastomosis

1014-A | DUAL SMALL MOLECULE INHIBITORS PROMOTE LIVER REGENERATION THROUGH YAP ACTIVATION IN HEALTHY AND DISEASED MURINE PARTIAL HEPATECTOMY MODELS

Ryan Watkins[1], EeeLN Buckarma[1], Chantal McCabe[1], Patrick Starlinger[1], Gregory J. Gores[1], Weijun Shen[2] and Rory Smoot[3], (1)Mayo Clinic, (2)Calibr at Scripps, (3)Mayo Clinic Rochester, Rochester, MN

Background: Pharmacologically enhancing liver regeneration after hepatectomy may avert complications such as post hepatectomy liver failure, a morbid condition. Yes-associated protein (YAP), a transcriptional co-activator, is instrumental in liver regeneration. We have shown that small molecule inhibitors NSC87877 (NSC) and mCLC846 (mCLC) enhance liver regeneration individually. Both activate YAP through the non-canonical and canonical pathways respectively. We have also previously shown that their underlying regenerative augmentation differs molecularly. Herein, we investigated the effects combined therapy with NSC and mCLC in murine partial hepatectomy models across multiple disease states including diet induced non-alcoholic steatohepatitis (NASH). **Methods:** Mice were treated with mCLC (100 mg/kg/d) and NSC (15 mg/kg/d) or vehicle immediately before and after standard two-thirds partial hepatectomy (PH). Twelve-week-old male C57BL/6J mice were utilized. RNA-sequencing was performed from liver lysate using Illumina Hi-Seq4000 followed standard bioinformatic analysis. Additional murine models underwent PH included: mice aged to 34 weeks under normal conditions (chow control) or with a high fat, high cholesterol, and high glucose and fructose diet to induce non-alcoholic steatohepatitis (NASH), homozygous null Mdr2 (Mdr2-/-), representing a model of primary sclerosing cholangitis, and extended hepatectomy in wild type mice (90% liver excision) with a right posterior lobe remnant, mirroring small for size syndrome. Liver regeneration was assessed by liver to body weight ratio 72 hours following surgery. Proliferation was assessed by immunoblot for proliferating cellular nuclear antigen (PCNA). **Results:** Wild type mice treated with NSC/mCLC had significantly increased liver to body weight ratio 72h post PH as compared to vehicle (5.6 % vs 2.6 %, $p < 0.001$) with elevated PCNA in treated mice. Transcriptomic analysis of regenerating remnants 40h following PH treated with NSC/mCLC identified upregulated genes consistent with the termination phase of liver regeneration, indicating an accelerated timeline. Mice undergoing extended hepatectomy had increased liver to body weight ratio when compared to vehicle treated mice (1.85 % vs 2.57 %, $p < 0.01$). Mdr2-/- mice regeneration was enhanced with NSC/mCLC with increased liver to body weight ratio (3.39 % vs 4.01 %, $p < 0.05$) which was not observed with single agent treatment. Chow control had increased liver to body weight ratio post PH (2.49 % vs 3.11 %, $p < 0.001$) with a 10-fold increase in PCNA. NASH mice survival was severely reduced when compared to chow controls 72h post PH (22.2 % vs 100 %, $p < 0.01$). Treated NASH mice had improved survival (58.3 % vs 22.2 %, $p < 0.05$). **Conclusion:** Dual YAP activation enhanced liver regeneration in healthy and deranged regenerative models: small for size syndrome, primary sclerosing cholangitis, and NASH with enhanced survival in NASH.

1015-A | EVALUATING THE CORRELATION BETWEEN AP DIAMETER, BODY SURFACE AREA AND HEIGHT FOR LIVER TRANSPLANT DONORS AND RECIPIENTS FOR THE ERA OF CONTINUOUS DISTRIBUTION

Catherine Kling[1], Christopher Little[1], Scott W. Biggins[2] and James D. Perkins[1], (1)University of Washington, (2) University of Washington, Seattle, WA

Background: Shorter height and lower body surface area (BSA) correlate with reduced deceased donor liver transplant (DDLT) access, resulting in longer waitlist times, higher incidence of waitlist mortality, and a lower overall transplant rate compared to larger candidates. To mitigate this disparity in the coming era of Continuous Distribution, implementable size-matching measures should be introduced to guide allocation policy and decision making. Liver anteroposterior (AP) diameter on cross-sectional imaging is considered an important measure of liver usability for DDLT, though it is not regularly obtained nor recorded in the United Network for Organ Sharing (UNOS) data sets. As such, we sought to correlate height and BSA, two universally available characteristics, to AP diameter in donors and recipients. Multivariable competing risk analysis was then used to correlate these variables with waitlist outcomes. **Methods:** AP diameter was measured via cross-sectional imaging in 143 DDLT donor-recipient pairs from a single center between 2021-2022 (Figure 1. AP diameter [black line] measured at the mid-hepatic point halfway between the mid-vertebral body [medial white line] and inner abdominal wall [lateral white line] at the level of the right hepatic vein). Linear, Pearson's and PhiK correlation coefficients were used to correlate

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

BSA and height to AP diameter. Competing risk analyses of waitlist outcomes were performed using UNOS data collected from 6/18/2013-3/20/2020. **Results:** Amongst DDLT donors, BSA correlated better with AP diameter than height (PhiK $R^2 = 0.63$ vs 0.20). For recipients, neither BSA nor height were good predictors of AP diameter (PhiK $R^2 = 0.34$ and 0.43). However, in a subset of recipients without ascites (35.7% of recipients), BSA did correlate well to AP diameter (PhiK $R^2 = 0.63$) but not to height. In the multivariable competing risk models, both taller height and greater BSA were associated with increased access to DDLT, decreased delisting for death or critical illness, and decreased dependence on living donor liver transplant; however, the BSA model slightly outperformed that of height (model concordance 0.748 vs 0.747). **Conclusion:** Taken together, these findings indicate that BSA correlates well with AP diameter in donors and recipients without ascites and serves as an effective predictor of waitlist outcomes. We posit that BSA can therefore be used as a surrogate for AP diameter to optimize donor liver allocation to small recipients.

1016-A | EVALUATION OF LIVER REGENERATION CAPACITY WITH THE USE OF GENABILIC ACID, SILYMARIN-CURCUMIN, GANODERMA LUCIDUM, AMINO ACID-MULTIVITAMIN MIXTURE, AND 2-METHYL-2-PHENOXY-PROPIONIC ACID BEFORE PARTIAL HEPATECTOMY: BIOCHEMICAL AND IMMUNOHISTOCHEMICAL EFFECTS IN RATS

Sencan Acar[1], Hüseyin Çakıroğlu[2], Erdem Çokluk[2], Özcan Budak[2] and Ahmet Tarık Eminler[2], (1)Amasya University Sabuncuoglu Serefeddin Eah, (2)Sakarya University Faculty of Medicine

Background: Remnant liver tissue is essential for the surgery of primary liver tumor, metastasectomy, or donor hepatectomy. There are various supplements that are stated to increase liver regeneration. We aimed to show whether there is an effective supportive treatment that can increase the safety of donors with insufficient remnants, as well as expand the donor pool, in countries where living donor liver transplantation is performed intensively, as in our country. Therefore, in our study to investigate the effects of different substance extracts on the regeneration capacity of residual liver tissue after hepatectomy. **Methods:** Rats of equal age and approximately equal weight were grouped into 6 groups: Group 1 = Sham group; Group 2 = Genabilic acid, 3/7 days, 6 weeks oral gavage, 10 mg/kg; Group 3 = Silymarin+curcumin, 6 weeks oral gavage, 200mg/kg+40mg/dose/day; Group 4 = Ganoderma lucidum, 900mg/kg oral gavage for 6 weeks; Group 5 = Mixture containing group B vitamins, amino acids, l-carnitine and sugars, 4 ml/kg for 1 week, IP; Group 6 = Phenoxy-2-methyl-2-propionic acid, 10 mg/kg for 1 week, IP. Subjects' mTOR, insulin, nesfatin, and leptin levels were checked. Proliferating cell nuclear antigen (PCNA) was performed for regeneration control and immunohistochemically, Ki-67, mTOR, VEGF, FGF, HGF, and Calpain-10 stainings were conducted from the liver. **Results:** In the comparison of the Sham group and the other groups; there was a significant difference in terms of insulin with group 4 ($p = 0.041$) and nesfatin with group 3 ($p < 0.001$) The other markers were similar. Proliferating cell nuclear antigen, Ki-67, mTOR, and Calpain-10 were significantly different in all groups ($p < 0.001$). It was also significantly different in terms of VEGF, FGF, and HGF with the other groups except group 4. **Conclusion:** It was determined that the silymarin-curcumin mixture was more successful in suppressing hunger hormones with an increase in nesfatin level, while Ganoderma lucidum caused a decrease in insulin levels. Considering the fact that regeneration of the liver with fibrosis is an undesirable situation, although it is thought that Ganoderma lucidum does not affect FGF levels, it creates a healthier regeneration tissue, but this has not been proven by immunostaining. In conclusion, no single agent is ideal in the prophylaxis of possible hepatic failure after hepatectomy. It is thought that combinations may be required in the use of such agents. It is clear that further research is needed.

1017-A | EXPERIENCE IN USE OF DONORS WITH ACTIVE HEPATITIS B FOR LIVER TRANSPLANT

Media N Ismael[1], Juan Gonzalez[1], Steve Shen[1], Andreas Zori[2], Consuelo Soldevila-Pico[1] and Roniel Cabrera[1], (1)University of Florida, (2)University of Florida, Gainesville, FL

Background: Organ shortage remains a major challenge in liver transplantation (LTx). Efforts have been made to increase the donor pool with high-risk organs but experience with active hepatitis B (HBV) liver donations lags behind. Careful selection of recipients and effective antiviral prophylaxis can reduce the risk of HBV transmission in the context of LTx. In this report, we summarize our center's experience in utilizing donor livers with active HBV **Methods:** Patients who underwent LTx at the University of Florida between 2020 and 2022 were retrospectively reviewed. Transplants from donors with HBV nucleic acid test (NAT) positive or hepatitis B surface antigen (HBsAg) positive livers were included in the study. Donor and recipient viral serologies pre- and post-transplant, treatment algorithms, and post-transplant management and survival were reviewed. **Results:** Eleven patients received LTx from donors with active HBV infection. Eight were men (72.7%) with a median age of 53 and MELD of 19 at transplant. The wait time ranged from a month to eight months. Only one recipient had chronic HBV infection prior to LTx, and none had active or previous hepatitis C (HCV). Seven patients had immunity to HBV at transplant (63.6%). Two donors were HCV antibody positive and two HCV NAT positive. The two patients who received livers from HCV NAT positive received Epclusa post-transplant. All patients received Hepatitis B immunoglobulin (HBIG) after transplant and placed on antiviral therapy for HBV. Everyone received immunosuppression per protocol with a short steroid taper, tacrolimus, and mycophenolate. Four showed positive HBsAg post-transplant with two of them developing low level viremia in the immediate post-transplant period that resolved within days. Only one patient had graft rejection that responded to pulse steroids. There were two deaths in this cohort, one due to cardiopulmonary arrest and the other due to liver failure with unclear etiology. Although this patient developed detectable sAg, HBV DNA was never detectable. The remaining patients did not have significant complications post-transplant with 6 surviving more than a year and the rest being transplanted within the past year. **Conclusion:** Utilizing donors with active HBV for LTx is feasible with good outcomes. There were no definite HBV related complications and viral suppression was achieved in all patients. Pre-transplant vaccination of recipients along with vigilant post-transplant follow up and a standardized protocol of testing ensure ability to control HBV and prevent viremia.

1018-A | EXPERIENCES OF ALCOHOL-RELATED LIVER DISEASE LIVER TRANSPLANT RECIPIENTS WITH AND WITHOUT 6 MONTHS OF PRE-TRANSPLANT ABSTINENCE

Janetta Brundage[1], Mayan Teles[1], Aura Abdeon[1], Andrea F. DiMartini[2], Geetanjali Chander[3], Olivia Kates[4], Hannah C. Sung[4], Andrew M. Cameron[1] and Po-Hung (Victor) Chen[4], (1)Johns Hopkins University, (2)University of Pittsburgh, (3)University of Washington, (4)Johns Hopkins University School of Medicine

Background: Historically, transplant centers have required liver transplant (LT) candidates with alcohol-related liver disease (ALD) to demonstrate 6 months of alcohol abstinence prior to receiving their LT, known as the "6-month rule." Differences in experiences between those transplanted before (early LT) and after (standard LT) 6 months of alcohol abstinence are understudied. Our qualitative study aimed to assess similarities and differences in ALD LT recipients' alcohol-related experiences and identify potential unique experiences of early LT recipients. Understanding these similarities and differences could help determine applicability of the 6-month rule. **Methods:** We conducted in-depth, semi-structured interviews (n = 39) with LT recipients from a single center from 2 patient groups: (a) early LT (ELT), who had < 6 months of alcohol abstinence prior to LT (n = 20) and (b) standard LT (SLT), who had ≥ 6 months of alcohol abstinence prior to LT (n = 19). We inductively analyzed interviews and generated themes within and across groups. **Results:** Across ELT and SLT groups, participants described similar alcohol-related experiences before their transplant. Some participants did not know that their level of alcohol use was causing damage to the point of needing a liver transplant. Others perceived that their alcohol use was "heavy" but did not, at the time, feel concerned because they were able to maintain relationships and work. Still others described their alcohol use as negatively impacting their relationships. ELT participants questioned if they were "deserving" of a LT more explicitly than SLT participants. An ELT participant expressed that they had felt "guilty" when they were accepted for a liver transplant after being denied at another center for not having at least 6 months of alcohol abstinence. The participant elaborated, "I can't take somebody else's liver because I don't deserve it." **Conclusion:** Themes indicate a lack of substantial differences between ELT and SLT experiences with alcohol. However, questioning their worthiness for transplant seems to be more pronounced with the ELTs. Our qualitative work has generated a hypothesis that differential perceptions in self-worth between ELT and SLT groups may not be attributable to alcohol-related history, but rather their experiences around the stigmatizing "6-month rule." Patient perceptions of bypassing the "6-month rule" may reinforce alcohol-related self-stigma.

1019-A | FACTORS ASSOCIATED WITH RECEIVING A LIVER TRANSPLANT FROM DECEASED DONORS LOCATED FAR FROM THE TRANSPLANT HOSPITAL

Neha Godbole, University of Miami and David Goldberg, University of Miami School of Medicine

Background: Increased distance between donor hospitals and transplant centers is associated with added logistics and cold ischemia times due to travel. Importing organs is associated with higher costs associated with travel by air of the organ (+/- the procuring team) and at times additional import fees. There are known disparities in access to a transplant based on insurance type, although these largely are related to access to the waitlist. However, because transplant centers often receive higher reimbursement from private insurers and Medicare, compared to Medicaid, there is the potential for disparities in receipt of far donors as a function of a patient's insurance. We sought to explore the association between insurance type and receipt of a far donor among liver transplant recipients. **Methods:** We conducted a retrospective cohort study using OPTN/UNOS study of adult deceased donor liver transplant recipients from 1/1/2015-3/31/2023. The outcome was defined as being transplanted with a liver from a donor located "far" from the transplant hospital (primary: 500 miles; secondary: 250 miles). Mixed effects logistic regression models were fit to evaluate the association between insurance type and receipt of a liver from a far donor, with state modeled as a random effect to account for baseline variability in reimbursement rates for patients with Medicaid based on state of residence. **Results:** Several clinical variables were associated with receipt of a liver

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transplant from a donor located far from the transplant hospital (Table 1). Increased MELD score was associated with a decreased odds of receiving a donor from a far hospital, while being mechanically ventilated or in the intensive care unit were associated with an increased odds. However, even after accounting for key clinical and demographic covariates, there was no significant difference in the odds of receiving a transplant from a donor located far from the transplant hospital for patients with Medicaid insurance compared to those with private or Medicare insurance (Table 1). Patients with "other" insurance were less likely to receive a transplant from a "far" donor using the secondary outcome definition of far as > 250 nautical miles from the transplant center to donor hospital. **Conclusion:** Although there are different clinical factors associated with receiving a liver transplant from a donor located far from the transplant hospital, patients with Medicaid insurance are no less likely to receive a transplant from a far donor. This despite the fact that Medicaid reimbursement rates for transplant are often less than private insurers and Medicare, and far donors are associated with increased costs. Even though there are disparities in access to the waitlist based on insurance type, a surrogate for socioeconomic status to some degree, it is reassuring that once waitlisted, transplant decisions and donor selection do not appear to be influence by potential differences in reimbursement.

1020-A | GENDER AND LEADERSHIP IN LIVER TRANSPLANTATION

Nazokat Otajonova[1], Luis Garrido-Treviño[2], Giovanna Saracino[2], Sumeet Asrani[2] and Anji Wall[3], (1)Baylor, (2) Baylor University Medical Center, Dallas, TX, (3)Baylor University

Background: Women are underrepresented in leadership positions throughout the world. We hypothesized that there are significant differences in leadership opportunities for women across transplantation in the US. **Methods:** We performed a cross-sectional study of 13 leadership position types of 114 transplant centers in the US. Data was collected from the OPTN and individual departments. We examined gender, terminal degrees, years in practice, academic degrees, and additional leadership roles. **Results:** *Overall:* In US programs, only 18.7% of abdominal transplant surgeons (132/705) and 33.5% of transplant hepatologists (226/674) were female. Among transplant surgeons, the female sex was associated with higher degrees ($p = 0.02$): more females had a master's (11.5% vs. 5.3%) or Ph.D. (13.7% vs. 12.3%) as compared to males. *Leadership:* Only 10-20% of leadership positions were held by females: LT Surgical Director (10.5%), LT Medical Director (21.1%), Transplant division chief (11.9%), and Hepatology/Gastroenterology chief (15.4%). Centers having female Division Chiefs/Directors were more likely to have female LT Surgical Directors ($p = 0.02$). A larger percentage of females needed to be full professors: For females, 80% and 73.3% of women needed to be a professor to advance to these chief roles; for males, it was 65.8% and 65.2% respectively. There was a significant difference by sex and academic rank ($p = < 0.01$) for liver transplant medical directorship. Women were more likely to be assistant professors (8, 33.3%), whereas men were more likely to be professors (33, 37.1%) or associate professors (20, 27.5%). **Conclusion:** Less than 20% of transplant leadership positions are secured by females. Despite comprising a substantial proportion of the medical workforce, and holding additional professional titles, women still encounter substantial obstacles in securing leadership positions within transplant centers and academia.

1021-A | IMPACT OF DONOR CORONARY ARTERY DISEASE ON PATIENT AND GRAFT SURVIVAL AMONG LIVER TRANSPLANT RECIPIENTS IN THE UNITED STATES★

Kenji Okumura, Ryosuke Misawa, Abhay Dhand, Suguru Ohira, Hiroshi Sogawa, Roxana I. Bodin, Gregory R. Veillette, David C. Wolf and Seigo Nishida, Westchester Medical Center

Background: While routine donor coronary angiograms are not performed routinely, but the impact of incidental coronary artery disease (CAD) detected during the donor evaluation process on liver graft outcomes is unknown. The aim of this study was to assess the impact of donor CAD on patient and graft survival in Liver transplant (LT) recipients. **Methods:** Data from adult LT recipients who received livers from donors with coronary artery angiograms in the United Network for Organ Sharing (UNOS) between 2002 and 2022 was analyzed. CAD was defined as > 50% obstruction of one or more coronary arteries on angiogram. **Results:** During the study period, 2663 LT recipients (CAD N = 665 vs non-CAD N = 1998) were identified. In 665 donors, 120(18%) had 3-vessel, 126 (19%) had 2-vessel and 419 (63%) has 1-vessel CAD. Donors with CAD were older (median age: 50 vs 45 y, $p < 0.001$), had lower BMI (26.9 vs 27.4 hours, $p = 0.018$), higher rate of hypertension (54% vs 37%, $p < 0.001$) and diabetes (21% vs 9.9%, $p < 0.001$), with lower HCV-NAT positive rates (1.8% vs 4.3%, $p = 0.035$). The quality of livers as assessed by serum bilirubin and macro/micro steatosis were equal in both groups. LT recipients in CAD group had lower MELD score (24 vs 26, $p = 0.002$). Five-year overall survival (CAD 72.9% vs non-CAD 77.7%, $p = 0.079$) and five-year graft survival (CAD 69.5% vs non-CAD 75.6%, $p = 0.041$) were worse in CAD group (Figure). No difference was seen in risk of vascular thrombosis post-LT in both groups. In multivariable cox-regression analysis, significant risk factors for five year-graft failure were donor 3-vessel CAD (hazard ratio, 1.64; 95% CI: 1.11-2.43; $p = 0.014$) and donor hypertension (hazard ratio, 1.30; 95% CI: 1.09-1.56; $p = 0.003$). **Conclusion:** Risk of five-year graft failure among LT recipients was increased when using livers from donors with known 3-vessel CAD and hypertension.

1022-A | IMPACT OF ETIOLOGY ON THE PREDICTION OF WAITLIST MORTALITY IN LIVER TRANSPLANT CANDIDATES

Nakia L Chung[1], Ajitha Mannalithara[1], W. Ray Kim[2] and Allison J. Kwong[1], (1)Stanford University School of Medicine, (2)Stanford University School of Medicine, Woodside, CA

Background: The US organ allocation system does not take into account liver disease etiology in the assessment of medical urgency gauged by the Model for End-Stage Liver Disease (MELD). The epidemiology and demographics of patients undergoing liver transplant (LT) have changed rapidly, including rising prevalence of alcohol-associated liver disease (ALD). MELD equations have not previously considered the possible contribution of the underlying etiology of liver disease to the prediction of waitlist mortality. Patients with different diagnoses may have different mortality risk. We tested whether the association between waitlist mortality and MELD differ by etiology. **Methods:** We evaluated all new adult waitlist registrations from Jan, 2016 to Dec, 2022 in the OPTN registry. Patients with exception points at listing or previous history of liver transplant were excluded. MELD-Na and MELD 3.0 was calculated for each new listing, and etiology was categorized into (ALD), non-alcoholic steatohepatitis (NASH), viral, cholestatic, and other based on listing diagnosis. ALD was subset into alcohol-associated hepatitis (AH) and

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

alcohol-associated cirrhosis (AC). Cox regression analysis was used to evaluate the hazard of 90-day waitlist mortality from registration, with censoring at liver transplant and adjustment for age. The effect of a 1-unit change in MELD was reported by etiology and MELD category (< 15, 15-24, 25-34, and 35+). **Results:** There were 69,390 eligible adults with end-stage liver disease listed for primary liver transplant, 25,107 (36%) with a primary diagnosis of ALD, 14,335 (21%) with NASH, 9,828 (14%) with viral hepatitis, 4,289 (6%) with cholestatic liver disease, and 15,768 (23%) with other diagnosis. Patients with ALD had higher median MELD-Na than other diagnoses (24 v 17, $p < 0.01$), and those with AH had higher MELD-Na than those with AC (36 v 23, $p < 0.01$). The age-adjusted hazard ratio for 90-day mortality was similar across etiologies, with a hazard ratio of 1.20, indicating a 20% increase in mortality risk for each 1-unit change in MELD-Na (Figure). The overall hazard ratio for AH was lower than all other diagnoses including AC, at 1.16 (95% CI 1.13-1.19), but similar to other etiologies at comparable MELD (35+). The results did not change materially when the data was analyzed using MELD 3.0. **Conclusion:** Given the increasing prevalence of ALD, AH, and NASH among liver transplant candidates, it is crucial to determine if the current tools used to predict waitlist mortality retain precision. In the current study, we demonstrated no significant etiologic differences using MELD-Na or MELD 3.0. Our study suggests that there currently is no need to adjust the MELD score for the underlying etiology of liver disease.

Figure. Age-adjusted hazard ratios for each 1-unit change in MELD-Na, (A) overall and (B) MELD 35+.

1023-A | IMPACT OF HIGH-VOLUME TRANSPLANTATION OF ALCOHOL-ASSOCIATED LIVER DISEASE ON WAITLIST OUTCOMES TRANSPLANTATION FOR HEPATOCELLULAR CARCINOMA AND OTHER INDICATIONS

Divya Ayyala[1], Jennifer L. Dodge[1], Kali Zhou[2], Norah Terrault[1] and Liyun Yuan[1], (1)University of Southern California, (2)University of Southern California, Los Angeles, CA

Background: Liver transplantation (LT) for alcohol-associated liver disease (ALD) is rising with potential effects for patients listed for LT with hepatocellular carcinoma (HCC) or Other indications (non-ALD, non-HCC). **Methods:** Using U.S. adults (N = 56,696) listed for primary LT from 10/8/2015 to 12/31/2021 with LT indications of HCC (N = 13,274), ALD (N = 20,570), and Other (N = 22,752), we examined the impact of center-level LT volume for ALD (ATxV, low to high tertiles T1◄T3) on waitlist outcomes within HCC policy Era 1 (6-month wait) and Era 2 (MMAT-3). The outcomes were (1) waitlist mortality (death, dropout on the waitlist for clinical deterioration) and (2) LT within 18 months. Multivariable competing risk regression estimated the adjusted sub-hazard ratios (sHR) for risk of waitlist outcomes with interaction effects to test whether ATxV had a differential impact by indication. **Results:** Of 56,596 candidates listed (31,293 in Era 1 and 25,303 in Era 2), the cumulative incidence of waitlist mortality did not differ by AtxV for HCC ($p = 0.48$) or Other ($p = 0.16$) (Figure B,C) in Era 1 and differed significantly by ATxV in Era 2 for HCC ($p = 0.03$) and Other indications ($p < 0.001$) with the highest mortality in ATxV T3 (Figure E,F). However, in Era 2, the adjusted waitlist mortality sHR for candidates listed at high (T3) vs low (T1) AtxV centers did not differ significantly among those with ALD [0.99 (0.66-1.26)], HCC [1.15 (0.96-1.38), interaction $p = 0.22$], and Other [1.13 (0.87-1.46), interaction $p = 0.16$] suggesting no differential effect of AtxV on waitlist mortality by indication. The cumulative incidence of LT differed by AtxV tertile for HCC (Era 1: $p < 0.001$, Era 2: $p < 0.001$) and Other indications (Era 1: $p = 0.007$, Era 2 $p < 0.001$) in Era 1 (Figure H,I) and Era 2 (Figure K,L) with the lowest incidence in T3. The adjusted LT sHR in Era 2 for candidates listed at high (T3) vs low (T1) AtxV centers did not differ significantly among those with ALD [1.04 (0.89-1.34) but was lower among HCC [0.89 (0.72-1.11, interaction $p = 0.08$] and Other indications [0.82 (0.67-1.01), interaction $p = 0.02$)] suggesting a potential differential effect of ATxV on LT by indication. **Conclusion:** High volume of LT for ALD has not negatively impacted waitlist mortality for HCC and other indications. However, we identified a potential adverse effect on LT probabilities for HCC and Other

1024-A | IMPACT OF LAPAROSCOPIC LIVER RESECTION FOR ACCESS TO THE WAITING LIST OF A SINGLE REGIONAL CENTER FOR LIVER TRANSPLANTATION IN SOUTHERN ITALY: ANALYSIS OF ENTRY AND DROP-OUT FLOWS OF PATIENTS WITH END-STAGE-LIVER-DISEASE.

Duilio Pagano[1], Fabrizio Di Francesco[1], Giuseppe Cabibbo[2], Sergio Li Petri[1], Ciro Celsa[2], Pasquale Bonsignore[1], Sergio Calamia[1], Alessandro Tropea[1], Caterina Accardo[1], Ivan Vella[1], Roberta Vella[1], Alessandro Grova[2], Marco Barbara[1] and Salvatore Gruttadauria[1,3], (1)University of Pittsburgh Medical Center in Italy, (2)Section of Gastroenterology & Hepatology, Department of Health Promotion Sciences Maternal and Infant Care, Internal Medicine and Medical Specialties, Promise, University of Palermo, (3) University of Catania, Catania, Italy

Background: Hepatocellular carcinoma (HCC) is the most common primary liver cancer, and both liver resection (LR) and liver transplantation (LT) are considered potentially curative options. We aimed to explore the impacting role of minimally invasive approach on entry and drop-out flows waiting list of a single regional center for LT in southern Italy with a very low deceased donation rate. **Methods:** We retrospectively analyzed our experience performed during a 7-year period between January 2016 and February 2023 in patients treated for end-stage-liver-disease (ESLD) and/or with surgically unresectable early and intermediate stage HCC. Linear correlation was used to evaluate dependence between the number of laparoscopic LR (LLR) treatments for HCC on the following flows of enrollments on the waiting list during the study period:-Enrollments present at the beginning of the year.-Enrollments that took place during the year, the Intention-To-Treat (ITT, present at the beginning of the year+admissions during the year).-Registrations present at the end of the year, and waiting for transplants for transplanted patients. **Results:** There were 282 HCC patients treated with a first-line approach of LLR ($n = 116$) or open LRs ($n = 166$), with an incremental number of LLR per months. Considering the number of LLR and the rate of drop-out of ITT population and the number of enrolled patients per year, we observed a strong inverse linear correlation (rho = -0.82, $p = 0.023$). (Figure 1) **Conclusion:** Minimally invasive surgical therapies for HCC has a specific impact on drop-out percentage of overall ITT population, and waiting time for transplants for transplanted HCC patients.

1025-A | IMPROVED ACCESS TO DECEASED DONOR LIVER TRANSPLANTATION FOR VETERANS AT VA TRANSPLANT CENTERS IN ASSOCIATION WITH THE MISSION ACT

Shivram Ayyappan Chandramouli[1], Samuel J. Kesseli[2], Andrew Barbas[2], Carl L. Berg[2] and Cynthia Moylan[2], (1) Duke University Health System, (2)Duke University

Background: The MISSION Act, effective June 6th, 2019, was designed to increase veteran access to providers outside the Veterans Affairs (VA) Health System. This was predicted to increase veteran access to geographically close non-VA transplant centers and decrease the VA transplant volume. There is limited data comparing pre- and post-MISISON Act trends in liver transplant (LT). Our aim was to explore pre- and post-MISSION Act LT rates, waitlist deaths, and 1-year graft survival at VA and non-VA centers. **Methods:** We conducted a retrospective cohort study using the Scientific Registry of Transplant Recipients (SRTR) data on LT across two, 2-year time periods before and after MISSION Act. Probabilities of expected LT outcomes are publicly available statistics calculated by the SRTR using Cox proportional hazard models based on national data. Three large volume VA LT centers (Portland, OR; Pittsburgh, PA; and Houston, TX) were considered, with all other LT centers designated as non-VA. We compared VA and non-VA for observed-to-expected (O:E) LT rates, waitlist deaths, and 1-year graft survival. Statistical analysis was conducted using RStudio. **Results:** Pre-MISSION Act, 14,513 deceased donor LTs (DDLTs) were performed between December 31, 2016, and December 30, 2018, with 163 (1.12%) performed at a VA center (Table 1). We found a significant difference between O:E LT rates at VA compared to non-VA centers (73.6% vs. 138%, $p = 0.02$). Post-MISSION Act, 14,327 DDLTs were performed between January 1, 2020, and December 31, 2021, with 89 (0.621%) performed at a VA center. O:E LT rates were no longer significantly different between VA and non-VA centers (57.0% vs. 117%, $p > 0.05$). We did not identify significant differences between VA and non-VA O:E waitlist death rates pre- (93.8% vs. 95.0%, $p > 0.05$) or post-MISSION Act (101% vs. 89.7%, $p > 0.05$) or in O:E 1-year graft survival pre- (93.9% vs. 160%, $p > 0.05$) or post-MISSION Act (90.2% vs. 86.5%, $p > 0.05$). **Conclusion:** The MISSION Act was intended to increase veteran access to non-VAHS. Our analysis of SRTR data reveals that DDLT observed-to-expected rates at VA centers improved post-MISSION Act without significant changes in waitlist deaths or 1 year graft survival. These findings suggest VA LT centers responded to the MISSION Act by increasing their ability to serve veterans with LT needs. Further analysis is needed to understand the impact of COVID19 on these results and longer-term outcomes.

Table 1. Trends in Liver Transplant Rates, Waitlist Mortality, and Graft Survival Pre- and Post-MISSION Act at VA and Non-VA Centers

	VA Centers	Non-VA Centers	P-value
Number of All Deceased Donor LTs			
Pre-MISSION Act	163	14,350	
Post-MISSION Act	89	14,238	
O:E Transplant Rates			
Pre-MISSION Act	73.6%	138%	0.02
Post-MISSION Act	57.0%	117%	0.11
O:E Waitlist Death Rates			
Pre-MISSION Act	93.8%	95.0%	0.83
Post-MISSION Act	101%	89.7%	0.31
O:E 1-Year Graft Survival			
Pre-MISSION Act	93.9%	160%	0.31
Post-MISSION Act	90.2%	86.5%	0.77

Pre-MISSION Act depicted as a two-year period from December 31, 2015, to December 30, 2018.
Post-MISSION Act depicted as a two-year period from January 1, 2020, to December 31, 2021.

1026-A | IMPROVING INFORMED CONSENT FOR LIVING LIVER DONORS: WHAT INFORMATION DO DONORS WANT ABOUT THEIR RECIPIENT?

Adrienne Chen[1], Allison Carroll[1], Elisa J. Gordon[2] and Josh Levitsky[1], (1)Northwestern University Feinberg School of Medicine, (2)Vanderbilt University Medical Center

Background: Living donor liver transplant (LDLT) has steadily increased over the past decade and now comprises 5-6% of all liver transplants. While information about the general donation process is disclosed during the informed consent process in LDLT evaluation, it is not known if more detailed information about recipients' short- and long-term outcomes, particularly in high-risk scenarios, would enhance living liver donors' (LDs) informed decision-making and willingness to donate. Our study aimed to assess information that prior LDs found pertinent to their donation process, and compare information needs between LDs and the

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

general public. **Methods:** We conducted two independent online surveys of: 1) prior LDs from Northwestern Memorial Hospital, and 2) a random sample of the public via Amazon Mechanical Turk. The survey assessed three common high-risk recipient scenarios: 1) alcoholic liver disease with high relapse risk (ALD), 2) acute time frame due to acute liver failure (ALF), and 3) hepatocellular carcinoma with high recurrence risk (HCC). Likert-scale responses were dichotomized for analysis. Data were analyzed using R and Orange with chi-squared analysis or Kruskal-Wallis H test. **Results:** There were 385 total participants (LD: 96, public: 289). Most LD and public participants were White, had a college education, health literate, and in excellent or very good overall health. The LD and public groups differed significantly in average age (LD 49, public 35), female gender (LD 64%, public 35%), Hispanic/Latinx identity (LD 5%, public 50%), and income > $75,000 (LD 73%, public 29%). Most participants were willing to donate, with the highest rate in HCC, then ALF, then ALD ($p = 0.045$) (Figure 1). The public was more likely to donate in ALD ($p < 0.001$) and ALF ($p = 0.006$), but LDs were more likely to donate in HCC ($p = 0.026$). Most LDs (81%) and public (80%) would find a consultation service (e.g., talking with a prior donor) helpful in the setting of ALF. Most participants desired more information in all scenarios, including the recipient's diagnosis, cause of liver failure, and prognosis of their condition with DDLT versus LDLT versus no transplant. **Conclusion:** Our findings suggest that LDs and the public desire information about their recipient's diagnosis, clinical condition, and projected outcomes to guide decision-making about donation. Implementation of a consultation service and rapid education in acute timelines might assist in LD decision-making with ALF. Transplant programs should assess potential LDLT recipients' willingness to share information about their diagnosis, condition, and outcomes with potential LDs to foster LD informed consent.

1027-A | INDICATION MODEL FOR LAPAROSCOPIC REPEAT LIVER RESECTION IN THE ERA OF ARTIFICIAL INTELLIGENCE: MACHINE LEARNING PREDICTION OF SURGICAL INDICATION

Eunjin Lee[1], Sung Jun Jo[2], Jong Man Kim[2], Jae-Won Joh[2], Jinsoo Rhu[2] and Gyu-Seong Choi[2], (1)Samsung Medical Center, (2)Samsung Medical Center, Sungkyunkwan University School of Medicine

Background: Laparoscopic repeat liver resection (LRLR) is still a challenging technique and requires a careful selection of indications, as the adhesion range is wide and the anatomy is different from previous surgeries. However, the current difficulty scoring system is not suitable for selecting indications. The purpose of this study is to develop the indication model for LRLR using machine learning and to identify factors associated with open conversion (OC). **Methods:** Patients who underwent repeat hepatectomy at Samsung Medical Center from January 2017 to December 2021 were investigated. Machine learning methods (random forest, support vector machine [SVM], extreme gradient boosting [XGB]) and logistic regression were used to develop indication model. The performance between the models was evaluated and risk factors associated with OC were also analyzed. **Results:** The cohorts of 110 patients with LRLR and 111 patients with open repeated liver resection (ORLR) were reviewed and analyzed. The previous open approach rate was higher in the ORLR group (75.7% vs 38.2%, $p < 0.001$). In the risk factor analysis of OC, twice previous abdominal operation (OR 6.56, $p = 0.009$) was the only factor associated with OC in multivariate analysis. The performance of the indication model showed similar predictive power in both random forest ($p = 0.720$) and logistic regression ($p = 0.733$). The difference in performance between the two models was not statistically significant ($p = 0.710$). Previous laparoscopic approach, present subsegmentectomy, and left side location of the present tumor were selected as important variables in both models. **Conclusion:** The performance of the indication model for LRLR showed good predictive power in both machine learning and logistic regression. The important variables for LRLR were previous laparoscopic approach, present subsegmentectomy, and left side location of the present tumor.

f 1028-A | INTERACTIONS BETWEEN RACE/ETHNICITY AND GENDER IN LIVER TRANSPLANTS: DO ACUITY CIRCLES MATTER?

Ahila Manivannan[1], AnnMarie Liapakis[2], Anna Mae Diehl[3], Elizabeth Verna[4], Vineeta Kumar[5], Reena J. Salgia[1], Trueman Wu[1], Mei Lu[6], Neehar Dilip Parikh[7] and Michelle Jesse[1], (1)Henry Ford Health, (2)Yale University, New Haven, CT, (3)University of Chicago, (4) Columbia University Irving Medical Center, New York, NY, (5)The University of Alabama at Birmingham, (6) 156 Pocatello Rd, (7)University of Michigan

Background: Despite continued efforts, there are well-documented disparities in liver transplantation (LT) from listing through post-transplant. National policies on allocation of deceased donor liver transplants (DDLT) aim to provide consistent and equitable access. However, the impacts of Acuity Circles (AC) and interactions between race and gender on delisting due to deterioration/death or receipt of DDLT have been minimally explored. **Methods:** Using data from the United Network for Organ Sharing (UNOS), we studied listed adults for DDLT from April 3, 2017, to October 4, 2022, a 60-month period (30 mo pre- and post-AC). Fine-Gray subdistribution hazard model was used to study AC impact on LT while delisting due to deterioration/death was used as a competing risk. The model focused on AC indicator by race by gender interactions, as well as AC by hepatocellular carcinoma (HCC) diagnosis interactions. **Results:** 59,592 patients (30,202 pre-AC, 29,390 post-AC) were studied. No 3-way (AC X race X gender) interaction was detected, indicating effect of race and gender on LT was consistent pre- and post-AC periods. However, there were significant gender by race or AC by HCC interactions (Table 1): patients with HCC had greater chance for LT than non-HCC, though post-AC this effect was reduced. AC increased LT 25% in patients without HCC. Across gender, White, Black, and Hispanic men were more likely to receive transplant compared to their female counterparts. Within gender, Black and Hispanic women were less likely to receive transplant than White women, with no significant differences between White and Asian women. For men, there were no statistical difference in likelihood for transplant between White versus Black or Hispanic men, but Asian men had a lower likelihood for LT than White men. Additional significant predictors outlined in Table 1. **Conclusion:** Accounting for listing characteristics, AC did not significantly impact interactions between gender and race on receipt of LT. However, AC may have improved access to LT amongst those without HCC but may have diminished access amongst those with HCC post-AC. Regardless of AC, there were important gender-race interactions requiring closer examination, particularly where Black and Hispanic women appear disproportionately negatively impacted. The same patterns were not noted across male racial categories, suggesting future research and interventions should target those at greatest risk.

Kim[1], Valluvan Jeevanandam[1], Mark Siegler[1], Nir Uriel[2] and Andrew I. Aronsohn[1], (1)University of Chicago Medical Center, (2)Columbia University Irving Medical Center, New York, NY

Background: Organ allocation in the United States (U.S.) to non-citizen, non-U.S. residents who travel for transplant (NC/NRTx) is controversial. Current policies may not be informed by the opinions of stakeholders, as there is limited data assessing knowledge or opinions of providers, patients or the general public on this issue. **Methods:** We conducted a cross-sectional, hospital-based pilot survey among providers and patients from December 2019 to June 2020 at a single large urban transplant institute. Surveys included 10 questions assessing knowledge and opinion on eligibility, prioritization, and limitations for deceased donor transplantation of different groups and 12 questions on demographic data. **Results:** 209 providers responded (61% female, median age 40) and 119 patients responded (62% female, median age 54). Awareness of eligibility for transplantation for U.S. citizens, non-U.S. citizens who reside in the U.S (NC/R) both legally and non-legally, as well as NC/NRTx was high in both groups, though both providers and patients were less aware of the eligibility of non-legal NC/R to both donate and receive organs. Overall, 79.3% of patients believed that NC/NRTx should be eligible for transplant in the U.S. compared to only 60.7% of providers ($p = 0.001$). Specifically, more providers (11.7%) than patients (4.2%) responded "Definitely not" ($p = 0.002$) and more providers (28.9%) than patients (13.6%) responded "Probably not" ($p = 0.002$). In sum, nearly 40% of providers indicated that NC/NRTx probably should not or definitely should not be allowed, as opposed to less than 18% of patients. Sub-analysis revealed that younger (<40) and male providers were more likely to be in support of transplanting NC/NRTx. **Conclusion:** The results of our preliminary study reveal that opinions regarding transplanting NC/NRTx exist on a spectrum and differ when comparing patients with providers. As variation in the practice of transplanting NC/NRTx exists both regionally and across transplant centers, it is critical that both national and regional stakeholder voices are considered to guide future policies regarding NC/NRTx in the U.S.

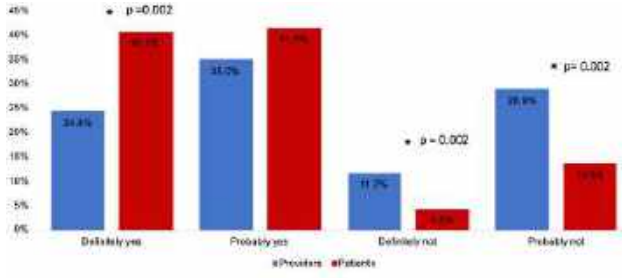

Figure 1: Opinions on Travel for Transplantation; "Do you think citizens of other countries should be allowed to travel to the U.S. in order to get organ transplants in the U.S.?"

1030-A | INTRA-OPERATIVE OUTCOMES IN DONATION AFTER CIRCULATORY DEATH LIVER TRANSPLANTATION USING NORMOTHERMIC MACHINE PERFUSION, OR NORMOTHERMIC REGIONAL PERFUSION VERSUS SUPER RAPID RECOVERY WITH STATIC COLD STORAGE

Rachel Quandahl, Shaheed Merani, Cale Kassel, Sheila Ellis, Alan N. Langnas, Benjamin Huerter and Luciano Vargas, University of Nebraska Medical Center

Background: Donation after circulatory death (DCD) is an increasingly prevalent practice in liver transplantation to address the persistent organ shortage. However, DCD liver transplantations procured with a super rapid recovery technique with static cold storage (SRR+CS) is associated with an increase in adverse outcomes including higher rates of early allograft dysfunction (EAD) and biliary complications when compared to transplants using donation after brain death. Regional perfusion (NRP) and normothermic machine perfusion (NMP) aim to reduce these complications. Outcomes related to long term graft function, patient survival, and allograft dysfunction when NRP and NMP are used in clinical transplant have been published recently. However, intra-operative hemodynamic outcomes and post-reperfusion syndrome between NMP and NRP are not well described nor compared directly. **Methods:** We performed a single-center retrospective clinical study of 50 DCD liver transplants in adult recipients using three techniques for DCD organ recovery and preservation (SRR+CS, NRP+CS, and SRR+NMP). Donor, recipient, and transplant characteristics were recorded and evaluated. Primary outcome measure was rate of post-reperfusion syndrome (as defined by Hilmi et. al.). Categorical variables were compared between groups using chi-square, and continuous variables compared using a non-parametric ANOVA. Additionally, donor and recipient variables were used to construct a binary logistic regression model for PRS. **Results:** Intra-operative outcomes demonstrated lower epinephrine dose needed on reperfusion in the SRR+NMP group (0 mcg) compared to SRR + CS (40 mcg) and NRP+CS (20 mcg), $p = 0.010$. There was a lower rate of post-reperfusion syndrome in both the NMP and NRP groups compared to the SRR + CS (33.3% in SRR+NMP,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

37.5% in NRP+CS and 75% in SRR+CS, $p = 0.025$). 70.8% of the SRR+CS group and 66.7% of the NRP +CS group were noted to have severe PRS, versus 33.3% of the SR+NMP group ($p = 0.430$). Post-transplant liver enzymes were significantly higher in the SRR +CS arm compared to NMP and NRP. Incidence of EAD and primary non-function (PNF) was not significantly different between groups. There was no difference in graft nor patient survival between groups. **Conclusion:** Machine perfusion in LT continues to demonstrate good outcomes in DCD liver grafts. Despite a growing number of publications supporting their use to lower EAD, improve biliary outcomes, and overall graft and patient survival, little has been shown on intra-operative outcomes. This study demonstrates for the first time NMP and to a certain extent, NRP, mitigates early reperfusion injury as measured by post-reperfusion syndrome when compared to SRR+CS. The lower incidence of PRS suggests a smoother hemodynamic profile and potentially improved outcomes for patients. In addition to increasing the available grafts for transplantation, NMP may also allow for higher risk patients to undergo LT.

