Background: The incidence and mortality of HCC continues to be on the rise in the US. Although liver transplantation is considered the curative therapy, a significant number of HCC cases are identified beyond MILAN criteria. Various Immune Checkpoint Inhibitors (ICI) have been recently approved as a treatment of advanced unresectable HCC. We report on the significant impact of complementing locoregional therapies (LRT) with ICIs ± VEGF Inhibitors. **Methods:** Between May 2018 and May 2023, 323 patients (pts) were diagnosed with HCC and managed by a liver cancer clinic. 197 pts were not prescribed ICI because it was not indicated, contraindicated, or pts had metastatic cancer. 126 pts were prescribed ICI as adjunctive therapy to LRT (primarily TACE ± RFA and Y-90). Of the 126 pts, 35 did not start ICI because of insurance denials, pt refusal, or referral to hospice. Of the 91 pts who started ICI, 72 received at least 2 doses and are the subjects of this analysis. ICI was infused per the package insert and pts were followed per standard of care. Labs, imaging, further locoregional interventions, disease progression, transplantation candidacy, and survival were analyzed. **Results:** Median follow-up was 27 (3-91) months. 73.6% were males. 70.2% Hispanic, 92.3% white. Mean age was 65.7 ± 8.5 years. Main underlying liver disease etiology was History of HCV. All were Child-Pugh A or B. BCLC classification pre-ICI: 32.6% A3, 15.4% A4, 33.8% B, and 18.2% C. ICI treatment: 52 pts (57.1%) were treated with nivolumab (nivo) only, 26 pts (28.6%) with nivolumab/ipilimumab (nivo/ipi), and 13 pts (14.3%) with atezolizumab/bevacizumab (ate/bev). Safety and Tolerability: Liver enzymes and MELD score were stable throughout treatment. 11 pts on nivo experienced controllable adverse events. In the nivo/ipi group, 4 pts discontinued ICI due to rash and 3 pts due to severe immune reaction. All pts who received ate/bev permanently discontinued treatment due to side effects including bleeding. Efficacy: 66.2% are still alive. Only 56% required LRT post-starting ICI. Recurrence was seen in 4 pts while on ICI and 8 pts after treatment discontinuation. 5% received a liver transplant. 15% of pts became MILAN eligible post ICI. Median duration on ICI was 13 (1-46) months. There was a statistically significant (p-values < 0.05) decrease in the average number of viable lesions as well as the average size of viable lesions post ICI treatment. Survival: Median survival from HCC diagnosis was 16 months in pts who did not receive ICI versus 35 months in those who did receive ICI (figure). **Conclusion:** In patients with advanced HCC the combination of LRT and ICI is: 1) safe and well-tolerated, 2) more effective than LRT alone, 3) patients required fewer LRT sessions after initiation of ICI, 4) had prolonged disease stability and overall transplant-free survival, and 5) maintained their status within MILAN criteria and decreased the dropout rate from the transplant list.

4035-A | COMPLIANCE OF HEPATOCELLULAR CARCINOMA SCREENING IN PATIENTS WITH CHRONIC VIRAL HEPATITIS

Byung Ik Kim[1], Ju-Yeon Cho[2], Yong Kyun Cho[1] and Won Sohn[1], (1)Sungkyunkwan University School of Medicine, (2)Chosun University

Background: This study aimed to investigate the compliance of the screening for hepatocellular carcinoma (HCC) in patients with chronic viral hepatitis. **Methods**: A cross-sectional study was conducted based on nationally representative samples from the Korean National Health and Nutrition Examination Survey 2007-2012. Of 50,405

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

participants, a total of 1,275 patients with chronic hepatitis B or chronic hepatitis C were included in the final analysis. We investigated compliance of HCC screening using ultranonography and serum alpha-protein. Univariable and multivariable logistic regression analyses were performed to evaluate the screening compliance associated risk factors such as age, sex, marital status, residential area, self-rated health status, education level, income status, private insurance for health care, alcohol and smoking. **Results**: The mean age of 1,275 patients was 49.4 years and male was 51% (n = 618). The compliance of HCC screening was observed in 508 patients (40%): within 6 months before the survey, 12 % (n = 155); 6-12 months, 11% (n = 134); > 12 months, 17% (n = 219). The multivariable analysis showed that compliance of HCC screening was significantly associated with age: 40-60 years (odds ratio [OR] 3.06 with 95% confidence interval [CI]: 2.26-4.15, $p < 0.001$), age: > 60 years (OR 2.92 with 95% CI: 1.93-4.42 $p < 0.001$), self-rated health status: moderate (OR 1.42 with 95% CI: 1.07-1.89, $p = 0.016$), self-rated health status: poor (OR 152 with 95% CI: 1.08-2.13, $p = 0.015$), education: university or higher (OR 1.37 with 95% CI: 1.04-1.81, $p = 0.025$), income: > 50 percentile (OR 1.95 with 95% CI: 1.49-2.56, $p < 0.001$) and private insurance for health care (OR 1.40 with 95% CI: 1.02-1.91, $p = 0.038$). **Conclusion**: Compliance of HCC screening was favorable in patients with older age, poor health status, higher education level, high income and private insurance for health care in Korea. These findings may be helpful to increase HCC screening and surveillance rate in patients with chronic viral hepatitis.

f 4036-A | CONCURRENT MULTI-ARM COMPARISONS OF PERCUTANEOUS ABLATION, OPEN OR LAPAROSCOPIC LIVER RESECTION FOR PATIENTS WITH BCLC STAGE 0-A HEPATOCELLULAR CARCINOMA

Zhihang Chen, Qian Zhou, Zebin Chen, Shunli Shen and Ming Kuang, The First Affiliated Hospital of Sun Yat-Sen University

Background: Liver resection and ablation remain the most common therapeutic options for BCLC stage 0-A hepatocellular carcinoma (HCC), but there is a lack of evidence to show which is the most suitable therapy. This study aimed to make multi-arm comparisons of the short-term and long-term outcomes of percutaneous ablation (PA), open (OLR) or laparoscopic liver resection (LLR) for these patients. **Methods:** This was a retrospective observational cohort study. Multiple generalized propensity score methods were performed to concurrently compare the clinical outcomes of these three treatment options to balance potential confounders. **Results:** Of 1778 patients included, 1237, 307 and 234 underwent OLR, LLR and PA, respectively. After overlap weighting, patients in the minimally invasive group (LLR and PA groups) had few postoperative complications and short postoperative hospital stays (both $P < 0.001$). The 5-year recurrence-free survival (RFS) rate was significantly higher in the LLR group when compared with the OLR and PA groups (56.2% vs. 47.2% vs. 28.3%, $P < 0.001$) while there were no significant differences in the 5-year overall survival (OS) rate among the three groups (86.5% vs. 82.4% vs. 78.9%, $P = 0.083$). Multivariable Cox analysis showed that LLR was an independent factor for better RFS. In subgroup analysis, the long-term outcomes of patients with BCLC stage A HCC were consistent with the whole population. **Conclusion:** In the observational study using various covariate adjustment analysis, LLR is not only minimally invasive, but also provides better RFS and equivalent OS for patients with BCLC stage 0-A HCC when compared with OLR and PA.

f 4037-A | CONVENTIONAL AND MACHINE-LEARNING BASED RISK SCORE REFLECTING INFLAMMATORY, FIBROSIS AND NUTRITIONAL STATUS FOR PATIENTS WITH EARLY STAGE HEPATOCELLULAR CARCINOMA – THE CATS-INF SCORE

Chun-Ting HO[1], Chien-Wei Su[1,2], Elise Chia-Hui Tan[3], Wei-Yu Kao[4], Yi-Hsiang Huang[1,2], Teh-Ia Huo[1,2], Ming-Chih Hou[1,2] and Jaw-Ching Wu[1], (1)National Yang Ming Chiao Tung University, (2)Taipei Veterans General Hospital, (3)China Medical University, (4)Taipei Medical University Hospital

Background: Field factors such as inflammatory, fibrosis and nutritional status play important roles in tumor microenvironment and determine the prognoses of patients with hepatocellular carcinoma (HCC). Machine-learning (ML) has become a promising method to identify significance of factors and predict outcomes of patients. We aimed to develop a risk score by combining conventional methods and ML according to serum biomarkers reflecting the field factors and stratify patients with early-stage HCC into different prognostic groups. **Methods:** A total of 1411 HCC patients within Barcelona Clinic Liver Cancer classification (BCLC)

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

stage 0 to A HCC diagnosed at Taipei Veterans General Hospital from 2012 to 2021 were retrospectively enrolled in the study and divided into training cohort (n = 988) and validating cohort (n = 423) randomly. Serum biomarkers and prognostic scores determining poor overall survival (OS) of the training cohort were first analyzed by conventional method (Cox proportional hazards model) and then validated by ML based methods (LASSO Cox regression). Factors that showed significance in all the above regression models were enrolled in the risk score. The risk score (CATS-INF score) was computed by utilizing coefficients from the multivariable Cox proportional hazard model and were standardized to a score ranging from 0 to 100. The total score of each patient was calculated and grouped into three categories (high, medium, and low risk) based on the 33rd and 66th percentiles. The CATS-INF score was then validated on the validation cohort. **Results:** After a median follow-up of 38.0 months (interquartile range IQR 18.0-57.0 mo), 368 patients died, and the 5-year OS rate was 67.5%. Age, curative treatment, solitary large HCC (SLHCC), serum creatinine, fibrosis-4 (FIB-4) score, Lymphocyte-to-monocyte ratio (LMR), albumin bilirubin (ALBI) grade and alpha fetoprotein (AFP) level were selected as factors of the risk score due to their significance in both Cox proportional hazards model and LASSO Cox regression. The formula of the CATS-INF score according to their coefficient is: CATS-INF score = 50×(Age > 65 y) + 77×(No curative treatment received) + 100×SLHCC + 46×(Serum Creatinine > 1.2 mg/dL) + 77×(FIB-4 > 3.25) + 47×(LMR < 3.62) + 68×(ALBI grade 2 or 3) + 60×(AFP > 20 ng/mL). The cut-off value between low, intermediate, and high-risk groups were 55 and 154, respectively. For patients in the validation cohort, the 5-year OS rates were 77.0%, 62.5% and 45.4% in the low, intermediate, and high-risk groups, respectively ($p < 0.001$). **Conclusion:** The CATS-INF score developed by non-invasive serum biomarkers reflecting field factors can efficiently stratify patients with early-stage HCC into different prognostic groups.

4038-A | COULD STEREOTACTIC RADIOSURGERY AS A PALLIATIVE MANAGEMENT OF HEPATOCELLULAR CARCINOMA LEAD TO IMPROVED SURVIVAL?

Khaled Abdel Karim[1], Waleed Abdel Atty Hamed[1], Gamal Esmat[2], Mohamed ElGharib[1] and Mohamed M Darwish[1], (1)Ain Shams University, (2)Cairo University

Background: The survival and treatment options for patients with hepatocellular carcinoma HCC presented with portal vein thrombosis are far from being satisfactory. The efficacy and safety of stereotactic radiosurgery SRS as a palliative treatment for those patients were proven earlier and we are here presenting our longer-term results. **Methods:** Between January 2020 and Jan 2023, we examined and followed up patients who were ineligible for local treatment of HCC and are having portal vein thrombosis PVT. SRS was offered to those patients as palliative treatment in a dose of 40 Gy in 5 fractions. The patient who showed radiological disease control or recanalization of the PVT were re-challenged for other treatment modalities. **Results:** Twenty-eight patients were enrolled, 23 were males, and only 5 were females. The median age of those patients was 62 years (range 44 to 73 y). They were having Child- Pugh B or early C (7-9). All the patients suffered from PVT (main portal vein or one of its branches). The 6, 12, and 24-months overall survival OS were 89%, 68%, and 40% respectively. Radiological response (stable disease and decreased tumour size) was found in 74% of cases (20/28) by the 3 months' first follow up. The thrombosed portal vein showed radiological signs of recanalization in 57% of treated patients. Those responding patients showed reduced levels of alpha fetoprotein and improved levels of local pain. No grade 4 adverse events were recorded. By the time of data analysis (February 2023) 12 patients were still alive (12 to 30 mo), 8 of those were re-challenged for sorafenib and/or TACE. **Conclusion:** SRS as a palliative treatment for advanced HCC could lead to improved survival in patients with good performance status. Larger size multicentre randomized studies with longer follow up are needed to solidify such results.
Disclosures: The following people have nothing to disclose: Khaled Abdel Karim, Waleed Abdel Atty Hamed, Gamal Esmat, Mohamed ElGharib, Mohamed M Darwish

4039-A | CURRENT PATTERN AND FUTURE PROJECTIONS OF PRIMARY LIVER CANCER IN THE GULF COOPERATION COUNCIL COUNTRIES: ANALYSIS FROM GLOBOCAN 2020 DATABASE

Saleh A Alqahtani[1,2], Saleh Alessy[1,3], Jerome Vignat[4], Ali Al-Zahrani[1], Freddie Bray[4] and Ariana Znaor[4], (1)

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

King Faisal Specialist Hospital and Research Center, (2)Johns Hopkins University, (3)King's College London, (4)The International Agency for Research on Cancer

Background: Liver cancer is among the leading causes of cancer morbidity and mortality globally, but the rates vary between countries. Little is known about the current pattern and future burden of liver cancer in the GCC countries (Saudi Arabia, Qatar, United Arab Emirates, Bahrain, Oman, and Kuwait). **Methods:** We used incidence estimates from the GLOBOCAN 2020 database developed by the International Agency for Research on Cancer, France. We provided the incidence and mortality estimates (numbers and with age-standardized incidence rates, ASRs) in 2020 and future projections for 2040. **Results:** Liver cancer was the seventh most common type of cancer in terms of incidence in the GCC countries in 2020, but the fourth leading cause of cancer deaths. Overall, the GLOBOCAN 2020 estimates indicate that new liver cancer cases (n = 1580) and deaths (n = 1,510) occurred in the GCC countries with ASRs (5.2/100,000) and (5.1/100,000), respectively. Liver cancer in 2020 was more common among males than females across the GCC countries, with the overall incidence ASR (5.9 VS 3.2) and mortality (5.8 VS 3.1), respectively. Saudi Arabia accounted for almost 73% of all cases and (72%) of all deaths from GCC countries and had the highest ASR incidence of liver cancer (5.2) and mortality (5.1) for both genders. By 2040, the number of liver cancer cases in the GCC is estimated to increase by 230%(n = 5205) from current estimates, while mortality will increase by 234% (n = 5059). **Conclusion:** Future cancer control policies in the GCC countries should comprehensively emphasize liver cancer risk factors from viral and nonviral etiologies to address the increasing burden of liver cancer.

4040-A | DECREASED RISK OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC HEPATITIS B TREATED WITH BESIFOVIR

Hyung Joon Yim[1], Seong Hee Kang[1], Young Kul Jung[1], Sang Hoon Ahn[2], Won Kim[3], Jin Mo Yang[4], Jae Young Jang[5], Yong Kyun Cho[6], Yoon Jun Kim[7], Dong Joon Kim[8], Young-Oh Kweon[9], Gun Young Hong[10], Joo Hyun Sohn[11], Jin-Woo Lee[12], Sung Jae Park[13], Yim Sun Young[14], Seung Kak Shin[15], Ji Hoon Kim[14], Yeon Seok Seo[16], Jin Kyung Park[17] and Soonho Um[18], (1)Korea University Ansan Hospital, Ansan, Republic of Korea, (2)Severance Hospital, Seoul, Republic of Korea, (3) Seoul National University, (4)The Catholic University of Korea, (5)Soonchunhyang University College of Medicine, (6)Sungkyunkwan University School of Medicine, (7)Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea, (8)Institute for Liver and Digestive Diseases, College of Medicine, Hallym University, Chuncheon 24252, Republic of Korea, (9) Kyungpook National University College of Medicine, (10)Kwangju Christian Hospital, (11)Hanyang University College of Medicine, (12)Inha University, (13)Inje University College of Medicine, (14)Korea University Hospital, (15)Gachon University Gil Medical Center, Incheon, South Korea, (16)Korea University Anam Hospital, Korea University Medical College, Seoul, Korea, Republic of (South), (17)Ildong Pharmaceutical Company, (18)Korea University College of Medicine

Background: Besifovir dipivoxil maleate (BSV) is a new potent antiviral agent approved in Korea. The favorable antiviral effect of BSV may lower the risk of HCC in patients with CHB. Nevertheless, there is currently a lack of information concerning the impact of BSV treatment on the occurrence of HCC. We aimed to assess the incidence of HCC under BSV therapy using clinical trial and real-world BSV data and to compare it with that observed during entecavir (ETV) or tenofovir disoproxil fumarate (TDF) therapy. **Methods:** We combined the phase 3 clinical trial data of BSV which was conducted for 8 years and retrospective data which was collected in the real-world. The retrospective cohort consisted of patients who initiated ETV, TDF, or BSV as a first treatment between 2007 and 2022 at five tertiary hospitals. Incidences of HCC under these antiviral therapies were compared. To further validate, we conducted propensity score matching with an optimal variable ratio of 1:2 or 1:1 for the ETV or TDF treatment groups, respectively. This approach allowed us to create matched cohorts and enabled a more meaningful comparison of HCC incidences between the groups. We performed the log-rank test to evaluate any significant differences. **Results:** A total of 385, 1139, and 688 patients were treated with BSV, ETV, and TDF, respectively. The incidence of HCC was significantly lower in the BSV group compared with ETV or TDF groups (BSV vs ETV, $P = 0.007$; BSV vs. TDF, $P = 0.015$). After propensity score matching, we observed that the incidence rate of HCC remained significantly lower in the BSV group in comparison to the ETV group ($P = 0.016$). However, there was no significant difference in HCC incidence rates between the BSV and TDF groups ($P = 0.253$). Further analysis using multivariable analysis within this matched cohort indicated that BSV significantly reduced the risk of developing HCC when compared to ETV. **Conclusion:** BSV therapy may improve prognosis of patients with CHB by decreasing the incidence of HCC.

4041-A | DIFFERENTIALLY REGULATED IMMUNE EXHAUSTION TARGETS BETWEEN HCC AND ICCA ARE POTENTIAL DIAGNOSTIC AND PREDICTIVE BIOMARKERS IN LIVER CANCER

Nada Abedin[1], Katrin Bankov[2], Steffen Gretser[2], Yiwei Fu[2], Katharina Filipski[3,4,5,6], Patrick N. Harter[3,4,5,6], Claudia Döring[2], Stefan Zeuzem[1] and Peter J. Wild[2], (1) University Hospital Frankfurt, Department for Internal Medicine I, (2)University Hospital Frankfurt, Senckenberg Institute of Pathology, (3)University Hospital Frankfurt, Neurological Institute (Edinger Institute), (4)Frankfurt Cancer Institute (FCI), (5) University Cancer Center (UCT) Frankfurt, (6)German Cancer Research Center (DKFZ), Heidelberg, Germany and " German Cancer Consortium (DKTK), Partner Site Frankfurt/Mainz

Background: Hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCCA) are increasingly important tumor entities, especially in young patients. Previous studies have looked at distinct methylation patterns in HCC. With the shift in etiologies and an increasing amount of patients at risk for developing de novo HCC without cirrhosis and an increasing incidence in iCCA, it is vital to develop safe and accurate biomarkers for the diagnosis and prognosis in these patients. While established markers for immunohistochemistry and serum markers are helpful in the diagnosis, they're neither specific, nor predictive. **Methods:** All tests were carried out based on formalin-fixed and paraffin-embedded (FFPE) tissue from resected liver lesions before treatment and with consistent follow-up data including post-surgical treatments, recurrence, survival data and other clinical conditions and risk factors. Total RNA and DNA was extracted from these tissues. The extracted RNA was used for a gene expression analysis with the nCounter® NanoString system and nCounter® Immune Exhaustion Panel. DNA methylation patterns were analysed using the Human Methylation EPIC array (Illumina) of all samples. **Results:** HCC cases clearly separated from iCCA cases in the unsupervised hierarchical clustering of gene expression and the DNA methylation pattern analysis. Several significantly dysregulared targets in HCC compared to iCCA were identified and correlated with clinical data. While established markers were also included in the analysis, new markers, i.e. ITGB8 and ALDH3A1 were identified as immune-modulatory target transcripts. Immunohistochemistry showed significant expression in HCC cases and expression of ALDH3A1 was significantly associated with lower recurrence free survival ($p < 0.05$). **Conclusion:** Our data shows that differentially regulated immune exhaustion targets between HCC and iCCA are of high interest in the development of clinical and therapeutic targets in liver cancer. Metabolite interconversion enzymes, such as ALDH3A1, are discussed to be essential for the activation or inactivation of anticancer drugs and could potentially affect drug treatment outcome, thereby representing potential biomarkers. Immunohistochemistry proved to be a valid diagnostic tool for ALDH3A1 expression and clinical data suggests prognostic value. Further validation studies need to be conducted to assess clinical relevance.

View High School, (2)Stanford University, (3)Cedars-Sinai Medical Center, Culver City, CA, (4)Stanford University Medical Center, Palo Alto, CA

Background: HCC is the 6th greatest mortality rate of all cancers in the USA with an upward trend in nonviral HCC from alcohol-associated and nonalcoholic fatty liver disease. Despite progress in early HCC detection, HCC treatment, and antiviral therapies for viral hepatitis, it is unclear if survival rates have improved in the recent decade and whether survival has improved consistently for both viral and nonviral HCC. **Methods:** To investigate the survival trends of patients with HCC, stratified by etiologies and HCC diagnosis year, between 2000 and 2017, the SEER-Medicare linked database was analyzed. HCC was diagnosed according to the International Classification of Diseases-Oncology-3 codes, site: C22.0 and histology: 8170-8175. Patients with HCC prior to Medicare coverage, prior malignancies, and without death certificates were excluded. **Results:** A total of 52,698 patients with HCC between 2000 and 2017 were included. Viral HCC patients were more likely to be Asian (18.0% vs. 10%) or Black (17.9% vs. 7.0%) with higher percentage of early HCC stage I/II (52.0% vs. 43.0%), all $P < 0.001$. Compared to HCC patients diagnosed 12/2013 and before, those diagnosed after 12/2013 were more likely to be obese (29.0% vs. 14.0%) and with early HCC stage I/II (35.0% vs. 26.1%), all $P < 0.001$. The 5-year cumulative survival were higher in viral vs. nonviral HCC (16.4% vs. 12.0%) and after 12/2013 vs before (17.1% vs. 12.1%), both $P < 0.001$. In stratified analysis by both etiology and time, survival was higher in viral HCC compared to nonviral patients during the pre as well as post 12/2013 periods (Figure 1A). Survival also increased significantly for both the viral and nonviral groups over time with rising median survival yearly (Figure 1B) and 5-year survival pre and post 12/2023 (Figure 1A, viral HCC increasing by 6.5% from 14.7% to 21.2% [a 44.2% increase] and nonviral increasing by 3.6% from 10.7% to 14.3% [a 33.6% increase]). On multivariable Cox's regression analysis adjusting for age, sex, race and ethnicity, tumor stage, cirrhosis status, HCC treatment, and time period, viral etiology was independently associated with higher survival as compared to non-viral etiology (adjusted hazard ratio [aHR] = 1.25, 95%CI 1.23-1.28), while HCC diagnosis after 12/2013 was also associated with higher survival compared to earlier time (aHR = 1.27, 95%CI 1.24-1.30), both $P < 0.001$. **Conclusion:** HCC were diagnosed in earlier stages in recent time, and HCC survival rates have improved over time but more for viral than nonviral etiology. However, overall 5-year survival was still low at only 14.3% for nonviral and 21.2% for viral etiology. Further efforts are needed to improve HCC surveillance and treatment.

4043-A | DRAMATIC INCREASE IN USE OF IMMUNOTHERAPY FOR HEPATOCELLULAR CARCINOMA (HCC) – A TERRITORY-WIDE STUDY FROM 2015-2022

Terry Cheuk-Fung Yip, The Chinese University of Hong Kong, Hong Kong, 91, China, Vincent Wai-Sun Wong, The Chinese University of Hong Kong, Hong Kong, China, Stephen Lam Chan, State Key Laboratory of Translational Oncology, Department of Clinical Oncology, Sir Yue-Kong Pao Center for Cancer, the Chinese University of Hong Kong and Grace Lai-Hung C Wong, The Chinese University of Hong Kong

Background: Immunotherapy is an established treatment for many malignancies including hepatocellular carcinoma (HCC). We aimed to determine the change in the usage of various immunotherapies since their availability in 2015 in Hong Kong. **Methods:** This was a territory-wide cohort study of HCC patients who had received at least one kind of targeted therapies (cabozantinib, regorafenib, sorafenib, ramucirumab) or immunotherapies (atezolizumab combined with bevacizumab, ipilimumab combined with nivolumab, or pembrolizumab) from 2015 to 2022 in Hong Kong. The secular trend of new prescriptions of these immunotherapies was analyzed. **Results:** We identified 3,013 HCC patients (mean age 61.0 ± 11.9 y, 71.9% male,

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

43.5% had chronic hepatitis B) who had received at least one line of systemic therapy, with 224 (7.4%) patients having received more than one line of systemic therapy. The usage of atezolizumab-bevacizumab combination has increased dramatically from 2020 (n = 10, 0.9%) to 2021 (n = 101, 6.0%). The prescription of ipilimumab-nivolumab combination has gradually increased from 2016 (n = 2, 1.4%) to 2021 (n = 49, 2.9%), then dramatically from 2022 (n = 38, 2.9% in the first 5 mo) onwards. Pembrolizumab use has increased noticeably from 2016 onwards and peaked in 2021 (Figure). **Conclusion:** We report a dramatic increase in the newly approved immunotherapy regimens atezolizumab-bevacizumab and ipilimumab-nivolumab combinations since their approval in 2020, and use of pembrolizumab peaked in 2021, whereas tyrosine kinase inhibitors dropped since 2019 likely because of the wide use of newly approved regimens. Figure. Secular trends on the relative representation of immunotherapy regimens and other systemic therapies for HCC patients in Hong Kong 2015-2022

4044-A | EARLY ANTIBIOTIC EXPOSURE, BUT NOT LATE EXPOSURE, DURING THE COURSE OF IMMUNOTHERAPY NEGATIVELY AFFECTS OUTCOMES IN PATIENTS RECEIVING FIRST-LINE ATEZOLIZUMAB PLUS BEVACIZUMAB FOR UNRESECTABLE HEPATOCELLULAR CARCINOMA

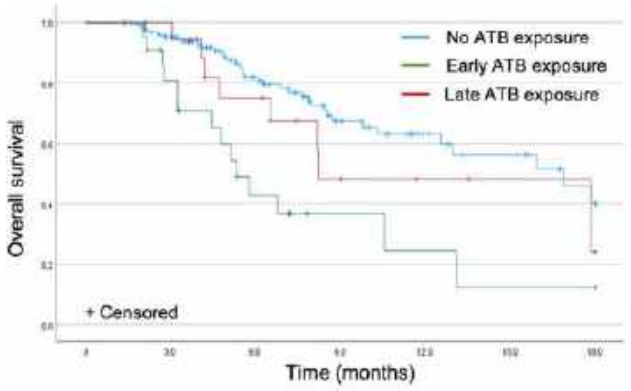
Aryoung Kim, Byeong Geun Song, Myung Ji Goh, Wonseok Kang, Dong Hyun Sinn, Geum-Youn Gwak, Yong-Han Paik, Moon Seok Choi and Joon Hyeok Lee, Samsung Medical Center

Background: Immunotherapy with atezolizumab plus bevacizumab (atezo/bev) represents the new standard of care in first-line systemic therapy of unresectable hepatocellular carcinoma (uHCC). While antibiotic (ATB) exposure may affect the therapeutic efficacy of immunotherapy through perturbation of gut microbiome, few studies have addressed the effect of early and late antibiotic exposure during the course of immunotherapy on the outcomes of uHCC patients receiving first-line atezo/bev therapy. **Methods:** In this single institution retrospective cohort study, patients with uHCC receiving atezo/bev as a first-line therapy between August 2020 and December 2022 were analyzed. Early ATB exposure was defined as exposure within 30 days of initiation of atezo/bev. Late ATB exposure was defined as exposure during the course of atezo/bev except for the initial 30 days. ATB exposure was correlated with outcomes in terms of progression-free survival (PFS) and overall survival (OS). Multivariable analysis was performed with the Cox proportional hazards model. Propensity score (PS) matching was performed in a 1:5 ratio of covariates including age, Child-Pugh score, model for end-stage liver disease score, albumin-bilirubin grade, and neutrophil-to-lymphocyte ratio. **Results:** A total of 177 patients with uHCC were included in the final analysis. Early ATB exposure (n = 22, 12.5%) was associated with shorter PFS (2.3 mo in early exposure vs. 6.3 mo, Log rank $p = 0.015$; HR 1.95, 95% CI 1.10-3.45, $p = 0.022$) and OS (5.4 mo in early exposure vs. 16.9 mo, Log rank $p < 0.001$; HR 2.10, 95% CI 1.10-4.02, $p = 0.024$). Similar results were observed in PS-matched analysis of PFS (2.3 mo in early exposure vs. 6.2 mo, Log rank $p = 0.024$) and OS (5.4 mo in early exposure vs. 15.9 mo, Log rank $p = 0.007$). Compared with no ATB exposure throughout the course of atezo/bev

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

therapy, late ATB exposure showed similar PFS (6.1 mo in late exposure vs. 6.5 mo, Log rank $p = 0.71$; HR 0.78, 95% CI 0.40-1.52, $p = 0.46$) and OS (8.2 mo in late exposure vs. 16.9 mo, Log rank $p = 0.29$; HR 1.18, 95% CI 0.54-2.57, $p = 0.68$). Interestingly, compared to early ATB exposure, late ATB exposure was associated with longer PFS (6.1 mo in late exposure vs. 2.3 mo, Log rank $p = 0.035$) and OS (8.2 mo in late exposure vs. 5.4 mo, Log rank $p = 0.09$). **Conclusion:** Early ATB exposure, but not late exposure, is associated with worse PFS and OS in patients with uHCC receiving first-line atezo/bev therapy. Prospective clinical and translational studies are necessary to understand the mechanisms underlying ATB-mediated alterations of gut microbiome and treatment response to atezo/bev therapy in patients with uHCC.



Antibiotics exposure	Log-rank p-value
None vs. Early exposure	<0.001
None vs. Late exposure	0.29
Early vs. Late exposure	0.09

4045-A | EARLY CHANGES IN ALPHA-FETOPROTEIN ARE ASSOCIATED WITH TREATMENT RESPONSE AND OVERALL SURVIVAL IN A REAL-WORLD COHORT OF HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS

Michael Li[1], Kate Kelley[1], Neil Mehta[1], Francis Yao[1], Lawrence Fong[1] and Jennifer C. Lai[2], (1)University of California, San Francisco, (2)University of California-San Francisco

Background: Multiple immune checkpoint inhibitor (ICI) regimens are now first-line therapy in advanced hepatocellular carcinoma (HCC), but there is limited data regarding early predictors of treatment response. **Methods:** We conducted a single-center retrospective cohort study of all HCC patients who received ICI therapy from 2016 onwards. The primary outcome was treatment response (complete or partial response as clinically assessed by the treating provider). The secondary outcome was time to all-cause death. **Results:** In the 173 study patients with available treatment response data, the median MELD was 10 [IQR 9, 16] and the median AFP was 138 [8, 1995]. 47 patients (27%) experienced treatment response. Median time from pre-treatment AFP to on-treatment AFP was 42 [29, 55] days. The median percent change in AFP was significantly different comparing patients with and without treatment response (-39% [-92%, -8%] vs 11% [-16%, 74%], respectively, $p < 0.001$). As a single predictor of treatment response, percent change in AFP had a c-statistic of 0.80. The optimal cutoff for percent change in AFP was -9.7% based on maximizing the J statistic; this cutoff had a sensitivity of 75% and a specificity of 71% for treatment response. After adjusting for ICI regimen, Child-Pugh class, and tumor burden, percent reduction in AFP was associated with treatment response (OR 1.21 for each 10% reduction in AFP, 95% CI 1.11-1.33, $p < 0.001$). Similar results were produced when a binary AFP variable using the cutoff of $\geq 10\%$ reduction was substituted for the continuous AFP variable in the model (OR 5.33 for patients who had $\geq 10\%$ early AFP improvement, 95% CI 2.42-11.74, $p < 0.001$). Patients with $\geq 10\%$ early AFP improvement also had improved overall survival compared to those with $< 10\%$ improvement (median 1.82 vs 0.73 y, log-rank $p < 0.001$; Figure A). Improved overall survival was also seen with further stratification of AFP improvement (median 2.34 vs 1.30 vs 0.73 years, log-rank $p < 0.001$; Figure B). After adjusting for ICI regimen, Child-Pugh class, and tumor burden using Cox regression, $\geq 10\%$ early AFP improvement was associated with reduced risk of death (HR 0.63, 95% CI 0.45-0.89, $p = 0.009$). **Conclusion:** Early changes in AFP within 2 months of ICI initiation predict treatment response and overall survival in HCC patients. A cutoff of $\geq 10\%$ AFP improvement may be clinically useful for early assessment of treatment benefit and in deciding whether to continue ICI therapy in high-risk patients.

4046-A | EFFECTIVENESS AND SAFETY OF MICROWAVE ABLATION FOR CHILD B EARLY STAGE HEPATOCELLULAR CARCINOMA

Nobuhito Taniki[1], Ryosuke Kasuga[2], Takaya Tabuchi[2], Po-sung Chu[2], Yukie Nakadai[2], Mayuko Kondo[2], Fumie Noguchi[2], Rei Morikawa[2], Takanori Kanai[2] and Nobuhiro Nakamoto[2], (1)Keio University, (2)Keio University School of Medicine

Background: Microwave ablation (MWA) is reported to be an effective locoregional ablation modality and probably comparable to radiofrequency ablation. Since most of the subjects of clinical trials which verify feasibility of MWA are hepatocellular carcinoma (HCC) patients who have preserved liver function with Child A, the influence regarding the impact of impaired hepatic reserve on treatment outcomes has not been well established. In the current study, we aimed to investigate effectiveness and safety of MWA for HCC patients with Child B and to develop the optimal treatment for patients with reduced hepatic reserve. **Methods:** This retrospective cohort study enrolled 513 microwave ablation treatments using Emprint ablation system (Covidien) during 2017 to 2022. The ablation procedures were operated under real-time ultrasound guidance. Of those, 477 treatments were operated under the tumor settings of HCC with 3 or less lesions of 30 mm in diameter or single lesions of 50 mm without major vessel involvement or extrahepatic metastasis. We compared patient background factors and treatment outcomes of 387 patients with Child A and 90 patients with Child B. Patient background factors were gender, age, body weight, platelet count, serum albumin, total bilirubin, prothrombin time, Fibrosis-4 (FIB-4) index, Aspartate Aminotransferase to Platelet Ratio Index (APRI), liver stiffness measured by elastography (Fibroscan, Echosense) and tumor settings (number and maximum diameter). Treatment outcomes were recurrence-free survival, severe complication rate, and incidence of postoperative bile duct injury (dilatation). **Results:** In the analysis of entire cohort, there was a significant increase in the number of tumors and the maximum tumor diameter in Child B cases compared with Child A cases. However, 477 subjects finally enrolled in the analysis under the limited tumor settings, the number of tumors and the maximum tumor diameter were comparable in both groups. Not only factors related to hepatic reserve, platelet count (Child A vs. Child B, 153 vs. 115×10^9/L, $p=0.0352$) and liver stiffness (Child A vs Child B, 19.4 vs 32.5 kPa, $p<0.0001$) showed significant difference in each group. All of the outcomes showed worse result in Child B cases in severe complication rate (Child A 3/384 0.8% vs Child B 4/86 4.4%, $p=0.0234$), recurrence-free survival, and incidence of bile duct dilatation. Furthermore, ascites was extracted as an independent factor as a risk factor contributing to bile duct dilatation. **Conclusion:** Child B patients are at increased potential risk for portal hypertension and low platelet counts in addition to impaired hepatic reserve, which may contribute to poor treatment outcomes. Aside from considering liver transplantation, proactive preoperative measures such as expanding the TPO receptor agonist indication criteria or adequate ascites control is needed for effective and safe MWA procedure.

4047-A | EFFECTIVITY AND TOLERABILITY OF CHEMOSATURATION OF THE LIVER WITH MELPHALAN FOR PATIENTS WITH PRIMARY OR SECONDARY LIVER TUMORS

Rhea Veelken, Sebastian Ebel, Manuel Florian Struck, Christian Girbardt, Focke Ziemssen, Timm Denecke, Thomas Berg and Florian Van Bömmel, University Hospital of Leipzig

Background: Chemosaturation by percutaneous hepatic perfusion (CS-PHP, CHEMOSAT®, Delcath) allows temporary administration of melphalan hydrochloride directly to the liver. This approach was shown

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to be effective in controlling tumor growth in patients with primary or secondary liver tumors. In those studies, CS-PHP was applied in various frequencies ranging from one to six times. We have retrospectively analysed the effectiveness and tolerability of CS-PHP given on an eight-weekly basis. **Methods:** CS-PHP was applied to patients with primary or secondary liver tumors based on board decision in one German center until disease progression, intolerability or complete response. Overall survival (OS) and overall response rates (ORR) were retrospectively assessed according to Response Evaluation Criteria In Solid Tumors (mRECIST). OS was analysed by Kaplan-Meier estimation. ORR included patients achieving complete (CR) or partial response (PR) after each treatment. Toxicity associated with CS-PHP was assessed according to Common Terminology Criteria for adverse events (CTCAEv4.03). **Results:** A total of 31 patients (21 (68%) female) was treated with 90 (median 2, range 1-6) CS-PHP between 2016 and 2022. Included patients had either unresectable intrahepatic metastases of ocular melanoma (OM, n = 17), intrahepatic cholangio carcinoma (ICC, n = 8), hepatocellular carcinoma (HCC, n = 2), ciliary body melanoma (n = 1), acinar cell carcinoma (n = 1), hepatic spread of pancreatic (PC, n = 1) or tonsillar carcinoma (n = 1). CS-PHP was performed 6 times in 5, 5 times in 4, 4 times in one, three times in 4, two times in 7 and one time in 10 patients.

The median OS of all patients since decision for CS-PHP was 67 (range, 41.31-92.89) weeks, and for patients with OM 76 (range, 56.5-95.5) weeks and for ICC 37 (range, 32.11-41.88) weeks, respectively. ORR was 66% to all CS-PHP treatments (60/90), including 85% of OM and 31.25% of ICC patients. In 5 patients, CR was achieved after a median of 5 (range, 2-6) CS-PHP. CS-PHP was abandoned due to disease progression in three patients after first CS-PHP, due intolerability in two and due to lost in follow up in 7 patients. Presence of extrahepatic tumor manifestations before CS-PHP was not associated with response or survival. In 12 patients developing extrahepatic tumor progress, one of them with bone marrow infiltration, CS-PHP was continued if liver tumors were still controlled. Hematological AEs included leukopenia (grade 2) or thrombocytopenia (grade 2-3) were transient. Febrile neutropenia occurred in two cases and was treated with G-CSF. **Conclusion:** CS-PHP induced response in the majority of malignant primary or secondary liver tumors. The procedure was safe and had few hematological side effects. The effectivity CS-PHP as long-term treatment needs to be validated in future studies.

Disclosures: The following people have nothing to disclose: Rhea Veelken, Sebastian Ebel, Manuel Florian Struck, Christian Girbardt, Focke Ziemssen, Timm Denecke, Thomas Berg, Florian Van Bömmel

4048-A | EFFECTS AND MECHANISMS OF THE SUBTYPES OF APOLIPOPROTEIN E TO THE IMMUNE STATE AND PROGNOSIS OF HEPATOCELLULAR CARCINOMA PATIENTS

Bowen Gao, Zhongshan Hospital, Fudan University

Background: Apolipoprotein E (apoE), mainly synthesized by the liver, which consists of three main isoforms: apoE2, apoE3 and apoE4, is one of the key molecules for lipid transportation and metabolism. Recent studies in melanoma have found that different subtypes apoE possess different levels of abilities of inhibiting the survival of myeloid-derived suppressor cells (MDSCs), thereby reducing their abundance and relieving their inhibitory effects on the immune response to tumours. It is a question worth further investigation as to whether tumour progression, immune status and prognosis of HCC patients may also differ depending on the subtype and expression of apoE. **Methods:** The first cohort included samples and clinical, pathological, laboratory information, along with 10 years' follow-up data of 360 HCC patients. Immunofluorescence staining of combinations of $CD11b^{+}/LOX1^{+}$ and $CD14^{+}/HLA\text{-}DR^{-/low}$ was performed on the tissue microarrays of tumor samples to assess the abundance of infiltrating polymorphonuclear granulocyte-like MDSCs (PMN-MDSCs) and monocyte-like MDSCs (M-MDSCs); immunohistochemistry was used to detect the expression of apoE2, apoE3, apoE4, arginase (ARG) and inducible nitric oxide synthase (iNOS). Survival analysis was performed using univariate and multivariate COX regression and the Kaplan-Meier method. Additional 39 patients who were diagnosed with HCC or hepatic vascular smooth muscle lipoma (AML, benign) were included in the second cohort. Peripheral blood samples were collected and divided into three groups of high/normal/low levels of apoE. Flow cytometry was applied to detect immune cells abundance. ANOVA and t-test were applied to compare the differences among groups. $p < 0.05$ was considered statistically significant in this study. **Results:** COX regression analysis showed H-score of apoE2 in tumour tissues below 16.01 (HR = 6.140, p = 0.00005) and H-score of apoE4 above 4.05 (HR = 7.001, p = 0.009) were significantly associated with shorter overall survival (OS). The density of infiltrated PMN-MDSCs (> 2.87 cells/mm^2 (HR = 3.762, p = 0.000009)) and proportion of M-MDSCs of total cells ($< 89.32\%$ (HR = 0.454, p = 0.006)) in tumour tissues were independent risk factors for shorter recurrence-free survival (RFS). A higher abundance of MDSCs in the blood in low apoE group was detected compared to the normal and high blood apoE levels. The number of $CD14^{+}/HLA\text{-}DR^{-/low}$ M-MDSCs (p = 0.0399) were higher than in the apoE high level group. CTLA-4^{+} T

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

lymphocytes were detected higher in the low apoE group than in the normal group. **Conclusion:** This study suggested that in HCC patients, the elevated abundance of MDSCs in the peripheral blood was negatively correlated with the level of apoE in peripheral blood, and the abnormal level of apoE was also associated with elevated levels of PD-1$^+$ and CTLA-4$^+$ T lymphocytes. ApoE2 subtype was a potential protective factor for HCC patient's OS and apoE4 subtype suggested poor prognosis.
Disclosures: The following people have nothing to disclose: Bowen Gao

4049-A | EFFECTS OF PROTON BEAM THERAPY ON LOCAL CONTROL AND HEPATIC RESERVE IN UNRESECTABLE HEPATOCELLULAR CARCINOMA

Ryotaro Sugata, Takuto Nosaka, Yu Akazawa, Kazuto Takahashi, Tatsushi Naito, Hidetaka Matsuda, Masahiro Ohtani and Yasunari Nakamoto, University of Fukui

Background: Proton beam therapy (PBT) achieves excellent long-term tumor control with minimal toxicity in patients with unresectable hepatocellular carcinoma (HCC); however, its effect on hepatic reserve have not been adequately studied. If the tumor size is large (>3 cm) or located in an area that is difficult to ablate, combined radiofrequency ablation (RFA) and transarterial chemoembolization (TACE) (TACE+RFA) is the standard locoregional therapy. This study compared the therapeutic effect of PBT with that of TACE +RFA on local control and hepatic reserve in patients with unresectable HCC. **Methods:** We retrospectively analyzed data of 68 patients with HCC unsuitable for surgical resection or RFA monotherapy due to tumor size, location, or comorbidities such as cardiopulmonary dysfunction, who were treated with PBT (22 patients) or TACE+RFA (46 patients) from January 2010 to March 2022. The PBT protocol was 66.0–80.5 CGE in 10–38 fractions. The therapeutic effects were assessed using local progression-free survival (PFS), 5-year overall survival (OS), and changes in hepatic reserve. **Results:** Among the patients treated with PBT/TACE+RFA, the median (range) age was 74 (54–88)/74 (57–85) years; median (range) tumor size was 2.7 (1.2–9.3)/2.7 (1.4–7.0) cm; median follow-up period was 34.9/38.8 months; 66.7/69.6% were modified Albumin-Bilirubin (mALBI) grade 1 or 2a. The 5-year local PFS was over 65% for both PBT and TACE+RFA. The OS at 5-year post-treatment was 82% and 28% in patients treated with PBT and TACE+RFA, respectively (hazard ratio, 0.29; 95% confidence interval, 0.13–0.64; $P<0.05$). The baseline ALBI score was maintained for 12 months in patients treated with PBT, but it was worse at 1 month and remained worsen for 12 months in patients treated with TACE+RFA. ($P<0.01$). At the 2nd and 3rd additional treatments, the baseline ALBI score was maintained in patients treated with PBT, but was worse in patients treated with TACE+RFA ($P<0.05$). **Conclusion:** In patients with unresectable HCC, PBT effectively maintains hepatic reserve and OS is better than that with TACE+RFA. PBT maintains hepatic reserve by reducing damage to non-tumorous liver tissue. PBT may be an effective first-line treatment for unresectable HCC.
Disclosures: The following people have nothing to disclose: Ryotaro Sugata, Takuto Nosaka, Yu Akazawa, Kazuto Takahashi, Tatsushi Naito, Hidetaka Matsuda, Masahiro Ohtani, Yasunari Nakamoto

4050-A | EFFICACY AND SAFETY OF LENVATINIB AS A FIRST-LINE THERAPY IN ELDERLY PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA

Toshiaki Abe, Mitusi Memorial Hospital, Takamasa Ohki, Shioda Memorial Hospital, Mayuko Kondo, Mitsui Memorial Hospital and Koki Sato, Misui Memorial Hospital

Background: Few studies have evaluated the efficacy and safety of lenvatinib (LEN) in elderly ($\geq$ 80 y of age) patients with advanced hepatocellular carcinoma (HCC), which we investigated and compared with other age groups as controls. **Methods:** In total, 53 elderly patients and 173 controls who underwent LEN treatment between March 2018 and November 2022 were recruited. Propensity score matching was used to reduce confounding factors, with adjustment for sex, maximum tumor diameter, tumor number, tumor embolization, and metastasis. This resulted in 52 patients in each group. The primary endpoint was overall survival (OS), and factors related to OS were examined. **Results:** There were no significant differences in patient characteristics between the two groups. The median survival duration was 14.5 months in the elderly group and 14.3 months in the control group ($P=0.254$). The 1-, 2-, and 3-year cumulative OS rates were 54.1%, 20.2%, and 10.1% in the elderly group and 64.0%, 25.7%, and 19.3% in the control group, respectively. Multivariate analysis revealed that Child–Pugh class and maximum tumor diameter were significantly related to OS ($P=0.01$, 95% confidence interval [CI] 1.002–1.014, hazard ratio 1.008), ($P=0.004$, 95% CI 1.279–3.657, hazard ratio 2.163). The median progression-free-survival duration was 12.5 months in the elderly group and 8.4 months in the control group; the difference was not significant. The response rate was 22.6% in the elderly group and 24.5% in the control

group ($P = 0.819$). The number and rate of Grade 3 or higher adverse events were significantly lower in the elderly group (n = 17, 32.7%) than in the controls (n = 33, 63.5%) ($P = 0.029$). **Conclusion:** LEN is effective and safe to use in elderly patients ≥80 years of age.

4051-A | EFFICACY AND SAFETY OF TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT IN PATIENTS WITH HEPATOCELLULAR CARCINOMA – A SYSTEMATIC REVIEW AND META-ANALYSIS

Marko Kozyk[1], Suprabhat Giri[2], Ankita Singh[3], Akash Roy[4], Kateryna Strubchevska[1], Taraprasad Tripathi[5] and Ranjan Kumar Patel[5], (1)Corewell Health William Beaumont University Hospital, (2)Nizam's Institute of Medical Sciences, (3)Seth GS Medical College and Kem Hospital, (4)Apollo Hospitals, Kolkata, (5)All India Institute of Medical Sciences, India

Background: Patients with hepatocellular carcinoma (HCC) and cirrhosis can present with features of severe portal hypertension, which can be worsened further with associated portal vein tumoral thrombosis (PVTT). Due to the technical difficulties and short survival of these patients, HCC was traditionally considered a relative contraindication for transjugular intrahepatic portosystemic shunt (TIPS). However, there is an increasing body of evidence supporting the use of TIPS in HCC. The present study aimed to analyze the efficacy and safety of TIPS in patients with HCC. **Methods:** A literature search of MEDLINE, Embase, and Scopus was conducted from 2000 to October 2022 for studies analyzing the outcome of TIPS in HCC. The primary outcomes were technical and clinical success, adverse events (AE), and mortality. The event rates were pooled using a random effects model. **Results:** A total of 19 studies with 1498 patients were included in the final analysis. The pooled technical and clinical success rates with TIPS in HCC were 98.8% (98.0 – 99.7) and 94.1% (91.2 – 97.0), respectively. The mean reduction in hepatic venous pressure gradient from baseline varied from 10 to 20.2 mm Hg, with a pooled mean difference of 13.65 mm Hg (95% CI: 12.05 – 15.24). After TIPS, ascites was controlled in 89.2% (85.1 – 93.3) of the cases, while rebleeding was observed in 17.2% (9.4 – 25.0) of cases on follow-up. The pooled incidence of overall AE, serious AE, and post-TIPS hepatic encephalopathy was 5.2% (2.5 – 7.9), 0.1% (0.0 – 0.4), and 25.1% (18.7 – 31.5), respectively. The reported serious AEs included: acute liver failure, tumor rupture causing intraabdominal bleeding, and post-TIPS intraabdominal bleeding. On follow-up, 11.9% (7.8 – 15.9) of the patients developed shunt dysfunction requiring reintervention. The pooled 1-year mortality rate with TIPS in HCC was 34.2% (95% CI: 18.9 – 49.5), with mortality being significantly higher in those undergoing TIPS for portal vein tumoral thrombosis (64.5%, 95% CI: 34.9 – 94.2) than those without (22.7%, 95% CI: 13.1 – 32.3) (p = 0.009). Table 1 summarizes the findings of the present analysis with subgroup analysis. **Conclusion:** The present analysis supports the feasibility, safety, and efficacy of TIPS in the management of portal hypertension in patients with HCC.

Table 1: Summary of findings for various outcomes with sub-group analysis

Parameters	Overall	PVTT group	PHT group	Mixed stents	Covered stents
Technical success	98.8% (98.0 – 99.7)	99.0% (96.8 – 1.00)	98.6% (97.5 – 99.6)	98.8% (97.7 – 99.9)	99.0% (97.5 – 1.00)
Clinical success	94.1% (91.2 – 97.0)	98.1% (96.3 – 99.8)	89.7% (85.3 – 94.1)	92.4% (87.9 – 96.9)	95.9% (91.2 – 97.0)
Control of ascites	89.2% (85.1 – 93.3)	92.1% (84.4 – 99.7)	87.3% (82.6 – 92.1)	92.2% (88.7 – 95.7)	76.2% (68.1 – 84.3)
Variceal rebleed	17.2% (9.4 – 25.0)	16.1% (10.0 – 31.2)	18.1% (9.1 – 27.1)	18.2% (8.0 – 28.5)	17.8% (5.3 – 30.4)
Adverse events	5.2% (2.5 – 7.9)	5.2% (1.9 – 8.6)	5.1% (1.4 – 8.8)	2.9% (0.0 – 5.7)	6.5% (3.2 – 9.7)
Serious adverse events	0.1% (0.0 – 0.4)	0.8% (0.0 – 2.1)	0.1% (0.0 – 0.4)	0.1% (0.0 – 0.4)	1.0% (0.0 – 2.5)
Hepatic encephalopathy	25.1% (18.7 – 31.5)	22.4% (15.1 – 29.7)	26.5% (18.7 – 31.5)	26.8% (19.8 – 33.9)	21.2% (10.3 – 32.1)
Shunt dysfunction	12.6% (8.5 – 16.8)	16.8% (6.2 – 27.3)	10.7% (6.5 – 14.8)	15.5% (8.9 – 22.1)	9.9% (5.3 – 14.4)
1-year mortality	34.2% (18.9 – 49.5)	64.5% (34.9 – 94.2)	22.7% (13.1 – 32.3)	25.1% (13.7 – 36.6)	61.8% (25.3 – 98.4)

PVTT: Portal vein tumoral thrombosis; PHT: Portal hypertension

Relpec Study Group and HCC 48 Group, (5)Imperial College London, (6)Hannover Medical School, (7)The Fourth Hospital of Hebei Medical University, (8) Fondazione Policlinico Universitario Campus Bio-Medico, (9)National Cheng Kung University, (10)City of Hope National Medical Center, (11)Medical University of Vienna, (12)Ehime Prefectural Central Hospital, (13) University of California, San Francisco, (14)Kindai University Faculty of Medicine, Osaka-Sayama, Japan, (15)Cedars-Sinai Medical Center, Los Angeles, CA

Background: Immune checkpoint inhibitors (ICIs) are increasingly used in patients with advanced hepatocellular carcinoma (HCC). However, data on ICI therapy in patients with advanced HCC and impaired liver function is scarce. Herein, we performed a meta-analysis to provide evidence for the efficacy and safety of ICI treatment for advanced HCC with Child-Pugh class B. **Methods:** PubMed, Embase, Web of Science, and Cochrane library were searched for relevant studies through 2022/6/15. Randomized controlled trials, cohort studies, or single-arm studies that investigated the efficacy or safety of ICI therapy for advanced HCC with Child-Pugh class B were included. Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines were followed to extract data. A random-effects model was adopted if the heterogeneity was significant (I^2 statistic > 50%); otherwise, the fixed-effects model was used. The objective response rates (ORR) and overall survival (OS) were considered to be the primary outcomes for the efficacy outcomes of ICI treatment for advanced HCC with Child-Pugh class B. The incidence of treatment-related adverse events (trAEs) was set as the major measure for the safety outcome. **Results:** A total of 22 studies, including 699 Child-Pugh B and 2114 Child-Pugh A advanced HCC patients, were included. Upon pooled analysis, the ORR and disease control rates (DCR) of Child-Pugh B patients treated with ICIs were 14% (95% confidence interval [CI] 11-17%) and 46% (95%CI 36-56%), with a median OS and median progression-free survival (PFS) of 5.49 (95%CI 3.57-7.42) and 2.68 (95%CI 1.85-3.52) months, respectively. The rates of any grade trAEs in Child-Pugh B patients were 40% (95%CI 34-47%), grade 3 or higher trAEs 12% (95%CI 6-23%). When compared to Child-Pugh A patients, the ORR (OR 0.59, 95%CI 0.43-0.81, $p < 0.001$) and DCR (OR 0.64, 95%CI 0.50-0.81, $p < 0.001$) of Child-Pugh B were lower. Child-Pugh class B was an independent predictor of a worse OS in advanced HCC patients treated with ICIs (hazard ratios (HR) 2.72, 95%CI 2.34-3.16 and adjusted HR 2.33, 95%CI 1.81-2.99). However, ICI did not associate with increased trAEs in patients with Child-Pugh class B. **Conclusion:** While the safety of ICI treatment was comparable between patients with versus without advanced liver disease, and this treatment resulted in a significant number of radiological responses, survival outcomes following ICI treatment are still inferior in Child-Pugh class B HCC patients questioning the effectiveness of ICI in this population.

4053-A | EFFICACY COMPARISON OF FIRST-LINE THERAPIES OF UNRESECTABLE HEPATOCELLULAR CARCINOMA IN OLDER AGE PATIENTS

Ahlim Lee[1,2] and Hyun Yang[2], (1)St. Vincent's Hospital, the Catholic University of Korea, (2)The Catholic University of Korea

Background: After the IMbrave150 trial, atezolizumab plus bevacizumab (AteBeva) became the first-line therapy for unresectable hepatocellular carcinoma (HCC). However, few studies compared efficacy in elderly patients older than 65 with lenvatinib or sorafenib, the other first-line therapies. This study compared the efficacy of first-line agents for unresectable HCC in patients over 65. **Methods:** Between September 2020 to December 2022, 162 patients older than 65 from eight hospitals of Catholic Medical Center receiving AteBeva, lenvatinib, and sorafenib were included. We excluded the patients who received systemic treatment before this therapy. Overall survival (OS), time to progression (TTP), and progression-free survival (PFS) were measured in each treatment group of patients. **Results:** In baseline characteristics, there were no significant differences among the three treatment groups in terms of median age, sex, etiology, Child-Pugh class, performance status of patients, and BCLC stage. At the time of analysis, 57 patients (35 %) had died. Survival rate was comparable between these treatment cohorts with AteBeva having a mean survival of 8.9 months compared to 11.0 months for those receiving lenvatinib, and 10.6 months for sorafenib ($p = 0.646$). Mean TTP and PFS showed differences between these groups (TTP 6.7 vs. 10.7 vs. 5.3 months, respectively, $p = 0.014$; PFS 5.8 vs. 7.8 vs. 4.5 months, $p = 0.055$). In best response analysis, AteBeva and

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

lenvatinib show superiority to sorafenib in terms of objective response rate (ORR) and disease control rate (DCR) with statistical significance (ORR 30.9 vs. 37.1 vs. 11.1%, respectively, p = 0.032; DCR 72.7 vs. 71.4 vs. 44.4%, p = 0.013). **Conclusion:** In patients older than 65, there was no significant difference in the treatment efficacy of the three first-line therapies for unresectable HCC in terms of OS. However, in TTP, ORR, and DCR, AteBeva and lenvatinib show superiority to sorafenib, and in PFS, lenvatinib is superior to sorafenib with statistical significance. Therefore, if elderly patients cannot be received AteBeva due to any complication risks, lenvatinib are commendable alternative without concern for decreased therapeutic effect. Further studies are needed to compare the exact treatment response.

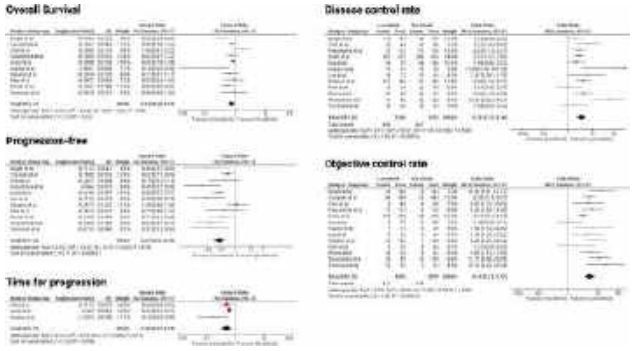
4054-A | EFFICACY OF LENVATINIB VERSUS SORAFENIB IN THE PRIMARY TREATMENT OF ADVANCED HEPATOCELLULAR CARCINOMA: A META-ANALYSIS

Vikash Jaiswal[1], Maha Hameed[2], Sidra Naz[3], Helen Huang[4], Shiva Gupta[5], Poulami Roy[6], Novonil Deb[6], Amira Mohamed Taha[7], Abdelrahman M Attia[8], Supti Dev Nath[9], Dattatreya Mukherjee[10] and Mostafa A Solimn[8], (1)Larkin Community Hospital, (2)Florida State University/Sarasota Memorial Hospital, (3)The University of Texas, MD Anderson Cancer Center, (4) Royal College of Surgeons in Ireland, (5)King George Medical University, (6)North Bengal Medical College and Hospital, (7)Fayoum University, (8)Cairo University, (9)John Hopkins University, (10)Raiganj Government Medical College and Hospital

Background: Molecular-targeted agents such as Lenvatinib and Sorafenib have been approved to treat hepatocellular carcinoma (HCC). However, the choice of drug among these two agents in the primary treatment for advanced HCC is still under debate with conflicting results. We sought to evaluate the efficacy of Lenvatinib and Sorafenib among patients with hepatocellular carcinoma. **Methods:** We performed a systematic literature search using PubMed, Embase, and Scopus for relevant articles from inception until 10th February 2023. The primary outcome of this meta-analysis was overall survival (OS). The secondary outcomes were progression-free survival (PFS), time to progression, objective response rate (ORR), and disease control rate (DCR). **Results:** A total of 13 studies with 3705 patients (1635 Lenvatinib vs. 2070 Sorafenib) were included in our analysis. The mean age of the patients in both groups was comparable (66.81 vs. 65.9 y). The pooled analysis of primary outcomes showed that compared with Sorafenib, the Lenvatinib-treated group of patients was associated with significantly better OS (HR 0.82 [95%CI: 0.69-0.97], P = 0.02). The pooled analysis shows that PFS (HR 0.67 [95%CI: 0.57-0.78], P < 0.00001) and time to progression (HR 0.49 [95%CI: 0.31–0.79; P = 0.004] were significantly better in the Lenvatinib group compared to Sorafenib. The pooled analysis also showed that the Lenvatinib group of patients had significantly better ORR (OR 5.43 [95% CI: 3.71–7.97; P < 0.00001], and DCR (OR 2.35 [95% CI: 1.75–3.16]; P < 00001) than those of the Sorafenib group. **Conclusion:** Our study shows that Lenvatinib was superior to Sorafenib in overall survival and progression-free survival in advanced hepatocellular carcinoma patients.



Disclosures: The following people have nothing to disclose: Vikash Jaiswal, Maha Hameed, Sidra Naz, Helen Huang, Shiva Gupta, Poulami Roy, Novonil Deb, Amira Mohamed Taha, Abdelrahman M Attia, Supti Dev Nath, Dattatreya Mukherjee, Mostafa A Solimn

4055-A | EFFICACY OF YTTRIUM-90 (Y90) RADIOEMBOLIZATION FOR DOWNSTAGING OR BRIDGE TO TRANSPLANTATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Meghana Ghattu, Rutgers Robert Wood Johnson Medical Center, Bjorn Engstrom, Abbott Northwestern Hospital - Allina Health, Sandra Castro-Pearson, Allina Health and John R. Lake, University of Minnesota

Background: Liver transplantation (LT) remains one of the few curative treatments for hepatocellular carcinoma (HCC).[1] Due to organ scarcity and stringent selection criteria many patients with HCC are unable to qualify or are subject to long waitlists.[1] Liver directed therapy (LDT) is commonly used in this

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

population for down-staging and as a bridge to transplant, with Y90 having a growing role.[2] However, there is relatively little information on long term outcomes in patients who received LT after Y90. **Methods:** We conducted a retrospective analysis of patients who underwent Y90 and subsequent LT at our center from Jan. 2013 – Dec. 2019. EMR was used to obtain baseline patient characteristics, explant histologic analysis, and long term follow up data. The cohort was divided into those with 100% necrosis of lesion on explant histology and 99% or less. Outcomes reported include overall survival (OS) and recurrence-free survival (RFS) at 2 and 5 years. Time-to-endpoint analyses were estimated using Kaplan–Meier curves. Univariate analyses were performed using a log-rank test. The small number of events prevented multivariate analyses. **Results:** In the study period, 28 patients underwent Y90 followed by LT. 9 patients were down-staged into Milan Criteria. 18 experienced 100% necrosis and 10 experienced 99% or less. At 2 years after LT, 3 of the 10 patients with 99% or less necrosis had recurrence followed by death in 2 (OS: 0.80, RFS: 0.70). Of the 18 patients with 100% necrosis, one patient experienced recurrence and death within 2 years from LT (OS: 0.94, RFS: 0.94). At 5 years from LT, 4 patients from the 99% or less group had recurrence and 2 died (OS: 0.80, RFS: 0.60). In those with 100% necrosis, 3 experienced recurrence and death within 5 years from LT (OS: 0.83, RFS: 0.83). None of the differences in OS or RFS were statistically significant at the 0.05 level. **Conclusion:** In this study we show that Y90 with subsequent LT has favorable long term recurrence free survival. In our cohort, most patients experienced 100% necrosis by explant histology, which was associated with a trend in improved outcomes at both 2 and 5 years from LT. The goal of Y90 LDT should be 100% necrosis. Extensive or complete necrosis after Y90 has been shown to have favorable long-term outcomes after LT in larger cohorts.[3] The small sample size limited the statistical power although these findings again support Y90 as an effective LDT for both down-staging and bridge to LT in patients with HCC.

4056-A | ENHANCING LAPAROSCOPIC HEPATECTOMY OUTCOMES IN LIVER CANCER WITH INDOCYANINE GREEN FLUORESCENCE IMAGING: A SYSTEMATIC REVIEW AND META-ANALYSIS★

Muhammed Elhadi Elfaituri, Ala Khaled, Hazem Faraj and Ahmed Msherghi, University of Tripoli

Background: Liver cancer is a significant global health challenge. Laparoscopic hepatectomy is increasingly recognized as a preferred surgical intervention, and Indocyanine Green (ICG) fluorescence imaging has emerged as a crucial component due to its capacity to enhance real-time intraoperative visualization of liver segments and vascular structures. However, the effects of ICG fluorescence imaging on operative outcomes following laparoscopic hepatectomy for liver cancer require comprehensive evaluation. This study aimed to determine the impact of ICG fluorescence imaging on operative outcomes, including operative time, blood loss, length of hospital stay, blood transfusion rate, and overall postoperative complications in laparoscopic hepatectomy for liver cancer. **Methods:** Electronic databases (PubMed, EMBASE, Cochrane Library, and Web of Science) were searched up to March 2023. Studies were included if they reported on patients undergoing laparoscopic hepatectomy for liver cancer and compared outcomes between groups using ICG fluorescence imaging and those not. Outcomes were presented as Mean Difference (MD) for continuous

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

outcomes and Relative Risk (RR) for dichotomous outcomes. A random-effects meta-analysis was performed, and heterogeneity was assessed using the I^2 statistic. Statistical analyses were performed using R (version 4.0.3) with the metafor and meta packages. **Results:** The meta-analysis included eight studies with 635 patients (280 in the ICG fluorescence group and 355 in the non-fluorescence group). ICG fluorescence imaging significantly reduced operative time (MD: -24.34 minutes, 95% CI = -47.33 to -1.35, P = 0.04, I^2 = 93%), blood loss (MD: -76.92 mL, 95% CI = -111.00 to -42.83, P < 0.01, I^2 = 77%), and length of hospital stay (MD: -1.57 days, 95% CI = -2.04 to -1.09, P < 0.01, I^2 = 74%). The rate of blood transfusions was not significantly different between the groups (RR: 0.69, 95% CI = 0.30 to 1.55, P = 0.37, I^2 = 61%). However, the incidence of overall postoperative complications was significantly lower in patients who underwent ICG fluorescence imaging (RR: 0.54, 95% CI = 0.38 to 0.77, P < 0.01, I^2 = 0%). **Conclusion:** This study suggests that ICG fluorescence imaging in laparoscopic hepatectomy for liver cancer may lead to significant improvements in short-term operative outcomes, including reduced operative time, less blood loss, and shorter hospital stays. Additionally, it appears to be associated with fewer overall postoperative complications. These findings underscore the potential value of ICG fluorescence imaging in improving surgical outcomes in liver cancer treatment. Further high-quality studies are needed to confirm these findings and evaluate this technology's cost-effectiveness.

4057-A | ETIOLOGY OF HEPATOCELLULAR CARCINOMA IN THE 27-COUNTY ROCHESTER EPIDEMIOLOGY PROJECT CATCHMENT AREA, 2010-2021

Caitlin Van Lith, Mayo Clinic and Lewis R. Roberts, Division of Gastroenterology and Hepatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Background: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related deaths globally, and the incidence of HCC in the US is rising. Risk factors for HCC, including viral hepatitis, non-alcoholic fatty liver disease, and alcoholic liver disease have been fluctuating in prevalence over the course of the last several decades. For example, hepatitis C treatment became widely available in the mid-2010s, raising the possibility of a decline in Hep C-related HCC. The Rochester Epidemiology Project (REP) was established in 1966 as a database for patient records in Olmsted County, MN, where the original campus of the Mayo Clinic resides. Beginning January 2010, the REP expanded to cover 27-counties in SE MN and W WI. This database contains 2,816,905 medical records from 1,354,296 persons. It is a rich resource for epidemiological studies and, on average, covers 66.2% of the population per census data (with Olmsted County in particular being upwards of 100% coverage). Previous REP studies have shown that the incidence of HCC has increased between 1976 and 2008, with chronic hepatitis C virus being replaced by alcoholic liver disease as the most common comorbidity. Over 2000 to 2014, hepatitis B virus increased among HCC patients while hepatitis C trended downwards. **Methods**: HCC patient records were identified from the REP using ICD-9 and 10 codes. Charts were hand-screened to ensure accurate coding. Patient records were reviewed for inclusion criteria: new diagnosis of HCC, age 20+ years at diagnosis, resident of 27-county area 1+ year before HCC diagnosis (to exclude patients traveling to the area for care). In total,1494 charts were flagged and reviewed, of which 36.75% met inclusion criteria for a final sample of 549 patients. The 2010-2021 period was split into 2 eras for analysis. Charts were reviewed by hand and using natural language processing to collect variables of interest including comorbidities and clinical outcomes. **Results**: Over the course of 2010-2021, hepatitis B and C virus rates remained steady among HCC patients. Prevalence of NAFLD and diabetes remained similar, though rates of hypertension and non-alcoholic steatohepatitis were statistically significantly higher in the second era as compared to the first (p = 0.013 and p = 0.00094, respectively). Prevalence of smoking was also unchanged. Analysis of clinical presentation and outcomes is in progress. Conclusion: It is essential to identify etiology of HCC to improve screening and diagnosis. This study provides a comprehensive update on the state, etiology, and outcomes of HCC in the area surrounding Rochester, MN. With this and subsequent studies, we will be able to track changes in risk factors over time and work to enhance screening protocols to target the most vulnerable populations.

4058-A | EVOLVING TRENDS IN HEPATOCELLULAR CARCINOMA IN INDIA - EXPERIENCE FROM A TERTIARY CARE CENTER

Sowmya T R[1], Anand V. Kulkarni[1], Mithun Sharma[2], Archana Chintam[1], Nagaraja Rao Padaki[2] and Duvurr Nageshwar Reddy[1], (1)Aig Hospitals, Hyderabad, India,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(2)Asian Institute of Gastroenterology, Hyderabad, Telangana, India

Background: Hepatocellular carcinoma (HCC) is a major complication and one of the leading causes of mortality in chronic liver diseases. The causes of HCC coincide with those of liver cirrhosis and there are epidemiological differences in different geographical areas. Hepatitis B virus (HBV) etiology is prevalent in China, India, Southeast Asia, and sub-Saharan Africa whereas chronic alcohol related liver disease is the most prevalent aetiology in central Europe and North America. Non-alcoholic steatohepatitis (NASH) related liver cirrhosis is increasing in prevalence world wide. Viral hepatitis B and C used to be leading causes of HCC in India. However, with a strong immunization program and availability of effective antiviral medications the trends in epidemiology of HCC in India are changing. In this study, we aim to identify the main etiological factors and clinical parameters of HCC patients in a tertiary care center in India. **Methods:** This is an observational study. We recorded the demographic details of all patients diagnosed with HCC at AIG hospitals, from November 2021 to April 2023 over a period of 18 months. HCC diagnosis was based on triphasic computerised tomography scan or dynamic magnetic resonance imaging of liver or biopsy as per INASL consensus. Aetiologies, prior comorbidities, stage of disease at diagnosis, presentation and treatment received were recorded. Barcelona clinic liver cancer (BCLC) system was applied for staging of HCC in patients with underlying cirrhosis whereas, TNM staging was done in non-cirrhotic HCC. **Results:** The results of the study are detailed in table 1. A total of 267 patients were diagnosed with HCC over a period of 18 months out of which 244 (91.3%) were males. Median age at presentation is 61years (Range-35-86 y). Out of 267 HCC patients, 250 (93.6%) had co-existing liver cirrhosis. Among cirrhotic HCC patients, non-alcoholic steatohepatitis (NASH) was the leading cause [n = 76 (30.4%)] followed by chronic hepatitis B and hepatitis C infections. Even among non-cirrhotic patients with HCC, underlying non-alcoholic fatty liver (NAFL) was observed in 9 (53%) patients. Most patients were diagnosed at BCLC – C stage and were offered systemic therapy [n = 120 (45%)]. Among advanced and terminal HCC patients (n = 139), who were not amenable for surgical or locoregional therapies, NASH was the leading aetiology found in 60 (43%) patients followed by hepatitis B [n = 31 (22.3%)]. **Conclusion:** NASH is the leading cause of HCC in our study. Most patients diagnosed with advanced HCC had NASH as the underlying aetiology. Even among non-cirrhotic HCCs, NAFL was a commonest association. Worldwide NASH is emerging as a leading cause of HCC. Hence, effective preventive strategies and population screening are the need of the hour.

Table 1. Demographic features, aetiology and clinical characteristics of patients with HCC

Total number of HCC	N=267		
Median age (Range)in years	61 (35-86)		
Gender (Male :Female)	244:23 (10:1)		
Underlying liver cirrhosis			
Yes	250 (93.6%)		
No	17 (4.4%)		
Aetiologies in HCC with cirrhosis	**N=250**		
Non-alcoholic steatohepatitis (NASH)	76 (30.4%)		
Chronic hepatitis B	73 (29.2%)		
Chronic hepatitis C	45 (18%)		
Alcohol related liver diseases (ARLD)	29 (11.6%)		
Cryptogenic	25 (10%)		
Autoimmune liver disease	1 (0.4%)		
Combined hepatitis B and C infection	1 (0.4%)		
Associated conditions in Non-cirrhotic HCC	**N=17**		
Non-alcoholic fatty liver			
Diabetes	9 (53%)		
Obesity (BMI- >25kg/m^2)	4 (23.5%)		
Chronic Hepatitis B infection	6 (35.3%)		
	2 (18%)		
Stage of HCC at diagnosis	**Cirrhosis- BCLC Staging(n=250)**	**N0 cirrhosis-TNM Staging(n=17)**	
	0- 2(0.8%)	Stage I-4 (23.5%)	
	A- 45 (18%)	Stage II-5 (29.4%)	
	B- 72(28.8%)	Stage IIIa- 6 (35.3%)	
	C- 120 (48%)	Stage IIIb- 1(5.9%)	
	D- 11 (4.4%)	Stage IV-1(5.9%)	
Main portal vein thrombosis (Tumour Thrombosis)	121 (45.3%)		
Metastatic disease at diagnosis	12 (4.5%)		
Treatment	**Number of patients**	**Tumour size (mean±SD) in centimetres**	**AFP (mean±SD) in ng/mL**

General Hospital, (6)National Hospital Organization Saitama Hospital, (7)National Hospital Organization Tokyo Medical Center, (8)Sano Kosei General Hospital, (9)Hino Municipal Hospital

Background: The patterns of tumor response by immune checkpoint inhibitors may behave like 'flare effect', such transient tumor increase could be evaluated as progressive disease (PD), which may result in discontinuation of treatment despite the therapeutic effect is achieved. Subgroup analysis of IMbrave150 shows efficacy in patients with unresectable hepatocellular carcinoma (HCC) treated with atezolizumab (Atezo) plus bevacizumab (Bev) beyond PD until loss of clinical benefit (Toh ASCO GI 2022). In the current study, we investigated the exploratory efficacy of Atezo plus Bev beyond radiological progression in real-world. **Methods:** 101 unresectable HCC patients who were treated with Atezo plus Bev were enrolled from 9 liver centers across Japan. In the presence of clinical benefit, patients with PD assessed by RECIST 1.1 could continue treatment until development of unacceptable toxicity or loss of clinical benefit judged by investigator. Loss of clinical benefit was defined as symptoms and signs indicating unequivocal progression of disease, decline in performance status that could be attributed to disease progression, and tumor progression at critical anatomical sites. Patients who received 2 or more cycles of Atezo plus Bev after first PD were classified as beyond PD group, and their outcomes were compared with patients who were treated with alternative regimens or discontinued chemotherapy after first PD. **Results:** The response rate of entire cohort was 24%, and the disease control rate was 69%. The median overall survival (OS) was 21.3 months, and the median progression-free survival (PFS) was 6.9 months. Of those, 44 patients had PD, of whom 17 patients continued Atezo plus Bev, 16 patients had alternative chemotherapy including lenvatinib, sorafenib, cabozantinib, and 11 patients discontinued chemotherapy after first PD. Of the patients who continued Atezo plus Bev, 76% were Barcelona Clinic Liver Cancer (BCLC) stage C while patients receiving other chemotherapy, 69% were BCLC stage C. Other patients background factors including hepatic reserve (35% Child-Pugh A5 vs 29% Child-Pugh A5) were also comparable in each group at first PD. The median OS from the time of first PD in beyond PD group was 17.9 months, while 4.7 months in patients who received alternative chemotherapy or discontinued chemotherapy ($p = 0.04$ log-rank test). In addition, the median OS of the 16 patients who had alternative chemotherapy showed 4.7 months, which was tend to be shorter compared with beyond PD group ($p = 0.269$ log-rank test). **Conclusion:** Our data suggest that patients who received Atezo plus Bev beyond radiological PD with maintained clinical benefit may contribute to prolong prognosis to some extent. Since there is a limitation by selection bias related to excluding patients with loss of clinical benefit, further investigation is needed to detect predictor that define treatment efficacy in such cases.

4060-A | EXPRESSION AND CLINICOPATHOLOGICAL SIGNIFICANCE OF FIBROBLAST GROWTH FACTOR RECEPTOR 2 (FGFR2) IN COMBINED HEPATOCELLULAR-CHOLANGIOCARCINOMA

Motoko Sasaki[1], Yasunori Sato[1] and Yasuni Nakanuma[2], (1)Kanazawa University Graduate School of Medical Sciences, (2)Fukui Saiseikai Hospital

Background: Fibroblast growth factor receptor 2 (FGFR2) fusions are detected in 10-20% of intrahepatic cholangiocarcinoma (iCCA) and are promising therapeutic targets for FGFR2 inhibitors. Combined hepatocellular –cholangiocarcinoma (cHCC-CCAs) shares various features such as histological findings of iCCA components, etiologies and possible cell origin with small duct type iCCA, however, there were few studies on FGFR2 fusions in cHCC-CCA, so far. Immunohistochemical FGFR2 expression is a candidate surrogate marker for detecting FGFR2 fusions. We examined the expression FGFR2 and their clinicopathological significance in combined hepatocellular – cholangiocarcinoma (cHCC-CCA) , in comparison with small and large duct types iCCA and hepatocellular carcinoma (HCC). **Methods:** FGFR2 expression was immunohistochemically assessed in the liver sections from 75 patients with cHCC-CCA (male[M]/female[F] = 51/24; etiology, B/C/alcohol/non-alcoholic fatty liver disease [NAFLD]/unknown: 24/24/5/6/16), 39 with small duct-type iCCA (M/F = 28/11; 1/8/6/1/23), 30 with large duct-type iCCA (M/F = 16/14; 2/2/0/1/25), and 35 with HCC (M/F = 32/3; 10/14/6/3/2). FGFR2 fusions were also detected by PCR and direct sequence. The association of FGFR2 expression with clinicopathological findings including histological features, etiologies and genetic alterations such as p53, ARID1A and BAP1 was analysed. **Results:** FGFR2 expression was detected in more frequently in patients with cHCC-CCA (21.3%) and small duct-type iCCA (23.1%), compared to patients with large duct type iCCA (3.3%) and HCC (0%) ($p < 0.05$). FGFR2 was not expressed in nonneoplastic bile ducts and hepatocytes. FGFR2 expression was significantly more prevalent in cHCC-CCA with a component of cholangiolocellular carcinoma ($p < 0.01$).

FGFR2-positive cHCC-CCAs and small duct-type iCCAs were significantly smaller size, compared to FGFR2-negative ones ($p < 0.05$). Genetic alterations of ARID1A, BAP1 and multiple genes were significantly more frequent in FGFR2-positive cHCC-CCAs, compared to FGFR2-negative cHCC-CCAs ($p < 0.05$). FGFR2 fusions were confirmed by PCR and direct sequence in FGFR2-positive cHCC-CCA and small duct-type iCCAs. **Conclusion:** FGFR2 expression was detected in cHCC-CCAs as frequently as small duct-type iCCAs. This finding suggests a possible therapeutic indication of FGFR2 inhibitors for the patients with cHCC-CCAs.

4061-A | EXTERNAL BEAM RADIATION THERAPY AND LIVER TRANSPLANTATION WITHOUT BRACHYTHERAPY IN THE CONTEXT OF PERI-HILAR CHOLANGIOCARCINOMA: A PROOF OF CONCEPT STUDY

Lydia Aurora Mercado[1], Harpreet K. Bhangu[1], Fernando Gil Lopez[1], Stephen Ko[1], Liu Yang[1], Justin H. Nguyen[2], Terri Menser[1] and Denise M. Harnois[1], (1) Mayo Clinic Florida, Ponte Vedra Beach, FL, (2)Mayo Clinic, Jacksonville, FL

Background: Perihilar cholangiocarcinoma (pCCA) is a rare malignant tumor, frequently presenting in an unresectable stage, with a poor short-term prognosis. Neoadjuvant chemoradiotherapy (Neo-CRT) followed by orthotopic liver transplantation (OLT) has achieved outstanding results in highly selected patients. The Mayo Clinic Rochester Protocol (MCRP) includes external beam radiotherapy (EBRT, 40-45 gray) along with infusional 5-fluorouracil (5-FU), followed by transcatheter brachytherapy (20-30 gray), and then oral capecitabine until OLT. The Mayo Clinic Florida (MCF) protocol does not include brachytherapy and instead includes larger doses of EBRT (45 Gy 1.5/day BID) and an external boost of up to 60 gray in hilum. **Methods:** We retrospectively examined the population both diagnosed with pCCA and meeting MCF protocol inclusion criteria (i.e., mass lesion with a radial diameter < 3 cm, tumor not extending below the cystic duct, medically candidate for OLT). Chart review was conducted in November 2022, and data was manually extracted including multiple years of follow-up. **Results:** A total of 15 patients were treated with Neo-CRT; 4 patients were removed from listing due to disease progression and 11 completed the modified MCRP and were transplanted. The mean age was 55 years, 60% were males, and the mean BMI was 22.71. PSC was the underlying disease (47%), alcoholic liver disease (7%), and the remainder had no underlying disease indicated. Bismuth-Corlette classification was present in 9%, 27%, 18%, and 45% for types 1, 2, 3, and 4, respectively. Tumor size diameter was 1-3 cm in 93% and < 1 cm in 7%. 93% of patients had endoscopic biopsy confirmation prior to OLT; 100% of patients' tumors were visible by imaging. All treated patients received DBD whole livers using the surgical piggyback technique, with a mean operating time of 321 minutes. On average, 3.8 units of blood were used during OLT. None of the patients presented hepatic artery thrombosis, biliary leakage, or biliary strictures after OLT. At explant, histopathology findings post-OLT included pCCA (45%), adenocarcinoma and intraductal papillary neoplasm (27%), and no remaining tumor (27%). Vascular grafts were used in 18% of the transplants (n = 2/11). The two- and five-year survival rates were 55% (n = 6/11) and 44% (n = 4/9), while the recurrence free survival rates were 64% (n = 7/11) and 56% (n = 5/9), respectively. **Conclusion:** When compared with historical data, the results of the modified MCRP using EBRT and OLT without brachytherapy showed similar survival and recurrence rates. The use of EBRT minimized the need for vascular grafts, this may represent another advantage to the use of EBRT rather than brachytherapy.

4062-A | FUNCTIONAL CURE OF HEPATITIS B IN CANCER PATIENTS UNDERGOING IMMUNE CHECKPOINT INHIBITORS

Hsien-Chen Mon[1], Pei-Chang Lee[1,2], Ya-Wen Hung[1,3], Chi-Jung Wu[1,4], Chieh-Ju Lee[1], Chen-Ta Chi[1,4], I-Cheng Lee[1,2], Ming-Chih Hou[1] and Yi-Hsiang Huang[1,2,4,5], (1)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, (2)Faculty of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan, (3)Health Examination Center, Taipei Veterans General Hospital, Taoyuan Branch, Taoyuan, Taiwan, (4)Institute of Clinical Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan, (5)Healthcare and Services Center, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Immune checkpoint inhibitors (ICIs) by blocking program death 1 (PD-1)/ programmed cell death-ligand 1 (PD-L1) axis can restore exhausted T cell immunity not only for cancer treatment but also potentially for curing chronic hepatitis B (CHB). One phase 1 study by one shot of very low-dose nivolumab in accompanied with nucleotide analogue (NUC) had

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

substantial effect on hepatitis B surface antigen (HBsAg) decline. It is interesting to delineate the impact of regular anti-cancer dosage of ICIs on HBsAg seroclearance in cancer patients, and the factors associated HBsAg loss. **Methods:** From 2016 to 2022, consecutive HBsAg-positive cancer patients receiving ICIs in Taipei Veteran General Hospital were retrospectively recruited. Patients co-infected with HCV, HDV, or HIV were excluded. Biochemical, virological factors and duration of ICIs were carefully recorded. **Results:** There were 165 cancer patients enrolled in this analysis, including 112 (67.9%) hepatocellular carcinoma (HCC) patients, and 139 under anti-PD-1 treatment. Of them, 128 (77.6) had already on NUC before ICI treatment. The median cycles of ICIs treatment were 11 (ranged 6-20). During a median follow-up of 18.8 months, 13 (7.9%) patients achieved HBsAg seroclearance. All the 13 patients had on NUCs during ICI treatment. In univariate analysis adjusting competing risk of death, low baseline HBsAg titer (<100 IU/mL; HR $=0.059$, $p<0.001$), and low baseline HBV DNA (<200 IU/ml; HR $=0.150$, $p=0.070$) were associated with HBsAg loss. In multivariate analysis, low HBsAg level was the only factor significantly associated with HBsAg seroclearance. Interestingly, the cumulative incidences of HBsAg loss in the 50 patients whose baseline HBsAg level <100 IU/ml were 5.2% at 12 months, 21.2% at 24 months, and 35.6% at 36 months. **Conclusion:** For cancer patients with baseline HBsAg <100 IU/ml, ICIs treatment could accelerate the chance of HBsAg seroclearance in whom on NUCs. This finding may provide important information for future trial design of ICIs to achieve functional cure in CHB patients.

Figure. HBsAg-Loss ratio separated by HBsAg 200 IU/mL prior ICI treatment.

4063-A | GEOGRAPHIC DISPARITIES IN HEPATOCELLULAR CARCINOMA INCIDENCE

Andrea R. Amaro[1], Timothy Zaki[1], Caitlin Murphy[2] and Amit G. Singal[3], (1)UT Southwestern Medical Center, (2)University of Texas Health Science Center at Houston, (3)University of Texas Southwestern Medical Center

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality in the U.S., with the highest incidence rate in Texas, although there is geographic variation within the state. To evaluate geographic disparities, we compared incidence rates and characteristics of persons with HCC along the Texas-Mexico border vs. other regions of Texas. **Methods:** We identified adults newly diagnosed with HCC and estimated age-adjusted incidence rates using population-based data from the Texas Cancer Registry between January 1, 2000 and December 31, 2019. Demographic and socioeconomic variables were obtained from the Robert Wood Johnson Foundation's County Health Rankings and the Area Health Resource File. We compared individual-, census tract-, and county-level characteristics of persons diagnosed with HCC living in the 32 Texas counties comprising the Texas-Mexico border and non-border counties. **Results:** From 2000 to 2019, age-adjusted incidence rates of HCC were 14.1 vs. 10.6 per 100,000 in border and non-border counties, respectively. There was a greater rise in HCC incidence rates in border compared to non-border counties from 2000-04 to 2015-19. Age-adjusted incidence rates were higher in border counties for men (incidence rate ratio [IRR] 1.32, 95% CI 1.27, 1.37) and women (IRR 1.48, 95% CI 1.39, 1.57), age ≥ 65 years (IRR 1.71, 95% CI 1.64, 1.78), and local (IRR 1.35, 95% CI 1.29, 1.41), regional (IRR 1.12, 95% CI 1.04, 1.21), and distant (IRR 1.42, 95% CI 1.30, 1.54) stage disease. Hispanic persons living in border counties were significantly older than non-border counties, as reflected by the difference in crude IRR (1.14, 95% CI 1.10, 1.18) vs. age-adjusted IRR (0.84, 95% CI 0.81, 0.87). Persons with HCC in border counties were more likely to be foreign-born (31.6% vs 9.7%), have Medicaid (24.5% vs 14.9%), and live in higher poverty neighborhoods (76.5% vs 36.2%) vs. non-border counties. Border counties have fewer primary care providers (40.3 vs 69.1 per 1,000) and gastroenterologists (0.9 vs 3.8 per 1,000), fewer persons with a college degree or higher (13.9% vs 23.9%), more uninsured (31.1% vs 25.9%) and

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

unemployed persons (6.8% vs 4.8%), and more children living in poverty (41.9% vs 21.4%) than non-border counties. **Conclusion:** HCC incidence rates are higher and rising faster along the Texas-Mexico border compared to non-border counties, potentially related to higher prevalence of Hispanic minorities, lower educational attainment, and greater rates of poverty. Improving access to healthcare through policy changes and clinical infrastructure expansion may address these social inequities.

4064-A | GERIATRIC NUTRITIONAL RISK INDEX FOR PREDICTING MUSCLE VOLUME LOSS IN HEPATOCELLULAR CARCINOMA PATIENTS: STRAIGHTFORWARD APPROACH FOR UTILIZATION

Emi Yanagihara[1], Atsushi Hiraoka[1], Hideko Ohama[1], Fujimasa Tada[1], Kousuke Nakatani[1], Yoshiko Fukunishi[1], Tomoyuki Ninomiya[1] and Yoichi Hiasa[2], (1) Ehime Prefectural Central Hospital, (2)Ehime, Toon-shi, Ehime, Japan

Background: Muscle volume decline (MVD) is a crucial prognostic factor for chronic liver disease (CLD) patients, though clinical prediction requires findings obtained with special technologies that are often expensive and not readily available, such as software for computed tomography or bioelectrical impedance analysis. This study examined use of geriatric nutritional risk index (GNRI), calculated using only serum albumin level, height, and body weight, to predict high risk for MVD in CLD patients with hepatocellular carcinoma (HCC). **Methods:** Four hundred forty-two HCC patients in Japan examined without prior treatment from January 2017 to June 2022 were enrolled (median age 74 y, male 72.6%, HCV:HBV:HBV and HCV:alcohol:others = 188:36:2:84:132, Child-Pugh A:B:C = 357:67:18, beyond Milan criteria 41.0%). With GNRI utilized to assess nutritional status, MVD was evaluated using the skeletal muscle index cut-off value of the Japan Society Hepatology (Hepatol Res 2016). This retrospective evaluation was conducted to investigate the relationship between GNRI and MVD. **Results:** MVD was noted in 105 (23.8%) patients and a significant relationship of GNRI with albumin-bilirubin (ALBI) score was found ($r = -0.738$, 95% CI: -0.778 to -0.692, $P < 0.001$). Values for GNRI nutritional status normal:mild decline:moderate decline:severe decline were 283:53:76:30, with the cut-off GNRI score for predicting MVD was 99.7 (specificity/sensitivity = 0.709/0.800) (AUC 0.813, 95% CI: 0.766-0.859), approximately the upper limit of mild nutritional decline status. For GNRI mild decline status (score < 98), the cut-off ALBI score was -2.478 (specificity/sensitivity = 0.867/0.764) (AUC 0.892, 95% CI: 0.863-0.921). Also, after excluding patients with ascites, the cut-off GNRI score for MVD was 99.7 (specificity/sensitivity = 0.760/0.744) (AUC 0.803, 95% CI: 0.747-0.858). MVD incidence increased with worsening nutritional status (normal 9.9%, mild decline 37.7%, moderate decline 47.4%, severe decline 70.0%; $P < 0.001$). **Conclusion:** GNRI in conjunction with body weight and serum albumin level can serve as an easy, effective tool for predicting MVD in CLD patients. Maintaining a normal GNRI score is important during the CLD clinical course before HCC development, and nutritional intake assessment and nutritional intervention should be proactively considered for patients with an abnormal score.

Centre De Recherche Du Centre Hospitalier De L'université De Montréal, (2)Centre De Recherche Du Centre Hospitalier De L'université De Montréal (CRCHUM), (3)Centre Hospitalier De L'université De Montréal, Montréal, UT, Canada, (4)Département De Médecine, Université De Montréal

Background: Hepatocellular carcinoma (HCC) is the most prevalent and deadly hepatic malignancy. The liver is a central organ of protein metabolism. Metabolic reprogramming is a hallmark of cancers, including HCC. This study aimed to identify changes in key pathways of glutamine, the most abundant amino acid, in HCC compared to cirrhotic and non-cirrhotic liver tissues. **Methods:** HCC (n = 32), adjacent paired cirrhotic liver (CL, n = 20), and non-cirrhotic liver (NCL, n = 20) samples were obtained from a single-center patient cohort at the Centre hospitalier de l'Université de Montréal. mRNA analyses were performed by qPCR whereas protein expression was measured by Western blotting. **Results:** Glutamine synthetase (GS) mRNA was higher in HCC samples compared to CL and NCL ($p < 0.05$). Kidney glutaminase (GLS1) mRNA was also higher in HCC than NCL ($p < 0.05$) but not CL. Liver glutaminase (GLS2) mRNA was lower in HCC compared to both CL and NCL (both $p < 0.0001$). Albumin (ALB) was also lower in HCC relative to CL ($p < 0.05$) and NCL ($p < 0.0001$), though CL also had decreased ALB levels compared to NCL ($p < 0.001$). As for protein expression, GS was higher in HCC than in CL and NCL ($p < 0.05$); its expression in HCC being much higher than in paired CL ($p < 0.0001$). GLS1 proteins were highly expressed in HCC but not in CL nor NCL ($p < 0.0001$), whereas GLS2 protein levels were higher in CL and NCL compared to HCC samples ($p < 0.0001$). Receiver operating characteristic (ROC) analyses between non-tumoral liver (CL and NCL) and HCC samples were performed for both mRNA and protein analyses. For mRNA, GLS2 was the best classifier of tissue sample type (AUROC = 0.947, $p < 0.0001$). Calculating the GS/GLS2 ratio increased ROC performance (AUROC = 0.955, $p < 0.0001$). Including albumin led to even improved ROC performance: GS/(ALB*GLS2) (AUROC = 0.969 (95%CI = 0.93-1.00), $p < 0.0001$). For protein expression, GS (AUROC = 0.926, $p < 0.0001$) and GLS2 (AUROC = 0.925, $p < 0.0001$) had better classifying performance than GLS1 (AUROC = 0.867, $p < 0.0001$). Similar to mRNA expression, calculating the GS/GLS2 protein ratio increased ROC performance (AUROC = 0.961 (95% CI = 0.91-1.00), $p < 0.0001$). **Conclusion:** HCC is characterized by a major reprogramming of key pathways of glutamine metabolism. Whereas GS and GLS1 are increased in HCC samples compared to both CL and NCL, GLS2 and ALB are both decreased in human HCC samples. Glutamine metabolism reprogramming has significant discriminative ability between HCC and non-tumoral liver samples.

4066-A | GLYPICAN-3 PROTEIN QUANTITATION AND CELLULAR LOCALIZATION IN PEDIATRIC LIVER TUMORS

Sepideh Besharati[1], Sofia Shaikh[2], Victoria Remotti[3], Ladan Fazlollahi[4] and Helen Remotti[4], (1)Columbia University, New York, NY, (2)Boston University Medical Center, (3)Northeastern University, (4)Columbia University Medical Center, New York, NY

Background: Glypican 3 (GPC3), a heparan sulfate proteoglycan and cell surface oncofetal protein which actives the canonical Wnt/beta-catenin pathway is highly expressed on hepatocellular carcinoma, fibrolamellar carcinoma (FLC) and hepatoblastoma (HB). Although studies to date have shown elevated GPC3 protein in FLC and HB, quantitative patterns of GPC3 expression including cellular localization (canalicular, cytoplasmic, membranous) have not been analyzed in these tumors. A variety of immunotherapeutic approaches that target GPC3 in clinical trials include vaccines, monoclonal and bispecific antibodies, antibody-drug conjugates, cytolytic T-cells, and CAR T-cells. In using GPC3-targeted immunotherapy in pediatric patients, one concern involves possible physiologic expression of GPC3 in the non-tumor liver, particularly in the first year of life. We aim to determine patterns of GPC3 protein in primary HB and FLC tumors and adjacent non-tumor liver tissue with GPC3 immunohistochemistry. **Methods:** Tissue microarrays of 27 HB, and 10 FLC were constructed. We evaluated the Cellmark GPC3 (1G12) mouse monoclonal antibody to detect GPC3 protein, by calculating an H-score, multiplying intensity of staining (0-3) with percent cells staining (0-100). H-score < 10, was considered negative. In addition, the pattern of protein staining (canalicular, cytoplasmic, membranous) was noted. **Results:** GPC3 positive staining was present in 21 of 27 HB with H-scores: range = 0-300, median = 210, interquartile range = 55-300. GPC positive staining was present in 8 of 10 FLC with H-scores: range = 0-300, median = 105, interquartile range = 18-225. The predominant pattern of GPC3 staining in HB was (5/21 canalicular, 11/21 cytoplasmic, 5/21 membranous) and in FLC was (2/8 canalicular, 3/8 cytoplasmic, 3/8 membranous). High level of GPC3 staining with H-score > 150 was identified in 15/27 HB (56%) and in 4/8 FLC (50%). Adjacent benign liver was analyzed in 25 HB cases and in 8 FLC cases, all of which were GPC3 negative. **Conclusion:** GPC3 protein is expressed in a large percentage of HB and FLC tumors, but with variable

intensity and distribution. Characterization of GPC3 tumor protein H-score and pattern of immunoreactivity are two independent parameters that may be helpful to quantitate GPC3 immunostaining of tumor and correlate with treatment response to a variety of GPC3 targeted therapeutics.

4067-A | HEPATIC ADENOMA IN WOMEN UNDERGOING IN VITRO FERTILIZATION (IVF): INSIGHTS FROM A COHORT STUDY

Reshma Reguram[1], Josephine Zhang[1], Lea Lemaitre[2] and Renumathy Dhanasekaran[3], (1)Stanford University, (2)Stanford University, Palo Alto, CA, (3)Stanford University - School of Medicine

Background: The use of *in vitro* fertilization (IVF) now accounts for 1-3% of live births in the US and Europe. IVF involves the administration of hormones such as LH, FSH, and estrogen to induce ovulation and enhance fertility. While the association between estrogen levels and hepatic adenoma growth has been established in the context of oral contraceptive use and pregnancy, the impact of IVF on hepatic adenomas is unknown. To address this knowledge gap, our study compares three patient cohorts with hepatic adenoma who underwent: IVF alone, IVF-pregnancy, and spontaneous pregnancy. **Methods:** We conducted a retrospective cohort study at a single center, focusing on reproductive-aged females with a mean age of 34 years (range 18-49) who underwent IVF and/or experienced pregnancy, and were diagnosed with hepatic adenoma between 2010 and 2021. Of the 150 patients identified through the Stanford Research Repository (STARR) tool, 18 met our inclusion criteria. We analyzed patient charts to evaluate the radiographic growth of hepatocellular adenomas before and after IVF and pregnancy. **Results:** Among the 18 patients included in the study, 28% (n = 5) comprised the IVF-only group, 33% (n = 6) composed the IVF-pregnancy group, and the remaining 39% (n = 7) formed the spontaneous pregnancy group. Hepatic adenoma diagnosis was based on characteristic imaging findings on CT or MRI in 83% of patients (n = 15), while 17% (n = 3) had biopsy-confirmed adenomas. Of the 18 patients, 28% (n = 5) had pre-existing hepatic adenomas, while 72% (n = 13) of adenomas were incidentally discovered during imaging conducted for IVF or pregnancy. Among the 11 patients who received IVF treatment, 7 were diagnosed with hepatic adenoma after starting IVF. Two of these patients had prior imaging that did not show any adenoma, indicating potential development during the hyperestrogenic state. Complications due to adenoma from IVF were rare. None of the patients with adenoma in the IVF-only and IVF-pregnancy cohorts needed surgical intervention and all were monitored conservatively. They neither experienced intralesional hemorrhage, transformation to hepatocellular carcinoma (HCC), or significant adenoma growth upon follow up imaging. **Conclusion:** In this study, we present the largest series of cases of hepatic adenoma in patients who underwent IVF. Most adenomas were incidentally detected during IVF treatment, raising questions about the need for screening in these patients. Moreover, IVF as an hyperestrogenic state may be associated with an increased risk for adenoma development, which needs to be confirmed in larger studies. Reassuringly, no significant growth of adenomas or complications were observed during IVF treatment or subsequent pregnancy in the patients studied. These findings provide valuable evidence to counsel patients with hepatic adenoma undergoing IVF that monitoring the adenomas without intervention is likely safe and appropriate.

4068-A | HEPATOCELLULAR CARCINOMA MANAGEMENT IN PATIENTS OVER AGE 70

Paul P. Hong[1], Karolina Krawczyk[1], John C. Hickernell[1], Kayeromi Gomez[2], Steven J. Scaglione[3], Christopher Molvar[1] and Jonah N. Rubin[1], (1)Loyola University Medical Center, Chicago, IL, (2)Loyola University Chicago, (3)Loyola University Health System

Background: Hepatocellular carcinoma (HCC) is the second most lethal cancer with an average age at diagnosis of 63 to 65 years old in North America and Europe. For those who qualify, standard of care is locoregional therapy (LRT) with or without liver transplantation (LT). Patients older than 70 years are at higher risk for poor outcomes with LT due to comorbidities and frailty. There is a lack of data regarding the optimal approach for these patients. The aim of our

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

study is to determine whether LT has an effect on survival compared to LRT alone. **Methods:** We performed a single-center retrospective study of HCC patients from 2012-2022. Patients were included if they were diagnosed with HCC at 70 years old or above and received LRT. Etiology of liver disease, baseline MELD score, comorbidities, BCLC score, Milan criteria, UCSF criteria, and LT outcomes were collected. Favorable treatment response was defined with LI-RADS or the mRECIST criteria. Wilcoxon Rank-Sum Test was used to compare patients age between the LRT and the LRT plus LT populations. Chi-square test and Fisher Exact Test were used in the remaining bivariate analysis. A log-rank test was used to compare the overall survival between the LRT and the LRT plus LT populations. **Results:** 690 patients who were diagnosed with HCC above the age 70 were identified with 127 patients undergoing LRT and 13 patients undergoing LRT followed by LT. Median age was 74 with 86% Male and 64% NASH cirrhosis. Patients who were younger were more likely to be transplanted ($p < 0.01$). The median baseline MELD score was 11 (IQR 9-15). 75 patients (54%) received Yttrium-90 (Y90) therapy, 54 received transarterial chemoembolization (TACE), and 12 patients received microwave ablation as the initial LRT. 100 patients (71%) treated with LRT had a favorable treatment response. Of the 13 patients who underwent LT, 10 received TACE and 5 patients received Y90 with favorable responses including 3 patients downstaging into Milan criteria. Average time on the LT waitlist was 343.1 days. Post-transplant median RETREAT score was 1 (IQR 0-7) and 2 patients developed tumor recurrence resulting in 1 death. Overall survival was improved with LT (71.9 versus 60.5 months, p-value < 0.0001) with 11 still alive. **Conclusion:** LT had a favorable effect on overall survival in HCC patients over 70 years old with a low rate of tumor recurrence. Patients over 70 years old should be continued to be considered for a transplant evaluation due to improved overall survival.

4069-A | HEPATOCELLULAR CARCINOMA RECURRENCE FOLLOWING TRANSPLANT: RISK FACTORS FOR OLIGOMETASTATIC VERSUS POLYMETASTATIC DISEASE

Nicole Paul[1], Timothy Lin[1], Diana Cheung[1], Harry Luu[1], Behnam Saberi[2], Shane Ottmann[1], Ahmet Gürakar[1], Mark Yarchoan[1], Amol Narang[1], Amy K. Kim[1] and Jeffrey Meyer[1], (1)Johns Hopkins University School of Medicine, (2)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School

Background: Despite utilization of pre-transplant selection guidelines like Milan and/or UCSF criteria, recurrence of hepatocellular carcinoma (HCC) occurs in up to one-fifth of liver transplantations. Furthermore, there is a lack of risk factors to predict the patterns of HCC recurrence, which carries significant implications for prognosis and therapeutic decisions. We aimed to investigate pre-transplant risk factors associated with limited (oligometastatic) vs. widespread (polymetastatic) recurrence. **Methods:** A retrospective review was conducted at a single institution to identify patients with HCC who underwent liver transplantation and subsequently experienced disease recurrence. Baseline demographics and clinical characteristics (such as downstage status and pre-transplant loco-regional treatments) were recorded. Explant pathology, including cellular differentiation and evidence of microvascular invasion, was reviewed. Post-transplant imaging at the time of recurrence was examined, and any site of radiographic recurrence was considered a metastatic lesion. Oligometastatic disease was defined as $< = 3$ lesions at recurrence, while polymetastatic disease was defined as > 3 metastases. Overall survival (OS) was compared between groups via the Kaplan-Meier method, and regression analyses were used to identify predictors of polymetastatic disease. **Results:** Forty-three patients in our cohort experienced HCC recurrence and were eligible for the study between 2005-2022. Patients with oligometastatic disease ($n = 27$) had improved survival compared to those with polymetastatic disease ($n = 16$) with a median survival of 16.2 (95% CI 11.3, 21.1) vs. 4.0 (95% CI 1.4, 6.6) months (log-rank $P = 0.001$) and 3-year OS rates of 28.4% vs. 6.3%. Pre-transplant clinical variables are outlined in Table 1.

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

Alpha-fetoprotein (AFP) level before transplantation > 100 ng/mL (OR = 4.4, 95% CI [1.107 – 17.482]), poor cellular differentiation (OR = 5.25, 95% CI [1.231 – 22.390]) and presence of microvascular invasion (MVI) in the explanted liver (OR = 21.82, 95% CI [2.503 – 190.121]) were predictors of polymetastatic HCC. In multivariable analysis, the impact of MVI was still observed (OR = 14.64, 95% CI [1.480-144.766]). **Conclusion:** The presence of microvascular invasion on explant pathology is a strong predictor of aggressive, polymetastatic HCC in post-transplant patients who have shorter survival than those with oligometastatic HCC. Risk factors for polymetastatic disease also include poor cellular differentiation on explant pathology and AFP > 100 ng/mL.

4070-A | HEPATOCELLULAR CARCINOMA-SPECIFIC ANTIGENIC PEPTIDE-MODIFIED DENDRITIC CELL EXOSOMES COMBINED WITH ANTI-PD-L1 TO ENHANCE IMMUNE RESPONSE IN HEPATOCELLULAR CARCINOMA

Weihua Li[1], Shumin Luo[1], Jing Chen[1], Fang Xu[1] and Li Xiao[2], (1)Beijing Youan Hospital Capital Medical University, Beijing, China, (2)Chengde Medical University

Background: Hepatocellular carcinoma is still a serious disease threatening people's health, and the number of incidences is expected to exceed one million cases in 2025. To clarify the value and potential of dendritic cell exosomes (DEX) modified with hepatocellular carcinoma-specific antigenic peptides in immunotherapy of hepatocellular carcinoma and to explore its potential immune mechanisms. Tumor cells can evade immune surveillance by overexpression of PD-L1 or activation of PD-L1/PD-1 signaling pathway, and high expression of PD-L1 in HCC tissues has been demonstrated; however, there are no clinical studies related to the treatment of HCC with PD-L1 inhibitors. **Methods:** DEX was extracted by ultracentrifugation and loaded with the hepatocellular carcinoma-specific antigens AFP and GPC3 and the N1ND peptide ($DEX_{AFP\text{-}GPC3\text{-}N1ND}$) that enhances cellular immune responses, and the role of $DEX_{AFP\text{-}GPC3\text{-}N1ND}$ in combination with anti-PD-L1 in hepatocellular carcinoma immunotherapy was investigated using liver cancer cell lines and humanized HCC-CDX mice. **Results:** In vitro: $DEX_{AFP\text{-}GPC3\text{-}N1ND}$ has hepatocellular carcinoma-specific immunogenicity and can effectively activate T cells, enhance the killing effect of T cells on hepatocellular carcinoma cell lines and elicit specific immune responses. It can effectively activate T cells and enhance T cell secretion of cytokine IFN-γ ($P = 0.037$). In vivo: $DEX_{AFP\text{-}GPC3\text{-}N1ND}$ inhibited the proliferation of hepatocellular carcinoma cells, affected the tumor microenvironment, and retarded tumor development in mice. In addition, the combination of PD-L1 monoclonal antibody could greatly enhance the anti-tumor immune function of $DEX_{AFP\text{-}GPC3\text{-}}$

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

$_{N1ND}$ by enhancing the immune memory against tumor re-challenge in hepatocellular carcinoma mice. **Conclusion:** The new findings demonstrate the immunomodulatory role of $DEX_{AFP\text{-}GPC3\text{-}N1ND}$ in combination with PD-L1 monoclonal antibody during HCC immunotherapy and provide a basis for the formulation of DEX vaccines targeting hepatocellular carcinoma, providing a scalable approach for personalized immunotherapy of HCC that can be extended to other tumors without the need to identify tumor antigens.

4071-A | HOW FIELD PRACTICE COMPLIES WITH BCLC 2022 RECOMMENDATIONS FOR HEPATOCELLULAR CARCINOMA MANAGEMENT

Eleonora Alimenti[1], Massimo Iavarone[2], Mariangela Bruccoleri[2], Angelo Sangiovanni[2], Barbara Antonelli[3], Anna Maria Ierardi[4] and Pietro Lampertico[2,5], (1) Department of Medical Sciences, University of Pavia, Pavia, Italy, (2)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (3)Division of General Surgery, Liver Transplant Center, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (4) Radiology Department, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (5)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: In 2022 the BCLC staging and treatment algorithm for hepatocellular carcinoma (HCC) management has been updated, granting for higher flexibility and customized management with a multidisciplinary decision process in the choice of the therapeutic strategy for HCC patients as compared to the 2018 version. Aim: To evaluate the adherence to BCLC 2022 in daily clinical practice as compared to the BCLC 2018 and its impact on patients' survival. **Methods:** 464 patients with de novo HCC in different stages, 317 BCLC 0-A, 77 BCLC B, 65 BCLC C and 5 BCLC D were discussed in a multidisciplinary team (MTD) meeting and were treated accordingly to the decision of the team. All patients were then followed until death or end of follow-up. **Results:** Overall, adherence to BCLC 2022 recommendations were similar to BCLC 2018 (72.2% vs 70.3%, $p = 0.56$), corresponding to an adherence per stage of 79% in BCLC 0/A, 63% BCLC B, 49% BCLC C and 60% BCLC D. Overall survival was higher in patients treated according to the BCLC 2022 algorithm ad compared to other treatment strategies (72.1% vs 43.7% at 5 y, p-value < 0.001) in BCLC 0/A patients. In BCLC B an upward stage migration was associated to a higher overall survival (96% vs 66% at 2 y $p = 0.007$), meanwhile no significant differences were observed in BCLC C (43.8% vs 33.3% $p = 0.28$). **Conclusion:** In our hands, the upgraded BCLC staging and treatment system did not modify the adherence to the algorithm, while we observed that the adherence to BCLC 2022 was associated with a better survival in early stages of HCC. In the intermediate stage the access to more radical treatments could improve survival compared to the BCLC 2022 proposals, while no differences were observed in the advanced stage.

4072-A | IDENTIFYING IMPORTANT TREATMENT ATTRIBUTES AMONG PATIENTS WITH HEPATOCELLULAR CARCINOMA: A QUALITATIVE STUDY

Andrew M. Moon[1], Randall Teal[1], Myra Waheed[1], Jessica Carda-Auten[1], Daniel Richardson[1], Hanna Sanoff[1], Robert S Sandler[1], Ethan Basch[1], Stephanie Wheeler[1], David Mauro[1], Ted K Yanagihara[1], David A. Gerber[2], Donna M. Evon[1] and Alfred Sidney Barritt IV[1], (1)University of North Carolina, (2)University of North Carolina at Chapel Hill

Background: Hepatocellular carcinoma (HCC) treatment decisions are often complex and may become increasingly so as new treatment options become available. To address this complexity, multidisciplinary tumor boards have emerged. Tumor boards improve survival in HCC but do not explicitly include input from patients. Preference-elicitation tools such as discrete choice experiments offer an opportunity to integrate patient preferences into tumor boards to improve the shared-decision making process. We performed qualitative interviews with HCC patients to identify common and important treatment attributes for inclusion in a discrete choice experiment. **Methods:** Participants with HCC identified through a multidisciplinary HCC clinic engaged in one-on-one, semi-structured interviews conducted by three qualitative interviewers prior to treatment (for patients who received treatment). Interviews were composed of open-ended questions about the disease experience, discussion of treatment options with providers, expected (or experienced) treatment risks/benefits, and patient values. Immediately following each baseline interview, interviewers performed a preliminary report identifying relevant or compelling concepts that arose across interviews. A full thematic analysis is ongoing. **Results:** The current analysis is based upon 25 of 30 patients with HCC who completed baseline interviews. Patients were 64% male, 79% white, 18% black, 4% Hispanic and 36% from rural areas. Treatments included TACE (32%), thermal ablation (29%), systemic therapy (20%), stereotactic body radiation therapy (4%), TARE (4%), and no treatment (12%). 21/25 (84%) of patients listed more than 1 attribute considered in treatment decisions and patients listed a median of 3 attributes (range 0-8) (Figure 1). The most commonly listed attributes were prolonging survival (n = 12) and/or, as described by patients, “cure/remove [the] cancer” (n = 10). Other commonly mentioned attributes included maintaining independence/reducing caregiver burden (n = 7), avoiding side effects (n = 5), and reducing treatment time (n = 4) or travel time (n = 4). **Conclusion:** In this study, most patients considered more than one attribute in HCC treatment decisions. In addition to prolonging life and maximizing treatment effectiveness, several additional treatment attributes were identified by patients with HCC. Attributes such as minimizing recovery time, treatment time, travel and costs may be used to facilitate shared-decision making for HCC treatments. Further work is needed to determine if treatment preferences would change if patients were informed of the non-curative nature of most HCC treatments. The treatment attributes discovered during this qualitative study will be synthesized with a literature review and provider interviews to be considered for inclusion in a discrete choice experiment of treatment attributes for patients with HCC.

alpha-fetoprotein (AFP), a useful prognostic model for immunotherapy in HCC cases. However, hepatic reserve function is also an important prognostic factor. A new prognosis prediction model based on modified albumin-bilirubin (ALBI) grade (mALBI: ALBI grade 2 divided into 2a and 2b using score of -2.27) (Liver Cancer 2017) was examined for hepatic reserve function assessment. **Methods:** We retrospectively assessed 719 advanced/unresectable HCC patients (u-HCC) treated with AB from October 2000 to December 2022 (median age 74 y, males 577 (80.3%), initial line use 487 (67.7%), BCLC (0: A:B:C:D = 11:44:257:390:17, HCV:HBV:HBV/HCV:alcohol:others = 239:117:1:159:203). As a new predictive model, AB use-line (later), age ($\geq$75 y), gender (female), body mass index ($\geq$25 kg/m^2), basal liver disease (non-viral hepatitis), BCLC stage ($\geq$C), CRP ($\geq$1.0 mg/dL), AFP ($\geq$100 ng/mL), and mALBI (2a or $\geq$2b) were used as prognostic factors, then prognostic predictive value was compared with CRAFITY. **Results:** Cox-hazard univariate analysis showed AFP ($\geq$100 ng/mL) (HR 1.706: 95%CI 1.327-2.194), BCLC stage $\geq$C (HR 1.587: 95%CI 1.219-2.067), CRP ($\geq$1.0 mg/dL) (HR 1.884: 95%CI 1.426-2.488), mALBI 2a (HR 1.726: 95%CI 1.190-2.501), and mALBI ($\geq$2b) (HR 2.233: 95%CI 2.351-4.447) as significant factors (each $P < 0.001$), while AFP ($\geq$100 ng/mL) (HR 1.531: 1.185-1.977, $P = 0.001$), BCLC stage $\geq$C (HR 1.393: 95%CI 1.061-1.828, $P = 0.017$), mALBI 2a (HR 1.765: 1.218-2.559, $P = 0.003$), and mALBI $\geq$2b (HR 2.967: 95%CI 2.141-4.111, $P < 0.001$) were that in multivariate analysis. Immunotherapy with AFP, BCLC, and mALBI (IMABALI) score, based on sum of points with 1 for AFP $\geq$100 ng/mL, BCLC stage $\geq$C, and mALBI 2a, and 2 for mALBI $\geq$2b according to HR, was developed. Akaike information criterion and concordance index values for OS and PFS were better (2799.0/0.688 and 5217.7/0.608, respectively) than those for CRAFITY (2846.5/0.606 and 5246.2/0.574, respectively). **Conclusion:** IMABALI score including detailed hepatic reserve function assessment might be a useful prediction model for AB against HCC in clinical practice.

4074-A | IMPACT OF FIRST-LINE SYSTEMIC THERAPY WITH ATEZOLIZUMAB PLUS BEVACIZUMAB IN PATIENTS WITH HCC

Kaho Aoe[1], Toshifumi Tada[2], Takashi Kumada[3], Atsushi Hiraoka[3], Masashi Hirooka[3], Kazuya Kariyama[4], Ei Itobayashi[3], Tsuji Kunihiko[3], Toru Ishikawa[3], Hidenori Toyoda[5], Takeshi Hatanaka[6], Satoru Kakizaki[7], Hideko Ohama[8], Fujimasa Tada[9], Kazuhiro Nouso[3] and Yoichi Hiasa[10], (1)Japanese Red Cross Society Himeji Hospital, (2)Japanese Red Cross Himeji Hospital, Himeji, Japan, (3)Relpec Study Group and HCC 48 Group, (4)Okayama City Hospital, (5)Ogaki Municipal Hospital, (6)Gunma Saiseikai Maebashi Hospital, (7) National Hospital Organization Takasaki General Medical Center, Takasaki, Gunma, Japan, (8) Takarazuka City Hospital, (9)Ehime Prefectural Central Hospital, (10)Ehime, Toon-shi, Ehime, Japan

Background: The study goal was to compare the outcomes of patients with unresectable hepatocellular carcinoma (HCC) who received atezolizumab plus bevacizumab (Ateoz/Bev) as either first- or later-line systemic therapy. **Methods:** A total of 430 patients with unresectable HCC treated with Atezo/Bev were included. Patients treated with Atezo/Bev as first-line systemic therapy for HCC were defined as the first-line group (n = 268), while those treated with Atezo/Bev as second- or later-line systemic therapy were defined as the later-line group (n = 162). **Results:** The median progression-free survival times in the first- and later-line groups were 7.7 months (95% confidence interval [CI], 6.7–9.2) and 6.2 months (95% CI, 5.0–7.7), respectively ($p = 0.021$). The median overall survival times in the first- and later-line groups were not available [NA] months (95% CI, 18.5–NA) and 17.8 months (95% CI, 15.1–20.3), respectively ($p = 0.084$). Regarding treatment-related adverse events, hypertension of any grade was more common in the first-line group than in the later-line group ($p = 0.025$). Univariate analysis with Cox proportional hazards modeling adjusted by inverse probability weighting, including patient and HCC characteristics, showed that the later-line group (hazard ratio [HR], 1.304; 95% CI, 1.006–1.690; $p = 0.045$) was

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significantly associated with progression-free survival. In a subgroup analysis of patients with Barcelona Clinic Liver Cancer (BCLC) stage B, the median progression-free survival times in the first- and later-line groups were 10.5 months (95% CI, 6.8–13.8) and 6.8 months (95% CI, 5.0–9.4), respectively ($p = 0.021$). In addition, among patients with a history of lenvatinib therapy, the median progression-free survival times in the first- and later-line groups were 7.7 months (95% CI, 6.3–9.2) and 6.2 months (95% CI, 5.0–7.7), respectively ($p = 0.022$). **Conclusion:** The use of Atezo/Bev as first-line systemic therapy in patients with HCC is expected to prolong survival.

4075-A | IMPACT OF MULTIPLE PRIMARY CANCERS ON OVERALL SURVIVAL OF PATIENTS WITH HEPATOCELLULAR CARCINOMA

Petr Hříbek[1,2], Sona Frankova[3], Johana Klasová[1], Klara Chmelova[3], Lucie Žabová[1], Jan Sperl[3] and Petr Urbánek[1], (1)Military University Hospital Prague, (2) University of Defense, Faculty of Military Health Sciences in Hradec Králové, (3)Institute for Clinical and Experimental Medicine

Background: With the increasing incidence of malignancies, we face situations where hepatocellular carcinoma (HCC) is not the only cancer in a particular patient. The increasing occurrence of multiple primary neoplasias (MPN) is a long-term trend linked with improved life expectancy, diagnostics, and progress in treatment options. The prevalence of MPN in patients with HCC and its impact on overall survival (OS) remains unknown. This problem is important in HCC patients potentially treatable by liver transplantation (LT) as the occurrence of other cancer could present a contraindication to LT. The aim of our work was to assess the frequency of MPN and its impact on treatment options and OS in these patients. **Methods:** We retrospectively analyzed a cohort of HCC patients treated at two tertiary centers in the Czech Republic. Four hundred ninety-seven patients with HCC in the cirrhotic liver (388/497 males, median age at diagnosis 65 y) were included. Liver cirrhosis etiology was ALD in 38%, viral hepatitis in 32%, NASH in 19%, autoimmune and cholestatic diseases in 10%, and 1% of other etiology. BCLC stages were 0+A 51%, B 27%, C 17%, and D 6%. The cohort was divided into two subgroups – LT (324 patients) and non-LT (173 patients). We analyzed MPN occurrence, its impact on survival, and a Cox regression analysis of risk factors worsening outcomes (obesity, cirrhosis etiology, concurrent type 2 diabetes, gender, and smoking status). **Results:** The MPN was found in 88 patients (18% of patients in the cohort). The most common MPN were prostate (15, 17%), skin (14, 15.9%), kidney (11, 12.5%), lung (9, 10.2%), and colorectal cancer (8, 9.1%), and represented 64.8% of all MPN. The median OS of the whole cohort, LT and non-LT subgroup was 70, 116, and 17 months respectively ($p < 0.0001$). The median OS in patients with HCC only and HCC with another cancer was 77 (95% CI 67– 96) and 50 months (95% CI 37–62), respectively; the difference was not statistically significant ($p = 0.25$). The survival of patients who underwent LT was significantly better than those who were contraindicated to LT owing to concomitant MPC (116 vs 35 months, $p < 0.0009$). Autoimmune etiology, NASH, HCC as the first diagnosed malignancy, and male sex were identified as factors significantly influencing patients' prognosis (HR 0.43, 3.2326, 0.70, and 1.43 respectively). **Conclusion:** In our cohort, the MPN frequency was 18%, predominantly with malignancies more frequent in males. The impact of MPN on OS was not significant, except for individual's contraindicated to LT due to MPN. The better prognosis was associated with the autoimmune etiology of cirrhosis, and HCC diagnosed as the first malignancy. Male sex and NASH worsened the outcomes.

4076-A | IMPACT OF NUCLEOS(T)IDE ANALOGUES ON THE RISK OF HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B PATIENTS: A TIME-DEPENDENT COX REGRESSION ANALYSIS

Makoto Moriyama[1], Ryosuke Tateishi[1], Mizuki Kinoshita[1], Tsuyoshi Fukumoto[1], Tomoharu Yamada[1], Taijiro Wake[1], Ryo Nakagomi[2], Takuma Nakatsuka[1], Tatsuya Minami[1], Masaya Sato[1], Mitsuhiro Fujishiro[1] and Kazuhiko Koike[1,2], (1)The University of Tokyo, (2) Kanto Central Hospital of the Mutual Aid Association of Public School Teachers, Tokyo, Japan

Background: The preventive effect of nucleos(t)ide analog (NA) use on HCC development in patients with chronic hepatitis B (CHB) is controversial due to the difficulty of conducting randomized controlled trials. **Methods:** In this single-center, retrospective study, NA-

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

naïve CHB patients without a history of HCC were enrolled and followed-up from the first visit on or after January 2000 to December 2020. Patients were categorized into the NA group, including those who started NA after study enrollment, and the non-NA group, including patients to whom NA was never administered during the follow-up period. After propensity score matching (PSM) to balance the confounding factors, we applied a multivariable time-dependent Cox proportional regression analysis with the initiation of NA as a time-dependent covariate. We also performed 1-year and 2-year landmark analyses in the PSM cohort to mitigate the immortal time bias, where patients were stratified according to NA use prior to the corresponding time points. We further performed a subgroup analysis according to the presence or absence of cirrhosis. **Results:** The baseline characteristics of 212 pairs of patients retrieved by PSM were comparable. During the mean follow-up of 12.9 and 6.8 years in the NA and non-NA groups, respectively, 25 and 28 patients developed HCC, respectively. Multivariable analysis with time-dependent covariates showed that NA did not affect HCC risk (HR, 0.68; 95% CI, 0.36–1.31; $p = 0.25$) after adjusting for other risk factors, including age, sex, and HBV viral load. The HRs for NA at the 1- and 2-year landmarks were 0.47 (95% CI, 0.17-1.34, p = 0.16) and 0.43 (95% CI, 0.16-1.11, p = 0.08), respectively, and NA use did not significantly reduce HCC risk. Subgroup analysis showed that NA use significantly reduced the risk of HCC in cirrhotic patients (HR, 0.26; 95% CI, 0.08–0.85; $p = 0.03$). **Conclusion:** The preventive effect of NA on hepatocarcinogenesis may be limited to cirrhotic patients.

4077-A | IMPACT OF SELF-REPORTED ANCESTRY IN HEPATOCELLULAR CARCINOMA IN HISPANIC POPULATIONS

Spencer Goble, Hennepin Healthcare, Cindy Narvaez-Barbecho, University of Minnesota, Minneapolis, Minnesota, Manaswita Tappata, University of Minnesota, Minneapolis, Minnesota, Minneapolis, MN, Jhon Edison Prieto Ortiz, Cehyd (Centro de Enfermedades Hepáticas y Digestivas), Domingo Balderramo, Hospital Privado Universitario De Córdoba, Córdoba, Argentina., Enrique Carrera Estupiñan, Departamento De Gastroenterologia y Hepatologia, Hospital Eugenio Espejo, Quito, Ecuador, Javier Diaz Ferrer, Universidad San Martin De Porres, Lima, Peru, Marco Arrese, Departamento De Gastroenterología, Facultad De Medicina, Pontificia Universidad Católica De Chile, Andre Boonstra, Erasmus University Medical Center, Rotterdam, Netherlands and Jose D. Debes, University of Minnesota

Background: Hepatocellular carcinoma (HCC) related to non-alcoholic fatty liver disease (NAFLD) is a growing health concern worldwide and particularly in areas of high NAFLD endemicity such as Latin America. This region has a mixed population with a diverse heritage that is rarely accounted for when looking at epidemiological studies. We assessed the differences in the epidemiology and outcomes of HCC in Latin Americans based on self-reported ancestry. **Methods:** We retrospectively evaluated data from the ESCALON network, which prospectively follows patients at risk of and with HCC in six countries in South America. Self-reported ancestry data was categorized as European, Amerindian, African, Asian, Indigenous, or other. For this study we divided ancestry in two categories: European and non-European. Individual's in each category were evaluated using comparative statistics for demographics, underlying liver disease, tumor characteristics and treatment. IRB approval was obtained from all participating institutions. **Results:** A total of 429 individual's with HCC from 6 countries in Latin America were studied, Argentina (34% n = 145), Chile (15% n = 66), Ecuador (15% n = 63), Peru (15% n = 66), Colombia (14% n = 60), and Brazil (7% n = 29). The median age was 68 years and 65% were male. 131 patients (30.5%) reported a European ancestry and 298 (69.5%) non-European ancestry. In those of European ancestry median age was 66 years and 72% were male. In the non-European ancestry cohort median age was 67 years and 62% were male. The most common causes of underlying liver disease were hepatitis C virus (38%) followed by alcohol use disorder (25%) in European ancestry and NAFLD (52%) followed by alcohol use disorder in non-European ancestry (23%). Both groups, European and non-European ancestry, had similar proportion of HCC diagnosed under surveillance (40% and 41% respectively) and similar presence of extrahepatic disease (47% and 50% respectively). 26% of those with European ancestry received curative therapy compared to 33% of those with non-European ancestry. **Conclusion:** This is the first study addressing ancestry in Latin Americans with HCC. We found that HCC related to NAFLD was more common in patients of non-European descent. Future studies are warranted to better understand the impact of genetics within specific regions of the continent to understand risk of HCC.

4078-A | IMPACT OF THE EARLY COVID-19 PANDEMIC ON INCIDENCE AND MORTALITY RATES OF HEPATOCELLULAR CARCINOMA AND CHOLANGIOCARCINOMA IN THE UNITED STATES

Jeff Liang[1], Yee Hui Yeo[2], Srinivas Gaddam[1], Walid S. Ayoub[1], Alexander Kuo[1], Hirsh Trivedi[1], Kamya Sankar[1], Jun Gong[1], Andrew Hendifar[1], Arsen Osipov[1], Kambiz Kosari[1], Nicholas Nissen[1], Nicole E. Rich[3], Amit G. Singal[3] and Ju Dong Yang[1], (1)Cedars-Sinai Medical Center, Los Angeles, CA, (2)Cedars-Sinai Medical Center, Culver City, CA, (3)University of Texas Southwestern Medical Center

Background: Hepatocellular carcinoma (HCC), the most common form of liver cancer, is a leading cause of cancer-related mortality in the United States; intrahepatic cholangiocarcinoma (iCCA) is the second most common form of primary liver cancer with rising incidence rates. Routine cancer surveillance in high-risk patients is recommended in HCC, but not for iCCA; however, the recent Coronavirus Disease 2019 (COVID-19) pandemic and associated quarantine policies may have limited patients' access to healthcare resources and screening tools. We aim to determine the impact of the pandemic on the incidence and mortality rate of HCC and iCCA in the U.S. **Methods:** We performed a retrospective study of the Surveillance, Epidemiology and End Results (SEER) Research Plus database, a population-representative sample obtained from 22 cancer registries covering approximately 48% of the U.S. Cases of HCC and iCCA diagnosed between 2000-2020 were identified using ICD-O-3 codes. Incidence and mortality rates per 100,000 individual's (age-adjusted to the 2000 US population) were calculated. Pearson's Chi-square test was used to compare HCC incidence stratified by sex and race. Overall incidence and mortality trends were calculated using the Joinpoint regression software. **Results:** The adjusted incidence rate of HCC in the first year of the pandemic was significantly reduced from the prior year (7.46 in 2020 vs 8.62 in 2019 per 100,000 person-years). There were no changes in sex or racial/ethnic disparities in HCC incidence in 2020 compared to the prior year ($p = 0.50$ and 0.48, respectively). In contrast, there was no significant difference in iCCA incidence rates in 2020 compared to the prior year (1.91 vs 1.81, respectively). Trend analysis of HCC incidence revealed a steep drop from 2019-2020 compared to the prior years (APC -15.1% vs -0.33%, respectively; $p < 0.001$), a pattern which was present when stratified by sex (2019-2020 APC -15.4% and -12.8% in males and females, respectively). In contrast, incidence rates of iCCA have been stable to slightly increasing since 2017 and did not change significantly in 2020. There was no significant difference in HCC or iCCA mortality in 2020 compared to prior years. **Conclusion:** There was a clinically significant reduction in HCC incidence in 2020 compared to prior years, although a significant change in mortality has not been observed. In contrast, no significant change in incidence was seen in iCCA, suggesting that the reduction in HCC diagnosis may be related to limited access to surveillance during the pandemic. Further studies examining the impact of COVID-19 on access to HCC surveillance, incidence and mortality trends are needed.

4079-A | INCIDENCE AND CHARACTERISTICS OF NON-MALIGNANT LIVER LESIONS DETECTED THROUGH ULTRASOUND BASED HEPATOCELLULAR CARCINOMA SURVEILLANCE

Samuel Hui[1,2], Andrew Nguyen[2], Suong Le[1,2], Anouk Dev[1,2] and Sally Bell[1,2], (1)Monash University, (2) Monash Health

Background: Ultrasound based hepatocellular carcinoma (HCC) surveillance reduces HCC related mortality in high-risk patients but may result in increased detection of non-malignant liver lesions (NMLL). This in turn leads to an increased utility of CT, MRI, or invasive procedures and may result in surveillance related harm. In this study, we report the incidence and characteristics of NMLL in a cohort of HCC surveillance patients in Melbourne, Australia. **Methods:** We analysed all patients who received an ultrasound for HCC surveillance at a tertiary hospital network in the first six months of 2017. Patients with prior HCC were excluded. Outcomes were followed until 2021 through review of the hospital electronic record. Primary outcomes were the incidence and characteristics of NMLL and frequency of downstream investigations, stratified by cirrhosis status. The secondary outcome was the incidence of new HCC diagnoses. Subgroup analysis was performed for patients who received surveillance outside Australian and US criteria. **Results:** 553 patients were included (mean age 54.5 ± 12.3 y, males 67.5%). Cirrhosis was present in 50.3%, of whom 87.8% were Child-Pugh A. Viral hepatitis was the underlying aetiology in 80.8%. Over a median follow-up of 4.7 years (IQR 4.6-4.8 y), NMLL were detected in 90 patients (16.3%), with no difference between cirrhotic and non-cirrhotic patients (17.6% versus 14.9%, $p = 0.45$). 71.1% of patients with NMLL proceeded to further investigations, which included CT (52.2%), MRI (40%), biopsy (1.1%) and surgical resection (1.1%). When evaluated with CT or MRI, 30% of NMLL were unable to be identified, 17.2% were probable haemangiomas, 15.6% were probable cysts and 10.9% were probable dysplastic nodules. Overall, 24 cases of HCC (4.3%) were diagnosed and occurred more frequently in cirrhotic patients (7.6% versus 1.1%, $p < 0.01$). 75% of HCC cases were Barcelona Clinic Liver Cancer Stage 0 or A at diagnosis. In the subgroup who underwent surveillance outside criteria ($n = 87$), no patient was diagnosed with HCC, but 14.9% were diagnosed with NMLL. 69.2% of patients with NMLL in this subgroup then underwent further investigation with CT, MRI or surgical resection. **Conclusion:** In a real-world cohort followed up for a median of 4.7 years, HCC surveillance resulted in the detection of NMLL in 16.3% and HCC in 4.3%. The yield of surveillance was significantly lower in non-cirrhotic patients with a similar incidence of NMLL but significantly fewer HCCs identified. Patients who underwent surveillance outside clinical guidelines derived no benefit from surveillance but were exposed to potential harm. Our study highlights the limitations of HCC surveillance in certain subgroups such as non-cirrhotic patients, as well as the need to investigate and develop tailored HCC surveillance programs.

4080-A | INCREASED INCIDENCE OF METASTATIC DISEASE IN TERATOID HEPATOBLASTOMA

Andres F. Espinoza[1], Ann Wang[1], Pavel Sumazin[2], Stephen F. Sarabia[2], Martin Urbicain[2], Andras Heczey[3], Prakash Masand[1], Sarah E. Woodfield[3], Sanjeev Vasudevan[1], Dolores Lopez-Terrada[2] and Kalyani Patel[1], (1)Baylor College of Medicine, (2)Baylor College of Medicine, Texas Children's Hospital, Houston, TX, (3) Texas Children's Hospital

Background: Hepatoblastoma (HB) is the most common primary hepatic malignancy in childhood, currently risk stratified based on clinical staging, age, and serum alpha-fetoprotein levels. Multiple histologic subtypes and significant intra-tumor heterogeneity have posed challenges in incorporating histology into risk stratification. The purpose of this study was to

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

review demographics and outcomes of teratoid HB, a rare histological subtype, in a single tertiary referral center. **Methods:** A retrospective chart review showed a total of 136 treated HB patients from October 2004 to January 2022 at Texas Children's Hospital in Houston, Texas. Of the total cohort, 15 patients were found to have HB with teratoid histology. Teratoid histology was defined as HBs with epithelial and mesenchymal components with additional heterologous elements such as neuroepithelium, mucinous or squamous component, or melanin. **Results:** Teratoid HB was found to occur more often in males (73.3%) and Hispanic (60.0%) patients compared to those with other HB subtypes (64.4%, $p = 0.49$; 52.2%, $p = 0.50$). The median age at diagnosis of those with teratoid histology was 1.4 years (IQR 1.1-2.6) compared to 1.7 years (IQR 0.8-2.1, $p = 0.27$) in patients with non-teratoid histology. Patients with teratoid HB had a slightly higher incidence of prematurity at 46.6% compared to 35.5% in our entire cohort ($p = 0.39$). Pretreatment extent of disease (PRETEXT) IV was the most common diagnosis in teratoid (40.0%) and non-teratoid (33.6%) cohorts ($p = 0.62$). Metastatic disease was noted in 46.6% of teratoid patients compared to 22.3% of all non-teratoid patients ($p = 0.04$). Micro-vascular invasion was noted in 26.6% of patients with teratoid HB, while 60% had vascular invasion on pre-operative imaging compared to 34.5% ($p = 0.80$) and 56.6% ($p = 0.54$), respectively, in the non-teratoid cohort. 20% of both teratoid and non-teratoid cohorts had relapsed disease. Patients with teratoid HB had a 3-year overall survival (OS) of 82% compared to 87% in those without teratoid histology ($p = 0.92$). **Conclusion:** Teratoid HBs showed higher incidence of metastatic disease in our cohort. Despite this, patients with teratoid HB seem to have similar demographics, risk factors, and OS as non-teratoid HB. To our knowledge, this one of the largest series evaluating demographics and outcomes of teratoid HB.

4081-A | INCREASING INCIDENCE OF LIVER CANCER IN OLD MEN: A POPULATION-BASED TIME-TREND ANALYSIS USING THE GLOBAL BURDEN OF DISEASES DATABASE, 1990-2019

Saqr Alsakarneh[1], Saeed Abughazaleh[2], Fouad Jaber[1], Remy Arwani[3], Mohammad Almeqdadi[4], Nikki Duong[5], Adel Muhanna[1], Kimberly Sanders[1], John Campbell[1], Anika Mittal[1] and Wendell K. Clarkston[1], (1)University of Missouri-Kansas City, (2)Tufts University, (3)Temple University, (4)Lahey Clinic Medical Center, (5)Virginia Commonwealth University Health System, Oakland, CA, United States

Background: Liver cancer is a leading cause of mortality in the US. Previous data showed an increasing incidence of liver cancer with greater rates in older adults. However, there are limited data on recent age and sex-specific incidence rates. The aim of this study was to conduct a time-trend analysis of liver cancer incidence rates using the Global Burden of Diseases (GBD) 2019 study database.
Methods: Data was obtained from the GBD 2019 database, an International database that covers 100% of liver cancer diagnosed cases in the US. Liver cancer incidence rates, age-adjusted to the standard US population, were calculated using SEER*Stat software (v.8.4.0.1, National Cancer Institute "NCI") and were stratified by gender, as reported in the database. Time-trends were estimated as annual percentage change (APC) and average APC (AAPC) using Joinpoint Regression Software (v.4.9.0.1, NCI) utilizing Monte Carlo permutation analysis to generate the simplest trend. Pairwise comparison was conducted between gender-specific trends using the tests of parallelism and coincidence. Age-specific trends were also assessed in two age sub-groups: younger adults aged 15-49 years and older adults aged 50-74 years. A two-sided P-value cut-off of 0.05 was utilized for statistical significance. **Results:** 483,002 patients were diagnosed with liver cancer in the US between 1990-2019. Overall, Liver cancer incidence rates have been significantly increasing in older adults but not in younger adults (AAPC = 3.32 vs 1.48; AAPC difference = 1.84, $P < 0.001$). Age-specific trends were not identical ($P < 0.001$) nor parallel ($P < 0.001$) suggesting that liver cancer incidence rates are different and increasing at a greater rate in older adults compared to younger adults. Similar results were seen in women (150,481 patients) with an absolute AAPC difference between older and younger adults of 0.46 ($P = 0.02$). However, in men (332,521 patients), while similar results were seen, a greater AAPC difference between younger and older men of 2.26 (< 0.001) was noted suggesting that the greatest disparity between liver cancer incidence trends between age-specific groups arises from men. **Conclusion:** Our results suggest that liver cancer

incidence trends have been increasing in older adults while stable in younger adults over the last three decades. The greatest difference between older and younger adults seemed to be arising from older men. While this increase can be due to increase in morbidities commonly associated with aging like alcoholic liver disease and non-alcoholic fatty liver disease, it can also represent a true increase in incidence. Future studies are warranted to investigate risk factors associated with the increasing incidence in older adults, especially older men.

Trend analysis of Liver Cancer Age-Standardized Incidence rate with Gender and Age Variations from 1990 to 2019

Incidence	Trends*			Age and gender-specific AAPC difference (95% CI)	Pairwise comparison P-values		
	Time period	APC (95% CI)	AAPC (95% CI)		Age and gender-specific AAPC difference	Coincidence§	Parallelism¶
All ages							
Young (15-49)	1990-2019	1.48 (0.78-2.18)	1.48 (0.78-2.18)	1.84 (2.52 to 1.15)	<0.001	<0.001	<0.001
Old (50-74)	1990-2019	3.32 (3.22-3.42)	3.32 (3.22-3.42)				
Males							
Young (15-49)	1990-2019	1.36 (0.56-2.17)	1.36 (0.56-2.17)	2.26 (3.04 to 1.48)	<0.001	<0.001	<0.001
Old (50-74)	1990-2019	3.62 (3.50-3.75)	3.62 (3.50-3.75)				
Females							
Young (15-49)	1990-2019	1.82 (1.40-2.24)	1.82 (1.40-2.24)	0.46 (0.87 to 0.04)	0.02	0.03	<0.001
Old (50-74)	1990-2019	2.28 (2.18-2.34)	2.28 (2.18-2.34)				

* Time-trends were computed using Joinpoint Regression Program (v4.9.0.1, NCI) with 2 maximum joinpoints allowed (3-line segments).
§ Tests whether age/gender-specific trends were identical. A significant P-value indicates that the trends were not identical (i.e., they had different incidence rates and coincidence was rejected).
¶ Tests whether age/gender-specific trends were parallel. A significant P-value indicates that the trends were not parallel (i.e., parallelism was rejected).

4082-A | INVASIVE MEASUREMENT OF HEPATIC VENOUS PORTAL GRADIENT BEFORE RESECTION OF HEPATOCELLULAR CARCINOMA

Petr Hříbek[1,2], Johana Klasová[1], Tomáα Tůma[1,2], Kateřina Menclová[1], Jiří Pudil[1] and Petr Urbánek[1], (1) Military University Hospital Prague, (2)University of Defense, Faculty of Military Health Sciences in Hradec Králové

Background: Many patients with hepatocellular carcinoma (HCC) could not be transplanted for plenty of reasons. However, sugery remains option in terms of overall survival (OS). As most HCC develops in the field of liver cirrhosis, the presence of portal hypertension is crucial for liver resection (LR). Liver vein catheterization with hepatic venous-portal gradient (HVPG) measurement is the standard procedure for the quantification of portal hypertension. We prospectively followed a cohort of patients planned for LR with HVPG measurement before the decision on a definitive indication for surgery. **Methods:** We present: 1) a cohort of all patients who underwent HVPG measurement before planned LR for HCC between 1/2016–1/2023, 2) an analysis of complications of the procedure, and 3) overall outcomes. The cohort counted 35 patients with liver cirrhosis (30 males, mean age 69.5 y). In all patients upper endoscopy was realized to exclude esophageal rices before HVPG measurement. Patients included into our analysis were not suitable for liver transplantation according to current guidelines. **Results:** The success rate of HVPG measurement was 91.4%, with serious complications in 2.9% of cases. Due to clinically significant portal hypertension (CSPH), resection was contraindicated in 31.3% of patients. One patient (5.9%) had a complicated postoperative course with fasciitis. None of the other resected patients (88.2%) was rehospitalized for surgical complications or liver events until the 90th day after surgery, with no reported death. The median of overall survival (OS) in resected subgroup was 70 months (95% CI 52-86), and 35 months 95% (CI 13-48) in conservatively treated patients. **Conclusion:** HVPG measurement is the gold standard for the quantification of portal hypertension. Hepatic vein catheterization is invasive, but a safe procedure, with a clear impact on HCC management considered for surgery, especially with benefit for patients rejected from liver transplantation. In our cohort with HVPG-guided indication for resection, the liver event as a complication of surgery was identified only in 5.9% of cases.

4083-A | INVESTIGATING HIGH RATES OF MISDIAGNOSIS AND POOR PROGNOSIS IN PRIMARY HEPATIC ANGIOSARCOMAS: A SYSTEMATIC REVIEW

Binyamin Ravina Abramowitz[1], Sanya Goswami[1] and Daniel Anthony DiLeo[2], (1)SUNY Downstate Health Sciences University, (2)VA New York Harbor Healthcare System

Background: Primary hepatic angiosarcoma (PHA) is a rare vascular malignancy of endothelial origin that accounts for only 2% of all hepatic primary tumors. It carries a poor prognosis given its highly malignant and rapidly progressive disease course. Its rarity has led to obscurity with its diverse clinical features making it an easily missed diagnosis for physicians. The diagnosis is confirmed via histopathology and a substantial percentage only by autopsy. We present a systematic review identifying patient cases of PHA to summarize and highlight new and existing literature to provide clarity of the challenges faced in the diagnosis and treatment of PHA. **Methods:** We performed a systematic literature search using predefined keywords within 3 databases (PubMed, EMBASE, and MEDLINE) to identify case reports and case series of PHA within the past ten years. A set exclusion criteria was applied. All remaining articles were assessed for selection and subsequent data extraction. We analyzed pooled individual clinical data regarding demographics, symptoms, treatments, and prognosis. **Results:** A total of 65 patients from 59 case

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

reports/case series were included in our study. 58.5% of all patients were male and the median age of onset was 64.5 years. The most common presenting symptom was right upper quadrant pain (50.8%), followed by abdominal distention (20%), weight loss (17%), and jaundice (17%). About 10.8% of all patients initially presented with a gastrointestinal bleed. Nearly half of all patients were initially misdiagnosed with either a benign tumor or with a malignancy other than angiosarcoma. Due to the rapidly progressive nature of the malignancy, 41.5% of patients were treated with only palliative or supportive care. Chemotherapy or targeted therapy was administered to 25% of patients and 21.5% were treated surgically. The median overall survival time was 4.5 months with a 1-year survival rate of 20%. **Conclusion:** PHA is a deadly disease with a grim prognosis. Although resection, targeted immunotherapy, and chemotherapy are commonly offered as initial treatments, in many cases rapid progression of the disease allows only for palliative treatment options. The high percentage of misdiagnosis in PHA patients likely contributes to the high rate of advanced disease progression and treatment failure. A study with a larger sample would be required to draw even more definitive patterns and algorithms to help successfully diagnose PHA.

4084-A | LENVATINIB-TRANSARTERIAL CHEMOEMBOLIZATION COMBINATION TREATMENT PROLONGS SURVIVAL COMPARED TO LENVATINIB SINGLE TREATMENT IN ADVANCED HCC PATIENTS WITH INTRAHEPATIC LESIONS

Sung Won Chung, Asan Medical Center, Seoul, Korea, Republic of (South), Won-Mook Choi, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South) and Kang Mo Kim, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: To prolong survival in patients with hepatocellular carcinoma (HCC), intrahepatic tumor control is important and to achieve this goal, attempts to combine systemic treatment with transarterial chemoembolization (TACE) has been investigated ever since. This study aimed to establish clinical efficacy of lenvatinib-TACE combination treatment. **Methods:** From 2018 to 2021, patients from a single tertiary center who were diagnosed with intrahepatic HCC lesion and received Lenvatinib as first-line systemic therapy were selected. Patients were divided into those who received TACE in conjunction with lenvatinib (combination group) and those who received lenvatinib alone (single group). The primary outcome was overall survival, while progression free survival (PFS) is a secondary outcome. Propensity score matching was applied to balance two groups. To evaluate underlying mechanism, Huh-7 cell lines were treated with lenvatinib or a placebo for 48 hours under either normoxia or hypoxia. We performed immunoblots, co-immunoprecipitation, quantitative polymerase chain reaction, and cell viability assays. **Results:** After balancing with propensity score matching (all standardized mean difference < 0.1), the combination group ($n = 35$) was associated with a lower risk of death (adjusted hazard ratio [aHR] $= 0.53$, 95% confidence interval [CI] $= 0.34–0.81$, $p = 0.004$) and longer PFS (aHR $= 0.50$, 95% CI $= 0.32–0.80$, $p = 0.004$) than the single group ($n = 80$). Under hypoxic conditions, lenvatinib suppressed hypoxia inducible factor 1 alpha (HIF-1α) protein expression in Huh-7 cell lines without affecting mRNA levels. Cell viability assays confirmed a reduction in the viability of Huh-7 cells when lenvatinib was administered under hypoxic conditions. **Conclusion:** Lenvatinib and TACE combination increases overall survival and prolongs progression. Potential mechanism seems to be related to lenvatinib lowers HIF-1α expression in hypoxic HCC cells via degrading HIF-1α proteins via increasing the ubiquitination pathway. In patients with uncontrolled intrahepatic lesion, lenvatinib-TACE combination needs to be considered.

4085-A | LIVER FUNCTION IS A PREDICTOR OF SURVIVAL IN PATIENTS WITH HEPATOCELLULAR CARCINOMA IN BEST SUPPORTIVE CARE

Claudia Campani[1], Laura Bucci[2], Valentina Adotti[3], Martina Rosi[3], Franco Trevisani[2], Fabio Marra[3] and Ita.Li.Ca., (1)University of Florence, Italy, (2)University of Bologna, (3)University of Florence

Background: The prognosis of patients with hepatocellular carcinoma (HCC) is very variable, and the relative contribution of tumor burden and liver dysfunction to survival is uncertain. Median overall survival (OS) of patients managed with best supportive care is around 3-6 months, although longer values may be observed in clinical practice. Aim of this study was to identify the factors linked to tumor or liver dysfunction associated with survival in patients with HCC treated with BSC. **Methods:** We retrospectively evaluated the clinical characteristics of 1414 patients who had an indication for BSC recorded in the Ita.Li.Ca. database between 2000 and 2020. We analyzed both patient and tumor characteristics to identify predictors of OS. **Results:** Median age was 69y and 76% of patients were male. Etiology included chronic viral infection (68.3%), alcohol use disorder (30.9%) and non-alcoholic steatohepatitis (8.3%). 67.4% of patients had a performance status 0-1 and 41.4% were in Child-Pugh B class. Median MELD was 13. 60% of patients had a multifocal HCC with a median number of 3 lesions and a median size of 33mm. 533 patients had vascular invasion. Median alpha-fetoprotein was 49.25 ng/ml. 111 patients were classified as BCLC-A, 148 as BCLC-B, 791 as BCLC-C and 325 as BCLC-D (12 unknown). No differences in terms of OS were observed considering the etiology of liver disease or the presence of cirrhosis. Obesity ($p < 0.001$), hypercholesterolemia ($p = 0.036$) and hypertriglyceridemia ($p = 0.034$) were associated with lower OS. Absence of symptoms (6 vs 10 months, $p < 0.001$), lack of vascular invasion (9.1 vs 5.03, $p < 0.001$), and absence of metastasis (8.167 vs 4.733 $p < 0.001$) were associated with a better OS. Survival in BCLC-A patients was longer than in stages B or C. Survival progressively declined according to severity of liver function using three different scores (CPS, ALBI, pALBI, $p < 001$). Women tended to survive longer 23 vs. 19 months, $p = 0.053$). Comparing patients surviving more or less than 12 months (398 vs. 1016), age, size of lesions, albumin, bilirubin, alpha-fetoprotein, and MELD were significantly different. At Cox univariate analysis presence of cirrhosis, number and size of lesions, vascular invasion, metastasis, ALBI and pALBI grades, MELD, and CPS were significantly associated with OS. Using different models to avoid colinearity ALBI, pALBI, and CPS maintained an independent prognostic role on OS. **Conclusion:** In a large series of patients with HCC in BSC, parameters of liver function are strongly associated with survival.

4086-A | LONG-TERM OUTCOMES OF RUPTURED HEPATOCELLULAR CARCINOMA

Kevin B. Harris, Faisal M. Nimri and Reena J. Salgia, Henry Ford Health

Background: It is estimated that spontaneous rupture of hepatocellular carcinoma (HCC) occurs in 2-5% of patients with HCC. Long-term outcomes in patients with ruptured HCC are not well described. Ruptured HCC requires a stepwise approach with control of bleeding followed by treatment for HCC. The spectrum of treatment options has expanded over the years for HCC. This study describes a single-center tertiary referral center experience with treating patients longitudinally with ruptured HCC. **Methods:** Between 2014 to 2022, our center experienced 7 cases of initial HCC presentation with a spontaneously ruptured hepatocellular carcinoma. **Results:** The average age of patients with ruptured HCC was 60 years old. Six of the patients (85.7%) were male and one patient (14.1%) was female. Six of the seven patients had underlying cirrhosis with 50% due to HCV, 33% due to alcohol and 16% due to a combination of HCV and alcohol. Three (42.9%) of the patients had Barcelona Clinic Liver Cancer (BCLC) stage B disease at presentation and four (57.1%) of the patients had BCLC stage C disease. None of the patients who presented with ruptured HCC were in an HCC screening protocol. Five (71.4%) of the patients had solitary hepatomas while two (28.6%) of the patients had multiple hepatomas at diagnosis. Both patients with multiple hepatomas had bilobar involvement. The median AFP level at presentation was 23.6 ng/mL (range 5.2 ng/mL to > 30000 ng/mL). Two (28.6%) of the patients at presentation were on aspirin and one (14.1%) was on a direct-acting oral anticoagulant (DOAC). Five of our patients were initially treated with bland embolization and two were initially treated with TACE. The patients received various subsequent treatments including bland embolization, TACE, TARE, SBRT and systemic therapies. None of our patients received surgical management or liver transplantation. The median overall survival from date of rupture was 817 days (range 381 d to 2796 d). **Conclusion:** Our series highlights the wide spectrum of outcomes for

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

patients with ruptured HCC. With improved treatment options, patient survival has increased. In this study, all patients survived at least one year and the longest survival was over 7 years. Noting the improved consideration by UNOS to patients with distant HCC rupture being considered for liver transplantation, continued attention to this group of patients can improve their outcomes.

4087-A | MONOCYTE TO HIGH-DENSITY LIPOPROTEIN CHOLESTEROL RATIO (MHR) AND ALBI GRADE FOR THE SURVIVAL PREDICTION OF PATIENTS WITH METABOLIC ASSOCIATED FATTY LIVER DISEASE (MAFLD) RELATED HCC

Tongguo Miao[1], Xianzhe Lou[2], Shiming Dong[1], Xiaoxiao Zhang[1], Xiwei Yuan[1], Lu Li[1], Weiwei Guan[1] and Yuemin Nan[1], (1)Third Hospital of Hebei Medical University & Hebei Key Laboratory of Mechanism of Liver Fibrosis in Chronic Liver Disease, (2)North China University of Science and Technology

Background: Metabolic syndrome is considered as a risk factor for Hepatocellular carcinoma (HCC). Metabolic-associated fatty liver disease (MAFLD) is proposed as a new terminology to replace NAFLD. There has been a dramatic increase in the number of patients associated with metabolic syndrome or metabolic dysfunction related HCC. Monocyte to high-density lipoprotein cholesterol (HDL-C) ratio (MHR) is a new prognostic measure associated with the body inflammatory and oxidative stress status. The ALBI grade offers a simple and reliable method of assessing liver function in HCC. Our hypothesis is that incorporating MHR and ALBI grade into one survival prediction model improves the survival prediction for patients with Metabolic Associated Fatty Liver Disease related HCC(MAFLD-HCC). **Methods:** This single center retrospective cross-sectional study primary cohort included 112 patients with MAFLD-HCC, and the internal validation cohort enrolled 37 patients with MAFLD-HCC. A multivariate Cox proportional hazard regression analysis was performed to identify the independent risk factors of survive, based on which the prediction nomogram models were constructed and validated. The concordance (C)-index, receiver operating characteristic (ROC) curve, and decision curve analysis (DCA) were used to assess the prognostic discriminative ability of the nomogram, ALBI grade, MHR, and MHR + ALBI grade. The overall survival (OS) curve of risk group stratification was calculated based on the nomogram risk score. **Results:** Multivariate analyses revealed that Extrahepatic metastases [hazard ratio with 95% confidence interval (CI) = 2.014(1.077-3.766), P = 0.028], Vascular invasion [2.075(1.068–4.03), P = 0.031], Barcelona staging B[2.369(1.091-5.144), P = 0.029], C[4.449(1.957-10.114), P < 0.001], D[26.473 (7.978-87.843), P < 0.001], elevated ALBI Class 3[11.687 (1.625-84.029), P = 0.015] , C-reactive protein (CRP) [1.018(1.006-1.03), P = 0.003], lactate dehydrogenase (LDH) [0.998(0.997-1.004), P = 0.003], and MHR[1.491 (1.24-1.791), P < 0.001] were independent risk factors for prognosis of MAFLD-HCC. BCLC stage, vascular invasion, extrahepatic metastases, LDH, CRP and MHR were selected to develop the nomogram. The C-index and calibration plots of the nomogram showed good discrimination and consistency for MAFLD-HCC. Additionally, compared with the other models, MHR + ALBI grade model [AUC = 0.885, 95%CI, (0.806-0.964)] showed better survival prediction ability in MAFLD-HCC. **Conclusion:** The novel survival prediction model showed better predicational outcomes of OS in patients with MAFLD-HCC. This model provides a personalized and convenient prognostic prediction tool for clinical applications.

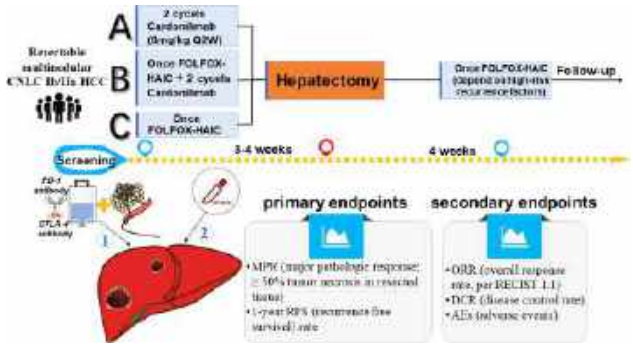
4088-A | NEOADJUVANT CADONILIMAB (PD-1/CTLA-4 BISPECIFIC ANTIBODY) PLUS TRANSHEPATIC ARTERIAL INFUSION CHEMOTHERAPY (HAIC) WITH FOLFOX FOR RESECTABLE MULTINODULAR CNLC Ib/IIa HEPATOCELLULAR CARCINOMA

Yonguang Wei, Zhiming Zeng, Guangzhi Zhu, Zili Lv and Tao Peng, The First Affiliated Hospital of Guangxi Medical University

Background: The recurrence rate of hepatocellular carcinoma (HCC) is high after surgery. However, there are no approved standard-of-care neoadjuvant or

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

adjuvant therapies. Multinodular HCC is a well-defined high-risk recurrence factor. Cadonilimab is a first-in-class bispecific, humanized IgG1 antibody (PD-1/CTLA-4). HAIC plus immunotherapy has synergistic antitumor effect. This trial is to evaluate the safety and efficacy of cadonilimab plus FOLFOX-HAIC as a neoadjuvant management for the resectable multinodular CNLC Ib/**a**a HCC. **Methods:** In this ongoing single-center, phase 2, open label, prospective cohort clinical trial (ChiCTR2200067161), eligible patients (pts) with resectable multinodular CNLC Ib/**a**a HCC were randomly assigned (1:1:1) to 3 arms and receive corresponding preoperative neoadjuvant therapy: (A) 2 cycles of cadonilimab (6mg/kg Q2W); (B) once FOLFOX-HAIC followed by 2 cycles of cadonilimab; (C) once FOLFOX-HAIC. All pts receive scheduled surgery on day 21-28 and postoperative adjuvant HAIC. The primary endpoints were major pathologic response (MPR rate defined as ≥50% tumor necrosis and 1-year recurrence free survival (RFS) rate. Main secondary endpoints included overall response rate (ORR, per RECIST 1.1), disease control rate (DCR), treatment-related adverse events (TRAEs). **Results:** From January 4 to May 23, 2023, 12 pts were enrolled. All pts were ECOG PS 0-1 and Child-Pugh A. Nine pts received scheming hepatectomy (4 pts in Arm A, 3 pts in Arm B, 2 pt in Arm C). Among them, all pts in Arm B achieved MPR, which all demonstrated focal heterogeneity with one lesion pathologic complete response and another partial response—0%, 10% and 70% respectively. No obvious tumor necrosis in Arm A and C, but the inflammatory infiltrating and fibrosis area in tumor accounted for 20-30% approximately. Based on RECIST 1.1 criterion, one (1/3) pts in Arm B achieved PR and other pts (9/10) met SD. DCR was 100%. The most common TEAEs in Arm B and C were ALT, AST and bilirubin increase (60.0%), which mainly resulted from HAIC. TEAEs occurred in Arm A were grade 1 bilirubin increase and triiodothyronine decrease (25%). No grade 3 or worse TEAEs occurred and no pts delayed surgery. The postoperative complications related to neoadjuvant therapy were not observed. **Conclusion:** This study preliminarily demonstrated that neoadjuvant cadonilimab plus FOLFOX-HAIC show promising antitumor activity with manageable safety for HCC. This trail is ongoing.



Disclosures: The following people have nothing to disclose: Yonguang Wei, Zhiming Zeng, Guangzhi Zhu, Zili Lv, Tao Peng

4089-A | NIVOLUMAB AS SECOND LINE THERAPY IMPROVES SURVIVAL IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA

Faisal M Sanai[1], Hassan Odah[1], Kanan Alshammari[2], Adnan Alzanbaqi[3], Morooj Alsubhi[1], Hani Tamim[4], Ashwaq Alolayan[2], Ahmed Alshehri[1] and Saleh A Alqahtani[5,6], (1)King Abdulaziz Medical City-Jeddah, (2) King Abdulaziz Medical City, King Abdullah International Medical Research Center, Ministry of National Guard Health Affairs, (3)King Abdallah Medical City-Makkah, (4)Alfaisal University, (5)Johns Hopkins University School of Medicine, (6)King Faisal Specialist Hospital and Research Center

Background: Limited data exists for nivolumab as a second-line treatment for hepatocellular carcinoma (HCC). We aimed to assess the efficacy and safety of nivolumab in patients with unresectable HCC who progressed during sorafenib treatment in a real-life cohort. **Methods:** In this retrospective, observational, multicenter study, adult Child-Pugh A/7B patients with HCC who tolerated sorafenib therapy but progressed were started on nivolumab (n = 38). A similar number of consecutive, unselected patients who were maintained on sorafenib therapy, regardless of tumoral response or progression, were used as historical controls (n = 42). Patients were assessed in terms of Eastern Cooperative Oncology Group (ECOG) performance status, macrovascular invasion, and extrahepatic disease to best supportive care plus oral sorafenib or intravenous nivolumab as second-line therapy. The primary endpoint was overall survival (defined as time from starting sorafenib in either group, up to death due to any cause) and analyzed by intention-to-treat. **Results:** The mean age of the overall cohort was 72.4 ± 10.1 years, of whom 87.5% were males, and 58.8% had underlying viral etiology. Patients in the two cohorts were similar except that those who received nivolumab as 2nd line therapy compared to sorafenib alone had more co-morbidities (70.0 vs 15.4%), more ECOG-2 status (21.4 vs 15.8%), and extravascular invasion (54.4 vs 21.8 %) ($P < 0.05$ for all). More patients in the nivolumab arm were Child-Pugh B (35.7 vs 21.1%), although this did not reach statistical significance ($P = 0.15$). Median survival was significantly higher in patients who received nivolumab compared to sorafenib alone (22.0 vs 11.0 mo, $P = 0.014$, Figure 1). Median survival after starting nivolumab as 2nd line therapy was 9.2 months,

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and time-to-tumor progression was 4.92 (IQR 3.2 – 6.3) months. **Conclusion:** Nivolumab is an effective second-line treatment option in unresectable HCC patients who progress on sorafenib, with significantly improved overall survival. These early real-life data offer encouraging results, and are similar to those shown in Phase 1/2a clinical trials, and data from larger, phase 3 clinical trials are awaited.

