1202-C | AUTOIMMUNE HEPATITIS AFTER ANTI-SARS-COV-2 VACCINATION: SYSTEMATIC REVIEW AND META-ANALYSIS

Hye Won Lee[1], Wonjoon Jang[1] and Seung Up Kim[2], (1) Yonsei University College of Medicine, (2)Severance Hospital, Seoul, Republic of Korea

Background: Vaccination against severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) is associated with autoimmune hepatitis. A systematic review and meta-analysis were conducted to assess the incidence of acute liver failure (ALF) following after SARS-CoV-2 vaccination. **Methods:** Patients diagnosed with autoimmune hepatitis following administration of the anti-SARS-CoV-2 vaccine from Pfizer, Moderna or AstraZeneca were eligible. ALF was diagnosed when the prothrombin time international normalized ratio exceeded 1.5 or total bilirubin level exceeded 11.7 mg/dL. **Results**: Of the 49 study participants, the majority were females (n = 34, 69.4%), and the median age was 62 years. Forty (81.6%) patients received mRNA vaccines, and 17 (34.7%) developed ALF. The rate of ALF was significantly lower among patients who received mRNA vaccines (28.6% vs. 77.8%, $p = 0.001$). Among the 12 patients who underwent liver biopsy, lobular hepatitis was identified in 12 (100%), eosinophilic infiltration in 6 (50%), and cholestasis and bile duct injuries in 2 (16.7%). Additionally, 4 (33.3%) patients in the non-ALF group had histologic fibrosis. Among the 35 patients who underwent autoimmune serology, anti-antinuclear antibodies were identified in 32, anti-smooth muscle antibodies in 12, and anti-mitochondrial antibodies in 4. Forty-two patients were treated with steroids with and without azathioprine; one underwent plasma exchange. Administration of Vaccines other than the mRNA vaccine (odds ratio [OR] = 15.7, 95% confidence interval [CI] = 1.32–188.0, $p = 0.029$) and an aspartate transaminase level > 1,000 IU/L (OR = 17.2, 95%

CI = 1.6–185.0, $p = 0.019$) were independent predictors of ALF. Five patients died due to autoimmune hepatitis after anti-SARS-CoV-2 vaccination. **Conclusion:** SARS-CoV-2 vaccination can cause acute live injury. Thus, patients who experience liver-related symptoms or liver enzyme abnormalities should be monitored closely.

1203-C | AWARENESS AND ATTITUDES OF HEPATITIS D TESTING AMONG PATIENTS WITH CHRONIC HEPATITIS B INFECTION: A TERTIARY CARE CENTRE EXPERIENCE

Faisal Abaalkhail[1,2], Asma AlNajjar[1], Waleed K Al-Hamoudi[1,3] and Saleh A. Alqahtani[1,4], (1)King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, (2)Alfaisal University, (3)Liver Disease Research Center, King Saud University, (4)John Hopkins University, Baltimore, MD

Background: Hepatitis D virus (HDV) infection affects 12 million people worldwide, and it always exists in the setting of hepatitis B, as it uses HbsAg for entry into the cells. The prevalence of HDV infection in HBsAg-positive patients ranges between 4.5 to 14.6%. Co-infection with HBV can result in serious and fulminant hepatitis. Superinfection with HDV accelerates cirrhosis and the risk of HCC. 10%–20% of people with HDV infection develop cirrhosis within 2 years, and 70%–80% do so within 5–10 years. Additionally, the incidence of hepatocellular carcinoma (HCC) and cirrhosis in HBV-HDV co-infection are 20% and 18%, respectively. Pegylated interferon (PEG-IFN) was the sole medication against HDV that was approved from 1980 until today. It is not a very effective treatment and carries many side effects. The prevalence of HDV infection in chronic hepatitis B patients even in the presence of hepatitis B vaccine remains underreported. Our study aims to report the prevalence of HBV/HDV co-infection with the comparison of morbidity and mortality outcomes, raise awareness of HDV testing, and analyze the attiude of hepatitis delta testing at our center. **Methods:** All patients tested for hepatitis D from September 2022-February 2023 were included. Demographic, biochemical, clinical and extensive viral serology workup was collected retrospectively. **Results:** Thirty-three patients out of the 1630 patients that were tested for hepatitis delta were found to have reactive hepatitis delta virus total antibody (0.5%). 19 patients were females and 14 were males. The mean recorded age was 47 years. 1 patient died of hepatocellular carcinoma-related complications. Eight patients with HBV/HDV coinfection had decompensated cirrhosis; 5 out of the eight had HCC. Two patients underwent liver transplantation during the above period. Decompensation was mostly characterized by varices, ascites, and hepatic encephalopathy. Median ALT was 61 U/L (range 20-2000). Median AFP was 4.8 ng/mL (range 1-11,100). **Conclusion:** Although delta serology was requested for patients with no evidence of prior hepatitis B infection such as oncology patients, we encourage more education and awareness about guidelines for hepatitis D testing. We plan to evaluate a larger number of patients with chronic HBV/HDV infection in the future, as HDV is under-evaluated in patients with advanced liver disease secondary to HBV.

Disclosures: The following people have nothing to disclose: Faisal Abaalkhail, Asma AlNajjar, Waleed K Al-Hamoudi, Saleh A. Alqahtani

1204-C | BULEVIRTIDE: YES OR NO? TREATMENT FOR HEPATITIS D AND BEYOND

Helen Yu Xu, Jamie Olivia Yang, Phillip Chen and Steven-Huy B. Han, University of California, Los Angeles

Background: Hepatitis D virus (HDV) causes both acute and chronic liver disease that requires the co-infection of the Hepatitis B virus (HBV). Both co-infection and superinfection of HDV with HBV can lead to significant morbidity and mortality. Chronic hepatitis D infection prevalence is likely underestimated given limited screening, particularly in the United States (US). The current standard of therapy, pegylated interferon alpha, has an undesirable side effect profile and does not specifically target the HDV viral life cycle. HDV and HBV rely on the sodium taurocholate co-transporting peptide (NTCP) for hepatocyte cell receptor entry. Bulevirtide is a first-in-class entry inhibitor drug that acts on NTCP to prevent viral entry into target cells in chronic HDV infection. Bulevirtide was conditionally approved in Europe in 2020, and is currently undergoing Phase 3 clinical trials in the US. In addition to bulevirtide, a number of other novel therapies or novel applications of existing therapies for chronic Hepatitis D are in various states of investigation. **Methods:** PubMed databases were reviewed. Eighty-six articles in total were identified with keyword “bulevirtide,” of these articles, twenty were included in consideration of the review for relevance and data. Current US clinical trial data and other investigational HDV therapies were also reviewed (see Table 1). This is the most comprehensive and updated review of bulevirtide and new therapies for chronic Hepatitis D. **Results:** In European clinical trials, virologic response of HDV to various bulevirtide doses combined with tenofovir was significantly higher than with tenofovir monotherapy.