1031-A | ISCHEMIC PRECONDITIONING AS A PROTECTIVE STRATEGY IN LIVER RESECTION: A COMPREHENSIVE SYSTEMATIC REVIEW AND META-ANALYSIS

Muhammed Elhadi Elfaituri, Ala Khaled, Hazem Faraj and Ahmed Msherghi, University of Tripoli

Background: Liver resection is an indispensable surgical treatment for various liver diseases. However, it frequently leads to ischemia-reperfusion injury (IRI), a principal cause of postoperative liver dysfunction and failure. Ischemic preconditioning (IPC), marked by short episodes of ischemia and reperfusion prior to an extended ischemic period, has demonstrated potential in mitigating IRI and improving postoperative outcomes subsequent to liver resection. This study aimed to determine the impacts of ischemic preconditioning on clinical outcomes in patients undergoing liver resection. **Methods:** We searched databases, including PubMed, Embase, and the Cochrane Library, for studies that compared IPC with standard care in liver resection up until April 2023. Primary outcomes encompassed operative time, blood loss, length of stay in ICU, and length of hospital stay, reported as Mean Difference (MD). Secondary outcomes included the number of patients requiring blood transfusion, postoperative ascites, postoperative mortality, post-operative liver failure, biliary complications, surgical site infection, and postoperative pulmonary complications, reported as Relative Risk (RR). Statistical analyses were performed using R (version 4.0.3) with the aid of metafor and meta packages. **Results:** Our meta-analysis incorporated 11 studies, accounting for 736 patients (365 in the IPC group and 371 in the control group). IPC was linked to a non-significant reduction in operative time (MD = -6.54 minutes, 95% CI = -18.43 to 5.37, $p = 0.28$, I2 = 64%), blood loss (MD = -51.2 ml, 95% CI = -107.63 to 5.23, $p = 0.08$, I2 = 71%), length of stay in ICU (MD = -0.24 d, 95% CI = -2.04 to 1.55, $p = 0.79$, I2 = 97%), and length of hospital stay (MD = -1.25 d, 95% CI = -3.03 to 0.58, $p = 0.17$, I2 = 90%). Additionally, IPC significantly decreased the risk of requiring a blood transfusion (RR = 0.70, 95% CI = 0.50 to 0.98, $p = 0.04$, I2 = 0%), yet did not significantly change the risk of developing postoperative ascites (RR = 0.59, 95% CI = 0.22 to 1.57, $p = 0.29$, I2 = 0%), postoperative mortality (RR = 1.14, 95% CI = 0.27 to 4.72, $p = 0.86$, I2 = 0%), postoperative liver failure (RR = 0.65, 95% CI = 0.34 to 1.26, $p = 0.2$, I2 = 0%), biliary complications (RR = 0.91, 95% CI = 0.49 to 1.67, $p = 0.76$, I2 = 0%), surgical site infection (RR = 0.62, 95% CI = 0.22 to 1.78, $p = 0.38$, I2 = 0%), and postoperative pulmonary complications (RR = 0.69, 95% CI = 0.29 to 1.63, $p = 0.4$, I2 = 0%). **Conclusion:** This study implies that ischemic preconditioning may reduce the need for blood transfusions in liver resection. Despite this, the significant heterogeneity in some outcomes and non-significant reductions in certain complications require cautious interpretation. Future research should prioritize large-scale, randomized trials to validate these results and further explore IPC's potential benefits and mechanisms.

1032-A | MRI LIVER OBVIATES NEED FOR LIVER BIOPSY FOR DONORS IN A LIVING DONOR LIVER TRANSPLANT SETTING

Alisha Chaubal[1], Rashmi Badhe[1], Ameet Mandot[1], Gaurav Chaubal[1], Gautham Pranesh[2], Samir Ramnik Shah[1] and Global hospital, (1)Global Hospitals, Mumbai, (2)Mitopower LLC

Background: Liver biopsy is the gold standard for determining acceptability of donors when CTLAI is between -5 to +5. However it is invasive and involves sampling of only a small portion of the liver. CT does not reliably detect fibrosis, iron overload and could lead to erroneous selection of donors. We propose that MRI- PDFF with elastography could overcome these deficiencies. We also wanted to determine a cut off value for fat on MRI which would correspond to 10% fat on biopsy. **Methods:** 102 prospective liver donors underwent CTLAI, MRI liver (PDFF, elastography, R2 sequencing) and liver biopsy. The strength of association between CTLAI, MRI-PDFF, fat content on biopsy was determined by non-parametric correlation. Cut offs, sensitivity and specificity for MRI-PDFF to determine steatosis and liver fat content of 10% or greater on biopsies was determined by Receiver Operator Characteristic (RoC) curves. The impacts of cut offs across tests were also determined. **Results:** Both CTLAI and MRI correlated with liver biopsy for fat but MRI had a stronger correlation. (Correlation coefficient 0.695 - MRI, -0.621 -CTLAI). Every unit increase in biopsy fat content is associated with 0.5 units increase in fat fraction on MRI. MRI with accepted cut-off of 6.25% was more sensitive than CTLAI cut off of +5 to determine liver fat > 10%(AUROC 0.859 - MRI, 0.814 - CTLAI) **Conclusion:** MRI liver is a reliable and non invasive method for donor liver assessment which supersedes CTLAI and can obviate the need for a liver biopsy. A cut off value of 6.25 % correlates with 10% macrosteatosis on a liver biopsy.

1033-A | MULTIVARIABLE LINEAR MODEL FOR PREDICTING GRAFT WEIGHT BASED ON 3-DIMENSIONAL VOLUMETRY IN REGARDS OF BODY WEIGHT CHANGE OF LIVING LIVER DONOR

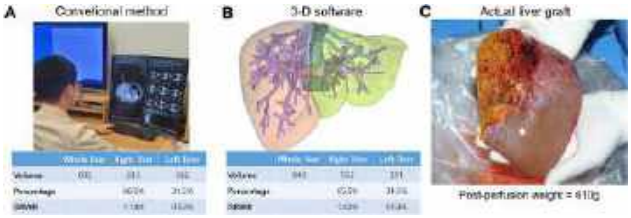
Youngju Ryu[1], So Young Lim[1], Gyu-Seong Choi[2], Jong Man Kim[2], Jae-Won Joh[2] and Jinsoo Rhu[2], (1)Samsung Medical Center, (2)Samsung Medical Center, Sungkyunkwan University School of Medicine

Background: The purpose of this study is to build a prediction model for estimating the graft weight in regards of different graft volumetry methods combined with other variables. **Methods:** Donors who underwent living donor right hepatectomy during March 2021 to March 2023 were included. Estimated graft volume measured by conventional method and 3-D software were collected as well as the actual graft weight.

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Univariable linear regressions were performed for estimating the predictability. Multivariable linear regression was performed to build a prediction model with higher accuracy. Donor groups were further divided into three groups according to the 3-D volumetry of < 700 cm^3, 700 to 899cm^3, and $\geq$ 900cm^3 to compare the performance of different models. **Results:** A total of 119 donors were included to the study. Conventional volumetry for predicting graft weight showed R^2 of 0.656 ($p < 0.001$) while 3-D software showed R^2 of 0.776 ($p < 0.001$). The R^2 of the multivariable model was 0.842 ($p < 0.001$) including for 3-D volume (ß = 0.623, $p < 0.001$), body mass index (ß = 7.648, $p < 0.001$) and amount of weight loss (ß = -7.252, $p < 0.001$). The median errors between different models to actual graft weight did not differ in donor groups $<$ 700cm^3 and 700 to 899cm^3, while the median error of univariable linear model using 3-D software (122.5, IQR 61.5-179.8) was significantly higher compared to that of multivariable adjusted linear model (41.5, IQR 24.8-69.8, $p = 0.003$) in donors with estimated graft weight $\geq$ 900cm^3. **Conclusion:** Univariable linear model with 3-D volumetry can be used with acceptable outcome for predicting right liver graft weight in donors with estimated graft volume less than 900cm^3. For donors with estimated graft volume $\geq$ 900cm^3, multivariable adjusted linear model showed higher accuracy.



Disclosures: The following people have nothing to disclose: Youngju Ryu, So Young Lim, Gyu-Seong Choi, Jong Man Kim, Jae-Won Joh, Jinsoo Rhu

f 1034-A | NATIONAL TRENDS IN UTILIZATION OF NORMOTHERMIC MACHINE PERFUSION IN DCD LIVER TRANSPLANTATION

Helen Tang, Samir Abu-Gazala, Nadim Mahmud and Peter Abt, Hospital of the University of Pennsylvania

Background: Organ scarcity remains a key issue in liver transplantation. Among efforts to expand the donor pool, advances in ex-situ normothermic machine perfusion (NMP) have improved outcomes compared traditional static cold storage (SCS) in donation after circulatory death (DCD) organs. We aimed to characterize trends in utilization of NMP vs. SCS in DCD liver transplantation in the U.S., and to determine if use of NMP has expanded to higher-risk donor-recipient pairs over time. **Methods:** This retrospective cohort study used data from the United Network for Organ Sharing database to identify recipient-donor adult liver transplant pairs from DCD donors from 1/2016-6/2022. Use of NMP vs. SCS was ascertained following prior methods. Key donor and recipient variables were also collected. Trends in utilization of NMP for DCD transplantation were plotted. Changes in donor risk index (DRI) and components between NMP vs. SCS were assessed across transplant year eras (2016-2018, 2019-2020, 2021-2022). To visualize changes in donor-recipient "risk" over time we plotted DRI against transplant MELD in each transplant era. Statistical comparisons were made using Kruskal-Wallis or Chi-square tests, where indicated. **Results:** 3,937 SCS and 127 NMP DCD donor transplants were included in the analytic cohort. Percent utilization of NMP ranged from ~0.4% to 3.5% from 2016 to 2021, and rose significantly to 11.2% in the first half of 2022 (break of secular trend $p < 0.001$; Figure 1A). Across transplant eras, median DRI increased significantly for both SCS and NMP ($p < 0.001$; Figure 1B/C); the magnitude of increase from 2016-2018 to 2021-2022 was larger for NMP (e.g., 1.8 to 2.4 for NMP vs. 1.9 to 2.0 for SCS). With NMP DCDs, there were significant increases in donor age (median 46 vs. 27, $p = 0.004$), national share proportion (31.4% vs. 0.0%, $p < 0.001$), and "cold ischemic time" (median 9.9 hours vs. 7.2 hours, $p < 0.001$) over time. Finally, there was a shift towards including higher DRI donors and higher transplant MELD recipients with NMP in later transplant eras (Figure 1B/C). **Conclusion:** In recent years, NMP utilization has increased and expanded to donors with higher DRI and recipients with higher MELD at transplant. This suggests increasing familiarity and risk tolerance with NMP technology. As NMP remains a relatively new technique, ongoing study of patient outcomes, organ allocation practices, and utilization patterns is critical.

1035-A | NOVEL INDICATIONS FOR NORMOTHERMIC MACHINE PERFUSION: A CASE SERIES

Rachel Todd[1], Andrew Rosowicz[1], Adam Kressel[2], Guy Meyerovich[2], Matthew Holzner[2], Parissa Tabrizian[2], Chiara Rocha[2], Antonios Arvelakis[2], Joseph DiNorcia[2], Marcelo Facciuto[2], Thomas Schiano[2], M. Zeeshan Akhtar[2] and Sander S. Florman[2], (1)Icahn School of Medicine at Mount Sinai, (2)Recanati/Miller Transplantation Institute at Mount Sinai

Background: Normothermic machine perfusion (NMP) is a tool for optimizing and assessing livers for orthotopic liver transplantation (OLT), with an additional benefit of facilitating management in cases with complex recipients. Here we describe two novel indications: combined heart-liver transplantation (CHLT) and re-transplant recipients. Our aim was to use NMP to expand our ability to serve complex surgical patients whilst protecting livers by minimizing cold ischemic time. Given the rise of CHLT for congenital heart disease sequelae and increased rates of re-transplantation, safe methods for extending storage times are needed. **Methods:** This single center retrospective review from August 2022 to May 2023 of all NMP cases included indications for NMP, viability data during NMP, and donor and recipient demographic information. Post-transplantation outcomes of primary non-function, early allograft dysfunction, reoperation rate, and biliary complications were analyzed. **Results:** Two CHLT, including one post-Fontan patient, and five re-transplant candidates were allocated livers placed on the OrganOx *metra*® system for NMP out of concern for recipient case complexity. The re-transplant cohort included one pediatric recipient and one simultaneous liver kidney (SLK recipient). One of the CHLT grafts also showed moderate microvesicular steatosis on biopsy, warranting viability assessment. NMP and surgical outcomes of remaining three cases in the cohort are described in Table 1. Of note, cold ischemia time (CIT) in CHLT may have been decreased by four to six hours compared to prior studies (5). Rates of primary non-function or early allograft dysfunction were 0%. Mean peak AST was 1003. Both CHLTs required re-operation by the cardiac team for hematoma evacuation. The pediatric patient underwent reoperation for planned delayed completion of the biliary anastomosis, hematoma evacuation, and subsequent duodenal and colonic repair. Two other re-transplant patients required reoperation for hematoma evacuation. No patients have experienced biliary complications to date. **Conclusion:** To our knowledge, these are the first reported cases of NMP utilized for CHLT and re-transplant recipients. This case series of normothermic machine perfusion (NMP) demonstrates its utility as a method of increasing total storage time while minimizing graft exposure to cold ischemia.

1036-A | OUTCOMES OF MACHINE PERFUSION IN LIVER TRANSPLANTATION: AN ANALYSIS OF THE UNOS DATABASE

Soo Young Hwang, Harvard T.H.Chan School of Public Health, Heidi Yeh, Massachusetts General Hospital and Wei Zhang, Massachusetts General Hospital, Brookline, MA

Background: Machine perfusion has been implemented as an alternative to the conventional static cold storage preservation method to reduce ischemia-reperfusion injury through more advanced organ preservation. The use of machine perfusion was first tracked by SRTR in 2016 and various approaches including hypothermic machine perfusion (HMP) and normothermic machine perfusion (NMP) have been reported ever since. Our aim is to explore the outcomes of liver machine perfusion in liver transplantation based on the United Network for Organ Sharing (UNOS) database. **Methods:** We retrospectively analyzed all adult patients aged 18 and above who received liver transplantation from adult deceased donors aged 18 and above according to the UNOS database from 2016 to 2022. All data regarding liver transplantation and follow-up

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

visits were retrieved at the end of 2022. Preservation time was defined as the time from cross-clamp to reperfusion, including machine perfusion time, when relevant. We compared outcomes on survival, acute rejection, and graft failure between the group that received machine perfusion versus the group that did not receive machine perfusion. The incidence rate of acute rejection was compared between the two groups. We performed a log-rank test to compare the survival function and graft survival between the two groups. **Results:** 841 patients who received liver transplantation with machine perfusion and 50,393 patients who received liver transplantation without machine perfusion were analyzed. The mean age of the donors and recipients was higher in the machine perfused group (donor 42.42 y versus 46.49 y; recipient 55.25 y versus 57.18 y) as well as the portion of patients over age 65. The machine perfused group had a statistically significantly longer preservation time of 9.32 hours compared to the non-perfused group of 5.98 hours. 76 cases (14.10%) of the machine perfused group and 4,797 cases (10.41%) of the non-perfused group were from donors after circulatory death (DCD). There was no statistically significant difference in the incidence rate (*p*-value 0.62) and the log-rank test of overall survival (*p*-value 0.3) and graft failure (*p*-value 0.4). **Conclusion:** Machine perfusion was implemented to increase the utilization of liver organs under sub-optimal quality and circumstances. Our results suggest that machine perfusion is associated with older donors, longer preservation times, and a higher portion of DCD grafts, but nevertheless has similar graft and patient survival as the non-machine perfusion group. Further epidemiological studies on the long-term outcome of machine perfusion in liver transplantation are needed to explore the effect of machine perfusion on the population level.

Table 1. Baseline characteristics of donors and recipients analyzed and main outcomes.

	No Machine Perfusion (n= 50,393)	Machine Perfusion (n= 841)	p-value
Donor			
Age (years)	42.42 ± 14.97	46.49 ± 13.94	<0.001
Age > 65	3,476 (6.90%)	66 (7.85%)	0.313

1037-A | PERFORMANCE OF RISK MODELS FOR POST-LIVER TRANSPLANT PATIENT AND GRAFT SURVIVAL OVER TIME

Lauren Shaffer[1], Samir Abu-Gazala[1], Peter Abt[2] and Nadim Mahmud[1], (1)Hospital of the University of Pennsylvania, (2)Perelman School of Medicine, University of Pennsylvania

Background: Organ scarcity in liver transplantation (LT) necessitates optimal selection of recipients and donors to minimize waitlist mortality and maximize post-transplant benefit. Several scores have been developed to predict post-transplant patient and graft survival by isolating elements of donor risk, recipient risk, or both. While the donor risk index (DRI) score has been the most widely used model since its development in 2006, several other prediction models have been created since, including the BAR score, P-SOFT and SOFT scores, and the ID2EAL-D/-DR scores. No studies to date examine the performance of these models over time, which is critical in an ever-evolving transplant landscape. We evaluated the discrimination and calibration of liver transplantation risk scores over time. **Methods:** This was a retrospective cohort study of liver transplantation events in the UNOS database from 2002-2021. We used Cox regression to evaluate model discrimination (Harrell's C) and calibration (testing of calibration curves) for post-transplant patient survival and graft survival. These were evaluated at 1, 3, and 5-year post-transplant timepoints, and sub-analyses were performed in the modern transplant era (post-2014). Stratified analyses were also performed for key donor-recipient characteristics. **Results:** In the analytic cohort, a total 112,356 liver transplants were included. The SOFT score demonstrated the highest discrimination of all scores for patient and graft survival at all timepoints (Figure panels A/B). However, the ID2EAL-DR score reflected the best balance of calibration and discrimination for both outcomes at longer timepoints (3 and 5 y post-transplant; data not shown). In stratified analyses, SOFT and ID2EAL-DR scores performed especially well in younger patients and those with higher MELD scores (Figure panel C). All prediction scores had generally declining discrimination over time (increasing transplant year), and scores relying on donor factors alone for prediction (i.e., DRI and ID2EAL-D scores) had consistently poor predictive performance ($C < 0.60$). **Conclusion:** Although the SOFT and IDEAL-DR scores had the best overall performance,

all prediction models demonstrated declining performance over time. This underscores the importance of periodically updating older prediction models and/or developing new models to reflect the evolving transplant field. Scores relying on donor factors alone do not meaningful inform post-transplant risk.

1038-A | POST LIVER TRANSPLANT OUTCOMES ARE PREDICTED BY ARTIFICIAL INTELLIGENCE MODEL DETECTION OF LIPOPELIOSIS ON PREIMPLANT FROZEN SECTION

Suaka Kagbo-Kue[1], Maxwell Smith[1], Alyssa McGary[2], Laura Budvytyte[1], Mariah Schroeder[1], David Chascsa[2] and Rolland C Dickson[2], (1)Mayo Clinic, (2)Mayo Clinic Arizona, Phoenix, AZ

Background: Steatosis in donor liver allografts is associated with post-transplant outcomes. However, accurate estimation is limited by marked observer variability which complicates assessment of steatosis cutoff values for transplantation. We previously developed and validated an artificial intelligence (AI) model (Aiforia) for detection and quantitation of lipopeliosis (LP), large droplet fat, and overall steatosis. LP is the coalescence of fat droplets from ruptured hepatocytes (Fig 1). Our hypothesis was that steatosis parameters would correlate with patient outcomes. **Methods:** We retrospectively applied the model to consecutive liver transplant patients with > 5 years of follow-up and available preimplant frozen section slides. The model results were compared to traditional and Banff estimates for steatosis and to clinical outcomes. Continuous variables were summarized using median and interquartile range, categorical variables were summarized using the frequency and percentage. Overall patient and graft survival were estimated using Kaplan-Meier method. Univariate analyses were assessed with Cox-regression. **Results:** 161 patients met inclusion criteria and were tested with Aiforia. 8 slides failed Aiforia due to poor preparation quality. 153 patients had steatosis measures by traditional, Banff, and Aiforia. There was strong correlation between all 3 methods of assessing hepatic steatosis, however, both the traditional and Banff methods significantly overestimated the percentage of steatosis in comparison to the AI model (Fig 2). The percentage and density of LP were associated with patient survival (HR = 1.39, 95% CI 1.09, 1.77, $p = 0.009$; and HR = 1.02, 95% CI 1.00, 1.04, $p = 0.044$, respectively) (Table 1). Preimplant steatosis by all three methods did not have significant impact on survival. **Conclusion:** Our study supports previous reports of overestimation of hepatic steatosis with traditional methods and shows similar overestimation using Banff criteria. Importantly, we found measures of LP in hepatic allografts detected by our AI model were strong and better predictors of post liver transplantation outcomes than overall percentage of fat. The use of an AI model to detect LP may help guide risk assessment of steatotic hepatic allografts, potentially increasing the successful utilization of these organs. A larger series is needed to confirm these findings.

1039-A | PSYCHOSOCIAL AND MEDICAL FACTORS ASSOCIATED WITH RECEIPT OF LIVER TRANSPLANT IN LISTED PATIENT WITH HEPATOCELLULAR CARCINOMA

Rami M. Youssef, Mark Obri, Erika Todter, Reena J. Salgia and Michelle Jesse, Henry Ford Health

Background: Patients with hepatocellular carcinoma (HCC) are less likely to receive liver transplantation (LT) than patients without HCC. The aim of this study was to explore sociodemographic, psychosocial, and medical factors associated with progression to LT, versus delisting, in patients with HCC listed for LT. **Methods:** Prospectively maintained database from a single center tracking all patients diagnosed with HCC from 2005-2022. Amongst those listed for LT, the main outcome was receipt of transplant (versus delisting for any reason). Predictors included sociodemographic, psychosocial, and medical characteristics. Given the exploratory nature, predictors were included in the final multivariable logistic model if univariable logistic regression results approached significant ($p < 0.1$). **Results:** Among 341 patients listed with HCC; mean age 59.6 years (SD 6.8); 265 male (77.7%); racial composition was 246 White (72.1%), 50 Black (14.7%), and 45 "other" (13.2%). 261 (76.5%) underwent LT, 80 (23.5%) were delisted (any reason, majority due to disease progression/ medical deterioration). Variables included in the model were age at transplant listing, marital status, whether the patient underwent treatment for HCC, and histories of tobacco use, alcohol abuse, hepatic encephalopathy, diabetes, hypertension, and dyslipidemia. Final model presented in Table 1. Significant predictors of receipt of LT in the final model included younger age at transplant listing, no history of tobacco use, and no history of alcohol abuse. **Conclusion:** HCC patients are often delisted due to HCC disease progression and/or death while on the LT waitlist. Our data suggests that patients who are listed at a younger age, do not have a history of tobacco use, or of alcohol abuse are more likely to successfully receive LT. Also, contrary to hypotheses, race/ethnicity was not significant suggesting improved equity across these groups.

Table 1: Effect of Predictors (Psychosocial, Sociodemographic and Medical) on the Odds of Transplant in Patients with HCC

Variable	Odds Ratio (Confidence Interval)	P-Value
Age at Transplant Listing (5-Year increase)	0.66 (0.50, 0.87)	0.003
History of Tobacco Use	0.42 (0.21, 0.85)	0.016
History of Alcohol Abuse	0.31 (0.16, 0.62)	0.001
Married/in a long-term committed relationship vs. Separated/Divorced[a]	1.42 (0.38, 5.26)	>0.999
Married/in a long-term committed relationship vs. Widow/er[a]	4.57 (0.85, 24.48)	0.101
Married/in a long-term committed relationship vs. Single[a]	1.19 (0.91, 1.56)	0.094
Separated/Divorced vs. Widow/er[a]	3.21 (0.42, 24.67)	0.753
Separated/Divorced vs. Single[a]	1.82 (0.42, 7.90)	>0.999
Widow/er vs. Single[a]	0.37 (0.05, 3.02)	>0.999
Underwent Treatment	0.51 (0.23, 1.10)	0.110
Hepatic Encephalopathy	0.68 (0.33, 1.40)	0.219
History of Diabetes	0.65 (0.35, 1.23)	0.183
History of Hypertension	0.63 (0.36, 1.12)	0.256
History of Dyslipidemia	0.57 (0.25, 1.28)	0.172

1040-A | QUANTIFYING REDUCTION OF WAITLIST TIME FOR LIVER TRANSPLANT RECIPIENTS ACCEPTING HEPATITIS C-POSITIVE ORGANS

Nicholas Hebda[1], Altaib Al Yassin[2] and Anita Krishnarao[1,2], (1)Umass Memorial Medical Center, (2) University of Massachusetts Medical School

Background: There has been increased utilization of livers from hepatitis C virus (HCV)-positive donors given favorable post-transplantation outcomes for liver transplant recipients over the recent years in the era of direct-acting antiviral (DAA) therapies. While the increased use of HCV-positive organs increases the potential donor pool and presumably decreases waitlist times for liver transplant recipients, there are limited published data quantifying the reduction of time on the waitlist for patients accepting HCV-positive liver offers. There is also an assumption that acceptance of HCV-positive liver offers may enable liver transplantation at lower Model for End-Stage Liver Disease (MELD) scores, but this perceived benefit has yet to be fully elucidated. **Methods:** We conducted a single center retrospective case-control study comparing liver transplant waitlist times and MELD scores at time of transplantation between recipients receiving HCV antibody (Ab)-positive and HCV Ab-negative livers. There were 34 patients who received HCV Ab-positive livers from donors with nucleic acid amplification testing (NAAT) data available within the 5-year study period of October 2017 through October 2022. Recipients of HCV Ab-positive livers from both NAAT-positive and NAAT-negative donors were matched with 34 controls of a similar age and MELD score at time of listing (within 1 point) who were listed without acceptance of HCV-positive organs. Time on waitlist (days) and MELD scores at time of liver transplantation were calculated

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

for each group. Time on waitlist for recipients of HCV Ab-positive livers was defined by the date from which the recipient was listed with acceptance of HCV-positive organs to the date of liver transplantation. **Results:** The average reduction of liver transplant waitlist time was 354 days (*p*-value 0.014) in patients who received HCV Ab-positive livers as compared to patients who were not listed for HCV-positive organs and received HCV Ab-negative livers, with an average and median MELD score of 20 in both groups at time of listing. There was no significant difference in MELD score at the time of transplantation between the groups with an average MELD score of 20 in patients receiving HCV Ab-positive livers and average MELD score of 19 in patients receiving HCV Ab-negative livers (*p*-value 0.65). **Conclusion:** This study supports and quantifies the assumption that acceptance of HCV-positive organs can reduce time on the liver transplantation waitlist, however, our results do not demonstrate lower MELD scores at time of transplantation for these recipients.

1041-A | RECURRENT HEPATIC ENCEPHALOPATHY AS A MELD EXCEPTION FOR LIVER TRANSPLANTATION

Isaac Ruiz[1], Mélanie Tremblay[2], Genevieve Huard[3], Yu Shi Wang[1], Julien Bissonnette[3], Catherine Vincent[3], Chantal Bémeur[1,4] and Christopher F. Rose[2,4], (1) Centre De Recherche Du Centre Hospitalier De l'Université De Montréal, (2)Hepato-Neuro Laboratory, Centre De Recherche Du Centre Hospitalier De l'Université De Montréal, (3)Centre Hospitalier De l'Université De Montréal, (4)Université De Montréal

Background: Model for End-Stage Liver Disease (MELD) is used worldwide to prioritize patients for organ allocation for liver transplantation (LT). This robust prognostic score does not include hepatic encephalopathy (HE). Therefore, some patients with recurrent HE may thus not be well served with this system. To mitigate this gap, "recurrent hepatic encephalopathy" has been proposed as a MELD exception point. Unfortunately, there is no formal policy regarding the number and duration of hospitalizations for recurrent HE. Data are lacking to reach consensus among centers. The objective of this study was to evaluate the number and length of stay of hospitalizations due to HE in patients with cirrhosis on the LT waiting list. **Methods:** This retrospective study includes all consecutive patients who underwent LT at the Centre hospitalier de l'Université de Montréal (CHUM) between January 2019 and December 2021. Only patients with confirmed cirrhosis by clinical, radiological or pathological findings were included. Patients with multiorgan transplantations, acute liver failure, and other indications of LT without cirrhosis were excluded. Data regarding hospitalizations one year before LT were collected. Clinical, biological, and radiological characteristics were collected for each hospitalization, including HE parameters and precipitating factors. **Results:** During the study period, 181 patients were transplanted in our center. One hundred and fifty-five patients with cirrhosis were included and were divided into two groups: "HE-group", patients that developed at least one episode of HE before LT, n = 103 (66.5%); "Non-HE-group", patients without history of HE, n = 52 (33.5%). In the HE-group, the number of patients who experienced at least one hospitalization for HE was 51/103 (49.5%). The median number of hospitalizations for HE per patient was 1.0 (range 1-11; mean 2.2). The median length of stay for each hospitalization was 10.5 days (range 1-127; mean 26.1). Seven of 103 patients (6.8%) were hospitalized due to HE until LT. Figure 1 shows the number of hospitalizations due to HE per patient before LT. **Conclusion:** This study demonstrates the high prevalence of HE in the waiting list for patients with cirrhosis and provides the first data on the number and duration of hospitalizations in this vulnerable population. According to our data, 4 hospitalizations and 10 days length of stay advocates to be a good cut-off to define "recurrent HE", thus supporting expert recommendations for MELD exception points for this complication. In addition, over a period of 3 years, 4 patients will have benefited from the MELD exception. This makes this criterion.

1042-A | RE-EVALUATING THE 6 MONTH RULE PRIOR TO LIVER TRANSPLANT: A CLINICAL PRACTICE GUIDELINE

Joanna Colleen Dionne[1], Simon Oczkowski[1], Susan Abbey[2], Vanessa Gruben[3], Jennifer Chandler[3], Marie-Chantal Fortin[4], Vladimir Marquez[5], Sylvia Carbert[6], Marilyn Swinton[1], Ted Christou[7], Fatima Dharsee[8], Clay Gillrie[8], Christina Pearson[8], Prosanto Chaudhury[9] and Nazia Selzner[2], (1)Mcmaster University, (2)University of Toronto, (3)University of Ottawa, (4)Universite De Montreal, (5)University of British Columbia, (6)Alberta Health Services, (7)Queen's University, (8)Canadian Blood Services, (9)Mcgill University

Background: The 6 months abstinence rule prior to liver transplant for alcohol related liver disease (ALD) prior to liver transplant (LT) has been called into question from evidence, ethical and legal lenses. The purpose of this clinical practice guideline (CPG) is to guide the assessment and management of ALD and LT. **Methods:** A committee including medical and surgical experts in liver transplant, addiction, ethics, law, methodology and patient partners developed a CPG according to GRADE Methodology. **Results:** Five conditional recommendations (very low certainty of evidence) and 2 best practice statements for patients undergoing LT were made. The recommendations included: 1) To not use the six-month rule as a sole criterion for liver transplant in ALD, 2) The definition of relapse should distinguish between: 1. non harmful relapse (e.g. occasional drinking or slip), 2. harmful drinking (e.g. physical, psychosocial implications, binge drinking/escalation drinking) and relapse monitored by biochemical markers when available, 3. During liver transplant workup, assessment of risk factor associated with post- transplant relapse (presence of uncontrolled psychiatric disease, history of smoking and multiple failed attempts of alcohol treatment) and protective factors (social support and employment) should be part of the assessment to allow for early intervention to mitigate risk factors, 4) The use of validated screening scoring systems and biomarkers for screening post-transplant relapse, 5) Integrated multidisciplinary teams with psychiatrists, addiction services to prevent relapse pre and post-transplant. The best practice statements included: 1) Listed and transplanted ALD patients should be intermittently screened for relapse pre and post-transplantation and 2) We suggest a holistic assessment for patients being evaluated for liver transplant, that not only take into account risk factors or other screening modalities, but a multi prong, multidisciplinary approach. **Conclusion:** This CPG provides evidence-based recommendations for listing and transplanting patients with ALD.

1043-A | SAFETY, EFFICACY AND OUTCOMES OF INTRAOPERATIVE CONTINUOUS RENAL REPLACEMENT THERAPY FOR CRITICALLY ILL CHILDREN WITH LIVER FAILURE

Kristin Juneau Dolan[1], Ayse Arikan[1], Sanjiv Harpavat[2], Muhammad Umair Mukhtar Mian[3], N. Thao N. Galván[4], Rahul Baijal[1] and Moreshwar S Desai[1], (1)Baylor College of Medicine, (2)Texas Children's Liver Center - Baylor College of Medicine, Bellaire, TX, (3)University of Missouri-Columbia, (4)Baylor College of Medicine, Houston, TX

Background: Intraoperative Continuous Renal Replacement Therapy (iCRRT) has been reported to prevent life-threatening complications, facilitate fluid management and maintain metabolic homeostasis during orthotopic liver transplantation (LT) in adults with severe pre-LT renal dysfunction. However, there is a paucity of data describing safety, feasibility and efficacy of iCRRT in pediatric LT. We report our experience and clinical outcomes of critically ill children with pre-LT renal dysfunction who received iCRRT. **Methods:** We conducted a retrospective cohort study of children requiring CRRT pre-LT (>24 hours) at a quaternary, free-standing children's hospital from 2014-2022. We compared key demographic characteristics, intraoperative events and post-LT outcomes of those who needed CRRT during LT (iCRRT group) with those who did not (non-iCRRT group). Statistical analysis included Fisher's Exact and Mann-Whitney tests to measure strength of univariate associations. **Results:** Out of 306 patients who received LT during the study period, 30 (10%) were supported on CRRT, of which 11 (36%) received iCRRT. In the iCRRT group (median age 11 months [IQR 7-64], 55% females), majority (82%) had acute on chronic liver failure (ACLF) and 64% had prior abdominal surgery (excluding a Kasai portoenterostomy). The iCRRT group had longer median anesthesia and surgical time; higher proportion

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of patients experiencing massive blood loss (more than total blood volume (TBV) of 80ml/kg); increased PRBC requirements and total fluid resuscitation more than 3 times TBV when compared to the non-iCRRT group (Table 1). There was no difference in intraoperative serum potassium (K+), bicarbonate (HCO_3) or lactate levels between two groups. Though the iCRRT cohort had longer intensive care unit (ICU) and hospital length of stay (LOS), there was no 30-, 60- or 90-day mortality in this group and 1-year post-LT mortality rates were comparable (Table 1). One patient had a circuit malfunction in the operating room requiring cessation of CRRT. **Conclusion:** iCRRT is feasible, safe and efficacious in critically ill children with pre-LT renal dysfunction. With minimal adverse events, it can maintain acid-base, fluid and electrolyte balance while allowing for appropriately aggressive resuscitation with fluid and blood products. Candidates for iCRRT need to be carefully chosen so that this highly resource intensive therapy can be optimally deployed to benefit this fragile population.

Table 1: Key differences in iCRRT and non-iCRRT patients

1044-A | SEX DISPARITY IN LIVING DONOR LIVER TRANSPLANTATION: U.S. ANALYSIS

Alexandra Shingina[1], James D. Perkins[2], Scott W. Biggins[3] and Kiran Bambha[2], (1)Vanderbilt University Medical Center, (2)University of Washington, (3) University of Washington, Seattle, WA

Background: Sex disparities in liver transplantation remain pervasive, including in living donor liver transplant (LDLT) where females account for the majority of living liver donors. We sought to describe sex distributions among living liver donors and LDLT recipients in the U.S. **Methods:** Using SRTR data (2002-2022), we identified all adult (> / = 18 yrs) living liver donors and all adult LDLT recipients. Data collection for living liver donors included: sex (male vs female), age at donation, marital status, education level, race/ethnicity, height, weight, hepatic lobe donated (right/left/left lateral), donor relationship to recipient, and ABO. Recipient data collection included: sex, age at transplant, MELD at listing and at transplant, race/ethnicity, liver disease etiology, height, weight, hepatic lobe received, relationship to donor, and ABO. Given the extended timeframe, we stratified the analyses by Era (Era 1:2002-2011; Era 2:2012-2022] to account for evolution in LDLT practice in the U.S. **Results:** Overall, 5429 adults [n = 1991 in Era1; n = 3438 in Era2] underwent LDLT. Adult females accounted for less than half of LDLT recipients (44% in Era1; 47% in Era2). Females represented the majority of living liver donors to adult recipients in both Eras, with increasing rates of female donors over time (51% Era1 vs 54% Era2). Female donors were more likely than male donors to donate their right lobe (93% vs 87% in Era1; 90% vs 82% in Era2, respectively), and right lobe living liver donors were more likely to be female vs male (53% vs 46% in Era1; 56% vs 43% in Era2, respectively). In Era2, females were more likely to donate to adult males, compared to males donating to adult females (49% vs 39%, respectively). (Table 1) **Conclusion:** Sex disparities are notable in LDLT in the U.S. with regards to both donors and recipients. Females account for 39% of all waitlisted liver transplant candidates [SRTR 2020 data], and account for 44-47% of LDLT recipients, but comprise over half (51-54%) of living liver donors. The interplay between anatomic differences between females and males, and societal roles and expectations that may differ in females and in males, create a complex set of interactions influencing LDLT from both the donor and recipient perspectives that warrant further evaluation.

	Total	2002-2011 Era	2011-2020 Era
LDLT Recipients	5429	1991	3438
Female (n,%)		879 (44%)	1618 (47%)
Living Liver Donor Female (n, %)	2887 (53%)	1023 (51%)	1864 (54%)
Female to Male Donation (n,%)		536/1112 (48%)	883/1820 (49%)
Female to Female Donation (n,%)		487/879 (55%)	981/1618 (61%)
Male to Male Donation (n,%)		576/1112 (52%)	937/1820 (51%)
Male to Female Donation (n,%)		392/879 (45%)	637/1618 (39%)

1045-A | TEMPORAL TRENDS AND UTILIZATION OF MINIMALLY INVASIVE VS. OPEN LIVER RESECTIONS

Vikram S Pothuri, Katelin B Nickel, Anne M Butler and Chet W Hammill, Washington University School of Medicine in St. Louis

Background: Minimally invasive (MI) liver resections are increasingly common, especially after the 2008 Louisville Statement endorsement. National administrative data previously demonstrated increased frequency of MI resections following the Louisville Statement (2009-2012), but MI was still much less frequent than open. Contemporary trends and utilization have not been studied with large-scale administrative data. **Methods:** Using the Healthcare Cost and Utilization Project (HCUP) Florida State Inpatient Database (SID), we identified adult patients who underwent elective liver resections in Florida from 2016-2021 using International Classification of Disease (ICD-10) procedure codes. We identified the number of MI resections and the proportion of total resections that were MI. We used multivariable logistic regression to assess the associations between patient-level variables and receipt of a MI (laparoscopic or robotic assisted) versus open resection. **Results:** 6,828 liver resections were identified, and 4,790 met inclusion criteria. 133 pediatric, 1,753 non-elective, and 152 cases with missing demographic data were excluded. Mean age was 61.3 years and 53.2% were female. The most common indications were secondary (42.0%) and primary malignancy (24.9%). Partial hepatectomy alone (81%) was more common than lobectomy +/- partial hepatectomy (19%). Of the 4,790 included, 1,349 (28.2%) were MI procedures. The percent of total resections that were MI increased from 21.3% in 2016 to 34.1% in 2021. In multivariable analysis, patients of Black race (vs. White, Odds Ratio (OR) 0.79 [0.63-0.99]), residing in a population of 250,000 to < 1 million (vs. > = 1 million, OR 0.67 [0.57-0.78]), with a secondary malignancy (vs. primary malignancy, OR 0.63, [0.53-0.76]), with a neuroendocrine tumor (vs. primary malignancy, OR 0.51 [0.27-0.94]), and with each additional Elixhauser comorbidity (OR 0.88 [0.85-0.92]) were less likely to undergo MI resection. Patients with a benign indication (vs. primary malignancy, OR 3.03 [2.41-3.82]) and partial hepatectomy (vs. lobectomy, OR 1.94 [1.58-2.37]) were more likely to undergo MI resection. **Conclusion:** From 2016-2021, the percent of total liver resections that were minimally invasive increased each year in the state of Florida. Black patients and patients in less populated areas were less likely to undergo minimally invasive liver resections. Decreased access, patient choice, and provider preference could contribute to these differences.

1046-A | THE COURSE OF INDETERMINATE LIVER NODULES IN THE SETTING OF LIVER TRANSPLANTATION FOR HEPATOCELLULAR CARCINOMA

Mohammed Rifat Shaik[1], Dabin Choi[2], Mohammad Bourmaf[2], Kabir Chhabra[2], David Lee[2], Zurabi Lominadze[3], Hyun S. Kim[2] and Kirti Shetty[4], (1) University of Maryland Medical Center Midtown Campus, (2)University of Maryland Medical Center, (3) University of Maryland Medical Center Baltimore, Baltimore, MD, (4)Department of Hepatology and Liver Transplantation, the University of Maryland, School of Medicine, Baltimore, MD, USA

Background: The characteristic imaging appearance of hepatocellular carcinoma (HCC) usually obviates the need for tissue diagnosis. However, the presence of indeterminate liver nodules (ILN) in up to 25% of those with cirrhosis can complicate the interpretation of imaging studies. The Liver Reporting and Data System (LI-RADS®) classification has standardized ILN nomenclature with LI- RADS 3 and 4 (LR3/4) categories denoting increased risk of malignant transformation. There is limited data on the significance of LR3/4 lesions occurring against a background of known cirrhosis / HCC. It has been postulated that these premalignant lesions could assert a “field effect” on and from HCC in terms of biological behavior. We investigated the behavior of ILN in a population undergoing LT for HCC at a major US transplant center. **Methods:** This was a retrospective cohort study utilizing a pathological

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

database identifying all patients who underwent LT for HCC. Variables of interest were extracted from the electronic medical record. All imaging studies were interpreted by experienced abdominal radiologists and discussed at a multidisciplinary conference. The index imaging study was denoted as the first study demonstrating HCC and the immediate pre-LT imaging study was within 90 days of LT. For continuous variables, means and standard deviations were calculated if normally distributed and medians (interquartile ranges IQR) were calculated if non normally distributed. Chi-square tests and Fisher exact tests were used to test between group differences for categorical variables. All *p*-values were reported as two-sided and a *p*-value < 0.05 was considered statistically significant. Institutional Review Board approval was obtained. **Results:** Between January 2019 and June 2022, a total of 72 adult LT recipients had HCC noted on explant pathology. Of these 11 were excluded due to non-availability of index imaging for discussion at our Tumor Board. The final study population included 61 patients. Of these, 44 (72%) were within Milan criteria at index imaging; those beyond were downstaged prior to LT. Fifty (81%) underwent liver directed therapy (LDT) prior to LT .Of the 11 patients who did not have LDT, 7 had HCC diagnosed on explant. A total of 13 LR3 and 13 LR4 lesions were diagnosed in 18 patients (29.5%) at index imaging.Table 1 compares those with and without these lesions. Progression to LR 5 lesions occurred in 5/13 LR3 lesions (38.5%) and 7/13 (53.8%) LR 4 lesions at median follow up to pre-LT imaging of 360 (range 90 – 1109) days .(table 2). On a patient level, 9/18 patients (50 %) had progression of LR3/4 to LR5 lesions. **Conclusion:** Fifty percent of HCC patients awaiting LT with LR3 /4 lesions noted on index MRI had progression of those lesions to HCC within a median follow up of 360 days. This progression has profound implications in terms of LT eligibility, requiring close follow up, multidisciplinary care and consideration of mass biopsy of IDL.

1047-A | THE ROLE OF DONOR ATTITUDES, PERSONAL CHARACTERISTICS, AND RELATIONSHIPS IN THE PURSUIT OF LIVING ORGAN DONATION

Eric Takoushian[1], Mateo Noriega[2], Ellie Brandon[2], Christopher France[3] and Benjamin Samstein[2], (1)Weill Cornell Medical College, (2)Newyork-Presbyterian/Weill Cornell Medical Center, (3)Ohio University

Background: There is little research to understand how personal attitudes and characteristics contribute to one's willingness to be a living liver donor, though these are known influences on blood donation and non-living organ registration status. The aim of this study is to understand how these factors influence the pursuit and completion of living donation to better understand donor recruitment and to identify potential donors most likely to progress to donation. **Methods:** A Likert scale survey was developed based on validated tools in blood donation research to identify motivations for organ donation and the qualities that make one more inclined to proceed with donation. This was distributed to all potential donors who reached out to our transplant center to inquire about living liver donation and were deemed eligible for donor evaluation. Results were compared between participants who progressed to full donor evaluation and those who did not, excluding participants who did not progress to evaluation due to recipient-related reasons. **Results:** 94 potential donors returned the survey over a 6-month period. 32 participants did not progress to evaluation due to their intended recipient no longer needing a donor and were excluded; 23 did not progress to evaluation due to personal decision; 39 did progress to evaluation, 7 of whom have donated to date. Figure 1 shows mean survey responses between two groups: those who progressed to donor evaluation and those who did not progress to donor evaluation due to personal decision. When characterizing progression to evaluation by relationship to recipient, 84% (16/19) of immediate family members, 88% (14/16) of extended family members, 50% (5/10) of altruistic donors, and 24% (4/17) of friends/community members progressed to evaluation. 36% of those who progressed to evaluation know someone who was a living organ donor, compared to 17% of those who did not progress to evaluation. **Conclusion:** There was no significant difference between these groups in personal characteristics or motivations, except for one 'warm glow' response which was greater in the group that did not progress to evaluation, which may reflect greater

perceived benefit to self from donation in this group. While all participants in this study took personal initiative to reach out about living donation, their progression toward living donation after initial contact is overwhelmingly driven by close personal relationship to their recipient, independent of personal characteristics or motivations. Only a few of our potential donors presented without an intended recipient, compared to blood donation which is inherently non-directed.

