Background: Exercise is an important therapeutic intervention for NASH, since no drug for NASH has been recognized. The hepatokine, selenoprotein P (SeP) has been reported to cause "exercise resistance" through reduced ROS production in skeletal muscle, and to be elevated in serum in NASH patients. Meanwhile, mitochondrial dysfunction is closely associated with pathogenesis of NASH. Therefore, we aimed to investigate whether hepatic mitochondrial quality control (mitophagy) attenuates SeP production and consequently ameliorates responsiveness to exercise. **Methods:** Iron chelator, deferiprone (DFP) was used as mitophagy trigger via mitochondrial ferritin (FTMT) induction, as reported previously (EMBO Rep 2020). The 7,12-dimethylbenz[a] anthracene (DMBA)-treated mice fed a high fat diet was used as an obesity-related HCC mouse model (NASH-HCC mice). Responsiveness to exercise was assessed by running endurance test in NASH-HCC mice treated with/without DFP. **Results:** Running distance in endurance test was significantly longer in control mice (C57/BL6 mice) than NASH-HCC mice after training for 4 weeks, suggesting that NASH-HCC mice have "exercise resistance". Hepatic *Sep* mRNA levels were significantly lower in NASH-HCC mice with DFP treatment than those without. FTMT knockdown by siRNA abrogated DFP-induced reduction of SeP expression in Huh7 cells and HepG2 cells, suggesting mitophagy-related reduction of SeP expression. Treatment with SeP repressed mitochondrial basal and maximal respiration in mouse myoblast cell line, C2C12 cells in a dose dependent manner. DFP significantly increased 2-thiobarbituric acid reactive substances (TBARS) level in skeletal muscle in exercised NASH-HCC mice, but not in non-exercised NASH-HCC mice. In parallel with increased TBARS production, peroxisome proliferators-activated receptor-γ co-activator 1α (PGC1α), which regulates mitochondrial biogenesis, was also increased in skeletal muscle in NASH-HCC mice treated with DFP. Grip strength significantly increased by exercise in NASH-HCC mice with DFP treatment, but not in those without. Finally, running distance in endurance test was significantly longer in NASH-HCC mice with DFP treatment than those without after training for 4 weeks. **Conclusion:** Mitophagy induction in the liver ameliorates responsiveness to exercise through downregulation of SeP in NASH-HCC mice.

Dae Won Jun[2], (1)Eulji Medical Center, (2)Hanyang University College of Medicine, (3)Hanyang University, (4)Uijeongbu Eulji Medical Center

Background: Necroptosis is an emerging cell death pathway that allows cells to undergo "cellular suicide" in a caspase-independent manner. We investigated the fate of hepatic stellate cells under necroptotic stimuli. **Methods:** Anti-fibrotic effects were assessed using common bile duct ligation (BDL) models in wild-type (WT) and mixed lineage kinase domain-like protein knockout (MLKL-KO) mice. Necroptosis was induced by tumor necrosis factor-α, pan-caspase inhibitors, and inhibitor of apoptosis protein inhibitors in HT-29 (colorectal cancer cells), U937 (monocytes), and LX-2 (hepatic stellate cells). LX-2 cell activation and death were evaluated after necroptosis with and without the MLKL inhibitor (necrosulfonamide). **Results:** The immunoreactive score of MLKL was higher in patients with non-alcoholic fatty liver disease than in healthy controls. Hepatic fibrosis was significantly decreased in MLKL-KO BDL mice compared to WT BDL mice. Necroptotic stimuli caused death of HT-29 and U937 cells. But necroptotic stimuli activated LX-2 cells instead of cell death. Necroptosis inhibitors attenuated fibrogenic change of LX-2 cells during necroptosis. Unlike HT-29 and U937, MLKL phosphorylation and oligomerization were not observed during necroptosis in LX-2 cells. Ribonucleic acid sequencing data showed that NF-κB signaling-related genes were increased in LX-2 cells after necroptosis stimuli. Stimulation of necroptosis in LX-2 cells increased nuclear expression of NF-κB, which decreased after necrosulfonamide treatment. Induction of necroptosis in LX-2 cells led to activation and autophagosome formation, attenuated by necrosulfonamide treatment. **Conclusion:** Hepatic stellate cells avoided necroptosis due to a lack of MLKL phosphorylation and oligomerization and activated via autophagosome and NF-κB pathways.

2319-C | HEPATIC YBX1 PROMOTES NAFLD AND NASH BY DIRECTLY ACTIVATING THE ADIPOGENIC C/EBPA:PPARG AXIS

James M. Jordan[1], Jixuan Qiao[1,2], Fahrettin Haczeyni[1] and Baran A. Ersoy[1], (1)Weill Cornell Medicine, NY, (2) University of North Carolina at Chapel Hill

Background: Y box-binding protein 1 (Ybx1), a nucleic acid-binding protein primarily known for its role in early development and stress-induced activation related to innate immunity and cancer, has also been implicated in metabolic disorders. Our prior studies have linked elevated YBX1 expression with non-alcoholic fatty liver disease (NAFLD). Using a hepatocyte-specific conditional knockout mouse model ($Ybx1^{LKO}$) in a diet-induced obesity (DIO) context, we found that Ybx1 contributes to the accumulation of hepatic triglyceride and cholesterol. Subsequent profiling studies revealed that Ybx1 regulates genes involved in adipocyte differentiation and lipid droplet formation, most of which are downstream of peroxisome proliferator-activated receptor gamma (PPARγ). Ybx1 also plays a role in hepatic cholesterol clearance and demonstrates anti-inflammatory properties, as shown by decreased macrophage infiltration following its suppression in a NASH mouse model. The aim of this study is to uncover the mechanism through which Ybx1 enhances adipogenic gene expression downstream of PPARγ. **Methods:** We implemented siRNA and adenovirus-mediated Ybx1 overexpression in primary human and mouse hepatocytes, as well as continuous hepatocytes, to investigate the effect of Ybx1 modulation on PPARγ mRNA levels. LC-MS/MS was used to identify proteins that coimmunoprecipitate (coIP) with YBX1 from nuclear lysates of hepatocytes isolated from DIO mice. The functional impact of PPARγ-related coIP hits were confirmed with siRNA in palmitate-treated hepatocytes. **Results:** We observed that Ybx1 is both necessary and sufficient to stimulate PPARγ transcription in response to palmitate-induced lipotoxicity in human and mouse primary hepatocytes. Furthermore, we showed that YBX1 binds to C/EBPα, a known transcriptional activator of PPARγ in differentiating preadipocytes. The suppression of C/EBPα entirely counteracted the transcriptional regulation of Ybx1 over PPARγ, affirming the critical role of a Ybx1/C/EBPα complex in DIO hepatocytes. **Conclusion:** While a significant increase in Ybx1 expression in differentiating preadipocytes may support healthy adipogenesis, our findings reveal a detrimental mechanism in which the maladaptive activation of Ybx1 within hepatocytes directly stimulates the C/EBPα:PPARγ pathway, leading to an increase in adipogenic gene expression that becomes lipotoxic within the liver. Given that YBX1 expression was found to surge by over 8-fold in the livers of obese NAFLD patients, YBX1 presents itself as a potential therapeutic target for NAFLD and NASH.

2320-C | HEPATOCYTE DEPLETION OF ERK5 IMPAIRS THE RESPONSE TO LIPOTOXIC OXIDATIVE STRESS RESULTING IN DEFECTIVE INSULIN RECEPTOR SIGNALING

Alessio Menconi[1], Giovanni Di Maira[1], Giulia Lori[1], Nadia Navari[1], Maria Letizia Taddei[1], Salvatore Petta[2], Rosaria Maria Pipitone[3], Claudia Campani[4], Cathy Tournier[5], Elisabetta Rovida[1] and Fabio Marra[1], (1) University of Florence, (2)Sezione Di Gastroenterologia, Dipartimento Promozione Della Salute, Materno-Infantile, Di Medicina Interna e Specialistica Di Eccellenza "G. D'alessandro", Università Di Palermo, Palermo, Italy, (3)University of Palermo, (4)University of Florence, Italy, (5)University of Manchester

Background: Insulin resistance is an early event in nonalcoholic fatty liver disease (NAFLD), but the molecular mechanisms underlying the reduced response to insulin are still elusive. The mitogen-activated protein kinase ERK5 has been implicated in the development of hepatic fibrosis and cancer. Aim of this study was to investigate the role of ERK5 in the regulation of hepatocyte sensitivity to insulin. **Methods:** A murine hepatocyte cell line (MMH) was silenced using lentiviral vectors encoding shRNA for the ERK5 gene. Mitochondrial depolarization was assayed using the TMRE staining protocol. OXPHOS was measured by Seahorse. Mice with hepatocyte-specific deletion of ERK5 (ERK5ΔHep) were fed with a high-fat diet (HFD) for 16 weeks. For Glucose and insulin tolerance tests were conducted injecting 1 g/kg BW glucose or 0.8 U/kg BW insulin, respectively, i.p. **Results:** MMH stably silenced for ERK5 showed reduced Akt activation following insulin stimulation. When ERK5-silenced cells were exposed to palmitic acid and then stimulated with insulin, Akt activation was abrogated, and expression of the insulin receptor (IR) reduced. Additionally, ERK5 silencing induced phosphorylation and activation of JNK, resulting in phosphorylation of IRS-1 on inhibitory residues (S307). In parallel, an increase of mitochondrial ROS generation was observed in ERK5-depleted MMH. ERK5 is known to induce a NRF2-dependent anti-oxidative stress response. Expression of the NRF2-target genes HMOX1 and NQO1 was reduced in ERK5-silenced MMH. Treatment with NAC, a free-radical scavenger, prevented the downregulation of the IR and the increase in IRS1 phosphorylation on S307. Measurement of the mitochondrial membrane potential indicated a strong depolarization in ERK5-silenced cells, together with an impairment of mitochondrial OXPHOS, associated with up-regulated expression of PGC-1alpha and TRIB3, a negative regulator of insulin signalling through inhibition of Akt. ERK5ΔHep mice exhibited impaired glucose tolerance and reduced insulin sensitivity. Hepatocyte depletion of ERK5 in vivo was also associated with reduced expression of IR, and increased expression of PGC-1α and TRIB3. **Conclusion:** We have elucidated a new role of ERK5 in maintaining hepatocyte insulin sensitivity, via an antioxidant response involving IRS-1, PGC-1α, and TRIB3, and converging on Akt activation.

2321-C | HEPATOCYTE HEDGEHOG ACTIVITY CONTROLS NAFLD SEVERITY BY REGULATING SENESCENCE-ASSOCIATED SECRETOME

Ji Hye Jun[1], Kuo Du[2], Seh-Hoon Oh[2], Raquel Maeso Díaz[2], Rajesh Kumar Dutta[3], Anna Mae Diehl[2] and Duke University, (1)Duke Universty, NC, (2)Duke University, (3)Duke University, Durham, NC

Background: NAFLD and other inflammatory liver diseases induce hepatocyte DNA damage and senescence. NAFLD severity correlates with the burden of senescent hepatocytes but the mechanisms driving hepatocyte senescence, and how this exacerbates NAFLD, are unknown. We recently discovered hepatocytes become senescent when Smoothened (Smo, an obligatory Hedgehog pathway component) is disrupted. Smo-depleted hepatocytes remain viable but their state change has a robust effect on hepatocyte-secreted proteins. Therefore, we hypothesized hepatocyte Smo activity controls NAFLD severity via the hepatocyte senescence-secretome. **Methods:** Adult $Smo^{flox/flox}$ mice were treated with control- or AAV8-TBG-Cre vectors to delete Smo specifically in hepatocytes, and fed with CDAA-HFD for 8 weeks to induce NAFLD; blood and livers were harvested for serological, histological, molecular and proteome-profiler analysis. Secreted proteins that were differentially abundant in sera of chow-fed Smo(-) and Smo(+) mice, and that were also differentially expressed in hepatocyte lysates from these two groups, were identified. AML-12 hepatocytes and primary Smo(-) hepatocytes were cultured with oleic and palmitic acid to model lipotoxic stress and treated with vehicle or proteins that were suppressed by Smo deletion; effects on lipotoxicity and senescence were compared. **Results:**

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

Depleting Smo in hepatocytes increased markers of DNA damage (8OHDG, γH2AX) and senescence (p16, p21), and exacerbated the effects of CDAA-HFD, increasing markers of steatosis (Oil-red O), lipotoxicity (4-HNE), and fibrosis (α-SMA, Sirius red). Compared to sera of Smo(+) mice, sera of Smo(-) mice were depleted of several proteins that are known to inhibit senescence, including FGF-1, P-selectin, and thymidine phosphorylase-TP. These proteins were also decreased in Smo(-) hepatocyte lysates. When added to AML-12 cells and Smo(-) primary hepatocytes during culture under lipotoxicity-inducing conditions, these proteins inhibited markers of lipotoxicity (4-HNE) and senescence (p16, p21, β-galactosidase) and enhanced viability. In AML-12 cells, TP increased Gli2, a down-stream transcription factor that is normally activated by Smo. **Conclusion:** Inhibiting Hedgehog signaling in hepatocytes exacerbates NAFLD by suppressing hepatocyte production of proteins that normally protect cells from lipotoxicity and senescence during metabolic stress. 2322-C | HEPATOCYTE-DERIVED EVS MEDIATES PATHOPHYSIOLOGICAL CHANGES IN GASTROCNEMIUS OF NASH MICE AS WELL AS SKELETAL MUSCLE CELLS

Akiko Eguchi[1], Motoh Iwasa[1], Hiroshi Yukawa[2,3], Naonobu Fujita[4], Satoru Noguchi[5], Shinichiro Hayashi[5], Yosky Kataoka[6], Hiroshi Kitamura[7], Ryuta Shigefuku[1], Yasuyuki Tamai[1], Ryo Nakagawa[3], Sanae Fukuda[8], Yoshinao Kobayashi[1], Masatoshi Watanabe[1], Yoshinobu Baba[2], Ariel E. Feldstein[9], Yoshiyuki Takei[1] and Hayato Nakagawa[1], (1)Mie University, (2)Nagoya University, (3)Chiba University, (4)Tokyo Institute of Technology, (5)National Center of Neurology and Psychiatry, (6)Riken Biosystems Dynamics Research, (7)Rakuno Gakuen University, (8)Kansai University of Welfare Sciences, (9)University of California, San Diego

Background: Sarcopenia is a common and potentially serious complication of chronic liver disease while potential humoral factors involved in liver-muscle cross-talk are not fully understood. We have demonstrated that hepatocyte-derived extracellular vesicles (HC-EV) from damaged hepatocytes are intercellular pathological mediators that contribute to the progression of liver disease. Here, we investigate whether HC-EV is an inter-organ disease mediator involved in skeletal muscle injury. **Methods:** Gastrocnemius injury in NASH mice fed with a choline-supplemented amino acid diet were accessed via qPCR, histological staining and electron microscopy. Pharmacokinetics of fluorescently labeled HC-EV were assessed by imaging. The characterization of HC-EVs isolated from NASH mice were performed by FACS, nanotracking and miR-array. The internalization and effects of HC-EV on skeletal muscle cells (C2C12 myotube) were assessed via laser confocal microscopy and qPCR. Circulating EV-miRs in human NASH with low skeletal muscle mass (LMM), NASH and healthy individual's ($n = 3$) were detected by miR-array. **Results:** Liver and spleen weights were increased ($p < 0.01$) in NASH mice associated with an increase of liver collagen1 and TNF-a mRNA levels ($p < 0.01$). Gastrocnemius muscle/body weight ratio was decreased in NASH mice ($p < 0.01$) associated with abnormal mitochondrial morphology and reduction of mRNA levels related to muscle differentiation (myogenin], metabolism (uncoupling protein 3, UCP3), repair (forkhead box protein O1, FOXO1) and mitochondrial function (cytochrome c oxidase subunit 2, mtCOX2) ($p < 0.05$). Imaging analysis revealed that a part of HC-EVs, which were increased ($p < 0.05$) in the blood of NASH mice, propagated to the gastrocnemius muscle. The number of HC-EVs isolated from mice was elevated in NASH mice compared to control mice ($p < 0.01$), consistent with the large size of EVs with a

diameter of 250 nm. HC-EVs were efficiently internalized into C2C12 myotubes and induced a reduction of mRNA levels related to muscle metabolism, repair and mitochondrial function (UCP3, FOXO1 and mtCOX2) ($p < 0.05$), which were consistent with those induced in the gastrocnemius muscles of NASH mice. The miR-array analysis detected 127 up-regulated and 140 down-regulated miRs ($p < 0.05$) in NASH-HC-EVs. 68 circulating EV-miRs were significantly changed in human NASH-LMM vs. NASH vs. healthy individual's ($P < 0.05$) and identified human NASH-LMM with a specificity of 0.98 and a sensitivity of 0.96. HC-EV-miRs were also detected in human NASH-LMM. **Conclusion:** HC-EVs contribute the development of skeletal muscle damage associated with chronic liver disease as an interorgan disease mediator. HC-EV-miR is a novel biomarker and may be involved in the progression of hepatic sarcopenia in NASH patients, while further investigations are warranted.

2323-C | HEPATOCYTE-SPECIFIC CK1ε DELETION IMPROVES FATTY LIVER AND AMELIORATES IN VITRO STEATOHEPATITIS IN MICE

Leya Mwense[1], Hyuneui Jeong[1], Daram Yang[1], Tien Huyen Ton Nu Bao[1], Sang-Ik Oh[1], Jong-Won Kim[2] and Bumseok Kim[1], (1)Biosafety Research Institute and College of Veterinary Medicine, Jeonbuk National University, Iksan 54596, Korea., (2)University of Pittsburgh, Center for Pharmacogenetics and Department of Pharmaceutical Sciences, Pittsburgh, PA

Background: The liver plays a major role as the body's glucose reservoir. However, excessive amounts of dietary refined sugar and high fructose are among the known causes of fatty buildup that can lead to fatty liver disease, which in turn is a diabetic chief determinant. Non-alcoholic fatty liver disease (NAFLD) is the usual outcome of obesity, dyslipidemia, and insulin resistance. Regardless of the rise in dietary trends linked to NAFLD, the most effective therapeutic strategy to combat liver disease is currently unavailable. Casein kinase 1 epsilon (CK1ε), a member of the serine/threonine family of protein kinases, may be a potential target for drug development as they are mostly overexpressed in various disease models. Its role in the development of acute and chronic liver diseases remains elusive. **Methods:** To identify the role of CK1ε in the progression of NAFLD, hepatocyte-specific CK1ε knockout mice (CK1ε $^{\Delta HEP}$) were first generated by crossing CK1ε $^{fl/fl}$ mice with Alb-Cre mice. An F2 generation of hepatocyte-specific CK1ε $^{fl/fl}$ Alb-Cre^{+} knock-out mice were then obtained. CK1ε $^{fl/fl}$ mice and CK1ε $^{\Delta HEP}$ were fed a Western diet (WD) and a normal chow diet (CD) for 16 weeks, respectively. **Results:** Compared with CK1ε $^{fl/fl}$ WD-fed mice, CK1ε $^{\Delta HEP}$ WD-fed mice gained significantly less body weight with improved oral glucose tolerance. As evidenced by histological changes, early-stage steatosis severity in CK1ε $^{\Delta HEP}$ WD-fed mice was also reduced. Strikingly, CK1ε $^{\Delta HEP}$ WD-fed mice showed significantly lower hepatic concentrations of total triglycerides and total cholesterol relative to CK1ε $^{fl/fl}$ WD-challenged mice. To further validate the novel function of CK1ε, primary hepatocytes were isolated from CK1ε $^{\Delta HEP}$ and treated with 0.4mM palmitic acid (PA). The results showed that CK1ε $^{\Delta HEP}$ decreased PA-induced inflammatory responses and lactate dehydrogenase compared to the counterpart CK1ε $^{fl/fl}$ PA control. Also, intracellular accumulation of lipids was significantly reduced in PA-induced CK1ε $^{\Delta HEP}$ and affected lipid metabolism. CK1ε $^{\Delta HEP}$ further attenuated PA-induced lipo-apoptosis in primary hepatocytes. As a molecular mechanism underlying CK1ε action, the non-canonical JNK/MAPK signaling pathway was considered, and phosphorylated c-Jun proteins were reduced significantly in the CK1ε $^{\Delta HEP}$ positive control than CK1ε $^{fl/fl}$ positive control (both *in-vitro* and *in-vivo*). **Conclusion:** This work highlighted the role of CK1ε as a NAFLD modulator via stimulating the JNK/MAPK signaling pathway. Therefore, CK1ε played a pivotal role in hepatic lipid accumulation. This role enables us to establish better therapeutic strategies targeting NAFLD. Keywords: Casein kinase 1 epsilon, Non-alcoholic steatohepatitis, Hepatocyte-specific, Inhibition

2324-C | HEPATOCYTE-SPECIFIC GROWTH DIFFERENTIATION FACTOR 15 OVEREXPRESSION AMELIORATES HIGH-FAT DIET-INDUCED OBESITY AND LIVER STEATOSIS VIA INDUCTION OF FIBROBLAST GROWTH FACTOR 21 IN MICE

Kento Takeuchi, Kanji Yamaguchi, Takao Shirono, Yusuke Takahashi, Kota Yano, Seita Kataoka, Yuya

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Seko, Michihisa Moriguchi and Yoshito Itoh, Kyoto Prefectural University of Medicine

Background: Growth Differentiation Factor (GDF) 15 is a stress-response endocrine growth factor that belongs to the TGFβ family and also has both hepatokine and mitokine aspects together with Fibroblast Growth Factor (FGF) 21. GDF15 is also induced by various cancer cells and platinum drugs, and is known to induce anorexia via its receptor GFRAL-RET, which is expressed in the in brainstem neurons. From a different point of view, it has been reported to improve glucose intolerance due to its potent anti-obesity effect, and NAFLD by enhancing metformin action in diabetic mouse models. Recently demonstrated, CNOT6L (CCR4-NOT Transcription Complex Subunit 6 Like), which is involved in deadenylation-dependent mRNA degradation, is expressed in a diet-induced manner and is involved in suppression of GDF15 and FGF21 expression at the transcription level. In this study, we examined the synergistic effects of GDF15 and FGF21 in a mouse NAFLD model. **Methods:** We examined hepatocyte-specific enhancer/promoter of GDF15 or FGF21 expression plasmids in high-fat diet (HFD)-fed male mice. One week after hydrodynamic injection of those plasmids via the tail vein of 8-week-old male B6 mice, the mice were divided into two groups and fed a normal diet and a HFD for 8 weeks to induce NAFLD. A control plasmid group was also established for each of these diets. After treatment, blood, liver and epididymal fat samples were collected and analyzed for the glycose and lipid metabolism-related gene expression **Results:** Once hydrodynamic injection for GDF15 or FGF21 delivery sustained high circulating levels of those respectively, resulting in marked reductions in body weight, epididymal fat mass, insulin resistance, and liver steatosis. The amount of food intake per mouse was unchanged in the first 4 weeks, but decreased in the GDF15-treated group in the latter 4 weeks. However, no difference was observed in food intake per body weight. Hepatic steatosis canceled in the GDF15-treated group. HFD increased hepatic CNOT6L and FGF21 mRNA expression but had no effect on GDF15 expression. On the other hand, HFD induced serum GDF15 and FGF21 levels. In addition, GDF15 treatment increase hepatic FGF21 mRNA expression but FGF21 treatment had no effect on GDF15 expression. GDF15 suppressed CNOT6L mRNA expression and stimulated ER stress-related pathways, which may have contributed to the increased expression of FGF21. **Conclusion:** GDF15 and FGF21, both liver-derived cellular stress response mitokines, have their blood levels increased in NAFLD. Recently, direct effects of GDF15 on the liver were reported, and in this study, induction of FGF21 expression in the liver was demonstrated under GDF15 overexpression.

2325-C | HEPATOCYTE-SPECIFIC UBC13 DELETION DRIVES NAFLD PROGRESSION VIA CELLULAR SENESCENCE AND GLUTAMINOLYSIS

Lien Reolizo, Cedars-Sinai Medical Center, Los Angeles, CA and Ekihiro Seki, Cedars-Sinai Medical Center, Torrance, CA

Background: Non-alcoholic fatty liver disease (NAFLD) is a complex and multifactorial disease characterized by a buildup of lipids in hepatocytes, to the more advanced non-alcoholic steatohepatitis (NASH) with inflammation and fibrosis. The incidence of NAFLD increases with age, and aging-related mechanisms such as cellular senescence have been proposed as pathogenic drivers. Cellular senescence is defined by permanent and irreversible cell cycle arrest and enhanced glutaminolysis improves survival of senescent cells. UBC13, a ubiquitin E2 conjugating enzyme, plays a crucial role in K63-linked polyubiquitination and promotes DNA repair. DNA damage accumulation is reported as a commonly underlying cause of cellular senescence. We hypothesize that UBC13 acts as a negative regulator of cellular senescence and glutamine metabolism during the development

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of NAFLD. **Methods**: Wild-type and hepatocyte-specific UBC13 knockout (UBC13 KO) developed NAFLD by high fat diet (HFD) feeding for 6 weeks. For senolytic treatments, (1) vehicle or Dasatinib (D:5 mg kg^{-1}) and Quercetin (Q:10 mg kg^{-1}) were administered via oral gavage or (2) intraperitoneally injected with vehicle or CB-839 (Glutaminase inhibitor; 10 mg kg^{-1}). To investigate ageing, mice were housed for various periods up to 15 months. **Results:** We identified that hepatocyte-specific deletion of UBC13 increased liver injury and hepatic steatosis. UBC13 KO induced DNA damage, marked by the presence of nuclear γ-H2AX foci and upregulation of cell cycle markers (p16, p21 and p53), leads to cellular senescence. We found that UBC13 deletion increased Glutaminase 1 (GLS1) expression, suggesting that overactivated glutaminolysis may contribute to hepatic cellular senescence. We demonstrated that inhibiting glutaminolysis by blocking GLS1 using CB-839 and senolytic combination of D/Q significantly mitigated liver injury, hepatic steatosis and senescence. Increased fat deposition severely impairs liver function and exacerbates the aging phenotype. Consistent with these findings, we discovered senescent hepatocytes accumulate in parallel with age which can be ameliorated by senolytic combination of D/Q and glutaminase targeting using CB-839. **Conclusion:** Together, these data indicate that UBC13 plays a causal role in the development of NAFLD pathogenesis, and that senescence can cause steatosis by inducing glutaminolysis. These findings support a cogent argument of targeting senescent cells for the treatment of NAFLD/NASH.

f 2326-C | HEPATOPROTECTION THROUGH REMOVAL OF MITOCHONDRIAL S-GLUTATHIONYLATION BY A CYSTEINE MUTANT ON THE COMPLEX I SUBUNIT

Suyavaran Arumugam, Yan Zhang, Yingdong Zhu, Wajahat Z. Mehal and Xinshou Ouyang, Yale University, New Haven, CT

Background: S-glutathionylation (SSG), a prevailing redox sensor, regulates mitochondrial metabolism and function. The significance of mitochondrial protein S-Glutathionylation (SSG) in hepatic metabolism and function remains understudied despite its crucial role. Aim: To provide a comprehensive review of oxidative stress-induced mitochondrial protein modifications, with a particular focus on SSG, and its effects on hepatic metabolism and function. **Methods:** Mouse primary hepatocytes were treated with MitoPQ, a mitochondria-targeted redox cycler followed by mitochondria isolation coupled LC-MS/MS analysis. Bioinformatic analysis identified protein modifications and further homology search. The human NDUFS6^{-C87S} mutant transgenic gene (Tg) mice were generated by retrieving the transgene cassette from the plasmid backbone, followed by standard pronuclear microinjection, embryo transfer, gestation, weaning, and genotyping. Lipid metabolism by BODIPY staining, MitoROS by mitoSOX staining, mitochondrial membrane potential (MMP) by JC-1, and Glucose tolerance test (GTT) on a High Fat Diet (HFD) were measured. **Results:** Proteome-wide analysis of mitochondrial protein modifications in mitoPQ-treated mouse hepatocytes revealed multiplex modifications with over 65 differentially expressed proteins with SSG modification. Gene Ontology (GO) classification has revealed complex I as a significant SSG target. The selective reduction of Cys87 residue containing NDUFS6 fragments is particularly interesting since NDUFS6 is a subunit of the first enzyme complex of ETC. Homology search indicates that C87 residue containing DNA sequence (CTGCGATGG) of NDUFS6 is highly conserved among species. The expression of SSG-resistant human NDUFS6^{-C87S} mutant in hepatocytes resulted in reduced lipid accumulation (over 50% reduction, $P < 0.01$), reduced mitoROS (over 80% reduction of mitoSOX, $P < 0.01$) and prevented the loss of MMP ($P < 0.01$) in response to palmitate stimulation. The human NDUFS6^{-C87S} Tg mice and littermates exhibited significant improvement in metabolic dysfunction as evidenced by significant enhancements in glucose tolerance through the GTT (Blood glucose level Tg vs WT, $P < 0.01$) when subjected to a HFD condition. Furthermore, the mitochondrial protein SSG in the Cys87 residue of NDUFS6 was lost in hepatocyte specific PKM2 knockout condition in response to mitoPQ, PKM2 is known a glycolytic rate enzyme in the regulation of mitochondrial metabolism and function. **Conclusion:** The removal of SSG in ETC complex I protein NDUFS6 by C87S mutation in hepatocytes improved mitochondrial oxidative reactions related to hepatic metabolism and function. Manipulation of NDUFS6^{-C87} such as through site mutation holds great potential as a therapeutic target for improving hepatic metabolism and mitigating steatosis in NAFLD/NASH.

2327-C | HIGH-FAT DIET INCREASES SUSCEPTIBILITY TO LIPOPOLYSACCHARIDE-INDUCED LIVER INJURY IN OBESE KK-AY MICE

Satoshi Sakuma, Kazuyoshi Kon, Kumiko Arai, Akira Uchiyama, Hiroo Fukada, Toshifumi Sato, Shunhei Yamashina and Kenichi Ikejima, Juntendo University School of Medicine

Background: Obesity and metabolic syndrome are the prominent risk factors for the multi-organ damage and mortality during systemic infectious diseases. Cytokine storm is a key event for the organ damage including severe liver injury, but the mechanism underlying the sensitization by metabolic dysfunction is still unclear. We investigated the impact of metabolic syndrome and high-fat diet (HFD) load in exacerbation of cytokine storm and liver damage following lipopolysaccharide (LPS) challenge using obese diabetic KK-A^y mice. **Methods:** Male KK-A^y mice were fed a diet containing high-fat (HFD) or control diet for 4 weeks. C57Bl6/J mice (BL6) was used as a control strain. Mice were sacrificed at 1-24 hr after intraperitoneal injection of LPS 5 mg/kg BW or saline. Apoptotic cell death was detected by TUNEL staining. Hepatic mRNA was measured by RT-PCR. **Results:** KK-A^y fed an HFD showed prominent hepatic steatosis after HFD feeding, whereas Bl6 mice developed trivial steatosis even after HFD. After a single injection of LPS, all Bl6 fed a control diet survived for 24hr, indicating that this dose was sublethal. HFD-fed BL6 died within 24 hr after injection of LPS nearly 20%. In sharp contrast, the mortality rate 24 hr after LPS injection reached 86% in HFD-fed KK-A^y, which was significantly higher than 16% of control diet-fed KK-A^y given LPS. Serum ALT levels 12 h after LPS in HFD-fed KK-A^y increased to 673 $\pm$ 191 IU/L, which were obviously higher than those in HFD-fed BL6 reaching 193 $\pm$ 58 IU/L. Indeed, HFD-fed KK-A^y showed marked apoptotic cell expression after LPS. Hepatic expression of TNFα mRNA 1 hr after LPS were almost doubled in HFD-fed KK-A^y as compared to control diet-fed KK-A^y. IL1β mRNA was also significantly higher in HFD-fed KK-A^y 1-3 h after LPS than those in control diet-fed KK-A^y. Prior to LPS, HFD-loaded KK-A^y showed increased hepatic expression of TLR-4 and CD-14 nearly 3-fold and 7.5-fold, respectively. Further, KK-A^y fed an HFD showed marked induction in hepatic LPS-binding protein (LBP) mRNA, the levels reaching 2.6-fold higher than those in control diet-fed KK-A^y. In contrast, HFD-induced increases in TLR-4, CD-14, and LBP were not observed in Bl6. Moreover, HFD-feeding elicited overexpression of IL-6 in the liver only in KK-A^y but not in Bl6. **Conclusion:** These findings clearly indicate that KK-A^y mice, which develop obesity and severe fatty liver following HFD-feeding, are obviously vulnerable to LPS, showing higher mortality and severer liver injury. The underlying mechanisms most likely involve sensitization of hepatic macrophages by upregulation of pattern-recognition receptors and inflammasome-related reactions against LPS, as well as induction of LBP production in hepatocytes caused by IL-6. It is therefore concluded that metabolic dysfunction-associated fatty liver appears to be an important risk factor of exacerbation in multiple organ failure including severe liver damage under condition of cytokine storm.

f 2328-C | HSD17B13 MODULATES HEPATOCYTE-TO-HEPATIC STELLATE CELL COMMUNICATION THROUGH DIHOMES AND INTERFERON SIGNALING

Wenqi Cui[1], Yanling Ma[2], Diego Miranda[3], Grant Budas[3] and Yaron Rotman[1], (1)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (2) NIH Clinical Center, (3)Gilead Sciences, Inc.

Background: Loss-of-function variants in *HSD17B13* protect against non-alcoholic steatohepatitis (NASH)-related fibrosis in humans. While HSD17B13-targeted therapies already show promising results in clinical trials, the molecular mechanism for protection and substrates of HSD17B13 remain largely unknown. We hypothesized that HSD17B13 regulates the communication between hepatocytes and hepatic stellate cells (HSC). **Methods:** *Hsd17b13* knockout (KO) and littermate control mice (n = 13-14) were fed with choline-deficient amino acid-defined high fat diet (CDAA-HFD) for 12 weeks to establish NASH fibrosis. A hepatocytes-to-HSCs conditioned media (CM) *in vitro* model was used to study HSD17B13-regulation of hepatocyte-to-HSC communication. RNA-seq with pathway analysis, metabolomics, and qPCR were utilized. Hepatic gene expression was examined in a cohort of NASH patients undergoing bariatric surgery and genotyped for *HSD17B13* variants. **Results:** *Hsd17b13* knockout (KO) attenuated NASH

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

fibrosis by 34% ($p = 0.003$) while upregulating hepatic interferon (IFN) signaling in CDAA-HFD fed mice, as previously reported. *In vitro,* silencing hepatocyte *Hsd17b13* upregulated IFN stimulated genes (ISG) (*Cxcl10*, 2.6-fold, $p = 0.03$; *Irf7*, 1.7-fold, $p = 0.004$; *Isg15*, 1.6-fold, $p = 0.001$) and exposing HSCs to CM from these hepatocytes decreased HSC activation ($p < 0.05$). LPS induction of hepatocyte IFN signaling was sufficient to decrease HSC activation by CM (50% reduction, $p < 0.05$). In patients with NASH (n = 244), hepatic expression of multiple ISGs was significantly upregulated (e.g. *ISG15*, 1.7-fold, $p < 0.0001$) in carriers of the protective *HSD17B13* rs72613567 TA variant. Metabolomic analysis revealed that hepatic levels of the linoleate metabolites 9,10-DiHOME and 12,13-DiHOME were lower in CDAA-HFD-fed KO mice (46%, $p < 0.02$ & 28%, $p < 0.02$, respectively). Treating hepatocytes *in vitro* with 9,10-DiHOME or 12,13-DiHOME significantly suppressed the induction of ISGs by *Hsd17b13* knockdown. **Conclusion:** We found that intact HSD17B13 impairs hepatic IFN signaling and that loss of HSD17B13 can restore this signaling *in vitro*, in mice, and in humans with NASH. Restoration of hepatocyte IFN signaling is sufficient to ameliorate HSC activation and subsequent fibrogenesis. We show that the suppression of IFN signaling by HSD17B13 is likely mediated by DiHOMEs, which are potential enzymatic products of HSD17B13. Taken together, our findings provide new insights on how HSD17B13 and HSD17B13-targeted therapies may affect NASH-related fibrosis.

2329-C | HUMAN NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) PROMOTING GCKR GENETIC VARIANT P446L PROMOTES GLYCOGEN AND TRIGLYCERIDE ACCUMULATION IN HUMAN LIVER HUH-7 CELLS

Yue Chen[1], Brahmpreet Saini[1], Jason Chen[2], Brian D Halligan[1] and Elizabeth K. Speliotes[1,3], (1)University of Michigan Medical School, (2)Northwestern University, (3)University of Michigan Medical School, Ann Arbor, Michigan, USA

Background: Nonalcoholic fatty liver disease (NAFLD) is caused by the accumulation of excess fat in liver and leads to cirrhosis. NAFLD is heritable, affects about 30% of the general population and is becoming the leading cause of liver disease. Human genome wide association studies have identified a genetic variant in GCKR(P446L) that promotes NAFLD but how this variant changes GCKR function to cause NAFLD is not known. Glucokinase regulator (GCKR) encodes glucokinase regulatory protein (GKRP) is expressed in liver and interacts with and inhibits glucokinase (GCK) to negatively regulate glucose utilization and storage. GKRP is a key player in regulation of hepatic GCK and glycogen synthesis in human hepatocyte. GKRP forms a complex with GCK, inhibiting GCK while also maintaining a stable pool of GCK available when needed. Prior in vitro studies have shown that the effect of GKRP on glycogen synthetic flux is nearly perfectly reciprocal to the effect of GCK on this flux. **Methods:** Using lentiviral integration, we created stable human Huh-7 cell lines with wildtype and mutant P446L GCKR overexpressed or knocked down using shRNAs. We measured intracellular triglyceride and glycogen levels using biochemical assays as well as lipid dyes and microscopy and quantitated it using cell profiler. We measured GYS2, GCK, GKRP, FASN and ACC protein levels using Western blot under various glucose concentrations. **Results:** GCKR(P446L) increased triglyceride and glycogen accumulation compared with GCKR(WT) overexpressed or control Huh-7 cells across different doses of glucose (0, 2, 5 and 25mM) after 8 hours of incubation. The most significant difference between WT and P446L occurred at 2mM glucose ($p < 0.05$). Overexpression of wild-type GCKR significantly decreased glycogen content compared with control cells only at 25mM glucose ($p < 0.01$). Knockdown of GCKR significantly increased cellular glycogen compared with control cells at 2 and 5mM glucose. Western blot results showed P446L variant significantly increased protein level of glycogen synthase (GYS2), Fatty Acid Synthase (FASN) and Acetyl- CoA Carboxylase (ACC) and glucokinase (GCK) compared to cells expressing vector and GCKR(WT) at 2 and 5mM glucose. Knockdown GCKR significantly increased GYS2 protein levels at 2mM glucose ($p < 0.0001$). **Conclusion:** GCKR (P446L) increased triglyceride and glycogen accumulation compared with GCKR (WT) in Huh-7 cells suggesting a cell autonomous effect of triglyceride and glycogen accumulation. GCKR (P446L) mimics the knockdown of GCKR in phenotypically in these assays suggesting that P446L mutation is a loss of function change. At least one-way GCKR(P446L) increases TG in liver is by increasing ACC and FASN levels to increase de novo lipogenesis. GCKR (P446L) may also increase glycogen accumulation at 2mM glucose by up-regulating GYS2. These experiments help explain how P446L causes liver damage.

f 2330-C | HYDROPHOBIC BILE ACIDS ACCELERATE NAFLD-ASSOCIATED HCC DEVELOPMENT IN A MOUSE MODEL WITH HUMAN-LIKE BILE ACID COMPOSITION

Hajime Ueda[1], Akira Honda[2], Teruo Miyazaki[1] and Tadashi Ikegami[2], (1)Tokyo Medical University Ibaraki Medical Center, (2)Gastroenterology, Tokyo Medical University Ibaraki Medical Center

Background: The mechanisms of developing hepatocellular carcinoma (HCC) in non-alcoholic fatty liver disease (NAFLD) remain unclear. Feeding a high-fat/high-sucrose diet (HFHSD) without cholesterol loading or a carcinogen to conventional mice rarely results in severe fibrosis or HCC development. Mice possess a highly hydrophilic and cytoprotective bile acid (BA) composition due to Cyp2a12 and Cyp2c70 genes, which are absent in humans. Therefore, we hypothesized that NAFLD disease progresses in mice as it does in humans when BAs are modified to be hydrophobic. **Methods:** Eleven-week-old C57BL/6J wild-type (WT) and C57BL/6J derived Cyp2a12/Cyp2c70 double knockout (DKO) mice were used. The mice from each strain were divided into two groups; one was given a normal diet (ND), and the other was administered an HFHSD. Samples were collected at 26, 41, 59, and 70 weeks of age for histopathological, biochemical, and immunological analyses. **Results:** No differences in body weight gain were observed between WT and DKO mice after feeding an HFHSD. Hepatic steatosis and insulin resistance were less severe in DKO mice than in WT mice, and no significant differences in hepatic inflammation markers were discovered between the two groups. However, hepatic fibrosis was more advanced in DKO mice than in WT mice, and HCC (a pathologically well-differentiated type) developed in 70% of the HFHSD-fed DKO mice at 59 weeks. Furthermore, at 70 weeks, HFHSD-fed DKO mice demonstrated severe hepatic fibrosis with the disappearance of hepatic lipid droplets and a 100% incidence of HCC. The BA pool of DKO mice was smaller than that of WT mice regardless of diet up to 26 weeks but was greater than that of WT mice at 59 weeks with increases in chenodeoxycholic acid and lithocholic acid. Hepatic oxysterol concentrations were higher in DKO mice than in WT mice and in HFHSD as compared to ND. RNA sequencing analysis of the liver at 41 weeks revealed significant differences in the expressions of several genes related to fatty acid metabolism, oxidative stress, and carcinogenesis between WT and DKO mice treated with HFHSD. **Conclusion:** Hydrophobic BA composition is necessary to induce severe fibrosis and HCC in mice without modifying genes essential in humans or administering non-physiological amounts of cholesterol or carcinogens. Increased hydrophobic BAs mitigate insulin resistance and hepatic inflammation, presumably by activating Takeda G protein-coupled receptor 5. However, hydrophobic BAs promote hepatic fibrosis and hepatocarcinogenesis, especially under conditions of NAFLD.

2331-C | INCREASED BAS WAS ASSOCIATED WITH CHOLESTATIC GENE PROFILE IN PATIENTS WITH NASH

Shih-Chieh Chien[1], Chiung-Yu Chen[1], Yau-Sheng Tsai[1], Pin-Nan Cheng[2], Hung-Wen Tsai[3], Yih-Jyh Lin[1], Shu-Chu Shiesh[1], Yen-Cheng Chiu[1] and Toad Chiu[3], (1)National Cheng-Kung University Hospital, (2)National Cheng Kung University Hospital, Taiwan, (3)National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: Increased serum bile acids (BAs) was observed in NASH patients but the pathogenesis was unclear. Through examine human serum and hepatic tissue samples, we dissected the profile of serum BAs and BA-related genes in NASH patients and examined its clinical significances. **Methods:** We prospectively collected hepatic tissues and serum samples from NASH patients and healthy living liver donors. By investigated tissue mRNA levels of BA related genes and measured their serum BAs levels, we established the pathophysiology in NASH related cholestasis. **Results:** We had collected 69 NASH patients and 10 healthy living liver donors (as control). Serum BAs were significantly increased in NASH patients, especially the primary and conjugated BAs ([NASH vs. control, mean (SEM): 3.94 (0.38) μM vs. 1.55 (0.71) μM, $p < 0.0001$]). Tissue mRNA analysis revealed that level of BA-related genes from NASH patients favoring cholestasis. Specifically, mRNA level of *CYP7A1* was significantly increased in NASH patients (relative expression level in NASH patients = 10.87 times of control $p < 0.001$). Fasting serum FGF19 was positively correlated with serum total primary BAs level (Rho = 0.38, $p < 0.001$). Clinically, the conjugated primary BA: glycocholic acid (GCA) was the most conspicuous BA that positively correlated with hepatitis markers, including ALT (Rho = 0.34, $p = 0.003$), AST (Rho = 0.43, $p = < 0.0001$), Alk-P (Rho = 0.24, $p = 0.04$) and GGT (Rho = 0.41, $p = 0.0002$). Clinical parameters of metabolic syndromes, including BMI, serum lipid and glucose profile were not correlated with serum GCA. **Conclusion:** In NASH patients, dysregulated BA homeostasis was

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

noted and favoring cholestasis. Serum GCA was the most obviously increased serum BAs which positively correlated with serum hepatitis markers.

2332-C | INHIBITING SARM1 IS MORE EFFICACIOUS THAN NICOTINAMIDE RIBOSIDE SUPPLEMENTATION FOR THE TREATMENT OF A MOUSE MODEL WITH NAFLD/NASH

Yasmine Liu[1], Angelique M.L. Scantlebery[2], Keno Strotjohann[1], Sandra Rodríguez-López[1], Xiaoxu Li[1], Krisztian Homicsko[3], Karen Smith[4], Jeffrey Ciavarri[4], Maroun Bou-Sleiman[1], Riekelt H Houtkooper[2] and Johan Auwerx[1], (1)École Polytechnique Fédérale De Lausanne, (2)Amsterdam University Medical Center, Amsterdam, Netherlands, (3)Lausanne University Hospital, (4)Mitobridge, Inc

Background: NAD+, nicotinamide dinucleotide, is a central metabolite for cellular redox balance and a pivotal cofactor for proteins regulating metabolism and health. NAD+ levels decline in a range of metabolic diseases including NAFLD/NASH. Boosting NAD+ levels, i.e.,through nicotinamide riboside (NR) supplementation, reverses the disease in mice. SARM1 (Toll/interleukin-1 receptor motif-containing 1) is a new NAD+-cleaving enzyme highly expressed in neurons. SARM1 activation consumes NAD+ and induces axon degeneration, specifically hepatic sympathetic neuropathy in NAFLD/NASH. Therefore, inhibiting SARM1 holds great promise to treat the disease. Despite their comparable activity on the hepatic NAD+ levels, a head-to-head comparison of the therapeutic outcomes between NR supplementation and SARM inhibition is lacking. Here, we examined the therapeutic effects of NR and a SARM inhibitor (SARMi) in a mouse model of NAFLD/NASH. **Methods:** C57BL/6J mice fed a western diet (WD) or chow were housed at thermoneutrality (TN; 30°C) for 23 weeks and treated with NR (500 mg/kg/day) and SARM1i (60 mg/kg/day) from week 9-23. Body weight was measured bi-weekly. Body composition, plasma circulating factors were assessed by EcoMRI and a Luminex system. Hepatic fibrosis and inflammation were assessed histologically. **Results:** Boosting NAD + levels with NR and SARM1i in NAFLD/NASH mice comparably attenuated the body weight gain and increased the percentage of lean mass (Fig A-B). SARM1i, but not NR, reversed the hyper-glycemia and decreased the liver weight (Fig C-D). Hepatic inflammation and fibrosis were reduced by both NR and SARM1i (Fig E). Further, a significant reduction in the plasma levels of the liver damage marker ALAT/ASAT ratio, the fibrosis marker TIMP-1 and the mitokine GDF-15 levels were seen after the SARM1i therapy but not with the NR treatment (Fig F). These data suggest a better therapeutic effect of SARM1i on the global metabolic stress in NAFLD/NASH. Lastly, liver transcriptome analysis substantiated the therapeutic effect of SARM1i, with the pathogenic changes underlying NAFLD/NASH including inflammatory responses, fibrotic processes, mitochondrial dysfunction among others being suppressed. **Conclusion:** SARM1i therapy is more efficacious than NR supplementation in reversing NAFLD/NASH in mice. The superior therapeutic effect of SARM1i supports the development of SARM1i to treat liver injury due to NASH and other etiologies.

Background: Inhibition of adipocyte triglyceride lipase (ATGL/PNPLA2) activity in insulin resistance and non-alcoholic fatty liver disease is an attractive therapeutic target via reducing fatty acid flux from adipose tissue to the liver. This study evaluated the impact of Atglistatin-mediated ATGL inhibition on the development of non-alcoholic steatohepatitis (NASH) in diabetic and hyperlipidaemic mice. **Methods:** Streptozotocin-injected male mice were fed an HFD to induce NASH. Atglistatin was administered on week 4 for four weeks. We analysed liver histology, hepatic lipid content, immunohistochemistry, RNA sequencing, and serum biochemistry. Mechanistically, we treated Caco2 cells and human primary extrahepatic cholangiocyte organoids with the human ATGL inhibitors NG-497. **Results:** Atglistatin reduced body weight (-2.54 g), fat (-40%), and liver mass (-23%) and significantly improved fasting blood glucose levels (-12%). In line with a trend for reduced ALT (-45%), AP (-25%), total acylglycerol (TAG), and cholesterol contents, we observed a significant improvement in histological liver injury assessed by H&E staining and NAFLD score (-45%). The NAFLD score revealed improvement of steatosis (-60%) and inflammation (-35%) but not ballooning in the Atglistatin group. The improved inflammation was consistent with the significant reduction of Mac2-positive cells in the liver (-50%) and gonadal white adipose tissues (gWAT) (-60%). Mechanistically, Atglistatin reduced *Cpt1α* and *Abca1*, suggesting impaired Pparα signalling that favours hydrophilic bile acid synthesis. In line, *Cyp7a1, Cyp27a1,* and *Cyp2c70* were increased while *Cyp8b1* was reduced. Intestinal lipid transporters in the Atglistatin-treated mice, like *Abca1* and *Cd36,* were reduced, consistent with the reduction of liver TAG species, mostly linoleic acids. To validate the *in vivo* findings in human cells, we used the novel human-specific ATGL inhibitor NG-497. Caco2 cells treated with NG-497 showed reduced *ATGL, ABCA1, FATP5*, and *MTTP*. Furthermore, PPARα signalling was impaired in extrahepatic cholangiocyte organoids treated with NG-497, as reflected by the significant reduction of *CPT1α* and *ABCA1.* **Conclusion:** Inhibition of ATGL activity reduces the availability of bona fide ligands for Pparα activation leading to impaired Pparα signalling, which translates into hydrophilic bile acid synthesis that interferes with dietary lipid absorption, improving the metabolic disturbances in the STAM model of NASH. The validation with the human-specific ATGL inhibitor should open a new clinical avenue for NAFLD clinical trial and treatment.

Co., Inc., South San Francisco, CA, USA, (5) Quantitative Biosciences, Merck & Co., Inc., Kenilworth, NJ, USA

Background: Nonalcoholic steatohepatitis (NASH) is a prevalent disease affecting 2-6 % of the global population and is expected to be a $10-35 billion market by 2030 but there are currently no approved therapies for this chronic liver disease. NASH can progress to more severe forms of disease including fibrosis, cirrhosis, hepatic decompensation, hepatocellular carcinoma, and death. The pro-inflammatory leukotriene B4 (LTB4)/leukotriene B4 receptor 1 (Ltb4r1) axis is a potential therapeutic target for the treatment of NASH and liver fibrosis. **Methods:** To understand the role of the LTB4/Ltb4r1 axis and validate the therapeutic efficacy of Ltb4r1 inhibition in a highly inflammatory and pro-fibrotic mouse model of NASH and fibrosis, we challenged mice with a choline-deficient, amino acid-defined high fat diet, treated with an Ltb4r1 antagonist at 30 or 90 mg/kg for 8 weeks, and evaluated liver function, histology, and gene expression at the end of the study. **Results:** We found that treatment with the Ltb4r1 antagonist had no impact on liver function enzymes, however we observed a significant reduction is plasma triglyceride and leptin levels compared to vehicle control. On histological endpoints, we observed no effect of Ltb4r1 inhibition on steatosis, inflammation, or ballooning scores. In addition, there was no significant difference in liver fibrosis with Ltb4r1 inhibition. Whole liver RNA-seq and pathway analysis revealed significant changes in fatty acid, arachidonic acid, and eicosanoid metabolic processes however this was not sufficient to influence histological endpoints, NAFLD activity score, and liver fibrosis. **Conclusion:** Overall, the data from this study suggests that targeting the LTB4/Ltb4r1 axis in highly inflammatory and pro-fibrotic conditions of chronic liver disease should be considered with caution.

f 2335-C | INTESTINAL IL-33-HIF-1α AXIS MEDIATES NAFLD PROGRESSION BY INCREASING GUT MICROBIOTA-DERIVED TMAO SYNTHESIS

Xiaojing Wang[1], Suping Hai[2], Xitang Li[2], Wenhui Wu[2], Qiang Gao[2], Binghui Yu[2], Erliang Xie[2] and Qin Ning[3], (1) Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology, (2)State Key Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (3)Institute and Department of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology

Background: Gut microbiota and its metabolites play a critical role in the occurrence and development of non-alcoholic fatty liver disease (NAFLD). As a dual-function protein, IL-33 performs distinct intracellular and extracellular functions. In this study, we investigated the effect of IL-33-Hif-1α axis mediated alteration of gut microbiota-derived metabolites on the regulation of NAFLD. **Methods:** Global IL-33 knockout mice (*Il33*$^{-/-}$) and intestinal epithelial-specific IL-33 knockout mice (*Il33*$^{\Delta IEC}$) and their control mice were fed either a chow diet or a 60% high-fat diet (HFD) for 24 weeks. 3,3-dimethyl-1-butanol (DMB) was administered to HFD-fed mice to inhibit gut microbiota-derived TMAO synthesis. Wild-type mice after gut microbiota depletion by antibiotic treatment were transplanted with suspension of gut microbiota from HFD-fed knockout mice and wild-type mice to determine the direct role of IL-33 in regulating gut microbiota in NAFLD. The bacterial community composition was determined by 16S rRNA sequencing. The serum metabolites were analyzed by liquid chromatography-mass spectrometry (LC-MS) metabolomics. Mouse spleen naïve CD4+ T cells and the intestinal epithelial cell line, Caco-2, were used for in vitro studies. **Results:** Intestinal IL-33 aggravated glucolipid metabolism disorders, inflammatory injury and fibrosis progression in NAFLD by disrupting the intestinal microenvironment. High-fat diet stimulated intestinal epithelial cells to produce a large amount of IL-33, and the increased IL-33 enters the epithelial nucleus, inhibiting the synthesis of Hif-1α and the activation of its downstream pathways, *Tff3* and *Adora2b*, which directly damaged the intestinal barrier. IL-33 released after intestinal epithelial cell damage promoted the expression of Hif-1α in intestinal lamina propria T lymphocytes through ST2, which directly up-regulated T-bet to promote Th1 differentiation, leading to the secretion of inflammatory cytokine IFN-γ and indirectly damaged the intestinal barrier. The dual regulatory effect of intestinal IL-33 lead to gut microbiota dysbiosis, that was, the up-regulation of TMA and its synthesis bacteria *Lachnoclostridium*, *Providencia*, *Desulfovibrio*, *Blautia* and *Prevotella*. Soon, the increased TMA is oxidized to TMAO in the liver, which caused hepatic oxidative stress injury and aggravated NAFLD progression. Transplantation of gut microbiota

from IL-33 knockout mice into wild-type mice could reverse NAFLD phenotype. **Conclusion:** Intestinal IL-33 mediates the dual regulation of intestinal Th1 cells and intestinal epithelial cells on Hif-1α function to induce gut microbiota derived TMAO synthesis and finally aggravate the progression of NAFLD. Targeting intestinal IL-33 may provide a new strategy for the treatment of NAFLD.

2336-C | KNOCKDOWN OF HYDROGEN PEROXIDE-INDUCIBLE CLONE-5 AMELIORATES LIVER FIBROSIS IN A MOUSE MODEL OF NASH

Masahito Noguchi[1], Masashi Sakaki[2], Aya Miyauchi[1], Momoko Kobayashi-Tanabe[1], Akira Miyazaki[1] and Joo-Ri Kim-Kaneyama[1], (1)Showa University, (2)Showa University, Tokyo, Japan

Background: Hydrogen peroxide-inducible clone-5 (Hic-5), also named transforming growth factor beta-1-induced transcript 1 protein (Tgfb1i1), was found to be induced by TGF-b. We previously reported that Hic-5 expression was strongly upregulated in activated hepatic stellate cells (HSCs) of human fibrotic liver tissue and BDL- or CCl_4-induced mouse liver fibrosis. Additionally, Hic-5 deficiency significantly attenuated mouse liver fibrosis and HSC activation through inhibition of the TGF-b/Smad2 signaling pathway in the activated HSCs (J. Hepatol. 2016). Against this background, here we investigated the involvement of Hic-5 in the regulation of NASH pathogenesis. **Methods:** We examined Hic-5 expression levels with the progression of hepatic fibrosis in a choline-deficient, methionine-depleted high-fat-diet (CDAHFD)-induced NASH mouse model. NASH models were also developed in Hic-5-knockout and wild-type mice to compare the pathological changes in NASH as well as the pathological changes induced by the suppression of Hic-5 after the induction of fibrosis. We also analyzed the distribution of Hic-5 expression in fibrotic liver tissue using tissue immunostaining and single-cell RNA-seq data from patients with cirrhosis from public databases. **Results:** Hic-5 mRNA expression was induced with an increase in liver fibrosis area in the NASH mouse model. Three weeks after the start of the NASH diet, a 3.7-fold ($p = 0.007$) increase in the level of Hic-5 compared with that in the control diet group was observed. Hic-5 deficiency significantly attenuated mouse liver fibrosis and Hic-5 knockdown by siRNA in vivo also suppressed liver fibrosis in the NASH mouse model. Single-cell RNA-seq analysis showed that Hic-5 expression was particularly induced in a specific cell population among HSCs of cirrhotic patients. **Conclusion:** The suppression of fibrosis progression by Hic-5 inhibition after the induction of liver fibrosis indicates that Hic-5 has potential as a therapeutic target molecule for NASH liver fibrosis.

2337-C | KUPFFER CELL-DERIVED IL-6 PROTECTS HUMAN HEPATOCYTES AGAINST LIPID DROPLET ACCUMULATION

Marisa Carbonaro, Regeneron Pharmaceuticals and Zhe Li, Regeneron Pharmaceuticals, Inc.

Background: Abnormal accumulation of lipid droplets in liver is a major feature of fatty liver disease, an increasing health issue in developed countries. It has been widely observed that, in humanized liver mice, in which donor human hepatocytes repopulate recipient rodent livers, engrafted human hepatocytes show defects including hepatosteatosis. Ameliorating such defects would improve the accuracy of the models to recapitulate normal human liver biology and shed light on some of the underlying mechanisms that regulate lipid accumulation in hepatocytes. **Methods:** Humanized liver mice were generated through engraftment of human hepatocytes into the livers of *FSRG* (*Fah*$^{-/-}$, *Sirpa*$^{hu/hu}$, *Rag2*$^{-/-}$, *Il2rg*$^{-/-}$) mice. Human Kupffer cells that produce hIL6 were engrafted through implantation of human hematopoietic stem cells (huHSC) into FSRG mice. Impaired IL6-GP130 signalling in engrafted human hepatocytes was restored through transduction of primary human hepatocytes with lentivirus carrying mouse IL6R or constitutively active GP130 expression vectors before implantation, or by systemic supplementation of hIL6 via either AAV dosing or genetic humanization of the murine *Il6* allele. **Results:** Abnormoal lipid droplet accumulation occurred in mouse liver engrafted with human, but not rodent hepatocytes. Providing human Kupffer cells via hematopoietic stem cell engraftment in humanized liver mice also corrected the abnormality. Restoration of hepatic IL6-GP130 signaling, through ectopic expression of mouse IL6R or constitutive activation of GP130 in human hepatocytes, or humanization of *Il6* allele in recipient mice, substantially reduced hepatosteatosis. **Conclusion:** Hepatosteatosis in humanized liver mice is associated with impaired IL6 receptor signaling in human hepatocytes, which is a result of incompatibility between murine IL6 expreesed in recipent mice and human IL6R expressed on donor hepatocytes. Hepatic GP130 signaling, maintained by IL6 that is normally provided by non-parenchymal liver cells, plays an important role in

protecting hepatocytes from excessive lipid accumulation. Our observations provide not only a method to improve humanized liver models, but also suggest therapeutic potential for manipulating GP130 signaling in human liver steatosis.

2338-C | LIPOLYTIC HORMONES GLUCAGON AND ISOPROTERENOL DO NOT ENHANCE DEFATTING EFFECT IN NUTRIENT-RESTRICTED EX VIVO STEATOTIC RODENT LIVERS ON NORMOTHERMIC MACHINE PERFUSION

Amin Mamoon Amin, Shawn Burgess and Justin Fletcher, UT Southwestern

Background: Discard of steatotic donor grafts continue to contract the previous liver organ pool. It is projected that liver graft utilization will decrease from 78% to 44% by 2030. Normothermic machine perfusion has enabled researchers to explore the rehabilitation of these organs using pharmacological agents. However, many of these agents lack FDA approval for human use or ex vivo organ applications. Here we present the effects of nutrient restriction and the use of lipolytic hormones to induce defatting in rodent models of hepatic steatosis. Our research has demonstrated that steatotic livers exhibit elevated oxidative metabolism and turnover in the tricarboxylic acid (TCA) cycle. We hypothesize that by restricting Free Fatty Acids (FFA) and other nutrient substrates in an ex vivo perfusion system, livers will utilize their excessive intrahepatic triglycerides (IHTG) as a fuel source. Additionally, we aim to determine whether the addition of lipolytic hormones, namely Glucagon and Isoproterenol, can enhance lipolysis. **Methods:** Male Ob/Ob mice aged 16-20 weeks were perfused under physiological temperature and pH using a solution devoid of FFA or glucose, containing 3% BSA, 25mM $NaHCO_3$, 118mM NaCl, 4.7mM KCl, 1.2mM $MgSO_4$, 1.2mM KH_2PO_4, and 0.8mM l-carnitine. Two groups received the addition of lipolytic hormones (10nM Glucagon and 20mM Isoproterenol) to the perfusate. Membrane oxygenation provided a 95/5% mixture of oxygen and CO_2. The livers were perfused for 6 hours, and a liver lobe was ligated and snap-frozen at specified intervals for IHTG quantification. **Results:** Although Glucagon (red) and Isoproterenol (purple) activated ketogenesis and increased endogenous glucose production, the steatotic livers perfused without any hormones lost 33% of their IHTG over the 6-hour perfusion period, compared to only 5% in the Glucagon group and 20% in the Isoproterenol group. **Conclusion:** Modest reductions in IHTG were observed with a perfusion solution devoid of nutrient substrates. The addition of lipolytic hormones did not enhance lipid disposal. This suggests that the Ob/Ob model may represent chronically steatotic livers that have undergone reprogramming, making them resistant to defatting even when exposed to lipolytic hormones. Further investigations are currently underway in our laboratory to elucidate these mechanisms.

2339-C | LIVER AND ADIPOSE TISSUE TRANSCRIPTOMICS IDENTIFY IMMUNE NETWORKS THAT REGULATE DISEASE SEVERITY IN PEOPLE WITH NASH AND NAFLD

Allison Wing, National Institutes of Health, Regina Umarova, National Institute of Diabetes and Digestive and Kidney Diseases, Maren Podszun, University of Hohenheim and Yaron Rotman, National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: A subset of people with non-alcoholic fatty liver disease (NAFLD) progress to non-alcoholic steatohepatitis (NASH) but the pathways underlying this progression are unclear. The close association of NAFLD with obesity suggests an important role for adipose tissue in NAFLD severity and progression. Using transcriptomics and gene co-expression analysis, we aim to discover tissue crosstalk and identify pathways in the liver and adipose tissue that underlie NAFLD severity. **Methods**: Paired same-day liver and subcutaneous adipose tissue samples were obtained from adult subjects with NAFLD participating in a clinical trial (NCT01792115). Gene expression was quantified by RNA sequencing, and co-expression networks within each tissue were constructed using Weighted Gene Co-expression Analysis (WGCNA). Genes associated with histological scores (NASH-CRN scoring system) and networks were integrated using Mergeomics software to identify causal NAFLD gene networks and predict key regulatory (driver) genes within the co-expression networks. Ingenuity Pathway Analysis

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was used to map co-expression networks to biological pathways. **Results**: Samples with histological scores were available from 17 subjects (median age 50, median NAS 3, 53% with NASH). In the liver, pathway analysis predicted an association of NAFLD activity score (NAS) with downregulation of interferon (*IFN*)-g signaling, with *MSR1* and *MRC1* identified as some of the key driver genes. In adipose tissue, a modest association between NAS and mitochondrial activity pathway was observed with no significant key drivers identified. However, several adipose tissue gene networks were significantly and highly correlated with hepatic portal inflammation scores. In the top three networks (FDR q < 1e-30 for all three), key driver genes *CD3D* and *RAC2*; *IKZF1* and *RGS18*; and *IRF5* and *CD45* were identified. These are predicted to be downstream of downregulated IFN-g signaling, as in the liver, and decreased T-cell pathways. **Conclusion**: We have identified gene co-expression networks which predict roles for downregulated IFN-g pathways across tissues in driving the severity of NAFLD. Importantly, adipose tissue inflammatory pathways were strongly associated with hepatic portal inflammation, suggesting a unique role for adipose-derived factors. Our findings highlight a role for hepatic and adipose aberrant IFN signaling in the progression of NAFLD.

f 2340-C | LOSS OF KUPFFER CELL TIM4-DEPENDENT EFFEROCYTOSIS PROMOTES LIVER FIBROSIS IN NONALCOHOLIC STEATOHEPATITIS★

Hongxue Shi[1], Xiaobo Wang[1], Mary P Moore[1], Luca Valenti[2] and Ira Tabas[1], (1)Columbia University, New York, NY, (2)Department of Transfusion Medicine and Haematology, Fondazione Irccs Ca' Granda Ospedale Maggiore Policlinico

Background: Nonalcoholic steatohepatitis (NASH) is an advanced stage of nonalcoholic fatty liver disease (NAFLD) and the leading cause of human chronic liver disease. Apoptosis in hepatocytes is a key feature during NASH progression, but precisely how apoptotic hepatocyte contributes to NASH progression, particularly the most important feature, liver fibrosis, remains incompletely understood. Cell death generally causes disease when clearance of dead cells by macrophages (efferocytosis) is impaired, leading to leakage of disease-causing factors. Herein, we investigate the role of liver resident Kupffer cell (KC)-dependent efferocytosis in the progression of NASH. **Methods:** KC-TIM4 expression was assayed in liver tissue sections obtained from humans and mice with normal and NASH. For mouse NASH, male C57BL/6J mice were fed either a high-fat choline-deficient L-amino-defined (HF-CDAA) diet for 4 weeks to induce early NASH, 10 weeks to induce advanced NASH, or a fructose-palmitate-cholesterol (FPC) diet for 16 weeks. For all mouse models, causation was tested by administering anti-TIM4 antibodies to wild-type mice, KC-*Timd4* knockout mice, or liver macrophages TIM4 restoration mice, followed by assessment of efferocytosis by liver macrophages and NASH fibrosis. For *ex vivo* studies, the engulfment of human and mouse apoptotic hepatocytes by primary human and mouse liver KCs was assayed. **Results:** We have shown that the accumulation of apoptotic hepatocytes in human and mouse NASH liver is associated with decreased KCs efferocytosis receptor TIM4 expression, which is consistent with impaired efferocytosis of apoptotic hepatocytes during NASH progression. The administration of anti-TIM4 inhibited the engulfment of apoptotic hepatocytes by primary human and mouse liver KCs *ex vivo*, which suppressed efferocytosis and accelerated liver fibrosis in the early experimental NASH model. Moreover, liver KC-*Timd4* deficiency caused impaired efferocytosis and accelerated liver fibrosis. In contrast, the restoration of TIM4 in liver macrophages improved impaired efferocytosis and decreased liver fibrosis in advanced NASH in our two models of diet-induced NASH. **Conclusion:** Decreased expression of KC-TIM4 occurs in NASH liver and is associated with impaired efferocytosis, and blocking TIM4-mediated efferocytosis accelerated liver fibrosis in early NASH, while restoration of TIM4 in macrophages recovered impaired efferocytosis and mitigated liver fibrosis in advanced NASH. These findings define a new mechanism contributing to NASH progression with potential therapeutic implications.

2341-C | LOSS OF OVARIAN HORMONE EXACERBATES DIET-INDUCED NAFLD

Xinlei Guo[1], Minji Koo[1], Honggui Li[2] and Chaodong Wu[2], (1)Texas a&m University, (2)Texas a&M University

Background: Non-alcoholic fatty liver disease (NAFLD), a common metabolic disease whose incidence is significantly increased by obesity, is characterized by excessive fat deposition in hepatocytes (steatosis). Simple steatosis progresses to non-alcoholic steatohepatitis (NASH), the advanced form of NAFLD, when the liver displays overt inflammatory damage. Much evidence indicates that the prevalence of obesity-induced NAFLD in women is much lower than that in men while

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

comparable findings are obtained from rodent studies. This demonstrates the prevalence disparity in NAFLD, which is attributable to, in large part, different levels of sex hormone especially estrogen between females and males. The present study aimed to explore the effect of loss of ovarian hormone on diet-induced NAFLD phenotype in mice. **Methods:** To achieve this, female wild type (WT) C57BL/6J mice were subjected to either sham operation or ovariectomy (OVX), at 5-6 weeks of age. After recovery for 1 week, the mice were fed a high-fat diet (HFD, 60% fat calories) for 12 weeks. Age-matched male mice were fed an HFD identically. Liver steatosis and inflammation, as well as systemic insulin sensitivity were examined. **Results:** Compared with HFD-male mice, HFD-female/sham mice displayed smaller degrees in hepatic steatosis as indicated the results of liver histology. However, the degrees of hepatic steatosis in HFD-female/OVX mice were much greater than those in HFD-female/sham mice, and comparable with those in HFD-male mice. Biochemical analysis indicated decreased expression of hepatic genes/enzymes in fatty acid oxidation. When liver inflammation was analyzed, liver sections from HFD-female/OVX mice and HFD-male mice displayed comparable numbers of F4/80 cells, but significant more F4/80 cells than those from HFD-female/sham mice. In addition, the phosphorylation levels of proinflammatory signaling through NF-kB p65 and JNK p46 in HFD-female/OVX mice were significantly higher than those in HFD-female/sham mice, but were comparable with those in HFD-male mice. These changes were likely attributable to increased hepatic expression of stimulator of interferon gene (STING), which is a critical mediator promoting macrophage proinflammatory activation. Consistent with NAFLD phenotype, the severity of diet-induced systemic insulin resistance in female/OVX mice was greater than that in female/sham, but comparable with that in male mice. **Conclusion:** Taken together, these results demonstrated that loss of ovarian hormone abolishes sex-based protective effects on diet-induced NAFLD in female mice. As such, enhancing estrogen actions may be viable for managing NAFLD in males.

2342-C | LOSS OF SULT2B1b PREVENTS HEPATIC STEATOSIS AND INSULIN RESISTANCE BY REGULATING ENERGY EXPENDITURE AND METABOLISM

Jingyuan Wang, Gregory M. Young and Wen Xie, University of Pittsburgh

Background: Obesity and Type II Diabetes (T2D) and their related comorbidities are one of the leading causes of loss of life and disability globally. The need to find potential therapeutic targets to help curb growing insulin resistance and obesity rates will be vital to stop this health crisis. Sult2b1b is a sulfotransferase that preferentially conjugates a sulfate group onto cholesterol to form cholesterol sulfate. Our previous study showed that over expression of Sult2b1b or treatment with cholesterol sulfate improved energy metabolism by reducing lipogenesis and gluconeogenesis. In this study, we aimed to investigate whether and how Sult2b1b inhibition affects the development of obesity and T2D. **Methods:** WT and Sult2b1b$^{-/-}$ male mice were fed with high-fat-diet (HFD) for 12 weeks to induce obesity and T2D. We also introduced the Sult2b1b$^{-/-}$ allele into the ob/ob mice by cross-breeding. Body weight and composition were monitored weekly. Glucose and insulin tolerance tests were performed every four weeks. Metabolic cage study, histological and biochemical analysis was conducted at the end point. **Results:** Sult2b1b knockout protected mice against hepatic steatosis and insulin resistance in both HFD-induced obesity and ob/ob background mice. Furthermore, the loss of Sult2b1b significantly decreased liver steatosis, hyperlipidemia, and white adipose tissue (WAT) inflammation. Metabolic cage study showed a significant increase of energy expenditure in the Sult2b1b$^{-/-}$ mice without changes in their locomotive activities. Transcriptome analysis indicated reduced gluconeogenesis in liver, increased fatty acid oxidation in WAT, and increased thermogenesis in skeletal muscle. **Conclusion:** Our results demonstrated that Sult2b1b played a regulatory role in the development of obesity and T2D. Given the protection provided through genetic ablation, inhibiting Sult2b1b may be a promising target to combat obesity and T2D.

2343-C | MANNOSE ATTENUATES HEPATIC STEATOSIS IN A MOUSE NAFLD/NASH MODEL AND HEPATOCYTES IN VITRO THROUGH MODULATION OF KHK EXPRESSION

John Hong[1], Joshaya Trotman[1], Yvette Carbajal[1], Mariel Glass[1], Peng Zhang[1], Liheng Wang[1], Li Chen[2], Mathieu M. Petitjean[3], Charles DeRossi[1] and Jaime Chu[4], (1) Icahn School of Medicine at Mount Sinai, (2)Pharmanest, (3)Pharmanest Inc, Princeton, NJ, United States, (4) Icahn School of Medicine at Mount Sinai, New York, NY

Background: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease worldwide, yet there are no approved therapies. We have previously shown that mannose, a simple sugar, can dampen hepatic stellate cell activation *in vitro*, but its role in NAFLD-induced steatosis has not been studied. **Methods**: We

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

used the well-validated FAT-NASH model (Tsuchida et al, J. Hepatology 2018) to induce hepatic steatosis. Mice were fed normal diet or FAT-NASH regimen (high fat, fructose, and cholesterol, and low dose CCl4) for 12 weeks. Mannose was supplied in drinking water (5% or 20%) for either the full 12 weeks to assess for preventative effects against steatosis development, or after a 6-week delay when steatosis and fibrosis are already present. Effectiveness was determined through standard histological assessment (hematoxylin and eosin (H&E) and oil red O (ORO) staining) and quantification of liver triglycerides (TG) and cholesterol. We further used an unbiased, AI-based approach to quantify steatosis phenotypes in liver sections (FibroNest™). Human hepatocytes (THLE-5B) were conditioned *in vitro* with 750 μM oleic + palmitic acid (2:1) without or with 100mM fructose to induce steatosis and treated with 25mM mannose for 72 hours. *In vitro* efficacy was assayed by ORO staining and western blot analysis. Mouse liver bulk RNAseq and western blots were performed. **Results**: *In vivo,* steatosis prevalence was reduced in all mannose-treated NASH mice groups, evident qualitatively with H&E and ORO staining and quantitatively with AI-based histological assessment ($p < 0.05$). Liver TG and cholesterol were also decreased in all treatment groups with the greatest reduction of liver TG seen in delayed 5% and 20% mannose treatments ($p = 0.002$ and 0.001 respectively). *In vitro,* 25 mM mannose decreased steatosis by 33% ($p < 0.05$). Interestingly, steatosis reduction with mannose treatment was only seen in fructose-conditioned hepatocytes and not in oleic + palmitic acid alone. Mouse bulk liver RNAseq and validating qPCR revealed fructolytic enzyme ketohexokinase (*Khk)* was increased in NASH mice compared to normal diet ($p < 0.01$) but was decreased with 5% and 20% mannose treatments ($p < 0.05$ and $p < 0.001$ respectively). Western blot assays confirmed reduction of KHK in all treatment groups with the greatest decrease in 20% mannose prophylactic treatments in mouse livers (66% reduction, $p = 0.01$) and with 25 mM mannose in human hepatocytes ($p = 0.01$). **Conclusion**: Our findings uncover mannose as a novel therapeutic for NAFLD/NASH, possibly acting through modulation of fructose metabolizing pathways. Ongoing studies will test the role of mannose and KHK in liver steatosis.

2344-C | MATERNAL OBESOGENIC DIET PROMOTES OFFSPRING NON-ALCOHOLIC FATTY LIVER DISEASE PROGRESSION WITH MICROBIOME DEPENDENT ALTERATIONS IN THE WEANING REACTION

Vung Lian[1], Holly Hinrichs[1], Monica Young[1], Phillip I Tarr[1], Nicholas Davidson[2] and Michael Thompson[1], (1) Washington University School of Medicine in St. Louis, (2)Washington University Medical School, Departments of Medicine and Molecular Biology and Pharmacology, Saint Louis, MO

Background: Maternal obesity is associated with development of hepatic steatosis in offspring and maternal obesogenic diet exposure promotes worse NAFLD in animal models. The mechanisms driving this programming event are not fully defined. One mechanism of transmission of developmentally programmed phenotypes is via transfer of an altered microbiome from Mom to offspring. The specific mechanism for how an altered offspring microbiome increases susceptibility to NAFLD is not clear. One path may be via a critical early life event termed the 'weaning reaction' that is dependent on the early microbiome and when altered results in worse pathologic inflammation in the offspring. Given that the microbiome is altered following maternal obesogenic diet exposure, we hypothesized that maternal obesogenic diet would affect the weaning reaction in offspring with an associated increase in progressive offspring NAFLD. **Methods:** Female mice were fed chow (CON) or high fat-fructose-cholesterol (HFFC) diet for 6 weeks and bred with lean males. A subset of these mice were cross-fostered with the opposite dam to evaluate the impact of the early microbiome. Terminal ileum was collected from offspring at 2, 3, 4, and 5 weeks of age to evaluate expression of *Tnfa* and *Ifng*. 16S sequencing of cecal contents of 3 week old offspring was performed. Offspring from each group were weaned to HFFC diet for 7 weeks to induce development of non-alcoholic steatohepatitis. Liver was collected for histopathologic analysis. **Results:** Ileal *Tnfa* and *Ifng* expression peaked at 3 weeks in CON offspring consistent with the pattern seen previously. A rise in ileal *Tnfa* and *Ifng* expression was not observed in HFFC offspring suggesting a loss of the weaning reaction. 16S sequencing at 3 weeks identified shifts in the microbiome in HFFC offspring. Alpha-diversity was decreased in HFFC offspring. Shifts in abundance of multiple genera were identified included increased *Lactobacillus* and increased *Akkermansia* in HFFC offspring. *Bacteroides* were decreased in HFFC offspring. In offspring weaned to HFFC diet, the degree of steatosis, inflammation, and fibrosis was increased in HFFC

offspring compared to CON offspring. Cross-fostering HFFC offspring with CON dam induced a weaning reaction while conversely cross-fostering CON offspring with HFFC dam attenuated the weaning reaction. Preliminary findings in male and female offspring show that cross-fostering HFFC offspring with a CON dam reduced hepatic inflammation and fibrosis during HFFC diet feeding. **Conclusion:** These findings provide preliminary evidence that maternal obesogenic diet exposure affects the weaning reaction with associated shifts in the offspring microbiome. This effect on the weaning reaction is associated with worse susceptibility to NAFLD in mice. Preliminary data show that this phenotype is dependent on early changes in the gut microbiome.

2345-C | MICRORNA-206-3p MIMICS THE FUNCTIONS OF LIPID-LOWERING MEDICATIONS, STATINS, AND LXRA AGONISTS

Ningning Liu, Chinese Academy of Sciences and Guisheng Song, University of Minnesota

Background: Hepatosteatosis, hypertriglyceridemia, and hypertriglyceridemia are interconnected metabolic disorders. This study is designed to characterize how MicroRNA-206-3p (miR-206) simultaneously prevents *de novo* lipogenesis (DNL), cholesterol synthesis, and VLDL production in hepatocytes but drives cholesterol efflux in macrophages. **Methods:** Mice were treated with a high-fat-high-cholesterol (HFHC) diet to induce hepatosteatosis, hypertriglyceridemia and hypercholesterolemia. MimiR-206 mimic was used to elevate levels of miR-206 in hepatocytes and macrophages of mice. AAV8 was used to specifically express miR-206 in hepatocytes. To calculate the VLDL production rate, mice were injected with Triton WR1339 and ^{35}S-methionine/cysteine to inhibit lipolysis and to label newly synthesized proteins. ^{3}H-cholesterol-labeled and acLDL-loaded J774 cells were used to determine if miR-206 drives cholesterol efflux. **Results:** Overload of cholesterol and triglycerides reduced miR-206 in hepatocytes and macrophages. A negative feedback between LXRα (liver X receptor) and miR-206 is formed to maintain high LXRα and low miR-206 in hepatocytes. Systemic administration of miR-206 alleviated hepatosteatosis, hypertriglyceridemia and hypercholesterolemia in mice. A significant reduction in LDL-cholesterol and VLDL-cholesterol but unaltered HDL-cholesterol was observed in miR-206-treated mice. Consistent with these observations, miR-206 reprogrammed the transcriptome of hepatocytes towards inhibition of DNL, cholesterol synthesis, and assembly and secretion of VLDL. In macrophages, miR-206 activated expression of genes regulating cholesterol efflux. Hepatocyte-specific expression of miR-206 reduced hepatic and circulating triglycerides and cholesterol as well as VLDL production, while transplantation of macrophages bearing miR-206 facilitated cholesterol efflux. Mechanistically, miR-206 impaired expression of *Lxrα* and *Hmgcr* by interacting with their respective 3'untranslated regions in hepatocytes but facilitated expression of *Lxrα* by directly targeting macrophage-specific TRPS1 (tricho-rhino-phalangeal syndrome 1), a transcription repressor of *Lxrα*, in macrophages. Disrupting the interaction of miR-206 with *Hmgcr* and *Lxrα* prevented miR-206 from inhibiting DNL, cholesterol synthesis and VLDL production. **Conclusion:** MiR-206 inhibits DNL and drives cholesterol efflux via differentially modulating LXRα in hepatocytes and macrophages, in addition to impairing cholesterol synthesis and VLDL production. MiR-206 simulates the functions of lipid-lowering medications, statins and LXRα agonists.

2346-C | MIR-122 OVEREXPRESSION INDUCES AUTOPHAGY VIA PKM2 DOWNREGULATION IN NON-ALCOHOLIC FATTY LIVER DISEASE

Md Musa Hossain, Amrendra Kumar Sah, Amit Mishra, Akanksha M and Senthil Kumar Venugopal, South Asian University, Rajpur Road, New Delhi-110068

Background: Non-alcoholic Fatty Liver Disease (NAFLD) has emerged as a leading global cause for chronic liver disease and results in a serious public health problem. microRNA-122, an abundant miRNA present in the liver, is downregulated in different cancers including hepatocellular carcinoma (HCC). Pyruvate Kinase (PK) is a rate limiting enzyme in the last physiologically irreversible step of glycolysis. Emerging evidence showed that PKM2 plays a significant role in HCC and is highly expressed in tumor tissues. Overexpression of PKM2 induces inflammation and inhibits autophagy and apoptosis in cancer cells. miR-122 targets PKM2 and it was hypothesized that PKM2 inhibition may downregulate in NAFLD, while inducing autophagy. Thus, PKM2 may represent a new target for monitoring and treatment of NAFLD. **Methods:** After animal ethics committee's approval, C57BL/6 mice were fed with control diet, choline sufficient L-amino acid (CSAA) diet and choline deficient L-amino acid (CDAA) diet. After 6, 18, 32 and 54 weeks, these

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

mice were euthanized, both protein and RNA were isolated from the liver tissues. The change in miR-122, PKM2, Atg7, Beclin-1, LC3B expression was analyzed by RT-PCR and Western blotting. The role of PKM2 and miR-122 regulation was elucidated in in-vitro studies. HepG2 cells were treated with free fatty acids (Oleic acid, Palmitic acid, Linoleic acid, 650 μM each). After 48 hours, miR-122 and PKM2 mRNA expression were analyzed using RT-PCR. Proteins were analyzed by immunoblotting technique after 72 hours. miR-122 mimic were used for miR-122 overexpression in HepG2 cells. PKM2 and autophagy marker proteins were analyzed. Knockdown of PKM2 was achieved using PKM2 specific siRNAs and autophagy markers were determined by immunoblotting. **Results:** In NAFLD mice model system, CDAA diet fed mice showed a downregulation of miR-122 expression, upregulation of PKM2 (p d 0.05) and the autophagy marker proteins Atg7, Beclin-1, LC3B was downregulated (p d 0.05). In FFAs-induced HepG2 cells, PKM2 expression was increased, while autophagy markers were downregulated significantly (p d 0.05). In miR-122 over-expressing HepG2 cells, the expression of PKM2 was down-regulated by two-fold (p d 0.05), while the autophagy markers were increased significantly. PKM2 down-regulation resulted in HepG2 cells, reversed the miR-122 induced changes. **Conclusion:** These results down regulation of miR-122 resulted in increased PKM-2 expression, and inhibiting PKM-2 resulted in an enhanced autophagy, suggesting that targeting PKM-2 could provide a novel strategy for regulating NAFLD progression leading to HCC.

2347-C | MODELLING THE BIOLOGICAL MECHANISMS OF A PNPLA3 AND HSD17B13 POLYMORPHISMS IN A 3D HUMAN LIVER SPHEROID OF NASH

Radina Kostadinova, Jesus Glaus, Angelina Freitag, Philipp Vonschallen, Arumugham Raghunathan and Francisco Verdeguer, Insphero

Background: Non-alcoholic steatohepatitis (NASH) is a progressive severe disease characterized by lipid accumulation, inflammation and fibrosis in the liver. Single nucleotide polymorphisms (SNPs) at specific loci have revealed differential propensity to develop NASH. Among them, “GG” rs738409 located in PNPLA3 results in the I148M amino acid change and increase the odd ratio to develop NASH. On the other hand, a truncating mutation in HSD17B13 leads to a protection from liver fibrosis in NASH. The mechanism of both PNPLA3 and HSD17B13 is not clearly understood. The aim of this study was to provide a human spheroid model carrying either PNPLA3 or HSD17B13 SNPs to phenotypically characterize their role in NASH development. **Methods:** Human 3D NASH model of spheroidal, scaffold free co-culture was developed of single donors from primary hepatocytes, Kupffer cells, liver endothelial cells and hepatic stellate cells. Single donor of primary hepatocytes were genotyped and selected for PNPLA3 rs738409 GG, GC or CC genotyes and HSD17B13 for major allele or minor T:A allele. **Results:** We show that steatotic and proinflammatory conditions lead to increased intracellular triglycerides levels and secretion of inflammatory markers IL-6, MIP-1α, TNF-α, IL-10, MCP-1 and IL-8 and increased secretion of procollagen peptides I and III. These results show a recapitulation of the hallmarks of NASH. PNPLA3(I148M) genotype in liver spheroids resulted in an increased levels of steatosis and fibrosis measured by triglyceride content and collagen secretion compared to the major allele. In line with these results, transcriptomics analysis show that both de-novo lipogenesis and fibrotic pathways are elevated in the PNPLA3(I148) donors compared to major allele. These results are in agreement with the expected phenotypic propensity to develop NASH in the human population carrying the PNPLA3(I148M) variant. We showed in addition an elevation of intracellular triglycerides but protection of fibrosis indicated by decreased procollagen 1 levels in the mutant HSD17B13 T:A variant. **Conclusion:** We show that genetically defined spheroid models containing relevant SNPs are a good tool to understand their biological mechanisms of action and would in addition help predicting drug responses for patients stratification.

2348-C | MOLECULAR PATHOGENESIS OF NASH THROUGH THE DYSREGULATION OF METABOLIC ORGAN NETWORK IN THE NASH DERIVED HCC MODEL MOUSE TREATED WITH STREPTOZOTOCIN-HIGH FAT DIET

Taishi Hashiguchi, SMC Laboratories, Inc.

Background: Non-alcoholic steatohepatitis (NASH) is an increasingly prevalent chronic liver disease. NASH patients often exhibit gut dysbiosis, and dysfunction in adipose tissue and metabolism. Although the mechanism of NASH progression has not been fully elucidated, the multiple parallel hits hypothesis suggests abnormalities in adipocytokines, intestinal microflora,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and endotoxins are intertwined, and could contribute to development of NASH. The STAM™ model is a clinically-correlated murine NASH model which shows the same pathological progression as human NASH patients, and has been widely used for pharmacological and basic research. However, analysis of the model has focused on the liver. Considering organ crosstalk, mutual biological communication between organs, interactions between the liver, and the gut and adipose tissue in the model should be clarified. **Methods:** NASH was induced in male mice by a single subcutaneous injection of 200 μg streptozotocin solution 2 days after birth and feeding with high-fat diet after 4 weeks of age. The mice were sacrificed at NASH stage, sampling colon and adipose tissue. Colon samples were snap frozen in liquid nitrogen and stored at -80˚C for tight junction-related protein analysis. Adipose tissue was prepared into paraffin blocks for HE staining. Blood adiponectin was analyzed to confirm changes in adipocytokine profile. **Results:** Tight junction-related proteins in the intestine of STAM™, analyzed by ELISA, showed that expression of ZO-1 decreased with the progression of disease. Increased expression of endotoxin in the blood was also observed in STAM™ mice. HE staining of adipose tissue revealed hypertrophy of adipocytes. Adiponectin expression was decreased in STAM™. **Conclusion:** Decreased expression of ZO-1 in the intestine of STAM™ mice suggests the occurrence of leaky gut, and abnormalities in adipocytokine secretion were also observed. Together with the liver, phenotypes in these organs are highly similar to human NASH patients, and might be involved in the pathogenesis of NASH.

2349-C | MUTATION OF PXR PHOSPHORYLATION MOTIF AT Ser347 IS ASSOCIATED WITH MORE SEVERE LIVER DAMAGE IN DIET-INDUCED NON-ALCOHOLIC STEATOHEPATITIS IN MICE.

Veronia Basaly[1,2,3], Rulaiha E Taylor[1,2,3], Bo Kong[1,2,3], Masahiko Negishi[4] and Grace L. Guo[1,2,3], (1) Department of Pharmacology and Toxicology, Rutgers, the State University of New Jersey, Piscataway, NJ, (2) Rutgers Center for Lipid Research, Rutgers, the State University of New Jersey, New Brunswick, NJ, (3) Environmental and Occupational Health Sciences Institute, Rutgers, the State University of New Jersey, Piscataway, NJ, (4)Pharmacogenetics Group, National Institute of Environmental Health Sciences, Nih, Chapel Hill, NC

Background: Non-alcoholic fatty liver disease (NAFLD) is a spectrum of liver disorders initially manifested as hepatic steatosis and may progress into inflammation (non-alcoholic steatohepatitis; NASH), fibrosis, cirrhosis, and hepatocellular carcinoma. Hepatic nuclear receptors (NRs) are a large group of transcription factors that regulate a variety of liver functions and affect NASH pathogenesis. Pregnane X Receptor (PXR, NR1I2) is a ligand-activated NR critical in regulating drug metabolizing enzymes and transporters and playing a key role in maintaining bile acid, glucose, lipid, and cholesterol homeostasis in the liver. The function and transcriptional activity of PXR can be regulated in a ligand-independent manner through post-translational modifications, such as phosphorylation at Ser347 in mice or Ser350 in humans. Mutation of this conserved phosphorylation motif of PXR *in vitro* alters human PXR transcriptional activity; however, the mechanism remains elusive. In this study, we utilized mice with a PXR Ser347Ala knock-in mutation (PXR-KI) to investigate the effects of blocking this phosphorylation site in NASH development. **Methods:** Six-week old wild-type (WT) and PXR-KI male mice, both on the C57BL/6J genetic background, were fed a high fat diet (HFD; diet with 40 Kcal% palm oil fat, 20 kcal% fructose, and 2% cholesterol), a low fat diet (LFD; 10 kcal% fat and carbohydrate mainly as corn starch), or a chow control diet (CCD) for 16 weeks. Hepatic injury, steatosis, inflammation, and fibrosis were assessed biochemically (ALT, ALP, triglycerides, total cholesterol, total bile acids), by H&E staining, hepatic lipid extraction (cholesterol, triglycerides), and qPCR. **Results:** On HFD, PXR-KI mice showed an increase in liver/body weight ratio compared to WT HFD, PXR-KI CCD, and LFD. Additionally, PXR-KI HFD mice displayed a trend of increased serum total bile acids, serum ALT, and hepatic triglycerides compared to WT HFD. Serum total cholesterol was significantly elevated in PXR-KI HFD as compared to WT-HFD and PXR-KI groups. Moreover, hepatic mRNA expression of genes related to lipid metabolism, *Cd36* (fatty acid uptake), *Fasn* (fatty acid synthase), and fibrosis *Col1a1* (collagen type 1), were elevated in PXR-KI HFD compared to WT HFD and PXR-KI CCD groups. Interestingly, the mRNA levels of *Fasn* were also increased in WT LFD compared to WT HFD. Further, the expression of PXR target gene, *Cyp3a11*, was decreased in mice fed HFD compared to CCD mice, while *G6pase* (glucose 6 phosphatase), was decreased in WT HFD compared to WT CCD and LFD. **Conclusion:** These data suggest that blocking PXR ser347 phosphorylation motif may exacerbate NASH progression, indicating the importance of this phosphorylation motif in regulating PXR functions including maintenance of bile acid, glucose, and lipid homeostasis and thus the development of NASH.

2350-C | NLRP3 INFLAMMASOME ACTIVATION IN NEUTROPHILS DRIVES HEPATIC STELLATE CELL ACTIVATION IN MURINE NON-ALCOHOLIC STEATOHEPATITIS

Benedikt Kaufmann[1,2], Laela Booshehri[1], Ola Leszczynska[1], Helmut Friess[3], Daniel Hartmann[3], Lori Broderick[1], Hal Hoffman[1] and Ariel E. Feldstein[1], (1)University of California, San Diego, (2)Klinikum Rechts Der Isar, (3)Technical University of Munich, Munich

Background: Chronic inflammation represents a central driver of disease progression in Nonalcoholic Steatohepatitis (NASH). Activation of the NLRP3 inflammasome, a cytosolic multiprotein complex that mediates sterile inflammatory responses, in leukocytes has been proposed to be a key driver of murine and human NASH. However, the relevance of NLRP3 inflammasome activation in either macrophages or neutrophils that contribute to the pathology of NASH remains unknown. In this study the contribution of neutrophil specific NLRP3 inflammasome activation in NASH was investigated. **Methods:** Neutrophil specific Nlrp3 knock-out mice were generated to investigate the role of NLRP3 inflammasome activation in neutrophils. A chronic (choline-deficient, L-amino acid-defined high-fat diet (CDAA-HFAT)) liver injury model was used to induce in vivo NLRP3 activation and fibrotic-non-alcoholic steatohepatitis (NASH). Mice were put on CDAA-HFAT diet for 10 weeks and liver steatosis, inflammation and fibrosis were analysed by immunohistochemistry and RT-PCR. **Results:** Neutrophil-specific Nlrp3 knock-out did not show a difference in the degree of steatosis compared to WT mice. Furthermore, population of Kupffer cells, the resident macrophages in the liver, was similar in both neutrophil-specific Nlrp3 knock-out and WT mice analysed by immunohistochemistry and RT-PCR. Interestingly, Neutrophil-specific Nlrp3 knock-out resulted in reduced mRNA levels of α-SMA and vimentin, markers for HSC activation, compared to WT mice analysed by RT-PCR. Furthermore, α-SMA expression was decreased on protein level in neutrophil-specific Nlrp3 knock-out mice compared to WT mice analysed by immunohistochemistry. Liver fibrosis, a key feature of NASH, was reduced in neutrophil-specific Nlrp3 knock-out mice compared to WT mice. Levels of mRNA of Col3a and CTGF were reduced in neutrophil-specific Nlrp3 knock-out mice compared to WT mice. **Conclusion:** This study provides novel insights in the cell-specific role of NLRP3 activation in neutrophils in the pathogenesis of NASH. NLRP3 inflammasome activation in neutrophils was identified as crucial for the progression to fibrotic-NASH.

2351-C | OAT BETA-GLUCAN AMELIORATES NON-ALCOHOLIC FATTY LIVER DISEASE IN A PREBIOTIC MANNER

Julius Werner Jaeger[1], Annette Brandt[2], Wenfang Gui[1], Timur Yergaliyev[3], Angélica Hernández-Arriaga[3], Mukil Marutha Muthu[3], Ahmed Elashy[1], Karolina Edlund[4], Antonio Molinaro[5], Diana Möckel[6], Jan Sarges[1], Jan G. Hengstler[7], Emina Halilbasic[2], Michael Trauner[8], Florian Kahles[1], Carolin Victoria Schneider[1], Twan Lammers[6], Hanns-Ulrich Marschall[9], Amélia Camarinha-Silva[3], Ina Bergheim[2], Christian Trautwein[10] and Kai M. Schneider[1], (1) University Hospital Rwth Aachen, (2)University of Vienna, (3)University of Hohenheim, (4)Leibniz Research Centre for Working Environment and Human Factors, (5)University of Gothenburg, (6)Rwth Aachen University, (7)Department of Toxicology, Leibniz Research Centre for Working Environment and Human Factors, Technical University Dortmund, Ardeystr 67, 44139, Dortmund, Germany, (8)Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, (9) University of Gothenburg, Gothenburg, Sweden, (10) Department of Internal Medicine III, University Hospital, Rwth Aachen, Germany

Background: The gut and liver have a close bilateral relationship that influences both liver pathology and hemostasis. Oat beta-glucan, a non-digestible polysaccharide, has shown promising effects on metabolic syndrome hallmarks such as hyperlipidemia. However, its impact on non-alcoholic fatty liver disease (NAFLD), particularly NAFLD fibrosis, remains unknown. Therefore, we investigated the effect of oat beta-glucan on NAFLD progression. **Methods:** We examined the effect of beta-glucan on NAFLD progression using a Western-style diet (WSD)-induced NAFLD model. We characterized the metabolic profile, including fat distribution, glucose tolerance, and lipid

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

metabolism, as well as hepatic inflammation and fibrosis. Additionally, we analyzed gut microbiota and bile acid composition. The gut microbiota was modulated using broad-spectrum antibiotics (Abx). **Results:** Oat beta-glucan supplementation did not affect the metabolic phenotype. However, treatment with beta-glucan reduced intrahepatic inflammation, which was associated with a significant reduction in infiltrating monocyte-derived macrophages (MoMFs), fibroinflammatory pathways, and hepatic fibrosis. This protective effect depended on the gut microbiota and was lost with Abx treatment. Oat beta-glucan modulated the gut microbiota composition in a prebiotic manner, partially reversing unfavorable changes associated with WSD and promoting protective taxa, including *Ruminococcus* and *Lactobacillus*. Consistent with these findings, we observed significantly reduced translocation of Toll-like receptor ligands after beta-glucan treatment. **Conclusion:** Our study identifies oat beta-glucan as a novel and potent dietary component that improves intrahepatic inflammation and fibrosis in diet-induced NAFLD. These results suggest that beta-glucan may be a cost-effective and well-tolerated new agent for preventing NAFLD progression, warranting assessment in clinical studies.

2352-C | ORAL SUPPLEMENTATION OF DIMETHYL FUMARATE AMELIORATES STEATOSIS AND FIBROSIS IN MOUSE MODEL OF NASH

Masaaki Mino[1], Eiji Kakazu[1], Akitoshi Sano[2], Toshihiro Sakata[1], Taiji Yamazoe[1], Michitaka Matsuda[1], Taizo Mori[1], Sachiyo Yoshio[1], Jun Inoue[3] and Tatsuya Kanto[1], (1)Department of Liver Disease, the Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, Japan, (2)Department of Gastroenterology, Tohoku University Graduate School of Medicine, Japan, (3)Division of Gastroenterology, Tohoku University Graduate School of Medicine, Japan

Background: Metabolic dysregulation, such as an imbalance of free fatty acids and amino acids (AAs), is involved in the development of steatosis and fibrosis in NASH. We previously showed that, in NASH model mice fed with a high-fat, methionine (Met)-restricted and Tyrosine (Tyr)-deficient diet, hepatic fumarate quantity and Nrf2 expression were decreased, resulting in the reduction of VLDL excretion from the liver. In this study, we aimed to evaluate the impact of the supplementation of fumarate ester, dimethyl fumarate (DMF), on the pathogenesis of NASH and disclose its metabolic mechanisms in NASH mouse model. **Methods:** In order to clarify the relationship between 24 plasma AAs and lipoprotein profiles, we enrolled 41 patients diagnosed with NAFLD by needle biopsy. In mouse experiments, C57BL/6 mice were fed with a high fructose, saturated fatty acid and cholesterol (FFC) diet for 20 weeks. We compared biochemical data, plasma lipoprotein profiles, and pathology among normal chow fed mice, FFC diet fed mice (FFC) and FFC diet plus DMF fed mice (FFC+DMF). Metabolites and metabolic genes in the liver were assessed using metabolomics (CE-TOFMS) and RNA-seq at short-term (2 weeks) and long-term (20 weeks), respectively. In order to elucidate antioxidant mechanism by DMF, intracellular reactive oxygen species (ROS), Nrf2 and AAs in hepatocytes were measured *in vitro* by fluorescent microscopy and HPLC, respectively. **Results:** In early-stage NAFLD patients, fumarate related AAs; Met, phenylalanine (Phe) and Tyr were positively correlated with the large VLDL-TG level and HOMA-R, supporting for the rationale of the fumarate supplementation. In mice, the FFC group became obese, hyperglycemic and exhibited pathological changes of NASH liver (steatosis, inflammation, ballooning and fibrosis) at 20 weeks. Metabolomics and RNA-seq revealed that the FFC group decreased the level of fumarate and increased beta oxidation (the elevation of acetyl CoA, Acaa1a and Hadh) at 2 weeks. Interestingly, at 20 weeks, beta oxidation was inversely decreased and then increased gluconeogenesis (the increase of NADH / NAD ratio and the decrease of fumarate related AAs), and then large VLDL-TG was significantly decreased. On the other hand, in the FFC +DMF group, obesity and hyperglycemia were prevented, and pathological changes of NASH liver were ameliorated and the lipoprotein profiles were normalized. Metabolomics analysis revealed that DMF supplementation restored these AAs levels and then improved beta oxidation and excess gluconeogenesis in the liver. *In vitro*, Monomethyl fumarate, derivate of DMF, resulted in the nuclear translocation of Nrf2 and decreased ROS and the fumarate related AAs consumption in hepatocytes treated with fatty acids. **Conclusion:** Oral supplementation of DMF could

2353-C | ORGAN-ON-A-CHIP NAFLD/NASH MODEL EXPRESSING PNPLA3-I148M AND TM6SF2-E167K ALLOWS FOR BIOMARKER DISCOVERY THROUGH UNTARGETED METABOLOMIC PROFILING.

Émanuel Paré, Claudia Carpentier, Maxim Maheux, Jérémy Loehr, Émilie Pic and Jacques Corbeil, Université Laval

Background: NASH is a disease with multiple causes ranging from genetic background, lifestyle, nutrition, and drugs. While most of the efforts are concentrated at detecting and treating the advanced forms of the disease, the lack of physiologically relevant models limits our ability to identify and treat at risk populations at the early stages. Moreover, current diagnostic and prognostic methods require invasive biopsies and expensive imaging devices with limited success. In this study, we used organ-on-a-chip to create a model that reproduces the main cellular characteristics of the disease: intracellular fatty acid accumulation, inflammation, apoptosis and fibrosis in a 3D co-culture of differentiated hepatic and stellate cells. We introduced the two primary genetic mutations associated with NAFLD/NASH to mimic genetic subgroups of the disease. New NASH biomarkers can be identified by treating the cells with fatty acids, diet-associated molecules and drugs and monitoring their impact on the abundance of specific metabolites. **Methods:** Clonal populations of HepaRG cells expressing PNPLA3-I148M or TM6SF2-E167K were generated using CRISPR-Cas9. The model was developed using the commercially available Organ-on-a-chip system from Mimetas®. A mixture of HepaRG and LX2 cells (ratio 9:1) was seeded in a type I collagen gel on a 2-lane Organoplate. Culture media and cell samples were analysed on an Acquity I-class UPLC system with either a BEH Amide or a CSH C18 column coupled to a Synapt G2-si mass spectrometer in MSe mode. Confocal microscopy was used to perform 3D imaging of cell and disease-relevant markers. **Results:** Treating the model with palmitic acid (PA) and oleic acid (OA) caused an accumulation of lipid droplets in hepatocytes without affecting other cell subtypes in the co-culture. Caspase 3/7 assays revealed that PA increased the number of apoptotic cells while OA did not. Moreover, a combination of PA and OA did not affect the number of apoptotic cells, suggesting a protective role for unsaturated fatty acids. Untargeted metabolomics and lipidomics analysis revealed distinct metabolic signatures between the mock-transfected and mutant cell lines. We identified 168 features that allow distinction of PNPLA3-I148M and 262 features for TM6SF2-E167K mutants. Preliminary functional analysis using Metaboanalyst 5.0 associated some of those features to amino acid-related metabolic pathways and further analysis and identification is under way. **Conclusion:** 1)Our model exhibits the main characteristics of the NAFLD/NASH. 2) We recapitulated the most common genetic background associated with NASH in a high-throughput model compatible with untargeted mass spectrometry. 3) This proof-of-concept established our ability to identify putative novel disease-related metabolomic biomarkers associated with specific genetic backgrounds.

2354-C | PATHOGENETIC ANALYSIS OF NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) AND NONALCOHOLIC STEATOHEPATITIS (NASH) WITH MULTI-CELL-LINEAGE HUMAN LIVER ORGANOIDS

Wenjun Zhang, Yujin Park, Deepthi Thadasina, Thi Minh Uyen Le, Ping Li and Burcin Ekser, Division of Transplant Surgery, Department of Surgery, University School of Medicine

Background: Nonalcoholic fatty liver disease (NAFLD) and its advanced form, nonalcoholic steatohepatitis (NASH), are prevalent liver diseases with no effective treatment available. Currently, there is a lack of a realistic *ex vivo* modeling system that recapitulates some of the *in vivo* pathophysiological microenvironment for studying the pathological response of different hepatic lineage cells during the progression of NAFLD/NASH. **Methods:** Primary human hepatocytes, hepatic stellate cells (HSCs), liver endothelial cells (LECs), cholangiocytes (CHOs), and Kupffer cells (KC) were isolated from liver explants of

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

healthy donors and NAFLD livers. Scaffold-free 3D human liver organoids (3D-HLOs) were created by co-culturing 5 major human hepatic cells (HC+LEC+HSC+CHOL+KC) in a low attachment 96-well plate. Normal 3D-HLOs were subjected to the different concentrations of free fatty acid treatment (FFA, oleic acid:palmitic acid, 2:1) with or without lipopolysaccharide (LPS) for 14 days to induce steatosis, fibrosis, LEC dysfunction, and inflammation. As a comparison, individual cell lines including HCs, CHOLs, and LECs were treated with different concentrations of FFA for 48 hours. Normal 3D-HLOs+FFA ± LPS and NAFLD 3D-HLOs were subjected to the treatment of leading compounds in clinical development for NASH including obeticholic acid (OCA, 1mM), lanifibranor (LAN, 10mM), FGF19 (10ng/ml) and Tirzeptide (200nM) for 7 days to assess the functionality of organoids and drug responses. RT-qPCR (PCR), immunoreactivity, EIA, and biochemistry assays were performed to determine 3D-HLO functional phenotype, fibrosis, angiogenesis, and secretion of albumin (ALB) and total bile acids (TBA). **Results:** FFA treatment induces a robust lipid accumulation in HCs and CHOLs, but much less in LECs. We found that FFA treatment significantly upregulated the expression of the genes in LECs that are related to angiogenesis (CDH5), epithelial-mesenchymal transformation (TGF-β2 and TGF-β3), cellular stress (P53), and inflammation (IL-32). 3D-HLOs treated with FFA+LPS had increased lipid accumulation, collagen deposition, and functional deterioration compared to FFA treatment alone. We found that OCA, LAN, FGF19, and Tirzeptide all failed to rescue the FFA+LPS-instigated reduction of ALB production. However, both OCA and LAN, but not FGF19 repressed the FFA+LPS-upregulated fibrosis (COL1A1, ACTA2) and angiogenesis (PECAM). **Conclusion:** Our muti-cellular 3D-HLOs provide a unique *in vitro* platform that is suitable for studying the pathogenic cellular interactive process in NAFLD/NASH that will help to interrogate the involvement of different hepatic lineages in the progression of NAFLD/NASH, which will augment the development of targeted and effective treatments.

2355-C | PCKS9 INHIBITION ATTENUATES STEATOSIS AND INFLAMMATION BY AMELIORATING ER STRESS IN NONALCOHOLIC FATTY LIVER DISEASE MOUSE MODEL

Myeong Jun Song, Departmecollege of Medicine, the Catholic University of Korea

Background: Nonalcoholic fatty liver disease (NAFLD) causes significant morbidity and mortality, and pharmacological treatment options are limited. Proprotein convertase subtilisin/kexin type 9 (PCSK9) promotes the degradation of the low-density lipoprotein receptor (LDL-R) thereby elevating plasma LDL cholesterol levels and the risk of coronary heart disease. Therefore, we investigated the role of PCSK9 inhibitor Evolocumab, a monoclonal antibody in liver fat accumulation and injury for the treatment of NAFLD **Methods:** In this study, we investigated the role of PCSK9 in diet-induced mouse model. Evolocumab (50 mg/kg) or vehicle was administered weekly for 12 weeks to mouse receiving a high fat diet or an isocaloric control diet. At the end of the treatment of PCSK9 inhibition, serum and liver samples were obtained for molecular characterization and histopathological analysis. **Results:** PCSK9 inhibition with evolocumab reduced high fat-induced hepatic triglyceride accumulation through regulation of lipid metabolism (modulation of the transcription factors (SREBP-1c) in liver and oxidation (PPARα and CPT1)), hepatocellular injury (ALT), hepatic inflammation (pro-inflammatory cytokines/chemokines (IL-1β, IL-6, TNFα, IL-10, and MCP-1). In line with these findings, a metabolic challenge using a high-fat diet attenuates severe hepatic steatosis, ER stress inflammation and fibrosis in the liver of mice treated with evolocumab compared to controls. **Conclusion:** We demonstrated that anti-PCSK9 treatment using evolocumab attenuated diet-induced steatohepatitis in the mouse model. Anti-PCSK9 treatment that spares liver metabolism may be a viable new therapeutic possibility for the treatment of NAFLD. Further studies are needed to elucidate the exact role of PCSK9 in NAFLD and to evaluate efficacy and safety of anti-PCSK9 treatment in patients with NAFLD.

Background: Metabolic liver disease and hepatocellular carcinoma (HCC) are major global health burdens with unsatisfactory treatment options. HCC is the third most common cause of cancer-related death and the leading cause of death among cirrhotic patients. While new treatments for HCC have been recently approved, chemopreventive strategies for HCC are lacking. Aiming to discover novel therapeutic targets, we combined genome wide transcriptomic analysis of liver tissues from patient with advanced liver disease and HCC and a cell-based system predicting liver disease progression and HCC risk. Computational analysis identified peroxiredoxin 2 (PRDX2) as a candidate driver of hepatocarcinogenesis. **Methods:** The role of PRDX2 in liver disease progression and HCC development was investigated by *Prdx2* KO in a state-of-art CRIPSR/Cas9 mouse model for NASH-induced hepatocarcinogenesis and a cell-line-derived xenograft (CDX) mouse model. The mechanism of action was explored using RNA-Seq analyses of mouse liver tissues and validated by perturbation studies in human liver cell-based models. **Results:** In vivo perturbation studies in a mouse model for NASH driven hepatocarcinogenesis showed that *Prdx2* KO robustly reduces steatosis and decreases HCC development. RNA-Seq analyses of mouse liver tissues with validation at the protein level showed that loss of *Prdx2* function suppresses oncogenic signaling (i. e. p38/MAPK, PI3K/AKT, STAT3 signaling) and improves metabolic liver functions (i.e cholesterol, fatty acid and bile acid metabolism) through activation of the AMPK. Finally, PRDX2 loss-of-function studies in hepatoma cell-based models and a CDX mouse model unraveled that PRDX2 mediates cancer cell proliferation, migration, invasion, and survival. **Conclusion:** Our findings demonstrate an important functional role of PRDX2 in metabolic liver disease and hepatocarcinogenesis. Targeting PRDX2 is a previously undiscovered therapeutic opportunity for the treatment of metabolic liver diseases and prevention of NASH-induced HCC.

2357-C | PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR AGONIST IVA337 AMELIORATES LIVER FIBROSIS IN 2D AND 3D NASH CELL CULTURE MODELS

Na Li[1], Shuai Wu[2], Xiaodan Li[3], Ling-Juan Zhang[2] and Xiao Liu[4], (1)Shanghai University of Medicine & Health Sciences, (2)State Key Laboratory of Cell Stress Biology, School of Life Sciences, Xiamen University, Xiamen, China, (3)School of Medical Technology, Shanghai University of Medicine & Health Sciences, Shanghai, China, (4)Yuanzhui Cell Biotechnology Company, Xiamen, China

Background: Nonalcoholic steatohepatitis (NASH) is advanced from nonalcoholic fatty liver disease (NAFLD), and it is characterized with severe hepatic fibrosis. The pan-peroxisome proliferator-activated receptor (pan-PPAR) agonist IVA337, and PPARγ agonist rosiglitazone (ROSI) are promising anti-NASH compounds, but the underlying mechanisms remain uncharacterized. **Methods:** Liver fibrosis models were established in 2D primary human hepatic stellate cells by adding TGFß1, and in 3D mouse liver spheroids containing primary hepatocytes, hepatic stellate cells, and non-parenchymal cells. The anti-fibrosis effects of IVA337 in these NASH models were evaluated by RT-qPCR, RNA sequencing and immunostaining. **Results:** In TGFß-stimulated hepatic stellate cells, IVA337 was more effective than ROSI in suppressing the expression of fibrosis-related genes expression (PAI1, COL1A1, and SMA). We successfully constructed a 3D mouse liver spheroids NASH model, which is characterized by low lipid content and high expression of fibrotic genes. We found that administration of either IVA337 or ROSI not only reduced the expression of fibrosis genes, but

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

also restored lipid content in the NASH spheroids as shown by bodipy staining. Additionally, immunostaining analysis showed that IVA337 was more effective than ROSI in reducing the expression of smooth muscle actin (SMA) and collagen. Furthermore, we performed bulk RNA-sequencing, and GO analysis identified several lipid pathways as the major effectors downstream of IVA treatment. Together, our results show that that pan-PPAR agonist IVA337 is effective in suppressing fibrosis development in the 2D and 3D NASH cell culture models, and our findings indicate that IVA337 exerts its anti-NASH effect by restoring the balance between lipogenesis and fibrogenesis. **Conclusion:** IVA337 is effective in suppressing liver fibrosis by modulating lipid metabolism.

2358-C | PNPLA3-148M IS ASSOCIATED WITH INCREASED CELLULAR METHYLATION ACTIVITY AND REDUCED ANTIOXIDATIVE STRESS CAPACITY IN THE PROGRESSION OF NON-ALCOHOL FATTY LIVER DISEASE

Zheyun Peng and Wanqing Liu, Wayne State University

Background: The PNPLA3 148I > M variant is associated non-alcoholic fatty liver disease (NAFLD) and its advanced stage non-alcoholic steatohepatitis (NASH). However, the detailed mechanism underlying this association remains incompletely understood. **Methods:** This study aims to further explore the molecular pathogenic mechanism of PNPLA3-148M-driven NASH via an integrated metabolomic and transcriptomic analysis in a humanized PNPLA3 mouse model. DNA 5-mC level was measured in the liver tissues. Transgenic mice carrying the human PNPLA3-148I or PNPLA3-148M gene isoform were fed a NASH-inducing AMLN diet for 24 weeks. Metabolomic analysis was conducted for the liver tissue and serum samples and transcriptome of the liver tissue was also analyzed via RNA-seq. **Results:** A total of 843 and 774 metabolites were profiled in mouse liver and serum samples, respectively. In the liver, levels of 101 metabolites were found to be significantly changed in the PNPLA3-148M group compared to the PNPLA3-148I mice ($p < 0.05$). Enrichment analysis revealed that pathways involving folate metabolism, choline metabolism, citric acid cycle, glutamate metabolism, and methionine metabolism were significantly different between the two strains. Remarkably, PNPLA3-148M was associated with a significantly decreased cellular methylation activity indicated by the decreased ratio of S-Adenosyl-L-homocysteine and S-adenosylhomocysteine (SAM/SAH) as compared to the PNPLA3-148I mice, which is in line with a downregulated Dnmt3b expression. In addition, the γ-glutamylcysteine, the precursor of GSH, was significantly reduced in PNPLA3-148M mice, along with a decreased ratio of GSH/GSSG, indicating a reduced capacity of response to oxidative stress in the PNPLA3-148M mice. In the serum, there were 109 metabolites found to be significantly changed between the two groups ($p < 0.05$) with the most of those metabolites being free fatty acids and intermediate metabolites of the fatty acid metabolism. The metabolites related to the above pathway (methylation and anti-oxidative stress) showed a trend of decreasing. Notably, a significant increase of acyl choline species was observed in the liver of PNPLA3-148M mice, while the serum choline level was found significantly reduced, indicating a choline-deficient situation in the PNPLA3-148M mice. **Conclusion:** Besides its role in lipids metabolism, PNPLA3-148M may also contribute to the development of NASH via modulating cellular methylation activity, which may further lead to genome-wide epigenetic regulation of both DNA and protein modification. The PNPLA3-148 isoform may also be associated with a reduced capacity in rescuing liver cells from oxidative stress.

2359-C | POTENTIAL THERAPEUTIC SIGNIFICANCE OF CHIT1 INHIBITION IN NASH-LIVER FIBROSIS

Si Hyun Bae[1,2], Jung Hoon Cha[2], Na Ri Park[2], Sung Woo Cho[2] and Pil Soo Sung[2,3], (1)Eunpyeong St. Mary's Hospital, the Catholic University of Korea, (2) The Catholic University Liver Research Center, Department of Biomedicine & Health Sciences, College of Medicine, the Catholic University of Korea, (3)Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, Republic of Korea

Background: According to recent research findings, macrophage activation and cytokine release play a central role in liver fibrosis. The secretion of human chitotriosidase (CHIT1) by inflammatory macrophages was observed, and this study primarily emphasized the relationship between CHIT1 and liver fibrosis. **Methods:** The concentration of CHIT1 in the serum of a cohort of liver fibrosis patients ($n = 62$) was assessed using ELISA. Furthermore, the gene expression levels of CHIT1 in liver tissues from a separate cohort of liver fibrosis patients ($n = 94$) were evaluated using the nCounter assay. The objective of this study was to investigate the underlying mechanism of CHIT1 and explore the therapeutic potential of inhibiting CHIT1

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

using OATD-01 in the treatment of NASH-liver fibrosis mice. Combination of Streptozocin (STZ) injection and high fat and high cholesterol diet (HFHC) was used to establish NASH-liver fibrosis model. **Results:** An increase in the concentration of CHIT1 in the serum of liver fibrosis patients was evaluated, as determined by ELISA, in the F3-F4 fibrosis stage compared to the F0-F2 stage ($P = 0.007$). Furthermore, gene expression of CHIT1 in liver tissue was assessed using the nCounter assay, demonstrating an increase as fibrosis stage progressed ($P = 0.006$). In the STZ-HFHC mouse model, liver fibrosis induction was confirmed, and increased CHIT1 expression was observed through immunohistochemistry (IHC). FACS analysis revealed an upregulation of CHIT1 expression in macrophages in the livers of the STZ-HFHC group compared to the control group. Treatment of STZ-HFHC mice with OATD-01 resulted in improved liver fibrosis, as confirmed by IHC, and a reduction in inflammation indicated by decreased serum levels of ALT and AST ($P = 0.05$). OATD-01 treatment also led to downregulation of fibrosis-related genes and immune-related genes in the liver of STZ-HFHC mice, as determined by qRT-PCR. Dose-dependent improvements in hepatic fibrosis were observed with OATD-01 treatment in the STZ-HFHC mouse model. The results strongly support the efficacy of OATD-01 in significantly improving hepatic fibrosis, with higher doses demonstrating a more pronounced effect. **Conclusion:** Our study provides compelling evidence for the significant involvement of CHIT1 in liver fibrosis, supported *by elevated CHIT1 expression observed in both human patients and mouse models. Notably, treatment with the CHIT1 inhibitor, OATD-01, exhibited a dose-dependent amelioration of hepatic fibrosis in the STZ-HFHC mouse model. These results* strongly indicate that targeting CHIT1 inhibition holds promise as a potential therapeutic approach for addressing NASH-associated liver fibrosis in human patients.

2360-C | PREDICTION OF CLINICAL NASH CANDIDATES WITH A HUMAN IN-VITRO AND SCREENING COMPATIBLE LIVER SPHEROID MODEL

Francisco Verdeguer, Radina Kostadinova, Thomas Hofstetter, Olivier Frey, Jesus Glaus, Angelina Freitag, Arumugham Raghunathan and Philipp Vonschallen, Insphero

Background: Non-alcoholic steatohepatitis (NASH) is a progressive severe disease characterized by lipid accumulation, inflammation, and fibrosis in the liver which lacks any approved drug therapy. Novel approaches to identify therapeutic candidates that predict clinical responses are needed. Human preclinical models, including organoids/spheroids, are powerful for translational drug discovery, however, the use of high-throughput scalable methods including drug screening is a current challenge. We aim at generating a spheroid NASH model amenable for high-throughput drug screening for a better prediction of clinical candidates. **Methods:** We developed a human 3D NASH model of spheroidal, scaffold free co-culture derived from primary hepatocytes, Kupffer cells, liver endothelial cells and hepatic stellate cells. We have defined specific steatotic and proinflammatory culture media conditions (NASH cocktail) containing high levels of sugars, free fatty acids and a LPS pulse compared to physiological control conditions. Spheroids were incubated with the NASH cocktail for 10 days and several clinical trial candidates were added during this period. We measured total intracellular triglycerides, a panel of inflammatory cytokines and pro-collagen 1 collected from media supernatants to investigate the therapeutic effect of the tested compounds including Firsocostat, Selonsertib, Resmetirom, GC1, Obeticolic acid, Elafibranor, Lanifibranor and combinations of those. **Results:** We have analysed the robustness of triglycerides and pro-collagen 1 assays to measuruing the Z' factors of control versus NASH. The data show $Z' > 0.5$ suggesting optimal conditions for throughput screening. Our pilot study with known clinical compounds predicts the expected clinical effects showing a good translation of steatotic, inflammatory or fibrotic phenotypes in liver spheroids. **Conclusion:** We have achieved conditions and drug predictions of NASH with a spheroid model for its use in high-througput screening of clinical candidates in NASH.

Ishizu[1], Takashi Honda[1], Masatoshi Ishigami[1], Hiroaki Wake[1] and Hiroki Kawashima[1], (1)Nagoya University Graduate School of Medicine, (2)Sapporo Medical University

Background: Lipid droplets (LDs) are organelles found in not only adipocytes but also various cells throughout the body, and they store excess energy while also fulfilling a multitude of physiological functions. In our recent report, we described two distinct types of intranuclear LDs observed in hepatocytes: one characterized by cytoplasmic and nuclear membrane invagination, and the other lacking such features. The objective of this study is to investigate the occurrence of these two types of intranuclear LDs in nonalcoholic fatty liver disease (NAFLD). **Methods:** This study included 27 patients with NAFLD who underwent liver biopsies. A part of the liver biopsy specimen was dissected and fixed for electron microscopic observation. Electron microscopy observations of liver biopsy samples were conducted independently from light microscopy-based clinical diagnosis. Depending on the presence of adjacent cytoplasmic invagination of the nuclear membrane, LDs in the nuclei were classified into two types: "true" nucleoplasmic LDs (nLDs) and cytoplasmic LD invagination with nucleoplasmic reticulum (cLDs in NR). **Results:** Liver biopsies were performed in 12 men and 15 women. The mean age was 56 years (range: 22 to 89 y). Liver biopsy-proven liver diseases included nonalcoholic steatohepatitis (NASH) in 16 patients and nonalcoholic fatty liver (NAFL) in 11 patients. Hematoxylin and eosin staining revealed that the severity of liver steatosis was 5–33% in 19 patients, 33–66% in five patients, and $>$ 66% in three patients. The mean NAFLD activity score was three (range: 1 to 5). Hepatocyte ballooning was confirmed in all patients with NASH. Electron microscopy revealed the presence of nLDs in 65% of the liver biopsy samples from patients with NAFLD, and cLDs in NR were observed in 23% of the samples. No significant correlations were found between the frequency of nLDs or cLDs in NR and the severity of liver steatosis, suggesting that the presence of nLDs or cLDs in NR does not directly reflect cytoplasmic lipid accumulation. Although the prevalence of nLDs in liver biopsies did not differ significantly between patients with NASH and NAFL (NASH: 63% vs. NAFL: 70%), the presence rate of cLDs in NR was significantly higher in patients with NAFL compared to those with NASH (NASH: 6% vs. NAFL: 50%, $P = 0.018$). **Conclusion:** This study unveiled the presence of two types of intranuclear LDs in patients with NAFLD, leading us to speculate about two distinct pathophysiological roles of nLDs and cLDs in NR in NAFLD.

f 2362-C | RECAPITULATING THE LIVER SINUSOID PHYSIOLOGY OF FULLY POLARIZED HEPATOCYTES, VASCULAR PLEXUS, STELLATE CELLS AND IMMUNE CELLS FOR ANTI FIBROTIC COMPOUND SCREENING

Flavio Bonanini, Roelof Dinkelberg, Vincent Van Duinen, Tessa Hagens, Nienke Kortekaas, Manuel Caro Torregrosa, Dorota Kurek, Paul Vulto and Kristin Bircsak, Mimetas

Background: Modelling the complex biology and physiology of the liver is imperative to unravel the pathogenic mechanisms of liver diseases and thus enable drug development. This requires biological models that closely mimic liver biology in its cellular composition, architecture and function. Yet, most multicellular systems result in a rather disorganized aggregate of different cell types or depend on their forceful confinement in separate microfluidic channels, often separated by artificial membranes. **Methods:** Human primary or stem cell-derived hepatocytes, liver endothelial cells, stellate cells and immune cells were introduced within a microfluidic setup of 64 parallel chips in a microtiter plate format. Confocal microscopy and transcriptomics were used to characterize and compare the model to native liver. We challenged the system with lipids or cytokines to induce steatotic and fibrotic phenotypes. High content confocal imaging and cytokine release measurements were used to evaluate the effect of clinically-relevant tool compounds in a fully automated setup. **Results:** Liver-derived endothelial cells self organized into sinusoidal-like structures, with dimension and marker expression consistent with and in close basolateral interaction with stellate cells. Hepatocytes were fully polarized and organized in distinct plate-like structures, separating interconnected endothelial vessels associated with functional

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

macrophages. Transcriptomics analysis revealed fidelity with the diversity of gene expression levels found in liver tissue with clear representation of all major liver cell types. Steatosis and fibrosis phenotypes could be induced as presented by visible hepatic lipid accumulation, stellate cell activation marker increase and cytokine release. Implementation of benchmark compounds led to a highly reproducible assay with performance within industry requirements for high-throughput screenings. A fully automated, multiplexed small scale anti-fibrotic drug screen identified eleven compounds that were able to revert the fibrotic phenotype, with two compounds also able to restore hepatocyte function and modulate vascular plexus morphology. **Conclusion:** We believe this comprehensive liver model reflects the cellular organization and interactions found within the liver lobule in an unprecedented manner. The system holds the potential for groundbreaking progress in liver disease modelling which, in addition to the steatosis and fibrosis modelling presented here, will be extended to infectious diseases and cancer. In conjunction with its high throughput capability, this has the potential to revolutionize drug discovery and develop therapies for complex liver diseases.

2363-C | REDUCTION OF TGF-β AND IMPROVEMENT OF FIBROSIS AFTER OPTIMIZATION OF FECAL MICROBIOTA TRANSPLANT WITH AN ENDOSCOPIC-PLACEMENT HYDROGEL IN A MURINE MODEL OF STEATOHEPATITIS WITH FIBROSIS

Ramon Bartoli Sole[1,2], Ignacio Iborra[3], Maria Torner Simó[3], Alba Ardevol Ribalta[3], Helena Masnou[2,3] and Rosa Maria Morillas[1,2,3], (1)Ciberehd, (2)Germans Trias I Pujol Research Institute (IGTP), (3)Hospital Germans Trias I Pujol

Background: Gut microbiota dysbiosis has become a key factor in the development and progression of non-alcoholic steatohepatitis (NASH) by influencing the immune and metabolic systems and increasing gut mucosa permeability to bacterial products, which in turns, activates the secretion of proinflammatory and profibrotic cytokines. Although fecal microbiota transplant (FMT) has been proposed as a new therapeutic strategy, effective colonization is difficult to achieve. Our group has developed an endoscopic-placement hydrogel (covergel) that, used as a vehicle, could improve FMT. Our aim was to compare the efficacy of FMT using covergel versus the standard method on gut permeability and plasma levels of proinflammatory (IL1-β) and profibrotic (TGF-β) cytokines and its effect on steatosis and fibrosis in a rat model of NASH with fibrosis **Methods:** 24 rats received a high-fat/cholesterol/fructose diet throughout the study (15 weeks) and CCl_4 for 12 weeks (NASH rats). 6 rats received standard chow (healthy rats). Feces from NASH and healthy rats were collected for FMT. At week 13, NASH rats were randomized into 3 groups for FMT by colonoscopy. Group 1: healthy feces in saline (HF-standard-FMT); group 2: healthy feces in covergel (HF-covergel-FMT); group 3: NASH feces in covergel (NASH-covergel-FMT). At week 15, rats were sacrificed to assess liver/body weight ratio, degree of liver fibrosis (Mason's trichromic) and steatosis (oil red), and plasma endotoxin, IL1-β and TGF-β levels (ELISA) **Results:** All NASH rats increased in body weight, whereas liver/body weight ratio normalized in group 2. Standard FMT showed a non-significant improvement in reversing fibrosis (groups 1 vs 3; $p = 0.084$). In contrast, HF-covergel-FMT reduced fibrosis (groups 2 vs 3; $p = 0.001$) and also showed a significant improvement compared to HF-standard-FMT (groups 2 vs 1; $p = 0.034$). FMT did not modify steatosis, being higher in all NASH groups. Endotoxemia and TGF-β levels decreased with HF-covergel-FMT vs. NASH-covergel-FMT (groups 2 vs 3; $p = 0.046$), being similar to healthy controls. In addition, TGF-β levels correlated with fibrosis degree (Pearson $= 0.797$, $p < 0.01$). However, FMT was unable to reduce IL1-β levels, being similar in all NASH groups **Conclusion:** FMT optimized with covergel significantly reduces fibrosis compared to the standard method, without changes in steatosis. In addition, it reduces the liver/weight ratio, endotoxemia, and TGF-β levels. The use of covergel improves the efficacy of standard FMT

2364-C | REGULATION OF LIVER FGF21 SECRETION BY THE INNATE IMMUNE SYSTEM

Neethu Alex[1], Samuel Piaker[1], Sudha Varadaraj[1], Nufar Edinger[2], Jay D. Horton[3] and Suraj J. Patel[1], (1)UT Southwestern Medical Center, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3)UT Southwestern Medical Center, Dallas, TX

Background: Inflammation and metabolic dysfunction are both known to play a role in alcohol-related liver disease. However, evidence for causal relationships between the two are sparse. The expression of interferon regulatory factor 3 (IRF3), a classical mediator of the innate immune response to viral infection, increases with the severity of alcohol-induced liver injury in human and mouse livers. In this study, we report a robust repression of the metabolic hormone fibroblast growth factor 21 (FGF21) by IRF3. **Methods:** Transgenic mice expressing a constitutively active (phospho-mimetic) mutant allele of IRF3 were used for gain-of-function studies, while liver-specific IRF3 knockout mice and WT mice injected with IRF3 antisense oligonucleotides (ASOs) were used for loss-of-function studies. FGF21 levels in the serum were measured by ELISA, following a single binge of ethanol without or after chronic binge ethanol feeding. Overexpression of constitutively active IRF3 and transcriptionally inactive IRF3 mutants in primary hepatocytes was carried out using an adenoviral expression system. RNA-Seq and CUT&RUN were used to determine the dataset consisting of the IRF3 transcriptome and cistrome, respectively. Plasmids expressing luciferase under the control of truncated versions of the FGF21 promoter region were used in combination with the luciferase assay system for linker scanning mutagenesis. **Results:** Transgenic mice expressing constitutively active IRF3 maintained lower circulating FGF21 levels compared to their wild-type littermates, even under the influence of alcohol – one of the most potent inducers of FGF21. Concordantly, loss of hepatocyte IRF3 in ethanol-binged mice increased FGF21 secretion. Moreover, the suppression of FGF21 by IRF3 slowed recovery from ethanol-induced intoxication in mice. IRF3-mediated inhibition of FGF21 was also seen in the presence of other triggers of FGF21 such as diet-induced obesity. Using a combination of RNA-Seq and IRF3 CUT&RUN analyses from primary hepatocytes overexpressing constitutively active IRF3, we determined that IRF3 is not a direct transcriptional repressor of FGF21. IRF3 mutants that do not translocate into the nucleus and bind to chromatin were used to demonstrate that transcriptionally active IRF3 is essential for suppression of FGF21. Using linker scanning mutagenesis of the FGF21 promoter, we identified a ~200bp region of DNA upstream of the transcription start site of FGF21, where the suppressive action of IRF3 occurs. **Conclusion:** Our data demonstrates the existence of a novel IRF3-FGF21 inhibitory axis that could be targeted to increase endogenous FGF21 secretion, decrease alcohol preference and reduce the severity of liver injury.

2365-C | ROLE OF HEPATIC STELLATE AND LIVER SINUSOIDAL ENDOTHELIAL CELLS IN A HUMAN PRIMARY CELL 3D MODEL OF NASH

Philip Tan[1], Traci Ostertag[1], Sara Brin Rosenthal[2], Daisy Chillin-Fuentes[3], Haylee Aidnik[1], Sara Linker[4], Keith Murphy[1], Jeffrey N Miner[1] and David A. Brenner[5], (1)Viscient Biosciences, (2)University of California, San Diego School of Medicine, (3)University of California, San Diego, (4)Salk Institute, (5)Sanford Burnham Prebys Medical Discovery Institute

Background: Nonalcoholic steatohepatitis (NASH) is an inflammatory and fibrotic liver disease that has reached epidemic proportions and has no pharmacological therapies. Research and drug development efforts are hampered by inadequate preclinical models. **Methods:** Three dimensional (3D) bioprinted liver disease tissues were built using primary human hepatocytes and non-parenchymal hepatic stellate cells (HSC), liver sinusoidal endothelial cells (LSEC), and macrophage/Kupffer cells (KC) from either healthy or NASH-diseased donors. Fibrosis was determined by measuring fibrotic markers using ELISA-based assays and histology, and by snRNAseq gene-expression analysis. Chimeric tissues composed of mixtures of diseased and healthy cell types were made and analyzed to assess the contribution of each individual cell type in NASH. **Results:** 3D bioprinted tissues with cells sourced from NASH-diseased patients exhibited a NASH phenotype including markers of fibrosis and fibrotic deposition. Importantly, this effect occurs without the addition of disease inducing agents. Bioprinted tissues composed entirely of healthy cells exhibit significantly less fibrosis. Chimeric tissues revealed a direct contribution for both HSCs

and LSECs in the development of NASH. Thus, the epigenetic changes in these two cell types persist from the diseased donor liver. **Conclusion:** This model represents a fully human system with potential to detect clinically active targets and eventually therapies.

2366-C | ROLE OF PREGNANE X RECEPTOR IN TYPE 1 AND TYPE 2 DIABETES

Daniel Okuwdili Nnamani[1], Sora Choi[2], Malvin Ofosu-Boateng[1], Elizabeth Twum[1], Lidya H Gebreyesus[1], Frank J. Gonzalez[3] and Maxwell Gyamfi[1], (1)The University of Tennessee Health Science Center, (2) North Carolina Central University, (3)National Cancer Institute

Background: Diabetes mellitus is a chronic metabolic disease with high morbidity and mortality rates. Type 1 diabetes accounts for 5-10% of cases of diabetes and is associated with loss of pancreatic beta cells and insulin deficiency. In contrast, type 2 diabetes is associated with obesity, insulin resistance, beta cell impairment, and insulin insufficiency. The pregnane X receptor (PXR) is a nuclear receptor involved in the regulation of enzymes that detoxify drugs and other xenobiotics in the liver and intestine. Studies have shown that PXR promotes obesity and suppresses gluconeogenesis and hyperglycemia. However, it is unknown whether PXR mediates the pathogenesis of diabetes. **Methods:** Adult male C57BL/6J (wild-type, WT) and *Pxr*-null mice were fed either normal chow or high-fat diet (HFD) for 16 weeks. At week 14, chow-fed and HFD-fed mice were each divided into two groups and administered either a single dose of streptozotocin (STZ, 100 mg/kg, ip) or vehicle. Blood was harvested at 1 and 2 weeks post-STZ and all mice were killed. Serum parameters, liver histopathology, immunoblotting, and gene expression analysis were examined. **Results:** Unexpectedly, STZ alone and HFD +STZ significantly increased blood glucose levels, but reduced serum insulin levels in WT mice, but not in *Pxr*-null mice, suggesting that PXR promotes the development of both type 1 and type 2 diabetes. In agreement with the observed hyperglycemia in WT mice, STZ suppressed the hepatic mRNA levels of both the glycolytic enzyme glucokinase (*Gck)* and glucose suppressor hormone fibroblast growth factor 21 (*Fgf21*). Interestingly, HFD alone-fed WT mice have metabolic syndrome characterized by obesity, dyslipidemia, hyperinsulinemia, hyperleptinemia, and marked liver injury in association with increased hepatic lipogenic gene mRNAs (*Pparg*, *Srebf1*, *Srebf2* and their target genes). Furthermore, HFD also increased hepatic mRNA levels of *Fgf21* and acyl-CoA oxidase 1 (*Acox1*) which might have protected obese HFD-fed WT mice against hyperglycemia. Importantly, inhibition of STZ-induced hepatic *Gck* mRNA expression may protect *Pxr*-null mice against T1DM and T2DM. **Conclusion:** Collectively, these results indicate that PXR deficiency protects against STZ-induced hyperglycemia, while PXR promotes obesity, T1DM, and T2DM development by inhibiting gene expression of *Gck* and *Fgf21* involved in glucose and insulin signaling. These data suggest PXR as a potential target for the treatment of diabetes.

2367-C | SESN2 MAINTAINS HEPATIC IMMUNE HOMEOSTASIS AND REDOX BALANCE BY INHIBITING RIPK3-MEDIATED NECROPTOSIS IN NON-ALCOHOLIC STEATOHEPATITIS

Zhang Jianbin, Xinhua Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China and Jiangao Fan, Department of Gastroenterology, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai 200092, China

Background: Necroptosis, a novel type of programmed cell death, is intricately associated with the inflammatory response. Currently, most studies focus on the activation of necroptosis, while the mechanisms underlying the negative regulation of necroptosis remain poorly understood. Here, we aimed to explore the functional significance and molecular mechanisms of Sestrin2 (SESN2), a highly evolutionarily conserved stress-inducible protein, in regulating necroptosis in non-alcoholic steatohepatitis. **Methods:** The effects of SESN2 overexpression or SESN2 knockdown on the regulation of necroptosis were assessed in the TNFα/Smac-mimetic/Z-VAD-FMK (T/S/Z)-induced cell necroptosis model. Western-blot, co-Immunoprecipitation, GST pull-down, and confocal assays were employed to explore the regulatory mechanisms including protein-protein interactions and post-translational modification (e.g., phosphorylation and ubiquitination). Additionally, we used GSK'872, a specific inhibitor of receptor-interacting serine/threonine-protein

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

kinase 3 (RIPK3), to determine which phenotypes of steatohepatitis in SESN2 knockout HepG2 cells/mice were due to RIPK3-mediated necroptosis in palmitic acid (PA)-induced *vitro* model and high-fat diet (HFD)-induced *vivo* model. **Results:** Our findings revealed that SESN2 was upregulated under conditions that induce necroptosis and functioned as a negative regulator of necroptosis. Mechanistically, we found that SESN2 interacted with RIPK3 and tuned down necroptosis by inhibiting the phosphorylation of RIPK3, promoting the ubiquitination of RIPK3 and preventing the formation of the RIPK1/RIPK3 necrosome. The depletion of SESN2 resulted in excessive necroptosis, accompanied by increased fat accumulation, inflammation, and oxidative stress in the experimental steatohepatitis model. Blocking necroptosis by RIPK3 inhibitor, GSK'872, prevented the liberation of pro-inflammatory cytokines and ROS generation, but not hepatocyte fat deposition, in both PA-treated SESN2-KO HepG2 cells and HFD-fed SESN2-KO mice, demonstrated that the hyperinflammation and excessive oxidative stress induced by a genetic deficiency in SESN2 is due to RIPK3-mediated necroptosis. **Conclusion:** Collectively, our results suggested that SESN2 inhibits RIPK3-mediated necroptosis; this regulation is an important for the immune homeostasis and the redox balance in the liver.

2368-C | SEXUAL DIMORPHISM IN THE GUT MICROBIOME OF NAFLD: ANALYSIS OF DOWNSTREAM TISSUE-SPECIFIC BACTERIAL COLONIZATION OF JEJUNUM AND DESCENDING COLON

Carlos Jose Pirola[1,2,3], Maria Silvina Landa[4], Adrian Salatino[5], Silvia Ines Garcia[4] and Silvia C. Sookoian[1,6], (1)Consejo Nacional De Investigaciones Científicas y Técnicas (CONICET), Buenos Aires, Argentina, (2) Systems Biology of Complex Diseases. Centro De Altos Estudios En Ciencias Humanas y De La Salud (CAECIHS), Universidad Abierta Interamericana, (3) Center for Traslational Research in Health, Universidad Maimonides, (4)Idim Conicet, (5)Max Planck Institute for Immunobiology and Epigenetics. Bioinformatics Facility, (6)Universidad Maimonides

Background: Evidence suggests that the gastrointestinal microbiome exerts a crucial role in the biology of NAFLD. Likewise, NAFLD pathophysiology is modified by gender differences that affect complex regulatory pathways. However, whether sexual dimorphism in the gut microbiome can contribute to the pathogenesis of NAFLD remains unknown. **Methods:** We performed sex-specific analyses of microbiome composition (high throughput 16S sequencing) in two structurally and functionally distinct anatomical gut regions, the small intestine and colon, in an experimental model of NAFLD and metabolic syndrome. We developed a high-fat diet (HFD)-induced NAFLD in the SHR (spontaneously hypertensive rat) and its control WKY (Wistar-Kyoto) rat strain. Eighteen-weeks old male and female SHR and WKY rats were divided into two experimental groups: standard chow diet and HFD (12 weeks, (n = 6/group). HFD-fed rats, irrespective of the strain, developed NAFLD. Tissues were snap frozen and stored at −80 °C. High-quality sequences were assigned to operational taxonomic units using the QIIME pipeline. Results are expressed at the genus level. **Results:** The overall microbiome composition of females and males with NAFLD differed significantly, including differences between topographical gut regions (Figure shows a hierarchical tree with abundance ratio in NAFLD vs. controls indicated by colors; a: distal jejunum; b: descending colon). Compared to males, female rats showed higher jejunal (F-value: 15; R-squared: 0.15, PC2 21%, PC3 13.2%) and colon microbiome beta diversity (F-value: 14; R-squared: 0.14; PC2 26.3%, PC3 12.9%); Bray-Curtis index [PERMANOVA] p = 0.001. Sex-specific analysis of relative bacterial abundances shows differences, including significant features in the jejunum (n = 35) and colon (n = 30). Identification of differentially abundant features by linear discriminant analysis effect size (LEfSe) showed distinctive differences between females and males with NAFLD (Figures c and d; top 15 significant features). **Conclusion:** This study demonstrates that there is sexual dimorphism in the gut microbiome of NAFLD, with microbial heterogeneity within different intestinal compartments. Gaining insight into the sex-specific differences in the microbiome composition between gut anatomical and functional regions, including the small intestine -the primary site for absorption of all nutrient-derived components, and the distal colon, may be used to tailor treatment strategies.

f 2369-C | SINGLE-CELL EXPRESSION OF HUMAN LIVER NASH INDICATES A LDB2-EXPRESSING NATURAL KILLER CELL POPULATION SUSCEPTIBLE TO FIBROTIC NICHE VIA ARREST OF CELL CYCLE

Nguyet T Luu[1,2], Cesar Prada[3], Thomas Monfeuga[3], Paul Horn[1,2], Reenam Khan[1,2], Celine Hernandez[1,2], Sanne Veidal[4], Dominik Pfister[4], Markus Latta[4], Enrique Toledo[3], Chris J Weston[1,2], Patricia Lalor[1,2] and Philip N. Newsome[1,2], (1)National Institute for Health Research, Biomedical Research Centre at University Hospitals Birmingham NHS Foundation Trust and the University of Birmingham, (2)Centre for Liver and Gastrointestinal Research, Institute of Biomedical Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham B15 2TT, UK, (3)Novo Nordisk Research Centre Oxford, Innovation Building, Oxford, UK, (4)Global Drug Discovery, Novo Nordisk a/S, Novo Nordisk Park 1, 2760 Maalov, Denmark

Background: Fibrosis is the principal driver of outcomes in NASH and yet there remains a lack of single-cell profiling efforts in NASH investigating immune and stromal cellular niches associated with cirrhosis. **Methods:** We profiled liver samples from 14 patients, five NASH (fibrosis stage 4), and nine pathologically normal livers (fibrosis stage 0). Liver tissue was from freshly collected biopsy specimens, explanted liver tissue collected during transplantation for NASH, or donor material surplus to transplantation requirements. For cell sequencing, fresh tissue was used to prepare single-cell suspensions by enzymatic dissociation, enrichment of hepatocytes and cell sorting for live cells. cDNA libraries were prepared using 10x Chromium solution and sequenced using Illumina Nextseq 500. Cellranger v7.0 and Scanpy v1.9.3 pipelines were used to align reads, count gene transcripts and identify the comprising cell-types, for which tissue composition and gene-expression differences were modelled. **Results:** We obtained > 40k high-quality single cells comprising T-lymphocytes, myeloid, endothelial/mesenchymal, hepatocytes, cholangiocytes and B-lymphocytes. We identified changes in tissue composition and cellular phenotype associated with cirrhosis. We identified an expansion of CD9-expressing and antigen-presenting myeloid cells in liver cirrhosis associated with a downregulation of the Interleukin-1 and TNF pathways. We observed perturbation of the T-lymphocyte compartment in fibrosis with underrepresentation of the NK populations and expansion of CD4/CD8 cells. We also detected the reduction of the LDB2-expressing NK population, which was associated with the repression of a cell-cycle-associated gene programme and enrichment of endothelium towards a subpopulation associated with the up-regulation of the IL27 and Rho signalling pathways. Finally, we observed that induction of extracellular-matrix-associated genes in cirrhosis was not restricted to the stellate cells, as cholangiocytes and hepatocytes also displayed up-regulation of several extracellular matrix components. **Conclusion:** Our results identify an NK population susceptible sensitive to the fibrotic niche, a role for the IL27 and Rho signalling pathways in fibrosis-associated vascular remodelling and suggest a multi-cell-type source of extracellular matrix components. These results constitute the most extensive single-cell transcriptomic profiling of T-lymphocytes of human NASH.

2370-C | SPATIAL AND SINGLE-CELL TRANSCRIPTOMICS REVEAL THE REGIONAL DIVISION OF THE SPATIAL STRUCTURE OF NASH FIBROSIS

Min-Ran Li[1], Li-Hong Ye[2], Ni Li[3], Calvin Pan Pan[4] and Er Hei Dai[2], (1)The First Affiliated Hospital of Jinan University, (2)The Fifth Hospital of Shijiazhuang, (3) Beijing Tsinghua Changgung Hospital, Beijing, China, (4)New York University Langone Medical Center, Flushing, NY

Background: To reveal the regional division of the spatial structure of NASH fibrosis and the communication relationship between cells in different regions and to analyse specific marker genes as potential therapeutic targets for NASH fibrosis. **Methods:** The liver sections of healthy controls, NAFL patients and NASH patients were measured by spatial transcriptomics, and integration analysis was performed with single-cell RNA-seq. Differential expression, functional pathway prediction, and deconvolution analysis revealed lineage-specific changes in gene expression, subpopulation composition and intercellular communication in NASH and identified key genes involved in HSC activation. The role of key genes in NASH fibrosis was verified in vitro and in vivo. **Results:** Descending and clustering analysis of 4114 nuclei from liver tissues of healthy controls, NAFL, and NASH showed that the distribution of cluster5 (fibrotic region) is dominated by lobules, and a small amount of fibrosis can be seen in the sink area. Functional analysis

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

suggested that differentially expressed genes of cluster5 were concentrated in ECM structural components and signalling molecules. Six cell types were obtained by integrating the single-cell sequencing dataset (GSE189175). Compared with the healthy control and NAFL groups, the NASH group had significantly increased proportions of HSCs and myofibroblasts, which were distributed in the lobule and the portal area around the fibrotic area. Simultaneously, the infiltration of Kupffer cells around the fibrotic area also increased. The cell communication analysis showed that diffusive cell communication was the main type, including endocrine, paracrine and autocrine communication, followed by ECM-receptor cell communication. According to the analysis of differentially expressed genes in the subsets, AEBP1 and DPT are relatively highly expressed in cluster5, as well as in HSCs and myofibroblasts. SCENIC analysis found that AEBP1+ and DPT+ myoblasts were involved in the activation of HSCs and fibrosis formation. Immunohistochemistry verified the high expression of AEBP1 and DPT in patients with NASH fibrosis. After transfection of AEBP1 and DPT interference fragments in LX2 cells in vitro, the mRNA level of Collagen I in cells was significantly lower than that of the siRNA-NC group and blank control group. **Conclusion:** Our study is the first to reveal lineage-specific changes in gene expression, subpopulation composition and cell communication in NASH fibrosis, providing new directions for potential therapeutic targets for NASH fibrosis.

2371-C | StarD5 LEVELS OF EXPRESSION CORRELATE WITH ONSET AND PROGRESSION OF NASH LIVER FIBROSIS

Daniel Rodriguez-Agudo[1], Genta Kakiyama[2], Nanah Bai-Kamara[3] and William M. Pandak Jr[1], (1)Virginia Commonwealth University, (2)Mcguire Veterans Affairs Medical Center, (3)VA Hospital

Background: Steroidogenic acute regulatory lipid transfer protein 5 (**StarD5**) transfers cholesterol to the plasma membrane (PM) in response to endoplasmic reticulum (ER) stress, preventing ER cholesterol accumulation. In addition to known decreases in PM cholesterol and altered PM fluidity, its knockout increases liver triglyceride levels; suggesting an unappreciated physiologic function. We attempted to further characterize StarD5 functions to determine why. **Methods:** livers from wild type (WT) mice and StarD5$^{-/-}$ fed a normal or a western diet were analyzed for protein expression by immunoblot, cholesterol, cholesterol metabolites and triglyceride levels, while blood was analyzed for glucose and insulin levels. Total RNA was isolated from WT and StarD5$^{-/-}$ mice for RNAseq and for a fibrosis gene expression panel. VLDL secretion levels were determined in wild type and StarD5$^{-/-}$ mice following tyloxapol injection. Fibrosis was determined by Masson's Trichrome staining of livers from WT and StarD5$^{-/-}$ mice fed a western diet. Rescue experiments were performed in StarD5$^{-/-}$ hepatocytes with an ADV-StarD5 and in StarD5$^{-/-}$ mice with an AAV9-StarD5 to determine reversal of the phenotype. **Results:** In addition to increased hepatic triglyceride/cholesterol levels, global StarD5 knockout (StarD5$^{-/-}$) mice displayed reduced plasma triglycerides and liver VLDL secretion as compared with wild type (WT) counterparts. Elevated Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) score demonstrated insulin resistance (IR). Interestingly, decreased hepatic StarD5 expression was found in WD-fed WT mice. WD-fed StarD5$^{-/-}$ mice up-regulated the transcriptional regulator Taz expression with accelerated liver fibrosis. Impaired oxysterol 7α-hydroxylase (Cyp7b1) protein coupled with accumulated toxic cholesterol metabolites (oxysterols) correlated with presentation of fibrosis. Oxysterol responsive protein levels including fatty acids synthetase (Fas) and Acetyl CoA-carboxylase (Acc) were correlated with increased *Srebp-1* mRNA levels in the StarD5$^{-/-}$ mice liver. In the gain-of-function study, AAV9-mediated hepatocyte selective StarD5 overexpression led to reduced hepatic triglycerides, and improved HOMA-IR scores in StarD5$^{-/-}$ mice. The impaired hepatic StarD5 and Cyp7b1 with elevated oxysterol were found in two additional mouse models of fibrosis and human NASH livers. **Conclusion:**

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Downregulation of StarD5 with hepatic lipid excess is an unappreciated key physiologic function directing lipid storage for future needs. Conversely, impaired StarD5 with prolonged lipid/cholesterol excess initiates/accelerates fatty liver's transition to fibrosis; mediated via dysregulation in the oxysterol signaling pathway.

2372-C | STATINS IMPROVE LIVER FUNCTION AND MINIMIZE THE DEGREE OF LIVER DAMAGE BY MODULATING CELL DEATH

Alejandro H. Gutierrez[1], Zheng Kang[1], Zoe Boyer-Diaz[2], Arantza Lamas Paz[1], Javier Vaquero[3,4], Rafael Bañares[3,4], Jaime Bosch[2,4,5], Jordi Gracia-Sancho[2,4,5], Jonel Trebicka[6,7], Yulia Nevzorova[1,3,4], Carlos Sanz-García[1] and Francisco Javier Cubero[1,3,4], (1) Complutense University School of Medicine, (2)Idibaps, (3)Instituto De Investigación Sanitaria Gregorio Marañón (IiSGM), (4)Centro De Investigación Biomédica En Red De Enfermedades Hepáticas y Digestivas (CIBEREHD), (5)University of Bern, (6) University Clinic Frankfurt, (7)European Foundation for the Study of Chronic Liver Failure and Grifols Chair, Barcelona, Spain

Background: Patients with advanced liver fibrosis are frequently treated with statins. However, how statins modulate liver cell function remains elusive. In the present work, we hypothesized that statins can modulate cell death, thereby ameliorating advanced chronic liver failure (ACLF). **Methods:** Carbon tetrachloride (CCl4) was used to induce liver fibrosis in Wistar and Sprague Dawley rats and rodents were treated with Simvastatin and Atorvastatin, respectively. After sacrifice, qRT-PCR, Western blot, and IF analysis were performed. Functional experiments were carried out with a human hepatocyte cell line (HepG2), and primary isolated hepatocytes from cirrhotic patients, treated with TNF/D-GalN in the presence or absence of statins. Finally, Western blot and qPCR analysis were performed in liver biopsies of twelve obese patients following bariatric surgery with NAFLD activity scores (NAS) ranging from 0 to 3, and a microarray analysis of ACLF patients was examined. **Results:** Cell death markers of apoptosis and necroptosis (phospho-MLKL and cleaved caspase 3 (CC3)) were overexpressed in liver extracts of patients with higher NAS scores and ACLF. Statins reduced CCl_4-induced overexpression of markers of liver fibrosis and inflammation, and apoptosis in animals with ACLF, thereby attenuating the expression of CC3, CC8 and TUNEL-positive cells. Moreover, statins therapy protected both HepG2 cells and cirrhotic primary hepatocytes from acute -induced cell death. **Conclusion:** Statin therapy enhanced liver function and reduced systemic inflammation in human cell lines and rat models of ACLF, thereby mitigating the severity of the condition. We describe a novel mechanism by which statins specifically protected against cell death.

2373-C | SUBCELLULAR DISPOSITION OF ADENOSINE A3 RECEPTOR IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: INSIGHTS INTO INTRANUCLEAR TRANSLOCATION

Huiyul Park[1], Sang Bong Ahn[2], Eileen Yoon[3], Hyunwoo Oh[4], Hyo Young Lee[4], Joo Hyun Sohn[3] and Dae Won Jun[3], (1)Hanyang University, (2)Eulji Medical Center, (3) Hanyang University College of Medicine, (4)Uijeongbu Eulji Medical Center

Background: Recent studies have shown decreased expression of adenosine A3 receptor (A3AR) in the liver of patients with non-alcoholic fatty liver disease (NAFLD), suggesting its potential involvement in NAFLD pathogenesis. However, the significance and role of intranuclear translocation of A3AR have not been thoroughly investigated. Thus, the aim of this study was to explore the differences in A3AR expression between NAFLD patients and healthy controls, specifically focusing on its subcellular distribution. **Methods:** A total of 163 NAFLD cohorts (Control: n = 61, NAFLD: n = 76, NASH: n = 26) were examined to compare A3AR expression in liver tissue and peripheral blood mononuclear cells (PBMCs). Immunofluorescence expression and cell fractionation techniques were utilized to analyze the subcellular distribution of A3AR following treatment with palmitic acid (PA) and oleic acid (OA). **Results:** Analysis of in-house and public RNA sequencing data revealed no significant differences in A3AR expression between healthy controls and NAFLD patients. Consistently, A3AR expression in PBMCs

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

showed no variation between the two groups. Intriguingly, differential expression of A3AR in intracellular compartments was observed in the liver tissue of healthy controls and NAFLD patients. Cytoplasmic A3AR was predominantly expressed in healthy controls, whereas nuclear A3AR was mainly observed in NAFLD patients. Furthermore, increased nuclear A3AR expression was detected in PA and OA-induced HepG2 cells, indicating its translocation from the cytoplasm. **Conclusion:** The findings suggest that steatosis may trigger the translocation of A3AR from the cytoplasm to the nucleus. Further investigations are warranted to elucidate the mechanisms underlying A3AR translocation and its functional implications in NAFLD pathophysiology.

2374-C | TARGETING CHRONIC VEGF-C SIGNALING MITIGATES DISEASE PROGRESSION IN NON-ALCOHOLIC STEATOHEPATITIS

Jason Eng[1,2], Seock-Won Youn[1], Bhairavi Swaminathan[1], Rahul Vadakath[1] and Jan Kitajewski[1,3], (1)University of Illinois at Chicago, (2)Cleveland Clinic Foundation, (3)University of Illinois Cancer Center

Background: The sinusoidal endothelial cells (LSECs) are critical regulators of homeostasis within the liver. In fact, disruption of normal LSEC physiology is one of the earliest hallmarks of liver disease. Thus, strategies which target factors involved in LSEC dysregulation may improve hepatic recovery and prevent the progression of certain pathological conditions, including non-alcoholic steatohepatitis (NASH). **Methods:** Using human and murine tissues, we observed drastically increased levels of vascular endothelial growth factor-C (VEGF-C) in NASH livers compared with non-diseased samples. To investigate the role of VEGF-C during disease progression, we performed additional studies in murine NASH models. In mice fed a western diet with carbon tetrachloride, overexpression of VEGF-C was accomplished with adeno-associated viral (AAV) infection. Conversely, blockade of the receptors for VEGF-C, VEGFR2 and VEGFR3, was achieved with lenvatinib, a tyrosine kinase inhibitor which primarily inhibits R2/R3 signaling at low doses. NASH severity was monitored by histology and serum liver chemistry analysis. To identify the potential mechanism in which VEGF-C drove disease progression, we performed single nuclei RNA sequencing on vehicle and lenvatinib treated NASH livers, and validated targets with qPCR and immunofluorescent studies. **Results:** We discovered that chronic VEGF-C expression exacerbated NASH progression in mice. Interestingly, we observed that VEGFR3-specific activation led to worsening steatosis, while VEGFR2/VEGFR3 activation enhanced both fibrosis and steatosis. Administration of low dose lenvatinib significantly delayed NASH progression by decreasing fibrosis, steatosis, and tumor nodule formation. Lastly, transcriptomic analysis revealed downregulation of several pathways associated with extracellular matrix interactions, angiogenesis, and inflammation. Several known molecules involved in NASH pathogenesis such as VCAM1, Notch receptors, and collagen proteins were simultaneously confirmed to be downregulated in response to lenvatinib treatment. **Conclusion:** Taken together, these findings indicate that chronic VEGF-C production in NASH plays a role in promoting liver fibrosis and steatosis, and that blockade of the downstream receptors, VEGFR2 and VEGFR3, may be a promising therapeutic strategy to mitigate disease severity and cancer development.

2375-C | TARGETING EFHD1 FOR LIVER DISEASE

David R Eberhardt, Sandra H Lee, Ashley R Bratt, Xue Yin, William L Holland, Sihem Boudina and Dipayan Chaudhuri, University of Utah

Background: New treatments for liver disease may arise by examining genes identified in genome-wide association studies (GWAS). Variation in one such gene, *EF-hand domain family member D1* (*EFHD1*), has been associated with liver injury biomarkers in multiple GWAS analyses. In these studies, higher serum biomarkers correlate with increased EFHD1 expression. EFHD1 is a poorly studied mitochondrial Ca^{2+}-binding protein, and how it regulates liver function is unknown. We sought to assess whether inhibiting hepatic EFHD1 could represent a novel therapy for treating metabolic liver disease. In human and mouse livers, EFHD1 is expressed at low levels preferentially in hepatocytes, with little to no expression in other cell types. It is found primarily on the outer mitochondrial membrane and inter-membrane space. **Methods:** To study the effects of EFHD1 inhibition on liver injury, we subject wild-type (WT) and

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

EFHD1 whole body knockout (*Efhd1*$^{-/-}$) mice to a high fat diet (HFD) and analyze their livers for disease markers. We also performed live-cell imaging using hepatocytes isolated from WT and *Efhd1*$^{-/-}$ mice. **Results:** In wild-type animals, hepatic EFHD1 levels increased during HFD, and male *Efhd1*$^{-/-}$ mice gained less weight (10.6 ± 1.6% less after 28 weeks HFD), despite similar levels of food intake, activity, and insulin resistance. RNA sequencing of *Efhd1*$^{-/-}$ livers from mice fed a HFD revealed a significant reduction in genes associated with inflammation, relative to wild-type animals, which was confirmed by histological analysis. We also observed fewer hepatocyte large lipid droplets (32.9 ± 3.1%, WT; 21.1 ± 3.5%, *Efhd1*$^{-/-}$) but not small lipid droplets. Mitochondria continuously undergo fission and fusion, and increased fission has been correlated with liver injury. We found EFHD1 was present at sites of ER-mitochondrial contact on the outer membrane, where fission and fusion occur. In fact, mitochondria in *Efhd1*$^{-/-}$ hepatocytes were around 100.03 ± 0.32% larger than controls, and showed less remodeling after activating cytoplasmic Ca^{2+} signals. Mechanistically, this may be due to interactions we identified between EFHD1 and the mitochondrial fission/fusion machinery. Thus, reducing fission by deleting EFHD1 may prevent mitochondrial damage and subsequent liver injury. **Conclusion:** These findings demonstrate that EFHD1 inhibition may be a promising therapy for liver injury.

2376-C | TARGETTING HEPATIC CALPAIN ACTIVITY PROTECTS AGAINST EXPERIMENTAL NASH FIBROSIS IN MICE

Jiang Li[1], Olivia B Bannister[1], Charis-Marie Vanderpuye[1], Juliane I Beier[1,2], Silvia Liu[1,2], Michael Merchant[3], Panagiotis V Benos[4], Andres Duarte-Rojo[5] and Gavin E. Arteel[1,2], (1)University of Pittsburgh, (2) Pittsburgh Liver Research Center, (3)University of Louisville, Louisville, KY, (4)University of Florida, (5) Northwestern University Feinberg Scho

Background: We recently showed that the pattern of degraded proteins in plasma samples from experimental and human NASH fibrosis differs dramatically from healthy livers; informatic analysis suggested robust elevated activation of the cysteine proteases Calpains 1 and/or 2 (Capn1/2) in both human and experimental NASH fibrosis (PMID: 36778394). Although Calpain 1/2 have been identified as key players of remodeling in other organs, they have not been investigated in NASH fibrosis. The purpose of the current study was to investigate the impact of targeted disruption of hepatic Calpain 1/2 activity in a preclinical mouse model of NASH fibrosis. **Methods:** 4 wk old C57Bl6/J mice were injected with recombinant adeno-associated virus type 8 vectors (rAAV8; 1×10^{11} PFU/mouse, i.p.) encoding shRNA against Capn4 (*Capns1*), or control scrambled rAAV8 vectors. After 4 wks, mice were fed ad libitum either a low-fat control diet (LFD: 13% saturated fat) or a 'Western'-style high-fat, high-fructose diet (HFD: 42% saturated fat) for 12 weeks. Liver tissue portions were frozen immediately in liquid nitrogen or preserved for FFPE or frozen tissue sectioning. Major endpoints were assessed by histology, biochemical analyses and/or gene expression. The expression of Capn1 and Capn2 in human NASH fibrosis was explored, using data from public study (GSE135251) of RNA-seq analysis of human NASH fibrosis, which includes patients at METAVIR fibrosis stage from 0 to 4. **Results:** rAAV8-mediated knockdown of Capn4 mediated a robust and stable suppression of hepatic *Capns1* expression, coupled with a nearly complete abrogation of detectable Capn1/2 enzyme activity. As expected, HFD caused obesity and insulin resistance (HOMA-IR) under these conditions. HFD also caused severe fatty liver, as determined by histological assessment and by biochemical analysis. HFD also induced expression of indices of fibrogenesis and collagen accumulation and caused the formation of "chicken-wire" fibrosis within the hepatic lobule, as determined by Sirius red staining. Knocking down Capn4 did not impact systemic indices of obesity and adiposity, but dramatically attenuated increases in all indices of steatosis and fat accumulation in the liver. Moreover, the increase in fibrosis caused by HFD was attenuated by knocking down Capn4. Analysis of human NASH fibrosis indicated that expression of Capn2 (but not Capn1) increased significantly with each fibrosis stage. **Conclusion:** Taken together, these results indicate that blocking calpain activity by targeting a key regulatory protein (Capn4) protects against lipid accumulation caused by HFD, despite not impacting overall weight gain. Moreover, knocking down Capn4 also attenuated fibrogenesis under these conditions. These data indicate that Capn1/2 activity may be critical in the transition from NAFLD to NASH fibrosis.