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Trials that compared combination bulevirtide plus pegylated interferon alpha vs interferon monotherapy also demonstrated significant increase in virologic response, as measured by undetectable HDV RNA at the end of the trial period. Liver stiffness was significantly decreased in the immediate vs delayed bulevirtide treatment arms. Treatment with different doses of bulevirtide were comparable. Across studies, bulevirtide was well-tolerated and no significant adverse events occurred or led to treatment discontinuation. **Conclusion:** Bulevirtide represents a potential major shift in treatment for chronic HDV, for which there is significant unmet need. European data suggests a promising future for bulevirtide in the treatment of chronic hepatitis D, which is associated with severe liver disease and complications, such as high rates of hepatocellular carcinoma. Ongoing US studies will elucidate whether bulevirtide may be useful in broad and diverse populations, particularly given differences in prevalence and demographics. These data could also inform the need for updated US screening guidelines. Future studies may investigate expanding inclusion criteria to include decompensated liver disease and other co-morbid conditions.

Table 1. Therapies for Chronic Hepatitis D

Compound	Company	Stage of Development	Mechanism of Action
Bulevirtide (previously known as myrcludex B)	Gilead	Phase III Conditional approval by EMA	Sodium taurocholate co-transporting polypeptide (NTCP) receptor antagonist
Pegylated Interferon alpha	Genentech	Off label use for Hepatitis D	Type I interferon
Lonafarnib	Eiger	Phase III	Farnesyltransferase inhibitor (farnesylation of Hepatitis D antigen mandatory for Hepatitis D virus (HDV) assembly)
Pegylated interferon lambda	Eiger	Phase III	Type III interferon
REP 2139	Replicor	Phase II	Nucleic acid polymer blocks assembly of Hepatitis B subviral particles to reduce HBsAg
JNJ-3989	Arrowhead/J&J	Phase II	Ribonucleic acid (RNA) interference compound
Ezetimibe	Merck	Phase II	Anti-cholesterol medication that can inhibit NTCP
VIR-2218	Vir biotechnology	Phase II	siRNA targeting HBx region of HBV genome
VIR-3434	Vir biotechnology	Phase II	Monoclonal antibody that blocks entry of HBV and HDV viruses into hepatocytes
HH-003	Huahui Health	Phase II	Monoclonal antibody targeting pre-S1 domain of HBV large envelope protein, blocking engagement of pre-S1 with NTCP
Hepalatide	Shanghai HEP pharmaceutical	Phase II	Peptide that blocks NTCP

Background: Compulsory hepatitis B virus (HBV) vaccination greatly reduced new hepatitis D virus (HDV) infections in native Italians. However, migratory

flows from HDV endemic areas, fostered by labor forces globalization, are increasingly reconstituting the reservoir of HDV in Italy. We investigated the current epidemiologic and medical features of contemporary HDV cases in Italy in order to determine the burden and features of HDV infection according to Country of origin, age, and regional distribution. **Methods:** Consecutive patients with chronic HDV infection referred to 14 different third-level Italian Centers (hepatology, infectious disease, and internal medicine units) were prospectively enrolled from August 2022 to April 2023. All patients aged ≥ 18 years, positive for hepatitis B surface antigen (HBsAg) and antibodies to HDV (anti-HD), were considered eligible. **Results:** Overall, 212 patients were recruited in the present cross-sectional study. Median age was 56 (IQR 45–62) years and most patients were males (n = 141; 66.5%). Native Italians were 127 (59.9%). Among patients born abroad, the majority (n = 72; 84.7%) were from East Europe, followed by Africa (n = 10; 11.8%), South America (n = 2; 2.4%), and West Europe (n = 1; 1.2%). Interestingly, the distribution of HDV patients born abroad appeared uneven in the Country, with a higher prevalence in North Italy as compared to the South (81 [52.9%] vs. 4 [6.8%]; $p < 0.001$). The mean number of foreign-born household members was 3.9 ± 2.4; the 7.1% was HBsAg-positive and the 4.6% was positive for anti-HD. However, the HBsAg and anti-HD serologic profile was unknown in 32.1% and 62.7% of total cases. In comparison to patients born abroad, native Italians were older (60, IQR 56–64, y vs. 43, IQR 37–50 y; $p < 0.001$), more likely to be male (72.4% vs. 57.6%; $p = 0.026$), with a more advanced liver disease (Cirrhosis: 62.8% vs. 50.0%; $p = 0.071$; hepatocellular carcinoma: 18.3% vs. 4.1%; $p = 0.004$). Conversely, patients born abroad showed higher ALT values (50, IQR 33–74 U/L vs. 36, IQR 26–59 U/L; $p = 0.005$), higher HBsAg levels (5468, IQR 672–11258 IU/mL vs. 1200, IQR 43–4440 IU/mL; $p < 0.001$), and low rate of HBV antiviral treatment (62.5% vs. 76.7%) as compared to native Italians. **Conclusion:** In Italy, patients born abroad accounted for nearly half of the overall HDV infections and will increasingly contribute to the medical burden of chronic hepatitis D in the years to come. *This research was supported by Gilead Sciences, Inc (study ID: IN-IT-980-6382).*

1206-C | CHARACTERISTICS OF BACTERIAL LIVER ABSCESS IN THE CHANGCHUN COVID-19 EPIDEMIC AND COMPARATIVE EVALUATION OF THE PAST THREE YEARS

Yu Tian[1], Xiao Yu Wen[2] and Meili Dong[1], (1)The First Hospital of Jilin University, (2)Center for Infectious Diseases and Pathogenic Biology / Department of Hepatology, the First Hospital of Jilin University

Background: During the period of the massive COVID-19 outbreak in Changchun last spring (March 1, 2022-June 30, 2022), the number of patients with bacterial liver abscess in our hospital was significantly higher than in previous years. This study provides an overview of the clinical and epidemiological characteristics of patients who developed bacterial liver abscess in the First Hospital of Jilin University during the COVID-19 outbreak last spring. **Methods:** This study screened all 37,411 patients discharged from the First Hospital of Jilin University during the COVID-19 epidemic in Changchun last spring and finally included 135 patients with bacterial liver abscess. We then collected their clinical data, outlined their clinical characteristics, and compared and analysed the incidence and causative flora of the bacterial liver abscess patients in this group with those in our hospital from March to June each year in 2019-2021. **Results:** From March to June 2022, BLA patients accounted for 0.36% of our total admissions, an increase from previous years ($p < 0.001$). The basic clinical characteristics of the 135 patients with bacterial liver abscesses are shown in Table 1. The majority of BLA patients were middle-aged and older males. The length of stay of 135 BLA patients was 11.00