1048-A | THE ROLE OF EXCEPTION POINTS IN THE WAITLIST AND POST-TRANSPLANT OUTCOMES OF CHILDREN AND ADULTS WITH FIBROCYSTIC LIVER-KIDNEY DISEASE LISTED FOR LIVER TRANSPLANT: IMPLICATIONS FOR THE NATIONAL LIVER REVIEW BOARD ERA

Benjamin E. Rosenthal[1], Peter Abt[2], K Rajender Rajender Reddy[1] and Therese Bittermann[1], (1) University of Pennsylvania, (2)Perelman School of Medicine, University of Pennsylvania

Background: Liver transplantation (LT) in the setting of fibrocystic liver-kidney disease such congenital hepatic fibrosis (CHF) and Caroli disease (CD) is poorly understood with no prior studies in adults. Our study aims to analyze the waitlist and post-transplant outcomes of such patients listed for LT, with a particular focus on the use of exception points. **Methods:** This was a retrospective cohort study of adults and children with CHF or CD listed for LT between 1/1/2003-12/31/2022 using Organ Procurement and Transplantation Network data. Descriptive statistics were used to compare subgroups. Univariable and multivariable competing risks analysis (Fine & Gray) evaluated the factors associated with waitlist mortality, specifying transplant as a competing risk. Post-transplant patient survival was evaluated using Kaplan-Meier curves and log-rank tests. **Results:** Out of 592 patients in the study, 66.4% had CHF and 33.6% had CD. Overall, 61.8% were listed for LT alone and 38.2% for SLK. Among those listed for LT alone, 17.4% had previous kidney transplantation. Adults were frequently young (median 40 years, IQR 29, 53) and with low laboratory MELD score (median 12, IQR 6, 20). Adults had lower albumin (3.4 vs 3.6 g/dL, $p = 0.025$) at listing, more hepatic encephalopathy (35.7% vs 9.1%, $p < 0.001$), more ascites (48.7% vs 29.3%, $p < 0.001$), and were less likely to be listed for SLK compared to pediatric patients (32.8% vs 48.1%, $p < 0.001$). The majority (61.3%) of patients received exception points, most often via the non-standard exception pathway (94.0% for pediatric and 83.0% for adult). While on the waitlist, patients with exception points were more likely to undergo transplantation (87.8% vs 61.7%) and markedly less likely to be delisted for death or for being too sick (2.6% vs 11.9%, $p < 0.001$). In the final multivariable model for waitlist mortality, only receipt of exception points was significantly associated with the outcome with an adjusted SHR of 0.24 ($p = 0.002$). Despite low MELD/PELD score at listing, living donor LT was underused among LT alone recipients (n = 274; 12.6% of adult LTs, 13.0% of pediatric), even among those without exception points (n = 142; 18.8% of adult LTs, 19.5% of pediatric). Unadjusted long-term patient survival was excellent overall (71.2% at 15 y), superior in children vs adults (Figure A; $p = 0.003$), in those receiving SLK vs LT alone (Figure B; $p = 0.049$), and not different for exception point recipients in either adults (Figure C; $p = 0.282$) or children (Figure D; $p = 0.426$). **Conclusion:** Receipt of exception points supersedes all other clinical factors in predicting waitlist outcome for children and adults listed for LT with CD/CHF, with most exceptions being granted via the non-standard pathway. There is currently no National Liver Review Board guidance for CD/CHF, in whom long-term post-transplant survival is excellent, representing an unmet need.

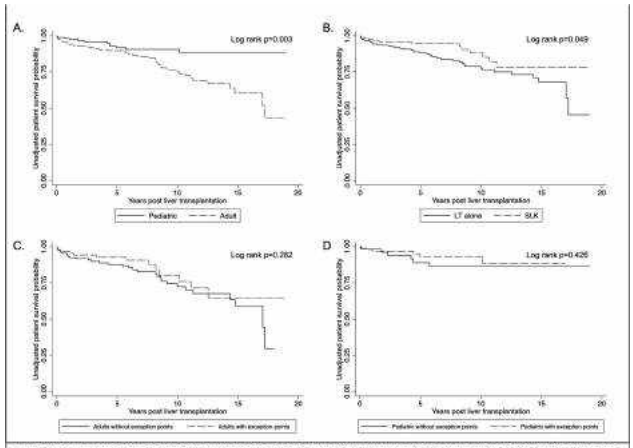

Figure A-D: Unadjusted patient survival probability for patients with Caroli disease and congenital hepatic fibrosis following liver transplant (LT) from 2003-2022 (n=425). **A.** All adult vs. pediatric LT recipients. **B.** Comparing simultaneous liver-kidney (SLK) transplant recipients vs. LT recipients alone. **C.** Adults transplanted with exception points compared to those without. **D.** Pediatric patients transplanted with exception points compared to those without.

1049-A | THE SEVERITY AND DURATION OF PRE-LIVER TRANSPLANT KIDNEY DYSFUNCTION PREDICTS ELIGIBILITY FOR SAFETY NET KIDNEY AFTER LIVER TRANSPLANTATION

Wesley Dixon[1], Sandy Feng[2], Garrett Roll[2], Cynthia Fenton[3] and Giuseppe Cullaro[4], (1)Brigham and Women's Hospital, (2)University of California, San Francisco, (3)University of California-San Francisco, (4)University of California San Francisco Medical Center

Background: Chronic kidney disease (CKD) is a major complication after liver transplantation (LT) associated with substantial morbidity and mortality. Knowing the drivers of post-LT CKD—with granular focus on the type, duration, and severity of pre-LT kidney dysfunction—can highlight intervention opportunities and inform dual-organ allocation policies. **Methods:** We retrospectively analyzed single-center data for adults who underwent liver-only deceased donor transplantation between 2016-2021. Pre-LT CKD was defined as eGFR < 60 mL/min/1.73 m^2 for ≥ 90 days or ≥ 72 days of renal replacement therapy (RRT). CKD stage was determined by eGFR at LT according to KDIGO guidelines. Pre-LT AKI was staged by comparing serum creatinine (sCr) at LT to baseline sCr ≤ 7 days prior to AKI start (stage 1: sCr ≥ 1.5x baseline, stage 2: sCr ≥ 2x baseline, stage 3: sCr ≥ 3x baseline or < 72 d of RRT). Patients meeting both criteria were labeled as AKI+CKD. Uni- and multi-variable logistic regression identified associations between patient characteristics and eligibility for safety net kidney after liver transplant (KALT) according to UNOS policy (eGFR ≥ 20 mL/min/1.73 m^2 or on RRT 2-12 mo after LT). Results are expressed as median (interquartile range) or odds ratio with 95% confidence interval [OR (CI)]. **Results:** Among 557 adults [68% male; age 60 (54-65) years; MELD-Na 23 (10-35); 14% DCD], 52% had normal pre-LT kidney function, 23% had AKI, and 25% had CKD or AKI+CKD. At LT, 20% were receiving RRT for 4.0 (2.0-6.5) days. After LT, eGFR at 1-yr was 67 (54-87) mL/min/1.73 m^2. A total of 6.5% qualified for safety net KALT. Of these, 50% met criteria at 2 months, 75% by 6 months, and 83% by 9 months post-LT (Figure 1). In our final multivariable model, pre-LT factors associated with KALT eligibility were recipient age [per 10 years, OR 1.6 (1.1-2.6)], sCr [per 1 mg/dL, OR 1.4 (1.0-2.0)], CKD duration [per week, OR 1.1 (1.0-1.1)], and RRT duration [per week, OR 4.2 (2.4-7.4)]. We did not identify significant interactions between age, CKD duration, RRT duration, or DCD status. **Conclusion:** Increasing duration and severity of pre-LT kidney dysfunction correlated with eligibility for safety net KALT. Avoidance of multiple risk factors through careful recipient and donor selection along with

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

measures (or therapies) to limit pre-LT kidney injury may reduce the risk of requiring KALT. More granular assessments (e.g., type, total duration, severity) of pre-LT kidney dysfunction must be considered in the design of future dual-organ allocation policies.

Figure 1. Cumulative incidence plot of safety net KALT eligibility.

Characteristic at LT	Eligible for KALT (n=36/557)	
	Univariable	Multivariable
Recipient age (per 10 yrs)	1.4 (1.0-2.1)	1.6 (1.1-2.6)
Serum creatinine (mg/dL)	1.8 (1.4-2.4)	1.4 (1.0-2.0)

1051-A | USING DATA-DRIVEN STRATEGIES TO IMPROVE TRANSPLANT ACCESS FOR VETERANS WITH CIRRHOSIS

Shari S. Rogal[1,2], Vera Yakovchenko[1], Michael F. Chang[3], Ruben Hernaez[4,5], Joseph A. Awad[6], Jennifer Anwar[7], Pratima Sharma[8], Patrick Spoutz[9], Manimegalai Murugavel[10], Mark A. Wilson[10], Jason A Dominitz[11], Heather M. Patton[12,13], Megan Adams[14] and Timothy R. Morgan[7], (1)VA Pittsburgh Healthcare System, (2)University of Pittsburgh, (3)VA Portland Health Care System, (4)Michael E. Debakey Veterans Affairs Medical Center, (5)Baylor College of Medicine, (6)VA Tennessee Valley Healthcare System, (7)VA Long Beach Healthcare System, (8)University of Michigan, (9)Veterans Integrated Service Network 20, (10)Veterans Health Administration, (11)VA Puget Sound Health Care System, (12)VA San Diego Healthcare System, (13)University of California, San Diego, (14)University of Michigan School of Medicine

Background: Prior work has identified low rates of transplant referral for people with cirrhosis across the US. To develop a plan to evaluate and improve transplant access for Veterans in VA care, VA surgical and hepatology leadership established a VA Transplant workgroup to 1) identify factors associated with liver transplant referral in VA and 2) understand barriers to referral for transplant evaluation to target future quality improvement and outreach efforts. **Methods:** We used the VA Corporate Data Warehouse to collect data about Veterans with hepatocellular carcinoma or cirrhosis who were in VA care during 2021. Logistic regression was used to assess the factors associated with transplant evaluation referral. Subsequently, a survey of potential barriers to and facilitators of transplant evaluation and referral was sent to the clinicians who care for Veterans with cirrhosis across the VA. Results were analyzed using descriptive statistics and used to inform future improvement efforts. **Results:** Of the 99,092 Veterans with cirrhosis, 18% were ineligible for liver transplant based on age (e 75) or limited life expectancy. Likewise, 64,252 had low MELD, no complications of cirrhosis, and no HCC. In a single year, transplant referrals were completed for 700 Veterans, including 7.3% of the high MELD and decompensation group. Factors significantly associated with transplant referral were being younger, married, and White (versus Black), and having fewer comorbidities, higher MELD, and no history of alcohol use disorder. While a third of Veterans were rural-dwelling, 95% were within 150nm of a tertiary VA; distance was associated with referral only for Veterans with HCC. Surveys were returned by 196 clinicians from across the VA and a wide range of specialty settings. Clinicians identified the biggest barriers to transplant evaluation as provider knowledge about evaluation, length of the transplant workup, and complications with post-transplant care and the complexity of engaging with non-VA, community care transplant centers. Common misconceptions about VA liver transplantation were identified. Clinicians requested virtual tumor boards and hepatology consultation, as well as other resources to support transplant referral. VA leadership is developing a transplant implementation roadmap to actively increase referral and evaluation for transplantation for all Veterans. **Conclusion:** The Liver Transplant Workgroup identified patient- and provider-level factors associated with transplant referral for high-need Veterans in VA. Future work includes offering training and education, as well as targeted outreach to improve access and equity of transplant referral for Veterans with HCC or cirrhosis. VA's national transplant program offers an opportunity

1052-A | USING NORMOTHERMIC MACHINE PERFUSION (NMP) TO ASSESS, RESUSCITATE AND RESCUE LIVERS FOR TRANSPLANTATION: FIRST 50 CASES OF A US SINGLE CENTER

Rachel Todd[1], Andrew Rosowicz[1], Matthew Holzner[2], Guy Meyerovich[2], Parissa Tabrizian[2], Chiara Rocha[2], Antonios Arvelakis[2], Joseph DiNorcia[2], Marcelo Facciuto[2], Thomas Schiano[2], M. Zeeshan Akhtar[2] and Sander S. Florman[2], (1)Icahn School of Medicine at Mount Sinai, (2)Recanati/Miller Transplantation Institute at Mount Sinai

Background: Normothermic machine perfusion (NMP) is a valuable tool used to evaluate marginal grafts for transplantation during organ preservation. Using the OrganOx *metra*® system, our goal was to expand our program's usage of marginal donor livers, benchmarking perfused livers against available viability criteria. **Methods:** This study is a single-center, retrospective review of all donor livers received at our institution for NMP evaluation from July 2022 to May 2023. A risk assessment tool was developed to evaluate the grafts chosen for NMP at our institution. Livers were deemed high risk if they met any of the following criteria: macrosteatosis > 30%, warm ischemia time > 30 minutes, prolonged donor down time, or donor hemodynamic instability requiring expedited procurement. Livers were broadly matched to recipients by placing high-risk livers in lower risk recipients. During NMP, all livers were evaluated for viability based on previously published data, including lactate clearance, glucose utilization, pH stability, and flow rates. Donor data, procedure details regarding NMP use, and recipient characteristics were collected. Post-transplant outcomes included rates of primary non-function, early allograft dysfunction (EAD), biliary complications, and 30-day/3-month recipient survival. **Results:** Over 280 days, 50 livers underwent NMP, of which 17 (34.0%) met our high-risk criteria. Mean pump perfusion time was 8.18 hours. Three of the high-risk livers did not meet viability criteria and were therefore discarded, of which two were DCD organs. Transplant outcomes are summarized in Table 1. For biliary complications, one patient experienced an anastomotic stricture. This graft did not meet our criteria for a high-risk liver. Rates of 30-day and 3-month survival were 97.8% and 94.1% respectively, and none of these patients received high-risk organs. **Conclusion:** Our center's experience demonstrates that NMP enables higher risk liver transplants to be performed safely. Our data supports the use of NMP, but caution and care are required to select the right liver for the right recipient.

	Overall Cases (n=47)	High Risk Livers (n=14)
Utilization Rate	47 of 50 (94.0%)	14 of 17 (82.4%)
DCD Donors	27 of 50 (54%)	4 of 17 (23.5%)
Recipient Characteristics		
Average Age (years)	56.3	60.1
Average MELD Score	21.1	19.1
Transplant Outcomes		
Primary Non-Function	0 (0.0%)	0 (0.0%)
Early Allograft Dysfunction	28 (59.6%)	9 (64.3%)
Biliary Complication	1 (2.1%)	0 (0.0%)
30-Day Survival (n=45, n=13)	44 (97.8%)	13 (100.0%)
3-Month Survival (n=34, n=12)	32 (94.1%)	12 (100.0%)

Background: Utilization of donation after circulatory death (DCD) grafts is crucial in addressing the organ shortage for liver transplantation, yet DCD grafts have exhibited inferior patient and graft survival compared to donation after brain death (DBD) grafts. Normothermic

machine perfusion (NMP) has been shown to decrease rates of ischemic cholangiopathy (IC), anastomotic biliary strictures, and early allograft dysfunction (EAD) in DCD grafts. Our center currently administers 2 mg tPA intra-arterially to DCD graft recipients after reperfusion. In this study, we explored application of tPA during NMP with FFP as a plasminogen source. Our aim was to evaluate effects on blood loss and incidence of IC. **Methods:** Organs were placed on the OrganOx *metra*® system. DCD grafts were given an initial bolus of 10 mg tPA, followed by a 40 mg infusion over 90 minutes. Fresh frozen plasma (FFP) was administered simultaneously in a 100 mL bolus plus a 150 mL infusion over 90 minutes. After NMP, grafts were flushed with Custodial solution to remove all blood products and intravascular tPA, and then brought to the surgical field. Retrospective review of all NMP cases at our center was conducted, including intraoperative transfusions, post-transplant outcomes, and 30-day survival. Patients whose grafts received tPA on the OrganOx *metra*® system were compared to those not receiving tPA via Mann-Whitney U tests for continuous variables and Fisher exact tests for dichotomous variables. **Results:** In total, tPA and FFP were administered to 16 DCD grafts and two DBD grafts with concern for poor cold flush during procurement. 32 other livers placed on NMP did not receive tPA and FFP. Three grafts (1 in tPA cohort, 2 in non-tPA cohort) were discarded after failing to meet viability criteria during NMP. Mean intraoperative transfusion requirements for both groups are summarized in Table 1, with no significant increase in the tPA/FFP cohort. There was no incidence of primary non-function or ischemic cholangiopathy (median follow-up of 4.4 mo for all cases). There was a significantly higher rate of reoperation for hematoma evacuation in the non-tPA cohort. All patients in the tPA cohort achieved 30-day survival. **Conclusion:** NMP is a safe mechanism of administering tPA and FFP to pre-transplant donor livers and prevents the need to administer this agent to the recipient after reperfusion. Our initial results demonstrate a shift in clinical practice in the use of tPA administration.

Case Characteristic	tPA Cohort (n=17)	non-tPA cohort (n=30)	p-value
Donor Type			
DBD	2	27	<0.01*
DCD	15	3	
Mean Intraoperative Transfusions			
pRBC	7.8 units	11.64 units	0.612
Cryo	0.18 units	0.64 units	0.301
FFP	10.1 units	16.8 units	1.998
Platelets	0.52 units	1.02 unit	1.999

1054-A | UTILIZATION OF COVID-19 POSITIVE VERSUS NEGATIVE DECEASED DONORS REGISTERED FOR LIVER TRANSPLANTATION IN THE UNITED STATES

Christopher Shi[1], Carolyn Chow[2], Samir Abu-Gazala[2] and Nadim Mahmud[2,3,4,5], (1)Rice University, (2) Hospital of the University of Pennsylvania, (3)Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, (4)University of Pennsylvania, (5)University of Pennsylvania Perelman School of Medicine

Background: COVID-19 (C19) infection in deceased donors for potential liver transplant (LT) is a commonly encountered clinical scenario. Recent literature suggests that short-term patient survival and graft survival are similar in C19(+) versus C19(-) donors. We aimed to evaluate trends in utilization of C19(+) versus (-) donors and identify variables associated with utilization versus discard. **Methods:** This was a retrospective cohort study of national registry (UNOS) deceased donors referred for possible LT between 7/2020 and 6/2022. We collected donor demographic data, categorized each individual as a donor after cardiac death (DCD) or donor after brain death (DBD), and identified corresponding UNOS regions. Donors were classified as C19(+) or (-) based on a nucleic acid or antigen test within 21 days of referral or transplant. The primary outcome was donor utilization for LT versus discard. Logistic regression was used to identify variables associated with this outcome. **Results:** We identified 23,809 deceased donors classified as follows: 9,434 (40%) C19(-) discarded, 13,654 (57%) C19(-) transplanted, 379 (2%) C19(+) discarded, and 342 (1%) C19(+) transplanted. Referred donors had median age 41 years, 63% were white, median BMI was 27, and 32% were DCD. C19(+) donors were significantly more likely to be DCD than C19(-) donors (41% vs. 32%, $p < 0.001$). During the study period, for C19(+) donors, the ratio of transplanted to discarded livers increased monotonically, while for C19(-) donors, the ratio decreased (each $P_{trend} < 0.001$; Fig. 1). In multivariable logistic regression, donor utilization was inversely associated with donor age (adjusted

OR [aOR] = 0.98, 95% CI 0.98-0.99; $p < 0.001$), DCD versus DBD classification (aOR = 0.075, 95% CI 0.070-0.080; $p < 0.001$), donor BMI (aOR = 0.96, 95% CI 0.96-0.97; $p < 0.001$), and C19(+) status (aOR = 0.78, 95% CI 0.62-0.98; $p = 0.031$). There was no interaction between C19 infection and UNOS region ($p = 0.08$). However, an interaction was identified between C19 infection and DCD vs. DBD ($p = 0.005$) such that the impact of C19(+) increased the probability of discard more for DCD than DBD, relative to C19(-). **Conclusion:** Though utilization has increased over time, a large proportion of C19(+) organs are discarded, likely in part related to higher proportion of DCD status. However, C19(+) status remained independently associated with discard after adjusting for key donor characteristics, with a particularly strong effect in DCD vs. DBD. In view of literature demonstrating acceptable post-LT outcomes for C19(+) donors, our data suggest that potentially transplantable C19(+) organs are likely being discarded.

1055-A | 18F-FAPI PET/CT CAN ACCURATELY EVALUATE THE EARLY-STAGE OF LIVER GRAFT FIBROSIS IN ADULT LT REPICIENTS

You wei Zhao[1], Xiaohan Fang[2], Man Xie[2,3], Jinzhen Cai[4], Guangjie Yang[5] and Wei Rao Sr.[6], (1)Division of Hepatology, Liver Disease Center, the Affiliated Hospital of Qingdao University, (2)Department of Gastroenterology, the Affiliated Hospital of Qingdao University, (3)The Affiliated Hospital of Qingdao University, (4)Department of Organ Transplantation, the Affiliated Hospital of Qingdao University, (5)Department of Nuclear Medicine, the Affiliated Hospital of Qingdao University, (6)Division of Hepatology, Liver Disease Center, the Affiliated Hospital of Qingdao University, Qingdao, 37, China

Background: To explore the value of Fluorine-18 labeled fibroblast activation protein inhibitor(^{18} F-FAPI) PET/CT in the assessment of early-stage graft fibrosis (S1-S2) after liver transplantation(LT). **Methods:** A total of 17 adult LT recipients (12 males and 5 females) were enrolled in this study. All patients received liver biochemistry, routine blood, coagulation, FibroScan, ^{18}F-FAPI-PET/CT and biopsy of liver graft. Then, the predicting values of four kinds of non-invasive methods including FIB-4, APRI, liver stiffness measurement (LSM) and maximum standardized uptake value (SUVmax), were compared in the evaluation of early-stage graft fibrosis. **Results:** Among the 17 adult LT recipients, 11 (64.7%) were in stage S0 fibrosis, 5 (29.4%) were in stage S1, and 1 (5.8%) was in stage S2. There were significant differences between LSM and SUVmax in early-stage hepatic fibrosis recipients and non-hepatic fibrosis recipients ($p = 0.04$; $p = 0.02$), while there was no significant difference in FIB-4 and APRI between the two groups ($p = 0.21$; $p = 0.92$). The critical value of LSM in predicting early-stage graft fibrosis was 8.2kPa and AUROC was 0.80 ($p = 0.012$), while the SUVmax was 2.0 and AUROC was 0.92 ($p = 0.006$). **Conclusion:** ^{18}F-FAPI PET/CT can accurately evaluate the early stage of liver graft fibrosis with higher diagnostic accuracy values than FibroScan, which is expected to be a new non-invasive diagnositic tool for adult LT repicients.

1056-A | A COMPLEX CASE OF POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER WITH MULTIPLE INTRACRANIAL HEMORRHAGES IN A LIVER TRANSPLANT RECIPIENT

Ahlam Alzoghoul[1], Umnia Shnawa[1] and Mohammad Almeqdadi[2], (1)Jordan University of Science and Technology, (2)Tufts Medical Center

Background: Post-transplant lymphoproliferative disorder (PTLD) is a well-known complication of solid organ transplantation, often associated with Epstein-Barr virus (EBV) infection. Central nervous system

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(CNS) PTLD is a rare manifestation, which can present with various neurological symptoms including intracranial hemorrhage. **Methods:** We report a 48-year-old male with a history of ulcerative colitis, primary sclerosing cholangitis, and liver transplantation who presented with multiple episodes of intracranial hemorrhage. The patient was maintained on tacrolimus and mycophenolate mofetil (MMF) for immunosuppression. Cerebrospinal fluid (CSF) analysis revealed elevated lymphocytes, low glucose, and high total protein, raising concerns for an inflammatory or malignant process. EBV DNA was not detected in the CSF, but the patient was EBV positive pre-transplant. Despite the lack of definitive tissue or cellular atypia, PTLD remained the top differential diagnosis. The patient's immunosuppression was reduced by stopping MMF, and he was started on a trial of rituximab. **Results:** Throughout his clinical course, the patient experienced multiple intracranial hemorrhages with worsening neurological symptoms, and progression of disease on MRI of the brain (*Figure 1*), ultimately leading to a brain mass biopsy. The biopsy revealed gliotic brain tissue, remote infarction, hemosiderin deposition, and lymphohistiocytic inflammation, but no definitive evidence of neoplastic or infectious processes. The patient's clinical course was complicated by post-dural puncture headaches, nausea, vomiting, and autonomic dysfunction. **Conclusion:** This case highlights the diagnostic challenges and management complexities of a presumed CNS PTLD in a liver transplant recipient with multiple intracranial hemorrhages. Despite the lack of definitive diagnostic findings, PTLD remained the most likely underlying etiology, and a multidisciplinary approach was critical in managing the patient's immunosuppression and neurological complications. This case underscores the need for further research and improved diagnostic strategies for CNS PTLD, as well as the importance of close monitoring and prompt intervention for neurological complications in transplant recipients.

1057-A | A DESCRIPTIVE ANALYSIS OF TWO UNITED STATES TRANSPLANT CENTERS' EXPERIENCE WITH HCV POSITIVE DONOR TO HCV NEGATIVE RECIPIENT LIVER TRANSPLANTATION

Raha Sadjadi[1], Anudeep Neelam[2], Pooja Rangan[1], Ritwik Keshav[1], Giorgio A. Roccaro[3] and Karn Wijarnpreecha[1], (1)University of Arizona College of Medicine Phoenix, Phoenix, AZ, (2)Icahn School of Medicine at Mount Sinai Morningside/West, (3)Emory University School of Medicine

Background: The liver donor pool continues to fall short of the demand for liver transplant (LT). The efficacy and safety of direct-acting antiviral agents (DAA) provides rationale for using hepatitis C virus (HCV) positive (+) donors to reduce this disparity. We describe two centers' experiences transplanting HCV + livers in to HCV negative (–) recipients with hopes of increasing utilization of HCV+ grafts for LT. **Methods:** This is a cohort study of patients who underwent LT at two transplant centers: Emory University Hospital and Banner University Medical Center Phoenix. For each center, data and outcomes were separately collected and compared between (1) LT recipients who received an HCV – graft and (2) HCV – LT recipients who received an HCV + graft. Emory data was prospectively collected from patients transplanted from 2019 – 2021. Phoenix data was retrospectively collected from patients transplanted from 2015 – 2022. We performed descriptive analyses to compare baseline demographics of the recipient and donor, immediate transplant related outcomes, and mortality in the first year following LT between HCV + and HCV – graft recipients at each center. Time to initiation of DAA in HCV+ LT recipients was also compared. **Results:** 732 LT recipients were analyzed, 112 (15.3%) from Emory and 620 (84.7%) from Phoenix. At both centers, there was no statistical difference between the group that received HCV – grafts and the group that received HCV + grafts in terms of recipient age at transplant, donor age, warm ischemic time, or graft failure/mortality in the first year following LT. In the Emory cohort, there was a statistically significant lower MELD at transplant in HCV – patients who received HCV + grafts and a shorter length of hospitalization after LT. The Emory cohort also trended towards a shorter cold ischemic time among patients who received HCV + LT. There was no difference between groups within these variables in the Phoenix cohort. Linear regression of the Emory cohort showed lower MELD at transplant drove the shorter hospital length of stay after LT. Median time to DAA at Emory was 2 days (vs 75 d at Phoenix). No Emory recipients of HCV+ grafts died. 5 HCV+ graft

recipients at Phoenix died from 2019 - 2020. Causes of death included (1) pneumonia, (2) graft failure/rejection, (3) metastatic angiosarcoma, (4) a combination of hemorrhagic shock, sepsis, and mesenteric ischemia with peritonitis, and (5) hemorrhagic shock. Only one of these deaths involved a donation after cardiac death graft. **Conclusion:** This multicenter experience shows that using HCV+ donors is not associated with worse immediate post-transplant outcomes or in one year post LT mortality. Our data supports widened use of HCV+ liver donors as standard practice.

1058-A | BARIATRIC SURGERY OUTCOMES IN LIVER TRANSPLANT PATIENTS: INSIGHTS FROM THE NATIONAL INPATIENT SAMPLE (NIS)

Mohamed Ahmed[1], Fouad Jaber[1], Ifrah Fatima[2], Saqr Alsakarneh[3], Islam Mohamed[3], Ahmed Elkafrawy[4] and Hassan Ghoz[1], (1)University of Missouri- Kansas City, (2)Univeristy of Missouri- Kansas City, Kansas City, MO, (3)University of Missouri-Kansas City, (4)University of Iowa Hospitals and Clinics

Background: Obesity, defined as a body mass index (BMI) > 30 kg/m2 is a worldwide epidemic. Bariatric surgery emerges as potential of cure however its safety in patients with Liver transplant (LT) remains understudied. The aim of this study is to evaluate outcomes of Bariatric surgery in LT patients. **Methods:** Patients hospitalized between 2016 and 2020 who were admitted for Bariatric surgery were identified using International Classification of Diseases Code,10th Revision Clinical Modification (ICD-10) identified from the Healthcare Cost and Utilization Project databases (HCUP) using the National inpatient sample (NIS). Patients with history of LT were compared to patients without LT. Bariatric surgeries included open and laparoscopic Roux-en-Y gastric bypass, open and laparoscopic sleeve gastrectomy, and biliopancreatic diversion-duodenal switch. **Results:** A total of 1042114 patients had Bariatric surgery, 330 (0.032%) patients had a history of LT. Mean age of the non-LT group was 46.5 (95% CI-46.3-46.6) years compared to 55.65 (95% CI- 52.1-59.1) years in the LT group. 76.3% of the non-LT group were females compared to 53.85% in the LT group. The mortality rate of the non-LT group was 0.7 % compared to 3.03% % in the other group ($p = 0.04$). Length of stay (LOS) was 3.32 (95% CI- 3.2-3.4) days in the non-LT group while it was 13.25 13.25 (95% CI-8.1-18.4) days in the LT group ($p < 0.01$). General characters are summarized in table 1. Univariate analysis showed that LT patients are more likely to have acute kidney injury (AKI), sepsis, GI bleed, need blood transfusion, pulmonary embolism, Anatomic leak and need Exploratory laparotomy (Table 2). Multivariate analysis adjusting for Age, Sex, primary payer, Race, Hospital bed size, hospital reaching status, hypertension, Diabetes and obstructive sleep apnea showed that LT does not increase mortality in patients undergoing Bariatric surgery (OR 0.0057, CI 0.0036-1.003), however it increases LOS (OR 6.49, CI 1.68-11.32). **Conclusion:** NASH is now the second leading etiology for LT in the United States and is predicted to become the first in short order. Recurrent NAFLD develops in 30%-60% of patients following LT which mean post-LT bariatric surgery incidence is likely to increase. While there is increase morbidities in this cohort of patients, it appears that mortality does not change significantly. There are some limitations in this study including inability to determine date of LT and long-term outcomes of Bariatric surgeries on weight loss.

1059-A | CHRONIC MYELOID LEUKEMIA IN A POST-LIVER TRANSPLANT PATIENT: A RARE COMPLICATION AND MANAGEMENT CHALLENGES

Umnia Shnawa[1], Ahlam Alzoghoul[1] and Mohammad Almeqdadi[2], (1)Jordan University of Science and Technology, (2)Tufts Medical Center

Background: Chronic myeloid leukemia (CML) is a rare complication in post-liver transplant recipients, with few cases reported in the literature. The optimal management of CML in this population remains a challenge due to potential drug interactions and adverse effects of tyrosine kinase inhibitors (TKIs) on liver function. **Methods:** We report a case of a 53-year-old male with a history of primary sclerosing cholangitis status post liver transplant in 2006, and ulcerative colitis status post total colectomy with ileostomy in place in 2008. The patient presented with worsening leukocytosis and was subsequently diagnosed with CML after confirmation of the 9;22 translocation and chronic phase disease on bone marrow biopsy (Table 1). The patient was initially started on dasatinib, but developed significant pericarditis and pericardial effusion, necessitating dose reduction and eventual discontinuation of the drug. Despite the known hepatotoxicity of TKIs, the patient's liver function remained stable on tacrolimus and prednisone immunosuppression. Further management options, including alternative TKIs such as imatinib or nilotinib, were considered in consultation with the transplant hepatology team. **Results:** This case highlights the rarity of CML as a complication in post-liver transplant patients and the challenges in managing these patients due to the potential adverse effects of TKIs on liver function and immunosuppression requirements. Previous case reports suggest that TKIs can be used in post-liver transplant patients without significant interaction with immunosuppressive agents, although hepatotoxicity remains a concern. In our patient, dasatinib was initially used, but ultimately discontinued due to significant pericarditis and pericardial effusion. The decision to switch to an alternative TKI will be based on a careful assessment of potential risks and benefits, with close monitoring of liver function and immunosuppression levels. **Conclusion:** CML in post-liver transplant patients is a rare complication with limited guidance on optimal management. This case highlights the importance of a multidisciplinary approach, including collaboration between hematology and transplant hepatology teams, to balance the potential benefits and risks of TKI therapy in this unique patient population. Further research is needed to better understand the safety and efficacy of TKI use in post-liver transplant patients with CML, as well as to establish best practices for managing these complex cases.

f 1060-A | CLEVER-LG (CELL-FREE DNA METHYLATION WITH CLINICAL VARIABLES) FOR EARLY RECOGNITION OF LIVER GRAFT PATHOLOGY USING MACHINE LEARNING★

Soumita Ghosh[1], Cristina Baciu[1], Maryam Naghibzadeh[1], Amirhossein Azhie[2], Khairunnadiya Prayitno[1], Sara Naimimohasses[1], Sandra Elisabeth Fischer[3], Arya Rahmani[1], Elisa Pasini[1], Michael Brudno[4], Elmar Jäckel[1], Daniel De Carvalho[5] and Mamatha Bhat[3], (1)Ajmera Transplant Center, University of Toronto, Toronto, ON, Canada, (2)Department of Internal Medicine, Max Rady College of Medicine, Rady Faculty of Health Sciences, University of Manitoba, Winnipeg, MB, Canada, (3)University of Toronto, (4)Department of Computer Science, University of Toronto, Toronto, on, Canada, (5)Princess Margaret Cancer Centre, University Health Network, Toronto, on, Canada

Background: Graft injury affects over 30% of Liver Transplant Recipients (LTRs) and the exact cause of injury can only be identified currently with a liver biopsy. Transplant recipients can develop graft injury due to various etiologies, such as T-cell mediated rejection (TCMR) and NASH (NASH-LT). The aim of our study was to develop a Machine Learning (ML) tool integrating clinical variables with methylation patterns on circulating DNA in plasma as a non-invasive diagnostic tool of graft pathology. **Methods:** We generated methylation profiles of circulating DNA in a pilot study of 43 LTRs (11 Non-alcoholic steatohepatitis (NASH-LT, 19 T-cell mediated rejection (TCMR), and 13 Control-LT), and developed an L2 regularized multinomial logistic regression ML approach across 101 bootstrapped models to distinguish between the graft conditions. NASH was associated with distinctive methylation patterns on genes involved in fatty acid metabolism, while activation of platelet-derived growth factors was identified in patients with TCMR. **Results:** Our ML models achieved a mean multi-classification accuracy of 0.91, with mean specificity and sensitivity of 0.94 and 0.91, respectively. Our models were found to be particularly adept at detecting TCMR and Control-LT, with mean true positive rates (TPRs) of 96% and 90%, respectively. For NASH-LT, the models achieved a performance with a mean TPR of 82%. Our one-vs-rest classification models achieved AUROCs of 0.992, 0.985 and 0.991 for TCMR, Control-LT and NASH-LT classes respectively. **Conclusion:** These results suggest that our ML tool, CleVER-LG, leveraging cell-free DNA methylation and clinical variables, is a promising non-invasive classifier of graft pathology in LTRs.

1061-A | CLINICAL FEATURES RELATED TO THE DEVELOPMENT OF NODULAR REGENERATIVE HYPERPLASIA POST LIVER TRANSPLANT: A CASE SERIES

Gabrielle Jutras[1], Isaac Ruiz[1], Genevieve Huard[2], Bich N. Nguyen[3], An Tang[3] and Julien Bissonnette[2], (1)Centre Hospitalier De L'université De Montréal, Montréal, QC, Canada, (2)Centre Hospitalier De l'Université De Montréal, (3)Centre Hospitalier De L'université De Montréal, Montréal, UT, Canada

Background: Nodular regenerative hyperplasia (NRH) is a rare hepatic condition that can occur before or after liver transplant (LT). It is defined by remodeling of the liver parenchyma in the form of nodules separated by trabeculae of atrophied hepatocytes. NRH has been associated with certain drugs and various hematologic and vascular conditions, but there is few data on the etiology, clinical course and prognosis in patient after liver transplantation. The aim of this study is to describe the characteristics of patients who developed a NRH after LT. **Methods:** This is a retrospective observational descriptive case series of all patients who developed a biopsy-proven NRH after LT at Centre Hospitalier de l'Université de Montréal (CHUM) between 2010 and 2020. **Results:** Of the 678 patients who underwent LT between 2010 and 2020, nine patients (1.3%) developed a NRH, of which 77.8% (7/9) were male. The mean age at LT was 57 (range 48-65). The indications for the liver transplant were decompensated cirrhosis due to alcohol (n = 1), metabolic-associated Fatty Liver Disease (MAFLD) (n = 2), primary sclerosing cholangitis (n = 3), primary biliary cirrhosis (n = 1) and acute liver failure (n = 1). The mean cold ischemia time was of 420 minutes [206-561]. The mean delay from LT to NRH diagnosis was 40 months [5-120]. At the time of diagnosis, 55.6% (5/9) were symptomatic for portal hypertension with the presence of ascites in 100% (5/5), splenomegaly in 80% (4/5) and/or esophageal varices in 40% (2/5). Only one patient had a history of azathioprine use prior to LT. Ischemic cholangiopathy was diagnosed in 66.7% (6/9) of patients with NRH, on average 21 months (range 3-46) before the diagnosis of NRH. The overall mortality rate in this cohort was 22.2% (2/9), and more precisely of 40% in symptomatic

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

patients compared with 0% in asymptomatic patients over a median follow-up of 47 months [3-124]. **Conclusion:** Our results suggest that ischemic cholangiopathy may be associated with the development of NRH after liver transplantation. To our knowledge, such an association has never been described in the literature. In addition, the mortality in symptomatic NRH patients seems to be is higher compare to asymptomatic patients. Further studies are needed to better examine these potential associations.

f 1062-A | COGNITIVE IMPAIRMENT, FRAILTY, AND LIVER TRANSPLANT RECOVERY: EARLY RESULTS FROM LIVCOG, A PROSPECTIVE MULTICENTER COHORT

Marina Serper[1], Douglas Schaubel[2], Adwait Chafale[2], Alexander E Burdzy[2], Maria Blanco[2], Ann Tierney[2], Sumeet Asrani[3], Peter Reese[2], Julia Yoshino Benavente[4] and Michael S Wolf[4], (1)University of Pennsylvania, Philadelphia, PA, United States, (2) University of Pennsylvania, (3)Baylor University Medical Center, Dallas, TX, (4)Northwestern University

Background: Few studies in liver transplantation (LT) have comprehensively evaluated cognitive and physical health and how it affects post-transplant quality of life, function, and longitudinal health outcomes. The NIH-funded LivCog cohort study is enrolling 450 LT recipients at 4 transplant centers in Pennsylvania, Illinois, and Texas and their caregivers to comprehensively examine cognitive function, physical function and how those factors affect post-LT quality of life and health outcomes. **Methods:** All enrolled patients have detailed clinical data on demographics, comorbidity, and pre-LT liver disease severity. Serial post-LT assessments include global cognition (Montreal Cognitive Assessment [MoCA], the comprehensive NIH Toolbox (NIHTB) that tests working memory, executive function, attention, processing speed, and verbal ability, animal naming test [ANT], and patient-perceived every day cognition [ECOG]. Physical function is assessed with the liver frailty index (LFI). Health literacy is assessed with the newest vital sign (NVS). A novel LT knowledge (LTKQ) questionnaire tests relevant transplant knowledge (immunosuppression safety, lab timing, side effects, etc.). Correlations between cognitive and frailty measures were assessed with Spearman correlation coefficients. **Results:** We present baseline data on n = 89 recent LT recipients, predominantly within 1 month of LT. Median patient age is 56 (IQR: 43-62; 85% are White; 7% are Black; 1% are Asian; 9% are of Hispanic ethnicity. Prior to LT 32% had viral hepatitis, 25% had NAFLD/NASH and 39% had alcohol-associated liver disease (ALD). A total of 37% of patients were frail. Based on the MoCA (score < 26) or ANT (score < 14), 46% exhibited at least mild cognitive impairment. Using the NIHTB scores adjusted for age, sex, and education, significant impairment (defined as < 1 SD below U.S population norms) was noted for 34% for attention, 22% for processing speed, 25% for working memory, and 8% for episodic memory. A total of 28% reported significant cognitive concerns by the ECOG scale. 16% of LTRs had limited health literacy. A correlation matrix between cognitive measures and frailty is shown in Table 1. Global cognition (MoCA) exhibited significant negative correlations correlated with LFI scores, (e.g. higher frailty scores, lower cognitive function scores). However, using a more nuanced assessment of cognition (NIHTB), only the executive function and working memory domains significantly correlated with physical frailty. **Conclusion:** In early results, we document high prevalence of objective cognitive impairment, physical frailty, and self-reported cognitive concerns during early post-LT recovery. Cognitive impairment though associated with physical frailty is a distinct phenotype. The cohort will examine longitudinal cognitive, physical, and health outcome trajectories to identify distinct phenotypes of post-LT health and their predictive factors.

Table 1. Correlation Matrix for selection cognition, transplant knowledge and frailty variables collected in the LivCog cohort thus far (n=89)

	MOCA	ANT	LTKQ	LFI	NIHTB
MoCA	1				
ANT	0.47	1

1063-A | DE NOVO GASTRIC CANCER AFTER LIVER TRANSPLANT AND THE CLINICAL STRATEGY

Wei Rao Sr.[1], Qun Zhang[2], Tian Qiu-Ju[2], Zhang Bei[3], Jinzhen Cai[4] and Man Xie[5], (1)Division of Hepatology, Liver Disease Center, the Affiliated Hospital of Qingdao University, (2)The Affiliated Hospital of Qingdao University, (3)Qingdao University, (4)Department of Organ Transplantation, the Affiliated Hospital of Qingdao University, (5)Department of Gastroenterology, the Affiliated Hospital of Qingdao University

Background: De novo malignancies has gradually become the greatest threat for the long-time survival after liver transplantation. The aim of our study is to investigate the clinical manifestations of de novo gastric cancer in liver transplant (LT) recipients, identify the risk and to explore the optimized screening protocol **Methods:** Endoscopic screening was performed prospectively on LT recipients received regular follow-up in our center, endoscopic manifestation and the characteristic of de novo gastric cancer(DN-GC) was analyzed. **Results:** In total, 274 cases were enrolled, and10 cases (3.6%) of DN-GC were diagnosed. The cumulated incidence of DN-GC in 3 years ,5 years and 10 years after liver transplantation was 3.3%, 8.0% and 8.0%, respectively. 70% (7/10) of DN-GC was undifferentiated type and 80% (8/10) of them was diagnosed at early stage. The cumulated survival rate in 3 years ,5 years and 10 years among the LT recipient with DN-GC were 87.5%, 72.9% and 72.9% respectively, while those rate among the LT recipient without DN-GC were 98.8%, 97.4% and 96.3% respectively, significantly difference was observed($p = 0.004$). CAG was the only risk factor of DN-GC after liver transplantation (9/1 vs 90/174, $p = 0.003$, $X2 = 9.067$). 109 of recipient without DN-GC received twice gastroscopy and 85.3% (58/68) of the recipients with chronic superficial gastritis (CSG) in the first gastroscopy was consistently diagnosed to be CSG in the second one. 39 received third gastroscopy, and 83.3% (20/24) of the recipients with CSG in the second gastroscopy was consistently diagnosed to be CSG in the third one. **Conclusion:** The incidence of gastric cancer was significantly elevated after liver transplantation which could decrease the patient's long-term survival. CAG was the only risk factor of DN-GC and mucosal condition was relatively stable after liver transplantation, therefor, active endoscopic screening was highly recommended for the LT recipients with CAG.

Table 2. Comparison of liver transplant recipients with or without de novo gastric cancer

	De novo gastric cancer (+)(N=10)	De novo gastric cancer (-)(N=264)	P-value	P-value
Age	55.70±7.846	54.88±10.135	0.852	0.803
Gender (M/F) (n/n)	10/0	203/61	2.983	0.085
Indication for LT(n) Alcoholic Non-alcoholic	1 9	17 247	0.617	0.367
Time from LT to gastroscope (months)	44.80±38.00	43.18±45.02	0.014	0.907
Atrophy (+/-) (n/n)	9/1	90/174	9.067	0.003

1064-A | DETECTION OF ANASTOMOTIC AND NON-ANASTOMOTIC STRICTURES USING QUANTITATIVE MRCP IN PATIENTS AFTER LIVER TRANSPLANTATION

Emmanuel Selvaraj[1], David Nasralla[2], Rajarshi Banerjee[3], John Karani[4], Arvind Pallan[5], Rutger Ploeg[1], Sara Upponi[6], Liam A. J. Young[3], Peter J. Friend[1] and Consortium for Organ Preservation in Europe (COPE), (1)University of Oxford, (2)Royal Free Hospital, (3) Perspectum Ltd., (4)King's College Hospital, (5)Queen Elizabeth Hospital, (6)Addenbrooke's Hospital

Background: Recent advances in machine perfusion technology using normothermic machine perfusion (NMP) instead of static cold storage (SCS) have reduced the insult to donor livers and improved post-transplant liver function. However in liver transplantation (LT), biliary complications remain a significant cause of morbidity and mortality. Patients with symptomatic biliary strictures often require intervention or re-transplantation. Early assessment and diagnosis of asymptomatic radiological strictures using magnetic resonance cholangiopancreatography (MRCP) may assist clinical decision making and allow evaluation whether NMP might reduce symptomatic biliary complications. Artificial intelligence-driven post-processing has enabled the quantitative assessment of MRCP and improved prognostication and monitoring of patients with biliary diseases. In this study, we studied the ability of quantitative MRCP to detect post-transplant biliary strictures. **Methods:** Patients in the COPE liver trial underwent a MRCP 6 months following LT with three radiologists performing a consensus read to detect anastomotic (AS) and non-anastomotic strictures (NAS). This study retrospectively processed the MRCP with MRCP+ (Perspectum Ltd, Oxford) to

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

extract quantitative metrics. A principal component analysis (PCA) was performed to reduce the number of quantitative MRCP metrics considered. Differences between patients with and without strictures were assessed (Wilcoxon tests). Diagnostic accuracy was assessed with the area under the receiver operator curve (AUROC). **Results:** 86 LT recipients had a quantifiable post-LT MRCP (male sex = 71%, donation after circulatory death = 31%, NMP = 56%). Radiologists identified 7 cases of NAS and 46 cases of AS. PCA demonstrated two main components in the data, one quantifying localised strictures and dilatations and a second quantifying the average size of bile ducts of the biliary tree. The length of strictures and dilatations was the single metric most representative of both components and was higher in patients with NAS compared to those without strictures (150 mm [110-246] vs 42 mm [18-98], $p = 0.02$). The length of strictures and dilatations detected NAS with AUROC = 0.75 (0.52-0.99). Significant prediction of AS was also observed. **Conclusion:** This study shows good agreement between quantitative MRCP and consensus radiologist assessment for the detection of anastomotic and non-anastomotic strictures in LT recipients. The next step is to examine the potential of quantitative MRCP facilitating identification of clinically relevant strictures even earlier after LT.