2377-C | THE CERAMIDE SYNTHASE (CERS) FAMILY AND RELATED LNCRNAS CONTRIBUTING TO NASH-HCC DISEASE PROGRESSION

Jing Zeng[1,2], Derrick Zhao[1], Yunling Tai[1], Lianyong Su[1], Xixian Jiang[1], Xuan Wang[1], Emily Gurley[1], Phillip B. Hylemon[1], Jiangao Fan[2], Sayed Obaidullah Aseem[3], Arun Sanyal[3] and Huiping Zhou[1], (1)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, (2) Department of Gastroenterology, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai 200092, China, (3)Department of Internal Medicine and GI Division, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298, USA

Background: Nonalcoholic fatty liver disease (NAFLD) is the fastest-rising cause of end-stage liver disease for liver transplantation. The underlying mechanisms of NAFLD progression from nonalcoholic steatohepatitis (NASH) to hepatocellular carcinoma (HCC) remain unclear. Ceramide synthases (CERSes) have been implicated in the pathogenesis of NASH-HCC. Ceramide is a key mediator of lipotoxicity in NASH. Long non-coding RNAs (lncRNAs) are important regulators in gene expression related to tumorigenesis. However, the specific roles of the CERSes and CERS-related lncRNAs (CERSRLs) in NASH-HCC development remain unknown and is the focus of this study. **Methods:** RNAseq data of HCC patients were obtained from The Cancer Genome Atlas (TCGA) database. Co-expression analysis was performed to identify CERSRLs in differentially expressed (DE) lncRNAs. Prognostic CERSRLs were selected using univariate Cox analysis, and a prognostic model was constructed. Model validation was performed using Kaplan-Meier curves based on risk scores. In separate study, DIAMOND NASH mouse model was used. Male mice (21-24 weeks old) were fed with Western diet and a high fructose-glucose water (WDSW) or chow diet ad libitum for 6 months or 1 year. The hepatic RNA transcriptome was analyzed using RNAseq. CrossMap was used to identify mouse CERSRLs based on human CERSRLs with Ensembl and NONCODE databases. Ceramide profiles in the serum and liver were quantified using LC-MS/MS. **Results:** CERSes were significantly upregulated in human HCC compared to healthy controls in TCGA. CERS1, CERS5, and CERS6 exhibited prognostic significance. Co-expression analysis identified 122 DE CERSLs, of which 23 were survival-related. A prognostic signature consisting of 6 CERSLs was constructed, with worse HCC prognoses in the high-risk group. In mouse model, all mice developed NASH and HCC after feeding with WDSW for 6 months and 1 year, respectively. We identified 110 potential mouse CERSLs. In both human HCC and mouse NASH-HCC, 3 DE CERSLs were identified as potential candidates for NASH and HCC, including 2 upregulated (Gad1os and Norad) and 1 downregulated Gm14164, compared to the controls in mice. LC-MS/MS data showed significant changes in ceramide profiles in NASH and HCC. **Conclusion:** Our study provides insights into the association between the CERSes and CERSRLs in the progression of NASH and HCC. Further research is needed for the potential application of CERSRLs as diagnostic or prognostic markers in the clinic. Keywords: non-alcoholic steatohepatitis; hepatocellular carcinoma; CERS; ceramide; lncRNA

2378-C | THE EFFECT OF GLYCINE ON PHOSPHOLIPIDS / SPHINGOLIPIDS COMPOSITION DURING HEPATO-CARCINOGENESIS IN HEPATOCYTE-SPECIFIC PTEN KNOCKOUT MICE

Kazuyoshi Kon[1], Hyeon-Cheol Lee-Okada[2], Kumiko Arai[1], Akira Uchiyama[1], Toshifumi Sato[1], Hiroo Fukada[1], Takehiko Yokomizo[2] and Kenichi Ikejima[1], (1) Juntendo University School of Medicine, (2)Juntendo University Graduate School of Medicine

Background: Phospholipids and sphingolipids are constituents of cell membranes, act as mediators, and are involved in various liver diseases including steatohepatitis. However, changes in these lipids during steatohepatitis-associated hepatocarcinogenesis are unknown. Here, we clarified changes in phospholipids and sphingolipids in the process from steatohepatitis to hepatocarcinogenesis by lipidomic analysis using hepatocyte-specific phosphatase and tensin homolog deleted from chromosome 10 (PTEN) knockout mice, and further analyzed the effects of administration of the amino acid glycine on lipid composition. **Methods:** Male Alb-Cre TG (+) PTEN$^{flox/flox}$ mice (PTEN KO) aged 11-17 weeks were fed a normal diet or a diet containing 5% glycine for 2 or 24 weeks. Wild-type or TG (-) mice fed a normal diet were used as control. The number of liver tumors with a diameter of 2 mm or more was counted. Hepatic lipid composition was comprehensively analyzed using liquid chromatography coupled to tandem mass spectrometry. **Results:** PTEN KO developed severe steatohepatitis, whereas 2-weeks administration of glycine improved steatohepatitis and significantly reduced serum AST and ALT levels. Lysophosphatidylcholine (LPC) 16:0, 18:2, 18:0, and 22:6 were significantly lower in liver tissue from PTEN KO, and glycine

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

administration elevated the LPC 16:0 levels almost to those of wild-type mice. In addition, lysophosphatidylethanolamine (LPE) 16:0, 18:2, 18:0, 20:4, and 22:6 were also decreased in the liver tissue of PTEN KO, and all but 22:6 were significantly increased by glycine. After 24 weeks, PTEN KO developed 2.6 ± 1.0 liver tumors, while glycine completely suppressed tumorigenesis to 0 ± 0. At this hepatocarcinogenic stage, hexosylceramide (HexCer) d18:1/16:0, d18:1/22:0, d18:1/24:0, lactosylceramide (LacCer) d18:1/24:0, sphingomyelin (SM) d18:1/16:0, 18:1/22:0, and 18:1/24:0 were significantly lower in PTEN KO than wild-type mice. By administration of glycine, HexCer and LacCer were almost completely increased to levels of wild-type mice, and SM was significantly increased only at 18:1/24:0. In contrast, the amount of ceramide (Cer) contained in the liver of PTEN KO was generally higher than that of wild-type mice, especially d18:1/22:0 and d18:1/22:0, which were more than twice that of wild-type mice. Administration of glycine completely suppressed these increases to levels comparable to wild-type mice. **Conclusion:** In the liver of hepatocyte-specific PTEN knockout mice, lysophospholipids such as LPC and LPE are decreased in the phase of steatohepatitis, and sphingolipids such as HexCer, LacCer, and SM are decreased and Cer are accumulated as instead in the stage of hepatocarcinogenesis. Glycine significantly ameliorates the alteration of lipid metabolism and is effective in suppressing steatohepatitis-related hepatocarcinogenesis.

2379-C | THE EFFECTS OF FLUORENE EXPOSURE IN CONJUNCTION WITH HIGH FAT DIET ON TOXICANT-ASSOCIATED FATTY LIVER DISEASE

Jianzhu Luo[1], Banrida Wahlang[1], Loretta Jophlin[1], Walter Watson[1], Collin M. M White[1], Shikshita Singh[2], Oluwanifemi Esther Bolatimi[1], Ngozi Victoria Adiele[1] and Matthew Cave[1], (1)University of Louisville, Louisville, KY, (2)University of Ottawa

Background: Fluorene belongs to the class of polycyclic aromatic hydrocarbons (PAHs) and is a major component of particulate matter ($PM_{2.5}$). Previous studies have demonstrated positive associations between PAH mixtures and risk for fatty liver disease (FLD). However, the impact of fluorene in the context of toxicant-associated FLD (TAFLD) remains to be elucidated. This study is to investigate the effects of fluorene exposure in TAFLD and identify mechanisms contributing to hepatic and metabolic disruption. **Methods:** Male C57BL/6 mice were fed either a low fat (CD) or high fat diet (HFD,42%) for 10 weeks; each diet group was then administered corn oil (control) or fluorene (50 mg/kg/day, daily gavage, 4 weeks). Mice were then euthanized; plasma and tissues were collected for downstream analysis. Results were analyzed using 2-Way ANOVA for two factors: 'diet" and "fluorene"; followed by contrast test analyses for different subgroup comparisons. **Results:** HFD-fed mice showed hepatic steatosis (H&E staining of liver sections), while fluorene exposure resulted in increased liver inflammatory infiltration. Consistently, assessment of hepatic gene expression demonstrated fluorene upregulation of mRNA levels for the inflammatory/fibrotic marker (*Tgfb1*) in HFD-fed mice. In terms of lipid metabolism, HFD upregulated hepatic expression of genes involved in lipid uptake (*Cd36*) and decreased expression of genes for de novo lipogenesis (*Fasn*) and lipid binding (*Fabp1*). Fluorene decreased *Fasn* and increased *Fabp1* mRNA levels only in CD-fed mice. Additionally, fluorene altered hepatic expression of genes involved in glucose and glycogen metabolism (increased gluconeogenic *Pck1*, decreased *Gck* expression) in CD-fed mice although this group exhibited lower fasting glucose levels and reduced hepatic glycogen storage, further implicating fluorene's disruption of glucose metabolism. While HFD feeding decreased mRNA levels of genes involved in hepatic recovery/function (*HNF4a, Egfr*), fluorene exposure further decreased *Egfr* mRNA levels in HFD-fed mice. Moreover, fluorene also decreased *Fgf21* mRNA levels in HFD-fed mice, suggesting possible liver damage in this group. Lastly, assessment of hepatic xenobiotic receptor activation demonstrated fluorene-mediated induction of target genes for the AhR (*Cyp1a2*), CAR (*Cyp2b10*), PXR (*Cyp3a11*). **Conclusion:** The current findings suggest that fluorene is a metabolism-disrupting chemical that can contribute to TAFLD, partially through diet-interactions and hepatic receptor activation.

2380-C | THE HEPATIC PROTEOME CHANGES IN NASH-SUSCEPTIBLE C57Bl6/J MICE INDUCED BY AN OBESOGENIC DIET.

Jiang Li[1], Toshifumi Sato[2], Daniel Wilkey[3], Panagiotis V Benos[4], Andres Duarte-Rojo[5], Gavin E. Arteel[1] and Michael Merchant[3], (1)University of Pittsburgh, (2) Juntendo University School of Medicine, (3)University of Louisville, Louisville, KY, (4)University of Florida, (5) Northwestern University Feinberg Scho

Background: Non-alcoholic steatohepatitis (NASH)-associated cirrhosis is an indication for liver transplant (LT). Post-LT NASH reoccurrence is associated with accelerated progression to fibrosis/cirrhosis and increased mortality. Efforts to study NASH relying on mouse models with ad libitum feeding of high-fat chow are confounded by strain-dependent effects. We hypothesized that hepatic proteomic comparisons of the western diet on obesogenic susceptible (C57Bl6/J) versus non-susceptible (AJ) mouse strains would yield novel and important insights the mechanisms of NASH development or disease progression. **Methods:** 8wks old, male AJ and C57Bl/6J mice were fed ad libitum either a low-fat control diet (LFD: 13% saturated fat) or a 'Western'-style high-fat, high-fructose diet (HFD: 42% saturated fat) for 12 weeks then fasted for 4h prior to sacrifice. Liver tissue was snap frozen immediately for proteomic and immunoblot analyses. Tissue (C57 or AJ mice LFD or HFD; $n = 4$ per group) were analyzed using a 2DLC-MS workflow and TMTPro isobaric reagents in a SP3 method on a Thermo Lumos tribrid instrument (UC, Davis Proteomics Core Facility). LCMS data were analyzed using ProteomeDiscoverer 2.4 with the TMTPro and SP3 nodes. Differences in protein abundance were estimated by ANOVA with FDR correction ($q < 0.05$ considered significant). **Results:** As expected, whereas sensitive C57Bl6/J mice gained dramatic weight on an HFD, insensitive AJ mice did not. This effect was coupled with an increase indices of insulin resistance (HOMA-IR), liver injury and fibrosis in the C57Bl6/J mice, but not in the AJ mice. 1,604 differentially abundant proteins (DAP) were observed by ANOVA correlating with Gene Ontological (GO) differences in fatty acid & amino acid metabolism (biological), acetyl CoA, long chain fatty acid and kynurenine metabolism (molecular), and mitochondrial electron transport function (cellular component). HFD to LFD induced 1,094 DAP in C57 and 59 in AJ mice. GO comparison of C57(HFD) to AJ (HFD) DAP identified roles for adenine, AMP and purine metabolism (biological); transporter associated with antigen processing (TAP) function (molecular); and mitochondrial respiratory chain and MHC I class I peptide loading (cellular). **Conclusion:** The western diet induces strain-dependent changes in the mouse hepatic proteome. Obesogenic susceptible C57Bl6/J mice responses suggests GO roles for altered adenine/AMP metabolism, antigen presentation, and mitochondrial function in susceptibility to NASH development.

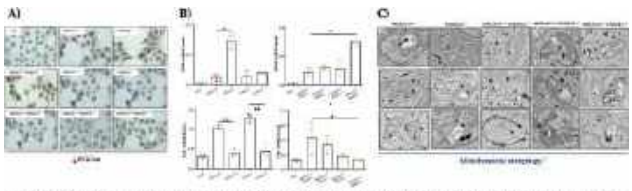
2381-C | THE OVEREXPRESSION OF TM6SF2 AND/OR MBOAT7 WILD-TYPE GENES RESTORES THE MITOCHONDRIAL LIFECYCLE AND ACTIVITY IN AN IN VITRO NAFLD MODEL

Erika Paolini[1], Miriam Longo[2], Marica Meroni[3], Giada Tria[1], Roberto Piciotti[4], Massimiliano Ruscica[5], Anna Ludovica Fracanzani[5] and Paola Dongiovanni[3], (1) Fondazione Irccs Ca Granda, Milano, Italy, (2) Fondazione Italiana Fegato, (3)Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, (4)General Medicine and Metabolic Diseases, Fondazione Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milano, Italy, (5)Università Degli Studi Di Milano

Background: Mitochondrial dysfunction plays a pivotal role in the transition from NASH up to HCC. The knockout (KO) of *MBOAT7* and/or *TM6SF2* hampers the mitochondrial dynamics in Hepg2 cells resulting in an

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

enrichment of misshapen and failed mitochondria. The overexpression of *MBOAT7* and/or *TM6SF2* wild-type genes in KO models through lentiviral vectors decreases the number of damaged-globular mitochondria, while increases the normo-shaped ones. To deepen the impact of *PNPLA3/MBOAT7/TM6SF2* loss-of-function mutations on mitochondrial aberrances, we investigated the mitochondrial lifecycle and activity in KO cells overexpressed for the wild-type forms of *MBOAT7* and/or *TM6SF2*. **Methods:** Mitochondrial lifecycle and activity were assessed through RT-PCR, Western Blot, Seahorse assay, immunohistochemistry, and transmission electron microscopy (TEM). **Results:** The overexpression of *MBOAT7*, *TM6SF2* or both decreased PGC1α levels, the master regulator of mitobiogenesis, which was activated in KO cells in response to fusion-fission unbalance, boosted the expression of Mfn1, Mfn2 (mitochondrial outer membranes proteins involved in fusion) and OPA1 (inner mitochondrial membranes fusion protein) whereas decreased FIS1 and DRP1 (fission proteins) levels, thus re-establishing the mitochondrial turnover. Consistently, the mitophagy pathways (PINK/PARKIN/BNIP3/BNIP3-L/LC3/phospho-UBIQUITIN) increased after the *MBOAT7* and/or *TM6SF2* overexpression, encouraging the disruption of damaged mitochondria that results in high number of intracellular autophagic structures assessed by TEM. The balance of mitochondrial biogenesis is essential for organelles' homeostasis and activity. Indeed, the overexpressed models augmented the COX-I/SDHA ratio, COX-III, and citrate synthase activity paralleling the mitochondrial oxygen consumption rate, thus recovering the OXPHOS capacity and Krebs cycle which were impaired in KO cells. Finally, lactate levels decreased after the upregulation of *MBOAT7* and/or *TM6SF2* wild-type genes together with the glycolytic extracellular acidification rate, thereby inhibiting the switch to anaerobic glycolysis which was promoted in KO cells to trigger tumorigenesis. **Conclusion:** Genetics impacts on mitochondrial maladaptation during NAFLD and the overexpression of *MBOAT7* and/or *TM6SF2* wild-type genes in KO HepG2 cells re-balances the mitochondrial lifecycle and turnover, thus ensuring the organelles' function and possibly reversing hepatocellular damage.



The overexpression of MBOAT7 and/or *TM6SF2* rebalances the mitochondrial lifecycle by decreasing PGC1α activity (A), increasing Mfn2 mRNA levels implicated in fusion (B), lowering the mRNA expression of *Fis1* involved in fission (B) and triggering mitophagy (C: autophagic structures are indicated by black stars).

2382-C | THE ROLE OF LIVER EPSINS IN NONALCOHOLIC STEATOHEPATITIS

Bo Zhu, Hao Wu, BeiBei Wang, YaoWei Lu and Hong Chen, Boston Children's Hospital, Harvard Medical School, Boston, MA

Background: Nonalcoholic steatohepatitis (NASH) is a common chronic liver disease that can advance to fibrosis, cirrhosis, and liver failure; however, no effective therapy is currently available. Epsin is an evolutionarily conserved protein family that involved in clathrin-mediated endocytosis. We found that both Epsin1/2 expressions in liver are significantly up-regulated by Western Diet (WD) induced NASH mice model, as well as in the liver biopsy from NASH patients. We hypothesize that the expressions of Epsin1 and Epsin2 in the liver are required for NASH progression. In this study, we aim to investigate the novel roles Epsin1 and Epsin2 in the liver during NASH pathogenesis and progression. **Methods:** We conditionally delete Epsin1/2 using Albumin-Cre (Liver-DKO). We then induce a mouse model of NASH by feeding both WT and Liver-DKO mice a WD+20%fructose for 52 weeks. We used single cell multiome, combined with molecular approaches to study the mechanisms. As a proof-of-concept, we test a strategy to deliver Epsin1/2 siRNAs encapsulated nanoparticles (NPs) targeting the liver via intravenous injection to treat diet induced NASH in mice. **Results:** We found WD-fed Liver-DKO mice have significant reductions in hepatic fibrosis formation and less lipid accumulation, and this associate with better glucose and insulin tolerance, as well as lower serum aspartate transaminase (AST) and alanine aminotransferase (ALT) when compare with WD-fed WT mice. Through analysis of the single cell multiome from the WT and Liver-DKO livers, we found more immune cells population with high amount of cytokines and chemokines expression in WT NASH mice compared with Liver-DKO. Interestingly, monocyte-derived inflammantory Kupffer cell (KCs) are enriched in WD-fed WT mice, however, embryonic-derived KCs are the enriched in liver DKO, and associate with dramatically reduced total KCs population. Mechanistically, we found more zone 2 hepatocytes identified in Liver-DKO compared with in WT-NASH mice. We also found that Liver-DKO has more diploid hepatocytes , and NASH mice have more aneuploid hepatocytes, suggesting that the Liver-DKO hepatocytes under NASH diet are more regenerative. We also found that HNF4a dramatically reduced in WD-fed WT mice, but its expression preserved in WD-fed Liver-DKO mice, suggesting the loss of hepatocyte identity was inhibited by Epsins deletion. Therapeutically, we found significant resolution of hepatic fibrosis after knockdown of Epsin1/2 siRNA NP treatment. **Conclusion:** We discovered the novel roles of liver Epsins in promoting NASH progression and outcome in mice. Liver specific deletion of Epsin1/2 significantly suppress NASH progression by preventing immune cells infiltration that

protect hepatocytes from severe chronic injury. Our preclinical data suggests specially targeting Epsin1 and Epsin2 in the liver could be a promising therapeutic strategy for NASH treatment.

2383-C | THE ROLE OF MITOCHONDRIAL QUALITY CONTROL FACTOR CLPP IN ADIPOCYTE-HEPATOCYTE CROSSTALK IN THE PROGRESSION OF NAFLD

Yoonsu Ha[1], Taek Kyong Kim[2] and Seung-Jin Kim[2], (1) Kangwon National University, (2)Global/Gangwon Innovative Biologics-Regional Leading Research Center (GIB-RLRC)

Background: Mitochondria are critical to cellular metabolism and stress responses, and their dysfunction is linked to human disease and pathology. Adipose tissue is a specialized connective tissue that stores energy in the form of lipids and has several other important functions in the human body such as an endocrine role and production of numerous bioactive factors. Liver is responsible for many important functions in the body that include detoxification, protein synthesis, and the production of chemicals that help digest food. These multiple functions of adipose tissue and liver contribute to the progression of NAFLD. Mitochondrial dysfunction can lead to inadequate mitochondrial quality control mechanisms and also it is associated with the dysfunction of adipose tissue and liver. In addition, recent studies indicate mitochondrial dysfunction in the pathology and etiology of hepatic steatosis, such as the adaptation and remodeling of mitochondria. However, it is still unclear whether inadequate mitochondrial quality control mechanisms are responsible for dysfunction of adipose tissue and liver. **Methods:** Primary adipocyte, hepatocyte cells were isolated from adipose tissues and livers of adult mice (6-8 wk) respectively. Isolated primary adipocytes were reprogrammed to become mature adipocytes. Mouse preadipocyte cell lines (3T3-L1) and primary adipocytes were transfected with a lentivirus that expresses shClpP. Transwell co-culture system was used to investigate the cell-cell interaction in vitro. **Results:** In this study, we found that loss of the function of ClpP, which is a key mitochondrial quality control factor, impairs adipogenic differentiation in adipocytes via senescence and subsequently induces proinflammatory-senescence-associated secretory phenotype (SASP) secretion. Interestingly, the conditioned media collected from ClpP depleted adipocytes were characterized by high MCP-1 content and led to hepatic inflammation in hepatocytes. **Conclusion:** Our findings establish a pivotal role for ClpP involved in mitochondrial quality control in adipocyte metabolism and provide new insights into therapeutic approaches to NAFLD associated with mitochondrial dysfunction.

2384-C | THE ROLE OF SERPINE1 IN HEPATIC STELLATE CELLS AS A THERAPEUTIC TARGET FOR NONALCOHOLIC STEATOHEPATITIS

Hyun Young Kim[1], Cuijuan Han[1], Sara Brin Rosenthal[1], Xiao Liu[1], Wonseok Lee[1], Haeum Jang[1], Karin Diggle[1], Tatiana Kisseleva[1] and David A. Brenner[1,2], (1) University of California, San Diego School of Medicine, (2)Sanford Burnham Prebys Medical Discovery Institute

Background: Nonalcoholic steatohepatitis (NASH) progresses from steatosis to steatohepatitis and fibrosis. Hepatic Stellate Cells (HSCs) are the major source of Collagen Type I-producing myofibroblasts in fibrotic liver. Using complimentary single nucleus (sn)RNA- and snATAC-sequencing analysis of HSCs from normal, NAFL, and NASH human livers, we identified a group of genes in which transcriptional and epigenetic activity was closely linked to the regulation of extracellular matrix organization network. The role of selected genes in fibrogenic activation of human HSCs was investigated using 3D human liver spheroids composed of all liver cells (isolated in our laboratory) and HSC-specific gene knockout in mice. **Methods:** NASH was induced in human liver spheroids generated by co-culturing human liver cells (60% hepatocytes, 40% non-parenchymal cells, and enriched HSCs at physiological ratios) in a growth factor-enriched media for 7 days, followed by stimulation with a NASH cocktail (oleate, palmitate, glucose, fructose, LPS, and TGFβ1) for additional 7 days. **Results:** Human liver NASH (vs control) spheroids upregulated G6Pase and CYP2E1 (indicative of hepatotoxic injury), lipid droplets, fibrogenic genes (Collagen Type I, αSMA). This effect was associated with increased SERPINE1 and SPON1 expression in activated Desmin^{+}αSMA^{+} aHSCs/myofibroblasts, suggesting that human NASH liver spheroids closely recapitulate responses of human liver to metabolic injury. The role of selected targets, SERPINE1, SPON1, GAS7, and LTBP2 in HSC activation was tested using dsiRNA. Transfection of human HSCs with gene-targeting (vs scrambled) dsiRNA knockdown of SERPINE1 significantly decreased the expression of markers of fibrosis, COL1A1 and ACTA2, in the human NASH liver spheroids. We hypothesized that genetic deletion of SERPINE1 (plasminogen activator inhibitor-1) can attenuate development of toxic liver fibrosis in mice. HSC-specific Serpine1 knockout mice, Lrat$^{\Delta Serpine1}$ mice, were generated by crossing of Lrat^{Cre}×Serpine1$^{flox/flox}$ mice. HSC activation and development of CCl_4-induced

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

liver fibrosis was strongly reduced in Lrat$^{\Delta Serpine1}$ mice (vs Serpine1$^{flox/flox}$ mice). **Conclusion:** Human liver spheroids serve as a useful tool to study NASH in a dish. Although SERPINE1 is expressed in different cell populations, our findings in human spheroids and HSC-specific Serpine1 knockout mice suggest that SERPINE1 in HSCs can become a target for anti-fibrotic therapy.

2385-C | THE rs72613567:TA SPLICE VARIANT OF HUMAN HSD17B13 REDUCES HEPATIC INFLAMMAGING TO AMELIORATE NONALCOHOLIC STEATOHEPATITIS AND FIBROSIS

Arun Sanyal[1], Mulugeta Seneshaw[2], Hae-Ki Min[2], Faridoddin Mirshahi[1], Michael Idowu[2], Prakash Ramachandran[3], John Min[2], Huiping Zhou[2], Siddharth Ghosh[2], Lauren Cowart[2], Yang Yue[2], Ekaterina Smirnova[4], Amon Asgharpour[5], Mohammad S. Siddiqui[2], Fadi N. Salloum[2] and Patricia J. Sime[2], (1) Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, (2) Virginia Commonwealth University, (3)Edinburgh University, (4)Virginia Commonwealth University, Richmond, VA, (5)Virginia Commonwealth University Health System

Background: The hydroxysteroid dehydrogenase 17 B13 isoform B (rs72613567) (HSD^B) confers protection from NASH and fibrosis. The underlying mechanisms are not known. AIMS: (1) To determine if the HSD splice variant (HSD^B) decreases fibrosis in the diet-induced animal model of NAFLD (DIAMOND^{TM}) mice, (2) To determine the impact of HSD^B on NASH-related mechanistic pathways **Methods:** NASH was induced by a high-fat diet with adlib sugar water (Western Diet (WD)). Liver targeted delivery of luciferase (negative control), HSD isoform A (HSD^A) or HSD^B was achieved using TBG-AAV vectors. Liver histology was assessed by H&E Sirius Red. The hepatic metabolome was interrogated using GCMS and LCMS. Gene expression was quantified by mRNA qPCR and protein expression by Western blot. **Results:** A total of 10 mice each on WD were randomly assigned to receive AAV-luc, AAV-HSD^A or AAV-HSD^B. Mice on chow diet (CD) were healthy controls. After 16 weeks on the diet, liver-specific expression of HSD was confirmed by qPCR and Western blot. *(A) Histology:* Mice on CD had normal histology. AAV-luc on WD developed steatohepatitis with stage 1-2 fibrosis as did AAV-HSD^A. In contrast, AAV-HSD^B only had steatosis with minimal or no fibrosis. *(B) Chemistry:* WD increased AST and ALT in AAV-luc and HSD^A; this was significantly abrogated by HSD^B. *(C) Metabolomics:* Compared to AAV-luc and HSD^A, HSD^B mice on WD had lower palmitate, 18:0 containing ceramides, reduced cholic acid and its derivatives, lower phosphocholine and higher arachidonic acid and anabolic profile (higher ketoglutarate:citrate). *(D) Molecular signaling:* WD increased de novo lipogenic gene expression along with ER stress, oxidative stress, autophagy, senescence, inflammation and fibrosis signaling in AAV-luc and HSD^A. In contrast, HSD^B decreased ($p < 0.05$ for all) senescence (p16, p21, p53) and downstream activation of inflammasome (ASC, NLRP3, Caspase-1, IL1-β), inflammatory- (p-JNK) and proliferative-signaling (p-ERK). Ceramide synthetase 1, 6 and the oxidative marker nrf2 was decreased in HSD^B. While GP130 was increased in all groups on WD, downstream p-STAT3 (Y705) but not (S727) was markedly suppressed in HSD^B. WD-induced fibrogenic drive (TGF-β, procollagen 1 and 3 and α-smooth muscle actin) was significantly decreased by HSD^B. **Conclusion:** The splice variant B of HSD17B13 reduces enhanced pro-fibrotic inflammaging in NAFLD to retard steatohepatitis and fibrosis.

2386-C | THE SUN1 H118Y VARIANT ASSOCIATES WITH HISTOLOGIC NAFLD AND INCREASES INSULIN RESISTANCE AND LIPID ACCUMULATION IN HUMAN HEPATOMA CELLS

Kapil K Upadhyay[1], Brandon Buscher[1], Xiaomeng Du[1], Yanhua Chen[2], Antonino Oliveri[1], Elizabeth K. Speliotes[3,4] and Graham F Brady[1], (1)Division of Gastroenterology and Hepatology, Department of Internal Medicine;, (2)University of Michigan, (3) University of Michigan Medical School, (4)University of Michigan Medical School, Ann Arbor, Michigan, USA

Background: Nonalcoholic fatty liver disease (NAFLD) is the most prevalent chronic liver disease and a growing cause of morbidity and mortality, with no FDA-approved treatment, highly variable progression, and complex environmental and genetic risk factors. We previously reported a genetic link between the common nuclear envelope protein coding variant rs6461378 (g.842031C > T; *SUN1* H118Y) and hepatic steatosis, as well as with NAFLD-related metabolic traits, including insulin resistance. Here we report that *SUN1* H118Y associates with histologic NAFLD and exerts a direct metabolic effect in hepatocyte-like cells *in vitro*. **Methods**: Using publicly available GWAS summary statistics, we performed an association analysis of *SUN1* H118Y with histologic NAFLD in the Elucidating Pathways of Steatohepatitis (EPoS) consortium dataset. A potential direct metabolic impact of SUN1 H118Y was tested in human hepatoma (Huh7 and HepG2) cells using semi-quantitative lipid staining (BODIPY 493/593) and determination of insulin-stimulated AKT phosphorylation via immunoblot, as well as transcriptional analysis (qPCR) of lipid-related gene expression. **Results:** Rs6461378-T positively associated with histologic NAFLD in the EPoS consortium cohort ($P = 0.017$), confirming the prior genetic association results and suggesting a possible direct impact on human liver disease. *In vitro*, HepG2 and Huh7 cells expressing SUN1 H118Y exhibited decreased insulin sensitivity, determined by insulin-stimulated AKT phosphorylation, compared to WT SUN1-expressing cells. Huh7 cells expressing SUN1 H118Y accumulated significantly more lipid than WT SUN1-expressing cells, with or without oleic acid treatment (all $P < 0.01$; Figure 1); a similar effect of SUN1 H118Y on lipid accumulation was seen in HepG2 cells. Further, we conducted a gene expression analysis of lipid regulatory genes to explore the underlying mechanism of lipid accumulation. Huh7 cells expressing SUN1 H118Y showed upregulation of *CD36, ELOVL1*,

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

and *ELOVL5* (encoding fatty acid elongases), while *ACOX1* (encoding a key β-oxidation pathway enzyme) was downregulated. **Conclusion:** Taken together, these data validate the previously reported associations of rs6461378-T with hepatic steatosis and NAFLD-related traits and suggest cell-autonomous mechanisms by which SUN1 H118Y may contribute to human NAFLD by promoting hepatocyte lipid uptake and storage and downregulating fatty acid β-oxidation.

f 2387-C | THIOESTERASE SUPERFAMILY MEMBER 2 INTERACTS WITH PHOSPHATIDYLCHOLINE TRANSFER PROTEIN IN SKELETAL MUSCLE TO PROMOTE NON-ALCOHOLIC FATTY LIVER DISEASE

Yang Xie[1,2] and David E Cohen[1,2], (1)Brigham and Women's Hospital, (2)Harvard Medical School

Background: Interactions between thioesterase superfamily member 2 (Them2), a long-chain fatty acyl-CoA thioesterase, and phosphatidylcholine transfer protein (PC-TP), a cytosolic lipid binding protein, regulate cellular fatty acid and glucose metabolism, as well as insulin signaling. We have demonstrated that global or skeletal muscle-specific, but not liver-specific deletion of Them2 protects mice against high-fat diet (HFD)-induced hepatic steatosis and insulin resistance characteristic of non-alcoholic fatty liver disease (NAFLD). Moreover, restoration of Them2 expression in skeletal muscle in *Them2*$^{-/-}$ mice is sufficient to promote NAFLD. The aim of this study was to elucidate whether Them2-PC-TP interactions in skeletal muscle are necessary for Them2 to induce NAFLD. **Methods:** *Them2*$^{-/-}$ mice received continuous administration of compound A1, an inhibitor of Them2-PC-TP interactions, via implanted mini-infusion pumps. Skeletal muscle-specific Them2 expression was then restored using recombinant adeno-associated virus serotype 8 driven by the muscle creatine kinase promoter, with LacZ as a control. Mice were fed a HFD (60% kcal from fat) for 12 w. Protein expression was ascertained by immunoblotting. Tolerance tests to glucose and insulin were conducted to assess glucose control. Hepatic steatosis was evaluated by H&E and oil red O staining, as well as enzymatic measurements of hepatic triglyceride concentrations. Membrane localization of glucose transporter type 4 (Glut4) in skeletal muscle was analyzed by confocal immunofluorescence imaging. Glucose uptake in the soleus muscle was measured using ^{3}H-2-deoxy-D-glucose. **Results:** Compound A1 administration abrogated the capacity for skeletal muscle-specific Them2 expression to promote hepatic steatosis and insulin resistance. For mice expressing Them2 relative to those expressing LacZ in skeletal muscle, this was evidenced by the absence of increased hepatic steatosis, of worsened glucose control or of decreased Glut4 membrane translocation and glucose uptake by skeletal muscle. **Conclusion:** The interaction of Them2 with PC-TP is critical to the capacity of skeletal Them2 to promote hepatic steatosis and insulin resistance. We speculate that both Them2 and PC-TP in skeletal muscle represent attractive targets in the clinical management of NAFLD.

2388-C | THYROID HORMONE RESCUES NON-ALCOHOLIC FATTY LIVER DISEASE IN MICE FED WESTERN DIET BY INCREASING HEPATIC SIRT3 EXPRESSION

Raghu Ramanathan, Sarah Ashley Johnson and Jamal A. Ibdah, University of Missouri-Columbia

Background: The therapeutic options for non-alcoholic fatty liver disease (NAFLD) are limited. Reduced hepatic mitochondrial fatty acid oxidation (FAO) and mitochondrial dysfunction play an important role in the pathogenesis of NAFLD. Thyroid hormone (TH) regulates lipid metabolism in the liver and may have important therapeutic potential in NAFLD. The goal of this study is to test whether thyroid hormone rescues NAFLD in mice fed western diet by increasing the expression of Sirtulin-3 (SIRT3), a master regulator of mitochondrial FAO. **Methods:** Six-month old wild-type male mice with C57BL/6 background were fed

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Western diet (Research Diets Inc, D12451 Rodent Diet, 45 kcal% fat, 1% cholesterol) for 16 weeks to induce NAFLD. The control mice (n = 6) received phosphate buffered saline (PBS), while the treatment group (n = 6) received triiodothyronine (T_3) 25μg/100g weight intraperitoneal (ip) for 7 days. After sacrifice, complete FAO were measured in fresh liver lysate. Sirtulin-3 (SIRT-3) gene and protein expression, as well as expression of other genes affecting mitochondrial function and mitophagy, were assessed along with histology and transmission electron microscopy (TEM). **Results:** T_3 resulted in 2-fold increase in complete hepatic CO_2 production compared to control PBS ($p < 0.01$, Fig. 1A). The levels of SIRT-3 in both gene and protein expression were significantly increased ($p < 0.05$, Fig. 1B & C) with TH treatment. T_3 increased expression of mitochondrial markers OPA-1 ($p < 0.01$) and COX-IV ($p < 0.05$) compared to control (Fig. 1D, F). In addition, T_3 increased expression of the mitophagy markers BNIP-3 ($p < 0.01$) compared to control (Fig. 1E). Liver histology showed that T_3 rescued NAFLD with significant reduction in steatosis and inflammation markers as compared to control mice (Fig. 1G). The TEM revealed significant improvements in mitochondrial structure compared to control (Fig. 1H). **Conclusion:** TH increases SIRT3 expression which leads to enhanced FAO and rescue of NAFLD in mice. Our study suggests that TH and SIRT-3 are potential targets for treatment of NAFLD by improving mitochondrial function and quality. (Supported by VA Merit 1BX 004710).

2389-C | TIR8 AMELIORATES NASH PROGRESSION BY MAINTAINING PPARA EXPRESSION AND REDUCING THE SENSITIVITY OF HEPATOCYTES TO LPS

Ying Shi[1], Xiao Guang Yang[2], Xiao Dan Zhong[1], Xu Shi[1], Ya Nan Li[1], Junqi Niu[1] and Yanhang Gao[1], (1)The First Hospital of Jilin University, (2)Northeast Normal University

Background: PPARα (peroxisome proliferator-activated receptor-α) serves as the primary regulatory factor in hepatic lipid metabolism. Its expression level influences beta-oxidation and lipid accumulation, making it a crucial target for ameliorating the onset and progression of nonalcoholic fatty liver disease (NAFLD). Moreover, aside from PPAR small molecule agonists, other hepatic endogenous molecular that can maintain the expression of PPARα during free fatty acid stress remain unclear. **Methods:** Bioinformatics was used to compare the gene transcription profiles of liver tissue in NASH patients and normal individual's in the GES database, in which TIR8 was identified. To determine the role of TIR8 in maintaining PPARα gene expression under conditions of lipid accumulation, a high-fat, high-cholesterol diet (HFHCD) induced NASH mouse model and the human liver cell line HepRG were used to investigate the effects of TIR8 on PPARα mediated hepatic lipid metabolism and inflammatory signaling pathways. Immunoprecipitation was used to study the reasons for TIR8 downregulation in hepatocytes under free fatty acid treatment. **Results:** This study found that the expression of TIR8 in the livers of NASH patients was significantly lower than in normal individual's, and the TIR8 gene level was also significantly downregulated in the livers of NASH mice induced by a high-fat, high-cholesterol diet. Knockout of the TIR8 gene accelerated the progression of NASH in mice, with more severe liver lipid deposition and damage than in wild-type mice. Exogenous TIR8 gene overexpression had a protective effect on the mouse liver, with significant improvements in lipid deposition, liver damage, and inflammation factor levels. In vitro studies showed that TIR8 overexpression could maintain PPARα levels in the HepRG liver cell line under free fatty acid stress and reduce the accumulation of triglycerides and formation of lipid droplets induced by palmitic acid/oleic acid. Mechanistically, we found that under the action of free fatty acids and LPS, proteasome 20sα subunit 4 (PMSA4) mediated the degradation of TIR8, which may be a key reason for further activation of inflammatory pathways and the decline of PPARα levels. **Conclusion:** In summary, the expression level of TIR8 is highly correlated with the progression of NASH. The degradation of TIR8 in hepatocytes may be a key reason for PPARα downregulation , leading to lipid metabolism disorder and inflammation mediated by PPARα. Therefore, stimulating the expression of TIR8 is beneficial for

2390-C | TRANSCRIPTOMIC PROFILING FOR AUTOPHAGY PATHWAY IN HUMAN FATTY LIVERS

Yiing Lin, William C. Chapman and Jae-Sung Kim, Washington University in St. Louis

Background: Nonalcoholic fatty liver disease (NAFLD) has become the most common liver disorder in the world, and its global prevalence increases steadily. Autophagy is a cellular process that clears unnecessary cellular constituents. How steatosis affects autophagy in non-parenchymal liver cells remains unknown. **Methods:** We obtained 10 discarded organ livers deemed unsuitable for liver transplant, including 4 mild (< 5 % steatosis), 4 moderate (5-50% steatosis), and 2 severe (> 50% steatosis) fatty livers. Using the Chromium Next GEM Single Cell 3' reagent kit and Chromium Next GEM Chip G Single Cell kit (10x Genomics, Pleasanton, CA), we conducted single-nuclei RNA-sequencing (snRNA-seq) targeting 11,000 nuclei per sample. Changes in autophagy genes involved in the stage of initiation, phagophore formation, elongation, and completion were analyzed in hepatocytes, Kupffer cells, stellate cells, sinusoidal endothelial cells, and cholangiocytes. **Results:** In hepatocytes, the SQSTM1/p62 gene, a marker of autophagic clearance, progressively increased with the severity of steatosis. Compared to mildly steatotic livers, SQSTM1/p62 expression levels in hepatocytes were 64% higher in severely steatotic livers. In striking contrast, its levels in non-parenchymal liver cells were substantially lower in severely steatotic livers than in mildly steatotic livers. Levels of SQSTM1/p62 expression in Kupffer cells, stellate cells, sinusoidal endothelial cells, and cholangiocytes of severely steatotic livers were 14%, 24%, 33%, and 43% of values in mildly steatotic livers, respectively. These results suggest that severe hepatic steatosis increases autophagy in non-parenchymal cells but decreases autophagy in hepatocytes. Analysis of the individual stages in the autophagy pathway revealed that the factors involved in the initiation (DEPTOR and TBK1), phagophore formation (VSP34, ATG14, and BIF1), elongation (ATG14), and completion (ATP6V1D and ATP6V1H) of autophagy were elevated in Kupffer cells, stellate cells, and sinusoidal endothelial cells of severely steatotic livers. Levels of DEPTOR, PRKN, NBR1, TBK1, ATG14, ATG3, ATG4B, ATG14, ATP6V1C1, ATP6V1H, and CTSD were elevated in cholangiocytes of severely steatotic livers. **Conclusion:** Autophagic response to steatosis in non-parenchymal liver cells differs from that in hepatocytes.

2391-C | TRANSLATIONAL CHARACTERIZATION OF THE TEMPORAL DYNAMICS OF METABOLIC DYSFUNCTIONS IN LIVER, ADIPOSE TISSUE AND THE GUT DURING DIET-INDUCED NASH DEVELOPMENT IN LDLR-/-.LEIDEN MICE

Eveline Gart, Tno

Background: >NAFLD progression, from steatosis to inflammation and fibrosis, results from an interplay of intra- and extrahepatic mechanisms. Disease drivers likely include signals from white adipose tissue (WAT) and gut. However, the temporal dynamics of disease development remain poorly understood. **Methods:** High-fat-diet (HFD)-fed Ldlr-/-.Leiden mice were compared to chow-fed controls. At t = 0, 8, 16, 28 and 38w mice were euthanized, and liver, WAT depots and gut were analyzed biochemically, histologically and by lipidomics and transcriptomics together with circulating factors to investigate the sequence of pathogenic events and organ cross-talk during NAFLD development. **Results:** HFD-induced obesity was associated with an increase in visceral fat mass, plasma lipids and hyperinsulinemia at 8 weeks, along with an increase in liver steatosis and circulating biomarkers indicative of liver damage (ALT, AST, CK18-M30, TIMP1). Liver steatosis was mainly attributable to increased triacylglycerols and to a lesser extent free-fatty acids, cholesteryl esters and diacylglycerols. In parallel, regulators involved in lipid catabolism (e.g., ACOX1) were deactivated and in lipid synthesis (e.g., SREBF1) activated by HFD. Subsequently, hepatocyte hypertrophy, oxidative stress (4-HNE) and hepatic inflammation developed. Hepatic collagen accumulated at t = 16w and became particularly prominent after 28-38 weeks. Epididymal WAT adipocytes were maximally hypertrophic from t = 8w, which coincided with inflammation development in this depot. Mesenteric and subcutaneous WAT hypertrophy developed slower and did not appear to reach a maximum within the period studied, with minimal inflammation. In the gut, HFD significantly increased permeability, induced a major shift in microbiota composition (ileum and colon) from t = 8w and associated with circulating gut-derived metabolite changes (short-chain fatty acids and bile acids). **Conclusion:** Ldlr-/-.Leiden mice on a HFD develop obesity, dyslipidemia and insulin resistance, essentially as observed in obese NASH patients. We demonstrate that marked epididymal-WAT inflammation, and gut permeability and dysbiosis precede the development of NAFLD stressing the importance of a multiple-organ approach in the prevention and treatment of NAFLD.

2392-C | TREATMENT OF GROWTH HORMONE ATTENUATES HEPATIC STEATOSIS IN NASH HAMSTERS BY REGULATING PATHWAY OF LIPID METABOLISM AND INFLAMMATION

Wei Zhang[1], Yijun Tao[2], Xiao Lin[2], Ping Ma[2], Gonglie Chen[2], Ling Zhang[2], Wei Huang[2], Xunde Xian[2], George Liu[2] and Yuhui Wang[2], (1)Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China, (2)Institute of Cardiovascular Sciences and Key Laboratory of Molecular Cardiovascular Sciences, Ministry of Education, Peking University, Beijing, China.

Background: Non-alcoholic fatty liver disease (NAFLD) is a major cause of chronic liver disease. However, most available animal models fail to mimic the spectrum of the disease from steatosis (NAFL) alone to steatohepatitis (NASH), cirrhosis, and hepatocellular carcinoma. Our present study defines wild type hamster with feeding high-fat diet (HFD) as a pre-clinical model of moderate steatohepatitis that mimics the human disease, including pathophysiologic characteristics and transcriptomic signature. Additionally, the reduction in hepatocyte growth hormone (GH)-signaling promotes the development of NAFLD, but the direct effects of GH on hepatocyte function have not been well characterized. We aimed to explore the mechanism of it in our hamster model. **Methods:** Wild type hamsters were fed a healthy chow diet or fed a HFD containing 5% lard and 0.5% cholesterol. The response to GH treatment for four weeks was evaluated in these models. RNA sequencing technology was used to test liver transcriptional differences. Human transcriptomic analysis were defined using a publicly available NASH gene expression profiling dataset (GSE48452 and 126848) allowing the comparison of biopsy-confirmed NAFL and NASH patients with normal controls. **Results:** The 16-weeks HFD induced obesity, hyperlipidemia, and increased alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels. Histological analysis in our hamsters exhibited: moderate-severe steatosis, hepatocellular ballooning necrosis, inflammation but mild hepatic fibrosis (Figure1A). Pathway enrichment analysis showed that our hamster model shared a relevant number of important pathways involved in NASH pathophysiology (Figure1B). Exogenous GH treatment decreased liver/body weight without affecting serum lipid profiles. Importantly, GH treatment attenuated hepatic steatosis and inflammation, and also reduced macrophage accumulation in liver. The hepatic mRNA levels of SREBP1C, SREBP2, CHREBP, CD36, and PPARγ were markedly decreased in GH treated hamsters without significant changes in other molecules related to lipid metabolism (Figure1C). And the hepatic expression IL-1β mRNA were decreased by GH treatment. **Conclusion:** Our study defines a translational model of NASH and found GH treatment could attenuate hepatic steatosis and inflammation with downregulation of genes involving lipogenesis /oxidation and inflammation in hyperlipidemic condition.

2393-C | TWO MEALS PER PERIOD PREVENTS FATTY LIVER BY STIMULATING ENERGY EXPENDITURE

Pamela Mattar[1,2], Andressa Reginato[2], Christian Lavados[2], Nuria Martinez-Lopez[1,2], Mridul Sharma[1,2], Gary Schwartz[2], Prashant Rajbhandari[3] and Rajat Singh[1,2,4], (1)University of California, Los Angeles, (2) Albert Einstein College of Medicine, (3)Diabetes, Obesity, Metabolism Institute, Icahn School of Medicine at Mount Sinai, (4)Liver Basic Research Center at University of California Los Angeles

Background: Intermittent fasting has been proposed as a non-invasive approach to reduce body weight and promote insulin sensitivity. Dietary interventions, e.g., caloric restriction has been shown to protect against NAFLD; however, caloric restriction is marred by poor compliance, impacting human translatability. This forms the basis for developing new dietary approaches to provide similar benefits without lowering caloric intake. We have shown that feeding animals twice-a-day (TAD), i.e., during two 2-hr feeding windows in the diurnal phase, without caloric restriction, protects against NAFLD by stimulating autophagy in liver. In ongoing studies, we are exploring how feeding TAD or twice-a-night (TAN) protects against NAFLD. **Methods**: *Animals*: Studies were performed in male mice of varying ages. *Experiments*: We performed comparative analysis of TAD feeding vs. our newly implemented TAN feeding wherein mice were fed during similar two 2-hr feeding windows in the nocturnal phase without eliminating calories. *Statistics*: Unpaired Student's T-test, one-way or two-way ANOVA followed by appropriate multiple-comparisons tests. **Results**: Comparative analysis revealed that TAD and TAN feeding each markedly reduces body weight, promotes insulin sensitivity, lowers liver triglyceride content and blocks liver inflammation. Using functional and histological approaches, lipidomics, and transcriptomics, we reveal that TAN-fed mice show improved systemic lipid catabolism and energy expenditure, thus funneling lipid away from the liver. Indeed, TAN feeding increases oxygen consumption rates in diverse tissues determined via Seahorse respirometry, decreases liver triglycerides and liver inflammatory and senescence markers. Given that autophagy mediates these benefits in TAD-fed mice, we suspect that stimulation of systemic autophagy drives these hepatoprotective benefits in TAN-fed mice. **Conclusion**: Our studies show that the increases in systemic lipid utilization by feeding two meals per period, in absence of caloric restriction, is sufficient to prevent NAFLD and steatohepatitis.

f 2394-C | Ubc13 PROTECTS AGAINST DEFECTIVE MITOPHAGY IN NON-ALCOHOLIC FATTY LIVER DISEASE BY PROMOTING K63-LINKED p62 UBIQUITINATION★

Feng Wang[1], Yoon-Seok Roh[1], Jin Lee[2], Jeong-Su Park[1], Hwan Ma[1] and Ekihiro Seki[3], (1)Chungbuk National University College of Pharmacy, (2)University of California, San Diego, La Jolla, CA, (3)Cedars-Sinai Medical Center, Torrance, CA

Background: Ubiquitination is a post-translational modification and contributes to mitophagy which plays an essential role in nonalcoholic fatty liver disease (NAFLD). Ubc13 is the only known ubiquitin-conjugating enzyme (E2) specialized in K63-linked polyubiquitination. However, the mechanism of how mitochondria quality control is regulated by Ubc13 in NAFLD remains unclear. **Methods:** Hepatocyte-specific Ubc13 knockout ($Ubc13^{\Delta Hep}$) and Ubc13/$p62^{\Delta Hep}$ mice were treated Fast food diet (FFD) for 8 weeks. Mitochondrial functions in hepatocytes were examined by Seahorse bioanalyzer and Mt-Keima system. RNA sequencing and proteomics analysis were performed using liver tissue. Spatial transcriptomics (GeoMX) analysis was performed using normal and NASH human liver tissues. **Results:** Hepatocyte-specific Ubc13 deletion induces cell death and inflammation. Multi-omics analysis (RNA sequencing and Proteomics) revealed that Ubc13 regulates mitochondrial integrity. Ubc13 deletion caused mitochondrial dysfunction. Since mitophagy plays a major role in mitochondrial quality control, we sought to determine how Ubc13 regulates mitophagy. We found that Ubc13 overexpression enhanced mitophagic clearance and Ubc13 deletion decreased it *ex vivo* and *in vitro*, indicating that Ubc13 promotes mitophagy in hepatocytes. Mitochondrial dysfunction is often observed in NAFLD patient livers, and our data showed hepatic expression of Ubc13 was significantly downregulated in livers of NAFLD patients analyzed by GeoMx and IHC, further suggesting the role of Ubc13 in mitochondrial functions in NAFLD. We also found that Ubc13 deletion in hepatocytes aggravated FFD-induced lipid accumulation and subsequent inflammation and fibrosis. Of note, proteomics analysis identified p62 is the most upregulated protein in liver of $Ubc13^{\Delta Hep}$ mice. Mechanistically, Ubc13 directly interacted with p62 at K7A and subsequently induced K63 ubiquitination, promoting mitophagy. We also found defective mitophagy by Ubc13 deletion induced p62 accumulation by suppressing p62

degradation. An additional deletion of p62 alleviated hepatic inflammation and fibrosis in Ubc13$^{\Delta Hep}$ mice, suggesting that the aberrant accumulation of p62 is associated with disease progression in Ubc13$^{\Delta Hep}$ mice. **Conclusion:** Our findings revealed that Ubc13-mediated p62 ubiquitination is an essential mechanism for mitochondrial quality control, which may prevent the development of NAFLD.

2395-C | ULTRASTRUCTURAL ANALYSIS OF VASCULAR ENDOTHELIAL GLYCOCALYX IN NONALCOHOLIC FATTY LIVER DISEASE

Ayumi Kuroda, Kodai Suzuki, Hideshi Okada, Hiroyuki Tomita, Chihiro Takada, Takahiro Yoshida, Shozo Yoshida and Shinji Ogura, Gifu University

Background: Non-alcoholic fatty liver disease (NAFLD) is regarded as a hepatic disease of metabolic syndrome that develops based on obesity, diabetes, dyslipidemia, and hypertension. Fatty liver, in which fat is deposited in the liver tissue, is thought to progress to non-alcoholic steatohepatitis and liver cirrhosis (NASH) when the tissue is exposed to certain stimuli such as oxidative stress and inflammatory cytokines. However, the mechanism of the progress is still unclear. The endothelial glycocalyx which is a glycoprotein on the surface of the vascular endothelial cells plays an important role in regulating vascular homeostasis. Therefore, we hypothesized that the hepatic endothelial glycocalyx injured associated with the progress of NAFLD. In this study, we analyzed the ultrastructure of the hepatic endothelial glycocalyx with scanning electron microscopy. **Methods:** Ten-week-old C57BL6 mice were fed methionine-choline-deficient diet (MCD) as NAFLD group, or standard diet as control group for 4 weeks. MCD diet inhibits triglyceride elimination from the liver and causes fat accumulation in the liver. Intrahepatic fibrosis and lipid droplets were evaluated by HE and Oil Red O staining. In addition to conventional 2.5% glutaraldehyde perfusion fixation, endothelial glycocalyx staining was performed to observe the labile endothelial glycocalyx by electron microscopy. Mice were anesthetized and then perfused with a solution composed of 2% glutaraldehyde, 2% sucrose, 0.1-M sodium cacodylate buffer (pH 7.3), and 2% lanthanum nitrate, at a steady flow rate. The freeze-fracture method was used to prepare samples for scanning electron microscopy. **Results:** MCD group showed a decrease in body weight and an increase in serum aspartate aminotransferase compared to the control group. Histologically, A prominent accumulation of lipid droplets was observed in the liver tissue of MCD group. Conventional scanning electron microscopy results showed destruction of the fenestrated structure of the hepatic sinusoidal endothelial cells, and it was suggested that the accumulation of lipid droplets compressed the bile ducts and inhibited bile excretion. Ultrastructural analysis by the glycocalyx method revealed that detachment of the intrahepatic microvessels in the MCD group compared to the control group. **Conclusion:** In conclusion, our data has shown that the endothelial glycocalyx damage is sustained due to a chronic inflammation at the initial NAFLD. It may lead to liver fibrosis and cirrhosis.

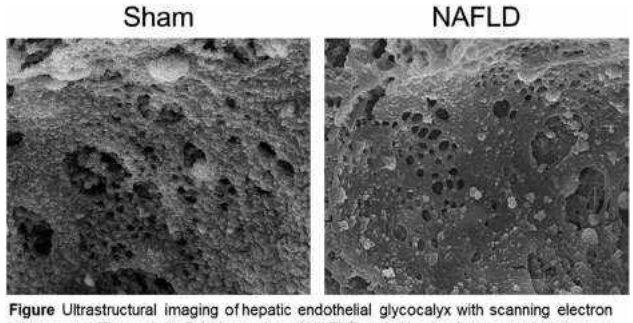

Figure Ultrastructural imaging of hepatic endothelial glycocalyx with scanning electron microscopy. The endothelial glycocalyx of NAFLD was damaged compared to the endothelial glycocalyx of sham.

f 2396-C | WESTERN DIET DAMPENS T REGULATORY CELL FUNCTION TO FUEL HEPATIC INFLAMMATION IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Sudrishti Chaudhary[1], Ravi Rai[1], Pabitra Pal[1], Dana Tedesco[2], Aatur Singhi[3], Satdarshan (Paul) Monga[1], Arash Grakoui[2], Smita Iyer[1] and Reben Raeman[1], (1) University of Pittsburgh, (2)Emory University School of Medicine, (3)University of Pittsburgh Medical Center

Background: The immunosuppressive T regulatory cells (Tregs) regulate immune responses and maintain immune homeostasis, yet their functions in metabolic dysfunction-associated steatotic liver disease (MASLD) pathogenesis remains controversial. **Methods:** Mice were fed a normal diet (ND) or a western diet (WD) for 16 weeks to induce MASLD. Diphtheria toxin injection to deplete Tregs in Foxp3DTR mice or Treg induction therapy in WT mice to augment Treg numbers was initiated at twelve and eight weeks, respectively. Liver tissues from mice and MASH human subjects were analyzed by histology, confocal imaging, and qRT-PCR. **Results:** WD triggered accumulation of adaptive immune cells, including Tregs and effector T cells, within the liver parenchyma. This pattern was also observed in MASH patients, where an increase in intrahepatic Tregs was noted. In the absence of adaptive immune cells in Rag1 KO mice, WD promoted accumulation of intrahepatic neutrophils and macrophages and exacerbated hepatic inflammation and fibrosis. Similarly, targeted Treg depletion exacerbated WD-induced hepatic inflammation and fibrosis. In Treg-depleted mice, hepatic injury was associated with increased accumulation of neutrophils, macrophages, and activated T cells within the liver. Conversely, induction of Tregs using recombinant IL2/aIL2 mAb cocktail reduced hepatic steatosis, inflammation, and fibrosis in WD-fed mice. Analysis of intrahepatic Tregs from WD-fed mice revealed a phenotypic signature of impaired Treg function in MASLD. Ex vivo functional studies showed that glucose and palmitate, but not fructose, impaired the immunosuppressive ability of Treg cells. **Conclusion:** Our findings indicate that the liver microenvironment in MASLD impairs the ability of Tregs to suppress effector immune cell activation, thus perpetuating chronic inflammation and driving MASLD progression. These data suggest that targeted approaches aimed at restoring Treg function may represent a potential therapeutic strategy for treating MASLD.

2397-C | YKL-40 DEFICIENCY ALTERS INFILTRATING NEUTROPHILS INFLAMMATORY GENE PROFILE IN NLRP3 INDUCED LIVER INFLAMMATION

Lin Kui[1], Andrea D. Kim[1,2], Hal Hoffman[1], Ben Croker[1] and Ariel E. Feldstein[1], (1)University of California, San Diego, (2)Johns Hopkins University, Baltimore, MD

Background: BRP-39 (breast regression protein 39; Chi3L1) and its human homolog YKL-40 is a well-established biomarker of liver fibrosis in NASH patients while the potential mechanistic contribution to NASH pathogenesis remains poorly understood. We have recently identified Chi3L1 as one of the top upregulated genes in the liver of mouse with inducible gain-of-function NOD-like receptor protein 3 (Nlrp3) activation that mimics several liver features of NASH (Hepatology 2022). **Methods:** Using Tamoxifen-inducible Nlrp3 knock-in Muckle wells (MW CRT) mice, Tamoxifen-inducible Nlrp3 knock-in Muckle wells BRP39 deficient mice (MW/BRP CRT), we investigated the consequence of BRP39 deficiency influencing NLRP3 induced liver inflammation, particularly looking at the change in gene expression of infiltrating neutrophils. ***Results:*** MW CRT have reduced bodyweight and increased liver weight (***$p < 0.001$) compared to WT mice. Contrastingly, MW/BRP CRT mice have improved bodyweight and liver weight (*$p < 0.05$) compared to MW CRT mice. Ly6G+ infiltrating neutrophils (**$p < 0.01$) were significantly lowered in MW/BRP CRT mice compared with MW CRT mice, furthermore immunofluorescence imaging revealed MW/BRP CRT mice whole liver having significantly less activated neutrophils with lower Ly6G+ and H3Cit+ expression (*$p < 0.05$) compared with MW CRT. Chemotaxis analysis revealed that MW/BRP CRT neutrophils migration ability is significantly reduced compared with MW CRT. RNA-seq of isolated whole-blood neutrophils revealed that MW/BRP CRT mice have reduced immune activation, migration, aggregation and signaling response compared to MW CRT. Among the top 25 differentially expressed genes (DEG), Complement

2398-C | ALPHA-LIPOIC ACID SUPPLEMENTATION FOR NON-ALCOHOLIC FATTY LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Islam Mohamed[1], Noor Hassan[2], Ifrah Fatima[3], Mohamed Abuelazm[4], Jagadish Koyi[3], Rawan Rajab[5], Hazem Abosheaishaa[6], Mohamed Ahmed[3], Wael T Mohamed[1], Khaled Elfert[7], Adel Muhanna[1], Laura M. Alba[8], Wendell K. Clarkston[1] and Hassan Ghoz[3], (1) University of Missouri-Kansas City, (2)University of Missouri- Kansas City, Kansas City, MO, (3)University of Missouri- Kansas City, (4)Tanta University, (5)University of Missouri Kansas City, (6)Icahn School of Medicine at Mount Sinai, (7)St. Barnabas Hospital, Bronx, NY, (8) Univeristy of Missouri- Kansas City, Kansas City, MO

Background: Non-alcoholic fatty liver disease (NAFLD) is the most prevalent form of chronic liver disease worldwide, often associated with obesity, type 2 diabetes, and insulin resistance. NAFLD can progress to more severe conditions, including liver cirrhosis and hepatocellular carcinoma. Current understanding of NAFLD pathogenesis is limited, and treatment options beyond weight loss are limited. Insulin resistance and chronic inflammation are known to contribute to NAFLD development and progression. Alpha-lipoic acid (ALA), an antioxidant with potential anti-inflammatory properties, has been investigated as a supplement for NAFLD. However, existing studies have produced conflicting results, making it challenging to determine the efficacy of ALA supplementation in NAFLD treatment. To address this uncertainty, we conducted a meta-analysis and systematic review to assess the efficacy of ALA for NAFLD treatment. **Methods:** We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs). We searched multiple databases, including PubMed, EMBASE, Web of Science, SCOPUS, and Cochrane, up to April 18th, 2023. The search utilized relevant keywords and MeSH terms. Data from eligible studies were analyzed using RevMan version 5.4 software. Continuous outcomes were assessed using the mean difference (MD), and corresponding confidence intervals (CI). The study protocol was registered prospectively in the PROSPERO database.

Results: In our meta-analysis, no significant differences were found between alpha-lipoic acid and placebo in terms of changes in the basal metabolic index (BMI) (MD: -0.39, 95% CI: [-1.78, 1.00], P = 0.58), body weight (MD: 0.54, 95% CI: [-5.71, 6.80], P = 0.87), waist circumference (MD: 0.48, 95% CI: [-8.50, 9.46], P = 0.92), hip circumference (MD: -0.11, 95% CI: [-11.81, 11.59], P = 0.99), aspartate aminotransferase (AST) (MD: 0.42, 95% CI: [-4.82, 5.66], P = 0.88), alanine aminotransferase (MD: 0.90, 95% CI: [-8.24, 10.05], P = 0.85), fasting serum glucose (MD: -3.01, 95% CI: [-10.26, 4.24], P = 0.42), and serum insulin (MD: -1.35, 95% CI: [-6.58, 3.89], P = 0.61). **Conclusion:** Our comprehensive meta-analysis, the first to investigate the effects of ALA for NAFLD, revealed no significant difference between ALA and placebo in the treatment of NAFLD. ALA supplementation did not show significant effects on key metabolic parameters, including BMI, body weight, waist circumference, hip circumference, AST, ALT, fasting serum glucose, and serum insulin levels. Further large-scale RCTs are warranted to obtain a more comprehensive understanding of the potential benefits of ALA in the treatment of NAFLD.

2399-C | ALTERATIONS IN THE ADIPOSE TISSUE TRANSCRIPTOMIC PROFILE ARE ASSOCIATED WITH e F2 LIVER FIBROSIS BUT ARE UNCHANGED BY A SYNBIOTIC INTERVENTION IN NAFLD

Josh Bilson[1], Carolina J. Oquendo[1], Eleonora Scorletti[2], Jenny Lord[1], Paul R. Afolabi[1], Giovanni Targher[3], Diana Baralle[1], Philip C. Calder[1], Christopher D Byrne[1] and Jaswinder K. Sethi[1], (1)University of Southampton, (2)University of Pennsylvania, (3) Universitaria Integrata of Verona

Background: Subcutaneous adipose tissue (SAT) dysfunction may be influenced by gut microbiota and contributes to NAFLD pathogenesis. Whether gene markers of SAT function are associated with liver fibrosis and can be influenced by a synbiotic treatment that changes gut microbiota is unknown. We investigated: (a) whether AT insulin resistance (IR), alterations in SAT transcriptomic profiles and a gene expression signature of SAT fibrosis are associated with the presence of e F2 liver fibrosis; and (b) whether a synbiotic treatment modified (a). **Methods:** Sixty-two patients with NAFLD (60% men) were studied prior to and following 12 months of treatment with synbiotic or placebo. RNA-sequencing was used to assess SAT transcriptomic profiles. A validated composite collagen gene expression (CCGE) score was used as a proxy of SAT fibrosis. Vibration-controlled transient elastography (VCTE)-validated thresholds were used to non-invasively assess liver fibrosis. Regression modelling and receiver operator characteristic curve analysis was used to test associations and risk prediction. **Results:** Patients with NAFLD and e F2 fibrosis (n = 24) had greater AT IR and a SAT gene expression signature characterised by an enrichment in inflammatory and extracellular matrix-associated gene expression compared to those with < F2 fibrosis (n = 38). Synbiotic treatment did not change SAT transcriptomic profiles or inflammatory/adipokine markers. The CCGE score was independently associated with (explaining 32% of the variance) and was a good predictor of e F2 fibrosis (AUROC 0.79, 95%CI 0.68-0.90). Associations between SAT transcriptomics and e F2 fibrosis were further reproduced using end-of-study data. **Conclusion:** A transcriptomic signature in SAT was associated with e F2 liver fibrosis but was unchanged by a synbiotic treatment. CCGE scores in SAT were a good predictor of e F2 liver fibrosis in NAFLD.

2400-C | ARTIFICIAL INTELLIGENCE BASED DIGITAL PATHOLOGY REVEALS FATTY ACID SYNTHASE (FASN) INHIBITOR ALONE OR IN COMBINATION WITH SEMAGLUTIDE IMPROVES FIBROSIS IN DIET-INDUCED OBESE MICE WITH BIOPSY-CONFIRMED NASH AND FIBROSIS

Wen-Wei Tsai[1], Mie Berke[2], Michael Feigh[2], Louis Petitjean[3], Li Chen[3], Eduardo Bruno Martins[1], George Kemble[1] and Marie O'Farrell[1], (1)Sagimet Biosciences, (2)Gubra Aps, (3)Pharmanest

Background: Increased *de novo* lipogenesis (DNL) drives the development of nonalcoholic steatohepatitis (NASH) and fatty acid synthase (FASN) is the rate-limiting enzyme in the DNL pathway. FASN inhibition not only reduces liver fat but also acts directly on immune and hepatic stellate cells reducing inflammation and fibrosis. Denifanstat (TVB-2640), a first in class FASN inhibitor, has demonstrated improvements in liver fat and biomarkers associated with inflammation and fibrosis in NASH trials. Semaglutide, a GLP-1 analog, reduced body weight and demonstrated NASH resolution in a recent NASH trial; however, it did not improve fibrosis compared to placebo. Aim: This study was designed to evaluate a FASN inhibitor alone and in combination with semaglutide on liver pathology, including NAFLD activity score (NAS) and fibrosis, in biopsy-confirmed NASH mice. **Methods:** Male C57BL/6J Gubra-Amylin-NASH (GAN) diet-induced obese mice with histologically-confirmed NAS (e 5) and fibrosis stage (F2-F3) were randomized and treated with either TVB-3664 (a surrogate FASN inhibitor for denifanstat, 10 mg/kg, PO, QD) or semaglutide (30 nmol/kg, SC, QD) alone or in combination for 12 weeks (Gubra, Denmark). High resolution phenotypic FibroNest analysis (PharmaNest, NJ) was used to evaluate changes in fibrosis. **Results:** Semaglutide significantly reduced body

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

weight alone or in combination with TVB-3664. TVB-3664 and the TVB-3664/semaglutide combination improved plasma ALT and AST, reduced total liver triglycerides and cholesterols, and decreased hepatocytes with lipid droplets and galectin-3 staining area. TVB-3664 and semaglutide significantly improved NAS (NAS e 1 point, 47% & 56%, respectively) and the combination showed further improvement (94%). Combination of TVB-3664/semaglutide decreased total liver area of picosirius red (PSR), collagen 1a1 and smooth muscle actin staining. Digital AI pathology algorithm assessment of post-treatment PSR staining (FibroNest) showed that TVB-3664 alone and the TVB-3664/semaglutide combination significantly reduced the phenotypic fibrosis composite severity score ($p < 0.05$ & $p < 0.01$, respectively, Figure 1) and parenchymal steatosis area ratio ($p < 0.01$) compared to vehicle. **Conclusion:** Combination treatment of FASN inhibitor and semaglutide showed further histological improvement of NAS and fibrosis compared to single agent treatment in a translational mouse model of NASH. These results support future clinical evaluation of denifanstat/GLP-1 combination therapy.

2401-C | ASC41, A THYROID HORMONE RECEPTOR B AGONIST, SHOWED LITTLE DRUG INTERACTION, SIGNIFICANT LIPID REDUCTION AND COMPARABLE PHARMACOKINETIC PROFILES AMONG CHINESE AND US HEALTHY SUBJECTS AND PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD): RESULTS FROM TWO PHASE 1 STUDIES

Jinzi Wu, Handan He and Yuemei Yan, Gannex Pharma Co., Ltd.

Background: ASC41 is a small molecule prodrug of thyroid hormone receptor β (THR-β) agonist. ASC41 is converted to its pharmacologically active metabolite ASC41-A by CYP3A4 in the liver. Here we report results of ASC41 drug-drug interaction (DDI) study in US healthy subjects and pharmacokinetic (PK), safety and pharmacodynamic (PD) in Chinese healthy subjects or US subjects with non-alcoholic fatty liver disease (NAFLD). **Methods:** NCT04527250 was a randomized, double-blind, placebo-controlled study to evaluate safety, tolerability, PK and PD of single and multiple ascending oral doses of ASC41. NCT04845646 was an open label, DDI study to evaluate effect of itraconazole (CYP3A strong inhibitor) and phenytoin (CYP3A strong inducer) on PK of ASC41 following a single dose of 5 mg ASC41 tablet and PK in NAFLD patients. **Results:** The active metabolite ASC41-A concentrations in plasma were approximately 20 times higher than those of ASC40 after oral dosing of ASC41. Both AUC and C_{max} of ASC41 and ASC41-A showed linear PK after single (1-20 mg) or multiple (1-5mg) doses. There were no clinically significant changes in the exposure of ASC41-A in the presence or absence of itraconazole (CYP3A4 strong inhibitor) or phenytoin (CYP3A4 strong inducer). PK profiles of ASC41-A were similar among US and Chinese healthy subjects, as well as NAFLD patients following a single dose of 5 mg ASC41 tablet (Figure 1). ASC41 induced significant reduction of lipid parameters, such as low-density lipoprotein cholesterol, triglycerides, and total cholesterol, but has no effect on high-density lipoprotein cholesterol after multiple ascending-dose range of 1-5 mg. No serious adverse events were reported across studies, and most adverse events were mild (grade 1) in severity and all were resolved with no sequelae. **Conclusion:** PK of ASC41-A was comparable among US and Chinese healthy subjects and NAFLD patients. ASC41 demonstrated significant reductions of lipids. ASC41 exhibited satisfactory safety and tolerability. Drug-Drug interactions of ASC41/ASC41-A with strong CYP3A4 inhibitor or inducer were low, showing competitiveness to other THR-β agonists in the late stage clinical development. It

is unlikely that there will be clinically significant drug-drug interactions between ASC41/ASC41-A and the most frequently used antidepressants and statins, indicating broad application in patients with NASH. ASC41 is currently in a 52-week Phase 2 trial to treat biopsy-confirmed NASH patients.

2402-C | ASSESSMENT OF LIVER FIBROSIS IN INDIVIDUALS WITH METABOLIC SYNDROME OR TYPE 2 DIABETES MELLITUS USING NON-INVASIVE TESTS

Robert Nastasa, Carol Stanciu, Ermina Stratina, Sebastian Zenovia, Cristina Muzica, Remus Stafie, Rotaru Adrian, Horia Minea, Laura Huiban, Stefan Chiriac, Catalin Sfarti, Camelia Cojocariu, Tudor Cuciureanu, Ana-Maria Singeap, Irina Girleanu and Anca Trifan, University of Medicine and Pharmacy "Grigore T. Popa", Iasi, Romania

Background: Individual's with metabolic syndrome (MS) or type 2 diabetes mellitus (T2DM) are at high risk for developing non-alcoholic fatty liver disease and advanced liver fibrosis. Although, there are currently no recommendations for screening patients with MS or T2DM. This study aimed to assess the diagnostic accuracy of non-invasive tests in predicting advanced liver fibrosis (e F3) in patients with MS or T2DM using the novel non-invasive score namely Agile 3+ score, which is done by combining straightforward clinical parameters with common laboratory biomarkers and liver stiffness measurements by vibration-controlled transient elastography. **Methods:** We prospectively enrolled patients with MS or T2DM which have been evaluated using non-invasive tests such as aspartate aminotransferase to platelet ratio index (APRI) score, fibrosis-4 (FIB-4) index, NAFLD fibrosis score (NFS), and Agile 3+ score in the Gastroenterology and Hepatology Institute Iasi, between August to October 2022. We calculated the area under the receiver operating curve (AUROC), specificity, sensitivity, negative predictive value (NPV), and positive predictive value (PPV) for each of these biomarkers in the detection of advanced liver fibrosis (e F3) compared with Agile 3+ score. In addition, we used Controlled Attenuation Parameter (CAP) with a cut-off ³ 274 dB/m for diagnosed non-alcoholic fatty liver disease (NAFLD). **Results:** Among 96 patients with T2DM and MS enrolled with a mean BMI of 26.98 ±4.73 kg/m2, 58 (60.4%) were females. According to Agile 3+ score, 28 (29.2%) individual's had at least advanced fibrosis (e F3) using a cut-off e 0.679. Moreover, 73 (76%) of the patients included in our study had NAFLD, according to a CAP ³ 274 dB/m. A significant correlation was found between Agile 3+ score and FIB-4 index ($r = 0.578$), NFS ($r = 0.591$), and APRI score ($r = 0.644$) ($p < 0.001$). The FIB-4 index had the highest NPV (90.12%) followed by the NFS score (86.61%). In comparison with Agile3+ score, all the biomarkers had relatively low specificity (< 80%) and PPV (< 75 %). Although, the major finding of our analysis was that all these biomarkers had relatively high NPV (> 85%) and accuracy (> 83%) for predicting advanced liver fibrosis. **Conclusion:** Novel non-invasive score, namely Agile 3+ score appear to improve identification of advanced fibrosis and cirrhosis, among MS and T2DM patients, who are at high risk to develop NAFLD and at least advanced fibrosis (e F3). Furthermore, it is possible to increase the PPV and reduce the number of cases with indeterminate results for the identification of cirrhosis and advanced fibrosis in patients with NAFLD, which would minimize the need for liver biopsy.

f 2403-C | BOS-580, AN INVESTIGATIONAL FGF21 ANALOG, IMPROVED MARKERS OF GLYCEMIC CONTROL AND LIVER STEATOSIS IN A DIABETIC SUB-POPULATION ENROLLED IN A PHASE 2a DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY IN PATIENTS WITH PHENOTYPIC NASH

Rohit Loomba[1], Tatjana Odrljin[2], Kris V. Kowdley[3], Jose E. Rodriguez[4], Nomita J. Kim[5], Alina Alvarez[6], Alicia Clawson[2], Mark Woodruff[2], Etienne Dumont[2], Eric Svensson[2] and Gerard Bain[2], (1)University of California, San Diego, San Diego, CA, (2)Boston Pharmaceuticals, (3)Washington State University, (4) Southwest General Health Care Center, (5)Accelemed, (6)Century Research Llc

Background: Type-2 diabetes (T2D) is commonly associated with NASH. FGF21 is known to improve glucose homeostasis through increase in peripheral insulin sensitivity and suppression of hepatic glucose production. We present below a sub-group analysis of the effect of BOS-580 on glycemia control biomarkers and liver fat reduction in T2D sub-populations enrolled in a phase 2a

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

study of BOS-580, an investigational FGF21 analog being studied for the treatment of NASH. **Methods:** Part A of phase 2a study BOS-580-201 enrolled 102 patients with obesity at risk for developing NASH, with VCTE liver stiffness measure (LSM) scores of 7-9.9 kPa, AST values of > 20 IU/mL, and body mass index (BMI) from 30-45 kg/m^2. Participants were randomized into 5 different dosing groups (75mg Q4W, 75mg Q2W, 150mg Q4W, a150mg Q2W, and 300mg Q4W) and administered BOS-580, an engineered variant of human FGF-21 fused to human IgG1-Fc, or placebo, for 12 weeks. Two sub-populations were identified based on baseline HbA1c values of e 5.7% (pre-diabetics and diabetics, n = 73) or e 6.5% (diabetics, n = 26). Glycemic markers including C-peptide and Hb1Ac, along with hepatic fat fraction (HFF), were evaluated in these sub-populations and the overall study population. **Results:** Baseline characteristics (age, gender, body weight, BMI, LSM score) were similar in T2D sub-populations to the overall study population. However, baseline HFF and AST values were higher in the HbA1c e 6.5% sub-population. After 12 weeks of treatment with BOS-580, C-peptide levels dropped 19.8% and absolute HbA1c levels decreased by 0.46% in the HbA1c e 6.5% sub-population, compared to decreases of 8.1% and 0.18%, respectively, in the overall study population. In addition, both overall reductions in HFF as well as the proportion of patients demonstrating at least a 50% reduction in HFF, were generally similar across all sub-populations. No treatment emergent adverse events of hypoglycemia were reported in any patient enrolled in the study. **Conclusion:** Once monthly or bi-weekly dosing of BOS-580 in patients with HbA1c > 5.7% had improvements in glycemic markers comparable to the overall study population, while those with HbA1c > 6.5% demonstrated numerically greater improvements in glycemic markers in a 12-week trial. The potential ability of FGF21-based NASH therapies to treat such patients could be particularly important given the prevalence of T2D in NASH patients and the role of FGF21 in improving glycemic control.

2404-C | CM-101, A CCL24 NEUTRALIZING ANTIBODY, SHOWED IMPROVEMENTS IN INFLAMMATORY, FIBROTIC, AND METABOLIC PATHWAYS IN PATIENTS WITH NASH: PROTEOMICS ANALYSIS OF A PHASE 2a STUDY

Revital Aricha, Ilan Vaknin, Tom Snir, John Lawler, Adi Mor and Matthew Frankel, Chemomab Ltd.

Background: CCL24 (eotaxin-2) is a chemokine that promotes cell trafficking and regulates inflammatory and fibrotic processes. CCL24 plays a central role in the development of hepatic fibrosis and liver injury. Patients with nonalcoholic steatohepatitis (NASH) were noted to have elevated levels of CCL24 and CCR3 in liver and blood samples. Phase 2a study (NCT05824156) of CM-101 in NASH patients, met safety goals and showed improved liver fibrosis biomarkers and physiological assessments. Here, we further elucidate the effect of CM-101 on disease related pathways through an analysis of proteomics data from the serum of patients in the NASH study. **Methods:** Twenty-three patients with NASH, diagnosed by liver biopsy, were randomized to receive 8 administrations of either CM-101 5mg/kg (n = 14) or placebo (n = 9) subcutaneously, every 2 weeks. End of study (EOS) visit occurred 6 weeks post last treatment, at week 20. Sera from patients were analyzed using the Olink™ proximity extension assay (PEA) of 3072 proteins. Differentially expressed proteins between CM-101 and Placebo treated patients were identified using a mixed effect model fitted to the data. To identify pathways differentially modulated from baseline to EOS between CM-101 and placebo groups, Gene Set Enrichment Analysis (GSEA) and Ingenuity Pathway analysis (IPA®) were performed. CCL24 engagement by CM-101 was assessed in the serum. The level of other CCR3 ligands, eotaxin-1 and eotaxin-3, were evaluated to

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

explore potential compensatory effect. **Results:** Serum proteomics analysis using GSEA showed that CM-101 treatment led to significant downregulation in multiple immune related pathways, suggesting amelioration of inflammation, as well as an increase in several metabolic pathways that represent improved glucose metabolism. IPA demonstrated consistent and significant reduction in liver related pathological pathways such as hepatic steatosis and the activation of hepatic stellate cells. Treatment with CM-101 revealed a strong target engagement-profile. Circulating levels of eotaxin-1 and eotaxin-3, which engage to the same receptor CCR3, were not changed during the clinical trial, suggesting no compensatory effect following CCL24 blockade by CM-101. **Conclusion:** The data suggest that CM-101 attenuates fibrotic and inflammatory pathways while improving metabolic pathways – all essential in mitigating the sequelae associated with progressive NASH and other fibrotic liver diseases. CM-101 is currently being evaluated in a PSC phase 2 study.

f 2405-C | COMPARING THE EFFICACY OF DIFFERENT FORMS OF INTERMITTENT FASTING IN THE MANAGEMENT OF NON-ALCOHOLIC FATTY LIVER DISEASE: A NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

Islam Mohamed[1], Mohamed Abuelazm[2], Ahmed Naeem[3], Bassant E. Katamesh[2], Mohammad Tanashat[4], Husam Abusuilik[5], Obieda Altobaishat[6], Mohamed Abdelnabi[7], Hazem Abosheaishaa[8], Mohamed Ahmed[9], Basel Abdelazeem[10] and Hassan Ghoz[9], (1)University of Missouri-Kansas City, (2)Tanta University, (3)Al-Azhar University, (4)Yarmok University, (5)Hashemite University, (6)Jordan University of Science and Technology, (7)University of Michigan, Ann Arbor, Michigan, (8)Icahn School of Medicine at Mount Sinai, (9)University of Missouri- Kansas City, (10) Mclaren Health Care-Flint

Background: Non-alcoholic fatty liver disease (NAFLD) is a prevalent metabolic disorder characterized by excessive accumulation of fat in the liver. It is strongly associated with obesity, insulin resistance, and other components of metabolic syndrome, making it a significant public health concern. Lifestyle modifications, including dietary interventions, have been suggested as means to improve NAFLD outcomes. Intermittent fasting (IF) has emerged as a potential therapeutic strategy. This network meta-analysis aims to compare the effectiveness of different regimens of IF in the management of NAFLD. **Methods:** A comprehensive literature search identified relevant RCTs investigating different regimens of IF for treating NAFLD. PubMed, EMBASE, Web of Science, SCOPUS, and Cochrane, were searched up to April 10th, 2023, using appropriate keywords and MeSH terms. Network analyses were performed using R software with the N-meta packages, Mean difference (MD) was used to pool continuous outcomes with 95% confidence intervals (CIs). Heterogeneity between studies was assessed using χ^2 and I^2 tests, considering heterogeneity at χ^2 P-value < 0.1 and $I^2 > 50\%$. Homogeneous data were pooled using a fixed-effect model, and heterogeneous data were pooled using a random-effect model. Our meta-analysis was registered in PROSPERO under the identification number CRD42023418467. **Results:** Our meta-analysis included 8 RCTs with a total of 635 participants. The 5:2 diet significantly improved liver stiffness compared to placebo (MD: -0.3403, 95% CI: [-0.6626, -0.0181], $p = 0.03$). However, both alternate-day fasting (ADF) and time-restricted feeding (TRF) did not show significant reductions in liver stiffness ; (MD: -0.1764, 95% CI: [-0.4728, 0.1200], $p = 0.2$) and(MD: -0.3817, 95% CI: [-0.9296, 0.1662], $p = 0.1$), respectively. TRF exhibited a significant improvement in liver steatosis (CAP score) (MD: -39.8267, 95% CI: [-64.7827, -14.8707], $p = 0.0018$). No significant changes were observed in AST, GGT, LDL cholesterol, total cholesterol, triglyceride levels, BMI, blood pressure, HOMA-IR, fasting blood sugar, lean body mass, or waist circumference across all IF regimens. However, ADF showed positive results in anthropometric measures, including significant improvements in lean body mass, waist

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

circumference, fat mass, and weight reduction ($p < 0.05$). **Conclusion:** Our network meta-analysis demonstrates the efficacy of intermittent fasting as a management strategy for NAFLD. Specifically, the 5:2 diet exhibited a significant improvement in liver stiffness, while TRF showed a significant improvement in liver steatosis. Furthermore, ADF was associated with positive changes in anthropometric measures. These findings have important implications for tailoring the management of NAFLD patients based on pre-dominant specific conditions such as steatosis, fibrosis, or insulin resistance.

2406-C | COMPARISON OF CIRRHOSIS SURGICAL RISK SCORES AND WEIGHT LOSS AMONG PATIENTS UNDERGOING BARIATRIC SURGERY

Darya Herscovici[1], Avery Pullman[1] and Richard Perugini[2], (1)UMass Memorial, (2)UMass Memorial Medical Center

Background: Nonalcoholic steatohepatitis (NASH) is a leading cause of liver disease for those awaiting transplant. Bariatric surgery (BS) leads to significant and sustained weight loss, correcting metabolic abnormalities associated with NASH, and offers an important intervention in the management of NASH. We present a comparison of surgical risk scores and weight loss outcomes in a population of patients with cirrhosis who underwent longitudinal sleeve gastrectomy (LSG). **Methods:** Inclusion criteria were all patients seen in BS clinic from Oct 2017-Mar 2021 with a concurrent diagnosis of cirrhosis who underwent LSG. Retrospective chart reviews were conducted on 3 groups of patients: Group A: Patients identified with non-alcoholic fatty liver disease (NAFLD), or NASH preoperatively, were evaluated by hepatology, and had a sinusoidal gradient < 8. Group B: Patients where cirrhosis was discovered at the time of BS and there was no evidence of portal hypertension. Group C: Patients who were referred to BS after having undergone a prior liver transplant for NASH. A VOCAL-Penn score measuring 90-day decompensation risk was calculated as a measure of cirrhosis surgical risk. NAFLD fibrosis score was calculated prior to LSG and one year post LSG. **Results:** Four patients met the inclusion criteria for group A. Prior to surgery, mean VOCAL-Penn score was 4.98% (+/- 1.04%) and mean NAFLD fibrosis score was 2.35 (+/- 0.26). One year after surgery, average patients' body weight decreased by 14.4% and mean NAFLD fibrosis score decreased by 0.86 (+/- 0.25). Seven patients met the inclusion criteria for group B. Prior to surgery, mean VOCAL-Penn score was 3.53% (+/- 0.54%) and mean NAFLD fibrosis score was 2.02 (+/- 1.01). One year after surgery, average patients' body weight had decreased by 23.9% and mean NAFLD fibrosis score increased by 0.17 (+/- 0.26). NAFLD fibrosis scores were not significant between groups A or B preoperatively or postoperatively ($p = 0.60$, $p = 0.82$). Four patients met the inclusion criteria for group C. Prior to surgery, mean VOCAL-Penn score was 2.83% (+/- 0.58%). One year after surgery, average patients' body weight had decreased by 26.5%. **Conclusion:** Cirrhosis is an important comorbidity of obesity, and requires the combined efforts of BS, hepatology, transplant surgery, and metabolic weight loss programs. This preliminary study demonstrates that patients who had already undergone a prior liver transplant on average had lower surgical risk and demonstrated greater weight loss than patients

who had not. It also demonstrates that patients who had been evaluated by hepatology had on average improved NAFLD fibrosis scores following LSG, suggesting that multidisciplinary optimization of liver function may be associated with improved outcomes following LSG.

f 2407-C | ECHOCARDIOGRAPHY-BASED MARKERS OF SUBCLINICAL CARDIAC DYSFUNCTION IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE AND PRESERVED EJECTION FRACTION: INTERIM DATA FROM A PROSPECTIVE COHORT

Angelo Armandi[1,2], Alessandro Andreis[1], Matteo Bellettini[1], Kamela Gjini[1], Irene Poggiolini[1], Gabriele Castelnuovo[1], Gian Paolo Caviglia[1], Chiara Rosso[1], Nuria Perez Diaz Del Campo[1], Davide Giuseppe Ribaldone[1], Giorgio Maria Saracco[1], Davide Castagno[1], Alberto Milan[1], Gaetano Maria De Ferrari[1] and Elisabetta Bugianesi[1], (1)University of Turin, (2) University of Mainz

Background: Individual's with Non-Alcoholic Fatty Liver Disease (NAFLD) have abnormal myocardial energy metabolism and reduced coronary functional capacity, even in the absence of risk factors for cardiovascular disease (CVD), potentially associated with cardiac fibrosis and heart failure. We aimed to evaluate diastolic and systolic function in NAFLD individual's with preserved ejection fraction. **Methods:** We prospectively enrolled patients with ultrasound-diagnosed NAFLD and without overt CVD undergoing screening echocardiography (Philips, Andover, US) including speckle tracking analysis for myocardial fiber deformation (strain) in all four cardiac chambers. Significant diastolic dysfunction was defined as mitral E/E' ratio > 9, while systolic dysfunction was defined by left ventricular global longitudinal strain (GLS) > -18%. Significant liver fibrosis (SLF) was non-invasively assessed by either FIB-4 score > 1.3 or liver stiffness measurement (LSM) > 7 kPa by transient elastography. Severe liver steatosis was defined by Controlled Attenuation Parameter (CAP) > 300 dB/m. **Results:** A total of 94 patients were included (median age 53.0 [44.5 – 62.5] years, male sex 43.2%). SLF was detected in 20.0% by FIB-4 and in 14.9% by LSM. Severe steatosis was present in 53.8% of cases. FIB-4 values were significantly higher in patients with diastolic ($p = 0.008$) and systolic ($p = 0.006$) dysfunction. In patients with SLF by either FIB-4 or LSM we found lower absolute values of left atrium reservoir strain (indirect marker of reduced compliance) ($p = 0.027$ and $p = 0.021$, respectively), lower values of left atrium conduit strain (indirect marker of impaired passive emptying) ($p = 0.020$ and $p = 0.0003$) and lower values of right atrium reservoir strain ($p = 0.011$ and $p = 0.007$). Patients with severe steatosis had increased epicardial fat tissue deposition ($p = 0.020$). In a multiple stepwise logistic regression model including type 2 diabetes (T2D), obesity, arterial hypertension, dyslipidemia, male sex and SLF by FIB-4, both SLF and T2D were significantly associated with diastolic dysfunction (Figure 1). **Conclusion:** NAFLD patients with SLF and without overt CVD have impaired pre-clinical markers of cardiac dysfunction. Increased FIB-4 is associated with diastolic dysfunction independently of major CVD risk factors. *The research was supported by the Italian Ministry for Education, University and Research (MIUR) under the programme "Dipartimenti di Eccellenza 2018-2022" Project code D15D18000410001.*

Parameter	Univariate analysis		Multivariate analysis	
	OR (95% CI)	P value	OR (95% CI)	P value
FIB-4 > 1.3	6.8 (1.8 – 25.5)	0.005	6.2 (1.5 – 25.1)	0.011
Type 2 diabetes	4.4 (1.4 – 14.6)	0.015	5.2 (1.4 – 20.0)	0.015
Obesity	1.2 (0.4 – 3.6)	0.765		
Arterial hypertension	2.2 (0.7 – 6.8)	0.154		
Male sex	0.9 (0.3 – 2.9)	0.950		
Dyslipidemia	0.8 (0.3 – 2.4)	0.690		

Univariate and multivariate logistic regression analysis for the association with diastolic dysfunction (increased E/E' ratio).

2408-C | LINAFEXOR: A PULSE FXR LIGAND THAT FITS METABOLIC CYCLE OF BILE ACIDS TO TREAT NASH

Huaqiang Eric Xu, Simm; Cascade Pharmaceutical

Background: Metabolism in all vertebrate animals is subject to 24-hour circadian control, and non-alcoholic steatohepatitis (NASH) is in part caused by bile acid malmetabolism that is out of circadian control.

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Farnesoid X receptor (FXR) ligands have shown promise in treating NASH by modulating bile acid synthesis and metabolism. This study investigates the efficacy and safety of Linafexor (CS0159), a pulse FXR ligand with a short half-life, aligning with the metabolic cycle of bile acids. The importance of considering circadian rhythm and metabolic regulation in drug design is emphasized. **Methods:** In vitro assays assessed Linafexor's FXR agonistic activity and selectivity. A four-week, randomized, placebo-controlled study was performed in 24-week Amylin diet-induced NASH mice, with Linafexor treatment administered daily at three dosage levels (0.1, 0.3, and 1.0 mg/kg). Liver histology, serum bile acid levels, and gene expression involved in bile acid synthesis and metabolism were analyzed. Phase 1 clinical studies included 10 cohorts: 6 single ascending dose (SAD) cohorts (0.2, 0.6, 1.0, 2.0, 4.0, and 8.0 mg/kg) and 4 multiple ascending dose (MAD) cohorts (0.4, 1.0, 2.0, and 4.0 mg/kg). Safety and toxicity were evaluated. **Results:** Linafexor demonstrated potent and selective FXR activation in vitro. In the murine NASH model, Linafexor treatment led to significant reductions in liver steatosis, inflammation, and fibrosis across all dosages, with the 0.3 mg/kg dose showing the greatest efficacy. Serum bile acid levels and gene expression were modulated in a circadian-dependent manner, consistent with Linafexor's short half-life and metabolic rhythms. Linafexor has unique tissue distribution, with a 10-fold enrichment in the liver. Phase 1 studies showed linear exposure of Linafexor with dosing and no adverse effects associated with treatment. **Conclusion:** Linafexor (CS0159), a pulse FXR ligand with a short half-life, demonstrated significant efficacy in treating NASH by modulating the metabolic cycle of bile acids in accordance with circadian rhythms. Circadian-dependent effects on bile acid metabolism may contribute to its enhanced efficacy and safety profile. The excellent safety profile observed in Phase 1 studies, along with an ongoing Phase 2 study, supports further investigation of Linafexor as a promising therapeutic option for NASH. Preliminary Phase 2 efficacy and safety data will be presented in the meeting.

f 2409-C | LIVER CELL-TYPE SPECIFIC MOLECULAR SIGNATURES MARKING TRANSITION FROM ADVANCED FIBROSIS TO CIRRHOSIS IN HUMAN NON-ALCOHOLIC STEATOHEPATITIS

Michael Feigh[1], Mathias Bonde Møllerhøj[2], Martin Rønn Madsen[2], Mikkel P Werge[3], Mikkel Christensen-Dalsgaard[2], Sanne Veidal[4], Lise C.B. Rudkjær[2], Elisabeth Douglas Galsgaard[5], Lise Lotte Gluud[3] and Henrik B. Hansen[2], (1)Gubra Aps, (2)Gubra, (3)Gastro Unit, (4)Global Drug Discovery, Novo Nordisk a/S, Novo Nordisk Park 1, 2760 Maalov, Denmark, (5)Novo Nordisk

Background: Hepatic fibrosis is the strongest predictor of morbidity and mortality in nonalcoholic steatohepatitis (NASH), establishing fibrosis as a critical therapeutic target in this disease. To improve treatment outcomes in NASH, the specific roles and molecular signaling mechanisms of hepatic cell types in the progression of fibrosis must be clarified. Here, we developed a transcriptomic map at cellular resolution, defining molecular signatures of parenchymal and non-parenchymal cell types across all stages of fibrosis in human NASH. **Methods:** Bulk RNA sequencing (RNAseq) was performed on snap-frozen liver biopsies obtained from a patient cohort of 40 obese individual's with NASH (stages F0-F4, n = 4-10 per fibrosis stage) or no/mild NAFLD (macrovesicular steatosis) without fibrosis (control group, n = 7). Paired single-nucleus (sn) RNA-seq analysis was performed on a subset of biopsies (control, NASH F0-1, NASH F2-3, NASH F4; n = 4 per group). Cell type deconvolution of differentially expressed genes in bulk RNAseq samples was based on corresponding snRNAseq data. **Results:** The transcriptomics platform enabled paired bulk and single-nucleus (sn) RNAseq analysis on small percutaneous/transjugular human liver biopsies (d 5 mg tissue). The number of differentially expressed genes increased progressively with disease severity. Transcriptome signatures were clearly separated from NASH patients with cirrhosis (fibrosis stage 4), demonstrating perturbations in genes associated with extracellular matrix remodeling and the immune system. Bulk RNAseq data were cross-referenced to public bulk RNAseq data sets for further data validation. snRNAseq yielded data from 33,764 nuclei after quality control, recovering all major liver cell types in both control and disease samples based on cell-specific marker genes. Subclustering of snRNAseq datasets revealed multiple subtypes of hepatic stellate cells (HSCs) relevant in the progression of fibrosis. **Conclusion:** We report a state-of-the-art integrative transcriptomics pipeline mapping molecular changes in liver non-parenchymal cell types covering the entire spectrum of fibrosis in NASH patients. Distinct

2410-C | META-ANALYSIS OF RNA-SEQ SIGNATURES ALLOWS FOR ROBUST DECONVOLUTION OF SINGLE CELL LINEAGES IN PATIENTS WITH NASH AND ADVANCED FIBROSIS

Tingbo Guo[1], Sha Cao[1], Tiebing Liang[2], Prakash Ramachandran[3] and Naga P. Chalasani[2], (1) Deparment of Biostatistics & Health Data Science, Indiana University School of Medicine, Indianapolis, Indiana, USA, (2)Division of Gastroenterology and Hepatology, Department of Medicine, Indiana University School of Medicine, Indianapolis, Indiana, USA, (3) Institute for Regeneration and Repair, Center for Inflammation Research, University of Edinburgh

Background: Non-alcoholic Fatty Liver Disease (NAFLD) is a progressive liver disease which can lead to cirrhosis and cancer. Necroinflammation and fibrosis are important intermediary steps prior to developing cirrhosis and they involve alterations in hepatic parenchymal and non-parenchymal cell (NPC) populations. Deconvolution of gene expression can be utilized for molecular phenotyping of cell populations within a tissue and can help better understand the disease pathogenesis and identify therapeutic targets. Aim: To conduct a meta-analysis of multiple human hepatic gene expression datasets for characterizing alterations in cell populations through deconvolution in patients with biopsy-proven NAFLD. **Methods:** We have conducted a meta-analysis of 9 hepatic bulk RNA-Seq and 4 microarray data from patients with human NAFLD. The total number of patients included was 1276; 576 with F0-F1 and 398 with F e 3 fibrosis. All data sets are available in the public domain except one. Using the unique top 50 high expression marker genes defined by the log2FC from liver single-cell RNA-seq data and a novel in-house deconvolution algorithm, we characterized 12 individual cell lineages: mononuclear phagocytes (MPs), plasmacytoid DCs, innate lymphoid cells (ILC), T cells, B cells, plasma cells, mast cells, endothelial cells, mesenchyme, mesothelia, hepatocytes, and cholangiocytes. Primary comparison was between advanced hepatic fibrosis (e F3) vs no/low fibrosis (F0-F1). Single cell deconvolution was conducted by employing the nonparametric Wilcoxon test to calculate the P-value for each dataset and then applied additive method for combining the p-values from the independent datasets. The adjusted meta P-value < 0.05 was considered significant for a cell population difference between two groups. **Results:** Deconvolution was initially conducted on individual bulk RNA-Seq and microarray datasets based on differentially expressed genes between F e 3 and F1-F0 and a meta-analysis of 13 deconvolution datasets was subsequently undertaken. Table 1 summarized cell lineages that are significantly different between F e 3 and F0-F1 groups. Among those cell types, F e 3 patients have increased cell proportions of several NPCs, including pDC, T cells, B cells, plasma cells, mast cells, endothelia, mesenchyme, and cholangiocytes when compared to F0-F1. **Conclusion:** Transcriptomic meta-analysis combined with deconvolution has identified a number of non-parenchymal cell lineages which are increased in the livers of patients with NASH and advanced fibrosis, highlighting the complexity of NASH pathobiology and the importance of targeting NPC cross-talk when exploring new therapeutic strategies.

Cell types	Cell propotion F≥3 higher than F0-F1	Cell propotion F≥3 less than F0-F1

Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA

Background: Manual histological evaluation of liver biopsy is the gold standard method for fibrosis staging in Non-Alcoholic Steatohepatitis (NASH), but it is limited by its inter and intra-reader variability. The use of single-fiber, quantitative and high resolution Digital Pathology image analysis offers the to describe specific traits that account for disease progression and/or regression or treatment response. In this exploratory post-hoc analysis, we used FibroNest digital pathology to identify fibrosis traits of treatment, and dose response from the phase 2b FALCON1 study of pegbelfermin (PGBF) in NASH (NCT0348699). **Methods:** Eligible adults were 18-75 years of age (N = 197) with NASH and stage 3 fibrosis diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria. During the 48-week double-blind treatment period, patients received subcutaneous 10mg, 20mg, or 40mg PGBF or placebo once weekly. Liver biopsies were obtained up to six months prior to or during screening and at week 24. Formalin-fixed, paraffin embedded sections of the liver biopsies were stained with Masson Trichrome and imaged at 40X. Each digital image was evaluated for quality along 20 dimensions (tissue processing, staining, and scanning) to generate a Digital Biopsy Adequacy Score (DBA). Quantitative image analysis was performed to extract single-fiber quantitative traits (qFTs, N = 315) from the fibrosis composition, morphometric and architectural histological phenotypes. Traits that exhibited a significant ($p < 0.05$) and meaningful ($> 20\%$) mean change from baseline were identified and reported, and then normalized and combined in a composite score of Treatment Engagement (TrES). **Results:** Groups sizes ranged from 34 to 39 per group for patients with paired data following removal of those samples considered nonvaluable for Pharmanest algorithms (i.e., DBA < 5). We identified 26 traits of response, 16 of which were readily interpretable (Fig. A, B). P-values of the group mean % change from baseline of the TrES for the placebo, 10mg, 20mg, 40mg groups are 0.09, 0.41, 0.05 and 0.04 respectively. The TrES relative % change from baseline exhibits a dose response trend (Fig), consistent with previous published results with some biomarkers (doi.org/10.1016/j.jhepr.2022.100661). The TrES corresponds well with NASH-CRN Fibrosis stages, but with a performance that is less than the FibroNest Phenotypic Fibrosis Score (Ph-FCS, as reported previously) at low levels of fibrosis (F1-2). **Conclusion:** Twenty-six histological traits of treatment response are identified with high-resolution digital Pathology methods and evaluated in the context of the PGBF intervention. The related Treatment Engagement composite continuous score detects the antifibrotic effect of PGBF treatment with moderate performance as seen for similar outcomes (Histology, fibrotic biomarkers) reported for this study.

2413-C | POPULATION PHARMACOKINETIC/ PHARMACODYNAMIC MODELING OF HEPATIC FAT FRACTION SUGGESTS EQUIVALENT EFFICACY BETWEEN ONCE MONTHLY AND BI-WEEKLY DOSING OF BOS-580 IN PHENOTYPIC NASH PATIENTS

Swapan Chowdhury[1], Aruna Dontabhaktuni[2], Tatjana Odrljin[1], Alicia Clawson[1], Etienne Dumont[1], Vijay Bhargava[3], Eric Svensson[1] and Serge Guzy[4], (1)Boston Pharmaceuticals, (2)Pharmapro Consulting Inc., (3) Nejay Consultant Inc, (4)Poppharm

Background: FGF-21 analogs have been shown to increase NASH resolution and improve fibrosis in NASH patients with once weekly and bi-weekly dosing. BOS-580 is an investigational FGF21-IgG fusion protein engineered to have an extended serum half-life in humans. In a healthy volunteer Phase 1 study, BOS-580 showed a dose-dependent increase in exposure with a terminal half-life of approximately 21 days following subcutaneous administration, suggesting the feasibility of bi-weekly or once monthly dosing. **Methods:** A Phase 2a study was designed to examine the safety, pharmacokinetics, and pharmacodynamics of a range of dose levels and dosing frequencies in a 12-week treatment period to identify an optimal regimen for patients with phenotypic NASH. Pharmacodynamic endpoints included % change from baseline in hepatic fat fraction as measured by MRI-PDFF. This study enrolled 102 patients, with a VCTE LSM score of 7-9.9 kPa, AST > 20 IU/ml, and MRI-PDFF e 10%. BOS-580 PK data from phase 1 studies with rich PK sampling were used to generate population PK (Pop-PK) estimates for BOS-580 that were then used to perform Bayesian analysis on the Phase 2a PK data with sparse sampling. A sequential PK/PD analysis followed on the MRI-PDFF data and individual predicted PK profiles from the Bayesian analysis. The PK/PD model was an indirect response model with MRI-PDFF reduction by the predicted drug concentration. A simultaneous PK/PD fit was performed to assess % change from baseline in MRI-PDFF for different doses and dosing regimens, and to determine the dose/regimen required to achieve 30, 50, and 70% MRI-PDFF reduction. **Results:** Pop-PK analysis identified dose proportional increases in AUC_{tau} at steady state; exposure was independent of dosing regimen for same total monthly dose. There was a good fit, with no obvious bias in the observed vs predicted PK and MRI-PDFF data. The PK/PD model predicted with high confidence the following: a) median % MRI-PDFF reduction with 150mg to 300mg monthly dose ranged from ~57-62% (Figure 1), b) at doses e 200mg monthly, > 70% of patients are predicted to reduce MRI-PDFF by > 50%, and c) the % reduction in MRI-PDFF is similar whether a total monthly dose is given bi-weekly or once-a-month (Figure 1). **Conclusion:** Once monthly dosing of BOS-580 appears to be as effective as bi-weekly dosing for the reduction of liver fat in patients with phenotypic NASH, supporting the notion that BOS-580 is an FGF-21 analog capable of once monthly dosing.

Figure 1: Median Model Predicted % HFF Reduction at Week 12 as a Function of Total Dose Administered for Both — Q4W and ---- Q2W

2414-C | POSTPRANDIAL PLASMA PROTEOMICS IN NON-ALCOHOLIC FATTY LIVER DISEASE

Maria Mironova, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, Paul S. Blank, National Institute of Child Health and Human Development, Regina Umarova, National Institute of Diabetes and Digestive and Kidney Diseases and Yaron Rotman, National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: The drivers of progression from steatosis to non-alcoholic steatohepatitis (NASH) and subsequent fibrosis in non-alcoholic fatty liver disease (NAFLD) are unclear. Most studies focus on long-term energy imbalance and the fasting state, while the acute alterations of metabolism after a single caloric load are relatively unstudied. We previously identified unique postprandial alterations in the plasma lipidome in subjects with NAFLD. We hypothesized that similar unique alterations will be seen in the plasma proteome. **Methods:** A single-center prospective study. Subjects with NAFLD and healthy controls were fed a standardized liquid mixed meal (Ensure Plus). Plasma samples were obtained at fasting, and 2 and 4 hours after the meal. The plasma proteome at each time point was measured using the SomaScan assay. Repeated measures ANOVA was used to assess temporal patterns, focusing on targets that had a significant groupXtime interaction. The KEGG database was used for pathway analysis. **Results:** We included 34 subjects with NAFLD and 7 controls. 1,317 unique proteins were quantified at each of the three time points. Of these, 42 plasma proteins were significant for interaction, i.e. had postprandial temporal patterns that significantly differed between NAFLD and controls, independently of fasting levels. Pathway analysis revealed enrichment of pathways in energy metabolism (as anticipated), cytokine signaling, complement cascade, and acute phase reaction, most likely derived from the liver. At the fasting state, NAFLD subjects had higher levels of chemokines CCL16, CCL21 and CCL23, hepcidin, complement decay accelerating factor (DAF), C1 esterase inhibitor, TNF receptor superfamily member 1B, and IL-1 receptor-like 1. Postprandially, however, there was an increase in these proteins in healthy controls while in NAFLD, they were either decreased or demonstrated a blunted response (Fig. 1). **Conclusion:** In this first study in humans exploring the postprandial plasma proteome in NAFLD, we identified a physiological postprandial upregulation of inflammatory plasma proteins that is impaired in people with NAFLD. Postprandial oxidative stress, endothelial dysfunction, and microbial translocation are all putative drivers of this response and also implicated in NASH. The decrease or blunting of postprandial inflammatory responses in subjects with NAFLD suggest impaired compensatory mechanisms in NAFLD and greater susceptibility to liver injury after a meal.

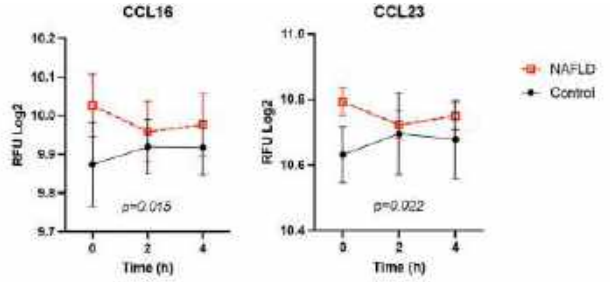

Figure 1. Example of postprandial behavior of chemokines CCL16 and CCL23. Data presented as mean ±SEM, p-values for groupXtime interaction (RFU - relative fluorescence units).

Background: Turkey is considered a high-risk region for NAFLD; however, there are limited prospective data available to evaluate its prevalence among at-risk Turkish populations with metabolic risk factors such as obesity, metabolic syndrome, and diabetes. Therefore, we aimed to estimate the prevalence of NAFLD and liver fibrosis, as well as identify associated factors, among Turkish individual's with multiple metabolic disorders. **Methods:** We enrolled 436 adult participants for a single-centered prospective study in an outpatient clinic during a one-year period. All participants presented with at least one component of the metabolic syndrome. Physical examination, anthropometrical assessment and blood analysis were performed in a standardized clinical research visit. Individual's with excessive alcohol consumption (>2U/day for women, >3U/day for men) were excluded. Controlled attenuation parameter (CAP), and liver stiffness measurements (LSM) by a Vibration controlled transient elastography (VCTE) device (FibroScan®; Echosens, Paris, France) were used to determine NAFLD and fibrosis, respectively. NAFLD was defined as CAP $\geq$ 248 db/M and fibrosis as LSM $\geq$ 7.2 kPa in XL probe and $\geq$ 7.9 kPa in M probe. Multivariable logistic and linear regression models were used to investigate the association of NAFLD and LSM with age, sex, waist circumference (WC), BMI, alcohol, smoking, diabetes, hypertension, dyslipidemia, metabolic syndrome, vitamin D deficiency, insulin resistance, transaminases, and HbA1c. **Results:** Overall, among the 436 individual's included in the analysis, NAFLD and fibrosis prevalence were 48.2% (95% CI: 43.5%, 52.9%) and 6.9% (95% CI: 4.9%, 9.7%), respectively. The mean CAP was 247.3 ± 49.7 db/M and the mean LSM was 5.3 ± 2.7 kPa. Multivariable logistic regression analysis of NAFLD revealed a significant association with obesity (OR = 3.999; 95% CI: 2.293, 6.974), male sex (OR = 0.483; 95% CI: 0.266, 0.876), metabolic syndrome (OR = 6.234; 95% CI: 3.401, 11.428), and vitamin D deficiency (OR = 1.831; 95% CI: 1.057, 3.174). Multivariable linear regression of LSM demonstrated a significant association with obesity (B = 1.079; 95% CI: 0.615, 1.543), insulin resistance (B = 0.070; 95% CI: 0.022, 0.119), and HbA1c (B = 0.273; 95% CI: 0.051, 0.494). **Conclusion:** NAFLD is prevalent in nearly half of the at-risk population studied. Male sex, obesity, metabolic syndrome, and vitamin D deficiency are significant risk factors associated with it. Despite the high NAFLD prevalence, liver fibrosis is less prevalent and is associated with obesity, insulin resistance and HbA1c. Further research is warranted in this population.

f 2416-C | PROTEIN BARCODE OF CIRCULATING EXTRACELLULAR VESICLES IN CHILDHOOD OBESITY ASSOCIATES WITH METABOLIC FACTORS FOR NAFLD AND MAY AFFECT THE FUTURE DEVELOPMENT OF MUSCLE AND NERVOUS SYSTEM

Yoshinao Kobayashi[1], Akiko Eguchi[2], Koshi Imami[3], Yasuyuki Tamai[1], Motoh Iwasa[1] and Hayato Nakagawa[4], (1)Mie University, (2)Mie University, Tsu, Mie, Japan, (3)Riken Center for Integrative Medical Science, (4)Mie University, Mie, Japan

Background: Childhood obesity frequently transitions to adult obesity and is known to be a risk factor for developing metabolic syndrome (MetS) including NAFLD. We had demonstrated that circulating extracellular vesicles (EVs) and EV-protein composition were significantly associated with MetS-related factors in adult. Here, we investigate the association of circulating EV numbers with metabolic factors and perform comprehensive proteomics analysis of EV cargo in children. **Methods:** Weight status of the enrolled 107 children (69 boys, 38 girls, median age, 10 y) with or without obesity was evaluated by both of body mass index (BMI)-for-age and relative body weight (RBW). Various metabolic parameters, including body composition, liver function, lipid and glucose metabolism, were measured. Additionally, the ratio of liver CT attenuation value/spleen CT attenuation value (liver/spleen CT) was measured as an index of hepatic steatosis. Circulating EV number was measured using Calcein AM staining and fluorescence flow cytometry. Comprehensive proteomic analysis was performed using nano liquid chromatography tandem-mass spectrometry. Correlation between circulating EV numbers and metabolic parameters were evaluated using Spearman's test and multiple regression analysis. Anthropometric and laboratory values among multiple groups divided by degrees of obesity were compared using Kruskal-Wallis test. **Results:** Circulating EV number was positively correlated with many physical and laboratory metabolic parameters, comprised BMI-for-age (rho = 0.450, $P < 0.001$), RBW (rho = 0.504, $P < 0.001$), ALT (rho = 0.273, $P < 0.05$) and triglyceride (TG, rho = 0.614, $P < 0.001$), whereas it was inversely correlated with liver/spleen CT (rho = -0.330, $P < 0.05$). TG (standard partial regression (SPRC) = 0.548, $P < 0.001$, 95% CI 0.404-1.041) and RBW (SPRC = 0.469, $P < 0.05$, 95% CI 0.090-0.851) were detected as an independent factor to determine the circulating EV number. Degree of obesity evaluated by RBW was significantly correlated with circulating EV number ($P < 0.001$) and liver/spleen CT ($P < 0.01$). Proteomic analysis identified 31 up-regulated and 45 down-regulated EV proteins in

childhood obesity. Gene ontology analysis revealed up-regulated proteins to be involved in various biological processes, including intracellular protein transport, protein folding, stress response, inflammation and immune response, which can modulate lipid and glucose metabolism. In addition, several proteins involving in development of skeletal and cardiac muscle and nervous system were up-regulated in childhood obesity. **Conclusion:** Circulating EVs of childhood obesity are significantly associated with MetS-related dysmetabolism including NAFLD. A special "barcode" of EV protein cargo indicates that childhood obesity may affect not only NAFLD, but also the future development of skeletal and cardiac muscles and nervous system.

2417-C | SAMM50-rs2073082, -rs738491 AND -rs3761472 INTERACTIONS ENHANCEMENT OF SUSCEPTIBILITY TO NON-ALCOHOLIC FATTY LIVER DISEASE

Jinhan Zhao[1], Jing Zhang[2], Yang Zhang[3], Xiaoyi Xu[1], Xinhuan Wei[3], Shuang Zhang[1], Hangfei Xu[1] and Xiao die Wei[1], (1)Department of Hepatology, Beijing Youan Hospital, Capital Medical University, (2)Beijing Youan Hospital, Capital Medical University, (3)Beijing Youan Hospital Capital Medical University, Beijing, China

Background: Genetic single nucleotide polymorphisms (SNPs) play a decisive role in the susceptibility and development of non-alcoholic fatty liver disease (NAFLD). Several studies have identified that three sorting and assembly machinery component 50 (SAMM50) polymorphisms (rs2073082, rs738491, rs3761472) are associated with an increased risk of NAFLD. However, the clinical significance of SAMM50 SNPs in relation to NAFLD remains largely unknown. Therefore, we conducted a clinical study and SNP-SNP interaction analysis to further elucidate the effect of SAMM50 SNPs on the progression of NAFLD in the elderly. **Methods:** Totally 1053 patients over age 65 years were recruited. Fatty liver was detected by abdomen ultrasound. Liver fat content and fibrosis stage were evaluated by Fibro Scan. Genomic DNA was extracted and then genotyped by Fluidigm 96.96 Dynamic Array. A multivariable logistic regression was used to evaluate the association between NAFLD and SNPs. SNP-SNP interactions were analyzed using generalized multivariate dimensionality reduction (GMDR). **Results:** The risk of NAFLD was substantially higher in people who carried SAMM50-rs2073082 G allele and -rs738491 T allele (OR, 1.962; 95% CI, 1.448-2.659; $p < 0.001$; OR, 1.532; 95% CI, 1.246-1.884; $p = 0.021$, respectively) compared to non-carriers. Carriers of the rs738491 T allele and rs3761472 G allele in the cohort showed a significant increase in liver stiffness measurements (LSM). The combination of three SNPs was showed the highest predictive power for NAFLD (cross-validation consistency [CVC], 10/10). Allele G-T-G carriers have a two-fold higher risk of NAFLD compared to haplotype A-C-A. **Conclusion:** Our results demonstrated that SAMM50-rs2073082 G and -rs738491 T allele were significantly associated with NAFLD susceptibility in Chinese elders, while rs738491 T allele and rs3761472 G allele were related to higher fibrosis. Furthermore, we present novel findings that a three-SNP combination model can accurately predict the risk of NAFLD vulnerability.

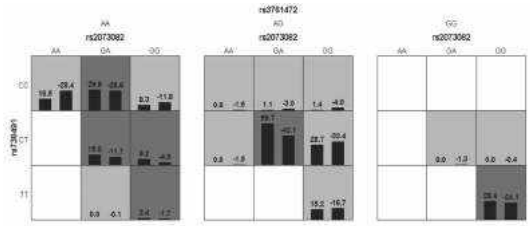

Figure legends:Gene–gene interactions among SAMM50 rs2073082, rs738491 and rs3761472 loci in NAFLD and Control subjects.The score distribution of NAFLD subjects (left black bar in boxes) and control subjects (right black bar in boxes) is shown for each genotype combination. High-risk genotype combinations are represented by dark gray shade cells, while light gray shade cells represent low-risk genotype combinations. Cells with no shading or white cells represent genotype combination for which no data is observed.

Disclosures: The following people have nothing to disclose: Jinhan Zhao, Jing Zhang, Yang Zhang, Xiaoyi Xu, Xinhuan Wei, Shuang Zhang, Hangfei Xu, Xiao die Wei

2418-C | SINGLE TESTING WITH MASLD MACHINE LEARNING MODELS (MASMLS) PERFORM EQUALLY TO CURRENT GUIDELINE ALGORITHMS OF SEQUENTIAL TESTING USING FIBROSIS-4 INDEX AND TRANSIENT ELASTOGRAPHY

Devon Chang[1], Emily Truong[2], Ju Dong Yang[2], Naim Alkhouri[3], Stephen A Harrison[4] and Mazen Noureddin[5], (1)Arnold O. Beckman High School, (2)Cedars-Sinai Medical Center, Los Angeles, CA, (3)Arizona Liver Health, Phoenix, AZ, (4)Pinnacle Clinical Research Center, San Antonio, TX, (5)Houston Research Institute, Houston, TX

Background: Current guidelines recommend screening patients with NAFLD (or MASLD) risk factors using sequential testing with FIB-4 followed by transient elastography, or FibroScan® (FIB-Fibro) to stratify risk for advanced liver fibrosis. We assessed the performance of a new MASLD machine learning model (MASML) (Chang et al. *Hepatology* 2022) (single test)

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

vs FIB-Fibro (sequential testing) in predicting the risk of significant/advanced liver fibrosis. **Methods:** MASML, a random forests model, was the best model among logistic regression, random forests, and artificial neural network to predict risk of significant/advanced fibrosis (≥F2/≥F3) using 17 routine demographic/clinical features in 1223 MASLD patients at multiple US centers. Patients had ≥1 MASLD risk factors (≥2 metabolic risk factors, type 2 diabetes, steatosis, high aminotransferases) and underwent liver biopsy, FibroScan®, and laboratory testing within a 6-month period. We used 80% of the cohort to train and 20% to test MASML. We assessed the correctly classified (CC) measurement percentage of indeterminate-risk patients, sensitivity (Sn), specificity (Sp), and accuracy (Ac) to compare MASML to FIB-Fibro. **Results:** There was no statistically significant difference between the CCs of MASML and that of FIB-Fibro (67.47% (CI: 64.67%-70.27%) vs 70.53% (CI: 66.51%-74.55%)), or between the percentage of indeterminate patients of MASML vs FIB-Fibro (14.16% (CI: 12.47%-15.86%) vs 11.51% (CI: 10.13%-12.89%)). For ≥F2, there was no significant difference in Sn or Ac between MASML and FIB-Fibro (Sn 0.78 (CI: 0.73-0.82) vs 0.85 (CI: 0.8-0.9); Ac 0.79 (CI: 0.77-0.81) vs 0.74 (CI: 0.7-0.77)). MASML had significantly higher Sp vs FIB-Fibro (0.81 (CI: 0.79-0.83) vs 0.55 (CI: 0.51-0.59)). For ≥F3, there was no significant difference in Sn between MASML and FIB-Fibro (0.73 (CI: 0.67-0.8) vs 0.68 (CI: 0.63-0.73)), and MASML had significantly higher Sp and Ac compared to FIB-Fibro (Sp 0.89 (CI: 0.87-0.92) vs 0.76 (CI: 0.71, 0.81); Ac 0.84 (CI: 0.83-0.86) vs 0.72 (CI: 0.68-0.76)). Other MLs are shown. **Conclusion:** Though there was no difference between MASML and FIB-Fibro in the prediction of risk of significant/advanced liver fibrosis, MASML had higher Sp than FIB-Fibro. Single test MASML may replace sequential FIB-Fibro in guidelines to identify at risk NASH patients, since MASML uses routine demographic/clinical features rather than costly imaging technology and can thus be used in primary care settings.

2419-C | SPLEEN STIFFNESS IS ASSOCIATED WITH GENDER AND BMI: RESULTS FROM A COHORT AT RISK OF NAFLD

Gediz Dogay Us[1,2], Ozgur Mustafa Koc[3], Francesco Innocenti[1], Ihsan Nuri Akpinar[2] and Ger H. Koek[1,3], (1) Maastricht University, (2)Pax Clinic, (3)Maastricht University Medical Center

Background: Spleen stiffness (SS) is a crucial diagnostic tool to rule out and rule in clinically significant portal hypertension, particularly in cases of viral etiology. While its correlation with liver stiffness (LS) has been established in viral liver disease, there is limited knowledge regarding SS and its associated risk factors in other etiologies. Additionally, there is a lack of evidence regarding the normal ranges of SS in populations at risk of NAFLD. Hence, we aimed to assess spleen stiffness and identify factors related to it in a population at risk of NAFLD with multiple metabolic disorders. **Methods:** We enrolled 436 adult participants for a single-centered prospective study in an outpatient clinic during a one-year period. All participants presented with at least one component of the metabolic syndrome. Physical examination, anthropometrical assessment and blood analysis were performed in a standardized clinical research visit. Individual's with excessive alcohol consumption ($>$2U/day for women, $>$3U/day for men) were excluded. Controlled attenuation parameter (CAP), liver stiffness measurements (LSM) and spleen stiffness measurement (SSM) by a Vibration controlled transient elastography (VCTE) device (FibroScan®; Echosens, Paris, France) were used to determine NAFLD, liver fibrosis and spleen stiffness, respectively. Spleen was located with the embedded ultrasound probe and the SS was measured with the spleen probe that can produce a 100-Hz wave. Univariable and multivariable linear regression analyses were used to investigate the association of SS with CAP and LS, respectively, adjusting for the following potential confounders: age, sex, WC, BMI, alcohol, smoking, diabetes, hypertension, dyslipidemia, metabolic syndrome, insulin resistance, transaminases, and Hba1c. **Results:** Mean spleen stiffness was 26.34 ($\pm$ 11.97) kPa in the recruited sample. The univariable analyses showed that spleen stiffness was positively associated with CAP (B = 0.042; 95% CI: 0.017, 0.066) and LSM (B = 1.472; 95% CI: 0.921, 2.023). After adjusting for age, sex, WC, BMI, alcohol, smoking, diabetes, hypertension, dyslipidemia and metabolic syndrome, insulin resistance, transaminases, and Hba1c, the association remained statistically significant with LSM (B = 0.952; 95% CI: 0.353, 1.551) but not with CAP (B = -0.006; 95% CI: -0.039, 0.027). In both adjusted models, SS was also significantly associated with BMI and gender. **Conclusion:** SS is associated with LS, male sex, and BMI in a population at-risk of NAFLD. The observed association between SS and LS reinforces previous evidence, while this study is the first to demonstrate an association between SS, gender and BMI. These findings may serve as a reference point for assessing SS, particularly in patients at risk of NAFLD. Further research is warranted to identify other risk factors that influence spleen stiffness across the spectrum of liver diseases.

2420-C | THE CONCOMITANT ZONAL QUANTIFICATION OF QSTEATOSIS AND QFIBROSIS USING HISTOINDEX AI DIGITAL PATHOLOGY IMPROVES DETECTION OF LIVER INJURY REGRESSION POST-BARIATRIC SURGERY

Vlad Ratziu[1], Raluca Pais[2], Judith Aron-Wisnewsky[3], Frederic Charlotte[4], Dean Tai[5], Elaine Lay Khim Chng[5], Desiree Abdurrachim[6], Chih-Liang Chin[7], Saswata Talukdar[7] and Asad Abu Bakar Ali[6], (1)Sorbonne Université, Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Institute of Cardiometabolism and Nutrition (ICAN), (2)Aphp, (3)Pitié-Salpêtrière Hospital, (4)Sorbonne Université, Ican Institute, Hôpital Pitié-Salpêtrière, (5)Histoindex Pte Ltd, Singapore, (6) Cardiometabolic Diseases, MSD, Singapore, (7) Cardiometabolic Diseases, Merck & Co., Inc., South San Francisco, CA

Background: Conventional microscopy histological reads are semi-quantitative and subjective. AI-assisted digital pathology (DP) allows automated and quantitative staging/grading of liver injury in NASH. We aimed to examine the potential of second harmonic generation/two photon excitation fluorescence (SHG/TPEF)-based AI DP to detect histological changes post-bariatric surgery and patterns of fibrosis and steatosis response. **Methods:** Unstained paired liver biopsies (baseline and $>$1-year post-surgery) from 41 obese patients with

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significant liver injury (SAF activity grades 3 or 4 or NASH CRN fibrosis stages 3 or 4, Hepatology Vol 76:456-68) were included. SHG/TPEF provided qualitative (qF-stage and qS-grade) and quantitative (continuous qF and qS scores) measurements of fibrosis and steatosis, respectively. Steatosis was quantified in lobular zones 1, 2 and 3 with concomitant measurement of fibrosis changes around the fat vacuoles. **Results:** The distribution of qF-stages was 0: 13%; 1: 18%; 2: 31%; 3: 33% and 4: 4% and that of qS-grades 0: 10%; 1: 26%; 2: 31%; 3: 33%. Fibrosis regression according to qF-stage was seen in 71% (29/41), stabilisation in 22% (9/41) and progression in 7% (3/41) of patients. The proportion of qF3/qF4 dropped from 56% preoperatively to 22% at follow-up. The change in qF score documented a more dynamic level of fibrosis changes with only 1 patient (2%) displaying stabilisation while 81% (33/41) had improved fibrosis and 17% (7/41) worsened. qS-grade documented steatosis reduction in 73%, stabilization in 17% and worsening in 10% which was corroborated by the qS score. Co-localisation analysis showed changes in steatosis led to changes in adjacent fibrosis. While pts with qS score reduction had fibrosis regression, those with stable or increased qS score had persistent fibrosis and steatosis in zones 2 and 3. **Conclusion:** SHG/TPEF analyses replicated the findings of conventional pathology (improvement in a majority of patients but persistence of advanced fibrosis despite successful bariatric surgery) while providing important additional insights: 1) continuous scores documenting a larger dynamic range of fibrosis change; 2) co-localization analyses detecting patterns and kinetics of fibrosis improvement in relation to steatosis regression. SHG/TPEF AI-DP provides a more thorough documentation of liver injury improvement post-bariatric surgery than conventional microscopy.

Figure: Sankey diagram showing the proportion of patients in each (A) steatosis grade and (B) fibrosis stage pre- and post-bariatric surgery according to SHG/TPEF AI-DP. Percentages detail the proportion of the total cohort in each stage/grade.

2422-C | VLDL LIPIDOMIC PROFILING REVEALS ALTERED GLUCOSYLCERAMIDE METABOLISM IN NONALCOHOLIC FATTY LIVER DISEASE RELATED LIVER FIBROSIS

David Guardamino Ojeda, Yusuf Yalcin, Michelle Lai and Z. Gordon Gordon Jiang, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: The secretion of very low-density lipoprotein (VLDL) is the primary mechanism by which hepatocytes remove lipids from its cellular organelles into the circulation. It is produced entirely by the liver and has a short-half life in the circulation. Hereby, lipid composition in VLDL provides a unique window to assess hepatocellular lipid homeostasis. This study aims to evaluate how VLDL lipid changes with liver fibrosis in nonalcoholic fatty liver disease (NAFLD). **Methods:** Fresh frozen plasma from 157 patients with biopsy proven NAFLD were used to prepare VLDL using ultracentrifugation. Lipidomic analysis was performed on lipids extracted from VLDL using Gas Chromatography / Mass Spectrometry (GC/MS). Lipidome values were normalized by total plasma VLDL particle concentration measured by NMR spectroscopy and batch effect was successfully removed using Limma algorithm. The relationship between lipidome and liver fibrosis was analyzed with multivariate regression in LipidR. **Results:** Out of the 1507 analyzed lipid species, we identified 8 significant lipid molecules associated with advanced fibrosis (F3-4) as compared to no or early-stage fibrosis (F0-2). Dihexoacylceramide (CerG2) 39:6, sterol (ST) 44:4 and phosphatidic acid (PA) 32:4 were upregulated, while cholesterol ester (ChE) 18:0, sphingomyelin (SM) 47:3, triacylglycerol (TG) 18:1/17:1/20:4, ceramide (Cer) 18:1/26:0 and SM 34:2 were downregulated (Figure 1). While the inverse association between ChE, TG and liver fibrosis have been reported previously, the correlation with sphingolipids were unexpected. Lipid subspecies analyses revealed a decrease in CerG2 precursors, including ceramides and sphingomyelin among those with advanced fibrosis. Meanwhile, CerG2, a type of glycosylated sphingolipids, showed a significant increase. Lipid set enrichment analysis confirmed the positive enrichment of sterol, monohexoacylceramide (CerG1) and CerG2 lipid species. Furthermore, advanced fibrosis was also associated with a loss of the heterogeneity in lipid hydrocarbon chain length and decrease in the number of unsaturated hydrocarbon bonds. In comparison, no significant lipid features were found to be associated with PNPLA3 rs738409 GG or TM6SF2 rs58542926 TT genotypes. **Conclusion:** Liver fibrosis in NAFLD is associated with distinct changes in VLDL lipid species and properties reflecting altered hepatocellular lipid homeostasis. Among these changes, an increase in CerG2 and a reciprocal decrease in

ceramide and sphingomyelin may be of novel biological significance, as recent studies have linked glycosphingolipids accumulation with hepatocellular carcinoma. Further investigations are warranted to elucidate the specific mechanisms through which these molecules contribute to fibrogenesis and carcinogenesis in NAFLD.

2423-C | A PHASE I TRIAL OF BETAINE 4 VS 8 G/D ON ALT IN NON-ALCOHOLIC FATTY LIVER DISEASE

Andrew Steven Lim[1], Sheena Cruz[2], Aliya Asghar[1] and Timothy R. Morgan[1], (1)VA Long Beach Healthcare System, (2)University of California, San Diego

Background: Betaine is a safe and inexpensive nutraceutical that has improved ALT and liver histology in some but not all clinical trials of NASH when administered at 20 g/day. The aim of this phase I trial was to determine whether betaine at a dose of 4 or 8 g/day improved ALT in patients with NAFLD. **Methods:** 44 subjects with clinically diagnosed NAFLD and ALT > 60 IU/L received betaine 4 g/d for 4 weeks and were then randomized to either 4 or 8 g/d for another 8 weeks. 22 patients (10 in 4g/d arm and 12 in 8g/d arm) had T2DM (A1c < 8.5). Primary outcome was change in ALT between Week 0 and Week 12. Laboratory tests and clinical assessments were performed monthly and at 4 and 12 weeks after stopping treatment. A paired-t-test was used to assess change in ALT and lab tests. **Results:** Age (48 ± 15 in 4g/d, 49 ± 13 in 8g/d), gender (95.5% male in 4g/d, 100% male in 8g/d), BMI (34.1 ± 6.5 in 4g/d, 34 ± 5.2 in 8g/d), A1c (among diabetics: 7.2 ± 0.55 in 4g/d, 7.5 ± 1.1 in 8g/d), LDL (117 ± 33 in 4g/day, 107 ± 37 in 8g/day), and ALT (98 ± 66 in 4g/d, 78 ± 26 in 8g/d) did not differ between groups at baseline. At Week 12, ALT improved significantly among both cohorts, with a greater improvement among subjects receiving 8 g/d (not significant vs. 4 g/d). ALT improved similarly among diabetics and non-diabetics. Mean weight loss was 1.5 kilograms and did not differ between groups. Betaine treatment increased HDL (change in HDL [2 ± 1 mg/dL; $p < 0.05$]) while LDL increased 3mg/dL. Betaine non-significantly changed A1c and fructosamine among subjects with DM. ALT increased towards baseline after stopping betaine. Adverse events were minimal. **Conclusion:** Betaine at a dose of 4 or 8 g/day for 12 weeks improved ALT among subjects with a clinical diagnosis of NAFLD and an elevated ALT. Betaine increased HDL and non-significantly changed in A1c, fructosamine, and LDL. Given the low cost and minimal adverse event profile, additional trials of betaine treatment of NAFLD should be considered.

2424-C | ADVERSE GASTROINTESTINAL EFFECTS OF SEMAGLUTIDE WERE NOT ASSOCIATED WITH MEDICATION DISCONTINUATION OR WEIGHT LOSS OUTCOMES IN PATIENTS WITH NAFLD

Adam Buckholz[1], Nicole Cornet[1], Lindsay Rogers[1], Aditi Rao[1], Patrick T Magahis[1], Tibor I. Krisko[1], Reem Sharaiha[1], Carolyn Newberry[1] and Sonal Kumar[2], (1) Newyork-Presbyterian/Weill Cornell Medical Center, (2) Weill Cornell Medical College, NY

Background: The GLP1 receptor agonist semaglutide has been purported as an effective treatment tool for patients with NAFLD, as it produces a 7-10% total body weight loss (TBWL). Gastrointestinal side effects (GISFx) related to associated delayed gastric motility may limit reaching approved medication dose. The relationship between side effects and weight loss outcomes is unknown. **Methods:** We retrospectively identified patients with NAFLD who initiated semaglutide in our multidisciplinary metabolic center from 2019-22. Those taking semaglutide for at least 6 months were included. The final measured weight while on drug during the study period was used to calculate % TBWL. Concomitant alternative anti-obesity medication (AOM), GISFx, discontinuation events, dose decrease due to side effects and baseline characteristics were

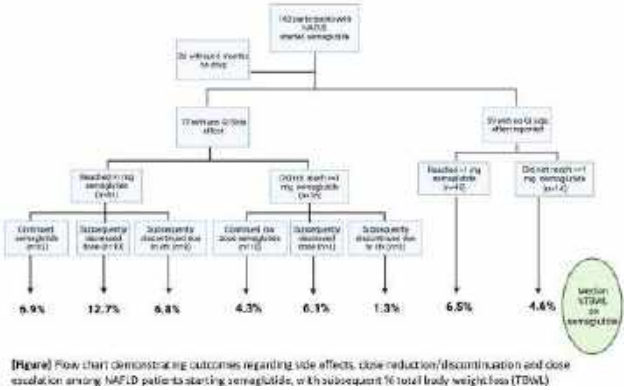
Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

collected. Dose of semaglutide at initiation, peak, and time of GISFx were also collected; reaching a full dose of semaglutide was considered e 1 mg/week. Outcomes of interest were %TBWL and e 7% TBWL at final weight in multivariable (MV) regression adjusting for developing GISFx, discontinuing due to GISFx, dose reducing, and peak semaglutide dose. **Results:** Of 162 NAFLD patients on semaglutide, the majority were female (74%) and 86 had concomitant T2DM (53%). Median baseline BMI was 36.2 (IQR 8.8) and 88 (54%) were on an additional AOM. 136 patients (84%) were on semaglutide at least 6 months; 12 were lost to follow up, 6 stopped early due to GISFx, and 8 stopped for other reasons such as insurance or availability. A majority of patients (77, 57%) reported a GISFx at a median dose 0.5 mg/week, the most common of which was nausea [Table]. There was no difference in discontinuation rates by side effect, but those with GERD and constipation received symptomatic therapy more than those with other symptoms ($p < 0.01$). Overall, 24 participants discontinued or dose reduced due to side effects after at least 6 months [Figure], but most (106, 77%) reached full dose. In MV regression, those who developed side effects did not have lower peak dose, more failure to reach > 1 mg/wk or more discontinuation. Only reaching full dose was significantly associated with TBWL (b = 3.15, 95% CI 0.12, 6.19 $p = 0.04$) while odds of reaching 7% TBWL neared significance (OR 2.19, 95%CI 0.89, 5.39 $p = 0.09$). Other factors (age, gender, ethnicity, other AOMs) did not attenuate this association, but were not included to avoid model overfitting. **Conclusion:** In a pragmatic study of weight loss in NAFLD patients on semaglutide, we found that development of side effects was not associated with likelihood of drug discontinuation, dose reduction, or % TBWL. Achieving full dose associated with more weight loss, regardless of development of GISFx. Further studies in a more controlled setting are needed, but this data suggests that semaglutide side effect management may be important to enable dose increase its dose dependent effect.

[Table] Side effects experienced among those on semaglutide and subsequent management by care team

Side effect	Reported n (%)	Decreased dose n (%)	Discontinued n (%)	Medication for symptom n (%)
Nausea	38 (27.9%)	9 (23.7%)	4 (10.5%)	6 (15.8%)
GERD	15 (11.0%)	3 (5.5%)	5 (33.3%)	10 (76.9%)
Diarrhea	10 (7.4%)	1 (10.0%)	2 (20.0%)	2 (20.0%)
Constipation	29 (21.3%)	5 (17.4%)	5 (17.2%)	17 (73.3%)
Abdominal pain	11 (8.1%)	4 (36.4%)	2 (18.2%)	0 (0%)
Total	77 (56.6%)	14 (18.2%)	10 (12.9%)	24 (27.6%)



[Figure] Flow chart demonstrating outcomes regarding side effects, dose reduction/discontinuation and dose escalation among NAFLD patients starting semaglutide, with subsequent % total body weight loss (TBWL)

2425-C | BENEFICIAL EFFECTS OF LUSEOGLIFLOZIN FOR HEPATIC STEATOSIS AND FIBROSIS INDEXES WITH A REDUCTION OF BODY WEIGHT AND AN INCREASE IN SERUM ALBUMIN LEVELS IN PATIENTS WITH DIABETES: A POOLED META-ANALYSIS OF PHASE III CLINICAL TRIALS USING INVERSE PROBABILITY TREATMENT WEIGHTING PROPENSITY ANALYSIS

Takumi Kawaguchi[1,2], Kenta Murotani[2,3], Yoko Shirouzu[4], Hitoshi Obara[3], Hironori Yamaguchi[4], Yuko Toyofuku[2], Fumi Kaneko[2] and Saeko Uchida[4], (1) Kurume University School of Medicine, (2)Kurume University Hospital, (3)Kurume University, (4)Taisho Pharmaceutical Co., Ltd.

Background: Luseogliflozin, a sodium-glucose cotransporter 2 (SGLT2) inhibitor, is known to decrease serum ALT levels in patients with diabetes. We aimed to investigate the effects of luseogliflozin on hepatic steatosis and fibrosis indexes as well as body weight and serum albumin levels in patients with diabetes using a pooled meta-analysis of phase III clinical trials. **Methods**: In this pooled meta-analysis, we included 5 phase III clinical trials from 121 centers. The primary outcomes were fatty liver index (FLI) and aspartate aminotransferase to platelet ratio index (APRI) after 24 weeks. Secondary outcomes were body weight and serum albumin level after 24 weeks. Statistical analysis was performed using propensity scoring analysis by the inverse probability of treatment weighting (IPTW) method. **Results**: Patients' characteristics were adjusted by 20 covariates including age, sex, BMI, FLI and APRI using IPTW. A total of 493 participants (luseogliflozin group n = 302, placebo group n = 191) were enrolled in this pooled meta-analysis. *Primary outcome*: Luseogliflozin significantly decreased FLI compared to placebo after 12/24 weeks (adjusted coefficient -6.804/-5.423, 95%CI -10.258 to -3.349/-8.760 to -2.086, P = 0.0002/.0016). There was no significant difference in APRI between the luseogliflozin and placebo groups at 12 weeks. However, luseogliflozin significantly decreased APRI compared to placebo after 24 weeks (adjusted coefficient -0.024, 95%CI -0.042 to

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

-0.007, P = 0.0066). Secondary outcomes: luseogliflozin significantly decreased body weight compared to placebo after 12/24 weeks (adjusted coefficient -1.360/-1.406, 95% CI -1.592 to -1.128/-1.728 to -1.084, P < 0.0001/ < 0.0001). No significant difference was observed in serum albumin levels between the two groups at 12 weeks. However, luseogliflozin significantly increased serum albumin levels (adjusted coefficient 0.044, 95%CI 0.001 to 0.087, P = 0.0472) compared to placebo after 24 weeks. **Conclusion**: This pooled meta-analysis demonstrated that luseogliflozin improved non-invasive indexes for hepatic steatosis and fibrosis in patients with diabetes. We also revealed that luseogliflozin reduced body weight and increased serum albumin levels. Thus, luseogliflozin may be beneficial for the regression of hepatic steatosis and fibrosis with the improvement of other prognostic factors including obesity and hypoalbuminemia in patients with diabetes.

2426-C | CLINICAL TRANSLATABILITY OF THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF NON-ALCOHOLIC STEATOHEPATITIS

Michael Feigh[1], Jacob Nøhr-Meldgaard[1], Martin Rønn Madsen[1], Susanne E. Pors[2] and Henrik B. Hansen[1], (1) Gubra, (2)Gubra a/S, Copenhagen, Denmark

Background: The Gubra-Amylin NASH (GAN) diet-induced obese (DIO) mouse is a comprehensively validated preclinical model of non-alcoholic steatohepatitis (NASH) with progressive fibrosis. The present study aimed to assess liver histopathological effects of 10 clinical candidates in the GAN DIO-NASH mouse with reference to histological primary endpoints reported in corresponding clinical phase-2/3 trials in NASH patients. **Methods:** Individual drug treatment studies were performed in male DIO-NASH mice fed the GAN diet (40 kcal-% fat, 22% fructose, 10% sucrose, 2% cholesterol) for e 34 weeks and with liver biopsy-confirmed NAFLD Activity Score (NAS e 5) and fibrosis (e stage F1) using the NASH Clinical Research Network (CRN) scoring system. GAN DIO-NASH mice (n = 14-18 per group) were administered resmetirom (THR-β agonist, 3 mg/kg, QD, PO), semaglutide (GLP-1 receptor agonist, 30 nmol/kg, SC, QD), obeticholic acid (FXR agonist, 30 mg/kg, PO, QD), tropifexor (FXR agonist, 0.3 mg/kg, PO, QD), cilofexor (FXR agonist, 30 mg/kg, PO, QD), lanifibranor (pan-PPAR agonist, 30 mg/kg, PO, QD), elafibranor (PPAR-α/δ agonist, 30 mg/kg, PO, QD), seladelpar (PPAR-δ agonist, 10 mg/kg, PO, QD), firsocostat (ACC inhibitor, 5 mg/kg, PO, QD), cenicriviroc (CCR2/5 receptor antagonist, 100 mg/kg, PO, BID), or vehicle for 12 weeks. Histopathological pre-to-post individual assessment of NAS and fibrosis stage was performed and evaluated against FDA/EMA-accepted co-primary/secondary histological endpoints (resolution of NASH with no worsening of liver fibrosis; e 1-stage fibrosis improvement without worsening of NASH). **Results:** Histological outcomes in GAN DIO-NASH mice were comparable to corresponding clinical trials for resmetirom (MAESTRO-NASH), semaglutide (Newsome et al. NJEM 2020), lanifibranor (NATIVE), tropifexor (FLIGHT-FXR), cilofexor (ATLAS) and seladelpar (Harrison et al., AASLD, 2020). Obeticholic acid reversed NASH but not fibrosis in GAN DIO-NASH mice, being line with the FLINT trial, whereas the opposite effect has been reported the pivotal REGENERATE trial. Elafibranor only resolved NASH, being consistent with the GOLDEN-505 trial but contrasting no histological benefits in the pivotal RESOLVE-IT trial. Firsocostat improved both NASH and fibrosis, although these endpoints were not met in the ATLAS trial. While cenicriviroc had no effect in GAN DIO-NASH mice, fibrosis was significantly improved in the AURORA trial. **Conclusion:** GAN DIO-NASH mice faithfully reproduce histological outcomes of several compounds profiled in clinical trials for NASH, highlighting clinical translatability and utility of the model in preclinical drug development.

2427-C | EFFECT OF METFORMIN ON LIVER TRANSAMINASES IN PATIENTS OF NON-ALCOHOLIC FATTY LIVER DISEASE: A SYSTEMATIC REVIEW

Hriday Shah[1], Charmy Parikh[2], Raj Harshadkumar Patel[3], Ramaswamy Sundararajan[4], Henil Upadhyay[5] and Aman Narula[1], (1)Gmers Medical College, Vadodara, (2)Harvard University TH Chan School of Public Health, (3) St. Mary Medical Center, Langhorne, (4)Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, (5) Pramukhswami Medical College, Anand

Background: Simple steatosis and nonalcoholic steatohepatitis are the two primary conditions under the umbrella of nonalcoholic fatty liver disease (NAFLD). Medications that improve insulin sensitivity, like metformin, may be useful in treating NAFLD patients since insulin resistance (IR) plays a crucial role in the

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

development of the disease. Our aim was to determine the effect of metformin use on liver transaminases in patients diagnosed with NAFLD.

Methods: Relevant studies were found by searching PubMed, PubMed Central, Science Direct, and Cochrane Library. The search was done on May 5, 2023. This review was carried out using the preferred reporting items for systematic review and meta-analysis (PRISMA) guidelines. Inclusion criteria were: published as randomized clinical trials (RCT) and observational cohort studies in the last eight years (2011-2023), full text in English only. In addition, we included studies in which NAFLD (defined as fatty liver on ultrasonography with alcoholic intake < 140 g and < 210 g per week for women and men, respectively, not treated with medications affecting hepatic steatosis and no history of autoimmune liver disease or viral hepatitis) patients were on Metformin therapy. Outcomes included changes in AST (aspartate aminotransferase), ALT (alanine aminotransferase), BMI (body mass index), and HbA1c (glycated hemoglobin). Studies that had follow-up periods of more than 20 weeks were included. Quality appraisal for publications was done using relevant assessment tools like the Newcastle-Ottawa scale, Cochrane risk-of-bias tool, etc. Articles that scored at least 70% using quality appraisal tools were included.

Results: Five studies were included, encompassing a total of 167 patients. Patients were followed for a range of 4-6 months. Two studies reported a significant reduction in serum AST and ALT concentrations post-metformin therapy ($p < 0.01$). Three of the five studies that evaluated the impact of Metformin on BMI, revealed a decline in this parameter as well, with two studies reporting a statistically significant difference ($p < 0.001$). Two studies investigated the effect of Metformin on HbA1C levels, both of which demonstrated a decrease after therapy.

Conclusion: Overall, this systematic review highlights that higher dosages and prolonged treatment durations of metformin lead to a downward trend in serum concentrations of AST, ALT, BMI, and HbA1C. Future prospective studies with longer follow-up periods can provide more information on this aspect of NAFLD treatment.

Table 1 - Effect of Metformin Therapy on AST, ALT, BMI, and HbA1c Levels

Study	Follow-up Period	Metformin Dose	Baseline				Change			
			AST	ALT	BMI	HbA1C	AST	ALT	BMI	HbA1C

2428-C | EFFECT OF WEIGHT LOSS AGENTS ON THE IMPROVEMENT OF LIVER INFLAMMATION AMONG METABOLIC ASSOCIATED FATTY LIVER DISEASE PATIENTS

Takamasa Ohki, Shioda Memorial Hospital

Background: Sodium-glucose co-transporter 2 (SGLT-2) inhibitors and Glucagon like peptide-1 (GLP-1) analogue are diabetes agents available on the market. Important advantage of SGLT-2 inhibitors and GLP-1 analogues are their favorable effects on the reduction of body weight (BW). The aim of this study is to analyze the effectiveness of SGLT-2 inhibitors and GLP-1 analogue as treatments for metabolic associated fatty liver disease (MAFLD) patients with type 2 diabetes mellitus (T2DM). **Methods:** We retrospectively enrolled consecutive 233 Japanese MAFLD patients with T2DM who were administered SGLT-2 inhibitors or GLP-1 analogues between 2010 June 1 and 2021 December 31. The last follow-up date was 2022 December 31. We divided these patients into two groups according to the BW reduction rate after 8 weeks (BW reduction rate equal to 3% or more than 3%; BWR-group N = 54, BW reduction rate less than 3%; CON-group N = 179). The primary endpoint was cumulative normalization rate of ALT and the secondary endpoint was cumulative re-exacerbation rate of patients who achieved normalization of ALT. We also assessed the factors which contributed to the normalization and re-exacerbation of ALT using COX hazard multivariate analysis.

Results: There were no significant differences about patients' backgrounds including proportion of initial administration rate of SGLT-2 inhibitors and GLP-1 analogue between BWR-group and CON-group. Normalization of ALT was observed in 47 (87.0%) patients of BWR-group and 137 (76.5%) patients of CON-group ($P = 0.13$) at the end of follow-up. The cumulative normalization rate of ALT was significantly differed between the two groups showing 3, 6 and 12 months of 26.4 %, 45.3%, and 60.5% in BWR-group, 12.3 %, 28.0% and 41.0% in CON group, respectively ($P < 0.01$). Multivariate analysis indicated that BW reduction equal to or for more than 3% within 8 weeks (HR: 0.67, 95%CI: 0.47-0.96, $P = 0.029$), serum albumin level (HR: 0.51 per 1 g/dl, 95%CI: 0.31-0.85, $P = 0.009$, and alteration of T2DM (HR: 0.69, 95%CI: 0.49-0.99, $P = 0.041$) as independent factors

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

contributed to the normalization of ALT. During the follow-up period, 103 of 184 patients (56.0%) who had achieved improvement of ALT experienced re-exacerbation. The cumulative re-exacerbation rate was 13.2%, 29.6%, and 44.1% at 6, 12 and 24 months, respectively. Multivariate analysis indicated that BW gain (HR: 2.21, 95%CI: 1.48-3.28, $P < 0.01$), and exacerbation of T2DM (HR: 2.13, 95%CI: 1.43-3.16, $P < 0.01$) as independent factors related to re-exacerbation. **Conclusion:** The administration of SGLT-2 inhibitors and GLP-1 analogues led not only good glycaemic control but also normalization of ALT with a favorable effect of BW reduction. BW reduction within 8 weeks after administration of these agents was an independent factor contributed to rapid improvement of ALT. Maintenance of BW and T2DM after normalization of ALT was also very important.

2429-C | EFFECTS OF DAPAGLIFLOZIN ON CARDIOVASCULAR OUTCOMES IN PATIENTS AT HIGH RISK OF ADVANCED LIVER FIBROSIS: POST HOC ANALYSES FROM THE DECLARE-TIMI 58 TRIAL

Jan Oscarsson[1], Monika Huhn[1], Ingrid Am Gause-Nilsson[1], Stephen D Wiviott[2], Filipe A Moura[2], John P. H. Wilding[3], Simona Cernea[4], Luc Van Gaal[5], Avivit Cahn[6], Deepak L Bhatt[7], Darren K McGuire[8], Peter A Johansson[1] and C David Sjöström[9], (1)Astrazeneca, (2) Brigham and Women's Hospital, Harvard Medical School, (3)University of Liverpool, (4)George Emil Palade University of Medicine, (5)Antwerp University Hospital, (6)Hadassah Medical Center, (7)Icahn School of Medicine at Mount Sinai Health System, (8)University of Texas Southwestern Medical Center, (9)Astrazeneca, Hovås, Sweden

Background: The Fibrosis-4 score (FIB-4) was originally developed to evaluate the risk for advanced liver fibrosis in patients with hepatitis C/HIV infection, incorporating age, transaminase levels, and platelet count. More recently, FIB-4 has been used to assess the risk for advanced liver fibrosis in patients with non-alcoholic fatty liver disease. The aim of this post hoc analysis was to investigate the prognostic value of FIB-4 for cardiovascular (CV) outcomes and the effects of dapagliflozin. **Methods**: The DECLARE-TIMI 58 randomized trial investigated the effect of dapagliflozin, a SGLT2 inhibitor, versus placebo in patients with type 2 diabetes with or at high risk for atherosclerotic cardiovascular disease (ASCVD). Baseline FIB-4 was calculated for all participants, with the present analyses stratified by the following FIB-4 categories: < 1.3, 1.3- < 2.67 and ≥ 2.67 and presented as HR (95%CI) for the effect of dapagliflozin versus placebo in the different FIB-4 categories. **Results**: Of 17,160 patients enrolled, a total of 16,240 patients were included in the present analyses, with median follow up of 4.2 years. The number of patients in the different FIB-4 categories were < 1.3; n = 9036 (55.6%), 1.3- < 2.67; n = 6583 (40.6%) and with ≥ 2.67; n = 621 (3.8%). The proportion of patients with established ASCVD at baseline did not differ across FIB-4 subgroups, ranging from 40 to 43%. The annualized event rate for the primary composite outcome of CV death and hospitalization for heart failure (HHF) across the 3 FIB-4 categories among participants receiving placebo was 1.4% in the < 1.3 category, 1.5% in 1.3- < 2.67 category and 2.9% in the ≥ 2.67 category. The corresponding annualized event rate among participants receiving dapagliflozin was 1.1%, 1.4% and 1.4%, respectively. The HR (95% CI) for the effect of dapagliflozin versus placebo on CV death and HHF was 0.81 (0.67-0.98) in the < 1.3 category, 0.91 (0.74-1.11) in the 1.3- < 2.67 category, and 0.50 (0.28-0.89) in the ≥ 2.67 FIB-4 category (see Figure). There was no overall effect modification by FIB-4 ($p_{interaction} = 0.18$). For the components of the composite, the HR (95% CI) for the effect of dapagliflozin versus placebo on CV death was 0.98 (0.76-1.26) and 1.05 (0.80-1.39) in the < 1.3 and 1.3- < 2.67 categories and 0.55 (0.26-1.15) in the ≥ 2.67 category. The effect on HHF was 0.74 (0.57-0.96) in < 1.3 and 0.79 (0.60-1.04) in the 1.3- < 2.67 categories, and 0.40 (0.17-0.97) in the ≥ 2.67 FIB-4 category. Additional adjusting for age, sex, and BMI gave similar results. **Conclusion**: In a randomized placebo-controlled study investigating CV outcomes in persons with type 2 diabetes and high atherosclerotic cardiovascular risk, high FIB-4 score was associated with higher CV risk; whereas dapagliflozin reduced risk for CV death/HHF across FIB-4 categories.

2430-C | EFFICACY OF SODIUM GLUCOSE CO-TRANSPORTER 2 INHIBITOR ON A PROGRESSION OF NONALCOHOLIC STEATOHEPATITIS IN A MURINE STEATOHEPATITIS MODEL

Young Chang, Soonchunhyang University

Background: Sodium glucose cotransporter 2 (SGLT2) inhibitors, an antidiabetic drug, have shown positive effects in diabetes and cavdiovascular diseases. It is unclear whether SGLT2 inhibition could exert a beneficial effect on nonalcoholic steatohepatitis (NASH)-associated liver fibrosis and hepatocellular carcinoma. **Methods:** We examined the beneficial effect of SGLT2 inhibitor, empagliflozin, in a murine NASH model. The choline-deficient, amino acid-defined diet (CDAA) with high fat diet was formulated and administered to 8-week-old male C57Bl/6J mice for up to 24 weeks. A total of 21 mice were divided into two groups, the control group and the SGLT2 inhibitor group. Five animals in each group were treated for 12 weeks, and the remaining five in the control group and six in the SGLT2 inhibitor group were treated for 24 weeks. **Results:** There was no significant difference in mean body weight between the control and treatment group after 12 weeks (24.19 g vs. 23.91 g; $P = 0.65$). Laboratory findings, including serum aspartate transaminase, alanine transaminase, creatinine, glucose, and triglyceride, also showed no statistical differences between groups (all $P > 0.1$). When hepatic fibrosis was assess by Sirius red staining, the area of collagen deposition was smaller in the SGLT2 inhibitor group (Figure 1). Moreover, 12 weeks of SGLT2 inhibitor treatment downregulated the expression of various fibrosis-related proteins in the liver compared to the control, indicating that SGLT2 inhibitor treatment attenuated hepatic fibrosis. After 24 weeks, the inhibitory effect of SGLT2 inhibitor on hepatic fibrosis was consistently observed as downregulated fibrosis-related proteins (Figure 2). However, multiple hepatic tumors developed in both groups without significant differences in tumor number and size (Figure 3). **Conclusion:** High fat-CDAA feeding in C57Bl/6J mice was identified as a suitable model of NASH developing robust fibrosis and hepatic tumor within 24 weeks. SGLT2 inhibitor showed the potential to attenuate hepatic fibrosis in the progression of NASH, whereas administration of SGLT2 inhibitor alone was insufficient to suppress the development of hepatic tumors.

Figure 1. The area of collagen deposition (Sirius-red) was smaller in (A) the SGLT2 inhibitor group than in (B) the control group.

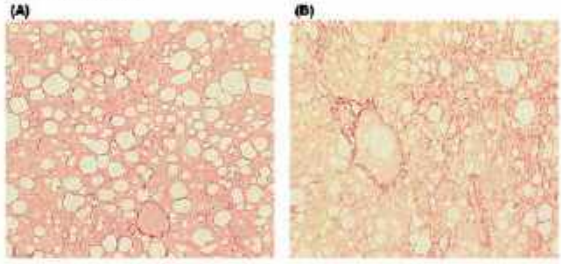

Figure 2. Both after (A) 12 weeks and (B) 24 weeks, SGLT2 inhibitor treatment downregulated the expression of various fibrosis-related proteins in the liver compared to the control.

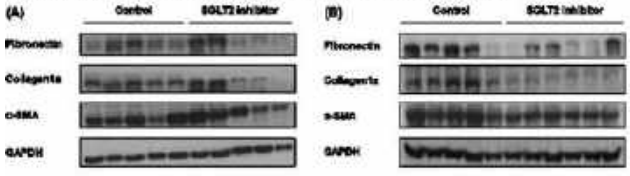

Figure 3. Multiple hepatic tumors developed in both groups without significant differences in tumor number and size. (A) control, (B) SGLT2 inhibitor treated

2431-C | HISPANIC PATIENTS WITH NAFLD SHOW LESS TOTAL BODY WEIGHT LOSS AFTER 12 MONTHS ON SEMAGLUTIDE COMPARED TO MATCHED NON-HISPANIC PEERS: DEFINING EFFECTS OF ETHNICITY ON WEIGHT LOSS OUTCOMES

Adam Buckholz[1], Nicole Cornet[1], Lindsay Rogers[1], Aditi Rao[1], Patrick T Magahis[1], Reem Sharaiha[1], Tibor I. Krisko[1], Carolyn Newberry[1] and Sonal Kumar[2], (1) Newyork-Presbyterian/Weill Cornell Medical Center, (2) Weill Cornell Medical College, NY

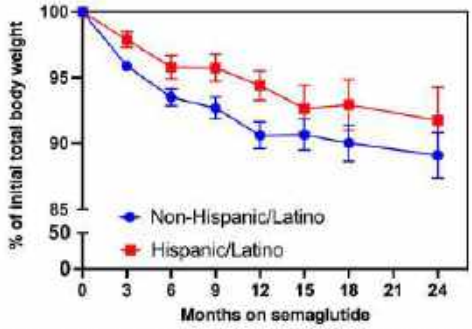
Background: The GLP1 receptor agonist semaglutide is a commonly used anti-obesity medications (AOM) with growing interest for use in NAFLD, where 7-10% total body weight loss (TBWL) improves outcomes. Demographic factors associated with successful weight loss on semaglutide in real-world settings remain unclear. **Methods:** In our multidisciplinary metabolic center, we retrospectively identified patients initiated on weekly subcutaneous semaglutide between 2019 and 2022. NAFLD was diagnosed by steatosis on imaging and/or FibroScan at initiation. Baseline clinical characteristics, concurrent AOM medication use, and outcomes including peak dose, side effects and need for discontinuation or dose reduction for any reason were collected. Weights were recorded at 3-month intervals (+/- 30 d) when available among those remaining on semaglutide. Weight loss of 7% of TBW at 12-months was considered the primary outcome. Propensity score (PS) analysis with single nearest neighbor matching on age, gender, side effects, and reaching 1 mg/wk was performed to determine the effect of Hispanic status on achieving 7% TBWL. **Results:** A total of 279 patients started semaglutide, of whom 162 (119/74% female) had NAFLD. Of these, mean age was 52.1, 86 (53%) had T2DM (mean A1C 6.7%, IQR 1.8), 82 (50.6%) had HTN, 143 (88.3%) had HLD and mean BMI was 36.2 (IQR 8.8). 107 had baseline FibroScan data, with mean kPa of 7.2 and CAP of 322. The most common starting dose was 0.25 mg/wk (154/95%) with a median peak dose of 1 mg/wk. 136 participants (84%) had at least 6 months of follow up on drug, and 98 participants (61%) had at least 12 months of follow up on drug. 12-month weight was available for 83 participants (51%); 39 (47%) of these achieved at least 7% TBWL. In univariable analysis [A], identifying as Hispanic was associated with significantly reduced odds of achieving 7% TBWL (OR 0.28, 95% CI 0.09-0.88, $p = 0.02$) and less mean %TBWL (5.6% vs 9.4%, $p < 0.05$), despite similar baseline characteristics to non-Hispanics, including age, gender, baseline BMI, prevalence of DM, CAP/kPa on FibroScan, use of concurrent AOMs, rate of reaching 1 mg/wk, and development of gastrointestinal side effects. In PS matched analysis, the effect of being Hispanic was 40% lower propensity (95% CI .09, .71 $p = 0.01$) for reaching 7%TBWL and 3.8% less TBWL overall ($p = 0.04$). Controlling for additional variables did not attenuate this association. At every "weigh in" date, the mean and median TBWL was lower for Hispanic than non-Hispanic patients [B]. **Conclusion:** In a retrospective analysis of all patients with NAFLD started on semaglutide, roughly half achieved 7% TBWL at 12-months, a clinically significant number. Importantly, however, there was reduced TBWL among Hispanics, the group with the highest NAFLD prevalence, which may lead to worsening disease disparity. Larger controlled studies may help determine the relative contribution of genetic or environmental factors to these findings.

[A] Univariable analysis of factors associated with achieving 7% TBWL at 12 months

	OR for 7% TWBL[95% CI]	p value
Age >50 (n=56)	1.83 [0.71-4.68]	0.21
Female gender (n=63)	1.71 [0.60-4.91]	0.32
Baseline T2DM (n=54)	0.75 [0.30-1.85]	0.53
Reached at least 1 mg/week (n=71)	1.28 [0.37-4.44]	0.69
Use of >=1 additional WLM (n=54)	0.76 [0.30-1.85]	0.53
Had a gastrointestinal side effect (n=47)	1.20 [0.50-2.86]	0.69
Non-Hispanic White (n=37)	3.08 [1.25-7.57]	0.01
Hispanic ethnicity (n=20)	0.28 [0.09-0.88]	0.02
Black (n=8)	1.14 [0.27-4.91]	0.86
Asian (n=9)	1.47 [0.37-5.92]	0.59



[B] At every 3-month time point after initiating semaglutide, those on drug had progressively more total body weight loss (%TBWL). However, at each time point Hispanic/Latino patients had significantly less weight loss as demonstrated by the 3 month average with SEM, although as fewer weights were available later in the study the difference was no longer statistically significant. Total n=162 at initiation, n=83 at 12 months, n=34 at 24 months.

2432-C | INVESTIGATING THE EFFECT OF ESSENTIAL PHOSPHOLIPIDS ON AN IN VITRO MODEL OF HUMAN STEATOSIS

Gina Valentino[1], Branko Popovic[2] and Paola Luciani[1], (1)University of Bern, (2)Sanofi

Background: Non-alcoholic fatty liver disease (NAFLD), the leading cause of liver dysfunction, progresses from steatosis to inflammation and fibrosis with an increasing risk for cirrhosis and liver cancer. The mechanisms underlying this pathophysiology is not fully understood. No approved NAFLD therapies exist, yet essential phospholipids (EPLs) are well-established for the adjunctive management of fatty liver disease, despite an unknow mechanism of action. Here, we assessed the effect of EPL-rich Essentiale® on lipid droplet size distribution and accumulation in an *in vitro* model of steatosis using differentiated HepaRG® cells, a suitable surrogate of

primary human hepatocytes. **Methods:** After differentiation of HepaRG cells per manufacturer´s instruction, we incubated them with a 2:1 molar ratio of oleic acid (OA) to palmitic acid (PA) at 0.75 mM concentration for 24h before further treatment. Liposomes (lipid concentration:1.5 or 3.8 mg/mL) composed of Essentiale® were incubated with steatotic cells in presence of OA/PA (condition A) or co-incubated with OA/PA during the induction of steatosis (condition B). We assessed Essentiale®'s effect on steatotic HepaRG cells, including cell proliferation, mitochondria related cytotoxicity, lactate dehydrogenase leakage and reactive oxygen species production. Lipid droplet quantification performed by labelling with BODIPY 493/503 and confocal microscopy. Immunofluorescence staining assessed ATGL-dependent lipolysis vs LC3B-dependent lipophagy. **Results:** Essentiale® did not change cell proliferation, damage plasma membrane, and increase mitochondria-related cytotoxicity. It did not trigger ROS from HepaRG cells in growth medium. Essentiale® at 1.5 and 3.8 mg/mL after induction of steatosis reduced the percentage of fat droplets (diameter > 2µm) from 14% (untreated cells) to 5% and 9%, respectively. Essentiale® treatment during OA/PA-induced steatosis yielded comparable results (7% and 6%, respectively). The fluorescence signal from ATGL antibody-treated steatotic HepaRG cells indicates lipolysis, as the main contributor to the reduction in lipid droplet count. **Conclusion:** Inducing steatosis on differentiated HepaRG cells mimics human steatosis. Treatment with Essentiale® effectively impacted fat deposits without compromising cell viability, membrane integrity, mitochondria, or oxidative stress This suggests Essentiale® could be safe in human steatosis.