Hassan[6], Katherine A. McGlynn[7] and Lewis R. Roberts[8], (1)Mayo Clinic, Rochester, Rochester, MN, (2)Mayo Clinic Rochester, Rochester, MN, (3)Mayo Clinic, Rochester, Minneapolis, MN, (4) Cholangiocarcinoma Foundation, (5)Baylor College of Medicine, (6)The University of Texas MD Anderson Cancer Center, (7)National Cancer Institute, (8)Division of Gastroenterology and Hepatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Background: Cholangiocarcinoma (CCA), is a highly lethal cancer that is often diagnosed at an advanced stage and consequently has a poor prognosis. The 5-year survival rate of CCA ranges from 7% to 20% and has not changed much in the past 3 decades. Although the disease is relatively uncommon, rates in the United States and internationally are rising, highlighting the need for novel, more effective treatment options. To better understand the inherited risk for CCA we aim to conduct a genome-wide association study (GWAS) on CCA patients, their family members with or without CCA, and unaffected controls. The overall goal is to verify novel loci and genetic factors that influence susceptibility to CCA by genetically delineating etiologic heterogeneity, and clinical outcomes of CCA patients by using a high-density single nucleotide polymorphism (SNP) analysis of genomic DNA from CCA patients, and controls. In addition to recruiting patients and controls from collaborating institutions within the United States and internationally, we have explored the feasibility of recruiting study participants through the website of the major advocacy group the Cholangiocarcinoma Foundation (CCF) which has 60 thousand hits per month, or alternatively at the annual cholangiocarcinoma conference organized by the CCF, which is attended by a substantial number of patients, family members, and advocates. Here we compare our experience with recruitment through the website versus recruitment in person at the annual meeting. **Methods:** Demographic information and family history are obtained for both recruitment options alongside an electronically signed consent form which gives a more detailed explanation of the study. Persons recruited through the website must locate a local laboratory or hospital to obtain the blood draw and which is willing to ship the samples back to the Mayo Clinic for centralized storage, while for the recruitment at the annual conference, we were able to obtain the blood samples at the time of enrollment and ship them in bulk back to the Mayo Clinic. **Results:** From 2021 to date, our institution has interacted with 194 patients through the CCF website and 191 patients from the 2023 Annual CCF conference. Patients were from 9 countries, with the United States making up most of the participants. **Conclusion:** A pro for the website recruitment is the ability to reach a more diverse cohort of participants regardless of the demographic location while the onsite recruitment at the conference proved to more efficient at enrolling participants. Both approaches proved effective in generating interactions with patients.

4091-A | NOVEL SERUM BIOMARKERS OF DRUG SELECTION FOR SORAFENIB AND LENVATINIB AND THEIR APPLICATION TO PREDICTING THE EFFICACY OF ATEZOLIZUMAB PLUS BEVACIZUMAB IN HEPATOCELLULAR CARCINOMA

Satoshi Narahara, Takayuki Tokunaga, Kentaro Tanaka, Hiroki Inada, Etsuko Iio, Yoko Yoshimaru, Takehisa Watanabe, Katsuya Nagaoka, Hiroko Setoyama and Yasuhito Tanaka, Faculty of Life Sciences, Kumamoto University

Background: Atezolizumab plus bevacizumab (Atezo +Bev), lenvatinib (LEN), and sorafenib (SFN) are frequently used for systemic chemotherapy for advanced hepatocellular carcinoma (HCC). Qualified drug selection strategies are required to improve survival. The purpose of this study is to identify useful serum biomarkers for drug selection before initiation of SFN and LEN therapy and to apply them to predict Atezo+Bev efficacy. **Methods:** 326 patients (pts) who received SFN, 151 pts who received LEN, and 87 pts who received Atezo+Bev from Jun 2008 to Mar 2023 have been enrolled in this study. Treatment response was evaluated by modified RECIST 3 months after starting SFN, 1 month after starting LEN, or 6 weeks after starting Atezo+Bev, pts with progressive disease were classified into Non-Responder (NR), and the others into Responder (R). Proteome analysis was employed using 5 serum samples of SFN group and 3 serum samples of LEN group from pts in the R and NR groups before treatment, followed by confirmation using ELISA with 20 samples of LEN and SFN group as a derivation cohort. Next, serum from before and 3 weeks after Atezo+Bev treatment (R: n = 18, NR: n = 10) was then used to measure the proteins from the aforementioned study. **Results:** From the ELISA results, cutoff values for angiogenesis-related protein (AGRP) in the LEN group and cell adhesion-related protein (CARP) in the SFN group were established using ROC analysis. Evaluation based on CARP and AGRP values in 40 patients with SFN or LEN showed significantly prolonged progression-free survival in the patients used appropriately (HR = 1.193, P = 0.044). Validation in another 40 cases showed a trend toward a difference in AGRP in the LEN group (P = 0.081). In Atezo+Bev, low AGRP1 at 3 weeks after treatment initiation contributed to OS prolongation (P = 0.015), the occurrence of irAE (P = 0.045) and Grade 3 or higher AEs such as proteinuria (P = 0.031) significantly contributed to response, and high Alb (P = 0.054) and low ALBI score (P = 0.012) at 3 weeks after treatment initiation significantly prolonged PFS. **Conclusion:** We identified a novel biomarker for selecting appropriate drugs of SFN and LEN, as well as may be useful for predicting the therapeutic effect of Atezo+Bev. Further validation study in a large number of cases would be required as considering age-appropriate treatment strategies for elder HCC patients.

4092-A | NUCLEIC ACID VARIANT PROFILES IN MATCHING TUMORS, CIRRHOTIC ADJACENT TISSUE AND PLASMA FROM HCC PATIENTS USING RNASEQ AND DNASEQ ANALYSIS

Sheikh Aejaz Sayeed[1], Daniel Zezulinski[1], Timothy M. Block[1], Coppola Gianfilippo[2], Ryan Hlady[3], Chen Liu[2] and Lewis R. Roberts[4], (1)Baruch S. Blumberg Institute, (2)Yale University, New Haven, CT, (3)Mayo Clinic Rochester, Rochester, MN, (4)Division of Gastroenterology and Hepatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Background: Genetic mutations can change how proteins function. Some mutations trigger changes in healthy cells to develop cancer. Compared to germline mutations present throughout the genome of an individual, somatic mutations develop in a particular tissue and could be detected in both DNA and RNA of that altered tissue. Among SNP and splicing variants, the latter are known to occur more frequently in RNA of normal and tumor tissues. It is becoming increasingly clear that unique RNA profiles and mutations in RNA within individual cancers may play a major role in defining both the biology of the cancer and its response to therapy. We decided to explore genome and transcriptome wide variants in hepatocellular carcinoma (HCC). **Methods:** Five clinically diagnosed early-stage HCC subjects were investigated for RNA and DNA variants. Matching specimens from each subject included the tumor, adjacent liver cirrhotic tissue (ALCT) and plasma. Total RNA and DNA was extracted from tumor tissue and ALCT, while only total RNA was extracted from plasma. Extracted DNA and RNA samples were QCd and sequenced. The resulting FASTQ

files were mapped to the hg38 human genome, using BWA for DNA and STAR for RNA to be processed using a GATK4 variant calling pipeline. The resulting variants were annotated by snpEff. Only variants found in regions shared between RNA and DNA were retained for analysis. **Results:** We report more variants in tumor tissue than in ALCT, up to 1.75 times from DNA, and up to 4.5 times from RNA. In comparing DNA with RNA, we identify up to 4 times more variants in DNA than RNA in ALCT and up to ~7 times in tumor tissue, while the DNA mean depth (per sample) is, on average, half of the RNA mean depth. In plasma RNA we identify systematically less variants than in RNA, from either tumor or ALCT. SNPs represent the predominant variant types in all samples, more so in the DNA call set than in RNA. Specifically, we find ~40 times more SNPs than INDELs in DNA and ~1.5 times in RNA. While there are ~4 times more SNPs called in DNA than in RNA, we also find ~4 times more INDELs called in RNA than in DNA. Focusing on variant impact, as annotated by snpEff, we find up to ~3 times (DNA) and up to 4.5 times (RNA) more high impact variants in tumor tissue than ALCT. Within the high impact set, we find similar proportions of variants with an effect on splicing. We find up to ~200 times more splicing related variants in RNA than in DNA from the same tissue. Interestingly, plasma RNA variants range from 20 to 75% of the tissue RNA variants. **Conclusion:** In summary, our investigations in matching specimens of HCC subjects show a higher number of variants in both DNA and RNA samples from tumors compared to ALCT samples and, importantly, shows that calling variants from RNA in tissue and plasma, may provide a potentially deeper insight in splicing perturbation events than DNA from WGS, thus revealing interesting variant profiles which could shed light on circulating biomarkers of detection of HCC in high-risk patients.

4093-A | OSTEOPENIC OCCULT VERTEBRAL FRACTURE IS ASSOCIATED WITH POOR ONCOLOGICAL OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA AFTER HEPATIC RESECTION

Koichiro Haruki[1], Kenei Furukawa[1], Munetoshi Akaoka[1], Tomohiko Taniai[1], Masashi Tsunematsu[2], Mitsuru Yanagaki[1], Shinji Onda[2], Yoshihiro Shirai[2], Michinori Matsumoto[2] and Toru Ikegami[1], (1)The Jikei University School of Medicine, (2)The Jikei University School of Medicone

Background: Although osteopenia has been associated with poor outcomes in patients with hepatocellular carcinoma (HCC), the oncological impact of occult vertebral fracture (OVF) has not been investigated. This study aimed to evaluate the significance of OVF in patients with HCC. **Methods:** The study comprised 235 patients who had undergone primary hepatic resection for hepatocellular carcinoma between 2008 and 2019. Osteopenia was evaluated with computed tomographic measurement of pixel density in the midvertebral core of the 11th thoracic vertebra. The height of central/anterior/posterior vertebrae was measured using sagittal computed tomography reconstruction between 11th thoracic vertebra to 5th lumber vertebrae. OVF was defined if the ratios of central/ anterior or central/posterior heights of the vertebrae < 0.8. Multivariate Cox proportional hazard models were conducted to assess disease-free and overall survival adjusting for potential confounders. **Results:** OVF was identified in 93 patients (40%), while osteopenia in 65 patients (28%). Osteopenic OVF was identified in 27 patients (12%). In multivariate analysis, gender ($p = 0.001$), serum PIVKA-II level ≥ 200 mAU/ml ($p < 0.001$), multiple tumors ($p < 0.001$), type of resection ($p < 0.001$), sarcopenia ($p = 0.005$), and osteopenic OVF (HR 3.06, 95% CI 1.79-5.22, $p < 0.001$) were independent and significant predictors of cancer recurrence, while gender ($p = 0.035$), HBsAg positivity ($p = 0.041$), Child-Pugh grade B ($p = 0.008$), poor tumor differentiation ($p = 0.041$), multiple tumors ($p = 0.002$), microvascular invasion ($p = 0.026$), sarcopenia ($p < 0.001$), and osteopenic OVF (HR 2.75, 95% CI 1.62-4.66, $p < 0.001$) were independent predictors of overall survival. **Conclusion:** Occult OVF is associated with poor oncological outcome in patients with hepatocellular carcinoma after hepatic resection. Our findings provide compelling rationale for the further investigation of interplay between tumor and bone metabolism.

Background: The concept of osteosarcopenia, which is concomitant osteopenia and sarcopenia, has been proposed as a prognostic indicator for cancer patients. However, the prognostic significance of osteopenia, sarcopenia, and osteosarcopenia in patients with intrahepatic cholangiocarcinoma (IHCC) has not been fully investigated. The aim of this study was to evaluate the prognostic significance of osteosarcopenia in patients with IHCC. **Methods:** The subjects of this retrospective study were 41 patients who underwent hepatic resection for IHCC. Osteopenia was assessed with pixel density in the mid-vertebral core of the 11th thoracic vertebra and sarcopenia was assessed by the psoas muscle areas at the third lumbar vertebra. Osteosarcopenia was defined as the concomitant occurrence of osteopenia and sarcopenia. We analyzed the association of osteosarcopenia with disease-free and overall survival and evaluated clinicopathologic variables in relation to the osteosarcopenia. **Results:** Eighteen (44%) of the 41 patients had osteosarcopenia. The patients with osteosarcopenia revealed lower body mass index ($p = 0.03$), lower bone mineral density ($p < 0.01$), lower psoas muscle mass area ($p < 0.01$), while there was no significant difference in other clicopathological variables such as tumor marker, systemic inflammatory markers. Multivariate analysis identified osteosarcopenia (hazard ratio 3.38, 95% confidence interval: 1.49–7.68, $p < 0.01$) as an independent predictor of disease-free survival, and age $\geq$ 65 years ($p = 0.03$) and osteosarcopenia (hazard ratio 6.46, 95% confidence interval: 1.76–23.71, $p < 0.01$) as independent predictors of overall survival. **Conclusion:** Preoperative osteosarcopenia may be a predictor of poor prognosis in patients undergoing hepatic resection for IHCC, suggesting that preoperative management to maintain muscle and bone intensity could improve the prognosis.

4095-A | OUTCOMES OF UNIFOCAL HCC: A COMPARISON OF SURVIVAL IN T1 VS T2 HCC

Suraj Pai[1], Shengchen Hao[1], Amit G. Singal[2] and Neehar Dilip Parikh[1], (1)University of Michigan, (2) University of Texas Southwestern Medical Center

Background: Although patients with T1 (< 2 cm) hepatocellular carcinoma (HCC) can be accurately diagnosed based on radiographic criteria, management of these patients remains controversial given exception points for liver transplantation (LT) are reserved for patient with T2 (³ 2 cm) tumors. Therefore, many centers choose a wait-and-ablate approach, whereby patients are observed and treated when the lesion exceeds 2 cm in maximum diameter. The clinical impact of this strategy on HCC outcomes is unknown. **Methods:** We conducted a single center retrospective study of adult patients newly diagnosed with unifocal HCC, based on LIRADS v2018, measuring between 1.0 and 3.0 cm at diagnosis between 2018 and 2023. We excluded those patients with a non-HCC liver malignancy. The primary outcome was transplant-free survival, stratified by tumor size (1-1.9 cm vs 2-3 cm). Survival analysis was completed using Kaplan-Meier, and the two groups were compared using multivariable Cox proportional hazard models. **Results:** Of 159 patients, 103 within the 1-1.9 cm category and 56 within 2-3 cm category. Patients had a median age of 65 years, 83% were Caucasian, and 70% were male. The primary etiologies of liver disease were hepatitis C virus (HCV) (28%), non-alcoholic fatty liver disease (NAFLD) (27%), and alcohol-related cirrhosis (23%). The median Child-Turcotte-Pugh (CTP) score was 6 (IQR: 5-7) and median AFP was 5 (IQR: 3-14). Nine patients (8.7%) in the 1-2 cm group and 7 (12.5%) in 2-3 cm group underwent LT, with a median time to transplant of 12.8 months. Median transplant-free survival was 49.1 (IQR: 34.8-72.7) months for the 1-1.9 cm cohort vs. 37.0 (IQR: 16.1-55.6) months for the 2-3 cm cohort ($p = 0.06$) (Figure). In multivariable analysis, decreased survival was significantly associated with age (HR 1.05 [95% CI: 1.02 – 1.09], CTP score (HR 1.91 [95% CI: 1.51 – 2.41], AFP level (HR: 1.004 95% CI: 1.002-1.006) and 2-3 cm tumor size (vs 1-1.9 cm) (HR 2.16 [95% CI: 1.20 – 3.87]. **Conclusion:** Patients with T1 HCC have superior outcomes compared to patients with T2 (2-3 cm) HCC suggesting that the widely used policy of wait-and-ablate may result in inferior patient outcomes. Current policies that give transplant priority for > 2 cm HCCs are justified, however biopsy proven T1 lesions could also be considered for transplant exception points and immediately treated, given the risks associated with larger tumor sizes.

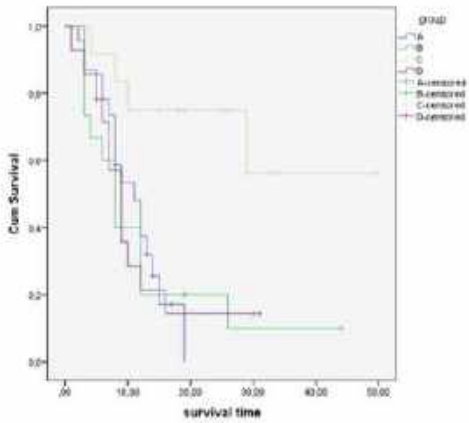
4096-A | PATTERN OF PROGRESSION TO BCLC-C STAGE SIGNIFICANTLY AFFECTS OBJECTIVE RESPONSE AND OVERALL SURVIVAL RATES IN ATEZO-BEV TREATED PATIENTS WITH ADVANCED HCC AND UNFAVORABLE OBJECTIVE TUMOR CHARACTERISTICS

Spyridon Pantzios, Antonia Syriha, Dionysia Mandilara, Orestis Sidiropoulos, Ioanna Stathopoulou, Georgia Barla, Nikolaos Ptohis, Petros Galanis and Ioannis S. Elefsiniotis, National and Kapodistrian University of Athens

Background: IMBRAVE150 study mainly included HCC patients in the BCLC-C stage with well compensated liver disease, irrespective of the type of progression to this stage. The aim of our study was to retrospectively evaluate, under real life conditions, the on-treatment survival of patients with advanced HCC (BCLC-C stage), either initially presenting in the advanced stage (iBCLC-C) or migrating from BCLC-A to BCLC-C stage (mBCLC-C) within 2 years after curative LR or RFA, treated either with atezolizumab-bevacizumab (ATZ/BEV) combination or with TKIs sequentially (sorafenib as 1st line and cabozantinib as 2nd line treatment). **Methods:** Sixty four cirrhotic patients with advanced HCC (56 males, mean age 67 years, 22 with diabetes, CPT-A = 45/B = 19, mean MELD-Na = 11, ALBI grade I = 20/grade II = 38, 28 with varices, 18 with extrahepatic disease, 24 with macrovascular invasion) who either initially presented in the BCLC-C stage and were treated with ATZ/BEV (group A, N = 23) or TKIs (group B, N = 15) or who migrated from BCLC-A to BCLC-C within 2 years after LR or RFA and were treated with ATZ/BEV (group C, N = 12) or TKIs (group D, N = 14) were evaluated. **Results:** The four groups were comparable for all the baseline parameters evaluated (age p = 0.9, gender p = 0.08, platelets p = 0.246, chronic liver disease etiology p = 0.408, coexistence of diabetes p = 0.314, presence of varices p = 0.066, CPT stage p = 0.067, ALBI grade p = 0.398) except for CPT score (p = 0.012) and MELD-Na score (p = 0.002). Objective response rates (both CR and PR) were frequently observed in group C (5/12, 41.66%) compared to group A (1/23), B (0/15) and D (1/14). Moreover, the on-treatment survival of group C patients seems to be significantly higher compared to those of group D (9m) patients (p = 0.007) as well as for group A and B. Using cox regression analysis, we observed that the ATZ/BEV on-treatment survival of group A (HR = 3.71, p = 0.02) was significantly worse than that of group C, adjusted for CPT, ALBI and MELD-Na (figure). We repeated the analysis, including only patients with MVI and/or EHD (excluding 18 patients stratified in BCLC-C due to poor PS only) and found that the survival benefit of group C patients seems to be preserved even in the most difficult-to-treat BCLC-C patients. **Conclusion:** ATZ/BEV therapy seems to benefit mainly BCLC-C patients who migrate from earlier stages after curative LR or RFA compared to patients initially presented in the advanced stage, irrespective of liver disease severity and these patients exhibit better disease response rates. These results seem to be preserved even in patients with objective tumor characteristics that reflect worst prognosis. Median survival of ATZ/BEV or TKI patients who were initially classified in BCLC-C stage was less than 12 months, irrespective of treatment schedule, as was post-recurrence survival of sequentially TKI-treated patients. Liver disease severity seems to drive the overall as well as post-recurrence survival.

Figure: Survival of group A (blue), B (green), C (yellow) and D (purple) and cox regression analysis for survival after the beginning of systemic therapy comparing group C to the other groups and adjusted for CPT, ALBI and MELD/Na scores.



Variables	Hazard ratio	95% confidence interval	P-value
Child number	1,03	0,69 to 1,52	0,89
Meld-Na	1,13	0,98 to 1,31	0,09
ALBI	0,86	0,47 to 1,57	0,62
A vs. C	**3,71**	**1,20 to 11,46**	**0,02**
B vs. C	2,89	0,87 to 9,56	0,08
D vs. C	3,14	0,95 to 10,35	0,06

4097-A | PERFORMANCE OF A MULTI-CANCER EARLY DETECTION (MCED) TEST FOR DETECTION OF HEPATOCELLULAR CARCINOMA (HCC) IN PATIENTS WITH CIRRHOSIS

Darine Daher[1], Purva Gopal[1], Todd Morgan[1], Marie V. Coignet[2], Vivian Xiao[2], Kathryn N. Kurtzman[2] and Amit G. Singal[1], (1)University of Texas Southwestern Medical Center, (2)Grail, LLC

Background: More than 80% of HCC cases develop in the setting of cirrhosis, informing the at-risk cohort for surveillance. Most HCCs are found beyond an early stage, highlighting a need for novel surveillance strategies. Increasing data also show heterogeneity in tumor biology and treatment response, highlighting a need for treatment response biomarkers. In this pilot study, we explored the potential of an MCED test to detect HCC in patients with cirrhosis and its association with treatment response. **Methods:** In this case-control study, biobanked plasma was processed from patients aged > 18 years with cirrhosis, without (controls) and with (cases) treatment-naive HCC. Cases and controls were matched on liver disease etiology, Child Pugh score, and Barcelona Clinic Liver Cancer (BCLC) stage. The MCED test employs a targeted methylation assay of circulating cell-free DNA with a machine learning algorithm to detect a shared cancer signal and predict cancer signal origin (CSO) across cancer types, and it was validated in the Circulating Cell-free Genome Atlas study, wherein high sensitivity for HCC was observed. Test performance for HCC detection was assessed blinded to case-control status. Test performance by treatment response was performed as an exploratory analysis. **Results:** There were no significant differences in clinical characteristics (median age, 63 years; male, 60%) between cases (n = 27) and controls (n = 17). Patients were diverse regarding race/ethnicity (36% non-Hispanic White, 36% Hispanic, 27% Black) and cirrhosis etiology (50% hepatitis C virus, 25% non-alcoholic steatohepatitis, 20% alcohol). 66% and 34% of patients had Child Pugh A and B cirrhosis, respectively. HCC cases were diverse in terms of BCLC stage (41% stage 0/A, 59% stage B), with 41% of cases being within Milan Criteria. MCED test sensitivity and specificity was 78% and 100%, respectively. CSO prediction accuracy was 100%; all cases with a cancer signal detected had a CSO prediction of liver/bile duct. All cases underwent transarterial chemoembolization (TACE) as initial HCC treatment. The MCED test detected a cancer signal in 67% of cases with an objective response to TACE and 87% of those with progressive disease (p = 0.24). **Conclusion:** Early findings in a small population indicate the MCED test's performance shows potential for early HCC detection and association with treatment response. Further research is needed to assess the full value of the test among patients at high risk for and with HCC.

National University Sejong Hospital, (2)Chungnam National University Hospital, (3)Department of Preventive Medicine, Chungnam National University College of Medicine, (4)Dreamcis Inc., (5)Department of Internal Medicine, Chungnam National University Hospital

Background: It has been reported that the discordance between preoperative radiologic and postoperative pathological findings adversely affects the survival rate in patients who underwent liver transplantation. However, there is no studies about impact of the discordance in patients who have undergone surgical resection. Therefore, we investigated the impact of these discrepancies on the prognosis in patients with hepatocellular carcinoma (HCC) who underwent resection. **Methods:** This study included patients who were diagnosed with HCC on magnetic resonance imaging and underwent surgical resection within 1 month of diagnosis from 2008 to 2016. A total of 1832 patients from the Korean Primary Liver Cancer Registry (KLCR) and 185 patients from Chungnam national university hospital (Daejeon, South Korea) were included in the nationwide cohorts and validation cohorts, respectively. For five factors, such as maximum tumor diameter, tumor number, vascular invasion, bile duct invasion, lymph node metastasis, the effects on the patient's survival according to the degree of discrepancies between magnetic resonance imaging and pathologic findings were analyzed using the Kaplan-Meier method. Furthermore, Cox proportion hazards regression analysis was used to evaluate the effect of the degree of discordance on survival rates independently. **Results:** When all five factors were concordant between radiologic and pathologic findings, the 1-year, 3-year, and 5-year survival rates were 96.5%, 87.0%, and 80.7%, respectively. However, in the case of three discrepancies, the 1-year, 3-year, and 5-year survival rates were 52.4%, 28.6%, and 28.6%, respectively. According to more discrepancies in five factors were, the survival rate was significantly lower ($p < 0.001$). Multivariate cox regression analysis showed that the discrepancy more than two factors between radiologic and pathologic findings (hazard ratio [HR], 4.726; 95% confidence interval [CI], 2.096-10.655), age (HR, 1.026; 95% CI, 1.013-1.040), diabetes mellitus (HR, 1.367; 95% CI, 1.065-1.755), platelet count (HR, 0.998; 95% CI, 0.997-1.000), serum albumin (HR, 0.712; 95% CI 0.559-0.905), maximum tumor diameter (HR, 1.125; 95% CI, 1.087-1.165), tumor number more than three (HR, 1.118; 95% CI, 1.405-3.773), vascular invasion (HR, 1.742; 95% CI, 1.170-2.595), lymph node metastasis (HR, 5.443; 95% CI, 2.669-11.099) were the independent significant predictors of the overall survival. **Conclusion:** Discordance between the preoperative radiologic findings and the postoperative pathological findings were significantly associated with survival rate in patients with HCC. Further studies on factors that can predict discrepancies and efforts to reduce discrepancies are needed.

Background: Hepatocellular carcinoma (HCC) is the fourth most common cause of cancer death globally. Many HCC patients are diagnosed at advanced stages with poor long-term survival. Sorafenib, a multi-kinase inhibitor is currently used in the second-line, providing a survival advantage over best supportive care. Most patients do not respond to sorafenib or progress on this therapy. Therefore, the validation of predictors of response that aid in the treatment selection for HCC remains of critical importance. We aimed to assess the association of FGF3, FGF4, and FGF19 amplification with response to sorafenib and survival after sorafenib initiation in patients with HCC, and also assessed the impact of FGF locus amplification on overall survival of patients not treated with sorafenib. **Methods:** 260 patients who received curative surgical treatment by resection or liver transplantation for HCC or who had liver biopsies performed for intermediate or advanced liver disease and had available formalin fixed paraffin embedded tissue were included in the analysis. All had mRNA sequencing and targeted mutational and copy number analysis performed on the Tempus platform. Statistical analysis was performed to assess the impact of FGF locus amplification on patient response and outcomes. **Results:** Of the 260 patients, 18 (6.9%) had amplification at the FGF locus, while 242 did not. Of the 18 with FGF locus amplification, 4 (22.2%) received sorafenib. All 4 initially had complete radiologic and biomarker responses to sorafenib. The median survival after initiation of sorafenib was significantly longer in the patients with FGF locus amplifications than in those without FGF amplifications (median survival 4.74 vs. 0.83 y; $p = 0.04$). Of the 242 patients who did not receive sorafenib, there was no difference in overall survival of patients with FGF locus amplifications vs. those without FGF amplification (median OS from the time of HCC diagnosis 4.19 vs. 10.06 y; $p = 0.33$). **Conclusion:** There is a significant association of FGF locus amplification with response to sorafenib, resulting in improved survival after initiation of sorafenib treatment compared to patients without FGF locus amplification. In contrast, FGF locus amplification by itself is not associated with improved survival of HCC patients in the absence of sorafenib treatment. Genomic testing at the FGF3-FGF4-FGF19 locus can be used as a predictor of response to sorafenib therapy and survival.

4100-A | PREDICTING EARLY HEPATIC DECOMPENSATION AND DEATH IN HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS: THE HCC-AIM SCORE

Michael Li[1], Kate Kelley[1], Neil Mehta[1], Francis Yao[1], Lawrence Fong[1] and Jennifer C. Lai[2], (1)University of California, San Francisco, (2)University of California-San Francisco

Background: Major immune checkpoint inhibitor (ICI) clinical trials in hepatocellular carcinoma (HCC) have been limited to Child-Pugh (CP) class A patients. Patients with more advanced liver disease and tumor burden are at increased risk of hepatic decompensation and death, though predictors of early adverse outcomes in ICI-treated patients are unknown. **Methods:** We conducted a single-center retrospective cohort study of all ICI-treated HCC patients from 2016 onwards. Hepatic decompensation was defined as development of ascites, encephalopathy, and/or variceal bleeding. The primary outcomes were early decompensation and early death (both within 90 d of ICI initiation). **Results:** In the 212 study patients, the median MELD was 10 and 62% were CP class A. Early decompensation occurred in 54 (25%) patients; ascites, encephalopathy, and variceal bleeding occurred in 59%, 44%, and 15% of these patients, respectively. Early death occurred in 47 (22%) patients. Patients with early decompensation were more likely to experience early death (59.3% vs 9.5%, RR 6.2, 95% CI 3.7-10.6, $p < 0.001$) and had shorter survival (median 80 vs 468 d, log-rank $p < 0.001$) than those without early decompensation. Furthermore, no patients with early decompensation experienced radiographic treatment response. The novel HCC-AIM (Adverse outcomes in IMmunotherapy) score was derived using LASSO regression. The four pre-treatment variables selected (CP class, # of liver tumors, AFP level, and sodium level) were assigned points based on their coefficients (Figure A). HCC-AIM had excellent discrimination (c-statistic 0.85, 95% CI 0.79-0.90) for early decompensation, with an optimism-corrected c-statistic of 0.81 on internal validation (10-fold cross-validation). HCC-AIM also performed well when predicting early death (c-statistic 0.82, 95% CI 0.76-0.88). An HCC-AIM cutoff of ≥ 10 had high specificity (91% and 86%) and high NPV (86% and 85%) for early decompensation and early death, respectively, and was associated with shorter time to death (Figure B). Only three out of 45 patients with a score ≥ 10 experienced radiographic treatment response. **Conclusion:** Early hepatic decompensation after ICI therapy for HCC is common and is strongly associated with early death. The novel HCC-AIM score predicted both early decompensation and early death and can be applied using pre-treatment data to identify high-risk patients in whom ICI treatment may be futile due to advanced liver disease and tumor burden.

Background: Single-cell transcriptomic profiling (scRNAseq) has allowed the characterization of tumor immune cell infiltration and how it relates to immunotherapy (IO) response in advanced HCC (aHCC). Here, we aimed to 1) derive gene expression signatures that recapitulate distinct single-cell derived immune cell types that can be applied to bulk RNAseq data and 2) evaluate their potential as predictive biomarkers of response to atezolizumab + bevacizumab (atezo+bev), current standard of care in aHCC. **Methods:** Using scRNAseq data from 31 aHCC biopsies, we defined gene signatures for 35 cell phenotypes using a customized bio-informatics pipeline based on differential gene expression analysis. The power of single-cell derived signatures to capture the presence of specific intra-tumoral cell types and predict IO response in bulk transcriptomic data was evaluated in 3 cohorts comprising 401 pre-treatment aHCC samples: 1) 65 atezo +bev-treated aHCCs (Training), 2) 253 patients treated with atezo+bev in the context of the IMBrave150 and GO30140 clinical trials (Validation; Zhu et al. 2022), and 3) 83 anti-PD1-treated aHCCs (Validation 2; Haber et al. 2023). We performed single-sample Gene Set Enrichment Analysis (ssGSEA) and Nearest Template Prediction (NTP) analysis. ssGSEA-derived scores and class prediction results were correlated with objective response to therapy and progression-free survival (PFS). Overall 30% responded to atezo+bev. **Results:** We successfully generated gene signatures for 21 out of 35 single-cell derived cell types in aHCC. Three signatures were consistently enriched in atezo+bev responders compared to non-responders, representing CD8 effector cells (CD8 Temra, CD8 Tex) and pro-inflammatory CXCL10+ macrophages. Tumors enriched with these immune-related signatures (immune responders; 15% of total) were significantly enriched in previously reported gene signatures of IO response, and displayed the highest transcriptomic similarity with anti-PD1 responders (FDR < 0.01). We identified two mechanisms associated with response: immune versus anti-angiogenic response. When evaluated by class prediction analysis (NTP), the 3 signatures defining immune HCC responders had an $> 83\%$ specificity to identify response and were associated with a significantly longer PFS when treated with atezo+bev ($p < 0.05$), but not with sorafenib. In contrast, atezo+bev responders lacking these immune-related subsets displayed a significantly higher expression of VEGFA and metabolism-related genes (anti-angiogenic responders; 15-20% of total). **Conclusion:** The combined intra-tumoural presence of CD8 effector cells and CXCL10+ macrophages prior to treatment is associated with improved survival in atezo+bev treated patients, demonstrating predictive value as biomarkers of response to atezo+bev. In a subset of patients, response to this combination may be predominantly driven by anti-angiogenic mechanisms.

4102-A | PREDICTING THE POTENTIAL OF ELIMINATING VIRUS-RELATED HEPATOCELLULAR CARCINOMA IN TAIWAN BY DEEP MACHINE LEARNING

Sih-Han Liao[1], Kuo-Liong Chien[2], Chi-Ling Chen[3], Chen-Yang Hsu[2], Chien-Hung Chen[4], Hsiu-Hsi Chen[2] and Jia-Horng Kao[5], (1)National Taiwan University Cancer Center, (2)College of Public Health, National Taiwan University, (3)National Taiwan University College of Medicine, (4)College of Medicine, National Taiwan University, (5)National Taiwan University Hospital

Background: To reduce the incidence of hepatocellular carcinoma (HCC), three change points of interventions have been implemented in Taiwan, including hepatitis B vaccination from 1984, universal health care from 1995, and antiviral therapy from 2004. The primary aim of this study was to predict when and how the elimination of virus-related HCC could be achieved by adding large-scale antiviral therapy to the causal chains of interventions with deep machine learning method. **Methods:** The digital twin design was envisaged to produce the virtual group after learning parameters that governed the direct and indirect causal chains of three change-point interventions, including the gradual expansion of antiviral therapy when making allowance for the heterogeneity of demographic and geographic variations. Bayesian causal graphic model was adopted to estimate when and how eliminating virus-related HCC with the incidence less than 4 per 100,000 could be achieved with large-scale antiviral therapy. **Results:** Based on the incidence predicted by the virtual group after learning the long-term time trend of HCC incidence pertaining to three-change points of direct and indirect causal chains, the elimination of virus-related HCC in Taiwan would be achieved by the end of 2045 when a further 16,812 virus-related HCC incident cases could be averted after treating 267,820 and 57,976 chronic hepatitis B and C patients with large-scale antiviral therapy, respectively. **Conclusion:** We demonstrate how to use the digital twin design with Bayesian causal graphic model to achieve the elimination of virus-related HCC when adding large-scale antiviral therapy to the existing three change-point interventions for HCC.

4103-A | PREDICTION OF HEPATOCELLULAR CARCINOMA AND BENEFIT OF ANTIVIRAL THERAPY IN CHB PATIENTS WITH SINGLE-NUCLEOTIDE VARIANTS OF PRE-S/S REGION

Wei Teng[1,2], Ting-Tsung Chang[3], Chien-Wei Su[4,5], Yuh-Jin Liang[2,6,7] and Jaw-Ching Wu[5,6,8], (1)Chang Gung Memorial Hospital, Linkou Medical Center, (2)Institute of Clinical Medicine, National Yang Ming Chiao Tung University, (3)National Cheng Kung University Hospital, (4)Taipei Veterans General Hospital, Taipei, Taiwan, (5) National Yang Ming Chiao Tung University, (6) Translational Research Division, Medical Research Department, Taipei Veterans General Hospital, (7) Taipei Veterans General Hospital, (8)Cancer Progression Research Center, National Yang Ming Chiao Tung University

Background: There were several hepatocellular carcinoma (HCC)-associated hepatitis B virus (HBV) single-nucleotide variants (SNVs) reported in a horizontal case-control study. This study investigated the predictive value of SNVs in Pre-S/S region in HCC development and evaluated the role of antiviral therapy in these patients in a longitudinal case-control study, especially in patients of grey zone (ALT < 80 U/L or HBV DNA < 2000 IU/ml) of current treatment guidelines. **Methods:** A total of 459 chronic hepatitis B (CHB) patients were retrospectively analyzed for SNVs associated with HCC occurrence during follow up at Taipei Veterans General Hospital and National Cheng Kung University Hospital from 1994-2014. Point mutations including six SNVs in genotype B HBV as well as 21 HCC-associated SNVs in genotypes C HBV according to a previous horizontal study were detected in baseline serum samples of these CHB patients and the results of SNVs were correlated with the outcomes of HCC and the benefit of antiviral therapy in reducing HCC during follow-up period. **Results:** Among the 459 enrolled patients, 297 (64.7%) were infected by genotype B and the remaining 162 (35.3%) patients were infected by genotype C. HCC occurred in 67 patients (14.6%) in a median follow-up period of 11.6 years. The most common point-mutations included G530A (90.9%) and T724C (97.5%) in S region among genotype B while A2889G to C3097A (up to 93.4%) in Pre-S1 region among genotype C HBV-infected patients. In multivariate analysis, age (hazard ratio [HR] = 1.063, $p < 0.001$ & HR = 1.093, $p < 0.001$) and family history of HCC (HR = 5.741, $p < 0.001$ & HR = 1.398, $p = 0.046$) were associated with HCC development while antiviral therapy (HR = 0.168, $p < 0.001$ & HR = 0.027, $p < 0.001$) was protective factor in genotype B and C HBV-infected patients respectively. Importantly, T53C SNV (HR = 2.719, $p = 0.026$; HR = 2.789, $p = 0.031$) and Pre-S/S deletion (HR = 2.885, $p = 0.017$; HR = 1.165, $p = 0.043$) were statistically significant associated with HCC development both in genotype B and C HBV-infected patients. Patients with antiviral therapy had lower HCC incidence compared to those without in patients with T53C SNV and pre-S/S deletion (both log-rank $p < 0.001$). **Conclusion:** Some SNVs in Pre-S/S region are associated with HCC and antiviral therapy could decrease HCC development in these patients.

Takami[2], (1)Yamaguchi University Graduate School of Medicine, (2)Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan

Background: The combination therapy of atezolizumab plus bevacizumab (atezo/bev) for treating unresectable hepatocellular carcinoma (HCC) was introduced in 2020. Despite the high objective response (OR) rate in the IMbrave150 trial, some patients had progressive disease (PD) at the initial imaging evaluation (early PD). Appropriate sequential treatment is important, and this study aimed to identify early indicators of OR and early PD to atezo/bev therapy focused on tumor marker trends. **Methods:** This retrospective study included 154 patients who had received atezo/bev at our hospital and affiliated institutions by December 2022 and aimed to evaluate predictors of treatment efficacy of atezo/bev for unresectable HCC. We examined predictors of treatment response separately in the high-alpha-feto-protein (AFP) (baseline AFP $\geq$ 20 ng/mL; n = 83) and the low-AFP (baseline AFP < 20 ng/mL; n = 71) groups. **Results:** The median patient age was 75 years, and 124 (77.4%) males were included in our study. Our cohort was characterized by mALBI grade 1/2a/2b/3: 46/38/68/2, BCLC A/B/C: 11/79/64, and a median AFP and des-gamma-carboxy prothrombin (DCP) of 31.1 ng/mL and 382.4 m AU/mL, respectively. In the high-AFP group, a decrease in AFP levels > 30% was an independent predictor of OR (odds ratio, 5.517; $p = 0.003$). In the low-AFP group, baseline DCP level < 40 mAU/mL was an independent predictor of objective response (odds ratio, 3.978; $p = 0.021$). The independent predictors of early PD were an increase in AFP level $\geq$ 30% at 3 weeks (odds ratio, 4.077; $p = 0.026$) and the presence of extrahepatic spread (odds ratio, 3.682; $p = 0.034$) in the high-AFP group and up-to-seven criteria, OUT, (odds ratio, 15.756; $p = 0.026$) in the low-AFP group.In the high-AFP group, median PFS was significantly longer with a decrease in AFP level > 30% (NE vs. 6.1 mo, $p = 0.015$).In the low-AFP group, median PFS was significantly longer in patients with baseline DCP level < 40 mAU/mL than in those with baseline DCP level $\geq$ 40 mAU/mL (not reached vs. 7.7 mo; $p = 0.001$) **Conclusion:** In atezo/bev therapy for unresectable HCC, the change in AFP levels at 3 weeks in patients with baseline AFP level $\geq$ 20 ng/mL and baseline DCP level or tumor burden in patients with AFP level < 20 ng/mL were found to predict treatment response. Thus, it appears reasonable to focus on tumor markers for early prediction of treatment response.

Disclosures: The following people have nothing to disclose: Norikazu Tanabe, Issei Saeki, Maho Egusa, Natsuko Nishiyama, Tsuyoshi Fujioka, Daiki Kawamoto, Ryo Sasaki, Tatsuro Nishimura, Toshihiko Matsumoto, Tsuyoshi Ishikawa, Takahiro Yamasaki, Taro Takami

4105-A | PREDICTORS OF HEPATIC DECOMPENSATION AFTER Yttrium90 TRANSARTERIAL RADIOEMBOLIZATION

Amelia Wong, University of Hawaii, Shirley Cheng, John a. Burns School of Medicine, Anthony Herrera, The Queen's Medical Center and Linda L. Wong, Department of Surgery, University of Hawaii, Honolulu, HI, USA.

Background: Yttrium 90 transarterial radioembolization (TARE) is an effective therapy for unresectable hepatocellular carcinoma (HCC) or to bridge/down-stage before transplant. Eligibility is generally limited to those with adequate renal function and bilirubin < 2-3 however, there is limited literature on optimal patient selection for TARE. This study aims to identify factors that increase readmission or liver decompensation after TARE. **Methods:** A retrospective review was conducted on patients with HCC between 2021 and 2022 who underwent Y90 TARE as their first treatment. Data collected: demographics, MELD and Childs score, tumor characteristics, treatment/readmission dates and associated complications within 60 days were extracted. Hepatic decompensation was defined as total bilirubin > 3 and any increase in MELD score resulting in readmission or death. Wilcoxon, Pearson's Chi-squared, and Fischer's tests were used to identify statistical significance. Logistic regression models were to predict the odds of decompensation in significant variables. **Results:** Of 138 patients identified, 7 (5.1%) developed hepatic decompensation requiring admission or death within 30 days and 15 (10.9%) within 60 days. Two patients (13.3%) required urgent transplant within 2 months due to decompensation. Pre-procedure albumin < 3.5 ($p = 0.0207$), INR > 1.2 ($p = 0.017$), ascites ($p = 0.036$), and elevated MELD ($p = 0.012$) and Childs ($p = 0.007$) scores are significant predictors of decompensation within 60 days while creatinine and sodium were not. Patients with Childs B score were 3-4 times more likely to have hepatic decompensation (28% vs 7.7%). For every unit increase in Child's score over 5.5, the odds of severe decompensation increased by a factor of 2.15. There were no tumor characteristics associated with increased risk of decompensation and no risk factors associated with mortality. **Conclusion:** Y90 TARE is a safe and effective treatment modality however 5% of patients have worsened liver function after treatment. As patients require reasonable renal function to receive IV contrast and ascites appears to be a significant factor in predicting decompensation, evaluating for Child's score A may be more useful in selecting candidates for TARE. Further risk stratification may be required for those with Child's score greater than 7.

4106-A | PREDICTORS OF POST-TRANSPLANT RECURRENCE OF HEPATOCELLULAR CARCINOMA BASED ON EXPLANT ANALYSIS: A MULTICENTER STUDY

Suraj Pai[1], Muhammad Hashim Hayat[2], Joseph Sushil Rao[3], Erin Bouquet[2], Ioannis Ziogas[2], Anthony Borgmann[2], Hassan Anbari[1], Christopher Slaughter[4], Oyedele A. Adeyi[3], Sophoclis Alexopoulos[5], Neehar Dilip Parikh[1], Varvara A. Kirchner[6] and Manhal Izzy[2], (1) University of Michigan, (2)Vanderbilt University Medical Center, (3)University of Minnesota, (4)Vanderbilt University, (5)Keck Medical Center of USC, Sacramento, CA, (6)Stanford University, Stanford, CA

Background: Liver transplantation (LT) is the curative treatment for patients with early unresectable hepatocellular carcinoma (HCC). While waitlisted for transplant, patients with HCC undergo locoregional therapy (LRT) to control tumor burden, limit drop out from waitlist, and mitigate the risk of post-LT recurrence. In this multicenter study, we aimed to identify risk factors that can predict post-LT recurrence of HCC. **Methods:** We performed a retrospective chart review of adult patients who underwent LT for HCC between 2014-2018 at three tertiary North American centers. Demographic data, clinical data, and pathology data (at the lesion level) were collected. The outcome of interest was post-LT recurrence. **Results:** We included 296 patients (270 without recurrence, 26 with recurrence) with a median age of 62 years (IQR 57-65y); 81% were male, 85% were white, 7% were African-American, and 7% were Asian. Common etiologies of liver disease were hepatitis C virus (51%), non-alcoholic steatohepatitis (35%), and hepatitis B virus (22%). Modalities of LRT included transarterial chemoembolization (178 patients), thermal ablation (30 patients), transarterial radioembolization (17 patients), and multimodal therapy (69 patients). On explant, median lesion size was 2.6cm (IQR 1.9-3.7cm) and 3.2cm (IQR 2.4-4.5cm) in the non-recurrence and recurrence groups respectively; 27% of patients had well-differentiated tumor, while 63% and 9% had moderate and poor/undifferentiated tumor, respectively. Amongst all patients, 220 (81%) had viable tumor(s) on explant, with a mean viability per subject (defined as the average of all lesions' viability on that subject) of 10%. Univariable analysis demonstrated an association between recurrence and larger lesion size (OR 1.27 [95% CI: 1.03-1.56], p = 0.02) (Table). Lesion viability on explant did not influence the risk of recurrence. Multivariable analysis confirmed that maximal tumor size independently associated with recurrence (OR 1.27 [95% CI: 1.01-1.57], p = 0.03) even after controlling for tumor differentiation. **Conclusion:** Lesion size on explant pathology is associated with higher risk of recurrence in patients who underwent LT for HCC. Neither tumor differentiation nor degree of viability predicted HCC recurrence post-LT in this study. These findings warrant validation with prospective studies.

f 4107-A | PREOPERATIVE AND POSTOPERATIVE VARIABLES FOR PREDICTING EXTRAHEPATIC METASTASIS OF HEPATOCELLULAR CARCINOMA AFTER CURATIVE SURGICAL RESECTION

Chang Hun Lee[1], Jae Hyun Yoon[2], Hoon Gil Jo[3], Eun Young Cho[3], Chung Hwan Jun[4] and In Hee Kim[1], (1) Jeonbuk National University Medical School and Research Institute of Clinical Medicine of Jeonbuk National University Hospital-Jeonbuk National University Medical School, (2)Chonnam National University Hospital, (3)Wonkwang University College of Medicine and Hospital, (4)Mokpo Hankook Hospital

Background: Factors associated with extrahepatic metastasis (EHM) after curative treatment of hepatocellular carcinoma (HCC) have rarely been investigated. This study aimed to assess EHM occurrence after curative resection in HCC patients. **Methods:** A retrospective review was conducted on treatment-naïve HCC patients who underwent curative resection between 2004 and 2019 at four tertiary hospitals. Recurrence characteristics after resection were evaluated, and predictors associated with EHM in HCC patients after curative resection were analyzed. **Results:** A total of 1,069 HCC patients treated with surgical resection were enrolled for the study. The mean age was 59.1 ± 10.2 years, with 85.8% of patients being male. The majority of patients (98.6%) had compensated liver cirrhosis, with chronic hepatitis B being the most common etiology of chronic liver disease (73.7%). During the follow-up period, there were 165 (19.6%) cases of EHM. Patients with EHM were younger and had a higher proportion of advanced modified UICC and BCLC stages, as well as a higher proportion beyond Milan criteria. Histologically, patients with EHM had larger tumor size and number, advanced Edmondson-Steiner (ES) grade, and a higher proportion of microvascular invasion, bile duct invasion, intrahepatic metastasis, and necrosis. Multivariate Cox regression analysis revealed that ln(Age), modified UICC stage, beyond Milan criteria, and ALBI grade ≥ 2 were independently significant factors associated with EHM in preoperative variables. Similarly, ln(Age), microvascular invasion, necrosis, beyond Milan criteria, and ALBI grade ≥ 2 were independently significant factors associated with EHM in postoperative variables. Kaplan-Meier plots clearly differentiated EHM-free survival among low, intermediate, and high-risk groups stratified by the EHM-preop and EHM-postop models. **Conclusion:** This study analyzed preoperative and postoperative variables to predict EHM following curative surgical resection, resulting in the development of statistical models (EHM-preop and EHM-postop). These models have the potential to aid in clinical decision-making, but further validation studies are necessary.

4108-A | PREVALENCE AND IMPACT OF PORTAL VEIN THROMBOSIS IN PATIENT WITH BILIARY MALIGNANCIES

Ayobami Olafimihan[1], Chidiebele Omaliko[2], Chun-Wei Pan[3], Sania Saleem[3], Chukwunonso Ezeani[4], Ifeoluwa Stowe[4], Oghenefejiro Ogwor[5], Praise Fawehinmi[6] and Rotimi Asemota[1], (1)John H Stroger Jr. Hospital of Cook County, (2)One Brooklyn Health - Brookdale University Hospital Medical Center, (3)John H. Stroger Jr. Hospital of Cook County, (4)Baton Rouge General Medical Center, Baton Rouge, LA, (5)St Peter University Hospital, New Brunswick, NJ, (6)University of Ilorin

Background: Portal vein thrombosis (PVT) is associated with gastrointestinal malignancies such as hepatocellular, biliary, pancreatic, and colonic cancers. PVT has been shown to portend a poor prognosis in some patients; however, uncertainty exists about the impact of PVT on patients admitted with biliary malignancies (gallbladder cancer and cholangiocarcinomas). **Methods:** Retrospective cohort analyses were performed using the National Inpatient Sample (NIS) data collected between 2016 and 2020. Multivariable logistic and linear regression models were used to examine the prevalence of PVT and its impact on biliary cancer (BC) patients. **Results:** There were a total of 82,850 inpatient admissions for BC, and the overall prevalence of PVT was 14%. Black race, male gender, younger age, teaching hospital, urban hospital, and large hospital were associated with higher PVT prevalence rates. Patients admitted for BC with PVT had increased all-cause mortality of 29% compared to those without PVT (odd ratio: 1.29, 95% confidence interval (CI) 1.12-1.50, p = 0.001), however, multivariate analysis revealed similar inpatient mortality outcomes between both cohort (adjusted odds ratio (AOR): 1.14, 95% CI 0.97-1.34, p = 0.112). BC patients with PVT had shorter mean LOS (6.4 vs. 6.6 d, p = 0.004), and lower mean total hospital charges by over $10,000 ($73, 278 vs $85,444, p < 0.001) when compared to their counterparts without PVT. BC patients with PVT had reduced

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

odds of sepsis (AOR: 0.75, 95%CI: 0.59-0.96%) and bile duct obstructions (AOR: 0.53, 95%CI: 0.46-0.61, $P < 0.001$), and were more likely to receive inpatient palliative team care (AOR:1.33, 1.19-1.47, $P < 0.001$). They were also less likely to undergo interventional procedures like common bile duct drainage (AOR: 0.3, 95% CI: 0.9-0.94, P: 0.041) and hepatobiliary duct device insertion (AOR: 0.45, 95% CI: $P < 0.001$) **Conclusion:** Hospitalized biliary cancer patients with PVT have similar adjusted odds of inpatient mortality, but lower LOS and healthcare utilization than biliary cancer patients without PVT.

Disclosures: The following people have nothing to disclose: Ayobami Olafimihan, Chidiebele Omaliko, Chun-Wei Pan, Sania Saleem, Chukwunonso Ezeani, Ifeoluwa Stowe, Oghenefejiro Ogwor, Praise Fawehinmi, Rotimi Asemota

4109-A | PROGNOSIS-ORIENTED DEFINITION OF BORDERLINE RESECTABLE HEPATOCELLULAR CARCINOMA

Koichiro Haruki[1], Norifumi Harimoto[2], Kenei Furukawa[1], Tomohiko Taniai[1], Munetoshi Akaoka[1], Mitsuru Yanagaki[1], Shinji Onda[3], Yoshihiro Shirai[3], Ken Shirabe[2] and Toru Ikegami[1], (1)The Jikei University School of Medicine, (2)Gunma University, (3)The Jikei University School of Medicone

Background: With the advances in multidisciplinary treatment of hepatocellular carcinoma (HCC), the definition of borderline resectable (BR) is warranted. We aimed to define BR-HCC using a prognosis-oriented approach. **Methods:** The study comprised a training cohort of 221 patients and an independent validation cohort of 181 patients who had undergone primary hepatic resection for HCC. To define the oncological borderline resectable (BR)-HCC, we investigated the risk factors for the early unresectable recurrence (beyond Milan criteria) within one year after hepatic resection using multivariate logistic regression models. We then developed BR score using identified risk factors and defined BR-HCC. The utility of the BR score was validated in the independent validation cohorts. **Results:** In the training cohort, the recurrence beyond Milan criteria within one year was observed in 28 patients (13%), and 5-year survival of those patients was 25%. Multivariate analysis identified the risk factors for the recurrence beyond Milan criteria within one year, including serum AFP level ≥ 12 ng/mL ($p = 0.02$), tumor diameter > 5 cm ($p = 0.02$), number of tumors ≥ 3 ($p = 0.001$), and macrovascular invasion ($p = 0.04$). BR-HCC was defined as tumors with more than two identified risk factors and 42 patients (19%) were recognized as BR-HCC with 5-year survival rate of 51%. In the validation cohort, BR-HCC was observed in 45 patients (25%) with 5-year survival rate of 42%. **Conclusion:** Prognosis-oriented definition of BR-HCC enable us to identify the patients who can develop early unresectable recurrence and have poor survival after hepatic resection for HCC. For BR-HCC, preoperative chemotherapy may be an option to improve the outcome after hepatic resection.

4110-A | PROGNOSTIC IMPACT OF THE PROGRESSION OF LUNG METASTASIS AFTER THE FIRST CYCLE OF ATEZOLIZUMAB PLUS BEVACIZUMAB IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Jiwon Yang, Jonggi Choi, Won-Mook Choi, Kang Mo Kim, Han Chu Lee and Ju Hyun Shim, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Atezolizumab plus bevacizumab (Atezo/Bev) has been established as a standard first-line systemic treatment for advanced hepatocellular carcinoma (HCC). We aimed to investigate overall and organ-specific responses and their impact on survival in a specific group of patients with HCC and pulmonary metastases receiving Atezo/Bev. **Methods:** This study included 73 consecutive HCC patients with at least one measurable lung metastasis and preserved liver function who received at least three 3-weekly cycles of Atezo/Bev at the Asan Medical Center, South Korea between 2018 and 2023. Responses assessment was based on RECIST v1.1: all metastatic lung lesions in present study were measurable. We defined “responders” as patients who achieved complete remission (CR) or partial remission (PR); and “progressors” as those with progressive disease (PD) at an initial evaluation after 3 cycles of treatment. The Kaplan-Meier method and Cox proportional model were used for overall survival (OS) analyses. **Results:** Of the 73 patients, 46 (63.0%) had a single lung metastasis with/without intrahepatic lesions, and 55 (70.3%) and 25 (34.2%) were accompanied by intrahepatic HCC and vascular invasion of the tumors, respectively. The OS rate at 1-, 3-, 5-years were 78.2%, 59.9%, and 49.9%, respectively in the entire cohort with a median follow-up of 10.6 months. Of entire patients, 8 (11.0%) achieved overall response (0 CR and 8 PR), with 27 (37.0%) lung-specific responders (4 CR and 12 PR). Overall and lung-specific progressors were 20 (27.4%) and 25

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(34.2%), respectively. Overall and pulmonary progressors had significantly lower survival rates than the counterparts (59.9% vs. 83.3% and 47.0% vs. 89.9% at 1 y; Ps < 0.05), as was neither overall nor pulmonary responders. The lung-specific progressor and presence of macrovascular invasion were independent factors affecting survival, irrespective of other intra- and extrahepatic status of the tumors. **Conclusion:** Based on our data, pulmonary response to Atezo/Bev could help clinicians decide whether to continue the drug or switch to second-lines at an early phase of the initial therapy for HCCs with metastasis to the lung.

4111-A | PROGNOSTIC NUTRITIONAL INDEX AS A PROGNOSTIC FACTOR FOR VERY EARLY STAGE HEPATOCELLULAR CARCINOMA

Chun-Ting HO[1,2], Chien-Wei Su[1,2], Elise Chia-Hui Tan[3], Wei-Yu Kao[4], Yi-Hsiang Huang[5,6], Teh-Ia Huo[1,2], Ming-Chih Hou[5,7] and Jaw-Ching Wu[1], (1)National Yang Ming Chiao Tung University, (2)Taipei Veterans General Hospital, (3)China Medical University, (4)Taipei Medical University Hospital, (5)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, (6)Faculty of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan, (7)Department of Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

Background: Field factors play more important roles in predicting the outcomes of patients compared with tumor factors in early-stage hepatocellular carcinoma (HCC). However, the prognostic ability of modern non-invasive serum marker scores for hepatic fibrosis and liver functional reserve on very early-stage HCC is still not yet determined. We aimed to investigate the performance of these serum marker scores in predicting the prognoses of patients with very early-stage HCC. **Methods:** A total of 450 patients with the Barcelona Clinic Liver Cancer (BCLC) classification stage 0 HCC diagnosed at Taipei Veterans General Hospital from 2012 to 2022 were retrospectively enrolled. Serum biomarkers and prognostic scores determining poor overall survival (OS) were analyzed by Cox proportional hazards model and logistic regression. We compared the homogeneity, and Akaike information criterion (AIC) among the prognostic nutritional index (PNI), AST to Platelet Ratio Index (APRI), albumin-bilirubin (ALBI) score, EZ (easy)-ALBI score, fibrosis (FIB)-4 score and lymphocyte-to-monocyte ratio (LMR) to determine the predictability on the OS of patients. **Results:** After a median follow-up of 35.0 months (interquartile range IQR 19.0-60.0 mo), 81 patients died, with a 5-year OS rate of 76.9%. Among the non-invasive serum marker scores, PNI had the best performance in predicting the OS of patients with the highest homogeneity and lowest AIC compared to other scores. Moreover, we stratified the patients into high-risk (PNI < 45) and low-risk (PNI > = 45) groups. It showed that the 5-year OS rates were 83.3% and 63.1% in the low-risk and high-risk PNI groups, respectively (p < 0.001). **Conclusion:** PNI had the best performance in predicting the OS for patients with very early-stage HCC.

Prognostic performance of serum markers in predicting the overall survival of 450 patients with very early stage hepatocellular carcinoma

	Homogeneity	AIC	P value
PNI	26.037	848.845	<0.001
APRI	4.590	857.308	0.031
EZ-ALBI	16.480	858.888	<0.001
ALBI	15.711	859.557	<0.001
FIB-4	11.308	866.428	0.001
LMR	5.335	867.650	0.077

4112-A | PROGNOSTIC SCORING SYSTEMS FOR LOCOREGIONAL THERAPY TO PREDICT ONE YEAR SURVIVAL IN HEPATOCELLULAR CARCINOMA: A SYSTEMATIC REVIEW

Esmeralda Vilchez[1], Christo Mathew[1], Frederick Peng[1], Nanfu Deng[2], Niharika Mallepally[3], Hyunseok Kim[4], Hashem B. El-Serag[1] and Ruben Hernaez[5], (1)Baylor College of Medicine, (2)UT Health, (3)Division of Gastrointestinal and Liver Diseases, Keck School of Medicine, University of Southern California, (4)Cedars-Sinai Medical Center, Los Angeles, CA, (5)BCM

Background: Locoregional therapies (LRT) are effective in halting hepatocellular carcinoma (HCC) growth. The outcome LRT is variable. However, rigorous evaluations and comparisons of prognostic models for predicting HCC survival after LRT are lacking. We systematically reviewed the performance and methodological quality of prognostic models assessing survival at one-year LRTs in HCC treatment using parameters readily available in the clinical setting **Methods:** We searched EMBASE and PUBMED from inception to 12/9/22. Inclusion criteria

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

focused on studies that provided data on developing or validating prognostic models using clinical variables. The primary outcome measure was the area under the receiver operating characteristics curve (AUROC) to predict one-year survival after treatment. Two investigators independently conducted data abstraction. Methodological quality was assessed using scoring systems adapted from the Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis (TRIPOD) statement and the Steyerberg system. We defined an acceptable quality study when the methods reported adequate variable selection, validation techniques, performance, calibration, and discrimination, being acceptable quality when they had ≥ 5 for TRIPOD or ≥ 7 for Steyerberg. To further emphasize the quality of the scoring systems, external validation (EV) was also considered. **Results:** Out of 1,267, 47 studies met our inclusion and exclusion criteria (Table). These studies examined primary transarterial chemoembolization (TACE), re-TACE, transarterial radioembolization (TARE) with Yttrium (Y) 90, primary radiofrequency ablation (RFA), microwave ablation (MWA), TACE or RFA, TACE or local ablation, percutaneous alcohol/ethanol injection (PAI/PEI), or resection, and combination of the prior LRT. AUROC for 1-year survival: primary TACE (AUROC, 0.57-0.89), re-TACE (0.66-0.82), Y90 TARE (0.76), initial RFA (0.69-0.79), MWA (0.73), TACE or RFA (0.89), TACE or local ablation (0.66), TACE, PAI, PEI, or resection (0.80), mixed LRT (0.69-0.81). The top performers in each category were: ALBI/PALBI score for primary TACE (0.84). For the rest of the categories: mART for re-TACE (0.82), SNAP-HCC for Y90 TARE (0.76, not EV), nomogram based on CONUT for initial RFA (0.80), nomogram for 1st guided microwave ablation (0.64, not EV), risk prediction model for TACE or RFA (0.89, not EV), modified MELD-based JIS for TACE, PAI, PEI, or resection (0.80), and nomogram for mixed LRT (0.78). **Conclusion:** Several high-quality clinical scoring systems are available prognosticate one-year survival in patients with undergoing LRT using readily available parameters. These models can assist clinicians and patients in making informed decisions regarding choosing LRT for HCC treatment.

4113-A | PROGNOSTIC VALUE OF EXPRESSION OF PD-1 AND CTLA-4 IN PERIPHERAL BLOOD IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Hyuk Soo Eun[1,2], Tae Hee Lee[3], Jeongdong Lee[3], Min Seok Kim[3], Woo Sun Rou[4], Hong Jae Jeon[5], Seok Hyun Kim[6], Byung Seok Lee[6], Hei-Gwon Choi[7], Ha Neul Kim[7], Tae Min Jang[8], Ji Ah Lee[8], Chae Yeon Son[8] and Jiyoon Bu[8], (1)Chungnam National University Hospital, (2)Chungnam National University, College of Medicine, (3)Daegu Health College, (4)Chungnam National University Sejong Hospital, (5)Department of Internal Medicine, Chungnam National University Sejong Hospital, (6)Department of Internal Medicine, Chungnam National University Hospital, (7)Chungnam National University, (8)Inha University

Background: Hepatocellular carcinoma (HCC) is the second most prevalent cause of cancer-related death worldwide. The poor prognosis of HCC is attributed to the lack of a biomarker that can effectively predict patients' responses to various treatments. In this study, we investigated the potential of programmed death 1 (PD-1) and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) gene expressions in peripheral blood mononuclear cells (PBMCs) as prognostic biomarkers for HCC. **Methods:** This study was approved by an institutional review board of Chungnam national University Hospital, Daejeon, Korea (CNUH- 2020-10-08). The buffy coat was excepted from EL buffer for erythrocytes lysis, and was treated with 20 µl proteinase, and mixed with 200 µl lysis buffer. The samples were incubated at 57 ˚C for 15 min, then, were reacted with 200 µl of ethanol. PD-1 and CTLA-4 DNA expressions were obtained by comparing the gene expression with the reference gene, *RPP30* ($2^{-\Delta Ct}$). $\Delta Ct = Ct$ (PD-1 or CTLA-4) – Ct (RPP30). **Results:** Neither CTLA-4 nor PD-1 gene expression in PBMCs was associated with the patients' tumor size, multifocality, and modified UICC stages. Specifically, the AUROC values for determining HCC patients with tumor sizes larger than the average, multifocal tumors, and high modified UICC tumor stages (>2) were all less than 0.720 ($p > 0.05$). Nevertheless, both genes were strongly associated with patients' outcomes. A Kaplan-Meier survival analysis revealed that patients with low CTLA-4 gene expressions ($\leq$ median) exhibited a 1.51-fold ($p = 0.022$) longer mean

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

overall survival (OS) than those with high CTLA-4 gene expressions. Moreover, PD-1 gene expressions demonstrated an even higher predictive value in estimating HCC patients' survival. None of the patients with low PD-1 gene expressions ($\leq$ median) died during this study, while patients with high PD-1 expressions showed a poor OS of 36.0 $\pm$ 9.0 months ($p < 0.001$). Interestingly, these biomarkers outperformed α-fetoprotein (AFP), which is the most frequently used biomarker in clinical trials. Patients with lower-than-the-median serum AFP scores had only a 1.17-fold longer OS than those with low serum AFP levels. Similarly, we examined the correlation between patients' progression-free survival (PFS) and the expression of each biomarker. Indeed, PD-1 gene expression was the only biomarker that showed a significant difference between patients with low and high biomarker expressions (3.06-fold longer PFS for patients with low PD-1 gene expressions; $p = 0.012$). **Conclusion:** In this study, we have demonstrated that the genes associated with immune checkpoint genes can be utilized as a prognostic biomarker for HCC. Notably, PD-1 gene expression in PBMCs has a great potential for estimating survival outcomes of patients with HCC.

4114-A | RADIOTHERAPY COMBINED WITH ATEZOLIZUMAB PLUS BEVACIZUMAB FOR HEPATOCELLULAR CARCINOMA WITH PORTAL VEIN TUMOR THROMBUS

Yunjeong Lee and Jin-Wook Kim, Seoul National University Bundang Hospital

Background: Based on the IMbrave150 trial, the combination of atezolizumab and bevacizumab is used as first-line standard of care for advanced hepatocellular carcinoma. However, the efficacy of the combination regimen has been unsatisfactory in HCC patients with portal vein tumor thrombosis (PVTT). The use of concomitant external beam radiation therapy may increase local tumor control rate, but it is not established whether addition of radiotherapy increases the tumor response rate in HCC patients on atezolizumab and bevacizumab combination. Here, we assessed the efficacy of the additional radiotherapy to the combination of atezolizumab/bevacizumab compared to the combination regimen alone. **Methods:** This retrospective study included 133 patients with the combination of atezolizumab and bevacizumab with or without concomitant radiotherapy from June 2003 to February 2023. The presence of portal vein thrombosis was defined as the intraluminal filling defect in portal venous system on computed tomography. The modified response evaluation criteria in solid tumors (RECIST) on CT/MRI images was used to assess treatment responses of each therapy. We carried out Kaplan-Meier and Cox regression analysis to estimate progression-free survival (PFS) and investigate the influence of concurrent radiotherapy on change in tumor burden. **Results:** A total of 56 patients received of atezolizumab and bevacizumab for HCC with portal vein invasion. Among the cohort, radiotherapy was added to 21 patients. Kaplan–Meier analysis estimated that the 6-month PFS rate of the total cohort was 70.6%. The concomitant radiation therapy was not shown to significantly improve PFS (HR = 0.40, 95% CI = 0.10 – 1.65; $p = 0.45$; Figure). **Conclusion:** Addition of external beam radiation did not significantly increase local tumor response rate in HCC patients with portal vein invasion. Further prospective studies would be warranted to validate our findings.

Internal Medicine, Dongnam Institute of Radiologic & Medical Sciences, (5)School of Medicine, Kyungpook National University, (6)Keimyung University School of Medicine, (7)College of Medicine, Kyungpook National University

Background: A recent phase 3 trial led to the approval of atezolizumab plus bevacizumab as first-line treatment for advanced hepatocellular carcinoma (HCC). However, real-world data regarding the response to this regimen are lacking in high-risk patients with advanced HCC. **Methods:** In this multicenter retrospective cohort study, 215 patients with advanced HCC who received atezolizumab plus bevacizumab treatment at four different tertiary hospitals were examined. High-risk patients had grade Vp4 portal vein thrombus, bile duct invasion, or more than 50% liver infiltration. **Results:** Among the 215 patients, 98 (45.6%) were in the high-risk population, 186 (86.5%) had Child-Pugh class A, 29 (13.5%) had Child-Pugh class B, and 128 (59.5%) had previously received neoadjuvant or concomitant radiation treatment. Analysis of the total population indicated that the median PFS was 8.00 months (95% CI, 6.82-9.18) and median OS was 11.25 months (95% CI, 9.50-13.10). In the high-risk population, the median progression free survival (PFS) was 6.50 months (95% CI, 3.93–9.08), and the median overall survival (OS) was 10 months (95% CI, 8.19–11.82). In the high-risk population, multivariate analysis indicated that receipt of neoadjuvant or concomitant radiation therapy was associated with better PFS and OS; median OS; 12.00 months (9.33-14.67) vs. 5.75 (3.24-8.26) and median PFS; 9.25 months (7.66-10.84) vs. 3.25 (2.27-4.23) in radiation and without radiation therapy, respectively. Ninety-two patients (42.8%) experienced adverse events of any grade; the most common adverse event was proteinuria (14.8%). **Conclusion:** Atezolizumab plus bevacizumab treatment showed consistent efficacy and tolerability in the total population and in the high-risk population. Previous radiation therapy increased PFS and OS in the high-risk group.

4116-A | RISK FACTORS AND NATURAL HISTORY OF HEPATOCELLULAR CARCINOMA (HCC): OBSERVATIONS FOLLOWING SUCCESSFUL SOFOSBUVIR-BASED TREATMENT IN HCV PATIENTS WITH CIRRHOSIS

K Rajender Rajender Reddy[1], Therese Bittermann[1], Nour Khaddaj-Mallat[2], Ingrid Zhou[2], Janine Zhu[2], Ryan Ea[2], Catherine Frenette[3], Stacey Scherbakovsky[3], Renee-Claude Mercier[3], Xu Zhang[3], Ben L. Da[3], Anu O. Osinusi[3], Andrew Joseph Muir[4], Ira M. Jacobson[5] and Alessandra Mangia[6], (1)University of Pennsylvania, (2) University of California at San Francisco, (3)Gilead Sciences, Inc., (4)Duke University, (5)NYU Grossman School of Medicine, (6)Liver Unit, Fondazione Irccs "Casa Sollievo Della Sofferenza", San Giovanni Rotondo, Italy

Background: Hepatitis C virus (HCV) infection is a major risk factor for hepatocellular carcinoma (HCC), including even patients who have achieved sustained virologic response (SVR). There is a need to identify predictors of HCC development after SVR to improve the efficiency of HCC screening. Data were analyzed to determine risk factors of HCC and characterize the natural history of HCC development in patients who have achieved SVR with sofosbuvir-based direct-acting antiviral therapy (DAA). **Methods:** Data were collected prospectively from a Gilead-sponsored registry (#NCT02292706) which enrolled and followed those with HCV cirrhosis who had achieved SVR with a sofosbuvir-based DAA regimen for up to 5 years. The primary outcomes were HCC, death in those who developed or never developed HCC. The risk factors of these outcomes were evaluated. Baseline characteristics at time of entry into the registry included demographics, HCV genotype, prior HCV treatment experience, hemoglobin A_1C, liver chemistries, Child-Pugh-Turcotte (CPT) score, enhanced liver fibrosis (ELF) score (F0-F2 $<$ 9.8, F3 = 9.8-11.3 and F4 $>$ 11.3) and liver stiffness (LS) by transient elastography (TE) (F0–2: $<$ 9.5 kPa; F3: 9.6–12.5 kPa; and F4: $>$ 12.5 kPa). Univariate and multivariate analyses were performed to determine risk factors for development of HCC and death by Cox regression analysis. A Kaplan-Meier plot was utilized to analyze time to HCC diagnosis. **Results:** Out of 1557 individual's in the registry, 132 developed de novo HCC. Baseline characteristics of those with HCC are as follows: mean age 61 years, 74% males, 90% white, mean (SD) body mass index (BMI) 28.9 (4.83), mean (SD) platelet count 118 (59.9) x10^3/μL, median (Q1, Q3) MELD score 8 (7, 10), median (SD) ELF score 10.7 (9.9, 11.6), median (Q1, Q3) FIB4 score 3.9 (2.3,

6.0), mean (SD) AFP level 75 (774.6), median (Q1, Q3) LS 20.4 kPa (12.6, 34.3) and CPT score of 5 (67%), 6 (15%), 7 (9%), 8 (2%), 9 (1%). 52% of patients who developed de novo HCC were diagnosed greater than 2 years after the start of the registry and only 12% developed de novo HCC within the first 6 months. Baseline albumin level < 3.5 g/dL ($p = 0.002$), LS by TE F4 ($p = 0.010$), platelets < 150 X10^3/uL ($p = 0.005$) and pre-treatment BMI ($p = 0.044$) were associated with de novo HCC (Table). Twenty patients (15.2%) with HCC died during the registry. Of those, patients with compensated liver disease at baseline (CPT A) had an 82% reduction in risk of death compared to those with decompensated liver disease (CPT B+C). **Conclusion:** Low albumin level, low platelet count, and F4 on LS are predictive of an increased risk of de novo HCC development in patients with cirrhosis who achieved SVR post DAA. These patients require close monitoring for several years following SVR. Mortality in those with HCC development was often in those with more advanced liver disease.

Table. Factors Associated with de-novo HCC and Deaths

Univariate Analysis Cox Regression Model			
De-novo HCC (n=132)			
Variable	Comparison	Hazard Ratio (95% Confidence Interval)	P-value
Age	> 65 vs < 65 years	0.959 (0.621; 1.482)	0.8507
Sex	Male vs female	1.388 (0.943; 2.043)	0.0963
Race	Black vs White	0.406 (0.166; 0.993)	0.0482
Pretreatment BMI	> 30 vs < 30kg/m^2	0.917 (0.640; 1.314)	0.6362
CPT	CPT A vs CPT B+C	0.461 (0.269; 0.791)	0.0049
HCV genotype	G3 vs Any Other	0.999 (0.665; 1.502)	0.9966
Prior treatment experience	Experienced vs Naive	1.323 (0.878; 1.992)	0.1805
Baseline ALT	≤ 1.5 vs > 1.5XULN	1.457 (0.464; 4.572)	0.5193
Baseline HbA$_1$c	> 5.7 vs < 5.7%	0.809 (0.560; 1.170)	0.2604
Baseline Albumin	<3.5 vs >3.5 g/dL	2.955 (1.750; 4.989)	<0.0001
Baseline LS by TE	F4 vs F0-F2	3.261 (1.819; 5.846)	<0.0001
	F3 vs F0-F2	1.674 (0.797; 3.518)	0.1739
Baseline Platelets	<150 vs >150X10^3/uL	2.766 (1.828; 4.184)	<0.0001
Multivariate Analysis Cox Regression Model			
De-novo HCC (n=132)			
Baseline Albumin	<3.5 vs >3.5 g/dL	2.561 (1.433; 4.578)	0.0015
Baseline LS by TE	F4 vs F0-F2	2.255 (1.215; 4.183)	0.0099
	F3 vs F0-F2	1.469 (0.696; 3.103)	0.3130
Baseline Platelets	<150 vs >150X10^3/uL	1.976 (1.231; 3.173)	0.0048
Pretreatment BMI	> 30 vs < 30kg/m^2	0.652 (0.431; 0.989)	0.0441
Deaths in patients with de novo HCC (n=20)			
Baseline CPT	CPT A vs CPT B+C	0.183 (0.069; 0.488)	0.0007

4117-A | RISK FACTORS ASSOCIATED WITH LATE HCC DETECTION IN PATIENTS WITH CHRONIC LIVER DISEASE UNDER REGULAR SURVEILLANCE

Jung Hwan Yu, Sangmi Jang, Young Joo Jin and Jin-Woo Lee, Inha University

Background: Hepatocellular carcinoma (HCC) has a very poor prognosis with a 5-year survival rate of less than 20%, and early diagnosis is very important. However, despite regular check-ups for high-risk groups of HCC, there are a few cases in which it is discovered as a late-stage of HCC. Therefore, this study intended to investigate the characteristics of patients with delayed HCC detection during regular HCC surveillance. **Methods:** Between January 2010 and December 2020, we analyzed patients with newly diagnosed HCCs who were screened for HCC by ultrasound or CT scan at least twice while following up for more than 1 year due to hepatitis B, hepatitis C, and chronic liver disease. **Results:** The mean age of a total of 223 HCC patients was 70 years, of which 152 were male, accounting for 68.1%. Among them, 196 patients (87%) were diagnosed with BCLC stage 0 or A, while 27 patients (13%) were found to be in BCLC stages B and C. When classified according to the TNM criteria, 154 patients (69%) were in stage I and 69 patients (31%) were in stage II or higher. In this study, a multivariate analysis performed to identify risk factors for patients diagnosed with late-stage HCC, CTP score was identified as a highly significant factor ($p = 0.002$, HR 1.547, 95% CI 1.177 - 2.032), while the presence of cirrhosis, BMI, and sex had no significant effect. **Conclusion:** We found that in patients with chronic liver disease who were screened regularly, patients with higher CTP scores were more likely to be diagnosed with HCC in late-stages. Therefore, although the presence of cirrhosis is also important for HCC surveillance, more careful attention is needed for patients with high CTP scores.

of California, Los Angeles, (4)Baylor College of Medicine, (5)UCSD, (6)VA San Diego Healthcare System, (7)UC Irvine, (8)Huntington Medical Research Institutes

Background: Hepatocellular carcinoma (HCC) and its mortality are on the rise. Early detection is associated with improved overall survival. Identifying clinical risk factors is key to implementing early prevention and risk stratifying patients who might benefit from early surveillance. Agent Orange (AO) is an herbicide that has been linked to several cancers; however, its association with hepatobiliary malignancies remains unclear. We aimed to assess the association between AO exposure and HCC in a large national Veteran cohort following the Vietnam era. **Methods:** We conducted a retrospective study of Vietnam Veterans (1966-1975) with established follow-up in the Veterans' Affairs between 2000-2019. AO exposure was defined as any Veteran flagged in the disability data as having been exposed to AO based on validated clinical surveys linked to service connection. Relevant clinical risk factors were collected, including etiologies of cirrhosis and features of the metabolic syndrome. Patients were stratified based on cirrhosis status, as defined by consecutive FIB-4 scores and cirrhosis ICD-codes. Incident HCC was the primary outcome identified using the VA Central Cancer Registry or validated ICD-codes. AO and HCC association was estimated using a multivariable Cox regression analysis, with death and liver transplant as competing events. **Results:** Of the 296,505 eligible Veterans, 170,090 (57%) were exposed to AO and 35,877 (12%) had cirrhosis. Veterans not exposed to AO were more likely to smoke (86.8% vs 85.9%, $p < 0.001$); use alcohol (42.8% vs 42.3%, $p = 0.0038$) and have viral hepatitis (37.8% vs 34.7%, $p < 0.001$). In a multivariable competing risk model, AO exposure did not affect the risk of HCC among patients with cirrhosis. However, self-identification as Hispanic (adj.HR = 1.51, 95%CI 1.30-1.75, $p < 0.0001$) or Black (adj.HR = 1.18, 95%CI 1.05-1.32, $p = 0.0035$), viral hepatitis (adj.HR = 3.71, 95%CI 3.26-4.24, $p < 0.0001$), alcohol liver disease (adj.HR = 1.32, 95%CI 1.19-1.46, $p < 0.0001$) and NAFLD (adj.HR = 1.92, 95%CI 1.72-2.15, $p < 0.0001$) were associated with incident HCC. Among Veterans without cirrhosis, hypertension (adj.HR = 1.63, 95%CI 1.23-2.15, $p = 0.0006$) and diabetes (adj.HR = 1.52, 95%CI 1.13-2.05, $p = 0.0053$) were also associated with HCC. Age at deployment was inversely associated with HCC in patients with cirrhosis (adj.HR = 0.96, 95%CI 0.95-0.98, p0.0001). After stratifying age at deployment by decades, we observed that early smoking and alcohol use were driving the HCC risk. **Conclusion:** AO exposure was not significantly associated with HCC in the largest national retrospective cohort of Vietnam Veterans to-date. Smoking, alcohol, viral hepatitis and NAFLD were the most important clinical risk factors for HCC. Metabolic risk factors were significant prior to the onset of cirrhosis. Our study highlights key modifiable risk factors that should be addressed early in HCC prevention.

4119-A | RISK OF ACUTE KIDNEY INJURY BY CHEMOTHERAPEUTIC AGENTS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA UNDERGOING TRANSARTERIAL CHEMOEMBOLIZATION

Byung Ik Kim[1], Yong Kyun Cho[1], Ju-Yeon Cho[2] and Won Sohn[1], (1)Sungkyunkwan University School of Medicine, (2)Chosun University

Background: Acute kidney injury (AKI) is a crucial factor for the prognosis of liver cirrhosis and it can develop in patients with hepatocellular carcinoma (HCC). This study aimed to evaluate the effect of chemotherapeutic agents on the risk of AKI in patients with HCC undergoing transarterial chemoembolization (TACE). **Methods:** A total of 370 HCC patients with baseline serum creatinine (SCr) ≤ 1.5 mg/dL undergoing TACE as an initial therapy were included. We compared the differences in the development of AKI between the use of doxorubicin and cisplatin in patients undergoing TACE for HCC. Also, the risk factors for the development of AKI were investigated during TACE. The AKI was defined based on the International Club of Ascites (ICA)-AKI criteria. **Results:** The mean age was 60.8 years. The mean SCr levels at baseline, one day, two months, and four months after TACE were 0.9, 0.9, 0.9, and 1.1 mg/dL, respectively. The AKI within four months after TACE developed in 43 patients (12%). The AKI stages were non-AKI in 327 (88%), stage 1 in 13 (4%), stage 2 in 12 (3%), and stage 3 in 18 patients (5%). The proportion of the use of cisplatin and doxorubicin was 18% (n = 65) and 82% (n = 305), respectively. There was no difference in baseline sCr levels between cisplatin group and doxorubicin group (0.9 $\pm$ 0.2 mg/dL vs. 0.9 $\pm$ 0.3 mg/dL, $p = 0.490$). However, the risk of AKI in cisplatin group was significantly higher than in doxorubicin group (29% vs. 8%, $p < 0.001$). Multivariable analysis indicated that the risk factors for AKI were serum albumin ≤ 3.5 g/dL (hazard ratio [HR] 3.44 with 95% confidence interval [CI] 1.51-7.82, $p = 0.003$), BCLC stage C (HR 6.48 with 95% CI 2.65-15.87, $p < 0.001$), presence of ascites (HR 9.43

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

with 95% CI 4.21-21.10, $p < 0.001$), and use of cisplatin (HR 3.02 with 95% CI 1.24-7.32, $p = 0.015$). **Conclusion:** The risk of AKI development is high in HCC patients treated with cisplatin-based TACE. The chemotherapeutic agent in patients receiving TACE for HCC should be chosen considering its nephrotoxicity in patients with hypoalbuminemia, advanced stage, and the presence of ascites, in particular.

f 4120-A | RISK OF HEPATITIS B VIRUS REACTIVATION IN HEPATOCELLULAR CARCINOMA PATIENTS WITH CURRENT OR PAST HEPATITIS B INFECTION RECEIVING IMMUNOTHERAPY: A TERRITORY-WIDE COHORT STUDY

Terry Cheuk-Fung Yip[1,2,3], Mandy Sze-Man Lai[1,2,3], Vincent Wai-Sun Wong[1,2,4], Stephen Lam Chan[5], Yee-Kit Tse[1,2,3], Henry Lik Yuen Chan[6,7] and Grace Lai-Hung C. Wong[1,2,3], (1)Department of Medicine and Therapeutics, the Chinese University of Hong Kong, (2) Medical Data Analytics Centre (MDAC), the Chinese University of Hong Kong, (3)Institute of Digestive Disease, the Chinese University of Hong Kong, (4) Chinese University of Hong Kong, Hong Kong, China, (5)State Key Laboratory of Translational Oncology, Department of Clinical Oncology, Sir Yue-Kong Pao Center for Cancer, the Chinese University of Hong Kong, (6)The Chinese University of Hong Kong, (7) Department of Internal Medicine, Union Hospital, Hong Kong

Background: Immunotherapy (IO) has emerged as a promising treatment for patients with hepatocellular carcinoma (HCC). However, patients with current or past hepatitis B virus (HBV) infection receiving IO carry a risk of HBV reactivation (HBVr). Thus, we examined their risk of HBVr and the impact of nucleos(t)ide analogue (NA) prophylaxis. **Methods:** Adult patients with current or past HBV infection receiving IO for HCC from March 2015 to March 2023 were identified using a territory-wide electronic database in Hong Kong. Current HBV infection was defined with positive hepatitis B surface antigen (HBsAg) and/or diagnosis codes. Past HBV infection was defined with negative HBsAg with positive hepatitis B core antibody. The primary outcome was HBVr defined according to the American Association for the Study of Liver Diseases (AASLD) criteria (*i.e.*, ≥1,000 IU/mL, ≥10,000 IU/mL, or ≥100-fold increase for current HBV with undetectable, unknown, and detectable baseline HBV DNA respectively; or development of detectable HBV DNA and/or HBsAg for past HBV). Secondary outcomes were HBVr based on the Asian Pacific Association for the Study of the Liver (APASL) and American Gastroenterological Association (AGA) guidelines. Patients were followed from the date of IO until the occurrence of HBVr, death, or last follow-up. **Results:** Of 414 HCC patients on IO (mean age 62 ± 11 y, 85.5% males), 89.4% and 10.6% had current and past HBV infection, of which 99.7% and 75.0% received NA prophylaxis respectively. Of the 414 patients, 23.2%, 16.7%, and 60.1% received atezolizumab-bevacizumab, nivolumab-ipilimumab, and pembrolizumab respectively; 43.7%, 26.1%, and 28.7% received HCC targeted therapy, transarterial chemoembolization (TACE), and systemic chemotherapy within 12 months before IO respectively. At a median (25th-75th percentile) follow-up of 7.0 (2.3-18.4) months, 8 (1.9%), 14 (3.4%), and 32 (7.7%) patients developed HBVr based on AASLD, APASL, and AGA criteria respectively. In multivariable analysis, NA prophylaxis (adjusted odds ratio [aOR] 0.05, 95% confidence interval [CI] 0.01-0.33, p = 0.002) and TACE within 12 months before IO (aOR 6.31, 95% CI 1.34-29.69, p = 0.020) were independently associated with a reduced and an increased risk of HBVr respectively (Table). Similar results were observed using the APASL and AGA criteria for HBVr. **Conclusion:** HBV-related HCC patients receiving IO have a risk of HBVr, especially those with prior TACE for HCC and without NA prophylaxis. Clinicians should closely monitor these patients and provide NA prophylaxis to prevent HBVr.

Table. Univariate and multivariable analysis with logistic regression after multiple imputation on factors associated with hepatitis B virus (HBV) reactivation in patients with current or past infection of hepatitis B and hepatocellular carcinoma (HCC) who received immunotherapy (IO).

HBV reactivation using AASLD 2018 guideline (reactivation rate=8/414 [1.9%])				
Parameters	Univariate analysis		Multivariable analysis	
	OR (95% CI)	p value	Adjusted OR (95% CI)	p value
Use of different IO				
- Pembrolizumab	Reference			
- Atezolizumab-Bevacizumab	1.04 (0.20 – 5.44)	0.965		
- Nivolumab-Ipilimumab	0.72 (0.08 – 6.25)	0.764		
HBV infection				
- Chronic HBV	Reference			
- Resolved HBV	9.15 (2.20 – 38.00)	0.002		
HBV antiviral prophylaxis	0.08 (0.01 – 0.42)	0.003	0.05 (0.01 – 0.33)	0.002
Age	1.01 (0.95 – 1.07)	0.833		
Male gender	1.19 (0.14 – 9.85)	0.872		
Presence of other cancers	0.94 (0.22 – 4.00)	0.935		
Alanine aminotransferase at IO (U/L)	1.01 (1.00 – 1.01)	0.140		
HBV DNA at IO (log_{10}IU/mL)	1.01 (0.85 – 1.19)	0.937		
HCC targeted therapy before IO	1.29 (0.32 – 5.24)	0.718		
Other chemotherapy before IO	4.27 (1.00 – 18.16)	0.049		
TACE before IO	4.90 (1.15 – 20.87)	0.031	6.31 (1.34 – 29.69)	0.020
Steroid/immunosuppressant use before IO	1.99 (0.47 – 8.49)	0.352		

CI = confidence interval, OR = odds ratio, TACE = transarterial chemoembolization.

4121-A | SCOPING REVIEW OF VALUES ELICITATION TOOLS FOR TREATMENT DECISIONS IN HEPATOCELLULAR CARCINOMA

Gabrielle Ritaccio[1], Alfred Sidney Barritt IV[1], Jamie Conklin[1], Daniel Richardson[1], Donna M. Evon[1], Hanna Sanoff[1], Robert S Sandler[1], Ethan Basch[1], Stephanie Wheeler[1] and Andrew M Moon[2], (1)University of North Carolina, (2)University of North Carolina, Durham, NC

Background: Better understanding of patient and clinician preferences and tradeoffs in hepatocellular carcinoma (HCC) treatment decisions could inform multidisciplinary tumor board discussions and shared decision making in clinic. Values elicitation methods assess preferences for treatment options or attributes of treatments. We performed a scoping review to summarize the published literature on the use of values elicitation tools for HCC treatment decisions. **Methods:** We included studies that (1) assessed the role of preference elicitation tools or willingness to pay/willingness to accept methods for treatment options for HCC and (2) included a study population of patients, caregivers and/or providers. We searched PubMed, EMBASE, Scopus and Cochrane Library databases for articles published before August 18, 2022 and extracted relevant characteristics from each included study. **Results:** The initial search yielded 1,434 unique results. After exclusion of non-relevant references, 10 studies remained. These included studies examining patient-preferences in early or advanced stage HCC (n = 5), a smartphone-based HCC treatment decision system (n = 2) and tradeoffs/treatment decisions of surgeons (n = 2) and GI/hepatologists (n = 1). Three (30%) of these studies were industry funded. No studies focused on intermediate stage HCC. The 9 studies quantifying patient or physician preferences used web-based surveys to offer hypothetical choice between treatment options to patients with cirrhosis or physicians who cared for patients with HCC. The studies of physicians focused exclusively on how treatment preferences are mediated by clinical factors (e.g., liver disease etiology/severity, waiting time to transplant) and facility-level factors (e.g. academic, transplant, HCC treatment volume). Attributes of treatment utilized in studies of patients are shown in Figure 1 with most focusing on efficacy, physical harms, and financial/time toxicity. Specific physical harms assessed were dependent on the study population/treatments assessed (e.g., hand-foot-skin reaction for tyrosine kinase inhibitors). Many of the studies reviewed suggested that patients place the most value on extending their overall survival but may be willing to forgo overall survival to avoid toxicities and maintain quality of life. **Conclusion:** Ten published studies have evaluated the role of preference elicitation tools or willingness to pay/accept methods in HCC treatment studies. The studies revealed a large scope of potential attributes that may be important to patients. Some studies suggested that patient preferences may differ from physician recommendations. More work needs to be done to compare and contrast patient and physician preferences for HCC treatment, particularly in intermediate stage HCC, and to synthesize this empirical evidence into useable decision support tools for patients.

4122-A | SERIAL CHANGES IN LIVER STIFFNESS MEASUREMENT PREDICT HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B PATIENTS WITH VIROLOGICAL RESPONSE

Nana Wang[1], Rongqin Zheng[2], Yuankai Wu[2], Yusheng Jie[2], Jinfen Wang[2], Manli Wu[2], Jiaxin Chen[3], Liuping Sha[2], Lili Wu[2] and Yutian Chong[2], (1)Third Affiliated Hospital of Sun Yat-Sen University, (2)The Third Affiliated Hospital of Sun Yat-Sen University, (3)The Fifth Affiliated Hospital of Sun Yat-Sen University

Background: To determine the predictive value of changes in liver stiffness measurement (LSM) for hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients with virological response, especially the serial LSM changes. **Methods:** This retrospective study enrolled CHB patients taking antiviral treatment and achieving virological response (hepatitis B virus DNA < 1000 IU/ml for more than 12 mo) between 2016 and 2019. Patients had at least two reliable LSMs by two-dimensional shear-wave elastography (2D SWE), and the first LSM was performed after achieving virological response. Univariable and multivariable Cox regression analysis were used to determine the risk factors for HCC. **Results:** Among 302 patients including 42 cirrhotic patients, 23 developed HCC. LSM changes included the change between first and last LSM and serial LSM changes. Serial LSM changes were classified into stable low LSM ($\leq$7.0 kPa), unstable LSM ($\leq$7.0 kPa at least once, $>$7.0 kPa at least once), and stable high LSM ($>$7.0 kPa). In the Cox regression analysis, single LSM (the first and last LSM), change between the first and last LSM, and unstable LSM were not associated with HCC; age at the time of first LSM and stable high LSM turned out to be the independent risk factors for HCC. The area under receiver operating characteristic curve of serial LSM changes (0.811) was similar to that of the multivariable model (0.748, $P = 0.170$). The performance of serial LSM changes was not affected by serial changes in alanine aminotransferase. In the subgroup analysis, only stable high LSM was significantly associated with HCC in non-cirrhotic patients ($P < 0.001$); neither the change between two LSMs nor serial LSM changes were associated with HCC in cirrhotic patients. **Conclusion:** Stable high LSM ($>$7.0 kPa) by 2D SWE was more important in predicting HCC than single LSM and change between two LSM in CHB patients with virological response, especially in non-cirrhotic patients. 4123-A | SERUM LEVELS OF CIRCULATING SOLUBLE B- AND T-LYMPHOCYTE ATTENUATOR IN UNRESECTABLE HEPATOCELLULAR CARCINOMA AS A PREDICTOR OF RESPONSE TO ATEZOLIZUMAB AND BEVACIZUMAB

Naoshi Odagiri, Hoang Hai, Le Thi Thanh Thuy, Yoshimi Yukawa-Muto, Kohei Kotani, Hiroyuki Motoyama, Ritsuzo Kozuka, Etsushi Kawamura, Atsushi Hagihara, Hideki Fujii, Sawako Uchida-Kobayashi, Masaru Enomoto and Norifumi Kawada, Osaka Metropolitan University Graduate School of Medicine

Background: Atezolizumab and bevacizumab (Atezo +Bev) therapy is widely used as a first-line drug for unresectable hepatocellular carcinoma (HCC). However, biomarkers that can predict its response and survival have not yet been established. We focused on circulating soluble immune checkpoint proteins (sICPs) and assessed the predictive and prognostic utility for clinical outcome of Atezo+Bev therapy. **Methods:** 33 patients with unresectable HCC who received Atezo+Bev therapy [24 males and 9 females; median age, 74 (range, 66–80) years] were included. Serum samples were collected at baseline and 4-7 days after the start of Atezo+Bev therapy. The concentration of 17 sICPs, including soluble form of B- and T- lymphocyte attenuator (sBTLA), sCD27, sCD28, T-cell immunoglobulin mucin-3 (sTIM-3), herpes virus entry mediator (sHVEM), sCD40, glucocorticoid-induced tumor necrosis factor receptor-related protein (sGITR), GITR ligand (sGITRL), lymphocyte-activation gene 3 (sLAG-3), sTLR-2, sPD-1, sCTLA-4, sCD80, sCD86, sPD-L1, sPD-L2, and inducible T-cell co-stimulator (sICOS) were measured using multiplexed fluorescent bead-based immunoassays with the Milliplex Map Kit (EMD Millipore Corporation, Burlington, MA, USA). **Results:** Of the 33 patients evaluated for treatment efficacy, the objective response rate (ORR) and disease control rate (DCR) were 30.3% (10/33) and 75.8% (25/33), respectively, with 1, 9, 15, and 8 patients experiencing complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD), respectively. Compared to the baseline, the concentrations of sBTLA, sCD27, sCD28, sCD80, sGITR, sGITRL, sICOS, sLAG-3, and sTLR-2 were significantly increased, while sCD40, sHVEM, sPD-1, and sTIM-3 were significantly decreased after the start of Atezo+Bev.

Baseline concentration of sBTLA (pg/mL) was higher in patients with objective response (138.45 vs. 106.11, p = 0.022). In the univariate Cox regression model, first line therapy (hazard ratio [HR] = 0.393 [95% CI: 0.159-0.974], p = 0.044) and baseline sBTLA ≥ 120 pg/mL (HR = 0.237 [95% CI: 0.085-0.660], p = 0.006) were significant prognostic factors relevant to progression free survivial (PFS). Multivariable Cox regression analysis revealed that baseline sBTLA ≥ 120 pg/mL was an independent prognostic factor of PFS (HR = 0.294 [95% CI: 0.102-0.848], p = 0.023). The baseline sBTLA ≥ 120 pg/mL group showed a significantly prolonged median PFS compared with the baseline sBTLA < 120 pg/mL group (9.3 vs. 4.2 mo, p = 0.003, log-rank test). **Conclusion:** We demonstrated that most sICPs undergo changes even within the early stage of 4-7 days after starting Atezo+Bev therapy. Furthermore, the baseline concentration of sBTLA has a prognostic value for objective response and is also an independent prognostic factor of PFS. Our results suggest that sBTLA has the potential to serve as a prognostic biomarker in patients with HCC receiving Atezo+Bev therapy.

Background: Atezolizumab plus bevacizumab (A+B) represents a standard of care front-line treatment in patients with advanced hepatocellular carcinoma (HCC). We investigated potential differences in efficacy and safety of immunotherapy between female versus male HCC patients. **Methods:** A restricted maximum likelihood random effects meta-analysis of five phase III trials that evaluated immune checkpoint inhibitors (ICI) in advanced HCC and reported overall survival (OS) hazard ratios according to sex was performed to evaluate sex-related differences in OS.

In a real-world cohort of 840 HCC patients from 22 centres included between 2018 and 2023, we directly compared the efficacy and safety of A+B between females and males. Best radiological response was

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

reported according to RECISTv1.1. Univariable and multivariable Cox regression analyses were calculated for OS, progression-free survival (PFS), and time to progression (TTP). **Results:** In the meta-analysis, immunotherapy was associated with a significant OS benefit only in male (pooled HR: 0.79 [95%CI: 0.73-0.86]) but not in female HCC patients (pooled HR: 0.85 [95%CI: 0.70-1.03], Figure). Among 840 patients, 677 patients (81%) were male (mean age 66 ± 11 y), and 163 patients (19%) were female (mean age 67 ± 12 y). Prevalence of cirrhosis, liver function and tumour stages were comparable between the two sexes. Grade ≥3 AEs occurred in 15% of female and 12% of male patients (p = 0.312). Type and severity of AEs were similar between the two groups. OS (median OS, 15.9 mo, 95%CI: 14.0-17.8 vs. 15.0 mo, 95%CI: 11.8-18.2; p = 0.409), PFS (median PFS, 6.6 mo, 95%CI: 5.7-7.5 vs. 7.3 mo, 95%CI: 4.8-9.9), and TTP (median TTP, 7.1 mo, 95%CI: 6.3-7.9 vs. 7.3 mo, 95%CI: 4.3-10.4) were comparable between male and female patients upon uni- and multivariable analyses (adjusted hazard ratio for OS, PFS, and TTP: 0.79 [95%CI: 0.59-1.04], 1.02 [95%CI: 0.80-1.30], 0.90 [95%CI: 0.68-1.18]). Objective response rate (24% vs. 22%) and disease control rate (59% vs. 59%) were also similar between males and females. **Conclusion:** Female phase III trial participants experienced worse OS following ICI therapy for advanced HCC, a finding that differs from real-world experience of patients treated with A+B. Further investigation of sex as a determinant of responsiveness to ICI should be prioritised.

4125-A | SINGLE-CELL RNA-SEQ-BASED SYSTEMIC IMMUNE PROFILING PREDICTS RESPONSE TO COMBINATION IMMUNOTHERAPY FOR ADVANCED HEPATOCELLULAR CARCINOMA

Akira Nishio[1], Takahiro Kodama[2], Kazuki Maesaka[2], Kazuma Daiku[1], Akira Doi[2], Yuki Tahata[2], Hayato Hikita[1], Tomohide Tatsumi[2] and Tetsuo Takehara[2], (1) Osaka University, Graduate School of Medicine, (2) Osaka University Graduate School of Medicine

Background: Immune checkpoint inhibitor has revolutionized the treatment of advanced hepatocellular carcinoma (HCC). The combination therapy of Atezolizumab with Bevacizumab (Atezo/Bev) has shown to improve the overall survival compared to sorafenib. However, little is known about how circulating immune cells would contribute to the response to Atezo/Bev therapy. Herein, we performed systemic immune profiling in advanced HCC patients using single-cell RNA sequencing (scRNAseq). **Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from HCC patients who received Atezo/Bev therapy in a prospectively registered multicenter study. We conducted scRNAseq and single-cell T cell receptor (scTCR) sequencing of PBMCs from 5 responders and 5 non-responders before and 6 weeks after Atezo/Bev therapy. After UMAP clustering and cell type annotation, differentially expressed genes between responders and non-responders and the diversity of TCR repertoire were analyzed. **Results:** First, 231,383 cells of 20 PBMCs from 10 patients were broadly annotated into 16 major subtypes based on their expression of canonical gene markers. Frequencies of

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

naive-like CD4T cells and naive B cells tended to be higher in responders at pretreatment and those of naive B cells were significantly higher in responder during therapy. Next, we focused on monocytes and T/NK cells. When 124,058 T and NK cells were re-clustered, 22 distinct clusters were identified. There was a difference in the frequency of CD4T cell subsets between responders and non-responders. The frequencies of clusters in CD8T cell didn't differ between groups, however, the GO analysis revealed that CD8T cell was more activated in responders than non-responders at pretreatment. The subset of monocytes, expressing gene X, exhibited higher frequencies in non-responders both at pretreatment and during therapy compared to those in responders. The diversity of TCR repertoire was greater in responders at pretreatment than non-responders. **Conclusion:** Our study proposes that the profile of circulating immune cells at pretreatment may be able to predict the response to Atezo/Bev therapy in HCC patients.

4126-A | SPATIOTEMPORAL REGULATION OF CHOLANGIOCARCINOMA GROWTH AND DISSEMINATION BY PERITUMORAL MYOFIBROBLASTS IN A Vcam1-DEPENDENT MANNER

Cheng Tian, St. Jude Children's Research Hospital and Liqin Zhu

Background: Intrahepatic cholangiocarcinoma (iCCA) is a type of highly aggressive primary liver cancer characterized by its dense desmoplastic stroma. Myofibroblasts (MFs) are present both within the tumor mass (intratumoral MFs, iMFs) and at the tumor border (peritumoral MFs, pMFs). The protumorigenic role of iMFs has been widely demonstrated in iCCA. However, little is known about the role of pMFs in iCCA development. We aim to investigate the spatiotemporal impact of pMFs on iCCA tumor cells and the potential underlying molecular mechanisms that mediate the dynamic iCCA-pMF interaction. Using a spheroid-based coculture system, we show that the initial iCCA-pMF contact is growth suppressive to tumor cells. However, prolonged iCCA-pMF interaction elicits significant tumor cell invasion and dissemination. **Methods:** An orthotopic allograft of metastatic ICC was generated to track the activation of iMFs and pMFs. Multiple coculture systems were established to assess the impact of iMFs and pMFs on ICC development. RNA-seq transcriptomic profiling was performed to examine ICC-induced liver host response. **Results:** iCCA-liver interaction induces rapid pMF activation in vivo; pMFs exhibit a strong suppressive effect on iCCA growth; prolonged iCCA-pMF interaction, however, elicits significant tumor cell invasion and dissemination; and (2) when tumor invades, pMFs gradually infiltrate into the tumor and become iMFs; iMFs promote tumor growth but have a weaker impact on tumor dissemination than pMFs. Molecularly, iCCA-pMF interaction induced upregulation of vascular cell adhesion molecular 1 (Vcam1) in tumor cells. Vcam1 knockout (Vcam1KO) iCCA cells reveals a heavy involvement of Vcam1 in epithelial-to-mesenchymal transition. While Vcam1KO has only a limited impact on iCCA cell growth in their monoculture, Vcam1KO tumor spheroids cocultured with pMFs exhibit severe defects in growth but significantly increased dissemination. Consistently, pharmacological inhibition ofVcam1 in vivo slows down tumor mass growth but promote tumor cell dissemination. **Conclusion:** his study suggests that tumor-pMF interaction is beyond simple pro- or anti-tumorigenic in iCCA, involving both the attempt of pMFs to block tumor growth and that of tumor cells to grow and disseminate under the pMF suppression in a Vcam1-dependent manner.

4127-A | SQUAMOUS CELL CARCINOMA AS A HISTOLOGICAL VARIANT OF INTRAHEPATIC CHOLANGIOCARCINOMA: FROM CASE REPORTS TO A NATIONAL CANCER DATABASE ANALYSIS OF 48 CASES

Jad Mitri[1], Elena Panettieri[2], Mohammad Almeqdadi[3], Hind El Naamani[2] and Eduardo Vega[2], (1)Saint Elizabeth's Medical Center, (2)St Elizabeth's Medical Center, (3)Tufts Medical Center

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Squamous cell carcinoma (SCC) is a rare subtype of intrahepatic cholangiocarcinoma (IHC). Prognosis is reportedly poor, limiting its previous literature to case series. Squamous cells of the intrahepatic bile ducts (IHBD) can become malignant in the setting of chronic inflammation, resulting in primary SCC. Metaplasia of underlying liver cysts is another proposed mechanism for the formation of SCC in the IHBD. The primary aim was to describe demographics, tumor characteristics, and survival outcomes in a cohort of 48 cases of primary SCC of the IHBD to better characterize this tumor. The secondary aim was to compare the findings to characteristics of patients with adenocarcinoma, the common IHC histological type. **Methods:** This retrospective study utilized data from the National Cancer Database. Patients were included if they had an ICD-O-3 (International Classification of Disease for Oncology, third edition) diagnosis of SCC (histology codes: 8070-8071) and adenocarcinoma of the IHBD (histology codes: 8140-9144-8310-8310-8480-8490). Demographics (age, race, sex, comorbidity index Charlson-Deyo score), tumor characteristics (grade, tumor size, metastatic sites, therapeutic approach, margin positivity), and survival outcomes were analyzed and compared between the SCC group and the adenocarcinoma group (control). A multivariate analysis was conducted after adjusting for relevant confounders. **Results:** 5207 patients with IHC were included: adenocarcinoma N = 5,159 and SCC N = 48. 0.92% of the patients had SCC, median age was 67.5 years with predominance of white males. Both groups shared similar demographic characteristics, tumor grade, Charlson-Deyo Score and metastatic sites. However, the SCC group had a significantly larger median tumor size(76.5 vs. 66 mm; p = 0.019). Tumor pathological stage was not included due to missing data in 45/48 SCC patients. Treatment modalities did not differ significantly between the two groups. (Table 1) In the multivariate analysis for survival, larger tumor size and positive surgical margins were each shown to be associated with increased mortality, respectively hazard ratio (HR) 1.455 [1.102-1.923] (p = 0.008) and HR 1.767 [1.274-2.451] (p = < 0.001). Females had better survival (HR 0.714 [.550- 0.926], p = 0.011). While SCC group had a higher tumor size, no significant differences in survival were found between SCC and adenocarcinoma patients (HR = 1.454; 95%CI = [0.541; 3.907], p = 0,458). **Conclusion:** The SCC variant of IHC is sparsely described in the literature. SCC is similar to adenocarcinoma in terms of characteristics and survival. Tumor size is larger for patients with SCC compared to adenocarcinoma. Due to the low prevalence of the SCC variant, more research is needed to better characterize this rare histological type. We recommend an extensive workup for alternative primary sites when encountering SCC of the IHBD given the paucity of cases.

4128-A | STAGE MIGRATION AFTER RADIATION THERAPIES FOR HEPATOCELLULAR CARCINOMA IS A SURROGATE OF OVERALL SURVIVAL

Suraj Pai[1], Shengchen Hao[1], Jonathan Melendez-Torres[2], Isaiah Brown[3], Muhammad Tahir[4], Anna Mae Diehl[3], Ammar Sarwar[4], Amit G. Singal[2] and Neehar Dilip Parikh[1], (1)University of Michigan, (2)University of Texas Southwestern Medical Center, (3)University of Chicago, (4)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and a major cause of cancer-related mortality worldwide. Locoregional therapies including stereotactic body radiation therapy (SBRT) and radioembolization (TARE) are recommended for intermediate stage disease; however, lack of surrogate endpoints have limited feasibility of

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

conducting comparative effectiveness clinical trials. We aimed to evaluate the association between stage migration and overall survival in patients with HCC undergoing treatment with SBRT or TARE. **Methods:** We conducted a retrospective study of adult patients from four tertiary care institutions in the United States. We included patients with HCC who received SBRT or TARE as initial treatment for HCC between 2008 and 2019. We excluded those with prior treatment, Barcelona Clinic Liver Cancer (BCLC) stage D disease, or those who died within 6 months of first HCC treatment. The primary outcome was transplant-free survival, with transplantation as a competing risk. The independent variable of interest was stage migration to a more advanced BCLC stage (e.g., BCLC stage B à C) within 6 months of HCC diagnosis. Survival analysis was completed using Kaplan-Meier and multivariable Cox proportional hazard models used to identify predictors of survival. **Results:** We included 266 patients with a median age of 65 years; 77% male and 66% White. The primary etiologies of liver disease were hepatitis C virus (32%), non-alcoholic fatty liver disease (21%), and alcohol-related cirrhosis and cryptogenic (14% each). Most (75%) had Child-Pugh class A and 25% Child Pugh B. Stage migration within 6 months was observed in 61 (23%) patients. Kaplan-Meier log rank analysis showed significantly shorter survival for those who experienced stage migration at 6 months (median 196 [IQR 103-421] days) vs those who did not (median 1197 [IQR 581-2274] days) (Figure). In multivariate Cox analysis, stage migration was significantly associated with worse survival (HR 3.99 [95% CI: 2.78 – 5.74]). Other predictors of worse survival included older age, Child-Pugh B cirrhosis, and higher AFP. **Conclusion:** Stage migration at 6 months is a surrogate endpoint for overall survival in patients with HCC undergoing radiation-based locoregional therapies (SBRT or TARE) and could be considered as an endpoint for future clinical trials.

4129-A | SURVIVAL OF CHOLANGIOCARCINOMA: SIGNIFICANCE OF RACE, SEX, AND OTHER TUMOR CHARACTERISTICS

Reena Razdan, Rutgers New Jersey Medical School and Nikolaos T. Pyrsopoulos, Rutgers University, Newark, NJ

Background: Cholangiocarcinoma (CCA) is a rare cancer derived from the bile ducts that is characterized by its late diagnosis and high mortality. The aim of this epidemiology study is to compare outcomes amongst demographics and tumor characteristics of CCA in order to better understand predictive markers for survival. **Methods:** We retrospectively analyzed the Surveillance Epidemiology and End Results (SEER) database of 17 registries made available by the National Cancer Institute in the USA. Patients with a histological diagnosis of malignant CCA per ICD-O-3 codes from years 2000-2019 were included. Demographic and tumor characteristics such as age, sex, race, primary tumor site, tumor stage, histologic grade, surgical intervention, and survival months (deaths attributable to cancer) were examined. We compared overall survival for patients with CCA using Cox proportional hazard regression analysis. Gender differences were further analyzed based on race. **Results:** We identified 23,501 patients with CCA. The median age was 69 years. Patient demographics included: 51.2% men, 48.8% women, 62.8% White, 15.9% Hispanic, 12.4% Asian/Pacific Islander, 8.0% Black, and 0.9% American Indian/Alaska Native. In our survival analysis, women had a lower risk of mortality as compared to men (HR 0.95, $p < 0.005$). However, this difference was eliminated on subgroup analysis by race- with only White women maintaining longer survival as compared to their men counterparts (HR 0.92, $p < 0.005$). Blacks (HR 1.09, $p < 0.005$, median

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

Overall Survival 7 mos), Hispanics (HR 1.08, $p < 0.005$, mOS 7 mos), and American Indians (HR 1.24, $p < 0.01$, mOS 6 mos) had worse outcomes compared to Whites (mOS 8). Patients who had surgery performed had longer survival compared to those who did not have surgery performed (HR 0.33, $p < 0.005$, mOS 34 mos vs mOS 5 mos). Higher histological grade was associated with poorer outcomes, with undifferentiated anaplastic Grade IV having the highest mortality (HR 1.61, $p < 0.005$, mOS 8 mos). While only 3.9% of CCAs arose from the gall bladder, this tumor location had one of the worst survival outcomes (HR 1.33, $p < 0.005$, mOS 5 mos). Conversely, CCA derived from the extrahepatic bile duct accounted for 29.6% of CCAs, but had the best survival outcomes (HR 0.85, $p < 0.005$, mOS 9 mos). **Conclusion:** Mortality differences between men and women were only maintained in White patient populations. Blacks, Hispanics, and American Indians had worse survival compared to Whites. Tumor location was associated with differences in mortality outcomes, with gall bladder CCAs having one of the poorest overall survival outcomes compared to other tumor locations. Further studies are needed to elucidate determinants of poor survival amongst these groups.

	All Sexes (Median Overall Survival Months Included)	Males	Females	Males v Females (Male Reference)
White	1.00 - OS 8	1.00	1.00	0.92 (0.89-0.96)
Black	1.09 (1.03-1.15) - OS 7	1.12 (1.05-1.22)	1.14 (1.05-1.24)	0.98 (0.87-1.11)
Hispanic	1.08 (1.03-1.12) - OS 7	1.05 (0.99-1.12)	1.14 (1.07-1.21)	1.02 (0.94-1.10)
Asian/Pacific Islander	1.03 (0.98-1.08) - OS 8	1.00 (0.93-1.07)	1.02 (0.95-1.10)	0.96 (0.87-1.05)
American Indian/Alaska Native	1.24 (1.08-1.45) - OS 6	1.24 (0.99-1.55)	1.21 (0.97-1.51)	0.92 (0.51-1.33)

4130-A | SURVIVAL OUTCOMES OF SINGLE CENTER COHORT VERSUS MULTICENTER COHORT ACCORDING TO THERAPEUTIC METHODS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

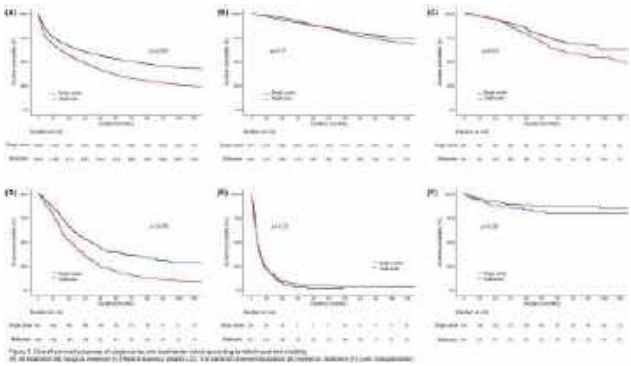
Ye Rim Kim[1], Sung Won Chung[1] and Ju Hyun Shim[2], (1)Asan Medical Center, Seoul, Korea, Republic of (South), (2)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Previous randomized controlled trials have demonstrated that multicenter studies provide higher level of external validity than single center studies; however, it is uncertain whether this finding necessarily indicates that results of retrospective single center cohort studies cannot be generalized to real-world clinical practice. Applicability of single center studies is particularly of relevance for hepatocellular carcinoma (HCC), a heterogeneous disease with various treatment options based on disease stage and liver function. We therefore aimed to compare the overall survival (OS) of HCC patients between a nationwide multicenter cohort and a representative single center cohort to evaluate the external validity of single center research. **Methods:** Patients diagnosed with HCC between January 2008 and December 2018 were retrospectively analyzed using data from the Korean Primary Liver Cancer Registry (multicenter cohort, $n = 16,443$), and Asan Medical Center HCC registry (single center cohort, $n = 15,655$). Primary outcome was OS, which was estimated using log-rank test and Cox proportional hazard analysis. OS was additionally compared among subpopulation of patients who met each AASLD guideline and received the corresponding treatment (radiofrequency ablation [RFA], transarterial chemoembolization [TACE], surgical resection, liver transplantation [LT], and systemic treatment) as initial therapy. **Results:** Overall, the multicenter cohort had shorter OS than the single center cohort (adjusted hazard ratio [aHR] = 1.17, 95% confidence interval [CI] = 1.13–1.20, $p < 0.001$). In patients who received RFA (aHR = 1.45, 95% CI = 1.08–1.95 $p = 0.01$) or TACE (aHR = 1.73, 95% CI = 1.49–2.02 $p < 0.001$) in accordance with the current AASLD guideline, the multicenter cohort showed higher risk of death. However, risk of mortality in patients who received systemic therapy (aHR = 0.94, 95% CI = 0.81–

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

1.10, p = 0.46), surgical resection (aHR = 1.06, 95% CI = 0.93–1.22, p = 0.38), and LT according to Milan criteria (aHR = 1.09, 95% CI = 0.54–2.18, p = 0.82) did not differ between the two cohorts. **Conclusion:** Despite the representative volume of our single center, there was a significant difference in OS between the single center and the multicenter cohort, and the difference was only minimal in patients who received systemic therapy, surgical resection, or LT according to the current treatment guidelines. Retrospective single center cohort studies must be interpreted with caution particularly when evaluating outcomes in HCC patients with heterogeneous tumor features.



Disclosures: The following people have nothing to disclose: Ye Rim Kim, Sung Won Chung, Ju Hyun Shim

f 4131-A | TEMPORAL TRENDS IN CLINICAL PATTERNS AND OUTCOMES OF PATIENTS WITH HEPATOCELLULAR CARCINOMA

Karim Seif El Dahan[1], Darine Daher[1], Ahmad Anouti[1], Nicole E. Rich[1], Alva Cano[1], Michael Gonzalez[1], Sara Verschleisser[1], Crystal Ransom[1], Erik Juarez Farfan[1], Osiris Carranza[1], Lisa Quirk[1], Todd Morgan[1], Lisa B. VanWagner[1], Sarah Rosanna Lieber[1], Thomas G. Cotter[1], Jeremy Louissaint[1], Yujin Hoshida[1], Madhukar Patel[1], Purva Gopal[1], Adam C. Yopp[1], Neehar Dilip Parikh[2] and Amit G. Singal[1], (1)University of Texas Southwestern Medical Center, (2)University of Michigan

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer death in patients with cirrhosis. Efforts to improve patient outcomes include optimization of surveillance strategies, expansion of curative treatment eligibility, and introduction of new therapy options. We aimed to characterize temporal trends of clinical outcomes in a large cohort of patients with HCC. **Methods:** We conducted a retrospective cohort study at two large health systems of patients diagnosed with HCC between January 2008 and December 2021. We created three subgroups, each spanning ~5 years, based on HCC diagnosis date: group 1 (2008–2012), group 2 (2013-2017), and group 3 (2018-2021). We used multivariable logistic regression to assess associations with early-stage HCC detection (BCLC stage 0/A), and curative treatment (liver transplant, surgical resection, or local ablation). We used multivariable Cox regression analysis to characterize associations with overall survival. **Results:** Of 2,042 patients with HCC (group 1: n = 566; group 2: n = 748; group 3: n = 728), median age was 61.4 years, and 76.1% were male. The cohort was diverse regarding race/ethnicity (36.0% White, 28.6% Hispanic, 28.1% Black) and etiology (56.8% hepatitis C, 39.9% alcohol, 15.0% NAFLD). Over time, median age increased (57.8, 60.6, and 63.9 y) and proportions of males decreased (77.7, 76.2, and 74.7%). The prevalence of hepatitis C (65.0, 60.7, and 46.4%) and alcohol (45.1, 41.7, and 34.1%) decreased, whereas NAFLD increased (7.8, 13.9%, and 21.7%). The proportion of BCLC stage 0/A increased over time (38.7, 44.7, and 56.2%; group 3 vs. 1: OR 2.27, 95% CI 1.63-3.20). Compared to group 1, patients in group 2 (OR 2.27, 95%CI 1.61-3.23) and group 3 (OR 1.88, 95%CI 1.28-2.77) had increased curative treatment. Median survival for groups 1, 2, and 3 were 9.8 (95%CI, 8.1-12), 19 (95%CI, 16-22), and 24 (95%CI 20-30) months, respectively. Group 2 (HR 0.83, 95%CI 0.72-0.95) and group 3 (HR 0.68, 95%CI 0.58-0.80) had significantly reduced mortality versus group 1. Group 3 had no significant difference in curative treatment than group 2 (OR 0.73, 95%CI 0.53-1.01) but improved survival (HR 0.81, 95%CI 0.69-0.95). **Conclusion:** There have been significant improvements in early HCC detection, curative treatment receipt, and overall survival among patients with HCC. However, over one-third of HCC are detected beyond an early stage and median survival remains below 3 years, highlighting a need for improvements in surveillance.

4132-A | TEMPORAL TRENDS OF HEPATOCELLULAR CARCINOMA IN THE UNITED STATES FROM 1999 TO 2020

Alexander Kusnik, Sarath Lal Mannumbeth Renjithlal, Keerthi Mannumbeth Renjith and Asim Mushtaq, Rochester Regional Health

Background: Hepatocellular Carcinoma (HCC) is a significant public health concern in the US, resulting in cancer-related deaths despite improvements in detection and treatment. To comprehensively understand HCC outcomes among different demographic groups (e.g., sex, race/ethnicity, location of death), it is important to observe trends and patterns to evaluate the effectiveness of past interventions. **Methods:** A cross-sectional analysis was conducted using the CDC-WONDER database to investigate the mortality patterns linked to Hepatocellular Carcinoma (HCC) using the ICD code (C22.0). The study employed death certificate data from the CDC WONDER database to identify deaths associated with HCC between 1999 and 2020. Age-adjusted mortality rates (AAMR) per 100.000 individual's and corresponding annual percentage changes (APC), along with 95% confidence intervals, were calculated using Joinpoint regression analysis. The analysis focused on assessing demographic and racial trends. **Results:** Between 1999 and 2020, there were 184,073 deaths related to Hepatocellular Carcinoma (HCC). Analysis of yearly trends showed an increase in the age-adjusted mortality rate (AAMR) from 1.9 (95% CI 1.8-1.9) in 1999 to 2.8 (95% CI 2.7-2.8) in 2020. Overall, the AAMR from 1999 to 2018 had an Annual Percentage Change (APC) increase of 1.92 (95% CI: 1.7 to 2.2). When considering gender, males had a higher AAMR of 4.1 (95% CI: 4.0-4.1), while females had a lower AAMR of 1.0 (95% CI: 1.0-1.0). Among ethnicities, Asian or Pacific Islanders had the highest AAMR of 4.5 (95% CI: 4.5-4.6), followed by Black or African Americans with an AAMR of 3.5 (95% CI 3.5-3.5), American Indian or Alaskan Natives with an AAMR of 3.3 (95% CI 3.1-3.4), and Whites with an AAMR of 2.1 (95% CI 2.1-2.2). Geographically, non-metropolitan rural areas had lower AAMR compared to urban areas. The highest AAMR was seen in the District of Columbia and Hawaii. Information on the location of death was available for all recorded deaths. Among these, 34.85% (64,157) occurred during inpatient admission or in the emergency room , 41.19% (75,825) occurred at home, 16.47% (64,930) occurred in nursing homes or long-term care facilities, 0.42% (17,620) were reported in hospices, and 3.36% (13,261) occurred at other or unspecified places. **Conclusion:** This study highlights a notable rise in the incidence of hepatocellular carcinoma (HCC), primarily affecting males. This increase can be attributed to various factors, including the persistent opioid crisis, the growing prevalence of obesity and diabetes, and the underdiagnosis of hepatitis B virus (HBV), despite advancements in hepatitis C virus (HCV) treatment. Additionally, a significant proportion of HCC-related deaths occurred at home, indicating a potential requirement for expanded home-based services to accommodate the increasing HCC incidence.

4133-A | THE CLINICAL SIGNIFICANCE AND TUMOR MICROENVIRONMENT OF VESSELS ENCAPSULATING TUMOR CLUSTERS (VETC)-POSITIVE HEPATOCELLULAR CARCINOMA

Tomohiko Taniai, Koichiro Haruki, Kenei Furukawa, Mitsuru Yanagaki, Munetoshi Akaoka and Toru Ikegami, The Jikei University School of Medicine

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Vessels encapsulating tumor clusters (VETC), which form cobweb-like networks and encapsulate tumor clusters, have been reported as poor prognostic indicators for patients with hepatocellular carcinoma (HCC). However, the clinical significance of VETC remains unclear. The aim of this study is to identify the clinical significance of VETC in patients with HCC and to elucidate immune cell profiling of VETC-positive HCC. **Methods:** This study comprised 229 patients with HCC underwent hepatic resection. The relationship between VETC and disease-free survival (DFS) or overall survival (OS) was retrospectively analyzed. We performed immunohistochemistry for CD34, CD8, CD163 to assess VETC, T cell, and macrophage, respectively. Immune cell count was performed in two lesions: tumor center (CT) and invasive margin (IM), and classified 3 categories: low, intermediate, and high. Thereafter, we retrospectively analyzed the clinicopathological characteristics of patients with VETC-positive HCC. **Results:** VETC was a poor prognostic indicator of DFS ($p < 0.01$) and OS ($p < 0.01$). In multivariate analyses, serum AFP ≥ 20 ng/ml ($p < 0.01$), multiple tumors ($p < 0.01$), and VETC-positive ($p = 0.02$) were significant poor prognostic factors for DFS, while moderate/poor differentiation ($p = 0.02$), tumor size ≥ 5 cm ($p = 0.02$), and VETC-positive ($p = 0.03$) were significant poor prognostic indicators for OS. Clinicopathologic characteristics in patients with VETC HCC were higher serum PIVKA-II level ($p < 0.01$), moderate/poor differentiation ($p < 0.01$), larger tumor ($p < 0.01$), multiple tumor ($p = 0.02$), high vascular invasion ($p < 0.01$), fewer CD8+CT ($p < 0.01$), and fewer CD163+CT ($p = 0.02$). **Conclusion:** VETC is a poor prognostic indicator in patients with HCC and is related to high PIVKA-II, poor differentiation, large and multiple tumors, high vascular invasion, and immune cold tumor micro environment.

4134-A | THE COMPARATIVE EFFICACY OF COMBINED LOCOREGIONAL AND SYSTEMIC THERAPIES IN HEPATOCELLULAR CARCINOMA (HCC) BCLC CLASS B: A BAYESIAN NETWORK META-ANALYSIS

Zixuan Xing[1], Yee Hui Yeo[2], Gin-Yi Lee[3], Mohammad Saeid Rezaee-Zavareh[4], Wenjun Wang[1], Fanpu Ji[5] and Ju Dong Yang[6], (1)The Second Affiliated Hospital of Xi'an Jiaotong University, (2)Cedars-Sinai Medical Center, Culver City, CA, (3)Department of Hospital Medicine, Rhode Island Hospital, MA, USA, (4)Middle East Liver Disease Center, (5)The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China, (6) Cedars-Sinai Medical Center, Los Angeles, CA

Background: Hepatocellular carcinoma (HCC) is the sixth leading cause of cancer death. It exhibits pronounced clinical and molecular heterogeneity. Locoregional therapy remains the primary treatment for HCC patients within the Barcelona Clinic Liver Cancer (BCLC) class B. Despite this, several subgroup analyses from large-scale trials have suggested potential benefits of systemic therapy in this patient population. Our study aimed to perform a network meta-analysis comparing locoregional and systemic therapies for patients with BCLC class B HCC. **Methods:** A comprehensive literature search was conducted on PubMed, Scopus, Web of Science, the Cochrane Controlled Register of Trials, clinicaltrials.gov, and WHO's International Clinical Trials Registry Platform, from inception to March 20, 2023. Double-blinded, randomized controlled trials investigating first-line systemic or locoregional therapies for HCC BLCL class B were obtained. Hazard ratios (HR) for overall survival (OS) were extracted. The regimens were grouped into four groups (transarterial chemoembolization [TACE] alone, TACE combined with immunotherapy, and TACE combined with tyrosine kinase inhibitor [TKI]). A Bayesian network meta-analysis was performed to compare and rank these regimens. **Results:** From a total of 17,206 records initially retrieved, 559 were included for full-text screening and nine eligible trials were included for network meta-analysis of OS. Six of the studies were performed in Asia. Regarding OS, compared to TACE alone, TACE-immunotherapy (HR: 0.60; 95% credible interval [CrI]: 0.39-0.92) was associated with a significantly higher survival probability, surpassing that of TACE-TKI (HR: 0.87; 95% CrI: 0.74-1.02) (Table 1). Data on progression-free survival, treatment response rates, and adverse events were meta-analyzed. **Conclusion:** This network meta-analysis supports the combination of TACE-immunotherapy and TACE-TKI for treating patients with HCC BCLC class B. Additional evidence on efficacy, adverse events, and subgroup analysis by tumor characteristics could further refine treatment strategies to optimize patient outcomes.

Table. League Table for Overall Survival and Progression-free Survival for Therapeutic Regimens for Patients with Hepatocellular Carcinoma BCLC Class B

Overall survival			
	TACE	TACE_immunotherapy	TACE_TKI
TACE	TACE	0.6 (0.39, 0.92)	0.87 (0.74, 1.02)
TACE_immunotherapy	1.67 (1.09, 2.55)	TACE_immunotherapy	1.45 (0.92, 2.28)
TACE_TKI	1.15 (0.98, 1.36)	0.69 (0.44, 1.09)	TACE_TKI

4135-A | THE CONDITION OF ACHIEVED SVR AT INITIATION OF 1st LINE SYSTEMIC THERAPY ON THE PATIENTS WITH HCV-RELATED UNRESECTABLE HEPATOCELLULAR CARCINOMA, PREMISING 2nd LINE THERAPY

Takayuki Tokunaga, Kentaro Tanaka, Satoshi Narahara, Hiroki Inada, Etsuko Iio, Yoko Yoshimaru, Takehisa Watanabe, Katsuya Nagaoka, Hiroko Setoyama and Yasuhito Tanaka, Faculty of Life Sciences, Kumamoto University

Background: The impact of eradication of hepatitis C virus (HCV) on the prognosis of the patients with HCV-related unresectable hepatocellular carcinoma (HCV-uHCC) remains to be clarified. We aimed to investigate the relationship between the condition of sustained virological response (SVR) and the clinical outcome of HCV-uHCC who received 1st line systemic therapy, premising 2nd line systemic therapy. **Methods:** Between October 2009 and August 2022, 124 HCV-uHCC with Child-Pugh class A liver function (CP-A) and performance status of 0-1 (PS0-1) received 1st line systemic therapy, including sorafenib, lenvatinib and atezolizumab plus bevacizumab therapy, consecutively in our hospital. Among them, 110 patients who had progression on 1st line systemic therapy were enrolled (median observation periods: 16.9 mo). The factors associated with overall survival (OS), time to progression (TTP), the eligibility for 2nd line systemic therapy (maintaining CP-A and PS0-1 at the progression of 1st line systemic therapy) and post progression survival (PPS) were analyzed, including the condition of SVR at the initiation of 1st line systemic therapy. **Results:** The analyzed 110 patients were characterized by PS0/1 (n = 94/16), Child-Pugh score 5/6 (n = 67/43) and Barcelona Clinic Liver Cancer Stage A/B/C (n = 8/43/59). Thirty-eight patients had achieved SVR before the initiation of 1st line systemic therapy. Median OS, TTP and PPS was 19.4, 3.6 and 14.5 months, respectively. The achieved SVR (HR, 0.47) and Child-Pugh score 5 liver function (HR, 0.49) at the initiation of 1st systemic therapy were favorable OS factors, compared to reference defined as non-SVR and Child-Pugh score 6 liver function, respectively. PPS was longer in those with SVR (21.2 mo) than those without (12.9 mo), while TTP was similar between those with and without SVR (3.9 vs. 3.4 mo). Between the patients with and those without SVR, there were weak correlation between OS and TTP (r = 0.42 and 0.34) and strong correlation between OS and PPS (r = 0.98 and 0.98). Sixty-five patients (59.1%) were eligible for 2nd line systemic therapy. The condition of both SVR and Child-Pugh score 5 liver function at the initiation of 1st line systemic therapy (OR, 4.9) was positively associated with the eligibility for 2nd line systemic therapy, with the condition of both non-SVR and Child-Pugh score 6 liver function defined as a reference. The patients who received subsequent therapy after progression of 1st line systemic therapy had favorable PPS (HR, 0.13) compared with those who did not. **Conclusion:** HCV-uHCC with SVR would have favorable OS and favorable PPS compared with those without SVR. HCV-uHCC with both SVR and Child-Pugh score 5 liver function especially could be eligible for 2nd line systemic therapy at the progression of 1st line systemic therapy. HCV-uHCC might have favorable PPS by achieving SVR after the progression of 1st line systemic therapy.

4136-A | THE EFFECT OF CIRCULATING IMMUNE-RELATED BIOMARKERS ON THE RISK OF HEPATOCELLULAR CARCINOMA DEVELOPMENT IN THE USA

Rikita I. Hatia[1], Donghui Li[1], Ping Chang[1], Prasun Jalal[2], Ahmed O. Kaseb[1] and Manal M. Hassan[1], (1) The University of Texas MD Anderson Cancer Center, (2)Baylor College of Medicine

Background: Dysregulation of immunological networks play a key role in the development and progression of

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hepatocellular carcinoma (HCC); however, the specific immunogenic processes influencing hepatic tumor development remain incomplete. There are limited reports about circulating immune factors that may serve as markers for HCC diagnosis. We aimed to assess the associations of blood-based biomarkers involved in immune responses and HCC diagnosis. **Methods:** Between 2001 and 2014, all newly diagnosed HCC patients were ascertained as part of an ongoing IRB-approved study at The University of Texas MD Anderson Cancer Center. Control participants were selected from healthy spouses of patients who were diagnosed with cancers other than liver and gastrointestinal cancers. Blood samples were collected at time of diagnosis or enrollment and sent to Myriad RBM, Inc. to test for a panel of 30 immune-related biomarkers. Using the median values of the biomarkers among the controls as a cutoff point, all participants were categorized into subjects with high and low levels of biomarkers. Odds ratio (OR) and 95% confidence interval (CI) values were estimated using multivariable conditional logistic regression analysis with adjustment for relevant confounders. **Results:** A total of 200 HCC case patients and 200 pair-matched healthy controls (age, sex, and race) were analyzed. The mean age ($\pm$ SD) for cases was 59.72 $\pm$ 10.11 years, and for controls, it was 60.17 $\pm$ 9.53 years. Most of the study population was white (72.0%). Table 1 presents the estimated OR and corresponding 95% CIs for HCC risk among subjects with high levels of biomarkers ($>$ median values of the controls) as compared to those with low levels ($\leq$ median value of the controls) after adjusting for age, sex, race, smoking, alcohol consumption, family history of cancer, viral hepatitis, and history of type II diabetes mellitus. The table highlights the significant associations between 11 immune-related biomarkers and HCC diagnosis. For example, subjects with a high level of angiopoietin-2 had 10-fold (95% CI:2.62-4.27) increased risk for HCC compared to subjects with low levels. Restricted analysis found significant association between the biomarkers and HCC risk in the absence of viral hepatitis and may be assessed in non-alcoholic fatty liver disease patients as diagnostic markers. We also found significant variations in the biomarker distribution among HCC case patients in the presence and absence of cirrhosis (diagnosed by pathology or radiology). **Conclusion:** Eleven immune-related markers showed significant and independent association with increased risk of HCC. These observations suggest a potential value of these plasma biomarkers in predicting the risk of HCC and expanding our current understanding of the role of inflammation in HCC development. Future validation of the results in independent population will need to be assessed for independent samples of HCC cases and controls.

Table 1. Association between HCC risk and circulating immune biomarkers

Characteristics	AOR (95% CI)*	*P* Value
Angiopoietin-2	10.05 (2.62-4.27)	0.001
B Cell-Activating Factor	5.14 (1.44-18.28)	0.011
Dickkopf-Related Protein 1	6.70 (1.96-22.86)	0.002
Erythropoietin	3.61 (1.05-12.39)	0.041
FASLG Receptor	4.18 (1.02-17.15)	0.047
Interferon Gamma Induced Protein 10	4.53 (1.21-16.96)	0.025
Macrophage Inflammatory Protein-3 Alpha	14.53 (3.62-58.40)	0.000
Macrophage Inflammatory Protein-3 Beta	3.98 (1.03-16.34)	0.050
Matrix Metalloproteinase-1	5.80 (1.63-20.70)	0.007
Matrix Metalloproteinase-7	4.27 (1.16-15.66)	0.029
TNF-Related Apoptosis-Inducing Ligand Receptor 3	3.83 (1.05-13.90)	0.041

*Adjusted OR for age, sex, race, smoking, alcohol consumption, family history of cancer, viral hepatitis, and history of type II diabetes mellitus

4137-A | THE EFFICACY AND SAFETY OF ATEZOLIZUMAB & BEVACIZUMAB IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA: THE REAL WORLD DATA

Sung Hwan Yoo, Hyun Woong Lee and Jung Il Lee, Gangnam Severance Hospital

Background: Treatment responses of unresectable hepatocellular carcinoma (HCC) remain unacceptably low and treatment modalities are limited. After the IMbrave 150 trial was announced, there are still few published data on the atezolimumab and bevacizumab in South Korea. We analyzed the efficacy and safety of atezolizumab & bevacizumab based on real world data. **Methods:** In retrospective cohort study, data on 28 patients with unresectable HCC, with Child-Pugh (CP) scores of 5-8, were collected from a university hospital between September 2020 and October 2022. All patients were treated with 1200mg of atezolizumab plus 15mg per kilogram of body weight of bevacizumab intravenously every 3 weeks. **Results:** From 28 patients with unresectable HCC, 92.8% were classified as Child-Pugh (CP)-A, 64.2% as Barcelona Clinic Liver Cancer (BCLC)-C. The median overall survival (OS) and time to progression (TTP) were 11.2 months, and 3.6 months in the atezolizumab & bevacizumab group. In univariate analysis, operation, European Cooperative Oncology Group, sodium level, PIVKA-II, hepatic encephalopathy,

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ascites, Child-Pugh score group, maximum tumor size, were significant prognostic factors of OS (p = 0.049, 0.011, 0.004, 0.013, 0.049, 0.005, 0.013). In multivariate analysis, PIVKA-II, hepatic encephalopathy, Child-Pugh score group, maximum tumor size were significant prognostic factors of OS (p = 0.007, 0.002, 0.002, 0.008). Major complications included hyperbilirubinemia (44.8%), ALT elevation (34.5%), liver failure (14.2%), infection (2.1%), cerebral haemorrhage (0.04%), and hematuria (0.04%). **Conclusion:** For managing unresectable HCC, atezolizumab & bevacizumab may be a valuable and safe treatment modality, but long-term follow-up and large scale studies are needed in the future.

4138-A | THE EXPRESSIONS OF AUTOTAXIN–LYSOPHOSPHATIDATE SIGNALING-RELATED PROTEINS IN CHOLANGIOCARCINOMA

Xuefeng Li, Kyoto University

Background: The expression of autotaxin (ATX)-lysophospholipid (LPA) signaling-related proteins have been shown to be associated with the physiological and pathological activities of various cancers. However, little is known about the clinical implications of ATX and LPA receptors (LPAR) in cholangiocarcinoma (CCA). **Methods:** Tumor tissue samples from 110 CCA patients were evaluated. The expressions of ATX, LPAR2, and LPAR6 were detected by immunohistochemistry (IHC). Moreover, the cellular localization of ATX in the tumor microenvironment was detected by immunofluorescence (IF) staining. Furthermore, serums from 35 CCA patients (collected and frozen within 1 week before hepatectomy) and 8 healthy volunteers were determined.Serum ATX levels were measured using a fluorescent enzyme immunoassay. **Results:** In CCA tissue, correlations between ATX and LPAR2 expression (Spearman r = 0.214; p = 0.0025), LPAR2 and LPAR6 expression (Spearman r = 0.775; p ≤ 0.001) were detected.High ATX expression was associated with poorer tumor grade (p = 0.038)and lymphatic metastasis (p = 0.024). The correlation of high ATX with shorter overall survival (OS) (p = 0.005) and recurrence-free survival (RFS) (p < 0.001) was detected by Kaplan-Meier curve analysis. In Cox regression analysis, high ATX expression (p = 0.001) was an independent factor associated with shorter RFS. Serum ATX levels were significantly higher in CCA patients compared with healthy controls (p = 0.007). Additionally, female CCA patients had significantly higher serum ATX levels than male CCA patients (p = 0.017). Moreover, we also determined that in the tumor microenvironment of CCA, ATX protein was expressed in tumor cells, cancer-associated fibroblasts, plasma cells, and epithelial cells. **Conclusion:** The highlight of this study is that it provides the first clinical evidence for the involvement of ATX in human CCA. Our present study demonstrated that the increased expression of ATX may promote tumorigenesis and progression of cholangiocarcinoma, affecting the long-term survival of patients.

4139-A | THE IMPACT OF COVID-19 ON THE DIAGNOSIS AND TREATMENT OF HEPATOCELLULAR CARCINOMA: ANALYSIS OF A NATIONWIDE REGISTRY FOR ADVANCED LIVER DISEASES (REAL)

Kazuya Okushin[1], Ryosuke Tateishi[1], Shinya Hirakawa[2], Hisateru Tachimori[2], Koji Uchino[1], Ryo Nakagomi[1], Tomoharu Yamada[1], Takuma Nakatsuka[3], Tatsuya Minami[3], Masaya Sato[3], Mitsuhiro Fujishiro[3], Kiyoshi Hasegawa[1], Yuichiro Eguchi[4], Tatsuya Kanto[5], Hitoshi Yoshiji[6], Namiki Izumi[7], Masatoshi Kudo[8] and Kazuhiko Koike[3,9], (1)The University of Tokyo, Tokyo, Japan, (2)Keio University, Tokyo, Japan, (3)The University of Tokyo, (4)Saga University, Saga, Japan, (5)National Center for Global Health and Medicine, Chiba, Japan, (6)Nara Medical University, (7)Musashino Red Cross Hospital, Tokyo, Japan, (8)Kindai University Faculty of Medicine, Osaka-Sayama, Japan, (9)Kanto Central Hospital of the Mutual Aid Association of Public School Teachers, Tokyo, Japan

Background: The novel coronavirus disease 2019 (COVID-19) had a tremendous impact on the treatment status of several malignancies and chronic diseases. We aimed to clarify the clinical situation for hepatocellular carcinoma (HCC) in the era of COVID-19 using a novel nationwide REgistry for Advanced Liver diseases (REAL) in Japan. **Methods:** We retrieved patients' data initially diagnosed with HCC between January 2018 and December 2021 from REAL. We analyzed patients' characteristics, including age, sex, background etiology, laboratory data, and symptoms and treatment modalities for each admission. We compared the treatment situation of HCC in the era before COVID-19 (2018 and 2019) and in the era of COVID-19 (2020 and 2021). **Results:** We analyzed 13,671 patients initially diagnosed with HCC in the relevant period (8,020 patients in the era before COVID-19 and 5,651 patients in the era of COVID-19). In terms of the etiology of liver diseases, the proportion of non-B, non-C was increased (from 55.4% to 60.2%) in the era of COVID-19, whereas the proportions of HBV and HCV were decreased. The maximum size of intrahepatic tumors did not change in the era of COVID-19 compared with the era before COVID-19 (mean [standard deviation, SD] = 4.4 [3.9] cm and 4.4 [3.9] cm), whereas the number of intrahepatic tumors was decreased (single, 2-3, and > 3 in 72.0% and 74.2%, 22.7% and 20.8%, and 5.3% and 5.0%, respectively). The rates of vascular invasions and extrahepatic spread remained unchanged. Liver function as expressed by Child-Pugh class was also unchanged (Child A, B, and C in 80.5% and 80.5%, 16.7% and 16.5%, and 2.8% and 3.0%, respectively). Overall, HCC was diagnosed in similar BCLC stages (0, A, B, C, and D in 19.5% and 18.8%, 26.9% and 26.6%, 35.4% and 35.3%, 14.9% and 15.9%, and 3.2% and 3.4%, respectively). Regarding treatment modality, systemic therapy was increased in the era of COVID-19 (from 3.7% to 6.8%). Stratified with the etiology, HCC was diagnosed at similar BCLC stages before and during the era of COVID-19 in HBV and non-B, non-C, whereas at later BCLC stages in HCV. In the HCV group, the number of intrahepatic tumors decreased (single, 2-3, and > 3 in 72.1% and 75.5%, 23.1% and 20.4%, and 4.8% and 4.1%, respectively), but the proportion of portal vein invasion increased (from 9.2% to 12.0%). **Conclusion:** The treatment status of HCC remained largely unchanged during the COVID-19 pandemic in Japan, but the impact varied according to etiology. The maximum size of intrahepatic tumors remained unchanged, and more patients were diagnosed with single nodule HCC in the era of COVID-19. These results might indicate the robustness of the HCC surveillance system in Japan.

4140-A | THE PROGNOSTIC EFFICACY OF BILIARY DRAINAGE IN HCC WITH BILE DUCT INVASION: A MULTICENTER RETROSPECTIVE COHORT STUDY WITH PROPENSITY SCORE MATCHING

Keungmo Yang[1], Hyun Yang[1], Chang Wook Kim[1], Heechul Nam[1], Ji Hoon Kim[1], Ahlim Lee[1], U Im Chang[1], Jin Mo Yang[1], Hae Lim Lee[1], Jung Hyun Kwon[1], Soon Woo Nam[1], Soon Kyu Lee[1], Pil Soo Sung[2], Ji Won Han[1], Jeong Won Jang[1], Si Hyun Bae[1], Jong Choi[1], Seung Kew Yoon[1] and Hee Yeon Kim[1], (1)The Catholic University of Korea, (2)The Catholic University Liver Research Center, Department of Biomedicine & Health Sciences, College of Medicine, the Catholic University of Korea

Background: Bile duct invasion (BDI) is rarely observed in advanced hepatocellular carcinoma (HCC), which can lead to hyperbilirubinemia. Nevertheless, it remains uncertain whether pre-treatment biliary drainage is effective for HCC patients with BDI and obstructive jaundice. This research aims to investigate the impact of biliary drainage on the prognostic outcomes of these patients. **Methods:** We retrospectively enrolled a total of 200 HCC patients with BDI from multicenter cohorts. Patients without obstructive

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

jaundice (total bilirubin level < 3 mg/dL; n = 99) or those who did not undergo HCC treatment (n = 37) were excluded from the further analysis. Finally, 64 patients with obstructive jaundice (43 with drainage and 21 without drainage) were included, and propensity score matching (PSM) was conducted. The modalities of biliary drainage were percutaneous transhepatic biliary drainage or endoscopic retrograde cholangiopancreatography. **Results:** Alpha-fetoprotein ($\geq$ 400 ng/mL) and the duration between BDI diagnosis and HCC treatment were significantly different variables in baseline characteristics between the groups receiving biliary drainage and those without drainage in HCC patients with obstructive jaundice. The biliary drainage group showed better overall survival (Median OS, 8.9 vs. 2.9 mo; $P = 0.006$) and progression-free survival (Median PFS, 4.5 vs. 2.0 mo; $P = 0.009$) compared to the non-drainage group. Multivariate analysis demonstrated that biliary drainage was a significantly favorable prognostic factor for OS (Hazard ratio 0.44, $P = 0.013$) and PFS (Hazard ratio 0.44, $P = 0.086$). Furthermore, the biliary drainage presented the beneficial results in the first response evaluation after HCC treatment ($P = 0.001$). Remarkably, there were similar results in OS ($P = 0.014$) and PFS ($P = 0.007$) after PSM analyses. **Conclusion:** Biliary drainage is an independent favorable prognostic factor for HCC patients with BDI and obstructive jaundice. Therefore, this study suggests that biliary drainage should be contemplated in the treatment of advanced HCC patients with BDI for better survival outcomes.

4141-A | THE ROLE OF ALFA-FETOPROTEIN IN HCC SURVEILLANCE IN A NATIONAL HEALTH INSURANCE CLAIMS DATABASE

Sang Bong Ahn[1], Dae Won Jun[2], Joo Hyun Oh[3] and Eileen Yoon[2], (1)Nowon Eulji Medical Center, (2) Hanyang University College of Medicine, (3)Eulji Medical Center

Background: Early detection of HCC increases the possibility of receiving curative treatment and is a very important factor in improving survival rate. Abdominal ultrasonography and serum AFP are the most commonly used methods for HCC surveillance. However, the role of AFP in HCC surveillance has not yet been established. This study aimed to investigate the management status of high-risk patients with HCC and the effect of AFP test on survival using National Health Database. **Methods:** We used data from the National Health Claims Database established by the National Health Insurance Service (NHIS) of Korea. The HCC patients were defined as all patients with newly diagnosed HCC (C22.0) between 2008 and 2014. **Results:** From 2008 to 2018, 185,316 patients were registered with KNHIS with HCC, and 81,520 patients newly diagnosed with HCC between 2008 and 2014 were enrolled in the study analysis. In all HCC patients, the survival rate was significantly higher when the AFP test was performed 3 or more times during the 2 years before HCC diagnosis. When analyzed by causative disease, HBV patients showed a marked increase in survival rate as the number of AFP tests increased compared to alcohol and HCV patients. **Conclusion:** In HCC surveillance, AFP is helpful in improving survival rates. In particular, hepatitis B patients showed a significant increase in survival rate

4142-A | THE USEFULNESS OF THE MUSCLE ATROPHY AND SUBCUTANEOUS ADIPOSE TISSUE RADIODENSITY IN PREDICTING THE PROGNOSIS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Masatsugu Ohara[1], Goki Suda[1], Takashi Kitagataya[2], Masato Nakai[3], Takuya Sho[1], Koji Ogawa[1] and Naoya Sakamoto[1], (1)Hokkaido University Hospital, (2)Mayo Clinic, (3)Hokkaido University Hospital, Sapporo, Japan

Background: Evaluation of skeletal muscle mass in patients with hepatocellular carcinoma (HCC) is considered as useful for predicting prognosis and identifying patients who are eligible for nutritional and exercise therapy. Although there are several methods of assessing skeletal muscle mass, we have previously reported that psoas muscle mass index (PMI) by manual tracing is more useful than BIA and PMI cutoff values. Recently, it has also been reported that subcutaneous adipose tissue (SAT) radiodensity affect the prognosis of patients with chronic liver disease including HCC. Therefore, we aimed to evaluate whether the PMI cutoff values in Japanese patients with HCC can be used to assess prognosis, and to evaluate whether the

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prognosis can be further stratified by PMI and SAT radiodensity. **Methods:** We retrospectively evaluated 201 patients with HCC who underwent CT and had muscle mass evaluated at our hospital between July 2015 and May 2021. Skeletal muscle mass was measured in the iliopsoas muscle in the L3 region using the manual tracing method, and we reported the cut off values (3.74 cm^2/m^2 for men and 2.29 cm^2/m^2 for women). SAT radiodensity were calculated using the previously reported cut off values (-83 HU for men and -74 HU for women, normal when lower than the cutoff values, and High SAT when higher than the cutoff values). **Results:** Patient characteristics was as follows: median age 71 years, 154 males, Child Pugh classification (A, B or C): 155 / 46, cirrhosis: 146, median observation period: 2.8 years. Muscle atrophy (MA) was observed in 67 patients (33.3%), and the patients with MA were significantly worse prognosis in the patients without MA (hazard ratio, HR 1.88; 95% confidence interval [CI] 1.18 - 2.99; $p < 0.004$). Prognosis stratified by SAT radiodensity was also significantly worse in the patients with high SAT radiodensity (HR 2.66; 95% CI 1.18 - 5.958; $p < 0.001$), as previously reported. Finally, stratification by MA and SAT radiodensity into 4 groups showed significantly different prognoses, and especially the patients with MA and high SAT had a poor prognosis (median OS in the patients without MA and with or without high SAT was undefined, 4.29 years in the patients with MA and without high SAT, and 1.04 years in the patients with MA and with high SAT; $p = 0.0017$). Furthermore, among the patients with Child-Pugh grade A, the patients with MA tended to be poor prognosis ($p = 0.05$), and the patients with high SAT had similar prognosis ($p = 0.12$). While, the patients with MA and high SAT had a significantly poorer prognosis (HR 3.48; 95% CI 1.03 - 11.7; $p = 0.044$). **Conclusion:** Combined evaluation of MA and SAT radiodensity can stratify the poor prognosis group in hepatocellular carcinoma and may serve as an evaluation item during nutritional intervention.

4143-A | THE VALUE OF HIFI MODEL BASED ON cfDNA GENOMIC FEATURES IN EARLY DIAGNOSIS AND PREDICTION OF HEPATOCELLULAR CARCINOMA

Linhan Li[1], Xiaobo Lu[2], Xiaozhong Wang[3], Xuan An[4], Quan Zhang[5], Hong Ren[1], Peng Hu[1], Dachuan Cai[1], Yinghua Lan[1], Dazhi Zhang[1] and Juan Kang[1], (1)Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital of Chongqing Medical University, (2)The First Affiliated Hospital of Xinjiang Medical University, (3)The Fourth Affiliated Hospital of Xinjiang Medical University (Xinjiang Hospital of Traditional Chinese Medicine), (4)Chongqing University Three Gorges Hospital, (5)The Affiliated Hospital of Guizhou Medical University

Background: The detection of cell-free DNA (cfDNA) is a promising early diagnosis method for hepatocellular carcinoma (HCC). We validated the cfDNA-based comprehensive diagnostic model (HIFI) and explored its value in the early diagnosis and prediction of HCC. **Methods:** cfDNA detection was performed in 126 patients with or without chronic liver disease from 5 centers, multi-dimensional gene variation indicators were analyzed, the results of HIFI was obtained and compared with imaging or HCC markers to evaluate the advantages of HIFI model compared with traditional methods. Moreover, we also conducted long-term follow-up to evaluate the predictive value of HIFI model in the occurrence of HCC. In addition, the sensitivity, specificity, PPV, and NPV of the aMAP score and HIFI models were compared at 10 months of follow-up to assess their predictive value for HCC. **Results:** Chi-square test and Kappa analysis showed that the diagnostic consistency between HIFI model and traditional methods (i.e., biopsy, hepatic arteriography, etc.) was significantly higher than that of AFP and PIVKA-II (Kappa = 0.461 vs 0.251 vs 0.287, $P \leq 0.05$). Moreover, the consistency of HIFI model combined with PIVKA-II was significantly higher than that of AFP combined with PIVKA-II and HIFI model combined with AFP (Kappa = 0.564 vs 0.267 vs 0.317, $P \leq 0.05$). During follow-up, a total of 103 patients were invovled with a median time of 11.5 months, the consistency of the HIFI model with traditional diagnostic methods was kappa = 0.530 at the 3 months($P = 0.000$). In addition, we used the HIFI model as a predictive model and compared it with the aMAP score at 10 months, the sensitivity, specificity, PPV and NPV of HIFI model in predicting HCC was 70.59%, 91.84%, 75.00% and 90.00%. When 50/60 is seted as the cut-off value of aMAP score, the sensitivity, specificity, PPV and NPV was 94.12/76.47%, 26.53/71.43%, 30.77/ 48.15% and 92.86 /89.74%. **Conclusion:** The study demonstrated the superiority of the cfDNA-based HIFI model as a method of early warning and diagnosis of HCC compared with the traditional serum markers AFP and PIVKA-II. Moreover, the predictive efficacy of the HIFI model remained high at 10 months, in terms of specificity and PPV, the HIFI model was even better than the aMAP score. Especially for non-HCC patients with negative HIFI result, the probability of progression to HCC in 10 months was very low. HIFI combined with PIVKA-II may be a reliable

4144-A | THERAPEUTIC EFFECTS OF GNMT INDUCERS FOR NON-ALCOHOLIC FATTY LIVER DISEASE AND HEPATOCELLULAR CARCINOMA

Yi-Ming Arthur Arthur Chen, Fu Jen Catholic University; National Health Research Institutes

Background: Glycine-N-methyl transferase (GNMT) downregulation results in nonalcoholic fatty liver disease (NAFLD) and spontaneous hepatocellular carcinoma (HCC) both. Overexpression of GNMT inhibits the accumulation of lipid in hepatocytes, the proliferation of liver cancer cell lines and prevents carcinogen-induced HCC, suggesting that GNMT induction is potential approaches for anti-NAFLD and anti-HCC therapy. **Methods:** Herein, we used Huh7 GNMT promoter-driven screening to identify two GNMT inducers from natural plant extracts library and small molecule library. First, 1,2,3,4,6-pentagalloyl glucose (PGG) was identified from the extract of Paeonia lactiflora Pall (PL). Second, compound K78 was identified and validated for its induction of GNMT and inhibition of Huh7 cell growth. Subsequently, we employed structure−activity relationship analysis and found a potent GNMT inducer, K117. The GNMT expression was further confirmed by reverse transcription-quantitative PCR (RT-qPCR) and Western blotting (WB) analysis using both in vitro and in vivo systems. **Results:** PGG and metformin were shown to upregulate liver mitochondrial GNMT protein expression. The high-fat diet (HFD)-induced NAFLD mice were treated with PGG and metformin. The combination of PGG and metformin nearly completely reversed weight gain, elevation of serum aminotransferases, and hepatic steatosis and steatohepatitis. In addition, the downregulated GNMT expression in liver tissues of HFD-induced NAFLD mice was restored. On the other hand, K117 inhibited Huh7 cell growth in vitro and xenograft in vivo. Oral administration can inhibit Huh7 xenograft in a manner equivalent to the effect of sorafenib. A mechanistic study revealed that both PGG and K117 are MYC inhibitors. Ectopic expression of MYC using CMV promoter blocked PGG- and K117-mediated MYC inhibition and GNMT induction. **Conclusion:** Our findings show that GNMT expression plays an important role in the pathogenesis of NAFLD and HCC, PGG and K117 are potential compounds for NAFLD-, HCC- and MYC-dependent cancers.

4145-A | THERAPEUTIC EXPERIENCE WITH HEPATECTOMY FOR INTRAHEPATIC RECURRENCE AFTER RADIOTHERAPY IN LIVER TUMORS: IMPLICATION OF THERAPEUTIC EFFECT BY PD-L1 ELEVATION VIA RADIATION

Keisuke Oyama, Yoshifumi Iwagami, Shogo Kobayashi, Kazuki Sasaki, Daisaku Yamada, Yoshito Tomimaru, Takehiro Noda, Hidenori Takahashi, Yuichiro Doki and Hidetoshi Eguchi, Osaka University

Background: Radiation therapy for liver tumors has become widespread with the development of stereotactic body radiotherapy (SBRT) and reported to have a high local therapeutic effect. Radiation therapy could affect tumor immunity not only locally but also outside the irradiation site. Based on the experience of hepatectomy for local recurrence after radiotherapy, we investigated the effects of radiotherapy for liver tumors on operative course and tumor immunity. **Methods:** From 2010 to 2022, we retrospectively analyzed patients who underwent hepatectomy for recurrence of the irradiated site after radiotherapy for liver tumors. Excluding radiotherapy for cholangiocarcinoma, 48 patients underwent radiotherapy for liver tumors. Of the 6 patients who underwent surgery, 1 patient with recurrence of liver tumor outside the irradiation site was excluded. Surgical course and pathological findings were investigated in 3 recurrence cases of hepatocellular carcinoma and 2 cases of metastatic colorectal cancer. **Results:** SBRT (50-55Gy/5 or 10fr) was performed for recurrent or refractory tumor after prior hepatectomy or transcatheter arterial chemoembolization (TACE). Tumor could be controlled temporarily after SBRT, however, recurrence occurred after 2.4 (0.9-5.5) years at the irradiation site. All 5 patients underwent hepatectomy for local lesions at the irradiation site. Only mild hepatic-diaphragmatic adhesions and hepatic atrophy were observed in surgical

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

findings. No postoperative complications were observed in any of the patients. There were no patients with decreased liver function or nutritional indicators (cholinesterase and albumin) 3 months after surgery. In the resected specimen, necrosis associated with radiotherapy was observed in the tumor area. Inflammation and fibrosis in the surrounding non-cancerous area did not show any clear changes compared to the previous operation. Expression of CD68 and PD-L1 was observed around the tumor on immunohistochemistry. While SBRT had a strong therapeutic effect on the tumor, a decrease in tumor immunity might be indicated around the irradiated tumor site. No recurrence was observed 3.2 (0.9-5.1) years after surgery. In all cases, no intrahepatic recurrence and metastases was observed outside the irradiation site after radiotherapy. **Conclusion:** Hepatectomy for recurrence of the irradiated site after SBRT was performed successfully without complications. Although tumor immunosuppression might be induced after radiotherapy in the irradiated site for liver tumors, tumor recurrence outside the irradiated site were not observed.