1065-A | DETECTION OF HEPATIC GRAFT STEATOSIS AND FIBROSIS AFTER LIVER TRANSPLANTATION USING MRI-PDFF & MRE TECHNIQUES

Lung Yi Mak[1], James Fung[1], Gladys Lo[2], Christine Shing-Yen Lo[2], Trevor Kwan-Hung Wu[3], Tiffany Cho-Lam Wong[3], Albert Chi-Yan Chan[3], Wai-Kay Seto[4] and Man-Fung Yuen[5], (1)Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, (2)The Hong Kong Sanatorium and Hospital, (3)The University of Hong Kong, (4) Department of Medicine, School of Clinical Medicine, the University of Hong Kong, (5)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR

Background: Although non-alcoholic fatty liver disease (NAFLD) is an uncommon indication for liver transplantation (LT) in Chinese, post-LT *de novo* NAFLD (PTNL) is increasingly observed, leading to graft dysfunction and fibrosis. We aimed to characterize PTNL and graft advanced fibrosis/cirrhosis (F3/F4) by magnetic resonance imaging (MRI) and transient elastography (TE) in subjects who underwent LT for non-NAFLD indications. **Methods:** Post-LT subjects were recruited for MRI and TE. MRI-proton density fat fraction (MRI-PDFF) and MR elastography (MRE) was performed using a 1.5 Tesla Optima 450W MR scanner with a 3D volumetric sequence. PTNL and F3/F4 was defined as MRI-PDFF ≥ 5% and MRE ≥ 3.64kPa, respectively. TE was performed by Fibroscan with controlled attenuation parameter (CAP) ≥ 248 dB/m and liver stiffness (LS) values obtained. Graft dysfunction was defined as persistent alanine aminotransferase (ALT) ≥ 40 U/L at ≥ 2 consecutive measurements at follow-up (FU). **Results:** 293 subjects (70.3% male, median age at LT: 52.1) were recruited. The majority (73.4%) was transplanted for hepatitis B virus (HBV)-related complications. MRI was performed at a median time of 12.2 years post-LT. The median body mass index was 23.7 kg/m^2 (59.7% overweight), with 61.4%, 41.3%, 37.9% and 59% subjects having central obesity, diabetes, dyslipidemia and hypertension, respectively, and were present in a significantly higher proportion of patients with PTNL than without (Figure 1A). According to MRI criteria, PTNL and F3/F4 was present in 30% and 9.6%, respectively. HBV-LT was associated with higher MRI-PDFF than non-HBV-LT ($p = 0.023$) but not associated with MRE or LS values (Figure 1B). Graft dysfunction was seen in 10.7% subjects, which was associated with MRI-PDFF (OR 1.084, 95%CI 1.023-1.149, $p = 0.006$), and MRE (OR 1.437, 95%CI 1.022-2.020, $p = 0.037$). LS highly correlated with MRE (r = 0.69-0.80, $p < 0.001$; AUROC for F3/F4: 0.89), while CAP

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

moderately correlated with MRI-PDFF ($r = 0.47$-0.56, $p < 0.001$; AUROC for PTNL: 0.83). TE measurements of CAP and LS correlated better with segments V-VIII (compared to segments II & III) and upper segment (compared to lower segment) on MRI, respectively (Figure 1C). **Conclusion:** MRI-PDFF and MRE identified a high prevalence of PTNL and F3/F4, associated with graft dysfunction and metabolic risk factors, among Chinese subjects transplanted for non-NAFLD. TE is more accurate for right hepatic lobe and upper segment measurement in the post-LT setting. Figure legend: (A) Prevalence of overweight, central obesity, diabetes mellitus, hypertension and dyslipidaemia among patients with and without PTNL. (B) MRI and TE parameters stratified by HBV-related LT or non-HBV related LT. (C) Heat map showing correlation between MRI and TE parameters.

1066-A | DOES LIVER TRANSPLANT STATUS AFFECT OUTCOMES OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY TUBE: INSIGHTS FROM THE NATIONAL INPATIENT SAMPLE (NIS)

Mohamed Ahmed[1], Ifrah Fatima[2], Fouad Jaber[3], Khaled Elfert[4], Saqr Alsakarneh[3], Islam Mohamed[3] and Alisa Likhitsup[5], (1)University of Missouri Kansas City, (2)Univeristy of Missouri- Kansas City, Kansas City, MO, (3)University of Missouri-Kansas City, (4)St. Barnabas Hospital, Bronx, NY, (5)University of Missouri Kansas City - Saint Luke's Health System, Novi, MI

Background: Liver transplants (LT) is becoming increasingly common with 1 year survival year approaching 90%. The improved life expectancy means that eventually, those patients are more likely to need Percutaneous endoscopic gastrostomy (PEG). The data about outcomes of PEG tube insertion in LT patients are scarce. This study examines outcomes of PEG in LT patients. **Methods**: Patients hospitalized between 2016 and 2020 who were admitted for PEG tube insertion were identified using International Classification of Diseases Code,10th Revision Clinical Modification (ICD-10) identified from the Healthcare Cost and Utilization Project databases (HCUP) using the National inpatient sample (NIS). Patients with history of LT were compared to patients without LT. **Results:** A total of 1193990 patients required PEG tube insertion, 1675 patients had a history of LT. Mean age of the non-LT group was 57.8 years compared to 56.6 years in the LT group. 44.2% of the non-LT group were females compared to 36.7% in the LT group. The mortality rate of the non-LT group was 9.4% compared to 11.3% in the other group, however the difference was non-significant (0.27). Length of stay (LOS) was 20.87 (95% CI- 20.7-21.1) days in the non-LT group while it was 22.65 (95% CI- 19.7-25.6) in the LT group, again the difference was non-significant (0.23). Univariate analysis showed that LT patients are more likely to have acute kidney injury (AKI) (OR 2.05, CI 1.64-2.5) and need blood transfusion (OR 1.4, CI 1.06-1.84). Post PEG complications, malfunction and infections were similar in both groups (Table 2). Multivariate analysis adjusting for age, sex, LOS, Hypertension, COPD, Diabetes mellitus and coronary disease showed that LT does not increase mortality in patients undergoing PEG tube (OR 1.12, CI 0.78-1.61). **Conclusion:** To our knowledge this is the largest study looking at PEG tube outcomes in patients with history of LT. There appears to be no increase in mortality or LOS in this cohort. There is an increased risk of AKI and needing blood transfusion. This study is limited by inability to determine functional status of patients and other variables not coded in the NIS. Despite that, it appears that PEG tube is a safe procedure in patients with LT.

General characteristics Table 1

	No Liver transplant	Liver transplant	P- VALUE
Female	527184 (44.22%)	615 (36.72)	0.04
Age	57.8 (CI-57.4-58.3)	56.63 (CI- 54.1-59.1)	0.315

f 1067-A | EARLY HOSPITALIZATION FOR ACUTE KIDNEY INJURY AFTER LIVER TRANSPLANTATION IS AN INDEPENDENT RISK FACTOR FOR DE NOVO END-STAGE RENAL DISEASE★

Ranganath G. Kathawate, Wayne State University and Therese Bittermann, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: Liver transplant (LT) recipients frequently suffer acute kidney injury (AKI). However, the clinical significance of these events with respect to long-term renal outcomes, such as *de novo* end-stage renal disease (ESRD), is not well established. **Methods:** This was a retrospective cohort study using Medicare claims data that were linked to the Organ Procurement and Transplantation Network database. All first LT alone recipients between 1/1/07-12/31/2016 were identified. Hospitalizations for AKI (+/- hemodialysis) and *de novo* ESRD (defined as new onset ESRD e 90 days post-LT) were identified using validated International Classification of Diseases 9/10 and Common Procedure Terminology codes. Multivariable Cox proportional hazards models evaluated the factors independently associated with (i) AKI hospitalization in the first year and (ii) *de novo* ESRD. Patients were censored at death, retransplantation, or end of follow-up. **Results:** The cohort included 11,326 LT recipients and was 64.0% male, 71.9% non-Hispanic White, 8.1% Black, 14.7% Hispanic with median age of 61 years (IQR 54-66). The most common listing reasons were Hepatitis C (36.3%), non-alcoholic steatohepatitis (14.5%), and alcohol-associated liver disease (21.7%). Median follow-up was 4.7 years (IQR 2.8-7.0). Overall, 5,594 AKI hospitalizations within 1-year post-LT were identified among n = 3,282 (29.0%) recipients, with 11.5% of these admissions warranting hemodialysis. Of patients not on hemodialysis pre-LT (n = 10,610), 809 (7.6%) developed *de novo* ESRD at a median 1.9 years (IQR 0.8-3.4) from LT. Black race ($p = 0.047$), eGFR < 90mL/min/1.73m^2 at LT ($p < 0.001$), diabetes ($p < 0.001$), severity of portal hypertension ($p < 0.001$), and receipt of organ procured after circulatory death ($p = 0.001$) were independently associated with an increased risk of early AKI hospitalization, while female sex ($p = 0.042$) and increasing center LT volume ($p < 0.001$) were associated with a decreased risk (Table). Patients with one readmission for AKI in the first year experienced a 63% increase in the risk *de novo* ESRD post-LT, while that of patients with e 2 was nearly 3-fold greater (Table). **Conclusion:** Nearly one-third of LT recipients were hospitalized at least once for AKI in the first year post-LT, which was in turn an independent risk factor for *de novo* ESRD. Strategies that help mitigate the risk of early AKI hospitalization, even for patients with mild renal dysfunction at LT, could therefore have the potential to reduce the long-term morbidity and mortality associated with post-LT ESRD.

Table:

Hospitalization for AKI in first year post-LT		
Covariate	Adjusted HR (95% CI)	P-value

1068-A | EFFECT OF AORTIC STENOSIS ON INTRA-OPERATIVE HEMODYNAMICS AND OUTCOMES IN LIVER TRANSPLANTATION

Seyed Khalafi[1], Mohanakrishnan Sathyamoorthy[2,3], Amar Gupta[4], James F. Trotter[4], Sumeet Asrani[4] and Stevan A. Gonzalez[1,2], (1)Baylor Simmons Transplant Institute, Forth Worth, TX, (2)Burnett School of Medicine at TCU, Fort Worth, TX, (3)Baylor Scott & White Heart & Vascular Hospital Fort Worth, Fort Worth, TX, (4)Baylor Simmons Transplant Institute, Dallas, TX

Background: The specific hemodynamic effects and outcomes related to aortic stenosis (AS) in patients with cirrhosis and portal hypertension who undergo liver transplant (LT) surgery are not well known. Our aim was to investigate how severity of AS may alter intra-operative hemodynamics among liver transplant candidates during liver transplant surgery. **Methods:** We performed a case-control study using a retrospective cohort of consecutive patients with AS who underwent LT at the Baylor Simmons Transplant Institute between

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

2010 and 2019. All patients underwent echocardiography pre-operatively. Severity of AS was defined by ASE echocardiographic criteria. Cases were matched 2:1 to controls without AS who underwent LT. Propensity score matching of cases to controls was performed by baseline covariates: age, MELD-Na, and gender. Patients who underwent definitive treatment of AS preoperatively by transcatheter replacement (TAVR) were excluded from analysis. **Results:** Overall, 106 patients with AS who underwent LT were identified; 90 (84.9%) had mild, 14 (13.2%) had moderate, and 2 (1.9%) had severe AS. Pre-operative TAVR was performed in 6 patients, including the 2 with severe AS. Compared with mild AS (n = 89), patients with moderate AS (n = 11) had lower post-bypass central venous pressure (CVP) (4 vs 7.5 mmHg, $p = 0.05$) and higher post-reperfusion arterial diastolic pressure (ADP) (65 vs 47 mmHg, $p = 0.009$) and mean arterial pressure (MAP) (79.5 vs 68.5 mmHg, $p = 0.035$). Compared with controls (n = 200), patients with AS had higher cardiac output (CO) at baseline (8.1 vs 7 L/min, $p = 0.02$) and post-bypass (8.0 vs 6.1 L/min, $p = 0.003$), lower systemic vascular resistance (SVR) at baseline (523.5 vs. 695 dyn/s/cm^{-5}, $p = 0.001$) and post-bypass (651 vs. 850 dyn/s/cm^{-5}, $p = 0.03$), and lower ADP post-reperfusion (47.5 vs. 52 mmHg, $p = 0.05$). Among our cohort of patients selected for LT, no difference in overall or graft survival was observed between AS vs controls (Figure, p = NS). Likewise, severity of AS defined by mild vs moderate was not associated with differences in overall or graft survival (p = NS). **Conclusion:** Liver transplant candidates with AS may demonstrate variations in intra-operative hemodynamics according to presence and severity of AS. Those with moderate AS appear to manifest higher diastolic pressure post liver transplant, while hemodynamic changes vs controls likely reflect compensatory changes in systemic vasodilation related to AS and underlying portal hypertension. In contrast with mild AS, selected candidates with moderate/severe AS may require additional evaluation and management to ensure these hemodynamic changes do not impact overall or graft survival.

1069-A | EFFECT OF DESENSITIZATION PROTOCOL ACCORDING TO THE DEGREE OF AMR RISK IN LIVING DONOR LIVER TRANSPLANT; RETROSPECTIVE COHORT STUDY

Jiyoon Kim[1], Sooho Kim[1], Minseo Jung[1], Ju Hyun Park[1], Nam-Joon Yi[1], Jeong-Moo Lee[1], Su Young Hong[1], Suk Kyun Hong[1], Kwang-Woong Lee[1], Kyung-Suk Suh[2] and YoungRok Choi[3], (1)Seould National University Hospital, (2)Seoul National University, (3) Seoul National University Hospital

Background: Graft failure associated with donor specific antibody (DSA) is rare but consistent in living donor liver transplant (LDLT). This study aims to analyze the outcomes of desensitization protocol according to the preoperative antibody mediate rejection (AMR) risk. **Methods:** We reviewed 998 cases of LDLT between January 1, 2012 and December 31, 2021 retrospectively. The desensitization treatment was protocolized for three different risk groups based on crossmatching(CDC), flow cytometry cross-matching (FCXM), and single antigen DSA test results: Rituximab + plasma pheresis for high risk (all positive), Rituximab only for intermediate risk (CBC-, FCXM+, DSA+), no treatment for low risk (only DSA+). The graft and patient survival of those retrospective cohort were analyzed. **Results:** From 640 ABO compatible cases there were 292(45.6%) and 348(54%) cases each before and after desensitization treatment was protocolized, with 2 (0.7%) and 4(1.1%) incidents of AMR respectively. From 69 cases with DSA test results, 20(29.0%) received Rituximab + plasma pheresis, 17(24.6%) received Rituximab only, and 32(46.4%) received no treatment. Number of cases in higher AMR risk group increased after protocol initiation($p = 10^{-8}$), while AMR risk did not show any significant difference($p = 0.69$). **Conclusion:** AMR incidence remaining relatively similar despite the significant increase in number of high-risk group recipients post protocol initiation, suggests that the desensitization treatment is effective. While we were not able to isolate the effects of treatments due to the limited number of patients with DSA test results, we were able to analyze various factors in relation to AMR. Studies including larger number of cases are needed to prove the necessity of desensitization protocol in clinical settings.

1070-A | EFFECTIVE USE OF VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY TO IDENTIFY DISTINCT CLINICAL PHENOTYPES OF LIVER TRANSPLANT RECIPIENTS WITH ADVANCED FIBROSIS AND NON-ALCOHOLIC FATTY LIVER DISEASE

Dempsey L Hughes[1], Mauricio Garcia Saenz de Sicilia[2], Andres Duarte-Rojo[3], Tamoore Arshad[4], Katie M Rude[2], Lyle Burdine[2], Richard T Spencer-Cole[2] and Mohammad S. Siddiqui[4], (1)Northwestern University, (2)University of Arkansas, (3)Northwestern University Feinberg Scho, (4)Virginia Commonwealth University

Background: Occurrence of nonalcoholic fatty liver disease (NAFLD) after liver transplantation (LT) is becoming increasingly common. While pre-LT NAFLD is associated with metabolic syndrome, the clinical phenotype of NAFLD and advanced fibrosis in LT recipients is not as well defined despite exposure to chronic immunosuppression placing these patients at higher metabolic risk. Vibration-controlled transient elastography (VCTE) has emerged as an effective, non-invasive method to determine presence of graft steatosis and fibrosis. We sought to determine if VCTE could distinguish clinical phenotypes of LT recipients with graft NAFLD and, moreover, compare NAFLD patients with advanced fibrosis (AF) to non-NAFLD patients with AF. **Methods:** LT recipients at two major LT centers underwent standard of care, fasting vibration controlled transient elastography (VCTE) between January 2015 and January 2022. Only patients with successful VCTE (10 valid readings with IQR/Median < 30%) were included. Patients with risk factors for inaccurate liver stiffness measurement (concurrent heart failure, hemodialysis-dependence, cholestatic hepatitis, chronic rejection) were excluded. Per previously established VCTE cut-off values, post-LT NAFLD was defined as CAP > 270 dB/m and advanced fibrosis was defined as > 10.5 kPa. **Results:** A total of 547 LT recipients completed VCTE. The median time from LT to VCTE was 28 months. NAFLD was present in 234 patients (43%), and advanced fibrosis was present in 94 patients (17%). The most common etiology of cirrhosis in the post-LT NAFLD group was NASH (32%) compared to alcohol (30%) in the non-NAFLD group. The overall burden of metabolic co-morbidities was significantly high and was even higher among patients with post-LT NAFLD (Figure 1A). No significant biochemical differences in NAFLD vs. non-NAFLD were noted except for higher triglycerides in the NAFLD group (189 ± 144 vs 132 ± 68, $p < 0.001$). The prevalence of metabolic comorbidities such as coronary artery disease, diabetes and obesity increased even further among patients with NAFLD and AF when compared to non-NAFLD AF (Figure 1B). **Conclusion:** VCTE is capable of identifying distinct clinical phenotypes of LT recipients with NAFLD and advanced fibrosis, and the present study provides novel data linking occurrence of post-LT NAFLD to higher metabolic disease burden. Moreover, progression to advanced hepatic fibrosis leads to further deterioration in metabolic health. These clinical phenotypes (Figure 1) should allow for better risk stratification and mitigation strategies in LT recipients to optimize outcomes. Further study is needed to confirm impact of at-risk clinical phenotypes on post-LT graft and patient outcomes. Mechanistic studies are also required to better understand the development of these distinct clinical phenotypes despite similar immunosuppression exposure.

1071-A | END-OF-LIFE CARE FOR PATIENTS WITH END-STAGE LIVER DISEASE REMOVED FROM THE LIVER TRANSPLANT WAIT LIST

Danny Belza[1], Dhruval Amin[1], Anne Foley[1], Peter Lazar[2], Hye Sung Min[2], Neil Marya[2] and Navine Nasser-Ghodsi[2], (1)University of Massachusetts Memorial Health Care, (2)UMass Chan Medical School

Background: Patients with end-stage liver disease (ESLD) who are not candidates for liver transplantation (LT) are at high risk of short-term mortality and infrequent or late involvement of palliative care (PC). The aim of this study is to characterize end-of-life care for patients removed from the LT waitlist. **Methods:** We performed a retrospective review of patients at our institution who had been listed for LT and removed from the waitlist because of medical or psychosocial contraindications between 2017 and 2022. **Results:** A total of 158 patients were included, with 19 patients alive at the end of the study period. The mean age was 57.3 ± 10.4 years with most patients being male (66%), White (91%), and having alcohol-related liver disease (53%). The mean biologic Model for End Stage Liver Disease-Sodium when patients were listed for LT was 17.8 ± 8.9, compared to 26.8 ± 11.7 at delisting ($p < 0.001$). The most common reason for delisting was sepsis (45%). Of the patients who died, 73% died in the hospital, 18% with hospice, 9% at home without services, and 1% at a skilled rehabilitation facility. Of the study patients, 70% were admitted to the intensive care unit during their terminal hospitalization or after delisting, with 49% mechanically ventilated, 47% having an enteral access device placed, and 41% being initiated on renal replacement therapy. A PC consult was performed for only 16% of patients, primarily when patients were hospitalized. The mean days from delisting to death was 147.4 ± 205.7 for patients with a PC consult and 59.6 ± 205.7 for patients without a PC consult. Patients with a PC consult had a statistically significant survival benefit up to 1 month ($p = 0.02$), but statistical significance did not persist over the entire study period ($p = 0.10$) (Figure 1A-D). Out of the 101 patients who died in the hospital, 93% were delisted and died on the same day and 89% were delisted and died during the same hospitalization. **Conclusion:** Patients with ESLD who are ultimately removed from the LT wait list are frequently delisted right before death, often in the setting of septic shock and intensive medical interventions without PC involvement. This likely reflects a culture of PC interventions starting when disease directed therapy ends and may delay recognition of when a patient is irreversibly too sick for transplant. This study will inform our future work to explore which patients on the LT wait list who are admitted to the hospital are at high risk of delisting and death and may benefit from early PC consultation. Figure 1A-D. Kaplan-Meier estimates demonstrating survival of study patients. Panel A reflects overall study survival for the entire study cohort during the study period. Panels B-D demonstrate survival for patients with or without a palliative care consultation at 30 days (B), 365 days (C), and at the end of the study period (D).

1072-A | EVALUATION OF THE EFFECT OF THE COVID-19 PANDEMIC ON THE RATE OF CLOSTRIDIUM DIFFICILE INFECTION FOLLOWING LIVER TRANSPLANTATION

Ahmed Mostafa Ibrahim[1], Ammad Javaid Chaudhary[1], Hope Baldwin[2], Arif Sarowar[2], Muhammad Zarrar Khan[3] and Syed-Mohammed Jafri[4], (1)Henry Ford Hospital, (2)Wayne State University School of Medicine, (3)Henry Ford Hospital, Detroit, MI, (4)Henry Ford Health System

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Of the multiple infections that liver transplant (LT) patients are vulnerable to, Clostridium difficile infection (CDI) is among the few that are potentially life-threatening. The incidence of CDI in this population generally ranges from 3-9%, with reports of rates as high as 30% in the literature. Risk of CDI is particularly high during the first year post-transplant when high-intensity immunosuppressive regimens are used in order to prevent transplant rejection. Despite this, information regarding factors affecting CDI occurrence in LT specifically is limited. Thus, this study aims to investigate the rate of CDI within 1 year of LT and assess for factors affecting these rates. We also intend to compare outcomes in LT occurring prior to and during the COVID-19 pandemic to evaluate for differences in the setting of heightened attention to hygiene associated with the pandemic. **Methods:** Adults (>18 y old) who underwent LT within our health system between January 2018 and December 2021 were included in our study. Demographic (age, race, gender) and transplant-related data (transplant indication, MELD at transplant, rejection episodes) was compared between patients with and without CDI occurrence within the first year of LT. Furthermore, patients were divided into pre-COVID and COVID groups (transplants occurring in 2018 and 2020, respectively) to assess for a relationship between CDI occurrence and timing of LT with respect to the COVID pandemic. **Results:** Of the 365 LT patients included, 30 (8.2%) had a CDI event. The mean age for those with CDI was 58.73 $\pm$ 9.16 years and 17 cases (56.6%) were men. Of the 30 patients who had CDI, 13 (43.3%) had a rejection episode within 12 months of transplant. There was no statistically significant difference in terms of demographics, mean MELD score, or indication for transplant between patients with and without CDI. However, mortality rate was significantly higher in patients with CDI within 1 year of transplant compared to those without CDI (26.7% vs 12.8%, $p=0.031$). Regarding outcomes in relation to the COVID pandemic, 9 of 81 (11.1%) patients in the pre-COVID group had CDI compared to 4 of 95 (4.2%) in the COVID group, although the difference did not reach statistical significance ($p=0.081$). Furthermore, mortality within 1 year of transplant was higher in patients with CDI in the pre-COVID group compared to those with CDI in the COVID group (3/9 vs 0/4). **Conclusion:** Our results show a significantly higher mortality rate in patients with CDI compared to those without, underlining the devastating nature of this infection, particularly in the LT population. We also saw that a large portion of patients with CDI had at least one rejection episode within 12 months of transplant. Finally, there was a marked reduction in the occurrence of CDI within the first year following LT during the COVID era, possibly owing to the intensification of hygiene practices during this time period.

1073-A | EVUSHELD IN LIVER AND KIDNEY TRANSPLANT PATIENTS – WAS IT WORTH IT?

Ammad Javaid Chaudhary[1], Hamna Fahad[1], Momin Samad[2], Sheema Rehman[2], Hope Baldwin[3], Ashley Francis[4], Fariba Rana[4], Yervant Ichkhanian[2], Diana Jomaa[5], Kartik Gupta[2] and Syed-Mohammed Jafri[6], (1) Henry Ford Hospital, Detroit, (2)Henry Ford Hospital, (3) Wayne State University School of Medicine, (4)Wayne State University, (5)Henry Ford Hospital, Detroit, Dearborn, MI, (6)Henry Ford Health System

Background: Immunosuppression in patients with solid organ transplant has raised significant concerns regarding outcomes of COVID-19 infection. Pre-exposure use of monoclonal antibodies, specific to certain viral strains as an adjunct to vaccination has been proposed to enhance the immune response following the vaccine. In this study, we aimed to assess the efficacy of the emergency use of Evusheld in this sub-population. **Methods:** This was a retrospective chart review study conducted at a tertiary care center during the time period of 2022 – 2023 during which adult patients (age >18 y old) with liver, kidney or simultaneous Liver-Kidney transplant who received Evusheld were included. Patients' demographics, disease characteristics, and outcomes were recorded in de-identified datasheets. The primary outcome was incidence of COVID-19 positive PCR test. Secondary outcomes included: progression to Interstitial lung disease (ILD),

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

rate of hospitalization. The Wilcoxon rank sum test, Pearson's Chi-squared test, Fisher's exact test and Wilcoxon rank sum exact test were used for univariate analyses. **Results:** Among 1149 who received solid organ transplant, 273 (23.7%) patients were diagnosed with COVID-19 from the advent of the pandemic, to February 2023. Patients infected with COVID-19 were more likely to be younger (mean age 61.6 ±10.9 y versus 63.4 ± 11.5 y, $p = 0.007$), of white race (25.6% versus black 15.2 % and others 14.7 %, $p = 0.014$). In the total population 26% (296) received Evusheld. Among those who received Evusheld the incidence of covid was 13% (37/296) compared to 28% (236/853) in the patients who did not receive the Evusheld, $p < 0.01$. Data for post covid ILD was available in only 43.7% (118) patients. Among those with data available, prevalence of post covid ILD was 0%(0/22) and 8.1% (8/96) among those who did and did not receive evusheld respectively, *p*-value 0.045. Among those with data available, 16.1% (5/31) patients were hospitalized after getting Evusheld as compared to 20.7% (46/176) in patients who did not receive evusheld, $p = 0.689$. **Conclusion:** Our data shows that Evusheild may have reduced incidence of COVID-19 and provided significant protection against post infectious ILD. It also showed that incidence of COVID-19 in post-transplant patients may be much higher than previously reported. Currently, the FDA has halted all use of Evusheild due to the combined frequency of non-susceptible SARS-CoV-2 variants nationally being more than 90%. However, they do recommend keeping the unexpired batches safe for future, in case new variants show susceptibility.

1074-A | EXPOSURE TO GLP1RA THERAPY IS ASSOCIATED WITH IMPROVED SURVIVAL IN POST LIVER TRANSPLANT PATIENTS WITH TYPE II DIABETES MELLITUS

Sudharshan Achalu[1], Rani Berry[2], Richie Manikat[2], Aaron Yeoh[2], Saurabh Gombar[3], Sun H Kim[1], T.Tara Ghaziani[2], Deepti Dronamraju[2], Renumathy Dhanasekaran[2], Allison J. Kwong[1], Natalie J. Torok[1], Aparna Goel[1], W. Ray Kim[4] and Paul Yien Kwo[1], (1) Stanford University School of Medicine, (2)Stanford University - School of Medicine, (3)Atropos Health, (4) Stanford University

Background: Non-alcoholic steatohepatitis (NASH) related cirrhosis is the most rapidly rising indication for liver transplantation, with high prevalence of both recurrent and de novo metabolic syndrome complications post-transplant. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have shown promise in improving cardiovascular and renal outcomes for liver transplant recipients with type 2 diabetes. Therefore, we aimed to investigate if post-transplant GLP-1RA exposure has an impact on a cohort of liver transplant recipients with type 2 diabetes. **Methods:** We conducted a retrospective review of patients who underwent orthotopic liver transplant at a single center between 2010 and 2022. Patients with a history of type 2 diabetes and at least 3 months of post-transplant GLP-1RA exposure were included in the cohort. Demographic data, along with clinical outcomes including cardiovascular events and mortality, were collected for analysis. The GLP-1RA cohort was compared to a cohort of post-transplant patients with type 2 diabetes that did not have exposure to GLP-1RA. Cohorts were compared unmatched, matched on basic demographics, and matched on high dimensionality propensity scores for survival. **Results:** We identified 43 individual's who received at least 3 months of GLP-1RA therapy post-transplant and compared with a group of 966 post-transplant individual's without GLP-1RA exposure. The mean age at the time of transplant was 55 years, with a mean follow-up duration of 4810 days. BMI [mean difference 3.4, 95% CI (-7.3,-0.59), $p = 0.01$] and weight [mean difference 11.35 lbs., 95% CI (-790,-92), $p = 0.01$] were higher in the GLP-1RA cohort after propensity matching

between the two groups. When assessing mortality rates, post-transplant GLP-1RA exposure was associated with significantly improved survival in both unadjusted [HR 0.34; 95% CI (0.13-0.92), $p = 0.03$] and propensity score matching analyses [HR 0.24; 95% CI (0.08-0.74), $p = 0.01$]. **Conclusion:** Our single-center study suggests that GLP-1RA exposure for a minimum of 3 months following liver transplantation is correlated with improved survival despite having higher BMI and weight. These results, if validated in other cohorts, would warrant further exploration in prospective trials to fully evaluate the potential benefits of post-transplant GLP-1RAs in liver transplant recipients with diabetes and other metabolic complications.

1075-A | GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS AND SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS EFFECT ON NEW ONSET POST-LIVER TRANSPLANT MAJOR ADVERSE CARDIOVASCULAR EVENTS

Kelli Kosako Yost, Qumber Ali, Megan B. Ghai, Majd Aboona, Paul Gomez, Pooja Rangan, Rohit Nathan, Mark Wong, Karn Wijarnpreecha, Moises Ilan Nevah Rubin, Michael Fallon and Ma Ai Thanda Han, University of Arizona College of Medicine Phoenix, Phoenix, AZ

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) and Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have gained popularity in recent years due to their cardiovascular benefits and weight loss potential in patients with type 2 diabetes mellitus. There is little data on these medications and their effect on MACE (major adverse cardiovascular events) in solid organ transplant populations. This study was done to assess the effect of a GLP-1 RA or SGLT2i on incidence of post-transplant MACE in post-liver or simultaneous post-liver kidney transplant (SLK) populations. **Methods:** A retrospective chart review was completed in a single hospital system reviewing any adult age ≥ 18-year-old with type 2 diabetes mellitus and either solitary liver or SLK from January 2012 to March 2022. GLP-1 RA or SGLT2i usage was determined, and demographic, clinical characteristics, and outcomes were compared between the two groups. The Mann-Whitney test and Fisher's exact or Chi-square test were used for continuous and categorical variables respectively and multivariate logistic regression was used to evaluate significant differences in outcomes between the two groups. Propensity score matched MACE free survival was explored. **Results:** Among 472 included patients, 32 patients received an GLP-1 RA or SGLT2i. After controlling for age at transplant, BMI at transplant, sex, hypertension, diabetes at listing, hyperlipidemia, chronic kidney disease, and tobacco use, the use of an SGLP-1 RA or GLT2i was associated with a significantly lower number of new onset post-liver transplant MACE (OR 0.24, CI 95% 0.070-0.85, $p = 0.027$). It was still significant after controlling for aspirin and statin use (OR 0.23, CI 95% 0.66-0.81, $p = 0.022$). Propensity score matched cumulative incidence of 5-year MACE free survival is shown in the figure. **Conclusion:** The use of a GLP-1 RA or SLGT2i in post-liver or post-liver kidney transplant populations was associated with a decreased number of new-onset post-liver transplant MACE after controlling for comorbidities, aspirin use, and statin use. The cumulative incidence of 5-year post-liver transplant MACE free survival was significantly higher in the GLP-1 RA and SGLT2i group after propensity score matching. These findings warrant further prospective studies to improve outcomes in this patient population.

1076-A | HEAD TRAUMA AS DONOR CAUSE OF DEATH IS ASSOCIATED WITH INCREASED GRAFT REJECTION AMONG LIVER TRANSPLANT RECIPIENTS

Ritwik Keshav, Sofia Fabrega, Pooja Rangan, Jonathan Lifshitz, Kelly Zucker, Raha Sadjadi, Rohit Nathan, Ma Ai Thanda Han, Karn Wijarnpreecha, Michael Fallon and Moises Ilan Nevah Rubin, University of Arizona College of Medicine Phoenix, Phoenix, AZ

Background: As the demand for liver transplantation grows, all potential transplantable livers must be considered for a match while considering a growing list of donor criteria. Human models of brain death (BD) and traumatic brain injury show pro-inflammatory cytokine production which can elicit a maladaptive hepatic response. This pro-inflammatory response may vary in quantity and quality, depending on the cause of BD. Here we describe the effects of head trauma as a donor cause of death (DCOD) on various recipient outcomes. **Methods:** Matched liver donor-recipient data from 2013-2021 were subsetted from the United Network for Organ Sharing database and hospital system records. Inclusion criteria were single organ, deceased donor liver transplants with recipients > = 18 years. Retransplanted patients and multi-organ transplants were excluded. Other DCOD that were not head trauma (HT), anoxia (AN), or cerebrovascular/stroke (CVS) were excluded (< 5%). Descriptive statistics and backwards, stepwise-multivariable regressions were performed for multiple demographic variables and outcomes, including mortality, rejection, graft failure, hospital/ICU length of stay, and post-operative complications. **Results:** Of the 603 matched donor-recipient records included: HT (n = 183); AN (n = 259); CVS (n = 161). Donors included 225 (37.3%) females and 162 (36.7%) donations after circulatory death. Donor comorbidities included hypertension (n = 217 [36.0%]), diabetes mellitus (n = 91 [15.0%]), and tobacco use > 20 pack years (n = 108 [17.9%]). Recipients included 226 females (37.5%) and BMI was grouped into lean (BMI < 25, n = 141 [23.4%]), and non-lean (BMI > = 25, n = 462 [76.6%]). Recipient liver disease etiology included alcoholic liver disease (n = 189 [31.3%]), Hepatitis C (n = 181 [30.0%]), NASH/NAFLD (n = 102 [16.9%]), autoimmune liver disease (n = 32 [5.3%]), and all other (n = 42 [7.0%]). HT was associated with significantly higher rates of graft rejection compared to AN and CVS respectively (22.8% vs 21.5% and 11.3%, $p = 0.025$). CVS had a significantly lower aOR (0.39, CI [0.19-0.77], $p = 0.007$) compared to HT. There were no significant group differences among DCOD for all other outcomes. **Conclusion:** The proinflammatory response from BD by HT may differ from other causes of BD, with various changes in MHC expression (and other receptors) in the allograft, which stimulate rejection. Our findings suggest that optimization of immunosuppression may be warranted depending on DCOD.

transplant centers. However, little information is available about the risk of viremia after HCV antibody-positive (Ab+) and nucleic acid testing negative (NAT-) donor liver transplants. **Methods:** We compared adult HCV- recipients of HCV Ab+/NAT- versus Ab- donor livers between 2016-2021 in the United States. We describe donor and recipient characteristics, HCV virologic outcomes at 6 and 12-month follow-up, and changes in utilization of HCV+ grafts by donor center over time. **Results:** 858 (3.0%) of 28,546 recipients received liver transplants from HCV Ab+/NAT- donors between 2016-2021. 761 (88.7%) recipients of HCV Ab + livers presented for evaluation after 6-months, only 11 of whom (1.4%) had HCV viremia. At 12-month follow-up, 602 (79.2%) recipients of HCV Ab+ livers were evaluated, with only 2 NAT+ recipients (0.3%). Lorenz curves demonstrate greater inequity between center-level utilization of HCV Ab+ vs. Ab- grafts (Gini coefficient = 0.43 for Ab+ vs. 0.33 for Ab-), however, center-level differences in utilization of Ab+ grafts have become less pronounced over time (Gini coefficient = 0.81 in 2016 vs. 0.48 in 2021). **Conclusion:** We report a national study of adult HCV nonviremic liver transplant recipients from HCV Ab+/NAT- donors with a HCV viremia rate of < 2%, and center-level inequities in HCV + graft utilization that improved over time. Our results demonstrate that HCV+ grafts should be utilized more aggressively, particularly at low utilizing centers across the country.

1078-A | HIGHER INTRA-OPERATIVE PEAK LACTATE VALUE MAY BE ASSOCIATED WITH PROLONGED HEMODIALYSIS REQUIREMENT AFTER LIVER TRANSPLANT ALONE IN PATIENTS WITH PRE-TRANSPLANT KIDNEY DYSFUNCTION

Katsunori Miyake, Saleh Al-Juburi, Kathleen Young, Lucy Ching Chau, Toshihiro Kitajima, Nikuwa Wickramaratne, Ahmed Nassar, Atsushi Yoshida, Dilip Moonka, Deepak Venkat, Marwan S. Abouljoud and Shunji Nagai, Henry Ford Hospital

Background: Liver transplant alone (LTA) patients with kidney dysfunction might require intraoperative CVVH which potentially leads to prolonged post-transplant hemodialysis requirement. While pre-transplant kidney function is a well-known factor associated with the likelihood of kidney function recovery after transplant, possible association with intraoperative factors was not well studied. Intra-operative lactate could be a good surrogate marker reflecting the surgical stress such as significant blood loss, prolonged ischemia time, and marginal liver graft function. This study aimed to investigate a possible association between intra-operative peak lactate value and prolonged post-LTA hemodialysis requirement. **Methods:** Medical charts of all liver transplant patients from August 2017 to December 2022 were retrospectively reviewed. LTA patients who required intraoperative CVVH due to kidney dysfunction were eligible for this study. The association between the intra-operative peak lactate value and the requirement of hemodialysis over 30 days post-LTA was evaluated. The median intra-operative peak lactate value of the patient population (4.5mmol/L) was used as a cut-off value to dichotomize patients (low lactate group: 4.5mmol/L <, high lactate group: > = 4.5mmol/L). **Results:** Among 548 liver transplant recipients during the study period, 433 underwent LTA, of whom 46 required intraoperative CVVH. Of these 46, 7 had a history of diabetes (15.2%) and 7 required hemodialysis before transplant (15.2%). After LTA, 11 required hemodialysis over 30 days (23.9%) (prolonged post-LTA hemodialysis requirement). In univariable logistic regression analysis, the risk of prolonged post-LTA hemodialysis was significantly higher in the high lactate group, compared to the low lactate group (OR: 5.34, 95%CI: 1.01-28.4, $p = 0.049$). History of diabetes and requirement of hemodialysis before LTA was also associated with prolonged hemodialysis requirement after LTA (OR: 6.10, 95% CI: 1.11-33.6, $p = 0.038$ and OR: 6.10, 95%CI: 1.11-33.6, $p = 0.038$, respectively). In multivariable analysis, the high lactate group was considered to be an

independent risk factor for prolonged post-LTA HD (OR: 13.8, 95%CI: 1.28-148.0, $p = 0.031$). **Conclusion:** Higher intra-operative peak lactate value significantly increases the risk of hemodialysis requirement over 30 days post-LTA. Intraoperative surgical stress may affect kidney function recovery and lactate values can be a good predictive marker.

Risk factor for prolonged hemodialysis over 30 days after liver transplant alone in patients with intraoperative CVVH

variables	OR	95%CI	P value
intra-operative peak lactate >=4.5mmol/L	5.34	1.01-28.4	0.049
Requirement of dialysis before transplant	6.10	1.11-33.6	0.038
History of diabetes	6.10	1.11-33.6	0.038

*Logistic regression analysis
Abbreviation: CVVH, continuous veno-venous hemodialysis

1079-A | HIGHER PLATELETS LEVELS IN POSTOPERATIVE ORTHOTOPIC LIVER TRANSPLANT PATIENTS ASSOCIATED WITH HIGHER RATES OF COMPLICATIONS

Emily E Currier[1], Arif Sarowar[1] and Syed-Mohammed Jafri[2], (1)Wayne State University, (2)Henry Ford Health System

Background: Prior research into the relationship between liver transplant outcomes and platelet levels is limited, but research has shown that peri-operative thrombocytopenia is linked to decreased outcomes and thrombocytopenia on postoperative day 5 have been linked to higher 90-day mortality. However, there is little known about the effect of immediate postoperative thrombocytopenia on long-term morbidity and mortality. The aim of this research was to investigate the relationship between platelet levels immediately post-transplant and one-year postoperative morbidity, including re-hospitalization, rejection, surgical complications, and graft failure, and mortality. **Methods:** A retrospective chart review was conducted at a diverse, urban transplant center and included 828 adults who underwent orthotopic liver transplant between 2012 and 2022. Data from medical charts including platelet levels, postoperative and surgical complications, platelet infusion history, acute and chronic rejection, graft failure, and death from time of transplant one-year postoperatively was recorded and analyzed. Immediate postoperative platelets levels were defined as platelets levels available closest to transplant surgery end time. To analyze postoperative survival, participants were separated into cohorts based on immediate postop platelet levels (uL): < 60,000, 61-90,000, 91-130,000, and > 130,000. **Results:** Average preoperative platelets levels were 99,000 uL (SD = 62,000) and average postoperative levels were 77,000 uL (SD = 50,000). Average time from surgery end to measurement of immediate postoperative platelet levels was 37.5 minutes. Contrary to data published thus far, this study showed that higher immediate post-operative platelet levels were found to be associated with a higher chance of readmission ($p = 0.046$) and acute rejection ($p = 0.007$). In fact, for every one unit increase in platelets, there was a 0.2% increased risk of readmission and 0.5% increased risk of acute rejection. Overall survival rate was found to be 82.8% and there was no significant difference found between post-op platelet levels and survival rates at one-year ($p = 0.628$). Furthermore, no significant difference was found between postoperative levels and chronic rejection, surgical complications, and graft failure at one year postoperatively. **Conclusion:** Overall, this study shows that post-operative thrombocytopenia might not be as detrimental to long-term outcomes as previously thought and shows that increased platelets may pose a slight increased risk of complications.

f 1080-A | HOME-BASED LIVER FRAILTY INTERVENTION (LIFT) IS FEASIBLE AND DECREASES FRAILTY IN LIVER TRANSPLANT CANDIDATES

Avesh J. Thuluvath, Praneet Polineni, Sheila Morrissey, Kimberly Belfanti, Mohammad Nizamuddin, Osama Siddiqui, Amna Daud, Dinee Simpson, Josh Levitsky, Ann-Marie Flores, Andres Duarte-Rojo and Daniela P. Ladner, Northwestern University Feinberg School of Medicine

Background: Frailty is prevalent in liver transplant (LT) candidates and is associated with increased waitlist and post- transplant mortality and increased frequency of hospitalizations. Currently, logistically feasible and scalable interventions to decrease frailty prior to LT are lacking. In this pilot study, we tested the feasibility and effectiveness of a novel home-based

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

"LIver FrailTy" (LIFT) intervention in LT candidates. **Methods**: Adult, English-speaking patients undergoing LT evaluation at a large transplant center were prospectively enrolled in the LIFT intervention from 10/2020-12/2021. The LIFT intervention consisted of a baseline physical therapy (PT) evaluation (including measurement of the Liver Frailty Index [LFI] and 4-Meter Gait Speed [4MGS]), an individualized home exercise prescription, exercise tracking using a smart phone application, home exercise equipment, reminders to exercise and remote LFI assessments via home dynamometer. Primary outcomes were feasibility (assessed via patient feedback and retention rate, accuracy and ease of remote LFI measurement), adherence to the exercise regimen (classified as adherent, partially adherent or non-adherent if patients attempted e 75%, 50-75% or < 50% of exercises respectively), change in frailty (from baseline to last frailty assessment) and hospitalization rate. **Results**: 54 LT candidates were enrolled in the study. The mean age was 57.2 (± 9.9) years, 59% were male and the mean MELD-Na was 16.0 (± 5.8), with 70% being decompensated (Table 1). All patients remained enrolled at 1 month and 82% at 3 months. The mean follow-up time was 259 (± 200) days. 60% of eligible patients underwent e 1 remote LFI measurement and exercise prescriptions were adjusted at least once on average based on remote frailty assessment. 31% of patients were adherent to prescribed exercises, while 38% were partially adherent and 31% non-adherent. 82.5% of subjects found the smartphone application easy to use and 90% agreed that the provided equipment helped them exercise. The mean change in LFI was -0.15 (3.63 vs 3.48, $p = 0.05$) and mean change in 4MGS was 0.51 meters/sec (3.59 vs 4.10, $p = 0.05$). The mean time between baseline and final frailty assessments was 216.4 (± 157.2) days. 23 patients were transplanted and 5 patients died during the follow up period. On Poisson regression analysis, change in LFI was not predictive of hospitalization rate, LT or death. However, a higher baseline LFI was associated with an increased hospitalization rate. **Conclusion**: LIFT is a feasible and effective intervention to decrease frailty in LT candidates, but is limited by suboptimal adherence. Future LIFT modifications will target improving patient adherence in order to optimize clinical outcomes.

1081-A | HOSPITAL-RELATED OUTCOMES OF LIVER TRANSPLANTATION IN PATIENTS WITH AUTO-IMMUNE HEPATITIS: A NATIONWIDE ANALYSIS

Ahmad Khan[1], Khadija Naseem[2], Abdullah Sohail[3], Ammad Javaid Chaudhary[4], Emad Mansoor[5] and Seth Nathan Sclair[5], (1)Case Western Reserve University, (2)Cleveland Clinic Foundation, (3)University of Iowa, (4)Henry Ford Hospital, Detroit, (5)University Hospitals

Background: Autoimmune hepatitis (AIH) represents around 5% of liver transplants in the United States and approximately 2%-3% in Europe. Patients with AIH are typically prescribed long-term corticosteroids and immunosuppressants, which increase their vulnerability to surgical and infectious complications during the early post-transplant period of liver transplantation (LT). There is limited knowledge regarding the hospital-related outcomes for AIH patients undergoing liver transplantation. Our objective was to conduct a comprehensive nationwide analysis to examine the hospital-related outcomes in AIH patients who undergo liver transplantation. **Methods:** We conducted a search in the National Inpatient Sample (NIS) and National Readmission Database (NRD) databases to identify adult AIH patients who underwent LT between 2016 and 2020, using the diagnoses and procedural codes specified in the International Classification of Diseases 10th Revision (ICD-10). Our primary outcomes focused on various measures, including inpatient mortality, all-cause 30-day readmissions, the need for mechanical ventilation, utilization of intensive care unit (ICU) services, and the occurrence of post-operative complications such as biliary leak, sepsis, shock, wound disruption, infection, hepatic artery thrombosis, and tracheostomy requirement. Secondary outcomes encompassed resource utilization parameters, such as the mean length of hospital stay (LOS) and total charges incurred during hospitalization. **Results:** A total of 75,580 adult patients underwent LT between 2016 and 2020 and out of them 2385 had a diagnosis of AIH (3.24%). Patients in the AIH group were younger with mean age 48.67 vs. 58.4 years and mostly females 71.49% vs. 28.51%). A total of 35 (1.46%) patients didn't survive the index hospitalization. All-cause 30-day readmission after the LT was recorded as 12.90% with most common reasons for readmissions included fever (R50.9), diarrhea (R19.7), acute kidney injury (N17.9), pleural effusions (J90)and unspecified liver transplant dysfunction, failure and rejection(T86.49). As regards to, post-operative complications, the incidence of post-surgical complications in AIH patients were not higher as compared to other LT patients. However, patients in the AIH group had a higher LOS (14.85 vs. 12.59, p-value: < 0.001) and hospitalization charges ($389,238 vs. $306,536, p-value: < 0.001). **Conclusion:** We found that AIH patients had significantly lower inpatient mortality in the index hospitalization of LT; however, they had increased LOS and mean hospitalization charges. Moreover, despite their immunocompromised status, these patients aren't at increased risk of post-surgical complications.