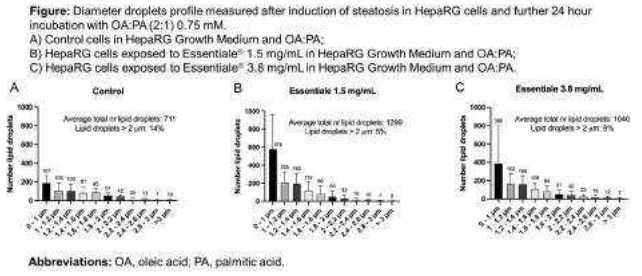

Figure: Diameter droplets profile measured after induction of steatosis in HepaRG cells and further 24 hour incubation with OA:PA (2:1) 0.75 mM.
A) Control cells in HepaRG Growth Medium and OA:PA;
B) HepaRG cells exposed to Essentiale® 1.5 mg/mL in HepaRG Growth Medium and OA:PA;
C) HepaRG cells exposed to Essentiale® 3.8 mg/mL in HepaRG Growth Medium and OA:PA.

Abbreviations: OA, oleic acid; PA, palmitic acid.

2433-C | NICLOSAMIDE ETHANOLAMINE (NEN) PROTECTS MOUSE LIVER FROM LIPOTOXICITY BY ACTIVATING NONCANONICAL p62-Keap1-Nrf2 PATHWAY

Yu Seol Lee, Yonsei University College of Medicine

Background: Nonalcoholic steatohepatitis (NASH) is one of most common liver diseases associated with metabolic disturbances, such as obesity, dyslipidemia, and type II diabetes. Despite its increasing prevalence, there is no approved drug for the treatment of NASH. Lipotoxicity-induced reactive oxygen species (ROS) has been known to be a major pathogenesis factor of NASH progression. Therefore, nuclear factor erythroid 2-related factor 2 (Nrf2), a pivotal transcription factor for the elimination of ROS, has been investigated as a potential therapeutic target for the treatment of NASH. Niclosamide ethanolamine (NEN), a FDA-approved drug as an anthelmintic, is recently reported to mitigate obesity-induced hepatic steatosis in high-fat diet (HFD)-fed mice. **Methods:** Male C57BL/6J mice fed a high-carbohydrate diet (HCD) after 24 h of fasting, injected with vehicle or NEN by oral gavage. After 18 h of feeding followed by fasting, the mice were sacrificed. serum alanine aminotransferase (ALT) level were measured and RNA or protein sample of liver tissue from them were analyzed by qRT-PCR or immunoblot assay. Also, to mimic lipotoxic condition, Mouse embryonic fibroblasts (MEFs) and HeLa cells expressing green fluorescent protein-conjugated LC3 (GFP-LC3/HeLa cells) were treated with palmitic acid with or without NEN. **Results:** Here, we revealed that NEN mediates AMPK-mediated phosphorylation of p62 at Ser351, resulting in activation of noncanonical Nrf2 pathway. Furthermore, NEN induces Sesn2-mediated AMPK activation and consequently promotes autophagic Keap1 degradation. We also showed that NEN protects cells and mouse liver from acute lipotoxic

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

2434-C | ORLISTAT FOR OBESE PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

Abdelrahman Mahmoud[1], Islam Mohamed[2], Mohamed Abuelazm[3], Ali Ashraf Salah Ahmed[1], Abdallah Saeed[3], Mahmoud Elshinawy[1], Omar Almaadawy[4], Hassan Ghoz[5] and Basel Abdelazeem[6], (1)Minia University, (2)University of Missouri-Kansas City, (3) Tanta University, (4)Medstar Health-Baltimore, (5) University of Missouri- Kansas City, (6)Mclaren Health Care-Flint

Background: Non-Alcoholic Fatty Liver Disease (NAFLD) is a significant contributor to chronic liver disease worldwide and currently holds the top spot for chronic liver disease in Western countries. In the United States, NAFLD is estimated to affect around 24% of the population. Orlistat blocks intestinal fat absorption leading to decreased liver fat content. Therefore, it is a viable option for NAFLD management. **Methods:** We conducted a systematic review and meta-analysis synthesizing randomized controlled trials (RCTs) which were retrieved by systematically searching: PubMed, EMBASE, Web of Science, SCOPUS, and Cochrane through March 27th, 2023. RevMan version 5.4 software was used to pool continuous outcomes using mean difference (MD) presented with the corresponding confidence interval (CI). Our protocol was prospectively published in PROSPERO with ID: CRD42023411654. **Results:** We included four RCTs with a total of 379 patients. Orlistat was effective in reducing liver fat content (MD: -5.02 with a 95% CI [-7.23, -2.82], P = 0.00001), alanine transferase (MD: -10.03 with a 95% CI [-17.80, -2.26], P = 0.01), aspartate transferase (MD: -4.29 with a 95% CI [-7.59, -0.99], P = 0.01), waist circumference (MD: -3.18 with a 95% CI [-4.25, -2.10], P = 0.00001), body mass index (MD: -1.03 with a 95% CI [-1.34, -0.73], P = 0.00001), total cholesterol (MD: -3.75 with a 95% CI [-4.02, -3.49], P = 0.00001), and low-density lipoprotein (MD: -3.83 with a 95% CI [-4.05, -3.61], P = 0.00001). However, orlistat was associated with increased serum triglycerides (MD: 7.46 with a 95% CI [6.48, 8.44], P = 0. 00001). **Conclusion:** Orlistat is a viable option for NAFLD management; however, it increases triglyceride levels. Which can be a potential limitation of orlistat use in patients with hypertriglyceridemia. More subtle RCTs with larger sample sizes, longer follow-up duration, and including patients with variable metabolic risk factors are still required before endorsement in clinical practice.

2435-C | STATIN USE IN NONALCOHOLIC FATTY LIVER DISEASE AND EFFECTS ON VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY-DERIVED SCORES - A POPULATION-BASED INVERSE PROBABILITY TREATMENT WEIGHTING ANALYSIS

Natchaya Polpichai, Weiss Memorial Hospital, Sakditad Saowapa, Texas Tech University Health Science Center, Aunchalee Jaroenlapnopparat, Mount Auburn Hospital/Harvard Medical School, Panisara Fangsaard, Bassett Medical Center, Pojsakorn Danpanichkul, Chiang Mai University, Phuuwadith Wattanachayakul, Einstein Medical Center, Vincent Chen, University of Michigan Medical Center, Yu JUN Wong, Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore; Changi General Hospital, Donghee Kim, Stanford University Medical Center and Karn Wijarnpreecha, Banner University Medical Center

Background: Nonalcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease globally. While statins have been found to reduce the risk of cardiovascular events in diabetics and chronic kidney disease, the clinical significance of statin use and severity of liver fibrosis in patients with NAFLD remains contentious. **Methods:** We performed a cross-sectional study using the National Health and Nutrition Examination Survey (NHANES) database from 1999-2018. Inverse probability of treatment weighting was introduced to reduce confounding. NAFLD was defined as hepatic steatosis (CAP score e 288 db/m) with negative hepatitis B surface antigen, hepatitis C RNA, Anti-HCV or substantial alcoholic use. The primary predictor was statin use. The outcomes were (1) at-risk steatohepatitis defined as Fibroscan-AST (FAST) score e 0.67, (2) significant or advanced fibrosis defined by liver stiffness measurement (LSM) e 8.8 and e 11.7 respectively, and (3) advanced fibrosis defined by AGILE3+ score e 0.68. **Results:** Out of 1,283 patients who had a diagnosis of NAFLD, 376 were prescribed statins. After adjustment for body mass index and diabetes, statin use was significantly associated with decreased risk for At Risk NASH, significant fibrosis, high AGILE score, with an odd ratio (OR): 0.289 (95% CI: 0.096 to 0.867), OR: 0.540 (95%CI: 0.306 to 0.953) and OR: 0.409 (95%CI: 0.224 to 0.747), respectively. A subgroup analysis was subsequently conducted to examine the effect of lipophilic and hydrophilic statins, but the effect was maintained only in lipophilic statins. **Conclusion:** Statin use was associated with less steatohepatitis and fibrosis in patients with NAFLD using robust casual inference and new Fibroscan™ scores.

Table : Outcomes

	Unadjusted		Model 1		Model 2	
	Odd ratios (95%CI)	p value	Odd ratios (95%CI)	p value	Odd ratios (95%CI)	p value

2436-C | THE EFFECTS OF SEMAGLUTIDE ON NAFLD IN OVERWEIGHT OR OBESE PATIENTS AT A MULTIDISCIPLINARY CLINIC

Rickisha Berrien-Lopez[1], Sherifatu Abu[1], Sameer Khan[2], Tinsay A. Woreta[2,3] and James P. Hamilton[2,3], (1)Department of General Internal Medicine, Johns Hopkins School of Medicine, Division of Hospital Medicine Johns Hopkins Bayview Medical Center, Baltimore, MD USA, (2)Division of Gastroenterology and Hepatology, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Johns Hopkins Healthful Eating, Activity & Weight Program, Johns Hopkins University School of Medicine, Baltimore, MD USA

Background: Nonalcoholic fatty liver disease (NAFLD) is strongly associated with metabolic syndrome. Current management centers around weight loss reduction as there are no pharmacological therapies approved for the treatment of NAFLD. The Johns Hopkins Healthful Eating, Activity & Weight Program (HEAWP) is a multi-disciplinary clinic with a dedicated focus on the management of metabolic syndrome and NAFLD. In this study, we assessed patients with NAFLD managed at the HEAWP clinic on semaglutide therapy to determine the impact on liver aminotransferases. **Methods:** This study

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

included adult patients with a clinical diagnosis of NAFLD seen at HEAWP from June 1, 2020 to June 1, 2022. Summary statistics were generated to characterize patients overall and by semaglutide and control groups. To assess significant differences between groups, Wilcox rank-sum tests were performed for continuous variables and Fisher's exact tests for categorical variables. The primary outcome was a change in alanine aminotransferase (ALT) at 6 months. Secondary outcomes included change in weight, BMI, and non-invasive measures of liver fibrosis (NAFLD Fibrosis Score, APRI, FIB-4). **Results:** A total of 70 patients with NAFLD seen at HEAWP were included in the analysis. 51% were female, 9% were Hispanic, and 67% were Caucasian. There were 17 patients in the semaglutide group and 53 in the control group. Median body weight and BMI were higher in the semaglutide group compared to the control group. The median NAFLD fibrosis score was higher at baseline in the semaglutide group compared to controls (0.2 vs -1.9, respectively, p-value 0.035). There was a reduction in ALT at 6 months in both the semaglutide and control groups (30.5 vs 12 IU/L, respectively, p-value 0.11). Median body weight at 6 months decreased by 3.4 kg in the semaglutide group as compared to 0.1 kg in the control group (p-value 0.06) and BMI decreased by 1.02 kg/m2 in the semaglutide group as compared to 0.03 kg/m2 in the control (p-value 0.056) at 6 months. There was a reduction in non-invasive markers of fibrosis at 6 months in both the semaglutide and controls with no difference between the groups (Table 1). **Conclusion:** This retrospective study showed that a multidisciplinary program is an effective treatment for patients with NAFLD which resulted in a significant reduction in ALT and non-invasive markers of liver fibrosis at 6 months. The use of semaglutide in a multidisciplinary program is associated with larger reductions in weight, BMI, and ALT at 6 months.

Table 1. Biochemical and metabolic changes from baseline to 6 months (N = 70)

	Total	Semaglutide group	Control group	p-value
N	70	17	53	
Body weight, kg, median (IQR)	-0.80 (-5.60, 2.10)	-3.40 (-8.00, 0.00)	-0.10 (-3.20, 2.20)	0.061
BMI, kg/m2, median (IQR)	-0.21 (-1.90, 0.65)	-1.02 (-2.46, -0.02)	-0.03 (-1.06, 0.93)	0.056
ALT, IU/L, median (IQR)	-14.00 (-25.00, -2.00)	-30.50 (-36.00, -25.00)	-12.00 (-14.00, 1.00)	0.11
NAFLD Fibrosis Score, median (IQR)	-0.21 (-0.99, 0.21)	-0.37 (-0.37, -0.37)	-0.04 (-1.35, 0.39)	0.83
APRI, median (IQR)	-0.11 (-0.17, -0.07)	-0.28 (-0.28, -0.28)	-0.11 (-0.14, 0.04)	0.25
FIB-4 Index, median (IQR)	-0.27 (-0.35, -0.06)	-0.27 (-0.27, -0.27)	-0.25 (-0.37, 0.02)	1.00

2437-C | THE IMPACT OF METFORMIN USE ON ALL-CAUSE MORTALITY AND HEPATIC DECOMPENSATION IN DIABETIC PATIENTS WITH COMPENSATED CIRRHOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Spyridon Peppas[1], Stavros Doumas[2], Jiling Chou[3], Ayah Arafat[3], Maria Gazi[4], Akram I Ahmad[1] and James H Lewis[5], (1)Medstar Washington Hospital Center, (2) Medstar Georgetown University Hospital, (3)Medstar Health Research Institute, (4)251 Air Force General Hospital, (5)Georgetown University Hospital

Background: Patients with cirrhosis have an increased prevalence of diabetes mellitus (DM), which in turn accelerates liver disease progression. The direct impact, however, of antidiabetic medication on the prognosis of this patient group remains unclear. Metformin, a first-line anti-diabetic oral agent, has demonstrated both antiaging and anticancer effects that exceed its impact on glycemic control. Furthermore, recent studies, suggest that metformin use in DM patients with cirrhosis improves mortality and rates of liver decompensation. The aim of this study was to determine the impact of metformin use on all-cause mortality and hepatic decompensation in DM patients with compensated cirrhosis. **Methods:** We performed a systematic review of the literature using Medline, Embase and Cochrane databases from inception to February 2023 to identify studies evaluating the effect of metformin use in DM patients with compensated cirrhosis of any etiology on all-cause mortality or transplantation and liver disease decompensation. We then pooled the identified studies and conducted a large scale meta-analysis. The risk of bias was assessed by ROBINS-I Cochrane tool. The log-transformed adjusted hazard ratios and 95% confidence intervals were evaluated and pooled in R software to conduct the analysis. The inverse variance method was used to calculate the random effects. To account for differences related to the specific etiology of cirrhosis a sensitivity analysis was conducted. **Results:** Six observational studies were identified and 28,332 metformin users and 32,276 non-metformin users were pooled and included in the analysis. Overall, metformin use was associated with reduced all-cause mortality or transplantation (HR: 0.55; 95% CI 0.37-0.82, 6 studies, figure 1) in diabetic patients with compensated cirrhosis. Overall, no benefit was demonstrated for metformin use in the prevention of liver decompensation (HR: 0.97; 95% CI: 0.77-1.22, 4 studies including a total of 60,258 patients, figure 2). Sensitivity analyses were conducted based on the etiology of cirrhosis. In two studies assessing patients with NASH, metformin use was associated with reduced all-cause mortality or transplantation (HR: 0.42 95% CI

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

0.33-0.54, total of 505 patients, figure 3). However, no benefit was shown in patients with cirrhosis secondary to hepatitis B or C (HR: 0.49; 95% CI 0.08-2.84, total of 17,324 patients, figure 4). Notably, substantial heterogeneity was appreciated between studies analyzed. **Conclusion:** Metformin use, in diabetic patients with compensated cirrhosis, reduces all-cause mortality or transplantation, but is not associated with prevention of decompensation. This association appears to be particularly strong in patients with NASH cirrhosis. Future studies are called for to define liver-specific metformin effects and identify cirrhotic patients that would benefit from metformin use.

2438-C | THREE-DIMENSIONAL PRIMARY CELL BASED LIVER MODEL PREDICTS CLINICAL OUTCOMES OF NASH IN VITRO

Vaidehi Joshi, Rachel Dudum, Payton Olson, Michelle Perez-Arreola, Keith Murphy and Jeffrey N Miner, Viscient Biosciences

Background: Non-alcoholic steatohepatitis (NASH) is a complex liver disease with no approved pharmacological treatments. One of the main challenges in NASH drug discovery is finding in vitro models that accurately recapitulate human NASH disease to offset poor efficacy rates in the clinic. In this study, we developed complex physiologically relevant 3D tissue models of NASH and assessed the ability to predict the response of four clinical compounds *in vitro* for NASH drug discovery. **Methods:** We developed high throughput 3-dimensional healthy and diseased tissues using primary human hepatocytes and non-parenchymal liver cells mixed in physiologically relevant cell ratios. The tissues were characterized using immunofluorescence, gene expression analysis, and functional assays. We then evaluated the ability of these diseased liver tissues to predict the response of clinical compounds with known outcomes in Phase 2 or Phase 3 clinical trials in NASH. **Results:** The 3D NASH tissues exhibited key features of disease and demonstrated a clear separation when compared to healthy liver tissues *in vitro*. Using the diseased 3D liver tissues, we were then able to accurately predict the response of Elafibranor (PPAR inhibitor, Genfit), Emricasan (pan-caspase inhibitor, Conatus/Novartis), Selonsertib (ASK1 inhibitor, Gilead) and OCA (FXR agonist, Intercept) *in vitro* using fibrosis as the primary endpoint. Elafibranor and Selonsertib, both increased markers of disease in our model, matching the outcomes in the Phase 3 clinical studies. OCA showed a significant decrease in collagen deposition while Emricasan failed to show any effect. The 3D liver models accurately predicted the response of clinical compounds on fibrosis. **Conclusion:** Our results demonstrate the advanced potential of our 3D liver tissues as a reliable preclinical screening tool for NASH drug discovery. These models offer a more physiologically relevant platform than traditional 2D cell culture systems or animal models for the evaluation of efficacy of clinical compounds and may accelerate the development of effective therapies for NASH and reduce clinical failures.

2439-C | A FIRST-IN-CLASS GALNAC-siRNA IMPROVES LIVER FUNCTIONS AND FIBROSIS OUTCOMES BY ENHANCING LIVER REGENERATION

Audrey Wang[1], Adelyn Tan[1], Mei Jia Tan[1], Sissi Lin[1], Binxia Yang[1], Torsten Wuestefeld[1,2], Yann Chong Tan[1] and Si Hui Tan[1], (1)Cargene Therapeutics, (2)Genome Institute of Singapore

Background: The liver's ability to regenerate itself after damage is unparalleled among all the organs in the body. However, this regenerative ability is impaired in aged and diseased liver, thereby precluding efficient recovery in most patients with liver diseases. In chronic liver diseases, prolonged and repeated insults lead to fibrosis and eventually cirrhosis if left untreated; natural history has shown that liver regeneration can reverse fibrosis. In acute situations, the critical loss of hepatocyte compromises liver functions and eventually leads to liver failure, and liver regeneration replenishes the lost hepatocytes to maintain liver functions. Therefore, enhancing liver regeneration is a viable approach for treating a spectrum of liver diseases. **Methods:** Through our *in vivo* RNAi functional screening and validation platform, we discovered and validated ITFG1 as a therapeutic target for enhancing liver regeneration. Silencing ITFG1 expression in hepatocytes enhances their proliferation in injured or diseased livers, making GalNAc-siRNA the most relevant therapeutic modality for targeting ITFG1. We developed a GalNAc-siRNA therapeutic CG-LR1, with our in-house platforms, and assessed its knockdown potency, safety, durability and therapeutic efficacy to improve liver function and fibrosis outcome in mouse disease models. CG-LR1 was then evaluated for its safety, pharmacodynamics and pharmacokinetics in rats and non-human primates (NHPs). **Results:** CG-LR1 is a first-in-class therapeutic targeting ITFG1, conjugated to our proprietary GalNAc. It has an IC50 of 1.5pM, minimal off targets and high stability. In mice, it has an ED50 of less than 1mg/kg with exquisite liver specificity conferred by the GalNAc ligand. CG-LR1 increases hepatocyte proliferation by more than 50% compared to control in partial hepatectomy, reduces serum biomarkers of liver injury, enhances liver regeneration and attenuates fibrosis in bile duct ligation mouse models with statistical significance. Long term knockdown of ITFG1 *in vivo* does not induce carcinogenicity or hepatomegaly, affirming the safety of this therapeutic approach. Hepatocellular carcinoma patients with low ITFG1 expression also present with better prognosis than those with high ITFG1 expression. In NHPs, CG-LR1 achieved greater than 80% knockdown with sustained silencing activity for more than 3 months with a single dose. **Conclusion:** ITFG1 silencing in hepatocytes with CG-LR1 enhances hepatocyte regeneration in injured and diseased livers to promote liver recovery across etiologies. CG-LR1 is a First-in-Class GalNAc-siRNA that can be broadly applied to acute and chronic liver diseases. CG-LR1's pharmacokinetics also support an infrequent dosing regimen, which helps to improve patient compliance.

2440-C | A PHASE 2a, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY TO ASSESS THE EFFICACY, AND SAFETY OF ALS-L1023 IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Eileen Yoon[1], Huiyul Park[2], Sang Bong Ahn[3], Hyunwoo Oh[4], Hyo Young Lee[4], Joo Hyun Sohn[1] and Dae Won Jun[1], (1)Hanyang University College of Medicine, (2)Hanyang University, (3)Eulji Medical Center, (4)Uijeongbu Eulji Medical Center

Background: Preclinical data have shown that the herbal extract, ALS-L1023, from Melissa officinalis reduces visceral fat and hepatic steatosis. We aimed to assess the safety and efficacy of ALS-L1023 as the treatment of non-alcoholic fatty liver disease (NAFLD). **Methods:** We conducted a 24-week randomized, double-blind, placebo-controlled 2a study in patients with NAFLD (MRI-proton density fat fraction [MRI-PDFF] e 8% and liver fibrosis e 2.5 kPa on MR elastography [MRE]) in Korea. Patients were randomly assigned to 1800 mg ALS-L1023 (n = 19), 1200 mg ALS-L1023 (n = 21), or placebo (n = 17) groups. Efficacy endpoints included changes in liver fat on MRI-PDFF, liver stiffness on MRE, and liver enzymes. **Results:** For the full analysis set, a relative hepatic fat reduction from baseline was significant in the 1800 mg ALS-L1023 group (-15.0%, p = 0.03). There was a significant reduction in liver stiffness from baseline in the 1200 mg ALS-L1023 group (-10.7%, p = 0.03). Serum alanine aminotransferase decreased by -12.4% in the 1800 mg ALS-L1023 group, -29.8% in the 1200 mg ALS-L1023 group, and -4.9% in the placebo group. ALS-L1023 was well tolerated and there were no differences in the incidence of adverse events among the study groups. **Conclusion:** ALS-L1023 could reduce hepatic fat content in patients with NAFLD.

2441-C | A STEPWISE SCREENING APPROACH USING NONINVASIVE TESTS TO IDENTIFY PHENOTYPIC NONALCOHOLIC STEATOHEPATITIS (NASH) PATIENTS WITH FIBROSIS FOR CLINICAL TRIALS

Rohit Loomba[1], Mazen Noureddin[2], Eric Lawitz[3], Kris V. Kowdley[4], Lois Lee[5], Amnon Schlegel[6], Hiba Graham[6], Lu Zhang[6], Kerry Russell[6] and Naim Alkhouri[7], (1) University of California, San Diego, San Diego, CA, (2) Houston Research Institute, Houston, TX, (3)Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, (4)Swedish Medical Center, Seattle, WA, (5)Terns Pharma, San Diego, CA, (6)Terns Pharma, Foster City, CA, (7)Arizona Liver Health, Phoenix, AZ

Background: Non-invasive tests (NITs) have become essential to help diagnose and stage nonalcoholic steatohepatitis (NASH). Biopsy-based screen failure (SF) rates are high in NASH trials, which lead to increased cost and extended enrollment durations. Per 2023 AASLD guidance, patients with at least stage 2 fibrosis are at increased risk of cirrhosis and liver-related complications. Patients with specific comorbidities such as type 2 diabetes mellitus (DM2), obesity and hypertension and biomarkers such as PDFF, cT1and other NITs may help define the NASH population. DUET is a randomized double-blind Phase 2a study fully enrolled and currently ongoing in patients with presumed NASH. A stepwise NIT screening approach was implemented to recruit patients likely to have NASH and a high degree of liver fat and fibro-inflammation, reflecting F2 and F3 fibrosis without requiring a biopsy. **Methods:** Initial screening (step 1) required age 18 – 75 years old and BMI e 25 kg/m^2, vibration controlled transient elastography (VCTE) of 7.6 to 21 kPa, and controlled attenuation parameter (CAP) of > 300 dB/m in patients without historical biopsy for fibrotic NASH within 1 year before randomization. Potential subjects remaining eligible after initial screening underwent MRI to assess liver fat content eligibility of e 10% by proton density fat fraction (PDFF) and fibro-inflammation defined as corrected T1 (cT1) e 800 msec (step 2). Common SF reasons were tabulated, and multiparametric MRI SF rates were calculated. Baseline criteria of the enrolled population were compared to the SF population as well as to the AASLD guidance for identifying patients with NASH. **Results:** 591 patients were screened and 162 were randomized; overall SF rate was 73%. The screening duration was 9 months. Of the 591 patients, 291 met step 1 eligibility criteria, with a SF rate of 51%. Of the 291 patients who underwent MRI assessments, 162 met MRI-PDFF and cT1 criteria resulting in a step 2 MRI SF rate of 56%. The randomized population had higher mean values for ALT and AST and a higher proportion of DM2 patients compared to the SF population (Table 1). cT1 values reflect the patients included in the study represent the at-risk NASH population according to the cutoff (e 875 msec) provided in the AASLD guidance. **Conclusion**: A stepwise screening approach beginning with clinical assessments, laboratory tests, and VCTE with CAP followed by MRI identified patients that were more likely to meet the eligibility criteria. As a result, fewer MRI assessments were required to fully enroll the study, reducing costs and the need for patients to be scheduled for a separate imaging visit.

Background: Nonalcoholic steatohepatitis (NASH) is characterized by build-up of fat within liver cells leading to fibrosis, steatosis, and hepatic injury. Inhibition of bile acid (BA) transporters is a potential therapeutic option to treat NASH by restoring lipid homeostasis and reducing inflammatory burden. We investigated the lipidomic modulation of the systemic apical BA transporter inhibitor A3907 in liver and plasma from ob/ob-NASH mice and A3907 phase 1 study subjects and matched this to NASH patients for translational validity. **Methods:** Leptin-deficient ob/ob mice were pre-fed Gubra-Amylin NASH diet, and liver pathology was confirmed by baseline liver biopsy. A3907 or vehicle was given by oral gavage once daily for 4−10 weeks. Lipidomics analyses were performed on mouse liver and plasma and on human plasma from a phase 1 A3907 study in healthy volunteers. **Results:** A3907 showed positive effects on liver weight, fibrosis progression, lobular inflammation, and steatosis scores. NASH leads to elevation of cholesteryl esters (CEs) in liver, which is reversed in a dose-dependent manner by A3907 treatment in ob/ob-NASH mice. After 10 weeks of treatment, liver CE levels dropped 23-fold, reaching concentrations observed in healthy humans. Lipidomics identified a reprogrammed fatty acid (FA) metabolism. In phosphatidyl-choline (PC) and -ethanolamines (PE), the portion of saturated (SFA), diunsaturated (DUFA) and polyunsaturated fatty acids (PUFAs) increased, counterbalanced by a decrease in monounsaturated FAs (MUFAs). A3907-treated animals showed preferences for dietary linoleic acid (FA18:2), activating the omega-6 pathway, leading to elevation of polar and neutral lipid species containing FA18:2 and upstream metabolic products by upregulation of FADS6 and FADS1 genes. The FA metabolic shift is counteracted by decreasing lipid species rich in MUFAs, suggesting that A3907 attenuates utilization of dietary SFAs and omega-9 FAs, supported by downregulation of SCD-1 and ELOVL-1 genes. Similar FA reprogramming was observed in the phase 1 clinical study. **Conclusion:** A3907 administration improves key plasma and liver histological NASH markers and reduces the NASH lipidomic fingerprint. This is triggered by selective FA metabolic reprogramming, restoring liver function by reducing the lipotoxic burden. We identify new mechanisms for treatment of NASH and fibrotic progression and show translational validity by linking effects in animal models with healthy volunteers treated with A3907.

2443-C | ADVANCING THE MULTI-TARGETED MECHANISMS OF ACTION OF A MITOCHONDRIAL ACTIVATOR (AXA-1125) FOR TREATING NASH USING A QUANTITATIVE SYSTEMS PHARMACOLOGY MODEL

Vinal V Lakhani[1], Ming Gao[2], Paul Hinderliter[2], Matthew Russel[2], Karim Azer[2] and Scott Q. Siler[1], (1) Simulations Plus, (2)Axcella Therapeutics

Background: Patients with non-alcoholic steatohepatitis (NASH) do not currently have options for pharmaceutical treatment. AXA-1125 is an endogenous metabolic modulator (EMM), which has shown efficacious potential when administered to patients in early clinical studies. *In vitro* studies and literature review have enumerated several contributing mechanisms of action (MoA's) by which AXA-1125 dosing may be reducing levels of ALT, liver fat, Pro-C3, and HbA1c in patients. To further advance and quantitate the differential multi-targeted mechanisms driving improvements seen in in the clinic, a quantitative systems pharmacology (QSP) model, NAFLDsym, was employed to simulate AXA-1125 under many combinations of candidate MoA's and further substantiate the MoA underlying the clinical benefit observed to date in patients. **Methods:** Clinical trial NCT04073368 was simulated by several software packages. Exposure of AXA-1125 was modeled in Monolix® using a 1-compartment model based on data from a single 22.6 g dose. This model was then used to predict the exposure of multiple doses (24 g BID) for 16 weeks using Simulx®. Separately, various candidate MoA's of AXA-1125 were mechanistically represented in NAFLDsym, including the secretion of incretins (GLP-1 and GIP) and relevant downstream effects, direct reduction of oxidative stress, increased AMPK-responsive enzyme expression, inhibition of hepatic stellate cell activation and proliferation, and decreased TNFα production. Each of these MoA's has the potential to reduce the hepatic lipid burden, lipotoxicity, inflammation and/or fibrosis. NAFLDsym simulations combined the predicted exposure of 24 g BID dosing with various combinations and strengths of candidate MoA's. Simulation results were evaluated against clinical data from a Phase IIa Study (AXA1125-003). **Results:** Simulations with NAFLDsym implicate multiple mechanisms that may be playing a role in the efficacy of AXA-1125. The clinical data were recapitulated in simulations invoking combinations of incretin secretion, and increased AMPK-responsive enzyme expressions. Additional simulations which further invoked direct antioxidant activity, or antioxidant activity and decreased TNFα production, increased fatty acid oxidation, also recapitulated clinical

observations. **Conclusion:** NAFLDsym, a QSP model of NAFLD/NASH, was used to investigate the combination of mechanisms playing a role in AXA-1125, a NASH therapeutic candidate. Here, NAFLDsym simulations support the following mechanisms contributing to the clinical response of AXA-1125: incretin effects, AMPK-responsive enzyme expression, antioxidant-mediated reduction of lipotoxicity, and inhibition of TNFα production. This works independently recapitulates previously published MoA findings, including AXA-1125 as a mitochondrial activator, and predicts novel contributions which require additional work to be validated and expanded upon.

2444-C | ANALYSIS OF HISPANIC/LATINX VS NON-HISPANIC/LATINX SUBGROUPS FROM THE REGENERATE TRIAL OF OBETICHOLIC ACID FOR THE TREATMENT OF NONALCOHOLIC STEATOHEPATITIS

Manal F. Abdelmalek[1], Lee Feinman[2], Jing Li[2], Pamela J. Davis[2], Amarita Randhawa[2] and Julio A. Gutierrez[3], (1)Mayo Clinic, Rochester, MN, (2)Intercept Pharmaceuticals, Inc., Morristown, NJ, (3)Verity Medical Foundation

Background: The prevalence and risk of nonalcoholic steatohepatitis (NASH) is highest in the Hispanic/Latinx (H/L) population. Obeticholic acid (OCA) is a farnesoid X receptor agonist studied as a treatment for pre-cirrhotic liver fibrosis due to NASH. We performed a subgroup analysis of the H/L vs non-H/L populations in the phase 3 REGENERATE trial of OCA in patients with pre-cirrhotic fibrosis due to NASH. **Methods:** Patients with biopsy-confirmed fibrosis stage F2 or F3 were randomized 1:1:1 to once-daily oral placebo, OCA 10 mg, or OCA 25 mg. The primary endpoint of the month 18 interim analysis was improvement in fibrosis e 1 stage with no worsening of NASH by a central or consensus (requiring agreement of 2 out of 3 pathologists) read method using the NASH Clinical Research Network scoring system. Secondary endpoints included change from baseline in serum alanine aminotransferase (ALT) at month 18. Safety was assessed by adverse events. **Results:** Of 931 patients in the intent-to-treat (ITT) population, 141 (15.1%) were H/L. Based on the central read, improvement in fibrosis e 1 stage with no worsening of NASH occurred in 8%, 12%, and 30% of H/L patients vs 14%, 18%, and 23% in the non-H/L patients receiving placebo, OCA 10 mg, and OCA 25 mg, respectively. The magnitude of the response ratios was similar to those observed in the overall ITT population and the consensus read methodology (Figure 1). Despite variability due to the small sample size of the H/L subgroup, the response ratio favored OCA 25 mg compared to placebo (3.60; 95% CI, 1.22–10.60), while a diminished response rate was seen in the non-H/L (1.62; 95% CI, 1.10–2.41). The mean change (SE) from baseline in ALT levels at month 18 in the H/L subgroup was -24.4 [11.4], -10.4 [5.2], and -50.9 [10.7] for placebo, OCA 10 mg, and OCA 25 mg, respectively, compared to -15.2 [3.6], -27.5 [3.0], and -32.1 [3.8], respectively, in the non-H/L subgroup. **Conclusion:** Among the H/L patients, the histological response to OCA was similar to the non-H/L population and consistent with the overall ITT population based on the central read. A larger placebo effect was also noted for the change in ALT levels in the H/L subgroup, as well as a greater reduction from baseline with OCA 25 mg compared to the non-H/L subgroup. The improvement in fibrosis e 1 stage with no worsening of NASH and reduction in ALT support the efficacy of OCA in this high-risk group of patients with pre-cirrhotic fibrosis due to NASH.

Background: Despite of increase in number of fibrosis due to NASH which becomes a major cause of liver-related outcomes, no approved drug is available. Recently, potential benefit of incretins such as glucagon (GCG), GIP and GLP-1 beyond metabolism has been proposed especially in inflammation and fibrosis. Thus, to optimally implement these incretins, efocipegtrutide, a long-acting GCG/GIP/GLP-1 triple agonist (HM15211), was developed. Here, we evaluated and compared the therapeutic effects of efocipegtrutide with available incretin drugs in TAA (thioacetamide)-induced liver injury and fibrosis mouse. **Methods:** TAA was interperitoneally injected to mouse for 12 weeks to induce liver injury and fibrosis, and efocipegtrutide was administered during last 10 weeks. Semaglutide and tirzepatide were included as comparative controls. At end of treatment, hepatic hydroxyproline content was measured and the liver tissues were subjected to H&E and Sirius red staining followed by histological grading. qPCR and ELISA were performed to evaluate relevant hepatic and blood bio-markers. **Results:** Efocipegtrutide treatment was associated with significant reduction of hepatic hydroxyproline content (231.9 nmol/g vs. 350.4 nmol/g for TAA, vehicle; $p < 0.001$) while that of semaglutide (322.5 nmol/g) or tirzepatide (322.1 nmol/g) had minor effects. Similarly, treatment of efocipegtrutide (0.83 %, $p < 0.001$), significantly reduced Sirius red positive area (vs. 5.75 % for TAA, vehicle), unlike neither semaglutide (4.93 %) nor tirzepatide (3.61 %). To further confirm the potential benefit of efocipegtrutide, histological grading was conducted by using Sirius red and H&E staining, in which efocipegtrutide (1.29, 1.00 vs. 3.00, 3.00 for TAA, vehicle) exhibited greater reduction effects on both fibrosis and portal inflammation score compared to semaglutide (2.14, 2.71) or tirzepatide (2.00, 2.57). Consistent with such histologic analysis, expression of hepatic marker genes for fibrosis and inflammation were significantly/numerically reduced only in efocipegtrutide group. Significant reduction in blood TIMP-1 level was also observed. **Conclusion:** Efocipegtrutide effectively improved liver inflammation and fibrosis in TAA mice. Notably, greater improvement effect over semaglutide and tirzepatide highlights the potential benefit of simultaneous use of GCG, GIP, and GLP-1. Thus, efocipegtrutide could be a novel therapeutic option for fibrosis due to NASH. Phase 2b study is ongoing to assess the clinical relevance of these findings.

2446-C | CHARACTERIZATION OF SENESCENT HEPATOCYTE IDENTIFIED NOVEL SENOLYTICS FOR NAFLD TREATMENT

Kuo Du[1], Liuyang Wang[1], Ji Hye Jun[1], Raquel Maeso Díaz[2], Rajesh Kumar Dutta[2], Seh-Hoon Oh[2], Pan Christopher[1], Dennis Ko[1], Xiao-Fan Wang[1] and Anna Mae Diehl[2], (1)Duke Universty, NC, (2)Duke University

Background: NAFLD is rapidly becoming the leading cause of chronic liver disease worldwide. Recent studies demonstrated that senescent hepatocytes accumulate in human NAFLD and correlate with adverse outcomes. However, the characteristics of senescent hepatocytes have not been defined, and it is unclear if/how the senescent phenotype itself affects NAFLD progression. Our study aimed to characterize senescent hepatocytes and identify novel therapeutic targets for NAFLD treatment. **Methods:** We performed RNA-seq and histological analysis on liver biopsies from NAFLD patients to evaluate senescence and correlate it with NAFLD severity. We also induced senescence in hepatocytes using AAV-TBG-p16 vectors in mice and CDK4/6 inhibitor in Huh7 cells, and compared the senescent hepatocyte transcriptome to human NAFLD to evaluate the clinical relevance of these models. The paracrine effects of senescent hepatocytes were studied by harvesting conditional medium and placing it onto proliferating hepatocytes, HSCs, macrophages, and LSECs. We also performed bioactive chemical library screening to identify novel senolytic hits, which were further validated in vitro and in mouse models of NAFLD. **Results:** Senescent markers and gene signatures were upregulated in human NAFLD and positively correlated with disease severity. Transcriptome analysis of senescent hepatocytes revealed a reduced liver-specific gene signature, while gene signatures associated with inflammation and fibrosis were highly upregulated, indicating a pathogenic role of senescent hepatocytes in NAFLD development. The transcriptomes of senescent hepatocytes overlapped with the differentially expressed gene profiles from NAFLD patients, distinguished NAFLD patients from healthy controls, and identified advanced fibrosis from mild fibrosis. The conditioned medium from senescent hepatocytes induced secondary senescence in proliferating hepatocytes and promoted HSC fibrogenesis, macrophage activation, and LSEC capillarization. Bioactive chemical library screening identified multiple senolytic candidates, some of which demonstrated therapeutic potential in mouse models of NAFLD. **Conclusion:** Our study suggests that hepatocyte senescence is a central pathogenic mechanism of NAFLD development, and we identified novel senolytics for NAFLD treatment. These findings provide a foundation

2447-C | COMBINATORY TREATMENT WITH MIR-22 ASO AND GLP-1 RA INCREASES POSITIVE OUTCOMES ON BODY WEIGHT AND LIVER PARAMETERS IN THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF NASH

Riccardo Panella[1,2], Simone Tomasini[1], Michael Feigh[3] and Sakari Kauppinen[1], (1)Aalborg University, (2) Resalis Therapeutics, (3)Gubra Aps

Background: miR-22 was identified as a crucial controller of lipid homeostasis, hepatic steatosis and inflammation. Both genetic and pharmacological inhibition are very effective in reducing body weight and increasing liver health in mouse and non-human primate models. Interestingly, unlike GLP-1 RA, the therapeutic effect of miR-22 inhibition is completely independent from food intake. Our hypothesis is that GLP-1 RA and miR-22 inhibition have two orthogonal mechanisms of action and they can cooperate leading to an increase of the positive effects observed with GLP-1 RA monotherapy **Methods:** Male C57BL/6 mice were fed the GAN diet high in fat, fructose and cholesterol for 38 weeks prior to study start. A liver biopsy was sampled 4 weeks prior to study start. Only animals with biopsy-confirmed NAFLD Activity Score (NAS e 5) and fibrosis stage e F1 were included and stratified into treatment groups. Mice were administered vehicle (n = 18) or Semaglutide (30 nM/kg, n = 18) or Semaglutide and anti-sense oligonucleotide targeting miR-22 (30nM/kg daily; 10mg/kg weekly n = 18) for 24 weeks. Mouse body weight was measured daily and histopathological pre-to-post individual assessment of NAS and fibrosis stage was performed to evaluate the effect of combinatory treatment. Other terminal endpoints in GAN DIO-NASH mice included quantitative liver histology, blood and liver biochemistry. **Results:** Combining GLP-1 RA and miR-22 pharmacological inhibition we prove that those 2 compounds have a strong synergetic effect with a resultant effect of doubling the number of mice that lost at least 20% of their initial body. Moreover our combinatory treatment was preventing the rebound in body weight observed in GLP-1 RA monotherapy. Importantly severe liver parameters (NAFLD, steatosis, lobular inflammation scores) show better improvement in the combinatory group compared to monotherapy **Conclusion:** Our combinatory therapeutic approach was also able to improve the positive effect on body weight and liver parameters already achieved with GLP-1 RA. Combination of GLP-1 RA and miR-22 inhibition was able to prevent the rebound in body weight observed in GLP-1 RA monotherapy, improving the overall effect of GLP-1 RA monotherapy on metabolism while being very well tolerated. Those data are paving the way to the first combinatory treatment for obesity and NAFLD based on targeting a non-coding RNA.

2448-C | CVI-2742, A LIVER-DIRECTED AND POTENT THR-BETA SELECTIVE AGONIST, DEMONSTRATES STRONG EFFICACIES IN REDUCING PLASMA CHOLESTEROL AND HEPATIC LIPIDS WITH DESIRABLE TISSUE DISTRIBUTIONS

Jingwen Liu and Zhenyu Wang, CVI Pharmaceuticals Shanghai Limited

Background: Non-alcoholic steatohepatitis (NASH) is characterized by liver steatosis, inflammation, and hepatocyte ballooning with varying degrees of fibrosis. Selective activation of thyroid hormone receptor-beta (THR-β) in liver tissue ameliorates NASH symptoms without causing cardiac abnormalities mediated by THR-α activation. Since THR-β is also expressed in several non-hepatic tissues, penetration of a THR-β agonist into extra hepatic tissues could induce unwanted side effects. Applying a two-step new screening method that combines THR mediated reporter activation assay and an active membrane transporter assay we have discovered a series of novel compounds including CVI-2742 that are liver-directed and potent THR-β selective agonists with EC_{50} in low nmol concentrations. Here we investigated the potency and liver-selectivity of CVI-2742 in biochemical assays and assessed its *in vivo* efficacy and tissue distribution in a hyperlipidemic mouse model. **Methods:** TRE-Luc reporter assays were conducted in HEK293A cells in the presence of THR-β expressing plasmid and a plasmid expressing human hepatic transporter OATP1B1 or a control plasmid pCI-Neo. Mice fed a diet containing 1% cholesterol and 0.5% cholic acid for 3 weeks received vehicle, or CVI-2742 at varying doses (0.5 mkg, 1 mkg and 5 mkg) for 7 days by oral gavage once a day. On day 8, animals were euthanized and blood and tissue samples of heart, brain and liver were collected for biochemical assays and LCMS/MS analysis of CVI-2742. Hepatic and cardiac gene expressions were analyzed by quantitative RT-PCR. **Results:** In the absence of OATP1B1, CVI-2742 activated THR-β with 81% T3 maximal activity at 552 nM EC_{50}, whereas with OATP1B1 being expressed, CVI-2742 activated THR-β with 90% T3 maximal activity at 59 nM EC_{50}, representing a 9.3-fold activity enhancement. In hyperlipidemic mice, compared to baseline, CVI-2742 dose-dependently reduced serum TC by 57% to 75% and TG by maximal 56% after 7-day treatment. Liver TG was reduced to a maximal level of 50% of vehicle control. Serum levels of ALT, AST, TSH and glucose were similar between vehicle and treatment groups. Hepatic mRNA levels of malic enzyme 1 were dose-dependently increased by CVI-2742 whereas mRNA levels of THR-α regulated genes Myh6 and Atp2a2 in heart tissues remained unchanged. Importantly, CVI-2742 were not detected in brain and were showed negligible levels in blood and heart but it was highly concentrated in livers. In mice treated with high dose (5 mpk) of CVI-NP2742, the compound liver to heart partition ratio is 65.5 and liver to plasma ratio is 60, which is superior to reported data from other THR-β agonists under clinical development. **Conclusion:** CVI-2742 is a liver-directed and highly potent THR-β selective agonist *in vitro* and *in vivo*. These preclinical data warrant further investigation of CVI-2742 as a potential treatment for NASH.

2449-C | CYSTAMINE D4 IMPROVES LIVER INFLAMMATION AND FIBROSIS IN A MURINE MODEL OF FIBROSING STEATOHEPATITIS

Ola Leszczynska, Benedikt Kaufmann, Thibault Alle, Christian Stoess, Hana Sung, Andrea D. Kim, Chelsea Tran, Agustina Reca, Carlo Ballatore, Ranjan Dohil and Ariel E. Feldstein, University of California, San Diego

Background: The development of NASH is greatly influenced by increased oxidative stress, resulting in excessive formation of reactive oxygen species. In this context, glutathione represents a component of antioxidant defense in the liver. Cysteamine supports glutathione synthesis and ameliorates oxidative stress. Further, we developed a deuterated derivative of cystamine to investigate its possible utility as a treatment for NASH. **Methods:** Mice were fed an L-amino acid-defined, high fat diet (CDAAHF) consisting of 60 kcal% fat and 0.1% methionine by weight or control diet for 10 weeks. At 6 weeks of the CDAAHF diet, mice underwent daily gavage for 4 weeks with drug 2 (D2, di-deuterated cystamine) or drug 4 (D4, tetra-deuterated cystamine) in single gavage 200 mg/kg bodyweight. The liver and blood readouts were investigated at 4 weeks post gavage by Western Blot, qPCR, and histological analysis. **Results:** Tissue section quantification revealed a decreased rate of apoptotic staining in D4 gavaged mice when compared to control mice (0.47 ± 0.2 vs 0.13 ± 0.08; 0.16 ± 0.11[%] Positive Area (PA), p d 0.0001). qPCR analysis of mRNA levels of Cxcl1, Ccl9 were significantly decreased in mice gavaged with D4 (0.4-Fold Change (FC), p d 0.0001; 0.6FC, p d 0.05) and D2 (0.4FC, p d 0.01; 0.6FC, p d 0.05) as compared to control animals with concomitant decrease of infiltrating inflammatory cells positive for Ly6c (0.3FC, p d 0.001; 0.1FC, p d 0.0001), and resident cells positive for F4/80 (0.8FC, p d 0.05; 0.8FC, p d 0.001). However, TNF-α mRNA levels were only downregulated in D4 gavaged mice, suggesting greater anti-inflammatory role of D4 over D2 (0.8FC, p d 0.01). Liver fibrosis development was ameliorated in D4 gavaged mice followed by

decreased levels of Picrosirius Red staining and mRNA downregulation of Col1a. α-SMA protein levels were significantly lower (2.7[%] PA vs control 4.8[%] PA, p d 0.01), indicating a decrease in hepatic stellate cell activation in D4 gavaged mice. The protein levels of 4HNE (4-hydroxyneonate) were significantly reduced in D4-gavage mice compared to D2 and controls (0.9FC vs 2.5FC, p d 0.05), which suggests D4 plays a role in reduction of oxidative stress in the liver. **Conclusion:** Our studies demonstrate that in the CDAAHF mouse model, compound efficacy increases proportionally with the deuterium content, with D4 being most active. These results show that deuterated cysteamine/cystamine derivatives reduce hepatocyte cell death, liver inflammation, and compensatory proliferation, which holds considerable promise to treat NASH.

2450-C | ECG QT INTERVAL CHANGES IN COMPENSATED NASH LIVER CIRRHOSIS WITH PORTAL HYPERTENSION. EXPERIENCE WITH BELAPECTIN, A GALECTIN-3 INHIBITOR

Pol Boudes, Steven Schoenfeld and Ezra Lowe, Galectin Therapeutics

Background: Liver cirrhosis is associated with prolonged QT/QTc intervals on ECG (> 450 ms in males and 460 ms in females)[1]. However, limited data are available in patients with compensated cirrhosis and portal hypertension (PH) and the clinical relevance of this QT increase is not well known. We describe QT/QTc intervals and clinical status of patients in a phase 2b, randomized trial (NCT 02462967) evaluating the safety and efficacy of belapectin, a galectin-3 inhibitor, in patients with Non-Alcoholic SteatoHepatitis (NASH) cirrhosis and PH. **Methods:** NASH cirrhosis was confirmed by histology. PH was established with a hepatic venous pressure gradient of at least 6 mm Hg. Patients on non-selective beta-blockers, with previous cirrhosis decompensation, medium or large size varices, a MELD e 15, or a Child-Pugh stage B or C, were excluded from the study. There was no eligibility restriction on QT/QTc duration. Patients received biweekly infusions of belapectin 2 mg/kg of lean body mass (LBM), belapectin 8 mg/kg of LBM, or placebo for 52 weeks. 12-lead electrocardiogram were done at screening, on treatment (7th infusion), and post treatment at week 57. QTc used the Bazett's correction. Screening, QTc changes, and increases above relevant thresholds are presented. Correlation between on-treatment QTc changes and belapectin plasma concentrations was explored (7th infusion). Adverse events (AE) and Serious AEs potentially associated with QTc prolongation (syncope, ventricular arrythmia including torsades de pointe, sudden death) were evaluated. **Results:** QTc intervals and changes are presented in the table. None of the QTc elevations were considered clinically relevant by Principal Investigators. There was no apparent correlation between belapectin plasma levels and changes in QTc. Across treatment groups, there were no treatment-emergent AEs that could be linked to a prolonged QT. **Conclusion:** QT/QTc prolongation is frequent in compensated cirrhosis with portal hypertension but does not appear symptomatic. In this study belapectin did not appear to be associated with adverse events related to QTc prolongation. 1 Bernardi, et al. Hepatology 1998;27:28-34

2451-C | EFFECT OF CONCOMITANT GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS FROM THE REGENERATE TRIAL OF OBETICHOLIC ACID FOR THE TREATMENT OF PRE-CIRRHOTIC FIBROSIS DUE TO NONALCOHOLIC STEATOHEPATITIS

Kris V. Kowdley[1], Amarita Randhawa[2], Jing Li[2], Hiral Patel[2], Christopher Gasink[2], Sangeeta Sawhney[2] and Scott Isaacs[3], (1)Liver Institute Northwest, (2)Intercept Pharmaceuticals, Inc., Morristown, NJ, (3)Emory University School of Medicine

Background: Type 2 diabetes mellitus (T2D) is a common comorbidity associated with nonalcoholic

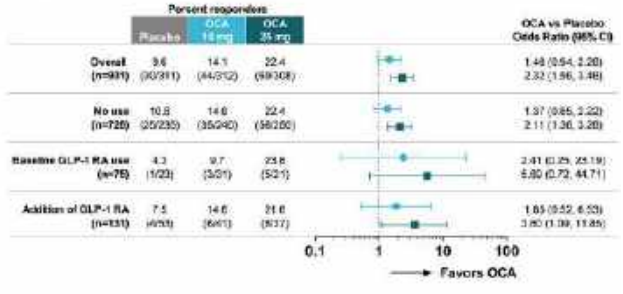
steatohepatitis (NASH). Glucagon-like peptide-1 receptor agonists (GLP-1 RA) are often-prescribed treatments for T2D and are also being investigated as NASH treatments. Obeticholic acid (OCA) is a farnesoid X receptor (FXR) agonist and antifibrotic agent studied as a treatment for pre-cirrhotic liver fibrosis due to NASH, which may often be used with GLP-1 RA. Herein, we assess the efficacy and safety of coadministration of OCA and GLP-1 RA in the phase 3 REGENERATE trial. **Methods:** In this phase 3 multicenter, randomized, double-blind, placebo-controlled study, subjects were randomized 1:1:1 to receive once-daily oral placebo, OCA 10 mg, or OCA 25 mg. The primary histological endpoint of the month 18 interim analysis (intent-to-treat [ITT], n = 931) was improvement in fibrosis ≥ 1 stage with no worsening of NASH using the NASH Clinical Research Network criteria. Safety was assessed in a larger population (n = 2477). **Results:** In the ITT population, 75 (8.1%) were on a GLP-1 RA for T2D at baseline, and 131 (14.1%) began a GLP-1 RA after the first dose of study drug. Concomitant use of GLP-1 RA was generally balanced across treatment arms. The percentage of subjects receiving OCA 25 mg that achieved the primary endpoint was 23.8% among those with baseline GLP-1 RA use, 21.6% of those who added a GLP-1 RA, and 22.4% in the overall ITT population, compared to 4.3%, 7.5%, and 9.6% receiving placebo, respectively (Figure 1). In the larger safety population, GLP-1 RA use was balanced across treatment arms, with 232 (9.4%) subjects on a GLP-1 RA at baseline and 422 (17.0%) beginning a GLP-1 RA during the trial. The incidence of pancreatitis was numerically higher among those on a GLP-1 RA (2.7% placebo, 1.2% OCA 10 mg, 1.3% OCA 25 mg) compared with the overall safety population (0.8% placebo, 0.6% OCA 10 mg, 1.0% OCA 25 mg). The use of GLP-1 RA in patients treated with OCA was not associated with additional biliary complications. **Conclusion:** Among patients with concomitant GLP-1 RA use and pre-cirrhotic fibrosis due to NASH in REGENERATE, OCA showed consistent efficacy in fibrosis improvement. There were no notable differences in the safety profile of OCA with GLP-1 RA use.

Figure 1. Improvement in fibrosis ≥1 stage with no worsening of NASH in subjects on a GLP-1 R agonist at baseline or began a GLP-1 R agonist after the first dose of study drug



"No worsening of NASH" was defined as no worsening of hepatocellular ballooning grade, no worsening of lobular inflammation grade, and no worsening of fibrosis grade.

Abbreviations: CI, confidence interval; GLP-1 RA, glucagon-like peptide-1 receptor agonist; NASH, nonalcoholic steatohepatitis; OCA, obeticholic acid.

2452-C | EFFICACY AND SAFETY OF EFINOPEGDUTIDE IN HISPANIC PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE: RESULTS FROM AN ACTIVE COMPARATOR-CONTROLLED STUDY

Manuel Romero-Gómez[1], Eric Lawitz[2], R. Ravi Shankar[3], Raymond L.H. Lam[3], Jianxin Lin[3], Keith D. Kaufman[3] and Samuel S. Engel[4], (1)Ucm Digestive Diseases, Virgen Del Rocio University Hospital, Instituto De Biomedicina De Sevilla, Ciberehd, University of Seville, Sevilla, Spain, (2)Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, (3)Merck & Co., Inc., Rahway, NJ, USA, (4) Global Clinical Development, Merck & Co., Inc., Rahway, NJ, USA

Background: Hispanic (HISP) patients have been reported to have a higher prevalence and severity of nonalcoholic steatohepatitis (NASH) compared to other ethnicities in the USA. We reported robust relative reductions from baseline (RRFB) in liver fat content (LFC) in a broad population of subjects with nonalcoholic fatty liver disease (NAFLD) in a study of efinopegdutide (EFI), a GLP-1/glucagon receptor coagonist, relative to the selective GLP-1 receptor agonist, semaglutide (SEMA). Here, we report RRFB in LFC in the HISP subgroup from this study. **Methods:** In this randomized, active comparator-controlled, open-label study, 145 subjects with NAFLD (18-70 y, BMI 25-50 kg/m^2, stable body weight, without T2DM or with T2DM with an A1C d 8.5% controlled by diet ± stable dose of metformin) and LFC e 10% (measured by MRI PDFF) at screening were randomized 1:1 to EFI 10 mg QW or SEMA 1.0 mg QW (titrated to target doses over 8 weeks) for 24 weeks. The primary efficacy endpoint was the least squares (LS) mean RRFB in LFC (%) at Week 24. **Results:** Among randomized subjects, 25 in the EFI group and 26 in the SEMA group were HISP. In the HISP subgroup, baseline characteristics were generally similar in the two treatment groups. Subjects were predominantly female (58.8%), < 65 years of age (88.2%, mean age: 51.6 y), white (90.2%), and obese (90.2%, mean weight: 96.3 Kg, mean BMI: 36.1 kg/m^2). Mean LFC at baseline was 22.3% in the EFI group and 19.9% in the SEMA group. The LS mean RRFB in LFC at Week 24 was significantly ($p = 0.001$) greater with EFI (76.4% [90% CI 67.1, 85.7]) than SEMA (50.5% [41.8, 59.3]) (figure). Median RRFB in LFC at Week 24 was 86.6% with EFI and 52.4% with SEMA. More subjects had RRFB in LFC at Week 24 of e 30%, e 50% and e 70% with EFI (84.0%, 76.0% and 72.0%, respectively) than SEMA (76.9%, 57.7% and 19.2%, respectively) (figure). After 24 weeks, 72% in the EFI group had a normal LFC (< 5%) compared with 26.9% in the SEMA group. LS mean RRFB in weight at Week 24 was similar in both groups (EFI 8.1% vs SEMA 7.3%, $p = 0.516$). In this HISP subgroup there were no meaningful differences between the two treatment groups in the incidences of adverse events (AEs) reported. **Conclusion:** In HISP patients with NAFLD, EFI 10 mg weekly led to a significantly greater reduction in LFC than SEMA 1 mg weekly, with a similar reduction in weight and a comparable incidence of AEs.

2453-C | EFFICACY OF EFINOPEGDUTIDE IN NONALCOHOLIC FATTY LIVER DISEASE: SUBGROUP ANALYSES FROM AN ACTIVE-COMPARATOR-CONTROLLED STUDY

Eric Lawitz[1], Manuel Romero-Gómez[2], R. Ravi Shankar[3], Raymond L.H. Lam[3], Jianxin Lin[3], Keith D. Kaufman[3] and Samuel S. Engel[4], (1)Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, (2)Ucm Digestive Diseases, Virgen Del Rocio University Hospital, Instituto De Biomedicina De Sevilla, Ciberehd, University of Seville, Sevilla, Spain, (3)Merck & Co., Inc., Rahway, NJ, USA, (4) Global Clinical Development, Merck & Co., Inc., Rahway, NJ, USA

Background: Efinopegdutide (EFI), a GLP-1/glucagon coagonist with ~2:1 GLP-1/glucagon receptor potency, has been shown to provide substantial reduction (72.7%) in liver fat content (LFC) compared to the selective GLP-1 receptor agonist semaglutide (SEMA; 42.3%) in a broad population of subjects with nonalcoholic fatty liver disease (NAFLD), with ~67% (EFI) vs ~18% (SEMA) achieving a normal LFC of < 5%. To further understand subject characteristics that might influence treatment response, we assessed the effects of EFI relative to SEMA on LFC in subgroups of patients from that study. **Methods:** In a Phase 2a, randomized, active-comparator-controlled, parallel-group, open-label study in subjects with NAFLD (18-70 y, body mass index [BMI] 25-50 kg/m^2, stable body weight, without type 2 diabetes [T2DM], or with T2DM with an A1C d 8.5% controlled by diet ± stable dose of metformin), participants with an LFC of e 10% were randomized in a 1:1 ratio to SC EFI 10 mg QW or SC SEMA 1 mg QW for 24 weeks. Both drugs were titrated to the target dose over an 8-week period. The primary efficacy endpoint was the least squares (LS) mean relative reduction from baseline in LFC (%) after 24 weeks of treatment. Subgroup analyses were performed based on the following baseline characteristics – gender, BMI, LFC, alanine aminotransferase (ALT), and presence of T2DM. **Results:** Mean baseline LFC tended to be higher in higher BMI, higher ALT and nondiabetic subgroups (TABLE); no notable difference was seen by gender. LS mean relative reductions in LFC, and between-group differences, in these subgroups were generally consistent with those observed in the overall cohort. Participants in the higher baseline LFC subgroups had greater LS mean relative reductions in LFC but were less likely to achieve an LFC < 5%, compared to the lower baseline LFC subgroup. **Conclusion:** In patients with NAFLD, treatment with EFI 10 mg weekly led to greater reductions in LFC, compared to semaglutide 1 mg weekly, across subgroups defined by demographic and disease-related baseline characteristics.

Subgroup	Treatment (n)	Mean Baseline LFC (%)	LS Mean Relative Reduction from Baseline in LFC at Week 24 (%)	% of Participants with Normal LFC at Week 24
Male	EFI (n=39)	22.0	71.6	61.5
	SEMA (n=41)	19.4	34.9	9.8
Female	EFI (n=33)	20.1	78.0	72.7
	SEMA (n=32)	19.4	50.1	28.1
BMI <30 kg/m^2	EFI (n=15)	19.2	79.1	86.7
	SEMA (n=18)	18.8	39.3	16.7

Background: Subjects with non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes mellitus (T2DM) present high progression of liver disease to fibrosis, which is the main determinant of long-term adverse outcomes. Data are accumulating on the benefits of sodium glucose cotransporter 2 inhibitors (SGLT-2i) on hepatic fibrosis mainly in pharmacologic or retrospective studies. Aim: to prospectively evaluate change in hepatic disease in patients with NAFLD and T2DM and predisposing factors, with particular regard to SGLT-2i. **Methods:** 237 T2DM outpatients (mean age 67 ±9 y, 54% male) were enrolled at the diabetology outpatient clinics and re-evaluated after 52 + 10 months. At baseline and follow-up information about diabetic control, metabolic comorbidities and medications were collected. NAFLD and liver fibrosis (LSM) were detected by ultrasonography and Fibroscan®. **Results:** During follow-up an increase in LSM (6.0 ± 2.8 vs 5.8 ± 2.7 kPa, $p = 0.02$) was registered, despite stability of diabetic control. LSM worsened in 133(56%) subjects, 92 (39%) having a worsening > 10% from baseline. At the end of follow-up, a higher prescription of SGLT2i was seen (20% vs 6%, $p < 0.001$). Patients with worsening versus non worsening of LSM had higher prevalence of increase in BMI during follow-up (45% vs 32%, $p = 0.06$), lower SGLT2i prescription (15% vs 27%, $p = 0.034$) and higher of sulfonylureas (23%vs 11%, $p = 0.016$). In multivariate

analysis adjusted for age, sex, liver enzymes, HbA1c and weight gain, use of SGLT2-inhibitors at follow-up was independently associated with a reduced risk of worsening of LSM (HR 0.34, 95% CI 0.13-0.88), even when considered > 10% from baseline. No impact of sulfonylureas was observed. **Conclusion:** Despite a high prevalence of fibrosis progression in NAFLD subjects with T2DM, we showed a potential effect of SGLT2-inhibitors in reducing the risk of worsening of liver stiffness. Therefore, our data suggest that using this category of antidiabetic drug in NAFLD patients may prevent progression of fibrosis, especially if weight control is obtained in these patients.

2455-C | EXPLORING THE THERAPEUTIC POTENTIAL OF PROSTAGLANDIN E2 EP4 RECEPTOR TARGETING IN HEPATIC FIBROSIS

Michael Schou Jensen[1], Ke Luo[2], Ann Catrine Daugaard Mikkelsen[1], Karen Louise Thomsen[3], Rajeshwar P. Mookerjee[1], Peter Olinga[2], Rikke Nørregaard[1] and Henricus Antonius Maria Mutsaers[1], (1)Aarhus University, (2)University of Groningen, (3) University College London

Background: Non-alcoholic fatty liver disease (NAFLD) is the most prevalent chronic liver disease globally, affecting approximately one-quarter of the world's adult population. NAFLD occurs as a spectrum from simple steatosis to non-alcoholic steatohepatitis (NASH), a more severe condition marked by steatosis, inflammation, hepatocyte injury (ballooning), and in advanced cases, fibrosis. In patients with NASH, hepatic fibrosis is the main determinant of mortality. However, no approved treatments are available currently, and liver transplantation remains the only curative option for most patients. Our previous studies have shown that modulating PGE2 receptor activity can attenuate renal fibrosis, prompting the investigation of its therapeutic potential in a hepatic context. Thus, we evaluated the anti-fibrotic potential of rivenprost, a PGE2 EP4 receptor agonist, in rat and human fibrotic precision-cut liver slices (PCLS). **Methods:** PCLS were prepared from either NASH rats, which received a high-fat, high-cholesterol diet for 16 weeks, or explanted cirrhotic livers of clinically diagnosed end-stage liver disease patients undergoing liver transplantation. Subsequently, PCLS were incubated with rivenprost (75 mM) for 48h. Fibrogenesis was evaluated on a gene and protein level by qPCR and ELISA, respectively. **Results:** qPCR revealed that treatment with rivenprost markedly reduced the gene levels of fibronectin (*Fn1*), a-smooth muscle actin (*Acta2*), collagen 1A1 (*Col1a1*), and tumor necrosis factor a (*Tnf*) in rat NASH PCLS. Similarly, we observed a decrease in the expression of *FN1*, *COl1A1*, *ACTA2* and *TNF* in human cirrhotic PLCS treated with rivenprost. In addition, rivenprost treatment resulted in a significant reduction in pro-collagen type I carboxy-terminal propeptide release by human cirrhotic PLCS, indicating a reduction in collagen type I production. **Conclusion:** Our results indicate that activation of the PGE2 EP4 receptor effectively reduces fibrosis in both rat and human cirrhotic PCLS. These findings warrant further research into the anti-fibrotic potential of rivenprost for the treatment of liver fibrosis.

2456-C | INHIBITION OF THE LYSOPHOSPHATIDIC ACID PATHWAY IMPROVES HEPATIC FIBROSIS AND PORTAL HYPERTENSION IN EXPERIMENTAL ADVANCED CHRONIC LIVER DISEASE

Peio Aristu[1], Zoe Boyer-Diaz[1], Anna Zagorska[2], Monika Sharma[2], María Andrés-Rozas[1], Grant Budas[2], Jaime Bosch[3] and Jordi Gracia-Sancho[1,3], (1)Barcelona Liver Bioservices (BLB), (2)Gilead Sciences, Inc., (3)Idibaps - Hospital Clínic Barcelona - Ciberehd, Barcelona, Spain

Background: Hepatic necroinflammatory processes are significant contributors to the progression of advanced chronic liver disease (ACLD), characterized by hepatic microvascular dysfunction, fibrosis, and portal hypertension. Lysophosphatidic acid (LPA), a paracrine factor obtained from the transformation of lysophosphatidylcholine by the enzyme autotaxin (ATX), activates hepatic stellate cells (HSCs) and promotes fibrogenesis. The present project aimed at characterizing the effects of inhibiting LPA in a pre-clinical model of advanced chronic liver disease. **Methods:** Cirrhotic rats with ascites (16 weeks CCl_4) randomly received either an inhibitor of autotaxin (ATXi, GLPG1690; 60 mg/kg/BID), an LPA receptor-1 antagonist (LPAR1i, AM095; 30 mg/kg/BID) or

vehicle for 14 days (n = 12/group). *In vivo* hepatic and systemic hemodynamics, and molecular markers of liver injury, fibrosis, inflammation, oxidative stress, cell death, hepatic stellate cells (HSC) activation and liver sinusoidal endothelial cells (LSEC) de-differentiation were determined. **Results:** Cirrhotic animals receiving LPA pathway inhibitors exhibited lower portal pressure compared to vehicle-treated rats (ATXi: 13.4 ± 0.5 Vs 15.1 ± 0.6 mmHg; -11%; LPAR1i: 12.1 ± 0.7 mmHg vs 14.9 ± 0.7; -18%), with no changes in portal blood flow, suggesting decreased intrahepatic vascular resistance. No differences in systemic hemodynamics were observed. Underlying mechanisms of hepatic microcirculatory modulation included improvement in HSCs and LSECs phenotype (ATXi: desmin -24%, Vcam1 -28%; LPAR1i: +35% nitric oxide availability, vWF -25%), and significant fibrosis regression (ATXi: Sirius red area -20%, collagen -35%; LPAR1i: Sirius red -24%, collagen -27%). These were associated with anti-inflammatory (ATXi: IL6 -56%, IL10 -45%; LPAR1i: IL10 -50%), anti-apoptotic (ATXi: cell death -30%, AST -25%; LPAR1i: Casp8 -30%), and antioxidant effects (ATXi: MDA -62%, peroxynitrite -45%; non-significant for LPAR1i). **Conclusion:** This study demonstrates that inhibition of the LPA pathway exerts beneficial effects in a pre-clinical model of decompensated cirrhosis, which lead to marked amelioration in fibrosis and portal hypertension. Our results encourage its clinical evaluation for the treatment of advanced chronic liver disease.

2457-C | LANIFIBRANOR IMPROVES LIVER HISTOLOGY AND MARKERS OF CARDIOMETABOLIC HEALTH IN PATIENTS WITH NASH INDEPENDENT OF PNPLA3 GENOTYPE: A RETROSPECTIVE ANALYSIS OF THE NATIVE STUDY

Louis H Griffel[1], Sven Francque[2], Manal F. Abdelmalek[3], Philippe Huot-Marchand[1], Lucile Dzen[1], Martine Baudin[1], Jean Louis Junien[1], Pierre Broqua[1] and Michael Cooreman[4], (1)Inventiva, (2)University of Antwerp, Edegem, Belgium, (3)Mayo Clinic, Rochester, MN, (4)INVENTIVA

Background: A polymorphism of patatin-like phospholipase domain-containing protein 3 (PNPLA3), I148M, is strongly associated with the risk for and the progression of nonalcoholic steatohepatitis (NASH). Lanifibranor, a pan-PPAR agonist, has shown efficacy on histological disease activity and fibrosis as well as on metabolic-immune markers of NASH in the phase 2b NATIVE study, corresponding to the role of PPAR signaling in the disease biology of NASH. We evaluated the impact of the PNPLA3 variant I148M on the histologic and metabolic-immune response to lanifibranor. **Methods:** NATIVE evaluated lanifibranor 800 and 1200 mg/d versus placebo in 247 patients with non-cirrhotic NASH for 24 weeks of treatment. Of these, 219 patients consented to genotyping for the PNPLA3 rs738409 SNP. 65 were II, 105 IM and 49MM, which is highest risk for disease severity and progression. Paired liver biopsy results were available for 207/219 patients. Histologic and metabolic-immune marker response was evaluated by PNPLA3 genotype. **Results:** There was no significant difference in demographics between the PNPLA3 types, although those with MM genotype were younger (mean age 50.9 vs 55.4 for II and 53.1 for IM) and were more likely to have Type 2 Diabetes (45% MM, 38% II, 41% IM). Pooled lanifibranor and placebo responses are presented in the table. There was no significant difference in response to lanifibranor by PNPLA3 genotype, despite the fact that MM genotype patients had more activity on biopsy than the II or IM patients (82% NAS > = 6, vs 74%, 70%), while there was no difference in fibrosis. Similarly, Improvement of metabolic-immune markers for lanifibranor vs placebo was observed to the same degree in the 3 PNPLA3 genotypes including glycemic control, insulin, HOMA-IR, Hs-CRP, CAP & adiponectin. **Conclusion:** The efficacy of lanifibranor on both liver histology and markers of cardiometabolic health appears to be independent of PNPLA3 status, despite MM genotype patients having more severe activity on liver biopsy.

2458-C | LANIFIBRANOR-ASSOCIATED ADIPONECTIN INCREASE CORRELATES WITH IMPROVEMENT OF HISTOLOGICAL AND SERUM MARKERS OF NASH SEVERITY BOTH IN TERMS OF ACTIVITY AND FIBROSIS

Michael Cooreman[1], Manal F. Abdelmalek[2], Philippe Huot-Marchand[1], Lucile Dzen[1], Martine Baudin[1], Jean Louis Junien[1], Pierre Broqua[1] and Sven Francque[3], (1) Inventiva, (2)Mayo Clinic, Rochester, MN, (3)University of Antwerp, Edegem, Belgium

Background: Lanifibranor has shown efficacy on liver histology and markers of cardiometabolic health (CMH) in patients with pre-cirrhotic NASH. We previously showed that increases in adiponectin (ADP) with lanifibranor correlated with improvement of CMH markers. We further analyzed the correlation between ADP increase and lanifibranor for 1) histological features of NASH severity, and 2) biomarkers of active NASH and fibrosis. **Methods:** The phase 2 NATIVE study evaluated lanifibranor 800 and 1200 mg/d versus placebo in 247 patients for 24 weeks. Paired samples for histological efficacy were available from 211 patients (72 on placebo, 66 and 73 on lanifibranor 800 and 1200 mg). Serum levels of ADP, pro-C3, and MACK-3 score (a score for active and fibrotic NASH calculated from HOMA, AST and CK-18) were measured at baseline (BL) and end of treatment (EOT). BL ADP levels were divided into low, medium and high (< 5, 5-10 and > 10 ug/mL); ADP increase at EOT was defined as unchanged, moderate and high (< 1.5-fold, 1.5-4-fold and > 4-fold change). Histological NASH activity grading (steatosis, inflammation, ballooning) and fibrosis staging were per NASH-CRN and SAF scoring. Histological endpoints were NASH resolution and no worsening of fibrosis (E1), improvement of fibrosis and no worsening of NASH (E2), and NASH resolution AND fibrosis improvement (E3). **Results:** BL ADP levels were low across groups. ADP increase at EOT correlated with all histological endpoints. Responders with lanifibranor (pooled) were for E1: 15, 44 and 57%, E2: 31, 35 and 53%, and E3: 15, 28 and 40% for ADP unchanged, moderate or high increase, respectively. With placebo, a small (10) % of patients had a moderate ADP increase (all < 4-fold), which also correlated with histological response, but to a lesser degree. Degree of ADP increase, both absolute and categorical, correlated with improvement of CRN-NAS and SAF-Activity scores as well as with individual components (steatosis, inflammation, ballooning). Lanifibranor-associated ADP increase correlated with improvement in fibrosis stage (38% vs 57% for ADP d 4 vs > 4-fold increase, respectively), pro-C3 levels and MACK-3 score. **Conclusion:** ADP increase with lanifibranor in patients with NASH correlated with improvement of histological and serum markers of NASH activity and fibrosis, further supporting that the observed improvements correlate with lanifibranor target engagement. ADP, across the spectrum of NASH, is a biomarker of lanifibranor-associated efficacy.

2459-C | LEVERAGING NAFLDSYM TO IDENTIFY OPTIMAL COMBINATION THERAPIES FOR NASH PATIENTS

Maria E Trujillo[1], Saswata Talukdar[2], Grant Generaux[3], Michael Kelley[3], Shailendra Tallapaka[1], Ramin Mehrani[1] and Scott Q. Siler[3], (1)Merck and Co Inc, (2) Cardiometabolic Diseases, Merck & Co., Inc., South San Francisco, CA, (3)Simulations Plus

Background: Non-alcoholic steatohepatitis (NASH) is a metabolic disease that is characterized by increased liver fat, inflammation, and fibrosis; if left untreated, results in cirrhosis, hepatocarcinoma, and increased mortality. The many pathways contributing to NASH complicate drug discovery, development, and ultimately treatment of patients with NASH. **Methods:** Here we describe how a Quantitative Systems Pharmacology (QSP) model, NAFLDsym, was leveraged in discovery and development decision-making to select the targets, identify mechanism-based biomarkers, and simulate clinical trials to predict the effects of targets/combination of targets in NASH virtual patients. The mechanisms evaluated included: a) decrease in food intake (FI) leading to 5% or 10% weight loss, b) 90% inhibition of de novo lipogenesis (DNL) with a 60% increase in fatty acid oxidation (FAO), c) inhibition of hepatic stellate cell (HSC) activation by 30%, 60%, or 90%, and d) reductions in lipotoxicity by 20%, 40%, or 60%. **Results:** Simulated decreases in FI or DNL/FAO resulted in comparable reductions in liver fat, alanine aminotransferases (ALT), NAFLD Activity Score (NAS). Effects of the two mechanisms on liver fat and fibrosis endpoints were additive, suggesting the mechanisms may be combined to provide greater benefits than as a monotherapy (Figure 1). The reduction in HSC activation had no effect on liver fat, ALT, or NAS when administered as a monotherapy. The reduction of lipotoxicity led to improvements in fibrosis stage, collagen, plasma Pro-C3, and plasma ALT but not liver fat. The effects of decreased FI or DNL/FAO on fibrosis score, liver collagen, and plasma Pro-C3 were enhanced when combined with the inhibition of HSC activation or reductions in lipotoxicity. **Conclusion:** These explorations confirm there are many pathways that contribute to the pathophysiology of NASH. Agents that reduce hepatic fat are foundational for NASH patients and adding drugs that reduce lipotoxicity/ HSC activation may be key to optimal therapy.

2460-C | microRNA-21: A NOVEL THERAPEUTIC OPTION THAT PROTECTS FROM HIGH-FAT-DIET-INDUCED LIVER DISEASE PROGRESSION

Urmila Prataprao Jagtap[1,2], Anan Quan[2], Yuho Ono[2], Imad A. Nasser[2], Gyongyi Szabo[2] and Frank Slack[2], (1)Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: Liver disease is a leading cause of morbidity and mortality worldwide. MicroRNAs play crucial roles in regulating the pathophysiological functions of the liver. MicroRNA-21-5p (miR-21) is known to be dysregulated in liver metabolism, non-alcoholic fatty liver disease, fibrosis, and hepatocellular carcinoma. Conversely, the protective effects of miR-21 have also been reported in liver disease. Owing to the huge heterogeneity and variability of miR-21, it has not been approved as a biomarker or therapeutic option for liver disease. In this study, we aim to understand the role of miR-21 in all stages of liver disease and identify its potential as a therapeutic target. **Methods:** Three-week-old B6/129S (WT) and miR-21 KO mice were administered a one-time intraperitoneal injection of carcinogen-diethylnitrosamine, fed either standard (Chow) or choline-deficient high-fat diet (HFD) and were monitored over 32 weeks. To evaluate miR-21 as a potential therapeutic target, WT mice were administered with negative control or miR-21 mimic through tail-vein injection at week 16. **Results:** WT mice on Chow showed no noticeable abnormalities. However, mice on HFD developed obesity early in the experiment. At week 16, HFD-fed mice displayed signs of liver injury, hyperglycemia, and insulin resistance. Histologic evaluation revealed features of NASH manifested by varying severity of steatosis, ballooning degeneration, lobular inflammation, and fibrosis. By week 24, a significant number of tumors were observed in the liver, identified as fatty adenomas. By week 32, all the phenotypes advanced to a more severe stage. As the disease progressed, interestingly, a striking downregulation was observed in miR-21 transcript levels. We observed that the knockout of miR-21 alone was sufficient to cause hepatomegaly, hyperglycemia, insulin resistance, and steatosis. Exposure to HFD in this background caused even worse and accelerated phenotypes in obesity, steatosis, NASH, and the highest levels of fibrosis. By 24 weeks, a huge tumor burden was observed, identified as hepatocellular carcinoma. Administration of miR-21 mimics rescued insulin sensitivity and showed a prominent reduction in steatosis, fibrosis, and tumor burden in WT mice. **Conclusion:** Our results suggest that the knockout of miR-21 is sufficient to cause a metabolic syndrome with steatosis and NASH in mice. These effects, when coupled with HFD, accelerate the rate and severity of liver disease, indicating that loss of miR-21 causes increased susceptibility to the manifestation of HFD-induced hepatic disease. We further show that the administration of miR-21 mimics in this background was able to ameliorate the liver disease phenotypes, highlighting its protective role and signifying its potential as a therapeutic agent.

2461-C | NONCLINICAL EFFICACY, PHARMACOKINETIC/PHARMACODYNAMIC (PK/PD), AND TOXICOLOGY PROFILE OF ALG-055009, A NOVEL AND POTENT THYROID HORMONE RECEPTOR B AGONIST, FOR THE TREATMENT OF NON-ALCOHOLIC STEATOHEPATITIS (NASH)

Dinah Misner[1], Kusum Gupta[1], Xuan Luong[1], Jerome Deval[1], Kha Le[2], Doug Clark[1], David McGowan[3], Meenakshi Venkatraman[1], Matthew McClure[1], David B. Smith[2], Tse-I Lin[1], Julian Symons[2], Lawrence M. Blatt[2], Leonid N. Beigelman[2] and Sushmita Chanda[2], (1)Aligos Therapeutics, Inc., (2)Aligos Therapeutics, Inc., South San Francisco, CA, USA, (3) Aligos Belgium BV

Background: NASH is characterized by hepatic inflammation/damage as a reaction to build-up of fat in the liver. Although no drugs are approved to treat NASH, thyroid hormone receptor β (THRβ) agonists have reduced liver fat, restored liver function and reversed inflammation/fibrosis in clinical trials. Here we present the preclinical development of ALG-055009, a second-generation THRβ agonist with improved potency and favorable selectivity. **Methods:** ALG-055009 was profiled in in vitro efficacy, ADME, and toxicology assays, and in vivo pharmacokinetic studies across species. The in vivo activity of ALG-055009 was evaluated in a diet

induced obesity (DIO) mouse model where male C57BL/6J mice were fed with a high fat diet for 14 weeks, followed by once daily (QD) or twice daily (BID) oral administration of ALG-055009 for 28 days. Pharmacodynamic endpoints included total/LDL cholesterol, liver enzymes, and thyroid hormones. Liver and heart gene expression was determined by qPCR. Repeat-dose toxicology studies were conducted in rats and dogs, up to 13-weeks in duration, and clinical pathology endpoints including thyroid hormones were assessed at 2-, 6-, and 13-weeks, as well as following 2- to 4-weeks of recovery. **Results:** In the DIO mouse model, where ALG-055009 was administered QD or BID for 28 days, dose-dependent increases in selective THRβ-induced liver gene expression were observed and were associated with reductions in serum total and LDL-C. In this model, 0.15 mg/kg BID was defined as the minimal efficacious dose, corresponding to ALG-055009 plasma C_{max} of 82.5 ng/mL, AUC_{0-24} of 515 ng•h/mL and C_{min} of 2.01 ng/mL. ALG-055009 is projected to have low potential for drug-drug interactions in humans, either as a perpetrator or victim. Additionally, ALG-055009 was well tolerated in both rats and dogs in repeat dose toxicology studies up to the highest doses tested. Dose-dependent changes in lipid parameters were observed in repeat-dose toxicology studies, whereas changes in total circulating thyroid hormones levels were observed at supratherapeutic exposures. **Conclusion:** ALG-055009 is a potent and selective THR-β agonist with favorable in vitro safety and ADME properties and repeat-dose toxicity profile in rats and dogs. ALG-055009 also dose-dependently reduced levels of atherogenic lipids. Combined, this profile indicates ALG-055009 has the potential to be a best-in-class THR-β agonist for the treatment of NASH.

2462-C | RESMETIROM IMPROVES THE ATHEROGENIC LIPID/LIPOPROTEIN PROFILE IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS: 52-WEEK DATA FROM THE PHASE 3 MAESTRO-NASH TRIAL

Naim Alkhouri[1], Pierre Bedossa[2], Cynthia D. Guy[3], Jörn M. Schattenberg[4], Rohit Loomba[5], Rebecca A. Taub[6], Dominic Labriola[6], Sam Moussa[7], Guy W. Neff[8], Arun Sanyal[9], Mazen Noureddin[10], Meena B. Bansal[11], Vlad Ratziu[12] and Stephen A Harrison[13], (1) Arizona Liver Health, Phoenix, AZ, (2)Newcastle University, (3)Duke University, (4)University of Mainz, (5)University of California, San Diego, San Diego, CA, (6)Madrigal Pharmaceuticals, (7)University of Arizona for Medical Sciences, (8)Tampa General Medical Group, Bradenton, FL, (9)Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, (10)Houston Research Institute, Houston, TX, (11)Icahn School of Medicine at Mount Sinai, (12)Assistance Publique-Hôpitaux De Paris, Paris, France, (13)Pinnacle Clinical Research Center, San Antonio, TX

Background: Cardiovascular disease (CVD) is a common cause of mortality in patients with nonalcoholic steatohepatitis (NASH). Data from the Phase 3 MAESTRO-NAFLD-1 trial demonstrated that resmetirom, an oral liver-targeted thyroid hormone receptor-β selective agonist, significantly improves the atherogenic lipid/lipoprotein profile in patients with presumed NASH. MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed NASH and fibrosis. Here we report data from MAESTRO-NASH demonstrating the effect of resmetirom on atherogenic lipid and lipoprotein levels. **Methods:** Adults with e 3 metabolic risk factors, liver stiffness e 8.5 kPa, hepatic fat e 8%, biopsy-confirmed NASH with F1B-F3 fibrosis, and a nonalcoholic fatty liver disease activity score (NAS) e 4 were eligible to participate in MAESTRO-NASH. Patients were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily. Dual primary endpoints at Week 52 were achievement of NASH resolution with no worsening of fibrosis or e 1-stage improvement in fibrosis with no worsening of NAS. The key secondary endpoint was percent change from baseline in low-density lipoprotein cholesterol (LDL-C) at Week 24. Additional endpoints included percent change from baseline in triglycerides, apolipoprotein B (apoB), apolipoprotein CIII (apoCIII), and lipoprotein (a) (Lp(a)). **Results:** As reported previously, both primary endpoints were achieved with both resmetirom 80 and 100 mg ($p < 0.0002$ vs placebo for all). At Week 24, LDL-C levels were significantly reduced from baseline with resmetirom 80 and 100 mg compared with placebo ($p < 0.0001$ vs placebo for both) (TABLE). In addition, triglycerides, apoB, apoCIII, and Lp(a) were significantly reduced from baseline with resmetirom versus placebo treatment at Week 24 ($p < 0.0001$ vs placebo for all); the significant reductions achieved with resmetirom treatment were maintained at Week 52. **Conclusion:** Resmetirom 80 and 100 mg significantly reduced atherogenic lipid/lipoprotein levels from baseline, including triglycerides, apoB, apoCIII, and Lp(a), by Week 24. Furthermore, improvements in the lipid/lipoprotein profile were

maintained over 52 weeks. The effect of potential NASH therapies on cardiovascular risk factors, including atherogenic lipids/lipoproteins, is important to consider as CVD is a common cause of mortality in patients with NASH and fibrosis.

TABLE. Percent change from baseline in lipid/lipoprotein levels at Weeks 24 and 52.

f 2463-C | RESMETIROM TREATMENT HELPS RESTORE THYROID HORMONE LEVELS IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS: 52-WEEK DATA FROM THE PHASE 3 MAESTRO-NASH TRIAL

Background: Thyroid hormone receptor (THR)-β regulates various metabolic pathways within the liver. However, patients with nonalcoholic steatohepatitis (NASH) have diminished hepatic THR-β signaling (due to decreased conversion of prohormone T4 to active hormone T3 in favor of increased conversion of T4 to inactive metabolite reverse T3 [rT3]). Resmetirom, an oral

liver-targeted THR-β selective agonist in development as a potential treatment for NASH, may address this underlying pathophysiology. Here we report data from the Phase 3 MAESTRO-NASH trial on the effect of 52 weeks of resmetirom treatment on thyroid hormone levels. **Methods:** MAESTRO-NASH (NCT03900429) is an ongoing randomized, double-blind, placebo-controlled trial to evaluate the efficacy of resmetirom in adults with biopsy-confirmed NASH and fibrosis. Eligible patients were adults with e 3 metabolic risk factors, liver stiffness e 8.5 kPa, hepatic fat e 8%, biopsy-confirmed NASH with F1B-F3 fibrosis, and a nonalcoholic fatty liver disease activity score e 4. Patients were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily. Circulating thyroid hormone levels (thyroid-stimulating hormone [TSH], free T3 [FT3], free T4 [FT4], and rT3) as well as the FT3/rT3 ratio were evaluated at Week 52 in the overall population, thyroxine-treated population, and euthyroid population. **Results:** In the overall population at Week 52, no significant change from baseline was observed in TSH or FT3 levels in either the 80- or 100-mg resmetirom group compared with placebo (TABLE). However, FT4 and rT3 levels were significantly reduced from baseline at Week 52 in both resmetirom groups compared with placebo ($p < 0.0001$ vs placebo for all). At Week 52, the FT3/rT3 ratio was also significantly increased with resmetirom versus placebo treatment ($p < 0.0001$ vs placebo for both resmetirom doses). Similar effects as reported for the overall population were noted in the thyroxine-treated and euthyroid populations. **Conclusion:** Resmetirom treatment did not reduce TSH or FT3 levels consistent with no impact on the central thyroid axis. In contrast, resmetirom treatment significantly reduced FT4 and rT3 levels consistent with increased conversion of T4 to active hormone T3 and decreased conversion of T4 to the inactive metabolite rT3. Overall, these data suggest resmetirom treatment may restore thyroid hormone levels within the liver of patients with NASH and fibrosis.

TABLE. Change from baseline in thyroid hormone levels at Week 52 in the overall population from MAESTRO-NASH.

2464-C | SEMAGLUTIDE AND LANIFIBRANOR DIFFERENTIALLY ALTER NASH AND LIVER FIBROSIS IN DIET-INDUCED OBESE HAMSTERS WITH OR WITHOUT FREE ACCESS TO ALCOHOL

Francois Briand, Natalia Breyner, Estelle Grasset and Thierry Sulpice, Physiogenex

Background: GLP-1 receptor agonist semaglutide (SEMA) and pan-PPAR agonist lanifibranor (LANI) are currently evaluated in humans for NASH treatment. While chronic alcohol intake may aggravate liver lesions in patients, rodent studies suggested that both GLP-1 and PPAR agonists reduce alcohol intake in mouse and rat, but these species are not truly alcohol dependent. The golden Syrian hamster spontaneously shows a high preference for alcohol and may represent a better animal model. Here we tested the effects of SEMA and LANI in diet-induced obese hamsters, a preclinical model with human-like NASH, with or without free access to alcohol. **Methods:** Hamsters' preference for alcohol and selection of alcohol % in drinking water were first confirmed in pilot studies. Next, obesity and NASH were induced with a free choice diet, which

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

presents hamsters with a choice between control chow or high fat/cholesterol diet, and normal water or 10% fructose water. After a 20-week diet induction, hamsters were maintained on the same diet with the 10% fructose water supplemented without or with 15% alcohol, and animals were simultaneously treated with vehicle, SEMA 0.06mg/kg s.c. QD or LANI 30mg/kg p.o. QD for 5 weeks. **Results:** When no alcohol was provided, SEMA induced a 17% body weight loss ($p < 0.01$ vs. vehicle) with a transient food intake lowering, but a continuous reduction in 10% fructose water intake and a higher normal water intake. Although SEMA did not reduce NAFLD Activity Scoring (NAS), including hepatocyte ballooning and fibrosis scores, it reduced liver triglycerides levels (-25%, $p < 0.01$). When alcohol was provided, SEMA had similar effects on body weight, food intake and normal water intake, while it significantly reduced fructose and alcohol intake during the 5-week treatment. However, SEMA had no effect on NAS and did not lower hepatic triglycerides levels anymore. When no alcohol was provided, LANI induced body weight loss (-5%), a gradual reduction in 10% fructose water intake and a higher normal water intake. LANI reduced liver lipids levels, NAS, and fibrosis score (all $p < 0.05$ vs. vehicle). As well, when alcohol was provided, LANI significantly reduced fructose and alcohol intake, liver lipids levels and NAS. **Conclusion:** SEMA and LANI both reduced fructose and alcohol intake but had different effects on NASH and liver fibrosis in obese NASH hamsters. This preclinical model will help to evaluate drugs targeting NASH on alcohol intake and their potential benefits in humans.

2465-C | SEMAGLUTIDE NORMALIZE SERUM TRANSAMINASE IN ABOUT HALF OF GLP1-RA NAÏVE TYPE 2 DIABETES (T2D) PATIENTS WITH NON-ALCOHOLIC-FATTY-LIVER-DISEASE (NAFLD)

Giovanni Petralli[1], Antonio Salvati[2], Simone Cappelli[2], Anna Solini[1] and Maurizia R. Brunetto[3], (1)Department of Surgical Medical, Molecular and Critical Area Pathology, University of Pisa, Pisa, Italy, (2)Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, University Hospital of Pisa, Pisa, Italy, (3)Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, University Hospital of Pisa

Background: NAFLD patients (pts) with T2D are at higher risk of liver disease progression. Until now GLP-1 receptor agonists (GLP1-ra) and Semaglutide demonstrated histological proven effects on Non-Alcoholic Steatohepatitis (NASH) in phase 2 trials, with a higher efficacy at a daily subcutaneous dosage of 0.4 mg (NASH-resolution in 59% of pts vs. 17% in the placebo group, 60% diabetic). We measured the same biomarkers of liver disease at baseline and after 6 months (t1) of Semaglutide treatment in a small cohort of GLP1-ra naïve T2D patients with NAFLD. **Methods:** Anthropometric characteristics, serum transaminases (AST,ALT), transient elastography (TE) by Fibroscan, and FibroScan-AST score (FAST) were analyzed at baseline (t0) and after 6.6 ± 0.9 months (t1) of Semaglutide titration (to 0.5-1.0 mg weekly if subcutaneous) or (to 7-14 mg daily if oral) in 42 consecutive overweight/obese T2D pts with NAFLD (age 60.5 ± 12.6 yrs, females 28.6%, BMI 31.5 ± 5.5 kg/m^2). **Results:** A significant ($p < 0.005$) t0-t1 reduction was found for Glycated Hemoglobin [9.0 (16-4) mmol/mol], body weight [5.1 ± 3.7 %], AST [5 (26-1) UI/L], ALT [13 (41-0) UI/L], and FAST [39.6 (54.8-20.4) %] while CAP and TE values did not vary significantly. At baseline ALT were elevated in 15/26 pts (57.7%) and normalized in 8/15 (53.0%) of them at t1. The baseline FAST score was 0.39 ± 0.32, with 9 (30%) patients classified as “at-risk” NASH and 5 (23.3%) as gray zone; a one class down-stepping was observed in 37.5% during follow-up, resulting in a significant distribution difference at the end of follow-up ($p = 0.004$). “At-risk” NASH was present in 2/24 (8.3%) of the pts at t1 and 7/24 (29.1%) were classified in the gray zone. The changes of FAST percentage were strongly correlated with AST, ALT, and CAP basal and variation values ($p < 0.005$), but not with Glycated Hemoglobin, Body Weight, and TE reductions. We observed a lower baseline BMI (31.1 ± 5.2 vs 38.0 ± 3.7 kg/m^2, $p = 0.026$) in pts with a FAST zone down-stepping during follow-up, whereas FAST changes were not correlated with body weight reduction e 5% or e 10%. Conversely, FAST down-stepping group presented a higher reduction of AST (42.0 ± 12.6% vs 12.4 ± 22.7%, $p = 0.001$) and ALT (49.8 ± 18.7% vs 14.2 ± 40.0%, $p = 0.023$) than the one without down-stepping. No significant difference was observed between these groups for body weight reduction (-5.2 ± 3.9 vs -4.2 ± 2.7). **Conclusion:** Semaglutide treatment for T2D in pts with NAFLD associates with a significant decline of AST, ALT and FAST as proxies of liver necroinflammation. Noteworthy, this amelioration was not related to glycemic control, nor to weight loss.

2466-C | THE GALECTIN-3 INHIBITOR GB1211 DOSE DEPENDENTLY REDUCES INFLAMMATION AND FIBROSIS IN A HIGH FAT DIET RABBIT MODEL OF NASH

Ian Holyer[1], Fredrik Zetterberg[1], Linda Vignozzi[2], Sandra Filippi[2], Paolo Comeglio[2], Annamaria Morelli[2], Ilaria Cellai[2], Giulia Guarnieri[2], Mario Maggi[2] and Robert Slack[1], (1)Galecto Biotech AB, (2)University of Florence

Background: Galectin-3 (Gal-3) is a pro-fibrotic β-galactoside binding lectin highly expressed in fibrotic liver & implicated in hepatic fibrosis. GB1211 is a novel orally active Gal-3 small molecule inhibitor that has high affinity for Gal-3 (human $K_D = 25$nM; rabbit $K_D = 12$nM) & high oral bioavailability in rabbits & man. In this study the efficacy of GB1211 was investigated in a high fat diet (HFD) rabbit model of non-alcoholic steatohepatitis (NASH). **Methods:** Male New Zealand White rabbits were individually caged under standard conditions in a temperature & humidity-controlled room on a 12h light/darkness cycle. After 1 week of regular diet (RD), rabbits were randomly assigned to 7 different groups (n = 6-10/group): RD/vehicle, HFD (8 weeks) & HFD/GB1211 (0.3, 1, 5 or 30 mg/kg GB1211 with vehicle/GB1211 *p.o.* dosed therapeutically *q.d.* 5 days per week from week 9) for 8 or 12 weeks. Liver inflammation, steatosis, ballooning, and fibrosis was measured via blood metabolic markers (glucose, cholesterol, triglycerides & transaminases) and histomorphological analysis (Masson's trichome, Giemsa, oil red O & picrosirius red (PSR)). Plasma concentrations of GB1211 were determined by LC-MS. **Results:** Inflammation score, steatosis (binomial score & % area oil red O), ballooning score & fibrosis (% PSR) were all significantly increased from RD to HFD vehicle groups. GB1211 demonstrated target engagement by significantly decreasing Gal-3 levels in the liver as measured via IHC and mRNA analysis. GB1211 dose dependently reduced biomarkers of inflammation (TLR4, IL-1β), liver function (AST, ALT, bilirubin) and fibrosis (PSR, vimentin). Doses of 1 mg/kg or above demonstrated consistent efficacy across the majority of biological endpoints and further supported the dosing regimens progressed into the clinic. **Conclusion:** GB1211 normalized inflammation & fibrosis in a HFD rabbit model of NASH & liver fibrosis following therapeutic dosing for 4 weeks in a dose dependent manner. This data supports the human GB1211 dose of 100 mg *b.i.d.* that has been shown to reduce key biomarkers of disease in a phase 2b study in liver cirrhosis (NCT05009680).

Hamamoto[1], Shuhei Shinoda[1], Toshihiko Matsumoto[1], Koichi Fujisawa[4] and Taro Takami[5,6], (1)Yamaguchi University Graduate School of Medicine, (2) Yamaguchi University, (3)Ajinomoto Co., Inc, (4) University of Occupational and Environmental Health, (5)Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan, (6)-

Background: Recently, Nonalcoholic fatty liver disease (NAFLD) and Metabolism-associated fatty liver disease (MAFLD) was the major prevalent liver disease worldwide and MAFLD, which could be defined with fatty liver, obesity, diabetes and metabolic syndrome was increased. Nonalcoholic steatohepatitis (NASH) has become the severe problem to make severe liver cirrhosis and hepatocellular carcinoma. However, the radical treatment was not still established for these diseases. We developed the iPS-derived mesenchymal stem cells (iMSCs) which induced undifferentiated iPS cells into mature and higher quality MSCs. The aim of this study is to investigate therapeutic effects of iMSCs on NAFLD/MAFLD in vivo and the mechanisms of ameliorating fatty deposition and fibrosis in liver. **Methods:** C57BL/6 mice were fed by the Gubra-Amylin-NASH (GAN) diet and with carbon tetrachloride by intraperitoneal administration per a week. The total study periods were 20 weeks. We divided into three groups, GAN diet only (GAN group), GAN diet with iMSCs-infusion via spleen (iMSC group), GAN diet with the iMSC-derived exosome intravenous injection (EXO group). We analyzed these livers by Masson trichrome (MT), Sirius–red, Alpha-SMA expression. The oxidative stress was analyzed by hepatic 8OHdG content. We analyzed some serum data and the mRNA-expressions of Type I procollagen, TIMP1, TIMP2, TGF-beta, alpha-SMA, MMP9, TNF-alpha, MCP-1, AFP,Hmox1, XBP1, ATF6, SREBP1, FAS, FGF21 were analyzed using both Real Time-PCR and DNA array. **Results:** After 20 weeks, iMSC and EXO-infused livers showed significantly reduced fibrosis ($p < 0.05$) and fatty deposition ($p < 0.05$), consistent with the lower number of D-PAS-positive cells ($p < 0.05$). Serum data also showed that iMSC and EXO mice significantly could show improved liver function and hyperlipidemia. Administration of iMSC and EXO group significantly reduced levels of 8OHdG ($p < 0.05$). iMSC and EXO group significantly inhibited fibrosis related genes (Type 1 procollagen, TIMP1, TGF-beta), ROS related genes (XBP1, ATF6), inflammation related genes (TNF-alpha, MCP1) mRNA expressions ($p < 0.05$). **Conclusion:** Our results indicated that iMSCs ameliorated fibrosis and fatty deposition in the liver and improved liver functions. The exosome derived from iMSCs was also crucial factor to improve liver environment. Our iMSCs will be the new cell source for the treatment for NAFLD/MAFLD related cirrhotic patients

2468-C | THE SEROTONIN RECEPTOR AGONIST PSILOCYBIN AS A NOVEL THERAPEUTIC APPROACH FOR NAFLD: PRECLINICAL STUDIES

Sara De Martin[1], Daniela Gabbia[2], Martina Colognesi[2], Ilaria Zanotto[2], Katia Sayaf[2], Stefano Comai[1], Andrea Mattarei[1], Marco Banzato[1], Franco Folli[3], Lucia Centofanti[3], Sergio Traversa[4], Marco Pappagallo[5] and Paolo L. Manfredi[5], (1)University of Padua, (2) University of Padova, (3)University of Milan, (4) Relmada Therapeutic Inc, (5)Relmada Therapeutics Inc

Background: Although NAFLD prevalence is rising globally, paralleling other metabolic disorders including obesity, there are no drugs approved for its cure. The serotonin receptor (5-HT2AR) agonist psilocybin, an alkaloid of *Psilocybe* mushrooms, reduced obesity in animal models. This study assessed the effects of non-psychedelic doses of psilocybin in mice with high-fat-high-fructose diet (HFHFD)-induced NAFLD. Mechanistic studies were performed on HepG2 cells and 3T3L1-derived adipocytes. **Methods:** The *in vitro* effect of psilocin was assessed on HepG2 cells treated with palmitic/oleic acid and on spheroids of 3T3L1-derived adipocytes w/ or w/o the 5-HT2AR antagonist ketanserin. Psilocybin was tested *in vivo* on C57BL/6 male mice fed with HFHFD (60% kcal from fat) for 17 weeks. One group ($n = 10$) received daily 0.05 mg/Kg*bw psilocybin and the other ($n = 10$) received vehicle by oral gavage. Standard diet-fed mice ($n = 10$) were used as controls. Body weight and food intake were assessed weekly. T-maze and Light-Dark-box tests were used to assess anxiety-like behavior and memory. Fasting glucose and triglycerides were measured before sacrifice. Liver histology was assessed by H&E and ORO staining. Blood immunophenotyping was performed by FACS and mRNA expression was evaluated by qPCR. **Results:** Psilocin decreased lipid accumulation in HepG2 cells and 3T3-derived spheroids ($p < 0.05$). These effects were reverted by ketanserin. In NAFLD mice psilocybin, beside ameliorating liver histology, reduced body weight by 12% and restored the levels of plasma and liver triglycerides of standard-diet fed mice. A significant decrease of fasting glucose ($p < 0.001$) and AUC was observed in the

OGTT. Without reducing food intake, psilocybin reduced anxiety-like behavior and improved memory ($p < 0.05$), modulated hepatic genes involved in de novo lipogenesis, glycolysis, b-oxidation, i.e., SREBP1 (2-fold decreased, $p < 0.05$), ChREBP (2-fold increased, $p < 0.05$ vs controls) and CPT-1 (3-fold increased, $p < 0.05$), and restored the phenotype of circulating NK cells, by reverting the increase of PD-1 expressing exhausted NK cells of NAFLD mice ($p < 0.01$). **Conclusion:** Oral 0.05 mg/Kg*bw psilocybin significantly reduced hepatic steatosis, blood glucose levels and body weight in NAFLD mice without detrimental CNS effects, by exerting a pleiotropic action on lipid and glucose metabolism. Psilocybin at low non-psychedelic doses may be a novel candidate therapy for NAFLD and associated metabolic disorders.

2469-C | THE THERAPEUTIC POTENTIAL OF N-ACETYLCYSTEINE IN NONALCOHOLIC FATTY LIVER DISEASE: A COMPREHENSIVE SYSTEMATIC REVIEW AND META-ANALYSIS OF PRECLINICAL STUDIES, INCORPORATING COMPREHENSIVE TRANSCRIPTOMIC ANALYSIS

Keungmo Yang, Hyun Yang, Si Hyun Bae and Chang Wook Kim, The Catholic University of Korea

Background: Nonalcoholic fatty liver disease (NAFLD) is continuously developed from simple steatosis to inflammation, fibrosis, and hepatocellular carcinoma. Although NAFLD has become the most prevalent chronic liver disease worldwide, there is still no definitive treatment, except for lifestyle interventions, which can be challenging to achieve. Over the past decades, several studies have reported the protective effects of N-acetylcysteine (NAC), an antioxidant, against drug-induced liver injury. However, it is still unclear whether NAC has therapeutic potential in NAFLD. **Methods:** Therefore, the present meta-analysis aimed to investigate the efficacy of NAC on NAFLD in preclinical studies. By searching PubMed, Web of Science, and Cochrane Library, a total of 13 studies were included. The methodological quality was assessed based on the SYstematic Review Centre for Laboratory animal Experimentation guideline, and heterogeneity was evaluated with I^2 and P values. Publication bias was assessed by Egger's test, and sensitivity analysis was performed. **Results:** The results demonstrated that NAC treatment significantly improved systemic and hepatic lipid metabolism ($P < 0.01$), inflammatory liver injury ($P < 0.01$), glucose intolerance ($P < 0.05$), and hepatic steatosis ($P < 0.01$) by restoring hepatic levels of glutathione (GSH) ($P < 0.05$) and GSH reductase ($P < 0.05$) compared to control groups in NAFLD-induced animals. However, the administration of NAC did not alter the hepatic levels of GSH peroxidase, catalase, and superoxide dismutase in animals with NAFLD. Furthermore, a comprehensive analysis of bulk, single-cell, and spatial transcriptomics data consistently revealed significant upregulation of the target pathways of NAC in the liver tissues from mice and patients with NAFLD, thereby reinforcing the potential application of NAC in clinical settings. **Conclusion:** In conclusion, to the best of our knowledge, this is the first study to investigate the efficacy of NAC in preclinical studies of NAFLD through a meta-analysis. Our findings indicate the potential application of NAC in future clinical trials for NAFLD, either as a stand-alone treatment or in combination with other drugs.

2470-C | THERAPEUTIC EFFECTS OF MOUSE BONE MARROW MESENCHYMAL STEM CELL-DERIVED EXTRACELLULAR VESICLES IN A MURINE MODEL OF NON-ALCOHOLIC STEATOHEPATITIS

Xinlei Li, Sherri Kemper and David Brigstock, Nationwide Children's Hospital

Background: Extracellular vesicles (EVs) are important intercellular conduits for transport and delivery of molecular signals that drive pathogenic processes in the liver such as inflammation, fibrosis, and tumorigenesis. On the other hand, certain populations of EVs may have beneficial properties that offer new approaches for treating liver disease. Here we investigated the therapeutic actions of EVs from mouse primary bone marrow mesenchymal stem cells (BM-MSC) in a mouse model of non-alcoholic steatohepatitis (NASH). **Methods:** BM-MSC were isolated from the tibia and femurs of Swiss Webster mice, cultured in specialized growth medium, and identified by the presence of BM-MSC markers using Western blot. EVs were collected from 48-hr serum-free medium, purified by sequential centrifugation, and characterized by Western blot and Nanosight Tracking Analysis (NTA). EVs (1e+9 particles) were administered i.p. three times/week in 8-wk male C57Bl6J mice that received either normal chow diet or a choline-deficient L-amino-defined diet containing high (60%) fat (HF-CDAA). After 4 weeks, mice were sacrificed and analyzed for hepatic damage (serum ALT), liver histology and hepatic production of NASH-related molecules by immunofluorescence or RT-qPCR. Additionally, human LX-2 hepatic stellate cells (HSC) were treated with BM-MSC EVs for 48hr prior to analysis of fibrotic, proinflammatory gene expression by RT-qPCR, or erastin-induced ferroptosis. **Results:** BM-MSC were positive for MSC markers (CD146/MCAM, CD44, and CD29). BM-MSC EVs (mean Ø = 126 nm) expressed MSC and EV markers (CD146, CD9, Tsg101), but not cell-associated markers (calnexin). Mice receiving HF-CDAA diet exhibited elevated serum ALT, steatosis, reduced expression of FASN or SREBP1c, enhanced expression of SCD2 and SREBP2, interstitial fibrosis, elevated hepatic αSMA protein and mRNA levels (indicative of activated HSC) and increased expression of CCN2 (CTGF) and Col1A1. Concurrent administration of BM-MSC EVs during 4 weeks of HF-CDAA diet resulted in reversal of NASH-associated changes including attenuated ALT levels, reduced histological damage to the liver, reversal of lipid metabolism transcript expression towards normal, and attenuated production and/or expression of αSMA, CCN2, or Col1A1 protein and/or mRNA. Treatment of LX-2 cells with BM-MSC EVs consistently reduced the expression of CCN2, Col1A1, αSMA, and TIMP3 but did not alter proinflammatory gene expression. Lastly, BM-MSC EVs and erastin co-treatment in LX-2 cells induced efficient ferroptosis. **Conclusion:** BM-MSC EVs are therapeutic for NASH liver damage, steatosis-related gene expression, and fibrosis-related gene expression, the latter of which appear attributable at least in part to direct suppressive actions of EVs on activated HSC.

2471-C | THERAPEUTIC EFFECTS OF OGB21502, A NOVEL TETRA-SPECIFIC DRUG, IN NON-ALCOHOLIC STEATOHEPATITIS (NASH) MICE MODELS

Ji-Hye Kim, Yunki Kim, Junyeob Lee, Jeonghwa Lee, Nakho Chang, DaeSeong Im and Sungjin Park, Onegene Biotechnology

Background: Non-alcoholic steatohepatitis (NASH) is a complex disease resulting from chronic liver injury associated with obesity, type 2 diabetes and inflammation by multiple mechanism. We hypothesize that simultaneous multi-target regulation and direct tissue targeting within the disease microenvironment could present a

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

holistic approach for treating NASH accompanied by fibrosis. To address this complex condition, we developed a novel tetra-specific drug called OGB21502 by combining GLP-1, GCG, FGF21 and IL-1RA using UniStac platform. In this study, we evaluate the effect of OGB21502 in GAN (Gubra-Amylin NASH) diet-induced obese (DIO) and CCl_4-induced mouse model. **Methods:** To induce obese mice, Male C57BL/6 mice were divided into two groups and subjected to a normal diet or a GAN diet, high in saturated fat (40%), fructose (22%), and cholesterol (2%) for 30 weeks. In the remaining 8 weeks, the mice were administered either OGB21502 or reference drugs (Fc-FGF21, obeticholic acid and semaglutide). In the second study, CCl_4-liver fibrosis model was induced by intraperitoneal injections (I.P.) of CCl_4 for 6 weeks. The OGB21502 or comparative control, obeticholic acid was subcutaneously administered for the last 4 weeks. After treatment, liver tissue and blood samples were used to evaluate histopathological characteristics and markers associated with steatosis and fibrosis. **Results:** In GAN-DIO mice, OGB21502 treatment resulted in reduction in liver weight, ALT and cholesterol levels compared to reference drugs. Notably, OGB21502 led to an improvement in levels of fasting blood glucose and insulin. In the CCl_4-induced mice model, treatment with the tetra-specific drug, OGB21502, demonstrated improved effects in liver inflammation and fibrosis score compared to dual (GLP-1/GCG) or triple (GLP-1/GCG/FGF21) treatments. OGB21502 reduced liver injury markers, including blood ALT and total bilirubin levels. Furthermore, the expression levels of fibrotic markers such as TGF-β, α-SMA, and LOLX-2 were significantly decreased in the OGB21502 treatment group. **Conclusion:** Overall, a novel tetra-specific drug, OGB21502 improved glucose level, insulin resistance, liver damage, inflammation as well as liver fibrosis through multiple animal models. These results demonstrate the potential of OGB21502 as an important alternative for treating severe NASH with metabolic dysfunction and fibrosis, due to synergistic effects across multiple targets.

2472-C | THERAPEUTIC HUMAN PLASMA FRACTION REVERSES HIGH FAT DIET-INDUCED LIVER TRANSCRIPTOME AND IMPROVES LIVER REGENERATION

Benson Lu, Alkahest

Background: The robust regenerative capacity of the mammalian liver declines with age and presence of steatosis. Heterochronic parabiosis between young and old mice demonstrated that exposure of aged liver to young circulation restores hepatocyte proliferation, suggesting that liver regeneration can be enhanced by altering the plasma proteome. However, the circulating factors responsible for driving the mechanisms of rejuvenation in aged hepatocytes have not been defined. In addition, it is unknown if the effect can be recapitulated by administration of human plasma proteins with the potential for therapeutic translation. We utilized a manufacturing scale subfraction approach to identify a therapeutically relevant human plasma fraction (PF) that enhances liver regenerative potential in a mouse model of partial hepatectomy. **Methods:** 20 month old C57/B6 mice were fed with high fat diet (HFD) or normal chow for 6 weeks before i.v. injection of PF or recombinant Secreted Phosphoprotein 1 (SPP1). 70% partial hepatectomy was performed post treatment and liver regeneration was evaluated with proliferation index. Single-nuclei RNA-seq was performed to compare liver transcriptome with HFD and PF treatment. **Results:** We found that PF increased liver regeneration and decreased senescence post hepatectomy in aged mice with steatosis. We further employed single-nuclei RNA-seq to interrogate transcriptomic landscape mediated by PF. We found that signatures altered by HFD were reversed by PF, specifically in pathways involving metabolism of lipids, amino acids, and bile acids. PF proteomic analysis, combined with liver RNA-seq, SPP1 as a candidate bioactive within PF that contributes to its activity in liver regeneration. Administration of recombinant SPP1 increased hepatocyte proliferation post hepatectomy. Utilizing a SPP1-derrived peptide with a restricted integrin receptor binding profile, we further defined a SPP1-driven mechanism critical for liver regeneration. **Conclusion:** Together, our data provide a therapeutically relevant approach to reverse age-related and HFD-induced decline of liver regeneration by altering the plasma proteomic composition. SPP1 is one of the several bioactive components identified within PF, demonstrating that our PF proteomic dataset will enable discovery and confirmation of additional drivers of activity to provide a deep mechanistic understanding for therapeutic modulation of liver regeneration.

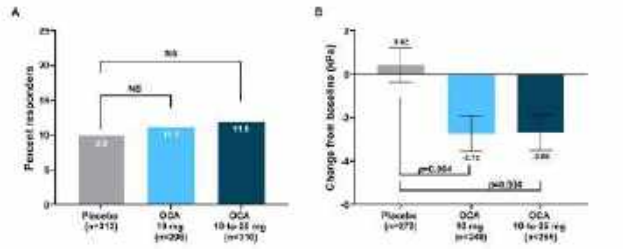
Abdelmalek[12] and Mary Rinella[13], (1) Sorbonne Université, Assistance Publique-Hôpitaux De Paris, Hôpital Pitié-Salpêtrière, Institute for Cardiometabolism and Nutrition, Paris, France, (2) Division of Gastroenterology, Hepatology and Nutrition, Virginia Commonwealth University, Richmond, VA, (3) Liver Institute Northwest, Seattle, WA, USA, (4) University of California, San Diego, La Jolla, CA, USA, (5)Pinnacle Clinical Research Center, San Antonio, TX, (6)Translational & Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Framlington Place, Newcastle upon Tyne, UK, (7)Newcastle Nihr Biomedical Research Center, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK, (8)Beatty Liver and Obesity Research Program, Center for Liver Diseases, Inova Medicine, Falls Church, VA, (9)Liver Institute of Virginia, Bon Secours Mercy Health, Bon Secours Liver Institute of Richmond, Bon Secours Liver Institute of Hampton Roads, Richmond and Newport News, Virginia, (10)Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, (11)Intercept Pharmaceuticals, Inc., Morristown, NJ, (12)Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, (13)University of Chicago, Pritzker School of Medicine, Chicago, IL, USA

Background: Obeticholic acid (OCA) is a first-in-class farnesoid X receptor agonist and antifibrotic agent in development for treatment of liver fibrosis due to nonalcoholic steatohepatitis (NASH). This phase 3 randomized, double-blind, placebo-controlled multicenter study evaluated the efficacy and safety of OCA in patients with compensated cirrhosis due to NASH. **Methods:** Patients with biopsy-confirmed compensated cirrhosis and no esophageal varices were randomized 1:1:1 to receive once-daily oral placebo, OCA 10 mg, or OCA 10-to-25 mg (OCA 10 mg titrated to 25 mg at month 3 if no safety or tolerability concerns). The primary endpoint was histological improvement in fibrosis by ≥ 1 stage with no worsening of NASH at month 12-18 by consensus read. Safety was assessed by treatment-emergent adverse events (TEAEs) and adjudicated cardiovascular, hepatic, and renal safety events. **Results:** The intent-to-treat population (N = 919) was mostly White (87%) and female (66%) with an average age of 60 years and diabetes at baseline (78%). Improvement of fibrosis by ≥ 1 stage without worsening of NASH occurred in 9.9% (placebo), 11.1% (OCA 10 mg), and 11.9% (OCA 10-to-25 mg) (Figure 1A). Reductions in liver stiffness by transient elastography occurred with OCA compared with placebo (Figure 1B). OCA resulted in reduced ALT levels vs placebo. TEAEs, serious TEAEs, and deaths were balanced across treatment groups. Pruritus was the most common TEAE. There were no fatal, irreversible, or severe adjudicated hepatic safety events related to OCA. Three events were adjudicated as moderate and possibly related to OCA; 2 (peak total bilirubin [TB] 3.5, 4.1 mg/dL) resolved with discontinuation of OCA; the third patient (peak TB 4.2 mg/dL) continued to experience fluctuations in laboratory values after discontinuing OCA. Serious gallbladder-related events occurred in ≤ 1% of subjects in all treatment groups. No difference was observed in adjudicated major cardiovascular events and acute kidney injury events across treatment groups. **Conclusion:** Histological reversal of cirrhosis over a short period is challenging. Although REVERSE did not meet its primary histological endpoint, reductions in liver stiffness with OCA suggest disease improvement. Other noninvasive tests and a more granular assessment of collagen burden may provide further insight into OCA's impact on cirrhosis. Notably, no deaths, liver transplants, or irreversible liver injury events related to OCA were observed in patients with compensated cirrhosis.

Figure 1. Efficacy of OCA in Patients with Compensated Cirrhosis. Improvement of fibrosis by ≥1 stage without worsening of NASH at month 12-18 **(A)** and change from baseline to month 18 in liver stiffness measurement by transient elastography **(B)**.



(A) "No worsening of NASH" was defined as no worsening of hepatocellular ballooning grade, of lobular inflammation grade, or of fibrosis grade. (B) Data are least squares mean ± SE calculated using mixed effect repeated measure model with treatment group, visit, visit by treatment interaction, and stratification factors (type 2 diabetes at enrollment) as fixed effects, and baseline as a covariate. Mean (SD) baseline liver stiffness (kPa) was 22.11 (12.18), 22.85 (12.55), and 23.13 (12.30) for placebo, OCA 10 mg, and OCA 10-to-25 mg, respectively.

Abbreviations: BRL, liraglutide; NASH, nonalcoholic steatohepatitis; NS, not statistically significant; OCA, obeticholic acid.

2474-C | TYROSOL REDUCES NASH-ASSOCIATED STEATOSIS, FIBROSIS AND INFLAMMATION BY MODULATING THE HEPATIC IMMUNE PHENOTYPE: PRECLINICAL EVIDENCES

Daniela Gabbia, Katia Sayaf, Martina Colognesi, Ilaria Zanotto, Francesco Paolo Paolo Russo and Sara De Martin, University of Padova

Background: The management of NAFLD and NASH represents a clinical challenge. Beneficial effects on liver health have been demonstrated by tyrosol (Tyr), a phenolic compound extracted from extra virgin olive oil. This study aims at evaluating Tyr effects on the hepatic and extrahepatic manifestations of metabolic liver diseases by using experimental 2D and 3D *in vitro* cellular models and a mouse model of NASH. **Methods:** The effect of Tyr *in vitro* was evaluated in 1) HepG2 cells treated with a palmitic:oleic acid mixture to induce fatty acid (FA) accumulation (fatty HepG2), 2) a co-culture of THP1-derived M1 macrophages and fatty HepG2, 3) multicellular spheroids of fatty HepG2, LX2 and THP1-derived macrophages mimicking the inflammatory NASH microenvironment. NASH was induced to C57BL6 mice with a high fructose-high fat diet administered for 14 weeks, combined to CCl_4 treatment (IP 0.05 ml/kg) in the last 4 weeks ($n = 12$). Tyr (10 mg/kg) was administered daily by oral gavage from week 4 ($n = 6$). A group of mice fed with standard diet ($n = 6$) was used as control. The open field, grid and rotarod tests were performed to evaluate NASH-related CNS disorders and sarcopenia. Liver histology was performed by H&E, Masson's trichrome, and ORO stainings. The protein expression of profibrotic αSMA and pro-oxidant NADPH oxidase isoform NOX1 was evaluated by IHC. Hepatic infiltration of CD4+, CD8+ lymphocytes, Tregs, M1- and M2- macrophages was assessed by means of FACS. **Results:** Tyr reduced FA accumulation in HepG2 cells in all the in vitro models ($p < 0.05$. In vivo, Tyr reduced steatosis, fibrosis, and the increase of aSMA expression observed in NASH animals ($p < 0.01$), as well as the number of hepatic inflammatory foci ($p < 0.05$). Tyr reduced NOX1 expression ($p < 0.05$). A drop of proinflammatory CD45+ F4/80+ CD86+ M1-type macrophages ($p < 0.05$), CD4+ ($p < 0.05$) and T helper effector CD4+ FoxP3- CD62L-lymphocytes ($p < 0.05$), and a concomitant increase of Treg CD4+ FoxP3+ cells ($p < 0.05$) was induced by Tyr. Moreover, Tyr attenuated fatigue and anxious behavior in NASH mice, restoring behevioral performances similar to those of healthy animals. **Conclusion:** In preclinical models, Tyr is effective in reducing steatosis, fibrosis, oxidative stress and inflammation, helping the resolution of NASH.

2475-C | A NATIONAL SURVEY ON THE RISING ROLE OF ENDOSCOPIC BARIATRIC PROCEDURES FOR THE MANAGEMENT OF NONALCOHOLIC STEATOHEPATITIS

Diana Jomaa[1], Yervant Ichkhanian[1], Yara Dababneh[1], Patrick Brown[1], Duyen Dang[1], Humberto Gonzalez[2], Deepak Venkat[1] and Tobias Zuchelli[1], (1)Henry Ford Hospital, (2)Henry Ford Health

Background: Weigh loss is the cornerstone of halting disease progression in patients with non-alcoholic fatty liver disease (NAFLD) and preventing nonalcoholic steatohepatitis (NASH). Patients who fail

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

to lose weight through conservative modalities are often offered the option of bariatric surgeries, but most patients are either high-risk surgical candidates or prefer non-surgical modalities. Endoscopic Sleeve Gastrectomy (ESG) was introduced as a minimally invasive bariatric procedure that provides patients with acceptable weight loss and improvement in their metabolic disease that contributes to NAFLD and NASH. In the study, we aimed to conduct a national survey to evaluate practicing gastroenterologist's perception on the role of ESG for managing NASH. **Methods:** We conducted a descriptive study through a national survey of 15 questions. The survey was built through an online cloud-based software, and a link was emailed to a total of 493 U.S. GI fellowship programs. The email recipients were asked to forward the survey link to additional faculty members. There was no monetary compensation for filling out the survey. The survey was anonymous, and no physician or patient identifier was shared. Total estimated time for completing the survey was 4 minutes. **Results:** A total of 54 responses were obtained during the time period 01-09-2021 and 2-12-2021, with estimated completion rate of 50%. Survey questions were summarized in Table 1. The majority of participants, 72%, were from tertiary care academic center, mostly commonly located in the Midwest, (39%). About half (48%) of the institutions had an established multi-disciplinary team to manage patients with NASH who failed to lose weight following conservative modalities, with 65% having an advanced endoscopist trained in bariatric endoscopy in the team. Providers were most commonly, advanced endoscopists (40%), hepatologists (26%), general gastroenterologists, (18%), and gastroenterology fellows (11%). More than half of the participants (62%) encountered NASH patients "sometimes" with BMI > 40 kg/m2 who failed the current standard of care noninvasive weight loss measures, and refused surgical bariatric procedures, or deemed not to be a surgical candidate. Providers reported that endoscopic bariatric options, most commonly ESG (80%), are "sometimes" discussed with the patients in 46% of the times. Barriers for referral for endoscopic bariatric procedures in NASH patients were overwhelmingly due to lack of insurance coverage in 86% of the times while 32% of the participants thought that there was still not enough literature. Advanced endoscopists reported that they are unable to obtain insurance coverage for managing NASH patients in 78% of the time. **Conclusion:** NASH is projected to be the leading cause of cirrhosis, and the utilization of novel management modalities such as ESG are overwhelmingly impacted by the health insurance reimbursement policies.

Table 1. Survey Questions

Question	Choices
Which best identifies you?	Gastroenterologist, Hepatologist, Advanced Endoscopist, Minority Specialist, etc specialist, GI fellow, Advanced Endoscopy Fellow, NP/PA, Resident/Fellow, Hepatology Fellow
How would you describe the Hospital/Health system you work at?	Tertiary care academic center, Veterans system, Community hospital, Private group practice
What region of the country do you practice in?	Northeast, Southeast, Midwest, West
If you are currently involved in clinical activity, how many years?	Free text
Do you have an established multidisciplinary team to discuss NASH patients who failed conservative weight loss measures, including pharmacotherapy, to achieve a sustainable total body weight loss (TBWL) of at least 10%	Yes, No
Do you have an advanced endoscopist trained in bariatric procedures in your multidisciplinary NASH team?	Yes, No
How often do you encounter NASH patients with BMI>40 kg/m2 who failed the current standard of care noninvasive weight loss measures, including pharmacotherapy, and refused surgical bariatric procedures (endoscopic sleeve gastrectomy, ESG)?	Almost never, Sometimes, Good portion (almost half of the time, Most of my patients
How often do you encounter NASH patients with BMI>40 kg/m2 who failed the current standard of care noninvasive weight loss measures, including pharmacotherapy, and are not surgical candidates for surgical bariatric procedures?	Almost never, Sometimes, Good portion (almost half of the time, Most of my patients
How often do you discuss with the patients if evaluation if and if the non-surgical (endoscopic) bariatric options?	Almost never, Sometimes, Good portion (almost half of the time, Most of my patients
If yes, are you aware of the upcoming endoscopic and transoral bariatric procedures, how often do you get referral from a gastroenterologist for patients in question # 1 and # 2 to evaluate for endoscopic bariatric procedures?	Almost never, Sometimes, All the time
If you are an advanced endoscopist and trained in bariatric procedures, how often do you get a referral from a gastroenterologist for patients in question # 1 and # 2 to evaluate for endoscopic bariatric procedures?	Almost never, Sometimes, All the time
How often do you discuss endoscopic bariatric options with NASH patients who BMI>40kg/m2 failed the current standard of care noninvasive weight loss measures, including pharmacotherapy?	Almost never, Sometimes, Good portion (almost half of the time, Most of my patients
What do you think is the barrier to referral for minimally invasive endoscopic bariatric procedures/evaluation in NASH patients? (multiple answers)	Lack of awareness and limited research, Expensive/ certain insurance coverage, No available specialist who can perform endoscopic bariatric procedures, In my group/hospital/area, costs doesn't think endoscopic bariatric procedures work in my opinion
If you are an advanced endoscopist, how often are you successful in obtaining insurance coverage for your NASH patient?	Almost never, Sometimes, Good portion (almost half of the time, Most of my patients
Which endoscopic bariatric procedure would you recommend for your NASH patient?	Intragastric balloon therapy, Endoscopic sleeve gastroplasty, Other (Insert free text)

2476-C | DIGITAL THERAPEUTICS LEAD TO CLINICALLY SIGNIFICANT BODY WEIGHT LOSS IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Somaya Albhaisi[1], Justin Tondt[2], John Cyrus[3], Rohit Loomba[4], David E Conroy[2], Vernon M Chinchilli[2] and Jonathan G. Stine[5], (1)Department of Internal Medicine, Virginia Commonwealth University, Richmond, VA, (2) Penn State, (3)VCU, (4)University of California, San Diego, San Diego, CA, (5)Penn State Health Milton S. Hershey Medical Center, Hershey, PA, USA

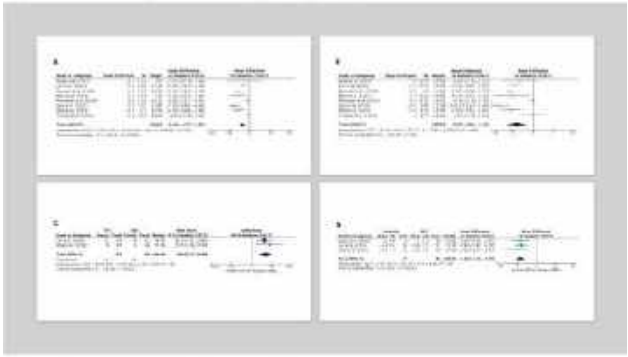
Background: Lifestyle intervention remains crucial in the management of nonalcoholic fatty liver disease (NAFLD). However, most patients are unable to achieve clinically significant body weight loss with traditional in-person approaches. Digital therapeutic (DTx)-delivered interventions offer promise to remove barriers to weight loss success inherent to traditional in-person programs, but their efficacy remains relatively unknown. We aimed to determine 1) the pooled body weight loss of DTx lifestyle intervention programs and 2) whether DTx lifestyle intervention programs lead to greater body weight loss than standard of care (SOC). **Methods:** Published studies were identified by searching the following electronic databases: MEDLINE (PubMed) and Embase (Ovid).

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The search criteria included publications through May 2023 with English language and human subject restriction. DTx intervention was compared to SOC. The primary outcome was change in body weight. Secondary outcomes included change in liver enzymes, liver fat, body fat, glycemic control and lipids. This study was registered on PROSPERO (42023420308). **Results:** Eight studies comprising 372 patients met inclusion criteria (mean age 47.3 y; BMI 33.2 kg/m^2). Mean body weight loss following DTx lifestyle intervention was -3.4 kg (95% CI -4.8, -2.0kg, $p < 0.01$) corresponding to -3.9% relative change (95% CI -6.6 to -1.3, $p = 0 < 0.01$). DTx lifestyle intervention was more likely to achieve body weight loss (absolute change -3.0 kg, 95% CI -4.3 to -1.8kg, $p < 0.01$, relative change -4.1%, 95% CI -5.4 to -2.8, $p < 0.01$) as well as clinically significant body weight loss of $> 5\%$ (OR 4.88, 95% CI 2.17-11.00, $p < 0.01$) than SOC. This was seen in parallel with reduction in liver enzymes, body fat, glycemic control and lipids. **Conclusion:** DTx-delivered lifestyle intervention programs lead to greater amounts of body weight loss than SOC, which uses a traditional, in-person resource-heavy approach. Clinically significant body weight loss with DTx was observed in parallel with improvement in routine clinical outcomes known to be important to patients with NAFLD, including those which surrogate for long-term outcomes. These results further support the role of DTx to deliver lifestyle intervention programs to patients with NAFLD and suggest that this scalable intervention offers promise to benefit the billions of patients worldwide who are living with NAFLD.

Figure 1- Pooled Efficacy of DTx in Leading to Body Weight Loss in Patients with NAFLD



A- Mean body weight loss with DTx is nearly 3.5 kg.
B- Mean relative body weight loss with DTx is nearly 4%
C- Subjects achieve 5% body weight loss or greater nearly 5x more often with DTx than SOC.
D- DTx leads to greater body weight loss than SOC.

2477-C | DIY CLINIC: DEVELOPMENT AND IMPLEMENTATION OF A SUCCESSFUL NON-ALCOHOLIC FATTY LIVER WEIGHT MANAGEMENT CLINIC WITHIN THE VA

Craig Casella[1], Jennifer Kerns[2], Marianna Papademetriou[2], Shruti Gandhi[2], Sabyasachi Sen[2], Atoosa Rabiee[2] and Jessica Davis[2,3], (1)Department of Veteran Affairs - DC, (2)Washington DC VA Medical Center, (3)Medstar Georgetown University

Background: 70% of patients with non-alcoholic fatty liver disease (NAFLD) have comorbid obesity. Intensive lifestyle counseling, anti-obesity medications (AOM) and bariatric surgery all have established benefits for patients with obesity. Less than 1% of patients eligible for antiobesity medications receive pharmacotherapy. We established a multi-disciplinary fatty liver weight loss clinic within the Washington, DC VA Medical Center to increase access to established obesity treatment in our NAFLD population. Here we describe the development of the program and early experience. **Methods:** Two hepatology providers collaborated with an obesity specialist to design a clinic format that would allow for multi-disciplinary management of patients with NAFLD and obesity. Patients were seen via telemedicine by a hepatology provider and jointly reviewed on a monthly basis by the entire clinician panel. As the clinic population grew a bariatric endoscopist and endocrinologists joined the multi-disciplinary discussion. Collaboration between the NAFLD clinician group and our dietician and pharmacy services streamlined access to AOM. Research collaborations were initiated by different members of the clinic panel. **Results:** From July 2022 to May 2023, 47 patients were seen in the fatty liver weight loss clinic. All patients were counseled on lifestyle changes and offered bariatric surgery referral if indicated. 38 (81%) patients were started

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

on AOM. Overall, patients lost mean (SD) 8.5 (10) lbs over a mean follow-up of 4.5 months. 33 patients were started on GLP-1 agonists, and 5 on other agents, most commonly metformin. Of the 9 patients not on therapy, 2 declined, 3 had contraindications, 3 were lost to follow-up and one has therapy pending. Among patients treated with AOM who had at least four weeks of therapy prior to analysis and reported a follow-up weight (n = 24), 37% achieved 5% or greater total body weight loss with mean follow-up of 6.3 months. 33 patients (70%) had baseline lipids, liver enzymes and A1c available and 36 (75%) had baseline fibrosis staging (25 pts transient elastography, 8 biopsy, 3 magnetic resonance elastography). Only 8 patients had follow-up metabolic parameter testing during study period. **Conclusion:** Our clinic has obtained pharmacotherapy for three quarters of patients seen. Founding this clinic with a bottom up approach allowed us to revise our process iteratively and successfully recruit clinicians from other key specialties who were more inclined to join an established clinic. The ability to see patients and host our multi-disciplinary panel virtually enhanced ease of care. Coming together as a NAFLD clinician panel provided leverage to address barriers to pharmacotherapy within our institution. Future plans include addition of a pharmacist and dietician to our multi-disciplinary team, increased follow-up of fibrosis stage and metabolic parameters, and continued periodic quality improvement assessments.

2478-C | EFFECT OF 12-WEEK INTERMITTENT CALORIE RESTRICTION ON LIVER FAT CONTENT IN COMPARISON WITH STANDARD-OF-CARE IN PATIENTS WITH NAFLD

Hwi Young Kim[1], Han Ah Lee[1], Hyeyoung Moon[2], Yuri Kim[2], Jeong Kyong Lee[2] and Hye Ah Lee[3], (1) Department of Internal Medicine, Ewha Womans University College of Medicine, Seoul, South Korea, (2) Ewha Womans University, (3)Clinical Trial Center, Ewha Womans University Seoul Hospital, Seoul, Korea, Republic of (South)

Background: Current guidelines do not recommend specific diet other than hypocaloric diet for patients with nonalcoholic fatty liver disease (NAFLD) because of insufficient data. This trial compared the effect of 12-week intermittent calorie restriction (ICR) and standard of care (SOC) on the changes in liver fat content. **Methods:** In this open-label randomized controlled trial (NCT05309642), NAFLD patients with magnetic resonance imaging-proton density fat fraction (MRI-PDFF) ≥ 8% were included. Sample size was calculated with the effect of ICR from previous study, 80% power and 20% dropout rate. Patients were randomly assigned in a 1:1 ratio to receive 12-week ICR (the 5:2 diet) or SOC (80% of recommended total calorie), and stratified according to their BMI ≥ 25 kg/m^2 or < 25 kg/m^2. The primary outcome was the proportion of patients who achieved the reduction of liver fat content measured by MRI-PDFF ≥ 30%. **Results:** Of the total 72 participants who underwent randomization (n = 36, the obese group; n = 36, the non-obese group), 63 patients (n = 34 [obese]; n = 29 [non-obese]) completed 12-week follow-up visits. A significantly greater proportion of patients in the ICR group achieved liver fat content reduction ≥ 30% compared to the SOC group (n = 24/32 [75.0%] vs. n = 15/31 [48.4%]; $P = 0.030$); obese group had a significant difference between the ICR and SOC groups (n = 11/17 [64.7%] vs. n = 5/17 [29.4%]; $P = 0.039$), however, non-obese group had not (n = 13/15 [86.7%] vs. n = 10/14 [71.4%]; $P = 0.311$). The relative reduction of body weight was comparable between the ICR and SOC groups (-5.5% vs. -4.0%; $P = 0.197$). There were no differences in the changes of liver stiffness measured using MR elastography (-0.1 kPa vs. -0.1 kPa), waist circumference (-7.0 cm vs. -6.5 cm), appendicular skeletal muscle mass (-0.6 kg vs. -0.3 kg), body fat (-3.0 kg vs. -2.2 kg), and levels of ALT (-19.0 IU/L vs. -14.0 IU/L), AST (-9.0 IU/L vs. -4.5 IU/L), triglyceride (-40.0 mg/dL vs. -32.5 mg/dL), total cholesterol (-3.0 mg/dL vs. -10.0 mg/dL), fasting glucose (-3.0 mg/dL vs. -1.0 mg/dL), HbA1c (-0.2% vs. -0.2%), and HOMA-IR (-1.0 vs. -0.1) between the ICR and SOC group (all $P > 0.05$). **Conclusion:** The ICR diet was more effective in reducing liver fat content in patients with NAFLD than SOC, suggesting its potential as an effective and feasible dietary intervention for this population. In addition, the impact of ICR diet was more prominent in the obese group compared to the non-obese group in our study.

2479-C | EVOLUTION OF DISEASE CHARACTERISTICS OF NAFLD PATIENTS WITH AND WITHOUT DIABETES: A META-ANALYSIS OF THE PLACEBO ARMS

Hwi Young Kim[1], Han Ah Lee[1] and Hye Ah Lee[2], (1) Department of Internal Medicine, Ewha Womans University College of Medicine, Seoul, South Korea, (2) Clinical Trial Center, Ewha Womans University Seoul Hospital, Seoul, Korea, Republic of (South)

Background: The natural course of nonalcoholic fatty liver disease (NAFLD) is incompletely understood, particularly in relation to the presence of diabetes. This meta-analysis aims to measure the changes in the severity of NAFLD over time by analyzing data from the placebo arms of randomized controlled trials (RCTs), in order to investigate the natural history of NAFLD. **Methods:** We systematically searched 4 databases (PubMed, Medline, Embase, and Cochrane), until December 2021 to identify RCTs of NAFLD that included a placebo treatment arm. Primary outcome was the progression or regression of NAFLD assessed with histology. The pooled mean differences were estimated using a generalized linear mixed model. **Results:** The meta-analysis incorporated 8 RCTs involving 386 patients without diabetes and 24 RCTs involving 637 patients with diabetes, respectively. The pooled estimate of median intervention period was 24.0 weeks. The pooled estimate of mean change in steatosis grade by histology was -0.1 (95% CI -0.3 to 0.1, $I^2 = 49.3\%$) in patients without diabetes, and -0.4 (95% CI -0.5 to -0.2, $I^2 = 0.0\%$) in patients with diabetes. The pooled estimate of mean change in liver fat content measured using magnetic resonance imaging in patients with diabetes was -1.3% (95% -2.2% to -0.4%, $I^2 = 46.5\%$). The pooled estimate of mean change in fibrosis grade by histology was 0.0 in both patients without (95% CI -0.1 to 0.2, $I^2 = 43.5\%$) and with diabetes (95% CI -0.2 to 0.1, $I^2 = 0.0\%$). The pooled estimate of mean change in NAFLD activity score was -0.5 (95% CI -0.8 to -0.3, $I^2 = 32.0\%$) in patients without diabetes, and -1.5 (95% CI -2.1 to -0.9, $I^2 = 46.5\%$) in patients with diabetes; specifically, 0.0 in both patients without (95% CI -0.2 to 0.0, $I^2 = 44.8\%$) and with diabetes (95% CI -0.3 to 0.4, $I^2 = 41.8\%$) for changes in lobular inflammation; -0.1 (95% CI -0.2 to 0.0; $I^2 = 46.5\%$) in patients without diabetes, and -0.2 (95% CI -0.3 to 0.0; $I^2 = 10.8\%$) in patients with diabetes for changes in ballooning. The pooled estimate of changes in mean body weight was +0.3 kg (95% CI -0.3 to 0.9 kg, $I^2 = 0.0\%$) in patients without diabetes, and -1.0 kg (95% CI -1.6 to -0.3 kg, $I^2 = 43.5\%$) in patients with diabetes. The pooled estimates of changes in serum aminotransferases in patients without and with diabetes were -20.2 IU/L (95% CI -26.4 to -14.0 IU/L, $I^2 = 44.6\%$) vs. -4.5 IU/L (95% CI -8.5 to -0.4 IU/L, $I^2 = 45.2\%$) for ALT, and -10.7 IU/L (95% CI -14.9 to -6.5 IU/L, $I^2 = 48.9\%$) vs. -2.6 IU/L (95% CI -5.0 to -0.1 IU/L, $I^2 = 45.7\%$) for AST, respectively. **Conclusion:** In the placebo arm, neither patients without diabetes nor those with diabetes showed a significant improvement in histology. However, patients without diabetes had a greater decrease in ALT and AST levels than those with diabetes. This finding suggests that the pooled analysis of studies with longer duration might be necessary to capture the potential difference in the evolution of characteristics of NAFLD according to the presence or absence of diabetes.

Table. Overall analysis of outcomes in patients without and with diabetes

	Patients without diabetes					Patients with diabetes				
	Number of studies	Sample size	Effect size	95% CI	I^2 (%)	Number of studies	Sample size	Effect size	95% CI	I^2 (%)
Primary outcomes										
Change in steatosis grade	7	369	-0.097	-0.288 to 0.095	49.3	4	78	-0.373	-0.518 to -0.227	0.0
Change in liver fat	-	-	-	-	-	21	546	-1.289	-2.205 to -0.373	46.5
Secondary outcomes

2480-C | EXERCISE ATTENUATES WESTERN DIET AGGRAVATED HEPATIC STEATOSIS AND FIBROSIS IN MS-NASH MICE WITHOUT WEIGHT LOSS

Fatiha Nassir, University of Missouri

Background: Metabolic-associated fatty liver disease (MAFLD) consists of fat accumulation in the liver due to obesity and insulin resistance-associated metabolic dysfunction. Current non-pharmacological therapeutic options for MAFLD focused on reducing or preventing weight gain through lifestyle modifications such as exercise, but little is known about the underlying mechanisms. Therefore, reproducible animal models to recapitulate the pathophysiology of MAFLD in humans are needed to improve our understanding of the mechanisms for the beneficial effect of exercise on the disease, and to explore novel therapeutic options. **Methods:** MS-NASH is a mouse model for lipotoxicity-induced metabolic dysfunction clinically relevant to human MAFLD progression. Six-week-old male mice were fed a control (CD) or western diet (WD) for twenty weeks. The mice remained sedentary or exercised via free access to running wheels. At the end of the 20

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

weeks, measures of glucose tolerance, blood glucose, triglyceride, hepatic steatosis, and fibrosis were assessed. **Results:** Compared to the CD, the WD increased body weight over the twenty weeks of dietary treatment, starting at three weeks of age. However, voluntary exercise did not alter body weight. The WD fed mice exhibited glucose intolerance compared to CD-fed mice, which was ameliorated with exercise. Exercise did not affect glucose tolerance in CD fed MS-NASH mice. Liver and fat weight increased in WD compared to CD fed mice. Exercise normalized the WD associated increase in fat mass but did not affect liver weight. The increase in blood glucose and triglyceride with WD was also normalized with exercise. Importantly, voluntary exercise improved hepatic steatosis (liver triglyceride, H&E staining, and Oil red-O staining) and fibrosis (serious-red staining) in both CD and WD fed mice. **Conclusion:** These data provide the first direct experimental evidence that voluntary running wheel exercise, independent of weight loss, prevents the aggravation of diet-induced hepatic steatosis and fibrosis in a clinically relevant mouse model of MAFLD. Ongoing studies will determine the mechanisms involved.

2481-C | IMPACT OF NONALCOHOLIC FATTY LIVER DISEASE ON WEIGHT LOSS AFTER BARIATRIC SURGERY: 5-YEAR POST-OPERATIVE ANALYSIS OF 714 PATIENTS ENROLLED IN A BARIATRIC SURGERY COHORT

Monica A. Tincopa[1], Mohammed Abu-Rumaileh[2], Raad Haddad[3], Matheos Yosef[3], Nazanene Esfandiari[3], Andrew Kraftson[3], Corey Lager[3], Shafaq Khairi[3], Jordan Bushman[3], Shokoufeh Khalatbari[3], Oliver Varban[3] and Elif Oral[3], (1)University of California San Diego, (2)University of Toledo, (3)University of Michigan

Background: Long-term longitudinal data on outcomes for non-alcoholic fatty liver disease (NAFLD) patients following bariatric surgery is limited and the sustainability of improvement in hepatic outcomes is not well established. The aim of this study was to assess the impact of bariatric surgery stratified by type of bariatric surgery and presence of NAFLD on weight, metabolic and hepatic outcomes over 5-years of follow-up. **Methods:** Adults who underwent sleeve gastrectomy (SG) or Roux-en-Y gastric bypass (GB) at our center between 2008-2013 were analyzed. Weight, lipids, A1c, liver enzymes, NAFLD Fibrosis score (NFS) and imaging data were obtained at baseline and yearly for up to 5-years post-surgery via retrospective chart review. NAFLD at baseline was assessed based on liver biopsy, imaging, or clinical diagnosis (ICD-9 or 10 codes) prior to surgery. Persistent NAFLD was defined based on evidence of hepatic steatosis on abdominal imaging (ultrasound, CT or MRI) over follow-up period. Descriptive and bivariate analyses were performed. **Results:** The cohort included 714 patients, 79% female, median age 45, median BMI 47.4 and 36% with diabetes. 221 patients had data confirming NAFLD at baseline (SG = 93, GB = 128). The SG group had significantly higher weight while the GB group had significantly higher A1c, cholesterol and triglycerides (TG). Individual's with NAFLD were older (47 vs 44), more often male (72.9 vs 81.7% female) and had a higher prevalence of diabetes, hypertension and dyslipidemia ($p < 0.001$). Figure 1 demonstrates trends in outcome parameters over 5-years of follow-up by surgery type and NAFLD status. At all-time points, the median weight loss was highest in the GB group. Individual's with NAFLD lost less total weight with the impact more pronounced in the GB group. The effect of NAFLD on reduction in TG was only significant in the GB during year two post-surgery. There were no statistically significant differences in change in LDL based on NAFLD status. Among those with NAFLD, those in the GB group had more improvement in NFS. In a multivariable model for percent total weight loss adjusted for baseline BMI, age, sex, surgery type, and follow-up time, only baseline diabetes and NAFLD were statistically significant covariates (p 0.002 and 0.006 respectively). Overall, 83 NAFLD patients (37.5%) had follow-up imaging with 28 (33.7%) having evidence of persistent NAFLD. Among those with persistent NAFLD, imaging post-surgery was done at 1-2 years in 28.7%, 2-4 years in 16.3%, and > 4 years in 55%. In a multivariable model, only baseline hyperlipidemia was independently associated with persistent NAFLD ($p = 0.04$). **Conclusion:** Patients with NAFLD undergoing bariatric surgery experienced less weight loss over 5-years of follow-up with GB having more beneficial impact on hepatic and metabolic outcomes. One-third of NAFLD patients with follow-up imaging had persistent NAFLD with baseline dyslipidemia as the only independent predictor.

f 2482-C | LONG-TERM ALL-CAUSE AND LIVER-RELATED MORTALITY OF PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)-RELATED LIVER CIRRHOSIS WHO UNDERWENT BARIATRIC SURGERY: A POPULATION-BASED STUDY

Nicholas Ajit Rouillard[1], Leslie Yeeman Kam[2], Scott D. Barnett[2], Richie Manikat[3], Ramsey C. Cheung[4] and Mindie H. Nguyen[2], (1)Stanford University Medical Center, (2)Stanford University Medical Center, Palo Alto, CA, (3)Stanford University - School of Medicine, (4)Veterans Affairs Palo Alto Health Care System

Background: NAFLD affects over one in three Americans and is a major cause of end-stage liver disease in the U.S., paralleling the obesity epidemic. Bariatric surgery is a treatment option for obesity that can lead to liver steatosis and fibrosis regression. However, long-term outcome data of bariatric surgery remains sparse, especially in cirrhosis patients. Therefore, we aimed to evaluate the long-term all-cause and liver-related mortality of a large population-based cohort of NAFLD patients with cirrhosis undergoing bariatric surgery in California, USA. **Methods:** We identified 101,651 patients with NAFLD (via ICD-9 codes) from the California's Department of Healthcare Access and Information database from 2005 to 2013 with linked data to the California Death Statistical Master File. Of these, 30,037 had cirrhosis (767 underwent bariatric surgery and 29,270 did not). Propensity score matching (PSM, on age, sex, race/ethnicity, health insurance type, Charlson comorbidity index [CCI], liver decompensation, and hospital size/setting) in a 1:5 ratio was performed to balance the background risks between bariatric and non-bariatric patients, yielding a PSM cohort of 636 bariatric and 3,180 non-bariatric patients. **Results:** At baseline, compared to the non-bariatric group, bariatric patients were 5 years younger (50.7 vs. 55.7 y; $p < 0.0001$), more likely female (70.3% vs. 54.6%; $p < 0.0001$), White (62.9% vs. 52.5%; $p < 0.0001$), with private insurance or seen at a large, academic, or urban hospital setting (all $p < 0.05$), while having lower CCI scores (1.62 vs. 2.78; $p < 0.0001$) and lower decompensated cirrhosis prevalence (57.8% vs. 82.4%; $p < 0.0001$). After PSM, the two study groups had similar age ($p = 0.88$), sex ($p = 0.96$), race/ethnicity ($p = 0.88$), and comparable insurance ($p = 0.58$) and decompensated cirrhosis distributions ($p = 0.59$), and hospital characteristics (all $p > 0.05$), though with lower CCI scores (1.58 vs. 1.68; $p < 0.0001$). Among the PSM cohort, the 5-year cumulative mortality rates were significantly lower for bariatric patients compared to non-bariatric controls for both all-cause mortality (36.4% vs. 46.7%; $p = 0.0047$) and liver-related mortality (2.39% vs. 9.52%; $p = 0.0064$; Figures 1AB). On multivariable Cox's regression analysis adjusted for age, sex, and CCI, bariatric surgery was independently associated with a 32% and 70% reduction in all-cause (aHR = 0.68, 95% CI: 0.53-0.88) and liver-related mortality (aHR = 0.30, 95% CI: 0.12-0.75), respectively. **Conclusion:** Patients with NAFLD and cirrhosis undergoing bariatric surgery experienced significant long-term benefits with lower all-cause and liver-related mortality and should be considered for obese patients who are reasonable surgical candidates.

Figure 1: Cumulative incidence of (A) overall mortality and (B) liver-related morality among NAFLD patients with baseline cirrhosis by bariatric status after PSM (N=3,816)

2483-C | NO FUNDING SOURCE

Shuai Chen[1], Xiurong Cai[2], Peng Song[1], Frank Tacke[2], Adrien Guillot[2], Liming Tang[1] and Hanyang Liu[1,2], (1) Nanjing Medical University, China, (2)Charité – Universitätsmedizin Berlin

Background: Nonalcoholic fatty liver disease (NAFLD) is one of the most common chronic liver diseases worldwide, composed of metabolic dysfunction, steatosis, inflammation and fibrosis. Importantly, nonalcoholic fatty liver (NAFL) caused by elevated hepatic lipid deposition acts as not only the consequence of obesity, but also the early stage of the NAFLD. It has been reported that morbidly obese patients represent more than 90% of patients with NAFLD. Till now, no effective resolutions have been approved to effectively prevent the disease progression. Current evidence suggests that weight loss has been considered as a potential treatment for NAFLD by remising hepatic steatosis, inflammation and fibrosis. Weight loss approaches include lifestyle alterations (mainly diet management), metabolic medicine and bariatric surgery (BS). Recently, BS is considered to be a novel disease-modifying therapy for NAFLD, according to clinical studies. Despite physiological alterations, underlying mechanisms of cellular crosstalk and microenvironment remain indeterminate. **Methods:** In this study, we gathered open bulk RNA-seq datasets from patient cohorts. Gene alterations of metabolism, inflammation and carcinogenesis were compared according to liver-derived transcriptomic data from post-surgery and diet-managed patients. Furthermore, we established mouse BS models (including sleeve gastrectomy and bypass surgery). As an ongoing work, we perform the single-cell transcriptomic analysis on liver tissues from mouse models [healthy, high-fat diet (HFD) + regression, HFD + sham surgery and HFD + BS mice). Furthermore, we will identify metabolism reprogramming and immune landscape according to cell clustering, cellular interactions and functional enrichment analysis. To reveal the metabolism-related immune modulation, the metabolism-immune association and key factors will be demonstrated. **Results:** We demonstrated that the post-BS livers show more improvements in metabolism-, inflammation- and carcinogenesis-related markers, compared to the diet management. In addition, differences were disclosed in immune cell infiltration (especially macrophage populations) in post-BS patients' livers. Accordingly, we speculate that the immune modulation in post-surgery livers might contribute to metabolic improvement, exerting superior effectiveness than the diet-management. On this basis, we will be able to reveal the metabolism reprogramming and immune modulation, aiming to characterize metabolism-inflammation interactions and key molecules in BS-intervened NAFLs. **Conclusion:** This study determined superior functions of BS on metabolism improvement and NAFL attenuation, compared to diet management. Furthermore, this study will disclose novel mechanisms and clinical potentials of the BS intervenes nonalcoholic fatty liver.

2484-C | OPTIMISTIC TRIAL: WEIGHT LOSS AND BODY COMPOSITION CHANGES FROM ALTERNATE-DAY MODIFIED FASTING AND CONTINUOUS LOW-CALORIE DIET: A FEASIBILITY TRIAL IN CIRRHOSIS PATIENTS WITH OBESITY

Winston Dunn[1], Felicia Steger[2], Joseph Donnelly[2], Jessica C. Rachman[2], Robert Montgomery[2] and Steve Herrman[2], (1)University of Kansas Medical Center, Kansas City, KS, (2)University of Kansas Medical Center

Background: Patients with advanced liver disease face challenges in achieving weight loss while preserving skeletal muscle mass. This pilot study aimed to evaluate the feasibility of alternate-day modified fasting (ADMF) and continuous low-calorie diet (LCD) interventions in promoting weight loss and preserving Fat Free Mass (FFM) in patients with Child-Pugh Class A cirrhosis and obesity. **Methods:** An open-label, randomized controlled trial was conducted involving 20 adult patients with cirrhosis and obesity. Participants were randomized to either the ADMF ($n = 11$) or LCD group ($n = 9$). Changes in body composition, sarcopenia measures, and functional outcomes were assessed over a 24-week period. **Results:** Thirteen participants completed the 24-week trial (ADMF: age = 54.4 ± 8.0; BMI = 35.9 ± 4.8; Body Fat Percent = 44.3 ± 5.1%, Female = 4; LCD: age = 54.7 ± 6.6; BMI = 39.5 ± 7.6; Body Fat Percent = 45.0 ± 8.9%, Female = 4). The ADMF group lost an average of 14.5 ± 6.9kg (13.4%) of total body weight, while the LCD group lost 11.4 ± 6.7kg (10.8%). Total body fat percent decreased in both groups (ADMF: -3.6 ± 3.2%; LCD = -2.5 ± 2.0%). Fat-free mass (FFM) accounted for 34.9 ± 17% of the total weight loss in the ADMF group and 32.1 ± 20% in the LCD group. The Liver Frailty Index (LFI) with a decreased in both group of (ADMF: 0.5 ± 0.3; LCD: 0.5 ± 0.2). Functional measures, such as Timed Chair Stands, showed improvement in both groups. **Conclusion:** This pilot study demonstrates the feasibility of the ADMF and LCD interventions in producing significant weight loss while improving body composition in patients with cirrhosis and obesity. Further research is needed to validate these findings in larger cohorts and to assess specific measures related to muscle quality and visceral fat.

2485-C | OPTIMIZING PATIENT MANAGEMENT FOR NONALCOHOLIC FATTY LIVER DISEASE THROUGH BEHAVIORAL RESOURCES & INTERVENTION THROUGH DIGITAL GROUP EDUCATION (BRIDGE)

Nghiem B. Ha[1], Lisa L. Catalli[1], Sara A. Miller[1], Eliana Z. Agudelo[2], Simone K. Madan[1], Riley Tan[1], Thomas J. Hoffmann[1], Miranda E. Surjadi[1], Danielle Brandman[3] and Jennifer C. Lai[1,4], (1)University of California, San Francisco, (2)University of California, San Francisco, San Francisco, CA, (3)Weill Cornell Medical College, New York, NY, (4)University of California-San Francisco, San Francisco, CA

Background: Managing nonalcoholic fatty liver disease (NAFLD) requires lifestyle and dietary modifications, but providers often lack the time and resources to offer effective counseling at each patient visit. A holistic, multicomponent group approach involving patient engagement can enhance the effectiveness of provider counseling. We developed BRIDGE, a novel small group program led by advanced practice providers (APPs) to enhance knowledge, confidence, and self-efficacy among patients with NAFLD regarding lifestyle management. **Methods**: BRIDGE is a video-based, 6-session (90 min each), bi-weekly, small group psychoeducational program led by APPs. Each session includes didactics, group discussion for peer-to-peer learning/support, and individual consultations to develop personalized behavioral-change strategies using motivational interviewing and cognitive behavioral techniques. Patients rated their knowledge, importance, and confidence to make health-habit changes on a 5-point scale survey. Mental and social health changes were measured using 6 Patient-Reported Outcome Measurement Information System (PROMIS) short forms 2-week before and after the program. **Results**: Included were 15 adults with NAFLD who completed BRIDGE from 9/2022-4/2023, with available pre-/post-surveys: 73% women, median age 62 years and BMI of 34 kg/m^2; 87% obese, 27% diabetes, 67% hypertension, and 67% hyperlipidemia. Race/ethnicity: 33% non-Hispanic white, 40% Hispanics, 26% Asian/Native American. All had severe steatosis with median (IQR) CAP of 339 dB/m (324-374); 20% had advanced fibrosis/cirrhosis. After completing BRIDGE, patients reported notable improvements in various life domains, including recognizing the importance of healthy habits, meaning and purpose, managing emotions/mental health, and seeking support, with significant improvements in knowledge and confidence in lifestyle changes to improve NAFLD (Figure). Most (73%) achieved weight loss (mean ± SD of 2.6 ± 4.7 kg) with significant improvement in muscle strengthening exercise frequency (mean ± SD increased of 2 ± 2 d, $p = 0.02$). Qualitative feedback from patients indicated high satisfaction with BRIDGE. **Conclusion**: Our novel telehealth psychoeducational program enhanced patients'

knowledge, confidence, and understanding of health-related behavioral changes for those with NAFLD, while also improving mental well-being and social support. Future research should identify the optimal program length for achieving and sustaining lifestyle changes, which can ultimately improve clinical outcomes.

Figure. Pre- and post-BRIDGE median composite score of patients' knowledge, importance and confidence in changing health habits, including change in mental and social domains of health

2486-C | PERK AMELIORATES HEPATIC LIPOTOXICITY VIA ACTIVATING THE p62-ULK1 AXIS-MEDIATED NONCANONICAL KEAP1-Nrf2 PATHWAY

Da Hyun Lee, Severance Biomedical Science Institute, Yonsei University College of Medicine

Background: Hepatic lipotoxicity is a crucial factor in nonalcoholic steatohepatitis resulting from excessive saturated fatty acid-induced reactive oxygen species (ROS)-mediated cell death, which is associated with the accumulation of endoplasmic reticulum (ER) stress in the liver. The unfolded protein response (UPR) alleviates ER stress by restoring ER protein folding homeostasis. However, whether UPR contributes ROS elimination under lipotoxicity remains unclear. The Kelch like ECH-associated protein 1 (KEAP1)-nuclear factor, erythroid 2 like 2 (Nrf2) pathway provides antioxidant defense against lipotoxic stress by eliminating ROS and can be activated by the p62-Unc-51 like autophagy activating kinase 1 (ULK1) axis. However, the upstream molecular regulator of the p62-ULK1 axis-induced KEAP1-Nrf2 pathway in the same context remains unidentified. **Methods:** PKR-like ER kinase (PERK) depleted mice were subjected to fasting followed by refeeding with high-carbohydrate, fat-free diet (HCD) and the effects on the KEAP1-Nrf2 pathway and autophagy were analyzed. Furthermore, the molecular mechanism of this pathway was assessed using *in vitro* samples. **Results:** Here, we demonstrated that PKR-like ER kinase (PERK), a UPR sensor, directly phosphorylates p62 and ULK1, thereby activating the noncanonical KEAP1-Nrf2 pathway. We elucidated the molecular mechanism underlying the PERK-mediated p62-ULK1 axis-dependent noncanonical KEAP1-Nrf2 pathway, which could represent a promising therapeutic strategy against hepatic lipotoxicity. **Conclusion:** Therefore, our findings suggest the next line of defense against ER stress-mediated lipotoxicity. In addition, we elucidated the molecular mechanism underlying the p62-mediated non-canonical KEAP1-Nrf2 pathway, which may serve as a promising new therapeutic target strategy against lipotoxicity in NASH treatment

2487-C | ROLE OF HONEY EXOSOME-LIKE NANOPARTICLES IN AGING-RELATED NON-ALCOHOLIC STEATOHEPATITIS

Baolong Liu and Jiujiu Yu, University of Nebraska Lincoln

Background: Non-alcoholic steatohepatitis (NASH), a progressive form of non-alcoholic fatty liver disease, has become a leading cause of liver failure. No therapeutics is currently approved to specifically treat this condition. We recently identified exosome-like nanoparticles in honey (H-ELNs) with potent anti-inflammatory functions. In this study, we assessed the role of H-ELNs in aging-related NASH. **Methods:** H-ELNs were isolated from honey using the standard ultracentrifugation method, and orally administered to 1-year-old C57BL/6J mice once a week for one year. When the mice reached two years old, they were sacrificed and their livers were collected for further analysis.

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The target cells of H-ELNs in aged liver were assessed. Finally, the biomolecules in H-ELNs were analyzed to elucidate the active components. **Results:** In naturally aged mice, the liver demonstrated extensive inflammation, fibrosis, and formation of nodules, which are typical manifestations of NASH. Interestingly, H-ELNs largely curbed this aging-related hepatic inflammation, fibrosis, and nodule formation. In the aged liver, Kupffer cells were mainly responsible for taking up H-ELNs. Further mechanistic studies showed that H-ELNs suppressed the functions of two transcription factors c-Jun and nuclear factor-kappaB (NF-kB), as well as the NLRP3 inflammasome in the aged liver. Luteolin, miR-5110, and miR-5108 in H-ELNs were found to potently inhibit both c-Jun and NF-kB activities. **Conclusion:** H-ELNs could serve as a promising user-friendly new agent to prevent NASH development.

2488-C | SUSTAINABILITY OF TOTUM-448 BENEFICIAL EFFECTS FOLLOWING INTERRUPTION OF SUPPLEMENTATION IN A HAMSTER MODEL OF DIET-INDUCED NASH

Vivien Chavanelle[1], Yolanda F. Otero[1], Doriane Ripoche[1], Marie Vallier[1], Cédric Langhi[1], Clément Besqueut-Rougerie[1], Valérie Hervieu[2], Béatrice Morio[3], Gaël Ennequin[4], Florian Le Joubioux[1], Thierry Maugard[5], Sebastien Peltier[1] and Pascal Sirvent[1], (1) Valbiotis, (2)Hospices Civils De Lyon, (3)Université Lyon1, (4)Université Clermont Auvergne, (5)Université La Rochelle

Background: Totum-448 is a patented combination of 5 plant extracts and choline. We previously showed that 12 weeks of supplementation with Totum-448 improved steatosis, inflammation, and fibrosis markers in hamsters with diet-induced NASH. In this work, we aimed at assessing the sustainability of Totum-448 associated beneficial effects on NASH by interrupting treatment after a 12-week supplementation period, in western-diet (WD)-fed hamsters. **Methods:** Male golden Syrian hamsters were fed a WD (high-fat, high-cholesterol) supplemented or not with Totum-448 (5%, WD+T-448) for 18 weeks. A 3rd group of hamsters was fed WD+T-448 for 12 weeks before switching to non-supplemented WD for 6 more weeks (WD+T-448-ON/OFF) and a 4th group of hamsters fed a normal diet (ND) was used as control. Food intake, body weight and body composition were monitored continuously. NASH was evaluated using circulating and hepatic biochemical and histological markers of steatosis, inflammation, and fibrosis. **Results:** After 18 weeks, Totum-448 supplemented animals displayed significantly lower liver lipids compared to WD (triglycerides, TG, total cholesterol, TC, and free fatty acids, FFA), as well as decreased area of Oil-Red-O-stained liver sections. Interruption of supplementation for 6 weeks in WD+T-448-ON/OFF resulted in a moderate increase in all liver lipids, compared to WD-T448, though remaining significantly lower than WD. Histological scoring of paraffin-embedded liver sections revealed a significant improvement of hepatic ballooning in 18-week supplemented animals (WD+T-488) that remained significantly ameliorated in WD+T-448-ON/OFF, compared to WD, although to a lesser extent. Finally, in WD+T-448, perirenal, inguinal, and mesenteric fat pad weights were increased and serum FFA levels were decreased, compared to WD, suggesting improved fat storage capacity and reduced lipolysis in adipose tissue. Group WD+T-448-ON/OFF exhibited an intermediate profile, in-between WD+T-448 and WD. **Conclusion:** Supplementation with Totum-448 for 18 weeks resulted in major improvements in several hallmarks of NASH development, including reduction of liver lipid content (steatosis) and ballooning, in WD-fed hamsters. Despite interruption of supplementation, group WD+T-448-ON/OFF displayed an intermediate profile, with most benefits conserved to a lesser degree. The improvement of lipid storage capacity in adipose tissue may constitute a first explanatory hypothesis.