4146-A | TISLELIZUMAB IN COMBINATION WITH ANLOTINIB AS FIRST-LINE TREATMENT FOR UNRESECTABLE HEPATOCELLULAR CARCINOMA: A SINGLE-CENTER, SINGLE-ARM, EXPLORATORY PHASE II CLINICAL STUDY

Shixue Laoguo, Huasheng Huang, Jie Zeng, Yangfeng Jiang, Cuizhen Liu, Ning Mo, Guangzhi Zhu, Fuchao Ma, Tao Peng, Lihua Yang, Zhiming Zeng and Jie Ma, The First Affiliated Hospital of Guangxi Medical University

Background: Patients with advanced hepatocellular carcinoma (HCC) have limited therapeutic options and poor overall prognosis. Programmed cell death protein-1(PD-1) inhibitors combined with tyrosine kinase inhibitors (TKIs) has demonstrated excellent clinical efficacy in the treatment of multiple malignancies. Therefore, based on the clinical results of tislelizumab (anti-PD-1 antibody) and anlotinib (a multi-target tyrosine kinase inhibitor) in HCC, we evaluated the efficacy and safety of tislelizumab in combination with anlotinib in patients with postoperative recurrence or advanced HCC. **Methods:** This was a single-center, single-arm, phase II clinical trial. Key inclusion criteria: aged 18-75 years, with unresectable HCC, ECOG PS 0-3, BCLC stage A-C and Child-Pugh score A-C were enrolled. Patients who met the inclusion criteria received tislelizumab (intravenous drip, 200 mg/d1, Q3W) and anlotinib (oral, 8-12 mg/d1-14, Q3W). The primary endpoint was objective response rate (ORR) per mRECIST. The secondary endpoints included disease control rate (DCR), overall survival (OS), progression-free survival (PFS), adverse events (AEs), and serious adverse events (SAEs). **Results:** In this study, a total of 30 HCC patients were enrolled from September-2020 to December-2021. They were followed up and their clinical data were tracked. The median age of the pts was 52.5 years (ranged 31-72 y), 17 pts (53.1%) ECOG PS 1, 19 pts (63.3%) BCLC stage C, 20 pts (66.7%) Hepatitis B virus infection and 14 pts (46.7%) had received prior local regional therapy. The ORR per mRECIST was 30% (95% CI, 12.6%-47.4%), with 6.7% (2/30) complete response (CR), 23.3% (7/30) partial response (PR), and 46.7% (14/30) stable disease (SD). The DCR was 76.7%(95%CI,60.6%-92.7%) With a median follow-up of 18.2 months, the estimated median PFS was 11.8 months, and the median OS was not reached. The most common AEs during follow-up were AST increased (53.3%), γ-GT increased (46.7%), and hypoalbuminemia (43.3%). No SAEs were observed. **Conclusion:** Tislelizumab combined with anlotinib in the treatment of unresectable HCC has showed high antitumor activity and good tolerance, which may be an effective and safe treatment option.

4147-A | TRANS ARTERIAL CHEMOEMBOLIZATION COMBINED WITH RADIOFREQUENCY ABLATION PROVIDES A BETTER OUTCOME IN HEPATOCELLULAR CARCINOMA IN TUMORS WITHIN MILAN CRITERIA

Mithun Sharma[1], Jagdeesh Singh[2], Padaki Nagaraja Rao[1], Sowmya T R[1], Manasa Alla[1], Anand V. Kulkarni[1] and Nageshwar D. Reddy[1], (1)Aig Hospitals, Hyderabad, India, (2)Asian Institute of Gastroenterology, Hyderabad, Telangana, India

Background: Transarterial chemoembolization (TACE) combined with radiofrequency ablation (RFA) is hypothesized to offer a better complete response when compared with TACE alone for tumors within the Milan

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

criteria. However, the data is scarce. Therefore, this study aimed to evaluate and compare the efficacy of sequential use of TACE plus RFA (TACE + RFA) versus RFA alone in HCC. **Methods:** This was a retrospective analysis of patients undergoing TACE +RFA and was compared with TACE alone. Since this was a retrospective review, the selection of patients in either arm was based on the preference of the interventional radiologist. The primary outcome was to compare response at 3 months, overall survival (OS) at 1 year, and disease-free survival (DFS). **Results:** Out of a total of 51 patients with a tumor size of 6.2. ± 2.3 cms, 26 patients underwent TACE + RFA. Majority (80%) of patients were in CHILD PUGH A/B and were not ready for a surgical intervention or liver transplantation. Complete response(CR) and partial response (PR) at 3 months as per the mRECIST criteria were noted in 18/26(69.2%) vs 16/25 (64%) and 4/26(15.2%) vs 10/25 (40%)patients respectively with TACE + RFA vs TACE alone. 3(11.56%) vs 3 (12%) in both arms had stable disease. The OS at 1 yr was better in the TACE+RFA arm [23(88.46%) when compared to TACE alone arm [20(80%)] . The rate of complications and duration of hospital stay was not different between the two arms. **Conclusion:** TACE + RFA vs TACE alone had similar short-term outcome though there was trend towards a better overall survival at the end of 1 year with similar rates of adverse event

4148-A | TREATMENT WITH GEMCITABINE/CISPLATIN AND DURVALUMAB FOR BILIARY TRACT CANCER – FIRST REAL-WORLD DATA FROM A GERMAN PATIENT COHORT

Florian Gerhardt[1], Christian Müller[2], Jack Chater[3], Aaron Schindler[1], Sebastian Ebel[4], Marino Venerito[5], Thomas Berg[4] and Florian Van Bömmel[1], (1)University Hospital Leipzig, (2)University Hospital Magdeburg, (3) Klinikum Chemnitz, (4)University Hospital of Leipzig, (5) Otto-Von-Guericke Universität Magdeburg

Background: Biliary tract cancers (BTC) is a rare and heterogenous disease with poor prognosis. Based on the results of the TOPAZ-1 trial, the combination therapy of gemcitabine and cisplatin with the immune checkpoint inhibitor durvalumab (GC+D) has recently been approved in Europe and in the US for the treatment of BTC. However, the role of this treatment outside of clinical studies has not yet been studied. We have studied tolerability and efficacy of GC +D in real-world patients. **Methods:** We retrospectively included patients treated with GC+D in German tertiary medical centers. Before approval of durvalumab, patients were treated based on cost approval by the their health insurance. Response was defined by RECIST1.1 criteria based on tomography after 12 weeks of treatment. Adverse events were categorized by CTCAE. **Results:** A total of 36 patients were treated with GC+D in 3 participating centers between August 2022 and May 2023 hereby receiving a mean of 4 (range, 1-11) cycles over a mean duration of 18 ± 13 (range, 4-60) weeks. Twenty-six, 7, 2 and 1 patient were in the age groups < 70, 70-75, 76-80 and > 80 years, respectively, 21 (58%) were female and 2 had liver cirrhosis. ECOG performance status grades were 0, 1 and 2 in 14, 21 an 1 patient. Nineteen patients had intrahepatic, 12 extra hepatic cholangio carcinoma and 5 gall bladder carcinoma. Staging after 12 weeks was performed in 20 patients, hereby showing stable disease in 8 (40%), partial response in 3 (15%) and progressive disease in 9 patients (45%). At the last reported staging, complete response was found in 1 (15%), stable disease in 8 (40%) and progressive disease in 9 (45%) patients. Grade 3/4 adverse events occurred in 5 patients and included anemia, thrombocytopenia and neutropenia. 3 patients had to stop treatment due to side effects. Immune-mediated side effects did not occur. Second line treatment was given to 6 patients, including FOLFOX (n = 3) and ivosidenib (n = 3). Fife patients died 1, 3, 3 and 6 months after GC+D treatment initiation due to thrombosis (n = 1) or cholangitis (n = 4), all of which were ECOG 1 or 2 at treatment initiation. **Conclusion:** The addition of durvalumab to gemcitabine and cisplatin did not lead to immune mediated side effects in this real-world cohort. Longer follow up and larger patient populations are needed to define the role of GC+D treatment for BTC outside of clinical trials.

4149-A | TUMOUR SEEDING WITH BIOPSY OF HEPATOCELLULAR CARCINOMA—A SYSTEMATIC REVIEW

Chunpeng Nie[1], Marcus Vaska[2], Jason Wong[1], Oliver F. Bathe[1], Stefan Przybojewski[1], Kelly Warren Burak[1], Patricia A. Tang[1] and Stephen E. Congly[1], (1)University of Calgary, (2)Alberta Health Services

Background: Biopsy of hepatocellular carcinoma (HCC) is not frequently done as contrast-enhanced imaging is generally able to provide a diagnosis non-invasively, and the potential risk of seeding remains a concern. However, biopsies of malignant liver masses may be valuable to

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

confirm a diagnosis of HCC to allow for selection of appropriate chemotherapy when imaging is inconclusive. A systematic review of the literature was conducted to understand the overall risk of tumour seeding with biopsy of HCC. **Methods:** EMBASE, MEDLINE (Ovid), CINAHL and Web of Science were reviewed from inception until August 31, 2022, with the search strategy design assisted by a medical librarian. Inclusion criteria were prospective or retrospective human cohort studies including randomized control trials (RCTs) and case series of any percutaneous liver biopsy of a lesion found to be a HCC, with the outcome of tumour seeding being reported. Studies reporting on non-liver cancers or seeding after intervention were excluded. Two individual's independently screened abstracts and extracted data; discrepancies were resolved by consensus. **Results:** A total of 2339 unique abstracts were identified. 94 underwent full text review and 37 studies were included in the analysis. All studies were retrospective in nature. 43% of the studies were from Asia, 38% from Europe and 16% from North America. The overall rate of tumour seeding was 0.62% (range 0-7.77%) in 13,959 biopsies performed. The average of the reported median lengths of follow-up was 35.8 months (range 10.5-60 mo). The mean duration between biopsy and diagnosis of cancer was 17.2 months. Risk factors for seeding reported included large tumour sizes and increased number of passes. **Conclusion:** Overall, the risk of tumour seeding with biopsy of HCC is low, and if clinically indicated the seeding risk should not preclude biopsy.

4150-A | UNCOVERING THE BURDEN OF BILIARY TRACT CANCER IN ASIA: GLOBAL BURDEN OF DISEASE STUDY PERSPECTIVES

Panisara Fangsaard, Bassett Medical Center, Pojsakorn Danpanichkul, Chiang Mai University, Natchaya Polpichai, Weiss Memorial Hospital, Aunchalee Jaroenlapnopparat, Mount Auburn Hospital/ Harvard Medical School, Chawin Lopimpisuth, University of Miami/Jackson Memorial Hospital and Karn Wijarnpreecha, University of Arizona College of Medicine Phoenix, Phoenix, AZ

Background: Biliary tract cancer (BTC) is the second most common type of hepatobiliary cancer worldwide and is known for its high mortality rate due to its advanced stage at diagnosis. The incidence of BTC varies globally, with certain regions in Asia exhibiting exceptionally high rates. However, research focusing on the disease burden in Asia is relatively scarce compared to the Western regions. To address the existing healthcare disparities, our study evaluated the burdens of BTC in Asia among all age groups, specifically in Southeast Asia (SEA) and the Western Pacific (WP). **Methods:** We retrieved the data from the Global Burden of Disease study to conduct a comprehensive analysis of the BTC burdens, including the incidence, mortality, and disability-adjusted life years (DALYs) of BTC across SEA and WP regions, from 2010 to 2019. The study also examined the trends and disparities in the burden of BTC across different nations and genders. **Results:** In 2019, the WP region had a higher incidence of BTC when compared to SEA (75,891 vs. 41,295). Over the study period, there was an increase in the BTC incidence rate in SEA (APC +0.62). In contrast, WP exhibited a decline (APC-1.62). Furthermore, the mortality trend decreased in WP (APC–1.78) but increased in SEA (APC+0.46). Nevertheless, the overall mortality in 2019 was higher in WP (65,405) than in SEA (39,373). In the SEA region, females carried greater burdens of BTC than males, with higher incidence (24,966 vs. 16,328), mortality

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(24,065 vs. 15,307), and DALYs (588,478 vs. 374,093). These burdens exhibited increasing trends among SEA's females, with rising incidence (APC+0.75), mortality (APC+0.60), and DALYs (+0.41). **Conclusion:** All burdens of BTC in WP remained high in 2019 despite decreasing trends over the past decade. In contrast, SEA experienced a significant increase in the overall incidence and mortality rates, posing potential healthcare burdens in the near future. Additionally, females in SEA experienced significantly increasing rates in the incidence, mortality, and DALYs associated with BTC, while males showed opposite trends regarding DALYs. These findings emphasize the urgent need for studying BTC within specific Asian regions. Further research is required to elucidate the underlying cause of this high-burden disease with gender disparities.

4151-A | UNMET SYSTEMIC THERAPY NEED FOR CHILD-PUGH CLASS B PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA – COMPARISON OF ATEZOLIZUMAB PLUS BEVACIZUMAB AND LENVATINIB

Hideko Ohama[1,2,3], Atsushi Hiraoka[1,2], Toshifumi Tada[2], Masashi Hirooka[2], Kazuya Kariyama[2], Ei Itobayashi[2], Tsuji Kunihiko[2], Toru Ishikawa[2], Hidenori Toyoda[2], Takeshi Hatanaka[2], Satoru Kakizaki[2], Atsushi Naganuma[2], Tomomitsu Matono[2], Fujimasa Tada[1,2], Kazuhiro Nouso[2], Yoichi Hiasa[2] and Takashi Kumada[2], (1)Ehime Prefectural Central Hospital, (2)Relpec Study Group and HCC 48 Group, (3)Takarazuka City Hospital

Background: Systemic treatment is generally recommended for unresectable hepatocellular carcinoma (uHCC) patients with Child-Pugh (CP)-A status. However, not all who undergo systemic treatment have good hepatic function, as some are known to develop poor hepatic function as a clinical manifestation. Given the urgent need for effective therapeutic strategies to treat u-HCC patients with CP-B, this study was conducted to compare the efficacy of lenvatinib (LEN) with that of atezolizumab plus bevacizumab (Atez/Bev). **Methods:** A total of 145 uHCC patients with ECOG performance status 0 or 1 and CP-B liver function who received Atez/Bev (n = 53) or LEN (n = 92) as initial systemic treatment from April 2018 to December 2022 were enrolled. Therapeutic response, evaluated using RECIST version 1.1, as well as clinical features and prognosis were retrospectively evaluated. **Results:** Median age for all patients was 71 years (interquartile range 61-77) and 113 (77.9%) were male. CP score was 7 for 105, 8 for 31, and 9 for 9 patients, while median ALBI score was -1.71. The Atez/Bev and LEN groups did not differ significantly for best response (complete response:partial response:stable disease: progressive disease = 0:12:20:12 vs. 5:22:24:19, p = 0.265). Also, there was no significant difference for progression-free survival (PFS) between them [median 5.7 (95% CI 3.6-7.9) vs. 4.4 (95% CI 3.5-5.9) months, p = 0.581]. Post-progression treatment was performed in 27.8% (5/18) of treatment failure cases in the Atez/Bev group and in 38.3% (23/60) of those in the LEN group (p = 0.58). Adverse events (AEs) (any grade/ ≥ grade 3) were observed in 83.0%/36.4% (n = 44/16) of the Atez/Bev group and 78.3%/36.1% (n = 72/26) of the LEN group (p = 0.53 and p = 1.0, respectively). **Conclusion:** PFS, post-progression treatment rate, and incidence of AEs were not significantly different between the Atez/Bev and LEN groups. Although both treatments showed equivalent effects, neither demonstrated sufficient therapeutic efficacy in the present cases. Development of an effective systemic therapy for uHCC patients with CP-B is needed in the near future.

Ashna Fatima Kamal[7], Dushyant Dahiya[8] and Sunny Patel[1], (1)Jacobi Medical Center/Albert Einstein College of Medicine, (2)Lincoln Medical Center, (3)The Brooklyn Hospital Center, (4)Santa Clara Valley Medical Center, (5)Hackensack Meridian Jersey Shore University Medical Center, (6)Loyola University Medical Center, Chicago, IL, (7)Southern Illinois University (SIU)), (8)The University of Kansas School of Medicine

Background: Portal vein thrombosis (PVT) is considered a negative prognostic factor in hepatocellular carcinoma (HCC) patients. Our study is the first to compare the baseline characteristics, hospital utilization, and outcomes associated with PVT in HCC patients across different racial groups within the United States (US). **Methods:** This is a retrospective longitudinal study of patients with a primary diagnosis of HCC. We retrieved data from the Nationwide Inpatient Sample (NIS) databases from the years 2016 to 2020 using ICD-10 CM codes. Multivariate regression analysis was applied to compare the outcomes in races, adjusted for patient and hospital confounders. A T-Test and Chi-Square test were performed to compare baseline characteristics (table 1). We used STATA® Version 17.0 Software for analysis. The p-value was set at $p < 0.05$ for statistical significance. **Results:** Among a total of 310,774 adults with HCC, 81% (N = 252,455) had PVT. Hispanic patients had the highest rate of PVT among all races. Black and Hispanic patients were found to have a lower income ($p = 0.00$) (table 1). Hispanic patients had a significant increase in total healthcare costs (coefficient: 39,753 US Dollars, $p = 0.006$, CI 95%: 11,260 - 68,2461) and higher (3+) Charlson Comorbidity Index ($p = 0.00$) as compared to Whites. Black patients had a higher mean length of stay (5.32 d, $p = 0.00$). In terms of the outcomes, Black patients had lower rates of portal hypertension (36.5%, $p = 0.00$) and esophageal varices without bleeding (18.4%, $p = 0.00$) as compared to White patients. Hispanic patients had lower rates of ascites (34.8%, $p = 0.00$). Black patients had the highest rate of inpatient mortality (15.2%, $p = 0.02$) and cardiac arrest (3.15%, $p = 0.00$). However, there was no significant difference found in terms of acute liver failure, intestinal infarction, inferior vena cava thrombosis, acute respiratory failure, or renal impairment among all race cohorts. **Conclusion:** Although Black patients had lower rates of complications related to PVT in HCC compared to other races, our study found that they had higher rates of cardiac arrest and mortality. This suggests that while Black patients may experience fewer PVT-related complications, they face significant risks of severe outcomes including higher mortality. Large-scale studies are necessary to determine factors associated with these findings.

4153-A | UNVEILING THE IMPACT OF HYPONATREMIA ON MORBIDITY, MORTALITY, AND RESOURCE UTILIZATION IN HEPATOCELLULAR CARCINOMA: FIVE YEAR NATIONWIDE ANALYSIS 2016-2020

Vikash Kumar[1], Fnu Vikash[2], Yassine Kilani[3], Uchit Thapa[4], Sindhu Vikash[2], Vijay Gayam[1] and Naresh Kumar[1], (1)The Brooklyn Hospital Center, (2)Jacobi Medical Center/Albert Einstein College of Medicine, (3)Lincoln Medical Center, (4)Bassett Medical Center

Background: Hyponatremia has long been recognized as a crucial prognostic marker in cirrhosis. In addition, a number of studies reported that the baseline serum sodium level and survival in liver cirrhosis patients awaiting liver transplantation are well correlated as part of a model for end-stage liver disease (MELD- Na). Hyponatremia is a common electrolyte disturbance in cancer patients and has been linked to unfavorable outcomes in a variety of malignancies. Risk factors for hyponatremia in cancer patients include pain, narcotic drugs, chemotherapy, treatment-induced nausea and vomiting, hydration, physical and emotional stress. However, to the best of our knowledge, its prognostic role in the field of Hepatocellular carcinoma has been

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

less investigated. Therefore, we evaluated mortality, morbidity, and resource utilization in Hepatocellular carcinoma patients secondary to hyponatremia. **Methods:** A retrospective analysis was performed by utilizing the National Inpatient Sample database 2016 -2020 and the ICD- 10 codes were used to identify the patients > 18 years old with the principal diagnosis of Hepatocellular carcinoma. Effect of hyponatremia was studied on mortality, morbidity, and resource utilization. Continuous variables were compared using the t- test, and Categorical variables were compared using the chi-square test. Multivariable regression analyses were performed adjusting for demographics, hospital-level characteristics, and relevant comorbidities. Confounding variables were adjusted using multivariate logistic and linear regression analyses. These included: gender, race, Charlson Comorbidity Index, chronic kidney disease, congestive heart failure, cirrhosis, nephrotic syndrome, hypothyroidism, adrenal insufficiency, alcohol use disorder, and admission for hypovolemia or psychogenic polydipsia and various patient and hospital characteristics.
Results: We identified a total of 237,905 patients with primary diagnosis of Hepatocellular carcinoma in 2016 to 2020, Of whom 23.3% (55,514) had hyponatremia on presentation. Mean age was 64 years and 77.3% were male. Patients with hyponatremia had 12.8 % in-hospital mortality, while 8.5% for patients without hyponatremia. After adjusting for confounders, hyponatremia imparted higher odds of mortality (Adjusted odds ratio (aOR) for mortality 1.47, 95% confidence interval (CI): 1.35–1.61, $P < 0.01$). Hepatocellular cancer patients with hyponatremia have higher odds of Sepsis (Odd ratio = 1.72), Acute kidney injury (Odd ratio = 2.37), and Acute liver failure (Odd ratio = 1.59). Hyponatremia also resulted in higher resource utilization marked by the length of stay, and hospital charges.
Conclusion: Our research suggests that having hyponatremia with hepatocellular carcinoma increases the risk of morality, lengthens hospital stays, and raises healthcare costs.

4154-A | VALIDATION OF A MACHINE LEARNING ALGORITHM, EVENDO, FOR PREDICTING HIGH-RISK ESOPHAGEAL VARICES IN HEPATOCELLULAR CARCINOMA

Jamie Olivia Yang[1], Punya Chittajallu[1], Jihane N. Benhammou[2,3], James Tabibian[4], Arpan Arun Patel[1], Rajat Singh[5] and Tien S. Dong[1], (1)University of California, Los Angeles, (2)University of California, Los Angeles, Los Angeles, CA, (3)VA Greater Los Angeles Healthcare System, (4)Olive View-UCLA, Burbank, CA, (5)Liver Basic Research Center at University of California Los Angeles

Background: For advanced unresectable hepatocellular carcinoma (HCC), treatment with atezolizumab and bevacizumab has become the standard of care since the IMBrave 150 trial in 2020. However, treatment with antiangiogenic agents carries increased gastrointestinal bleeding risk. Therefore, patients are often required to undergo esophagogastroduodenoscopy (EGD) prior to initiating therapy, which can delay care. In 2019, the EVendo score was developed and validated as a non-invasive model to predict presence of esophageal varices (EV) in non-HCC cirrhotic patients. We sought to validate whether the EVendo score could be used to accurately predict the presence of EV and varices needing treatment (VNT) in patients with HCC. **Methods:** From 9/2004 to 12/2021, within two hospital systems, we identified 263 patients with HCC. We excluded 168 patients who did not receive an EGD after HCC diagnosis or did not lab information available. Of the remaining 95 patients, we collected clinical variables for 100 total EGDs. We included demographic data, prognostic scores (CTP, MELD-Na), and clinical parameters needed to calculate an EVendo score at the time of EGD (INR, AST, BUN, hemoglobin, platelet count, and presence of ascites). We compared the EVendo model prediction to the gold standard endoscopic report in predicting presence of EV. VNT was defined as medium or large varices, or small varices with high risk stigmata. Varices not needing treatment (VNNT) were defined as small varices without high risk stigmata or no EV. **Results:** Of the 95 patients analyzed, 50.5% were non-white, 83.15% were male, and the average age was 66.9 years. 64.2% of patients had CTP A, and 18.9% had CTP B. The average MELD-Na score was 12.35 (range 6-36). Of the 100 EGDs performed the EVEndo score had a sensitivity of 100%, specificity of 42.8% for VNT, positive predictive value of 34.9%, and a negative predictive value of 100%. A total of thirty six EGDs in this cohort could have been deferred if the EVendo score was applied **Conclusion:** The EVendo score was 100% sensitive and had a 100% negative predictive value in predicting VNT in a cohort of patients with HCC. These results are comparable to the Baveno VII criteria that have previously only been validated in non-HCC cirrhotic patients. Although additional validation cohorts are needed, this suggests that EVendo could potentially be applied in patients with HCC to avoid unnecessary EGDs, healthcare costs, and delays in initiating HCC treatment.

4155-A | VALIDATION OF THE "AMAP" SCORE FOR PREDICTING HEPATOCELLULAR CARCINOMA DEVELOPMENT IN CHRONIC HEPATITIS B PATIENTS IN THAILAND

Apichat Kaewdech[1], Suraphon Assawasuwannakit[2], Supakorn Chaiwiriyawong[1], Pimsiri Sripongpun[3], Naichaya Chamroonkul[1] and Teerha Piratvisuth[4], (1) Prince of Songkla University, (2)Prince of Songkla University, Thailand, (3)Prince of Songkla University, Hat Yai, Thailand, (4)Nkc Institute of Gastroenterology and Hepatology, Songkhla, Thailand

Background: Hepatocellular carcinoma (HCC) is a prevalent cancer worldwide, including in Thailand. Identifying high-risk patients for HCC surveillance is crucial. The aMAP score, introduced in 2020, has demonstrated accurate HCC risk prediction across various etiologies and populations. However, its external validation in Thai chronic hepatitis B patients has not been assessed. This study aimed to evaluate the aMAP score's efficacy and compare it with other risk scores for predicting HCC development in Thai chronic hepatitis B (CHB) patients. **Methods:** We retrospectively analyzed CHB patients from January 1, 2011, to December 31, 2019. Data on demographics, clinical parameters, cirrhotic status, HCC imaging, and AFP were collected to calculate the aMAP score (0-100) based on age, gender, albumin-bilirubin, and platelets. The aMAP score's predictive accuracy was assessed using time-dependent area under the receiver operating characteristic (AUROC) curve. **Results:** The study included 1060 eligible CHB patients with a mean follow-up time of 8.6 years, and 124 patients (11.7%) developed HCC. The cumulative HCC incidences in the aMAP low-, moderate-, and high-risk groups at 1, 3, 5, and 10 years were significantly different (log-rank $P < 0.0001$) (Figure 1A). The aMAP score's AUROCs for HCC prediction at 1, 3, 5, and 10 years were 0.696, 0.714, 0.732, and 0.740, respectively. Among the risk scores, CU-HCC had the highest AUROCs (0.800), followed by REACH-B (0.748), aMAP (0.732), PAGE-B (0.722), and mPAGE-B (0.719) (Figure 1B). **Conclusion:** The aMAP score is a valuable tool for predicting HCC risk in Thai CHB patients and can enhance surveillance strategies. Nonetheless, its performance was inferior to CU-HCC, suggesting the need for new predictive tools for HCC surveillance.

4156-A | Y-90 MICROSPHERE TREATMENT OF HEPATOCELLULAR CARCINOMA (HCC) PATIENT-DERIVED TUMOROIDS AND CELL LINES REVEALS HETEROGENEITY OF RESPONSE

Christopher Malone[1], Alexander Zheleznyak[2], Naomi Sonnek[2], Robert Sullentrup[2], Valerie Blanc[2], Benjamin S Strnad[2], Darren Nix[2], Xiuli Liu[2], Paul Cliften[2], Jason Weber[2], Ryan Fields[2], Matthew Ciorba[2] and Nicholas Davidson[3], (1)Washington University in St. Louis, St. Louis, MO, (2)Washington University in St. Louis, (3) Washington University Medical School, Departments of Medicine and Molecular Biology and Pharmacology, Saint Louis, MO

Background: Despite the reported positive relationship between tumor absorbed dose and response in patients with hepatocellular carcinoma (HCC) undergoing Y-90 radioembolization (Y-90-RE), significant heterogeneity in outcomes remain. This supports the role underlying HCC biological heterogeneity plays in treatment response. Here, we assess the response of human HCC cell lines spanning the transcriptomic spectrum and patient-derived tumoroids to glass Y-90 microspheres *in vitro*. **Methods**: A panel of Human HCC cell lines (HepG2 and PLC/PRF/5 characterized by high expression of hepatocyte and liver progenitor genes, and SNU-449 and SNU-423, characterized by high expression of stem cell and epithelial-mesenchymal transition genes) and a selected tumoroid were treated at escalating activities (0-20 MBq/ml) of glass Y-90 microspheres (Therasphere, Boston Scientific) for 10 days *in vitro*. Cell viability was determined with MTT assay to generate area-under-curve (AUC) values. Patient-derived HCC tumoroids were generated from extra tumor tissue obtained from eligible patients presenting for standard of care biopsy or ablation of suspected HCC through an ongoing adaptive approach. **Results**: The tumoroid derived of a patient with Hepatitis C liver disease with a solitary 7 cm, moderately differentiated HCC who underwent Y-90-RE with local recurrence 7 months after treatment was selected for *in vitro* Y-90 microsphere treatment given its potential for clinical and *in vitro* correlation. Tumoroid whole exome sequencing demonstrated mutations in known HCC driver genes *AXIN1*, *TERT*, and *KEAP1* and histological cellular morphology representative of the original tumor. This tumoroid demonstrated relative resistance to Y-90 microsphere treatment *in vitro*, with an AUC similar to the SNU-423 cells (Fig 1A). In contrast, PLC/PRF/5 cells demonstrated greater sensitivity to Y-90 treatment (Fig 1A). Similarly, SNU-449 cells demonstrated resistance to *in vitro* treatment compared to HepG2 cells that was most pronounced when utilizing Y-90 microspheres of low specific activity (51 Bq/sphere) (Fig 1B). **Conclusion**: HCC cell lines and tumoroids demonstrate heterogenous sensitivity to Y-90 microsphere treatment *in vitro*, potentially reflected by underlying transcriptomic profiles. Establishing patient derived HCC tumoroids for *in vitro* Y-90 microsphere treatment screens is feasible and serves as a powerful platform to assess biological underpinnings of Y-90-RE response with the advantage of being linked to clinical metadata.

Chunlan Zhang[1], Luping Lin[1], Huimin Fan[1], Aiqi Lu[1], Zhuxiang Zhao[2], Yujuan Guan[1] and Jianping Li[1], (1) Guangzhou Eighth People's Hospital, Guangzhou Medical University, (2)Guangzhou First People's Hospital, (3)Guangdong Provincial People's Hospital

Background: Hepatocellular carcinoma (HCC) is one malignancy with the fourth highest morbidity and the second highest mortality among all cancers in China. Most patients were found at middle- or late-stage with poor therapeutic response and high recurrence rate. It is of great significance to apply a highly sensitive and specific assay to HCC screening to reduce the HCC incidence and increase the early detection rate. In this study, a liquid biopsy-based circulating cell-free DNA (cfDNA) sequencing assay was used for HCC screening in HCC high-risk population. We hope that the present study may provide a new strategy for HCC prevention in the population. **Methods:** Patients were recruited based on the definition of HCC high-risk and very high-risk population in the Chinese guideline for liver cancer screening (2022, Beijing). Ten milliliters of peripheral blood were collected and the plasma was isolated for cfDNA detection. The assay detects a panel of methylation, mutation and protein markers developed for HCC screening, and a diagnostic model was established by combining the assay results with family history and demographic information. The interpretation of the assay was dichotomized into positive and negative groups. The dynamic changes of conventional serological markers and ultrasound/CT/MRI/pathological examinations were followed up. Statistics were performed to calculate the positive predictive value (PPV), negative predictive value (NPV), sensitivity and specificity. **Results:** A total of 95 HCC high-risk and very high-risk patients were recruited from 3 medical centers, with an average age of 50. 63 ± 11.49 years (mean ± SD), in which 72. 6% (69/95) of patients were male. The assay was positive in 26 cases and negative in 69 cases. Mutations of one or more related genes (TP53, CTNNB1, TERT) were found in 13.7% (13/95) of patients, with a mutation abundance between 0.5 0 and 3%. Among them, 5 patients with confirmed HCC exhibited a mutation abundance between 0.90 and 3%, while 8 patients without HCC exhibited a mutation abundance between 0.50 and 20 . A total of 92 patients were followed up for 6-12 months, and eight of them were diagnosed HCC by dynamic contrast-enhanced CT/MRI or pathology. The PPV was 29.2% (7/24), and the NPV was 98.5% (67/68), and the sensitivity was 87.5% (7/8) at a specificity of 79.8% (67/84). In contrast, the sensitivity was only 50.0% (4/8) for AFP. The assay detected HCC 1-6 months prior to the diagnosis by CT/MRI in 4 of 7 patients with confirmed HCC diagnosis, and detected the rest 3 HCC patients in parallel with CT/MRI. **Conclusion:** The performance of the HCC screening assay was superior to the existing serological markers in the high-risk and very high-risk population of HCC. It detected HCC earlier than imaging examinations and may help clinicians diagnose and treat early-stage HCC.

Table 1 Baseline Characteristics

	Positive	Negative	Total
N	26	69	95
Age (year)	48.8±10.7	55.4±12.4	50.6±11.5
Male (%)	14 (53.8)	55 (79.7)	69 (72.6)
AFP (>7ug/L)	16 (61.5)	22 (31.9)	38 (40.0)
DCP (>40mAU/ml)	9 (34.6)	2(2.8)	11(11.6)
Methylation (>0.7)	19 (73.1)	5 (7.2)	24 (25.2)

f 4158-A | A DEDICATED AUTOMATIC RECALL HEPATOCELLULAR CANCER SURVEILLANCE PROGRAM IMPROVES RETENTION RATES: A POPULATION BASED COHORT STUDY

Mayur Brahmania[1], Stephen E. Congly[1], Kelly Warren Burak[1], Yashasavi Sachar[2], Brendan Cord Lethebe[1], Jessie Hart Szostakiwskyj[1], David Lautner[1], Alexandra Medellin[1], Deepak Bhayana[1], Jason Wong[1], Matthew Sadler[3], Meredith A. Borman[1], Alexander Aspinall[1], Carla S. Coffin[1], Mark Gordon Swain[1] and Abdel Aziz Shaheen[1], (1)University of Calgary, (2)Western University, (3)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

Background: Hepatocellular carcinoma (HCC) surveillance programs are affected by adherence, which may be due to patient, clinician and system barriers. The impact of a dedicated automatic recall HCC surveillance program on retention rates in patients eligible for screening is unknown. We aimed to describe and evaluate the largest HCC surveillance program in the Canadian public health care system. **Methods:** Data was collected from January 1, 2013 to December 31, 2022 from a retrospective cohort of subjects enrolled in a semi-annually surveillance program as per AASLD HCC guidance. The program is a publicly funded automated recall system servicing eligible patients in the Calgary Health Zone (~1.6 million), Canada. Patients were excluded if there was incomplete data or did not meet indications for screening. Multivariable logistic regression was used to identify predictors of non-retention to surveillance. All statistical analyses were done in R (version 4.1.1). **Results:** A total of 7,432 patients were included in the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

study. The median was age 55.5 years (IQR: 45.5-63.8), 60% were male, 46% of Asian descent, and 53% with HBV infection as the reason for HCC surveillance, while 46% had cirrhosis (36% alcohol). Median follow-up was 4.9 years (IQR: 1.5-7.2). Overall, 54% of patients were retained in the surveillance program, while 21% left for potential medical reasons at some point of time in the study (7% death; 62.3% with a high risk (>1cm) or an inconclusive lesion identified or did not scan well), and 25% were not retained. Median time in the program for those not retained was 0.78 (IQR: 0.0-2.0) years (vs 6.4 years retained; IQR: 5.0-8.3; p = <0.001). Subjects not retained (vs retained) were more commonly male (61% vs 58%; p = <0.001), Caucasian (42% Caucasian vs 38% Asian vs 12% African; p = 0.001), and had either HBV (46%) or HCV (22%) as their primary diagnosis for screening (vs 17% alcohol; 5% autoimmune; 7% NASH; p = 0.001). In multivariable logistic regression analysis, older age at enrollment (OR = 0.99; CI = 0.98-0.99), Asian descent (OR = 0.64; CI = 0.54-0.76) and having a non-HCV etiology (Alcohol OR = 0.75; CI: 0.58-0.98; HBV: OR = 0.54; CI = 0.38-0.69; NASH: OR = 0.55, CI = 0.42-0.74) were factors associated with enhanced retention in the screening program. **Conclusion:** A dedicated automated recall HCC surveillance program has a high retention rate in a large multi-ethnic cohort of patients. Significant factors associated with with non-retention included a diagnosis of HCV and younger age, highlighting potential populations to target for intervention.

4159-A | A REASSESSMENT OF NON-INVASIVE APPROACH FOR THE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA

Yuquan Qian[1], Qiaoyuan Lu[2], Isaac Rodriguez[1], Xiangde Min[3], Matthias Froelich[1], Muzaffer Reha Ümütlü[4], German A. Castrillon[5], Carlos Romero Alaffita[6], Juan Alberto Garay Mora[7], Zhiqiang Guo[8], Christel Weiss[1], Stefan Schönberg[1], Matthias Ebert[1], Yingshi Sun[2] and Andreas Teufel[1], (1)Medical Faculty Mannheim, Heidelberg University, (2)Peking University Cancer Hospital and Institute, (3)Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (4)University Hospital, Lmu Munich, (5) University of Antioquia, (6)Universidad Autónoma De San Luis Potosí, (7)Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, (8)Shanxi Province Fenyang Hospital

Background: Under current guidelines, hepatocellular carcinoma (HCC) diagnosis primarily relies on CT or MRI, with biopsy strictly regulated. However, combined hepatocellular-cholangiocarcinoma (cHCC-CC), a type of liver cancer exhibiting histological elements of both HCC and cholangiocellular carcinoma (CCC), typically presents a combination of HCC and CCC radiological features on imaging. Moreover, platinum drugs offer the most promising initial treatment for patients with unresectable or advanced cHCC-CC, deviating significantly from the approach for HCC. Therefore, our study aims to investigate the ability of imaging techniques to differentiate between HCC, CCC, and cHCC-CC, thereby emphasizing its clinical significance. **Methods:** A database search was conducted to identify patients diagnosed with HCC, CCC, and cHCC-CC between June 2010 to September 2020. Following quality control measures, the study included 68 MRI scans from patients, comprising 30 with HCC, 23 with CCC, and 15 with cHCC-CC. The diagnoses of all patients were confirmed through histological evidence obtained within a maximum of four weeks prior to or following the MRI scans. Subsequently, seven radiologists from Asia, Europe, North America, and South America, including abdominal imaging experts (AIEs) and non-abdominal imaging experts (NIEs) or trainees, independently and blindly assessed the MRI scans. They evaluated various MRI features and established a differential diagnosis encompassing HCC, CCC, and cHCC-CC.

Results: The AIEs exhibited high proficiency in utilizing MRI images exclusively for the diagnosis of HCC (70%-100%) and CCC (73.9%-91.3%). They outperformed NIEs/trainees (all p values < 0.01), achieving correct rates of 26.7%-66.7% for HCC and 21.7%-60.9% for CCC. However, their ability to accurately distinguish cHCC-CC (6.7%-53.3%) was limited and comparable to NIEs/trainees (26.7%-46.7%). Furthermore, there was greater consistency in MRI feature assessment among AIEs for HCC and CCC when compared to cHCC-CC. Notably, there were no significant differences observed in the impact of a cirrhotic background on the diagnosis of HCC and cHCC-CC among AIEs. Moreover, there was non-significant inter-continental variability in overall liver cancer diagnosis and the diagnosis rates of the three types of liver cancer by AIEs. **Conclusion:** MRI imaging showed good discrimination between HCC and CCC particularly when diagnosed by abdominal imaging experts. However, accuracy in detecting cHCC-CC was very limited among all participating radiologists. Thus, liver biopsy remains important for the accuracy of diagnosis and selection of medical treatment modalities.

4160-A | CLINICAL PHENOTYPES OF BENIGN HEPATIC LESIONS

Michael Bradley Andrews[1], Manaswitha Thota[1], Jonathan Paul Van Name[1], Tamas Gal[1] and Richard K. Sterling[2], (1)Virginia Commonwealth University, (2) Virginia Commonwealth University Health System

Background: Most benign hepatic lesions occur in isolation. The clinical and demographic phenotype in patients (pts) with more than one lesion can overlap making treatment decisions challenging. To address this gap in knowledge, our aim was to describe the clinical and demographic characteristics in a cohort of pts with benign hepatic lesions to predict the lesion based on clinical data and oral contraceptive (OCP) use. We particularly wanted to know how common the two more clinically relevant lesions, hepatic adenoma (HA) and focal nodular hyperplasia (FNH) occurred and could a "clinical phenotype" identify these patients. **Methods:** This was a single institution retrospective case series using bioinformatics and natural language processing to identify eligible pts with HA, FNH, hemangioma (HM), and cysts (C) undergoing imaging (MRI, CT, or US). Demographics and laboratory values such as aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), albumin, hemoglobin (Hgb), platelets, prothrombin time (PT), and OCP use were collected. Descriptive analysis was performed. Differences between groups were assessed by ANOVA or Wilcoxon tests for continuous variables and chi-square for categorical variables with alpha 0.05. Variables identified on univariate analysis with $p < 0.2$ were included in multivariate analysis to identify independent factors associated with the different lesion groups. **Results:** The statistically significant differences across all groups ($n = 216$) on univariate ANOVA were age, sex, AST, ALP, albumin, Hgb, platelets, PT, and OCP use (Table). After adjusting for ALT in the multivariate model, statistically significant differences across all groups were age, sex, ALP, and Hgb. The statistically significant differences between HA and FNH on univariate ANOVA were sex, AST, ALT, ALP, albumin, and Hgb. After adjusting for platelets, PT and OCP use, there remained significant differences in ALP and Hgb between those with HA and those with FNH. Combination lesions were observed in 28 (12%): C + HM (2), C + FNH (8), C + HA (4), HM + FNH (7), HA + HM (2), FHN + HM (1), and HA + FNH (4). **Conclusion:** Predicting the etiology of benign hepatic lesions based on patient demographics, common

laboratory values, and a brief history including OCP use alone is difficult. However, we identified the most important demographic (age, sex) and laboratory values (ALP, Hgb) to assist in building a differential.

4161-A | CLINICOPATHOLOGICAL CHARACTERISTICS AND MOLECULAR ANALYSIS OF LYMPHOCYTE-RICH HCC

Kana Tsutsui[1], Masamichi Nakayama[1], Sachiko Ogasawara[1], Jun Akiba[2] and Hirohisa Yano[1], (1) Kurume University School of Medicine, (2)Kurume University Hospital

Background: In the WHO Classification of Digestive System Tumours, 5th Edition (2019), a new subtype of hepatocellular carcinoma (HCC), designated lymphocyte-rich HCC (LR-HCC), has been proposed. In LR-HCC, lymphocytes outnumber tumor cells in most fields on H&E staining. HCC is one of the malignant tumors with poor prognosis, whereas this new subtype is considered to have a relatively good prognosis. As it is a newly proposed subtype with rare frequency (< 1% of all HCCs), there have been few coherent reports on its clinical and pathological features. In this study, we examined the clinicopathological and molecular features of LR-HCC. **Methods:** 1) In the present study, 451 surgically-resected HCC cases without previous treatment history from 2012 to 2021 at our hospital were analyzed. Clinicopathological characteristics of LR-HCC and the other HCC (non-LR-HCC) subtypes were compared. To evaluate intratumoral infiltrating lymphocytes, immunostaining for CD3, CD20, and CD8 was performed in LR-HCC. 2) Neoplastic and nonneoplastic hepatocytes from LR-HCC (n = 4) were collected with a laser microdissection system, and RNA was extracted, followed by microarray analysis to examine molecules involved in lymphocytic infiltration. 3) The immunohistochemical expression of identified molecules was examined in LR-HCC (28 cases) and non-LR-HCC (30 cases). **Results:** 1) There were 28 cases (6%) of LR-HCC. No statistically significant differences were found in the clinicopathological features, including prognosis, between LR-HCC and non-LR-HCC cases. The 5-year survival rate for LR-HCC was over 90%. There were significantly more CD3+ cells than CD20+ cells ($p < 0.0001$) in tumor infiltrating lymphocytes, and most of them were CD8+ T cells. 2) Microarray analysis revealed that CCL20 which induces lymphocyte migration, was highly expressed in LR-HCC cases. 3) Immunohistochemical study revealed that CCL20 expression was significantly higher in LR-HCC ($p < 0.01$) tumor cells compared with non-LR-HCC. Expression of CCR6, the only known receptor for CCL20, was confirmed in infiltrating lymphocytes in LR-HCC. **Conclusion:** This study suggests that LR-HCC is not a very rare subtype with no significant differences in clinicopathological features compared with non-LR-HCC subtypes although the 5-year survival rate was favorable and over 90%. CCL20 expression appears to contribute to rich CD8+ lymphocyte infiltration in LR-HCC.

4162-A | CONTRAST-ENHANCED ULTRASOUND (CEUS) FOR THE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA (HCC) IN ADULTS WITH CHRONIC LIVER DISEASE. A COCHRANE SYSTEMATIC REVIEW AND METANALYSIS

Mirella Fraquelli[1], Tin Nadarevic[2], Agostino Colli[1], Cristina Manzotti[3], Vanja Giljaca[4], Damir Miletic[5], Davor Stimac[5] and Giovanni Casazza[3], (1)Fondazione Irccs Ospedale Maggiore, Policlinico Milano, (2)University of Rijeka, (3)University of Milan, (4)Heart of England NHS Foundation Trust, Birmingham, UK, (5)Clinical Hospital Centre Rijeka

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: HCC mostly occurs in people with chronic liver disease (CLD) and ranks fourth in terms of cancer-related deaths. CEUS is used as an add-on test to confirm focal liver lesions suspected as HCC after prior diagnostic tests (abdominal ultrasound and/or alpha-foetoprotein measurement). According to guidelines either computed tomography (CT) or magnetic resonance imaging (MRI), showing typical hallmarks are sufficient to diagnose HCC in cirrhotics. However, a significant number of tumors showing atypical imaging features are missed. The use of CEUS in the diagnostic HCC algorithm remains controversial, with relevant guidelines disagreement. This systematic review assesses CEUS the diagnostic accuracy of CEUS for the diagnosis of HCC of any size and at any stage and of resectable HCC in adults with CLD, in a surveillance program or in a clinical setting. **Methods:** Cross-sectional designs, using one of the acceptable reference standards (pathology of the explanted liver and histology of resected or biopsied focal liver lesion with at least a six-month follow-up) were included. Standard Cochrane methods were used to screen studies, extract data, and assess the risk of bias and applicability concerns, using the QUADAS-2 checklist. The bivariate model was used for the estimation of summary sensitivity and specificity. Certainty of the evidence was graded using GRADE. **Results:** We included 23 studies (6546 participants), all judged at high-risk of bias in at least one domain; 13/23 studies were at high concern for applicability. For HCC of any size and any stage: sensitivity was 77.8% (95%CI 69.4% to 84.4%) and specificity 93.8% (95%CI 89.1% to 96.6%); for resectable HCC: sensitivity 77.5% (95%CI 62.9% to 87.6%) and specificity 92.7% (95%CI 86.8% to 96.1%). The observed heterogeneity in the results remains unexplained. **Conclusion:** Using CEUS, as an add-on test following abdominal ultrasound, to diagnose HCC of any size and stage, 22% of people with the tumor would be missed, and 6% of people without it would unnecessarily undergo further testing or inappropriate treatment. As to resectable HCC we found that 23% of people with resectable tumor would incorrectly be unresected, while 8% of people without it would undergo further inappropriate testing or treatment. Our ability to draw confident conclusions is limited by the high risk of bias of included studies, heterogeneity, imprecision of the results and concerns on their applicability.

4163-A | DETECTION OF HYPERMETHYLATED CpG ISLANDS IN CELL-FREE DNA: A BETTER CLINICAL TOOL IN THE DIAGNOSIS AND MANAGEMENT OF HEPATOCELLULAR CARCINOMA.

Dinesh Jothimani[1], Srikar Raman[2], Mullaiezhili Manoharan[3], Evangeline Simon[3], K Sree Durgalakshmi[4], Hemalatha Ramachandran[3], Ashwin Rammohan[3], Mukul Vij[3], Vasanthakumar Gunasekaran[3], Mohamed Rela[3] and Mohammed Farouk[3], (1)Rela Institute and Medical Centre, (2) Tvaster, (3)Dr Rela Institute and Medical Centre, (4) Tvaster Genkalp, Chennai

Background: Advances in the field of genetics has enabled novel modalities to diagnose hepatocellular carcinoma (HCC) since it is well known that the current diagnosis through biomarkers such as alpha feto-protein has low sensitivity and specificity. Genetic-based diagnosis is challenging since HCC occurs through extremely complex genetic alteration process, and occurs from multiple genetic aberrations. To use mutational markers for detecting HCC can be achieved only by using expensive and time-consuming modalities such as Next Generation Sequencing (NGS). Alternatively, developments in the field of epigenetics is aiding in exploration of epigenetics for diagnostic applications for various cancers. Epigenetic modifications usually occur through DNA methylation regulating tumorigenesis and cancer progression. Herein, we report affordable and accessible methylation profiling using droplet digital PCR (ddPCR) in combination with Sequencing Independent Quantitative Methylation Profiling (qSIMP) platform based screening tool (qSIMP-HCC) for detection, recurrence monitoring and surveillance of HCC. **Methods:** Using a novel multiplex panel of 4 genes, we determined hypermethylation levels in CpG islands of multiple genes namely Vimentin, RGS10, RUNX2 and ST8SIA6. Methylation levels of cfDNA extracted from blood was analyzed using ddPCR and multiparameter approach was deployed to assess the risk status of patients based on methylation levels. We analyzed a cohort of plasma samples from HCC patients ($n = 39$) and control individual's including cirrhotic patients not diagnosed with HCC ($n = 89$). The results for combined sample set ($n_{total} = 128$) was determined and qSIMP-HCC results was compared with AFP. **Results:** The training set results indicated a marked difference in methylation levels between the control

and HCC subjects wherein a two tailed p value of 0.0022 ($p < 0.01$) at 95% confidence interval suggests the difference between the groups is very statistically significant. A receiver operating characteristic curve (ROC) of our model to detect HCC patients revealed AUC of 0.91 (95% CI = 0.88–0.94) with sensitivity, specificity and accuracy of 82.05%, 83.15% and 82.81% respectively. The data was significantly better than AFP marker (n = 122) that showed a sensitivity of 40% at cut off value at 10ng/ml. **Conclusion:** Based on the data, the epigenetic qSIMP-HCC tool has a great potential to serve as a robust platform for surveillance, detection and management of HCC.

4164-A | DIAGNOSTIC ACCURACY OF PROTEIN INDUCED BY VITAMIN K ABSENCE (PIVKA-II) FOR HEPATOCELLULAR CARCINOMA (HCC) AMONG CAUCASIAN CIRRHOTIC PATIENTS WITH DIAGNOSTIC OR NON-DIAGNOSTIC SERUM A-FETOPROTEIN (AFP) LEVELS

Antonia Syriha, Dionysia Mandilara, Spyridon Pantzios, Petros Galanis, Ioanna Stathopoulou, Georgia Barla and Ioannis S. Elefsiniotis, National and Kapodistrian University of Athens

Background: To evaluate the accuracy of serum biomarkers (AFP, PIVKA-II) for HCC diagnosis among patients with liver cirrhosis. **Methods:** 218 consecutive patients with liver cirrhosis with (n = 90, HCC group) or without (n = 128, control group) concomitant histologically confirmed HCC were evaluated for serum levels of the two biomarkers, during a programmed outpatient visit. Patients with HCC (n = 90) were categorized in stage 0/A (n = 12, 13.3%), stage B (n = 21, 23.3%), stage C (n = 48, 53.3%) and stage D (n = 9, 10%), according to BCLC staging system. **Results:** The two groups were comparable according to all baseline parameters evaluated (gender, CPT score, MELD score, ALBI grade, presence of varices, cirrhosis etiology), except for age, platelet count and presence of diabetes. Mean/median levels of AFP (14310/239.1 vs 11.3/4.0, $p < 0.001$) and PIVKA-II (11676/4082 vs 882/45.8, $p < 0.001$) were significantly higher in HCC group compared to control group. The AUROC curve and the best proposed cut-off value for HCC diagnosis were 88%/ 12.35 ng/ml and 84.4%/ 677.13 mAU/ml for AFP and PIVKA-II, respectively, whereas the diagnostic accuracy was slightly better (AUROC 90.2%) combining the two biomarkers. The diagnostic accuracy of each biomarker separately was low for BCLC 0/A (AUROC 65.8% for AFP and 65% for PIVKA-II) and BCLC B HCC patients (AUROC 86.4% for AFP and 79.5% for PIVKA-II) and was acceptable only among BCLC-C stage HCC patients (AFP: AUROC = 94.3%, best proposed cut-off value = 12.35 ng/ml and PIVKA-II: AUROC = 91.3%, best proposed cut-off value = 253.51 mAU/ml). The combination of the two biomarkers presented acceptable diagnostic curves in BCLC-B (AUROC = 92.4%) as well as BCLC-C (AUROC = 95.7%) stage HCC patients. Excluding HCC patients with AFP levels above 400 ng/ml, the diagnostic accuracy of each biomarker separately as well as the combination of them was low (less than 90%) in the whole group and in all BCLC groups, except for the combination of biomarkers in the BCLC-C group (AUROC = 90.5%). **Conclusion:** Each biomarker separately showed moderate accuracy in detecting HCC in patients with liver cirrhosis, except for those staged in BCLC-C stage. The combination of the two biomarkers presented acceptable results in the HCC diagnosis of BCLC-B as well as BCLC-C patients. The diagnostic accuracy of PIVKA-II in patients with relatively low AFP levels (< 400 ng/ml) remained at low level except for those of BCLC-C stage.

Figure 1. ROC curves for AFP, PIVKA-II and their combination for the diagnosis of HCC in the whole study population.

4165-A | ELEVATIONS IN LIVER TESTS PREDICT THE PRESENCE OF LIVER METASTASES IN PATIENTS WITH COLORECTAL CANCER

Alexandra V. Kimchy[1], Harjit Singh[1], Esha Parikh[1], Jessica Rosenberg[1], Kavya Sanghavi[2] and James H. Lewis[1], (1)Georgetown University Hospital, (2)Medstar Research Institute

Background: The predictive value of biochemical liver tests in patients (pts) w/ liver metastases (mets) has not been fully characterized. We analyzed liver tests in pts w/ liver mets from primary colorectal cancer (CRC) at the time of diagnosis of mets. **Methods:** Inpatient encounters were retrospectively reviewed for pts w/ CRC from 2016-2020. ICD9/ICD10 was used to identify pts w/ CRC liver mets who were compared to age, gender matched controls who had CRC w/o liver mets. Pt characteristics, treatment and diagnostics were acquired from chart extraction. Liver test results were obtained from the time detection of liver mets w/ imaging. Pts w/ a history of liver disease or w/o imaging and/or biopsy confirming liver mets were excluded. Differences in medians were determined using Kruskal Wallis or Wilcoxon rank-sum tests and categorical variables using chi-square analyses. Sensitivity (SE) and specificity (SP) were calculated for abnormal values of liver tests in relation to liver mets using 2x2 contingency tables. **Results:** Of the 499 pts w/ CRC, 68 pts (14%) had a diagnosis of liver mets confirmed with imaging. Bone mets were present in few pts w/ CRC and rates did not significantly differ in those w/ and w/o liver mets. Median liver enzyme levels were significantly higher in pts w/ liver mets than w/o liver mets (AST 36 vs 21; $p < 0.001$) (ALT 26 vs 24; $p = 0.018$) (ALP 135 vs 94; $p < 0.001$) but not for total bilirubin (0.5 vs 0.4; $p > 0.05$). Most pts w/ liver mets presented w/ elevated AST (52%) or ALP (56%) while fewer pts had elevations in ALT (29%) or total bilirubin (15%). Pts w/ liver mets presented w/ AST, ALT, or ALP $\geq$3xULN in 37%, 25% and 29% of pts. None of the pts w/o liver mets had elevations to this degree (Table 1). SE and SP of elevated liver tests for the presence of liver mets were AST (51%, 78%), ALT (29%, 94%), and ALP (56%, 76%). The optimal cutoff for diagnosis of liver mets according to SE and SP was $\geq$2xULN for AST (60%, 90%), $\geq$1.25xULN ALT (85%, 33%), and $\geq$1.5xULN for ALP (79%, 85%). Elevations in AST and ALP, or AST and ALT increased the SP of the tests for liver mets to 93% and 94%. **Conclusion:** Liver enzymes were significantly higher in pts w/ liver mets than those w/o liver mets. AST, ALT or ALP $\geq$3xULN were indicative of the presence of liver mets as those w/o liver mets did not have elevations to these levels. Elevated AST and ALP or AST and ALT demonstrated high SP for the presence of liver mets. Our results suggest that using the thresholds of $\geq$2xULN for AST, $\geq$1.25xULN for ALT, and $\geq$1.5xULN for ALP may improve the diagnostic accuracy of these tests for liver mets and indicate which pts should undergo further evaluation with diagnostic imaging. Longitudinal studies of liver tests following the diagnosis of CRC are needed to confirm elevations are predictive of mets prior to detection w/ imaging.

Table 1: Patient characteristics and biochemical liver test abnormalities in patients with and without colorectal liver metastases

	Patients with Liver Metastases (n=68)	Matched controls (n=54)	p-value

4166-A | EXHALED VOLATILE ORGANIC COMPOUNDS AS POTENTIAL DIAGNOSTIC BIOMARKER FOR EARLY HEPATOCELLULAR CARCINOMA IN AT-RISK POPULATION

Roongruedee Chaiteerakij, Thanikarn Sukaram, Chonlada Phathong, Rungsun Rerknimitr and Rossarin Tansawat, Chulalongkorn University

Background: Volatile organic compounds (VOCs) were shown as promising biomarkers for diagnosis of several cancers including hepatocellular carcinoma (HCC). We previously found that HCC patients had different VOCs profile from non-HCC individual's. We aimed to investigate the performance of VOCs for diagnosing early-stage HCC in patients who are at-risk for HCC. **Methods:** We prospectively collected exhaled breath samples from 87 early-stage HCC patients, 90 cirrhotic patients, and 72 chronic HBV-infected patients. VOCs were identified using thermal desorption-gas chromatography/field-asymmetric ion mobility spectrometry. An association between VOCs and HCC was determined using logistic regression analysis. ROC curves were generated to assess the discrimination power between early HCC and non-HCC patients. Diagnostic performance of VOCs was compared to serum alpha-fetoprotein (AFP) using c-statistics. **Results:** Of the 87 HCC patients, 35 (40%) and 52 (60%) were in BCLC stage 0 and A, respectively. Mean age as well as proportion of males, patients with chronic HBV and HCV infection, NAFLD, and diabetes were not statistically different between the three groups. HCC and cirrhosis groups had similar proportions of patients with Child-Pugh class A (91% vs. 91%) and class B (9% vs. 9%). The median (range) AFP levels were 4.8 (1-643) vs. 3.0 (1-18) vs. 1.9 (1-6) in the HCC, cirrhosis, and HBV groups respectively, $p < 0.001$. Of the 9 investigated VOCs, the levels of 5 VOCs including acetone dimer, 1,4-pentadiene, acetone monomer, isopropyl alcohol, and dimethyl sulfide were significantly different between the three groups. By multivariate analysis adjusted for liver function tests and AFP level, acetone dimer was the VOC most significantly associated with early HCC, with an adjusted OR of 31.30 (5.35-183.14), $p < 0.001$. Likewise, among cirrhotic patients, acetone dimer was independently associated with HCC, with an adjusted OR of 15.61 (2.76-88.28), $p = 0.002$. Acetone dimer at an optimal cutoff of 4.668 AU outperformed AFP at an optimal cutoff of 3.02 ng/mL in differentiating between HCC vs. non-HCC patients, with 88.5% vs. 67.1% sensitivity, 82.7% vs. 65.4% specificity, 84.7% vs. 66.0% accuracy, and AUROC of 0.914 vs. 0.724; $p = 0.017$, 0.0001, < 0.001, and 0.001, respectively. These findings remained true for differentiating between HCC vs. cirrhotic patients, i.e., 86.2% vs. 61.2% sensitivity, 87.6% vs. 66.2% specificity, 86.9% vs. 63.5% accuracy, with AUROC of 0.908 vs. 0.665; $p = 0.007$, < 0.001, < 0.001, and 0.002, respectively. **Conclusion:** Exhaled VOC has potential for non-invasive biomarker for early HCC diagnosis in high-risk patients. Utility of VOCs as a HCC surveillance tool is needed to be further explored.

4167-A | HEPATOCELLULAR CARCINOMA SURVEILLANCE WITH PERSONALIZED SCREENING INTERVALS INCORPORATING RISK STRATIFICATION USING MRI IN CIRRHOSIS: INTERIM ANALYSIS OF PROSPECTIVE COHORT STUDY

Byeong Geun Song, Myung Ji Goh, Seungchul Han, Wonseok Kang, Tae Wook Kang, Geum-Youn Gwak, Yong-Han Paik, Moon Seok Choi, Joon Hyeok Lee, Dong Hyun Sinn and Woo Kyoung Jeong, Samsung Medical Center

Background: The current recommend method for hepatocellular carcinoma (HCC) surveillance using US has limited sensitivity in detecting early-stage tumor, which can result in surveillance failure (HCC diagnosed at an advanced stage). This prospective cohort study was designed to evaluate effectiveness of HCC surveillance using gadoxetic acid-enhanced MRI at a personalized screening intervals in patients with cirrhosis. **Methods:** We prospectively included a total of 86 patients with cirrhosis between May 2021 and October 2022. Included patients received HCC surveillance using gadoxetic acid-enhanced MRI according to pre-defined personalized screening intervals for a period of three years. Patients were categorized into low risk (no radiologic feature or hallmark of cirrhosis), intermediate risk (radiological cirrhosis), and high risk (high risk nodules considered LR-3 or LR-4 on LI-RADS) according to MRI at enrollment. Then, HCC surveillance was performed using MRI according to pre-defined personalized screening intervals (3 to 36 months according to current and/or previous MR findings). The primary outcome was screening failure, defined as the diagnosis of HCC at an advanced stage (above Milan criteria). The secondary outcomes were tumor diagnosed at very early stage (single tumor < 2cm in diameter) and missing rate (interval HCC, defined by tumor detected outside MRI screening). The cohort size was set at 86, taking into account a significance level of 0.10, a power of 0.80, a one-sided expected difference of 6% of

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

surveillance failure rate, and an estimated drop-out rate of 2%. **Results:** This is an interim analysis based on pre-defined protocol, as 10 cases of HCC was diagnosed in this cohort. The median follow-up duration was 17.7 months (range: 10.4-26.3 mo), and 143 MRI was performed (min – max, 1-5 times per person). There was no case of screening failure. There was one case of missed cancer, which diagnosis was triggered by increased serum alpha-fetoprotein level. Among nine HCC patients detected during MRI surveillance, seven patients were diagnosed at a very early stage, and two patients were diagnosed at early stage (tumor size was less than 3cm). **Conclusion:** This interim analysis showed that HCC surveillance with personalized screening intervals that take into account the risk stratification of HCC using gadoxetic acid-enhanced MRI may be promising surveillance strategy in patients with liver cirrhosis. The study expected to end in April 2025.

Disclosures: The following people have nothing to disclose: Byeong Geun Song, Myung Ji Goh, Seung-chul Han, Wonseok Kang, Tae Wook Kang, Geum-Youn Gwak, Yong-Han Paik, Moon Seok Choi, Joon Hyeok Lee, Dong Hyun Sinn, Woo Kyoung Jeong

f 4168-A | METHYLATION MARKERS OF HEPATOCELLULAR CARCINOMA ARE DETECTABLE IN CELL-FREE SALIVARY DNA

Catherine Mezzacappa[1], Zhanwei Wang[2], Lingeng Lu[1], Harvey Risch[1], Tamar H. Taddei[1] and Herbert Yu[1,3], (1) Yale University, New Haven, CT, (2)University of Hawaii, (3)Department of Epidemiology, the University of Hawaii Cancer Center, Honolulu, HI, USA

Background: Alterations to DNA methylation have been identified in both hepatocellular carcinoma (HCC) tumor tissue and peripheral blood cell-free DNA (cfDNA) from affected individual's. DNA methylation patterns in non-viral HCC differ from those in virally mediated HCC. These markers have potential applications in HCC screening, prognostication, and treatment. Non-invasive markers of HCC risk are needed as metabolic dysfunction associated liver disease becomes increasingly prevalent. **Methods:** This is an observational feasibility study performed on a subset of cases and controls identified from a previously conducted case control study of genetic and environmental risk factors for HCC. Cases included adults aged 47 – 85 years with a first diagnosis of HCC and without a history of viral hepatitis diagnosed between January 2011 and February 2016 residing in three northeastern states. Controls were matched on age, sex, and state and contacted using random-digit dialing. Cell-free DNA was extracted from frozen saliva samples from 12 cases and 12 controls, half of whom (6 cases and 6 controls) had metabolic dysfunction associated steatotic liver disease (MASLD). The log fold change in cfDNA methylation was measured at 1359 CpG sites representing 25 candidate genes previously identified to have aberrant methylation in HCC in the total sample and in the MASLD subset. **Results:** Of the 25 candidate genes, 16 had at least one CpG site with significantly different methylation across HCC cases and controls in the total sample. In the MASLD subset, 59 CpG sites representing 19 of the 25 candidate genes were differentially methylated across HCC status. Fifteen genes were shared by both groups. Sites differentially methylated in HCC cases included genes encoding tumor suppressors (APC, p15, p16, PRDM2, RASSF1A, RASSF5), regulators of cell cycle progression and death (DAPK1, SFRP1, WIF1), DNA repair (MGMT, MLH1), and transcription factors for related proteins (NKX6-2, RUNX3, TBX15, TP73). **Conclusion:** Cell-free DNA extracted from saliva may be a feasible alternative to blood in the era of non-invasive cancer screening and risk stratification.

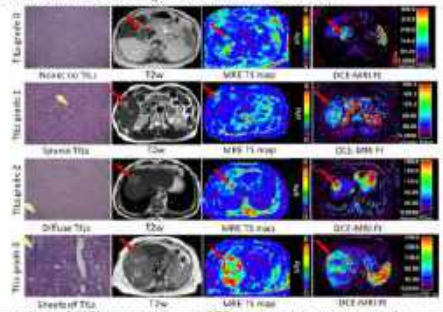
Background: Immunotherapy is now considered first line therapy for unresectable hepatocellular carcinoma (HCC), with overall response rates as high as 36% at 18 months (when combining atezolizumab with bevacizumab). There is however little knowledge about predictive factors of immunotherapy response in HCC, with data suggesting that background tumor immunophenotype plays a role. The purpose of our study is to assess the value of multiparametric magnetic resonance imaging [(mp)MRI] for prediction of HCC immunophenotype. **Methods:** This is a single-center prospective study in which 30 patients (M/F 22/8, mean age 61.8 y) with resectable HCC underwent mpMRI, of which a subset of 17 patients underwent neoadjuvant immunotherapy (with cemiplimab) followed by post-treatment mpMRI prior to resection. An mpMRI protocol containing sequences without and with hepatoboliary contrast agent was performed 3 months prior to resection. The following whole tumor functional characteristics were measured: stiffness (using MR elastography), T1 relaxation time (using T1 mapping), apparent diffusion coefficient (using diffusion-weighted imaging) and flow/perfusion (using dynamic contrast-enhanced MRI). Background immunophenotype was characterized based on grade of tumor infiltrating lymphocytes (TILs) (none: grade 0, sparse: grade 1, diffuse: grade 2, sheets of TILs: grade 3) assessed on resected tumor samples. Differences between independent groups were tested for significance using Mann Whitney U tests. ROC analysis was performed to evaluate the diagnostic performance of the MRI parameters for prediction of abundant TILs (grade 3). **Results:** Out of 30 tumors (mean size 4.89 ± 3.79 cm, range: 1.5-16.2 cm) assessed, 10 tumors demonstrated abundant TILs (grade 3) at histopathology, the rest demonstrating grade 0-2. Tumors with TILs grade 3 were larger, stiffer and had lower flow than tumors with TILs grades 0-2 (Figure 1). Tumor size at MRI, tumor stiffness measured with MRE, and perfusion/flow parameters mean transit time, arterial flow, total flow, time-to-peak, upslope had very good diagnostic performance (Figure 1, AUC = 0.74-0.81, p = 0.008-0.035) for identification of tumors with TILs grade 3 vs grade 0-2. Native/HBP T1 and ADC were not significantly associated with TILs. A binary logistic regression model combining tumor stiffness and time-to-peak showed very good diagnostic performance for identifying tumors with abundant TILs with AUC (CI) = 0.86 (0.71-0.99), p = 0.002, sensitivity 0.89 and specificity 0.67. **Conclusion:** Our results demonstrate the potential utility of mpMRI parameters in predicting background HCC immunophenotype. These findings require validation in an independent cohort.

Figure 1: Top: Examples of patients with HCC tumors of different MRI findings and immunophenotypes. 73-year-old male (HCC with TILs grade 0), 45-year-old male (HCC with TILSs grade 1), 68-year-old male (HCC with TILSs grade 2) and 77-year-old female (HCC with TILSs grade 3) are illustrated (red arrows indicate the lesions in the images). Slides in the first column illustrate histopathological characteristic tumor infiltration lymphocytes grades (0, 1, 2, 3, yellow arrow). The second column illustrates anatomical T2w images, the third column illustrates stiffness maps of MRE and the fourth column illustrates perfusion maps (total flow FI) of DCE-MRI. Tumors with abundant TILs are larger and stiffer, with reduced flow.



Bottom: Comparison of MRI parameters and AFP measured in tumors and the corresponding AUC for pathological characteristics, tumor infiltration lymphocytes (TILs) at resection.

Chen[1], Abhijit Bhat[1], Guangzhou Han[1] and Gary Li[1], (1) Rayzebio, (2)Peptidream

Background: Glypican-3 (GPC3) is a membrane-associated heparan sulfate proteoglycan primarily involved in embryonic development, and is minimally expressed in normal adult tissues. Significant upregulation of GPC3 protein has been observed in hepatocellular carcinomas (HCC), and is associated with poor prognosis. The differential expression of GPC3 between tumor and normal tissues provides an opportunity for targeted radiopharmaceutical therapy (RPT) to treat HCC, a leading cause of cancer-related deaths worldwide. **Methods:** RAYZ-8009 is comprised of a proprietary macrocyclic peptide binder to GPC3, which is connected to chelator DOTA that can be complexed with different radioisotopes. The binding affinity was determined by surface plasma resonance (SPR), and radioligand binding assay in human HCC cell line HepG2. The cross-species binding was assessed by radioligand binding with recombinant mouse, cynomolgus monkey, and human GPC3. Internalization was measured in HepG2 cells at various time points. In vivo biodistribution and anti-tumor efficacy studies were performed in nude mice bearing subcutaneous or orthotopic xenografts. The non-human primate (NHP) PET imaging was performed with ^{64}Cu-labeled binder. **Results:** RAYZ-8009 showed high binding affinity to human GPC3 with a K_D of 0.7 nM. The binding potency was maintained across mouse, cynomolgus monkey and human GPC3. Potent cellular binding was confirmed in HepG2 cells, and was independent of the choice of isotope. ^{177}Lu-RAYZ-8009 achieved efficient internalization upon binding to HepG2 cells. Biodistribution of ^{177}Lu-RAYZ-8009 showed sustained tumor uptake and fast renal clearance. Minimal or no uptake was observed in other normal tissues. Tumor-specific uptake was also demonstrated in orthotopic tumors with no uptake in surrounding liver tissue. In the NHP PET study, rapid clearance in the kidneys and minimal uptake in other organs were observed. Furthermore, significant tumor growth inhibition and survival benefit were achieved with ^{177}Lu- and ^{225}Ac-labeled RAYZ-8009 in GPC3-expressing HCC xenografts. **Conclusion:** Preclinical in vitro and in vivo data in multiple species demonstrate the potential of RAYZ-8009 as a theranostic agent for the treatment of patients with GPC3-positive HCC.

4171-A | PREDICTION OF HEPATOCELLULAR CARCINOMA THROUGH ACCURATE CHARACTERIZATION OF INDETERMINANT LIVER NODULES USING AI ANALYSIS OF MULTIPARAMETRIC MR SCANS

Toussef Qureshi[1], Linda Azab[1], Lixia Wang[1], Yibin Xie[1], Ju Dong Yang[1], Debiao Li[1], Walid S. Ayoub[1] and Shenaz Hussain[2], (1)Cedars-Sinai Medical Center, Los Angeles, CA, (2)UC Davis

Background: Accurate assessment of precancerous nodules in the liver assists in timely detection of malignancies and the overall management of Hepatocellular carcinoma (HCC). However, current radiological characterization of indeterminate nodules is challenging as these lesions have vague and unclear characteristics and some of them eventually turn into HCC. In this preliminary study, we aim to develop a model that performs an automated analysis of indeterminate liver nodules in multiparametric MR scans and classifies them into low and high-risk (nodules developing into HCC during follow up) nodules. **Methods:** An extensive radiomic analysis of liver nodules in cirrhotic patients was performed using a set of 41 multiparametric MR scans including 11 healthy (i.e., having benign LIRAD-2 or 3 nodules) and 30 pre-HCC (i.e., having nodules that later turned into HCC-LIRAD-4). Hundreds of radiomic features consisting of size, shape, signal intensity and textural properties of liver nodules were extracted and considered for statistical analysis. In a thorough comparative examination, several textural features were identified that were unique and significantly different between the two groups. Subsequently, an artificial intelligence (AI) classifier was trained to perform automated binary classification of these MR scans based on the newly identified predictors using the same 41 scans. A three-fold cross-validation was performed to evaluate the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

performance of the proposed model. **Results:** The radiomic analysis identified 25 statistically significant radiomic features of liver nodules that help distinguishing benign nodules and those turning into HCC, including inverse clusters, heterogeneity, entropy, and joint energy (Figure 1). The average classification accuracy, sensitivity, and specificity achieved in each validation fold was 76%, 0.76 and 0.75 respectively (95% CI:0.5-0.92). **Conclusion:** This study is a proof of concept that AI analysis can identify unique radiomic features of indeterminant liver nodules using multiparametric MR scans and adequately assist in the categorization of benign and high risk lesions. Such features are usually uninterpretable by current radiological parameters or unappreciated by the naked eye. By performing automated analysis of indeterminate nodules, the proposed model identifies those that are likely to turn into HCC, assisting in early detection of the HCC.

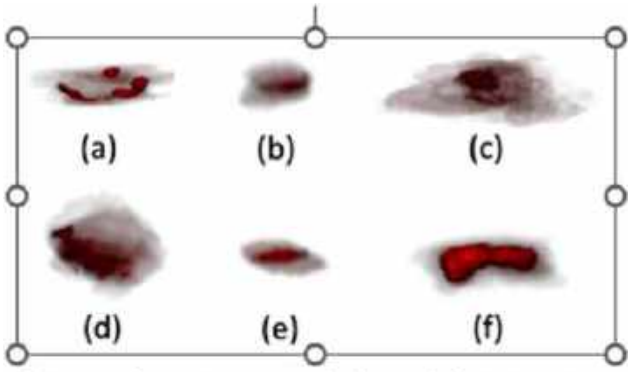

Figure 1: Joint heat map of statistically significant features. (a-c) benign nodules, (d-f) nodules turned into HCC later.

4172-A | SENSITIVITY AND SPECIFICITY OF CT/MRI LIVER IMAGING REPORTING AND DATA SYSTEM CATEGORY 5 VS COMBINED 4 AND 5 FOR THE DIAGNOSIS OF HCC: A SYSTEMATIC REVIEW AND META-ANALYSIS

Sunyoung Lee, Severance Hospital, Yonsei University College of Medicine, Claude B. Sirlin, University of California, San Diego and Victoria Chernyak, Memorial Sloan-Kettering Cancer Center

Background: To estimate pooled meta-analytic sensitivities and specificities of CT/MRI Liver Imaging Reporting and Data System (LI-RADS, LR)-5 vs combined LR-4 and LR-5 (LR-4/5) categories for the diagnosis of hepatocellular carcinoma (HCC). **Methods:** Comprehensive searches of MEDLINE and EMBASE databases was conducted from inception to January 03, 2023, reporting the diagnostic performance of LR-5 and combined LR-4/5 for HCC with use of CT/MRI LI-RADS version 2014, 2017, or 2018. A bivariate random-effects model was used to calculate the pooled per-observation sensitivity and specificity. Subgroup analysis was performed based on imaging modalities and type of MRI contrast material. **Results:** Sixty-nine studies qualified for the meta-analysis, comprising 15,108 observations including 9,928 HCCs. The combined LR-4/5 showed significantly higher pooled sensitivity (83.0% [95% CI, 80.3–85.8%] vs 65.7% [95% CI, 62.4–69.1%]; $P < 0.001$), but lower pooled specificity (75.0% [95% CI, 70.5–79.6%] vs 91.7% [95% CI, 90.2–93.1%], $P < 0.001$) than LR-5. Subgroup analyses showed that the sensitivities of combined LR-4/5 were higher than those of LR-5 (67.4% vs 50.5%, $P = 0.018$ for CT; 86.5% vs 73.2%, $P < 0.001$ for extracellular agent [ECA]-MRI; and 84.8% vs 63.9%, $P < 0.001$ for gadoxetate disodium [Gx]-MRI), and the pooled specificities of combined LR-4/5 were lower than those of LR-5 (82.0% vs 93.8%, $P < 0.001$ for CT; 76.3% vs 92.6%, $P = 0.035$ for ECA-MRI; and 73.4% vs 92.1%, $P < 0.001$ for Gx-MRI). **Conclusion:** Our meta-analysis estimated the magnitude of changes in the sensitivity and specificity of imaging criteria when LR-4 and LR-5 categories are combined. These findings may inform management guideline across the globe.

4173-A | SERUM ALPHA-FETOPROTEIN VALUES DIFFER BY ETIOLOGY OF LIVER DISEASE IN PATIENTS WITH CIRRHOSIS

Nicole J. Kim[1], Philip Vutien[1], Martha C Michel[2] and George Ioannou[1,2], (1)University of Washington, (2) Veterans Affairs Puget Sound Healthcare System

Background: Hepatocellular carcinoma (HCC) screening with imaging and serum alpha-fetoprotein (AFP) testing is recommended every 6 months in patients with cirrhosis. A serum AFP value > 20 is considered positive. We aimed to assess whether serum AFP values differ by etiology of liver disease in patients with cirrhosis. **Methods:** Using data from the national U.S. Veteran Affairs Corporate Data Warehouse, we identified all patients with a new diagnosis of cirrhosis documented between 1/1/2001 and 1/1/2019, who were still alive and without a diagnosis of hepatocellular carcinoma (HCC) as of 1/1/2019 and who had a serum AFP level measured in calendar year 2019 (n = 56,869) – the last year before COVID-19 disrupted HCC screening. We assessed serum AFP levels performed in 2019 (median and by category 0-5, > 5-10, > 10-20, > 20-100, and > 100 ng/mL) overall and by etiology of liver disease (categorized as cured hepatitis C [HCV], active HCV, alcohol-associated liver disease [ALD], non-alcoholic fatty liver disease [NAFLD], and other [chronic hepatitis B virus, hemochromatosis, primary biliary cholangitis, autoimmune hepatitis, primary sclerosing cholangitis, and cryptogenic liver disease]). **Results:** This cohort of 56,869 cirrhosis patients with serum AFP measurements in 2019 included 36.0% with cured HCV (n = 20,482), 25.2% with ALD (n = 14,324), 15.4% with NAFLD (n = 8,755), 13.7% with active HCV (n = 7,772), and 9.7% with other etiologies (n = 5,536) of cirrhosis. Among all patients with cirrhosis, the median AFP level was 3.46 ng/mL and 4.5% (n = 2,539) had an AFP > 20 ng/mL. When evaluating by etiology of cirrhosis, median AFP values were 4.32 ng/mL in active HCV, 3.70 ng/mL in cured HCV, 3.33 ng/mL in ALD, 3.00 ng/mL in NAFLD, and 2.90 ng/mL in other cirrhosis ($p < 0.0001$). The proportion of patients with an AFP > 20 was 12.2% (n = 949) in active HCV, 4.4% (n = 906) in cured HCV, 2.4% (n = 346) in ALD, 2.1% (n = 188) in NAFLD, and 2.7% (n = 150) in other cirrhosis ($p < 0.0001$). **Conclusion:** Among U.S. Veterans with cirrhosis, the proportion with AFP > 20 varies by almost 5-fold according to etiology of liver disease. Patients with active HCV had the highest AFP levels, followed by cured HCV, ALD, and NAFLD cirrhosis. Additional studies are needed to evaluate how the performance of AFP as a screening test for HCC varies by etiology of liver disease and whether the threshold value that determines a positive screening test needs to vary by etiology of liver disease.

Table. AFP levels among patients with cirrhosis, by etiology of liver disease

		All Patients (N=56,869)	HCV-Active (n=7,772) (13.7%)	HCV-Cured (n=20,482) (36.0%)	Alcohol (n=14,324) (25.2%)	NAFLD (n=8,755) (15.4%)	Other (n=5,536) (9.7%)
AFP levels	Median AFP	3.46	4.32	3.70	3.33	3.00	2.90
	0-5 (%)	40,837 (71.8)	4,450 (57.3)	14,154 (69.1)	10,651 (74.4)	7,118 (81.3)	4,464 (80.6)
	>5-10 (%)	10,418 (18.3)	1,647 (21.2)	4,269 (20.8)	2,661 (18.7)	1,164 (13.3)	677 (12.2)
	>10-20 (%)	3,075 (5.4)	726 (9.3)	1,153 (5.6)	666 (4.7)	285 (3.3)	245(4.4)
	>20-100 (%)	1,320 (2.3)	557 (7.2)	426 (2.1)	171 (1.2)	89 (1.0)	77 (1.4)
	>100 (%)	1,219 (2.1)	392 (5.0)	480 (2.3)	175 (1.2)	99 (1.1)	73 (1.3)

f 4174-A | SODIUM-GLUCOSE COTRANSPORTER 2 INHIBITORS AND REDUCED RISK OF LIVER CANCER IN PEOPLE WITH TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY

Pin-Chia Huang[1] and Kevin Sheng-Kai Ma[1,2,3], (1) Harvard T.H. Chan School of Public Health, (2) University of Pennsylvania, (3)Massachusetts General Hospital

Background: Patients with type 2 diabetes mellitus (T2DM) are at a great risk of liver cancers including hepatocellular carcinoma (HCC). However, it remains unclear whether new antidiabetic treatments have the potential to prevent HCC or potentially increase its incidence. Therefore, the objective of this study was to assess the effect of sodium glucose co-transporter 2 inhibitors (SGLT2i) on the risk of developing liver cancer in patients with type 2 diabetes mellitus (T2DM) compared to other oral antidiabetic drugs. **Methods:** Patients with T2DM treated with SGLT2i, dipeptidyl peptidase-4 inhibitors (DPP4i) or glucagon-like peptide-1 receptor agonists (GLP-1 RA) between 2014 and 2023 were retrieved from a population-based cohort study across the United States. Patients with T2DM on SGLT2i were propensity score matched on demographic characteristics, comorbidities, medical history, and lab data with patients with T2DM on DPP4i and on GLP-1 RA, respectively. The primary outcome of interest was the occurrence of new-onset liver cancer, including hepatocellular carcinoma and intrahepatic cholangiocarcinoma. Logistic regression was employed to estimate the odds ratio (OR) and its corresponding 95% confidence intervals (CIs), while Cox proportional hazards regression was used to estimate the hazard ratio (HR) and its 95% CIs for the development of liver cancer. **Results:** A total of 1,877,388 patients diagnosed with T2DM were included in the study before propensity score matching. After propensity score matching, among the SGLT2i group, out of the 706,381 individual's, 1,042 individual's developed

incident liver cancer during the follow-up period. In comparison, within the DPP4i group consisting of 706,379 individual's, 1,766 individual's developed incident liver cancer during the follow-up period. Patients on SGLT2i were associated with a significantly reduced risk of new-onset liver cancer as compared to those on DPP4i (HR = 0.87, 95% CI: 0.81, 0.95; OR = 0.59, 95% CI: 0.55, 0.64). Likewise, patients on SGLT2i presented with a significantly lower risk of new-onset liver cancer, as compared with those on GLP-1 RA (OR = 0.86, 95% CI: 0.77, 0.95). **Conclusion:** Findings of the present study demonstrated a significantly reduced risk of liver cancer following the use of SGLT2i in patients with T2DM. Clinical trials are warranted to validate the findings.

4175-A | SONIC HEDGEHOG EXPRESSION IN STEATOHEPATITIC HEPATOCELLULAR CARCINOMAS AND ITS CLINICOPATHOLOGIC SIGNIFICANCE

Hironori Kusano[1,2], Sachiko Ogasawara[2], Minori Omuraya[2], Masayuki Okudaira[3], Shinji Mizuochi[2], Yutaro Mihara[2], Yoshinao Kinjyo[2], Yuta Yano[2], Masamichi Nakayama[2], Reiichiro Kondo[2], Yoshiki Naito[4], Jun Akiba[4], Osamu Nakashima[5] and Hirohisa Yano[2], (1)National Hospital Organization Kokura Medical Center, (2)Kurume University School of Medicine, (3)National Hospital Organization Nagasaki Medical Center, (4)Kurume University Hospital, (5)St Mary's Hospital

Background: The dysregulation of the Hedgehog signaling pathway has been reported to be implicated in the pathogenesis of non-alcoholic steatohepatitis, and the expression of the sonic hedgehog (SHh) protein, a pivotal molecule in the Hedgehog pathway, is found in ballooned hepatocytes. This study aims to investigate the clinicopathologic significance of SHh expression in steatohepatitic hepatocellular carcinoma (SH-HCC). **Methods:** Real-time PCR and immunohistochemistry were employed to examine the gene and protein expression of SHh in SH-HCC. Additionally, a series of conventional HCC (C-HCC) was analyzed as a control group. Clinicopathologic analysis was also carried out. **Results:** The prevalence of SH-HCC was 3%, and it was significantly associated with a high prevalence of diabetes mellitus. SHh mRNA was detected in all cases of SH-HCC, while 23% of C-HCC cases did not show SHh mRNA expression. Statistically, there was no significant difference in SHh mRNA expression level between SH-HCC and C-HCC. At the protein level, the high expression group of SHh was more frequent in SH-HCC. Although there was no significant prognostic difference between SH-HCC and C-HCC, high SHh protein expression was an independent poor prognostic factor in HCCs. **Conclusion:** SHh expression was significantly higher in SH-HCC compared to C-HCC at the protein level. High SHh protein expression was identified as an independent poor prognostic factor in HCCs. Our findings suggest that SHh could potentially serve as a therapeutic target for patients with HCC.

4176-A | TUMOR STIFFNESS MEASUREMENT USING MAGNETIC RESONANCE ELASTOGRAPHY CAN PREDICT RECURRENCE AND SURVIVAL AFTER CURATIVE RESECTION OF HEPATOCELLULAR CARCINOMA

Hayato Abe, Yukiyasu Okamura, Tatsuo Kanda and Masahiro Okada, Nihon University School of Medicine

Background: Tumor stiffness measurement using magnetic resonance elastography (MRE) can assess tumor mechanical properties and predict hepatocellular carcinoma (HCC) recurrence. This study aimed to investigate preoperative tumor stiffness on MRE as a predictor of overall survival (OS) and recurrence-free survival (RFS) in patients with solitary nodular HCC who underwent curative resection. **Methods:** Seventy-eight patients with solitary nodular HCC who underwent preoperative MRE and curative resection were retrospectively analyzed. Potential associations of tumor stiffness and other clinicopathological variables with OS and RFS were analyzed in both univariate and multivariate Cox proportional hazards analyses. The optimal tumor stiffness cutoff value was determined using the minimal *P*-value approach. **Results:** In multivariate analysis, tumor stiffness (hazard ratio [HR] 1.29; 95% confidence interval [CI], 1.06–1.56; $P = 0.013$) and vascular invasion (HR 2.56; 95% CI, 1.24–5.17; $P = 0.012$) were independent predictors of RFS. For OS, tumor stiffness (HR, 1.33; 95% CI, 1.02–1.76; $P = 0.037$) was the only independent predictor. The optimal tumor stiffness cutoff value was 5.81 kPa for both OS and RFS. Patients with tumor stiffness ≥ 5.81 kPa had a significantly greater risk of death (HR 6.10; 95% CI, 2.11–21.90; $P < 0.001$) than those with

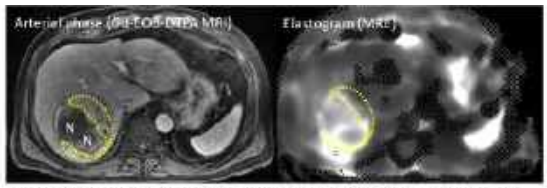
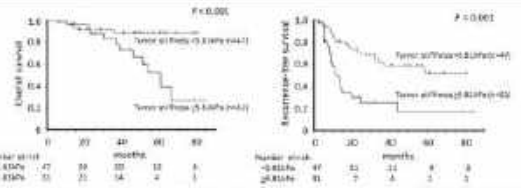
tumor stiffness < 5.81 kPa. **Conclusion:** Preoperative tumor stiffness as measured by MRE was a predictor of OS and RFS in HCC patients who underwent curative resection. Higher tumor stiffness was associated with higher risk of recurrence and death.



Case1: On the elastogram map, the mean tumor stiffness (dotted line), referring to the arterial phase and excluding a necrotic area (N), was 6.75 kPa.



Kaplan–Meier curves for overall and recurrence-free survival with patients stratified according to tumor stiffness.

4177-A | ULTRASOUND LIVER IMAGING REPORTING AND DATA SYSTEM VERSION 2017: A SYSTEMATIC REVIEW AND META-ANALYSIS

Sunyoung Lee, Severance Hospital, Yonsei University College of Medicine, Claude B. Sirlin, University of California, San Diego and Victoria Chernyak, Memorial Sloan-Kettering Cancer Center

Background: We performed a systematic review and meta-analysis to determine the pooled proportions for each ultrasound (US) category and visualization score, the pooled percentages of probably or definitely hepatocellular carcinoma (HCC) and malignancy for US-3 category, and risk factor for US visualization score C on US Liver Imaging Reporting and Data System (LI-RADS) version 2017. **Methods:** We systematically searched databases to identify research articles that performed screening or surveillance US in patients at high risk for HCC according to US LI-RADS version 2017, published from January 1, 2017 to January 3, 2023. A random-effects model was used to calculate the meta-analytic pooled proportions and odds ratios (ORs). **Results:** Fifteen articles were finally included in the analysis, which consisted of 27,681 US examinations. The pooled proportions of each US LI-RADS category were 89.7% (95% CI [confidence interval], 86.7–92.6%) for US-1, 3.8% (95% CI, 1.8–5.9%) for US-2, and 6.3% (95% CI, 4.6–8.0%) for US-3. The pooled percentages of probably or definitely HCC and malignancy were 19.0% (95% CI, 12.3–25.6%) and 20.0% (95% CI, 14.5–25.5%), respectively. The pooled proportions of each US LI-RADS visualization score were 54.7% (95% CI, 44.2–65.2%) for A, 33.9% (95% CI, 27.5–40.2%) for B, and 6.7% (95% CI, 5.2–8.3%) for C. Obesity (OR, 2.37; 95% CI, 1.57–3.59; $P < 0.001$), nonalcoholic fatty liver disease (OR, 2.24; 95% CI, 1.64–3.06; $P < 0.001$), and Child-Pugh classification B or C (OR, 2.41; 95% CI, 1.43–4.06; $P = 0.001$) were significantly associated with US visualization score C. **Conclusion:** Approximately 90% of US screening or surveillance examinations were negative, 4% sub-threshold, and 6% positive. Approximately one in five US-3 observations represents probably or definitely HCC. Approximately 7% of US examinations had severe limitations for visualization. Alternative surveillance strategies might be considered in patients with risk factors for severe visualization limitations.

f 4178-A | A NEAR-INFRARED-MODULATED SYSTEM ENABLING EFFICIENT DELIVERY OF GLUCOSE DERIVATIVE AS A NEW THERAPEUTIC STRATEGY FOR LIVER CANCER

Kyo Sasaki[1], Satoshi Arai[2], Keisuke Hino[3] and Sohji Nishina[1], (1)Kawasaki Medical School, (2)Kanazawa University, (3)Shunan Memorial Hospital, Ube, Japan

Background: 2-Deoxy-D-glucose (2DG), a glucose derivative, has been reported to have cytotoxic effects against several cancers. However, the clinical application of 2DG was not recognized because of adverse events due to high dose administration. We developed cancer-specific drug delivery system (DDS) using 2DG encapsulated poly [lactic-co-glycolic acid (PLGA) nanoparticles (2DG-PLGA-NPs) (Cell Mol Gastroenterol Hepatol 2021). This system showed strong antitumor effect by cytotoxicity and antitumor immunity without any adverse events in mouse HCC models. The aim of this study was to assess antitumor effect of a novel DDS which delivers and releases 2DG more efficiently into cancer cells, using thermodynamic cell engineering. **Methods**: We engineered the liposomal nanoparticles (LNPs) where 2DG was encapsulated and a photothermal agent (a near-infrared absorbing dye) was embedded in the lipid membrane. The surface of LPNs was modified with cancer cell-targeting cyclic peptide (iRGD) which specifically binds to $\alpha v\beta 3/\alpha v\beta 5$ integrin highly expressed on the surface of tumor vessels and

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

tumor cells and then exposes CRGDK peptide after degradation by protease. LNPs are specifically transported into tumor cells by binding to neurophilin-1 through CRGDK peptide. Consequently, this engineered LNPs (termed as iRGD-2DG-nanoheater [iRGD-2DG-NanoHT]) was more specifically delivered to tumor cells and enabled more vigorous release of 2DG through the phase transitions after near-infrared irradiation. **Results:** We found that iRGD-2DG-NanoHT was much more accumulated in liver tumors than 2DG-NanoHT without iRGD in DEN-treated mice. Compared with 2DG-PLGA-NPs, iRGD-2DG-NanoHT exhibited more vigorous antitumor effect, which promoted necroptosis evidenced by phosphorylation of RIPK3 and MLKL and increased the release of high mobility group box-1 (HMGB-1) that functions as damage-associated molecular pattern (DAMP). Interestingly, iRGD-2DG-NanoHT also enhanced antitumor immunity demonstrated by increased $CD8^+$ T cell infiltration and suppressed Treg infiltration. **Conclusion:** iRGD-2DG-NanoHT which exhibits more cytotoxicity and antitumor immunity may be a promising DDS as a new therapeutic strategy for HCC.

4179-A | A NOVEL TUMOR SUPPRESSIVE ROLE OF NUCLEAR RECEPTOR NR2E3 IN HEPATOCARCINOGENESIS

Kyounghyun Kim[1], Yuet-Kin Leung[1], Soeun Park[1], Sung-Gwon Lee[2] and Chungoo Park[2], (1)University of Arkansas, (2)Chonnam National University

Background: We previously reported that an orphan nuclear receptor NR2E3 is essential for activating p53 in toxicant-induced liver injuries. Without NR2E3 expression, p53 was inactive in toxicant-induced liver injuries due to reduced chromatin accessibility of DINO (Damage Induced Noncoding RNA) induced by NR2E3 loss. DINO is a long noncoding RNA that interacts and stabilizes p53 protein to activate the p53 signaling cascade. Since p53 is a well-established tumor-suppressor gene in liver cancer, we aim to determine further the role of NR2E3 in toxicant-induced liver injury and carcinogenesis. **Methods:** We used DEN (diethylnitrosamine) as a hepatotoxicant to induce liver injury and carcinogenesis in wild-type and NR2E3 knockout (KO) mice. To determine the effects of NR2E3 loss on gene expression and chromatin accessibility changes, we performed RNA-seq and FAIRE (Formaldehyde-Assisted Isolation of Regulatory Elements)-seq analyses using wild-type and NR2E3 KO liver tumor lysate. **Results:** There were increased levels of DEN-induced liver injury and p53 inactivation observed in NR2E3 KO mice. Consistently, we observed significantly enhanced liver tumor progression and formation in NR2E3 KO mice, supporting a tumor suppressive and preventive role of NR2E3. Furthermore, gene set enrichment analysis (GSEA) results indicated that NR2E3 loss dysregulated multiple signaling pathways, such as c-Myc and mTOR, which can contribute to liver tumor development.Moreover, FAIRE-seq analysis revealed that the NR2E3 loss altered global chromatin accessibility corresponding to the pro-oncogenic signaling pathways. Lastly, to confirm whether c-myc and mTOR pathways are dysregulated in liver cancer patients expressing low levels of NR2E3, we divided liver cancer patients in TCGA data into two groups: NR2E3 high vs. Low expressing patient groups and then performed GSEA analysis. In the patient group expressing low NR2E3, we consistently observed the dysregulated or activated c-myc and mTOR signaling pathways. **Conclusion:** The loss of NR2E3 leads to altered chromatin accessibility at the epigenetic level, resulting in dysregulation or activation of crucial signaling pathways linked to liver injuries and tumor formation. Our data support that NR2E3 is a novel preventive and tumor suppressor gene in liver injuries and cancer by regulating epigenetic homeostasis.

4180-A | A SINGLE NUCLEOTIDE POLYMORPHISM IN HNF1A INDUCES NAFLD AND HEPATOCELLULAR CARCINOMA

Juanita L. Merchant, Heyu Song and Matthew Vance, University of Arizona, AZ

Background: We recently reported that a single nucleotide polymorphism (Rs1800574) in the DNA binding domain of transcription factor Hepatic Nuclear Factor 1 alpha (HNF1A) occurs with increased frequency in subjects with early onset colorectal cancer. The missense mutation changes an alanine to a valine residue at 98 and is sufficient to create reduced protein function ($HNF1A^{A98V}$), which we recently demonstrated using gel shift assays. Mutations in this locus are also associated with diabetes, dyslipidemia and hepatic adenomas. Therefore, we tested the hypothesis that this loss of function mutation also perturbs liver function. **Methods**: A point mutation was introduced into the mouse genome by CRISPR/Cas9. Mice were bred onto a C57BL/6 genetic background and mice heterozygous ($HNF1A^{A98V/+}$) and homozygous ($HNF1A^{A98V/A98V}$) for the variant were placed on a high fat diet (HFD, 60% fat) for up to 12 -14 months. Bulk RNA-Seq, qPCR,

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

immunohistochemistry and western blots were used to quantify changes. To dissect how elevated fat might affect levels with reduced HNF1A function, we performed bulk RNA-Seq and identified differentially expressed genes between the six groups. Plasma was analyzed for changes in liver enzymes and evidence of metabolic changes. **Results**: Within 6 months, only mice carrying the missense mutation developed fatty liver, elevated serum triglyceride and ALT levels. Similarly, insulin levels were elevated consistent with the presence of the metabolic syndrome. Using the picrosirius red stain revealed the presence of higher fibrosis in the mutant mice on the HFD. There were no significant changes in these parameters in mice on a normal chow or WT mice on the HFD demonstrating that the loss of function mutation was sufficient to induce changes but only in the presence of a fatty meal. Genes related to increased inflammation such as STAT3 and SOCS3 were differentially expressed and was highest in the homozygous group on the HFD. By 12 months, 2/8 *HNF1A*$^{A98V/A98V}$ mice developed liver tumors within a background of fatty liver on normal chow, while none of the WT or heterozygous mice developed tumors. By contrast, on the HFD, 3/5 heterozygous and 5/5 homozygous mice for the HNF1A^{A98V} variant developed tumors. None of the WT mice on the HFD developed liver tumors. The histology was consistent with hepatocellular carcinoma and stained for oncogenes such as cMET. **Conclusion**: A loss of function mutation in the DNA binding domain predisposes mice and possibly human subjects to NAFLD and HCC.

4181-A | ADMINISTRATION OF INTERLEUKINS 2 AND 18 WITH ANTI-PD-L1 ANTIBODY SUPPRESSES LIVER TUMOR GROWTH BY INCREASING EARLY MEMORY CD8 T CELL NUMBERS

Kiminori Kimura[1], Masamichi Kimura[1], Michinori Kohara[2], Haruki Okamura[3] and Yoshimasa Tanaka[4], (1)Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, (2)Tokyo Metropolitan Institute of Medical Science, (3)Hyogo College of Medicine, (4)Nagasaki University

Background: Hepatocellular carcinoma (HCC) is an intractable cancer with poor prognosis. Although various therapeutic drugs, including immune checkpoint inhibitors and tyrosine kinase inhibitors, have been evaluated for HCC treatment, their efficacies have, to date, been insufficient; the development of new drugs is therefore desired. **Methods:** A combination treatment with recombinant interleukin (IL)-2+recombinant IL-18 +anti-programmed death-ligand 1 (aPD-L1) antibody (Ab) was developed to activate an antitumor immune response. We found that it exerted antitumor effects against liver tumors in aged *Mdr2*-knockout mice, a hepato-carcinogenesis model with persistent liver inflammation similar to human hepatocellular carcinoma. The antitumor effects were evaluated based on tumor size assessed using computed tomography scans and serum alpha fetoprotein levels.To evaluate which inflammatory cell populations were infiltrated and activated, intrahepatic lymphocytes (IHLs) were isolated from the liver, and immunological analysis was performed. To investigate which T cells are essential for the antitumor effect of rIL-2+rIL-18+aPD-L1Ab administration, the changes in tumor size were examined using aCD8 neutralizing Ab, aasisloGM1 Ab, and aCD4 neutralizing Ab. Finally, to evaluate whether IL-18 and IL-18BP are involved in human liver diseases, serum IL-18BP levels from patients with HCC were compared with those in healthy volunteers (n = 24) and patients with HCV-derived chronic hepatitis (CH; n = 30), liver cirrhosis (LC) (n = 15), and HCC (n = 69). **Results:** The antitumor effects in terms of tumor progression were observed after rIL-2+rIL-18+aPD-L1Ab treatment but not after rIL-2+aPD-L1Ab or rIL-18+aPD-L1Ab treatment. Intrahepatic lymphocyte analysis showed marked infiltration by CD8 T cells, especially CD44^{-}CD62L^{+}, CD44^{+}CD62L^{+}, and Ly108^{+}CD69^{+} cells, following administration of the three drugs. In addition, serum interferon gamma, tumor necrosis factor alpha, and CXCL10 levels increased and IL-18 binding protein (BP) levels decreased. The antitumor effect was abolished with co-administration of aCD8-neutralizing Ab but not with aCD4-neutralizing Ab and aasialoGM1, indicating that CD8 T cells are required for this effect. Patients with HCC showed significantly higher levels of serum IL-18BP than patients with LC or CH. **Conclusion:** This triple combination treatment induced and maintained early memory CD8 T cells in the liver and may thus be a promising new immunotherapy for HCC.

4182-A | ATTENUATED LIVER TUMORIGENESIS IN FEMALE MICE IS ATTRIBUTED TO CONSERVED POLA1 EXPRESSION BY SMP30

Su-Min Baek and Jin-Kyu Park, Kyungpook National University

Background: POLA1 is located on X chromosome as well as SMP30. Traditionally, POLA1 is known to have a central role in DNA replication. However, in more recent studies, POLA1 is suggested to be involved in DNA repair process. Most of the studies were performed on the cancer cell lines only, so in the present study, we observed the role of POLA1 in hepatocellular tumorigenesis in mouse gender difference models associated with SMP30 expression levels. **Methods:** liver tumorigenesis was induced by combination of CCl_4 and Western diet administration for 28 weeks. Gross examination and histopathological analysis, serum ALT, AST, and ALB levels, immunofluorescence and immunohistochemistry were additionally analyzed to assess liver injury and tumorigenesis. Microarray analysis and qRT-PCR were performed to reveal the related genes. AML12, HepG2 and Hepa1c1c7 cells were also used to replicate *in vivo* condition. **Results:** Liver tumorigenesis was induced in all the mice regardless of gender. However, the number and maximum tumor nodule sizes were remarkably higher in male mice than in female mice ($p < 0.01$). Serum ALT, AST, and ALB levels and MPO positive neutrophils also showed higher liver injuries in male mice. Consistent with liver injury, glutamine synthetase, a liver tumorigenesis marker, showed higher positive cells in male mice both in nodule and parenchymal lesions. In both microarray analysis and qRT-PCR, POLA1 expression was upregulated in female tumor group while the gene was decreased in male tumor group. In addition, POLA1 expression was also increased in female tumor group than in female control group while no significant changes were observed between male tumor group and male control group. SMP30 showed a similar pattern. Consistent with *in vivo*, POLA1 expression was the highest in AML12, a normal hepatocyte cell line, but decreased in HepG2 and Hepa1c1c7, hepatocellular carcinoma cell lines. Moreover, in AML12 cells, POLA1 decreased with cell injuries following the increase in dose of palmitic acid and CCl_4. Moreover, SMP30 siRNA showed gradual decrease in POLA1 expression levels dose-dependently while POLA1 expression levels did not affect SMP30 expression levels in HepG2 cells. **Conclusion:** The study suggests the novel role of POLA1 and its association with SMP30 in liver tumorigenesis. The different expression levels of POLA1 and SMP30 expression levels in male and female ultimately resulted in gender disparity in the liver tumorigenesis.

4183-A | BAICALEIN INHIBITS THE PROLIFERATION OF HUMAN HEPATOCELLULAR CARCINOMA CELLS VIA MIR-5100-MEDIATED REGULATION OF SMARCA2-JAK2-STAT3 SIGNALING

Ying Guo[1,2,3], Jun Li[1,2], Jin Sun[1,2], Beibei Bie[1,2], Hongwei Tian[1,2], Mengjiao Shi[1,2], Mengchen Zhu[1,2], Jiazhen Zhu[1,2], Pengfei Liu[1,2] and Zongfang Li[1,2,3], (1) National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2) Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3)Shaanxi International Cooperation Base for Inflammation and Immunity, Xi'an, China

Background: Baicalein is a bioactive flavonoid that has been shown to have anticancer activity. However, it is unclear whether baicalein's antiproliferative effects are related to its regulation of miRNA expression such as miR-5100 in hepatocellular carcinoma. **Methods:** We used qRT-PCR experiments to verify whether the changes in miR-5100 expression after baicalein intervention were consistent with the previous miRNA chip results. The expression of miR-5100 in 36 pairs of human hepatocellular carcinoma and paracancerous samples was also detected by qRT-PCR. CCK-8, plate clone formation assay and flow cytometry were used to detect the effects of overexpression of miR-5100 on proliferation, clone formation, cell cycle distribution and apoptosis of two hepatoma cell lines. Further luciferase reporter and western blotting were used to identify target genes, while exploring possible downstream molecular mechanisms. **Results:** We

demonstrated that baicalein can inhibit cell proliferation in human hepatoma cells, and the expression of miR-5100 in cells is significantly upregulated after baicalein intervention. The expression of miR-5100 in clinical HCC samples was decreased (n = 36, $P = 0.0007$), and it was negatively correlated with SMARCA2 expression (n = 36, $P = 0.0013$). Overexpression of miR-5100 can inhibit proliferation and clone formation of hepatoma cells, block cell cycle in S phase, and induce apoptosis (the total apoptosis rate increased from 19.58 ± 2.0% to 34.30 ± 3.0%, 13.85 ± 1.3% to 40.97 ± 3.2%, respectively). After baicalein or miR-5100 treatment, the expression of target gene SMARCA2 protein was down-regulated. Luciferase report experiment confirmed that miR-5100 could bind to the 3 'UTR of SMARCA2. Mechanistic analysis showed that baicalein directly targeted SMARCA2 by upregulating miR-5100, thereby inhibiting the transduction of the JAK2-STAT3 signaling pathway. **Conclusion:** The study confirmed for the first time that baicalein regulates the activity of JAK2-STAT3 signaling pathway by upregulating the expression of miR-5100 in hepatoma cells, thereby inhibiting the proliferation and clonal formation, blocking the S-phase cell cycle, and inducing apoptosis of hepatoma cells.

4184-A | BETA-CATENIN INFLUENCES B CELL RECRUITMENT TO THE TUMOR MICROENVIRONMENT IN BETA-CATENIN-MUTATED HEPATOCELLULAR CARCINOMA CONTRIBUTING TO PATIENT SURVIVAL

Brandon M. Lehrich[1], Junyan Tao[1], Evan Delgado[1], Aatur Singhi[2], Silvia Liu[1] and Satdarshan (Paul) Monga[1,2], (1)University of Pittsburgh, (2)University of Pittsburgh Medical Center

Background: Immune checkpoint inhibitors (ICIs) for hepatocellular carcinoma (HCC) focus on T cell and tumor cell engagement. ICIs demonstrate improved overall survival (OS) for subsets of HCC patients, yet nearly all β-catenin-mutated HCC patients exhibit no benefit. The mechanisms underlying lack of response to ICIs in this subset remain poorly understood. Recently, B cells aggregated in tertiary lymphoid structures (TLS) have been implicated in ICI response in other solid tumors. Here, we investigate the role of B cells in β-catenin-mutated HCC. **Methods:** We queried TCGA and Cancer Digital Slide Archive for HCC patients with CTNNB1 mutation (encoding β-catenin), for B cell gene signatures and presence of TLS on hematoxylin and eosin (H&E) slides. We surveyed our clinically relevant HCC mouse models of T41A-CTNNB1-G31A-NFE2L2, S45Y-CTNNB1-hMET, cMYC-hMET, and FGF19-hMET for B cell markers by immunohistochemistry (IHC). Also, β-catenin-mutated models were treated with b-catenin inhibitor to address influence of β-catenin on immune cell infiltration. Lastly, we compared bulk RNA-sequencing data of β-catenin knockout (β-KO) and β-catenin-mutated livers and performed promoter enrichment analysis (PEA) on the differentially expressed genes (DEGs). **Results:** We observed the cohort of 97 β-catenin-mutated HCC cases to have low expression of 101/200 genes from a previously reported B cell gene signature. Importantly, in TCGA increased expression of multiple B cell surface markers (CD20, CD37, CD38, and CD79A) and presence of TLS were prognostic for improved disease-free survival specifically in β-catenin-mutated HCC patients. We independently confirmed lack of B cell infiltration in glutamine synthetase (a marker for β-catenin activity) positive patients at UPMC. In our HCC mouse models, we noted decreased $CD20^+$ and $CD79A^+$ immune infiltration via IHC in both β-catenin-mutated models compared to cMYC-hMET and FGF19-hMET non-b-catenin mutated models. Also, utilizing b-catenin inhibitor to the CTNNB1-mutated tumors not only reduced tumor burden, but also transformed the tumor microenvironment (TME). Analysis of DEGs using the Molecular Signatures Database demonstrated increased expression of pathways in B cell activation, proliferation, and lineage commitment. To address mechanism of β-catenin driving a B cell excluded TME, we performed PEA on the DEGs comparing β-KO and β-catenin-mutated livers and found low expression of POU2F1, a known regulator of CXCL13 (a chemokine promoting B cell recruitment and TLS formation) in β-catenin-mutated livers. **Conclusion:** β-catenin influences B cells in the TME of β-catenin-mutated HCCs and correlates to the patient survival. Future studies aim to explore the POU2F1/CXCL13 axis in driving ICI response.

4185-A | CHARACTERIZATION OF CEACAM6 MOLECULAR FUNCTION AND MECHANISM IN GALLBLADDER CANCER AGGRESSIVENESS

Raisatun Nisa Sugiyanto[1], Felicia Truckenmueller[1], Kira Guer[1], Thorben Huth[1], Aslihan Inal[1], Ivonne Heinze[2], Joanna Kirkpatrick[2], Angelika Fraas[1], Benjamin Goeppert[1], Stefan Pusch[3,4], Arianeb Mehrabi[5], Peter Schirmacher[1], Alessandro Ori[2] and Stephanie Roessler[1], (1)Pathology Institute, University Hospital Heidelberg, (2)Leibniz Institute on Aging, Fritz Lipmann Institute, (3)Clinical Cooperation Unit Neuropathology, German Cancer Research Center (DKFZ), (4) Department of Neuropathology, Institute of Pathology, University Hospital Heidelberg, (5)Department of General Visceral and Transplantation Surgery, University Hospital Heidelberg

Background: Gallbladder cancer (GBC) represents the most common biliary tract cancer. The molecular drivers for GBC aggressiveness are poorly identified. Carcinoembryonic Antigen-related Cell Adhesion Molecule 6 (CEACAM6) has been reported to be oncogenic in various tumor entities, yet CEACAM6 function in GBC is poorly understood. This study combines proteomic analysis of GBC patient samples, in vitro and in vivo characterizations of CEACAM6 function, and molecular mechanism investigation of CEACAM6 function in supporting GBC aggressiveness **Methods:** Mass-spectrometric analysis of 5 GBC and 5 healthy gallbladder FFPE tissues was performed. Differentially expressed proteins were analyzed to elucidate oncogenic protein in GBC. Transient siRNA knockdown and stable inducible cells were established to understand the CEACAM6 molecular function in vitro. RNASeq was conducted to reveal significant pathways perturbed by CEACAM6 expression. The molecular functions investigation in vivo was done by injecting cells to ATYM-Foxn1nu/nu nude mice via lateral tail-vein injection and to observe tumor cell growth in mice lungs for 4 weeks. BirA-BioID followed by mass-spectrometry was conducted to identify CEACAM6 interaction partners. Co-immunoprecipitation (CoIP), proximity ligation assay (PLA), and siRNA knockdown experiment were performed to validate the interacting partner candidates' physical interaction and molecular function. **Results:** Carcinoembryonic Antigen-related Cell Adhesion Molecule 6 (CEACAM6) presented as one of the strongest upregulated proteins in GBC proteomics (fold-change = 5.54, adjusted pval $\leq$ 0.01). CEACAM6 overexpression promoted migration and invasion of GBC cells, but reduced cell adhesion and colony formation. Less cell adhesion and tumor growth of cells with higher CEACAM6 expression were also observed in the in vivo lateral tail-vein injection experiment. Conversely, the knockdown of CEACAM6 reduced cell proliferation, colony formation, and migration, but increased cell adhesion. BirA-BioID followed by CoIP and PLA revealed that CEACAM6 signaling to promote migration was independent of Integrin Alpha-2 (ITGA2), but dependent on Integrin Beta-1 (ITGB1) and Protein Kinase C Delta (PRKCD). Correspondingly, integrin, AKT, and ERK signaling pathways were among the most significantly enriched pathways after CEACAM6 overexpression and knockdown in RNASeq analysis. Inhibition of AKT and ERK with inhibitors abrogated their downstream signaling and counter-attacked the CEACAM6-induced migration. **Conclusion:** CEACAM6 supports GBC aggressiveness by promoting cell migration and invasion, but reducing cell adhesion. CEACAM6 directly interacts with ITGA2, ITGB1 and PRKCD, and the migratory promotion of CEACAM6 depends on ITGB1 and PRKCD. Inhibition of CEACAM6 and/or administration of AKT and ERK inhibitors might be potential strategies to abrogate GBC aggressiveness.

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Portal fibroblasts are activated (aPFs) in response to cholestatic liver injury. They proliferate, upregulate Collagen Type I and critically contribute to liver fibrosis. aPFs express Mesothelin (Msln) and mucin16 (Muc16), both of which activate TGFβ1 signaling and Thy-1 which prevents TGFβ1 signaling. We investigated the role of Msln$^+$, Muc16$^+$, and Thy-1$^+$ aPFs in the pathogenesis of cholestatic fibrosis and cancer in aged (16-18 mo) multidrug resistance protein 2 knockout mice (Mdr2-/- mice), which develop sclerosing cholangitis and biliary fibrosis due to a defect in phosphatidylcholine secretion into bile. **Methods:** Mdr2-/- mice were crossed with Msln-/-, Muc16-/-, or Thy-1-/- mice. Development of liver fibrosis and cancer was compared in male and female mice ($n > 12$/group) using immunohistochemistry, qRT-PCR, and Western blotting. **Results:** All mice in the Mdr2-knockout background developed adenomas and hepatocellular carcinoma (GPC3$^+$Sox9$^+$ HCC) but not cholangiocarcinoma. HCC size and numbers were reduced in Mdr2-/-Msln-/- and Mdr2-/-Muc16-/- mice, which were associated with downregulation of tumor-associated markers AFP, Nox2, p67phox, phospho-Stat3. The numbers of F4/80+ myeloid cells, Desmin+, αSMA+ HSCs, and CD34 + aPFs were reduced in the non-tumor tissues of these mice (vs Mdr2-/- mice). Expression of inflammatory (CD68, Ly6G, IL1β, IL6, IL8) and fibrogenic genes (Col1a1, αSMA, TIMP1, TGFβ1) was also reduced in Mdr2-/-Msln-/- mice and Mdr2-/-Muc16-/- mice. In contrast, Mdr2-/-Thy-1-/- and Mdr2-/- mice showed no differences in tumor size/numbers, although expression of HCC-associated genes AFP and GPC3, inflammation, and liver fibrosis were exacerbated in aged Mdr2-/-Thy1-/- mice (due to increased aPF activation). Since recent studies linked HCC in aged mice to the increased accumulation of senescent hepatocytes, we assessed hepatocyte senescence. Indeed, expression of senescent markers β-gal, p21, p16, Bcl-2, Bcl-w and Bim was markedly reduced in Mdr2-/-Thy-1-/- and Mdr2-/- mice, while proliferation markers Ki67, Cyclin D, phospho-Akt were upregulated (vs Mdr2-/- or Mdr2-/-Thy-1-/- mice), suggesting that genetic deletion of Muc16 (which serves as a signal transduction receptor of Msln) and Msln prevents hepatocyte senescence in Mdr2-/- mice. **Conclusion:** Here we report a novel function of portal fibroblasts as drivers of cholestatic fibrosis, ductular reaction, inflammation, hepatocyte senescence, and HCC in aged mice, demonstrating the key role of the tumor microenvironment.

Background: Cholangiocarcinoma (CCA) is a highly aggressive adenocarcinoma with unsatisfactory treatment options. Claudin-1 (CLDN1) is a transmembrane protein expressed in tight junctions and at non-junctional localization mediating cell plasticity and signaling. We have previously developed highly specific monoclonal antibodies (mAbs) targeting exposed CLDN1 with an excellent safety profile (Roehlen et al. Science Transl Med 2022). Here, we aimed to investigate the role of non-junctional CLDN1 as a driver and therapeutic target for invasive and metastatic CCA. **Methods:** Comprehensive expression analyses were used to evaluate CLDN1 as a target for CCA treatment. Proof-of-concept studies were performed using humanized H3L3 CLDN1 mAbs in cell line-derived (CDX) and patient-derived xenograft (PDX) mouse models. CT imaging was used to investigate CLDN1 mAbs efficacy on CCA metastasis *in vivo*. Perturbation studies combined with single-cell and bulk RNA-Seq as well as proteomics were applied to study tumor cell fate and signaling. **Results:** Analyses of CLDN1 protein and RNA expression in CCA patient tissues revealed a robust CLDN1 upregulation. Single-cell RNA-Seq unraveled a high CLDN1 expression in tumor cells and cancer-associated fibroblasts (CAFs) showing an EMT phenotype with an upregulated vimentin and TNFα signaling. Targeting non-junctional CLDN1 using highly specific

mAb H3L3 demonstrated a significant anti-tumoral effect in intra- and extra-hepatic CCA CDX and PDX models. CLDN1 mAbs strongly inhibited migration and invasion in cell-based models and lung metastasis formation *in vivo*, suggesting a key role of CLDN1 in tumor metastasis. Mechanistically, CLDN1 mAb suppressed key signaling pathways implicated in CCA pathogenesis and their downstream target genes, including Notch1, SRC-Akt, and Hippo-YAP. CLDN1 mAbs suppressed pathways associated with stemness, EMT and extracellular matrix remodeling in single-cell RNA-Seq of CCA PDX model. Finally, patient-derived CLDN1-expressing CAFs markedly enhanced CCA tumor growth *in vivo* and modulated CCA EMT in co-culture studies. **Conclusion:** Collectively, our results uncover CLDN1 as a driver for CCA invasion and metastasis by modulating tumor cell signaling, EMT and the tumor microenvironment. Proof-of-concept studies using CLDN1-specific mAbs as a single agent reveal CLDN1 as an innovative therapeutic target for advanced CCA.

4188-A | CROSS TALK BETWEEN SIRT6 AND TGF-BETA SIGNALING MODULATE HUMAN NASH-HCC

Xiyan Xiang[1], Xiaochun Yang[1], Krishanu Bhowmick[1], Kazufumi Ohshiro[1], Anil K Vegesna[1] and Lopa Mishra[1,2], (1)The Institute for Bioelectronic Medicine, Feinstein Institutes for Medical Research, & Cold Spring Harbor Laboratory, Department of Medicine, Division of Gastroenterology and Hepatology, Northwell Health, Manhasset, New York, USA., (2)Center for Translational Medicine, Department of Surgery, the George Washington University, Washington, DC, USA., Washington, DC

Background: NASH driven HCC is rising alarmingly in the US. Yet, signaling mechanisms that control transformation to cancer are incompletely understood. SIRT6, a protein deacetylase, limits lipogenic activity and protects against TGF-β induced liver fibrosis. We identified a key regulatory loop in NASH/HCC development, where TGF-β signaling-βII-spectrin (SPTBN1) and SMAD3, induces SIRT6 expression *(FASEB J 2022;36.6)*. Liver-specific βII-spectrin knockout (LSKO) blocks NASH and HCC *(Sci Transl Med 2021;13:624)*. In addition, a highly expressed human HCC βII-spectrin-D1089Y somatic mutation disrupts SMAD3 activity (*Gastro 2018; 154:195-210*). Human HCC TCGA data reveal decreased SIRT6 correlating with altered TGF-β signaling. Here we explored the extent of βII-spectrin-D1089Y regulation of SIRT6 expression through SMAD3, and the combined roles of SIRT6 and SPTBN1 in human HCC. **Methods:** SIRT6 levels were examined in SPTBN1^{D1089Y} mutant and LSKO liver tissues. TGF-β/Smad3 pathway activity was analyzed in SPTBN1^{D1089Y} mutant cells with/without TGF- β treatment. SIRT6 expression was examined in mouse and human NAFLD/NASH (CITE-seq dataset (GSE156059 and NASH/HCC (GSE48452). snRNA-seq analysis of liver tissue from LSKO mice fed on NC, WD, and WD plus DEN was conducted. Differential microbiome phenotypes were explored in HCC patients with altered SIRT6 and SPTBN1. **Results:** SIRT6 RNA/protein levels are decreased in liver tissue from SPTBN1^{D1089Y} mutant and SIRT6 is decreased to a greater extent in LSKO mice ($p < 0.05$). TGF-β pathway activity is significantly impaired in SPTBN1^{D1089Y} mutants with decreased phospho-Smad3 levels and 3-TP promoter luciferase activity ($p < 0.05$). SIRT6 RNA expression in mice with NAFLD/NASH is significantly decreased in macrophages. Analyses of human NASH-HCC ($n = 15$), snRNA-seq data identify a subset of hepatocytes with an increase in SPTBN1 and SIRT6, but not SMAD3. Microbiome analysis show that the microbiome species such as Metallospheara, Fodinicurvata, and Sclerodarnavirus are significantly higher ($p < 0.05$) in HCC patients with altered SIRT6 and SPTBN1. **Conclusion**: Our studies indicated that 1. SIRT6 is regulated by βII-spectrin-D1089Y. Yet only part of SIRT6 regulation by βII-spectrin is through Smad3. 2. The data support a SMAD dependent as well as a SMAD3 independent role of SPTBN1 in regulating SIRT6. 3. βII-spectrin-D1089Y together with SIRT6 deficiency increased susceptibility to NASH/HCC in mice via regulating the microbiome.

4189-A | DEVELOPMENT OF NOVEL HUMAN HEPATOCELLULAR CARCINOMA MODELS USING GENETICALLY MODIFIED HUMAN HEPATOCYTES IN FSRG HUMANIZED LIVER MICE

Marisa Carbonaro and Zhe Li, Regeneron Pharmaceuticals

Background: The incidence of liver cancer is growing worldwide, and it is estimated that by 2025, over 1 million individual's will be affected by liver cancer every year.

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Hepatocellular carcinoma (HCC) accounts for about 90% of primary liver cancer cases and is one of the leading causes of death from cancer worldwide. Establishing animal models that faithfully replicate the human disease is critical to improve our understanding of HCC pathogenesis and to test new therapeutic strategies. Here, we describe a novel human HCC model using genetically modified human hepatocytes in a humanized liver mouse. **Methods:** Primary human hepatocytes (PHH) were modified *ex vivo* through lentivirus or Lipid Nanoparticle (LNP)-mediated delivery of CRISPR/Cas9 components, resulting in over-expression of oncogenes or inactivation of tumor suppressor genes. These genetically engineered PHH were engrafted into the livers of FSRG ($Fah^{-/-}$, $Sirpa^{hu/hu}$, $Rag2^{-/-}$, $Il2rg^{-/-}$) mice, developed by Regeneron VelociGene technology, in which mouse liver parenchyma can be replaced with human hepatocytes. **Results:** Tumor formation was validated in livers engrafted with human hepatocytes after different combinations of genetic modification, including over-expression of cMYC plus $HRAS^{v12}$, and cMYC over-expression together with p53 KO. Tumor progression could be monitored by measuring human Alpha Fetoprotein (AFP) in serum of engrafted mice. Liver tumors were positive for fumarylacetoacetate hydrolase (FAH) and human Asialoglycoprotein Receptor 1 (ASGR1), confirming their human origin, as well as the proliferation marker, Ki67, and Glypican-3 (GPC3), which is frequently over-expressed in HCC and a potential therapeutic target. **Conclusion:** In these studies, mice were engrafted with a mix of lentivirus-transduced and non-transduced hepatocytes, resulting in humanized livers with both normal and transformed human hepatocytes, providing an ideal system to recapitulate neoplastic transformation and clonal expansion of human hepatocytes carrying oncogenic mutations as well as to test the specificity of novel therapies. By combining genetic manipulation of human hepatocytes with the FSRG humanized liver mouse platform, we have established a flexible system to model clinically relevant combinations of HCC mutations for both new target discovery and therapeutic testing.

4190-A | EFFICACY OF RNAi-MEDIATED BETA-CATENIN INHIBITION IN MULTIPLE IMMUNOCOMPETENT MOUSE MODELS OF HEPATOCELLULAR CARCINOMA

Brandon M. Lehrich[1], Junyan Tao[1], Silvia Liu[1], Evan Delgado[1,2], Anya Singh Varma[1], Yuqing Liu[1], Minakshi Poddar[1], Sucha Singh[1], Tulin Dadali-Abel[3], Wendy Broom[3], Aaron W. Bell[1] and Satdarshan (Paul) Monga[1,4], (1)University of Pittsburgh, (2)University of Pittsburgh, Pittsburgh, PA, United States, (3)Alnylam Pharmaceuticals, (4)University of Pittsburgh Medical Center

Background: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related mortality globally. Approximately 25-35% of HCC patient tumors have mutations in β-catenin (CTNNB1). Several studies have indicated that this HCC subclass is almost entirely resistant to immunotherapy regimens, which are the current standard of care. Preclinical studies have elucidated addiction to β-catenin signaling in β-catenin-mutated HCC, making this target prime for precision medicine therapeutics. **Methods:** We inhibited β-catenin mRNA levels in the G31A-NFE2L2-T41A-β-catenin and hMet-S45Y-β-catenin mouse models of HCC which each represent around 9-12% of all human HCC. Starting at two different timepoints following hydrodynamic tail vein injection (HDTVi), animals were administered siRNAs formulated in lipid nanoparticles (LNP) targeting either CTNNB1 (LNP-CTNNB1) or scrambled control (LNP-CTRL). **Results:** LNP-CTNNB1 administered once weekly for six weeks starting at 5 weeks post HDTVi, when microscopic tumor foci were present, demonstrated complete tumor responses (CR) compared to LNP-CTRL in both models. Three days following the last dose in each model, the LNP-CTNNB1 group had normal liver weight/body weight ratio (4-4.5%) and histologically normal liver parenchyma compared to significant tumors in the LNP-CTRL group ($p < 0.001$). Additionally, the LNP-CTNNB1 group had durable responses up to 3 weeks following treatment cessation. Notably, a delayed treatment with LNP-CTNNB1 starting at 8 weeks post HDTVi, when macroscopic tumor nodules were present, delayed disease progression. To investigate the underlying mechanisms, livers were harvested 3 days after a single LNP dose. LNP-CTNNB1 treatment decreased activation of several β-catenin target genes (Glul, Axin2, Lect2), along with decreasing tumor cell proliferation markers (Ki67, Ccnd1), inhibition of mTOR pathway signaling components, and increased tumor cell death observed via TUNEL immunohistochemistry. Strikingly, the LNP-CTNNB1 group revealed dynamic shifts in the tumor microenvironment, including alterations in gene signatures related to type I interferon response, lymphoid progenitor cell differentiation, antigen presentation, and T cell cytokine production. **Conclusion:** Our studies demonstrated the efficacy of RNAi-mediated inhibition of CTNNB1 for β-catenin-mutated HCC and provide strong preclinical evidence to support clinical translation as monotherapy as well as in combination with other treatments.

4191-A | EPIGENETIC CONTROL OF SLC7A11 UPREGULATION BY TET1 INHIBITS FERROPTOSIS IN CHOLANGIOCARCINOMA

Hongze Chen[1], Muhammad Azhar Nisar[1], Eve Elkins[1], Sonali Notani[1], Xiao-Ming Yin[1], Shaolei Lu[2], Xuewei Bai[3] and Chiung-kuei Huang[1], (1)Tulane University School of Medicine, New Orleans, LA, (2)Alpert Medical School of Brown University, (3)The First Affiliated Hospital of Harbin Medical University

Background: Ferroptosis is a form of iron-dependent cell death and has emerged as a potential cancer target. It is commonly observed that iron overload occurs in patients with chronic liver diseases, which are risk factors for cholangiocarcinoma (CCA) incidence. However, ferroptosis is not active in CCA patients, suggesting that some mechanisms may block the activation of ferroptosis pathways in CCA. This study aimed to determine the epigenetic control of ferroptosis in CCA. **Methods:** The expression of ferroptosis-associated genes and DNA methylation enzymes were analyzed using RNA sequencing data retrieved from the TCGA and GEO resources. The Kaplan-Meier analysis was used to investigate the correlation between these gene levels and CCA survival. In vitro cell culture and in vivo preclinical CCA models were adopted to evaluate the causative impacts of the identified genes on ferroptosis and CCA progression. **Results:** We found that the ferroptosis suppressing gene-SLC7A11 is associated with poor prognosis in human CCA patients. Besides, high TET1 is correlated with CCA prognosis, suggesting the potential link between TET1 and SLC7A11. Knockdown of TET1 suppresses CCA cell survival due to increased cell ferroptosis since the ferroptosis inhibitor robustly reversed the impact of TET1 downregulation on CCA cells. Consistently, inhibiting TET1 reduced SLC7A11 expression, resulting in ferroptosis. Overexpression of SLC7A11 rescued the effects of TET1 knockdown on CCA cells. Mechanistically, inhibiting TET1 enzymatic functions downregulated SLC7A11 expression resulting in ferroptosis in CCA cells. In contrast, activating TET1 induced SLC7A11 levels leading to reduced ferroptosis. The treatment of DNA methylation inhibitor 5-azacytidine reversed the suppressive effects of TET1 downregulation on SLC7A11, thereby suggesting that TET1 regulates ferroptosis in CCA tumors through epigenetic control of SLC7A11. Further, we found that the ferroptosis inducers (Erastin and RSL3) suppressed CCA viability robustly but to a less extent in TET1 knockdown CCA cells. Similarly, UC-514321 significantly inhibited CCA malignant progression by suppressing the TET1-mediated SLC7A11 mechanism. More importantly, all these treatments substantially suppressed CCA malignant progression in the orthoptic CCA xenograft model. **Conclusion:** Our data demonstrated that ferroptosis is inhibited in CCA by the TET1-mediated SLC7A11 upregulation. Targeting the TET1/SLC7A11 axis may be potential therapeutic approach for CCA patients.

4192-A | EXTRACELLULAR MATRIX REMODELING IN THE PROGRESSION OF PRIMARY SCLEROSING CHOLANGITIS TO CHOLANGIOCARCINOMA: INSIGHTS FROM AN ANIMAL MODEL

Massimiliano Cadamuro[1], Samantha Sarcognato[2], Romina Fiorotto[3], Silvia Cagnin[4], Noemi Girardi[4], Nora Cazzagon[4], Enrico Gringeri[4], Umberto Cillo[4], Claudia Mescoli[4], Maria Guido[2,4], Paolo Simioni[4,5], Jesus M. Banales[6], Mario Strazzabosco[3] and Luca Fabris[3,4,5], (1) Univeristy of Padua, (2)Azienda ULSS2 Marca Trevigiana, (3)Yale University, New Haven, CT, (4) University of Padova, (5)Padua University-Hospital, (6) Biodonostia Research Institute, Donostia University Hospital, University of the Basque Country (UPV-EHU), Ciberehd, Ikerbasque, , Donostia, Spain

Background: Primary Sclerosing Cholangitis (PSC) is a chronic biliary disease characterized by peribiliary fibrosis evolving to cholangiocarcinoma (CCA). As PSC, CCA is characterized by prominent extracellular matrix (ECM) accumulation. Despite this association, the mechanisms by which fibrosis is accompanied by dysplasia and malignant transformation remain uncharted, reflecting the lack of an appropriate experimental model to capture the sequence from PSC to CCA (CCA/PSC). In this study, we aimed at developing an animal model of CCA/PSC to assess changes in ECM proteins typically up-regulated in CCA (Osteopontin (OPN), Tenascin C (TnC) and Periostin (POSTN)), as potential biomarkers enabling early detection of tumoral lesions in PSC. **Methods:** Mrd2$^{-/-}$ mice, a well-established PSC model, were treated with thioacetamide (TAA), a profibrogenic toxicant, to induce CCA, and sacrificed at different time points (12 and 28 weeks, both n = 4) and compared with controls (Mdr2$^{-/-}$

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

without TTA and WT+TAA mice, both n = 4). ECM phenotyping was performed in liver sections from mice and human archival samples of CCA/PSC (n = 5) by immunohistochemistry (IHC) for OPN, TnC and POSTN. *In vitro*, human CCA cells (HUCCT-1, EGI-1) and primary human PSC cells were treated for 24h with OPN (10nM), TnC (100nM), and POSTN (100nM) to evaluate cell viability (MTS), migration (wound healing), and cancer stem cell (CSC)-like phenotypic switch (CD133 and CD44, real-time PCR). **Results:** Upon TTA treatment, Mdr2$^{-/-}$ mice but not controls developed biliary dysplasia (2/4 at 12, 1/4 at 28 weeks) and intrahepatic CCA (1/4 at 12, 3/4 at 28 weeks). IHC showed a progressive increase from classic ductal to dysplastic and neoplastic lesions for TnC, POSTN, and more prominently for OPN, similarly to what seen in human samples. *In vitro,* 24h treatment with ECM proteins enhanced migratory properties in CCA, but not in PSC cells. POSTN, and less efficiently TnC and OPN, induced a significant upregulation of CD133 and CD44 in both CCA and PSC cells, signature of CSC-like phenotype. **Conclusion:** The Mdr2$^{-/-}$+TAA mouse recapitulates the pathogenetic sequence biliary fibrosis-biliary dysplasia-CCA. In both murine and human samples OPN, TnC and POSTN are overexpressed in malignant lesions. *In vitro*, ECM proteins, particularly POSTN, induce a CSC-like switch in CCA and PSC cells, in support of their tumor-initiating role. ECM proteins may serve as putative tissue biomarkers for CCA surveillance in PSC patients.

4193-A | FUNCTIONAL DICHOTOMY OF BILIARY PRIMARY CILIA IN LIVER INJURY AND CHOLANGIOCARCINOMA DEVELOPMENT

Jinbiao Chen[1], Fan Zhang[2], Ngan Ching Cheng[1], Ken Liu[1], Sofia Ferreira-Gonzalez[3], Jennifer R Gamble[1], Emad Ei-Omar[2], James G Kench[4], Stuart J Forbes[3] and Geoffrey McCaughan[1], (1)Centenary Institute, (2)Unsw, (3)Centre for Regenerative Medicine, Institute for Regeneration and Repair, the University of Edinburgh, (4)RPA Hospital

Background: We have previously published that Primary cilia (Pc) mediate canonical Hedgehog (Hh) signalling in the ductular reaction (DR) in experimental and human cirrhosis. However, our recent publication indicated that Pc loss in biliary epithelial cells (BEC) induced the proliferation of BECs and biliary cystic formation in experimental fibrosis models. We now aim to examine the effect of Pc loss on the development of cholangiocarcinoma in BEC-specific PTEN knockout (KO) mice. **Methods:** C57BL/6J-congenic Pten-flox and kif3a-flox mice crossed with CK19CreERT knockin mice to produce BEC-specific KO of PTEN, kif3a (Pc loss) or both (DKO) following tamoxifen (TAM) administration in adult mice. Thioacetamide (TAA) was used to induce liver injury and fibrosis for up to 20 weeks. Mice were culled at weeks 14 and 18 post-TAM administration. Tissue samples were examined with histopathological assays and RNA-seq. The SLHD Animal Welfare Committee approved animal breeding and experimental protocols. **Results:** In BEC-specific PTEN KO mice (PTEN-BKO), intraductal papillary neoplasm of the bile duct was evidenced in the large intrahepatic bile ducts. TAA administration induced cholangiocarcinoma (CCA) formation. Pc were lost in these CCA cells. To test whether Pc loss actually played a role in the development of CCA, PTEN-BKO mice were crossed with BEC-specific kif3a KO mice to produce double KO (DKO) mice. When these DKO mice consumed TAA, the number and size of CCAs were significantly increased compared with PTEN-BKO mice. Histological analysis indicated increased expression of PCNA, Sox9, phospho-ERK, infiltration of neutrophils and macrophages, and the presence of significant stroma formation similar to that seen in human CCA. RNA-seq analysis revealed that expression levels of 288 genes were significantly increased in PTEN-BKO and DKO liver tissues compared with wild-type (WT) liver tissues. For example, CCA tumour marker genes, such as msln, S100A6, and DMBT1, were dramatically increased in PTEN-BKO and DKO livers compared with WT livers. More importantly, a set of genes over-expressed in human CCA with poor prognosis were enriched in PTEN-BKO and DKO liver tissues. Multiple MAPK genes or signalling pathways and some stem cell markers, such as CD44 and DCLK1, were upregulated in PTEN KO or DKO livers. Interestingly, more than 8% of up-expressed genes in PTEN-BKO and DKO livers are targets of the JNK pathway, which was well-documented to promote CCA growth. Further analysis is ongoing. **Conclusion:** Loss of Pc in BEC could have been secondary to the oncogenic transformation, but the increase of CCA in DKO mice indicates a role for Pc in the progression of CCA. Cholangiocarcinoma in such mice shared significant features of human CCA, including many overlapping upregulated genes, thus providing a pre-clinical model for testing new therapeutic approaches.

4194-A | GDF11 ACTS AS A CHEMO-SENSITIZER WITH CISPLATIN AND SORAFENIB TREATMENTS IN HCC-DERIVED CELLS

Natanael German Ramirez[1,2], Arturo Simoni Nieves[3], Maria Guadalupe Isabel Domínguez Gómez[4], Monserrat Gerardo Ramirez[5], Benjamín Peréz Aguilar[1], Leticia Bucio Ortiz[1], Verónica Souza Arroyo[1], Roxana Uri Miranda Labra[1], Concepcion Gutierrez Ruiz[1] and Luis Enrique Gómez Quiroz[1], (1)Area De Medicina Experimental y Traslacional. Division De Ciencias Biologicas y De La Salud. Universidad Autonoma Metropolitana Unidad Iztapalapa, (3)Roger Williams Institute of Hepatology, (4)Division De Investigacion Basica. Instituto Nacional De Cancerologia, (5)Johannes Gutenberg University

Background: Hepatocellular carcinoma (HCC) accounts for 90% of liver tumors, representing the third leading cause of cancer-related deaths worldwide. Actual drugs have poor therapeutic outcomes in HCC and novel effective therapies are required for the treatment of this disease. The Growth and Differentiation Factor 11 (GDF11) is a TGF-β superfamily member with several biological roles including cancer. Our group has demonstrated the anti-tumoral activity of GDF11 on HCC-derived cell lines reducing cell proliferation, metabolism, migration, and invasive capacity. In the present work, we also report the chemo-sensitizing effects of GDF11 in the HCC-derived Huh7 cell line in combination with sorafenib (Sfb) and cisplatin (Cisp) treatments. **Methods:** The Huh7 cell line was pre-treated with 50 ng/ml of GDF11 for 72 h with changes of medium every 24 h. After pre-treatment of GDF11, we added Cisp or Sfb at different concentrations and incubated the cells for 48 h. For ALK5 receptor inhibition experiments, we added 5 μM of SB-431542 in the GDF11 pre-treatments. Subsequently, we performed cell viability, spheroid formation assays and western blot analysis. We report the data as the mean ± S.E.M. of at least three independent experiments. We performed an analysis of variance (ANOVA) followed by the Tukey multiple comparison test. Significance was set at $p \leq 0.05$. **Results:** The GDF11 pre-treatment reduced the IC_{50} of Cisp in the Huh7 cell line from 22.11 μM to 6.611 μM and the Sfb concentration from 17.12 μM to 12.8 μM. GDF11 decreased the cell viability in the Huh7 cell line in combination with 6.611 μM Cisp or Sfb 16 μM compared to treatment alone. Also, GDF11 alone significantly lessened the spheroid diameter, NT: 114.4 μm, GDF11: 35.58 μm, Sfb: 43.43 μm and GDF1 + Sfb: 28.26 μm; and the spheroid number, NT: 177.5 ± 46.28, GDF11: 25.00 ± 25.13, Sfb: 34.22 ± 32.05 and GDF1 + Sfb: 5.667 ± 6.59. Also, we characterized that the GDF11 chemo-sensitizing effects are mediated through the ALK5 receptor. The ALK5 inhibitor SB-431542 abrogated the phosphorylation of SMAD-2 and counteracted the chemo-sensibilization effects induced by GDF11 pre-treatment. **Conclusion:** The GDF11 could be a promising new adjuvant therapy in the HCC treatment, allowing the use of lower chemotherapeutic doses and reducing the adverse side effects of these therapies. Grant: Antonio Ariza Cañadilla, FUNDEHPA.

University College of Pharmacy, (2)University of California, San Diego, La Jolla, CA, (3)Cedars-Sinai Medical Center, Torrance, CA

Background: Sorafenib-resistance is often seen in the patients with late-stage hepatocellular carcinoma (HCC) and it is a serious concern for the treatment of these patients. Of note, Sorafenib induces mitochondrial dysfunction and mitophagic cell death. Sorafenib resistance is associated with the activation of GP130 signaling, inhibiting mitochondrial quality. However, how mitophagic cell death regulates sorafenib resistance through GP130 and mitochondrial dysfunction in HCC is not fully understood. **Methods:** Hepatocyte-specific TAK1 deleted (TAK1ΔHep) and TAK1/ GP130ΔHep were used for in vivo study. Histology, immunoblots, qPCR, microscopy, FACS, and seahorse bioanalyzer were used for analyzing liver and tumor tissues and Hep3B cells. **Results:** We identified that sorafenib suppressed GP130 signaling and that GP130 signaling was activated in sorafenib-resistant HCC. The number and maximum size of spontaneous HCC in 9-month-old TAK1ΔHep mice were decreased when hepatocyte GP130 was additionally deleted. Expression of pro-carcinogenic H-19, c-SRC, and MDM2 was increased in 1-month-old TAK1/GP130ΔHep mice compared to TAK1ΔHep mice. An additional GP130 deletion induced decreases in mitochondrial respiration and glycolysis, suggesting that GP130 protects against mitochondrial dysfunction in HCC. Interestingly, GP130 deletion increases PRKN and BECN1 interaction and translocation to normal mitochondria and subsequent degradation, hereafter referred to as mitophagic cell death. Furthermore, inhibition of BECN1 restores GP130 deletion-induced mitophagic cell death in HCC, suggesting that GP130-mediated mitophagic cell death is dependent on BECN1. Mechanistically, GP130 inhibited BECN1-mitophagic cell death through STAT3 (T705) phosphorylation independently of mTORC1 activation. Notably, enhanced BECN1 through a combination of sorafenib and inhibition of GP130 increased mitophagic cell death, reducing sorafenib resistance and tumor growth. In addition, enhanced mitophagic cell death through inhibition of GP130 effectively killed sorafenib-resistant HCC cells by silencing sorafenib resistance. We further defined the relationship between GP130, BECN1, and PRKN expression and sorafenib resistance in terms of HCC patients, RNA sequencing datasets. **Conclusion:** These results provide the importance of GP130 in the development of sorafenib resistance and could be an innovative treatment strategy for sorafenib-resistant patients by regulating the GP130-STAT3-BECN1-regulated mitophagic cell death.

4196-A | INTERFERON-RELATED GENE EXPRESSION CHANGES MEDIATED BY ALPHA-FETOPROTEIN IN PATIENTS WHO DEVELOPED HEPATOCELLULAR CARCINOMA AFTER HEPATITIS C VIRUS ERADICATION

Katsuya Nagaoka[1], Masakuni Tateyama[1], Satoshi Narahara[1,2], Sotaro Kurano[1], Kentaro Tanaka[2], Hiroki Inada[2], Takayuki Tokunaga[2], Etsuko Iio[2], Yoko Yoshimaru[2], Takehisa Watanabe[2], Hiroko Setoyama[2], Hideaki Naoe[1] and Yasuhito Tanaka[1], (1)Graduate School of Medical Sciences, Kumamoto University, (2) Faculty of Life Sciences, Kumamoto University

Background: Alpha fetoprotein (AFP) is a serum protein found in fetuses during early pregnancy and has been used as a tumor marker for hepatocellular carcinoma (HCC). Serum AFP levels are often elevated in chronic hepatitis C, even in the absence of HCC. In fact, we have reported that even slightly elevated AFP levels in the range of less than 20 ng/mL are a risk factor for liver carcinogenesis in chronic liver disease (J Gastroenterol. 2011; 46: 92.). Thus, AFP expression increases with hepatitis and tumor growth, but conversely, it is not well understood whether AFP expression affects the cellular environment in hepatocarcinogenesis. **Methods:** To elucidate the function of AFP in

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

liver/ hepatocellular carcinoma cells, *in vitro* experiments were conducted using human cell lines (hepatocarcinoma-derived cells HepG2 and normal hepatocyte-like cells HuSE) with an AFP overexpressing expression system. The human AFP gene was cloned, and the AFP protein was expressed using pcDNA3-Flag vector. RNA was extracted from the cells, and RNA-seq was performed using a next-generation sequencer to comprehensively analyze changes in gene expression. In addition, from patients who developed hepatocellular carcinoma after Sustained Virological Response (SVR) of chronic liver disease type C, RNA was extracted from the cancerous and non-cancerous parts of liver resection specimens and changes in gene expression were analyzed. **Results:** Comprehensive analysis of gene expression changes in AFP-expressing cell lines and bioinformatics analysis by Gene Set Enrichment Analysis (GSEA) revealed that differentially expressed genes in the AFP-expressing cells were significantly associated with interferon-α/γ, and genes involved in fatty acid metabolism than in the control. Analysis of cancerous and non-cancerous area of liver resected tissue showed a significant positive correlation between AFP gene expression and interferon-α related gene expression, both cancerous and non-cancerous area. In addition, the expression of AFP gene expression and VEGFA gene expression were strongly correlated in cancer regions. **Conclusion:** These results showed a correlation between the elevated AFP gene expression in hepatocellular carcinoma tissue with elevated interferon-α-related gene expression and altered VEGFA gene expression in patients with chronic liver disease with slightly elevated serum AFP levels in the range of less than 20 ng/ml. These results suggest that even a slight increase in AFP expression may have a certain impact on the hepatocellular carcinoma microenvironment.

f 4197-A | IRF2 EXPRESSION IN B-CATENIN-MUTATED HEPATOCELLULAR CARCINOMAS PROMOTES INFLAMMATION AND REDUCED TUMOR BURDEN

Evan Delgado[1], Panari Patel[2], Junyan Tao[1], Yekaterina Krutsenko[2], Brandon M. Lehrich[1], Anya Singh Varma[1], Ravi Rai[1], Minakshi Poddar[1], Sucha Singh[1], Aaron W. Bell[3], Reben Raeman[1] and Satdarshan (Paul) Monga[1], (1)University of Pittsburgh, (2)University of Pittsburgh School of Medicine, (3)University of Pittsburgh, Sewickley, PA

Background: The current standard of care for unresectable HCC is combination immune checkpoint inhibitors (ICIs), whose foundation was laid by the IMbrave150 trial. Because of imperfect response rates to ICIs, specific molecular aberrations have been implicated in diverse responses to ICI therapy. 30% of patients that harbor mutations in *CTNNB1*, the gene that encodes β-catenin, seem to respond poorly to ICI intervention. However, understanding if *CTNNB1* mutations directly contribute to immune escape in clinical HCC is still in need of investigation. Here, we investigate whether promoting an inflammatory response is sufficient to prevent HCC progression. **Methods:** Bioinformatic analysis was performed on b-catenin loss or gain of function livers to identify mechanisms of immune cell regulation. Next, HCCs generated in mice by co-delivering mutant-β-catenin-(S45Y) and the MET tyrosine kinase (B+M model) that represent 11% subset of HCCs with a 69% genetic accuracy to patients was used to validating *in silco* findings. The interferon response transcription factor, IRF2, was delivered alongside oncogenes in the B+M model. HCC burden was assessed in controls and +IRF2 condition. IRF2 activity was also measured by immunoblot and immunostaining. Intrahepatic and peripheral immune populations were characterized by FACS and by immunostaining to identify shifts in the immune microenvironment and exhaustion. **Results:** Overexpression of IRF2 was detectable in HCC nodules by 4 weeks post-HCC induction, which led to a significant reduction in overall tumor burden 7.5 weeks after HCC induction. We also found a significant accumulation of intratumoral $CD45^+$ cells after IRF2 expression in the B+M model. FACS identified significant shifts towards a less exhausted immune microenvironment, and a decreased accumulation of immunosuppressive FoxP3+ T-regulatory cells. We also asked if endogenous IRF2 stimulation is sufficient to

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

drive a functional inflammatory response. B+M animals treated daily with 1×10^4 IU IFNy for 4 weeks led to a modest 10% reduction in overall disease burden. **Conclusion:** Activating the interferon response in *CTNNB1*-mutated HCC is sufficient to reduce overall tumor burden and disease. This is driven by an inflammatory response characterized by less exhausted cytotoxic T-cells and immunosuppressive T-regs. Our data indicates inducing cytotoxic inflammation in β-catenin-mutated HCCs may be an effective method to produce an anti-tumor response.

4198-A | KIDNEY GLUTAMINASE IN HEPATOCELLULAR CARCINOMA: A NOVEL DRUGGABLE TARGET ADDRESSING CANCER CELL METABOLIC REPROGRAMMING

Vincent Tambay[1], Valérie-Ann Raymond[2] and Marc Bilodeau[2,3], (1)Centre De Recherche Du Centre Hospitalier De L'université De Montréal, (2)Centre De Recherche Du Centre Hospitalier De L'université De Montréal (CRCHUM), (3)Département De Médecine, Université De Montréal

Background: Hepatocellular carcinoma (HCC) is a major contributor to the global cancer burden, in part due to very limited therapies. Reprogramming of glutamine metabolism is a putative determinant of HCC pathogenesis. Glutaminase (GLS) is a major pathway used by cancer cells to metabolize glutamine. **Methods:** Tumorigenic murine HCC Dt81Hepa1-6 (Dt81) cells and isolated primary murine hepatocytes (HP) were cultured with CB-839, a kidney GLS (GLS1) inhibitor. The influence of CB-839 on cellular activity was assessed on viability (MTT), proliferation, ammonia production, and glutamine and glutamate content (LC/MS). The expressions of various genes or proteins linked to glutamine metabolism were measured by qPCR and Western blotting, respectfully. Glutamine consumption was measured by ^{3}H-glutamine uptake assay. **Results:** GLS1 mRNA expression was higher in Dt81 than in HP ($p < 0.01$), whereas that of liver GLS (GLS2) was inversely higher in HP than in Dt81 ($p < 0.01$). In Dt81 cells, CB-839 [1 μM] significantly decreased ammonia production from 0.75 ± 0.06 to 0.19 ± 0.09 μmol/mg protein ($p < 0.01$), but not in HP. The Dt81 glutamine/glutamate ratio increased from 2.54 ± 0.14 to 9.20 ± 0.34 upon CB-839 [1 μM] treatment ($p < 0.0001$), suggestive of decreased glutaminolysis. CB-839 decreased ^{3}H-glutamine uptake in HP ($p < 0.05$) but to a lesser extent than in Dt81 ($p < 0.0001$). GLS1 mRNA increased ($p < 0.01$) in a dose-dependent manner with CB-839 in Dt81 but not in HP, whereas GLS2 remained unchanged in both cell types. Lactate dehydrogenase tended to decrease whereas glutamine and asparagine synthetases tended to increase with CB-839 exposure. CB-839 decreased HP and Dt81 viability ($p < 0.0001$), Dt81 being more sensitive to CB-839 ($23.2 \pm 1.36\%$ decrease at 1μM) than HP ($11.9 \pm 3.0\%$ decrease at 1μM). CB-839 treatment also slowed Dt81 cell doubling time from 36.04 ± 2.02h to 129.4 ± 52.8h [10 μM] ($p < 0.05$). Interestingly, replenishing α-ketoglutarate, a metabolite downstream GLS, restored cell viability in Dt81 treated with CB-839 ($p < 0.0001$). **Conclusion:** In murine HCC cells, GLS reprogramming is targetable through the non-competitive inhibitor CB-839. Indeed, targeting GLS in HCC impairs cancer cell metabolism, which in turn leads to cell death and decreased proliferative capacity. These findings highlight the fundamental importance for glutamine metabolism in murine HCC cells compared to normal hepatocytes.

f 4200-A | LOSS OF GLUTAMINE SYNTHETASE EXACERBATES MYELOID CELL INDUCED IMMUNOSUPPRESSION IN B-CATENIN-MUTATED HEPATOCELLULAR CARCINOMAS

Evan Delgado[1], Panari Patel[2], Junyan Tao[1], Silvia Liu[3], Brandon M. Lehrich[1], Minakshi Poddar[1], Sucha Singh[1], Aaron W. Bell[4] and Satdarshan (Paul) Monga[1], (1)University of Pittsburgh, (2)University of Pittsburgh School of Medicine, (3)Pittsburgh Liver Research Center, (4)University of Pittsburgh, Sewickley, PA

Background: Around 30% of HCC cases harbor mutations in *CTNNB1*, the gene that encodes β-catenin. These tumors can be identified with high sensitivity and specificity on histology by tumor-wide positivity for Glutamine Synthetase (GS), encoded by *Glul,* a well-known b-catenin target gene. Previously, the b-catenin-GS-glutamine-mTORC1 axis has been examined in b-catenin-mutated HCCs which demonstrate high susceptibility to mTOR inhibitors in preclinical models. Here, we investigate this axis further by targeting GS in b-catenin-mutated HCCs with a major focus on tumor immune environment. **Methods:** HCCs were induced in *Glul*-floxed mice by co-delivering mutant-β-catenin-(T41A) and mutant nuclear factor erythroid 2–related

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

factor 2 (Nrf2-G31A) (B+N model). *Glul* elimination following tumorigenesis was achieved by delivering AAV8 carrying Cre-recombinase. HCC burden was assessed in *Glul*-KO and controls. We preformed 10x Genomics Spatial Gene Expression profiling to measure mRNA with fluorescent immunostaining in tandem, as well as single-cell RNA-sequencing (scRNA-Seq) to identify changes in the immune microenvironment in *CTNNB1*-mutated HCCs ± GS. **Results:** *Glul* was sufficiently deleted by two weeks from HCCs in the B+N model using AAV8-Cre. This was associated by decreased intratumoral glutamine levels. Interestingly, 4.5-weeks post *Glul* elimination, a significant increase in LW/BW ratio indicating a greater tumor burden was observed which also persisted at 7-weeks. Spatial expression analysis showed decreases in *Mrc1*, *Adgre1*, *Cd68*, *Vsig4*, and *Cxcr4,* markers of myeloid cells, which was also validated by immunohistochemistry. sc-RNA-Seq data identified a specific increase in the numbers of myeloid cells expressing immunosuppressive patterns in GS-knockdown HCCs. Finally, disease burden is unchanged following macrophage depletion in B+N control animals. **Conclusion:** Our data indicate that GS-loss increases the immunosuppressive function of myeloid cells thus contributing to the increase in disease burden in *Glul*-KO animals. Since myeloid cells are still detected in these tissues, our data suggests intrinsic *Glul* expression and in turn tumoral glutamine levels in β-catenin-mutated HCCs alter resident macrophage function and physiology. It is unclear if tumor associated macrophages in HCCs are dysfunctional Kupffer cells or originate from other myeloid populations. More information may provide insight into HCC disease pathogenesis and information regarding ICI efficacy.

4201-A | LOSS OF hepaticTsc1 PROMOTES LIVER CYSTOGENESIS AND TUMORIGENESIS VIA A NON-CANONICAL mTORC1-TFEB-DEPENDENT MECHANISM

Chen Zhang[1], Sha Neisha Williams[1], Hong-Min Ni[2] and Wen-Xing Ding[3], (1)The University of Kansas Mediacal Center, (2)The University of Kansas Medical Center, (3) University of Kansas Medical Center, Kansas City, KS

Background: The integration of various environmental cues by mTORC1 is crucial in regulating cell growth and metabolism. Activation of mTORC1 occurs when growth factors or amino acids stimulate Rag GTPase heterodimeric complexes, such as Rag A/C, at the lysosomal surface. In mice, the loss of Tsc1 leads to activation of mTORC, increased ductular reaction (DR), cystogenesis, and spontaneous liver tumorigenesis. While mTORC1-mediated phosphorylation inactivates Transcription factor EB (TFEB), a master transcription factor of autophagy and lysosomal biogenesis, emerging evidence highlights that TFEB is dephosphorylated and hyper-activated in TSC-associated kidney cystogenesis and cancer. The purpose of this study was to investigate whether and how loss of hepatic Tsc1 activates TFEB and promotes liver cystogenesis and tumorigenesis. **Methods:** *Tsc1* Flox/Flox and *Tfeb* Flox/Flox mice were crossed with albumin Cre mice to generate liver-specific *Tsc1* knockout (L-*Tsc1* KO) and L-*Tsc1/Tfeb* double KO (DKO) mice. Additionally, a liver-specific *Tfeb* knockin (L-*Tfeb*-KI) mouse was created. These mice were housed for various time points up to 12 months, and biochemical and histological analysis was conducted on blood and liver tissues. **Results:** In L-*Tsc1* KO mice, levels of phosphorylated S6 and 4EBP1 increased, indicating the activation of mTORC1. Surprisingly, L-*Tsc1* KO mice also had increased levels of dephosphorylated TFEB with increased TFEB nuclear translocation resulting in increased lysosomal biogenesis, indicating TFEB activation in a noncanonical-mTORC1 dependent mechanism. Mice with L-*Tsc1* KO developed liver cysts, hepatocellular carcinoma, and cholangiocarcinoma when they were aged at 8-12-months old. This was significantly inhibited by further deletion of TFEB in L-*Tsc1* KO mice (DKO mice). We also observed increased YAP1 activation, decreased HFN4α, and increased Rag A/C proteins in L-*Tsc1* KO mice, which were all blunted by deletion of TFEB, indicating a feed-forward loop of TFEB-mTORC1. Moreover, L-*Tfeb*-KI mice had increased DR, hepatocyte degeneration, fibrosis at 2-months-old, and developed polycystic liver diseases and cholangiocarcinoma-like phenotypes at 8-months-old, reminiscent but worsened phenotypes of L-*Tsc1* KO mice. **Conclusion:** Our findings reveal a non-canonical mTORC1 pathway that promotes TFEB activation leading to hepatocyte degeneration, increased DR, cystogenesis, and liver tumorigenesis. Selective targeting of this non-canonical mTORC1 pathway may be a promising approach for polycystic liver disease and cholangiocarcinoma mediated by TSC1 mutations.

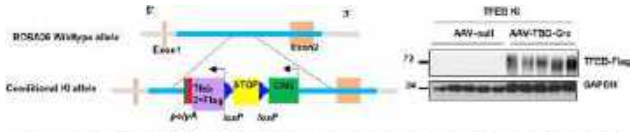

Figure. Generation of conditional TFEB KI mice. (A) TFEB-flag^{KI} mice were injected with AAV8-null or AAV8-TBG-cre (2X10e 11 GC/mouse)to generate liver-specific TFEB-KI mice. (B) After AAV injection for 14 days, total liver lysates were subjected to western blot analysis.