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(6.00,18.00) days, which was longer than in previous years ($p = 0.026$). White blood cell count, C-reactive protein, alkaline phosphatase, and urea nitrogen all increased to varying degrees compared to previous years, whereas HDL decreased to varying degrees. The blood culture were as follows(n = 69): Aseptic growth (59.42%), Klebsiella pneumoniae (30.43%), Escherichia coli (4.35%), Mycobacterium fragilis (1.45%), Enterococcus faecalis (1.45%), Staphylococcus epidermidis (1.45%), and acid-producing Klebsiella (1.45%). The pus culture results were as follows (n = 90): Klebsiella pneumoniae (72.22%), aseptic growth (14.44%), Escherichia coli (4.44%), Enterococcus faecalis (2.22%), Pseudomonas aeruginosa (2.22%), Acinetobacter baumannii (1.11%), Klebsiella aerogenes (1.11%), Klebsiella acidophilus (1.11%), Enterococcus leadus (1.11%).Bacterial liver abscesses occurred in the right lobe in 58.46% of cases, and were solitary in 66.15% of cases. People with diabetic mixed bacterial liver abscesses had a significantly higher rate of *Klebsiella pneumoniae* infection (83.78%) and were more likely to have combined lung abscess bilateral pleural effusions and infectious shock than people with non-diabetic mixed bacterial liver abscesses. **Conclusion:** In conclusion, patients had longer hospital stays, higher white blood cell counts and CRP levels during the Changchun COVID-19 epidemic than during the same period in previous years. The primary causative organism was *Klebsiella pneumoniae*, and the majority of patients recovered with treatment. Mixed liver abscesses caused by *Klebsiella pneumoniae* were more common in diabetic patients.

1207-C | CRISPR/Cas13a-ASSISTED ACCURATE AND PORTABLE HEPATITIS D VIRUS RNA DETECTION

Xiangying Zhang, Feng Ren, Yuan Tian and Zihao Fan, Beijing Youan Hospital Capital Medical University, Beijing, China

Background: Hepatitis delta virus (HDV) infection accelerates the progression of chronic hepatitis B virus infection (HBV), posing a large economic and health burden to patients. At present, there remains a lack of accurate and portable detection methods for HDV RNA. Here, we aim to establish a convenient, rapid, highly sensitive and specific method to detect HDV RNA using CRISPR-Cas13a technology. **Methods:** We downloaded the genome sequence from the HDV database, performed multisequence alignment, and designed and screened CRISPR RNA (crRNA), reverse transcription polymerase chain reaction (RT-PCR) and reverse transcription recombinase-aided amplification (RT-RAA) primers binding in the conserved sequence region. After processing the synthetic plasmids and samples using thermal shock, we established fluorescence and lateral flow strip assays based on CRISPR-Cas13a combined with RT-PCR and RT-RAA, respectively. Clinical plasma samples were further validated by a CRISPR-Cas13a-based assay. **Results:** For synthetic HDV RNA plasmids, the sensitivity of RT-PCR-CRISPR-based fluorescence assays was 1 copy/μL, higher than that of reverse transcription quantitative real-time PCR (RT-qPCR) (10 copies/μL) and reverse transcription droplet digital PCR (RT-ddPCR) (10 copies/μL); for HDV RNA-positive samples, the sensitivity of RT-RAA-CRISPR-based fluorescence and lateral flow strip assays was 10 copies/μL, as low as that of RT-qPCR and RT-ddPCR, and the assay took only approximately 85 minutes. Additionally, the positivity rates of anti-HDV IgG-positive samples detected by the RT-qPCR, RT-ddPCR, RT-PCR-CRISPR fluorescence and RT-RAA-CRISPR lateral flow strip methods were 66.7% (96/144), 76.4% (110/144), 81.9% (118/144), and 72.2% (104/144), respectively. **Conclusion:** We developed a highly sensitive and specific RT-PCR-CRISPR assay, as well as a portable and easy RT-RAA-CRISPR-based assay for the detection of HDV RNA, which could be a prospective measure for monitoring the development of HDV infection and evaluating the therapeutic effect.

1208-C | DELTA DESCRIBE: A 5-YEAR SNAPSHOT OF NATIONAL DELTA HEPATITIS SCREENING IN METROPOLITAN FRANCE

Veronique Loustaud-Ratti[1], Sandrine Francois[2], Sophie Alain[1], Marilyne Debette Gratien[1], Paul Carrier[1] and Celine Rigaud[1], (1)Limoges University Hospital, (2) Service d'Hépato-Gastroentérologie, CHU De Limoges

Background: HDV infection is a public health disease. In metropolitan France, very few studies focused on reference centers, assess the prevalence of HDVAb at about 4 %. We have a need of real life data on delta screening. Our objectives were to define over five years, the number of Delta tests performed, compare it to that potentially expected, and describe global characteristics of patients and prescribers. **Methods:** Retrospective study on data issued from the French Health insurance (SNDS) (2016 to 2020). A snapshot of HDV, HBV, HIV and HCV tests performed is provided; then a description of epidemiological characteristics of patients receiving HDV tests with the profile of prescribers. Extractions of SNDS data are achieved through targeting algorithms and patients'duplicates are discarded. The expected number of HDVAb tests is calculated from the estimate of the positivity of HBsAg tests prescribed in France (0,8%). **Results:** Over the five years period, 18 021 850 HCVAb, 20 127 962 HIVAb, 18 736 721 HBsAg, 88 275 HDVAb and 10 306 HDVRNA tests were performed. We observe a 30% increase of HBV tests between 2016-2019 and a decrease of 6% between 2019 and 2020 (COVID pandemic). The number of HDVAb increases by 81% between 2016 and 2019 and decreases by 5% between 2019 and 2020. The number of HDVRNA increases by 80% between 2016 and 2019 with a peak between 2019 and 2020 +26% despite the pandemic (transitional authorization of Bulevirtide in Sept 2019 and marketing in Sept 2020). Of the expected HDVAb tests, 46% only were done in 2016 and 64% in 2020. Patients were screened for HDV mainly in Paris region 31% and south of France (Occitanie, PACA, Auvergne Rhône Alpes) 24%; 40% of them corresponded to a precarious profile or migrant status. Prescribers were mainly general practitioners (GP) 64% and gynecologists 19% for HBV and GPs 78% and hepatogastroenterologists 11% for HDV. By focusing on some populations of interest: in pregnant women in 2020 only 0.16% of HBV screenings were followed by an HDV test. In patients followed for chronic HBV infection, 22.7% benefited from delta screening. **Conclusion:** In real life, HBV screening which is essential for delta screening has increased over the 5 years. The number of HDVAb tests performed was multiplied by 1.8, with a clear impact of the arrival of bulevirtide but should still be 1.5 times greater. Reflex testing for HDV should be universally accepted as it increases the number of HDV cases revealed.