2489-C | THE IMPACT OF WEIGHT LOSS PROGRAMS ON BMI TRAJECTORY IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: A VETERANS HEALTH ADMINISTRATION STUDY

Nadim Mahmud, Hospital of the University of Pennsylvania and David E. Kaplan, Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA

Background: Weight loss is the mainstay of management for patients with non-alcoholic fatty liver disease (NAFLD), and first-line recommendations advise lifestyle changes incorporating diet and exercise. The impact of formal weight loss programs has not been studied at a population level in NAFLD patients. This is of interest given that delays in achieving significant weight loss will increase the risk of progressive fibrosis, metabolic and cardiovascular morbidity, and cancer risk. We studied the impact of referral to MOVE!, a nationally-implemented, behavioral weight loss program in the Veterans Health Administration (VHA), on weight trajectories in NAFLD patients. **Methods:** This was a retrospective cohort study of VHA patients with body mass index (BMI) > 35 and NAFLD, identified using a validated algorithm, who were referred to MOVE! between 1/2008-12/2022. Baseline demographic, BMI, and comorbidity data were collected. Time-updated BMI was ascertained every 90 days through 5 years of follow-up. A median spline curve of BMI over time was plotted; bariatric surgery events were identified, and BMI trajectory data were censored at time of surgery. Stacked bar charts depicting percentage weight loss or gain (cut points 5%, 7%, 10%) over time were evaluated. **Results:** A total 87,469 NAFLD patients were included from 125 VHA centers. The cohort had median age 56 years (IQR 46, 64), 87.4% male, 61.0% white, with baseline BMI 39.1 (IQR 36.8, 42.5), and 51.1% had diabetes. Through 5 years, 2,137 (2.4%) received bariatric surgery, at median 20.6 months follow-up (IQR 11.1, 37.0). Median BMI for the cohort decreased minimally over 5 years, from ~39.1 to ~38.5 (Figure panel left). The majority of patients had no meaningful weight loss or weight gain through maximum follow-up (Figure panel right). At 5 years, 13.7% achieved > 10% weight loss, 8.0% achieved 7-10% weight loss, 7.4% achieved 5-7% weight loss, and 70.9% experienced either no meaningful weight loss or had significant weight gain. **Conclusion:** In this large VHA cohort of NAFLD patients referred to the MOVE! weight loss program, the majority (70.9%) experienced either no meaningful weight loss or gain significant weight. Bariatric surgery is utilized very infrequently in this cohort. Future studies should aim to identify factors associated with good response to lifestyle modification programs; our data also argue for more aggressive utilization of bariatric surgery when patients develop appropriate indications.

2490-C | THE INDEPENDENT EFFECT OF EXERCISE ON HISTOLOGICAL OUTCOMES IN BIOPSY-PROVEN NON-ALCOHOLIC FATTY LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

George Chen, Bubu A Banini, Albert Do, Craig Gunderson, Saif Zaman and Joseph K. Lim, Yale University, New Haven, CT

Background: In patients with non-alcoholic fatty liver disease (NAFLD), weight reduction achieved via lifestyle modification including exercise and dietary interventions has been shown to improve histological outcomes. However, the independent effect of exercise on liver histology in NAFLD remains unclear. As such, we conducted a systematic review and meta-analysis of the independent effect of exercise on histological endpoints in biopsy-proven NAFLD. **Methods:** A systematic literature search of Embase, PubMed, and Web of Science databases was performed from inception to October 2022 in accordance with PRISMA guidelines. Articles were selected based on the following inclusion criteria: (1) involved human subjects with biopsy-proven NAFLD, (2) analyzed the independent effect of exercise on histological endpoints, and (3) were interventional studies. Meta-analysis was performed for histological outcomes with complete pre- and post-intervention data reported by at least three studies. The pooled effect of exercise on histological outcome was estimated by calculating the standardized mean difference in a random-effects model. Statistical heterogeneity between studies was quantified using Cochran's Q test. **Results:** Our initial literature search yielded 271 unique articles. After removing studies not meeting the inclusion criteria, we identified a total of four interventional studies that assessed the independent effect of exercise on histological outcomes in biopsy-proven NAFLD. Two studies showed significant exercise-induced improvement in both liver fibrosis and hepatocyte ballooning, while two studies did not detect significant changes in histological parameters. Among measured histological outcomes, liver fibrosis, Brunt grade, and NAS met criteria for meta-analysis with data available from a minimum of three studies. The pooled effect size of exercise on liver fibrosis (mean difference [MD] -0.18; 95% confidence interval [CI] -0.95 to 0.60; $p = 0.65$), Brunt grade (MD -0.01; CI -0.48 to 0.45, $p = 0.96$), and NAS (MD 0.61; 95% CI -0.44 to 1.66; $p = 0.26$) was not statistically significant compared to the control groups (Figure 1A-C). High heterogeneity was observed between the studies for all three histological outcomes ($I^2 = 75\%$ for liver fibrosis; 75% for Brunt grade; 71% for NAS). **Conclusion:** This is the first meta-analysis to investigate exercise-induced changes in liver histology in patients with NAFLD. Based on the current literature, we found that exercise does not independently affect histological outcomes in NAFLD. Additional well-powered randomized controlled trials are needed to better understand the impact of exercise on histological and clinical endpoints in NAFLD.

Michigan, (2)Northwestern University, (3)San Francisco State University, (4)None, (5)University of Michigan Medical School

Background: No medications are currently available for treatment of nonalcoholic fatty liver disease (NAFLD), an increasingly prevalent disease afflicting about 25% of US adults and more than 50% of people with type 2 diabetes. Our preliminary data suggests that insulin resistance and the G allele of rs738409 interact to create a much greater risk of developing NAFLD. One promising way to reduce insulin resistance is using a very low-carbohydrate (VLC) eating pattern, also known as a ketogenic or "keto" dietary pattern, which is a VLC, moderate protein, higher fat eating pattern. **Methods:** This was a single-arm, online trial in adults with rs738409-GG or -CG. Participants completed measures related to intervention feasibility, acceptability, and physical and patient-reported outcomes. Participants were taught to follow an ad libitum very low-carbohydrate eating pattern (20-35 net or non-fiber grams) of carbohydrates per day for 4 months, as well as supplementary psychological tools to support adherence. **Results:** Of the 11 participants who were enrolled, 9/11 (82%) completed study outcomes, and 8/11 (73%) attended at least half of the sessions. Across all participants, the following reduced by a statistically significant amount: body weight decreased 10.9% ($p < 0.001$), HbA1c reduced 9.4% ($p = 0.001$), insulin reduced 30.7% ($p = 0.020$), insulin resistance reduced 36.8% ($p = 0.007$), triglycerides reduced 14.3% ($p = 0.021$), abdominal symptoms reduced 33.2% ($p = 0.044$), emotional function improved 22.6% ($p = 0.16$) and fatigue reduced 27.1% ($p = 0.024$). Six participants were adherent to the eating pattern (defined based on their 4-month 24-hour dietary recalls), 3 participants were not adherent, and 2 had no 4-month 24-hour dietary recall. For the participants who were adherent, the following reduced by a statistically significant amount: body weight decreased 12.0% ($p < 0.001$), average liver lobe fat percent decreased 53.1% ($p = 0.001$), AST reduced 33.9% ($p = 0.006$), ALT reduced 47.5% ($p = 0.003$), HbA1c reduced 7.7% ($p = 0.014$), insulin reduced 40.5% ($p = 0.023$), and insulin resistance reduced 44.0% ($p = 0.019$); LDL-cholesterol levels were not significantly changed. Of the 9 participants who provided 4-month self-report information, intervention satisfaction was high (mean 6.22, 95% CI 5.58 to 6.85), with 5/9 (56%) rating the intervention the top score. Only 11% reported that they would stop the assigned eating pattern as soon as `the study was over, and 44% stated that they did not plan to ever stop following it. **Conclusion**: Results support the feasibility, acceptability, and preliminary efficacy of the VLC intervention in adults thought to have a higher genetic risk for NAFLD. Overall, the results of this pilot study suggest that a VLC eating pattern may be a safe and efficacious approach for this population.

2492-C | UNDERSTANDING BARRIERS IN NON-ALCOHOLIC LIVER DISEASE (NAFLD) MANAGEMENT: INSIGHTS FROM A MULTI-DISCIPLINARY SURVEY OF PHYSICIANS IN EUROPE (BARRIERS-NAFLD)

Laurent Castera[1], William Alazawi[2], Elisabetta Bugianesi[3], Cyrielle Caussy[4], Massimo Federici[5], Manuel Romero-Gómez[6], Jorn Schattenberg[7], Ron Basuroy[8], Preethy Prasad[8], Dmitry Estulin[9] and Jeffrey V. Lazarus[10], (1)Department of Hepatology, Beaujon Hospital, AP-HP, Université Paris Cité, Inserm UMR1149, Clichy, France., (2)Queen Mary University of London, UK, (3)University of Turin, (4)Lyon 1 University and Lyon South Hospital, (5)University of Rome Tor Vegata, (6)Ucm Digestive Diseases, Virgen Del Rocio University Hospital, Instituto De Biomedicina De Sevilla, Ciberehd, University of Seville, Sevilla, Spain, (7) University Medical Center Mainz, (8)Novo Nordisk a/S, (9)Novo Nordisk Health Care AG, (10)Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain

Background: Management of nonalcoholic fatty liver disease (NAFLD) and nonalcoholic steatohepatitis (NASH) remain challenging due to several factors including awareness of the diseases, availability of treatments, and lack of adoption and adherence to clinical practice guidelines. As a result, patients may not receive appropriate interventions such as lifestyle modifications, contributing to disease progression and increased risk of complications. This study aimed to identify insights and key challenges physicians face when managing NASH. **Methods:** A real-world, cross-sectional, quantitative survey was conducted from March to May 2023, among hepatologists/gastroenterologists with a subspecialty in hepatology and metabolic physicians (MPs) who are actively managing at least 30 patients with type 2 diabetes and/or obesity per month (endocrinologists, general practitioners, family physicians and internal medicine physicians without a subspecialty in hepatology) in five European countries (France, Germany, Italy, Spain and United Kingdom). Participants completed an anonymous online survey, and descriptive statistics were used to analyse the data.

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

Results: Among 249 hepatologists and 376 MPs, respondents cared for an average of 143 patients per month with or suspected to have NAFLD/NASH. The majority of hepatologists (62%) and MPs (60%) reported patient comorbidities influenced the diagnosis of NASH. Hepatologists were predominantly influenced by the availability of diagnostic methods (63%) followed by national guidelines (58%), whereas MPs were most influenced by the availability (56%) and invasiveness (49%) of the diagnostic method. Hepatologists reported being more aware of EASL (2021) guidelines (55%) for diagnosing and treating/managing NASH, whereas MPs reported being aware of ADA guidelines (34%). Additionally, 11% of participants reported not being aware of any clinical guidelines for NASH. The factors most commonly preventing adoption of clinical guidelines in NASH diagnosis, treatment and management were patient refusal of recommended treatments (44% hepatologists, 46% MPs), patient refusal for recommended diagnostic tests (42% hepatologists, 45% MPs), the invasiveness of recommended diagnostic tests (39% hepatologists, 43% MPs), and the availability of diagnostic tests (33% hepatologists, 47% MPs) (Figure 1). **Conclusion:** This study found that physicians report multiple challenges associated with managing NASH and further highlights the different influences and approaches taken by physicians to diagnose, monitor, and treat patients with NASH. The findings emphasize the need for increased awareness, definitive guidance and education to assist hepatologists and MPs treating NASH in adopting and adhering to clinical practice guidelines and non-interventional treatments and diagnostic tools.

2500-A | CHANGING PA STUDENTS MEDICAL BIASES AGAINST PATIENTS WITH LIVER DISEASE

Amanda DeVoss, University of Wisconsin-Madison

Background: Patients with alcohol-induced liver disease are often blamed for their disease and receive poor health care due to bias. Training physician assistants (PAs) to recognize their biases towards patients with liver disease plays an important role in decreasing the unintentional acts of bias that influence the care that patients with liver disease will receive. **Methods:** Between 2020-2023, PA students were asked about biases towards patients with liver disease, specifically about alcohol-induced liver disease. Students were also asked whether they think patients with alcohol-induced liver disease should undergo a liver transplant. Students then underwent a liver related curriculum, which was designed to discuss evidence-based medical decisions regarding all types of liver disease and liver transplantation. Following this curriculum, PA students were again assessed on their biases for patients with liver disease. **Results:** PA students were asked if they had a bias against patients with liver disease. On average from 2020-2023, 35.5% of students identified a bias against patients with liver disease. Students were also asked whether they think patients with alcohol-induced liver disease should undergo a liver transplant. On average, 39% of students believed these patients should not have a liver transplant. Students participated in lectures and interactive sessions about a variety of liver diseases. Evidence based medicine is brought into the curriculum to specially address transplantation for patients with alcohol-induced liver disease. Open discussions on bias against patients with liver disease is fostered by the faculty. After completing the curriculum PA students were again assessed on their biases for patients with liver disease. On average, 18% of students identified a bias against patients with liver disease, showing a 17.5% reduction. Students were also asked if they think patients with alcohol-induced liver disease should undergo a liver transplant. On average, 13% of students believed these patients should not have a liver transplant, a 26% reduction. **Conclusion:** Open-discussions aimed at biases towards patients with alcohol-induced liver disease prove to be a means of reducing medical bias. Each year there is an overwhelming positive change, with students acknowledging less bias against patients with liver disease and advocating for patients with alcohol-induced liver disease to receive a liver transplant.

f 2501-A | EVALUATION OF SAFETY OF A NURSE-LED PARACENTESIS MODEL FOR PATIENTS WITH DECOMPENSATED LIVER DISEASE IN AMBULATORY CARE: A RETROSPECTIVE REVIEW★

Molly McDonald[1], Carmen Fang[1], Colina K. Yim[2], Pam Hubley[1], Ina Cherepaha-Kantorovich[1], Sharlene Camaya[1], Christine Song[1] and Elizabeth Lee[1], (1) University Health Network, (2)University of Toronto

Background: Ascites is a common symptom of decompensated liver disease, managed by large volume paracentesis (LVP) when low-sodium diets and diuretics are ineffective. Typically LVPs are performed by a physician (MD) or a nurse practitioner (NP), and treatment delays can occur due to limited personnel and competing clinical responsibilities. An ambulatory liver clinic located in a quaternary care hospital in

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

Toronto, Canada, opened a procedure room staffed by a trained registered nurse (RN) to perform LVPs for the purposes of accommodating increasing numbers of patients requiring LVPs to reduce Emergency Room (ER) and General Internal Medicine (GIM) admissions for ascites management. This study evaluates the safety of this RN-led paracentesis model and examines the geographic range served by this hospital for ambulatory LVPs. **Methods:** A retrospective chart review (June 6, 2022 - Feb 28, 2023) was conducted on patients who underwent LVPs in this hospital's designated ambulatory settings (Medical Day Unit (MDU) and the liver clinic's procedure room). A frequency analysis of post-LVP complications subgrouped by the type of healthcare practitioner who performed the procedure (RN, NP, MD) was completed. Post-LVP complications were reviewed: skin infection, bowel perforation, abdominal wall abscess, hematoma/hemorrhage, arterial injury, and catheter fragment left in the abdominal wall/cavity. Spontaneous bacterial peritonitis was not considered a post-LVP complication. Other data collected for this study included: disease etiology, procedure location, proceduralist's designation, post-LVP related hospital admissions, and the patient's residential postal code. **Results:** 124 unique patients underwent LVPs in the designated ambulatory settings. A total of 580 LVPs were performed. 55.2% (n = 320) were performed in the liver clinic's procedure room, and 44.8% (n = 260) were performed in MDU. Disease etiologies included: alcohol associated liver disease (40.3%), nonalcoholic fatty liver disease (22.6%), viral hepatitis infection (13.7%), autoimmune liver disease (5.6%), and other etiologies (17.7%). Out of the 580 LVPs, 55.5% (n = 322) were performed by an RN, 33.6% (n = 195) were performed by an MD; and 10.9% (n = 63) were performed by an NP. There were no identified post-LVP complications, regardless of the proceduralist. 118 of the 124 patients live within the city of Toronto and the Greater Toronto Area (GTA), areas that are notably served by at least 15 academic and community hospitals. Of note, patients are currently travelling up to 360 km (224mi) to undergo LVPs due to limited local access to care. **Conclusion:** This RN-led paracentesis model demonstrated an equivalent level of safety to their NP and MD counterparts. This data could lead to the adoption of similar models of care in centers that deliver ambulatory care for patients with decompensated liver disease as a strategy for readmission avoidance and timely access to local care.

2600-A | BENEFICIAL EFFECTS OF BUSHEN FORMULA ON CHRONIC HEPATITIS B PATIENTS BY REGULATING TFH AND B-CELL SUBSETS

Longshan Ji, Rongjie Zhang, Jinghan Wei, Xin Zhang, Yating Gao, Miao Fang, Zhuo Yu, Lin Cao, Yueqiu Gao and Man Li, Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine

Background: Bushen Formula (BSF) is the effective traditional Chinese medicine (TCM) for chronic hepatitis B(CHB). Our previous studies have suggested that the combination treatment of BSF with entecavir results in significant decrease of serum hepatitis B virus (HBV) DNA, increase of HBeAg and HBsAg negative conversion in CHB patients without serious adverse events. However, the special effectiveness of BSF treating CHB and its relevant mechanism were not clear. We aimed to confirm the therapeutic effects and explore the pharmacological mechanisms of BSF on CHB. **Methods:** 266 CHB patients were enrolled into the retrospective study, which were categorized into treatment group (T-Group: receiving BSF plus Peg-IFN-α for 24 weeks) and control group (C-Group: receiving Peg-IFN-α for 24 weeks). Patients in T-Group and C-Group were grouped into subgroups including T1/C1 groups (Peg-IFN-α for the first time) and T2/C2 groups (Peg-IFN-α for more than 6 mo). Serum HBV markers and HBV DNA levels were tested. Chinese medicine symptom complex score was evaluated and recorded. Ultra-high performance liquid chromatography-quadrupole-orbitrap-high resolution mass spectrometry (UPLC-Q-Orbitrap-MS) and network pharmacological analysis were conducted to obtain the potential target pathways of BSF on CHB. Characteristics of peripheral follicular helper T cells (Tfh) and B-cell subtypes in CHB patients were analyzed by flow cytometry. In vitro, the co-culture system of $CXCR5^+$ cells and HepG2.2.15 cells was used to explore the immunoregulatory roles of BSF. **Results:** The rate of HBsAg decline e 1lg IU/ml in T2-Group was higher than that in C2-Group (35.7% vs 15.9%, $P < 0.05$). The rate of HBsAg decline e 1lg IU/ml and the HBeAg negative rate in T2-Group were higher than those in T1-Group (35.7% vs 14.7%, $P < 0.05$; 58.6% vs 6.3%, $P < 0.05$). The Clinical efficacy of TCM Syndrome in T-Group is significantly better than that in C-Group. BSF up-regulated the frequencies of Tfh and its IL-21 level and IL-21R level on B-cell. BSF reduced HBsAg and HBeAg levels in the co-culture system of $CXCR5^+$ cells and HepG2.2.15 cells, and up-regulated Tfh frequencies and down-regulated B-cell frequencies. **Conclusion:** Taken together, our findings indicated that BSF contributed to the decrease of HBsAg and the

clearance of HBeAg, and improved TCM symptoms in CHB patients with partial response to Peg-IFNα, which maybe correlated with the differentiation of Tfh through IL-21/IL-21R signaling.

2601-A | CELLULAR IMMUNE RESPONSE TO A SINGLE DOSE OF LIVE ATTENUATED HEPATITIS A VIRUS VACCINE IN OBESE CHILDREN AND ADOLESCENTS

Voranush Chongsrisawat[1], Tanatchabhorn Soponkanabhorn[1] and Supranee Buranapraditkun[2,3], (1)Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, (2)Division of Allergy and Clinical Immunology, Faculty of Medicine, Chulalongkorn University, and King Chulalongkorn Memorial Hospital, (3)Center of Excellence in Vaccine Research and Development (Chula Vaccine Research Center-Chula VRC), Faculty of Medicine, Chulalongkorn University

Background: Obese children are at an increased risk of developing nonalcoholic fatty liver disease. Individual's with chronic liver disease may have a compromised immune system, which can make them more susceptible to hepatitis A virus (HAV) infection. There is limited data available on the cellular immune response to a live attenuated HAV vaccine, especially in children with obesity. This study aimed to compare antigen-specific interferon (IFN)-γ+ T cell activation in obese children/adolescents with healthy counterparts before and after immunization with a single dose of live attenuated HAV vaccine. **Methods:** This study obtained blood samples from our previous study titled "Impact of Obesity and Being Overweight on Immunogenicity to Live Attenuated Hepatitis A Vaccine in Children and Young Adults". Prior to enrollment, all 212 subjects had never received any HAV vaccine and were seronegative for anti-HAV. Participants were vaccinated with the H2 strain, freeze dried, live attenuated HAV vaccine. For this study, we analyzed stored peripheral blood mononuclear cells (PBMCs) collected from 30 obese subjects aged 8-14 years (15 males) and 30 normal-weight healthy controls of the same age and sex. PBMCs were collected before and 8-9 weeks after HAV vaccination for analysis. Recombinant antigen from HAV-VP3 was used to stimulate PBMCs and the IFN-γ enzyme-linked immunospot (ELISpot) assay was performed to evaluate the immune response. **Results:** The between-group analysis revealed that the T cell response of obese participants was comparable to that of normal controls both before and after vaccination (Figure). The change in IFN-γ production from before to after vaccination in the obese group was not significantly different from that of the control group. In the obese group, there was no correlation between IFN-γ production and clinical characteristics such as sex, BMI, waist circumference, truncal obesity, and acanthosis nigricans. **Conclusion:** Testing for cellular immune response offers a comprehensive understanding of the overall immune response to vaccination, especially for intracellular pathogens such as viruses. The present study, which represents the first exploration of this significant aspect, suggests that obesity does not have an impact on short-term cellular immune response to live attenuated HAV vaccination.

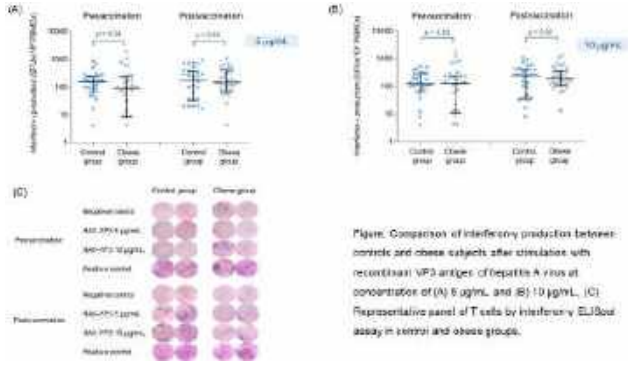

Figure. Comparison of interferon-γ production between controls and obese subjects after stimulation with recombinant VP3 antigen of hepatitis A virus at concentration of (A) 5 μg/mL and (B) 10 μg/mL. (C) Representative panel of T cells by interferon-γ ELISpot assay in control and obese groups.

f 2602-A | CHARACTERIZATION OF THE ANTIBODY REPERTOIRE AGAINST mAChR3 IN PATIENTS WITH PBC AND PSC★

Anne Olbrich[1], Asis Mousa[1], Madlen Oelsner[1], Danilo Deichsel[1], Toni Herta[2], Madlen Matz-Soja[1,2], Beate Preuss[3], Reinhild Klein[3], Tobias Müller[4], Barbara Malik[5], Julia Benckert[5] and Thomas Berg[6], (1) University Hospital Leipzig, (2)Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany, (3)University Hospital Tübingen, (4)Kliniken Berlin, (5)Charité Berlin, (6) University Hospital of Leipzig

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are rare chronic inflammatory biliary diseases. Specific auto-antibodies against the muscarinic acetylcholine receptor type 3 (mAChR3) may contribute to the pathogenesis of these biliary inflammation by modulating mAChR3-mediated signaling. **Methods:** We analyzed the sera from PBC (n = 95) and PSC patients (n = 47) for the presence of functional active mAChR3 auto-antibodies. Subsequently, peripheral blood from 32 patients was examined for mAChR3-binding memory B cells using the labeled mAChR3-peptides. Using FACS, we isolated CD19 +CD27+IgG+ memory B cells that bind to mAChR3 peptide on a single-cell level from one index patient with small duct PSC. We amplified the heavy chain (IgH) and corresponding light chain (IgL) gene transcripts for each cell using nested reverse transcription PCR and expressed them *in vitro*. **Results:** We detected mAChR3 auto-antibodies in 6% of the PBC patients and in 17% of the PSC patients. We found circulating anti-mAChR3 memory B cells in all patients and CD19+CD27+IgG +mAChR3+ cells from a subset of these patients on a single-cell level. PBC patients exhibited a significantly higher number of mAChR3+-peptide reactive memory B cells compared to PSC patients. Sequence analyses revealed a substantial proportion of mutated and hyper-mutated antibodies. Moreover, we could show that CDR3 regions of the mAChR3-specific B cells were elongated compared to our healthy control group. After recombinant expression, the antibodies were tested in a cell culture model, demonstrating their ability to inhibit or stimulate *in vitro*. **Conclusion:** Our investigation of mAChR3 autoantibody expression in PBC and PSC patients could be of significant importance for understanding the etiopathogenesis of these diseases. The identified antibodies will undergo further testing to determine their impact on the bicarbonate umbrella.

f 2603-A | IL-33/AMPHIREGULIN-MEDIATED REGULATION OF ACUTE IMMUNE-MEDIATED HEPATITIS

Selina Wachtendorf, Fitriasari Jonin, Aaron Ochel, Fabian Heinrich, Gisa Tiegs and Katrin Neumann, University Medical Center Hamburg-Eppendorf

Background: In acute immune-mediated hepatitis, the alarmin IL-33 is released by necrotic hepatocytes to activate type 2 innate lymphoid cells (ILC2s) and regulatory T cells (Tregs) expressing the IL-33 receptor ST2. We have previously shown that ILC2s aggravate liver injury in acute immune-mediated hepatitis. Since IL-33 induces expression of amphiregulin (AREG), which has been linked with tissue repair and immunosuppression, we investigated the immunoregulatory role of the IL-33/AREG axis in acute immune-mediated hepatitis. **Methods:** Mice were treated with concanavalin (Con)A to induce acute immune-mediated hepatitis. ST2-deficient (*Il1rl1*$^{-/-}$) and *Areg*$^{-/-}$ mice were used for functional analyses. The immunosuppressive function of Tregs was analyzed in vitro and in vivo. Phenotype analyses were done by flow cytometry. **Results:** We showed that hepatic *Il33* and *Areg* expression was induced in acute immune-mediated hepatitis. IL-33-responsive ST2$^+$ Tregs constituted an effector Tregs subset in the liver, which was highly activated in hepatic inflammation. *Il1rl1*$^{-/-}$ mice developed more severe liver injury, that was associated with an overall reduced Treg activation due to lack of ST2$^+$ Tregs. Hepatic ILC2s and ST2$^+$ Tregs expressed AREG in response to IL-33 and in acute immune-mediated hepatitis. Interestingly, *Areg*$^{-/-}$ mice developed more severe liver injury than wild-type mice, which correlated with stronger activation and IL-13 expression of hepatic ILC2s, while the frequency of ST2$^+$ Tregs was reduced. Importantly, this Treg subset was characterized by a high potential to protect from acute immune-mediated hepatitis. We further demonstrated that AREG suppressed the expression of IL-13 by hepatic ILC2s in vitro. In contrast, AREG induced activation, expansion and AREG expression in ST2$^+$ Tregs. Moreover, Tregs from *Areg*$^{-/-}$ mice were impaired in their capacity to suppress the activation of CD4$^+$ T cells in vitro. **Conclusion:** We here describe an immunosuppressive role of the IL-33/AREG axis in acute immune-mediated hepatitis, in which AREG suppresses the activation of ILC2s while maintaining ST2$^+$ Tregs and reinforcing their immunosuppressive function in liver inflammation.

2604-A | NON-ALCOHOLIC STEATOHEPATITIS (NASH) RESULTS IN ACCUMULATION OF CLONALLY EXPANDED CD8+ T CELLS IN THE LIVER

Abbigayl E.C. Burtis, Destiny M.C. DeNicola, Megan E. Ferguson, Beth A. Jiron Tamburini, Austin E. Gillen and Matthew A. Burchill, University of Colorado - Anschutz Medical Campus

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Chronic liver disease due to NASH is a rapidly increasing epidemic that is predicted to become the number one cause of liver transplantation worldwide. While many aspects of the pathogenesis of NASH have been studied, T cell function in NASH is still unresolved. In these studies, we aimed to determine if T cells are responding to antigens in the liver to modulate disease progression. **Methods:** To define the contribution of T cells in the progression of NASH, we utilized a combination of flow cytometry and single-cell RNA sequencing of T cells in the liver during the progression and resolution of NASH. Specifically, we interrogated T cells in the liver of mice fed a High-Fat, High Cholesterol (HFHC) diet for 25 or 31 weeks, mice fed HFHC diet for 26 weeks then control diet for 5 weeks, or caloric matched control diet. **Results:** In these studies, we found that NASH resulted in a dramatic accumulation of CD8+ T cells in the liver. Analysis of liver infiltrating CD8 T cells showed that T cells from the NASH and diet reversal model expressed markers of chronic antigenic stimulation including PD1, TIGIT, and Tox. Furthermore, T cell receptor (TCR) repertoire analysis demonstrated that T cells in the liver of mice with NASH had a significant reduction in TCR diversity. This reduction in diversity was driven by the expansion of T cell clones that represented up to 60% of the total T cell population in the liver. Diet reversal led to recovery of a higher TCR diversity and a correlative reduction in liver injury, providing evidence of an active role of T cell expansion in the progression of NASH-induced liver disease. Surprisingly, there was little overlap found in the TCR sequences of the clonally expanded T cells between individual mice fed the same NASH-inducing diet. This suggests that multiple antigens may be driving the expansion of T cells during NASH. **Conclusion:** Together our studies demonstrate that antigenic stimulation is driving the expansion and accumulation of CD8+ T cells in the liver during NASH and points to an active role for T cells in the progression of NASH-induced liver disease. Thus, current studies are aimed at identifying the antigenic driver(s) of expansion and if specific depletion of clonally expanded T cells alters the progression of NASH. Thus, investigation into the cause of the clonal expansion and what role the expanded T cells play in the progression of NASH has the potentiation to transform the treatment of this pervasive disease.

2605-A | THE ROLES AND MECHANISM OF DHX34 ABLATION IN ENHANCING TUMOR IMMUNOGENICITY IN HEPATOCELLULAR CARCINOMA

Hongwei Tian[1], Chunli Zhang[1], Zeyu Li[1], Limin Huang[1], Yanhua Mu[1], Gaixia He[1], Jin Sun[1], Ting La[1], Guangyao Kong[1,2], Jing Geng[1,2] and Zongfang Li[1,2,3], (1)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2) Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3)Shaanxi International Cooperation Base for Inflammation and Immunity, Xi'an, China

Background: Tumor immunotherapy has achieved significant clinical efficacy in recent years, but only some patients respond to immunotherapy, mainly because the tumor microenvironment inhibits the anti-tumor immune response. DHX34 is one of the RNA helicases, and its role in the regulation of tumor immune microenvironment has not been studied. Analysis of the clinical database of liver cancer in the early stage showed that DHX34 was highly expressed in liver cancer, and was negatively correlated with patient survival, T cell infiltration, and inflammatory cytokines expression. **Methods:** We knocked out DHX34 expression in HepG2, which significantly promoted the expression of inflammatory factors in vitro, enhanced T cell activation and effector function, and significantly enhanced the anti-tumor effect in vivo. **Results:** Mechanistic studies have shown that DHX34 knockout differential gene enrichment is in validating relevant pathways, mainly affecting type I interferon pathways. DHX34 knockout enhances the expression of ISGs genes such as RIG-I, MDA-5, MAVS and IFN-a, IFN-b, and overexpression of DHX34 partially inhibits or does not affect ISGs gene expression. At the same time, knocking out DHX34 also enhanced the expression of chemokines such as CXCL9 and CXCL10, which contributed to immune cell infiltration into the tumor microenvironment. We also found that DHX34 knockout leads to the accumulation of endogenous dsRNA in cells, and excess dsRNA can induce the activation of type I interferon pathway, leading to the expression of downstream effector factors, promoting the infiltration of inflammatory cells in the tumor microenvironment, and enhancing the anti-tumor immunity effect. **Conclusion:** Overall, this study elucidates the molecular mechanism by which DHX34 promotes tumor growth by reducing endogenous dsRNA accumulation and inhibiting type I interferon

2606-A | EXPERIMENTAL MODEL OF SEVERE ALCOHOL-ASSOCIATED HEPATITIS IN MICE INDUCED BY DUAL INJURY OF CHRONIC ALCOHOL AND NASH DIET RECAPITULATES KEY FEATURES OF HUMAN DISEASE

Mrigya Babuta, Caroline Morel, Marcelle Ribeiro, Charles Calenda and Gyongyi Szabo, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: The prevalence of alcohol-associated hepatitis (AH) is increasing in the USA and this coincides with the obesity epidemic. However, current experimental models in mice cannot fully replicate the severe alcohol-associated steatohepatitis (AH) and significant fibrosis found in human disease or mimic the potentially combined insult of obesity, NASH and alcohol. The aim of this study was to develop a new alcohol feeding model that recapitulates the robust inflammatory and fibrotic phenotype characteristic of human AH. **Methods:** 8-10 weeks old male C57BL/6 mice received either chow or high fat-cholesterol-sugar diet (NASH diet) for 3 months. Some of the chow and NASH diet fed mice received alcohol in drinking water (*ad libitum*) plus weekly alcohol binges for 3 months. Liver tissue was analyzed for fibrosis, inflammation and regeneration markers by immunohistochemistry, qPCR, ELISA and western blotting. **Results:** Chronic alcohol plus NASH diet resulted in increased liver damage indicated by highly elevated ALT and bilirubin levels, compared to all other groups. Liver steatosis was significantly greater in the alcohol plus NASH diet compared to all other experimental groups based on oil-o-red staining, liver triglyceride levels and a dramatic increase in gene expression in fatty acid metabolism including adipose differentiation related protein, diglyceride acyltransferase, and fatty acid binding protein. The inflammatory phenotype of human AH was also recapitulated in the liver of chronic alcohol plus NASH diet fed mice, including increased monocyte chemoattractant protein-1, interleukin 6 and interleukin-1B protein levels as well as increased $CD68^+$ macrophages and $Ly6G^+$ neutrophils in the liver. Sirius red staining and expression of collagen 1, alpha-smooth muscle actin indicated advanced fibrosis in livers of alcohol plus NASH fed mice. In addition, indicators of epithelial to mesenchymal transition including higher snail and decreased expression of occludin, claudin and hepatocyte nuclear factor were present in chronic alcohol plus NASH diet fed mice compared to any of the other groups. Furthermore, chronic alcohol plus NASH diet led to hepatocyte dedifferentiation as marked by increase in albumin, hepatocyte growth factor and $Ki67^+$ cells. We also found enhanced ductular reaction and dysregulated hedgehog signaling consistent with advanced alcoholic hepatitis. **Conclusion**: We show that chronic alcohol administration with a NASH diet recapitulates key characteristics of human AH including liver damage, steatosis, systemic inflammation and liver immune cell infiltration. This model results in advanced liver fibrosis, ductular reaction and hepatocyte dedifferentiation suggesting a feasible model of human severe alcoholic hepatitis.

2607-A | GLYCINE PREVENTS MURINE AUTOIMMUNE CHOLANGITIS AND PANCREATITIS INDUCED BY DOUBLE-STRANDED RNA THROUGH MODULATION OF INNATE IMMUNE RESPONSES

Akira Uchiyama, Kazuyoshi Kon, Satoshi Sakuma, Kumiko Arai, Toshifumi Sato, Hiroo Fukada, Reiko Yaginuma, Kyoko Fukuhara, Shunhei Yamashina and Kenichi Ikejima, Juntendo University School of Medicine

Background: Autoimmunity is postulated to play a pivotal role in the pathogenesis of a variety of hepato-biliary and pancreatic diseases, including primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), and autoimmune pancreatitis (AIP). Glycine, a non-essential amino acid, has been shown to prevent experimental liver injuries by attenuating hepatic innate immune responses to gut-derived endotoxin. In this study, we evaluated the effect of glycine on double-stranded RNA-induced innate and auto-immune responses in the liver and pancreas. **Methods:** Female, 8-week-old C57Bl6 mice were fed a diet containing 5% glycine or casein as controls, and given repeated, intra-peritoneal injections of poly I:C (5 μg/g BW, twice/week) for up to 24 weeks. Some mice were euthanized following a single injection of poly I:C in combination with one-week pre-feeding with glycine-diet. Serum alkaline phosphatase (ALP) and amylase (AMY) levels were measured, and histopathological features of the liver and pancreas were assessed. Expression of immune cells were evaluated by immunohistochemical staining for F4/80, CD3, and CD20. Serum anti-mitochondria antibody (AMA)-M2 and anti-lactoferrin (LF) antibody were detected by ELISA. Hepatic mRNA levels for TNFα, IL-1β, IL-6, IFNα and IFNβ were quantified by real time RT-PCR. **Results:** Repeated injection of poly I:C induced overt inflammatory infiltration in the portal area, predominantly lymphocytes surrounding bile ducts, and massive distraction of pancreatic acinar cells with infiltration of inflammatory cell and mild fibrosis after 16 weeks and later. Indeed, the number of F4/80-, CD3- and CD20-positive cells were significantly increased with repeated injection of poly I:C in both liver and pancreas. These pathological changes of cholangitis and pancreatitis were largely ameliorated in mice fed a glycine-containing diet for 8 weeks starting from 16 weeks of poly I:C treatments; poly I:C-induced increases in ALP and AMY levels were markedly blunted in mice given glycine-containing diet. Repeated injections of poly I:C also elicited increases in serum AMA-M2 and LF levels, which were also blunted significantly in mice fed a glycine-containing diet. On the other hand, a single injection of poly I:C elicited transient, swift elevations in hepatic mRNA levels for TNFα, IL-1β, and IL-6, as well as IFNα and IFNβ; however, all of these parameters were blunted significantly in mice fed a glycine-diet. **Conclusion:** These findings clearly indicated that dietary glycine prevents development of autoimmune-related cholangitis and pancreatitis induced by repeated injections of poly I:C, most likely through attenuating innate immune responses. It is postulated that glycine is a promising immuno-nutrient for the treatment of autoimmune hepato-pancreatic diseases.

2608-A | NANOPARTICLE-BASED ANTIFIBROTIC THERAPY FOR TREATMENT OF LIVER FIBROSIS

Sufeng Zhang[1,2,3], Rachel Zhang[1], Bruna Santos[1], Katrina Garrow[1], Adam Mohamed[1], Keiko Ishida[3], Wiam Madani[3], Alison Hayward[3], Niora Fabian[3], Joshua R. Korzenik[1,2] and Carlo Giovanni Traverso[1,2,3], (1)Brigham and Women's Hospital, (2)Harvard Medical School, (3)Massachusetts Institute of Technology

Background: Primary Sclerosing Cholangitis (PSC), an inflammatory disease of the liver without any therapy, leads to fibrosis and cirrhosis. Liver fibrosis results from abnormal wound repair during chronic liver injury, representing a clinical challenge. Inflammatory response accompanies fibrosis development, during which excessive inflammatory cytokines and molecules promote the activation and proliferation of hepatic satellite cells (HSCs) and lead to hepatocyte necrosis and apoptosis. Sulfasalazine (SSZ) was shown in retrospective studies to be beneficial for treating PSC. A prospective clinical trial is currently in process. SSZ was also found to be anti-fibrotic by increasing HSCs apoptosis. Hence, SSZ may reduce inflammation and reverse fibrosis in PSC and other liver diseases. However, the possible side effects on liver or kidney damage limit further studies on SSZ as anti-fibrotics. **Methods:** We aim to assess whether a nanoparticle (NP) delivery system can target SSZ to the liver for effective treatment. To this end, we encapsulated SSZ in albumin-based NPs, characterized the formulated NPs, investigated SSZ release from NPs, and evaluated the SSZ-loaded NPs in rodent models of liver fibrosis. When establishing the liver fibrosis models, we used $n = 5$ mice per group and $n = 4$ rats per group in the treated and control groups. NPs were administered intravenously to animals. The severity of liver fibrosis was determined by H&E histology and Sirius Red staining. **Results:** The characterization showed that NP

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

sizing was tuned by the concentration of albumin used for NP formulation. The encapsulation efficiency (EE) of SSZ in NPs indicated that a higher albumin concentration led to a higher EE of SSZ. Next, we investigated the SSZ release from NPs and found that the supernatant from lipopolysaccharide-activated macrophages triggered SSZ release from NPs much faster than simulated intestinal fluids. Further, we established two rodent models of liver fibrosis, including thioacetamide (TAA) in mice and carbon tetrachloride (CCl4) in rats. With dye-conjugated NPs, the *in vivo* biodistribution study demonstrated that the SSZ-loaded NPs accumulated in the liver compared to other organs in CCl4-induced fibrosis in rats (Fig. 1). **Conclusion:** Our work revealed the potential of liver-targeting SSZ-loaded NPs for effective fibrosis treatment. Our next step is to fine-tune the SSZ delivered to the liver to maximize efficacy and minimize side effects.

2609-A | SINGLE NUCLEUS RNA-SEQUENCING REVEALS REGENERATIVE PROPERTIES OF EXOGENOUS IL-4 ON HEPATOCYTES IN MURINE PRECISION-CUT LIVER SLICES

Damra Camat[1,2], Diana Nakib[1,2], Sai Chung[1,2], Yijia Liu[1], Catia Perciani[2], Agata Bartczak[2], Michael Liyaw Cheng[1], Olivia Ivana Pezzutti[1], Sadaf Mazhab Jafari[1], Xue-Zhong Ma[2], Ian McGilvray[2] and Sonya A MacParland[1,2], (1)University of Toronto, (2)University Health Network

Background: The precision-cut liver slice (PCLS) model is a unique platform because it allows for the culturing and modulating of parenchymal and non-parenchymal cell types in intact liver tissue. Objectives: To extend the use of PCLS beyond drug assays, it is critical to standardise a protocol that allows slices to remain viable in culture for extended periods of time. We have established a reproducible workflow with a fixed end point that would allow for assessment of the effects of introduced interventions such as treatment with the pro-regenerative cytokine, interleukin 4 (IL-4). **Methods:** Liver slices were cultured for 5 days in the presence or absence of IL-4 to assess the impact on hepatocyte viability and regeneration. In cultured slices, we assessed morphology and apoptosis (H&E and TUNEL staining), proliferation (Ki-67 staining) and viability (ATP assay). To examine cellular pathways impacted by IL-4 treatment, single-nucleus RNA-sequencing (snRNA-seq) was performed on 4 slices per condition on Day 1 and Day 3. **Results**: IL-4 treated slices generated higher levels of ATP and displayed decreased apoptotic nuclei with an increased number of viable nuclei through the culture period. Ki-67 staining revealed that on Day 3 of culture, slices treated with IL-4 showed significantly more proliferating cells compared to untreated slices. SnRNA-seq revealed the presence of viable hepatic populations previously atlased in the murine liver in both IL-4 treated and untreated slices with transcripts associated with regenerative pathways (i.e., *Egr1*, *Rela*, *Gabpb1* and *Ets2*) enhanced in the IL-4 treated slices. **Conclusion:** We identified IL-4 as a potential promoter of regeneration and viability of hepatocyte-like and cholangiocyte-like cells. This renders IL-4 as a potential therapeutic modifier of hepatic disease and avenue of continued investigation.

Background: The liver is the most common site for organ metastasis. The spleen and liver are connected anatomically and physiologically. All splenic blood perfuses to the liver through the portal vein. But it is unclear whether splenic myeloid cells are involved in the pro-metastatic niche formation and thus promote liver metastasis. Therefore, the aim of this research is to explore the function of splenocytes in liver metastasis **Methods:** Male or female C57BL/6 mice or KikGR mice aged 6-10 weeks were used in animal experiments. Experimental liver metastasis in mice was performed by implanting melanoma B16-GFP cells into the portal vein of mice using a 32 G syringe. Then the C57BL/6 mice were randomly divided into two groups, and mice in group A were adoptive transfer of spleen-derived cells of KikGR mice through the tail vein, followed by B16-GFP cells inoculated; mice in Group B were transplanted with KikGR mouse spleen to C57BL/6 mice, followed by B16-GFP cells inoculated through the portal vein. Additionally, KikGR mice were surgically exposed the spleen, and irradiated the spleen under a 405nm laser. The cells in the spleen were photoconverted by irradiation, so that the splenic cells emit red fluorescence, and then B16-GFP cells were inoculated through the portal vein, labeled as group C. When B16-GFP cells were seeded for 24 hours, the distribution of KikGR-positive cells in the liver were observed by intravital imaging through an image window in the abdomen of the mice. By which we determined whether spleen-derived myeloid cells participated in the pro-metastatic niche formation in liver. **Results:** GFP-positive B16 cells were detected in the livers of all three groups of mice by liver intravital imaging. In the livers of mice in groups A and B, a large number of KikGR-positive cells were detected; In group C mice, a large number of photoconverted KikRed-positive cells were detected in the liver. In these three groups of mice, spleen-derived myeloid cells ($KikGR^+$ cells) tended to be distributed around GFP-expressing tumor cells. **Conclusion:** As tumor cells enter the liver niche, splenic myeloid cells also rapidly recruited to the liver to facilitate the pro-metastatic niche formation.

f 2611-A | CROSS-COMPARTMENT SINGLE-CELL TRANSCRIPTOMICS OF HUMAN IMMUNE CELLS REVEALS DYNAMIC PERTURBATIONS IN MONOCYTES AND MACROPHAGES IN NAFLD/NASH

Michael S. Wallace[1], Hailey Patel[1], Michael Butler[1], Christopher Oetheimer[2], Joshua Elbaz[1], Charlotte Laurent Costentin[1], Owen Martin[1], Lai Ping Wong[1], Ulandt Kim[1], Edgar D. Charles[3], Ruslan Sadreyev[1], Raymond T. Chung[2] and Nadia Alatrakchi[2], (1) Massachusetts General Hospital, Harvard Medical School, (2)Massachusetts General Hospital and Harvard Medical School, (3)Bristol Myers Squibb

Background: Nonalcoholic fatty liver disease (NAFLD)/nonalcoholic steatohepatitis (NASH) is the most common cause of liver disease worldwide. Of those with NASH, a significant portion will progress to cirrhosis/fibrosis or liver failure, for which no approved therapies exist. Monocytes and macrophages (Mo/Ma) play a critical role in liver pathogenesis. However, their extreme complexity and often opposing functions are poorly understood and access to liver tissue is limited in humans, hampering the development of targeted therapies. We sought to characterize the single-cell transcriptome of Mo/Ma in human NAFLD using the less invasive fine needle aspirate (FNA) approach, which enriches immune cell populations. **Methods:** We analyzed single-cell RNA-sequencing data corresponding to paired liver FNAs and peripheral blood mononuclear cells (PBMCs) from 25 participants with histologically confirmed NAFLD, including 4 with simple steatosis, 10 with early NASH (F0-F1), 9 with advanced NASH (F2-F4), and 2 controls without steatosis. **Results:** The expected immune cell populations were captured, as well as small numbers of hepatocytes and hepatic stellate cells, in the liver compartment from each patient. We observed differences in gene expression across immune cell types between the two compartments. Mo/Ma showed a significant increase with the advancement of NASH; this increase was confined to the liver. This shift was accompanied by increased interferon-stimulated gene (ISG) expression in monocytes in both tissue compartments and in macrophages in the liver. Monocyte gene signatures were associated with NAFLD/NASH progression, with distinct features in each compartment. In CD14+ monocytes, we detected

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

multiple inflammatory and feedback anti-inflammatory patterns as early as simple steatosis, specific to the liver compartment, which fluctuated throughout the course of NAFLD/NASH progression. CD14+ monocytes were heterogeneous and showed segregation of distinct programs (S100, MHC-II, and ISG), which were validated by tissue staining. We delineated macrophage populations and potentially profibrotic gene expression associated with advanced NASH and suggest potential developmental trajectories for these populations based on CD14+ monocyte subpopulations. **Conclusion:** We identified dynamic inflammatory perturbations in NAFLD monocytes in the liver as early as steatosis, prior to histological confirmation of inflammation, and identified genes associated with NASH progression to fibrosis.

f 2612-A | MACROPHAGE NUCLEOTIDE CATABOLISM INHIBITS THE DEVELOPMENT OF HEPATOCELLULAR CARCINOMA

Chuanli Zhou, Shuang Liang and Zhenyu Zhong, University of Texas Southwestern Medical Center

Background: Hepatocellular carcinoma (HCC), the dominant form of primary liver cancer, has emerged as the second leading cause of cancer-related deaths. The development of HCC is closely linked to chronic liver inflammation and impaired macrophage function. However, the precise molecular mechanism responsible for this dysregulation has remained elusive, posing a significant obstacle in the development of effective anti-HCC therapies. **Methods:** Experimental HCC models in *Samhd1*$^{F/F}$ and *Samhd1*$^{\Delta Mye}$ mice, and *in vitro* studies with BMDMs stimulated with conditioned medium released from DEN-treated hepatocytes were conducted. SAMHD1 oxidation and enzymatic activity were analysed in tumor associated macrophages and compared with liver macrophages from non-tumor regions. **Results:** In this study, we demonstrate a crucial role of SAMHD1 as a gatekeeper in macrophages, curbing uncontrolled liver inflammation and inhibiting HCC development in mice. By functioning as a dNTPase, SAMHD1 effectively restricts the abnormal accumulation of cytosolic dNTPs, averting uncontrolled neosynthesis of mitochondrial DNA (mtDNA) and the subsequent overproduction of mtROS. Consequently, this regulatory process effectively limits the production of chemokines CXCL1/2, thereby preventing excessive neutrophil infiltration into the liver, which is known to promote HCC progression. Interestingly, our findings also unveil extensive oxidation and functional impairment of SAMHD1 in HCC-associated liver macrophages, implying that the liver microenvironment actively inhibits SAMHD1 to facilitate tumorigenesis. **Conclusion:** Collectively, our results establish macrophage nucleotide catabolism as a pivotal factor in preventing liver inflammation and HCC, shedding light on the previously unrecognized role of SAMHD1 dysregulation as a pathogenic mechanism underlying HCC development.

2613-A | ROLE OF IFNL4 GENOTYPE IN HEPATIC INFLAMMATION AMONG BLACK INDIVIDUALS WITH CHRONIC HEPATITIS C

Harish Gopalakrishna[1], Ruth Pfeiffer[2], Sabrina C Ramelli[2], Ludmila Prokunina-Olsson[2], Stephen M Hewitt[2], David E Kleiner[3], Marc G. Ghany[1] and Thomas O'Brien[2], (1)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (2)National Cancer Institute, Bethesda, MD, United States, (3)Laboratory of Pathology, National Cancer Institute, Bethesda, MD

Background: Genetic variants in the interferon lambda region have been linked to hepatic inflammation and fibrosis progression in liver disease of several etiologies, including chronic hepatitis B, chronic hepatitis C and nonalcoholic steatohepatitis. The *IFNL4* rs368234815-TT allele abrogates expression of the IFNL4 protein and *IFNL3* rs4803217-G stabilizes *IFNL3* mRNA. Previous efforts to determine the causal variant for hepatic inflammation were hampered by strong linkage disequilibrium (LD) between these variants in populations of European ancestry; LD is weaker in populations of African ancestry. We examined associations of *IFNL4* and *IFNL3* variants with hepatic inflammation in Black patients with chronic hepatitis C virus (HCV) infection. **Methods:** The VIRAHEP-C trial compared response to peginterferon-α among Black and White patients who were infected with HCV genotype 1; this analysis is limited to Black patients. Pre-treatment liver biopsies were scored for inflammation using the modified Histology Activity Index (HAI) scoring system (portal 0-4, peri-portal 0-10, lobular 0-4) and for fibrosis using the Ishak scoring system (0-6). DNA specimens were genotyped for *IFNL4* rs368234815, *IFNL4* rs12979860 (previously known as 'IL28B') and *IFNL3* rs4803217 using TaqMan assays. Associations of the variants with hepatic inflammation and fibrosis were examined using logistic regression models in which the score was treated as an ordinal variable. We used the Akaike information criterion to assess model fit. **Results:** Among 169 Black participants, 65% were male with median age of 49 years. Total HAI scores were mild (0-6) in 25%, moderate (7-12) in 70% and severe (13-18) in 5%; 66% of patients had mild (Ishak 0-2), 29% had moderate (3-4) and 5% had severe fibrosis (5-6). *IFNL4*-ΔG and *IFNL3* rs4803217-T allele frequencies were 66% and 61%, respectively. *IFNL4*-TT/TT genotype was associated with 3.72-fold (p = 0.01) greater portal and 3.23-fold (p = 0.02) greater periportal inflammation compared to *IFNL4*-ΔG/ΔG (Table 1). Genotype analyses for the *IFNL3* rs4803217 and *IFNL4* rs12979860 variants revealed weaker, non-statistically significant associations with inflammation; the model based on genotype for *IFNL4* rs368234815 fit the data best (Table 1). In these patients with predominately mild fibrosis, we saw no association between any of the variants and increased fibrosis. **Conclusion:** *IFNL4*-TT/TT genotype, which eliminates IFNL4 protein expression within hepatocytes, was associated with greater hepatic inflammation; the weaker associations observed for *IFNL3* rs4803217 and *IFNL4* rs12979860 likely reflect LD. These results suggest that therapeutic administration of IFNL4 protein could ameliorate inflammation in patients with chronic liver diseases lacking curative therapies, such as chronic hepatitis B and nonalcoholic steatohepatitis.

Table 1. Associations for genotypes of *IFNL4* rs368234815, *IFNL4* rs12979860 and *IFNL3* rs4803217 with hepatic inflammation scores for the portal region - Black participants, Virahep-C.

Variant	Genotype	#	(%)	OR	p-value	AIC
IFNL4-ΔG/TT rs368234815	ΔG/ΔG	70	41.4	_		333.7
	ΔG/TT	83	49.1	0.93	0.82	
	TT/TT	16	9.5	3.72	0.01	
IFNL4 rs12979860	T/T	56	33.1	_		338.4
	T/C	93	55.0	0.99	0.97	
	C/C	20	11.9	2.14	0.13	
IFNL3 rs4803217	T/T	55	32.5	_		338.3
	T/G	94	55.6	0.89	0.72	
	G/G	20	11.9	2.00	0.17	

AIC, Akaike information criterion - a lower score indicates better model fit.

Coimbra, (4)Faculty of Medicine of the University of Coimbra, (5)Barcelona Liver Bioservices (BLB), (6) Instituto Superior De Engenharia De Coimbra, (7) Inselspital - University of Bern, Bern, Switzerland

Background: Cell senescence characterized by a permanent cell cycle arrest and a senescence associated secretory phenotype, plays a key role in multiple pathologies associated with advanced age. Indeed, the aged liver exhibits hepatic microcirculatory dysfunction and sinusoidal fibrosis, which may be partly due to cell senescence. Senolytic drugs, such as navitoclax, able to interfere with the pro-survival pathways of senescent cells, can ameliorate pathological effects of senescence. However, translation of these compounds to the clinic is still limited due to low cell specificity and toxic effects. Here, we aimed at developing a nanoformulation containing navitoclax as an efficient strategy to target the hepatic sinusoid in preclinical models of healthy aging. **Methods:** Nanoformulation: A library of ~40 nanoparticles containing navitoclax was designed to be disassembled only in cells exhibiting high levels of SA-B-galactosidase activity. The bioactivity of the nanoformulations was screened to identify the best one targeting senescent endothelial cells. Hepatic effects: 20 months old Wistar rats were treated with either vehicle, soluble navitoclax (50mg/kg/day) or navitoclax-containing nanoparticles (NPs; 0.2mg/kg/day) ($n = 8$ per group). After a four-week resting period, *in vivo* hepatic and systemic hemodynamic, biochemical parameters, as well as molecular markers of liver fibrosis, senescence, and hepatic phenotype were assessed. **Results:** The NP library screening showed a nanoformulation with an optimized senolytic index of over 40x when compared with soluble navitoclax. Upon *in vivo* administration, selected NPs were mostly accumulated in the liver. Aged animals treated with NPs exhibited a reduction in portal pressure compared to vehicle (8.6 ± 0.2 vs. 9.3 ± 0.3, $p = 0.059$), with no changes in portal blood flow, suggesting decreased intrahepatic vascular resistance. Interestingly, hemodynamic improvement was not observed with the oral navitoclax treatment. Beneficial effects of novel NPs were associated with reduction in senescence markers (IL6 -72% and MMP13 -57%), improvement in hepatocyte phenotype (+52% hnf4; +51% slc22a, +5% albumin production) and, importantly, amelioration of hepatic fibrosis (-21% in Sirius red staining). **Conclusion:** Specifically targeting liver senescent cells in aging is possible using a novel formulation of senolytic nanoparticles. This technology rejuvenates liver function & architecture, thus representing a unique therapeutic opportunity for diseases coursing with cellular senescence.

2615-A | ATORVASTATIN REDUCES INFLAMMATORY BIOMARKERS TNF-A, CD62L AND MMP-2 IN CIRRHOSIS. RESULTS FROM A RANDOMIZED PLACEBO-CONTROLLED TRIAL

Thit Mynster Kronborg, Hvidovre University Hospital

Background: Patients with cirrhosis and portal hypertension endure a high risk of complications. Besides anti-inflammatory and anti-fibrotic effects, statins may reduce portal pressure and thus the risk of complications and mortality. We aimed to investigate the effects of atorvastatin treatment on hospital admissions, mortality, inflammation and lipidomics in cirrhosis with portal hypertension. **Methods:** We performed a double-blinded, randomized, placebo-controlled clinical trial in patients with cirrhosis and portal hypertension. Atorvastatin (10-20 mg/day) was administered for six months. We measured splanchnic hemodynamics and analyzed cellular biomarkers and lipidomics at baseline and after six months. **Results:** Seventy-eight patients were randomized with 38 patients allocated to atorvastatin and 40 patients to placebo. Fifty-nine patients completed six months of intervention. Liver-related complications and mortality were similar between the groups. The hepatic venous pressure was unchanged after six months of atorvastatin (change -0.4 mmHg (16.1 vs. 15.5, $p = 0.6$)) and placebo (change -0.4 mmHg (15.1 vs. 14.7, $p = 0.6$)). The MELD score was unchanged in both groups. Atorvastatin decreased the cellular biomarkers TNF-α,

CD62L and MMP-2 (*p*-values; 0.005, 0.011, and 0.023, respectively). **Conclusion:** In patients with cirrhosis, atorvastatin was safe to use, and induced anti-inflammatory effects with minor effects on lipids during a six-month treatment period. Atorvastatin did not reduce mortality, risk of liver-related complications, or hepatic venous pressure within six months of treatment. Future studies focusing on intervention in earlier stages of cirrhosis are desired.

2616-A | EXERCISE REDUCES INFLAMMAGING IN SARCOPENIC CIRRHOTICS BY MODULATING NEUTROPHILS, MEMORY B CELLS AND IL-6 DYNAMICS

Preeti Negi, Nidhi Nautiyal, Swati Thangariyal, Ashmit Mittal, Rakesh Kumar, Shiv Kumar Sarin and Sukriti Sukriti, Institute of Liver and Biliary Sciences

Background: Sarcopenia is a multifactorial, progressive and generalized loss of skeletal muscle mass associated with inflammation, untimely immune ageing. The muscle regenerative capacity relies on the interplay between skeletal muscle and immune cells, as the later removes damaged cells and secretes growth factors for satellite cell proliferation and differentiation. However, moderate exercise enhances rejuvenation of immune cells and improves muscle growth. The aim of the study was to investigate effect of exercise in reprogramming the immune cells, reducing inflammation and improving muscle strength. **Methods:** Altogether 64 cirrhosis patients were included [78.1 % male, age 50 ± 12yr; MELD 14.5 (IQR 9.7-20.2], 42 with sarcopenia (SP) and 22 non-sarcopenic (NSP). Appendicular skeletal muscle index [ASMI {< 5.5 kg/m^2 for women, < 7.0 kg/m^2 for men}], dual-energy X-ray absorptiometry (DXA), gait speed, liver frailty index were measured to assess sarcopenia. High-dimensional immune profiling for monocytes, neutrophils, T and B cell subsets in peripheral blood [by flow cytometry], plasma levels of IL-6, TNFα, Myostatin and Follistatin [by ELISA] and gene expression for senescence associated secretory proteins [SASP; {IL-1b, MAPK3, CXCL10, TNFα, p21, p53] and IL-10, IL-22, IL-17A, Caspases [by q-Real time PCR] were performed. All parameters were measured before and immediately post-exercise. The exercise involved cycling on a half bicycle, sitting on a chair for 20 minutes with maximum safe effort. **Results:** Absolute counts of neutrophils (77.2 ± 12.9 vs 64.7 ± 13.6; $p = 0.03$) found high, while low lymphocytes ($p < 0.001$; 17.5 ± 5.6 vs 26.3 ± 9.4) and neutrophil/lymphocyte ratio (NLR)(4.23 ± 1.1 vs 2.9 ± 0.8; $p = 0.03$) was observed at baseline in SP. The frequency of memory B cells (12.2 ± 5.9 vs 4.5 ± 2.9; $p = 0.038$) significantly increased with low naïve B cells in SP than NSP, (taking the immunological space). Post- exercise, neutrophils and memory B cells significantly decline in SP patients ($p = 0.05$;$p = 0.015$). In plasma, IL-6 ($p = 0.04$), TNFα levels ($p = 0.03$) were high in SP than NSP at baseline. The myostatin (MYST) and follistatin were comparable in both groups. The MYST levels were inversely proportional to MELD-Na($r = -0.289$; $p = 0.002$). NLR and IL-6 was found to be independent predictors of sarcopenia (AUROC-0.75, $p = 0.004$ and 0.72, $p = 0.014$). The mRNA levels of SASP were > 3 fold up-regulated ($p < 0.05$) and IL-10 and IL-22 was > 4 fold down-regulated in SP than NSP. Interestingly, post-exercise, IL-6 levels significantly decline in SP patients ($p = 0.015$) but no changes were observed in MYST or follistatin in SP group. The SASP mRNA levels decline post exercise in both SP and NSP patients ($p < 0.001$). **Conclusion:** Exercise induces immune cells reprogramming by removing memory B cells, reducing inflammation and immune-senescence. The beneficial and immediate effect of exercise potentiates, better management of sarcopenia in liver disease condition.

Table A: Physical and Biochemical Parameters of Patients with and without Sarcopenia

S.No.	Parameters	Sarcopenia (SP)	Non-Sarcopenia (NSP)	p-value
1	BMI (kg/m^2)	23.1±3.43	26.77±5.94	0.43
2	Gait Speed (m/s)	0.7±0.18	1.14±0.18	0.00
3	Frailty Index	6.53±0.5	3.29±1.33	0.00
4	ASMI (kg/m^2)	6.37±0.74	7.57±0.85	0.02
5	MELD-Na	15.41±4.58	13.86±5.53	0.08
6	Neutrophil/lymphocyte Ratio	4.23 (3.1-4.7)	3.04 (1.6- 3.4)	0.03
7	Memory B-Cells	12.2±5.9	4.5±2.9	0.03
8	Naïve B-Cells	8.12±1.2	6.2±2.3	0.00
9	IL-6 (pg/ml)	6 (2.7- 7.2)	3.5 (1- 5.1)	0.04
10	TNF-α (pg/ml)	20.08 (8.2- 28.1)	9.03 (3.1-9.3)	0.03
11	Myostatin (ng/ml)	13.3 (7.3-14.1)	11.8 (7.2-12.1)	0.12
12	Follistatin (ng/ml)	3.45 (0.5-5.3)	2.03±2.21 (0.4-2.6)	0.41

2617-A | FERROPTOSIS INDUCES TLR9-DEPENDENT ACTIVATION OF HEPATIC INFLAMMATORY RESPONSES

Mo Wang, Nanjing Drum Tower Hospital Affiliated to Nanjing University and Suzhen Yang, Gulou Hospital Associated with Nanjing University

Background: Hepatocyte death is an important cause of liver inflammation that ultimately leads to liver fibrosis, cirrhosis, and cancer. Ferroptosis is an emerging type of hepatic death associated with non-alcoholic fatty liver disease (NAFLD), but the mechanisms by which ferroptosis triggers inflammatory responses remain poorly understood. **Methods**: We utilized mouse model of NAFLD that was induced by feeding a Western diet (WD) for 16 weeks, and primary cultured mouse hepatocytes and Kupffer cells (KCs). Ferroptosis was induced by pharmacological inducer RSL3 and determined by propidium iodide (PI) staining in cultured cells and by TUNEL staining in mouse livers. The expression of inflammatory cytokines was determined by ELISA and qRT-PCR, and the number of myeloid cells in the liver was determined by staining of CD45. **Results**: We showed that 200 nM RSL3 induced robust ferroptosis of primary hepatocytes as determined by the number of PI-positive cells. RSL3 treatment (5 mg/kg) induced a significantly higher number of TUNEL-positive cells in mice with NAFLD than the control group. Compared to RSL3-treated chow-fed mice and untreated WD-fed mice, RSL3-treated WD-fed mice showed markedly higher production of inflammatory cytokines including the TNF-a and IL-1b as determined by ELISA and qRT-PCR. Increased inflammation in RSL3-treated NAFLD mice was further confirmed by the higher number of cells positive for CD45 staining. To assess the mechanisms of ferroptosis induced inflammatory response, we isolated extracellular vesicles (EVs) from both the culture media of RSL3-treated cells and the sera of RSL3-treated mice. EVs of RSL3-treated hepatocytes and mice both induced significant increases in the expression of cytokines including TNF-a and IL-1b. Intriguingly, the mRNA expression of TLR9 was also induced in EV-treated KCs and in the liver of RSL3-treated mice. Inhibition of TLR9 by its antagonist ODN 2088 mitigated EV-induced cytokine expression in KCs. The loss of TLR9 significantly attenuated RSL3-induced production of TNF-a and IL-1b in both chow and WD-fed mice. Moreover, by qPCR analysis we have identified a higher abundance of mitochondrial DNA (mtDNA) and less genomic DNA (gDNA) in the harvested EVs. Pretreatment of the isolated EVs by sonication and DNase I reduced the induction of TNF-a and IL-1b by cultured KCs. **Conclusion**: Ferroptosis induces the secretion of mtDNA-enriched EVs that induce TLR9-dependent inflammatory responses by the macrophages in NAFLD.

2618-A | IMAGING MASS CYTOMETRY ANALYSIS REVEALS CXCL9-DEPENDENT PRESERVATION OF INTRA-HEPATIC MACROPHAGE POPULATIONS IN CONGESTIVE HEPATOPATHY

Moira Hilscher, Hospital of the University of Pennsylvania, Siyuan Ma, Vanderbilt University Medical Center, Hongzhe Li, University of Pennsylvania, Nawras Habash, Mayo Clinic and Vijay Shah, Mayo Clinic Rochester, Rochester, MN

Background: Congestive hepatopathy (CH) has traditionally been described as a bland, non-inflammatory hepatopathy. As a result, an in-depth analysis of the intra-hepatic immune landscape has not been completed in CH. Our studies show that the subpopulation of liver sinusoidal endothelial cells proximal to the central veins express CXCL9. In order to investigate the impact of CXCL9 on the immune microenvironment in CH, we performed imaging mass cytometry (IMC) on liver tissue obtained from patients with CH, Fontan-associated liver disease (FALD), and healthy controls (HC). As CXCL9 has been implicated in macrophage chemotaxis, we hypothesized that macrophages mediate congestive fibrosis. **Methods:** We stained tissue sections with 27 antibodies specific for structural and immune cell types. Multiplexed images were processed for cell segmentation. Per-cell mean signal intensity was then exported for normalization and analysis. Self-organizing map clustering was used for cell clustering and cell type phenotyping. **Results:** In order to address our hypothesis, we initially assessed changes in immune cell density in fibrotic regions. With the exception of naive T cells, we found that all immune cell subsets displayed highly significant enrichment patterns in fibrotic regions (Table 1). We then assessed changes in the intrahepatic innate and adaptive immune responses. Our analysis revealed that cell density, including immune cells, is decreased in diseased versus control tissues. A notable exception are intra-hepatic macrophages which are preserved in the setting of FALD and CH. In contrast, CH and FALD demonstrate a significant decrease in the intra-hepatic adaptive immune response compared to HCs (FALD versus HC median difference -81.904 cells/mm^2, p-value 3.36x10^{-4}; CH versus HC median difference -90.136 cells/mm^2, p-value 2.62x10^{-4}). To determine the impact of this change in the intra-hepatic adaptive

immune response, we tested if interaction frequency of immune cell populations correlated with clinical covariates. Post multiple-testing correction, the interaction between CD4 and CD8 T-cells correlated negatively with both fibrosis stage and with MELD-Na score (coefficient -0.911, p-value 0.048), suggesting that the decline in intra-hepatic adaptive immune cell populations is associated with more severe disease. **Conclusion:** FALD and CH are characterized by preservation of intra-hepatic macrophages which we hypothesize accelerate congestive fibrosis. Decreases in the adaptive immune cell populations, including CD4 and CD8 T-cells, may be associated with a more severe clinical phenotype.

2619-A | REDUCED INFLAMMATORY POTENTIAL OF TUMOR ASSOCIATED MACROPHAGES PROMOTES T CELL TOLERANCE AND EXHAUSTION IN HUMAN HEPATOCELLULAR CARCINOMA

Jawairia Atif[1,2], Lawrence Wood[1,2], Lewis Liu[2], Catia Perciani[2], Xue-Zhong Ma[2], Justin Manuel[2], Tommy Ivanics[2], Marco Claasen[3], Roxana Bucur[2], Tallulah Andrews[4], Anand Ghanekar[5], Trevor J. Pugh[1,6,7], Gary Bader[1,8], Ian McGilvray[2], Gonzalo Sapisochin[2] and Sonya A MacParland[1,2], (1)University of Toronto, (2) University Health Network, (3)Toronto General Hospital, (4)University of Western Ontario, (5)The Hospital for Sick Children, (6)Princess Margaret Cancer Centre, (7) Ontario Institute for Cancer Research, (8)Donnelly Centre for Cellular and Biomolecular Research

Background: While hepatocellular carcinoma (HCC) is the seventh most common cancer worldwide, it is the third most lethal, reflecting the inadequacy of its current treatments. Despite recent advances in immunotherapy, response rates in HCC are still relatively low. HCC commonly occurs on a background of chronic liver disease (CLD) due to hepatitis C virus (HCV) or hepatitis B virus infection, or alcohol use disorder. The sequential changes to the immune microenvironment in the liver from health to CLD to HCC tumors are not well characterized. Immunoregulatory tumor-associated macrophages (TAMs) are enriched in the tumor microenvironment (TME) and have been linked to T cell tolerance and dysfunction in an HCC setting and represent potential targets for the treatment of HCC. **Methods:** Using single-cell RNA and TCR sequencing, we generated a transcriptomic atlas of 185,000 cells from healthy human livers (n = 11), chronic HCV infection (n = 5), and treatment-naive HCC resection samples from the tumour core (n = 11), the tumour-margin (n = 11), and adjacent-normal livers (n = 11) of varying aetiologies. Intracellular cytokine staining and *in vitro* assays were employed to determine the functional state of primary tumor-associated macrophages (TAM). Flow cytometry was used to validate T cell and TAM phenotypes. **Results:** All major non-parenchymal cell types display gradients of cell phenotypes spanning the healthy tissue to the tumour core, suggesting a sequential reprogramming of the cellular landscape with respect to the tumour. An enrichment of exhausted and clonally expanded CD8 + T cells (*TOX, PDCD1*), regulatory T cells (*FOXP3*) (Tregs), and immune-regulating macrophages (*MRC1, TREM2, CD9*) defines the tumor-core relative to the healthy and the adjacent-normal liver. We note the presence of a conserved TAM population in all patients, regardless of aetiology. With increased proximity to the tumor, macrophages secrete less TNF-α following *in vitro* LPS and IFN-γ stimulation and interact with T cells through more immunoregulatory pathways. Furthermore, TAMs exhibit reduced expression of pro-inflammatory genes, such as those in the cGAS-STING pathway. **Conclusion:** We present a geographically resolved single-cell transcriptional examination of the immune landscape in human HCC. Etiology-conserved pathways driving an immunoregulatory TAM phenotype are enriched in the TME and present opportunities for generating unified approaches to targeting all types of HCC.

2620-A | SINGLE CELL DISSECTION OF HUMAN CHECKPOINT INHIBITOR AND AUTOIMMUNE HEPATITIS REVEALS INSIGHTS INTO LIVER IMMUNE TOLERANCE

Molly Thomas[1], Tos Chan[1], Neal Smith[1], Shreyash Sonthalia[1], Marc S. Sherman[1], Swetha Ramesh[2], Alice Tirard[1], John McGuire[1], Mazen Nasrallah[3], Kasidet Manakongtreecheep[4], Jessica Tantivit[5], Leyre Zubiri[1], Dejan Juric[1], Ryan Sullivan[1], Nir Hacohen[6], Genevieve Boland[1], Georg M. Lauer[7], Kerry Reynolds[1] and Alexandra-Chloé Villani[1], (1)Massachusetts General Hospital, (2)UCLA, (3)Mass General Brigham, (4) Harvard University, (5)UCSD, (6)Broad Institute of MIT and Harvard, (7)Massachusetts General Hospital and Harvard Medical School

Background: Immune checkpoint blockade (ICB) targeting PD-1 and CTLA-4 to treat cancer has revolutionized immuno-oncology. However, therapy is limited by frequent immune-related adverse events, including hepatitis (irHepatitis), which occurs in ~1-17% of patients. While irHepatitis is often mild, it can cause severe hepatic dysfunction, lead to delays in cancer therapy, and is often treated with immunosuppressive agents that may compromise anti-tumor immune responses. irHepatitis shares clinical and histologic features with autoimmune hepatitis (AIH). The study of irHepatitis and AIH is therefore important for understanding how immune tolerance is lost across a spectrum of inflammatory liver diseases. **Methods**: To characterize the cellular and molecular underpinnings of irHepatitis, we used single-cell and single-nuclei RNA sequencing with paired T-cell receptor and B-cell receptor sequencing to characterize ~300,000 cells from the liver and blood of 23 patients (9 irHepatitis, 4 AIH, 3 controls on ICB, 7 controls not on ICB). irHepatitis was defined by a hepatocellular or cholestatic rise in liver function tests and centrilobular or panlobular histiocytic liver injury requiring steroids. Controls had drug-induced liver injury, hepatic steatosis, non-alcoholic steatohepatitis, primary biliary cirrhosis, or venous outflow obstruction not requiring immunosuppression. **Results**: In irHepatitis, we detected clonally-related, liver T cells expressing *CXCL13* and expanded cycling and cytotoxic CD8 T cells that spanned effector to exhausted phenotypes. Parallel analysis of tissue immune cells from patients with AIH or irHepatitis enabled the identification of cell types and states both common and unique to each type of immune-mediated liver injury. Analysis of matched blood samples from the same patient cohort revealed how cellular and transcriptional signatures in the liver were mirrored in circulating immune cells. Lastly, analysis of hepatocytes, cholangiocytes, and mesenchymal cells revealed inflammatory signatures suggesting liver parenchymal dysfunction. **Conclusion**: In defining the cellular and transcriptional programs that are altered in irHepatitis and AIH, we have identified novel pathways that could be therapeutically targeted to treat liver inflammation and have determined how PD-1 and CTLA-4 signaling may contribute to immune tolerance in the liver.

f 2621-A | TARGETING CXCL9/CXCL10/CXCL11 USING NOVEL EPIGENOMIC CONTROLLERS FOR THE TREATMENT OF INFLAMMATORY LIVER DISEASE

Christopher Pedigo, Justin Chen, Yoseph Kassa, Wanzhu Zhao, Jeremiah Farelli, Amy McCurley, Joseph Newman, Charles O'Donnell and Thomas McCauley, Omega Therapeutics

Background: Hepatitis is a broad pathophysiological feature common to acute and chronic liver diseases characterized by activation of inflammatory mechanisms, including increased interferon gamma (IFNG) expression. IFNG is a pleotropic proinflammatory cytokine released by immune cells that contributes to liver injury by stimulating the release of chemokines CXCL9, CXCL10 and CXCL11 from hepatocytes. CXCL9-10-11 bind CXCR3 on T cells and promote their recruitment to the site of inflammation. Through our OMEGA platform, we are able to rapidly develop programmable mRNA medicines called Omega Epigenomic Controllers (OECs) to precisely tune gene expression at the pre-transcriptional level. OECs are mRNA therapeutics currently delivered in tissue-specific lipid nanoparticles (LNPs) that site-specifically modulate epigenetic states. Using OECs to simultaneously target all three *CXCL9-10-11* genes in a liver-specific manner represents a novel and promising strategy for treatment of inflammatory liver disease. **Methods:** The multigenic Insulated Genomic Domain (IGD) and component sequences driving epigenetic control of the *CXCL9-10-*

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

11 gene cluster were interrogated and OECs were designed to modulate expression of *CXCL9-10-11* in mouse and human cells. AML-12, Hepa1-6 mouse liver cell lines and primary human hepatocytes were stimulated with IFNG, and chemokine expression was analyzed by qPCR and/or Luminex. To determine the relative contribution of CXLC9, CXCL10, and CXCL11, cells were transfected with LNP-encapsulated OECs and conditioned media was used in a Boyden Chamber assay to evaluate effects on T-cell migration. **Results:** IFNG stimulation of primary human hepatocytes, as well as murine hepatic AML12 and Hepa1-6 cells, resulted in significant increases in *CXCL9*, *CXCL10* and *CXCL11* mRNA expression, simulating the pathophysiology seen in liver inflammation. Treatment with combinations of OECs targeting *CXCL9-10-11* potently downregulated *CXLC9-10-11* mRNA expression and corresponding protein levels relative to the IFNG-treated control. Further development led to a single bicistronic OEC that epigenetically targeted the *CXCL9-10-11* IGD, resulting in the simultaneous reduction of *CXLC9-10-11* mRNA expression. Exposure of primary human T-cells to conditioned hepatocyte media following IFNG stimulation and OEC treatment, resulted in a significant reduction in T-cell mediated migration, compared to IFNG-stimulated control. **Conclusion:** Here we demonstrate the development of a rationally and prospectively designed OEC which potently inhibits *CXCL9-10-11* expression in hepatocytes. Liver-specific multiplexed targeting of *CXCL9-10-11* with a programmable epigenomic mRNA therapy offers a novel approach to the treatment of inflammatory liver diseases.

2622-A | THE CYTOTOXIC MOLECULES GRANZYME B AND TRAIL DIFFERENTIALLY AFFECT THE IMMUNOPATHOGENESIS OF MURINE SCLEROSING CHOLANGITIS

Katrin Neumann[1], Mareike Kellerer[1], Sana Javed[1], Laura K Berkhout[1], Christian Casar[1], Nico Will[1], Dorothee Schwinge[1], Christoph Schramm[2] and Gisa Tiegs[1], (1)University Medical Center Hamburg-Eppendorf, (2)University Medical Centre Hamburg-Eppendorf

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by biliary inflammation and fibrosis. We observed an increased interferon (IFN)γ response in PSC patients and in a mouse model of sclerosing cholangitis. IFNγ induced expression of the cytotoxic effector molecules granzyme B (GzmB) and tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) in intrahepatic NK and $CD8^+$ T cells and mediated liver fibrosis in *Mdr2*$^{-/-}$ mice. Here, we analyzed the appearance of cytotoxic lymphocytes in PSC patients and investigated the significance of GzmB and TRAIL for PSC progression in *Mdr2*$^{-/-}$ mice. **Methods:** Single-cell RNA-seq and CITE-seq analysis was combined with multi-parameter flow cytometry. *Mdr2*$^{-/-}$ x *GzmB*$^{-/-}$ and *Mdr2*$^{-/-}$ x *Tnfs10*$^{-/-}$ mice were used for functional analyses. Cholangiocytes were visualized by immunohistochemistry. Liver injury and fibrosis were determined by standard assays. **Results:** We identified $CD8^+$ T cell clusters with a cytotoxic gene expression profile in the livers of PSC patients. GzmB and TRAIL expression was increased in hepatic $CD8^+$ T cells and NK cells in *Mdr2*$^{-/-}$ mice compared to wild type controls. Lack of GzmB did not affect the phenotype of these cytotoxic lymphocyte subsets but resulted in less severe liver injury and fibrosis. In contrast, disease severity of sclerosing cholangitis was aggravated in the absence of TRAIL. This was associated with increased expression of IFNγ and GzmB by NK and T cells, enhanced survival of hepatic T cells and expansion of cholangiocytes and stellate cells. **Conclusion:** While GzmB induces hepatic cell death and fibrosis in sclerosing cholangitis, TRAIL suppresses inflammatory and cytotoxic immune responses subsequently leading to reduced stellate cell activation and fibrosis.

f 2623-A | TWO TRANSCRIPTIONALLY AND FUNCTIONALLY DISTINCT WAVES OF PRO-INFLAMMATORY VERSUS PRO-REPAIR NEUTROPHILS DURING ACUTE LIVER INJURY

Yousef Maali[1], Manuel Flores Molina[1,2], Omar Khedr[1], Mohamed Abdelnabi[1,2] and Naglaa H. Shoukry[1,2], (1)Centre De Recherche Du Centre Hospitalier De L'université De Montréal (CRCHUM), (2)Université De Montréal

Background: Neutrophils are key inflammatory players during acute liver injury (ALI) where they infiltrate necrotic areas. Emerging evidence suggests that neutrophils also contribute to inflammation resolution and tissue repair. However, the different neutrophil subsets involved in this

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

process are not well defined. Herein, we sought to characterize neutrophils recruited at different stages following ALI, hypothesizing that each recruitment event corresponds to a different neutrophil subset with distinct functions. **Methods:** We used the CCl_4-induced ALI model and employed flow cytometry, multiplex-immunofluorescence (mIF), and qRT-PCR to examine intrahepatic neutrophil populations during the inflammatory (24 hrs), early repair (48 hrs) and late repair phases (72-96 hrs) post-CCl_4. We also sorted intrahepatic neutrophils and analyzed their transcriptional profiles using RNA-seq. Finally, we performed *ex-vivo* assays on sorted neutrophil to examine protein translation by puromycin incorporation assay, mitochondrial function using Mitotracker® Green and Red, and cell metabolism by Seahorse XF Cell Mito Stress Test. **Results:** We detected two temporarily distinct waves of neutrophils: (i) during necroinflammation (at 24 hrs) and (ii) during late repair (at 72 hrs). The early wave of neutrophils was preceded by and overlapped with an increase in gene expression of the major neutrophil chemoattractant *Cxcl1* while the second wave was associated with increased *Cxcl5.* Using RNA-seq analysis and validation by *ex-vivo* approaches, we identified distinct transcriptomic and functional profiles of early and late neutrophils. Early neutrophils were characterized by: (i) up-regulation of inflammatory cytokines (e.g., *Il12a*) and of the chemokine receptor *Cxcr5*, (ii) activation of the non-canonical NF-κB pathway, (iii) reduction of protein translation and (iv) decreased oxidative phosphorylation. In contrast, the late wave neutrophils exhibited an angiogenic profile with up-regulation of several genes and pathways associated with tissue repair and angiogenesis (e.g., *Cxcr4, Fgg, Cox-2)*. **Conclusion:** We report two waves of intrahepatic neutrophils with distinct transcriptomic and functional profiles during ALI. The first wave presents a pro-inflammatory profile, whereas the second wave exhibits an angiogenic and pro-repair profile. This study underscores the heterogeneity in neutrophils and their emerging role in tissue repair during ALI.

2700-A | ASSESSING INTESTINAL PERMEABILITY IN PRIMARY SCLEROSING CHOLANGITIS USING A TRIPLE SUGAR TEST

Emma Rosenbluth[1], Imran Nizamuddin[2], Daina Ringus[1], Gregory Dean[3], Stephen Hanauer[1] and Josh Levitsky[1], (1)Northwestern University Feinberg School of Medicine, (2)Washington University School of Medicine in St. Louis, (3)University of Michigan

Background: While the pathogenesis of primary sclerosing cholangitis (PSC) remains enigmatic, the potential role of intestinal permeability has been postulated to account for the recognized association with ulcerative colitis (UC). The gut microbiome has been an attributable risk factor in both PSC and UC and either pre-existing increased gut permeability or active mucosal inflammation could account for translocation of bacteria, toxins, and pathogen-associated proteins to the liver via the portal system. However, few studies have been done to support this theory. We aimed to measure small and large intestinal permeability among patients with PSC and PSC/UC to evaluate this potential causative association. **Methods:** Subjects 18 years and older with a diagnosis of PSC, PSC and UC, and healthy controls were recruited from General Medicine and Gastroenterology clinics at Northwestern Memorial Hospital. To assess intestinal permeability, we used a 'triple sugar test', which measures urinary excretion of orally administered oligosaccharides (mannitol, lactulose, and sucralose). Subjects were asked to drink a 100 mL solution of 5g lactulose, 2g mannitol, and 2g sucralose and collect a 24-hour urine sample in two parts: 0-6 hours and 6-24 hours. Urine concentrations of each sugar were measured via mass spectrometry. The 0-6 hour lactulose/mannitol recovery ratio (LMR) was used to assess small intestinal permeability and the 6-24 hour percent recovery of sucralose assessed colonic permeability. Groups were compared using t-test for continuous variables and Fisher's exact for categorical variables. **Results:** There were 11 subjects with PSC (4 with PSC alone, 7 with PSC/UC) and 10 controls. Those with PSC were older (43 vs 33, $p = 0.036$) and less likely white (63.6% vs 70%, $p = 0.03$) compared to controls (Table 1). There were no significant demographic differences between the PSC and PSC/UC groups. There was no significant difference in the 0-6 hour LMR in PSC vs control (0.0339 vs 0.0126, $p = 0.3$) or PSC alone vs PSC/UC (0.0676 vs 0.0146, $p = 0.4$). There was no significant difference in the 6-24 hour percent recovery of sucralose in PSC vs control (0.75% vs 0.51%, $p = 0.5$) or PSC alone vs PSC/UC (1.3% vs 0.51%, $p = 0.5$). **Conclusion:** We found no significant difference in either small intestinal or colonic permeability between the PSC and control groups or between those with PSC alone and those with PSC and UC. While our sample size is limited, these preliminary data do not support the association of increased intestinal permeability compared to healthy controls. Further studies are warranted to explore the potential role of the intestine in the pathogenesis of PSC.

2701-A | BACTEROIDES VULGATUS AMELIORATE NAFLD BY MODULATING GUT MICROBIOME AND JAK-STAT PATHWAY

Sang Jun Yoon, Jung A Eom, Kyeong Jin Lee, Sang youn Lee and Ki Tae Suk, Institute for Liver and Digestive Diseases, College of Medicine, Hallym University, Chuncheon 24252, Republic of Korea

Background: Nonalcoholic fatty liver disease (NAFLD) is one of the most prevalent forms of liver disease worldwide. However, definitive medical treatments have not been. Recently, the gut microbiome has been linked to a number of diseases. This study aimed to elucidate the underlying mechanisms of western diet-induced NAFLD associated with the gut microbiome by gut-liver axis and explore the effects of *Bacteroides vulgatus* from the gut metagenomic and liver tissue analysis perspective. **Methods:** Six weeks old C57BL/6J mice were fed the Western diet with/without strains for 12 weeks. *B. vulgatus* and *V. dispar* were administered at a concentration of 2×10^9 CFU/day. We compared NAFLD activity score (NAS), histopathological analysis of liver tissue, fecal microbiome analysis, gut permeability analysis, liver tissue microarray and check markers level for inflammation and lipogenesis in the liver. **Results:** Western diet induces NAFLD through dysbiosis caused by reduction in *Bacteroidetes* and an increase in *Proteobacteria* phyla. But treat strain groups shows increase *Bacteroidetes* and decrease *Proteobacteria* phyla, and *Helicobacter* genus. Treat *B. vulgatus* shows significant results in serum total cholesterol level (153.29 ± 13.75, $P<0.001$), L/B ratio (4.41 ± 0.32, $P<0.0001$), CD68 (11.81 ± 5.58, $P<0.01$) and improved NAS (2.57 ± 1.13, $P<0.01$) compared with the western diet group (total cholesterol 213.5 ± 27.07; L/B ratio 5.45 ± 0.26; CD68 30.26 ± 8.79; NAS 4.7 ± 1.57). To determine the mechanism of the gut-liver axis, checked the gut permeability and found that the gut tight junction genes and proteins were higher in the *B. vulgatus* group than in the western diet group. Moreover, *B. vulgatus* downregulated the inflammation (TNF-α, $10.36\pm3.01/1.66\pm1.08$, $P<0.001$; IL-6, $5.61\pm4.06/1.58\pm0.41$, $P<0.05$) by regulating the fatty acid uptake (CD36, $10.37\pm2.51/2.84\pm2.03$, $P<0.05$), synthesis (FAS, $15.54\pm7.64/5.23\pm3.52$, $P<0.05$; SREBP-1c, $24.26\pm6.96/10.54\pm4.67$, $P<0.05$), and oxidation (PPARα, $6.09\pm1.29/12.29\pm1.76$, $P<0.001$) level. Microassay and geneset enrichment analysis were performed with RNA from liver tissue to identify differences in the Jak-STAT pathway. As a results, *B. vulgatus* ameliorates NAFLD through modulation of gut microbiota and Jak-STAT pathway resulting in reduced steatosis. **Conclusion:** Our study highlighted the association between gut microbiota and NAFLD and the importance of the gut-liver axis and confirmed the potential of *B. vulgatus* to improve NAFLD. Studying the mechanisms between probiotics and NAFLD will help design novel therapies.

f 2702-A | CARROT AND GINGER EDIBLE EXOSOMES RESTORE GUT MICROBIOME AND AMELIORATE HEPATIC INJURY BY REDUCING SYSTEMIC AMMONIA LEVELS: A COMPARATIVE STUDY

P. Debishree Subudhi, Jitendra Kumar, Anupama Parasar, Shivani Gautam, Varun Suroliya, Chhagan Bihari, Shiv Kumar Sarin and Sukriti Baweja, Institute of Liver and Biliary Sciences

Background: Elevated plasma ammonia is attributed to hepatic dysfunction and increased gut permeability and systemic inflammation. There is an urgent need of candidates which can reinstate the gut commensals, reduce ammonia levels and prevent hepatic injury. Hence, we investigated the effects of edible exosomes from carrot (CarEx) and ginger (GinEx) in reducing ammonia, changes in gut microbiome in acute hepatic encephalopathy model. **Methods:** Edible exosomes fractioned from black carrots (*Pusa Asita*) and Ginger (*Gingiber officinale*) by differential ultracentrifugation and characterized by transmission electron microscopy and nanoparticle tracking assay. Proteomics was performed to evaluate cargoes. Prophylactic administration of CarEx and GinEx was orally administered daily for 10 days with vehicle and lactulose in thioacetamide(TAA) induced acute hyperammonemia rat model. Ammonia, liver functionality was quantified with behavioral functions and gut microbiota assessment by 16s metagenomics. **Results:** The concentration of CarEx, $2.65x10^9 \pm 0.65$ and GinEx, 1.17 x 109 particles/ mL with zeta potential -17.7 ± 2.4mV and -20.0 ± 2.0mV. Cargo proteins identified as bactericidal zeta toxin proteins, superoxide dismutase (anti-oxidant) and ferritin (cellular homeostasis) in CarEx. However, zingipain (anti-fungal,anti-inflammatory), Geranyol dehydrogenase(ant-microbial) in GinEx. After stomach like invitro digestion, no changes in concentration were found but particle size reduced (35-200nm) with intact zeta potential. Oral administration of CarEx in TAA animals reduced the plasma ammonia levels 92.2 ± 13.6mmol/L($p = 0.0151$), AST($p = 0.0043$) and increased albumin ($p = 0.0079$), whereas found comparable after GinEx,105.1 ± 25.9mmol/L and lactulose,157.9 ± 46.6mmol/L than vehicle. Both CarEx and GinEx improved cognition but CarEx have shown resurgence($p = 0.043$) by increasing the cellular anti-oxidant defence (Gsr,$p = 0.0357$) .In CarEx group, > 5 fold upregulation of urea cycle enzymes (ornithin; $p = 0.0159$, arginase; $p = 0.0159$) than GinEx. The expression of occludin was also higher in CarEx than GinEx, lactulose or vehicle ($p < 0.001$). 16s metagenomics showed both CarEx and GinEx enhanced the colonisation of Firmicutes. CarEx enhanced abundance of Lachnospiraceae ($p = 0.0303$), Lactobacillaceae ($p = 0.0286$) than vehicle, which provide energy to maintain gut epithelia and short chain fatty acid production. Also, CarEx decreased growth of urease producing family *Enterobacteriaceae*($p = 0.0043$) which is not found after GinEx intervention. **Conclusion:** Carrot edible exosomes demonstrated superior effects in reducing plasma ammonia levels, improving liver function, cognition, enhancing the gut barrier integrity and attenuates the colonisation of urease producing bacteria in the gut.

Hospital, (2)Yamagata University, Yamagata, Japan, (3) Faculty of Life Sciences, Kumamoto University, (4)The University of Tokyo, (5)Nara Medical University, (6)Nagoya City University Graduate School of Medical Sciences, (7) Nara Medical University, Kashihara Nara, Japan

Background: Metabolites and gut microbiome, which form the gut-liver axis, interact and maintain homeostasis. We analyzed and reported that gut microbiome is altered in chronic hepatitis C (CHC) patients from the early stage and dysbiosis worsens with disease progression (Clin Infect Dis. 2018). In this study, we evaluated the characteristics of intestinal environment before and after hepatitis C virus (HCV) elimination and its relationship to the disease progression based on fecal bile acids composition. **Methods:** Thirty-eight CHC patients (20 chronic hepatitis [CH] and 18 cirrhosis [LC]) were enrolled in this study. The main exclusion criterion was prescription of ursodeoxycholic acid (UDCA). The enrolled patients provided their feces three times: before HCV elimination, 24 weeks after achieving virological remarkable response (SVR), and 48 weeks after SVR. Additionally, 23 healthy individual's were enrolled as the control group. Fecal bile acids were measured by a triple quadrupole mass spectrometer. The samples were classified into three clusters (deoxycholic acid [DCA] type, lithocholic acid [LCA] type, and UDCA type), according to the bile acids with high relative proportions and based on the enterotyping method (Nature, 2011). This study was approved by the ethical review committee of our institute. **Results:** Regarding the fecal bile acid composition before HCV elimination, 40% were LCA type (8/20), 35% were UDCA type (7/20), 25% were DCA type (5/20) in CH, and 44.4% were LCA type (8/18), 33.3% were UDCA type (6/18), 22.2% were DCA type (4/18) in LC, indicating that LCA and UDCA types were predominant under HCV infection. In contrast, in healthy individual's, 4.3% (1/23) were LCA type, 17.3% (4/23) were UDCA type, and 78.3% (18/23) were DCA type. Regarding the fecal bile acid composition at 48 weeks after achieving SVR, 15% (3/20) were LCA type, 25% (5/20) were UDCA type, 60% (12/20) were DCA type in CH. That is, in CH, HCV elimination significantly increased DCA type ($p = 0.025$). Meanwhile, in LC, 38.9% (7/18) were LCA type, 33.3% (6/18) were UDCA type, and 27.8% (5/18) were DCA type, showing no remarkable change from that under HCV infection ($p = 0.70$). **Conclusion:** The intestinal environment in terms of enterotypes is dominated by DCA types in healthy individual's, and LCA or UDCA types in CHC before HCV elimination. After achieving SVR, in CH, the frequency of DCA types approached that of healthy individual's. On the other hand, in LC, the frequency of DCA type did not change before and after HCV elimination. Generally, HCV elimination corrects BA imbalance. However, the degree of recovery depends on the disease progression.

Figure Comparison of fecal bile acid composition before and after HCV elimination by disease progression

Background: Bile acids and gut microbiota, which form the gut-liver axis, interact and help to maintain homeostasis. In this study, we investigated the causes of dysbiosis in chronic hepatitis C (CHC), based on cluster analysis of the fecal bile acid composition (cluster analysis). **Methods:** One hundred CHC patients (9 with persistently normal ALT, 60 chronic hepatitis, 18 cirrhosis and 13 hepatocellular carcinoma), whose gut microbiota were analyzed in a previous study (Clin Infect Dis, 2018), and 23 healthy individual's were enrolled. The main exclusion criterion was prescription of ursodeoxycholic acid (UDCA). Fecal bile acids were measured by a triple quadrupole mass spectrometer. For cluster analysis, the samples were classified into three clusters (deoxycholic acid [DCA] type, lithocholic acid [LCA] type, and UDCA type), according to the bile acids with high relative proportions and based on the enterotyping method (Nature, 2011). Correlations between clusters and bacteria were analyzed using the envfit function and displayed as vectors in principal component analysis scatter plots. This study was approved by the ethical review committee of our institute. **Results:** Cluster analysis showed that 42% (42/100) of CHC patients were classified as the LCA type and 33% (33/100) as the UDCA type. In contrast, 78.3% (18/23) of healthy individual's were classified as the DCA type (Figure). Regarding the correlation between clusters and bacteria, most decreases of Clostridiales and Bacteroidales in CHC correlated with the DCA and LCA types, while *Streptococci* and *Lactobacilli,* which increased in CHC, correlated with the UDCA type. At the family level, Lachnospiraceae, Ruminococcaceae, and Rikenellaceae were most frequently correlated with the DCA, LCA, and UDCA types, in that order, while Streptococcaceae and Lactobacillaceae were correlated with the UDCA and LCA types, in that order. Streptococcaceae and Lactobacillaceae were most abundant in the order of the UDCA, LCA and UDCA types. At the species level, *Streptococci* and *Lactobacilli*, which increase in the gut of CHC patients, were inversely correlated with the relative amount of DCA in stool samples. **Conclusion:** By cluster analysis, CHC was classified as LCA or UDCA types, while healthy individual's were classified as the DCA type. DCA is hydrophobic and highly toxic to bacteria. In CHC, *Streptococci* and *Lactobacilli* may have escaped growth control due to decreased DCA in the intestinal environment, resulting in dysbiosis.

Figure The result of cluster analysis of the fecal bile acid composition in chronic hepatitis C patients

2705-A | GUT BACTERIA PHENOTYPING USING DYNAMIC BREATH ANALYSIS

Ahmed Tawfike, Antonio Murgia, Iris Banda, Yusuf Ahmed, Menisha Manhota, Federico Ricciardi, Kelly Sweeney, Louise Nicholson-Scott, Lucinda McConville, Olga Gandelman, Max Allsworth, Billy Boyle and Giuseppe Ferrandino, Owlstone Medical

Background: Gut microbiota dysbiosis results in overproduction of metabolites that exacerbate certain chronic diseases. For example, ethanol and 2-3-butanediol, produced by carbohydrate fermentation, were found associated with non-alcoholic steatohepatitis (NASH). Similarly, trimethylamine, produced from choline, is further metabolized in the liver to trimethylamine-N-oxide, a metabolite found associated with NASH severity and that exacerbate cardiovascular diseases. We explored the feasibility of a novel approach to measure gut bacteria metabolites, which can be applied to assess the extent of gut bacteria metabolism in diseases populations. **Methods:** A total of

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

8 healthy subjects were recruited with age e 18 years and body weight e 50 Kg. Subjects were instructed to fast overnight and to not drink alcoholic beverages the day before the experiments. Breath samples were collected before, and up to 90 minutes after ingestion of 75g of glucose with a time resolution of 5 minutes. Compounds of interest were measured using SIFT-MS with direct sampling. Results were expressed as part per billion (PPB v/v) as function of time post glucose ingestion. **Results:** Ambient measurements showed that all the investigated compounds were absent before and after conducting the experiment. Median (M) and interquartile range (IQR) baselines levels (before glucose administration) of ethanol, propanoic acid, and acetoin (an intermediate of the 2-3-butanediol fermentation), were respectively 99.4 [71.6-182.4], 13.3 [10-16.2], 3.2 [2.7, 4.2] PPB (Fig.1A). Post glucose ingestion we observed spikes of these compounds in breath of up to respectively 8629, 153, and 20 PPB (Fig. 1B). Additional diseases associated compounds, unrelated to glucose ingestion, were also detected, such as trimethylamine (M: 42.3, IQR: 33.6-54.3 PPB) (Fig.1C), methanol (M: 443, IQR: 199-531.4 PPB) (Fig.1D), and methane (M: 26988, IQR: 10100-76213 PPB) (Fig.1E). **Conclusion:** Dynamic breath analysis can be used for the clinical characterization of gut bacteria metabolism in healthy and disease populations to establish correlations between metabolites and disease severity and progression, as well as interaction of gut microbiota with response to therapeutic interventions. This non-invasive method can replace the current need for blood collection allowing scaling to large cohort populations.

2706-A | GUT MICROBIOTA AS MEDIATOR AND MODERATOR BETWEEN HEPATITIS B VIRUS AND HEPATOCELLULAR CARCINOMA

Zhiyuan Bo[1], Yi Yang[2], Qikuan He[1], Bo Chen[1], Gang Chen[1] and Yi Wang[2], (1)The First Affiliated Hospital of Wenzhou Medical University, (2)Wenzhou Medical University

Background: Emerging evidence has demonstrated an intrinsic linkage between the gut microbiome and hepatitis B virus (HBV) induced liver diseases for its cross-talk with the gastrointestinal tract, termed the “gut-liver” axis. But the impact of gut microbiome on HBV-related hepatocellular carcinoma (HCC) remains unclear. Herein, we comprehensively signified the microbial as mediator and moderator between HBV and HCC and introduced a machine learning (ML) approach to predict the risk of HCC. **Methods:** Patients with chronic liver diseases or HCC were prospectively recruited between 2019 and 2022. Fecal samples were collected and subjected to 16S rRNA gene sequencing to determine differential taxa. The mediation/regulation effect of gut microbiome were explored between HBV and HCC using Bootstrap and Johnson-Neyman techniques. Univariate and multivariate logistic regression was applied to identify risk clinical characteristics. Several ML methods were employed to construct gut microbe-based models. The predictive performance was assessed using receiver operating characteristic curves, decision curves and calibration curve analyses. **Results:** A total of 571 patients were involved in the study, including 374 patients with HCC and 197 patients with chronic liver diseases. After propensity score matching to adjust confounding variables, 147 pairs of participants were enrolled in subsequent analysis. *Bacteroidia* and *Bacteroidales* were demonstrated to exert mediating effects between HBV and HCC, and the moderating effects varied across *Bacilli*, *Lactobacillales*, *Erysipelotrichaceae*, *Actinomyces* and *Roseburia*. HBV, alpha-fetoprotein, alanine transaminase, triglyceride and Child-Pugh were identified as independent risk factors for HCC occurrence. Seven ML-based HBV-gut microbe classifiers were established to predict HCC, with AUCs ranging from 0.802 to 0.910 that outperformed the clinical features-based model (AUC of 0.661). Furthermore, the merged clinical-HBV-gut microbe models exhibited a comparable performance to HBV-gut microbe models (AUCs from 0.833 to 0.913). **Conclusion:** Gut microbes

2707-A | GUT MICROBIOTA OF PATIENTS WITH HEPATITIS B VIRUS-RELATED CIRRHOSIS PROMOTES CIRRHOSIS DEVELOPMENT BY INJURING INTESTINAL BARRIER FUNCTION IN MICE

Yang Zhao[1,2], Ying Guo[1,2], Xi Chen[1,2], Na Huang[1,2], Hongwei Tian[1,2], Zhang Shaoying[1,2], Aiyu Zhang[1,2], Guangyao Kong[1,2], Jian Zhang[1,3] and Zongfang Li[1,2,3], (1)Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3) Department of General Surgery, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an 710004, Shaanxi Province, China

Background: The gut microbiota is critical in maintaining intestinal barrier function. Microbiome dysbiosis and intestinal barrier dysfunctions are closely related to cirrhosis development and further complications. The present study investigated the effects of gut microbiota in patients with hepatitis B virus (HBV)-related cirrhosis on intestinal barrier function and hepatic fibrosis through fecal microbiota transplantation (FMT) experiments. **Methods:** This study recruited 12 cirrhotic patients and 12 healthy individual's from the Second Affiliated Hospital of Xi'an Jiaotong University. The fecal samples with obvious differences in microbiota structure were selected (5 cases in each group), and the bacterial suspension was prepared. Male C57BL/6 mice were randomly divided into four groups: healthy control group (HC), liver cirrhosis model group (LC), model group + bacterial suspension of healthy individual's (FMT-HI), model group + bacterial suspension of cirrhotic patients (FMT-CP). Carbon tetrachloride-induced cirrhosis model was established and mice were gavaged with bacterial suspension, lasting for 12 weeks. Colon and liver pathological morphology were observed by hematoxylin-eosin and sirius red staining, intestinal barrier function was detected using enzyme-linked immunosorbent assay and fluorescent probe, expressions of intestinal mucosal barrier and hepatic fibrosis related factors were detected by real-time quantitative polymerase chain reaction and immunofluorescence. **Results:** Compared with the intestinal bacterial suspension of healthy individual's, the cirrhotic mice treated with bacterial suspension of patients showed reduced expression of MUC2 and Claudin-2 in the colon, and increased concentrations of FITC-dextran and endotoxin in peripheral blood. The expression levels of various profibrotic cytokines (such as TGF-β1, IL-6, IL-17A) and α-smooth muscle actin in the liver were increased, and the hepatic fibrosis was aggravated **Conclusion:** The gut microbiota of HBV-related cirrhotic patients can reduce the intestinal barrier function and promote cirrhosis development in mice.

2708-A | HOW PLANT BASED FOOD AND CULINARY MEDICINE IS TRANSFORMING HEPATOLOGISTS INTO CHEFS AND EDUCATORS

Thusha Nathan, None

Background: Physicians are challenged with their patients exposure to unhealthy food. Low income populations especially do not have access to healthy produce and/ or come from generational models that do not give them the tools on how to cook healthy meals. With the crisis of NAFLD and progression to cirrhosis , I propose that physicians practicing hepatology become versed in culinary medicine, that is, teaching their patients healthy meals and how to cook them. The physician , becomes an educator and a chef, in partnership with their patient. **Methods:** While working at a hepatology clinic, in the low income area of Fort Smith Arkansas, I implemented plant based diets into patients daily lives. I used recipe variations I learned while attending Brightwater Culinary School and those I learned while training to be a raw food chef in Bali, Indonesia. Culinary medicine is a growing field where physicians learn culinary skills to then pass those onto their patients. These programs are already taking shape in medical and culinary schools across the country. I implemented these diets using mostly plant based meals, in 500 patients over two years. Most of these low income patients had no access to plant based food nor basic knowledge of how to cook healthy meals. I instructed them on how to make tasty, healthy, low fat meals with the resources available to them. The key to culinary medicine is the breadth of variety and cooking techniques that the physician learns , that they then pass onto their patients. When the patients were given gourmet inspired recipes, presented to them by their physician, that were simple to prepare, they were compliant with these dietary changes.

After two years- I saw marked emotional, physical, physiologic and lab improvement in their outcomes. **Results:** 100% of my patients agreed that few, if any, physicians discussed actual recipe preparation with them. 100% of my patients agreed that they felt a stronger connection to implement these changes because they were coming directly from the physician. 93% of my patients had weight loss of 10 pounds or greater, and 75% of my patients had improvement in their liver function tests and Hemoglobin A1C measured over 2 years. **Conclusion:** I propose that hepatologists engage in culinary medicine, and promote healthy, mostly plant based meals to their patients . This creates a deep bond of education and improved outcome between the physician and patient. Furthermore, in low income populations, patients do not have access to healthy food and rely on their physician to be an educator and break generational gaps in healthy food choice lifestyles. My results show that culinary medicine is an exciting and engaging field where the physician becomes a chef . These classes are already being implemented in medical schools across the country- including the University of Arkansas Medical Health Sciences Center.

2709-A | HYPERAMMONEMIA IN CIRRHOSIS ALTERS EXERCISE INDUCED ALTERATIONS IN THE GUT MICROBIOME

Annette Bellar[1], Naseer Sangwan[1], Avinash Kumar[1,2], Saurabh Mishra[1], Nicole M. Welch[1] and Srinivasan Dasarathy[1], (1)Cleveland Clinic, (2)All India Institutes of Medical Sciences

Background: Patients with cirrhosis have loss of muscle mass and increased fatigue that are mediated by hyperammonemia. The gut microbiome (GMB) is believed to be a major contributor to hyperammonemia of liver disease. Even though ammonia causes perturbations in gut function, it is not known if the GMB Is altered during hyperammonemia. Skeletal muscle ammoniagenesis is increased during endurance exercise (EE) in healthy subjects. It is however not known if EE alters the GMB either in normal or hyperammonemic states. We aimed to identify whether: 1. 4 weeks of EE by voluntary wheel running (VWR) alters the GMB in vehicle-(phosphate buffered saline,PBS) treated mice; 2. Hyperammonemia alters the GMB either in the basal state or in response to EE. **Methods:** Hyperammonemia was induced in wild type, C57BL6 male mice at 8 weeks of age by surgical placement of osmotic pumps that delivered 2.5mmol/kg/day ammonium acetate (AmAc) or vehicle (PBS) for 6-weeks. After 2 weeks of pump placement, the PBS or AmAc treated mice were assigned to either 4 weeks of VWR or usual activity (UA). Mice were housed individually and a stool sample was collected prior to hyperammonemia at baseline (BL), 2 weeks after hyperammonemia, and after 4 weeks of exercise. Samples were stored in Zymo's DNA solution and batch processed for 16S sequencing, Shannon Alpha and beta diversity, and species prevalence were measured and analyzed using R. **Results:** At BL there was no difference in Shannon diversity between the mice groups (PBS-UA, PBS-VWR, AmAc-UA, AmAc-VWR) . At 2 weeks of pump placement before exercise, AmAc mice had a lower Shannon diversity ($P = 0.041$) compared to PBS. After 4 weeks of VWR or UA, Shannon diversity was similar in the PBS-UA and PBS-VWR ($P = 0.88$). In the post VWR/UA groups, AmAc-UA differed from either PBS-UA or PBS-VWR ($P = 0.031$ and 0.021 respectively). AmAc-VWR had the lowest Shannon diversity compared to the other groups. (PBS-UA $P = 0.019$, PBS-VWR $P = 0.016$, AmAc-UA $P = 0.028$). (Fig. 1) These results suggest that with AmAc treatment, 4 weeks of VWR resulted in lower Shannon Diversity of the GMB. Beta diversity, or diversity between the groups at BL was similar in the 4 mice groups. At 2 weeks after pump placement , AmAc mice clustered distinctly compared to PBS. After 4 weeks of UA/VWR, PCA plots showed distinct clustering of the PBS-VWR mice compared to the other groups. AmAc-UA and AmAc-VWR were clustered closely and were also near the PBS-UA. **Conclusion:** These data show that hyperammonemia alters Shannon diversity and beta diversity of the GMB. Exercise induced changes in beta diversity were most prominent in the PBS group with less changes during hyperammonemia. These data suggest that hyperammonemia can alter the alpha and beta diversity in response to exercise. Microbiome dependent responses to exercise may be different in hyperammonemic patients including those with liver disease and have implications for defining exercise programs in liver disease.

2710-A | IDENTIFICATION AND CHARACTERIZATION OF THE GUT MICROBIAL SPECIES INVOLVED IN HEPATIC ENCEPHALOPATHY FROM THE ANALYSIS OF PATIENTS ADMINISTERED RIFAXIMIN★

Yoshimi Yukawa-Muto, Tomonori Kamiya, Norifumi Kawada and Naoko Ohtani, Osaka Metropolitan University Graduate School of Medicine

Background: Hepatic encephalopathy (HE) is one of the complications of liver cirrhosis (LC), and is partly caused by elevated blood ammonia (NH_3) levels due to NH_3-producing bacteria. However, the causative bacteria and corresponding mechanisms remain unclear. Therefore, we aimed to identify gut bacteria involved in the pathophysiology of HE, based on the analysis of the gut microbial profiles before and after rifaximin (RFX) administration in both effective cases and non-effective cases. **Methods**: From April 2017 to March 2020, fecal samples were collected from 24 decompensated LC patients who developed HE, 27 compensated LC patients, and 26 healthy controls. We compared the gut microbial profiles using sequence analysis of the 16S rRNA gene. 1) We identified candidate gut bacteria by Lefse analysis, and assessed whether the oral administration of the identified gut bacterial species enhances blood NH_3 levels and changes brain amino acid metabolites levels in a CCl_4-treated cirrhosis mouse model. 2) After 4 weeks of oral RFX administration, patients whose plasma NH_3 levels were reduced by RFX were defined as "responders," and patients whose plasma NH_3 levels showed no decrease were considered as "non-responders." We screened for the bacterial species associated with hyperammonemia in the non-responder group, and their functions were analyzed in vitro. 3) Metabolomic analysis of plasma and metagenomic analysis of fecal DNA were performed to investigate the pathophysiology of the non-responders. **Results**: 1) *Streptococcus salivarius* (*S. salivarius*), which harbors the urease gene, was the most abundant species in the decompensated LC (HE) group. The plasma NH_3 levels were increased in the mice treated with the urease-positive *S. salivarius* compared to the control mice. Moreover, significantly higher glutamine levels were detected in the mouse brains treated with the urease-positive *S. salivarius*. 2) *Ruminococcus gnavus* (*R.gnavus*) was significantly more abundant in RFX non-responders than responder patients after 4 weeks of RFX administration. *R.gnavus* itself had no NH_3-producing ability but was found to enhance the recombinant urease activity. 3) In RFX non-responders, conjugated secondary bile acid concentration in plasma was significantly lower than those of responders and bile acid-inducible (bai)-operon was not detected in their feces. In culture, the minimal inhibitory concentration of RFX against *S.salivarius* and *R.gnavus* was significantly decreased by the combination of conjugated secondary bile acids and RFX. **Conclusion**: *S.salivarius* and *R.gnavus* were identified as the specific gut bacterial species abundant in patients with HE. *R. gnavus* can enhance the urease activity of the co-existing urease-positive bacteria, that could contribute to NH_3 production. Conjugated secondary bile acids enhance the efficacy of RFX, suggesting the possibility of combination therapy with conjugated secondary bile acids and RFX.

2711-A | INTESTINAL ACYL-CoA THIOESTERASE 12 PROMOTES HISTONE H3 AND PPARΓ ACETYLATION TO PRESERVE BARRIER FUNCTION AND PROTECT AGAINST NON-ALCOHOLIC STEATOHEPATITIS

Akiko Sugiyama[1], Susan J Hagen[2] and David E Cohen[1], (1)Brigham and Women's Hospital, Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: Acyl-CoA thioesterase 12 (Acot12), which hydrolyzes acetyl-CoA into acetate plus CoA, is robustly expressed in cytosol of small intestinal epithelial cells (IECs) and is markedly induced by high fat diet (HFD) feeding. We have shown that intestinal Acot12 promotes lipid absorption through the upregulation of PPARγ target genes and protects against non-alcoholic steatohepatitis (NASH) by suppressing HFD-induced IEC necroptosis, which preserves barrier function. Because acetyl-CoA is the substrate for protein acetylation, this study explored an association between nuclear protein acetylation in IECs and Acot12-mediated control of barrier function. **Methods:** Intestinal-specific *Acot12*$^{-/-}$ (*I-Acot12*$^{-/-}$) and control mice were fed a HFD for 12 w. Small intestine and liver were harvested for gene expression by quantitative real-time PCR and protein expression by immunoblot analysis. Necroptotic cell death was determined by immunohistochemistry (IHC) for mixed lineage kinase domain-like pseudokinase (MLKL). Lipopolysaccharide (LPS) concentrations in the portal blood and collagen deposition in liver were quantified. Acot12 localization was determined by IHC and by immunoblotting of nuclear and cytoplasmic

IEC proteins. Acetylation of total nuclear proteins, as well as histone H3 were evaluated by immunoblotting. PPARγ acetylation was determined following immunoprecipitation. **Results:** As we previously reported for lipid regulatory genes, jejunal expression of the anti-inflammatory PPARγ target gene *Il10* was downregulated in *I-Acot12*$^{-/-}$ mice. This occurred in concert with MLKL translocation to the plasma membrane of jejunal villus IECs, indicative of the activation of necroptosis, as well as with an increase in portal vein LPS concentrations and the induction of hepatic collagen deposition. Acot12 was present in the cytoplasm but not in the nucleus of IECs. In the absence of Acot12, we observed reduced acetylation of a subset of nuclear proteins, including H3 (H3K9, H3K14, H3K27) and PPARγ. **Conclusion:** Acot12 in the IEC cytoplasm promotes nuclear protein acetylation, most likely by generating acetate that becomes a key source of nuclear acetyl-CoA. We speculate that intestinal Acot12-mediated acetylation of histone H3 and PPARγ protects against NASH through the transcriptional upregulation of anti-inflammatory and the transrepression of inflammatory target genes, which collectively repress IEC necroptosis and preserve gut barrier function.

f 2712-A | INTESTINAL DYSBIOSIS IS ASSOCIATED WITH RISK OF ACUTE CELLULAR REJECTION AFTER LIVER TRANSPLANT IN PATIENTS WITH AUTOIMMUNE LIVER DISEASE

Yael R. Nobel, Heekuk Park, Medini K. Annavajhala, Alice M. Tillman, Dwayne Seeram, Dalia H. Moallem, Angela Gomez-Simmonds, Elizabeth Verna and Anne-Catrin Uhlemann, Columbia University Irving Medical Center, New York, NY

Background: Patients with autoimmune liver disease (AILD) – including autoimmune hepatitis (AIH), primary sclerosing cholangitis (PSC), and primary biliary cirrhosis (PBC) – are at increased risk for acute cellular rejection (ACR) after liver transplant (LT). The gut microbiota influence adaptive immunity and could contribute to ACR risk. We investigated the potential of the gut microbiota as a biomarker of ACR risk in patients with AILD. **Methods:** This was a nested case-control study of all LT recipients with AILD within a prospective cohort. Cases had biopsy-proven ACR (Banff score $>=4$) within 1-year post-LT, and controls had no ACR within 1 year. Serial pre- and post-LT stool samples, until time of ACR (cases) or 1-year post-LT (controls), underwent DNA extraction and 16S rRNA sequencing. Taxonomic differences were assessed using DADA2. **Results:** Of 39 patients with AILD (49% AIH, 26% PSC, 8% AIH-PSC, 18% PBC), we identified 14 cases who developed ACR and 25 controls. ACR occurred at median 84 days post-LT. Disease severity, pre-LT medication exposures, rates of living donor LT, and use of post-LT immunosuppression induction did not differ between groups. Cases were younger than controls (median 31 vs. 61 years, $p<0.01$) and trended toward higher rates of IBD (29% vs. 4%, $p=0.09$) and use of broadened peri-LT antibiotic regimens (57% vs. 24%, $p=0.09$). Gut microbiota composition was ascertained in 85 stool samples (84% post-LT) and differed significantly between groups. Post-LT, cases had significantly lower alpha diversity ($p=0.03$; Fig. 1A), altered beta diversity (weighted Unifrac $p<0.01$), and differential abundance of multiple taxa. Cases had higher Proteobacteria/Firmicutes ratio ($p=0.10$) and lower Bacteroidota/Firmicutes ratio ($p=0.03$) (Fig. 1B-C). Using Phylogenetic Investigation of Communities by Reconstruction of Unobserved States (PICRUSt), several projected bacterial functional pathways differed between groups. Cases had reduced abundance of multiple pathways of branched-chain essential amino acid (BCAA) biosynthesis. **Conclusion:** Among patients with AILD undergoing LT, risk of ACR was associated with significantly altered gut microbiota composition. Patients who developed ACR had increased abundance of Proteobacteria, which produce pro-inflammatory bacterial lipopolysaccharide, and reduced abundance of BCAA biosynthesis pathways. These findings may provide a foundation for development of a novel microbial biomarker of ACR risk in LT recipients with AILD.

2713-A | INTESTINAL MICROBIOME ASSOCIATED WITH EFFICACY OF ATEZOLIZUMAB AND BEVACIZUMAB THERAPY FOR HEPATOCELLULAR CARCINOMA

Yosuke Inukai, Kenta Yamamoto, Takashi Honda, Shinya Yokoyama, Takanori Ito, Norihiro Imai, Yoji Ishizu, Masanao Nakamura, Masatoshi Ishigami and Hiroki Kawashima, Nagoya University Graduate School of Medicine

Background: The treatment of hepatocellular carcinoma (HCC) has advanced in recent years with the introduction of several new agents. Atezolizumab, an immune checkpoint inhibitor (ICI), has been used in combination with Bevacizumab, an angiogenesis inhibitor, as a first-line treatment for unresectable HCC. Some studies have reported on the relationship between ICIs and the intestinal microbiome, with intestinal bacteria-mediated mechanisms thought to be involved in their efficacy and in adverse events. However, no studies have reported on specific intestinal microbiome associated with the efficacy of Atezolizumab and Bevacizumab. We analyzed fecal samples collected before treatment to investigate the relationship between the intestinal microbiome and the efficacy of Atezolizumab and Bevacizumab. **Methods:** We enrolled a total of 37 patients with advanced HCC who received treatment with Atezolizumab and Bevacizumab. Prior to the treatment, we collected fecal samples from the patients. Based on their best response to RECIST during the treatment period, we divided them into two groups: responders (complete response, partial response or stable disease) and non-responders (progressive disease). Using QIIME2, we analyzed the gut microbiome and compared the patient characteristics and gut microbiome composition between the two groups. Additionally, we conducted further analysis to investigate the relationship between the intestinal microbiome and prognosis. **Results:** Of these 37 patients, 28 were categorized as responders and 9 were categorized as non-responders. The median age of the two groups was 74 years, and liver function was significantly better in the responder group. When comparing the alpha and beta diversities, there were no significant differences between the two groups, and the proportions of microbiota were similar as well. In a comparison of the relative abundance of intestinal microbiome in the two groups, *Bacteroides stercoris* and *Parabacteroides merdae,* which have been reported to be associated with ICI effects, was higher in the responder group than in the non-responder group. When patients were divided into groups based on the presence or absence of these bacteria, the group lacking both *Bacteroides stercoris* and *Parabacteroides merdae* was significantly older, had higher levels of AFP, and showed worse progression-free survival and overall survival. **Conclusion:** Our study suggests that specific intestinal microbiome may play a crucial role in determining the treatment response of HCC patients receiving Atezolizumab and Bevacizumab therapy. These findings may pave the way for the development of novel microbiome-based therapeutic strategies for enhancing the efficacy of immunotherapy in HCC patients.

f 2714-A | ISOLATION OF MYENTERIC AND SUBMUCOSAL PLEXUS FROM MOUSE GASTROINTESTINAL TRACT AND SUBSEQUENT CO-CULTURE WITH SMALL INTESTINAL ORGANOIDS

Cristina Llorente, UC San Diego

Background: Liver disease is a major global health issue, causing millions of deaths annually.

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Understanding its contributing factors, including alterations in intestinal homeostasis, is essential for effective prevention and treatment. Intestinal homeostasis is regulated by the interplay between the epithelium, the Enteric Nervous System (ENS), and immune cells, which influence the intestinal microbiota. In vitro models using neuronal cultures or organoids are needed to study the complex cellular interactions between the ENS and intestinal epithelium. **Methods:** We have pioneered an innovative 3D in vitro technique for coculturing small intestinal organoids with myenteric and submucosal neurons. The method entails a meticulous three-tiered process of cell isolation. Notably, we have made advancements in: (1) refining the isolation technique for cultivating the myenteric plexus, resulting in a mixed culture comprising enteric neurons and glial cells; (2) enhancing the isolation of the submucosal plexus, yielding a mixed culture of submucosal enteric neurons and glial cells; and (3) subsequently co-culturing myenteric and submucosal neurons with small intestinal organoids generated from pluripotent stem cells. **Results**: This co-culture system enables the establishment of neural connections with various cell types derived from the intestinal epithelium of the organoids. Through this cutting-edge technique, we can investigate the regulatory interactions among crucial intestinal cell populations and their alterations in the context of liver disease. Furthermore, we have developed a method for microinjecting the luminal space of small intestinal organoids with fluorescently-labeled dextran or ovalbumin. **Conclusion**: This technique provides a valuable platform for studying the role of the ENS and intestinal epithelium in liver disease. By establishing neural connections with various cell types derived from the organoids, we can investigate the regulatory interactions and their alterations in the context of liver disease. The technique could be useful in understanding the role of the ENS in maintaining cellular integrity, intestinal permeability, cellular physiology, and nutrient absorption. It also provides insights into intestinal stem cell behavior, proliferative-to-differentiation dynamics, and the role of the ENS in stimulating the secretion of intestinal epithelium-derived molecules involved in microbiota regulation and immune system modulation. Additionally, this technique offers the opportunity to explore signaling transduction pathways involved in these processes. This platform can be studied using a wide array of molecular and biochemical applications. The broad applicability of this technique can be extended to other experimental setups, incorporating alternative microinjections, including the introduction of specific bacterial species relevant to liver diseases.

f 2715-A | MICROBIAL TRANSLOCATION IS ASSOCIATED WITH HEPATIC FIBROSIS BUT NOT STEATOSIS IN WOMEN WITH AND WITHOUT HIV

Maria J. Duarte[1], Phyllis C. Tien[1], Ani Kardashian[2], Yifei Ma[1], Mark H. Kuniholm[3], Adaora A Adimora[4], Margaret Fischl[5], Audrey L. French[6], Elizabeth T. Topper[7], Deborah Konkle-Parker[8], Howard Minkoff[9], Ighovwerha Ofotokun[10], Michael Plankey[11], Anjali Sharma[12] and Jennifer C. Price[1], (1)University of California, San Francisco, (2)University of Southern California, Los Angeles, CA, (3)University at Albany, State University of New York, (4)University of North Carolina at Chapel Hill, (5)University of Miami Miller School of Medicine, (6) CORE Center/Stroger Hospital of Cook County, (7) Johns Hopkins Bloomberg School of Public Health, (8) University of Mississippi Medical Center, (9)State University of New York Downstate Health Sciences University, (10)Emory University School of Medicine, (11)Georgetown University Hospital, (12)Albert Einstein College of Medicine

Background: Non-alcoholic fatty liver disease (NAFLD), a leading cause of liver-related morbidity and mortality, is highly prevalent in people living with HIV (PLWH). Gut microbial translocation (MT) may play a role in NAFLD pathogenesis. Although HIV is associated with gut permeability, few studies have evaluated the interaction of the gut-liver axis on NAFLD in PLWH. We determined associations of HIV and circulating biomarkers of MT with hepatic steatosis and fibrosis in a large US cohort of women living with HIV (WLWH) and women living without HIV (WLWOH). **Methods:** Vibration controlled transient elastography (VCTE) was conducted from 2013-2018 among 1203 women without viral hepatitis (854 WLWH, 349 WLWOH). Serum biomarkers of MT were measured within 6 months of the VCTE visit: kynurenine to tryptophan (KT) ratio, intestinal fatty acid binding protein (I-FABP, a marker of gut epithelial integrity), and immune activation markers soluble CD14 (sCD14) and soluble CD163 (sCD163). We used multivariable linear regression to evaluate independent associations of each biomarker, HIV, and demographic, metabolic, and HIV-specific covariates with hepatic steatosis (controlled attenuation parameter [CAP]) and fibrosis (liver stiffness [LS]). **Results:** Median age was 49 years, 74% were non-Hispanic Black and over half were obese. Among WLWH, median CD4 count was 685 cells/mm^3. MT biomarker levels were higher in WLWH ($p < 0.001$ for each). There was no statistically significant difference in CAP and liver stiffness values amongst WLWH vs WLWOH (median CAP 248 dB/m for both and median LS 5.1 vs 4.9 kPa, respectively). In multivariable

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

regression, greater BMI and insulin resistance (HOMA-IR) were associated with higher CAP whereas age and greater BMI were associated with higher LS. Higher KT ratio and sCD14 were associated with lower CAP values, whereas higher levels of MT biomarkers were significantly associated with higher LS ($p < 0.001$ for 3 of 4 biomarkers, Table 1). **Conclusion:** Compared to WLWOH, WLWH have higher circulating biomarkers of MT. Interestingly, KT ratio and sCD14 were positively associated with hepatic fibrosis but had inverse associations with steatosis. This suggests that MT may be a mechanism by which HIV increases the risk of hepatic fibrosis but not steatosis. This study lays the groundwork for future efforts evaluating the relationship between MT, microbial composition, and liver disease in PLWH.

Table1: Association between biomarkers of MT and Liver Vibration Controlled Transient Elastography Measures

Controlled Attenuation Parameter (change in dB/m per biomarker IQR, 95% CI)			
	Entire Cohort	Women Living with HIV	Women Living without HIV
KT ratio	-5.9 (-9.6, -2.2)*	-8.4 (-10.8, -2)*	0.56 (-7.9, 9)
I-FABP (pg/mL)	-1.5 (-5.6, 2.6)	-2.6 (-7.2, 1.9)	2.3 (-6.6, 11)
sCD14 (ng/mL)	-5.1 (-9, -1)*	-4.3 (-8.9, 0.3)	-4.2 (-12.5, 4)
sCD163 (ng/mL)	-0.03 (-3.9, 3.8)	0.07 (-4.6, 4.7)	4.5 (-3.1, 12.2)

Liver Stiffness (% change per biomarker IQR, 95% CI)			
	Entire Cohort	Women Living with HIV	Women Living without HIV
KT ratio	6.2% (3%, 9.5%)*	4.3% (0.5%, 8.4%)*	5.8% (-0.7%, 12.7%)
I-FABP (pg/mL)	1.2% (-2%, 5%)	3.5% (-0.5%, 8%)	-2.2% (-8.5%, 4.4%)
sCD14 (ng/mL)	7.7% (4%, 11%)*	6.2% (2%, 10%)*	11.3% (4.7%, 18.3%)*
sCD163 (ng/mL)	12.5% (9%, 16%)*	12.2% (8%, 17%)*	10.7% (4.7%, 17.1%)*

*p<0.05, p-values were calculated by linear regression
CAP linear models controlled for age, BMI (continuous), race, insulin resistance (HOMA IR), alcohol use (abstinent, light, moderate, heavy), current tobacco use, The model for women living with HIV was also adjusted for CD4 count, CD4 nadir, HIV viral load (undetectable vs not), and protease inhibitor use
LS linear model controlled for HIV status, CD4 count, and HIV viral load (log(plus)1), age, BMI (continuous), race, insulin resistance (HOMA IR), alcohol use (abstinent, light, moderate, heavy), current tobacco use, menopause state and CAP score. The model for women living with HIV was also adjusted for CD4 count, CD4 nadir, HIV viral load (undetectable vs not), and protease inhibitor use
LS scores were log transformed. Biomarker levels were log transformed and underwent standardization defined as the log transformed variable divided by IQR
To account for missing data, we employed the full information maximum likelihood (FIML) approach.

2716-A | MULTI-OMICS ANALYSIS OF SEX-SPECIFIC HEPATOTOXICITY WITH TOXICANT EXPOSURES: ROLE OF THE GUT-LIVER AXIS

Zayna Qaissi[1], Richa Singhal[1], Shikshita Singh[2], Tyler C Gripshover[1], Eric C Rouchka[1], Jianmin Pan[3], Michael Merchant[1], Shesh N Rai[3] and Banrida Wahlang[1], (1) University of Louisville, Louisville, KY, (2)University of Ottawa, (3)University of Cincinnati

Background: Toxicants such as polychlorinated biphenyls (PCBs) have been associated with sex-dependent liver outcomes, with female mice exhibiting greater susceptibility for toxicant-associated steatohepatitis (TASH). While mechanisms such as metabolic/endocrine disruption have been identified, they do not sufficiently explain these sex-specific outcomes. Alternative mechanisms including PCB effects on gut microbiome warrant investigation. Therefore, this study's objective is to identify PCB-induced changes in the hepatic proteome and gut microbiome to determine disruption of physiological gut-liver interactions. **Methods:** Male and female C57BL/6 mice were exposed to Aroclor1260 (commercial PCB mixture, 20 mg/kg) and PCB126 (20 µg/kg) *p.o* for 2 weeks. Hepatic tissue was collected at euthanasia for peptide measurements (LC/MS). Cecal and ileal samples were isolated for 16S sequencing (analyzed using QIIME2) and gene expression analysis (RT-PCR) respectively. **Results:** Distinct hepatic proteomes were observed dependent on sex and exposure with 297 proteins modified in PCB-exposed male *vs.* female mice. While both PCB-exposed sexes showed hepatic aryl hydrocarbon receptor (AHR) activation, females also exhibited increased protein abundance for other AHR targets including flavin-monooxygenases and CD36. Computational analysis using MetaCore identified enriched "fatty acid metabolic process" in PCB-exposed females. Notably, PCB-exposed females had decreased activation (*z*-score) for hepatocyte nuclear factor (HNF4a), which is crucial for normal hepatocyte function. With regards to metagenomics, PCB-exposed females exhibited the lowest alpha diversity (OTUs). Beta diversity (UniFrac) was also significantly different with both sex and PCB exposures. PCB-exposed females but not

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

males showed decreased abundance for the beneficial, gut health-promoting bacterial family, *Bifidobacteriaceae*. Ileal gene expression assessment demonstrated decreased mRNA levels for genes encoding gut barrier and antimicrobial proteins (*Cldn2*, *Muc2*, *Tff3*) and AHR target (*Cyp1a2*) in PCB-exposed females, implicating an unhealthy mucosal environment. **Conclusion:** Females were more responsive to altered lipid processes coupled with modified gut microbiota and compromised, intestinal environment, thus providing evidence for gut microbiome as an additional player in sex-specific PCB toxicity. Future studies include designing intervention strategies such as probiotics to attenuate PCB-mediated TASH.

f 2717-A | PROTON PUMP INHIBITOR TREATMENT IS ASSOCIATED WITH A HIGHER MORTALITY IN CIRRHOTIC PATIENTS: A MULTICENTER STUDY

Junsik Yoon[1], Ji Hoon Hong[2], Soo Young Park[3], Seung Up Kim[4], Hwi Young Kim[5], Ju Yeon Kim[2], Moon Haeng Hur[6], Min Kyung Park[2], Yun Bin Lee[6], Han Ah Lee[5], Gi-Ae Kim[7], Dong Hyun Sinn[8], Sung Jae Park[1], Youn-Jae Lee[1], Yoon Jun Kim[9], Jung-Hwan Yoon[2] and Jeong-Hoon Lee[10], (1)Inje University College of Medicine, (2)Seoul National University College of Medicine, (3)School of Medicine, Kyungpook National University, (4)Yonsei University College of Medicine, Seoul, Republic of Korea, (5) Department of Internal Medicine, Ewha Womans University College of Medicine, Seoul, South Korea, (6)Seoul National University Hospital, (7)Kyung Hee University School of Medicine, Seoul, South Korea, (8)Samsung Medical Center, (9)Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea, (10)Seoul National University College of Medicine, Seoul, South Korea

Background: Proton pump inhibitors (PPI) are frequently used in patients with cirrhosis. This study aimed to determine whether PPI use is associated with the prognosis of patients with cirrhosis. **Methods:** We conducted a multicenter retrospective cohort study involving 1,485 patients who had experienced hepatic encephalopathy (HE) from 7 referral centers in South Korea. The primary outcome was overall survival and secondary outcomes included the development of cirrhotic complications, including recurrent HE, spontaneous bacterial peritonitis (SBP), hepatorenal syndrome (HRS), and gastrointestinal bleeding. Patients treated with PPI with a mean defined daily dose (mDDD) e 0.5 (in the PPI group) were compared to those treated with PPI of an mDDD < 0.5 (non-PPI group) for each outcome. **Results:** Among 1,485 patients (median age, 61 y; male, 61%), 232 were assigned to the PPI group and 1,253 were assigned to the non-PPI group. PPI use was independently associated with a higher risk of death (adjusted HR [aHR] = 1.72, 95% confidence interval [CI] = 1.40–2.12, P < 0.001). This result was reproducible after propensity score-matching (PSM) (aHR = 1.61, 95% CI = 1.28–2.04, P < 0.001; Figure 1). PPI use was an independent risk factor of recurrent HE (before PSM: aHR = 1.89, 95% CI = 1.50–2.38, P < 0.01; after PSM: aHR = 1.62, 95% CI = 1.24–2.12, P < 0.001), SBP (before PSM: aHR = 1.57, 95% CI = 1.17–2.10, P = 0.003; after PSM: aHR = 1.94, 95% CI = 1.43–2.64, P = 0.02), HRS (before PSM: aHR = 1.66, 95% CI = 1.10–2.49, P = 0.01; after PSM: aHR = 1.76, 95% CI = 1.10–2.83, P = 0.008), and gastrointestinal bleeding (before PSM: aHR = 1.46, 95% CI = 1.11–1.93, P = 0.008; after PSM: aHR = 1.53, 95% CI = 1.10–2.11, P < 0.001). **Conclusion:** The use of PPI was independently associated with increased risks of mortality and cirrhotic complications.

2718-A | RECOGNIZE SMALL INTESTINAL BACTERIAL OVERGROWTH (SIBO), WITH BREATH TEST CHARTS, DUE TO SULPHATE-REDUCING BACTERIA

Clara Peña Cañaveras[1], Silvia Miro Canís[1], Anna Puiggros-Font[1], Sonia Albertos Rubio[2], Clara Maria Aubo Delgado[1], Veronica Campos Garrido[1] and Miguel Angel Benitez Merelo[1], (1)Clilabdiagnostic, (2)Consorci Sanitari De L'alt Penedés-Garraf

Background: The intestinal microbiota has a remarkable role in our health since it influences not only the intestinal transit, but also is related to the immune, endocrine system, urinary system, etc. It may even be involved in the development of cancer. An increased number of bacteria colonizing the small intestine can produce a form of dysbiosis called small intestinal bacterial overgrowth (SIBO). It is estimated that up to 35% of the general population may suffer from SIBO. Breath testing is the noninvasive test widely used to diagnose SIBO. It is based on the fact that human body cells do not produce the gases that are being detected. The measured gases are: Hydrogen when there was mainly excessive proliferation of bacteria and Methane when there was an overgrowth of methanogenic archaea. Hydrogen sulfide is also produced by sulphate-reducing bacteria invasion, but the breath test charts can't detect it. Determine the number of SIBO that is due to sulphate-reducing bacteria and be aware of its incidence in the curve interpretation to classify patients correctly. **Methods:** Sibo-kit test (Isomed®) is used to measure the concentration of hydrogen and methane in exhaled air, after oral administration of lactulose, in 132 patients, using CO2 concentration as an internal control. Gases elevation greater than 20 ppm in H2 and/or greater than 10 ppm in CH4, respect to basal values, indicates the presence of the microbiota in the small intestine and therefore a positive SIBO. The graphs of patients with SIBO due to sulphate-reducing bacteria does not detect gaseous HS, so the curve is totally flat. 132 patients conducted in the Departament of Gastroenterology, were recluted during one year: 108 female and 24 male pacients, aged 15-80 years (mean:45 y). **Results:** 48 were negative (36.4%), 58 were SIBO positive (43.9%) and 26 were suggestive of SIBO due to sulphate-reducing bacteria (19.7%). **Conclusion:** As our results showed, the 19.7% of patients have a flat curve, which may make you think that the patient did not take the product. However, patients with SIBO from sulfate-producing bacteria also have flat curves because it does not detect gaseous HS. It must be considered to avoid false negative results. A misinterpretation of the graph will result in patients not being treated for SIBO.

Disclosures: The following people have nothing to disclose: Clara Peña Cañaveras, Silvia Miro Canís, Anna Puiggros-Font, Sonia Albertos Rubio, Clara Maria Aubo Delgado, Veronica Campos Garrido, Miguel Angel Benitez Merelo

2719-A | REGULATION OF SPLENIC-DERIVED REGULATORY T CELLS BY BACTEROIDES PROMOTES HEPATIC FIBROSIS PROGRESSION

Aiyu Zhang[1,2,3], Yang Zhao[1,2,3], Xi Chen[1,2,3], Zhang Shaoying[1,2,3], Qian Wang[1,2,3], Guangyao Kong[1,2,3] and Zongfang Li[1,2,3], (1)Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3)Shaanxi International Cooperation Base for Inflammation and Immunity, Xi'an, China

Background: To investigate the predominant bacterial species involved in promoting liver cirrhosis progression through gut dysbiosis and provide experimental evidence for understanding the role of dysbiotic gut microbiota in promoting liver fibrosis and finding new strategies for liver fibrosis prevention and treatment by regulating the gut microbiota. **Methods:** (1) A mouse model of liver fibrosis was established by intraperitoneal injection of carbon tetrachloride in SPF-grade C57BF/6 mice. Flow cytometry was used to assess the changes in $Foxp3^+$ regulatory T cells (Tregs) in the liver of model and control group mice. The changes in Treg cells in the liver were also evaluated after splenectomy in the model group mice. (2) Stool samples were collected from 25 patients with liver cirrhosis, portal hypertension, and hypersplenism before and six months after splenectomy. The collected stool samples were subjected to 16S rDNA sequencing, and bioinformatics analysis was performed to compare the abundance changes of bacterial species in the gut microbiota before and after surgery in the patients. **Results:** (1) Flow cytometry analysis revealed a significant increase in $Foxp3^+$ Tregs in the liver of the liver fibrosis model mice compared to the control group. The proportion of Treg cells in the liver of the splenectomy group mice was significantly reduced compared to the mice with intact spleens, but similar to that of the control group mice. (2) Before splenectomy, the abundance of *Bacteroides* was significantly higher than other bacterial species in the stool samples of clinical patients. Six months after splenectomy, the relative abundance of

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Bacteroides decreased, and the microbial diversity in the patients' feces increased, indicating recovery of the patients' health. **Conclusion:** *Bacteroides* in the gut microbiota of liver cirrhosis patients may promote the recruitment of Treg cells in the liver by their metabolite polysaccharide A, which regulates the migration of $Foxp3^+$ Tregs through CD39. The increased Treg cells in the liver alter the liver's immune microenvironment, thereby promoting liver fibrosis progression. The significant decrease in liver Treg cell proportion after splenectomy suggests that the spleen may be a major source of Treg cell recruitment in fibrotic liver.

2720-A | RETOXIFICATION OF GLUCURONIDATED BILE ACIDS BY BETA-GLUCURONIDASE ENZYMES FROM INTESTINAL MICROBIOTA: A NOVEL TARGET FOR THE TREATMENT OF BILE ACIDS-RELATED DISEASES OF THE GUT-LIVER AXIS

Salma Dzanouni, William Gagnon, Mélanie Verreault, Jocelyn Trottier and Olivier Barbier, Université Laval, Faculty of Pharmacy, Québec, Canada

Background: The hepatic accumulation of toxic bile acids (BAs) is a major outcome of cholestatic liver diseases. Glucuronidation is an efficient and inducible detoxification reaction for BAs. Our lab has recently observed that glucuronidated BAs (BA-G) are efficiently deconjugated to toxic BAs by microbial β-glucuronidase (GUS) enzymes from the large intestine. This study aimed at elucidating how the GUS activity is regulated enzymatically, pharmacologically and by the diet. **Methods:** GUS assays were performed with 50μM BA-G in the presence of human or murine fecal proteins (5μg) at 37°C for 30min. The formation of unconjugated BAs was resolved using LC-MS/MS. For enzymatic screening, 11 BA-G species were assayed with feces from human (5♀: 5**B**) or CD1 mice (2♀:2**B**). For inhibition assays, the enzymatic reaction was performed with a pool of human (5**B**: 5♀) or murine (4**B**:4♀) feces in the presence of 200μM amoxapine. Finally, GUS assays were also performed using feces from human donors harvested before and after consumption of either 280g/day of frozen raspberries (16♀:7**B**) or 50g/day of freeze-dried blueberry powder (13♀:11**B**) for 8 weeks. **Results:** All BA-G assayed were reactive with human and murine feces, with percentage of deconjugation varying from $0.4 \pm 0.1\%$ with HDCA-6G and female mice samples to $47.1 \pm 12.4\%$ with LCA-24G and male mice feces. The inhibition rate of GUS activity caused by amoxapine was higher in women than in men ($68.3 \pm 2.9\%$ versus $49.6 \pm 1.9\%$ reduction of LCA-3G to LCA conversion, for example). Assay with β-MCA-24G and murine feces also revealed sexual dimorphism with amoxapine being more efficient in female samples. Interestingly, in human volunteers, the consumption of blueberry extracts caused a significant ($p < 0.01$) reduction of LCA-3G deconjugation in men, while the GCDCA-3G to GCDCA conversion remained unaffected in the 2 sexes after a 8-week period of a diet enriched in raspberries. **Conclusion:** This study illustrates for the first time, the role of intestinal microbial GUS enzymes in the reactivation of nontoxic BAs into toxic acids. The sex-, enzymatic- pharmacological- and diet-dependent modulation of this activity is also revealed. Overall, our results identify these enzymes as novel pharmacological targets for the treatment of BA-related diseases of the gut-liver axis.

2800-C | "BREAKING BARRIERS, BRIDGING GAPS: UNVEILING THE IMPACT OF HEALTH DISPARITIES IN PATIENTS WITH LIVER CIRRHOSIS AT A COMMUNITY HOSPITAL"

Adalberto Guzman[1], Evelyn Calderon Martinez[1], Wern Lynn Ng[1], Samanta Landazuri[2], Anas Atrash[1] and Douglas M. Levin[3], (1)UPMC, (2)University of the Americas, (3)Ohio State University, Columbus, OH, United States

Background: Liver cirrhosis represents a critical global public health challenge, with its prevalence and impact on morbidity and mortality escalating in the United States. Disparities in liver disease prevalence, complications, outcomes, mortality, and treatment accessibility are closely intertwined with social determinants. **Methods:** Using Epic's SlicerDicer function, patients admitted to any hospital of UPMC Central PA between January and December of 2022 with a diagnosis of cirrhosis of any type were identified using ICD-10 codes. A total of 389 patients were enrolled. We reported continuous variables as mean, standard deviation and range for the normal distribution, and median and interquartile range for the abnormal distribution. The categorical variables were reported as number (percent). We used chi-square test to analyze between group differences for mortality and readmission analysis. The Fisher exact test was employed when any of the expected frequencies was five or less. We used the Wilcoxon rank-sum test to analyze the differences in length of stay, as appropriate. A p value less than 0.05

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was considered statistically significant. All the analyses were done by SAS 9.4 (SAS Institute, Cary NC). **Results:** Among the patient population analyzed, 239 (61.4%) were male, with a mean age of 62.2 ± 9. Approximately 73% had Medicaid or Medicare as their primary insurance. Interestingly, there were no notable differences in mortality, length of stay, or readmission rates between English-speaking and non-English-speaking patients, suggesting that the extensive utilization of interpreter services in our hospitals may contribute to equitable outcomes. Notably, patients lacking insurance exhibited higher mortality rates and longer lengths of stay compared to those with Medicaid and Commercial insurances ($p < 0.0001$). Moreover, mortality rates were notably elevated among patients aged above 65 (45.7%, $p < 0.0001$). However, no statistically significant disparities in mortality, length of stay, or readmission were observed when comparing between genders. **Conclusion:** Our analysis demonstrated that language barriers were effectively addressed through the extensive use of interpreter services, resulting in comparable mortality, length of stay, and readmission rates between English-speaking and non-English-speaking patients. However, patients lacking insurance faced higher mortality rates and longer hospital stays compared to those with Medicaid and Commercial insurances, emphasizing the significance of adequate insurance coverage in improving outcomes. The mortality rate was notably higher among patients aged above 65, underscoring the need for tailored interventions for this age group. Gender did not show statistically significant differences in mortality, length of stay, or readmission. These findings highlight the importance of comprehensive care strategies for individual's affected by liver cirrhosis.

Disclosures: The following people have nothing to disclose: Adalberto Guzman, Evelyn Calderon Martinez, Wern Lynn Ng, Samanta Landazuri, Anas Atrash, Douglas M. Levin

2801-C | A NOVEL CASE FINDING DATABASE CAN BE UTILISED TO IDENTIFY AND TARGET INDIVIDUALS IN AREAS OF DEPRIVATION AT RISK OF ADVANCED LIVER DISEASE

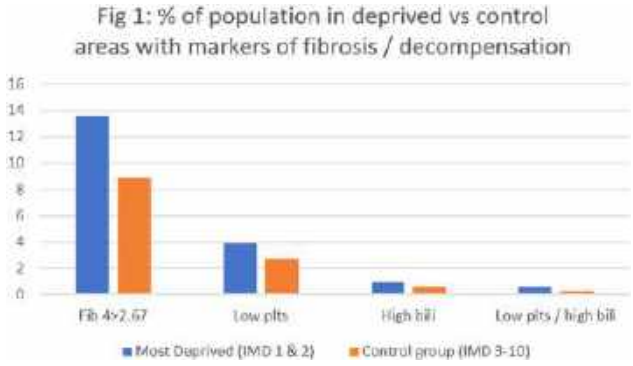
Christina Owen, Timothy Jobson, John Creamer, Emma Wesley and Almuthana Mohamed, Somerset NHS Foundation Trust

Background: Chronic liver disease often presents late, despite guidelines for diagnosis and staging. This may be worse in areas of deprivation. In the NHS in England the 'Core20Plus5' programme provides a mandate for tackling inequalities. 'Core20' refers to individual's in the 20% most deprived geographical areas defined by the Index of Multiple Deprivation (IMD). This ranks the population by decile; IMD deciles 1 & 2 represent the target population. In Somerset, England we created a novel case finding database using existing blood test results on 0.6m individual's to identify patients at risk of chronic liver disease. We tested the hypothesis that this database could be used effectively to target individual's in deprived areas. **Methods:** The database was used to identify adults aged 30-65 and risk stratify for chronic liver disease using persistent elevation of ALT ($\geq$90 d), FIB-4, and our recently developed Cumulative Liver Damage Index (CLDI - integral of ALT over time). Analyses were performed by IMD-decile, comparing IMD 1&2 (most deprived 20%) with the rest of the population. Additional searches were performed using low platelet (plt) count as a marker of possible portal hypertension, and elevation of bilirubin (bili). **Results:** 9.9% of the Somerset population live in areas of IMD 1&2; (i.e. Somerset is less deprived than the English average). These individual's had on average 19.5% more blood tests than those in less deprived areas. There was no significant difference between IMD deciles for persistently abnormal ALT, investigation with second line tests (liver screen), and distribution of CLDI. For those with persistently elevated ALT, a Fib 4 was calculated if possible; 13.6% in deprived areas (IMD 1 & 2) had FIB-4 > 2.67 compared to 8.9% of control (IMD 3-10); $p = 0.015$. For patients with a CLDI > 100k unit.days, 3.9% of deprived had low plts, c.f. 2.7% of control; 0.9% of deprived had a bili > 50umol/l (2.92mg/l) c.f. 0.6% control, and 0.6% of deprived had both elevated bili and low plts c.f. 0.3% control (all $p < 0.001$) (Fig 1). **Conclusion:** A case finding approach is applicable to the most deprived individual's in the population. We identified likely chronic liver disease in deprived areas at similar rates to the general population, but those in deprived areas had more indicators of fibrosis and decompensated disease. These data show that this

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

novel tool has potential to identify patients from areas of deprivation at risk of advanced liver disease.



Disclosures: The following people have nothing to disclose: Christina Owen, Timothy Jobson, John Creamer, Emma Wesley, Almuthana Mohamed

f 2802-C | ALARMING MORTALITY TRENDS IN ALCOHOLIC LIVER DISEASE RELATED MORTALITY AMONG ADULTS IN THE UNITED STATES FROM 1999-2020

Yousaf Zafar[1], Melanie Baker[1], Arsalan Zafar Iqbal[1], Laila Manzoor[1], Isaac Dodd[1] and Jan Petrasek[2], (1) University of Mississippi Medical Center, (2)Texas Liver Institite

Background: Alcohol-related Liver Disease (ARLD) refers to Liver damage caused by excess alcohol intake. In the United States, between 2010 and 2016, alcohol-related liver disease was the primary cause of nearly 1 in 3 liver transplants, surpassing hepatitis C. In this descriptive study we compared trends in US mortality rates from ARLD from 1999 and 2020. **Methods:** We sought to identify temporal, geographic, age and sex-based mortality trends of ARLD related deaths in the US over the past 2 decades. This population-based study utilized the CDC WONDER database to identify ARLD-related deaths occurring within the US between 1999 and 2020. ARLD-related crude and age-adjusted mortality rates (CMRs and AAMRs, respectively) were determined. Join point regression was used to determine trends in CMR/AAMR using annual percent change (APC) in the overall sample in addition to demographic (sex, race/ethnicity, age) and geographic (rural/urban, statewide) subgroups. **Results:** Between 1999 and 2020, a total of 447,676 deaths related to ARLD were reported. The overall AAMR increased significantly from 5.1/100,000 in 1999 to 13/100,000 in 2020. Men had a higher mortality than women (In 2020 alone AAMR was 22.6 Vs 9.6). APC continues to be higher in both sexes with APC increasing significantly in 2018 to 2020 (In males APC was 10.9 (95CI% 4.6-17.6) Vs females 14.7 (95%CI 8.2-21.6). ARLD related mortality was disproportionately seen to affect American Indians dispropotionately with AAMR in 2020 alone was 88.4 (95%CI 83.9-93) compared to other races- AAMR in Whites were 16.5 (95%CI 16.3-16.7), African American was 10.3 (95%CI was 9.9-10.7). Although trends in Metro and Nonmetro areas have increased over the past 2 decades, patients in the rural areas tend to be more affected. Overall, the trends for all groups assessed worsened from 2018-2020. New Mexico, South Dakota, and Wyoming seem to be states that have the highest AAMR from ARLD. **Conclusion:** ALRD -related AAMR were observed more among men, Americans Indians, and individual's living in rural areas. American Indians seem to be dispropotionately affected by ALRD with trends suggesting mortality increasing at an alarming rate. Discerning the reasons for the increase in ALRD-related mortality among these groups and examining the impact of the social determinants of heath may represent important opportunities to enhance care.

2803-C | DESIGN AND IMPLEMENTATION OF EQUITY-FOCUSED VIDEO-BASED PATIENT EDUCATION FOR LIVER TRANSPLANT EVALUATION

Alexandra Strauss, Mary Rudolfi, Alexander Ginietis, Ahmet Gürakar, Neha Rajpal and Tanjala S. Purnell, Johns Hopkins University

Background: Patients undergoing liver transplant (LT) evaluation are faced with an arduous process that can be difficult to navigate. Social determinants of health, such as health literacy and patient-provider trust, may contribute to racial/ethnic disparities in evaluation completion. Generally, video-based patient education (VBPE) has been shown to improve patient outcomes, but there is no broadly available VBPE tailored to LT evaluation from a health equity perspective. Our aim was to create equity focused VBPE and within 6 weeks of implementation to achieve a 75% view rate by our LT clinic patients. **Methods:** In this quality improvement study, we reviewed the literature about VBPE and cultural sensitivity (e.g., Suitability Assessment of Materials, Patient Education Materials Assessment Tool) to develop a short video that is 1) racially/gender diverse, 2) simple verbiage without written words (i.e., accessible to all health literacy levels), 3) available audio/visually in 5 languages. We uploaded the video to a VBPE system within our electronic health record, so we could send/track it via the patient portal. From 4/3/23-5/22/23, we sent VBPE to patients undergoing outpatient evaluation. We performed typical process improvement techniques, such as Plan-Do-Study-Act cycles, tracers and Cause-Effect analysis to identify barriers. **Results:** The final video is publicly available online (https://www.youtube.com/watch?v=ezBg1vX0Ozg). Of the 43 patients undergoing evaluation, 24 (56%) watched the VBPE and 8 (19%) watched more than once. We identified barriers related to people (e.g., too sick/encephalopathy, overwhelmed, perceived as unnecessary, not tech-savvy), equipment (e.g., no patient portal access, difficulty navigating to video, instructions to video in English), methods (e.g., timing when to send video, sending is cumbersome/burdensome), environment (e.g., hospitalized after sending, rehabilitation center, lack of support system to encourage. By addressing several issues, we increased view rate from 33% and 16% in weeks 1-2 to 80% by week 6 (Figure). **Conclusion:** Through a health equity lens, we created a culturally-sensitive and broadly accessible VBPE for patients undergoing LT evaluation. We showed implementation in a busy clinic is feasible. This video can be adopted by other transplant centers as it describes widely standard procedures for evaluation. Further work is needed to assess the impact of the video on outcomes and to explore patient feedback.

2804-C | DISTRESSED COMMUNITIES INDEX IN PATIENTS UNDERGOING LIVER TRANSPLANTATION IN A TERTIARY CARE CENTER IN MISSISSIPPI

Yousaf Zafar[1], David Landon Zepponi[1], Jonathan Parke[1], Laila Manzoor[1], Arsalan Zafar Iqbal[1], Chad Blackshear[1] and Jan Petrasek[2], (1)University of Mississippi Medical Center, (2)Texas Liver Institite

Background: Earlier research has revealed inequalities in transplantation rates among certain groups such as women, non-Caucasians, individual's without insurance or with public insurance, and those residing in rural areas. The Distressed Communities Index (DCI) serves as a mechanism to gauge the relative economic welfare of communities in the United States and sheds light on disparities at a local level throughout the country Our objective was to establish if there is correlation between patient that are evaluated and not listed for transplant and their respective DCI. We hypothesized that there would be significant correlation among patients with liver disease who are not listed and their DCI score. **Methods:**

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

A retrospective center-specific study with 1,509 adults that were undergoing liver transplant evaluation at the University of Mississippi Medical center from 2013 to 2023 were assessed for demographic data and DCI using their house zip code. This was correlated with whether they were evaluated, declined for Liver transplant, waitlisted, and eventually transplanted. **Results:** The cohort included 56% males and was 71% white. The mean age at evaluation was 55 years. 52% of patients evaluated had public insurance, 33% had private, 6% supplemented public insurance with private policies, 9% were uninsured. Patients were grouped by follow-up status: 220 were declined transplant, 857 were referred or lost to follow-up post-evaluation, 89 were placed on the waitlist, and 343 received transplantation. Among the patients declined for transplant, black patients had a 15.6-unit higher DCI than whites (95% CI 11.4,19.9; $p < 0.001$) and publicly insured patients had a 7.7-unit higher DCI than those with private insurance (95% CI 3.5,11.9; $p < 0.001$). Among the transplanted patients, black participants had a 14.2-unit higher DCI that whites (95% CI 7.4,12.1; $p < 0.001$). Results are based on the interaction effects of transplant group by hypothesized disparity from serial OLS regression models. **Conclusion**: Although formal testing indicates that DCI was not broadly associated with transplantation status, the data suggests some racial and insurance disparities could exist. Specifically, the results support an association with higher DCI in African Americans, although the variability was higher among those awaiting transplantation. Similarly, albeit less pronounced, was an association with higher DCI in patients with public insurance. Alternatively, our data did not suggest disparities based on sex, age at the time of evaluation or any effect modification based on the year of enrollment.

2805-C | EXAMINING THE IMPACT OF DEMOGRAPHICS ON OUTCOMES AND TRANSPLANT EVALUATION IN INFECTED PATIENTS IN THE MEDICAL INTENSIVE LIVER UNIT: EXPERIENCE FROM A QUATERNARY CENTER

Sarah Khan[1], Hanna Hong[2], Sofia Molina Garcia[1], Stephanie Bass[1], Christine Koval[1], Aanchal Kapoor[1], Omar T. Sims[1] and Christina C. Lindenmeyer[1], (1) Cleveland Clinic, (2)Cleveland Clinic Lerner College of Medicine

Background: Prior studies have shown disparities in evaluation, listing and transplant rates on the basis of sex, race and socioeceonomic status. Few studies have examined disparities in transplant and outcomes in the critical care setting, which may further be impacted by infections and illness severity (i.e., acute-on-chronic liver failure, ACLF). We aimed to determine if age, sex, and race are independently associated with mortality, length of stay (LOS), and transplant evaluation among infected patients in the medical intensive liver unit (MILU). **Methods:** We conducted a study utilizing our prospective, longitudinal MILU registry of culture-positive patients admitted from August 2018- September 2022. A total of 211 patients with infections were included in the analysis. Univariate modeling was used to examine associations between demographics and outcomes of interest. **Results:** Of patients, 27 had fungal and 183 had bacterial infections. Median age was 58 years, and the majority were male (59.5%) and white (74.3%). Of non-white patients, 15.7% were Black, 3.8% were multiracial, and 0.5% were American Indian and Asian. Most patients had cirrhosis (77.9%), followed by severe acute liver injury (16.3%) and acute liver failure (5.8%). Altogether, 105 patients were evaluated for LT, 61 were listed, and 26 patients subsequently underwent transplant. Age, sex, and race were not associated with overall survival, hospital LOS, and ICU LOS (Table 1). However, age decreased the odds of transplant evaluation (HR = 0.98, 95% CI 0.95-0.99, $p = 0.039$), and white patients had increased odds of transplant evaluation (HR 2.46, 95% CI 1.31-4.63, $p = 0.005$). White patients had more favorable odds of listing and LT, but these were not statistically significant (HR = 2.02, 95% CI 0.78-5.24, $p = 0.15$; HR 2.27, 95% CI 0.75-6.88, $p = 0.146$ respectively). **Conclusion:** Among critically-ill patients with infections, white patients were significantly more likely to be evaluated for transplant. This disparity likely also translated to lower odds of listing and transplantation in non-white patients, but our study was likely underpowered in LT listing and transplantation modeling to detect statistical significance. Our work supports further investigation of disparities in transplantation among critically ill infected patients with liver disease, who may also be vulnerable to bias against transplant due to organ failures and associated ACLF. Our study was limited in accounting for non-demographic factors impacting transplantation evaluation.

2806-C | EXPLORING THE LINK BETWEEN LIVER CIRRHOSIS SEVERITY AND 30-DAY READMISSION RATES IN HIGH-RISK PATIENTS

Rajmohan Rammohan[1], Melvin Joy[2], Dilman Natt[1], Sai Greeshma Magam[1], Achal Patel[1], Abhishek Tadikonda[1], Jiten Desai[1], Sandra Gomez[1], Rucha Jiyani[1], Saher Sheikh[1], Susan Bunting[1] and Paul Mustacchia[1], (1)Nassau University Medical Center, (2) Nassau University Medical Center, East Meadow, NY

Background: Early hospital readmissions among cirrhotic patients present a challenge for inpatient hospital facilities. Cirrhosis patients experience 1-month readmission rates ranging from 20-35%. Timely identification of high-risk patients could enable targeted interventions to minimize readmissions. Our study aimed to develop an automated risk model for 30-day readmissions in cirrhotic patients, leveraging electronic medical record (EMR) data obtained during initial hospitalization. Key factors assessed in this study include socioeconomic status (Medicare/Medicaid), gender, number of previous admissions within the past year, ascites, thrombocytopenia, low alanine aminotransferase levels, hyponatremia, anemia, and Model for End-stage Liver Disease (MELD) scores. **Methods:** We analyzed the Nationwide Readmission Database (HCUP) from 2019 to 2022 and collected data on 1,748,576 adult patients readmitted within 30 days. Our study initially employed standard logistic regression and decision tree methodologies to identify influential variables and establish significant decision rules. Subsequently, we divided the original dataset into strata and applied logistic regression to each stratum. Lastly, we examined the risk and accuracy of interacting variables in the logistic regression models through the use of Area under the Curve (AUC) and Odds Ratio assessments. **Results:** Between 2019 and 2022, a total of 1,748,576 patients were readmitted. After propensity score matching, 24,988 patients (mean age 57.4 $\pm$ 12.4, 54% women) were included in the study. We compared 11,444 (45%) liver cirrhosis patients to 13,544 (54%) patients without liver cirrhosis. Multiple logistic regression of the independent variables revealed a 7.2% readmission probability in the insurance group ($p < 0.01$), 4.2% for CAD ($p = 0.01$), and 4.8% for HLD ($p < 0.01$). The lower median income quartile (25k-35k) showed a 7.2% increase in readmissions ($p = 0.02$). Increased odds of readmission were observed in patients with a history of HLD requiring medication (2.4, $p < 0.01$), median household income (OR 2.19, $p < 0.01$), and insurance status (OR = 1.53, $p < 0.01$). Furthermore, female patients demonstrated higher odds of readmission (OR 1.21, $p < 0.01$). The accuracy of gender and insurance status was also significant, with gender AU ROC at 0.550 ($p < 0.01$) and insurance status AU ROC at 0.641 ($p < 0.01$), compared to logistic regression. **Conclusion:** Our findings indicate that patients with comorbid medical conditions, insurance status, gender, and those in the second income quartile exhibit a heightened risk for readmission. Further studies are required to assess whether implementing targeted interventions for high-risk patients can effectively reduce readmissions.