4202-A | LOWER LEVELS OF BILE ACIDS FROM FGF15 OVEREXPRESSION IS ASSOCIATED WITH REDUCED HEPATOCELLULAR CARCINOGENESIS IN A NOVEL HCC MOUSE MODEL WITH COMBINED FXR DEFICIENCY AND CO-EXPRESSION OF C-MET/β-CATENIN

Bo Kong[1], Katherine D Otersen[2], Vik Meadows[3], Zhenning Yang[1], Rulaiha E Taylor[4], Zakiyah Henry[2], Veronia Basaly[2] and Grace L. Guo[3], (1)Rutgers, the State University of New Jersey, (2)Rutgers University, (3)Rutgers University, Piscataway, NJ, (4) Environmental and Occupational Health Sciences Institute, Rutgers, the State University of New Jersey, Piscataway, NJ

Background: Nuclear receptor farnesoid X receptor (FXR) induces fibroblast growth factor 19 (FGF19) in humans, and FGF15 in mice, to suppress bile acid (BA) synthesis in the liver through the activation of FGF receptor 4 (FGFR4) on hepatocytes. The BA-FXR-FGF15-FGFR4 signaling axis has been implicated in promoting hepatocyte cell proliferation and liver regeneration in mice. While FGF19 is implicated in human HCC formation, FXR deficiency leads to increased hepatocellular carcinoma (HCC) development. Our previous study found that FGF15 overexpression prevented HCC development in FXR knockout (KO) mice. Since FXR can prevent HCC development in both BA-dependent and -independent pathways, and FGF15 is also involved in regulating a variety of liver functions, the underlying mechanisms by which FGF15 prevents HCC development induced by FXR deficiency were investigated. **Methods:** Six to eight weeks old male FXR KO mice with and without enterohepatic *Fgf15* overexpression (FXR KO/*Fgf15* Tg) were injected with 20 mg plasmids of pT3-EF1a-H-c-Met and pT3-EF1a-H-N90-β-catenin, along with the Sleeping Beauty transposase (pCMV-SB10), using hydrodynamic tail vein injection. HCC prevalence and tumorigenesis gene expression, at both mRNA and protein levels, were determined in all mice six weeks post injection. **Results:** Co-expression of human c-Met and β-catenin mutation (ΔN90-β-catenin) led to enhanced liver tumor prevalence in both FXR KO and FXR KO/*Fgf15* Tg mice. Compared to FXR KO/*Fgf15* Tg mice, FXR KO mice had increased tumor burden, revealed by higher liver weight and liver/body weight ratio after hydrodynamic transduction. Western blotting of cell proliferation markers, CyclinD1 and PCNA, and Ki-67 immunohistochemistry with semi-quantification, further confirmed higher cell proliferation in livers of FXR KO compared to FXR KO/*Fgf15* Tg livers. **Conclusion:** BAs act as promoting agents and are implicated in c-Met/b-Catenin-driven HCC development. These findings suggest that the reduced bile acid levels due to FGF15 overexpression may contribute to the amelioration of tumorigenesis in FXR KO mice.

f 4203-A | MET AND FIBROBLAST GROWTH FACTOR 19 CO-ACTIVATION IN HEPATOCELLULAR CARCINOMA: BIOLOGICAL IMPLICATIONS AND CLINICAL RELEVANCE

Brandon M. Lehrich[1], Junyan Tao[1], Silvia Liu[1] and Satdarshan (Paul) Monga[1,2], (1)University of Pittsburgh, (2)University of Pittsburgh Medical Center

Background: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-associated mortality globally with limited treatment options. Developing clinically relevant models may improve our understanding of the heterogenous biology of HCC and provide a platform to screen potential therapeutic targets. Met is frequently overexpressed in HCC, yet selective Met inhibitors have not yielded improved patient outcomes, necessitating the need to explore how other driver oncogenes cooperate in the pathogenesis of Met-activated HCC. Here, we investigate cooperation between Met and fibroblast growth factor 19 (FGF19) signaling in HCC. **Methods:** We queried The Cancer Genome Atlas (TCGA) for co-activation of Met and FGF19 in HCC to derive a Met/FGF19 gene signature. We also followed HCC development in mice through co-overexpression of Met/FGF19 via hydrodynamic tail vein injection delivery with sleeping beauty transposon/transposase (HDTVi-SBTT) system. Lastly, we compared similarity of gene expression signatures between the Met/FGF19 mouse model to human HCC. **Results:** Overall, 43 (11%) of 377 HCC patients in TCGA exhibited co-activation of Met/FGF19. Co-expression of Met & FGF19 in mice via HDTVi-SBTT yielded well differentiated HCC development and mortality by 13-15 weeks. These HCC were positive for the FGF19 receptor, FGFR4, along with mammalian target of rapamycin (mTOR) pathway targets, including p-mTOR-S2448, p-S6-235/236, p-S6-240/244, and p-4EBP1-T37/46. Bulk RNA-sequencing and Ingenuity pathway analysis (IPA) on differentially expressed genes (DEGs) comparing Met/FGF19 mouse tumors to normal mouse liver revealed activation of metabolism

pathways (oxidative phosphorylation, fatty acid beta-oxidation, and cholesterol biosynthesis). Interestingly, analysis of the DEGs from the mouse model using the Molecular Signatures Database showed activation of T and B cell activation, proliferation, and lineage commitment pathways. Also, immunohistochemistry demonstrated increased intratumoral infiltration of $CD4^+$, $CD8^+$, and $CD20^+$ immune cells. We also observed a high concordance (74.9% transcriptome similarity and 48 common IPA pathways) of the preclinical model to human HCC with Met/FGF19 co-activation. **Conclusion:** Co-activation of Met & FGF19 occurs in a significant subset of HCC patients with co-expression leading to HCC development in mice. This Met/FGF19 preclinical model provides an improved platform to test various targeted and immunotherapies.

4204-A | METHYLTRANSFERASE-LIKE PROTEIN 3 (METTL3) PROMOTES CHOLANGIOCARCINOMA DEVELOPMENT AND PROGRESSION: EVIDENCE FOR INVOLVEMENT OF HIPPO-TAZ SIGNALING AND REGULATION BY NOTCH PATHWAY

Wenbo Ma, Tulane University, New Orleans, LA

Background: N6-methyladenosine (m6A) modification of RNA has recently emerged as a new regulatory mechanism in carcinogenic processes. In this study, we aimed to investigate the effect and the mechanism of the m6A methyltransferase METTL3 in cholangiocarcinoma (CCA) development and progression. **Methods:** The development of CCA was induced by SB transposase-mediated integration of oncogenes (NICD/Akt) to the FVB/NJ mice via hydrodynamic tail vein (HDTV) injection. CCA xenograft was developed by inoculation of human CCA cells with or without METTL3 depletion by shRNA into the livers of SCID mice. m6A RNA immunoprecipitation followed by high-throughput sequencing (MeRIP-seq) was used to map transcriptome-wide m6A in METTL3 depleted cells. **Results:** Our data show that METTL3 is upregulated in human CCA and promotes the growth and invasiveness of CCA cells. Depletion of METTL3 by shRNA or by the next generation GapmeR antisense oligonucleotides (ASOs) significantly inhibited human CCA cell growth *in vitro* and in SCID mice. We also observed increased METTL3 expression in mouse CCA induced by hydrodynamic tail vein injection of NICD and myr-Akt. Knockdown of METTL3 by shRNA reduced the development of NICD/Akt-induced CCA in mice. Our findings suggest that METTL3 inhibition may represent a potential therapeutic strategy for the treatment of CCA. Mechanistically, our data show that METTL3 mediated m6A modification enhanced the expression of the Hippo pathway effector TAZ protein in an YTHDF1 dependent manner. Depletion of METTL3 by shRNAs or GapmeR ASOs reduced the level of TAZ protein. Furthermore, our data showed that Notch signaling is involved in the upregulation of METTL3 in CCA cells. Accordingly, inhibition of Notch signaling decreased the protein levels of MELLT3 and its downstream effector TAZ. **Conclusion:** This study describes a novel Notch-METTL3-TAZ signaling axis which is importantly implicated in cholangiocarcinoma development and progression. Our findings provide encouraging preclinical evidence for targeting METTL3-mediated RNA m6A modification in cholangiocarcinoma treatment.

4205-A | MICRORNA-1297 IS INVOLVED IN THE RESISTANCE OF LENVATINIB IN HEPATOCELLULAR CARCINOMA

Takayuki Kogure[1], Mari Satoh[1,2], Takehito Ito[3] and Kennichi Satoh[1], (1)Tohoku Medical and Pharmaceutical University, (2)Tome City Toyosato Hospital, (3)Tohoku Medical and Pharmaceutical University Wakabayashi Hospital

Background: Lenvatinib for treating hepatocellular carcinoma (HCC) has a superior response rate, although its overall survival is non-inferior to sorafenib, suggesting tumor cells acquire resistance during therapy. Hypoxia in the tumor microenvironment has been reported to play a critical role in the acquisition of drug resistance. Tyrosine kinase inhibitors with inhibitory effects on VEGF prevent tumor angiogenesis, resulting in significant hypoxia in the tumor. We aimed to elucidate the mechanism of lenvatinib resistance acquisition and the involvement of microRNAs under hypoxia in HCC. **Methods:** HCC cell lines, PLC/PRF/5, HepG2, Hep3B, and Huh7 were cultured in 95% air and 5% CO_2 (normoxia) or in 94% N_2 with 1% O_2 and 5% CO_2 (hypoxia). Anchorage-dependent proliferation was assessed with a metabolic assay, and induction of apoptosis was evaluated by morphologically and caspase-3/7 assay. A genome-wide profiling using 3D-Gene® Human miRNA/mRNA Oligo chips (Toray Industries) was performed to identify microRNAs altered in acquiring resistance to lenvatinib. HCC cells were electroporated with synthetic precursors of microRNAs to force the expression. **Results:** Lenvatinib inhibited cell growth in a concentration-dependent manner. IC_{50} of lenvatinib (72 hr) by MTS assay significantly increased under hypoxia in all cell lines tested, suggesting the acquisition of lenvatinib resistance.

Under hypoxia, the number of morphologically determined apoptotic cells induced by lenvatinib was 22.4% and 19.6% decreased, and caspase-3/7 activity was 26.4% and 18.7% decreased compared to normoxia in PLC/PRF/5 and HepG2, respectively. A genome-wide profiling showed 42 microRNAs with increased expression in PLC/PRF/5 treated with lenvatinib under normoxia, and 28 of these showed decreased expression under hypoxia. Among these, we focused on microRNA-1297 (miR-1297) for further investigation. Prior forced expression of miR-1297 by electroporation of synthetic precursor partially restored the impaired cytotoxicity of lenvatinib against HCC cells under hypoxia. To investigate the genes regulated by miR-1297, we performed genome-wide profiling of mRNA in PLC/PRF/5 under forced expression of miR-1297. By the forced expression of miR-1297, 27 genes decreased more than 2-fold. Network analysis of these genes suggested that miR-1297 regulates a group of genes with TGF-b receptor1 as a hub. **Conclusion:** miR-1297 may play a role in lenvatinib resistance induced by hypoxia by regulating TGF-b receptor1 signaling. These observations demonstrate that microRNAs could be an attractive target for overcoming lenvatinib resistance in HCC.

4206-A | MICRORNA-223 ATTENUATES HEPATOCARCINOGENESIS BY BLOCKING HYPOXIA-DRIVEN ANGIOGENESIS AND IMMUNOSUPPRESSION

Yaojie Fu, National Institutes of Health (NIH)

Background: The current treatment for hepatocellular carcinoma (HCC) to block angiogenesis and immunosuppression provides some benefits only for a subset of patients with HCC, thus optimized therapeutic regimens are unmet needs, which require a thorough understanding of the underlying mechanisms by which tumor cells orchestrate an inflamed tumor microenvironment with significant myeloid cell infiltration. MicroRNA-223 (miR-223) is highly expressed in myeloid cells but its role in regulating tumor microenvironment remains unknown. **Methods:** Wild-type and miR-223 knockout mice were subjected to two mouse models of inflammation-associated HCC induced by injection of diethylnitrosamine (DEN) or orthotopic HCC cell implantation in chronic carbon tetrachloride (CCl4)-treated mice. **Results:** Genetic deletion of miR-223 markedly exacerbated tumorigenesis in inflammation-associated HCC. Compared with wild-type mice, miR-223 knockout mice had more infiltrated programmed cell death 1 (PD-1+) T cells and programmed cell death ligand 1 (PD-L1+) macrophages after DEN+CCl4 administration. Bioinformatic analyses of RNA sequencing data revealed a strong correlation between miR-223 levels and tumor hypoxia, a condition that is well-documented to regulate PD-1/PD-L1. In vivo and in vitro mechanistic studies demonstrated that miR-223 did not directly target PD-1 and PD-L1 in immune cells rather than indirectly downregulated them by modulating tumor microenvironment via the suppression of hypoxia-inducible factor 1α-driven CD39/CD73-adenosine pathway in HCC. Moreover, gene delivery of miR-223 via adenovirus inhibited angiogenesis and hypoxia-mediated PD-1/PD-L1 activation in both HCC models, thereby hindering HCC progression. **Conclusion:** MicroRNA-223 plays a critical role in modulating hypoxia-induced tumor immunosuppression and angiogenesis, which may serve as a novel therapeutic target for HCC.

f 4207-A | MIRABEGRON LIMITS HCC PROGRESS UNDER HIGH-FATTY TUMOR MICROENVIRONMENT VIA ACTIVATION OF ADIPOSE BROWNING

Juan Gao, Karolinska Institutet; The Third Affiliated Hospital of Sun Yat-Sen University

Background: Obesity, a metabolic syndrome (MS) with increasing incidence worldwide, is also a high-risk factor for various tumors. Metabolic associate fatty liver disease was considered as the liver manifestations of MS. Systematic free fatty acids (FFAs) accumulation leads to tumor progress by inducing the tumor's metabolic reprogramming. Our previous studies suggested cold exposure suppresses tumor growth by brown fat activation alters global metabolism (Seki et al., 2022, Nature 608). Brown fat activation is a promising therapeutic approach to reverse systematic metabolic disorders and reshape the metabolism of tumor microenvironment. Mirabegron, a β3-adrenoreceptor agonist approved for treating overactive bladder syndrome in patients, was indicated as an

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

activator the brown adipose and triggers of white adipose beigeing (Sui W, et al. PNAS. 2019 May). We are interested in how the host metabolism reshapes the hepatocellular carcinoma (HCC) microenvironment. We also gain insight into the potential mechanisms of the combination of metabolic stimulators and existing drug therapies. **Methods:** To establish metabolic abnormalities in animal models, adult male C57BL/6N mice were fed with high-fat diet (HFD, 60% fat calories) for more than 3 months to reach obesity and liver steatosis. Hepa1-6 hepatocarcinoma cells were implanted in the mice's liver under inhaling anaesthetization as the orthotopic HCC models. Approximately 1 week after tumor implantation, mice were randomly grouped. 1mg/kg mirabegron or equivalent vehicle (PEG) were orally administrated to mice for 8 weeks. Then mice were sacrificed, blood, liver with tumor and adipose tissue were collected for histological and biochemistry analysis. **Results:** Compared to the vehicle group, the body weight and BMI of obese mice showed a reduce in the mirabegron group in the second week, with noticeable differences between the two groups ($p < 0.05$) after 8 weeks of treatment. Histological analysis of brown adipose tissue supported an activated phenotype in the mirabegron group, which comprised the smaller diameter of lipid droplets in adipocytes. The tumor volumes of HCC were limited in the mirabegron group than in the vehicle group ($p < 0.05$). Furthermore, histopathology showed that the liver steatosis was relieved in the mirabegron group ($p < 0.01$). And cell proliferation and fatty acid uptake of the tumor were decreased in the mirabegron group, showed by IHC staining of KI67 ($p < 0.01$) and CD36 ($p < 0.05$). Besides, qPCR indicated that several metabolic-related genes were downregulated in the tumors of the mirabegron-treated group, such as *cd36* ($p < 0.001$), *fabp4* ($p < 0.001$), *plin2* ($p < 0.05$) and *glut1* ($p < 0.001$). **Conclusion:** Mirabegron limits HCC progress under high-fatty tumor microenvironment via activation of adipose browning. The combination of adipose activators and other therapies may contribute to better outcomes in HCC patients with metabolic disorders.

Disclosures: The following people have nothing to disclose: Juan Gao

4208-A | MITOCHONDRIAL BIOENERGETIC CAPACITY DICTATES THE PROLIFERATIVE POTENTIAL OF HUMAN HEPATOCELLULAR CARCINOMA CELLS

Elizabeth R M Zunica, Christopher L Axelrod and John P Kirwan, Pennington Biomedical Research Center

Background: Hepatocellular carcinoma (HCC) is the most frequent primary hepatic malignancy, with limited therapeutic options for most patients, and thus, a leading cause of global cancer-related death. Mitochondrial efficiency is essential to cancer survival and progression by supplying the energy and macromolecules requisite to initiate and sustain growth and is implicated as a key mediator of plasticity and drug resistance. Here, we evaluated the extent by which mitochondrial efficiency contributes to HCC cell growth by using a pharmacological uncoupler of oxidative phosphorylation (OXPHOS) to restrict bioenergetic efficiency. **Methods:** Bioenergetic efficiency was evaluated by high-resolution respirometry and extracellular acidification monitoring in non-malignant hepatocytes (AML12) and a malignant HCC (HEPG2) line. Dose-response relationships between BAM15, a mitochondrially-targeted uncoupler, and proliferation/apoptosis were determined by light microscopy and Caspase 3-7 activity assay with Sorafenib as a validation agent. Cell viability was then simultaneously measured in 17 human immortalized HCC cell lines using a DNA-barcode multiplexed profiling after exposure to BAM15. **Results:** HCC cells displayed a classical Warburg-like energetic phenotype with downregulated OXPHOS and upregulated glycolysis. Loss of OXPHOS capacity in HCC was predominantly associated with impaired succinate oxidation, which serves as the primary coupling control pathway in hepatocytes. We observed that in HEPG2 cells, BAM15 decreased cell proliferation in the low, micromolar range, with an $IC_{50} = 3.7$ μM. Furthermore, we observed that in HEPG2 cells, BAM15 more effectively and sensitively induced cellular apoptosis than Sorafenib. From lineage-based screening, we observed that the anti-proliferative effects of BAM15 were not cell-line specific, with a median $IC_{50} = 2.9$ μM and ~85% with $IC_{50} < 4$ μM across HCC's, consistent with HEPG2 cells. **Conclusion:** HCC is associated with loss of OXPHOS capacity via impairments in succinate-linked coupling of ATP synthesis. Congruently, restricting bioenergetic efficiency broadly impairs proliferative potential and induces apoptosis in HCC. Taken together, these data support bioenergetic efficiency as a potentially druggable metabolic process to treat HCC.

and Michael J. Sofia, Arbutus Biopharma, Warminster, PA

Background: Hepatocellular carcinoma (HCC) is a global challenge due to its high morbidity and mortality rate. The standard of care for advanced HCC in front line and second line therapy consists of two distinct systemic approaches: tyrosine-kinase and immune checkpoint inhibitors; however, relapses and dose-limiting tolerability associated with systemic adverse events following treatment with either therapy have been observed. Development of oral, tissue-tropic immune checkpoint small-molecule inhibitors that could facilitate ease of administration, exhibit better tissue penetration, and reduce systemic exposure may potentially result in improved efficacy for advanced HCC with reduced systemic toxicity. As a preclinical proof-of-concept, small-molecule PD-L1 inhibitors with differential liver and plasma pharmacokinetic profiles were evaluated in a novel orthotopic syngeneic immunocompetent HCC model to evaluate the correlation between pharmacokinetics and anti-tumor efficacy. **Methods:** A H22 mouse hepatoma cell line expressing human PD-L1 and luciferase was generated and cells were intrahepatically transplanted into BALB/c-hPD-1/hPD-L1 double knock-in mice to develop a humanized orthotopic syngeneic HCC model. Animals were orally administered small-molecule human PD-L1 inhibitors once-daily for 26 days, and tumor growth was monitored by *in vivo* bioluminescence imaging. Target occupancy in tumors was determined by flow cytometry. Additionally, the combination of a small-molecule PD-L1 inhibitor with VEGFR2-TIE2 inhibitor regorafenib was also assessed. **Results:** 88% of tumor-bearing mice demonstrated 80% or higher tumor growth inhibition (TGI) after 26 days of oral treatment with a small-molecule PD-L1 inhibitor either alone or in combination with regorafenib. For the small-molecule PD-L1 inhibitors tested, higher liver concentrations and high liver-to-plasma ratio was associated with increased efficacy in this orthotopic HCC mouse model. Efficacy was associated with $\geq$ 60% PD-L1 target occupancy in animals treated with small-molecule PD-L1 inhibitors. **Conclusion:** Treatment with oral small-molecule PD-L1 inhibitors possessing liver-tropic pharmacokinetic profiles was associated with increased efficacy and tumor clearance in a novel humanized orthotopic HCC mouse model. These data suggest that development of small-molecule PD-L1 inhibitors with biodistribution to the liver may provide benefit in the treatment of HCC.

4210-A | PGAM5 KNOCKOUT IN HEPATOCELLULAR CARCINOMA CELLS REDUCES FABP1 EXPRESSION AND LONG-CHAIN FATTY ACID UPTAKE

Andrea N. Johnston, Chin-Chi Liu and Ganesan Muthusamy, Louisiana State University

Background: Overexpression of tumoral phosphoglycerate mutase 5 (PGAM5), the Ser/His/Thr phosphatase, is correlated with reduced survival in hepatocellular carcinoma, colon cancer, and melanoma. In hepatocellular carcinoma, interference with PGAM5 expression reduces tumor growth. This phenotype has been attributed to decreased mitophagy and promotion of apoptosis, but whether PGAM5 influences lipid metabolism in hepatocellular carcinoma, as it does in colon cancer, is unexplored. **Methods:** ATP production, cell growth, and long-chain fatty acid uptake were measured in wild type and PGAM5 knockout HepG2 and Huh7 cells. Expression of hepatocellular fatty acid transporters, CD36, SLC27A2, SLC27A5, and FABP1, was measured by real-time qPCR and Western blot. **Results:** Deletion of PGAM5 attenuates hepatocellular carcinoma cell growth and ATP production. PGAM5 knockout reduced palmitate induced steatosis and expression of FABP1 in HepG2 and Huh7 cell lines. **Conclusion:** PGAM5 regulates fatty acid metabolism in hepatocellular carcinoma. Downregulation of the fatty acid transporter FABP1 caused by PGAM5 knockout, may be responsible for reduced long-chain fatty acid uptake and a dysregulated intracellular lipidome.

Adam C. Yopp[4], Emilie Crouchet[5], Thomas F. Baumert[5], Naoto Fujiwara[1] and Yujin Hoshida[1], (1)UT Southwestern Medical Center, Dallas, USA, (2)Kurume University School of Medicine, Japan, (3)Keio University School of Medicine, Tokyo, Japan, (4) University of Texas Southwestern Medical Center, (5) University of Strasbourg, Inserm, Institut De Recherche Sur Les Maladies Virales Et Hépatiques Umr-S1110, 67000 Strasbourg, France

Background: Prevention of NAFLD-related HCC is an urgent unmet need. Our previous study in NAFLD cirrhosis patient cohorts identified a transcriptomic signature of HCC risk (Prognostic Liver Signature [PLS]-NAFLD) and IDO1+ dendritic cells in the fibrotic portal tracts as a candidate target that may be treated with a small molecule inhibitor, epacadostat, under clinical development in various solid cancers. **Methods:** Epacadostat was orally given (50 mg/kg, 5 d/week) to CDA/HFD rats (n = 10 per arm for each sex) for 8 weeks after establishing cirrhosis and before developing HCC. Tumor number, histology including NAS components, and immunostaining of relevant immune cell markers were assessed. Bulk and single-nuclei RNA-seq of liver tissues and metagenomic 16S rRNA-seq of stool, liver, and blood samples were conducted. Organotypic ex vivo culture of precision-cut liver slice (PCLS) from NAFLD patients was also performed. **Results:** Fewer tumor nodules were observed in the epacadostat-treated rats compared to the vehicle controls irrespective of tumor size ($p = 0.03$). The chemopreventive effect was more prominent in male ($p = 0.02$) compared to female ($p = 0.45$) rats. Of note, amelioration of hepatocyte injury (measured by AST/ALT) was minimal. Reduction of liver fibrosis was measurable only by Sirius red-based collagen proportionate area but not fibrosis staging. There was a trend of reduction of in the number of $IDO1^+$ cells in fibrotic tissues near the portal tracts. RNA-seq of liver tissues revealed modulation of immune-suppressive tissue microenvironment that involves certain subsets of macrophages, Tregs, T cells, and NK cells. Sex difference in modulation of gut dysbiosis was observed. In the ex vivo clinical PCLS culture, epacadostat modulated high-risk pattern of PLS-NAFLD signature in a subset of patients, supporting its clinical relevance. **Conclusion:** Our pre-clinical study suggests that epacadostat is a candidate HCC immuno-preventive agent to be considered for early clinical testing in NAFLD patients at risk of developing HCC.

4212-A | PREDICTING THE EFFICACY OF COMBINATION CHEMOTHERAPY FOR ADVANCED HEPATOCELLULAR CARCINOMA BY TUMOR IMMUNE MICROENVIRONMENTAL ANALYSIS

Shuhei Yamamoto[1], Takahiro Kodama[1], Kazuki Maesaka[1], Akifumi Kuwano[2], Kenta Motomura[2], Akira Doi[1], Yuki Tahata[1], Akira Nishio[1], Hayato Hikita[1], Tomohide Tatsumi[1] and Tetsuo Takehara[1], (1)Osaka University Graduate School of Medicine, (2)Iizuka Hospital

Background: Atezolizumab/bevacizumab (Atezo/Bev) combination immunotherapy became the first line therapy of advanced hepatocellular carcinoma (HCC). However, about 20% of patients are non-responders. We explored predictors of therapeutic efficacy of Atezo/Bev by analyzing tumor immune microenvironment. **Methods:** Total 23 advanced HCC patients who underwent liver tumor biopsy prior to Atezo/Bev therapy were enrolled in this study. RNA-seq of tumor biopsy specimens was performed and the relationship between transcriptome data and treatment response was investigated. We utilized transposon-based intrahepatic delivery of a pooled 10-oncogene cDNA library via hydrodynamic tail vein injection (HTVi), resulting in multiple genetically-heterogenous HCC formation in wild-type mice. We treated these mice with either vehicle or combination immunotherapy using anti-PD-L1 and anti-VEGF antibodies, and sought for secreted factors elevated in the immunotherapy-sensitive or resistant tumors. **Results:** The response rate of 23 HCC patients was 43.5% by mRECIST and the median progression-free survival (PFS) was 167 days. RNA-seq results showed that the gene expression related to T cell migration, activation, and exhaustion were significantly higher in responders compared to non-responders. Gene signature analysis showed that

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

effector T cells were abundant in responder. The Interferon and antigen-presentation (IFNAP) signature, Atezolizumab Bevacizumab response signature (ABRS), Immune signature, T cell exhaustion signature were higher in responder than non-responders. PFS was significantly prolonged in patients with high ABRS scores compared to those with low ABRS scores. Single set gene set enrichment analysis showed activation of antigen processing and presentation mechanisms, Jak/Stat signaling pathway, B cell and T cell signaling pathways, and chemokine signaling pathway in responders, but no correlation with WNT signaling pathway. In HCC mouse models, combination immunotherapy suppressed angiogenesis, increased CD8T cells, CD4T cells, and dendritic cell markers within the tumor, and prolonged survival. Treatment-resistant tumors showed poor lymphocytic infiltration (TIL) within the tumor and significant downregulation of various MHC class I and II molecules. **Conclusion:** In advanced hepatocellular carcinoma, the presence of TILs may be important for response to ATZ/BEV therapy.

4213-A | RACE-RELATED DIFFERENTIAL ALTERNATIVE RNA SPLICING OF POLYBROMO 1 (PBRM1) IN HEPATOCELLULAR CARCINOMA

Kara Wegermann[1], Bonnie LaCroix[2], Kathleen Cuprak[3], Tyler Allen[2], Nicholas O'Grady[2], Rachel A Myers[2], Cynthia Moylan[2], Anna Mae Diehl[2], So Young Kim[2], Muthana Al Abo[2], Steven Patierno[2] and Jennifer Freedman[2], (1)Duke University, Hillsborough, NC, (2) Duke University, (3)Q2 Solutions

Background: Racial disparities in outcomes of hepatocellular carcinoma (HCC) are multifactorial. We previously reported differential alternative RNA splicing between HCC from Black and White patients in The Cancer Genome Atlas (TCGA). One of these events was exon 28-29 skipping in polybromo 1 (*PBRM1*), which participates in chromatin remodeling. The aim of this study was to assess whether expression of race-related *PBRM1* splice variants affected HCC cell biology and/or transcriptome. **Methods:** CRISPR-Cas9 genome editing of Huh7 and Hep3B HCC cells was performed to generate pools expressing *PBRM1* skipping exons 28-29. Single cell clones were isolated using single cell plating and limiting dilution. Incucyte proliferation and migration (WoundMaker) assays and RNAseq using total RNA were used to compare phenotypes of parental and edited cells. **Results:** CRISPR-Cas9 edited single cell clones did not express *PBRM1* exons 28-29. No overall differences in proliferation or migration between parental and edited cells were observed. For Huh7 and Hep3B, as shown in Figure 1, 280 genes (71 upregulated, 209 downregulated) and 530 genes (278 upregulated, 252 downregulated), respectively, were differentially expressed between parental and edited cells (adjusted p-value < 0.05, log FC of at least +/- 1). 32 genes were differentially expressed in both Hep3B and Huh7 between parental and edited cells. Among the most significant were amphiregulin (*AREG)*, a member of the *EGF* family, apolipoprotein B mRNA editing enzyme catalytic subunit 3C (*APOBEC3C*), an RNA editing enzyme, and 3-hydroxy-3-methylglutaryl-CoA synthase 1 (*HMGCS1*), an enzyme in the mevalonate pathway that is inhibited by metformin. Each was previously linked to survival in HCC. Genes with large fold change included plasminogen activator inhibitor-1 (*SERPINE1*), which inhibits fibrinolysis and has roles in cell adhesion and migration, and solute carrier family 51 subunit beta (*SLC51B*), a bile acid transporter. Gene set enrichment analysis using clusterProfiler with all genes over each cell line and splicing event revealed significant enrichment in 106 (Huh7) and 10 (Hep3B) KEGG pathways. **Conclusion:** CRISPR-Cas9 genome editing to generate Huh7 and Hep3B cells expressing a differential alternative RNA splicing event between HCC from Black and White patients in TCGA *(PBRM1* skipping exons 28-29) resulted in significant changes in aggregate gene expression, without altering cell proliferation or migration. Race-related differential alternative RNA splicing of *PBRM1* may have implications for HCC biology and disparities. 4214-A | ROLE OF ACYL-CoA MEDIUM-CHAIN SYNTHETASE 5 IN HEPATOCELLULAR CARCINOMA

Lei Yang, Kien Pham, Yibo Xi and Chen Liu, Yale University, New Haven, CT

Background: Liver cancer is a significant public health concern as it is the second leading cause of cancer-related deaths worldwide. Hepatocellular carcinoma (HCC) is the most common type of liver cancer, and despite advances in treatment, it remains a malignancy with a poor prognosis. Understanding the molecular mechanisms underlying HCC is essential for developing effective treatments. Acyl-CoA medium-chain synthetase 5 (ACSM5), an enzyme involved in fatty acid metabolism, is downregulated in HCC, but its oncogenic roles in this cancer are not well understood. **Methods:** In the study, we analyzed the expression levels of ACSM5 in HCC patient samples and cell lines. The *in vitro* and *in vivo* effects and regulatory mechanisms of ACSM5 were investigated with a newly established ACSM5-overexpressing stable HCC cell line, Huh7-ACSM5. **Results:** Our results showed that ACSM5 was downregulated in HCC patient samples, as well as in Huh7 and HepG2 cells. Overexpression of ACSM5 in Huh7 cells led to decreased proliferation and migration in vitro, reduced cell colony formation capacity, and inhibited tumor growth in mouse xenografts. Furthermore, we found that overexpression of ACSM5 reduced the phosphorylation of STAT3, which, in turn, regulated TGF-β expression. **Conclusion:** Our findings suggest that ACSM5 downregulation may contribute to the development of HCC, providing new insights into the oncogenic role of ACSM5 in HCC and highlighting its relevance as a potential biomarker and therapeutic target for this deadly cancer.

4215-A | SELECTIVE PAD4 INHIBITION DELAYS METASTATIC TUMOR GROWTH IN THE LIVER BY MODULATING THE HEPATIC TUMOR MICROENVIRONMENT

Jieun Kim[1], So Yeon Kim[1], Dhanalakshmi Sivanandhan[2], Luca Rastelli[2] and Ekihiro Seki[1], (1) Cedars-Sinai Medical Center, Los Angeles, CA, (2) Jubilant Therapeutics Inc.

Background: Liver metastasis is the most important determinant for patients with pancreatic ductal adeno-

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

carcinoma (PDAC) and colorectal cancer (CRC). Liver microenvironment affected by underlying liver disease, such as alcoholic liver disease, can impact the progression of liver metastasis. However, the molecular mechanism of liver metastasis affected by underlying liver disease is not fully understood. Infiltration of neutrophils is a typical feature of alcoholic liver disease, and neutrophils can change hepatic microenvironment. Peptidylarginine deiminase 4 (PAD4) is an enzyme primarily expressed in neutrophils, and is involved in protein citrullination that contributes to neutrophil extracellular traps (NETs) formation and modulate extracellular matrix, such as collagen. In this study, we investigated the role of PAD4 in liver metastasis using a novel PAD4 inhibitor in development by Jubilant Therapeutics Inc. **Methods:** C57BL/6 wild-type or neutrophil-specific PAD4-deleted mice were intrasplenically injected with either mouse PDAC Pan02 or CRC MC38 cells to develop liver metastasis. Neutrophil-specific PAD4-deleted mice were generated by crossing Pad4 flox mice with MRP8-Cre mice. A novel PAD4 selective inhibitor, JBI-1044, was administered twice daily via oral gavage. Alcoholic liver injury was induced by feeding mice either an isocaloric or 5% (v/v) ethanol Lieber-DeCarli diet for 6 weeks. **Results:** Chronic ethanol feeding exacerbated liver metastasis along with increased PAD4 expression, neutrophil infiltration and collagen deposition, as well as decreased survival rate of tumor-bearing mice. In contrast, PAD4 deletion in neutrophils suppressed metastatic tumor growth in the liver by suppressing neutrophil infiltration and collagen deposition. Selective inhibition of PAD4 with JBI-1044 significantly improved the survival of mice bearing PDAC or CRC tumors in the liver by reducing their metastatic burden. Pad4 inhibition resulted in decreased neutrophil infiltration and collagen accumulation. The levels of citrullinated type 1 collagen were also reduced by PAD4 inhibition. **Conclusion:** PAD4 expression is associated with the progression of PDAC and CRC liver metastasis. PAD4 plays pivotal roles in reshaping liver tumor microenvironment through the modulation of neutrophil functions and collagen deposition. PAD4 inhibition by JBI-1044 suppressed liver metastasis, providing new insight of potential therapies targeting PAD4 in PDAC and CRC liver metastasis.

4216-A | SELECTIVE TARGETING OF INTEGRIN avβ8 EFFECTIVELY SUPPRESSES TUMOR GROWTH IN THE NEW PSC-ASSOCIATED CHOLANGIOCARCINOMA MODEL (SB CCA.Mdr2-/- MOUSE)

Pinzhu Huang[1], Wen Gao[1], Heansika Matta[1], Disha Skelton-Badlani[1], Natalia Blanco[2], Min Lu[2], Blaise Lippa[2], Bruce N Rogers[2] and Yury V. Popov[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)Morphic Therapeutics

Background: We have established a new model of cholangiocarcinoma (CCA) in Mdr2-/- with primary sclerosis cholangitis (PSC)-like disease (termed SB CCA.*Mdr2-/-*) which recapitulates predisposition to CCA in human PSC. Systemic TGF-β blockade has been reported to enhance anti-tumor efficacy of immune checkpoint inhibitors, but its development has been hindered by systemic toxicity. Here we report therapeutic efficacy of selective antibody targeting of TGFb-activating integrins avβ6 and avβ8 in comparison to pan-TGFb inhibition in our SB CCA. *Mdr2-/-* model. **Methods:** Ten-week old Mdr2-/- mice with advanced congenital PSC-like progressive biliary disease were subjected to hydrodynamic tail vein injection of sleeping beauty transposon-transposase system with activated forms of AKT (myr-AKT) and Yap (YapS127A). Neutralizing antibodies for pan-TGF-β (1D11), integrin avβ8 (C6D4), or integrin avb6 (3G9) alone and with anti-PD-1 mAb were administered into tumor-bearing mice 1-4 weeks post transduction, in comparison to IgG control or anti-PD1(n = 10-16/group). Expression of TGF-β1, integrin β6, PD-1, PD-L1, and CK7 were analyzed by immunohistochemistry (IHC), integrin β8 was determined by in situ hybridization. Tumor burden was analyzed by CK7+ tumor numbers and mRNA levels of AKT and YAP1. Desmoplastic stroma of the tumors was analyzed via Sirius Red morphometry. **Results:** In our SB CCA.*Mdr2-/-* model, TGF-β1 expression was prevalent in all CCA tumors and 88.2% of CCA tumors expressed various levels of integrin b6 and were positive for integrin β8 mRNA. PD-L1+ tumor cells, PD-1+ and CD8+ infiltrating lymphocytes were enriched in desmoplastic CCA tumors. However, anti-PD-1 alone was not efficacious. Monotherapy with 1D11 or 3G9 led to a trend of decreased tumor burden, but only C6D4 significantly reduced tumor growth (CK7+ tumor numbers) compared to the IgG group (30.00 ± 4.68 vs. 59.87 ± 5.67, p = 0.0109). Combination of 1D11/anti-PD-1 showed only a trend to enhance the efficacy of pan-TGFb mAb alone.

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Interestingly, C6D4/anti-PD-1and 3G9 /anti-PD-1 combinations did not show synergistic anti-tumor activity. Tumor burden assessed by mRNA levels of transgene oncogenes YAP1/AKT or morphometric analysis of CK7+ tumors showed that monotherapy with the C6D4 alone was superior to combination therapy with anti-PD-1 as a CCA treatment. Collagen morphometric analysis showed that the 1D11 potently attenuated desmoplastic reaction in all CCA tumors. Integrin avβ8- or avβ6-targeting resulted in diminished desmoplastic reaction in only a subset (about 50%) of tumors, which suggested that anti-tumor efficacy was not primarily driven by suppression of desmoplastic tumor stroma. **Conclusion:** We show that integrin avβ8 is required for desmoplastic CCA growth and represents a novel therapeutic target for CCA. These data support clinical development of avβ8 integrin-selective inhibitors for CCA.

4217-A | SORT1 PROMOTE THE METASTASIS AND INVASION OF HEPATOCELLULAR CARCINOMA VIA P38/Β-CATENIN/ZEB1 SIGNALING PATHWAY

Hongjie Chen[1], Shaohang Cai[1], Jie Peng[1], Chen Shuwei[2], Wei Liao[2] and Lili Liu[2], (1)Nanfang Hospital, Southern Medical University, (2)Sun Yat-Sen University Cancer Center

Background: Metastasis stands as the primary determinant of the dismal prognosis observed in hepatocellular carcinoma (HCC) patients. Hence, unraveling the intricate molecular mechanisms governing hepatocellular carcinoma (HCC) metastasis is of paramount importance in the field. **Methods:** We conducted an analysis of SORT1 expression in a tissue microarray (TMA) consisting of 781 HCC samples. The impact of SORT1 on HCC onset and progression was investigated both in vivo and in vitro. **Results:** Elevated SORT1 expression was positively correlated with increased tumor number, advanced TNM stage and vascular invasion. Mechanistically, SORT1 binds to p38 and enhances its stability. Furthermore, p38 phosphorylate GSK-3β at Ser9, which promotes nuclear accumulation of β-catenin, leading to the transcription of ZEB1 and secretion of exosomes. Knockdown of SORT1 and ZEB1 inhibited HCC metastasis, whereas upregulation of ZEB1 restored SORT1 knockdown-induced suppression of HCC metastasis. SORT1 is regulated by SREBP2 through protein-protein interaction, as confirmed by IP-MS, CO-IP, immunofluorescence, and CHX experiments. **Conclusion:** In light of these results, SORT1 as a potential prognostic biomarker in HCC and targeting p38/β-catenin signaling pathway, could be an effective therapeutic strategy against HCC metastasis.

4218-A | STEMNESS AND EPITHELIAL-MESENCHYMAL TRANSITION CONTINUITY IN PRIMARY LIVER CARCINOMAS SPECTRUM

Joana Espírito Santo[1,2], Ana Ladeirinha[2], Ana Alarcão[2], Eugeniu Strelet[3], Marco Reis[3], Rui Santos[1] and Lina Carvalho[1,2], (1)Coimbra Hospital and University Centre, (2)Faculty of Medicine, University of Coimbra, (3) Department of Chemical Engineering, University of Coimbra

Background: Tumor cell plasticity promotes primary liver carcinomas (PLC) cellular heterogeneity and is likely to contribute to therapy resistance. Hepatocellular carcinomas (HCCs), combined hepatocellular-cholangiocarcinomas (cHCC-CCAs) and intrahepatic cholangiocarcinomas (iCCAs) are composed of different degrees of hepatocytic and/or cholangiocytic differentiation, often displaying stemness and epithelial-mesenchymal transition (EMT) features. We aimed to analyze the expression of hepatic progenitor cells (HPC) and mesenchymal markers across the PLC spectrum. **Methods:** A series of 44 HCCs without HPC features, 42 HCCs with at least one HPC immunomarker expressed, 3 cHCC-iCCAs and 5 small-duct type iCCAs was studied. World Health Organization 2019 histopathological criteria were applied; proliferation (ki67;p53) HPC/cholangiocytic (EpCAM/BerEp4; CK19; CK7) and mesenchymal (ASMA; vimentin) markers immunoexpression was searched in tumor and peritumoral parenchyma. **Results:** Thirty-six HCCsHPC-, 38 HCCsHPC+, 2 cHCC-iCCAs and 3 iCCAs developed in a cirrhotic background; alcoholic liver disease was the dominant etiology and metabolic associated fatty liver disease was relevant in HCCHPC- and iCCA cases. Moderately differentiated tumors (G2) prevailed across the spectrum. Distinct immunoexpressions ($p < 0.05$) were reported (Table 1):

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

- Ki67 positive tumor cells were less frequent in HCCsHPC- (n = 7) when compared with HCCsHPC + (n = 8), cHCC-iCCAs (n = 2) and iCCAs (n = 3);
- p53 tumoral expression was predominant in iCCAs (n = 4) in comparison with HCCsHPC+ (n = 11) and HCCsHPC- (n = 5);
- EpCAM expression predominated in cHCC-iCCAs (n = 3) and in iCCAs (n = 4), but no difference was observed in between the 2 groups of carcinomas;
- CK19 and CK7 expression prevailed in cHCC-iCCAs and iCCAs, with CK7 expression being more frequent than CK9 expression in HCCsHPC+ (n = 6 vs n = 38);
- ASMA positive tumoral cells were mostly seen in HCCsHPC+ (n = 15), however ASMA expression in stromal cells was more prevalent in cHCC-iCCAS (n = 3) and in iCCAs (n = 4);
- HCCsHPC- (n = 14) expressed vimentin in tumor cells less frequently than cHCC-iCCAs (n = 3), while vimentin stromal cells expression was progressively more frequent in HCCsHPC+ (n = 25) and in cHCC-iCCAs (n = 3) and iCCAs (n = 5).

Conclusion: Stemness and EMT continuity in PLC seems to be reflected by a gain of tumoral HPC and vimentin expression and ASMA and vimentin stromal expression from HCCsHPC+ to iCCAs, where combined tumors are likely to be closer to iCCAs rather than to HCCs. This study emphasizes the translational relevance of understanding tumor cell plasticity in relation to stemness and EMT during PLC carcinogenesis.

Immunohistochemical phenotype	HCC HPC negative (n=44)	HCC HPC positive (n=42)	cHCC-iCCA (n=3)	iCCA (n=5)

4219-A | TARGETING CDK5/PAK1 ATTENUATES LIPID OVERLOAD-INDUCED HEPATOCELLULAR CARCINOMA VIA SUPPRESSING LYSOSOMAL STRESS-DEPENDENT M2 MACROPHAGE TRANSITION.

Tongguo Miao[1], Ying Zhang[1], Xianzhe Lou[2], Weiwei Guan[1], Lu Li[1], Xiwei Yuan[1] and Yuemin Nan[1], (1)Third Hospital of Hebei Medical University & Hebei Key Laboratory of Mechanism of Liver Fibrosis in Chronic Liver Disease, (2) North China University of Science and Technology

Background: Immunotherapy has revolutionized cancer treatment. Unfortunately, most tumor types do not respond to immunotherapy due to a lack of enhancing inflammation in tumor microenvironment (TME), a contributing factor is lysosomal stress (LS). How LS impacts the TME remains understudy. **Methods:** We investigated the role of the CDK5/PAK1 pathway in the regulation of lysosomal stress in hepatocellular carcinoma (HCC) development by conducting metabolomic analysis, gene expression profiling and immunohistochemistry analyses in RAW264.7 cells, oncogene-induced HCC mouse models and human HCC samples. **Results:** We investigated the role of the CDK5/PAK1 pathway in the regulation of lysosomal stress in hepatocellular carcinoma (HCC) development by conducting metabolomic analysis, gene expression profiling and immunohistochemistry analyses in RAW264.7 cells, oncogene-induced HCC mouse models and human HCC samples. **Conclusion:** This study suggests that CDK5/PAK1 pathway inhibition is a potential approach to broaden immunity therapies by suppressing lipid overload-mediated, LS-dependent M2 transition and supports the translation of this novel approach to further improve response rates for proliferation and metastatic hepatocellular carcinoma.

Division of Transplant Surgery, Department of Surgery, University School of Medicine, (6)Wayne State University

Background: The human PNPLA3 rs738409 variant encoding methionine at residue 148, commonly known as 148M variant, has been implicated in a broad spectrum of liver diseases including alcoholic and nonalcoholic fatty liver diseases; however, its role in alcohol-associated liver cancer pathogenesis remains elusive. **Methods:** To investigate the impact of the PNPLA3-148M variant on alcohol-associated liver cancer, we treated control and PNPLA3-148M transgenic mice with 5% ethanol diet for 12 weeks plus once a week carbon tetrachloride injection for 10 weeks. Liver histology was analyzed after animal euthanasia. Cancer-related genes and pathways were analyzed by RNA-seq and confirmed by immunoblotting. Tumor microenvironment was analyzed by spatial transcriptomics. **Results:** After the 12-week ethanol diet feeding, PNPLA3-148M transgenic mice developed multi-nodule hepatocellular carcinoma (HCC). The incidence of HCC in the PNPLA3 transgenic mice was 2.5 fold higher than that in the wild-type control mice. Biochemical analysis revealed that the PNPLA3-148M mouse livers had much higher levels of oxidative stress and DNA damage. RNA-seq analysis uncovered changes in multiple pathways including upregulation of steroid hormone biosynthesis and chemical carcinogenesis and downregulation of cell adhesion, cell differentiation, and immune processes. Spatial transcriptomics further identified multiple differential cell clusters, including a cluster downregulated in the PNPLA3-148M liver, which had enriched genes in defense response and cell death regulation. Immunoblotting and immunostaining confirmed a number of those genes. **Conclusion:** Our data have demonstrated a critical role of the 148M variant of PNPLA3 in the alcohol-associated liver cancer development. PNPLA3-148M has a remarkable effect on multiple cell processes in the liver that contribute to the elevated risk of liver cancer.

4221-A | THE POSITIVE CORRELATION BETWEEN SPLENOMEGALY AND HEPATOCELLULAR CARCINOMA PROGRESSION BY ESTABLISHING A MOUSE MODEL VIA HYDRODYNAMIC TAIL VEIN INJECTION OF ONCOGENE PLASMID

Yanhua Mu[1,2], Ke Du[1,2], Yameng Wei[1,2], Ni Guo[1,2], Junqiao Feng[1,2], Qian Wang[1,2], Gaixia He[1,2], Jin Sun[1,2] and Zongfang Li[1,2,3], (1)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2)Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3)Department of General Surgery, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.

Background: Splenomegaly is common in patients with hepatocellular carcinoma (HCC) during clinical treatment, but the reason remains unclear. We establish mouse model of HCC by hydrodynamic tail vein injection (HTVI) to explore the relationship between spleen and liver cancer progression. **Methods:** 6-8 weeks male balb/c mice were injected with 10% volume of body weight solution containing oncogene plasmids within 8 seconds. Mice in the control group were given an equal volume of PBS by HTVI. 12 weeks later, mice were sacrificed and tumor formation was observed. **Results:** Hepatocellular carcinoma (HCC) is the main type of primary liver cancer. A mouse model of hepatocellular carcinoma was established by HTVI of Sleeping Beauty (SB) plasmid and oncogenic plasmid. Compared with control group, the body weight of the mice in liver cancer group decreased, and the liver weight ratio increased significantly. The liver surface of mice in normal group was smooth and elastic with normal morphology. The liver volume of the mice in liver cancer group was significantly increased, the texture was harder, and a large number of granular and nodular changes appeared on the liver surface, with obvious tumor formation. In addition, we found that the spleen weight of the liver cancer group was larger than normal group, and spleen weight was positively correlated with liver tumor formation. Finally, we infer that splenomegaly is closely related to the progression of HCC.

Conclusion: Our data suggest that the spleen may play a role in the occurrence and development of HCC, which provides new ideas for the clinical treatment of liver cancer.

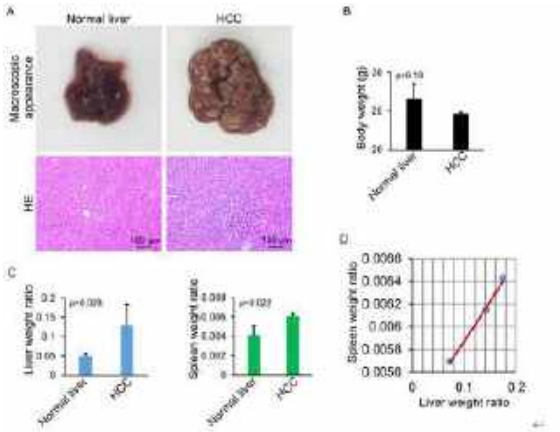

Figure1. Splenomegaly is closely related to the progression of liver cancer. A. Macroscopic and histological features of mouse model. B. Body weight data for each group of mice. C. Liver index and spleen index of mice in each group (liver index means liver to body weight ratio, spleen index means spleen to body weight ratio). D. Correlation between liver index and spleen index in HCC group mice.

4222-A | THE PRESENCE OF TGF-β1/SMAD3-ENHANCED GLI2 ISOFORMS CONTRIBUTES TO MALIGNANT BEHAVIORS OF HEPATOCELLULAR CARCINOMA

Jia Ding[1], Yue Ma[2], Yongyu Yang[2], Li Zhang[2], Huiyan Li[2], Pingguo Liu[3] and Jian Wu[2,4,5], (1)Department of Gastroenterology, Shanghai Jing'an District Central Hospital, Shanghai 200040, China, (2)Dept. of Medical Microbiology, Fudan University School of Basic Medical Sciences, Shanghai 200032, China, (3)Dept. of Hepatobiliary Surgery, Zhongshan Hospital Affiliated to Xiamen University, Xiamen 361004, China, (4)Shanghai Institute of Liver Diseases, Fudan University Shanghai Medical College, Shanghai 200032, China, (5)Fudan University, Department of Gastroenterology and Hepatology, Zhongshan Hospital, Shanghai, China

Background: Major focus has been paid to pivotal roles of hedgehog signaling (Hh) in hepatocellular carcinoma (HCC) and considered Hh as a potential target. However, inconsistent expression between Sonic ligands (SHh) and GLI2 was demonstrated in our preliminary analysis of HCC specimens, which accompanied with increased TGF-β1 and SMAD3 protein. This study aims to evaluate the correlation between SHh-independent GLI2 expression with clinicopathologic characteristics, and investigate the promoting effect of TGF-β1/SMAD3 on GLI2 and its isoforms in HCC. **Methods:** Critical components of Hh and TGF-β1 pathways were examined in 21 pairs of HCC specimens, and SHh-independent GLI2 expression was verified in a separate cohort of 56 HCC patients by immunochemistry (IHC) staining. Different gene profiles of four GLI2 isoforms and mutual target genes co-regulated by GLI2 and p-SMAD3 were investigated by chromatin immunoprecipitation (ChIP) assay. The effect of the TGF-β receptor inhibitor on lung metastasis was evaluated in an *in situ* xenograft mouse model. **Results:** SHh and GLI2 protein were increased in 52.38% and 47.62% of HCC specimens. However, SHh protein was not increased in 80% GLI2-positive specimens compared to their pericancerous counterparts. Among them, TGF-β1/SMAD3 were present in 75% GLI2-positive specimens with SHh-low expression. Positive GLI2 staining was found in 72.2% of sections with low SHh staining of 56 HCC patients; whereas SMAD3 protein displayed an increase in 61.54% of SHh-low and GLI2-positive sections. Mean overall survival (OS) of patients with high and low GLI2 protein was 18.3 months and 17.6 months ($p = 0.68$); and patients with high GLI2 protein had a shorter disease-free survival (DFS) than those with low GLI2 expression (12.40 *vs* 16.31 months, $p = 0.0429$). Neither OS nor DFS displayed statistically significant difference in patients with high and low SHh immunopositivity. In addition to five known isoforms, two new GLI2 isoforms 6&7 were identified with transactivating activity in HCC specimens. CoIP and ChIP assay demonstrated that p-SMAD3 interacted with active GLI2 isoforms to transactivate mutual target genes (NOTCH2, VIM, ABCC1 and MMP2) in modulation of stemness, epithelial-mesenchymal transition, chemoresistance and metastasis in poorly-differentiated hepatoma cells. A dual TGF-β receptor inhibitor, LY2109761 sensitized poorly-differentiated hepatoma cells to Sorafenib, and reduced pulmonary metastasis in mice with *in situ* liver xenograft tumors. **Conclusion:** High GLI2 expression was correlated with recurrence in HCC. SMAD3 interacted with active GLI2 isoforms to enhance transcription of genes involved in stemness, epithelial-mesenchymal transition, chemo-resistance and metastasis. The elucidation of the non-canonical hedgehog signaling mechanisms via TGF-β1/SMAD3/GLI2 axis may facilitate to optimize therapeutic strategies for advanced HCC.

4223-A | THE RNA METHYLTRANSFERASE METTL16 ENHANCES CHOLANGIOCARCINOMA GROWTH THROUGH PRDM15-MEDIATED FGFR4 EXPRESSION

Nianli Liu[1], Jinqiang Zhang[1], Weina Chen[1], Wenbo Ma[1] and Tong Wu[1,2], (1)Tulane University, New Orleans, LA, (2)Tulane Medical Center

Background: RNA N6-Methyladenosine (m6A) modification is implicated in the progression of human cancers including cholangiocarcinoma (CCA). METTL16 is recently identified as a new RNA methyltransferase responsible for m6A modification, although the role of METTL16 in CCA has not yet been examined. The current study aims to investigate the effect and mechanism of the RNA methyltransferase METTL16 in CCA. **Methods:** We analyzed the mRNA expression of METTL16 in several human CCA cohorts and evaluated its protein expression by immunochemical staining of human CCA tissues. CRISPR/Cas9 and siRNA approaches were used to knockdown METTL16 in CCA cells, and the cells were analyzed for their malignant characteristics in vitro and in SCID mice. To identify METTL16 targets, we performed m6A-seq and RNA-seq, followed by m6A-qPCR, qPCR, RIP, and ribosome immunoprecipitation assays. We performed ChIP-qPCR and co-immunoprecipitation assays to determine the regulatory mechanisms of METTL16 expression in CCA cells. **Results:** We observed that the mRNA and protein levels of METTL16 were noticeably increased in human CCA tissues when compared to normal bile ducts. We found that depletion of METTL16 by CRISPR/Cas9 or siRNA significantly inhibited human CCA cell proliferation in vitro and decreased CCA progression in SCID mice. We identified PRDM15 as a key target of METTL16 in CCA cells by analyzing m6A-seq data. Accordingly, depletion of METTL16 reduced PRDM15 expression in CCA cells. Mechanistically, our data showed that METTL16 regulated PRDM15 protein expression via YTHDF1-dependent translation. We observed that restoration of PRDM15 expression partially rescued the deficiency of CCA cell proliferation/colony formation induced by METTL16 depletion. Our subsequent analyses revealed that METTL16-PRDM15 signaling regulated the expression of FGFR4 in CCA cells. Specifically, we observed that PRDM15 protein was associated with the FGFR4 promoter to regulate its expression. Regulation of FGFR4 by METTL16 signaling was further corroborated by the positive correlation between METTL16 and FGFR4 expression in human CCA tissues under immunohistochemical stains. Furthermore, we showed that the histone acetyltransferase p300 cooperated with the transcription factor YY1 to regulate METTL16 gene expression via histone H3 lysine 27 (H3K27) acetylation in CCA cells. **Conclusion:** This study describes a novel METTL16-PRDM15-FGFR4 signaling axis which is crucial for CCA growth and may have important therapeutic implications.

4224-A | TRANSPOSON-BASED ONCOGENES INTEGRATION IN Abcb4(Mdr2)-/- MICE RECAPITULATES HIGH SUSCEPTIBILITY TO CHOLANGIOCARCINOMA IN PRIMARY SCLEROSING CHOLANGITIS

Pinzhu Huang[1], Wen Gao[1], Yury V. Popov[1], Guangyan Wei[1], Jesse Kirkpatrick[2], Yi Lin[1], Li Tan[1], Disha Skelton-Badlani[1], Li Chen[3], Mathieu M. Petitjean[4], Kahini Vaid[1], Shuangshuang Zhao[1], Xin Chen[5], Gregory J. Gores[6] and Alicia Lugovskoy[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)Massachusetts Institute of Technology, (3) Pharmanest, (4)Pharmanest Inc, (5)University of Hawaii Cancer Center, (6)Mayo Clinic

Background: Cholangiocarcinoma (CCA) is a dreaded complication of primary sclerosing cholangitis (PSC), difficult to diagnose and associated with high mortality. Lack of animal models of CCA recapitulating the hepatic microenvironment of progressive sclerosing cholangitis hinders development of novel treatments. Here we sought to develop and characterize such PSC-associated CCA model in mice. **Methods:** Ten-week-old *Mdr2*-/- mice with congenital PSC-like progressive biliary disease, and healthy wild-type littermates (WT) were subjected to either modified retrograde biliary instillation or hydrodynamic tail vein injection of sleeping beauty transposon-transposase plasmid system with activated forms of AKT (myr-AKT) and Yap (YapS127A) protooncogenes (SB AKT/YAP1). ALK5 inhibitor (SB-525334, 300 mg/kg in diet) or placebo diet was administered into tumor-bearing mice to interrogate the functional role of TGFβ signaling in our model. Tumor phenotype, burden and desmoplastic reaction were analyzed based on histological staining. **Results:** While SB AKT/YAP1 plasmids via retrograde biliary injection caused tumors in *Mdr2*-/- but not in healthy wildtype mice, only 26.67% (4/15) of these tumors were CCA. Alternatively, hydrodynamic tail vein injection of SB AKT/YAP1 resulted in robust tumorigenesis in all fibrotic *Mdr2*-/- mice with high CCA burden relative to healthy

mice. Tumors expressed CK19, and exhibited a profound desmoplastic reaction. Pharmacological pan-TGFβ inhibition via ALK5 inhibitor reduced both tumor burden and desmoplastic tumor stroma compared to placebo. **Conclusion:** We established a new high-fidelity cholangiocarcinoma model in mice, termed SB CCA.*Mdr2-/-*, which recapitulates the increased susceptibility to CCA in the setting of progressive biliary injury and fibrosis observed in PSC. Furthermore, pharmacological targeting of ALK5 in our model suggests that TGFβ signaling functionally drives CCA tumorigenesis and promotes desmoplastic reaction.

4225-A | ULTRASOUND NONINVASIVELY STIMULATING THE SPLEEN TO ENHANCE HEPATOCELLULAR CARCINOMA IMMUNOTHERAPY

Wei Dong[1,2,3], Guihu Wang[1,2,3], Yingxue Liang[1,2,3], Wenjuan Li[1,2,3], Heyuan Liu[1,2,3], Jun Li[1,2,3], Libo Yao[1,2,3], Shemin Lu[1,2], Pengfei Liu[1,2,3], Guangyao Kong[1,2,3] and Zongfang Li[1,2,3], (1)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2)Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (3)Shaanxi International Cooperation Base for Inflammation and Immunity, Xi'an, China

Background: The spleen is the largest secondary lymphoid organ and distributed with an extensive meshwork of nerve fibers in all splenic compartments. Ultrasound triggering the splenic neural-immune reflex showed a significant mitigation effect on chronic inflammatory diseases, but the potential roles and underlying mechanisms in cancer management have not been defined and reported. This study was designed to explore whether ultrasound stimulating spleen was effective in alleviating hepatocellular carcinoma (HCC) proliferation, and the mechanism of enhanced antitumor immunity. **Methods:** We first verified the therapeutic efficacy in various HCC tumors by spleen modulation with ultrasound under specific parameters screened before. Furthermore, we investigated whether ultrasound stimulating spleen could improve antitumor immunity by increasing the proportions of CD4 T cells, CD8 T cells, NK cells, B cells, Mφ, DCs to resist the immunonegative Treg cells and MDSCs, or regulating inflammatory and anti-inflammatory cytokines. Subsequently, scRNA, nerve blockade and immune cell clearance were utilized to reveal immune cell activation, metastasis and its communication with cancer cells. **Results:** Ultrasound stimulating spleen could effectively suppress proliferation of xenograft HCC (Figure 1A-B) and HCC in situ (Figure 1C-D). Flow cytometry proved that specific cancer-suppressing immune cells, CD8 T cells, NK cells, Mφ and DCs, increased significantly in spleen and tumor after ultrasonic irradiation (Figure 1E-F). And the number of immunonegative cells (i.e. MDSC, Treg) was significantly reduced. These results sufficiently proved the application prospect of ultrasound stimulating spleen to increase the number of cancer-fighting immune cells for HCC immunotherapy. **Conclusion:** Ultrasound could non-invasively, targeted and safely stimulate the spleen to activate immune cells suppressing tumor proliferation, which will open a new era of clinical treatment of cancer.

4226-A | ZONATION-SPECIFIC HEPATOCARCINOGENESES UNDER NASH AND ASH IN DIABETIC MICE

Tian Tian[1,2], Chunbao Sun[1], Sreenivasulu Basha[1], Hua Wang[2] and Liya Pi[1], (1)Tulane University School of Medicine, New Orleans, LA, (2)Anhui Medical University

Background: Nonalcoholic steatohepatitis (NASH) and alcoholic steatohepatitis (ASH) are high risk factors for hepatocellular carcinoma (HCC). Both NASH and ASH are two histologically similar liver pathologies but their hepatocarcinogeneses in relation to liver zonation remain elusive. It is difficult to study these pathological processes in human due to their asymptomatic phenotype at early stage. This study aims to compare NASH or ASH progression to HCC in diabetic murine livers. **Methods:** NASH-associated HCC (NASH-HCC) was induced by neonatal subcutaneous administration of streptozotocin (STZ) and high fat diet (HFD) feeding in the STAM model. Another two models of alcohol-induced HCC were generated in STZ-treated livers with or without HFD feeding. RNA seq analysis in these tumors and adjacent tissues were compared. Digital spatial profiling (DSP) was also performed to discern extent of immune cell infiltration, cell proliferation, and

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cell death using barcoded antibodies. **Results:** Pericentralized/deperiportalized tumors expressing gene signatures like Hoshida subclass S3 in human HCC that contained ß-catenin mutations were found in the STAM model. These tumors resulted from periportal senescence and upregulated Wnt/ß-catenin targets including glutamine synthetase (Gs), and downregulation of genes in urea cycle, amino acid catabolism, and growth hormone/Ras signaling. Superimposed alcohol exposure in the STAM model exacerbated steatosis, hepatocyte damage, and ductular reaction (DR). Although alcohol decreased occurrence rates of the Gs^+ HCC, it provoked nonpericentral Gs^- tumors and promoted cytokeratin 19^+ cholangiocarcinoma (CCA). In the third model, alcohol alone after STZ administration caused pericentral senescence and triggered HCC that was opposite to the Gs^+ NASH-HCC in the STAM model. We observed downregulation of Wnt/ß-catenin targets including stemness regulators Lgr5, Tbx3, axin2, and Lef1. This type of ASH-HCC resembled Hoshida subclass S1 of human HCC with predominant activation of transforming growth factor (TGF)ß and Myc pathways. Furthermore, the ASH-HCC were Gs^- depericentral tumors and mimicked metabolic reprogramming in human livers with alcoholic hepatitis (AH). DSP revealed differential immune cell infiltrations and cell death activation in cell fractions of Gs^+ HCC, Gs-HCC, and CCA compared to intratumoral myofibroblasts, and their adjacent tissues. **Conclusion:** HFD induces Gs^+ pericentral HCC due to periportal senescence in the STAM model, whereas alcohol inhibits the Gs^- depericentral HCC. Superimposed alcohol exposure causes synergistic effects of NASH and ASH that exacerbates steatosis, hepatocyte damage, and DR leading to tumor heterogeneity with extensive DR and mixed HCC/CCA. These models mimic liver pathologies in human HCC/CCA and provide new platforms to dissect molecular mechanisms of distinct hepatocarcinogenesis among NASH, ASH, or both.

4300-A | 25HC3S ALLEVIATES INJURED LIVER FUNCTION AND DECREASES MORTALITY BY PROMOTER 5mCpG DEMETHYLATION SIGNALING PATHWAYS

Shunlin Ren[1,2], Michael Fuchs[3], William M. Pandak Jr[1] and Yaping Wang[1], (1)Virginia Commonwealth University, (2)Mcguire VA Medical Center, (3)Mcguire Veterans Affairs Medical Center, Moseley, VA

Background: Acute liver failure (ALF) is a dramatic and devastating disease. ALF often results in severe hepatocyte injury and apoptosis, leading to massive necrosis in the liver and the sudden death. Severe lipopolysaccharide (LPS)- and acetaminophen (ATMP)-induced hepatotoxicity are the most frequent causes of ALF. Currently, treatment options for ALF are extremely limited. 25-Hydroxycholesterol 3-sulfate (25HC3S, DUR928, or larsucosterol) has been demonstrated to alleviate injured liver function and decrease mortality in the acute liver failure in mouse models. The present study was designed to explore molecular mechanism(s) by which 25HC3S can be used to treat ALF. **Methods:** ALF mouse models were established by intravenous injection with LPS or ATMP. The injured liver function was treated with intraperitoneal administration of 25HC3S. Serum enzymatic activities were determined in our clinic laboratory. Western blot and mRNA sequencings were used to determine levels of gene expression; Whole genome bisulfite sequencing (WGBS) analysis was used to determine demethylation of ^{5m}CpG in promoter regions; DSS software (DSS 2.34.0) was used to identify differentially methylated regions (DMRs); and KOBAS software (KOBAS 2.0) was to test the statistical enrichment of DMR related genes in KEGG pathways. **Results:** Administration of 25HC3S decreased serum liver-impaired markers and alleviated liver, lung, and kidney injury. Subsequently, 25HC3S increased the survival rates in the LPS- or ATMP-induced mouse model, only 10% of the animals survived 96 hours without 25HC3S versus 90% survival with the 25HC3S. These effects resulted from the inhibition of the expression of genes involved in the pro-inflammatory response and apoptosis as well as the simultaneous induction of the expression of genes involved in cell survival. WGBS analysis showed that 25HC3S increased demethylation of ^{5m}CpG in key promoter regions and thereby increased expression of

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

genes involved in the MAPK-ERK and PI3K-Akt signaling pathways. 25HC3S exhibited significantly stronger effects in these activities, indicating that 25HC3S, a potent epigenetic regulator, plays an important role in the inflammatory response, cell apoptosis, and cell survival by demethylation of promoter ^{5m}CpG and upregulation of MAPK and PI3K signaling pathways in vivo. **Conclusion:** 25HC3S is a potent epigenetic regulator and has the potential to serve as a novel biomedicine in the therapy of ALF and acute multiple organ failure.

f 4301-A | A SIMPLE DYNAMIC SCORE ILBS-ALF-DYNAMIC SCORE (ILADS) RELIABLY PREDICTS MORTALITY IN ACUTE LIVER FAILURE PATIENTS WITH CEREBRAL EDEMA

Rakhi Maiwall[1], Samba Siva Rao Pasupuleti[2], Ashinikumar Kumar Hidam[3], Neha Chauhan[3], Harsh Vardhan Tevethia[1], Prashant Aggarwal[3], Shivali Panwar[3], Meenu Bajpai[3] and Shiv Kumar Sarin[4], (1) Institute of Liver and Biliary Sciences, New Delhi, (2) Mizoram University (A Central University), Pachhunga University College Campus, (3)Institute of Liver and Biliary Sciences, (4)Ilbs

Background: The outcomes of acute liver failure (ALF) have improved with increasing use of therapeutic plasma-exchange (TPE) and continuous renal replacement therapy (CRRT). Currently, there are no dynamic scores which incorporate assessment of cerebral edema, and impact of these therapeutic modalities for determining outcome in these patients. **Methods:** Prospective cohort of 170 adult patients with ALF requiring mechanical ventilation for cerebral edema (confirmed by CT-scan) with no option of liver transplant were enrolled. One point each for the class value was assigned for the significant parameters from the Cox-regression model for the calculation of the score for prediction of 21-day mortality. The score was calculated for day 2 and day 3 and compared to the other prognostic scores. **Results:** Patients with ALF (aged 31.0 ± 11.0 yrs, 47.6% males, 33% meeting KCH criteria 79% viral-related, 50% with sepsis) were enrolled of which 47.6% died. Sixty-one patients (36%) underwent TPE and/or CRRT. Five dynamic variables serum bilirubin (mg/dl) [(< 12 vs 12-18 vs. ≥ 18) [HR 1:2.11(1.10,4.04):3.59(1.99,6.46)], arterial lactate;(umol/L)[< 2.6 vs.2.6-5.0 vs. ≥ 5) [HR1:(3.84,1.72-8.57):(6.66,2.95-15.04)], ammonia ≥ 211mg/dl, (HR 1.90 (1.19-3.02) international normalized ratio (INR) ≥ 4.16 (HR 2.78,1.79-4.30) and optic nerve sheath diameter (ONSD) (< 4.5 vs.4.5-5.12 vs. ≥ 5.12 mm) [HR 1: (2.82,1.34-5.93): (5.32,2.58-10.96) and 2 fixed variables jaundice-to-encephalopathy time (days) (HR1.05 ,1.01-1.09) and age (≥ 32 y) (HR 2.13, (1.38-3.30) predicted 21-day mortality. With each unit increase in the (ILADS) ILbs-ALF-Dynamic Score, the hazard of death increased by 49% [HR1.4, 1.3-1.6)]. Patients who underwent TPE/CRRT had significantly lower mortality (26.4% vs 57.3%; $p < 0.001$, HR 0.43, 0.24-0.78). The ILADS ≥ 12 at day 1 (sensitivity 95.5%, specificity 72.0%; AUROC 0.89 (0.79-0.94)] and ILADS ≥ 11 at day 2 or 3 for patients who underwent TPE/CRRT (sensitivity 92.3%, specificity 53.8%; AUROC 0.80 (0.67-0.92)] accurately predicted mortality. At day 2, a progressive or persistent increase in serum bilirubin (≥ 16mg/dl); (HR 2.381.53,3.70), lactate (≥ 3.9 umol/L) (HR 2.85,1.76,4.59), ammonia (≥ 410 mg/dl) (HR 1.65, 0.82-3.30), INR (≥ 6.7) (HR 3.22,1.88,5.51) and ONSD (≥ 4.0mm)(HR 2.49,1.59,3.89) independently predicted worse outcomes. The ILADS score performed better than other scores; Harrell's C-index; ILADS (0.78), SOFA (0.61), APACHE (0.60), ALFED (0.62) and KCH (0.61). **Conclusion:** The ILADS score comprising of 5 simple dynamic and 2 fixed prognostic variables can reliably stratify patients of ALF with cerebral edema at high risk of 21-day mortality. Therapeutic interventions targeting the components of ILADS could be assessed dynamically with the score to stratify patients for super-urgent liver transplant.

f 4302-A | ACTIVATION OF HEPATOCYTE p53 TRIGGERS ACUTE LIVER FAILURE WITH MULTIPLE ORGAN DYSFUNCTION.

Jihyun Sung[1], Hayato Hikita[1], Yuki Makino[1], Seiya Kato[1], Yoichi Sasaki[1], Kenji Fukumoto[1], Kazuhiro Murai[1], Kunimaro Furuta[1], Akira Nishio[1], Takahiro Kodama[2], Tomohide Tatsumi[1] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2) Osaka University Graduate School of Medicine

Background: Acute liver failure (ALF) is characterized by massive hepatocyte cell death in a short term for which no effective treatment exists except liver

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transplantation. We previously reported that constitutive activation of p53 in hepatocytes caused continuous hepatocyte cell death leading to liver fibrosis and carcinogenesis. Meanwhile, its impact on acute liver diseases remains unknown. This work aims to study the role of p53 on ALF and investigate its potential as a therapeutic target. **Methods:** Gene Expression Omnibus (GEO) dataset was used for the analysis of RNA-seq in human ALF liver (GDS4387). Acetaminophen (APAP) or concanavalin A (ConA) were used to induce ALF in mice. Mdm2, a negative regulator of p53, was knocked out inducibly and specifically in hepatocytes (AlbCreER $mdm2^{fl/fl}$+tamoxifen) (Mdm2Δhep mice) to analyze the impact of acute activation of hepatocyte p53. p53 was further deleted in Mdm2Δhep mice (AlbCreER $mdm2^{fl/fl}$ $p53^{fl/fl}$+tamoxifen). CL-2, HepG2 (hepatocyte cell), LX-2 (hepatic stellate cell), and HK2 (renal proximal tubule epithelial cell) were used for culture. **Results:** In GEO datasets, hepatic cdkn1a, a representative target of p53, was up-regulated in ALF patients compared with the normal liver samples. C57B6J mice administered with APAP or ConA showed upregulation of p21 mRNA and p53 protein in the liver, indicating the activation of p53 pathway. Compared with Cre- littermates, Mdm2Δhep mice showed activation of p53 signaling in hepatocytes 72 hours after tamoxifen injection. Mdm2Δhep mice demonstrated extensive cell death and senescence in hepatocyte, together with the elevation of serum ALT and bilirubin. Apart from the liver, multiple organ injury was noted as the increase of TUNEL-positive cells and infiltration of inflammatory cells in the kidney, heart, colon, and lung, and elevation of serum cystatin C. All of Mdm2Δhep mice died within 168 hours after tamoxifen injection. Of note, further deletion of hepatocyte p53 negated all of these findings in Mdm2Δhep mice. Single-cell RNA-seq and multiplex cytokine assay showed the elevation of multiple inflammatory cytokines in hepatocytes, hepatic non-parenchymal cells and serum in Mdm2Δhep mice. Among these cytokines, we focused leukemia inhibitory factor (LIF), which was the most elevated inflammatory cytokine in RNA-seq of Mdm2Δhep mice liver. LIF increased by nutlin-3, an inhibitor of Mdm2, in CL2 and HepG2, indicating that LIF is a direct target of p53 in hepatocytes. Recombinant LIF up-regulated inflammatory cytokines including LIF itself in LX-2 and HK2. LIF was elevated in multiple injured organs in Mdm2Δhep mice, suggesting the possibility of LIF-mediated systemic inflammatory reaction. **Conclusion:** Hepatic p53 was activated in the liver of ALF. Acute activation of hepatocyte p53 triggers inflammatory reaction and ALF with multiple organ injury. Activated p53 may represent a novel therapeutic target against ALF.

4303-A | ACUTE LIVER FAILURE IN CORANAVIRUS DISEASE-19: A NATIONWIDE STUDY

Sajana Poudel[1], Ayusha Poudel[1], Kalpana Ghimire[2], Sumina Rai[1], Prakriti Subedi[2], Karun Shrestha[2] and Manoj Ghimire[3], (1)John H Stroger Jr. Hospital of Cook County, (2)St Barnabas Hospital, (3)Mayo Clinic Florida, Ponte Vedra Beach, FL

Background: COVID-19 is a global pandemic caused by the SARS-CoV-2 virus that can cause multiorgan damage including liver. Hepatic dysfunction has been observed in 14-53% of patients with COVID-19, and studies have shown that COVID-19 is associated with severe acute liver injury and acute liver failure. The liver may be susceptible to the virus due to ACE2 receptors in biliary and liver epithelial cells, and a hyperinflammatory response leading to a cytokine storm can also contribute to liver damage. little is known about risk factors and clinical course for patients with significant liver injury attributed to COVID-19. The aim of this article is to describe the prevalence and risk factors for development of acute liver failure in COVID-19 patients and investigate the impact its impact on patient outcomes. **Methods:** All adult patients (age > 18 y) old with COVID-19 and acute liver failure admitted in 2020 were identified from the Nationwide Inpatient Sample (NIS). Data on demographic information, baseline clinical characteristics, and outcome variables such as mortality, hospital length of stay, and total hospital charges were collected and analyzed. Statistical analysis was performed by using the survey procedures function in the STATA v.17. Statistical significance was defined by the two-sided t-test with a p value < 0.05. **Results:** A total of 1,050,045 patients were admitted to the hospital with COVID-19 pneumonia, out of which 6,665 cases (0.9%) developed acute liver failure during hospitalization. The incidence of acute liver failure in COVID-19 patients was found to be high among the black population (20.4% vs 17.8%, $p = 0.002$) and Hispanics (25.5% vs 19.8%, $p < 0.01$). The prevalence of heart failure (12% vs 8%, $p < 0.01$), chronic kidney disease (17% vs 13%, $p = 0.002$) and chronic liver disease(5% vs 1%, $p < 0.01$) were higher in patients who developed ALF. Patients with ALF had higher incidence rates of septic shock (53.79% vs 3.78%, $p < 0.001$), acute kidney failure (39.46% vs 3.11%, $p < 0.01$), and mechanical ventilation requirements (78.1% vs 8.9%, $p < 0.01$). It was associated with higher mortality (72.39% vs 10.78%, $p < 0.01$), longer

duration of hospital stay (mean duration: 18 d vs 7 d, $p < 0.01$), and higher total hospital charges ($355,512 vs $76,822, $p < 0.01$) than those without acute liver failure. Advanced age, development of septic shock, and requirement of mechanical ventilation were found to be predictors of mortality in a multivariate regression model. **Conclusion:** The occurrence of acute liver failure in COVID-19 patients is associated with significant adverse outcomes, including higher mortality rates, longer hospital stays, and increased treatment costs. This emphasizes the need for effective management of acute liver failure in COVID-19 patients to improve their prognosis, reduce the burden on the healthcare system, and optimize resource allocation

4304-A | ASSESSMENT AND PROPER DIAGNOSIS OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN THE SETTING ACUTE LIVER FAILURE

Ahmad Anouti[1], Hamza Dahshi[2], Jody A. Rule[1], Christian Wysocki[2], William M. Lee[1] and Shannan R. Tujios[2], (1)University of Texas Southwestern Medical Center, (2)University of Texas Southwestern

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a severe and life-threatening disease that is challenging to diagnose and can present as acute liver failure (ALF) with coagulopathy, altered mental status and elevated liver tests. We reviewed all cases considered as possible HLH in the ALF Study Group (ALFSG) registry over the 22 years of the study, and assessed the diagnostic criteria HLH score, H score, and measured interleukin-18 (IL-18) and soluble interleukin-2 receptor (sIL-2r), recognized biomarkers of HLH, in putative cases as well as other etiologies of ALF as comparison groups. **Methods:** We analyzed data on patient demographics, biochemical features, IL-18 and sIL-2r as well as outcomes for 434 subjects enrolled in ALFSG between January 1, 2000, through December 31, 2016, who either met criteria for HLH or who had other diagnoses but striking biochemical values including elevated ferritin that might mimic HLH. Biomarkers were collected one to two days after patients were admitted to the study hospital. Differences in categorical variables between patients with and without HLH were analyzed using Chi-Square and Fishers tests. Whereas differences in continuous variables between patients with vs without HLH were analyzed using One-Way ANOVA and Kruskal Wallis tests. **Results:** 18 cases of HLH were reported within the ALFSG by the site investigator of which, upon thorough review: 7 (47%) were considered HLH definite cases, 6 (40%) were possible HLH cases, and 5 (33%) were unlikely HLH cases (Table 1). HLH definite cases had significantly greater ferritin levels ($p = 0.047$), H scores ($p < 0.001$), IL-18 ($p = 0.003$), s-IL2r ($p = 0.005$), HLH scores ($p < 0.001$), and temperature ($p = 0.002$) as well as significantly more frequent organomegaly (hepatomegaly and/or splenomegaly, $p = 0.003$) and Epstein Barr virus presence ($p = 0.001$). By comparison, APAP, DILI, and viral etiologies, as expected, had lower HLH and H scores as well as IL-18 and sIL2r levels but overlapped with many ferritin levels (Figure 1). Moreover, ROC curves for HLH definite cases showed an area under the curve of 0.69 for Ferritin, 0.93 for Total IL-18, 0.83 for sIL-2r, 0.96 for HLH score, and 0.88 for H score. Missing values for calculating H and HLH scores may have impacted the categorization of HLH cases. **Conclusion:** The proper assessment and diagnosis of HLH remains challenging. Accurate collection of requisite lab values can improve diagnosis of HLH in the setting of ALF. Ferritin levels are highest in HLH and APAP cases. Even within ALF cases, HLH diagnostic markers varied, but sIL-2r and IL-18 were significantly different compared to other etiologies and could aid in the proper diagnosis of HLH. Despite limitations, HLH and H score are highly discriminant identifying HLH in patients with ALF. EBV viremia is a common precipitant in HLH cases presenting with ALF.

Table 1: Characteristics of patients diagnosed with ALF based on etiology

Criteria	HLH Definite N=7	HLH Possible N=6	HLH Unlikely N=5	APAP N=62	DILI N=29	Viral N=39

4305-A | BACTERAEMIA IN PATIENTS WITH ACUTE LIVER FAILURE IS DEPENDENT ON THE AETIOLOGY AND HYPERAMMONAEMIA

Anna Cavazza, Gjulio Ciroi T M, Tasneem Pirani, William Bernal and Mark John William McPhail, King's College Hospital

Background: Acute liver failure (ALF) is a life threatening condition associated with immunological disarray and risk of infection. The role of prophylactic antimicrobials is debated and there is increased multi-drug resistant (MDR) pathogens affecting similar populations. We aim to define the burden of resistant organisms and determine which factors predict development of bacteraemia in the modern era. **Methods:** A retrospective observational study of 571 ALF patients admitted between 2010 and 2022 to the Liver Intensive Care (LICU) at King's College Hospital, London. Demographic, laboratory and microbiological data were obtained. Statistical analysis including multivariate logistic regression was performed. Multidrug resistant organisms were defined as resistant to more than one antimicrobial. **Results:** Five hundred and seventy one ALF patients were included, 63% female (358/571), median age 40 (range 15-87) years. The aetiology was due to acetaminophen (APAP) in 48% (274/571). 25% were transplanted (141/571), 28% died (158/571), 47% spontaneously survived (272/571). The median length of stay in LICU was 21 (0-315) days.35% (122/345) and 44% (88/200) had positive cultures pre liver transplant (OLT) in the early (2010-2016) and late (2017-2022) era, 51% (43/84) and 61% (25/41) post-OLT respectively. Resistant organisms were present in cultures in 21% (76/365) in the early and 26% (52/203) late era. 11% (34/322) and 9% (17/185) developed bacteraemia in the early and late era respectively. The median time from admission to bacteraemia was 9 (0-103) days. MDR bacteraemia was observed in 41% (14/34) in the early and 35% (6/17) in the late era. Fungaemia was observed in 1.3% (4/299) and 4% (4/100) with positive β-d-glucan (BDG) in 21% (14/66) and 26% (43/163) respectively in the early and late era. Multivariate analysis showed aetiology and ammonia as significant predictors of bacteraemia (respectively Odds Ratio 3.4 (95% CI 1.1-9.8, $p = 0.022$); OR 1.009, (95% CI 1.0-1.0, $p = 0.010$). Further age/gender controlled model with aetiology and ammonia as independent predictors demonstrated aetiology significant predictor (OR 2.3, 95% CI 1.1-4.6, $p = 0.016$). **Conclusion:** Bacteraemia complicates 10% of ALF cases, with resistant organisms found in 23% of positive cultures. ALF aetiology and ammonia level were significant predictors of bacteraemia which remains a late complication. The role and length of antimicrobial prophylaxis requires re-evaluation in the modern era.

4306-A | CHARACTERIZATION AND THERAPY SIMULATION OF BIOENGINEERED LIVER GRAFTS FOR EXTRACORPOREAL LIVER ASSISTANCE IN ACUTE LIVER FAILURE

Aron R. Stumbras[1], Shawn A. Riesgraf[1], R. Noelle Palumbo[1], Victoria L. Nelson[1], Marie S. Balboa[1], Zachary A. Hannah[1], Ernesto R. Resnik[1], Christopher J. Fecteau[1], John R. Lake[1,2] and John J. Barry[1], (1) Miromatrix Medical Inc., (2)University of Minnesota

Background: Extracorporeal bioengineered liver (BEL) grafts offer a novel therapy for patients with Acute Liver Failure as a bridge to transplant or recovery by metabolizing ammonia and performing other hepatic functions. Miromatrix has previously reported functional BELs seeded with human and porcine hepatocytes. Here we demonstrate liver specific functions and an extracorporeal therapy simulation using BELs manufactured from entirely human-derived cells. **Methods:** Porcine livers were decellularized using previously published methods to create a porcine liver extracellular matrix (PL-ECM). The PL-ECM was seeded with human umbilical vein endothelial cells (HUVECs) and allowed to culture in a bioreactor for 8-19 days before seeding with primary human hepatocytes. Spent media was analyzed for urea, fibrinogen, alpha-1-antitrypsin (A1AT), and other BEL metabolites. Culture media was dosed with ammonium chloride, unconjugated bilirubin, or acetaminophen and sampled at relevant intervals to analyze ammonia clearance, bilirubin conjugation, and xenobiotic metabolism, respectively. To evaluate longevity of function, BELs underwent a simulated cold storage and transport study three days after hepatocyte seeding in which they were subjected to cold storage for 12 hours in Belzer UW solution and then returned to culture and functionally characterized for 72hrs. To evaluate compatibility as a bedside therapy, BELs were installed as part of an extracorporeal blood circuit (EBC) consisting of a Baxter Prismax® perfusion system, a customized

Baxter Prismaflex® tubing set, and components from an OrganOx metra® Liver Perfusion Pack and evaluated using media perfusion. **Results:** BELs seeded with primary human hepatocytes demonstrated ureagenesis, ammonia clearance, protein production, bilirubin conjugation, and xenobiotic metabolism during 72 hours of in vitro culture. Following a cold storage and transport simulation, BELs demonstrated stable ureagenesis, ammonia clearance, and protein production for up to 96 hours. BELs also demonstrated stable ureagenesis, protein production, and other metabolic activity for the 72-hour therapy window evaluated in the EBC. **Conclusion:** The described isolation, seeding, and culturing strategy generates functional BELs capable of a variety of liver specific functions. This study demonstrates that seeding BELs with primary human hepatocytes results in retention of function after cold storage and compatibility with perfusion systems and components commonly used for EBC therapies.

4307-A | COMPARISON OF MOLECULAR ADSORBENT RECIRCULATING SYSTEM TO STANDARD OF CARE IN ACUTE LIVER FAILURE

Kinnari Modi[1], Dylan Lopez[1], Blake Thompson[1], Wenjing Cai[1], Parvez S. Mantry[2], Mingyang Cui[1] and Hellen Oduor[1], (1)Methodist Dallas Medical Center, (2) The Liver Institute at Methodist Dallas

Background: Molecular Adsorbent Recirculating System (MARS) has been utilized in patients with severe liver failure with AKI and PSE at our center for the last 3 years. The aim of this study was to compare change in bilirubin, ammonia, PSE stage, and 28-day transplant free survival in those undergoing MARS to standard of care (SoC) in patients with acute liver failure (ALF) and acute-on-chronic liver failure (ACLF). **Methods:** This is a single center retrospective propensity-matched study performed at Methodist Dallas Medical Center. Data included patients with alcoholic hepatitis (AH), ACLF or ALF who underwent MARS or SoC from January 2019 to March 2022. MARS was performed 12 hrs/day for 5 days – MARS was interrupted in the case of hemodynamic instability, clinical deterioration, or in cases of substantial clinical improvement. Measured outcomes included change in bilirubin, ammonia, MELD-Na scores and PSE stage pre- and post-MARS. We assessed their overall mortality after receiving MARS or SoC therapy. Wilcoxon signed-rank test was used to compare continuous variables. Chi-squared test was used for categorical variables. **Results:** We used propensity score methods to assess efficacy of MARS vs SoC therapy in patients with ALF and ACLF. Before matching, 42 patients underwent MARS and 109 patients received SoC. After matching based on MELD-Na, age and gender, 68 patients (42 MARS and 26 SoC) were included in the final analysis. In the MARS group, mean sessions of MARS was 4. There was a statistically significant difference in bilirubin (median 20.35 vs 17) and ammonia levels (median 67 vs 31) pre- and post-MARS. The proportion of patients with stage 3 or 4 PSE significantly decreased after MARS therapy (28/42 vs 15/42). Comparing groups, the MARS groups had a significantly greater decrease in bilirubin ($p = 0.05$) and proportion of patients with PSE ($p = 0.05$). There was no significant difference in ammonia or survival. In MARS group, 28-day transplant free survival was 38.4% (15/39) – 3 patients had liver transplant. In the SoC group, 28-day transplant free survival was 42.3% (11/26) – none had liver transplant. **Conclusion:** In this propensity-matched analysis, there was a significantly greater decrease in bilirubin and proportion of patients with PSE stage 3-4 in the MARS group compared to SoC. There was not a significant difference in 28-day transplant free survival. We plan to increase the number of historical controls for future analysis.

4308-A | DDX3X REGULATES THE FUNCTIONAL TRANSITION OF ENDOPLASMIC RETICULUM STRESS IN THE PROGRESSION OF LIVER FAILURE

Feng Ren, Xiangying Zhang, Ling Xu and Zhongping Duan, Beijing Youan Hospital Capital Medical University, Beijing, China

Background: Endoplasmic reticulum (ER) stress plays a critical role in the progression of liver failure (LF), but

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

the underlying molecular mechanisms remainunclear. Here, we explored DDX3X to regulate cell fate under ER stress in theprogression of LF. **Methods:** Primary hepatocytes isolated from C57BL/6 mice were induced ER stress with tunicamycin (TM). $DDX3X^{fl/fl}$ and $DDX3X^{\Delta Hep}$ mice were induced ER stress with TM and liver injury with ConA, respectively. The expression of DDX3X were also analyzed in healthy, chronic hepatitis B (CHB) patients and HBV-associated LF patients. **Results:** DDX3X increased and translocated into nucleus with prolonged ER stress, and phosphorylation modification of DDX3X is the mechanism to regulate its subcellular localization. Under short-term ER stress, DDX3X was mainly expressed in cytoplasm and interacted with PPARα, which reduced the phosphorylation of DDX3X to promote the adaptive cell response. Under prolonged ER stress, phosphorylated DDX3X increased nuclear translocation to promote cell apoptosis by CHOP activation. In addition, DDX3X plays dual roles during Con A-induced liver injury, which exerts a protective effect in early phase (6 h) and a pro-injury effect in later phase (24 h). Moreover, compared with CHB, the level of DDX3X in serum and liver tissue was increased in patients with HBV-associated LF, and serum DDX3X consistent decline was correlated with a good prognosis. **Conclusion:** Our novel findings document the key regulatory function of DDX3X signalling in the pathophysiology of liver failure, and provide a rationale to target DDX3X as a refined therapeutic strategy to ameliorate liver injury.

f 4309-A | EARLY INITIATION OF THERAPEUTIC PLASMA EXCHANGE (TPE) IMPROVED OUTCOMES IN PATIENTS WITH IMPENDING ACUTE LIVER FAILURE (ALF)

Manasa Alla[1], Anand V. Kulkarni[1], Mithun Sharma[2], Anand Gupta[1], Shantan Venishetty[1], Sowmya T R[1] and Nagaraja Rao Padaki[1], (1)Aig Hospitals, Hyderabad, India, (2)Asian Institute of Gastroenterology, Hyderabad, Telangana, India

Background: Acute liver failure (ALF) with progressive cerebral edema is associated with high mortality for which liver transplantation is the only definitive treatment. Therapeutic plasma exchange (TPE) is an excellent bridging therapy for patients with ALF. TPE may prevent (contain) the cytokine storm and also has been reported to resolve hepatic encephalopathy (HE). We evaluated the efficacy and outcomes of early introduction of TPE in patients with impending ALF (Bil ≥ 5mg/dl, INR ≥ 1.5 with grade I/II encephalopathy) in comparison to ALF patients. **Methods:** We conducted a retrospective study from Jan 2022- March 2023 of all patients admitted with impending ALF at a tertiary care center. Among 38 patients admitted with a diagnosis of ALF, 16 patients with grade I/II HE (as per West Haven's criteria) & were categorised as impending liver failure (Group I) and 22 patients as ALF group with clinical features of (grade III/IV) HE at admission (Group II). 8 patients had spontaneous improvement in INR on follow up & were excluded for the study. Single volume TPE was offered in both the groups. Clinical & biochemical parameters & outcome measures were analysed. **Results:** Total 30(10 in group I & 20 in group II) patients were analysed. Most common aetiologies were viral hepatitis(16/30;60%) followed by drug induced liver injury (9/30; 30 %). Mean age of ALF patients was 21.2 ± 5.3 years and M:F ratio was 23:7. Mean MELD scores were comparable in group I vs group II (30.1 ± 7.4 vs 32 ± 8.1,p = 0.53). All patients received standard medical care, including N-acetyl cysteine and nutritional support. Mean bilirubin and INR was comparable in both the groups {23 ± 5.9 mg/dl vs 25 ± 7.1 mg/dl, p = 0.44; 3.91 ± 1.5 vs 4.1 ± 1.72, P = 0.76}. Higher arterial ammonia was noted in the group II {90 ± 34.7 mmol/L vs 110 ± 23.9 mmol/L, P = 0.07}. TPE was initiated in all patients with mean days post admission {1.6 ± 0.8; 2.1 ± 0.7, P = 0.59} & received higher mean no of TPE sessions in group II {2 ± 1.6 vs 4 ± 1.9, P < 0.05}. Mean days of hospitalization were higher in ALF group {9 ± 3.2 vs 12 ± 3.9 days,P = 0.04}. Incidence of AKI {20% (2/10) vs 25% (5/20) P = 0.30} & sepsis was comparable in both the groups {20% (2/10) vs 30 % (6/20), P = 0.58}. Early introduction of TPE reduced the progression to ALF in 90% (9/10) patients in the impending ALF group. 30-day transplant free survival was higher in group I {90% (9/10) vs 25% (5/20), P = 0.001}. High serum procalcitonin (≥ 2ng/mL) with AUC of 0.83 (sensitivity of 91%, specificity of 92%) and low fibrinogen (< 100mg/dl) with AUC = 0.84 (sensitivity of 88%, specificity of 90%) were found to be significantly associated with high mortality. **Conclusion:** ALF is characterised by rapid deterioration especially when cerebral edema sets in due to the hyperinflammatory state & early initiation of therapeutic

4310-A | EARLY LIVER TRANSPLANT MAY IMPROVE OUTCOMES IN PATIENTS WITH ANTITUBERCULAR THERAPY RELATED ACUTE LIVER FAILURE - (ATT- ALF) A PROSPECTIVE COHORT STUDY

Rakhi Maiwall[1], Ashinikumar Kumar Hidam[2], Harsh Vardhan Tevethia[1], Prashant Aggarwal[2], Rajan Vijayaraghavan[2], Shivali Panwar[2], Neha Chauhan[2] and Shiv Kumar Sarin[3], (1)Institute of Liver and Biliary Sciences, New Delhi, (2)Institute of Liver and Biliary Sciences, (3)Ilbs

Background: Patients with antitubercular related acute liver failure (ATT-ALF) have worse outcomes. Therapeutic plasma-exchange (TPE) improves survival in patients with ALF. We aimed to investigate the profile, prognostic factors, and the impact of TPE in improving outcomes of ATT-ALF compared to other etiologies. **Methods:** Prospective observational cohort study of ALF patients admitted to the intensive care unit. Cox-regression survival analysis was performed **Results:** Of the 170 ALF patients, 20(11.76 %) comprised ATT-ALF, majority had viral-related ALF in 94(79%). The most common indication of ATT was pulmonary in 40% followed by disseminated disease in 5 (25%).The most common ATT regime was rifampicin, isoniazid and ethambutol in 15 (75%). Patients with ATT-ALF were older [(39.4 ± 12.3) vs. (29.9 ± 10.34) years; $p < 0.001$], with lower aspartate and alanine amino-transferase (IU/L) [(815.08 ± 791) vs. (1769.24 ± 1449.94); $p = 0.019$], [(612.0 ± 781.0) vs. (1028.23 ± 1187.62); $p = 0.004$] respectively, and, higher proportion of patients meeting king's college criteria (KCC) [8 (61.5%) vs. 34 (36.6%); $p = 0.08$], but comparable MELD [(30.5 ± 10.2) vs. (29.2 ± 9.7); $p = 0.71$] and SOFA scores [(11.3 ± 2.8) vs. (11.5 ± 2.9); $p = 0.51$] compared to other etiologies. The mean jaundice to encephalopathy time was significantly longer in patients with ATT-ALF [(8.25 ± 5.73) vs. (6.04 ± 4.50) days; $p = 0.02$]. Patients with ATT-ALF had significantly worse 21-day transplant-free survival [HR 1.96, 1.01-3.89]. On multivariable analysis, higher age ($p = 0.003$, HR 1.03, 1.01-1.04), optic nerve sheath diameter (ONSD) ($P < 0.001$, HR 1.61, 1.29-1.99), presence of sepsis ($p = 0.002$, HR 2.13, 1.31-3.47) and ATT-ALF ($p = 0.049$, HR 1.76, 1.00-3.15) were independent predictors of worse survival, while use of TPE conferred better survival ($p = 0.005$, HR 0.44, 0.24-0.77). In the subset of patients with ATT-ALF, TPE could not improve survival [$p = 0.53$, (HR 0.61, 0.13-2.89)]. In these patients, higher ONSD [(7.5 ± 0.9) vs. (6.1 ± 1.0) mm; $p = 0.008$], serum bilirubin [(20.2 ± 6.1) vs. (12.3 ± 4.2)mg/dl; $p = 0.01$), serum ammonia [(313.3 ± 173.2) vs. (204.7 ± 48.7)mg/dl; $p = 0.04$),and shorter time from the initiation of ATT to the development of jaundice [(25.8 ± 14.3) vs. (87.5 ± 43.9)days; $p = 0.017$) significantly predicted higher mortality. **Conclusion:** Patients with ATT-ALF have worse outcomes and high mortality in the absence of liver transplant. TPE improves survival in patients with ALF, however, it does not confer survival benefit in ATT-ALF. Higher bilirubin and ammonia, shorter time to the development of jaundice from ATT initiation and severe cerebral edema govern worse outcomes in ATT-ALF indicating need of early liver transplantation. Trials exploring the benefits of TPE in ATT-ALF patients are needed.

4311-A | EFFECTIVE ALBUMIN CONCENTRATION IN CHRONIC LIVER FAILURE IS DETERMINED MAINLY BY REVERSIBLE FACTORS: POSSIBLE THERAPEUTIC CONSEQUENCES

Margret Paar[1], Vera Heike Fengler[2], Gilbert Reibnegger[1], Kerstin Schnurr[3], Katja Waterstradt[3], Sebastian Patrick Schwaminger[1], Rudolf Ernst Stauber[1] and Karl Oettl[1], (1)Medical University of Graz, (2)University of Graz, (3)Medinnovation Gmbh

Background: Serum albumin from patients with chronic liver failure is reduced in its concentration, structurally modified and impaired in its functionality what led to the concept of the effective albumin concentration. Albumin exhibits binding/transport function for endo- and exogenous molecules and is used as therapeutic agent (e.g., infusion, dialysis devices); its functionality is thus of clinical and pharmacological interest. The effective albumin concentration could be affected by post-translational modifications (PTM) and bound ligands most probably influencing its conformation. We evaluated binding properties of albumin from patients with acute decompensation of cirrhosis with or without acute-on-chronic liver failure, therapeutic infusion solutions, and in vitro modified albumin to determine the impact of ligands and most frequent PTM in liver disease on albumin functionality. **Methods:** We applied EPR spectroscopy with 16-doxyl stearic acid as ligand and fluorescence titration with dansylsarcosine to characterize binding properties of albumin. The latter were investigated in i) purified albumin from plasma of liver patients and healthy controls, ii) in vitro oxidized or glycated albumin, iii) therapeutic albumin before and after stabilizer removal. Binding data were related to albumin redox states in terms of cysteine-34 (Cys-34) as well as bilirubin and fatty acid contents. **Results:** Albumin from patients with chronic liver failure and therapeutic albumin showed in part severely restricted binding properties (e.g., Binding efficiency (BE) is reduced to 34%, $P = 0.004$ in patients, and 38%, $P = 0.0005$ in therapeutic albumin). Removal of bilirubin from patients' albumin and stabilizers from therapeutic albumin led to substantial improvement of binding properties. Reversibly oxidized albumin with disulfide at Cys-34 had somewhat decreased binding properties (e.g., BE is reduced to 62%, $P < 0.0001$) while irreversible oxidation of Cys-34 or glycation had only minor impact. **Conclusion:** Impaired binding properties of albumin in patients with chronic liver failure or therapeutic albumin are determined primarily by reversible factors like binding/removal of (patho)physiological ligands or stabilizers and reversible oxidation of Cys-34. Other PTM like irreversible oxidation or glycation are less representative for albumin's effectiveness. Whether the quality of albumin is impaired primarily due to molecule modifications or by the pathological environment in terms of high ligand concentrations remains open.

4312-A | FOXA2 IS ESSENTIAL FOR CPS1 TRANSCRIPTION TO MAINTAIN THE UREA CYCLE AND PREVENT HYPERAMMONEMIA IN ACUTE LIVER FAILURE

Rui Liu[1], Rilu Feng[1], Chenhao Tong[1], Tao Lin[1], Xiaofeng Li[2], Carsten Sticht[3], Stefan Munker[4], Yujia Li[1], Sai Wang[1], Matthias Ebert[1], Huiguo Ding[5], Hua Wang[2], Honglei Weng[1] and Steven Dooley[1], (1)Department of Medicine II, Section Molecular Hepatology, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, (2)The First Affiliated Hospital of Anhui Medical University, Hefei, China, (3)NGS Core Facility, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, (4)Department of Medicine II, University Hospital, Ludwig-Maximilians-University Munich, Munich, Germany, (5)Department of Gastroenterology and Hepatology, Beijing You'an Hospital, Capital Medical University, Beijing, China

Background: Disruption of the urea cycle results in hyperammonemia and thus causes hepatic encephalopathy (HE), a lethal complication of acute liver failure (ALF). A complete urea cycle requires six enzymes, including the rate-limiting enzyme carbamoyl phosphate synthetase I (CPS1). To date, the detailed regulation of CPS1 transcription in order to maintain urea cycle in ALF remains largely unknown. **Methods:** Expression of CPS1 and transcription factors such as FOXA2 and C/EBPα was examined by immunohistochemistry in liver tissues collected from 78 ALF patients including 27 with HE. The regulatory mechanisms of these factors on CPS1 transcription were investigated in different cell lines and primary cells. The effect of FOXA2 in ALF was further investigated in acetaminophen-treated mice with or without adeno-associated virus serotype 8 (AAV8)-Foxa2 injection. **Results:** Physiologically, CPS1 transcription requires FOXA2 to maintain chromatin accessibility on their enhancers, which provides open binding sites for C/EBPα. In ALF, hepatic C/EBPα expression is inhibited by inflammation. In this setting, retinoic acid receptor synergizes with FOXA2 to maintain CPS1 transcription. Once ALF patients suffer from massive hepatic necrosis, liver progenitor cells perform the urea cycle to prevent hyperammonemia by initiating a transcription network comprising FOXA2 and C/EBPα. In ALF, HE occurs in patients lacking expression of these transcription factors. In mice with acetaminophen-induced ALF, injection of Foxa2-AAV8 maintains urea cycle and prevents hyperammonemia. **Conclusion:** FOXA2 is essential for maintaining the urea cycle to prevent hyperammonemia. Pharmaceutical induction of hepatic FOXA2 expression might represent a novel approach to treat HE in ALF.

4313-A | HEPATIC BIOPRINTED TISSUE THERAPEUTICS (BTTS) DEMONSTRATE COMPARABLE FUNCTION WHEN IMPLANTED INTO INTRAPERITONEAL OR SUBCUTANEOUS SITES

Christopher Dickman, Zainab A. Bazzi, Oksana Nemirovsky, Farin Vaez Livary, Fiona Li, Stephanie A. Campbell, Haley Tong, Rishima Agarwal, Matthew R. Zeglinski, Jaedyn D. Foley, Lyndsey Hayes, Paola Romero, Mahinur Efe, Simon Beyer, Tamer Mohamed, Reza Jalili, Samuel Wadsworth, Spiro Getsios and Rafal P. Witek, Aspect Biosystems

Background: Standard of care treatment for many liver diseases including acute liver failure (ALF) and urea cycle disorders (UCDs) consist of liver transplantation. This is effective but invasive and requires chronic immune suppression and can result in bleeding. Recent research has demonstrated promising results for encapsulated hepatocytes implanted into the intraperitoneal (IP) space as a treatment for pediatric ALF. It is unclear if this procedure can be completed at less invasive surgical sites. The subcutaneous (SubQ) space has the benefit of being comparatively non-invasive as well as being larger and in some liver diseases the IP space may be fouled with ascites. This abstract describes the implantation of hepatic BTTs containing primary human hepatocytes (PHHs) and mesenchymal stromal cells (MSCs) into both the IP and SubQ spaces of NSG mice. **Methods:** PHH and MSC cells were formed into spheroids prior to mixing with an alginate-based biomaterial. Using Aspect Biosystems' proprietary microfluidic 3D bioprinting technology, the spheroids were 3D printed into BTTs. BTTs were then implanted into both IP and SubQ spaces of NSG mice. Plasma was collected at regular intervals over a period of 4 weeks. Human albumin was measured via ELISA. **Results:** In mice that received BTTs into the IP space, (n = 4) mean human albumin levels were 1137 ng/mL after 1 day and rising to 2186 ng/mL after 2 weeks. Mice that received BTTs in the SubQ space (n = 5) had day 1 mean human albumin levels of 793 ng/mL with levels rising to 1970 ng/mL after 2 weeks. Mice receiving BTTs to the SubQ space had faster wound healing when compared to mice receiving IP surgery. **Conclusion:** Hepatic BTTs maintain high function when implanted into either the SubQ or IP space of NSG mice. SubQ surgeries were comparatively non-invasive. These observations suggest that a minimally invasive surgery for implantation of liver cell therapies may have several benefits. The larger space available for SubQ implantation could allow for the implantation of larger BTTs, as well as for more frequent monitoring and replacement. Decreased invasiveness may also make the procedure an option of non-life-threatening liver diseases, or in patients who may not tolerate surgery. In the future, we aim to test the implantation of larger BTTs into the SubQ space of rats and additionally examine the longer-term function of SubQ BTTs in an in vivo efficacy model of metabolic liver diseases including PKU and A1AT deficiency.

4314-A | HEPATIC BIOPRINTED TISSUE THERAPEUTICS (BTTS) RESCUE MICE FROM CCI4-INDUCED ACUTE LIVER FAILURE

Christopher Dickman, Zainab A. Bazzi, Oksana Nemirovsky, Farin Vaez Livary, Fiona Li, Stephanie A. Campbell, Haley Tong, Rishima Agarwal, Matthew R. Zeglinski, Jaedyn D. Foley, Lyndsey Hayes, Paola Romero, Mahinur Efe, Simon Beyer, Tamer Mohamed, Reza Jalili, Samuel Wadsworth, Spiro Getsios and Rafal P Witek, Aspect Biosystems

Background: Acute liver failure (ALF) and Acute-on-chronic liver failure (ACLF) are treated with liver transplantation. The limited supply of donor organs results in a large number of patients dying while awaiting surgery. Researchers have begun to examine the transplantation of isolated primary human hepatocytes (PHHs) with promising results in pediatric ALF patients. Implementation of this process remains a challenge due to the absence of a standardized treatment. This abstract describes experiments using Bioprinted Tissue Therapeutics (BTTs) containing PHHs and mesenchymal stromal cells (MSCs) to treat immune competent mice with CCl_4-induced ALF. **Methods:** To create hepatic BTTs, PHHs and MSCs were co-aggregated into spheroids and then suspended in an alginate-based biomaterial. Aspect Biosystems' proprietary microfluidic 3D bioprinting technology was used to generate BTTs. ALF was induced in C57BL/6 mice via SubQ injection of CCl_4. Mice were implanted with hepatic BTTs or cell-free controls into either the intraperitoneal (IP) or subcutaneous (SubQ) space. Survival was measured for 7 days after implantation and livers were embedded upon loss of the mouse or at day

7. Plasma was collected at days -7, 1 and 7 post-surgery. **Results:** BTT treatment was capable of rescuing mice with ALF. When BTTs were implanted into the IP space (n = 15), B6 mice had a survival rate of 78% when compared to 46% for mice receiving cell-free controls (n = 15). When implanted into the SubQ space, BTTs were also capable of improving survival. With a day 7 survival rate of 85% vs 50% for treated (n = 7) vs control (n = 8) mice. To confirm these results this experiment was repeated with cells from an alternate PHH donor. With the alternate donor the survival rate for mice receiving SubQ BTTs was 50% (n = 8) vs 13% for control mice (n = 8). Collectively the combined survival rate for BTT-treated mice was 68% vs 35% for untreated animals with a p-value of 0.003. **Conclusion:** Hepatic BTTs are capable of rescuing mice from ALF induced via injection of CCl_4. Implantation of BTTs into either SubQ or IP sites resulted in comparable efficacy. This data suggests that BTTs could be used as a bridge to transplantation or recovery in individual's with ALF or ACLF. Given the high function of these BTTs, it is also possible that they may have efficacy in the treatment of chronic metabolic liver diseases. In the future we aim to scale these BTTs towards the treatment of a rat model of ALF.

4315-A | HEPATOCYTE GROWTH FACTOR RECEPTOR (C-MET) IS REQUIRED FOR LIMITING HEPATOTOXICITY, PROMOTING LIVER REGENERATION AND RECOVERY FOLLOWING ACETAMINOPHEN-INDUCED ACUTE LIVER FAILURE IN MICE

Siddhi Jain[1], Ranjan Mukherjee[2], Matthew Avery Copeland[2], John Stoops[2], Wendy M. Mars[2] and Bharat Bhushan[2], (1)University of Pittsburgh, Pittsburgh, PA, (2)University of Pittsburgh

Background: c-MET receptor, also referred as hepatocyte growth factor (HGF) receptor, plays a crucial role in promoting hepatocyte proliferation following partial hepatectomy (PH). However, elimination of HGF/c-MET signaling can be compensated by other proliferative pathways in the PH model. The involvement of c-MET in acetaminophen (APAP)-induced liver injury (AILI), the clinically-relevant model of acute liver failure, remains underexplored. The role of c-MET in AILI cannot be assumed identical to its role in PH of a healthy liver, as the regenerative response in AILI is intricately governed by the presence of substantial liver injury and inflammation, distinguishing it from PH. In our earlier study, we identified a clear dose-dependent activation pattern of c-MET in response to APAP overdose in mice. **Methods:** To investigate the causal role of c-MET in AILI and associated regeneration, we utilized an albumin-CRE system to specifically delete c-MET in the liver. Both wild-type (WT) and liver-specific c-MET KO mice were given 300 mg/kg of APAP to examine liver injury, regeneration parameters, and associated signaling cascade at multiple time points. **Results:** While, the initial liver injury appeared comparable in both WT and c-MET KO mice, severe inhibition of liver regeneration was observed in c-MET KO mice leading to uncontrolled progression of liver injury and significant mortality. Hepatocyte proliferation was almost completely blocked in c-MET KO mice. WT mice showed robust regeneration response and complete recovery. In c-MET KO mice, the mechanisms that initiate APAP-induced liver injury, such as metabolic activation of APAP, formation of APAP-protein adducts, and activation of JNK, remained unaltered. ERK signaling was inhibited in c-MET KO mice causing failed activation of core cell cycle machinery (i.e., phosphorylation of retinoblastoma protein and induction of cyclin D1), resulting in impaired liver regeneration. Analysis of RNA-seq data demonstrated failed activation of several important regulators of hepatocyte proliferation in c-MET KO mice. **Conclusion:** The liver-specific c-MET deletion inhibited hepatocyte proliferative signaling and blocked liver regeneration, resulting in uncontrolled liver injury progression and failed recovery following APAP overdose. The absence of c-MET signaling was not compensated by other proliferative pathways signifying its important role in recovery following APAP-induced acute liver failure.

4316-A | INHIBITION OF INTERLEUKIN-6 REDUCES HEPATIC ENCEPHALOPATHY AND MEDIATORS OF IMMUNE SUPPRESSION IN MICE WITH CLINICALLY RELEVANT ACETAMINOPHEN-INDUCED ACUTE LIVER FAILURE

Bryan L. Copple, Jenna Strickland, Katherine Roth and Cheryl Rockwell, Michigan State University

Background: In severe cases of acetaminophen (APAP) overdose, acute liver injury rapidly progresses to acute liver failure (ALF), producing life-threatening

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

extrahepatic complications including hepatic encephalopathy, multi-organ dysfunction syndrome, and severe immune suppression. The mechanisms linking liver injury to the pathogenesis of systemic complications remain poorly defined. **Methods:** To gain insight into these mechanisms, we utilized an experimental setting of APAP overdose in which mice were treated with a hepatotoxic dose of APAP (300 mg/kg) that fails to progress to ALF (referred to AALI) or a dose of APAP (500 mg/kg) that produces clinically relevant ALF (referred to AALF). **Results:** Compared to mice with AALI, AALF mice developed features of hepatic encephalopathy, including cerebral edema, reduced cerebral blood flow, and neurological deficits in reflexes and locomotor activity. Further, levels of IL-10 and PD-L1, associated with immune suppression in ALF patients, were markedly higher in AALF mice. Remarkably, despite striking differences in measures of hepatic encephalopathy and immune suppression, peak liver injury and blood ammonia concentrations, a putative causative factor in hepatic encephalopathy, were not different between mice with AALI and mice with AALF. Clinical studies have demonstrated an association between high blood levels of IL-6 and severity of hepatic encephalopathy in ALF patients. Consistent with these findings, plasma concentrations of IL-6 were greater in AALF mice. To examine whether IL-6 is causally involved in the pathogenesis of hepatic encephalopathy and immune suppression, AALF mice were treated with either IL-6 neutralizing antibody or isotype control antibody. Neutralization of IL-6 did not impact liver injury, blood ammonia concentrations, or hepatocyte proliferation, however, it restored cerebral blood flow, reduced brain edema, and improved neurological deficits. Further, neutralization of IL-6 reduced hepatic levels of IL-10 and PD-L1. **Conclusion:** These studies demonstrate that elevated blood concentrations of ammonia alone are insufficient to produce hepatic encephalopathy in mice with AALI. Moreover, these studies indicate that IL-6 is causally involved in the development of hepatic encephalopathy and in the immune suppression that occurs in APAP-induced ALF.

4317-A | LIVER STIFFNESS MEASUREMENT HELPS THE CLINICAL DECISION MAKING IN ACUTE LIVER FAILURE

Francesca Maria Trovato[1], Florent Artru[1], Rosa Miquel[2], Tasneem Pirani[2] and Mark John William McPhail[2], (1) King's College London, (2)King's College Hospital

Background: Acute liver failure (ALF) is a rare life-threatening disease requiring intensive care admission and often liver transplant, where the accurate selection of patients is crucial. Liver elastography is a non-invasive tool that can measure hepatic stiffness but previous results have been inconclusive in ALF. **Methods:** Patients admitted between October 2021 to March 2023 to the Liver Intensive therapy unit at King's College Hospital with ALF and acute-on-chronic liver failure (ACLF) were recruited, with healthy individual's (HC) used as controls. Imaging was performed using a Philips Affiniti 70. Average shear wave velocity was recorded with ElastPQ on the right and left liver lobes and the spleen. Portal vein flow, hepatic artery resistive index (HARI) and peak systolic velocity were also recorded. Physiological and histological data, when available, were used as comparison. **Results:** Forty patients with ALF, 22 patients with ACLF, and 9 HC were included in the study. 30% of ALF patients died and 30% were transplanted within 90 days from admission. Liver stiffness measurement of the right lobe (LSM) accurately identified HC (5.6 ± 2 kPa), ALF (31.7 ± 17kPa) and ACLF (76.3 ± 71 kPa) patients (ALF vs ACLF, $p = 0.0301$). Spleen size and stiffness discriminated between ALF (10.4 ± 2 cm and 21.4 ± 16.6kPa) and ACLF (14 ± 2.3 cm and 42.6 ± 26 kPa). At admission LSM was not different between ALF patients that spontaneously survived vs patients who died or were transplanted in the following 90 days. However, the trend over the first 10 days of admission was different with a peak of LSM between day 6 and 8 in spontaneous survivors followed by reduction during the recovery phase. Conversely, ALF patients with poor prognosis showed a persistently increased LSM. No correlation was found with the amount of noradrenaline used, the mean arterial pressure (MAP), the central venous pressure (CVP). In ACLF, LSM correlated directly with right lobe diameter and the highest values were found in alcoholic hepatitis and Wilson's disease ($LSM > 100$kPa). 10 ALF explants and 6 ACLF explant/biopsy were analysed. Confluent hepatocellular necrosis characterised ALF, while intralobular inflammation was a feature present in both diseases. Cholestasis, particularly in the cytoplasmatic compartment was present mainly in ACLF and correlated with high values of LSM (Spearman $r = 0.54$, $p = 0.034$). **Conclusion:** LSM identifies acute from acute-on-chronic liver failure together with spleen volume and stiffness. In ALF stiffness peaks at day 7 of admission with subsequent reduction in patients spontaneously surviving. Histology suggests that cytoplasmatic cholestasis might be related to higher stiffness. Further studies, in a larger cohort, are needed to better understand the diagnostic role of liver stiffness in acute liver failure and whether

addition of these values to existing prognostic criteria could improve sensitivity and specificity.

4318-A | MESENCHYMAL STEM CELL'S SMALL EXTRACELLULAR VESICLES PROMOTE HEPATOCYTE REGENERATION VIA ATTENUATING MACROPHAGE EXTRACELLULAR TRAPS

Zhihui Li[1], Jing Zhang[2], Shibo Meng[1], Weizhen Weng[1], Junyi Wang[1] and Bingliang Lin[1], (1)The Third Affiliated Hospital, Sun Yat-Sen University, (2)Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-Sen University

Background: Acute liver failure (ALF) is a a severe clinical syndrome characterized by dysregulated immune response and extensive hepatocytes death without effective therapies. Hepatocyte regeneration is the key to rescuing ALF. Previous studies have confirmed that macrophage extracellular traps (METs) has been associated with immune-mediated diseases and small extracellular vesicles (sEVs) act as mediators in the inhibition of inflammation by mesenchymal stem cells (MSCs). The aim of this study was to explore the role of MSC-derived sEVs (MSC-sEVs) and METs in treating mice with ALF. **Methods:** To establish the ALF cell model of THLE-2 cell line induced by H2O2 and ALF mouse model induced by LPS/D-GalN, collect and identify MSC-sEVs, and added to METs-induced macrophages THP-1 cell, then co-culture with ALF hepatocytes. To detect the proliferation and apoptosis of ALF hepatocytes by fluorescent labeling technique, meanwhile, detect the METs' quantity by immunofluorescence technique and Western Blotting. MSC-sEVs were injected into ALF mouse through the tail vein to assess the effect in ALF mouse. To test the survival, changes in serology, liver pathology, the molecules and genes of proliferation and apoptosis, and the yield of METs in different phases by Western Blotting, qPCR and immunohistochemistry technique. **Results:** The MSC-sEVs were merged with ALF cell model, and the proliferation and activity of ALF hepatocytes was increased in vitro. Likewise, the treatment of MSC-sEVs led to higher 24 h mouse survival rates and significant reductions in METs' formation and liver injury compared to treatment with sEV-free concentrated medium, and the inflammatory infiltration and hyperemia of the liver tissue were decreased. METs decreased when macrophages were subjected to MSC-sEVs(Fig), and when METs were co-cultured with hepatocytes, apoptosis increased and proliferation decreased, which were reversed by the inhibition of METs. **Conclusion:** Mesenchymal stem cell's small extracellular vesicles can improve the prognosis of acute liver failure by reducing apoptosis and promoting hepatocyte proliferation in vitro and in vivo. The function of ameliorating liver injury may be achieved by attenuating macrophage extracellular traps.

4319-A | MESENCHYMAL STEM CELLS PRETREATED WITH INTERLEUKIN-33 ATTENUATE ACUTE LIVER FAILURE BY IMPROVING MIGRATION AND POLARIZING M2 MACROPHAGES

Hui Yuan, Jiali Song, Linya Peng and Chuanlong Zhu, The First Affiliated Hospital of Nanjing Medical University

Background: Mesenchymal stem cells (MSCs) are highly effective in the treatment of acute liver failure (ALF). The efficacy of MSCs is closely related to the inflammatory environment. Therefore, we investigated

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the functional changes of MSCs in response to interleukin-33 (IL-33) stimulation. **Methods:** The BMSCs were pretreated with 10ng/ml IL-33 for 24 h. The differentially expressed cytokines between BMSCs and IL-33 pretreated BMSCs (BMSCs-33) were screened by PCR Array and verified by western blot. Transwell and in vivo imaging were used to detect the migration ability of BMSCs and BMSCs-33. Bone marrow macrophages (BMDM) were co-cultured with BMSCs and BMSCs-33, and the ratio of M1/M2 polarization was detected by western blot and immunofluorescence, and the changes of NF-κB pathway proteins in BMDM were explored. The rat liver cell line BRL 3A was treated with 2mg/ml D-GalN and 1ug/ml LPS, and then co-cultured with BMDM. The apoptosis pathway proteins and apoptosis ratio of BRL 3A cells were detected by western blot and flow cytometry. Rats with acute liver failure were injected with $1x10^7$ cells /kg BMSCs and BMSCs-33 via the tail veins, respectively. The changes in transaminase levels, HE pathology, and 7-day survival rate were compared. **Results:** PCR Array results showed that CCR2 expression was increased in BMSCs-33. CCL2 cytokine expression was the highest in the liver of ALF rats. Under the induction of CCL2, the migration number of BMSCs-33 group was higher than that of BMSCs group (123.40 $\pm$9.13 *vs* 81.00 $\pm$4.30, $p<0.05$). In vivo imaging results showed that the number of BMSCs-33 migrating to the injured liver was significantly increased, and this effect was attenuated after knocking down CCR2. Upon LPS stimulation, the NF-κB pathway of BMDM was activated and its phenotype was polarized toward M1. BMSCs-33 inhibited the expression of p-IκBα and p-p65 protein in BMDM, and the polarization ratio of M2 macrophages was also higher than that in BMSCs group (73.30% $\pm$3.96% *vs* 50.99% $\pm$4.20%, $p<0.05$). M2 macrophages could further inhibit the expression of inflammatory factors IL-1β and IL-6 in hepatocytes, reduced the levels of C-Caspase3 and Bax protein in hepatocytes. Finally, animal experiments showed that ALT and AST levels of rats in BMSCs-33 group were 602.20 $\pm$246.01 U/L and 2,354.48 $\pm$755.30 U/L, respectively, which were significantly lower than those in D-GalN/LPS group (11,669.75 $\pm$976.93 U/L, 11,966.48 $\pm$2381.60 U/L, $p<0.05$).) and BMSCs group (3,270.82 $\pm$96.01 U/L, 7,622.17 $\pm$216.51 U/L, $p<0.05$). The 7-day survival rate of BMSCs-33 group was also higher than that of BMSCs group (62.50% *vs* 37.50%). **Conclusion:** BMSCs-33 increases its homing ability to damaged liver through CCR2/CCL2 axis and inhibits the NF-κB pathway of BMDM to induce M2 macrophage polarization. IL-33 can improve the efficacy of BMSCs in the treatment of ALF, which provides a new strategy for clinical treatment.

4320-A | SYSTEMATIC LITERATURE REVIEW OF BIOLOGICAL AND NONBIOLOGICAL ARTIFICIAL LIVER SUPPORT TRIALS

Robert S. Brown Jr[1], Robert A. Fisher[2], Ryan J. Imhoff[2] and William H. Thatcher[2], (1)Weill Cornell Medicine, NY, (2)Cti Clinical Trial and Consulting Services

Background: Liver failure is a leading cause of morbidity and mortality. Due to organ scarcity, research on liver support systems such as bioartificial livers (BAL), nonbiological artificial livers (NBAL), and xenogeneic whole-organ extracorporeal liver perfusion (X-ECLP) has become vital. **Methods:** A systematic approach based on PRISMA guidelines was used to search the Medline database (via PubMed) for English-language studies evaluating ex-vivo liver perfusion in humans through December 2, 2022. All studies were screened for clinical trials. Amidst the recent discussions and recommendations of porcine donors as the most feasible modality of xenoperfusion, relevant porcine X-ECLP case reports and series were also included. This was due to the absence of published trials in any whole-organ or X-ECLP approaches. **Results:** Two reviewers screened 694 records and found 58 eligible studies: 16 on BAL, 32 on NBAL, and 10 on X-ECLP using porcine livers (1 found in bibliographic review). Table 1 provides a summary of the included studies. The majority were small-scale trials, including Phase I (10), Phase I/II (1), Phase II/III (1), proof of concept (2), pilot (2), investigational device exemption (1), and investigator-initiated randomized trials (20). There were 5 porcine X-ECLP case reports and 5 case series. The average sample size was 43 (range: 1-234) among BAL/NBAL and 7 (1-45) for X-ECLP. Primary endpoints focused on safety/adverse events and survival. Some common AEs included hypotension, administration site reactions, bleeding events, and infections. Porcine X-ECLP similarly studies focused on safety and survival, while also reporting on porcine endogenous retrovirus cross-infection and donor organ survival. **Conclusion:** Ex-vivo liver support systems have had significant research interest, but trials of BALs and NBALs have not consistently demonstrated substantial improvement in patient outcomes. The lack of success may be attributed to ill-defined patient populations, small sample size, variability in patient management protocols, and the critical timing of device use. Larger randomized controlled trials and optimization of patient selection to achieve a homogeneous study group, device management, and treatment protocols are crucial. Lessons learned from past studies can guide much-needed future research in improving outcomes for patients with liver failure.

Table 1. Summary of Included Studies

	Sample Size, mean (range)	Most Common Primary Endpoints	Most Common Adverse Events
Total number of articles included in review	–	–	–
Biological artificial liver support	–	–	–
Academic Medical Center BAL (AMC-BAL)	11 (7-14)	Adverse events, Transplant status	Hypotension
Bioartificial Liver Support System (BLSS)	4 (NA)	Adverse events, Transplant status, liver function	Hypoglycemia, hypotension
Extracorporeal Liver Assist Device (ELAD)	64 (5-203)	Liver function, transplant status, survival	Administration site conditions, respiratory and vascular disorders
HepatAssist	285 (24-171)	Survival, transplant status	Hypotension
Modular Extracorporeal Liver Support (MELS)	8 (NA)	Adverse events	None reported
Radial-Flow Bioreactor BAL (RFB-BAL)	7 (NA)	Adverse events, transplant status	None reported
Nonbiological artificial liver support	–	–	–
Extracorporeal albumin dialysis (ECAD)	17 (9-24)	Adverse events, liver function	Administration site conditions
Hemodialysis (HD)	20 (NA)	Plasma amino acid levels, Fisher ratio	None reported
Hemodiafiltration (HDF)	19 (4-32)	Liver function, survival	Bleeding, cerebral edema
Hemoperfusion	62 (NA)	Survival	Cerebral edema, renal failure, uncompensated metabolic acidosis, encephalopathy
MARS	39 (2-149)	Liver function, survival, inflammatory markers	Neurologic disorders, renal disorders, bleeding, infections
Plasma exchange (PE)	128 (7-234)	Survival, liver function, inflammatory markers	Administration site conditions, respiratory disorders
Prometheus system	53 (4-145)	Liver function, inflammatory markers, survival	Bleeding, infections
Xenogeneic ECLP	–	–	–
Whole porcine liver perfusion	8 (1-45)	Feasibility, liver function, consciousness	Bleeding, respiratory disorders

4321-A | THE THERAPEUTIC CAPACITIES OF THREE-DIMENSIONAL HUMAN UMBILICAL MESENCHYMAL STEM CELLS IN ACUTE LIVER FAILURE MICE

Liang Peng, Third Affiliated Hospital of Sun Yat-Sen University, Shu Zhu, The Third Affiliated Hospital of Sun Yat-Sen University and Zhiyong Zhang, The Third Affiliated Hospital of Guangzhou Medical University

Background: The mortality rate of acute liver failure (ALF) is extremely high. Mesenchymal stem cells (MSCs) could alleviate liver damage as a regenerative medicine treatment. In recent years, more and more studies have shown that three-dimensional (3D) culture can increase the therapeutic potential of MSCs in other disease models. This study aims to compare the therapeutic capacities of mesenchymal stem cells cultured in 3D and 2D conditions in mice with ALF. **Methods:** We employed 3D dynamic system with microcarriers and traditional 2D culture flasks to amplify human umbilical cord MSCs. Severe liver damage formed in 8-week old male C57BL/6J mice as animal model by intraperitoneal injection of 250mg/kg thioacetamide. 1×10^6 2D or 3D MSCs dissolved in 100ul PBS or 100ul PBS alone were administered via tail vein 12 hours later after modeling. Cost, survival rate, serum transaminase, and liver necrosis area fraction of each group were measured and compared. **Results:** 1. Both 2D and 3D cultivation maintain the morphology, multidirectional differentiation ability and surface molecular marker expression of MSCs. 2.To harvest 1×10^{10} MSCs, 3D cultivation reduces labor cost, energy consumption and space occupation by 83.3%, 97%, 80% compared to 2D cultivation, respectively. 3. Compared to the PBS group, The overall survival improved significantly in both 2D and 3D MSCs groups (PBS vs. 2D, $p=0.0124$. PBS vs. 3D, $p=0.0009$). The level of serum aspartate aminotransferase (AST) decreased in MSCs groups. (36h: PBS vs. 2D, 8767.14 ± 2457.29U/L vs. 5673.00 ± 2541.11U/L, $p=0.01$, PBS vs. 3D, 8767.14 ± 2457.29 U/L vs. 6289.5 ± 1935.99U/L, $p=0.012$. 60h: PBS vs. 2D, 4325.00 ± 1025.30U/L vs. 966.67 ± 409.18U/L, $p=0.001$, PBS vs. 3D, 4325.00 ± 1025.30U/L vs. 1400.00 ± 1020.94U/L, $p=0.002$.) The liver necrosis area fraction decreased significantly in MSCs groups. (60h: PBS vs. 2D, 0.71 ± 0.08 vs. 0.43 ± 0.07, $p=0.02$, PBS vs. 3D, 0.71 ± 0.08 vs. 0.34 ± 0.10, $p<0.000$. 84h: PBS vs. 2D, 0.44 ± 0.07 vs. 0.17 ± 0.04, $p=0.001$, PBS vs. 3D, 0.44 ± 0.07 vs. 0.13 ± 0.12, $p=0.007$.) There was no significant difference in overall survival rate, serum level of AST, and liver necrosis area fraction between 2D and 3D MSCs in ALF mice. **Conclusion:** 1. Both 2D and 3D MSCs have achieved good therapeutic capacities in acute liver failure. The effect of 3D MSCs on acute liver failure mice was not inferior to that of 2D MSCs.

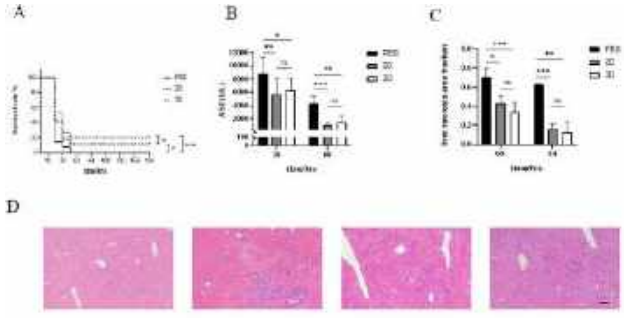

Figure: A. Survival analysis of each group. B. The serum level of AST in each group at 36h and 60h after TAA injection. C. Quantification of necrotic area fraction of each group at 36h and 60h after TAA injection. D. Representative H&E staining images of liver sample from Normal Control, PBS, 2D, 3D groups collected at 84h after TAA injection. scale bar: 100um.

4322-A | TRENDS OF ACUTE LIVER FAILURE IN MARIJUANA USERS

Raissa Nana Sede Mbakop Forlemu[1], Hamsika Moparty[2], Elizabeth Soladoye[1], Arnold Nongmoh Nongmoh Forlemu[2], Kikelomo Olaosebikan[1], Praneeth Bandaru[2], Vikash Kumar[2], Vijay Gayam[2] and Madhavi Reddy[2], (1)Piedmont Athens Regional, Athens, GA, (2) The Brooklyn Hospital Center

Background: Marijuana is among the most used recreational drugs in the United States and has been associated with a variety health hazards, including acute liver injury (ALF). A few case reports have described marijuana as rarely being associated with acute and fulminant liver failure. However, with more US states legalizing marijuana and with the growing use of this product, it is likely the prevalence and incidence of negative effects of marijuana will rise. Using a nationwide inpatient database, this study evaluated the prevalence of ALF in patients using marijuana and described the trends and hospital outcomes of ALF in marijuana users based on demographics and race. **Methods:** We conducted a nationwide review from 2016 to 2017 using the National Inpatient Sample (NIS) data. NIS is the largest publicly available all-payer inpatient database in the United States with more than seven million hospital stays each year, as a part of the Healthcare Cost and Utilization Project (HCUP). Patients $\geq$ 18 years old with ALF were identified using the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) codes. Student t-tests and chi square tests were used to analysis continuous and categorical variables respectively. Odds ratios (OR) and confidence intervals (CI) at 99% are reported. **Results:** The number of patients with ALF were 75,910. Among patients with ALF, the number of marijuana users was 2,263, with a prevalence of 3.0% of ALF patients who are marijuana users. Marijuana users with ALF were older with a female predominance compared to those users without ALF. ALF rates were higher in Native American (5.4%) and Black (3.7%) marijuana users compared to other races. Majority of marijuana users with ALF were on Medicaid or self-pay with the lowest median household income. Regarding outcomes, Asian marijuana users with ALF were more likely to be on mechanical ventilation compared to other races (1.35 (0.74 – 2.46). On the other hand, Hispanics and Whites were more likely to be on vasopressor support (OR 1.54, CI: 1.18 – 2.02; OR 2.25, CI: 1.24 – 4.08). As expected, length of stay, total hospital charges, and mortality were higher for marijuana users with ALF compared to those without ALF. **Conclusion:** We found marijuana users with ALF to be slightly older with female predominance compared to non-marijuana users with ALF. Native American and Black marijuana users were more likely to have ALF compared to other races. On the other hand, Hispanic and White marijuana users with ALF where more likely to require vasopressor support. Socioeconomic factors likely play a role in the trends observed in this study.

Marijuana users with acute liver failure; outcomes by race

	Acute liver failure	No acute liver failure	Mean difference or odds ratio, confidence interval
Marijuana use (%)	3.0	2.6	1.14 (1.09 – 1.19)
Age, years	41.85	39.01	2.84 (2.26 – 3.42)
Length of stay, days	7.44	5.14	2.30 (1.96-2.65)
Total hospital charges, $	96,900.72	38,535.13	58,365.59 (52,255.10 – 64,476.08)
Mechanical ventilation (%)	6.1	6.6	0.91 (0.84 – 0.97)
White	2.4	2.5	0.97 (0.88 – 1.08)
Black	3.2	3.8	0.84 (0.71 – 1.00)
Hispanic	2.5	2.7	0.80 (0.61 – 1.06)
Asian	1.4	1.0	1.35 (0.74 – 2.46)
Native American	4.4	5.1	0.85 (0.44 – 1.63)
Vasopressor support (%)	13.6	9.1	1.57 (1.28 – 1.93)
White	1.9	1.3	1.54 (1.18 – 2.02)

4323-A | VIRAL KINETICS, HUMORAL IMMUNITY AND SERUM CYTOKINE PROFILES DIFFERENTIATE TYPICAL ACUTE HEPATITIS B (AVHB) FROM HBV-ASSOCIATED ACUTE LIVER FAILURE (HBVALF) AND ACUTE-ON-CHRONIC LIVER FAILURE (CHBALF)

Patrizia Farci[1], Ronald E Engle[1], Davide De Battista[1], Hanh Nguyen[1], Jody A. Rule[2], Sandra Kendra[1], Zhaochun Chen[1], Harvey J. Alter[3] and William M. Lee[2], (1)Hepatic Pathogenesis Section, Laboratory of Infectious Diseases, National Institute of Allergy and

Infectious Diseases, National Institutes of Health, (2) University of Texas Southwestern Medical Center, (3) Department of Transfusion Medicine, Clinical Center, National Institutes of Health, Bethesda, MD

Background: The mechanisms determining the outcome in acute HBV infection: self-limited hepatitis (AVHB), acute liver failure (HBVALF), and acute-on-chronic liver failure (CHBALF), are poorly understood. We used sera from the US Acute Liver Failure Study Group and Hepatitis B Research Network to study the virus-host interplay, comparing the 3 phenotypes. **Methods:** 216 serial serum samples from 46 patients with well-characterized HBV phenotypes—13 AVHB, 25 HBVALF and 8 CHBALF—were analyzed for HBV genotype, IgM anti-HBc and anti-HBs titers, as well as quantification of HBsAg, HBV core-related antigen (HBcrAg), HBV DNA, HBV RNA and HDV RNA. Additionally, 19 cytokines were tested serially in the 3 groups. We also separated the HBVALF group into early (<10d onset to encephalopathy, HE; $N=7$), HBVALF late (>10d, $N=11$) and acute liver injury (INR 2.0, no HE; ALI, $N=7$). Among HBVALF, 41% died or required transplantation: all AVHB and ALI patients survived. Titers are given in logs. **Results:** The most significant serological differences were: (a) IgM anti-HBc titers were higher in HBVALF (median, 6.6 log) than CHBALF (1.3) or AVHB (4.7); (b) HBsAg was lower in HBVALF (3.7) than in AVHB (4.7), but similar to CHBALF (3.4); (c) HBcrAg was higher in CHBALF (7.0) than HBVALF (5.9) but similar to AVHB (6.6); (d) HBV RNA was undetectable in AVHB, but present in 75% of CHBALF (4.0) and at low levels in 20% of HBVALF. All were positive for HBV DNA without significant differences between groups. Distinct cytokine profiles were observed. AVHB demonstrated significant induction of the IFN-inducible chemokine IP10 and MIP-1b, whereas HBVALF had significant elevation of the pro-inflammatory cytokines IL-4, IL-6, MCP-1, sCD137 and TNF-a. CHBALF showed the highest levels of IL-8, HBcrAg and HBV RNA along with the lowest titers of IgM anti-HBc. These patterns persisted after admission. Within the HBVALF group, distinct signatures were observed comparing HBVALF early with ALF late and ALI. The outcomes for the HBVALF late presenters were very poor (9/11 died/OLT) and significantly different from early presenters (3/7). Spontaneous survival correlated with significantly higher values of TNF and IP10 at admission. **Conclusion:** There are distinct serologic, virologic and cytokine profiles differentiating classic AVHB from HBVALF and CHBALF. Moreover, it provides the first evidence that early and late ALF differ in their profiles and outcomes suggesting different mechanisms of pathogenesis.

4324-A | WAITLIST AND POST-TRANSPLANT OUTCOMES OF PREGNANCY VERSUS NON-PREGNANCY RELATED ALF IN THE US (1992-2021)

Sajid Jalil, The Ohio State University Wexner Medical Center, Mohamed A. Elfeki, University of South Dakota Sanford School of Medicine, Muhammad Arsalan Arshad, Avera Mckenna University Hospital and Transplant Institute, Deepan Panneerselvam, University of South Dakota, Sioux Falls, SD, Yong-Fang Kuo, University of Texas Medical Branch, Juan Pablo Arab, University of Western Ontario, London, ON, Canada, Robert J. Wong, VA Palo Alto Healthcare System, Zobair M. Younossi, Inova Health System and Ashwani K. Singal, University of South Dakota

Background: Pregnancy-related acute liver failure (P-ALF) outcomes have not been well-documented in the literature. This study aims to compare waitlist and post-transplant outcomes of P-ALF versus non-pregnancy-related ALF (NP-ALF) using the United Network of Organ Sharing (UNOS) database. **Methods:** Using the UNOS data (1992-2021), we analyzed outcomes of P-ALF and NP-ALF. Baseline characteristics were compared between groups at listing. Outcomes studied were cumulative 90-day waitlist mortality (WLM) competing for receipt of liver transplant and 5-yr post-transplant patient survival. **Results:** Of 3,542 females aged 16-43 listed for ALF, 84 (2%) listed for P-ALF were more likely to be black (21% vs11%, $p=0.033$), have ventilatory failure (56% vs. 41%, $p<0.005$), be on pressors (58% vs. 43%, $p<0.005$), require dialysis (23% vs.10%, $p<0.001$), and have higher INR (4.53 vs. 2.74, $p<0.001$). The cumulative 90-day WLM was lower in P-ALF vs. NP-ALF (7.4 vs. 16.6%, $p<0.001$), Fig. 1A. The post-transplant survival rates at 5-yr were similar (82% vs 79%, $p=0.89$). Subgroup analysis after excluding listings for viral hepatitis ($N=1834$, with 40 P-ALF) showed similar results on 90-day WLM (7.6% vs. 17.2%, $p<0.001$). The 90-day WLM remained lower in P-ALF in a propensity matched cohort (1:10) of 710 ALF patients, 7.9% vs. 17.8% $p<0.001$, (Fig. 1B). In a Fine and Gray regression model controlled for listing year and MELD score, 90-day WLM was lower in P-ALF with sub-hazard ratio of 0.42 (95%CI, 1.06-5.39, $p=0.035$). **Conclusion:** In this UNOS database analysis of ALF among women of childbearing age, the waitlist outcome is better in pregnant compared to non-pregnant women. Further studies are needed to

examine mechanisms of these findings and explore etiology-based outcomes in women with ALF during pregnancy.

4325-A | WAITLIST AND POST-TRANSPLANT OUTCOMES OF PREGNANCY-RELATED ACUTE LIVER FAILURE IN THE US (1987-2021)

Sajid Jalil, The Ohio State University Wexner Medical Center, Mohamed A. Elfeki, University of South Dakota Sanford School of Medicine, Muhammad Arsalan Arshad, Avera Mckenna University Hospital and Transplant Institute, Deepan Panneerselvam, University of South Dakota, Sioux Falls, SD, Yong-Fang Kuo, University of Texas Medical Branch, Juan Pablo Arab, University of Western Ontario, London, ON, Canada, Robert J. Wong, VA Palo Alto Healthcare System, Zobair M. Younossi, Inova Health System and Ashwani K. Singal, University of South Dakota

Background: The outcomes of acute liver failure (ALF) during pregnancy are shown to be better compared to ALF in women of childbearing age who are not pregnant. However, data on etiology-based outcomes of ALF in women during pregnancy are limited. We compared waitlist and post-transplant outcomes of ALF in pregnant women comparing pre-eclampsia (PE) vs. acute fatty liver of pregnancy (AFLP) using the UNOS database (1987-2021). **Methods:** Baseline characteristics among pregnant women with ALF were compared between PE vs AFLP at listing. Cumulative incidence of 90-day waitlist mortality (WLM) (competing for receiving liver transplant) and post-transplant survival estimates were analyzed. **Results:** Of 84 pregnant women listed for liver transplantation due to ALF, 45 were listed for PE and 39 for AFLP. At the time of listing, compared to AFLP, those listed for PE were more likely to have ventilatory failure (67 vs. 44%, $p = 0.033$) and require pressors (69 vs. 46% $p = 0.035$). A total of 9 women died within 90-day of listing, 8 with PE vs. 1 with AFLP, $p = 0.067$. The cumulative incidence function of 90-day WLM was higher in women listed for PE compared to those listed for AFLP (19.3% vs 5.7% $p < 0.005$), Figure 1. The 5-yr post-transplant patient survival rates were similar (80.1% vs 84.2%, $p = 0.668$). On a Fine and Gray regression model controlled for listing year, the 90-day WLM was about 10-fold higher in PE vs. AFLP with sub-hazard ratio (95% confidence interval) of 9.97 (1.64-60.55), $p = 0.013$. **Conclusion:** In this analysis of UNOS database on pregnant women listed for liver transplantation due to ALF, the 90-day WLM is worse if the ALF is induced by PE rather than AFLP. Studies are needed to improve management and prevention of PE during pregnancy and prevent development of ALF.

f 4400-A | ADAPTIVE RESPONSE TO AMMONIA MEDIATED IMPAIRED PROTEOSTASIS OCCURS BY INCREASED LEU UPTAKE VIA SLC7A5

Saurabh Mishra[1], Dawid Kroku[2], Nicole M. Welch[1], Annette Bellar[1], Avinash Kumar[3], Maria Hatzoglou[2] and Srinivasan Dasarathy[4], (1)Cleveland Clinic, (2)Case Western Reserve University, (3)All India Institutes of Medical Sciences, (4)Cleveland Clinic Foundation

Background: Sarcopenia or loss of skeletal muscle mass and physical frailty in liver disease is mediated by an ammonia-dependent mechanism. The hyperammonemic stress response (HASR) in skeletal muscle shares some features of the amino acid starvation and the unfolded protein responses (UPR). During HASR, phosphorylation of eukaryotic initiation factor 2 alpha (eIF2a) is increased, mTORC1 signaling and protein synthesis are less, and autophagy flux is increased. L-leucine, transported intracellularly by SLC7A5, supports skeletal muscle protein homeostasis during HASR. Since expression for SLC7A5 is increased during HASR, we sought to determine if the increased expression of SLC7A5 is a cytoprotective adaptive response to HASR. **Methods:** Studies were done in differentiated murine C2C12 myotubes. HASR was induced by 10mM ammonium acetate treatment for 24h in WT and SLC7A5 knock down myotubes. The protein synthesis was analyzed by 3H phenylalanine incorporation. Sodium-dependent and independent leucine uptake and signaling responses were quantified in control (shSCR) and shRNA against SLC7A5 (shSLC7A5) myotubes infected with the corresponding lentivirus. Responses to 2-aminobicyclo-(2,2,1)-heptane-2-carboxylic acid (BCH), a chemical inhibitor of SLC7A5 were evaluated to determine if SLC7A5-dependent or -independent leucine uptake occurs during hyperammonemia. Responses to 0.25mM L-leucine or 0.25mM LLME (L-Leucyl methyl ester that is transported via transporter independent cellular entry for leucine) were quantified. Also eIF2a phosphorylation, mTORC1 signaling, and autophagy markers were quantified by immunoblots. mTORC1 subcellular localization and activation was also determined by immunofluorescence. All experiments were performed in at least 3 biological replicates. **Results:** Hyperammonemia resulted in a time and concentration dependent inhibition of protein synthesis in myotubes. Leucine uptake was increased during hyperammonemia and occurred in an SLC7A5 dependent mechanism as noted by chemical and genetic depletion of SLC7A5. Additionally, transporter independent uptake of LLME but not L-leucine reverses some but not all components of HASR doing SLC7A5 depletion. LLME but not L-leucine reversed hyperammonemia induced impaired mTORC1 signaling and increased autophagy markers. LLME but not L-leucine reversed ammonia induced subcellular localization of phosphorylated mTOR in myotubes. **Conclusion:** We show by chemical and genetic modulation that the amino acid exchanger, SLC7A5 mediates an adaptive response during hyperammonemia. Targeting SLC7A5 and developing transporter independent analogs of leucine can be a potential therapeutic approach to reverse sarcopenia in liver disease. The mechanisms of transport independent rescue of the hyperammonemia-mediated decrease in mTOR signaling and increased autophagy need to be determined in future studies.

f 4401-A | CCL19-PRODUCING FIBROBLASTS PROMOTE TERTIARY LYMPHOID STRUCTURES FORMATION AND LOCAL ANTI-TUMOR IgG RESPONSE IN COLORECTAL CANCER LIVER METASTASIS

Yifan Zhang[1], Xinyue Zhang[1], Kai Lei[1], Lixia Xu[1], Sui Peng[1], Changjun Yin[1], Zhihang Chen[1], Ming Kuang[2] and FAH-SYSU Authors' Group, (1)The First Affiliated Hospital, Sun Yat-Sen University, (2)The First Affiliated Hospital of Sun Yat-Sen University

Background: Liver metastasis is a leading cause of colorectal cancer-related deaths. Tertiary lymphoid structures (TLSs) have been believed to play a crucial role in colorectal cancer liver metastasis (CRLM), however, their formation and function in CRLM remains unclear. In current study, we aimed to investigate the clinical implication, function and neogenesis of TLSs in CRLM. **Methods:** We retrospectively included 178 patients with CRCLM treated by surgical resection. The distribution and prognostic significance of peri- and intra-tumoral TLSs were determined by pathological review. Single-cell RNA sequencing (scRNA-seq), spatial enhanced resolution omics-sequencing (stereo-Seq), and multiplexed immunofluorescence were applied to characterize the tumor immune micro-environment with or without TLSs. **Results:** Peri- and intra-tumoral TLSs were observed in 80.9% and 11.2% of patients respectively, both of which were associated with beneficial clinic outcomes. We proposed a novel classification criterion by combining the present of peri- and intra-tumoral TLSs, we showed that this new classification criterion predicts cancer prognosis independent of clinicopathological factors. Mechanistically, we revealed that TLS+ tumors are enriched with IgG+ plasma cells (PCs), while, TLS- tumors are characterized with IgA+ PCs. By analyzing BCR sequences of tumor infiltrated B cells and PCs and generating monoclonal antibodies in vitro, our data showed that IgG+ PCs produced tumor-targeting IgG antibodies locally, which in turn, promote tumor cell apoptosis. Interestingly, we identified a subset of $CCL19^{+}$ fibroblasts enriched around TLSs, facilitating lymphocyte trafficking in CRLM. Tumor CCL19 levels were positively correlated with benefit prognosis in CRLM patients. Furthermore, we demonstrated that CCL19 treatment promoted TLSs neogenesis in a mouse model. **Conclusion:** We characterized the spatial distribution and prognostic value of TLSs in CRLM at the single cell resolution. Moreover, we demonstrated that CCL19-producing fibroblasts regulate TLSs formation and local IgG-mediated immunity. Our data suggested novel therapeutic opportunities to control CRLM.

f 4402-A | CELLULAR BIOENERGETIC CAPACITY TRANSITIONS FROM OXIDATIVE PHOSPHORYLATION TO GLYCOLYSIS IN TELOMERASE INHIBITION-INDUCED SENESCENT HEPATOCYTES IN MOUSE

Pavitra Kumar[1], Mohsin Hassan[1], Frank Tacke[1] and Cornelius Engelmann[1,2,3], (1)Department of Hepatology and Gastroenterology, Charité Universitätsmedizin, Berlin, Germany, (2)University College London Medical School, (3)Berlin Institute of Health, Germany

Background: Cellular senescence is a state in which cells become resistant to growth-promoting stimuli and apoptosis, resulting in permanent cessation of cellular proliferation. This leads to a prolonged 'zombie-like' state, which can have detrimental effects on tissues relying on their regenerative capacity for homeostasis, such as the liver. Cells undergo a drastic metabolic shift as they adapt to senescent phenotype, potentially affecting the function of the liver. There are diverse factors triggering senescence and this heterogeneity makes it difficult to distinguish and target senescent cells therapeutically. Therefore, in the present study, we aim to characterize, specifically, the link between telomerase inhibition-induced senescence and metabolic capacity in primary hepatocytes and hepatocyte-derived liver organoids. **Methods:** Primary hepatocytes, isolated by collagenase-perfused mice liver (C57BL6/J; 18-23 weeks), were cultured overnight in buffered William's E-medium supplemented with 2% FBS, L-glutamine, and hepatocyte growth supplements. Hepatocyte-derived organoids were developed by culturing cells in a 3D matrix for two weeks. Cells or organoids were treated with 20 μM of BIBR-1532 (telomerase inhibitor) for 12, 24, 48, or 72 hours. Senescence was assessed by senescence-associated (SA)-β-galactosidase activity, immunofluorescence, immunoblotting (p53, p21, and γH2Ax), and senescence-associated secretory phenotype (SASP) candidates. Cellular bioenergetics was measured by XFe Seahorse analyzer with 10 mM glucose, 2 mM pyruvate, and 1 mM glutamine as substrates. **Results:** Dosages and time of treatment were optimized on the primary hepatocytes (five dosages and four-time points, from 12-72 hours). The results showed that BIBR-1532 increased phosphorylation of histone (γH2Ax), a DNA damage marker, by 10-fold ($p < 0.001$), and SA β-

galactosidase activity by 11-fold ($p < 0.001$) (Figure 1A). Arrested proliferation is an important feature of senescence cells and the primary hepatocytes have limited proliferation in 2D culture. To overcome this limitation, we validated the results in hepatocyte-derived organoids and observed similar findings (Figure 1A). Coincided with DNA damage, BIBR1532 stabilized p53, increased p21 levels, and SASP (CCL2, CXCL2, IL6, IL10, TNFα, and MMP13). In contrast to the studies in immortalized cell lines, telomerase inhibition initially (up to 24 hours of treatment) increased oxidative phosphorylation capacity, however, in the later senescence phase, the cellular bioenergetics became predominantly glycolytic (Figure 1B). **Conclusion:** BIBR-1532 (telomerase inhibitor) induces senescence phenotype in mouse primary hepatocytes. Cellular bioenergetic capacity transitions from oxidative phosphorylation to glycolysis in BIBR-1532 treated hepatocytes, which may affect the hepatocytes' response to toxins and inflammation.

4403-A | CHARACTERIZING THE TUMOR SUPPRESSOR ACTIVITY OF RAB17 IN HEPATOCELLULAR CARCINOMA

Lauren R. Bassaro and Pamela L. Tuma, The Catholic University of America

Background: Hepatocellular carcinoma (HCC) is the key histologic type of liver cancer, responsible for the bulk of liver cancer diagnoses and deaths. A crucial cancer event is cell polarity loss during the epithelial to mesenchymal transition which is characterized by repressed polarity protein expression, including the loss of rab17. Rab17 was first identified as an epithelial cell-specific small GTPase and we have shown it regulates transcytotic vesicle fusion at the apical membrane via interactions with syntaxin-2 (target SNARE). Others have shown that reduced rab17 levels are associated with increased HCC aggressiveness. Because rab17 expression is reduced by ERK activation during early stages of oncogenesis, and because ERK and other molecular players in the MAP kinase pathway are druggable therapeutic targets, we examined how rab17 re-expression reverses the oncogenic phenotype. **Methods:** For these studies, we have exogenously re-expressed rab17 in Clone9 cells. Notably, these hepatoma-derived cells lack endogenous rab17 expression. To uncover mechanistic details of how rab17 is anti-oncogenic, we also reintroduced rab17 in its constitutively GTP- or GDP-bound states or rab17 that is sumoylation-deficient. **Results:** Expression of wild-type rab17 led to the formation of actin-based, cholesterol-dependent (not microtubule dependent) protrusions. Marker analyses confirmed the protrusions are filopodial-like, not lamellipodia-like, and contain focal adhesion proteins. Rab17 mutant analysis revealed that protrusion formation was GTP-dependent and partially sumoylation-dependent, and expression of wildtype and GTP-bound rab17 resulted in reduced cell migration. In contrast, GDP-bound rab17 expression did not promote protrusion formation or alter cell migration. Wildtype and GTP-bound rab17 were detected in the distal tips of protrusions and colocalized with syntaxin-2. **Conclusion:** We propose that in non-polarized Clone9 cells, rab17 expression redirects vesicle fusion to syntaxin-2 at the apical surface leading to protrusion formation. We propose that rab17 expression induces more adhesive filopodia formation at the expense of Arp2/3-rich lamellipodia thereby decreasing cell migration. Because both the actin-based protrusions and invadopodia are cholesterol-dependent, we further propose that raft-associated proteins are redirected from sites of invadopodia formation to the lateral edges, thereby producing filopodia and promoting the anti-oncogenic phenotype.

homeostasis, and regeneration. However, functions of β-catenin in cholangiocytes remains poorly understood. β-catenin is part of adherens junctions (AJs) where its loss is known to be compensated by γ-catenin, a highly homologous desmosomal protein. In the present study we inducibly and specifically delete both β- and γ-catenins from biliary epithelium to determine role of AJs in bile ducts. **Methods:** We utilized *Opn-iCreERT2+/-; Ctnnb1-fl/fl; Jup-fl/fl* mice (DKO), in which both β-catenin (*Ctnnb1*) and γ-catenin (*Jup*) are acutely deleted from biliary epithelium by Tamoxifen-inducible, cholangiocyte-specific osteopontin-driven expression of Cre-recombinase. 4 doses of Tamoxifen (100mg/kg) were administered to adult animals intraperitoneally and tissues were harvested at various time points after the injections. Tamoxifen-treated *Opn-iCreERT2-/-* sex-matched littermates were used as controls. **Results:** DKO mice showed acute mortality as compared to the controls with survival dropping to 50% within 3 weeks and 100% by 4.5 weeks. DKO mice exhibit decreased body weight, jaundice and lethargy and showed significantly elevated serum ALT, AST, ALP, BR, cholesterol and reduced glucose. A 10-fold decrease in bile flow rate was evident in DKOs following duct cannulation. Total bile acid (BA) levels increased 10^3- fold in the serum and 10-fold in the liver tissue of DKO mice and distinct BA profiles with majority being primary hydrophilic conjugated species. Histology revealed multiple biliary infarcts, inflammation, stellate cell activation and severe portal fibrosis in DKO livers. These findings along with alterations in BA metabolism were corroborated by bulk-RNA sequencing ingenuity pathway analysis (IPA) as well. qRT-PCR showed alterations in number of BA transporters and synthesis genes. CK19-positive bile ducts were malformed, irregular, and sometimes with absent lumen. India ink injections in the common bile duct, showed abundant blebbing throughout the biliary tree. Single-nucleus RNA sequencing (Nuc-Seq) revealed novel hepatocyte clusters as well as distinct population of cholangiocytes in DKO livers. The DKO-associated genetic signature included 381 DEGs that depict aberration in the epithelial cell junctions and upregulation of necroptosis. **Conclusion:** Dual loss of b-catenin and g-catenin from cholangiocytes causes serious intrahepatic cholestatic injury which is associated with notable morbidity and mortality. This model may provide novel insights in the role of cell-cell junctions in bile duct structure and function.

f 4405-A | DYNAMIC REGULATION OF HEPATIC STEATOSIS BY TORSINA AND ITS ACTIVATORS

Ji-Yeon Shin[1], Antonio Hernandez-Ono[1], Yi-Peng Susan Zhao[1], Cecilia Ostlund[1], Michael Lee[1], William T. Dauer[2], Henry N. Ginsberg[1] and Howard J. Worman[1], (1)Columbia University, New York, NY, (2)University of Texas Southwestern Medical

Background: Abnormal hepatic lipid metabolism leads to nonalcoholic fatty liver disease, which can progress to nonalcoholic steatohepatitis (NASH). TorsinA is an ATPase in which lacks intrinsic enzyme activity without its activators lamina-associated polypeptide 1 (LAP1) or luminal domain-like LAP1 (LULL1). We previously demonstrated that while depletion of torsinA leads to striking triglyceride (TG) accumulation in hepatocytes, depletion of LAP1 showed moderate hepatic steatosis. We therefore tested if LULL1, another activator of torsinA, is involved in the process. We next tested if depletion of both activators *in vivo* leads to similar hepatic steatosis phenotypes seen in liver-specific torsinA deletion (A-CKO) mice. We further tested if the marked TG accumulation phenotype of A-CKO mice is reversible upon the acute restoration of torsinA *in vivo*. **Methods:** We generated hepatocyte-specific LULL1 conditional knockout mice (LUL-CKO) and injected these mice with a viral vector carrying a shRNA against LAP1 to deplete hepatocytes of both LULL1 and LAP1. We also used viral vectors to express flag-tagged wild type torsinA onto A-CKO mice. We then measured the hepatic TG content, TG secretion rate and performed fluorescence confocal microscopy to analyze lipid droplets in isolated hepatocytes. **Results:** LUL-CKO mice with depletion of LULL1 from hepatocytes had a minimal reduction in hepatic TG secretion and no steatosis. However, depletion of LAP1 from hepatocytes of LUL-CKO mice (depletion of both LAP1 and LULL1) led to marked hepatic steatosis (Figure 1) and reduction in TG secretion. Confocal microscopic analysis showed a marked accumulation of cytosolic lipid droplets in hepatocytes with combined depletion of both LAP1 and LULL1. Restoration of torsinA expression rescued hepatic steatosis phenotype of A-CKO mice within five days post injection of adenovirus expressing wild type torsinA (Figure 1). **Conclusion:** Combined LAP1 and LULL1 depletion from mouse hepatocytes delineate a functional relationship of these activators of torsinA in liver TG secretion and steatosis. LAP1 appears to be a more important activator of torsinA in hepatocytes than LULL1. However, LULL1 still activates torsinA to some degree in hepatocytes, as depletion of both LAP1 and LULL1 results in marked steatosis similar to those that occur with torsinA

depletion. Acute restoration of torsinA *in vivo*normalizes marked hepatic steatosis phenotypes of A-CKO mice. These collective data demonstrate that torsinA and its activators dynamically regulate hepatic steatosis *in vivo*.

4406-A | HEPATOCYTE-INTRINSIC HUMORAL FACTORS DETERMINE THE ENVIRONMENTAL NICHE FOR HEPATOCYTE FATE DECISION AND MAINTENANCE

Yuji Ishida[1,2], Go Sugahara[1,3], Chihiro Yamasaki[3], Sho Morioka[3], Mikaru Yamao[3], Jae-Jin Lee[4], Yasuhito Tanaka[5], Meng Li[6], Hyungjin Eoh[4], Chise Tateno[3] and Takeshi Saito[1,4], (1)Medicine, Division of Gastrointestinal and Liver Diseases, Keck School of Medicine, University of Southern California, (2) Phoenixbio Co., Ltd., Higashi-Hiroshima, Japan, (3) Phoenixbio Co., Ltd., (4)Molecular Microbiology and Immunology, Keck School of Medicine, University of Southern California, (5)Faculty of Life Sciences, Kumamoto University, (6)USC Libraries Bioinformatics Service, University of Southern California

Background: The tissue-specific microenvironment determines cell identity; therefore, in vitro fate maintenance of primary cells, such as human hepatocytes (HH), has been regarded implausible. The implementation of 3D culture, microscale-bioprinting approach, or the supplementation of 5 chemicals (5C), have been shown to reduce the extent of fate decline. Furthermore, our recent work refining 2D-HH culture approach revealed that HH undergo processes of recovery from injury imposed by the procurement procedure and reinstating proper characteristics, all of which point to a role of hepatocyte-intrinsic factors in defining the fate of HH. **Methods:** HH, either primary or humanized liver chimeric mice (HLCM)-derived, were cultured with medium containing hepatocyte-specific supplements for 7 days, allowing HH to restore their genuine characteristics. The medium of fate recovered-HH was pooled as the conditioned medium (CM), and its impact on HH fate and function was contrasted with that of fresh medium (FM), FM supplemented with 5C, or Matrigel. Freshly isolated HH were cultured for 7 days with CM, FM, FM-5C, or FM-Matrigel, followed by the assessment of transcriptome, bile excretion function, CYP activity, and hepatitis B virus (HBV) infectivity. In addition, CM- or FM-treated HH were implanted to the host mouse of HLCM to validate its role on fate maintenance. **Results:** The transcriptome of CM-treated (CM-HH) exhibited a significant degree of similarity to that of freshly isolated HH. In contrast, HH treated with FM, FM-5C, or FM-Matrigel revealed significant upregulation of TGFβ-YAP/TAZ pathway and dedifferentiation or cholangiocyte transdifferentiation marker genes. Consequently, the activity of bile excretion and CYP enzymes, and HBV infectivity were all superior in CM-HH compared to other conditions. Moreover, the engraftment of CM-HH in the liver of HLCM host mouse demonstrated a level of efficiency comparable to that of freshly isolated HH, providing additional evidence on the significance of CM. Furthermore, the proteome analysis of CM and follow up studies with loss of function approach suggested that the formation of macromolecular complex comprised of ECM-related molecules and coagulation factors serves as the critical determinant of HH fate maintenance. **Conclusion:** Our work revealed that hepatocyte-intrinsic humoral factors produced from terminally differentiated HH create the environmental niche required for hepatocyte fate decision and maintenance.