1082-A | HOW STATIN USE IN LIVER TRANSPLANT RECIPIENTS IMPACTS RISK OF POST-TRANSPLANT MAJOR ADVERSE CARDIAC EVENTS AND MORTALITY

Megan B. Ghai, Kelli Kosako Yost, Pooja Rangan, Rohit Nathan, Mark Wong, Karn Wijarnpreecha, Moises Ilan Nevah Rubin, Michael Fallon and Ma Ai Thanda Han, University of Arizona College of Medicine Phoenix, Phoenix, AZ

Background: The Atherosclerotic Cardiovascular Disease (ASCVD) risk score guides the initiation of statins in adults 40 years and older. Liver transplant recipients (LTRs) are at risk of developing coronary artery disease, with a prevalence of 55.3% 5-years post-transplant. Yet, only 23-41% of LTRs that qualify for a statin are prescribed one. Here we aim to evaluate statin utilization and its impact on major adverse cardiovascular events (MACE) and mortality among LTRs. **Methods:** A retrospective analysis of adult LTRs at a single-center from January 2013 to March 2022 was performed. Patients that qualified for a statin for primary or secondary prevention of ASCVD based on the American College of Cardiology guidelines were identified. Those who had been prescribed a statin within 18 months of transplant were compared with those who had not. Descriptive statistics, including patient demographics and comorbidities were produced. New-onset MACE and mortality after 18 months of transplant were calculated. Chi-squared and Fisher's exact tests and Wilcoxon Rank Sum tests were used to assess categorical and continuous variables, respectively. Multivariate logistic regression was used to evaluate the association of statin use with mortality, adjusting for post-transplant MACE and comorbidities of ASCVD, including sex, age, body mass index, smoking, diabetes, hypertension, and hyperlipidemia. **Results:** Included were 258 LTRs ages 40-75 years, of whom 136 (52.7%) were not prescribed a statin and 122 (47.3%) were prescribed a statin (Table 1). There were no significant demographic differences between the two populations. Among the comorbidities assessed, hyperlipidemia was significantly increased among the group taking a statin (no statin = 41.9%, statin = 89.3%, $p < 0.001$). New-onset MACE events did not vary significantly between the two groups (no statin = 15.4%, statin = 18.0%, $p = 0.58$). However, mortality was lower in those prescribed a statin (no statin = 22.8%, statin = 9.8%, $p = 0.005$). The adjusted odds of death in LTRs taking a statin were significantly less than those not taking a statin (aOR = 0.21, 95% CI [0.08, 0.54], $p < 0.001$). **Conclusion:** We have shown that guideline-directed statin initiation is occurring in less than 50% of LTRs. Further, we showed that mortality is reduced among LTRs prescribed a statin, though MACE were not. This indicates that statins have a protective effect in LTRs separate from that of reducing MACE. Increased adherence to guideline-directed statin initiation among LTRs should be pursued to improve mortality.

Table 1: Descriptive Statistics and Outcomes

		Liver Transplant Recipients Not Prescribed a Statin	Liver Transplant Recipients Prescribed a Statin	P - value
Liver Transplant Recipients in which Statins are Indicated, n(%)		136 (52.7)	122 (47.3)	
Patient Characteristics				
Sex, n(%)				p = 0.68

1083-A | IDENTIFYING RISK FACTORS FOR POSTOPERATIVE DELIRIUM IN LIVER TRANSPLANT RECIPIENTS

Erica Roman[1], David Salerno[2], Mia Genovese[1], Arun Jesudian[3], Benjamin Samstein[4] and Danielle Brandman[5], (1)New York Presbyterian Medical Center, Weill-Cornell, (2)New York Presbyterian Weill Cornell Medical Center, (3)Weill Cornell Medicine, NY, (4) Newyork-Presbyterian/Weill Cornell Medical Center, (5) Weill Cornell Medical College, New York, NY

Background: Postoperative delirium in liver transplant recipients (LTR) is a common complication that can lead to increased length of stay (LOS) and emotional distress for both patients and caregivers. The purpose

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of this study was to identify the incidence and risk factors for delirium in the early post-liver transplant period. **Methods:** This was a retrospective chart review of all adult LTR who received a transplant between 1/2022 and 4/2023. In June 2022, an Enhanced Recovery After Surgery (ERAS) protocol was reviewed and implemented with all multidisciplinary team members. Elements of the protocol included reduced dose of intraoperative corticosteroids, subsequent steroid doses administered every morning instead of BID, end of case intraoperative extubation when clinically feasible, multimodal analgesia, early removal of surgical drains, implementation of dietary and physical therapy plans and education for multidisciplinary providers and patients about expected LOS. Patients were identified as having delirium via chart review and adjudication from two independent reviewers. The primary outcome was the incidence of delirium. Variables associated with delirium were assessed using logistic regression. **Results:** A total of 76 LTR were included in this analysis. The median age was 56 years (interquartile range 25-75%, 48-65), the majority of patients were male (63%), and etiology of end stage liver disease was similar between groups with the most common being NASH (24%) and alcohol-associated cirrhosis (24%). Median MELD at transplantation was 17 (11–26). The incidence of delirium was 11 (14.5%). Patients with delirium, more frequently experienced prolonged intubation greater than 48 hours (45.5% versus 3.1%; $p < 0.001$) and had longer ICU length of stay (median 4 d [IQR 25-75, 3-7] versus 3 d [IQR 25-75, 2-4]; $p = 0.022$). In patients receiving methylprednisolone 500 or 1000 mg, the incidence of delirium was 7 (16.3%) versus 4 (12.1%) in those receiving methylprednisolone 250 mg ($p = 0.747$) In multivariable regression, independent factors associated with delirium were prolonged intubation for longer than 48 hours (adjusted odds ratio 102, 95% CI [7-1495]) and previous history of psychiatric illness (aOR 10, 95% CI [1.1-94.6]). The overall post-transplant LOS was 15 (12-29) vs 11 (9-18) days in patients with vs without delirium ($p = 0.027$). Patients with and without delirium had similar rates of rejection within 90 days of liver transplant ($p = 0.225$). **Conclusion:** Prolonged intubation, previous psychiatric history and longer ICU LOS were associated with delirium during the index hospitalization following liver transplantation. Early extubation post-transplant may reduce the risk of delirium, and further studies are needed to identify what other interventions help to reduce delirium in this patient population.

1084-A | IMPACT OF PHOSPHATIDYLETHANOL IN SURVEILLANCE FOR ALCOHOL USE IN POST-LIVER TRANSPLANT POPULATION.

Sergio Anthony De La Torre Jr., Brittney Ibrahim, Kabir Rahal, Katherine Meneses, Jasleen Singh, Gina Choi, Steven-Huy B. Han, Sammy Saab and Akshay Shetty, University of California, Los Angeles

Background: Alcohol-related liver disease (ALD) is the leading indication for liver transplantation in the United States, and over the last decade there has been a slow rise in the percentage of ALD patients representing the post-liver transplant (OLT) population. Therefore, there has been growing demand for improved surveillance protocols for the post-OLT patients. Phosphatidylethanol (PEth), a direct alcohol biomarker, is increasingly being utilized as a marker for alcohol use and was introduced at our institution in 2019 as part of the surveillance protocol. The aim of this study is to describe the impact of PEth in surveillance for alcohol use after liver transplant. **Methods:** Here, we conducted a single-center retrospective study to assess the impact of the introduction of PEth for surveillance of alcohol use in addition to standard of care, which included interviewing patients along with assessing random serum ethanol levels. We reviewed the impact of PEth as a marker of detecting alcohol use and its correlation with negative health outcomes by comparing two cohorts of post-OLT patients who were transplanted for ALD between 2016-2018 (before the introduction of PEth), and 2019-2022 (after the introduction of PEth). **Results:** We reviewed 235 patients who were transplanted for ALD during this time period and 43 (18.3%) patients were noted to have at least one episode of alcohol relapse after their transplant. Patients with alcohol relapse were noted to have more frequent episodes of elevated liver function tests compared to non-relapsed patients (4.37 episodes vs 2.45 episodes respectively, $p < 0.001$). The number of hospitalizations was also noted to be elevated among relapsed vs non-relapsed patients, however this was not statistically significant (2.95 vs 2.60 respectively, $p = 0.332$). Relapse rates between the two time periods, before and after the introduction of PEth, were similar (17% vs 19%, $p = 0.613$), however detection of alcohol relapse was most commonly confirmed by PEth alone, which accounted for 75% of all relapses, closely followed by self-reporting (18.7%). No difference was noted in rates of graft rejection or mortality between the two groups, nor between patients who did or did not relapse.

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: Overall, PEth is an effective surveillance tool in the post-liver transplant population to monitor for alcohol relapse. Early detection of relapse can lead to opportunities for early intervention by providing patients resources and referring them to behavioral medicine so they may remain abstinent.

1085-A | IMPACT OF TACROLIMUS EXPOSURE ON CANCER-RELATED MORTALITY FOLLOWING LIVER TRANSPLANT

Jiawei Cui[1], Christopher L Coe[2], Adesola Oluwagbemiga Oje[1], Ashley Spann[1], Lei Fan[1], Alexandra Shingina[1], Martha Shrubsole[1], Kymberly Watt[3], Muhamed Baljevic[1] and Manhal Izzy[1], (1) Vanderbilt University Medical Center, (2)UCLA Health, (3)Mayo Clinic, Rochester, MN

Background: Calcineurin inhibitors (CNIs), notably tacrolimus, are the mainstay of immunosuppression post-liver transplant (LT). However, CNIs are associated with carcinogenesis and prior studies suggest an association between tacrolimus exposure and De novo malignancy (DNM). DNM carries a high risk of mortality for LT recipients (LTR). This study aims to assess the impact of tacrolimus exposure on cancer-related mortality in LTRs. **Methods:** We performed a retrospective records review of adult LT only recipients who underwent LT between 1/1/2009 to 12/31/2018 at a North American Center. LT recipients whose CNI was tacrolimus were included. Patients who developed cancer within 1st year post-LT and those who exposed to cyclosporine were excluded. Demographic and clinical data were collected. Tacrolimus trough levels for each individual were measured and mean, median, and area under the curve for various periods of time (1-90 d, 91-365 d, 1-365 d, 366-730 d, and 1-730 d) were calculated. **Results:** Of 732 patients who were included, 110 developed DNM after the 1st year post-LT. Forty patients developed solid organ malignancy, 4 developed hematologic malignancy, and 71 developed skin cancer (64 non-melanoma and 7 melanoma). There were 134 deaths of which 20 were cancer-related. On univariable analysis (Table 1), only smoking was associated with cancer-related mortality. For all-cause mortality, advancing age at LT and smoking were associated with increased risk while azathioprine was protective. On multivariable analysis controlling for age at LT, gender, smoking, and pre-LT diabetes, the degree of exposure to tacrolimus during the aforementioned time intervals was not associated with cancer-related or all-cause mortality. These results did not change when tacrolimus exposure was quantified via mean, median, or area under the curve. **Conclusion:** The current study findings suggest that increased tacrolimus exposure does not impact cancer-related mortality in liver transplant recipients. The results highlight the detriment of smoking in LTRs.

Table 1

Variables	Cancer-related mortality		All-cause mortality	
	HR (95% CI)	P	HR (95% CI)	P

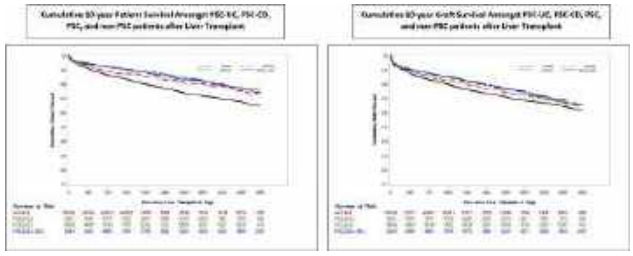
Lin[1], Jeffrey Lowell[2], Keith Sultan[1], Ramona Rajapakse[3], Arun Swaminath[1] and Sanjaya Kumar Satapathy[3], (1)Northshore University Hospital/Long Island Jewish Hospital, (2)Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, (3)Northwell Health, Forest Hills, NY

Background: Liver transplant (LT) is the only curative treatment for patients with primary sclerosing cholangitis (PSC) and end-stage liver disease. The concomitant presence of inflammatory bowel disease (IBD), such as Ulcerative Colitis (UC) and Crohn's disease (CD) is common in PSC, however there is limited data on LT mortality and graft outcomes in PSC with IBD. We aimed to analyze the impact of coexistent IBD on patient and graft survival after LT. **Methods:** We conducted a retrospective analysis using the United Network for Organ Sharing-Standard Transplant Analysis and Research (UNOS-STAR) database. We evaluated 112,955 patients transplanted from April 2002 to November 2022. We excluded patients < 18 years old, living donor liver transplants, split livers, non-heart beating donors, and dual transplants. Primary outcomes of interest were all-cause mortality and graft survival after LT assessed over a 10-year follow-up period. Patients with PSC were matched 1:1 with non-PSC patients based on gender, age at transplant, MELD score, and BMI. PSC patients were grouped into PSC-No IBD, PSC-CD and PSC-UC. The association between the groups and all-cause mortality and graft survival after LT was assessed using both univariate and multivariate Cox proportional regression analysis with hazards ratio and its 95% confidence interval. *p* values were two-sided and reported as significant at < 0.05. All analyses were conducted using SAS 9.4 (SAS, Cary, NC). **Results:** After exclusion, there were 7168 patients, with 3570 in the control group and 3598 in the PSC group (550 with CD, 1804 with UC, 1244 without IBD). Kaplan-Meier survival analysis showed PSC-UC have significantly better patient survival, followed by PSC-No IBD, and then PSC-CD compared to the matched control group ($p < 0.0001$). PSC subjects have significantly better graft survival compared to the control group ($p < 0.0001$). Cox proportional hazard model analysis revealed IBD subjects have a significantly decreased risk of all-cause mortality compared to the control subjects [OR 0.650, 95% CI (0.583-0.725 $p < 0.0001$] after controlling for confounders such as diabetes, age, ventilatory support status, serum albumin, and long cold ischemia time (CIT). The cause of death did not differ significantly between the PSC and control groups. **Conclusion:** Our study finds patients with PSC-IBD have significantly improved mortality and graft survival compared to non-PSC patients, with PSC-UC having lowest mortality. This may be related to immunosuppressive medication usage, duration of disease, and pathophysiology of IBD. These findings will help inform clinical decision-making and counseling for PSC-IBD patients who are considering LT. Further investigation is needed to explore causality of this connection.



Disclosures: The following people have nothing to disclose: Maham Ghani, Salima Makhani, Ethan Berman, Alexa Giammarino, Justin Lin, Jeffrey Lowell, Sanjaya Kumar Satapathy

1087-A | INCIDENCE AND RISK FACTORS OF GRAFT-VERSUS-HOST DISEASE AFTER LIVER TRANSPLANTATION: A NATIONAL STUDY 2010-2020

Yuting Huang[1], Yichen Wang[2] and Liu Yang[1], (1)Mayo Clinic Florida, Ponte Vedra Beach, FL, (2)Trinity Health of New England

Background: Graft-versus-host disease (GVHD) is a common complication of hematopoietic cell transplantation, and incidence is low in liver transplantation (LT). Estimating the incidence of GVHD after LT is challenging due to the paucity of available data collected by the United Network for Organ Sharing. Current GVHD incidence estimates are derived from single institutional studies and range from 0.1% to 2% but the national incidence of GVHD post LT is unknown. **Methods:** This retrospective cohort study used the National Readmission Database (NRD) to calculate the incidence rate of GVHD after LT within 1 year using survival analysis. Variables were extracted from the NRD including age, gender, race, median household income, and primary expected payer. The comorbidity burden was quantified using the Elixhauser index.Predictors of GVHD after LT were identified using univariate and multivariate Cox regression analysis. In-hospital all-cause mortality rates were determined using discharge status in the NRD. **Results:** From 2010 to 2020, out of 88,433 LTs, there were 383 cases of GVHD within 1 year after LT. The incidence rate of GVHD within one year after LT was 1.0% (95% confidence interval [CI], 0.8% to 1.3%). We observed no statistically significant

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

change in the incidence rate trend of GVHD after LT from 2010 to 2020 (beta-coefficient, -0.07%; 95% CI, -0.17% to 0.04%; $p = 0.188$). The in-hospital and calendar-year all-cause mortality rates of GVHD hospitalization were 20.8% and 41.7%, respectively. In addition, 19.1% of patients who did not pass away on the index GVHD hospitalization received a palliative care consult within that calendar year. Interestingly, alcoholic liver disease was associated with a lower risk of GVHD (adjusted hazard ratio, 0.57; 95% CI, 0.36 to 0.91; $p = 0.018$), while a higher risk was found in index hospitalizations for LT with COVID-19 infection before LT. Hematological abnormalities were commonly observed during hospitalizations related to GVHD, with essential hypertension being the most prevalent comorbidity. **Conclusion**: Our study provides the first national estimates of the incidence and mortality rates of GVHD post-LT in the United States. Patients with alcoholic liver disease undergoing LT had a lower probability of developing GVHD post-transplant. COVID-19 infection before the LT was associated with an elevated risk of GVHD. The mortality rate associated with GVHD hospitalization was high, with over 40% of patients died and about additional 20% received palliative care consult within one calendar year. Our study provides valuable insights into the incidence, risk factors, and outcomes of GVHD post-LT in the United States, and underscores the importance of addressing modifiable risk factors that may contribute to GVHD after LT.

1088-A | INCIDENCE OF POST-TRANSPLANT DIABETES MELLITUS IN LIVER TRANSPLANT RECIPIENTS IS INFLUENCED BY OPTN REGION

Mohammad Qasim Khan, University of Western Ontario, Kymberly Watt, Mayo Clinic, Rochester, MN and Chloe Teasdale, Columbia University, New York, NY; City University of New York

Background: Post-transplant diabetes mellitus (PTDM) is associated with significant morbidity and mortality in liver transplant recipients (LTRs). We estimated and compared the incidence of PTDM across the Organ Procurement and Transplantation Network (OPTN) in the United States. **Methods:** The OPTN database was used to identify adult, primary, deceased donor, LTRs transplanted between January 1, 2007, and December 31, 2016, with no prior history of diabetes. We compared the characteristics of LTRs with and without PTDM using chi-square and t-tests. Kaplan Meier analyses were utilized to calculate the cumulative incidence of PTDM, stratified by OPTN Region. Multivariable Cox-proportional hazards regression analyses estimated the hazards of PTDM in each OPTN Region. **Results:** LTRs who developed PTDM were predominantly White (69.7%), males (69.0%) transplanted in Regions 3 (East and West South Central / South Atlantic) (21.6%), 2 (Middle Atlantic) (14.9%), 5 (Pacific / Mountain South) (11.6%) and 4 (West South Central) (8.6%), for either hepatitis C (23.5%) or hepatocellular carcinoma (23.3%). LTRs developing PTDM differed significantly from those without PTDM with respect to numerous sociodemographic factors: gender composition, ethnicity, education, insurance status, region of transplant, BMI at transplant, indication and donor age. Overall, the cumulative incidence of PTDM at 1-year, 3-years and 5-years post-transplant was 11.9%, 15.9% and 18.7%, respectively. A statistically significant difference in time to development of PTDM was observed between the OPTN regions. Region 3 had the highest cumulative incidence of PTDM at 1-year, 3-years, and 5-years post-transplant of 17.67% (95% CI: 16.73-18.61%), 21.45% (95% CI: 20.43-22.47%) and 23.61% (95% CI: 22.49-24.73%) respectively. This was followed by Region 2, with cumulative incidence of PTDM at 1-year, 3-years, and 5-years post-transplant of 14.47% (95% CI: 13.45-15.49%), 19.91% (95% CI: 18.73-21.09%), and 23.17% (95% CI: 21.84-24.5%), respectively. Region 1 (New England) had the lowest cumulative incidence of PTDM at 1-year, 3-years, and 5-years post-transplant of 7.33% (95% CI: 6.01-8.65%), 10.00% (95% CI: 8.47-11.53%), and 11.47% (95% CI: 9.64-13.30%), respectively. There were higher adjusted hazards ratios (aHR) of PTDM (relative to Region 1), in descending order, in LTRs transplanted in Regions 3, 2, 8, 9, 4, 7 and 10 (Table 1). **Conclusion:** Significant variability exists in the incidence of PTDM across OPTN regions with highest risk in Regions 3, 2 and 8. Centers in these Regions are encouraged to re-evaluate practice policies and design interventions aimed at mitigating risk.

1089-A | LIVER TRANSPLANT FAST TRACK: A MULTIDISCIPLINARY APPROACH TO REDUCING LENGTH OF STAY

Mia Genovese[1], David Salerno[2], Erica Roman[1], Arun Jesudian[3], Benjamin Samstein[4] and Danielle Brandman[5], (1)New York Presbyterian Medical Center, Weill-Cornell, (2)New York Presbyterian Weill Cornell Medical Center, (3)Weill Cornell Medicine, NY, (4) Newyork-Presbyterian/Weill Cornell Medical Center, (5) Weill Cornell Medical College, New York, NY

Background: Enhanced recovery after surgery protocols have been implemented in a variety of solid organ transplant programs. The purpose of our study was to evaluate the impact of a standardized protocol in liver transplant recipients (LTR) on length of stay (LOS) during the index hospitalization post-LT. **Methods:** This was a quality improvement study of all adult LTR who received a transplant between 1/2022 and 3/2023. Patients were stratified into pre- and post-implementation groups. A Fast Track protocol was reviewed and implemented by all multidisciplinary team members in June 2022. Elements of the protocol included reduced intraoperative corticosteroids (from methylprednisolone 1000 mg to 250 mg), conversion of steroid taper to be administered once daily instead of BID, optimal end of case intraoperative extubation, multimodal analgesia, early removal of surgical drains, implementation of dietary and physical therapy plans and education for multidisciplinary providers and patients about expected LOS. The primary outcome was post-LT LOS; secondary outcomes were ICU LOS, rejection at 60 days and readmission within 30 days of discharge. **Results:** A total of 75 LTR were included with 76 distinct episodes of transplant. There were no significant differences in baseline characteristics between groups. The median age was 56 years (IQR, 48-65), the majority of patients were male (63%), and etiology of end stage liver disease was similar between groups with the most common being NASH (24%) and alcohol associated cirrhosis (24%). Median MELD at transplantation was 17 (11-26). The median length of stay was 16 days (IQR, 11-24) and 11 days (IQR, 9-17) in the pre- and post- implementation groups, respectively ($p = 0.058$). ICU LOS was 3 (IQR, 2-5) and 3 (IQR, 2-4) in the pre- and post-implementation groups, respectively ($p = 0.933$). The incidence of treated rejection at 60 days was 7.4% (95% CI, 1.9-26.5) and 9.6% (95% CI, 3.7-23.8) in the pre- and post-implementation groups, respectively ($p = 0.386$) [Figure 1A]. Readmission at 30 days was 29.6% (95% CI, 16.1-50.6) and 31.2% (95% CI, 19.3-47.8) in the pre-implementation and post-implementation groups, respectively ($p = 0.515$) [Figure 1B]. **Conclusion:** Implementation of a Fast Track protocol in a high acuity liver transplantation program was feasible and safe and may be associated with a reduction in hospital length of stay.

f 1090-A | LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED HEPATITIS COMPARED TO CIRRHOSIS: 273 TRANSPLANTS OVER 11 YEARS

Gene Y. Im[1], Katrina Villanueva[2], Alexander Vogel[2], Stephanie Rutledge[1], Thomas Schiano[2] and Sander S. Florman[2], (1)Icahn School of Medicine at Mount Sinai, (2)Recanati/Miller Transplantation Institute at Mount Sinai

Background: Alcohol-associated liver disease (ALD), including alcohol-associated hepatitis (AH) and alcohol-associated cirrhosis (AC), is the leading indication for LT in the U.S. Outcome studies of these LT populations with alcohol biomarker monitoring and long-term follow-up are lacking. The aim of this study is to compare the outcomes of relapse, rejection and survival in LT for AH versus AC. **Methods:** Using a prospectively-maintained database, we performed a retrospective cohort-comparison study of patients who underwent LT for ALD at our center, including AH and AC but excluding hepatocellular carcinoma, from 1/1/2012 to 1/1/2023. We gathered and analyzed data regarding patient demographics, drinking after LT from alcohol biomarker monitoring (urine ethyl glucuronide and/or phosphatidylethanol), biopsy-proven acute cellular rejection (BPAR) and patient survival. Alcohol relapse was defined as per NIAAA definitions. Statistical analyses were performed using SPSS. **Results:** Over the 11-year study period, 113 LT for AH and 160 LT for AC were performed at our center. (Figure 1) For both groups, LT volume increased during the COVID-19 pandemic (2020-23). Recipients of LT for AH vs AC were younger (median [IQR] (age 43 years [36-51] v 60 [52.5-65], $p < 0.001$) and had higher proportion of women (38% v 23%, $p = 0.008$), White race (65% v 50%, $p = 0.02$) and MELD-Na at LT (median 40 [36-40] v 33 [27-38], $p < 0.001$). Alcohol biomarker monitoring was performed after LT in 100% and 74% of LT for AH and AC recipients, respectively. While LT for AH recipients had higher rates of alcohol relapse compared to AC (32% v 18%, $p < 0.001$), rates of BPAR (11% v 14%, $p = 0.48$) and 1-year survival were similar (96% v 91%, $p = 0.15$). In contrast, recipients of LT for AH vs AC had significantly higher overall survival (94% v 82%, $p = 0.009$) at median of 2.5 years follow-up. (Figure 2) Overall, the most common causes of death were perioperative complications (43%) and cardiovascular disease (23%). **Conclusion:** Despite higher rates of relapse detected by alcohol biomarker monitoring, LT for AH recipients have higher overall survival compared to AC. This further supports the practice of LT for AH and deemphasizing the 6-month rule in favor of comprehensive psychosocial evaluations in patients with ALD.

1091-A | LIVER TRANSPLANTATION FROM COVID POSITIVE DONORS: TRENDS IN UTILIZATION, DISCARD & LONG-TERM OUTCOMES IN THE UNITED STATE

Kenji Okumura, Ryosuke Misawa, Abhay Dhand, Hiroshi Sogawa, Gregory R. Veillette, Roxana I. Bodin, David C. Wolf and Seigo Nishida, Westchester Medical Center

Background: Transplantation of organs from COVID positive (COVID+) donors is increasing. The aim of this study was to assess the trends in utilization, discard, and longer-term outcomes in liver transplant (LT) recipients who received organs from COVID+ donors. **Methods:** Rates of utilization, discard, and outcomes of SOT from deceased donors with a recent positive COVID PCR test from respiratory tract between March 2020 and December 2022 were analyzed using the de-identified UNOS database. Post-transplant survival analysis was performed using Kaplan-Meier method and Cox-hazard proportional regression model. **Results:** Overall, during the study period, 1185 COVID+ donors led to the transplantation of 1249 kidneys, 592 livers, and 168 hearts. The center-wise acceptance rate for livers from COVID+ donors increased from 53% in 2021 to 89% in 2022. Discard rates of livers from COVID+ donors remained low (3.1%) and was not significantly different than COVID negative (COVID-) donors (4.3%). When compared to 18,009 COVID- donors, 592 COVID+ donors were younger (median 40 vs 42 y, $p=0.019$), had similar median serum total bilirubin (0.6 mg/dl, $p=0.15$) and similar cold ischemia time (5.81 vs 5.77 hours, $p=0.52$). Length of hospital stay and rates of rejection prior to discharge (COVID+ 4.7% vs COVID- 4.2%, $p=0.56$) were similar in both the groups. The median waitlist time for recipients of COVID+ organs was lower (35 vs 41 d, $p=0.087$). The median follow-up period was 360 (172-670) days. Six-months, one-year and 18-month overall and graft survivals were comparable between recipients of COVID+ and COVID- donors (figure 1). In multivariable analysis, COVID+ was not associated with statistically significant increased risk of mortality (hazard ratio 1.22; 95% confidence interval 0.85-1.75, $p=0.30$) or graft failure (hazard ratio 1.33; 95% confidence interval 0.98-1.79, $p=0.066$). **Conclusion:** Utilization of livers from COVID+ donors has improved across various transplant centers in the US. Liver discard rate from COVID+ donors remain low. While longer-term outcomes of LTs from COVID+ donors are encouraging and are helping to successfully expand the donor pool, further follow up is needed to monitor for any further change in risk of graft failure.

1092-A | LIVER TRANSPLANTATION PROFILE AMONG TEENAGERS IN THE UNITED STATES

Maria Stepanova[1], Dipam Shah[2], Reem Al Shabeeb[2], Katherine Elizabeth Eberly[2], Veronica Nguyen[3], Janus Ong[4], Saleh A Alqahtani[5,6] and Zobair M. Younossi[3,7,8], (1)Center for Outcomes Research in Liver Diseases, Washington, DC, (2)Inova Health Systems Medicine Service Line, Falls Church, VA, (3)Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, (4)College of Medicine, University of the Philippines, Manila, Philippines, (5)Johns Hopkins University School of Medicine, (6)King Faisal Specialist Hospital and Research Center, (7)Center for Liver Disease, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, VA, (8)Inova Medicine, Inova Health System, Falls Church, VA

Background: Indications for liver transplantation (LT) may vary between different age groups. Our aim was to assess trends in indications and outcomes in teenagers listed for LT in the U.S. **Methods:** We used the Scientific Registry of Transplant Recipients (SRTR) 2008-2022 to collect data for all teenagers (13-19 y) listed for a LT in the U.S. The study outcomes were receiving a LT and time to post-transplant mortality for recipients. The cut-off date for the outcomes was March 2, 2023. **Results:** There were 2,813 teenage LT candidates listed between 2008 and 2022. Mean age was 17 years (SD 2), 45% male, 57% white, 17% black, 5% Asian, 19% Hispanic, 95% U.S. citizens, and 39% covered by Medicaid. Mean MELD score was 19.4 (SD 10.5). The most common indication for LT was acute liver disease (24%), followed by biliary atresia or hypoplasia (12%), autoimmune hepatitis (11%), and primary sclerosing cholangitis (PSC) (10%). At the same time, the prevalence of chronic viral hepatitis (B or C), NASH, and alcoholic liver disease (the most common indications for LT in adults) did not exceed 1%. Nevertheless, 2.8% of teenage candidates also had hepatocellular carcinoma (HCC). There were no significant differences in the distributions of LT indications between subgroups of younger (12-16) vs. older (17-19) teenagers, with the exception of PSC which was less common among younger patients: 8% vs. 12% ($p < 0.01$). Excluding two most recent years (2021,2022), 67% received a LT after a mean of 217 days (SD 372) after listing. This rate remained stable during the study years ($p > 0.05$). In addition, 13% of candidates were removed from the list due to improvement and 9% died or deteriorated while waiting for a LT. In multivariate analysis, independent predictors of a higher chance of receiving a LT included more recent calendar year, younger age, higher MELD score, and a listing diagnosis of acute liver disease or copper metabolism-related liver disease (all $p < 0.01$). In those who received a LT, 3-year survival was 90% with a trend in improvement from the early study years (86%) to those transplanted in 2017-2019 (91%, $p = 0.07$). Higher post-transplant mortality in adolescents was associated with older age, having Medicaid, being re-transplanted, and having HCC (adjusted hazard ratio [aHR] > 1, all $p < 0.01$), while listing diagnoses of copper and other metabolism-related liver diseases were associated with lower post-transplant mortality (aHR < 1, all $p < 0.01$). **Conclusion:** Indications for liver transplantation among teenagers in the U.S. are different from those recorded for adults or younger children. There is a trend towards improvement of post-transplant outcomes in teenagers in the U.S.

1093-A | LOW SOCIOECONOMIC STATUS IS NOT ASSOCIATED WITH LONG-TERM POST-LIVER TRANSPLANT SURVIVAL

Gabriella Aitcheson[1], Sanjna Vinze[2], Marwan S. Ghabril[1], John Holden[2], Naga P. Chalasani[3], Marco Lacerda[1], Chandrashekhar Kubal[1] and Lauren D. Nephew[1], (1)Indiana University, (2)Indiana University School of Medicine, (3)Indiana University Medical Center, Indianapolis, IN

Background: Social determinants of health (SDOH) have been associated with poor waitlist outcomes. However, it is unclear how these factors affect short and long-term post-liver transplant (LT) survival. Further understanding the full spectrum of predictors of post-LT outcomes will be an important part of continuous distribution modeling. We aim to explore the impact of individual- and area-level social determinants of health (SDOH) on this outcome. **Methods:** Adults who underwent LT at Indiana University Hospital from 12/2011 to 6/2019 were included. Demographics, clinical variables, and individual-level SDOH were collected from our transplant database and EMR. Addresses were linked to the American Community Survey to determine census-tract level SDOH and rural vs. urban residence. Low-SES was defined as being insured by Medicaid,

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

having disability income, or living in a neighborhood in the highest quartile for income below the federal poverty level. Multivariable Cox survival analysis was used to explore the association between these SDOH and death/graft loss at 1, 3 and 5-years. **Results:** The cohort included 687 patients with 34% women and 5% Black race. The most common etiology was viral hepatitis (47%) followed by NASH (24%). HCC occurred in 23% and the median MELD at LT was 22 (IQR 18-26). Regarding the SDOH, 39.2% of the cohort had high school level education or less, 36.5% were insured by Medicaid, 41.3% received their income from disability, 29.4% were unmarried/without partner, 20.1% of residents lived in neighborhoods in the fourth quartile for highest proportion of incomes below the federal poverty level. 65.7% of patients in this cohort were defined as low-SES. Death or graft loss occurred in 158 patients over a median follow up time of 5.7 years (IQR 4.0-7.25). Survival rates were 91.0%, 82.1%, and 62.2% at 1,3, and 5-year respectively. On multivariable 1-year survival analysis, there was a significantly higher hazard of mortality in those who received disability income (HR 4.46, 95% CI 1.83-10.89, $p < 0.001$) and those with NASH compared to hepatitis-c virus (HR 2.62, 95% CI 1.02-6.72, $p = 0.045$). Three-year survival was associated only with MELD at LT (HR 1.03, 95% CI 1.003-1.05, $p = 0.027$). There were no significant predictors of 5-year survival. Low SES did not predict 1, 3, or 5-year survival (figure). **Conclusion:** Despite a large portion of this cohort being of low SES, only disability income was associated with short-term post-LT mortality. There was no association between SDOH and longer-term survival. This suggests that thorough pre-LT evaluations may select the "fittest" candidates, even in the face of a high burden of adverse SDOH. Furthermore, as UNOS works to implement a continuous distribution model that facilitates more patient-centric and equitable organ allocation, elucidating how to equitably incorporate post-LT outcomes will be critical.

1094-A | MULTIDISCIPLINARY CARE IMPROVES TRANSPLANT RATES IN CRITICALLY ILL PATIENTS WITH ADVANCED LIVER DISEASE

Alaina Miller[1], Aanchal Kapoor[1], Gianina Flocco[1], Stephanie Bass[1], Bridget Dolan[1], Jamak Modaresi Esfeh[2], Koji Hashimoto[1] and Christina C. Lindenmeyer[1], (1)Cleveland Clinic, (2)Cleveland Clinic, Pepper Pike, OH

Background: One of only a few liver-specific Intensive Care Units (ICU), the Medical Intensive Liver Unit (MILU) offers multidisciplinary care for critically ill patients with advanced liver disease, including patients waiting or being evaluated for liver transplant (LT). The goal of this improved care model has been to optimize and standardize evidence-based management, and to promote opportunities for LT. We aimed to determine the impact of the MILU model on end points of care and rates of LT. **Methods:** The MILU opened at a large quaternary referral LT center in August 2018. Consecutive MILU patients admitted between 08/2018 and 05/2023 were included and compared to patients admitted to the medical ICU (pre-MILU) between 09/2017 and 08/2018. Pre-MILU patients were defined as having decompensated cirrhosis or acute liver failure identified by ICD-9 codes and confirmed by chart review. Patients were followed from admission to discharge, death or LT (and if transplanted, for 12 months post-LT). MILU data was extracted from a prospectively maintained longitudinal registry; pre-MILU data was retrospectively extracted from the electronic health record. Demographics, diagnosis, clinical and transplant data was collected. The 2-sample t-test was used to compare severity of liver disease between cohorts. **Results:** Out of 1366 MILU admissions, 1011 individual patients were included in the MILU cohort; 293 patients were included in the pre-MILU cohort. The most common etiology of liver disease was alcohol-associated in both the pre-MILU and MILU cohorts

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(42% versus 44%). Prior to MILU inception, only 37% of patients meeting MILU criteria were seen by Hepatology in ICU; 100% of MILU patients were co-managed by ICU and Transplant Hepatology. Compared to pre-MILU patients, MILU patients had increased severity of liver disease stratified by the MELD-Na score (24.08 vs 26.35, $p = 0.0005$). In the 12 months prior to MILU, 5 patients were bridged from ICU to LT, whereas in calendar year 2021, 30 (of 189 admitted) patients were transplanted directly from MILU, with improved 1-year post-LT survival (80% versus 93.3%). **Conclusion:** The MILU's unique clinical care pathways, the products of inter-professional collaboration and expertise, have improved care and facilitated expedited access to LT providers. Our experience demonstrates an expected temporal increase in severity of illness and enhanced collaboration, with the product being higher rates of successful LT for critically ill patients associated with improved post-LT survival. Formalized sub-specialty multi-disciplinary intensive care services may be proposed as a future standard of care for large LT centers.

1095-A | NATURAL COURSE AND PROGNOSTIC SIGNIFICANCE OF INTRA-OPERATIVE SPONTANEOUS BACTERIAL PERITONITIS: A SINGLE-CENTER CASE-SERIES

Joseph Cappuccio[1], Karim Osman[1], Cristina Batarseh[1], Brenda Amuchi[1] and Amir Ahmed Qamar[2], (1)Lahey Hospital and Medical Center, (2)Lahey Clinic Medical Center

Background: Patients with decompensated cirrhosis carry an increased risk for life-threatening infections. Specifically, patients with clinically significant ascites may develop spontaneous bacterial peritonitis (SBP) which perturbs a high mortality rate without prompt intervention. Despite this, the post-transplant ramifications of undetected or undertreated SBP have been minimally investigated to date. As such, our evaluation tracks the natural course of specific instances of intraoperative SBP (IOSBP) identified via ascitic fluid analysis performed at the time of liver transplantation (LT). **Methods:** We retrospectively reviewed a cohort of 428 patients who underwent LT between January 2015 and December 2020. We defined IOSBP by an absolute neutrophil count (ANC) ≥ 250/μL and/or a positive culture in ascitic fluid obtained during LT. Subjects were followed from the time of LT until last follow-up or death. **Results:** We identified fifteen total patients who met criteria for IOSBP. Of these, eleven patients (2.6%) had culture positive ascitic fluid, three (0.7%) had ANC > 250, and one (0.2%) had both culture positive ascites and ANC > 250. Of the fifteen patients identified, three patients died at the time of follow-up, and one patient died within one year of LT. Additional baseline and clinical features are available in Table 1a & b. Figure 1 describes the natural course of IOSBP for all fifteen patients. **Conclusion:** Our study adds to the limited data evaluating any prognostic link between perioperative infection and post-operative outcome in the setting of LT. Our review further suggests the possibility of an otherwise clinically silent phenomena which may persist in patients with decompensated cirrhosis even despite appropriate antimicrobial prophylaxis following index spontaneous bacterial peritonitis. Our limited sample size restricted our ability to perform a meaningful comparative statistical analysis. Still, further analyses are needed to determine pre-operative risk factors which may impact post-transplant outcomes.

1096-A | NATURAL HISTORY OF LIVER TRANSPLANTATION FOR HBV AND HDV INFECTION OVER 30 YEARS: A SINGLE CENTER EXPERIENCE IN ITALY

Clara Dibenedetto[1], Lorenzo Canova[1], Elia Fracas[1], Elisa Farina[1], Michele Sagasta[1], Sonia Stella[1], Barbara Antonelli[2], Lucio Caccamo[2], Pietro Lampertico[1,3] and Maria Francesca Donato[1], (1)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2) Division of General Surgery, Liver Transplant Center, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (3)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: Hepatitis Delta (HDV) and hepatitis B (HBV) virus infections might both induce end-stage liver disease (ESLD) and/or hepatocellular carcinoma (HCC) leading to liver transplant (LT). This study aims to compare epidemiological features and clinical outcomes of HDV and HBV recipients transplanted at Policlinico Maggiore Hospital Milan, Italy. **Methods:** We enrolled in the study 265 patients transplanted for ESLD/HCC due to HDV and HBV infections in the last 30 years. **Results:** Based on preliminary data from 104 LT recipients transplanted between 2010 to 2022, 55 showed HBV etiology (52,8%) and 49 were HDV-infected. The indication for LT for HCC was higher for HBV-LT recipients compared to HDV ones (41.5% vs 22.4%; $p = 0.494$) while ESLD was the prevalent indication in patients transplanted for HDV infection (77.6% vs 30,2%; $p < 0.001$). Acute liver failure (ALF) and acute-on-chronic liver failure (ACLF) as indications to LT were registered in 13 (24.5%) and 2 (3.8%) HBV recipients respectively. No cases of ALF/ACLF were observed among HDV infected LT recipients. The median age at the time of transplantation was significantly lower in HDV patients compared to HBV (49 vs 60 years old respectively; $p < 0.001$). Diabetes and chronic kidney disease after LT were significantly higher in HBV recipients ($p < 0.01$ and $p < 0.006$, respectively). However, there were no significant differences in post-transplant survival (see Figure 1), recurrence of HBV infection, recurrence of HCC and episodes of graft rejection between the two groups. In 18 patients, hepatitis B immunoglobulin (HIGB) were discontinued during late post-transplant follow up and no cases of HBV recurrence were observed. Notably, 2 patients were treated with HDV therapy (bulevirtide) before transplantation. **Conclusion:** As expected HDV recipients were younger than HBV infected patients at LT, reflecting the more aggressive course of HDV infection. Nevertheless, a similar post-transplant survival was

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

observed in both groups. Limited data are currently available regarding the impact of bulevirtide on post-transplantation outcomes. The analysis of the whole cohort of HBV and HDV transplanted patients will be presented at the meeting.

Figure 1. HBV and HDV survival post-LT

1097-A | NEUROLOGIC COMPLICATIONS EARLY AFTER LIVER TRANSPLANT

Michelle Knizner[1], Heather S. Snyder[1], Sarah Todd[1] and Ram M. Subramanian[2], (1)Emory University Hospital, (2)Emory University

Background: Liver transplant recipients are at risk for developing neurologic complications early after transplant. Perioperative factors may alter risk, including etiology of liver disease, Model for End-Stage Liver Disease (MELD) score, hepatic encephalopathy, and medication use. The purpose of this study was to identify perioperative risk factors for neurologic complications post-liver transplant. **Methods:** A single-center, retrospective, case-control study was conducted of adult liver transplant recipients from 2017-2022. Patients were placed into one of two cohorts: those who experienced a neurologic complication within 30 days post-transplant versus those who did not. The primary outcome was the association between perioperative factors and post-transplant neurologic complications. Secondary outcomes included incidence of neurologic complications, change in immunosuppression (IS) regimen, and hospital length of stay. **Results:** There were 614 liver transplants that occurred during the prespecified time frame, and 1 patient was excluded due to age. Of the remaining 613 patients, 162 (26%) experienced a neurologic complication and 451 did not. The following perioperative factors were significantly higher in the neurologic complication group: white race, alcoholic cirrhosis, nonalcoholic steatohepatitis, history of hepatic encephalopathy (HE), MELD score ≥ 30, chronic kidney disease, hepatorenal syndrome, need for continuous renal replacement therapy (CRRT) pre-transplant, pre-transplant hospital length of stay, and pre-transplant ICU stay. These variables were included in a binary logistic regression, and history of HE ($p < 0.001$), MELD ≥ 30 ($p = 0.04$), hepatorenal syndrome ($p = 0.04$), and CRRT ($p = 0.002$) were associated with the development of neurologic complications. The IS regimen was changed from tacrolimus to cyclosporine in 46% of patients who experienced a neurologic complication. The median post-transplant hospital length of stay was significantly longer in patients experiencing with a neurologic complication (16 d in neurologic complication arm vs. 9 d in those without neurologic complication, $p < 0.001$). **Conclusion:** Perioperative factors associated with the development of post-liver transplant neurologic complications include HE, high MELD, hepatorenal syndrome, and use of CRRT. Monitoring patients with one or more of these factors may be useful in identifying neurologic complications and optimizing management post-transplant.