1209-C | DEMOGRAPHIC AND GEOGRAPHIC PREVALENCE OF HEPATITS A IN UNITED STATES

Ayusha Poudel[1], Sajana Poudel[1], Manoj Ghimire[2], Smriti Khanal[3] and Anurag Adhikari[4], (1)John H Stroger Jr. Hospital of Cook County, (2)Mayo Clinic, (3) Cook County Hospital, (4)New York City Health and Hospitals/ Jacobi

Background: The incidence of Hepatitis A infection has been trending down in the United States especially after the recommendation of childhood vaccination in 1996. Current infection is seen in people mostly among travelers from endemic countries or food from endemic countries. Outbreaks tend to occur in high risk population like men those who have sex with men, homeless, those with poor sanitation and those who use illicit drugs. **Methods:** This is a retrospective study of the National Inpatient Survey (NIS) database of year 2016 to 2020. Patients with the primary diagnosis of Hepatitis A and above 18 years of age were included in the study. The demographic, geographic, health insurance and prior co-morbidity information were included and further analyzed in the study. **Results:** 4000 patients were found to be admitted with the primary diagnosis of Hepatitis A infection, out of which 3990 also had coma and 10 did not have coma. 8% of the patients also had acute liver failure. 60.6% of the patients were male and 39.4% of the patients were female. The mean age of Hepatitis A patient was 43.4.81.31% were Whites, 7.58% Blacks, 4.42% Hispanics, 0.7% Asians and 1% were Native Americans.11.62% of the Hepatitis A patients had Medicare, 30.56% Medicaid, 21.59% had a private insurance and 30.56% were under self-coverage. The distribution of hospitals reporting Hepatitis A were 9.34% in the North East, 15.91% in the Mid West, 66.67% in the South and 8.08% in the West.5.43% of the Hepatitis A patient had diabetes, 21.97% had hypertension, 0.88% had heart failure, 1.52% had chronic kidney disease, 11.87% had

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hyperlipidemia **Conclusion:** The proportion of Hepatitis A infection seems to be high among the males than females. Whites as compared to other races and the Southern states seem to have more burden of Hepatitis A.

1210-C | DETECTION AND QUANTIFICATION OF HEPATITIS DELTA VIRUS RNA BY THREE DIFFERENT ASSAYS

Marta Illescas-López[1], Lucía Chaves-Blanco[1], Adolfo De Salazar[1], Melisa Hernandez[2], Raquel Carracedo[3], Laura Viñuela[1], Eduardo Lagarejos[2], Sara Pereira[3], Ana Fuentes[1], María Cea[3], Alberto De La Iglesia[4], Carolina Freyre Carrillo[5], Asunción Iborra[6], María Del Valle Odero[7], Aurora García-Barrionuevo[8], Fernando Fernández-Sánchez[9], Antonio Aguilera[10], María José Pena[2] and Federico Garcia[1], (1)Hospital Universitario Clínico San Cecilio, (2)Hospital Universitario De Gran Canaria Doctor Negrín, (3)Hospital Clínico Universitario De Santiago De Compostela, (4)Hospital Infanta Elena, (5)Hospital De Puerto Real, (6)Hospital Universitario Virgen De La Arrixaca, (7)Hospital De Jerez De La Frontera, (8)Hospital Universitario Clínico Virgen De La Victoria, (9)Hospital Costa Del Sol, (10)Complejo Hospitalario Santiago De Compostela

Background: Detection and quantification of Hepatitis delta virus (HDV) RNA in these patients is crucial for diagnosis and, recently, also for treatment management. Little is known on the impact of HDV genotype on severity of the disease and on the accuracy of viral load tests. The aim of this study was to evaluate and compare the efficacy of the three commercial assays for the detection and quantification of HDV RNA. **Methods:** Sixty-two HDV-RNA positive samples previously analysed with Hepatitis Delta RT-PCR system kit (Vircell, Granada, Spain) were tested in parallel with EurobioPlex HDV assay (Eurobio Scientific, France), and sixty-one of them with RoboGene HDV RNA Quantification kit (Roboscreen Diagnostics, Leipzig, Germany). In addition, 91 samples from HBsAg positive but anti-HDV negative were analysed. For genotyping, an amplicon-based sequencing strategy with overlapping primers was used to amplify the whole genome of HDV on a Nextseq 1000 (Illumina). **Results:** Using the EurobioPlex HDV kit, 61 samples scored positive and 1 negative; with the Robogene HDV Kit, 60 scored positive and 1 negative. Considering the qualitative result, the concordance between the Vircell Hepatitis Delta kit and the EurobioPlex HDV and the RoboGene kit was 98.4%, while the concordance between EurobioPlex HDV kit and RoboGene HDV RNA kit was 100%. All 90 samples from HBsAg positive anti HDV negative tested negative by all three HDV-RNA assays. Considering, the Robogene assay as reference, sensitivity (S), specificity (Sp), and positive (PPV) and negative (NPV) predictive values were as follows: EurobioPlex, 100% (CI 95% 94.1-100%), 100% (CI 95% 96.0-100%), 100% (CI 95% 94.1-100%), 100% (CI 95% 96.0-100%); Vircell HDV-RNA kit, 100% (CI 95% 94.1-100%), 98.9% (CI 95% 94.1-99.9%), 98.4% (CI 95% 91.3-99.9%), 100% (CI 95% 96.0-100%). In terms of quantitative results of HDV RNA (log IU/ml), correlation coefficients were: 0,703 for Hepatitis Delta RT-PCR vs EurobioPlex HDV, 0,833 for Hepatitis Delta RT-PCR vs RoboGene HDV RNA Quantification and 0,825 for EurobioPlex HDV vs RoboGene HDV RNA Quantification. The Bland-Altman statistical analysis yielded a mean bias of 2,083 Log10 UI/mL and -1,283 Log10/mL between Eurobio/Vircell and Robogene/Vircell respectively, what showed significant differences in the quantitative performance of all the three kits compared. Full HDV genome sequencing data is available in 47 samples: 41 were annotated as genotype 1 and 6 as genotype 5. **Conclusion:** The three HDV-RNA assays evaluated have shown a good concordance in terms of qualitative detection. However, we have observed important differences at the quantitative level. We highlight that these three assays are not interchangeable for monitoring HDV viral load during HDV treatment. All three systems were able to detect and quantify HDV-RNA from patients infected by genotypes 1 and 5.
Disclosures: The following people have nothing to disclose: Marta Illescas-López, Lucía Chaves-Blanco, Adolfo De Salazar, Melisa Hernandez, Raquel Carracedo, Laura Viñuela, Eduardo Lagarejos, Sara Pereira, Ana Fuentes, María Cea, Alberto De La Iglesia, Carolina Freyre Carrillo, Asunción Iborra, María Del Valle Odero, Aurora García-Barrionuevo, Fernando Fernández-Sánchez, Antonio Aguilera, María José Pena, Federico Garcia