4407-A | IDENTIFICATION OF THE ELUSIVE LIPOPHAGY RECEPTOR FOR LIPID TURNOVER IN LIVER

Debajyoti Das[1], Mridul Sharma[1], Deepanshi Gahlot[2,3], Jennifer T. Aguilan[4], Simone Sidoli[4], Mathieu Bourdenx[5,6], Lipi Thakural[2,3], Nuria Martinez-Lopez[1,7] and Rajat Singh[1,4,7], (1)University of California, Los Angeles, (2)Csir-Institute of Genomics and Integrative Biology, (3)Academy of Scientific and Innovative Research, (4)Albert Einstein College of Medicine, (5) UCL Queen Square Institute of Neurology, (6)UK Dementia Research Institute, (7)Liver Basic Research Center at University of California Los Angeles

Background: Lipophagy is a cellular mechanism for degradation of lipid droplets (LD) via autophagy. It is well-established that defects in lipophagy/autophagy lead to hepatic lipotoxicity across the broad pathophysiological spectrum of fatty liver disease. Indeed, dampened autophagy and steatosis during obesity underscore the importance of this pathway in liver pathobiology. Despite extensive research, little is known about the mechanisms of selective recognition and sequestration of LD by autophagosomes, which will lead to ultra-precise targeting to selectively activate lipophagy without affecting other forms of autophagy. **Methods:** Animal models: Studies were performed in 2-10-month-old male and female mice. Liver-specific *Atg7*^{KO} mice were generated by administration of AAV8-TBG-iCre and control and *Atg7*^{KO} livers were harvested after 8 weeks. DNA or siRNA transfection: Transfections in NIH3T3 cells and AML12 hepatocytes were performed using Lipofectamine3000. In vivo DNA and siRNA delivery was performed using in vivo-jetPEI® and Invivofectamine™ 3.0, respectively. Phosphoproteomics: Fed and 20-hour fasted liver homogenates, and control and 6-hour serum-starved AML12 hepatocytes were homogenized in 2% SDS + 5 mM DTT buffer, and proteins were digested in S-trap columns, and peptides analyzed by nLC-MS/MS. Confocal imaging: Hepatocytes in serum-free medium in presence or absence of oleic acid were subjected to multiplex colocalization using spinning disc super-resolution microscopy (Nikon CSU-W1). Statistical analyses were performed via unpaired Student's t-test or one/two-way ANOVAs and appropriate post-hoc testing. **Results:** We report fasting-induced enrichment of selective phosphosites in liver that regulate hepatic lipid metabolism. From amongst these phosphoproteins, we identified a novel receptor for lipophagy that governs LD degradation in liver during fasting and lipotoxic stress. We show that Casein kinase 2 (CSNK2)(EC 2.7.11.1)-mediated phosphorylation regulates the function of this novel protein towards LD sequestration. We have identified lipid binding and LC3 (light chain 3) interacting regions on this phosphoprotein, which allow binding to LD and autophagosomes, respectively, and inactivating these regions cause lipid accumulation. These findings have informed the generation of a highly sensitive and specific lipophagy reporter that will provide an efficient readout for lipophagy flux in cellulo and in vivo. **Conclusion:** We have identified a previously unknown selective receptor that targets LDs for lysosomal degradation. Selective phosphorylation of this target is of crucial importance for recognition and degradation of LDs in lysosomes. This discovery and the novel reporter will help develop novel compounds to selectively activate lipophagy to prevent human NAFLD and NASH.

f 4408-A | IMPAIRED EXERCISE RESPONSES IN LIVER DISEASE IS MEDIATED BY MOLECULAR AND METABOLIC PERTURBATIONS DURING HYPERAMMONEMIA

Annette Bellar[1], Avinash Kumar[2], Nicole M. Welch[1], Saurabh Mishra[1] and Srinivasan Dasarathy[1], (1) Cleveland Clinic, (2)All India Institutes of Medical Sciences

Background: The benefits of endurance exercise (EE) in healthy subjects have been well studied and include reduction in fat mass, improved cardiorespiratory responses, and mitochondrial function. In sedentary adults, EE can also increase lean body mass to a limited extent. EE has been used as a treatment for cardiac and metabolic disorders and may be beneficial in cirrhosis, however there are limited data on response to EE in patients with liver disease. EE also increases ammonia generation, which may increase comorbidities of cirrhosis including hepatic encephalopathy and sarcopenia. In this study, we evaluated the effect of voluntary wheel running (VWR) in a mouse model of hyperammonemia. **Methods:** Hyperammonemia was induced in 8-week aged, wild type, C57BL6 mice by surgical placement of osmotic pumps to deliver 2.5mmol/kg/day Ammonia Acetate (AmAc) or vehicle (PBS) for 6weeks. After 2 weeks of pump placement, the PBS or AmAc treated mice were randomly assigned to 4w of VWR or usual activity (UA). Body weight and grip strength were measured weekly. All animals were

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

sacrificed after 4 weeks of UA or VWR and organs including skeletal muscle were harvested and weighed. A portion of fresh muscle tissue was used for mitochondrial oxygen consumption studies by high sensitivity respirofluorometry using substrate, uncoupler, inhibitor, titration protocols. **Results:** We found no change in total bodyweight, lean body mass, or fat mass between the 4 groups (PBS-UA, PBS-VWR, AmAc-UA, AmAc-VWR) pre- and post-exercise (Fig1). Gastrocnemius muscle mass was not different in response to exercise in the PBS group (PBS-UA vs. PBS-VWR, $p > 0.05$). AmAc-UA mice has lower gastrocnemius muscle mass compared to PBS-VWR ($p = 0.004$) or PBS-UA ($p = 0.003$). Gastrocnemius muscle mass in AmAc-VWR was greater than that in the AmAc-UA group ($p = 0.047$). Interestingly, muscle mass in the AmAC-VWR was similar to that in the PBS-UA group, but less than that in the PBS+VWR mice ($p = 0.04$). Grip strengths did not change in any of the groups over time. Mitochondrial oxidative responses were similar in the gastrocnemius muscle in the PBS-UA, PBS+VWR, and AmAc-VWR mice. Complex I linked (ADP/Glutamate), rotenone sensitive, Complex II (Succinate), and maximum respiration was less in the AmAc-UA ($p \leq 0.05$) vs. PBS+UA/VWR or AmAc+VWR. EE for 4 weeks in a validated mouse model of hyperammonemia did not alter body composition. However, gastrocnemius muscle mass was lower during hyperammonemia and was partially restored by 4-weeks of VWR that recapitulates EE in preclinical models. Mitochondrial oxidative responses were impaired by hyperammonemia that were also partially reversed by VWR (EE). Lack of improvement in grip strength is consistent with previous data on EE. **Conclusion:** Responses to EE were impaired by hyperammonemia. Ammonia lowering measures and potentially adding resistance exercise may be more beneficial in reversing sarcopenia of liver disease.

4409-A | JCAD DEFICIENCY ACCELERATES NASH-HCC DEVELOPMENT THROUGH LEAKAGE OF BILE ACIDS DUE TO IMPAIRED INTRAHEPATIC BILIARY DUCT INTEGRITY

Li Zhang[1], Yongyu Yang[1], Yuan Zhou[1], Zhonghua Wang[1], Jia Ding[2] and Jian Wu[1,3,4], (1)Dept. of Medical Microbiology, Fudan University School of Basic Medical Sciences, Shanghai 200032, China, (2)Shanghai Jing'an District Central Hospital, (3)Shanghai Institute of Liver Diseases, Fudan University Shanghai Medical College, Shanghai 200032, China, (4)Fudan University, Department of Gastroenterology and Hepatology, Zhongshan Hospital, Shanghai, China

Background: JCAD was originally recognized as an E-cadherin-based cell conjunction, and is attributed to development of cardiovascular disorders. Our previous study demonstrated that JCAD acts as an upstream regulator of Hippo signaling pathway *in vitro*. The present study aims to investigate the influence of JCAD on hepatocellular canaliculus and biliary epithelial cell (BEC) integrity during NASH-HCC development. **Methods:** Wild-type (WT) and JCAD knockout (KO) mice were fed high-fat and calorie diet plus high fructose and glucose in drinking water (HFCD-HF/G) for 14 mon or choline-deficient high fat diet (CD-HFD) for 12 mon respectively for induction of NASH-HCC ($n = 10$). NASH phenotypes and tumor incidence were investigated. **Results:** JCAD knockout increased liver tumor incidence and malignancy in both HFCD-HF/G (10/10 vs. 5/10; $p < 0.05$) and CD-HFD (4/10 vs. 2/10) models. Lipid metabolism and insulin resistance did not differ between WT and KO mice, however liver hydroxyproline content was significantly increased in JCAD-KO mice (0.8 vs. 0.3 μg/mg, $p < 0.001$ in HFCD-HF/G model; 0.4 vs. 0.25 μg/mg, $p < 0.05$ in CD-HFD model). Notably, cholestatic manifestations including significantly elevated bile acid levels (71 vs. 9 μmol/L, $p < 0.001$ in HFCD-HF/G model; 86 vs. 9 μmol/L, $p < 0.05$ in CD-HFD model), dilated bile canaliculi and increased expression of CK19, diminished tight junction protein of occludin and zonula occludens protein 2 as well as altered gene expression of bile acid production, absorption and transportation in KO mice indicate that JCAD knockout contributed to cholestasis which facilitated the NASH-HCC progression. Mass spectrometric analysis revealed that strikingly elevated serum tauroconjugates of β-muricholic acid and cholic acid mainly accounted for the difference in bile acid. Incubation of primary hepatocytes with mixed bile acids and 1% CA feeding as well as BDL model in mice recapitulated the cholestasis-elicited expression of genes involved in pluripotency and stemness of hepatocytes. Moreover, JCAD deficiency led to impaired barrier function *in vitro* as indicated by reduced transepithelial electrical resistance (TER) by 42%

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

($p < 0.001$) and increased FITC-dextran leakage (siJCAD vs. siCNTL: 1278 vs. 1027 AU/h, $p < 0.05$); whilst, intra-hepatocyte paracellular permeability was increased in JCAD-KO mice (KO vs. WT: 754 vs. 572 AU/5min, $p < 0.01$). **Conclusion:** Loss of JCAD disrupted structural and functional integrity of tight junction in both hepatocytes and BECs, which led to BA leakage. JCAD-KO mice fed NASH diet for a long term accelerated malignant transformation through BA toxicity. Delineation of bile acid impacts on hepatic malignant transformation enables to develop new strategies in NASH-HCC prevention and treatment.

f 4410-A | LIPID-DRIVEN mTORC1 SIGNALING IN LIVER

Henrietta Bains[1], Debajyoti Das[2], Nuria Martinez-Lopez[2], Jennifer T Aguilan[1], Simone Sidoli[1], Mathieu Bourdenx[3,4], Laura Beth J McIntire[5] and Rajat Singh[1,2,6], (1)Albert Einstein College of Medicine, (2) University of California, Los Angeles, (3)UCL Queen Square Institute of Neurology, (4)UK Dementia Research Institute, (5)Weill Cornell Medicine, NY, (6) Liver Basic Research Center at University of California Los Angeles

Background: mTOR complex 1 (mTORC1) signaling is critical for growth and proliferation. Dysregulation of mTORC1 signaling in obesity alters lipid metabolism in liver through its effects on lipogenesis and autophagy. In the physiological state, mTORC1 signaling is activated by diverse nutrients. However, whether lipids activate mTORC1 in liver *in vivo* remains unknown. **Methods:** *Animal models*: Studies were performed in 4-8-month-old C57BL/6 male mice fed a regular chow or a high-fat diet (HFD; 60% kcal from fat). As model of dietary lipid availability, mice were fasted for 3 hours (to shut down mTORC1 activity) and subjected to an oral gavage of corn oil for 30 minutes. *Nucleic acids transfections*: Hepatocyte cell lines were transfected with DNAs or siRNAs using Lipofectamine3000 or RNAiMAX Reagent, respectively. Liver-specific delivery of siRNAs was performed using Invivofectamine™ 3.0 Reagent. *Lipidomics*: Lipids from liver homogenates were extracted and analyzed by LC-MS/MS. *Proteomics*: co-IP eluents from cell lysates were resuspended in 2% SDS/5 mM DTT buffer, digested in S-trap columns, and peptides were analyzed by nLC-MS/MS. *Confocal imaging*: Serum-starved cells exposed to phosphatidic acid or amino acids were tracked via laser scanning microscopy to monitor mTOR subcellular localization. *Statistics*: Unpaired Student's T-test, one-way or two-way ANOVA followed by appropriate multiple-comparisons tests. **Results:** Our studies show that mTORC1 in liver is activated by a dietary corn-oil gavage. Follow up studies in hepatocytes indicate that distinct lipid species, including phosphatidic acids (PA), activate mTORC1 in culture. Elevated levels of PA during obesity lead to mTORC1 hyperactivation in hepatocytes, likely contributing to fatty liver disease. Using proteomics, we have also found that availability of PA is sensed by unique mTOR binding partners, not known to regulate sensing of amino acids or cholesterol. These unique mTOR-binding proteins drive PA-driven mTORC1 activation at late and recycling endosomes. In fact, deletion of these newly identified protein factors blocked mTORC1 activity in response to PA. **Conclusion:** Our ongoing studies reveal that selective targeting of novel mTOR-binding proteins could be a new therapeutic approach in protecting against fatty liver by curtailing age- and obesity-associated mTORC1 hyperactivity.

f 4411-A | MITOCHONDRIA-LOCALIZING FLUOROPHORES ARE MARKERS TO VISUALIZE LOBULAR ZONATION IN MOUSE LIVER

Kenji Takemoto, Matthew Savoca, Zhi Zhong and John J. Lemasters, Medical University of South Carolina

Background: The liver has a complex architecture to manage its various physiological roles. Liver lobular zonation is a well-known feature of liver parenchymal organization. Understanding of lobular involvement in liver disease provides important insights into pathophysiology. In general, visualization of liver zonation requires specific immunostaining procedures. Here, we developed a novel method to visualize mouse liver zonation using mitochondria-localizing fluorophores. **Methods:** Male C57BL/6J mice were injected by tail vein with 0.05 or 0.5 μmol of Mitotracker Red (MTR), which covalently labels polarized mitochondria, 1 h prior to liver fixation or intravital multiphoton microscopy. After paraformaldehyde fixation, liver tissues were mounted in 5% agarose, and 100-μm sections were prepared with a vibratome. Sections were incubated anti-CYP2E1 (pericentral) and/or anti-E-cadherin (periportal) antibodies for 72 h. Fixed sections were imaged with a Zeiss LSM 880 confocal microscope in super resolution Airyscan mode. Intravital imaging was performed with an Olympus FV1200 multiphoton microscope. Some mice were injected with

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

0.05 μmol rhodamine 123 (Rh123), a fluorophore that non-covalently labels polarized mitochondria, at 1 h after MTR injection followed by intravital imaging. **Results:** On intravital imaging, MTR and Rh 123 fluorescence co-localized into mitochondria. Intensities of MTR and Rh123 fluorescence positively correlated ($r = 0.678$, $p < 0.0001$), which indicated similar distribution. Intensity of MTR and Rh 123 fluorescence in pericentral regions averaged 64 and 74% less than in periportal regions. In fixed liver sections, strong CYP2E1 labeling was confined to pericentral regions, whereas strong E-cadherin labeling was confined to periportal regions with relatively sharp demarcations between the two areas. However, gradation of MTR fluorescence across the liver lobule was continuous without a sharp demarcation between zones at both 0.05 and 0.5 μmol MTR. The maximum ratio of periportal to pericentral MTR fluorescence in sections was ~2. **Conclusion:** After tail vein injection, mitochondria-localizing fluorophores label periportal hepatocytes more strongly than pericentral hepatocytes, providing a new approach to identify zones of the liver lobule. This novel method may allow cell sorting of living periportal and pericentral hepatocytes without using immunologic tags.

f 4412-A | MITOCHONDRIA-LYSOSOME RELATED ORGANELLES MEDIATE MITOCHONDRIAL CLEARANCE TO PROMOTE HEPATOCYTE DEDIFFERENTIATION

Chen Zhang[1], Xiaowen Ma[1], Hong-Min Ni[2] and Wen-Xing Ding[3], (1)The University of Kansas Mediacal Center, (2)The University of Kansas Medical Center, (3) University of Kansas Medical Center, Kansas City, KS

Background: Hepatocyte dedifferentiation is a common feature for chronic liver diseases such as alcohol-associated hepatitis (AH) and non-alcoholic steatohepatitis (NASH). Mitochondria play critical roles in regulating cellular redox homeostasis, lipid metabolism, energy production, and cell death. Mitochondrial dysfunction is associated with various chronic diseases including AH and NASH. To maintain hepatic mitochondrial homeostasis, Dysfunctional and surplus mitochondria can be removed via multiple pathways such as mitophagy, a selective autophagy process. However, whether and how mitochondria homeostasis would affect hepatocyte dedifferentiation are unknown. **Methods:** Primary cultured mouse hepatocytes from wildtype or genetic knockout of PARKIN, ATG5 and DRP1 as well as GFP-mCherry-COX8 mitophagy reporter assay and super-resolution and ultrastructural electron microscopy analysis were used in this study. **Results:** We identify a previously undescribed intracellular hybrid mitochondria-lysosome organelle (termed the mitochondria-lysosome related organelle, MLRO) in prolonged cultured hepatocytes. MLRO is an electron-dense organelle that has either a single or double membrane with both mitochondria and lysosome markers. Mechanistically, MLRO is likely formed from the fusion of mitochondria-derived vesicles (MDVs) with a lysosome through a PARKIN, ATG5, and DRP1-independent process, which is negatively regulated by transcription factor EB (TFEB) and associated with mitochondrial protein degradation and hepatocyte dedifferentiation. MLRO, which is galectin 3 positive, is reminiscent of damaged lysosome and could be cleared by overexpression of TFEB resulting in attenuation of hepatocyte dedifferentiation. **Conclusion:** Results from this study indicate that MLRO may act as a novel alternative mechanism for mitochondrial quality control independent of canonical autophagy/mitophagy involved in hepatocyte dedifferentiation. Manipulation of TFEB may be beneficial for improving the pathogenesis of AH and NASH by inhibiting hepatocyte dedifferentiation.

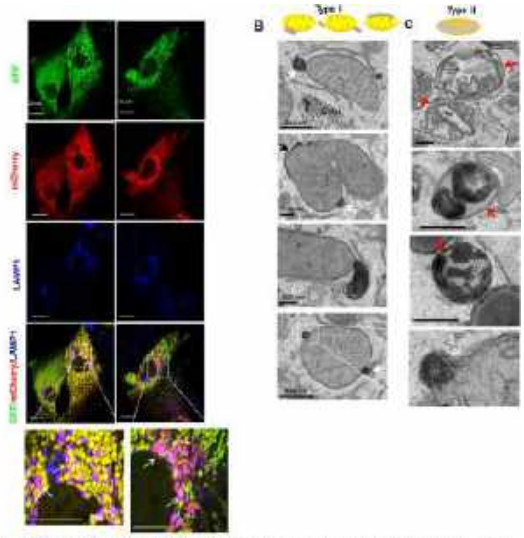

Figure. Ultrastructure of the Mitochondria-Lysosome Related Organelle (MLRO) in primary cultured mouse hepatocytes. (A) Primary mouse hepatocytes were infected with adenovirus-COX8-GFP-mCherry (10 MOI) from seeding overnight. Cells grown on coverslips were fixed in 4% PFA at indicated time points followed by LAMP1 immunofluorescence staining. Representative images from confocal microscopy analysis are shown. Arrows denote the colocalization of red-only mitochondria from COX8-GFP-mCherry assay with the lysosomal marker LAMP1. J McIntire[4], Leslie Gunther-Cummins[3], Frank P Macaluso[3], Jennifer T Aguilan[3], Simone Sidoli[3], Mathieu Bourdenx[5,6] and Rajat Singh[1,2,3], (1)University of California, Los Angeles, (2)Liver Basic Research Center at University of California Los Angeles, (3)Albert Einstein College of Medicine, (4)Weill Cornell Medicine, NY, (5)UK Dementia Research Institute, (6)UCL Queen Square Institute of Neurology

Background: Fasted livers take up free fatty acids from circulation to support mitochondrial respiration. We do not completely understand the mechanisms driving these mitochondrial adaptations when nutrients are scarce. **Methods:** *Animals*: Studies were performed in 2-10-month-old male and female mice. Liver-specific *Rictor* knock-out (*Rictor*^{KO}) mice were generated by injecting *Rictor*$^{flox/flox}$ mice with AAV8-TBG-iCre for 8 weeks. *DNA/siRNA transfections*: In vitro transfections were performed using Lipofectamine3000. Delivery of DNA to liver was performed via In vivo-jetPEI®, and siRNA was delivered using Invivofectamine™ 3.0. *Subcellular fractionation* was performed as described by Wieckowski MR et al. *Nat Protoc* (2009). Phosphoproteomics: Liver homogenates and mitochondrial-associated membranes (MAM) or co-IP eluents were resuspended in 2% SDS/5 mM DTT buffer, digested in S-trap columns, and peptides were analyzed by nLC-MS/MS. *Confocal imaging*: Serum-starved cells exposed to MitoTracker™ Green FM (to stain for mitochondria) were tracked via laser scanning microscopy. *Statistics*: Unpaired Student's T-test, one-way or two-way ANOVA followed by appropriate multiple-comparisons tests. **Results:** We have found that extended periods of fasting paradoxically stimulate the nutrient-sensitive mTORC2 pathway in liver. mTORC2 reactivation in liver supports fasting-induced increases in mitochondrial fission and respiration. Accordingly, inactivation of mTORC2 in liver by knocking-out its regulatory protein, RICTOR (*Rictor*^{KO}), impairs fasting-induced increases in fission and mitochondrial respiration. Consequently, fasted *Rictor*^{KO} livers exhibit marked accumulation of triglycerides due to failure to mobilize these lipids. Using quantitative phosphoproteomics, we identified a new role for mTORC2 and its downstream phosphotargets in driving mitochondrial fission in liver by regulating the recruitment of novel regulatory proteins to MAMs, which are contact sites for ER-mediated mitochondrial fission. **Conclusion:** Nutrients activate mTOR signaling for anabolic functions; however, fasting-induced reactivation of mTORC2 plays an unexpected role in mitochondrial division and respiration. Stimulating mTORC2 could help prevent NAFLD by stimulating mitochondrial function and lipid disposal.

4414-A | SDR CHARACTERIZATION IN HEPATIC METABOLISM

Nolwenn Samson[1,2], Cristina R. Bosoi[1,2], Mathilde Mouchiroud[1,2], Laura Tribouillard[1,2], Yves Gélinas[1,2], André Marette[1,2] and Mathieu Laplante[1,2], (1)Université Laval, (2)Centre De Recherche De L'institut Universitaire De Cardiologie Et De Pneumologie De Québec

Background: The liver is a critical hub for numerous physiological processes, including macronutrient metabolism, endocrine control of growth signalling pathways, lipid and glucose homeostasis, bile acid production, and amino acid metabolism. Over the years, several proteins and signalling nodes have been identified as playing key roles in regulating the response of the liver to fasting. Despite these advances, new discoveries are constantly emerging and our understanding of the molecular mechanisms controlling this important biological process keeps evolving. Therefore, the main objective of this project is to identify and characterize new proteins regulating liver metabolism in response to fasting. **Methods:** We used hepatocytes isolated by serial dilutions and obtained more than 30 new clonal lines. Hepatic glucose production was assessed in these clonal lines since it is a process that occurs during fasting. Some of these lines produced low glucose amounts (Low Lines) whereas others produced high amounts (High Lines). To identify the factors involved in this variability between these lines, we performed transcriptomic assays between High and Low lines, and obtained 25 new targets that were never linked to the hepatic response to fasting before. **Results:** Our first interesting candidate is a *short dehydrogenase reductase* (*Sdr*) gene whose expression is higher in High Lines versus Low Lines. This *Sdr* gene encodes for a protein of unknown function. Using immunofluorescence studies, we identified SDR as a mitochondrial protein. Our studies also indicate that *Sdr* is induced by fasting and PPARα, and repressed by insulin. Knockdown of *Sdr* in vitro decreases oxygen consumption and fatty acid oxidation, suggesting a role in mitochondrial metabolism. Furthermore, the FXR signalling pathway is downregulated in hepatocytes knockdown for *Sdr*. *In vivo*, mice with *Sdr* knockout exposed to a high fat diet have an impaired hepatic glucose production. **Conclusion:** With our work, we hope to elucidate SDR function in systemic metabolism.

4415-A | THE INTERACTION BETWEEN CD36 AND oxLDL CONTRIBUTES TO LYMPHATIC DYSFUNCTION IN CHRONIC LIVER DISEASE

Destiny M.C. DeNicola[1], Alyssa Goldberg[2], Megan E. Ferguson[1], Abbigayl E.C. Burtis[1], Jamie Shirley[1], Beth A. Jiron Tamburini[1] and Matthew A. Burchill[1], (1) University of Colorado - Anschutz Medical Campus, (2) Children's Hospital Colorado

Background: Chronic liver disease disrupts the trafficking of high molecular weight proteins and cells out of the liver via the lymphatics. This lymphatic dysfunction can be attributed to an oxidized low-density lipoprotein (oxLDL) mediated increase in the expression of the key junctional protein, VE-Cadherin. However, the precise molecular mechanism by which oxLDL impacts lymphatic permeability in the liver is unknown. In these studies, we aimed to define the cell surface receptors and signaling pathways that are activated by oxLDL to reduce lymphatic function in the liver. **Methods:** To define this signaling pathway, we utilized both siRNA mediated knock-down and blocking antibody treatments to prevent oxLDL binding to cell surface receptors in primary human lymphatic endothelial cells (hDLEC) and primary Liver Sinusoidal Endothelial Cells (hLSECs). Using western blot, flow cytometry, and immunofluorescence, we measured VE-cadherin surface levels after oxLDL treatment with or without receptor blockade in LECs. Furthermore, we defined the signaling pathway activated by oxLDL using both phospho-kinase arrays and western blot. Finally, we utilized transwell assays to define the cell surface receptors that regulate LEC permeability *in vitro.* **Results:** Here we found that oxLDL stimulation results in a rapid (1-2h) upregulation of cell surface VE-cadherin in LECs but not LSECs. This increase is contingent on CD36 receptor signaling. Additionally, this effect is not the result of preventing oxLDL uptake entirely, as CD36 blockade did not impact the amount of oxLDL that entered the cells. Furthermore, this CD36-dependent upregulation of VE-Cadherin is unique to oxLDL, as treatment with the CD36 ligand, Palmitic Acid, does not result in increased VE-Cadherin expression in LECs. Finally, oxLDL treatment of LECs results in the CD36 dependent activation of a signaling cascade that involves both SRC-family kinase activation and GSK-3a inhibition to stabilize VE-Cadherin on the cell surface. **Conclusion:** The above studies demonstrate that the specific interaction between oxLDL and the CD36 receptor induces VE-Cadherin increase to change permeability in LECs. It also identifies likely downstream signaling intermediates mediating this response. This lays the groundwork for understanding lymphatic dysfunction in chronic liver disease and potential therapeutic targets for restoring lymphatic function and liver homeostasis during disease.

4416-A | TWO HEPATIC PEROXISOME POPULATIONS DIFFERENTIALLY RESPOND TO ALCOHOL-INDUCED OXIDATIVE STRESS VS LIPID OVERLOAD

Ramyajit Mitra, Oluwaseyi Okesooto and Pamela L. Tuma, The Catholic University of America

Background: Peroxisomes have a wide array of functions, and are constantly responding to cellular metabolic states including ROS and lipid overload. Oxidative stress and hepatic steatosis are well known hallmarks of alcohol associated liver diseases. Here we propose that two peroxisome populations differentially respond to alcohol-induced ROS vs. lipid overload. **Methods:** Peroxisome numbers, distributions, morphology, dynamics, and peroxisome-organelle contacts were examined morphologically (using confocal microscopy) or biochemically (by immunoblotting) in polarized hepatic WIF-B cells treated in the absence or presence of EtOH and/or oleic acid (to mimic Western diet) or in livers from EtOH -fed rats (5 weeks; Lieber Decarli). **Results:** Our studies revealed that at steady state, there is considerable peroxisomal heterogeneity. Few peroxisomes are labeled with catalase whereas there are greater numbers of peroxisomes positive for ABCD3, a long chain fatty acid transporter. When treated with EtOH, peroxisome numbers increased for both populations, but the increase was greater for catalase+ peroxisomes suggesting their enhanced response to EtOH-induced ROS. Studies with the CYP2E1 inhibitor, diallyl sulfide, and the anti-oxidant, n-acetylcysteine confirmed these results. We also determined that peroxisome distributions were microtubule dependent and that in EtOH-treated cells, the ABCD3+ peroxisomes (but not catalase+ ones) colocalized with acetylated microtubules emanating from canalicular surface preventing interactions with that surface. We further observed that the ABCD3+ peroxisomes (but not catalase+ ones) in cells treated with both EtOH and oleic acid form several contacts with the large lipid droplets and that these contacts were dependent on acetylated microtubules. Catalase+ peroxisomes made many fewer droplet contacts. These results suggest that the two peroxisome populations differentially respond to EtOH-induced ROS (catalase+) vs. lipid overload (ABCD3+).

Conclusion: Considering there are no treatments available to alleviate or reverse the disease state in the progression of ALD, explicitly understanding the specific molecular mechanisms that contribute to observed clinical pathologies is essential in identifying novel therapeutic targets. Since peroxisomes are involved in a wide array of cellular functions including, but not restricted to, regulating oxidative stress and lipid homeostasis, investigating their response to alcohol is of paramount importance.

4417-A | CHOLESTENOIC ACID AS ENDOGENOUS EPIGENETIC REGULATOR DECREASES LIPID ACCUMULATION IN HUMAN HEPATOCYTES

Yaping Wang, William Pandak and Shunlin Ren, Virginia Commonwealth University

Background: Cholestenoic acid (CA), along with 27HC and 25HC, is a natural ligand for LXRs and is synthesized in mitochondria. Previous studies have demonstrated the involvement of 27HC and 25HC in lipid metabolism, inflammatory responses, and cell apoptosis. However, the physiological and pathological roles of CA remain unclear. This study aimed to investigate the molecular mechanism underlying the potential role of CA in hepatic lipid homeostasis. **Methods:** Enzyme kinetic analysis was utilized to examine the impact of CA on the activities of three DNA methyltransferases (DNMTs). Human hepatocytes cultured in high glucose medium were utilized as a non-alcoholic fatty liver disease model. Human whole-genome bisulfite sequencing (WGBS) and messenger RNA sequencing were used to investigate the relationship between DNA methylation and gene expression. Additionally, untargeted lipidomics analysis was performed to assess the impact of CA on lipid levels. **Results:** Enzyme kinetic studies revealed that CA specifically inhibits the activity of DNMTs.WGBS analysis showed an increased number of differential methylation regions (DMRs) over time between the control and CA-treated groups. Hypomethylated DMRs in the promoter region after CA treatment were significantly enriched in lipid metabolism-related processes and metabolic signaling pathways. mRNA sequencing analysis indicated significant modulation of numerous gene clusters by CA, with the number of differentially expressed genes increasing over time. Down-regulated genes were significantly enriched in lipid biosynthesis processes and KEGG pathways related to steroid biosynthesis, terpenoid backbone biosynthesis, metabolic pathways, and cholesterol metabolism. RT-qPCR and western blot analyses validated the results of RNA sequencing and WGBS, confirming the time- and dose-dependent decrease in gene expression and protein levels of key genes involved in lipid synthesis, along with the increase in regulatory genes associated with calcium and ERK signaling pathways. Untargeted lipidomics analysis further demonstrated that CA significantly decreased lipid levels. **Conclusion:** This study highlights CA as a distinct endogenous epigenetic regulator that decreases lipid accumulation in human hepatocytes by demethylating DNA ^{5m}CpG of essential genes involved in hepatic lipid metabolism. This study emphasize the significance of CA as a potential therapeutic target for metabolic disorders, specifically hyperlipidemias.

4418-A | DISCOVERY OF A NOVEL REGULATORY MOLECULE: 3β-HYDROXY-5-CHOLESTENOIC ACID 3-SULFATE, SECRETED BY HEPATOCYTES AND SUPPRESSES INFLAMMATORY RESPONSES IN MACROPHAGES

Yaping Wang, William Pandak and Shunlin Ren, Virginia Commonwealth University

Background: Cholestenoic acid (CA) is a natural ligand for LXRs and is synthesized in mitochondria, along with 27HC and 25HC. Our previous study uncovered CA as an endogenous epigenetic regulator that reduces lipid accumulation in human hepatocytes by demethylating key genes related to lipid metabolism. Nevertheless, the metabolic pathway of CA remains elusive. This study aims to investigate the metabolic pathway of CA in human hepatocytes and explore the biological functions of its metabolites. **Methods:** LC-MS/MS was used to monitor the metabolic pathway of CA in human hepatocytes. Human hepatocytes cultured in high glucose medium were used as a non-alcoholic fatty liver disease (NAFLD) model to examine the effect of CA3S on lipid metabolism. Human macrophage cells induced by 2 ug/ml Lipopolysaccharide (LPS) were used as an inflammation response model to investigate the effect of CA3S on inflammation response. RT-qPCR was used to analyze the effect of CA3S on gene expression related to lipid metabolism and inflammation response. **Results:** HepG-2 cells were treated with 20 uM CA for various durations (0, 1.5, 3, 6, 12, and

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

24 hours). The cultured media samples were collected, extracted, and analyzed using LC-MS/MS. The results showed a decrease in CA (m/z 415) levels in the cultured media as culturing time increased. A new molecular ion (m/z) 495 appeared at 1.5 hours and reached a maximum (90%) at 24 hours. Further investigation using tandem MS fragmentation revealed three major fragments: m/z 80, m/z 97, and m/z 415. Comparison with a synthesized compound confirmed the new m/z 495 compound as 3β-hydroxy-5-cholestenoic acid 3-sulfate (CA3S). The analysis revealed the presence of CA3S in the intercellular space of HepG-2 cells with CA treatment, indicating its sulfation and release from hepatocytes. To explore its biological function, CA3S was synthesized and purified in the lab. Treatment of HepG-2 cells with purified CA3S down-regulated lipid biosynthesis genes (hmgr, fas, and pcsk9) according to RT-qPCR results. Additionally, treating macrophage cells with CA3S significantly reduced the expression of inflammatory cytokine genes (il-1a, il-6, and cox2) induced by LPS, as demonstrated by RT-qPCR. **Conclusion:** Our findings indicate that CA can be sulfated to CA3S in human hepatocytes and subsequently released. CA3S exhibits an anti-inflammatory effect on human macrophage cells, suggesting its potential as a therapeutic agent for inflammation-related conditions.

4419-A | EFFICACY OF VEGFR2-TARGETED THERAPY AFTER ATEZOLIZUMAB AND BEVACIZUMAB COMBINATION THERAPY IN HEPATOCELLULAR CARCINOMA

Kouki Nio[1], Gen Sugiyama[1], Hikari Okada[1] and Taro Yamashita[2], (1)Kanazawa University Graduate School of Medicine, (2)Kanazawa University

Background: Atezolizumab, an anti-PD-L1 antibody, plus bevacizumab, an anti-VEGFA antibody, combination (ABC) therapy for advanced hepatocellular carcinoma (HCC) has widely been used in clinical practice as a first-line treatment. Ramucirumab, an anti-VEGFR2 antibody, has been shown to be effective for advanced HCC with high AFP levels, but its efficacy after ABC therapy is unclear. In this study, we aimed to analyze the effect of the anti-VEGFR2 antibody after combination therapy with anti-PD-L1 and anti-VEGFA antibodies in vivo. **Methods:** A patient-derived xenograft (PDX) model was used to confirm the efficacy of anti-mouse VEGFR2 antibody (DC101), provided by Eli Lilly and Company, on human HCC xenograft. A syngeneic mouse model of AFP/EpCAM-positive HCC, which shows poor prognosis with stem cell features, was used to assess the efficacy of DC101 after combination therapy with anti-PD-L1 and anti-VEGFA antibodies. The dose of 40 mg/kg/mouse of DC101 was administered intraperitoneally to mice twice a week. In a syngeneic model, DC101 was administered for 5 weeks sequentially after 2 weeks of combination therapy. Gene expression in tumor tissues was examined by microarray expression analysis. Protein expression in tumor tissues was determined by immunohistochemical staining, immunofluorescent staining, and multiplexed spatial proteomics. The identity of single cells in tumor tissue was defined by protein expression profiles from multiplex spatial proteomics **Results:** In a PDX model, DC101 significantly suppressed tumor growth with the inhibition of the proximity of AFP-positive human HCC cells and VEGFR2-positive mouse vascular endothelial cells. In addition, in a syngeneic mouse model, sequential DC101 treatment after combination therapy showed a significant anti-tumor effect. Analysis of gene and protein expression in tumor tissues revealed that DC101 significantly suppressed a stem cell marker EpCAM expression as well as the vascular endothelial marker. Interestingly, DC101 treatment reduced the number of CD8-T cells positive for PD-L1 and TIGIT in tumor tissues, which are immune checkpoint molecules associated with T-cell exhaustion. **Conclusion:** The anti-VEGFR2 antibody not only inhibits angiogenesis but also suppresses cancer stem cells and activates tumor immunity, and it might be effective in AFP-positive advanced HCC after ABC therapy.

4420-A | EFFICIENT ENGRAFTMENT, VIRAL TRANSDUCTION AND CORRECTION OF LIPID ACCUMULATION IN HUMAN HEPATOCYTES IN AN FRG RAT LIVER HUMANIZATION MODEL

Marisa Carbonaro and Zhe Li, Regeneron Pharmaceuticals

Background: Humanized liver models, in which the host liver parenchyma is replaced by human hepatocytes, have been increasingly used in drug development and disease research. In the leading humanized liver mouse model, Fumarylacetoacetate Hydrolase (Fah), Recombination Activating Gene (Rag)-2 and Interleukin-2 Receptor Gamma (Il2rg) genes are

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

inactivated simultaneously. Rag2/Il2rg KO results in immuno-suppression, while Fah KO leads to hepatoxicity, allowing for repopulation with FAH^+ human hepatocytes (HH). However, generation of similar recipient rats by inactivating multiple genes simultaneously in this species has been challenging. **Methods:** Using VelociGene and 1-cell-embryo-targeting technologies we generated an $Fah^{-/-}$, $Rag1/2^{-/-}$, $Il2rg^{-/-}$ (FRG) rat. FRG rats were maintained on NTBC to prevent Fah KO-induced toxicity. Liver damage in FRG rats upon NTBC withdrawal was validated by survival and hepatotoxicity studies and $Fah^{+/+}$ rat, mouse or human hepatocytes were used to rescue the lethal phenotype. Engraftment of HH in FRG rats was confirmed by serum ELISA of human proteins and liver IHC/ISH with human-specific hepatocyte markers. HH-specific gene delivery was achieved by viral transduction *in vivo* using AAV-NP59, or *in vitro* by lentiviral infection of primary human hepatocytes prior to engraftment. Moreover, to correct hepatosteatosis in the humanized liver rat model, we restored IL6 signaling through ectopic expression of rat IL6R via *ex vivo* lentiviral infection of HH, or *in vivo* AAV9-hIL6 dosing. **Results:** FRG rats could be highly engrafted with HH. Humanized liver rats expressed human proteins in the serum (hALB, etc.), had normal liver zonation and could be infected with the HH-specific AAV-NP59. We also developed methods to transduce primary human hepatocytes with lentivirus *ex vivo,* followed by efficient repopulation in the FRG rat. We found that rat IL6R expression restored IL6 signaling and resulted in a significant reduction in lipid accumulation. Finally, we showed that supplementing human IL6 reversed hepatosteatosis in the humanized rat liver. **Conclusion:** We have developed an FRG rat model in which rat livers can be repopulated with HH. Further, excessive lipid accumulation in engrafted HH, a major defect of the model, can be corrected by restoring IL6 signaling. Importantly, we developed approaches for gene delivery through viral transduction of HH, providing a novel platform to study liver disease and hepatocyte-targeted therapies.

4421-A | ESTABLISHMENT OF PRIMARY HEPATOCYTE METHODS TO EVALUATE THE BINDING AND ENDOCYTOSIS EFFICIENCY OF GALNAC CONJUGATES

Mengjie Wang, Xiaoting Du, Rui Li, Yunbo Wang, Zhengxian Gu and Qiong Zhou, Wuxi Apptec

Background: The development of oligo therapeutics is impaired by lack of efficient and specific delivery strategies. Significant progresses have been made by conjugating oligo to triantennary GalNAc (T-GalNAc) targeting ASGPR, which is contributed to the specific and abundant expression of ASGPR on hepatocytes. To expedite the development of oligo drugs, it is essential to assess the binding and endocytosis efficiency of GalNAc conjugates in cell-based assays. Towards this end, we established ex vivo assays of primary hepatocytes to assess and predict the hepatic delivery efficiency of GalNAc-oligo conjugates. **Methods:** Primary hepatocytes of human (PHH), mouse (PMH) and C. monkey (PCMH), as well as HepG2 cells were used for assessing the delivery efficiency of GalNAc-oligos. ASGPR protein and mRNA in PHH were assessed by immunofluorescence and RT-qPCR, respectively. Binding and uptake efficiency of GalNAc in hepatocytes were evaluated by direct (fluorescent labeled GalNAc) and competitive (unlabeled GalNAc) flow cytometry (FCM) methods. In the competitive FCM, Cy5 labeled GalNAc (EE-Cy5) was used as a competitor. GalNAc3 conjugated and free siRNAs were used to determine the GalNAc dependence of the endocytosis. To test the robustness of the assays, EE-Cy5 was tested at different concentrations in PHH, and T-GalNAc ligand L96 was tested in various cells. Furthermore, T-GalNAc, mono GalNAc and GalNAc3 conjugated molecules were tested to further validate the system. **Results:** ASGPR mRNA and protein were successfully detected in PHH by RT-qPCR and immunofluorescence, respectively. In the binding assay, EE-Cy5 had Vmax values of 14313 in PHH and 19879 in PMH, but only 1983 in HepG2 cells. The direct FCM analysis exhibited that EE-Cy5 was efficiently taken up by both PHH and HepG2 cells. GalNAc3-siRNA conjugates, but not free siRNAs, competitively inhibited the EE-Cy5 uptake, indicating the GalNAc dependence of the endocytosis. Furthermore, the competitive FCM assay with different concentrations of EE-Cy5 in PHH and L96in PHH, PCMH and HepG2 cells showed high performance with Z factor values of > 0.55. In addition, MonoGalNAc, T-GalNAc3 and GalNAc3 siRNA conjugates had inhibition of EE-Cy5 uptake and the assay showed high reproducibility. **Conclusion:** We have established a set of ex vivo assays to assess the binding and uptake efficiency of GalNAc conjugates in primary hepatocytes from various species, as well as HepG2 cells. We propose to apply the methods to assessment of delivery efficiency of GalNAc conjugates at the early stage to expedite the development of oligo drugs.

4422-A | HEPATOCELLULAR CARCINOMA PROGRESSION DUE TO INCREASED EMT THROUGH NOX2-MEDIATED SREBP2 STIMULATION IN HEPATOCYTES

Hei-Gwon Choi[1], Ha Neul Kim[1], Eun Hyuk Soo[2] and Soon Ok Kim[1], (1)Chungnam National University, (2) Chungnam National University Hospital

Background: Progression of hepatocellular carcinoma (HCC) is a disease caused by the transformation of hepatocytes into malignant cells, that is, the transformation of normal cells into cancer cells was involved various causes. To date, the effects of several NOX families on the development and occurrence of HCC have been studied. But Studies on the effects of NOX2 on HCC development are lacking. Therefore, we investigated the effects of NOX2 on hepatocarcinogenesis and development. **Methods:** Mouse HCC model Mouse HCC model genetically induced HCC using the Sleeping Beauty transposon system. To genetically induce HCC, HRASG12V was overexpressed and NOX2 and p53 were silenced in the liver. MOUSE treated with the Sleeping Beauty transposon system were sacrificed after 5 weeks. Patient sample Patient tissues were obtained from HCC patients who underwent surgery at Chungnam National University Hospital. **Results:** To investigate the effect of NOX2 activity on HepG2, NOX2 activity was induced by treatment with palmitate. As a result, NOX2 activity by palmitate treatment in HepG2 inhibited AMPK activity and induced SREBP2 activity. In addition, it was confirmed that this NOX2 activity mainly occurs in the membrane, not in the cytoplasm. Interestingly, NOX2 silencing reduced HCC trans-migration, whereas NOX2 overexpression increased HCC trans-migration. In this process, slug and N-cadherin, which are EMT signaling, are involved. In particular, it was confirmed that NOX2 has an association with slug. In addition, it was confirmed that SREBP2 is involved between NOX2 and EMT signaling, and that SREBP2 silencing leads to a decrease in slug as well as HCC trans-migration. Through this, we thought that the NOX2-EMT-SREBP2 pathway would induce the development of HCC, and to prove this, We decided to test the effect of NOX2 silencing on hepatocarcinogenesis in the MOUSE HCC model. As a result, NOX2 silencing significantly reduced the number and size of HCC in mouse HCC model. Moreover, in mice, intrahepatic NOX2 silencing resulted in decreased SREBP2 activity and EMT signailing in HCC tissue. It was confirmed that intrahepatic NOX2 silencing led to decreased generation and development of HCC. NOX2 expression in the patient's HCC did not correlate with the size of HCC, but showed a tendency toward reduced survival. And It was demonstrated that NOX2 expression in HCC was proportional to N-cadherin and slug expression through western blot and proportional to SREBP2 expression through qPCR. **Conclusion:** NOX2 regulates HCC migration by regulating EMT signaling through SREBP2. This suggests that NOX2 can be used as a new indicator for the severity of HCC as well as a new treatment target.

4423-A | IDENTIFICATION OF microRNAs INVOLVED IN RESISTANCE OF LENVATINIB UNDER HYPOXIA IN HEPATOCELLULAR CARCINOMA

Mari Satoh[1,2], Takayuki Kogure[2], Takehito Ito[3], Masanori Takahashi[2], Kensuke Usui[2], Kouji Okada[2] and Kennichi Satoh[2], (1)Tome City Toyosato Hospital, (2)Tohoku Medical and Pharmaceutical University, (3) Tohoku Medical and Pharmaceutical University Wakabayashi Hospital

Background: Among the multi-kinase inhibitors for the treatment of hepatocellular carcinoma (HCC), lenvatinib has shown a superior response rate. However, its overall survival is non-inferior to sorafenib, suggesting the acquisition of resistance during the treatment. Lenvatinib induces severe hypoxia in the tumor by inhibiting VEGF receptors, which could be the critical factor in resistance to multi-kinase inhibitors. We aimed to elucidate the mechanism of lenvatinib resistance under hypoxia in HCC. **Methods:** Human HCC cell lines were cultured in 95% air and 5% CO_2 (normoxia) or 94% N_2 with 1% O_2 and 5% CO_2 (hypoxia). Anchorage-dependent proliferation was assessed with an MTS assay. The genome-wide profiling of microRNAs and mRNAs was performed using 3D-Gene® Human miRNA Oligo chips or 3D-Gene® Human mRNA Oligo chips (Toray Industries) in HCC cells. HCC cells were electroporated with synthetic precursors of microRNAs to force the expression. **Results:** HCC cells, PLC/PRF/5, and Huh7 showed a marked increase of HIF1a protein with no significant change in the growth curve through 96 hours of culture in hypoxia. Lenvatinib inhibited cell growth in a concentration-dependent manner, and this effect was reduced under hypoxia with an IC_{50} (normoxia/hypoxia, μM) of 13.1/21.6 in PLC/PRF/5 and 22.7/25.0 in HepG2. 48 microRNAs were differentially expressed in PLC/PRF/5 treated with lenvatinib in the normoxic condition (42 increased and 6 decreased). Of the 42 microRNAs increased, 28 showed decreased expression in PLC/PRF/5 treated with lenvatinib under hypoxia. Among these, we focused on microRNA-491-5p (miR-491), which showed

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the most significant change in expression. Using the MTS assay, we examined whether forced expression of miR-491 restores the decreased cytotoxicity of lenvatinib on HCC cells under hypoxia. The viability of cells treated with lenvatinib (12.5 and 25 μM) under hypoxia was 79.8% and 58.2% with miR-491 forced expression, significantly lower than 90.2% and 75.9% with negative control, respectively. Similar results were observed in Huh7, Hep3B, and HepG2. The genome-wide profiling of mRNAs in HCC cells with miR-491 forced expression was performed to identify its targets. The 168 genes were commonly altered in PLC/PRF/5, Huh7, and HepG2, associated with RNA splicing, cell cycle, and cell adhesion. **Conclusion:** miR-491 is involved in hypoxia-induced lenvatinib resistance, and modulating its expression restores lenvatinib cytotoxicity partly. These observations identify microRNAs as a promising target to overcome lenvatinib resistance in HCC.

4424-A | INVITROGEN" VIVOFECTAMINE" LNP FORMULATIONS FOR SAFE AND EFFECTIVE LIVER-SPECIFIC IN VIVO GENE DELIVERY

Koshi Kunimoto, Neha Parayath, Virginia Sanabria Aragon, Ty Jaouni, Peter Lam, Arezki Boudif, Joel A Jessee, Genia Verovskaya and Jason Potter, Thermo Fisher Scientific

Background: The rapidly expanding use of gene products such as mRNA, siRNA, and gRNA as therapeutic tools has created a need for innovative and optimized delivery methods. Leveraging over 30 years of lipid-based delivery expertise and the Design of Experiments (DOE) approach, we developed lipid nanoparticles (LNPs) capable of efficiently delivering gene products specifically to the liver, lung, and spleen. Here, we report on our Vivofectamine™ LNP formulations that allow for organ-specific delivery to the liver as safe nanocarriers for gene products. Our LNPs are suitable for enzyme replacement, gene knockdown and genome editing applications (for research use only). **Methods and Results:** Lipid solutions were formulated with firefly luciferase mRNA and luciferase activity was visualized in mice 4 hours after intravenous injection. Our leading candidate liver LNP was 15000x more potent than its first-generation predecessor and has shown dose-dependent bioluminescence from luciferase activity. To understand cellular targeting in the liver, we utilized Ai14 Tomato reporter mouse model. After delivery of Cre mRNA-LNP complexation, targeted cells were visualized by cryosectioning and staining tissues with markers for cholangiocytes, sinusoidal cells, and Kupffer cells. Our results demonstrated that virtually all hepatocytes became tdTomato+ after delivery of 0.1 mg/kg mRNA-LNP dose. We further performed in vivo knockdown using Factor VII (FVII) siRNA. The siRNA knockdown efficiency reached over 95% at a 0.2mg/kg siRNA dose. Finally, we analyzed the efficiency of In vivo gene editing by delivering Cas9 mRNA and gRNA complexed with our lipids, and observed over 40% knockout of transthyretin (TTR) gene after a single injection. To understand the safety of our lipids, we analyzed changes in body weight, liver enzymes, serum cytokines, organ histology and hematological parameters. Our results confirmed that our LNP had low toxicity over a range of doses. **Conclusion:** Liver-specific Vivofectamine™ LNPs can efficiently achieve in vivo gene expression, knockdown, and knockout with good safety. Our Vivofectamine™ LNP Library aims to help our customers solve their nucleic acid delivery challenges by speeding up the translation from the bench to the clinic. Research Use Only.

4425-A | LIVERCELLPATH: A RESOURCE TO HELP EVALUATE HUMAN LIVER CELL LINES AS MODELS FOR HUMAN LIVER BIOLOGY

Brian D Halligan[1], Yue Chen[2], Antonino Oliveri[3], Maurice Tohme[1] and Elizabeth K. Speliotes[4], (1) University of Michigan School of Medicine, (2)University of Michigan, (3)University of Michigan, Ann Arbor, MI, (4)University of Michigan Medical School

Background: Primary hepatocytes are difficult to obtain and dedifferentiate quickly in cell culture making them challenging to use to model chronic liver disease. Human hepatocellular carcinoma (HCC) lines can be easily propagated but are often aneuploid and important genes or biological pathways of interest may not be expressed. We used RNAseq to measure gene expression and to determine exome genotypes from five different HCC lines and compared these to normal human primary heptocytes. We also determined exonic variation in these cell lines. We created a new software

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

application, CorrPaths, that reports gene expression and exonic variation across these cell lines to facilitate identifying cell lines suitable for modeling particular aspects of liver biology and diseases. **Methods:** RNAseq was performed on HepG2, HepG2-C3A, HuH-7, SNU-475 and THLE-1 cell lines and compared with RNAseq from six primary hepatocyte datasets from GEO. Gene expression levels for HCC lines were determined using TopHat and DESeq2 and compared to primary hepatocytes with CorrPaths. Exome sequences from HCC lines were mapped to reference human genome sequences using GATK. Some results were confirmed with Western blotting. **Results:** Examination of the Reactome XENOBIOTICS pathway (R-HSA-211981) shows that many of the P450 cytochromes expressed by primary hepatocytes (CYP2E1, CYP2C8, CYP2C9, CYP3A4, CYP2A6) are nearly completely absent in all cell lines. Analysis of the GLYCOGEN_SYNTHESIS pathway (R-HSA-3322077) shows that unlike primary hepatocytes and liver tissue, all cell lines express the muscle form of glycogen synthase (GYS1) rather than the liver form of glycogen synthase (GYS2). This result was confirmed by Western blotting of GYS1 and GYS2 in HuH-7 cells compared with liver tissue extracts. Genotyping HuH-7 and HepG2 shows that both HuH-7 and HepG2 cell lines are homozygous for the PNPLA3 SNP (rs738409; I148M) known to increase NAFLD making them good models for this disease. The liver specific output from CorrPaths, LiverCellPath, can be used online or offline. Its produces an Excel file that can be easily shared with other users, exported to HTML, and can be encrypted for use with sensitive data. **Conclusion:** Choosing the correct model biological system is critical for functional experimentation. Using LiverCellPath as an experimental design tool can guide users to chose a cell line suitable for their biology based on gene expression and exonic variation.

4426-A | LONG NON-CODING RNA DDX11-AS1 CONTRIBUTES TO HEPATOCELLULAR CARCINOMA PROGRESSION VIA ACTIVATING CARBONIC ANHYDRASE IX EXPRESSION AND THE MEK/ERK PATHWAY

Jin Sun[1,2], Yingnan Li[1,2], Mengjiao Shi[1,2], Hongwei Tian[1,2], Yanhua Mu[1,2], Jiazhen Zhu[1,2], Jun Li[1,2] and Zongfang Li[1,2], (1)National & Local Joint Engineering Research Center of Biodiagnositics and Biotherapy, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China., (2) Shaanxi Provincial Clinical Research Center for Liver and Spleen Diseases, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.

Background: The molecular mechanisms driving hepatocellular carcinoma (HCC) remain largely obscure. Long non-coding RNAs (lncRNAs) as critical factors play key roles in HCC progression. The aim of this study was to investigate the expression, roles, and mechanisms of action of the lncRNA DDX11-AS1 in HCC. **Methods:** The expression of DDX11-AS1 was determined by qRT-PCR. Subcellular distribution of DDX11-AS1 was detected by RNA-FISH. The roles of DDX11-AS1 in HCC was evaluated by performing in vitro and in vivo loss-of-function assays. The potential DDX11-AS1-controlled genes was identified by RNA-seq. The biological role of DDX11-AS1 in promoting HCC progression through its downstream gene CA9 was validated by rescue experiments. **Results:** DDX11-AS1 was elevated in several HCC cell lines as well as tissues. DDX11-AS1 was distributed both in the nucleus and the cytoplasm of HCC cells. Knockdown of DDX11-AS1 could significantly suppress cell proliferation, migration as well as invasion, and induce a cell cycle arrest and apoptosis in vitro. Tumor growth in subcutaneous mouse model was also inhibited by DDX11-AS1 knockdown. RNA-seq revealed that a total of 365 differentially expressed genes (DEGs) were screened out, including 211 up-regulated and 154 down-regulated genes, respectively. KEGG enrichment analysis and western blot validation demonstrated DDX11-AS1 could positively modulate the MEK/ERK pathway. In addition, rescue experiments showed that DDX11-AS1 could accelerate HCC progression via upregulating its downstream gene carbonic anhydrase IX (CA9). **Conclusion:** Long non-coding RNA DDX11-AS1 contributes to hepatocellular carcinoma progression via activating CA9 expression and the MEK/ERK pathway.

4427-A | MITOCHONDRIAL AND NUCLEAR GENOME-MATCHING HYPOTHESIS WITH RESPECT TO ATP SYNTHESIS DURING RAPID LIVER REGENERATION

Akira Tanaka, Kyoto, Japan

Background: 13 genes of ATP synthesis remain in mitochondria (MT), although ca 350 genes had moved to nucleus (NU). Complex I, III and IV of electron (e)

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transfer system coupled with proton (p) pumps yield membrane potential (MP) across MT inner membrane , while ATP synthetase convert ADP and Pi to ATP by p-translocation through p-channel using the gradient. MT assembly is performed in the phospholipid bilayer both by MT-gene-coded subunits which are transcripted in MT ribosome and by NU-gene-coded subunits which are trafficking and targeting from cytosol through the membrane to MT. During rapid hepatocyte regeneration, NU genome is duplicated by cell division cycle, while the number of MT is reduced by half due to cytosol heredity and then divide and proliferate independent of cell cycle. Therefore, MT and NU genome-matching is likely to affect MT ATP synthesis during rapid hepatocyte regeneration. We have reported the following results in isolated rabbit liver MT at 24 hours after 70% hepatectomy, kinetic study of MT oxidative phosphorylation, Mt content of cytochromes, phospholipid composition of MT membrane, inhibitor titration analysis, MP and voltage span between NADH and O2. **Methods:** To study conformational changes in e-transfer and p-translocation due to the MT and NU genome matching hypothesis, regarding e-transfer, e-current (I), V and e-resistance, regarding p-translocation, p-flow (JH+), MP and p-conductance (CMH+) were evaluated from previous studies. I and JH+ were calculated based on stoichiometry of O/e and ATP/p. E-resistance indicates biophysical characteristics of spatial position changes of e-transfer centers as Fe and Cu in the complexes independent of driving force.To elucidate the location of the conformational changes, location site of specific inhibitors and the inhibitory mechanisms of reduction of activating energy at each catalytic site were studied. **Results:** The decreased R of e-transfer by 31.4% and the increased CMH+ of p-translocation by 9.0% were found to accelerate ATP synthesis by 76.1% with changes in Km during regeneration. Biophysical changes in Complex I, III, IV and ATP synthetase were suggested by different patterns of inhibitor titration. **Conclusion:** These studies suggest that MT and NU genome-matching based on different genomic background facilitates ATP synthesis during liver regeneration and the conformational changes are likely to take place at the junction of these two type subunits.

4428-A | PFOA EXPOSURE RESULTS IN SEX-DEPENDENT EFFECTS ON HEPATIC AND WHOLE-BODY LIPID HOMEOSTASIS THAT DIFFER BY PPARA STATUS

Frederick Ekuban[1], Greylin Nielsen[2], Dibson Dibe Gondim[1], Wendy Heiger-Bernays[2], Thomas Webster[2], Matthew Cave[1,3] and Jennifer Schlezinger[2], (1) University of Louisville, Louisville, KY, (2)Boston University, (3)Robley Rex VAMC

Background: Per- and polyfluoroalkyl substances (PFAS) are a large group of persistent chemicals that have been released pervasively in the environment leading to widespread exposure for human populations. Studies on animals and humans indicate that the liver is a sensitive target organ for PFAS toxicity. Here, we test the hypothesis that the effects of perfluorooctanoic acid (PFOA) exposure in mice expressing mouse PPARα are characterized largely through PPARα-dependent mechanisms while the effects of non-PPARα dependent mechanisms will be more apparent in mice expressing hPPARα and to a greater extent in PPARα null mice. **Methods:** Female and male mPPARα, hPPARα, and PPARα null mice aged 6-7 weeks were placed on a American diet and exposed to PFOA at 0 or 3.4 μM via drinking water for 14 weeks. Exposure assessments, metabolic phenotyping, liver mRNA and histological analysis were conducted. **Results:** The mean serum PFOA concentration at the end of the study was 39 + 18 μg/mL. PFOA treatment led to reduced weight gain in male mPPAR-α and female hPPARα mice, while it did not affect male hPPARα and PPARα null mice nor female mPPARα and PPARα null mice. Furthermore, PFOA increased liver-to-body weight ratio, in all genotypes and both sexes, indicating that liver enlargement occurs at least partially through non-PPARα dependent mechanisms. Although hepatic triglycerides remained unchanged across all groups, serum and hepatic cholesterol concentrations were increased by PFOA treatment in a PPARα-dependent manner in female mice. In contrast, PFOA increased serum triglycerides in male hPPARα mice. In response to PFOA exposure, mPPARα mice showed a significantly reduced total steatosis in both sexes. PFOA did not change the extent of steatosis in hPPARα or PPARα null mice. Interestingly, female hPPARα mice exhibited a substantially lower levels of both basal and PFOA-induced steatosis compared to their male counterparts. PFOA increased mRNA expression of PPARα-target genes, *Pdk4* and *Acox*, in mPPARα mice; PFOA increased CAR and PXR target gene expression only in hPPARα mice. Additionally, *Cyp7a1*mRNA expression was downregulated in a PPARα-dependent manner. **Conclusion:** These findings indicate sex-specific effects of PFOA exposure on liver and whole-body lipid homeostasis, mediated in part via PPARα dependent mechanisms with important differences between mouse and human PPARα, and identifies hPPARa mice as a valuable in vivo model for toxicological research.

4429-A | PHYSOXIC STRESS OF HYPERAMMONEMIA IN LIVER DISEASE CAUSES SKELETAL MUSCLE MITOCHONDRIAL OXIDATIVE DYSFUNCTION AND SARCOPENIA

Nicole M. Welch[1], Saurabh Mishra[1], Annette Bellar[1], Mathew Luknis[1], Vandana Agrawal[1] and Srinivasan Dasarathy[2], (1)Cleveland Clinic, (2)Cleveland Clinic, Cleveland, OH, United States

Background: Sarcopenia (skeletal muscle loss) and physical frailty in liver disease are due to hyperammonemia-induced mitochondrial dysfunction. Skeletal muscle is a metabolic partner to hepatocytes in cirrhosis with increased uptake and metabolism of excess ammonia. Physoxic (physiological oxygenation without hypoxia) stabilizes hypoxia-inducible factor (Hif1α) during hyperammonemia. Integrated multiomics analyses with experimental validation in myotubes and muscle tissue with loss and gain of function show Hif1α- and ammonia-dependent and independent changes during physoxia. We identified Hif1α as a mediator of muscle mitochondrial dysfunction and sarcopenia in cirrhosis. **Methods:** Mice with/without *Hif1α* muscle specific deletion(*Hif1α*^{msd}) and wild-type(WT) or *Hif1α* knockout(*Hif1α*KO) murine myotubes were treated with/without ammonium acetate(AmAc, 10mM in myotubes, 2.5mmol/kg/d in mice delivered via implanted osmotic pump). Studies were done in differentiated murine C2C12 myotubes. CRISPR/Cas9 gene deletion was used to generate pools of *Hif1a*KO and WT cells. Colonies with *Hif1a*KO were selected by flow cytometry single cell sorting and expression validated by immunoblotting. Expression of HIF1a in *Hif1α*KO myoblasts were performed to replenish HIF1α. Mice with *Hif1α*^{msd} were generated by crossing *Hif1α*^{flox} mice with human skeletal actin mice with tamoxifen-inducible C*re* (JAX.org). Multiomics analyses included bulk RNAseq (with deconvolution for single nuclear analyses) and proteomics in myotubes(n = 3) and mouse skeletal muscle (n = 4-6). Readouts included protein expression by immunoblotting, free radical detection via flow cytometry quantification of %MitoSOX fluorescence (mitochondrial free radicals), ATP generation using fluorescence assay (Promega), and tricarboxylic acid (TCA) cycle intermediates by gas chromatography/mass spectrometry. **Results:** Most differences in mRNA expression in myotubes are explained by *Hif1α* presence/absence. Ammonia results in more differentially expressed genes in WT than in *Hif1α*KO cells (Fig1A). Cellular processes enriched in genes with increased expression in *Hif1α*KO+AmAc include complex I of the electron transport chain, cellular respiration, muscle contraction, muscle tissue development. Free radicals were lower and ATP content higher in AmAc-treated myotubes with *Hif1α*KO (vs.WT). Ammonia-induced lower ATP content did not occur with *Hif1α*KO (Fig1B). Lower TCA cycle intermediates (citrate, a-ketoglutarate) with AmAc did not occur with *Hif1α*KO. Protein synthesis is increased with deletion of *Hif1α* in cellular and tissue models and AmAc-induced decrease in skeletal muscle weight is reversed with *Hif1α*^{msd}. **Conclusion:** Hyperammonemia induced mitochondrial oxidative and intermediary metabolite abnormalities with impaired protein synthesis are mediated via HIF1α, a novel target for potential therapeutics to treat sarcopenia in cirrhosis.

4430-A | PI3K/AKT SIGNALING ON IMMUNE ESCAPE AND IMMUNE INFILTRATION IN HCC RECURRENCE

Chong Wa To[1], Soumita Ghosh[1], Xun Zhao[1], Elisa Pasini[2], Sandra Elisabeth Fischer[3], Elmar Jäckel[2], Anand Ghanekar[4], Gonzalo Sapisochin[1] and Mamatha Bhat[1], (1)University Health Network, (2)Ajmera Transplant Center, University of Toronto, Toronto, ON, Canada, (3)University of Toronto, (4)The Hospital for Sick Children

Background: Hepatocellular carcinoma (HCC) is a highly heterogeneous disease with complex mechanistic pathogenesis, which contributes to aggressive HCC recurrence. Additionally, the use of immunosuppressive medication is also considered a risk factor of HCC recurrence post-transplant. In this study, we aim to investigate the genetic evolution of HCC recurrence and the impact of immunosuppressive medication on recurrent HCC after transplantation. **Methods:** We analyzed the transcriptomic profiles of tumor samples from 12 pairs of patients with recurrent HCC. Of these patients, 7 underwent liver transplantation while 5 underwent liver resection. Only the transplant cohort received immunosuppressive medication. Functional enrichment and protein-protein interaction network analyses were performed. Top 10 hub genes were then screened and the pattern of immune infiltration in recurrent HCC tumors was also estimated. **Results:** PI3K/Akt signaling and cytokine-mediated signaling were found to play a significant role in HCC recurrence. The recurrent tumors exhibited not only upregulation of immune-escape genes, such as *CD274* and *CTLA4*, but also cytokine genes, such as *IL6* and *TNF*. Our results also showed significantly higher infiltration of activated mast cells in recurrent HCC tumors. In the transplant cohort, higher monocytes and lower M1 macrophages were infiltrated in the tumors. Furthermore, we suggested different potential drugs, such as Doxorubicin and LIN001-260, to target multiple hub genes. **Conclusion:** PI3K/Akt signaling potentially enhanced the expression of immune-escape genes and triggered cytokine secretion, leading to alterations in the immune cell infiltration pattern in HCC recurrence.

Disclosures: The following people have nothing to disclose: Chong Wa To, Soumita Ghosh, Xun Zhao, Elisa Pasini, Sandra Elisabeth Fischer, Elmar Jäckel, Anand Ghanekar, Gonzalo Sapisochin, Mamatha Bhat

f 4431-A | QUANTITATIVE PROTEOMICS REVEAL THE CLINICAL POTENTIAL OF AMINOACYL-tRNA SYNTHETASES IN AGGRESSIVE HEPATOCELLULAR CARCINOMA

Natalia Herman-Sanchez[1,2,3,4], Juan Luis López-Cánovas[1,2,3,4], Victor Amado[1,5,6], Javier M. Zamora-Olaya[1,5,6], Manuel Rodríguez-Perálvarez[1,5,6], Raúl M. Luque[1,2,3,4] and Manuel D. Gahete[1,2,3,4], (1) Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), 14004-Córdoba, Spain., (2) Department of Cell Biology, Physiology and Immunology, University of Córdoba, 14004-Córdoba, Spain., (3)Reina Sofía University Hospital (HURS), 14004-Córdoba, Spain., (4)Ciber Pathophysiology of Obesity and Nutrition (CIBERobn), Córdoba, Spain, (5) Department of Hepatology and Liver Transplantation, Reina Sofía University Hospital, 14004- Córdoba, Spain., (6)Ciber Hepatic and Digestive Diseases (CIBERehd), Córdoba, Spain

Background: Hepatocellular carcinoma (HCC) genetic and transcriptomic signatures have been widely described. However, its proteomic characterization, which might reveal functionally relevant and potentially targetable alterations, is scarce. Therefore, we performed non-targeted quantitative proteomics of HCC samples from different aetiologies. **Methods:** Cytosolic and nuclear proteome of tissues from HCC patients (n = 42; HCC vs. adjacent tissue) and healthy controls (n = 5) were determined by SWATH-MS-based proteomics. The alterations were confirmed in 7 *in silico* HCC cohorts. *In vitro* assays (proliferation, migration, colonies/tumorspheres) were performed in liver cancer cell lines (HepG2, Hep3B, SNU-387) after silencing and overexpressing *VARS1*. Untargeted proteomics were performed on VARS1-overexpressing Hep3B and SNU-387 cells. **Results:** Non-targeted proteomics revealed a profound dysregulation of the cytosolic (n = 507 proteins) and nuclear (n = 925 proteins) tumoral proteomes. This proteomic profile identified two patients subgroups, one of them with higher aggressiveness and with a profound dysregulation of the aminoacyl-tRNA synthetases (ARSs), which catalyse tRNA aminoacylation. Their dysregulation was corroborated in *in silico* HCC cohorts and associated with aggressive and metabolic features (i.e., survival, recurrence, obesity). GSEA confirmed that patients with upregulation of the ARSs machinery have genomic (i.e. *TP53* mutations) and transcriptomic characteristics of the proliferative HCC subclass. The valine tRNA-aminoacyl synthetase, VARS1, was consistently overexpressed in HCC

cohorts and associated with NASH-aetiology. VARS1 modulation had a slight impact on proliferation/migration although it significantly altered cells dedifferentiation capacity and the expression of mesenchymal and stemness-related markers. Untargeted quantitative proteomics and *in vitro* validations on Hep3B and SNU-387 cells overexpressing *VARS1* demonstrated a decreased expression of the scaffold protein *MAGI-1*, a known tumour suppressor in HCC. Thus, VARS1 might be exerting its role through the modulation of MAGI-1-mediated cell junctions. **Conclusion:** Our study demonstrates the dysregulation of the tRNA-aminoacylation machinery in aggressive HCC and the potential of these proteins, specially VARS1, as therapeutic targets in HCC. 4432-A | RONA-APOC3, AN INVESTIGATIONAL RNAi-MEDIATED APOLIPOPROTEIN C3 GENE SILENCING, DEMONSTRATES SIGNIFICANT EFFICACY AND GOOD SAFETY IN PRECLINICAL MODELS

Xujie LIU, Guoqing Cai, Guofeng Meng, Hongli Guo, Xiaoyan Yang, Xinxin Xu, Cong Huang, Junkai Liu, Hao Zou, Jinyu Huang, Jianwu Fang and Stella Shi, Rona Therapeutics

Background: Human genetic analysis has identified that individual's with loss-of-function mutations in apolipoprotein C3 (APOC3) have lower levels of serum triglycerides (TGs) and decreased risks of cardiovascular disease (CVD). APOC3 regulates circulating levels of TG and lipoprotein metabolism via lipoprotein lipase (LPL) -dependent and -independent pathways. Severe hypertriglyceridemia (SHTG) significantly increases risk of acute pancreatitis. Thus, reduction and maintenance of TGs levels can reduce the risks of acute pancreatitis and CVD in patients with SHTG. **Methods:** A highly potent and specific siRNA conjugate, RONA-APOC3, was designed with RAZOR™ platform to target human and non-human primate (NHP) APOC3 transcripts. Primary human hepatocytes (PHH) and Hep3B cells were employed to demonstrate knockdown efficiencies *in vitro*. Human APOC3 transgenic mouse models were used to evaluate pharmacodynamic effects on reductions of serum APOC3, TG and LDL-C levels *in vivo*. Toxicities and off-target risks were evaluated in PHHs and rats. **Results:** A series of *in vitro* and *in vivo* studies were performed to confirm the candidate sequences. The half-maximal inhibitory (IC_{50}) values of RONA-APOC3 were 0.0033nM and 0.0027nM in PHH and Hep3B, respectively. In hAPOC3 transgenic mice, RONA-APOC3 significantly reduced serum APOC3 protein by up to 95.2% and lowered TG by 94.1% in parallel following a single subcutaneous injection at 3 mg/kg. At Day 70 postdosing, APOC3 level was still 49.1% lower than the baseline and TG level was 38.6% lower in parallel. Bioinformatic analysis indicated that the off-target risk of RONA-APOC3 was relatively low. Non-clinical toxicity studies showed that RONA-APOC3 has a good safety profile in rodents. **Conclusion:** RONA-APOC3 is a hepatocyte-targeted RNA interference therapeutic designed to specifically silence hepatic APOC3 mRNA expression. A series of non-clinical studies demonstrated that RONA-APOC3 reduced serum APOC3 protein and TG level with good safety and tolerability. RONA-APOC3 is a potential therapeutic option for patients with SHTG.

4433-A | STABILIZATION OF O-GLCNACYLATION INCREASES EZH2 DIRECT TARGETS IN HEPATOCELLULAR CARCINOMA

Margot Thirion[1], Coline Kerbaj[1], Marie-Laure Plissonnier[1], Massimiliano Cocca[1], Vincenzo Alfano[1], Francesca Guerrieri[1], Claude Caron De Fromentel[1], Massimo Levrero[1,2] and Mirjam B. Zeisel[1], (1)Cancer Research Center of Lyon (CRCL), Umr Inserm 1052 Cnrs 5286 Mixte Clb, Université Lyon 1 (UCBL1), (2) Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France

Background: Enhancer of Zeste Homolog 2 (Ezh2) is frequently upregulated in hepatocellular carcinoma (HCC) tissues and increased Ezh2 expression correlates with HCC aggressiveness and/or poor prognosis. Ezh2 knockdown in HCC cells has been shown to reverse tumorigenicity in a nude mouse model, suggesting a potential therapeutic value of Ezh2 inhibition in HCC. The histone methyltransferase Ezh2 inhibitor tazemetostat has been FDA-approved for locally advanced or metastatic epithelioid sarcoma. However, this inhibitor demonstrated low efficacy in solid tumors suggesting that histone methyltransferase independent functions of EZH2 play an important role in cancer. As the catalytic subunit of PRC2, Ezh2 is responsible for H3K27 di- and trimethylation associated with gene repression. In additional to this canonical activity, Ezh2 can also activate gene transcription. Ezh2 activity is regulated by post-

translational modifications, including glycosylation by O-GlcNAc transferase (OGT). We have previously shown that OGT expression is increased in tumor tissues from HCC patients. Interestingly, it has been reported that OGT and Ezh2 co-repress a defined tumor suppressor genes in breast and colon cancer cells. The aim of our project is to assess whether OGT and EzH2 can regulate cancer-associated pathways in HCC and to determine the underlying molecular mechanisms. **Methods:** Ezh2 and OGT expression was analyzed in paired liver tumor and peri-tumor tissue samples derived from HCC patients. Ezh2 and OGT target genes were identified in human hepatoma cells following Ezh2 or OGT silencing using RNA-sequencing (RNA-seq) and chromatin immunoprecipitation followed by sequencing (ChIP-seq). The role of O-GlcNAcylation in Ezh2 chromatin recruitment was assessed using mutant Ezh2 and ChIP-qPCR. **Results:** We show that OGT and Ezh2 are upregulated in tumor tissues as compared to peri-tumor tissues in HCC patients from two different cohorts. RNA-seq and ChIP-seq analysis of human hepatoma cells indicate that OGT and Ezh2 co-modulate the expression of a significant number of genes, including genes involved in cell cycle and cancer pathways. While a set of co-regulated genes appears to be co-repressed by Ezh2 and OGT, our data suggest that Ezh2/OGT mostly promote gene expression in liver cancer. Interestingly, stabilization of O-GlcNAcylation increased the number of Ezh2 and Ezh2/OGT target genes and EZH2 O-GlcNAcylation plays a role in EZH2 recruitment to the promoter of defined HCC-relevant direct target genes. **Conclusion:** OGT and Ezh2 are two druggable targets that co-regulate cancer-related gene expression in transformed liver cells. Our data suggest that O-GlcNAcylation of Ezh2 and/or other co-factor(s) contributes to define the repertoire of Ezh2 targets in liver cancer and provide important insights for epigenetic strategies as potential future anti-HCC therapies.

4434-A | THE ROLE OF BETA-CATENIN IN REGULATING AUTOPHAGY DURING PORPHYRIA

Anu Balogun and Kari Nejak-Bowen, University of Pittsburgh

Background: The porphyrias are a group of metabolic disorders caused by inherited or acquired deficiency of any of the eight enzymes involved in heme biosynthesis, resulting in abnormal accumulation of heme precursors and their intermediates in organs such as the liver. Porphyrias are incurable, so novel therapies that have pleiotropic effects on disease progression would significantly improve patient quality of life. Because the liver is either a source or sink for accumulation of heme precursors, or porphyrins, we investigated the role of Wnt/beta-catenin signaling, a pathway that contributes to unique hepatic attributes such as zonation, autophagy, and metabolic regulation. Our earlier reports indicate that loss of hepatocyte beta-catenin protects mice from experimental porphyrin-induced liver injury. This was due to downregulation of key heme enzymes, fewer porphyrin-protein aggregates, and increased autophagy. In this study, we investigated the hypothesis that increased clearance was due to loss of glutamine synthetase (GS), a target of beta-catenin that regulates mTORC1 activation and thus autophagy. **Methods**: 3,5-Diethoxycarbonyl-1,4-dihydrocollidine (DDC), a xenobiotic compound that causes accumulation of porphyrin plugs in bile ducts, was fed to *Glul*$^{fl/fl}$ mice subjected to global Wnt inhibition using a PORCN inhibitor that blocks secretion of Wnt ligands, AAV8-Cre-mediated recombination to delete hepatic GS, or both. Half of these mice were also subjected to treatment with leupeptin to measure autophagic flux. Porphyrin accumulation, protein aggregation, autophagic vacuoles, mitochondria morphology, single cell spatial transcriptomics, mRNA expression, and mass-to-charge ratios of heme enzymes were assessed. **Results**: Our findings indicate that Cre-mediated deletion of GLUL (GS KO) or global Wnt inhibition results in defective GS activity in the liver. Phospho-mTOR-Serine2448, an indicator of active mTORC1 and autophagy in zone-3 hepatocytes, was decreased in both groups. A surplus amount of autophagic vacuoles engulfing defective mitochondria and porphyrin accumulates were observed via Transmission Electron Microscopy in GS KO as well as a decrease in heme biosynthesis and autophagy proteins. **Conclusion**: Inhibiting hepatic Wnt signaling results in lower levels of glutamine and mTOR activity, prompting an increase in autophagy that clears the accumulated porphyrin-protein complexes and helps alleviate porphyria (Figure 1). These observations collectively offer a novel opportunity to treat porphyria by targeting the Wnt/beta-catenin signaling pathway.

4435-A | THE USE OF GALNAC CONJUGATED siRNA IN HEPATOPAC MICROPATTERNED HEPATOCYTE CO-CULTURES TO ASSESS GENE KNOCKDOWN IN A LONG-TERM CULTURE MODEL

Karissa Cottier, Devika Bhalerao, Jeannemarie Gaffney and Scott Heyward, Bioivt

Background: Oligonucleotide therapeutics are an increasingly popular modality due to their high selectivity and relative safety compared to small molecules. For liver diseases, N-Acetylgalactosamine (GalNAc)- conjugation of siRNA is used to direct liver delivery by its strong affinity for the hepatocyte-specific asiaglycoprotein receptor (ASGPR). The continued successful development of GalNAc-siRNA therapeutics relies on the use of validated preclinical models for screening and optimization. Here we characterized the HEPATOPAC ® model, a micropatterned co-culture for long-term (at least 28 d) primary human hepatocyte culture for ASGPR expression, GalNAc siRNA uptake, and target knockdown over a period of 14 days. **Methods:** HEPATOPAC cultures using primary human hepatocytes (PHH) from four donors. 50nM of Cy-3 GalNAc-siRNA targeting GAPDH was added to the culture medium 24-hours prior to plate fixation or RNA collection on day 0 (day 1 for Cy3-GalNac siRNA), 4, 7, 10, and 14 of culture.. ASGPR1 expression, by immunostaining, and Cy3-GalNAc siRNA uptake were visualized and quantified using high content imaging (HCI). GAPDH mRNA expression was measured using RT-PCR from Cy3-GalNAc GAPDH siRNA or GalNAc scramble siRNA treatments . The mean knockdown, Cy3-GalNAc siRNA uptake, and surface ASGPR expression were paired by PHH lot and day of culture and a linear correlation was performed. **Results:** In all lots, maximal ASGPR expression and GalNAc siRNA uptake were observed at 4 hours post plating (Day 0). In two of the PHH lots, ASGPR expression and siRNA uptake were maintained from days 2-14 (~12% change from D2-D14), while in two other lots, levels steadily declined (~37% change from D2-D14). There was a significant linear correlation of ASGPR expression vs. Cy3-GalNAc siRNA uptake ($R^2 = 0.582$, $P < 0.0001$). Knockdown of GAPDH showed less variation between lots and over time compared to ASGPR expression and siRNA uptake(2-14% difference between day 2 and 14). Percent knockdown showed a significant correlation to both ASGPR expression ($R^2 = 0.206$, $P = 0.044$) and Cy-GalNAc siRNA uptake ($R^2 = 0.398$, $P = 0.003$). **Conclusion:** The HEPATOPAC model is a long-term culture system which maintains high levels of drug metabolizing enzymes, transporters, and urea and albumin formation. In this study, HEPATOPAC cultures maintain functional ASGPR1 expression and GalNAc siRNA uptake for at least 14 days of culture. In these studies, we found a strong correlation between ASGPR expression, GalNAc-siRNA uptake, and percent knockdown of target mRNA. Together, these data support the utility of the HEPATOPAC system to examine inter-individual variation and screen GalNAc siRNA uptake and resulting knockdown in longer-term studies.

4436-A | TRANSCRIPTIONAL REPRESSION OF POLARITY PROTEIN EXPRESSION IN HEPATOCELLULAR CARCINOMA

Saniya Davis, The Catholic University of America and Joeffrey Chahine, Medstar Georgetown

Background: Over 80% of human cancers originate from polarized epithelial cells. As the invasive phenotype is acquired, cells undergo an epithelial-mesenchymal transition (EMT) where apical-basolateral polarity is lost. The focus of our lab is to understand the mechanisms that regulate the establishment and maintenance of hepatic polarity. However, our interest has shifted to the mechanisms regulating polarity loss in hepatocellular carcinoma (HCC). Early stages of HCC are associated with chromosome 8q24 amplification and the overexpression of the potent oncogene, *c-Myc*. Myc not only activates other genes that promote oncogenesis, but also represses transcription factors responsible for polarity protein expression, including Miz1. EMT regulation by Zeb1 also promotes the loss of polarity protein expression while reinforcing c-Myc expression. Is this transcriptional regulation occurring in HCC? **Methods:** To establish this clinically, 150 resected human HCC samples were examined by immunohistochemistry. As proof of principle experiments to test for the polarity protein transcriptional regulatory loop, c-Myc, Miz1, Zeb1 and polarity protein levels are being examined in polarized hepatic WIF-B cells, and HCC-derived Hep3B cells in the presence or absence of agents that alter c-Myc, Miz1 or Zeb1 transcriptional activities. **Results:** No c-Myc or Zeb1 reactivity was observed in benign human tissue whereas nuclear staining was observed for both in malignant tissue whereas the opposite was observed

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

for Miz1 and polarity proteins. When quantitated across grades, Miz1 and polarity protein labeling decreased for all grades whereas c-Myc and Zeb1 peaked in stages 3 and 4. In polarized WIF-B cells, both c-Myc and Zeb1 were low whereas polarity protein and Miz1 levels were high. The opposite was seen in Hep3B cells. Myc activation led to Miz1 nuclear labeling in foci consistent with its repression. When c-Myc expression was decreased, Miz1 nuclear labeling was more diffuse, consistent with its activation. When Zeb1 expression was inhibited, cells regained a more polarized phenotype. **Conclusion:** We propose that during early-stage HCC, chromosome 8q24 is amplified leading to c-Myc overexpression. As HCC progresses, Myc expression is further enhanced leading to Miz1 transcriptional repression and decreased polarity protein expression. Concomitantly, Zeb1 expression increases to drive EMT also repressing polarity gene expression.

f 4437-A | ACTIVATION OF RECEPTOR-MEDIATED G12 SIGNALING HAS PRONOUNCED EFFECTS ON HEPATIC GLUCOSE FLUXES★

Srinivas Pittala[1], Dhanush Haspula[1], Yinghong Cui[1], Owen P McGuinness[2], Asuka Inoue[3] and Jurgen Wess[1], (1)Nih-Niddk, (2)Vanderbilt University Medical Center, (3)Tohoku University

Background: G protein coupled receptors (GPCRs) play a key role in regulating whole body glucose homeostasis. In the presence of agonist ligands, GPCRs can activate four distinct classes of heterotrimeric G proteins: Gs, Gi/o, Gq, and G12. At present, little is known about the metabolic consequences of GPCR-mediated activation of G proteins of the G12 family. **Methods:** The hepatocytes of the liver play a central role in maintaining euglycemia. To elucidate the vivo metabolic roles of hepatocyte G12 signaling, we generated a new mouse line that expresses a CNO-sensitive, G12-coupled designer GPCR (G12 DREADD; DREADD = designer receptor exclusively activated by a designer drug) selectively in hepatocytes (Hep-G12D mice). CNO is a synthetic small molecule that can selectively activate the G12 DREADD but is otherwise pharmacologically inert. In addition, we generated a mouse model that lacks functional Ga12 selectively in hepatocytes (Hep-G12 KO mice). These mutant mice were subjected to a series of metabolic tests to examine how activation of hepatic G12 signaling or hepatocyte G12 deficiency affect glucose tolerance, insulin sensitivity, in vivo glucose uptake, and various other metabolic parameters. **Results:** We found that selective activation of hepatocyte G12 signaling led to greatly enhanced blood glucose levels under both fed and fasting conditions. In vivo studies of hepatic glucose fluxes showed that these effects were due to an increased rate of glycogenolysis and gluconeogenesis. The G12D-mediated hyperglycemic effects were absent in mice lacking functional G12 in hepatocytes, indicating that the G12D designer receptor selectively activates G12. Studies with isolated hepatocytes prepared from Hep-G12D mice demonstrated that G12D-mediated glucose production required signaling via RhoA and ROCK1. We also showed that activation of endogenous sphingosine-1-phosphate receptors (subtype 1) stimulates hepatic glucose production via a similar pathway. **Conclusion:** In conclusion, our results show, for the first time, that hepatic G12 signaling plays a key role in regulating whole body glucose homeostasis.

f 4438-A | DELETION OF OGT IN HEPATOCYTES: A SPONTANEOUS MODEL OF ADVANCED LIVER FIBROSIS ASSOCIATED WITH REDUCTION OF FXR ACTIVITY

Lucia Parlati[1], Fadila Benhamed[1], Marion Regnier[1], Anne Muhr-Tailleux[2], Tarik Issad[1] and Catherine Postic[1], (1)Université Paris Cité, Institut Cochin, Cnrs, Inserm, Paris, France, (2)University De Lille, Inserm, CHU Lille, Institut Pasteur De Lille, Lille, France

Background: O-GlcNAcylation (O-GlcNAc) is a post-translational modification, controlled by two enzymes, OGT (O-GlcNAc transferase), which adds a molecule of N-AcetylGlucosamine to serine or threonine residues, and OGA (O-GlcNAcase), which eliminates it. Our data report that mice with a constitutive or inducible hepatocyte *Ogt* deletion have massive necroptosis, inflammation, and fibrosis (1). Farnesoid X receptor (FXR) is a transcription factor regulated by O-GlcNAcylation and its activation has hepatic anti-inflammatory and antifibrotic effects in patients with NASH (2). We explored whether the hepatic phenotype of mice with hepatocyte *Ogt* deletion was associated with the dysregulation of FXR activity. **Methods:** We analyzed liver histologies, cytolysis and cholestasis markers, the expression of genes involved in inflammation, oxidative and ER stress and FXR target genes in control mice (OGT^{LWT}) and mice with a constitutive (OGT^{LKO}) or inducible and selective deletion of hepatocyte *Ogt* (OGT^{INDLKO}) 8 weeks after birth or after hepatocyte *Ogt* deletion, respectively. We also studied serum bile acids (BA) in 8-week-old OGT^{LKO} mice. We used male and female mice. **Results:** We confirmed that, if compared to OGT^{LWT} mice, 8-week-old OGT^{LKO} mice and OGT^{INDLKO} mice 8 weeks after hepatocyte *Ogt* deletion have increased

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

markers of inflammation (*Tnfa*, *Mcp1, F4/80*) (Fig.1D, 1L), oxidative stress (*Nqo1, Nrf2, Gsta1, Gstm3*) (Fig. 1E, 1M), ER stress (CHOP) (Fig.1B,1J) and a severe hepatic phenotype with exacerbated proliferation and activation of hepatic stem cells, advanced liver fibrosis with regenerative nodules (Fig.1F, 1N) and increased transaminases and alkaline phosphatase (Fig. 1C,1K). Interestingly, OGT^{LKO} and OGT^{INDLKO} mice have a decreased expression of *Fxr* and its target genes (Fig. 1G, 1O) This was associated, in OGT^{LKO} mice, with a modification in serum BA profile: the vast majority of unconjugated BA were decreased in OGT^{LKO} mice, including TUDCA, which suppresses ER stress activation. Consistent with transcriptional analysis, the FXR antagonist named Tauro-conjugated β-muricholic acid was significantly increased in OGT^{LKO} mice, thus confirming the reduction in FXR activity in absence of hepatocyte *Ogt* (Fig.1H). **Conclusion:** Loss of hepatocyte *Ogt* results in a severe hepatic phenotype with inflammation and fibrosis that could be associated with a dysregulation of FXR activity. Modulation of FXR O-GlcNAcylation may be a therapeutic target in the treatment of chronic liver diseases.

f 4439-A | IL-17/Act1 SIGNALING REGULATES TNF/TNFRI RESPONSES IN HEPATOCYTES IN MICE WITH ALCOHOL ASSOCIATED LIVER DISEASE (AALD)

Raquel Weber[1], Vivian Zhang[1], Gen Yamamoto[2], Ju Youn Kim[3], Ji Young Kim[3], Na Li[4], Leon Lin[3], Michael Karin[3], David A. Brenner[5] and Tatiana Kisseleva[5], (1) University of California San Diego, (2)University of Kyoto, (3)UCSD, (4)The Ohio State University, Wexner Medical Center, (5)University of California, San Diego School of Medicine

Background: IL-17 signaling plays a key role in the development of steatosis, fibrosis, and HCC. The hepatocyte deletion of IL-17RA in AALD mice (IL-$17RA^{\Delta Hep}$) strongly decreased expression of TNF Receptor 1 (TNFR1), suppressed ER stress, *de novo* lipogenesis, fibrosis and HCC. Re-expression of TNFR1 in hepatocytes of AALD IL-$17RA^{\Delta Hep}$ mice failed to restore steatosis and fibrosis, indicating that IL-17 may regulate TNFR1 signaling in alcohol-injured hepatocytes. Recent studies show that nuclear factor-kappa-B activator 1 (Act1) mediates IL-17 signaling by binding IL-17RA, and activating NFkB via TNF receptor Associated Factor 6 (TRAF6) ubiquitination. Act1 also phosphorylates IKK to stabilize mRNAs of IL-17 target genes. We hypothesize that IL-17RA/Act1 axis regulates key responses in alcohol-injured hepatocytes and we aim to identify the mechanism by which IL-17RA/Act1 coordinates TNF signaling and ER stress in hepatocytes in AALD. **Methods:** DEN-challenged IL-$17RA^{\Delta Hep}$ mice were infected with hepatocyte-specific AAV8-TBG-GFP-control or AAV8-TBG-TNFR1 and fed with HFD+EtOH for 18 weeks. Hepatic levels of Act1, TRAF6 and IKK were quantified. To translate our findings, primary human hepatocytes were transfected with dsi-IL-17RA, dsi-Act1 or dsi-control RNA; the hepatocytes were stimulated with IL-17A ± TNF, and the expression of IL-17A and TNF target genes/proteins were evaluated. **Results:** The expression of Act1 was decreased in livers of HFD+EtOH-fed IL-$17RA^{\Delta Hep}$ mice. As a result of Act1 downregulation, expression of Act1 targets, pIKK and TRAF6, were also reduced. Hepatic re-expression of TNFR1 did not restore TNF/TNFR1-mediated responses or the loss of Act1 phenotype in AALD IL-$17RA^{\Delta Hep}$ mice, indicating that IL-17RA/Act1 signaling is upstream of TNF signaling. Remarkably, all three transmembrane ER stress sensors (PERK, ATF6 and IRE1α) were suppressed in IL-$17RA^{\Delta Hep}$ hepatocytes, indicating that IL-17RA/Act1 is a key mediator of ER stress in AALD. In human primary hepatocytes transfected with dsi-IL-17RA stimulated with IL-17A ± TNF, the nuclear translocation of Act1 was also impaired, as shown by confocal microscopy. In support, knockdown of Act1 in human primary hepatocytes resulted in downregulation of IL-6, Cxcl1 and TNF mRNA and suppression of ER stress and lipogenesis. **Conclusion:** IL-17RA/Act1 signaling mediates TNF responses and ER stress in AALD. Targeted inhibition of IL-17RA/Act1 axis in steatotic hepatocytes may provide a new strategy to treat AALD and HCC.

4440-A | INHIBITION OF PREGNANE-X RECEPTOR SIGNALING IMPROVES OBESITY BY SUPPRESSING ADIPOGENESIS AND INDUCING ADIPOSE TISSUE BROWNING GENES IN FEMALE MICE

Lidya H. Gebreyesus[1], Sora Choi[2], Malvin Ofosu-Boateng[1], Elizabeth Twum[1], Daniel Okuwdili Nnamani[1], Frank J. Gonzalez[3] and Maxwell Gyamfi[1], (1)The University of Tennessee Health Science Center, (2) North Carolina Central University, (3)National Cancer Institute

Background: Obesity is more prevalent in women and increases after menopause and thus poses a significant health risk. However, the underlying mechanisms of sexual dimorphic obesity remain poorly understood. Adipose tissue plays a crucial role in energy homeostasis and metabolic regulation, with the browning of white adipose tissue (WAT) emerging as a potential therapeutic target for combating obesity. Pregnane X receptor (PXR) is a nuclear receptor that detoxifies drugs and xenobiotics in the liver and intestine. Recent reports indicate that PXR regulates lipid and glucose metabolism and contributes to diet and drug-induced obesity. Interestingly, the interplay between the liver and white adipose tissue has been implicated in the pathogenesis of obesity. We hypothesized that PXR promotes severe obesity and inflammation in menopausal females by modulating adipogenesis and thermogenesis genes in white and brown adipose tissues (BAT). **Methods:** Eight-week-old female C57BL/6J wild-type and *Pxr*-null mice were subjected to either control (12% fat) or HFD (45%) for 52 weeks. A comprehensive study involved weekly assessments of body weight, food intake, glucose tolerance tests, serum analysis, gene and protein expression, and RNA sequencing. **Results:** After 52 weeks, the body weight (70.2 ± 3.7g vs 47.6 ± 3.1g, $P < 0.0001$), perigonadal WAT (9.12 ± 0.15 vs 3.76 ± 0.15, $P < 0.0001$), and BAT (0.87 ± 0.28 vs. 0.35 ± 0.32, $P < 0.01$) of the HFD-fed wild-type mice were significantly higher than the HFD-fed *Pxr*-null mice. Serum leptin (2-fold) and insulin (5-fold) levels were also increased in HFD-fed wild-type female mice. WAT adipogenesis genes such as aldo-keto reductase family 1 member B8 (*Akr1b8*) (3-fold), uncoupling protein 2 (*Ucp2*) (2-fold), and inflammatory genes, interleukin-1 receptor-associated kinase 4 (*Irak4*) (1.5-fold) were increased in HFD-fed female wild-type mice. In contrast, female *Pxr*-null mice were resistant to these changes. Similarly, RNA-seq showed that inflammatory and obesity-associated genes were only differentially upregulated in HFD-fed wild-type mice. Parallel to this, the basal levels of BAT genes, Cbp/p300-interacting transactivator 1 (*Cited1*), uncoupling protein 1 (*Ucp1*), and zinc finger protein ZIC 1 (*Zic1*) were increased in *Pxr*-null mice but not in wild-type mice. **Conclusion:** PXR deletion suppressed obesity and inflammatory genes in WAT and induced browning genes in female mice. These findings highlight the intricate interplay between PXR and metabolic processes, offering insights into the potential for PXR as a therapeutic target for obesity and inflammation-related disorders in females.

4441-A | MyD88-DEPENDENT, RHBG-INDEPENDENT SIGNALING RESPONSE RESULTS IN MITOCHONDRIAL DYSFUNCTION AND SENESCENCE IN SKELETAL MUSCLE DURING HYPERAMMONEMIA

Saurabh Mishra[1], Nicole M. Welch[1], Annette Bellar[1], Shashi S. Singh[2], Avinash Kumar[3] and Srinivasan Dasarathy[4], (1)Cleveland Clinic, (2)Case Western Reserve University, (3)All India Institutes of Medical Sciences, (4)Cleveland Clinic, Cleveland, OH, United States

Background: We have noted that Rh family B glycoprotein(RhBG), an ammonia transporter protein, interacts with Myeloid differentiation primary response 88 (MyD88), an innate immune signal transduction adaptor to initiate downstream signaling responses to activate the p65FkB-myostatin axis and cause sarcopenia in liver disease.. We dissected the molecular mechanism(s) of hyperammonemia induced mitochondrial oxidative dysfunction and post mitotic senescence. **Methods:** Differentiated murine C2C12 myotubes with knockout (KO) of RhBG or MyD88 were generated using CRISPR/Cas9. Physiological relevance was established in 8 week old, male and female C57Bl6 mice with floxed or muscle specific deletion (msd) of RhBG or MyD88. Myotubes were either untreated (UnT) or treated with 10mM ammonium acetate(AmAc) for

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

24h. Hyperammonemia was induced in mice by an osmotic pump that delivered either 2.5mmol/kg/d of AmAc or vehicle alone (PBS) for 4 weeks. Mitochondrial oxidative function was analyzed using high resolution respirometry. ATP content, free radicals (FR), and lipid peroxidation (thiobarbituric acid reactive substances-TBARS) were analyzed fluorometrically. Expression of proteins in the electron transport chain (ETC), carbonylated proteins, and senescence markers (p16, p21, p53, senescence associated β-galactosidase-SABG) was measured by immunoblotting. All data are expressed as mean ± SD from at least 3 biological replicates for cells and at least 6 mice in each group. **Results:** Hyperammonemia impairs mitochondrial oxidation (complexes I,III, and IV responses to substrates and inhibitors) including fatty acid oxidation (FAO) in wild type (WT) myotubes and muscle tissue from mice with $RhBG^{flox/flox}$ or $MYD88^{flox/flox}$ that are reversed by MYD88KO but not RhBGKO in both myotubes and muscle tissue. Expression of NDUFB8 expression is less with ammonia that is reversed by MYD88 not RhBG deletion. Mitochondrial FR generation, lipid peroxidation, and protein carbonylation are significantly less with MyD88KO (vs. WT) in myotuhbes and skeletal muscle from $MYD88^{msd}$ (vs. $MYD88^{flox/flox}$) mice but not with RhBGKO. Hyperammonemia induced perturbations in response to mitochondrial oxidative dysfunction are reversed by MYD88 KO but not RhBGKO. Expression of senescence markers are significantly less with MyD88KO and deletion of MYD88 (but not RhBGKO) reversed ammonia-induced skeletal muscle post-mitotic senescence. **Conclusion:** MyD88 deletion but not RhBG, the ammonia-transceptor *in-vivo* and *in vitro* increases mitochondrial respiration and fatty acid oxidation and reverses hyperammonemia induced mitochondrial oxidative dysfunction. Consistently, deletion of MYD88 but not RhBG, reversed oxidative stress and post-mitotic senescence in skeletal muscle. Ammonia induced perturbations in mitochondrial oxidative function and senescence are mediated via an RhBG independent, MYD88 dependent mechanism.

f 4442-A | NUCLEAR LOCALIZATION OF ACYL-CoA THIOESTERASE 12 PROTECTS AGAINST HEPATIC STEATOSIS BY REDUCING PPARG ACETYLATION

Mariana Acuna[1], Xu Xu[2], Haiyue He[3], Lay-Hong Ang[2], Akiko Sugiyama[1], Susan J. Hagen[2] and David E Cohen[1], (1)Brigham and Women's Hospital, Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3) Xiangya Hospital of Central South University

Background: Acetyl-CoA is a substrate for both lipid synthesis and protein acetylation. Acyl-CoA thioesterase 12 (Acot12), the enzyme that hydrolyzes acetyl-CoA into acetate in liver cytosol, comprises two tandem thioesterase (THIO) domains and a C-terminal lipid-binding START domain. We have reported that Acot12 protects against hepatic steatosis by selectively down-regulating the transcription of glycerolipid biosynthetic genes, which are targets of PPARg. Because PPARg is activated by acetylation, the aim of this study was to determine whether Acot12 translocates to the nucleus where it could hydrolyze acetyl-CoA and thereby reduce acetylation of nuclear proteins that control gene transcription. **Methods:** Acot12 expression in cytosolic and nuclear fractions of alpha mouse liver 12 (AML12) cells and of livers from C57BL/6J mice was determined by immunoblot analysis and by immunofluorescence. Localization of Acot12 was also assessed in Hepa1-6 cells transfected with constructs comprising eGFP-tagged full length Acot12, the THIO (Acot12ΔSTART) or the START (Acot12ΔTHIO) domain. Transfected cells were treated with leptomycin B (LMB) to inhibit nuclear efflux. Chow fed *Acot12*$^{-/-}$ and wild type mice were subjected to 6 h fasting. PPARg expression was determined by qPCR and immunoblot analysis. Protein acetylation was determined by immunoblot analysis using an acetyl-lysine antibody. Acetylation of PPARg was determined following immunoprecipitation. **Results:** Acot12 was mainly expressed in the cytosolic fraction but was also clearly identified in the nuclei of both cells and liver tissues. Nuclear localization was observed following transfection with Acot12ΔTHIO, but not full length or Acot12ΔSTART, and was more pronounced with LMB treatment. This was in keeping with the presence of a nuclear localization sequence within the START domain identified by amino acid sequence analysis. Whereas no differences in protein acetylation were observed in whole liver lysates from

Acot12$^{-/-}$ mice, acetylation of multiple proteins were observed in nuclear fractions, including PPARg. **Conclusion:** Acot12 in liver exhibits nuclear localization that is mediated by the lipid-binding START domain. We speculate that Acot12 within the nucleus selectively reduces protein acetylation by limiting the local availability of acetyl-CoA. Acot12-mediated decreases in PPARg acetylation protect against hepatic steatosis by limiting the expression of glycerolipid biosynthetic genes.

4443-A | THE RNA BINDING PROTEIN Zfp36l1 MAINTAINS LIVER HOMEOSTASIS AND PROTECTS MICE FROM LIVER INJURY BY MODULATING Jag1/NOTCH PATHWAY

Rajesh Kumar Dutta[1], Seh-Hoon Oh[1], Kuo Du[2], Matthew B. Friedersdorf[1], Jack D. Keene[1], Perry J. Blackshear[3] and Anna Mae Diehl[1], (1)Duke University, (2)Duke University, Durham, NC, (3)National Institute of Environmental Health Sciences

Background: Liver injury triggers both de-differentiation of hepatocytes into ductal cells and differentiation of ductal cells into hepatocytes. Restoring liver homeostasis is crucial for preventing liver disease progression. ZFP36L1, a member of the ZFP36 family of RNA-binding proteins interacts with AU-rich elements found in the 3' untranslated region (UTR) of mRNA molecules, thereby modulating the expression of target genes. Hepatocyte Zfp36l1 has been implicated in the regulation of bile acid metabolism, a critical function of mature hepatocytes. We investigated the impact of L1 deficiency on liver homeostasis and its role in the development of liver diseases. **Methods:** Zfp36l1 fl/fl (L1 fl/fl) and liver-specific (albumin-Cre) zfp36l1 knockout (L1 KO) mice were subjected to models of alcoholic and nonalcoholic liver injury. We used standard biochemical and histological methods to compare liver injury and inflammation in L1 fl/fl and KO mice, and RNA seq analysis to compare gene expression in L1 KO and L1 fl/fl hepatocytes. Findings in mice were compared to liver RNA seq data from humans with fatty liver diseases. **Results:** L1 expression was significantly reduced in human nonalcoholic steatohepatitis (NASH) and severe alcohol-associated hepatitis (SAH). Hepatic expression of L1 was also decreased in mice with fatty liver injury. Depleting zfp36l1 in hepatocytes promoted ductal cell accumulation and significantly exacerbated inflammation and fibrosis in mouse models of alcoholic and non-alcoholic liver disease. Gene Ontogeny analysis of RNAseq data showed that the most significantly upregulated pathways in zfp36l1-KO hepatocytes control development and differentiation. L1 KO hepatocytes and AML12 cells with siRNA-mediated knockdown of L1 exhibited Notch pathway activation, while L1 overexpression downregulated Notch signaling, suggesting that the phenotype of L1 KO mice might be due to upregulation of some gene that is directly targeted by L1. We found that L1 directly interacts with the 3'UTR of the Notch ligand Jag1 and attenuates its expression, explaining how L1KO activates Notch L1 signaling. **Conclusion:** Hepatocytes require Zfp36l1 to limit Jag1 expression and constrain Notch signaling in order to maintain their mature phenotype.

4444-A | UNRAVELING THE ROLE OF HEPATOCYTE PPAR GAMMA IN PRE-CLINICAL MODELS OF NASH WITH OBESITY AND INSULIN RESISTANCE.

Marta Sierra Cruz, Samuel Man Lee, Jose Muratalla, Izabela M Hawro and Jose Cordoba-Chacon, University of Illinois at Chicago

Background: Non-alcoholic steatohepatitis (NASH) is positively associated with obesity, insulin resistance, and the expression of hepatic peroxisome proliferator-activated receptor γ (PPARγ) in mice and humans. The induction of human-like NASH with obesity and insulin resistance in mice with diets is yet challenging. Furthermore, the pathogenic role of PPARγ in hepatocytes in models of NASH remains controversial. **Methods:** To refine our model of NASH and to assess the role of hepatocyte PPARγ in NASH, control and hepatocyte-specific PPARγ knockout ($Pparg^{\Delta Hep}$) were generated in mice with pre-established diet-induced obesity (DIO, 16 weeks of high fat diet, 60% Kcal from fat diet). These mice were then fed for 8 weeks with: (1) HFCF diet: 45% Kcal from fat (trans-fat), 2% cholesterol and 22% fructose; or (2) HFC+Fr diet: 60% Kcal from fat and 2% cholesterol, plus 10% fructose in drinking water. Another cohort of adult male and female control and $Pparg^{\Delta Hep}$ mice was fed a HFC+Fr diet for 24 weeks. **Results:** In DIO mice, HFCF, but not HFC+Fr diet, reduced adiposity and insulin levels. However, both diets increased liver weight and promoted NASH. These results suggested that HFC+Fr diet may evoke a more robust model of human-like NASH with obesity and insulin resistance. Interestingly, $Pparg^{\Delta Hep}$ reduced steatosis in DIO mice, and the progression of NASH and fibrosis in HFC+Fr-fed mice. In a separate cohort of mice, HFC+Fr diet promoted severe obesity: 54.88 ± 3.75g (males) and 45.49 ± 7.42g (females), and insulin resistance. However, NASH was developed only in HFC+Fr-fed male mice. A RNAseq analysis revealed that HFC+Fr diet increased the expression of genes involved in fibrosis and inflammation in the liver of male mice. Interestingly, $Pparg^{\Delta Hep}$ reduced liver weight, plasma ALT, hepatic triglyceride accumulation, and liver fibrosis in HFC+Fr-fed male mice, without reducing adiposity or insulin resistance. Also, $Pparg^{\Delta Hep}$ reduced the expression of genes associated with fibrosis and inflammation. In addition, the expression of genes involved in amino acid and steroids metabolism were increased in $Pparg^{\Delta Hep}$ mice which may prevent NASH development and improve liver health. **Conclusion:** The composition of NASH-inducing diets is essential to reproduce human-like NASH with obesity and insulin resistance in mice. Furthermore, hepatocyte PPARγ activity is associated with the downregulation of genes involved in amino acid and steroid metabolism that might impact the development of fibrosis and inflammation.

4445-A | ZINC FINGER PROTEIN 791 IS A NOVEL TARGET FOR INTERFERON-MEDIATED SUPPRESSION OF LIVER CANCER INITIATION

Jin Lee, University of California San Diego and Gen-Sheng Feng, University of California, San Diego

Background: The poor survival of most hepatocellular carcinoma (HCC) patients is due to: a) lack of effective diagnostic biomarkers for early stages of HCC; and b) no intervention strategy available for HCC at early stages, although it is considered as a promising option to cure HCC. While dissecting roles of cytoplasmic signaling molecules in hepatocarcinogenesis using the Mx1-cre inducible mouse gene targeting system, we identified a potent liver tumor-inhibitory effect of poly-inosinic-polycytidylic acid (polyIC), a synthetic dsRNA used to induce the *Mx1-cre* system. Injection of polyIC at the pre-cancer stage robustly suppressed HCC by eliciting multiple innate immune functions in the liver. We performed RNA-seq analysis in several mouse models following injection of polyIC to search for molecules that are possibly involved in the anti-HCC activity of the synthetic dsRNA. Interestingly, bioinformatic data analysis showed only one gene whose expression was severely suppressed by polyIC in all liver samples, i.e. a zinc finger protein (Zfp)791. Zfp791 was preferentially expressed in zone 3 hepatocytes and its expression was aberrantly increased in tumors driven by oncogenic β-catenin. Zfp791 in hepatocytes was severely suppressed in β-catenin-deficient liver but was re-appeared following exogenous expression of oncogenic β-catenin. We hypothesized that Zfp791 might operate by interacting with β-catenin in cancer cells and will be a target molecule in polyIC-mediated prevention of HCC initiation at the early HCC stage. **Methods**: This study utilized hydrodynamic tail vein injection of oncogenes (β-catenin/MET) and Zfp791-specific CRISPR/Cas9 into mice to investigate a pro-oncogenic role of Zfp791. To interrogate the mechanism of Zfp791 regulation by β-catenin, Chip-seq was conducted in cancer cell lines bearing either wild-type or oncogenic mutant β-catenin. Immunofluorescence,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Western blot and qRT-PCR were used to elucidate the role of Zfp791 in Wnt/β-catenin signaling. To elucidate the underlying molecular and cellular mechanisms, we used co-culture system and chemical-induced interferon (IFN)-1 receptor knockout mice. **Results**: We identified Zfp791 as a critical player in β-catenin signaling in pericentral hepatocytes. Loss of Zfp791 suppressed β-catenin-driven hepato-oncogenesis in mice, and elevated Zfp791 expression was detected in human HCCs with *CTNNB1* mutations in association with poor prognosis. polyIC-mediated inhibition of the Zfp791/β-catenin axis was alleviated in IFN-1 receptor knockout mice and IFNs suppressed Zfp791 and β-catenin expression. Clinical data analysis revealed downregulation of Zfp791 and β-catenin signature genes in livers of IFN-treated patients with hepatitis B or C viruses. **Conclusion**: Taken together, Zfp791 could be utilized as a biomarker for HCC at the early stage and may also a new therapeutic target of IFN therapy for a subset of HCC patients with β-catenin mutations.

4446-A | HETEROGENOUS PERIBILIARY GLANDS ORCHESTRATE COMPARTMENTALIZED EPITHELIAL RENEWAL

Serrena Singh[1], Tifanny Budiman[1], Makoto Taketo[2], Benjamin Simons[3] and Vikas Gupta[1], (1)Yale School of Medicine, New Haven, CT, (2)Kyoto University, (3) Gurdon Institute

Background: The largest branches of the biliary tree have complex glandular elements connecting to a surface epithelium. It is unknown whether a stem cell compartment is responsible for biliary epithelial renewal. We aimed to determine how epithelial renewal was organized in the large extrahepatic bile duct in a mouse model. **Methods:** Non-biased clonal lineage tracing was combined with 3-dimensional imaging to trace the fates of epithelial clones over 1.5 years. Single cell sequencing was used to transcriptomically define epithelial subpopulations, which were spatially delineated. Biased lineage tracing targeting the pit and base of the peribiliary glands was employed and quantitatively analyzed. Genetic β-catenin gain of function was used to modulate cellular identity. **Results:** We show that cholangiocytes within the pits of the peribiliary glands have higher rates of proliferation than the rest of the gland. Marker free clonal lineage tracing displayed that peribiliary pits renewed the biliary surface epithelium whereas basally localized cells contributed to maintenance of the base and body of the gland in large complex glands. This contrasted that of the minority of superficial glands, which showed base derived clones contributing to surface epithelial renewal. Lineage tracing directed at peribiliary pits displayed accelerated labeling kinetics of the surface epithelium whereas basally directed lineage tracing confirmed that cells remained within the gland of large complex glands. Single-cell sequencing with trajectory analysis identified transcriptomic gradients across the gland with Olfm4, Aqp5, and Muc6 enriched within the base of the gland. However, all cholangiocytes within the large ducts displayed marked plasticity, changing cellular identity upon fasting and refeeding. β-catenin gain of function caused expansion of the Muc6+ population and gain of gastric chief cell makers Troy and Pgc. **Conclusion:** Together, these results define how the interplay between renewal and plasticity support the maintenance and remodeling of the bile duct in response to demand and has implications for understanding the development of biliary carcinogenesis.

4447-A | INTERACTION BETWEEN MESENCHYMAL STEM CELLS AND LIVER SINUSOIDAL ENDOTHELIAL CELLS ACTIVATES HEPATIC PROGENITOR CELLS

Han Seul Ki, Soon Koo Baik and Moon Young Kim, Yonsei University Wonju College of Medicine

Background: The hepatic progenitor cell (HPC) is an innate stem cell in the liver and the main cell in liver regeneration. Induce that the proliferation and regenerative activity of HPC is the main issue in the liver regeneration field. Liver sinusoidal cells (LSECs) inactivation and stabilization are essential in accelerating the regression of fibrosis and inhibiting the progression of cirrhosis. LSEC also has been known to activate HPC through the Wnt-β-catenin signaling. However, the method to stabilize LSECs is not yet established. Therefore, we investigated the functional recovery of LSECs through mesenchymal stem cells (MSCs) and whether it can induce HPCs activation. **Methods:** To evaluate the

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

stabilization of LSEC by MSC, the recovery of fenestrae of LSECs was confirmed by Scanning Electron Microscope (SEM) after co-culture. Changes in various factors affecting the stabilization of LSEC were also confirmed by real-time polymerase chain reaction and Western blot. The specific cell markers of the isolated mouse LSECs and MSCs were confirmed by FACS. In addition, HPCs were cultured using the culture soup obtained by co-culture of LSECs and MSCs, and the activities of HPCs were analyzed. **Results:** In human-derived MSC and LSCE co-culture, LSEC showed recovery of fenestrae with increased expression of VEGF, eNOS, HGF, Wnt2, and Wnt9b in LSEC compared with control. Also, when LSECs and MSCs isolated from mice were co-cultured, the expression of VEGF and HGF, which play an important role in maintaining the morphology of LSEC, increased. The expression of Wnt9b, which acts as an angiocrine factor in liver regeneration, was also increased. In the culture of HPC, when the soup obtained from LSEC during LSEC and MSC co-culture was added, an increase in HPC activity was observed compared to the control group. The proliferation of stem progenitor cells was doubled in both 24 and 48 hours compared to the control group. Also, the expression of VEGF and Wnt2 increased in HPC at 24 hours, and the expressions of HGF, VEGF, and Wnt9b increased at 48 hours. **Conclusion:** MSC showed the property that can induce stabilization (undifferentiated) LSEC. Stabilized and functionally recovered LSEC by MSC also induced the proliferation and increased the activity of HPCs and which suggests a possibility that MSC-based recovery of LSEC in hepatic fibrosis can be helpful in the promotion of liver regeneration through HPC activation.

f 4448-A | MODELING HEPATO-HEMATOPOIETIC DEVELOPMENT IN FETAL LIVER ORGANOIDS FROM HUMAN PLURIPOTENT STEM CELLS★

Milad Rezvani[1,2,3], Kyle Lewis[3], Susanna Quach[1], Kentaro Iwasawa[3], Julian Weihs[1], Hasan Al Rezva[3] and Takanori Takebe[3,4,5,6,7], (1)Charité Universitätsmedizin Berlin, (2)Berlin Institute of Health (Center for Regenerative Therapies, Clinician-Scientist Program), Beijing, China, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Center for Stem Cell & Organoid Medicine (CuSTOM), Cincinnati Children's Hospital Medical Center, (5)Division of Developmental Biology, Cincinnati Children's Hospital Medical Center, (6)Institute of Research, Tokyo Medical and Dental University, (7)Osaka University

Background: The fetal liver is a hematopoietic organ during development, harboring a highly heterogenous lympho-hematopoietic population. To better understand the blood-liver niche during inaccessible stages of human development, a model is required to recapitulate, probe and manipulate this dynamic microenvironment. Human liver organoids from pluripotent stem cells (PSC) recapitulate early embryogenesis yet lack the interplay between hepatic and hematopoietic ontogeny. **Methods:** We developed human fetal liver-like organoids (FLOs) endowed with a Notch-permissive niche, allowing for the concomitant emergence of endoderm-derived hepatoblasts, mesoderm-derived hemogenic endothelial cells and hematopoietic progenitors with broad myeloid, erythroid, lymphoid differentiation potential. We inferred differentiation trajectories and functional crosstalk through a comprehensive workflow involving longitudinal single-cell RNA-Sequencing, integration into the human fetal liver atlas, spatial analysis of highly multiplexed immunofluorescence and mechanistic validation via FACS-based lineage depletion. To model the divergence into heterogenous immune lineages, including neutrophil granulocytes and macrophages, we generated highly hematopoietic FLOs (hFLOs) by adding a small molecule-cytokine cocktail (UM171/IL3/IL34/GM-CSF). We assessed immunoreactive functions and hepatobiliary injury in response to bacterial, lipotoxic and cholangiotoxic milieus. **Results:** Trajectory analysis from FLOs to hFLOs revealed the emergence of 21 hematopoietic populations from 24 found in the human fetal liver atlas while maintaining hepatoblasts and fetal liver mesenchyme. Crosstalk between hepatoblasts and endothelium dominated the cellular niche interactions, mainly via Notch signaling. We found that EPCAM+ hepatoblastsand

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

KDR+ endothelium, but not NCAM+ mesenchyme were essential in maintaining hematopoietic output. We confirmed hepatobiliary and hematopoietic capacity via differentiation into AFP+ALB+ fetal hepatocytes with cytochrome activity, CK19+ luminal-forming cholangiocytes, erythro-myeloid colony formation and lymphoid differentiation into fetal B1-cells. Upon infection of hFLOs with bacteria or exposure to palmitic acid, we observed effective phagocytosis by macrophages and neutrophil granulocytes and a neutrophil-predominant steatohepatitis-like reaction, respectively—while exposure to biliatresone dysregulated morphogenesis to multiple lumina in a ductular-like reaction. **Conclusion:** Our data support the concept of intrinsic liver organoid capacity for hematopoietic development. FLOs serve as a tractable tool to model the blood-liver niche in human ontogeny and the multicellular response to various injury triggers.

4449-A | TRAINED IMMUNITY CONTRIBUTES TO IMMUNOREGULATION IN HUMAN BONE MARROW MESENCHYMAL STEM CELLS

Bingqi Li[1], Xi Liang[2], Jing Jiang[1], Jiaojiao Xin[1], Dongyan Shi[1], Lulu He[1], Jinjin Luo[1], Shiwen Ma[1], Hui Yang[1], Xingping Zhou[1], Jiaxian Chen[1] and Jun Li[1], (1) The First Affiliated Hospital, Zhejiang University School of Medicine, (2)Taizhou Central Hospital (Taizhou University Hospital)

Background: The immunoregulation function of human bone marrow mesenchymal stem cells (hBMSCs) plays an important role in the treatment of cytokine storm in severe liver diseases. However, the complex immune microenvironment in vivo challenges the survival and function of hBMSCs. Trained immunity has been proved to improve the adaptability of immune cells and therapeutic effect. This study aims to enhance the immunoregulation function of hBMSCs by trained immunity to optimize stem cell therapy strategies. **Methods:** Trained immunity of hBMSCs (T-hBMSCs) were performed with pro-inflammatory cytokines IFN-γ and TNF-α as "trainers" to induce hBMSCs for 24 hours, the untrained-hBMSCs (UT-hBMSCs) were performed with medium as control. Then same dosage "trainers" or patient serum derived from acute-on-chronic liver failure (ACLF) were used to assess the function of hBMSCs after 48 hours cleaning. Culture supernatant and cell samples were collected to perform flowcytometry, qRT-PCR and transcriptome analysis. **Results:** The surface markers of T-hBMSCs detected by flowcytometry were positive for CD73, CD166 and CD90, but negative for CD45, CD34 and CD79a, which was consist with UT-hBMSCs. Trilineages differentiation of hBMSCs after training was also maintained. The results showed that the pro-inflammatory genes (IL-1β, IL-6 and IL-8, all $p < 0.0001$) and immunosuppressive genes (PDL-1 and IDO, both $p < 0.0001$) expressed in T-hBMSCs were all higher than UT-hBMSCs. After 48 hours cleaning, the expression of immunomodulatory genes especially IDO still significantly higher with the expression levels of inflammatory genes especially IL-1β in T-hBMSCs gradually returned to the baseline state. The results showed that the expression of IDO was significantly elevated in T-hBMSCs compared to UT-hBMSCs upon the same dosage "trainers" or ACLF patient-derived serum restimulation (5-fold vs. 4606-fold, both $p < 0.0001$). Gene set enrichment analysis revealed that trained immunity activated the NF-kB signaling pathway related to innate immune and further induced JAK-STAT pathway in T-hBMSCs causing an increase in IDO expression. The higher expression level of IDO inhibited the proliferation and activation of T lymphocytes, resulting from the enhanced immunoregulation function of T-hBMSCs. **Conclusion:** Trained immunity enhances the immunoregulation function of hBMSCs and contributes to optimize the stem cell therapy strategies, indicating the potential of T-hBMSCs for future clinical applications.

Swathi Kari[1], Arielle Klepper[3], Catherine Magee[1], Miranda E. Surjadi[1], Jennifer Y. Chen[1], Jacquelyn J. Maher[3], Mandana Khalili[1], Miles Conrad[1], Michael Ohliger[1], James Grenert[1], Bruce M. Wang[4], D. Montgomery Bissell[5], Sandy Feng[1], Marcial Sebode[6], Jennifer C. Price[1], Emily J. Rothbaum Perito[3], Michele M. Tana[1] and Jameson Wu[7], (1)University of California, San Francisco, (2)Chan Zuckerberg Biohub, (3) University of California, San Francisco, San Francisco, CA, (4)University of California San Francisco Medical Center, (5)University of California, San Francisco, Berkeley, CA, (6)University Medical Center Hamburg-Eppendorf, Hamburg, Germany, (7)University of Pittsburgh

Background: AIH disproportionately affects women and Black, Indigenous, and People of Color (BIPOC). Latinx patients with AIH more frequently have cirrhosis at presentation. Prior studies have linked age of presentation with progression to cirrhosis and decompensation events. *Aims*: To assess the clinical presentation, treatment response, and clinical outcomes in prospectively followed AIH patients. **Methods:** Clinical data from AIH patients within Prospective Observational Study to Understand Liver Diseases (POSULD) were analyzed with a focus on age, disease activity (transaminases, IgG), fibrosis stage at presentation; treatment response after $>=6$ months of therapy; and fibrosis progression (biopsy or elastography). **Results:** Of 54 patients with AIH enrolled 2018-2023, 78% were female, 53% were Latinx, 47% non-Latinx white, 7% Black, and 9% Asian American. Among Latinx patients, 54% were born in Mexico, and 42% in Central America. Median age at presentation of AIH in Latinx patients was 53y (range 17-79) vs. 64y (range 45-79) in non-Latinx patients ($p=0.0001$). Thirty-seven (69%) patients were Type 1. A drug/toxin was suspected as a trigger in 4%. On index biopsy ($n=54$), 13% also had PBC, and 11% NAFLD. Six (20%) of the Latinx pts had cirrhosis at presentation, compared to 1 (3.4%) in non-Latinx patients ($p=0.39$). AST, ALT, and IgG value at enrollment and after 6-12 months of therapy were not significantly different in the Latinx vs. non-Latinx AIH patients. Fatigue at enrollment was similar in both groups (3.00 vs. 2.95, scale 0-4, $p=0.81$). Of 16 Latinx and 7 non-Latinx AIH pts with serial fibrosis assessments, 3 Latinx had fibrosis progression, compared to 0 non-Latinx patients ($p=0.67$). 6% of patients died or decompensated during follow-up (5 Latinx, 3 non-Latinx). **Conclusion:** Latinx patients with AIH are, on average, significantly younger at diagnosis. Longer follow-up will determine if these patients are more likely to develop cirrhosis and experience decompensation.

4501-C | AZATHIOPRINE ON RISK OF EXTRAHEPATIC MALIGNANCY IN PATIENTS WITH AUTOIMMUNE HEPATITIS: A NATIONWIDE CLAIMS STUDY IN SOUTH KOREA

Sung Hwan Yoo, Jung Il Lee and Hyun Woong Lee, Gangnam Severance Hospital

Background: Long-term immunosuppressive therapy in patients with autoimmune hepatitis (AIH) increases the risk of extrahepatic malignancy in addition to hepatocellular carcinoma. However, the risk of extrahepatic malignancy is unknown in Korean AIH patients. We aimed to evaluate the impact of azathioprine (AZT) treatment on extrahepatic malignancy risks. **Methods:** We identified all persons diagnosed with AIH between 2008 and 2020. We included 8,280 patients with AIH, using the national claims data of the Health Insurance Review and Assessment Service (HIRA). The numbers of patients treated with and without AZT were 3,059 and 5,221, respectively. We estimated the cumulative risks of extrahepatic malignancy and hazard ratios (HRs) between patients treated with and without AZT. **Results:** Among 8,280 patients, the mean age was 56.7 ± 13.5 years, 84.3% were women, and the follow-up period was 49.8 ± 43.1 months. The mean age and sex are not different between patients treated with and without AZT. However, the number of patients with diabetes was higher in patients treated with AZT (31.3% vs. 28.0%). The number of patients with liver cirrhosis was higher in patients treated without AZT (36.0% vs. 38.9%). At the time of diagnosis, 85.5% of patients with AZT and 30.0% of patients without AZT were treated with steroids for more than 90 days (P < 0.001). The incidence of extrahepatic malignancy was 1.36 and 1.23 per 100 person-years in the patients treated with AZT and without AZT, respectively (P = 0.685). After we adjusted for confounding by age, sex, diabetes, and liver cirrhosis, the HR was 1.09 (95% confidence interval 0.79–1.51, P = 0.600). **Conclusion:** The national claims data of HIRA did not show that AZT significantly increases the risk of extrahepatic malignancy among AIH patients.

Table 2 Cancer risks for patients with AZT and without AZT in AIH

4502-C | BIOMARKER DISCOVERY IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Claire Harrington[1], Swathi Krishnan[2], Scott Roberts[2], Allison Carroll[1], Paolo Cravedi[3], Neil Kelleher[1], James L. Boyer[2], Marina G. Silveira[2], Eleonora Forte[1], David N. Assis[2] and Josh Levitsky[1], (1)Northwestern University Feinberg School of Medicine, (2)Yale School of Medicine, New Haven, CT, (3)Icahn School of Medicine at Mount Sinai, New York, NY

Background: Autoimmune hepatitis (AIH) is a rare disease characterized by a loss of immunological tolerance and persistent hepatic immunoreactivity requiring immunosuppressive therapy (IST). Novel biomarkers are needed to better understand AIH pathogenesis, predict patients at high risk for relapse, and assess suitability for IST withdrawal. The study aim is to investigate candidate blood biomarkers of AIH activity vs. quiescence to eventually guide and personalize IST management. **Methods:** Blood samples from 38 patients were collected and segregated into three groups: active AIH at liver biopsy (AD) (n = 11), AIH with complete biochemical response on IST for > 1 year (RT) (n = 16), and AIH with complete biochemical response off IST for > 1 year (NRT) (n = 11) from two liver centers.

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Healthy controls (n = 5) from a biorepository were also included. Between the groups, we compared results from a large discovery panel of 92 plasma inflammatory markers (OLINK) as well as targeted candidate biomarkers (Sandwich ELISA) identified from prior studies (Harrington et al, *Hepatology* 2022). **Results:** The mean AIH cohort age was 55.6 yo, 82.2% female, and 71.1% Caucasian. The AD group had significantly higher levels of BAFF, CDCP1, and CXCL11 vs. all other groups. AD also had a higher ferritin, sCD74 and sCD74/MIF ratio vs. the RT group. Compared to healthy controls, the NRT group had higher levels of MCP-3, CCL3, and IL-10RB and the RT group higher levels of MCP-3, CCL3, and CCL19. Interestingly, the NRT group (off IST) had higher ferritin levels and sCD74/MIF ratio vs. the RT group (*Figure 1*), despite both having normal liver enzymes and IgG levels. **Conclusion:** Our study reveals several inflammatory biomarkers associated with active vs. biochemically quiescent AIH, supporting their potential use for detecting immunoactivity. In addition, the biomarker differences between inactive AIH vs. healthy controls and, importantly, inactive AIH on vs. off IST suggest a potential role to detect immunoactivity despite normal liver tests, which may be useful when considering IST withdrawal. We are currently performing detailed PBMC immunophenotyping and proteomic analyses to identify additional biomarkers, to be presented subsequently. Further validation of these biomarkers is needed to elucidate their clinical utility above currently available tests.

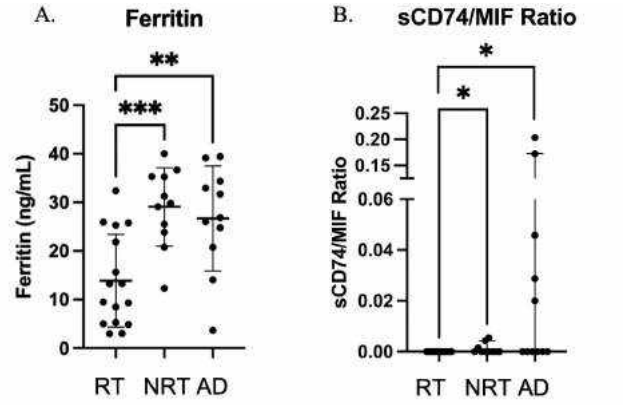

Figure 1: Using ELISA, analysis resulted in a significant finding of higher ferritin (A) and sCD74/MIF ratio (B) in the NRT group compared to the RT group.
RT (stable on IS >1 yr), NRT (stable off IS >1 yr), AD (active AIH)

4503-C | CAN LMS (LIVER MULTISCAN) BE AN ALTERNATIVE TO LIVER HISTOLOGY IN MANAGING ADULT AIH?

Abdullah Mubarak[1], Sai Priya Metla[1], Mahnoor Fatima[1], Caleb Keng[1], James Gray[1] and Liver Center of Texas, (1)Liver Center of Texas

Background: Autoimmune hepatitis (AIH) is a chronic liver disease caused by an abnormal immune response targeting the liver cells, leading to ongoing inflammation and potential liver fibrosis. While immunosuppressive therapy remains the primary treatment for AIH, monitoring disease progression and response to treatment is crucial. Liver enzymes and CBC are done routinely to monitor patients for response to treatment, relapse or flares of autoimmune hepatitis. Liver biopsy remains the mainstay to assess remission, relapse or flare of autoimmune liver disease. Unfortunately, Liver biopsy is invasive and apart from biochemical evaluation, Liver Multi Scan (LMS) can be used as an alternative to evaluate autoimmune hepatitis. **Methods:** 3 patients from our database with a diagnosis of Autoimmune liver disease who had LMS were analyzed for this study. Laboratory data, LMS (cT1), and index liver biopsy findings were reviewed. **Results:** Index liver biopsy of all three subjects were reviewed and two of them had findings consistent with autoimmune hepatitis and one had features of autoimmune cholangiopathy. All the subjects were on anti-inflammatory therapy with prednisone (one was switched from Budesonide to prednisone) along with Azathioprine (2 subjects) and Cellcept. All of the subjects were followed quarterly to biannually with close monitoring of her liver enzymes and CBC for any bone marrow suppression. The average duration of immunosuppression was 60 months (AIC), 48 months (AIH) and 12 months (AIH). All of their liver function tests were normal for > 6 months and patients were interested in dose reduction or withdrawal of therapy. Liver biopsy was suggested but two subjects wanted an alternative method to assess liver inflammation LMS scan was done as an alternative to liver biopsy to determine liver inflammation using cT1 scores. Their average cT1 score was 836 (Table 1). **Conclusion:** Biochemical and histological resolution is required to stop treatment for patients with AIH. All patients showed biochemical resolution and LMS was used to determine indirect histological resolution. Ct1 values < 875 are considered a benchmark in NASH patients as marker of reduced liver inflammation. While further research is needed and larger volume of patients need to be

analyzed, LMS is a non-invasive and cost-effective tool to utilize for evaluating treatment response and optimizing therapeutic strategies in AIH management.

4504-C | CHILDREN WITH AIH RECEIVING STANDARD-OF-CARE THERAPY DEMONSTRATE LONG-TERM EXCESS WEIGHT GAIN AND OBESITY: AN UNDER-RECOGNIZED COMPLICATION OF PEDIATRIC AIH THERAPY

Or Steg Saban[1], Syeda Aiman Fatima[1], Shannon M. Vandriel[2], Amrita Mundh[1], Vicky Lee Ng[3], Simon C. Ling[3], Robert H.J. Bandsma[3] and Binita M. Kamath[4], (1) The Hospital for Sick Children, Toronto, (2)The Hospital for Sick Children and the University of Toronto, (3) Division of Gastroenterology, Hepatology and Nutrition, the Hospital for Sick Children, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada

Background: The management of autoimmune hepatitis (AIH) can be challenging, given the need for chronic therapy with potential side effects. Standard-of-care (SOC) treatment in children includes induction with Prednisone 1-2mg/kg daily, combined with Azathioprine. In patients responsive to SOC, the dose of Prednisone is gradually reduced over 6 months to ≤5-10mg daily. There are limited data showing reduction in height in patients treated with high-dose prednisone, but no literature available about growth in SOC AIH treatment. We aimed to test the hypothesis that children with AIH on SOC treatment have altered growth trajectories. **Methods:** Children newly diagnosed with AIH 2000-2022 in a single tertiary center had weight and height measurements every 6 months for 2 years, then yearly for up to 5 years and Z-scores were calculated. Patients were excluded if not treated with SOC treatment or if < 1 year of follow-up. Chi-squared test was applied to obesity prevalence. Wilcoxon signed-rank tests were used to compare Z-scores for weight, height, and BMI at baseline (before therapy) and 1 and 2 years (after therapy). **Results:** 43 patients (65% females, median age at diagnosis 10.4 years, IQR 7.5-13.4) were included and followed for a median of 4 years (IQR 3-5). 91% of the patients had AIH type 1. The median Z-scores for baseline weight, height, and BMI were 0.3, 0.3, and 0.4, respectively. 1 year after treatment, Z-scores for weight (1.0, $p < 0.01$) and BMI (1.4, $p < 0.01$) increased substantially. 2 years after treatment, Z-scores for weight and BMI remained significantly elevated ($p < 0.01$ and ($p < 0.01$). The prevalence of obesity *increased* significantly between baseline and Year 1 (4.6% vs. 32.6%, $p < 0.01$) and remained significant in Year 2 (35.1%, $p < 0.01$). 10 patients (23.2%) had excessive weight gain (increase of ≥1.0 SD in BMI Z- score) after 1 year of treatment, and 8 patients (21.6%) had excessive weight gain after 2 years. No patients had new-onset short stature (height z- score ≤ -2), but 7 patients (16.2%) had new-onset growth delay (a decrease of ≥1.0 in height Z-score) during follow-up. **Conclusion:** It is well-established that excessive steroid exposure is associated with weight gain. This study demonstrates that children with AIH receiving SOC treatment demonstrate long-term excess weight gain and obesity. These data indicate the need to re-evaluate treatment algorithms for pediatric AIH in terms of steroid dosing and potential non-steroid alternatives.

4505-C | GLUCOSE METABOLISM REPROGRAMMING OF NEUTROPHILS IN AUTOIMMUNE HEPATITIS

Chen Huang and Li Yang, West China Hospital, Sichuan University

Background: Autoimmune hepatitis (AIH) is an inflammatory liver disease caused by immune homeostasis imbalance. Neutrophils participate in

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the pathogenesis of autoimmune disorders through neutrophil extracellular traps (NETs), degranulation, and cytokine production. Enhanced glycolysis promotes neutrophil activation, thereby leading to autoimmune disorders. However, there are limited studies reporting the function of neutrophils and the effect of neutrophil metabolic reprogramming in AIH. The aim of this study was to examine alterations in neutrophil numbers and functions in AIH while exploring associations between dysregulated neutrophils and glucose metabolism. **Methods:** Neutrophil frequency and functions were detected in AIH patients and healthy controls (HCs). Hepatic infiltration of neutrophils in AIH patients was evaluated by immunohistochemistry. Activation markers in circulating neutrophils and serum levels of MPO were assessed. In Con A-induced immune hepatitis, a Ly6G neutralizing antibody was administered to deplete neutrophils. Moreover, this study collected circulating neutrophils from AIH patients and HCs for RNA sequencing. In addition, the parameters related to glucose metabolism were assessed in PMA-treated neutrophils. Finally, the effect of the glycolytic inhibitor 2-DG on neutrophils was investigated in vitro. **Results:** The frequency of CD66b+/MPO+ neutrophils was increased in liver biopsies of AIH patients. The mRNA levels of activation markers were elevated in circulating neutrophils of AIH patients. AIH patients also had higher MPO serum levels than HCs. Moreover, NET formation was increased in liver tissues and circulating neutrophils of AIH patients. Ly6G neutralizing antibody treatment resulted in depletion of neutrophils, which was confirmed by flow cytometry. Notably, neutrophil depletion alleviated liver apoptosis and necrosis in Con A-induced immune hepatitis, suggesting a pathogenic role of neutrophils in AIH. Moreover, RNA sequencing indicated downregulation of the oxidative phosphorylation (OXPHOS) pathway in circulating neutrophils of AIH patients. Altered expression was confirmed by qPCR. After PMA stimulation, glucose uptake and lactic acid production were enhanced in primary human neutrophils. In addition, the expression of key glycolytic genes was increased in PMA-induced neutrophils. 2-DG reduced PMA-induced NETs in vitro. **Conclusion:** Neutrophils accumulated in the livers of AIH. Circulating neutrophils from AIH patients exhibited an activation phenotype, enhanced glycolysis, and reduced OXPHOS compared with those from HCs. Neutrophil depletion alleviated Con A-induced immune hepatitis, suggesting a pathogenic role of neutrophils in AIH. Glucose metabolism reprogramming in neutrophils may promote their activation, thus leading to immune disorders in AIH. Inhibiting glycolysis may reverse neutrophil dysfunction in AIH patients.

f 4506-C | HIGH BURDEN OF UNMET NEEDS IN PATIENTS WITH AUTOIMMUNE HEPATITIS IS EXACERBATED BY LOW SOCIOECONOMIC STATUS

Carolyn Haugh[1], Emma Jones[2], Kelsey Green[1], Brittany Baker[1], Naga P. Chalasani[3], Craig Lammert[1] and Lauren D. Nephew[4], (1)Indiana University School of Medicine, (2)University of Indianapolis, (3)Indiana University Medical Center, Indianapolis, IN, (4)Indiana University

Background: Diminished quality of life has been well characterized in autoimmune hepatitis (AIH) patients, however the full spectrum of unmet needs in this population is not fully known. We hypothesized that there is a high burden of unmet needs in patients with autoimmune hepatitis and this burden differs by socioeconomic status (SES). **Methods:** Online community members of the Autoimmune Hepatitis Association were invited to complete a modified 50-item

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

version of the SLE Patient Needs Questionnaire (SLENQ), a validated tool that evaluates unmet need across seven domains: physical, daily living, psychological/spiritual, health services, health information, social support and employment/financial. Demographic data, fibrosis severity, and country of residence were captured. Low-SES was defined as annual household income < 30k per year, education level less than high school, or report of moderate-high concern for lack of reliable transportation, food, or housing in the last year. Multivariable logistic regression was used to evaluate the association between unmet needs and SES. **Results:** There were 397 participants; 87.8% identified as female, 16.4% of lived outside the USA, and 26.2% were classified as low-SES. 44.3% of participants reported a moderate-high burden of unmet needs related to gaining information about treatment and side-effects. There was a significant difference in all seven physical needs questions between low-SES and moderate-high SES participants (all p-values < 0.05). Participants within the low-SES group also reported higher prevalence of unmet needs regarding healthcare providers taking them seriously (p = 0.005), addressing financial concerns (p < 0.0001), and coping with changes in their sexual relationships (p = 0.029). On multivariable logistic regression, controlling for race, gender, fibrosis stage, and USA residence, participants within the low-SES group had a higher odds of reporting unmet needs in fatigue (OR 6.73, 95% CI 1.50-30.23), depression (OR 2.87, 95% CI 1.33-6.22), health care staff sensitivity (OR 3.35, 95% CI 1.61-6.95), and lack of opportunity to speak with other people with AIH (OR 5.67, 95% CI 1/61-19.88) than those in the moderate-high-SES group. **Conclusion:** There is high burden of unmet needs in all patients with AIH that is exacerbated by low-SES. These data can help inform interventions to improve health service delivery, treatment options, and the mental health care of patients with AIH.

4507-C | IDENTIFYING PATHOGENIC CELL POPULATIONS WITH GENETIC VARIANT PREDISPOSITION IN PRIMARY SCLEROSING CHOLANGITIS THROUGH SINGLE-CELL MULTIOME PROFILING

Zi Yang, Ramesh Kudira, Joseph Wayman, Xiaoting Chen, Anthony Bejjani, Leah Kottyan, Matthew Weirauch, Lee A. Denson, Alexander G. Miethke and Emily Miraldi, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background: Primary sclerosing cholangitis (PSC) is a slowly progressive destruction of the biliary tree which commonly requires liver transplantation for complications of biliary fibrosis and cholangiocarcinoma. The development of targeted therapies is hampered by our incomplete understanding of disease pathogenesis, driven by interactions between genetic predisposition and environmental factors. **Methods:** To understand the disease pathogenesis and identify cellular drivers and related molecular mechanisms, we performed single-cell multiome-seq, an assay that simultaneously measures gene expression and chromatin accessibility in single nuclei, on frozen explanted liver tissue and biopsy samples from patients with early PSC (n = 2), end-stage disease (n = 3), and from healthy controls (n = 2). We analyzed changes in gene expression and chromatin accessibility between patient and control groups. We performed Regulatory Element Locus Intersection (RELI) analysis to identify cell-type-resolved accessibility overlapping disease risk variants, nominating pathogenic cell populations. **Results:** 12 major liver epithelial and immune cell types were identified across 63,257 nuclei from 7 multiome-seq samples. RELI analysis revealed significant overlaps of PSC genetic risk loci in immune cell accessible chromatin regions (FDR < = 10%), suggesting T cells as the pathogenic cell population. We identified a risk locus, rs13140464, downstream of IL21 overlapping T-cell-specific accessibility, associated with higher *IL21* gene expression in the disease context. **Conclusion:** Single-cell multiome-seq analysis recovered major cell populations in the liver and identified changes in gene expression and chromatin accessibility under disease

4508-C | IL-16 AND IL-10 AS BIOMARKERS OF DISEASE ACTIVITY AND RESPONSE TO TREATMENT IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Vanessa Navalhas-Cipriano[1], Francis Dilauro[1], Valérie-Ann Raymond[1], Catherine Vincent[1,2], Fernando Alvarez[3], Marc Bilodeau[1,2] and Pascal Lapierre[1,2], (1) Centre De Recherche Du Centre Hospitalier De L'université De Montréal (CRCHUM), (2)Département De Médecine, Université De Montréal, (3)Service De Gastroentérologie, Hépatologie Et Nutrition, CHU Sainte-Justine, Université De Montréal

Background: First-line treatment achieves an adequate response in 80-90% of patients with autoimmune hepatitis (AIH). However, 10-20% of patients may progress to cirrhosis or liver transplantation. Currently, no clinical, biological, or histological parameters can predict the initial response to treatment or long-term remission. Therefore, there is a crying need for reliable biomarkers to predict disease activity and response to treatment. This study aimed to identify biomarker(s) of disease activity and treatment response in AIH patients. **Methods:** Using our AIH patient's biobank, a cross-sectional immunological profiling of cytokines linked to subtypes of CD4 T cells and flow cytometry analysis of CD4 T cells was performed on biological samples at the time of diagnosis and during treatment to identify putative biomarkers associated with disease activity and/or a favorable response to treatment. **Results:** Expression of the anti-inflammatory cytokine IL-10 by PBMCs increased significantly after treatment in AIH patients that respond to treatment (13.64 $\pm$ 2.84 Fold vs. 3.36 $\pm$ 3.1, n = 9, p = 0.017) while plasma levels of IL-16 decreased (542.3 $\pm$ 107.2 vs. 338.7 $\pm$ 22.7 pg/mL after treatment, n = 116, p = 0.0099). AIH patients with elevated ALT levels (> 40 IU/L) have significantly higher plasmatic levels of IL-16 than those with normal ALT levels (< 40 IU/L) (71.34 $\pm$ 33.85, n = 243, p = 0.0359). Patients that respond to treatment also had higher $CD3^+CD4^+FoxP3^+CD25_{high}CD127_{low}$ regulatory T cells (Tregs) levels after treatment (5.38% $\pm$ 0.42%, n = 6), similar to that of healthy controls (4.93% $\pm$ 0.55%, n = 5), compared to patients before treatment and these levels correlate with IL-10 expression ($r^2 = 0.6484$, n = 9, p = 0.0088) and plasmatic levels of IL-16 ($r^2 = 0.1864$, n = 49, p = 0.0020). Plasmatic levels of IL-16 also correlate with the levels of activated CD4 and CD8 T cells ($r^2 = 0.1469$, n = 49, p = 0.0066 and $r^2 = 0.08227$, n = 49, p = 0.0457, respectively). PCA Analysis shows that $CD4^+$ and $CD8^+$ $CXCR3^+$ T cells and Treg levels are responsible for most of the variance of ALT levels (n = 131). Using chemotaxis assays, IL-16 was found to promote the migration of $CD4^+$ but not $CD8^+$ T cells from AIH patients (CD4/CD8 ratio of 14.82 $\pm$ 7.424 (IL-16 50ng/mL) vs 2.583 $\pm$ 2.583 (Control), n = 3). **Conclusion:** IL-10 and CD4 regulatory T cells are increased in AIH patients that respond to treatment while IL-16 levels are decreased suggesting that these could be putative biomarkers for disease activity and treatment response in AIH patients. These results also suggest that IL-16 could affect both pro-inflammatory and anti-inflammatory pathways and thus influence AIH activity in these patients. The identification of reliable biomarkers could allow for the prediction of treatment response in treatment-naïve patients and the development of effective personalized therapy and could be a milestone achievement for the clinical management of difficult-to-treat AIH patients.

4509-C | INVESTIGATING MIF AS A BIOMARKER OF DISEASE SEVERITY IN AUTOIMMUNE HEPATITIS

Swathi Krishnan[1], Scott Roberts[2], Yanhong Deng[2], Lin Leng[2], Marina G. Silveira[2], Richard Bucala[2], James L. Boyer[2] and David N. Assis[2], (1)Yale New Haven Hospital, Stamford, CT, (2)Yale School of Medicine, New Haven, CT

Background: The presentation and clinical course of autoimmune hepatitis (AIH) is highly variable and immune biomarkers of disease severity are lacking. Novel biomarkers could help identify patients with more aggressive phenotypes requiring second-line immunosuppression (IS). Macrophage migration inhibitory factor (MIF), a pro-inflammatory mediator, and sCD74, the circulating MIF receptor, are implicated in AIH (Assis et al, Hepatology 2014). We studied MIF as a candidate biomarker of disease severity in AIH. **Methods:** 139 serum samples from 106 adult AIH patients were accessed from the Yale Liver Center Biorepository. Serum MIF and sCD74 expression were measured by sandwich ELISA. The high-risk *MIF* -173 C/G polymorphism was tested. Clinical and outcomes data, including AIH disease activity state (active, biochemical response on or off IS), fibrosis stage, IS requirements (first line, second/third line), and time to response were recorded. **Results:** The mean age was 55 years and 82% were female. There was no significant difference in serum levels of MIF or sCD74 between AIH disease activity states, mild vs. advanced fibrosis, or steroid use at the time of sample collection. However, significantly higher median levels of MIF (4 vs. 1.3 ng/mL, $p = 0.004$) and sCD74 (86 vs. 7.1 ng/mL, $p = 0.003$) were found in patients requiring second- and third-line IS (cyclosporine, mercaptopurine, mycophenolate, rituximab, and tacrolimus) compared to patients on first-line therapy with azathioprine. A subgroup of patients with available *MIF* -173 G/C polymorphism data were analyzed, revealing a trend toward longer time to biochemical response in patients with one or more C alleles vs. GG (36 vs. 13.9 months, p = NS). Additional *MIF* genotype data is being processed for subsequent analysis. **Conclusion:** Our study shows that circulating MIF and sCD74 levels are significantly higher in AIH patients requiring second- and third-line IS vs. standard IS with thiopurines. This suggests that these candidate immune-based biomarkers may be able to identify patients with severe disease and complex immunoreactivity requiring more aggressive IS regimens to achieve biochemical response. Ongoing analysis of high-risk *MIF* polymorphisms will clarify the possible association between the -173C allele and time to biochemical response. MIF, sCD74, and similar candidate immune-based biomarkers should be further evaluated as predictors of AIH disease severity.

4510-C | METABOLIC REPROGRAMMING OF CD4+ T CELLS BY MESENCHYMAL STEM CELL-DERIVED EXTRACELLULAR VESICLES ATTENUATES AUTOIMMUNE HEPATITIS THROUGH MITOCHONDRIAL CONTENT TRANSFER

Mengyi Shen and Li Yang, West China Hospital, Sichuan University

Background: Autoimmune hepatitis (AIH) is a serious liver disease characterized by immune disorders (e.g., abnormal T cell activation), and more efficient therapies for treating AIH are urgently required. However, the metabolic features of $CD4^+$ T cells in AIH and the corresponding targeted therapies have not been well-explored. This study aimed to explore the role of glucose metabolism of $CD4^+$ T cells in AIH and further elucidate the metabolic reprogramming effect and underlying mechanism of mesenchymal stem cell-derived extracellular vesicles (MSC-EVs) in AIH. **Methods:** $CD4^+$ T cells of AIH patients were isolated from peripheral blood by immunomagnetic cell sorting, and the levels of key enzymes related to glycolysis were measured. Liver biopsy specimens from AIH patients were stained with CD4 and GLUT1 (carrier proteins responsible for glucose transport). 2-Deoxy-D-glucose (a glycolysis inhibitor) or MSC-EVs were injected into AIH mice to evaluate their therapeutic effects. RNA- sequencing was used to identify the gene profile changes in $CD4^+$ T cells subjected to MSC-EVs. We confirmed the metabolic reprogramming effect MSC-EVs on $CD4^+$ T cells and identified the functional cargos. **Results:** Enhanced glycolysis of $CD4^+$ T cells was verified as a key factor in AIH in patient samples and mouse models. More importantly, MSC-EV treatment reduced activation and induced metabolic reprogramming of $CD4^+$ T cells, ameliorating liver damage in AIH mice. Mechanistically, we found that MSC-EVs transferred functional mitochondrial electron transport chain proteins to induce metabolic switch of $CD4^+$ T cells. Conversely, disruption of mitochondrial function in donor cells attenuated the rescue effect of MSC- EVs on suppressing glycolysis and activation in $CD4^+$ T cells. **Conclusion:** This study

highlights that MSC-EVs can metabolic reprogram T cell phenotype by transferring mitochondrial components, which may offer a new avenue for treating autoimmune disease, such as AIH.

f 4511-C | NEUTROPHIL EXTRACELLULAR TRAPS PROMOTE AUTOIMMUNE HEPATITIS THROUGH INHIBITING THE SUICIDE OF CD8+ T CELLS★

Han Wang[1], Yu Lei[1], Yu Chen[1], Shuhui Wang[1], Dean Tian[1], Hai Huang[2] and Mei Liu[1], (1)Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (2)Center for Immunology and Inflammation, Feinstein Institutes for Medical Research, Manhasset, NY

Background: Autoimmune hepatitis (AIH) is a chronic, progressive, and immune-mediated liver injury. Its prevalence has been increasing worldwide. The treatment of AIH is challenging and currently relies on corticosteroid therapy. Innate and adaptive immunity play critical roles in AIH pathogenesis. In AIH, $CD8^+$T cells actively invade hepatocytes, enter endosomal/lysosomal compartments, and are degraded (the "suicidal emperipolesis")[1]. Our most recent findings revealed neutrophil extracellular traps (NETs) link the crosstalk between innate and adaptive immunity by directly interacting with hepatic regulatory T cells[2]. However, the role of NETs in the setting of AIH remains unknown. Here we aim to elucidate the mechanisms by which AIH-induced NETs promote the development of AIH by arresting hepatic $CD8^+$T cells and preventing their suicidal emperipolesis. **Methods:** A well-established AIH model was performed by hydrodynamic transfecting with human CYP2D6 plasmid into C57Bl/6 mouse liver. DNase to inhibit NETs or peptidyl arginine deiminase 4 knockout (PAD4 KO) mice (genetically unable to form NETs) were utilized *in vivo* experiments. **Results:** AIH was successfully established as autoantibodies and characteristic pathological features of AIH were observed in the mice livers at four weeks. Utilizing 10x Genomics RNA-sequencing (RNA-seq), we uncovered the presence of a distinctive cluster of autoreactive $CD8^+$T cells that exhibited aggregation within the liver of AIH mice. Cith-H3 and MPO levels (the specific NETs markers) increased in the livers and sera of AIH mice, respectively. We confirmed a positive correlation between hepatic NETs and $CD8^+$T cells in AIH patients and mice. Using confocal microscopy, we observed NETs arresting $CD8^+$T cells. Inhibiting NETs protected liver injury in AIH mice, which was predominantly linked to the reduced quantity and functional impairment of hepatic $CD8^+$T cells. *In vitro*, the transwell experiment revealed NETs possess the ability to hinder the migration of $CD8^+$T cells towards hepatocytes. Flow cytometry indicated that NETs promoted $CD8^+$T cells function by augmenting their secretion of TNF-α and IFN-γ. Seahorse data suggested the oxidative phosphorylation of $CD8^+$T cells enhanced significantly after NETs treatment. Bulk RNA-seq confirmed that most differentially expressed genes of $CD8^+$T cells after NETs treatment enriched in the metabolic pathways. **Conclusion:** NETs capture hepatic $CD8^+$T cells and prevent their suicidal emperipolesis. NETs promote AIH progression through the crosstalk between innate and adaptive immunity and maybe the potential therapeutic targets.

4512-C | PNEUMOCYSTIS JIROVECII PNEUMONIA IN AUTOIMMUNE HEPATITIS PATIENTS: TRENDS, RISKS, AND HOSPITALIZATION OUTCOMES (2016-2020)

Chun-Wei Pan[1], Bashar M Attar[1] and Ayobami Olafimihan[2], (1)John H. Stroger, Jr. Hospital of Cook County, (2)John H Stroger Jr. Hospital of Cook County

Background: Pneumocystis jiroveci pneumonia (PCP) is an opportunistic infection that is well known for correlation with HIV infection, and it's considered as AIDs defining illness. However, with recent advancement in antiretrovirals, the epidemiology has shifted, it's becoming increasingly common in non-HIV individual's and data have suggested clinical courses can be more critical in these individual's. Limited data have been investigated on the risks and in-hospital outcomes of PCP among patients with autoimmune hepatitis. Our study aimed to analyze the contemporary trend of PCP admission rates among autoimmune hepatitis patients and investigate the associated infection risk and hospital outcomes. **Methods:** We surveyed the National Inpatient Sample Database from 2016-2020, by identifying hospitalization with corresponding international disease classification ICD-10 for PCP, and further stratified the cohort into those with autoimmune hepatitis and without. We also analyzed the prevalence of risk factors for development of PCP among autoimmune hepatitis. **Results:** From 2016 to 2020, we identified 110 hospitalizations for PCP among patients concurrently diagnosed with autoimmune hepatitis, accounting for 0.09% of total admissions. Patients in the PCP cohort had an unadjusted mortality rate of 27.3%, compared to 4.0% in the alternative reason for admission cohort. After adjusting for sex, age, and Charlson comorbidity index, the odds of mortality increased 12.2-fold in the PCP cohort ($P < 0.01$). Furthermore, the PCP cohort had a longer mean length of stay (12.0 d) compared to the autoimmune hepatitis patients without PCP infection (5.8 d), with a significant difference of 5.0 days ($P < 0.01$) after adjustments. The most notable additional risk factors for PCP were HIV (18.18% in the PCP cohort vs. 0.63% in the non-PCP cohort, $P < 0.05$), connective tissue disorder (CTD), chronic steroid use, lymphoma, and a past medical history of organ transplant. Over the study period, the annual percentage change in PCP cases among autoimmune hepatitis patients was 18.37%, whereas the national trend of PCP cases decreased from 9,410 in 2016 to 8,295 in 2020, with an annual percentage change of -2.51. **Conclusion:** Our study highlights an emerging trend of increasing PCP incidence among autoimmune hepatitis patients, contrasting with a national decrease in overall PCP cases. This elevated risk leads to greater in-hospital mortality and longer hospital stays in this population. The notable risk factors associated with PCP in autoimmune hepatitis patients include HIV, connective tissue disorders, chronic steroid use, lymphoma, and a history of organ transplantation. These findings point towards the need for identifying additional risk factors and potentially implementing preventative measures in autoimmune hepatitis patients.

Table 1. Summary of outcomes: Mortality, LOS, and Total Charge. Summary of additional risk factor for PCP

Primary Outcome	No PCP		PCP		Adjusted odds ratio	P value
Inpatient mortality	4.0%		27.3%		12.2 (3.9-37.5)	P<0.01
Secondary outcome						
LOS (Days)	5.8 (5.7-5.9)		12.0 (8.8-15.2)		Adjusted absolute difference: 5.4 (2.0-8.8)	P<0.01
Total Charge	71,884 (69,561-74,106)		191,xxx (110,073-268,263)		Adjusted absolute difference: 111,326 (30785-191,913)	P<0.01
Risk factor	NO PCP		PCP			
	%	95CI	%	95CI		
HIV	0.63%	(0.52-73.84)	18.18%	7.0-39.6		
Lymphoma	3.22%	(1.05-1.41)	13.64%	4.46-34.79		
Leukemia	0.48%	0.39-0.58)	0.00%	0		
Past history of organ transplant	2.73%	2.50-2.97	4.55%	0.64-26.16		
CTD	11.97%	11.51-12.44	31.82%	15.97-53.29		
Hematopoietic transplant	0.17%	0.12-0.24	0.00%	0		
Chronic steroid use	14.25%	13.74-14.79	22.73%	9.78-44.39

4513-C | PRESENCE OF LIVER DISEASE HETEROGENEITY CAN SUPPORT DISTINGUISHING BETWEEN AUTOIMMUNE HEPATITIS OVERLAP AND NON-ALCOHOLIC FATTY LIVER DISEASE

Elizabeth Shumbayawonda, Perspectum, Gideon Hirschfield, Toronto Centre for Liver Disease, University of Toronto, Toronto, Ontario, Canada, Rajarshi Banerjee, Perspectum Ltd., Emma Culver, Oxford University Hospitals, Michael A. Heneghan, King's College Hospital, London, United Kingdom, Kento Imajo, Shin-Yurigaoka General Hospital and Mazen Noureddin, Houston Liver Institute, Houston, TX

Background: Autoimmune hepatitis (AIH) is relatively rare, while non-alcoholic fatty liver disease (NAFLD), and the more progressive form non-alcoholic steatohepatitis (NASH), is the leading cause of liver disease in the West. Given the high prevalence of NAFLD and obesity, overlap between these two conditions is also on the rise. AIH treatment can include the use of steroids which have adverse metabolic effects that can worsen NAFLD. Quantification of overall liver disease activity can be achieved using cT1 from MRI, and disease heterogeneity observed and quantified using the interquartile range (IQR) of the resulted map of the liver. Our aim was to explore the utility of imaging and blood biomarkers to stratify between AIH/NAFLD overlap and NAFLD alone. **Methods:** We retrospectively examined MRI biomarkers (cT1 IQR, MRI-PDFF), blood biomarkers (ALT, AST) and vibration controlled transient elastography liver stiffness measure (LSM) from 165 patients, N = 37 (aged 24-70) on treatment with histologically confirmed AIH and 128 with histologically confirmed NAFLD/NASH (aged 24-84). Comparisons between AIH/NAFLD and NAFLD were performed using Kruskal-Wallis rank sum test. All patients had fatty liver which was defined as MRI-PDFF $\geq$ 5%. **Results:** Treatment plans for patients with AIH/NAFLD require careful consideration to avoid accelerating the comorbid fatty liver disease. In this cohort, those with NAFLD alone had higher liver fat (PDFF) compared to those with AIH/NAFLD overlap (13.4% vs 9.5%, $p < 0.001$ respectively). However, conversely, those with AIH/NAFLD overlap had more heterogenous disease with higher cT1 IQR compared to those with NAFLD alone (103ms vs. 81ms, $p < 0.001$). There were no significant differences between blood markers ALT (69.9 vs 63.5, $p = 0.07$), AST (61.1 vs 47.7, $p = 0.495$) and LSM (9.9 vs. 11.5, $p = 0.061$) between those with AIH/NAFLD and those with NAFLD alone respectively. **Conclusion:** Heterogeneity in liver parenchymal fibro-inflammation is a feature of AIH in comparison to NAFLD and may reflect differences in disease pathophysiology. MRI biomarkers have utility to support patient stratification and aide management as no specific treatment guidelines are available to guide treatment goals in those with AIH/NAFLD overlap. Figure: Boxplots showing differences in MRI biomarkers (cT1 IQR, MRI-PDFF), blood biomarkers (ALT, AST) and vibration controlled transient elastography liver stiffness measure (LSM).