2807-C | GENDER AND RACIAL DISPARITIES IN OUTCOMES OF ACUTE LIVER FAILURE: A NATIONAL POPULATION BASED STUDY

Chidiebele Omaliko, One Brooklyn Health - Brookdale University Hospital Medical Center, Ayobami Olafimihan, John H Stroger Jr. Hospital of Cook County, Chukwunonso Ezeani, Baton Rouge General Medical Center, Baton Rouge, LA, Oghenefejiro Ogwor, St Peter University Hospital, New Brunswick, NJ, Chidiebube Jeremiah Ugwu, East Tennessee State University, Favour Markson, Lincoln Medical Center and Nzubechukwu Ugochukwu, Nnamdi Azikiwe University Teaching Hospital

Background: Acute Liver Failure (ALF) is associated with significant health care burden as well as mortality, morbidity and need for liver transplantation in the USA. There is a paucity of data that describe the sociodemographic differences in the outcomes of hospitalized patients admitted with acute liver failure. In this retrospective cohort study, we evaluated the racial and gender differences in the outcomes of patients hospitalized for acute liver failure. **Methods:** Using the National Inpatient Sample (NIS) database, we identified patients with a principal diagnosis of acute liver failure between 2016 - 2020 and divided them based on the different races and gender. Patients aged less than 18 years were excluded from the analysis. Using a multivariate analysis, we assessed for differences in the primary outcome of inpatient mortality while the secondary outcomes were hospital length of stay (LOS) and total hospital charges (THC). **Results:** There were 135,520 hospitalizations with a principal diagnosis of acute liver failure, with the majority (66.6%) being White, while Native Americans with 2,174 patients (1.7%) had the fewest hospitalizations. There was a significant difference in inpatient mortality among the different races ($p = < 0.01$), with Blacks having the highest mortality rate (12.2%) and Hispanics with the least mortality (7.1%). We also found a significant difference in mortality between females and males ($p = 0.03$). When secondary outcomes were analyzed, there was a significant difference in LOS between the races ($p = 0.002$), with Blacks having the longest length of stay (7.4 d) and Native Americans with the least (5.0 d). Regarding total hospitalization charges, Asians had the highest ($127,365), whereas Native Americans had the lowest ($46,530). This difference in hospitalization charges among the races was found to be statistically significant ($p = 0.000$). Between females and males, total hospitalization charges were also significantly different ($p = 0.042$), however length of hospital stay was not ($p = 0.429$). **Conclusion:** Our study found a significant difference in in-hospital mortality, length of stay and total hospitalization charges among the different races when admitted with a principal diagnosis of acute liver failure. There was also a significant difference between females and males as regards mortality and total hospitalization charges but no difference in length of stay. The reasons for these disparities are varied and not fully defined, hence there is a need to further understand and mitigate factors which can contribute to health disparity in acute liver failure.

f 2808-C | GENDER DISPARITIES IN ALCOHOLIC LIVER DISEASE RELATED MORTALITY IN UNITED STATES FROM 1999-2020

Fariha Ilyas[1], Hassam Ali[1], Maheen Ilyas[2], Mahnoor Khalid[3], Pratik Patel[4], Alexa Giammarino[5] and Sanjaya Kumar Satapathy[6], (1)East Carolina University, (2) New York Institute of Technology, (3)Foundation University Medical College, (4)Northwell Health, Forest Hills, NY, (5)Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, (6)Zucker School of Medicine - Hofstra University

Background: Alcohol Liver Disease (ALD) remains one of the leading causes of cirrhosis and nearly half of cirrhosis-related deaths in the United States. Previously, men were more affected by ALD compared to women. However, mounting evidence suggests increasing prevalence of alcohol abuse amongst women. Women are more sensitive to adverse health effects with lesser exposure than males. Our study aims to further illustrate the gender disparity in mortality of ALD. **Methods:** We used CDC Wide-ranging Online Data for Epidemiologic Research (CDC WONDER) to access National Vital Statistics System data from 1999-2020. ALD related deaths in adults with age 25-85+ years were identified. Deaths were shown as age adjusted mortality rates (AAMR) per 100,000 population. Joinpoint regression was used to examine changes in trend, average annual percent change (AAPC) and annual percentage change (APC) in ALD related deaths, stratified by gender. **Results:** Between 1999 and 2020, 372,900 deaths

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

related to ALD. AAMR increased from 6.7/100,000 in 1999 to 12.1/100,000 in 2020, showing a significant average annual percentage change (AAPC) of 2.7% (95% CI: 2.2%-3.2%, P < 0.001) (Figure 1A). For females, AAMR increased from 2.7/100,000 in 1999 to 6.4/100,000 in 2020 (Figure 1B). The overall trend showed a significant 3.9% AAPC (95% CI: 3.2%-4.7%, P < 0.001). For males, AAMR increased from 8.8/100,000 in 1999 to 13.9/100,000 in 2020, with an AAPC of 2.1% (95% CI: 1.4%-2.8%, P < 0.001). Comparing the cohorts revealed a significant 1.9% AAPC difference (95% CI: 0.8%-2.9%, P < 0.001), indicating a more pronounced mortality increase in females. **Conclusion:** Our study examined trends in ALD related mortality from 1999 to 2020, revealing a significant increase in mortality rates, with a more substantial rise amongst females. An increasing predominance of ALD in women may prognosticate future significant increase in morbidity and mortality related to liver cirrhosis, breast cancer, cardiovascular disease, and fetal alcohol spectrum. Our study highlights the importance of understanding the changing epidemiology and addressing individual, societal, and environmental factors influencing alcohol abuse and ALD.

2809-C | HIGHER HOUSEHOLD DYSFUNCTION IN ADVERSE CHILDHOOD EXPERIENCES SCORE (ACES) ASSOCIATES WITH AN INCREASED RISK OF CIRRHOSIS IN ADULTHOOD

Kaia C. Miller[1], Alice Parish[1], Donna Niedzwiecki[1], Melissa A. Troester[2], Joellen M. Schildkraut[3], Andrew Joseph Muir[1], Cathrine Hoyo[4] and Cynthia Moylan[1], (1) Duke University, (2)University of North Carolina - Chapel Hill, (3)Emory University, (4)North Carolina State University

Background: Adverse childhood experiences (ACEs) have been linked to the development of chronic liver disease later in life. Historically, this link was driven by increased risk behaviors for viral and alcohol-related liver disease (ALD). With the rise of non-alcoholic steatohepatitis (NASH) in recent decades and its different underlying risks, we aimed to characterize the current association between ACEs and cirrhosis. **Methods:** We conducted a cross-sectional analysis of participants (pts) enrolled in the Southern Liver Health Study, a multi-site study investigating the association between environmental contaminants and liver cancer. We included two cohorts: pts with cirrhosis and healthy controls without cirrhosis aged 40-75 years enrolled between 1/1/2022 and 1/31/23. History of ACEs was collected using a validated survey with a score ranging from 0-8. Demographic information was obtained for all pts and additional medical history was obtained via chart review for pts with cirrhosis enrolled at Duke. Pt characteristics were summarized and adjusted multivariable logistic regression models were used to test the association between ACEs and cirrhosis. **Results:** 461 pts were included in the final analyses (cirrhosis, n = 187; healthy control, n = 274). Pts with cirrhosis were more likely to be older than controls (median: 61 vs. 58.5 yrs), male (46% vs. 28%), and non-Hispanic White (79% vs. 61%) (Table 1). Both cohorts reported a median of 1 ACE while more pts with cirrhosis reported e 4 ACEs than healthy controls (20% vs. 15%). NASH was the most common etiology of cirrhosis (49%), followed by ALD (24%). Cirrhosis was significantly associated with history of at least one ACE in the household dysfunction domain but not total ACE score or history of ACEs in the childhood abuse domain. Pts with cirrhosis reporting an annual household income of less than $50,000 was significantly associated with a total ACE score of e 4 (OR 3.07; 95% CI 1.35-6.97). **Conclusion:** Reporting at least one ACE relating to household dysfunction associated with a 78% higher odds of cirrhosis in adulthood. High total ACE score along with a low household income also significantly associated with cirrhosis. While we did not find an association between total ACE score and cirrhosis, we found that certain ACEs impact risk for cirrhosis more than others and that this may be impacted by other factors such as income. The high prevalence of NASH cirrhosis and different risk behaviors may explain these findings, but larger studies are needed. Future efforts should investigate whether and how ACEs differently impact the likelihood of cirrhosis and its various etiologies.

f 2810-C | IMPACT OF FAMILY INCOME-TO-POVERTY RATIO ON LONG-TERM MORTALITY OF PERSONS WITH CHRONIC LIVER DISEASE IN THE UNITED STATES, 1999 – 2018

Brian Thanh Nguyen[1], Vy H. Nguyen[2], Michael H Le[3], Linda Henry[4], Ramsey Cheung[4] and Mindie H. Nguyen[4], (1)Brown University, (2)Stanford University Medical Center, (3)Larner College of Medicine at the University of Vermont, San Jose, CA, (4)Stanford University Medical Center, Palo Alto, CA

Background: Chronic liver disease (CLD) is associated with increased morbidity and mortality. Understanding health disparity among those with CLD is imperative to develop appropriate interventions. We studied the demographics and mortality outcomes of those with CLD by socioeconomic (SES) level in the United States. **Methods**: In this retrospective study, data from NHANES from 1999-2018 linked with mortality files were used. All adults (20+ years) were included. CLD included viral hepatitis, defined by laboratory results, nonalcoholic fatty liver disease (NAFLD) by the US-FLI, and alcohol associated liver disease (ALD) by excessive alcohol consumption and liver enzymes. SES was defined as an income-to-poverty ratio of < 5 (low income) and e 5 (high income). The primary outcome was mortality. **Results**: We included a cohort of 59,204 individual's: 47,224 without CLD and 11,980 with CLD. Overall, the mean age was 49.59 ± 17.24, 57.06% male, 66.5% non-Hispanic White, 12.26% non-Hispanic Black, 17.57% Hispanic, and 3.67% Asian. Most (80.02%) CLD individual's did not have a college degree, and most were low-income (79.18%). Stratified by income-to-poverty ratio, the low-income cohort among those with CLD had a mean age of 49.09 ± 17.94, 55.17% male, 62.98% Non-Hispanic White, 13.61% Non-Hispanic Black: 13.61%, 10.59% Hispanic 10.59%, 3.37% Asian, P < 0.001), the majority did not have post-high school education (e bachelor's degree: 13.73%). In the overall cohort, 8.4% of individual's died during follow-up (n = 4,984 deaths; 4494 deaths in income-to-poverty ratio < 5 group and 490 deaths in e 5 income-to-poverty group). After adjusting for age, sex, and race and ethnicity, individual's in the low-income cohort compared to the high-income cohort were 2.01 (HR: 2.01; 95% CI: 1.79-2.26) times more likely to die, which was similar when analyzed by etiology- viral hepatitis (HR: 2.05; 95% CI: 1.31-3.24) and NAFLD (HR: 2.32; 95% CI: 1.69-3.18) but not by AFLD (HR: 1.17; 95% CI: 0.55-2.51). **Conclusion**: Individual's whose income-to-poverty ratio was < 5 were disproportionately represented among those with CLD. Outside of non-Hispanic Whites, Hispanics

carried the greater burden for NAFLD and AFLD, while non-Hispanic Blacks carried a greater burden for viral hepatitis, as did those with a lower education level and low-income women. Interventions must not only be culturally appropriate but also require attention to the potential lack of health literacy and be sex-specific.

Table 2. Characteristics of chronic liver disease patients by family income-to-poverty ratio

Characteristics	Family income-to-poverty ratio ≥ 5 (N=2,494)	Family income-to-poverty ratio < 5 (N=9,486)	P-value

2811-C | IMPACT OF SELF-REPORTED RACE AND ETHNICITY IN HOSPITALIZED PATIENTS WITH ACUTE KIDNEY INJURY AND CIRRHOSIS: RESULTS FROM THE HRS HARMONY CONSORTIUM

Paige McLean Diaz[1], Justin M. Belcher[2], Nneka Ufere[1], Eric Przybyszewski[1], Robert M Wilechansky[1], Giuseppe Cullaro[3], Kavish R. Patidar[4], Raymond T. Chung[5], Kevin R. Regner[6] and Andrew Allegretti[1], (1) Massachusetts General Hospital, (2)Yale University, New Haven, CT, (3)Columbia University Medical Center, New York, NY, (4)Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center, (5)Massachusetts General Hospital, Harvard Medical School, (6)Medical College of Wisconsin

Background: Race and ethnicity influence outcomes in patients with cirrhosis, though their impact on resource allocation and mortality in those hospitalized with acute kidney injury (AKI) is not well described. **Methods**: we performed a multicenter (15 hospitals, 11 transplant centers) retrospective cohort study of consecutive patients hospitalized with cirrhosis and AKI. Primary exposures were self-reported race and ethnicity. The primary outcome was 90-day mortality using an adjusted Fine and Grey model with competing risk of liver transplant. **Results**: 2063 patients were included. 81.1% (n = 1582) were non-Hispanic White (NHW), 8.6% (n = 178) were Hispanic, and 10.6% (n = 303) were Non-White, Non-Black (NWNB). Compared to NHW patients, Non-Hispanic Black (NHB) patients had more hypertension (69.9% vs. 57.7%) and chronic kidney disease (35.2% vs. 30.3%, p < 0.01 for both). Median MELD-Na score (26) was similar across racial and ethnic groups. Rates of HRS-AKI, peak AKI stage, intensive care unit admission, and length of stay did not differ significantly between groups. Compared to non-Hispanic patients, Hispanic patients required more dialysis (24.2% vs. 17%, p = 0.02) and had higher rates of liver transplant evaluation (12.4% vs. 5.2%, p = 0.001). Hispanic patients who died were less likely to receive palliative care consultation (23.9% vs. 42%, p < 0.001). Compared to NHW patients, NHB patients were less likely to be transferred to a liver transplant center from a community hospital (13.2% vs. 25%, p < 0.001) and less likely to be listed for liver transplantation (8.5% vs. 15.1%, p = 0.01). After adjusting for confounders, in multivariable analysis, neither ethnicity (non-Hispanic aHR 1.34 [95% CI 0.96, 1.88], p = 0.09), nor race (Black aHR 1.25 [95% CI 0.97, 1.62], p = 0.09) was associated with 90-day mortality. **Conclusion**: By race and ethnicity, there are no significant differences in 90-day mortality among hospitalized patients with AKI and cirrhosis. However, important differences in resource allocation, such as palliative care consultation rates and transfer to a liver transplant center, were identified that warrant further investigation.

Table 1: Demographics of Admitted Patients with AKI and Cirrhosis

	Overall	White	Black	Non-White/Non-Black	P-Value
n	2063	1676	176	211	
Age (years) median [IQR]	62.0 [54.0, 69.0]	62.0 [54.0, 69.0]	62.0 [55.0, 68.0]	59.0 [50.0, 66.5]	0.01

2812-C | INTERACTION BETWEEN RACE AND HEALTH INSURANCE STATUS IS ASSOCIATED WITH CRITICAL HEALTH DISPARITIES IN HEPATOCELLULAR CARCINOMA OUTCOMES

Sirisha Gaddipati, Leo S. Kleyman, Daniela Prieto Bello, Vijay Mehta, Stephanie M. Castañeda, Gloria E. Figueroa and Patricia D. Jones, University of Miami Miller School of Medicine

Background: Critical disparities exist in hepatocellular carcinoma (HCC) outcomes; Black race and insurance type are associated with differences in presentation, treatment, and survival. Inequities between private and government insurance may exacerbate racial disparities. Most studies examine insurance type *en bloc* despite differences between traditional Medicare (TM) and Medicare Advantage (MA). Our study explored the association of race/ethnicity and insurance on diagnosis, treatment, and survival in diverse patients with HCC. **Methods:** Since 2018, patients with HCC from the University of Miami and Jackson Memorial Hospitals have been enrolled into an observational longitudinal cohort. We performed chart review from electronic medical records to determine and categorize insurance type at diagnosis. We used descriptive statistics for demographics and disease-specific characteristics, and examined associations between race, insurance, and treatment outcomes using Pearson's chi-squared and Kruskal-Wallis rank sum tests. **Results:** The sample consisted of 872 patients and was 11.3% Black, 32.5% White, 51.5% Latino, 3.1% Asian, and 1.8% other. Median age at cancer diagnosis was 64 years and 74.9% were male. Individual's with private insurance or Medicare were significantly more likely to receive treatment compared to those with Medicaid or without insurance, $p < 0.001$. See Table 1. When stratified by Medicare type, 80.8% of TM patients were treated compared to 71.1% of MA patients, $p < 0.05$. Median survival was highest in Medicare patients (641.5 d) compared to all other insurance types, $p = 0.002$. Median survival was higher in TM patients (783 d) compared to MA patients (405 d), $p < 0.001$. Only 51% of Black patients received treatment compared to 81% of White, 75.2% of Latino, and 92.6% of Asian patients. Black patients were more likely to have Medicaid, especially managed-care Medicaid, and MA. Only 50% of Black patients with Medicare received treatment compared to 83.5% of White, 78.9% of Latino, and 100% of Asian patients with Medicare, $p < 0.001$. Even at early-stage diagnosis, Black patients were least likely to receive treatment, $p = 0.03$. **Conclusion:** Despite having insurance, Black patients have less access to HCC treatment compared to White, Latino and Asian patients. Insurance type is remarkably important to HCC outcomes. Efforts to educate communities on insurance coverage limitations, assess managed care Medicare and Medicaid plan quality, and advocate for coverage expansion are profoundly needed to improve HCC disparities.

Table 1: HCC outcomes (stage at time of diagnosis, receipt of treatment, and survival) based on health insurance status at diagnosis and race.

f 2813-C | NEIGHBORHOOD DEPRIVATION INDEX IS ASSOCIATED WITH INCREASED MEDICATION LEVEL VARIABILITY INDEX AMONG ADULT LIVER TRANSPLANT RECIPIENTS AT A SINGLE CENTER

Laila Fozouni[1], Sharad Wadhwani[1], Jennifer C. Lai[2] and Giuseppe Cullaro[1], (1)University of California, San Francisco, (2)University of California-San Francisco, San Francisco, CA

Background: The neighborhood deprivation index (NDI) measures one's neighborhood socioeconomic environment and predicts health outcomes among liver transplant recipients. Higher medication level variability index (MLVI), a biomarker of immunosuppression nonadherence, is associated with cellular rejection. We evaluated the relationship between neighborhood deprivation and MLVI. **Methods:** We included adult liver transplant (LT) recipients at a single center with > 1 year follow up. NDI was calculated using a validated composite measure, including 6 domains of deprivation. The NDI ranges from (0,1) and is available at the census tract level; patients' addresses were geocoded to identify their NDI. MLVI was defined as the standard deviation of e 3 sequential tacrolimus trough levels, dichotomized at MLVI > 2, based on prior studies. We used univariable and multivariable logistic regression to associate MVLI and NDI; NDI was transformed to a scale of 0-10 in regression models. **Results:** A total of 1480 LT recipients were included; 36% were female, median age was 65, and 27% had Hepatitis C. 28 participants experienced death within 1 year post-LT and 83 within 3 years; 3 participants required re-transplantation. When stratified by neighborhood deprivation (high, medium, and low), patients with high deprivation indexes were more likely to speak Spanish (13% vs 4.5% and 2.4%, $p < 0.001$), to be hospitalized at 1 year (26%, vs 19% and 24%, $p = 0.026$), and 3 years (41% vs 30% and 34%, $p = 0.009$) post-LT. Participants with high deprivation indexes were more likely to have high MLVI at 3 years (69% vs 61% and 57%, $p = 0.001$) post-LT. In univariable logistic regression, each 1 point increase in NDI was associated with a 1.2 times higher odds of MLVI > 2 at 3 years (95% CI 1.1 1.3). After adjusting for language, race, and relationship status, this association remained significant: aOR 1.2, 95%CI 1.1 - 1.3. **Conclusion:** After adjusting for language, race, and relationship status, neighborhood deprivation was significantly associated with increased MLVI at 3 years post LT—an effect that was independent of self-identified race. Future studies should investigate the factors of where patients live, eat, and work that drive poor medication adherence.

Characteristics of 1480 Patients Hospitalized by Deprivation Index

Characteristic	Low Deprivation, N = 492[1]	Medium Deprivation, N = 488[1]	High Deprivation, N = 500[1]	p-value[2]

2814-C | PATIENT PERSPECTIVES ON LIVER TRANSPLANT EVALUATION: A QUALITATIVE STUDY

Alexandra Strauss[1], Janetta Brundage[1], Carolyn N. Sidoti[2], Vedant S. Jain[3], Ahmet Gürakar[1], Katlyn Mohr[1], Macey L. Levan[2], Dorry L. Segev[4], James P. Hamilton[5] and Hannah C. Sung[1], (1)Johns Hopkins University, (2) New York University, (3)Carle Illinois College of Medicine, (4)NYU Langone Health, (5)Johns Hopkins Medicine, Baltimore, MD

Background: Completing the liver transplant (LT) evaluation process requires patients to navigate logistical, financial, and other factors in a timely manner. This complexity is compounded by high-stakes interactions with many healthcare providers. We aimed to examine patients' perceptions and experiences during LT evaluation and characterize key supports and barriers for patients during evaluation. **Methods:** We performed a single center qualitative study with patients actively undergoing LT evaluation from 3/1/2021 and 5/26/2021. We thematically analyzed semi-structured interviews (n = 14). **Results:** We interviewed 7 (50%) women, and 3 (21%) participants that self-identified as either Black, Hispanic, or American Indian/Alaskan Native. Our analysis generated 8 themes within 5 thematic categories related to patient engagement (i.e., patient involvement/activation in their healthcare; Figure) in the LT evaluation process: 1) psychological impact of evaluation on participants' lives, such as feeling overwhelmed and making sense of needing a transplant; 2) information received during evaluation, including identifying relevant information and using different methods of finding information; 3) prior medical experience of the participant, specifically applying prior experiences to LT evaluation; 4) communication between participants and transplant providers, such as difficulty in understanding provider roles and appreciating provider demonstrations of empathy; and 5) support system of the participants, particularly relying on loved ones who take on multiple roles related to transportation, scheduling, or advocacy. **Conclusion:** Participants described psychological, informational, and interpersonal supports and barriers related to patient engagement in LT evaluation. Insights from this work can inform practice improvements and targeted interventions for reducing barriers and increasing patient engagement during the LT evaluation process to improve completion of evaluation and timeliness of listing.

f 2815-C | PATIENT SATISFACTION WITH TELEHEALTH VISITS IN RURAL COMPARED TO URBAN COMMUNITIES

Corrin Hepburn[1], Jonah N. Rubin[1], Karolina Krawczyk[1], Scott J. Cotler[2], Steven J. Scaglione[3] and Cara Joyce[1], (1)Loyola University Medical Center, Chicago, IL, (2)

Loyola University Chicago, (3)Loyola University Health System

Background: Recent studies performed in urban communities with access to technology suggest high patient satisfaction with telehealth. While virtual visits can increase the reach of clinical practice, technological barriers may reduce patient satisfaction in rural communities. Our aim was to compare preference for telehealth between hepatology patients living in urban and rural areas. **Methods:** A telephone survey was administered to hepatology patients who had a telehealth visit at our center from 3/20-3/21. Patient characteristics and survey responses were compared by urban and rural location as defined by the census tract based on zip code using Student's T-tests for continuous variables and Chi-Square or Fisher's exact test for nominal variables. Adjusted odds ratios were estimated from multivariable logistic regression models. **Results:** 164 out of 400 patients completed the survey (41%) with a mean age of 64 ± 10 years, 54% male and 75% non-Hispanic white. The most common etiologies of liver disease included alcohol (32%), non-alcoholic steatohepatitis (30%) and hepatitis C (22%). Compared to urban patients, rural patients had twice the transportation time to clinic (59 vs 30 minutes, $p < 0.001$), and were more likely to cancel due to transportation issues (46% vs 13%, $P < 0.001$). Rural patients also reported less proficiency with technology including more technical difficulties, such as less frequent daily computer use (29% vs 67%, $P < 0.001$), logging on to the portal or accessing the camera/microphone (75% vs 25%, $P < 0.001$) and less comfort with their devices (54% vs 9%, $P < 0.001$). (Table 1) Compared to patients who used computers for telehealth, smartphone use (aOR: 6.47, 95% CI: 2.40-19.3) and tablet use for telehealth (aOR: 5.23, 95% CI: 1.87-16.1) were associated with higher likelihood of telehealth visit preference. (Table 2). Overall, similar proportions of rural and urban patients were willing to have telehealth visits in the future (79% vs 86%, $p = 0.26$). However, rural patients were less likely to prefer telehealth compared to urban patients (aOR: 5.20, 95% CI: 2.15-13.7), and were more satisfied with in person visits than urban patients (79.2% vs. 37.9% $P < 0.001$). **Conclusion:** Rural patients reported more technical challenges to telehealth than urban patients. Rural patients favored in person hepatology visits despite having higher drive time and more transportation issues. Research is needed to improve telehealth delivery and satisfaction for rural patients.

Table 1 Bivariate Analysis

Region	Rural, N = 48	Urban, N = 116	p-value

2816-C | PATIENTS WITH HEPATITIS B INFECTION ARE HIGHLY REPRESENTED IN DEPRIVED AREAS, LESS ENGAGED WITH HEALTHCARE AND CAN BE RAPIDLY IDENTIFIED USING A NOVEL CASE-FINDING DATABASE TO HELP ACHIEVE THE CHRONIC HEPATITIS B ELIMINATION 2030 GOAL

Background: Hepatitis B virus (HBV) is a global health problem with an estimated 200,000 individual's with chronic HBV in the UK, 95% of which are in immigrant populations. The goal of WHO HBV elimination by 2030 is challenging even in the UK partly because HBV is commoner in deprived areas, and a failure in investigation and referral pathways. The NHS England 'Core20Plus5' programme gives a mandate for tackling inequalities. 'Core20' refers to individual's in the 20% most deprived areas defined by the Index of Multiple Deprivation (IMD deciles 1 & 2). We tested the hypothesis that our novel case-finding database developed in Somerset (covering 0.6 million population) could identify HBV infected patients and provide means to target those in deprived areas. **Methods**: We configured our case-finding database to identify adult patients with HBV infection (positive HBV surface antigen). Within the tool, searches were stratified by IMD decile. Patients electronic records were reviewed to categorise as follows: 1) no data, 2) out of the area, 3) never referred, 4) never engaged following referral, 5) lost to follow-up (patient disengagement or system issues) and 6) actively followed or treated (chronic HBV or followed to surface antigen loss). Individual's in deprived areas data (IMD deciles 1 & 2) were compared to control (IMD 3 – 10). **Results**: Correcting for the known lower immigrant population we predicted 900 chronic HBV patients in Somerset (estimated 0.45% prevalence within the UK). The case finding database identified 302 HBV+ve patients. A deprivation score was available for 98.8% of the population. 9% of the whole Somerset population came from deprived areas compared to 24% of men and 12% of women with HBV ($P < 0.001$). Overall, 38% of patients with HBV were either not referred, didn't engage or subsequently lost to follow-up, and 97 patients were identified for further investigation/recall. There was a trend towards worse treatment rates in IMD 1 & 2 with 48% men and 47% women not appropriately engaged (Fig 1). **Conclusion**: HBV continues to be underdiagnosed with only 1/3 of expected patients identified in Somerset. This is likely to be multifactorial, including lack of screening of patients with abnormal LFTs and other risk factors. HBV is more common in deprived areas and our case finding database will now be used to target patients for treatment. In addition, it will be used to target individual's with persistently abnormal LFTs not previously tested for HBV.

Fig 1: Number of patients by referral & treatment category for deprived/not deprived; male/female

Background: Access to care in cirrhosis is based on insurance in most cases, which could be private (Pvt) or public based on individual centers/countries. However, the role of specific types of insurance on outcomes in a global cohort of cirrhosis inpts is unclear. **Methods**: The CLEARED Consortium enrolled cirrhosis inpts without COVID-19 who were followed during the admission & 30 days post-discharge. To ensure equity only 50 pts/site were allowed. Demographics, cirrhosis details, admission labs/drugds & hospital course were recorded. Outcomes were mortality & liver transplant (LT) in-hospital & 30 days post-discharge. Centers with predominantly public vs Pvt insurance were compared. Multi-variable analysis for LT & mortality was performed. **Results**: 4238 pts from 104 centers across 6 continents were included. 3013 (71%) were public; rest Pvt. Pvt insurance pts (USA, India, & centers in Latin America, Africa & Asia) were younger, more likely to have prior hospitalizations, HRS, refractory ascites, HE, AKI and more likely NASH, alcohol but lower viral hepatitis cirrhosis etiologies (Fig A). Pvt pts had higher MELD, were more likely to be on NSBB, SBBPr, rifaximin, lactulose & diuretics & had higher MELD score. These pts had ↓liver/infection-related & ↑liver-unrelated admissions. Among liver-related, pvt insurance pts had more HE & AKI/electrolyte changes but lower anasarca & HBV flares vs public. Outcomes: Pvt insurance pts had lower length of stay (LOS), ↑ ICU, & in-hospital AKI. Similar inpt mortality but higher inpt LT in Pvt was seen. Discharge: Pvt pts were discharged at a higher MELD, had a higher readmission and lower lost to follow-up rate. ↑LT rate & ↓mortality at 30-days was seen in Pvt pts (Fig B). Multivariable analysis: *30D mortality* was ↓with Pvt vs public(OR 0.45, $p < 0.0001$), alcohol etiology (0.70,$p = 0.004$), LT listed (0.45, $p < 0.0001$) & HBV antivirals (0.67,$p = 0.02$) & ↑with admission infections (1.93,$p < 0.001$), ICU need(4.18, $p < 0.0001$), & high discharge MELD-Na (1.21, $p < 0.001$). *30D LT* conversely was ↑in Pvt vs public (OR 2.1, $p < 0.001$), LT listed (11.0,$p < 0.001$), liver-related admission (2.33,$p = 0.02$),lactulose (2.1, $p < 0.001$),ICU transfer(4.76,$p < 0.001$) & high discharge MELD-Na (1.04,$p < 0.001$) & ↓with admission infections(0.53,$p = 0.003$). **Conclusion**: In this large multi-national consortium, cirrhosis pts with access to Pvt insurance had a similar inpt mortality despite more advanced cirrhosis on admission versus centers with mostly public insurance. Pvt insurance was linked to ↓ LOS, & likely resultant ↑30-day readmissions vs public insurance. However, more pts with Pvt insurance were listed for LT, & got inpt & 30-days post-discharge lT. This translated into lower mortality independent of demographics, medications, & in-hospital course. Systematic differences in Pvt versus public insurance, especially related to LT access, should be accounted for in cirrhosis outcomes analysis.

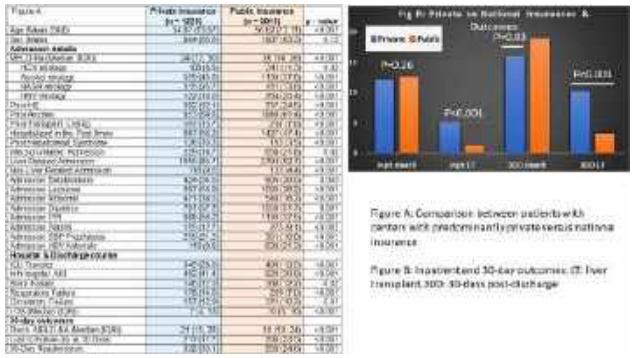

Figure A: Comparison between patients with centers with predominantly private versus national insurance

Figure B: Inpatient and 30-day outcomes: (f: liver transplant,30D: 30-days post-discharge

2818-C | RACIAL DISPARITIES IN ADHERENCE TO FOLLOW-UP AND ACHIEVEMENT OF SUSTAINED VIROLOGIC RESPONSE IN PATIENTS INFECTED WITH HEPATITIS C: A TERTIARY CENTER STUDY AND OPPORTUNITIES FOR FURTHER INVESTIGATION

Clive Jude Miranda[1], Alexander Mark Carlson[2], Slah Khan[2], Farhan Azad[2] and Naren Srinath Nallapeta[2], (1) University at Buffalo, Buffalo, NY, (2)University at Buffalo

Background: Hepatitis C virus (HCV) is a worldwide public health and economic burden and is a leading cause of hepatocellular carcinoma, cirrhosis, and end stage liver disease. Despite the availability of efficacious and safe antiviral therapies, significant barriers still exist to achieving global eradication of HCV. Racial disparities exist among HCV treatment rates and adherence to follow-up. In the United States, most HCV patients are non-Hispanic Caucasians but roughly 3% of the black population is infected with HCV. Factors such as lack of access to healthcare, limited financial resources, and language barriers can all contribute to low treatment adherence rates among racial minorities. In our HCV tertiary care center, we aim to investigate race and its role in patient adherence to follow-up and achievement of sustained virologic response (SVR). **Methods:** A retrospective review of our institution's database was conducted from 2014 to 2022 for patients treated for HCV. Data collected included age, gender, race, and psychiatric comorbidities. Multiple logistic regression models were created to assess for statistical significance between demographic variables. Races were categorized as white, black (African/African American), Hispanic, and other. **Results:** A total of 1790 patients (66% male) between ages 20-89 being treated for HCV in our institution during 2014-2022 were identified. Racial breakdowns were 56% white, 31% black, 9% Hispanic, and 4% other. 1373 of these patients (77%) were compliant with follow-up, with a 95% SVR achievement rate observed in this cohort with no differences in race, age, sex, or language spoken. The remaining 417 patients (23%) were deemed non-compliant. Compliance was defined as being seen in our tertiary center over the past year or having achieved SVR. Non-compliance was defined as being lost to follow-up or not being seen in our institution over the past year. Of the non-compliant patients, racial breakdowns were 63% white, 21% black, and 8% Hispanic, and 8% other (Figure 1). An overwhelming majority of these patients were of poor

socioeconomic status ($p < 0.001$) and further investigation revealed that many of them also missed several other healthcare appointments, had a history of medical noncompliance, and had difficulties with both transportation and telephone accessibility. Concurrent treatment for opiate use disorder and the presence of psychiatric disorders were also observed in this noncompliant patient population. This demographic was also 1.7 times more likely to have a psychiatric condition [95% CI 1.32-2.06, $p < 0.01$]. **Conclusion:** Race can play a role in follow-up and SVR achievement in HCV patients. However, factors such as psychiatric comorbidities, concurrent drug use, and socioeconomic status may actually act as effect modifiers or prove to be confounding variables. Further investigation is needed in order to pinpoint disparities in HCV treatment among different racial groups.

2819-C | RACIAL DISPARITIES IN THE OUTCOMES OF HEPATORENAL SYNDROME HOSPITALIZATION: A NATIONAL POPULATION-BASED STUDY

Chukwunonso Ezeani, Baton Rouge General Medical Center, Baton Rouge, LA, Chidiebele Omaliko, One Brooklyn Health - Brookdale University Hospital Medical Center, Oghenefejiro Ogwor, St Peter University Hospital, New Brunswick, NJ, Favour Markson, Lincoln Medical Center, Ogochukwu Ugochukw, Our Lady of the Lake Childrens Hospital, Chidiebube Jeremiah Ugwu, East Tennessee State University, Omotola Oredipe, Cook County Health and Ayobami Olafimihan, John H. Stroger Jr. Hospital of Cook County, Chicago, IL

Background: There are scarce data describing the outcomes of hospitalized patients with hepatorenal syndrome (HRS) stratified by race. In this retrospective cohort study, we evaluated the differences in outcomes, stratified by race, among patients hospitalized with a diagnosis of HRS. **Methods:** Data was obtained from the 2016 to 2020 National Inpatient Sample (NIS) database. Our primary outcome was inpatient mortality while secondary outcomes were hospital length of stay (LOS), total hospital charges (TOTCHG). We conducted the analysis using the STATA software. Multivariate linear and logistic regression analysis was used to adjust for confounders. **Results:** There were 223,590 hospitalizations with a principal or secondary diagnosis of HRS, with blacks having the majority (67%) and the least being native Americans (1.9%). Among patients who were managed in the hospital for HRS, blacks had a 20% increase ($p = < 0.01$), Asians had a 25% increase and natives had an 18% increase in the odds of mortality compared to whites, while adjusting for age, hospital bed size and region ($p = 0.01$). When secondary outcomes were assessed, there was significant difference in LOS between the races ($p = < 0.01$) with blacks on average having 0.96 day increase in hospital stay, and Hispanics having a 0.6 day increase compared to white. The difference in length of stay in Asians and natives was not significant ($p = 0.055$ & 0.374 respectively). When total hospitalization charges were analyzed, blacks, Hispanics, and Asians had increased charges while natives had lower charges and the difference was significant ($p = 0.000$) **Conclusion:** Our study revealed a significant difference among different races who had HRS during hospitalization, with regards to inpatient mortality, length of stay and total hospital charges. While the reasons for the reasons for these differences are varied, and not fully defined, there is need for concerted effort to mitigate factors known to contribute to health inequality in liver diseases including socioeconomic status, access to health care, environmental and societal factors as well as implicit bias.

Background: Globally, the COVID-19 pandemic increased the incidence and severity of alcohol-associated liver disease (ALD). Racial and social inequalities were magnified worldwide, including in Brazil, worsening health outcomes in minorities. We aim to determine the timely impact of the COVID-19 pandemic on ALD hospitalization rates for different ethnic groups in Brazil. **Methods:** We analyzed ALD related hospitalizations from Brazil's public health database from May 2017 to December 2022. Interrupted time series regression was used to model the association between the pandemic's emergence and monthly total ALD related hospitalizations and monthly total ALD related hospitalizations by four ethnic subgroups: Black, Mixed Ethnicity, Black and Mixed Ethnicity combined, and Others (White and Unknown Ethnicity). We obtained 34 data points before COVID-19 and 34 data points afterwards. **Results:** There were 84,787 ALD related hospitalizations during the study period. The mean age of hospitalized patients was 54 years, and 83.6% were male. The mean length of hospital stay was 8.6 days. After March 2020, at the start of the COVID-19 pandemic, there was a significant increase in ALD monthly hospitalization rates for the total population (0.065, 95% CI = 0.045 to 0.085, $p < 0.01$), Black population (0.0028, 95% CI = 0.006 to 0.050, $p < 0.05$), Mixed Ethnicity population (0.077, 95% CI = 0.063 to 0.090, $p < 0.01$), and for Mixed Ethnicity + Black population (0.066, 95% CI = 0.053 to 0.079, $p < 0.01$). The only subgroup that did not show a significant increase in hospitalizations was the Others subgroup population (0.059, 95% CI = -0,014 to 0.133, $p > 0.1$). The in-hospital mortality rate was 19.4% among the total population, which was evenly distributed among ethnicities, the rates for each being Black 19.49%, Mixed Ethnicity 18.80%, White 20.20% and Unknown Ethnicity 18.97%. **Conclusion:** The COVID-19 pandemic has led to increases in ALD hospitalizations. The rise in ALD hospitalizations was only significant in the Black and Mixed Ethnic, the poorest subpopulations in Brazil. This study aligns with existing literature suggesting the pandemic has accelerated health disparities and outcomes. Further studies are required to understand the impact of the pandemic on social, racial, and healthcare inequalities.

2821-C | SEX OR INDICATION: DIFFERENCES IN LT ACCESS IN MEN AND WOMEN UNDERGOING LTE FOR ACUTE ALCOHOL ASSOCIATED HEPATITIS VS CHRONIC ALCOHOL LIVER DISEASE

Katherine M. Cooper[1], Alessandro Colletta[2] and Deepika Devuni[1], (1)UMass Chan Medical School, (2) UMass Chan Medical School, Worcester, MA

Background: Women have with liver disease often have poorer outcomes than men including increased death with acute on chronic liver failure and decreased access to liver transplant. However, few studies have compared outcomes in men versus women with acute alcohol associated hepatitis (AAH). We sought to evaluate sex differences in outcomes in patients with AAH compared to alcohol associated cirrhosis being evaluated with early sobriety (< 6 mos). We hypothesized that women would have worse outcomes than men and that the relative disparity in LT rate would persist in each group as the MELD scoring system is used for allocation in both sets of patients. **Methods:** Patients completing LTE with early sobriety between 2018 and 2021 were included. Patients were categorized by chronicity of ALD: cirrhosis from ALD (cALD) vs. alcohol associated hepatitis (aALD). To identify sex differences in outcomes of AAH, we compared variables in men (M) vs. women (W) with aALD and cALD, respectively. We also compared variables within sex to identify the effect of disease chronicity on outcomes in men and women. **Results:** 162 patients were identified (67 women, 95 men) of which 33% were being evaluated with AAH. A higher percentage of women were evaluated for AAH compared to men, though not to a significant degree (39% vs. 28%, $p = 0.16$). Use of steroids for aALD was similar in men and women (73% vs. 82%, $p = 0.47$). In the aALD cohort, there were no sex differences in MELD score (34 W vs. 36M), LT rate (46% W vs. 56% M, $p = 0.49$) or death at 1 year (29% W vs. 16% M, $p = 0.24$). In the cALD cohort, MELD score and 1 year death rate did not differ by sex (29% W vs. 20% M, $p = 0.29$) but women were transplanted less than men (24% W vs.44% M, $p = 0.04$). Renal replacement therapy (RRT) at the time of LTE was the most common in women with aALD, though this was not statistically more than men. There were no sex differences in post-LT renal replacement therapy for aALD at 6 months ($p = 0.17$) or 12 months ($p = 0.17$)) or for cALD at 6 months ($p = 0.95$) or 12 months ($p = 0.85$). In women, aALD did not affect risk of death but was

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

associated with 250% increased odds of LT compared to cALD. On multivariable logistic regression controlling for age and MELD, sex was a statistically significant predictor of transplant the cALD group ($p = 0.03$) but not in the aALD group ($p = 0.74$). **Conclusion:** In contrast to our hypothesis, LT outcomes for men and women with AAH were similar. We also observed reduced sex-based disparity in LT in the aALD group relative to cALD despite similar MELD scores between sexes with aALD, though these MELD scores were notably higher than the cALD group. Efforts to understand sex-based disparities in LT and improve access for women may be augmented by evaluating the AAH LT pathway and studying nationwide trends in AAH may inform practices to improve outcomes in women.

f 2822-C | SOCIODEMOGRAPHIC DISPARITIES AND LIVER DISEASE IN SARCOPENIC PATIENTS

Camille A. Kezer[1], Puru Rattan[2], Ryan Lennon[1], Blake Kassmeyer[1], Patrick S. Kamath[3], Vijay Shah[4] and Douglas A. Simonetto[4], (1)Mayo Clinic, (2)Mayo Clinic - Rochester, (3)Mayo Clinic, Rochester, MN, (4)Mayo Clinic Rochester, Rochester, MN

Background: Sarcopenia, a disease of low muscle mass, is common in patients with liver disease and is associated with poor outcomes. Treatment of sarcopenia involves a multi-disciplinary approach of nutrition and exercise. There are many sociodemographic, behavioral, and medical aspects that have been associated with sarcopenia, however these factors have not been fully investigated in patients with liver disease. Aim: To determine demographic and socioeconomic associations in the development of sarcopenia in patients with liver disease. **Methods:** A cohort of adults from the National Health and Nutrition Examination Survey (NHANES) 1999-2006 was analyzed. Subjects were classified as having liver disease based on amino-transferase levels as previously described. Sarcopenia was defined using appendicular lean mass (obtained by Dual-energy X-ray Absorptiometry, DEXA) adjusted for body mass index (BMI). Due to missing and invalid DEXA data, NHANES employed multiple-imputation methodology to provide complete and representative data. All analyses were conducted separately on each multiple imputation data set and combined via Rubin's rules. *P*-values for group comparisons were calculated by testing logistic regression parameter estimates. Cox proportional hazards regression was used for mortality analysis with mortality data available until 2015. **Results:** Of 16,072 subjects, 8,734 had liver disease and 807 subjects with liver disease had sarcopenia. Sarcopenia (HR 1.36), liver disease secondary to alcohol (HR 1.24) and viral hepatitis (HR 1.75), male sex (HR 1.54), age (HR 1.08), household income < 75 K (HR 1.63-1.99), and all levels of education less than a college degree (HR 1.60-2.13) were associated with increased mortality. Liver disease of other causes was associated with reduced mortality (HR 0.83). In a multivariate composite model, the following factors were associated with sarcopenia: Non-alcoholic fatty liver disease (NAFLD) (OR 1.68), male sex (OR 1.24), age (OR 1.05), Mexican American race (OR 3.03), other Hispanic race (OR 1.91), race other than White (OR 1.50), household income < 75 K (OR 1.57-1.72), and levels of education less than a college degree (OR 1.38-1.97). Black patients had less sarcopenia compared to non-Hispanic White patients (OR 0.25). **Conclusion:** There are multiple sociodemographic disparities in the development of sarcopenia. Patients with NAFLD are at higher risk of sarcopenia than patients with other etiologies of liver disease.

2823-C | THE COVID-19 PANDEMIC WORSENED DELAYS FOR HISPANIC PATIENTS REFERRED FOR LIVER TRANSPLANT

Ritodhi Chatterjee[1], Karthik Goli[1], Jeong Woo Han[1], Chun-Sing Huang[1], Nicole E. Rich[2], Ruben Hernaez[1], John A. Goss[1], Fasiha Kanwal[1], George Cholankeril[1] and Tzu-Hao (Howard) Lee[1], (1)Baylor College of Medicine, (2)University of Texas Southwestern Medical Center

Background: The pathway to liver transplant (LT) is a complex, stepwise process involving referral, evaluation, and waitlisting. Prior studies have identified disparities post-listing, but there is a paucity of data on inequities further upstream in the LT cascade. Our aim was to identify disparities underlying the LT referral and evaluation phases in relation to the COVID-19 pandemic. **Methods:** We performed a retrospective cohort study of adult patients referred for LT at a large transplant center during periods defined as pre-COVID (6/1/2018-5/31/2019) and COVID (6/1/2020-5/31/2021) eras. Referral phase (RP) was defined as time from LT referral to start of evaluation, and evaluation phase (EP) as time from evaluation start to waitlisting. Factors associated with delays in RP were identified using a Cox proportional hazard model; factors associated with delays in EP were identified using a Fine-Gray hazard model, with clinical recovery and drop out treated as competing risks. **Results:** In total, 712 patients were referred for LT during the study period (358 pre-COVID, 354 COVID). 61% were men, and the cohort was racially and ethnically diverse (52% White, 32% Hispanic, 10% Black). Of those referred, 544 (76%) started evaluation and 329 (46%) were ultimately waitlisted. Referral: Hispanic patients had longer RP compared to White patients (median 28.0 vs 22.5 d) after adjusting for covariates listed in Table 1 (HR 0.72, 95% CI 0.57–0.91). Presence of cardiometabolic risk factors was also associated with longer RP. Female sex, inpatient referral, MELD-Na > 25, and education level less than high school correlated with shorter RP (Table 1). Evaluation: Adjusting for covariates, Hispanic patients also had longer EP versus White patients (median 27.0 vs 21.0 d) in the COVID era (HR 0.58, 95% CI 0.36–0.93), but not in the pre-COVID era. Patients with college degrees and hepatocellular carcinoma had shorter EP in the COVID era only. Older age was associated with longer EP in both eras. **Conclusion:** Disparities in time to LT evaluation and waitlisting were exacerbated by the COVID-19 pandemic. Hispanic patients experienced longer wait time to start LT evaluation following referral compared to White counterparts, and also took longer to be waitlisted during COVID. Our data call for heightened monitoring of steps in the LT referral and evaluation process, and interventions are needed to ensure equitable and timely access to LT for underrepresented minority populations.

Table 1: Multivariable analysis of associations between patient demographics and time spent in referral and evaluation phases of liver transplant process

f 2824-C | TRANSPORTATION BARRIERS MAY IMPACT EVALUATION TIME AMONG LIVER TRANSPLANT CANDIDATES: A PROSPECTIVE STUDY

Angela Chahine[1], Christopher Wong[1], Aaron Ahearn[1] and Kali Zhou[2], (1)University of Southern California, (2) University of Southern California, Los Angeles, CA

Background: Access to transportation is a vital component of the transplantation process, yet transportation barriers are not well characterized in the adult liver transplant (LT) population. We examined sociodemographic qualities of LT candidates with transportation barriers and impact on time to completion of LT evaluation. **Methods:** Consecutive patients at Keck

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

USC Liver Transplant clinic at initial LT visit were approached to complete a survey between 11/1/2021-12/19/22. The 40-item multi-lingual survey assessed: 1) access to transportation, 2) transportation barriers, 3) technology access, and 4) social determinants of health (SDOH). We defined transportation barrier as reporting one of the following: unreliable transportation, some/a lot of trouble getting to clinic visits, or missing visit due to transportation. Sociodemographic differences between those with and without barriers were described. We then examined the relationship between presence of transportation barrier and time to completion of LT evaluation (=referral date to selection committee date) using Kaplan-Meier analysis. **Results:** Of 219 patients surveyed, 51 (23.3%) reported transportation barriers (41.7% surveyed in Spanish vs 14.7% in English). 92.7% owned a car with the vast majority either driving oneself or being driven to clinic visits. 5.9%, 4.1%, and 5.9% reported using public transport, rideshares/taxis, and medical transport, respectively. Few (<5%) reported the cost of gas or parking as significant barriers; 31.9% reported their usual driver sometimes not being available, 88.9% of the time due to work. Those with transportation barriers (vs none) had more negative SDOH indicators ($p < 0.05$): no car (13.7% vs 4.2%), unsteady living situation (28.0% vs 10.2%), food insecurity (54.9% vs 15.6%), financial stress (62.7% vs 41.7%), high school education (71.4% vs 53.2%), not employed (91.8% vs 75.6%), and non-private insurance (86.0% vs 66.5%). They were also more likely to be foreign-born (82.4% vs 53.6%), non-citizens (58.8% vs 27.3%), and not married (58.0% vs 39.2%) ($p < 0.05$). There was a trend towards longer time to LT evaluation completion among those with transportation barriers (median 151 d vs 134 d; see Figure). **Conclusion:** In this prospective cohort of LT candidates, nearly 1 in 4 reported experiencing transportation barriers, which may result in delays in completion of their evaluation. Providing transportation support may be one strategy to improve LT outcomes.

2825-C | TRENDS IN HEPATITIS C-RELATED MORTALITY AMONG ADULTS IN THE UNITED STATES FROM 1999-2020

Yousaf Zafar[1], Omar Rizwan Sheikh[1], Adnan Zafar[2], Arsalan Zafar Iqbal[1], Isaac Dodd[1], Laila Manzoor[1] and Jan Petrasek[3], (1)University of Mississippi Medical Center, (2)Magnolia Regional Heath Center, (3)Texas Liver Institite

Background: Hepatitis C Virus (HCV) is the most common blood-borne infection in the United States, and a leading cause of liver disease, transplant, and mortality. When curative direct-acting antiviral medications for hepatitis C became available in 2014, hepatitis C elimination became a realistic goal. The CDC goal is to reduce HCV-related mortality by 65% (from 2015) by 2030. **Methods:** We sought to identify temporal, geographic, age and sex-based mortality trends of HCV-related deaths in the US over the past 2 decades. This population-based study utilized the CDC WONDER database to identify hepatis C-related deaths occurring within the US between 1999 and 2020. HCV-related crude and age-adjusted mortality rates (CMRs and AAMRs, respectively) were determined. Join point regression was used to determine trends in CMR/AAMR using annual percent change (APC) in the overall sample in addition to demographic (sex, race/ethnicity, age) and geographic (rural/urban, statewide) subgroups. **Results:** Between 1999 and 2020, a total of 324,008 deaths related to HCV were reported. The overall AAMR increased from 2.9/100,000 in 1999 to 4.3/100,000 in 2020. Although the AAMR have declined since 2014, Men remain 2.5 times more predisposed to HCV related deaths compared to females. African Americans remain more predisposed than other ethnic groups and non-metro areas more than urban setting despite trends showing an overall improvement in the mortality rates from HCV related deaths. District of Colombia, Oregon, California, and Oklahoma largely affected. **Conclusion:** Hepatitis C-related CMR/AAMR were observed more among men, African Americans, and those from rural areas although trends have been decreasing in all groups likely due to HCV therapy. Discerning the reasons for the differences in Hepatitis C-related mortality among these groups and examining the impact of the social determinants of heath may represent important opportunities to enhance care.

2826-C | TRENDS IN LIVER DISEASE MORTALITY AMONG AFRICAN AMERICAN AND WHITE POPULATIONS IN THE UNITED STATES, 1999-2020

Yuting Huang[1], Yichen Wang[2] and Liu Yang[1], (1)Mayo Clinic Florida, Ponte Vedra Beach, FL, (2)Trinity Health of New England

Background: Liver disease is a significant public health concern in the United States, with notable disparities in mortality rates between different racial groups. This study aims to analyze the trends in liver disease mortality among African American and White populations between 1999 and 2020, and to explore the differences in mortality patterns by age, census region, and urbanization levels. **Methods:** We utilized the CDC WONDER database to ascertain age-adjusted liver-related mortality rates in Black and White Americans from 1999 to 2020. Liver-related mortality was defined as cases where the cause of death was liver disease. Linear regression analysis was employed to calculate the annual percent change (APC). Age-adjusted absolute rate difference and rate ratio were computed by subtracting and dividing the White population's rate from that of the Black population. The 95% confidence interval for these measures was estimated using the normal approximation method. **Results:** Between 1999 and 2020, liver diseases accounted for 171,627 Black and 1,314,903 White deaths. Age-adjusted mortality rates for African Americans decreased from 22.5 to 20.1 per 100,000 person-years (APC -0.4%, 95% CI -0.6% to -0.2%), whereas an increase was observed for Whites, from 17.9 to 25.3 per 100,000 person-years (APC 1.4%, 95% CI 1.4% to 1.7%). The absolute rate difference in 1999 was 4.6 (95% CI 4.2 to 5.0) and in 2020 it was -5.2 (95% CI -5.4 to -5.0). Correspondingly, the rate ratio decreased from 1.26 (95% CI 1.22 to 1.29) in 1999 to 0.79 (95% CI 0.78 to 0.81) in 2020. This pattern was evident in all census regions except the Midwest, more pronounced among younger (age 25-64) than older (age 65+) population, and observed across different urbanization levels. The pattern may be attributable to increasing alcohol-related liver disease and NASH-related deaths in Whites and tapering in viral hepatitis and liver cancer-related deaths in African Americans. **Conclusion:** Our findings reveal a concerning increase in liver disease mortality rates among White populations and a reassuring decline in African American populations from 1999 to 2020. This pattern is partially due to shifts in causes of liver-related deaths, with reductions in viral hepatitis and deceleration in liver cancer-related deaths in African Americans and increased alcohol-related liver disease and NASH in Whites. In light of these findings, targeted public health interventions and policies addressing racial group-specific needs are crucial.

2827-C | TRENDS OF CHRONIC LIVER DISEASES BY INCOME LEVEL AND SOCIOECONOMIC FACTORS IN THE U.S. NATIONAL POPULATION

Eunice Yewon Lee[1], Vy H. Nguyen[1], Ramsey Cheung[2] and Mindie H. Nguyen[2], (1)Stanford University Medical Center, (2)Stanford University Medical Center, Palo Alto, CA

Background: With polarizing income disparities between the top 20% and remaining 80% of the U.S. population, quality of healthcare may be prone to risk. By investigating the prevalence of chronic liver disease (CLD) based on income to poverty ratio and trends over time, we aimed to determine the impact of socioeconomic status on liver health risks. **Methods:** We combined data from 10 survey cycles (1999-2018) in NHANES. To model the existing 20-80 national divide observed in income groups, we divided participants into high- and lower-income groups by their income to poverty ratio using the cut-off point of 5 as it gave the closest proportion: 25-75. **Results:** Our study included 59,204 adult participants. 44,462 (75.1%) had an income to poverty ratio < 5 (lower-income) and 14,742 (24.9%) had ³5 (higher-income). The weighted prevalence of HCV, HBV, NAFLD, and ALD in lower-income groups were 2.2% (n = 876), 5.5% (n = 2,200), 33.8% (n = 4,345), and 4.7% (n = 2,086), respectively compared to lower rates in higher-income groups: 1.0% (n = 82), 3.2% (n = 263), 29.6% (n = 798), and 3.9% (n = 354). Lower-income groups had higher odds of having history of any CLD (odds ratio (OR), 1.22; 95% CI, 1.08—1.37; P = 0.001), when adjusted for age, sex, race and ethnicity, education, and country of birth. The same trend was observed for history of HCV infection (OR, 2.03; 95% CI, 1.46—2.81, P < 0.0001), HBV infection (OR, 1.47; 95% CI, 1.26—1.72; P < 0.0001), and NAFLD (OR, 1.17; 95% CI, 1.02—1.35; P = 0.030). From 1999 to 2018, lower-income groups had higher rates of viremic HCV infection (P < 0.0001), viremic HBV infection (P = 0.016), NAFLD (P < 0.0001), and AFLD (P < 0.0001) than higher-income groups. In terms of CLD prevalence trends over time, we found higher rates of viremic HCV infection (HCV antibodies positive and HCV-RNA present) in lower-income groups than higher-income groups (P < 0.0001). For current HBV infection (HBsAg positive), no clear trend over time was observed, but lower-income groups exhibited higher prevalence than higher-income groups (P = 0.016). However, prevalence of NAFLD and AFLD increased over time (NAFLD lower-income, P = 0.001; AFLD higher-income, P = 0.04) with similar disparities between income groups. (Figure 1) **Conclusion:** The prevalence of 4 major CLDs significantly differed between higher- and lower-income groups from 1999 to 2018. Recently in 2017-2018, higher median liver stiffness also highlighted the more advanced liver disease in lower-income groups, demonstrating the impact of poverty and socioeconomic factors on the prevalence and severity of liver diseases of various etiologies.

Figure 1. Trends in Prevalence of (A) viremic HCV infection, (B) present HBV infection, (C) NAFLD, and (D) ALD, by income group over time

2828-C | UNCOVERING INSIGHTS ON ACUTE VARICEAL HEMORRHAGE: A CROSS-COUNTRY SURVEY STUDY ON THE MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDING IN LATIN AMERICA

Josealberto Sebastiano Arenas-Martinez[1], Jesús Alejandro Ruiz Manríquez[2], Wagner Enrique Ramirez Quesada[3], Antonio Olivas Martinez[4], Luis C Chávez-García[2], Erick Jasso-Baltazar[5], Thamy Leidy Beltré-González[6], José Carlos Ticona-Pérez[7], Karla Avendano[8], Venny Alberto Venegas Gomez[2], Carlos Alonzo Garcia[9], Maria Fernanda Vasquez-Carit[10], Juanita Perez-Escobar[11], Godolfino Miranda Zazueta[12], Graciela Elia Castro-Narro[13] and Luis Eduardo Zamiora-Nava[2], (1)Instituto Nacional De Ciencias Medicas y Nutricion, (2)Instituto Nacional De Ciencias Medicas y Nutricion Salvador Zubirán, (3)Clínica Equilibrium, (4)University of Washington, (5)Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, (6)Centro Médico Real Gastro-Metrics, (7) Hospital Regional Honorio Delgado, (8)Hospital Monte Sinaí, (9)Clínica Integra Medical Center, (10)Sistema De Estudios De Posgrado, Universidad De Costa Rica, (11)Hospital Juárez De México, (12)Instituto Nacional De Ciencias Médicas y Nutrición "Salvador Zubirán", (13)Medica Sur Clini

Background: Acute variceal hemorrhage (AVH) is a serious complication of portal hypertension and is associated with high mortality and high cost. Limited information exists regarding AVH management accessibility in Latin America (LATAM).This study aims to gather data on AVH management and resource availability across LATAM. The goal was to bridge the knowledge gap, enhance medical attention, and optimize specialized care for patients with AVH in the region. **Methods:** A survey was conducted using Microsoft Forms with recruitment via social media invitations and collaboration with local medical associations. It gathered data on demographics, clinical practices, and specialized resource availability. The LATAM countries were classified based on economic development (World Bank's classification system). Variables are described using percentages or medians and interquartile ranges and compared among socioeconomic regions using a X^2 test or analysis of variance as appropriate. **Results:** In total, 798 respondents from 20 LATAM countries completed the survey. The median age was 39 years, with 80% attending specialists, 14% residents, and 6% fellows. Countries were represented by 6% high-income, 72% upper-middle income, and 21% lower-middle income populations. Gastroenterology (62%) was the predominant specialty followed by internal medicine (23%), gastrointestinal endoscopy (18%), and hepatology (18%). Tertiary care centers accounted for 45% of the participants' primary activities, followed by second-level care (30%) and private practice (21%). As for the existence of endoscopy suites, there were no differences between surveyed countries but their availability 24/7 remains higher in high income countries. The availability of vasoactive drugs correlated with economic development. The detailed findings are presented in Table 1. **Conclusion:** In LATAM, the absence of standardized protocols, limited resources, and expertise pose challenges in AVH management. Enhancing access to specialized care and implementing standardized protocols is crucial to improve patient outcomes in the region.

2829-C | ADVOCATING FOR ACTION IN HCC TO DELIVER IMPARTIAL AND PERSONALIZED CARE: AN OBSERVATIONAL HEALTH EQUITY TOOL PILOT STUDY

Jocelyn Timko, Linda Gracie-King, Marc Viens and Victor Ocana, AXIS Medical Education

Background: Hepatocellular carcinoma (HCC) incidence and mortality rates have risen among American Indian/Alaska Native, Hispanic, and Black populations in the US, and are expected to increase in older populations due to

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hepatitis C, cirrhosis, obesity, diabetes, and non-alcoholic steatohepatitis. Screening and surveillance of these conditions occur less often in many Hispanic and Black populations, delaying HCC diagnosis. The project reviewed health disparities, inequities, and care variations with an aim to improve health equity using a customized Observational Health Equity Tool (OHET). The tool was designed to help identify a baseline of data that supports or refutes whether bias exists during HCC treatment encounters. Observations were scored from 0 = no effort to 4 = exemplary effort. **Methods:** The OHET Pilot Study was implemented at 3 US cancer centers. AXIS provided training and a customized manual for the observer on how to administer and score the observations. AXIS hypothesized that an OHET can assist clinicians in: (1) identifying baseline data that supports or refutes whether bias exists during treatment encounters, and (2) overcoming potential implicit bias and health disparities in HCC treatment planning. This activity was provided by AXIS and supported by education grants from Genentech and Exelixis. **Results:** Data from the 3 sites was collected from 30 patients with HCC, (minority cohort n = 10; non-minority n = 20). Observations proved inconclusive because the observers in all 3 sites failed to include the sensitive question asking whether the patient has experienced prior discrimination regardless of their race or ethnicity. This lack of data reinforces that a patient's race influences the patient/provider interaction. This is further compounded by the small sample size of minority patients. **Conclusion:** The OHET proved inconclusive in determining whether bias exists during treatment encounters, primarily due to poor survey administration and observer bias. The data suggested that the survey model failed to consider the likelihood that all survey questions would not be completed in one discrete encounter. The OHET may be better suited as a longitudinal study following a larger number of overall patients and more than one encounter. While this study proved inconclusive, it produced the insight that providers need to ask the difficult questions related to discrimination and bias.

2830-C | ASSESSMENT OF THE METABOLIC HEALTH OF YOUNG INDIANS (18-25 YEARS) - AN INTERIM ANALYSIS OF PILOT PHASE I PROJECT ON STRONGER INDIA THROUGH A MILLION HEALTH EDUCATED STUDENTS (SMILES)

Kanica -[1], Priyanka Shenoy[1], Guresh Kumar[1] and Shiv Kumar Sarin[2], (1)Institute of Liver and Biliary Sciences, New Delhi, (2)Institute of Liver and Biliary Sciences

Background: Young adults are now known to be quite prone to develop fatty liver, NAFLD, heart attack or various Non Communicable Diseases (NCDs) like diabetes and hypertension. Much of the rise in such situations at young age is attributed to lifestyle changes like ultra-processed foods, reduced physical activity and increasing substance abuse in the Gen Z. SMilES (Stronger India through a Million Health Educated Students) initiative is designed to touch base with at least a million young adults in the age range of 18-25 years in India, to understand various risk factors for Fatty Liver and other NCDs amongst them. **Methods:** An online, pre tested, closed ended, self-assessment questionnaire under the mandate of 'Healthy Liver Healthy India' was administered to the young adults to screen for the most important risk factors for fatty liver and other NCDs with the help of trained epidemiologist through an on-line supervised survey. The initiative was started as a pilot study in New Delhi and is now planned for national implementation through various college networks. We aim to target one million college students of India between the age range of 18- 25 years to screen for the presence of risk of developing NCDs and fatty liver and to risk stratify them into Red (High risk), Yellow (Moderate risk) and Green (Low Risk) in Phase I. **Results:** Starting January 2023, we enrolled 4060 young adults across New Delhi. The grouping category was calculated using discriminant analysis and it was found that proportions in Red, Yellow and Green are 11%, 20.8% and 68.3% respectively. Further the cut offs for the score that we obtained from these variables using CART (Classification and Regression Tree) analysis came out be < 11 for green, 11-14 for yellow and > 14 for red. This was based on the scoring of factors as gender, BMI (17% obese, 12.2% overweight), waist circumference (39.2% action group II), presence of acanthosis nigricans (9.4%), personal and family history of thyroid (1.1%; 17.2%)/ Diabetes (7.9%; 26%)/ hypertension (2.4%; 30.6%)/ liver disease (1.7%; 8.7%)/ PCOS (3.1%; 2.1%)/ dyslipidaemia (10.5%)/ gallstones (7.7%)/ cancers (2.5%)/ cardiovascular diseases (5.7%), diet factors (non veg (52.2%)/ fast food (96.7%)/ sweets (92.4%)), smoking tobacco (3.9%), smokeless tobacco (1%), alcohol (5.6%) and physical activity of less than 150 minutes/week (54.3%). **Conclusion:** Our initial results show that nearly one in three young Indians has a moderate or high risk of metabolic diseases, with a predisposition to those with a positive family history of metabolic traits. Nearly all the interviewed subjects were consuming fast food and sweets with relatively less physical activity in half. A larger data set on the health stats of the young will help us to develop strategies for phase II, where interventions to reduce the proportion of red and yellow category of subjects will be undertaken.

f 2831-C | AWARENESS OF SIGNIFICANT LIVER FIBROSIS IN PATIENTS WITH NAFLD DIFFERS ACROSS ETHNICITIES

Fernando Bril and Meagan Gray, University of Alabama at Birmingham

Background: Non-alcoholic fatty liver disease (NAFLD) is a rapidly rising cause of liver fibrosis in the United States, however awareness amongst patients remains low. Previous reports suggest that the awareness of liver disease amongst Non-Hispanic Blacks is lower than other ethnicities, which may contribute to health disparities in this population. The purpose of this study is to evaluate the awareness of liver disease amongst patients with clinically significant or advanced fibrosis secondary to NAFLD across ethnic groups. **Methods:** Data were derived from the National Health and Nutrition Examination Surveys (NHANES) 2017-2020, which included a total of 7,767 adults with valid transient elastography (TE) measurements. Participants with excessive alcohol consumption, alternative etiologies of liver disease, and/or steatogenic medications were excluded. Patients of multiracial origin or without ethnic information were also excluded. Liver stiffness measurements ≥ 8.2 and ≥ 9.7 kPa were used to define the presence of significant (≥ F2) and advanced (≥ F3) fibrosis, as previously reported. Awareness of liver disease was assessed based on a positive response to "ever told you had any liver condition" on the Medical Conditions Questionnaire. **Results:** A total of 6,365 adults were included after secondary causes of liver disease were excluded; 50% male, 24.7% Hispanic, 35.2% Non-Hispanic White, 27.0% Non-Hispanic Black, and 13.1% Non-Hispanic Asian. The prevalence of clinically significant fibrosis was 8.7% (n = 555) and advanced fibrosis was 3.0% (n = 342) based on TE. The awareness of liver disease amongst patients with clinically significant fibrosis was highest in the Hispanic population and lowest in the Non-Hispanic Black population (p = 0.008) (Table 1). Amongst patients with advanced fibrosis, knowledge of liver disease was similar across ethnic groups, although numerically lower in Non-Hispanic Black patients (Table 1). **Conclusion:** In a large diverse national dataset, awareness of liver disease in patients with clinically significant or advanced fibrosis secondary to NAFLD was low across all ethnic groups. However, in subjects with clinically significant fibrosis, awareness was significantly lower among Non-Hispanic Black patients. Efforts to increase awareness of NAFLD and its risk to progress to fibrosis and cirrhosis are encouraged across all ethnic groups.

Table 1. Subject demographics and awareness of liver disease across fibrosis stage

	Hispanic (n=1,569)	Non-Hispanic White (n=2,243)	Non-Hispanic Black (n=1,717)	Non-Hispanic Asian (n=836)	p value

2832-C | CLEARING THE PATH: IMPROVING RIFAXIMIN ACCESS FOR LIVER PATIENTS AND EVALUATING IMPACT ON HOSPITAL READMISSION

Daniel Cain[1], Sommer Smith[2], Apurva A. Modi[3] and Shovendra Gautam[1], (1)TCU School of Medicine/ Baylor All Saints – Internal Medicine Residency Program, (2)Baylor Scott & White All Saints Medical Center, Forth Worth, TX, (3)Baylor Simmons Transplant Institute, Forth Worth, TX

Background: Hepatic Encephalopathy (HE) is a debilitating complication of chronic liver disease and accounts for roughly 55,000 hospitalizations each year. Rifaximin is known to decrease hospitalizations for patients with HE. Access to rifaximin has been a barrier to many due to the high cost associated with the medication. We describe a quality improvement project conducted in a real-world cohort which led to successful and timely access to rifaximin to patients with access barriers. **Methods:** This project is a prospective observational study on cohort of patients at an academic institution with a large transplant center with barriers in access to rifaximin. The method used was the classic Plan Do Check Act (PDCA) cycle. Data was collected from July 2021 through September 2022. This was accomplished by creating an EMR tool to identify patients who were prescribed rifaximin and then coordinating between the inpatient providers and outpatient hepatology clinic to ensure prior authorization (PA) or a prescription assistance program (PAP) was completed when required and that a follow-up was arranged. **Results:** A total of 258 patients were included in the current study after being identified as having inpatient prescriptions for rifaximin. 49 (18.9%) patients were identified as needing a referral to the hepatology outpatient clinic staff and potentially requiring a PA, 28 (10.85%) patients required a PA, 13 (5%) patients required a PAP, and 5 (1.9%) required a PAP after a PA was approved. All 28 (100%) patients in need of a PA and the 13 (100%) in need of a PAP received approval and were able to get a prescription for rifaximin filled, which was the primary goal of the project. Regarding the secondary goal of decreasing 30-day readmission rate, 9/28 (32%) of the PA patients were readmitted within 30 days of discharge. 3/28 (11%) of these patients were readmitted due to HE. 6/28 (21%) PA patients had a prior history of being readmitted within 30 days of discharge prior to the start of this project. Even after obtaining PAs, all 6/6 of these patients were readmitted within 30 days, 2/6 (33%) of them being for HE. **Conclusion:** The primary goal was to improve patients' access to rifaximin, which was achieved with 100% success for those requiring a PA or PAP. The secondary goal of reducing 30-day readmissions (all cause all conditions) was not successful, though further monitoring will continue. In conclusion, prioritizing PA processing prior to discharge is highly recommended to ensure patients with a history of HE with access to this morbidity-preventing medication.

2833-C | EARLY MENOPAUSE AND PRIMARY OVARIAN INSUFFICIENCY IN WOMEN WITH AND WITHOUT CHRONIC HEPATITIS C: A RETROSPECTIVE OBSERVATIONAL STUDY OF WOMEN IN THE UNITED STATES

Harriet Dickinson, Sohul Shuvo, Laura E. Telep, Lauren Liu and Annalisa Rubino, Gilead Sciences, Inc.

Background: Women living with chronic hepatitis C (HCV) are believed to have an elevated risk of early menopause (EM, i.e. menopause before the age of 45) or primary ovarian insufficiency (POI, i.e. menopause between the ages of 20-39). EM and POI are associated with several deleterious effects including infertility and osteoporosis. It is also thought that women living with HCV may experience worse menopausal symptoms compared to their uninfected peers. In this study we aim to understand the proportion of women who experience EM/POI in cohorts of HCV infected and uninfected women, and whether women with HCV experience worse menopausal symptoms. **Methods**: This is a retrospective observational cohort study of administrative healthcare claims data for

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

women aged 20-44 insured by commercial plans in the United States from 01 Jan 2006 to 31 Dec 2021. Two age-matched cohorts of women with and without evidence of HCV were created to estimate the proportion of EM/POI during 2006-2014 (i.e. during the ICD9 era). Later, among all available women with EM/POI, two unmatched cohorts of women with or without HCV between 2006 and 2020 were also formed. **Results**: The proportion of women with EM/POI was 14.2% in women living with HCV, and 5.5% in age-matched women without HCV between 2006-2014. Among women with HCV, the proportion with POI was 9.6% and EM 4.6%. Among women with no evidence of HCV, the proportion with POI was 3.7% and EM 1.8%. In the unmatched cohorts with EM/POI, those with HCV had higher levels of obesity before EM/POI diagnosis (11.9%), compared to women without evidence of HCV (7.7%). HCV-infected women had higher levels of vasomotor symptoms (13.5% versus 8.9%), osteoporosis (3.9% versus 0.7%) and incontinence (5.6% versus 2.6%) than uninfected women within 365 days of their initial EM/POI diagnosis. The use of hormone replacement therapy (HRT) was low in both cohorts, with < 1.5% of women receiving treatment within 365 days of EM/POI onset. **Conclusion**: Nearly one in seven women living with HCV aged 20-44 had a diagnosis for EM/POI, compared to one in 18 women without HCV. Women in the HCV cohort had higher prevalence of negative symptoms associated with EM/POI than in the non-HCV cohort. The treatment of women with EM/POI with HRT was found to be extremely low, highlighting opportunities for further treatment discussions. Such conclusions may inform treatment provisions for women living with HCV. Women with EM/POI should also be screened for HCV.

Age-matched groups (women between 20 and 44 years)	Year								
	2006	2007	2008	2009	2010	2011	2012	2013	2014
EM/POI in women living with HCV (%)	14.4	12.5	15.3	14.3	12.3	15.9	12.8	15.0	15.1
EM/POI in women with no evidence of HCV (%)	5.5	5.6	4.0	5.0	4.4	5.9	6.2	5.6	7.6

2834-C | ELIMINATING HCV INFECTION FROM PRISONS IN SICILY: THE SINTESI PROJECT

Fabio Cartabellotta[1,2], Lorenza Di Marco[2,3], Fabio Santangelo[2], Fabrizio Scalici[4], Rosario Insinna[4], Tullio Prestileo[2,5], Maria Giovanna Minissale[1,2], Vincenza Calvaruso[2,6], Antonio Craxi[2] and Vito Di Marco[2,6], (1) Department of Medicine Buccheri -La Ferla Hospital, Palermo, Italy, (2)Sicilian Network for Therapy, Epidemiology and Screening in Hepatology (SINTESI), Italy, (3)Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Moderna, Italy, (4)Medical Area of the "Pagliarelli-Lorusso" Prison, Palermo, Italy, (5)Uosd Infectious Pathologies of Vulnerable Populations, Arnas-Civico Hospital, Palermo, Italy, (6)Gastroenterology & Hepatology Unit, Department of Health Promotion, Mother & Child Care, Internal Medicine & Medical Specialties (PROMISE), University of Palermo, Palermo, Italy

Background: In all countries HCV among prisoners has a higher prevalence than in the general population. Specific models of screening and linkage to care are needed to improve the care cascade. **Methods:** The SIcilian Network for Therapy, Epidemiology and Screening In Hepatology (SINTESI) run an HCV point-of-care project in all 23 prisons of Sicily. All prisoners received information on HCV screening and the possibility of receiving treatment with Direct Acting Antiviral (DAA) while incarcerated. HCV status was assessed by screening all subjects for anti-HCV by rapid oral test (OraQuick HCV) and immediate reflex testing for HCV-RNA (GeneXpert-HCV Viral Load, Cepheid). HCV RNA positive subjects received DAA therapy within 72 hours of screening. All prisoners signed an informed consent to use personal data. Chi-square test was used to analyze differences between groups **Results:** Among 5,912 prisoners (98% of entire prison population) informed of the screening project, 4,911 (83%) accepted to undergo HCV testing. The mean age was 42 years (range 18-86) and 95.8% was males. Non-Italian origin accounted for 12.2% of prisoners (3.7% other EU countries, 7.5% Africa, 0.6% Asia and 0.2% South America). Overall, 245 subjects (5%) testes anti HCV positive, with a prevalence of 4.9% among males and 6.7% among females ($p = 0.25$). We evaluated the risk of drug addiction in subjects with HCV infection in a prison. A prevalence of 25% (25/99) was found among PWUDs on opioid substitution, as compared to 2.9% (30/1,040) in non-PWUDs ($p < 0.0001$). Among 245 anti HCV positive prisoners, 20 refused to be tested for HCV-RNA, 100 tested negative (80 had a history of viral clearance under previous DAA treatment while 20 did not report previous

therapy for HCV) and 125 were HCV-RNA positive. Twelve of the latter refused treatment, while 113 started a cycle of DAAs while incarcerated. Among 56 subjects assessable for SVR, 55 (98%) obtained HCV clearance. **Conclusion:** In Sicily, HCV infection is 4 times more common among people in prison than in the general population mostly due to parenteral drug use. Half of the prisoners with a positive screening were unaware of their HCV status and only 32% had received DAAs previously. A one shot HCV test-and-treat point-of-care approach is highly effective in this setting. The project was approved by the Regional Department of Health and the Regional Department of Prisons and was funded by HCV STAT (Simplification and Test and Treat Strategies toward HCV Elimination) program of Gilead Sciences

2835-C | ESTABLISHMENT OF A COMMUNITY-ACADEMIC PARTNERSHIP TO ENHANCE EQUITABLE RESEARCH PRACTICES WITH PEOPLE WHO INJECT DRUGS

Claire McDonell, Maia Scarpetta, Aanchal Narang, Ryan Assaf and Meghan Morris, UCSF

Background: People who inject drugs (PWID) are a socially marginalized population underrepresented in all levels of academic research. Establishing partnership between researchers and community members who work directly with PWID improves research rigor and equitable research and clinical approaches. However, outside of formal community-based participatory research (CBPR), there is limited literature discussing formation and evaluation strategies of community-research partnerships focused on PWID. **Methods:** Using principles from CBPR, we established a Community Academic Partnership group (CAP) to inform the development, implementation, interpretation, and dissemination of a randomized clinical study of hepatitis C virus (HCV) treatment initiation for young adult PWID (YPWID). An inductive member-guided approach informed CAP membership and group structure, norms and success indicators. **Results:** CAP members met monthly for the first 6-months and quarterly thereafter, indefinitely. Members represented academic institutions (n = 4), CBOs (n = 5) and YPWID (n = 2) and held roles including research assistance, outreach, case management, and senior leadership. The majority identified as cis-female (56%) and nonbinary (22%). A majority of members (56%) identified as white or Latino/a/x (33%). Results from the Measurement Approaches to Academic Partnership Success (MAPS) questionnaire indicated members prioritized four dimensions of success (in ranked order): valuing community knowledge, valuing opinions and experiences of individual members when working together, involving community partners throughout the research process, and addressing conflicts collaboratively. A history of positive collaboration among members and partners' commitment to group priorities were ranked as least important dimensions. Meetings were deemed worthwhile in the short-term due to food and honorarium provided, witnessing progress, and respectful engagement. Members viewed long-term CAP success as bringing the community's voice to the research process, demystifying research, and tailoring research to the needs of young PWID. **Conclusion:** Extending CBPR approaches to the process of forming and establishing a CAP requires willingness to share ownership of the CAP with all members and results in collaboration models that prioritize knowledge sharing and amplify historically marginalized voices.

2836-C | ETHNICITY AND ITS EFFECT ON LIVER CIRRHOSIS REMISSION IN POST-BARIATRIC PATIENTS

Rajmohan Rammohan[1], Sai Greeshma Magam[1], Melvin Joy[2], Dilman Natt[1], Achal Patel[1], Abhishek Tadikonda[1] and Paul Mustacchia[3], (1)Nassau University Medical Center, (2)Nassau University Medical Center, East Meadow, NY, (3)Nassau Univeristy Medical Center

Background: The impact of race on fatty liver disease outcomes in post-bariatric surgery patients is a vital yet understudied area of research. Racial and ethnic differences in genetic, metabolic, and lifestyle factors have been observed to influence disease progression and response to treatment. Notably, certain racial groups may exhibit a higher propensity for developing fatty liver disease post-surgery, impacting prognosis and management strategies. Understanding these racial disparities can significantly enhance personalized care, improving liver health outcomes for all post-bariatric surgery patients **Methods:** Our study conducted a retrospective analysis of patients undergoing bariatric surgery at our institution from 2009-2022. We gathered extensive data, including comorbidities, insurance, pre-and post-surgery Fibrosis scores, pathology reports, and baseline characteristics using ICD and CPT codes. A 20% Fibrosis score improvement was marked as positive, with duration

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

calculated from surgery day. Propensity score matching allowed baseline characteristic comparison. We used Kaplan Meier estimations to determine the improvement of liver cirrhosis among races and the Odds ratio to identify factors independently influencing the outcome **Results:** Our hospital conducted 960 bariatric surgeries from 2009-2022. Among these, 165 patients (17%) with pre and post-surgery fibrosis scores were studied. Fibrosis scores improved in 81 patients (8.1%), averaging 40.59 ± 20.76 months post-surgery. The average age was 50.29 ± 12.17, with females constituting 52%. The racially diverse cohort included 30.3% African American, 24.8% White, 48% Asian, and 17.5% Hispanic. Asians (29%) took the longest to show liver cirrhosis improvement (log-rank Mantel cox: 17.651, $p < 0.01$). Patients with higher education demonstrated faster cirrhosis improvement (OR:1.23, $P = 0.015$) **Conclusion:** Our study reveals racial disparities in post-bariatric surgery fatty liver disease outcomes. Among 165 analyzed patients, 8.1% saw improved fibrosis scores post-surgery, with Asians taking the longest to show cirrhosis improvement. Additionally, higher education patients improved more quickly, suggesting a socioeconomic influence on health outcomes. These insights call for further research on genetic, metabolic, and lifestyle influences to enhance personalized care strategies

2837-C | FOOD INSECURITY POTENTIATES THE RISK OF NAFLD AMONG THOSE OF HISPANIC ANCESTRY: A NATIONALLY REPRESENTATIVE STUDY

Sebastian Niezen[1], Daniela Goyes[2], Aarshi Vipani[3], Ju Dong Yang[4], Walid S. Ayoub[4], Alexander Kuo[4], Michelle Long[5] and Hirsh Trivedi[4], (1)University of Pittsburgh Medical Center, (2)Yale University Medical Center, New Haven, CT, United States, (3)Karsh Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Los Angeles, CA, (4)Cedars-Sinai Medical Center, Los Angeles, CA, (5)Section of Gastroenterology, Evans Department of Medicine, Boston University School of Medicine

Background: Food insecurity, or inadequate access to nutritious food, is prevalent to Hispanic households that contributes to metabolic risk. A growing body of evidence has demonstrated an association between food insecurity and NAFLD. However, the association between these factors in individual's with Hispanic ancestry remains unknown. We aim to evaluate the influence of food insecurity on Hispanic ethnicities risk of NAFLD. **Methods:** We used data from the 2017-2020 pre-pandemic cycle of National Health and Nutrition Examination Survey (NHANES). Our analysis was restricted to participants aged 20 years and older who underwent VCTE. Food security status was assessed utilizing the US Food Security Survey Module. Data was obtained through questionnaire, physical examination, and laboratory tests. We constructed multivariable linear and ordinal logistic regression models to determine the association between Hispanic ethnicity and both LSM and CAP for fibrosis and steatosis, respectively. Covariates included age, sex, income, BMI, type 2 diabetes, food security, and education level. We posteriorly stratified our population based on reported food security status and re-constructed the models. As sensitivity analysis we excluded those who reported binge drinking (5+ drinks for men and 4+ drinks for women daily). **Results:** Among 6,945 eligible participants, individual's with Hispanic ancestry had higher CAP scores (275.4 ± 61.8 dB/m) compared to non-Hispanic individual's (261.4 ± 61.9 dB/m). Under multivariable analysis, those with Hispanic ancestry had significantly higher CAP scores (Beta-coefficient: 10.2 dB/m, 95% CI: 6.1 – 14.4 dB/m, $P = 0.001$). After stratifying based on food security status, both food-secure and food-insecure individual's of Hispanic ancestry demonstrated stronger association with steatosis compared to non-Hispanics. After stratifying based on food security status, the association in food insecure Hispanics was most pronounced (Beta-coefficient: 11.8 dB/m, 95% CI: 4.4- 19.3 dB/m, $P = 0.003$). The association remained significant after excluding binge drinkers (Beta-coefficient: 10.5 dB/m, 95% CI: 5.7 – 15.4, $P < 0.001$). No significant association was observed for LSM on either analysis. **Conclusion:** The prevalence of food insecurity is increasing nationally, particularly among Hispanic populations. Food insecurity potentiates the risk of NAFLD among those of Hispanic ancestry.

2838-C | HEPATOCELLULAR CARCINOMA MANAGEMENT IN A MULTIDISCIPLINARY CLINIC IMPROVES CARE IN POPULATIONS IMPACTED BY HEALTH DISPARITIES

Maryam Zafer[1], Kelli Liu[1], Adam M Burgoyne[2], Kathryn Fowler[1], Zachary Berman[1], Tanya Wolfson[1], Jesse Nodora[1] and Yuko Kono[1], (1)University of California San Diego, (2)UC San Diego School of Medicine

Background: Health disparities affect morbidity and mortality due to Hepatocellular Carcinoma (HCC). The multidisciplinary model of HCC management has shown survival benefit but the effect on patients impacted by disparities is not well-established. This study compares outcomes among patients with HCC as differentiated by 1 – treatment in a multi-disciplinary clinic or standard of care; 2- socioeconomic factors associated with disparate care. **Methods:** A retrospective chart review assessed patients with HCC at the University of California, San Diego Medical Center from 2016 to 2022. Data were compared between patients seen in the multi-disciplinary (MDD) and control Hepatology clinics. Patients were summarized by demographic factors and metrics related to disease stage and medical care. Treatment and outcome measures were compared using the chi-square test for categorial variables or Fisher's exact test for groups with low proportions. **Results:** A total of 304 patients comprised the MDD (n = 204) and control (n = 100) cohorts of which 32.4% and 41.0% were of Hispanic origin, respectively. More Hispanic compared to non-Hispanic patients met metrics associated with disparate care, such as under-insurance (MDD cohort: 53.0% vs. 35.0%; $p = 0.022$). MDD compared to control patients had advanced disease (median T-stage: T2 vs. T1; $p < 0.0005$, BCLC stage: B vs. A; $p < 0.0005$). MDD patients had fewer missed appointments (27.0% vs. 60.0%; $p < 0.0005$), loss to follow up (7.8% vs. 22.0%; $p < 0.0005$) and shorter time to treatment after intake (median days 33.0 (IQR 15.0-55.0) vs. 68.5 (46.5-99.5); $p < 0.0005$). MDD Hispanic patients had fewer missed appointments (30.3% vs. 58.5%; $p < 0.001$), loss to follow-up (6.1% vs. 22.0%; $p < 0.05$) and time to treatment (median days 38.0 (IQR 21.25-61.5) vs. 68.5 (44.5-118.5); $p = 0.001$) compared to control Hispanic patients. Intervals from diagnosis to treatment (median days 63.0 (IQR 33.0-140.0) vs. 73.0 (51.0-112.0); $p = 0.234$) and referral to intake (median days 16.0 (IQR 11.5-27.0) vs. 18.0 (9.0-31.5); $p = 0.864$) were comparable. The latter was longer among MDD Hispanic patients (median days 21.0 vs. 15.0; $p < 0.05$). **Conclusion:** The MDD model facilitated timely initiation of therapies in patients with HCC, closer engagement in care, and was protective against loss to follow-up, including among Hispanic patients. Patients referred to the MDD clinic had advanced disease and were slow to establish care. Future efforts should encourage early primary provider referrals and address barriers to intake.

2840-C | INNOVATIVE MODELS TO GUIDE EQUITABLE VIRAL HEPATITIS HEALTH DEPARTMENT PROGRAMS

Zakiya Grubbs and Jasmine West, Nastad

Background: The increasing burden of viral hepatitis, limited resources, and rapid turnover at health departments (HD) has highlighted the need to build HD capacity and strengthen collaborations grounded in health equity and harm reduction for people who inject drugs (PWID). Since 2019, NASTAD has implemented the Hepatitis Technical Assistance Center (HepTAC) for HD viral hepatitis prevention and surveillance staff by providing technical assistance (TA) and hosting the Virtual Learning Collaborative (VLC). TA requests range from epidemiology and surveillance to medication access to

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

strategic planning. NASTAD hosts VLC didactic presentations, moderated discussions, and workshops led by HD staff i.e. equitable approaches to data collection; engaging non-traditional partners and people with lived experience (PWLE); removing restrictions to hepatitis treatment. NASTAD continues to address intersecting health inequities, and in 2022 established the Hepatitis Network for Education and Testing (HepNET), a network of HD government and community partners focused on addressing the unmet needs of PWIDs to improve access to viral hepatitis services. Through the monthly HepNET Learning Communities (LC), the Leading with Lived Experience Consultants provides TA to 3 jurisdictions to improve testing and linkage to care strategies for PWID with a commitment to racial justice and health equity. **Methods:** NASTAD uses a mixed methods approach to evaluate the effectiveness of these models to increase HD knowledge and capacity to implement a range of hepatitis services. Surveys and focus groups are utilized to garner feedback for improvement. **Results:** Between August 2019 and October 2022, HepTAC received 153 TA requests where 92% of survey respondents learned new information and 82% have already used this information in their work. From VLC sessions from August 2021 to July 2022, 94% of survey respondents found the sessions applicable to their work, 95% learned something new, and 85% are prepared to apply what they learned. Participants in VLC focus groups reiterated the usefulness of the sessions and opportunities to learn from peers. Similarly, the HepNET LC assessment demonstrated that 90% of participants are somewhat or very satisfied with the LC activities (February to April 2023), and awareness of intersectional identity and the multiple ways PWIDs are marginalized increased by 75%. **Conclusion:** Through engagement with HepNET and HepTAC models, HD staff have increased knowledge to implement key viral hepatitis strategies and develop tools to equitably engage PWLE. This multi-modal approach has proven responsive to the changing needs of HDs with limited resources and has advanced health equity in HD programming.

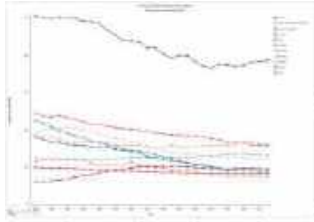
2841-C | MORTALITY RATES DUE TO CIRRHOSIS OF THE LIVER IN WESTERN COUNTRIES: 1990 TO 2019

Noel Balli[1], Connor Yost[1], Cathleen Kuo[2] and Kamalani Hanamaikai[1], (1)A. T. Still University School of Osteopathic Medicine in Arizona, (2)University of Buffalo

Background: Cirrhosis of the liver is a prevalent cause of death globally, with the most common contributors being Hepatitis B, Hepatitis C, alcohol consumption, and non-alcoholic fatty liver disease. The objective of this study is to examine the mortality rates associated with liver cirrhosis in ten major Western nations from 1990 to 2019. **Methods:** The Global Burden of Disease Database provided the data for this study, which investigated the age-standardized mortality rates linked to cirrhosis and other chronic liver ailments in ten Western countries (Australia, Argentina, Brazil, Canada, Colombia, France, Germany, Mexico, the United Kingdom, and the United States). **Results:** Of the ten countries examined in this study, eight have experienced a decline in mortality rates per 100,000 individual's linked to cirrhosis and other chronic liver conditions over the last three decades. Mexico had a disproportionately high mortality rate compared to the other nine countries included in the study, accounting for 28.33% of the ten-country total mortality rate in 1990, and 28.40% in 2019. Our analysis also investigated the various factors responsible for cirrhosis, including hepatitis B, hepatitis C, alcohol consumption, non-alcoholic fatty liver disease (NAFLD), and other causes. Among these, alcohol use had the highest proportion of deaths attributable to liver cirrhosis in 2019 at 37.85%, followed by hepatitis C (27.01%), NAFLD (14.17%), and hepatitis B (6.46%). **Conclusion:** While Western countries have witnessed a decline in the mortality rate associated with liver cirrhosis over the past three decades, Mexico and other Latin American nations still experience a disproportionate burden. To address this issue, more robust public health initiatives are necessary to raise awareness of the detrimental impact of chronic alcohol abuse. The findings of this study are particularly relevant to southern border states, where many Mexicans and other Latin Americans seek medical care.



Country	Mortality Rate 1990	% of total mortality	Mortality Rate 2019	% of total mortality
Australia	2.41	4.25	3.77	4.24
Argentina	18.55	10.48	18.16	11.86
Brazil	24.47	13.72	15.79	11.59
Canada	3.93	5.57	8.31	6.13
Colombia	11.54	6.47	7.49	5.53
France	18.11	10.15	8.34	6.56
Germany	19.22	10.77	12.26	9.04
Mexico	50.54	28.33	38.68	28.40
USA	12.68	7.00	13.18	9.68
UK	6.15	3.45	9.53	7.00
Total	178.4	100	136.2	100

Cause of Cirrhosis	Mortality Rate 1990	% of total	Mortality Rate 2019	% of total
Alcohol Use	66.47	37.26%	51.55	37.85%
Hepatitis C	45.69	25.61%	36.79	27.01%
NAFLD	22.57	12.65%	19.3	14.17%
Hepatitis B	18.36	10.29%	8.8	6.46%
Other	25.32	14.19%	19.75	14.50%
All Causes	178.41	100%	136.19	100%

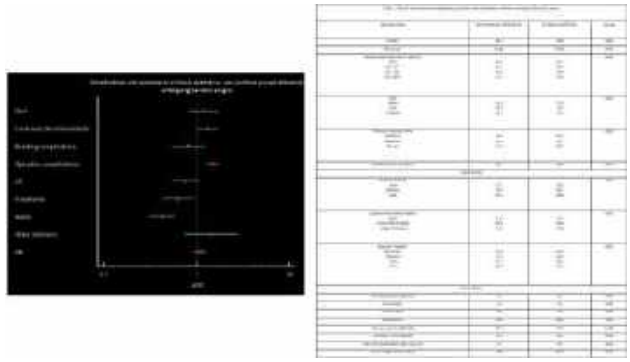
2842-C | POST BARIATRIC SURGERY OUTCOMES IN PATIENTS WITH CIRRHOSIS: A NATIONAL INPATIENT SAMPLE DATABASE STUDY

M'hamed Turki[1], Renuka Verma[2], Kamleshun Ramphul[3], Hemamalini Sakthivel[4] and Tejas Joshi[1], (1) Marshall University, (2)Guru Gobind Singh Medical School, (3)Independent Researcher, (4)One Brooklyn Health System/Interfaith Medical Center Program

Background: Bariatric surgery (BS) may improve the long-term prognosis in obese patients with cirrhosis. As these patients are prone to multiple infections and complications following surgeries, we sought to compare the postoperative course following bariatric surgery in obese individual's with and without a diagnosis of cirrhosis in the United States. **Methods:** We performed a retrospective study of obese adults (BMI e 30.0) that underwent a BS between 2016 and 2020 using the National Inpatient Sample. Comparisons between two cohorts of cirrhosis and non-cirrhosis patients via Chi-Square tests, t-tests, and logistic regressions were formed as appropriate. **Results:** Our sample consisted of 912999 cases of bariatric procedure (30.6% classified as Mixed Bariatric procedure), with 5470 (0.6%) patients with cirrhosis. Both groups included mostly females, whites, and private insurance coverages. In addition, most procedures were performed in the southern part of the United States, involving urban teaching hospitals and centers with large bed sizes. Patients with cirrhosis were older (mean age 53.22 vs. 44.49 y, $p < 0.01$). These patients also expressed a higher prevalence of multiple comorbidities (table 1). After careful adjustment of confounders, patients with cirrhosis showed higher odds of cardiovascular and thromboembolic events (aOR 1.331, $p = 0.03$), operative complications (aOR 1.491, $p < 0.01$), while reporting lower odds of pneumonia (aOR 0.634 , $p = 0.017$) and sepsis (aOR 0.428, $p < 0.01$). No differences in bleeding complications, urinary tract infections, other infections, acute kidney injury and mortality were observed between the two groups. **Conclusion:** As previously described in the literature, patients with cirrhosis are at an overall higher risk for cardiovascular and thromboembolic events throughout their lifetime. This study is demonstrating that the postoperative course following BS is no exemption. This study is suggesting that a diagnosis of cirrhosis in patients undergoing BS should probably warrant extra precautions for thromboembolic and cardiovascular events. As it has been reported in the past, patients with cirrhosis are comparatively receiving less chemical prophylaxis for deep venous thrombosis due to abnormalities in their INR; this might also partially explain our findings. We suggest proper screening and systemized post-operative protocols to help improve these outcomes.



Disclosures: The following people have nothing to disclose: M'hamed Turki, Renuka Verma, Kamleshun Ramphul, Hemamalini Sakthivel, Tejas Joshi

2843-C | POST LIVER TRANSPLANTATION OUTCOMES AMONGST HISPANIC PATIENTS TRANSPLANTED DUE TO FATTY LIVER DISEASE - SINGLE CENTER STUDY

Suaka Kagbo-Kue[1], David Chascsa[2], Jaclyn Tuck[1], Alyssa McGary[2] and Blanca Lizaola-Mayo[2], (1)Mayo Clinic, (2)Mayo Clinic Arizona, Phoenix, AZ

Background: Non-alcoholic steatohepatitis (NASH) is projected to become the leading indication for liver transplantation (LT) in the next decade in the United States due to the rising prevalence of obesity. The prevalence of non-alcoholic fatty liver disease (NAFLD) is higher and develops at a younger age in the Hispanic population, and is more frequently associated with hepatocellular carcinoma (HCC). Racial and ethnic disparities in liver transplantation are well-recognized but there remains limited data on survival outcomes among minorities. We investigated outcomes of mortality, graft survival and recurrence of hepatic steatosis among Hispanic patients. **Methods**: We retrospectively evaluated electronic medical records (EMR) of patients who underwent LT from January 2010 to June 2022 in our facility, were Hispanic and transplanted due to NASH cirrhosis with/without HCC and/or cholangiocarcinoma. Patients with other causes of chronic liver disease were excluded. Continuous variables were summarized using median and interquartile range (IQR), and categorical variables were summarized using frequency and percentage. Overall survival and graft survival were estimated using the Kaplan-Meier method. Univariate analyses were assessed with Cox-regression. **Results**: Out of 279 Hispanic patients transplanted during the study interval, 70 patients met selection criteria. The median age at transplant was 61, with similar distribution of males (48.6%) and females (51.4%). Majority of patients were high school level

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of education (54.3%), and 30% were working for income at listing. 32.9% had coexisting HCC. Mean MELD at transplant was 20.7%. All patients received donation after cardiac-death organs. Average BMI at transplant was 30.7%, pre-LT metabolic comorbidities included type 2 diabetes(DM2) (71.4%), hypertension (71.4%), hyperlipidemia (HLD) (25.7%), obesity (37.1%) and sleep apnea (7.1%). 11.4% had a simultaneous kidney transplantation (KT). Post LT, median follow-up IQR was 3 years; predominant new onset metabolic comorbidities were DM2 (10%) and HLD (21.4%); mean BMI at 1 year post LT was 29.7, and trended up to 33.1 at 3 years, peaking at 36.7 at 10 years. 2.9% had bariatric surgery(BS) post LT, while additional 11.9% were referred for BS but were yet to complete. Advanced NASH-related fibrosis evaluated by liver biopsy or non-invasive elastography was 2.4% at 1 year and stable (9.1%) at 2 and 5 years respectively. 8.6% of patients experienced graft failure; survival at 1, 2 and 5 years was stable at 91.4%. There was no significant association between BMI and mortality or graft failure. **Conclusion**: Our study highlights that Hispanic patients transplanted due to NASH have favorable post LT outcomes, however, there was limited sample size to determine the role of recurrent NASH and metabolic comorbidities in post LT outcomes. The importance of more research involving minority populations cannot be overemphasized.

2844-C | RACIAL DIFFERENCES IN LIVER FIBROSIS - ENVIRONMENT OR BIOLOGY?

Michael L. Attanasi, Medical University of South Carolina, Mount Pleasant, SC and Don C. Rockey, Medical University of South Carolina

Background: Liver histology is the classic method for staging the severity of liver fibrosis, which in turn is one of the most important clinical predictors of outcome. Here, we have hypothesized that environmental or genetic factors may influence the propensity to develop fibrosis among racial groups, which in turn could impact the progression of liver disease. **Methods**: We examined the liver histology of all patients over 18 years of age who underwent liver biopsy at the Medical University of South Carolina (MUSC) from January 1, 2013 to July 1, 2021. Patients with malignancy, liver metastases, or missing data were excluded. Fibrosis was quantitated using the Metavir system (F0 = no fibrosis to F4 = histological cirrhosis). **Results**: Of 3,572 patients undergoing liver biopsy, approximately one-third had a biopsy to investigate chronic liver disease. This group included 850 (77%) White patients and 251 (23%) Black patients. Black patients had a higher prevalence of HBV (7% vs 2%), HCV (22% vs 14%), and autoimmune hepatitis (AIH) (14% vs 7%), while White patients had a higher prevalence of alcoholic liver disease (23% vs 14%) and non-alcoholic steatohepatitis (NASH) (16% vs 4%). Black patients had a higher prevalence of metabolic syndrome (36% vs 20%). White patients had an overall greater burden of fibrosis than Black patients (Table) and higher prevalence of cirrhosis (40% vs 30%, $p = 0.056$). However, overall, inflammation was significantly greater in Black patients (Table). Of note, patients with alcoholic liver disease had a greater prevalence of cirrhosis than those with other causes of cirrhosis; the prevalence of cirrhosis within each group was as follows: alcohol - 64%; HBV - 40%; HCV - 29%; HCV with alcohol - 47%; NASH - 36%; AIH - 29%; drug-induced liver injury - 8%; other - 30%; unknown - 27%; $p < 0.001$). In patients with NASH, the average steatosis grade was twice as high for Black as White patients (Table). White patients had higher prevalence of esophageal varices (41% vs 26%, $p < 0.01$), hepatic encephalopathy (22% vs 14%, $p < 0.01$), and splenomegaly (28% vs 9%, $p < 0.001$). Cumulative 5- year mortality was similar among White and Black patients (30% vs 28%). Patients with alcoholic liver disease had significantly higher cumulative 5-year mortality than other liver diseases (alcohol - 51%; HBV – 18%; HCV - 15%; HCV with alcohol - 29%; NASH - 30%; AIH – 20%; drug-induced liver injury – 17%; other - 43%; unknown - 25%; $p < 0.001$). **Conclusion**: White patients had a greater overall burden of fibrosis than Black patients, and a higher prevalence of NASH despite a lower prevalence of metabolic syndrome. Clinical complications of cirrhosis were more prominent in White than Black patients, although mortality was similar in both groups. The data suggest that there are inherent differences fibrosis in Black and White patients and suggest that fibrosis progression may be worse in White than Black patients.

Table. Fibrosis, Inflammation and Steatosis Stages and Grades

	White	Black	p
Average Fibrosis Stage	2.3 (0.1)	2.1 (0.1)	< 0.05
Score 0	162 (19%)	53 (21%)	NS
Score 1	156 (18%)	53 (21%)	NS
Score 2	102 (12%)	33 (13%)	NS
Score 3	88 (10%)	36 (14%)	NS
Score 4	342 (40%)	76 (30%)	NS*
Average Inflammation Grade	1.2 (0.0)	1.3 (0.1)	< 0.05
Grade 0	120 (17%)	30 (14%)	NS
Grade 1	282 (40%)	79 (37%)	NS
Grade 2	168 (24%)	58 (27%)	NS
Grade 3	112 (16%)	39 (18%)	NS
Grade 4	11 (2%)	6 (3%)	NS
Average Steatosis Grade	0.8 (0.0)	0.4 (0.0)	< 0.001
Grade 0	394 (49%)	160 (69%)	< 0.001
Grade 1	245 (30%)	52 (22%)	< 0.001
Grade 2	96 (12%)	12 (5%)	< 0.001
Grade 3	77 (10%)	8 (3%)	< 0.001

f 2845-C | RACIAL, ETHNIC AND GENDER ENROLLMENT DISPARITIES IN NON-ALCOHOLIC FATTY LIVER DISEASE CLINICAL TRIALS IN THE UNITED STATES

Phillip Leff[1], Naim Alkhouri[2], Amit G. Singal[3], Karn Wijarnpreecha[4], Mazen Noureddin[5] and Nicole E. Rich[3], (1)Creighton University, (2)Arizona Liver Health, Phoenix, AZ, (3)University of Texas Southwestern Medical Center, (4)University of Arizona College of Medicine Phoenix, Phoenix, AZ, (5)Houston Research Institute, Houston, TX

Background: There are significant racial and ethnic disparities in NAFLD prevalence and severity in the U.S., with the highest burden in Hispanic men. Yet, disparities in enrollment in contemporary NAFLD trials (enrolling from 2017-present) have not been investigated. Thus, we aimed to characterize contemporary enrollment data from therapeutic NAFLD trials in adults aged > 18 years. **Methods:** We performed a systematic literature search in clinicaltrials.gov and PubMed for all NAFLD therapeutic trials in the U.S. from January 2011 to February 2023. Demographics of interest included: race, ethnicity (Hispanic vs. non-Hispanic) and reported gender. Enrollment fraction (EF), i.e., the number of trial enrollees divided by number of patients with NAFLD matched to the period of trial enrollment using estimates of the U.S. prevalence of NAFLD using NHANES 2017-2018 and 2020 U.S. Census data. **Results:** Among the 341 trials identified, 95 met inclusion criteria (n = 63 with US-only enrollment). Of these, 24 (25.3%) had not yet reported or published demographic enrollment data. Among the 71 trials (n = 9105 participants) reporting enrollment data, 8.5% were phase 1 and 74.6% were phase 2/3; 65.3% were sponsored by industry, 30.4% academia and 4.3% other. Women (n = 5137) comprised a higher proportion of trial participants compared to men (n = 3955; 56.4% vs 43.6%); this gender disparity was consistent across intervention type (drug vs. behavioral), time period (2011-2017 vs 2018-present), and US-only vs multinational trials, but not trial phase (phase 1 trials: 57.7% men vs 42.3% women). Men had a lower EF compared to women (0.002% vs 0.004%, p = 0.01) despite comprising an

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

estimated 57.2% of prevalent NAFLD cases. Race was reported in only 53/71 trials (n = 6984 participants; 86.2% White, 3.1% Black, 5.0% Asian, 0.5% AI/AN), while ethnicity was reported in only 36/71 trials (n = 5015 participants; 31.5% Hispanic, 68.5% Non-Hispanic). The proportion of studies reporting enrollment data on race increased significantly over time (62.8% in 2011-2017 vs. 89.3% in 2018-present, $p < 0.01$), whereas there was a slight decrease in the proportion reporting ethnicity over the same time period (41.9% vs 39.3%, $p = 0.10$). Among studies reporting ethnicity, Hispanic patients (comprising 20.1% of prevalent NAFLD cases) comprised 31.5% of trial participants. Overall, EF was highest among Asian (0.04%) and Hispanic participants (0.02%). Despite accounting for 8.8% of prevalent NAFLD cases, Black patients comprised only 3.1% of trial participants (EF 0.007%). This disparity remained consistent across trial phase, sponsor, and intervention type. **Conclusion:** There are persistent racial, ethnic and gender disparities in enrollment in NAFLD clinical trials and underreporting of race and ethnicity of participants. Improving equitable access to NAFLD trials is not only morally imperative, but informs benefits across subgroups and improves generalizability of results.

2846-C | REPRODUCTIVE HEALTH CHARACTERISTICS IN PRE-MENOPAUSAL WOMEN WITH NAFLD

Grace Zhang, UCSF, San Francisco, CA, Yanin Srisengfa, UCSF and Monika Sarkar, University of California, San Francisco

Background: NAFLD is rising in reproductive-aged women, which has implications for pre-conception and pregnancy-related outcomes. Reproductive measures in young women with NAFLD are limited. **Methods:** We conducted a retrospective survey among reproductive-aged women (ages 18-45 y) with NAFLD and elevated liver tests at our center. Participants completed a one-time 80-question REDCap survey with branching logic from 2017-2023. NAFLD was diagnosed by imaging and/or biopsy in the absence of other causes of liver disease. Metabolic parameters were reported within 6 months of NAFLD imaging or biopsy. Prevalence of reproductive outcomes such as infertility, pregnancy events and complications were compared between our cohort and the general United States (U.S.) population using chi-square, with $p < 0.05$ considered statistically significant. **Results:** There were 79 reproductive-aged participants with NAFLD and elevated liver tests (median ALT U/L 72U/L, IQR 37-98). Median age was 34 years; 66% were White, and 34% Hispanic. Metabolic conditions included BMI > 30kg/m2 in 90% (median BMI 37.3, IQR 33.3- 42.4), diabetes mellitus in 23%, polycystic ovary syndrome in 53%, and dyslipidemia in 53%. Transient elastography-controlled attenuation parameter (TE-CAP) (n = 52), noted severe steatosis (CAP e 300 dB/m) in 70% and hepatic fibrosis (TE > 7kPa) in 29%. In those with liver biopsy (n = 56), 48% had NASH, 55% had > / = stage 1 fibrosis, and 7% had advanced fibrosis. For reproductive outcomes, 39% reported prolonged time to conception (> 12 mo). As compared to the general population, 21% in NAFLD vs 6% in the general population reported infertility, 48% vs 20% had prior miscarriage, and 54% vs 1% had recurrent miscarriages (all p values < 0.001) (Figure). Among those with pregnancies (n = 27), 37% reported gestational diabetes mellitus (vs 9% in the general population), 22% reported gestational hypertension (vs 8%), and 50% reported pre-term labor (vs 10%, all p values < 0.001). Prevalence of low birth weight was similar in our cohort at 9% vs 8% in the general population. **Conclusion:** In young women with NAFLD

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

and elevated liver tests nearly half had histologically-confirmed NASH as well as fibrosis. These women with NAFLD also had higher rates of infertility, miscarriages, and higher rates of metabolic complications during pregnancy. Early collaboration with reproductive endocrinology and maternal-fetal medicine may help optimize reproductive outcomes in young women with NAFLD.

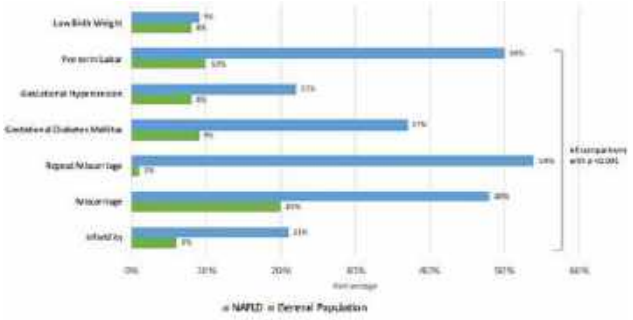

Figure. Prevalence of obstetric outcomes in women with NAFLD versus the general United States population (estimates from the Mayo Clinic 2020, and Centers for Disease Control 2020-2021).

2847-C | RISK FACTORS FOR MORTALITY AFTER SURGERY IN PATIENTS WITH CIRRHOSIS: A MULTICENTER COHORT

Martín Pacheco Serrano, Instituto Nacional De Ciencias Medicas Y Nutricion Salvador Zubiran, Ignacio García Juárez, Instituto Nacional De Ciencias Medicas y Nutricion, Jacqueline Cordova Gallardo, Hospital General Manuel Gea Gonz and David Medina-Julio, Hospital General Manuel Gea Gonzalez

Background: Patients with cirrhosis have a high risk of postoperative mortality compared with the average population. Because risk factors determined in different populations may not be generalizable to other ones, we conducted this retrospective study to evaluate the risk factors associated with mortality after surgery in a mexican cohort of patients with cirrhosis. **Methods:** We conducted an observational, retrospective study of patients with cirrhosis who underwent major surgery, at two centers located in Mexico City. Cox regression analysis was used to evaluate the impact of demographic, clinical, and biochemical characteristics on post-operative mortality. **Results:** We included data from 228 surgeries performed in 173 patients between January 2015 and September 2022. The median of age were 60 years (IQR 52-68) and 59.8% were women. The most frequent etiologies of cirrhosis corresponded to MAFLD (36.4%) and viral (21.4%). Most patients were Child-Pugh B/C (62.4%), with a median of MELD-Na of 15 (IQR 10-21). Most patients had already presented a decompensation event in the past (69.9%), mostly ascites (52%). Regarding other comorbidities, the most frequently found were diabetes mellitus (40.5%) and arterial hypertension (33-5%). The median of BMI were 25.6 (IQR 22.5-29.3). Regarding the ASA classification, 57.2% of patients were considered ASA 4. With respect to the type of surgery, the most frequently found were open abdominal (39.3%), chest/cardiac (16.8%) and abdominal wall (15.6%). A high proportion of procedures were considered emergent (43.4%). Mortality was calculated at 30(11.6%), 90(16.8%) and 180 days (18.5%) after surgery. A cox regression analysis was used to evaluate the impact of demographic, clinical, and biochemical characteristics on post-operative mortality. We found that a MELD-Na greater than 20 were associated with 30-day (HR = 6.33; 95%CI 2.7-14.84; p = 0.00), 90-day (HR = 3.62; 95%CI 1.9-6.7; p = 0.00) and 180-day mortality (HR = 4; 95%CI 2.2-7.2; p = 0.00). An emergent procedure and a type of surgery distinct from abdominal laparoscopic and abdominal wall, were associated with 90-day (HR = 2.44; 95%CI 1.1-5.8; p = 0.045 and HR = 10.96; 95%CI 2.6-46.4; p = 0.00, respectively) and 180-day mortality (HR = 2.35; 95%CI 1.1-5.3; p = 0.04 and 12.42; 95% CI 2.9-52; p = 0.00, respectively), but no 30-day mortality. By contrast, a blood urea nitrogen greater than 21 mg/dl were associated with 30-day (HR = 3.9; 95%CI 1.4-10.6; p = 0.00) and 90-day mortality (HR = 2.2; 95%CI 1.14-4.2; p = 0.02), but no 180-day mortality. **Conclusion:** A MELD-Na score greater than 20 points, were independently associated with early and long-term mortality after surgery. An emergent procedure and a type of surgery distinct from abdominal laparoscopic and abdominal wall, were associated with long-term mortality but no short-term mortality. By contrast, a BUN concentration greater than 21 mg/dl, was independently associated with early mortality.

2848-C | SCREENING AND LINKAGE TO CARE FOR CHRONIC LIVER DISEASE AMONG REFUGEE PATIENTS PRESENTING FOR DOMESTIC MEDICAL EXAMINATION IN THE UNITED STATES

Sara Chapin[1], Julia Gasior[2], Vincent Lo Re III[2], Nadim Mahmud[1], Aba Barden-Maja[1] and Jessie Torgersen[2], (1)Hospital of the University of Pennsylvania, (2) University of Pennsylvania Perelman School of Medicine

Background: Chronic liver diseases (CLD), including hepatitis B virus (HBV) and hepatitis C virus (HCV) infections, alcohol-related liver disease (ALD), and nonalcoholic fatty liver disease (NAFLD), are a major cause of global morbidity and mortality. Little is known regarding CLD screening and subsequent care among refugees, a vulnerable population with time-limited medical coverage. We sought to determine the prevalence of CLD and linkage to specialty care among refugees undergoing domestic medical examination (DME) in the United States (US). **Methods:** We conducted a single center, cross-sectional study of refugees ≥ 18 years old presenting for DME in Philadelphia, PA between March 2017 and March 2021. Patient demographics, clinical and laboratory values were abstracted from the DME with follow up data collected through 9 months following DME. CLD screening was defined by collection of HCV antibody, HBV surface antigen, alcohol use history, and assessment of metabolic syndrome [MetS]. MetS was defined by US National Cholesterol Education Program Adult Treatment Panel III criteria. CLD etiology was defined as follows: chronic HBV (≥ 1 positive HBsAg), HCV (detectable HCV RNA), ALD (> 7 drinks/week in women or > 14 drinks/week in men with ≥ 1 alanine aminotransferase [ALT] elevation > 40 U/L in men or > 30 U/L in women, excluding HBV and HCV), and NAFLD (MetS plus ≥ 1 ALT elevation without HBV, HCV or ALD). Linkage to care for viral hepatitis was defined by ≥ 1 office visit with Hepatology or Infectious Disease and treatment initiation was defined by ≥ 1 prescription for antiviral therapy. Linkage to care for ALD and NAFLD was defined as ≥ 1 office visit with counseling on alcohol cessation or weight loss, respectively. **Results:** 276 refugees were included (median age, 34 years [IQR: 26-42]; 56.2% male), from 34 countries (32.3% Southeast Asia, 27.9% Europe, 21.7% Africa, 15.2% Eastern Mediterranean, 2.9% Americas). HBV and HCV screening was performed in 96% and 34.7%, respectively. Chronic HBV was diagnosed in 4 (1.4%) refugees, of whom 3 were linked to care and 2 initiated antiviral therapy. HCV was identified in 2 (0.7%) refugees; both were linked to care and completed direct-acting antiviral therapy. Alcohol use history was recorded in 85.5%, identifying 2 (0.7%) refugees with ALD, both received counseling. MetS was identified in 10.1%; however, waist circumference was missing in 100% and body mass index was missing in 61.2% of DMEs. Five (1.8%) patients met criteria for NAFLD, with 2 receiving weight loss counseling. **Conclusion:** Near universal HBV screening (96%) was achieved among refugees completing DME, with much lower screening for HCV, ALD, and NAFLD. Improved CLD screening among refugees is needed to better understand disease burden. Successful linkage to specialist care and treatment initiation can be achieved in this vulnerable population.

2849-C | SCREENING FOR HEPATITIS B IN THE BRONX WEST AFRICAN COMMUNITY WITH A BLOOD PRESSURE CUFF

Mandira Shashank[1], Julie Nguyen[1], Jessie Birnbaum[1], Fatima Omarufilo[1], Emmanuel U Emeasoba[1], Kwabena Boakye[1], Viktoriya Khaitova[1], Daniel Guttman[1], Mugdha Parulekar[1], Molly Fisher[1] and Samuel H. Sigal[2], (1)Montefiore Medical Center, (2)Montefiore Medical Center and Albert Einstein College of Medicine

Background: Hepatitis B (HBV) and hypertension (HTN) represent major health burdens in West Africa (WA). Underdiagnosis and inadequate control for both conditions are major public health concerns in WA, and the situation is further complicated in immigrants due to unfamiliarity with the US healthcare system. In contrast to HBV which is not well understood and associated with stigma, HTN is readily recognized as an important medical condition. We describe how HTN screening can facilitate HBV screening and enrollment into the US healthcare system. **Methods:** A 30-minute culturally sensitive educational program on HTN was delivered in collaboration with local faith-based organizations. A brief 5-minute presentation on HTN was also presented upon request at various community gatherings. Names and contact information were obtained after the events for those interested in attending a HTN screening clinic visit at which time a free blood pressure cuff was provided, HBV testing

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

performed, and referrals of family and friends obtained. For those with HTN, participation in ongoing care was assessed. Insurance (ins) was arranged for eligible individual's, and linkage to ongoing care was provided for those without previous integration. **Results:** Seven 30-minute and five 5-minute presentations were conducted. After the 30-minute presentation, 207 of 396 attendees (52.3%) requested a clinic screening visit, and 69 (33.3%) returned for the appointment. Eighty-three individual's requested a clinic screening after the 5-minute presentation, and 52 (62.6%) returned for the appointment. Thirty-two individual's who were at a presentation but did not register subsequently contacted the Program for an appointment. A total of 94 referrals were made. 190 (69.6%) of the individual's evaluated had an elevated blood pressure or history of HTN, including 44 (16.1%) with newly diagnosed and 41 (15%) with severe HTN (>160/90) that required urgent intervention. All individual's except for 2 who reported previous testing agreed to HBV testing. 20 individual's (7.4%) were HBsAg positive. Among the 133 patients with HTN, 27 were not integrated into the US healthcare system. Arrangements for ins coverage and transition into ongoing care were made for all as indicated. **Conclusion:** HTN screening with the offer of a free blood pressure cuff can be effectively utilized to promote HBV screening and integration into the US healthcare system.

2850-C | SIMILAR REJECTION AND RETRANSPLANT RATES BUT DECREASED SURVIVAL AMONG AFRICAN AMERICAN PATIENTS FOLLOWING LIVER TRANSPLANTATION

Mark Obri[1], Suhaib Alhaj Ali[2], Spandana Alluri[2], Momin Samad[2], Mohamed Ramzi Almajed[2], Yervant Ichkhanian[2] and Syed-Mohammed Jafri[3], (1)Henry Ford Health, (2)Henry Ford Hospital, (3)Henry Ford Health System

Background: There are known disparities in medicine in regards to sex and race. Investigation is important to evaluate these disparities and to aim to correct them, offering the best outcome for a diverse range of patients. The study aims to compare liver transplant outcomes based off of the race of the patient. **Methods:** A retrospective study was conducted at a single tertiary liver transplant center and was comprised of patients who underwent liver transplant from 2009 to 2019. The primary outcome was the rate of survival among different races. Secondary outcomes measured included the rate of rejection and re-transplant among different races in addition to the rate of survival among different sexes and donor types. **Results:** This study included 450 patients with race distribution of 83.6% white patients (n = 376), 10.4% black patients (n = 47), and 6.0% patients classified as "Other" races (n = 27). The primary outcome was the rate of survival compared amongst the three groups at 1 year, 3 years, and last known follow-up. Differences in survival rate among the three groups at 1 year was not statistically significant. At 3 years, the survival rate for white patients was 88.6%, black patients was 74.5%, and other patients was 92.6%; the chi-square statistics was 8.2 ($p = 0.016$) which is statistically significant at $p < 0.05$. At the last known follow-up, survival rate for white patients was 82.2%, black patients was 66.0%, and other patients was 88.9%; the chi-square statistic was 8.3 ($p = 0.016$) which is significant. Re-transplant rates did not significantly differ between races with re-transplant rates among white, black, and other patients at 4.3%, 1.2%, and 3.7% respectively. Rejection rates did not significantly differ between races with white, black, and other patients at 24.5%, 31.9%, and 18.5% respectively. Comparisons of survival among patients with difference sexes did not demonstrate a statistically significant difference. **Conclusion:** Correlation exists between different patients races and survival among liver transplant patients. Patients who are black have a statistically lower survival rate (66.0%) compared to those who are white (82.2%) or other (88.9%). Further investigation with larger population sizes including epidemiological studies and subgroup analyses is necessary to delineate the disparities which influence these outcomes. Published literature suggests that access to care, socioeconomic

2851-C | THE TRIPLE BURDEN: HOW OBESITY AND LIVER CIRRHOSIS INFLUENCE PATIENT OUTCOMES, LENGTH OF STAY, AND HEALTHCARE COSTS"

Rajmohan Rammohan[1], Sai Greeshma Magam[1], Melvin Joy[2], Dilman Natt[1], Achal Patel[1], Abhishek Tadikonda[1], Jiten Desai[1], Sandra Gomez[1], Susan Bunting[1] and Paul Mustacchia[1], (1)Nassau University Medical Center, (2)Nassau University Medical Center, East Meadow, NY

Background: Liver cirrhosis is a significant public health issue in the United States, contributing to substantial morbidity and mortality rates. The prevalence of liver cirrhosis among US adults stands at 0.27%, which translates to 633,323 cases. Obesity is a well-established factor in the development of nonalcoholic fatty liver disease. Between 1999 and 2020, the obesity rate in the US population rose from 30.5% to 41.9%, while the prevalence of severe obesity increased from 4.7% to 9.2%. If obesity is not effectively addressed at an early stage, an inflammatory process begins within the liver, potentially leading to fibrosis and compromised liver function, ultimately resulting in cirrhosis. **Methods:** The Nationwide Inpatient Sample database was examined for the years 2019-2022, and data on 11,413 liver cirrhosis patients' hospital admissions were collected. Following propensity score matching, 5,097 patients were included in the study. Patients were categorized into three groups based on their BMI: Group A [>35] with 1,379 patients (27.1%), Group B [30-34] with 1,308 patients (25.6%), and Group C [25-29] with 2,410 patients (47.2%). Our study initially employed the Kaplan-Meier curve and Log Rank Mantel-Cox test to compare the three groups. Subsequently, we stratified the original dataset and applied the Hazard ratio to identify factors contributing to an extended length of stay. **Results:** A total of 5,097 liver cirrhosis patients were analyzed in this study. The median length of hospital stay, as determined by the Kaplan-Meier Curve, was 10 ± 5 days for Group A, 8 ± 4 days for Group B, and 3 ± 2 days for Group C. The Log Rank Mantel-Cox comparison among the three groups was statistically significant, with a p-value of 0.045. Factors that extended the length of hospital stay included abnormalities in COPD ($HR = 0.546$, $p < 0.01$), renal failure ($HR = 0.446$, $p = 0.04$), and heart failure ($HR = 0.716$, $p < 0.012$). Patients with more than two chronic diseases experienced a significantly longer stay ($HR = 0.746$, $p < 0.023$) compared to those without comorbidities. **Conclusion:** Obesity in liver cirrhosis patients, when accompanied by comorbidities, can impact the length of hospital stays. Factors contributing to extended stays can lead to increased healthcare costs.

2852-C | UNDIAGNOSED CIRRHOSIS IN A NATIONAL COHORT OF VETERANS WITH DEMENTIA WITH POTENTIAL HEPATIC ENCEPHALOPATHY OVERLAP, IS HIGHER IN MINORITIES

Jasmohan S. Bajaj[1], Scott Silvey[2] and Nilang Patel[2], (1) Virginia Commonwealth University and Central Virginia Veterans Healthcare System, Richmond, VA, (2)Virginia Commonwealth University and Richmond VA Medical Center

Background: Dementia and hepatic encephalopathy (HE) can overlap given the increasing age of pts with cirrhosis. Within the Veterans Health Administration (VHA) patients in those with diagnosed cirrhosis, 8% have dementia with overlap with HE. HE is treatable, unlike dementia but only if suspected/identified. However, the rate of undiagnosed cirrhosis in those with dementia is unclear. **Aim**: Determine the rate and determinants of undiagnosed cirrhosis in Veterans with dementia **Methods**: Using the VHA Corporate Data Warehouse from 2009-2019, we identified pts with dementia at e 2 time-points with validated codes. We then excluded pts with diagnosed cirrhosis & complications. The remaining pts were studied using the FIB-4 with > 3.25 and for sensitivity with a > 2.67 threshold. We collected AST/ALT values within 2 yrs after dementia diagnosis & capped the age at

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

65 years to reduce confounding due to age. Crude comparisons: We compared demographics, co-morbidities [Charlson comorbidity index (CCI), organ dysfunction, diabetes, stroke, cardiovascular diagnoses], lifestyle (alcohol, tobacco), others (head injury, PTSD, depression) & hepatitis B/C. Multivariable logistic regression: 2 models were created using covariates that were significantly different; one for FIB-4 > 3.25 & one for > 2.67. **Results**: Of 287,257 patients with dementia, 38% were excluded for reasons shown in Fig A. Of the remaining 177422, 5.3% had FIB-4 > 3.25 while 10.3% patients had FIB-4 > 2.67. Crude comparison (Fig B): With > 3.25, high FIB-4 pts were more likely to be older, male, of Hispanic ethnicity and races other than White. High FIB-4 pts had higher alcohol use, HIV, hepatitis, & comorbidities such as hypertension, heart/kidney disease, PVD and stroke. In low FIB-4 pts, rural residence, tobacco use, diabetes, sleep apnea, head injury, depression and PTSD were higher. Similar trends were seen with > 2.67 cut-off. Multivariable regression: In the FIB-4 > 3.25 model, all variables were significant apart from head injury, sleep apnea, PVD, HIV, & Hispanic ethnicity (Fig C). In the FIB-4 > 2.67 model, all variables were significant, including Hispanic ethnicity but not sleep apnea, hypertension, head injury, & HIV. In both models, high FIB-4 scores were associated with CHF, hepatitis, alcohol use disorder, & male sex, while those with lowest odds ratios were white race, diabetes, tobacco use & hyperlipidemia. **Conclusion**: In Veterans with dementia without cirrhosis, we found undiagnosed cirrhosis in 5-10% of patients, the rate of which was higher in minorities. HE and dementia symptoms can overlap, therefore, missed cirrhosis could be associated with treatable HE that could improve symptoms and daily functioning. Determinants for undiagnosed cirrhosis were stable across FIB-4 thresholds. Clinicians encountering pts with dementia should focus on minorities, living in urban areas and with prior hepatitis and alcohol use, to ensure cirrhosis and potential HE is not missed

2853-C | USING EXPLANATORY MIXED METHODS TO UNDERSTAND DISEASE-RELATED STIGMA AMONG KOREAN AMERICANS WITH CHRONIC HEPATITIS B (CHB)

Ann Klassen[1], Eunji Kim[1], Giyoung Lee[1], Katherine Clegg Smith[2], Hie-Won L. Hann[3], Mimi Chang[4], Ho Bae[4], Kyunghee Koh[5] and Hee-Soon Juon[5], (1)Drexel University Dornsife School of Public Health, (2)Johns Hopkins Bloomberg School of Public Health, (3)Thomas Jefferson University Hospital, Philadelphia, PA, (4) Coalition of Inclusive Medicine, (5)Thomas Jefferson University

Background: Stigma regarding infectious diseases is known to cause emotional distress, isolate individual's from their social networks, impact adherence and health outcomes, and undermine societal support for affected groups. However, it is less well understood how stigma is experienced differently within specific patient groups, and which patient groups should be prioritized for support. **Methods:** Our NIDDK-funded longitudinal cohort study, Bio-Psycho-Social Drivers of Disparities in Liver Disease Progression among Korean Americans with Hepatitis B Infection (MPI: Juon/Klassen), follows 365 patients at two clinical sites, collecting retrospective and prospective medical data, as well as structured surveys, in-depth qualitative interviews, hair cortisol biomarkers of chronic stress, and GIS-based analyses of neighborhood resources. This analysis focuses on survey responses to the HBQOL-Stigma subscale, and associations with psychosocial characteristics, including depressive symptoms and acculturative stress. A purposively selected subset of 30 participants is participating in 60-minute audio-recorded in-depth interviews, to elaborate qualitatively on patterns observed in the structured data. Thematic coding uses MAXQDA qualitative software, facilitating integration of quantitative and qualitative patterns. **Results:** The six-item, 30-point stigma index had strong reliability (alpha = 0.92), with a mean score of 5.4, and a range of 0-24. In a multivariable regression model, older age was significantly associated with lower self-reported stigma. Women as well as those with higher depressive symptoms and acculturative stress reported

greater hepatitis B-related stigma. In qualitative interviews, respondents elaborated that their CHB status was not internalized as part of their identity, but that they did feel CHB-related stigma, and were cautious about disclosure. Some viewed CHB stigma as higher among Korean-Americans than in Korea, due to the insular nature of U.S. immigrant communities. Others felt that older generations stigmatized CHB due to its potential threat to financial success and longevity. Younger patients felt that among their peers, CHB was mostly unknown and thus less stigmatized, but misperceptions about severity and contagiousness were common. **Conclusion:** Mixed methods approaches to understanding complex disease-related experiences can identify strategies for tailored education to reduce CHB-related stigma within cultural subgroups.

2854-C | VIRAL HEPATITIS B AND C IN A VULNERABLE POPULATION (MIGRANTS & HOMELESS). FIVE-YEAR RESULTS OF A PROSPECTIVE COHORT IN A LARGE ELIMINATION PROGRAM

Victor De Ledinghen[1], Anne-Laure De Araujo[2], Julie Dupuy[2], Rhizlane Houmadi[2], Adèle Delamarre[3], Paul Hermabessière[2] and Juliette Foucher[2], (1)Centre D'investigation De La Fibrose Hépatique, Bordeaux University Hospital, Pessac, France; Inserm U1053, Bordeaux University, Bordeaux, France., (2)CHU Bordeaux, Bordeaux, France, (3)Ordeaux

Background: Migrants and persons experiencing homelessness encounter many barriers to HBV/HCV care (from screening to treatment and follow-up). Therefore, it is necessary to provide easy and rapid access to diagnosis, treatment and follow-up, to these patients. In 2017, we started a program to promote more equitable link to care by bringing screening into the community and promoting easy access to care and follow-up in this population. The current study aimed assess this elimination strategy based on a community intervention and simplified access to care in our metropolis of about 800,000 inhabitants. **Methods:** From January 2017 to March 2023, all patients who attended our simplified access to care after a screening in any community center in our area were included. All patients had a clinical, biological, virological, morphological assessment, met a nurse and a physician, and another appointment was organized for their follow-up. In HCV patients, treatment was initiated as soon as possible and the follow-up was stopped after SVR, except in cirrhotic patients. In HBV/HDV patients, a follow-up at least once a year was organized. **Results:** A total of 728 patients were screened by 50 community centers and referred to our center. Among them, 83 (11.4%) never attended the first appointment. Characteristics of the 645 other patients were: male 499 (77.4%), mean age 30.7 yrs (148 patients (22.9%) were < 18 y). Main countries of birth were Guinea (122), Georgia (69), Mali (57), and Ivory Coast (53). Viral infections were HBV 492 (76.3%), HCV 118 (18.3%), HDV 30 (4.7%) and coinfections 5 (0.7%). Median time between arrival in France and the first consultation was 158 days. 118 HCV monoinfected patients were included: 12 patients had spontaneous clearance of HCV infection. Among these 106 patients, 77 received a treatment. SVR was available in 58 patients (75.3%), treatment is on-going in 10 and 9 patients (11.7%) did not attend the visit to assess SVR. 492 HBV monoinfected patients were included. 9 patients had negative HBsAg. Median follow-up was 13.2 months (extremes: 0-74.3 mo). After exclusion of patients seen during the last year, this follow-up was 17.2 months. 33 patients were HBeAg+. Among them, 5 (15.2%) were lost to follow-up. 107 patients had HBeAg- hepatitis (HBV-DNA > 2000 IU/ml) and 70 (65.4%) received a treatment. 21 patients (19.6%) were lost to follow-up. 343 had HBeAg- infection. Among them, 130 (37.9%) were lost to follow-up. Cascade of viral elimination is indicated in Figure. **Conclusion:** In this very difficult to manage population, the elimination of viral hepatitis is possible by working very closely with all community structures in the region. The care pathway was easy with very quick access to our expert center and 89% of patients attended the first appointment. Less than 20% of treated patients were lost to follow-up. This program is on-going with more community centers.

3000-A | A NOVEL BEDSIDE METHOD TO QUANTIFY ASCITES SEVERITY VIA PARACENTESIS PRESSURE

Nikhilesh R Mazumder[1], Elliot B. Tapper[2], Sardar Ansari[1] and Anna Lok[2], (1)University of Michigan, (2) University of Michigan Medical Center

Background: High-pressure 'tense' ascites is the most debilitating form of ascites, requiring paracentesis to decompress. Tense ascites is thought to relate to more severe portal hypertension and more advanced liver disease. While thrombocytopenia is known to correlate with severity of portal hypertension and likelihood of variceal bleeding independent of MELD, its correlation with ascites pressure has not been studied. We describe a novel method to measure ascites pressure in outpatients undergoing paracentesis ("Paracentesis pressure") and explore its relationship to known measures of liver disease severity. **Methods:** Adult outpatients undergoing therapeutic paracentesis were consented. An open-ended manometer and stopcock from a lumbar puncture kit was placed inline with the paracentesis tubing. The zero point was at the level of the xiphoid process at the mid-axillary line corresponding to the anatomical location of the right atrium with the patient lying at 30 degrees. Pressures were measured at end expiration during gentle breathing with suction disconnected. Pressure measurements were taken at the procedure start and repeated at 1.5L increments until the end of the procedure. Routine labs were obtained. Univariate and multivariate linear regression was performed after outlier analysis based on Cook's distance to evaluate the relationship between ascites pressure, volume, thrombocytopenia, and lab measures of liver disease severity. **Results:** Eighty five procedures among 34 patients were included for analysis. Patients had a mean MELD-Na of 15.9 (SD 7), albumin of 3.3 (SD 0.5) g/L, and platelet count of 103 (SD 43)K/uL. At procedure start, paracentesis pressure was a mean of 11.2 (SD 3.8) cm H_2O, dropping to a mean of 2.9 (SD 3.9) cm H_2O after the removal of an average of 7.1L. MELD-Na was not associated with platelet count, opening pressure or volume drained ($p > 0.05$ for all). Thrombocytopenia was significantly associated with initial paracentesis pressure (Figure, 0.3 cmH_2O per 10K/uL drop, $p < 0.01$) but not with volume drained ($p = 0.06$). Serum albumin was not significantly associated with initial paracentesis pressure ($p = 0.06$) or volume drained ($p =$ NS). **Conclusion:** In this preliminary study, we describe a bedside method using readily available materials to determine ascitic pressure in outpatients undergoing therapeutic paracentesis. The opening paracentesis pressure correlated with platelet count, but not MELD-Na, supporting its role as a MELD-independent marker of portal hypertension. Future studies should evaluate paracentesis pressure against HVPG in measuring portal hypertension in patients with ascites.

3001-A | ACUTE KIDNEY DISEASE IS COMMON AND ASSOCIATED WITH HIGH MORTALITY IN CIRRHOTIC PATIENTS WITH ACUTE KIDNEY INJURY

Jeongeun Song, Byung Seok Kim and Chang-Hyeong Lee, Daegu Catholic University School of Medicine

Background: Acute kidney disease (AKD) is the persistence of acute kidney injury (AKI) for up to 3 months, which

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

is proposed to be the time-window where critical interventions can be tried to change clinical outcomes of AKI. In cirrhosis, AKD and its impact on outcomes have been insufficiently evaluated. We aimed to investigate the incidence and clinical outcomes related to AKD in patients with cirrhosis and AKI. **Methods:** Cirrhotic patients, who were hospitalized from January 2014 to December 2017 at Daegu Catholic University Hospital, were assessed for AKI and AKD, and followed-up for 180 days. AKI, AKD and CKD were defined based on KDIGO and ADQI AKD and renal recovery consensus criteria, respectively. The primary outcome was mortality at 90 and 180 days, and the secondary outcome was de novo chronic kidney disease (CKD). **Results:** Of the 392 hospitalized patients with cirrhosis, AKI developed in 36.5% (n = 143). AKD occurred in 32.9% (n = 47) of AKI patients. The cumulative incidence of mortality was significantly higher in patients with AKD compared to to those without AKD: 90-day 12.8% vs. 61.7%, 180-day 17.7% vs. 68.8% ($p < 0.001$). On multivariable analysis, patients with AKD had higher risk of mortality at 90 dyas (hazard ratio [HR] 7.73; 95% CI 3.00-19.92; $p < 0.001$) and 180 days (HR 7.45; 95% CI 3.17-17.49; $p < 0.001$). The incidence of de novo CKD was 14.9% of AKD patients, but there was no occurrence of de novo CKD in patients without AKD. **Conclusion:** AKD develops in about 1 in 3 hospitalized cirrhotic patients with AKI and it is related to worse survival and de novo CKD.

Table1. Comparison of clinical characteristics between patients with and without AKD

Variables	No-AKD n=47	AKD n=47	*P* value
Age, years	52 (47-63)	58 (51-66)	0.196

3002-A | ADIPOSE COMPARTMENTS PREDICT SEVERITY OF PORTAL HYPERTENSION AMONG PATIENTS WITH CIRRHOSIS

Mohammad S. Siddiqui[1], Danielle Kirkman[1], Vaishali Patel[2], Seung Lee[2], Jennifer Linge[3], Geneva Roche[1], Hiba Kamal[1], Per Widholm[3], Olof Dahlqvist Leinhard[4] and Mikael Fredrik Forsgren[4], (1)Virginia Commonwealth University, (2)Virginia Commonwealth University Health System, (3)Amra Medical AB, (4) Amra Medical

Background: Recent studies highlight the limited prognostic value of MELD score in cirrhosis and underscore the importance of developing additional multi-modal biomarkers. While skeletal muscle mass is a robust predictor of clinical outcomes in patients with decompensated cirrhosis, there is little data evaluating the relationship between other body compartments, such as adipose tissue, and portal hypertension. Thus, the aim of the current study was to evaluate the association between adipose tissue compartments and portal hypertension among patients with cirrhosis. **Methods:** 37 patients (29 females) with cirrhosis underwent 8-min magnetic resonance imaging (MRI) and blood work after an overnight fast. The MRI based assessment was measured via AMRA® Researcher and quantified body fat compartments that included abdominal subcutaneous adipose tissue (ASAT), liver fat content (LF), muscle fat infiltration (MFI) and visceral adipose tissue (VAT). MFI was adjusted for sex differences. Complications of portal hypertension included history of ascites, esophageal varices, acute variceal hemorrhage, hepatic encephalopathy, and spontaneous bacterial peritonitis. Mixed model linear regressions was used for statistical testing between body fat compartments and history of portal hypertension complications, etiology of chronic liver disease and gender. **Results:** The average MELD score of the study cohort was 13 and the most common etiology of cirrhosis was alcoholic and nonalcoholic steatohepatitis (n = 20). There was less body fat in those patients with a history of decompensation events when compared to patients who did not have a decompensating events (Figure 1). The data from linear regression models with standardized β-coefficient is as follows: MFI -2.62 pp ($p = 0.02$), VAT -2.57 L ($p = 0.01$), ASAT -3.35 L ($p = 0.06$), and liver fat -2.94 percentage points ($p = 0.03$). In addition to aggregate endpoint of presence of any decompensating event, an association between lower fat compartments and individual portal hypertension complications was also noted. The

association between body compartments and previous portal hypertension complications was independent of gender and etiology of chronic liver disease leading to cirrhosis. In multivariate models all the fat compartments, including ASAT (p = 0.049), were significantly associated with presence of portal hypertension. **Conclusion:** The current study provides data demonstrating the relationship between portal hypertension related complications and lower adipose tissue depots. These findings have the potential to provide additional risk stratification tools in patients in whom the MELD score may not be as robust of predictor of clinical events. However, this requires further validation in well-designed prospective studies.

3003-A | APPLICATION OF A FIB-4/VITRO SEQUENCE FACILITATES CACLD DIAGNOSIS AND RISK STRATIFICATION FOR SIGNIFICANT PORTAL HYPERTENSION WITHOUT NEED FOR LIVER STIFFNESS MEASUREMENT

Lukas Hartl[1,2], Georg Semmler[1,2], Mathias Jachs[2,3], Benedikt Simbrunner[4,5], Benedikt Silvester Hofer[5,6], Lorenz Balcar[2,7], Michael Schwarz[2,3], Laurenz Fritz[1], Anna Schedlbauer[1], Katharina Stopfer[1], Daniela Neumayer[1], Jurij Maurer[1], Robin Szymanski[1], Bernhard Scheiner[1,2], Michael Trauner[1], Thomas Reiberger[2,3] and Mattias Mandorfer[1,6], (1)Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, (2) Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria, (3)Medical University of Vienna, (4)Cemm Research Center for Molecular Medicine of the Austrian Academy of Sciences, (5)Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, (6)Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, (7)Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria

Background: The population at risk for liver-related complications is defined by compensated advanced chronic liver disease (cACLD), while presence of clinically significant portal hypertension (CSPH) identifies the target population for prevention of hepatic decompensation. Liver stiffness measurement (LSM) via vibration-controlled transient elastography enables non-invasive diagnosis of these conditions, but its availability is oftentimes limited to tertiary care, potentially impeding the identification of cACLD/CSPH in the community. Thus, we developed a routine laboratory-based algorithm to (i) identify patients with cACLD via fibrosis-4 index (FIB-4) and (ii) subsequently rule-in/rule-out CSPH using von Willebrand factor antigen/platelet count ratio (VITRO). **Methods:** FIB-4 cohort: To determine a FIB-4 cut-off for cACLD diagnosis, all patients with suspected cACLD undergoing LSM and FIB-4 assessment between 2007-2021 were characterized and followed-up for development of hepatic decompensation. VITRO cohort: cACLD patients (diagnosed by the FIB-4 cut-off) with hepatic venous pressure gradient (HVPG) measurement were analysed. **Results:** FIB-4 cohort: Among 6182 patients (median follow-up [FU] time: 54.6 mo) hepatic decompensation occurred in 3.4% (n = 211). Both LSM (AUC 0.90; 95%CI: 0.86-0.92) and FIB-4 (AUC 0.91; 95%CI: 0.88-0.94) exhibited excellent accuracy in predicting hepatic decompensation within 2 years of FU. FIB-4 e 1.75 (corresponding to LSM e 10kPa) was determined as cut-off for cACLD identification, ruling-out cACLD in 72% of patients. Patients with FIB-4 < 1.75 had negligible risk of of hepatic decompensation at 5 years of FU (cumulative incidence 0.03%). VITRO cohort: 317 cACLD patients (CSPH prevalence: 62.8%, n = 199/317) were included. Accuracy for diagnosing CSPG was similar for VITRO (AUC 0.85; 95%CI: 0.80-0.89), LSM (AUC 0.85; 95%CI: 0.81-0.89; DeLong-Test: p = 0.903) and the ANTICIPATE

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

model (AUC 0.89; 95%CI: 0.86-0.93; p = 0.109). VITRO < 1.0 ruled-out (prevalence: 11.4%; sensitivity 97.5%) and VITRO e 2.5 ruled-in CSPH (prevalence: 41.6%; specificity 90.6%), with results comparable to the Baveno VII cut-offs LSM d 15kPa + PLT e 150G/L (prevalence: 10.1%; sensitivity: 99.0%) and LSM e 25kPa (prevalence: 44.2%; specificity: 89.0%). **Conclusion:** FIB-4 e 1.75 identifies cACLD and VITRO < 1.0 / e 2.5 rules-out/rules-in CSPH with a similar diagnostic accuracy as criteria based on LSM. Simple laboratory tests may broaden the access to risk stratification and facilitate early intervention to prevent first hepatic decompensation.

3004-A | ASCITES IN A SICKLE CELL PATIENT

Nilofar Najafian[1], Sammy Saab[2], Samuel W. French[1] and Akshay Shetty[2], (1)University of California-Los Angeles, (2)University of California, Los Angeles

Background: Sickle cell hepatopathy is an entity with a wide range of clinical presentations. Though sickling of red blood cells in hepatic sinusoids is commonly seen, no prior cases of associated portal hypertension have been reported in the absence of cirrhosis. **Methods:** Clinical data was extracted from the medical records and interpreted in this case report. **Results:** A post-liver transplant sickle cell patient was found to have acute sickle hepatic crisis and new onset ascites. Fluid analysis revealed a high SAAG, high protein ascites without evidence of a peritoneal infection. Transthoracic echocardiogram showed intact left ventricular function and normal right ventricular systolic pressure. Portal pressure measurements showed right atrial pressure of 8 mmHg, free hepatic vein pressure 12 mmHg, wedged hepatic vein pressure 21, and elevated hepatic venous pressure gradient (HVPG) of 9mm Hg. Trans-jugular liver biopsy showed pan-lobular vascular congestion and sinusoidal congestion in absence of rejection, steatosis, or fibrosis, suggesting sinusoidal obstruction syndrome in the setting of hepatic sickling as the cause of portal hypertension (Figure 1). **Conclusion:** Sinusoidal obstruction syndrome is an entity that may be seen in patients with sickle cell disease even after liver transplantation. Proactive practices post-transplant may help minimize recurrent sickle cell hepatopathy and development of portal hypertension.

3005-A | BASELINE CORTISOL LEVELS DO NOT PREDICT ADRENAL DYSFUNCTION IN DECOMPENSATED CIRRHOSIS

Matthew Schliep, Brian Wentworth, Wendy M Novicoff, Zachary Henry and Helmy Siragy, University of Virginia

Background: Adrenal dysfunction (AD) is common in patients with decompensated cirrhosis. Data from the general population suggests that a low isolated morning total cortisol (TC) level may predict adrenal insufficiency, yet whether this can be extrapolated to patients with cirrhosis and hypoproteinemia is unknown. We aimed to assess whether an isolated morning cortisol level (both total and plasma free) predicted an impaired response to ACTH stimulation testing in non-critically ill patients with cirrhosis. **Methods:** We performed a single-center, retrospective cohort study including patients with decompensated cirrhosis admitted without critical illness or hemodynamic instability who underwent ACTH stimulation testing between Jan 1, 2017 and February 28, 2022. All patients had baseline TC and plasma free cortisol levels (PFC) drawn, then were administered standard-dose (250 μcg) synacthen stimulation test. An abnormal cortisol response (AD) was defined as an increase (delta) of TC < 9 μg/dL after 60 minutes. Between group variables were compared using the appropriate univariate test (mean ± SD, median (IQR), two-tailed independent t-test, or Mann-Whitney U test). Multivariate logistic regression models were constructed to investigate whether basal cortisol levels and/or other common clinical parameters (albumin level, HDL level, MELD score) predicted the presence of AD. A sensitivity analysis utilizing a TC < 5 μg/dL threshold was also performed. **Results:** One hundred and twenty-two patients were included for analysis; 58 met criteria for AD. Demographic variables, disease etiology, and electrolyte profile were similar between patients with and without AD. Patients with AD had more severe liver disease (Child-Pugh C classification: 76% vs. 37%, $p < 0.001$; MELD score: 20 vs. 17, $p = 0.008$) and hypoalbuminemia (2.6 vs. 2.9 mg/dL, $p = 0.019$). Basal TC (OR 1.000, 95% CI 0.912-1.096, 0.993) and PFC (OR 1.213, 95% CI 0.614-2.399, $p = 0.578$) were not predictive of AD on multivariate regression. A basal TC < 5 μg/dL also did not predict AD presence (OR 0.979, 95% CI 0.403-2.376, $p = 0.963$). MELD score and albumin level were significant independent predictors of AD in all models (Table 1). **Conclusion:** Baseline cortisol levels do not predict ACTH stimulation response in non-critically ill patients with decompensated cirrhosis. The presence of AD appears related to disease severity but formal adrenal axis testing is necessary for appropriate assessment.

Table 1. Multivariate analysis of predictors of adrenal dysfunction

Variables	Odds Ratio	95% CI	P value
*Model 1**			
Baseline TC	1.000	0.912-1.096	0.993
Albumin	0.384	0.182-0.811	**0.012**
HDL	1.003	0.969-1.038	0.856
MELD score	1.100	1.025-1.181	**0.008**
*Model 2**			
Baseline PFC	1.213	0.614-2.399	0.578
Albumin	0.375	0.176-0.801	**0.011**
HDL	1.004	0.972-1.038	0.793
MELD score	1.095	1.021-1.175	**0.011**
*Model 3**			
Baseline TC < 5 μg/dL	0.979	0.403-2.376	0.963
Albumin	0.384	0.186-0.793	**0.010**
HDL	1.003	0.970-1.038	0.846
MELD score	1.101	1.026-1.181	**0.008**

* AUC: Model 1 = 0.688, Model 2 = 0.687, Model 3 = 0.688.

3006-A | CAUSAL EFFECT OF ALBUMIN INFUSION FOLLOWING LARGE-VOLUME PARACENTESIS: RE-EVALUATION OF THE AASLD PRACTICE GUIDANCE WITH REGRESSION DISCONTINUITY

Tomohiro Tanaka[1], Michael P Jones[2] and George Wehby[2,3], (1)University of Iowa Carver College of Medicine, (2)Center for Access and Delivery Research

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

and Evaluation (CADRE), Iowa City VA Health Care System, (3)University of Iowa College of Public Health

Background: The 2021 AASLD Practice Guidance recommends using albumin infusion to prevent post-paracentesis circulatory dysfunction when > 5 liter of ascites are removed. However, the optimal cutoff for initiating albumin infusion following large-volume paracentesis (LVP) based on ascites removed remains understudied. **Methods:** We conducted a retrospective cohort study at a U.S. academic healthcare center on all patients who underwent outpatient LVP between 2019 and 2022. Patients with spontaneous bacterial peritonitis, post-LVP adjustment of diuretics, and/or hospitalization were excluded. The institution strictly followed the Guidance, which recommends albumin infusion for patients who had e 5 liters of ascites removed, making the cohort suitable for a Quasi-experimental, sharp regression discontinuity (RD) design to estimate the local average treatment effect of albumin infusion on the trajectory of serum creatinine and serum sodium levels. We also conducted sensitivity analyses using different kernel functions, bandwidths, and regression models that included both fixed effects (confounders) and random effects (unique patients). **Results:** Over the study period, a total of 1457 LVP procedures were performed on 236 unique patients, with a median of 2 procedures and an interquartile range (IQR) of 6 per patient. In our main RD models, we used a local polynomial and linear RD estimation. Results revealed that administering albumin infusion at threshold of 5 L of ascites removal led to a significant reduction in serum creatinine levels by 0.05 (95%CI: 0.01-0.097) and 0.048 (0.01-0.086) mg/dl/day, and an increase in serum sodium levels of 0.34 (95%CI: 0.12-0.6) and 0.39 (0.16-0.61) mEq/L/day, respectively, compared to those who did not receive albumin infusion (Figure). The RD plots also indicated elevated serum creatine and reduced serum sodium levels after draining 3-4 liters of fluid, approaching levels similar to or worse than with albumin infusion at 5 liters or more, suggesting potential benefits for albumin replacement at a lower cut-off. **Conclusion:** RD models provide strong evidence that administering albumin infusion just above 5L of ascites removal during LVP has significant benefits. The consistency of findings across sensitivity analyses underscores the robustness of the effect size estimation. Findings support the conduct of clinical trials to evaluate the efficacy of albumin infusion in patients who undergo LVP and have 3-5 or 4-5 liters of ascites removed.

3007-A | CLINICAL FEATURES OF ACUTE KIDNEY INJURY-NON HEPATORENAL SYNDROME VERSUS TYPE 1 HEPATORENAL SYNDROME IN PATIENTS WITH CIRRHOSIS AND ASCITES FROM A SINGLE QUATERNARY REFERRAL ACADEMIC CENTRE

Neha Tiwari[1], Chinmay Bera[2], Cynthia Tsien[3], Audrey Kapelera[1], Nazia Selzner[3] and Florence Wong[1], (1) Division of Gastroenterology and Hepatology, Toronto General Hospital, Toronto, ON, Canada, (2)University Health Network, (3)Ajmera Transplant Center, University of Toronto, Toronto, ON, Canada

Background: The re-classification of renal dysfunction in cirrhosis to acute kidney injury (AKI), replacing type 1 hepatorenal (HRS1), is meant to lead to earlier diagnosis and treatment. The aim of this study was to identify clinical features that distinguish AKI-non-HRS1 (NHRS1) from HRS1 to facilitate earlier recognition of pending HRS1. **Methods:** Retrospective study of patients with cirrhosis and ascites from a single quaternary centre from Apr 2020 to Mar 2021 identified patients who fulfilled the 2015 International Ascites Club (IAC) diagnosis of AKI. They were then separated into those fulfilling the 2007 IAC diagnostic criteria of HRS1 vs. those who did not. Data were collected on demographics, clinical features, AKI characteristics, AKI and patient outcomes at 6 months. Multivariate analysis for factors predicting AKI severity was done. **Results:** 81 of 306 patients with ascites of various severities had 120 AKI episodes (stage 1: n = 84, stage 2 but not HRS1: n = 11, HRS1: n = 25). The 1st 2 groups

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

formed the NHRS1 group. The HRS1 group were mostly alcoholics (93%) ($p = 0.03$ vs. NHRS1) with a shorter history of ascites (17M vs. 28M, $p = 0.04$), but a frequent history of SBP ($p = 0.05$). 55% of HRS1 patients presented as outpatients ($p = 0.01$ vs. NHRS1) with evidence of liver failure (INR: 2.1 vs. 1.6, $p = 0.02$, bilirubin: 175 vs. 45μmol/L, $p = 0.001$). The NHRS1 group was more likely to have dehydration as an AKI precipitant (34% vs. 8%, $p = 0.03$), whereas infection was the more frequent precipitant in HRS1 patients (32% vs. 6%, $p < 0.001$). 88% of HRS1 patients received midodrine and albumin, vs. 31% in the NHRS1 group ($p = 0.008$), whereas 8% of HRS1 and 41% NHRS1 patients received albumin only ($p < 0.001$). HRS1 patients received a mean of 321g of albumin vs. 107g in the NHRS1 group ($p < 0.001$). Response to treatment in HRS1 was inferior to that of NHRS1 ($p = 0.006$), as these patients had other organ failures (mean 2.3 organ failure vs. 1.3 in NHRS1 group, $p < 0.001$). Survival at 6 months was significant reduced ($p < 0.001$) in the HRS1 group due to recurrent stage 2 AKI ($p = 0.001$) and repeat hospital admissions ($p < 0.001$). For every 5-point increase in MELD, there is a 2.13 X the risk for the development of HRS1. **Conclusion:** This study identifies the profile of the patient likely to develop HRS1, with baseline MELD as a strong predictor. Every effort should be made to prevent MELD increase, as this may reduce the chance of HRS1 development, a condition with a potentially fatal outcome.

3008-A | COMPARISON OF MELD AND MELD-NA AS PROGNOSTIC SCORE FOR PATIENTS UNDERGOING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT PLACEMENT

Akash Singh, Sagar Desai, Manisha Verma, Manish Thapar, Balasubramani Natarajan, Paul Brady and Richard S. Kalman, Einstein Healthcare Network

Background: The purpose of this study was to compare the ability of the model for end-stage liver disease (MELD) and sodium MELD (MELD-Na) scoring systems to predict outcomes after transjugular intrahepatic portosystemic shunt (TIPS) placement. MELD has traditionally been seen as the gold standard for post-TIPS mortality prediction. **Methods:** Eighty-five consecutive patients who underwent TIPS placement were retrospectively reviewed. The primary outcomes were death within 30 days and 90 days after TIPS placement (30- and 90- day mortality, respectively), and secondary outcome included death within 365 days after TIPS placement (365-day mortality). **Results:** Mortality rates within 30, 90, and 365 days after TIPS placement were 10.6% (9/85), 15.3% (13/85), and 21.2% (18/85). Simple logistic regression showed that MELD score predicted 30-day mortality (odds ratio [OR], 1.166; 95% CI, 1.059–1.285; $p = 0.002$) and 90-day mortality (OR, 1.154; 95% CI, 1.052–1.266; $p = 0.002$). MELD-Na score also predicted 30-day mortality (OR, 1.61; 95% CI, 1.059–1.273; $p = 0.001$) and 90-day mortality (OR, 1.144; 95% CI, 1.051–1.245; $p = 0.002$). In comparing the ROC AUCs for MELD with MELD-Na, they were similar in predicting 30-day mortality ($p = 0.367$) and 90-day mortality ($p = 0.218$). However, 365-day mortality prediction was significantly better with MELD as compared to MELD-Na while comparing both AUCs ($p = 0.041$). Overall, 30-day readmission rate after TIPS placement was 35% (30/85). The most common diagnosis at the time of readmission was decompensation of liver disease associated with hepatic encephalopathy (50%). There were five patients with high MELD-Na e 17, and low MELD < 15. There was no 90-day mortality in this

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

group, but the rate of readmission was 40%. **Conclusion:** MELD and MELD-Na are similar in predicting 30-day mortality and 90-day mortality. However, MELD seems to be more predictive of 365-day mortality than MELD Na. MELD should remain the gold standard for prediction of post-TIPS mortality at one year.

3009-A | CONSULTATION TO HEPATOLOGY INCREASE RATES OF ANTIBIOTIC PRESCRIPTION FOR SPONTANEOUS BACTERIAL PERITONITIS PROPHYLAXIS AND REDUCED HOSPITAL MORTALITY FROM FUTURE SPONTANEOUS BACTERIAL PERITONITIS EPISODES

Parth Bhupendra Patel[1], Sujan Ravi[1], Ore Adekunle[1], Udita Gupta[1], Thomas Ruli[1], Mohamed Galal Shoreibah[2] and University of Alabama at Birmingham, (1)University of Alabama at Birmingham, (2)University of Alabama at Birmingham, Birmingham, AL

Background: Spontaneous bacterial peritonitis (SBP) is a common yet serious infection that occurs in cirrhotic patients with ascites. SBP has been shown to have a mortality rate of 80% with a delay in antibiotics being associated with an increased mortality. Many are familiar with the concept of initiating antibiotics due to elevated polymorphonuclear leukocytes or positive ascitic fluid cultures, but many are unaware of discharging patients with antibiotics for primary SBP prevention. In patients who meet criteria for low protein ascites (<1.5 g/dL) and advanced liver failure (Child-Pugh >9 and serum bilirubin >3mg/dL) or renal impairment (serum creatinine of >1.2 mg/dL, BUN levels >25 mg/dL, or sodium of <130 mEq/L) antibiotics such as Norfloxacin or Bactrim should be prescribed to prevent SBP episodes. We hypothesize that consultation to Hepatology in cirrhotic patients needing a paracentesis will lead to more antibiotic prescriptions, reduced in-hospital mortality, and increased prevention of future SBP episodes. **Methods:** We performed a retrospective cohort study and included cirrhotic patients admitted in 2021 that required a paracentesis. Data collected includes baseline characteristics, specific type of cirrhosis, whether Hepatology was consulted, total protein values collected during the admission, antibiotic prescriptions, the rate of future SBP episodes, and in-hospital mortality. Univariate and multivariate logistic regression analysis were performed for these outcomes. **Results:** Our cohort ($n=321$) had an average age of 57.5 $\pm$ 11.11, an average BMI of 29.28 $\pm$ 14.01, and 193 (60%) of the cohort was male. Most of the cohort had either NASH (29.28%) or alcoholic (38.01%) cirrhosis. Out of 321 patients, 263 patients met criteria to check a total protein while 201 patients actually got a total protein check this admission or during a previous admission. Of these 201 patients, 100 (31.1%) patients met the requirements for initiation of antibiotics for SBP prevention. Out of these 100 patients, Hepatology was consulted on 24 patients and discharged with antibiotics while 5 patients were discharged on antibiotics without a Hepatology consult. When Hepatology was consulted, there were 2 episodes of future SBP events compared to 12 episodes occurring in the group without Hepatology consultation (p-value of 0.0001). When Hepatology was consulted hospital mortality due to SBP was 2 patients compared to 12 deaths in the no consult group (p-value of 0.0001). **Conclusion:** SBP is serious infection that has a high mortality rate of 80% with a delay in antibiotics being associated with an increased in-hospital mortality. Those patients that had a Hepatology consult were shown to have more antibiotics prescribed, less future SBP episodes, and an improvement in hospital mortality due to SBP. Our study shows that a timely consultation to Hepatology can be helpful in improving patient mortality and SBP prevention.

3010-A | COULD REAL TIME MONITORING OF URINE CONDUCTANCE IDENTIFY NATRIURESIS IN PATIENTS WITH CIRRHOSIS AND ACUTE KIDNEY INJURY?

Bill Zhang[1], Marlyn J. Mayo[2], Orson Moe[2] and Matthew Leveno[2], (1)University of Texas Southwestern Medical School, (2)University of Texas Southwestern Medical Center

Background: End-stage liver disease complicated by renal hypoperfusion and rapidly progressive acute kidney injury (AKI) carries high short-term mortality. Extrapolating from studies in patients with hepatorenal syndrome (HRS), it is possible that early treatment with vasopressors drives an increase in mean arterial pressure (MAP) sufficient to reverse the prerenal injury. Unfortunately, there is no clear guidance for the optimal

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prospective MAP target and it stands to reason that this will differ between patients. The onset of natriuresis may be a useful early marker of improved renal perfusion and could signal the arrival at the optimal MAP. However, it is impractical to measure serial urine electrolytes with the frequency required for titration of IV vasopressors. We hypothesized that changes in urinary conductance could serve as a practical surrogate for changes in urinary sodium concentrations. **Methods:** ICU patients with shock and AKI were prospectively enrolled. Serial urine samples were collected for spot urine sodium, potassium, chloride, and creatinine. In addition, each sample underwent conductivity testing using a benchtop meter. To assess whether changes in conductance predict changes in sodium, we compared each time point to the one immediately prior - a correct prediction was made if conductance and sodium both increased or both decreased at the next time point. If sodium was unchanged, the new time point was discarded as urine electrolytes were not sensitive to changes in sodium below 1 mEq/L. Results were analyzed using Fisher's Exact Test and Pearson correlation coefficient (*MATLAB ver. R2022a*). **Results:** A total of 97 paired urine sodium and conductance measurements were made in 10 patients, 8 of whom had cirrhosis. After excluding time points where sodium did not change from the previous time point, 56 paired measurements remained. Changes in conductance correctly predicted changes in sodium 36/56 times ($p = 0.029$). In five patients, conductance was significantly and positively correlated with sodium (representative patient in Figure 1). Two out of five patients whose conductance did not correlate with sodium had already developed acute renal failure and likely lacked the ability to manipulate renal sodium handling. **Conclusion:** Urine conductance appears to predict urine sodium, and thus natriuresis, in patients with cirrhosis and AKI. Serial monitoring of urine conductance may be a practical surrogate for detecting natriuresis and could inform clinical decision making when assessing hemodynamics.

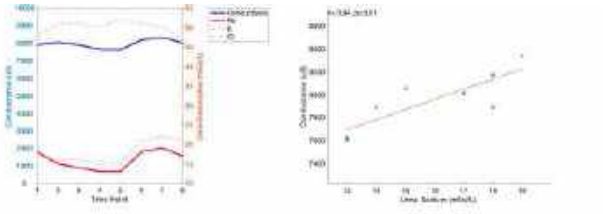

Figure 1. Representative urine electrolyte and conductance measurements from a patient. Left: urine conductance (solid blue) tracks urine sodium (solid red) over time. Right: urine conductance is significantly correlated with urine sodium measurements in this patient ($r = 0.84$, $p < 0.01$).