1211-C | DISSEMINATED HSV-2 HEPATITIS IN A LIVER TRANSPLANT PATIENT PRESENTING AS FEVER OF UNKNOWN ORIGIN

Kunal Elete, Machaiah Madhrira, Sridhar Allam, Ashraf Reyad and Randy Nguyen, Medical City Fort Worth

Background: Herpes simplex virus (HSV) is a rare cause of acute hepatitis with high mortality. Transplant recipients are at especially high-risk of opportunistic infections due to chronic immunosuppression. Here, we present a case of disseminated HSV-2 hepatitis in a liver transplant patient who presented with a fever of unknown origin (FUO). **Methods:** A 67-year-old female with a history of alcoholic cirrhosis s/p liver transplant

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(2017), and end-stage renal disease due to non-recovered hepatorenal syndrome s/p renal transplant (2022) presented with recurrent fever. Patient was initially hospitalized for 1 week due to FUO. Her workup comprised of pan-cultures, a respiratory panel, and renal/liver allograft function testing were all negative. After treatment with empiric antibiotics and resolution of fevers, she was thought to have viral syndrome and discharged home. However, symptoms recurred within 48 hours of improvement. Additional workup included hepatitis panel, testing for viral and fungal infections, imaging of head/chest/abdomen, upper and lower endoscopies, lumbar puncture, and echocardiogram, which were unrevealing. With persistent fevers, increases in serum creatinine and AST from initial values were noted. She also developed two ulcerated plaque lesions on her right thumb and lower abdomen. MRI of abdomen and biopsy of skin lesions and kidney and liver transplants were pursued. **Results:** Kidney biopsy was unremarkable. Liver allograft biopsy was positive for HSV hepatitis with extensive necrosis. Skin punch biopsies showed HSV infection as well and serologic testing for HSV resulted positive for HSV-2 IgG and DNA PCR. She was started on IV Acyclovir at 10mg/kg with resolution of fevers, normalization of AST, and improvement of skin ulcers. On discharge, she was transitioned to oral Valacyclovir for an additional 3-6 months of therapy. **Conclusion:** HSV-2 typically causes genital herpes, but it can also cause systemic infections in immunocompromised hosts. Hepatitis secondary to infection with HSV-1 or HSV-2 is a rare complication that can lead to acute liver failure (ALF) if not promptly diagnosed and treated. In one study, HSV hepatitis occurred most frequently in the setting of disseminated herpes in solid organ transplant patients. Our patient was unusual with her fairly indolent course, whereas most of the literature describes patients with more fulminant courses. Early recognition, diagnosis and initiation of treatment with IV Acyclovir can help prevent ALF.

1212-C | ENHANCING HEV DIAGNOSTIC TESTING IN RESOURCE-LIMITED SETTINGS: DEVELOPMENT AND EVALUATION OF AN IN-HOUSE ELISA METHOD FOR SEROPREVALENCE ESTIMATION IN CAMBODIA

Ulugbek Khudayberdievich Mirzaev[1,2], Bunthen E[1,3], Serge Ouoba[1,4], Ko Ko[1], Aya Sugiyama[1], Tomoyuki Akita[1], Kazuaki Takahashi[1] and Junko Tanaka[1], (1) Department of Epidemiology, Infectious Disease Control and Prevention, Graduate School of Biomedical and Health Sciences, Hiroshima University, Japan, (2) Scientific Research Institute of Virology, Tashkent, Uzbekistan, (3)Payment Certification Agency (PCA), Ministry of Health, Phnom Penh, Cambodia, (4)Unité De Recherche Clinique De Nanoro (URCN), Institut De Recherche En Sciences De La Santé (IRSS), Nanoro, Burkina Faso

Background: In regions with limited access to clean water and sanitation facilities, such as Cambodia, Hepatitis E virus (HEV) is a significant public health concern. To improve diagnostic testing and public health interventions, it is essential to develop accurate and affordable methods. In this study, we aim to create an accurate in-house ELISA test for detecting HEV, compare it with a commercial kit, and estimate the prevalence of HEV in Cambodia, where the reported anti-HEV IgG positivity rate was 18.4% in 2014. **Methods:** This is a continuum of study on hepatitis B mother-to-child transmission conducted in Siem Reap, Cambodia from February 2020 to December 2021. Inhouse double antigen Sandwich ELISA method was developed to detect anti-HEV where enzyme-conjugated antigen was used instead of enzyme-conjugated secondary antibody. To validate inhouse ELISA, 262 pregnant women's serum randomly selected among overall 1565 were tested both commercial (Institute of Immunology, Japan) and inhouse ELISA. The validation of test was examined by receiver operation curve analysis using JMP 16.0 (SAS, USA). The performance of the new test was evaluated by sensitivity, specificity, positive and negative predictive values. The discriminatory power of the test was assessed by ROC curve. We also estimated Youden index and Cohen's kappa coefficient. All 1565 samples will be detected for anti-HEV using inhouse ELISA method and then estimate its prevalence. **Results:** In our preliminary study, out of 262 samples, 25 (9.5%) tested positive for the commercial anti-HEV IgG test. By ROC analysis, the

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

optimal cutoff for inhouse ELISA was 0.11 and its sensitivity and specificity were 84% and 91.2% respectively. The AUC was calculated to be 0.868, indicating good discriminatory power. The inhouse ELISA showed Youden index of 0.755 and Cohen's kappa coefficient of 0.425. The positive and negative predictive values were 0.512 and 0.982 respectively. **Conclusion:** In this study among pregnant women in Siem Reap, Cambodia, the prevalence of hepatitis E virus (HEV) infection using a commercial ELISA kit was found to be 9.5%. The newly developed in-house sandwich method demonstrated promising sensitivity and specificity in detecting HEV IgG antibodies, making it a valuable tool for screening, especially in resource-limited settings. Further we planned to test all 1565 samples by new method and will present the results at the conference.