4514-C | PREVALENCE OF AUTOANTIBODIES IN PATIENTS WITH AUTOIMMUNE HEPATITIS AT UNIVERSITY MEDICAL CENTER HCMC★

Huy Nguyen Huu, Suong Thi- Bang Nguyen, Phong Vi Kim, Nga Cao Minh, Thong Luu Nguyen Trung, Chi Mai Thi Bich, Khoi Le Minh and Bac Nguyen Hoang, University Medical Center Hcmc

Background: Autoimmune hepatitis (AIH) is an acute or chronic inflammatory disease of the liver caused by an immune response of unknown origin. AIH is a rare disease but with increasing incidence in Asia–Pacific area. Autoantibodies are a key diagnostic tool in AIH. This study aimed to describe the clinical, paraclinical characteristics and prevalence of autoantibodies in patients with autoimmune hepatitis at University Medical Center HCMC. **Methods:** Cross-sectional descriptive study. 72 patients diagnosed with autoimmune hepatitis according to the shortened scoring table Hennes EM 2008 in combination with the standard diagnosis scoring system of autoimmune hepatitis amended in 1999 and treated at the University Medical Centre in Ho Chi Minh City from January 2018 to April 2022. **Results:** In 72 patients with autoimmune hepatitis, mean age ± standard deviation is 56.3 ± 16.8 years; the proportion of female was 72.2% and male was 27.8%. Approximately half of patients presented with symptoms of acute hepatitis. Cirrhosis was found in 34.7% with an elevated APRI and FIB-4 scores. Biochemical analysis revealed elevated alanine transaminase (109 (49.3-499)), aspartate transaminase (105 (49-383), and gamma glutamyl transferase (127 (58-349)). Marker autoantibodies ANA (+): 62,5%, ASMA (+): 44,4%, F-Actin (+): 15,3%, AMA (+): 6,9%, LKM (+): 2,8%. **Conclusion:** AIH is characterized by female predominance, elevated liver transaminases. ANA, ASMA are the most frequent autoantibodies generated in patients with AIH.

4515-C | PROVIDER SUBSPECIALTY IS NOT ASSOCIATED WITH ACHIEVING CORTICOSTEROID-SPARING MAINTENANCE THERAPY IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Lina Yagan[1], Cynthia Levy[2], David Goldberg[2] and Therese Bittermann[3], (1)University of Pennsylvania Hospital, Philadelphia, Pennsylvania, USA, (2) University of Miami, (3)Hospital of the University of Pennsylvania, Philadelphia, PA

Background: Autoimmune hepatitis (AIH) is a rare liver disease that warrants experienced treatment decision-making. The optimal treatment of AIH includes avoidance of corticosteroids (CS). We aimed to evaluate whether provider subspecialty was associated with receiving corticosteroid-sparing maintenance therapy in a large AIH patient cohort. **Methods:** This was a retrospective cohort study of adults with AIH identified using a validated algorithm in the Optum® Clinformatics© Deidentified Data Mart, a U.S. health insurance database. All patients were followed 2 years from the date of their first ICD-9/10 code for AIH (first year = baseline period; second year = observation period). Dominant regimen was defined as that received > 6 months during the observation year. Using provider taxonomy codes, we classified patients according to whether they had only outpatient visits with general gastroenterology (GI) providers or ≥ 1 visit with a hepatology (Hep) provider during the baseline period. Multivariable logistic regression models evaluated the association of AIH care type with receipt of CS-sparing treatment as dominant regimen (i.e., azathioprine [AZA] or mycophenolate mofetil [MMF] monotherapy vs CS +/- AZA/MMF). **Results:** The study cohort included 3,591 patients, of whom 81.2% were female, 65.5% White, 11.1% Black, 11.8% Hispanic and with median age 61.3 (IQR: 50.4-69.9) years. During the baseline period, 6,041 outpatient visits with an associated ICD-9/10 code for AIH were identified, of which 91% were with a GI or Hep provider. Among the n = 1,489 patients with ≥ 1 outpatient AIH visit with a GI/Hep provider, 79.4% were managed by GI only. There was no difference in sex (p = 0.976) or race/ethnicity (p = 0.281) according to whether patients were managed by GI only or Hep +/- GI. However, patients managed by Hep +/- GI were younger (median 56.8 vs 61.4 years; p < 0.001) and more likely to have cirrhosis (47.9% vs 33.6%; p = 0.001). Geographic differences in the percent of AIH patients with ≥ 1 Hep provider visit were observed, from 9.5% in the West North Central to 42.3% in the West South Central divisions (p < 0.001 overall; Figure A). A similar pattern was observed for AIH patients with cirrhosis (p < 0.001; Figure B). No temporal trends were seen (p = 0.437). Among the patients with ≥ 1 GI or Hep AIH visit during the baseline period, dominant regimens filled during the observation period included 49.2% AZA/MMF monotherapy, 14.6% AZA/MMF with CS, and 10.4% CS monotherapy. In multivariable models, provider type was not associated with receipt of CS-sparing treatment: adjusted OR 0.98 (p = 0.915). No interaction was found between provider type and coexistence of cirrhosis (p = 0.526). **Conclusion:** The majority of AIH care in the U.S. is provided exclusively by general GI providers, though geographic heterogeneity exists. The likelihood of achieving CS-sparing maintenance therapy was not different according to AIH provider subspecialty.

Hansen[19] and Karim Mohammed Qumosani[1], (1) Western University, (2)Li Ka Shing Knowledge Institute, St Michael's Hospital, Unity Health Toronto, (3) University of Toronto, (4)Toronto General Hospital Research Institute, (5)King Saud Bin Abdulaziz University for Health Sciences, (6)King Faisal Specialist Hospital and Research Centre, (7)Imam Mohammed Bin Saud Islamic University, (8)University of Alberta, AB, Canada, (9)Royal University Hospital, (10) Département De Médecine, Université De Montréal, (11)Queen's University Cancer Research Institute, Kingston, ON, Canada, (12)University of Ottawa, (13) University of Calgary, (14)Université De Sherbrooke, (15)University of British Columbia, (16)Dalhousie University, (17)Toronto Centre for Liver Disease, University of Toronto, Toronto, Ontario, Canada, (18) Univeristy of Alberta, Edmonton, AB, Canada, (19) Toronto General Hospital University Health Network, Rotterdam, Netherlands

Background: We investigate the ability of the Aspartate transaminase to Platelet Ratio Index (APRI) and Fibrosis-4 score (FIB4) to discriminate for liver fibrosis stage based on liver biopsy in patients with autoimmune liver disease. **Methods:** Using data from the Canadian Network for Autoimmune Liver Disease, Liver biopsy was compared to AST/Platelet Ratio (APRI) and Fibrosis-4 score (FIB-4) within one year from Liver biopsy date. Logistic regression was used to assess the association of APRI and FIB-4 with fibrosis stage (F0 vs. F1-4 and F0-2 vs. F3-4). Area under the curve (AUC), sensitivity, specificity, and their 95% CI are reported along with positive predictive value and negative predictive value, with cut off points defined by using Youden's index (the maximum value of sensitivity + specificity). All analyses were performed in R version 4.2.2 **Results:** A total of 815 patients were included out of which 682 (83.7%) were female. The mean age was 61 years (SD 15.5), 228 (27.9%) patients had autoimmune hepatitis (AIH), 465 (57.1%) patients had Primary Biliary Cholangitis (PBC), and the remaining 122 (15%) had overlap syndrome (OS). F0 fibrosis was present in 132 (16.2%) patients, 364 (44.6%) had F1-F2 fibrosis, and the remaining 319 (39.1%) had F3-F4 fibrosis. Median APRI was 0.65 (25^{th}-75^{th} 0.17-2.80) and the median FIB-4 was 1.40 (25^{th}-75^{th} 0.71-2.73). APRI analysis: Overall, the area under the curve for APRI to discriminate for Fibrosis stages 1-4 was 0.58 (95% CI: 0.53-0.63). For AIH, PBC, and OS respectively, the positive predictive values for F1-F4 Fibrosis were 85.2%, 89.4%, 95% and the negative predictive values for F1-F4 fibrosis were 22.2%, 20.3%, 19.0% (Table1). Overall, APRI was associated with moderate-to-severe fibrosis (F3-4) in people with PBC (OR = 1.27; 95%CI = 1.16-1.40). In addition, APRI was associated with moderate to severe fibrosis in OS with (OR = 1.19; 95%CI 1.06-1.34) while it was associated in AIH (OR = 0.99, 95%CI = 0.97-1.02). FIB-4: analysis: Overall, the area under the curve for FIB-4 to discriminate for Fibrosis stages 1-4 was 0.48 (95%CI: 0.43-0.54). For AIH, PBC, and OS respectively, the positive predictive values for F1-F4 Fibrosis were 89.4%, 88.3%, 95.0% and the negative predictive values for F1-F4 fibrosis were (22.2%, 18.8%, 14.7%) (Table1). FIB-4 was not associated with moderate to severe fibrosis in AIH, PBC or OS. (OR = 1.01,95% CI = 0.97 -1.05), (OR = 1.39, 95%CI = 1.07-1.8), (OR = 1.12, 95%CI = 0.9- 1.40) respectively. **Conclusion:** APRI score and FIB-4 score had reasonable PPV however, poor NPV, and therefore, both APRI and FIB-4 can't be used to stratify patients with or without fibrosis. In patients with PBC and OS, higher APRI score was associated with advanced fibrosis.

APRI	Cut-off	AUC, (95% CI)	Sensitivity, % (95% CI)	Specificity, % (95% CI)	PPV, %	NPV, %

4517-C | SIGNIFICANT SOCIOECONOMIC IMPACT ON PATIENT AND GRAFT SURVIVAL AMONG PATIENTS WITH AUTOIMMUNE LIVER DISEASES: A 20-YEAR PERSPECTIVE

Romelia Barba Bernal[1], Leandro Sierra[1], Ana Marenco-Flores[1], Daniela Goyes[2], Bryan Ferrigno[3], Wilfor Diaz Fernandez[3], John Esli Medina Morales[4], Vilas Patwardhan[1], Behnam Saberi[1] and Alan Bonder[1], (1) Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, (2)Yale University Medical Center, New Haven, CT, United States, (3)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (4) Rutgers New Jersey Medical School, Kearny, NJ

Background: Autoimmune liver diseases (ALD) including AIH, PBC, and PSC account for a significant minority of liver transplants (LT) performed in the United States. We have previously shown that certain social determinants of health have an impact on waitlist mortality amongst patients with ALD listed for LT. Less is known regarding the impact on post-LT patient and graft survival amongst this patient population. We sought to analyze the impact of social determinants of health on ALD patients post-LT, focusing on graft and patient survival. **Methods:** We used the OPTN/United Network of Organ Sharing (UNOS) database to identify adult patients with ALD listed for LT between January 2002 and December 2021. Data extracted included diagnosis, MELD score, age, gender, ethnicity, and socioeconomic variables. The primary outcome was to analyze survival for LT recipients. Chi-Square and ANOVA tests were used for comparative analysis. Kaplan-Meier analysis was used for survival calculation. To identify significant predictors of survival, we conducted forward stepwise multi-variate Cox regression analyses adjusted for recipient and donor characteristics. **Results:** 9470 LT between 2002 and 2021 were for AILD indication. Most patients were Caucasian, with female predominance among the AIH and PBC groups. Age was comparable among the three groups. Our analysis revealed that the AIH group had a higher median BMI than the PBC and PSC groups (28, 26, and 25%) and was significantly more likely to have diabetes (22%, 17%, and 11%). Regarding the socioeconomic distribution, the PSC group was likelier to have higher education, private insurance, and working for income than the AIH and PBC groups. Citizenship was comparable among the three groups. No college education (HR, 1.16; 95% CI, 1.06–1.26; $p = 0.001$), having public insurance (HR, 1.15; 95% CI, 1.06–1.25; $p = 0.001$), and no income (HR, 1.41; 95% CI, 1.24–1.60; $p = 0.000$) had a detrimental impact on post-LT patient survival. The same socioeconomic variables were associated with an increased risk of post-LT graft failure, no-college education (HR, 1.13; 95% CI, 1.05–1.23; $p = 0.002$), public insurance (HR, 1.15; 95% CI, 1.06–1.25; $p = 0.001$), and no income (HR, 1.21; 95% CI, 1.09–1.35; $p = 0.000$). (Tables 1 & 2) **Conclusion:** This analysis displays findings suggestive that social determinants of health including education, insurance status, and financial security, seem to have a detrimental impact on post-LT patient and graft survival.

4518-C | SILENCING OF ARYL HYDROCARBON RECEPTOR REPRESSOR MODULATES Th17-CELL IMMUNITY IN AUTOIMMUNE HEPATITIS

Barbora Gromova[1], Li Gao[1], Wei Zhang[1], Lina Zhang[1], Silvia Nastasio[2], Alan Bonder[3], Vilas Patwardhan[3] and Maria Serena Longhi[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)Boston Children's Hospital and Harvard Medical School, Boston, MA, (3)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School

Background: Th17-cells play a key role in the pathogenesis of autoimmune hepatitis (AIH), a severe liver disease that often progresses to end-stage hepatopathy, despite immunosuppression. Aberrant Th17-cell response in AIH is linked to inability to respond to aryl-hydrocarbon-receptor (AHR) activation by endogenous or exogenous ligands. Once activated, AHR translocates to the cell nucleus where it modulates gene expression. In turn, AHR is regulated by aryl-hydrocarbon-receptor-repressor (AHRR), which inhibits AHR transcriptional activity. In this study, we investigated whether, in AIH, altered Th17-cell response to AHR activation derives from aberrant AHRR regulation. **Methods:** Th17-cells, obtained from the peripheral blood of AIH patients (n = 29) and healthy controls (n = 19) were exposed to the AHR endogenous ligand L-kynurenine (L-kyn), with or without AHRR siRNA. Therapeutic effects of AHRR silencing were tested in a model of Concanavalin-A (Con-A)-induced liver injury in humanized mice. **Results:** AHRR was markedly upregulated at both mRNA and protein levels in AIH Th17 cells, following exposure to L-kyn. In AIH, silencing of AHRR by siRNA boosted Th17-cell response to L-kyn, as reflected by increased levels of *CYP1A1*, the main gene controlled by AHR, and by decreased *IL17A* expression. Blockade of AHRR limited the differentiation of naïve CD4-cells into Th17 lymphocytes and modulated Th17-cell metabolic profile by increasing the levels of anti-inflammatory metabolites like uridine and allantoin. Treatment with 2'-deoxy-2'-fluoro-d-arabinonucleic acid (FANA) oligos to silence AHRR *in vivo*, reduced ALT levels and attenuated lymphocyte infiltration on histology in *NOD/scid/gamma* mice, pre-emptively reconstituted with human CD4 cells, and subsequently exposed to Con-A. Further, FANA-treated mice displayed increased proportions of intrahepatic IL-10$^+$ and FOXP3$^+$ CD4 lymphocytes, when compared to vehicle-treated mice. **Conclusion:** In AIH, blockade of AHRR restores Th17-cell response to AHR activation and limits Th17-cell differentiation while promoting generation of anti-inflammatory metabolites. *In vivo*, silencing of AHRR attenuates liver damage in *NOD/scid/gamma* mice, while boosting intrahepatic immunoregulatory CD4 subsets. Silencing of AHRR might represent a novel therapeutic strategy to modulate effector Th17-cell immunity and restore immune homeostasis in AIH.

4519-C | TACROLIMUS AS A SECOND LINE THERAPY IN STEROID-TACROLIMUS-MYCOPHENOLATE-MOFETIL REFRACTORY AUTOIMMUNE HEPATITIS: EXPERIENCE FROM A TERTIARY CARE CENTER

Mithun Sharma, Anand V. Kulkarni, Manasa Alla, Sowmya T R, Padaki Nagaraja Rao, Shantan Venishetty, Rajesh Gupta and Nageshwar D Reddy, Aig Hospitals, Hyderabad, India

Background: The response of autoimmune hepatitis to a combination of steroids and azathioprine is excellent, with approximately 16-20% of patients requiring second-line medications like mycophenolate mofetil (MMF)

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

or tacrolimus (TK). These 2nd line drugs' efficacy is considered lower than standard therapy. We report a single-center experience of using tacrolimus in the steroid, azathioprine, and MMF refractory AIH patients. To evaluate the efficacy and safety of tacrolimus as a second-line therapy in patients with AIH. **Methods:** A retrospective data analysis of AIH patients treated from 2012 to 2022 were analyzed. The clinical, immunological, and biochemical parameters were recorded. The response was defined as normalization of transaminases and IgG. **Results:** Out of 210 patients with AIH, 7 (3.34%) patients (5 female and 2 males) who were nonresponsive/intolerant to MMF received tacrolimus (TK). 6 patients were intolerant to Azathioprine and MMF, and one patient showed an inadequate response to both the drugs. Remission with TK was 71.4% with monotherapy, and two patients(28.57%) required an additional prednisolone dose to achieve disease control. The median dose of tacrolimus was 5 mg, and the median level to achieve remission was 7 ng/dl. The median time receiving tacrolimus was 20 months. Calcineurin inhibitor nephrotoxicity was seen in 2/7 (28.57%) patients, and treatment had to be discontinued in one patient. **Conclusion:** Tacrolimus is a safe and effective alternative to MMF in refractory AIH.

4520-C | THE INFLUENCE OF ETHNICITY ON THE EPIDEMIOLOGY AND PHENOTYPES OF AUTOIMMUNE HEPATITIS IN CANTERBURY, NEW ZEALAND

Asim Abdulhamid[1], Catherine A. Stedman[1], Michael John Burt[1] and Jing Hieng Ngu[2], (1)Te Whatu Ora Waitaha Canterbury, (2)Christchurch Hospital

Background: The etiology of autoimmune hepatitis (AIH) remains unknown. There is a paucity of data on the influence of ethnicity on the epidemiology and phenotype of the disease. We aim to (i) describe the epidemiology of AIH in Europeans and non-Europeans, and (ii) compare the phenotypes of European and non-European AIH patients in Canterbury, New Zealand. **Methods:** Cases that fulfilled the Simplified Diagnostic Criteria of AIH were prospectively included in the Canterbury AIH registry. AIH patients that were diagnosed before 31st December 2021 were included for analysis. Population data were obtained for NZ Statistics. In 2021, Canterbury had a population of 650,200 and 64% identified themselves as Europeans. **Results:** A total of 312 AIH patients were included. The majority (90.4%) were of European descent. The point prevalence of AIH in European on 31st December 2021 in Canterbury is 47.6/100,000 (95% CI 41.0-54.2/100,000), whereas for non-European it is 11.1/100,000 (95% CI 6.8-15.3/100,000). The incidence of AIH in 2021 for Europeans is 1.9/100,000 (95% CI 0.6-3.3/100,000), whereas for non-Europeans it is 0.4/100,000 (95% CI 0-1.3/100,000). Interestingly, comparing European and non-European AIH patients, there was no significant difference in gender, autoantibodies, immunoglobulins, age at diagnosis, response to treatment and transplant-free survival. **Conclusion:** The prevalence of AIH is significantly higher in Europeans than non-Europeans in Canterbury, in this population-based study. However, there was no difference in the disease manifestation and outcomes between European and non-European AIH patients. Ethnicity appeared to influence disease susceptibility but not disease phenotype.
Disclosures: The following people have nothing to disclose: Asim Abdulhamid, Catherine A. Stedman, Michael John Burt, Jing Hieng Ngu

f 4521-C | THE RELAXIN FAMILY PEPTIDE RECEPTOR 1 (RXFP1) IDENTIFIED AS A NOVEL TARGET OF AUTOANTIBODIES IN PATIENTS WITH AUTOIMMUNE HEPATITIS (AIH) BY PROTEOME-WIDE PROGRAMMABLE PHAGE DISPLAY (PHIP-SEQ)

Arielle Klepper[1], Andrew Kung[1], Sara Vasquez[1], Anthea Mitchell[1], Sabrina Mann[1], Isaac Avila-Vargas[1], Swathi Kari[1], Melawit Tekeste[1], Javier Castro[1], Briton Lee[1], Mandana Khalili[1], Jennifer Y. Chen[1], Jennifer C. Price[1], Emily J. Rothbaum Perito[2], D. Montgomery Bissell[3], Sandy Feng[1], Jacquelyn J. Maher[2], Jennifer C. Lai[4], Christina Weiler-Normann[5], Ansgar W. Lohse[5], Joseph DeRisi[6] and Michele M. Tana[1], (1)University of California, San Francisco, (2)University of California, San Francisco, San Francisco, CA, (3)University of California, San Francisco, Berkeley, CA, (4)University of California-San Francisco, San Francisco, CA, (5) University Medical Centre Hamburg-Eppendorf, (6) UCSF, Chan Zuckerberg Biohub

Background: Identification of autoantigens remains a critical challenge in understanding and treating autoimmune diseases; the role of autoantibodies in the pathophysiology of autoimmune hepatitis (AIH) is uncertain. We aimed to use Phage Immunoprecipitation-Sequencing (PhIP-Seq) to identify novel autoantibodies specific to patients with AIH. **Methods:** We performed PhIP-Seq on serum or plasma from 413 subjects to identify autoantibodies that distinguish AIH patients ($n = 115$) from healthy controls ($n = 94$) or those

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with other liver diseases (metabolic associated fatty liver disease, $n = 178$; primary biliary cholangitis, $n = 26$). Phage were cloned to express > 700,000 overlapping short peptides spanning the human proteome for immunoprecipitation with serum autoantibodies. Antibody-bound phage were sequenced to identify peptide-coding genes. Peptides were considered significant if they were enriched > 2.5 standard deviations from the mean of healthy controls in > 6% of AIH samples. PhIP-Seq findings were validated using a split luciferase binding assay (SLBA). Blocking assays were performed in the THP1 monocyte cell line, incubated with patient serum [1:100] prior to stimulation with relaxin (R&D systems). Signaling was quantified using the cAMP-Glo assay (Promega). **Results:** A logistic regression classifier demonstrated that we can differentiate patients with AIH from controls based on peptide-level proteome-wide PhIP-Seq autoantibody profiles (AUC = 0.84). To further investigate the autoantibodies most specific to AIH, we identified significant peptides with > 98% specificity to AIH relative to all controls. Top candidates included anti-SLA, a well-recognized autoantibody in AIH, as well as antibodies targeting a linker region of the relaxin family peptide receptor 1 (RXFP1), which is required for receptor activation. RXFP1 is a G-protein coupled receptor that binds relaxin, an anti-fibrogenic molecule shown to reduce the myofibroblastic phenotype of hepatic stellate cells. Eight of nine patients with antibodies to RXFP1 had evidence of advanced fibrosis (F3 or greater). SLBA was used to orthogonally validate antibodies targeting RXFP1 in a subset of AIH and control patients (Fig 1a). Serum from AIH patients positive for anti-RFXP1 antibody was able to block relaxin signaling in THP1 cells relative to anti-RXFP1 antibody-negative control serum ($p < 0.05$, Fig 1b, c); depletion of IgG abrogated this effect. **Conclusion:** We used the PhIP-Seq platform to discover novel autoantigens in AIH and identified RXFP1 as a highly specific disease target. Anti-RXFP1 antibodies are capable of blocking relaxin signaling via RXFP1, diminishing the anti-fibrotic properties of the molecule. Identification of anti-RXFP1 in patient serum may enable risk stratification of AIH patients for fibrosis progression and lead to the development of novel strategies for disease intervention.

4522-C | THE ROLE OF MAIT CELLS IN CHILDREN WITH AUTOIMMUNE LIVER DISEASE

Suz Warner, University of Birmingham, Birmingham, United Kingdom; Birmingham Children's Hospital

Background: Mucosal-associated invariant T (MAIT) cells, defined as CD3+ Valpha7.2+ CD161++ T lymphocytes, are the most abundant intra-hepatic T cell population in adults. MAIT cells are increasingly recognised to play a central role in hepatic immunosurveillance, tissue maintenance and repair. In adults with autoimmune liver disease (AILD), MAIT cell frequency and cytokine production are significantly depleted due to activation-induced cell exhaustion and dysfunction. Furthermore, chronic MAIT cell activation in AILD predisposes to liver fibrosis which was shown to be interleukin-17A (IL-17A) dependent. AILD is a lifelong immune mediated liver disease which often starts in childhood but the biological characteristics and functional activity of MAIT cells in children with AILD has not been investigated. **Methods:** We performed mass cytometry by CyTOF (Cytometry by Time of Flight) on peripheral blood mononuclear cells (PBMC) from children with AILD (AIH type 1, N = 8, median age 14yrs (range 9-14), and PSC, N = 8, 14yrs (range 12-15) and in healthy children (HC) (N = 8, 12yrs (range 5-15)). PBMCs treated with CytoStim, an antibody based polylconal activator of T lymphocytes, for 4hours prior to downstream CyTOF investigation (STIM). Untreated paired PBMCs from the same patients were used as controls (UNSTIM). MAIT cell and conventional CD3+ cytokine production, measured as the median metal intensity (MMI), were recorded. **Results:** Our results show stimulated (STIM) blood MAIT cells from children with PSC had higher TNF-a production than AIH patients and healthy children (HC) (Figure 1). Reduced MAIT cell Granzyme B and IFNy expression were observed from the AIH and PSC cohorts compared to HC. IL-17A production was induced in the 4hour incubation period, an observation not previously reported in adult MAIT cells which requires prolonged activation. The patients' CD3+ T lymphocyte cytokine expression levels were also assessed and are presented for comparison. Of note, CD3+ TNF-a production was 20-fold less than observed in MAIT cells from the same patients. Furthermore, no CD3+ IL-17A production was observed in all three cohorts. **Conclusion:** In conclusion, reduced IFNγ and Granzyme production in our paediatric AILD cohort is consistent with MAIT cell dysfunction observed in adult AILD. However, higher MAIT cell TNF-a and IL-17A production in the PSC cohort following acute activation suggests TNF superfamily pathway preservation and a greater potential for early release of the chronic inflammatory and pro-fibrotic cytokine IL-17A in children, both of which could contribute to autoimmune liver disease progression.

4523-C | THE ROLE OF METABOLIC ASSOCIATED DISEASES AND LIVER STEATOSIS IN AUTOIMMUNE HEPATITIS

Kehui Liu[1], Mingyang Feng[1], Wanqing Chi[2], Xiaoyin Wang[1], Yezhou Ding[1], Shike Lou[1], Gangde Zhao[1], Li Ziqiang[1], Qing Xie[1], Lanyi Lin[1], Shisan Bao[3] and Hui Wang[1], (1)Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (2)Yale University School of Public Health, New Haven, CT, (3)University of Sydney

Background: This study aimed to investigate the impact of metabolic associated diseases (MADs) on patients with autoimmune hepatitis (AIH). **Methods:** This cross-sectional study analysed the clinical characteristics of 283 AIH patients who underwent liver biopsy from January 2016 to February 2022. The study collected extensive clinical and histological data. **Results:** Among the enrolled AIH patients, 87.3%, 38.9% or 43.1% had MADs, NAFLD, or severe fibrosis,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

respectively. AIH patients with NAFLD were older and predominantly overweight/obese. Fibrosis was more severe in patients with NAFLD than in those without (50.9% vs. 38.2%, $p < 0.05$). Severe liver fibrosis (stages 3 to 4) was independently associated with male gender (odds ratio, 4.388; $p = 0.030$), age ≥ 60 (odds ratio, 6.053; $p = 0.007$), higher TC level (odds ratio, 2.913; $p = 0.028$), and combination with MADs (odds ratio, 28.969; $p = 0.020$). **Conclusion:** The study findings suggest that metabolic factors aggravate hepatic fibrosis in AIH patients, highlighting the importance of screening for MADs and NAFLD among these patients. Proactive interventions should be provided to manage the progression of AIH.

4524-C | THE UNUSUAL PRESENCE OF MIXED OVERLAP SYNDROME IN A SINGLE COHORT OF PATIENTS WITH AUTOIMMUNE LIVER DISEASES

Ana Marenco-Flores[1], Romelia Barba Bernal[1], Leandro Sierra[1], Bryan Ferrigno[2], Daniela Goyes[3], Wilfor Diaz Fernandez[2], John Esli Medina Morales[4], Alan Bonder[1] and Vilas Patwardhan[1], (1)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3)Yale University Medical Center, New Haven, CT, United States, (4)Rutgers New Jersey Medical School, Kearny, NJ

Background: The term overlap syndrome describes variant forms of autoimmune liver disease, including autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC), and sclerosing cholangitis (PSC). Patients with overlap syndromes exhibit both hepatic and cholestatic liver function tests, as well as histological features of AIH, PBC, or PSC. The most prevalent presentation is the AIH-PBC overlap syndrome, which has been reported in nearly 10% of adults with AIH or PBC and may be associated with a poor prognosis. Due to their rarity, few studies have described the presence of other overlap syndrome variants. This study aimed to define the prevalence of uncommon overlap syndromes in a well-characterized prospective cohort of AIH, PBC, and PSC patients seen at a tertiary referral center and to describe their clinical characteristics. **Methods:** We conducted a single-center, observational cohort study from our autoimmune liver registry. We recorded demographics, clinic, and liver biopsies from 1131 patients from January 2018 to May 2023. Our registry is composed of patients with a primary diagnosis of AIH (n = 608), PBC (258), and PSC (265). Data included biochemical profiles, autoimmune markers, liver histology, and imaging reports. **Results:** From our cohort of 1131 patients, 20 met the criteria for uncommon overlap syndromes, representing a prevalence of 1.76%. The subjects were divided into four different groups: AIH-PSC, PBC-PSC, AIH-PBC-PSC, and AIH-IgG4 Cholangiopathy. Their mean age was 34, 62, 38, and 73, respectively. Patients were predominantly female, except for the AIH-PSC group. The white Caucasian ethnicity prevailed in all four groups. At baseline, the mean ALP was 437U/L for the AIH-PSC group and 102U/L for the PBC-PSC group. The mean AST and ALT values in the AIH-PBC-PSC group were 597U/L and 135U/L, respectively. In most cases, liver biopsy has been used to identify the AIH component of overlaps (88%); only 2% of patients were diagnosed with clinical findings. The diagnosis of PBC overlap was made based on the presence of antimitochondrial antibodies (AMA) and histopathological findings. In PSC overlaps, magnetic resonance cholangiopancreatography (MRCP) and biopsy were the most common methods of diagnosis (47% each), followed by clinical findings (6%). Only two patients were diagnosed with AIH-PBC-PSC overlap. **Conclusion:** Accurate and timely diagnosis for uncommon overlap syndrome is challenging but may improve long-term outcomes in these patients. Therefore, there is a need to develop

standard diagnostic criteria and therapeutic interventions for this specific group of patients.

4525-C | TSBP1 IS ASSOCIATED WITH AUTOIMMUNE HEPATITIS RISK

Craig Lammert, Kelsey Green, Marco A Abreu and Tae-Hwi Schwantes-An, Indiana University School of Medicine

Background: The HLA class II allele associated with the DRB1 locus is the commonly described genetic risk factor for autoimmune hepatitis (AIH), yet it accounts only a small amount of AIH risk variance. In this study, we aimed to further characterize genetic contributions to AIH by identifying novel associations and genetic overlap across polygenetic risk catalog. **Methods:** AIH cases were defined per standard criteria. Cases were recruited from a well-established institutional AIH cohort consisting of patients visiting our center between 1995 and 2020. Liver disease-free controls were chosen from Indiana Biobank-Liver Cohort (IB-LC) among participants without existing ICD codes for liver diseases in their electronic medical record. GWAS (genome-wide association study) was conducted using PLINK comparing AIH cases versus liver-disease free controls adjusting for age, sex, and two principal components for ancestry stratification. PheWAS (phenome-wide association study) of polygenic risk scores (PRS) to identify diseases that share genetic risk factors with AIH was conducted in R. 3,284 PRSs from PGS Catalog v2023-01-19, were calculated in our cohort using the Michigan Imputation Server. To test association between each PRS and AIH, we used logistic regression with normalized PRS as continuous explanatory variable with age and sex as covariates. **Results:** In total, there were 420 AIH cases and 3,170 liver disease-free controls with available genotypes. In GWAS, we observed a genome-wide associated locus on chromosome 6, rs6910668, an intronic variant in *TSBP1* (Testis Expressed Basic Protein 1) with a p-value of $7.71e^{-12}$ (odds ratio [OR] = 1.83 for each G allele) (Figure). For PheWAS of PRS, we used a Bonferroni corrected p-value threshold of $1.52e^{-05}$. Out of 3,284 PRSs tested, 25 PRS were statistically significant. Top five associated (by p-value) PRSs were for predicting the risk of celiac disease (p-values ranging between $8.23e^{-12}$ to $4.50e^{-11}$) with increasing PRS score for celiac disease also leading to increased risk for AIH. PRSs for lung cancer, liver disease, hypothyroidism, and lupus were also associated with AIH. **Conclusion:** We identified a new genome-wide association on chromosome 6 for increasing the risk of AIH. We also observed variants that increase risk for developing celiac disease, lung cancer, hypothyroidism, and lupus also increased risk of AIH. These relationships may identify previously unknown genes/genetic variants that underlie AIH.

4526-C | TTHE DIAGNOSTIC/ PROGNOSTIC ROLE OF RANTES, IP-10 AND MCP-1 KYNETICS PROFILES IN AIH PATIENTS DURING IMMUNOSUPPRESSIVE TREATMNT

Giuseppe Colucci[1], Enrico Sguazzini[2], Sara Colonia Uceda Renteria[3], Riccardo Perbellini[4], Clara Dibenedetto[3], Pietro Lampertico[5] and Maria Francesca Donato[3], (1)Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico,, (2)Università Del Piemonte Orientale (UPO), (3)Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, (4)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (5) University of Milan

Background: The CC5, CXC3 and CC2 chemokines (CK) pathways are known to play a role in the pathogenesis of Auto Immune Hepatitis (AIH). Monitoring these CK has been previously shown to correlate with response to treatment in HCV related chronic hepatitis and cirrhosis. In his respect, we intended to assess the potential clinical utility of RANTES (CCL5), IP-10 (CXCL10) and MCP-1 (CCL2) in predicting stable disease remission in AIH patients receiving immunuppressive therapy. **Methods:** Plasma samples of 53 patients with AIH were analyzed at the time of treatment

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

initiation and at biochemical, clinical and histological remission. RANTES, IP-10 and MCP-1 levels were determined by ELISA tests (Quantikine ELISA Kit R&D System). A group of 49 healthy donors (HD) served as controls **Results:** At baseline, while median IP-10 and MCP-1 levels were higher in AIH patients than in HD (261 pg/ml vs 101 pg/ml, $p > 0.01$ and 689 pg/ml vs 330 pg/ml, $p > 0.01$, respectively), median RANTES levels were similar in AIH patients and in HD, but differed according to the subsequent increasing or decreasing kinetics (28765 pg/ml vs 52010 pg/ml and 70960 pg/ml vs 52010 pg/ml, $p > 0.01$, respectively). At remission, both groups showed no significant differences compared to HD. IP-10 and MCP-1 values showed a significant decrease from baseline to remission approaching those of HD (501 pg/ml vs 106 pg/ml and 689 pg/ml vs 387 pg/ml, $p > 0.01$, respectively). **Conclusion:** In conclusion, monitoring plasma IP-10 and MCP-1 in levels, as well as RANTES levels may help in predicting stable AIH remission and in supporting the decision if and when to suspend immune suppressive, maintenance therapy. RANTES may also be useful in patients with low baseline levels.

4527-C | WHOLE-TRANSCRIPTOMICS, METABOLOMICS AND CYTOKINOMICS PROFILING REVEALS MOLECULAR MECHANISMS INVOLVED IN RESPONSE OF PBC/AIH OVERLAP SYNDROME

Fan Yang, West China Hospital, Sichuan University

Background: PBC/AIH overlap syndrome (OS) refers to the coexistence of features of autoimmune hepatitis (AIH) with primary biliary cholangitis (PBC), but poor understanding of its pathogenesis has limited effective clinical management of these patients. The aim of this work was to provide an overview of potential molecular mechanisms and crucial metabolic pathways underlying PBC/AIH OS by integrating whole-transcriptomics and metabolomics combined with the multiple analysis of plasma cytokines. **Methods:** We performed whole-transcriptome sequencing ($n = 5$) based on the liver tissues of responders (R) and non-responders (NR) from ten PBC/AIH OS patients. Peripheral blood metabolomics were performed on plasma from 50 PBC/AIH OS patients subdivided into R ($n = 20$) and NR ($n = 30$). A large panel of cytokines was evaluated on the same plasma using LEGENDplex™ bead-based immunoassay technology. **Results:** There were 223 differentially expressed (DE) mRNAs, 189 DE lncRNAs, 39 DE circRNAs and 63 DE miRNAs in total. Functional pathway analysis revealed transcriptional levels were mainly related to immune response, metabolic process and cytokine signaling. 71 metabolites showed significant differences between the two groups. Joint-pathway analysis showed altered pathways aberrantly expressed were mainly enriched in glutathione metabolism, primary bile acid biosynthesis, taurine and hypotaurine metabolism. Furthermore, significant differences were detected in inflammatory cytokines and peripheral blood immune cell profiles between two groups. **Conclusion:** Overall, this exploratory study provides an overview of potential molecular mechanisms and crucial metabolic pathways underlying PBC/AIH overlap syndrome, which may further assist in the development of therapeutic targets of these patients.

Background: We disclosed an involvement of biliary epithelial senescence in the pathogenesis of primary biliary cholangitis (PBC) and other cholangiopathies. Recent studies suggest that a unique subtype of programmed death-ligand 1 (PD-L1)-positive senescent cells escape from immune-surveillance and express higher levels of senescence associated secretory phenotypes (SASPs). The expression of PD-L1 reportedly depends on cGAS (cyclic GMP-AMP synthase-STING (stimulator of interferon genes)) pathway. We hypothesized that a unique PD-L1-positive subtype of senescent biliary epithelial cells (BECs) may be related to the pathogenesis of PBC in association with cGAS-STING pathway. **Methods:** The expression of PD-L1, STING and their association with senescent markers $p16^{INK4a}$ and $p21^{WAF1/Cip1}$ were immunohistochemically determined in livers taken from the patients with PBC ($n = 87$; early stage [stages 1, 2], 54: late stage [stages 3,4], 33) and 107 control diseased and normal livers, including primary sclerosing cholangitis (PSC). Cellular senescence was induced in cultured BECs by a treatment with serum depletion or glycochenodeoxycholic acid (GCDC, 200mM) for 4-7 days. The effect of STING inhibition on mRNA and protein expression of PD-L1, STING and various SASPs including interferon (IFN)-beta and interferon induced protein with tetratricopeptide repeats 3 (Ifit3) was examined using *si*RNA in senescent BECs. Proliferation activity and cellular senescence were detected by WST-1 assay and senescence-associated ß-galactosidase (SA-ß-gal), respectively. **Results:** The increased expression of PD-L1 was seen in a part of senescent BECs with $p16^{INK4a}$ and/or $p21^{WAF1/Cip1}$ in bile duct lesions in PBC. The expression of PD-L1 was significantly increased in BECs in the damaged small bile ducts involved in cholangitis in PBC, compared to control livers ($p < 0.01$). In contrast, PD-L1 was not expressed in BECs in ductular reactions in PBC and control livers. The expression of STING was significantly increased in BECs in small bile ducts and ductular reactions in PBC, compared to control livers ($p < 0.01$). The expression of PD-L1, STING and SASPs (IFN-beta, Ifit3) was significantly increased in senescent BECs induced by a treatment with serum depletion or GCDC ($p < 0.01$) and it was significantly suppressed by a knockdown of STING using *si*RNA ($p < 0.01$). A proliferation activity and cellular senescence were not affected by STING inhibition in BECs ($p < 0.01$). **Conclusion:** A unique subtype of senescent BECs with PD-L1 expression was present in BECs involved in destructive cholangitis but not in ductular reactions in PBC. This finding suggests a heterogeneity in senescent BECs in PBC. Senescent BECs with PD-L1 expression associated with cGAS-STING pathway may be involved in the pathogenesis of PBC.

f 4529-C | A MULTICENTER RANDOMIZED TRIAL COMPARING DENOSUMAB AND ZOLEDRONIC ACID FOR OSTEOPOROSIS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (DELTA STUDY)

Yoshitaka Arase[1], Tatehiro Kagawa[1], Yusuke Mishima[1], Kota Tsuruya[1], Shunji Hirose[1], Koichi Shiraishi[1], Keisuke Kakisaka[2], Tadashi Namisaki[3], Kosuke Matsumoto[4], Toru Setsu[5], Haruki Uojima[6], Masanori Abe[7], Taeang Arai[8], Tomomi Okubo[9], Masanori Atsukawa[8], Akira Honda[10], Shuji Terai[5], Hitoshi Yoshiji[3], Atsushi Tanaka[4] and Ministry of Health, Labour and Welfare (Japan) Research Project, The Intractable Hepatobiliary Disease Study Group, (1)Division of Gastroenterology and Hepatology, Department of Internal Medicine, Tokai University School of Medicine, (2)Iwate Medicial University, (3)Nara Medical University, (4)Teikyo University School of Medicine, (5)Graduate School of Medical and Dental Sciences, Niigata University, (6)National Center for Global Health and Medicine, (7)Ehime University Graduate School of Medicine, (8)Nippon Medical School Hospital, (9) Nippon Medical School Chibahokusoh Hospital, (10) Joint Research Center, Tokyo Medical University Ibaraki Medical Center

Background: Osteoporosis is a major complication in patients with primary biliary cholangitis (PBC). Denosumab, a fully human monoclonal antibody against the receptor activator of nuclear factor-κB ligand (RANKL), increases bone mineral density (BMD) by inhibiting development and activity of osteoclasts and decreasing bone resorption. In this study, we compared the effects and safety of denosumab and bisphosphonates for osteoporosis in patients with PBC. **Methods:** We performed a multicenter, randomized, open-label, parallel-group trial in Japanese PBC patients with osteoporosis. Subjects were randomized 1:1 to subcutaneous denosumab 60mg every 6 months (D group) or bisphosphonate therapy with intravenous zoledronic acid (ZOL) 5 mg once-yearly (Z group). The primary end point was the mean percentage change in lumbar spine and total hip BMD between baseline and 12 months. We tested the non-inferiority of denosumab to ZOL with a non-inferiority margin of −2.4% for lumbar spine and −0.9% for total hip. Secondary endpoints were changes in laboratory parameters and the incidence of adverse events. **Results:** A total of 47 patients were enrolled and randomly assigned to the D group ($n = 25$) and the Z group ($n = 22$) between May 2018 and March 2021. Of these, 41 patients (87.2%) completed the study (D group, $n = 21$; Z group, $n = 20$). Baseline demographics and clinical characteristics were similar between the two groups. BMD at lumbar spine increased from baseline

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by 7.5% and 6.4% in the D and Z group, respectively, demonstrating the non-inferiority of denosumab with a difference of 1.1% (95% CI; −1.6%~3.8%). The increase in BMD at total hip was greater in the D group (5.0%) than that in the Z group (2.6%), but the difference did not meet non-inferiority (95% CI; −1.3% ~6.2%). The ratio of ALP to upper limit of normal (ULN) significantly decreased from 1.2 ± 0.9 at baseline to $0.9 \pm 0.8 \times$ULN at 12 months in the D group ($P < 0.01$) and from 1.1 ± 0.6 to $0.8 \pm 0.5 \times$ULN in the Z group ($P < 0.01$), but the rates of change in ALP did not differ between groups (−24.8% vs. −23.1%, $P = 0.75$). The bone turnover markers significantly decreased in both groups, but the rates of change were not different between groups; tartrate-resistant acid phosphatase 5b (−52.9% vs.−49.6%, $P = 0.73$) and bone-type ALP (−45.0% vs.−36.9%, $P = 0.27$). The incidence of adverse events was significantly lower in the D group compared with the Z group (14.3% [hypocalcemia 2, arthralgia 1] vs. 45.0%[fever 7, hypocalcemia 2, headache 2, nausea 1, back pain 1, myalgia 1], $P = 0.03$). In this study period, fresh vertebral fractures and osteonecrosis of the jaw were not observed. **Conclusion:** Denosumab was non-inferior to ZOL in increasing BMD at lumbar spine in 12 months and was associated with fewer adverse effects than ZOL. Denosumab is a highly useful therapeutic agent for osteoporosis in patients with PBC.

4530-C | A PILOT STUDY EXAMINING A LOW-SULFUR/LOW-PROTEIN DIET VERSUS THE SPECIFIC CARBOHYDRATE DIET IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

Gila Feinman Sasson[1], Demsina Babazadeh[1], Macie Andrews[1], Shelley Hurwitz[1], Maia Paul[1], Nadine Javier[1], Malav Dave[1], Alexandra Austin[1], Linda Gray[2], Francene Steinberg[2], Elaine Souza[2], Daniel S. Pratt[3], Christopher L. Bowlus[4] and Joshua R. Korzenik[1], (1) Brigham and Women's Hospital, (2)University of California, Davis, (3)Massachusetts General Hospital, (4)University of California Davis, Sacramento, CA

Background: Little is known about the role of diet in primary sclerosing cholangitis (PSC) despite increasing interest in diet as a therapeutic approach. An emerging dietary therapy from ulcerative colitis (UC) studies suggest high-sulfur/high-protein diet may be associated with increased disease activity. This study compares the effects of a low-protein diet (LPD) and Specific Carbohydrate Diet (SCD) on clinical, microbial and metabolomic parameters in PSC. We propose that SCD, with higher protein content, increases disease activity and LPD reduces activity, as assessed by alkaline phosphatase (ALP), through modulatory effects on the gut microbiome. **Methods:** Individual's with a diagnosis of large-duct PSC were screened for eligibility including ALP > 1.5 x upper limit of normal, and randomized 1:1 to LPD or SCD for 8 weeks under dietitian supervision, with an option to continue self-directed for 4 additional weeks. The primary outcome was within-group change in ALP. Participants attended 7 video visits with dietitians. Diet was assessed using 3-day food diaries every 2 weeks and a baseline Food Frequency Questionnaire. Blood and stool were collected every 4 weeks. Groups were compared with exact Wilcoxon-Mann-Whitney tests. **Results:** Twenty participants were enrolled. Decrease in ALP (defined by ≥ 10% reduction) in LPD was seen as early as week 4 and was sustained throughout week 8. At week 4, 60% in LPD demonstrated ≥ 10% reduction in ALP (14.72- 39.65%) compared to 22% in SCD (11.59-23.76%) (P = 0.05). Macronutrient analysis of week 4 ALP response demonstrated decreased protein consumption in responders at week 2 (P = 0.02), between weeks 0 and 2 (P = 0.03), and the average of weeks 2 and 4 compared to week 0 (P = 0.03). There was no significant difference in carbohydrate consumption between responders and non-responders. LPD reported lower protein consumption at all time points (P < 0.05) while SCD reported lower carbohydrate consumption at all time points (P < 0.05 at baseline and weeks 6-10), confirming dietary compliance in both groups. Metabolomic data submitted separately further supports an association between LPD and ALP response, particularly in the subset of individual's with PSC-UC. **Conclusion:** Our analysis demonstrates that LPD is associated with a meaningful ALP reduction that appears to be driven by protein consumption. In contrast, a high protein diet is associated with worsening ALP. Additional dietary and microbiome analyses will better understand the impact of diet on microbiome and disease activity in PSC.

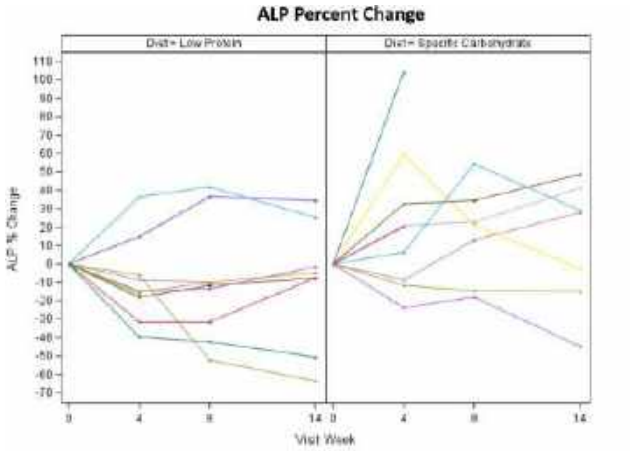

Figure 1. Percent change in ALP in the Low Protein Diet and Specific Carbohydrate Diet groups

4531-C | ANALYSIS OF NONINVASIVE DIAGNOSTIC PREDICTORS IN PATIENTS WITH PBC-AIH OVERLAP SYNDROME BASED ON CLINICAL AND PATHOLOGICAL CHARACTERISTICS

Li Zhang[1], Hongmei Wu[1], Li Liu[2], Xiaofeng Shi[1], Peng Hu[3] and Yu Lei[1], (1)Institute for Viralhepatitis, Second Affiliated Hospital of Chongqing Medical University, (2) Second Affiliated Hospital of Chongqing Medical University, (3)Second Affiliated Hospital of Chongqing Medical University, Chongqing, China

Background: Primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH) are main categories of autoimmune liver disease. Approximately 20% of PBC patients displayed overlapping features of both PBC and AIH, referred as PBC-AIH overlap syndrome (PBC-AIH OS). Early diagnosis and proper treatment of PBC-AIH OS are crucial for the prognosis of these patients. This study aimed to explore non-invasive hematological indicators for early diagnosis of PBC-AIH OS. **Methods:** By retrospective analysis, the general characteristics, clinical manifestations, biochemical tests, immunological tests, liver histological examinations, and imaging examinations in pathology suggested non-cirrhotic patients with PBC-AIH OS and PBC at the time of initial diagnosis were analyzed. The correlations between blood indexes and histopathological features were analyzed. Univariate logistic regression analysis and multiple-factors analysis via multivariate logistical regression were used to predict the diagnosis of PBC-AIH OS based on the hematological indicators. **Results:** A total of 83 pathologically non-cirrhotic AILDs patients were included in this retrospective study who underwent liver biopsy. There were no statistically significant differences in mean age, sex, or symptoms between PBC-AIH OS and PBC patients. Compared to PBC patients, PBC-AIH OS patients showed significantly high levels of serum globulin, ALT, AST, total bilirubin, direct bilirubin, ALP, GGT, total bile acid, IgG and significantly low levels of serum albumin and cholinesterase. Univariate logistic regression analysis and multiple-factors analysis via multivariate logistical regression showed that direct bilirubin (DBIL), total bilirubin (TBIL) and IgG were significant predictors of PBC-AIH OS. Histopathological analysis of liver

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

indicated that all patients had different degrees of intrahepatic small bile duct injury, while PBC-AIH OS patients also had moderate to severe interface hepatitis. In addition, compared with PBC patients, Metavir score showed that the liver fibrosis grade of PBC-AIH OS patients was significantly higher (The degree of inflammation and fibrosis were statistically different, $P < 0.05$). In addition, in both PBC-AIH OS and PBC patients, a subset of patients who did not progress to histologically cirrhosis developed intrahepatic ductopenia (30.77% and 22.73%, respectively), and biliary enzyme and bilirubin levels were significantly elevated in these patients. **Conclusion:** The degrees of hepatocyte inflammation, cholestasis and liver fibrosis in PBC-AIH OS patients were significantly higher than that in PBC patients. No matter in PBC-AIH OS or PBC patients who have not progressed histologically to cirrhosis, a portion of them have intrahepatic loss of small bile ducts and greater cholestasis. DBIL, TBIL and IgG can be used as noninvasive diagnostic indicators to predict PBC-AIH OS.

4532-C | ASSESSMENT OF BIOPSY-PROVEN LIVER FIBROSIS BY TRANSIENT ELASTOGRAPHY (FIBROSCAN) IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A REAL-WORLD STUDY IN CHINA

Jialiang Chen, Yao Liu, Yufei Bi, Fangyuan Gao and Xianbo Wang, Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: Noninvasive measurement of liver stiffness with transient elastography (TE) by Fibroscan has been widely used for the assessment of liver fibrosis in various chronic liver diseases, including primary biliary cholangitis (PBC). However, previous studies using TE to diagnose liver fibrosis in PBC mainly focused on Western populations, while there is still a lack of relevant research from Asian or Chinese populations. The current study aimed to investigate the real-word diagnostic performance of liver stiffness measurement (LSM) for the determination of fibrosis stage in Chinese patients with PBC. **Methods:** A total of 277 patients (88.4% female, median age: 52 y) diagnosed with PBC who underwent liver biopsy and LSM by Fibroscan were retrospectively enrolled from January 2008 to December 2021 in a tertiary hospital in China. Histological and fibrosis stages were determined according to the Ludwig's classification and METAVIA scoring system. Spearman correlation test was used to analyze the correlation of LSM and fibrosis stage. The accuracy of LSM for the determination of histological and fibrosis stages were determined by a receiver operating characteristics (ROC) curve analysis and compared with that of other serum fibrosis models, including the aspartate aminotransferase to platelet ratio index (APRI), fibrosis-4 (FIB-4), AST/ALT ratio (AAR) and Mayo risk score (MRS). Optimal cutoff values between fibrosis categories were determined at the maximum total sensitivity and specificity. **Results:** The number of patients with fibrosis stages F0-F1, F2, F3, and F4, were 131 (47.3%), 40 (14.4%), 20 (7.2%), and 86 (31.0%), respectively. The number of patients with histological stages I, stage **a**, stage III, and stage **c** , were 89 (32.1%), 66 (23.8%), 36 (13.0%), 86 (31.0%), respectively. LSM ranged from 2.8 to 75.0 kPa (median, 10.1 kPa). LSM was correlated to both fibrosis (Spearman's $r = 0.753$, $P < 0.001$) and histological ($r = 0.778$, $P < 0.001$) stages. The areas under the ROC curves of LSM for diagnosing fibrosis stages $\geq$F2, $\geq$F3, and F4 were 0.902 (95%CI: 0.860-0.934), 0.920 (0.881-0.949), and 0.904 (0.863-0.936), respectively. The optimal cutoff values of LSM for fibrosis stages $\geq$F2, $\geq$F3, and F4 were 9.4, 14.9, and 16.1 kPa, respectively. LSM was significantly superior to FIB-4, APRI, AAR, and MRS in detecting severe fibrosis ($\geq$F3) and advanced histological stage (stage III/**c**) (all $P < 0.05$). **Conclusion:** Liver stiffness measurement using TE in real-world setting has high accuracy in assessing fibrosis and histologic stage in Chinese PBC patients, reinforcing its role as a first-line investigation in the noninvasive assessment of patients with PBC.

4533-C | ASSOCIATION BETWEEN ABO BLOOD TYPE AND HISTOLOGIC FIBROSIS STAGE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Jialiang Chen, Yao Liu, Yufei Bi, Fangyuan Gao and Xianbo Wang, Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: Primary biliary cholangitis (PBC) is an immune-mediated chronic cholestatic liver disease that can progress to liver fibrosis and cirrhosis. Advanced histologic stage has been proven to be an independent predictive factor of liver transplantation or death in PBC patients. The non-O phenotype of the ABO genotype has been linked with an increased risk of liver fibrosis in hepatitis C. We aimed to investigate the association between blood group status and histological stage in patients with PBC. **Methods:** A single-center retrospective observational study were performed in a tertiary hospital in China. From January 2008 to December 2021, a total of 246 patients diagnosed with PBC who underwent liver biopsy and ABO blood type measurement were retrospectively collected. The Ludwig's classification was used to evaluate histological stages. Multivariate logistic regression was used to assess the relationship between ABO blood groups and histological stage. The adjusted odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. PBC. **Results:** In our study population, there were 218 (88.6%) women, with a mean age of 51.2 $\pm$ 9.5 years. There were 57 patients (23.2%) in histological stage I, 56 (22.7%) in stage **a**, 44 (17.9%) in stage III and 89 (36.2%) in stage **c** . The proportion of blood groups A, B, AB and O were 34.1%, 29.3%, 6.5%, and 30.1%, respectively. Patients with non-O blood groups (A, B, or AB type) had a significantly higher risk of histological advanced-stage (stage III/**c**) than those with blood group O (crude OR = 2.02, 95% CI: 1.16 - 3.51; the fully adjusted OR = 4.48, 95% CI: 1.30 - 15.37). There was a significant interactive effect of AMA antibodies, gp210 antibodies, and non-O blood groups on histological stage in patients with PBC ($P_{\text{interaction}} < 0.05$). When AMA or gp210 antibodies are negative, patients with non-O blood groups have a higher risk of advanced histological stage (crude OR = 4.52, 95% CI: 1.70 - 12.06; crude OR = 4.40, 95% CI:1.54 - 12.57). **Conclusion:** This is the first study that has evaluated the potential relationship between PBC histological stage and ABO blood groups. This study indicates that PBC patients with non-O blood group types have a higher risk for advanced histological stage compared with O blood group patients, suggesting that ABO blood group must be taken into account for accurate assessment of the risk of fibrosis severity in patients with PBC.

Disclosures: The following people have nothing to disclose: Jialiang Chen, Yao Liu, Yufei Bi, Fangyuan Gao, Xianbo Wang

f 4534-C | ASSOCIATIONS BETWEEN LIVER BIOMARKERS AND CLINICAL OUTCOMES IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: A RETROSPECTIVE REAL-WORLD STUDY

Jun Xu[1], Jessica Duchen[2], Luke Liu[1], Catherine Frenette[1], Stephanie Watkins[1], William Barchuk[1], Lisa Boyette[1] and Shahed Iqbal[1], (1)Gilead Sciences, Inc., (2)Trinetx LLC

Background: Primary sclerosing cholangitis (PSC) is a disease of inflammation and fibrosis of the bile ducts. PSC is not well characterized due to small study samples and patient heterogeneity. We explored the associations between liver biomarker levels and clinical outcomes in a large cohort of patients with PSC. **Methods**: Adult patients with $\geq$2 PSC ICD10 codes (K83.01) were included from the TriNetX Research Database. Liver biomarkers (albumin, total bilirubin, ALP, ALT, AST and APRI) at baseline and 6−12 months prior to an outcome were measured. Outcomes included: cirrhosis, decompensation, liver failure, liver cancer and a composite outcome (cirrhosis/liver transplant/death). Associations between biomarker levels and outcomes were assessed using Cox proportional hazard models including age, sex, region, IBD treatment, comorbidities, neutrophil, platelets and lymphocyte counts. Adjusted Hazard Ratios (aHR) with 95% confidential intervals (CI) were reported for higher quartiles (Q2−Q4) of biomarker measures vs Q1. **Results**: PSC patients (N = 2373) were mostly 35 −64 years (57%, mean: 50 $\pm$ 17 y), male (60%), and white (80%) with a mean follow-up of 4.2 years. Percent changes in biomarkers from baseline to outcomes were associated ($p < 0.05$) with most events (Figure 1). In adjusted models, baseline higher ALT was associated (Q3 vs Q1) with composite outcome [aHR (95% CI): 1.67 (1.1−2.6)] and liver failure [4.6 (1.3−16.8)]; AST (Q4 vs Q1) with decompensation [3.8 (1.2−11.6)] and liver cancer [3.7 (1.2−11.6)]; ALP (Q4 vs Q1) with liver failure [6.1 (1.7−21.7)]; and total bilirubin (Q4 vs Q1) with composite outcome [1.6 (1.0−2.4)]. However, for liver cancer, PSC patients had lower ALP (Q4 vs Q1) at baseline [0.3 (0.1−0.6)]. For biomarkers at outcomes (Q4 vs Q1) lower albumin correlated with risk of cirrhosis [aHR (95% CI): 0.5 (0.3−0.7)], composite outcome [0.4 (0.2−0.6)], decompensation, [0.2 (0.05

−0.5)], liver failure [0.3 (0.1−1.0)] and liver cancer [0.3 (0.1−0.9)]; increased ALP was associated with a composite outcome [1.8 (1.0−3.2)]; total bilirubin with decompensation [4.6 (1.2−17.3)]; and increased ALT was associated with cirrhosis [2.0 (1.2−3.4)] and composite outcome [2.2 (1.2−3.8)]. **Conclusion**: Liver biomarkers at baseline and changes during follow-up were associated with PSC outcomes. Further research is needed to identify the exact clinical correlates and confirm prognostic thresholds for these biomarkers.

4535-C | CLINICAL CHARACTERISTICS, TREATMENT, AND OUTCOMES OF PRIMARY SCLEROSING CHOLANGITIS IN CHINESE PATIENTS

Tongtong Meng[1,2], Xiaoqian Xu[2], Weijia Duan[1], Junqi Niu[3], Huiguo Ding[4], Wen Xie[5], Lu Zhou[6], Bangmao Wang[6], Jie Li[7], Xinyan Zhao[1], Xiaojuan Ou[1], Hong You[8], Jidong Jia[1] and Yuanyuan Kong[2], (1)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (2)Clinical Epidemiology and EBM Unit, Beijing Friendship Hospital, Capital Medical University, Beijing Clinical Research Institute, Beijing, China, (3)Department of Hepatology, First Affiliated Hospital of Jilin University, Changchun, China, (4)Department of Gastroenterology and Hepatology, Beijing You'an Hospital, Capital Medical University, Beijing, China, (5)Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (6)Department of Gastroenterology and Hepatology, Tianjin Medical University General Hospital, Tianjin, China, (7) Department of Infectious Diseases, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, China, (8)Liver Research Center, Beijing Friendship Hospital, Capital Medical University

Background: Primary sclerosing cholangitis (PSC) is a rare liver disease, and its epidemiology has not been well described in China. Our study aimed to depict the demographic and clinical profile of Chinese patients with PSC. **Methods:** The PSC cases were identified by a retrospective review of electronic medical records (EMRs) for the inpatients and outpatients from May 2009 to May 2023 in eight tertiary hospitals in China. ICD-10 and natural language, together with clinical records including biochemical, imaging (MRCP/ERCP), and/or liver biopsy were used to confirm the PSC cases. Data on demographic characteristics, clinical and biochemical profiles, treatment, and clinical outcomes were retrieved. **Results:** Finally, 108 PSC cases were enrolled with a median age of 47 (33, 57) years and 45.4% male patients. The median interval from the first onset of PSC-related symptoms to definitive diagnosis was 1.0 (IQR: < 1.0, 3.0) years. While 63 (58.3%) patients were diagnosed by imaging, 24 (22.2%) by

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

liver biopsy, and 17 (15.7%) by a combination of histology, imaging, biochemistry, and other clinical features. The first clinical presentations were jaundice (42.7%,41/96), fatigue (31.3%, 30/96), abdominal discomfort (29.2%, 28/96), and pruritus (16.7%, 16/96). The median levels of alkaline phosphatase, glutamyl transpeptidase, total bilirubin, and total bile acid were 309.5 U/L (*IQR*: 176.8 U/L, 513.3 U/L), 251.0 U/L (*IQR*: 113.5 U/L, 543.5 U/L), 51.6 μmol/L (*IQR*: 19.1 μmol/L, 139.9 μmol/L), 60.2 μmol/L (*IQR*: 17.2 μmol/L, 135.2 μmol/L), respectively, with no statistical difference in gender ($P = 0.601$~0.896). The proportions of elevated immunoglobulin G and immunoglobulin M were 40.2% and 20.0% in PSC cases, respectively, with no statistical difference in gender. The antineutrophil cytoplasmic antibody (ANCA) positive rate was 38.6% (27/70), with a higher rate in males than in females (58.1% *vs.* 23.1%, $P = 0.006$). Totally, 23.9% (21/88) patients were concomitant with inflammatory bowel disease (IBD), and 9.1% (8/88) with other autoimmune diseases. Eighty-six patients had prescription records, with 89.5%, 62.8%, 29.1%, and 9.3% of them taking ursodeoxycholic acid, hepatoprotective agents, steroid/immunosuppressive agents, and antibiotics, respectively. The 3-year cumulative rates of decompensated cirrhosis and liver transplantation/death were 37.6 % (95% *CI*: 26.4%, 50.3%), and 26.4% (95%*CI*: 16.3%, 39.8%), respectively. The 5-year cumulative rates of decompensated cirrhosis and liver transplantation/death were 55.5% (95%*CI*: 40.0%, 70.0%), and 41.3% (95%*CI*: 26.5%, 57.9%), respectively. **Conclusion:** In China, PSC patients had a more balanced gender distribution, less concomitant IBD, and a lower ANCA-positive rate. In terms of treatment, the main focus was on symptomatic treatment to improve liver biochemistry.

Disclosures: The following people have nothing to disclose: Tongtong Meng, Xiaoqian Xu, Weijia Duan, Junqi Niu, Huiguo Ding, Wen Xie, Lu Zhou, Bangmao Wang, Jie Li, Xinyan Zhao, Xiaojuan Ou, Hong You, Jidong Jia, Yuanyuan Kong

4536-C | CLINICAL COURSE OF PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

Kazuma Shinkai[1], Hayato Hikita[1], Kazuki Maesaka[2], Akira Doi[2], Yuki Tahata[2], Kazuhiro Murai[1], Takahiro Kodama[2], Tomohide Tatsumi[2] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2) Osaka University Graduate School of Medicine

Background: The clinical course of patients with primary sclerosing cholangitis (PSC) and factors associated with transplantation free prognosis have not been fully investigated in Japan. The aim of this study was to assess the clinical course of patients with PSC in our hospital and to clarify the factors related to transplantation free prognosis. **Methods:** Patients with PSC who have visited our hospital from January 2000 to March 2022 were searched from the medical record and enrolled in this study. Their characteristics at diagnosis were evaluated. The time from the date of diagnosis to liver transplantation or death was calculated as transplantation free survival. The factors associated with transplantation free survival were analyzed using Cox proportional hazards model. **Results:** Of 48 PSC patients who have visited our hospital, the characteristics at diagnosis were available in 40 patients. Twenty-eight patients were males and median age at diagnosis was 34 (6-75) years. Patients with Child-Pugh classification A, B, and C were 31, 5, 4, respectively. Patients with ALBI grade 1, 2, and 3 were 17, 18, and 5, respectively. Median MELD score was 8 (5-23). Nineteen patients were classified in the New Mayo model low-risk group, 16 were in the intermediate-risk group, and 5 were in the high-risk group. Sixteen patients were complicated by ulcerative colitis. Median transplantation free survival was 2034 (12-7990) days, and 8 patients received liver transplantation and 7 died. In univariate analysis, γ-GTP, albumin, total bilirubin, PT-INR, Child-Pugh classification, ALBI grade, MELD score, and the New Mayo model were associated with transplantation free survival. Multivariate analysis showed that albumin and total bilirubin were the independent factors associated with transplantation free survival. Transplantation free survival rate at 5 years after diagnosis was 100% in the low-risk group, 58.4% in the intermediate-risk group, 0% in the high-risk group of New Mayo model. Transplantation free survival rate at 5 years after diagnosis was 100% in ALBI grade 1, 67.8% in grade 2, and 0% in grade 3. Of 7 patients who died, 5 patients were awaiting transplantation. Of these patients, 4 patients had rapidly progressing liver failure triggered by events such as ascites exacerbation, portal vein thrombosis, spontaneous bacterial peritonitis, rupture of esophageal varices, pyogenic cholangitis. One patient, who was complicated by ulcerative colitis, died of pneumocystis carinii pneumonia. **Conclusion:** Albumin and total bilirubin at diagnosis were independent prognostic factors in patients with PSC at our hospital. The New Mayo model and ALBI grade may be useful for risk stratification for transplantation and mortality. Patients awaiting transplantation should be carefully monitored for complications of portal hypertension and infectious disease.

4537-C | CLINICAL SUPPORT USING DEEP LEARNING TO PREDICT THE NEED FOR INTERVENTION IN ELDERLY PATIENTS WITH PRIMARY BILIARY CHOLANGITIS FROM MULTICENTER DATA

Takafumi Tonouchi[1], Hiroteru Kamimura[2], Hiroki Maruyama[1], Suguru Miida[1], Norihiro Sakai[2], Yusuke Watanabe[2], Naruhiro Kimura[2], Toru Setsu[2], Hiroyuki Abe[1], Takeshi Yokoo[2], Akira Sakamaki[2], Atsunori Tsuchiya[1], Kenya Kamimura[3] and Shuji Terai[2], (1) Niigata University, (2)Graduate School of Medical and Dental Sciences, Niigata University, (3)School of Medicine, Niigata University

Background: In Japan, a super-aging society ahead of all over the world, more than 40% of the population has six or more types of drugs called polypharmacy. Aging society caused the number of cases of elderly-onset primary cholangitis (PBC). In addition, many patients are taking multiple medications such as antihypertensive and hyperlipidemic drugs at the time of diagnosis, and even ursodeoxycholic acid (UDCA) may cause polypharmacy and poor oral compliance when the number of tablets is large, and some patients are troubled by the dosage and administration method. Disease types are divided into hepatic failure type, portal hypertensive type, and asymptomatic to slowly progressive type. Even in the slowly progressive type, the pattern of progression may not be linear due to treatment modification. In addition, ALBI score and grade have recently been reported as prognostic indicators. We aimed to demonstrate the safety of UDCA dose reduction in patients with the settled disease and low medication adherence and to improve polypharmacy by using AI tools. The predictive models were built based on algorithms set up by SONY Neural Network Console, and their accuracy was compared using statistical analysis. **Methods:** Patients enrolled in this study prior to 2018 and with 10 years of continuous data were included. Liver biopsy, stage classification, AST, ALT, Alb, T-bil, esophageal varices, itchy skin, UDCA dosage at diagnosis, and AST, ALT, Alb, T-bil one year after starting medication, and ALBI score after 10 years were incorporated into a Deep Neural Network as supervised data. Patients with onset at age 65 years or older and with 10 years of follow-up were validated as test data. **Results:** Of the 140 cases, 85% were female, age 58 (28-78) years, with the asymptomatic carrier (18%), ALBI score -2.95 (-3.75-1.05) at diagnosis and -2.85 (-3.41-1.17) at 10 years. In addition, 10 cases with onset over 60 years of age and follow-up over 10 years, age 62 (60-72) years, data at the first visit and 1 year later were entered as test data. Machine learning results showed that only 2 of the 30 cases were incorrect, and the overall accuracy rate was over 90%. Furthermore, patients whose ALBI grade changed had a correct answer rate of about 80%. **Conclusion:** In patients with asymptomatic PBC patients detected by medical checkups or promising long-term prognosis, and in routine clinical practice, deep learning can be used to predict ALBI scores at 10 years with high predictive accuracy using data from one year later as a decision-making tool for therapeutic intervention. The results also suggest deep learning can contribute to the selection of UDCA dosage and prevent polypharmacy. Disclosures: The following people have nothing to disclose: Takafumi Tonouchi, Hiroteru Kamimura, Hiroki Maruyama, Suguru Miida, Norihiro Sakai, Yusuke Watanabe, Naruhiro Kimura, Toru Setsu, Hiroyuki Abe, Takeshi Yokoo, Akira Sakamaki, Atsunori Tsuchiya, Kenya Kamimura, Shuji Terai

4538-C | CLINICAL TRIAL AND REAL-WORLD OUTCOMES IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS TREATED WITH OBETICHOLIC ACID PER CURRENT US LABEL

Kris V. Kowdley[1], Gideon Hirschfield[2], Tracy Mayne[3], Elizabeth S. Malecha[3], Charles Coombs[4], Erik Ness[3], John D. Seeger[5] and M. Alan Brookhart[6,7], (1)Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, Seattle, WA, USA, (2)Toronto Centre for Liver Disease, Toronto General Hospital, University of Toronto, Toronto, Ontario, Canada, (3)Intercept Pharmaceuticals, Inc., Morristown, NJ, (4)Real World Evidence, Syneos Health, Morrisville, NC, USA, (5)Optum Epidemiology, Boston, MA, (6) Target Rwe, Durham, NC, (7)Department of Population Health Sciences, Duke University, Durham, NC

Background: Obeticholic acid (OCA) received accelerated approval for primary biliary cholangitis (PBC) in 2016 based on significant reduction in alkaline phosphatase, a surrogate marker predictive of clinical outcomes. The label has been revised twice, excluding patients with hepatic decompensation or comorbid cirrhosis + portal hypertension (PH). Data from the COBALT phase 3b/4 outcomes trial with external control (EC) and the fully real-world HEROES study were reanalyzed, including only patients consistent with current US prescribing information (USPI) and using an expanded composite endpoint including PH. **Methods:** COBALT, a double-blind, placebo-controlled trial, randomized subjects to OCA treatment (5 mg titrated to 10 mg if tolerated) or placebo (intent-to-treat analysis). An EC group was created from the US Komodo Health database using standardized morbidity ratio (SMR) weighting (as-treated analysis). HEROES, a nested trial emulation using the Komodo Health database, compared SMR-weighted patients treated with OCA with those who were eligible for OCA but not treated with OCA (as-treated). We reanalyzed data from patients consistent with current USPI (excluding hepatic decompensation and cirrhosis + PH). In consultation

with the FDA, the original endpoint of death, liver transplant, uncontrolled ascites, model for end-stage liver disease (MELD) score > 15, and hospitalization for hepatic decompensation was expanded to include additional decompensating events and PH. COBALT EC and HEROES excluded MELD. **Results:** In COBALT RCT, 21/81 (25.9%) OCA-treated and 19/68 (27.9%) placebo subjects experienced a composite event (HR, 0.88; 95% CI, 0.47–1.65). In the COBALT as-treated EC analysis, 10/81 (12.4%) OCA-treated patients and 18/74 (24.6%) non–OCA-treated weighted controls experienced an event (HR, 0.36; 95% CI, 0.16–0.79). In the HEROES trial emulation, 8/308 (2.6%) OCA-treated and 28/310 (9.0%) non–OCA-treated weighted controls experienced an event (HR, 0.46; 95% CI, 0.16–0.91). **Conclusion:** Among patients consistent with the current USPI, a composite endpoint of death, liver transplant, and progression to hepatic decompensation and/or PH was less frequent for OCA-treated patients. Despite substantial treatment crossover and informative censoring, the COBALT RCT showed a non-statistically significant efficacy signal in favor of OCA treatment, and both the COBALT EC and HEROES trial emulation studies showed statistically significant superiority of OCA vs non-treatment.

Figure. Time to composite FDA expanded endpoint for (A) COBALT intent-to-treat analysis, (B) COBALT external control as-treated analysis, and (C) HEROES trial emulation as-treated analysis.

4539-C | CMV INFECTION AND ACUTE CELLULAR REJECTION ARE ASSOCIATED WITH RISK OF RECURRENT PRIMARY SCLEROSING CHOLANGITIS AND GRAFT FAILURE AFTER LIVER TRANSPLANTATION

Mojmír Hlavatý, Lukas Bajer, Jan Brezina, Pavel Wohl, Istvan Modos, Julius Spicak and Pavel Drastich, Institute for Clinical and Experimental Medicine

Background: Primary sclerosing cholangitis (PSC) is a chronic liver disease causing inflammation of the bile ducts, forming progressive strictures and stenoses of bile ducts resulting in recurrent cholangitis, liver cirrhosis and death. Liver transplantation (LT) is necessary for most of the patients as the only curative treatment. However, about 30% of patients develop recurrence of PSC (rPSC), which negatively impacts the outcome of liver grafts and patients. The pathogenesis of recurrent disease is multifactorial, but not entirely understood. **Methods:** The aim of this study was to evaluate the risk factors for rPSC and graft failure (GF) in patients after LT for PSC and PSC/AIH overlap syndrome. Furthermore, we evaluated the patient survival, graft survival and the patient survival after post-LT. In this single-centre retrospective study (IKEM, Prague, Czech Republic), we included patients who underwent LT for PSC in our transplant centre between 1996-2019. **Results:** A total of 160 patients after LT for PSC and PSC/AIH overlap syndrome were included in the study. Biliary strictures after LT developed in 67 (41.88%) patients, of which 16 (23.88%) were anastomotic. rPSC was confirmed in totally 51 (31.87%) patients. The mean time to diagnosis of rPSC was 6.2 (CI 95% +- 1.04) years. In multivariant analysis of risk factors for rPSC: Cytomegalovirus (CMV) infection (HR 3.21; 95% CI 1.43-7.19), at least one episode of acute cellular rejection (ACR) (HR 3.00; 95%CI 1.00-9.03) and length of hospitalization after LT (HR 1.03; 95% CI 1.01-1.05) were statistically significant predictors of rPSC.
Liver retransplatation (reLT) due to GF was performed in 23 patients (15.22%). The cause of GF was as follows: rPSC in 18 patients (78.26%), hepatic artery thrombosis in 2 patients (8.69%), primary graft dysfunction in 2 patients (8.69%) and persistent biliary leak in 1 patient (4.35%). The median time to reLT due to rePSC was 8.59 (IQR 6.84,13.81) years. Furthermore, 3 patients required 2nd reLT and 1 patient 3rd reLT. In multivariant survival analysis, CMV infection after LT (HR 5.00; 95%CI 1.22-20.5), PSC/AIH overlap syndrome (HR 6.4; 95% CI 1.13-36.4) and length of hospitalization after LT (HR 1.04; 95%CI 1.01-1.07) were significant predictors for GF. Overall survival of patients in 5 years after LT was 89.5%. **Conclusion:** Based on our results, ACR, CMV infection and length of hospitalization post-LT were significant risk factors for rPSC. PSC/AIH overlap syndrome, length of hospitalisation post-LT and CMV infection were associated with worse liver graft outcome.

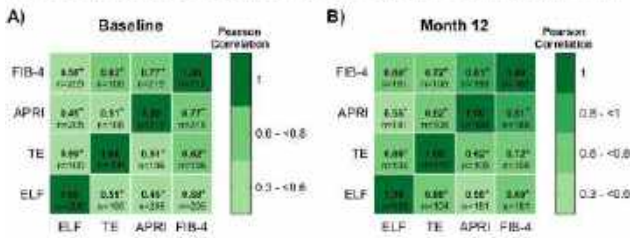
4540-C | CORRELATIONS BETWEEN FIBROSIS SCORING SYSTEMS AND TRANSIENT ELASTOGRAPHY IN THE PHASE 3 POISE STUDY OF OBETICHOLIC ACID IN PRIMARY BILIARY CHOLANGITIS

Robert G. Gish[1], Darren Wheeler[2], Radhika Nair[2], Tracy Mayne[2], Erik Ness[2], Elizabeth S. Malecha[2], Jing Li[2] and Alan Bonder[3], (1)Robert G Gish Consultants LLC, (2) Intercept Pharmaceuticals, Inc., Morristown, NJ, (3) Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School

Background: Transient elastography (TE) is a widely used, non-invasive method of evaluating hepatic fibrosis, a key prognostic factor in primary biliary cholangitis (PBC). However, not all practice sites have access to the equipment required to perform TE. Therefore, scoring systems such as Fibrosis-4 (FIB-4) represent a more feasible approach for many clinicians. We performed a post hoc sub-analysis of the phase 3 POISE PBC study to assess the correlations of TE with fibrosis scoring systems. **Methods:** POISE was a phase 3, randomized, double-blind trial evaluating obeticholic acid in patients with PBC. TE, enhanced liver fibrosis (ELF) score, FIB-4 score, and aspartate aminotransferase to platelet ratio index (APRI) were measured at baseline and Month 12. Associations across TE, ELF score, FIB-4, and APRI at baseline and Month 12 were evaluated via Pearson correlation. **Results:** At both baseline and at Month 12, all correlations across the 4 fibrosis markers were moderate or strong and statistically significant (Figure). Notably, of the 3 scoring systems (ELF, FIB-4, and APRI), FIB-4 had the highest correlation with TE at both time points (baseline [n = 106], 0.62; Month 12 [n = 106], 0.72; $P < 0.0001$ for both time points). The correlations between ELF and TE were 0.59 and 0.66 at baseline (n = 100) and Month 12 (n = 104), respectively ($P < 0.0001$ for both time points), and correlations between APRI and TE were 0.51 and 0.62 at baseline (n = 106) and Month 12 (n = 106), respectively ($P < 0.0001$ for both time points). **Conclusion:** This post hoc sub-analysis of the phase 3 POISE trial demonstrated significant associations across all 4 fibrosis markers. At both time points, the correlation between FIB-4 and TE was stronger than the correlations between ELF and TE and APRI and TE. Although FIB-4 is not validated in PBC, the moderately strong observed correlation with TE suggests that FIB-4 may be a possible surrogate for evaluating fibrosis in patients with PBC, especially in the case of limited access to TE.

Figure. Correlation across fibrosis markers at baseline (A) and Month 12 (B).



*Indicates $P<.0001$ for a given correlation.

4541-C | COVID PANDEMIC IMPACT ON CARE DELIVERY AND QUALITY OF LIFE AMONG PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A LARGE CANADIAN STUDY

Elizabeth Baguley[1], Madelyn Knaub[1], Gail Wright[2], Jessica VanDyke[1], Mark Gordon Swain[1], Deirdre McCaughey[1], Gideon Hirschfield[3] and Abdel-Aziz Shaheen[4], (1)University of Calgary, (2)Canadian PBC Society, (3)Toronto Centre for Liver Disease, University of Toronto, Toronto, Ontario, Canada, (4)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

Background: The pandemic-related restrictions impacted care delivery, particularly during the first year. We assess the impact of the pandemic on care delivery for patients with primary biliary cholangitis (PBC) and describe the quality of life they experienced during this time. **Methods:** The 29-item Patient-Reported Outcomes Measurement Instrument Survey (PROMIS-29) and a PBC Care Delivery questionnaire were administered to patients with PBC (n = 339), followed by two focus groups for patients (n = 14) and stakeholders (n = 3) between August 2021 and June 2022. The PROMIS-29 has seven health domains measured as T-Scores, including pain interference, depression, physical function, ability to participate in social roles/activities, fatigue, anxiety, and sleep disturbance, and a single pain intensity item. PROMIS-29 scores were compared between our PBC cohort and a reference population from the 2000 General US Census. Additionally, we compared PROMIS-29 scores of our population based on experienced care delay (laboratory work and imaging) and appointment type (in person vs. virtual). **Results:** Participants were primarily females (93.5%) and Caucasian (89.1%), with a median age of 62 yrs (IQR:55-70). Median time from PBC diagnosis was 9 years (IQR: 4-18). During the pandemic, most participants (76.4%) had ≥ 50% of their hepatologist appointments virtually; however, post-pandemic only 22.4% preferred to continue with virtual appointments. Many participants (34.6%) experienced at least one delay in obtaining laboratory work, imaging, or medications. Participants scored significantly worse ($p < 0.001$) in all PROMIS-29 domains compared to the general population. Participants who experienced delays in care had higher fatigue ($p = 0.001$), anxiety ($p = 0.007$), and sleep disturbance ($p = 0.006$) scores, and more difficulty participating in social roles and activities ($p = 0.019$), compared to individual's who had no care delays (Table 1). No significant differences were found between PROMIS-29 scores and appointment type (Table 1). Focus groups indicated both patients and stakeholders agreed on the importance of in-person appointments, while recognizing that virtual care may play a role in post-pandemic care. **Conclusion:** For post-pandemic care, the majority of PBC patients and providers preferred in-person appointments. PBC patients experienced poor quality of life during the pandemic compared to the general population, particularly those with delayed care.

Table 1: Quality of life measures for entire PBC cohort, including comparisons between timing of care (delayed verse non-delayed) and type of appointment (virtual verse in-person) during the pandemic

Quality of Life Measure	Entire PBC cohort (n=339)	Experienced care delays (n=117)	Did not experience care delays (n=221)		Virtual appointments ≥ 50% (n=259)	In-person appointments ≥ 50% (n=38)

4542-C | DECIPHERING OF THE HEPATIC SINGLE-CELL INTERACTOME IN PRIMARY SCLEROSING CHOLANGITIS★

Oleksandr Petrenko[1,2,3], Carolina Mangana[3], Thomas Sorz[1,2,3], Benedikt Silvester Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Kerstin Zinober[1,2], Vlad Taru[1,2], Philipp Schwabl[1,2,3], Barbara Maier[3], Claudia Daniela Fuchs[1], Michael Trauner[1] and Thomas Reiberger[1,2,3], (1) Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, (2)Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, (3)Cemm Research Center for Molecular Medicine of the Austrian Academy of Sciences

Background: Primary sclerosing cholangitis (PSC) is a rare liver disease characterized by cholangitis and periportal fibrosis resulting in bile duct sclerosis. In this study, we aimed to investigate the hepatic cell-cell interactions that drive PSC progression and perform in silico ligand screening. **Methods:** We used single-cell and single-nuclei RNA sequencing of primary non-parenchymal cells isolated from explanted livers of three PSC patients. The obtained dataset was integrated into human non-diseased and cirrhotic liver scRNA-seq datasets (MacParland 2018; Ramachandran 2019) for reference-guided clustering and annotation using Harmony and Seurat. We identified key gene signatures involved in the cellular crosstalk and performed differential interaction analysis versus other

aetiologies with CellChat and NicheNet. Targets specific to PSC were then subjected to *in-silico* compound screening by predicted binding probability against the library ofof FDA-approved small molecules using AutoDock Vina. **Results:** We obtained 35501 cell transcriptomes from three human PSC liver samples. We detected an abundance of activated γδ-T-cells and a depletion of tolerogenic MARCO+ Kupffer cells (KC) in PSC. Activated KC were major sources of incoming and outgoing signaling based on cell ligand-receptor analysis. KC were enriched for *MIF*, *HMGB1*, and *HMGB2* genes compared to other immune cell populations and interacted with non-parenchymal cells via ITGB2, THBS and Galectin pathways. In the cell interaction analysis, we identified 57 ligands, 77 receptors and 257 downstream targets with significant differential expression in PSC vs. other etiologies – with SLIT2-ROBO1/4, RUNX1, and RELN identified as novel targets. Molecular docking prioritized small molecules as potential ligands for such PSC targets (e.g., nilotinib and rucaparib for ROBO4). **Conclusion:** We discovered perspective molecular targets in PSC with their ligands for further *in vitro* and *in vivo* investigations aiming at the development of new therapeutic strategies. The identified targets are currently being validated by Imaging Mass Cytometry and LC-MS proteomics, and their role in biliary fibrosis is being accessed using transcriptomes of Mdr2$^{-/-}$ KO mice.

4543-C | DEVELOPMENT OF A PRIMARY BILIARY CHOLANGITIS (PBC)-SPECIFIC VERSION OF CHRONIC LIVER DISEASE QUESTIONNAIRE: CLDQ-PBC

Zobair M. Younossi[1], Maria Stepanova[2], Issah Younossi[2] and Andrei Racila[3], (1)Inova Medicine, Inova Health System, Falls Church, VA, (2)Center for Outcomes Research in Liver Diseases, Washington, DC, (3)Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA

Background: Primary biliary cholangitis (PBC) is an important chronic liver disease (CLD) leading to cirrhosis and impaired patient reported outcomes (PROs). We aimed to develop PBC-specific version of CLDQ instrument. **Methods:** From our Liver Database, we included patients with PBC who had completed CLDQ, clinico-laboratory data, and other PRO instruments (Short Form-36 (SF-36) or Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F)). The 29 items of CLDQ were subjected to item reduction by excluding items with a score of 6 or 7 (highest possible scores, suggesting the item was never or hardly ever a problem for patients with PBC over the recall period of 2 weeks) chosen by > 65% PBC subjects; remaining items were subjected to exploratory factor analysis to explain 95% of variance. A standard instrument validation pipeline with internal consistency and validity assessments were applied to the new CLDQ-PBC. **Results:** Data were available for 108 PBC patients: 57 ± 11 years old, 7% male, 58% with cirrhosis, 24% with advanced cirrhosis (CPT class B or C), 93% on UDCA. Of the 29 CLDQ items, none met the exclusion criteria. Exploratory factor analysis suggested that 95% of variance could be explained by 7 factors. Based on evaluation of factor loadings and face validity assessment by three hepatology experts, those factors yielded the domains of Diet, Emotion, Fatigue, Itch, Symptoms, Sleep, and Worry (CLDQ-PBC). The domains of CLDQ-PBC demonstrated varying internal consistency: good to excellent Cronbach's alpha 0.85-0.93 for 5/7 domains. The item-to-own domain correlations were > 0.60 for 24/26 items from the 5 internally consistent domains (Emotion, Fatigue, Symptoms, Sleep, Worry). For the two domains with lower internal consistency and/or comprehensiveness (Diet, Itch), we included additional relevant items using focus groups, expert opinions, and literature review. For the valid domains, known-groups validity tests discriminated between PBC patients with and without cirrhosis, with and without advanced cirrhosis, as well as presence or absence of history of depression ($p < 0.05$ for 3-5 domains). The highest correlated domains of SF-36 with those of CLDQ-PBC were: Mental Health for Emotional (rho = +0.88), Physical Functioning and Vitality for Fatigue (both rho ≥ +0.83), Vitality and Social Functioning for Sleep (both rho ≥ +0.60), Vitality for Symptoms (rho = +0.74), and Social Functioning for Worry (rho = +0.73) (all $p < 0.0001$). Fatigue domain of CLDQ-PBC was also highly correlated with Fatigue Scale of FACIT-F (rho = +0.85), and Worry domain of CLDQ-PBC was negatively correlated with the level of alkaline phosphatase (rho = -0.38, $p = 0.0082$). **Conclusion:** CLDQ-PBC was developed based on the original CLDQ. The new instrument has evidence for internal consistency and validity, and is being fully validated using an external cohort.

4544-C | DISPARITIES EXCESS MORTALITY IN CIRRHOTIC PATIENTS WITH PRIMARY BILIARY CHOLANGITIS AND PRIMARY SCLEROSING CHOLANGITIS DURING THE COVID-19 PANDEMIC

Xinyuan He[1], Ning Gao[1], Fan Lv[2], Fengping Wu[1], Yi Liu[1], Lamei Li[1], Walid S. Ayoub[3], Yee Hui Yeo[4] and Fanpu Ji[1,2,5], (1)The Second Affiliated Hospital of Xi'an Jiaotong University, (2)Xi'an Jiaotong University, (3) Cedars-Sinai Medical Center, Los Angeles, CA, (4) Cedars-Sinai Medical Center, Culver City, CA, (5) Shaanxi Provincial Clinical Medical Research Center of Infectious Diseases

Background: The COVID-19 pandemic increased liver-related mortality and had etiology disparities. Previous

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

study showed ursodeoxycholic acid (UDCA), commonly used in primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) treatment, was associated with both a decrease in SARS-CoV-2 infection and a reduction in severe or critical COVID-19 among patients with cirrhosis. We estimated the monthly age-standardized mortality (ASMR) with cirrhosis, further categorizing by etiologies to investigate the potential affect of UDCA on PBC/PSC-related mortality during the COVID-19 pandemic. **Methods:** Using Vital Statistics Online Data Portal of the of the National Vital Statistic System, we calculated the monthly ASMR of cirrhosis aged 25 years or older and stratified by etiology from 2012 to 2021. We conducted a Prophet model to predict mortality rates in 03/2020-12/2021 based on the trend between 01/2012 and 02/2020 to determine the impact of the pandemic on cirrhosis-related mortality. By calculating the difference between observe and predicted mortality rate, we quantified the impact of the pandemic on people with cirrhosis and stratified by etiology. **Results:** Among 878,601 cirrhosis-related deaths identified from 1/1/2012-12/31/2021, there was a significantly increasing trend in cirrhosis-related mortality during the pandemic from 3.026 to 3.680 in 03/2020 and 12/2021, with an average excess mortality of 14.46% (95%CI 11.89 to 17.02%, $p < 0.001$). The observed mortality rates were higher than the predicted values for alcohol-associated liver disease (ALD), HCV, and non-alcoholic fatty liver disease (NAFLD) (all $p < 0.05$), with an average excess mortality of 24.81% (95%CI 20.95 to 28.68%), 21.24% (95%CI 16.70 to 25.77%) and 6.11% (95% CI 2.29 to 9.92%), respectively. Notably, PBC/PSC-related cirrhosis deaths did not show this increase, with an average excess mortality of -1.69% (95%CI -5.63 to 2.25%, $p = 0.44$), similar to hepatitis B virus (HBV)-related deaths (Figure 1). Additionally, there were small to negligible proportions (less than 9 decedents) of COVID-19 among decedents in the PBC/PSC and HBV subgroups. **Conclusion:** Our study found no significant increase in mortality related to PBC/PSC during the pandemic and had a lower excess mortality when compared to the pre-pandemic period and to other etiologies of cirrhosis.

4545-C | EFFECT OF OBETICHOLIC ACID ON PROGNOSTIC THRESHOLDS OF GAMMA-GLUTAMYL TRANSFERASE AND ALKALINE PHOSPHATASE LEVELS: SUB-ANALYSIS OF THE PHASE 3 POISE TRIAL IN PRIMARY BILIARY CHOLANGITIS

Alan Bonder[1], Darren Wheeler[2], Radhika Nair[2], Erik Ness[2], Elizabeth S. Malecha[2] and Robert G. Gish[3], (1) Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, (2)Intercept Pharmaceuticals, Inc., Morristown, NJ, (3)Robert G Gish Consultants LLC

Background: A recent study from the Global PBC study group has shown that gamma-glutamyl transferase (GGT) $\geq 3.2\times$upper limit of normal (ULN) and alkaline phosphatase (ALP) $\geq 1.5\times$ULN increases the risk of liver transplantation or death in patients (pts) with primary biliary cholangitis (PBC); GGT also increases the prognostic value of ALP (Gerussi A, et al. *Clin Gastroenterol Hepatol.* 2021). Obeticholic acid (OCA), a selective, potent farnesoid X receptor agonist, received accelerated approval in 2016 for the treatment of PBC based on biomarker improvement in POISE, a 12-month randomized, double-blind, placebo-controlled phase 3 study. Here, we evaluate the impact of OCA on achievement of GGT $< 3.2\times$ULN and ALP $< 1.5\times$ ULN. **Methods:** Pts with PBC who were receiving a stable dose of ursodeoxycholic acid (UDCA) or who were unable to tolerate UDCA were randomized to receive placebo, OCA 5−10 mg (OCA titration), or OCA

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

10 mg daily. POISE included a 12-month double-blind (DB) period followed by a 5-year open-label extension (OLE), in which all pts were initially treated with OCA 5 mg daily. Serum GGT and ALP levels were assessed at baseline and every 3 months. Pts with baseline GGT $\geq 3.2\times$ULN and ALP $\geq 1.5\times$ULN were included in this analysis. Responders were defined as pts with GGT $< 3.2\times$ULN and ALP $< 1.5\times$ULN. *P*-values for comparing treatments were obtained via Cochran-Mantel-Haenszel test. **Results:** In the DB intention-to-treat (ITT) set (N = 203), the proportion of responders increased over time in both OCA arms through DB Month 12 vs placebo, with the highest responder rates observed in the OCA 10 mg arm (Figure). In the OCA titration arm, 17% (11/66) were responders at DB Months 9 and 12. In the OCA 10 mg arm, the highest responder rate was observed at DB Month 9 (31% [21/68]), followed by DB Month 12 (26% [18/68]). One responder was observed in the placebo arm at DB Months 6 and 9; the comparisons of both OCA arms vs placebo reached significance ($P < 0.05$) at each post-baseline 3-month time point. In the OLE ITT set (N = 119), the proportion of responders generally increased over time, ranging from 16% (19/118) at DB Month 3 to 38% (35/91) at OLE Month 51 (Figure). At OLE Month 60, 37% (17/46) were responders. **Conclusion:** Among evaluable pts treated with OCA, the proportion of GGT and ALP responders generally increased over 72 months of treatment, suggesting that OCA may have the potential to reduce GGT and ALP levels below the thresholds that are prognostic for worse clinical outcomes.

Figure. GGT/ALP responders (ie, pts with GGT <3.2×ULN and ALP <1.5×ULN) at each time point.

4546-C | EFFECTS OF THE MELD EXCEPTION POINT POLICY CHANGE ON APPROVED APPLICATIONS AND WAITLIST OUTCOMES AMONG PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS AND CIRRHOSIS

Melinda Wang, University of California, San Francisco, Jennifer C. Lai, University of California-San Francisco, San Francisco, CA and Michael Li, University of California San Francisco

Background: As the risk of adverse outcomes related to bacterial cholangitis is not reflected in the MELD score for patients with primary sclerosing cholangitis (PSC), transplant centers can apply for MELD exception points for PSC patients meeting certain criteria. In June 2021, new National Liver Review Board (NLRB) guidance with more lenient criteria for PSC patients with a history of bacterial cholangitis was implemented. We sought to characterize the effect of this policy change on application acceptance rates and waitlist outcomes

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

among patients with PSC. **Methods:** Patients with a primary diagnosis of PSC in the Standard Transplant Analysis and Research (STAR) files 20 months before and after the policy change were included in this study. MELD exception applications for cholangitis were defined as those classified as "Other" in the STAR files and petitions for other reasons such as cholangiocarcinoma or hepatocellular carcinoma were excluded. Covariates associated with MELD petition denial were identified using logistic regression, and survival analysis was used to assess time to a composite outcome of waitlist death or dropout **Results:** Overall, 1330 and 791 PSC patients were listed before and after the policy change, respectively, and 232 (11%) reached the composite outcome. There was no difference in time to waitlist death or dropout comparing pre- vs post-policy change patients (aHR 0.89, 95%CI 0.65-1.21, p = 0.44). 61 patients had exception applications submitted prior to the policy change compared to 60 after. There was no difference in number of total exception applications submitted per patient (median 1 [IQR 1, 3] vs 2 [1, 2] applications, p = 0.60), and there was no difference in time to waitlist death or dropout comparing the patients with exception applications submitted pre- vs post-policy change (HR 1.13, 95%CI 0.32-4.02, p = 0.85). However, the post-policy change period was associated with decreased odds of application denial (aOR 0.59, 95%CI 0.35-0.98, p = 0.04). **Conclusion:** Our findings suggest that the MELD exception policy change for PSC has made submitted applications more likely to be accepted. The change did not impact waitlist outcomes in patients who had exception applications submitted, though longer follow-up time is needed for further investigation. The policy change also did not affect waitlist outcomes among all listed PSC patients, likely due to the small proportion of patients who ever had a MELD exception application submitted.

Table. Hazard Ratio Associated with Denied MELD-Na Exception Points by Application

4547-C | EFFICACY, SAFETY AND TOLERABILITY OF VOLIXIBAT IN PATIENTS WITH INTRAHEPATIC CHOLESTASIS OF PREGNANCY: A CASE SERIES OF 4 PATIENTS

Caroline Ovadia[1], Sophia Stone[2], Baha Sibai[3], Elaine Chien[4], Douglas B Mogul[4], Furong Li[4], Pamela Vig[4] and Catherine Williamson[5], (1)King's College London, London, United Kingdom, (2)St. Richard's Hospital, University Hospitals Sussex NHS Foundation Trust, Chichester, United Kingdom, (3)University of Texas, Texas Medical Center, Houston, Texas, (4)Mirum Pharmaceuticals, Inc., Foster City, California, (5) Imperial College London, London, United Kingdom

Background: Intrahepatic cholestasis of pregnancy (ICP) is the most common hepatic disorder that presents during pregnancy involving cholestatic pruritus, elevated serum bile acids (sBA), and increased risk of adverse perinatal outcomes. Volixibat (VLX) is a minimally absorbed ileal bile acid transporter (IBAT) inhibitor that interrupts the enterohepatic recirculation. IBAT inhibitors in patients with ICP have never been characterized. Herein, we describe 4 ICP patients treated with VLX under the OHANA trial (NCT04718961). **Methods:** Patients with ICP, sBA > ULN, and pruritus were treated with open-label VLX 20mg or 80mg BID until delivery, with dose modifications permitted for tolerability. Daily pruritus scores (Adult ItchRO 0-10 scale; 0 = no itch to 10 = worst possible itch), sBA, liver enzymes, hematology, perinatal outcomes and treatment-emergent adverse events (TEAEs) were assessed. **Results:** Over 1,000 patients were invited to participate. 26 were screened and 4 patients enrolled; small numbers were primarily due to patient reticence for trial participation in pregnancy or not meeting criteria to screen (68.2%) or withdrawal of consent (22.7%). Two patients initiated VLX at 80mg BID; the other two started at 20mg BID. Baseline pruritus scores were 2.2, 5.3, 7.0 and 7.3, with respective peak sBA levels prior to the first VLX dose of

8.9, 111.7, 9.1, and 41.2 μmol/L. Treatment duration varied from 1 week to 7 weeks. All patients experienced reductions in pruritus from Baseline regardless of VLX dose with intermittent relief coinciding with resumption of dosing where doses were interrupted. sBA nadir values all reached < 6 μmol/L following VLX. No clinically meaningful changes in liver enzymes or hematology parameters were observed. All patients had healthy live births (at weeks 34, 35 and two to term). The most frequent TEAEs were gastrointestinal (GI) in nature and mild to moderate in severity. Three of 4 patients experienced diarrhea and/or abdominal cramping leading to dose reduction, treatment interruption and/or early discontinuation. One patient tolerated treatment until delivery with no dose modifications due to AEs. **Conclusion:** VLX demonstrated improvements in pruritus and sBA in 4 patients with ICP, signaling proof of concept in this disease. However, studies in pregnancy are inherently difficult to enroll as shown in this trial. These data warrant further research.

4548-C | HIGH RECURRENCE RATE OF PRIMARY SCLEROSING CHOLANGITIS AFTER LIVER TRANSPLANTATION IN A SYSTEMATIC EVALUATION

Lise Katrine Engesæter[1,2,3,4], Henrik Mikael Reims[5], Krzyztof Grzyb[5], Andreas Abildgaard[6], Ida Bjørk[6], Tom H. Karlsen[1,2,3,4], Kristian Bjoro[1,2,4], Kirsten M. Boberg[1,2,4], Johannes R. Hov[1,2,3,4] and Espen Melum[1,2,3,4,7], (1)Norwegian PSC Research Center, (2) Institute of Clinical Medicine, (3)Research Institute of Internal Medicine, (4)Section of Gastroenterology, (5) Department of Pathology, (6)Department of Radiology, (7)Hybrid Technology Hub, Center of Excellence

Background: Primary sclerosing cholangitis (PSC) recurrence after liver transplantation (LTX) is a common clinical problem with large variation in reported rates that could be dependent on follow-up strategies. In this study, we reevaluated magnet resonance cholangiography (MRC) examinations and liver biopsies to provide accurate data up to 15 years after transplantation. **Methods:** Patients listed for LTX with PSC in Norway between 1988-2016 were identified. MRC scans and liver biopsies performed up to 2018 were re-evaluated. Between 2007-2017, routine liver biopsies and MRC were planned at 1, 3 and 5 years and then every 5 years. MRC scans were evaluated by two abdominal radiologists and liver biopsies by two liver pathologists, all blinded for clinical information except for the post-transplant state. Recurrent PSC (rPSC) was defined by cholangiographic findings or histology according to the Graziadei criteria. **Results:** Two-hundred and twenty-seven PSC patients were transplanted in the study period (76% male, 81% IBD). Median age at transplantation was 43 years (range 16-72). One-hundred and eighty (79%) had at least one available MRC scan and/or liver biopsy. Median follow-up after transplant was 3.3 years (range 0-21). During follow-up, 115 (51%) fulfilled the criteria for rPSC (median 5.1 y post-LTX) at either a routine follow-up or examination due to clinical indication. Patients with hepatic artery complications (n = 29, 13%), a sole anastomotic stricture or early bile duct strictures (n = 6, 3%) were censored in survival analyses and not given a diagnosis of rPSC. In a cross-sectional analysis of patients with at least one year follow-up without graft loss (n = 211), 27 patients (13%) fulfilled rPSC criteria on at least one routine MRC or biopsy. At three years 27% (53/194) had rPSC, at five years 43% (72/164), at 10 years 55% (56/97) and at 15 years follow up 45% (19/42). A diagnosis of rPSC before or at the 1-year follow-up was associated with an increased risk of retransplantation or death (hazard ratio [HR] 7.4, 95% CI 3.3 to 16.6), while in a similar analysis of patients reaching the 5-year follow-up without graft loss, the HR for re-LTX or death in those with rPSC was 3.9 (95% CI, 2.0-7.6). **Conclusion:** Systematic reevaluation of MRC and histology at a large single center suggests that rPSC occurs in about half of the transplanted PSC patients. An early diagnosis of rPSC has a particularly strong impact on retransplantation-free survival.

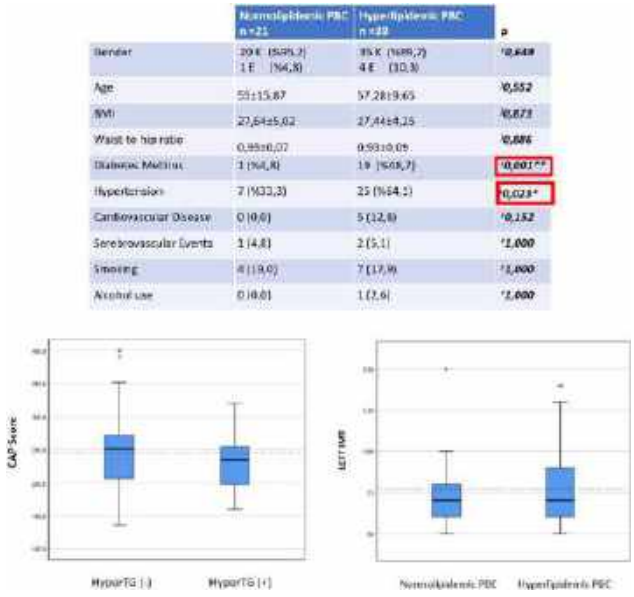
4549-C | HYPERLIPIDEMIA, ATHEROSCLEROSIS AND HEPATOSTEATOSIS IN PRIMARY BILIARY CHOLANGITIS: WHAT IS THE RISK?★

Aylin Coskun, Aslı Çifcibaşı Örmeci, Bilger Çavuş, Ibrahim Volkan Senkal, Edanur Karapınar, Arzu Poyanlı, Filiz Akyuz, Kadir Demir, Fatih Besisik and Sabahattin Kaymakoglu, Istanbul University, Istanbul Faculty of Medicine

Background: Primary biliary cholangitis is a chronic autoimmune cholestatic liver disease that mainly affects women. Cholestasis and also PBC-specific mechanisms result in hypercholesterolemia in up to %76 of patients. Because cardiovascular diseases are the most common cause of death worldwide, hyperlipidemia in PBC has a huge importance. Additionally, mild hypertriglyceridemia may be seen in PBC and it is important to know whether this situation leads to hepatosteatosis. This study aims to establish hyperlipidemia, subclinical atherosclerosis parameters, and hepatosteatosis degrees in PBC. **Methods:** This is a single-center cross-sectional study, 160 PBC patient files have been examined in Istanbul Faculty of Medicine. Those with overlap syndrome and non-volunteers were excluded from the study. A total of 60 PBC patients and a control group of 44 over 18 years old without chronic liver disease were included. We noted demographic features, BMIs, Waist-to hip ratios, lipid profiles, UDCA responses, APRI scores, fibrosis, and CAP scores measured with Fibroscan. Radiologist measured intima-media thickness and plaque presence with bilateral carotid Doppler ultrasonography. **Results:** A total of 104 people were categorized into four groups due to their lipid status. We defined hypercholesterolemia as the use of antihyperlipidemic treatment or total cholesterol level higher than 6.2 mmol/L. Hyperlipidemic PBC (n = 39), normolipidemic PBC (n = 21), hyperlipidemic control (n = 12), and normolipidemic control (n = 32) groups were compared. IMT values (0.75 ± 0.21 vs 0.78 ± 0.23) and presence of plaques (7 (33.3%) vs 14 (35.9%)) between the matched for demographic data hyperlipidemic PBC and normolipidemic PBC groups was not found to be significant. (p = 1,00) The effect of the variables on the presence of plaque is examined; Age (p = 0,001, OR: 1,187) and presence of diabetes mellitus (p = 0,003, OR: 8,412) were independent risk factors and lipid levels had no effect on the presence of plaque. Age (p = 0.001, OR: 0,006), gender (p = 0,025, OR:0,177), and BMI (p = 0,035, OR:0,009) were seen as risk factors in the regression analyses performed on IMT, the effect of lipid levels was not observed. When hyperlipidemic and normolipidemic PBC patients were compared, no significant difference was found between Apri scores (p = 0,190), Fibrosis levels (p = 0,551), CAP scores (p = 0,099), presence of cirrhosis (p = 1,00) and UDCA responses (p = 0,694). When the PBC group was separated according to the presence of hypertriglyceridemia, there was no difference in CAP scores between the two groups.(p = 0,361) **Conclusion:** In this study, hypercholesterolemia which is frequently observed in PBC, was not associated with subclinical atherosclerosis parameters. It is also observed that hypertriglyceridemia did not cause an increase in hepatosteatosis. Patients should be followed up in terms of cardiovascular risk, taking into account additional comorbid diseases and age.



Disclosures: The following people have nothing to disclose: Aylin Coskun
Disclosure information not available at the time of publication: Aslı Çifcibaşı Örmeci, Bilger Çavuş, Ibrahim Volkan Senkal, Edanur Karapınar, Arzu Poyanlı, Filiz Akyuz, Kadir Demir, Fatih Besisik, Sabahattin Kaymakoglu

4550-C | IDENTIFYING DRIVERS OF PATIENT (PT) PREFERENCE IN THE TREATMENT OF PRURITUS IN PRIMARY BILIARY CHOLANGITIS (PBC)

Anna Halliday[1], Helen T Smith[1], Dorothy Szinay[2], Andy Walker[1], Keila Meginnis[3], Sebastian Heidenreich[2] and Jaein Seo[4], (1)GSK, London, UK, (2)Evidera, London, United Kingdom, (3)Evidera, Glasgow, United Kingdom, (4)Evidera, Bethesda, MD

Background: Pruritus is common in PBC and can significantly impact pts' quality of life (QoL). Cholestyramine is recommended as the first-line treatment option for pruritus in PBC, but tolerability, inconvenient administration, and limited efficacy data restrict its use. Pt-focused drug development can help address this unmet need, but an understanding of pts' perspectives on pruritus and treatments is required. This study

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

conducted semi-structured qualitative pt interviews to explore pts' experiences, expectations, and concerns with regards to pruritus and treatments. **Methods:** Semi-structured virtual interviews were designed following a literature review and conducted with pts from the USA, Germany, UK, and Italy. Eligible pts self-reported a PBC diagnosis and had a worst itch score of ≥4 on a 0–10 numerical rating scale (NRS) in the past 2 months. Interviews had four parts: 1) pruritus experience, 2) treatment desires and concerns, 3) treatment experience, 4) hypothetical choice questions that required pts to make trade-offs between two options. Responses were used in an inductive thematic analysis and visually summarized. **Results:** Ten pts per country were interviewed (N = 40); most were female (78%) and mean (standard deviation) age was 52.5 (15.2) years. For 53% (n = 21), pruritus had started within the last 3 years. On the NRS, pts rated their pruritus over the last 2 months on average as mean 5.4 (range 2–10), and worst itch as mean 7.1 (range 4–10). Key themes that emerged from pt discussions were visualized with a concept map (Figure). Pruritus was widespread over pts' bodies, persistent despite scratching, and described as 'crawling', 'burning' and 'nettles'. Pruritus impacted social interactions, sleep quality, appearance, emotional stability, and work productivity. Many pts wished for complete resolution, but primarily wanted treatment to reduce pruritus severity (60%; n = 23). Of those who had ever received cholestyramine (n = 12), 62% reported a repulsive taste and texture; 50% mentioned concerns about interactions between cholestyramine and PBC medication. From five potential pruritus medication side effects, diarrhea and nausea were of greatest concern. **Conclusion:** Pruritus impacts QoL in PBC in several ways and the limitations of existing treatments mean pts would welcome alternative options. Future research will establish the relative importance to pts of treatment aspects such as administration, benefits, and tolerability.

4551-C | IMPACT OF TYPE 2 DIABETES MELLITUS ON LIVER FIBROSIS AND HEPATIC STEATOSIS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A LONGITUDINAL STUDY

Elizabeth Williams, Craig Lammert and Raj Vuppalanchi, Indiana University School of Medicine

Background: Type 2 diabetes mellitus (T2DM) is strongly associated with hepatic steatosis. However, the impact of T2DM on the progression of liver fibrosis and hepatic steatosis in patients with primary biliary cholangitis (PBC) requires further investigation. This study aims to explore the influence of T2DM on the development of hepatic steatosis and liver fibrosis in patients with PBC, both at their initial visit and during follow-up. **Methods:** A retrospective analysis was conducted to identify PBC patients at Indiana University Health using ICD9 and ICD10 codes to identify a cohort of 570 patients through electronic health record query. Data was collected through manual review of EHR after confirmation of the PBC diagnosis, as per the AASLD criteria. The median follow-up duration was 3.6 years (interquartile range: 1.6-6.6). T2DM status was determined based on a hemoglobin A1c > 6.5% or the use of anti-diabetic medications at any point during the study. FibroScan assessments were performed to evaluate the extent of hepatic steatosis and liver fibrosis. Hepatic steatosis was defined as a controlled attenuation parameter (CAP) greater than 285 dB/m, while clinically significant liver fibrosis was defined by a liver stiffness

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

measurement (LSM) exceeding 8.5 kPa. Data comparisons were analyzed using t-tests and chi-squared tests. **Results:** Among the participants, 160 individual's had a FibroScan at their initial visit, and 319 of them had at least one FibroScan assessment during follow-up. At the initial visit, patients with both PBC and T2DM were more likely to have NAFLD (CAP > 285 dB/m) compared to those without T2DM (54% vs. 28%, p-value 0.011, relative risk [RR] 2.9, 95% confidence interval [CI] 1.3-6.9) (Table 1). The degree of liver fibrosis at the initial visit was similar between PBC patients with and without T2DM (p-value = 0.127) (Table 1). However, at the most recent follow-up, patients with both PBC and T2DM had a significantly higher prevalence of hepatic steatosis (57% vs. 38.0%, p-value 0.012, RR 2.1, 95% CI 1.2-3.9) and clinically significant liver fibrosis (77% vs. 46%, p-value < 0.001, RR 4.1, 95% CI 2.1-8.1) (Table 1). **Conclusion:** Among patients with PBC, the presence of T2DM at the initial visit is associated with an increased likelihood of hepatic steatosis, but not clinically significant liver fibrosis. However, over time, patients with PBC and T2DM have a significantly higher risk of developing both hepatic steatosis and clinically significant fibrosis compared to those without T2DM.

4552-C | INCREASED RISK OF OSTEOPOROTIC FRACTURE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Jihye Lim[1], Ye-Jee Kim[2], Sehee Kim[2] and Jonggi Choi[2], (1)Yeouido St. Mary's Hospital, (2)Asan Medical Center, Seoul, Korea, Republic of (South)

Background: Patients with primary biliary cholangitis (PBC) have suspicions of having increased risk of osteoporosis and osteoporotic fracture. However, large-scale studies have been restricted due to low incidence of PBC and osteoporotic fracture. This study aimed to investigate the relationship between PBC and the likelihood of osteoporotic fracture analyzing with a long term and nationwide real-world data. **Methods:** The claims data from the Korean National Health Insurance Service (NHIS) between 2007 and 2020 had been analyzed. A total of 4,951 patients with PBC were included in the study and randomly matched with a control group of 19,793 individual's based on age, sex, and duration of follow-up, using a 1:4 ratio. Fractures of the vertebrae, hip, distal radius, and proximal humerus were defined as osteoporotic fracture. The incidence rate (IR) and hazard ratio (HR) were obtained to reveal the impact of PBC on osteoporotic fracture. **Results:** Over a median follow-up period of 5.37 years, PBC cohort experienced a total of 524 osteoporotic fractures with an IR of 18.59 per 1,000 person years which was notably higher than that of matched cohort (IR of 10.98 per 1000 person years). After adjustments with clinical factors including age, sex, socioeconomic status, comorbidities, decompensated cirrhosis, body mass index, smoking, alcohol, exercise, and health checkup, PBC elevates the risk of osteoporotic fracture by 1.63-fold (95% confidence interval [CI], 1.20–2.22, P = 0.002). Vertebrae was particularly susceptible to osteoporotic fracture in PBC patients with adjusted hazard ratio of 2.23 (95% CI, 1.04–4.76). In gender-specific analysis, the risk of osteoporotic fractures was found to be 2.53 times higher in male PBC patients (95% CI, 1.84–3.48) and 1.59 times higher in female PBC patients (95% CI, 1.41–1.79) than non-PBC male and female control, respectively. **Conclusion:** Patients diagnosed with PBC had a higher risk of experiencing osteoporotic fractures when compared to their matched controls. Considering the related morbidity and mortality of osteoporotic fracture, it is imperative to be aware of osteoporotic fracture risk and take preventive measures in PBC population.

Janssen[1], Bettina E. Hansen[1], Nicole S. Erler[1], Adriaan J. Van der Meer[1] and Dutch PBC Study Group, (1) Erasmus MC, University Medical Center Rotterdam, (2) Amsterdam University Medical Center, Amsterdam, Netherlands, (3)Radboud University Medical Center, Nijmegen, (4)University Medical Center Groningen, Groningen, (5)Leiden University Medical Center, Leiden, (6)Reinier De Graaf Gasthuis Hospital Group, Delft, (7)Noordwest Ziekenhuisgroep, Alkmaar, (8) University Medical Center Utrecht, Utrecht, (9)Antonius Hospital, Nieuwegein, (10)Catharina Hospital, Eindhoven, (11)Rijnstate Hospital, Arnhem, (12) Maastricht University Medical Center, Maastricht, (13) Maxima Medisch Centrum, Eindhoven, (14)Zuyderland Medisch Centrum, Heerlen, (15)Gelre Hospitals, Apeldoorn-Zutphen, (16)Jeroen Bosch Ziekenhuis, Den Bosch, (17)Albert Schweitzer Hospital, Dordrecht, (18) Onze Lieve Vrouwe Gasthuis, Amsterdam, (19) Diakonessenhuis, Utrecht, (20)Hospital De Gelderse Vallei, Ede, (21)Medical Center Leeuwarden, Leeuwarden, (22)Tergooi MC, Hilversum-Blaricum, (23) Viecurie, Venlo, (24)Canisius/Wilhemina Hospital, Nijmegen, (25)Bernhoven, Uden, (26)Deventer Hospital, Deventer, (27)Medical Center Haaglanden, Den Haag

Background: Large population-based studies are needed to gain more insight in the epidemiology of primary biliary cholangitis (PBC). We assessed the incidence of PBC in the Netherlands over time through the nationwide Dutch PBC Cohort Study (DPCS). **Methods:** DPCS is a retrospective registry in all Dutch hospitals in which every identifiable patient with an established PBC-diagnosis in the Netherlands from 1990 onwards is included. Comprehensive and systematic case identification (based on diagnosis/treatment codes, antimitochondrial antibodies test results, and locally available registers based on liver disease diagnosis or outcome) was performed by two dedicated investigators of the research team according to local possibilities. The current incidence assessment was restricted to the time period between January 2008 (general introduction of electronic patient records) and December 2018 (the year prior to the start of data collection). Incidence rates (per 100.000 persons) and annual changes were estimated using Poisson regression. Incidence differences in sex and age groups (20-45, 45-65, and $\geq$65 y) were calculated with rate ratios. The yearly size of the general population was retrieved from the Dutch Central Bureau of Statistics. **Results:** In total, 4370 patients with a confirmed PBC diagnosis were identified in all 71 hospitals in the Netherlands, of which 2187 were diagnosed between 2008 and 2019. Mean age at diagnosis was 58.7 (SD 12.6) years and 1925 (88%) patients were female. The median yearly incidence rate was 1.33 (IQR 1.29-1.58) per 100.000 persons. The incidence rate ratio (IRR) adjusted for age and year, was 8.81 (95%CI 7.74-10.03, $p < 0.001$) for female patients compared to male patients. Patients between 45-65 years and $\geq$65 years showed an adjusted IRR of 3.90 (95%CI 3.43-4.42, $p < 0.001$) and 3.86 (95%CI 3.38-4.42, $p < 0.001$) compared to patients between 20-45 years (Figure). Over time, the adjusted annual IRR was 1.03 (95%CI 1.01-1.04, $p < 0.001$). Similar annual IRRs were shown for patients between 45-65 years (IRR 1.03, 95%CI 1.02-1.05, $p < 0.001$) and for patients $\geq$65 years (IRR 1.04, 95%CI 1.02-1.07, $p = 0.001$). The annual IRR of patients between 20-45 years was 0.97 (95%CI 0.93-1.00, $p = 0.07$). **Conclusion:** Based on this nationwide registry including every identifiable patient with PBC in the Netherlands, the overall incidence of PBC slowly increased over the recent years. However, in the Dutch population < 45 years of age the incidence of PBC remained stable.

4554-C | INDUCED REGULATORY T CELLS VIA CYCLIN-DEPENDENT KINASE INHIBITION FROM PATIENTS WITH PRIMARY BILIARY CHOLANGITIS ARE SUPPRESSIVE AND STABLE IN AN INTERFERON ENRICHED ENVIRONMENT AND ARE EPIGENETICALLY DIFFERENT FROM NATURAL REGULATORY T CELLS.

Vincenzo Ronca[1,2,3,4], Kayani Kayani[1,2], Scott Davies[1], Masaya Arai[2], Yamami Nakamura[2], Natsumi Okamoto[2], Norisha Mikami[2], Naganari Ohkura[2], Jason White[2], Naomi Richardson[1], Pietro Invernizzi[3], Shimon Sakaguchi[2] and Ye Htun Oo[1], (1)University of Birmingham, Birmingham, United Kingdom, (2)Osaka University, (3)University of Milano-Bicocca, (4) European Reference Network on Hepatological Diseases (ERN RARE-LIVER)

Background: The use of autologous regulatory T cells (Treg) as cell therapy in autoimmune disease has been proposed. Potential limitation of such approach lies on the dysfunction and/or instability that these cells might have in patients with autoimmune conditions. Primary biliary cholangitis (PBC), is a chronic, cholestatic liver disease. A reduction in number, lineage stability and functionality of Tregs has been observed in patients with PBC. We aimed to produce stable and function induced Tregs (SFiTregs) from PBC-derived effector CD4 cells in vitro, via cyclin-dependent kinase (CDK8/19) inhibition and compare their epigenetic profile, their lineage stability and suppressive function with natural Tregs in patients with PBC **Methods:** CD4+ T cells were magnetically enriched from peripheral blood mononuclear cells (PBMCs) of PBC patients. CD4+T cells were activated through TCR stimulation by CD3+ activator beads and cultured in presence of AS2863619 (4-[1-(2-methyl-1H-benzimidazol-5-yl)-1H-imidazo[4,5-c] pyridin-2-yl]-1,2,5-oxadiazol-3-amine dihydrochloride) and IL-2. FoxP3, CTLA4 and Helios expression was assessed in SF-iTregs via flow cytometry and by bisulphite sequencing pre- and post-activation in presence of Th1 polarising cytokines. The functionality of Tregs and SF-iTregs was investigated by in vitro suppression assays using CellTrace Violet dye-labelled effector T-cells, CD3 activator beads and IL-2. For the all three cell populations, nTreg, Tnaive, SF-iTregs, Foxp3 gene locus for STAT5 binding, H3K27ac, and chromatin status was characterized by Chromatin immunoprecipitation followed by sequencing (ChIP-seq) and assay for transposase-accessible Chromatin using sequencing (ATAC-seq). **Results:** The chemical inhibition of cyclin-dependent kinase 8/19 and the deprivation of CD28 signal induced DNA hypomethylation in Treg signature genes. We obtained a 100-fold increase in the cell number and the product was suppressive and pure (> 90% FOXP3 expressing cells). Furthermore, the SFiTregs were found to be more stable compared with nTreg when cultured for 6 days in Th1 polorising conditions. ATAC-seq and ChIP-seq confirmed that Treg specific epigenetic changes in the SF-iTregs were comparable to nTreg at the baseline. However, differentially accesible regions of SF-iTregs differ significantly when compared to nTreg. **Conclusion:** We applied a novel technique to generate abundant, functional regulatory T cells from peripheral T CD4+ cells in patients with PBC. This approach would allow us to overcome the potential limit of using autologous ex-vivo expanded Tregs based therapy and generate a more stable product to infuse in the inflamed envoirment typical of the liver of PBC patients.

4555-C | IS AMA-NEGATIVE PRIMARY BILIARY CHOLANGITIS MORE COMMON IN BLACK PATIENTS?

Elizabeth Williams[1], Lauren D. Nephew[2], Craig Lammert[1] and Raj Vuppalanchi[1], (1)Indiana University School of Medicine, (2)University of Pennsylvania, Indianapolis, IN

Background: Primary biliary cholangitis (PBC) is predominantly observed in middle-aged White women, with rare occurrences reported in the Black population. This study aimed to identify any disparities in clinical, biochemical, and elastography between Black and White patients diagnosed with PBC. **Methods:** A retrospective analysis was conducted through electronic health records (EHR) query using ICD 9 and ICD10 codes at Indiana University Health to identify 536 individual's with a confirmed diagnosis of PBC, as per the AASLD criteria. Laboratory data were collected from their initial visit through manual EHR. For patients who underwent vibration-controlled transient elastography using FibroScan, the presence of hepatic steatosis was defined as a controlled attenuation parameter (CAP) greater than 285 dB/m, and clinically significant liver fibrosis was determined by a liver stiffness measurement (LSM) exceeding 8.5 kPa. T-tests and chi-squared analyses were employed to compare differences between Black and White patients with PBC. **Results:** The median follow-up duration was 3.7 years (interquartile range: 1.7-6.9). Among the PBC cohort, 23 patients (4.2%) were Black. Black patients with PBC were significantly less likely to test positive for anti-mitochondrial antibody (AMA) compared to White patients with PBC (23% vs. 76%, p-value < 0.001) (Table 1). Additionally, Black patients exhibited significantly higher alkaline phosphatase levels than White patients (389 ± 262 U/L vs. 257 ± 228 U/L, p-value = 0.007) (Table 1). A FibroScan evaluation was conducted during the initial visit for 11 Black and 132 White PBC patients, while 17 Black and 275 White patients underwent FibroScan at some point during their follow-up. Black and White patients with PBC displayed similar degrees of hepatic steatosis, liver fibrosis, and rates of liver transplantation (Table 1). **Conclusion:** This study indicates that Black patients with PBC are significantly less likely to test positive for AMA. Therefore, it suggests a lower threshold for performing a liver biopsy in Black patients who exhibit elevated alkaline phosphatase levels, signs of liver disease, and suspected PBC.

Patient Characteristics	Total Cohort (N=536)	Black (n=23)	White (n=513)	p-value

4556-C | LANDSCAPE OF PERIPHERAL IMMUNE CELLS AND IDENTIFICATION OF BIOMARKERS FOR PRIMARY BILIARY CHOLANGITIS

Hoang Nam Pham, University of Science and Technology of Hanoi, Linh Pham, Texas A&M University-Central Texas and Keisaku Sato, Indiana University

Background: Primary biliary cholangitis (PBC) is an autoimmune liver disease caused by the immune system attacking the bile ducts. Detailed mechanisms of autoimmunity and the roles of immune cells in PBC are largely unknown. Diagnosis of PBC is based on blood tests for anti-mitochondrial antibody (AMA); however, some PBC patients are negative for AMA and invasive liver biopsy testing is required for inconclusive cases. The current study aims to

determine immune cell proportions in blood samples of PBC patients and to identify novel PBC biomarkers that lead to non-invasive diagnostic blood testing. **Methods:** Human transcriptomic profiling data of blood samples (GSE119600) were obtained from Gene Expression Omnibus (GEO). Immune cell proportions in blood samples were calculated by CIBERSORTx using LM22, which is a signature matrix established for peripheral immune cells. To identify novel PBC biomarkers, differentially expressed genes (DEGs) were identified using GSE119600 data. DEGs in GSE119600 were compared to those identified in other microarray data (GSE79850 and GSE159676). Identified candidate DEGs were further analyzed for function enrichment, protein-protein interaction network, and molecular complex using R studio and Cytoscape. To evaluate the diagnostic potentials of candidate biomarkers in blood testing, receiver operating characteristic (ROC) curve analysis was performed using GSE119600 data. **Results:** In blood samples, PBC patients had elevated proportions of M0 macrophages, monocytes, neutrophils, $CD4^+$ memory T cells, and Tregs, and decreased proportions of resting NK cells and $CD8^+$ T cells compared to healthy individual's. Analysis and comparison of DEGs identified 12 candidate genes that were significantly upregulated in PBC patients. Enrichment analysis identified 5 biological functions/pathways, and these pathways, such as osteoclast differentiation, were associated with autoimmunity or PBC. ROC curve analysis for blood samples showed that one of the candidate genes, ITGAL, had good diagnostic potentials to distinguish PBC status from healthy individual's, as well as from other diseases, such as primary sclerosing cholangitis, indicating that transcriptomic analysis of ITGAL using blood samples could be a novel diagnostic approach for PBC. **Conclusion:** PBC patients have unique peripheral immune cell proportions compared to healthy donors. ITGAL could be a potential diagnostic biomarker to identify PBC status by non-invasive blood testing.

4557-C | LIVER TRANSPLANTATION FOR PRIMARY BILIARY CHOLANGITIS IN THE U.S. IN 2008-2022

Maria Stepanova[1], Katherine Elizabeth Eberly[2], Dipam Shah[2], Reem Al Shabeeb[2], Veronica Nguyen[3], Janus Ong[4], Saleh A Alqahtani[5], Linda Henry[2,3,6] and Zobair M. Younossi[3,6,7], (1)Center for Outcomes Research in Liver Diseases, Washington, DC, (2)Inova Health Systems Medicine Service Line, Falls Church, VA, (3) Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, (4)College of Medicine, University of the Philippines, Manila, Philippines, (5)Johns Hopkins University School of Medicine, (6)Center for Liver Disease, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, VA, (7)Inova Medicine, Inova Health System, Falls Church, VA

Background: Primary biliary cholangitis (PBC) is an important cause of chronic liver disease (CLD) that can lead to advanced cirrhosis requiring liver transplantation (LT). We assessed recent trends and outcomes of liver transplant recipients with PBC in the U. **Methods:** From the Scientific Registry of Transplant Recipients (SRTR 2008-2022), we selected all adult ($\geq$18 y) LT candidates and recipients with PBC, with or without hepatocellular carcinoma (HCC). **Results:** Between 2008-2022, 167,919 LT candidates with a known etiology of chronic liver disease were included in this study. Of these, 3.0% had PBC. The average number of listings for PBC per year was 321 (SD 30) in the most recent 5 years. The prevalence of PBC among LT candidates without HCC was 3.5%, changed from 4.0% (2008) to 3.5% (2014) to 2.7% (2022) (decreasing trend $p < 0.0001$). In contrast, the prevalence of PBC among candidates with HCC did not change (average 1.0%, ranging from 0.7% (2007) to 1.4% (2022); $p > 0.05$). Transplant candidates with PBC were, on average, 58 (SD 10) years old, 85% female, 70% white, 7% black, 19% Hispanic, 3% Asian, 31% college-educated, 26% employed, 57% covered by private insurance, 29% Medicare, 12% Medicaid, < 1% uninsured, and 5% were re-transplants. Additionally, 28% were obese (BMI $\geq$30), 15% with type 2 diabetes, with a mean MELD score of 23 (SD 10). Excluding those listed during the most recent two years (2021-2022), 62% of PBC candidates (60% in PBC without HCC and 73% in PBC with HCC, $p = 0.0001$) received a transplant after mean 258 (SD 382) days. Furthermore, 26% died or deteriorated on the list (27% without HCC vs. 20% with HCC, $p = 0.02$), 3% were removed from the list due to improvement, and 7% were removed for other causes. Among transplant recipients with PBC, post-transplant mortality was 7.5% at 1 year, 12.5% at 3 years, 15.7% at 5 years, 28.2% at 10 years. Over time, post-transplant mortality in PBC followed a decreasing trend: 3-year mortality was 17.2% in 2008, 12.4% in 2014, and 11.9% in 2019 (trend $p = 0.06$). In a multivariate survival model, independent predictors of post-transplant mortality in PBC included older age (adjusted hazard ratio (aHR) (95% CI) = 1.020 (1.008-1.031) per year), male sex (aHR = 1.37 (1.09-1.72)), lack of college education (aHR = 0.78 (0.63-0.95)), pre-transplant type 2 diabetes (aHR = 1.50 (1.20-1.88)), cancer (aHR = 1.36 (1.04-1.78)), receiving a re-transplant (aHR = 1.75 (1.23-

2.47)), and being on life support (aHR = 1.83 (1.35-2.48)) ($p < 0.05$) while there was no significant association of post-transplant mortality with calendar year ($p = 0.11$) as well as race/ethnicity, type of insurance coverage, obesity, MELD score, and having HCC (all $p > 0.05$). **Conclusion:** The proportion of PBC among patients in need of a LT is decreasing, potentially due to available effective treatments. Regardless of the presence or absence of HCC, patients with PBC experience high post-transplant survival.

4558-C | NETWORK ANALYSIS OF SYMPTOMS EXPERIENCED BY PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS★

Melinda Wang[1], Amy M. Shui[1], Joanne Hatchett[2], Ruth-Anne Pai[2], Rachel Gomel[2], Mary Pressley Vyas[3], Sarah Curup Callif[2], Ricky Safer[2], Christopher L. Bowlus[4], Donna M. Evon[5], Jennifer C. Lai[6] and Michael Li[7], (1) University of California, San Francisco, (2)PSC Partners Seeking a Cure, (3)PSC Partners Seeking a Cure Canada, (4)University of California Davis, Sacramento, CA, (5)University of North Carolina, (6) University of California-San Francisco, San Francisco, CA, (7)University of California San Francisco

Background: Patients with primary sclerosing cholangitis (PSC) experience numerous symptoms that impact quality of life. PSC Partners Seeking a Cure developed the international "Our Voices" survey to capture the presence, severity, and impact of PSC symptoms on quality of life. We sought to identify PSC-specific symptom clusters and relationships between these symptoms to better understand the lived experience of PSC patients. **Methods:** Presence and severity of 16 symptoms potentially related to PSC were identified from the "Our Voices" survey. LASSO regularized partial correlation network analyses were performed to model unique interactions between symptoms. The primary analysis utilized symptoms reported within the past 6 months of survey completion. Secondary analyses included active symptoms and symptoms at their worst. Expected influence, which accounts for both positive and negative associations and assesses the nature and strength of a node's cumulative influence within a network, was computed for all symptoms in each network. The Spinglass algorithm was employed to identify symptom communities. **Results:** Among 970 total participants, 54% were women, most were white (70%), and 70% had inflammatory bowel disease (IBD). 88% of patients reported experiencing symptoms. Four dominant communities were identified across networks including psychological symptoms (anxiety, depression), gastrointestinal symptoms (anorexia, nausea/vomiting, liver pain, abdominal pain), cholestasis-related symptoms (pruritus, insomnia, night sweats, jaundice), and global symptoms (fatigue, weakness, joint pain, other pain, brain fog, encephalopathy) (Figure). Of the 16 PSC symptoms, fatigue and weakness consistently had the greatest expected influence across the multiple networks generated in the primary and secondary analyses. On subgroup analysis, symptoms with the strongest influence among patients with and without IBD were similar (IBD: fatigue and insomnia; no IBD: fatigue and anorexia). **Conclusion:** Our analyses suggest that the complex relationships between PSC symptoms organize into four dominant, clinically-relevant clusters. Fatigue and weakness emerged as the symptoms with the strongest influence across the primary and secondary analyses. Our data emphasize the co-occurring nature of PSC symptoms, identify highly influential symptoms, and highlight the need to develop patient-reported outcome measures to assess changes in these key symptoms in clinical trials.

Figure. LASSO regularized partial correlation network of 16 symptoms reported in the past 6 months using communities determined by Spinglass algorithm

4559-C | NEXT GENERATION HEPQUANT TESTS PREDICT CLINICAL OUTCOME IN PRIMARY SCLEROSING CHOLANGITIS

Michael P. McRae, Custom DX Solutions LLC, Steve M. Helmke, Hepquant and Gregory T Everson, Hepquant, Englewood, CO

Background: We quantified liver function and portal-systemic shunting in primary sclerosing cholangitis (PSC) using V1.1 of the HepQuant SHUNT test (Everson et al. 2007) and NEXT GENERATION tests (V2.0 and LDT 1.0) based on a compartmental model (McRae et al. 2022). We compared test results to standard laboratory tests and clinical models in the prediction of clinical outcome. **Methods:** Forty-seven patients, spanning the clinical spectrum of PSC, underwent baseline tests. Forty-six were retested at baseline for reproducibility by intraclass correlation coefficient (ICC). The cohort was followed prospectively for clinical outcomes, and forty were retested after 1 year. For each test, 20 mg of [24-13C]cholate (13C-CA) was injected intravenously and [2,2,4,4-2H]cholate (d4-CA) was administered orally. Blood was sampled at 0, 5, 20, 45, 60, and 90 minutes for serum cholate concentrations. In V1.1, clearances were calculated from the measured 13C-CA and d4-CA concentrations. The clearances for

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

V2.0 were derived from model parameters fit to the 13C- and d4-CA concentrations at 20 and 60 minutes and for LDT 1.0, only d4-CA concentrations at 20 and 60 minutes. A disease severity index (DSI) and portal-systemic shunt (SHUNT%) were calculated. **Results:** The within-subject reproducibility was excellent and comparable across Test versions with ICCs ≥ 0.89 for DSI and SHUNT%. Three subgroups of progressors, slow (n = 28), moderate (n = 16), and rapid (n = 3), were suggested from age-related degree of hepatic impairment. Rapid progressors were characterized by high SHUNT% at relatively young age. Moderate/rapid progressors had higher DSI, SHUNT%, and lower Portal HFR and hepatic reserve, worse laboratory tests, higher levels of IL-6, IL-8, and GM-CSF, and were more likely to experience clinical outcome compared to slow progressors. In univariate analysis SHUNT% was the strongest single predictor of new clinical decompensation, liver-related death, or liver transplantation (n = 13 with clinical outcomes, AUROC 0.886 for V1.1, 0.853 for V2.0, and 0.834 for LDT 1.0) with no significant differences in operating characteristics between Test versions. **Conclusion:** HepQuant's Test parameters of liver function and physiology correlate with laboratory and clinical evidence of PSC disease severity, identify progressor groups, and predict risk for clinical outcome. All versions of the HepQuant Test had excellent reproducibility.

Prediction of clinical outcome (new clinical decompensation, liver-related death, or liver transplantation) and reproducibility of DSI and SHUNT% in a cohort with Primary Sclerosing Cholangitis (PSC)

Parameter	Version	AUROC (95% CI)	%CV	Min. Detectable Diff.	ICC (95% CI)	p-value
DSI	SHUNT V1.1	0.812 (0.551-0.921)	9.21%	2.68	0.91 (0.84-0.95)	<0.001
	SHUNT V2.0	0.801 (0.594-0.930)	10.77%	3.19	0.89 (0.81-0.94)	<0.001
	LDT 1.0	0.814 (0.620-0.924)	10.33%	3.02	0.89 (0.82-0.94)	<0.001
SHUNT%	SHUNT V1.1	0.886 (0.734-0.958)	10.51%	5.88	0.91 (0.85-0.95)	<0.001

Background: Obeticholic acid (OCA) is the approved second-line treatment for patients with primary biliary cholangitis (PBC). Biochemical response by POISE criteria is achieved in ~40% of patients, according to registrative and post-marketing studies. The aim of the present study was to derive the OCA response score (ORS) for predicting response to OCA therapy at 12 and 24 months. **Methods:** We used data from the Italian RECAPITULATE (N 441, women 88%, mean age 57.8, cirrhosis 34%; Italy) and the IBERIAN (N 244, women 93%, mean age 56.6, cirrhosis 23%; Spain-Portugal) OCA real-world cohorts to derive and validate a scoring system including only widely available pre-treatment variables (ORS), or also the change of alkaline phosphatase(ALP)/upper limit of normal(ULN) and total bilirubin after 6 months' therapy (ORS+). Multivariable Cox's regressions with backward selection method were applied to obtain parsimonious predictive models. The predicted outcomes were biochemical response to OCA according to either POISE (ALP/ULN < 1.67 with a reduction of at least 15%, and normal bilirubin), or ALP/ULN < 1.67, or NORMAL RANGE criteria (NR, ALP/ULN < 1 and alanine aminotransferase(ALT)/ULN < 1 and normal bilirubin). **Results:** After variable selection procedures, the ORS was derived in the RECAPITULATE cohort and included age at OCA start, pruritus, cirrhosis, ALP/ULN, ALT/ULN, GGT/ULN and total bilirubin (for predicting POISE response), pruritus, cirrhosis, ALP/ULN, GGT/ULN and total bilirubin (for ALP/ULN < 1.67 response) and pruritus, ALP/ULN and total bilirubin (for NR response). The ORS+ was also derived by including the relative changes of ALP/ULN and of total bilirubin at 6 months. Good discriminative properties for both ORS and ORS+ were observed in the RECAPITULATE cohort (c-statistics: POISE criteria $= 0.77$ and 0.84; ALP/ULN $< 1.67 = 0.79$ and 0.88; NR criteria $= 0.73$ and 0.82, respectively), and confirmed in the IBERIAN validation cohort (c-statistics: POISE criteria $= 0.70$ and 0.81; ALP/ULN $< 1.67 = 0.72$ and 0.82; NR criteria $= 0.71$ and 0.86, respectively). Bootstrap validation evidenced modest overfitting (calibration slopes > 0.90). Mean absolute errors < 0.08 were observed in the IBERIAN cohort, indicating adequate models' calibration (Figure 1). **Conclusion:** The ORS accurately predicts OCA response at 12 and

24 months, according to different biochemical criteria. This will enable to enhance allocation of second-line therapies in PBC with a personalised medicine approach.

4561-C | PREDICTORS OF GRAFT AND PATIENT SURVIVAL IN PRIMARY BILIARY CHOLANGITIS RECIPIENTS UNDERGOING LIVING DONOR LIVER TRANSPLANTATION

John Esli Medina Morales[1], Mohamed Ismail[2], Romelia Barba Bernal[3], Yazan Abboud[4], Leandro Sierra[5], Ana Marenco-Flores[6], Daniela Goyes[7], Behnam Saberi[5], Vilas Patwardhan[5] and Alan Bonder[5], (1)Rutgers New Jersey Medical School, Kearny, NJ, (2)Rutgers New Jersey Medical School, (3)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Brighton, MA, (4)Department of Internal Medicine, Rutgers New Jersey Medical School, Newark, NJ, USA., (5)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, (6)Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Brookline, MA, (7)Yale University Medical Center, New Haven, CT, United States

Background: Few studies have explored the effect of living donor liver transplantation (LDLT) in patients with primary biliary cholangitis (PBC). Early recurrence of PBC and poorer outcomes have been reported. However, long-term analyses comparing post-transplant outcomes among liver transplantation (LT) types are scarce. In this study, we aimed to compare deceased donor liver transplantation (DDLT) vs LDLT to determine the survival outcomes and to identify recipient and donor characteristics associated with patient mortality and graft failure. **Methods:** A retrospective cohort analysis of adult patients with PBC registered in the Organ Procurement and Transplantation Network (OPTN) database who received primary LT between 2002 and 2019 was analyzed. Recipient characteristics such as demographics, comorbidities,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

pre-transplant labs, along with donor demographics were included. The primary outcomes were graft and patient survival at 1-,3-, 5- and 10 years post-LT. Stepwise Cox proportional hazard regression models were used to identify significant graft and patient survival predictors. **Results:** 3,328 DDLTs and 405 LDLT recipients were identified. On unadjusted analysis, LDLT recipients showed superior survival compared to DDLT at 1-, 3-, 5-, and 10-years (92.5%, 89.3%, 87.9%, 87.0%, 77.3% vs 91.1%, 88.1%, 86.1%, 82.1%, 70%, respectively). No significance was found in graft survival in LDLT recipients compared to DDLT (88.4%, 85.3%, 82.6%, 79.3%, 70.5% vs 88.9%, 85.7%, 83.6%, 79.7%, 67.2%; respectively). On univariate analysis, recipient age at transplant, male gender, recipient weight, presence of diabetes, use of mechanical ventilation, LDLT, donor age and weight were significantly associated with graft survival ($p < 0.05$). Recipient age at transplant, male gender, recipient weight, presence of diabetes, history of previous abdominal surgery, use of mechanical ventilation, portal vein thrombosis, LDLT, donor age, donor race, and cold ischemia time were associated with patient survival ($p < 0.05$). On multivariate analysis, recipient age at transplant, male gender, recipient weight, mechanical ventilation use, diabetes, and donor age were significantly associated with poorer graft and patient survival (table 1). **Conclusion:** No difference was found in graft and patient survival in PBC recipients undergoing LDLT compared to DDLT. Recipient factors such as recipient age at transplant, male gender, recipient weight, mechanical ventilation, diabetes, and donor age were associated with poorer post-LT outcomes. Prospective analyses are required to validate these findings.

Table 1. Stepwise multivariate Cox proportional hazard analyses of predictors of post-transplant graft and patient survival in PBC recipients

	Hazard Ratio	95% CI	p-value
GRAFT SURVIVAL			
Recipient Age	1.11	1.04 - 1.18	p<0.001
Recipient Weight	1.01	1.00 - 1.12	0.004
Male gender	1.22	1.05 - 1.41	0.009
Diabetes	1.22	1.05 - 1.43	0.011
Ventilator	1.72	1.34- 2.21	p<0.001
Donor Age	1.01	1.00 - 1.01	p<0.001
PATIENT SURVIVAL			
Recipient Age	1.28	1.20 - 1.37	p<0.001
Recipient Weight	1.01	1.00 - 1.01	0.004

4562-C | PREGNANCY OUTCOMES IN WOMEN WITH BILIARY TRANSPORTER GENES ABCB4 AND ABCB11 MUTATIONS

Yooyun Chung[1], Richard J. Thompson[1], Deepak Joshi[1], Mussarat N. Rahim[1], Catherine Williamson[2] and Michael A. Heneghan[1], (1)Institute of Liver Studies, King's College London, London, United Kingdom, (2) Imperial College London, London, United Kingdom

Background: Mutations in the bile acid (BA) transporter genes can result in intrahepatic cholestasis of pregnancy (ICP), cholelithiasis and progressive familial intrahepatic cholestasis. Severe ICP is associated with adverse fetal outcomes including preterm births and stillbirths whilst posing a challenge in the management of intractable pruritus for some women. **Methods:** A prospective database of self-reported pregnancies from women with liver disease was used to identify pregnancies with BA transporter gene mutations. Liver transplantation (LT) patients were excluded. Data on demographics, pregnancy outcomes and biochemical markers were gathered from medical records. **Results:** There were 28 pregnancies from 17 women with BA transporter gene mutations between 2001-2021 at King's College Hospital (Table 1). Median age at conception was 30 years (IQR 25-34). One woman with 2 pregnancies was cirrhotic at conception. Eight women with 12 pregnancies had cholecystectomy prior to conception and 1 required cholecystectomy post-partum. Median age at cholecystectomy was 21 years (IQR 18-29). ICP occurred in 22 pregnancies with median gestation at onset of 18 weeks (IQR 13-22). Median peak BA was 250 (IQR 160-400). All ICP patients received ursodeoxycholic acid and adjunct therapies included BA sequestrants ($n = 1$), rifampicin ($n = 4$), antihistamine ($n = 2$), nasobiliary drainage ($n = 1$) and plasma exchange ($n = 1$). Two patients received phototherapy post-partum. There were 26 live births with 2 terminations. Majority had spontaneous vaginal delivery ($n = 17$), 4 had planned caesarean (CS), 2 emergency CS and data missing in 3. There were 19 preterm births of which 2 were very preterm (< 32 weeks gestation) and 17 moderate (32-36 weeks). Median birthweight was 2565g (IQR 2120-3212). Five babies required admission to special care baby unit (SCBU) of which 4 were short stays and the babies were healthy. The patient with cirrhosis had preconception MELD score 10, decompensated during pregnancy and required LT within 1-year post-partum. The baby had a prolonged admission in SCBU. There were no stillbirths or miscarriages. **Conclusion:** There is a high rate of ICP and preterm births in women with BA transporter gene

mutations. Despite the high BA there were no stillbirths and overall had good outcomes in this case series. Management of pruritus is difficult with often suboptimal response and requires an individualised approach.

4563-C | PREVALENCE AND TREATMENT OF PRURITUS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC): RESULTS FROM THE GERMAN PBC REGISTRY

Toni Herta[1], Annegret Franke[2], Heike Bantel[3], Marko Damm[4], Rainer Günther[5], Frank Tacke[6], Gerald Denk[7], Matthias Hinz[8], Jörn M. Schattenberg[9], Tobias Boettler[10], Nicole Koeppe-Bauernfeind[2], Christian Trautwein[11], Thomas Berg[12], Johannes Wiegand[1] and Andreas E. Kremer[13], (1)Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany, (2)Clinical Trial Centre, University of Leipzig, Leipzig, Germany, (3)Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology at Hannover Medical School, Hannover, Germany, (4)Department of Internal Medicine I, Martin Luther University, Halle, Germany, (5) Department of Internal Medicine I, University Medical Center Schleswig-Holstein (UKSH), Campus Kiel, Kiel, Germany, (6)Department of Hepatology and Gastroenterology, Charité Universitätsmedizin, Berlin, Germany, (7)Department of Medicine II, University Hospital, Ludwig-Maximilians-University Munich, Munich, Germany, (8)Gastroenterology Practice, Herne, Germany, (9)I. Department of Medicine, University Medical Centre Mainz, Johannes Gutenberg University, Mainz, Germany, Mainz, Germany, (10)Department of Medicine II, University Hospital Freiburg, Freiburg, Germany, (11)University Hospital, Rwth Aachen, (12) University Hospital of Leipzig, (13)Department of Gastroenterology and Hepatology, University Hospital Zürich, Zürich, Switzerland, Zurich, Switzerland

Background: Pruritus is a major symptom of primary biliary cholangitis (PBC). Systematic data on prevalence and treatment of pruritus in patients with PBC is limited. We therefore characterized PBC patients with pruritus in the German real-world setting. **Methods:** The German PBC Registry is a nationwide database for routine clinical data of 32 centers, which recruited PBC patients between September 2019 and January 2023. Pruritus was recorded with a 4-point Lickert scale as absent, mild, moderate, or severe by the treating physician. Fisher's Exact test, Chi²-test or Mann-Whitney-U-test were used to analyze statistical differences for significance ($p < 0.05$). **Results:** Pruritus was noted in 117/496 (24%) of patients (87% female, median age at diagnosis 50 years, 15% with cirrhosis, median UDCA daily dosage 12.7 mg/kg) and classified as mild, moderate, or severe in 57 (49%), 41 (35%), and 19 (16%) cases. Patients with pruritus were younger at PBC diagnosis (50.7 ± 11.2 vs. 54.8 ± 11.8 years, $p < 0.001$) and reported more often depression (14.5% vs. 6.1%, $p = 0.006$) than individual's without pruritus. They were significantly more often treated at academic than non-academic centers (79.5% vs. 20.5%, $p < 0.0001$). The prevalence of pruritus in academic centers was 27% ($n = 93/345$) and in non-academic centers 16% ($n = 24/151$) ($p = 0.0081$), with a range of 0-86% and 0-50% at both care levels, respectively. 56/496 (11%) and 48/496 (9.7%) of patients received second line PBC therapy with bezafibrate or obeticholic acid. Prevalence of pruritus was not significantly different between both second line treatment groups (27% vs. 31%), or between UDCA responder patients and primary UDCA incomplete responders according to Paris II criteria (21% vs. 27%). Antipruritic therapies were infrequently used: bezafibrate $n = 15$, antihistamines $n = 7$, cholestyramine $n = 3$, sertraline $n = 2$, rifampicin $n = 1$, steroid-containing ointment $n = 1$, opiate-antagonists $n = 0$. **Conclusion:** Pruritus is common and inadequately treated in PBC patients. Diagnosis highly depends on the treating physician and needs harmonization. Education about antipruritic therapies should be improved.

4564-C | PRIMARY SCLEROSING CHOLANGITIS: EXPERIENCE FROM A TERTIARY CARE CENTER IN ASIA

Mithun Sharma[1], Anand V. Kulkarni[2], Rajesh Gupta[2], Nitin Jagtap[1], Padaki Nagaraja Rao[2], Manasa Alla[2], Anuradha Sekaran[2], Shantan Venishetty[2], Sowmya T R[2] and Nageshwar D Reddy[2], (1)Asian Institute of Gastroenterology, Hyderabad, Telangana, India, (2)Aig Hospitals, Hyderabad, India

Background: The incidence of primary sclerosing cholangitis (PSC) are less in India when compared to the Western world. This study reports the clinical profile of one of the largest reported case series of PSC from India **Methods:** Retrospective data from 2012 to January 2023 were retrieved for clinical profile, development of cholangiocarcinoma, presence of concomitant autoimmune hepatitis (AIH), presence of inflammatory bowel disease, presence of dominant stricture and risks involved with endoscopic interventions **Results:** 48 patients of PSC (40 male and 8 female) were included. The mean age of presentation was 25 +_ 9 yrs. The most common presenting feature was jaundice in 68% of patients and 38% of cases had a preceding history of cholecystectomy. The median duration between the detection of PSC and cholecystectomy was 5.4 years. Large duct PSC was in 33(75%) patients as detected by MRCP while biopsy small duct in the remaining. The median duration of follow-up was 3.4 yrs (1.2 to 8.2 yrs). The dominant stricture was present in 12(25%) at presentation while an additional 4 (8.33%) developed in the follow-up period. Cholangiocarcinoma was detected in 1 patient at the time of presentation while an additional 6(12.5%) developed at a median of 2.7 yrs. Spy cholangioscopy was done in 3 patients. Endoscopic intervention was done in 8 patients but was associated with sepsis in 50% of patients. 3 patients underwent liver transplantation and all were doing fine at a median 3 years follow-up. Associated inflammatory bowel disease was present in 15(31.25%) patients and was mostly ulcerative colitis. Mortality during this follow-up period was 8(16.65) **Conclusion:** PSC is a disease that affects the young population with a high transition to cholangiocarcinoma and interventions are associated with the risk of contaminating the ductal system. There is lower incidence of IBD in Asians. Transplantation of the liver is associated with a good prognosis

4565-C | PRURITUS IS COMMON AND BURDENSOME IN PATIENTS (PTS) WITH CHRONIC LIVER DISEASE (CLD): FINDINGS FROM A CROSS-SECTIONAL NATURAL HISTORY STUDY

Usha Gungabissoon[1], Ellie McDermott[2], Andrew Lovley[3], Kristen L McCausland[3], Monica Frazer[3], Kaitlin LaGasse[3], Gideon Hirschfield[4], Jake Hunnicutt[5],

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

Ashleigh McGirr[6] and Helen T Smith[1], (1)GSK, London, UK, (2)GSK, Stevenage, Hertfordshire, UK, (3) Qualitymetric Incorporated, LLC, Johnston, RI, USA, (4) Toronto Centre for Liver Disease, University of Toronto, Toronto, Ontario, Canada, (5)GSK, Collegeville, PA, USA, (6)GSK, Mississauga, Ontario, Canada

Background: Pruritus is a common condition associated with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC). There are limited data reporting pruritus in other CLDs such as autoimmune hepatitis (AIH), chronic hepatitis B/C (Hep B/C), non-alcoholic steatohepatitis (NASH) and cholestatic or mixed drug-induced liver injury (DILI). We aimed to understand the severity and impact of pruritus in CLDs using screening and baseline data from our online, patient-reported outcome study. **Methods:** Adult patients (pts) with CLDs were recruited in the USA, UK, Canada, and Germany and screened online for pruritus and eligibility. Among screened pts, pruritus burden was assessed using the worst itch numerical rating scale (WI-NRS; scale 0–10) with a 3-month recall and reported for overall (score ≥ 1) and moderate-to severe itch (score ≥ 4). Eligible pts were those who reported pruritus within the prior 3 months, and had a CLD diagnosis confirmed by a third party (using documentation from healthcare providers or medical records). Pts with other pruritus causes, previous liver transplant, or end-stage liver disease were excluded. Baseline demographics and pruritus characteristics from the past 2 weeks are reported for eligible pts. **Results**: From 717 screened pts, 56% indicated some degree of pruritus, 42% reported moderate-to-severe itch (Table). Pruritus frequency was highest among pts with Hep B/C (70%/73%), and NASH (69%). Of those screened, 357 met further eligibility criteria. In eligible pts, there were notably more females in AIH, PBC, and PSC, similar proportions in Hep C, DILI, and NASH, and more males in the Hep B cohort. Pts were mostly white/Caucasian (78%, range 22–94%) and mean (SD) age was 51.1 (12.8) years (range 44.1–57.1). In eligible pts, 80% experienced pruritus for ≥ 2 days/week in the last 2 weeks, with the highest in pts with DILI (95%), and Hep C (91%); with one third itching every day. Similar percentages of pts in each cohort (27% overall; range 16–34%) reported scratching enough to make their skin raw on ≥ 2 days/week in the past 2 weeks. This was highest in pts with PBC (34%) and DILI (32%). **Conclusion**: Initial findings from this multi-country study highlight that overall and moderate-to-severe pruritus is common ($>40\%$) and burdensome ($>25\%$ scratched enough to make their skin raw on ≥ 2 days/week in the last 2 weeks) in pts with CLD, emphasizing an unmet need in these pts. Funding: GSK (209971).

Table: Pruritus frequency and itch characteristics at screening and in eligible patients at baseline

Cohort	Screening data: N	Screening data: Reported pruritus in past 3 months (WI-NRS ≥1), n (%)[1]	Screening data: Reported moderate-to-severe pruritus in past 3 months (WI-NRS ≥4), n (%)[1]	Baseline data from eligible patients: N	Baseline data from eligible patients: Reported itch on ≥2 days per week in the past 2 weeks, n (%)	Baseline data from eligible patients: Reported scratching enough to make skin raw on ≥2 days per week in the past 2 weeks, n (%)
Overall Sample[2]	717	403 (56)[3]	302 (42)	357[4]	284 (80)	96 (27)
Autoimmune hepatitis (AIH)	99	40 (40)	33 (33)	36	30 (83)	8 (22)
Chronic viral hepatitis B (Hep B)	50	35 (70)	26 (52)	28	21 (75)	7 (25)
Chronic viral hepatitis C (Hep C)	77	56 (73)	40 (52)	54	49 (91)	15 (28)
Drug-induced liver injury (DILI)[5]	35	19 (53)	13 (36)	19	15 (95)	5 (32)
Non-alcoholic steatohepatitis (NASH)	97	67 (69)	45 (46)	61	49 (80)	10 (16)
Primary biliary cholangitis (PBC)	174	85 (49)	68 (39)	80	62 (78)	27 (34)
Primary sclerosing cholangitis (PSC)	173	88 (51)	65 (37)	74	52 (70)	22 (30)

Note: Target recruitment sample sizes were initially chosen for the estimation of the frequency of pruritus overall and within each liver disease group, estimations of moderate-to-severe pruritus were added post-hoc. The available sample size may not be sufficient for a reliable estimate of the frequency of moderate-to-severe pruritus and interpretations should be made with caution. [1]Derived based on WI-NRS (on a 0–10 scale) with a 3-month recall period administered at screening, before eligibility criteria were applied. [2]Disease-specific prevalence was not estimated for alcoholic liver disease (ALD) or non-alcoholic fatty liver disease (NAFLD) due to limited sample size (N=1 and 4 for ALD and NAFLD, respectively, at baseline). [3]Of 468 individuals deemed eligible to participate, 46 pts did not return or complete baseline survey before the survey was closed. [4]This included both cholestatic and mixed drug-induced liver injury patient populations.

4566-C | QUANTITATIVE ASSESSMENT OF ANTI-MITOCHONDRIAL ANTIBODIES IN PRIMARY BILIARY COLANGITIS: A CROSS-SECTIONAL ANALYSIS

Lorenzo Canova[1], Elisabetta Degasperi[1], Maria Paola Anolli[1], Marta Borghi[1], Riccardo Perbellini[1], Sonia Stella[1] and Pietro Lampertico[1,2], (1)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2) CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: In patients with primary biliary cholangitis (PBC), quantitative assessment of anti-mitochondrial antibodies (AMA)-M2 is currently available, however its clinical meaning is still unknown. Aim of our study was to analyse quantitative AMA-M2 in PBC patients and its correlation with clinical features. . **Methods:** PBC patients followed in a tertiary hepatology Italian centre with available quantitative AMA-M2 values were included in a cross-sectional analysis. PBC was diagnosed according to international recommendations, response to Ursodeoxycholic acid (UDCA) was defined according to Paris-II criteria. Demographic, clinical and biochemical features were collected ±3 months from AMA assessment. AMA was tested by chemiluminescence immunoassay (CLIA) (assay range 0-3000 AU/mL). **Results:** Overall, 92 PBC patients (87% females) were included. At the time of AMA assessment, median age was 67 (39-93) years, ALT 30 (8-258) U/L, ALP 0.7 (0.2-4.4) ULN, 38% patients with ALP > 1.5 ULN, gGT 1.44 (0.2-14.3) ULN, IgM 237 (39-1,037) mg/dl, liver stiffness measurement (LSM) 5.9 (3.9-38.6) kPa, 23% with advanced fibrosis (Stage III-IV Ludwig). Median time since PBC diagnosis was 89 (1-433) months, 91% patients were UDCA-treated, 19% under second-line therapy due to UDCA non-response. Overall, in the 49 (53%) patients with quantifiable AMA, median value was 319 (20-2500) AU/mL, while AMA-M2 tested > 3000 AU/mL in 43 (47%) patients. No statistically significant differences were observed between patients with AMA titers above *vs.* below 3000 concerning most important clinical, biochemical and disease features: age ($p = 0.18$), sex ($p = 0.31$), BMI ($p = 0.34$), advanced fibrosis stage ($p = 0.55$), LSM values ($p = 0.73$), disease duration ($p = 0.78$), UDCA response ($p = 0.45$), ALT ($p = 0.97$), ALP ($p = 0.78$) values and ALP ULN categories (< 1.5 ULN *vs.* 1.5-2.0 ULN *vs.* > 2 ULN, $p = 0.84$), gGT ($p = 0.49$) and IgM ($p = 0.84$) values. The same was true when AMA values were analyzed according to multiple thresholds (AMA < 300 *vs.* 300-1000 *vs.* 1000-3000 *vs.* > 3000). Conversely, in patients with AMA < 3000, male sex was associated with lower AMA-M2 values (56 *vs.* 426, $p = 0.02$). **Conclusion:** In UDCA-treated PBC patients, lower AMA-M2 levels were associated only with male gender, while they did not correlate with other clinical or disease features.