1098-A | NUMBER OF LIFE-YEARS GAINED IN RELATION TO RECIPIENT AGE IN LIVER TRANSPLANT

Bishoy Lawendy[1], Shiyi Chen[2], Mouaid Alim[2,3] and Mamatha Bhat[2,3], (1)University of Western Ontario, (2) University Health Network, (3)University of Toronto

Background: Liver transplant (LT) is lifesaving for patients with end stage liver disease. However, it is unclear how many additional years of benefit are derived based on the age of the recipient, and how this compares to the life expectancy of the general population across age groups. **Methods:** We used data from the Scientific Registry of Transplant Recipients (SRTR). Adults transplanted after 1st of January 2003

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

surviving > 1 year or waitlisted were included. The SRTR data system includes data on all donor, waitlisted candidates, and transplant recipients in the US. Cox hazard model MVA was used to analyze the risk factors for mortality. Life expectancy was calculated as the area under survival curve. Given the limitations on SRTR dataset, our follow up was maximum 16 years. **Results:** We included 101,770 individual's (82,514 transplanted and 19,256 non-transplanted). One year post LT, life expectancy based on age of LT was: 12.46 years (20s), 12.87 years (30s), 12.72 years (40s), 11.56 years (50s), 10.91 years (60s), & 9.53 years (70s). Figure 1 displays life expectancy post LT stratified by sex and age in comparison to the US general population. Males without diabetes had significantly longer life expectancy at transplant than diabetic males: 50s (11.7 vs 10.4 y, $p = 0.0009$); 60s (11.1 vs 9.8 y, $p = 0.0002$); 70s (10.4 vs 7.2 y, $p = 0.001$). Compared to the general U.S. population, life expectancy in our study sample was significantly shorter. LT improved survival significantly relative to patients on the waitlist in all age groups with 5 years added (18-30 y old), 6.5 years added (30-50 y old), 6.4 years added (50-70 y old), & 3.9 years added (> 70 y old). In the LT cohort, the proportion of patients whose cause of death graft failure was: 22.7% (18-30 y old), 13.7% (30-50 y old), 7.1% (50-70 y old) & 2.9% (> 70 y old). Male sex, diabetes, & history of coronary artery disease were negatively correlated with survival (HR 1.19, $p < 0.001$), (HR 1.32, $p < 0.001$), (HR 1.32, $p < 0.001$). **Conclusion:** Our findings demonstrate a consistent survival benefit of LT across ages studied, and that life expectancy was not necessarily greater among younger recipients. Young recipients (18-30 y) had a higher proportion of graft failure as their cause of death. Recipients across age groups had 2.67 times greater mortality than the general population, indicating the need for significant efforts to optimize long-term survival after LT. It is important to interpret these results in the context of our follow up as our follow up was 16 years, which might underestimate life expectancy in younger patients.

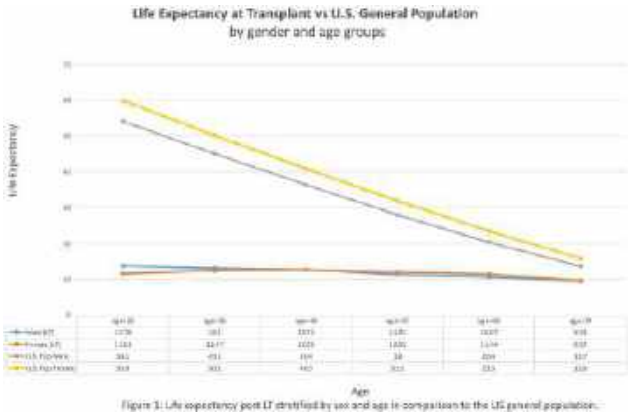

Figure 1: Life expectancy post LT stratified by sex and age in comparison to the US general population.

1099-A | OPIOID USE AFTER LIVER TRANSPLANTATION: PREDICTORS OF HIGH RISK USE AND OPIOID-RELATED COMPLICATIONS

Olgert Bardhi[1], Yue Jiang[2], Alex R. Jones[1], Prajwal Gowda[3], Madhukar Patel[1], Van Ngo[1], Mary Olumesi[1], Jessica Francois Whitt[1], Raelene E. Trudeau[1], Alvaro Noriega Ramirez[1], Arjmand R. Mufti[1], Lisa B. VanWagner[1], Amit G. Singal[1] and Sarah Rosanna Lieber[1], (1)University of Texas Southwestern Medical Center, (2)Duke University Medical Center, (3)UT Southwestern School of Medicine

Background: Opioid use disorder contributes to high morbidity and mortality. Liver transplant recipients (LTRs) are a high risk population given potential pre-existing substance use and psychiatric comorbidities, but limited data exist on opioid use after LT at the national level. We assessed opioid use, prescribing practices, factors associated with high-risk use, and opioid-related complications among LTRs. **Methods:** Adult LTRs were identified using CPT codes from 2006-2021 in IQVIA Pharmetrics Plus, a medical and pharmacy database nationally representative of commercially insured patients. ICD 9/10 codes were used to identify complications associated with opioid use, defined as suicide/self-harm, substance use disorder, chronic pain syndromes, altered mental status, or fractures/falls. Opioid use was evaluated 30-90 days post-LT; high risk use was defined as > 50 morphine milligram equivalents (MME) per day or concurrent benzodiazepine use. We identified factors associated with high-risk use using a multivariable logistic regression model. Landmark survival analysis using a multivariable proportional hazards regression model was used to assess associations between opioid use and complications. **Results:** We identified 1,318 LTRs, of whom 379 (28.8%) had opioid use–50 with high-risk opioid use. In multivariable analysis, female sex (aOR 2.74 [95% CI: 1.45, 5.23]), pre-LT opioid use (aOR 3.64 [1.96, 6.84]), and depression (aOR 2.15 [1.01, 4.38]), were significantly associated with high-risk opioid use. Opioid complications were observed in 231 (61%) of opioid users. In landmark analysis, non-high risk and high risk opioid use were associated with increased complications (aHR 1.43 [95% CI: 1.20, 1.70] and aHR 2.10 [1.45, 3.04], respectively). In multivariable analysis, age at LT > 50 years (aHR 1.28 [[1.06, 1.56]), pre-LT depression (aHR 1.46 [1.16, 1.84]), anxiety (aHR

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

1.45 [1.11, 1.89]), pain disorder (aHR 1.94 [1.36, 2.76]), substance use disorder (aHR 1.66 [1.40, 1.98]), modified Charlson comorbidity score > 3 (aHR 1.56 [1.29, 1.87]), alcohol-associated liver disease (aHR 1.47 [1.10, 1.98]), and pre-LT opioid use (aHR 1.22 [1.02, 1.47]) were associated with complications. **Conclusion:** More than 1 in 4 LTRs used opioids within 3 months of LT. Worse clinical outcomes were seen among opioid-users, especially those with high-risk use. Use of prescription opioids, particularly in high doses and with benzodiazepines, should be cautioned in post-LT patients especially among vulnerable populations with psychiatric comorbidities.

Table 1: Sociodemographic and Clinical Characteristics of Adult Liver Transplant Recipients Stratified by Opioid Use Post-LT* (N=1,318)

1100-A | OUTCOMES ASSOCIATED WITH RECURRENT AUTOIMMUNE LIVER DISEASE FOLLOWING LIVER TRANSPLANTATION IN PATIENTS AT TERTIARY REFERRAL CENTER OF MEXICO

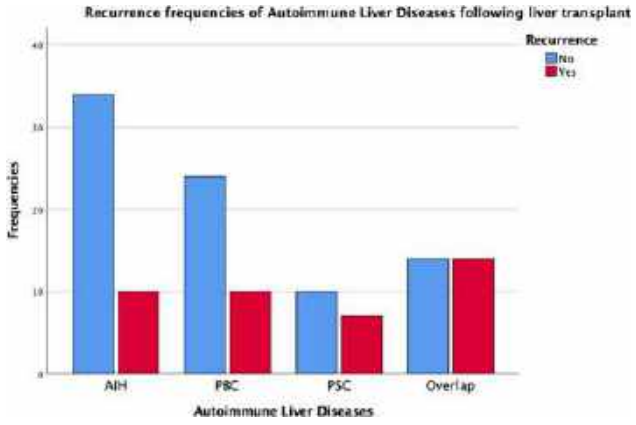
Carolina Ivette Ivette Zubia-Nevárez, Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, Ignacio García Juárez, Instituto Nacional De Ciencias Medicas y Nutricion and Leticia Martínez, Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubiran, MEXICO CITY, SL, Mexico

Background: Autoimmune Liver Disease (AILDs) involves Autoimmune Hepatitis (AIH), Primary Biliary Cholangitis (PBC), Primary Sclerosing Cholangitis (PSC) and Overlap Syndromes (OS). Liver transplant (LT) represents the treatment in advance stages and has a 5-year survival greater than 70%, approximately. Recurrence after LT is common (17-41%) and has been associated with decreased graft survival, the need of re-transplantation and whether it reduces long-term survival. **Aim:** To describe the prevalence of AILDs recurrence, risk factors, recurrence-free-survival (RFS) and long-term survival. **Methods:** A Cross-sectional retrospective study of patients diagnosed with AILDs (by biopsy, Cholangiopancreatography or Paris criteria according to etiology) who underwent orthotopic LT from January 2000 to December 2021, was performed. We analyzed age, sex, comorbidities, biochemical data, MELD score, Child-Pugh, presence of recurrence (based on AASLD guidelines), graft rejection and use of immunosuppressant. Frequencies, Hazard-ratios (CI95%), Student's t-test or U-Mann-Whitney, and Kaplan-Meyer survival analysis (Log-Rank) were reported. **Results:** Of 500 patients who underwent LT, 123 (24.6%) had AILDs as etiology. Female sex was the most prevalent (74.8%), mean age was 52 ± 13.3 years-old. AIH, PBC, PSC and OS corresponded to 35.8, 27.6, 13.8 and 22.7%, respectively. Most had a Child-Pugh C (61.8%). Recurrence was found in 32.5%, being more prevalent in OS (50%). The median days-to-recurrence was 881 (50-3384). RFS was lower in patients with age-at-LT < 42 years-old (Log rank $p = 0.002$), autoimmune comorbidity (Log rank $p = 0.03$), > 1.1 IgG reference levels (Log rank

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

$p = 0.03$) and initial immunosuppression with Basilixi-mab (Log rank $p < 0.001$). Elevated pre-LT IgG levels (2896.8 ± 1281 vs. 21268 ± 22 mg/dL, $p = 0.005$) and prolonged use of Mycophenolate mofetil ($p < 0.001$) were associated with overall recurrence of AILDs and AIH+OS group. Graft rejection occurred in 26% (21.1% acute), being more frequent in AIH (29.5%) and PBC (29.4%). Overall-survival at 5 and 10 years was 89 and 84%, respectively. 12.2% of patients died; initial immunosuppression with Daclizumab was associated with higher risk of mortality (HR 5.8, CI95% 0.39-0.94, $p = 0.01$) compared to Basiliximab group. **Conclusion:** The recurrence in AILDs after LT was 32.5% and agrees with previously described. RFS at 1 and 5 years are 99% and 88.8%, respectively. Factors associated with lower RFS are age < 42 years-old at LT, prolonged use of Mycophenolate Mofetil, higher levels of IgG Pre-LT and initial immunosuppression with Basiliximab. No difference in long term survival was found in the presence of recurrence. Initial induction with Daclizu-mab was associated with higher risk of mortality.



Disclosures: The following people have nothing to disclose: Carolina Ivette Ivette Zubia-Nevárez, Ignacio García Juárez, Leticia Martínez

1101-A | OUTCOMES FOLLOWING USE OF HEPATITIS B SURFACE ANTIGEN POSITIVE LIVER ALLOGRAFTS IN HEPATITIS B SURFACE ANTIGEN NEGATIVE RECIPIENTS

Adam Seth Myer, Drake Seccurro, Kenneth E. Sherman and Yeshika Sharma, University of Cincinnati

Background: Liver transplantation remains the definitive treatment for patients with cirrhosis. There is a large gap between the number of organs available and the number of organs needed. The use of hepatitis B surface antigen positive (HBsAg+) grafts remains controversial, and outcomes have yet to be defined. **Methods:** A retrospective review of using HBsAg+ organs was performed. Data were collected in accordance with hospital protocol. Post transplant monitoring of HBV DNA and HBsAg was done at 3-and 12-month intervals, followed by surveillance. Between 2019 and 2021, 10 HBsAg negative recipients at a single institution received HBsAg+ donor livers. All liver allografts were also HBV NAT+. 4 recipients were nonreactive to Anti-HBc and Anti-HBs, 5 were reactive to Anti-HBs and nonreactive to Anti-HBc and 1 was reactive to Anti-HBc and Anti-HBs. 7 were female, 3 were male, mean age at time of transplant (60.2 ± 6.0), BMI (30.8 ± 8.6), and MELD-Na (16 ± 5.7). Etiologies of cirrhosis were NASH (n = 4) alcohol (n = 3), cryptogenic (n = 1), colon metastasis (n = 1), and hepatitis C (n = 1). All patients received standard immunosuppression, and entecavir 0.5 mg daily was initiated post operatively on day 0 and continued indefinitely. **Results:** 2 patients died post-operatively at 1-month related to complications of sepsis and thrombosis, respectively. Out of the 8 patients at the 3-month mark, 4 patients had no detectable serum HBV DNA and remained undetectable. 2 recipients had detectable serum HBV DNA at 3 months, but this disappeared in subsequent evaluations. 2 patients had persistent HBV DNA levels. The first had an initial HBV DNA of 8000 IU/mL, which plateaued to 1200 IU/mL on entecavir, and switched to tenofovir alafenamide (TAF), and then tenofovir disoproxil fumarate (due to cost) and remained undetectable. The other recipient had an HBV DNA level of 4208 IU/mL, which increased to 40000 IU/mL while on entecavir, but a switch to TAF led to undetectable levels. 5 patients became HBsAg+ and 1 patient was not checked for HBsAg. 2 recipients achieved loss of HBsAg within 2 and 3 years post operatively. Kaplan Meier analysis showed no difference in survival compared to all transplants done at our center in the same period ($p = 0.53$, HR = 1.59, CI = 0.39- 6.51). **Conclusion:** There is limited guidance on the use of HBsAg+ liver allografts and experience are primarily limited to HBsAg+ recipients. In our case series, the use of these organs in HBsAg negative recipients did not affect graft function or survival.

1102-A | OUTCOMES IN PATIENTS WITH AND WITHOUT LIVER CIRRHOSIS FOLLOWING EMERGENCY SURGERY FOR INCARCERATED VENTRAL HERNIA

Alex Richard[1], Adam Skura[1], Nicole Cherng[1,2], Richard Perugini[1,2] and James Carroll Jr.[1,2], (1)University of Massachusetts Chan Medical School, (2)UMass Memorial Medical Center

Background: Patients with cirrhosis are complex surgical candidates, carrying high rates of morbidity and mortality. We sought to classify surgical risk in the management of incarcerated ventral hernia in patients with cirrhosis compared to patients without cirrhosis undergoing the same intervention. **Methods:** In this retrospective chart review, we identified adults who underwent emergency surgery for incarcerated ventral hernia at an academic tertiary referral and liver transplant center from October 2017- April 2023. Patients with a recorded diagnosis of cirrhosis were identified. Intraoperative and postoperative factors including length of stay (LOS), ICU LOS, and mortality at discharge and within 1 year were collected for all patients. Data were collected to determine MELD-Na and Child-Pugh-Turcotte (CPT) score for patients in the cirrhosis group. **Results:** Ninety-one patients met inclusion criteria with 64 (70%) patients in the non-cirrhosis group and 27 (29.6%) patients in the cirrhosis group (2 CPT-A, 17 CPT-B, 8 CPT-C). The cirrhosis group had significantly greater 1-year mortality (11/27; 41%) compared to the non-cirrhosis (6/64; 9%) group ($p < 0.01$). The cirrhosis group additionally had a longer mean LOS ($p = 0.01$) and required more frequent admission to the ICU ($p < 0.01$), postoperatively. Bowel resection occurred more frequently in patients with cirrhosis ($p = 0.02$). **Conclusion:** We demonstrate significantly increased morbidity and mortality in patients with cirrhosis undergoing emergency surgery for incarcerated ventral hernia. Guidelines on timing and management of surgery among patients with cirrhosis remain controversial, but consideration of elective interventions to avoid emergent surgery in patients with cirrhosis is warranted.

1103-A | OUTCOMES OF ACUTE PANCREATITIS AMONG LIVER TRANSPLANTATION PATIENTS: ANALYSIS OF NATIONAL INPATIENT SAMPLES

Chidiebele Omaliko, One Brooklyn Health - Brookdale University Hospital Medical Center, Chukwunonso Ezeani, Baton Rouge General Medical Center, Baton Rouge, LA, Ayobami Olafimihan, John H Stroger Jr. Hospital of Cook County, Oghenefejiro Ogwor, St Peter University Hospital, New Brunswick, NJ, Favour Markson, Lincoln Medical Center and Festus Ibe, Albert Einstein Medical Center

Background: Liver transplantation is associated with an increased burden of medical diseases including higher incidence and severity of acute pancreatitis compared to the general population. There is however scarce data related to outcomes of acute pancreatitis among patients with a transplanted liver compared to the general population. We aimed to compare these two populations and determine if hepatic transplantation status was associated with worse outcomes in acute pancreatitis. **Methods:** We identified all patients with a primary discharge diagnosis of acute pancreatitis from the 2016 to 2020 National Inpatient Sample (NIS) database and then divided them into two groups based on liver transplantation status. Patients aged less than 18 years were excluded from the analysis. Using a multivariate analysis, we assessed for differences in the primary outcome of inpatient mortality, while the secondary outcomes were hospital length of stay (LOS) and total hospital charges (THC). **Results:** Of the 1,387,709 hospitalizations with a primary diagnosis of acute pancreatitis, 1875 patients (0.01%) had prior liver transplantation. There was no statistically

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significant difference between the mortality rate in liver transplant patients (1.07%) compared to the non liver transplant patients (0.58%) with a *p* value of 0.666. Similarly, the LOS was not significantly different between the two groups with an average LOS of 4.6 days in liver transplant patients and 4.3 days in non liver transplant patients, *p* value of 0.296. The average total hospital charge for patients with acute pancreatitis was $40,854 with an average charge of $51,872 for liver transplant patients and $40,839 for non liver transplant patients. There was no statistically significant difference in total hospital charges between the two groups (*p* value of 0.899). **Conclusion:** Although liver transplantation is associated with an increase in incidence and severity of acute pancreatitis, our study did not show a statistically significant difference in mortality rates, length of hospital stay or total hospital charges between liver transplant patients and non liver transplant patients with a discharge diagnosis of acute pancreatitis. Further studies are needed to further elucidate the relationship between liver transplantation and acute pancreatitis.

1104-A | OUTCOMES OF LIVER TRANSPLANT RECIPIENTS HOSPITALIZED WITH COVID-19 INFECTION: A NATIONWIDE ANALYSIS

Abdellatif Ismail, University of Maryland Medical Center, Midtown Campus, Ahmad Khalaf, Hennepin Healthcare and Kirti Shetty, Department of Hepatology and Liver Transplantation, the University of Maryland, School of Medicine, Baltimore, MD, USA

Background: Currently, available data regarding the impact of liver transplantation (LT) on the outcomes of patients hospitalized with COVID-19 is conflicting. This study aims to compare the outcomes and resource utilization between patients with and without a history of LT hospitalized with COVID-19 infection. **Methods:** We conducted a retrospective review using the Nationwide Inpatient Sample (NIS) database, the largest all-payer inpatient database in the United States. This review included all adult patients hospitalized in 2020 with COVID-19 as the primary diagnosis in hospitals throughout the United States. Covariates retrieved included demographic variables, LT status, need for intubation, and length of stay (LOS). Univariable and multivariable logistic and linear regression analyses were conducted, adjusting for age, sex, and comorbidities. The alpha level was set at 0.05. **Results:** Out of 1,050,720 adults admitted with COVID-19 as the primary diagnosis, 1455 had a secondary diagnosis of LT. LT recipients were significantly more likely to be younger with a higher Charlson Comorbidity Index (CCI) and less likely to be Black. However, there were no statistically significant differences between the two studied groups concerning mortality and the need for invasive ventilation. There were also no differences in LOS, hospital charges, and intubation rates. Table 1 summarizes these outcomes. **Conclusion:** We compared mortality rates, need for invasive ventilation, length of stay, and total hospital charges between patients with and without LT hospitalized in the US for COVID-19 infection in 2020. We concluded that LT status did not confer higher mortality or increased resource utilization. While some previous studies have demonstrated higher susceptibility of transplant recipients to COVID-19, attributed to immunocompromised status, other registry studies have been conflicting. A recent meta-analysis showed a similar risk of adverse outcomes in LT recipients, who were also noted to have a lower mortality risk than other solid organ transplant recipients. Ours is the first study to examine outcomes in a large hospitalized cohort of LT recipients early in the COVID-19 pandemic when management guidelines were still in development. Despite these limitations, LT recipients were not demonstrated to be at risk for higher mortality. With the development of highly effective vaccines and social distancing protocols, LT recipients continue to experience equivalent risks of hospitalization and mortality compared to the general population.

Outcome	Cohort	Value	Odds ratio (95% CI)	P-value	Adjusted odds ratio (95% CI)	P-value
In-hospital mortality (percentage)	COVID-19 without LT	11.17	-	-	-	-
	COVID-19 with LT	10.31	0.91 (0.62-1.34)	0.646	1.07 (0.73-1.57)	0.735
Invasive ventilation (percentage)	COVID-19 without LT	8.5	-	-	-	-
	COVID-19 with LT	9.6	1.14 (0.76-1.71)	0.511	1.13 (0.75-1.69)	0.559
Mean length of stay (days)	COVID-19 without LT	7.48	-	-	-	-
	COVID-19 with LT	6.85	-0.63 (-1.37 to 0.12)	0.099	-0.60 (-1.35 to 0.15)	0.114
Total hospital charge (US $)	COVID-19 without LT	78,557	-	-	-	-
	COVID-19 with LT	83,696	5139 (-9132 to 19411)	0.480	4287 (-10037 18612)	0.557

1105-A | PATIENT PERSPECTIVES ON SOLID ORGAN TRANSPLANTATION FROM DONORS WITH HEPATITIS C-VIREMIA FOR RECIPIENTS WITHOUT HEPATITIS C-VIREMIA

Karen B. Vanterpool[1], Kadiatou Diallo[1], Ellie Kim[2], Sarah E. Van Pilsum Rasmussen[2], Morgan Johnson[2], Zachary Predmore[2], Brittany Barnaba[2], Niraj Desai[2], Hannah C. Sung[2], Olivia Kates[2], Jeremy Sugarman[2] and Christine M. Durand[2], (1)New York University Grossman School of Medicine, (2)Johns Hopkins University School of Medicine

Background: Direct acting antivirals (DAAs) have enabled transplantation from donors with hepatitis C viremia to recipients without hepatitis C viremia (HCV D+/R-). These transplants have been shown to have excellent medical outcomes. Prior qualitative studies on recipient experiences with HCV D+/R- transplants have exclusively enrolled kidney and lung transplant recipients within clinical trials. Less is known about the psychosocial impact and experiences of HCV D+/R- recipients, particularly outside of clinical trials and across multiple organ types. **Methods:** We conducted in-depth, semi-structured interviews with patients at a single center who received transplants outside of clinical trials and were treated for HCV post-transplant to assess their experiences and perspectives. We used thematic analysis to analyze the interviews. **Results:** We conducted interviews between May 2020 through June 2021. We attempted to contact 32 HCV D+/R- recipients and 24 participated (kidney n = 8; lung n = 7; liver n = 5; heart n = 3; simultaneous heart and kidney n = 1). The participation rate was 73% (2 unable to contact, 5 declined, 2 ineligible). Most participants were Male (75%), White (77%), with a mean age of 64 years. Most (62%) received HCV treatment within one month following transplant (ranging from 1 d to 2 mo). Interviewees described their reasons for accepting an HCV D+ organ, challenges and concerns with HCV D+ transplants, the impact of HCV D+/R- transplants on their lives, and their overall experience with HCV D+ transplants. Interviewees' reasons for accepting an HCV D+ organ were based on perceiving it as an "expedient" pathway to transplant and a "safe" option due to the effectiveness of HCV treatment. Some interviewees were concerned about HCV treatment costs and unexpected delays in treatment. Interviewees recounted negotiations with insurance companies for coverage of HCV treatment, which delayed initiation of HCV treatment. After transplant, most did not recall experiencing stigma from others regarding the transplant, yet some reported that their families had concerns about the risk of HCV transmission. Overall, interviewees had positive transplant experiences related to survival, improved health, physical activity, and quality of life. **Conclusion:** Our findings suggest that HCV D+/R- transplant recipients of all organ types outside of clinical trials had positive experiences with little to no concerns about accepting an HCV D+ organ. However, a lack of clarity regarding HCV treatment costs and delays may raise concerns for those receiving future HCV D+/R- transplants as clinical care. Prior to transplant, patients would likely benefit from education about potential HCV treatment costs, insurance-related processes, and risks associated with delays in treatment timing.

f 1106-A | PATIENT REPORTED OUTCOMES AND PATIENT REPORTED OUTCOMES MEASURES POST LIVER TRANSPLANTATION: IMPROVING QUALITY OF LIFE POST TRANSPLANT

Ali Vedadi, University of Ottawa; University of Toronto

Background: Generic or condition-specific Patient-reported Outcome Measures (PROMs) are used to measure physical, mental and social aspects of health to promote patient-centered care. We aimed to identify and summarize generic and transplant specific PRO domains and PROMs that have been assessed and used in liver transplant candidates and recipients. **Methods:** We searched Medline, Embase, Cochrane Database of Systematic Reviews and Register of Trials, PsychInfo, and CINAHL from inception to now, and included studies addressed a PRO or PROM in LT candidates or recipients. Studies were screened by two or more reviewers and included if they met inclusion criteria for our study. Full-text articles were reviewed, and information pertaining to study design, location, date, PROs, PROMs administered was abstracted. **Results:** 341 studies yielded 189 unique PRO domains. Mental health domains (depression, anxiety, and guilt) were most frequently assessed, followed by domains of physical and social health. Fifty-one generic and three condition-specific unique PROMs were identified, with only 13% (n = 45) of studies including condition-specific tools. The most frequent PROMs were the SF-36, Nottingham Health Profile, Hospital Anxiety and Depression Scale, followed by the Liver Disease Quality of Life (LDQoL). The only LT-specific questionnaire identified in our search was the pLTQ, which covers

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transplant-specific domains such as concerns about rejection, side effects of immunosuppressive medication, and post-surgical physical function. **Conclusion:** Very few studies used transplant-specific PROMs, which may partly be related to the scarcity of liver transplant specific instruments. Together, a core set of liver transplant specific PRO domains and recommended PROMs can facilitate standardized assessment and monitoring of key patient-valued outcomes to ensure routine clinical care is truly patient-centered.

1107-A | POOR DENTITION IS ASSOCIATED WITH POOR POST-TRANSPLANT SURVIVAL AMONG ALCOHOL-ASSOCIATED LIVER DISEASE PATIENTS

Tomoki Sempokuya, Patrick Twohig, Shaheed Merani and Nathalie Khoury, University of Nebraska Medical Center

Background: Alcohol-associated liver disease (ALD) has become the leading cause of liver transplantation. Previous studies have tried to identify optimal selection criteria for ALD patients, but many liver transplant centers struggle to select suitable candidates because current prediction models rely on subjective data, such as self-reported alcohol intake. Poor dental hygiene has been associated with overall adverse health outcomes, but has not been evaluated in the post-liver transplant population. Dental clearance is a routine process in most transplant centers, and dental status may provide objective data on self-care. This study evaluated an association between poor dental health and transplant outcomes. **Methods:** We retrospectively identified patients evaluated and listed for liver transplantation at the University of Nebraska Medical Center from 1/1/2015 to 1/1/2020. We then selected patients with a primary or secondary diagnosis of ALD. We obtained data on demographics, concurrent liver disease diagnosis, MELD-Na score, dental status, substance use, social work, neuropsychology, and psychiatry evaluations, committee decision, compliance status, and survival data. We separated patients into two groups: Normal dentition vs. Dental caries, including dental caries, abscess, gingivitis, and edentulous. Survival analysis was done with the Kaplan-Meier survival curve and multivariate analysis with the Cox-proportional Hazard model. **Results:** After excluding patients with unclear dental status, 177 patients were included in this study, with 125 in the dental caries group and 52 in the normal dentition group. The median MELD-Na score at the listing was 17. There were no differences in committee decisions, substance use, and underlying psychiatric comorbidities for baseline characteristics. Concurrent history of hepatitis C infections were higher in the dental caries group (25.6% vs. 9.6%). Post-transplant survival was significantly higher for the normal dentition group than the dental caries group ($p = 0.03$), but post-listing survival did not show a significant difference ($p = 0.09$). The Multivariate Cox Proportional Hazard model did not show a significant hazard ratio for dental status. **Conclusion:** This study showed a decreased post-transplant survival among ALD patients with poor dentition pre-transplant. However, this trend didn't remain significant after multivariate analysis, implying that dental status might be a proxy for other factors. Integrating objective dental status data into prediction models may improve the liver transplant selection process.

1108-A | POST-TRANSPLANT SPONTANEOUS BACTERIAL PERITONITIS DOES NOT WORSEN MORTALITY: A RETROSPECTIVE ANALYSIS OF POST-TRANSPLANT FACTORS AFFECTING MORTALITY

Joseph Cappuccio[1], Karim Osman[1], Brenda Amuchi[1] and Amir Ahmed Qamar[2], (1)Lahey Hospital and Medical Center, (2)Lahey Clinic Medical Center

Background: Hepatic decompensation is widely known to be associated with increased mortality in patients with cirrhosis. Spontaneous Bacterial Peritonitis (SBP) in patients with decompensated cirrhosis further compounds the risk of mortality and may hasten the need for liver transplant (LT). Many patients may continue to experience post-transplant ascites (PTA) and subsequent post-transplant SBP (PTSBP). The clinical impact of PTA and PTSBP remains unclear. Our study aims to determine the prognostic impact of PTA and PTSBP. **Methods:** The study was approved by the Institutional Review Board. Adult patients with cirrhosis, who underwent LT at our institution from 2015-2020, were retrospectively reviewed. Post-transplant ascites was defined by ascites 1 month after LT. PTSBP was diagnosed by an absolute neutrophil count ≥ 250/μL in post-transplant ascitic fluid. Patients were followed from baseline (date of LT) until last follow-up or death. Censoring occurred at the time of last follow-up. Cumulative incidence of outcomes was determined by the Kaplan-Meier method. A Cox regression analysis was conducted to examine mortality association with various predictive factors. **Results:** 428 patients had a LT. 70 patients had PTA (16.35%) and 26 (6.07%%) had at least one episode of PTSBP. Of these, 17 patients were noted to have positive growth on culture taken from ascitic fluid. Culture species included Vancomycin Resistant Enterococcus (6), Enterococcus Faecalis (3), Extended Spectrum Beta Lactamase Klebsiella (2), Coagulase Negative Staphylococcus (2), Enterococcus Faecium (1), Methicillin Resistant Staph Aureus (1), and Streptococcus Anginosus (1). Patients developed their first episode of SBP 0.63 (0.40-3.80) months after their LT. Model for end stage liver disease (MELD-Na) score was associated with mortality in both univariable and multivariable analyses [HR 1.12 (1.10 - 1.15), $p = < 0.001$]. Further, the presence of PTA was significantly associated with mortality [HR 2.06 (1.09 - 3.70), $p = 0.03$]. PTSBP was not found to have a significant association with mortality [HR 1.35 (0.53 - 3.39), $p = 0.53$] (Table 1). The median survival of patients who developed and did not develop PTSBP was more than 5 years (Figure 1). **Conclusion:** Our study highlights that PTSBP may not be associated with worsened survival probability. Interestingly, the presence of PTA was associated with worsened mortality. We acknowledge that the limited sample size and scope of follow-up may alter our observed results. Additional studies are needed to further clarify the clinical implications associated with PTA and PTSBP as well as a potential need for standardization of screening and therapy.

1109-A | PREDICTIVE ROLE OF TRICUSPID REGURGITATION SEVERITY AMONG PERI-LIVER TRANSPLANT PATIENTS: RESULTS FROM A LARGE TERTIARY CARE CENTER

Diana Jomaa[1], Yervant Ichkhanian[1], Kartik Gupta[1], Ammad Javaid Chaudhary[1] and Syed-Mohammed Jafri[2], (1)Henry Ford Hospital, (2)Henry Ford Health System

Background: Cardiovascular disease remains a major contributor to morbidity and mortality among liver transplant (LTx) patients. Tricuspid regurgitation (TR) has been known to contribute to worse outcomes pre-LTx and post-LTx due to hepatic congestion and poor cardiac reserve. In this study, we aimed to further investigate the predictive value of moderate or severe TR on the mortality of pre-and post-LTx patients. **Methods:** This was a retrospective chart review of adult patients (> 18 y of age) who were listed or received LTx during the time period of 2015-2020 at Henry Ford Hospital. Patients who were lost to follow-up post-transplant were excluded from the study. Patients' baseline disease characteristics, most recent pre-LTs transthoracic echocardiogram results were recorded in pre-designed de-identified data sheets. The primary outcome were survival at 1 year and 3 years from the initial LTx evaluation time. **Results:** A total of 1189

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patient records were reviewed, and 609 (51%) (mean age 55.71 ± 10.89, Female 504 (42%)) satisfied the inclusion criteria and were enrolled in the study. Of the 609 patients who were listed, 404 (66%) received LTx during the duration of the study. The prevalence of moderate to severe TR was significantly higher among patients who were not listed (8.45%) as compared to patients who were listed (4.43%), ($p = 0.005$). Among the patients who received LTx (n = 404), the percentage of patients who had moderate-severe TR was 4.5% as compared to 4.4% among the patients who did not receive LTx (n = 580), ($p = 0.97$). One year survival among patients who received LTx was 94% with no significant difference in terms of the rate of moderate to severe TR among the alive vs. the deceased group (4.2% vs. 9.2%, $p = 0.284$, respectively). Similarly, three years survival among patients who received LTx, (survival rate: 84%), and there was no significant difference in-terms of rate of moderate to severe TR (4.4% vs. 5.6%, $p = 0.284$, respectively). Upon stratifying the population based on age and severity of TR, there was no association between moderate-severe TR and 3-year mortality in patients pre-LTx and post-LTx with hazard ratios of 0.744 (95% CI 0.438-1.262) and 0.877 (95% CI 0.517-1.487) respectively. **Conclusion:** Our study provides further insight into the survival rates of patients with TR pre and post-LTx. There is no association between TR and increased risk of mortality in patients pre-LTx or post-LTx. However, there may be an association between degree of TR and getting listed for Tx.

1110-A | PREVALENCE OF PRE TRANSPLANT CARBAPENEM RESISTANT ENTEROBACTERALES (CRE) AND VANCOMYCIN RESISTANT ENTEROCOCCI (VRE) RECTAL COLONISATION AND ITS IMPACT ON POST LIVER TRANSPLANT OUTCOMES

Ameet Mandot[1], Tejas J Joshi[1], Wasim Khot[1], Uday Sanglodkar[1], Alisha Chaubal[1], Hardik R Shah[1], Gaurav Chaubal[1], Aditya Nanavati[1], Rajeev Sinha[1], Hunaid Hatimi[1], Gautham Pranesh[2] and Samir Ramnik Shah[1], (1)Global Hospitals, Mumbai, (2)Mitopower LLC

Background: The data regarding the impact of pre transplant rectal colonization with Carbapenem Resistant Enterobacterales (CRE) and Vancomycin Resistance Enterococci (VRE) organisms on post-transplant outcomes in patients undergoing Liver Transplant, especially from countries with high burden of these infections is scarce. The aim of this study was to assess the prevalence of CRE, VRE rectal colonization and its impact on post transplant outcomes in liver recipient. **Methods:** We did a retrospective cohort study of patients undergoing liver transplant from Jan 2022 to Jan 2023 at our center. We analyzed the prevalence of CRE, VRE colonization in rectal swab and data related to post transplant CRE, VRE infections & mortality from patients records till 3 months post transplant. **Results:** Amongst the 119 patients (79% males) with median age of 45 years, the prevalence of pretransplant CRE and VRE colonization was 32/118 (27.11%) and 9/117 (7.69%) respectively. At a follow up of three months, 20/117(17.09%) and 2/117 (1.71%) patients had developed post-transplant infection with CRE and VRE organisms respectively. In patients who were pretransplant colonised with CRE in rectal swab, the risk of CRE infection (22.6% vs 15.3 %, OR 1.61) [CI 0.57–4.51] and mortality (12.5% vs 4.7% OR 2.92)[CI 0.68- 12.49] within 3 months post-transplant were numerically higher but not statistically significant. There was no association of pre transplant VRE colonisation on post transplant VRE infection and mortality. Post transplant CRE and VRE infection was not associated with any increase in post-transplant mortality. **Conclusion:** There is high prevalence of CRE rectal colonization (27.11%) in patients undergoing liver transplantation in this study. In these CRE colonised recipients there is increased risk of CRE infection & mortality though not statistically significant. This raises issue of choice of pre operative prophylactic antibiotic and the need for change in those who are noted to be colonised with CRE organism.

1111-A | PROGRESSION OF INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF THE PANCREAS AFTER LIVER TRANSPLANT

Bradley T Busebee[1], Jerry Chin[2], Kristin Mara[1], Bradley K. Johnson[1] and Kymberly Watt[3], (1)Mayo Clinic, (2) Waikato Hospital, (3)Mayo Clinic, Rochester, MN

Background: Liver transplantation (LT) and immunosuppression are associated with an increased risk of malignancy. Intraductal papillary mucinous neoplasms (IPMN) are relatively low-risk pre-malignant lesions, though the risk of progression is not well understood in the transplant population. **Methods:** All patients undergoing LT at a large, multi-site academic institution between 1999 and 2012 with mention of IPMN by automated chart review were reviewed. Patients with suspected IPMN within a year prior to transplant were included in the below analysis. Suspected IPMN was defined as either 1) a lesion described as a probable IPMN in a cross-sectional radiology or endoscopic ultrasound report or 2) lesions described as potential IPMNs with potential or definite pancreatic duct (PD) communication and absence of amylase and CEA levels below 250 U/L and 192 ng/mL. The primary outcome was defined as IPMN progression to cancer or development of new, worrisome features (WF) by Sendai criteria post-LT. **Results:** 146 patients with suspected IPMNs were identified. The average clinical follow-up time was 7.8 years. Pre-LT, 1 patient had worrisome features. Post-LT, 7 patients met the primary outcome (5.8%); 2 patients developed cancer associated with a suspected IPMN (1.4%), 6 developed WFs (4.2%), and 1 patient developed both cancer and a WF (0.7%). The average time to the primary outcome was 7.9 years. Cox-proportional-hazard analysis showed no significant difference in the incidence IPMN progression for age, gender, family history of pancreatic cancer, immunosuppression type ($p > 0.05$), continuous tacrolimus trough levels (HR 1.1, $p = 0.44$), or number of active immunosuppression medications (HR 1.39, $p = 0.71$), while combined kidney/liver transplantation (HR 31.6, $p = 0.005$) and pre- LT cholangiocarcinoma (HR 9.9, $p = 0.012$) were significantly associated with progression and a history of smoking (HR 4.42, $p = 0.092$) trended toward association with progression. **Conclusion:** The rate of IPMN progression in LT recipients was similar to that published previously for the general population. Novel findings include combined organ transplant and previous cholangiocarcinoma increased risk of IPMN progression, whereas immunosuppression intensity measures showed no apparent association. IPMNs are indolent lesions resulting in a small event number over long-term follow-up. Larger studies with long term follow-up are needed.

1112-A | RANGE OF DONOR DERIVED CELL FREE DNA IN LIVER TRANSPLANT RECIPIENTS – AN EXPLORATORY ANALYSIS

Kinnari Modi[1], Grigoriy Shekhtman[2], Tara Ruder[2], Hellen Oduor[1], Mingyang Cui[1] and Parvez S. Mantry[3], (1)Methodist Dallas Medical Center, (2)Caredx, (3)The Liver Institute at Methodist Dallas

Background: Donor-derived cell-free DNA (dd-cfDNA) is a serum biomarker widely used to detect graft injury and early rejection in solid organ transplant. Nevertheless, data on the clinical utility of dd-cfDNA in liver transplant recipients with stable allograft function is limited. Therefore, we evaluated dd-cfDNA in liver transplant recipients with normal liver function tests (LFTs). **Methods:** Data was retrospectively collected from 47 liver transplant recipients with dd-cfDNA (AlloSure, CareDx Inc.) measurements from August 2021 to April 2023 at our center. Patients with stable LFTs and no evidence of concurrent rejection were included in the analysis. For patients with multiple dd-cfDNA values, the first value with corresponding LFTs within 30 days was used. The immunosuppression (IS) regimen for these patients consisted of a combination of tacrolimus/ sirolimus/cyclosporin with mycophenolate mofetil (MMF) and/or prednisone. We assessed dd-cfDNA ranges for patients at different times in their post-transplant course. **Results:** 37 patients with dd-cfDNA assessment and LFTs WNL were included. Patients were a median of 1049 days post-transplant (PTX). Of the 37 patients, 11 (29.7%) were $<$ 1-year PTX and 26 (70.2%) were $\geq$ 1-year PTX. Compared to patients $<$ 1-year PTX, patients $\geq$ 1-year PTX were significantly less likely to be on triple IS and prednisone ($p < 0.01$) (Table 1). The population median dd-cfDNA in stable liver allograft recipients was 2.75%. Median dd-cfDNA were significantly higher in patients who were $\geq$ 1-year PTX compared to patients $<$ 1-year PTX (2.9% vs. 1.4%, $p = 0.005$) (Fig. 1). **Conclusion:** Our data show dd-cfDNA is higher in stable liver allograft recipients $\geq$ 1-year PTX compared to earlier PTX, though identifying other contributing factors in a larger population is needed. Notably, more patients $<$ 1-year PTX were on triple IS than those $\geq$ 1-year PTX; therefore, determining if lower dd-cfDNA is associated with higher levels of IS may aid in the potential use of dd-cfDNA for IS titration. Prospective studies are assessing dd-cfDNA patterns in both rejection and stable liver allograft patients. Future directions include exploring the relationship of dd-cfDNA values with changes in IS regimens.

Table 1. Demographic and clinical characteristics of stable liver allograft recipients. AST, aspartate transaminase; ALT, alanine transaminase; ALP, alkaline phosphatase; IQR, interquartile range; MMF, mycophenolate mofetil; PTX, post-transplant.

1113-A | RAPID DEVELOPMENT OF POST-LIVER TRANSPLANTATION NODULAR REGENERATIVE HYPERPLASIA AND PORTAL HYPERTENSION FOLLOWING PERFUSION PUMP USE: A CASE SERIES

Sachiko Oshima[1], Wei Chen[1], Aparna Rege[1], Andrew Barbas[1] and Stephanie Garbarino[2], (1)Duke University, (2)Duke University, Durham, NC

Background: Over the past two decades, solid organ transplant has increasingly relied on normothermic perfusion pumps to extend organ preservation times compared to traditional static cold storage. On September 28, 2021, the TransMedics Organ Care System (OCS) became the first perfusion pump to receive FDA approval for use in liver transplantation (LT). Since then, perfusion pump use has spread widely due to its ability to significantly extend ex-vivo organ viability time. However, limited data exists on the potential adverse consequences of widespread pump implementation. **Methods:** We present a case series of two patients who rapidly developed biopsy proven nodular regenerative hyperplasia (NRH) and portal hypertension following LT with perfusion pump utilization for deceased donor organs at a single institution in 2022-2023. **Results:** Patient one is a 56-year-old male whose donor was a 65-year-old female with chronic hepatitis C who died following a CVA. Patient two is a 50-year-old male whose donor was a 59-year-old male with no known past liver disease who died from cardiac arrest. Both donor organs were placed on the TransMedics OCS pre-transplant for 7 hours and 38 minutes and 18 hours and 29 minutes, respectively. Within weeks of transplant, both patients developed clinical signs of portal hypertension with ascites, hepatic hydrothorax and renal dysfunction requiring initiation of renal replacement therapy. Transjugular pressure readings revealed portal pressure gradients of 12 mmHg and 11 mmHg on initial biopsies which increased to peaks of 18 mmHg and 14 mmHg. Pathology was notable for NRH in both cases without evidence of rejection or fibrosis (Figure). Extensive workup did not reveal a secondary cause for portal hypertension. Both patients required prolonged hospitalizations with consideration of re-transplantation, but were eventually able to stop renal replacement therapy and diuretics with resolution of portal hypertensive symptoms. **Conclusion:** Post-LT portal hypertension resulting from NRH is a rare phenomenon, with few cases reported and none in the immediate post-

transplant setting. While NRH is idiopathic in its etiology, vascular flow abnormalities have historically been linked with its development. Therefore, we hypothesize that use of normothermic perfusion pumps which were used in both cases presented here may be linked to the rapid development of post-transplant NRH. Reassuringly, both patients improved with time and did not require re-transplant.

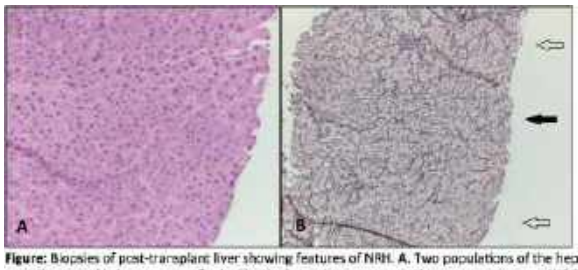

Figure: Biopsies of post-transplant liver showing features of NRH. **A.** Two populations of the hepatocytes - smaller, atrophic hepatocytes, flanked by the larger hepatocytes in the regenerative area (H&E, 100x) **B.** Reticulin stain highlights the key feature of NRH with alternately expanded (white arrows) and compressed (black arrow) hepatic plates (Reticulin, 100x).

1114-A | RISK FACTORS FOR GRAFT-VERSUS-HOST DISEASE IN LIVER TRANSPLANT RECIPIENTS

Frank Lee[1], Kymberly Watt[2], Supavit Chesdachai[1], Tayyab Diwan[1], Timucin Taner[1], Charles B. Rosen[1], Michael D. Leise[1] and Julie Heimbach[1], (1)Mayo Clinic Rochester, Rochester, MN, (2)Mayo Clinic, Rochester, MN

Background: Graft-versus-host disease (GVHD) following liver transplantation (LTx) is a rare and highly fatal complication with few effective treatment options. Identifying risk factors may help prevent this outcome. Cited risk factors include younger donor-older recipient age difference and greater matches between donor-recipient HLA loci. Low vitamin D has been associated with GVHD in bone marrow transplant (BMT). Our study's aim is to assess these risk factors within our single-center experience of GVHD with case-matched controls, in order to determine if avoiding donor-recipient age disparity or close HLA matches is warranted. **Methods:** A single-center retrospective study analyzed all liver transplant recipients from 2002 to 2022, identifying those diagnosed with GVHD. A 4:1 match of controls-to-cases was performed with respect to age, sex, race, and end-stage liver diagnosis. **Results:** GVHD incidence was 0.5% (12/2440 recipients). Time from transplant to presentation was 57 days on average. Time from presentation to confirmed diagnosis was 25 days on average. Clinical presentation was common in skin (12/12), bone (10/12), and gastrointestinal tract (9/12). GVHD mortality rate was 75% (9/12) with mean time from presentation to death of 119 days. 1. Donor-recipient age mismatch Donor age less than recipient age was seen in 75% of GVHD cases. Comparison of GVHD vs. control showed no statistical difference in age mismatch ($p = 0.156$). 2. HLA matching Greater HLA matching was observed in the GVHD group however was not statistically significant ($p = 0.071$). There were 2 cases in the GVHD group in which the donor graft was homozygous (single loci at A, B, DR) and had no mismatches with the recipient. 3. Vitamin D GVHD patients' vitamin D levels at time of transplant were wide-ranging (10-52 ng/mL). No statistical difference was seen between GVHD and matched controls ($p = 0.444$). **Conclusion:** Prior cited risk factors of younger donor-older recipient age difference and high HLA loci matching were not supported in this study; however, HLA loci matching may be a valid association ($p = 0.071$) but underpowered by our small sample size. Vitamin D was determined not to be a risk factor despite its association in BMT. Larger multicenter studies, which would ideally pool together these rare cases of GVHD, are required to further clarify risk factors and inform clinical judgment when selecting donor grafts to minimize GVHD risk.