Background: Hepatitis B virus (HBV) and Hepatitis delta virus (HDV) coinfection causes the most aggressive form of viral hepatitis in humans. There are limited epidemiological studies in North America. **Methods:** In this retrospective cohort study we analyzed demographic and clinical outcomes including non-invasive fibrosis assessment using serum fibrosis markers and transient elastography (i.e., FibroScanÒ) in HBV/HDV coinfected patients from the Canadian Hepatitis B Network. **Results:** In 158 HDV antibody positive patients, 32.9% were female (range 26.0-40.6, n = 155), mean age was 48.6 years (IQR 45.0, 49.0) and 12.7% (19/149) were born in Canada. Reported countries of origin in 126 foreign-born patients included endemic regions (i.e., Mongolia, Sudan, Liberia, Romania, Vietnam, Afghanistan, Russia, Cameroon). More patients were Black (38.3% (57/149) ($p < 0.01$) vs. 20% (30/149) Asian, 6 % (9/149) White. At initial visit, 14.4% (19/132) were HBeAg positive, median HBV DNA was 2.5 Log IU/mL (IQR 2.1, 2.8) and 74% (95/130 tested) were HDV RNA positive. Anti-HBV nucleos(t)ide analogue therapy was prescribed in 65% (104/158) of which 29.4% (31/104) were also treated with Pegylated-Interferon. Individual's were more likely to receive antiviral therapy if diagnosed with cirrhosis ($p < 0.03$). Reported health risks included any alcohol use: 34.8% (52/158), smoking (27.8%, 44/158), and hypertension 16.5% (26/158). 43.7% (69/158) were cirrhotic, 7.6% (12/158) were identified with hepatocellular carcinoma, and 4.4% (7/158) underwent liver transplantation. In those with available TE data collected to date, 64.9% (61/94) had > F2 fibrosis (TE > 7.3 kpA). In some patients with only minimal-mild fibrosis, increase in liver stiffness measurement (71.4% of those tested) and non-invasive serum markers (i.e., APRI > 1.5 in 69.2% tested) occurred between years 1- 5 of follow-up. **Conclusion:** The majority of chronic hepatitis Delta patients living in Canada are born in endemic regions and present with advanced fibrosis or end-stage liver disease (cirrhosis and HCC) at young age. Serial follow-up data in some patients show fibrosis progression based on non-invasive testing, highlighting need for close follow-up. Funding: Gilead

1214-C | EPIDEMIOLOGY OF HEPATITIS DELTA INFECTION: REAL-WORLD DATA FROM A LARGE HEALTHCARE PROVIDER IN ISRAEL

Rawi Hazzan[1,2], Marvin Rock[3], Ankita Kaushik[3], Odelia Liani[4], Yonatan Green[4], Eran Bar-Haim[4], Clara Weil[5], Sivan Gazit[5] and Chong Hoon Kim[3], (1)Azrieli Faculty of Medicine, Bar-Ilan University, (2)Maccabi Healthcare Services, (3)Gilead Sciences, Inc., (4)Gilead Sciences Israel Ltd, (5)Kahn Sagol Maccabi Research and Innovation Center, Maccabi Healthcare Services

Background: Hepatitis delta virus (HDV) infection occurs in patients with underlying hepatitis B virus (HBV) infection and is associated with more rapid liver disease progression. The epidemiology and characteristics of HDV patients in Israel are not well described. This study aimed to describe the prevalence and incidence of HDV among adults in Israel. **Methods:** A retrospective cohort study was performed using anonymized data from Maccabi Healthcare Services (MHS) covering 1.8 million adults in Israel. Chronic HBV with/without HDV was defined using diagnosis and laboratory data from 1/1/1998 to 12/31/2010. Prevalence cohorts included all HBV monoinfection (HBV-mono) or HDV patients aged ≥ 18 years in 2010-2021. Incidence cohorts included patients newly diagnosed with HBV-mono or HDV in 2010-2021 at age ≥ 18 years. Period and annual HDV prevalence rates and incidence rates were calculated among (1) all chronic HBV patients and (2) all MHS members (enrolled ≥ 1 d in a given period). For the incidence calculation, the denominator excluded individual's with HDV diagnosis prior to the start of the period. Patient characteristics among prevalent HBV-mono and HDV patients at the end of the study period (2021) were described. **Results:** In 2010-2021, the average annual HDV prevalence and incidence rates among HBV patients (general population) were 2.3% (0.012%) and 0.11% (0.59/100,000), respectively. The prevalence and incidence of HDV among HBV patients in 2021 was 2.3% and 0.07%. The number of HDV patients increased from 159 in 2010 to 208 in 2021. In 2021, prevalent HDV patients (n = 208) had a mean [sd] age of 54.5 [13.3] years, and 54.3% were males; prevalent HBV-mono patients (n = 2,795) had a mean age of 53.3 [13.9] years, and 57.9% were males.

Symbols: ƒ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: Results of this real-world analysis indicate that HDV prevalence and incidence were 2.3% and 0.1% among HBV-infected adults in Israel during 2021, respectively. The number of prevalent HDV patients increased from 159 to 208 from 2010 to 2021. Given the low rates of screening and diagnoses of HDV globally, findings from this study underscore the need for continued efforts in the early identification of HDV infection among people with HBV infection and for the development of effective strategies for the management and treatment of the prevalent as well as incident patients with HDV.

1215-C | EPIDEMIOLOGY OF HEPATITIS E VIRUS IN PATIENTS WITH CHRONIC LIVER DISEASE ACROSS SOUTH AMERICA

Maria Belen Pisano[1], Anabella Fantilli[1], Spencer Goble[2], Domingo Balderramo[3], Jhon Edison Prieto Ortiz[4], Marco Arrese[5], Enrique Carrera[6], Javier Diaz Ferrer[7], Angelo Mattos[8], Andre Boonstra[9], Jose D. Debes[10] and Viviana Elizabeth Re[1], (1)Instituto De Virología "Vanella", Facultad De Ciencias Médicas, Universidad Nacional De Córdoba, Argentina, (2) Hennepin Healthcare, (3)Hospital Privado Universitario De Córdoba, Córdoba, Argentina., (4)Cehyd (Centro de Enfermedades Hepáticas y Digestivas), (5) Departamento De Gastroenterología, Facultad De Medicina, Pontificia Universidad Católica De Chile, (6) Universidad San Francisco De Quito, Ecuador, (7) Universidad San Martin De Porres, Lima, Peru, (8) Federal University of Health Sciences of Porto Alegre, Porto Alegre, Brazil, (9)Erasmus University Medical Center, Rotterdam, Netherlands, (10)University of Minnesota