4567-C | REAL-WORLD CLINICAL CHARACTERISTICS AND TREATMENT PATTERNS OF PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN THE UNITED STATES

Nisreen Shamseddine[1], Hongbo Yang[2], Su Zhang[2], Dongni Ye[2], Sonal Kumar[3] and Kris V. Kowdley[4], (1) Ipsen Biopharmaceuticals, Inc., (2)Analysis Group, Inc., (3)Weill Cornell Medical College, (4)Liver Institute Northwest

Background: Patients (pts) with primary biliary cholangitis (PBC) are at a risk of progression to end-stage liver disease. Ursodeoxycholic acid (UDCA) and obeticholic acid (OCA) are currently approved treatments (Txs) for PBC in the United States (US). Delayed Tx can negatively impact the prognosis of PBC. This study assessed clinical characteristics and Tx patterns of pts with PBC during their Tx journey. **Methods:** This retrospective cohort study used IQVIA PharMetrics® Plus data (2016-2022). Three non-mutually exclusive pt cohorts were created: 1) pts with newly-diagnosed untreated PBC (newly-diagnosed cohort), 2) pts initiated first-line Tx (UDCA) (1L cohort), and 3) pts initiated second-line or more Tx (OCA/fibrates ± UDCA) (2L+ cohort). Index date was defined as the initial PBC diagnosis, 1L Tx initiation, or 2L Tx initiation, for each cohort, respectively. Baseline characteristics, measured 12-months before index, were summarized for each cohort. Tx sequence and time to 1L Tx initiation, based on Kaplan-Meier (KM) analysis, were described for the newly-diagnosed cohort. Time to 1L Tx discontinuation and time to 2L Tx initiation were described for the 1L

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cohort. Time to 2L Tx discontinuation was summarized for the 2L+ cohort. **Results:** A total of 1,549, 1,462, and 158 pts met eligibility criteria and were included in the newly-diagnosed, 1L, and 2L+ cohorts, respectively (Table 1). Baseline comorbidity burden was the highest in the 2L+ cohort, followed by the 1L and the newly-diagnosed cohort; baseline pruritus rate was also the highest in the 2L+ cohort. In the newly-diagnosed cohort, with a median follow-up of 18.3 months, 1,018 (65.8%) pts received $\geq$1 Tx after the initial diagnosis. While the median time from initial PBC diagnosis to 1L initiation was 1.2 months, 27.2% of pts did not initiate any Tx at 4 years after diagnosis based on the KM analysis. In the 1L cohort, with a median follow-up of 19.9 months, 440 (30.1%) pts discontinued 1L Tx (median time to 1L Tx discontinuation: 51.0 months); 121 (8.3%) pts initiated 2L Tx. In the 2L+ cohort, with a median follow-up of 15.1 months, 23 (14.6%) pts discontinued 2L Tx and the median time to 2L Tx discontinuation was not reached. **Conclusion:** This analysis suggests that pts with PBC in the 2L+ setting have the highest comorbidity burden. Additionally, despite approved Txs, a non-trivial proportion of PBC pts appear to remain untreated years after diagnosis, and 2L Tx initiation rate also appears low, highlighting an unmet need in this population.

Confidential

Table 1. Key baseline characteristics among patients in the newly-diagnosed, 1L, and 2L+ cohort, respectively

Demographic characteristics	Newly-diagnosed (N=1,549)	1L (N=1,462)	2L+ (N=158)
Age at index date (years), mean ± SD	54.0 ± 11.1	54.4 ± 10.3	54.5 ± 9.9

4568-C | REAL-WORLD EVIDENCE, CLINICAL CHARACTERISTICS, & DISEASE PROGRESSION INSIGHTS FROM A GLOBAL COHORT OF PRIMARY BILIARY CHOLANGITIS PATIENTS DIAGNOSED BETWEEN 2015 AND 2023

Gianni Amato and Courtney Thompson, Trinetx

Background: Primary biliary cholangitis (PBC) is a rare autoimmune liver disease characterized by impaired bile flow, inflammation, & bile duct damage. Disease characteristics include elevated markers of cholestasis, along with symptoms of fatigue and pruritus. Treatment includes first-line ursodeoxycholic acid (UDCA) & second-line obeticholic acid (OCA). PPARδ agonists are under investigation. **Methods:** This study utilized TriNetX Dataworks Global Network & extracted electronic health records (EHR) from 67 global healthcare organizations (HCOs). Eligible patients were identified with ICD-10 codes K74.3 to K74.5. Descriptive statistics were reported and time to event analysis was used to explore the cohort which includes real-world evidence (RWE) of patients diagnosed between 2015 and 2023. Demographics, diagnoses, procedures, medications, serum liver tests, genomics, and time to event variables, including advanced fibrosis, cirrhosis, portal hypertension, hepatocellular carcinoma, liver transplant, or death, were measured. **Results:** The cohort includes 33,095 patients across 67 HCOs. Of these, 74% were female, 72% were white, and 65% were non-Hispanic. The mean (SD) age was 65 (14) years & mean (SD) duration of PBC was 11 (6) years. Patients had multiple comorbidities, including disorders of the endocrine, circulatory, genitourinary, blood, skin, and subcutaneous tissue systems. Baseline mean (SD) levels of ALP, ALT, AST, GGT, total bilirubin, and albumin were 184 (187), 51.4 (19.2), 84.8 (55.0), 192 (305), 2.15 (4.94), and 3.72 (0.86), respectively. Patients were stratified based on GLOBE score and UDCA response for time-to-event analysis. Approx. 45% of patients progressed to a more severe condition during the course of their disease. Approx. 17,600 received UDCA, & 1,119 received OCA. Within eight years of diagnosis, approximately 45% of high-risk patients who failed or were intolerant to UDCA or OCA progressed to more severe disease states, including liver failure, liver transplant, or hepatocellular carcinoma, and had a combined real-world Hazard Ratio (HR) of 11.2 (95% CI 9.1–21.9). **Conclusion:** This study underscores the vital role of RWE in understanding the management and progression of primary biliary cholangitis & analyzes biochemical factors of progression to more severe disease states. Insights from robust longitudinal datasets are essential for drug developers and clinical practitioners to get a comprehensive view of progression in PCB in the real-world.

Table 1.1 Demographics and Baseline Characteristics of Primary Biliary Cholangitis (PBC) Patients in a Global Longitudinal Database Stratified by Risk

Risk*	Low	High	Total
N (%)			
Female	6,367 (26)	18,123 (74)	24,490
Caucasian	6,910 (29)	16,919 (72)	23,829
History of Pruritis	5,957 (18)	27,139 (82)	33,096
UDCA Experienced	7,572 (43)	10,037 (57)	17,609

Background: At present, fibrates can be used off-label among patients with primary biliary cholangitis (PBC). We aimed to evaluate the real-world use and effectiveness of fibrates in a nationwide cohort. **Methods:** For this analyses all patients in the Dutch PBC cohort study - a retrospective study in all Dutch hospitals including every identifiable patient with PBC from 1990 onwards - who initiated fibrates during follow-up were included. Biochemical measurements before the start of fibrates and those closest to 12 months (minimum nine months, maximum 18 months) were used. Fibrate-induced biochemical changes during the first year were assessed by median (IQR) changes (Δ) in the upper limit of normal (ULN) and dichotomously (normal ALP or bilirubin $\leq$0.6xULN). **Results:** In total, 318 patients (female *n = 291*; 91.5%) with PBC who initiated fibrates during follow up were included, of which 4 (1.2%) did not use ursodeoxycholic acid. Fibrates of use were bezafibrate (*n = 311;* 97.8%), ciprofibrate (*n = 5;* 1.6%) and gemfibrozil (*n = 2;* 0.6%). At start of fibrate therapy, median age was 55.3 (IQR 48.4–64.4) years, 45 (14.2%) had cirrhosis, median ALP was 2.42xULN (IQR 1.58-3.51), and median bilirubin was 0.55xULN (IQR 0.41-0.94). Fibrate therapy was discontinued within the first year in 67 (21.1%) patients, another 63 (19.8%) patients had not (yet) reached nine months of treatment. The change in ALP and bilirubin could be assessed in 165 and 148 patients, respectively. Overall, the median ΔALP and Δbilirubin were -1.03 (IQR -0.60 to -1.77) and -0.08 (IQR -0.20 to 0.06), respectively. The median ΔALP was -0.58 (IQR -0.79 to -0.14) for patients with an ALP $\leq$ 1.67xULN at baseline versus -1.33 (IQR -2.14 to -0.81) for those > 1.67xULN ($p < 0.01$). The median Δbilirubin was 0.00 (IQR -0.10 to 0.06) for patients $\leq$0.6xULN at baseline, versus -0.17 (IQR -0.35 to 0.00) for those > 0.6xULN ($p < 0.01$). At 12 months, 49/158 (31.0%) patients with elevated baseline ALP reached normalization and 20/72 (27.4%) with a baseline bilirubin > 0.6xULN were below this threshold. **Conclusion:** In this nation-wide real-world study, fibrate use was associated with statistically significant reductions in cholestatic surrogate markers after one year of therapy, with about a third of patients reaching the most stringent biochemical treatment goals. However, discontinuation rate was high, indicating the need to optimize fibrate treatment strategies.

4570-C | REEVALUATING THE TREATMENT INDICATIONS FOR PRIMARY BILIARY CHOLANGITIS - ANALYSIS OF A NATIONWIDE SURVEY COHORT IN JAPAN-

Kosuke Matsumoto[1], Junko Hirohara[2], Toshiaki Nakano[2] and Atsushi Tanaka[1], (1)Teikyo University School of Medicine, (2)Kansai Medical University

Background: PBC Clinical practice guidelines state that patients with abnormal ALP values are eligible for treatment, but there is no clear evidence supporting this recommendation. In this study, we retrospectively examined the association among ALP levels at baseline, treatment, and long-term prognosis, using a large cohort of patients with PBC in Japan to reevaluate the indications for treatment of PBC. **Methods:** From patient data (n = 9919) enrolled in the cohort of PBC, we extracted patients in which ALP level at presentation, presence or absence of treatment during the course of the disease, and long-term prognosis were all recorded. Enrolled patients were classified into 4 groups: ALP less than the upper limit of normal (ULN) at baseline (< 1 group), ALP with 1-1.5 xULN (1-1.5 group), ALP with 1.5-2 xULN (1.5-2 group), and ALP > 2 xULN (> 2 group). The association of treatment with long-term outcome was statistically analyzed in each group. **Results:** Of the 6595 patients enrolled for the study, 1676 were in the < 1 group (male/female = 213/1463, age at diagnosis 58.5 ± 11.1 y), 1817 in the 1-1.5 group (224/1593, 58.5 ± 11.1 y), 1045 in the 1.5-2 group (146/899, 58.0 ± 11.2 y), and 2057 patients in the > 2 group (334/1723, 20.0 ± 11.2 y). In each group, 1527 (91%), 1718 (95%), 986 (94%), and 1954 (95%) were treated with ursodeoxycholic acid and/or bezafibrate, respectively. The mean observation periods were 8.0, 7.6, 7.5, and 7.2 years, and death or liver transplantation (LT) occurred in 120 (7.2%), 130 (7.2%), 103 (9.9%), and 339 (16.5%) patients, respectively. When the association between treatment and LT-free survival was examined by the Kaplan-Meier method, there was no significant difference between treatment and non-treatment in the < 1 group ($p = 0.326$), but significant difference was observed in the other groups (1-1.5 group $p = 0.049$, 1.5-2 group $p = 0.029$, > 2 group $p < 0.001$). Cox regression analysis using sex, age at diagnosis, albumin, bilirubin, symptom status, and treatment as covariates, and LT or death as the endpoint, showed that treatment status was not significant in the < 1 and 1.5-2 groups, but was a significant factor in the 1-1.5 and > 2 groups (1-1.5 group HR = 0.531, 95%CI 0.28-0.99, $p = 0.048$; > 2 group HR = 0.397, 95%CI 0.27-0.59, $p < 0.001$). **Conclusion:** For patients with ALP levels within ULN at presentation, treatment is unlikely to have any effect on long-term prognosis. In contrast, a more detailed analysis of the effect of treatment on patients with ALP levels 1-2 times higher than the baseline ALP level is warranted.

4571-C | RESPONSE TO URSODIOL THERAPY IN REDUCING ALKALINE PHOSPHATASE TO NORMAL LEVELS IN PRIMARY BILIARY CHOLANGITIS IN A DIVERSE COMMUNITY PRACTICE

Austin Mueller, Wayne State University School of Medicine and Syed-Mohammed Jafri, Henry Ford Health System

Background: Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease that can lead to advanced fibrosis and cirrhosis. First-line treatment is ursodiol (UDCA), which decreases hepatic synthesis of cholesterol and desaturates biliary cholesterol. The objective is to assess the effectiveness of UDCA on lowering alkaline phosphatase (ALP) levels in patients diagnosed with PBC. **Methods:** A retrospective review was conducted at a diverse urban academic center to obtain UDCA dosage and ALP values at the start of UDCA therapy and at 6 and 12 month periods to correlate with long term survival. Covariants such as Fibroscan results and liver transplant status were analyzed followed by chi-squared tests and linear regression analysis. **Results:** 122 newly-presenting PBC patients were treated only with UDCA. Mean age was 61.6 years old (range 26-90). 73% (n = 89) of the patients were females. The mean liver stiffness by Fibroscan evaluation was 9.7 kPa with standard

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

deviation (SD) of 6.65 (n = 47). Results were tiered based on low (< 130), medium (130-200) and high (> 200) ALP levels. At baseline, the percentage of patients in low, medium, and high ALP groups were 11%, 36%, and 53%, respectively. After 12 months of treatment, the percentage of patients in low, medium, and high ALP groups were 42%, 33%, and 21%, respectively. Treatment regimen was defined as low dose (< 10mg/kg/day, 31%), medium dose (10-15mg/kg/day, 51%) and high dose (> 15mg/kg/day, 18%). The mean UDCA dose was 11.7 mg/kg/day (SD 4.44) upon initiation of therapy. Baseline ALP levels in low, medium and high dose UDCA groups was 47%, 53%, and 59%, respectively. ALP > 200 at 12 months in low, medium and high dose UDCA groups was 21%, 18%, and 18%, respectively. Overall 20.9% of patients had ALP > 200 after 12 months. 56.5% of patients had ALP > 130 at 12 months. The chi-square test showed no significant association between categorical UDCA dose and categorical ALP at 6 and 12 months. Linear regression analysis showed no significant UDCA dose effect on change in ALP from baseline to 6 and 12 months. The 3 and 5 year survival following diagnosis was 96% (n = 117) and 95% (n = 116), respectively. Survival at 3 and 5 years was 100% in those with 12 month ALP < 130, 97.6% and 95.1% in those with 12 month ALP 130-200, and 95.7% in those with 12 month ALP > 200, respectively. In patients with ALP > 200 at baseline, 44.4% had a Fibroscan value < 8kpa vs 18.5% had a Fibroscan value > 14 kpa. In patients with ALP > 200 at 12 months, 21.7% had a Fibroscan value < 8kpA vs 0% had a Fibroscan value > 14kpa. **Conclusion:** Initiating UDCA decreased the number of patients with ALP > 200 at 6 and 12 months compared to baseline. UDCA therapy aids survival but failed to reduce ALP levels < 200 in 20% of patients. Additional therapies should be considered for these patients.

4572-C | SAFETY, TOLERABILITY, AND PHARMACOKINETIC EFFECTS OF ELAFIBRANOR CO-ADMINISTRATION WITH SIMVASTATIN: AN OPEN-LABEL PHASE I TRIAL

Costello Medical[1], Benjamin Miller[1], Sarah Mazain[1], Rémy Hanf[2] and Carol Addy[3], (1)Ipsen, (2)Genfit S.a., (3)Genfit Corp

Background: The dual peroxisome proliferator-activated receptor (PPAR)α/δ agonist elafibranor is under development for treatment of primary biliary cholangitis (PBC). *In vitro* studies have demonstrated that elafibranor and its main active metabolite, GFT1007, do not have major effects on CYP450 activity. Patients with PBC often receive concomitant antihyperlipidemic therapies such as simvastatin, a sensitive substrate of CYP3A4. **Methods:** In this phase I, open-label, drug-drug interaction (DDI) trial (EudraCT: 2009-012523-28) investigating elafibranor and simvastatin, healthy participants were randomized into two groups: Group 1 received single oral doses of simvastatin 20 mg (Days 0 and 16) and once daily oral doses of elafibranor 80 mg (Day 2–17); Group 2 received single oral doses of elafibranor 80 mg (Days 0 and 28) and once daily oral doses of simvastatin 20 mg (Day 14–41). Pharmacokinetic parameters derived for elafibranor, GFT1007, and simvastatin included maximum observed plasma drug concentration (C_{max}) and area under the concentration-time curve from time 0–24 hours ($AUC_{(0–24)}$), which were analyzed using an ANOVA model. Adverse events (AEs) were described according to MedDRA (version 12.0) classifications. Treatment-emergent AEs (TEAEs), vital signs, laboratory safety, and ECG parameters were recorded. **Results:** 31 White male participants were randomized; data are reported for 28 who completed the trial. Mean (standard deviation) age was 27.2 (6.1) years. Point estimates and 90% confidence intervals for C_{max} and $AUC_{0–24}$ values for elafibranor, GFT1007, and simvastatin are presented in the Table; no significant differences were reported. 28 TEAEs were reported by 17 participants; 24/28 were mild/moderate, 4/28 were severe. 3 AEs were considered treatment related, 6 possibly related, and 19 not related. No TEAEs were considered co-administration related. The most common TEAEs were headaches (n = 6) and diarrhea (n = 4). 1 serious AE occurred, prior to any study treatment. No clinically relevant safety findings were linked to elafibranor and/or simvastatin intake, except for an expected decrease in lipid parameters. **Conclusion:** Simvastatin and elafibranor co-administration was well tolerated in healthy male participants. There was no clinically meaningful effect of elafibranor administration on the C_{max} or daily exposure of simvastatin or *vice versa*. Therefore, co-administration of elafibranor with substrates of CYP3A4 is not expected to result in clinically significant DDIs.

Table: Pharmacokinetic parameters of elafibranor, GFT1007, and simvastatin single dose and concomitant treatment

	Group 1 (elafibranor as the perpetrator)			Group 2 (simvastatin as the perpetrator)					
	Simvastatin			Elafibranor			Elafibranor main metabolite (GFT1007)		
	Arithmetic Mean (SD)		Point estimate (90% CI)	Arithmetic Mean (SD)		Point estimate (90% CI)	Arithmetic Mean (SD)		Point estimate (90% CI)
	Simvastatin + elafibranor	Simvastatin alone		Elafibranor + simvastatin	Elafibranor alone		Elafibranor + simvastatin	Elafibranor alone	
C_{max} (ng/mL)	8.63 (5.87)	11.78 (5.53)	0.64 (0.44, 0.93)	680 (354)	835 (345)	0.77 (0.59, 1.00)	2,430 (974)	2,510 (524)	0.91 (0.76, 1.09)
AUC_{0-24} (ng/mL*h)	23.70 (15.05)	23.98 (14.51)	0.94 (0.76, 1.17)	1,360 (477)	1,320 (340)	1.00 (0.92, 1.09)	7,940 (1,190)	7,390 (1,290)	1.07 (1.02, 1.13)

To investigate the impact of elafibranor on the simvastatin PKs, Group 1 received single oral doses of simvastatin 20 mg on Days 0 and 16, and once daily oral doses of elafibranor 80 mg from Day 2 to Day 17. To investigate the impact of simvastatin on elafibranor PKs, Group 2 received single oral doses of elafibranor 80 mg on Days 0 and 28, and once daily oral doses of simvastatin 20 mg from Day 14 to Day 41. Arithmetic mean values for Group 2 are presented to 3 significant figures. AUC_{0-24}, concentration-time curve from time 0–24 hours; CI, confidence interval; C_{max}, maximum observed plasma drug concentration; PK, pharmacokinetic; SD, standard deviation

4573-C | SELADELPAR ACTIVITY IN A PRE-CLINICAL MODEL OF HUMAN PBC

Mei Li[1], Yana Geng[1], Ke Luo[1], Dorenda Oosterhuis[1], Alan R Gorter[1], Vincent De Meijer[2], Edward E. Cable[3] and Peter Olinga[1], (1)University of Groningen, (2)University Medical Center Groningen, (3)Cymabay Therapeutics

Background: Seladelpar, a selective peroxisome proliferator-activated receptor delta (PPARδ) agonist, has shown promising results in improving cholestasis in primary biliary cholangitis (PBC) patients in clinical trials. However, relevant pre-clinical PBC models to study possible targets and treatments are currently lacking. The human precision-cut liver slices (PCLS) model holds promise as it closely mimics the diverse liver cell types in a relevant pathological environment. In this study, we evaluate the effect of seladelpar by using PCLS from transplantation explants from PBC patients. **Methods:** The human PCLS were prepared from liver explants from PBC patients (n = 3) and subsequently cultured in William's E Medium with or without 2 μM of seladelpar up to 48 hours. The viability of the PCLS was assessed by measuring the ATP level in PCLS. The pyruvate dehydrogenase kinase 4 *(PDK4)* gene expression in the human PBC PCLS was assessed over time as a marker for PPARδ activation. Additionally, RNA-sequencing was performed on PBC PCLS after 48 hours of culture to investigate different pathways associated with PPARd activation. **Results:** The human PBC PCLS were viable with or without 2 μM seladelpar up to 48 hours of incubation, indicating that the PBC PCLS can be cultured for 48 hours. In addition, the *PDK4* expression was significantly increased, 10-fold, after 48 hours of incubation. Indicating that in PBC PCLS the marker of PPARd can be activated by 2 μM seladelpar. Furthermore, pathway enrichment analysis of the RNA-sequencing data revealed that the PPAR signaling pathway and the fatty acid degradation pathway were significantly enriched in slices that were treated with 2μM of seladelpar, which is in line with seladelpar results in other studies. **Conclusion:** By using pharmacological activity of seladelpar as proof-of-concept, PCLS obtained from end-stage PBC patients closely mimic the pathophysiological environment of PBC, and can serve as a relative inexpensive, reproducible, and valuable pre-clinical model for studying treatments.

f 4574-C | SERUM AUTOTAXIN (ATX) AND FIBROBLAST GROWTH FACTOR-19 (FGF-19) ARE BIOMARKERS OF LINERIXIBAT TREATMENT RESPONSE IN PATIENTS (PTS) WITH CHOLESTATIC PRURITUS ASSOCIATED WITH PRIMARY BILIARY CHOLANGITIS (PBC)

Sumanta Mukherjee[1], Linda Casillas[1], Brandon Swift[2], James Fettiplace[3], Sugato Das[4], Megan McLaughlin[1] and Andreas E. Kremer[5], (1)GSK, Collegeville, PA, USA, (2)GSK, Durham, NC, USA, (3)GSK, London, UK, (4)GSK, Hyderabad, India, (5)University of Zürich, Zürich, Switzerland

Background: Cholestatic pruritus (itch) is common in PBC and is associated with significantly impaired quality of life. Lysophosphatidic acid (LPA) and bile acids may have a pathophysiological role in pruritus. ATX is the primary enzyme that produces LPA and is a surrogate for LPA levels. ATX activity correlates with itch intensity in PBC. Linerixibat is a minimally absorbed, small-molecule ileal bile acid transporter inhibitor that improves pruritus and reduces systemic bile acid levels, ATX, and FGF-19, a downstream effector of farnesoid X receptor activation and regulator of bile acid biosynthesis.[1] Here, we analyze the association between itch response and changes in ATX and FGF-19 biomarker levels following linerixibat treatment. **Methods**: The Phase 2b, placebo-controlled, dose-ranging GLIMMER study (NCT02966834) enrolled 147 adult pts with PBC and pruritus.[1] Pts were randomized to receive linerixibat or placebo for 12 weeks (Weeks 4–16). Pts reported itch on a 0–10 numerical rating scale. As pt numbers were too low to analyze biomarkers in individual dose groups, the two twice daily (BID) dose groups, 40 and 90 mg BID which showed a greater response in pharmacodynamic biomarkers compared to once daily dosing, were combined. Serum ATX and FGF-19 levels were compared post hoc in pts receiving linerixibat 40/90 mg BID or placebo, at baseline versus Week 16, in itch responders and non-responders. Responder analysis from individual dose groups is not shown. Itch responders were defined as pts with a monthly itch score improvement of ≥2 at Week 16 compared with baseline. **Results**: Pts treated with linerixibat 40/90 mg BID (n = 45), or placebo (n = 36) were included; baseline demographics have been

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

reported previously.[1] Itch responders in the 40/90 mg BID group, but not in the placebo group, had greater reductions in serum ATX at Week 16 compared with baseline (Figure 1A). In linerixibat -treated pts, ATX levels at Week 16 were reduced in itch responders compared to non-responders, and in comparison with placebo (Figure 1B). Similarly, FGF-19 reduction was associated with itch response in pts receiving linerixibat 40/90mg BID compared with placebo. **Conclusion**: Serum ATX and FGF-19 may function as biomarkers of itch response to linerixibat treatment. Reductions in these biomarkers are associated with clinical response in pts with PBC and pruritus. Reference: [1]Levy C, et al. *Clin Gastroenterol Hepatol*. 2022;S1542-3565(22)01021-7. f 4575-C | SUPPRESSING CHOLESTATIC FIBROTIC PROGRESSION BY TARGETING JCAD IN HEPATIC STELLATE CELLS

Li Xie[1], Hui Chen[1], Yuan Zhou[1], Li Zhang[1], Yongyu Yang[1], Xiuping Liu[2] and Jian Wu[1,3,4], (1)Dept. of Medical Microbiology, Fudan University School of Basic Medical Sciences, Shanghai 200032, China, (2) Department of Pathology, Shanghai Fifth People's Hospital, School of Basic Medical Sciences, Fudan University, Shanghai 200032, China, (3)Fudan University, Department of Gastroenterology and Hepatology, Zhongshan Hospital, Shanghai, China, (4) Shanghai Institute of Liver Diseases, Fudan University Shanghai Medical College, Shanghai 200032, China

Background: Activated hepatic stellate cells (HSCs) are the main cellular effectors in liver fibrosis in response to cholangiocyte damage. JCAD is a membrane conjunction protein, and was found to interact with LATS2 in the Hippo-YAP signaling pathway and to promote the transition from NASH to HCC. However, its participation in cholestatic fibrosis has not been explored yet. The present study aims to investigate the critical role of JCAD in cholestatic fibrosis in HSC-specific JCAD knock-out (HSC-JCAD-

KO) mice. **Methods:** Serial sections in the liver tissue of PBC patients were immunohistochemically stained. Hepatic fibrosis was induced by bile duct ligation (BDL) in wild-type (WT) and HSC-JCAD-KO mice. *In situ*-activated HSCs were isolated 0, 5 or 14 days after BDL. **Results:** Consistent with staining of serial sections from PBC patients, immunofluorescent staining of cholestatic liver revealed that JCAD was co-localized with smooth muscle α-actin (α-SMA) and was significantly up-regulated in activated HSCs in WT mice with BDL. Biochemical tests and H&E staining indicated that conditional inactivation of JCAD in HSCs did not significantly affect liver injury. However, hepatic fibrosis was remarkably ameliorated in HSC-JCAD-KO mice as documented by liver hydroxyproline content (0.31 ± 0.04 vs. 0.46 ± 0.06μg/mg, $p = 0.0541$) when compared to WT mice with BDL. Meanwhile, collagen deposition was dramatically reduced in HSC-JCAD-KO compared to WT mice as visualized by Trichrome staining and semi-quantitation score (2.72 ± 0.08 vs. 5.76 ± 0.28%, $p < 0.01$). Second harmonic generation/two-photon excitation fluorescence microscopy with artificial intelligence analysis further revealed that fibrotic reduction was significant in the HSC-JCAD-KO mice undergone BDL, especially in the transitional and periportal areas (0.55 ± 0.10vs. 1.06 ± 0.14 %, $p < 0.05$). Liver levels of α-SMA protein in HSC-JCAD-KO mice were markedly lower than WT. Gene expression of TGF-β, CTGF, α-SMA, Col-1α1, and TIMP1 was strikingly enhanced in WT mice after BDL; whereas these markers were significantly suppressed in HSC-JCAD-KO mice. Moreover, JCAD deprivation significantly attenuated *in situ* activation of HSCs and decreased gene expression of TGF-β, CTGF, α-SMA, Col-1α1 and TIMP1, especially in 14 days after BDL. Furthermore, JCAD depletion reduced YAP/TAZ/TEAD transcriptional activity as documented by YAP/TEAD-based dual-luciferase reporter assay (54.8 ± 1.8 vs.113.0 ± 3.8 ratio, $p < 0.05$) compared to the controls; whereas, JCAD over-expression caused a significant induction of 8xGTIIC luciferase reporter activity. **Conclusion:** HSC-specific JCAD knock-out effectively halted hepatic fibrosis induced by bile duct ligation and the underlying mechanisms is attributed to suppressed Hippo-YAP signaling activity in HSCs. The elucidation of the critical role of JCAD in HSCs enables to develop molecular intervention against cholestasis-associated fibrosis.

4576-C | SURVIVAL OF PATIENTS WITH DECOMPENSATED PRIMARY BILIARY CHOLANGITIS IN THE ERA OF OBETICHOLIC ACID AND MELD 3.0

Mai Sedki[1], Nakia L Chung[1], Aparna Goel[1], Aldo J. Montano-Loza[2], Allison J. Kwong[3], Kazunari Sasaki[1], W. Ray Kim[1] and Ajitha Mannalithara[1], (1)Stanford University School of Medicine, (2)University of Alberta, AB, Canada, (3)Stanford University

Background: Since the approval of obeticholic acid (OCA) for the treatment of primary biliary cholangitis (PBC) in 2016, there have been concerns regarding hepatotoxicity, particularly in patients with advanced liver disease. In this study, we look for evidence of excess mortality among PBC patients awaiting liver transplantation (LT) following the approval of OCA, incorporating the latest version of the model for end-stage liver disease (MELD 3.0) for survival prediction. **Methods:** Data for all PBC patients with Child-Turcotte-Pugh (CTP) class B or C waitlisted for primary LT between Jan 2005 and Dec 2021 were extracted from the Organ Procurement and Transplantation Network registry. Patients were divided into two cohorts based on the date of waitlist registration: before (pre-OCA era) and after May 2016 (OCA era). We applied Cox regression to predict 90-day survival based on MELD 3.0 in a subset from the pre-OCA era and validated the prediction in the same era. We then compared observed versus predicted survival in the OCA era and calculated the standardized mortality ratios (SMRs). **Results:** There were 5,061 waitlist registrants with PBC, of whom 4,405 met the inclusion criteria, with 2,606 subjects in the pre-OCA era and 1,502 in the OCA era. The pre-OCA group was randomly divided into model training ($n = 1,825$) and validation sets ($n = 781$). As expected, MELD 3.0 was highly predictive of 90-day mortality among patients waitlisted for PBC with a hazard ratio of 1.220 (95% confidence interval [95%CI]: 1.196-1.245, $p < 0.001$) per 1 MELD point and Harrell's c-index of 0.860. When the survival prediction model was applied to the pre-OCA era validation subset, the observed and expected 90-day survival matched closely (Figure A, $p = 0.38$, GND test). In the OCA era, waitlist registrants were 59 years (median) and 85% were women, 65% white, 22% Hispanic, 9% black and 3% Asian. The median MELD 3.0 was 21 and the CTP score was 10 at registration. In Figure B, when the survival prediction model derived and validated from the pre-OCA era was applied to predict the number of deaths in the OCA era, the observed ($n = 124$ deaths)

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was nearly identical to the predicted (n = 126 deaths). The SMR was 0.82 (95%CI: 0.61-1.10) on day 15, 1.09 (95%CI: 0.87-1.36) on day 30, and gradually decreased to 0.99 (95%CI: 0.83-1.18) on day 90. **Conclusion:** MELD 3.0 is highly predictive of 90-day mortality in liver transplant waitlist registrants with PBC and hepatic decompensation. Based on the MELD 3.0-based survival prediction estimates, the survival of PBC patients in the OCA era was comparable to that in the pre-OCA era.

4577-C | SYMPTOMS OF PRIMARY SCLEROSING CHOLANGITIS (PSC) IN THE LAST MONTH: PRELIMINARY DATA FROM THE PSC-PARTNERS PATIENT REPORTED OUTCOME MEASURE PROJECT

Donna M. Evon[1], Kaya Merkler[1], Bryce Reeve[2], Chelsea Anderson[1], Ricky Safer[3], Joanne Hatchett[3], Rachel Gomel[3], Christopher L. Bowlus[4] and David N. Assis[5], (1)University of North Carolina, (2)Duke University, (3)PSC Partners Seeking a Cure, (4) University of California Davis, Sacramento, CA, (5)Yale School of Medicine, New Haven, CT

Background: Patient-reported symptoms of primary sclerosing cholangitis (PSC) are not well documented. We are studying symptoms of PSC for the comprehensive development of PSC-specific patient-reported symptom measures fit for clinical trials. **Methods:** Patients with PSC were recruited through the PSC Partners Patient Registry. Inclusion criteria were PSC diagnosis, age 18 or older, English-speaking, living in the US, symptomatic within the last 5 years, and not waitlisted nor a recipient of a liver transplant. Patients engaged in a phone survey to screen for the presence, frequency, severity, and distress of 13 symptoms associated with PSC, using a modified version of the Memorial Symptom Assessment Scale. Patients indicated if they had experienced each symptom in the last month (yes/no). If yes, they were queried about symptom frequency (How often did you experience fatigue?), severity (How severe was the fatigue?), and distress (How much did the fatigue distress or bother you?). Response options were based on a 4- or 5-point ordinal scale. Patients classified each symptom as definitely, partially, or unrelated to PSC. Sociodemographics and patient-reported medical history related to PSC were recorded. **Results:** Participants (currently N = 24 in interim sample) were 63% female, 88% white, with a mean age of 49 (SD = 12.6). 87% were college educated, 58% were working and 21% were retired. 75% had irritable bowel disease, 79% had large duct PSC, 17% had autoimmune hepatitis, 33% had cirrhosis, and two reported symptoms consistent with decompensated cirrhosis. Fatigue (71%) was the most prevalent symptom in the past month (See table below). Over 50% of patients experienced difficulty sleeping, daytime drowsiness, anxiety, pruritus, brain fog, and pain over the liver. Between 85-100% of patients indicated that these symptoms were definitely or partially related to PSC. Between 29-46% of patients experienced nausea, other belly pain, sadness, or night sweats. For symptoms that were prevalent in more than 50% of patients, 46-69% of patients rated these symptoms as “frequent” or “always constant”; 61-84% rated these symptoms as “moderate” to "very severe," and 30-94% rated these symptoms as “somewhat” to “very much” distressing. **Conclusion:** Among symptomatic adults with PSC, over 50% report issues with fatigue, sleep, anxiety, itch, brain fog, and liver pain within the last month that are frequent, moderate in severity, and distressing. Planned in-depth qualitative interviews are the critical next step towards understanding the breadth and depth of PSC symptoms to develop PSC-specific patient-reported symptom measures.

4578-C | THE CHALLENGE OF CONFIRMATORY TRIALS IN RARE DISEASE: LESSONS LEARNED FROM THE COBALT TRIAL IN PRIMARY BILIARY CHOLANGITIS

Kris V. Kowdley[1], Tracy Mayne[2], Darren Wheeler[2], Elizabeth S. Malecha[2], Erik Ness[2] and Nora Cazzagon[3], (1)Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, Seattle, WA, USA, (2)Intercept Pharmaceuticals, Inc., Morristown, NJ, (3)Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy

Background: Recruitment and retention are difficult in rare disease clinical outcomes trials, particularly when a study drug is commercially available or when markers of disease progression are readily observable, which lead to functional unblinding, informative censoring, and treatment crossover.

We explore these issues in the COBALT phase 3b/4 confirmatory outcomes trial of obeticholic acid (OCA) for the treatment of primary biliary cholangitis (PBC). **Methods:** COBALT was a randomized, double-blind, placebo-controlled outcomes trial. Patients were randomized to placebo or OCA 5 mg daily, titrated to 10 mg if tolerated. We examined recruitment before and after commercial OCA availability; discontinuation of investigational product (IP); association between IP discontinuation and alkaline phosphatase (ALP) levels, a surrogate marker of disease progression in PBC; crossover to other therapies (commercial OCA, fibrates, or ursodeoxycholic acid [when not used at baseline]); and the impact of treatment crossover on ALP levels. **Results:** Recruitment met projections and dropout was negligible before OCA became commercially available. Subsequently, recruitment

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

slowed, and dropout increased (Figure 1A). The study was terminated early with 80% targeted enrollment (OCA, n = 168; placebo, n = 166). Figure 1B shows ALP levels over time by treatment for subjects who continued IP (solid circles) and discontinued IP prior to an endpoint event (open circles). Placebo subjects who discontinued IP had consistently higher ALPs just prior to discontinuation, suggestive of functional unblinding. As shown in Figure 1C, peak discontinuation of OCA occurred during the first 6 months (blue bars) largely due to pruritus (40%), with almost no initiation of commercial treatment (blue line). Peak placebo IP discontinuation occurred in the first 24 months, when initiation of commercially available PBC therapy peaked at 27%. ALP levels of patients initiating commercial PBC therapy decreased in both treatment groups and were sustained after initiating commercial treatments, with a greater decrease in the placebo group (Figure 1D). **Conclusion:** In the COBALT trial, functional unblinding and early treatment crossover in the placebo group led to loss of balance, biasing results and compromising their interpretation. Alternative study designs (eg external controls) are needed to assess the efficacy and safety of commercially available study drugs in rare diseases.

4579-C | THE EXTERNALLY-LED PATIENT-FOCUSED DRUG DEVELOPMENT MEETING FOR PRIMARY SCLEROSING CHOLANGITIS: INSIGHTS ON PATIENT INVOLVEMENT IN CLINICAL TRIALS

Michael Li[1], Ruth-Anne Pai[2], Rachel Gomel[2], Mary Pressley Vyas[3], Sarah Curup Callif[2], Joanne Hatchett[2], Ricky Safer[2], Christopher L. Bowlus[4] and Jennifer C. Lai[5], (1)University of California, San Francisco, (2)PSC Partners Seeking a Cure, (3)PSC Partners Seeking a Cure Canada, (4)University of California Davis, Sacramento, CA, (5)University of California-San Francisco

Background: New AASLD guidance recommends consideration of all patients with primary sclerosing cholangitis (PSC) as potential candidates for clinical trials. However, the factors influencing patient interest and the barriers preventing inclusive and accessible participation in trials for PSC have yet to be elucidated. We investigated PSC patient interest in trial participation and identified factors associated with willingness to participate in drug trials. **Methods:** Patient-Focused Drug Development (PFDD) is an FDA initiative to ensure that patient experiences and perspectives on drug development are captured. PSC Partners developed the international "Our Voices" survey to inform the development of the Externally-Led PSC PFDD meeting. Our team of researchers and patient advocacy representatives analyzed data from this survey, which included 797 adults with PSC. **Results:** Patients identified slowing disease progression as the most important drug development outcome (67%). 89% of patients identified their hepatologist/gastroenterologist as who they would approach for advice about trials. 61% of patients reported being willing to participate in drug trials, while only 26% of patients reported ever being asked to participate. Notable frequently reported barriers to trial involvement included unknown long-term risks (71%), long travel times to study center (32%), a liver biopsy requirement (27%), and concerns about taking too much time off work (22%). On multivariable logistic regression, pruritus (aOR 1.61, 95% CI 1.07-2.44, $p = 0.023$), jaundice (aOR 0.34, 95% CI 0.19-0.62, $p < 0.001$), and inflammatory bowel disease (aOR 0.64, 95% CI 0.42-0.98, $p = 0.042$) were associated with willingness to participate in disease-modifying therapy trials (Figure). Pruritus (aOR 2.25, 95% CI 1.50-3.39, $p < 0.001$) was also independently associated with willingness to participate in symptom treatment trials. **Conclusion:** Hepatologists/gastroenterologists are trusted by PSC patients and must be responsible for closing the gap between trial interest and participation. Pruritus is one of the most influential symptoms associated with willingness to participate in drug trials and can serve as an indicator of patient interest in trial participation. Patient advocacy groups like PSC Partners can play a crucial role in further investigation to understand the gaps between clinical trial interest, referral, and participation, with an emphasis on promoting equity and diversity in clinical trials.

Logistic regression model, willingness to participate in disease-modifying therapy trials for PSC

Covariate	Odds Ratio	95% CI	p-value
Pruritus	1.61	1.07-2.44	0.023

4580-C | THE IMPACT OF CONCOMITANT NON-ALCOHOLIC FATTY LIVER DISEASE ON PRIMARY SCLEROSING CHOLANGITIS

Ana Marenco-Flores[1], Leandro Sierra[1], Romelia Barba Bernal[1], Bryan Ferrigno[2], Daniela Goyes[3], Wilfor Diaz Fernandez[2], Vilas Patwardhan[1] and Alan Bonder[1], (1) Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medical School, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3)Yale University Medical Center, New Haven, CT, United States

Background: Primary sclerosing cholangitis (PSC) is a rare chronic cholestatic liver disease characterized by inflammation and fibrosis of bile ducts. PSC is a progressive condition that can lead to fibrosis and cirrhosis, the only definitive treatment is transplant. Non-alcoholic fatty liver disease (NAFLD) is becoming one of the fastest-growing leading indications for liver transplants. There is a scarcity of studies examining the impact of PSC and concomitant NAFLD on disease progression, compared to PSC alone. Understanding the impact of concomitant NAFLD on PSC progression is crucial for patient management and prognostication. We aimed to evaluate the effect of fatty liver disease on patients with PSC. **Methods:** We conducted a single-center, observational cohort study from our prospective autoimmune liver disease registry. We compared patients with PSC alone to patients with PSC and NAFLD. NAFLD was defined as hepatic steatosis by imaging (MRI, CT scan, ultrasound, and transient elastography) or biopsy in the absence of excessive alcohol consumption (< 14 drinks/week for women, < 21 drinks/weekfor men). Patient's demographic and clinical characteristics were collected and compared among the two groups. Statistical analysis evaluating for significant differences was performed using Chi-square and t-tests. **Results:** We identified 85 patients with PSC and 71 with features of both PSC

and NAFLD. Patients with PSC and concomitant NAFLD (PSC-NAFLD) were older (47 vs. 40; p = 0.008) and more likely to be men than the PSC group (58% vs. 48%; p = 0.236). The PSC group had a higher percentage of White Caucasians (82% vs. 73%; p = 0.003). Markers of liver inflammation were higher at the time of diagnosis in patients with PSC alone than in patients with PSC-NAFLD overlap (ALP: 245 vs. 211; ALT: 91 vs. 81; AST: 68 vs. 59; total bilirubin: 1.07 vs. 1.04; p > 0.05 for all). Body mass index (BMI) was significantly higher in the PSC-NAFLD group (30 vs. 27; p = 0.005). Among patients with available liver biopsies, PSC patients were more likely to have moderate to severe activity (40% vs. 15%; p = 0.026) and advanced liver fibrosis (30% vs. 18%; p = 0.081). (Table 1) **Conclusion:** NAFLD does not appear to adversely affect PSC disease progression. Surprisingly, patients with PSC alone had more active disease and advanced fibrosis compared to those with PSC-NAFLD. Further studies investigating the impact of NAFLD on PSC are warranted.

Table 1. Baseline characteristics

4581-C | THE IMPACT OF DIETARY INTERVENTIONS ON METABOLOMIC PROFILE AND DISEASE PROGRESSION IN PRIMARY SCLEROSING CHOLANGITIS PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Xiaole Yin[1], Zheng Sun[1], Shanlin Ke[1], Shaikh Danish Mahmood[2], Gila Feinman Sasson[2], Demsina Babazadeh[2], Macie Andrews[2], Shelley Hurwitz[2], Maia Paul[2], Nadine Javier[2], Malav Dave[2], Alexandra Austin[2], Dan Pratt[3], Christopher L. Bowlus[4], Linda Gray[4], Francene Steinberg[5], Elaine Souza[5], Yang-Yu Liu[1] and Joshua R. Korzenik[2], (1)Channing Division of Network Medicine, Brigham and Women's Hospital, (2)Brigham and Women's Hospital, (3)Massachusetts General Hospital, (4)University of California Davis, Sacramento, CA, (5)University of California, Davis

Background: Primary sclerosing cholangitis (PSC) is a chronic liver disease often associated with inflammatory bowel disease (IBD). Diet plays an important role in the host health and disease. However, the role of diet in modifying disease progression in PSC and associated IBD remains underexplored. **Methods:** We undertook a longitudinal study involving PSC patients (n = 20), which were randomly subjected to one of the following two distinct dietary interventions for 8 weeks: Low Protein Diet (LPD, n = 10) or Specific Carbohydrate Diet (SCD, n = 10). Diet was recorded in detail and stool samples were obtained at 4 time points for whole metagenomic sequencing and global untargeted metabolomics. Alkaline Phosphatase (ALP) values were measured to reflect potential disease amelioration. **Results:** A total of 20 PSC patients were enrolled including 10 with ulcerative colitis (UC), 3 with Crohn's disease (CD) and 7 with PSC alone. The clinical results are reported in detail in a separate abstract. We report here the microbial analysis. Our results showed a significant correlation between dietary intervention and disease progression via Lasso regression indicating lower ALP values with lower protein intake compared to baseline. A total of 1428 detected metabolites were analyzed using linear multivariable models to identify key metabolite features in response to the LPD. We identified 27 elevated and 9 decreasing metabolites, which align with previously known metabolite sets associated with IBD, CD, and UC, but unreported in PSC before. Moreover, enrichment analysis highlighted *ammonia recycling* and *methionine metabolism* as key pathways influenced by LPD dietary interventions. The notable metabolites including p-cresol sulfate and methionine represent organic sulfur acids and derivatives, and L-glutamine represents nitrogen metabolism. We finally performed stratified analysis, finding that LPD to be especially beneficial in terms of high metabolomic response for PSC patients with UC (but not PSC patients with CD, or PSC alone), which is consistent with the clinical response. Longitudinal observation in this subgroup illustrated a clear reduction in sulfur and nitrogen-related metabolites under LPD. **Conclusion:** Dietary interventions, particularly LPD, significantly influence disease progression in PSC patients with UC, offering potential as a supplementary therapeutic strategy. Our study also reveals unique metabolite responses to dietary modifications, expanding our understanding of metabolic

mechanisms in PSC and associated IBD. Further research is warranted to optimize dietary strategies for individual patient subgroups.

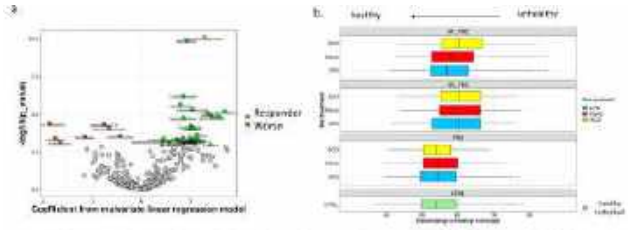

Figure 1. The metabolite profile under the dietary intervention. a. The multivariate analysis highlights the metabolites with significant changes under the LPD treatment for PSC patients. b. The stratification analysis showed LPD to be especially beneficial for PSC patients with UC.

Background: Primary biliary cholangitis (PBC) is an autoimmune, chronic cholestatic liver disease involving bile ducts. Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease worldwide and affects up to 25% of the general population. Therefore, it is not surprising that both pathologies can coexist. However, data regarding the impact of concomitant NAFLD on PBC treatment response or disease progression is scarce. Therefore, this study aimed to evaluate the relationship between coexistent fatty liver on the treatment response of PBC patients. **Methods:** We conducted a single-center, observational cohort study from our prospective autoimmune liver disease registry. We compared patients with PBC alone to patients with PBC and concomitant NAFLD who received treatment with ursodeoxycholic (UDCA). NAFLD was defined as hepatic steatosis by imaging (MRI, CT scan, ultrasound, and transient elastography) or biopsy in the absence of excessive alcohol consumption (<14 drinks/week for women, <21 drinks/week for men). Patient's demographic and clinical characteristics were collected. We used the GLOBAL-PBC score to assess treatment response. Statistical analysis evaluating for significant differences was performed with Chi-square and t-tests. **Results:** We identified 129 patients with PBC and 87 patients with both PBC and NAFLD. Patients with PBC-NAFLD were younger (59.8 vs. 65.8; $p=0.0001$). The PBC group was significantly more likely to be women than the PBC-NAFLD cohort (98% vs. 89%; $p=0.005$). At diagnosis, the ALP levels were significantly higher in PBC-NAFLD than in the PBC group (224 vs. 210; $p=0.020$). Other markers tended to be higher at diagnosis in the PBC group than in patients with PBC-NAFLD (mean ALT: 53 vs. 51, AST: 45.9 vs. 45.8; $p>0.05$ for both). Body Mass Index (BMI) was significantly higher in the PBC-NAFLD group compared to PBC alone (30.7 vs. 29.6; $p=0.049$). Patients with PBC-NAFLD were more likely to have a higher percentage of treatment response compared to the PBC group, with a trend towards higher response rates at a five-year follow-up. The rate of responders at one-year follow-up was 83% vs. 85%; $p=0.680$ and the five-year follow-up was 81 vs. 92% in the PBC groups and PBC-NAFLD, respectively; $p=0.021$. (Figure 1) **Conclusion:** The presence of NAFLD may not adversely affect the course of PBC. PBC-NAFLD patients might present earlier to physicians and treating NAFLD might improve the course of PBC. Moreover, it is possible that individual's with NAFLD are more motivated to make positive lifestyle changes, which could have indirect benefits for their overall health, including their response to PBC treatment. Further studies investigating the impact of concomitant NAFLD on PBC patients are warranted.

Table 1. Baseline characteristics

	PBC-NAFLD N=87	PBC N=129	p Value
Age, ± mean (SD)	59.8 (9.9)	65.8 (11.5)	0.0001
Gender, female n (%)	77 (99)	126 (98)	0.005
BMI, ± mean (SD)	30.7 (5.6)	29.6 (6.4)	0.049
Diabetes mellitus, n (%)	35 (40)	17 (13)	0.000

4583-C | THE PRESENCE OF HEPATITIS B CORE ANTIBODY CORRELATES WITH RISK OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Jialiang Chen, Yao Liu, Yufei Bi, Fangyuan Gao and Xianbo Wang, Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: Chronic kidney disease (CKD) is a common comorbidity in patients with chronic liver diseases, especially in chronic hepatitis B and decompensated cirrhosis. Whether the same is true for patients with primary biliary cholangitis (PBC) who have recovered from previous HBV infections remains to be determined. This study aimed to investigate the association between antibody to hepatitis B core antigen (anti-HBc) and risk of CKD in patients with PBC who test negative for hepatitis B surface antigen (HBsAg). **Methods:** A total of 1257 patients diagnosed with PBC at first admission from a tertiary hospital in China were divided into anti-HBc-positive ($n=503$) and anti-HBc-negative ($n=754$) cohorts. All patients tested negative for HBsAg. Demographic, clinical, and laboratory features were retrospectively analyzed from January 2008 to December 2021. Serum creatinine-based equations from the Chronic

Kidney Disease Epidemiology Collaboration (CKD-EPI) were used to estimate the glomerular filtration rate (eGFR). CKD was defined as an eGFR < 60 mL/min/1.73 m². Univariate and multivariate logistic regression analyses were conducted to determine the risk factors of CKD. The adjusted odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. **Results:** In our study population, there were 1080 (85.9%) women, with a median age of 57 years. Compared with the anti-HBc-negative cohort, the median age was higher in the anti-HBc-positive cohort (59 vs. 56 years, $P < 0.001$). Anti-HBc-positive cohort also had higher median levels of blood urea nitrogen (4.81 vs. 4.57 mmol/L, $P = 0.016$), serum creatinine (59.4 vs. 57.4 μmol/L, $P = 0.009$), and lower median levels of eGFR (101.1 vs. 103.0 mL/min/1.73 m², $P = 0.011$). The overall prevalence of CKD was 8.3% (104/1257), accompanied by 232 patients (18.5%) with mild renal impairment (eGFR < 90 but ≥ 60 mL/min/1.73 m²). Anti-HBc-positive cohort had a higher prevalence of CKD than the anti-HBc-negative cohort (11.3% vs. 6.2%; OR = 1.92, 95% CI: 1.28 – 2.88, $P = 0.002$). In the multivariate analysis, anti- HBc positive (OR = 1.56, 95% CI: 0.98 – 2.46, $P = 0.057$), age (OR = 1.12, 95%CI: 1.09 – 1.15, $P < 0.001$), current smoking (OR = 2.97, 95% CI: 1.30 – 6.79, $P = 0.010$), hypertension (OR = 1.85, 95% CI: 1.15 – 2.98, $P = 0.011$) and decompensated cirrhosis (OR = 3.71, 95%CI: 2.10 – 6.57, $P < 0.001$) were independent factors associated with the presence of CKD. **Conclusion:** Previous hepatitis B virus infection was associated with chronic renal dysfunction of PBC, potentially leading to poorer outcomes. PBC patients with anti-HBc positive in clinical practice should strengthen follow-up of renal function.

Table 1 Univariate and multivariate logistic regression analysis for the risk of chronic kidney disease (CKD) in patients with PBC.

Variable	Univariate analysis	*P* value	Multivariate analysis	*P* value
	Crude OR (95% CI)		*Adjusted OR (95% CI)

f 4584-C | TRANSCRIPTOME ANALYSIS REVEALS ADAPTIVE RESPONSES TO HYPOXIA IN THE CEREBRAL CORTEX OF CHOLESTATIC MICE

Wagdi Almishri, Mark Gordon Swain and Charlotte D'Mello, University of Calgary

Background: We have previously shown that patients with the cholestatic liver disease primary biliary cholangitis (PBC) exhibit significant cerebral cortical hypoxia (Duszynski. Hepatology. 2020). However, the cause of cortical hypoxia in PBC remains unknown. We therefore used a mouse model to examine the impact of cholestasis on cerebral hypoxia development. **Methods:** Male C57BL/6 mice (Jackson; 10 wks old) were subjected to either bile duct ligation (BDL) or sham surgery (n = 6 mice/group). Ten days post-surgery mice were evaluated for hypoxia-associated gene expression alterations and metabolic pathway adaptations in the cerebral cortex using mRNA-seq and Ingenuity Pathway Analysis bioinformatics software (IPA; Qiagen). **Results:** Key hypoxia response-related genes were significantly dysregulated in the cerebral cortex of BDL vs sham mice, including a significant 1.5-fold increase ($pŽ\ 1.3x10^{-3}$) in Hif-1α (master regulator of hypoxia cellular responses) gene expression, a 2.8-fold decrease ($pŽ4.5x10^{-2}$) in gene expression of the HIF-1α- degrading enzyme (P4ha1), and a 28-fold increase ($pŽ1.4x10^{-5}$) in gene expression of the enzyme Pdk1 (regulates HIF-1-dependent hypoxia-induced anaerobic glycolysis) in BDL vs sham mice. IPA Pathway Analysis software was used to identify hypoxia-related biological pathway gene expression signature changes in the cerebral cortex of BDL vs sham mice. BDL was associated with enriched gene expression in the *Oxidative Phosphorylation* ($pŽ3.1x10^{-2}$), *Mitochondrial Function* ($pŽ1.5x10^{-2}$), and *Unfolded Protein Response* ($pŽ1.7x10^{-5}$) pathways. To delineate a possible mechanism driving these brain cortical hypoxic changes, we employed brain spinning disc confocal intravital microscopy (methods, D'Mello. Gastroenterol. 2017) and identified robust recruitment of monocytes into brain cortical blood vessels in BDL mice (none in sham mice) with associated cortical capillary 'plugging' (Fig. 1). **Conclusion:** BDL mice demonstrate gene expression changes in the cerebral cortex indicating significant tissue hypoxia – similar to findings in PBC patients. We suggest brain hypoxia-related changes in cholestatic liver disease are driven by monocyte recruitment to cerebral blood vessels and associated capillary

'plugging' leading to impaired microregional blood flow. The BDL mouse model represents a valuable tool to mechanistically define this process and to develop potential therapeutic approaches to address this issue (eg. anti-cell adhesion approaches).

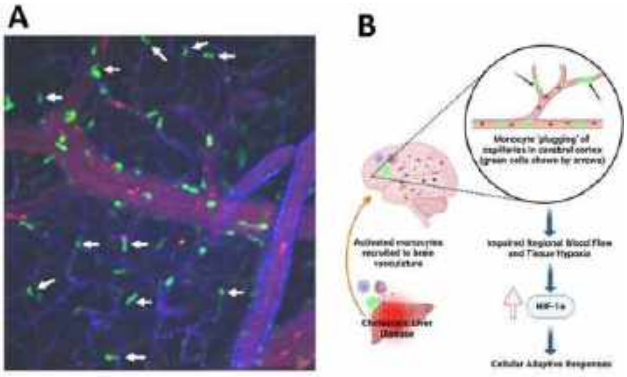

Fig.1. (A) Representative image of cerebral intravital microscopy from a LysM-GFP+ BDL mouse, showing cerebral cortical blood vessels 10 days post-surgery (methods D'Mello et al. J Neurosci 2009, and Gastroenterology 2017). LysM-GFP+ monocytes are green; platelets are red (PE-CD49b), and endothelial cells are blue (APC-CD31). White arrows indicate immobile green GFP+ monocytes 'plugging' cerebral cortical capillaries (< 30 μm diameter). (B) A schematic representation, created with BioRender.com, depicts a hypothesized mechanism whereby cholestatic liver disease activates circulating monocytes, which are subsequently recruited to roll and adhere along the cerebral endothelium, consequently causing physical 'plugging' of smaller capillaries, impairing downstream blood flow, and leading to microregional cortical hypoxia.

4585-C | TRENDS IN AUTOIMMUNE LIVER DISEASE RESEARCH SINCE THE OCCURRENCE OF THE COVID-19 PANDEMIC: A BIBLIOMETRIC ANALYSIS

Taylor Beedie, Children's Hospital, London Health Sciences Centre; Lawson Health Research Institute and Andreanne N. Zizzo, Children's Hospital, London Health Sciences Centre, Western University

Background: Autoimmune liver diseases (AILDs) consist of 3 main diagnoses; autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC). Much research today continues to be dedicated to the field of AILDs to understand the disease characteristics, its treatment, outcomes and modelling prognostic and diagnostic models. Bibliometric studies are helpful for providing a scope of the current publication landscape within a particular field and aid in assisting the path within which future research should direct their efforts. Since the onset of the COVID-19 pandemic, there have been no studies investigating the course of research on AILDs, and how this may influence future research endeavours. **Methods:** An expert librarian driven literature search was conducted on September 10, 2021 using multiple databases. A total of 697 included papers were then coded for type of article, subject population, area of research and publishing journal. Univariate analysis was performed to compare trends in publication between adults and paediatric studies. Data was then imported in VOSViewer for visual analysis, term occurrences and relationship mapping. **Results:** Our literature search determined that 10x as many adult papers (87.5%) were published in a two year time frame compared to paediatric papers (8.6%). Paediatric papers were more focused on AIH ($p = 0.01$), whereas adult papers were split between PBC and AIH. The majority of papers explored disease characteristics, and the most common study types across both adults and paediatrics were retrospective studies and case reports. It was surprising to discover that a low number of publications investigated COVID-19 and autoimmune liver diseases (adults = 2.6%, paediatrics = 1.7%). **Conclusion:** The publications during 2020 and 2021 on AILDs primarily used adult case presentations/reports with PBC and AIH. Authors focused on disease characteristics and diagnosis, with less emphasis on outcomes, treatment, response to therapy and novel therapy. Overall, the area not well represented was therapeutic advances, which may suggest that future studies will use these prior case presentations to report treatment options and responses. Future studies may also want to consider more research within paediatrics as the current landscape is heavily focused on adults. Only a small percentage of papers explored the interaction between COVID-19 and AILDs, which may provide an opportunity for furture investigations to explore a possible influence of the pandemic on autoimmune liver diseases.

4586-C | TYPE-I INTERFERONS ARE SELECTIVELY ELEVATED IN PRIMARY SCLEROSING CHOLANGITIS AND CORRELATE WITH DISEASE ACTIVITY

Rebekka J.S. Salzmann[1], Christina Mehrfeld[2], Sophia Rottmann[1], Tudor Mocan[3], Arnulf G. Willms[4], Marcin Krawczyk[5], Piotr Milkiewicz[6,7], Miroslaw T. Kornek[1], Bettina Langhans[1], Leona Dold[1] and Veronika Lukacs-Kornek[1], (1)University Hospital Bonn, (2)Saarland University Medical Center, (3)Babeş-Bolyai University, (4)German Armed Forces Central Hospital Hamburg, (5)Saarland University Hospital, (6)Medical University of Warsaw, (7)Pomeranian Medical University

Background: The level of type-I interferons (IFNs) in primary sclerosing cholangitis (PSC) was investigated to evaluate its association with disease activity and progression. **Methods:** Bioactive type I IFNs were evaluated in murine model of PSC and in human patients' sera using a cell-based reporter assay and ELISA techniques. In total, 70 healthy participants, 81 PSC, and 24 patients with primary biliary cholangitis (PBC) as well as 9 patients with autoimmune hepatitis (AIH) were enrolled in this study. **Results:** Bioactive type-I IFNs were elevated in liver and serum of multi drug resistance protein 2 deficient (Mdr2) animals and the frequency of plasmacytoid dendritic cells, the main producers of type-I IFNs, were 3-fold increased in the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

livers of Mdr2 animals compared to wild types. In accordance with results in the above animal model of PSC, bioactive type-I IFNs were elevated in the sera of PSC patients as compared to healthy controls as well as patients with PBC and AIH (all $p < 0.05$). This test showed good diagnostic performance with a sensitivity of 80.56%, a specificity of 85.19% and an AUROC value of 0.89 in distinguishing PSC from healthy individual's. PBC patients did not demonstrate elevated IFN levels and remained similar to heathy individual's. Notably, PSC patients demonstrated significantly ($p = 0.039$) higher serum levels of type I IFNs compared to AIH (sensitivity of 86.7% and a specificity of 55.6% and an AUROC value of 0.778). The highest correlation of bioactive IFNs with laboratory parameters was found to be with alanine phosphatase ($r = 0.50$, $p < 0.001$) and bilirubin ($r = 0.43$, $p = 0.004$), moderate correlation with disease duration ($r = 0.42$, $p < 0.05$) but no correlation with fibrosis stage ($r = 0.18$, $p = 0.38$). Among the type-I IFN subtypes IFNα, β and IFNω could be detected in PSC patients, IFNω had the highest concentration detected (ng/mL) with a mean of 154.531 ng/mL. **Conclusion:** The selectively elevated bioactive type-I-IFNs could suggest a novel inflammatory pathway that might also have a hitherto unrecognized role in the pathomechanism of PSC

4587-C | UNDERSTANDING THE EXPERIENCE OF PEOPLE LIVING WITH PRIMARY BILIARY CHOLANGITIS: DEVELOPMENT OF AN EXPERIENCE MAP

Alexander Artyomenko[1], Abi Bowden[2], Maureen Christie[3], Robert Mitchell-Thain[4] and Marwan Sleiman[1], (1)Ipsen, (2)Health Unlimited, (3)PBC Foundation, (4) PBC Foundation, Edinburgh, United Kingdom

Background: Primary biliary cholangitis (PBC) is a rare autoimmune disease of the liver, characterized by destruction of the bile ducts[1]. People with PBC can experience non-specific symptoms such as pruritus, fatigue and joint pain[1]. The severity of symptoms and their impact on quality of life do not always correlate with liver biochemistry or disease progression[1]. This incongruence affects most of the PBC population; although many people are asymptomatic at diagnosis, 50% may develop symptoms after 5 years and 95% by 20 years post-diagnosis[2]. Nevertheless, the experience of people living with PBC is highly variable and current understanding is limited. Aims: To further understand patient experience throughout the disease course, people living with the disease were consulted to capture their thoughts, feelings and symptoms, and the overall impact of PBC on their lives. **Methods:** An initial review of online sources, including publicly available literature, medical and patient organization websites, and patient stories, was conducted to identify key themes: overall experience, symptoms, emotional impact, evolving patient needs, and medical team interactions. These themes were used to guide a meeting with a steering committee of seven PBC patient advocates. Insights were validated via 1:1 interviews and a visual experience map was created and finalized with the steering committee. **Results:** The PBC journey was divided into six distinct periods, representing diagnosis, living with PBC, and progression to end-stage liver disease (Table 1). Key clinical experiences, including representative measures for liver biochemistry, were added to provide a clinical reference point. The resulting map highlights that effective management of PBC requires a multi-factorial approach, aspiring for normal liver biochemistry whilst achieving low symptom burden and optimizing quality of life. Most importantly, people with PBC express a strong need to have their experiences acknowledged and addressed by management strategies, alongside any clinical measures. **Conclusion:** We present an initial patient experience map for PBC, a visual aid to align approaches to treatment and care with patient-reported experiences and needs. Future validation with a targeted survey in a wider group of patients will aim to strengthen these findings and ensure accurate representation of the PBC population. References: 1. 4588-C | UNITED STATES (US) PREVALENCE OF DIAGNOSED PRIMARY BILIARY CHOLANGITIS: 41 PER 100,000 ADULTS WITH WIDE REGIONAL VARIABILITY

Keri-Ann Buchanan-Peart[1], Joanna P. MacEwan[2], Alina Levine[2], Radhika Nair[3], Darren Wheeler[3], Erik Ness[3], Tracy Mayne[3] and Cynthia Levy[1], (1)University of Miami Health System, (2)Genesis Research, (3)Intercept Pharmaceuticals, Inc., Morristown, NJ

Background: Primary biliary cholangitis (PBC) prevalence in the US has been extrapolated from small regional databases. However, environmental and genetic factors vary considerably by region, potentially influencing prevalence. Our objective was to estimate a robust national prevalence while quantifying regional variability. **Methods:** We included patients in the Komodo Health claims database in 2021 and with 1 inpatient or 2 outpatient (separated by > 1 d) claims with a PBC diagnosis [ICD9 (571.6) or ICD10 code (k74.3)] with first claim between 1/1/14 and 12/31/21. We excluded patients < 18 years old or missing a 3-digit ZIP code. We characterized patients by age, sex, and race/ethnicity, and adjusted PBC prevalence by sex, age, and census population at the 3-digit zip-code tabulation area (ZCTA3) level to calculate prevalence per 100,000 adult population. We created heat maps for absolute number and prevalence by ZCTA3. **Results:** Of the 106.8 million patients in Komodo Health database in 2021, 41,426 met PBC diagnosis criteria. Patients were predominantly female (83%) with a mean age of 61.9 years (SD = 13.2). Of the 31,806 (76.8%) patients with race/ethnicity information, 67.6% of patients were White, 16.9% Hispanic/Latino, 7.6% Black, and 3.5% Asian/Pacific Islander. The adjusted prevalence of patients with PBC in 2021 was 40.9 per 100,000 adult population, or 105,506 adult patients nationally. The absolute number of patients varied by population density, with the highest numbers in the largest metropolitan statistical areas, eg, New York, Los Angeles, Chicago, and Houston (Figure 1A). Prevalence showed a markedly different pattern, with the highest number per 100,000 in rural areas in the Midwest, with pockets in the West and along the Appalachians in the Mid-Atlantic (Figure 1B). **Conclusion:** These data, using a large nationally representative sample adjusting for population and patient demographics, provide the best estimate of diagnosed PBC patients to date. The greatest burden of PBC exists in major cities, which may be best equipped to address treatment needs given the presence of major university hospitals. The high prevalence in more rural areas leaves several unanswered questions regarding the potential presence of environmental and genetic factors which may be driving highly localized spikes in prevalence, as well as access to specialty care for treating rare disease. Further analyses are underway to address these outstanding questions.

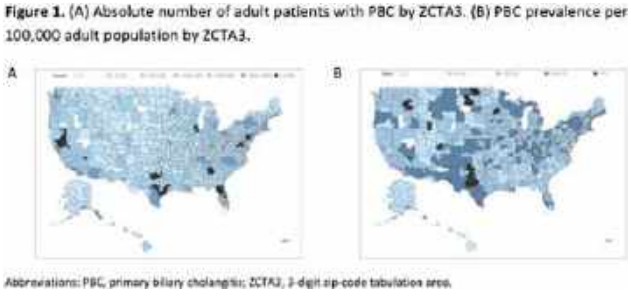

Figure 1. (A) Absolute number of adult patients with PBC by ZCTA3. (B) PBC prevalence per 100,000 adult population by ZCTA3.

Abbreviations: PBC, primary biliary cholangitis; ZCTA3, 3-digit zip-code tabulation area.

4590-C | URSODEOXYCHOLIC ACID FOR THE TREATMENT OF HEPATIC SARCOID: A PRE-POST STUDY

Ethan M. Weinberg[1], Aimee Stonelake[1], Emily Toal[1], Kelly Borges[1], Colin Ligon[2], Milton Rossman[1] and K Rajender Rajender Reddy[1], (1)University of Pennsylvania, (2)Bon Scours

Background: Sarcoidosis is a poorly defined autoimmune disease characterized by the formation of sterile granulomas in affected organs, including the liver. The diagnosis of hepatic sarcoid is often presumed based upon an elevated liver-specific iso-enzyme of alkaline phosphatase or imaging findings suggestive of portal hypertension,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hepatomegaly, or liver lesions in a patient with known sarcoidosis; a minority are diagnosed through liver biopsy. The primary treatment of sarcoidosis in those with symptoms is immunosuppression. However, given its excellent safety profile and minimal side effects, ursodeoxycholic acid (UDCA) could be a first-line treatment for hepatic sarcoid. We set out to evaluate the effects of UDCA on hepatic sarcoid in a single-center open-label, pre-post study design. **Methods:** We conducted a 12-month open-label single-arm pre-post pilot study for patients with hepatic sarcoid. After enrollment, patients were observed for 6 months followed by 6 months of weight-based UDCA (13-15mg/kg) divided into two daily doses. Key inclusion criteria were a diagnosis of systemic sarcoidosis with evidence of liver involvement as denoted by elevated liver-specific alkaline phosphatase plus any of the following: granulomas on liver biopsy, hepatomegaly on imaging, or portal Hypertension (via imaging or endoscopy) or granulomas on liver biopsy (not attributable to infection) with concomitant elevated liver-specific alkaline phosphatase. The primary endpoints were decrease in alkaline phosphatase (ALP) or gamma-glutamyl transferase (GGT) at month 6 of UDCA treatment. Key secondary endpoint included decreases in alanine aminotransferease (ALT), aspartate aminotransferease (AST), and liver stiffness (kPa) as assessed by vibration-controlled transient elastography (VCTE). **Results:** 10 patients were screened for participation in the study from August 2018 to July 2020; seven were enrolled. Target enrollment was 10 patients – the study was terminated prior to achieving target enrollment due to the COVID-19 pandemic. One patient dropped out during the first month of observation due to new diagnosis of esophageal cancer. Six completed the 6-month observation and UDCA periods. One patient stopped UDCA within the first month of active treatment due to side effect of nausea. There was a decrease in ALP and GGT at six-months of UDCA treatment (ALP - 257.6 to 202.2, $p = 0.23$; GGT – 302.5 to 111.8, $p = 0.059$, Figure 1). There was also decreases in all key secondary endpoints (ALT - 50.8 to 29.8, p = NS; AST – 40.3 to 31.2, p = NS, VCTE kPa – 8.3 to 6.3, p = NS). **Conclusion:** UDCA is safe for use in patients with sarcoidosis with liver involvement. This pilot study suggests a role for UDCA in the treatment of hepatic sarcoid, with improvements in hepatic biochemical tests and liver stiffness. Multi-centered studies of longer duration are needed to assess the impact of UDCA on hepatic sarcoid. Figure 1 – Hepatic biochemical tests, baseline to Month 12

4591-C | WIDESPREAD DYSREGULATION OF METABOLIC STRESS PATHWAYS IS A CHARACTERISTIC OF PRIMARY BILIARY CHOLANGITIS (PBC): COMPARISON OF THE SERUM METABOLOMES OF PBC PATIENTS TO MATCHED HEALTHY VOLUNTEERS

Yun-Jung Choi[1], Jeffrey D. Johnson[1], Andrew J. Schwab[2] and Charles A. McWherter[1], (1)Cymabay Therapeutics, (2)Metabolon

Background: Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease characterized by progressive inflammation and destruction of small intrahepatic bile ducts. Current analytical methods can measure over 1000 metabolites to define a serum metabolome. Comparison of the serum metabolomes of patients with PBC to matched healthy volunteers (HV) is a comprehensive approach to discover novel disease signatures and therapeutic opportunities for this disease. **Methods:** Serum

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

samples were collected from 161 PBC patients in a phase 3 study (ENHANCE: NCT03602560) and from 55 healthy volunteers prospectively recruited by matching age, gender and BMI to PBC patients. Serum metabolomic analyses were performed using UHPLC-MS/MS (Metabolon, Inc). The relative abundance of each identified metabolite between PBC patients and HV was evaluated. **Results:** A total of 1031 metabolites were identified from global metabolomic analysis of serum from patients with PBC and HV. Among these, 468 (45%) of the total metabolites were significantly increased in PBC and 189 (18%) were significantly decreased ($p < 0.05$). There was a clear separation between the overall metabolomic profiles of PBC patients and HV (Figure). Bile acids were broadly elevated, and the data reveal new details for less abundant, but potentially consequential differences among them. Many biochemical changes implicate metabolic stress brought about by the mitochondrial dysfunction consequent in PBC: medium- and long-chain fatty acids were elevated, and fatty acid dicarboxylates and fatty acyl carnitines were broadly increased consistent with insufficient beta-oxidation. Ceramides and lysophospholipids, markers of oxidative stress and inflammation, were also significantly elevated in PBC. PBC patients also showed non-lipid metabolomic changes that reflect perturbed energy balance and reduced metabolic capacity of the liver. **Conclusion:** PBC patients displayed broad changes in serum metabolites reflective of metabolic stress indicating mitochondrial defects and liver dysfunction associated with their cholestasis. This new detailed map of metabolomic changes in matched cohorts of significant size sheds light on the broad metabolic pathology of PBC. These results will aid in our understanding of the substantial impact of PBC on systemic metabolism and energy balance and will help guide efforts to advance therapeutics to counteract the integrated metabolic effects of cholestasis in PBC patients.

4600-C | FARNESOID X RECEPTOR (FXR) CONTROLS CHOLANGIOCYTE INJURY RESPONSES IN EXPERIMENTAL BILIARY ATRESIA★

Astha Malik[1], Annika Yang Vom Hofe[1], Bryan Donnelly[1], Brandee Wagner[2], Gregory M. Tiao[1] and Alexander G. Miethke[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Metacrine, Inc

Background: Biliary atresia (BA) is a fibroinflammatory obliteration of the extrahepatic biliary tree in neonates. We previously showed FXR agonist tames macrophage mediated proinflammatory cytokine production in sclerosing cholangitis and to reduce serum bile acid concentrations in experimental BA. Here we examine its effects on infection of cholangiocytes with rhesus rotavirus (RRV) and on progression of biliary fibrosis in RRV-induced neonatal bile duct obstruction. **Methods:** Newborn BALB/c mice were injected with $1.5X10^6$ FFU of RRV to induce experimental BA followed by daily orogastric gavage of 10 mg/kg of the non-steroidal FXR agonist, M044, or vehicle (corn oil) in controls. Mice were sacrificed 7 days post RRV (d7pRRV). Livers and bile ducts were micro dissected to determine viral titers by focus forming assay, to quantitate gene expression by qPCR, and to assess liver fibrosis by Sirius Red staining of liver sections. In vitro, primary neonatal cholangiocytes were infected with RRV or challenged with LPS or TCDCA while exposed to M044 or vehicle. Protein and gene expression levels were quantified using western blot, ELISA, and qPCR. **Results:** Compared with controls, treatment with FXR agonist following RRV challenge induced hepatic expression of *Shp*, target gene of FXR, and significantly repressed both proinflammatory and profibrogenic genes, including *Tnfa, Cxcl9, Cxcl10* and *Pdgfb.* FXR agonist treatment lowered viral titers in livers (average viral particles: $9,700 \pm 11000$ vs 280 ± 160 FFU/ml in vehicle vs M044; $p < 0.005$) and to lesser extent in extrahepatic bile ducts ($11,100 \pm 4,700$ vs $4,400 \pm 1700$ FFU/ml; $p = 0.045$). FXR agonist reduced progression of periportal fibrosis (Figure 1A). FXR protein was expressed in neonatal cholangiocytes as demonstrated by western blot. Incubation of neonatal cholangiocytes with FXR agonist prior to RRV exposure lowered viral replication in dose dependent manner. Furthermore, it reduced secretion of profibrogenic TGFb1 by cholangiocytes upon stimulation with LPS or TCDCA (Figure 1B). **Conclusion:** Pharmacological activation of

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

FXR confers renders cholangiocytes resistant to infection with double stranded RRV and represses their proinflammatory and profibrogenic responses. Given the preclinical anti-cholestatic, anti-inflammatory, and anti-fibrogenic effects of non-steroidal FXR agonist, this class of drugs may be considered for clinical trials in infants with BA.

Figure 1: FXR agonist represses profibrogenic responses by cholangiocytes. A| Photomicrographs of liver sections stained with Sirius Red from neonatal mice on d7p RRV. B) TGFb1 protein concentrations measured by ELISA in supernatants from cultured neonatal cholangiocytes stimulated with 10ng/ml of LPS or 100μM of TCDCA in presence of FXR agonist (or vehicle).

4601-C | GENETIC SURVEY FOR MODIFYING GENES IN KASAI PORTOENTEROSTOMY OUTCOMES

Aaron Bennett, Phoebe Wood, Bryanna Domenick and Elizabeth Rand, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Biliary atresia (BA) is the most common cause of obstructive cholestasis in neonates. Primary treatment of BA is surgical correction via Kasai Portoenterostomy (KPE). Despite surgical remediation of the obstruction, approximately half of patients with BA will require liver transplantation (LT) by two years of age due to complications of persistent cholestasis, and another large group requires LT later in childhood or young adulthood due to complications of portal hypertension and hepatic cirrhosis. Multiple clinical factors have been investigated to prognosticate post-KPE outcomes, including age at KPE, the trend of conjugated bilirubin, surgical technique, center experience, and post-KPE steroid use. Genetic studies have not identified an etiology of BA, however underlying known cholestatic genes have not been studied as potential modifiers of post-KPE outcomes. **Methods:** Liver explant tissue samples were saved in an IRB approved biorepository. Explant specimens from patients with BA post-KPE were sent for genomic DNA extraction and genetic panel analysis of 77 genes implicated in disorders of cholestasis (PreventionGenetics Cholestasis Panel). Patient demographic and clinical data were collected via electronic chart review. Patients were dichotomized into early LT and late LT groups, representative of persistent cholestasis post-KPE and non-cholestatic cirrhosis respectively. The presence of genetic variants were compared between the two groups. **Results:** Fifty-three patients were included in our analysis. Both groups had a similar age at KPE (median age 2.1 months). The early LT group, as anticipated, had cholestasis at LT while the late LT group had complications related to portal hypertension. Forty-nine patients (92%) had abnormal genetic variants identified. Differences in prevalence of genetic variants are shown in Table 1. **Conclusion:** Multiple factors contribute to post-KPE outcomes in patients with BA. Underlying genetic variants associated with disorders of cholestasis may modify post-KPE outcomes. We found a higher prevalence of multiple genes implicated in disorders of cholestasis, including CFTR, in the early LT cohort. While this study is not properly powered to identify statistically significant differences in genetic variants due to its inherently small sample size, mutations in CFTR are of particular interest given the advent of CFTR modulating therapies and the potential for disease modifying intervention. Additional studies evaluating the prevalence of cholestasis related genetic variants in a larger sample of patients with BA, and the function of specific CFTR variants in this cohort, may highlight novel methods of prognostication and intervention.

4602-C | IMPROVEMENTS IN PRURITUS WITH MARALIXIBAT ARE ASSOCIATED WITH IMPROVED QUALITY OF LIFE FOR PATIENTS WITH PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS: DATA FROM THE MARCH-PFIC TRIAL

Amal A. Aqul[1], Alexander G. Miethke[2], Chuan-Hao Lin[3], Gilda Porta[4], Étienne M. Sokal[5], Douglas B. Mogul[6], Tiago Nunes[6], Marshall Baek[6], Pamela Vig[6], Ulrich Baumann[7] and Richard J. Thompson[8], (1)University of Texas Southwestern Medical Center, Dallas, Texas, (2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (4) Hospital Sirio Libanes, Sao Paulo, Brazil, (5)Cliniques Universitaires Saint-Luc, (6)Mirum Pharmaceuticals, Inc., Foster City, California, (7) Hannover Medical School, Hannover, Germany, (8) Institute of Liver Studies, King's College London, London, United Kingdom

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) is a group of rare genetic disorders characterized by retention of bile acids leading to cholestatic pruritus, impaired growth and end-stage liver disease. Pruritus, the most burdensome symptom of PFIC, occurs in the majority, and leads to sleep disturbances, self-mutilation, decreased school performance, and impaired quality of life (QoL). MARCH-PFIC (MARCH) was a Phase 3 trial of maralixibat (MRX), an ileal bile acid transporter inhibitor, that demonstrated significant reductions in pruritus. Here, we analyze whether improvements in pruritus are associated with an increase in QoL for patients with PFIC. **Methods:** Participants from MARCH in the All-PFIC cohort (BSEP, FIC1, MDR3, TJP2, and MYO5B) were randomized to receive MRX 570 μg/kg BID or placebo (PBO) for 26 weeks. Change from Baseline (BL; CFB) in QoL was assessed from BLto Week 18-26 for pruritus responders [≥ 1-point change in ItchRO (Obs)] using the PedsQL, Peds-QL Social Functioning (PedsQL-SF), Peds-QL Physical Functioning (PedsQL-SF), and the Family Impact Total Scale (FI-T); all instruments use a 0-100 scale with higher scores indicating better QoL. **Results:** 64 participants (31 BSEP, 13 FIC1, 9 MDR3, 7 TJP2, 4 MYO5B) were randomized (33 MRX, 31 PBO). BL disease characteristics were well-balanced between MRX and PBO, and participants had similar BL QoL score (e.g., PedsQL: 56 vs 63). In MRX, the CFB in PedsQL for pruritus responders was 22 ($p < 0.0001$) with no significant CFB for non-responders (-2; $p = 0.7062$) and relative change between groups was significant ($p = 0.0014$). In PBO, there was no difference between responders and non-responders ($p = 0.8192$). The PedsQL-SF, PedsQL-PF and FI-T showed similar patterns, with MRX demonstrating significant CFB for social/physical functioning and family impact among pruritus responders, but minimal CFB among non-responders, such that there was significant relative change for PedsQL-SF ($p = 0.0011$) and PedsQL-PF ($p = 0.0012$) and trend towards relative change in FI-T ($p = 0.0895$). In the PBO group, there was no significant difference between pruritus responders and non-responders for PedsQL-SF, PedsQL-PF, and FI-T. **Conclusion:** In MARCH, pruritus control among MRX recipients was associated with clinically significant improvements in QoL across several domains. These data indicate that improvements in pruritus in patients with PFIC on MRX are associated with significant improvements in social and physical functioning as well as benefit to the family.

Shneider[17] and the Childhood Liver Disease Research Network (ChiLDReN), (1)Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (2) University of Michigan, (3)Arbor Research Collaborative for Health, (4)UPMC Children's Hospital of Pittsburgh, Pittsburgh, Pennsylvania, (5)Riley Hospital for Children, (6)Texas Children's Hospital, Baylor College of Medicine, (7)Children's Hospital of Colorado and University of Colorado School of Medicine, (8)Children's Healthcare of Atlanta, (9)University of California, San Francisco, (10)The Children's Hospital of Philadelphia and the University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, (11)Children's Hospital Los Angeles, Los Angeles, CA, (12)University of Washington School of Medicine, (13)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (14) Division of Gastroenterology, Hepatology and Nutrition, the Hospital for Sick Children, Toronto, ON, Canada, (15)Primary Children's Hospital, (16)University of Michigan Hospitals and Health Centers, (17)Texas Children's Hospital, Houston, TX

Background: Secondary prophylaxis of gastroesophageal variceal hemorrhage is recommended in adults, and by corollary in pediatrics. However, there are few real-world studies of implementation. We describe the outcomes of gastrointestinal hemorrhage (GIH) in a large multi-center cohort of participants with biliary atresia (BA) and portal hypertension at hepatology centers in North America. **Methods:** Data from two prospective longitudinal studies of BA, PROBE and BASIC, in ChiLDReN, were analyzed in parallel. PROBE captures incident cases of BA < 6 months old, while BASIC includes a prevalent cohort > 6 months old. The clinical course of participants with GIH was analyzed for those with their native liver and possible or definite clinically evident portal hypertension. **Results:** A total of 180 participants were included in this analysis; 96 PROBE and 84 BASIC. The median age at the qualifying episode of GIH was 11 and 77 months in PROBE and BASIC, respectively. 32 (38%) of PROBE participants had a successful hepato-portoenterostomy (HPE) (TB < 2 mg/dL within 3 months of HPE). Following the index episode of bleeding, endoscopy was performed in 110 participants (61%). Esophageal varices were reported in 96 participants with 68 noted to have varices of grade II-III or higher. Comparison of participants undergoing endoscopy with or without intervention, to those who did not undergo an endoscopy after the index bleed are listed (TABLE). Participants who did not have endoscopy were younger, listed for transplant prior to GIH and did not have a draining HPE. 44 participants (30%) underwent liver transplant (LT) within 3 months of the index bleed. 31/44 were listed for LT prior to the index bleed and the median PELD at transplant was 24. There was no difference in transplant-free survival in those who underwent banding or sclerotherapy compared to those who did not. Secondary prophylaxis, consisting of at least two endoscopic interventions with 3 months of the index bleed, was performed in only 17 participants overall (9.4%). **Conclusion:** This real-world data from hepatology centers in North America demonstrates that BA patients with a GI bleeding episode do not typically receive conventional secondary prophylaxis. A nuanced approach appears based upon expected transplant-free survival and the endoscopic appearance of varices. Optimal approaches for management of variceal hemorrhage in biliary atresia warrant continued investigation.

Table 1: Descriptive characteristics by treatment response at time of bleed

		Banding/Sclerotherapy		Endoscopy w/o Banding/Sclerotherapy		No endoscopy		
		N	n (%) or median (range)	N	n (%) or median (range)	N	n (%) or median (range)	p-value
Listing status at time of [Endo/SE] bleed								0.039
	Listed before index bleed	84	28 (33.3%)	32	6 (18.8%)	31	16 (51.6%)	
Age at bleed, reported (months)		93	32 (4, 363)	32	63 (5, 250)	55	14 (4, 232)	0.005
Total bilirubin (mg/dl)		53	2.5 (0.3, 26.5)	21	1.2 (0.2, 23.6)	19	13.8 (0.7, 35.5)	<.001
TB <2 mg/dL by M3		46	20 (43.5%)	12	7 (58.3%)	27	5 (18.5%)	0.029
TB at enrollment >6 mg/dL (BASIC)		39	5 (12.8%)	18	2 (11.1%)	21	11 (52.4%)	<.001
Varices grade III+ at bleed		73	46 (63%)	22	4 (18.2%)			<.001

4604-C | MARALIXIBAT LEADS TO SIGNIFICANT IMPROVEMENT IN CHOLESTATIC PRURITUS FOR CHILDREN WITH PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS DUE TO TJP2 OR MYO5B DEFICIENCY: DATA FROM THE MARCH-PFIC TRIAL

Alexander G. Miethke[1], Gilda Porta[2], Adib Moukarzel[3], Chuan-Hao Lin[4], Daniel D'Agostino[5], Douglas B Mogul[6], Tiago Nunes[6], Raul Aguilar[6], Pamela Vig[6], Fang Kuan Chiou[7] and Richard J. Thompson[8], (1) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Sao Paulo School of Medicine, Sao Paulo, Brazil, (3)Hotel Dieu De France Saint Joseph University Hospital, Beirut, Lebanon, (4) Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (5)Hospital Italiano De Buenos Aires, Buenos Aires, Argentina, (6)Mirum Pharmaceuticals, Inc., Foster City, California, (7)Kk Women's and Children's Hospital, Singapore, (8) Institute of Liver Studies, King's College London, London, United Kingdom

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) is a heterogeneous family of disorders of bile formation with the most commonly identified causes being deficiencies in BSEP, FIC1, and MDR3. Although other, rarer, causes continue to be discovered, all types share a phenotype characterized by elevated serum bile acids (sBA), cholestatic pruritus, impaired growth, and progressive liver disease. MARCH-PFIC (MARCH) was a randomized Phase 3 trial of maralixibat (MRX), an ileal bile acid transporter (IBAT) inhibitor, vs placebo (PBO), that achieved its primary and key secondary endpoints of pruritus and sBA reduction. Here we report on use of MRX in TJP2 and MYO5B deficiencies from the first trial of IBAT inhibition that included these subtypes. **Methods:** MARCH has been previously described. Data comparing change from Baseline (BL; CFB) to Weeks 15-26 for key efficacy endpoints (pruritus using 0-4 ItchRO[Obs], sBA, and bilirubin) were analyzed for individual's with TJP2 or MYO5B deficiency. **Results:** In TJP2 deficiency (n = 6 MRX; n = 1 PBO), the median (range) of BL ItchRO(Obs) for MRX was 2.5 (1.5-3.6) with CFB of -1.9 (-0.4 to -3.4) with no change for the individual on PBO. BL sBA for MRX was 205 (96-428) μmol/L with CFB of -138 (-10 to -342) μmol/L; the individual on PBO also decreased sBA from 196 to 50 μmol/L. There were no meaningful changes in total and direct bilirubin for either group. In MYO5B deficiency (n = 2 MRX; n = 2 PBO), both individual's on MRX had complete resolution of pruritus, with BL ItchRO(Obs) of 4 and 3 decreasing to 0; one individual on PBO had no change through end of study, and the other stopped at Week 6 for no perceived benefit. Both individual's on MRX had complete normalization of sBA, from BL of 88 and 422 μmol/L to 4 and 2 μmol/L; one on PBO had normal BL sBA which was maintained through Week 26 and the other had elevated sBA at BL to Week 6. One individual on MRX had elevated BL bilirubin which normalized from 4.9 to 0.3 mg/dL (total) and 4.0 to 0.1 mg/dL (direct); both individual's on PBO had normal BL bilirubin. Safety signals were consistent with other PFIC types. **Conclusion:** MARCH is the first trial of IBAT inhibition to show benefit for TJP2 and MYO5B deficiencies. All individual's receiving MRX had large improvements in pruritus and most had large reductions in sBA. Normalization of bilirubin was observed in a MYO5B patient. Individual's receiving PBO typically had little benefit. These data support the ongoing efficacy of MRX for PFIC across a broad range of types.

4605-C | MARALIXIBAT LEADS TO SIGNIFICANT IMPROVEMENTS IN CHOLESTATIC PRURITUS FOR CHILDREN WITH PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS WITHOUT A GENETIC DIAGNOSIS: DATA FROM THE MARCH-PFIC TRIAL

Simon P. Horslen[1], Adib Moukarzel[2], Alexander G. Miethke[3], Naveen Mittal[4], Udeme Ekong[5], Nagraj Kasi[6], Douglas B Mogul[7], Tiago Nunes[7], Raul Aguilar[7], Pamela Vig[7], Susan M. Gilmour[8] and Richard J. Thompson[9], (1)UPMC Children's Hospital of Pittsburgh, Pittsburgh, Pennsylvania, (2)Hotel Dieu De France Saint Joseph University Hospital, Beirut, Lebanon, (3) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)University of Texas Health Science Center at San Antonio, San Antonio, Texas, (5)Medstar Georgetown University Hospital, Washington DC, (6) Medical University of South Carolina, Charleston, South Carolina, (7)Mirum Pharmaceuticals, Inc., Foster City, California, (8)University of Alberta, AB, Canada, (9) Institute of Liver Studies, King's College London, London, United Kingdom

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) is a heterogeneous family of disorders of hepatocellular bile formation leading to cholestatic pruritus, growth deficits and liver failure. Whereas PFIC is commonly caused by mutations in *ATP8B1*, *ABCB11*, and *ABCB4*, new genes continue to be identified and other individual's have a PFIC phenotype without an identifiable cause. In the MARCH-PFIC (MARCH) Phase 3 trial, maralixibat (MRX), an ileal bile acid transporter (IBAT) inhibitor, achieved its primary and key secondary endpoints of improvement in pruritus, serum bile acids (sBA), and bilirubin for patients with BSEP deficiency and the All-PFIC cohort (i.e., with a genetic diagnosis). Here we present data on the efficacy and safety of MRX for individual's without an identified cause, the first time IBAT inhibition has been studied in this population. **Methods:** MARCH has been previously described. Participants were randomized to receive MRX 570 μg/kg BID or placebo (PBO) for 26 weeks. Data on key efficacy endpoints (pruritus, sBA, and bilirubin) were analyzed for participants with no diagnostic variants identified using a mixed effects model of repeated measurements. **Results:** 8 patients with PFIC, but without a genetic cause, were randomized (n = 3 MRX; n = 5 PBO). MRX and PBO were well-balanced with respect to Baseline pruritus score (3.4 vs 3.3 on 0-4 ItchRO[Obs] score) and sBA (140 vs 129 μmol/L). In the MRX group, significant changes from Baseline (CFB) were observed in ItchRO(Obs) response (-2.6; $p < 0.0001$), whereas no significant CFB was seen in PBO (0.05; $p = 0.8263$) and relative change between groups was significant (-2.6; $p < 0.0001$). The mean percentage of assessments with severity scores of 0 (none) or 1 (mild) was greater in the MRX group (66.8%) compared to PBO (0.4%) and the relative difference was significant ($p = 0.0007$). Large reductions of –105 μmol/L in sBA were observed in the MRX group ($p = 0.1000$) and no change in PBO. Decreases in total and direct bilirubin (-1.50 mg/dL; $p = 0.0602$; -1.23 mg/dL; $p = 0.0271$) were observed in the MRX group, while there was no improvement in PBO. One serious adverse event (UTI, unrelated) was reported in the MRX group. Diarrhea was reported in 2 (66.7%) MRX and 2 (40%) PBO, all mild in severity. No participants discontinued treatment. **Conclusion:** This is the first evidence of IBAT inhibition in patients with the PFIC phenotype without a genetic cause. MRX was associated with improvements in pruritus and sBA vs no change in PBO.

4606-C | NEUTROPHIL-DERIVED LL-37 IS INCREASED IN EARLY BILIARY ATRESIA AND CAN AFFECT LEUCOCYTE RECRUITMENT BY UPREGULATING ENDOTHELIAL ADHESION FACTORS

Christoph Slavetinsky[1], Jule Basenach[1], Franziska Ott[1], Stefan Fleischmann[1], Tobias Miserre[1], Lena Schultheis[1], Silvio Nadalin[2], Steffen Hartleif[1], Stephan Singer[2], Jörg Fuchs[1] and Ekkehard Sturm[3], (1) University Children´s Hospital Tübingen, (2)University Hospital Tübingen, (3)University Children's Hospital Tübingen

Background: Biliary atresia (BA) is a life-threatening liver disease characterized by progressive liver inflammation, fibro-obliterative obstruction of bile ducts due to an unknown trigger and major indication for liver transplantation in childhood. Liver inflammation of BA is characterized by a decrease of T regulatory and NK cells, but infiltration of cytotoxic T cells, circulating macrophages and neutrophils causing massive oxidative stress. The role of the soluble immune barrier of the biliary tree in hepatic pathophysiology in children is unknown. We planned to determine the expression profiles of common antimicrobial peptides and proteins in BA and analyze their role in hepatic/biliary damage, inflammation, and leucocyte trafficking. **Methods:** Expression of LL-37, LEAP-1, Lysozyme, and MBL was analyzed by qPCR from patient liver tissue of BA (n = 62) and familial cholestasis (PFIC, n = 18; ALGS, n = 6) at early and late disease stages expressed as proportion of age-matched normal controls (n = 19). LL-37 expression was correlated with pro-fibrotic activity (TGF-ß), adhesion factor expression (e.g., ICAM-1) and cholestasis (e.g., bile acids) by regression analysis, and localized in liver sections by immunohistochemistry and immunofluorescence (IF). Primary endothelial cells (HUVECs, LSECs) were treated with recombinant LL-37, assessed for cell viability (MTT assay), upregulation of adhesion factors (qPCR, IF), and *in vitro* adhesion of leucocytes (endothelium adhesion assay). **Results:** Liver gene expression of LL-37 but not of LEAP-1, Lysozyme and MBL is significantly upregulated 18-fold exclusively in early BA ($P = 0.001$) vs. 3-fold in familial cholestasis (ns). LL-37 expression in BA correlates with TGF-ß ($R^2 = 0.26$, $P = 0.007$) and ICAM-1 ($R^2 = 0.12$, $P = 0.006$) but not with cholestasis markers. LL-37 in BA is localized in neutrophils and on endothelial cells co-localizing with adhesion factors. Recombinant LL-37 has a dose-dependent cytotoxic effect on endothelia (HUVECs, $P = < 0.0001$; LSECs, $P = < 0.0001$) upregulating adhesion factors (ICAM-1: HUVECs, $P = 0.01$; LSECs, $P = < 0.0001$. P-selectin: HUVECs, $P = 0.0007$; LSECs, $P = < 0.0001$. E-selectin: HUVECs, $P = 0.02$; LSECs, $P = 0.001$.) and increasing *in vitro* adhesion of THP-1 cells by twofold ($P = 0.04$). **Conclusion:** LL-37 is upregulated in early BA, most likely due to neutrophil invasion which may release LL-37 on endothelia. In consequence, fibrotic activity may be induced by endothelial stress and subsequent upregulation of adhesion factors enabling increased binding of leucocytes. LL-37 may act as propagator of inflammation and leucocyte trafficking in BA.

4607-C | RHESUS ROTAVIRUS INFECTION OF PLASMACYTOID DENDRITIC CELLS DRIVES NATURAL KILLER CELL ACTIVATION LEADING TO BILE DUCT OBSTRUCTION★

Stephen J. Hartman[1], Bryan Donnelly[1], Sujit K. Mohanty[2], Haley Temple[1], Rajamouli Pasula[1], Holly M Poling[1] and Gregory M. Tiao[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)United States Department of Agriculture (USDA-ARS)

Background: Biliary atresia (BA) is a neonatal fibro-obliterative cholangiopathy resulting in life-threatening bile duct obstruction, which is universally fatal without early surgical intervention. BA's etiology remains unknown, but a murine model exists where infection of neonatal BALB/c mice with rhesus rotavirus (RRV) induces biliary obstruction akin to human BA. We have demonstrated that strain-specific activation of natural killer (NK) cells plays a critical role in the obstruction process. In this study we evaluated the mechanism of NK cell activation. **Methods:** BALB/c pups were injected with RRV and Ro1845 – a strain incapable of inducing murine BA – and viral titers were measured in liver NK and plasmacytoid dendritic cells (pDCs) at 7 days post infection (DPI). Flow cytometry was performed on uninfected murine pDCs to evaluate their surface receptors. Naïve pDCs at day of life (DOL) 2 and DOL10 were infected with RRV in vitro and evaluated for viral titer. Naïve NK cells were co-cultured with pDCs from RRV- and Ro1845-infected pups and evaluated for NK cell activation. *In vivo*, pDCs were selectively depleted by diphtheria toxin in mouse pups and then infected with RRV. **Results:** There was no significant difference in RRV and Ro1845 titers in NK cells at 7 DPI. PDCs from RRV-infected mice had significantly higher viral titer compared to Ro1845-infection. By flow, pDCs possessed only one known rotavirus receptor: heat shock cognate 70 protein (Hsc70), which decreased with increasing age. Naïve pDCs from DOL2 pups produced significantly higher viral titers than DOL10. Flow cytometry demonstrated pDCs from RRV-infected pups had significantly higher activation compared to saline and Ro1845-infected pups (Figure 1). Naïve NK cells co-cultured with RRV-infected pDCs exhibited higher activation compared to pDCs from saline and Ro1845-injected pups. After pDC depletion, RRV-infected pups revealed patent bile ducts and a significant reduction of NK cells on liver histology, contrasting with the obstructed control mice. **Conclusion:** RRV infection of pDCs leads to their activation and this activation potentiates activation of NK cells inducing biliary obstruction observed in the murine model of BA. We have previously demonstrated that only rotavirus strains containing an "SRL" motif on their attachment protein, such as RRV, can bind to Hsc70 and induce the murine model of BA, whereas other viruses cannot bind Hsc70, which may explain their low infectivity in pDCs and diminished NK cell activation.

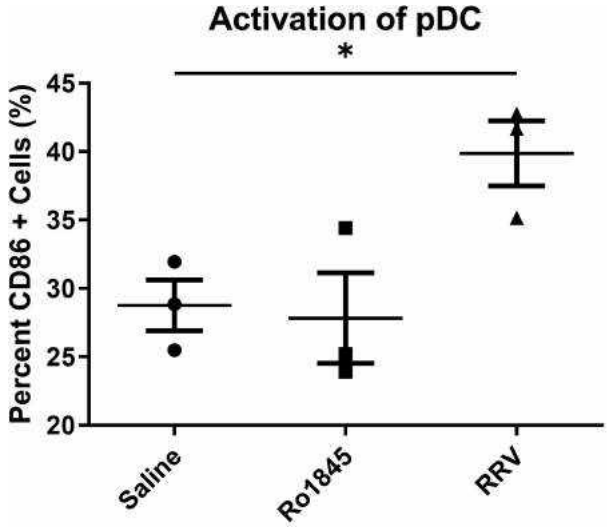

Figure 1: Flow cytometry demonstrating percentage of activated pDCs (% CD86+) isolated at 7 days post-injection.

4608-C | THE ROLE OF ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY IN PAEDIATRIC CHOLANGIOPATHIES

Homira Ayubi[1], Oliver Pickford Scienti[2], Usama Alfarsi[1], Tassos Grammatikopoulos[3,4], Marianne Samyn[5], David Reffitt[1], John Devlin[1], Phillip Harrison[1] and Deepak Joshi[6], (1)King's College Hospital NHS Trust, (2) Institute of Cancer Research to Royal Marsden NHS Trust, (3)King's College London, (4)King's College Hospital NHS Trust, (5)King's College Hospital, (6) Institute of Liver Studies, King's College London, London, United Kingdom, London, United Kingdom

Background: Cholangiopathies represent a significant proportion of paediatric liver disease. However, there is little information on the role and safety of endoscopic retrograde cholangiopancreatography (ERCP) in this population. We present data on safety and outcomes in paediatric patients undergoing ERCP. **Methods:** Data was collected on all paediatric patients (< 18 y old) from an electronic endoscopic database) between 2008 - 2022. Data collected included patient age, gender, diagnosis, indications and therapy. Complications were also reviewed for primary and subsequent ERCPs. **Results:** In total, 230 ERCP procedures were

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

performed for 103 patients (60 male). All ERCP cases were performed under general anaesthetic. The median age of the patient population was 11 years (range 22 d-16 y). 72% weighed above 20 kg. 19 patients had concurrent IBD. Successful cannulation was achieved in 89% of cases. All patients received prophylactic antibiotics pre and post procedure. The most common indication was for a dominant stricture (DS), 66%. Primary sclerosing cholangitis and autoimmune sclerosing cholangitis accounted for only 26% of the cases. There was no obvious difference in the rates of sphincterotomy performed between the DS and non-DS groups (22 vs 18 %). 191(83%) ERCPs were performed for DS. DS patients required more ERCPs (median 2, range 1-14 vs median 1, range 1-3, $p < 0.005$)). DS patients were more likely to require a stent (50% vs 5%), with plastic stents more frequently used. Overall, the mean change in bilirubin, alkaline phosphatase and gamma glutamyl transferase post procedure was -35.7 μmol/l, -77.3 IU/L and -34.3 IU/L, respectively. Time to liver transplantation was 4.9 years (range 0.17 – 11). At the time of follow up, 8 patients had died. Causes of death included graft dysfunction post liver transplant, disseminated malignancy and respiratory failure. The overall complication rate of ERCP in the paediatric population was 3.0%. Individual complication rates for post ERCP bleeding, pancreatitis, cholangitis and perforation were 0.9%, 1.3%, 1.3% and 0.4% respectively. **Conclusion:** ERCP appears to be safe and efficacious in paediatric patients. It plays an integral role in the management of paediatric cholangiopathies.

4609-C | TIME-COURSE RNASEQ REVEALED DYNAMIC TRANSCRIPTIONAL CHANGES IN A MOUSE MODEL OF TOXIN-INDUCED BILIARY ATRESIA

Shang-Hsin Wu[1], Abigail Spingarn[2] and Xiao Zhao[1], (1) Columbia University Vagelos College of Physicians and Surgeons, New York, NY, (2)Columbia University Irving Medical Center, New York, NY

Background: We have previously established a toxin-induced biliary atresia (BA) model in the zebrafish using biliatresone, an isoflavonoid causatively linked BA outbreaks in newborn Australian livestock. Here, we aimed to elucidate mechanisms underlying BA pathogenesis using a biliatresone-induced mouse model of biliary injury. **Methods:** We injected BALB/c mouse pups intraperitoneally with biliatresone (30μg/g) *vs* vehicle control between one and two days of age. Histopathological analyses of the extrahepatic bile ducts (EHBD) and livers were performed using H&E and immunofluorescence staining. For global gene expression profiling, EHBD and livers were harvested separately at 6 hr, 12 hr, 24 hr, 72 hr, and 7 days post exposure for RNA extraction. Sequencing was performed on the Novaseq S4 and differential gene expression analyses were obtained using DESeq2. **Results:** We found that intraperitoneal injection of biliatresone led to obstructive jaundice in selected pups secondary to extrahepatic bile duct injury, resulting in liver cholestasis, similar to the human disease. Specifically, we observed that 100% of neonatal mice would develop jaundice and significant weight loss within 72 hr of toxin injection, which would persist or progress in 48.6% of pups 7 days post injection with associated acholic stool and a maximum survival time of 18 days. The remaining neonatal mice would recover with no perceivable jaundice. Gross morphological examination of the EHBD at 72 hr post biliatresone injection revealed thickened common bile ducts (CBD). While the CBD in the recovered pups appeared indistinguishable from the controls at 7 days post exposure, they appeared narrowed in the jaundiced pups, resulting in upstream biliary dilation and inspissated bile with sludge. Subsequent histological analyses and immunofluorescence staining of Z0-1 in the EHBD of these pups showed luminal occlusion and aberrant Z0-1 patterning, suggestive of loss of cellular integrity and polarity. Ductular reaction was observed in the liver tissues at 7 days. Time-course transcriptional profiling revealed a number of differentially expressed genes (DEGs) across different timepoints post toxin exposure in the EHBD and livers. Gene ontology enrichment analyses of DEGs in the EHBD samples revealed enrichment of genes involved in stress responses early on post exposure (6hr, 12hr), consistent with prior zebrafish studies. The enriched pathways shifted to cell migration, cell adhesions and maintenance of polarity in the intermediate times points (24h, 72hr), and inflammatory signaling involving the innate immune system at the late time point (7 d). **Conclusion:** We utilized a novel mammalian BA model to identify dynamic transcriptional changes in the EHBD in response to toxic insult that may shed valuable insights into the mechanisms driving injury progression in BA and inform the rational design of therapeutic strategies.

4610-C | TREATMENT WITH MARALIXIBAT FOR REFRACTORY PRURITUS IN PATIENT WITH ARTHROGRYPOSIS RENAL DISEASE AND CHOLESTASIS SYNDROME

Tamir Diamond[1,2], Iraklis Petrof[2], Christa Seidman[2], Elizabeth Rand[1,2] and Alanna Strong[2], (1)University of Pennsylvania, (2)Children's Hospital of Philadelphia, Philadelphia, PA

Background: Arthrogryposis-renal dysfunction-cholestasis (ARC) syndrome is a rare, autosomal recessive multisystemic disorder with almost universal mortality in childhood. Cholestasis is a cardinal feature of the disorder resulting in fat-soluble vitamin deficiency, growth failure and debilitating pruritus. Pruritus is often exacerbated by concurrent ichthyosis, resulting in self-mutilating behaviors and poor quality of life. Here we present a single Subject Investigational New Drug Study (sIND) using Maralixibat, an ileal bile acid transport inhibitor, to treat an 11-month old female with ARC syndrome and severe pruritus, refractory to medical therapy. **Methods:** Patient was treated with standard FDA-approved Maralixibat dosing for Alagille Syndrome of 190mcg/kg/day, followed by an increase to 380mcg/kg/day. Patient was monitored during clinic visits and with laboratory evaluations according to study protocol. During the treatment protocol, the patient continued to be closely followed by nephrology for diabetes insipidus, and by palliative/hospice care. **Results:** Prior to initiation of therapy patient's serum bile acids were notable for elevated cholic acid of > 75 umol/L, chenodeoxycholic acid of 39.3 umol/L, ursodeoxycholic acid of 18.3 umol/L (patient was on ursodiol) and total serum bile acids of > 132.9 umol/L. INR was normal (0.76), while total and conjugated bilirubin were 4 mg/dL and 1.8mg/dL respectively. After 4 weeks of treatment, pruritus and total serum bile acids were unchanged (131.8 umol/L). After 9 weeks of therapy, patient developed worsening jaundice, rise in total and conjugated bilirubin (5.3mg/dL and 2.1mg/dL, respectively), and hypopigmented stools when transitioned from infant to pediatric hydrolyzed formula. Liver ultrasound showed no signs of biliary obstruction. Formula was changed to a different pediatric hydrolyzed brand. Twelve weeks after initiation of therapy, daily dosing was increased to 380mcg/kg/day according to protocol; however, cholestasis continued to worsen with total and conjugated bilirubin rising to 9.8mg/dL and 5.1mg/dL respectively, in addition to worsening pruritus correlating with rise in total bile acids of > 166.4umol/L. Over the next 4 weeks the patient continued to have debilitating pruritus, hypopigmented stools as well as worsening diarrhea. Because of ongoing diabetes insipidus as part of her phenotype patient had worsening dehydration in the setting of worsening diarrhea. Sixteen weeks after initiation of therapy Maralixibat was discontinued due to lack of efficacy. Patient ultimately died 18 weeks after initiation of study. **Conclusion:** This is the first reported sIND trial of Maralixibat for treatment of ARC syndrome. Maralixibat was not beneficial in palliating pruritus in the severe phenotype of our patient. Further studies in larger populations with varying severity of phenotype would be beneficial to further evaluate efficacy.

4611-C | A PILOT STUDY USING TRANSIENT ELASTOGRAPHY FOR SCREENING IN CHILDREN WITH CYSTIC KIDNEY DISEASES

Annie S. Jacobs[1], Sasha R. Kapil[2], Wendy Morlan[1], Sushil Gupta[1] and Jean P. Molleston[3], (1)Indiana University School of Medicine/Riley Hospital for Children, (2)University of Texas Southwestern, (3) Indiana University

Background: Congenital Hepatic Fibrosis (CHF) is a portobiliary anomaly with multiple associations, including cystic kidney diseases. Classically, CHF is associated with autosomal recessive polycystic kidney disease. However, there are case reports of hepatic fibrosis resulting in portal hypertension in patients with autosomal dominant polycystic kidney disease. Our study objective is to use vibration-controlled transient elastography (VCTE) to determine the baseline liver stiffness measurements (LSM) in pediatric patients with cystic kidney diseases and compare to reported normal values. **Methods:** A single-center cohort study of children with cystic kidney diseases was completed. ICD 9 and10 codes were used to identify subjects within our practice. Retrospective chart review provided demographic and clinical information. VCTE (FibroScan, Echosens, Paris, France) was performed to obtain LSM (kPa) at time of enrollment. Data was compared to published mean LSM values. **Results:** Baseline data on 28 patients with cystic kidney disease was collected: 9 (32%) autosomal recessive polycystic kidney disease (ARPKD), 9 (32%) autosomal dominant polycystic kidney disease (ADPKD), 3 (11%) nephronophthisis, and 7 (25%) other cystic kidney disease. Mean age was 10.1 years. While the mean LSM in this cohort was not above normal, 10 subjects had a LSM greater than 2 standard deviations above the mean: 7 ARPKD (7.3 kPa, 7.9 kPa, 10.2 kPa, 13.1 kPa, 13.2 kPa, 18.3 kPa, 32.7 kPa), 1 ADPKD (8 kPa), 1 bilateral cystic renal dysplasia (9.4 kPa), and 1 nephronophthisis

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

(75 kPa). **Conclusion:** Data on liver stiffness and its progression in the spectrum of cystic kidney disease is rare. Although most subjects did not have elevated LSM, there were ten identified patients with ARPKD, ADPKD, bilateral cystic renal dysplasia, and nephronophthisis with increased LSM compared to normals for age. LSM may progress over time. We plan to obtain longitudinal data to provide important insight into the role of VCTE in monitoring liver stiffness in cystic kidney disease.

4612-C | AN UNUSUAL CAUSE OF LOW CERULOPLASMIN IN A PAIR OF AUTISTIC TWINS

Vipreet Janjua and Nanda Kerkar, University of Rochester, New York

Background: Low ceruloplasmin is often used as a screening test for Wilson disease (WD). Ceruloplasmin is an alpha-2 glycoprotein that belongs to the family of multi-copper oxidases that do not transport copper but instead contain 95% of the copper in serum. The *Ceruloplasmin gene* is located on chromosome 3 and the protein being an essential ferroxidase is responsible for oxidizing ferrous to ferric ion. Low Ceruloplasmin levels may also be found in Menke's disease, malignancy, inflammatory bowel disease, thyroid disease, neonates, heterozygotes for WD and aceruloplasminemia **Methods:** Electronic medical record review **Results:** A 12-year-old Hispanic nonverbal autistic male with history of constipation and urticaria pigmentosa was referred for elevated serum transaminases with normal bilirubin levels. Physical exam was unremarkable. Initial screening for common causes of liver disease was negative including viral hepatitis, autoimmune hepatitis and alpha-1antitrypsin deficiency. Initial ceruloplasmin level was 6 mg/dL (normal 20-35mg/dL) so a screen for WD was commenced. We repeated the ceruloplasmin level that was low again (6 mg/dL). In addition, Kayser-Fleischer ring was not noted on slit lamp exam and 24-hour urine copper level was noncontributory. He was lost to follow-up for a few years and then presented with increased tiredness and weight loss. A liver biopsy was performed and histology showed near normal liver parenchyma with no significant portal or lobular inflammation. Liver copper was reported to be below 50 mcg/g which was within normal limits. Liver copper > 250mcg/g of liver tissue is diagnostic of WD. His autistic, twin brother also had a low ceruloplasmin level and screening in him for WD was also negative, but liver biopsy was not performed. Our patient had a history of genetic testing done during investigation of autism and was found to have duplication of chromosome 22, negative fragile X testing and also had no mutation in *ATP7B* (gene for WD). On Invitae sponsored copper metabolism gene panel, he was noted to have a single pathogenic variant in the *Ceruloplasmin gene* that prevents incorporation of copper in Ceruloplasmin and disrupts iron metabolism. His serum ferritin was normal at 40ng/ml (normal 20-200 ng/ml). **Conclusion:** Our patient is a heterozygote for aceruloplasminemia, as was his twin brother. This is a rare cause of low ceruloplasmin. Aceruloplasminemia is an autosomal recessive condition that has symptom onset in the 40s to 50s and primarily presents with neurological disease (gait abnormalities, memory and speech impairments) as well as diabetes mellitus associated with iron overload. As genetic testing is becoming more available in the general clinical setting, this case illustrates the importance of considering alternative etiologies for low ceruloplasmin in addition to Wilson disease.

4613-C | CLINICAL, GENETIC, AND PATHOLOGIC FEATURES, TREATMENT, AND LONG-TERM OUTCOME IN PATIENTS WITH BENIGN RECURRENT INTRAHEPATIC CHOLESTASIS: A MULTICENTER STUDY IN JAPAN

Ken Kato[1], Shuichiro Umetsu[2], Takao Togawa[3], Koichi Ito[3], Takayoshi Kawabata[4], Teruko Arinaga-Hino[1], Naoya Tsumura[1], Ryosuke Yasuda[1], Yutaro Mihara[1], Hironori Kusano[1], Shogo Ito[3], Kazuo Imagawa[5], Hisamitsu Hayashi[6], Ayano Inui[2], Yushiro Yamashita[1] and Tatsuki Mizuochi[1], (1)Kurume University School of Medicine, (2)Saiseikai Yokohamashi Tobu Hospital, (3) Nagoya City University Graduate School of Medical Sciences, (4)Ishikawa Prefectural Central Hospital, (5) University of Tsukuba, (6)The University of Tokyo

Background: There have been few reports of benign recurrent intrahepatic cholestasis (BRIC) from East Asia. We aimed to clarify clinical, genetic, and pathologic features, treatment and long-term outcome in Japanese patients with BRIC. **Methods:** We recruited patients with BRIC type 1 (BRIC-1) or type 2 (BRIC-2) who visited at 4 pediatric and 1 adult centers in Japan between April 2007

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and March 2022. Demographic, clinical course, laboratory blood tests, molecular genetic results concerning *ATP8B1* or *ABCB11* gene, histopathological findings in the liver, and treatment were retrospectively examined. **Results:** Seven Japanese patients with BRIC (4 males and 3 females; 4 BRIC-1 and 3 BRIC-2) were enrolled. Median age at onset in patients with BRIC-1 was 12 years while BRIC-2 was 1 month. Number of intermittent cholestatic attacks varied from 1 to 8 during 11 years of median follow-up period. Six patients received a regular education; only 1 attended special education. No patients had developed cirrhosis. Three patients with BRIC-1 had compound heterozygous variant in the *ATP8B1* gene and 1 had heterozygous while 2 patients with BRIC-2 had compound heterozygous in the *ABCB11* gene and 1 had heterozygous. Liver biopsy specimens during the cholestatic attacks showed that fibrosis stage varied from none to moderate but inflammation grade showed none or mild. Rifampicin was administered to 3 patients for their cholestatic attacks and was effective in all of them while cholestyramine to 2 patients and was effective in both. **Conclusion:** To our knowledge, this is the first report of multicenter study for patients with BRIC from East Asia. Onset age and number of intermittent cholestatic attacks varied. Rifampicin and cholestyramine were effective for the cholestatic attacks. No patients developed cirrhosis and most patients showed normal growth and development. Long-term outcome of Japanese patients with BRIC was fairly good.

4614-C | DOWNREGULATION OF SOX9 MEDIATED BY REDUCED NOTCH AND HIPPO SIGNALING RESULTS IN BILE DUCT PAUCITY AND IMPAIRED DUCTULAR REACTION IN AN iPSC-DERIVED, HUMAN, THREE-DIMENSIONAL MODEL OF ALAGILLE SYNDROME

Marie-Agnès M'Callum, Silvia Selleri, Quang Toan Pham, Alexandre Archambault-Marsan, Kristen Vieira-Lomasney and Massimiliano Paganelli, CHU Sainte-Justine, Université De Montréal

Background: Alagille syndrome (ALGS) is an autosomal dominant multisystemic disease resulting in bile duct paucity, cholestasis and progressive fibrosis. The genes involved (JAG1, NOTCH2) belong to the Notch signalling pathway. The aim of this study was to develop a representative human model of ALGS and use it to better understand the pathophysiology of the disease. **Methods:** We developed a 3D in vitro model of ALGS by generating liver organoids from human induced pluripotent stem cells (iPSC). Two isogeneic iPSC clones with mutations in exon 23 of JAG1 gene (large deletion in A2, single base substitution in B3) were generated with CRISPR/Cas9. Mutated iPSCs and an isogeneic control were differentiated into hepatic (HPC), mesenchymal (MPC) and endothelial (EPC) progenitor cells and used to compose the liver organoids. Within the organoids, these cells interact to become hepatocytes, biliary epithelial cells, and stellate and sinusoidal cells, and form ductal plate structures and bile ducts (Raggi et al. Stem Cell Reports 2022). We studied the impact of the mutations on the different liver cell types and assessed bile duct formation and fibrogenesis in the organoids. We also generated hybrid organoids mixing mutated and control progenitors to assess the role of each cell type in determining the disease phenotype. **Results:** The different JAG1 mutations of the two clones resulted in HPCs with different hepatic and Notch pathway gene expression profiles, as expected from the known phenotypic heterogeneity of ALGS. JAG1mutation also affected mesenchymal and endothelial progenitors, with EPC showing an impaired capacity to form vessels in vitro. Organoids from the two mutated clones lacked biliary structures compared to healthy organoids (see Figure), reproducing the bile duct paucity of ALGS. Among the 18 hybrid organoid conditions generated, only organoids with healthy HPCs were able to form proper biliary structures (although JAG1 mutation in EPC and MPC resulted in dysmorphic organoids), attesting that mutation in parenchymal cells drives the disease phenotype. No significant apoptosis was detected in JAG1-mutated organoids, but profibrotic markers were overexpressed. Although YAP1 was overexpressed in mutated HPC cultured in 2D (with clear difference between the two mutated clones), YAP/TAZ and SOX9 were underexpressed in JAG1-mutated organoids, which well correlated with ductular paucity. A loss of CFTR and β-catenin resulted in increased NF-κB expression in mutated organoids, but this did not result in the expected ductular reaction. **Conclusion:** We generated a representative human developmental model of Alagille syndrome using complex liver organoids derived from iPSCs. These organoids reproduced the histological phenotype of Alagille syndrome, allowing for the study of the pathophysiology of bile duct paucity and lack of ductular reaction.

Background: Alagille syndrome (ALGS) is a rare, genetic, multisystem disease that affects the liver and can lead to cholestasis, with resultant impairments in lipid absorption and subsequent fat-soluble vitamin (FSV) deficiency. In the 24-week ASSERT study, treatment with odevixibat resulted in significant improvements in pruritus and reductions in bile acids versus placebo in patients with ALGS. Here, we summarize effects related to FSVs in ASSERT. **Methods:** Patients eligible for ASSERT were those of any age with ALGS, history of significant pruritus, and elevated serum bile acids; patients were randomized 2:1 to odevixibat 120 μg/kg/day or placebo. Vitamins A, D, E, and international normalized ratio (INR; surrogate for vitamin K) were measured at screening, randomization, and 2−6 times through week 24. Treatment-emergent adverse events (TEAEs) resulting from new or worsening FSV deficiency refractory to clinically recommended vitamin supplementation and possible sequelae of FSV deficiency were evaluated. **Results:** Overall, 52 patients (mean age, 6.3 y) received odevixibat (n = 35) or placebo (n = 17); all 52 patients completed the study. At baseline, mean levels of vitamins A, D, E, and INR were generally within normal range, reflective of vitamin supplementation received by most patients. Overall, no clinically relevant changes were observed in mean FSV levels or INR in patients receiving odevixibat or placebo during the study. In total, 6 patients reported TEAEs related to FSV levels (odevixibat, n = 3 [9%]; placebo, n = 3 [18%]). Two of these (odevixibat, n = 1 [3%]; placebo, n = 1 [6%]) had TEAEs of vitamin D deficiency that were refractory to clinically recommended vitamin supplementation; both were nonserious, did not lead to treatment interruption, and were assessed as unrelated to study drug. The 4 additional patients with TEAEs related to FSV levels had increased INR (odevixibat, n = 1; placebo, n = 2) or decreased vitamin A and vitamin E serum levels (odevixibat, n = 1 each [both in the same patient]) that were not considered refractory to clinically recommended vitamin supplementation. TEAEs of possible sequelae of FSV deficiency had a similar incidence with odevixibat (n = 5 [14%]) and placebo (n = 3 [18%]; Table); the most common in the odevixibat group was hematoma, reported in 3 (9%) patients and all attributed to trauma. Most TEAEs possibly secondary to FSV deficiency were reported as Grade 1 or 2 in intensity, were nonserious, and did not lead to treatment interruption or discontinuation. Review of the Kaplan-Meier curve for time to onset of these sequelae indicated no difference between treatment groups. **Conclusion:** In the ASSERT study, treatment of patients with ALGS with odevixibat for up to 24 weeks was not associated with clinically meaningful changes in mean FSV levels or INR. Possible sequelae of FSV deficiency were reported at similar incidence with both odevixibat and placebo.

Table: TEAEs of Potential Sequelae of FSV Deficiency in Patients With Alagille Syndrome in ASSERT

Patients, n (%)	Placebo (n=17)	Odevixibat (n=35)
Any potential sequelae events	3 (18)	5 (14)
Hematoma	0	3 (9)
INR increased	2 (12)	1 (3)
Coagulopathy	0	1 (3)
Hematemesis	0	1 (3)
Contusion	0	1 (3)
Epistaxis	2 (12)	0

FSV, fat-soluble vitamin; INR, international normalized ratio; TEAE, treatment-emergent adverse event.

Background: Progressive familial intrahepatic cholestasis (PFIC) is a group of inherited liver diseases with clinical features that may include elevated serum bile acids and severe pruritus. The efficacy and safety of odevixibat, an ileal bile acid transporter inhibitor, were evaluated in two phase 3 trials in patients with PFIC called PEDFIC 1 and PEDFIC 2. In these studies, odevixibat treatment reduced serum bile acids and improved pruritus. Using pooled data from these trials, we assessed treatment effects in patient subgroups defined by demographic and baseline characteristics. **Methods:** Patients eligible for PEDFIC 1 (NCT03566238) and PEDFIC 2 (NCT03659916) had elevated serum bile acids and significant pruritus at screening. PEDFIC 1 was a 24-week, double-blind study in children with PFIC1 or PFIC2; patients were randomized to placebo, odevixibat 40 µg/kg/day, or odevixibat 120 µg/kg/day. PEDFIC 2 is an ongoing, open-label extension study in which patients from PEDFIC 1 or newly enrolled patients with any PFIC type receive odevixibat 120 µg/kg/day. In a pooled analysis of data from patients' first dose of odevixibat in PEDFIC 1 and/or PEDFIC 2 to a data cutoff date of July 31, 2022, we evaluated the percentage of patients with a serum bile acid response (ie, serum bile acids reduced $\geq$70% from baseline or levels $\leq$70 µmol/L) and the proportion of positive pruritus assessments (PPAs) at the patient level (ie, scratching score $\leq$1 or a $\geq$1-point drop from baseline based on the validated PRUCISION instrument [range 0–4; higher scores indicate worse symptoms]) over 72 weeks of treatment in patient subgroups defined by age, sex, PFIC type, baseline serum bile acid level, baseline pruritus score, baseline alanine aminotransferase or total bilirubin level, and concomitant use of ursodeoxycholic acid and/or rifampicin. Safety was evaluated by monitoring treatment-emergent adverse events (TEAEs). **Results:** Overall, 119 patients comprised the pooled population (median age, 5.9 y; 45% female; 29% PFIC1, 60% PFIC2, 6% PFIC3, 5% other PFIC type). Median (range) exposure to odevixibat was 82 weeks (4 to 201 weeks). In the overall odevixibat-treated group, 29 of 63 (46%) patients with data at week 72 met serum bile acid response criteria. Over the 72-week treatment period, the mean (SE) proportion of PPAs was 73% (4%). The percentage of patients with a serum bile acid response and the mean proportion of PPAs in various patient subgroups are shown in the Table. In the overall population, 108/119 (91%) of patients reported TEAEs; most were mild to moderate in severity. **Conclusion:** All patient subgroups had clinically meaningful decreases in serum bile acid levels and improvements in pruritus score from baseline, although the magnitude of efficacy response was variable in some subgroups. TEAEs with odevixibat in this pooled analysis were consistent with previously reported results.

Table. Rate of Serum Bile Acid Response and Mean Proportion of PPAs With 72 Weeks of Odevixibat Treatment: Subgroup Analyses Using Data From the PEDFIC Studies

	n/N[a]	Percentage (95% CI) of Patients With a Serum Bile Acid Response[b] at Weeks 70–72	n	Mean (SE) Proportion of PPAs[c] From Weeks 0–72, %
Overall odevixibat-treated population	29/63	46 (33–59)	60	73 (4)
By age

Verkade[20], Andrew Wehrman[21], Christine Clemson[22], Qifeng Yu[22], Quanhong Ni[22], Jessica Ruvido[22], Susan Manganaro[22] and Jan P. Mattsson[22], (1)Hassenfeld Children's Hospital at NYU Langone, (2) Univ Lille, CHU Lille, (3)King's College Hospital, (4) Hannover Medical School, Hannover, Germany, (5) Charité Universitätsmedizin Berlin, (6)University Hospital of Padova, (7)The Children's Memorial Health Institute, (8)Istanbul University, Istanbul Faculty of Medicine, (9)Children's Mercy Hospital, (10)Meyer Children's University Hospital of Florence, (11)Johns Hopkins University School of Medicine, (12)Hôpital Universitaire Necker-Enfants Malades, (13)University of Malaya, (14)Bambino Gesù Children's Hospital Irccs, (15)University of California San Francisco, (16) Hospices Civils De Lyon, Hôpital Femme-Mère-Enfant, (17)Université Catholique De Louvain, Cliniques St Luc, (18)University Children's Hospital Tübingen, (19) Wilhelmina Children's Hospital, University Medical Centre Utrecht, (20)University of Groningen, Beatrix Children's Hospital/University Medical Centre Groningen, Groningen, Netherlands, (21)Boston Children's Hospital and Harvard Medical School, Boston, MA, (22)Albireo Pharma, Inc.

Background: Clinical manifestations of Alagille syndrome (ALGS) include elevated levels of bile acids and severe pruritus associated with impaired sleep and quality of life. Odevixibat is a potent, selective inhibitor of the ileal bile acid transporter and effectively reduced bile acids and improved pruritus and sleep in patients with ALGS in the phase 3 ASSERT study. We examined efficacy and safety outcomes in patients who met criteria for pruritus response following 24 weeks of treatment in ASSERT. **Methods:** Patients with a confirmed diagnosis of ALGS, history of significant pruritus, and elevated serum bile acids were randomized 2:1 to odevixibat 120 μg/kg/day or placebo. Patient pruritus and daytime tiredness were rated by caregivers using the PRUCISION observer-reported outcome (ObsRO) tool (range: 0–4; higher scores indicate worse symptoms). Efficacy outcomes evaluated in pruritus responders (defined as patients achieving a ≥1-point decrease in ObsRO scratching score from baseline to weeks 21–24) were change from baseline in ObsRO scratching score, serum bile acids, ObsRO sleep parameters, and caregiver-reported Pediatric Quality of Life Inventory (PedsQL) scores; safety outcomes included treatment-emergent adverse events (TEAEs). **Results:** Overall, 52 patients (mean age, 6.3 y) received odevixibat (n = 35) or placebo (n = 17) in ASSERT, and all 52 patients completed the study. Six (35%) patients receiving placebo and 28 (80%) patients receiving odevixibat were pruritus responders. Pruritus responders treated with odevixibat (mean age, 7.1 y) had a mean scratching score of 2.8 at baseline and 0.9 at weeks 21−24; these pruritus responders also had mean reductions in bile acids and improvements in sleep parameters and PedsQL scores compared with baseline (Table 1). Among odevixibat-treated pruritus responders, 21 (75%) of 28 reported any TEAE; most TEAEs were mild or moderate in severity. Serious, drug-related TEAEs

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

(hematemesis and international normalized ratio increased) were reported in a single patient who had enteroviral gastroenteritis; the serious TEAEs resolved after 2 days, and no change was made to odevixibat dose. **Conclusion:** In the ASSERT study, patients with ALGS who had a pruritus response following treatment with odevixibat also had clinically meaningful mean reductions from baseline in bile acids and improvements in sleep and quality of life. In addition, most TEAEs in odevixibat-treated pruritus responders were mild or moderate, and none led to study discontinuation.

Table 1. Pruritus, Bile Acids, Sleep, and Quality of Life in Pruritus Responders With Alagille Syndrome Treated With Odevixibat

	Baseline		Week 24[a]		
	n	Mean (SE)	n	Mean (SE)	Mean (SE) Change From Baseline
Scratching score	28	2.8 (0.1)	28	0.9 (0.1)	−2.0 (0.1)
Bile acids, µmol/L	28	243 (23)	28	136 (19)	−107 (23)
Sleep parameters					
Days seeing blood due to scratching, %	28	35 (6)	27	5 (2)	−30 (5)
Days with help falling asleep, %	28	59 (8)	27	15 (6)	−44 (8)
Days with soothing, %	28	68 (8)	27	16 (5)	−53 (8)
Days sleeping with caregiver, %	28	40 (9)	27	8 (5)	−34 (8)
Daytime tiredness	28	2.2 (0.2)	28	1.0 (0.2)	−1.3 (0.2)
PedsQL total score[b]	24	68 (3)	25	83 (2)	16 (4)[c]

[a]Scratching score and sleep parameters values are at weeks 21−24, bile acid values are at the average of weeks 20 and 24, and PedsQL scores are at week 24. [b]PedsQL total score range: 0−100 (higher scores indicate improved quality of life). [c]n=23 patients. PedsQL, Pediatric Quality of Life Inventory.

4618-C | PREVALENCE AND CHARACTERISTICS OF NON-ALCOHOLIC STEATOHEPATITIS (NASH) AMONG PEDIATRIC POPULATION IN THE UNITED STATES: A CROSS-SECTIONAL STUDY USING MARKETSCAN® DATABASES

Xiao Zhang[1], Tongtong Wang[1], Xinyue Liu[1], Gail Fernandes[1], Samuel S. Engel[2] and Ravi Shankar[1], (1) Merck Sharp & Dohme LLC, a Subsidiary of Merck &

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

Co., Inc., Rahway, NJ, USA, (2)Global Clinical Development, Merck & Co., Inc., Rahway, NJ, USA

Background: Non-Alcoholic Steatohepatitis (NASH) is the most rapidly increasing indication for liver transplantation in the United States and is associated with obesity, type 2 diabetes (T2D), and metabolic syndrome. There are limited epidemiologic data in the pediatric population (< 18 y) and its subgroups. This cross-sectional study was conducted to estimate the prevalence of NASH in the pediatric population overall and by subgroups including age, sex, obesity, T2D, and metabolic syndrome. **Methods:** IBM® MarketScan® Commercial Claims and Encounters Database (CCAE) and IBM® MarketScan® Multi-State Medicaid Database (Medicaid) were used for the analyses. Pediatric patients who had ≥ 1 medical encounter from 01-JAN-2020 to 31-DEC-2020 with ≥ 6 months of continuous enrollment before the most recent medical encounter were included. NASH was confirmed if an International Classification of Diseases, 10th Revision (ICD-10-CM) diagnosis code for NASH (K75.81) was present in patient's medical history. **Results:** As shown in Table 1, a total of 1,476 and 410 pediatric NASH patients were identified in Medicaid and CCAE databases, with a prevalence of 0.036% (95% confidence interval (CI): 0.034%-0.038%) in Medicaid, as compared to 0.011% (95% CI: 0.010%-0.012%) in CCAE. In both databases, prevalence of NASH increased by age, and NASH was more prevalent in those who were male, obese, had T2D, and had metabolic syndrome. Among all pediatric NASH patients, majority were ≥ 10 years old, male, and obese. **Conclusion:** In this cross-sectional study, we found that the pediatric population who were older, male, obese, had T2D, or had metabolic syndrome had a higher prevalence of NASH. Slightly higher prevalence was identified in Medicaid than CCAE, potentially due to the underlying different enrollee makeup in the two databases. Despite the potential underdiagnosis of NASH and the limitations of claims databases in real-world setting, the low observed prevalence may suggest a low overall NASH prevalence in the US pediatric population. Additional studies in the population are required to better quantify disease burden and subgroups that might have a higher risk of the disease.

Table 1. Prevalence of NASH in pediatric population (aged < 18 years), overall and by subgroup, based on IBM® MarketScan® Commercial Claims and Encounters Database (CCAE) and IBM® MarketScan® Multi-State Medicaid Database (Medicaid)

	Medicaid				CCAE

f 4619-C | SARCOPENIC OBESITY CORRELATES WITH HEPATIC STEATOSIS, BUT NOT INSULIN SENSITIVITY, IN ADOLESCENTS WITH OVERWEIGHT AND OBESITY

Julia M Boster[1], Melanie G Cree[1], Megan M Kelsey[1], Kristen J Nadeau[1], Alexander Chaidez[2], Zhaoxing Pan[3] and Shikha S. Sundaram[2], (1)University of Colorado Anschutz Medical Campus and Children's Hospital Colorado, (2)Children's Hospital of Colorado and University of Colorado School of Medicine, (3)University of Colorado School of Medicine

Background: Sarcopenic obesity (SO) is characterized by concurrent increased fat mass and decreased muscle mass and is associated with adverse cardiometabolic outcomes in adults. The incidence and implications of SO in childhood and adolescence are poorly understood. This study aimed to assess pediatric SO and determine its relationship with hepatic steatosis and insulin sensitivity. **Methods:** This is a secondary analysis of dual energy x-ray absorptiometry (DXA) data collected across 7 metabolic studies in adolescents with a range of BMI's at the University of Colorado. Appendicular lean mass (ALM) measured by DXA was used to calculate skeletal muscle mass index (SMI (%) = ALM(kg)/weight(kg)x100). Liver, visceral, and subcutaneous fat were measured with MRI and fasting laboratory assessments for insulin sensitivity (HOMA-IR, 1/fasting insulin) were collected. Spearman correlation was used to assess the relationship between SMI, fat distribution (liver, subcutaneous, and visceral fat), and insulin sensitivity. **Results:** SMI was calculated in 230 adolescents with overweight/obesity (OO, mean age 15.2 ± 2.4 y, mean BMI 18.7 kg/m^2, 88% female) and 76 with lean weight (LN, mean age 13.7 ± 2.6 years, mean BMI 34.3 kg/m^2, 59% female). Adolescents with OO had a significantly lower mean SMI than LN controls

(23.7 ± 2.9% vs 31.8 ± 4.5%, $p < 0.001$). In OO, SMI inversely correlated with percent liver fat ($r = -0.26$, $p < 0.001$), visceral fat ($r = -0.42$, $p < 0.001$), and subcutaneous fat ($r = -0.52$, $p < 0.001$) (Figure 1A-C). SMI had a weak inverse correlation with fasting glucose ($r = -0.20$, $p = 0.004$) and hemoglobin a1c ($r = -0.15$, $p = 0.04$) but not with HOMA-IR or 1/fasting insulin ($r = -0.02$, $p =$ NS). SMI also correlated inversely with leptin ($r = -0.65$, $p < 0.001$) and adiponectin concentrations ($r = -0.15$, $p = 0.03$). **Conclusion:** As assessed by SMI on DXA, a significantly lower proportion of body weight is made up of muscle mass in adolescents with OO as compared to LN controls, indicating that SO is already present in a young age group. SO correlates with increased hepatic steatosis and visceral and subcutaneous adiposity, but less so with markers of insulin sensitivity, in adolescents with OO. As such, interventions targeting muscle health and function starting in childhood and adolescence may be important in the management of pediatric NAFLD. Future studies using more robust measures of insulin sensitivity are needed to identify predictive cut-off values for pediatric SO.

4620-C | SUCCESSFUL RESOLUTION OF ACUTE NEONATAL LIVER FAILURE AND SECONDARY AKR1D1 DEFICIENCY BY ORAL CHOLIC ACID REPLACEMENT THERAPY

Kenneth David Reginald Setchell[1], Sarah Keeme[2], Kathy Campbell[1] and Amy Feldman[3], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2) University of Colorado Denver School of Medicine and Children's Hospital Colorado, Aurora, CO, (3)University of Colorado

Background: Bile acid synthesis disorders (BASD) are a well-established class of metabolic liver disease. Hepatotoxicity is caused by a lack of synthesis of the normal primary bile acids that promote bile flow and accumulation of atypical bile acids and intermediary metabolites. In the Δ^4-3-oxosteroid 5b-reductase (AKR1D1) deficiency, the second most common BASD, accumulation of hepatotoxic/cholestatic Δ^4-3-oxo bile acids that cannot be transported across the canaliculus, causes severe neonatal liver disease with rapid progression to cirrhosis. Diagnosis is complicated by the fact that Δ^4-3-oxo bile acids are often transiently elevated in the urine of healthy infants during early life and also a feature of end-stage disease. Cholic acid therapy, approved for primary BASD has not been studied as an adjunctive therapy in patients with a 'secondary' AKR1D1 deficiency from acute or advanced liver disease. **Methods:** Presented is a case of a patient with Neonatal Acute Liver Failure (NALF) with elevated atypical Δ^4-3-oxo bile acids that subsequently was proven by genetic analysis to be a 'secondary' AKR1D1 deficiency. Cholic acid (Cholbam (10 mg/kg bw/day) treatment led to a complete resolution of liver failure. The patient was a male born in NALF with extensive negative evaluation and found on urine fast atom bombardment ionization mass spectrometry (FAB-MS) to have an AKR1D1 deficiency. Due to clinical deterioration, and with this finding, cholic acid therapy was started on day of life (DOL) 8 and he was evaluated for liver transplantation on DOL 9. Rapid whole genome sequencing was pending at the time of cholic acid initiation. **Results:** Rapid whole genome sequencing did not identify a primary AKR1D1 deficiency. Despite this, his NALF rapidly improved after initiation of cholic acid, and he was discharged by DOL 38 without a need to list for transplantation. By DOL 84, his liver biochemical testing improved and cholic acid was discontinued. Subsequent urine FAB-MS analysis revealed a normal profile with a disappearance of the atypical Δ^4-3-oxo bile acids consistent with a complete resolution of his 'secondary'AKR1D1 deficiency. **Conclusion:** Neonates in NALF with a biochemically confirmed 'secondary' AKR1D1 deficiency may show a successful clinical response to cholic acid therapy.

4621-C | A KNOCKIN BSEPE297G MOUSE PRESENTS WITH CHOLESTASIS AND IS A NOVEL TRANSLATIONAL MODEL OF PFIC2

Eric Bell[1], Jennifer Truong[1], Patrick Stoiber[1], Youhwa Jo[1], Renata Franca[1], Eitan Hoch[1], Yong Ren[1], Alastair Garfield[1] and Jonathan Moore[2], (1)Rectify Pharmaceuticals, (2)MIT

Background: Progressive Familial Intrahepatic Cholestasis type 2 (PFIC2) is a rare pediatric liver disease caused by genetic variants in the bile salt export pump (BSEP, *ABCB11*). The E297G variant is one of the most prevalent drivers of PFIC2 (when inherited biallelically), leading to impaired bile acid efflux and consequential hepatic accumulation and toxicity. Here, we present a novel PFIC2 mouse model harboring the $BSEP^{E297G}$ variant. Characterization of this mouse demonstrates its recapitulation of key translational aspects of the human disease and can serve as a new tool to evaluate novel therapeutics for the treatment of PFIC2. **Methods:** $BSEP^{E297G}$ knock-in mice were generated using CRISPR/Cas9-mediated gene editing in congenic C57BL/6 zygotes. Comprehensive phenotyping of the male and female wildtype (WT), heterozygous (HET) and homozygous (HOM) mice was undertaken from 6 weeks of age to assess clinically relevant markers of progressive cholestasis, liver damage and PFIC2 pathophysiology. Including, serum, biliary and liver bile acid concentration, bile acid composition, liver enzymes, gene expression and liver histopathology. **Results:** HOM $BSEP^{E297G}$ mice recapitulate the key clinical aspects of PFIC2. While females exhibited a more severe disease phenotype, both sexes demonstrate the hallmark presentation of cholestasis and hepatoxicity. Female HOM $BSEP^{E297G}$ mice exhibited progressive increases in serum total bile acids (TBA), and markers of liver damage from 6 to 12 weeks of age. As predicted, no significant change in GGT was observed. At 12 weeks serum TBA was increased 92%, and ALT and ALP were increased 48% and 88%, respectively. Importantly, biliary TBA content was dramatically decreased by 82% while liver TBA increased 203%, consistent with BSEP insufficiency and cholestasis. Furthermore, *in vitro* bile acid efflux capacity of primary hepatocytes isolated from the livers of $BSEP^{E297G}$ mice highlighted a gene dosage impact of the E297G variant. **Conclusion:** HOM $BSEP^{E297G}$ mice are a validated translational model of PFIC2 demonstrating the expected mechanistic and pathophysiological characteristics of the human disease. This model will significantly advance an understanding of the underlying molecular BSEP deficits driving cholestasis and provides a powerful *in vivo* platform to evaluate potential disease modifying therapeutics for the treatment of PFIC2.

f 4622-C | CELL-SPECIFIC EXPRESSION OF HIF1α ENABLES FXR AGONIST-MEDIATED PROTECTION FROM PARENTERAL NUTRITION ASSOCIATED CHOLESTASIS

Swati Ghosh[1], Michael W Devereaux[1], Karim C. El Kasmi[1] and Ronald J. Sokol[1,2], (1)Department of Pediatrics, University of Colorado School of Medicine, (2)Digestive Health Institute, Children's Hospital Colorado

Background: Parenteral nutrition (PN)-associated cholestasis (PNAC) is caused by chronic PN in the setting of intestinal injury/failure. Suppression of hepatocyte FXR signaling contributes to PNAC pathogenesis. Intestinally absorbed LPS and PN-derived phytosterols combine to activate hepatic macrophages to produce pro-inflammatory cytokines (e.g., IL-1β) which then suppress hepatocyte FXR signaling. Recently, we reported an anti-apoptotic role of an FXR agonist, GW4064, during PNAC (*Ghosh* et al.*,Hepatology Communication 2023)*.Hypoxia-inducible factor 1-α (HIF1α) is a transcription factor that plays a vital role in cell proliferation, survival and glucose metabolism in liver and macrophages. However, its role in PNAC is not known. Here we examined the interaction of HIF1α and FXR signaling in macrophages and hepatocytes in a PNAC mouse model. **Methods:** PNAC mouse model (oral DSSx4d followed by TPNx14d; DSS-PN) received GW4064 (30mg/kg/day) in PN solution (days 4-14 of PN; DSS-PN/GW4064). Macrophage specific HIF1α -knockout mice, Huh7, Raw 264.5 cells and THP-1 cells were used. **Results:** GW4064 treatment significantly reduced liver apoptosis in DSS-PN mice. Bulk RNA sequencing and qPCR showed increased *H19*, and decreased *HIF1a,* mRNA expression and its targets in DSS-PN liver. We performed RNA-immunoprecipitation and found HIF1α interacted with H19 and GW4064 treatment enhanced this interaction, which has been shown to be anti-apoptotic. GW4064 treatment induced *HIF1a* mRNA and its targets (*Slc2a2*, *Hk2* and *Vegfa*) in liver of DSS-PN mice. siRNA-HIF1α knockdown in Huh7 cells significantly reduced expression of *ABCB11*, *NR0B2 and ABCC2* with further reduced expression of

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

these genes in Huh7 cells incubated with IL-1ß + phytosterols, even in the presence of FXR agonist. HIF1α stabilization by the PHD inhibitor, DMOG, in Raw 264.5 macrophages prevented GW4064 from suppressing LPS-induced *Il-1b* expression. Macrophage specific HIF1α-knockout DSS-PN mice had decreased AST and ALT and upregulated mRNA of *Abcb11*, *Nrob2* and *Abcg5* relative to wild type mice. Moreover, in THP-1 monocytes line, GW4064 suppressed the LPS-induced increase in *IL-6* and *TNF* expression, and this inhibition was enhanced by siRNA-HIF1α. **Conclusion:** This study suggests that *inhibition* of HIF1α in macrophages may enhance FXR activation and enable its protective effects in PNAC. Conversely, *activation* of HIF1α in hepatocytes by GW4064 may also be protective in PNAC. Thus cell-specific modulation of HIF1α may have therapeutic benefit in PNAC.

4623-C | CHARACTERISATION OF A NOVEL BILE SALT EXPORT PUMP DEFICIENCY MOUSE MODEL WITH THE P.E297G MUTATION

Antonia Felzen, Milaine V Hovingh, Rick Havinga, Niels Mulder, Martijn Koehorst, Bart Van De Sluis, Jan Freark De Boer, Folkert Kuipers and Henkjan J. Verkade, University Medical Center Groningen

Background: Bile Salt Export Pump (BSEP) deficiency, or PFIC2, is a rare genetic liver disease. It often leads to end-stage cholestatic liver disease and need for transplantation. The p.E297G missense mutation with suggested residual BSEP function is associated with a milder course of disease and delayed need for transplantation. BSEP knock-out mouse models exist, but are unfit to study interventions aiming to improve BSEP function, due to complete absence of BSEP protein. No *in vivo* models with milder mutations are available. Therefore, we aimed to generate a p.E297G BSEP knock-in (KI) mouse model. **Methods:** The KI model was generated by CRISPR-Cas9 technology. Female and male KI mice (n = 8, each) and WT littermates (n = 7, each) were fed chow diet, terminated at age 14 weeks and characterized for BSEP expression and liver pathology. The BSEP transport capacity of was determined *in vivo* by measuring bile flow during IV administration of increasing dosages of the bile acid tauroursodeoxycholic acid (TUDCA). **Results:** Western blotting showed reduced BSEP protein expression in KI vs. WT livers, due to impaired BSEP glycosylation. The capacity to induce bile flow upon TUDCA administration was strongly reduced in KI mice (Figure). Median liver weight was increased in KI vs. WT mice (Females: 2.1g vs. 1.0g; Males: 2.3g vs 1.4g; each $P < 0.001$). Median plasma AST levels were also significantly increased in KI vs. WT mice (Females: 187 vs. 50 μmol/l; Males: 198 vs. 60 μmol/l , $P = 0.01$ and $P < 0.001$; resp.), as were median plasma ALT levels (Females: 160 μmol/l vs. 25 μmol/l; Males: 248 μmol/l KI vs. 30 μmol/l; $P = 0.02$ and $P < 0.001$; resp.). Histological analysis showed mild fibrosis in KI livers. **Conclusion:** The p.E297G mouse model displays marked liver pathology and provides a new model for BSEP deficiency with suggested residual BSEP function. We anticipate its importance for future *in vivo* testing of medications that stimulate residual BSEP functionality.

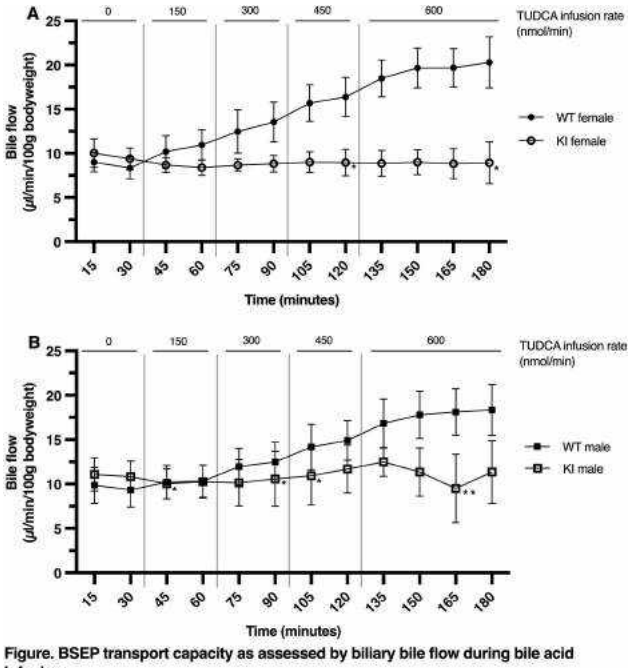

Figure. BSEP transport capacity as assessed by biliary bile flow during bile acid infusion.
Bile acid infusion was performed with TUDCA in female (A) and male (B) BSEP KI and WT mice (n=8 for all groups). The TUDCA infusion rate is depicted at the top of the graph. Bile was collected in time intervals of 15min. *Several KI mice did not survive until the end of the experiment. Data are expressed as mean ± SD. Statistics: interaction genotype-time: P<0.0001 in (A) and (B). *BSEP (bile salt export pump); SD (standard deviation); KI (knock-in); WT (wild-type); TUDCA (tauroursodeoxycholic acid).*

4624-C | CONCANAVALIN A MODELS THE INFLAMMATORY PHENOTYPE OF PEDIATRIC ACTIVATED T-CELL HEPATITIS/ ACUTE LIVER FAILURE

Tamir Diamond[1,2], MIchelle Lau[1], Niansheng Chu[1], Portia Kreiger[1,2] and Edward Behrens[1,2], (1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of Pennsylvania

Background: Pediatric acute liver failure (PALF) incidence in the United States is estimated at 500-600 cases annually with most patients not having a unifying diagnosis. Over the last decade, there has been growing evidence that the liver injury in many cases of indeterminate pediatric acute liver failure (iPALF) is mediated by a hyperinflammatory response. These patients have a dense hepatic infiltrate of effector tissue resident memory (TRM) CD8 T-cells (CD8+, CD103+ and perforin+) in liver tissue specimens with a transcriptional profile of activated IFNg pathways. Subsequently, our group has labeled this entity Activated T-cell Hepatitis (TC-PALF). To date there was no animal model that mimics the pathophysiology of TC-PALF. **Methods:** WT C57BL/6 mice (WT) females were treated with low dose (10mg/kg/dose) Concanavalin A (ConA), a lectin known to induce acute immune mediated hepatitis and fulminant necrosis in high doses (15-40mg/kg/dose) with goal to stimulate CD8 T cell response without significant tissue necrosis. Measurement of serum cytokines, splenocytes and intrahepatic leukocytes were performed 12 hours post conA injection. To study the interferon gamma response in hepatocytes *infgr* flox/flox-Albumin-cre mice from both sexes were treated with 5mg/kg/dose conA, and measurement of serum cytokines, ALT and intrahepatic leukocytes were performed 12 hours post injection and compared to controls. **Results:** Mice treated with ConA replicated the TC-PALF characteristics compared to PBS controls including elevated ALT (mean 2078 U/L SEM $\pm$530.3 vs.197.5U/L SEM $\pm$75.65 $P < 0.05$) (Figure 1A), serum soluble IL2-r (mean 1853 pg/mL SEM $\pm$144.5 vs. 582.3 SEM $\pm$ 109.2 $P < 0.0001$) (Figure 1B), and increase in percent of hepatic CD8 T cells (mean 32.86% SEM $\pm$ 1.077 vs. 18.65 SEM $\pm$ 1.247 $P < 0.001$) with predominance of effector TRM CD8 T cells (CD69+ CD103+ Granzyme B +) (Figure 1C and D). Those that lacked the hepatic IFNg response (*infgr* flox/flox-Albumin-cre) had moderate decrease in hepatitis measured by ALT (Figure 1E) and production of the IFNg induced chemokine CXCL9 (Figure 1F). In addition, serum sIL-2r, a marker for lymphocyte activation was decreased in *infgr* flox/flox-Albumin-cre group (Figure 1G), suggestive the intrinsic hepatic IFNg response is critical for lymphocyte activation in murine TC-PALF. **Conclusion:** Low dose ConA hepatitis models many feature of the immunological milieu of TC-PALF. Hepatocytes have an intrinsic IFNg response that contributes to hepatocellular injury and hypercytokinemia in this model. This model will assist with understanding the role of hepatic and non-hepatic IFNg response in pathogenesis of TC-PALF.

4625-C | FXR AGONIST INDUCED INTESTINAL FGF15/19 REGULATES FXR SIGNALING IN LIVER IN LITHOCHOLIC ACID DIET-INDUCED ACUTE CHOLANGIOPATHY MOUSE MODEL.

Swati Ghosh[1], Michael W Devereaux[1], Aimee Anderson[1], David J Orlicky[2] and Ronald J. Sokol[1,3], (1) Department of Pediatrics, University of Colorado School of Medicine, (2)Department of Pathology, University of Colorado, (3)Digestive Health Institute, Children's Hospital Colorado

Background: Lithocholic acid (LCA) containing diet in mice causes an acute cholangiopathy with hepatocyte necrosis. The aim of this study is to determine effects and mechanisms of FXR agonists (GW4064 and obeticholic acid [OCA]) in the acute LCA mouse model of cholestasis. **Methods:** Adult C57/B6 mice were fed either 1% LCA supplemented diet for 2 days or chow (controls). A group of mice received either i.v. GW4064 (30mg/kg/bw) or i.v. OCA (20mg/kg/bw) through central venous catheter daily for 2 days prior

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to and including the 2 days of the LCA diet. Huh7, THP1, and T84 human cells were also studied. **Results:** LCA mice had markedly increased serum AST, ALT and total bile acids; liver histology showed ductular reaction, macrophage infiltration and hepatocyte necrosis; and hepatocyte mRNA expression of *BSEP, Abcg8, SHP*, *LRH-1* and *MRP2* were reduced relative to chow mice. Biochemistry, histology and gene expression were all normalized by both of the FXR agonists, except *Cyp7a1* which remained suppressed. Hepatic mRNA levels of *Il-6,* and *Tnf* were elevated in the LCA mice; FXR agonist treatment markedly reduced these mRNA levels. We next determined that the i.v. FXR agonist induced ileal expression of *Fgf15*, *Nr0b2, Nr5a2,* and *Abcg5,* which were suppressed in LCA mice (except for *Fgf15).* ChIP assay showed that OCA increased the binding of FXR to the ileal *Fgf15* promoter. To determine if the protective effect of FXR agonists in this model involved the gut-liver FGF15/19 axis, a series of co-culture experiments were performed using T84 intestinal epithelial cells and Huh7 cells. Incubation of the T84 cells with LCA (100uM) in the presence or absence of OCA or GW4064 overnight was cocultured with Huh7 cells in lower insert. FXR agonist induced expression of *FGF19* and *SHP* in T84 cells which was surprisingly associated with upregulation of *Nr0b2* and *ABCB11* with downregulation of *CYP27A1* mRNA in Huh7 cells. Furthermore, treatment of Huh7 cells with FGFR4 inhibitor (H3B-6527) partially prevented OCA or GW4064 mediated upregulation of *BSEP* or *SHP* in Huh7 cells after exposure of T84 to LCA.Finally, recombinant FGF19 treated T84 cells induced *BSEP* and decreased *CYP27A1* expression in Huh7 cells, indicating hepatocyte FXR targets may also be regulated by FGF19. **Conclusion:** FXR agonists increase intestinal FGF19 by enhancing FXR binding to *FGF19* promoter, that then induces hepatocyte bile exporters to decrease bile acid levels in hepatocytes, thus alleviating LCA mediated hepatocyte injury.

4626-C | INVESTIGATION OF POLYMORPHISM IN THE GENE ENCODING MRGPRX4 AND PRURITUS SEVERITY IN CHOLESTATIC CHILDREN

Minna Rodrigo, Daphne Chien, James Limjunyawong, Xinzhong Dong and Wikrom Karnsakul, Johns Hopkins University School of Medicine

Background: Many pediatric patients who suffer from cholestatic liver disease also suffer from severe pruritus which is often refractory to antipruritic therapy. Mas-related G protein-coupled receptor X4 (MRGPRX4) is an itch receptor found in dorsal root ganglion sensory neurons that innervate the skin and is activated by bile acids. Additionally, cholic acid is a potent ligand for the MRGPRX4 receptor. However, the contribution of genetic variations in the gene encoding MRGPRX4 remains unknown. Among the single nucleotide polymorphisms (SNPs) harbored within coding regions of MRGPRX4, the most common missense SNP is Tyr54Cys (A to G mutation) with an allele frequency of 31.7%. Therefore, our study aimed to explore the potential association between Tyr54Cys and cholestatic pruritus in children. **Methods:** We conducted a case-control pilot study of children diagnosed with Alagille syndrome and Progressive Familial Intrahepatic Cholestasis (PFIC). Cases included individual's having one of these diagnoses who also experienced pruritus, while controls consisted of individual's with one of the above-mentioned diagnoses but without pruritus. Pruritus reports were obtained from both inpatient and outpatient records. The severity of pruritus was classified based on the number of prescribed antipruritic treatments (Table 1). Whole blood samples were collected from enrolled individual's and DNA was isolated and sequenced with a specific focus on Tyr54Cys. We investigated the correlation between this polymorphism and the degree of pruritus. Serum total and fractionated bile acid profiles were also performed in all cases. **Results:** We have sequenced DNA for four subjects, three of whom had Alagille syndrome and one who had PFIC3. As shown in Table 1, Patients A and B were 3-year-old males with Alagille syndrome and a history of mild/moderate pruritus. Their MRGPRX4 sequencing revealed heterozygosity for the G/A variant. Patient C, a 12-month-old male with Alagille syndrome and a history of severe pruritus, was found to be homozygous for the G/G at this site. Patient D, a 16-year-old male with PFIC, had no history of pruritus and was homozygous for the wild-type allele at this site. All subjects exhibited elevated levels of serum cholic acids, which correlated with patients' pruritus symptoms and their history of antipruritic therapy. **Conclusion:** In this cohort, the majority of patients experienced pruritus in the setting of their cholestatic liver disease. The only patient without pruritus exhibited above-baseline bile acid levels but was homozygous for the wild-type variant of MRGPRX4 at codon 54. Further investigation with a larger dataset is warranted and mechanistic studies aiming to determine if this mutation affects bile acid binding affinity or the receptor's signaling pathway are ongoing to provide a better understanding of the relevance of this SNP. Furthermore, the exploration of other SNPs in the MRGPRX4 gene is underway as well.

4627-C | L-CARNITINE PROTECTS AGAINST BILE ACID-INDUCED MITOCHONDRIAL DYSFUNCTION AND IGF-1 IMPAIRMENT IN RAT HEPATOCYTE CULTURES

Wafa'a Al-Qabandi, Mayra Alsaeid and Gursev Dhaunsi, Kuwait University

Background: Bile acids play a major role in many vital functions of the liver and several extrahepatic tissues; however, their excessive amounts are known to exert hepatotoxic effects. Aim of this study was to examine the effect of Glycochenodeoxycholic acid (GCDC) on mitochondrial function and Insulin-like growth factor (IGF-1) activity in hepatocyte cultures. **Methods**: GCDC (0-100 μM) was added to primary hepatocyte cultures in the presence /absence of L- Carnitine (L-Crtn). DNA synthesis was measured by bromo-deoxyuridine (BrdU) incorporation assay. Activities of the key mitochondrial enzymes Carnitine palmitoyltransferase-1 (CPT-1), Cytochrome c oxidase (COX) and Palmitoyl CoA oxidase (PCO) were assayed in cell homogenates. Gene expression of peroxisome proliferator activated receptor gamma coactivator 1-α (PGC-1α) and IGF-1 receptor was evaluated by RT-PCR. **Results**: GCDC was observed to significantly ($p < 0.01$) decrease the enzyme activities of CPT-1, COX and PCO. GCDC also significantly ($p < 0.01$) decreased the gene expression of PGC-1α. IGF-1-induced DNA synthesis and gene expression of IGF-1 receptor were significantly decreased in hepatocytes following GCDC treatment. Addition of L-Crtn (5mM) to hepatocyte cultures restored CPT-1 enzyme activity to nearly normal levels and markedly reduced GCDC-induced impairment of COX and PGC-1α, however, no marked effect was noticed on PCO activity. In addition, the gene expression of IGF-1 receptor in GCDC treated hepatocytes was significantly increased ($p < 0.05$) by L-Crtn. **Conclusion**: This study demonstrates that GCDC-induced hepatotoxic effects are possibly mediated through mitochondrial dysfunction and impairment of growth promoting IGF-1 activity. L-carnitine has potential beneficial effects against bile acid-induced cytotoxicity through upregulation of CPT-1 activity as well as gene expression of PGC-1α and IGF-1 receptor.