1115-A | SARCOPENIA PREDICTS POSTRANSPLANT SURVIVAL IN HISPANIC MALE RECIPIENTS

Matías Hernández[1], Carlos Benítez[2], Cecilia Besa[1,3], Antonia Pastore[1], Catalina Grandy[1], Josefa Ghiglino[1], Constanza González[1], Leyla Hadad[1], Jacinta Hermosilla[1], Alejandro Villalon[1] and AASLD Sarcopenia-LT Authors' Group, (1)Pontificia Universidad Católica De Chile, (2)Pontificia Universidad Católica De Chile, Chile, (3)Millenium Institute for Intelligent Helthcare Engineering

Background: An association between sarcopenia and mortality post liver transplantation (LT) has been suggested; however, Skeletal Muscle Index (SMI) cut-off points have not been validated in Hispanic population. In this study, we aim to validate the currently proposed cut-off points. **Methods:** We retrospectively analyzed a cohort of liver transplant recipients at the UC-Christus Clinical Hospital between 2016 and 2020. SMI was measured in CT and MRI by two readers using NIH ImageJ software. Sarcopenia was defined as SMI < 50 cm^2/m^2 in male and < 39 cm^2/m^2 in female patients. Associations between sarcopenia and mortality were analyzed using Cox proportional hazard models. We used univariate and multivariate Cox proportional regression models to predict post-LT mortality. **Results:** 157 liver recipients were included. Mean age 58 ± 10 y/o; 59% male. Main etiologies were NASH 47%, alcohol 13%, autoimmune hepatitis 10%, PBC 7.6%, HCV 6.4%, others 16%. Serum creatinine 1.2 ± 1.0, total bilirubin 8.0 ± 11, INR 2.2 ± 2.3, Na 136.2 ± 6.2, albumin 3.2 ± 0.7, MELD-Na 26 ± 6. Child-Pugh score A/B/C: 11%/34%/55% respectively; 34.4% of patients had sarcopenia. Men had a significantly higher prevalence of sarcopenia compared to women (46.2% vs. 17.2%, $p = < 0.001$). Sarcopenic men had a longer length of stay than non-sarcopenic (24 ± 21 vs. 12 ± 5 d, $p = 0.047$). Sarcopenia was not associated with a higher mortality post-LT. However, in men, sarcopenia was associated with a higher risk of post-LT mortality (HR = 7.0, 95% CI [1.6-32], p = 0.011). In the multivariate analysis, the association between sarcopenia and post-transplant mortality in the male population remained significant (HR = 11.03, 95% IC [1.41-86.3], p = 0.022), MELD (HR = 1.1, 95% IC [1.01-1.21], $p = 0.033$), BMI (HR = 0.82, 95% IC [0.69-0.97], $p = 0.023$) and HTA (HR = 3.18, 95% IC [1-10.08], $p = 0.05$). **Conclusion:** Sarcopenia evaluated by SMI is associated to a markedly reduced survival in male liver recipients. *MH and CB share co-first authorship*

1116-A | STATIN USE IS NOT ASSOCIATED WITH THE INCIDENCE OF POST-LIVER TRANSPLANT ADVERSE CARDIOVASCULAR OUTCOMES

Debra W Yen, Jacob A Ciricillo, Yeshika Sharma, Askanda Osman, Michael Clanahan, Roman A Jandarov, Inuk Zandvakili and Amoah Yeboah-Korang, University of Cincinnati

Background: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality after liver transplantation (LT). Statin therapy is recommended for primary and secondary prevention of ASCVD, though statins remain underutilized in patients with liver disease. In part, adherence is hindered by safety concerns, including the rare risk of hepatotoxicity. Limited data exists on statin use and the incidence of adverse cardiovascular events (CVE) after LT. The primary aim of this study was to determine the association between statin use before or after LT and CVE post-LT. **Methods:** A retrospective review was performed of LT recipients from 2012-2016 at a single center with follow-up through Jan 2023. Hospital discharge ICD-codes and manual chart review were used to identify the primary outcome of post-LT CVE (myocardial infarction, coronary revascularization, heart failure, atrial fibrillation, ventricular tachycardia or fibrillation, cardiac arrest, or stroke). Statin use pre-LT and at 1-, 3- and 5-years post-LT were recorded. Bivariate and multivariate logistic regression were performed. **Results:** Among 364 LT recipients, 65.4% were male, 90.7% Caucasian, mean age 55.9 + 10 at LT, and NASH cirrhosis in 23.1%. 104 patients (28.8%) had a CVE post-LT. All-cause mortality post-LT was 26.9%. Incidence of post-LT CVE was 17% at year 1, 7.4% at year 2-3, and 10.4% after year 3. 49

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients (13.5%) were on statins pre-LT, 15.8% at post-LT year 1, 24.4% at post-LT year 3, and 33.7% at post-LT year 5. Pre-LT statin use was not associated with CVE at any year post-LT. In the bivariate analysis, statin use in post-LT year 1 was associated with significantly increased incidence of CVE at any year post-LT and CVE 1-year post-LT (Table 1). Statin use at 3 or 5 years post-LT was not associated with CVE after post-LT year 3. After multivariate adjustment for age at transplant and history of ischemic heart disease, CAD, diabetes, atrial fibrillation, hypertension, and heart failure, there was no association between pre or post-LT statin use and incidence of post-LT CVE or all-cause mortality. **Conclusion:** In this retrospective cohort, statin use before or after LT was not associated with incidence of post-LT CVE or all-cause mortality after multivariate adjustment of age and pre-LT CV conditions. These findings may be attributable to the majority of post-LT CVE occurring in year 1, with heart failure and atrial fibrillation being most common. However, future directions include multicenter prospective studies and further investigation of the impact of statin adherence for primary and secondary prevention on post-LT CVE.

1117-A | TACROLIMUS USE, COMPARED TO CYCLOSPORINE USE, IS NOT ASSOCIATED WITH WORSE GRAFT OR PATIENT SURVIVAL FOR PATIENTS TRANSPLANTED FOR PBC

Nathan Pham, Lei Yu, Nicole J. Kim, Meredith Pearson, Erin Cleveland, Iris W. Liou, Renuka Bhattacharya, Scott W. Biggins, Rotonya M. Carr and Philip Vutien, University of Washington

Background: Recurrent primary biliary cholangitis (rPBC) affects up to 46% of patients who undergo orthotopic liver transplant (OLT) for PBC. Cyclosporine use, compared to tacrolimus use, has been associated with reduced rates of rPBC. However, it is uncertain if cyclosporine use is also associated with improved graft and recipient survival in a US cohort. In this study, we aimed to assess the association between tacrolimus and cyclosporine use on graft loss and mortality among recipients transplanted for PBC. **Methods:** We analyzed all adult U.S. recipients with primary biliary cholangitis undergoing liver transplant from 1/1988 to 12/2022 in the Organ Procurement and Transplantation Network (OPTN) database. Patients were divided into tacrolimus and cyclosporine groups based on immunosuppression regimen at time of . We excluded pediatric, living donor, re-OLT, and multi-organ transplant recipients. We used Kaplan-Meier survival curves and multivariable mixed Cox proportional hazards regression (adjusting for recipient age, sex, MELD, history of hepatocellular carcinoma (HCC), donor donation after cardiac death (DCD) status, and transplant cold ischemia time) to determine the association between immunosuppressive regimen and graft loss or mortality. **Results:** Among 5311 patients, 3765 (70.9%) received tacrolimus and 1546 (29.1%) received cyclosporine. The majority (n = 1362, 88.1%) of patients who received cyclosporine underwent OLT from 1988 to 1999, while the majority of those who received tacrolimus (n = 2976, 79.0%) underwent OLT after 1999.The median follow-up time was 8.5 years (IQR 13.3 y). The overall 5-year graft survival rate was 83.2% for the tacrolimus group and 83.2% for the cyclosporine group (logrank $p = 0.11$). The overall 5-year recipient survival rate was 86.6% for the tacrolimus group and 86.5% for the cyclosporine group (logrank $p = 0.67$). There was not a significant association between tacrolimus vs. cyclosporine use and graft survival (adjusted HR 0.67, 95% CI 0.25-1.83) or patient survival (adjusted HR 0.82, 95% CI 0.26-2.64). Among those who had a listed cause of death, 19 (4.1%) in the cyclosporine group and 27 (4.5%) in the tacrolimus group died from recurrent disease ($p = 0.7$). **Conclusion:** Although prior studies have identified an association between tacrolimus and increased rates of rPBC in patients who underwent OLT for PBC, this analysis of the OPTN database demonstrated no association between use of tacrolimus or cyclosporine at discharge with regards to graft or patient survival. Future studies should continue to investigate if there a relationship between immunosuppression regimen and graft or patient survival.

1118-A | THE ASSOCIATION OF WAITLIST DURATION WITH GRAFT FAILURE AFTER LIVER TRANSPLANT DIFFERS BASED ON AGE

Ashley Spann, Irene Feurer, Scott Rega, Seth J. Karp and Manhal Izzy, Vanderbilt University Medical Center

Background: With increasing demand for organs, patients tend to wait for long periods. Concomitantly, there has been an increase in the age of patients on the waitlist as well as transplants in older patients over the past decade. Prior data suggested adverse impact of advancing age on liver transplant outcomes. It is unknown, however, if the duration of waitlisting influences this association. We aimed to assess the joint effects of age at transplant and pre-transplant waitlist duration (WLD) on likelihood of graft failure (GF). **Methods:** This retrospective analysis analyzed adult liver only deceased-donor transplant recipients between 3/1/2002 and 1/1/2021 using Scientific Registry of Transplant Recipients Standard Analysis Files. Exclusion criteria were age < 18 years, prior transplant, being Status 1A at transplant, receiving Model for End-Stage Liver Disease (MELD) exception points for hepatocellular carcinoma, and inadequate or unavailable follow-up. The primary outcome was graft failure, defined as re-transplantation or death from any cause. Age at transplant was classified as < or ≥ 55-years based on the 50th percentile threshold. Kaplan-Meier and Cox proportional hazards regression models analyzed the effects of age at transplant (years), age group, WLD (months), MELD at transplant, gender, race, and the age group by WLD interaction on the likelihood of GF. **Results:** A total of 61,526 patients were included (64% male, 88% white). Patient age at transplant and WLD averaged 54 ± 10 years and 7.2 ± 13.6 months. Overall analyses demonstrated that age (≥ 55 y), MELD at LT, WLD, race and gender were significantly associated with GF (all $p < 0.05$). A statistically significant age group by WLD interaction ($p < 0.001$) indicated that the effect of WLD on GF varied between the age groups. Subsequent age group-specific multivariable models are summarized in the Table. These multivariable models demonstrated that: 1) patients ≥ 55 had increased likelihood of GF with longer WLD; 2) increasing MELD at LT was independently associated with GF only among patients ≥ 55; and 3) male gender and black race were associated with increased risk of GF, whereas non-white non-Black race was associated with reduced likelihood of GF. **Conclusion:** This study highlights the differential effect of WLD on risk of graft loss in patients above and below age 55 after adjusting for effects of MELD, race and gender. For patients under age 55, longer WLD is associated with reduced likelihood of graft failure after liver transplantation. Whereas, among those 55 years or older, increased WLD and higher MELD score at LT are associated with increased likelihood of graft failure. These findings may advocate for stronger consideration of higher risk grafts in patients 55 and older to decrease WLD before further progression of severity of liver disease.

1119-A | THE BURDEN OF PSYCHIATRIC DISEASE AND TREATMENT PATTERNS FOLLOWING LIVER TRANSPLANTATION–A LARGE NATIONAL DATABASE INVESTIGATION

Alex R. Jones[1], Yue Jiang[2], Prajwal Gowda[3], Madhukar Patel[1], Ben Lippe[1], Akhil Shenoy[4], Tami Gurley[1], Van Ngo[1], Mary Olumesi[1], Raelene E. Trudeau[1], Alvaro Noriega Ramirez[1], Layne Jordan-Genco[1], Arjmand R. Mufti[1], Amit G. Singal[1], Lisa B. VanWagner[1] and Sarah Rosanna Lieber[1], (1)University of Texas Southwestern Medical Center, (2)Duke University, (3)UT Southwestern School of Medicine, (4)Columbia University Medical Center, New York, NY

Background: Psychiatric disease is common after liver transplantation (LT) and associated with worse patient and graft outcomes. Management is essential to improving care for LT recipients yet has not been well characterized. We aimed to describe the burden of psychiatric disease and treatment patterns among a nationally representative cohort of LT recipients. **Methods:** LT recipients aged 18-64 years with ≥ 6-month pre-LT and ≥ 1-year post-LT outcomes from 2006-2021 were identified using IQVIA PharMetrics Plus, a nationally representative U.S. database of commercial medical and pharmacy claims. Psychiatric disease was defined using ≥ 2 outpatient or ≥ 1 inpatient ICD-9/10 codes. Pharmacologic therapy and psychotherapy were identified by CPT codes. We used multivariable logistic regression to identify factors associated with psychiatric disease and subsequent receipt of pharmacologic therapy. **Results:** Among 1,742 LT recipients, 496 (28%) were diagnosed with psychiatric disease (Table 1). Factors significantly associated with psychiatric disease included female sex (aOR 1.66, [95% CI 1.29, 2.13]), longer LT hospitalization length of stay (aOR 1.68 [1.31, 2.16]), modified Charlson Comorbidity Index (CCI) > 3 (aOR 1.60 [1.12, 2.26]), and pre-LT psychiatric history (aOR 6.05 [4.76, 7.74]). Among these patients, 321 (65%) received pharmacologic therapy, 161 (32%) received psychotherapy, 99 (20%) received multimodal therapy, and 113 (23%) received no therapy. Of 405 LT recipients on pharmacologic therapy pre-LT, 306 (76%) continued therapy post-LT. Predictors of receiving pharmacotherapy post-LT included HCC (aOR 2.05 [1.27, 3.35]), and pre-LT psychiatric disease (aOR 3.01 [1.97, 4.63]). SSRIs were the most prescribed medications (37%), followed by benzodiazepines (18%), and atypical antipsychotics (14%). Among all claims for psychotropic medications, 23% were prescribed by primary care providers, 10% by psychiatrists, and 7% by hepatologists. Severe psychiatric complications after LT occurred in 9 patients (2%) (1 suicidal ideation; 8 psychiatric hospitalizations). **Conclusion:** Over 1 in 4 LT recipients were diagnosed with psychiatric disease in a large national database, with two-thirds requiring pharmacologic therapy, and just under a quarter receiving no therapy. Female sex, increased comorbidity, prolonged LT length of stay and preexisting psychiatric disease were associated with psychiatric diagnosis, highlighting potential vulnerable populations in need of psychiatric monitoring and treatment post-LT.

Table 1: Sociodemographic and Clinical Characteristics of Adult Liver Transplant Recipients Stratified by Psychiatric Comorbidity (N=1,742)

VARIABLE	POPULATION			P VALUE

1120-A | THE EFFECT OF TENOFOVIR DISOPROXIL FUMARATE USE ON BONE MINERAL DENSITY IN LIVER TRANSPLANT RECIPIENTS

Ilker Turan[1], Ferit Celik[1], Alper Uysal[1], Ali Senkaya[2], Esra Nur Nur Durmazer[1], Murat Zeytunlu[3], Fulya Gunsar[1], Zeki Karasu[1] and Ulus S. Akarca[1], (1)Ege University Faculty of Medicine, Izmir, Turkey, (2) Department of Gastroenterology, (3)Ege University Faculty of Medicine, Organ Transplantation Application and Research Center, Izmir, Turkey

Background: The impact of tenofovir disoproxil fumarate (TDF) on bone mineral density (BMD) is well-known, but there is a lack of sufficient data regarding its effects in liver transplant patients. We aimed to investigate the effect of TDF use on BMD in patients who underwent liver transplantation due to hepatitis B-related liver disease. **Methods:** The results of bone densitometry [dual-energy X-ray absorptiometry (DEXA)] performed with a one-year interval were evaluated for 79 patients who underwent liver transplantation and initiated TDF between July 2009 and June 2019. Wilcoxon analysis was used to analyze research data. **Results:** Thirty patients who started TDF without baseline DEXA measurement were excluded from the identified 79 patients. Forty-nine patients who had baseline DEXA measurement before initiating the medication and had the first follow-up DEXA measurement within the first year after medication initiation were included into the study. Among the patients, 32 (65%) were male, and the mean age was 53. Patients were evaluated at the outpatient clinic every three months. Follow-up DEXA measurements were repeated in all 49 patients at the one year. The mean baseline FRAX major osteoporotic fracture risk and hip fracture risk were 3.98% and 0.48%, respectively. The mean baseline values ($\pm$SD) of bone mineral density for total hip and lumbar spine (L1-L4) were 0.93 ± 0.15 g/cm2 and 0.95 ± 0.34 g/cm2, respectively. After one year, BMD values for total hip and L1-L4 were 0.95 ± 0.37 g/cm2 and 0.97 ± 0.18 g/cm2, respectively. When comparing the two measurements, there were no significant differences in total hip ($p = 0.54$) and L1-L4 ($p = 0.07$) BMD measurements. The mean baseline T-score ($\pm$SD) for total hip and L1-L4 were -0.71 ± 1.1 and -0.92 ± 1.3, respectively. The T-scores for total hip and L1-L4 at the one year later were -0.86 ± 1.1 and -1.04 ± 1.3, respectively. The statistical analysis using Wilcoxon test for the one-year change in L1-L4 T-score revealed a significantly lower T-score measurement ($p = 0.014$). **Conclusion:** Our study demonstrated a significant decrease in lumbar BMD after one year of TDF use in liver transplant recipients.

1121-A | THE NATIVE AMERICAN LIVER TRANSPLANT EXPERIENCE AT A LARGE SOUTHWESTERN LIVER TRANSPLANT CENTER

David Chascsa[1], Blanca Lizaola-Mayo[1], Caroline C Jadlowiec[1], Adam J Milam[1], Nathan L Delafied[1], Elizabeth H Stearns[1], Timethia J Bonner[2] and Rolland C Dickson[1], (1)Mayo Clinic Arizona, Phoenix, AZ, (2) Mayo Clinic

Background: Health equity in liver transplantation (LT) implies providing fair access and prioritizing patients who will most benefit from LT. American Indian (AI) patients accounted for 0.8% of LTs performed in 2020 according to OPTN, despite increased prevalence of end-stage liver disease (ESLD) in AI populations. Further highlighting the health disparity, only 30% of AIs awaiting solid organ transplantation underwent transplant compared with 49% of waiting non-Hispanic White (NHW) patients. The Mayo Clinic in Arizona (MCA) is a high-volume LT center geographically near large AI populations. We sought to characterize the LT experience of AI patients at MCA. **Methods:** This was a retrospective cohort study of all patients referred for LT at MCA from 2017 to 2022. Race and ethnicity were self-reported. Transplant specific details included total number of referred patients by race and ethnicity, number evaluated and transplanted, etiology of ESLD, graft loss and death. Stata was used to perform statistical analysis. Chi square was used to determined statistical significance with a p-value < 0.05. **Results:** AIs accounted for 4% (n = 135 of 3218) of LT referrals. Compared to Black, Hispanic and NHW cohorts, a smaller percentage of referred AI patients underwent evaluation. Evaluated AIs were statistically less likely to be listed for LT compared to NHW patients (Table 1). The percentage of referred AI patients undergoing LT

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was statistically lower than NHWs. Once listed, the percentage of AIs undergoing LT was similar to NHWs. Alcohol (ALD) and NASH cirrhosis comprised 64% of LT indications for AI patients. ALD prevalence increased from < 20% in 2017 to 37.5-100% in subsequent years. No cholestatic or autoimmune ESLD was observed. The AI cohort had 9 (33.3%) graft failures and 7 (25%) deaths. Total graft failures and deaths were significantly higher in AIs than NHWs. Causes of graft failure or death included: primary non-function, DCD-cholangiopathy, metastatic hepatobiliary malignancy, chronic rejection, COVID-19, acute-on-chronic respiratory failure, hemorrhagic stroke, and cardiac arrest. **Conclusion:** AIs comprised a small percentage of those referred for LT at a large LT center positioned in a favorable geographic area to serve AI patients. This was higher than the overall UNOS percentage but likely lower than expected for the geographic area. Of AIs referred for LT, a substantially smaller percentage were transplanted despite the same leading indications for LT. In our cohort, the lower number referred that were transplanted and lower number evaluated that were waitlisted accounted for the disparity. Graft and patient survival were also significantly lower. We suspect these disparities are attributable to social determinants of health such as language barriers, transportation, and unfamiliarity with the transplant process. Novel interventions such as an AI patient navigator are needed to achieve health equity.

1122-A | THE RELATIONSHIP BETWEEN SERUM ATHEROGENIC RISK AND NONALCOHOLIC FATTY LIVER DISEASE AMONG LIVER TRANSPLANT RECIPIENTS

Shreya Garg[1], Alok Baral[1], Audrey Ang[1], Madison Nguyen[1], Rehan Razzaq[1], Tamoore Arshad[1], Hiba Khan[1], Ian O'Connor[1], Siddiq Elmahdi[1], Michael Tseng[1], Vaishali Patel[1], Margery Connelly[2] and Mohammad S. Siddiqui[1], (1)Virginia Commonwealth University Health System, (2)University of Florida

Background: Liver transplant (LT) recipients are at increased risk of atherosclerotic cardiovascular disease. A strong association between nonalcoholic fatty liver disease (NAFLD), fibrosis severity and atherosclerosis has been demonstrated in the general (e.g. non-transplant) population, however, no such data exists in LT recipients. Thus, it remains unclear if the presence of NAFLD increases the risk of atherosclerosis above and beyond that of LT alone. Thus, the aim of the current study was to better define the interaction between atherosclerosis and NAFLD among LT recipients. **Methods:** In this prospective study, 111 LT recipients were prospectively enrolled. All study participants underwent vibration controlled transient elastography and had blood drawn after an overnight fast. A controlled attenuation parameter (CAP) value > 270 dB/m was defined as presence of NAFLD. Atherogenic risk was quantified via NMR-based measurement of LDL, VLDL and HDL particles. Lipoproteins associated with increased atherogenic risk include smaller LDL and HDL size and increased small LDL and large VLDL particle concentrations with a concomitant decrease in large HDL particles. **Results:** Prevalence of NAFLD was 52% in the LT recipient cohort. Plasma LDL-C was similar between patients with and without NAFLD, however, patients with NAFLD had lower HDL-C (44 ± 16 vs. 56 ± 16 mg/dL; $p < 0.001$) and higher triglycerides (185 ± 121 vs 122 ± 51 mg/dL; $p = 0.003$). LT recipients with NAFLD had a more atherogenic lipoprotein profile characterized by smaller LDL particle size (20.54 ± 0.67 vs. 20.94 ± 0.53 nm; $p = 0.019$), HDL particle size (8.99 ± 0.51 vs. 9.37 ± 0.64 nm; $p < 0.001$) and VLDL particle size (50.4 ± 9.0 vs 45.1 ± 8.0 nm; $p < 0.001$). NAFLD was associated with an increase in size and concentration of atherogenic VLDL and LDL particles, and a decrease in anti-atherogenic HDL particles (Figure 1). Finally, Lipoprotein Insulin Resistance Index (LP-IR), a composite measure of atherogenic lipoprotein concentrations and insulin resistance that is linked to increased CVD risk, was significantly higher among LT recipients with NAFLD (56 ± 22 vs $37 \pm 20\%$; $p < 0.001$). **Conclusion:** The presence of NAFLD in LT recipients is associated with increased

markers of atherosclerotic risk and thus establishes post-LT NAFLD as a risk factor for CVD. Additional prospective studies are required to better understand how NAFLD and circulating lipoproteins may interact together to promote atherosclerotic events.

FIGURE 1: Impact of NAFLD on Lipoproteins in LT recipients

1123-A | THE ROLE OF IMMUNOSUPPRESSION REGIMEN CHOICE ON THE RISK OF EARLY AND LATE OPPORTUNISTIC INFECTIONS AFTER LIVER TRANSPLANTATION

Alyssa Mezochow[1], Ranganath G. Kathawate[2], David Goldberg[3] and Therese Bittermann[1], (1)University of Pennsylvania, (2)Wayne State University, (3)University of Miami

Background: The burden of opportunistic infections (OIs) after liver transplantation (LT) has not been evaluated on a large scale. Further, the significance of certain clinical factors, such as immunosuppression decision-making, on this risk in adults is unknown. **Methods:** This was a retrospective cohort study of first LT alone recipients between 1/1/2007-12/31/2016 using Medicare claims data linked to the Organ Procurement and Transplantation Network database. Early (d 1 y from LT) and late (> 1 y) hospitalizations for OIs were identified using validated ICD-9/10 codes. Multivariable Cox proportional hazards models evaluated the factors independently associated with early or late OI hospitalization. Patients were censored at death, retransplantation or end of follow-up. **Results:** The study cohort (n = 11,320) was 64.0% male, 71.9% White, 14.7% Hispanic, and 8.1% Black with median age of 61 years (IQR: 54-66). Liver disease etiologies included: hepatitis C virus (36.3%), alcohol-associated liver disease (ALD; 21.7%) and non-alcoholic steatohepatitis (NASH; 14.5%). Median follow-up time was 4.7 years (IQR: 2.8-7.1). During follow-up, 13.2% of the cohort had e 1 OI hospitalization. Among the 2,638 individual OI hospitalizations identified, 61.9% occurred d 1 year from LT. OI causes included: cytomegalovirus (45.4%), aspergillus and endemic mycoses (20.6%), disseminated candidiasis (10.8%), varicella zoster virus (12.7%), tuberculosis and non-tuberculous mycobacteria (4.4%) and other (4.2%). Neither induction therapy ($p = 0.173$) nor maintenance regimen at LT discharge ($p = 0.288$) were associated with early OI hospitalization (Table). However, maintenance regimen at 1 year was associated with late OI hospitalization ($p < 0.001$) with steroid-based and mechanistic target of rapamycin inhibitor-based regimens conferring the highest risk (Table). An increased risk of early OI was also observed with NASH or primary sclerosing cholangitis (PSC; HRs 1.30 and 1.91 vs ALD; $p = 0.001$) and worsening creatinine (HR 1.11 per 1mg/dL; $p = 0.001$, and of late OI with PSC (HR 1.82 vs ALD; $p = 0.003$) and in women (HR 1.30; $p = 0.002$). **Conclusion:** Over 1 in 10 patients are hospitalized for an OI post-LT. While early immunosuppression choice was not associated with OI hospitalization d 1 year from LT, maintenance regimen at 1 year led to a differential risk of late OI. Further evaluation of the increased risk of post-LT OI observed among female, NASH and PSC recipients is warranted.

1124-A | TRAJECTORIES OF PAIN IN CIRRHOSIS PATIENTS FROM BEFORE TO AFTER LIVER TRANSPLANTATION

Jessica Beth Rubin[1,2], Rebecca Loeb[1], Cynthia Fenton[1] and Jennifer C. Lai[1], (1)University of California-San Francisco, (2)San Francisco VA Health Care System

Background: Pain is highly prevalent in cirrhosis patients and is often presumed to be related to complications of decompensated liver disease. Thus, we believe that pain will improve after liver transplantation (LT), though actual pain trajectories from before transplant to after transplant have not been characterized. We sought to explore the relationship between pre- and post-LT pain severity in a large retrospective cohort of cirrhosis patients. **Methods:** We included all patients with cirrhosis seen for an initial visit in UCSF hepatology clinics 2013-2022 who subsequently underwent LT. Baseline pain severity was defined as the average Numeric Rating Scale (NRS) score recorded during hepatology clinic visits over the 6 months prior to LT; post-LT pain was recorded at clinic visits from months 2-12 post-LT (excluding immediate post-operative period). Pain severity was classified using well-defined cutpoints of: none (0) mild (1-3), moderate (4-6), or severe (7-10). In addition to NRS scores, we also collected baseline sociodemographic, clinical, and laboratory variables. We created a LOESS curve to display pain severity over time by baseline pain category (no/mild vs moderate/severe), and then used generalized estimating equations to model the effect of time, baseline pain, demographic, and clinical covariates on the change in pain since baseline. **Results:** 556 patients who underwent liver transplant at UCSF met our inclusion criteria; median age was 59 (IQR 53-63); 69% were male and 43% were non-LatinX White. The most common cirrhosis etiology was alcohol (40%). A median of 1 NRS score (IQR 1-2) was recorded during the baseline period, during which 23% reported moderate/severe pain. A median of 5 pain scores (IQR 3-6) were collected during follow up from months 2-12 post-LT. Overall, pain continually decreased with each passing month over the year post-LT ($b_{time} = -0.08$). On average, patients with moderate/severe baseline pain showed a greater reduction in pain after LT compared to patients with mild/no baseline pain ($b_{bl\ pain} = -4.2$). Patients with moderate/severe pain reported an average *reduction* of 2.9 NRS points from pre- to 6-months post-LT, while those with no/mild pain reported an average *increase* of 1 NRS point during this same time period—a difference which persisted after controlling for demographic and clinical covariates (Figure). **Conclusion:** Pre-LT pain severity is the most significant predictor of change in pain after LT: patients with moderate/severe pain before LT experience meaningfully *reduced* pain within the months following transplant, whereas patients with no/mild pain experience mildly *increased* pain, trends which persist up to 1-year post-LT. These findings suggest that the most severe pain in this population may be related to cirrhosis complications and thus may also improve rapidly post-LT; these data may help providers set expectations for patients regarding pain severity in the year following LT.

1125-A | UTILIZATION AND OUTCOMES OF HEPATITIS B VIRUS-POSITIVE GRAFTS FOR LIVER TRANSPLANTATION IN THE UNITED STATES

Kenji Okumura, Abhay Dhand, Ryosuke Misawa, Hiroshi Sogawa, Gregory R. Veillette, Roxana I. Bodin, David C. Wolf and Seigo Nishida, Westchester Medical Center

Background: As demand for transplantation increases, livers from hepatitis B virus (HBV) positive donors have been used to expand the donor pool. The aim of our study was to assess the nationwide trends and outcomes of liver transplantation (LT) while using grafts from HBV+ donors in HBV negative (HBV-) recipients. **Methods:** HBV+ grafts comprised to two groups: HBV+ donor: defined as either HBV NAT or HBV surface antigen-positive, and HBc+ donor: defined as HBV core antibody positive along with negative HBV NAT and HBV surface antigen. HBV negative donor (HBV-) was defined as HBV NAT, HBV surface antigen and HBc antibody negative. Using the United Network for Organ Sharing database between Jan-2015 to 2022, HBV+ (n = 59), HBc+ (N = 568) and HBV- (n = 9,043) adult LT recipients were identified. Multi-organ transplant and re-transplant were excluded. Propensity score matching was performed using 6 variables. Post-transplant survival analysis was performed using Kaplan-Meier method and Cox-hazard proportional regression model. **Results:** The number of LT using HBV+ grafts increased during the study period ($p < 0.032$). In HBV+ and HBc+ groups, recipients were older (median age: 59 vs 57, $p < 0.010$), had higher rates of diabetes (32% vs 27%, $p = 0.020$), lower rate of dialysis at transplant (3.4 % vs 8.3% vs 16%, $p < 0.001$), lower median MELD scores (18 vs 20 vs 25, $p < 0.001$), and lower rate of ICU admission at transplant (1.7% vs 9.9% vs 15%). There was an increase in percentage of national organ sharing ($p < 0.001$), and utilization of concurrent HCV positive organs ($p < 0.001$). Donor characteristics were similar in both the groups. Overall survival and graft survival were comparable between HBV+, HBc+ and HBV- in non-matched and matched cohorts. (figure 1). HBV+ and HBc+ grafts were not associated with any increase in mortality (HR 1.06, 95% CI 0.94-1.19, $p = 0.35$) or graft loss (HR 1.06, 95% CI 0.94-1.18, $p = 0.34$) during the median follow up period of 4 years. No seroconversion in the recipients was reported from HBV+ or HBc+ livers within three years post-transplant and no increase in rate of rejection episodes were noted within one-year post-transplant. **Conclusion:** Overall and graft survival of liver transplant recipients using HBV+ or HBc+ livers were comparable to HBV negative liver transplants. With careful recipient selection and further advances in HBV vaccination and therapeutics, LT using HBV+ donors can be used to successfully expand the donor pool.

1126-A | UTILIZATION OF SGLT2 INHIBITORS AND GLP-1 AGONIST IN LIVER TRANSPLANT RECIPIENTS: ASSESSING CURRENT PRACTICE AND EXPLORING EXTRAHEPATIC MANIFESTATIONS OF POST TRANSPLANT NAFLD

Hamza Khan, Benjamin Heriford, Lily Kuo, Jonathan Selzman and Fabian Rodas, UT Health San Antonio

Background: Nonalcoholic fatty liver disease (NAFLD) is a prevalent comorbidity among liver transplant recipients (LTR) and is associated with disease progression and complications. Despite limited data on novel diabetic agents in NAFLD and post-LTR,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

medications such as sodium-glucose cotransporter 2 (SGLT2) inhibitors and glucagon-like peptide 1 (GLP-1) agonists are increasingly being prescribed for glycemic management in this population. This study aims to evaluate the extent of utilization of SGLT2 inhibitors and GLP-1 agonists in a cohort of LTR and investigate the rates of NAFLD and extrahepatic manifestations of NAFLD. **Methods:** A retrospective chart review was conducted on patients who underwent transplantation at a large tertiary academic medical center. Inclusion criteria included liver transplantation between 2013 and 2017 and a diagnosis of type 2 diabetes mellitus (T2DM). Exclusion criteria included multiorgan transplantation or death within one year post-transplantation. Baseline data, including demographics, were obtained prior to transplantation, and subsequent follow-ups were conducted at 1, 3, and 5-year post-transplant intervals. The rates of the following complications were assessed: metabolic syndrome (MS), NAFLD (diagnosed by ultrasound or biopsy), heart failure (HF), major adverse cardiovascular events (MACE), and composite kidney outcomes. **Results:** A total of 83 patients were included in this study (75% male, 70% Hispanic, mean age 64). Among them, 73 patients (83%) underwent orthotopic liver transplantation (OLT), while 10 patients (12%) underwent living donor transplant (LDT). At 5 years of follow-up, 12 patients (15%) were prescribed a GLP-1 agonist, while 8 patients (9%) were prescribed an SGLT2 inhibitor. The rate of NAFLD was 52% (86% de novo, 14% recurrent). Extrahepatic complication rates among patients who developed NAFLD compared to those who did not develop NAFLD are detailed in Figure 1. MS was strongly correlated with the development of NAFLD ($r = 0.315$, $p = 0.004$). **Conclusion:** Patients who developed NAFLD had higher rates of HF and cardiovascular events. Patients with MS were more likely to develop NAFLD. SGLT2 inhibitors and GLP-1 agonists have shown promise in reducing these complications. Although our cohort size was insufficient to assess the long-term benefits of these agents, our findings underscore the necessity for large-scale and multicenter clinical trials to establish their safety in liver transplant recipients.

1127-A | VACCINATION, MONOCLONAL ANTIBODY AND MYCOPHENOLATE EFFECTS ON CLINICAL OUTCOMES IN LIVER VERSUS KIDNEY TRANSPLANT RECIPIENTS WITH COVID-19 INFECTION

Ashley Francis[1], Sara Farooqui[1], Suraj Suresh[2] and Syed-Mohammed Jafri[3], (1)Wayne State University School of Medicine, (2)Henry Ford Health, (3)Henry Ford Health System

Background: We aim to evaluate how vaccination, monoclonal antibody (MAB) treatment, and mycophenolate use correlate to outcomes for liver and renal transplant (LRT) recipients infected with SARS-CoV-2. **Methods:** A retrospective study of LRT recipients diagnosed with COVID-19 between 3/2020 to 1/2022 was performed. We recorded data on patient demographics, immunosuppressants, vaccine dose numbers, MAB treatment, hospitalization, length of stay (LOS, days), mechanical ventilation (MV) use, as well as 3- and 6-month mortality. **Results:** Of 255 LRT recipients diagnosed with COVID-19, 68 (26%) liver, 177 (69%) renal, and 10 (4%) dual LRT patients were identified. When comparing liver transplant to renal transplant patients, there was no significant difference in hospitalization and mortality. Overall, no significant correlation was found between number of vaccine doses (up to 3) and hospitalization rates ($p = 0.948$), LOS ($p = 0.688$), 3-month mortality ($p = 0.549$), or 6-month mortality ($p = 0.595$). 65 (25%) patients were treated with MABs; these had fewer hospitalizations (37% vs 68% $p < 0.001$) and a trend towards reduced mortality at 3 months (11% vs 18% $p = 0.177$) and 6 months (11% vs 20% $p = 0.092$). However, when comparing 12 liver transplant to 51 renal transplant recipients treated with MABs, there was no significant difference in hospitalization or mortality at 3 or 6 months. Mycophenolate use in 199 patients was associated with increased hospitalization (62% vs 55% $p = 0.383$), MV (24% vs 10% $p = 0.135$), and mortality at 3 and 6 months respectively when compared to non-users (18% vs 9% $p = 0.099$ and 20% vs 11% $p = 0.123$). Of 78 liver transplant patients, 53 (68%) were on mycophenolate. Similarly, within this group, mycophenolate use was associated with increased hospitalization rates (58% vs 44% $p = 0.231$), and mortality at 3 and 6 months respectively when compared to non-users (19% vs 0% $p = 0.020$ and 11% vs 0% $p = 0.014$, respectively). Of 187 renal transplant patients, 152 (81%) were on mycophenolate.

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Within this group, there was no difference in hospitalization rates among users and non-users (62% vs 62%). When comparing 47 liver to 146 renal transplant patients on mycophenolate (excluding dual LRT patients), there was no significant difference in hospitalization ($p = 0.672$) or mortality at 3 months ($p = 0.595$) or 6 months ($p = 0.530$). **Conclusion:** Our data demonstrates that MAB treatment significantly reduces hospitalizations and 3- and 6-month mortality, irrespective of the type of transplant. Mycophenolate was associated with increased hospitalizations and mortality rates, with common trends seen in liver transplant patients alone. Our data further suggests that a 3-vaccine series was inadequate to predict improvements in clinical outcomes for LRT recipients, suggesting further study of a fourth mRNA vaccine dose and the use of tixagevimab/cilgavimab.

1128-A | WEIGHT STATUS OF PATIENTS AT THE MOMENT OF LIVER TRANSPLANTATION: NOT ONLY A PROBLEM OF NAFLD PATIENTS!

Isaac Ruiz[1], Mélanie Tremblay[2], Melissa Bouhraoua[1], Crystèle Hogue[1], Amal Trigui[1], Genevieve Huard[3], Catherine Vincent[3], Christopher F. Rose[2,4] and Chantal Bémeur[1,4], (1)Centre De Recherche Du Centre Hospitalier De l'Université De Montréal, (2)Hepato-Neuro Laboratory, Centre De Recherche Du Centre Hospitalier De l'Université De Montréal, (3)Centre Hospitalier De l'Université De Montréal, (4)Université De Montréal

Background: The global obesity epidemic continues to progress at an alarming rate. Non-alcoholic fatty liver disease (NAFLD), the hepatic manifestation of metabolic syndrome, is becoming the most common cause of end-stage liver disease (ESLD) and indication for liver transplantation (LT). Documenting the weight status of patients at the moment of the LT is imperative to better understanding of nutritional status evaluation and to improve the management pre and post-operatively of patients. The aim of this study was to evaluate the weight status as part of the nutritional status of patients at the moment of LT, overall and according to the primary liver cirrhosis etiology. **Methods:** This is a retrospective analysis including all consecutive patients who underwent LT at the Centre hospitalier de l'Université de Montréal (CHUM) between 2019 and 2021. Only patients with biological, clinical and or radiological confirmed cirrhosis were included. Presence and degree of ascites were recorded. Underweight, overweight and obesity was defined as body mass index (BMI), < 18, equal or superior to 25.0 and 30.0, respectively. Results of BMI were corrected by the presence of ascites and/or oedema. **Results:** During the study period, 181 patients were transplanted at the CHUM. 155 patients with cirrhosis were included in this study. Among them, 104/155 (67.1%) were men, mean age was 52 years old (range 18-69). At the moment of transplantation, overall median BMI was 24.4 (range 14.9 – 43.1, mean 25.5). Underweight was present in 12/155 (7.7%), overweight was present in 58/155 (25.8%), and obesity was present in 47/155 (21.3%). According to the main etiology of chronic liver disease, underweight/overweight/obesity was present in patient with NAFLD (5/21/38, %), but surprisingly also in hepatitis C (0/25/63 %), hepatitis B (12/25/0 %), primary sclerosing cholangitis (11/21/0, %), primary biliary cholangitis (8/8/23 %), and alcohol (10/29/12, %). Table 1 shows the percentage of patient per weight group, the median BMI and range of patients according to the main etiology of chronic liver disease. **Conclusion:** At the moment of LT, 55% of patient display an underweight or an overweight/obesity. This study highlights the unsatisfactory nutritional status of cirrhotic patients at the moment of the LT. Therapeutic and management strategies pre- and post-LT are mandatory using a multidisciplinary team, including nutritional intervention, while emphasizing weight stigma awareness.

Table 1. Weight status of patients according to the main etiology of chronic liver disease.

Etiology (%)	<18 Underweight	18-25 Normal	25-30 Overweight	>30 Obesity	Median	Min	Max

f 1129-A | A NOVEL HCC WAITLIST DROPOUT SCORE: BIOMARKER INTEGRATED DROPOUT GRADIENT ESTIMATION (BRIDGE)★

Jonathan Li[1], Jeff Liang[2], Vatche G. Agopian[3], Kelley Nunez[4], Joshua Norman[5], Naomy Kim[2], Jung Yum[6], Shreya Gumate[7], Ari J. Cohen[8], Kambiz Kosari[2], Nicholas Nissen[2], Francis Yao[9], Paul Thevenot[10], Ju Dong Yang[2] and Neil Mehta[11], (1)UCSF, (2)Cedars-Sinai Medical Center, Los Angeles, CA, (3)David Geffen School of Medicine at UCLA, (4)Ochsner Health System, (5)Stanford Healthcare, (6)University of California, Los Angeles, (7)UCLA, (8)Ochsner Health System, New Orleans, LA, (9)University of California, San Francisco, San Francisco, CA, (10)Alton Ochsner Medical Foundation, (11)University of California, San Francisco

Background: Alpha-fetoprotein (AFP) is a well-established biomarker for HCC, but AFP-L3 and des-gamma-carboxyprothrombin (DCP) are complementary to AFP in predicting high risk explant pathology and post-transplant (LT) outcome. Additional studies have suggested that AFP-L3 and DCP are superior to AFP in predicting HCC waitlist outcome. The objective of this study is to incorporate AFP-L3 and DCP into a novel dropout risk score. **Methods:** We analyzed data from an ongoing, multicenter study of patients initially listed for transplant with HCC exception between July 2017 and August 2022 and had all three biomarkers (AFP, AFP-L3 and DCP) collected within 90 days of listing. The primary outcome was waitlist dropout due to tumor progression, clinical deterioration, or death. Using the Fine and Gray competing risk (CR) regression model (competing risk: LT), we developed a multivariate prediction model for waitlist dropout. The BRIDGE dropout risk score was then created based on the final multivariable model coefficients, which were scaled and rounded to the nearest integer to produce a simplified point scale. **Results:** Our cohort comprised 427 HCC patients from 4 high-volume LT centers with median listing AFP of 6 ng/mL (IQR 4-17), AFP-L3 8% (IQR 1-13%), DCP 1 ng/mL (IQR 0.8-3.1), Child-Pugh (CP) score 6 (IQR 5-8), and MELD-Na 10 (IQR 8-14). Overall, 53% underwent LT and 22% (n = 93) had dropout. Median follow up after listing was 12 months, and cumulative probability of dropout due to tumor progression, clinical deterioration, or death within 12 months of listing was 13.5%. On CR multivariable analysis, tumor burden beyond Milan criteria, listing AFP > 100, AFP-L3 > 35%, DCP > 7.5, and CP score were significant predictors of waitlist dropout. These five variables were used in the BRIDGE dropout risk score (Figure). Median BRIDGE score was 3 (IQR 1-10). The BRIDGE score stratified 1-year waitlist dropout probabilities ranging from 8.9% with a score < 10, 18.9% with a score of 10-18, and 43.8% with a score of > 18. The addition of AFP-L3 and DCP improved model fit compared to a model without both biomarkers by the log likelihood ratio test ($p < 0.014$). **Conclusion:** To our knowledge, this is the first multicenter study incorporating complete biomarker data (AFP, AFP-L3, DCP at listing), tumor burden and liver disease severity (MELD-Na and Child-Pugh score) into a simple, novel HCC waitlist dropout risk score (BRIDGE). The ability of the BRIDGE score to stratify patients based on risks of waitlist dropout may have important implications for the organ allocation policy that currently gives the same priority to all HCC patients listed for LT.