Background: Hepatitis E virus (HEV) is a zoonotic disease frequently associated with self-limited acute hepatitis. Multiple studies have reported that individual's with immunosuppression and/or chronic liver diseases can develop chronic HEV. The epidemiology of the virus is understudied in the Hispanic population. This study aimed to describe the frequency of HEV infection in patients with chronic liver diseases across Latin America. **Methods:** We evaluated the presence of IgG anti-HEV (ELISA, Diapro) in 716 serum samples collected from patients in 6 countries of Latin America through the ESCALON network (http://www.escalon.eu): Argentina (n = 162), Brazil (n = 54), Chile (n = 123), Colombia (n = 260), Ecuador (n = 61) and Peru (n = 56). Causes of chronic liver diseases included: hepatocellular carcinoma (HCC, n = 170), cirrhosis (CR, n = 387), infection with hepatitis B virus (HBV, n = 26) or hepatitis C virus (HCV, n = 14) and non-alcoholic fatty liver disease (NAFLD, n = 119). **Results:** The mean age of the patients was 62.9 years (range 18-91), 56.4% were male and 43.6% female. The global IgG anti-HEV prevalence in the continent was 16.1% (115/716). Out of this, 38.6% were female (44/114) and 61.4% male (70/114). Specific seropositivity rates by country were: 1.9% (3/162) in Argentina, 14.8% (8/54) in Brazil, 48.8% (60/123) in Chile, 8.5% (22/260) in Colombia, 18% (11/61) in Ecuador and 19.6% (11/56) in Peru. When stratified by liver disease, the prevalence was: 20.1% (78/387) in patients with cirrhosis, 19.4% (33/170) in HCC, 1.7% (2/119) in NAFLD, 3.8% (1/26) in subjects with HBV infection and 7.1% (1/14) in those with HCV infection. **Conclusion:** This is the first study addressing HEV in patients with chronic liver disease in multiple countries in Latin America, and the first report overall of HEV among some of the countries, such as Ecuador and Peru. We found a high prevalence of IgG anti-HEV in all groups of patients compared to the general population, particularly in Chile. In depth studies to understand the the implications of this increased sero-epidemiology are needed.

1216-C | EVALUATING THE REGIONAL PREVALENCE AND INCIDENCE OF HEPATITIS DELTA VIRUS AMONG ADULTS WITH HEPATITIS B VIRUS INFECTION IN ITALY

Pietro Lampertico[1,2], Elisa Giacomini[3], Melania Dovizio[3], Luca Degli Esposti[3], Melania Leogrande[3], Ankita Kaushik[4], Chong Hoon Kim[4] and Marvin Rock[4], (1)Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, (2)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, (3)Clicon S.r.l. Società Benefit, Health, Economics & Outcomes Research, (4)Gilead Sciences, Inc.

Background: Hepatitis delta virus (HDV) occurs as a co- or superinfection with hepatitis B virus (HBV), causing a more severe form of viral hepatitis than HBV infection alone. Yet, the epidemiology of HDV in Italy is not well characterized. This study aimed to evaluate the national and regional prevalence and incidence of HDV infection among adults in Italy. **Methods:** A retrospective observational study was conducted using administrative databases derived from a sample of local health units that covered around 12 million persons across Italy. Such databases contain all the healthcare resources and services reimbursed by the National Health System funded on the principle of universal coverage for all citizens. Adults with ≥ 1 diagnosis (*ICD-9-CM* or exemption code) of HDV or HBV were screened from Jan 1, 2014, to Dec 31, 2020; patients with HDV or HBV monoinfection were identified from Jan 1, 2015, to Dec 31, 2019 (identification period), with their index date defined as the first diagnosis. Annual prevalence was calculated based on the lifetime prevalence approach for which adults diagnosed on or before the year of assessment were included. Incidence was measured as the proportion of newly diagnosed adults with HDV (numerator) among patients diagnosed with HDV or HBV (denominator). **Results:** Among 11,161 patients with HBV monoinfection or HDV screened during the study period, 9,045 met inclusion criteria. The average annual HDV prevalence and incidence among patients with HBV in Italy throughout the study period were 6.8% and 0.8%, respectively. The average annual prevalence of HDV among the Northern and Central regions was 4.5% and 5.5%, respectively, while the average annual prevalence was numerically higher in the Southern region at 8.9%. **Conclusion:** Overall average annual prevalence and incidence of HDV in Italy were 6.8% and 0.8% between 2015 and 2020. HDV prevalence was higher in the Southern region of Italy compared with its Northern and Central regions, perhaps due to greater influx of immigration to Southern Italy. Findings from this study underscore the need for continued efforts in the early identification of HDV infection among people with HBV infection and for the development of effective strategies in the treatment and management of HDV, considering prioritization based on the regional prevalence and incidence.

Table. HDV prevalence and incidence rates among patients with HBV in Italy by year

Year	National prevalence rate	National incidence rate	Northern prevalence rate	Central prevalence rate	Southern prevalence rate
2015	7.1%	1.2%	4.4%	4.9%	9.9%
2016	7.0%	1.2%	4.4%	5.2%	9.3%
2017	6.8%	0.8%	4.5%	5.4%	8.8%
2018	6.7%	0.8%	4.6%	6.1%	8.4%
2019	6.7%	0.5%	4.6%	5.8%	8.4%
2020	6.6%	0.3%	4.6%	5.4%	8.4%

HBV, hepatitis B virus; HDV, hepatitis delta virus.

1217-C | EVALUATION OF EUROBIOPLEX EBX-071, A NEW COMMERCIAL KIT FOR HDV VIRAL LOAD QUANTIFICATION

Athenaïs Gerber[1], Emeline Huault[2], Valerian Delagarde[1], Emmanuel Gordien[1], Frederic Le Gal[1], Claude Giry[2] and Segolene Brichler[1], (1)CHU Avicenne, (2)Eurobio Scientific

Background: HBV-HDV coinfection leads to the most severe form of chronic viral hepatitis, however only few virological tools are currently available. Both commercial and in-house RT-qPCR tests are used for RNA quantification worldwide but results are not yet fully