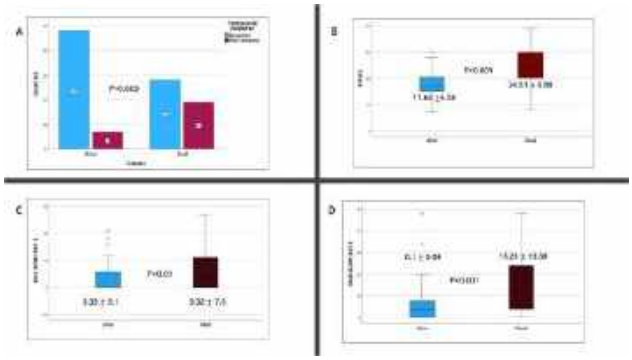
3011-A | CRITICALLY ILL CIRRHOSIS PATIENTS RECEIVING TERLIPRESSIN + ALBUMIN FOR HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY (HRS-AKI) MUST BE MONITORED WITH POINT-OF-CARE ULTRASONOGRAPHY

Vedaghosh Amara, Pooja Karandikar, Anand Gupta, Sivakumar Reddy, Arun T.M Kumar, Sowmya T R, Manasa Alla, Shantan Venishetty, Mithun Sharma, Nageshwar D Reddy, Padaki Nagaraja Rao and Anand V. Kulkarni, Aig Hospitals, Hyderabad, India

Background: Terlipressin plus albumin (terli+alb) is recommended for patients with cirrhosis and hepatorenal syndrome-acute kidney injury (HRS-AKI). Pulmonary overload is a significant adverse event associated with the use of terli+alb. Therefore, we aimed to evaluate the role of Radiographic Assessment of Lung Edema (RALE) score and Lung UltraSonography (LUS) in critically ill cirrhosis (CIC) patients who receive terli +alb. **Methods:** Consecutive CIC patients with HRS-AKI who received terli+alb in the liver ICU from 28-04-2022 to 16-10-2022 were included in the study. Terlipressin was infused at a dose of 2 mg/day,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

increased every 48 hours in case of non-response, and albumin was infused at 20 g/day. The primary objective was to assess the RALES and LUS scores at baseline and day 3. The secondary objective was to determine the terlipressin response and predictors of in-hospital mortality. **Results:** 102 patients (alcohol-60.8%; age-50 ± 12.18 y; serum creat-2.55 mg/dl) received terli+alb for HRS-AKI. Of them, 55 survived (Gr. A), and 47 died (Gr. B) in hospital. Baseline serum creatinine (2.02 vs. 2.25 mg/dl), MELD NA score (26.4 vs. 25.3), SOFA score (12 vs. 11.63), and dose of terli+alb were similar among both groups. The proportion of patients with culture-proven infection was similar among both groups (21.8% vs. 30.4%). Thirteen percent in Gr. A compared to 55.3% in Gr. B were on mechanical ventilation ($P < 0.001$) at baseline. While on follow-up, only 11% in Gr. A and 95.7% in Gr. B required mechanical ventilation ($P < 0.001$). 12.7% in Gr. A and 40.4% n Gr. B were terlipressin non-responders ($P = 0.003$) (Fig. A). APACHE score was higher in Gr. B patients than in Gr. A (Fig. B). Rales score on days 1 (Gr. A: 3.34 ± 5.08 vs Gr. B:6.32 ± 7.57; $P = 0.01$) and 3 (Gr. A: 6.1 ± 8.64 vs. Gr. B: 15.26 ± 13.38;$P < 0.001$) were higher in Gr. B patients compared to Gr. A (Fig. C, D). 66% had worsening RALES scores on day 3 in Gr. B compared to 41.8% in Gr. A. ($P = 0.01$). LUS score worsened in 66% ($n = 31$) of patients in Gr. B compared to 40% ($n = 22$) in Gr. A ($P = 0.03$). The proportion of patients developing terlipressin adverse events (any grade) was more in Gr. B (23.4%) than in Gr. A (11%; $P = 0.07$). On multivariate logistic regression analysis, RALES score at day 3 (1.07 [1.02-1.13];$P = 0.003$), baseline APACHE score (OR, 1.18 [1.08-1.29];$P < 0.001$) and terlipressin non-response (OR, 4.91 [1.49-16.2];$P = 0.009$) predicted in-hospital mortality. **Conclusion:** Critically ill cirrhosis patients receiving terli+alb must be monitored with point-of-care ultrasonography. RALES score, APACHE score, and terlipressin non-response predict mortality in critically ill cirrhosis patients with HRS-AKI.



Disclosures: The following people have nothing to disclose: Vedaghosh Amara, Pooja Karandikar, Anand Gupta, Sivakumar Reddy, Arun T.M Kumar, Sowmya T R, Manasa Alla, Shantan Venishetty, Mithun Sharma, Nageshwar D Reddy, Padaki Nagaraja Rao, Anand V. Kulkarni

3012-A | DESPITE A MINORITY BEING ELIGIBLE FOR CURATIVE OPTIONS, LINKAGE TO PALLIATIVE CARE REMAINS SUBOPTIMAL IN CIRRHOSIS-RELATED REFRACTORY ASCITES

Marcus Rex English[1], Jordache Ellis[2], Yazan Haddadin[1,2] and Sumita Verma[1,2], (1)University Hospitals Sussex NHS Foundation Trust, Brighton, UK, (2)Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Despite refractory ascites (RA) having a median transplant-free survival of six to twelve months, palliative care (PC) input in this cohort remains uncertain. We aimed to assess outcomes in cirrhosis-related RA with emphasis on the provision of PC. **Methods:** This single centre retrospective cohort study assessed patients admitted with RA (Jun 2012-Jun 2019) with last follow up on 31st Mar 2020. RA was defined as either diuretic intolerant or diuretic resistant ascites with three or more large volume paracentesis (LVP). **Results:** During the study period, 13% (89/667) of patients identified with cirrhosis-related ascites developed RA. The mean age was 59 ±13 years and 70% were male. The aetiologies of cirrhosis were alcohol (80%), metabolic associated fatty liver disease (18%) and viral hepatitis (10%). Median number of LVPs was 5 (IQR 3-8). Median CPS, MELD and UKELD scores were 9 (IQR 8-10), 13.8 ± 5.0 and 55.9 ± 5.3 respectively with 67% on diuretics at the time of RA diagnosis. Comorbidities included diabetes mellitus (33%), cardiovascular (33%) and psychiatric (24%) disorders. Overall, 37% had a prior history of spontaneous bacterial peritonitis. Though 38% were referred for a liver transplant/ trans-jugular intrahepatic porto-systemic shunt (TIPS), only 13% received one. Palliative long-term abdominal drains (LTAD) were inserted in 11 patients. Although 56% had documented end of life care discussions, only 33% were referred to PC. Time from RA diagnosis to PC referral was 15 weeks (IQR 4-32), time from PC referral to death being 9 weeks (IQR 4-16). Independent predictors of referral to PC were LTAD insertion (OR 11.0, CI 2.11-57.0, $p < 0.01$) and age (OR 1.57/ten years, CI 1.04-2.38, $p = 0.03$). There was a trend for PC referral to be a predictor of death outside hospital (OR 2.83, CI 0.89-9.04-0.89, $p = 0.078$). Compared to no intervention, receiving transplant/TIPS but not LTADs was associated with a significantly higher one-year survival (83% vs. 44% $p = 0.011$ and 36% vs 44% $p = 0.987$ respectively) (Fig 1). Independent predictors of mortality were undergoing transplant/TIPS (OR 0.15, CI 0.03-0.65, $p = 0.011$) and psychiatric co-morbidity (OR 0.32 CI 0.10-0.97 $p = 0.045$). **Conclusion:** One year survival of patients with cirrhosis-related RA who do not undergo TIPS/

transplant remains poor. Despite this, only a third are referred to PC and often too late. More research into the optimal timing and nature of PC interventions in RA is required.

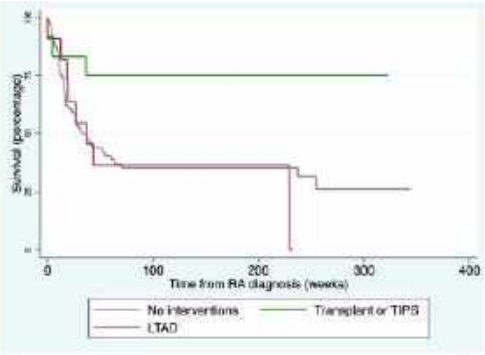

Fig 1 KM survival of patients with RA who underwent either TIPS/transplant or LTAD insertion compared to those who did not receive any intervention (p=0.011 and 0.987 respectively)

3013-A | EFFICACY OF CONTINUOUS TERLIPRESSIN INFUSION IN HRS-AKI IN A TRANSPLANT-ENRICHED POPULATION: A COMPARATIVE PROSPECTIVE AND RETROSPECTIVE COHORT STUDY

K Rajender Rajender Reddy[1], Ethan M. Weinberg[1], Stevan A. Gonzalez[2], Manhal Izzy[3], Douglas A. Simonetto[4], R. Todd Frederick[5], Raymond A. Rubin[6], Zachary Fricker[7], Jade Ikahihifo-Bender[1], Maggie Harte[1], Grace Kim-Lee[1], Sherry Witkiewicz[8], William Tobin[8] and Khurram Jamil[9], (1)University of Pennsylvania, (2)Baylor Simmons Transplant Institute, (3)Vanderbilt University Medical Center, (4)Mayo Clinic Rochester, Rochester, MN, (5)California Pacific Medical Center, (6)Piedmont Transplant Institute, (7)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (8)International Healthcare, LLC, (9) Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Hepatorenal syndrome-acute kidney injury (HRS-AKI), a serious complication of decompensated cirrhosis with limited therapeutic options, is associated with significant morbidity and mortality. Liver transplant (LT) is the definitive treatment but access is limited. Continuous terlipressin infusion may provide HRS reversal and renal outcome benefits and as such was assessed in a population enriched with LT candidates. **Methods:** An open-label study of continuous terlipressin infusion (INFUSE; NCT04460560) was completed in a prospective cohort of 50 patients with cirrhosis, ascites, and HRS-AKI based on the 2015 revised diagnostic criteria. The cohort was enriched with patients listed/in evaluation/eligible for LT. ACLF grade 3, serum creatinine (SCr) > 5.0 mg/dL, or MELD e 35 were exclusions. Following a 0.5 mg bolus, terlipressin was administered via continuous infusion at 2 - 8 mg/day based on SCr response and tolerability. A comparator cohort included 50 retrospective patients who received midodrine plus octreotide (M&O) or norepinephrine (NorEpi) for HRS-AKI and would have met INFUSE criteria. Complete response (CR) was defined as e 30% decrease in SCr with end of treatment (EOT) SCr d 1.5, partial response (PR) as e 30% decrease in SCr with EOT SCr > 1.5, and non-response (NR) as < 30% decrease in SCr. **Results:** (See table) CR was more often in the prospective continuous terlipressin infusion cohort compared to the retrospective M&O/NorEpi cohort (64% vs 16%, $p < 0.001$). Survival at days 30 and 90 of follow-up, while numerically higher in the prospective cohort, was statistically similar (Day 30: 94% vs 80%, $p = 0.07$; Day 90: 78% vs 68%, NS). RRT was uncommon among terlipressin CR or PR, while common among NR (3% vs 12.5% vs 70%, $p < 0.001$). LT alone was achieved in a higher proportion of terlipressin CR than PR or NR (63% vs 6% vs 31%, NS). One patient in the prospective cohort had hypoxic respiratory failure that responded to diuretics; one had a possibly drug-related rash. SAEs were not captured in the retrospective cohort. **Conclusion:** Response rates and SCr decline were greater in the prospective terlipressin infusion cohort compared with a retrospective M&O/NorEpi cohort. While continuous terlipressin infusion significantly decreased MELD and SCr at EOT, 90-day LT rates were high and similar between cohorts, and terlipressin CR had a higher rate of LT alone than PR or NR. RRT was required more often in the terlipressin NR group.

f 3014-A | EFFICACY OF TARGETED AND RESPONSE-GUIDED ALBUMIN THERAPY VERSUS STANDARD MEDICAL TREATMENT IN OUTCOMES OF RECURRENT ASCITES IN PATIENTS WITH DECOMPENSATED CIRRHOSIS

Rakhi Maiwall[1], Neha Chauhan[1], Ashinikumar Kumar Hidam[1], Sherin Thomas[1], Anupam Kumar[1], Jaswinder Maras[1], Neha Sharma[1], Jaya Benjamin[2], Sukriti Sukriti[1] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, (2)Institute of Liver and Biliary Sciences, New Delhi, (3)Ilbs

Background: Long-term albumin administration improves outcomes in patients with uncomplicated ascites. Considering the cost and scarcity of albumin an individualized approach may be better for patients with recurrent ascites (RA). We aimed to compare a targeted and response-guided albumin strategy (Alb-Tr) in improving 6-month mortality compared to standard medical treatment (SMT). **Methods:** Single-center open-label randomized controlled trial. Patients in (Alb-Tr) arm received 20% albumin targeting serum albumin > 3 gm/dl at 60grams for 2 weeks followed by 20-40 grams/week until ascites control, or for a maximum of 12 months. Patients in both groups received SMT (salt restriction, diuretics +/- large volume paracentesis). Our primary endpoint was 6-month mortality. We also studied the impact of Alb-Tr vs. SMT on renal biomarkers, albumin modifications, C-reactive protein (CRP), monocyte function and mitochondrial respiration at 1-month. (Alb+SMT, n = 25, SMT- n = 25) **Results:** A total of 106 patients, mean age (48.8 ± 9.5 y, 84% males, 69% alcohol-related, with MELD 16 ± 5 were randomized [Alb-Tr; n = 52 versus SMT; n = 54). The two groups were comparable at baseline. A trend towards reduced mortality was noted in (Alb-Tr) [2(3.8%) vs. 8(15.4%); Log rank p = 0.06, HR 4.21, (0.89-19.8)]. The control of ascites was superior in (Alb-Tr) (52% vs.12%; p < 0.001), with reduction in therapeutic paracentesis (p < 0.001), lower incidence of acute kidney disease (AKD) (28% vs. 64%;p < 0.001), chronic kidney disease (CKD) (8% vs. 25%; p = 0.03) and hospitalizations (42%vs.72%;p = 0.004). The development of infections (25% vs. 37%; p = 0.39), hepatic encephalopathy (5.8% vs. 9.6%; p = 0.46) was not different. The dose of albumin was significantly higher in Alb-Tr [(224.4 ± 152.2) vs.(113.7 ± 137.4) gms; p < 0.001], with higher proportion of patients achieving the target albumin > 3 gm/dl (80.8% vs. 46.2%; p < 0.001) which was associated with higher ascites resolution (39.1%vs. 19.4%; p = 0.04), a trend towards lower AKD (20.3% vs. 36.1%; p = 0.08) and CKD development (11.1% vs. 25%; p = 0.07). A significant decrease in renal biomarkers, the HNA2 fraction, CRP, with improvement in monocyte and mitochondrial function was observed in Alb-Tr. At baseline, significantly higher levels of HMA, lower levels of HNA1 and on follow-up an improvement in mitochondrial respiration after albumin was observed in patients who achieved ascites resolution. (Figure) **Conclusion:** A targeted and response-guided albumin strategy reduces mortality, adverse renal outcomes and achieves better ascites control in patients with RA. Improvement in renal and innate immune function and a reduction in the irreversibly oxidized albumin fraction could explain the beneficial effects of long-term albumin. Albumin modifications and measurement of mitochondrial function could be potential biomarkers for identifying patients who would achieve ascites resolution after albumin therapy.

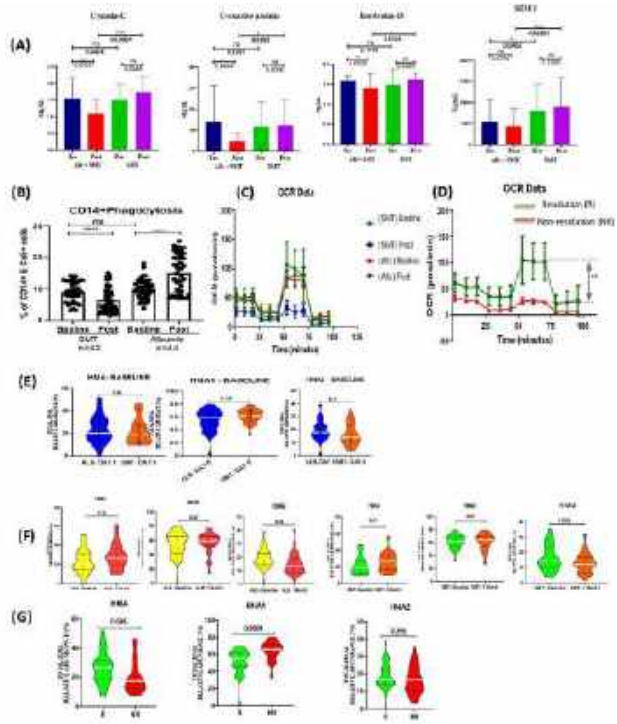

Fig. (A) Graph represents the levels of renal injury markers such as cystatin-C,IL-18 and KIM-1 were significantly increased in follow up plasma samples of SMT groups while they significantly declined in ALB+SMT group . A decrease in CRP was observed in Alb+SMT vs. SMT (B and C) Improvement in monocyte function and mitochondrial function in Alb+SMT vs. SMT (C) showing real time changes OCR in response to oligomycin, FCCP and rotenone antimycin in baseline and follow-up ALB+SMT and SMT groups (D) Improvement in mitochondrial function in patients with ascites resolution(R) compared to no-resolution(NR) (E&F) shows comparable quantitative assessment of total human mercaptoalbumin (HMA), human non-mercaptoalbumin (HNA1), (HNA2) at baseline were not different with decrease in HNA2 in Alb+SMT (G) Patients with resolution of ascites (R) had higher HMA and lower HNA1 compared to those who did not resolve in Alb+SMT (NR)group.

f 3015-A | EMPAGLIFLOZIN IN DIURETIC REFRACTORY ASCITES (DRAIN-EM): RESULTS OF A SINGLE-CENTER FEASIBILITY STUDY

Aparna Goel[1], Branden D. Tarlow[1,2], Allison J. Kwong[3], Kelly Hu[1], Xingxing Cheng[1], Sun H Kim[3], Vivek Charu[1], Deepti Dronamraju[1], W. Ray Kim[1] and Paul Yien Kwo[3], (1)Stanford University Medical Center, (2)The Oregon Clinic, (3)Stanford University School of Medicine

Background: Ascites is the most frequent complication of cirrhosis. Current pharmacologic therapy is limited to diuretics, but diuretic resistance develops in up to 10% of patients yearly. Sodium-glucose co-transporter-2 inhibitors (SGLT2-I) may be effective in this setting due to their nephroprotective effect from reducing renal hypoxia, in addition to causing glycosuria and increased sodium excretion. We conducted a pilot feasibility study to evaluate empagliflozin in managing diuretic-resistant ascites in patients with decompensated cirrhosis. **Methods:** Single-arm, single-center study at Stanford University from 12/2021-5/2023. Eligible patients were > 18 years with decompensated cirrhosis complicated by diuretic-resistant ascites defined as 1) inability to mobilize ascites despite maximum tolerated dose of diuretics, 2) rapid re-accumulation of ascites requiring serial large volume paracentesis (LVP) or 3) development of diuretic-related complications such as azotemia, electrolyte disturbances or hepatic encephalopathy. Patients with eGFR < 30 or hypotension requiring vasopressor therapy were ineligible. Enrolled patients received empagliflozin 10mg daily for 12 weeks, with regular study visits to assess drug side effects, renal function, ascites volume, overall health status and quality of life measured by SF-36 survey. Secondary endpoints included reduction in abdominal ascites, renal function, and hepatic encephalopathy. **Results:** Eighteen patients were screened, 14 (78%) enrolled and 8 (57%) completed the study. Reasons for early termination included liver transplant (n = 1), TIPS (n = 2), acute kidney injury (n = 1) and patient preference due to ongoing volume retention within one month (n = 2). All patients were able to comply with the study procedures. Most participants were male (71%), non-Hispanic (71%) with cirrhosis due to alcohol (36%) or NASH (64%) (Table 1). Median MELD-Na was 17 and stable during the study. There was a strong trend for reduction in volume of ascites removed by LVP during the study compared to the 12 weeks prior (mean change -16.7L, p = 0.07, Wilcoxon signed rank test). Renin and aldosterone levels increased during the study without a significant change in serum creatinine (mean change -0.05, p = 0.48), indicative of enhanced diuresis. Furosemide dosage was reduced in 4/8 (50%) by a mean of 40mg/day, while spironolactone dose was increased in one patient by 25mg. Four patients elected to continue empagliflozin off-label after study completion. **Conclusion:** In this 12-week feasibility study of patients with decompensated cirrhosis and diuretic-resistant ascites, empagliflozin seemed to improve diuresis and reduce need for LVP. These results are promising for potential clinical efficacy in patients with ascites due to decompensated cirrhosis and support larger clinical trials.

3016-A | EXTERNAL VALIDATION OF THE EXPECT TIPS SCORE IN A NORTH AMERICAN COHORT

Roy X Wang, University of Pennsylvania, Philadelphia, PA, David E. Kaplan, Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA and Nadim Mahmud, Hospital of the University of Pennsylvania

Background: Given the risks of transjugular intrahepatic portosystemic shunt (TIPS) implantation, prediction models are used for risk stratification. The Elderly Patients Calculator TIPS (ExPeCT) score is the most recent validated TIPS prediction model and was developed in an Italian cohort. We sought to validate the ExPeCT model in a large North American cohort. **Methods:** This was a retrospective study of patients with cirrhosis in the Veterans Health Administration who received TIPS from 2008-2022. Linear predictors of the ExPeCT model, Model for End-Stage Liver Disease Sodium (MELD-Na) score, and Freiberg index of post-TIPS survival (FIPS) score were calculated and incorporated into univariable Cox regression models for post-TIPS survival analysis. The cohort was divided into younger age (<70 y) and older age (≥ 70) subcohorts to evaluate the overall and older-age versions of the ExPeCT prediction model. Discrimination through maximum follow up was evaluated using Harrell's C index. Discrimination at 6, 12, 24, and 36 months (mo) was calculated using time dependent area under the curve (AUC). Calibration of prediction models was evaluated by joint hypothesis testing of the intercept (null = 0) and slope (null = 1) at 6, 12, 24, and 36 mo, with $p < 0.05$ representing poor calibration. **Results:** The analytic cohort included 1,412 patients who received TIPS, with 1,231 patients <70 years of age and 181 patients >70 years of age. Older patients were more likely to have non-alcoholic fatty liver disease and had higher rates of diabetes, coronary artery disease, and heart failure. Older patients had higher post-TIPS mortality at 12 mo (38.7% vs 29.7%, $p = 0.014$), 24 mo (50.8% vs 41.6%, $p = 0.019$), and 36 mo (58.0% vs 49.5%, $p = 0.032$). In the younger age cohort, the overall ExPeCT model had the highest discrimination (Harrell's C: 0.622), while MELD-Na score had the lowest discrimination (Harrell's C: 0.579; Figure A). In contrast, MELD-Na score had the highest discrimination (Harrell's C: 0.585), while ExPeCT score had the lowest discrimination (Harrell's C: 0.564) in the older age cohort (Figure B). MELD-Na score had the best calibration across all time points in both cohorts ($p > 0.05$ for all). **Conclusion:** The ExPeCT score had the highest discrimination in the younger age cohort and the lowest in the older age cohort compared to FIPS and MELD-Na scores. The ExPeCT score represents a useful tool to assist in risk stratification of patients <70 years of age undergoing TIPS procedure. Refitting and/or addition of model parameters to increase discrimination of the ExPeCT model for patients >70 years of age is needed to improve performance in North American populations highly enriched in metabolic and cardiovascular disease.

3017-A | HEPATORENAL SYNDROME MORE SIGNIFICANTLY ASSOCIATED RISK OF DEATH IN WOMEN COMPARED TO MEN UNDERGOING INPATIENT LIVER TRANSPLANT EVALUATION

Katherine M. Cooper[1], Alessandro Colletta[2], Christopher Zammitti[1] and Deepika Devuni[1], (1)UMass Chan Medical School, (2)UMass Chan Medical School, Worcester, MA

Background: Serum creatinine (sCr) has known limitations in diagnosing renal dysfunction in advanced liver disease (AdLD). Previous studies on hepatorenal syndrome (HRS) utilized sCr e 2.5 as a diagnostic criterion. This has resulted in reduced representation of women in the literature on the epidemiology and treatment of HRS. While this definition was updated in 2015, there is a lack of data on outcomes in men versus women since this time. We aimed to compare the impact of HRS on survival in patients undergoing inpatient liver transplant evaluation (LTE). **Methods:** Patients who completed urgent LTE for CLD over a 4-year period were retrospectively analyzed. We chose to compare inpatients who were approved to start LTE to limit the impact of access to an LT center or dialysis on outcomes. Presence of HRS was determined using ICD-10 codes and confirmed using clinical documentation (e.g., nephrology consultation, urine sediment assessment, urine electrolytes). Rate of HRS was compared between men and women. Mortality rate and transplant rate were compared by HRS status in men and women, in addition to age, MELD, height, and weight. The impact of HRS on mortality risk in the total cohort and in each sex was determined using univariate, multivariate, and Cox logistic regression. **Results:** 160 patients were analyzed (67 women, 93 men) of which 98 (61%) were diagnosed with HRS. Rate of HRS diagnosis did not differ between men and women (62% vs. 60%, p = 0.73). Age, sCr, MELD, transplant rate, mortality rates were similar in men and women with HRS [not shown]. Mortality rate was higher in women with HRS than without HRS (37.5% vs. 14.8%, OR: 3.5, p = 0.04), but morality rate did not differ by HRS status in men (36.2% vs. 17.3% OR 1.9, p = 0.18) (Table 1). This relationship persists on multivariate logistic regression controlling for age, ethnicity, MELD, and etiology of cirrhosis (data not shown). Cox hazard regression revealed a HRS to be associated with a HR 2.9 [p = 0.09] in women, compared to 1.4 [p = 0.44] in men (Table 1, bottom panel). **Conclusion:** Our results suggest the negative impact of HRS on survival may be more profound in women than in men being evaluated for LT. Women with HRS had a similar sCr than men in our analysis, which may be correlated with lower GFR and explain some differences in survival. While our study design did not allow for monitoring trends in sCr, we studied a high-risk population with access to LT services and renal replacement therapy. We highlight that women undergoing inpatient LTE are at increased risk of death due to renal failure. Alternate forms of GFR measurement may allow for early recognition and improve outcomes in women.

Sharma[1], Nageshwar D Reddy[1], Lakshmi P K[2], Rajesh Gupta[1], Padaki Nagaraja Rao[1] and Anand V. Kulkarni[1], (1)Aig Hospitals, Hyderabad, India, (2)Pulla Reddy College of Pharmacy

Background: Human albumin (HA) solution is currently recommended only for patients with spontaneous bacterial peritonitis (SBP) and acute kidney injury (AKI). However, its use in-hospitalized patients is quite frequent for various indications, including hypoalbuminemia, hyponatremia, and non-SBP infections. We aimed to compare the outcomes of patients receiving HA in recommended vs. not recommended indications. **Methods:** In this prospective study, consecutive hospitalized patients who received HA were included. The objectives were to compare the baseline characteristics, dose, and duration of HA administration, change in MELD NA score, resolution of infection and hyponatremia, and mortality among patients who received the HA for recommended (Gr. A) and not recommended indications (Gr. B). **Results:** 396 hospitalized patients received HA. Of them, 45.5% (n = 180) had AKI and/or SBP (Gr. A) at admission, and 54.5% (n = 216) of patients received albumin for non-recommended indications (Gr. B). The mean age (53 ± 13.46 y), sex (females-15%), and etiology distribution were similar among both groups. Indications in the Gr. B was cirrhosis with ascites and hypoalbuminemia-71.3% (n = 154); cirrhosis with overt hepatic encephalopathy and hypoalbuminemia-26.4% (n = 57); variceal bleed with hypoalbuminemia-2.3% (n = 5). The proportion of patients with concomitant hyponatremia (serum sodium < 130 meq/dl) was 47.8% in Gr. A and 44% in Gr. B (P = 0.47). MELD NA was significantly higher in Gr. A patients (27.32 ± 8.6 vs. 21.23 ± 7.3 in Gr B; P < 0.001) due to higher creatinine (2.5 ± 1.96 vs. 0.98 ± 0.33; P < 0.001), while the serum albumin levels were similar among both groups (2.71 ± 0.61 vs. 2.88 ± 2.13; P = 0.31). The total dose of HA was higher (88 ± 61.62 g vs. 71.31 ± 488.17 g; P = 0.003), and the duration was longer (4 ± 2.37 vs. 3.4 ± 1.82 d; P = 0.005) in Gr. A than Gr. B. At admission, 30% in Gr.A and 15.3% in Gr. B had a microbiologically proven infection (P < 0.001). Seventy-eight percent (141/180) had a resolution of AKI with albumin infusions in Gr. A while 5.5% (12/216) developed AKI (rise in sCr by > 0.3 mg/dl) in-hospital in Gr. B.On Kaplan-Meier analysis, mortality in Gr. A was higher than in Gr. B (21.1% vs. 6%; P < 0.001) (Figure). The proportion of patients achieving resolution of infection was similar among both groups (Gr. A: 79.6% vs. 94% in Gr. B; P = 0.1), while hyponatremia resolution was significantly higher in Gr. B (94.7%) than in Gr. A (75.6%; P < 0.001). The incidence of albumin-induced fluid overload was 2.8% in Gr. A compared to 1.4% in Gr. B (P = 0.32). **Conclusion:** Human albumin infusion is safe and effective even in patients without AKI and SBP and leads to the resolution of hyponatremia and infection.

3019-A | INCREASED BASELINE INDICATORS OF INFLAMMATION IN PATIENTS WITH HEPATORENAL SYNDROME TYPE 1 AND GRADE 3 ACUTE-ON-CHRONIC LIVER FAILURE: IMPLICATIONS FOR TERLIPRESSIN THERAPY

Florence Wong, Toronto General Hospital, Toronto, ON, Canada, S. Chris Pappas, Orphan Therapeutics, Hugo E. Vargas, Mayo Clinic Arizona, Phoenix, AZ and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Patients with hepatorenal syndrome type 1 (HRS1) and grade 3 acute-on-chronic liver failure (ACLF3) have an increased incidence of respiratory failure (RF) when treated with terlipressin. Patients with HRS1 with ACLF grade d 2 (ACLF d 2) do not have the same risk for RF. Concomitant albumin use has been excluded as a likely cause of increased risk for RF in patients with HRS1 and ACLF3 treated with terlipressin. This study aims to explore inflammation as a contributor to the development of RF in HRS1 patients with ACLF3 treated with terlipressin. **Methods:** Pooled data from the two largest terlipressin HRS1 trials were reviewed (CONFIRM-NCT02770716 and REVERSE-NCT01143246). Patients were separated into ACLF d 2 and ACLF3 groups baseline. Available clinic-biochemical parameters suggestive of inflammation were compared. **Results:** 292 patients received terlipressin:236 with ACLF d 2 group, 56 with ACLF3. Mean age 54.6 years, 58% male, mean MELD score

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

32.96. Patients with ACLF3 had more features of inflammation at baseline as suggested by tachycardia (82 ± 15 vs. 79 ± 15beats/min in ACLF d 2, p = 0.09), tachypnea (18.6 ± 2.9 vs. 17.8 ± 3.2 breaths/min, p = 0.007) without evidence of respiratory distress as indicated by similar SpO_2/FiO_2 ratios (400 ± 134 vs. 450 ± 56, p = 0.38) compared to the ACLF d 2 group. White cell count was significantly higher (10.9 ± 5.1 vs. 8.5 ± 5.7, p < 0.001) in subjects with ACLF3 despite similar incidence of prior infection (55.4% vs. 44.3%, p = 0.14) and similar percentage of patients on antibiotic just prior to receiving terlipressin (60.7% vs. 54.4%, p = 0.46). The ACLF3 group also had higher baseline MELD of 39.3 ± 1.7 (vs. 31.2 ± 6.2, p < 0.001) despite similar baseline serum creatinine levels (3.5 ± 0.9mg/dL vs. 3.9 ± 1.0mg/dL), suggesting marked liver dysfunction in the ACLF3 patients. Significantly more ACLF3 patients had alcoholic hepatitis at baseline (53.6% vs. 30.0%, p = 0.002) than ACLF d 2 patients. Similar differences in inflammatory parameters were also observed in 199 placebo ACLF3 vs ACLF d 2 patients. **Conclusion:** While placebo patients with ACLF3 also had increased baseline inflammatory features, our previous study showed the incidence of RF in the placebo ACLF3 group was low. (Wong F. et al. APT 2022; 56: 1284). Although not confirmed by inflammatory biomarkers, the current results suggest that the combination of terlipressin and intense inflammation may play a significant role leading to RF in HRS1 ACLF3 patients.

3020-A | INCREASED MORTALITY AND GROWING CONCERN FOR EMERGENCE OF GRAM- POSITIVE BACTERIA AND MULTI-DRUG RESISTANT BACTERIA

Parth Bhupendra Patel[1], Sujan Ravi[1], Udita Gupta[1], Ore Adekunle[1], Thomas Ruli[1], Mohamed Galal Shoreibah[2] and University of Alabama at Birmingham, (1)University of Alabama at Birmingham, (2)University of Alabama at Birmingham, Birmingham, AL

Background: Spontaneous bacterial peritonitis (SBP) is a serious infection that occurs in cirrhotic patients with ascites. SBP has been shown to have a mortality rate of 80% with a delay in antibiotics being associated with an increased mortality. The most prevalent bacterial organisms that are associated with SBP are typically gram- negative rods from the gastrointestinal track that can often be treated with fluoroquinolones or 3rd generation cephalosporins. However, there is a growing concern for an increased presence of gram-positive bacteria as well as multi-drug resistant organisms (MDRO) causing SBP. Those who have SBP or are prescribed antibiotics for primary SBP prevention are typically discharged with a fluoroquinolone or Bactrim. In this project we aim to evaluate the incidence of multi-drug resistant bacteria and gram-positive bacteria in cirrhotic patients with SBP and assess their impact on mortality. **Methods:** We performed a retrospective cohort study and included cirrhotic patients admitted in 2021 that required a paracentesis. Data collected includes baseline characteristics of the patients, specific type of cirrhosis, whether Hepatology was consulted, the rate of antibiotic prescriptions, the number of SBP episodes, the type of organism causing SBP, antibiotic resistance, the incidence of future SBP episodes, and the rate of in-hospital mortality. Univariate and multivariate logistic regression analysis were performed for these outcomes. **Results:** Our cohort (n = 321) had an average age of 57.5 ± 11.11, BMI of 29.28 ± 14.01, and 193 (60%) were male. Most of the cohort had either NASH (29.28%) or alcoholic (38.01%) cirrhosis. Out of 321 patients, 31 patients developed SBP during this admission and 34 patients developed SBP during future admissions. Of the 31 patients who had SBP this admission, 8 (25%) developed methicillin-resistant staphylococcus Aureus (MRSA) SBP and 16 (51%) developed GNR SBP. Of the 34 patients who developed future SBP episodes, 6 (17%) developed MRSA SBP and 11 (31%) developed

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

GNR SBP. Of the 16 GNR SBP, 9 demonstrated resistance to fluoroquinolones, 2 demonstrated resistance to 3 rd generation cephalosporins, and 3 demonstrated resistance to Bactrim. Of the 11 future GNR SBP episodes, 7 (64%) were resistant to fluoroquinolones, 2 (18%) were resistant to 3 rd generation cephalosporins, and 4 (36%) were resistant to Bactrim. Of the 14 antibiotic resistant GNR SBP patients, 12 patients expired while only 2 patients remained alive (P-value of 0.005). **Conclusion:** SBP is serious infection that has a high mortality rate of 80% with a delay in antibiotics being associated with an increased in-hospital mortality. It appears that the presence of MDRO is becoming more commonplace with many organisms being resistant to fluoroquinolones, Bactrim, and 3 rd generation cephalosporins. Our study also demonstrates higher mortality due to drug-resistant GNR and an increased prevalence of MRSA SBP.

3021-A | INTEGRATION OF POINT-OF-CARE ULTRASOUND (POCUS) IN AN INTERNAL MEDICINE RESIDENCY PRACTICE FOR DIAGNOSIS OF HEPATORENAL SYNDROME: A STANDARDIZED APPROACH

Adalberto Guzman[1], Evelyn Calderon Martinez[1], Wern Lynn Ng[1], Anas Atrash[1] and Douglas M. Levin[2], (1) UPMC, (2)Ohio State University, Columbus, OH, United States

Background: The current diagnostic criteria for HRS-1 rely on the absence of renal function improvement after two days of intravenous volume expansion or diuretic withdrawal. However, determining the need for volume expansion in suspected cases of HRS-1 lacks specific indicators. The hypothesis put forward is that point-of-care ultrasound (POCUS) can offer a more accurate assessment of volume status in cirrhosis patients with AKI, aiding in confirming or excluding the diagnosis of HRS-1. **Methods:** This study aimed to assess the intravascular volume status in cirrhosis patients with AKI and diagnosed with HRS-1, who were considered adequately repleted. Internal medicine residents participating in the pilot study performed point-of-care ultrasound on patients previously diagnosed with cirrhosis and meeting the AKI-HRS criteria upon admission. The study evaluated the clinical usefulness of point-of-care ultrasound (POCUS) in measuring the diameter of the inferior vena cava (IVCD) and the collapsibility index (IVCCI). Early improvement in kidney function was defined as a decrease of 20% or more in serum creatinine (sCr) levels within 48 to 72 hours. **Results:** The study enrolled a total of 33 patients. The evaluation of volume status revealed an average serum creatinine (sCr) level of 3.4 $\pm$ 1.7 mg/dL and a mean Model for End-Stage Liver Disease (MELD) score of 28 $\pm$ 9. Among the participants, 9 individual's (29%) were identified as having depleted fluid levels, indicated by an IVCD of less than 1.3 cm and an IVCCI greater than 40%. Additionally, 8 patients (25%) were classified as having expanded fluid levels due to an IVCD greater than 2 cm and an IVCCI less than 40%. Furthermore, 4 patients (11%) were diagnosed with intra-abdominal hypertension (IAH) based on an IVCD of less than 1.3 cm and an IVCCI less than 40%. Notably, a total of 12 patients (34%) demonstrated early improvement in kidney function following therapeutic interventions guided by POCE. These interventions included volume expansion, diuresis, or paracentesis, tailored to the specific fluid status classification of depletion, expansion, or IAH, respectively. **Conclusion:** This study examined the effectiveness of point-of-care echocardiography (POCUS) in assessing fluid status in cirrhosis patients with hepatorenal syndrome type 1 (HRS-1) and acute kidney injury (AKI). The findings suggest that POCUS, specifically measuring the inferior vena cava diameter (IVCD) and collapsibility index (IVCCI), can provide valuable information for determining fluid status in these patients. Therapeutic interventions guided by POCUS, such as volume expansion, diuresis, or paracentesis based on fluid status classification, resulted in early improvement in kidney function in 34% of patients. Early detection and targeted interventions addressing reversible causes of AKI, such as hypovolemia or hypervolemia, are essential for improving patient outcomes.

3022-A | INTRAVENOUS N-ACETYLCYSTEINE AND ORAL MISOPROSTOL IN COMBINATION MAY BE EFFECTIVE IN TREATING HEPATORENAL SYNDROME

Marko Kozyk, Kateryna Strubchevska, Jain Ritika and Tusar Desai, Corewell Health William Beaumont University Hospital

Background: Hepatorenal syndrome (HRS) is an ominous complication of de-compensated cirrhosis. We report here our experience in treating eight

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

patients with de-compensated cirrhosis and acute kidney injury (AKI) 2-3 who did not respond to treatment with albumin and or octreotide/midodrine, with a combination of intravenous n-acetylcysteine infusion (NAC) and oral misoprostol. NAC infusion has previously been reported to reverse HRS in 12 patients with a three-month survival rate of 58% (Holt, Lancet, 1999). Oral misoprostol and albumin infusions have been used to temporarily reverse HRS in 4 patients (Fevery, J Hepatology, 1990). **Methods:** AKI was defined by the ICA-AKI criteria of 2015, six patients had AKI-3, two patients had AKI-2. One patient had preexisting chronic kidney disease stage 3a. All patients had de-compensated cirrhosis, alcoholic cirrhosis in seven patients and NASH-cardiac cirrhosis in one patient (BMI 50, EF 20%). Three patients had prior episodes of AKI that were treated successfully with NAC. Five patients were classified as acute on chronic liver failure type three. Five patients failed to respond to albumin infusions before NAC administration. Three patients failed octreotide and midodrine before NAC was given. NAC was used at a dose of 100 mgs/kg infused over 24 hours. Two patients received a loading dose of 150 mgs/kg over two hours. Seven of eight patients also received misoprostol 100 ugs 3-4 x a day. **Results:** Mean age of the patients was 48 $\pm$14. There were seven men and one woman in the study. Five patients responded to NAC without receiving albumin infusions during NAC treatment. All patients survived the hospitalization and were discharged home. One patient died 28 days after discharge and 40 days after starting NAC infusion. Another patient died eleven months after discharge. One patient received a liver transplant ten weeks after discharge. Five remaining patients were alive without liver transplantation six months to five years after discharge. Table 1 summarizes the findings of the present study. **Conclusion:** Intravenous NAC infusion and misoprostol in combination may be effective in treating hepatorenal syndrome that has not responded to albumin, octreotide, or midodrine. Further studies are warranted.

f 3023-A | MELD-SODIUM-CIRRHOTIC CARDIOMYOPATHY SCORE OUTPERFORMS MELD-SODIUM SCORE IN PREDICTING 90-DAY MORTALITY IN HOSPITALIZED PATIENTS WITH CIRRHOSIS

Kamal Kajal, Post Graduate Institute of Medical Education and Research, Manhal Izzy, Vanderbilt University Medical Center and Madhumita Premkumar, Postgraduate Institute of Medical Education & Research, Chandigarh, India

Background: Cirrhotic cardiomyopathy (CCM) affects approximately 35% of patients with cirrhosis. An increased E/e' ratio, reflective of increased left ventricular filling pressures, and decreased mitral septal e' velocity, reflective of impaired relaxation, are two core components of the revised 2020 criteria of CCM. Data about the utility of bedside, point-of-care ultrasound (POCUS) and echocardiography (POC-Echo) with tissue Doppler imaging in patients with cirrhosis are limited. Conventional prognostic models in this patient population (e.g., Model for End-Stage Liver disease score) lack cardiac and hemodynamic variables which can be associated with adverse outcomes in patients with cirrhosis. **Methods:** This is a prospective study of two cohorts of critically ill patients who were admitted to the Liver intensive care unit in a single center between December 2019 and December 2022. The discovery cohort had ACLF and severe sepsis (with mean arterial pressure < 65mmHg) (NCT05059795; N = 120). Validation cohort had hepatorenal syndrome- acute kidney injury (HRS-AKI; NCT05434286; N = 140). Patients with coronary artery or valvular heart disease, those on dialysis, uncontrolled thyroid disease, porto-pulmonary hypertension, dilated cardiomyopathy, and hepatocellular carcinoma were excluded. CCM was defined per the CCM consortium 2020 criteria. We used a regression-based model to assess if CCM markers can predict mortality in critically ill patients with cirrhosis. The markers were integrated with MELD-Na to improve the predictive performance in the discovery cohort of ACLF with severe sepsis. We validated the derived score in the validation cohort of cirrhosis with HRS-AKI, based on the International Club of Ascites (ICA) criteria. **Results:** The discovery cohort of ACLF with severe sepsis had 120 patients [59% men, aged 49 $\pm$ 12 years, 56% alcohol-related disease, and median MELD-Na of 30(27 - 32)], of whom 68/120(56.6%) had circulatory failure, with overall mortality of 72/120(60%). CCM was present in 63/120(52.5%). The MELD-Na-CCM model was computed as MELDNa+1.815*E/e'(septal) +0.402*e' (septal) based on multivariable logistic regression for prediction of 90-day mortality. In the discovery cohort, MELD-CCM outperformed MELD-Na

(z-score = 2.07, $P = 0.038$) in predicting 90-day mortality. In the validation cohort of 140 patients with HRS-AKI, (84% men, aged 45.8 ± 12.9 years, 59% alcohol-associated, MELDNa 25 ± 5.6), thirty-four patients (24.3%) met criteria for CCM, with overall mortality at 90 days being 23(16.4%). Furthermore, in the validation cohort as well, MELD-CCM outperformed MELD-Na (z-score = 1.99, $P = 0.046$) in predicting 90-day mortality. **Conclusion:** POC-Echo measurements of CCM markers, namely, E/e' and e' significantly improve the predictive performance of MELD-Na for 90-day mortality. Further studies are needed to evaluate the implications of POCUS integration into modern hepatology practice.

3024-A | NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN PREDICTS THE EFFICACY OF TOLVAPTAN AND POST-TREATMENT ACUTE KIDNEY INJURY IN PATIENTS WITH LIVER CIRRHOSIS

Masato Nakai, Takashi Kitagataya, Masatsugu Ohara, Takuya Sho, Goki Suda, Koji Ogawa and Naoya Sakamoto, Hokkaido University Hospital

Background: Acute kidney injury (AKI) is associated with liver cirrhosis (LC), water retention, diuretics for treating water retention; it has a poor prognosis. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) has attracted attention as an early diagnostic marker of AKI and reportedly predicts a poor prognosis in decompensated LC. This study investigated the usefulness of uNGAL in predicting the short- and long-term effects of tolvaptan (TVP) and the incidence of AKI post-TVP administration. **Methods**: Of the LC cases with water retention, 86 with available pre-treatment uNGAL were analyzed. A short-term response was defined as weight loss of e 1.5 kg within the first week according to the Japanese evidence-based clinical practice guidelines for LC; a long-term response was defined as a short-term response without early recurrence defined in the EASL practice guidlines. The uNGAL usefulness in predicting the short- and long-term effects of TVP and AKI incidence post-TVP administration was investigated. **Results**: The median pre-treatment uNGAL was 17.95 ng/ml. Short-term effects of TVP were observed in 52 patients. Of these, 15 patients had an early recurrence. Short-term responders had significantly lower uNGAL levels than non-responders. ROC analysis showed that the optimal cut-off value of uNGAL for predicting the short-term response was 50.2 ng/ml. In multivariate analysis, significant short-term predictive factors were C-reactive protein (CRP) < 1.4 mg/dl, uNa/K ratio e 3.51, and uNGAL < 50.2 ng/ml. Patients were classified according to these three cut-off values, with short-term response rates of 92.9%, 68.8%, 26.7%, and 0% for 0, 1, 2, and 3 points, respectively. In subanalyses of the cohorts excluding patients with pre-treatment AKI complications, uNGAL was also similarly predictive of short-term response to TVP. Long-term responders had better prognosis than non-responders and patients with early recurrence. CRP < 0.94 mg/dl and uNGAL < 50.2 ng/ml were significant factors for predicting the long-term response of TVP. Patients were classified according to these two cut-off values, with long-term response rates of 66.7%, 32.2%, and 0% for 0, 1, and 2 points, respectively.The AKI incidence post-TVP was 8.1% (n = 7). Patients with AKI after TVP administration had significantly higher NGAL values ($p < 0.01$). The best cutoff, which is predictive of the incidence of AKI post-TVP administration, was 38.1 ng/ml with an area under the receiver operating characteristic curve (AUCROC) of 0.898. This was a better value than other renal function-related factors, such as uL-FABP, sCr, sBUN, uUN, and uNa/K ratio or CRP. **Conclusion**: uNGAL is a useful predictor of the short- and long-term efficacy of TVP and can be useful in predicting AKI incidence post-TVP administration.

Chaitra Chandra Shekar and Ashis Mukhopadhya, NHS Grampian

Background: Cirrhosis is an increasingly prevalent condition associated with significant morbidity and mortality. When these patients have unscheduled admissions following decompensation, lengths of stay, readmissions rates, and mortality can be very high. Ideally, factors leading to decompensation like diuretic dose or laxative treatment would be optimised to prevent admission in the first place but early detection can be challenging. In 2019, the nurse led close monitoring out -patient clinic was set up in Aberdeen Royal Infirmary to support patients with decompensated liver disease post-discharge. Patients are reviewed in 1-2 weeks, clinical examinations, routine tests, prescription modification and day case ascetic drains can be arranged. A multi-disciplinary team meeting for patient discussion occurs the following day. **Methods:** We performed a retrospective analysis of the case mix at our site between 2018 and 2022 to determine if there was a difference in lengths of stay, readmission rates, and mortality rates of the patients who attend the close monitoring clinic (CMC) compared to those who did not. Case identification was by using ICD-10 discharge codes encompassing decompensated liver disease **Results:** The mean number of admissions with decompensated liver disease each year was 136. On average, readmissions comprised 59% of total admissions. The close monitoring clinic had 560 appointments with 203 unique patients between 2019 and 2022, averaging 140 appointments and 59 unique patients per year. The average length of stay reduced significantly from 6.8 to 3.8 days (mean difference: 2.9 d, $p < 0.05$) if a patient attended CMC compared to if they had not. The 7 day readmission rate reduced significantly from 5.7% to 1.2% (mean difference: 4.5%, $p < 0.05$) if a patient attended CMC in the preceding year compared to if they had not. The 28 day readmission rate reduced from 21.7% to 3.1% (mean difference: 18.6%, $p < 0.05$). The 7 day mortality rate reduced significantly from 4.8% to 1.6% (mean difference 3.2%, $p < 0.05$) if a patient attended CMC compared to if they had not. The 28 day mortality rate reduced from 6.1% to 2.9% (mean difference 3.1%, $p < 0.05$). **Conclusion:** The close monitoring clinic is an effective intervention to reduce length of stay, readmission, and mortality. It also lowers the onus on hepatology consultant outpatient appointments. These improvements translate into fewer inpatient resources needed to care for this cohort and thus can be a cost-effective investment for healthcare systems.

3026-A | OBSTRUCTED UMBILICAL HERNIA OUTCOMES IN HOSPITALIZED DECOMPENSATED CIRRHOSIS SUBJECTS.; NATION WIDE TRENDS.

Mubeen Khan Mohammed Abdul[1], Waseem Amjad[2], Kamran Safdar[3], Ajay Sahajpal[1] and Sanjaya Kumar Satapathy[4], (1)Advocate Aurora St Lukes' Medical Center, (2)Harvard University Medical School, (3) University of Cincinnati, (4)Division of Hepatology, Northwell Health, and Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, USA.

Background: Obstructed ventral / umbilical hernia are associated with high morbidity and mortality in cirrhosis and surgery is often deferred in decompensated cirrhosis. Aim:Assess safety outcomes of obstructed ventral/umbilical hernia repair in cirrhosis. **Methods:** Study population consisted of national readmission database from last quarter of 2015 to 2017. Outcomes of obstructive ventral/umbilical hernia in relationship with surgical repair was computed in a multivariate model adjusted for age, gender, co morbid conditions and hepatic de compensatory events **Results:** There were 1946 subjects with obstructed umbilical/ventral hernia. Of them 446 subjects had surgical repair. Laparoscopic repair was done in 138 subjects. Mean age of those who underwent surgical repair was 60.50 $\pm$ 11.4 years and 60.5% were men. Ascites (70.9% vs. 54.8%, $p < 0.001$) and hepatic encephalopathy (10.8% vs. 6.1%, $p = 0.046$) was more prevalent in non-surgical repair group. Although multivariable adjusted hospital cost was higher in ventral hernia repair group (β: 28597, 95% CI: 5296 – 51897, $p = 0.02$), this was not associated with higher in-hospital mortality (OR: 0.43, 95% CI: 0.16-1.18, $p = 0.10$), 30-day readmission (HR: 1.26, 95% CI: 0.80 – 1.96, $p = 0.32$), and length of stay. Surgical repair in decompensated cirrhosis was associated with higher length of stay (β: 6.89, 95% CI: 1.59 – 12.19, $p = 0.01$) but similar mortality (OR: 0.47, 95% CI: 0.08 – 0.61, $p = 0.38$), 30-day readmission (HR: 0.63, 95% CI: 0.06 – 6.55, $p = 0.69$) and hospitalization cost was as compared to conservative group. Laparoscopic repair was associated with reduced hospital cost as compared to open repair (β: -31879, 95% CI: -64302 – 544, $p = 0.05$). **Conclusion:** Obstructed Umbilical/ventral hernia repair was safe in cirrhosis patients and did not increase mortality in decompensated cirrhosis. Laparoscopic repair improved hospital cost as compared to open repair. Future prospective studies are recommended to identify the role of surgical repair in decompensated cirrhosis.

3027-A | PATIENT DEMOGRAPHICS, COMORBIDITIES, AND HOSPITAL CHARACTERISTICS OF HEPATORENAL SYNDROME

Ayusha Poudel[1], Taha Teaima[2], Sajana Poudel[1], Eman Elhamamsy[3] and Anurag Adhikari[4], (1)John H Stroger Jr. Hospital of Cook County, (2)Cook County Hospital, (3)Ain Shams University, (4)New York City Health and Hospitals/ Jacobi

Background: Hepatorenal syndrome (HRS) is a functional renal failure that develops as a consequence of decreased renal blood flow in patients with late-stage cirrhosis and ascites. The diagnosis requires combination of clinical observation and laboratory criteria. **Methods:** This is a retrospective study of the National Inpatient Survey (NIS) database of year 2020 including all adults age 18 and above with the discharge diagnosis of liver disease with and without hepatorenal syndrome. We identified the population with Chronic Liver disease with cirrhosis and Acute Kidney Disease with or without chronic kidney disease by searching the NIS database using the International Classification of Disease-10 (ICD-10). Inpatient mortality, morbidity, mean length of stay (LOS), mean total hospital charge (THC) and multivariate logistic regression, and linear regression analyses were used to analyze the data. **Results:** Out of 120,840 liver cirrhosis hospitalizations, 10,750 (8.9%) had developed hepatorenal syndrome. Patients with liver cirrhosis and hepatorenal syndrome had higher adjusted odds of inpatient mortality (Adjusted odds ratio [aOR]: 4.88, 95% confidence interval [CI]: 4.15-5.72, $p < 0.001$), longer mean LOS of 4.9 days (95% CI: 4.33-5.51, $p < 0.001$), and higher mean total hospital cost of $ 99255 (95% CI: 75731.6 - 122779.3, $p < 0.001$) than those without HRS. Out of all the patients admitted with cirrhosis, 5810 (4.8%) people died and in the subgroup with hepatorenal syndrome, 17.63% died ($P = 0.0000$). The OR for mortality in patients who develop hepatorenal syndrome is 5.8 [CI 5.06-6.64]. The mean length of stay in patients with HRS is 11.48 ± 0.36 days vs 5.34 ±0.5 days in patients without hepatorenal syndrome. The total cost of hospital stay was for patients with HRS was $192881 ± 15687 compared to those without which was $70293 ± 1796. The prevalence of sepsis in patients with HRS was 13.35% compared to those without which was 2.72% ($P = 0.000$), prevalence of mechanical ventilation was higher in the HRS subgroup at 6.98% vs 1.56% ($P = 0.0000$) and AKI prevalence in HRS was 89.58% vs 24.72% in HRS subgroup. ($P = 0.0000$) **Conclusion:** The patient with hepatorenal syndrome has in increased risk of mortality, longer days of hospital stay and higher hospital cost than those without. The risk of developing morbidities was also higher in the HRS subgroup.

3028-A | PATIENT SUBSET ANALYSIS OF THE REVERSE PHASE III STUDY: THE IMPACT OF TERLIPRESSIN TREATMENT ON RATES OF TRANSPLANT, DIALYSIS, AND SURVIVAL IN PATIENTS WITH HEPATORENAL SYNDROME

Samuel H. Sigal, Montefiore Medical Center and Albert Einstein College of Medicine, Arun Sanyal, Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, VA, Mark Wong, Banner University Medical Center, Brendan M. McGuire, University of Alabama at Birmingham, Birmingham, AL, Bilal Hameed, University of California San Francisco, San Francisco, CA and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Patients (pts) with untreated rapidly progressive hepatorenal syndrome (HRS) experience early mortality without liver transplantation (LT). Although HRS treatment can lower prioritization for LT due to a decrease in MELD score, a requirement for renal replacement therapy (RRT) is associated with poor survival. To determine the impact of terlipressin (terli) on LT and survival in pts with HRS, we analyzed data from the Phase lll, randomized, placebo (pbo)-controlled REVERSE study. **Methods:** A subset of US pts from the REVERSE study (excluding those with hepatocellular carcinoma, alcoholic hepatitis, or aged > 70 y) were analyzed ($N = 125$) by treatment group (terli, $n = 66$; pbo, $n = 59$). Pts were divided into the following groups by treatment response: HRS reversal (serum creatinine [SCr] d 1.5 mg/dL), partial response (PR; SCr

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

decreased > 0.3 mg/dL from baseline to end of treatment [EOT]), no response (NR), and those requiring RRT. The proportion of pts, (1) alive without RRT without LT, (2) alive with RRT with LT, (3) alive with RRT without LT, (4) alive with RRT with LT, or (5) dead, were assessed for each group at post-treatment Day 30, 60, and 90. Pts with HRS reversal were analyzed at the EOT for change in MELD score. **Results:** Reason for EOT: confirmed HRS reversal, 16.7% vs 15.3% ($P = 0.830$); RRT in 10.6% vs 11.9% ($P = 0.824$); EOT status: decrease in SCr, 31.8% vs 22.0% ($P = 0.220$); increase in SCr, 30.3% vs 37.3% ($P = 0.409$); for pts treated with terli and pbo, respectively. In pts with HRS reversal, survival without RRT at Day 90 was 100% for terli- and 55.6% for pbo-treated pts, respectively. Survival without RRT with/without LT progressively decreased in the PR and NR groups. Among those with RRT (n = 18), few pts were alive without LT at Day 90 (Figure). Baseline MELD scores were similar across treatment groups (mean [SD]: terli, 33.16 [6.16]; pbo, 32.67 [5.13]). HRS reversal was associated with decreased MELD scores (mean [SD]: terli, -4.4 [2.95] vs pbo, -5.6 [4.12]; $P = 0.5032$) from baseline to EOT. The incidence of LT at Day 30 was similar between the terli and pbo groups (30.3% vs 32.2%; $P = 0.819$). **Conclusion:** This post hoc subgroup analysis of pt data from REVERSE demonstrates clinical benefits among those who achieved HRS reversal and progressively worse outcomes for those with a PR or NR. Survival without LT is extremely limited for those who progress to RRT. Although MELD scores decreased with HRS reversal, overall LT rate was not adversely affected.

Figure. Clinical response at Day 90 by treatment response

f 3029-A | Patients with Cirrhosis and Significant Ascites are At High Risk of Cirrhotic Cardiomyopathy

Xiaohan Ying[1], Anton Jordan De Witte[2], Adesola Oje[3], Ashley Spann[3], Christopher Slaughter[2], Jeffrey Annis[2], Yushan Pan[4], Catherine Ng[5], Evan Sholle[5], Russell Rosenblatt[6], Evan Brittain[2], Brett Fortune[7] and Manhal Izzy[3], (1)Weill Cornell Medicine, NY, (2)Vanderbilt University, (3)Vanderbilt University Medical Center, (4) Massachusetts General Hospital, (5)Cornell University, (6)Weill Cornell Medicine, Scarsdale, NY, (7)Montefiore Medical Center

Background: Cirrhotic Cardiomyopathy (CCM) entails alternations of cardiac structure and function among patients with cirrhosis in the absence of alternative cardiac pathology. CCM criteria were revised in 2020 reflecting advancement in echocardiographic technology. Prior studies showed an association of refractory ascites with decreased cardiac output and hemodynamic changes. However, data are lacking regarding the impact of ascites on cardiac function assessed by contemporaneous echocardiographic markers. This study aims to evaluate the association of hepatic ascites with CCM and its echocardiographic markers per 2020 criteria. **Methods:** We performed a retrospective cohort study of adult

patients who were evaluated for and received liver transplantation at two tertiary centers between January 1, 2015 and December 31, 2018. We excluded patients with primary cardiac disease, those without cirrhosis, and recipients of multi-organ transplant. Demographic, clinical, and echocardiographic data were collected. Univariable and multivariable logistic regression models were developed to determine associations between ascites and CCM, while controlling for traditional risk factors for cardiac dysfunction. We defined the severity of ascites based on Child Pugh classification as well as the International Ascites Club grading, where grade 2/3 ascites is equivalent to significant ascites. **Results:** Out of 348 patients, 207 (59.5%) had sufficient data to assess CCM, which was present in 48 patients (23%). The univariable analysis for CCM associations is depicted in Table 1. On multivariable analysis controlling for age, non-alcoholic steatohepatitis (NASH), and hypertension, significant ascites was strongly associated with CCM (aOR 2.65, 95% CI: 1.19 to 6.57, $p = 0.024$). Further multivariable analyses, controlling for the aforementioned covariates, were performed for individual markers of CCM and showed statistically significant associations with ascites: Ejection Fraction [EF] (β coefficient 2.02, 95% CI: 0.40 to 3.64, $p = 0.014$), left atrial volume index (LAVI) (β coefficient 5.96, 95% CI: 3.14 to 8.79, $p < 0.001$), E/e', which reflects left ventricular filling pressures (β coefficient 1.03, 95% CI 0.23 to 1.83, $p = 0.012$), and septal e', which reflects myocardial relaxation (β coefficient 0.70, 95% CI: 0.04 to 1.37, $p = 0.038$). **Conclusion:** Patients with cirrhosis and significant ascites were at increased risk for CCM. Furthermore, significant ascites was associated with hyperdynamic cardiac changes as demonstrated by increased EF and e', and with structural changes as demonstrated by increased LAVI. These findings elucidate potential implications of the interplay between CCM and decompensated cirrhosis and its clinical manifestations, such as refractory ascites and hepatorenal syndrome.

3030-A | POINT OF CARE ULTRASOUND (POCUS) PERMITS EARLY INITIATION OF TERLIPRESSIN IN SUSPECTED HRS-AKI

Akash Roy[1], Indrajeet Tiwary[1], Subhash Tiwari[1], Madhumita Premkumar[2], Surender Singh[3] and Mahesh Goenka[1], (1)Apollo Hospitals, Kolkata, (2)Pgimer, Chandigarh, (3)Sgpgims, Lucknow

Background: The conventional definition of Hepatorenal Syndrome-Acute Kidney Injury (HRS-AKI) revolves around an initial strategy of volume expansion in suspected cases before initiating vasoconstrictor therapy. Early initiation of terlipressin has been shown to be feasible in HRS-AKI in ACLF. Volume status assessment using point of care ultrasound (POCUS) allows for early stratification of volume status and may allow for goal-directed early terlipressin initiation. We aimed to assess the use and safety of POCUS-assisted terlipressin initiation in HRS-AKI as a single-arm pilot study. **Methods:** Consecutive patients with suspected HRS-AKI (e Stage IB but excluding volume expansion criteria of ICA-HRS AKI criteria) were assessed with POCUS for inferior vena cava diameter (IVCD) and IVC collapsibility index (IVCCI). Patients were classified as volume replete if IVC at index assessment was > 1.3cm and IVCCI $< 40\%$. Volume replete(VR) suspected HRS-AKI were initiated simultaneously on terlipressin 1mg every 6 hours along with the continuation of 20% intravenous albumin without awaiting the recommended 48 hours volume expansion criteria. Terlipressin response at day 7 was assessed using standard criteria. **Results:** 21 (40.3%) patients [age 51.23 ± 10.9 years, 80.9% males, 61.9% NASH cirrhosis, MELD 19(18-21)] were volume replete at index POCUS with mean IVCD 1.78 ± 0.18 cm. Baseline creatinine and creatinine at diagnosis of HRS-AKI were 1.02 ± 0.16mg/dl and 2.2 ± 0.49mg/dl, respectively. Overall, 17 (80.95%) responded to terlipressin with complete response in 13(61.9%) and partial response in 4(19.04%). At diagnosis, creatinine was higher in non-responders [2.75(2.2-2.3) vs 1.9 (1.9-2.1) $p = 0.01$]. Serious adverse events were noted in 2(9.5%) patients. **Conclusion:** POCUS-guided initiation of terlipressin in HRS-AKI is safe and feasible. Volume-replete patients at index diagnosis may be candidates for early initiation of terlipressin. However, further refinements in POCUS criteria and randomized allocation are required for the further validation of the hypothesis.

3031-A | PRE LIVER TRANSPLANT SERUM CREATININE TRENDS DIFFER IN MEN AND WOMEN WHO REQUIRE POST LIVER TRANSPLANT RENAL REPLACEMENT THERAPY

Katherine M. Cooper[1], Alessandro Colletta[2] and Deepika Devuni[1], (1)UMass Chan Medical School, (2) UMass Chan Medical School, Worcester, MA

Background: Serum creatinine (sCr) is a poor marker of renal function in patients with advanced liver disease (AdLD). However, changes in sCr are still used to monitor the course of renal dysfunction in individual patients. We aimed to evaluate sex differences the relationship between sCr trends and post-liver transplant (LT) renal outcomes in patients with AdLD requiring inpatient LT evaluation (LTE). **Methods:** Urgent LTE's for AdLD over a 4-year period at our center were analyzed (n = 210); fulminant liver failure patients were excluded. MELD-Na labs from the time of LTE and the time of LT were collected. Metrics included "Delta -Cr", "Cr slope" and "post-LT RRT". "Delta Cr" was defined as the difference in sCr at the time of LTE (Cr_{LTE}) and sCr at the time of LT (Cr_{LT}). "Slope-Cr" was defined as "Delta Cr/waitlist days." Post-LT-RRT_{30d} was defined was RRT requirement e 30 days post -LT. Patient's were dichotomized by whether or not their sCr reduced pre-LT (-Delta Cr vs. +Delta Cr). Data was compared between women and men (Top panel) and further by pre-LT RRT status (bottom panel). Data analysis included Fishers Exact test and T tests**. Results:** 210 patients were analyzed. Alcohol was the most common AdLD etiology (61%) with no differences by sex. 39% underwent LT (43 men, 39 women) of which 41.5% required e 1day of pre-LT RRT. Post-LT-RRT_{30d} occurred in 24.4% (23.1% women vs. 25.6% men, p = 0.79). Women with post-LT-RRT_{30d} had a larger reduction in sCr between LTE and LT compared to women without post-LT-RRT_{30d} (Delta Cr: -0.98 vs. +0.25, p = 0.07). When accounting for waitlist, this relationship persists(Slope-Cr: -0.23 vs. +0.04, p = 0.06). Men with post-LT-RRT_{30d} had a large increase in sCr between LT and LTE (Delta Cr 0.97 vs. 0.01, p = 0.12). These directionalities persists on subgroup analysis in patients with and without pre-LT RRT (bottom panel). A down-trending sCr (- Delta Cr) did not affect rate of post-LT-RRT_{30d} in women (61.1% vs. 57.1%, p = 0.80), but was associated lower rate of post-LT-RRT_{30d} in men (31.3% vs. 70.4%, p = 0.01**). Conclusion:** Predictors of post-LT renal function differ between men and women. Pre-LT renal function is considered a strong predictor of post-LT renal outcomes, but this may be less applicable to women with AdLD. In our analysis, a reduction in sCr between LT and LTE was observed in women requiring post-LT RRT while an increase sCr between LTE and LT was observed in men requiring post-LT RRT. These findings remained profound when accounting for waitlist days and when accounting for pre-LT renal replacement therapy. While this cohort is small, our results suggest a quick decline in sCr may portend a poor prognosis with post-LT for women. Potential causes of this phenomenon include increased muscle wasting between LTE and LT in women compared to men or more prevalence of critical illness myopathy in women compared to men at the time of LTE. Other methods of assessing GFR should be used routinely, particularly in women who present with AdLD.

3032-A | PREDICTING BIOMARKERS UNEARTHED USING URINARY PROTEOMICS FOR ACUTE KIDNEY INJURY (AKI) IN DECOMPENSATED CIRRHOSIS (DC)

Virendra Singh[1], Inder Bhan Singh II[2], Arka De[3], Vivek Kumar[3], Jasvinder Nain[3] and Ashok Kumar[4], (1)Punjab Institute of Liver and Biliary Sciences, Mohali, India, Chandigarh, CH, India, (2)Postgraduate Institute of Medical Education and Research, (3)Post Graduate Institute of Medical Education and Research, (4)Post Graduate Institute of Medical Education & Research

Background: AKI in decompensated cirrhosis adversely affects outcome before as well as after transplant in these patients. AKI occurs In around 20% of DC patients who are admitted. There is not much knowledge available about the prevalence of AKI in DC outpatients. Furthermore, there has not been much research done on the clinical indicators of AKI development in this situation. This ongoing longitudinal prospective study uses untargeted mass spectrometry-based urine proteomics to investigate the function of urinary biomarkers and assess the predictors of AKI among DC patients in the outpatient environment. **Methods:** Total 123 consecutive outpatients with DC were recruited. Patients with chronic kidney disease are excluded. All patients were followed up for a year at three-month intervals to observe the development of AKI, or more often if deemed clinically required. The International Club of Ascites (ICA) criteria was used to define AKI. Liquid chromatography-mass spectrometry (LC-MS) was used to do urine protein profiling, and Proteome Discoverer 3.0 was used to infer the results. **Results:** One hundred and twenty three patients (age: 50.94 ± 9.32 years, males: 104 (84.5%) were recruited and were included for analysis. The commonest etiologies included alcohol (n = 66, 53%), NAFLD (n = 25, 20.3%), and chronic viral hepatitis (n = 21, 17.07%). Median duration of follow-up was 6 (1-12) months. AKI developed in 21 (17.07%) patients on follow-up. At baseline around 1700 proteins in urinary samples were scanned. Baseline Beta 2 microglobulin, Uroplakin-1a, Cornifin-A and B, Urinary retinol binding protein 4, and Uromodulin (p = 1.1e-7, 6.6e-7, 1.7e-2, 2.3e-4, 2.3e-4, and 2.6e-2; respectively) were significantly higher in patients who developed AKI. NGAL at baseline was significantly higher in mortality group with Area under ROC value of 0.9903 and p-value of < 0.0001. **Conclusion:** The incidence of AKI in outpatients with decompensated cirrhosis was 17.07%. Beta 2 microglobulin, Uroplakin-1a, Cornifin-A and B, Urinary retinol binding protein 4, and Uromodulin may help in identification of patients who have a higher risk of AKI development and NGAL may act as mortality marker in DC patients with AKI.
Disclosures: The following people have nothing to disclose: Virendra Singh, Inder Bhan Singh, Arka De, Vivek Kumar, Jasvinder Nain, Ashok Kumar

3033-A | PREDICTING FUTURE DECOMPENSATION IN PATIENTS WITH CIRRHOSIS: A MACHINE LEARNING APPROACH TO RISK STRATIFICATION AT THE FIRST PATIENT VISIT

Micah Grubert Van Iderstine[1], Braedon Griggs[1], Olivia Thorleifson[1], Gerald Y. Minuk[2] and Nabiha Faisal[1], (1) University of Manitoba, (2)Department of Internal Medicine, University of Manitoba, MB, Canada

Background: Decompensation is a major turning point in the course of chronic liver disease. Determining which patients with cirrhosis will decompensate is challenging due to the complex non-linear relationships between lab values and patient outcomes. We aimed to develop and validate machine learning (ML) models to predict hepatic decompensation in a timely and accurate manner at the first patient visit. **Methods:** This study used a retrospective province-wide cohort of 3483 adult patients with cirrhosis or its complications seen in hepatology clinics between 1987 and 2023. Patients were identified to have cirrhosis and classified as either compensated or decompensated based on diagnostic and prescribing codes. We identified eleven potential biochemical and demographic predictors that can be evaluated at the first clinic visit. Patients were randomly selected for model development (80%, n = 2786) and validation (20%, n = 697). Twelve ML classification models including Support Vector Machine, Random Forest, XGBoost and AdaBoost were trained and tuned to differentiate between compensated and decompensated patients. Predictor inclusion and model selection were conducted with 10-fold cross-validation. Model performance was evaluated using precision, recall and f1 score. **Results:** Of the 3483 patients with cirrhosis, 992 patients were eventually diagnosed with decompensation and 2491 patients remained compensated. The mean age was 51.8 years, 50.5% were male, and mean length of follow-up was 7.5 years. Prediction on the validation dataset indicated that the AdaBoost classifier performed best with a

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

compensated precision rate of 0.893 and decompensated recall of 0.791. The compensated recall was 0.616, and f1 score was 0.729. The decompensated patient precision was 0.421, and f1 score was 0.55 (Figure 1A, 1C). Ten-fold cross validation accuracy was 71.6% (SD = 2.5%). The AUC-ROC for the binary decision was 0.76 (Figure 1B). The features of highest predictive value were found to be INR, platelets, sodium, creatinine, albumin and bilirubin. **Conclusion:** The machine learning models developed using a province wide hepatology ambulatory database of cirrhosis patients can potentially define a high-risk group early in the course of disease. This, in turn, can lead to improved clinical outcomes and aid in treatment decision-making and prognostication. Additional external validation is needed to confirm the reliability and generalizability of these models.

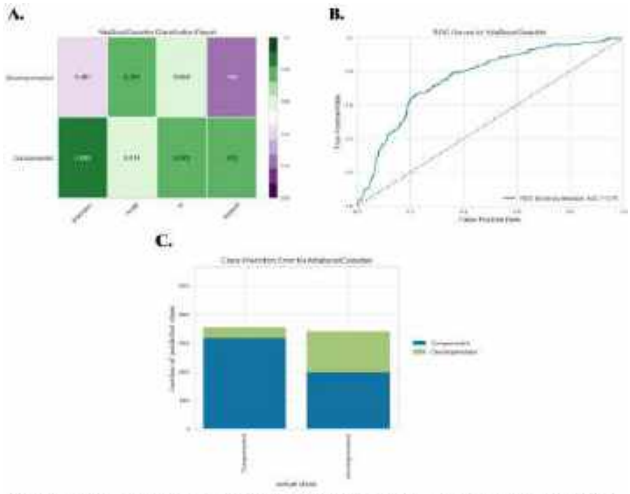

Figure 1. AdaBoost model performance metrics (A), receiver operator curve (B), and class prediction error chart (C). The columns of the class prediction chart illustrate the predicted distribution of patient outcomes compared to the actual outcomes shown in color.

Disclosures: The following people have nothing to disclose: Micah Grubert Van Iderstine, Braedon Griggs, Olivia Thorleifson, Gerald Y. Minuk, Nabiha Faisal

3034-A | PREDICTORS OF RENAL DYSFUNCTION IN PATIENTS UNDERGOING TIPS FOR DECOMPENSATED CIRRHOSIS

Shilpa Junna[1], Abhishek Shenoy[2], Sarah Uttal[2], Shantanu Warhadpande[2], Seth Waits[2], Robert J. Fontana[2] and Pratima Sharma[2], (1)Cleveland Clinic Foundation, (2)University of Michigan Medical Center

Background: Transjugular intrahepatic portosystemic shunts (TIPS) can improve hemodynamics in cirrhotic patients with complications of portal hypertension, however there are significant cardiac and renal implications associated with this procedure. While the cardiac effects are often instantaneous, changes in renal function may not be seen for up to several weeks. In this study, we examined the trajectory of serum creatinine (SCr) after TIPS placement and factors associated with worsening SCr post-TIPS. **Methods:** Data was collected retrospectively on all patients aged e 18 years who underwent TIPS for complications of decompensated cirrhosis at our institution from July 2017 to June 2022. Patients were followed until death or 12/31/2022. The primary outcome was change in SCr from baseline (within 30 d pre-TIPS) to post-TIPS (within 6 mo of TIPS), and was defined as a change of 0.01 mg/dL or higher. These patients were then divided into those with worsening or improving SCr post-TIPS. We subsequently used multivariate logistic regression to identify independent predictors of change in SCr post-TIPS. **Results:** The median age of the 165 patients was 59 years (20-85 y), 46% were female and 85% Caucasian. The leading etiologies of liver disease were NAFLD (39%) followed by alcohol associated disease (32%). The median MELD-Na score at the time of TIPS was 12 (6-30). The median SCr pre-TIPS was 0.97 mg/dL (0.39-4.7 mg/dL). Improvement in SCr post-TIPS was seen in 54% of patients (median 0.14 mg/dL) and an increase in SCr was noted in 46% (median 0.19 mg/dL). Only 4% of patients required renal replacement therapy post-TIPS. Median pre- and post-TIPS HVPG were 16.5 and 8 mm Hg, respectively (Figure 1). After adjusting for age at TIPS, sex, etiology of cirrhosis, pre-TIPS MELD Na, and pre-TIPS SCr, pre-TIPS HVPG was independently associated with worsening SCr post-TIPS. Every unit increase in pre-TIPS HVPG was found to worsen the SCr by 7% (OR: 1.074, $p < 0.025$) post-TIPS. Hospitalizations within 90 days of TIPS were more prevalent in those whose renal function had worsened compared to those with improvement (51% vs. 44%, $p = 0.05$). Interestingly, listing for liver transplantation and 1-year mortality were similar in both groups. **Conclusion:** Overall, worsening of SCr within 6 months of TIPS was seen in half of our cohort. Despite the significantly higher proportion of hospitalizations among those with renal dysfunction after TIPS, the survival and liver transplantation listing rates at 1-year post-TIPS were similar in both groups. Pre-TIPS HVPG appears to play an important role in predicting a patient's risk of renal dysfunction post-TIPS and may be useful in guiding post-TIPS management.

3035-A | PREVALENCE OF HEART FAILURE AND HEPATIC CONGESTION IN NEPHROGENIC ASCITES: HISTOPATHOLOGIC AND ECHOCARDIOGRAPHIC CHARACTERIZATION

Areeba Khwaja[1], James Patton[2], Brian K. Carlile[3], James F. Trotter[4], Hussien Elsiesy[2], Bernard V. Fischbach[2], Mohanakrishnan Sathyamoorthy[5,6] and Stevan A. Gonzalez[2,6], (1)Mcgovern Medical School, University of Texas Health Science Center at Houston, Fort Worth, TX, (2)Baylor Simmons Transplant Institute, Forth Worth, TX, (3)Baylor Scott & White All Saints Medical Center, Fort Worth, TX, (4)Baylor Simmons Transplant Institute, Dallas, TX, (5)Baylor Scott & White Heart & Vascular Hospital Fort Worth, Fort Worth, TX, (6)Burnett School of Medicine at TCU, Fort Worth, TX

Background: Factors associated with development of nephrogenic ascites among patients with end-stage renal disease (ESRD) remain poorly characterized. Patients with ESRD are at increased risk of heart failure (HF). Comprehensive assessment of nephrogenic ascites vs cardiogenic ascites by transjugular (TJ) liver biopsy, echocardiography, and peritoneal fluid analysis could more accurately discriminate etiology, guide management, and ascertain clinical outcomes. **Methods:** Non-cirrhotic patients with ascites attributed to 1) ESRD maintained on hemodialysis or 2) HF were identified through a clinical hepatopathology database at a tertiary care hepatology program from 2011 to 2021. Liver histopathology and echocardiography data were reviewed on all patients. **Results:** 39 patients were identified: 24 with ESRD/nephrogenic and 15 with cardiogenic ascites. ESRD patients were younger ($p = 0.02$) and more commonly Hispanic or Black ($p = 0.03$). All cardiogenic ascites patients had established HF and no ESRD; common causes of HF included ischemic cardiomyopathy (CM, 27%), valvular heart disease (27%), and nonischemic CM (20%). Patients with ESRD had notably increased peritoneal fluid protein (median 4.5, range 3.0-5.8 g/dL) vs cardiogenic ascites (3.3, 2.0-4.6 g/dL; $p = 0.003$), while cardiogenic ascites was more frequently associated with a serum-ascites albumin gradient (SAAG) > 1.1 (82% vs 17%; $p = 0.001$). Liver biopsy included TJ hepatic venous pressure gradient (HVPG) in 35/39 (90%). Absence of cirrhosis was confirmed in all patients: 61.5% fibrosis stage 0-1, 25.6% stage 2. Bridging fibrosis was present in 4 patients, all with HVPG d 5. Sinusoidal dilation/congestion was associated with reduced right ventricular systolic function on echocardiogram ($p = 0.02$), elevated TJ free hepatic vein pressure (HVP) > 10mmHg ($p = 0.001$), and was present in 14/15 (93%) of the cardiogenic cohort, yet was also observed in 15/24 (62.5%) with ESRD. The frequency of HVPG > 5mmHg was similar in cardiogenic (20%) vs ESRD (15%, $p = 0.70$), and HVPG > 9 was observed only in 2 patients with cardiogenic ascites. Elevated HVP > 10mmHg was more common in cardiogenic ascites (93% vs 55%, $p = 0.01$), and was strongly associated with decreased survival among patients with ESRD (1-yr survival 0.38 vs 1.00, $p = 0.04$). **Conclusion:** Although peritoneal fluid characteristics differ between cohorts, histologic evidence of hepatic congestion is frequently observed in patients with ESRD and nephrogenic ascites, suggesting HF as an underlying cause. As right heart dysfunction with elevated HVP may have a greater impact on outcomes among patients with ESRD, further investigation identifying risk factors and early echocardiographic features of HF in this population is needed.

3036-A | PREVENTION OF MORTALITY WITH LONG-TERM HUMAN ALBUMIN ADMINISTRATION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS AND ASCITES: DESIGN AND STATUS OF THE PRECIOSA STUDY

Tarek Hassanein[1], Paolo Angeli[2], Wim Laleman[3], Tamara Milanovic[4], Gergana Taneva[5], Mireia Torres[6], Peter Nelson[6], Javier Fernandez[7,8] and On behalf of the PRECIOSA Study Investigators, (1)Southern California Research Center, (2)Padua Hospital University, (3) University Hospital Gasthuisberg, KU Leuven, (4) University Clinical Center of Serbia, (5)Saint Sophia Medical College, (6)Grifols, (7)Hospital Clínic, Idibaps and Ciberehd, (8)EF Clif, Easl-Clif Consortium and Grifols Chair

Background: Patients with decompensated cirrhosis develop ascites, variceal bleeding, hepatic encephalopathy, and bacterial infections, complications associated with worse survival compared to compensated cirrhosis. A pilot study suggested that long-term human albumin administration in decompensated cirrhotic patients may improve circulatory function and systemic inflammation. The aim of this pivotal study is to assess long-term

Albutein 20% (Grifols) treatment for patients with decompensated cirrhosis and ascites. **Methods:** A phase 3, multicenter, randomized (1:1), controlled, parallel-group, open-label study compares standard medical treatment (SMT) + Albutein 20% (1.5 g/Kg body weight, maximum 100 g/patient, every 10 ± 2 days up to 12 mo; treatment arm) versus SMT alone (control arm). Eligible patients are adult (>18 y old), diagnosed with liver cirrhosis and ascites, hospitalized for acute decompensation, with or without a history of acute-on-chronic liver failure (ACLF) at admission or during hospitalization but without ACLF at screening, and a CLIF-C AD score > 50 points. **Results:** As of May 2023, enrollment has been completed at 69 sites across North America and Europe, with 477 patients screened, and 410 patients randomized (the target enrollment). Primary efficacy endpoint is the time to liver transplantation or death through 1 year after randomization. Secondary efficacy endpoints include time to liver transplantation through 3 and 6 months, time to death through 3, 6, and 12 months, number of paracenteses and incidence of refractory ascites. Exploratory endpoints are incidence of ACLF through 3, 6 and 12 months, number and length of hospital and ICU admissions, incidence of cirrhosis-related complications, albumin concentration and albumin binding capacity, incidence of TIPS, CLIF-C OF, CLIF-C ACLF and CLIF-C AD, MELD, Child Pugh score and quality of life. Safety endpoints include adverse events, vital signs, physical and laboratory examinations. **Conclusion:** PRECIOSA should provide pivotal results on the efficacy and safety of long-term albumin therapy to potentially improve survival in decompensated cirrhosis and ascites (NCT03451292, EudraCT: 2016-001789-28).

3037-A | PROGNOSTIC SIGNIFICANCE OF ACUTE KIDNEY INJURY STAGE 1B IN HOSPITALIZED PATIENTS WITH CIRRHOSIS: A U.S. NATIONWIDE STUDY

Kavish R. Patidar[1,2], Giuseppe Cullaro[3], Mobasshir A Naved[4], Shaowli Kabir[5], Ananth Grama[4], Eric S. Orman[6], Salvatore Piano[7] and Andrew S Allegretti[8], (1) Baylor College of Medicine, (2)Michael E. Debakey Veterans Affairs Medical Center, (3)University of California San Francisco Medical Center, (4)Purdue University, (5)University of Kentucky, (6)Indiana University, (7)University of Padova, (8)Division of Nephrology, Department of Medicine, Massachusetts General Hospital

Background: Understanding the prognostic significance of acute kidney injury (AKI) stage 1B [serum creatinine (sCr) > 1.5mg/dL], compared to stage 1A (sCr < 1.5mg/dL) in an U.S. population is important as it can impact initial management decisions for AKI in hospitalized cirrhosis patients. Therefore, we aimed to define outcomes associated with stage 1B in a nationwide U.S. cohort of hospitalized cirrhosis patients with AKI. **Methods:** Hospitalized cirrhosis patients with AKI in the Cerner Health Facts database from 1/2009-09/2017 (n = 6,250) were assessed for AKI stage 1 (≥ 1.5-2-fold increase in sCr from baseline) and were followed for 90-days for outcomes. Primary outcome was 90-day mortality; secondary outcomes were in-hospital AKI progression and AKI recovery (return of sCr < 0.3 mg/dL of baseline). Competing risk multivariable analysis was performed to determine the independent association between AKI stage 1B, 90-day mortality (liver transplant as competing risk) and AKI recovery (death and liver transplant as competing risk). Multivariable logistic regression analysis was performed to determine the independent association between AKI stage 1B and

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

AKI progression. **Results:** 4,654 patients with stage 1 were analyzed: 1A (44%) and 1B (56%). Patients with stage 1B were older [median (interquartile range) 64 (56, 73) vs. 58 (50, 67) years, $p < 0.001$], more likely to be male [67% vs. 54%, $p < 0.001$), have non-alcoholic steatohepatitis [47% vs. 34%, $p < 0.001$], pre-existing chronic kidney disease (CKD) [60% vs. 9% ($p < 0.001$)], and ascites [66% vs. 60%, $p < 0.001$] compared to patients with stage 1A. Stage 1B patients had significantly higher cumulative incidence of 90-day mortality compared to stage 1A patients, 27% vs. 20% ($p < 0.001$) (Figure). On multivariable competing risk analysis adjusting for severity of liver disease and pre-existing CKD, patients with stage 1B (vs. 1A) had higher risk for mortality at 90 days [sHR 1.52 (95%CI 1.20-1.92), $p = 0.001$] and decreased probability for AKI recovery [sHR 0.76 (95%CI 0.69-0.83), $p < 0.001$]. Furthermore, on multivariable logistic regression analysis, AKI stage 1B (vs. 1A) was independently associated with AKI progression, OR 1.42 (95%CI 1.14-1.72) ($p < 0.001$). **Conclusion:** AKI stage 1B patients have significantly higher risk for 90-day mortality, AKI progression, and reduced probability of AKI recovery compared to AKI stage 1A patients. These results validate the prognostic significance of AKI stage 1B in an U.S. based population.

Figure: Comparisons of Cumulative Incidence of Mortality Between Patients with AKI Stage 1A and Stage 1B.

Background: Regional differences in cirrhosis etiologies, precipitating events, clinical practice may have an impact on AKI characteristics, AKI & patient outcomes across different parts of the world. We aim to assess these aspects of AKI amongst a global population of cirrhosis inpatients. **Methods:** The CLEARED Consortium prospectively enrolled cirrhotic inpatients from 6 continents. Baseline demographics, medications, admission & in-hospital details, AKI occurrence/severity, patient & AKI outcomes and survival at 1 month were collected. Multivariate analysis for AKI development using potential negative impact factors and patient's regional location was done. **Results:** 4161 patients were enrolled. Amongst the various regions, subcontinent India enrolled more men (81.6%) who were younger from than any other regions ($p < 0.001$ for both). Most common cirrhosis etiology was alcohol in Europe/Australia (74%), NASH in North (Nth) & South (Sth) Americas (26%) and hepatitis B in China & rest of Asia (45%) ($p < 0.001$ for all). Diuretics were the most commonly used drug (>50% in all regions except India of 47.5%) followed by PPI (31% in China/Asia, 55% in India) ($p < 0.001$ for all). The admission MELD-Na varied (highest India: median = 28; lowest China/Asia: median = 17, $p < 0.001$). Common AKI precipitants were excess diuretics (Sth America 45% to Africa/Mid East 60%, $p < 0.001$), admission infection (China/Asia: 26% to Africa/Mid East 42%, $p < 0.001$). AKI distribution showed stage 1 H45% and stage 3 H30%. Most AKI were already present at admission (H70% India & Nth America, H60% in Africa/Middle East, and least in Europe/Australia = 23.6%) ($p < 0.001$). There were great variations in albumin (40% in China/Asia to 77% in India, $p < 0.001$) and vasoconstrictor use (24% in Sth America to 80% in India, $p < 0.001$) amongst AKI patients. Discharge MELD-Ma improved for patients without AKI or whose AKI resolved, but not for patients whose AKI only partially or not resolved. Multivariate analysis showed that diabetes, hypertension, prior LVP, admission parameters including NSBB use, MELD-Na and infection, as well as nosocomial infection all had a negative effect on AKI development. Using Nth Am. as an index, being in Sth Am. had 2X the risk, whereas all other regions had lower risk for AKI development ($p < 0.001$). AKI resolution & 30-day survival also varied across the continents (Figure). **Conclusion:** AKI incidence, precipitants, treatment and resolution in cirrhotic patients vary significantly around the world, which in turn may impact 30-day survival. Improved strategies for AKI prevention, diagnosis and management need to be devised to improve global outcomes.

3039-A | ROLE OF PORTOSYSTEMIC SHUNT AND PORTAL VEIN STENT IN MANAGING PORTAL HYPERTENSION DUE TO HEMATOLOGICAL DISEASES

Jae-Sung Yoo[1], Jeong Won Jang[2], Jong Choi[2], Seung Kew Yoon[2] and Pil Soo Sung[3], (1)Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, Republic of Korea, (2)The Catholic University of Korea, (3)The Catholic University Liver Research Center, Department of Biomedicine & Health Sciences, College of Medicine, the Catholic University of Korea

Background: Considerable patients with hematological malignancies experience complications related to portal hypertension. Many of these patients experience many complications of portal hypertension, including life-threatening complications such as varix bleeding. In our study, we sought to analyze the prognosis of patients of hematological malignancies with portal hypertension treated with transjugular intrahepatic portosystemic shunt and portal vein stents. **Methods:** We retrospectively assessed patients with hematological malignancies with portal hypertension who had complications including varix bleeding and ascites. We evaluated the prognosis of enrolled patients who were treated with portal vein stents and transjugular intrahepatic portosystemic shunts and also evaluated factors that seemed to be associated with their prognosis. **Results:** 11 patients were evaluated; the average age of the patients was 53.6 years old and 9 patients were female. The median total bilirubin of the 11 patients was 2.73; the median INR of the patients was 1.17; the average albumin of the 11 patients was 3.7. None of the patients tested positive for HBV or HCV infection. 3 patients had portal vein thrombosis. The average follow-up duration after TIPS or stent insertion procedure was 660 days and the median follow-up duration was 420 days. 4 patients were myelodysplastic syndrome patients; 3 patients were primary myelofibrosis (all positive for JAK2 V617F mutation) patients; 2 patients were multiple myeloma patients; 1 patient was essential thrombocytosis patient. Of the 11 patients, 1 patients experienced rebleeding. 2 patients also experienced rebleeding but this was because they went through TIPS closure or revision due to repetitive hepatic encephalopathy. 5 patients died during the follow-up, two of which were related to portal hypertension. 8 patients showed resolution of portal hypertension (HVPG 23 mmHg -> 5 mmHg) following TIPS and stent insertion. **Conclusion:** Portosystemic shunt and stent installation is an effective treatment option in managing portal hypertension due to hematological diseases.

Table 1. Baseline characteristics of enrolled patients

	Total (n=11)
Sex (M/F)	2(18%)/9(82%)
Age	53.64±9.82
Etiology	
Primary myelofibrosis	3 (27.27%)
JAK2 V617F mutation	(3)
Myelodysplastic Syndrome	3(27.27%)
Multiple myeloma	2(18.18%)
Essential thrombocytosis	1(9.09%)
Aplastic anemia	1(9.09%)
Polycythemia Vera	1(9.09%)
HBsAg	0
Anti-HCV Ab	0
Portal vein thrombosis	4(36.36%)
Treatment	
Eculizumab	2(18.18%)
Ruxolitinib	1(9.09%)
History of BMT	1(9.09%)
No history of chemotherapy or BMT	7(63.63%)

Table 2. Prognosis and changes in liver function of enrolled patients

	Total (n=11)
Initial lab	
Median total bilirubin (mg/dL)	0.88
Median albumin (g/dL)	3.7
Median INR	1.17
Last lab	
Median total bilirubin (mg/dL)	0.63
Median albumin (g/dL)	3.6
Median INR	1.14
Deaths	5
Portal hypertension related mortality	2
Rebleeding or aggravation	3

3040-A | SERUM CYSTATIN C PREDICTS THE DEVELOPMENT OF ACUTE KIDNEY DISEASE AND WORSE OUTCOMES IN PATIENTS WITH REFRACTORY ASCITES- A PROSPECTIVE COHORT STUDY

Rakhi Maiwall[1], Samba Siva Rao Pasupuleti[2], Neha Chauhan[1], Ashinikumar Kumar Hidam[1], Sherin Thomas[1] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, (2)Mizoram University (A Central University), Pachhunga University College Campus, (3)Ilbs

Background: Refractory ascites (RA) is one of the dreaded complications of cirrhosis. There are marked systemic and splanchnic hemodynamic alterations resulting in low mean arterial pressure (MAP) and decreased renal perfusion. There are no prospective studies evaluating the incidence, risk factors and role of Cystatin C (CysC) in predicting the development of acute kidney disease (AKD) in patients with cirrhosis and RA. **Methods:** Prospective cohort of RA were enrolled and serum CysC was performed for all patients. The primary outcome was development of AKD at 3-months. AKD and CKD were defined based on estimated glomerular filtration rate (eGFR) derived from the modification of-diet-in-renal-disease (MDRD6) on two consecutive occasions, 3 months apart. Binary logistic regression and competing risk-survival analysis was performed with TIPS, liver transplant and death as competing events to AKD or CKD. **Results:** A total of 297 patients with mean age 50.3 ± 10.0years, 86.9% males, 62% with alcohol-associated liver disease, 51% frail, with mean MELD 17 ± 7 and CTP 10.8 ± 1.9 were enrolled. These patients were followed for a median of 7.2 (2.8-17.7) months. The mean serum CysC was 1.6 ± 0.5 ng/ml. At follow up, 77 (26.2%) and 48 (16.3%) developed AKD and CKD respectively, 55 (18.7%) died, 14 (4.8%) underwent TIPS and 20(6.8%) liver transplantation. On multivariable logistic regression analysis, higher serum CysC (OR 2.58, 1.2-5.6), lower baseline eGFR (OR 0.10, 0.04-0.27), lower mean arterial pressure (OR 0.95, 0.91-0.99), presence of frailty (OR 4.78, 1.99-11.44) and the use of beta-blockers (OR 2.63, 1.23-5.65) significantly predicted the development of AKD at 3-months. On competing risk survival analysis, CysC (sHR 2.06, 1.15-3.67) and presence of frailty (sHR 1.85; 95% CI 1.03-3.31) independently predicted AKD. Higher CysC (sHR 2.80, 1.22-6.43), presence of frailty (sHR 2.67, 1.08-6.59) and AKD were significant risk factors for CKD (sHR 2.80, 1.47-5.34). Patients with AKD also had significant lower proportion of patients who achieved ascites control (47.1% vs. 27.3%; $p = 0.002$) and higher mean number of hospitalizations 0.27 ± 1.28 vs. 0.64 ± 0.98; $p < 0.001$). With each unit increase in CysC the instantaneous risk of AKD and CKD increased by 53 % and 138% respectively. A cut-off CysC of 1.4 ng/ml could predict the risk of AKD (HR 1.86, 1.06-3.26) and CKD (HR 5.52, 1.92-15.83). The development of AKD was also associated with higher mortality (HR 1.37, 1.01-2.36). **Conclusion:** Almost one-third of patients with refractory ascites develop AKD which is an independent predictor of CKD, lower ascites control, higher need of hospitalizations and mortality. Serum Cystatin C could guide risk stratification of patients with refractory ascites for adverse renal outcomes. Beta-blockers lead to higher risk of AKD development and should be carefully used in patients with refractory ascites who are frail, with lower mean arterial pressure and higher CysC.

3041-A | SEX-BASED DISPARITIES IN BASELINE CHARACTERISTICS AND CLINICAL OUTCOMES OF PATIENTS WITH DECOMPENSATED CIRRHOSIS AND HEPATIC HYDROTHORAX

Mohamed Ismail, Rutgers New Jersey Medical School, Newark, NJ, Jennifer Asotibe, Rutgers New Jersey Medical School, Emmanuel Akuna, Albert Einstein Healthcare Network and Bubu A Banini, Yale University, New Haven, CT

Background: Although disparities in chronic liver disease by sex have been well described, sex-based disparities, specifically among patients with decompensated cirrhosis (DC) and concurrent hepatic hydrothorax (HHT), are lacking. We aimed to assess sex-based disparities in patient characteristics, etiologies of liver disease, and outcomes of patients with DC and HHT to determine if sex should be considered when approaching the early stages of the management of decompensated cirrhosis. **Methods:** Data from the 2016 -2019 National Inpatient Sample (NIS) database for patients admitted with cirrhosis were analyzed. By applying a stepwise and comprehensive set of inclusion and exclusion criteria, patients with decompensated cirrhosis with HHT were identified and analyzed. We further stratified the outcomes by gender. The primary outcome was inpatient

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

mortality. Secondary outcomes were hospital length of stay, total hospital charges, odds of development of respiratory failure, electrolyte derangements, sepsis, and need for paracenteses. Univariate and multivariate regression analyses were performed to adjust for confounders. **Results:** From 2016-2019, a total of 590,789 patients with a diagnosis of cirrhosis were admitted; 339,334 patients had decompensated cirrhosis, of which 15,397 patients (4.5%) had concurrent HHT. There were 8870 (57.6%) male patients with DC with HHT compared to 6524 (32.3%) female patients. The mean age was 59 years for male patients versus 62 years for females ($p < 0.0001$). Sex disparities seen among patients with HH were similar to disparities in the overall cohort of patients with DC. Compared to males, females had a higher prevalence of NASH (5.98% vs. 14.06%; $p < 0.0001$) and autoimmune hepatitis (0.74% vs. 2.88%; $p < 0.0001$) as an etiology for cirrhosis. On the other hand, males were more likely to have chronic hepatitis B (1.47% vs. 0.75%, $p < 0.0001$) and C (9.77% vs. 7.51%, $p < 0.0001$) as the etiology for cirrhosis compared to females. Male patients had lower odds of developing hypokalemia when compared to female patients (17.61% vs. 24.20%, $p < 0.0001$) but higher odds of developing hyponatremia compared to female patients (31.36% vs 28.34%, $p < 0.05$). There were no statistically significant differences in the odds of mortality, sepsis, respiratory failure, need for paracentesis, length of stay, or total hospital charges between males versus females. **Conclusion:** This study highlights sex-based disparities in baseline characteristics and etiologies of liver disease in patients with DC and concurrent HHT. These findings should be taken into consideration when approaching the early stages of the management of patients with decompensated cirrhosis.

f 3042-A | SMALL FREQUENT PARACENTESIS USING AN INDWELLING CATHETER IS SAFE AND MORE EFFECTIVE AS COMPARED WITH REPEATED LARGE VOLUME PARACENTESIS IN CIRRHOTIC PATIENTS WITH REFRACTORY ASCITES (I-CARE)★

Manasa Alla[1], Saggere Muralikrishna Shasthry[2], Amar Mukund[1] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, (2)Instiyue of Liver and Biliary Sciences, (3)Ilbs

Background: Refractory ascites in cirrhosis carries a high mortality rate (up to 50 % in 6 mo). Repeated large volume paracentesis (LVP) has been associated with high morbidity, increased risk of acute kidney injury (AKI) & post paracentesis circulatory dysfunction (PPCD). We hypothesised that repeated small volume paracentesis through percutaneous indwelling drain (PCD) would decrease refilling, paracentesis related complications & requirement by over 50% over 3 months. **Methods:** We screened 187 consecutive patients with refractory ascites admitted at a tertiary care center from 2020-2022 and analysed a total of 121 patients (60 in LVP, 61 in the PCD). Clinical and hemodynamic parameters within study period were recorded. Primary end point was to assess the proportion of patients with 50% reduction in need for paracentesis over 3 months after enrolment in comparison to the pre enrolment 3 month data. Proportion of patients developing hepatic encephalopathy(HE), hyponatremia, AKI, PPCD, SBP at day 5 were also assessed. **Results:** Baseline demographics and clinical parameters, mean CTP and MELD scores were comparable{9.81 ± 1.31 vs. 9.5 ± 1.3, $P = 0.81$; 21.76 ± 3.9 vs 22.3 ± 3.03, $P = 0.55$} in LVP and PCD arms respectively. Mean amount of fluid removed was higher in LVP over 28 days{37 ± 13.04 vs. 30.7 ± 1.03, $P = 0.05$}. Proportion of patients needing reduction in paracentesis by 50% over 3-month was 68.8% (42/61) in PCD arm vs. 0% (0/60). Percentage decrease in paracentesis in the PCD group over 3-month follow up was 56.7 % vs. -21.6% in LVP arm ($P < 0.001$). Increased interval between paracentesis noted in PCD group (15.25 ± 6.05 d vs. 8.36 ± 2.18 d, $P < 0.05$). Between day 1 to day 5, a greater reduction in MAP was noted in the LVP arm compared to PCD arm (-10.1 ± 8mmHg vs. -2.7 ± 3 mmHg, $P = 0.03$). Incidence of PPCD was comparable between the two arms [31.6 % (19/60) vs. 29.5 % (18/60), $P = 0.98$]. Similarly, incidence of complications i.e, HE, infections, AKI episodes over 3 months were comparable between groups. Improved diuretic tolerability (mean dosage) was noted in PCD group at 3 month follow up with no difference in the 3 month mortality{10/60 (16.6%) vs.11/61 (18.03%), $P = 0.42$}. **Conclusion:** PCD guided gradual decompression of ascites is safe and superior to LVP and is aa better alternative in decreasing morbidity such as ascites refilling rates; reducing number of paracentesis and increasing the interval between paracentesis with improved quality of life.

3043-A | TERLIPRESSIN TREATMENT AND TIME TO CLINICAL RESPONSE: CHARACTERIZATION OF HEPATORENAL SYNDROME REVERSAL USING A POOLED DATABASE OF 3 PLACEBO-CONTROLLED PHASE III CLINICAL STUDIES

Brendan M. McGuire, University of Alabama at Birmingham, Birmingham, AL, Stevan A. Gonzalez, Baylor Simmons Transplant Institute, Prasun Jalal, Baylor College of Medicine and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Hepatorenal syndrome (HRS) is a potentially reversible form of acute kidney injury that can be treated with terlipressin (terli), an FDA-approved therapy for adult patients (pts) with HRS and rapidly worsening kidney function. Lower baseline serum creatinine (SCr) is positively associated with HRS reversal in pts randomized to terli (odds ratio [95% CI]: 0.483 [0.361–0.645], $P < 0.001$; Curry MP et al. *Hepatol Commun*. 2023;7(1): e1307). This study assessed the timing of HRS reversal using a pooled dataset from 3 North American-centric placebo (pbo)-controlled Phase III clinical studies. **Methods:** Pooled data from 3 clinical studies (OT-0401, REVERSE, and CONFIRM) that evaluated terli treatment of pts with HRS (N = 608), were assessed for time to HRS reversal and the proportion of pts achieving HRS reversal (numerically and cumulatively) per day. HRS reversal was defined as the proportion of pts with a SCr of d 1.5 mg/dL while on treatment, up to 24 hours after the last dose of study drug (days 1–15). Baseline renal function was assessed (via SCr levels) as a predictor of clinical response (HRS reversal) by multivariate logistic regression analysis. **Results:** HRS reversal was achieved by more pts in the terli group than the pbo group (33.2% [117/352] vs 16.4% [42/256], respectively; $P < 0.001$). Among pts who achieved HRS reversal, the mean (SD) time to HRS reversal was roughly 6 days across treatment groups (terli, 6.3d [3.02]; pbo, 6.7d [3.29]). Most (> 80%) pts had achieved a response by day 10 (Figure). The day that demarcated the greatest proportion of pts who achieved HRS reversal was day 3 (5.1%) in the terli group and day 5 (3.1%) in the pbo group. Similar to the previously reported data on terli, lower baseline SCr was also positively associated with HRS reversal for the pbo group (odds ratio [95% CI]: 0.437 [0.284–0.67], $P < 0.001$). Among patients in both treatment groups, lower baseline SCr was an independent predictor of HRS reversal. **Conclusion:** The greatest proportion of pts achieved HRS reversal as early as day 3 in the terli group, compared with day 5 for the pbo group. Most responses were achieved by day 10 with few additional pts achieving HRS reversal beyond day 10. While lower baseline SCr was a positive predictor of HRS reversal across treatment groups, overall, more pts treated with terli achieved HRS reversal than pbo. This analysis further supports the use of terli therapy, at a lower SCr, in pts with HRS to expedite time to clinical response.

Figure. Proportion of patients achieving hepatorenal syndrome (HRS) reversal by day (Pooled intent-to-treat population)

Chicago, IL, (3)Massachusetts General Hospital and Harvard Medical School, (4)Massachusetts General Hospital, Anodover, MA

Background: Alcohol-associated liver disease (ALD) represents a spectrum of liver pathology including decompensated cirrhosis and has a rising burden in the United States. Ascites is a common complication of progressive chronic liver disease including ALD and is associated with high morbidity and mortality. We tested the hypothesis that serum proteomics identifies biomarkers of ascites in adults with ALD. **Methods:** A prospective cohort of adult patients with alcohol use disorder and healthy controls was evaluated to determine serum proteomics biomarkers of ascites. Patients with other (non-alcohol) etiologies of liver disease were excluded. Proteomic analysis was performed on serum samples using the aptamer-based proteomic SomaScan platform to quantify 1305 proteins. **Results:** 87 adults with AUD and 6 controls were assessed including 29% women with median age 50.5 years, median BMI 25.2 kg/m2. Mean alcohol consumption was 65.9 +/- 62.6 drinks/week. Ascites status was determined from radiographic data (ultrasound or CT) and categorized as none (n = 62), trace (n = 5), small (n = 14), moderate (n = 8), or large (n = 4). Multivariable ordinal logistic regression models adjusting for age, sex, and BMI were used in analyses of ascites status to identify proteins associated with ascites severity (Figure 1A). Principal component analyses were used to demonstrate relative protein abundance grouped by ascites severity (none, trace/small, moderate/large) (Figure 1B). **Conclusion:** Large-scale serum proteomics identifies biomarkers that correlate with severity of ascites in patients with ALD. MRC1, EFEMP1, FLRT3, FLRT2, ALCAM represent potential proteomic biomarkers of ascites in ALD. Further evaluation of proteomic signatures of ascites and portal hypertension are warranted.

Figure 1. Proteomic signature of ascites in alcohol-associated liver disease*

A	Gene ID	β	p-value	B
	MRC1	1.07	1.96×10^{-9}	
	EFEMP1	1.75	3.15×10^{-9}	
	FLRT3	0.87	3.62×10^{-9}	
	FLRT2	2.01	6.16×10^{-9}

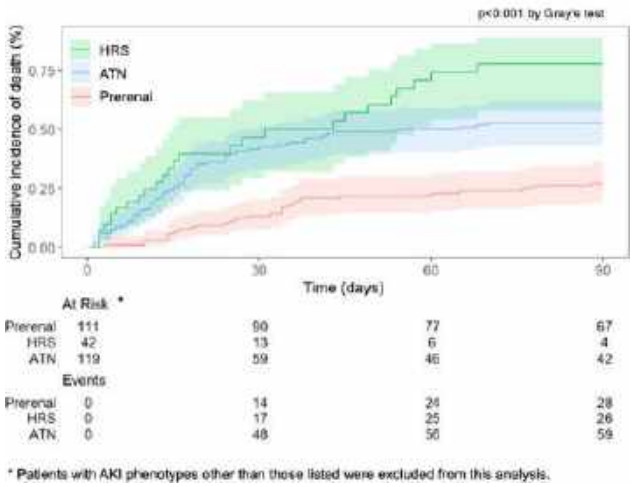
Background: The development of acute kidney injury (AKI) in the setting of alcohol-associated hepatitis (AH) pertains a poor prognosis. However, whether the presence of AH itself drives worse outcomes in patients with cirrhosis and AKI is unknown. **Methods:** Retrospective cohort study of 11 hospital networks of consecutive adult patients admitted in 2019 with AKI and cirrhosis. Alcohol-associated hepatitis was defined as per NIAAA Alcoholic Hepatitis Consortia criteria. AKI phenotypes (prerenal, acute tubular necrosis [ATN], hepatorenal syndrome [HRS]) were determined by two adjudicators and a tiebreaker in case of disagreement. Cumulative incidence of death was calculated at 90 days from admission, with liver transplant (LT) as a competing risk for AH and AKI phenotypes. Competing risk multivariable analysis (LT as competing risk) was performed to determine the independent association between AH and 90-day mortality. **Results:** A total of 2,062 patients hospitalized with cirrhosis and AKI were included, of which 303 (15%) had AH. Most patients with AH had underlying alcohol-associated cirrhosis (87%), while few had hepatitis C or mixed etiology. Patients with AH, compared to those without, were younger (median age 53 vs 63, $p < 0.001$), had less chronic kidney disease (16% vs 33%, $p < 0.001$), more frequently had ascites (87% vs 76%, $p < 0.001$) and had higher Model for End-stage Liver Disease-Sodium (MELD-Na) scores on admission (median 32 vs 25, $p < 0.001$), driven mostly by bilirubin and INR. AKI phenotype significantly differed between patients with and without AH ($p < 0.001$), with ATN occurring more frequently in patients with AH (39% vs 29% in those without AH). Patients with AH fared worse overall, reaching more severe peak AKI stage, requiring more renal replacement therapy (RRT) and having a higher cumulative incidence of death at 90 days (45% vs 38%, $p = 0.026$). Using no AH as reference, the unadjusted sHR for 90-day mortality was higher for AH (sHR 1.24 [95%CI 1.03-1.50, $p = 0.024$]), but this was not significant when adjusting for MELD-Na. Interestingly, while HRS and ATN were associated with similar prognoses in the overall cohort, in patients with AH specifically, the 90-day cumulative incidence of death was significantly higher for HRS compared to ATN (78% vs 53%, Figure). Finally, amongst patients treated with RRT (n = 373), those with AH had similar 90-day mortality compared to those without (36% vs 41% respectively, p = NS). **Conclusion:** Hospitalized patients with cirrhosis and AKI presenting with AH have higher 90-day mortality than those without AH, but the worse outcomes may be driven by worse synthetic dysfunction rather than AH itself. Comparable survival of patients treated with RRT suggests that the presence of AH alone should not be a contraindication to starting RRT.

Figure Cumulative incidence of death in patients with alcohol-associated hepatitis, by AKI phenotype



* Patients with AKI phenotypes other than those listed were excluded from this analysis.

3046-A | THE IMPACT OF MELD SCORE AND ACLF GRADE ON OUTCOMES OF HEPATORENAL SYNDROME FOLLOWING TREATMENT WITH TERLIPRESSIN AND ALBUMIN IN PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS

Ethan M. Weinberg, Perelman School of Medicine, University of Pennsylvania, Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ, Richard Deng, Tech Data Corporation and K Rajender Rajender Reddy, University of Pennsylvania

Background: Hepatorenal syndrome with acute kidney Injury (HRS-AKI) is a devastating complication of end-stage liver disease (ESLD). Liver transplant (LT) is the best treatment for ESLD for patients who experience HRS-AKI; however, most patients with HRS-AKI are not candidates for LT, including many patients with acute alcohol-associated hepatitis (AH). Unlike decompensated cirrhosis, AH is characterized by an acute inflammatory syndrome, providing a unique reversible component in which LT may be avoided in those who recover. Reversal of HRS-AKI in AH is imperative to allow patients to recover clinically and seek treatments for alcohol use disorder. Terlipressin is the only FDA-approved treatment for HRS. The CONFIRM trial, the largest randomized control trial (RCT) for HRS treatment with terlipressin, suggested that those listed for transplant with Model for ESLD (MELD) scores e 35, acute-on-chronic liver failure-grade 3 (ACLF-3), or serum creatinine (SCr) > 5.0 mg/dL may not benefit from terlipressin treatment. In this study, we sought to evaluate the interplay between renal and hepatic function in HRS reversal and survival among patients with AH who were enrolled in three large RCTs. **Methods:** Patients with a diagnosis of AH and cirrhosis from three Phase III double-blind, placebo-controlled studies of terlipressin plus albumin for the treatment of HRS type 1, were included (RCTs: NCT00089570, NCT01143246, NCT02770716). Patients were divided into two groups based on SCr at baseline: SCr d 3.0 or SCr > 3.0. Each group was then further divided based on baseline MELD (< 35, e 35) and ACLF grade (0–2, 3) and evaluated for HRS reversal and 90-day survival. **Results:** Across three RCTs, 205 patients with AH and cirrhosis were randomized to terlipressin plus albumin (SCr d 3.0, n = 76; SCr > 3.0, n = 129). HRS reversal was most likely to occur among patients with SCr d 3.0 with low MELD, although HRS reversal among those with SCr d 3.0 and high MELD was more likely than in patients with SCr > 3.0 for either MELD group (Table). HRS reversal was more likely among patients with SCr d 3.0; those with SCr d 3.0 and ACLF-3 were more likely to experience HRS reversal than patients with SCr > 3.0, regardless of ACLF grade (Table). In the overall cohort, within subgroups (MELD < 35, MELD e 35, ACLF-0–2, ACLF-3), 90-day survival did not differ between SCr d 3.0 vs SCr > 3.0. However, HRS reversal among transplant-free terlipressin patients with AH, regardless of baseline SCr, did predict 90-day survival (17/39, 43.6% vs 11/62, 17.7%, $P = 0.0047$). **Conclusion:** Terlipressin plus albumin is an effective treatment for HRS-AKI in patients with AH. For such patients, early treatment (SCr d 3.0) with terlipressin may increase the likelihood of HRS reversal, even among patients with MELD e 35 or ACLF-3. HRS reversal with terlipressin plus albumin in patients with AH may increase 90-day survival, likely because of the potential for recovery from AH.

Table. HRS reversal among patients with AH (at baseline) randomized to receive terlipressin

HRS reversal, n/N (%)	SCr ≤3.0 mg/dL (n=66)	SCr >3.0 mg/dL (n=116)	*P* value
MELD <35	14/24 (58.3)	9/33 (27.3)	.0183
MELD ≥35	16/42 (38.1)	12/83 (14.5)	.0028
HRS reversal, n/N (%)	**SCr ≤3.0 mg/dL (n=76)**	**SCr >3.0 mg/dL (n=129)**	***P* value**
ACLF grade 0–2	27/55 (49.1)	17/89 (19.1)	.0001
ACLF grade 3	7/21 (33.3)	6/40 (15.0)	.0967

P values were calculated via a Chi-square test.

ACLF, acute-on-chronic liver failure; AH, alcohol-associated hepatitis; HRS, hepatorenal syndrome; MELD, Model for End-Stage Liver Disease; SCr, serum creatinine.

3047-A | THE INCREASING BURDEN OF AKI AND HRS IN HOSPITALIZED PATIENT WITH CIRRHOSIS DIFFERENTIALLY AFFECTS FEMALE PATIENTS

Ann T. Ma[1], Arshad Imrit[2], Marwa Ismail[2], Surain B Roberts[3], Fahad Razak[2,4], Amol A Verma[2,5] and Gideon Hirschfield[6], (1)Toronto Centre for Liver Disease, University Health Network, (2)St. Michael's Hospital, Unity Health Toronto, (3)Li Ka Shing Knowledge Institute, St Michael's Hospital, Unity Health Toronto, (4)University of Toronto, (5)Dept of Medicine and Ihpme, University of Toronto, (6)Toronto Centre for Liver Disease, University of Toronto, Toronto, Ontario, Canada

Background: Acute kidney injury (AKI) is a frequent complication in hospitalized patients with cirrhosis and results in significant morbidity and mortality. Hepatorenal syndrome (HRS), a specific type of AKI, is particularly associated with poor outcomes in the absence of liver transplant. However, the burden and changing epidemiology of AKI and HRS are not well described in Canada. **Methods:** Data from 04/2015 to 03/2020 were obtained from 29 hospitals in Ontario, the most populated province in Canada, participating in the GEMINI collaborative. Using data from hospital information systems linked to administrative data, we included patients admitted with cirrhosis, as defined by having any discharge diagnosis from a previously validated approach using the international classification of diseases, 10th Revision—enhanced Canadian version (ICD-10-CA), and similarly identified admissions for AKI and HRS. We used logistic regression with cluster robust standard errors to estimate the trends over time. **Results:** A total of 26,221 admissions for 12,288 patients with cirrhosis were included (64% male, mean age 63). AKI was present in 6,997 (26.7%) episodes and HRS in 1,433 (5.4%). Patients who developed AKI were slightly older (mean age 65 vs 62 in those without AKI). AKI was associated with significantly worse outcomes, with higher need for ICU and mechanical ventilation, longer length of hospitalization and higher in-hospital mortality. The latter was 33.6% in those with AKI vs 8.4% in those without. Patients with AKI had 5-fold higher odds of dying in hospital (OR 4.97, 95%CI [4.61-5.35], $p < 0.001$). We found that the odds of having AKI rose over time among hospitalized patients with cirrhosis (OR 1.06, 95%CI [1.04-1.07], $p < 0.001$, Figure panel A), as did the odds of having HRS (OR 1.08, 95%CI [1.04-1.11], $p < 0.001$). Meanwhile, over the 6 years of observation, the mean age of patients admitted with AKI remained stable, as did their risk of in-hospital death. Finally, the odds of female patients being affected by HRS also increased over time (OR 1.07, 95%CI [1.00-1.15], $p = 0.042$, Figure panel B). **Conclusion:** The burden of AKI and HRS in patients admitted with cirrhosis in Ontario is increasing, and the proportion of female patients affected by HRS is as well. The temporal trends in this study may inform future considerations for therapies, such as terlipressin, which is becoming more widely available in North America.

3048-A | THE PREVALENCE AND CLINICAL FEATURES OF ACUTE KIDNEY INJURY ACROSS VARIOUS STAGES OF ASCITES IN PATIENTS WITH CIRRHOSIS FROM A SINGLE QUATERNARY REFERRAL ACADEMIC CENTRE

Neha Tiwari[1], Chinmay Bera[2], Cynthia Tsien[3], Audrey Kapelera[1], Nazia Selzner[3] and Florence Wong[1], (1) Division of Gastroenterology and Hepatology, Toronto General Hospital, Toronto, ON, Canada, (2)University Health Network, (3)Ajmera Transplant Center, University of Toronto, Toronto, ON, Canada

Background: Dynamic change in serum creatinine (sCr) is now used for the definition & severity staging of acute kidney injury (AKI). It is now recognized that many past patients with minor acute sCr changes, especially outpatients, could have been missed as having AKI. This study aims to assess the prevalence, clinical features of all stages of AKI amongst all patients with ascites at a quaternary academic centre. **Methods:** All patients with cirrhosis and ascites from Apr 2020-Mar 2021 were identified through patient records, and charts retrospectively assessed to collect demographics, clinical features, medications, ascites severity, AKI development, AKI and patient outcomes at 6 months. Multivariate analysis for factors predicting AKI development and resolution was done. **Results:** 306 patients were identified, 115 (38%) with refractory ascites (RA) as per International Club of Ascites criteria. 262 (86%) were outpatients. Patients with RA were compared to non-RA group (n-RA). RA patients were older (62yrs vs. 58 yrs, $p = 0.01$) with 70% men (vs. 61% n-RA, $p =$ n.s.). There was no difference in cirrhosis etiology, or complications between the 2 groups. 70% of RA patients had tense ascites, with 98% requiring regular large volume paracenteses (LVP) ($p < 0.001$ vs. n-RA). Similar proportion of n-RA patients were on diuretics (79%) vs. the RA patients (68%), $p = 0.11$, but more RA patients were on meds for encephalopathy, and SBP prophylaxis (both $p < 0.001$), and less RA patients were on beta-blockers ($p = 0.004$). Baseline MELD-Na was higher in the RA group (18.1 ± 4.7 vs. 17.2 ± 6.8, $p = 0.01$), likely related to the presence of CKD in 23% of RA patients ($p = 0.02$). AKI occurred in 39% of RA and 19% of n-RA patients ($p < 0.001$). Most were stage 1 AKI, treated with albumin ± vasoconstrictor with similar response. LVP ($p = 0.002$) and baseline MELD-Na ($p = 0.01$) predicted AKI development, while lower peak sCr predicted AKI resolution ($p = 0008$). 11 (3.6%) n-RA and 22 (19%) RA patients developed ACLF, with 86% RA patients had their renal failure as part of the ACLF syndrome ($p < 0.001$ vs. n-RA patients). 6-month survival was similar between the 2 groups. **Conclusion:** AKI occurs not infrequently in n-RA patients who are mostly treated as outpatients. Although most are stage 1 AKI, 27% were severe and would be classified as type 1 HRS. ACLF in n-RA patients often involves organ failure other than renal failure. Therefore, patients with n-RA need to be monitored closely even when treated as outpatients.

3049-A | TOTAL BILIRUBIN AT TIME OF ADMISSION PREDICTS RESPONSE TO TREATMENT FOR TYPE I HEPATORENAL SYNDROME

Steve Qian[1], Zohaib Ijaz[2], Andreas Zori[1], Giuseppe Joseph Morelli[2], Roberto J. Firpi[1], Roniel Cabrera[1] and Amir Y Kamel[1], (1)University of Florida, (2)University of Florida, Gainesville, FL

Background: Type 1 hepatorenal syndrome (HRS) is a manifestation of decompensated cirrhosis and is characterized by rapid onset of renal failure with doubling of serum creatinine (Cr) to > 2.5 within a two-week period. Prognosis is poor with only 10% of patients surviving longer than 90 days[1]. Treatment of HRS in the United States is primarily with albumin, midodrine, and octreotide[2]. Data on response to therapy has remained mixed, with few studies on predictors of response. The aim of this study to assess the role of total bilirubin, albumin, and international normalized ratio (INR) as predictors for response to treatment in type 1 HRS. **Methods:** We performed a retrospective chart review on 371 adults with ICD-9/10 codes for decompensated cirrhosis and acute kidney injury. Patients were determined to have Type 1 vs 2 HRS as per the International Club of Ascites (ICA) guidelines. Patients had to meet the following criteria: cirrhosis with ascites, an acute increase in Cr to greater than 2.5 within a two-week span, absence of shock defined as systolic blood pressure (SBP) < 90, no recent exposure to nephrotoxic agents, the absence of proteinuria (> 500 g/dl) or pre-existing parenchymal disease, and no improvement in creatinine after discontinuation of diuretics and starting volume expansion. Other exclusion criteria included cardiac/respiratory failure, or prior beta-blocker use for variceal bleeding. All patients with treated with a combination of albumin, midodrine, and octreotide. Response to treatment was defined as the following within 3 days of initiation: Complete response – decrease in Cr to < 1.5, partial response – decrease in Cr by > 50% from baseline but not to < 1.5, incomplete – decrease in serum Cr by < 50% and not less than < 1.5, no response – no decrease in Cr. Total bilirubin, albumin, and INR at admission were compared among the different responder groups. Two-tailed T-testing was used for statistical analysis. **Results:** Out of a total of 61 included patients, 25 (40.98%) achieved no response, 6 (9.84%) had partial response, 9 (14.75%) had incomplete response, and 21 had complete response (34.43%). The mean total bilirubin (mg/dL) in the respective groups were 12.4 ± 4.75, 12.25 ± 6.67, 11.13 ± 8.43, and 6.71 ± 1.97. The mean albumin (g/dL) in each respective group was 2.75 ± 0.24, 2.65 ± 0.60, 2.59 ± 0.34, 3.09 ± 0.12. Mean INRs were 1.94 ± 0.28, 2.32 ± 0.86, 2.47 ± 1.00, and 1.76 ± 0.06. When compared to the no response group, the complete response group had a lower mean total bilirubin ($p = 0.038$), with no significant differences in their albumin ($p = 0.068$) and INR ($p = 0.37$). **Conclusion:** Patients that underwent with albumin, midodrine, and octreotide for type 1 HRS with a complete response had a lower mean total bilirubin at the time of admission when compared to their non-responder counterparts. There were no significant differences in mean albumin and INR between the two groups.

3050-A | TRANSIENT ELASTOGRAPHY PREDICTS THE PRESENCE OF SYSTEMIC VENOUS CONGESTION IN AMBULATORY PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

Paola Guerrero[1], Ignacio García Juárez[2], Hiram Noel Tadeo[3], Eduardo Rios Argaiz[3] and Alfonso Fernandez-Ramirez[1], (1)Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, (2)Instituto Nacional De Ciencias Medicas y Nutricion, (3)Instituto Nacional De Ciencias Medicas y Nutrición Salvador Zubirán

Background: Development of Venous Excess Ultrasound Score (VExUS) as a non-invasive tool for venous congestion has allowed bedside patient assessment by abdominal doppler ultrasound imaging.

However, as venous congestion turns into hepatic congestion, we can try to apply these data to other non-invasive tools.

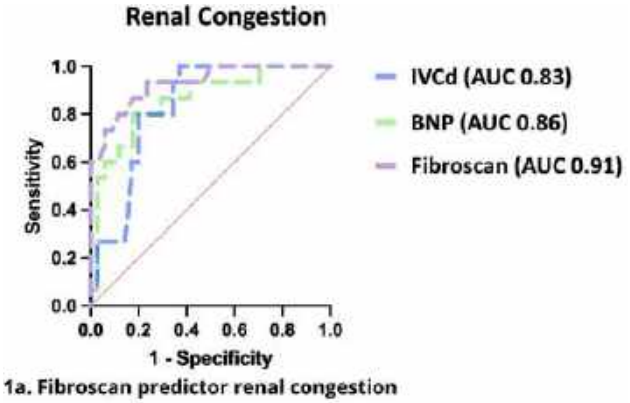
Although an increase in liver stiffness is related to an elevation of liver congestion in patients with heart failure, the relevance of transient elastography (Fibroscan) has not been studied in the context of venous congestion due to right heart failure, which could be a new easy, quickly and reliable non-invasive method to detect these alterations. Aim: To assess the relationship between venous congestion by VExUS and Fibroscan in outpatients with pulmonary hypertension or right heart failure. **Methods:** Patients with diagnosis or high probability of pulmonary arterial hypertension between january 2022 to january 2023 at the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán were eligible. We excluded patients with a low-probability pulmonary arterial hypertension (TRV < 2.8 m/s PASP < 36 mmHg), acute heart failure, cirrhosis (Child Turcott Pugh B or C), chronic kidney disease or renal replacement therapy, solid organ transplantation or portal thrombosis.

Fibroscan examinations with M or XL probe was performed by an echosens-certified gastroenterologist. VExUS was performed by 4 trained physicians (one nephrologist and three internists) with inter-observer Kappa Index 0.90 (0.86-0.97). Sociodemographic and clinical variables were

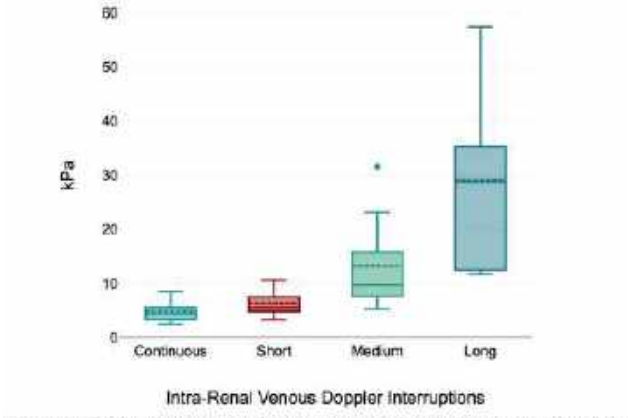
Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

collected and descriptive statistics using frequency and proportions for categorical variables were used. Correlation analysis was carried out using Pearson's coefficient individually between the kPa measurement by Fibroscan and the variables: PASP, IVCd, percentage of IVC collapsibility and portal vein pulsatity. Statistical significance was at p-value of < 0.05. **Results:** 58 patients were included, (82%) were women. The mean age was 57 yo.
A significant correlation was observed between liver stiffness measured in kPa and PASP, IVC diameter, and portal vein pulsatility.
Liver stiffness was higher in patients with VExUS 2 or 3 (mean 14.5, RIC 9.1-30.2) than VExUS 0 or 1 (mean 5.2, RIC 3.9-6.9) and intra-renal venous Doppler interruptions.
When compared with BNP and IVCd; Fibroscan was a better predictor of renal congestion (AUC 0.91). **Conclusion:** Liver stiffness is greater in patients with VEXUS 2-3 vs VExUS 0-1 score, demonstrating that greater congestion means greater liver stiffness. Fibroscan is a better predictor than BNP and IVCd of renal congestion. In addition, transient elastography is a fast, safe and easy to perform non-dependent operator, that determines venous congestion in the same way that invasive tools.
Additional studies are needed to defined the fibroscan role in venous congestion assessment.



1a. Fibroscan predictor renal congestion



1b. correlation intra-Renal venous Doppler interruptions vs kPa

3051-A | TRENDS IN REMOTE PATIENT MONITORING ALERTS PRECEDING HOSPITAL READMISSION IN CIRRHOSIS PATIENTS WITH ASCITES

Kamalpreet S. Hara[1], Daniel Penrice[1], Beatriz Sordi Chara[1], Katherine Williams[1], Sara Kloft-Nelson[1], Vijay Shah[1], Patrick S. Kamath[2] and Douglas A. Simonetto[1], (1)Mayo Clinic Rochester, Rochester, MN, (2)Mayo Clinic, Rochester, MN

Background: Patients with decompensated cirrhosis are at high risk of hospitalizations and emergency department (ED) visits, with complications of volume overload being a common reason for readmission. Remote patient monitoring (RPM) programs may play an essential role in post-hospital care to potentially prevent hospital visits and reduce health care costs. This early analysis of our institutional experience with a cirrhosis-specific RPM program focuses on identifying potential signals preceding hospital visits. **Methods:** Hospitalized patients with decompensated cirrhosis were enrolled in a 90-day RPM program from April 2021 to October 2022. Daily vital signs (blood pressure, heart rate, oxygen saturation, temperature, weight) and symptom-based surveys were collected from home, and alerts were generated based on predefined thresholds. Retrospective analysis of RPM patients with current or diuretic-responsive ascites was performed to identify alert patterns that preceded hospital visits. **Results:** Of the 61 enrolled patients, 55 patients had ascites or a history of diuretic-responsive ascites. During the RPM monitoring period 21 patients were readmitted (38%) and 7 visited the ED (13%). In those who were readmitted, alerts for low systolic blood pressure (SBP < 90 mmHg) were triggered in 62% of patients and was the second-most frequent alert (24%) behind weight alerts. Those with high heart rate alerts (HR > 110 bpm) had increased rates of hospital readmission compared to those with no readmission or only ED visits (52% vs 14% vs 22%). To determine if vital sign monitoring alerts or survey alerts preceded first readmission, we analyzed frequency of alerts triggered in the days leading up to first readmission. Of the 21 patients who were readmitted during the study, median time to first readmission was 37 days (IQR 51). 7 patients had SBP alerts before their first readmission with median time from alert to readmission of 2 days (IQR 8). Similarly, 7 patients had HR alerts prior to readmission, with a median interval of 10 days (IQR 14.5) between alert and date of readmission. In the 2 weeks prior to readmission, 16 of 21 patients reported worsening symptoms on daily questionnaire generating a total of 80 alerts with a median of 4 alerts per patient (IQR 6). Most common symptomatic complaints prior to readmission were abdominal distension (30%), shortness of breath (28%) and ankle swelling (28%). **Conclusion:** These preliminary findings suggest a potential trend in vital signs and symptoms after hospital discharge

that may precede impending hospital readmissions. Larger studies are needed to determine whether these patterns are independent predictors of hospitalizations and whether timely interventions may improve outcome.

f 3052-A | UNDERSTANDING THE RELATIONSHIP BETWEEN MEAN ARTERIAL PRESSURE AND TERLIPRESSIN IN HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY REVERSAL: A POST HOC ANALYSIS OF THE CONFIRM, REVERSE, AND OT-0401 TRIALS

Giuseppe Cullaro, University of California San Francisco Medical Center, Kavish R. Patidar, Section of Gastroenterology, Department of Medicine, Baylor College of Medicine and Michael E. Debakey Veterans Affairs Medical Center, Andrew S Allegretti, Division of Nephrology, Department of Medicine, Massachusetts General Hospital and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Currently, only terlipressin is approved by the FDA for the treatment of hepatorenal syndrome-acute kidney injury (HRS-AKI). It is hypothesized that terlipressin reverses HRS-AKI by increasing mean arterial pressure (MAP). Here, we tested this hypothesis utilizing data from 3 large Phase III trials—CONFIRM, REVERSE, and OT-0401. **Methods:** To determine the impact of terlipressin on MAP: 1) We compared the daily median MAP between treatment and placebo and 2) completed a linear mixed-effects model with fixed effects for treatment and time and a random intercept for each subject. To determine the impact of MAP on HRS-AKI reversal: 1) We completed time-dependent Cox models and 2) determined target MAP cut-offs by comparing log-rank statistics. To determine the impact of the relationship between MAP and terlipressin on HRS-AKI reversal: 1) We tested the interaction between MAP and terlipressin in Cox models for HRS-AKI reversal and 2) completed a mediation analysis between terlipressin and time-weighted MAP on full HRS-AKI reversal. **Results:** A total of 477 patients were included in this analysis (61% received terlipressin). At baseline, MAP was similar in the terlipressin and placebo groups (median: 77 vs 76 mmHg, $P = 0.4$); however, after randomization, MAP was significantly higher in the terlipressin group (medians [mmHg]: Day 1: 85 vs 75; Day 2: 79 vs 75; Day 3: 81 vs 76; $P < 0.001$ each). In the mixed-effects model, terlipressin was associated with a 6.1 mmHg increase in MAP ($P < 0.001$) with no significant interaction between treatment and time ($P > 0.05$). In a time-dependent Cox model, each 5 mmHg increase in MAP was associated with a HR of 0.86 (95% CI 0.8–0.9) for HRS-AKI nonreversal. A MAP cut-off of 84.7 mmHg demonstrated the strongest association with HRS-AKI nonreversal (Figure). There was no significant interaction between MAP and terlipressin (HR 1.01, 95% CI 0.99–1.03). In the mediation analysis, MAP was a significant mediator of the impact of terlipressin on HRS-AKI reversal (average causal mediation effect: 35%, 95% CI 21%–50%). **Conclusion:** In this analysis, terlipressin led to an immediate, sustained increase in MAP, with a cut-off of 84.7 mmHg being a key pharmacodynamic target for HRS-AKI reversal. Our findings support that MAP is a significant mediator in the impact of terlipressin on HRS-AKI reversal.

f 3053-A | URINARY PROTEOMICS DIVULGES PREDICTIVE PROTEINS AND BIOLOGICAL PATHWAYS IN ACUTE KIDNEY INJURY WITH DECOMPENSATED CIRRHOSIS (AKID) STUDY

Inder Bhan Singh II[1], Arka De[1], Vivek Kumar[1], Surender Singh[1], Ashok Kumar Yadav[1] and Virendra Singh[2], (1) Post Graduate Institute of Medical Education and Research, (2)Punjab Institute of Liver and Biliary Sciences, Mohali, India, Chandigarh, CH, India

Background: Pre- and post-transplant outcomes are negatively impacted by the emergence of acute kidney injury (AKI) in decompensated cirrhosis (DC). It is challenging to do non-invasive research on the early development of AKI in DC. We anticipated that urinary proteomics would provide insight on the many processes underlying the development of AKI in DC. **Methods:** Patients with DC are included in our prospective longitudinal study, and we monitor them for the emergence of AKI in an outpatient setting. Out of 82 patients, 21 have so far gone on to develop AKI. These 21 AKI patients' baseline urine proteins were compared to those of 21 propensity-matched patients who did not develop AKI. The criteria of the International Club of Ascites were used to define AKI. Liquid chromatography-mass spectrometry (LC-MS) was used to do urine proteomics, and Proteome Discoverer 3.0 was used to infer the results. Several bioinformatic tools (gprofiler for gene ontology (GO), String and Cytoscape for networking, Reactome for pathway analysis) were used to identify the pathways that contributed to the development of AKI. To ascertain if Reactome pathways are enriched, the hypergeometric distribution test was applied. The Benjamani-Hochberg approach was used to adjust the derived probability score for the false discovery rate (FDR). **Results:** We discovered many pathways that were possibly implicated in the development of AKI and observed distress in AKI group using LC-MS. Reactome, included 66 of the 82 identities from the sample, and at least one of them hit 608 pathways. 75 proteins were significantly elevated in the AKI group and 137 had a log2 difference in comparison to patients without AKI, according to a proteomic study of more than 1700 proteins. Significant pathways identified included neutrophil degranulation, Innate Immune System, platelets degranulation, defects in vitamin and co-factor metabolism, activation of C3 and C5, attenuation phase and cellular response to heat stress (Figure 1). **Conclusion:** The development of AKI in outpatient DC patients could possibly be significantly impacted by immunity and inflammatory responses, according to urinary proteomics.

3054-A | UTILITY OF CONCURRENT ADMINISTRATION OF ALBUMIN WITH TERLIPRESSIN FOR THE TREATMENT OF HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY: A POOLED ANALYSIS OF TWO RANDOMIZED CONTROLLED TRIALS

Manhal Izzy, Vanderbilt University, Florence Wong, University of Toronto, K Rajender Rajender Reddy, Perelman School of Medicine, University of Pennsylvania, Douglas A. Simonetto, Mayo Clinic Rochester, Rochester, MN, Ethan M. Weinberg, University of Pennsylvania, Kevin Moore, University College London, S. Chris Pappas, Orphan Therapeutics and Khurram Jamil, Mallinckrodt Pharmaceuticals, Bridgewater, NJ

Background: Hepatorenal syndrome-acute kidney injury (HRS-AKI) is a serious complication of decompensated cirrhosis. The AASLD guidelines recommend co-administration of albumin with terlipressin for the treatment of HRS-AKI. This study aims to evaluate clinical outcomes in patients who received terlipressin with albumin compared to those receiving terlipressin alone. **Methods:** This is a post hoc analysis of pooled data from 2 randomized controlled trials (RCTs; REVERSE; NCT01143246 and CONFIRM; NCT02770716) studying terlipressin use in patients with HRS-AKI. While albumin was recommended to be co-administered with terlipressin, its use and

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

dosages were at the discretion of the investigators. Patients who received terlipressin with albumin were compared to those who received terlipressin only. All patients received albumin prior to terlipressin treatment. The outcomes were HRS-AKI reversal (primary) and respiratory adverse events (secondary). **Results:** Of the 296 patients in REVERSE and CONFIRM who received terlipressin, 172 were men, median age was 54 years, and mean MELD was 33; 46 patients received terlipressin alone. Potential predictors for HRS-AKI reversal were analyzed (Table); albumin use pre-terlipressin initiation in both groups was comparable and co-administration of albumin with terlipressin was not associated with a greater rate of HRS-AKI reversal compared with terlipressin alone ($P = 0.675$). In the overall cohort, the only factors that predicted reversal in multivariable analysis were duration of terlipressin treatment (OR 1.22, 95% CI 1.13-1.32, $P < 0.001$) and baseline MELD score (OR 0.95, 95% CI 0.91-0.99, $P < 0.001$). Respiratory events were associated, in the univariable analysis, with higher baseline MELD, ACLF grade 3, lower pre-event GFR, higher pre-event or day of event albumin level, lower dose of terlipressin on event date, and lower average daily dose of terlipressin. In the multivariable analysis, only baseline MELD (OR 1.06, 95% CI 1.001-1.11, $P = 0.027$) and terlipressin dose on the event date (OR 0.62, 95% CI 0.51-0.75, $P < 0.001$) were significant predictors. **Conclusion:** These results from 2 RCTs suggest that in select patients (e.g., with signs of fluid overload), using terlipressin without albumin does not compromise efficacy. Larger RCTs are needed to further support these findings. The comparable respiratory event rate, regardless of albumin use, emphasizes the need for careful selection and monitoring of patients even when using terlipressin without albumin.

Table. Demographic and Clinical Characteristics of Patients who Received Terlipressin Only Versus Terlipressin Plus Albumin in CONFIRM and REVERSE

Variable	Terlipressin + albumin (n=250)	Terlipressin only (n=46)	*P* value
Age, years	54.8 (10.55)	53.3 (10.16)	0.454
Sex (male), n (%)	147 (58.8)	25 (54.3)	0.574
Baseline MELD score	32.9 (6.51)	33.2 (6.53)	0.744
Child Pugh score	10.1 (1.83)	10.2 (1.89)	0.521
Pre-terlipressin albumin cumulative dose, g	327.9 (180.37)	334.1 (179.54)	0.798
Serum albumin level pre- terlipressin initiation, g/dL	4.1 (0.80)	3.6 (0.49)	0.329
Serum albumin difference between EOT and Day 1, g/dL	0.3 (0.63)	−0.2 (0.49)	<0.001
Duration of terlipressin from Day 1 to EOT (SD)	6.6 (4.44)	4.5 (3.05)	0.004
Daily dose of terlipressin from Day 1 to EOT, mg	3.6 (1.43)	2.9 (1.18)	0.008
Terlipressin dose at EOT, mg	2.7 (1.69)	2.4 (1.47)	0.325
HRS reversal, n (%)	84 (33.6)	14 (30.4)	0.675
Respiratory events (Respiratory failure, pleural effusion, pulmonary edema, hypoxia, dyspnea) as adjudicated by investigators, n (%)	84 (33.6)	15 (32.6)	0.896
Respiratory failure/ acute respiratory failure, n (%)	31 (12.4)	11 (23.9)	0.040

Unless indicated, the data are presented as mean (standard deviation).
EOT, end of treatment; HRS, hepatorenal syndrome; MELD, Model for End-Stage Liver Disease.

3055-A | L-ORNITHINE L-ASPARTATE(LOLA) VERSUS STANDARD MEDICAL THERAPY (SMT) FOR IMPROVEMENT OF SARCOPENIA IN PATIENTS WITH CIRRHOSIS -A RANDOMIZED OPEN LABEL TRIAL

Rameez Raja Najar, Amrish Sahney, Manav Wadhavan, Prem Kumar Ganesan, Ajay Kumar, Jc Vij, Neha Berry, Reethesh S R, Pulkit Sondhi and Md Nuruddin Ansari, BLK MAX SS Hospital New Delhi

Background: Sarcopenia predisposes to hepatic encephalopathy due to reduced muscle capacity to scavenge ammonia. LOLA by reducing ammonia levels have a role in improving hepatic encephalopathy. Hyperammonaemia is one of the important mechanism for sarcopenia in cirrhosis. We thus aimed to assess the efficacy of LOLA in improving sarcopenia in liver cirrhosis. **Methods:** This study was conducted in a tertiary care hospital in India over a period of 2 years and all cirrhotic patients seen as outpatient were screened for sarcopenia(Anthropometry, CT L3 muscle area and index (Skeletal muscle index, SMI) by sliceOmatic application and Frailty by Liver frailty index(LFI)) at baseline and at follow up at 6 months. We excluded patients of child class C in our study. After exclusion, 48 patients had sarcopenia and were randomised through block randomization to receive either LOLA (5gm orally thrice daily) plus SMT((Protein 1.5 g/kg/day, Cal 35kcal/kg/day)-(LOLA Group, n = 20) or SMT alone (control group, n = 17). Patients were followed for 6 months. Patients were called fortnightly for adverse events related to treatment or any decompensation due to disease per se during 6 months follow up period. Standard statistical analysis was done. **Results:** In this open-label randomised trial, 37 cirrhotic patients with sarcopenia completed the study. All baseline characteristics were comparable between the two groups. The prevalence of sarcopenia was predominantly seen in age group > 50 years, Child Pugh class B and in MELD score in the range of 15-29. At 6months follow up, there was trend towards improvement in sarcopenia (SMI) in LOLA group compared to control group with delta SMI(SMI Δ0-6) of 0.155 vs 0.015 respectively(p value = 0.09). There was improvement in Liver frailty index (LFI Δ0-6) by 0.19 (15%) which was statistically significant (3.64 ± 0.28 in LOLA group vs. 3.98 ± 0.26 in control group, 95% confidence interval -0.06 to -0.318, p valve = 0.005). Also at follow up, patients in LOLA group showed significant improvement in PHES score (17% vs 5.9%, $p < 0.05$) compared to SMT group. **Conclusion:** Ours is the first study to compare the efficacy and safety of LOLA in improving sarcopenia in liver cirrhosis. Though there was statistically non-significant trend towards improvement in SMI in LOLA group compared to control group but there was statistically significant improvement in LFI and MHE in LOLA group compared to control group. Larger sample size is required to assess the significant improvement in muscle mass by adding ammonia lowering agent (LOLA) to standard medical therapy.

University, Beijing, China, (11)Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: Recombinant human albumin (rHA) is an alternative to human serum albumin (HSA) for the management of ascites in cirrhotic patients. This phase a study was designed to evaluate dose effect, safety and immunogenicity of rHA injection in treatment of hypoalbuminemia in cirrhotic patients with ascites. It is to provide the basis for the design of Phase III clinical trial. **Methods:** This multicenter, blinded, positive controlled, phase a/III, adaptive design and seamless connection study enrolled 90 Chinese subjects divided into two dose cohorts(Figure 1). Each cohort included 45 subjects who were randomized 2:1 to receive rHA or HSA, respectively, at a dose of 10 g/day (14 d of administration) or 20 g/day (7 d of administration). All subjects were followed-up for 56 days after the treatment was concluded. The primary objective was to assess the initial efficacy, dose effect, safety and immunogenicity of rHA. Efficacy was assessed by monitoring serum albumin concentration and plasma colloid osmotic pressure (PCOP) before and after each dose of rHA or HSA. The time required for the serum albumin concentration to reach 35 g/L was also monitored. Safety was determined by the incidence, intensity, and seriousness of adverse events. **Results:** Improvement of serum albumin concentration in the rHA cohorts was similar to that in the HSA cohorts during both treatment and follow-up. In two dose groups, the increase of the serum albumin level and PCOP in 20 g/d group were faster than those in 10 g/d group. The incidence of adverse events was similar between the rHA and has cohorts, and no dose-response relationships were observed for adverse events. No anti-drug antibodies were found in an immunogenicity study. **Conclusion:** The efficacy and safety of rHA injection (the investigational drug) was basically the same with HSA (the control drug) in two dose groups (CTR20212001). The results of this clinical trial support the investigational drug to enter Phase III study. Since 20 g/d group has the same safety risk as 10 g/d group, and 20 g/d could increase the level of albumin and PCOP more quickly than 10 g/d, the dose of 20 g/d was recommended for Phase III study.

3057-A | A NOVEL SWEAT SENSOR DETECTS INFLAMMATORY BIOMARKERS IN INPATIENTS AND OUTPATIENTS WITH CIRRHOSIS

Brian C. Davis[1], Kevin Lin[2], Andrew Fagan[3], Michael Fuchs[4], Puneet Puri[5], Mary Leslie Gallagher[6], Travis Mousel[3], Shalini Prasad[7], Sriram Muthukumar[2] and Jasmohan S. Bajaj[8], (1)Hunter Holmes McGuire VA Medical Center, (2)Enlisense Inc, (3)Virginia Commonwealth University and Richmond VA Medical Center, (4)Mcguire Veterans Affairs Medical Center, Moseley, VA, (5)Virginia Commonwealth University, (6) McGuire Veterans Affairs Medical Center, (7)University of Dallas, (8)Virginia Commonwealth University and Central Virginia Veterans Healthcare System

Background: Biomedical sensing, especially related to inflammatory markers, could increase insight into cirrhosis-related complications. Sweat sensing using the AWARE sensor could be used to monitor minute-by-minute changes in inpts/outpts with cirrhosis, which is a non-invasive monitoring modality. Aim: Define relationship of serum and sweat inflammatory markers in cirrhosis. **Methods**: Inpatients or outpatients with cirrhosis underwent AWARE sensor application daily for up to 3 days (Fig A). Daily blood CRP, IL-6 &TNF measurements were performed and compared with sweat values of these analytes. Serum value at each blood draw & sweat time-weighted average values of analytes were compared between inpts & outpts and correlated with each other. Blood IL-6/TNF were analyzed using ELISA while blood CRP was sent to our clinical lab. Quality of life using Sickness Impact Profile (SIP: high = worse with physical and psychological domains) was studied. Correlations between sweat & serum analytes with MELD-Na and SIP scores were performed. **Results**: 32 pts (10 outpt/22 inpts) were included. All outpts were seen for 3 days, while 13 inpts were seen for 2 days and 7 for 3 days with daily blood draws. Day 1 data, which was available on everyone, was analyzed and is presented. All inpts were admitted

for cirrhosis-related complications (14 with infections, 8 with AKI/electrolyte issues, 8 with hepatic encephalopathy, 5 with ascites) and had mean Length of stay of 5.5 ± 0.81 days. 12 were on antibiotics. MELD score and all inflammatory markers were higher in inpts over several days (Fig B). SIP total/physical were higher in inpts. Correlation of sweat and serum IL-6, TNF & CRP were highly significant across groups, even though the values were higher in inpts (Fig C-E). This pattern was also seen in sweat and serum comparisons, which showed that regardless of the fluid tested, inpts had higher concentrations (Fig F-H). Correlations between MELD-Na, Total SIP, Physical SIP & the analytes showed that SIP & Physical SIP were only correlated with sweat CRP but not blood CRP, while the opposite pattern was seen with IL-6 and TNF, where blood values were more correlated. Both CRP in blood and serum were linked with MELD-Na but only blood TNF and IL-6 and not sweat levels were linked with MELD-Na (Fig I) **Conclusion**: We showed good correlation between sweat and serum values of CRP, IL-6 and TNF in outpatients and inpatients with cirrhosis. Values of both sweat and serum analytes were higher in inpatients compared to outpatients. Quality of life was significantly linked with sweat CRP but not serum CRP but the opposite pattern was seen with IL-6 and TNF. CRP values, regardless of serum or sweat, were linked with the MELD-Na. The differential linkage of sweat CRP to quality of life may be a novel pattern to evaluate for long-term management of these patients. The AWARE sensor is feasible in inpatients and outpatients with cirrhosis and show similar patterns to blood levels of CRP, IL-6 and TNF.

3058-A | A PROSPECTIVE STUDY EVALUATING THE PREVALENCE AND SEVERITY OF PSYCHIATRIC DISORDERS IN PATIENTS WITH CIRRHOSIS OF LIVER AND AT 3months FOLLOW UP DURING THE EARLY POST COVID ERA

Ameet Mandot, Global Hospitals, Mumbai and Vishal Ramchandra Shriwastav, Bombay Hospital and MRC

Background: Psychiatric disorders (depression, anxiety, stress) are frequently observed in patients with cirrhosis of liver and significantly impact their overall health outcomes. Mental health evaluation in chronic diseases is not given enough importance in a developing country like India with burdened healthcare system. There have been few studies of their prevalence among patients with cirrhosis of liver in pre COVID and COVID era. However the data on prevalence of psychiatric disorders in cirrhotics in early post COVID era is limited and also the progression of pyschiatric diseases with progression of cirrhosis is not well studied. We aimed to characterize the prevalence of psychiatric disorders: depression, anxiety and stress in cirrhosis of liver at presentation and their association with MELD-NA score at 3 months during the early post COVID era. **Methods:** We performed a prospective study with sample size of 135 indoor and OPD patients with newly diagnosed cirrhosis from March 2022 to March 2023 at a single tertiary care private hospital in

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

Mumbai. Depression, anxiety and stress were assessed using DASS-21 questionnaire at the time of diagnosis. Patients were followed up after 3 months and severity of psychiatric disorders were again measured and correlated with MELD-NA score using Chi square and t tests. **Results:** Most common psychiatric disorder was depression followed by anxiety and stress. The prevalence of mild, moderate and severe depression at enrolment was 45.2%, 28.1% ,15.6% respectively and on 3 months follow up was 39.3%, 31.1% and 21.5% respectively. The prevalence of mild, moderate and severe anxiety at enrolment was 30.4%, 25.2%, 17.2 % respectively and on 3 months follow up was 26.7%, 28.9% and 18.8% respectively. The prevalence of mild, moderate and severe stress at enrolment was 3.7%, 26.7%, 15.6% respectively and on 3 months follow up was 6.7%, 31.9% and18.5% respectively. There was a positive association between severity of depression and MELD-NA score (P = 0.022, C.I. = 95%), a positive association between severity of anxiety and MELD-NA score (P = 0.038, C.I. = 95%) and a positive association between severity of stress and MELD-NA score (P = 0.010, C.I. = 95%) at . These associations were found to be statistically significant. At 3 months also the severity of all 3 psychiatric disorders corelated positively with MELD Na scores. **Conclusion:** Liver cirrhosis is associated with increased prevalence of psychiatric disorders with more than 70 % percent patients having varying degrees of psychiatric diseases. Their severity increases with increase in MELD-NA score at presentation and at 3 months.

Table 10. Association between DASS 21 Scores and MELD NA Score of the patients on ADMISSION:

DASS 21 Scores		MELD NA Score				Total		p value
		< 15		≥ 15				
Depression	Normal	13	14.6%	2	4.4	15	11.1%	0.022
	Mild	45	50.6%	16	34.8	61	145.2%	
	Moderate	21	23.6%	17	36.9	38	28.1%	
	Severe	10	11.2%	11	23.9	21	15.6%	
Anxiety	Normal	29	32.6%	8	17.4%	37	27.4%	0.038
	Mild	29	32.6%	12	26.1%	41	30.4%	
	Moderate	21	23.6%	13	28.3%	34	25.2%	
	Severe	10	11.2%	13	28.3%	23	17.0%	
Stress	Stress	57	64.0%	16	34.8%	73	54.1%	0.010
	Mild	3	3.4%	2	4.3%	5	3.7%	
	Moderate	17	19.1%	19	41.3%	36	26.7%	
	Severe	12	13.5%	9	19.6%	21	15.6%

3059-A | A QUICK AND ACCURATE TOOL COMBINED NUMBER CONNECTION TEST A WITH ANIMAL AND VEGETABLE NAMING TEST TO IDENTIFY MINIMAL HEPATIC ENCEPHALOPATHY IN HOSPITALIZED PATIENTS

Qiuyu Cheng[1], Yunhui Liu[2], Gege Wu[3], Hao Ye[4], Zhongyuan Yang[2], Zhongwei Zhang[2], Meng Zhang[2], Tingting Liu[2], Yuxin Niu[1], Deyan Tian[2], Xiaoyun Zhang[2], Xiaoping Luo[3], Xiaojing Wang[1], Tao Chen[1] and Qin Ning[1], (1)Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology, (2)Department of Infectious Diseases, Tongji Hospital, Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology, Wuhan, 430030, Hubei, China, (3)Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, (4)People's Hospital of Jingshan City

Background: Minimal hepatic encephalopathy (MHE) is easy to be ignored in hospitalized patients due to its inconspicuous symptoms and time-consuming diagnosis. We aimed to establish a quick and accurate diagnostic tool of MHE for inpatients. **Methods:** A total of 123 healthy volunteers and 252 inpatients with cirrhosis or acute-on-chronic liver failure (ACLF) without overt hepatic encephalopathy (OHE) were prospectively included and underwent the psychometric hepatic encephalopathy score (PHES), animal naming test (ANT), vegetable naming test (VNT), and animal and vegetable naming test (AVNT). Serum ammonia was measured among patients. Meanwhile, the newly occurred OHE during hospitalization was observed. **Results:** A diagnostic nomogram named AVNA via a combination of AVNT with number connection test A (NCT-A) was established, with an AUC of 0.98 (97.1% sensitivity, 93.2% specificity and 94.1% accuracy) for development cohort (n = 152) and 0.91 (87.9% sensitivity, 79.1% specificity and 82.0% accuracy) for validation cohort (n = 100), respectively. Patients with AVNA diagnosed MHE exhibited higher risk of 30-day OHE development in comparison with AVNA diagnosed none-MHE (P < 0.001). Moreover, the average time of AVNA test was significantly shorter than the PHES test (151 ± 77 sec to 398 ± 192 sec, P < 0.001). Decision curve analysis (DCA) demonstrated that serum ammonia did not have additional positive net benefits to AVNA for almost all of the threshold probabilities. **Conclusion:** A fast and accurate test AVNA with AVNT and NCT-A was established for inpatients with cirrhosis or ACLF, which enables appropriate diagnosis of MHE in daily clinical practice.

3060-A | A SPECIALIZED HEPATIC ENCEPHALOPATHY TESTING CLINIC IMPROVES RATIONAL DECISION MAKING FOR HE THERAPY AND CAN DETECT ALTERNATIVE CAUSES FOR COGNITIVE IMPAIRMENT IN CIRRHOSIS

Asiya Tafader[1], Mahum Nadeem[1], Dan Park[1], Andrew Fagan[1], Brian C. Davis[1], Michael Fuchs[2], Puneet Puri[3], HoChong Gilles[4], Jennifer Miller[4], Felicia Tinsley[1] and Jasmohan S. Bajaj[5], (1)Virginia Commonwealth University and Richmond VA Medical Center, (2) Mcguire Veterans Affairs Medical Center, Moseley, VA, (3)Division of Gastroenterology, Hepatology, and Nutrition, Richmond VA Medical Center, Richmond, VA, (4)Mcguire Richmond VA Medical Center, (5)Virginia Commonwealth University and Central Virginia Veterans Healthcare System

Background: Cognitive impairment in cirrhosis could have many underlying causes but most are presumed to be hepatic encephalopathy (HE) & are reflexively treated (Fig A) with either lactulose (difficult to tolerate) or rifaximin (expensive). Moreover, many pts may not have HE as the cause for these symptoms. Most pts are not routinely tested for minimal HE(MHE) and the utility of on-demand MHE testing/interpretation in clinical settings needs to be studied. **Methods**: We set up an on-demand standard of care HE testing clinic (Fig A). Pts were tested separately from their original clinic visit for cognitive issues elicited by clinicians, pts or caregivers. The clinic involves specialized testing (Mini-mental status exam [MMSE out of 30, >25 = no dementia, psychometric hepatic encephalopathy score (PHES) & EncephalApp Stroop] by a trained medical assistant, Results were interpreted by a hepatologist after chart/medication review and recommendations were noted in the record and sent to referring clinicians. Time spent on testing/interpretation and for the medical decisions made were recorded. **Results**: From 2012-2022, 282 mostly male pts were evaluated, majority (84%) were due to cognitive complaints by pts/families. Of the patients referred, four had MMSE <25, which were then referred for dementia evaluation without further tests.

No-MHE patients: 111 (39%) had normal cognitive performance (Fig C). These pts (Fig B) were younger, less likely to have prior HE, depression, lower MELD-Na, and ascites vs who tested impaired. Anxiety, chronic pain, gender, etiology, & race were similar. *Action for no-MHE pts*: Most (N = 84) were reassured of their normal results & did not need lactulose. The rest, were referred to other specialties if requested.

Cognitively-impaired: We continued current Rx, i.e. no therapy because the pt refused or continued same HE regimen in 47(17%). Of the rest, 56 (20%) were initiated on lactulose, & 27 (10%) were started on rifaximin. The remaining 37 pts were judged to have issues unrelated to cirrhosis as the major contributor(s) to their cognitive impairment. These were related to pain medications, obstructive sleep apnea, dementia, and neuro-modulator therapy, for which they were either referred to their primary care doctors, neurologists, or pain management.

Time needed: Medical assistant took 34 ± 12 min/pt. The hepatologist took 12 ± 5 min to interpret & complete the recommendations, which were billed for. **Conclusion**: A dedicated US-based HE testing clinic run by a trained medical assistant and supervised by an attending reduced reflexive HE therapy initiation in the majority of patients. On specialized testing that <40 minutes to perform & interpret, and which was billable, 39% pts showed normal cognition & were spared reflexive lactulose. 14% pts needed referral for other neurocognitive issues & only 30% needed HE therapy change, or initiation. Dedicated HE testing clinics may be effective in streamlining HE management.

3061-A | ALCOHOL AGGRAVATES NEUROLOGICAL DYSFUNCTION AND LEADS TO PERMANENT CELL INJURY IN RATS WITH CHRONIC LIVER DISEASE

Farzaneh Tamnanloo[1,2], Xiaoru Chen[1], Mariana M. Oliveira[1], Mélanie Tremblay[1] and Christopher F. Rose[1,2], (1)Hepato-Neuro Laboratory, Centre De Recherche Du Centre Hospitalier De l'Université De Montréal, (2)Université De Montréal

Background: Hepatic encephalopathy (HE) is a debilitating neurological complication of chronic liver disease with alcohol being a common etiological factor. However, excessive alcohol consumption has been shown to impact neurological integrity. To date, the influence of alcohol in the development of HE remains unclear. Therefore, we examined the effect of constant alcohol consumption on neurological decline in rats with chronic liver disease induced via bile-duct ligation (BDL). **Methods:** 6-week BDL rats and Sham-operated controls were used. Day 7 after surgery, rats were administered Alcohol (51% v/v Ethanol) twice a day (dose of 3g/kg, via gavage) for 4 weeks. Motor coordination (rotarod) and anxiety-like behavior (open field (OF) and elevated plus maze (EPM)) were assessed at day 40. Upon sacrifice, brains were collected, and western blot and immunohistochemical (IHC) analyses were used to investigate neuronal integrity in frontal cortex and cerebellum. **Results:** Alcohol further impaired motor coordination in BDL rats when compared to SHAM-Alcohol ($p < 0.01$). Furthermore, BDL-Alcohol rats demonstrated an increase in anxiety-like behavior; increase in time spent in the closed arms of EPM and decrease in time spent in the center of the OF ($p < 0.05$ vs SHAM-Alcohol). BDL-Alcohol rats demonstrated a decrease in neuronal markers of NeuN and SMI311 ($p < 0.01$ and $p < 0.05$, respectively), an increase in apoptotic markers of cleaved/pro-caspase3 ($p < 0.001$), an increase in necroptosis markers of pRIP3 and pMLKL ($p < 0.01$ and $p < 0.001$, respectively), a decrease in total antioxidant capacity ($p < 0.001$) and an increase in oxidative stress marker of 4-HNE ($p < 0.05$) in the cerebellum (not found in frontal cortex) compared to all groups. IHC results confirmed the colocalization of apoptotic marker (cleaved Caspase3) and necroptosis marker (pMLKL) in the granular and Purkinje layer neurons of the cerebellum of BDL-Alcohol rats. **Conclusion:** Constant alcohol consumption exacerbates HE and leads to neuronal loss via apoptosis and necroptosis in the cerebellum. Additionally, higher levels of oxidative stress marker of 4-HNE and decreased total antioxidant capacity in the cerebellum of BDL-Alcohol rats suggest that oxidative stress is a triggering factor leading to neuronal loss/injury. These results demonstrate an adverse effect of constant alcohol consumption on the development of HE and neuronal integrity in chronic liver disease.

3062-A | ANALYSIS OF RELEVANT FACTORS OF PORTAL VEIN THROMBOSIS IN LIVER CIRRHOSIS

Jinglan Jin[1], Xiaotong Xu[1], Yuwei Liu[1], Hang Li[1] and Yaya Li[2], (1)First Hospital of Jilin University, (2)First Hospital of Jilin Hospital

Background: To investigate the usefulness of interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), protein C (PC), and thromboelastography (TEG) to serve as a predictor of portal vein thrombosis (PVT) in patients with liver cirrhosis. Additionally, we examined the clinical signifcance of the above indicators in terms of disease progression. **Methods:** A total of 123 patients with liver cirrhosis were recruited from May 2021 to December 2021, according to the imaging fndings. They were divided into the PVT group ($n = 52$) and the non-PVT group ($n = 71$). Furthermore, patients with PVT were divided into plasma transfusion groups ($n = 13$) and non-plasma transfusion groups ($n = 39$).

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The basic general information, past medical history, laboratory, and imaging examination data were collected and analyzed. **Results:** In univariate analysis, there was no signifcant diference between the two groups in IL-6, PC, reaction time(R), alpha angle (Angle), maximum amplitude, or coagulation index (CI) ($P > 0.05$). TNF-α in the PVT group was signifcantly lower than that in the non-PVT group ($P = 0.001$). K-time (K) in the PVT group was signifcantly higher than that in the non-PVT group($P = 0.031$). There was no signifcant diference in IL-6, TNF-α, PC, or TEG between diferent Child–Pugh classifcation groups ($P > 0.05$). There were no signifcant diferences in TEG between the plasma transfusion group and the non-plasma transfusion group. In Binary logistic regression analysis, TNF-α (OR = 0.9881, 95%CI = 0.971, 0.990, $P < 0.001$), K (OR = 1.28, 95% = 1.053, 1.569, $P = 0.014$), activate partial thromboplastin time(APTT) (OR = 0.753, 95% CI = 0.656, 0.865, $P < 0.001$), portal vein diameter(OR = 1.310, 95%CI = 1.108, 1.549, $P = 0.002$) and the history of splenectomy or embolism (OR = 7.565,95%CI = 1.514, 37.799, $P = 0.014$)were related to the formation of PVT. **Conclusion:** TNF-α, K, APTT, portal vein diameter, and splenectomy or embolism history were associated with PVT formation, but IL-6 was not.