Table:

Variables	Multivariate SHR (95% CI)	Multivariate Coefficients	p-value	Points
Initial HCC Beyond Milan Criteria	1.93 (1.53 – 2.42)	0.656	p < 0.001	10
Listing AFP > 100 ng/mL	1.98 (1.60, 2.45)	0.685	p < 0.001	10
Listing AFP-L3 > 35%	1.77 (1.19, 2.63)	0.572	p = 0.005	9
Listing DCP > 7.5 ng/ml	1.25 (1.04, 1.49)	0.220	p = 0.016	3
Listing Child-Pugh Score	1.07 (1.02, 1.12)	0.067	p = 0.002	1 (per point above 5)

1130-A | ACUTE CELLULAR LIVER REJECTION FOLLOWING COVID-19 INFECTION

Stela Celaj[1], Rachel Hannum[1], Roy Frye[2] and Obaid Shakil Shaikh[3], (1)University of Pittsburgh Medical Center, (2)VA Pittsburgh Healthcare System, (3) University of Pittsburgh

Background: The management of liver transplant (LT) patients who contract COVID-19 poses

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

challenges given the chronic immunosuppression associated with transplantation. So far, studies have shown that immunosuppression itself does not seem to confer an increased risk of severe COVID disease and mortality in LT recipients. It is currently unclear whether the immune dysregulation associated with COVID-19 infection and/or modifications in immunosuppression increase the risk of rejection. **Methods:** Here we report a rare case of acute cellular rejection (ACR) following the onset of COVID-19 infection. The patient is a 59-year-old male with prior history of hepatitis C and alcoholic cirrhosis who had undergone deceased donor liver transplant 7 years prior. He was transitioned to tacrolimus monotherapy four months post-transplant and had stable graft function. Hepatitis C was treated post-transplant with successful sustained virologic response. **Results:** He presented with respiratory symptoms, with no recent travels or new medications prior. A respiratory viral panel was negative except COVID-19 PCR was positive. He was vaccinated with two doses of Pfizer-BioNTech a year ago. Liver enzymes were found to be significantly elevated on presentation from normal prior 2 months ago: ALT 775, AST 747, ALP 134, Tbili 1.6, tacrolimus level 9.1, Cr 1.2 (at baseline). Liver enzymes continued to progressively rise with peak levels ALT 1017, AST 959, AP 147, T Bili 2.1 (Fig 1 A). Serology was negative for acute viral infections (Hepatitis A, B, C, E, Epstein-Barr Virus and Cytomegalovirus). Alcohol levels on admission and phosphatidylethanol were negative. Liver ultrasound with doppler revealed patent hepatic vasculature and graft without intrahepatic or extra hepatic biliary dilation. Subsequent liver biopsy showed severe cellular rejection (Fig 1 B). The patient was treated with bolus methylprednisolone and increased tacrolimus goal 8-10. His liver enzymes subsequently improved and normalized entirely 2 months after the infection. **Conclusion:** To the best of our knowledge, this is one of the first reported cases of late ACR following COVID-19 infection. Prior studies have only reported ACR in the setting of withdrawing or decreasing immunosuppression in patients with COVID-19. In this case, the patient had maintained adequate level of immunosuppression as documented with therapeutic tacrolimus levels over the course of 7 years post LT. Though a causative relationship between COVID-19 and rejection cannot be definitively established, the timing of infection and rejection, and lack of other classical risk factors for ACR (inadequate immunosuppression, history of autoimmune liver disease, prior rejection episodes) or other infectious and metabolic triggers, infer a likely association between the two.This case highlights the importance of careful monitoring of allograft function in setting of COVID-19 infection.

1131-A | DEVELOPMENT OF CLINICAL ALGORITHM UTILIZING VIBRATION CONTROLLED TRANSIENT ELASTOGRAPHY TO DETECT ADVANCED HEPATIC FIBROSIS IN LIVER TRANSPLANT RECIPIENTS

Dylan Vainer[1], Tamoore Arshad[2], Hiba Khan[1], Alok Baral[1], Shreya Garg[1], Audrey Ang[1], Vaishali Patel[1], Vinay Kumaran[1], David Anthony Bruno[1], Seung Lee[1], Amit Sharma[1], Mark Dhinesh Muthiah[3], Anh Bui[2] and Mohammad S. Siddiqui[1], (1)Virginia Commonwealth University Health System, (2)Virginia Commonwealth University, (3)National University Health System (NUHS)

Background: Vibration controlled transient elastography (VCTE) based liver stiffness measurement (LSM) is an excellent 'rule-out' test for advanced hepatic fibrosis in liver transplant (LT) recipients, however, its ability to 'rule-in' the disease is suboptimal. While supplementing LSM with bio-clinical data has provided promising results (i.e. FAST, Agile 3/4), they have not resulted in similar improvement in diagnostic performance when compared to LSM alone, due to the altered physiology of the LT recipients. This study aimed to improve diagnostic performance of LSM in LT recipients. **Methods:** Adult

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

LT recipients with a liver biopsy and VCTE were included (N = 150). Sequential covering analysis (SCA) was performed to create rules to identify patients at low or high risk for advanced fibrosis (stage 3-4). The rules created via SCA were then compared to LSM alone at 'ruling in' and 'ruling out' advanced fibrosis. **Results:** The rules created via SCA are depicted in Figure 1A. Advanced hepatic fibrosis was definitively excluded in patients with either LSM < 7.45kPa (n = 72) or 7.45 d LSM < 12.1kPa and time from LT < 5.6 years (n = 25). Conversely, likelihood of advanced fibrosis was 95% if patients had LSM > 14.1 and controlled attenuation parameter d 279dB/m (n = 21). Thus, 118 (79%) were correctly identified and 32 (21%) would have required a biopsy to establish the diagnosis. Compared to previously established LSM based cutoff values of 10.5 kPa (Youden index) and 13.3 kPa (maximized specificity), the false positive rates of sequential covering analysis was 1% compared to 16.5% with LSM e 10.5 kPa and 8.3% with LSM e 13.3 kPa. The true positive rates were comparable at 87% for sequential covering analysis, 93% for LSM e 10.5 kPa and 83% for LSM e 13.3kPa. Implementing SCA lead to correct characterization of 65% of patients who were ruled out for advanced fibrosis with 100% accuracy (Figure 1B) and 14% of patients who were ruled in for advanced fibrosis with 95% positive predictive value. The intermediate zone consisted of 21% of the cohort with a 28% prevalence of advanced hepatic fibrosis. The developed sequential covering analysis approach was validated using leave 1-out cross validation with similar diagnostic performance. **Conclusion:** The proposed clinical sequential covering analysis allows for better risk stratification when evaluating for advanced fibrosis in LT recipients compared to LSM alone. Additional efforts are necessary to further reduce the number of patients with indeterminate results in whom a liver biopsy may be required.

1132-A | EARLY ALCOHOL RELAPSE IN LIVER TRANSPLANT RECIPIENTS ASSOCIATED WITH SIGNIFICANT HEPATIC FIBROSIS

Daniel Thomas Gildea[1], Stephanie M Woo[1], Ade Waterman[1], Cristian D Rios Perez[1], Krystina A Johnson-Laghi[1], Amol S. Rangnekar[1] and Christine C Hsu[1,2], (1)Medstar Georgetown University Hospital, (2) National Institute of Health

Background: Alcohol relapse (AR) after liver transplant (LT) has been associated with graft loss and diminished survival. Post-LT patient fibrosis in the setting of alcohol relapse is not well described. Our aim was to examine the effects of AR on graft fibrosis and evaluate whether noninvasive scoring systems can estimate fibrosis in these patients. **Methods:** This is a retrospective study with patients who underwent LT for a primary indication of alcoholic liver disease (ALD) at a single large academic transplant center between January 2015 and October 2022. Data collected include demographics, psychosocial variables, presence and timing of AR, lab values to calculate APRI and FIB4 scores, and liver biopsy findings. Comparisons between AR and non-AR patients were made using Chi-square and two sample t-tests. **Results:** Of 159 total patients transplanted for ALD, 36 (23%) had AR post-LT. AR occurred at a median of 348 days, with 64% of AR occurring within 1 year post-LT. Predictors of AR included pre-LT psychiatric diagnosis (OR 7.9, $p < 0.01$) or medication use (OR 10.6, $p < 0.01$) and failed alcohol rehab pretransplant (OR 10.2, $p < 0.01$). Among 72 patients with liver biopsies, 18% had stage 2-4 fibrosis (significant fibrosis or SF) and 85% of SF was seen within 2 years of LT. Three patients had e F3 fibrosis, two due to recurrent alcoholic hepatitis and one due to chronic rejection. In the entire cohort, SF was present in 29% of AR vs. 13% of non-AR patients ($p = 0.08$). After excluding biopsies that showed fibrosis due to acute cellular rejection, AR was associated with increased risk of SF (33% AR vs. 4% non-AR, $p < 0.01$). Patients with SF had higher mean APRI (2.0 vs 0.9, $p = 0.03$) and higher mean FIB-4 (4.2 vs 2.4, $p < 0.05$) scores. **Conclusion:** Post-LT AR is associated with increased risk of SF (33%) within 2 years of transplant. As most liver biopsies were prompted by abnormal liver-associated enzymes, the true burden of SF may be

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

underestimated particularly in patients who underreport alcohol use or follow up less often post-LT. APRI and FIB-4 scores were higher in patients with SF in our cohort. Noninvasive testing for fibrosis should be further investigated in the post-LT population, particularly in patients with ALD.

Table 1: Demographics and Data for Alcohol Associated Liver Disease Post-LT Patients with Liver Biopsies After Excluding Acute Cellular Rejection Biopsies

	Relapse*	Non-Relapse*	p-value

1133-A | ENDOSCOPIC TREATMENT OF BILIARY COMPLICATIONS AFTER LIVER TRANSPLANTATION: SINGLE TERTIARY CENTER EXPERIENCE

Bulent Odemis[1], Cagdas Erdogan[1], Muhammed Bahaddin Durak[2] and Cem Simsek[1], (1)Ankara City Hospital, Ankara, Turkey, (2)Mehmet Akif Inan Training and Research Hospital, Sanliurfa, Ankara, Turkey

Background: Biliary complications are the most common post-liver transplant (LT) complications, with an incidence of 15% - 45%. This study aimed to evaluate the efficacy and long-term outcomes of endoscopic treatment in patients experiencing biliary complications following liver transplantation. **Materials and Methods:** A retrospective study of 85 patients was conducted between March 2011 and February 2021. Inclusion criteria were elevated cholestasis enzyme levels in patients who underwent duct-to-duct anastomosis during liver transplantation and had biliary complications documented by imaging. In cases of anastomotic/non-anastomotic stenosis, the maximum number of plastic stents/metal stents were used. For stenosis that could not be passed with ERC, the percutaneous-endoscopic-rendezvous procedure was employed. Magnetic-compression-anastomosis (MCA) was utilized if the stenosis could not be passed endoscopically or percutaneously. In patients with anastomotic leakage, naso-biliary drainage tubes, plastic stents, or stents were inserted across the leak location following sphincterotomy. Clinical Success was defined as improved stricture or leakage on cholangiography and lower cholestasis enzyme levels after 12 months of endoscopic therapy. The procedure was standardized according to the single expert endoscopist's (BO) preference. **Results:** A total of 657 procedures were performed on 85 patients, with a mean follow-up of 33.8 months. Biliary stenosis was detected in 71 patients, and biliary leakage in 14 patients. ERC successfully passed the proximal end of the stenosis in 49 of 71 patients with biliary stenosis. The rendezvous method with PTC was used in 15 patients, and the MCA technique in 7 patients. Stent-free follow-up was achieved in 64.8% (46/71) of patients with biliary stenosis, with a mean treatment duration of 12.3 months and an average stent-free follow-up of 28.8 months. Endoscopic treatment is ongoing in the remaining 25 patients. In patients with anastomotic leakage, the clinical success rate of endoscopic treatment was 100%. In 10 of 14 biliary leakage patients, anastomotic leakage was repaired in a single session, with three patients requiring two sessions and one patient requiring four sessions. NBD was placed in 9 of 14 patients with biliary leak. The rate of complications was 12.3%. Twenty patients experienced stent migration. Fourteen individual's had cholangitis, 12 had pancreatitis, 5 had bleeding, and 1 had magnet migration. Four patients died throughout the follow-up period. One patient died because of the process (cholangiosepsis). The remaining 3 patients died of non-procedural causes. **Conclusion:** Combining percutaneous intervention and magnetic compression anastomosis with endoscopic treatment improves success rates in addressing liver transplantation-related biliary complications. However, a subset of patients may require longer treatment durations than anticipated.

1134-A | FEASIBILITY OF MEDICATION ASSISTED TREATMENT FOR ALCOHOL USE DISORDER POST-LIVER: INTERIM RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Divya Ayyala[1], Thomas Bottyan[2], Amandeep Sahota[3], Jennifer L. Dodge[1], Norah Terrault[1] and Hyosun Helen Han[1], (1)University of Southern California, (2)Stanford, (3)Kaiser Permanente

Background: Medication assisted treatment (MAT) for alcohol use disorder (AUD) may benefit liver transplant (LT) recipients with alcohol-associated liver disease (ALD), yet data on safety and acceptability of MAT in LT recipients are lacking. **Methods:** An interim analysis of a single-center randomized 2:1 controlled study of acamprosate 666 mg TID +standard of care (SOC) vs SOC in adults post-LT for ALD. Key inclusion criteria were adults > 18 years post-LT (spanning eras of different sobriety requirements) for ALD with creatinine clearance > 30 mL/min. The primary outcome was feasibility (acceptability and study completion rates). Secondary outcomes included safety (differences in side effects in acamprosate vs SOC) and efficacy (reduction in cravings and self-reported drinking). The Penn Alcohol Craving Scale (PACs), Timeline Follow-back, and side effects were ascertained weekly for 1-3 months. Relapse was defined as positive PeTh (abstracted retrospectively) or self-reported alcohol use. **Results:** Of 71 adults approached, 23 enrolled (15 acamprosate, 8 SOC), of which, 6 withdrew (2 acamprosate, 4 SOC) and 1 was lost to follow up (acamprosate). Those that declined vs enrolled were of similar age, gender, pre-LT mean SIPAT score, median duration of sobriety pre-LT, history of alcohol-associated hepatitis, rehabilitation, alcohol-related legal issues (Table). Adults that declined (vs enrolled) were temporally closer to time of LT (21.9 mo vs 38.9 mo, $p = 0.049$), more frequently had comorbid psychiatric diagnosis (36.4 vs 7.1%, $p = 0.006$), and history post-LT of slip or relapse (39.1 vs 14.6%, $p = 0.01$). Reported reasons for declining participation included absence of cravings (14.6%), abstinence > 1 year (6.3%), afraid of side-effects (35.4%), belief MAT would be unhelpful (20.8%), and lack of interest in research (6.3%) (Table). Of adults that enrolled and completed > 4 weeks of the study (8 acamprosate vs 3 SOC), mean follow-up (11.5 vs 14 weeks) and completion rates of surveys (54.8 vs 58.5%) were similar with 100% compliance to medications in the acamprosate arm. In MAT vs SOC arms, the overall severity of baseline cravings was low (median PACs: 8.4 vs 7.6%) with no difference in the mean reduction in PACs (1.33 vs -2.00, $p = 0.12$) and with no relapses in either group. Reported side effects were similar between both groups, with no treatment withdrawals due to adverse events. **Conclusion:** Low enrollment rates were likely influenced by inclusion of patients many years post-LT and patient's lack of familiarity of MAT and its benefits. Acamprosate was well-tolerated post-LT, yet concerns regarding side effects was among the most common reasons for non-participation. Earlier post-LT introduction of MAT for AUD coupled with education of patients of the value of MAT in management of AUD likely are needed to increase acceptance of MAT by LT recipients.

Table 1: Baseline Characteristics of Enrolled vs Non-Enrolled

Characteristic	Enrolled (N=23)	Non-Enrolled (N=48)	p value*
Age (when approached), median years (IQR)	52.74 (21.73)	55.63 (17.12)	0.50

1135-A | HEPATITIS B PROPHYLAXIS AFTER LIVER TRANSPLANTATION

Maxat Doskhanov[1,2], Baimakhanov Bolatbek[3], Skakbayev Aidar[1], Shokan Kaniyev[1], Erbol Serikuly[1], Aziza Khajiyeva[1], Daniyar Mukazhanov[1], Zhambyl Ospan[1], Serik Tileuov[1], Baglan Askeyev[1] and Abzal Ismatov[1], (1)Syzganov Scientific Center of Surgery, (2) Syzganov National Scientific Center, (3)Syzganov Scientific Center of Surgery of Surgery

Background: Patients undergoing liver transplantation for hepatitis B–related liver disease are prone to recurrence. The mainstay of prophylaxis has been passive immunotherapy with hepatitis B immune globulin (HBIG). Antiviral therapy with tenofovir has proven effective in lowering hepatitis B virus (HBV) DNA and improving histology in patients with hepatitis B infection; its role in prophylaxis against hepatitis B recurrence following liver transplantation is under investigation. Viral breakthrough and resistance, however, are a significant problem with monotherapy with either HBIG or lamivudine. The efficacy of combination tenofovir /HBIG prophylaxis has not been reported. **Methods:** 96 underwent transplantation for decompensated liver disease owing to hepatitis B in Syzganov national scientific center. Mean age of patients was 42.8 ± 9 years old. 75 patients begun to receive Tenofovir (150 mg po/d) before and after transplantation. 4 patients received entacovir. Other was not received treatment. **Results:** Human immunoglobulin was not used after liver transplantation in our study, despite that no acute hepatitis was observed in any patient. On postoperative period, 3 patients had positive HbsAg At a median interval of 49.6 ± 16.1 days following tenofovir treatment, all HBV DNA–positive patients cleared HBV DNA from the serum. The median follow-up was $212{,}2 \pm 109{,}7$ weeks. Actuarial 5-year patient and graft survival was 75%. Only 1 patient had recurrence of hepatits B after a year of transplantation. Tenofovir suppresses HBV replication in patients awaiting liver transplantation. **Conclusion:** Tenofovir and entecavir show good results in the preoperative and postoperative period. Nucleoside analogues with good results of antiviral therapy are not an indication pre- and post operation period.

Disclosures: The following people have nothing to disclose: Maxat Doskhanov, Baimakhanov Bolatbek, Skakbayev Aidar, Shokan Kaniyev, Erbol Serikuly, Aziza Khajiyeva, Daniyar Mukazhanov, Zhambyl Ospan, Serik Tileuov, Baglan Askeyev, Abzal Ismatov

1136-A | LIVER TRANSPLANTATION MANAGES ELEXACAFTOR/TEZACAFTOR/ IVACAFTOR LIVER INJURY, AND IMPROVES PULMONARY FUNCTION, WITHOUT RECURRENCE OF LIVER INJURY DESPITE RESUMPTION OF THERAPY FOLLOWING TRANSPLANTATION

Richard Gilroy[1], Sophie Hansen[1,2], Holly Rupone[2] and Laurie LeClair[2], (1)Intermountain Health, (2)University of Utah

Background: Cystic fibrosis (CF) is a potentially lethal inherited disease caused by mutations of the CF transmembrane conductance regulator (CFTR) gene. These mutations lead to impairment of CFTR mRNA and protein expression, transmembrane receptor function and stability of the transmembrane receptor. Cystic fibrosis impacts the lungs most notably; however, pancreatic and liver involvement are not uncommon. Lung disease carries the greatest morbidity and often results in recurrent infections, bronchiectasis, antibiotic resistance, and repeated hospitalizations. The CFTR modulator class of medications have the ability to enhance the transmembrane receptors function with 5 of the 6 classes of CFTR gene mutations able to be targeted by current therapies. These medications provide significant benefits, a significant reduction in pulmonary exacerbations, and when initiated early may prevent the development of CF associated complications. Unfortunately, these therapies are independently associated with elevated liver enzymes in 10% of patients and an elevated bilirubin > 2x the ULN in registry studies. **Methods:** Here we described the outcome of transplantation for a patient with cystic fibrosis, complicated by lung, pancreatic and liver disease who experienced recurrent hospitalizations prior to combination therapy with elexacaftor, tezacaftor, and ivacaftor and consequently developed cholestasis after 2 years of treatment. His drug-induced cholestasis resolved with cessation of therapy and recurrence of cholestasis occurred with resumption. During his absence of use of the medication, hospitalizations for cystic fibrosis exacerbations occurred approximately every 8 weeks, in contrast, only 1 hospitalization occured when on therapy. He was evaluated for liver transplantation with the primary indication being cystic fibrosis associated exacerbations in the absence of CFTR modulator therapy that occurred in the presence of cystic fibrosis associated cirrhosis. **Results:** His liver transplant was uncomplicated and discharge occurred on postoperative day 7. On postoperative day 30 his combination therapy of elexacaftor, tezacaftor, and ivacaftor was resumed without incident. 3 months post-transplant, his

lab values are as follows: AST 29 U/L, ALT 26 U/L, alkaline phosphatase 50 U/L and bilirubin 0.8 mg/dL. There has been no hospitalization or cystic fibrosis exacerbation. **Conclusion:** This is the first reported liver transplant for cystic fibrosis in which the indication for transplantation was to provide the ability to safely reinitiate CFTR modulator therapy in a patient with compensated cystic fibrosis associated cirrhosis.

1137-A | LONG-TERM OUTCOMES OF LIVER TRANSPLANTATION FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA BEYOND MILAN CRITERIA: A MULTICENTER COHORT STUDY

Heechul Nam[1], Pil Soo Sung[2], Hee Yeon Kim[1], Ho Joong Choi[1], Jung Hyun Kwon[1], U Im Chang[1], Chang Wook Kim[1], Si Hyun Bae[1], Young Kyoung You[1], Jong Choi[1], Seung Kew Yoon[1], Jin Mo Yang[1] and Jeong Won Jang[1], (1)The Catholic University of Korea, (2)The Catholic University Liver Research Center, Department of Biomedicine & Health Sciences, College of Medicine, the Catholic University of Korea

Background: Recent guidelines recommend that liver transplantation (LT) can be considered for patients with hepatocellular carcinoma (HCC) that exceeds Milan criteria (MC) if they have been successfully downstaged to within MC. However, multi-center studies analyzing long-term outcomes are lacking. This study aims to identify prognostic factors for overall survival (OS) and recurrence after LT in downstaged patients with HCC beyond MC. **Methods:** This is a multi-center retrospective study on consecutive patients with HCC underwent LT at 6 academic centers from September 1995 to September 2022. The associations of factors on OS and recurrence rate were analyzed using Cox proportional hazards regression and multivariable logistic regression models. **Results:** The study included 614 HCC patients who underwent LT and were categorized into three groups: within MC (n = 380), successfully down-staged (DS, n = 120), and not down-staged (NoDS, n = 114). The median age of the patients was 54 years (IQR, 50-60 y) and the majority of them were male (509 [82.9%]). The mean follow-up after LT was 77.1 months ± 67.8, corresponding to a total of 3904.6 person-years. During this follow-up period, there were 179 deaths and 104 cases of HCC recurrence. There were significant differences observed in OS based on MC and downstaging. The OS rates at 1, 3, 5, 10, and 20 years were 92.5%, 85.4%, 82.9%, 75.1%, and 63.3% for patients within MC; 89.8%, 74.8%, 68.1%, 59.5%, and 51.0% for DS; and 72.9%, 52.1%, 50.8%, 39.7%, and 36.9% for NoDS, respectively ($p < 0.001$). Recurrence rates were also significantly better for the DS group compared to the NoDS group. The recurrence rates at 1, 3, 5, 10, and 20 years were 2.5%, 6.7%, 8.8%, 9.8%, and 9.8% for patients within MC; 13.9%, 25.6%, 27.1%, 29.3%, and 29.3% for DS; and 36.3%, 43.9%, 48.5%, 48.5%, and 56.3% for NoDS, respectively ($p < 0.001$). In the DS group, independent prognostic factors associated with recurrence after LT were neutrophil-to-lymphocyte ratio (NLR) ≥ 2 at LT (HR, 2.625; 95% CI, 1.150-5.992; $p = 0.022$), alpha-fetoprotein (AFP) ≥ 100 (HR, 2.741; 95% CI, 1.147-6.548; $p = 0.023$), and microvascular invasion (MVI) on explant pathology (HR, 2.622; 95% CI, 1.138-6.044; $p = 0.024$). **Conclusion:** This multi-center retrospective cohort study with long-term follow-up demonstrated favorable outcomes in patients with HCC who achieved successful downstaging to meet MC before undergoing LT. Specifically, patients with NLR (< 2), AFP (< 100), and no MVI exhibited significantly lower recurrence rates and better post-LT outcomes. These findings suggest the importance of successful downstaging and highlight the potential prognostic value of NLR, AFP, and MVI in predicting outcomes after LT for HCC.

1138-A | METABOLIC FLEXIBILITY PREDICTS RESPONSE TO SAROGLITAZAR TREATMENT IN LIVER TRANSPLANT RECIPIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE

Mohammad S. Siddiqui[1], Deven Mr V. Parmar[2], Farheen Shaikh[3], Nihal Shaikh[3], Anh Bui[1], Vaishali Patel[4] and Arun Sanyal[5], (1)Virginia Commonwealth University, (2)Zydus Cadila, (3)Zydus Therapeutics, (4) Virginia Commonwealth University Health System, (5) Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA

Background: Metabolic flexibility is the ability to match biofuel availability to utilization with the carbohydrate being the major fuel source in the fed state and fatty acids in the fasted state. Metabolic *inflexibility*, refers to reduced ability to readily transition between fuel sources. In liver transplant (LT) recipients, reduced metabolic flexibility has been associated with non-alcoholic fatty liver disease and future risk of weight gain. Currently, there is no data in interaction between metabolic flexibility and pharmacological intervention. **Methods:** In this proof of concept, open-label trial, single-arm study, 15 adult patients with NAFLD as determined by controlled attenuation parameter were treated with saroglitazar magnesium 4mg daily for 24 weeks. Key exclusion criteria included graft cirrhosis, more than mild alcohol use, GFR < 60, and concomitant use of GLP-1 receptor agonists. Metabolic flexibility was measured at baseline and end of treatment (EOT) using whole room calorimetry and expressed as respiratory quotient (RQ). Peak RQ represents maximal carbohydrate metabolism and occurs in the post-prandial state, while trough RQ represents maximal fatty acid metabolism occurring in the fasted state. **Results:** In the overall cohort, a numerical improvement in RQ was noted from baseline and EOT, however, this did not reach statistical significance. Baseline metabolic flexibility was associated with likelihood of treatment response as defined by at least 5% reduction in liver fat from baseline to EOT (Figure 1). More specifically, responders had shorter time to peak RQ (275 ± 82 vs. 388 ± 82 minutes $p = 0.03$). An improvement in time to peak was noted in responders (275 ± 82 to 246 ± 65 min) and non-responders (388 ± 82 to 281 ± 97 min) from baseline to EOT, however, this did not reach statistical significance. Finally, lower resting RQ was noted in patients who were more likely to respond to saroglitazar than non-responders. **Conclusion:** In LT recipients, baseline metabolic flexibility predicts response to saroglitazar, first in LT population. While the current study was not designed to evaluate the impact of saroglitazar on metabolic flexibility, it does provide empiric data suggesting the impact of saroglitazar on liver fat is independent of metabolic flexibility. Moreover, the data would also suggest a potential positive effect of saroglitazar on metabolic flexibility, however, well designed studies are required to better evaluate this relationship.

1139-A | PALLIATIVE CARE IN PATIENTS WITH BCLC-D HEPATOCELLULAR CARCINOMA LIVER TRANSPLANTATION-INELIGIBLE: RESULTS FROM A SURVEY AMONG ITALIAN HEPATOLOGISTS AND PALLIATIVE CARE PHYSICIANS

Massimo Iavarone[1], Lorenzo Canova[1,2], Eleonora Alimenti[1,3], Diego Taveggia[4], Alessio Aghemo[5,6], Gino Gobber[7], Giuseppe Cabibbo[8], Simone Veronese[9], Vincenza Calvaruso[8], Luciano Orsi[10], Paolo Caraceni[11,12] and Pietro Lampertico[1,13], (1)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2) Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy, (3)University of Pavia, Department of Medical Sciences, Pavia, Italy, (4) Department of Oncology and Palliative Care, Asst Lodi, Lodi, Italy, (5)Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy, (6) Division of Internal Medicine and Hepatology, Humanitas Research Hospital Irccs, Rozzano, Italy, (7) UO Palliative Care, Department of Primary Care, Apss Trento, Italy, (8)Gastroenterology & Hepatology Unit, Department of Health Promotion, Mother & Child Care, Internal Medicine & Medical Specialties (PROMISE), University of Palermo, Palermo, Italy, (9)Fondazione Faro ETS, Turin, Italy, (10)Italian Journal of Palliative Care, Italy, (11)Department of Medical and Surgical Sciences, Alma Mater Studiorum - University of Bologna, Bologna, Italy, (12)Unit of Semeiotics, Liver and Alcohol-Related Diseases, Irccs Azienda Ospedaliero-Universitaria Di Bologna, Bologna, Italy., (13)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: Delays and limitations of palliative care (PC) in patient with Barcelona Clinic Liver Cancer (BCLC) D hepatocellular carcinoma (HCC) liver transplantation (LT)-*ineligible* may be explained by different perceptions between hepatologists and PC physicians in the absence of shared guidelines. We aimed to assess clinicians' attitudes towards PC in BCLC-D HCC. **Methods:** Members of the Italian Association for the Study of Liver Disease (AISF) and the Italian Society of Palliative Care (SICP) were invited to a web-based survey consisting of 17 questions to investigate the general approach, the management of cirrhosis complications and pain palliation in patients with BCLC-D HCC **Results:** A total of 97 hepatologists and 70 PC physicians completed the survey: $>80\%$ of both categories currently follow 1-19 patients with LT-*ineligible* BCLC-D HCC. Moreover, 58% of hepatologists collaborates with PC physicians in the management of BCLC-D patients, while the 55% of PC physicians takes care of patients independently. Management of cirrhosis and its complications, such as administration of albumin or prescription of esophagogastroduodenoscopy, anticoagulation and antiviral treatments or indication for paracentesis, differed significantly between the two groups (Table 1). Both hepatologists and PC physicians (42% and 64% respectively) prefer to avoid NSAIDs for pain control, while full-dose acetaminophen is widely used among hepatologists, but only in few among PC physicians (64% vs 26%, $p<0.001$). Opioids are commonly used by both categories, generally (61% and 67.4%, respectively) used at full dosage, regardless of patient's liver function. **Conclusion:** This survey highlights significant differences in the approach to patients with BCLC-D HCC LT-*ineligible*, between hepatologists and PC physicians, reinforcing the need for both studies dedicated to palliative care and shared guidelines among specialists.

1140-A | PROACTIVE RELAPSE PREVENTION APPROACH REDUCES RELAPSE RISK IN HIGH-RISK LIVER TRANSPLANT RECIPIENTS

Ethan Berman[1], Maham Ghani[1], Alexa Giammarino[1], Justin Lin[2], Jeffrey Lowell[1], Omoakhe Tisor[1], Michael Ramada[1], Mark Patrick Cubillan[2], Salima Makhani[1], Aaron Winnick[3], Nitzan C. Roth[3], Harmit S. Kalia[3], James S. Park[3], Alvin Htut[3], Christian Kuntzen[3], Nabil Dagher[3], Ahmed Fahmy[3], Elliot Grodstein[3], Lawrence Lau[3], Hatef Massoumi[4], Gerardo Tamayo-Enriquez[3] and Sanjaya Kumar Satapathy[3], (1)Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, (2) Northshore University Hospital/Long Island Jewish Hospital, (3)Northwell Health, Forest Hills, NY, (4)Lenox Hill Hospital

Background: Ensuring appropriate candidate selection for liver transplantation and monitoring sobriety pre-transplant are crucial for reducing the risk of alcohol relapse post-liver transplant in patients with cirrhosis. The use of Phosphatidylethanol (PEth), a biomarker for assessing chronic alcohol use, offers valuable insights into monitoring alcohol consumption over an extended period. This study aimed to evaluate the effectiveness of a proactive alcohol relapse prevention program in maintaining sobriety pre- and post-liver transplantation among high-risk individual's. **Methods:** Retrospective data were collected for patients who underwent liver transplantation for alcohol-related etiologies at a tertiary care medical center between December 2019 and May 2023. All patients participated in a structured alcohol relapse prevention program before and after transplantation. Pre- and post-transplant PEth levels were utilized to assess alcohol use and relapse. Patients were categorized as high risk if they had a positive PEth level or reported alcohol use 3 months prior to transplant. Descriptive and statistical analyses were conducted to compare relapse rates between patients with and without relapse. The Chi-square test determined the significance of relapse between high-risk and low-risk patients. **Results:** Among the 63 liver transplant recipients, 33 (52.4%) exhibited a positive PEth level or reported alcohol use within 3 months pre-transplant, and 9 (14.3%) experienced relapse after transplant. Of these, 27 (42.9%) were classified as high risk, while 36 (57.1%) were considered low risk. No statistically significant difference was observed in relapse rates between the high-risk group (n = 4, 14.8%) and the low-risk group (n = 5, 13.9%) ($p = 0.917$, OR 1.078 [95% CI 0.26-4.47]). **Conclusion:** Our study showed that transplanting high risk patients with recent alcohol use within 3 months did not have a higher relapse rate when compared to low risk patients when a proactive relapse prevention program is instituted. Further prospective studies should be

1141-A | PROGNOSTIC VALUE OF CORONARY ARTERY CALCIUM SCORING FOR LIVER TRANSPLANT RECIPIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Paul P. Hong[1], Spencer C. Lacy[1], Menhel Kinno[1] and Steven J. Scaglione[2], (1)Loyola University Medical Center, Chicago, IL, (2)Loyola University Health System

Background: Cardiovascular disease is a major cause of morbidity and mortality in liver transplant (LT) patients. Coronary angiography is the gold standard for assessing coronary artery disease, but its invasive nature has known risks and complications. Coronary artery calcium (CAC) scoring is a non-invasive assessment of coronary artery disease with an unclear role in risk stratification prior to LT. This systematic review and meta-analysis evaluated the prognostic value of CAC for preoperative risk assessment in LT recipients. **Methods:** We performed a systematic literature review to identify clinical studies that evaluated CAC in patients undergoing LT. The primary outcome of major adverse cardiovascular events (MACE) was reported as random effects risk ratio (RR) with 95% CI. **Results:** Our search yielded 2,978 potential studies. We included 6 studies reporting on 1,215 patients. There was an increased risk of MACE in patients with high CAC with an RR of 3.07 (95% CI 1.89-5.00, $p < 0.01$). The pooled composite odds ratio of CAC for predicting MACE in multivariable analysis was 3.26 (95% CI 1.75-6.06, $p < 0.01$). **Conclusion:** This systematic review and meta-analysis suggest that high CAC is associated with increased risk of MACE in LT recipients. High CAC score (> 400) may serve as a predictive model for an adverse post-LT outcome; additionally, this infers that an invasive cardiac testing may be more harmful than beneficial for this subgroup. Larger studies are needed to determine the role of CAC in cardiac risk stratification in this patient population.

f 1142-A | SIGNIFICANT REDUCTION IN POST-TRANSPLANT HEPATOCELLULAR CARCINOMA RECURRENCE IN THE POST-SIX-MONTH WAITING POLICY ERA

Lina Yagan[1], Nadim Mahmud[1,2,3,4], Maarouf A. Hoteit[5], K Rajender Rajender Reddy[5], Peter Abt[5] and Samir Abu-Gazala[1], (1)Hospital of the University of Pennsylvania, (2)Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, (3)University of Pennsylvania Perelman School of Medicine, (4) University of Pennsylvania, (5)Perelman School of Medicine, University of Pennsylvania

Background: In 2015, the United Network for Organ Sharing (UNOS) mandated a policy change introducing a six-month waiting period before MELD exception points are granted to liver transplant (LT) candidates with hepatocellular carcinoma (HCC). This study analyzes the impact of policy and associated practice patterns on post-LT HCC recurrence. **Methods:** This was a retrospective cohort study of UNOS registry patients with HCC who underwent LT from 1/2010-5/2019. Transplant data included demographics, liver disease etiology, laboratory MELD, waitlist time, and donor after cardiac death versus donor after brain death. HCC-specific data included alpha fetoprotein, maximum viable tumor diameter + number of viable tumors on imaging, receipt of locoregional therapy (LRT), and explant pathology data used to calculate RETREAT score. The primary exposure was pre/post policy era, divided at 10/8/15. Kaplan-Meier analysis was used to evaluate unadjusted differences in HCC

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

recurrence and mortality between policy eras, and sequential Cox regression models were performed for adjusted analyses. Competing risks were accounted for where applicable. **Results:** A total 7,940 patients were included, 5,879 (74.0%) pre-policy and 2,061 (26.0%) post-policy. Post-policy patients were older, more likely to have non-alcoholic fatty liver disease, received more LRT, and had lower AFP levels and smaller tumor sizes at transplant. Post-policy era was associated with an unadjusted 35% reduction in risk of post-LT HCC recurrence (HR 0.65, 95% CI 0.52-0.80, $p < 0.001$; Figure 1A). After adjusting for tumor characteristics at listing this association remained (SHR 0.69, 95% CI 0.55-0.86, $p = 0.001$; Figure 1B), however after additionally adjusting for LRT episodes and RETREAT score, there was no longer a statistically significant association (SHR 0.77, 95% CI 0.59-1.00, $p = 0.054$; Figure 1C). Similarly, in unadjusted analysis, there was a significant reduction in mortality associated with post-policy era (HR 0.81, 95% CI 0.72-0.92, $p = 0.001$; Figure 1D), but this association was null after comprehensive covariate adjustment (SHR 0.94, 95% CI 0.80-1.11, $p = 0.46$; Figure 1F). **Conclusion:** We observed a significant reduction in post-LT HCC recurrence and mortality after policy implementation. Sequential analyses demonstrate that this difference is likely mediated through waitlist selection of relatively healthier patients, increased opportunity for LRT use, and potential selection of favorable tumor biology.

Daisuke Imai[1], Marlon Levy[1] and David Anthony Bruno[1], (1)Virginia Commonwealth University Health System, (2)Virginia Commonwealth University

Background: Traditionally, LT programs required 6-months (M) of abstinence prior to listing in alcohol-associated liver disease (ALD). Recently, LT has been offered to those with < 6M sobriety including those with acute alcohol-associated hepatitis (AH). The Sustained Alcohol use post-Liver Transplant (SALT) and the High-Risk Alcohol Relapse (HRAR) scores were developed to predict return to alcohol use after LT. However, their utility is controversial. Our aim was to assess the utility of these scores to predict alcohol use after LT in those with ALD. **Methods:** A retrospective analysis of deceased donor LT 10/2018 to 4/2022 was performed. Demographic, clinical, and laboratory data were collected. All patients (pts) underwent careful pre-LT psychosocial evaluation. Data on alcohol use, substance abuse, prior rehabilitation, and legal issues were collected. Post-LT, all were encouraged to participate in rehabilitation programs and underwent random PeTH testing. Pts with ALD were stratified by < or > 6M sobriety prior to listing. Those with < 6M were further stratified as acute AH by NIAAA criteria and non-AH. The primary outcome was utility of the SALT and HRAR scores to predict return to alcohol use (+ PeTH) within 1 year after LT. **Results:** Of the 365 LT, 171 were for ALD: 86 had > 6M sobriety and 85 had < 6M sobriety; 41 with AH and 44 non-AH. Demographics, clinical, and psychosocial characteristics among these groups are shown (Table). Those with < 6M sobriety were younger, less likely African American, had higher MELD-Na and on the transplant waiting list for fewer days. In those with AH, the mean time of abstinence to LT was 58d, 71%% failed prior rehabilitation. One-year survival was similar among the 3 groups (90-93%). Following LT, return to drinking was similar in the AH (24%) compared to < 6M non-AH (15%) and > 6M ALD (22%). Only 4% had return to heavy drinking. The accuracy of the SALT score to predict return to alcohol was low (accuracy 0.63) with poor sensitivity (46%), specificity (68%), and positive predictive value (26%) with good negative predictive value (83%). HRAR had similar utility: accuracy (0.61), Sens 37%, Sp 67%, PPV 22%, and NPV 81%. **Conclusion:** In carefully selected pts undergoing LT for ALD with post-LT AALD counseling, while 1-yr survival was excellent, return to any drinking was observed in 15-24%, with heavy drinking in only 4%. Both SALT and HRAR scores had good NPV in identifying pts at low risk for recidivism.

1144-A | VIBRATION CONTROLLED TRANSIENT ELASTOGRAPHY BASED PARAMETERS PREDICTS CLINICAL OUTCOMES IN LIVER TRANSPLANT RECIPIENTS

Alok Baral[1], Shreya Garg[1], Audrey Ang[1], Madison Nguyen[1], Rehan Razzaq[1], Tamoore Arshad[2], Hiba Khan[1], Ian O'Connor[1], Siddiq Elmahdi[1], Michael Tseng[1], Vaishali Patel[1], Anh Bui[2] and Mohammad S. Siddiqui[2], (1)Virginia Commonwealth University Health System, (2)Virginia Commonwealth University

Background: Liver stiffness measurement (LSM), a surrogate measure of hepatic fibrosis, can be readily measured via vibration controlled transient elastography (VCTE) as a point of care test. LSM has been validated for detection of advanced hepatic fibrosis in liver transplant (LT) recipients. However, it is currently not known if LSM can predict risk of clinical outcomes. Thus, the present study aimed to evaluate the relationship between LSM and clinical outcomes. **Methods:** The study included adult LT recipients (N = 342) who had a successful VCTE between 2015 and 2022 for routine clinical care. VCTE was performed after an overnight fast and a cutoff value of LSM ≥ 10.5 kPa was used for significant fibrosis, while a controlled attenuation parameter (CAP) ≥ 270 dB/m was used for presence of hepatic steatosis based on prior published literature. Patients with history of end organ damage (i.e. heart failure, renal failure requiring HD, liver graft failure etc.) were excluded. The primary outcome of the study was all-cause mortality. The secondary outcomes included new-onset coronary artery disease (CAD), myocardial infraction (MI), and graft cirrhosis. Multivariate Cox regression models were constructed that included body mass index, age, gender, diabetes status and etiology of liver disease as covariates. **Results:** The study cohort included 67 (19.6%) patients with LSM ≥ 10.5kPa. The median time from LT to VCTE was 68.1 (IQR 21.5, 144.6) months. A total of 59 LT recipients died over a median follow up of 34.6 (IQR 25.4, 55.4) months. Baseline LSM was a strong and statistically significant predictor of all-cause mortality (Figure 1A). The relationship between LSM and all-cause mortality remained significant in multivariate modeling with HR of 2.14 (95% CI 1.25, 3.66, $p = 0.006$). LSM was not associated with future risk of MI or development of CAD. No interaction between choice of immunosuppression (cyclosporine vs. tacrolimus) and LSM and mortality were noted. Finally, a strong independent relationship between CAP and

Symbols: ƒ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

future risk of MI was noted (Figure 1B). **Conclusion:** The present study provides data demonstrating a strong association between VCTE-based parameters and clinical outcomes in LT recipients. The likely mechanism linking VCTE to non-hepatic outcomes is simultaneous activation of inflammatory and injury pathways throughout the body (i.e. heart, kidneys, liver) that compete to produce a clinical outcome.

1200-C | AN IN VITRO CULTURE MODEL FOR THE INDUCTION OF HDV REPLICATION IN A HBV EXPRESSING CELL LINE

Matthieu Blanchet[1], Lena Angelo[1], Yasmine Tetreault[1], Marwa Khabir[1], Camille Sureau[2], Andrew Vaillant[3] and Patrick Labonte[1], (1)Inrs-Centre Armand-Frappier Santé Biotechnologie, (2)Umr Inserm U 1259, (3) Replicor Inc.

Background: Individual's chronically infected with both Hepatitis B virus (HBV) and Hepatitis D virus (HDV) present an increased risk to develop cirrhosis and hepatocellular carcinoma in comparison to HBV mono-infected individual's. The number of HDV infected individual's worldwide is estimated to be between 20 and 40 million, a strong incentive to further engage in the search for new antivirals using innovative and practical *in vitro* models. Here we present the HepG2BD cell line as a novel *in vitro* culture system for inducible HDV replication in HBV replicating cells. **Methods:** Engineering: The HepG2BD cell line derives from HepG2.2.15 cells in which a HDV cDNA sequence under the control of a Tet-Off promoter is inserted into the adeno-associated virus integration site 1 (AAVS1) safe harbor site. The insertion at this precise location was conducted using the CRISPR-Cas9 technology for reliable initiation/repression of HDV RNA replication, and production of infectious HDV virions in a cell line that constitutively expresses HBV. Characterization: HDV RNA in cells and supernatants was quantified by RT-qPCR and Northern blot, HBV RNA in cells was monitored by RT-qPCR. Secreted HBV particle concentrations were evaluated by qPCR after anti-PreS1 immunoprecipitation. Secreted HBsAg was quantified by ELISA. Cellular presence and localization of HDAg in various cell culture conditions was monitored by confocal immunofluorescence. Infectivity of secreted HDV virions was measured by inoculation of NTCP-Huh7 cells followed by RT-qPCR. **Results:** The presented cell line is, to our knowledge, the first one to allow full replication of both HBV and HDV. This cell line shows proper induction of the HDV lifecycle. The interplay between HBV and HDV was detected in many instances. Differentiation into more classic hepatocyte morphology was associated with an increased concentration of both HDV and HBV in the supernatant. **Conclusion:** This new and unique model will be instrumental for the screening/characterization of new antivirals targeting both viruses (such as REP 2139). The HepG2BD cell line is also expected to help in our understanding of the dynamic interplay between the HBV and HDV lifecycles, and in identifying cellular factors involved.

College, Chicago, IL, (6)Hannover Medical School, (7) Hospital Universitario Vall D'hebron and Ciberehd Del Instituto Carlos III, (8)Adelphi Real World, (9)Adelphi Values

Background: Hepatitis D virus (HDV) is the most severe form of viral hepatitis which leads to faster progression to cirrhosis and is associated with worse health-related quality of life (HRQoL). There is currently no validated HRQoL patient-reported outcome (PRO) measure in HDV. The current research aimed to qualitatively explore the HDV patient experience and relevance of the Hepatitis Quality of Life Questionnaire (HQLQv2) and the Fatigue Severity Scale (FSS) for use in HDV, and to capture quantitative, real-world insights into the experience of HDV. **Methods:** Qualitative interviews (n = 31) and a cross-sectional survey (n = 144) were conducted in parallel with adults untreated for HDV in Italy, Germany, Spain, and the US. Patients who had experienced an acute episode of liver disease, received interferon in the past six months, or were diagnosed with hepatitis C were excluded. Interview participants described their experience living with HDV and completed the HQLQv2 and FSS using a think-aloud approach to assess relevance of the instruments. Survey participants completed a set of measures quantitatively assessing HDV impacts (including the HQLQv2 and FSS). **Results:** The qualitative interview sample (63% female; mean age: 52.8) included patients with a range of liver fibrosis stages (F0-F4C). The quantitative survey sample (74% male; mean age: 52.8) included patients across all liver fibrosis stages (F0-F4D). Interviews found that fatigue was the most frequently reported symptom and HDV significantly impacted patients' emotional wellbeing. Participants understood the HQLQv2 and FSS as intended, and concepts assessed were considered relevant to HDV by most participants. Survey results highlighted that all participants experienced fatigue, but F4 participants reported more severe fatigue. Of the four HQLQv2 domains (general health distress, hepatitis-specific limitations, distress, positive wellbeing), positive wellbeing scores were significantly lower across the sample and lowest in F4D participants. **Conclusion:** HDV has a significant negative impact on patients' HRQoL with greater impacts in those with more severe HDV. Findings from both studies are complementary and confirm that the HQLQv2 and FSS are valid and appropriate for use in HDV populations across different liver fibrosis stages, assessing fatigue and HRQoL impacts. Further research to evaluate the psychometric validity of the PROs is recommended to support trial endpoints and track disease severity.