4628-C | LIVER DYSFUNCTION IN DOWN SYNDROME

Lauren Dunn[1,2], Kohl Kinning[1,2], Neetha Eduthan[1,2], Katherine Waugh[1,2], Paula Araya[1,2], Kyndal Schade[1,2], Keith Smith[1,2], Angela Rachubinski[1,2], David J Orlicky[1], Matthew Galbraith[1,2], Joaquin Espinosa[1,2] and Kelly Sullivan[1,2], (1)University of Colorado Anschutz Medical Campus, (2)Linda Crnic Institute for Down Syndrome

Background: Trisomy of chromosome 21 (T21) gives rise to Down syndrome (DS), a condition defined for decades by cognitive deficits, craniofacial anomalies, and a decreased lifespan. Research over the past 40 years has revealed a more complex picture of DS, characterized by an increased prevalence of numerous conditions including autoimmune disorders, heart defects, and Alzheimer's Disease. The diversity of this disease spectrum implies impacts of T21 across tissue systems. The nature of T21 and the presence of the extra chromosome in every cell type supports the hypothesis that DS is a multi-organ condition and should be studied as such. Although there are modest increases in biliary atresia and autoimmune hepatitis in DS, these conditions are extremely rare. Liver function in DS has been almost exclusively studied through the lens of transient abnormal myelopoiesis, a perturbation in fetal hematopoiesis which takes place in the liver and can be a precursor to pediatric leukemias. Several recent reports have identified widespread liver dysfunction via imaging-based methods (Valentini et al., 2017). Few studies, however, have examined the impact of T21 on liver function throughout development and into adulthood and none have aimed to elucidate the mechanisms by which this phenotype

occurs. **Methods:** Here we report the results from SOMAscan proteomic and metabolomic analyses of plasma from ~400 individual's in the Human Trisome Project Biobank, including more than 300 with DS. Using a mouse model of DS, we also report histopathology and transcriptome analysis of the liver, along with plasma proteome and metabolome measurements. **Results:** Our plasma proteomic and metabolomic analyses from individual's with DS revealed the dysregulation of several pathways consistent with liver dysfunction, broadly involving the immune system, protein synthesis, and metabolism. Consistent with previous work from our group, we report that the Dp16 mouse model of DS exhibits substantial liver pathology, including periportal inflammation and ductular reaction, without elevation of ALT or AST (Tuttle et al., 2020). Transcriptome analysis of Dp16 livers revealed potential mechanisms of pathogenesis and plasma samples show alterations of key biosignatures consistent with those seen in the human population. **Conclusion:** Individual's with DS may experience widespread liver dysfunction. Further research is needed to define the mechanisms driving liver dysfunction in DS, understand the role trisomy of human chromosome 21 plays, and elucidate potential therapeutic targets.

4629-C | NAT10-MEDIATED ac4C MODIFICATIONS PROGRAM JUVENILE NAFLD IN RESPONSE TO MATERNAL HIGH FAT DIET FEEDING

Ren Tianyi[1], Jiangao Fan[2], Qianren Zhang[1] and Rui Xue[1], (1)Department of Gastroenterology, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine,, (2)Department of Gastroenterology, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai 200092, China

Background: Growing evidence has shown that early life exposure to maternal high fat diet (HFD) during pregnancy and lactation increases the risk of non-alcoholic fatty liver disease (NAFLD) in juvenile offspring, which involves epigenetic machinery. As a novel epi-transcriptomic modification, ac4C could enhance the expression of target gene by increasing mRNA stability and translation efficiency. The aim of this study was to explore the involvement of ac4C and its writer protein NAT10 in maternal HFD-induced NAFLD. **Methods:** 6-week-old female C57BL/6J mice were fed either chow diet or HFD for 6 weeks before fertilization and kept on the same diet throughout gestation and lactation. Chow-fed male hepatocyte-specific *Nat10* knockout (*Nat10*^{HKO}) mice were mated with chow-fed or HFD-fed (6-week feeding before fertilization, maintained respective diets during gestation and lactation) female *Nat10*$^{fl/fl}$ mice to generate *Nat10*^{HKO} and *Nat10*$^{fl/fl}$ littermates which could be subdivided into 4 groups: chow *Nat10*$^{fl/fl}$, chow *Nat10*^{HKO}, HFD *Nat10*$^{fl/fl}$ and HFD *Nat10*^{HKO}. All pups were sacrificed at weaning to assess body weight, liver histopathology and lipid metabolism. Transcriptomic-wide mapping of ac4C modification was performed on mRNA samples isolated from primary hepatocytes of pups, with the aid of RNA-seq and acetylated RNA immunoprecipitation sequencing (acRIP-seq). **Results:** C57BL/6J offspring of HFD dams weighed more at weaning, exhibited higher hepatic triglyceride levels, had more hepatic lipid accumulation, expressed significantly higher NAT10, and presented markedly improved ac4C abundance in hepatocyte mRNAs, when compared with pups of chow C57BL/6J dams. Similarly, pups of the HFD *Nat10*$^{fl/fl}$ group exhibited more lipid droplets and triglyceride contents in livers than offspring from the chow *Nat10*$^{fl/fl}$ group. However, genetic ablation of *Nat10* in offspring hepatocytes markedly ameliorated hepatic steatosis induced by maternal HFD feeding. Moreover, hepatic expressions of lipogenesis-associated proteins, including SREBP-1c, phosphorylated ACC and FASN were also inhibited in HFD *Nat10*^{HKO} pups when compared with HFD *Nat10*$^{fl/fl}$ pups. The combined analysis of RNA-seq and acRIP-seq data showed that *Nat10* deletion led to significantly reduced ac4C abundance in *Srebp1c*, *Acc* and *Fasn* mRNAs, which was in line with suppressed transcriptional expressions and reduced half-lives of these mRNAs. Moreover, lipoprotein associated genes including *Fatp2*, *Apob*, *Mttp*, and *Apol9a* were also found downregulated in *Nat10*^{HKO} livers than *Nat10*$^{fl/fl}$ livers, due to almost diminished ac4C peaks in relevant mRNAs. *In vitro* experiments further confirmed that *Nat10* knockdown suppressed the ability of HepG2 cells to uptake and deliver lipids. **Conclusion:** NAT10-mediated ac4C modification played an important role in maternal-HFD-induced offspring NAFLD, which also serves as a potential therapeutic target.

4630-C | SINGLE-CELL ATLAS OF HUMAN PEDIATRIC LIVERS REVEALS A MYELOID SPECIFIC INFLAMMATORY SIGNATURE ENRICHED IN THE PEDIATRIC LIVER

Rachel D Edgar[1,2], Diana Nakib[1,3], Damra Camat[1,2,3], Jawairia Atif[1,2,3], Sai Chung[1,2,3], Catia Perciani[1,2,3], Lewis Liu[1,2,3], Xue Zhong Ma[2], Nilosa Selvakumaran[4], Justin Manuel[1,2], Blayne Sayed[2,4], Ian McGilvray[1], Koen Huysentruyt[4], Amanda Ricciuto[4], Yaron Avitzur[4], Gary Bader[3,5] and Sonya A MacParland[1,3,6], (1) University Health Network, (2)Toronto General Research Institute, (3)University of Toronto, (4)Sick Kids Hospital, (5)Donnelly Centre for Cellular and Biomolecular Research, (6)University Health Network, Toronto General Research Institute

Background: The liver is vital for metabolism and immune function. Although it is known that the liver is composed of a heterogeneous mix of cell types, how these cell types contribute individually, and in concert, toward liver function remains poorly understood. What is known about healthy liver function, cellular heterogeneity and cell structures is primarily based on studies of the adult liver. Comparatively little is known about the pediatric liver. To better understand cellular drivers of childhood liver diseases, including many rare metabolic and immune disorders, we generated single-cell RNA-seq (scRNA-seq) maps of the normal pediatric liver and employed this map to examine disease-specific populations in biopsies from pediatric patients with Intestinal Failure-Associated Liver Disease (IFALD). **Methods:** Here we integrated 10x Genomics scRNA-seq from adult normal, pediatric normal and pediatric IFALD livers for a total of 15 profiled livers. **Results:** The normal pediatric liver map consists of 20,519 cells from caudate liver lobes of 5 pediatric transplant donors aged 2-17 years. In comparison to an adult map (25,460 cells; age 26-69) we observed differences in myeloid populations in the pediatric liver. Specifically, pediatric Kupffer-like cells (*MARCO+C1QA+VSIG4+*) exhibited higher expression of inflammatory cytokines and chemokines than adults (*CCL4*, *CCL3* and *IL1-β*). Using the normal pediatric liver map as a comparator for three IFALD biopsies (12,015 cells; age 4 mo-9 y) we were able to identify myeloid cell populations specific to IFALD as well as higher expression of profibrotic genes (*LY96*) in IFALD Kupffer-like cells. **Conclusion:** The normal pediatric liver map will allow for further comparison of adult and pediatric livers, which could establish commonalities and pediatric-specific differences—an important issue as there are clear differences in pediatric and adult liver function. In addition the map will serve as an important comparator for the study of pediatric liver diseases.

Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, (3) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Cincinnati Children's Hospital Medical Center, Blue Ash, OH

Background: We recently reported a homozygous truncating mutation in the *ABCC12* gene encoding an ABC transporter, MRP9, in a child with idiopathic low GGT cholestasis and bile duct paucity. Subsequently, additional rare variants were detected in children with chronic liver disease. In CRISPR/Cas9 gene-edited zebrafish and mouse model organisms, *Abcc12* deficiency rendered cholangiocytes susceptible to bile acid-induced apoptosis. Here we examine the impact of *Abcc12* deficiency on biliary fibrosis progression. **Methods:** 45-day-old, male WT and *Abcc12-/-* mice were treated with 0.1% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) admixed to chow for 7 days prior to the assessment of liver fibrosis by image analysis of Sirius Red (SR) stained liver sections, serum liver biochemistries by colorimetry, and liver mononuclear cell composition by flow cytometry. Single-cell RNA-seq (scRNAseq) data from a time course study in WT mice challenged with DDC was mined for cellular crosstalk between biliary epithelial and stellate cells using CellChat. Bulk RNAseq was performed on intrahepatic cholangiocytes from neonatal WT and *Abcc12-/-* mice and from adult zebrafish of both genotypes. **Results:** Hepatocellular injury and cholestasis were aggravated in *Abcc12-/-* compared with WT mice following the DDC challenge, as indicated by higher serum ALT and total bilirubin levels (Figure A). Image analysis of Sirius Red stained liver sections revealed accelerated liver fibrosis (Figure B). Exacerbated cholestatic liver injury and fibrosis in *Abcc12-/-* mice was accompanied by expansion of hepatic Ly6C-low monocytes ($3.9 \pm 0.6\%$ vs $0.6 \pm 0.4\%$; $p = 0.0015$) and reduced number of CD4 lymphocytes ($1.3 \pm 0.3\%$ vs $12.9 \pm 1.0\%$, $p = 0.0003$) compared to WT. CellChat analysis of scRNAseq data from WT mice challenged with DDC predicted profibrogenic signaling from cholangiocytes to hepatic stellate cells involving the ligands - *Sema3/4*, Laminin (*Lam a1, Lam b2, Lam c2, Lam c3*), and *Gdf* (*Gdf9, Gdf15*). These genes were upregulated in cultured cholangiocytes from neonatal *Abcc12-/-* vs WT mice. Pathway enrichment analysis of RNAseq data of freshly isolated biliary cells showed upregulation of pathways indicative of defective maturation, tight junction formation, and epithelial-to-mesenchymal transition in *abcc12-/-* vs wt zebrafish. Expression of profibrogenic genes such as *tgfb3, fzd2*, and*Itgb3*was upregulated in mutant zebrafish cholangiocytes. **Conclusion:** *L*oss of *Abcc12*/MRP9 predisposes to profibrogenic gene expression leading to accelerated fibrosis in a mouse model of xenobiotic sclerosing cholangitis.

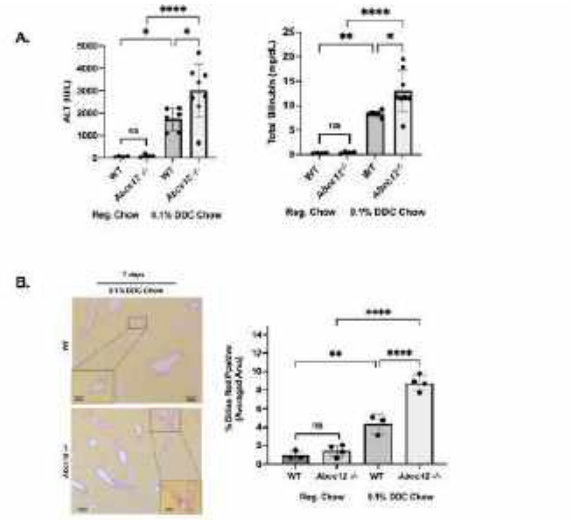

Fig1. *Abcc12-/-* deficiency contributes to liver injury. 4632-C | THE PROGRESSION AND COMPOSITION OF HEPATOBLASTOMAS WITH CARCINOMA FEATURES

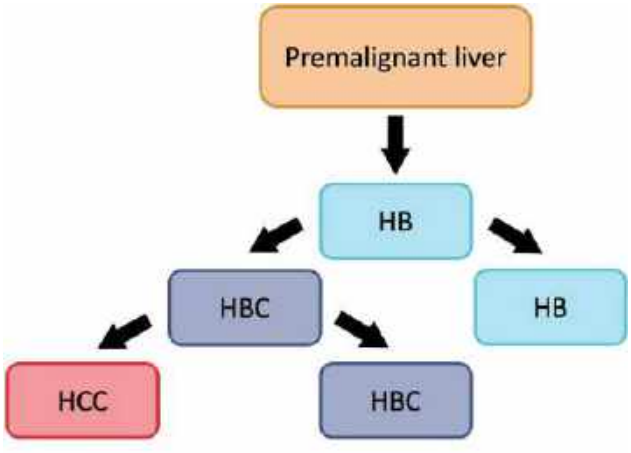
Xinjian Yu, Stephen F Sarabia, Martin Urbicain, Dolores Lopez-Terrada and Pavel Sumazin, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

Background: Liver cancer is a leading cause of cancer-related deaths, and its incidence in children is rising. Childhood liver cancers are commonly classified as either hepatoblastoma (HB) or hepatocellular carcinoma (HCC). HBs have an 80% overall survival rate and predominantly affect young children, while HCCs have an overall survival rate of 30% and predominantly affect older children and young adults. Interestingly, some studies pointed to hepatocellular cancers with shared HB and HCC histological and molecular features that are almost always associated with clinically aggressive features and poor outcomes (Prokurat et al., 2002; Eichenmüller et al., 2014; Ranganathan et al., 2020).

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Methods: We investigated neoplasms that display a combination of HB and HCC histological features, either across large tumor areas or focally using bulk RNA and DNA profiling in multiple tumor regions in search of recurring alterations and dysregulated genes and pathways. We also profiled RNA and DNA in select tumors and their models at single-cell resolutions. We compared molecular and clinical profiles across subclasses of these cancers and contrasted them with features of HBs and HCCs. **Results:** We showed that cancers with combined HB and HCC features are genetically heterogeneous and may be composed of subclones with features of fetal or embryonal HBs, features of HCCs, and other subclones that are distinct from both HBs and HCCs. Because of their overall shared histological, molecular, and clinical features, we designated these cancers HBs with HCC features (*HBC*s) and showed that HBCs have poor outcomes. In our single-institution study, high-dosage chemotherapy followed by complete resection or transplantation at early treatment stages significantly improved (hazard ratio 2.5X-4.3X at 95% confidence) outcomes. HBC patients that were treated with standard therapy had a 5-year survival rate of 30% (Sumazin et al., 2022). Our single-cell resolution profiles suggested that HBCs contain cells with both HB and HCC molecular features and that these cells exhibit common genetic alterations with HB-like and HCC-like cells found in the same tumors. Moreover, we proposed a diagnostic algorithm to classify patients into HBs, HBCs, and HCCs using a combination of molecular and histological features at diagnosis. **Conclusion:** Our analyses suggested that HBCs are molecularly, histologically, and clinically distinct from HBs and HCCs and that they include cancer cells with both HB and HCC features. Phylogeny analyses suggested that HBCs are derived from HB-like cells and may be precursors to HCC-like progenies, suggesting that HBCs are intermediate liver cancers. We proposed a model for HBC progression, as shown in the figure.



Hypothesized model for HBC genesis

4633-C | ALPHA FETOPROTEIN (AFP) LEVELS AND THE LIVER INJURY UNIT (LIU) SCORE PREDICT OUTCOME IN NEONATAL ACUTE LIVER FAILURE

Priya S. Rolfes, Shikha S. Sundaram, Ronald J. Sokol and Sarah A. Taylor, Children's Hospital of Colorado and University of Colorado School of Medicine

Background: Neonatal acute liver failure (NALF) is a rare disease for which there are currently no reliable prognostic indicators. Alpha fetoprotein (AFP) is an established biomarker for hepatic regeneration and is used in the diagnosis of gestational alloimmune liver disease (GALD), a leading cause of NALF. The Liver Injury Unit (LIU) score has previously been shown to predict outcomes in pediatric ALF, with higher scores predicting death or need for liver transplant (LT). We aimed to determine if there is an association between AFP level or the LIU score and outcome in patients with NALF. **Methods:** A single-center retrospective chart review from Jan. 2005 to Dec. 2022 was conducted on neonates $< / = 30$ days of life with NALF, as defined by an INR $> / = 2$ and liver dysfunction. Comparisons were made by outcome of survival with native liver (SNL) versus LT or death using the Mann-Whitney U test and Kaplan Meier Survival analysis. The predictive ability of lab tests was evaluated by receiver operating characteristic (ROC) analysis. **Results:** 54 patients (50% F) met inclusion criteria. Etiologies of NALF included viral infection (20%), GALD (20%), ischemic/cardiac (20%), genetic (13%), Trisomy 21-associated myelodysplasia (9.3%), hemophagocytic lymphohistiocytosis (3.7%), unidentified (9.3%), multiple diagnoses (1.9%), or other (1.9%). Median age at presentation was 5.5 days (IQR 1.0-11 d) and overall SNL was 44% ($n = 24$). There were no differences in age at presentation, gestational age, or birthweight between patients with or without SNL ($p > 0.05$ for all). AFP levels were available for 31/54 (57%) patients and were significantly higher in SNL patients ($p = 0.034$). AFP levels differed more significantly by SNL outcome among the 22 non-GALD patients ($p = 0.001$, Fig. 1A). Non-GALD patients with an AFP < 4775 ng/mL had 89% sensitivity and 100% specificity to predict death or transplant with an area under the ROC curve of 0.89. Among the full cohort with complete lab data ($n = 47$), LIU score differed

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significantly with a median score of 145 in SNL and 241 in non-SNL patients ($p < 0.001$). Stratification of patients by previously established LIU score quartiles showed significantly different rates of SNL ($p = 0.002$, Fig. 1B). **Conclusion:** AFP and LIU score may be useful prognostic indicators in NALF. Given that patients with GALD have very high AFP values (often > 100,000 ng/mL), the prognostic value of AFP is likely greater in NALF patients without GALD and may be helpful in transplant decision making.

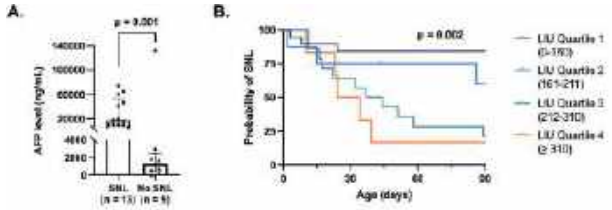

Figure 1. **A.** AFP values are significantly higher among non-GALD patients that survive without death or transplant. **B.** Kaplan Meier Survival analysis until death/transplant or age at last follow-up shows significant differences by LUI score quartile (data shown up to 90 days). LIU = 3.584 * peak total bilirubin (mg/dl) + 1.809 * peak PT (seconds) + 0.307 * peak ammonia (umol/L).

4634-C | EARLY EXTUBATION AS A PATHWAY TO RECOVERY AFTER PEDIATRIC LIVER TRANSPLANTATION.

Manpreet Kaur Virk[1], Muhammad Umair Mukhtar Mian[2], Thomas Fogarty[1], N. Thao N. Galván[3], Sanjiv Harpavat[4,5], Moreshwar S Desai[6] and Jorge Antonio Coss-Bu[1], (1)Baylor College of Medicine, Texas Children's Hospital, Houston, TX, (2)University of Missouri-Columbia, (3)Baylor College of Medicine, Houston, TX, (4)Texas Children's Liver Center - Baylor College of Medicine, Bellaire, TX, (5)Texas Children's Liver Center - Baylor College of Medicine, (6)Baylor College of Medicine

Background: Successful early extubation (EE) after liver transplantation (LT) has been shown to reduce ICU and hospital length of stay, infectious and vascular complications, sedation use, and has improved graft and patient survival. Though ideal, EE may not always be feasible in many recipients. Failed extubations and emergent reintubations can be catastrophic and can increase patient morbidity and mortality reversing any gains achieved from EE. Thus, it is important to identify those children who can benefit from EE so that failure rates can be minimized. Recent Early Recovery After Surgery guidelines in adults recommend all patients be screened for EE but no such guidelines currently exist for pediatrics, since little is known about predictors associated with EE after pediatric LT. Aim: We investigated the predictive factors associated with successful EE (within 24 hours of LT) in infants and children after orthotopic LT. **Methods:** We conducted a retrospective cohort analysis of children listed for LT (2011-2020) at a quaternary, free-standing children's hospital. Subjects with clinical (lab and ventilator parameters) and left ventricular mass indexed to height$^{2.7}$ and relative heart wall thickness (RWT) obtained on pre-LT 2D echocardiogram (2DE) were included Statistics: Fisher's Exact and Mann-Whitney tests to measure strength of univariate associations. **Results:** Median [IQR]. Results: Out of 338 (184;54% were female, 167; 49% with cirrhosis), 246 (73%) children successfully extubated on post operative day 0. When compared between early and delayed extubation; median age (months) 60 (20,142) vs 13 (8, 43), $p < 0.001$, weight 18 kg (11,38) vs 10 (8,15) $p < 0.0001$, PELD was 26 (12, 30) vs 26 (17,33) p ns, Total OR time (mins) 350 (321,391) vs 383 (341, 426) $p < 0.0001$, intraoperative blood loss (ml/kg) 7 (4,13) vs 18 (8,39) $p < 0.0001$, ICU LOS (days) was 3 (2,5) vs 22 (10,43) $p < 0.0001$, Hospital LOS (days) 13 (8,22) vs 51 (26,108); $p < 0.0001$. Of those patients not extubated on post operative day 0 ($n = 67$) median respiratory rate 28 (24, 32), V_t (ml/kg) 8 (7, 9), Peak Inspiratory Pressure (cmH_2O) was 22 (19,28), Peak End Expiratory Pressure (cmH_2O) 5 (5,7), Mean Airway Pressure (cmH_2O) 11 (9,13), inspiratory time (sec) 0.7 (0.6, 0.9), PaO_2 (mmHg) 195 (143, 251), LVMI (g/m2.7) 50 (39, 70) vs 72 (49, 97) $p < 0.0001$, and RWT 0.35 (0.31, 0.4) vs 0.37 (0.33, 0.42) $p = 0.003$. See table 1 for predictors of successful early extubation. **Conclusion:** Majority of patients in our cohort were successfully extubated within 24 hours post-LT. Several factors such as older age, normal LV geometry on 2DE, absence of cirrhosis, lower intraoperative blood loss and lower operative time are associated with successful EE. Early screening for eligibility and protocolized pathways are needed to accelerate liberation from mechanical ventilation and decrease overall morbidity in this population.

Table 1. Predictors of successful early extubation in children after liver transplantation

Variable	Odds Ratios	95% C.I.	P value
Age > 1 yr.	7.14	4.05 – 12.6	< 0.0001
Absence of cholestatic disease	2.72	1.65 – 4.48	< 0.0001
Absence of cirrhosis	1.78	1.09 – 2.89	0.0204
ABO liver compatibility	3.54	1.47 – 8.51	0.0047
No history of abdominal surgery	1.75	1.05 – 2.90	0.0316
Home before liver transplantation	6.21	3.69 – 10.5	< 0.0001
Absence of Cirrhotic Cardiomyopathy	3.53	1.98 – 6.29	< 0.0001

Analysis by univariate logistic regression; C.I.: confidence interval

f 4635-C | IDENTIFYING DRIVERS OF COST IN PEDIATRIC LIVER TRANSPLANTATION

Divya Sabapathy[1], Kathleen Hosek[2], Fong Lam[1], Moreshwar S Desai[1], Eric Williams[3], John A. Goss[1], Jean Raphael[1] and Michelle Lopez[1], (1)Baylor College of Medicine, (2)Texas Children's Hospital, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background: Pediatric liver transplant (LT) is a resource-intensive intervention with center-specific variation in practice and outcomes. Under the same regulatory purview as adult LT centers, pediatric centers face intense pressure to optimize outcomes and finances across a lower patient volume. Thus, there is need to characterize unnecessary variations in care, and identify actionable targets for performance improvement. We examined national resource utilization, and outcome patterns in pediatric LT to test the *hypothesis that there are unique hospital factors and modifiable drivers of cost associated with greater total cost of care.* **Methods:** We reviewed children (age < 21 y) receiving a LT from 2010-2020 in the Pediatric Health Information System. Repeat and dual-organ transplants were excluded. All Patient Refined Diagnosis Related Group (APR-DRG) classifications were used as a proxy for patient severity of illness (SOI) and risk of mortality (ROM). Primary outcomes of interest were total cost, both per LT and by service-line (Clinical, Pharmacy, Supply, Imaging, Lab, and Other). Secondary outcomes were: mortality, care complications, and key metrics of resource utilization, including total parenteral nutrition (TPN), and mechanical ventilation (MV). To facilitate comparisons, patients were stratified into high-, intermediate-, or low-cost hospital tertiles based on LT cost. Data were analyzed with summary statistics, and multivariable linear regression. **Results:** We identified 3295 patients from 30 hospitals. While the median cost per LT was $150,836 [IQR $104,481, $250,129], there was marked variance in cost within, and between, hospital tertiles (Figure 1). High-cost hospitals (HCH) cared for more patients with the highest SOI and ROM levels (67% and 29%, respectively), compared to intermediate (60%, 21%; $p < 0.001$), and low (51%,16%; $p < 0.001$) cost hospitals. There was a higher prevalence of MV, TPN use, renal comorbidities and surgical complications at HCH than other tertiles. Service-lines contributing most to total cost were: Other 37.3%, Clinical 26.1%, and Pharmacy 11.3% (Figure 2). Admission to a HCH was the largest, independent contributor to total cost ($154,003), followed by renal comorbidities ($67,798), and TPN use ($39,903). **Conclusion:** There exists significant variation in the cost of pediatric LT care. Future studies are planned to examine drivers of cost and associated clinical outcomes at a more granular level, with the goal of standardizing care. Such efforts may uniquely benefit the sicker patient cohort that require the strategic resources located within high-cost hospitals to achieve the best outcomes.

4636-C | Immediate Post-operative Infections After Liver Transplantation in Children

Elise Kang[1], Alicia M Alcamo[2], Danielle Maue[3], Fernando Beltramo[4], Asumthia Jeyapalan[5], Michael Nares[6], Alexandra Monde[7], Leslie Ridall[8], Sameer Kamath[9], Courtney M Rowan[3], Richard Mangus[10], Shubhi Kaushik[11], Matt S Zinter[12], Joseph Resch[13], Kristina Betters[14] and Mercedes Martinez[15], (1) New York Presbyterian, (2)Children's Hospital of Philadelphia, (3)Indiana University School of Medicine, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)Miller School of Medicine, (6)University of Miami-Miller School of Medicine, (7)Medstar Georgetown University Hospital, (8)University of Colorado, (9)Duke University School of Medicine, Chapel Hill, NC, (10) Indiana University Medical Center, (11)Icahn School of Medicine at Mount Sinai, (12)University of California, San Francisco & UCSF Benioff Children's Hospitals, (13)University of Minnesota, (14)Vanderbilt University School of Medicine, (15)Newyork-Presbyterian, Department of Pediatrics

Background: Post-operative Infections (POI) are a leading cause of morbidity and mortality after liver transplantation. Single-center studies have identified risk factors for early infections, but large-scale studies are lacking. **Methods:** We performed a retrospective, multi-center cohort study of pediatric liver transplant recipients from 2017-2018 at 12 US liver transplant centers. We assessed the association of pre- and peri-operative variables with POI that occurred while in the pediatric intensive care unit. Continuous data was compared using the Wilcoxon rank-sum test and categorical data with the chi-squared test. In addition, multivariable logistic regression was used to identify independent predictors of infection using stepwise backward

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

elimination for p-value > 0.3. **Results:** In the immediate post-operative period, 76/327 (23%) patients developed POI (49% bacterial, 9% viral, 13% fungal, 17% culture negative, and 12% polymicrobial). Abdominal/surgical site and bloodstream infections were most common at 29% and 26%, respectively. Compared to children without POI, POI patients were younger (median 1.0y [IQR 0.6-3.5] vs 3y [IQR 0.8–11], p < 0.001), more likely to have an underlying immunodeficiency (5% vs 0.4%, p = 0.011), and be hospitalized prior to transplant (49% vs 31%, p = 0.004). Further, POI patients were more likely to have open fascia (42% vs 20%, p < 0.001), longer duration of mechanical ventilation (median 2.4d [IQR 0.5-8.5] vs 0.6d [IQR 0.0-2.1], p < 0.001), allograft thrombotic complications (49% vs 18%, p < 0.001), and receive blood products (74% vs 46%, p < 0.001). In addition, patients with POI had longer hospital length of stay (median 23d [IQR 17-34] vs 13d [IQR 9-20], p < 0.001), more graft loss (9% vs 0.4%, p < 0.001), and mortality (5% vs 0.4%, p = 0.002). On multivariable analysis, independent predictors of POI included younger age (OR = 0.92 (95%CI 0.87-0.98), p = 0.006), history of immunodeficiency (OR = 12.6 (95%CI 1.3-122.9), p = 0.03), open fascia (OR = 3.3 (95%CI 1.8-5.9), p < 0.001), and hospitalization before transplant (OR = 2.0 (95%CI 1.1-3.5), p = 0.02). **Conclusion:** One in five patients developed POI in the immediate postoperative period. Predictors of POI included younger age, history of immunodeficiency, open fascia, and hospitalization prior to transplant. POI were associated with significant morbidity, including prolonged length of stay, graft loss, and mortality. These data support the need for prospective studies to better characterize POI risk factors and develop protocols to prevent POI to ultimately optimize graft and patient survival.

Table 1: Post-operative Infection Type, Location, and Variables Associated with Increased Risk of Developing Post-operative Infections after Liver Transplantation in Children

	Infection (n = 76)	No Infection (n = 251)	p - value
Pre-transplant Variables			
Age (years), median (IQR)	1.0 (0.6, 3.5)	3.0 (0.8, 11.0)	<0.001
Indication for transplant			0.4
Acute liver failure	7 (9.2%)	30 (12.0%)	
Chronic liver disease	39 (51.3%)	115 (45.8%)	
Malignancy	3 (3.9%)	18 (7.2%)	
Metabolic/genetic disease	27 (35.5%)	81 (32.3%)	
Re-transplantation	0 (0.0%)	7 (2.8%)	
Type of Graft			0.15
Whole	34 (44.7%)	136 (54.2%)	
Split	42 (55.3%)	115 (45.8%)	
Donor Type			0.43
Deceased Donor	67 (88.2%)	212 (84.5%)	
Living Donor	9 (11.8%)	39 (15.5%)	
History of immunodeficiency	4 (5.3%)	1 (0.4%)	0.01
Hospitalization prior to transplant	37 (48.7%)	77 (30.7%)	0.004
ICU prior to transplant	23 (30.3%)	49 (19.5%)	0.06
Peri-operative Variables			
Open fascia	32 (42.1%)	49 (19.5%)	< 0.001
Length of MV (days), median (IQR)	2.4 (0.5, 8.5)	0.6 (0.0, 2.1)	< 0.001
Thrombotic complication	37 (48.7%)	46 (18.3%)	< 0.001
Received blood products	56 (73.7%)	116 (46.2%)	< 0.001
In-Hospital Complications			
Length of stay (days), median (IQR)	23.0 (17.0, 34.0)	13.9 (9.0, 20.0)	< 0.001
Graft loss	7 (9.2%)	1 (0.4%)	< 0.001
In-hospital mortality	4 (5.3%)	1 (0.4%)	0.002

Type and Source of Early Postoperative Infections Amongst Pediatric Liver Transplant Recipients

Infection Type		Location of Infection	
Bacterial	37 (48.7%)	Surgical Site	22 (29%)
Viral	7 (9.2%)	Blood	20 (26%)
Fungal	10 (13.2%)	Culture Negative	18 (24%)
Culture Negative	13 (17.1%)	Respiratory	14 (18%)
Polymicrobial	9 (11.8%)	Urine	2 (3%)

4637-C | INVASIVE FUNGAL INFECTIONS IN CHILDREN ON LIVER TRANSPLANT WAITLIST: A LARGE SINGLE CENTER EXPERIENCE

Madelyn Cohen, Flor Munoz and Krupa Mysore, Texas Children's Hospital, Baylor College of Medicine

Background: Invasive fungal infections (IFIs) are associated with high morbidity and mortality in patients awaiting liver transplant (LT), and can often result in being delisted. Although well described in adults, the incidence and outcomes of IFI's in children awaiting LT is largely undefined. We aimed to assess the incidence, clinical manifestations, and outcomes of IFI in children on LT waitlist. **Methods:** Medical records of children listed for LT between January 2012 and December 2022 were retrospectively reviewed. IFI was defined as having histopathological evidence of fungal tissue invasion, isolation of fungal pathogen in blood culture or from a normally sterile body fluid or site, or imaging and clinical course consistent with IFI. Patients listed for multiple-organ transplantation, or who previously received LT were excluded. Statistical analyses were done on GraphPad Prism 9.3 **Results:** Twenty-four of 507 children (4.7%) listed for LT over an 11-year period had IFI; 12 (50%) were female, median age at listing was 7.6 yrs (IQR 0.7, 13.7 yrs). Median native PELD score at listing was 14 (IQR:8, 22). The most common infection was blood stream (12/24, 50%), followed by UTI (4/24, 17%) and peritonitis (2/24, 8%). Candida species were isolated in 20 (83%) cases, 2 had a mold. Biliary atresia (7/24, 29%) and other cholestatic liver disease (7/24, 29%) were major indications for LT. The median time to infection from listing was 28 days (IQR: 6, 171) overall. 11 (46%) patients with IFI died. Among patients who died, median age at listing was 9.1 yrs compared to 1.2 yrs in children who survived (p = 0.09). The median time from listing to IFI was 28 days in children who died and 9.5 days among survivors. The median time from infection to death was 11 days. The median time from infection to LT among survivors was 91 days. The number of children with decompensated cirrhosis (symptomatic ascites and/or a history of variceal hemorrhage) at listing was similar amongst the groups. There were no significant differences between baseline laboratory values at time of listing in

both groups including total bilirubin, INR, albumin, WBC, absolute lymphocyte count, platelets and renal function. The incidence of bacterial and viral infections, and antibiotic exposure in the month preceding IFI was similar amongst the groups. **Conclusion:** The incidence of IFI in children awaiting LT at our institution was 4.7%, and mortality was very high, approaching 50%, in patients with IFIs. Children who died of IFI were older and were infected later after listing, but otherwise had similar indications for LT, PELD scores, and liver laboratory indices at the time of listing. Candida species were the most common cause of IFI. In contrast to adults, the incidence of bacterial and viral infections was similar in both groups, suggesting that death may actually be associated with IFI in these children. Multicenter studies are needed to identify risk factors for IFI's in children on LT waitlist.

4638-C | MAKING THE INVISIBLE VISIBLE - UNCOVERING DISCREPANCIES BETWEEN PARENT AND CHILD/YOUTH REPORTS ON A PEDIATRIC LIVER TRANSPLANT PROM

Mary Flanagan[1,2], Tomisin John[1,2], Anthony Otley[3] and Vicky Lee Ng[1,2], (1)Division of Gastroenterology, Hepatology and Nutrition, the Hospital for Sick Children, Toronto, ON, Canada, (2)Transplant and Regenerative Medicine Centre, the Hospital for Sick Children, University of Toronto, Toronto, Canada, (3)Division of Gastroenterology & Nutrition, IWK Health Centre, Halifax, Canada

Background: Research on discrepancies between self- and proxy-reported patient-reported outcomes in children who have undergone liver transplantation (LT) is limited. The PeLTQL® is a validated disease-specific self- and proxy-reported HRQOL tool for children post LT, and is a non-stigmatizing option to screen for anxiety and depression. This study aimed to 1) evaluate and compare subjects identified as at risk of anxiety and depression and 2) describe discrepancies between self- and proxy-reported PeLTQL scores. **Methods:** PeLTQL completed by patient-parent dyads at LT clinic between 03/13-05/22 were reviewed. Each question is answered using a Likert scale from 1-5 (best to worst) and reversed scored to a 0-100 point scale (Likert 1 = 100 to Likert 5 = 0). PeLTQL scoring generates 4 scores (total score (PeLTQL-TS) and 3 subdomain scores (Future Health (FH), Coping & Adjustment (C&A) & Social-Emotional (SE)) with higher values indicative of better HRQOL. PeLTQL-TS $\leq$ 62.5 indicates risk for anxiety or depression ("at-risk"). Discrepancy was defined for each question as self response-proxy response. We targeted identification of specific questions with discrepant results of -100 (self response of 0 - proxy response of 100). **Results:** PeLTQL data from 139 patient-parent dyads were reviewed. Demographics, PeLTQL scores & discrepancies are provided in the table. Median self and proxy-reported PeLTQL-TS and subdomain scores were not statistically different. Questions about their surgical scar (20%), overly protective parents (16.5%) & hurting their allograft (14%) were most frequently of concern for patients. 22% patients were identified as "at-risk" with self report total and subdomain scores significantly lower than proxy scores. At-risk patients scored lowest in FH subdomain and the majority of questions with a "-100" discrepant result were related to FH (58%). At risk patients had increased concerns about their surgical scar (42%), overly protective parents (45%) and hurting their transplanted graft (29%). **Conclusion:** Parents of LT recipients identified to be at risk of anxiety or depression on disease-specific HRQOL questionnaires score their HRQOL significantly higher than their children, underscoring the importance of hearing the patient voice. Worries about future health and their scar are of particular concern for at-risk patients. These important mental health findings highlight opportunities for anticipatory guidance and targeted education by pediatric LT care teams.

Table: Patient demographics, clinical characteristics, PeLTQL scores & discrepancies of children post LT

		All (n=139)	At-Risk (n=31)	Not At-Risk (n=108)	p value
Patient Demographics & Clinical Characteristics

4639-C | Prophylactic Antimicrobial Usage Following Pediatric Liver Transplantation

Elise Kang[1], Alicia M Alcamo[2], Danielle Maue[3], Fernando Beltramo[4], Asumthia Jeyapalan[5], Michael Nares[6], Alexandra Monde[7], Leslie Ridall[8], Sameer Kamath[9], Courtney M Rowan[3], Richard Mangus[10], Shubhi Kaushik[11], Matt S Zinter[12], Joseph Resch[13], Kristina Betters[14] and Mercedes Martinez[15], (1) New York Presbyterian, (2)Children's Hospital of Philadelphia, (3)Indiana University School of Medicine, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)Miller School of Medicine, (6)University of Miami-Miller School of Medicine, (7)Medstar Georgetown University Hospital, (8)University of Colorado, (9)Duke University School of Medicine, Chapel Hill, NC, (10) Indiana University Medical Center, (11)Icahn School of Medicine at Mount Sinai, (12)University of California, San Francisco & UCSF Benioff Children's Hospitals, (13)University of Minnesota, (14)Vanderbilt University School of Medicine, (15)Newyork-Presbyterian, Department of Pediatrics

Background: Although clinical guidelines exist for antimicrobial prophylaxis following adult liver transplantation, consensus on pediatric-specific prophylaxis has not been established. Few single-center studies have assessed antibiotic utilization, but large-scale studies are lacking. **Methods:** We performed a retrospective, multicenter cohort study of pediatric liver transplant recipients admitted to the pediatric intensive care unit (PICU) from 2017-2018 at 12 US liver transplant centers. We assessed the utilization of prophylactic antimicrobials following transplantation. In addition, we examined differences in rates of post-operative infections in the PICU with antimicrobial prophylaxis usage as well as differences in antimicrobial usage if fascia remained opened post-operatively using chi-square tests. A p-value < 0.05 was considered significant. **Results:** Following transplantation, 91% (299/327) of patients received prophylactic antimicrobials. There was no significant difference in the post-operative infection rate between those with and without antimicrobial prophylaxis (29% vs 23%, $\chi^2 = 0.54$, $p = 0.46$). Significant variability existed in the utilization of various antimicrobials amongst different transplant centers. The most common antimicrobials included piperacillin-tazobactam (62%), fluconazole (42%), vancomycin (18%), and cefepime (10%). Patients with open fascia had higher rates of cefepime (22% vs 5%, $p < 0.001$), fluconazole (66% vs 32%, $p < 0.001$), metronidazole (20% vs 4%, $p < 0.001$), and vancomycin (54% vs 6%, $p < 0.001$) usage and lower rates of ceftriaxone (0% vs 8%, $p = 0.007$) and piperacillin-tazobactam (47% vs 66%, $p = 0.002$) usage compared to those without open fascia. Open fascia was associated with lower rates of prophylactic antibiotic usage (82.5% vs 94.3%, $\chi^2 = 10.80$, p-value $= 0.001$). 75% ($n = 21$) of patients without antimicrobial prophylaxis were limited to one center. Of the 76 children with post-operative infections, 65% were bacteria. The most common bacteria identified were *Escherichia coli* and *Staphylococcus epidermis*. 17% of post-operative infections were viral, all of which were respiratory infections. 13% were fungal, most commonly *Candida* species. **Conclusion:** Significant variability exists in antimicrobial utilization amongst pediatric liver transplant centers. Open fascia patients received broader spectrum antibiotics. Open fascia was also associated with lower rates of prophylactic antibiotic usage, likely reflective of infrequent antimicrobial prophylaxis use at certain centers. These data support the need for prospective studies to optimize antimicrobial regimens to reduce the risk of post-operative infections and develop protocols to ultimately optimize graft and patient survival.

Utilization of Antimicrobial Prophylaxis in Pediatric Liver Transplant Recipients

Antimicrobial	# of Patients	%
Ampicillin	1	0
Cefazolin	16	5
Caspofungin	2	1
Cefepime	32	10
Clindamycin	1	0
Ceftriaxone	20	6
Fluconazole	136	42
Metronidazole	28	8
Meropenem	16	5
Micafungin	18	6
Piperacillin-tazobactam	202	62
Vancomycin	60	18

Select Antimicrobial Prophylaxis by Open Fascia

Antimicrobial	Open Fascia (n= 81)	No Open Fascia (n = 246)	p-value
Cefepime	19 (22%)	13 (5%)	< 0.001
Ceftriaxone	0 (0%)	20 (8%)	0.007
Fluconazole	57 (66%)	79 (32.1%)	< 0.001
Metronidazole	17 (20%)	11 (4%)	< 0.001
Piperacillin-tazobactam	40 (47%)	163 (66%)	0.002
Vancomycin	46 (54%)	14 (6%)	< 0.001

4640-C | CAREGIVER-REPORTED SYMPTOM BURDEN AND PREFERENCES FOR THERAPEUTIC GOALS IN PEDIATRIC PRIMARY SCLEROSING CHOLANGITIS

Holly Payton Shifman[1], Joanne Hatchett[2], Ruth-Anne Pai[2], Ricky Safer[2], Rachel Gomel[2], Mary Pressley Vyas[3], Susan O'Dell[2], Sarah Curup Callif[2], Michael Li[4], Jennifer C. Lai[5] and Sharad Wadhwani[6], (1)Oakland University William Beaumont School of Medicine, (2) PSC Partners Seeking a Cure, (3)PSC Partners Seeking a Cure Canada, (4)University of California San Francisco, (5)University of California-San Francisco, San Francisco, CA, (6)University of California, San Francisco

Background: Primary sclerosing cholangitis (PSC) is a rare, chronic, cholestatic liver disease with no FDA-approved treatments available. Research focusing on pediatric patients with PSC is limited. We sought to characterize symptom burden and barriers to clinical trial enrollment for pediatric PSC patients and their caregivers. **Methods:** We analyzed survey responses from pediatric PSC patients and their caregivers using the PSC Partners Patient Registry 'Our Voices' survey. This registry, created in 2014, collects data on patient demographics, disease status, concurrent diagnoses, medications, clinical trial enrollment, and quality-of-life measures with the goal of incorporating patient experiences and priorities into drug development and clinical trial design. **Results:** Our analysis included 51 surveys (28M/23F) from pediatric PSC patients and their caregivers (90% caregivers, 10% patients). Most children were between 13 and 17 years old at the time of survey completion (67%), and the majority self-identified as White (88%) and non-Hispanic/non-Latino (88%). The most common symptoms reported by children include: fatigue (71%), abdominal pain (69%), anxiety (59%), loss of appetite (51%), insomnia (49%), and pruritis (45%). When experiencing symptoms at their worst, over half of the patients reported limitations in physically demanding activities (67%), work/school duties (63%), social life activities (55%), and less physically demanding activities for fun or exercise (53%). While more than 50% of patients/caregivers expressed willingness to participate in clinical trials, none of these patients reported current or previous enrollment in trials for new or investigational PSC drugs. Only one patient reported ever being asked to participate in a trial for investigational treatment of PSC. **Conclusion:** This study revealed substantial symptom burden among pediatric PSC patients and impact on daily activities and quality of life, as reported by both patients and caregivers. Despite the majority expressing willingness to participate in clinical trials, none had done so, indicating unmet needs in trial availability and accessibility for this population. Future efforts should focus on developing patient-centered clinical endpoints, increasing trial availability for pediatric PSC patients, and reducing logistical barriers to trial involvement.

f 4641-C | COMBINATION IMMUNOSUPPRESSION IS ASSOCIATED WITH BETTER NATIVE LIVER SURVIVAL IN CHILDREN WITH AUTOIMMUNE HEPATITIS PRESENTING IN ACUTE LIVER FAILURE: AN INDIVIDUAL PATIENT DATA META-ANALYSIS

Harry Sutton, Toronto Hospital for Sick Children, Aly Fawzy, University of Toronto, Shannon M. Vandriel, Hospital for Sick Children and Binita M. Kamath, The Hospital for Sick Children, Toronto, ON, Canada

Background: Autoimmune hepatitis (AIH) in children has diverse presentations, however when presenting in acute liver failure (ALF) it can be fatal and often requires liver transplantation (LT). LT may be avoided with immunosuppressive therapy (IS). Large cohort studies on paediatric AIH presenting in ALF are lacking and management of these patients varies. This Individual Patient Data Meta-Analysis (IPD) was conducted to characterize and examine management and outcomes in this population. **Methods:** This systematic review was conducted according to the Preferred Reporting Items for Systematic Review and Meta-Analyses of individual participant data (PRISMA-IPD) statement. Database searches were conducted in PubMed and Embase. English studies published between 2000-2020 were included. Included patients were those < 21 years of age presenting for the first time in PALF, defined by their local institution, diagnosed with type 1 or 2 AIH based on serum immunoglobulin levels, autoantibodies and liver histopathology. Exclusion criteria included positive hepatitis A-E serology, evidence of drug-induced liver injury, MDR3 deficiency or Wilson Disease, previous corticosteroid treatment, and LT not readily available at the reporting institution. Data extracted included clinical and biochemical characteristics, medical therapies and outcomes. **Results:** 325 patients from 61 identified studies, an additional five patients from our institution who met eligibility criteria were included for a total of 330 patients (Figure 1), 67% female, with a median age of 10 (range 6-14). Overall, 60% (n = 197/330) had native liver survival (NLS), 35% underwent LT (n = 116/330) and 5% (n = 17/330) died. The use of corticosteroids (CS) with a secondary IS conferred a 2.5-fold increase in the chance of NLS compared to CS alone (95% CI 1.3 – 5.1, $p = 0.008$). Patients with AIH-2 made up over one third (n = 25/68) of our cohort and were significantly younger at presentation in comparison to those with AIH-1 (6.9 y vs. 11.0 y; p = 0.044). AIH-2 was associated with a 3.3-fold increase in risk of LT or death compared to those with AIH-1 (95% CI 1.1- 10.0, $p = 0.03$). **Conclusion:** Children presenting for the first time with AIH in ALF have a good chance at native liver survival with IS therapy. The combination of two or more IS agents is associated with better NLS. AIH-2 is associated with worse outcomes in AIH-ALF. These data offer hope for NLS in AIH-ALF and suggest a need to identify biomarkers which predict which children require combination IS in order to avoid LT.

4642-C | INTRAHEPATIC TREGS IN POST-TRANSPLANT ALLOIMMUNE HEPATITIS DISPLAY AN ACTIVATED PHENOTYPE WITH ALTERED SUSCEPTIBILITY TO APOPTOSIS

Kumar Subramanian[1], Jhalen Ascue[2], Vinona Muralidaran[2], Nada A. Yazigi[3], Khalid M Khan[2], Bernadette E. Vitola[2], Stuart S. Kaufman[2], Alexander Kroemer[2], Thomas Fishbein[2], Eric Haas[4] and Udeme Ekong[1], (1)Medstar Georgetown Transplant Institute, (2)Medstar Georgetown University Hospital, (3)Medstar Georgetown University Hospital, Washington, DC, (4) Ionic Cytometry Solutions

Background: Post-transplant alloimmune hepatitis (DAIH) shares overlapping histologic and biochemical features with autoimmune hepatitis (AIH). Critical immune events that discriminate the two diseases remain unknown. We hypothesized that these immune events may occur in the regulatory T cell (Treg) compartment. We used mass cytometry & unsupervised clustering algorithm Flow self-organizing map (FlowSOM) to interrogate the distribution of subsets within *ex-vivo* $CD25^{hi}CD127^{lo/neg}FoxP3^{+}$ Treg in peripheral blood (PB) & liver (IH) of children with DAIH & non-transplanted children with AIH. **Methods:** Enriched $CD4^{+}$ T cells from peripheral blood mononuclear cells (PBMC) & intrahepatic lymphocytes (IHL) of children with DAIH (n = 5), AIH (n = 5), biopsy proven acute rejection (AR) (n = 3), liver transplanted children with graft dysfunction (n = 6), & liver transplanted children with normal graft function (LTC) (n = 14) were expanded in culture with Dyna beads CD3/CD28, rIL-2 & TGF-b for 5-days prior to FACS sorting of Tregs. For FACS sorting, Tregs were identified by high expression of CD25 & low expression of CD127. *Ex-vivo* sorted PB

and IH Tregs were then stained for mass cytometry with metal-conjugated monoclonal antibodies (CD49D, CD4, CCR4, CD45RA, CD3, CD39, FoxP3, CD95, CD45RO, CD25, CD152, HLA-DR, CD127, CD73, NRP1, Helios, LAP, CD45). Cells were acquired using a CyTOF Helios mass cytometer. CyTOF data was time-based bead normalized using standard procedures. The data were then uploaded to OMIQ (Omiq.ai), manually gated using Gaussian parameters to resolve live, intact, single cells for further analysis. Expression levels were arcsinh transformed with a cofactor of 5 and compared across disease groups within the Treg population. To further investigate the differences between disease states, clustering was performed using FlowSOM (Van Gassen, et al. 2015) & visualized using dimensionality reduction using UMAP (McInnes & Healy, et al. 2018). All statistical analyses were performed in GraphPad Prism v9 (Dotmatics). **Results:** Demographics reported in Table 1. 10 clusters identified within PB & liver Tregs that were different between DAIH and AIH patients, as well as between patients with DAIH and LTC subjects. Specifically, IH Tregs of DAIH patients were characterized by a higher expression of CCR4, Helios, CD95, and CD25 compared to IH Tregs of AIH patients ($p = 0.0037$; < 0.0001; 0.0004; 0.002 respectively) & IH Tregs of LTC subjects ($p = 0.0093$; < 0.0001; 0.0003; 0.004 respectively). PB Tregs of DAIH patients were characterized by a higher expression of Helios, CD25, FoxP3 compared to PB Tregs of AIH patients ($p = 0.0006$; 0.0021; 0.01 respectively). **Conclusion:** Intrahepatic Tregs of patients with DAIH are characterized by a more activated phenotype with altered susceptibility to apoptosis when compared to AIH patients. Improvement of Treg survival may hold a promising new therapeutic approach for patients with autoimmune liver disease.

4643-C | PEDIATRIC HEPATITIS C PATIENT CASCADE OF CARE IN A TERTIARY ACADEMIC MEDICAL CENTER UTILIZING AN INTEGRATED HEALTH SYSTEM SPECIALTY PHARMACY MODEL

Alicia B. Carver, Cori Edmonds, Kristen Whelchel, Ryan Moore, Leena Choi and Lynette A. Gillis, Vanderbilt University Medical Center

Background: Direct-acting antivirals (DAAs) received FDA-approval for treatment of hepatitis C virus (HCV) in ages 12-17 years in 2017 and ages ≥ 3 years in 2019. Pediatric hepatologists at the Monroe Carrell Jr. Children's Hospital Pediatric Hepatology Clinic at Vanderbilt began utilizing an integrated Health System Specialty Pharmacy (HSSP) model in 2017 to assist with DAA selection, insurance approval, dosage form administration practice, and treatment monitoring from medication initiation to sustained virologic response (SVR). The purpose of this study was to examine the cascade of care (CoC), describe barriers to successful CoC advancement and identify factors associated with the time from HSSP referral to medication initiation in this patient population. **Methods:** This was a single-center, retrospective cohort study of hepatitis C patients < 18 years old evaluated by a pediatric hepatologist at the Monroe Carrell Jr. Children's Hospital Pediatric Hepatology Clinic at Vanderbilt between January 2017 and September 2022. **Results:** 119 patients (male, 53%; white, 73%; median [interquartile range (IQR)] age, 5 years [5-8 y]; median [IQR] weight 22.1kg [15.05-32.95kg]) were included. In the CoC (Figure 1), 119 patients were evaluated in clinic, 73 (61%) were referred to the integrated HSSP, 69 (58%) successfully administered the practice dosage form, 64 (54%) received insurance approval, 64 (54%) initiated treatment, 64 (54%) completed treatment, 60 (50%) completed SVR labs, and 58 (49%) achieved SVR. Reasons for patient non-advancement through the CoC are included in Figure 1. In patients aged 3-5 years, 57% (35/61) failed to advance beyond clinic evaluation, whereas fewer patients aged 6-11 (21%; 9/42) and 12-17 (13%; 2/16) failed to advance beyond clinic evaluation to referral to the integrated HSSP. Overall, the most common reasons for non-referral were loss to follow-up (18%; 22/119) and negative confirmatory HCV testing (12%; 14/119). The time from integrated HSSP referral to medication initiation was impacted by DAA availability [OR = 41.47; $p < 0.001$] and successful administration of the practice dosage form at the initial clinic visit [OR = 3.94; $p = 0.004$]. **Conclusion:** Utilization of an integrated HSSP was effective in navigating pediatric HCV patients

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

through the treatment cascade to achievement of SVR. Ongoing efforts should focus on linkage to care following initial clinic evaluation, as it remains a challenge in this population. Delayed DAA availability lengthened time from HSSP referral to medication initiation, however, this was due to time period of the study. Although the ability to administer the practice dosage form also delayed time to treatment initiation, all patients able to administer practice dosage form at home successfully completed prescribed treatment course.

4644-C | PEDIATRIC HEPATITIS C PATIENT OUTCOMES IN A TERTIARY ACADEMIC MEDICAL CENTER UTILIZING AN INTEGRATED HEALTH SYSTEM SPECIALTY PHARMACY MODEL

Alicia B. Carver, Cori Edmonds, Kristen Whelchel, Ryan Moore, Leena Choi and Lynette A. Gillis, Vanderbilt University Medical Center

Background: Direct-acting antivirals (DAAs) received FDA-approval for treatment of hepatitis C virus (HCV) in ages 12-17 years in 2017 and ages ≥3 years in 2019. Pediatric hepatologists at the Monroe Carrell Jr. Children's Hospital Pediatric Hepatology Clinic at Vanderbilt began utilizing an integrated Health System Specialty Pharmacy (HSSP) model in 2017 to assist with DAA selection, insurance approval, dosage form administration practice, and treatment monitoring from medication initiation to sustained virologic response (SVR). The purpose of this study was to evaluate efficacy of DAAs in pediatric hepatitis C patients utilizing an integrated HSSP model. **Methods:** This was a single-center, retrospective cohort study of hepatitis C patients < 18 years old evaluated and referred to the integrated HSSP for DAA treatment consideration by pediatric hepatologists at the at the Monroe Carrell Jr. Children's Hospital Pediatric Hepatology Clinic at Vanderbilt between January 2017 and September 2022. **Results:** Of the 73 patients referred to the integrated HSSP, 64 (86%) successfully initiated DAA treatment. Reasons for not initiating treatment included: ongoing dosage form administration practice (5.5%; 4/73), loss to follow-up (4.1%; 3/73), treatment by outside provider (1.4%; 1/73) and pregnancy (1.4%; 4/73). Baseline characteristics of the 64 patients who initiated treatment are included in Table 1. Most patients (67%; 43/64) were prescribed a 12-week course of ledipasvir/sofosbuvir (LDV/SOF). All 64 patients who initiated treatment successfully completed the prescribed course. Fifty-eight patients (91%) achieved SVR; 2 (3%) were lost to follow-up, 2 (3%) are not yet eligible for SVR, 1 (1.6%) was reinfected, and 1 (1.6%) was a true failure. Just over half (53%; 34/64) of patients experienced at least one side effect, with nausea/vomiting (25%; 16/64), headache (20%; 13/64), fatigue (20%; 13/64), and sleep disturbances (8%; 5/64) being the most common. Less than half (31%; 20/64) of patients reported any missed doses. Most missed doses were due to vomiting (9%; 6/64) followed by medication administration difficulty (6%; 4/64). The patient who failed to achieve SVR reported 13 missed doses. Drug interactions were minimal (17%; 11/64) and all were managed by the pharmacist; most frequently by holding the interacting medication (9%; 6/64) followed by adjusting the timing of administration of the non-DAA medication (6%; 4/64). **Conclusion:** Utilization of an integrated HSSP model for insurance approval, initiation, and management of all-oral DAAs in pediatric hepatitis C patients yielded high rates of therapy completion and SVR.

4645-C | SCREENING FOR LIVER FIBROSIS IN PEDIATRIC/YOUNG ADULT PATIENTS WITH IBD ON METHOTREXATE: A SINGLE CENTER EXPERIENCE

Anne Lyon[1], Elif Ozdogan[1], Enju Liu[2], Nan Du[1] and Christine K. Lee[2], (1)Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital and Harvard Medical School, Boston, MA

Background: Methotrexate (MTX), an immunomodulator used to treat inflammatory bowel disease (IBD) has been reported to cause liver fibrosis and steatosis with long term use. There are limited adult studies assessing the prevalence of liver fibrosis in patients on MTX, with disparate results regarding association between MTX cumulative dose and risk of fibrosis. There have been no pediatric studies to date. Transient elastography (TE, FibroScanχ) is a non-invasive, ultrasound-based imaging study which can predict liver fibrosis by liver stiffness measurement (LSM) and steatosis by controlled attenuation parameter (CAP). Understanding the prevalence of MTX-associated liver side effects in children will be important to inform best practices for care of children with IBD. This study aimed to describe the LSM and CAP measurements for pediatric and young adult patients with IBD on MTX who underwent TE at Boston Children's Hospital (BCH). **Methods:** Patients seen in a BCH GI clinic with an IBD diagnosis, on MTX and who underwent TE study for clinical indications from 1/2015- 1/2023 were eligible for retrospective review. LSM with $>60\%$ success and interquartile/median ratio $<30\%$ were valid. Abnormal LSM was any measurement >6kPa and clinically significant fibrosis with an LSM >8.6kPa. Abnormal steatosis was defined as a CAP >215. **Results:** A total of 43 patients (median age 18.1y, 6.4-24.5 y, 65% males) met eligibility criteria with a diagnosis of Crohn disease in 39 (93%). The median ALT was 15 (IQR, 12-22) and MTX cumulative dose was 1950 mg (IQR, 1220-3310 mg). Median LSM was 4.5 kPa (2.8-7.8 kPa) with 5 patients (11.6%) with LSM $\geq$ 6 kPa and predicted fibrosis score of F1-2. Median CAP was 200 (102-361). Fifteen patients (34%) had a CAP score $\geq$ 215 (217-361) with a median BMI Z-score of 0.52 (N = 13, -1.2 to 1.88). MTX cumulative dose, MTX duration, age, BMI, ALT did not have a significant association with LSM or CAP. **Conclusion:** This is the first study using TE to assess liver fibrosis and steatosis in children/ young adult patients with IBD on long term MTX therapy. In this cohort of patients at a large quaternary pediatric hospital, there were 11.6% of patients with liver fibrosis and greater than 1/3 of patients (34%) with steatosis. While adult studies have had conflicting results regarding the significance of MTX on liver fibrosis/ steatosis, this may be due to a greater degree of metabolic factors in adults. In this pediatric population, the impact of MTX on liver fibrosis and steatosis was considerable enough to warrant future prospective, non-invasive investigation.

4646-C | SINGLE CENTER SURVEY OF PREVALENCE OF VIRUSES IN PEDIATRIC LIVER EXPLANTS

Adriana Perez, Phoebe Wood, Zachary J Savage, Olivia Vaccaro and Elizabeth Rand, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Adenovirus has been implicated as a cause of acute liver failure (ALF) following a global outbreak of adenovirus associated ALF in 2021. In order to understand the association between adenovirus and ALF it is important to know the baseline prevalence of adenovirus (and other childhood viruses) in the population of children undergoing liver transplant for acute and chronic liver disease. Various viruses are known to cause acute hepatitis with or without synthetic liver dysfunction. In 2021 clustered cases of "acute severe hepatitis" and ALF in young children were reported in association with adenovirus infection. For this reason, we have performed viral PCR for adenovirus, EBV, CMV, and HHV-6 on stored liver explant tissue collected as part of an IRB approved liver repository at the Children's Hospital of Philadelphia. Our objective was to perform retrospective evaluation of prevalence of hepatotropic viruses among children who underwent liver transplant at our center. **Methods:** We studied 33 frozen hepatic explant samples (originally collected between 2004 and 2021 and stored at -80 degrees) which fell into 3 categories; acute liver failure (ALF, n = 18; 13 indeterminate, 5 with specific diagnoses), acute on chronic liver failure (ACLF, n = 7),

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and chronic liver disease (CLD, n = 8). DNA was extracted via the Qiagen EZ system and accompanying EZ virus mini kit. Viral PCR testing was done using ThermoFischer QuantStudio Real Time PCR using commercially available primers with appropriate positive and negative controls. **Results:** Adenovirus was detected by PCR in a single case of indeterminate ALF transplanted in 2019 (1/18) and in none of the ACLF or CLD cases. CMV was detected in two ALF cases, one indeterminate (not the same as the adenovirus case) and one with bile acid synthesis defect, CMV was not detected in any other group. There were no EBV positive specimens in any group. As expected, HHV-6 was more prevalent, 21 of 33 specimens were positive including 12/13 indeterminate ALF cases; 2/5 specific ALF cases; 2/7 ACL; and 5/8 CLD. **Conclusion:** This retrospective study of the prevalence of common childhood viruses in liver explants provides important baseline information for those studying potential viral etiologies of acute liver failure. HHV-6 was observed in 21/33 (64%) of all liver explants even in stable outpatients with CLD underscoring the high prevalence but non-specific association with acute disease. HHV-6 prevalence did not statistically differ among our study groups.

4700-C | A HIGH-PERFORMANCE COMPUTING ANALYSIS OF CHOLESTASIS-ASSOCIATED GENE VARIANTS IN PATIENTS WITH CHOLESTASIS PHENOTYPE OF UNCLEAR ETIOLOGY

Jonas Schumacher[1], Toni Herta[1], Thomas Berg[2], Frank Lammert[3], Lutz Brusch[4], Susanne Weber[5], Michael Kuecken[4], Madlen Matz-Soja[1], Janett Fischer[1], Markus Casper[5], Albrecht Böhlig[1] and Irina Lambert[5], (1) Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany, (2)University Hospital of Leipzig, (3)Medizinische Hochschule Hannover Mhh, Hannover, Germany, (4)Tu Dresden, (5)Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany

Background: Heterozygous pathogenic mutations or common polymorphisms in genes encoding the hepatocanalicular transporters *ATP8B1*, *ABCB11* and *ABCB4*, or the bile acid ligand farnesoid X receptor (*FXR*) might contribute to liver injury in patients with an otherwise unexplained cholestasis phenotype. We aimed to determine the extent to which individual genetic variants of these transporters or their combinations play an etiopathogenetic role in patients with chronic unexplained cholestasis. **Methods:** Retrospective screening of patients of the University Medical Centre Leipzig identified a cohort of 234 patients with chronic unexplained cholestasis. Genotyping was performed using TaqMan assays, and the frequencies of *ABCB4* rs1202283 (c.504 T > C), *ABCB4* rs2109505 (p.711A > T), *ABCB4* rs2230028 (p.R652G), *ABCB4* rs2302387 (p.L59L), *ABCB4* rs45575636 (p.R590Q), *ABCB11* rs2287622 (p.A444V), *ABCB11* rs497692 (c.3084A > G), *ABCB11* rs11568367 (p.N591S), *ABCB11* rs58238559 (p.T175A), *ABCB11* rs11568372 (p.E297G), *ABCB11* rs72549402 (p.D482G), *ATP8B1* rs12968116 (p.R952Q), *ATP8B1* rs146599962 (p.N45T), *ATP8B1* rs34018205 (p.E429A), *ATP8B1* rs121909100 (p.I661T) and *FXR* rs56163822 (c.-1G > T) variants of the patient cohort were compared to a cohort of 254 healthy controls. High performance computing analysis was applied to correlate combinations of homo- or heterozygous genetic variants in *ATP8B1*, *ABCB11*, *ABCB4* and *FXR* with elevated liver enzymes in the patient cohort. **Results:** Heterozygous pathogenic mutations or any common polymorphisms in *ATP8B1*, *ABCB11*, *ABCB4* or *FXR* were similarly frequent in patients and controls (8.97% vs. 9.05%; 100% vs. 100%). Heterozygosity for the common polymorphism *ATP8B1* p.R952Q correlated with elevated serum bilirubin levels in the patient cohort ($p = 0.02$), and was more frequently found in patients as compared to controls (12.8% vs. 1.6%, $p < 0.0001$). No other single variant correlated with elevated liver enzyme activities. We next evaluated whether any combination of common variants showed an association with patients phenotype. Here the combination of heterozygous *ATP8B1* p.N45T (pathogenic) and the common homozygous SNP *ABCB4* c.504 T > C correlated with levels of serum alanine transaminase ($p = 0.009$), aspartate transaminase ($p = 0.006$), and gamma-glutamyltransferase ($p = 0.033$). This combination tended to be more frequent in patients than controls (2.16% vs. 0.4%, $p = 0.09$). The combination of homozygous *ATP8B1* p.R952Q and heterozygous *ABCB11* p.A444V correlated with serum alkaline phosphatase levels ($p = 0.001$). and was more frequent in patients as compared to controls (10.23% vs. 1.2%, $p = 0.0001$). **Conclusion:** Certain combinations of common genetic variants in cholestasis-associated genes show an association with cholestatic enzyme profiles and may be causally involved in the development of previously unexplained cholestatic liver injury.

Morgan[9], Julie Lynch[4] and Kyong-Mi Chang[2,6], (1)Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, PA, (2)Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, (3)VA Informatics and Computing Infrastructure, (4)VA Informatics and Computing Infrastructure (VINCI), (5) University of Pennsylvania, Philadelphia, PA, (6)Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA, (7)University of Pennsylvania, (8)Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (9)VA Long Beach Healthcare System

Background: Nonalcoholic fatty liver disease (NAFLD) is a leading cause of chronic liver disease. GWAS studies identified multiple NAFLD-associated genetic variants in large cohorts with NAFLD phenotypes based on clinical and radiological data. However, non-invasive assessments of NAFLD have limitations, and histopathologic evidence of inflammation and fibrosis remains the gold standard to diagnose and stage NAFLD-NASH. Thus, we aimed to isolate a biopsy-proven NAFLD cohort in the VA Million Veteran Program (MVP) mega-biobank using natural language processing (NLP) of liver biopsy reports for downstream genomic analysis. **Methods:** Using CPT codes for liver biopsy results (4700, 47001, 47100), the MVP database was searched via the VA informatics and computing infrastructure (VINCI) studymart tool. An annotation guideline was developed to extract labels such as steatosis, fibrosis and inflammation. Using this, 3 annotators independently reviewed 400 biopsy reports, with weekly adjudication based on overall concordance (Inter-annotator agreement or IAA) until achieving an IAA of > 90% for Steatosis and > 80% for Fibrosis and Inflammation. The finalized guideline was validated by 2 clinicians to confirm the NLP logic. These reports were then split into training and testing set of data which were used for the development of a rule-based NLP system. **Results:** We identified 9,687 MVP participants with liver biopsy reports between 2002-2020, with broad use of histologic scoring systems consistent with Kleiner, Knodell HAI, Scheuer, Ishak and Metavir. Our NLP approach identified hepatic steatosis in 3,449 participants including 29% with advanced fibrosis and 65% with inflammation, consisting largely of males (92%) with mean age of 56, diverse ancestry (69% white, 23% black, 7% hispanic) and enriched for obesity (68%), dyslipidemia (85%) and diabetes (81%). NLP performance scores were: Precision 0.922 (Steatosis)/ 0.969 (Fibrosis)/ 0.793 (Inflammation); Recall 0.972 (Steatosis)/ 0.714 (Fibrosis)/0.809 (Inflammation) and F1(harmonic mean of precision and recall): 0.946 (Steatosis)/ 0.822 (Fibrosis)/0.801 (Inflammation). **Conclusion:** We identified a diverse cohort of 3449 Veterans with biopsy-defined hepatic steatosis, fibrosis, and inflammation using an NLP algorithm with high scores for precision, recall, and F1 (> 0.8 for most domains). Further efforts are ongoing to confirm and optimize our method to uncover genetic associations with biopsy-proven NAFLD and NASH.

Category	N	Mean Age (SD)	Males	White	Black	Hispanic	Advanced fibrosis	Inflammation	T2D	BMI>30	Dyslipidemia
Total	9687	57 ± 9	93%	69%	23%	7%	29%	65%	77%	56%	79%
Steatosis+	3449	56 ± 10	92%	69%	23%	8%	29%	65%	81%	68%	85%

4702-C | DIFFERENTIAL RNA EXPRESSION AND EXPRESSION QUANTITATIVE TRAIT LOCI ANALYSIS IDENTIFIES NOVEL GENETIC VARIANTS ASSOCIATED WITH RECURRENT NONALCOHOLIC STEATOHEPATITIS (NASH) AFTER LIVER TRANSPLANTATION FOR NASH CIRRHOSIS

Christopher Danford[1], Richard Gilroy[2], Nephi Walton[2] and Bryce Christensen[2], (1)Intermountain Health, Millcreek, UT, (2)Intermountain Health

Background: Despite identical recipient genetics and similar recipient environmental exposures, only a minority (10-40%) of patients transplanted for NASH cirrhosis develop recurrent NASH post-transplant.[1] We hypothesize that the genetic profile of the donor liver may account for some degree of protection from recurrent NASH post-transplant. **Methods:** We included all patients who had previously undergone liver transplantation at Intermountain Medical Center for the indication of NASH cirrhosis who had at least one liver biopsy ≥ 6 months post-transplant with sufficient tissue for genotyping and RNA sequencing. The primary outcome was recurrent NASH on post-transplant biopsy. Secondary outcomes included hepatic steatosis without NASH and NASH with fibrosis on post-transplant biopsy. **Results:** We identified 8 patients with sufficient tissue for RNA sequencing in the Intermountain Biorepository. Four of 8 patients (50%) developed recurrent NASH and 3/8 (37.5%) developed recurrent NASH with fibrosis by a mean of 5.3 years post-transplant. Thirteen genes were found to be differentially expressed in those with recurrent NASH compared to those without. KEGG analysis identified "fatty acid metabolism", "biosynthesis of unsaturated fatty acids", "steroid biosynthesis", "retinol metabolism", and "PPAR signaling pathway" as those pathways most associated with differential RNA expression in recurrent NASH. Of these genes, four had liver-specific expression quantitative trait loci (eQTLs) meaning differential expression could be due to variants acquired from the donor liver (Table 1). Thirty-eight genes were differentially expressed in those with recurrent NASH and fibrosis compared to those without. Of these, eight had liver-specific eQTLs (Table 1). **Conclusion:** Studies evaluating the genetic underpinnings of NASH and cirrhosis have been limited by small patient population and inadequate patient phenotyping. In this study we demonstrate that by controlling environmental exposure and recipient genetics, we can identify several biologically plausible variants that modulate risk of recurrent NASH post-transplant despite small population. These results likely have implications for NASH outside the post-transplant population.

4703-C | GENE EXPRESSION OF HEPATOCELLULAR CARCINOMA BIOMARKERS ON LIVER TISSUE OF TYPE-2 DIABETES PATIENTS

Evelyn Calderon Martinez[1], Adalberto Guzman[2], Wern Lynn Ng[3], Fatma Yilmaz[1], Maria Joseph[1] and Christian Zevallos-Delgado[4], (1)Umpc Central PA, (2)University of Pittsburgh, Harrisburg, PA, (3)UPMC, (4)University of Houston

Background: Diabetes is one of the most common diseases in the world and it is projected to affect 693 million people in 2045. Obesity is a known risk factor for cardiovascular diseases, cancers, and diabetes. The liver is one of the many organs affected by diabetes and obesity. Diabetes can increase by 2 to 3-fold the risk of Hepatocellular Carcinoma (HCC) and exacerbate the progression of fibrosis in Non-Alcoholic Steatosis Hepatica (NASH). **Methods:** For this study, gene expression data uploaded by Pihlajamaki, J., et. al. was obtained from the Gene Expression Omnibus (GEO ID: GSE15653). This data was obtained from patients with Type 2 Diabetes (well and poorly controlled) and non-diabetic patients (lean and obese). The differential expression of genes (DEG) was assessed using GEO2R tool using the list of HCC gene biomarkers proposed by Zhou, Z. et al, Wang, X. et. al., and Gholizadeh, M. et al. **Results:** The results have shown that genes that have been found to be downregulated in HCC such as TAT (Tyrosine Aminotransferase)(p. adjs = 0.01363, logFC = 2.15), CYP2C9 (Cytochrome P450 family 2 subfamily C member 9) (p. adj = 0.0049, logFC = 3.23), and PTEN (Phosphatase and tensin homolog) (p. adj = 0.000575 and log FC = 2.39) genes are upregulated on liver samples from lean patients compared with poorly controlled diabetic obese patients. ASPM (Assembly Factor For Spindle Microtubules) (p. adjs = 0.02562, logFC = 3.37) which is normally is upregulated in HCC was found to be upregulated in on liver samples from lean patients. When comparing the above genes' expression between nondiabetic obese patients vs well-controlled diabetics, or well-controlled vs uncontrolled diabetics, or lean patients vs well-controlled diabetics, there was not a significant differential in expression. **Conclusion:** The dysregulated expression of HCC biomarkers on liver samples from obese poorly controlled T2D patients represents the importance of the hepatic damage due to uncontrolled-diabetes and obesity. In addition, a well-controlled diabetic patient has similar HCC-gene expression than a healthy lean patient.

4704-C | GENOMIC CHARACTERISTICS OF HEPATOCELLULAR CARCINOMA PATIENTS WITH RESPONSE TO SORAFENIB

Yim Sun Young[1], Ji Hoon Kim[1], Hyung Joon Yim[2], Yeon Seok Seo[1], Jong Eun Yeon[1], Young-Sun Lee[1], Taehyung Kim[3], Seong Hee Kang[4], Yoonseok Lee[1], Jong Su Kim[1], Chang Hee Jung[1] and Korea University Hospital, (1)Korea University Hospital, (2)Korea University Ansan Hospital, Ansan, Republic of Korea, (3)Korea University Ansan Hospital, (4)4 Seasons Granwell Corp.

Background: Sorafenib is a multiple receptor tyrosine kinase inhibitor which is the standard systemic therapy for advanced hepatocellular carcinoma (HCC). However, the objective response rate is low only reaching 10%. We implemented RNA sequencing (RNA-seq) in HCC tumors to identify potential biomarkers that would predict response to sorafenib and uncover underlying biological features associated with better response. **Methods:** A total of 33 patients who had undergone liver resection prior to sorafenib treatment were enrolled. Matched tumor/surrounding tumor tissues were obtained and RNA-seq was performed. Cluster analysis was performed and gene signature associated

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

with sorafenib response was identified. The gene signature was validated in independent STORM cohort. Gene network analysis by Ingenuity Pathway Analysis (IPA) was performed to uncover activated pathways and key upstream regulators associated with response to sorafenib. The composition of infiltrated immune cells in tumors was investigated using the CIBERSORTx algorithm. **Results:** The mean age was 58 ± 11 years with male predominance (81.8%), median CTP score was 5 (range, 5-8) and 57.6% of the patients switched to second-line chemotherapy mostly due to progression. The best response among 33 patients was complete response observed in 1 patient, partial response in two patients, stable disease in 12 patients while 18 patients showed disease progression. Gene signature (721 genes) associated with disease control (SD, PR, CR vs. no response) was derived using cluster analysis and was named as Korea University Sorafenib Response (KUSOR) gene signature. When applied on STORM cohort, KUSOR gene signature was able to predict patients who do not recur on adjuvant setting of sorafenib treatment after HCC resection or ablation with sensitivity of 91% and specificity of 74%. Gene network analysis by IPA revealed that patients who showed disease control were characterized by IL-6 and IL-1ß activation. In contrast, MYC was more activated in HCC tumors showing no benefit of the treatment, suggesting that MYC may trigger resistance of HCC cells to sorafenib. In addition, regulatory T cells (Treg cells) and M2 macrophage fractions were significantly higher in poor response group while the fraction of activated NK cells and CD4 cells were substantially higher in disease control group. **Conclusion:** Our study reveals that KUSOR gene signature identified patients who would show disease control when treated with sorafenib. MYC promotes hepatocarcinogenesis in chronic liver disease and overexpression is associated with poor response. It can also be inferred that poor response to sorafenib could be related immune evasion through overexpression of Treg cells and M2 macrophages in tumor microenvironment. Our study is in accord with previous studies where MYC activation was related to poor response to sorafenib indicating that combination therapy should be recommended in these patients.

4705-C | GENOMICS REVEALS MOLECULAR CLASSES OF MICROVASCULAR INVASION IN HEPATOCELLULAR CARCINOMA

Jingwei Wei[1], Xue Yang[2], Hongjun Li[2] and Jie Tian[1], (1) Chinese Academy of Sciences, Institute of Automation, (2)Beijing Youan Hospital Capital Medical University, Beijing, China

Background: HCC is a prevalent malignancy with dismal prognosis. Microvascular invasion (MVI) is a crucial independent risk factor for early postoperative HCC recurrence. Identifying genetic subtypes of MVI could aid in developing targeted therapies to reduce recurrence risk. This study aimed to analyze genomics data to elucidate the molecular mechanism underlying MVI. **Methods:** This study enrolled 83 HCC patients from Beijing Youan Hospital. Paraffin-embedded tissue specimens (tumor and peritumoral tissue) underwent quality control and pathological interpretation. Whole exome sequencing (WES) involved DNA extraction, quality evaluation, library preparation, hybridization capture-based sequencing, and subsequent bioinformatics analysis (data preprocessing, mapping, evaluation, variant detection, somatic mutation calling, filtering, and annotation). **Results:** Among the 83 patients, 40 (48.19%) were MVI-positive, while 43 (51.81%) were MVI-negative. A total of 12,394 non-synonymous somatic mutations were identified, predominantly missense mutations. The frequency of $T > C$ transitions differed significantly between the MVI-positive and MVI-negative groups (20.64 ± 5.46 vs. 23.91 ± 6.39, $p = 0.015$). Notably, the gene FLG showed a significant difference in mutation frequency between the MVI-positive and MVI-negative groups ($p = 0.017$). Six driver genes were identified in the MVI-positive group: four tumor suppressor genes (TP53, ALB, TSC2, and BRD7) and two oncogenes (CTNNB1 and MMP17). The mutation frequency of TSC2 was significantly higher in the MVI-positive group (40%) than the MVI-negative group (16.3%) ($p = 0.016$). Similarly, BRD7 exhibited a significantly higher mutation frequency in the MVI-positive group (47.5%) compared to the MVI-negative group (23.3%) ($p = 0.021$). Additionally, significant differences were observed in the copy number deletions of AXIN1 and CDH1 between the MVI-positive and MVI-negative groups ($p = 0.011$ and 0.017). Univariate logistic regression analysis indicated that gene variations in BRD7, TSC2, AXIN1, and CDH1 were associated with MVI grouping. In multivariate logistic regression analysis, only gene variations in CDH1 remained significantly associated with MVI grouping ($p = 0.007$). **Conclusion:** This whole-exome analysis provides insights into the genetic characteristics of

MVI in HCC patients, contributing to the understanding of the underlying molecular and physiological mechanisms and serving as a basis for targeted treatments for MVI.

4706-C | HIGHER PRE-TREATMENT HCV VIRAL LOAD RESETS POST-CURE INTERFERON-STIMULATED GENE (ISG) EXPRESSION IN THE PERIPHERAL BLOOD AND LIVER: EVIDENCE FOR INNATE IMMUNE TRAINING

Ang Cui[1,2], Bo Li[1,2], Jacinta A. Holmes[3,4], Michael S. Wallace[4], Anna L.K. Gonye[2,4], Christopher Oetheimer[4], Pierre Tonnerre[4], David Lieb[2], Aileen Ma[2], Kela Roberts[2], Marcos Damasio[4], Joelle Brown[4], Moshe Sade-Feldman[4], Jasneet Aneja[4], Eliana T. Epstein[4], Shadi Salloum[4], Arthur Y Kim[4], Georg M. Lauer[4], Nir Hacohen[2,4], Raymond T. Chung[4] and Nadia Alatrakchi[4], (1)Harvard University, (2)Broad Institute of MIT and Harvard, (3)St.Vincent's Hospital Melbourne, (4)Massachusetts General Hospital and Harvard Medical School

Background: Chronic viral infections, including HCV, involve a prolonged immune response and can potentially have a lasting effect on the host immune system even after the virus has been eliminated. While incomplete recovery of T cell functions has been characterized, less is known about alterations in innate immune architecture after HCV cure. Curative direct-acting antiviral (DAA) regimens, coupled with the availability of paired liver fine-needle aspirates (FNAs) and longitudinal peripheral blood mononuclear cells (PBMCs), provide a unique opportunity to assess the alteration of innate immune cell programs after the cure of chronic HCV infection. **Methods:** We studied 23 HCV patients before and after uniformly curative DAA treatment. ISG expression was quantified in liver myeloid cells using plate-based single-cell RNA-seq (scRNA-seq). ISG expression is also quantified in PBMCs using the NanoString technology (74 ISGs), with data being analyzed for gene expression relative to housekeeping genes. **Results:** Dynamic alterations in innate immune profiles were observed in both liver and blood after virus antigen removal, including an anticipated decrease in baseline elevated interferon-stimulated gene (ISG) expression during chronic HCV infection. We did not observe a direct correlation between ISG expression and viral load (VL) pre-treatment. However, we observed a directly inverse relationship between pre-treatment VL and post-cure ISG expression in myeloid cell types in the liver. This inverse relationship was reflected in the periphery as well, and patients with HCV VL > 800,000 IU/mL pre-DAA had significantly lower PBMC ISG levels 3 months post-DAA compared to patients with low pretreatment VL. **Conclusion:** Chronic high HCV viral load is strongly associated with a lower absolute level of basal ISG expression in the host post-cure. These findings support a resetting or training of innate immunity during chronic infection, which has implications for innate immune responses to future infections or disease development.

4707-C | INCREASED ELECTROSTATIC COMPLEMENTARITY BETWEEN PRIMARY TUMOR ADAPTIVE IMMUNE RECEPTOR CDR3 AND HEPATITIS C VIRUS EPITOPES CORRELATES WITH IMPROVED PATIENT SURVIVAL AND DIFFERENTIAL GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA

Joanna Song[1], Andrea Chobrutskiy[2], Boris Chobrutskiy[2], Konrad Cios[1], Taha Huda[1], Rachel Eakins[1] and George Blanck[1,3], (1)University of South Florida Morsani of Medicine, (2)Oregon Health and Science University Hospital, (3)H. Lee Moffitt Cancer Center and Research Institute

Background: Adaptive immune receptors (AIRs), e.g., immunoglobulins (IGs) and T-cell receptors (TCRs), have been identified in the tumor environment of many cancers. However, their features, such as the complementarity determining region-3 (CDR3), are not well studied in hepatocellular carcinoma (HCC), especially in the context of established contributors of HCC, such as chronic hepatitis C virus (HCV) infection. This project aims to better understand AIRs present in the HCC microenvironment and how CDR3s specificity to HCV antigens correlates with clinical features, including patient survival and gene expression. **Methods:** AIR recombination reads were recovered from primary tumor sample whole exome sequences (WXS) and RNA sequences (RNAseq) of 377 HCC cases in The Cancer Genome Atlas Liver Hepatocellular Carcinoma (TCGA-LIHC) dataset and WXS of 89 HCC cases in the Human Genome Sequencing Center at Baylor College of Medicine (HGSC-BCM) HCC dataset. Corresponding TCGA-LIHC TCR beta chain (TRB) and IG heavy chain (IGH) CDR3s were identified and used to compute electrostatic-based complementarity scores (CSs) with known HCV epitopes from the Immune Epitope Database. Cases were stratified by CSs to study association with overall (OS) and disease-free (DFS) survival distinctions via Kaplan-Meier analyses and gene expression distinctions via Pearson's correlation. CS calculation algorithm was benchmarked by comparing CSs produced from HCV-positive and HCV-negative cases in HGSC-BCM. **Results:** A 3:1 ratio of IG:TCR was observed in both the 189 and 106 recombination reads recovered from TCGA-LIHC and HGSC-BCM, respectively. Higher CSs between TCGA-LIHC TRB CDR3s and HCV epitope HCV*71871 correlated with increased DFS probabilities for CDR3s derived from WXS ($p = 0.0296$) and RNAseq ($p = 0.0327$). CSs from these two sets of CDR3s were also inversely associated with the expression of proliferation-related gene b-related factor 2 (BFR2) (WXS $p = 0.00718$, $R = -0.595$; RNAseq $p = 0.00466$, $R = -0.190$). Greater expression of BRF2 was linked to decreased DFS probabilities via KM analysis in HCC cases independent of CS ($p = 0.0316$). Higher CSs between TCGA-LIHC HCC IGH CDR3s and HCV epitope HCV*13458 as well as increased OS probabilities were observed for both WXS ($p = 0.0127$) and RNAseq ($p = 0.0189$) sources of CDR3s. HCV-positive HCC patients in HGSC-BCM showed greater CSs TRB CDR3s and HCV*71871 ($p = 0.0488$) as well as IGH CDR3s and HCV*13458 ($p = 0.0599$). These results indicated a predominantly humoral immune response to HCC from AIR recombination reads obtained from two independent sources. Increased complementarity of HCC-resident AIR CDR3s with two HCV epitopes were in correlation with better survival probabilities in HCC cases. **Conclusion:** This study demonstrates the potential use of CDR3 sequences as biomarkers for HCC patient stratification and as guides for therapeutic development.

4708-C | LONG-TERM PROGNOSTIC MODEL OF DECOMPENSATED CIRRHOSIS BASED ON MULTIMODAL CT IMAGING DYNAMIC LIVER VOLUME CHANGES

Qijuan Zang[1], Chengbin Zhu[1], Juan Li[1], Siyi Liu[1], Yingren Zhao[2] and Yingli He[2], (1)The First Affiliated Hospital of Xi'an Jiaotong University, (2)The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi, China

Background: Liver volume directly reflects liver capacity and the number of liver cells macroscopically and is an essential quantitative index to evaluate liver reserve function. During the progression of cirrhosis, alterations occur in the morphology and dimensions of the liver, with the liver volume remaining stable or exhibiting a relatively increase in early stages, followed by a reduction in volume during advanced stages, and a gradual decline in the liver's reserve function. Nevertheless, clinical implications of the dynamic changes in liver volume remains indeterminate. The objective of this study is to clarify the role of liver volume changes in the long-term prognosis of patients with decompensated cirrhosis. **Methods:** This retrospective study involved the analysis of 282 patients diagnosed with decompensated cirrhosis, with a median age of 54 years. The study utilized two abdominal computed tomography (CT) scans, conducted at baseline and at a 1-2-year follow-up, to measure liver volume and chest width, respectively, in order to calculate standard liver volume (ELV) and the rate of change of liver volume

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ratio (ΔLV/ELV%) over the course of 1 to 2 years. A COX regression analysis was employed to construct a prognosis model, and a normogram was established to further evaluate the results. The prognostic model's predictive efficacy was evaluated using the area under the subject operating characteristic curve (AUC), sensitivity, and specificity. The model's accuracy was assessed using the calibration curve, while the clinical practicability was evaluated through decision curve analysis (DCA). **Results:** The results of the multivariate COX regression analysis indicate that ΔLV/ELV% (OR:0.318,95% CI: 0.111-0.909) and albumin(ALB) (OR:0.931, 95% CI: 0.891-0.973) exhibit a protective effect on the prognosis of patients with decompensated cirrhosis, whereas alkaline phosphatase(AFP) (OR:1.004, 95% CI: 1.001-1.007) and alpha-feto-protein(AFP) (OR:1.005, 95% CI: 1.001-1.009) are associated with an increased risk of poor prognosis in such patients, suggesting the possibility of death competition in HCC. Prognostic models were developed based on the aforementioned factors, namely ΔLV/ELV %, ALB, ALP, and AFP, with corresponding C-indexes of 0.786(95%CI :0.761-0.810) and 0.752(95%CI 0.725-0.780). The LAAA method was employed to predict the AUC for 1-year, 3-year, and 5-year survival rates of decompensated patients, yielding values of 0.783, 0.806, and 0.796, respectively. The correction curve exhibits proximity to the ideal reference line, and the DCA curve demonstrates a significant improvement in the net benefit of the model. **Conclusion:** Dynamic liver volume change is closely related to the long-term prognosis of decompensated cirrhosis patients. The LAAA model, which is based on the Δ LV/ELV%, is deemed a reliable predictor of the long-term prognosis of patients with decompensated cirrhosis.

4709-C | MAXIMIZING INSIGHTS FROM WHOLE EXOME SEQUENCING TO ADVANCE DIAGNOSIS OF LIVER DISEASE

Chigoziri Konkwo, Joseph Brancale and Silvia M. Vilarinho, Yale School of Medicine, New Haven, CT

Background: Chronic liver disease (CLD) is the 11th leading cause of death worldwide. Up to 25% of patients with CLD have an unknown cause, and our group has previously shown that whole exome sequencing (WES) can provide a diagnosis in over 25% of these cases. Hence, approximately two-thirds of these patients remain undiagnosed. Thus, we hypothesized that annual re-analysis of undiagnosed cases, alongside modernizing of our WES pipeline would increase diagnostic rate. **Methods:** A new WES pipeline was developed by aligning individual sequences to the Human Pangenome Reference Consortium v1 pangenome and surjected to the linear GRCh38. Genetic variants were called with DeepVariant, and annotated with Annovar, Variant Effect Predictor, and SnpEff, incorporating novel pathogenicity prediction tools. In addition, we include annotation for liver cell type-specific gene expression extracted from our group's liver cell atlas. This WES pipeline also incorporates rare-variant phasing with SHAPEIT5, so allele-specific inheritance patterns for candidate compound heterozygous variants can be predicted. This pipeline was benchmarked against our standard GATK-based pipeline using a subset of WES samples from patients with liver disease, with a diverse set of causative genes and inheritance patterns. **Results:** This new WES pipeline recapitulated all previously identified disease-causing variants. New pathogenicity scoring tools allowed for better characterization of genetic variants. Specifically, SpliceAI identified cryptic splicing variants previously annotated as synonymous. Additionally, rare-variant phasing reliably predicted compound heterozygous variants in individual's for whom parental sequences are unavailable. This pipeline also recurrently identified a few homozygous variants in multiple patients, the majority of which appear in regions poorly covered in large databases, suggesting that these variants are systematically missed when using older analytical tools. Lastly, our re-analysis approach also uncovered a patient with a novel disease caused by recessive mutations in *TULP3*. **Conclusion:** An ancestrally-diverse pangenomic reference successfully identifies liver disease-causing variants. Re-analysis of WES data from patients with undiagnosed liver disease curtails the number of idiopathic cases, and its

f 4710-C | PNPLA3 GENOTYPE IS ASSOCIATED WITH RISK OF HCC BUT NOT DECOMPENSATION IN PATIENTS WITH COMPENSATED CIRRHOSIS

Esteban Urias[1], Nicholas Tedesco[1], Karn Wijarnpreecha[2] and Vincent Chen[3], (1)University of Michigan, (2)University of Arizona College of Medicine Phoenix, Phoenix, AZ, (3)University of Michigan Medical Center

Background: The *PNPLA3*-rs738409-G, *TM6SF2*-rs58542926-T, and *HSD17B13*-rs6834314-A polymorphisms have been associated with cirrhosis, hepatic decompensation, and hepatocellular carcinoma (HCC). However, whether they remain associated with HCC and decompensation in people who already have cirrhosis remains unclear, which limits clinical utility of genetics in risk stratification as HCC is uncommon in the absence of cirrhosis. We aimed to characterize the effects of PNPLA*3*, *TM6SF2*, and *HSD17B13* genotype on hepatic decompensation, hepatic cellular carcinoma (HCC), and transplant-free survival in patients with baseline compensated cirrhosis. **Methods:** We conducted a single-center retrospective study of patients in the Michigan Genomics Initiative. Participants underwent genotyping on an Illumina HumanCoreExome v.12.1 array. Patients were screened for cirrhosis based on diagnosis codes, transient elastography, imaging, endoscopic evidence of varices, or liver biopsy, followed by manual chart review to verify diagnosis of cirrhosis and determine development of decompensation, HCC, death, and liver transplant. The primary predictors were *PNPLA3*, *TM6SF2*, and *HSD17B13* genotypes. Primary outcomes were either decompensation, HCC, or the combined endpoint of liver transplant or death. We conducted competing-risk Fine-Gray analyses with age, sex, etiology, and genetic principal components as covariates with a 180 day landmark to evaluate effects of the predictors and calculate cumulative incidence. **Results:** We identified 655 patients with baseline compensated cirrhosis. Median age was 58 years, 43% were female, and 93% were Caucasian. Mean follow-up time was 4.5 years. 16% had viral hepatitis, 17% had alcoholic liver disease, and 57% had non-viral non-alcoholic liver disease, and the remaining had mixed etiologies. During follow-up, 49% of patients developed decompensation, 10% developed HCC, 8% underwent liver transplant, and 28% died. *PNPLA3*-rs738409-G genotype was associated with risk of incident HCC: adjusted hazard ratio (aHR) 2.92 [1.42-5.99], $p = 0.0035$ for GG vs. CC genotype. Five-year cumulative incidence of HCC was higher in *PNPLA3*-rs738409-GG carriers than -CC/-CG carriers: 14.1% (7.2-23.3%) vs. 6.3% (4.1-9.0%), $p = 0.0097$. *PNPLA3* genotype was not associated with decompensation or the combined endpoint of liver transplant or death. *TM6SF2* and *HSD17B13* genotypes were not associated with decompensation or HCC in this cohort ($p > 0.05$ for both). **Conclusion:** The *PNPLA3*-rs738409-G allele is associated with increased risk of HCC among patients with baseline compensated cirrhosis. People with cirrhosis and *PNPLA3*-rs738409-GG genotype may warrant more intensive HCC surveillance.

4711-C | PROTECTIVE ROLE OF A GLYPICAN-6 POLYMORPHISM IN BILE DUCT STRICTURE FORMATION AFTER LIVER TRANSPLANTATION

Ruslan A. Mammadov, Jasmijn W. Selten, Monique M.A. Verstegen, Floris J.M. Roos, Henk P. Roest, Cornelia J. Verhoeven, Herold J. Metselaar, Maikel P. Peppelenbosch, Jan N.M. IJzermans and Luc J.W. Van Der Laan, Erasmus MC

Background: Bile duct strictures both non-anastomotic and anastomotic are one of the most common complications after liver transplantation, with an incidence of approximately 30%. The origin of these strictures seems multi-factorial, but damage to the bile duct stem cell niche is found to play an important role. Glypican-6 (*GPC-6*) has recently been identified as an stem cell niche factor important for stimulation of the Wnt-signaling pathway. However, the role of GPC-6 has not been established in bile duct strictures post transplantation. **Methods:** A retrospective, PCR-based, SNP analysis was performed for GPC-6 status on sequential collected blood samples from donors and recipients of a liver transplantation between 1989 and 2011. PSC patients were excluded from the analysis. Statistical analysis was performed using SPSS statistics 25 (SPSS Inc., Chicago, IL, USA). Prediction analyses were performed through backward stepwise Cox proportional hazards regression and expressed as the hazard ratio (HR). **Results:** GPC-6 status could be identified in 299 recipients, 291 donors and 197 paired donor-recipient combinations. Of the 299 transplantation recipients, biliary strictures occurred in 101 grafts (33%). Distribution of the *GPC-6* polymorphism did not differ between the recipient (AA (n = 47) vs AG/GG (n = 252)) and donor (AA (n = 46) vs AG/GG (n = 245)) (p = 0.818). However, donor *GPC-6* AA genotype was identified as a protective factor for non-anastomotic biliary strictures (p = 0.016) but not for anastomotic strictures (Figure 1A). Interestingly, *GPC-6* AA genotype also played a strong protective role against anastomotic strictures but only for recipients (p < 0.0001), and was not significant in patients with non-anastomotic strictures (Figure 1B). Cumulative incidence of overall biliary complications was significantly lower in the recipients who received a graft from donor AA genotype vs on time (p = 0.001; Cox reg = 0.004) as well as the effect of GPC6 AA genotype on graft survival (p = 0.045; Cox reg = 0.04). Multivariate analysis with other known risk factors for bile duct strictures showed *GPC-6* AG/GG genotype as an independent risk factor for biliary strictures (p = 0.049). **Conclusion:** The *GPC-6* rs9524260 AA genotype is a protective factor for the development of bile duct strictures after liver transplantation in non-PSC patients.

f 4712-C | RECAPITULATING HEPATOCELLULAR CARCINOMA'S COMPLEX BIOLOGY AND DIVERSE TREATMENT RESPONSE IN A PATIENT-DERIVED MICROFLUIDIC MODEL

Orsola Mocellin[1], Abbie Robinson[1], Aleksandra Olczyk[1], Stephane Treillard[1], Thomas Olivier[1], Chee P. Ng[1], Jeroen Heijmans[1], Arthur Stok[1], Gilles Van Tinderen[2], Monique M.A. Verstegen[2], Flavio Bonanini[1], Sebastian J. Trietsch[1], Henriëtte L. Lanz[1], Paul Vulto[1], Jos Joore[1] and Karla Queiroz[1], (1)Mimetas, (2)Erasmus MC

Background: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and is closely associated with progressive stages of liver diseases. Its transformation, survival, progression and metastasis have been associated with regulation mechanisms orchestrated by the tumor stroma. Patient differences in tumor composition and cellular signaling are reflected in the diversity of therapy response. Hence, comprehensive in vitro models that capture patient-specific tumor and stromal components are necessary to elucidate and evaluate anticancer therapy. **Methods:** Patient-derived dissociated HCC cells from eight different patients were combined with tumor-derived fibroblasts and endothelial cells within a microfluidic setup comprising 64 parallel chips in a microtiter plate format. Cultures were challenged with an individual or combinatorial treatment from a panel of tool compounds for 72 hours in an automated setup. We used immunofluorescence and high content confocal imaging to assess the structural and biological interaction between cancer cells and the associated stroma. Viability assessment, artificial intelligence-based vascular morphology characterization and multiplexed chemokine/cytokine release measurements were used to elucidate patient and drug-dependent effects of single or combinatorial treatments. **Results:**

Cellular interaction within the microfluidic platform led to a vascularized tumor construct, with hepatocellular carcinoma aggregates being enveloped and traversed by a lumenized and interconnected vascular plexus, in association with tumor-derived fibroblasts. Compound treatment led to profound differences across the tested parameters, indicating different anticancer effects in conjunction with the biological diversity of the patient material. Finally, morphological assessment revealed distinct compound-induced effects on the tumor's vascular organization. **Conclusion:** We present a vascularized patient-derived HCC model that includes relevant cellular players of the tumor microenvironment found in vivo. These co-cultures are highly suitable for studying specific cell types as well as patient-specific responses. We envision that this system has the potential to provide a platform for understanding the interplay between different cell types present in hepatocellular carcinomas, with sufficient scalability ease of use for industrial and clinical implementation.

4713-C | TARGETING FGFR2-FUSIONS WITH ANTIBODY THERAPEUTICS IN INTRAHEPATIC CHOLANGIOCARCINOMA

Saireudee Chaturantabut[1,2,3,4], Sydney Oliver[1], Dennie T. Federick[1], John Kim[1], Foxy Robinson[1] and William R. Sellers[1,2,4], (1)Broad Institute of MIT and Harvard, Cambridge, MA, USA, (2)Dana-Farber Cancer Institute, Boston, MA, (3)Faculty of Pharmacy, Silpakorn University, Thailand, (4)Harvard Medical School, Boston, MA, USA

Background: Translocations involving the Fibroblast Growth Factor Receptor 2 (FGFR2) are found in 10-15% of intrahepatic cholangiocarcinoma. Treatment of these patients with FGFR1-3 kinase inhibitors, induces tumor regressions, though response rate appears limited due to the acquired resistance or to suboptimal dosing which is limited by drug adverse effects. Therefore, therapeutics that drive activity specifically towards FGFR2, such as antibody drugs, are needed to enhance drug efficacy and reduce adverse effects. To this end, we first 1) ask whether the extracellular domain (ECD) of FGFR2-fusion is functional, and then 2) we sought to investigate if antibodies against the ECD could perturb the growth of FGFR2 fusion transformed cells. **Methods:** To determine whether the ECD is functional and important for transformation of FGFR2-BICC1 fusion, D1, D2, D3, and D2-3 deletion FGFR2-BICC1 constructs were generated. To evaluate the roles of ECD in transformation capacity and growth of FGFR2-BICC1, we utilized focus formation and viability assays respectively in FGFR2-BICC1 expressing NIH3T3 cell line. To investigate the roles of ECD in FGFR2-fusion receptor dimerization, we developed a NanoBiT assay, in which the ECD deletion FGFR2-BICC1 constructs were coupled to LgBiT or SmBiT fragments and luminescence can be detected upon receptor dimerization. FGFR2 downstream signaling was investigated via immunoblotting for phosphorylated FGFR, FRS, AKT, MEK, and ERK. Six FGFR2 specific antibodies were selected and produced in the Expi293T system. We validated the antibody binding affinities and cell viability assays were performed using CellTiter-Glo to determine the impact of antibodies on FGFR2 fusion transformed cells. **Results:** We have shown that D1, D2, D3, and D2-3 deleted FGFR2-BICC1 ECD decreased growth and transformation of FGFR2 fusion driven cells. Proliferation of FGFR-BICC1 expressing cells was further stimulated by FGF10 ligand. Using NanoBiT assay, we have shown that D2, D3, and D2-3 deletions decreased dimerization as compared to the FL FGFR2-BICC1. Interestingly, D1 deletion increased receptor dimerization. Consistent with dimerization results, D1 deleted FGFR2-BICC1 showed increased downstream signaling while D2, D3, and D2-3 deleted FGFR2-BICC1 had decreased phosphorylation of FGFR2 downstream effectors. Importantly, antibodies against FGFR2 ECD inhibited FGFR2-fusion driven growth and transformation. **Conclusion:** Here, we have shown that ECD of FGFR2 plays important roles in cellular growth and survival of FGFR2-fusion driven cells and is necessary for full transformation of FGFR2 fusions. Moreover, antibodies against FGFR2 ECD had activities in FGFR2-fusion driven growth, demonstrating that the antibody-based therapeutics may form the basis for a new treatment strategy that is more specific, has less side effects, and improves ICC treatment outcome.

Background: Hepatocellular carcinoma (HCC) remains lethal rising in parallel with risk factors such as alcohol-induced cirrhosis and non-alcoholic steatohepatitis (NASH). Nearly 40% of HCCs have alterations in the TGF-β pathway. Yet, context dependent TGF-β tumor suppression or tumor promotion remain poorly understood. ALDH2, a key enzyme that metabolizes and clears both lipid end products (e.g., 4-Hydroxynonenal) and alcohol (e.g., Acetaldehyde) activity is markedly reduced in HCC and ~560 million people globally. We reported that TGF-β/SPTBN1/SMAD3 mutant mice develop HCC with high ALDH2 levels and altered microbiomes (*JCI 2016, 126(2):527-542*). Recently, we found that liver-specific knockout of a TGF-β/SMAD adaptor βII-spectrin ($SPTBN1^{LSKO}$), blocks NASH and HCC, and βII-spectrin siRNA reverses NASH in human NASH 3D cultures (*Sci Transl Med 2021, 13:624*). We therefore sought to first identify new biomarkers that predicted HCC in NASH-cirrhotic patients, by capturing ongoing biology in the liver through the TGF-β pathway and next examined whether βII-spectrin modulates ALDH2 in NASH and HCC. **Methods:** We examined 7,000 serum proteins in 427 patients with cirrhosis, conducted human genomic studies, analyzed animal models targeting a SMAD3 adaptor SPTBN1 intercrossed with ALDH2 knockouts, performed mechanistic analyses, microbiome, and snRNA-seq analyses. **Results:** 1. We identified a TGF-β regulated serum protein biomarker panel that could potentially predict progression of cirrhosis to cancer. 2. SPTBN1intercrosses with a key enzyme in ALDH2 deficient mice (ASKO) develop NASH, metabolic syndrome (MetS) and cancer. ASKO mice showed sex difference-based decreases in anti-inflammatory species microbiome patterns and significantly decreased colonic Tregs. snRNA-seq analysis revealed disrupted TGF-β signaling in ASKO mice. 3. SPTBN1 siRNA blocked NASH and diet/chemical induced HCC in the mutant mice with restoration to tumor suppressor TGF-β signaling. In addition, SPTBN1 siRNA-mediated therapy in the mouse model and in a 3D human NASH coculture system restored disrupted TGF-β signaling observed in ASKO mice to a normal phenotype. **Conclusion:** Our work provides an important platform from large-scale genomic studies to animal models to signaling studies for analyzing MetS and NASH-liver conditions that are linked to altered gut health. Furthermore, our data suggest that SPTBN1, an intrinsically disordered protein is a potential therapeutic target for preventing or reversing NASH.

4715-C | THE POINT OF NO RETURN IN CHRONIC LIVER DISEASES: WHEN RECOVERY OR CURE ARE IMPOSSIBLE

Piet De Groen, University of Minnesota

Background: Despite an unusual ability to regenerate, at some point in time a chronic, progressive liver disease becomes irreversible. At this stage recovery or cure is impossible and death is inevitable. Recent publications pose that a constant rate of somatic mutations is the cause of all intrinsic human diseases, including Primary Biliary Cholangitis (PBC) and Hepatocellular Cancer (HCC; Front Astron Space Sci 9:1067491). Diseases characterized by multiple somatic mutations show a tapering exponential population distribution where one disease event, e.g., one polyp, is common and many events, e.g., 10 polyps, are rare. Hypothesis: A defined period of survival can be regarded as a disease event representing cumulative germline and somatic mutations. Therefore, when advanced PBC and HCC are not or ineffectively treated, survival adheres to an exponential model as previously described for colorectal and pancreas cancer (Am J Gastroenterol 2020;115:s43). The same exponential model was shown to predict distribution of additional autoimmune diseases in PBC (Hepatology 2022;76:S1493). Aim: To determine whether mortality of advanced PBC and HCC adheres to an exponential model. **Methods**: To estimate untreated PBC mortality, the original Mayo Model from 1989 based on 418 patients (NEJM 1989;30:1709) was used; less than half of the patients had been treated with d-penicillamine which had no effect on survival. To estimate untreated HCC survival, SEER Medicare data from either untreated (73%) or sorafenib treated (23%) patients (N = 1532) were used; sorafenib did not alter mortality in this patient cohort (Oncologist 2016;21:1113). The exponential model consisted of the omnipresent neoplasia equations (ONE) as published. Mayo model and observed HCC data were matched at the first observation event, 1 year for the Mayo Model and 1 month for the HCC observed data. Averages over 3-5 months for each 1-month mortality estimate were applied to observed HCC data to eliminate outliers and short-term fluctuation. The Pearson correlation coefficient (PCC) was determined. **Results**: The ONE model agreed with the Mayo Model matched at the 1-year mortality time point at year 1, 3 and 5 (see Fig 1A; PCC = 0.97). The match between ONE and HCC observed data was nearly perfect (see Fig 1B; PCC = 0.99). **Conclusion**: ONE-modeled data, matched to early mortality, closely predicts observed mortality data of untreated liver diseases. As ONE assumes a constant rate of somatic mutations in all cells, a specific liver prediction model based on a limited panel of liver-derived markers such as the MELD, especially in the presence of attempts at treatment, can never apply to all types of liver disease. Moreover, the ONE model suggests that a single point of no return, i.e., the threshold beyond which recovery or cure are impossible, can never be identified as any combination of germline and somatic mutations can lead to death.

1259-C | BULEVIRTIDE MONOTHERAPY IN PATIENTS WITH NON-COMPENSATED LIVER CIRRHOSIS DUE TO HEPATITIS D

Natalia Alexandrovna Barsukova[1], Pavel Bogomolov[2], Alexey O. Buyeverov[1,3], Sergei Koblov[1], Ekaterina Isaeva[1], Michail Vladislavovich Kalashnikov[1], Nadezhda Anatolyeva Shub[4] and Maria Valeryevna Arapova[4], (1)Moscow Regional Research and Clinical Institute of M. F. Vladimirsky, (2)State Budgetary Institution of Health Care of Moscow Region "Moscow Regional Research Clinical Institute after M.F. Vladimirsky", (3)Sechenov First Moscow State Medical University (Sechenov university), (4)Center Targetnoy Therapii LLC

Background: Bulevirtide (BLV) is a first-in-class entry inhibitor approved as therapy for patients with chronic hepatitis D (CHD). Efficacy and safety of BLV in patients with non-compensated HDV liver cirrhosis has not been explored. **Methods:** Patients received antiviral therapy with Bulevirtide 2 mg per day subcutaneously for 24 weeks. 4 patients with non-compensated liver cirrhosis (1 man, 3 women) underwent clinical, laboratory and instrumental examination. The average age of patients was 42.5 years (from 32 to 52 y). During the objective examination the presence of ascites and hemorrhagic syndrome and encephalopathy was assessed. The laboratory and instrumental examination included routine blood tests, PCR of HBV DNA and HDV RNA, ultrasound examination and GI endoscopy. **Results:** None of the patients had previously received antiviral therapy for hepatitis D. All patients had been treated with nucleot(s)ide analogues for at least 12 months (3 patients tenofovir, 1 patient entecavir). Initially, non-compensated HDV-liver cirrhosis was diagnosed in all patients. 2 patients were treated BLV monotherapy in low accelerated dose regimen (LADR) mode (2 mg x 3 times a week subcutaneously). The remaining patients were treated BLV in full dose (2 mg per day subcutaneously). After 24 weeks of BLV monotherapy improvement were seen of Child-Pugh scores in all patients, while liver function was compensated in two. Two patients had a decrease from 9 to 7 points on the Child Pugh scale. Two had an improvement to recompensation from 7 to 6 points on the Child Pugh scale. ALT activity decreased to normal in 2 patients. In one patient decrease the level of HDV RNA more than 2 lg from the baseline was registered. Three patients had a stable platelet count or an increase from the initial level, only one had a slightly decreased platelet count. No one was found to have focal liver formations and an increase in the level of alphafetoprotein. In all patients, the control GI endoscopy revealed a decrease in the diameter of the esophageal veins, but one required endoscopic ligation. One patient was found to have non-occlusive portal vein thrombosis during BLV treatment, which required oral anticoagulants. Bulevirtide treatment was well tolerated, no serious adverse events were registrated. **Conclusion:** BLV monotherapy, including LADR, can use in patients with non-compensated HDV liver cirrhosis and may improves liver function despite the absence of viral response.
Disclosures: The following people have nothing to disclose: Natalia Alexandrovna Barsukova, Pavel Bogomolov, Alexey O. Buyeverov, Sergei Koblov, Ekaterina Isaeva, Michail Vladislavovich Kalashnikov, Nadezhda Anatolyevna Shub, Maria Valeryevna Arapova

1526-C | A COMPOSITE SCORE CONSISTING OF BOTH CCCDNA TRANSCRIPTIONAL ACTIVITY AND IMMUNOLOGICAL MARKERS ACCURATELY REFINES HBEAG-NEGATIVE CHRONIC HEPATITIS B PHASES

Ivana Carey[1], Mark Anderson[2], James Lok[1], Christiana Moigboi[1], Gavin A. Cloherty[2], Geoffrey M. Dusheiko[1] and K. Agarwal[1], (1)King's College Hospital, (2)Abbott Laboratories, IL

Background: HBeAg-negative chronic hepatitis B (CHB) is a variable disease with phases determined by HBV DNA and ALT levels: 'infection' phase (HBV DNA <2000 IU/ml & normal ALT) vs. 'hepatitis' phase (HBV DNA >20000 IU/ml & elevated ALT). Over 30% HBeAg-negative patients fall within a 'grey zone' (HBV DNA 2000–20000 IU/ml & normal ALT). Novel serological markers of cccDNA transcriptional activity: hepatitis B core-related antigens (HBcrAg) and pre-genomic HBV RNA (pgRNA) are relevant in separating HBeAg-negative patients ('infection' vs. 'hepatitis') and so reducing the number of indeterminate 'grey zone' patients. As CHB is an immune-mediated disease, the pro-inflammatory chemokine CXCL10 and soluble (s) PD-1 (exhaustion marker) levels may refine HBeAg-negative phases further. Combining these serum markers to create a composite score may increase our ability to stratify HBeAg-negative phases. **Aim:** To compare serological, virological and immunological markers in HBeAg-negative patients and determine whether these markers are able to refine HBeAg-negative CHB phases based on HBV DNA & ALT levels ('infection', 'grey zone' & 'hepatitis') and create a composite score. **Methods:** Serum samples from a cross-sectional cohort of 562 untreated HBeAg-negative patients (median age 38 y, 204 males) were tested for routine diagnostic markers: HBV DNA (Roche TaqMan, IU/ml), quantHBsAg (Abbott Architect, IU/ml),

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

biochemical (ALT, IU/L) and further tests were performed for the biomarkers: HBcrAg (CLEIA Fujirebio, log_{10}U/ml), pgRNA (Abbott Diagnostics dual-target real-time-PCR assay, LLQD = 0.4 log_{10}U/ml), CXCL10 and sPD-1 serum levels by ELISA [pg/ml]. Patients were divided into 3 groups based on HBV DNA levels: 'infection' (< 2000 IU/ml), 'grey zone' (2000-20000 IU/ml) and 'hepatitis' (> 20000 IU/ml) phases. The results were compared by AUC-ROC, univariate and multivariate analysis. The scoring system for the composite score was calculated using only markers with AUC-ROC > 0.7. **Results:** Patients in 'infection' phase (n = 293) have lowest levels in all markers in contrast to 'grey zone' (n = 215) and 'hepatitis' (n = 54) phase patients by univariate analysis (Figure). However, only HBV DNA, HBcrAg, pgRNA, CXCL10 and sPD-1 levels differed between groups by multivariate and AUC-ROC analysis (Figure). The cut offs for the composite score were: HBcrAg (< 3 log_{10}U/ml), pgRNA (< 0.4 log_{10}U/ml), CXCL10 (< 150 pg/ml) and sPD-1 <150 pg/ml). The composite score was able to stratify 'grey zone' phase patients with greater accuracy than individual markers (AUC-ROC = 0.81). **Conclusion:** The combination of novel cccDNA transcriptional activity biomarkers (HBcrAg and pgRNA), with immunological markers (CXCL10 and sPD-1), refined delineation betwen 'active' vs. 'inactive' HBeAg-negative phases. Larger studies validating these markers to confirm their prognostic clinical significance are needed to reduce the uncertainty of 'grey zone' patients.

Table:

	Infection phase (n=293)	Greyzone Patients (n=215)	Hepatitis phase (n=54)
Median HBV DNA	183 IU/ml	4470 IU/ml	83150 IU/ml
Median HBsAg	2387 IU/ml	5355 IU/ml	5933 IU/ml
Median HBcrAg	3.6 log_{10}U/ml	3.5 log_{10}U/ml	4.3 log_{10}U/ml
Median pgRNA	1.22 log_{10}U/ml	2.2 log_{10}U/ml	2.33 log_{10}U/ml
Median CXC10	122 pg/ml	218 pg/ml	285 pg/ml
Median sPD1	78 pg/ml	158 pg/ml	238 pg/ml
Median FIB4	0.65	0.95	1.25
Median APRI	0.22	0.29	0.42
Median fibroscan	4.3 kPa	5.1 kPa	7.0 kPa
Median composite marker	2	3	7

Composite marker score:

	Levels	Score
HBcrAg [log_{10}U/ml]	<3	0
	>3	1
pg HBV RNA [log_{10}U/ml]	<0.4	0
	>0.4	1
CXCL10 [pg/ml]	<150	0
	>150	1
sPD-1 [pg/ml]	<150	0
	>150	1
HBV DNA [IU/ml]	<2000	1
	2000 - 20000	2
	>20000	3

1527-C | MECHANISM RESEARCH ON THE INTERACTION BETWEEN HEPATITIS B VIRUS X PROTEIN AND LINE-1

Zhao Xu, Pujun Gao, Ke Zhao, Juan Du and Qiang Zhou, The First Hospital of Jilin University

Background: Long interspersed element type 1 (LINE-1), as the only active non-LTR endogenous retroelements that can replicate autonomously in human genome, has impact on genome evolution and triggering innate immune system. Little research focus on the interaction between LINE-1 and the HBV. HBV regulates natural immune responses through various pathways during its infection and replication while LINE-1 can activate the interferon signal system, indicating HBV is likely to interact with LINE-1. HBx protein is a multifunctional regulator with the ability to bind RNA and DNA, suggesting that HBx protein may interact with LINE-1. The research investigates whether there is interaction between HBx and LINE-1 and further explore the mechanisms of the interaction. **Methods:** we use Flow cytometry and LINE-1 retrotransposition assay to confirm the interaction between HBx and LINE-1. In order to explore the mechanisms of the interaction between HBx and LINE-1, we take different assays, such as Western blotting, Luciferase, co-IP, RT-qPCR to confirm whether HBx regulate LINE1 promoter activity, LINE-1 RNA, LINE-1 protein, LINE-1 RNP or the ability of integration. Finally, to explore the interplay among HBx, LINE-1 and the innate immune system by using ELISA, Western blotting, Luciferase, RT-qPCR etc. **Results:** 1.HBx suppresses LINE-1 retrotransposition. By using LINE-1 retrotransposition assay and Flow cytometry, we find that HBx could significantly reduce the replication activity of LINE-1 retrotransposition. 2. HBx reduces LINE-1 expression through LINE-1 RNA regulation. By using different assays, we find that HBx could reduce ORF1p and ORF2p expression without affecting the LINE-1 promoter activity, HBx suppressed LINE-1 activity by sabotaging the stability of LINE-1 RNA. 3.By suppressing LINE-1 activity, HBx partly regulates innate immune activation. **Conclusion:** The results reveal the new functions of HBx and provide new information on the intricate interaction between HBx, LINE-1, and innate immune systems. The results may also highlight the potential of designing novel HBx-targeting anti-HBV drugs and optimize anti-HBV treatment strategies.

f 1739-A | DIFFERENTIAL DRUG RESPONSES AMONGST 4 IDIOSYNCRATIC DRUG-INDUCED LIVER INJURY PATIENT-DERIVED HUMAN LIVER ORGANOIDS

Charles Zhang[1], Sophia Meyer[1], Max Garcia[1], Megan Procario[1], Andrew Tucker[1], Robert J. Fontana[2] and Jonathan Sexton[3], (1)University of Michigan, (2) University of Michigan Medical Center, Ann Arbor, MI, (3)University of Michigan Medical Center

Background: Idiosyncratic drug-induced liver injury (iDILI) is a rare but important cause of liver injury believed to arise, in part, from aberrant host immunity. Most in vitro models of DILI focus on primary human hepatocytes or cell lines and do not account for the potential role of non-parenchymal cells or inflammatory stimuli in iDILI susceptibility. This study reports the differential response between iPSC-derived human liver organoids (HLOs) obtained from 4 well characterized iDILI patients with and without proinflammatory cytokine priming before drug exposure. **Methods:** 4 patients with iDILI due to a single agent and a high causality score enrolled in the DILIN Prospective Study provided a blood sample for PBMC isolation. PBMCs were reprogrammed to iPSCs and differentiated into HLOs containing hepatocyte-like, stellate-like, and Kupffer-like cells over 28 days. HLOs were dispersed into a high-throughput 384-well system and treated with a library of 64 intrinsic and idiosyncratic hepatotoxins (including amoxicillin/clavulanate, sulfamethoxazole/trimethoprim, and green tea extract) in 10-point, 2-fold dose-response. HLOs were also primed with proinflammatory cytokines prior to drug exposure to mimic in vivo conditions. Hepatotoxicity was measured by loss of cell viability and phenotypic profiling using high-content imaging. Cellpose was used for nuclei segmentation followed by feature extraction using CellProfiler generating $>1{,}000$ morphological and intensity features per cell. HLO drug response was determined through a combination of loss of viability and phenotypic distance scoring vs vehicle control. **Results:** The 4 patients presented differential hepatotoxicity across a panel of 64 DILI-associated drugs, with 11 drugs responding in all patients, 24 in three patients, 17 in two, 8 in only one, and sulindac in no patients (Fig 1). A subset of active drugs is shown in Fig 1A and UpSet analysis showing differential drug response is shown in Fig 1B with the most reactive patient (patient 1) responding to 44 drugs and the least reactive (patient 2) responding to 38 out of 64 drugs. Prominent differences were observed with acetaminophen, fialuridine, isoniazid, and atorvastatin. Results of treatment with the panel of 64 drugs and variable concentrations of the specific implicated agent in the presence and absence of the proinflammatory cytokines TNF-α and IFN-γ will be presented. **Conclusion:** Our study introduces a unique method to assess personalized DILI risk. By expanding our panel of iDILI patient HLOs, we have the potential to create a more sensitive and specific *in vitro* test system that incorporates immune signaling. In addition to assessing personalized DILI risk, and potentiation by cytokine stress, our in vitro multicellular HLO model may provide novel mechanistic insights into the pathogenesis of iDILI.

1740-A | A HIGH THROUGHPUT AUTOMATABLE MICROFLUIDIC LIVER ORGANOID CHIP FOR LONG-TERM DILI MODELLING

Charles Zhang[1], Sumin Kim[2], Sophia Meyer[1], Amber Jolly[2], Byungjun Lee[2], Jiho Kim[2], Sanghee Yoo[2], Tsung-Li Liu[2], Kyusuk Baek[2], Robert J. Fontana[3] and Jonathan Sexton[4], (1)University of Michigan, (2) Qureator, (3)University of Michigan Medical Center, Ann Arbor, MI, (4)University of Michigan Medical Center

Background: Recent research has demonstrated the superiority of iPSC-derived human liver organoids (HLOs) and microfluidic liver chips over established hepatocyte cultures in terms of cell maintenance and physiologic relevance for various liver diseases including drug-induced liver injury (DILI). However, limitations include cost, scalability, and reproducibility. Herein, we describe a long-term high-throughput microfluidic liver chip for studying chronic liver diseases compatible with standard laboratory automation technologies. **Methods:** iPSC-derived HLO cells were embedded in hydrogel on 16-well Qureator Curio-Barrier microfluidic devices and cultured in a standard incubator. Media was collected to monitor albumin production over 28 days. Chips at days 7, 14, 21, and 28 were assessed for CYP450 expression by qPCR and activity through substrate metabolism, and immunostained for hepatocyte markers. Day 7, 14, and 21 chips were treated with acetaminophen, fialuridine, or vehicle control for an additional week to assess hepatotoxicity response by ALT release and reduction in albumin production. After the 1-week treatment, chips were fixed and stained for nuclei, cell region, and lipid content followed by automated water-immersion confocal microscopy and image-based morphological characterization. **Results:** HLOs consistently released albumin across 21 days of culture with a slight reduction in the last 7 days. CYP450 expression levels remained consistent across chips of all timepoints and HLOs maintained hepatocyte marker expression. Day 7, 14, and 21 chips treated with acetaminophen and fialuridine released ALT and had reduced albumin production consistent with DILI. **Conclusion:** Our findings establish that the Curio-Barrier devices successively maintained HLOs over 28 days in a high-throughput format. In addition to future DILI research, this platform may prove useful for other chronic liver diseases such as Hepatitis B and NAFLD.

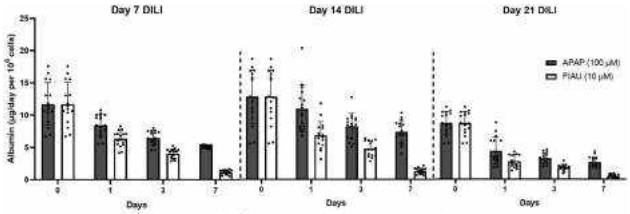

Figure: HLOs grown on Curio-Barrier chips for 7, 14, and 21 days are responsive to known DILI compounds

2495-A | NASH CIRRHOSIS: THE INTRA-HEPATIC HEMODYNAMIC ABNORMALITY (IHHA) OF CIRRHOSIS MEASURED BASELINE AND CHANGE OVER TIME PREDICTS CLINICAL OUTCOMES AND SURVIVAL

John C. Hoefs, University of California Irvine

Background: The intra-hepatic hemodynamic abnormality (IHHA) of cirrhosis determines quantitative hepatic function and correlates with clinical outcomes. In hepatitis C (investigated in the HALT-C trial), the IHHA was measured on the Quantitative liver-spleen scan (QLSS) as PHM (perfused hepatic mass) and out-performed any combination of histology and routine LFT in correlation with clinical outcomes over 8 years (*Hep, 55;1019-1029, 2012.*) Early studies showed that patients with CLD have the IHHA regardless of cause and correlates with the functional hepatic mass (Am J Gastro, 92:2054-2058, 1997). We hypothesize the outcomes of NASH cirrhosis are will be related to IHHA as measured by PHM. **Methods:** 13 patients with NASH cirrhosis were identified based on liver biopsy or nodularity of liver surface with collaterals by CT/MRI/US and followed for up to 13 years. Sulfur colloid liver-spleen scan as processed by Hepatiq for measurement of PHM (n = 100-110), functional spleen volume (fSV) (N = < 2.5 cc/lb IBW), and functional liver volume (fLV) (n = 7-12 cc/lb IBW). Data was obtained from a clinical database for clinical complications (death, ascites, encephalopathy, VB), ultrasound and routine blood tests. Statistics: Change over time was measured as delta (delta = PHM initial – last scan), delta/time observed and by the linear regression slope of change over time. A linear regression r2 of > 0.4 was considered significant for description of slope. Results are presented as box plots w/observed data overlays and tested using a Kruskal-Wallis rank test (ie, nonparametric t test). **Results:** The mean number of scans per patient was (7.5+/-2.5) over the mean number of years (8.1+/-3.2) of follow-up. 6 patients had complications and 1 had VB and Ascites prior to the first scan with no problems thereafter. 1 patient had a gastric bypass and lost 30 lb prior to the first scan. The main therapy was by control of predisposing factors of DM (11), hyperlipidemia (10), and obesity (3 patients had lean body NASH). Vitamin E was given for all patients and was taken some of the time by most. We divided patients into 2 groups based on progression to clinical complications including death: 1) 8 patients with no clinical problems and 2) 5 who

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

progressed to clinical problems 5 of which died, had a LT or were accepted on the LT list. One death was from HCC. All 5 patients in group B who died had a PHM < 95 at baseline (figure) and had progression in PHM by linear regression slope (−0.0139 +/- 0.011 vs -.0013 +/- 0.0032; $p < 0.001$) and delta initial to final PHM (figure). Routine blood tests, MELD, Fib4 and US were not significantly different. **Conclusion:**1. Many patients with NASH cirrhosis do not progress over time to clinical problems or death. 2. IHAA as measured by PHM could identify patients at baseline or by deterioration during f/u who would progress to clinical problems and death. 3. The presence of NASH cirrhosis is not sufficient to predict a bad outcome and IHAA should be measured by PHM.

2496-A | UNDERSTANDING RISK FOR NON-ALCOHOLIC STEATOHEPATITIS AND NON-ALCOHOLIC FATTY LIVER DISEASE IN MEDICARE AND MEDICAID CLAIMS

Katherine Nelson[1], Jonathan Gellar[2], Ryan Taylor Anderson[2], Patrick Campbell[1] and Arnold Chen[2], (1) Merck & Co., Inc., (2)Mathematica

Background: To build models using Medicaid and Medicare claims data to quantify the relationship between patient characteristics and diagnoses of NAFLD and NASH. **Methods:** Patients with a NAFLD or NASH diagnosis were identified in Medicare and Medicaid claims from 2018-2019 for all U.S. counties using criteria adapted from the methodology used in the CMS Chronic Conditions Warehouse. Diagnosis flags for NASH or NAFLD were given to patients who have ≥ 1 inpatient/skilled nursing facility /home health agency claim or 2 health options program (HOP)/carrier claims with diagnosis codes associated with the NASH or NAFLD. We considered any beneficiary diagnosed with NASH to also have NAFLD even in the absence of a NAFLD diagnosis. We built random forest models to assess the relationship between predictors (patient demographics and clinical risk factors: glucose intolerance, type 2 diabetes, metabolic syndrome, hypertension, and dyslipidemia) and diagnosed NAFLD or NASH. We fit one model to estimate risk of NAFLD among all patients, and another to estimate risk of NASH among patients with NAFLD ("NASH|NAFLD") in each target population. We calculated adjusted odds ratios for all binary or categorical predictors as marginal effects. **Results:** Sample sizes were 31,056,598 of Medicaid beneficiaries, 42,810,168 Medicare, and 10,151,582 dually eligible beneficiaries. All clinical risk factors had strong adjusted associations with NAFLD diagnosis (see Table 1). Risk factors were strongly associated with a diagnosis of NASH|NAFLD, with the strongest adjusted associations for metabolic syndrome and type 2 diabetes. Females had higher odds of both NAFLD and NASH|NAFLD than similar males. Hispanic and Asian beneficiaries had higher adjusted odds of NAFLD compared to white beneficiaries, but there were smaller differences between these three race/ethnicity groups for NASH|NAFLD. Black beneficiaries had lower odds of NAFLD and NASH|NAFLD than white beneficiaries. **Conclusion:** Specific patient demographic and clinical factors might help identify patients at high risk for NAFLD or NASH|NAFLD. These models may be useful for identifying undiagnosed individual's at high risk for developing NAFLD or NASH. Some observed differences between predictors may be due to under-diagnosis or

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

failure to include diagnoses on claims for certain populations. This potential bias should be accounted when applying the models for health care planning.

Table 1. Prevalence, unadjusted odds ratio, and adjusted odds ratio of both NAFLD and NASH (among those with NAFLD) for each categorical model predictor

Variable	Level	Percent/ Mean*	NAFLD			NASH (Given NAFLD)		
			Prevalence	Unadjusted OR	Adjusted OR	Prevalence	Unadjusted OR	Adjusted OR

2497-A | HEPATIC IMMUNE CELL PROFILING OF THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF NASH WITH ADVANCED FIBROSIS AND HCC

Kristoffer Voldum-Clausen[1], Jacob Nøhr-Meldgaard[2], Alex Frias Hernandez[1], Michael Feigh[2] and Henrik B. Hansen[2], (1)Gubra a/S, (2)Gubra

Background: Non-alcoholic steatohepatitis (NASH) has become an emerging risk factor for the development of liver fibrosis and hepatocellular carcinoma (HCC). Recent data suggest that NASH–HCC patients are less responsive to HCC-targeted immunotherapies, likely owing to NASH-related aberrant immune cell regulation. To gain further insight into immune cell regulations in NASH-driven HCC, we profiled liver leukocyte populations in the translational Gubra Amylin NASH (GAN) diet-induced obese (DIO) and biopsy-confirmed mouse model of advanced fibrosing NASH and HCC. **Methods:** C57BL/6JRj male mice were fed the GAN diet (40 kcal-% fat, 22% fructose, 10% sucrose, 2% cholesterol) or chow diet for 58 weeks before randomization. Prior to randomization all animals underwent liver biopsy for histological confirmation (fibrosis stage 3, steatosis score 3, inflammation score ≥ 2) using the non-alcoholic fatty liver disease activity scoring (NAS) and fibrosis staging system. Animals were terminated at 70 weeks on diet. Liver single-cell samples were stained using two distinct panels (lymphoid and myeloid panel). These panels targeted specific cell-surface markers to detect and quantify leukocyte subsets, including monocytes/macrophages, neutrophils, T-cells, B-cells, Natural killer (NK) and NK T-cells. Flow cytometry was employed for data analysis, enabling detailed characterization of liver immune infiltrated cell populations. **Results:** The GAN DIO-NASH-HCC mouse is a translational model of HCC development on the background of severe NASH and fibrosis here we show that DIO-NASH-HCC mice demonstrate marked expansion of hepatic resident and infiltrating monocyte/macrophage (Infiltrating monocytes, Ly6C^{++}cells, Kupffer, F4/80^{high} CD11c^{low} cells, and dendritic-like, F4/80^{low} CD11c^{high} cells) and specific T-cell populations, particularly CD8^{+} T cells. Moreover, CD8^{+} T cells have recently been implicated in NASH–driven HCC and have been linked to reduced efficacy to HCC-targeted immunotherapies in NASH patients. **Conclusion:** This study highlights the significance of understanding the interactions between immune cells and the development of HCC in the context of NASH. This knowledge can help guide the development of new and innovative anti-cancer drug concepts specifically targeting NASH-driven HCC.

2498-A | SEMAGLUTIDE-INDUCED WEIGHT LOSS LEADS TO SIGNIFICANT IMPROVEMENT OF HEPATIC STEATOSIS ASSESSED BY FIBROSCAN® CONTROLLED ATTENUATION PARAMETER (CAP) IN PATIENTS WITH BIOPSY-PROVEN NON-ALCOHOLIC STEATOHEPATITIS (NASH)

Savvoula Savvidou[1], Polyxeni Agorastou[1], Ioanna Papagiouvanni[1], Efrosyni Tsirogianni[1], Pavlina Pantelidou[2], Prodromos Hytiroglou[2] and Ioannis Goulis[1], (1)Hippocration University Hospital of Thessaloniki Greece, (2)Medical School of Aristotle University of Thessaloniki, Greece

Background: Improving hepatic steatosis, the "first hit" in the development of non-alcoholic steatohepatitis (NASH), is a feasible target achieved by weight loss, either with diet, bariatric surgery or pharmacotherapy such as the newly introduced glucagon-like peptide-1 agonist, semaglutide. Moreover, Controlled Attenuation Parameter (CAP) assessed by FibroScan® was shown to accurately estimate the degree of underlying steatosis. Primary aim of this study was to prospectively investigate non-invasively the effect of semaglutide-induced weight loss in patients with biopsy-proven NASH. **Methods**: Consecutive patients with biopsy-proven non-cirrhotic NASH were evaluated with somatometrics, blood tests and transient elastography with FibroScan® mini 430+ (M/XL probes). Liver Stiffness Measurement (LSM) and CAP were simultaneously measured in kPa and dB/m, respectively, by a single operator. Fibrosis-4 (FIB-4) and Fibroscan-AST (FAST) scores were calculated. Histologic assessments were performed by a single expert pathologist according to Kleiner´s classification [4 grades for steatosis (S0 to S3), 5 stages for fibrosis (F0 to F4)]. A subgroup of patients, not different in baseline characteristics, was treated with subcutaneously 2.4mg/week semaglutide for approximately six months, beginning with a 16-week escalation period (0.25->0.5->1->1.7->2.4 mg). Repeated elastography was performed by the same operator, and statistical comparisons were tested with Wilcoxon-rank test for paired samples. **Results**: Forty-six pts were recorded: 16 males/30 females, age 52.6 ± 13.1, BMI 29.7 ± 4.7 kg/m^2, diabetes in 16 pts (34.8%). Baseline laboratory tests [medians with interquartile range (IQR)]: AST 37U/L (25-60), ALT 50U/L (36-75), γGT 51U/L (25-177), PLT 221x10^9/μL (212-270), and 39.1% of patients with FIB-4 ≥1.3. Baseline elastography: median LSM 10.4kPa (IQR 7.5-15.4), CAP 295dB/m (IQR 258-345), while high FAST was recorded in 32.6% of patients. Histology revealed 16 patients (34.7%) with definite severe NASH. High diagnostic accuracy of elastography in identifying advanced fibrosis (F3-F4) with LSM and high-grade steatosis (S3) with CAP was shown with AUROCs 0.898 (95% CI 0.795-1, $p=0.001$) and 0.841 (95% CI 0.716-0.967, $p=0.001$), respectively. Repeated elastography was performed after a median of 6.5 months (IQR 3-11.2). The entire subgroup of patients administered semaglutide (n = 25) exhibited significant weight loss (range 6.8% to 27.3%) while presenting only minor side effects (primarily nausea). Reductions in CAP correlated to the degree of weight loss, and were accompanied by similar reductions (down to normal) in ALT levels. [GRAPH] LSM reductions did not reach the level of statistical significance. **Conclusion**: Semaglutide-induced weight loss was shown to improve both aminotransferases and hepatic steatosis. FibroScan® with CAP is a useful tool that can reliably assess non-invasively treatment of NASH.

2499-A | HEPATOPROTECTIVE EFFECTS OF SEMAGLUTIDE IN THE CDAA-HFD MOUSE MODEL OF ADVANCED NASH WITH PROGRESSIVE FIBROSIS

Kristoffer Voldum-Clausen[1], Jacob Nøhr-Meldgaard[2], Denise Oró Bozzini[2], Michael Feigh[3] and Henrik B. Hansen[2], (1)Gubra a/S, (2)Gubra, (3)Gubra Aps

Background: The glucagon-like-peptide (GLP)-1 analogue semaglutide is currently approved for the treatment of type 2 diabetes and obesity. Semaglutide has recently been reported to promote NASH resolution (Newsome et al., NEJM, 2020) and is currently in phase 3 clinical trial (ESSENCE) for NASH. The present study aimed to evaluate early vs. late-stage treatment intervention with semaglutide in the non-obese choline-deficient

L-amino-acid defined high-fat diet (CDAA-HFD) mouse model of advanced NASH with progressive fibrosis. **Methods:** C57BL/6JRj mice were fed chow or CDAA-HFD (45 kcal% fat, 0.1% methionine, 1% cholesterol, 28 kcal% fructose) for 3 or 6 weeks prior to treatment start (i.e. before or after onset of fibrosis, respectively). Animals were randomized into treatment groups based on body weight. A baseline group (n = 12) was terminated at study start (3 and 6 weeks). CDAA-HFD fed mice (n = 12 per group) received treatment (SC) with vehicle or semaglutide (30 nmol/kg) for 8 or 9 weeks. Chow-fed mice (n = 8) served as normal controls. Terminal endpoints included plasma biomarkers alanine/aspartate aminotransferase (ALT/AST), metallopeptidase inhibitor 1 (TIMP-1) and amino terminal peptide of type III procollagen (PIIINP), liver biochemistry, NAFLD Activity Score (NAS), fibrosis stage and quantitative liver histology. **Results:** Both early and late-stage intervention with semaglutide reduced body weight and liver weight in CDAA-HFD mice. While neither intervention improved NAS, early treatment start with semaglutide improved fibrosis stage. Notably, both interventions equally reduced liver hydroxyproline concentrations and quantitative levels of fibrosis (% area of PSR) as well as reduced levels of the fibrosis biomarkers TIMP-1 and PIIINP. Irrespectively of intervention timing, semaglutide did not influence plasma ALT/AST. **Conclusion:** Semaglutide demonstrates limited therapeutic efficacy in the non-obese CDAA-HFD mouse model of NASH with progressive fibrosis. In this model, the modest anti-fibrotic effects of semaglutide are not accompanied by improved hallmarks of NASH, suggesting complex hepatoprotective effects of semaglutide.

2855-C | NATIONAL, STATE AND COUNTY PREVALENCE OF DIAGNOSES OF NON-ALCOHOLIC FATTY LIVER DISEASE AND NON-ALCOHOLIC STEATOHEPATITIS IN THE UNITED STATES MEDICAID AND MEDICARE POPULATIONS

Katherine Nelson[1], Ryan Taylor Anderson[2], Jonathan Gellar[2], Patrick Campbell[1] and Arnold Chen[2], (1)Merck & Co., Inc., (2)Mathematica

Background: To produce geographic estimates of Medicare and Medicaid patients diagnosed with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH), and to assess the geographic association with where access to care measured by the social vulnerability index (SVI). **Methods:** Patients with a NAFLD or NASH diagnosis were identified in Medicare and Medicaid claims from 2018-2019 for all U.S. counties using criteria adapted from the methodology used in the CMS Chronic Conditions Warehouse. Diagnosis flags for NASH or NAFLD were given to patients who have ≥ 1 inpatient/skilled nursing facility/home health agency claim or 2 health options program (HOP)/carrier claims with diagnosis codes associated with the NASH or NAFLD. Social determinants of health were measured at the county-level using the SVI (high SVI = greater social vulnerability) developed by the CDC. Terciles were calculated for disease prevalence and SVI scores. The relative national prevalence of disease and SVI ranges were mapped at the county-level using the ArcGIS software platform in a multi-variate analysis of geographic distribution. **Results:** Nationally, 1.43% and 0.13% of Medicare and Medicaid beneficiaries, respectively had claims with NAFLD and NASH diagnoses. Dual beneficiaries had the highest proportion of claims with a NASH and NAFLD diagnoses. At the state level NASH diagnoses were associated with 0.06 – 0.25%, 0.00 – 0.10% and 0.09 – 0.42% of claims for Medicare, Medicaid, and dual beneficiaries, respectively. NAFLD diagnoses were associated with 0.58 – 2.50%, 0.39 – 1.80% and 1.42 – 3.48% for Medicare, Medicaid and dual beneficiaries, respectively. Counties with a high prevalence of diagnosed NAFLD and NASH and a high SVI were primarily located in southeast and southwest states (Figure 1). Counties with low prevalence of diagnosed NAFLD and NASH and low SVI were mostly located in midwestern states. **Conclusion:** This is the first study to calculate state and county-level NASH and NAFLD prevalence using Medicaid and Medicare claims. Estimates may underestimate the population prevalence due underdiagnosis and low claim volume. Results show a clustering of high NASH prevalence and high social vulnerability across the southwest and southeast states. This information identifies NASH patient populations at the highest risk of experiencing disparities across the US and identifies patient populations that could most benefit from an improved patient care pathway.

3169-A | OUTCOMES OF LAPAROSCOPIC APPENDECTOMY AMONG ADULTS WITH AND WITHOUT CIRRHOSIS; ANALYSIS UTILIZING LATEST 2016-2020 NATIONAL INPATIENT SAMPLE

Tejas Vijay Joshi, Marshall University, Renuka Verma, Guru Gobind Singh Medical School, Kamleshun Ramphul, Independent Researcher and Hemamalini Sakthivel, One Brooklyn Health System/Interfaith Medical Center Program

Background: The use of laparoscopic appendectomy instead of open approach has risen drastically over the last decades. As there is a paucity of recent data among cirrhosis patients, we aim to conduct a retrospective study via a large national hospitalization database. **Methods:** Adults requiring endoscopic percutaneous appendectomy between 2016- 2020 were studied via hospital records from the National Inpatient Sample provided by HCUP, AHRQ, and collaborators. We compared cohorts with and without cirrhosis for different patient and hospitalization characteristics and outcomes. **Results:** A total of 531665 cases of laparoscopic appendectomy were performed in the United States between 1st January 2016 to 31st December 2020. Our sample further identified 2365 (0.4%) cases with a diagnosis of cirrhosis, with a higher mean age (58.27 years) than the non-cirrhosis group (45.51 years, $p < 0.01$). Most cirrhosis patients were Males (61.7%) while in the non-cirrhosis group it was almost equally balanced between the two sexes. Both cohorts had many patients racially classified as White. While Private insurances covered a higher portion of non-cirrhosis patients, Medicare was the preferred form of insurance among those with cirrhosis. Most procedures were conducted in the southern region of the United States and involved urban teaching centers and centers classified as large bed size. Cirrhosis patients reported higher prevalence of diabetes, hypertension, peripheral vascular disease, smoking, obesity, chronic kidney disease, prior stroke, prior myocardial infarction, depression, drug abuse, alcohol abuse, lipid disorder, and a higher mean Charleston Comorbidity Index score. They were also at higher risk of acute kidney injury, septicemia, use of mechanical ventilation, and death. Their hospitalization was longer (mean Length of stay 5.37 vs. 2.86) with a higher mean hospital charge ($84358 vs. $55510). **Conclusion:** Patients with cirrhosis undergoing laparoscopic appendectomy were older with more comorbidities. They also experienced more complications and had a longer. This correlated to a higher healthcare cost burden. As their existed a paucity of information on cirrhosis severity, we utilized this national data base to complete a large population-based analysis. Our findings mirror other smaller studies and retrospective analyses, but this is the first study to report this data from the latest information provided by the 2016-2020 national inpatient sample.

Table 1. Characteristics of patients with and without cirrhosis undergoing laparoscopic appendectomy in the United States

Characteristics	Non-cirrhosis group (n= 529300) (%)	Cirrhosis (n=2365) (%)	p-value
Patient and hospital characteristics			
Mean age (years)	45.51	58.27	<0.01

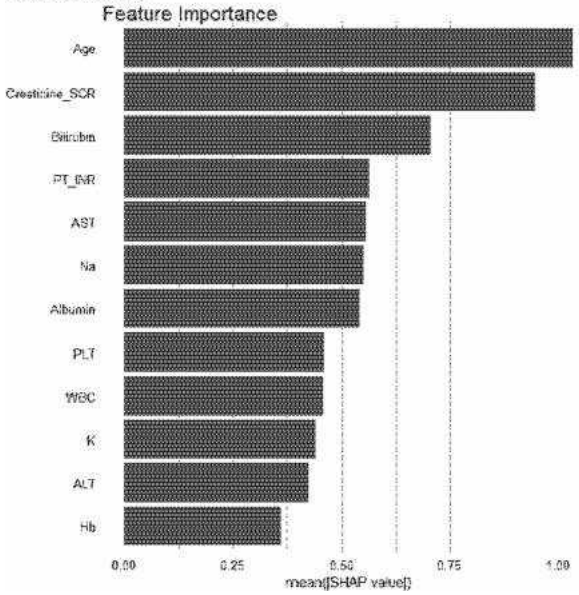
3170-A | PREDICTORS OF 30-DAY MORTALITY IN ACUTE HEPATIC DECOMPENSATION: A NATIONWIDE COHORT STUDY WITH LABORATORY DATA OF ICU ADMISSIONS

Yee Hui Yeo[1], Yi-Hsian Lin[2], Hsiu J. Ho[2], Yao-Chun Hsu[3] and Chun-Ying Wu[2], (1)Cedars-Sinai Medical Center, Culver City, CA, (2)Institute of Biomedical Informatics, Institute of Public Health, National Yang-Ming University, Taipei, Taiwan., (3)E-Da Cancer Hospital, I-Shou University

Background: Acute decompensation of cirrhosis portends a dire prognosis, frequently requiring intensive care unit (ICU) admission for vigilant management. Despite unmet needs, prior studies have been limited by cohorts with limited size or selection bias. We presented a nationwide cohort of ICU admissions with laboratory data due to hepatic decompensation and showed the predictors of mortality. **Methods:** Data were sourced from Taiwan's National Health Insurance Research Database, which comprised all ICU admissions in Taiwan from 1/1/2015 to 12/31/2018 due to acute decompensation of cirrhosis. Acute decompensation was defined using ICD-9 (2015) and ICD-10 (2016-2018) codes and included spontaneous bacterial peritonitis, gastric/esophageal variceal hemorrhage, hepatic encephalopathy, and ascites ($\geq$ 3 outpatient or 1 inpatient diagnosis of chronic liver diseases or cirrhosis). Available data comprised demographic, clinical, and laboratory parameters. The study endpoint was 30-day mortality. The cohort was divided into training (70%) and validation (30%) cohorts. Predictors of mortality were determined using the Xgboost machine learning model. The SHAP score was assessed to ascertain each variable's contribution to the model. **Results:** We identified 10,855 ICU admissions due to acute decompensation, with a mean age of 61.1 years (SE 14.4), and were predominantly male (70.2%). The majority of patients had a diagnosis of alcohol-associated liver disease (46.3%), followed by hepatitis B (31.7%) and hepatitis C (24.7%) infection. Comorbidities were prevalent, with diabetes (40.1%), COPD (21.3%), coronary artery disease (18.2%), and malignancy (20.5%) featuring prominently. Laboratory data included median ALT 33 U/L (interquartile range [IQR] 21-59), AST 64 U/L (IQR 38-130), total bilirubin 2.27 mg/dL (IQR 1.2-5.0), platelet count $107*10^9$/L (IQR 66-168), WBC count $9.7*10^9$/L (IQR 6.3-15.3), and creatinine 1.26 mg/dL (IQR 0.88-2.17). Using the Xgboost model, we attained high values of accuracy, precision, F1 score, and recall in both training and validation cohorts (all above 0.995). Age, creatinine, and total bilirubin emerged as the top three predictors of 30-day mortality, followed by INR, AST, sodium, and albumin levels. **Conclusion:** We showed the 30-day mortality predictors in a nationwide ICU cohort of patients with acute hepatic decompensation using a sophisticated machine learning model. This can inform more nuanced patient monitoring and management strategies.

Figure 1. The contribution of each variable to the predictive model (Xgboost: eXtreme Gradient Boosting)



Disclosures: The following people have nothing to disclose: Yee Hui Yeo, Yi-Hsian Lin, Hsiu J. Ho, Yao-Chun Hsu, Chun-Ying Wu

3226-A | PREDICTIVE MACHINE LEARNING MODELS FOR SHORT-TERM MORTALITY IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE

Yee Hui Yeo[1], Mengyi Zhang[2], Jian Zu[2], Jeff Liang[3] and Fanpu Ji[4], (1)Cedars-Sinai Medical Center, Culver City, CA, (2)School of Mathematics and Statistics, Xi'an Jiaotong University, Xi'an, Shaanxi, China, (3)Cedars-Sinai Medical Center, Los Angeles, CA, (4)The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Acute-on-chronic liver failure (ACLF), characterized by rapid progression and high short-term mortality, requires better predictive mortality factors. In this study, we aimed to investigate the influencing factors and short-term mortality risk in patients with ACLF. **Methods:** We utilized the MIMIC-IV database, an extensive dataset containing over 40,000 patients admitted to ICU at the BIDMC. The dataset includes demographic information, comorbidity data, treatment details, laboratory variables, vital signs, and clinical outcomes for each admission. Using the North American Consortium for End-Stage Liver Disease

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

diagnostic criteria, we identified ACLF patients and determined the 30-day mortality rate. We then applied Pearson's correlation analysis to identify variables with significant mortality associations. We developed and compared nine machine learning prediction models for short-term mortality forecasting and examined key influencing factors. **Results:** Our study identified 5994 cirrhosis patients. After excluding patients with a history of HIV, transplantation, and malignancies, and including patients who met the criteria for organ failure, a total of 1996 patients with two organ failures were included. The average age was 58.5 years (SE 12.1), with 65.5% of patients being male. Renal failure was the most prevalent organ failure (74.9%), followed by circulation (57.2%), respiration (24.3%), and brain (23.9%). The 30-day mortality rates in patients with 2, 3, and 4 organ failures were 35.2%, 62.5%, and 96.8%, respectively. Correlation analysis identified age, INR, total bilirubin, ventilation necessity, renal replacement therapy, WBC count, and creatinine level as variables with significant correlation coefficients. CatBoost and LightGBM models emerged as the most accurate models, with AUROC values of 0.91 and 0.92, respectively (Figure). The F-test further demonstrated that these variables significantly contributed to the predictive value. **Conclusion:** We established a large ACLF cohort and determined the 30-day mortality rate. Our models with high predictive accuracy suggest that age, INR, total bilirubin, ventilation necessity, renal replacement therapy, WBC count, and creatinine level are potential predictive factors for short-term mortality. Further validation of these models is warranted.

Figure. AUROC to denote the predictive accuracy of two machine learning models (a) CatBoost AUROC = 0.91 (b) LightGBM, AUROC = 0.92

3636-C | PORPHYROMONAS GINGIVALIS STRAIN W83 INFECTION INDUCES LIVER INJURY IN EXPERIMENTAL ALCOHOL-ASSOCIATED LIVER DISEASE (ALD) IN MICE

Yun Zhou[1], Wenke Feng[1,2] and Craig J. McClain[1], (1) University of Louisville, Louisville, KY, (2)Tulane University, New Orleans, LA

Background: The liver plays a crucial role in defending against infections. *Porphyromonas gingivalis (P. gingivalis*) is a dominant oral bacterium in chronic periodontitis and is associated with multiple systemic diseases. Our previous study revealed an association between *P. gingivalis* and the development/severity of alcohol-associated liver disease (ALD) in patients. This study aims to investigate the potential causal role of *P. gingivalis in* the development of experimental ALD using mice. **Methods:** C57BL6 mice were fed a Lieber-DeCarli liquid diet containing 5% ethanol for 10 days. Two days before tissue sample collection, mice were administered *P. gingivalis* strain W83 (*Pg*) via intraperitoneal injection. The control group consisted of isocaloric pair-fed mice. Liver injury and inflammation were assessed. **Results:** Pair-fed mice with *Pg* infection (PF+*Pg)* exhibited an immune response to combat infections. However, alcohol-fed mice with *Pg* infection (AF+*Pg*) displayed noticeable abscess lesions in the liver and elevated serum ALT levels. These mice also showed significant downregulation of proinflammatory cytokine gene expression which may have played a role in decreased clearance of *Pg* from the liver. Furthermore, alcohol-fed mice with *Pg* infection (AF +*Pg)* demonstrated increased neutrophil infiltration, as confirmed by chloroacetate esterase (CAE) staining, and elevated gene expression levels of neutrophil cytosol factor 1 (Ncf1), lipocalin 2 (Lcn2), and Complement component C5a receptor C5ar1, which are associated with neutrophil-associated inflammation. Compared to PF+*Pg* mice, AF+*Pg* mice exhibited downregulation of NADPH oxidase 2 (Cybb) gene expression, leukocyte adhesion molecule Cd18, and Toll-like receptor adaptor Myd88. This resulted in impaired clearance of *Pg* and other bacteria in the liver, increased susceptibility to infections, and inflammation-associated hepatic necrotic cell death, which likely contributed to liver injury through the priming of immune cell infiltration. **Conclusion:** Our study suggests that systemic *Pg* infection exacerbates alcohol-induced liver injury. Alcohol consumption impairs the liver's ability to clear periodontal bacteria originating from periodontitis pathogenesis. The accumulation of oral pathogenic bacteria further contributes to liver injury and promotes liver lipogenesis. These findings provide additional

evidence for the role of *P. gingivalis* infection as a "second hit" in the development and progression of ALD (Supported by NIH grants).

3637-C | DRAMATIC INCREASE IN ADMISSIONS FOR ALCOHOLIC HEPATITIS DURING THE COVID-19 PANDEMIC YEARS IN VICTORIA, AUSTRALIA: UNINTENDED CONSEQUENCES OF COMMUNITY LOCKDOWNS?

Timothy Phan[1], Thang Dao[1], John Santamaria[1], Barbara Demediuk[1], Marno C. Ryan[2], Tim Papaluca[1], Jacinta A. Holmes[3], David M. Iser[2], Paul V. Desmond[4], Thai Hong[5], Catherine Croagh[1], Yvonne Bonomo[1], Adam Pastor[1], Joan Ericka Flores[6], Jessica Howell[7] and Alexander J. Thompson[8], (1)St. Vincent's Hospital, Melbourne, (2)St. Vincent's Hospital, (3)St.Vincent's Hospital Melbourne, (4)St Vincent's Hospital Melbourne, Fitzroy, VIC, Australia, (5)St Vincent's Hospital Melbourne, Australia, (6)St. Vincent's Hospital, Melbourne, Alphington, VIC, Australia, (7)St Vincent's Hospital Melbourne, Australia, Clifton HIll, VIC, Australia, (8)University of Melbourne

Background: The coronavirus disease 2019 (COVID-19) pandemic was associated with direct excess of morbidity and mortality related to respiratory disease. In addition, emerging data suggests indirect health consequences related to the pandemic and community lockdowns, including increased alcohol consumption and alcohol-related harm. We have observed an anecdotal increase in the number of admissions for alcoholic hepatitis (AH) since the start of 2020. In this study we have evaluated temporal trends in hospital admissions for AH, comparing the pandemic years (2020 – 2022) with the preceding decade (2010 – 2019). **Methods:** In this retrospective cohort study, we analysed the patient database at St. Vincent's Hospital Melbourne for admissions with AH (ICD code k70.1) between January 2010 and December 2022. The medical records of a representative sample of the extracted patients were reviewed to confirm the accuracy of AH ICD coding. AH was defined as at least three of the following criteria: (1) elevated alanine amino transferase (ALT) or aspartate aminotransferase (AST) >50 IU/L, (2) AST:ALT ratio >2, (3) an elevated international normalised ratio (INR) >1.2, or (4) elevated total bilirubin >30 μmol/L. We then analysed admissions for AH recorded in the Victorian Admitted Episodes Dataset (VAED) maintained by the Victorian Department of Health. Interrupted time-series and Poisson linear regression analyses were used to compare trends in number of patients admitted with AH between the two time periods (2010 – 2019 vs. 2020 – 2022). **Results:** A total of 367 admissions with AH among 264 unique patients were identified during this time period at our institution. The median age of patients was 48 years (IQR 40, 57) and 68.6% were male. There was a significant increase in the number of admissions with AH during the years 2020-2022 compared to the years 2010 – 2019 (Figure 1A, $p<0.001$). There was an increase in AH admissions among both males and females, but the relative increase was greater in females ($p<0.001$, figure 1A). A similar phenomenon was observed in the VAED dataset; interrupted time-series analysis confirmed a significant increase in AH cases from the beginning of 2020 (Figure 1B, $p<0.05$). Extraction of detailed clinical data is ongoing. **Conclusion:** Admissions with alcoholic hepatitis have increased dramatically since the start of the COVID-19 pandemic, with relative greater increases in females. There is an urgent need for funding to develop and prioritise public health strategies to address the harms of excess alcohol consumption.

Figure 1: A. Admissions to St Vincent's Hospital Melbourne with alcoholic hepatitis (k70.1), 2010-2022. B. Admissions with alcoholic hepatitis (k70.1) registered in the VAE, 2010 - 2022

3817-C | CAREGIVER BURDEN AMONG INFORMAL CAREGIVERS OF PATIENTS AWAITING LIVER TRANSPLANTATION

George Cholankeril[1], Christopher Woodrell[2], Hoda Badr[1], Mark E Kunik[1], Zahraa Al Lami[1], Hashem B. El-Serag[1] and Fasiha Kanwal[1], (1)Baylor College of Medicine, (2)Icahn School of Medicine at Mount Sinai

Background: Informal caregivers of patients with chronic liver disease could experience significant burden from caregiving with negative consequences for caregivers' and patients' outcomes. However, this burden is poorly understood in caregivers of patients undergoing liver transplant (LT) evaluation, which is the period of heightened vulnerability for patients and their caregivers. **Methods:** We conducted a prospective study in informal caregivers of LT candidates between January 2023 and May 2023 to examine the magnitude of and factors associated with caregiver burden. Coordinator assisted Zarit Burden Interview (ZBI) questionnaire (22-item) was used to assess perceived caregiver burden, with ZBI score ≥ 21 indicating high caregiver burden. We also collected data on caregiver's health-related quality of life (Short form, SF-36), perception of social support (Interpersonal Support Evaluation List, ISEL), as well as caregiver and patient characteristics. We used generalized linear regression models to evaluate associations with ZBI score and logistic regression to identify factors that were independently associated with high caregiver burden (ZBI ≥ 21). **Results:** In total, 83 primary caregivers participated in the study, with 60.2% caring for patients undergoing evaluation and 39.8% caring for patients on the liver transplant waitlist. Median age of caregivers was 50 years [IQR, 22], 66.7% were female, 51.2% White, 34.1% Hispanic, and 56.5% were sole caregivers. Overall, 37.6% (n = 31) reported some degree of caregiver burden, and 9.6% (n = 8) experienced moderate to severe caregiver burden. Significantly higher (worse) ZBI scores were seen in caregivers who were women, older in age, non-Hispanic, and sole caregivers (Table 1). Lower levels of caregiver perceived social support (ISEL), general well-being (SF-36), mental health, and vitality were associated with higher ZBI scores. Caregivers of patients in the evaluation phase had higher odds of experiencing burden than patients on the waitlist. In multivariable analyses, higher patient frailty (OR, 1.92, 95% CI, 1.03-3.62) and MELD (OR, 1.12, 95% CI, 1.01-1.25), as well as lower caregiver vitality (OR, 1.08, 95% CI, 1.01-1.18), were associated with increased burden. **Conclusion:** Informal caregivers of LT candidates experience high burden during the evaluation and waitlist phases. It is crucial to provide support and resources to caregivers to mitigate their burden and improve their well-being throughout the transplant process.

Table. Characteristics of informal caregivers of liver transplant candidates and predictors for caregiver burden

		ZBI Score	*Caregiver Burden (ZBI ≥ 21)* N=31	
	Total N=83	Median ZBI [IQR]	Univariate Odds Ratio (95% CI)	*P* value