3064-A | BRANCHED CHAIN AMINO ACIDS SUPPLEMENTATION IMPROVES MUSCLE MASS, MUSCLE FUNCTION, AND FRAILTY IN PATIENTS WITH LIVER CIRRHOSIS: A RANDOMIZED CONTROLLED TRIAL

Puja Bhatia Kapoor[1], Jaya Benjamin[1], Rakhi Maiwall[1], Harsh Vardhan Tevethia[1], Rajan Vijayaraghavan[1], Guresh Kumar[1], Yogendra Kumar Joshi[1] and Shiv Kumar Sarin[2], (1)Institute of Liver and Biliary Sciences, New Delhi, (2)Institute of Liver and Biliary Sciences

Background: Progressive loss in muscle mass, strength and performance along with frailty are common complications in liver cirrhosis (LC). Within the realm of nutritional management, apart from a high calorie and high protein diet along with organized exercise, the role of myotropic nutrients like branched chain amino acids (BCAA) is promising, yet lacks corroboration from randomized controlled trials. Aim: Primary aim was to assess the effect of BCAA on muscle mass; secondary aims included effect on muscle strength and performance, frailty, health related quality of life (HRQoL), insulin like growth factor 1(IGF1) and myostatin. **Methods:** In this open label, randomized controlled trial, after screening 302 patients, 62 meeting the inclusion criteria (Fig 1A) were randomized to either intervention or control group, receiving 16gm/day of BCAA or whey protein (WP) respectively in addition to a diet providing 35 Kcal and 1.35 gm protein/kg wt and standard medical therapy, along with 30 minutes exercise for 12 weeks. Patients were followed-up to collect clinical, nutritional and biochemical details. Appendicular skeletal muscle mass (ASMM) was assessed by DEXA. Muscle strength by Hand Grip Dynamometer, muscle performance by 6 minute walk distance (6MWD), frailty by liver frailty index, and HRQoL by Chronic Liver Disease Questionnaire. IGF1 and myostatin levels were assessed by ELISA. **Results:** In all 62 patients [age: 47.3 ± 10.2 years, male (100%), etiology: (Alcohol: Cryptogenic: NASH: Others = 60%:22%:8%:10%), BMI: 20.8 ± 2.1 (kg/m2), CTP 7.9 ± 0.8] were randomized to BCAA (n = 31) and WP (n = 31) group. As per ITT analysis both the groups were comparable at baseline. 90 day mortality was comparable between the two groups [1(3.2) vs 2(6.5); $p = 0.822$).17 patients were lost to follow-up; 42 (Fig 1A) were analyzed as per-protocol. By the end of 12 weeks ASMM and 6MWD improved significantly in the BCAA group. Overall 26 patients (62%) had improved ASMM which was more frequent in the BCAA group (76 vs. 47.6%; 0.045) (Fig 1C). Anabolic marker-IGF1 improved significantly in the BCAA group only, whereas myostatin, the catabolic marker increased in the WP group, while remaining unchanged in the BCAA group (Table 1). CTP score, frailty and HRQoL improved significantly in both groups (Fig 1B); however, muscle strength remained unchanged. **Conclusion:** High calorie high protein diet along with exercise are imperative for improving frailty and HRQoL in cirrhosis, but only BCAA really spurs muscle mass, muscle performance and IGF1.

3065-A | CHANGE IN FRAILTY STATUS WITH NUTRITIONAL THERAPY IN CIRRHOTIC PATIENT – A RANDOMIZED CONTROLLED TRIAL

Sudhir Maharshi, Shyam Sunder Sharma and Saksham Seth, SMS Medical College & Hospitals, Jaipur, India

Background: Frailty is characterised by low physiologic reserve and decreased functional status and is associated with poor prognosis in patients with cirrhosis. There is limited data on nutritional intervention on frailty status in cirrhosis. Aim was to assess the effects of nutritional therapy on changes in frailty status in cirrhotic patients. **Methods:** A randomised controlled trial conducted in a tertiary care centre on patients with cirrhosis, who were randomised to assigned to nutritional therapy (group A: 30–35 kcal/kg/day, 1.0–1.5 g protein/kg/day;) and no nutritional therapy (group B: patients continued on their same diet) for 6 months. Frailty status was assessed by liver frailty index (LFI) and gait velocity(GV). Primary endpoints were improvement or worsening in frailty status. Secondary endpoints were improvement of other nutritional parameters and liver functions. **Results:** Till date 34 patients were randomised to group -A ($n = 18$, age 43.4 ± 9.8 yr, 14 men) and group-B ($n = 16$, age 42.7 ± 10.1 yr, 12 men). Alcohol was most common (64%) aetiology. Baseline characteristics including age, body mass index (BMI), haemoglobin, MELD score, mid arm circumference (MAC), hand grip (HG), GV and LFI were comparable in both the groups. Improvement in GV (ΔGV 0.99 ± 0.32 vs -0.82 ± 0.28, $p = 0.001$), LFI (ΔLFI -0.62 ± 0.24 vs 0.3 ± 0.32, $P = 0.001$) HG strength (ΔHG 4.2 ± 1.3 vs -2.9 ± 1.2, $p = 0.001$), MAC (ΔMAC 2.69 ± 0.28 vs -2.15 ± 0.26, $p = 0.01$) was observed in group A compared to group B at the end of study. Liver functions assessed by Child Turcotte Pugh and Model for end stage liver disease also significantly improved in group A compared to group B, $p < 0.001$. **Conclusion:** Nutritional therapy is effective in the improving the frailty status, nutritional parameters and liver functions in cirrhotic patients.

3066-A | CLINICAL PREDICTORS AND OUTCOMES OF RAPID SKELETAL MUSCLE LOSS IN PATIENTS WITH CIRRHOSIS

Nghiem B. Ha[1], Bo Fan[1], Amy M. Shui[1], Chiung-Yu Huang[1] and Jennifer C. Lai[1,2], (1)University of California, San Francisco, (2)University of California-San Francisco, San Francisco, CA

Background: Skeletal muscle mass is a strong predictor of morbidity and mortality in cirrhosis patients and therefore, represents a key potential interventional endpoint to improve outcomes. However, the average expected *rate of change* of skeletal muscle in this population has not been well characterized, hampering efforts to design adequately powered trials. In this study, we aimed to characterize the rate of change in skeletal muscle mass and evaluate its associations with clinical outcomes in cirrhosis patients. **Methods**: Included were prospectively enrolled ambulatory adults with cirrhosis awaiting liver transplant with at least 2 available abdominal CT scans within 6 months at enrollment and within 6 months of study endpoint from 2/2015-1/2018. Skeletal muscle index (SMI) was quantified by CT at the L3 vertebrae, normalized for height (cm^2/m^2). Percent change in SMI (ΔSMI/year) was calculated as (follow-up SMI - baseline SMI) / (baseline SMI) x 100 / interval between CT in years. The primary outcome was waitlist mortality, defined as death or delisting for being too sick for transplant. **Results**: Among 171 patients included: 32% were women, 56% were white with a median age 62 year. Median follow-up was 12 months (IQR 9-18). Median (IQR) ΔSMI/year was -1.1% (-8.4, 5.0) for the entire cohort, and similar for men with -1.1% (-7.3, 4.5) and women with -2.4% (-9.2, 8.2). "Rapid muscle loss" was defined by the worst 25^{th} percentile value for ΔSMI/year at less than -8.4% ($n = 43$). Patients with rapid muscle loss had more ascites (63% vs. 44%), higher median MELD (14 vs 12), frailty (19% vs 13%), and higher baseline SMI (55 vs 51 cm^2/m^2 in men and 45 vs 39 cm^2/m^2 in women). Presence of ascites was a significant predictor of rapid muscle loss (OR 2.17, 95% CI 0.07-4.41), remaining significant after adjusting for age, sex, MELDNa, frailty, and baseline sarcopenia (OR 2.10, 95%CI 1.01-4.92). Cumulative incidence of waitlist mortality was significantly higher in patients with rapid muscle loss compared to all others at 12-month (27% vs 9%) and 36-month (77% vs 43%) (Figure). In univariable Cox regression, rapid muscle loss was associated with waitlist mortality (HR 2.62, 95%CI 1.33-5.15), which remained significant after adjusting for age, sex, ascites, encephalopathy, MELDNa, and baseline SMI (HR 2.71, 95%CI 1.30-5.66). **Conclusion**: Patients with cirrhosis experience ~1% muscle loss *per year*. For reference, natural age-related decline in muscle mass is ~2% *every 10 years* in the general population. In cirrhosis patients,

rapid muscle loss was independently associated with higher waitlist mortality. Our data are essential for determining the effect size necessary to adequately power clinical trials targeting therapeutic interventions aimed at improving muscle mass in this population.

Figure. Cumulative incidence of waitlist mortality through 36 months according to change in skeletal muscle index by ΔSMI/year (%) loss

3067-A | DETERMINING CLINICALLY MEANINGFUL DIFFERENCE IN BASELINE ENCEPHALAPP STROOP VALUES TO PREDICT HE-RELATED OUTCOMES WITH MULTI-CENTER VALIDATION

Gowthami Kanagalingam[1], Dan Park[2], Bryan Badal[3], Andrew Fagan[2], K Rajender Rajender Reddy[4], Jacqueline G. O'Leary[5], Jennifer C. Lai[6], Puneeta Tandon[7], Florence Wong[8], Patrick S. Kamath[9], Guadalupe Garcia-Tsao[10], Scott W. Biggins[11], Hugo E. Vargas[12], Chathur Acharya[13] and Jasmohan S. Bajaj[2], (1)Virginia Commonwealth University, (2)Virginia Commonwealth University and Richmond VA Medical Center, (3)Virginia Commonwealth University and Richmond VA Medical Center, Richmond, VA, (4) University of Pennsylvania, (5)Utsw, Dallas, TX, (6) University of California-San Francisco, San Francisco, CA, (7)University of Alberta, AB, Canada, (8)Toronto General Hospital, Toronto, ON, Canada, (9)Mayo Clinic, Rochester, MN, (10)Department of Digestive Diseases, VA - CT Healthcare System, (11)University of Washington, Seattle, WA, (12)Mayo Clinic Arizona, Phoenix, AZ, (13)Ohio State University Wexner Medical Center

Background: EncephalApp Stroop is a simple method to diagnose minimal hepatic encephalopathy & is linked with overt HE (OHE), & hospitalizations. Aim: (i) define Stroop OffTime+OnTime completion time test/retest variation and baseline differences in this completion time that would predict increased risk of OHE/hospitalizations over time & (ii) to validate this time difference in a second cohort. **Methods**: 3 prospective cohorts were enrolled: *Cohort 1:* Stroop at baseline then followed till OHE/hospitalization or last clinical outcome available from 2 centers (University+VA), *Cohort 2*: Test/retest cohort from University+VA & *Cohort 3:* Multi-center cohort followed for 3 mths. OffTime+OnTime was used as Stroop outcome (Fig A).
Cohort 1: Baseline cirrhosis details, co-morbidities & medications were collected. Stroop values were studied using Cox proportional hazards with OHE/hospitalization as primary outcomes. Baseline Stroop values between those who developed OHE/hospitalization sooner vs rest were compared unadjusted & adjusted for clinical variables.
Cohort 2: A separate group underwent Stroop twice without underlying clinical change.
Cohort 3: Cirrhosis outpts from 10 N American sites underwent Stroop & were followed for 3 mths for OHE-related hospitalizations. Baseline adjusted/unadjusted Stroop differences were compared to cohort 1. **Results**: 2-center cohort: 278 pts (62 y, 96% men, MELD-Na 11, 33% prior OHE, 41% ascites) were followed for a median of 7 (3,24 IQR) mths. 16% developed OHE & 12% OHE hospitalization at a median of 6 & 3 mths post-testing respectively. On Cox Proportional hazards for OHE, Stroop time $p = 0.002$, MELD-Na $p < 0.0001$ & ascites $p = 0.003$, were significant; similar variables (Stroop $p < 0.001$, MELD-Na $p = 0.009$, Ascites $p = 0.03$ & beta-blockers $p = 0.04$) were significant for OHE hospitalization. Prior HE, meds & demographics were not linked. After adjusting, we found significant baseline Stroop differences between those that developed outcomes/not (Fig B).
Test-retest cohort: 44 pts (66 y, 42 men, MELD-Na 10, Prior OHE 25%, 34% ascites) received Stroop

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

twice a median of 13 (4-24) mths apart without significant change in OffTime+OnTime (212.4 ± 65.1 vs 210.44 ± 79.9 sec, p = 0.75)

Multi-center cohort: 357 pts (59 y, 69% men, MELD-Na 15, Prior OHE 38%, 73% ascites) were recruited from 10 sites. 14 (4%) developed 3-mth OHE hospitalizations, who were more likely to have prior OHE & higher MELD. Despite the cohort differences (outcome numbers, patient details & f/u duration), we found similar adjusted Stroop baseline differences in pts with/without OHE development (Fig C).

Conclusion: In this prospective study with multi-center validation, we found that > 60 second OffTime+OnTime difference on Stroop portended an increased risk of OHE & related hospitalizations over median 7 months, which is higher than test/retest variations. Baseline Stroop time differences may add to OHE risk prediction over simple clinical models.

3068-A | DIASTOLIC DYSFUNCTION IN CIRRHOTIC CARDIOMYOPATHY: A PROSPECTIVE OBSERVATIONAL COHORT STUDY ON SHORT-TERM OUTCOMES IN CIRRHOTIC PATIENTS UNDERGOING TIPS

Yaozu Liu[1,2,3], Fangmin Meng[1,4], Wen Zhang[1,2,3], Jingqin Ma[1,2,3], Zhiping Yan[1,2,3], Cuizhen Pan[1,4] and Jianjun Luo[1,2,3,5], (1)Shanghai Institute of Medical Imaging, (2)Department of Interventional Radiology, Zhongshan Hospital, Fudan University, (3)National Clinical Research Centre for Interventional Medicine, Zhongshan Hospital, Fudan University, (4)Department of Echocardiography, Zhongshan Hospital, Fudan University, (5)Centre for Tumor Diagnosis and Therapy, Jinshan Hospital, Fudan University

Background: The placement of Transjugular intrahepatic portosystemic shunt (TIPS) results in a sudden increase in central circulating blood volume, which requires proper regulation of the cardiovascular system. The presence of diastolic dysfunctional cirrhotic cardiomyopathy indicates myocardial dysfunction which may lead to adverse outcomes in patients treated TIPS. However, data regarding population primarily affected by hepatitis B virus (HBV) infection remains limited. Furthermore, impaired cardiac function may influence portal pressure gradient (PPG) and right atrium (RA) pressure measurements, potentially influencing the efficacy of TIPS. The aim of our study was to investigate the impact of diastolic dysfunction on TIPS. **Methods:** A consecutive case series of patients with cirrhosis aged 18-65 years who underwent TIPS were prospectively studied. Left ventricular (LV) filling pressure was evaluated using four criteria based on the algorithm proposed by the Cirrhotic Cardiomyopathy Consortium (CCC). Patients with systolic dysfunction (defined as LVEF d 50% or LV GLS absolute value < 18%) were excluded from the study to eliminate the effects of systolic dysfunction. All participants were followed up for at least one year post-TIPS, with the primary study endpoint being all-cause mortality following the procedure. **Results:** From June 2020 to January 2022, 82 patients were included. According to the Cirrhotic Cardiomyopathy Consortium (CCC), 48.8% had no LVDD, 20.7% had grade 1, 14.6% had grade 2 (CCM), and 15.9% were indeterminate. The incidence of diastolic dysfunctional CCM is 14.6% in our study. The results indicate that RAP increased after TIPS and returned to baseline after 48 hours in patients with CCM (4.63 ± 2.46 VS 6.42 ± 2.75 $p = 0.076$). In contrast, patients without CCM had lower RAP than baseline after 48 hours (4.63 ± 3.05 VS 5.64 ± 3.19, $p = 0.001$). And no statistical significance was observed in the comparison of various pressures at different times between CCM and non-CCM patients ($p > 0.05$). At the end of follow-up, 5 (6.1%) patients died. LAVI($P = 0.049$, HR 1.169, 95%CI [1.001-1.365]), MELD score($P = 0.026$, HR = 3.082, 95% CI [1.142-8.319]) and preoperative RAP ($p = 0.044$, HR = 2.015, 95%CI [1.018-3.987])were significantly associated with the mortality. **Conclusion:** In conclusion, cirrhotic patients with HBV infection as the primary etiology exhibit an effective regulatory capacity in response to hemodynamic alterations elicited by TIPS within short-term, irrespective of CCM presence. A longer and comprehensive evaluation are needed to find out the impact on outcomes in the future studies.

3069-A | DISCHARGE SERUM POTASSIUM IN HOSPITALIZED CIRRHOSIS PATIENTS DOES NOT AFFECT CLINICAL OUTCOMES

Kimberline Chew[1], Katherine Ni[1], Zoe Verzani[2], Jang Hyun Kim[1], Lewis Paulino[1], Danielle Garfunkel[1], Max Schechter[3], Lital Aliasi-Sinai[4], Daniel Alvarez[1], Brett Fortune[1] and Clara Tow[1], (1)Montefiore Medical Center, (2)Weill Cornell Medical Center, (3)Albert Einstein College of Medicine, (4)Sackler School of Medicine

Background: Patients with advanced cirrhosis frequently have impaired potassium homeostasis. Potassium disturbances have been linked to unfavorable outcomes in patients with cirrhosis. Studies have looked at baseline potassium levels on admission, however there is limited investigation on the effects of discharge potassium levels towards outcomes in cirrhosis patients. **Methods:** We retrospectively developed a cohort of 253 hospitalized patients with cirrhosis between January to December 2021 at a major urban liver transplant health system. Potassium levels (K) were collected and verified through individual chart reviews. Serum potassium levels at discharge were classified into two categories: K < 4.0mEq/L and K ≥ 4.0mEq/L. We analyzed the effects of discharge potassium on a primary outcome of all-cause 1-year mortality, while secondary outcomes were re-admission rates at 90 days and 1 year. Two-sample t-tests/Wilcoxon tests or Chi-square/Fisher's exact tests were used to compare the variables as appropriate. A multivariable logistic regression model was used to study the impact of discharge potassium on the outcomes adjusted for clinically relevant covariates, included based on prior literature. **Results:** Baseline characteristics between patients with K < 4.0mEq/L and K ≥ 4.0mEq/L at discharge (n = 98 [39%] and 155 [61%], respectively) were similar in terms of age, gender, Model for End-Stage Liver Disease-Sodium (MELD-Na) score, MELD score, Child-Pugh score, diuretics use, presence of Hepatocellular Carcinoma (HCC), presence of Transjugular Intrahepatic Portosystemic Shunt (TIPS), lactulose usage, and type of cirrhosis. Median serum potassium and serum magnesium levels on admission were significantly lower in patients with K < 4.0mEq/L at discharge. There was no difference in all-cause death at 1 year between the two groups (p-value = 0.3). Having a potassium level of ≥ 4.0mEq/L at discharge was associated with fewer 90-day readmissions (p-value = 0.044) and 1-year readmissions (p-value = 0.03) in the unadjusted model. After adjusting for relevant covariates, there was no difference for 90-day readmissions (aOR 0.75, 95% CI 0.38-1.48) or 1-year readmissions (aOR 0.75, 95% CI 0.38-1.48) (Table 1). **Conclusion:** Our study demonstrates that discharge potassium levels did not affect all-cause death at 1 year nor readmissions at 90 days and at 1 year. Our findings may also reflect study limitations due to type II error. Further elucidation into potassium homeostasis using larger cohorts is warranted to advance our understanding potassium's impact on clinical outcomes.

Table 1: Baseline characteristics and adjusted odds ratio of clinical outcomes for discharge potassium levels of < 4.0mEq/L and ≥ 4.0mEq/L

Baseline Characteristic	Potassium < 4.0mEq/L at discharge (n = 98)	Potassium ≥ 4.0mEq/L at discharge (n = 155)	P-value
Age, median (IQR)	62 (56-70)	64 (57-71)	0.4
Women, n (%)	36 (37)	70 (45)	0.2
MELD-score, median (IQR)	14 (10-20)	14 (9-18)	0.5
MELD-Na score, median (IQR)	17 (10-22)	16 (9-21)	0.3
Child-Pugh score, median (IQR)	8.0 (6.0-10.0)	7.5 (6.0-9.0)	0.089
On diuretics, n (%)

3070-A | DISTINGUISHING CEFEPIME INDUCED NEUROTOXICITY FROM HEPATIC ENCEPHALOPATHY: LESSONS FROM A CASE SERIES OF CEFEPIME NEUROTOXICITY IN HOSPITALIZED PATIENTS WITH CIRRHOSIS

Frances Lee, Vishwajit Kode and Todd Frederick, California Pacific Medical Center

Background: Cirrhosis can increase the risk of adverse side effects from medications, including those that are renally excreted due to portal hypertension, portosystemic shunts, and loss of protein binding capacity with hypoalbuminemia. Cefepime is a fourth-generation cephalosporin, known to induce cefepime induced neurotoxicity (CIN), defined as alterations in neurologic and psychologic function within 4-6 days of cefepime initiation that resolves with cefepime withdrawal. While described in patients with renal insufficiency, this phenomenon is increasingly described in patients with cirrhosis through case reports. **Methods:** This is a single center case series of hospitalized patients with cirrhosis exposed to cefepime in a tertiary care center in San Francisco between January 2018 to November 2022. These patients were reviewed from 430 charts gathered by data stewards using ICD-10 codes. Patients were selected for this case series if there was neurologic improvement with cefepime discontinuation, and diagnosis of CIN was made by transplant hepatologist or neurologist. **Results:** There were 8 patients with documented cefepime induced neurotoxicity during our study period. The average age was 58 years old, and 37% or 3 were female. 50% of the patients had a history of alcohol related liver disease, while one patient had received a liver transplant within 30 days of cefepime exposure. 87.5% or 7 patients had renal disease, of which 85.7% or 6 patients were on dialysis. 87.5% or 7 of the patients had hypersomnolence, 37.5% or 3 had myoclonus, 12.5% or 1 had agitation, and 12.5% or 1 had dizziness and aphasia. The patient with agitation was the only patient to not receive benzodiazepine and opiates during their cefepime exposure. The average MELD and MELD-Na score were 24 and 27, respectively. **Conclusion:** Distinguishing CIN from overt hepatic encephalopathy may be difficult to untangle for clinicians. This study demonstrates that while CIN may present with hypersomnolence, distinguishing features of CIN include myoclonus, agitation, aphasia, and dizziness. CIN is not limited to specific etiologies of liver disease and may occur shortly after orthotopic liver transplantation. Based on this series, cefepime use in patients with dual renal and decompensated cirrhosis should be reconsidered, particularly in those with higher MELD scores. This study can improve decision making for antibiotic administration and inform clinicians in their choice of antibiotic use.

3071-A | EARLY ALBUMIN INFUSION MAY IMPROVE OUTCOMES IN MULTIDRUG-RESISTANT ORGANISM INFECTIONS AMONG PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

W. Ray Kim[1], Elisabet Viayna[2], Thomas Ardiles[3], Rahul Rajkumar[4], Kunal Lodaya[4] and Seungyoung Hwang[4], (1)Stanford University School of Medicine, Woodside, CA, (2)Grifols, SA, (3)Grifols, SSNA, (4)Boston Strategic Partners, Inc.

Background: Spontaneous bacterial peritonitis (SBP) due to multidrug-resistant organisms (MDROs) is a growing problem that portends higher rates of complications and mortality. Given that albumin infusion in conjunction with antibiotics is a guideline-recommended SBP treatment strategy, we aimed to determine the impact of albumin infusion timing on MDRO incidence and key clinical outcomes in patients with SBP. **Methods:** We used a nationwide Electronic Health Record (EHR) data set (Cerner Real World Data®) to extract real-world data on adult patients (e 18 y old) who received antibiotics and albumin while hospitalized with SBP between 01/01/2012–06/30/2022. ICD-9/10 codes, laboratory, and medication records were utilized to identify SBP cases and report patients' demographic and clinical characteristics at presentation (baseline). Albumin administration within 24 hours of hospital admission was defined as 'early albumin' while 'late albumin' comprised cases of albumin administration after 24 hours of admission. Descriptive analyses were performed to evaluate the overall antimicrobial administration pattern and to assess the impact of albumin infusion timing on various outcomes of interest, including MDRO incidence, in-hospital mortality, and hospital length of stay (LOS). MDROs were assessed based on EHR presence of ICD codes indicating resistance to antimicrobial drugs (ICD-9: V09; ICD-10: Z16) or administration of imipenem, meropenem, meropenem-

vaborbactam, polymyxin b, avibactam-ceftazidime, and tigecycline during the hospital encounter. **Results:** A total of 12,570 admissions were identified. The mean age was 56.7 years and 62% were men. The mean baseline MELD-Na was 24.4 and 18% of hospitalizations ended with the patient's death. Third-generation cephalosporins were the most administered antibiotic class (71.6%). Early albumin was administered in 8,180 (65.1%) cases. Compared to the late albumin group, the early group had a shorter LOS (median: 6.1 vs. 9.8 d) and a lower incidence of MDROs (13.6% vs. 17.7%) despite a higher baseline MELD-Na (mean: 25.5 vs. 22.3). Regardless of albumin use, cases of MDRO infections had longer LOS (median: 12.7 vs. 6.8 d) and higher in-hospital mortality (33.3% vs 15.0%) compared to non-MDRO cases. **Conclusion:** This real-world data shows that SBP treated with antimicrobials and early albumin had shorter LOS and lower rates of MDROs, despite a higher baseline MELD-Na. MDRO infections had a longer LOS and higher in-hospital mortality rate compared to non-MDRO cases overall. Further studies are warranted to evaluate additional interactions between albumin infusion timing and MDRO-related outcomes in SBP.

Table 1: Real-world data of SBP hospitalizations treated with antibiotics and albumin from 2012 to 2022

Characteristic/Outcome	Overall (N=12,570)	Early Albumin (≤24 hours) (n= 8,180)	Late Albumin (>24 hours) (n= 4,390)
Age, years, mean ± SD	56.7 ± 12.7	56.3 ± 12.4	57.4 ± 13.2
Male, n (%)	7,843 (62.4)	5,167 (63.2)	2,676 (61.0)
Baseline MELD-Na, mean ± SD	24.4 ± 8.3	25.5 ± 8.2	22.3 ± 8.0
In-hospital mortality, n (%)	2,229 (17.7)	1,444 (17.7)	785 (17.9)
Hospital LOS, days, median [p25, p75]	7.2 [4.3, 12.9]	6.1 [3.8, 10.7]	9.8 [5.9, 16.7]
Presence of MDRO, n (%)	1,888 (15.0)	1,113 (13.6)	775 (17.7)
In-hospital mortality, n (%)	628 (33.3% of 1,888)	389 (35.0% of 1,113)	239 (30.8% of 775)
Hospital LOS, median [p25, p75]	12.7 [6.9, 22.9]	10.0 [5.7, 18.2]	17.1 [9.5, 29.8]

3072-A | ELEVATED PLASMA NEUROFILAMENT LIGHT CHAIN AND GLIAL FIBRILLARY ACIDIC PROTEIN LEVELS ASSOCIATED WITH PRESENCE OF MINIMAL HEPATIC ENCEPHALOPATHY

Qiuyu Cheng[1], Yunhui Liu[2], Gege Wu[3], Zhongyuan Yang[2], Zhongwei Zhang[2], Meng Zhang[2], Tingting Liu[2], Yuxin Niu[1], Deyan Tian[2], Xiaoyun Zhang[2], Xiaoping Luo[3], Xiaojing Wang[1], Tao Chen[1] and Qin Ning[1], (1)Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology, (2)Department of Infectious Diseases, Tongji Hospital, Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology, Wuhan, 430030, Hubei, China, (3)Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Astrocytes and neuronal dysfunction participate in the development of hepatic encephalopathy (HE). We aimed to investigate the association of plasma neurodegenerative biomarkers with minimal HE (MHE) and overt HE (OHE). **Methods:** This proof-of-concept study included 124 hospitalized patients with cirrhosis. The Psychometric Hepatic Encephalopathy Score was used to diagnose MHE. Plasma neurofilament light chain (NfL), glial fibrillary acidic protein (GFAP), tau, and ubiquitin carboxy-terminal hydrolase L1 (UCHL1) levels were measured using a single-molecule array. **Results:** A total of 46 patients without prior OHE (n = 109) were diagnosed with MHE. NfL and GFAP levels were significantly higher in patients with MHE than in those without MHE ($P < 0.05$). NfL levels were independently associated with the presence of MHE in multivariable logistic regression analysis (odds ratio 1.013, 95% confidence interval 1.001–1.025; $P < 0.05$). NfL, GFAP, tau, and UCHL1 levels did not differ in patients with and without virus hepatitis-related cirrhosis. NfL and GFAP levels correlated with IL-6 levels (Spearman's r = 0.3 and 0.255, $P < 0.05$, respectively). Tau levels were associated with the MELD score (Spearman's r = 0.236, $P < 0.05$), and plasma UCHL1 levels were correlated with serum albumin and ascites (Spearman's r = -0.219 and 0.281, $P < 0.05$, respectively). However, IL6 levels but not neurodegenerative biomarkers seem to have significant impact on the development of OHE. **Conclusion:** Plasma NfL and GFAP levels were significantly higher in patients with MHE as candidate blood biomarkers.
Disclosures: The following people have nothing to disclose: Qiuyu Cheng, Yunhui Liu, Gege Wu, Zhongyuan Yang, Zhongwei Zhang, Meng Zhang, Tingting Liu, Yuxin Niu, Deyan Tian, Xiaoyun Zhang, Xiaoping Luo, Xiaojing Wang, Tao Chen, Qin Ning

3073-A | ESTABLISHMENT OF A NONINVASIVE DIAGNOSIS MODEL OF PORTOPULMONARY HYPERTENSION

Department of Hepatology, the First Hospital of Jilin University, (2)The First Hospital of Jilin University

Background: Systolic pulmonary artery pressure calculated based on echocardiography provides an objective measure for the noninvasive detection of portopulmonary hypertension(POPH),while echocardiography is not routinely used to assess patients with portal hypertension, and computed tomography (CT)of the lungs is commonly used to judge complications of liver disease. The ESC guidelines recommend the use of the main pulmonary artery diameter (mPAD) measured by CT to help diagnose of pulmonary hypertension. The aim of this study was to develop a non-invasive diagnostic model for suspected POPH patients using mPAD measured by lung CT in combination with routine laboratory indices in hepatology to screen for suspected POPH patients requiring further assessment by cardiac ultrasound at low cost and high accessibility, to improve screening rates and subsequently facilitate early diagnosis and intervention, and to improve clinical prognosis. **Methods:** 493 patients with severe portal hypertension had their cardiac ultrasound and lung CT parameters measured during their hospitalization, and common laboratory parameters were measured. **Results:** A total of 493 patients with severe portal hypertension underwent echocardiography, including 41 patients with suspected POPH (sPAP > 40 mmHg). Age, albumin, mPAD, ascending aortic diameter (aAD), mPAD/aAD, and albumin-bilirubin score (ALBI) were statistically significant ($p < 0.05$) in univariate analysis. Multivariate backward stepwise regression analysis identified albumin, mPAD, splenorenal shunt, and ALBI as independent factors for sPAP > 40 mmHg ($P < 0.05$). The logical diagnostic equation predicting suspected POPH was equation Y = -3.906-0.272 albumin (g/l) + 0.221 mPAD (mm) + 2.225 (splenorenal shunt: yes = 1, no = 0)-1.929 ALBI. The AUC value for the diagnostic equation was 0.841 (95% CI: 0.779-0.902), indicating that the predicted probabilities from the logical equation were not significantly different from the actual probabilities and were well differentiated. The goodness-of-fit test (Hosmer-Lemeshow test $p = 0.978$) and the clinical decision analysis test performed well. Both the 5-fold and 10-fold cross-validation of the logistic equations showed good predictive performance of the model, with AUCs of 0.8258 and 0.8262 respectively, and good diagnostic performance of the diagnostic formula. **Conclusion:** This study developed a diagnostic model to identify patients with suspected POPH in patients with severe portal hypertension, and the model may assist in screening patients who require further evaluation with cardiac ultrasound or even right heart catheterisation.

3074-A | ETIOLOGIC DIFFERENCES IN RISK OF HEPATIC DECOMPENSATION AND HEPATOCELLULAR CARCINOMA

Michelle Ng[1], Sruthi Yekkaluri[1], Jeremy Louissaint[1], Lisa Quirk[1], Karim Seif El Dahan[1], Darine Daher[1], Nicole E. Rich[1], Sarah Rosanna Lieber[1], Thomas G. Cotter[2], Lisa B. VanWagner[1], Arjmand R. Mufti[1], Neehar Dilip Parikh[3], Purva Gopal[1] and Amit G. Singal[1], (1)University of Texas Southwestern Medical Center, (2) University of Texas Southwestern Medical Center, Dallas, TX, (3)University of Michigan

Background: There has been shifting epidemiology for cirrhosis over time, with an increasing proportion of cases due to non-viral etiologies including alcohol (ALD) and NAFLD. The anticipated impact of this change in epidemiology on cirrhosis prognosis is unknown. **Methods:** We included adult patients with cirrhosis at two large urban health systems in the United States. Patients with history of HCC or both ascites and hepatic encephalopathy at baseline were excluded. Our primary outcome was incident hepatic decompensation, defined as new onset hepatic encephalopathy or ascites after index visit, and secondary outcome was development of HCC. We used the Fine-Gray subdistribution hazards model to characterize time to both events, with liver transplantation and death as competing events and multivariable Fine-Gray regression models to identify associated factors. **Results:** We identified 201 patients with cirrhosis, with median age 62 years, 55.7% male. Cohort was diverse regarding race/ethnicity (54.7% White, 11.4% Black, 26.4% Hispanic) and liver disease etiology (24.4% HCV, 22.9% alcohol, and 31.3% NAFLD). During median follow-up of 28.1 months,

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

39.8% of patients had new hepatic decompensation and 14.4% developed HCC; 8.0% underwent transplant, and 17.9% died. The cumulative incidences of hepatic decompensation and HCC at 1, 2, and 3 years were 16.4% and 6.3%, 24.1% and 8.6%, and 31.6% and 9.2%, respectively. In multivariable analyses adjusted for age, sex, and Child Pugh components, liver disease etiology was significantly associated with both risk of hepatic decompensation and HCC. Compared to HCV infection, patients with NAFLD had higher hazards of hepatic decompensation (subdistribution HR [SHR] 2.01, 95%CI 1.02 – 3.97); ALD also had higher risk, but this did not reach statistical significance (SHR 1.69, 95%CI 0.82 – 3.47). The cumulative incidences of hepatic decompensation by etiology were as follows: HCV infection (30.7), NAFLD (76.2) and ALD (53.5) per 1000 person-years. Conversely, ALD (SHR 0.11, 95%CI 0.02 – 0.48) had lower hazards of HCC compared to HCV infection; HCC risk was lower with NAFLD, but this did not reach statistical significance (SHR 0.44, 95%CI 0.16 – 1.18). The cumulative incidences of HCC by etiology were as follows: HCV infection (36.4), NAFLD (22.9) and ALD (9) per 1000 person-years. **Conclusion:** The changing epidemiology of liver disease will likely result in notable changes in cirrhosis prognosis, with increased incidence of hepatic decompensation and reduced HCC.

3075-A | FECAL CARRIAGE OF MULTIDRUG-RESISTANT ORGANISMS INCREASES THE RISK OF HEPATIC ENCEPHALOPATHY IN CIRRHOTIC PATIENTS: INSIGHTS FROM GUT MICROBIOTA AND METABOLITE ANALYSIS

Peishan Wu[1,2], Kuei-Chuan Lee[1,3], Pei-Chang Lee[1,3], Yun-Cheng Hsieh[1,3], Yi-Tsung Lin[1,4], Han-Chieh Lin[1,3] and Ming-Chih Hou[1,2,3], (1)Department of Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, (2)Endoscopy Center for Diagnosis and Treatment, Taipei Veterans General Hospital, Taipei, Taiwan, (3)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, (4)Division of Infectious Diseases, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Multidrug-resistant bacterial infections negatively impact the prognosis in cirrhosis. We aimed to investigate the interaction among fecal carriage of multidrug-resistant organisms (MDROs), gut microbiota, associated metabolites, and clinical outcomes in cirrhosis. **Methods:** A prospective study enrolled 88 cirrhotic patients and 22 healthy adults. Patients were followed for at least one year and the cirrhosis related clinical outcomes were recorded. Cox proportional hazards regression models were used to identify predictors for clinical outcomes. Fecal microbiota were analyzed using 16S rRNA gene sequencing, and untargeted metabolomics analysis of plasma samples was performed on a UPLC-MS platform. **Results:** Cirrhotic patients had higher rates of fecal MDRO carriage compared to healthy population (33% vs. 9.1 %, $p = 0.026$), with ESBL-producing *Escherichia coli* predominance (59%). MDRO carriers had higher serum levels of lipopolysaccharide (LPS) (16.5vs. 12.2 ng/ml, $p = 0.006$) and higher rates of admission within 30 days (34.5% vs 13.6%, $p = 0.002$) than non-carriers. Within one year, 36 patients developed cirrhosis-related complications, and MDRO carriers had higher rates of hepatic encephalopathy (HE) than non-carriers (20.7 vs. 3.4%, $p = 0.008$). Cox-regression analysis identified lower serum levels of sodium (< 139 mmol/L), high levels of LPS (> 13.6 ng/mL) and fecal MDRO carriage as potential predictors for HE. Fecal microbiota analysis showed a marginal decrease in alpha diversity in cirrhotic patients with MDRO colonization, but no statistical significance was observed between MDRO carriers and non-carriers ($p = 0.159$). Nevertheless, a significant dissimilarity of beta diversity on fecal microbiota was observed between healthy control and

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cirrhotic patients regardless of MDRO carriage ($p = 0.001$), as well as between cirrhotic patients with and without MDRO carriage ($p = 0.033$). LEfSe analysis showed a prominence of Bacilli, Lactobacillales, Lactobacillaceae and Lactobacillus in the feces of cirrhotic patients with MDRO carriage. Associations between differential bacterial metabolites, MDRO carriage, and the development of HE were further investigated, and 32 metabolites were found to be associated with MDROs and the occurrence of HE. Among them, lysine and PS(20:0/24:1(15Z)) were upregulated, while PI (18:1(11Z)/18:1(11Z)) was downregulated in MDRO carriers compared with non-carriers, independently of the severity of cirrhosis. **Conclusion:** Fecal carriage of MDROs may play a role in modifying the gut microbiota and associated metabolites in cirrhosis, potentially contributing to the development of HE in those with MDRO carriage. These findings provide valuable insights in identifying patients who would benefit from aggressive surveillance of fecal MDROs and developing targeted interventions to mitigate the risk of HE.

3076-A | FIFTEEN-YEAR TRENDS IN THE PREVALENCE OF DECOMPENSATED CIRRHOSIS AND OVERT HEPATIC ENCEPHALOPATHY AMONG MEDICARE BENEFICIARIES IN THE UNITED STATES (2006-2020)

Robert J. Wong[1,2], Patrick Gagnon-Sanschagrin[3], Zeev Heimanson[4], Jessica Maitland[3], Remi Bellefleur[3], Annie Guérin[3], Ankur A Dashputre[5], Brock Bumpass[5], Olamide Olujohungbe[5], Danellys Borroto[5] and George J. Joseph[5], (1)VA Palo Alto Healthcare System, (2) Stanford University School of Medicine, (3)Analysis Group, Inc., (4)Salix Pharmaceuticals, (5)Bausch Health

Background: Development of hepatic decompensation, including overt hepatic encephalopathy (OHE), in patients with cirrhosis is associated with significant morbidity. Understanding the burden of cirrhosis and its complications over time is important to accurately assess healthcare utilization. This study describes the trends in decompensated cirrhosis among Medicare beneficiaries in the United States (US), with a focus on the prevalence of OHE and related hospitalizations and medication use. **Methods:** Medicare beneficiaries aged ≥ 65 with cirrhosis (≥ 2 diagnoses of cirrhosis or its complications; ICD-9/10 codes) were identified using the 100% Medicare Research Identifiable Files (2006–2020). For each year, the prevalence of decompensated cirrhosis (defined as ascites, variceal bleeding, hepatorenal syndrome, OHE, or spontaneous bacterial peritonitis) and OHE were estimated among patients with cirrhosis who had Medicare enrolment for the entire calendar year. Prevalence of decompensated cirrhosis and OHE among patients with cirrhosis were reported overall and by age and sex. Annual prevalence of OHE medication use (lactulose and/or rifaximin) among patients with cirrhosis and OHE hospitalizations (≥ 1 inpatient stay with OHE as a primary diagnosis) among patients with OHE were estimated from 2006-2020. **Results:** Among patients with cirrhosis, the prevalence of decompensated cirrhosis grew by 0.9% year-over-year (YOY; $p < 0.001$) from 36.7% in 2006 to 42.7% in 2020; the prevalence of OHE grew by 2.7% YOY ($p < 0.001$) from 14.9% to 20.9%, respectively (Figure). Using multiple sensitivity analyses, the prevalence of OHE among patients with cirrhosis ranged from 20.9% to 31.7% in 2020. The prevalence of OHE appeared higher among males (2006: 15.5%; 2020: 22.2%) than females (2006: 14.5%; 2020: 19.7%) and higher among patients aged 65-74 (2006: 15.8%; 2020: 22.9%) than those ≥ 75 (2006: 13.6%; 2020: 18.2%). Rifaximin utilization among patients with cirrhosis was 1.2% at its approval in 2010, 4.1% in 2014, and 3.1% in 2020. Among patients with OHE, the prevalence of OHE hospitalizations was 36.9% in 2006 and declined to 9.5% in 2020. **Conclusion:** Over the past 15 years, the prevalence of decompensated cirrhosis and OHE has notably increased among Medicare beneficiaries to over 40% and 20%, respectively in 2020. Over this same period, there were declines in OHE hospitalizations, which may reflect improvements in management of OHE. Future studies are warranted to explore the factors contributing to the observed trends.

f 3077-A | HEAR-MHE: SPEECH IDENTIFIES MINIMAL HEPATIC ENCEPHALOPATHY AND PREDICTS FUTURE OVERT HEPATIC ENCEPHALOPATHY

Patricia Pringle Bloom[1], Caitlyn Fisher[1], Nazokat Otajonova[2], Luis Garrido-Treviño[3], Aran Farrell[2], Jessica Robin[4], Sumeet Asrani[3] and Anna Lok[5], (1) University of Michigan, (2)Baylor, (3)Baylor University Medical Center, Dallas, TX, (4)Winterlight Labs, (5) University of Michigan Medical Center

Background: There is high demand for a simple diagnostic test to identify minimal hepatic encephalopathy (MHE) or predict future overt HE (OHE). Current tools are burdensome, therefore rarely used in practice. If MHE is identified, treatment can improve quality of life and other outcomes. We aimed to evaluate if recorded speech: 1) correlates with validated HE tests, 2) can diagnose MHE in patients without prior HE, and 3) predicts future OHE. **Methods**: In a prospective study ("HE Audio Recording to Detect MHE" or HEAR-MHE), we enrolled 169 outpatients with cirrhosis from two geographically disparate centers. Patients underwent psychometric HE score (PHES; validated test to diagnose MHE), animal naming test, and audio recording while reading a paragraph. Speech variables (acoustic, lexical, and syntactic) were automatically extracted from the audio recordings via the Winterlight Labs Smartphone analysis platform, an app initially designed to characterize speech in dementia, and immediately transmitted data to the research team via a secure server. Patients were prospectively followed for 6 months to identify OHE episodes. Patients with cirrhosis were in 3 non-overlapping categories: (1) prior OHE + HE treatment, (2) MHE with no prior OHE (diagnosed by PHES d -4), (3) no MHE. Linear, logistic, and Cox regression predicted PHES, MHE, and time to OHE respectively. **Results**: Patients were median 63 years (IQR 55, 68), 52% male, median MELD 9 (IQR 7, 12), 39% had alcohol and 33% fatty liver-related cirrhosis. Audio recordings were median 36 seconds (IQR 33, 41). Speech correlates with PHES: 82 speech variables significantly associated with PHES in the overall cohort ($P < 0.05$ with false discovery rate [FDR] adjustment for multiple testing) – 5 speech tempo and 77 acoustic variables. A model of 5 speech variables (2 speech tempo and 3 acoustic) was strongly associated with PHES ($r^2 = 0.28$, $P < 0.0001$). Speech associates with MHE: 71 speech variables significantly differed between patients with and without MHE (i.e. groups 2 and 3; $P < 0.05$ with FDR adjustment) – 4 speech tempo and 67 acoustic variables. A model of 2 speech variables (1 speech tempo and 1 acoustic) was comparable to animal naming test to identify MHE (AUC 0.70 vs 0.66, $p = 0.19$). Speech predicts future OHE: There were 13 OHE events in 10 patients with cirrhosis (6 with prior OHE, 2 with MHE, 2 without OHE or MHE), median 33 days from enrollment. A model including speech rate and two acoustic variables predicted time to OHE ($P = 0.0001$). Specifically, a speech rate < 133 words/min had significantly shorter time to OHE than e 133 words/min (HR = 0.11, $P = 0.001$). **Conclusion**: Recorded speech while reading a paragraph – a quick and easy test – was associated with PHES, was able to identify MHE, and predicted future OHE. Speech is simple to record, provides immediate point-of-care data, and represents a promising biomarker in HE.

3078-A | IMAGE ANALYSIS OF CARDIAC HEPATOPATHY SECONDARY TO CHRONIC HEART FAILURE: MACHINE LEARNING VERSUS GASTROENTEROLOGY AND RADIOLOGY SPECIALISTS

Suguru Miida[1], Hiroteru Kamimura[2], Hiroki Maruyama[1], Takafumi Tonouchi[1], Norihiro Sakai[2], Yusuke Watanabe[2], Naruhiro Kimura[2], Toru Setsu[2], Hiroyuki Abe[1], Takeshi Yokoo[2], Akira Sakamaki[2], Atsunori Tsuchiya[1], Kenya Kamimura[3] and Shuji Terai[2], (1) Niigata University, (2)Graduate School of Medical and Dental Sciences, Niigata University, (3)School of Medicine, Niigata University

Background: Liver damage secondary to chronic heart failure is called cardiac hepatopathy and is known as nutmeg liver, but its morphological characteristics in terms of medical imaging are not defined and are unclear. We aimed to analyze morphological features of Cardiac Hepatopathy from CT images of the liver using machine learning. Tricuspid regurgitation (TR) was used as an indicator of congestion. **Methods:** A total of 139 patients (90 males, mean age 73.1 ± 14.4 y) who had undergone echocardiography between April 2011 and April 2020 at our hospital and whose liver morphology was confirmed on liver CT images around 2 years were included. To exclude patients with liver damage due to non-cardiac causes, patients who were positive for hepatitis virus, heavy drinkers of alcohol, and autoimmune hepatitis, were excluded. Based on the ultrasonographic findings, patients were classified into three groups (53 patients with mild TR, 66 patients with severe TR, and 20 patients with severe TR). Among the various findings of congestive hepatopathy in CT images, we focused mainly on the dilation of the paraumbilical vein dilation caused by chronic congestion and hepatic right and left lobe diameter. We selected a single-slice CT image at the level where the paraumbilical vein is identifiable, as both lobes of the liver and the dilated findings of the inferior vena cava (IVC) could also be evaluated. We used SONY Neural Network Console to build the multilayer neural network algorithm to predict the severity of TR based on a single-slice CT image of the liver. The model was trained on 105 randomly selected cases as teacher data, and 34 cases were used as test data, and the accuracy was compared with that of four physicians specializing in gastroenterology and 3 physicians specializing in radiology. **Results:** Univariate analysis of blood test findings and echocardiographic data for each severity of TR in the three groups showed significant correlations in ALP, γ-GTP, TRPG (tricuspid regurgitant pressure gradient), and IVC diameter. The average accuracy rate of the specialists was 41.5%, whereas that of the machine learning was 63.9%, which was significantly better image discrimination. **Conclusion:** The results showed that machine learning can capture the morphological characteristics of liver damage associated with heart failure, and may contribute to the elucidation of the heart-liver interaction, which is a new background factor for liver disease in the future.
Disclosures: The following people have nothing to disclose: Suguru Miida, Hiroteru Kamimura, Hiroki Maruyama, Takafumi Tonouchi, Norihiro Sakai, Yusuke Watanabe, Naruhiro Kimura, Toru Setsu, Hiroyuki Abe, Takeshi Yokoo, Akira Sakamaki, Atsunori Tsuchiya, Kenya Kamimura, Shuji Terai

3079-A | IMPACT OF OBESITY AND SARCOPENIA WHEN ESTIMATING GLOMERULAR FILTRATION RATE IN PATIENTS WITH COMPENSATED NASH CIRRHOSIS AND PORTAL HYPERTENSION. A NEED FOR POPULATION-SPECIFIC AND RACE-SPECIFIC VALIDATION

Pol Boudes, Galectin Therapeutics, Eric Lawitz, Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, Don C. Rockey, Medical University of South Carolina, Stephen A Harrison, Pinnacle Clinical Research Center, San Antonio, TX and Naga P. Chalasani, Indiana University School of Medicine

Background: Serum creatinine (sCr) informs about renal function and drives the estimation of glomerular filtration rate (eGFR) by commonly used formulas. As a surrogate of muscle mass, sCr also informs about nutritional status (sarcopenia). In liver cirrhosis, particularly NASH cirrhosis where many patients are hypertensive and diabetics, both altered renal function and sarcopenia may have opposite influence on sCr and the best way to estimate GFR is uncertain. Furthermore, limited data is available in patients with portal hypertension (PH) due to NASH cirrhosis. Hence, we evaluated multiple creatinine-based eGFR equations in these patients. **Methods:** Patients (N = 161) enrolled in a prospective clinical study (NCT 02462967). NASH cirrhosis was confirmed by histology and other etiologies excluded. PH was established with a hepatic

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

venous pressure gradient of at least 6 mm Hg. Patients on non-selective beta-blockers, with previous cirrhosis decompensation, medium or large size varices, a MELD e 15, a Child-Pugh stage B or C, or an eGFR of less than 50 ml/minute estimated by Cockcroft-Gault (C-G) were not eligible. sCr was measured by a central laboratory. GFR was estimated by the C-G (includes age and weight), Modification of Diet in Renal Diseases (MDRD, includes age and sex, adjusted for black race) and Chronic Kidney Disease Epidemiologic collaboration (CKD-EPI 2009, includes age and sex, adjusted for black race), and CKD-EPI 2021 (not adjusted for black race) formulas. Descriptive summaries were provided (overall, by sex and diabetes status) and eGFRs results were compared between formulas. **Results:** The mean (SD) age was 58.4 (8.4) and weight was 98.2 (21) kg, 72% were females, 69% hypertensive, and 61.5% diabetics. All patients were of non-black race. sCr ranged from 27 to 124 μmol/L [normal range 62-124 μmol/L or 0.7-1.4 mg/dL], with a mean of 62.3 (18), 57.6 (17) and 74.6 (15), overall and for females and males, respectively; and 63.6 (16) and 61.5 (20) for non-diabetics and diabetics, respectively. 64.6% of patients had a sCr at or below the normal range for the central laboratory. The mean (SD) estimated GFR in ml/minute for the C-G, MDRD, CKD-EPI 2009 and 2021 were 150.3 (47), 102.3 (30), 95.7 (17), 98.6 (16), respectively. Compared to the MDRD, the C-G overestimated GFR by a mean of 52.8 mL/minute, frequently providing impossibly high values. Compared to CKD-EPI 2009 and 2021, the MDRD differed by more than 10 mL/minute in 40.4% and 50.9% of patients, respectively. **Conclusion:** In NASH cirrhosis with PH, obesity and low sCr confound the results of frequently used eGFR formulas. This could support the use of cystatin C-based formulas in this population. However, none of the eGFR equations, whether cystatin-based or not, have been validated in NASH cirrhosis, including various race/ethnic groups, and a reliable estimation of GFR is urgently needed.

3080-A | INCREASED HYPERSENSITIVITY TO OXIDATIVE STRESS VIA IMPAIRED Keap1-Nrf2 FUNCTION IN C2C12 MYOTUBES EXPOSED TO AMMONIA

Akitoshi Sano[1], Jun Inoue[1], Eiji Kakazu[1,2], Masashi Ninomiya[3], Mio Tsuruoka[3], Kosuke Sato[1], Satoko Sawahashi[1] and Atsushi Masamune[3], (1)Tohoku University Hospital, (2)The Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, (3)Tohoku University Graduate School of Medicine

Background: Sarcopenia exacerbates the prognosis of patients with liver cirrhosis. While hyperammonemia has been reported to impair skeletal muscle through myostatin, the association between skeletal muscle and oxidative stress responses under high levels of ammonia exposure has not been analyzed. This study aimed to investigate the relationship between hyperammonemia and oxidative stress responses in skeletal myotubes. **Methods:** Mouse C2C12 myoblasts were cultured in Dulbecco's Modified Eagle growth medium (DMEM) supplemented with 10% fetal bovine serum and high glucose. Upon reaching confluence, the myoblasts were differentiated into myotubes by replacing the medium with differentiation medium (DM) containing 2% horse serum for 7 days. On day 7 post differentiation, the medium was replaced with either DM or amino acid-modified medium (AMM) with varying concentrations of ammonia. The AMM consisted of the average concentration of plasma amino acids from patients with advanced cirrhosis (Kakazu E, et al. Hepatology. 2009 Dec; 50(6):1936-45), and L-glutamine in the medium was replaced with GlutaMAX™. Protein expression of myosin heavy chain (MYH) and nuclear factor erythroid-2-related factor 2 (Nrf2) was determined using western blotting. ROS levels in C2C12 myotubes and myoblasts were measured using fluorescent staining and flow cytometry. TCA cycle intermediates were measured through absorbance measurements. **Results:** Accurate measurements were challenging in DMEM of DM culture due to the spontaneous generation of ammonia mainly caused by L-glutamine metabolism. However, using AMM medium, in which L-glutamine was replaced with GlutaMAX™, effectively suppressed this phenomenon. The addition of ammonia to the medium decreased MYH protein expression in C2C12 myotubes. Furthermore, ammonia enhanced the accumulation of ROS induced by H2O2 in C2C12 cells. While H2O2 stimulation increased intranuclear Nrf2 protein expression in C2C12 myotubes, ammonia exposure suppressed this effect. Ammonia addition resulted in decreased levels of certain TCA cycle intermediates, including α-ketoglutarate and fumarate, in C2C12 myotubes. The Keap1-Nrf2 system serves as an important regulatory mechanism of the oxidative stress response. It has been reported that fumarate, a TCA cycle intermediate, alters the structure of the Nrf2 binding site of Keap1, promoting the nuclear translocation of Nrf2. The findings of this study suggest that the reduction of TCA cycle intermediates induced by ammonia in myotubes diminishes the nuclear translocation of Nrf2 and the response to oxidative stress. **Conclusion:** High levels of ammonia induce hypersensitivity to oxidative stress through impaired Keap1-Nrf2 function, resulting from imbalances in TCA cycle intermediates in C2C12 myotubes.

Background: The potential influence of co-factors on the course of cirrhosis after etiological therapy is poorly defined. Interferon-free antiviral therapies offer a unique possibility to study the impact of metabolic-dysfunction associated fatty liver disease (MAFLD) on the evolution of patients with HCV-related cirrhosis and portal-hypertension (PH) after achieving sustained virological response (SVR). This study investigates the influence of MAFLD on long-term outcomes after achieving SVR in patients with HCV-related cirrhosis and PH. **Methods:** We investigated a multicenter European cohort of patients previously included in a pooled IPD-analysis (https://doi.org/10.1016/j.jhep.2022.08.025). All had HCV-related cirrhosis with PH at baseline, demonstrated by an HVPG e 6mmHg, and all achieved SVR to antiviral therapy before 2018. Presence of MAFLD according to criteria defined by an international expert consensus (https://doi.org/10.1016/j.jhep.2020.03.039), was investigated at baseline. After SVR patients were followed until June-2022. We investigated whether MAFLD influences the risk of cirrhosis decompensation and mortality in a competing-risk framework. **Results:** 409 patients were included, 70 of them (17%) with MAFLD and 99 (24%). At baseline, metabolic derangements such as obesity, diabetes and arterial-hypertension were more frequent among patients with MAFLD. Baseline Child-Pugh, MELD, HVPG and presence of varices were similar in both groups. Patients with MAFLD less frequently had previous decompensation (13% vs 28%, P = 0.007) and NSBBs-therapy (20% vs 35%, P = 0.017). During a mean follow-up of 78 months (IQR, 64-85) after SVR, cirrhosis decompensation occurred in 27% MAFLD vs 11% without-MAFLD and death occurred in 29% vs 11%, respectively. The risk of developing decompensating events was higher in patients with MAFLD than in those without (sHR = 2.49, 95% CI = 1.44-4.29; P = 0.001). The risk of death was also higher in MAFLD-patients (sHR = 2.64, 95%CI = 1.55-4.47; P < 0.001). The 99 patients (24%) with history of alcohol-consumption had higher risk of decompensation (sHR = 2.30, 95%CI = 1.35-3.92; P = 0.002) and a non-significantly higher mortality risk (sHR = 1.41, 95%CI = 0.79-2.50; P = 0.245). Both MAFLD and alcohol consumption were independent predictors of decompensation by competing-risk multivariate regression, while MAFLD and previous decompensation were predictors of death. **Conclusion:** This study shows that, in patients with HCV-related cirrhosis and PH, the presence of MAFLD markedly increases the risks o decompensation and death during long-term follow-up after SVR. This suggests, that MAFLD may constitute a co-factor worsening prognosis in cirrhosis once the primary etiological factor has been removed/suppressed.

Background: The hyperinflammatory state of patients with acute decompensation (AD) of cirrhosis is associated with mitochondrial dysfunction, which together represent important drivers of disease progression to acute-on-chronic liver failure. Elevated circulating levels of acylcarnitines predict mortality in these patients. Here, we hypothesize that they are not mere biomarkers of mitochondrial dysfunction but also exert detrimental effects on mitochondria of circulating immune cells. **Methods:** Plasma levels of acylcarnitines were measured in 20 patients with AD cirrhosis and 10 healthy subjects. The effects of selected medium- and long-chain acylcarnitines on mitochondrial function were screened in peripheral leukocytes from healthy donors. Changes in the mitochondrial membrane potential (MMP) and mitochondrial respiration were determined using the cationic dye JC-1 and the Agilent Seahorse XF technology. Mitochondrial ultrastructure was assessed by transmission electron microscopy. Gene expression at the mRNA and protein levels was measured by real-time PCR and Western blot, respectively. **Results:** Acylcarnitine levels were increased in blood of patients with AD cirrhosis in parallel with inflammatory cytokines and chemokines. Among the different acylcarnitines, the long-chain C16:0-carnitine impaired MMP and reduced spare respiration of peripheral mononuclear leukocytes without affecting mitochondria ultrastructure and cell viability. Importantly, C16:0-carnitine induced mitochondrial oxidative stress, suppressed the expression of the antioxidant *HMOX1* gene and increased *CXCL8* expression and IL-8 release in a concentration-dependent manner. The suppressive effect of C16:0-carnitine on *HMOX1* expression was reversed by etomoxir, which blocks the entrance of acylcarnitines into the mitochondrial matrix. Likewise, induction of *CXCL8* by C16:0-carnitine was prevented by the fatty acid beta-oxidation inhibitor trimetazidine. The impairment of mitochondrial membrane potential and mitochondrial oxidative stress associated with C16:0-carnitine was less severe when leukocytes were incubated in the presence of albumin. **Conclusion:** Our results indicate that elevated circulating long-chain acylcarnitines in patients with AD cirrhosis has the potential to actively promote mitochondrial dysfunction in immune cells, thereby contributing to systemic hyperinflammatory responses in these patients.

3083-A | LONG-TERM EFFICACY AND OUTCOMES OF ORAL L-CARNITINE ADMINISTRATION IN PATIENTS WITH HYPERAMMONEMIA OR HEPATIC ENCEPHALOPATHY: A MULTICENTER RETROSPECTIVE STUDY

Joji Tani, Asahiro Morishita and Tsutomu Masaki, Kagawa University, Faculty of Medicine

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Hepatic encephalopathy (HE) is a neuropsychiatric manifestation that can occur in a number of conditions, including acute liver failure, advanced liver cirrhosis (LC) and portosystemic shunt (PSS) . Many patients with HE complain of lethargy, excessive daytime sleepiness, and sleep disturbances, which have a negative impact on their quality of life. There are few data on the long-term efficacy of L-carnitine administration in improving blood ammonia concentration (BAC) and preventing recurrence of HE. **Methods:** This study aimed to determine the effects of long-term L-carnitine administration on BAC and HE. Of 444 patients with L-carnitine administration from April 2012 to March 2021, we enrolled 242 patients with hyperammonemia or HE. A multicenter retrospective study was conducted to determine the long-term efficacy of L-carnitine administration. Using changes in BAC, recurrence rate of HE, number of hospitalizations, and prognosis at follow-up after L-carnitine therapy, we aimed to clarify the medium- and long-term therapeutic effects of L-carnitine on HE and hyperammonemia in a multicenter study. **Results:** Median BAC at the start and at 12, 24, 48, 96,144, and 192 weeks was 123, 95.5, 88, 83, 96, 82, and 86 μg/dL, respectively. BAC were significantly lower than those at the start ($p < 0.05$, respectively). The median improvement time to normalization of BAC was 100 days. The median BAC improvement time was significantly earlier in patients with an initial dose of more than 1500 mg (63 d with more than 1500 mg and 140 d with less than 1500 mg; $p = 0.0034$, log-rank test). The 113 patients with a history of hospitalization for HE followable for 2 years before and after L-carnitine therapy had a total of 183 hospitalizations for HE before treatment, compared with 62 hospitalizations after treatment ($p < 0.001$). The event incidence rate due to HE, such as emergency hospitalization, emergency transport, or additional medications, at 60, 180, 360, 720, and 1080 days after L-carnitine administration was 5.7%, 16.9%, 20.3%, 29.5% and 38.5%, respectively. The change in MELD scores before and after L-carnitine administration was statistically significant, while other variables did not show significant changes. The 180-, 360-, 720-, 1080-, and 1440-day OS rates after oral L-carnitine administration were 78.7%, 69.4%, 52.6%, 46.0%, and 32.8%, respectively. Finally, the median survival time was 880 days. Multivariate analysis revealed that the presence of ascites ($p = 0.0334$), ALBI score ($p = 0.0108$), and history of HCC ($p = 0.0098$) at baseline were significant factors associated with the OS rate. **Conclusion:** We found that oral L-carnitine administration was effective in patients with hyperammonemia or HE, reduced the number of hospital admissions due to HE in our multicenter study. Long-term L-carnitine administration is effective in hyperammonemic patients, and can reduce hospitalizations and events due to HE.

3084-A | LOW SKELETAL MUSCLE INDEX IS A PREDICTOR OF LIVER-RELATED EVENTS AND MORTALITY IN PATIENTS WITH CIRRHOSIS INDEPENDENTLY OF PORTAL HYPERTENSION

Ikram Abow-Mohamed[1], Balqis Alabdulkarim[1], Xun Zhao[1], Dana Kablawi[1], Estelle Desgagne[1], Marc Deschenes[1], Philip Wong[2], Tianyan Chen[2], Giada Sebastiani[1], Benjamin Rehany[1], Mohamed Abu-Nada[1], David Valenti[1], Ali Bessissow[1] and Amine Benmassaoud[1], (1)Mcgill University Health Centre, (2) Department of Medicine, McGill University Health Centre, Montreal, QC, Canada

Background: Sarcopenia is prevalent in cirrhosis and is linked with mortality. However, its role in relation to portal hypertension is unclear. This study investigated the impact of muscle mass and portal hypertension on major liver events and mortality. **Methods:** This retrospective cohort study included adult patients with cirrhosis and available Hepatic Venous Pressure Gradient (HVPG) from 2012 to 2022. Total skeletal and psoas muscle indices (SMI, PMI) and subcutaneous adipose tissue index (SATI) at the 3rd lumbar vertebrae were measured at the time of HVPG using computed tomography images and *CoreSlicer*, a body composition analysis software. Sarcopenia was defined as SMI $< 39 cm^2/m^2$ in females and $< 50 cm^2/m^2$ in males and its predictors were assessed by logistic regression. Predictors of (i) new hepatic decompensation (ascites, hepatic encephalopathy, variceal bleeding), (ii) liver-related event (decompensation, hepatocellular carcinoma, liver transplantation, death), and (iii) mortality were assessed by Cox regression analysis. **Results:** Overall, 121 patients were included (46% with sarcopenia, 38% males, mean age 58.3 years, 34% with non-alcoholic fatty liver disease, median HVPG 10mmHg, median Model for end-stage liver disease (MELD) 13, 55% with prior decompensation). Sarcopenia was more likely in those with a prior decompensation (70% vs 43%, $p < 0.003$), lower ALT (21 vs 40, $p < 0.001$), lower PMI ($4.1 cm^2/m^2$ vs $5.9 cm^2/m^2$, $p < 0.001$), lower SATI ($37.4 cm^2/m^2$ vs $76.4 cm^2/m^2$, $p < 0.001$). After adjusting for age, prior decompensation, and ALT, SATI was the only independent predictor of sarcopenia (aOR 0.98, 95%CI 0.97-0.99). Over a median follow-up of 14.5 months, 32% of patients had a decompensation,

59% had a liver-related event, and 29% died. For new decompensation, after adjusting for HVPG and MELD, SMI (aHR 0.97, 95%CI 0.94-1.00) and sarcopenia (aHR 1.83, 95% CI 0.95-3.54) tended towards being independent predictors. For liver-related events, after adjusting for HVPG and MELD, SMI was an independent predictor (aHR 0.97, 95%CI 0.95-0.99), but not sarcopenia. For mortality, after adjusting for HVPG and MELD, SMI was significant predictor (aHR 0.96, 95% CI 0.92-0.99) while sarcopenia tended towards significance (aHR 1.95, 95%CI 0.98-3.89) (Table1). **Conclusion:** Our study demonstrates that low SMI is an important predictor of significant liver-related events and mortality, independently of portal hypertension in patients with cirrhosis.

3085-A | LOW SUBCUTANEOUS ADIPOSE TISSUE INDEX IS AN INDEPENDENT PREDICTOR OF MORTALITY IN FEMALE PATIENTS WITH CIRRHOSIS

Ikram Abow-Mohamed[1], Balqis Alabdulkarim[1], Xun Zhao[1], Dana Kablawi[1], Estelle Desgagne[1], Marc Deschenes[1], Philip Wong[2], Tianyan Chen[2], Giada Sebastiani[1], Benjamin Rehany[1], Mohamed Abu-Nada[1], David Valenti[1], Ali Bessissow[1] and Amine Benmassaoud[1], (1)Mcgill University Health Centre, (2) Department of Medicine, McGill University Health Centre, Montreal, QC, Canada

Background: Sarcopenia is an established predictor of worse outcomes in patients with cirrhosis. The clinical significance of low adipose tissue mass in this population is not well defined. This study investigated the impact of adipose tissue mass on mortality in patients with cirrhosis **Methods:** This retrospective cohort study included adult patients with cirrhosis and available Hepatic Venous Pressure Gradient (HVPG) from 2012 to 2022. Subcutaneous, visceral, and total adipose tissue indices (SATI, VATI, TATI) and total skeletal and psoas muscle indices (SMI, PMI) at the 3rd lumbar vertebrae were measured at the time of HVPG using computed tomography images and *CoreSlicer*, a body composition analysis software. Sarcopenia was defined as SMI < $39cm^2/m^2$ in females and < $50cm^2/m^2$ in males. Youden's Index (YI) cut-off was determined using the area under the receiver operating characteristics (AUROC) curves for SATI, VATI, TATI and mortality. Predictors of adipopenia and mortality were assessed by logistic and Cox regression analyses, respectively. **Results:** Overall, 121 patients were included (62% females, mean age 58.3 y, 34% with non-alcoholic fatty liver disease, median HVPG 10mmHg, median Model End-Stage Liver Disease (MELD) 13, 55% with prior decompensation). Over a median follow-up of 14.5 months, 35 (29%) patients died. SATI had highest AUROC (0.64, 95%CI 0.53-0.74) to predict death compared to VATI (ROC = 0.57) and TATI (ROC = 0.61). Based on YI, adipopenia^{SATI} was d $91.98cm^2/m^2$ (sensitivity 94%, specificity 35%). Adipopenia^{SATI} was present in 89 (74%) patients. Predictors of adipopenia^{SATI} included male sex (OR 0.43, 95%CI 0.19-0.97), prior decompensation (OR 2.70, 95%CI 1.17-6.21), low SMI (OR 0.93, 95%CI 0.89-

0.97), and sarcopenia^{SMI} (OR 2.86, 95%CI 1.19-6.87). After adjustment, male sex (aOR 0.43, 95%CI 0.18-0.99) and sarcopenia^{SMI} (aOR 2.85, 95%CI 1.17-6.94) were independent predictors of adipopenia^{SATI}. For mortality, HVPG (aHR 1.06, 95%CI 1.01-1.11), MELD (aHR 1.09, 95%CI 1.03-1.15), and adipopenia^{SATI} (aHR 4.76, 95%CI 1.13-20.13) remained independent predictors (Table1). When stratified by sex, adipopenia^{SATI} was an independent predictor of mortality only in females (aHR 6.35, 95%CI 1.04-38.65). **Conclusion:** Our study reveals a significant association between low SATI and mortality in female patients with cirrhosis independently of HVPG and MELD. We propose a cut-off to identify adipopenia^{SATI} and allow risk stratification.

Table 1. Predictors of mortality by cox regression analysis

	Univariate analysis (HR, 95%CI)	Multivariate analysis (aHR, 95%CI)
Age, per year	1.021 (0.992-1.052)	1.030 (0.997-1.064)

3086-A | LOWER LIVER STIFFNESS MEASUREMENT IN PATIENTS WITH CIRRHOSIS PREDICTS A LOWER RISK OF HEPATIC DECOMPENSATION

Gloria Horta[1], Iyiad Alabdul Razzak[1], Xinyuan Zhang[2], Xuehong Zhang[3], Christopher Danford[4] and Michelle Lai[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)Brigham and Women's Hospital, Harvard Medical School, (3)Brigham and Women's Hospital, (4)Intermountain Health

Background: Cirrhosis from chronic liver disease is a global health burden with increasing incidence and mortality worldwide (Cheemerla et al., 2021). Once compensated cirrhosis progresses to decompensated disease, the median survival drops significantly from > 12 years to ~2 years, respectively (D'Amico et al., 2006). Vibration-controlled transient elastography (TE) is a commonly used non-invasive test measuring liver stiffness (LSM) used to diagnosis cirrhosis (Braude et al., 2023). In this study, we evaluated the role of TE in stratifying patients with cirrhosis in terms of their risk for developing decompensation. **Methods**: This is a retrospective-prospective cohort study of patients with cirrhosis conducted at the Liver Center of Beth Israel Deaconess Medical Center. A diagnosis of cirrhosis was based on liver biopsy, radiographic features of portal hypertension or nodular liver, prior LSM of > 12 kPa and thrombocytopenia, and/or endoscopic features of portal hypertension. Other historical clinical data relevant to cirrhosis (including comorbidities, prior decompensation events, prior TE results) were extracted. Subject enrollment began in August 2020 with an intended follow-up period of 8 years. Subjects were seen at 6 months intervals after enrollment. At the time of enrollment, all subjects underwent TE by FibroScan (Echosens), and LSMs were recorded in Kilopascals (kPa). We dichotomized subjects into TE < 10 kPa group and TE > = 10kPa group. We used multivariate logistic regression to evaluate whether TE > = 10kPa predicted liver decompensation events (defined as variceal hemorrhage, hepatic encephalopathy, and/or ascites), adjusting for covariates including age, sex, race, primary liver disease, and Child-Pugh score. **Results**: Two hundred sixty-five adult subjects with cirrhosis (mean age = 60; female = 40%) were included. The risk of at least one decompensation event was significantly lower in the TE < 10kPa group (OR: 0.31; 95% CI 0.16-0.60) (Table 1). Subgroup analysis of sixty-one subjects who had a prior TE showed a trend towards lower incidence of complications in subjects who had a decrease in their LSM, however, statistical significance was not reached (OR: 0.16; 95% CI 0.02-1.43). **Conclusion**: In patients with cirrhosis, a LSM < 10 kPa by TE predicts a significantly lower risk of liver decompensation.

Table 1. Logistic regression

	TE >= 10kPa N = 160	TE < 10kPa N = 105
At least 1 complication		
Case, n (%)	88 (55.0)	38 (36.2)
OR (95% CI)	1 (ref)	0.31 (0.16, 0.60)
- Variceal hemorrhage		
Case, n (%)	59 (40.4)	24 (25.8)
OR (95% CI)	1 (ref)	0.48 (0.26, 0.91)
- Hepatic encephalopathy		
Case, n (%)	36 (22.5)	14 (13.3)
OR (95% CI)	1 (ref)	0.28 (0.10, 0.74)
- Ascites		
Case, n (%)	44 (27.5)	22 (21.0)
OR (95% CI)	1 (ref)	0.66 (0.38, 1.16)

3087-A | MENINGEAL LYMPHANGIOGENESIS IS AN IMPORTANT PHYSIOLOGICAL COMPENSATORY MECHANISM OF HEPATIC ENCEPHALOPATHY IN RATS WITH ADVANCED LIVER CIRRHOSIS

Shao-Jung Hsu[1,2], Hui-Chun Huang[1,2], Ming-Chih Hou[1,2] and Fa-Yauh Lee[1,2], (1)Taipei Veterans General Hospital, Taipei, Taiwan, (2)National Yang Ming Chiao Tung University, Taipei, Taiwan

Background: Hepatic encephalopathy (HE) is a lethal complication of liver cirrhosis and is derived from neuroinflammation and hyperammonemia. Meningeal lymphatics drain the waste and maintain the homeostasis of the brain. Previous study suggested that enhanced meningeal lymphangiogenesis in early cirrhosis ameliorated neuroinflammation and HE. However, meningeal lymphatic function in advanced liver cirrhosis has not been surveyed. This study aimed to evaluate the role of meningeal lymphatic system in advanced liver cirrhosis. **Methods:** Liver cirrhosis was induced in male Sprague-Dawley rats by common bile duct ligation. Early cirrhosis or late cirrhosis developed 4 or 6 weeks after operation, respectively. In addition, sham or deep cervical lymph node ligation was performed in parallel groups with advanced liver cirrhosis to block meningeal lymphatic drainage. **Results:** Rats with advanced liver cirrhosis had more severe portal hypertension, portosystemic collaterals, and hyperammonemia. However, there was no significant differences in the locomotor function and neuroinflammation between early and advanced cirrhotic rats. Interestingly, advanced liver cirrhosis group compared to early cirrhosis had meningeal lymphangiogenesis ($P = 0.047$), increased tracer uptake in brain ($P = 0.045$) and meningeal lymphatic drainage ($P = 0.001$). Blocking meningeal lymphatic drainage by deep cervical lymph nodes ligation inhibited meningeal lymphatic drainage and significantly deteriorated locomotor function and neuroinflammation in rats with advanced liver cirrhosis. **Conclusion:** Meningeal lymphangiogenesis developed in advanced liver cirrhosis and prevented the deterioration of neuroinflammation and hepatic encephalopathy. Meningeal lymphangiogenesis is an important physiological compensatory mechanism of hepatic encephalopathy in advanced liver cirrhosis.

3088-A | MILDLY LOW SERUM LEVEL OF SODIUM IN CHRONIC LIVER DISEASE IS ASSOCIATED WITH SARCOPENIA AND IMPACTS POOR PROGNOSIS: A SINGLE-CENTER RETROSPECTIVE STUDY IN JAPAN

Atsushi Nakamura and Takeshi Ichikawa, Nipponkokan

Background: Recently, there has been growing interest in the association of mild chronic hyponatremia with sarcopenia and life span. Experiments in mouse models have shown that chronic hyponatremia induces hypogonadism and muscle atrophy (*Age 2013*). In chronic liver disease (CLD), hyponatremia is associated with portal hypertension (encephalopathy, ascites) and worse prognosis, and while sarcopenia is considered an independent associated factor with poor prognosis. In this study, we investigated the relationship between serum sodium levels and portal hypertension (PHT), sarcopenia in CLD by analyzing MR elastography (MRE) imaging data. **Methods:** This is a single-center, retrospective study of 741 patients (mean age 62 y, 60% male, 43% viral, 60 HCC) who underwent MRE. Serum sodium levels (mEq/L) were divided into 5 groups: < 135, 135-136, 137-138, 139-140, and > 140. PHT was evaluated by thrombocytopenia (< 150K), varices (any) and ascites ($\geq$ Grade 1), and sarcopenia was diagnosed by PSMI (M/F: 12.62 / 9.77 cm^2/m^2), which is height-corrected paraspinal muscle area (PSMA) on MRI images (Cureus 2022). The ACLD was defined as F stage 3/4 on MRE. Albumin-bilirubin (ALBI) score was used to evaluate hepatic reserve function, and modified ALBI grade was used to classify severity. **Results:** 1) Serum level of sodium: The 5 groups were 19, 34, 95, 238, and 355 patients, respectively. Thrombocytopenia (%) was 63, 38, 29, 19, 17, varices (%) 57, 50, 30, 14, 12, ascites (%) 47, 32, 16, 5, 3, and sarcopenia (%) 74, 62, 43, 24, 23, all increased at < 139 mEq/L ($p < 0.01$ for each). Mean liver stiffness (LS) in the 5 groups: 6.6 $\pm$ 2.7, 5.7 $\pm$ 3.8, 4.2 $\pm$ 2.6, 3.2 $\pm$ 1.8, 3.2 $\pm$ 1.8 kPa, with a threshold for LS predicting low sodium (< 139) of $\geq$ 3.4 kPa (AUC 0.68, $p < 0.01$). The LS thresholds predicting each event of PHT were then $\geq$ 3.5 kPa for thrombocytopenia, $\geq$ 4.7 kPa for varices, and $\geq$ 5.5 kPa for ascites (AUC 0.82 - 0.95, $p < 0.01$ for each), while sarcopenia was $\geq$ 3.4 kPa (0.67, $p < 0.01$). Multivariate analysis of risk factors for low sodium (< 139) in CLD revealed BUN, LS, ALBI score and sarcopenia ($p < 0.05$ for each). 2) Prognosis in ACLD: Liver-related deaths in 280 patients were 38 (mean follow-up: 27.1M). Kaplan-Meier curves for each serum level of sodium (Fig 1A) showed significantly poor survival at < 139 mEq/L (log-rank test $p < 0.01$). Prognostic analysis of the Cox proportional hazards model showed that mALBI grade

2b/3 (HR 6.05, 95%CI 2.42-15.99) and sarcopenia (HR 3.44, 95%CI 1.40-19.28) were poor prognostic factors ($p < 0.05$ both). **Conclusion:** Mild low sodium levels (< 139 mEq/L) in Japanese CLD were associated with PHT, suggesting that the coexistence of sarcopenia may impact poor prognosis.

3089-A | MUSCLE FAT INFILTRATION, A POTENTIAL RISK MARKER, INCREASES RAPIDLY IN PATIENTS WITH COMPENSATED LIVER CIRRHOSIS – INTERIM RESULTS FROM THE PROSPECTIVE MULTI-CENTER CIRRHOSIS COHORT STUDY ACCESS-ESLD

Mikael Fredrik Forsgren[1,2], Wile Balkhed[2], Patrik Nasr[2], Daniel Sjögren[3], Jennifer Linge[1,2], Anna Cederborg[2], Markus Holmberg[2], Nils Dahlström[2], Henrik Stjernman[3], Martin Rejler[3], Stergios Kechagias[4], Olof Dahlqvist Leinhard[1,2] and Mattias Ekstedt[4], (1)Amra Medical AB, (2)Linköping University, (3)County Hospital Jönköping, (4)Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden

Background: There is an unmet need for accurate and robust biomarkers identifying patients with compensated liver cirrhosis at risk of developing decompensation and other liver-related clinical events. Such biomarkers may also support the development of therapeutic options. A magnetic resonance imaging (MRI) based assessment (Muscle Assessment Score [MAsS]) combining sex-adjusted thigh muscle fat infiltration (MFI) and muscle volume z-score (MVZ), has been developed to describe muscle health. Large population studies have shown that MAsS better predicts physical function and hospitalization than its individual components. MAsS can be used to detect muscle composition (MC) phenotypes, of which the adverse MC (high MFI and low MVZ) independently predict all-cause mortality. The aim was to assess rate of change in MAsS and how MC phenotypes at baseline relates to clinical parameters at baseline and 6-months follow-up in ACCESS-ESLD – a prospective longitudinal multi-center cohort study of patients with liver cirrhosis. **Methods:** MAsS was measured using AMRA® Researcher based on an 8 min MRI acquired on the same day as blood samples and Child-Pugh score (CPT). MC phenotypes were defined according to literature. T-tests were used for statistical testing and mixed-effects modeling to asses the rate of change. **Results:** The first 34 patients (19 males; BMI 29.9 ± 6.6 kg/m^2, age 67 ± 8 yrs; mainly alcohol related cirrhosis and NAFLD, but also hepatitis B and/or C, and autoimmune diseases) with MRI and blood sample analysis at baseline and 6-months were included. MFI increased according to a rate of +0.329 pp/year ($p = 0.008$). There was a non-significant change in MVZ (-0.08 SD/year), see Fig. Compared to all other patients, subjects with the high MFI MC phenotype at baseline had: i) higher bilirubin at 6-months compared to baseline (+1.6 μmol/L, $p = 0.041$), and ii) similar CPT score at baseline (5.5 v. 5.3, $p = 0.432$), but iii) higher CPT score at 6-months (6.1 v. 5.5, $p = 0.034$). Interestingly, two patients had increased CRP of 29 mg/dL (+26 from baseline) and 86 (+84 from baseline) mg/dL at 6-months follow up – both had high MFI (11.8 and 14.6%) at baseline and no other patients had more than 5 mg/dL increase. **Conclusion:** In patients with compensated liver cirrhosis, MFI increased at a rate which is x2-3 higher than observed in general- and type-2 diabetes populations (see Fig), while muscle volume appeared stable in a 6-month time frame. Furthermore, patients with liver cirrhosis and high muscle fat MC phenotype had increased bilirubin levels 6 months later and a mild increase in CPT compared to the patients without the high muscle fat MC phenotype. The results suggest that MAsS, and in particular MFI, could be used for risk stratification of patients with compensated liver cirrhosis.

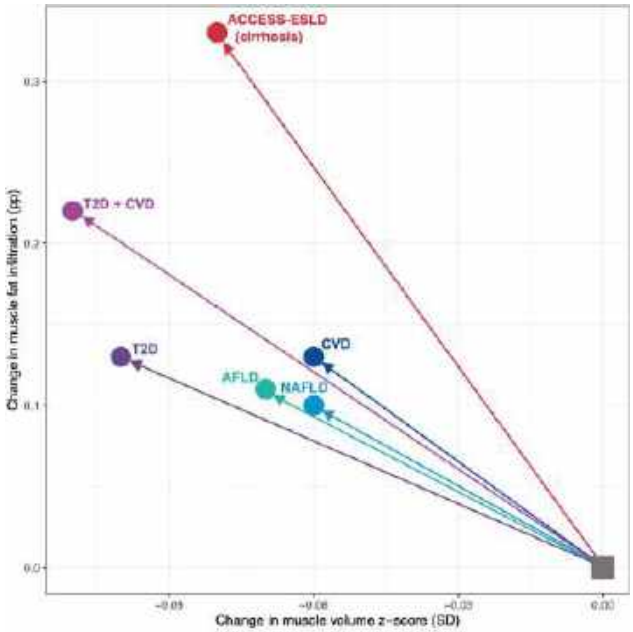

Figure 1 Average 1-year change in muscle composition in ACCESS-ESLD in the context of other disease groups stratified from the longitudinal UK Biobank: non-alcoholic fatty liver disease (NAFLD, N=353), alcoholic fatty liver disease (AFLD, N=350), cardiovascular disease (CVD, N=180), type 2 diabetes (T2D, N=135), and participants with both T2D and CVD (N=17).

3090-A | MUSCLE VOLUME Z-SCORE IS LOWER IN HIGH-RISK PATIENTS AWAITING LT – INTERIM RESULTS FROM A LIVER TRANSPLANT WAITLIST NATURAL HISTORY STUDY

Mikael Fredrik Forsgren[1,2], Seung Lee[3], Jennifer Linge[1,2], Danielle Kirkman[4], Vaishali Patel[3], Per Widholm[2], Geneva Roche[4], Hiba Kamal[4], Olof Dahlqvist Leinhard[1,2] and Mohammad S. Siddiqui[4], (1) Linköping University, (2)Amra Medical AB, (3)Virginia Commonwealth University Health System, (4)Virginia Commonwealth University

Background: There is an unmet need for accurate and robust biomarkers identifying patients with liver cirrhosis at risk of adverse clinical events while waiting for liver transplantation (LT). Such biomarkers may also support the development of therapeutic options. A magnetic resonance imaging (MRI) based assessment (Muscle Assessment Score [MAsS]) combining muscle fat infiltration and muscle volume z-score (MVZ), has been developed to describe muscle health. Large population studies have shown that MAsS predicts physical function and hospitalization. Importantly, MVZ has been shown to be independent to sex and BMI. There is no data on evaluation of MVZ in patients awaiting LT. The aim was to assess the relationship between MVZ and L3 skeletal muscle index (L3-SMI) to blood samples and MELD in a prospective longitudinal study of patients with liver cirrhosis who are awaiting LT. **Methods:** MAsS and L3-SMI was measured using AMRA® Researcher based on an 8 min MRI acquired within the same week as blood samples (bilirubin, albumin, glomerular filtration rate [eGFRcr], blood urea nitrogen to creatinine ratio [BUN:Cr]). MELD scores (1.0, Na, 3.0) were calculated. T-test and Pearson correlation were used for statistical testing. **Results:** The first 31 patients (10 males, BMI 29.3 ± 6.6 kg/m^2, age 55 ± 11 yrs, with NASH cirrhosis or alcoholic-related cirrhosis) with complete MRI and blood samples at baseline were included. There was no difference in MVZ nor L3-SMI between NASH (n = 20) and alcoholic-related cirrhosis. Patients with low albumin had lower MVZ (-1.53 v -0.57 SD, p = 0.048) as did those with high total bilirubin (-1.89 v -0.56 SD, p = 0.011). There was no difference for eGFRcr. Patients with high blood urea had smaller muscles than those with low (-1.73 v -0.17 SD, p = 0.023) – within those groups there were no difference in kidney function (eGFRcr). L3-SMI was lower for patients with low compared to high blood urea (40.7 v 48.6 cm^2/m^2, p = 0.043), no other blood test where significant for L3-SMI. MVZ was strongly correlated with MELD-Na and 3.0. L3-SMI was not correlated to any MELD score (Fig). **Conclusion:** In patients with liver cirrhosis awaiting LT, MVZ was low for abnormal albumin, bilirubin, and blood urea. Those patients had between 1-1.5 SDs smaller muscles than expected compared to those presenting within normal levels. In addition, MVZ had a strong negative correlation with modern MELD scores. The same associations were only found for L3-SMI within blood urea, indicating that MVZ has a stronger link to poorer patient condition. Since body composition z-scores are independent to BMI and sex it may be translated in to the clinic much easier than volumetric measurements. Thus, z-scores may have the potential to supplement the diagnostic performance of the MELD score to predict clinical events and therefore improve clinical care for patients awaiting transplant, this requires further validation in well designed prospective studies.

3091-A | NEUROFILAMENT LIGHT CHAIN AS POTENTIAL BIOMARKER FOR OVERT HEPATIC ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS

Diederick van Doorn[1], Koos De Wit[1], Bregje Mol[1], Lonneke Van Vught[1], Frederik Nevens[2], Ulrich H. Beuers[1], Cyriel Y. Ponsioen[1], Charlotte Teunissen[1] and Bart Takkenberg[1], (1)Amsterdam University Medical Center, Amsterdam, Netherlands, (2)Uz Leuven, Leuven, Belgium

Background: Hepatic encephalopathy (HE) is one of the most frequent complications of cirrhosis. Hyperammonemia plays a key-role in its pathogenesis and is currently the only biomarker in blood supporting the clinical diagnosis. However, ammonia is less suitable for monitoring and predicting HE severity and outcome. Several studies showed that HE causes irreversible damage to the brain. Cerebral damage may induce a release of neuronal proteins like neurofilament light chain protein (NfL) and glial fibrillary acidic protein (GFAP) in body fluids including blood plasma. We hypothesized that neuronal proteins could be potential blood biomarkers for HE. **Methods:** Patients' plasma samples from three prospective cohorts were analyzed using single molecule assay (Simoa). Included patients had different stages of liver disease and HE severity and were matched based on age and sex using propensity matching. The first cohort consisted of 34 patients with primary sclerosing cholangitis (PSC) with compensated disease without overt HE (68 % male, 55 y (± 14)) and functioned as negative disease control group. The second cohort consisted of 17 patients with advanced liver disease without overt HE before elective transjugular intrahepatic portosystemic shunt (TIPS) placement (65 % male, 61 y (± 10)). The third cohort consisted of 17 patients with decompensated cirrhosis admitted to the ICU for stage IV overt HE (53 % male, 58 y (± 11)). **Results:** A total of 68 samples were analyzed. Median NfL concentrations were for the PSC group: 7.3 pg/ml [5.6 - 9.6 pg/ml], the pre-TIPS group 29.3 pg/ml [16.6 - 35.8 pg/ml] and the ICU group 38.6 pg/ml [30.1 - 57.0 pg/ml]. Concentrations in the pre-TIPS group and ICU group were both higher compared to the PSC group (both $p < 0.001$) and concentrations in the ICU group were also higher compared to the pre-TIPS group ($p = 0.03$) (Figure 1). Median GFAP concentrations were 83.8 pg/ml [66.9 - 106.6 pg/ml], 125.8 pg/ml [88.5 - 166.8 pg/ml] and 138.7 pg/ml [100.9 - 178.2 pg/ml] for the PSC group, pre-TIPS group and ICU group, respectively. Concentrations in the pre-TIPS group and ICU group were higher compared to the PSC group ($p < 0.001$ and $p = 0.02$) while there was no observed difference between the ICU and pre-TIPS group. Plasma NfL and GFAP concentrations correlated with Model for End-Stage Liver Disease (MELD) scores ($R = 0.58$ and $R = 0.40$, *$p < 0.001$, each*). **Conclusion:** Plasma NfL deserves further evaluation as a potential biomarker for oHE and strongly correlates with the MELD score in our limited cohort.

3092-A | NEUTROPHIL-TO-LYMPHOCYTE RATIO PREDICTS SHORT- AND LONG- TERM READMISSION OF PATIENTS WITH HEPATIC ENCEPHALOPATHY

Rui Huang and Lin Zhang, Peking University People's Hospital

Background: Hepatic encephalopathy (HE) is an important complication of end-stage of liver disease, portending poorer outcomes. The readmission rate of patients with cirrhosis was 20-30% in 30 and 90 days, and the most common reason was HE. Several factors were reported as predictors of readmission in HE patients. However, long-term studies are lacking and few new serological indicators beyond liver parameters have been found. Aiming to explore simple and effective predictors of short- and long-term readmission of HE patients, we performed this retrospective study. **Methods:** We performed a single-center retrospective study of adult patients who were admitted with HE. The primary endpoint was the first liver-related readmission in 30, 90 and 180 days. Logistic regression analysis and multiple linear regression analysis were performed to describe predictors associated with readmission and length of the first hospitalization. **Results:** 424 patients, who were admitted with HE, were included. 24 (5.7%), 63 (14.8%) and 92 (21.7%) patients were

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

readmitted within 30, 90 and 180 days, respectively. 283 (66.7%) were males, and the mean age was 59.9 ± 11.5 years. 120 (28.3%) patients were with alcoholic liver disease (ALD). 40 (9.4%), 246 (58.0%) and 67 (15.8%) patients had hepatocellular carcinoma (HCC), ascites and variceal bleeding at baseline, respectively. Patients readmitted in 180 days were older (62.0 ± 9.6 & 59.3 ± 12.0, $p = 0.008$), with higher proportion of no insurance (27.2% & 15.7%, $p = 0.010$), ALD 37.0% & 25.9%, $p = 0.027$), chronic kidney disease (CKD) (22.8% & 11.7%. $p = 0.007$), HCC (16.3% & 7.5%, $p = 0.012$) and ascites (70.7% & 54.5%, $p = 0.004$) than those without readmission in 180 days. The most common reason of readmission was HE: 15 (62.5%), 30 (47.6%) and 48 (52.1%) patients were readmitted for HE in 30, 90 and 180 days, respectively. Besides, patients who were readmitted had higher level of neutrophil-to-lymphocyte ratio (NLR) at first discharge (8.17 ± 12,1 & 3.95 ± 4.96 ; 7.17 ± 9.72 & 3.67 ± 4.44; 6.80 ± 8.62 & 3.47 ± 4.28 , $p < 0.001$) than those without readmission in 30, 90 or 180 days. In logistic regression analysis, no insurance, ALD, ascites, model for end-stage liver disease (MELD) score and NLR at first discharge were significant predictors of readmission in 30, 90 and 180 days. Besides, age and HCC were also significantly associated with 90- and 180-day readmission (table 1). Variceal bleeding ($p = 0.006$), CKD ($p = 0.003$) and MELD score at discharge ($p = 0.024$) were significantly associated with the length of hospitalization at patients' first admission. **Conclusion:** NLR at discharge was the significant predictor of short- and long-term readmission of patients with HE. CKD was the significant factor affecting the length of hospitalization at the first admission in patients with HE.

Table 1 Predictors of 30-, 90-, 180-day readmission.

Characteristics	β	p value	OR	95% CI
30-day readmission				
No Insurance	1.155	0.047	3.173	1.015, 9.915
Alcoholic liver disease	1.302	0.037	3.675	1.081, 12.491
Ascites	2.019	0.006	7.529	1.780, 31.855

3093-A | NONALCOHOLIC FATTY LIVER DISEASE IS A SIGNIFICANT BURDEN AMONG OLDER ADULTS WITH CIRRHOSIS: STUDY OF AN ASIAN COHORT

Chanda Ho[1], Amber Chung[2], Wei Quan Teo[2], Prema Raj[2], Hiang Keat Tan[1] and Jason Pik Eu Chang[1], (1) Singapore General Hospital, (2)Singhealth-Duke Nus Transplant Centre

Background: As life expectancy is increasing worldwide, the rates of liver transplantation (LT) are also increasing among older adults. In Singapore, however, patients are ineligible for deceased donor liver transplantation beyond the age of 70. Without liver transplantation as a curative treatment option, the burden of liver disease will continue to increase in this cohort of patients. Therefore, it is important to understand the natural history of cirrhosis and decompensated liver disease in an older cohort of patients. The study aim was to describe the clinical outcomes of a cohort of older patients with cirrhosis aged e 70 years, including death. **Methods:** Patients admitted to a large tertiary public hospital in Singapore from January 1-December 31, 2018 with ICD-10 codes for cirrhosis (validated in a prior study) were captured. Various outcomes were tracked via manual chart abstraction by two independent investigators. Outcomes including decompensation were tracked until December 31, 2022. **Results:** Out of 924 distinct patients with cirrhosis, 233 were e 70 years old at the time of admission. Chart review revealed 57.1% patients had decompensated liver disease at time of diagnosis. The most common etiologies of cirrhosis were NAFLD/NASH (30%), Hepatitis B (25%), and cryptogenic cirrhosis (26.6%). During the study period, 174 (74.6%) had at least one decompensating event of which hepatocellular carcinoma was the most common (82 out of 174). Of the study cohort, 58 (27.3%) patients had no other comorbid illness, 99 (42.4%) had at least one comorbidity of which diabetes mellitus was the most common (59.6%), and 76 patients (32.6%) had > 1 comorbidity. Mortality data were also captured as follows: 1 year (17.2%), 3 year (33.9%), 5 year (46.8%). **Conclusion:** The burden of liver disease is significant among older adults, especially those without LT as a treatment option. These data highlight the significant role and burden of fatty liver disease and diabetes in this older cohort of cirrhosis patients and the need not only for care coordination amongst general practitioners and specialists to care for this population but also the need for greater preventive services to address risk factors for diabetes and NAFLD upstream.

3094-A | NOSOCOMIAL SPONTANEOUS BACTERIAL PERITONITIS IS ASSOCIATED WITH INCREASED 30-DAY MORTALITY IN HOSPITALIZED PATIENTS WITH DECOMPENSATED CIRRHOSIS

Laura E. Lavette, Nicolas M. Intagliata and Zachary Henry, University of Virginia

Background: Spontaneous bacterial peritonitis (SBP) is one of the most common causes of infection in decompensated cirrhosis and is associated with high morbidity and mortality. Nosocomial infections have been associated with increased mortality in studies conducted in Europe and Asia; however, data are limited for patients in the United States. We aimed to examine the relative impact of nosocomial SBP (n-SBP) compared to community acquired SBP (ca-SBP) among patients hospitalized at a single center in the United States. **Methods:** Adult patients with cirrhosis and SBP were retrospectively enrolled over an 8-year period. SBP was defined as ascites fluid with >250 PMN/mm3 without an alternative explanation for peritonitis. Nosocomial infection was defined as SBP occurring greater than 48 hours after hospitalization. Patients with miscoded diagnoses, non-neutrocytic bacterascites, secondary peritonitis, or SBP diagnosed prior to hospital transfer were excluded. Significant predictors on univariate analysis ($p>0.05$) were combined in a multivariate analysis. **Results:** Of 554 patients with cirrhosis and peritonitis, 222 met criteria for SBP, 87 cases with n-SBP and 135 cases with ca-SBP. Patients with n-SBP had significantly higher MELD scores at admission as compared to ca-SBP (26 vs 22, $p=0.02$), longer length of stay (13 d vs 8 d, $p<0.001$), and were more likely to be admitted to the ICU (49% vs 20%, $p<0.001$). There was an increased rate of ascites culture positivity in the ca-SBP group as compared to the n-SBP (32% vs 17%, $p=0.01$), but no significant difference in blood culture positivity or presence of multi-drug resistant organisms. The most common organisms cultured from ascites were Escherichia coli and Klebsiella pneumoniae with no significant differences between the two groups. There was no difference in use of proton pump inhibitors, non-selective beta blockers, or prophylactic antibiotics at admission between groups. Patients with n-SBP had a higher risk of 30-day mortality compared to patients with ca-SBP. On multivariate analysis, n-SBP (OR 2.1, 95% CI 1.1 – 4.0), MELD (OR 1.1, 95% CI 1.04 – 1.12), and admission to the ICU (OR 3.4, 95% CI 1.7 – 6.7) were independent predictors of mortality at 30 days. **Conclusion:** N-SBP is associated with an increased risk of death and is an independent predictor of 30-day mortality in patients with decompensated cirrhosis. Risk factors for the development of n-SBP may include factors such as prior history of SBP, multiple procedures and hospitalizations, and development of acute-on-chronic liver failure. Further study is needed to identify risk factors for n-SBP given the high risk of mortality identified in this cohort.

3095-A | PARADOXICAL ASSOCIATION OF MELD-NA SCORE AND RATES OF BLOODSTREAM INFECTIONS IN PATIENTS WITH CIRRHOSIS AT AN URBAN INSTITUTION

Nandakumar Mohan[1], Prutha Shah[1], Matthew Moran[2] and Kevin B Lo[2], (1)Albert Einstein Medical Center, Philadelphia, PA, (2)Albert Einstein Medical Center

Background: The model for end-stage liver disease (MELD-Na) score is a prospectively developed and validated chronic liver disease severity scoring system that uses a patient's laboratory values for serum bilirubin, serum creatinine, and the international normalized ratio (INR), and Sodium level to predict three-month survival. Patients with cirrhosis are at higher risk for infections as compared to the general population. This study aims to determine whether the MELD-Na score can act as a predictor for bloodstream infections (BSI) in patients with cirrhosis. We hypothesize that higher MELD-Na scores will correlate with higher rates of BSI. **Methods:** In our retrospective chart review, patients with cirrhosis over eighteen years of age admitted from 2017 through 2018 were identified by query of the hepatology inpatient and consultation service database. Bloodstream infection (BSI) was defined as patients with microbiologic growth in blood cultures. Patients were excluded if pregnant or immunosuppressed from medication, malignancy, uncontrolled HIV infection, or were using beta-blocker medications. For all study patients, MELD-Na

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

scores were collected, and association and comparison between patients with BSI and without were done. Skewed variables were presented as medians (Interquartile range) and compared using the Wilcoxon rank sum test. Multivariable logistic regression was used to assess the independent association of the MELD Score and BSI. **Results:** Of the 420 patients with cirrhosis, the mean age was 59.1 ± 10.9. 44% were female, 54% were Caucasian, 23% were African American and 9% were Hispanic, see the rest of the demographic and clinical parameters stratified by the presence of BSI in table 1. Out of all the patients, 67 (16%) had bloodstream infections. Patients with BSI had significantly lower baseline MELD scores 15 (12-22) vs 21 (15-26) $p < 0.001$. After multivariable logistic regression accounting for age, gender, race, and other potentially associated comorbidities, the baseline MELD score was significantly inversely associated with BSI OR 0.91 95%CI (0.87-0.95) $p < 0.001$. Both the Caucasian race and the presence of ESRD on dialysis were associated with higher odds of BSI (see table 2). Looking at the components of the MELD score aside from renal function, patients with BSI had significantly lower total bilirubin levels, higher sodium and a trend towards lower INR which is congruent with the inverse MELD score association. **Conclusion:** Patients in our cohort with BSI had significantly lower MELD scores compared to those without BSI, this seemingly paradoxical association should be further explored. Individual variables of the MELD-Na score are consistent with this inverse association as well which is perplexing, especially when serum sodium levels are considered.

3096-A | PLATELET ENHANCES THE ACCURACY OF SPLEEN STIFFNESS MEASUREMENT AND LIVER STIFFNESS MEASUREMENT TO PREDICT CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN CIRRHOSIS PATIENTS

Yu JUN Wong[1], Geraldine Lim[2], Siew Yoon Yap[2], Yajie Zhang[2], Juyuan Toh[2], Carolyn Yap[2], Jessica Tan[1] and Rahul Kumar[1], (1)Department of Gastroenterology & Hepatology, Changi General Hospital, (2)Clinical Trial Research Unit, Changi General Hospital

Background: Spleen stiffness measurement (SSM) and liver stiffness measurement (LSM) have been proposed to identify cirrhosis patients with clinically significant portal hypertension (CSPH). The wide adoption of SSM was limited by inconsistent cut-off values, high failure rate in inexperienced operator and obese patients. It was unclear if the combination of platelet could further improve the accuracy of SSM and LSM to predict CSPH in cirrhosis patients. We aim to compare the performance of LSM, SSM, with or without platelet to predict CSPH in cirrhosis patients. **Methods:** We prospectively included cirrhosis patients between May 2022 to January 2023. Both LSM and SSM were performed using 50-Hz vibration-controlled transient elastography (VCTE) after 4 hours of fasting. CSPH was defined as either the presence of gastroesophageal varices, collaterals, ascites, hepatic encephalopathy, or HVPG > 10mmHg. Performance of LSM and SSM were compared across various cirrhosis stages: compensated cirrhosis (CC) without CSPH, CC with CSPH, and decompensated cirrhosis (DC). **Results:** A total of 60 cirrhosis patients (95% Child-Turcotte-Pugh class A, 75% ALBI grade 1, 45% had CSPH) were included. The median (IQR) age was 63 (56-70) and 48% were male. Median (IQR) BMI was 26.9 (23.1-29.5), with 23% being obese. NASH (35%) was the commonest etiology, followed by HBV (32%) and autoimmune (17%). Median (IQR) LSM was 14.0kPa (10.4-22.9); median SSM was 28.9kPa (23.8-51.3). Technical success of LSM and SSM using 50Hz VCTE was 82% and 75%, respectively; 10% require XL probe. The median platelet count was 163x10^9/L (100-207), ALT was 28U/L (21-46), and bilirubin was 13umol/L (7-17), respectively. Both SSM and LSM correlate well with each other ($r = 0.704$, $p < 0.0001$), and increase with progressive cirrhosis stages ($p < 0.05$). Both SSM (AUC: 0.73, 95%CI: 0.58-0.88) and LSM (AUC: 0.72, 95%CI:

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

0.57-0.87) had comparable accuracy to predict CSPH. Youden index identified SSM > 50kPa and LSM > 25kPa as the optimal cut-off to rule in CSPH. Both SSM > 50kPa and LSM > 25kPa has similar accuracy to rule-in CSPH (specificity: 95.7%-96.2%, PPV: 91.7%). Combination of platelet count (< 140x10^9/L) significantly improves the prediction for CSPH using SSM > 50kPa (AUC: 0.85, 95%CI: 0.72-0.97) or LSM > 25kPa (AUC: 0.81, 95%CI: 0.68-0.94) (Figure 1). **Conclusion:** Both SSM > 50kPa and LSM > 25kPa have good accuracy to rule in CSPH in cirrhosis patients, which was further enhanced with the combination of platelet count.

3097-A | POST-TIPS RIGHT ATRIAL PRESSURE AND LEFT ATRIAL VOLUME INDEX PREDICT HEART FAILURE AND MORTALITY: DUAL CENTER EXPERIENCE

Previn Ganesan[1,2], John Laurenzano[3], Claire Harrington[1], Christopher Slaughter[4], Lisa B. VanWagner[5], Anthony Borgmann[3], Deepak Gupta[3], Nikhilesh Mazumder[6], Justin Richard Boike[1] and Manhal Izzy[3], (1)Northwestern Memorial Hospital/ Northwestern University, (2)Northwestern University, (3) Vanderbilt University Medical Center, (4)Vanderbilt University, (5)University of Texas Southwestern Medical Center, (6)University of Michigan Hospitals and Health Centers, Ann Arbor, MI

Background: Heart failure (HF) after Transjugular Intrahepatic Portosystemic Shunt (TIPS) occurs in up to 20% of patients within the first year. Understanding factors associated with development of HF among TIPS candidates is critical. We aim to evaluate the utility of hemodynamic measurements obtained immediately pre- and post-TIPS placement (intraprocedural) along with echocardiographic features of cirrhotic cardiomyopathy (CCM) in identifying patients at risk of post-TIPS HF and death. **Methods:** We performed a retrospective cohort study of adult patients seen at two tertiary care centers who underwent TIPS between 2010 and 2015 without pre-existing clinical coronary artery disease or significant valvular heart disease. Time-to-event and landmark analyses were used to assess associations of intraprocedural hemodynamics and pre-/post-TIPS echocardiographic parameters of CCM with HF hospitalization and mortality during 2 years of follow up. **Results:** A total of 360 patients (40% female, 67.5% Caucasian) met study criteria. Alcohol-associated liver disease was the most common etiology of cirrhosis (31.1%). Potential predictors of HF and mortality were analyzed (Table 1). Intraprocedural post-TIPS right atrial pressure (RAP) was associated with increased risk of HF hospitalization on univariate and multivariate analyses accounting for age and MELD (univariate HR 1.10 [1.04-1.16]; multivariate HR 1.10 [1.04-1.17]) per unit mmHg). An intraprocedural post-TIPS RAP cut off value of > 22 mmHg was associated with increased risk for HF (multivariate HR 2.71, p = 0.015, accounting for age and MELD). Pre-TIPS echocardiographic diagnosis of CCM was not associated with HF hospitalization or mortality. However, on landmark analysis of impact of echocardiographic changes within the first 180 days post-TIPS on subsequent mortality, increasing left atrial volume index (LAVI) was associated with increased mortality (HR 1.08 [1.01-1.15] per unit ml/m^2). **Conclusion:** Higher intraprocedural post-TIPS RAP and increase in LAVI after TIPS are associated with HF hospitalization and death, respectively. Echocardiographic features of CCM pre-TIPS were not associated with either outcome. These findings highlight the importance of intraprocedural hemodynamic measures and surveillance echocardiography in identifying patients at risk of HF hospitalization and death. Prospective evaluation of hemodynamic and CCM markers in relation to post-TIPS outcomes is warranted.

3098-A | PREDICTION MODEL OF PORTAL HYPERTENSION USING MACHINE LEARNING ANALYSIS IN CIRRHOSIS PATIENTS

Han Seul Ki, Soon Koo Baik and Moon Young Kim, Yonsei University Wonju College of Medicine

Background: Prediction of portal pressure has a crucial role in management of cirrhosis. Increased portal pressure drives poor outcomes in cirrhosis. Non-invasive methods for liver fibrosis for cirrhosis are widely investigated. However, measurement of hepatic venous pressure gradient is the gold standard for the presence of portal hypertension. Patients should undergo invasive measurement for pressure gradient measurement. We designed the model to predict portal pressure using the non-invasive parameters based on 670 pressure gradient data. **Methods:** We analyzed 670 patients' data who undergo hepatic vein pressure gradient (HVPG) measurement (2000. January – 2014. April). The procedure was performed in a stable state before the patients was planned to discharge. Unbiased manner of statistical was applied to select the HVPG-related predictors. The variable was categorized into continuous or categorical variables using class function in R Base package. Based on unbiased manner, HVPG and candidate features were entered into univariate linear regression (LiR) as independent and dependent variables. Next, specific cut-offs, including actual *p*-value or top ranking based on its ascending ordering, were applied to select the HVPG-related variables. Using the selected predictors and multivariate LiR, the HVPG prediction model was constructed. The multivariate LiR provided a value per a subject as the estimated value of HVPG, and the comparative analyses between the estimates and real HVPG values were conducted. To obtain the generalized finding, random sampling validation was used. The dataset was randomly divided into training and testing datasets with ratio of 0.7 to 0.3. The feature selection and establishment of HVPG estimation model was conducted exclusively using the training dataset. Performance measurement was conducted using the testing dataset. The tasks, including the random dataset split, feature selection, and establishment of HVPG prediction model were iterated at 50 times, yielding fifty lists of the candidate predictors and estimated HVPG values of testing dataset. **Results:** According to the rank-based manner, top 10 features provided the best performance among four cases (top 5, top 10, top 15, and top 20, Figure 1). We established three performance models using each factor, the CTP and MELD score. In factor model, the predictive function using simple factors is not inferior to others. Moreover, MAE (mean absolute error) shows a better result compared to CTP model. In predictive model of CSPH (HVPG e 10mmHg), the AUC was reported to 0.82. **Conclusion:** Increased portal pressure can be accessed by non-invasive parameters and machine learning analysis.

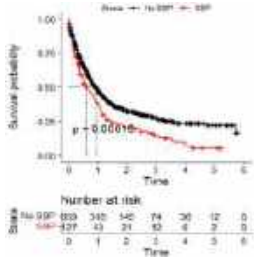
3099-A | PROGNOSTIC PREDICTABILITY OF SPONTANEOUS BACTERIAL PERITONITIS IN DECOMPENSATED CIRRHOSIS

Joseph Cappuccio[1], Karim Osman[1], Cristina Batarseh[1], Brenda Amuchi[1] and Amir Ahmed Qamar[2], (1)Lahey Hospital and Medical Center, (2)Lahey Clinic Medical Center

Background: Spontaneous Bacterial Peritonitis (SBP) remains a concerning complication associated with decompensated cirrhosis. Mortality rapidly increases with delayed intervention in the acute setting. Even despite acute resolution, SBP may serve as a predictor of worsened survival long term. Our retrospective analysis aims to investigate the prognostic predictive power of previously treated SBP and whether liver transplant (LT) impacts survival in this population. **Methods:** The study was approved by the Institutional Review Board. A prospectively maintained cohort of adult patients with cirrhosis, being evaluated for LT at our institution, was retrospectively reviewed from 2015-2020. SBP was diagnosed by an absolute neutrophil count (ANC) e 250/μL in ascitic fluid. Outcome of interest was LT or death. Patients were followed from baseline (date of LT evaluation) until last follow-up or death. Censoring occurred at the time of last follow-up. Cumulative incidence of outcomes was determined by the Kaplan-Meier method. Cox proportional hazard regression identified associations between covariates and outcomes. **Results:** 992 patients were evaluated for LT at our institution, of which 127 had SBP. SBP was associated with higher risk of mortality [1.49, 95%CI 1.21-1.83, P-value < 0.001]. The presence of ascites, hepatic encephalopathy (HE), hepatocellular carcinoma (HCC), and higher MELD-Na were also significantly associated with higher mortality (table 1). Survival probability at 1 and 5 years were significantly reduced in the SBP group when compared to the non-SBP group (Figure 1). Further, survival probability at 1- and 5-year time points were < 50% and < 25% respectively in the SBP group (Figure 1). **Conclusion:** Our analysis highlights the association between SBP and worsened survival probability. Given the complex physiology observed in decompensated cirrhosis, several factors may contribute to a worsened survival probability in subjects with known prior SBP. We acknowledge that variation in timing of intervention and non-uniform management of SBP may impact survival.



Variables	Univariable		Multivariable	
	HR (95% CI)	P-value	HR (95% CI)	P-value
Age	1.00 (1.00-1.01)	0.21		
Female	0.95 (0.83-1.11)	0.62		
Ascites	1.33 (1.15-1.54)	<0.001	0.88 (0.72-1.08)	0.15
Hepatic encephalopathy	1.64 (1.33-1.83)	<0.001	1.32 (1.10-1.58)	<0.001
Variceal hemorrhage	0.98 (0.75-1.19)	0.85		
HCC	3.70 (3.03-3.93)	<0.001	1.32 (1.23-1.67)	<0.001
SBP	1.49 (1.21-1.83)	<0.001	1.19 (0.94-1.62)	0.17
MELD-Na	1.11 (1.10-1.12)	<0.001	1.12 (1.11-1.13)	<0.001

3100-A | REGIONAL VARIATIONS ACROSS THE UNITED STATES IN THE PREVALENCE OF OVERT HEPATIC ENCEPHALOPATHY AND RIFAXIMIN UTILIZATION AMONG COMMERCIALLY AND MEDICARE INSURED ADULTS

Robert J. Wong[1,2], Ankur A Dashputre[3], Patrick Gagnon-Sanschagrin[4], Zeev Heimanson[5], Jessica Maitland[4], Remi Bellefleur[4], Annie Guérin[4], Martha Sikes[3], Brock Bumpass[3], Olamide Olujohungbe[3], Danellys Borroto[3] and George J. Joseph[3], (1)VA Palo Alto Healthcare System, (2)Stanford University School of Medicine, (3)Bausch Health, (4)Analysis Group, Inc., (5)Salix Pharmaceuticals

Background: Overt hepatic encephalopathy (OHE) is a serious complication of liver cirrhosis and rifaximin 550mg is indicated to reduce the risk of OHE recurrence in adults. Regional variations in the prevalence of OHE and rifaximin prescription patterns—which may inform state-specific healthcare policies—are not well characterized. This study describes state-level prevalence of OHE and rifaximin prescriptions among patients with cirrhosis in the United States (US) in 2020. **Methods:** MarketScan Commercial Claims Database (age 18-64) and 100% Medicare Research Identifiable Files (age e 65) were used to identify patients with continuous health plan enrolment for the 2020 calendar year. Prevalent cases of OHE were identified in 2020 as the observed proportion of patients with e 1 diagnosis of OHE among patients with cirrhosis (e 2 diagnoses of cirrhosis or cirrhosis-related complications). Rifaximin utilization was calculated as the proportion of patients with e 1 rifaximin prescription fill in 2020 among patients with cirrhosis. The prevalence of OHE and rifaximin utilization were estimated separately for the commercial and Medicare populations. In states with denominator/

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

numerator counts < 11, the regional prevalence was imputed based on US Census regions. **Results:** In 2020, the overall prevalence of OHE among commercial and Medicare patients with cirrhosis were 21.4% and 20.9%, respectively. Prevalence of OHE ranged across states from 17.3% in Illinois to 28.9% in New Mexico for the commercial population and 14.0% in Vermont to 28.9% in Utah for the Medicare population (Figure). In 2020, the overall prevalence of rifaximin utilization among commercial and Medicare patients with cirrhosis were 6.3% and 3.1%, respectively. Prevalence of rifaximin utilization was generally higher among the commercial population (range: 4.5% in Michigan to 10.6% in Kansas) relative to the Medicare population (range: 2.2% in Arizona to 5.6% in North Dakota). **Conclusion:** One in five patients with cirrhosis in the US were estimated to have OHE in 2020 both in commercially insured and Medicare populations; commercially insured patients had greater utilization of rifaximin despite the similar rates of OHE. Further research is warranted to evaluate possible reasons for state-level variability observed in the prevalence of OHE and rifaximin use, which may reflect state-specific policies, access to healthcare, and patient demographics.

3101-A | RELATIONSHIP BETWEEN SERUM ZINC LEVELS AND COMPLICATIONS IN PATIENTS WITH CIRRHOSIS COMPLICATED BY HEPATOCELLULAR CARCINOMA

Satoko Sawahashi[1], Akitoshi Sano[2], Jun Inoue[1], Masashi Ninomiya[3], Mio Tsuruoka[3], Kosuke Sato[4] and Atsushi Masamune[3], (1)Tohoku University Hospital, (2) Tohoku University Graduate School of Medicine, Sendai-shi, Japan, (3)Tohoku University Graduate School of Medicine, (4)Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Zinc deficiency is common in patients with cirrhosis, and hypozincemia is known to be a factor influencing hepatic encephalopathy. This study investigated the factors associated with zinc deficiency and complications in patients with cirrhosis complicated by hepatocellular carcinoma (HCC) in our hospital. **Methods:** We studied 731 patients who were admitted to our department for treatment of HCC from July 2008 to June 2021. Fasting blood samples were collected in the early morning after admission. Skeletal muscle mass index (SMI) was calculated by measuring muscle mass at the level of the third lumbar vertebra using the manual trace method from CT scans taken before and after treatment. The cut-off value for zinc was set at 80 μg/dL, according to the Japanese Society of Clinical Nutrition's "Guidelines for the Treatment of Zinc Deficiency 2018". **Results:** Among all patients, zinc deficiency was present in 625 (85.5%). Zinc deficiency was significantly higher in patients taking diuretics ($p < 0.0001$) and in those with hypoalbuminemia ($p < 0.0001$). Serum zinc levels showed a significant negative correlation with plasma ammonia ratio ($R = -0.30$, $p < 0.001$) and a positive

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

correlation with SMI (R = 0.11, p = 0.0039) and plasma BCAA levels (R = 0.47, p < 0.0001). Serum ammonia levels were significantly higher (P < 0.0001) in individual's with serum zinc levels below 80 μg/dL. In addition, SMI (p = 0.008) and plasma BCAA levels (p = 0.0002) were also significantly lower in these patients. **Conclusion:** Zinc deficiency was common in patients with cirrhosis complicated by HCC, especially in those taking diuretics and those with hypoalbuminemia. Zinc deficiency was associated with hyperammonemia, lower BCAA levels, and lower SMI. These findings highlight the importance of zinc deficiency in the management of complications in patients with cirrhosis complicated by HCC.

3102-A | RIFAXIMIN REDUCES HEALTHCARE UTILIZATION IN PATIENTS WITH CIRRHOSIS AND RECURRENT EPISODES OF HEPATIC ENCEPHALOPATHY: A RETROSPECTIVE EFFICACY STUDY

Diederick van Doorn[1], Kirsi Van Eekhout[1], Koos De Wit[1], Lubburtus C. Baak[2], Michael Klemt-Kropp[3], Bart Verwer[4], Philip W Friederich[5], Gijs J. De Bruin[6], Xander Vos[7] and Bart Takkenberg[1], (1)Amsterdam University Medical Center, Amsterdam, Netherlands, (2)Olvg, (3) Noordwest Ziekenhuisgroep, Alkmaar, (4)Spaarne Gasthuis, (5)Meander Medical Center, Amersfoort, Netherlands, (6)Tergooi MC, Hilversum-Blaricum, (7) Dijklander Ziekenhuis

Background: Hepatic encephalopathy (HE) is a frequent complication of cirrhosis. Rifaximin has been approved and included in guidelines for secondary prevention of HE, but there are few real-world data on its efficacy and impact on healthcare utilization. In this study, we aimed to assess the efficacy of rifaximin as secondary prophylaxis for HE in Dutch patients. **Methods:** We conducted a retrospective cohort analysis from March 2010 to May 2023 in patients from 7 hospitals in the province of North Holland (The Netherlands) who received rifaximin as secondary prophylaxis for HE. Data were collected and compared six months before and six months after the prescription of rifaximin. The primary endpoint was overall survival (OS). Secondary endpoints were the effect of rifaximin on the number of admissions, admission days, and emergency department visits for complications of cirrhosis. Healthcare utilization was defined as any contact with the hospital. **Results:** We included 108 patients [65% male; median age 67.5 (IQR: 60.3-75.0)] with a median Model for End-stage Liver Disease (MELD) score of 15 (IQR 12-20). Most common etiology was alcoholic liver disease (52%). Median post-prescription follow-up for the entire cohort was 62 months (95%CI 51-73) with 63% being deceased. Median OS was 24 months (95%CI 8.9-39). The mean number of HE episodes after rifaximin was 0.96 and was lower than before rifaximin (2.2; p < 0.001). In addition, healthcare utilization decreased from 5.5 contacts in the six months before rifaximin to 3 contacts in the six months after rifaximin (p < 0.001). The mean number of hospital admissions decreased from 1.7 admissions per patient (± 1.7) before to 1.0 admissions (± 1.3; p = 0.001) after starting rifaximin, but mean length of hospital stay did not differ. The mean number of outpatient visits decreased from 2.4 visits per patient (± 1.9) to 1.8 visits (± 1.4; p = 0.004). The mean number emergency department presentations without admission decreased from 0.35 per patient (± 0.6) to 0.17 (± 0.5; p = 0.039). **Conclusion:** Prescribing rifaximin as secondary prophylaxis for HE significantly reduces the number of episodes of HE and, consequently, the healthcare utilization of patients.

Disclosures: The following people have nothing to disclose: Diederick van Doorn, Kirsi Van Eekhout, Koos De Wit, Lubburtus C. Baak, Michael Klemt-Kropp, Bart Verwer, Philip W Friederich, Gijs J. De Bruin, Xander Vos, Bart Takkenberg

3103-A | RISK FACTORS AND PROGNOSTIC SCORES ASSOCIATED WITH HEPATOCELLULAR CARCINOMA DEVELOPMENT IN PATIENTS WITH HEPATITIS B VIRUS

Ploutarchos Pastras, Evangelos Zazas, Maria Kalafateli, Ioanna Aggeletopoulou, Efthymios Tsounis, Stavros Kanaloupitis, Konstantinos Zisimopoulos, Eleni-Eirini-Konstantina Kottaridou, Aspasia Antonopoulou, Dimosthenis Drakopoulos, Georgia Diamantopoulou, Aggeliki Tsintoni, Konstantinos Thomopoulos and Christos Triantos, University Hospital of Patras

Background: Hepatitis B virus (HBV) infection constitutes a common cause of hepatocellular carcinoma (HCC) development. The identification of HCC risk factors and the comparison of prognostic scores are essential for early diagnosis and prognosis. The aim of this observational, retrospective study is to evaluate the clinical risk factors associated with HCC in HBV. **Methods:** Seven hundred seventy consecutive adults (n = 770) [mean age:48 (range:36-61)] with HBV, referred to our outpatients' Hepatology clinic between

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

01/1993 and 09/2020, were evaluated. Clinical data were examined as potential HCC risk factors and 5 prognostic scores were compared. **Results:** Forty-five patients (4.8%) presented HCC, whereas 725 did not. HCC patients were older ($p < 0.001$, 95%CI:1.071-1.178), were mainly male ($p = 0.001$, 95%CI:2.326-28.644), had increased cirrhosis rate at baseline ($p < 0.001$, 95%CI:4.448-33.017), and alcohol abuse ($p = 0.036$, 95%CI = 1.056-5.216), presented elevated platelets ($p < 0.001$, 95%CI:1.004-1.014), body mass index ($p < 0.711$, 95%CI:0.96-1.03) and HBV DNA ($p < 0.448$, 95%CI = 0.795-1.261) compared to non-HCC patients. The prognostic scores, GAG-HCC (Guide with age, gender, HBV DNA, core promoter mutations and cirrhosis-HCC) (Area = 0.911, 95% CI:0.856-0.967), PAGE-B (Area = 0.856, 95%CI:0.798-0.915), CU-HCC (Chinese University-HCC) (Area = 0.753, 95%CI:0.664-0.841), FIB-4 (fibrosis-4) (Area = 0.769, 95%CI:0.690-0.847), REACH-B (risk estimation for hepatocellular carcinoma in chronic hepatitis B) (Area = 0.804, 95%CI:0.736-0.871) were compared by ROC curve. Kaplan Meier Analysis was only used to GAG-HCC and PAGE-B scores (both $p < 0.001$ in high score for HCC occurrence). **Conclusion:** Most patients who developed HCC were older men, with liver cirrhosis, history of alcohol consumption and lower platelet values. GAG-HCC and PAGE-B scores appear to be reliable prognostic factors for the evaluation of HCC development risk in HBV patients.

3104-A | SLEEP DISTURBANCE IN PATIENTS WITH CIRRHOSIS AND TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT

Ming Zhao, Xuefeng Luo, Xiaoze Wang and Yuling Yan, West China Hospital, Sichuan University

Background: Sleep disturbance (SD) is common in patients with cirrhosis and may lead to poor quality of life. Data regarding post-TIPS SD is scarce. The present study was designed to investigate the incidence and outcomes of post-TIPS SD. **Methods:** From August 2018 to November 2019, 73 patients treated with TIPS were prospectively enrolled. The Pittsburgh Sleep Quality Index (PSQI) used to assess sleep quality, and the presence of hepatic encephalopathy was evaluated using the West Haven criteria before and after TIPS. The primary outcome was the incidence of SD after TIPS. **Results:** 19 patients (26%) were the new onset of SD after TIPS and the median time from TIPS creation to the occurrence was 67 (40-98) days. Minimal hepatic encephalopathy (MHE) after TIPS (OR = 3;95% CI 1,8.78; P = 0.046) was demonstrated as an independent risk factor for SD. Five of six (83%) patients with SD improved after treatment with eszopiclone. Ten of thirteen (77%) patients with SD improved spontaneously without treatment. The incidence of MHE in patients with SD was higher than that in patients without SD (58% vs 31%, P = 0.04). **Conclusion:** The incidence of SD is not uncommon in patients who underwent TIPS. MHE is an independent risk factor associated with post-TIPS SD. Eszopiclone may be effective and safe for patients with SD after TIPS. ClincialTrials.gov number, NCT03685994.

3105-A | SMARTPHONE APPLICATION BASED LACTULOSE TITRATION FOR PREVENTION OF HEPATIC ENCEPHALOPATHY

Beatriz Sordi Chara[1], Kamalpreet S. Hara[2], Daniel Penrice[2], Kathryn A. Schmidt[1], Asaf Kraus[3], Jacob Anstey[3], David Tiede[3], Vijay Shah[2], Patrick S. Kamath[1] and Douglas A. Simonetto[2], (1)Mayo Clinic, Rochester, MN, (2)Mayo Clinic Rochester, Rochester, MN, (3)Dieta Health, Oak Park, CA

Background: Lactulose is the first line treatment for Hepatic Encephalopathy (HE). Patients are instructed to self-titrate to achieve 2 to 4 bowel movements (BM) per day. The mobile application “Dieta Health” is a digestive health tracking tool designed to analyze pictures of stools taken by users and provide an Artificial Intelligence (AI) derived interpretation of the stool characteristics, including the Bristol Stool Scale (BSS). In this pilot study, we enrolled subjects prescribed lactulose to determine if an AI enabled application could improve the rate at which patients met BM goals and the acceptance of such tool in this population. **Methods**: Our study included patients with cirrhosis receiving lactulose for prevention of HE, who were being followed at the Hepatobiliary Clinic at Mayo Clinic Rochester. The participants downloaded the Dieta app on their smartphones and were instructed to capture pictures of BM during the 4-week study period. Surveys were delivered to track daily intake of lactulose. During the first 14 days (lead-in phase), data was collected but no intervention was performed. For the last 2 weeks (intervention phase), patients received daily lactulose dose recommendations, according to a

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

decision algorithm that considered the BM frequency and BSS from the previous 24 hours, with a goal range BM target of 2-4 per day in the BSS 3-5 range. Compliance with the recommendations was classified as low if followed < 50% of the time, and high, e 50% of the time. **Results**: Currently, 39/50 patients have been enrolled, 24 (61.5%) completed/active in the study, and 15 (38.4%) dropouts. Two subjects received liver transplant during the period, and the rest dropped out due to individual reasons. Out of 235 recommendations sent, 63 (26.8%) suggested increasing dose, 88 (37.4%) maintaining current dose, and 35 (14.8%) had subjects decrease or stop lactulose for the day. Among the 13 patients who have completed the study, 74/163 (45.4%) represented days at goal for BM during the lead phase. During the intervention phase, patients with high compliance with the recommendations showed 30/59 (50.8%) days at goal. While low compliant patients were at goal for 38/95 (40.0%) days. Patients were compliant with image uploading, on average, 94% of the time. Average compliance with recommendations on the days image data was uploaded reached 43.6%. The End of Study Survey revealed that most patients (76.8%) found the app user-friendly, and (69.1%) found recommendations helpful. Nine (75%) subjects would always recommend the app, and 7 (53.7%) felt that symptoms were better controlled while using the application. **Conclusion**: This feasibility pilot study suggests that stool image assessment through a smartphone application may be a useful tool for accurate determination of BSS and personalized daily lactulose titration. Future iterations of the existing app interface, based on patient subject will likely improve patients` satisfaction and compliance.

3106-A | SPONTANEOUS PORTOSYSTEMIC SHUNTS AS A THERAPEUTIC TARGET FOR PORTOPULMONARY HYPERTENSION

Tsuyoshi Ishikawa[1], Natsuko Nishiyama[1], Maho Egusa[1], Tsuyoshi Fujioka[1], Daiki Kawamoto[1], Ryo Sasaki[1], Tatsuro Nishimura[1], Norikazu Tanabe[1], Issei Saeki[1] and Taro Takami[2], (1)Yamaguchi University Graduate School of Medicine, (2)-

Background: Spontaneous portosystemic shunts (PSSs) have been reported to contribute to the onset of portopulmonary hypertension (PoPH) via pulmonary arterial pressure elevation by increasing pulmonary flow volume due to progressive hyperdynamic circulation and pulmonary vascular resistance following vasoactive factor-mediated pulmonary vasoconstriction. The present study aimed to investigate changes in pulmonary hemodynamics and vasoactive factors by PSS occlusion and to demonstrate the effects of balloon-occluded retrograde transvenous obliteration (BRTO) on cardiopulmonary circulation in portal hypertension. **Methods:** This retrospective study included 40 patients with portal hypertension and spontaneous PSSs (median PSS diameter: 13.56 mm) who underwent BRTO at our hospital. Blood examination, chest computed tomography (CT), and transthoracic echocardiography (TTE) were performed before and 1 month after the procedure. We statistically analyzed the changes in serological and hemodynamic parameters by BRTO. **Results:** PSS occlusion led to significantly decreased levels of brain natriuretic peptide (53.9 to 40.0 pg/mL, $p < 0.05$), endothelin-1 (ET-1: 1.62 to 1.31 pg/mL, $p < 0.01$), and 5-hydroxytryptamine (52.6 to 45.5 ng/mL, $p < 0.05$). BRTO resulted in a significant reduction in the main pulmonary artery diameter (mPA-D: 26.5 to 25.6 mm, $p < 0.01$), mPA-D to ascending aorta diameter ratio (mPA-D/aAo-D: 0.83 to 0.81, $p < 0.05$), and inferior vena cava diameter (IVC-D: 18.4 to 17.7 mm, $p < 0.01$), as observed on the chest CT. TTE showed a decrease in tricuspid regurgitation pressure gradient (TRPG: 27.5 to 24.9 mmHg, $p = 0.06$) by the occlusion of PSSs. Additionally, reductions in mPA-D, mPA-D/aAo-D, and TRPG following BRTO were equivalent in patients with PSS e 13.56 mm (large PSS group, $n = 20$) and those with PSS < 13.56 mm (small PSS group, $n = 20$). However, postoperatively, a significant decrease in

IVC-D (18.1 to 17.4 mm, $p < 0.01$) was observed only in the large PSS group; conversely, a significant decrease in ET-1 levels (1.56 to 1.09 pg/mL, $p < 0.01$) was observed only in the small PSS group, suggesting a different mechanism for regulating pulmonary hemodynamics by the PSS diameter. **Conclusion:** Besides preventing vasoactive factors from entering the pulmonary circulation without being inactivated by hepatic metabolism, BRTO may also decrease pulmonary flow volume, thereby improving cardiopulmonary hemodynamics. Thus, PSS occlusion could be a potential therapy for PoPH through pulmonary flow control and vasoactive factor regulation regardless of the degree of portosystemic shunting.

Background: Bacterial infections in cirrhosis are linked to higher mortality. The global burden of multi-drug resistance (MDR) is on the rise but regional data in China remains unavailable. We aimed to investigate infection and impact of regional variations on outcome across a national population of inpts with cirrhosis. **Methods**: We collected data from pts non-electively admitted with cirrhosis at 23 centers in China from 2018 to 2019. Data were collected for demographics, comorbidities, etiology of cirrhosis, cause of admission, medical history and hospital course. All infections were confirmed with prespecified criteria and clinically suspected without evidence were excluded. Once infection was diagnosed, the characteristics, microbiology, antibiotic and outcome data were collected. Patients were followed until death, transplantation, or 90-day post-discharge. **Results**: Infection was confirmed in 342 of 1294 pts (26%) among from 6 administrative regions. Infection characteristics A total of 372 episodes (#) of infection were confirmed with balanced source of acquisition (31% community, 39% health-care, 30% nosocomial). No.1 type was pneumonia (45%) followed by SBP (23%) and spontaneous bacteremia (11%). Organisms were

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

identified in 106 # (29%) with 62% GNB, 20% GPC and 9% fungi. MDR was confirmed in 14% of all # and 57% in # with isolated organisms. Regional variations EastNorth sites had the highest infection rate, yet lowest rate of organism isolation and MDR infection than other sites, whereas WestNorth sites were literally the opposite (Fig.1A). Despite of the highest rate of MDR infection in WestNorth sites, the resolution of infection was highest with the highest rate of eABT efficacy (44 vs 26% in WestSouth and < 20% in the rest regions).Infection type and pathogens varied significantly across regions (Fig.1B). Independent risk factors for MDR infection were infection in WestNorth China, prior infections before hospitalization, and UTI or bacteremia. Patient outcome Occurrence of infection significantly decreased 28-, 90-day transplant-free survival, leading to more ACLF, AKI and ICU transfer, longer hospital stay and more readmission after discharge. (Fig.1C). eABT were given promptly (within 24h of infection) in 76% and initiated with broad coverage in 67% of infections, leading to an overall 81% of resolution. Multivariable analysis demonstrated that infections with inefficient eABT are associated with 7- and 4-fold risk of 28- and 90-day mortality, respectively, independent of overt ascites, ACLF and AKI (Fig.1D). **Conclusion:** In this national cohort of inpatients with cirrhosis in China, bacterial infection is prevalent and MDR bacteria is emerging with regional variations and may be underestimated due to low identification of pathogens. Future work should focus on improving microbiology and antibiotic resistance data availability in guiding effective antibiotic treatment while suppressing MDR spread.

3108-A | SYSTEMATIC UNDERCOUNTING OF OVERT HEPATIC ENCEPHALOPATHY HOSPITALIZATIONS IDENTIFIED BY USING HOSPITAL-ADMINISTERED MEDICATION DATA

Arun Jesudian[1], Patrick Gagnon-Sanschagrin[2], Jessica Maitland[2], Deborah Chan[2], Kana Yokoji[2], Annie Guérin[2], Zeev Heimanson[3], Ankur A Dashputre[4], Brock Bumpass[4], Olamide Olujohungbe[4], Danellys Borroto[4] and George J. Joseph[4], (1)Weill Cornell Medicine, NY, (2)Analysis Group, Inc., (3)Salix Pharmaceuticals, (4) Bausch Health

Background: Overt hepatic encephalopathy (OHE) is a serious neurological disorder, and OHE hospitalizations are burdensome for patients, caregivers, and the healthcare system. The absence of an OHE-specific diagnosis (dx) code may lead to an underestimation of the burden of OHE hospitalizations. This study used dx codes in conjunction with hospital-administered medications to identify OHE hospitalizations in the United States among insured adult patients. **Methods:** OHE hospitalizations were identified in the PINC AI™ Healthcare Database (PHD; 2015–2022). Hospitalizations with a dx for other rifaximin indications (traveler's diarrhea/irritable bowel syndrome with diarrhea) were excluded. OHE hospitalizations were defined as follows: OHE as a primary dx (definition 1), or in-hospital rifaximin/lactulose use combined with a dx for altered mental status, unspecified encephalopathy, or cirrhosis (definition 2). Hospitalization characteristics (treatments, diagnoses), hospital characteristics (urban/rural, bed size), and outcomes (billing charge [2022 USD], length of stay [LOS]) were descriptively reported. Outcomes were assessed separately for the two definitions of OHE hospitalizations and for Medicare and commercially insured patients. **Results:** There were 33,127 OHE hospitalizations identified based on definition 1 and 99,217 additional OHE hospitalizations identified based on definition 2. OHE hospitalizations based on definition 1 had a mean hospital billing charge of $56,648, a mean LOS of 5.2 days, and the majority received in-hospital lactulose (91.9%; average time to first dose: 0.2 d) and/or rifaximin (61.9%; average time to first dose: 0.7 d). OHE hospitalizations based on definition 2 had a mean hospital billing charge 2.5 times higher ($139,870) and a mean LOS 2.0 times longer (10.4 d) than those based on definition 1, and the majority received in-hospital lactulose (96.4%; average time to first dose: 1.9 d) and/or rifaximin (55.3%; average time to first dose: 2.6 d). OHE hospitalizations, irrespective of definition 1 or 2, had similar rates of OHE-related medication administration, comorbidities, and hospital characteristics. Results were consistent irrespective of insurance type. **Conclusion:** Identifying OHE hospitalizations solely based on the presence of a primary diagnosis for OHE significantly

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

underestimates the rate, LOS, and costs of OHE hospitalizations.

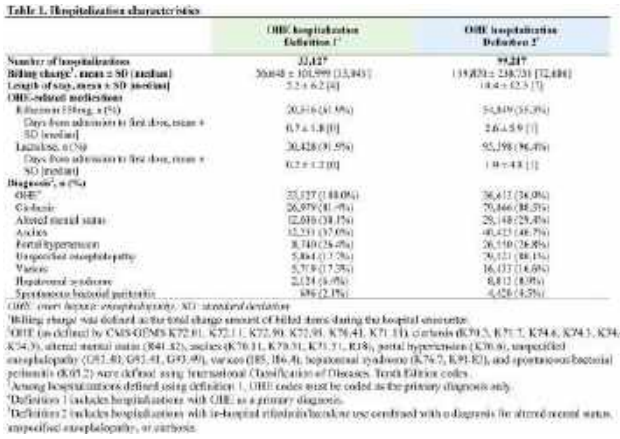

Table 1. Hospitalization characteristics

	OHE hospitalization Definition 1*	OHE hospitalization Definition 2†
Number of hospitalizations	33,127	99,217
Billing charge‡, mean ± SD (median)	50648 ± 101,999 (33,943)	139,820 ± 238,731 (72,686)
Length of stay, mean ± SD (median)	5.2 ± 6.2 (4)	10.4 ± 12.3 (7)
OHE-related medications		
Rifaximin (550mg, n (%))	20,316 (61.3%)	54,849 (55.3%)
Days from admission to first dose, mean ± SD (median)	6.7 ± 5.8 (5)	2.6 ± 5.9 (1)
Lactulose, n (%)	30,428 (91.9%)	95,398 (96.1%)
Days from admission to first dose, mean ± SD (median)	0.2 ± 1.2 (0)	1.9 ± 4.8 (1)
Diagnosis§, n (%)		
OHE*	33,127 (100.0%)	36,417 (36.7%)
Cirrhosis	26,879 (81.1%)	79,466 (80.1%)
Altered mental state	12,689 (38.3%)	29,148 (29.4%)
Ascites	15,231 (37.6%)	40,423 (40.7%)
Portal hypertension	8,740 (26.4%)	26,510 (26.8%)
Unspecified encephalopathy	5,864 (17.7%)	20,521 (20.1%)
Varices	5,719 (17.3%)	16,037 (16.2%)
Hepatorenal syndrome	2,124 (6.4%)	8,812 (8.9%)
Spontaneous bacterial peritonitis	696 (2.1%)	4,458 (4.5%)

OHE, overt hepatic encephalopathy; SD, standard deviation.
*Billing charge was defined as the total charge amount of billed items during the hospital encounter.
†OHE (as defined by CMS-HCPCS: K72.01, K72.11, K72.90, K72.91, K76.41, K71.10) cirrhosis (K70.3, K71.7, K74.6, K74.3, K74.4, K74.5), altered mental status (R40.42), ascites (K76.11, K76.81, K71.51, R18), portal hypertension (K76.6), unspecified encephalopathy (G93.40, G93.41, G93.49), varices (I85, I86.4), hepatorenal syndrome (K76.7, K91.82), and spontaneous bacterial peritonitis (K65.2) were defined using International Classification of Diseases, Tenth Edition codes.
‡Among hospitalizations defined using definition 1, OHE codes must be coded as the primary diagnosis only.
§Definition 1 includes hospitalizations with OHE as a primary diagnosis.
¶Definition 2 includes hospitalizations with in-hospital rifaximin/lactulose use combined with a diagnosis for altered mental status, unspecified encephalopathy, or cirrhosis.

3109-A | TASTE AND SMELL CHANGES AFFECT EATING-RELATED QUALITY OF LIFE AND ARE LINKED WITH COGNITIVE IMPAIRMENT IN CIRRHOSIS AND RENAL FAILURE PATIENTS

Andrew Fagan[1], Courtney Brown[2], Mary Leslie Gallagher[3], Travis Mousel[1], Michael Fuchs[4], Puneet Puri[5], Brian C. Davis[6], James Wade[5], Nilang Patel[1] and Jasmohan S. Bajaj[7], (1)Virginia Commonwealth University and Richmond VA Medical Center, (2) Richmond VAMC, (3)McGuire Veterans Affairs Medical Center, (4)Mcguire Veterans Affairs Medical Center, Moseley, VA, (5)Virginia Commonwealth University, (6) Hunter Holmes McGuire VA Medical Center, (7)Virginia Commonwealth University and Central Virginia Veterans Healthcare System, Richmond, VA

Background: Cirrhosis is linked with poor nutrition, which could partly be due to anorexia in hepatic encephalopathy (HE) & coexistent renal failure. Taste & smell perception affect appetite but their role in cirrhosis ± dialysis are unclear. Aim: Define impact of cognitive impairment in cirrhosis ± dialysis on taste & smell perception & study their impact on eating-related QOL. **Methods**: Healthy people & outpts with cirrhosis (± decompensation), on dialysis underwent taste & smell tests, cognitive testing using (PHES, high = better, Stroop, high = worse), SAS questionnaire for olfactory impact on life (high = worse) and quality of life (QOL) testing using Sickness Impact Profile (SIP, high = worse), which also has an "eating" QOL component. Pts with past/current COVID-19, current/recent alcohol or tobacco use were excluded. Tastes studied were sweet, sour, salty, brothy & bitter. Smell was tested using the NIH toolbox. Taste & smell results were compared between groups & correlated with cognition. Multi-variable analysis for taste/smell & eating portion of SIP was performed. **Results**: 59 subjects (22 healthy, 21 cirrhosis & 16 dialysis), predominantly men, were included (fig A). Of the cirrhosis pts, 8 were compensated, 13 decompensated (11 HE; all lactulose/8 rifaximin, MELD 11). Diabetes was similar across diseased pts. Taste & smell test: Controls had the best taste discrimination while cirrhosis & dialysis pts were similarly impaired; no impact of HE was seen. Sweet & sour tastes were most affected. While smell detection was not different, diseased groups had worse SAS results (FigA). Correct taste and smell were linked ($r = 0.5, p < 0.001$). Diabetes did not affect taste/smell.
Cognitive tests & QOL: Eating-related and overall QOL was worst in advanced pts (Fig B). Stroop & PHES impairment were also worse in diseased pts vs controls. Taste was significantly correlated with PHES ($r = 0.4$, $p = 0.02$) and Stroop regardless of HE or dialysis (Fig B). Smell perception percentile was only correlated with Stroop (Fig C).
Multivariable analysis: for *taste*, high (or good) PHES (T value 2.5, $p = 0.01$) & smell results (2.2, $p = 0.03$) were contributory, while for *smell*, taste correct results (T value 2.6, $p = 0.02$), low (= good) Stroop (-0.32, $p = 0.008$) & age (2.2, $p = 0.03$) were linked. Eating impairment on SIP was linked with high (= worse) Stroop (T value 2.2, $p = 0.03$) & high (= worse) SAS smell QOL questionnaire (2.8, $p = 0.008$). **Conclusion**: Taste perception and smell-related quality of life in cirrhosis is significantly impaired compared to controls and is similar to dialysis pts. Smell-related QOL & advanced disease affected eating behavior. Cognitive impairment, especially on Stroop, rather than simple HE/decompensation was linked with taste and smell. Altered taste and smell perception should be considered as a contributor towards poor nutrition, eating and QOL in patients with cirrhosis and renal failure, especially those with cognitive impairment.

3110-A | THE ASSOCIATION BETWEEN ANGIOTENSIN CONVERTING ENZYME INHIBITOR OR ANGIOTENSIN RECEPTOR BLOCKER EXPOSURE AND PROGRESSION OF CIRRHOSIS

Roy X Wang, University of Pennsylvania, Marina Serper, University of Pennsylvania, Philadelphia, PA, United States, Tamar H. Taddei, Yale University, New Haven, CT, David E. Kaplan, Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA and Nadim Mahmud, Hospital of the University of Pennsylvania

Background: Angiotensin converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARB) may reduce fibrosis, portal hypertension, and hepatic decompensations in patients with chronic liver disease or compensated cirrhosis. However, the clinical benefits and role of ACEi/ARB in cirrhosis remains unclear. To characterize this, we evaluated the association between ACEi/ARB and progression of cirrhosis in a national cohort. **Methods:** Using the Veterans Health Administration, we performed a retrospective, active comparator new user study of patients with Child-Turcotte-Pugh (CTP) Class A cirrhosis newly initiated on ACEi/ARB or calcium channel blockers (CCB, comparator). Kaplan-Meier analysis was used to evaluate unadjusted associations between medication exposure and incident development of CTP Class B/C cirrhosis. Inverse probability treatment weighting (IPTW) was used to balance key confounders in Cox regression analyses. Subgroup analyses characterized the impact of diabetes, heart failure, and chronic kidney disease on the association between ACEi/ARB exposure and development of CTP Class B/C Cirrhosis. **Results:** The cohort included 588 ACEi/ARB and 249 CCB new initiators. ACEi/ARB users were more likely to have a higher BMI (29.6 vs 27.5 $p < 0.001$), have lower stages of CKD, and more metabolic comorbidities including diabetes, coronary artery disease, and heart failure with reduced ejection fraction. In unadjusted Kaplan-Meier analysis, ACEi/ARB exposure was not associated with incident development of CTP Class B/C cirrhosis ($p = 0.97$, Figure A). Similarly, in fully adjusted IPTW Cox regression, ACEi/ARB exposure was not associated with development of CTP Class B/C cirrhosis (hazard ratio [HR] 0.85, 95% confidence interval [CI] 0.70-1.03, $p = 0.10$, Figure B). In subgroup analyses, ACEi/ARB exposure was associated with reductions in development of CTP Class B/C cirrhosis in patients with diabetes, without heart failure, and with early stage CKD (Stage 0-2) and associated with increased development of CTP Class B/C in patients with heart failure (Figure C). **Conclusion:** In patients with CTP A cirrhosis overall, ACEi/ARB exposure was not associated with development of CTP Class B/C disease, however we did identify relevant subgroups where the risk was either increased or decreased. Future research should better characterize cirrhosis patient subgroups that may benefit from ACEi/ARB exposure and elucidate underlying mechanisms.

3111-A | THE PREVALENCE OF CIRRHOTIC CARDIOMYOPATHY ACCORDING TO DIFFERENT DIAGNOSTIC CRITERIA

Lixia Ma and Zhang Jing, Beijing Youan Hospital Capital Medical University, Beijing, China

Background: Cirrhotic cardiomyopathy (CCM) is cardiac dysfunction in patients with end-stage liver disease in the absence of prior heart disease. Recently published criteria by 2019 Cirrhotic Cardiomyopathy Consortium set a lower threshold for reduced ejection fraction to diagnose systolic dysfunction in cirrhotic patients. We aimed to assess the prevalence of cirrhotic cardiomyopathy according to different diagnostic criteria. **Methods:** The patients with liver cirrhosis in Beijing You'an Hospital affiliated to Capital Medical University were collected continuously from 2020 to 2022. They were divided into CCM group and CCM-free group.The diagnosis of CCM was based on the Montreal 2005 World Congress of Gastroenterology criteria or 2019 Cirrhotic Cardiomyopathy Consortium criteria. Echocardiography was performed by an experienced cardiologist (ID) on a iE33 ultrasonography. **Results:** A total of 186 patients with cirrhosis fulfilled the inclusion criteria. Overall CCM prevalence of 2005 criteria was significantly higher compared to for and 2019 criteria : 32.26% VS 25.81% ($P < 0.0001$). The concordance was observed between the 2005 criteria and 2019 criteria (k = 0.403).In 35/48 patients of CCM according to 2019 criteria,Systolic dysfunction was more frequently diagnosed compared to 3/60 patients according to 2005 criteria(75% vs 5%, $P < 0.0001$).On the contrary,diastolic dysfunction was fewer frequently diagnosed in CCM according to 2019 criteria compared to 2005 criteria(25% vs 95%, $P < 0.0001$). **Conclusion:** A considerably higher prevalence of systolic dysfunction according to the 2019 criteria was observed. Long-term follow-up studies are needed to establish the validity of these criteria to predict clinically relevant outcomes.

Table5 Factors associated with the presence of diastolic and systolic dysfunction in CCM

	2019 Consortium criteria		P值	2005 Consortium criteria		P值
Dysfunction	Systolic	Diastolic		Systolic	Diastolic	
N(%)	36(75)	12(25)	**<0.001**	3(5)	57 (95)	**<0.001**

3112-A | THYROXINE LEVELS PREDICT THE DEVELOPMENT OF BRAIN FAILURE IN PATIENTS WITH CIRRHOSIS

Anand V. Kulkarni, Moiz Vora, Ramyasri Ramagundam, Sowmya T R, Shantan Venishetty, Manasa Alla, Mithun Sharma, Nageshwar D Reddy and Padaki Nagaraja Rao, Aig Hospitals, Hyderabad, India

Background: In-hospital development of overt hepatic encephalopathy (HE) is not uncommon. Until recently, there were no simple biomarkers to predict the

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

development of HE. A recent study reported that thyroxine levels predict the development of brain failure (grade 3-4 HE) in hospitalized patients. We aimed to validate the role of thyroid function tests in the prediction of brain failure. **Methods:** In this single-center prospective study, we enrolled consecutive patients with cirrhosis admitted to our hospital from September 10, 2022, to April 1, 2023. The primary objective was to assess the incidence of brain failure, and the secondary was to compare the characteristics of patients who developed brain failure, including baseline demographics, thyroid profile, duration of hospital stay, and in-hospital mortality. **Results:** A total of 164 patients (age-52.41 ± 11.03; NASH-36%; MELD NA-22.25 ± 6.95) without brain failure and acute-on-chronic liver failure were included in the study. Baseline characteristics, including age, sex distribution, comorbidities, the reason for admission, and MELD NA score, were similar among both groups. The most common indication for admission was infection (22%). The incidence of brain failure was 19.5% (95%CI, 13.35-27.6) during a mean hospital stay of 6.71 ± 4.25 days among 164 patients. Thirty-one percent of those who developed brain failure and 15% of those who did not develop brain failure were admitted for grade 1-2 HE. Total thyroxine (T4) levels were significantly lower in patients who developed brain failure compared to those who did not (5.2 ± 1.12 vs. 6.24 ± 1.88 mg/ml; P = 0.003). Free T4 levels were also lower in patients with brain failure (1.1 ± 0.31 vs. 1.25 ± 0.32 ng/ml; P = 0.01) (Figure). However, there was no difference in the T3, free T3, and TSH levels among the two groups. The duration of hospital stay was longer in patients who developed brain failure (8.56 ± 4.31 vs. 6.26 ± 4.13 d; P = 0.006). In-hospital mortality was higher in those who developed brain failure (28%) than those who did not (13%; P = 0.05). On univariate logistic regression analysis, grade 1-2 HE at admission (OR, 2.54 [1.05-6.17];P = 0.04), total thyroxine (0.64 [0.47-0.87];P = 0.005) and free T4 levels (OR, 0.17 [0.04-0.71];P = 0.01) predicted development of brain failure while on multivariate logistic regression analysis, only total thyroxine levels predicted the development of brain failure (odds ratio, 0.64 [0.47-0.88];P = 0.005). AUROC for T4 was 0.63% (95%CI, 0.53-0.72; P = 0.02) for the prediction of brain failure. **Conclusion:** Total thyroxine levels predict the development of brain failure in patients with cirrhosis admitted to the hospital. This simple economical biomarker is an excellent tool for the prediction of HE.

3113-A | TIME TICKS FASTER: TRENDS OF TIME TO DECOMPENSATION AMONG PATIENTS WITH CIRRHOSIS, 2011-2021

Bima J Hasjim[1], Mitchell Paukner[1], Mohsen Mohammadi[1], Praneet Polineni[2], Therese Banea[1], Lisa B. VanWagner[3], Andres Duarte-Rojo[4], Lihui Zhao[1], Sanjay Mehrotra[1] and Daniela P. Ladner[5], (1) Northwestern University, (2)Northwestern University, Chicago, IL, (3)University of Texas Southwestern Medical Center, (4)Northwestern University Feinberg Scho, (5)Northwestern Memorial Hospital

Background: The past decade has been marked by events that have effected cirrhosis management and its outcomes. We performed a population-based study in a large metropolitan area to investigate trends in time to decompensation over the past decade. **Methods:** We conducted a retrospective analysis of adult patients (> 17-years-old) with cirrhosis using the CAPriCORN database – a multicenter, electronic health record database in the Chicago metropolitan area from 2011-2021. Eras in the past decade were categorized into < 2014 (1/1/2011-12/31/2013), 2014-COVID (1/1/2014-1/19/2020), and COVID (1/20/2020-8/1/2021). Cirrhosis outcomes, frailty (defined by the Hospital Frailty Risk Score), and COVID-19 were defined by validated ICD and CPT codes. Time to decompensation were reported using the Kaplan Meier method. Cox proportional hazard models were used to identify the associated hazard of decompensation while controlling for clinical covariates. **Results:** Among 44,893 patients with cirrhosis, the mean (± SD) age was 59.4 (± 12.5) years; follow-up was 3.21 (± 3.28) years, 42.2% were women, 47.1% were Non-Hispanic White, 15.0% Black, 8.3% Hispanic and 44.5% were enrolled in Medicare/Medicaid. Patients who were diagnosed with cirrhosis more recently experienced faster times to decompensation compared to those who were diagnosed earlier in the decade (p < 0.001, *Figure*). Between eras, there were differences in frailty, age, and etiology at cirrhosis diagnosis (p < 0.001). Patients who had intermediate (HR:1.18, CI:1.13-1.24, p < 0.001) and high (HR:1.37, CI:1.30-1.45, p < 0.001) risk of frailty had an increased hazard of decompensation. When adjusting for frailty, there was no difference in hazard of decompensation between < 2014 and 2014-COVID era, although patients diagnosed in the COVID era had a higher hazard (HR:1.44, CI:1.33-1.56, p < 0.001). There was an interaction between HCV etiology and era of diagnosis – those diagnosed after 2014 had lower hazards of decompensation (p < 0.010).

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: In the last decade, patients experienced faster times to decompensation compared to those diagnosed earlier in the decade. In part, these differences may be associated with increasing frailty. Though this effect is seen across etiologies, patients with HCV had a lower hazard of experiencing a decompensation event among patients diagnosed with cirrhosis after 2014, which may reflect the effect of direct acting antivirals in these patients.

3114-A | TIPS PLACEMENT TO REDUCE PORTAL HYPERTENSION PRIOR TO BARIATRIC SURGERY IN MORBIDLY OBESE PATIENTS WITH CIRRHOSIS

Raluca Pais[1], Yasmina Chouik[2], Lucile Moga[3], Louise Lebedel[4], Caroline Jezequel[5], Maud Robert[6], Emilie Malézieux[7], Christine C. Silvain[8], Hélène Larrue[9], Delphine Weil Verhoeven[10], Laurent Genser[11], Jerome Dumortier[12], Vlad Ratziu[13], Dominique Thabut Damais[14] and Rudler Marika[1], (1)Aphp, (2)Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France, (3)Hôpital Beaujon, (4)CHU Caen, (5) CHU Rennes, (6)Hôpital Herriot, (7)CHU Montpellier, Montpellier, France, (8)CHU Poitiers, (9)CHU Toulouse, (10)CHU Besançon, (11)Pitié-Salpêtrière Hospital, (12) CHU Lyon, (13)Assistance Publique-Hôpitaux De Paris, Paris, France, (14)Groupement Hospitalier Aphp-Sorbonne Université, Hôpital De La Pitié-Salpêtrière, Paris, France

Background: Because of the increasing prevalence of non-alcoholic fatty liver disease (NAFLD), it is expected that more candidates to bariatric surgery (BarS) will have cirrhosis. In cirrhotic patients (pts), clinically significant portal hypertension (CSPH) increases mortality after abdominal surgery. We aimed to study the impact of pre-operative transjugular intrahepatic portosystemic shunt (TIPS) placement on the outcome of BarS in pts with cirrhosis. **Methods:** Multicentric retrospective cohort of pts with cirrhosis (histology or noninvasive methods) undergoing BarS. Hepatic venous pressure gradient (HVPG), and TIPS placement were performed before BarS according to centers' policy. The primary outcome was one-year decompensation-free survival in pts with TIPS (TIPS-g) or without pre-operative TIPS (no TIPS-g). Secondary outcomes were development of acute on chronic liver failure (ACLF) and acute decompensation (AD) at 28, 42, 90 days, 1 year after BarS. **Results:** Between 2010 and 2021, 50 pts were included (92% Child-Pugh A, MELD score 8 (6–13), male gender 46%, age 55 ± 12 yrs, BMI 38.3 ± 13 kg/m2, Roux-en-Y gastric bypass 56%, TIPS placement 18%). There were no significant differences at baseline between TIPS-g and no TIPS-g for age, gender, BMI, % of type-2 diabetes, or BarS procedure. At baseline, TIPS-g pts had more frequently previous decompensation (22% vs 0%, $p = 0.002$), more esophageal varices (EV) (large EV, 56% vs 0%, $p < 0.001$), a higher HVPG (14 (11-19.5) vs 7 (6.5-8) mmHg, $p < 0.001$), and a higher MELD score (10 (9.5-11) vs 7 (7-8), $p = 0.01$. After TIPS, mean HVPG decreased to 7 (IQR, 3-7) mmHg ($p = 0.027$), which was similar to mean HVPG in the no TIPS-g. The mean weight loss was 31 ± 12 kg at one year and similar between groups. Hospital stay after BarS was similar in the 2 groups ($p = 0.77$). The one-year decompensation-free survival was 80% (TIPS-g) and 90% (no TIPS-g), $p = 0.53$. All patients were alive one year after BarS. Two patients in the no TIPS-g developed transient grade 1 ACLF immediately after BarS, vs none in the TIPS-g. MELD score was higher in the TIPS-g at day 28, 42 and 90 after BaS ($p = 0.006$, $p = 0.008$, and $p = 0.004$), but one-year MELD score and AD were similar in the 2 groups ($p = 0.74$ and $p = 0.99$). **Conclusion:** In pts with cirrhosis and severe portal hypertension undergoing BarS, TIPS was successfully and safely performed and

reduced HVPG. This led to similar outcomes after BarS as in pts without TIPS placement.

3115-A | UNIQUE MORPHOMETRIC AND HISTOPATHOLOGIC FEATURES OF HEARTS IN PEDIATRIC CIRRHOSIS

Dalia A Bashir[1], Taylor Kaye Nack[1], Noelle Gorgis[1], Manpreet Virk[1], Kelby Fuller[1], N. Thao N. Galván[2], Kalyani Patel[1], Sanjiv Harpavat[3] and Moreshwar S Desai[1], (1)Baylor College of Medicine, (2)Baylor College of Medicine, Houston, TX, (3)Texas Children's Liver Center - Baylor College of Medicine, Bellaire, TX

Background: Cirrhotic cardiomyopathy (CCM) is a consequential co-morbidity in children with cirrhosis with adverse impact on perioperative outcomes. Despite the clinical relevance, little is known about the pathophysiology of pediatric CCM, as it has yet not been characterized beyond mere echocardiography (2DE). We aimed to review autopsy reports to identify morphometric and histo-pathologic features of the hearts in children with end stage cirrhosis to better define pediatric CCM. We hypothesized that *the hearts of children with end stage cirrhotic liver disease exhibit features on necropsy that are distinct from those without cirrhosis.* **Methods:** We retrospectively reviewed cardiac autopsy records of children with end stage liver disease listed/transplanted at our institution from 2004-2021. Those with incomplete autopsies, co-existing congenital heart defects and Alagille syndrome were excluded. Presence of hypertrophy, edema, inflammation, fibrosis, and other microscopic features were compared between those with and without cirrhosis of liver/graft at time of demise. Heart weights were documented at necropsy, and % increase in weights (from standard norms for age) were compared between groups. 2DEs done immediately prior (median days 7[IQR: 3,35]) to autopsy were correlated to cardiac necropsy findings. Statistics: Mann Whitney test for continuous variables and Fisher's exact test for categoric variables; Spearman (rho) for correlation. **Results**: Median [IQR] **Results:** Of 35 necropsies (median age 30 [10,68] months; 54% females), 18 (52%) had cirrhotic liver/graft confirmed on histology at necropsy. Compared to children with non-cirrhotic livers/grafts, those with cirrhosis had significantly higher heart mass indexed to height, % increases in heart weights from established norms, higher frequency of bi-ventricular myocyte hypertrophy, and endo-myocardial fibrosis (TABLE). Frequency of myocardial edema, inflammation, ischemia, and contraction band necrosis was comparable between groups (TABLE). Additionally, raw LV mass and LV mass indexed to height obtained on 2DE done prior to autopsy tightly correlated with raw heart mass (rho = 0.87; 95%CI (0.75-0.94); $p < 0.001$) and heart mass indexed to height (rho = 0.6; 95% CI (0.3-0.8); $p = 0.007$) obtained at time of autopsy. **Conclusion:** Cardiomegaly, interstitial myocardial fibrosis and bi-ventricular hypertrophy appear to be more prevalent in pediatric end stage cirrhotic liver disease. Discovery of bi-ventricular involvement and endo-myocardial fibrotic changes suggest a potential role for a systemic mediator in pathologic liver-heart interaction. Furthermore, a tight correlation of 2DE with cardiac necropsy findings support the use of 2DE as an effective non-invasive modality to detect CCM. Further studies are needed to identify the triggers/metabolites for CCM, so that treatments can be designed to halt/reverse the progression of this cardiomyopathy.

Parameter	Cirrhotic (n=18)	Non-cirrhotic (n=17)	p value
Age at death (mo)	19 [8,75]	32 [14,70]	0.4

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Patients with decompensated cirrhosis are associated with various complications alongwith increased inpatient mortality.However data regarding appropriate triaging of these patients is lacking.The study was aimed to identify risk factors and develop a machine learning model to predict mortality in cirrhotic patients presenting to the ER **Methods:** Cirrhotic Patients presenting to emergency room were prospectively enrolled between February 2023 to April 2023 . Baseline data at admission including demographics, laboratoty values were included.AI-modelling was done after appropriate mining, feature engineering, splitted randomly into train and test sets (70:30).The objective of the study was to identify risk factors in the ER for prediction of mortality in patients with liver cirrhosis **Results:** A total of 355 patients were included for the analysis; males(62.1%),MELD score 19 ± 3.6,predominant etiology ethanol(47.9%) and NASH(26.7%), overall mortality seen in 91(20.7%)patients. Triaging to ward/ high dependency unit(HDU)/ intensive care unit(ICU) was seen in 164(46.6%)/100(28.3%)/73 (20.7%) patients respectively with in -hospital ICU transfers(IH-ICU) in 39(11%)patients. Predominant patient complaints at ER included altered sensorium(n = 82(23.2%), bleeding(n = 71(20.1%), breathlessness requiring oxygen supplementation(n = 49(13.8%).Sepsis at admission alongwith (n = 43/12.1%) heamodynamic shock were significant (n = 42/11.9%) ($P < 0.01$).Nosocomial sepsis was seen in 18(5.1%) with overall SIRS at admission in 155(46.1%) patients.Mean arterial lactate was 2.6 ± 2.1mmol/L with presence of Acute Kidney Injury(AKI) in 56(15.9%)patients.Carbapenem use was reported in 121(34.1%) with antibiotic escalation in 161 (45.5%) patients($p < 0.01$).Door to antibiotic time /door to fluid time was 9.5 ± 4.4 mins/13.7 ± 7.3 mins ($p < 0.01$) respectively.On multivariate analysis NASH (O.R-3.3 95%C.I-1.41-7.42),history of ascitic tap(O.R-2.2 95% C.I-1.06-4.05),history of pneumonia(O.R-7.2 95% C.I-1.2-41.8),duration of hospital stay > 5 days(O.R-7.6 95% C.I-4.1-14.2), ICU admission(O.R-6.1 95% C.I-3.0-12.2) were found to be significant($p < 0.01$) factors for mortality. The REACH-ER model was formulated with AUROC-83.7 ($p < 0.01$), and a score > 28 predicted in-hospital mortality. Using neural networks the overall accuracy of the model was 89.96% with NPV 94% and specificity 95 %.The training cohort had an accuracy of 86% while testing cohort had an accuracy of 74%. The independent variables of importance included duration of hospital stay > 5days (100%)/ICU(96.6%)/NASH(88.2%)/Ascitic tap(48.5%)/ pneumonia(16.8%) **Conclusion:** The REACH-ER ML model can reliably predict mortality in cirrhotic patients presenting to the ER. Simple ML algorithms besides clinical syndromic presentation could help in treatment decisions, prognostications, and escalation of care including early transplant work-up

3117-A | VALIDATION AND CUTOFF TIME OF THAI ENCEPHALAPP STROOP TEST FOR DIAGNOSIS OF COVERT HEPATIC ENCEPHALOPATHY

Apiwat Augkaros[1], Atchara Sereepaiboonsub[1], Theeranun Sanpajit[1], Jasmohan S. Bajaj[2] and Sakkarin Chirapongsathorn[1], (1)Phramongkutklao Hospital and College of Medicine, Division of Gastroenterology and Hepatology, Department of Medicine, (2)Virginia Commonwealth University

Background: The EncephalApp Stroop Test was developed to diagnose covert hepatic encephalopathy (CHE). However, information regarding the best cut-off (Ontime+OFFtime) is still scant in outside North America populations. We aim to analyze the usefulness of this diagnostic method and to describe a cut-off value of the Thai version EncephalApp (Thai EncephalApp) stroop test to screen CHE in Thailand. **Methods:** In this cross-sectional and single-center study, median and 95% higher from the expected Stroop value for every healthy controls defined the

diagnosis of CHE. We evaluated gender, age, education, etiology of cirrhosis, Child-Pugh/MELD scores, and previous hepatic encephalopathy (HE). Healthy controls and patients without HE were compared for the task validation. The Chi-square and Mann-Whitney tests, and logistic regression analysis were used for statistical evaluation. **Results:** We included 171 patients with cirrhosis (79% male) and 144 controls (46% male) around 51y. Viral hepatitis (47%) was the major etiology of cirrhosis. The median MELD was 10 and Child-Pugh A was more frequent (84%). There was no significant difference in test results between controls and patients without HE. The regression formula in healthy people was made using age, gender, and education, of which only age and education were significant which a cut-off of > 175 sec defined the diagnosis of CHE (OffplusOn = 121 + 1.35 Age[year] – 1.77 Study[year]) which found 39% of CHE. Patients with CHE on Thai EncephalApp Stroop Test was additive to MELD score with p = 0.06 on multivariate analysis. **Conclusion:** Thai EncephalApp Stroop Test may be useful in a stepwise diagnosis algorithm or even as a stand-alone screening tool to detect CHE in Thai patients with cirrhosis.

3118-A | VALIDATION AND IMPACT OF RECOMPENSATION USING BAVENO VII CRITERIA AFTER SUSTAINED VIRAL RESPONSE AMONG PATIENTS WITH HEPATITIS C-RELATED DECOMPENSATED CIRRHOSIS TREATED WITH DIRECT ACTING ANTIVIRALS

Luis Alejandro Rosales Renteria[1], Diana Laura López Rubio[1], Nancy Midory Hirata Medina[1], Hiram Jaramillo[1], Jocelin Sandoval Briones[1], Laramie Tinoco[1], Diana Sandoval Gutierrez[1], David Prieto Nava[2], Araceli Bravo Cabrera[3], Rodolfo Ruiz Luján[1], Maria Sarai González Huezo[2] and Jesús Alberto Camacho Escobedo[1], (1) Hospital General De Mexicali, (2)Centro Médico Issemym, (3)Centro Médico Issemym, Estado De Mexico

Background: Chronic hepatitis C virus (HCV) infection is a leading cause of chronic liver disease (CLD) worldwide. Its prevalence is of particular significance in developing countries. Generalized access to Direct Acting Antivirals (DAA) in public healthcare has greatly increased the rates of sustained virological response (SVR), but evidence that correlates it with clinically significant improvement is lacking. The Baveno VII consensus has recently proposed the term of cirrhosis recompensation as objective evidence of clinical improvement. In the present study, we aimed to validate this new definition in patients with HCV-related cirrhosis treated with DAA after SVR. **Methods:** This is a single center, prospective cohort study, which included all patients with decompensated ACLD (dACLD) due to HCV, older than 18 years, that had received DAA and achieved SVR, at our institution in Mexicali, Mexico, from January 1, 2018, to October 31, 2021. Baseline patient characteristics were collected, participants were followed up for clinical events, biochemical tests, and VCTE at the time of SVR, 12 weeks and 52 weeks after achieving virological cure, the primary endpoint was cirrhosis recompensation rate according to BVII definition, direct comparison of variables and outcomes was established between those who reached the PO. Secondary outcomes were improvement in CTP, MELD-Na, LS by VCTE, and absolute platelet count. Multivariate regression was used to identify predictors of recompensation. Patients with an additional etiology of CLD, severe

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

extra-hepatic organ dysfunction or active malignancies were excluded. **Results:** A total of 108 patients that were treated with DAA and achieved SVR were studied, 67% were men with a median of 51 years in the whole cohort. The most frequent multimorbidity was T2DM (11.5%). At 52 weeks, 57 patients achieved resolution of ascites, EH, and absence of recurrent variceal bleeding for at least 12 months (52.7%). Compared to those that did not achieve recompensation, recompensated patients had a lower Median MELD-Na at 12 and 52 weeks (12 vs 15; 10 vs 14, respectively), were more often classified as CTP A at the same cutoffs (66% vs 39% week 12; 92% vs 43% week 52), had a higher number of patients with > 150,000 Plt (87% vs 37% at week 52), and more frequently had a LS < 12 kPa by VCTE at 52 weeks (47% vs 13%). As regards to predictors for reaching the primary outcome, a reduction in MELD-Na > 2 absolute points at week 12 or 52 (OR 1.06, 95% CI 1.03-1.10, $p < 0.05$), and an overall MELD-Na equal or < 11 (OR 1.10, 95% CI 1.05-1.15, $p < 0.05$) were the factors with the higher odds of cirrhosis recompensation. **Conclusion:** Our study showed that among patients with HCV infection and decompensated cirrhosis treated with DAA and SVR, achieving recompensation correlated to an improvement in clinical scores, a higher proportion of patients with normal platelets and overall, a lower LS by VCTE.

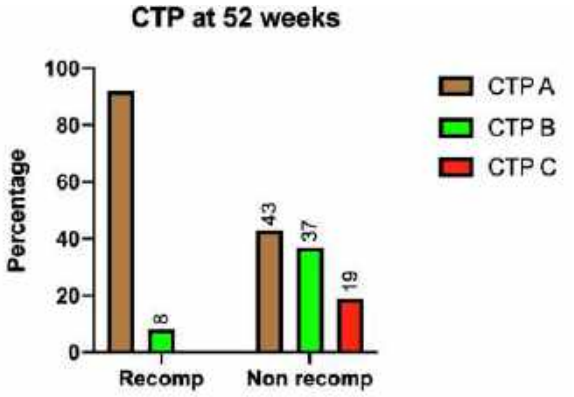

Figure 1. *CTP score at 52 weeks amongst patients that achieved recompensation vs those who did not.*
At 52 weeks, 92% of patients with recompensation were classified as **CTP A**, compared to only 43% of patients without recompensation. 8% of recompensated patients were **CTP B**, but that number increased to 37% for non-recompensated. Finally, 19% patients without recompensation remained at **CTP C**.

Disclosures: The following people have nothing to disclose: Luis Alejandro Rosales Renteria, Diana Laura López Rubio, Nancy Midory Hirata Medina, Hiram Jaramillo, Jocelin Sandoval Briones, Laramie Tinoco, Diana Sandoval Gutierrez, David Prieto Nava, Araceli Bravo Cabrera, Rodolfo Ruiz Luján, Maria Sarai González Huezo, Jesús Alberto Camacho Escobedo

3119-A | VENOUS THROMBOEMBOLISM RISK IN PATIENTS WITH CIRRHOSIS INFECTED WITH COVID-19: A MULTI-CENTER PROPENSITY-MATCHED ANALYSIS.

Khadija Naseem[1], Abdullah Sohail[2], Ahmad Khan[3] and Talal Adhami[1], (1)Cleveland Clinic Foundation, (2) University of Iowa, (3)Case Western Reserve University

Background: Previous studies have demonstrated that COVID-19 infection predisposes to developing venous thromboembolic events (VTE), and the risk is substantially increased in patients with underlying coagulopathic disorders, including cirrhosis. Using a large research network, this study aimed to examine the incidence of VTE in patients with cirrhosis, both with and without concurrent COVID-19 infection. **Methods:** We queried the TriNetX electronic health records network (with over 100 million patients) between January 1, 2020, and December 31, 2022, to identify all the patients with cirrhosis. These patients were then stratified into two groups (COVID and non-COVID) based on the presence or absence of COVID-19. Two well-matched cohorts (with and without COVID) were created using a 1:1 propensity score matching model. Patients under 18 years old, with pre-existing VTE diagnoses, or already receiving therapeutic anticoagulation were excluded. We estimated the incidence of VTE, and using a Cox model, we compared incidences of VTE in propensity score-matched cohorts of cirrhosis patients with and without COVID-19. We also compared the incidence of pulmonary embolism (PE), portal vein thrombosis (PVT), and deep venous thrombosis (DVT). **Results:** We identified a total of 170,988 patients with cirrhosis, out of which 62,423 (36.50%) were in the COVID group and 108,565 (63.50%) were in the non-COVID group. The patients in the non-COVID group were older (60.14 ± 13.24 vs. 59.37 ± 13.3, $P < 0.01$) than the COVID group, and majority were male and Caucasian. The COVID group had substantially higher comorbidities, including hypertension, diabetes mellitus, and malignancy (Table 1). Before propensity score matching, the COVID group had a greater incidence of VTE compared to the non-COVID group (0.88% vs. 0.42%, odds ratio [OR] 2.10, 95% confidence interval [CI] 1.85-2.39). This difference persisted after propensity score matching (0.88% vs. 0.44%, OR 2.24, 95% CI 1.90-2.63). Additionally, on subgroup analysis, the COVID group had a higher incidence of PE, PVT, and DVT. **Conclusion:** Our findings indicate that patients with cirrhosis and concurrent COVID-19 infection have a twofold increased risk of developing VTE compared to those without COVID-19. However, further prospective studies are required to determine whether this patient population will benefit from a prophylactic full-dose anticoagulation approach

3120-A | VIBES MNEMONIC: A SYSTEMATIC APPROACH TO MANAGING COMPLICATIONS OF CIRRHOSIS IMPROVES RESIDENT CONFIDENCE

Rachael Mahle, Marc S Sherman and Esperance AK Schaefer, Massachusetts General Hospital

Background: Management of patients with cirrhosis is challenging and complex, and important elements of clinical care may be overlooked. A systematic approach to patients with cirrhosis was developed at our institution in 2009 which is used widely by housestaff and medicine faculty. The framework, titled VIBES, highlights cirrhosis-specific complications including Volume (ascites, hepatic hydrothorax, renal function), Infection (spontaneous bacterial peritonitis (SBP)), Bleeding (varices, portal hypertensive gastropathy, portal vein thrombosis), Encephalopathy (hepatic encephalopathy (HE)), and Screening/Surveillance (hepatocellular carcinoma (HCC) screening, hepatitis vaccination). We evaluated if this structured approach improves trainee comfort with care of patients with cirrhosis. **Methods:** Internal medicine residents were surveyed prior to and 3 months into intern year. During the 3 month window, trainees were educated on the VIBES framework formally (faculty lecture) and informally (residents). The survey assessed the impact of incorporating the VIBES structure on their comfortability managing patients with cirrhosis using Likert scales. **Results:** 73 responses were received (n = 43 for the pre-survey and n = 24 for the post-survey). There was a statistically significant increase in reported intern comfort of the management of ascites ($p < 0.01$), SBP ($p < 0.01$), esophageal varices ($p < 0.01$), HE ($p < 0.01$), and HCC ($p = 0.047$). Management of hepatorenal syndrome trended towards but did not reach significance ($p = 0.12$). Among respondents, 75.0% felt the mnemonic broadened their differential for patients with cirrhosis, 95.6% felt it improved quality of care for patients with cirrhosis, and 87.5% felt it helped them more clearly communicate care for patients with cirrhosis with other providers. **Conclusion:** Use of the VIBES framework significantly improves trainee confidence in managing patients with cirrhosis in nearly all facets of management. In addition, trainees unanimously reported the approach broadened their differentials, improved inter-provider communication, and overall improved the quality of care for patients with cirrhosis. Early education and utilization of this framework in medical training has the promise of improving care of this complicated patient population. Widespread use of this simple conceptual framework and mnemonic has the potential to reduce provider-level contribution to the considerable variation in inpatient cirrhosis mortality.

3121-A | ZINC DEFICIENCY ASSOCIATED WITH INCREASED RISK OF MORTALITY IN PATIENTS WITH ADVANCED LIVER DISEASE

Ronald Samuel[1], Anjiya Shaikh[2], Tzu-Hao (Howard) Lee[1], Vinh Vincent Tran[1], Kadon Caskey[1], Scott Berger[1], Basim Ali[1], Cameron Goff[1], Christo Mathew[1], Marguerite Poche[1], Prisca Pungwe[1], Norvin Hernandez[1], Richard Bui[1], Ryan Ward[1], Ankur Patel[1], Seulgi Kim[1], Zahraa Al Lami[1], Ruben Hernaez[1], Abbas Rana[1], Rise Stribling[1], John A. Goss[1], Hashem B. El-Serag[1], Fasiha Kanwal[1] and George Cholankeril[1], (1) Baylor College of Medicine, (2)University of Connecticut

Background: Zinc deficiency has been associated with complications in patients with cirrhosis, such as hepatic encephalopathy. However, the impact of zinc deficiency on mortality in these patients is poorly understood. We aimed to assess the effect of zinc deficiency on liver transplant (LT) waitlist outcomes and the role of zinc supplementation. **Methods:** We performed a retrospective cohort study in all adult patients added to the LT waitlist at our institution from January 2017 to August 2018 with follow-up through April 2023. Serum zinc levels were collected in all patients prior to listing as part of LT evaluation protocol. Patients with zinc deficiency, defined as Zinc levels < 60 (mcg/dL), were prescribed parenteral zinc supplementation (50 mg daily). Repeat serum zinc levels were collected within 3-12 months after initiation of supplementation. Differences in repeat

zinc level were compared using paired t-test. Multivariable Fine and Gray analyses were performed to assess the risk of waitlist dropout (death or deterioration) from baseline zinc level, accounting for competing risks of LT and delisting for improvement. **Results:** Of the 300 patients listed for LT, 69.3% (n = 208) had zinc deficiency. Compared to patients with normal zinc levels, patients with zinc deficiency had a higher proportion of female, alcohol-associated liver disease (ALD), and absence of hepatocellular carcinoma (HCC). Patients with zinc deficiency also had a significantly higher MELD-Na score at listing, and were more likely to have severe hypoalbuminemia (< 2.5 mg/dL), ascites, hepatic encephalopathy, and hepatic hydrothorax (Table 1). In our multivariable competing risks analysis, zinc deficiency was associated with 3.8 fold higher risk (sHR, 3.75, 95% CI, 1.32 – 10.61) of mortality accounting for age, gender, ALD, HCC, and MELD-Na at listing. 78 patients with zinc deficiency had repeat levels measured after at least 3 months of supplementation, of which 93.6% (n = 73) had persistently low zinc levels, and no significant difference in repeat measurements (P = 0.6). **Conclusion:** Zinc deficiency is common in patients with advanced liver disease and is a significant predictor for waitlist mortality. However, parenteral zinc supplementation did not significantly alter zinc levels. Further investigation into the complexity of zinc absorption and metabolism in advanced liver disease, better strategies for zinc supplementation, possible relation to frailty, and the potential impact on patient outcomes are needed.

3122-A | DIFFERENCES IN METABOLITES AND PHYSIOLOGICAL MAKER BETWEEN HEPATIC VENOUS PRESSURE GRADIENTS BY PORTAL VEIN BLOOD IN PATIENTS WITH LIVER FIBROSIS

Sang youn Lee, Su Been Lee, Kyeong Jin Lee, Jung A Eom, Sung- Min Won, Dong Joon Kim and Ki Tae Suk, Institute for Liver and Digestive Diseases, College of Medicine, Hallym University, Chuncheon 24252, Republic of Korea

Background: Liver fibrosis interferes with normal function by altering the structure of a particular organ and is one of the main causes of death. Liver cirrhosis (LC) is defined as an advanced stage of liver fibrosis with hepatic vasculature and structural distortion. The development of portal hypertension is characteristic of LC. We investigate the difference in metabolites in portal vein blood according to the degree of hepatic venous pressure gradient (HVPG) in patients with hepatic fibrosis. **Methods:** We used humanely collected portal vein blood (PVB). We mixed PVB with Acetonitrile:3'-distilledwater = 1:1 (v/v) and centrifuged at 13200 rpm and 4°C for 5 minutes after vortex for 1 min and sonicate for 5 min under ice. After transferring the supernatant to a new tube, Acetonitrile:Methanol = 1:3 (v/v) was added and then proceeded as described above. The supernatant was transferred to a new tube and concentrated with a speed vacuum concentrator. The HPLC conditions used were as follows: column temperature was set at 30 °C, injection volume was 10 μL, mobile phase A was water with 0.1% formic acid and mobile phase B was 5 acetonitrile. **Results:** We measured the biochemical indicators HVPG, ALT, AST and Albumin using humanely collected PVB. The group consisted of three stages according to the degree of HVPG. The average HVPG of each group was 6 ± 2.3, 14.1 ± 0.4, and 22.2 ± 4.2, showing differences between groups. The intergroup AST indices were 57 ± 14.5, 74 ± 37.6, and 103 ± 48.7, indicating a proportional increase with increasing HVPG values. However, ALT and Albumin indices did not show differences between groups. PVB was sampled in each group and metabolite was analyzed by HPLC to confirm differences between groups. At the peak of retention time 4, 14 minutes, it can be seen that the area value is 139.4, 45.4, 16.2 mAU and 21.2, 9.2, 7.1 mAU and low from the group with high HVPG. On the other hand, at the peak of Retention time 9 minutes, it can be seen that the group with high HVPG has

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

a large area value of 0.3, 0.8, and 107.6 mAU. **Conclusion:** We investigated differences in biochemical indices and metabolites in PVB in patients with liver fibrosis according to the degree of HVPG. Differences in biochemical indices according to the stage of HVPG were confirmed. In addition, metabolites were confirmed through HPLC, and differences in patterns depending on the stage were confirmed. This suggests that hepatic fibrosis patients can be a maker of severity without measuring HVPG.

3123-A | HEPATIC LSECTIN REDUCTION CONTRIBUTES TO T HELPER 17 CELL EXPANSION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS

Sebastian Martínez[1,2], Enrique Angel[1,2], Isabel Gómez-Hurtado[3], Anabel Fernandez Iglesias[4], Javier Morante[1,5], Jordi Gracia-Sancho[3,6], Esther Caparrós[1] and Ruben Frances[1,2,3], (1)Miguel Hernández University, Spain, (2)IIS Isabial, Alicante, Spain, (3) Ciberehd, Instituto De Salud Carlos III, Madrid, Madrid, Spain, (4)Idibaps, Barcelona, Spain, (5)Instituto De Neurociencias, Csic-Umh, San Juan De Alicante, Spain, (6)Idibaps - Hospital Clinic Barcelona, Barcelona, Spain

Background: Liver Sinusoidal Endothelial Cells (LSECs) are considered promoters of immune tolerance during hepatic homeostasis. We propose that the innate receptor C-type lectin LSECtin mediates this immunomodulatory function. During liver damage, LSECtin negatively regulates hepatic T-cell immune response through its interaction with different effector T-cell ligands. We have shown the negative transcriptional regulation of LSECtin in LSECs from experimental models of cirrhosis, resulting in a proinflammatory Th17 cell differentiation. Thus, our aim is to investigate LSECtin expression during liver disease progression in human hepatic tissue and its relationship with T cell expansion. **Methods:** Cirrhotic liver tissue was obtained from patients with alcohol or non-alcoholic steatohepatitis who underwent liver transplantation. Patients were grouped in compensated (n = 6) or decompensated (n = 7) based in their clinical characteristics. Non-lesioned non-tumorous liver tissues were used as healthy controls (n = 5). IHC staining was used to assess different proinflammatory and profibrogenic markers as well as LSECtin, TBET, RORγT and FOXP3 expression. Isolated RNA was subjected to RNAseq, performed in an Illumina platform HiSeq2500 and the transcriptomic profile of cirrhotic livers during disease progression was defined. LSECtin, RORγT and FOXP3 expression was correlated using this data. **Results:** LSECtin expression was progressively reduced in hepatic tissue from compensated and decompensated patients, as shown by IHC (Figure 1A). This was further confirmed by Western Blot and qPCR. The expression of transcription factors related to Th1, Th17 and Treg is shown in Figure 1B-1D. RORgT and FOXP3 were progressively increased in hepatic tissue from compensated to decompensated disease. TBET didn't show significant differences between groups. RNAseq analyses confirmed the significantly increased expression of RORgT and FOXP3 transcripts levels in patients compared to healthy livers. An inverse significant correlation was observed for LSECtin with RORgT ($r = -0.573$; $p = 0.003$) and FoxP3 ($r = -0.438$; $p = 0.003$), whereas no correlation could be established between LSECtin and Tbet ($r = -0.007$; $p = 0.735$). **Conclusion:** Th17 cell expansion is inversely associated with LSECtin expression in hepatic tissue of cirrhotic patients. The recovery of LSECtin could ameliorate the unbalanced inflammatory milieu and contribute to restore homeostasis in patients with cirrhosis.

3124-A | IMPACT OF THROMBOCYTOPENIA IN CHRONIC LIVER DISEASE

Oyedotun Babajide[1], Elizabeth Soladoye[2], Oluwanifemi Balogun[3], Abayomi Oyenuga[4] and Kalpana Panigrahi[1], (1)One Brooklyn Health-Interfaith Medical Center, (2) Piedmont Athens Regional, Athens, GA, (3)Albert Einstein Medical Center, Philadelphia, PA, (4)University of Minnesota

Background: Chronic liver disease (CLD) is a leading cause of morbidity and mortality worldwide, with an estimated 1.5 billion cases and over 1.32 million deaths in 2017. Thrombocytopenia is a common complication of CLD-related portal hypertension with its severity and frequency directly related to the severity of CLD. There are multiple pathophysiologic mechanisms for thrombocytopenia including; decreased activity of thrombopoietin, hypersplenism in portal hypertension, medications, and suppressive effects of alcohol on the bone marrow from chronic alcoholism. This study aimed to investigate the relationship between thrombocytopenia and health outcomes of patients with chronic liver disease. **Methods**: This one-year retrospective study evaluated the effects of thrombocytopenia on patients with CLD using the 2017 Nationwide Inpatient Sample (NIS) database. We identified and categorized adults with a diagnosis of chronic liver disease into those with an additional diagnosis of thrombocytopenia and those without. We evaluated the association between thrombocytopenia and the following outcomes: mortality, hospitalization cost, and length of stay (LOS) while adjusting for age, sex, race, elective vs non-elective admissions using multivariate logistic regression. All statistical analysis was done using SAS.9.0 **Results**: Within the identified 299,104 records with a diagnosis of CLD without missing covariates, 16.04 % (n = 47,965) had an additional diagnosis of thrombocytopenia, while 83.96% (n = 251,139) did not. In our general sample of CLD patients, the average age was 58.4 years (SE = 0.08 y), 55.6% were men, 66.7% white, and 89.7% were non-elective admissions. Amongst patients with CLD and thrombocytopenia, the mean age was 59.3 years (SE = 0.09 y), 61.2% were men, 66.9% white and 93.2% were non-elective admissions. In patients with CLD without thrombocytopenia, the average age was 58.3 years (SE = 0.08 y), 54.6 % were men, 66.6% white, and 88.9% were non-elective admissions. Using multivariable models, patients with thrombocytopenia had higher odds of in-hospital mortality (OR: 1.30; 95% CI: 1.26-1.35) and higher hospital costs ($107,444 vs. $90,256, $P < 0.0001$) compared to those without thrombocytopenia. In addition, the LOS (5.86 d vs 5.14 d, $p < 0.0001$) was statistically significant **Conclusion:** Thrombocytopenia has a negative impact on patients with CLD, associated with increased mortality and hospitalization costs compared to CLD patients without thrombocytopenia lending credence to its use as a predictor of mortality and morbidity in these patients

3125-A | INFLAMMATION BIOMARKERS REFLECT DISEASE SEVERITY AND DISCRIMINATE CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN CIRRHOSIS

Emilie Skovgaard, Nordic Bioscience a/S; University of Copenhagen, Nina Kimer, Bispebjerg University Hospital, Troels Malte Busk, Hvidovre Hospital, Morten Karsdal, Nordic Bioscience a/S, Denmark, Diana J. Leeming, Nordic Bioscience A/S and Søren Møller, Hvidovre Hospital, Hvidovre, Denmark

Background: Patients with cirrhosis and portal hypertension (PH) often develop complications that must be carefully monitored. The degree of PH is measured by the hepatic venous pressure gradient (HVPG), which however is an invasive procedure and search for noninvasive alternatives are warranted. This study aimed at investigating inflammation biomarkers for cirrhotic disease activity and to predict HVPG and clinically relevant HVPG cut-offs. **Methods:** The cohort included 105 patients with cirrhosis (Child Pugh classification A: n = 36, B: n = 34, C: n = 35) and 39 healthy controls. HVPG was assessed in patients with cirrhosis by liver vein catheterization. Inflammation biomarkers for type I collagen degradation (C1M) and a human neutrophil elastase fragment of calprotectin, a marker of neutrophil activity (CPa9-HNE), and the fibrogenesis biomarker of type III collagen (PRO-C3), were assessed in plasma EDTA samples from the hepatic vein. The performance of each marker to detect cirrhotic disease severity and clinically relevant HVPG cut-offs was determined as well as the correlation between each biomarker and HVPG. **Results:** PRO-C3 and CPa9-HNE correlated significantly with HVPG

($R_s = 0.34$ and $R_s = -0.31$ respectively, $p < 0.001$ for both). PRO-C3 significantly separated controls from all Child Pugh groups ($p < 0.0001$) and controls from HVPG cut-offs (HVPG < 10: $p < 0.001$, HVPG ≥ 10: $p < 0.0001$), and furthermore separated patients with HVPG < 10 mmHg from patients with clinically significant PH (HVPG ≥ 10 mmHg). Both inflammation markers, C1M and CPa9-HNE, decreased with cirrhotic disease severity and could significantly discriminate mild from moderate cirrhosis (C1M: $p < 0.05$, CPa9-HNE: $p < 0.01$) and mild from severe cirrhosis (C1M: $p < 0.05$, CPa9-HNE: $p < 0.0001$). Both markers could separate clinically significant PH from patients with HVPG < 10 mmHg. **Conclusion:** PH and increased disease severity in patients with cirrhosis were associated with a decrease in the inflammation related biomarkers, C1M and CPa9-HNE, whereas these were associated with an increase of the fibrogenesis biomarker PRO-C3. This might suggest that inflammation becomes less prominent in patients with moderate and severe cirrhosis and PH as compared to mild cirrhosis.

3126-A | IT'S TIME TO REDEFINE CALORIE TARGETS IN CRITICALLY ILL VENTILATED PATIENTS WITH LIVER CIRRHOSIS – EVIDENCE FROM INDIRECT CALORIMETER BASED RANDOMIZED CONTROLLED TRIAL

Varsha Shasthry[1], Jaya Benjamin[2], Rakhi Maiwall[2], Guresh Kumar[3], Prashant Agarwal[1], Shiv Kumar Sarin[4] and Yogendra Kumar Joshi[2], (1)Ilbs, (2)Institute of Liver and Biliary Sciences, New Delhi, (3)Institute of Liver and Biliary Sciences, New Delhi, India, (4)Institute of Liver and Biliary Sciences

Background: Energy expenditure (EE) may not be augmented in all patients with liver cirrhosis (LC), critical illness and mechanical ventilation (MV) may influence it further. The energy requirement(ER) in critically ill ventilated patients with LC is not yet known. Over or underfeeding might influence clinical outcomes. Indirect calorimeter (IC) is the gold standard method to measure EE. Hence we aimed to study the effect of IC-guided energy delivery on the clinical outcome of mechanically ventilated patients with LC, primarily on the duration of MV and secondarily on changes in EE(Kcal/day), respiratory quotient (RQ), substrate oxidation(% of EE), nitrogen balance (NB) along with mortality at day 7 and day 28. **Methods:** In this single-center, non-blinded randomized, controlled trial conducted at an exclusive liver intensive care unit (ICU), MV patients with LC expected to stay for > 3 days (n = 252) were screened. Thereafter, 83 patients meeting inclusion and exclusion criteria were randomized to the intervention arm i.e. enteral nutrition (using polymeric formula) with ER measured by IC (MER; n = 42) and the control arm, ER estimated at 35-40 kcal/kg ideal body weight (IBW)/day as per recommendations (EER; n = 41). Intervention protocol was till weaning or death whichever was earlier. The protein target was 1.5g/Kg IBW in both groups. IC (Quark RMR) was performed under the steady state in all 83 patients on alternate days. NB was calculated using 24-hour urinary urea nitrogen. **Results:** The baseline characteristics of the patients are given in Table 1. The measured EE was significantly lower than the estimated (1689 ± 463 vs.2375 ± 295, $p < 0.001$). Energy and protein adequacy were comparable. There was no difference in the median duration of MV (days) between MER and EER groups [7 (IQR 5-10) vs. 8 (IQR 5-10); $p = 0.63$], however, the proportion of patients weaned off was significantly higher in the MER group compared to EER [13(31%) vs.5 (12.2%); $p = 0.038$; OR 3.2]. The measured EE, RQ, fat, and carbohydrate oxidation were comparable between the groups. Mean NB was positive in both groups. 7-day mortality was significantly lower in MER compared to the EER group [13/42(30.9) vs.21/41 (51.2); Log-rank $p = 0.025$]; 28-day mortality was comparable. **Conclusion:** The energy requirements in ventilated patients with liver cirrhosis are lower than recommended in the guidelines. Providing calories guided by IC, particularly in the initial 7 days of ICU admission increases the chances of weaning and survival in these patients.

3127-A | LIVER STIFFNESS MEASUREMENT STRONGLY CORRELATES WITH SYSTEMIC INFLAMMATION IN STABLE CIRRHOSIS PATIENTS

Yu JUN Wong[1,2], Heng Yi Tan[3], Geraldine Lim[4], Siew Yoon Yap[4], Seok Hwee Khoo[4], Jessica Tan[1], Rahul Kumar[1,2] and Paul Edward Hutchinson[3], (1)Department of Gastroenterology & Hepatology, Changi General Hospital, (2)Duke-Nus Medical School, Singhealth, (3) Flow Cytometry Laboratory, Life Sciences Institute, National University of Singapore, (4)Clinical Trial Research Unit, Changi General Hospital

Background: Liver stiffness measurement (LSM) is a non-invasive prognostic fibrosis marker which predicts liver-related events in liver cirrhosis patients (PMID: 36064306). While liver inflammation may influence LSM, the association between LSM and systemic inflammation in stable cirrhosis patients is unknown. We aim to evaluate the association between changes in LSM and systemic inflammation in stable cirrhosis patients. **Methods**:This single center prospective cohort study recruited stable cirrhosis patients between 1st May 2022 to 31st January 2023. Peripheral blood serum was collected on the same day of liver stiffness measurement (LSM). LSM was performed using vibration-controlled transient elastography (VCTE) as per manufacturer's instruction. Primary predictor was the changes in LSM. The primary outcomes were changes in serum cytokines measured using BioLegend LegendPlex Assay. Patients with signs of infection or on immunosuppressants within 2 weeks were excluded from the analysis. **Results:** A total of 46 stable cirrhosis patients (95.8% Child-Pugh Class A, 75% ALBI grade 1) were analyzed. The median (IQR) age was 63 (56-71), 54.2% were male; with NASH (43.8%) being the predominant cirrhosis etiology in this cohort, followed by HBV (39.6%) and HCV (12.5%). Median (IQR) FIB-4 was 2.2 (1.4-3.5); median LSM was 14.1kPa (11.1-19.6), with 100% having reliable LSM (IQR/M < 0.3). At baseline, the median (IQR) white cell count (WBC) was 6.4 (5.2-7.5), neutrophil/leukocyte ratio (NLR) was 1.8 (1.5-2.8), BMI was 27.1 (23.8-30.1), and ALT was 30 (22-46). LSM strongly correlates with multiple inflammatory cytokines: IFN-γ (0.68, $p < 0.001$), TNF-α ($r = 0.66$, $p < 0.001$), IL-1β ($r = 0.61$, $p < 0.001$), IL-8 ($r = 0.64$, $p = 0.001$), IL 18 ($r = 0.59$, $p < 0.001$), IL-10 ($r = 0.57$, $p < 0.001$), TGF-β1 ($r = 0.60$, $p < 0.001$). Among patients with normal ALT (< 35 IU/ml), these correlations remained strong: IFN-γ (0.70, $p < 0.001$), TNF-α ($r = 0.72$, $p < 0.001$), IL-1β ($r = 0.68$, $p < 0.001$), IL-8 ($r = 0.70$, $p < 0.001$), IL 18 ($r = 0.59$, $p = 0.001$), IL-10 ($r = 0.63$, $p = 0.002$), and TGF-β1 ($r = 0.65$, $p = 0.001$). IFN-γ, TNF-α, IL-23 and LSM increase as cirrhosis stages progress from compensated cirrhosis without clinically significant portal hypertension (CSPH), compensated cirrhosis with CSPH to decompensated cirrhosis (Figure 1). Neither the age, BMI, white cell count, neutrophil/leukocyte ratio, ALT, AST nor platelet correlates with any of these cytokines. **Conclusion:** LSM strongly correlates with systemic inflammation in stable cirrhosis patients. Our novel finding suggests LSM and measurement of serum inflammatory cytokines may aid in further phenotyping stable cirrhosis patients beyond fibrosis stage.

3128-A | MELD 3.0: AN UPDATED MODEL FOR PREDICTION OF MORTALITY AMONGST PATIENTS WITH CIRRHOSIS VALIDATED IN A LARGE TERTIARY HOSPITAL IN SINGAPORE

Hong-Yi Lin[1], Pooi Ling Loi[2], Jeanette Pei-Xuan Ng[3], Wei Quan Teo[4], Amber Chung[4], Prema Raj[4] and Jason Pik Eu Chang[3], (1)Yong Loo Lin School of Medicine, National University of Singapore, (2)Department of Gastroenterology & Hepatology, Singapore General Hospital, Singapore, (3)Singapore General Hospital, (4) Singhealth-Duke Nus Transplant Centre

Background: The original Model for End-Stage Liver Disease (MELD) was introduced to predict 3-month survival to prioritize organ allocation for liver transplantation and has been updated since its inception. A recent study in the USA optimized the current model (MELDNa) with new variables and updated coefficients to propose MELD 3.0, the latest model which could suggest better prediction of 3-month mortality. This study aims to validate the prognostic performance of MELD 3.0 in patients with cirrhosis admitted to Singapore's largest tertiary hospital. **Methods:** Demographical, clinical, biochemical and survival data of patients with cirrhosis admitted to Singapore General Hospital (SGH) from January 01, 2018, to December 31, 2018, were studied retrospectively. Area under the receiver operating characteristic curves (AUROC) was computed to determine the discriminative effects of three prognostic models (MELD 3.0, MELDNa, and MELD) to predict 1-month (30-day), 3-month (90-day) and 1-year (365-day) mortality and compared with the DeLong's test. Youden's index was used to determine the optimal MELD 3.0 cut-off for high-risk patients. Competing risk analysis was performed for patients at various risk levels. **Results:** 862 patients were included (median age 70.0 years [IQR 63.0–78.7], 65.4% males, 75.8% Chinese). The proportion of patients with Child-Turcotte-Pugh classes A/B/C at admission were 55.5%, 35.5% and 9.0% respectively. The median scores of MELD 3.0, MELDNa and MELD were 12.2 (IQR 8.7–18.3), 11.0 (IQR 8.0–17.5), 10.3 (IQR 7.8–15.0) respectively. The 30-day, 90-day, 365-day mortality were 5.7%, 13.2% and 26.9% respectively. MELD 3.0 performed significantly better compared to MELDNa and MELD in predicting 30-day, 90-day, 365-day mortality (AUROC of MELD3.0/MELDNa/MELD: 0.823/0.793/0.783, 0.754/0.724/0.707, 0.682/0.644/0.654, in predicting 30-day, 90-day, 365-day mortality respectively, all $p < 0.05$) (Table 1). Patients with a MELD 3.0 score > 17 had high risk of 90-day mortality. When compared to patients with MELD 3.0 score d 17, patients with MELD 3.0 score > 17 had significantly poorer survival ($p < 0.05$) and had higher 90-day mortality (46.8% vs 16.4%). **Conclusion:** MELD 3.0 performed better than its predecessors in predicting mortality in patients with cirrhosis admitted to SGH, consistent with the findings in the recent USA study. MELD 3.0 score > 17 predicts higher mortality.

Table 1: AUROC of each prognostic model at various survival timepoints. Comparison of the AUROC of the prognostic model against MELD 3.0 using the DeLong's test.

	1-month mortality (95% CI)	p-value	3-month mortality (95% CI)	p-value	1-year mortality (95% CI)	p-value

3129-A | NONINVASIVE DIAGNOSIS OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION WITH MR ELASTOGRAPHY, T1, AND T1Á MAPPING OF THE LIVER AND SPLEEN

Efe Ozkaya[1], Octavia Bane[1], Amine Geahchan[1], Paul Kennedy[1], Stefanie Hectors[1], Aaron Fischman[1], Swan N. Thung[2] and Bachir Taouli[3], (1)Icahn School of Medicine at Mount Sinai, (2)Icahn School of Medicine at Mount Sinai (ISMMS), (3)Mount Sinai Hospital, New York, NY

Background: Portal hypertension (PH), a common complication of liver cirrhosis, is defined as an elevated portal venous pressure gradient across the liver due to increased intra-hepatic vascular resistance. PH is diagnosed via invasive measurement of hepatic venous pressure gradient (HVPG) > 5 mmHg, and clinically significant PH (CSPH) by HVPG e 10 mmHg. Quantitative magnetic resonance imaging (MRI) has shown promise for non-invasive diagnosis and characterization of liver disease and PH. The goal of our study is to evaluate the diagnostic value of MR elastography, T_1, and $T_{1\rho}$ mapping in patients with chronic liver disease. **Methods:** Our prospective IRB approved study included 67 patients (M/F = 35/32, mean age 52.5 y, range 19-79y) with chronic liver disease of mixed etiologies and suspected PH. All patients underwent abdominal MRI at 1.5T (Aera, Siemens) including MRE, $T_{1\rho}$, and T_1 mapping pre and post injection of gadoxetate disodium at the hepatobiliary phase (HBP) of the liver and spleen (Figure 1). Invasive HVPG measurements and transjugular liver biopsy were performed within 1 month of MRI. 2D MRE and 3D MRE were performed at 60 Hz using SE-EPI sequences and dual passive drivers enabling simultaneous liver and spleen acquisition. For T_1 mapping, an IR Look-Locker protocol with 32 inversion times, was used before and 20 minutes after injection of gadoxetate. T_1 maps were generated in MATLAB 2021 by fitting the signal to modified Look-Locker equation. $T_{1\rho}$ maps were obtained mid-liver and mid-spleen by mono-exponential fit of four images at 500Hz spin- lock frequency and 4 different spin-lock times. Association between liver/spleen MRI parameters with HVPG were assessed using Spearman correlation. Diagnostic models combining multiple parameters were constructed by logistic regression. The diagnostic performance of the parameters and models for prediction of CSPH was determined by ROC analysis. **Results:** Mean HVPG measurement was 6.3 ± 5.1 mmHg, and 13 (19%) patients had CSPH. 2D MRE of the liver ($r = 0.450$, $p < 0.001$), 2D MRE of the spleen ($r = 0.434$, $p < 0.001$), and 3D MRE of the liver ($r = 0.428$, $p = 0.002$) showed the strongest correlations with HVPG compared to other parameters (Figure 1). For prediction of CSPH, the best diagnostic performance was observed with 2D MRE spleen stiffness (AUC = 0.869; Figure 1, $p < 0.001$). This was followed by 2D MRE liver stiffness, T1-HBP and liver $T_{1\rho}$ with AUCs 0.817 (0.768 = 0.970), 0.806 (0.683-0.928), and 0.802 (0.671-0.934), respectively. A logistic regression model combining 2D MRE spleen stiffness with liver and spleen $T_{1\rho}$ diagnosed CSPH with AUC = 0.917 (0.807-1.00). **Conclusion:** 2D MRE spleen stiffness is a promising biomarker of CSPH. Our results show that hemodynamic changes associated with PH can be diagnosed non-invasively through splenic stiffness measurement, and through combinations of liver and spleen quantitative MRI parameters.

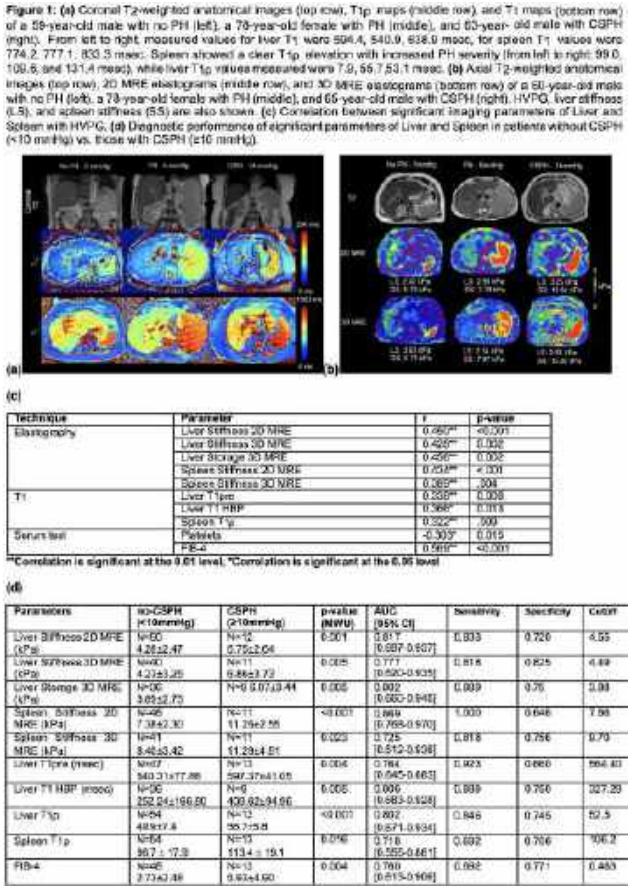

Figure 1: (a) Coronal T2-weighted anatomical images (top row), $T1\rho$ maps (middle row), and T1 maps (bottom row) of a 59-year-old male with no PH (left), a 78-year-old female with PH (middle), and 63-year- old male with CSPH (right). From left to right, measured values for liver T1 were 594.4, 640.9, 638.0 msec, for spleen T1 values were 774.2, 777.1, 833.3 msec. Spleen showed a clear $T1\rho$ elevation with increased PH severity (from left to right: 99.0, 109.6, and 131.4 msec), while liver $T1\rho$ values measured were 7.9, 55.7,53.1 msec. (b) Axial T2-weighted anatomical images (top row), 2D MRE elastograms (middle row), and 3D MRE elastograms (bottom row) of a 59-year-old male with no PH (left), a 78-year-old female with PH (middle), and 65-year-old male with CSPH (right). HVPG, liver stiffness (LS), and spleen stiffness (SS) are also shown. (c) Correlation between significant imaging parameters of Liver and Spleen with HVPG. (d) Diagnostic performance of significant parameters of Liver and Spleen in patients without CSPH (<10 mmHg) vs. those with CSPH (≥10 mmHg).

3130-A | PHARMACOKINETICS AND SAFETY OF BELAPECTIN, A CANDIDATE DRUG FOR NASH CIRRHOSIS, IN SUBJECTS WITH NORMAL HEPATIC FUNCTION AND SUBJECTS WITH VARYING DEGREES OF HEPATIC IMPAIRMENT

Ezra Lowe[1], Steven Schoenfeld[1], Eric Lawitz[2], Stephen A Harrison[3], Zeid Kayali[4] and Pol Boudes[1], (1)Galectin Therapeutics, (2)Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, (3) Pinnacle Clinical Research Center, San Antonio, TX, (4) Inland Empire Liver Foundation

Background: Belapectin is a large polysaccharide carbohydrate molecule that inhibits the glycoprotein galectin-3. Belapectin is currently under evaluation in a Phase 2b/3 trial as a monotherapy for the prevention of esophageal varices in patients with NASH cirrhosis and portal hypertension. A Phase 1, open-label, non-randomized, parallel-group study was conducted to determine the effect of hepatic impairment on the pharmacokinetics (PK), safety, and tolerability of a single IV infusion of belapectin at 4 mg/kg Lean Body Mass (LBM) compared to matched healthy subjects with normal hepatic function (NCT04332432). **Methods:** Subjects were enrolled based on their hepatic function, as determined according to the Child-Pugh score: Mild (Child A), Moderate (Child B), and Severe (Child C). Healthy subjects with normal hepatic function were demographically matched by age (± 10 y), sex, and body mass index (BMI ± 20%) to subjects with hepatic impairment. Plasma concentrations of belapectin were determined with a validated bioanalytical assay at pre-infusion, 3, 24, 36, 48, 72, 120, 210, and 336-hours post-infusion. Safety evaluation included adverse events, ECGs, biochemistry, and hematology. **Results:** The study enrolled and dosed 38 subjects (8 mild, 8 moderate, 8 severe, 14 healthy). All subjects received a single dose of belapectin at 4 mg/kg LBM. Belapectin was well tolerated and appeared safe. There were no treatment emergent SAEs; all adverse events reported were mild, except for one subject who experienced nausea and vomiting of moderate severity. There were no ECG findings, and no subject discontinued prematurely from the study. A summary of geometric means (CV%) of key PK parameters of belapectin is in the Table. **Conclusion:** Belapectin at 4 mg/kg LBM, the highest dose evaluated in the ongoing Phase 2b/3 study, appeared safe and was well tolerated. Hepatic function had minimal impact on key PK parameters of belapectin suggesting that no dose adjustment of belapectin will be required for patients with increasing severity of hepatic impairment.

TABLE: Geometric Means (CV%) of Key Pharmacokinetic Parameters of Belapectin in Subjects with Normal Hepatic Function and Subjects with Varying Degrees of Hepatic Impairment

PK Parameter	Hepatic Function			
	Normal (n=14)	Mild (n=8)	Moderate (n=8)	Severe (n=8)
C_{max} (µg/mL)	42.6 (20.2)	41.3 (16.2)	38.3 (25.4)	37.2 (12.5)
AUC_{0-t} (µg·hr/mL)	2,360 (24.3)	2,440 (28.0)	2,410 (25.2)	2,210 (22.2)
AUC_{0-inf} (µg·hr/mL)	2,400 (26.6)	2,500 (26.6)	2,500 (26.0)	2,300 (21.7)

f 3131-A | SINGLE NUCLEAR RNA SEQUENCING OF TERMINAL ILEUM IN PATIENTS WITH CIRRHOSIS DEMONSTRATES MULTI-FACETED ALTERATIONS IN THE INTESTINAL BARRIER

Xixian Jiang[1], Andrew Fagan[2], Bhaumik Patel[2], Huiping Zhou[3] and Jasmohan S. Bajaj[2], (1)Department of Microbiology and Immunology, Medical College of Virginia and Mcguire Veterans Affairs Medical Center, Virginia Commonwealth University, Richmond, VA, (2) Virginia Commonwealth University and Richmond VA Medical Center, (3)Virginia Commonwealth University

Background: Cirrhosis & hepatic encephalopathy (HE) is associated with systemic inflammation and intestinal barrier dysfunction. However, the expression of inflammatory, defensin and mucus-producing genes at single cell level in the small intestine of patients with varying stages of cirrhosis is unclear. Aim was to determine differences in the key gene expression related to the production of mucus, defensins & inflammatory mediators in cirrhosis vs controls. **Methods**: Prepped colonoscopy was performed with pinch biopsies of the terminal ileum (TI) in controls, compensated (comp) & early decompensated (decomp);

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

early (on lactulose) & advanced (on rifaximin). snRNA-seq was performed and Seurat 4.0, an R package was employed to analyse the feature-barcode matrices. Cell-type-specific marker genes were used for the identification of cell types. QIAGEN Ingenuity Pathway Analysis (IPA) was used to identify the cell-type specific pathways dysregulated in cirrhosis. Specific genes related to inflammation (IL-1, IL-6, TNFa) and mucus production were compared across all cell types and within enterocytes, goblet, and Paneth cells. **Results**: Subjects: We performed snRNA-seq in 4 subjects who were age-matched (56 y); the highest MELD was in the advanced decomp group (14) vs early decomp (9) vs comp (6). SnRNAseq successfully identified all different cell types. There is a significant loss of stem cells in all cirrhosis pts (1.55-5.74% vs 21.5% controls). The relative proportion of Paneth cells was higher in advanced decomp (18% vs 4-8% in the rest).
Inflammatory genes: IL1, IL6 and TNF-related genes were significantly upregulated in the enterocytes in all decompensated subjects, especially those with advanced HE compared to healthy control (Fig 1C).
Paneth cells: The greatest expression of defensin-coding genes was in controls, compensated cirrhosis vs decomp pts (advanced or not).
Goblet cells: Lower expression of goblet cell markers (FcGBP,CLCA1, and SPDEF, involved in differentiation of goblet cells, improving mucus regeneration and suppressing inflammation) was seen in advanced decomp pts. However, MUC2 expression, involved in mucin production was higher in both decomp groups. IPA: We found higher IL6, IFN gamma and alpha activation, adhesion, cytotoxicity, and migration of polymorphs and lymphocytes and lower xenobiotics handling (PXR, RXR) and protein kinase signaling in advanced decomp vs remaining groups. **Conclusion**: Using snRNA-seq in the terminal ileum of patients with compensated and decompensated cirrhosis compared to controls, we found a higher inflammatory expression along with suppressed defensin and mucus stabilization gene expression in decompensated compared to other groups. All cirrhosis pts had lower stem cell population versus controls. These alterations may contribute to the many aspects of intestinal barrier dysfunction in advanced cirrhosis.

3132-A | A NONINVASIVE MODEL TO PREDICT CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN PORTO-SINUSOIDAL VASCULAR DISEASE

Harish Gopalakrishna[1], Maria Mironova[2], Nehna Abdul Majeed[1], Asif Ali Hitawala[3], Shani Scott[1], Jaha Norman-Wheeler[1], David E Kleiner[4], Christopher Koh[3] and Theo Heller[1], (1)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (2)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, (3)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (4)Laboratory of Pathology, National Cancer Institute, National Institutes of Health

Background: Porto-sinusoidal vascular disease (PSVD), formerly referred to as idiopathic non-cirrhotic portal hypertension, encompasses a diverse group of disorders that primarily affects the porto-sinusoidal vascular system resulting in portal hypertension. Multiple etiologies including immunologic, hematologic, genetic disorders, infections, toxins, and drugs can cause PSVD. Variceal bleeding is the common initial manifestation of clinically significant portal hypertension (CSPH) in patients with PSVD. BAVENO VII criteria are a validated noninvasive model to identify CSPH and varices in cirrhotic patients. However, these criteria do not apply to PSVD. We aimed to develop a noninvasive diagnostic model for predicting varices and CSPH in PSVD. **Methods:** We included a single center cohort of biopsy proven PSVD patients who were part of a prospective natural history protocol (NCT02417740). All patients had liver stiffness (LSM) measured using transient elastography and upper endoscopy or imaging studies assessing for presence of CSPH. CSPH was defined by BAVENO VII specific criteria as the

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

presence of any one of: varices on endoscopy, portal hypertensive bleeding, or porto-systemic collaterals on imaging. Univariate analysis was used to examine variables that can predict varices and CSPH. Multivariate model was constructed using a logistic regression analysis of statistically significant variables in univariate analysis. A sequential-testing algorithm was developed using the best performing model. **Results:** Of the 44 patients, 28 (64%) had varices and 35 (79.5%) had CSPH. LSM was higher in patients with varices (12.7 kPa vs 6 kPa, $p < 0.01$) and CSPH (12 kPa vs 5.4 kPa, $p < 0.01$). Platelet count was lower in patients with varices (71 vs 151, $p < 0.01$) and CSPH (84 vs 144, $p = 0.03$). Multivariate analysis combining LSM, and platelet count predicts varices (AUROC 0.82 ± 0.07, $p < 0.01$) and CSPH (AUROC 0.86 ± 0.07, $p < 0.01$). A step-wise algorithm combining LSM of 10 kPa and platelet of 80 x 10^9 /L was developed.(Figure) This algorithm performed with specificity of 81%, negative predictive value (NPV) of 81% and positive predictive value (PPV) of 89% to detect varices ($p < 0.001$). The same model performed with sensitivity of 77%, specificity of 89% and PPV of 96% to detect CSPH ($p < 0.001$). Accuracy of the model for predicting varices and CSPH was 93% and 80%, respectively. **Conclusion:** We developed a simple model by combining LSM with platelet count that can be used to identify CSPH in PSVD patients. This noninvasive model can predict the risk of varices and aid in deciding the need for endoscopic surveillance or initiating therapy for portal hypertension. However, this model requires further validation in a larger independent cohort.

3133-A | ACCURACY OF A DEDICATED 100 HZ VIBRATION-CONTROLLED SPLEEN STIFFNESS MEASUREMENT VERSUS BAVENO CRITERIA FOR THE DETECTION OF VARICES IN PATIENTS WITH COMPENSATED CIRRHOSIS

Angelo Armandi[1,2], Tiziana Sanavia[2], Emma Vanderschueren[3,4], Georg Semmler[5], Antonio Liguori[6], Salvatore Petta[7], Maurice Michel[1], Merle Marie Werner[1], Talal Merizian[1], Christian Labenz[1], Mathias Jachs[8], Mattias Mandorfer[5], Wim Laleman[3,9], Luca Miele[6], Thomas Reiberger[10] and Jörn M. Schattenberg[1], (1)University of Mainz, (2)University of Turin, (3)University Hospitals Leuven, (4)Catholic University of Leuven, Department of Chronic Diseases, Metabolism and Aging (CHROMETA), Leuven, Belgium, (5)Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, (6)Università Cattolica Di Roma, Department of Internal Medicine, Fondazione Policlinico a. Gemelli, (7)Sezione Di Gastroenterologia, Dipartimento Promozione Della Salute, Materno-Infantile, Di Medicina Interna e Specialistica Di Eccellenza "G. D'alessandro", Università Di Palermo, Palermo, Italy, (8)Medical University of Vienna, (9)Catholic University of Leuven, Leuven, Belgium, (10)Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna

Background: Clinically significant portal hypertension (CSPH) marks a critical step in the natural history of compensated advanced chronic liver disease (cACLD) and may lead to esophageal varices (EV). The Baveno VI criteria suggest liver stiffness measurement (LSM) and platelet count (PLT) for non-invasive identification of cACLD patients not requiring screening gastroscopy. We investigated the accuracy of the novel 100 Hz vibration-controlled transient elastography-based spleen stiffness measurement (SSM) exam for the identification of EV in cACLD patients. **Methods:** Retrospective study of Mainz, Vienna, Leuven, Rome and Palermo. Patients with cACLD of any etiology (LSM e 10kPa or histological F4 fibrosis), but without previous decompensation (bleeding, encephalopathy, ascites) were included. SSM and LSM were obtained using Fibroscan F630 d 1 month within screening gastroscopy. Prediction performance between different SSM cut-offs with respect to the Baveno criteria (LSM > 20kPa and/or PLT < 150 G/L) were compared by logistic regression with 10-fold cross-validation, adjusted for age, gender, BMI, transaminases, INR, albumin, and bilirubin. Backward feature selection based on likelihood ratio test was applied to identify significant confounders. Performance was calculated by

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

balanced accuracy (BA), specificity (SP) and sensitivity (SE). Wilcoxon test was used to evaluate significant performance improvement of SSM cut-offs with respect to Baveno criteria, or to signifcant confounders. **Results:** 343 cACLD patients with a median age of 59 years (60.3% male) and NAFLD as the main etiology (51.3%) were included. 137 had EV with 49 high-risk EV (HR-EV), while median SSM, LSM and PLT were 40.5kPa, 21kPa and 139 G/L, respectively. The figure shows BAs at different SSM cut-offs, compared to Baveno (red line). The best overall performance with all-type EV was at SSM = 60 kPa (BA = 0.72, SP = 0.86, SE = 0.58); Baveno: BA = 0.66, SP = 0.86, SE = 0.39. Comparing HR-EV vs. absence of EV, the best cut-off was at 50kPa (BA = 0.71, SP = 0.95, SE = 0.47; Baveno: BA = 0.56, SP = 0.92, SE = 0.29). These SSM thresholds significantly improved BA when significant confounders were considered. **Conclusion:** The novel spleen-dedicated 100 Hz SSM is associated with presence of EV in cACLD patients. In both all-type EV and HR-EV, SSM showed better accuracy than the Baveno LSM-PLT criteria, achieving a better trade-off between SP and SE.

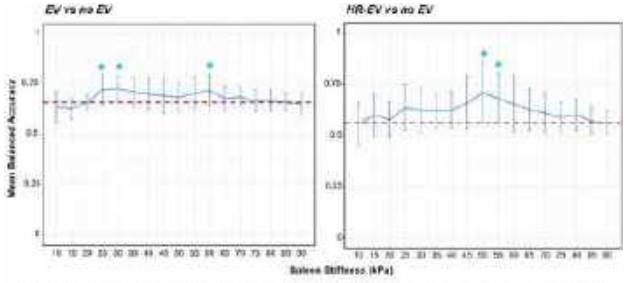

Figure 1. Mean Balanced Accuracy at different Spleen Stiffness cut-offs. Dashed red line: Baveno performance. The asterisk indicates that the SSM models showed a balanced accuracy significantly higher (i.e. Wilcoxon test p-value <5%) with respect to both the same model including only the selected confounders and Baveno.

3134-A | AN INTERNATIONAL SURVEY ON PRACTICE PATTERNS FOR THE MANAGEMENT OF GASTRIC VARICES

Lolwa Al-Obaid[1], Mohammad Bilal[2], Katarzyna M. Pawlak[3], Nadeem Tehami[4], Diogo De Moura[5], Rashid Ns Lui[6], Jayanta Samanta[7], Aymen Almuhaidb[8], Andres Rodriguez Parra[9], Andres Cardenas[10], Marvin Ryou[11] and Ahmad Najdat Bazarbashi[1], (1)Washington University in St. Louis, (2)University of Minnesota, (3) Samodzielny Publiczny Zaklad Opieki Zdrowotnej Ministerstwa Spraw Wewnetrznych I Administracji w Szczecinie, (4)University Hospital Southampton NHS Foundation Trust, (5)Universidade De Sao Paulo Hospital Das Clinicas Da Faculdade De Medicina De Ribeirao Preto, (6)The Chinese University of Hong Kong, (7)Postgraduate Institute of Medical and Educational Research, (8)King Faisal Specialist Hospital and Research Center, (9)Hospital General Dr Manuel Gea Gonzaleza, (10)Barcelona Clinic, Barcelona, Spain, (11)Brigham and Women's Hospital

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Gastric varices (GV) account for 10-20% of all variceal bleeding and are associated with significant morbidity and mortality. Management of GV include medical, endoscopic and interventional radiology (IR) therapies, however, many of these therapies remain debated with few well-established societal guidelines. The aim of this study was to evaluate international practice patterns of providers managing GV. **Methods:** A 34 item online questionnaire assessing baseline demographics of survey respondents and practice patterns managing GV were sent to providers caring for patients with gastrointestinal disorders. Data was analysed based on survey responses. Mean with standard deviations were calculated for continuous data, while percentages were calculated for categorical data. **Results:** A total of 187 respondents from 6 continents were included. Demographics are summarized in table 1. More than half respondents were from North America and Asia. Advanced endoscopy was the most common subspecialty. Beta blockers were the most common primary prevention modality across all regions (n = 128, 68.7%). Respondents in North America were more likely to refer patients to IR for the management of bleeding isolated gastric varices (IGV-1) than physicians in all other regions (49.2% vs 10.6%, p = 0.0001). Compared with hepatologists, interventional endoscopists were more likely to recommend EUS-guided coil therapy for management of initial and recurrent bleeding IGV-1 (20% vs 3.3%, p = 0.037, 30.3% vs 3.2%, p = 0.0011). For bleeding gastroesophageal varices type-1 (GOV-1), endoscopic variceal ligation (EVL) was uniformly the most common treatment approach (n = 108, 57.8%). While glue injection was the most common method of endoscopic treatment for bleeding IGV-1/GOV-2 overall, physicians in Asia used it more frequently than all other regions (83% vs 50.1 % p = 0.0001). N-Butyl-2-Cyanoacrylate was the most commonly used glue (n = 89, 48.1%). Surveillance EGD was recommended one month following endoscopic glue injection by 72.5% of respondents. EUS-guided coil therapy for bleeding GV was used more frequently in North America than other regions combined (34% vs 5%, p = 0.0001) [Figure 1] with 83.7% of respondents preferring the use of coil with glue as opposed to coils alone, with 87.8% favoring 19g needles. Significant variability existed in recommended surveillance timeline post EUS-coil therapy. Respondents in North America and Europe were more likely to refer patients with recurrent GV bleeding to IR, compared with their counterparts in all other regions (67% vs 48%, p = 0.0092). **Conclusion:** This study highlights geographic variations in the management of GV, likely due to resources, expertise and historical practice patterns. EUS coil therapy is increasingly being utilised in North America, while traditional endoscopic glue injection continues to be the most common endoscopic approach.

3135-A | ASPIRIN REDUCES RISK OF ASCITES AND ENCEPHALOPATHY IN CIRRHOTIC PATIENTS WITHOUT INCREASING THE RISK OF GASTROINTESTINAL BLEEDING

Roie Tzadok, Nir Bar, Ayelet Grupper, Eugene Feigin and Helena Katchman, Tel Aviv Sourasky Medical Center

Background: There is accumulating data regarding the beneficial effects of aspirin on the advancement of liver fibrosis, both in animal models and on laboratory indices of fibrosis. Aspirin was also shown to be associated with reduced HCC risk in cirrhotic patients. This study was aimed to evaluate clinical outcomes in cirrhotic patients treated with aspirin in comparison to non-treated cirrhotic patients.

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Methods: In a retrospective study at Tel Aviv Sourasky Medical Center, we compared aspirin treated cirrhotic patients for various indications to non-treated patients. Patients were followed-up for composite clinical outcomes, including decompensations, thrombotic and vascular complications (portal vein thrombosis, DVT, TIA, CVA, acute coronary syndrome and myocardial infarction) and HCC. Cox regression multivariate models were used to compare clinical sequalae between the groups. **Results:** From 2009-2018, 2413 patients with cirrhosis were treated at our center. One thousand and sixty-nine patients were followed up for a minimum of three months (median 13 mo, IQR 33.1-57.67 mo). One hundred and thirty-six patients (12.7%) were treated with aspirin for various indications. Baseline clinical and laboratory characteristics of both groups were comparable. Aspirin use was associated with risk reduction for decompensations, including a composite risk of ascites and hepatic encephalopathy, in a multivariate Cox regression analysis ($p = 0.035$). Aspirin use showed a tendency toward encephalopathy risk reduction as a single variable ($p = 0.055$), but not for the development of ascites. Aspirin was not associated with an increased risk of gastrointestinal bleeding in both univariate ($p = 0.281$) and multivariate analyses models adjusted for gender, age, platelet count, MELD score, statin, beta blocker and PPI use ($p = 0.446$). **Conclusion:** Aspirin use may confer a protective effect against a composite outcome of hepatic encephalopathy and ascites, and is not associated with increased risk of gastrointestinal bleeding in patients with cirrhosis. Further prospective studies on larger cohorts are necessary to elucidate its mode of action and confirm our findings.

3136-A | CLINICAL MALNUTRITION IS ASSOCIATED WITH WORSE OUTCOMES IN PATIENTS WITH PORTAL VEIN THROMBOSIS: A FIVE-YEAR NATIONWIDE ANALYSIS

Yassine Kilani[1], Syeda Ashna Fatima Kamal[2], Priscila Castro Puello[1], Saqr Alsakarneh[3], Mohammad Aldiabat[4], Vikash Kumar[5] and Fnu Vikash[6], (1)Lincoln Medical Center, (2)Southern Illinois University (SIU)), (3)University of Missouri-Kansas City, (4)New York University, (5)The Brooklyn Hospital Center, (6)Jacobi Medical Center

Background: Portal vein thrombosis (PVT) is most commonly associated with liver cirrhosis, but is also seen in prothrombotic conditions, including cancers. Chronic malnutrition is common in this population, however, there is no literature describing the effects of malnutrition on the outcomes of PVT. Therefore, the authors of this study aimed to update the literature. **Methods:** This is a retrospective longitudinal study of patients admitted with a diagnosis of PVT. Using weighted data from the Nationwide Inpatient Sample (NIS) database from 2016 to 2020, we assessed PVT outcomes (mortality, hospital utilization, total healthcare charges, complications) in patients with and without malnutrition. Baseline characteristics were analyzed using T-test and Chi-Square, and a multivariate regression analysis was used to estimate outcomes for patients with malnutrition. Data analysis was performed using STATA® Version 17.0 Software, with statistical significance set at $p < 0.05$. **Results:** Among a total of 252,455 hospital admissions with a diagnosis of PVT, 57,020 (22.6%) had a secondary diagnosis of clinical malnutrition. Malnutrition was associated with a 90,540 U.S. dollar increase in total healthcare charges (95%CI: 79,657 - 101,422), and a 6-day increase in the length of stay (95%CI: 5.63 - 6.47). Pertaining to complications, malnutrition was associated with higher risks of mortality (adjusted Odds ratio (aOR) = 1.66, 95%CI: 1.52 - 1.80), acute intestinal ischemia (aOR = 1.24, 95%CI: 1.08 - 1.43), post-hemorrhagic anemia (aOR = 1.45, 95%CI: 1.35 - 1.55), hypovolemic shock (aOR = 1.66, 95%CI: 1.37 - 2.02), acute kidney injury (aOR = 1.66, 95%CI: 1.57 - 1.77), sepsis (aOR = 2.02, 95%CI: 1.87 - 2.18), pulmonary embolism (aOR = 1.38, 95%CI: 1.18 - 1.61), acute respiratory failure (aOR = 1.98, 95%CI: 1.84 - 2.13), and cardiac arrest (aOR = 1.32, 95%CI: 1.05 - 1.68). Malnutrition was associated with a significant reduction of esophageal varices with bleeding (aOR = 0.91, 95%CI: 0.68 - 1.23), esophageal varices without bleeding (aOR = 0.73, 95%CI: 0.66 - 0.82), gastric varices (aOR = 0.70, 95%CI: 0.60 - 0.81) (figure 1). **Conclusion:** The prevalence of clinical malnutrition in patients admitted with PVT is high. Moreover, malnutrition seems to be associated with worse outcomes in patients admitted with PVT. Therefore, it is imperative that clinicians address malnutrition in order to improve survival, complications, and hospital utilization of patients with PVT.

3137-A | COMPARISION OF SPLENIC STIFFNESS MEASUREMENT BY TRANSIENT ELASTOGRAPHY USING 100Hz PROBE WITH BAVENO CONSENSUS CRITERIA TO PREDICT HIGH RISK ESOPHAGEAL VARICES IN CHRONIC LIVER DISEASE

Harsh Prakash Jain, Manas Kumar Kumar Panigrahi, Prajna Anirvan, Mohd imran Chouhan Sr, Abhijeet Rai, Shubham Gupta, Mansi Choudhary, Hemanta Kumar Nayak and Subash Chandra Samal, All India Institute of Medical Sciences, Bhubanswar, India

Background: Clinically significant portal hypertension (CSPH) in patients with chronic liver disease (CLD) portends risk of variceal bleeding. Esophageal varices are classified into high and low risk based on endoscopic appearance. However, prevalence of High Risk Esophageal Varices (HREV) is low in early cirrhosis. Using non-invasive tools with high negative predictive value for HREV can avoid endoscopies in these patients. We evaluated the diagnostic performance of Splenic Stiffness Measurement (SSM) by Transient Elastography (TE) using a 100 Hz probe and compared it with Baveno Criteria to predict HREV. **Methods:** Consecutive individual's with cirrhosis were enrolled. Relevant blood investigations and endoscopy were performed to detect and grade esophageal varices. Liver Stiffness Measurement (LSM) and SSM were performed by TE . A dedicated 100 Hz probe was used for SSM. **Results:** From June 2021 to April 2023, 281 patients with cirrhosis were screened and 156 were enrolled. Etiology of cirrhosis in these patients was attributed to alcohol, chronic viral hepatitis and other etiologies in 68 (43.5%), 30 (19.2%) and 58 (37.1%) patients, respectively. HREV were detected by endoscopy in 52 (33.3%) patients. SSM using 100 Hz probe was successfully performed in 98% (n = 153) of the patients enrolled. On multivariate analysis, only SSM was significantly associated with HREV. AUROC of LSM and SSM and platelet count to predict HREV was 0.643 and 0.805, respectively . Sensitivity, specificity, negative predictive value and positive predictive value were 94.2%, 52.8%, 94.8% and 49.9%, respectively when SSM cut-off upto 35 kPa was used to rule out HREV. Using this cut-off, 5.7% HREV were missed and 37.1% endoscopies were spared which was more than twice the number of endoscopies spared using either Baveno VI (16.5%) or Baveno VII (16.6%) criteria in the same population. On subgroup analysis, SSM, Baveno VI and VII criteria performed worse for alcohol related CLD (n = 68) as compared to non-alcohol related etiologies (n = 88) with lower number of endoscopies spared (32.3% vs 40.9%, 7.3% vs 23.8% and 5.8% vs 22.7%, respectively) with rate of missed HREV < 5% for all three non-invasive tools. **Conclusion:** Our study highlighted few important lacunae in the literature. Firstly, the cut-offs used by non-invasive tools to predict HREV seem to be affected by ethnicity, etiology of CLD and method of SSM measurement (100 Hz vs 50 Hz). Secondly, the Baveno consensus criteria need validation before the same recommended cut-offs can be used with SSM@100Hz. Thirdly, despite SSM demonstrating acceptable performance in predicting HREV, need of the ideal noninvasive tool remains unmet.

Table: Comparison of diagnostic performance of Splenic Stiffness Measurement, Baveno VI and Baveno VII Criteria to predict High Risk Esophageal Varices in Chronic Liver Disease

Diagnostic performance of SSM, Baveno VI and Baveno VII criteria in CLD (n=156)			
	SSM@100 Hz	Baveno VI criteria	Baveno VII criteria
Sensitivity	94.2%	100%	100%
Specificity	52.8%	21%	23.0%
Positive Predictive Value	50.0%	39.9%	39.3%
Negative Predictive Value	94.8%	100%	100%
Positive Likelihood Ratio	2.0	1.33	1.30
Negative Likelihood Ratio	0.11	0	0
Diagnostic Accuracy	66.0%	49.9%	48.6%
HREV miss rate	5.7%	0	0
Endoscopy spare rate	37.3%	16.6%	16.3%
Diagnostic performance of SSM, Baveno VI and Baveno VII criteria in Alcohol related CLD (n=68)			
Sensitivity	95.8%	82.7%	100%
Specificity	47.7%	0	9.0%
Positive Predictive Value	49.9%	31.0%	37.4%
Negative Predictive Value	95.4%	0%	100%
Positive Likelihood Ratio	1.83	0.83	1.10
Negative Likelihood Ratio	0.09	*	0
Diagnostic Accuracy	64.8%	29.1%	41.0%
HREV miss rate	4.1%	17.2%	0
Endoscopy spare rate	32.3%	7.3%	5.8%
Diagnostic performance of SSM, Baveno VI and Baveno VII criteria in CLD with etiology other than alcohol (n=88)			
Sensitivity	92.8%	100%	100%
Specificity	56.8%	33.1%	35.5%
Positive Predictive Value	49.9%	41.1%	44.7%
Negative Predictive Value	94.4%	100%	100%
Positive Likelihood Ratio	2.14	1.50	1.54
Negative Likelihood Ratio	0.13	0	0
Diagnostic Accuracy	68.1%	54.5%	55.6%
HREV miss rate	7.1%	0	0
Endoscopy spare rate	40.9%	22.7%	23.8%

*NPV could not be calculated in this group because there were no true negative cases identified by Baveno VI criteria in this group
CLD - Chronic Liver Disease, HREV - High Risk Esophageal Varices, SSM - Splenic Stiffness Measurement by Transient Elastography using 100 Hz probe

3138-A | DEVELOPMENT OF A SCORING SYSTEM FOR PREDICTING ESOPHAGEAL VARICES WORSENING AFTER BALLOON-OCCLUDED RETROGRADE TRANSVENOUS OBLITERATION

Tatsuro Nishimura[1], Tsuyoshi Ishikawa[1], Maho Egusa[1], Natsuko Nishiyama[1], Tsuyoshi Fujioka[1], Daiki Kawamoto[1], Ryo Sasaki[1], Norikazu Tanabe[1], Issei Saeki[1] and Taro Takami[2], (1)Yamaguchi University Graduate School of Medicine, (2)Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan

Background: Balloon-occluded retrograde transvenous obliteration (BRTO) is a safe and effective treatment for gastric varices (GV) and refractory hepatic encephalopathy (HE) associated with portosystemic shunts (PSSs). However, esophageal varices (EV) worsening after BRTO is the most concerning postoperative complication. The present study aimed to statistically identify predictive factors of EV worsening after BRTO and develop a new scoring system for EV worsening. **Methods:** Seventy-six patients with PSSs who had undergone BRTO for GV or HE [mean age = 67.6 years; female/male = 37/39; Child-Pugh class A/B/C = 37/32/7; mean Hepatic venous pressure gradient = 10.8 mmHg] at our hospital between April 2008 and March 2021 were enrolled in this retrospective study. Statistical analysis identified factors associated with the EV worsening after BRTO, and the Kaplan-Meier method determined the cumulative EV worsening rates. **Results:** BRTO was successfully performed in all 76 patients. During a median follow-up period of 18.0 months (range 0-120 mo), EV worsening was observed in 50 patients, of whom 42 showed worsening of the F category, 5 showed appearance of red color sign and 3 showed rapture of EV. The cumulative EV worsening rates at 12-, 24-, and 36 months were 35.5 %, 51.5 %, and 58.1 %, respectively. Univariate analysis using the Cox proportional hazards model revealed a significant association of EV worsening after BRTO with male, platelet count d $8.3x10^4$ /μL, MELD-Na score > 11, and presence of EV before BRTO. Multivariate analysis showed that male (hazard ratio [HR] 2.27, 95%CI 1.17-4.39, P = 0.013), platelet count d $8.3x10^4$ /μl (HR 2.11, 95%CI 1.06-4.19, P = 0.032) and presence of EV before BRTO (HR 2.36, 95%CI 1.06-5.27, P = 0.029) were significant independent risk factors of EV worsening. The rate of EV worsening was significantly higher patients in male, platelet count d $8.3x10^4$ /μL and presence of EV before BRTO (P < 0.001). We developed a scoring system for predicting EV worsening after BRTO consisting of the above 3 factors, which ranged from 0 to 3 points (because the HR of each factor is almost equal, one point for each factor). Patients stratified into 4 groups according to this score showed significantly different cumulative EV worsening rates (0 vs 1 vs 2 vs 3 points: median time to EV worsening, not reached vs 19.2 vs 10.2 vs 6.5 mo; P < 0.001). **Conclusion:** EV worsening after BRTO can be predicted by 3 factors: "male", " platelet count d $8.3x10^4$ /μL" and "presence of EV before BRTO". We have established a new scoring system for predicting EV worsening after BRTO. And we developed a risk stratification and postoperative strategy by this scoring system. This scoring system helps detect EV worsening as early as possible after BRTO and can make it possible to perform early endoscopic treatment in the event of worsening to risky varices.

3139-A | DOES STATUS MATTER? ANALYZING OUTCOMES BETWEEN TEACHING STATUS AND MORTALITY IN US HOSPITALS: A NATIONAL STUDY OF PATIENTS WITH COVID-19 AND VARICEAL BLEEDING

Marisa Pope[1], Brian Blair[1], Lucy Joo[1], C Jonathan Foster[1], Yaser Khalid[2] and Neethi Dasu[1], (1)Jefferson Health NJ, (2)Wright Center for Gme/Geisinger Health System

Background: Esophageal varices occur within the portal system in patients with liver cirrhosis. Variceal hemorrhage can be a fatal complication of liver cirrhosis. The COVID-19 pandemic posed a huge dilemma within gastroenterology due to limited endoscopic procedures given risk of exposure to respiratory droplets. In addition, larger teaching hospitals in urban areas had been associated with higher mortality rates during the COVID-19 pandemic. The aim of this study is to compare tertiary care centers versus teaching hospitals and identify differences in mortality rates during COVID -19 in patients with variceal bleeding. **Methods:** All patients aged 18 years and above with COVID-19 with a concomitant diagnosis of variceal bleed were identified from the year 2020 were identified from the US Nationwide Inpatient Sample (NIS), an extensive publicly available all-payer inpatient care database in the USA. Multivariate regression analysis was used to estimate the odds ratios of in-hospital mortality, the average length of hospital stay (LOS), and hospital charges (TOTHC), after adjusting for age, gender, race, primary insurance payer status, hospital type and size (number of beds), hospital region, hospital teaching status, and other demographic characteristics. In addition, the relationship between hospital teaching status and outcomes, including mortality, post-procedural bleeding, CVA (cerebrovascular accident), acute kidney injury (AKI), and sepsis, were analyzed. **Results:** Our study identified approximately 1,685,745 patients with COVID-19, of which 45,590 were diagnosed with variceal bleeding. The

average age was noted to be 63. *The analysis revealed no difference in mortality or length of stay (LOS) between patients admitted to teaching and non-teaching hospitals*. Admission to the ICU, however, was higher in patients at teaching hospitals (OR 5.18, CI: 5.02-5.35), p = 0.00). Total hospital charges were higher in patients admitted to teaching hospitals ($16,805.71, CI: $14,511.44 - $19,099.98), p = 0.00). Independent positive predictors of increased mortality, LOS, and TOTHC are identified in Table 1. **Conclusion:** In patients with COVID-19 and concomitant variceal bleeding, although total hospital charges were higher in patients admitted to teaching hospitals, there was no noted difference in mortality or length of stay. We further identified complications (post-procedural bleeding, CVA, AKI) that increased mortality, LOS, and TOTHC in patients admitted to teaching hospitals. The presence of sepsis did lead to an increased LOS and TOTHC in patients admitted to teaching hospitals but did not affect mortality. This data suggests that a healthcare facility's teaching status does not necessarily worsens patient outcomes with regard to mortality and identifies crucial risk factors that, if identified early, can be beneficial in mitigating further risk in teaching hospitals.

3140-A | EFFICACY AND SAFETY OF ENDOSCOPIC ULTRASOUND GUIDED EMBOLIZATION FOR PRIMARY PROPHYLAXIS OF LARGE CARDIO-FUNDAL GASTRIC VARICES -A SINGLE CENTER EXPERIENCE

Ahmed El Sabagh[1,2], Ronald Samuel[1], Islam Mohamed[1,2], Megha Bhongade[1], Prasun K. Jalal[1], Tara Keihanian[1] and Kalpesh Patel[1], (1)Baylor College of Medicine, (2)Faculty of Medicine, Ain Shams University

Background: Gastric variceal bleeding is a life-threatening condition with a high mortality rate. Bleeding risk from gastric varices is lower compared to esophageal varices, but usually is more severe with a higher mortality rate. Primary prophylaxis of gastric varices can potentially reduce the risk of hemorrhage and improve survival. Endoscopic ultrasound (EUS) guided embolization of gastric varices is an effective treatment modality for gastric varices. Limited data exists regarding the efficacy of this procedure in the primary prophylaxis against bleeding from large cardio-fundal gastric varies. The aim of our study is to show the efficacy and safety of EUS-guided gastric varices embolization for primary prophylaxis against gastric variceal bleeding. **Methods:** A single-center retrospective observational study evaluating patients with large cardio-fundal gastric varices without prior bleeding who underwent EUS-guided coiling and glue injection for primary prophylaxis against bleeding from gastric varices between January 2016 and September 2022, at Baylor College of Medicine. The primary outcome was EUS confirmed gastric varices obliteration. Secondary outcome was post-treatment gastric variceal bleeding rate within six months. **Results:** Twenty-one patients underwent primary prophylaxis for large cardio-fundal gastric varices during the study period (61.9% female). Mean age of patients was 60.2 ± 14.0. Concurrent liver cirrhosis was found in 90.5% (n = 19) of the patients. Only 57.1% (n = 12) of patients were on beta blocker before the endoscopic therapy. Technical success - defined as achieving complete embolization of the targeted gastric varices confirmed by EUS colored Doppler imaging - was achieved in 100% of patients. The mean number of coils was 4.0 ± 1.4 and mean glue volume of 1.5 ± 0.6 ml. Out of the 21 patient who received the procedure, 15 of them had a follow-up EUS in over 4.7 ± 2.3 months. EUS- confirmed gastric varices obliteration was noted in 13 patients (86.7%). The two patients with recurrent gastric varices were successfully treated with EUS-guided embolization with 2.5 ± 0.7 coils and 2.5 ± 0.7 ml glue. Post-treatment gastric variceal bleeding within 6 months occurred in one patient that required repeat EUS-guided embolization and glue with a good outcome. No patients required alternative treatment with TIPS or other modalities within 6 months. No serious adverse events including anesthesia complications, procedural bleeding, or embolic events were noted due to the procedure. **Conclusion:** EUS-guided embolization of large cardio-fundal gastric varices can be considered an effective and safe modality for primary prophylaxis against bleeding in cirrhotic patients. Larger prospective randomized trials are needed to highlight the efficacy and safety of this technique in larger population with cirrhosis, including patients with non-cirrhotic portal hypertension and extra-hepatic portal obstruction.

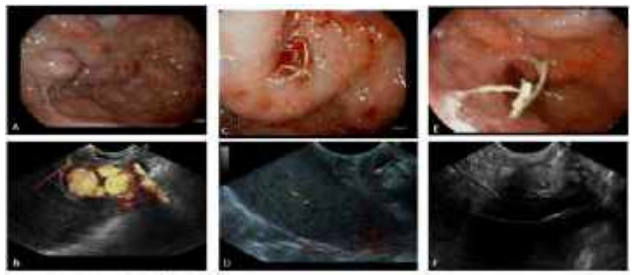

Figure 1: EUS-guided coil embolization.
A: Gastric varices noted in the gastric fundus seen endoscopically and under EUS with doppler (B). C: Gastric varices after glue and coiling in the gastric fundus endoscopically and with EUS with doppler showing obliteration (D). E: Follow-up after 4 months demonstrates extruding cyanoacrylate on EGD and obliteration of varices on EUS (F).

3141-A | EFFICACY AND SAFETY OF PERCUTANEOUS TRANS-HEPATIC OR TRANS-SPLENIC VARICEAL OBLITERATION FOR GASTRIC VARICEAL BLEEDING

Hyun Young Woo[1], Jeong Heo[2], Ki Youn Yi[1], Young Joo Park[1] and Chang Won Kim[3], (1)Department of Internal Medicine, College of Medicine, Pusan National University and Biomedical Research Institute, Pusan National University Hospital, (2)Department of Internal Medicine, College of Medicine, Pusan National University and Biomedical Research Institute, Pusan National University Hospital, Busan, Republic of Korea, (3)Department of Radiology, College of Medicine, Pusan National University and Biomedical Research Institute, Pusan National University Hospital

Background: Gastric variceal bleeding (GVB) is a serious complication of liver cirrhosis that is associated with increased mortality. GVB can be managed by endoscopic variceal ligation (EVL) or radiological interventions, such as balloon-ccluded retrograde transvenous obliteration (BRTO) or transjugular intrahepatic portosystemic shunt (TIPS). Although many studies showed that BRTO has advantages over TIPS, BRTO requires a gastrorenal shunt. We evaluated the efficacy and safety of percutaneous trans-hepatic or trans-splenic variceal obliteration (PTVO) as an alternative for management of GVB when BRTO is impossible. **Methods:** Seventeen patients (mean age 59 y, 13 men) with liver cirrhosis who received PTVO for uncontrolled GVB from October 2017 to January 2023 were retrospectively examined. Efficacy was evaluated by the rate of successful prevention of rebleeding during follow-up, and improvement of liver function based on Child-Pugh (CP) class. Safety was evaluated by the rate of postprocedural complications. **Results:** The causes of cirrhosis were hepatitis B (n = 3), hepatitis C (n = 2), alcohol consumption (n = 4), autoimmune hepatitis (n = 2), and a combination of factors (n = 6). Before procedure, eight had CP class A, seven had CP B, and two had CP C. The PTVO was performed using a trans-splenic approach (n = 7) or a trans-hepatic approach (n = 10), and was successful in all patients. However, two experienced rebleeding during hospitalization; one was considered irrecoverable and expired and the other received embolization. CP class improved in 3 patients (33.3%) and remained the same in 6 patients (66.7%) at 1 to 3 months. CP class improved in 1 patient (14.3%), remained the same in 5 patients (71.4%), and worsened in 1 patient (14.3%) at 6 months. **Conclusion:** PTVO of patients with cirrhosis led to no significant deterioration in liver function or procedure-related complications. This procedure can be considered an effective and safe option for patients with GVB when a conventional approach is not possible.

3142-A | EFFICACY AND SAFETY OF THALIDOMIDE IN PREVENTING RECURRENT BLEED FROM GASTRIC ANTRAL VASCULAR ECTASIA IN PATIENTS WITH LIVER CIRRHOSIS

Sowmya T R[1], Anand V. Kulkarni[1], Mithun Sharma[2], Padaki Nagaraja Rao[1] and Duvurr Nageshwar Reddy[1], (1)Aig Hospitals, Hyderabad, India, (2)Asian Institute of Gastroenterology, Hyderabad, Telangana, India

Background: Recurrent gastrointestinal bleed due to gastric antral vascular ectasia (GAVE) is an uncommon complication in patients with liver cirrhosis. Apart from variceal bleed, bleed from GAVE can add to significant morbidity in these patients causing anemia, recurrent blood transfusions and hospitalizations. GAVE does not respond to medical therapy with beta blockers. Endo therapy such as argon plasma coagulation (APC) can be useful for acute bleed however recurrence is not uncommon. Medical management to prevent recurrent bleeding episodes using oral thalidomide therapy, which is hypothesised to act on vascular endothelial growth factor receptors (VEGF) preventing angiogenesis has been observed in certain case reports of GAVE. However, the data about its efficacy and safety in larger group of cirrhotic patients is lacking. In this study, we aimed at comparing the efficacy of thalidomide in terms of number of days of hospitalizations, number of blood transfusions for anemia and number of endoscopic treatment sessions for GAVE before and after oral thalidomide treatment for a minimum period of 6 months. **Methods:** This is a pre - post intervention study where 25 patients of liver cirrhosis presenting with more than one episode of GI bleed from GAVE were included. Patients with acute variceal bleed were excluded. Acute episode of bleed from GAVE was managed by endotherapy in the form of APC and subsequently patients were started on oral thalidomide therapy at a dose of 50mg per day. Patients were followed for a total duration of 1 year with a follow up interval of 3 months. Recurrent episodes of bleed, hospitalizations and requirement of blood transfusions were

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

recorded. Patients were enquired for adverse effects of thalidomide at every follow up visit. **Results:** A total of 25 patients with liver cirrhosis were included in the study. Median age of patients was 55 years. Majority of patients were males (n = 18). Most common etiology of cirrhosis in these patients was non- alcoholic steatohepatitis (NASH) which was observed in 17 (68%) patients. Diabetes mellitus was the most common co-morbidity among these patients observed in 11 (44%) patients. Mean dose of thalidomide administered was 50mg per day for a median duration of 6 months. Out of 25 patients, only one patient (4%) required hospitalization for a duration of 2 days and one session of APC for GAVE during a follow up period of 1 year. Only 2 patients required (1unit each) blood transfusions in view of anaemia after initiation of thalidomide therapy during a follow up period of 1 year. Table 1 describes the results of the study. No major adverse effects were observed in any of these patients except for 3 patients who reported mild fatigue. One patient had mild lower limb peripheral neuropathy which resolved with symptomatic therapy. **Conclusion:** Thalidomide is a safe and effective option for prevention of recurrent gastrointestinal bleed due to GAVE in patients with liver cirrhosis.

Total Number of patients		N=25
Median age	55years (Range- 40-74years)	
Gender – Male:Female	18:7	2.6:1
Etiology of liver cirrhosis	NASH	17 (68%)

Background: Tamponade is used as a bridge therapy in patients with refractory portal hypertension related bleeding (R-PHT-B). The need for tamponade is rare, and the prognostic determinants of patients receiving tamponade are not well known. Esophageal stents (ES) have been introduced to replace balloon tamponade, but to date, there are few data comparing the effectiveness of these two procedures, and the use of ES has not demonstrated a survival benefit. **Methods:** We retrospectively analyzed a French nationwide cohort of patients treated with tamponade for R-PHT-B. Primary outcome measure

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was day(d)-42 survival. Multivariate analyses were conducted using a Cox model adjusted to a propensity score evaluating the probability of having received an ES. **Results:** 69 pts (65 cirrhotics, 87% males, 57yrs, 94% Child-Pugh B/C) admitted for R-PHT-B between 2002 and 2023 in University (N = 7) or General (N = 5) hospitals who underwent tamponade were included. Initial endoscopy and attempt to control bleeding had been performed in 88% and 70% of patients, respectively. Tamponade was performed using balloon or ES (Danis stent) in 40 and 29 patients, respectively. Our propensity score incorporated 21 variables and was able to predict the use of ES (rather than balloon tamponade) in 86% of patients with high accuracy (AUROC = 0.94). A rescue TIPS (rTIPS) was placed in 20 patients (29%), before d4. No difference was observed between the two procedures regarding the occurrence of complications. Overall mortality was 46% at d5 (due to refractory hemorrhagic shock for 75% of cases), and 65% at d42 (mainly due to persistent bleeding and multi-organ failure). In univariate analyses, d42-survival was higher in patients with ES *vs.* balloon tamponade (58% *vs.* 32%, p = 0.034), in those with rTIPS *vs.* others (63% *vs.* 38%, p = 0.048), and in patients with better liver function as indicated by a MELD score < 30 (75% vs. 30%, p = 0.026) or no history of hepatic encephalopathy (56% *vs.* 10%, p = 0.046). Multivariate Cox analysis adjusted for MELD score and propensity score ($R^2 = 0.29$) confirmed that the use of ES (HR = 4.32, 95%CI:1.34-13.99; p = 0.014) and of rTIPS (HR = 3.08, 95%CI:1.04-9.10; p = 0.042) were two independent predictors of d42-survival. **Conclusion:** In patients who undergo tamponade for refractory portal hypertention related bleeding, the use of esophageal stent, as well as rescue TIPS placement, are independent predictors of day 42 survival.

3144-A | HIGH CORRELATION OF HEPATIC SHEAR WAVE VELOCITY WITH ESOPHAGEAL VARICES COMPLICATION RATE IN PATIENTS WITH CHRONIC LIVER DISEASES

Shouichi Namikawa[1,2], Takuto Nosaka[1], Yu Akazawa[1], Tatsushi Naito[1], Kazuto Takahashi[1], Hidetaka Matsuda[1], Masahiro Ohtani[1] and Yasunari Nakamoto[1], (1)University of Fukui, (2)Japan Community Health Care Organization Fukui Katsuyama General Hospital

Background: Histological evaluation by liver biopsy is considered the gold standard for assessing liver disease; however, it is highly invasive. Non-invasive liver stiffness measurement by shear wave elastography (SWE) is effective for evaluating the hepatic fibrosis stage and related diseases. In this study, we investigated the correlations of liver stiffness with hepatic inflammation/fibrosis, functional hepatic reserve, and related diseases in patients with chronic liver disease (CLD). **Methods:** Shear wave velocity (Vs) values were measured using point SWE in 71 patients with liver disease from 2017 to 2019. Liver biopsy specimens and serum biomarkers were collected at the same time, and splenic volume was measured using computed tomography images with the software Ziostation2. Esophageal varices (EV) were evaluated by upper gastrointestinal endoscopy. Youden's index (sensitivity + specificity - 1) was used to identify the optimal cutoff point. **Results:** Among CLD-related function and complications, Vs values were highly correlated with liver fibrosis and EV complication rates (P < 0.05). The median Vs values for liver fibrosis grades F0, F1, F2, F3, and F4 were 1.18, 1.34, 1.39, 1.80, and 2.12 m/s, respectively. Comparison of receiver operating characteristic (ROC) curves to predict cirrhosis showed that area under the ROC (AUROC) curve for Vs values was 0.902, which was not significantly different from the AUROCs for the FIB-4 index, platelet count, hyaluronic acid, or type IV collagen 7S, while it was significantly different from the AUROC for mac-2 binding protein glycosylation isomer (M2BPGi) (P < 0.01). Comparison of ROC curves to predict EV showed that the AUROC for Vs values was 0.901, which was significantly higher than the AUROCs for FIB-4 index (P < 0.05), platelet count

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

(P < 0.05), M2BPGi (P < 0.01), hyaluronic acid (P < 0.05), and splenic volume (P < 0.05). The optimal cutoff value of Vs based on Youden index was 2.08 with a sensitivity of 80.0% and specificity of 85.4%. In patients with advanced liver fibrosis (F3+F4), there was no difference in blood markers and splenic volume, while Vs value was significantly higher in patients with EV (P < 0.01). **Conclusion:** Hepatic shear wave velocity was highly correlated with EV complication rates in chronic liver diseases as compared to blood markers and splenic volume. In advanced CLD patients, Vs values of SWE are suggested to be effective in predicting the appearance of EV noninvasively.

3145-A | IMPACT OF RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM INHIBITORS AND NON-SELECTIVE BETA-BLOCKERS AS PRIMARY PROPHYLAXIS OF ESOPHAGEAL VARICEAL BLEEDING, ASCITES, HEPATIC ENCEPHALOPATHY, AND MORTALITY IN COMPENSATED CIRRHOTIC PATIENTS

Julton Tomanguillo Chumbe[1], Mark Ayoub[2], Lauren Searls[2], Hamid Ullah[2], Frank Annie[2], Ebubekir Daglilar[1] and Nadeem Anwar[1], (1)West Virginia University - Charleston Area Medical Center, Charleston, WV, (2) Charleston Area Medical Center/WVU Charleston Division

Background: Bench studies have shown that renin-angiotensin-aldosterone system (RAAS) inhibitors significantly reduce liver fibrogenesis and portal hypertension. Despite encouraging results in animal studies, replication of these benefits has been poorly reported in clinical studies. This study aimed to evaluate the impact of RAAS inhibitors and non-selective beta-blockers (NSBB) as primary prophylaxis in compensated cirrhotic patients for esophageal variceal bleeding (EVB), ascites, hepatic encephalopathy (HE), hepatorenal syndrome (AKI-HRS), and mortality. **Methods:** We queried the Trinetx-Research Network (92 health care organizations within the USA) between 2011 and 2020. Patients with compensated cirrhosis were divided into two cohorts; a first cohort of patients on NSBB (Propranolol or Nadolol) and Renin-angiotensin-aldosterone system (RAAS) inhibitors; and a second cohort of patients on NSBB alone. **Results:** 54,138 patients with compensated cirrhosis were included in this analysis. Of these 41.7% (n = 22,577) were on both NSBB and a RAAS inhibitor, and 58.3% (n = 31,560) were only on NSBB. The raw data showed that the patients in the NSBB and RAAS group were older (69.4 ± 10.6 vs 65.9 ± 12.2, P < 0.001), and had higher rates of key comorbidities such as chronic heart failure (8.3 vs 3.6, P < 0.001), chronic kidney disease (9.9 vs 4.4%), CAD (12.9% vs 5.5%, P < 0.001), and diabetes mellitus (47.6% vs 20.9%, P < 0.001). Subsequently, two well-matched cohorts were created using a 1:1 propensity-scored matching model (17,318/17,318). Patients on NSBB and a RAASS inhibitor had lower mortality rates at 6 months (4.2% vs 4.7%, P = 0.01), and 12 months (6.6% vs 8.2%, P = 0.0002); lower EVB at 6 months (1.7% vs 2.1%, P = 0.004), and12 months (2.3% vs 2.8, p = 0.0009); lower ascites at 6 months (1.1% vs 1.5%, p = 0.003), and 12 months (1.7% vs 2.1%, p = 0.01); lower HE at 6 months (0.5% vs 0.7%, p = 0.01), and at 12-months no significant decrease in HE (0.9% vs 1.1%, P = 0.05), No significance difference was found between cohorts on the rate of AKI-HRS and SBP. **Conclusion:** In a large nationwide study, the adjunctive therapy of a RAAS inhibitor in compensated cirrhotic patients on NSBB had a significantly lower rate of EVB, ascites, and mortality (up to 1-year) when compared with patients on NSBB alone.

3146-A | IMPACT OF RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM INHIBITORS AND NON-SELECTIVE BETA-BLOCKERS ON ESOPHAGEAL VARICEAL BLEEDING AND MORTALITY IN PATIENTS WITH DECOMPENSATED CIRRHOSIS: A NATIONWIDE ANALYSIS

Julton Tomanguillo Chumbe[1], Mark Ayoub[1], Lauren Searls[1], Hamid Ullah[1], Frank Annie[1], Ebubekir Daglilar[2] and Nadeem Anwar[2], (1)Charleston Area Medical Center/WVU Charleston Division, (2)West Virginia University - Charleston Area Medical Center, Charleston, WV

Background: Routinely, the use of renin-angiotensin-aldosterone system inhibitors (RAASi) in patients with decompensated cirrhosis is not recommended due to the increased risk of renal dysfunction. However, many of these patients have heart failure, hypertension, and chronic kidney disease, where the use of RAASi are indicated as guideline-directed medical therapy. Therefore, the use of RAASi in many of these patients cannot be avoided. The aim of this study is to assess the impact of combined RASSi use with NSBB versus

NSBB alone on rate of esophageal variceal bleed (EVB) and mortality. **Methods:** We queried the Trinetx-Research Network (92 health care organizations within the USA) between 2011 and 2019. Patients with decompensated cirrhosis were divided into two cohorts; a first cohort of patients who received NSBB (Propranolol or Nadolol) and RAASi; and a second cohort of patients on NSBB alone. We compared all-cause mortality, EVB, ICU length of stay (ICU LOS) at 6-months, and 1 year between propensity matched (PSM) pairs of patients. **Results:** A total of 85,015 subjects were included in this analysis. Of these, 31,693 (37%) were taking NSBB as well as a RASSi and 53,322 (63%) only NSBB. Raw data showed the NSBB and RAASi group were older (69.7 ± 10.5 vs 65.8 ± 11.6, $P < 0.001$), and had higher rates of key comorbidities such as chronic heart failure (20.5% vs 14.5%, $p < 0.001$), diabetes mellitus (58.1% vs 28.2%, $p < 0.001$), and hypertension (80.7% vs 46.0%, $p < 0.001$). Subsequently, two PSM cohorts were created using a 1:1 model (25,571/25,571). The NSBB and RASSi group had a lower rate of EVB compared to NSBB group at 6-months (4.6.% vs 5.1%, $P = 0.005$), and 1-year (6.0% vs 6.8%, $P = 0.0005$); lower mortality at 6-months (12.5% vs 13.2%, $P = 0.01$), and 1-year (18.5% vs 19.3%, $P = 0.01$); lower ICU LOS at 6-months (11.6% vs 12.4%, $P = 0.008$), and 1-year (15.3% vs 16.6%, $P < 0.0001$); although this benefit on the hospital LOS was not seen at 6-months (12 d vs 12 d, $P = 0.09$), or 1-year (7 d vs 7 d, $P = 0.14$). No increase rate of hepatorenal syndrome (HRS) was found between RAASi to NSSB versus NSSB only at 1 year (5.3% vs 5.6%, $p = 0.27$) **Conclusion:** In a large nationwide study, patients with decompensated cirrhosis on NSBB and a RAASi had a statistically significant lower rate of esophageal bleeding, mortality, and ICU-length of stay. The addition of RAASi to a NSSB was not significantly associated with increased rate of HRS.

3147-A | INDEX PRESENTATION AND DECOMPENSATION OF CIRRHOSIS VARY ACCORDING TO THE UNDERLYING ETIOLOGY

Mithun Sharma[1], Anand V. Kulkarni[2], Sowmya T R[2], Manasa Alla[2], Shantan Venishetty[2], P. Nagaraja Rao[1] and Nageshwar D Reddy[2], (1)Asian Institute of Gastroenterology, Hyderabad, Telangana, India, (2)Aig Hospitals, Hyderabad, India

Background: Ascites have been reported as the initial most common decompensating event in patients with liver cirrhosis. However, data are scarce regarding the mode of initial diagnosis of cirrhosis and whether the initial decompensating event varies based on the underlying etiology. The current study was designed to evaluate these two important events in the natural history of liver cirrhosis. **Methods:** All consecutive patients presenting to the liver outpatient clinic of the institute and the emergency room were included in the study. A detailed history was taken to find out how the first diagnosis of liver cirrhosis was made, along with a note of the presenting features. The first decompensating event was defined as the development of ascites, variceal bleed, hepatic encephalopathy, or rise in serum bilirubin to greater than 2 mg/dl. The underlying etiology of liver disease was confirmed as per the standard definitions used for NASH, Alcohol associated cirrhosis(AAC), alcoholic hepatitis, autoimmune hepatitis, Wilson's disease, primary biliary cholangitis, primary sclerosing cholangitis etc. **Results:** A total of 1035 liver cirrhosis patients were included in the study. Of these, 710(68.89%) were alcohol-associated, while the remaining were hepatitis B 65(6.58%), hepatitis C (12(1.16%), Autoimmune hepatitis(15(1.45%), PBC (2 (0.19%) and the remaining NASH related (230 (22.23%). The most common reason why cirrhosis was detected was an episode of upper gastrointestinal bleeding in AAC (42%). In comparison, in all other etiologies of cirrhosis, the initial reason for cirrhosis detection was the development of edema and or ascites (48.2%). Incidental detection of cirrhosis during a routine evaluation was significantly higher in NASH-related cirrhosis (23.6%) than in other etiologies. In our cohort, the most common decompensating event in cirrhosis was ascites (overall 72.4%) across all etiologies, while alcoholic patients had a significantly more proportion of bleeding episodes as initial decompensating events (26.4%) versus 12.2% in other etiologies ($p < 0.002$). In addition, a significantly more number of hepatocellular carcinoma as the index presentation was found in hepatitis B-related CLD (11.4%) vs non viral etiologies (2.8%). **Conclusion:** Alcohol-associated cirrhosis has a different mode of initial presentation of cirrhosis leading to the first diagnosis and is associated with significantly more bleeding episodes as the index decompensating event. HCC are more common at the first diagnosis in patients with hepatitis B.

3148-A | LOW PLATELET COUNT, HIGH ASPARTATE AMINOTRANSFERASE-TO-PLATELET RATIO (APRI), AND HIGH FIBROSIS-4 SCORE ARE ASSOCIATED WITH DECOMPENSATION IN PATIENTS WITH LIVER CIRRHOSIS

Xinyuan Zhang[1], Iyiad Alabdul Razzak[2], Gloria Horta[2], Longgang Zhao[1], Christopher Danford[3], Michelle Lai[2] and Xuehong Zhang[4], (1)Brigham and Women's Hospital, Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3)Intermountain Health, (4)Brigham and Women's Hospital

Background: There are a few studies suggesting aspartate aminotransferase (AST)-to-platelet ratio (APRI) and Fibrosis-4 (FIB-4) score's utility in predicting liver-related complications in patients with non-alcoholic fatty liver disease (NAFLD). However, to our knowledge, their performances have not been studied in patients with liver cirrhosis. This study aims to examine if such clinical noninvasive markers could predict the risk of liver decompensation in patients with liver cirrhosis. **Methods:** Beginning August 2020, we developed a prospective cohort of patients with liver cirrhosis at the Liver Center of Beth Israel Deaconess Medical Center, with intended follow-up visits every 6 months. Cirrhosis diagnosis was based on liver biopsy, imaging, vibration-controlled transient elastography, and/or endoscopic features. This study included 246 patients who received lab tests at enrollment, e.g., platelet count, AST, and alanine transaminase (ALT). We further calculated APRI and FIB-4 as the main predictors, and classified them based on clinically meaningful cutoffs. Outcome was liver decompensation events, including variceal hemorrhage, hepatic encephalopathy, and ascites. Demographics and clinical data, e.g., age, sex, race, primary liver disease, and body mass index (BMI), were recorded. Multivariable logistic regression models were fitted to estimate odds ratios (OR) and area under the receiver operative curve (AUC). **Results:** By up to four follow-up visits, 119 patients had at least one liver-related complications. Low platelet count (< 150k/uL to e 150k/uL; OR = 2.89; 95% confidence interval (CI): 1.49, 5.60; model AUC = 0.831), high APRI (> 0.5 to d 0.5; OR = 3.58; 95% CI: 1.84, 6.95; model AUC = 0.840), and FIB-4 (> 1.4 to d 1.4; OR = 2.58; 95% CI: 1.18, 5.64; model AUC = 0.826) were strongly associated with higher risk of decompensation, after adjusting for age, sex, race, primary liver disease, BMI, and Child-Pugh score. Significant associations persisted when adjusting for Model for End-Stage Liver Disease (MELD) score. Specifically, high APRI was strongly associated with higher risk of variceal hemorrhage (OR = 6.32; 95% CI: 3.05, 13.1) and FIB-4 was strongly associated with hepatic encephalopathy (OR = 5.50; 95% CI: 1.61, 18.8). **Conclusion:** Platelet count, APRI, and FIB-4 are inexpensive, readily available tools to identify patients with liver cirrhosis who are at higher risk for liver decompensation. Of note, APRI > 0.5 and FIB-4 > 1.4 showed strongest associations in our liver cirrhosis cohort, independent of Child-Pugh and MELD scores. Future studies are warranted to replicate their clinical application.

3149-A | LYMPHOCYTE-RELATED NUTRITIONAL MARKERS AND MUSCLE VOLUME ASSESSMENT ARE USEFUL FOR PREDICTING PROGNOSIS IN LIVER CIRRHOSIS COMPLICATED WITH PORTAL HYPERTENSION

Arisa Yamamoto, Takuto Nosaka, Yu Akazawa, Kazuto Takahashi, Tatsushi Naito, Hidetaka Matsuda, Masahiro Ohtani and Yasunari Nakamoto, University of Fukui

Background: Malnutrition and metabolic abnormalities with liver disease induce sarcopenia and affect pathogenesis, therefore, their clinical importance has been increasingly recognized. Lymphocyte-related nutritional markers are simple immunotrophic markers, although the association with muscle volume or long-term prognosis in cirrhosis has not been fully evaluated. In this study, we examined the association between lymphocyte-related nutritional markers, muscle volume and long-term prognosis in cirrhosis patients with portal hypertension. **Methods:** The

subjects were 96 cirrhotic patients with non-ruptured esophageal and gastric varices who underwent initial endoscopic treatment or B-RTO from April 2006 to March 2023. Median age 69 (40-88) years, male/female ratio 63/33, median observation period 1075 (11-5831) days, background liver diseases: HBV 3/HCV 33/ Alcohol 35/ Others 25, pre-treatment Child-Pugh classification: A 44/ B 43/ C 9. Lymphocyte-related nutritional markers were examined by Neutrophil-to-lymphocyte ratio (NLR), Prognostic Nutritional Index (PNI), and Controlling Nutritional Status (CONUT). Muscle volume was measured using a 3D medical imaging workstation ziostation2 and evaluated by Psoas Volume Index (PVI) (cm3/m2), which is the volume of the psoas major muscle divided by the square of the height. Sarcopenia was defined using the psoas major index (PMI) (cutoff values: male 6.36 cm2/m2, female 3.92 cm2/m2). **Results:** Cumulative survival rates were 87.1% at 1 year, 63.7% at 3 years, and 41.2% at 5 years. The mean/median values of each marker before treatment were NLR $2.37 \pm 1.68/2.12$, PNI $40.1 \pm 6.30/40.1$, CONUT $4.57 \pm 2.62/4.00$, PVI male: $128.9 \pm 39.8/124.2$ cm3/m2, female: $90.0 \pm 20.3/91.2$ cm3/m2, 28 patients (29.2%) were classified as sarcopenia group. When the cut-off values were set to NLR 3.0, PNI 40, and CONUT 5 according to previous reports, NLR e 3.0, PNI d 40, CONUT e 5, and sarcopenia groups had significantly worse prognosis ($p < 0.05$). PVI showed a very strong correlation with PMI ($r = 0.827$, $p < 0.001$), but there was no significant correlation between each lymphocyte-related nutritional marker and PVI. In multivariate analysis of survival, age e 65 years, NLR e 3.0, and albumin level < 3.5 g/dL were independent prognostic factors ($p < 0.05$). **Conclusion:** In liver cirrhosis patients with portal hypertension, lymphocyte-related nutritional markers NLR, PNI, and CONUT were all associated with life prognosis, suggesting that these may be useful as prognostic indicators and nutritional intervention markers. Objective quantification of psoas muscle volume by 3D-CT can more accurately assess muscle mass and sarcopenia, and may help predict prognosis in liver cirrhosis patients.

3150-A | MAGNETIC RESONANCE ELASTOGRAPHY (MRE) NON-INVASIVELY PREDICTS HIGH-RISK ESOPHAGEAL VARICES IN OBESE NAFLD CIRRHOSIS

Akash Roy[1], Awanish Tewari[1], Nipun Verma[2], Usha Goenka[1], Surabhi Jajodia[1], Swayambhu Banerjee[1], Vikram Patil[1] and Mahesh Goenka[1], (1)Apollo Hospitals, Kolkata, (2)Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Liver stiffness measurement (LSM) by magnetic resonance elastography (MRE) is helpful in the prediction of esophageal varices (EVs) and high-risk varices (HRVs) in cirrhosis. Conventional transient elastography has been shown to underperform in high-risk varices (HRVs) prediction in obese non-alcoholic fatty liver disease (NAFLD) cirrhosis. MRE-LSM for predicting EVs and HRVs, specifically in obese NAFLD cirrhosis, remains relatively unexplored. **Methods:** In a prospective study, consecutive patients with NAFLD compensated cirrhosis who were obese (Body mass index e 25kg/m2) and underwent MRE (Philips Ingenia 3.0T with mDixon quant software) for LSM and endoscopy for screening of varices were enrolled. Diagnosis of cirrhosis was based on clinical parameters and imaging (ultrasonography and computed tomography). The diagnostic performance of MRE for predicting the presence of EVs and HRVs was evaluated using the area under receiver-operating characteristics curves ((AUROC), and regression analyses were performed for multiple variables related to the presence of EVs or HRVs. **Results:** 82 obese patients (mean age 53.85 ± 9.62, 29.6% females, mean BMI 29.1 ± 3.39) with compensated NAFLD cirrhosis (70.3% Diabetes, 49.3% Hypertension, 19.7% Dyslipidemia) were enrolled. 47 (58.0%) had EVs, 20 (24.6%) had HRVs. Median [95% confidence interval (CI)] MRE-LSM was 4.9(4.6-5.1), 4.9(4.6-5.3) and 5.6(5.0-6.10) for no varices, low risk varices (LRVs) and HRVs respectively, with differences being significant between LRVs and HRVs ($p < 0.01$). AUROC for MRE-LSM for any varices, LRVs, and HRVs were 0.55(0.43-0.66, $p = 0.45$), 0.57(0.46-0.68, $p = 0.25$) and 0.66(0.55-0.76, $p = 0.02$, cut-off > 5.2) respectively. Odds ratio (95%CI) for MRE-LSM and platelet count (PLC) for HRVs were 1.57(1.01-2.4) and 0.98 (0.97-0.99), respectively. Logistic regression model with MRE-LSM and PLC had an AUC of 0.70(0.59-0.80, $p = < 0.01$). **Conclusion:** MRE-LSM is significantly higher in obese NAFLD compensated cirrhosis with HRVs than those without EVs or LRVs. MRE-LSM, in combination with PLC, identifies HRVs in obese NAFLD cirrhosis.

3151-A | MULTICENTER VALIDATION OF THE EVENDO SCORE TO NONINVASIVELY RISK STRATIFY PATIENTS WITH CIRRHOSIS UNDERGOING INITIAL VARICEAL SCREENING

Andrew Richard Roney[1], Pauline Yasmeh[2], Tien S. Dong[1], Harry Trieu[3] and James Tabibian[2], (1)University of California, Los Angeles, (2)Olive View-UCLA, Burbank, CA, (3)University of Southern California

Background: Many patients with cirrhosis have either no esophageal varices (EVs) or only low-risk EVs (LREVs) on initial screening esophagogastroduodenoscopy (EGD) and do not directly benefit from a screening EGD, yet still face the associated hazards of sedation and procedure-related complications. Non-invasive methods are thus needed to identify patients who may defer initial screening EGD and thereby avoid the associated risks and costs. The EVendo score, a machine learning-based tool, predicts the presence of EVs and high-risk EVs (HREVs) using readily available clinical data. We aimed to further validate the EVendo score in patients undergoing initial screening EGD. **Methods:** We conducted a multicenter retrospective study of screening EGDs performed from January 2019 through May 2020 at the Veterans Affairs West Los Angeles Medical Center, Olive View-UCLA Medical Center, and Ronald Reagan UCLA Medical Center. Patient demographic, biochemical, clinical, and endoscopic data prior to EGD were abstracted from electronic medical records. Patients with a prior EGD or prior episode of variceal bleeding were excluded. The EVendo score was calculated for each patient, and its ability to predict any EVs and HREVs was assessed. **Results:** A total of 133 patients were included in the study. Ninety-two patients were classified as CTP Class A, 31 as Class B, and 10 as CTP Class C. The etiologies of cirrhosis were as follows: alcohol (n = 46), HCV (n = 29), NASH (n = 31), HBV (n = 5), autoimmune hepatitis (n = 5), and multifactorial (n = 17). There were no statistically significant differences in patient demographics or biochemical data, except for platelet count, between those with and without HREVs. The EVendo score had a sensitivity of 97.1% and a negative predictive value of 96.8% for detecting HREVs. For detecting the presence of any EVs the EVendo score had sensitivity of 92.3% and a negative predictive value of 80.6%. Using the EVendo score would have reduced initial screening EGD by 22.6% (30/133), missing 2.9% of HREVs (1/34). The number of initial screening EGDs avoided in CTP class A patients increased to 30.4% (28/92), missing 4.5% of HREVs (1/22). **Conclusion:** This study validates the high sensitivity and negative predictive value of the EVendo score and its potential for non-invasively identifying patients who can avoid initial screening EGD on the basis of low probability of HREVs. Furthermore, in CTP class A patients an even higher percentage of EGDs can be spared, potentially due to the lower probability of these patients having portal pressures significant enough to cause HREVs compared to CTP class B and C patients.

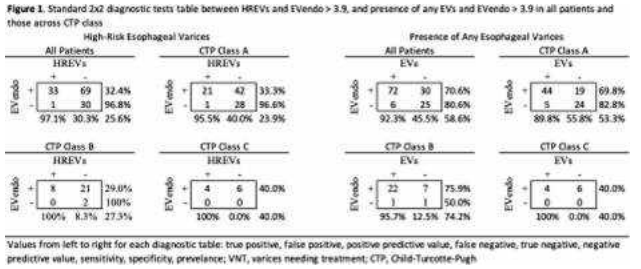

Figure 1. Standard 2x2 diagnostic tests table between HREVs and EVendo > 3.9, and presence of any EVs and EVendo > 3.9 in all patients and those across CTP class

Values from left to right for each diagnostic table: true positive, false positive, positive predictive value, false negative, true negative, negative predictive value, sensitivity, specificity, prevelance; VNT, varices needing treatment; CTP, Child-Turcotte-Pugh

3152-A | NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING CARRIES THE SAME SHORT-TERM PROGNOSIS AS VARICEAL BLEEDING IN PATIENTS WITH CIRRHOSIS AND SHOULD BE CONSIDERED A DECOMPENSATING EVENT

Rajiv Kurup, Deloshaan Subhaharan, Tehara Wickremeratne, Andrew Sloss, Jonathan Mitchell, Rohit Gupta and James Patrick O'Beirne, Sunshine Coast University Hospital

Background: According to the Baveno consensus recommendations, upper gastrointestinal bleeding (UGIB) that occurs secondary to portal hypertension

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in patients with cirrhosis is considered a decompensation event and is associated with a high mortality rate. Nevertheless, it remains uncertain whether non-portal hypertension-related bleeding carries the same level of prognostic significance. This study aimed to compare the survival rates between portal hypertension-related and non-portal hypertension-related bleeding in patients with cirrhosis. **Methods:** This retrospective study included patients with cirrhosis admitted to Sunshine Coast University Hospital with UGIB, hepatic encephalopathy, ascites, and jaundice between November 2016 and October 2020. Patients were divided into portal hypertension-related bleeding, non-portal hypertension-related bleeding and outcomes were compared to other causes of decompensation. UGIB from portal hypertension-related bleeding was classified as either secondary to gastro-oesophageal varices or portal hypertensive gastropathy. Gastroscopy reports were analysed, and variceal bleeding was defined in accordance with the Baveno criteria. **Results:** 243 patients were included. The majority of patients were male (65.8%) and the median age was 59 years (IQR 50-67). The main aetiology of cirrhosis was alcohol in 63%. 106 patients were Child-Pugh (CP) class C and 81.1% were admitted with other causes of decompensation. The median CP score was 7 for both portal hypertension-related bleeding (IQR 5-9.5) and non-portal hypertension-related bleeding (IQR 5-9) with no significant difference between these groups (p 0.66). In comparison, patients with other causes of decompensation had a median CP score of 10 (IQR 8-11) which was significantly higher than the UGIB group ($p < 0.001$). 84 patients presented with UGIB with 45 (53.6%) being portal hypertension-related and 39 from other causes including Mallory Weiss tears and oesophageal and gastric ulcers. There was no significant difference in 30-day, 90-day and 1-year survival between portal hypertension-related and non-portal hypertension-related bleeding. There was a significant difference in overall survival between the UGIB group and patients with other causes of decompensation (p 0.002). However, there was no significant difference in overall survival between portal hypertension-related and non-portal hypertension-related bleeding. **Conclusion:** This data suggests that early outcomes in patients admitted with portal hypertension-related and non-portal hypertension-related bleeding are similar. Therefore, even non-portal hypertension-related bleeding can be considered as a decompensating event and could influence mortality possibly by serving as a trigger for acute-on-chronic liver failure. The diversion of survival curves on prolonged follow up confirms the impact of portal hypertension on long-term prognosis.

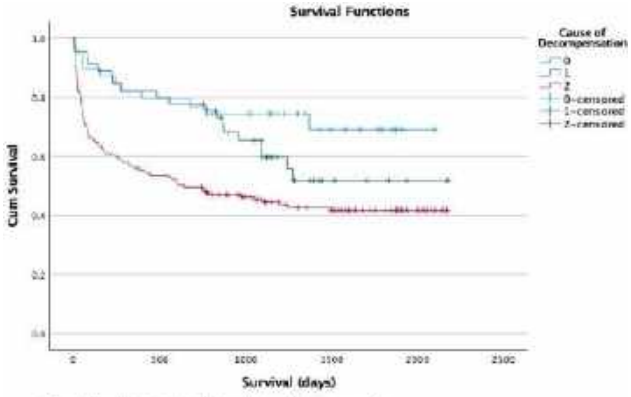

Figure 1: Overall survival in patients with hepatic decompensation.
0 = non-portal hypertension bleeding, 1 = portal hypertension bleeding, 2 = other causes of decompensation

3153-A | OUTCOMES AND PROGNOSTIC FACTORS OF CIRRHOTIC PATIENTS WITH ACUTE VARICEAL BLEEDING AND CONCURRENT HEPATOCELLULAR CARCINOMA

Guofeng Liu[1], Xuefeng Luo[2], Xiaoze Wang[1] and Tong Xiang[1], (1)West China Hospital, (2)West China Hospital, Sichuan University

Background: The treatment outcomes and risk factors for poor prognosis of acute variceal bleeding (AVB) in hepatocellular carcinoma (HCC) patients remain unclear. Hence, we assessed the clinical outcomes and prognostic factors of these patients. **Methods:** This is a retrospective case-control study. AVB patients with HCC admitted between 2016 and 2019 were included. For each patient with HCC, a patient without HCC was matched by age, sex, and Child-Pugh class. Follow-up was continued until death and transplantation. **Results:** A total of 286 patients were included. The five-day treatment failure, 6-week mortality, and 1-year mortality rates of all enrolled AVB patients were 26.6%, 19.6%, and 36.1%, respectively. HCC patients had higher 6-week and 1-year mortality (26.6% vs. 12.6, $P = 0.003$; 53.3% vs. 18.9%, $P < 0.001$, respectively). Among AVB patients with HCC, alpha-fetoprotein (AFP) levels (HR, 1.001;95% CI, 1.000-1.002; $P = 0.001$), BCLC stage (C-D vs. 0-B) (HR, 7.752; 95% CI, 1.688-35.592; $P = 0.008$), transcatheter arterial chemoembolization (TACE) treatment (HR, 0.293; 95%CI, 0.102-0.842; $P = 0.023$), and Child-Pugh score (HR, 1.496, 95% CI, 1.210-1.849; $P < 0.001$) were independent risk factors

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of 6-week mortality in multivariate analysis. Furthermore, the risk of 6-week mortality was significantly higher among patients with a Child-Pugh score e 9 and BCLC stage C–D ($P < 0.0001$). **Conclusion:** AVB patients with HCC had a worse prognosis than patients without. The Child-Pugh score and the presence and stage of HCC are strong predictors of 6-week mortality.

3154-A | OUTCOMES OF OUTPATIENT ELECTIVE ESOPHAGEAL VARICES BAND LIGATION IN CIRRHOTIC PATIENTS WITH SIGNIFICANT THROMBOCYTOPENIA

Julton Tomanguillo Chumbe[1], Mark Ayoub[2], Lauren Searls[2], Frank Annie[2], Harleen Chela[2], Nadeem Anwar[1] and Ebubekir Daglilar[1], (1)West Virginia University - Charleston Area Medical Center, Charleston, WV, (2)Charleston Area Medical Center/ WVU Charleston Division

Background: Current guidelines recommend against platelets transfusion prior to emergent esophageal varices band ligation (EVL) in cirrhotic with a platelet count less than $50*10^3$/uL. However, recommendations for elective esophageal varices ligation less clear. This study aims to assess the outcomes of cirrhotic patients who underwent EVL as an outpatient. **Methods:** Adult patients 18 years and older with the diagnosis of cirrhosis with and without significant thrombocytopenia, as defined by the cut-off of $50*10^3$/uL, were identified using TriNetX database between 2007 and 2020. Patients who received platelets transfusion on the day of band ligation were excluded. TriNetx includes clinical data from a total of 106 different healthcare organizations in 14 countries. Patients with cirrhosis with significant thrombocytopenia who underwent outpatient elective EVL were divided into two cohorts; the first cohort comprised patients with significant thrombocytopenia (platelet count between 30 and $49*10^3$/uL); and a second cohort of patients with platelet greater and equal than $50*10^3$/uL. We compared the rate of mortality and esophageal variceal bleeding propensity score matched (PSM) pairs of patients. **Results:** A total of 7,392 cirrhotic patients that underwent outpatient EVL were included in this analysis. Of these 8.9% (n = 664) had significant thrombocytopenia, and 91.1% (n = 6,726) had platelets greater and equal than $50*10^3$/uL. The raw data showed that patients with significant thrombocytopenia were younger (59.7 ± 13 vs 62.4 ± 12.7, $P < 0.0001$), and there was no significant difference in key comorbidities. Subsequently, two well-matched cohorts were created using a 1:1 PSM based model (664/664). No significant difference was noted between cirrhotic patients with and without significant thrombocytopenia in the rate of post-EVL esophageal variceal bleeding, mortality at 14 days and 1-month. The end-point were not statistically different in both group in terms of 14-days esophageal varices bleeding (10.54% vs 12.50%, $P = 0.26$), 14-days mortality (2.86%% vs 3.31%%, $P = 0.63$), and 1-month mortality (4.51% vs 6.17%, $P = 0.17$). **Conclusion:** Elective endoscopic bad ligation is safe with platelet count greater and equal than 30 $*10^3$/uL comparing to threshold of $50*10^3$/uL. This lower threshold may prevent unnecessary use of platelet transfusions.

Disclosures: The following people have nothing to disclose: Julton Tomanguillo Chumbe, Mark Ayoub, Lauren Searls, Frank Annie, Harleen Chela, Nadeem Anwar, Ebubekir Daglilar

3155-A | PORTAL HYPERTENSION MANIFESTATIONS OF CROHN'S DISEASE

Keiya Watakabe, Shun Kaneko, Yasuhiro Asahina, Miyako Murakawa, Tatsuya Suzuki, Yuka Hayakawa, Kento Inada, Tomohiro Mochida, Taro Shimizu, Jun Tsuchiya, Masato Miyoshi, Fukiko Kawai-Kitahata, Kento Takenaka, Toshimitsu Fujii, Sei Kakinuma, Mina Nakagawa and Ryuichi Okamoto, Tokyo Medical and Dental University

Background: The screening and diagnosis of portal hypertension (PH) have been difficult especially in non-liver chronic disease, despite severe complications. Inflammatory bowel diseases (IBD) are associated with a variety of extraintestinal manifestations, including hepatobiliary disorders. The hepatobiliary manifestations are reported in both ulcerative colitis (UC) and Crohn's disease (CD) but are more commonly reported about UC. The aims of this study were to reveal the prevalence of advanced liver

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

disease and PH in CD which was less reported, and to identify risk factors. **Methods:** CD patients receiving MRI test (n = 459) were recruited prospectively form Tokyo Medical and Dental University Hospital between April 2017 and September 2021. Fatty Liver and spleen index were diagnosed by MRI. The risk factors and prevalence of PH were analyzed. **Results:** A total of 459 CD patients were median age 33 (18-85) years, majority male (70.0%). 79 cases (17.2%) had fatty liver. During a median follow-up of 3.2 years, we identified 5 (1.1%) cases of PH. Underlying liver disease of PH included non-alcoholic steatohepatitis (NASH, n = 2), granulomatous hepatitis (n = 1), drug induced liver injury (n = 1), and primary sclerosing cholangitis (PSC, n = 1). Median FIB-4 (3.34 vs 0.622) and spleen index (63.75 cm^2 vs 27.03 cm^2) were significantly higher in patients with PH than other CD patients, respectively ($p < 0.001$). Case 1; A 40-year-old man who had a history of three times intestine resections due to bleeding and perforation required liver transplantation due to liver failure caused by progression of NASH decompensated cirrhosis. Case 2; A 45-year-old man was maintained clinical remission of CD with anti-integrin therapy. During follow-up, esophagogastric varices, aggravated splenomegaly and thrombocytopenia were found. He was finally diagnosed granulomatous hepatitis from liver biopsy. The endoscopic injection sclerotherapy for varices, and anti-TNFα for granuloma hepatitis and CD were administered. **Conclusion:** CD patients found to be included some advanced liver disease and PH cases, despite their younger age. PH was not caused only by NASH. FIB-4 and spleen index are also useful in liver surveillance in regular MRI follow up of CD patients.

Disclosures: The following people have nothing to disclose: Keiya Watakabe, Shun Kaneko, Yasuhiro Asahina, Miyako Murakawa, Tatsuya Suzuki, Yuka Hayakawa, Kento Inada, Tomohiro Mochida, Taro Shimizu, Jun Tsuchiya, Masato Miyoshi, Fukiko Kawai-Kitahata, Kento Takenaka, Toshimitsu Fujii, Sei Kakinuma, Mina Nakagawa, Ryuichi Okamoto

3156-A | PORTAL VEIN THROMBOSIS PREDICTS HIGHER MORTALITY IN CIRRHOSIS PATIENTS WITH ACUTE VARICEAL BLEEDING: A SINGAPORE NATIONWIDE AVB AUDIT

Yu JUN Wong[1,2], Margaret Li Peng Teng[3], Alyssa Sim[4], Marianne De Roza[5], Jia Hong Koh[3], Guan Sen Kew[3], Garrett Kang[1], Jonathan Kuang[4], Htay Myat Thet[6], En Xian Sarah Low[6], Kai Lim[7], Pooi Ling Loi[7], Xuhui Teoh[8], Gabriel Liu Yuan Cher[8], Jing Liang Ho[9], Siti Maryam Abdul Rahman[10], Kenny Sze[8], Guan Wee Wong[6], Andrew Kwek[1], Wei Lyn Yang[4] and Jason Pik Eu Chang[11], (1)Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, (2) Duke-Nus Medical School, Singhealth, Singapore, (3) Division of Gastroenterology & Hepatology, National University Hospital, Singapore, (4)Department of Gastroenterology & Hepatology, Tan Tock Seng Hospital, Singapore, (5)Department of Gastroenterology & Hepatology, Sengkang General Hospital, Singapore, (6)Division of Gastroenterology, Department of Medicine, Ng Teng Fong General Hospital, Singapore, (7)Department of Gastroenterology & Hepatology, Singapore General Hospital, Singapore, (8)Department of Gastroenterology & Hepatology, Khoo Teck Puat Hospital, Singapore, (9)Department of Medicine, Woodlands Health, Singapore, (10)Clinical Trial Research Unit, Changi General Hospital, (11)Singapore General Hospital

Background: Portal vein thrombosis (PVT) was associated with a higher risk of acute variceal bleeding (AVB) and rebleeding in cirrhosis patients. However, it's impact on the mortality risk beyond the setting of liver transplantation remained debatable (eg: in the setting of AVB). Using the Singapore nationwide AVB audit registry, we sought to determine the prognostic impact of PVT in cirrhosis patients presented with AVB. **Methods:** Medical records of AVB patients hospitalized in all public hospitals in Singapore from January 2015 to December 2020 were individually reviewed by investigators. Primary predictor was the presence of PVT, identified based on imaging within 6 months of the AVB episode. Primary outcome was 6-week mortality, secondary outcomes included rebleeding at 5 days and mortality at 1 year. Baseline differences between PVT and non-PVT groups were balanced using propensity score matching (PSM), adjusting for gender, cirrhosis etiology, Child-Turcotte-Pugh (CTP) class, ascites, presence of hepatocellular carcinoma (HCC), AST and platelet count. Sensitivity analysis was performed in (1) AVB patients without HCC, (2) MELD d 10 and (3) MELD > 10, to account for tumour thrombus and severity of cirrhosis. **Results:** Among 888 cirrhosis patients (mean age 62, 75% male) with AVB from seven hospitals in Singapore studied, 15% had PVT. AVB patients with PVT were more likely to be female with HBV-related cirrhosis and had more advanced liver disease ie: ascites, higher CTP score, higher AST, and more likely to have HCC (*67% vs 17%, $p < 0.0001$*). In the PSM cohort (n = 262) with balanced distribution in gender, cirrhosis etiology, cirrhosis severity (ie: CTP score, MELD score, liver decompensating events), and HCC between the PVT and non-PVT group, AVB patients with PVT had similar 5-days rebleeding rate, but were more likely to be hypotensive upon presentation (*28% vs 13%, $p = 0.003$*), and had higher mortality at 6-week (*30% vs 16%, $p = 0.009$*) and 1-year (*64% vs 36%, $p < 0.001$*). In multivariate analysis, PVT predicted a higher 1-year mortality after adjusting for HCC, gender, CTP and MELD score (*OR: 2.9, 95%CI: 1.6-5.3*). Sensitivity analysis showed PVT was

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

associated with a higher 1-year mortality, regardless of low or high MELD score, (MELD d 10: *64.5% vs 12.1%, p < 0.0001;* MELD > 10: *63% vs 44%, p = 0.013*); and also in patients without HCC (*37% vs 18%, p = 0.004*). **Conclusion:** The presence of PVT predicts a poorer prognosis in cirrhotic patients with AVB even after adjusting for the severity of cirrhosis and HCC. PVT commonly co-exist with HCC, which is an important consideration when individualizing treatment decision for PVT in patients with AVB.

3157-A | POST EVL BLEED IS DEPENDENT ON BOTH OPERATOR AND PATIENT RELATED FACTORS

Mithun Sharma[1], Harsh Vardhan Tevethia[2], Anand V. Kulkarni[3], Manasa Alla[3], Shantan Venishetty[3], Sowmya T R[3], Padaki Nagaraja Rao[3] and Nageshwar D Reddy[3], (1)Asian Institute of Gastroenterology, Hyderabad, Telangana, India, (2)Institute of Liver and Biliary Sciences, New Delhi, (3)Aig Hospitals, Hyderabad, India

Background: Early post endoscopic variceal (EVL) bleeding, particularly in patients with prophylactic variceal ligation, is a major concern. Studies have shown that it is associated with higher MELD score, a higher number of bands used, the presence of gastric varices, and lower hemoglobin at admission. There has always been a need to evaluate if the risk is increased due to other causes like the experience of the operator, the type of underlying liver disease, or the level at which these bands are applied **Methods:** This was a prospective study to evaluate the incidence and identify the risk factors for early posy EVL bleeding in patients with liver cirrhosis. All adult patients above 18 years who underwent EVL at the Institute were included in the study. The etiology of underlying liver disease, the indication of EVL, the experience of the endoscopist [residents in final year training or junior consult defined as less than 2 years of completing GI training or consultant (> 2 yrs)], number of bands applied, the highest level at which it was applied, use of proton-pump inhibitors post procedure etc were noted in pre-designed sheets. These patients were followed up for the next 3 weeks either physically or by telephonic interview. Any patient who had a hemoglobin drop > 1 g/dl or had episodes of hematemesis or melena had a relook endoscopy to identify the cause of the bleed. **Results:** During the study period from January 2021 to January 2023, 687 EVL patients were included, of which 108 were for acute bleeding, 204 underwent prophylactic EVL, and the remaining patients had repeat EVL for variceal eradication. The incidence of a bleed within 3 weeks was 26/687 (3.87), and 90% of bleed occurred within 2 weeks. The most common bleed was melena 21/26 (80.7), followed by hematemesis in 3/26(11.5%) and the remaining had hemoglobin drop. Possible band slippage and active spurting bleed were found in 2/3 of patients with hematemesis, which was controlled by repeat ligation, and one patient underwent rescue TIPS. There was a significant bleed in EVL done by residents (10/26 post-EVL bleeders, OR 4.6). The other risk factors were patients with CHILD B/C (OR 6.8), patients who had scarred tissue at the banding site as assessed by the endoscopist OR 3.75), using more than 5 bands (OR 2.4) and if bands were applied at the perforating zone(OR 3.5). There was no association with the level of platelet count or the INR value. **Conclusion:** Early post EVL bleeding is dependent on both the operator and patient-related factors. Advanced liver disease, repeated banding sessions, and application of more bands coupled with a relatively inexperienced operator could lead to more complications, though this needs to be further evaluated in a study powered specifically to meet this end point.

Disclosures: The following people have nothing to disclose: Mithun Sharma, Harsh Vardhan Tevethia, Anand V. Kulkarni, Manasa Alla, Shantan Venishetty, Sowmya T R, Padaki Nagaraja Rao, Nageshwar D Reddy

f 3158-A | POST-TIPS SHORT-TERM LOW MOLECULAR WEIGHT HEPARIN FOR THE PREVENTION OF EARLY TIPS DYSFUNCTION: A RANDOMISED CONTROLLED TRIAL

Xiaoze Wang[1], Xuefeng Luo[2] and Guofeng Liu[1], (1) West China Hospital, (2)West China Hospital, Sichuan University

Background: Transjugular intrahepatic portosystemic shunt (TIPS) dysfunction is defined as a loss of decompression of the portal venous system due to occlusion or stenosis of the TIPS. Whether post-TIPS LMWH was necessary when polytetrafluoroethylene-covered stent was used during TIPS creation was not answered. The present study was designed to evaluate the effect of short-term use of LMWH on early TIPS dysfunction. **Methods:** Between September 2015 and

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

October 2017, consecutive eligible patients with cirrhosis and portal hypertension were randomly assigned to receive LMWH for three days after TIPS procedure (n = 62) or not (n = 62), respectively. All patients were followed up over a twelve-month period. The primary endpoint was TIPS patency rate at one year. Secondary endpoints were overall survival and LMWH-related complication. This trial was registered in ClinicalTrials.gov (NCT03171727). **Results:** During a median follow-up of 54.6 months, the TIPS patency rate at one year was 91.7% in the LMWH group and 93.5% in the control group (HR 1.52, 95% CI 0.78-2.99, P = 0.22). In multivariable logistic regression, stent shortening in the hepatic vein (HR 4.54; 95% CI 1.02-21.42; P = 0.041) was demonstrated as an independent significant risk factor for shunt dysfunction. There were no statistically significant differences in survival (93.5% vs. 95.1% at 1 year; HR = 1.05, 95% CI 0.48-2.31, P = 0.90) or adverse events between the two groups. **Conclusion:** Short-term use of LMWH after TIPS creation may not be necessary as it does not result in a distinct patency and survival benefit in covered TIPS.

Ricardo Albarran-Anguiano[1], Shivang S. Mehta[2], Apurva A. Modi[2], Themistoklis Kourkoumpetis[2], Saleh Elwir[3], James F. Trotter[3] and Stevan A. Gonzalez[2], (1) Baylor Scott & White All Saints Medical Center, Fort Worth, TX, (2)Baylor Simmons Transplant Institute, Forth Worth, TX, (3)Baylor Simmons Transplant Institute, Dallas, TX

Background: Proton pump inhibitors (PPI) are frequently used following endoscopic variceal ligation (EVL) in both acute hemorrhage or elective procedures; although PPI therapy may decrease postbanding ulcer size, its impact on bleeding risk is not well defined. **Methods:** Retrospective cohort study of consecutive patients with cirrhosis who underwent elective or emergent esophagogastroduodenoscopy (EGD) between January 2021 and October of 2022 were evaluated for bleeding outcomes following EVL based on PPI use in a large tertiary care hepatology practice affiliated with a liver transplant program. **Results:** 197 patients were included in the cohort: 39% alcohol-related cirrhosis, median MELD-Na 14 (range 6-40), 34% Child's Classification C, 65% ascites, 46% encephalopathy. Overall, 162 (82%) required EVL and 100 (51%) underwent EGD while hospitalized. Hospitalized patients were less likely to undergo EVL (71% vs. 94%, p < 0.001) and more frequently had non-variceal sources of bleeding (p = 0.002). Among those requiring EVL, 18/162 (11%) experienced a bleeding episode within 30 days following the procedure, which occurred more frequently in those who underwent EVL while hospitalized (21% vs. 3%, p < 0.001). In those with post-EVL bleeding, a post-banding ulcer was identified in 11/18 (61%) and active bleeding was seen in 9/18 (50%) on follow up EGD. Overall, PPI therapy given at the time of EVL had no impact on incidence of post-EVL bleeding events (Figure). Among hospitalized patients who underwent EVL, 66/71 (93%) received PPI therapy, which was given by oral administration (26%), IV push (41%), or continuous infusion (33%), and 70% received at least 72 hrs of therapy. Formulation, dose, or duration of PPI had no association with incidence of post-EVL bleeding among hospitalized patients (p = NS). Among outpatients who underwent elective EVL, PPI therapy was given less frequently in 61/91 (67%, p < 0.001) and administered orally as once daily (57%) or twice daily (43%). In the outpatient setting, PPI dose or duration also had no association with incidence of post-EVL bleeding (p = NS). **Conclusion:** PPI therapy at the time of EVL may not decrease the risk of post-EVL bleeding regardless of hospitalization status or PPI formulation, dose, and duration. Risk-benefit of PPI use should be assessed prior to decisions on initiating therapy.

3160-A | PROSPECTIVE EVALUATION OF PATIENTS WITH NON-CIRRHOTIC PORTAL HYPERTENSION: A SINGLE CENTER STUDY

Maria Mironova[1], Harish Gopalakrishna[2], Nehna Abdul Majeed[1], Asif Ali Hitawala[3], Shani Scott[4], David E Kleiner[5], Christopher Koh[3] and Theo Heller[6], (1) National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, (2)Clinical Research Section, Gaithesberg, MD, (3)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (4)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (5)Laboratory of Pathology, National Cancer Institute, Bethesda, MD, (6)Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health

Background: Non-cirrhotic portal hypertension (NCPH) is a spectrum of liver diseases, including porto-sinusoidal vascular disorder (PSVD), that is associated with elevated portal pressures in absence of cirrhosis. Unlike cirrhosis, patients with NCPH have preserved liver synthetic function, however, develop similar complications of portal hypertension (PH). The mechanisms, natural history, and diagnostics approach to NCPH are not fully explored. We aimed to study disease progression and outcomes in NCPH. **Methods:** Patients with NCPH or known to be at risk for NCPH by the virtue of underlying disease were enrolled into single center prospective study NCT02417740. Patients with evidence of other liver diseases, including cirrhosis were excluded. Clinically significant portal hypertension (CSPH) was diagnosed by presence of varices, including esophageal (EV), portal hypertensive gastropathy or portosystemic collaterals. All participants had an initial liver biopsy. Blood work, liver stiffness measurement (LSM) and abdominal imaging was repeated every 6 to 12 months. Patients with CSPH underwent esophagogastroduodenoscopy for EV screening. **Results:** 47 patients were enrolled, 36 (77%) had CSPH and 11 (23%) had absence of CSPH despite having biopsy features suggestive of PSVD or predisposition due to underlying disease. Median follow-up time was 43 months. Patients with CSPH were mostly White, (97.2%), older, mean age 50.9 ± 13.8 years, had higher spleen-height ratios, and lower platelet counts than patients without CSPH. Most frequent underlying disorders in both groups were primary immunodeficiencies (47%), and autoimmune disorders (13%). 25% patients with CSPH had no underlying diagnosis identified. Most common features in liver biopsies were nodular regenerative hyperplasia (51% of all biopsies), perisinusoidal fibrosis (47%), obliterative portal venopathy (23%), and sinusoidal dilation (21%). Patients with CSPH had significantly higher LSM by transient elastography, median 9.7 kPa vs 5.0 kPa. No patient without CSPH died or had any liver-related complications during the follow-up period (Fig. 1). 7 (19%) of patients with CSPH died, 1 received a liver transplant and 5 (14%) had decompensation (new-onset variceal bleeding (VB), ascites and/or spontaneous bacterial peritonitis). 6/7 of deaths were related to PH or liver disease, 1 died from recurrence of acute lymphoblastic leukemia. **Conclusion:** We observed significant rates of decompensation events in the group with CSPH. The rates of VB were lower than reported previously, although this may be due to inadequate follow up, alternatively regular follow-up allowed for early intervention, initiation of beta blockers and prevention of complications. NCPH has potential for significant morbidity and mortality and close follow-up of patients is crucial.

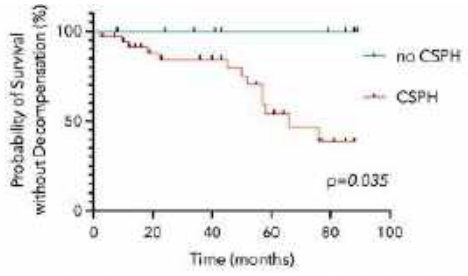

Figure 1. Probability of being alive without decompensation in presence of clinically significant portal hypertension (CSPH) in NCPH cohort was 91% at 1 year, 84% at 2 years, and 54% at 5 years.

f 3161-A | RECALIBRATED MELD 3.0 PERFORMS BEST TO PREDICT 6-WEEK MORTALITY AFTER ACUTE VARICEAL BLEEDING: EXTERNAL VALIDATION IN A LARGE MULTINATIONAL COHORT

Adam Buckholz[1], Yu JUN Wong[2], Rochelle Wong[3], Michael P. Curry[4], Gyorgy Baffy[5], Erik Chak[6], Tarun Rustagi[7], Le Shaun Ang[8], Wen Hui Leia Teo[8], Arpan Mohanty[9] and Brett Fortune[10], (1)New York Presbyterian Hospital Program, (2)Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, (3)Weill Cornell Medicine, NY, (4) Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (5)VA Boston Healthcare System, (6)Univ of California Davis School of Medicine, (7)California Pacific Medical Center, (8)Changi General Hospital, (9)Boston University School of Medicine, (10) Montefiore Medical Center

Background: Acute variceal bleeding (AVB) due to cirrhosis results in 15-20% mortality within 6 weeks, but accurate risk stratification remains elusive. We aim to externally validate the recalibrated Child-Turcotte-Pugh (CTP) and MELD/MELD 3.0 model for the prediction of 6-week mortality using a large multinational cohort of cirrhosis patients with AVB. **Methods:** The development cohort (DC) consists of consecutive cirrhosis patients presenting with AVB identified retrospectively from 2 hospitals in New York. The primary predictors included liver disease indices such as CTP Score, MELD, or MELD 3.0. These indices were recalibrated using logistic recalibration and internally validated using bootstrapping with replacement. The primary outcome was 6-week mortality according to Baveno 6 consensus. Predictive value was quantified as a combination of discrimination by AUROC, and calibration by Hosmer-Lemeshow (HL) test by splitting the cohort into quintiles ($p > 0.05$ means statistically calibrated) and furthermore by the Brier Score, which measures disagreement between observed and forecasted outcome (lower # = better agreement). External validation of the recalibrated models was performed using a multinational AVB cohort (2012-2020) from four US Centers (UC) and one Singapore Center (SC). **Results:** There were 126 patients in the DC, 229 in the UC, and 143 in the SC (total n = 498) with overall 6-week mortality 16%, similar among sites. Patients in the SC had a significantly lower baseline MELD (11.9 vs 16.3, $p < 0.01$) and CTP Score (7.3 vs 8.9, $p < 0.01$) with higher mean age (60.6 vs 58.4, $p < 0.01$) compared to the DC, while the DC and UC had similar baseline characteristics. Each liver index had similar discrimination ($p > 0.05$) for 6-week mortality [Fig 1A]. The performance of all indices were suboptimal in DC and overall cohort before recalibration. Upon logistic recalibration with bootstrapping, the equation obtained for CTP was logit = -6.44 + 0.503*CTP, for MELD was logit = -4.54 +0.159*MELD and for MELD 3.0 was logit = -4.76 + 0.152*MELD 3.0, all of which were internally valid for 6-week mortality prediction after AVB. In external validation, only MELD 3.0 remained calibrated at $p > 0.05$ in both the UC and SC [Fig 1B-D], and had the lowest, albeit similar, Brier Score (MELD 0.120, CTP 0.113, MELD 3.0 0.112). In a LOWESS smoothing model [Fig 1E], observed 6-week mortality was consistently below 5% among those with MELD 3.0 < 12 and > 20% among those with MELD 3.0 > 20. **Conclusion:** In a large diverse multinational cohort of patients with AVB, we recalibrated and externally validated MELD 3.0 as the best liver index in predicting 6-week mortality after AVB. Use of simple predicted mortality thresholds may aide clinicians in the management of these patients and provide important measures for future therapeutic trial design.

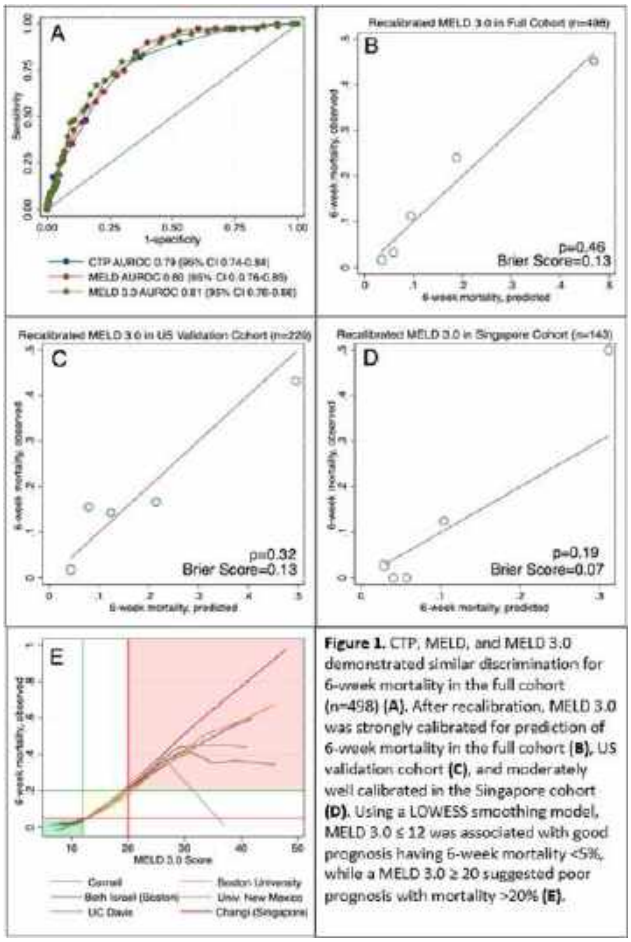

Figure 1. CTP, MELD, and MELD 3.0 demonstrated similar discrimination for 6-week mortality in the full cohort (n=498) **(A)**. After recalibration, MELD 3.0 was strongly calibrated for prediction of 6-week mortality in the full cohort **(B)**, US validation cohort **(C)**, and moderately well calibrated in the Singapore cohort **(D)**. Using a LOWESS smoothing model, MELD 3.0 ≤ 12 was associated with good prognosis having 6-week mortality <5%, while a MELD 3.0 ≥ 20 suggested poor prognosis with mortality >20% **(E)**.

3162-A | ROLE OF SPLENIC STIFFNESS IN THE PREDICTION OF VARICEAL BLEED(VB) IN PATIENTS WITH CIRRHOSIS- SAVIOR STUDY

Harsh Vardhan Tevethia[1], Anirban De[1], Ankur Jindal[1], Vinod Arora[2], Guresh Kumar[3] and Shiv Kumar Sarin[4], (1)Ilbs ,New Delhi, (2)Institute of Liver and Biliary Sciences, New Delhi, India, (3)Institute of Liver and Biliary Sciences, New Delhi, (4)Institute of Liver and Biliary Sciences

Background: Hepatic venous pressure gradient(HVPG) and Liver stiffness(LS) have been shown to be correlated with with variceal bleed in cirrhosis patients. Splenic stiffness(SS) has been shown to correlate with HVPG. We investigated the role of splenic stiffness in the prediction of variceal bleed(VB) in patients with cirrhosis **Methods:** Patients presenting with AVB(Group 1) were prospectively enrolled between April 2021 to May 2022 admitted in the GI Bleed unit at ILBS New Delhi. Patients seen during the same period without AVB who had undergone HVPG (Group 2) were included as controls. Baseline data at admission including HVPG, LS, SS were included. Associations were determined using logistic regression analysis. The primary objective of the study was to assess the role of SS in the prediction of AVB and Liver Related Events(LRE) in comparison to LS and HVPG **Results:** Altogether 320 patients were analysed, 80 with AVB (Group 1) and 240 without bleed (group 2), [males(56.8%),MELD score 15 ± 2.1,predominant etiology ethanol(46.3%) followed by NASH(32.3%)]. The baseline HVPG was higher in AVB than non-AVB group (18.91 mmHg vs 15.78 mmHg $p < 0.01$) along with higher LS(48.2kPa vs 33.kPa, $P < 0.01$). The SS was higher in the AVB group(74.3kPa vs 56kPa $P < 0.01$).Development of LRE was also higher in the AVB group (46.3% vs 21.7% $P < 0.01$). Baseline SS e 69.7kPa along with LS e 45.9kPa and HVPG > 17.5mmHg predicted LRE ($P < 0.01$). Corelation with HVPG was significant with both LS and SS respectively ($P < 0.01$).The AUROC for SS was 87.8(95%C.I-80.2-94.2) as compared to HVPG which was 76.1(95%C.I-66-86.1) and for LS 72.3(95%C.I-61.5-83.1).SAVIOR score for the prediction of AVB using significant non-invasive parameters on multivariate analysis;SS(O.R-1.07 95%C.I-1.0-1.1),LS(O.R-1.03 95% C.I-1.01-1.05),bilirubin(O.R-0.94 95%C.I-0.88-0.99), ethanol etiology (O.R-2.02 95%C.I-1.07-3.71) was created, and gave an AUROC of 84.3($P < 0.01$) with high sensitivity 76% ,specificity 75% and negative predictive value 77%. **Conclusion:** Splenic stiffness closely correlates with the degree of portal hypertension, more so compared to HVPG and LS. A baseline SS of more than 69.8kPa as well as SAVIOR Score > 30 could help stratify patients who need aggressive surveillance as well as better preventive strategies including dosing of beta-blockers and endoscopy prophylaxis

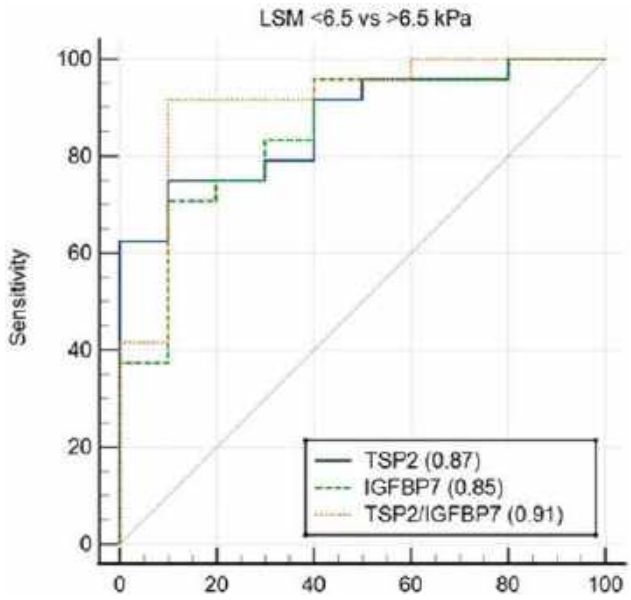
f 3163-A | SERUM THROMBOSPONDIN 2 AND INSULIN-LIKE GROWTH FACTOR PREDICT ADVANCED LIVER FIBROSIS WITH COMMON VARIABLE IMMUNODEFICIENCY

Rambabu Surabattula[1], Valentina Strohmeier[2], Anna-Maria Globig[2], Sudharani Myneni[1], Maximilian Heeg[2], Gerhard Kindle[2], Sigune Goldacker[2], Caroline Von Spee-Mayer[2], Michele Proietti[2,3], Birke Bausch[2], Dominik Bettinger[2], Michael Schultheiss[2], Robert Thimme[4], Klaus Warnatz[2] and Detlef Schuppan[1,5], (1) University Medical Center Mainz, (2)University Medical Center Freiburg, (3)Hannover Medical School, (4) University of Freiburg, (5)Harvard Medical School

Background: Timely detection of segmental fibrosis and portal hypertension as a manifestation in a significant subgroup of patients with common variable immunodeficiency (CVID) represents a challenge, since it is usually not associated with classical liver cirrhosis. So far there are no standard biomarkers to diagnose portal hypertension in patients with CVID. To identify relevant markers, we assessed elastography and novel serum markers of liver fibrogenesis and metabolism/inflammation in well-defined cohort of patients with CVID. **Methods:** Sandwich ELISAs measuring the matricellular fibrosis markers thrombospondin-2 (TSP2) and thrombospondin-4 (TSP4) and the metabolism/inflammation/fibrosis-related markers insulin-like growth factor binding protein-7 (IGFBP7), CD163 and a disintegrin and metalloprotease thrombospondin like-9 (ADAMTS9) were established in-house using combinations of recombinantly expressed proteins, commercial and self-produced monoclonal and polyclonal antibodies. Sensitivity and specificity were optimized, with intra- and Inter assay variations for serum or plasma below 10% and 15%, respectively. We included 39 CVID patients of whom 27 showed clinically significant portal hypertension as defined by either the presence of esophageal varices, hypertensive gastropathy or ascites. Most patients presented with liver stiffness measurement (LSM) above 6.5 kPa suggesting significant fibrosis. **Results:** Patients with LSM above 6.5 kPa vs LSM below 6.5 kPa displayed significantly higher serum levels of TSP2 (118 vs 69 ng/ml) and IGFBP7 (187 vs 135 ng/ml). No significant difference was observed for TSP4, ADAMTS9 and CD163. Both TSP2 and IGFBP7 correlated well with LSM values. The underlying biochemistry as well as the results support a prominent role of TSP2 in liver fibrogenesis due to CVID, and of IGFBP7 in fibrogenic inflammation. Both parameters separated patients with LSM above 6.5 kPa and signs of portal hypertension from those with LSM below 6.5 kPa with an AUROC of 0.87 (TSP2) and 0.85 (IGFBP7). Furthermore, the combination of TSP2 & IGFBP7 showed the highest AUROC (0.91). **Conclusion:** The matricellular serum marker TSP2 and metabolism/fibrosis related marker IGFBP7 predicted advanced fibrosis and portal hypertension in CVID patients. The novel markers may support early antifibrotic interventions for CVID. Confirmation of these findings in larger, prospective cohort is on the way.



Disclosures: The following people have nothing to disclose: Rambabu Surabattula, Valentina Strohmeier, Anna-Maria Globig, Sudharani Myneni, Maximilian Heeg, Gerhard Kindle, Sigune Goldacker, Caroline Von Spee-Mayer, Michele Proietti, Birke Bausch, Dominik Bettinger, Michael Schultheiss, Robert Thimme, Klaus Warnatz, Detlef Schuppan

3164-A | SPLEEN STIFFNESS AS A NON-INVASIVE TEST TO EVALUATE ESOPHAGEAL VARICES NEEDING TREATMENT AND PORTAL PRESSURE GRADIENT IN LIVER CIRRHOSIS

Jeong-Ju Yoo, Soonchunhyang University Bucheon Hospital, Sang Gyune Kim, Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Bucheon, Republic of Korea and Young Seok Kim, Soon Chun Hyang University

Background: One of the complications of liver cirrhosis is an increase in the stiffness of the spleen, which is thought to be related to changes in blood flow within the liver and the spleen. Spleen stiffness (SS) in liver cirrhosis has been studied as a potential diagnostic and prognostic tool, as well as a predictor of clinical outcomes. The purpose of this study is to find out whether SS value can predict the presence of esophageal varices or gastric varices and how it correlates with hepatic venous pressure gradient in patients with liver cirrhosis. **Methods:** Three hundred fifty-seven consecutive patients with liver cirrhosis were enrolled in this study between Sep 2021 and Jan 2023.

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

SS and liver stiffness (LS) were measured by Fibroscan® 630 Expert device. **Results:** The number of patients with any grade of esophageal varies, varices needing treatment (VNT), and gastric varices was 178 (52.3%), 107 (31.4%), and 32 (9.4%), respectively. SS had high predictive power for any grade of esophageal varix (Se 0.811, Sp 0.921, AUROC 0.863), VNT (Se 0.952, Sp 0.788, AUROC 0.841). SS was also effective in predicting gastric varices (Se 0.843, Sp 0.665, AUROC 0.683), Among a variety of predictive models, liver stiffness × spleen stiffness × spleen volume/platelet count predicted the presence of VNT most accurately (Se 0.907, Sp 0.771, AUROC 0.814). SS and HVPG showed a good relationship below HVPG 16mmHg ($p < 0.001$), but at a higher value, the correlation was poor. SS measurement failure occurred in a total of 28 patients (7.84%), and spleen volume smaller than 183 ml was closely related to measurement failure. **Conclusion**: SS is a very useful test for predicting esophageal varices, varices needing treatment and gastric varies in cirrhosis.

3165-A | SPLEEN STIFFNESS DETERMINED BY SPLEEN-DEDICATED DEVICE ACCURATELY PREDICTED ESOPHAGEAL VARICES IN CIRRHOSIS PATIENTS

Jiqing Liu[1,2], Hangfei Xu[1], Weiyuan Liu[1], Hongmei Zu[2], Huiguo Ding[3], Fankun Meng[1] and Jing Zhang[4], (1) Beijing Youan Hospital Capital Medical University, Beijing, China, (2)The Fourth People's Hospital of Qinghai Province, (3)Department of Gastroenterology and Hepatology, Beijing You'an Hospital, Capital Medical University, Beijing, China, (4)Beijing Youan Hospital, Capital Medical University

Background: The advantages of spleen stiffness in prediction of high-risk varices (HRV) in cirrhosis patients have been confirmed. Recently, a new device with 100Hz probe dedicated to spleen stiffness measure (SSM) was developed. The clinical applicability of SSM@100Hz in HRV prediction by comparing to other non-invasive tests (NITs) is still unknown. **Methods:** One hundred and seventy-one cirrhosis patients who performed esophagogastroduodenoscopy (EGD) examination were included. The SSM and liver stiffness measurement were evaluated by 100Hz probe and 50Hz probe, respectively. SSM of 22 healthy controls was also evaluated by 100Hz probe. **Results:** The failure rates of SSM examination of cirrhosis and controls were 2.9% and 4.5%, respectively. The means of SSM were 56.4 ± 21.6kpa and 13.8 ± 6.7 kPa in cirrhosis and controls. SSM increased paralleled with the severity of esophageal varices. The AUC of SSM for HRV prediction was 0.881(95%CI 0.829~0.934) with cut-off at 43.4kPa. The accuracy, false negative rate and EGD spare rate were 86.5%, 2.5% and 24.3%, respectively. For HRV prediction, SSM was comparable to expanded Baveno e and f and superior to other NITs. As to viral vs. non-viral cirrhosis and compensated vs. decompensated cirrhosis, the cut-off and performance of SSM were different. **Conclusion:** SSM@100Hz can predict HRV with high accuracy and low missed HRV rate. We suggested that SSM@100Hz could be used separately due to its simplicity and efficacy. Meanwhile, the cutoffs need further study according to cause of cirrhosis and liver function.

3166-A | TEMPORAL TRENDS IN RED BLOOD CELL, PLASMA, AND PLATELET TRANSFUSIONS AMONG US HOSPITALIZATIONS FOR ACUTE VARICEAL BLEEDING FROM 2007-2020

Pavan Vuddanda[1], Brett Fortune[2] and Arpan Mohanty[1], (1)Boston Medical Center, Boston, MA, (2)Montefiore Medical Center

Background: Acute variceal bleeding (AVB) in cirrhosis is associated with high morbidity and mortality. Blood transfusion is a crucial component in management of AVB and is essential for maintaining organ perfusion. However, aggressive volume expansion with blood transfusions is associated with higher portal pressures and increased risk of rebleeding. In the last decade, guidelines have recommended a restrictive packed red blood cell (PRBC) transfusion strategy and avoidance of using fresh frozen plasma (FFP) and platelets in AVB. National temporal trends in PRBC, FFP and platelet transfusion in AVB, in

Symbols: **f** , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

response to these guidelines, have not been studied. **Methods:** We used the National Inpatient Sample, the largest all-payer inpatient database representing 94% to 97% of the US population, to evaluate national trends in PRBC, FFP and platelet transfusions in AVB from 2007 to 2020. Hospitalization for AVB for patients e 18 years were identified with appropriate ICD-9/10 codes. The three independent outcomes were percentage of hospitalizations with one or more PRBC, FFP and platelet transfusions, respectively. Trends analyses were conducted using join-point regression to estimate the average annual percent change (AAPC) with 95% CIs and the Cochrane-Armitage test was used to determine the significance of the trend. As there was an inflection point in 2010 determined by join-point regression, the analyses focused on trends in the pre-COVID era between 2010 to 2019. **Results:** Between 2010 and 2019 there were 329013 hospitalizations for AVB. The rate of PRBC transfusion decreased from 47% to 36% (AAPC -2.7%, 95% CI [-4.5, -0.9]). The rate of platelet transfusion decreased from 10% to 8.1% (AAPC = -2.8%, 95% CI [-4.1, -1.5]). The rate of FFP transfusion decreased from 19% to 10% (AAPC = -6.6%, 95% CI [-7.6, -5.5]). (Figure 1) Significant decrease in all transfusion types were seen in all strata of sex, admission type, and hospital region. When stratified by teaching hospital status, an increase in the trend of PRBC (AAPC 2.2%, 95% CI 1.5 to 2.8) and platelet transfusion (AAPC 2.0%, 95% CI, 0.3-3.8) was seen in urban teaching hospitals. **Conclusion:** The decline in PRBC, FFP and platelet transfusions suggest adoption of guidelines and evidence supporting restrictive transfusion strategies. Increase trend in PRBC and platelet transfusion in teaching hospitals may be reflective of sicker patients. Further studies are needed to define and optimizing FFP and platelet transfusion use in AVB. Figure 1. Temporal Trends in Red Blood Cell, Plasma, and Platelet Transfusions Among US Hospitalizations for Acute Variceal Bleeding from 2007-2020

3167-A | TRENDS AND ETIOLOGIES OF VARICEAL UPPER GASTROINTESTINAL BLEEDING HOSPITALIZATIONS IN THE UNITED STATES

Khaled Elfert[1,2], Vijay Gayam[3], Praneeth Bandaru[3], Tamta Chkhikvadze[4], Nithan Narendra[5] and Madhavi Reddy[3], (1)St. Barnabas Hospital, Bronx, NY, (2)Cuny School of Medicine, (3)The Brooklyn Hospital Center, (4)SUNY Downstate Health Sciences University, (5)St. Barnabas Hospital

Background: Variceal upper gastrointestinal bleeding (VUGIB) is a severe condition associated with portal hypertension and is a leading cause of mortality. Risk factors include hepatitis B and C, alcohol-related liver disease and non-alcoholic steatohepatitis (NASH) among others. **Methods:** In this study, we aimed to analyze the etiologies and trends of VUGIB hospitalizations in the United States between 2016 and 2020 using data from the National Inpatient Sample database. We included patients aged 18 years or older with a principal diagnosis of VUGIB, excluding elective admissions. Etiologies were determined based on ICD-10 diagnostic codes for secondary diagnoses. Trends over the years were examined using linear regression analysis. **Results:** Our study population comprised 36,190 hospitalizations. Over the study period, we observed a decline in the number of VUGIB hospitalizations, with 8,700 hospitalizations in 2016 decreasing to 6,125 hospitalizations in 2020. The analysis of etiologies revealed that 39.79% of patients had a secondary diagnosis of alcoholic liver disease, 19.73% had a secondary diagnosis of Hepatitis C viral infection, 10.32% had a secondary diagnosis of non-alcoholic steatohepatitis (NASH), and 5.89% had a secondary diagnosis of portal vein thrombosis. Less than 5% of all hospitalizations with VUGIB were attributed to chronic hepatitis B, primary biliary cholangitis, autoimmune hepatitis, primary sclerosing cholangitis, Budd-Chiari Syndrome, or hemochromatosis (Table 1). The proportion of patients with alcoholic liver

disease decreased between 2016 and 2018 (from 43.7% to 36.1%), but increased between 2018 and 2020 (from 36.1% to 41.6%) (P-trend 0.0001). Conversely, the proportion of patients with Hepatitis C virus decreased from 22.3% in 2016 to 16.7% in 2020 (P-trend < 0.0001). **Conclusion:** Our study highlights a decrease in the number of hospitalizations for VUGIB from 2016 to 2020. Alcoholic liver disease was the most prevalent etiology, followed by Hepatitis C virus infection and NASH, with a decreasing trend in HCV-related VUGIB cases. The recent increase in the proportion of alcoholic liver disease-related VUGIB in 2020 may be associated with the heightened alcohol consumption during the COVID-19 pandemic.

Table 1

Disease	Percentage	Number
Alcoholic liver disease	39.79%	14400
Hepatitis C infection	19.73%	7140
Non-alcoholic steatohepatitis	10.32%	3735
Portal vein thrombosis	5.89%	2130
Hepatitis B infection	2.22%	805
Autoimmune hepatitis	1.09%	395
Primary biliary cholangitis	0.77%	280
Hemochromatosis	0.5%	180
Budd Chiari Syndrome	0.22%	80
Primary sclerosing cholangitis	0.14%	50