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

standardized. The first pangenomic EurobioPlex HDV kit (EBX-004, Eurobio Scientific) was commercialized in 2016. Here we evaluated the performances of its new version EBX-071. **Methods:** We used the WHO International Standard to evaluate repeatability and reproducibility, and samples from our collection, with diverse genotypes and viral loads (VL), to assess sensitivity (lower limit of detection LLOD and quantification LLOQ) and specificity. A large study with clinical samples containing all 8 circulating genotypes was also performed to compare the older (EBX-004) and new (EBX-071) tests from Eurobio. **Results:** Quantification standards are now provided in a ready-to-use format, and the whole process is validated with the simultaneous detection of an endogenous internal control. We obtained a valid result for 98.3% of all samples (1453/1478). Coefficients of variation were < 5% for repeatability and < 10% for reproducibility, with every tested condition (1/100^{e} and 1/1000^{e} WHO, n = 24 each for repeatability and n = 120 for reproducibility). A 100% specificity was observed when testing 100 HBV/HDV negative blood donor samples, 100 HBV positive/HDV negative patient samples and 25 samples positive for another virus (HIV, HAV, HBV, HCV, HEV). No interference or inhibition was noted with high titers of triglyceride or bilirubin. Similar results were observed on paired plasma and serum samples (n = 24, mean difference of 0.1 log IU/mL). LLOD and LLOQ were found at 20 IU/mL and 50 IU/mL respectively (serial dilutions of the WHO standard, HDV-1 genotype, confirmed with samples of all genotypes). 98.9% concordant results were obtained when comparing EBX-004 and EBX-071 tests (6 discordant results/561 tests, all concerning samples with VL < 3 log IU/mL), however the latter gave lower results (constant difference of 0.88 log IU/mL). WHO standard quantification with the EBX-071 kit led to values very close to its theoretical value (2.75 vs 2.76 log IU/mL at 1/1000^{e}). **Conclusion:** The performances of the EurobioPlex EBX-071 test, when operated on a CFX96 device along with a m2000sp RNA extraction, are very good and in accordance with state-of-the-art recommendations. The kit was also improved for practical use. A very important point is the recalibration of the standard curve to allow a better targeting on the WHO standard, which represents a big step towards HDV VL universal harmonization.

1218-C | FINDINGS FROM A ROUTINE SCREENING PROGRAM FOR HEPATITIS DELTA VIRUS AMONG HEPATITIS B SURFACE ANTIGEN POSITIVE PATIENTS IN A CHICAGO-BASED HEALTHCARE SYSTEM

Bijou Hunt[1], Maggie Li[2], Andrea Nunez-Garcia[1] and Nancy Glick[1], (1)Sinai Chicago, (2)Northwestern University

Background: In 2022, eight US-based sites with routine hepatitis B (HBV) screening in place implemented universal hepatitis delta virus (HDV) screening among patients testing positive for hepatitis B surface antigen (HBsAg). Here we focus on outcomes from one of the eight sites, a Chicago-based healthcare system. **Methods:** A daily report was run to return a list of all patients testing positive for HBsAg (HBV+) across the system (inpatient, outpatient, and emergency department). For those HBV+, testing was manually added for HDV antibody (Ab) and ribonucleic acid (RNA) tests. Data for these patients was abstracted from the EMR and aggregated for the period 4/15/2022 – 2/28/2023. **Results:** A total of 6,631 patients were tested for HBsAg. While the majority of HBsAg testing occurred among non-Hispanic (NH) black patients (30.6%), HBV + occurred most frequently among NH Asian (54.5%), followed by NH Black (21.2%), and NH White (9.8%), and was infrequent among Hispanic/Latino patients (0.8%, n = 1). Females were slightly more likely to be tested for HBsAg (53.5%), but made up a smaller proportion of HBV+ (42.4%). Outpatient testing locations performed the most HBsAg tests and returned the largest proportion of HBV+. Of the 6,631 patients tested for HBsAg, 2% were HBV+ (n = 132); of these, 71% were successfully tested for HDV Ab and RNA (n = 94). Among the 94 tested for HDV, 3 were HDV Ab positive (HDV Ab+) (3.2%) and 2 were RNA positive (RNA+) (2.1%). All HDV Ab+ cases were tested in outpatient locations associated with large immigrant patient populations. The two RNA+ cases occurred among patients from Ukraine and Eritrea; both were male and mean age was 40 years. **Conclusion:** Guidelines for HDV screening among HBV+ differ with some suggesting a risk-based approach and others a universal approach; data collected thus far do not yet provide solid support for one of these over the other. Implementing HDV screening is greatly facilitated when a routine HBV screening program is already in place. However, even for sites with an existing HBV screening program, challenges will arise in the lab process where insufficient samples result in an inability to process the follow-up HDV testing; and where lack of available reflex testing will require add-on testing that may result in missed follow-up HDV testing. Based on the data

collected to date, it is too soon to draw conclusions about the epidemiology, surveillance, and policy implications for screening guidelines.

Table 1. Hepatitis B and D testing and outcomes by demographics and testing location: Sinai Chicago, 4/15/22 – 2/28/23.

1219-C | HDV PERSISTS IN HUMAN HEPATOCYTES UNDERGOING CELL DIVISION IN HUMAN LIVER CHIMERIC MICE BUT IS POTENTLY INHIBITED BY PEGYLATED INTERFERON-ALPHA TREATMENT

Maura Dandri[1,2], Annika Volmari[1], Tassilo Volz[1,2], Marc Lütgehetmann[1], Simon P Fletcher[3], Meghan Holdorf[3] and Robert C Muench[3], (1)University Medical Center Hamburg-Eppendorf, (2)German Center for Infection Research, (3)Gilead Sciences, Inc.

Background: The endogenous interferon response is not sufficient to abrogate hepatitis D virus (HDV) replication, nor to inhibit cell division-mediated spread of HDV in vivo *(Giersch, Gut 2019)*. However, studies in humanized mice stably infected with both HDV and hepatitis B virus (HBV) demonstrated the ability of pegylated interferon-alpha (pegIFN±) to suppress patient-derived HDV strains *(Giersch, JHEPRep 2023)*. Moreover, in vitro studies showed that IFNa exerts stronger anti-HDV activities in hepatoma cells undergoing cell division (*Zhang, JHepatol 2022)*. The aim of this study was to investigate the impact of cell division and pegIFN± treatment on HDV replication *in vivo*. **Methods:** To promote division of virally-infected human hepatocytes in vivo, uPA/SCID/IL2Rγ$^{-/-}$ (USG) mice (N = 15) received primary human hepatocytes (PHH) isolated from a mouse previously reconstituted with adult PHH and stably infected with HBV and HDV (HBV viremia 1.7 ´ 10^9; HDV 5.3´ 10^8). Virological markers and IFN response were analyzed by qRT-PCR, ELISA and immunofluorescence. From week 1 to 8 after PHH transplantation, half of the mice received pegIFN± s.c. (25ng/g biweekly) to assess its impact on HDV, HBV and cell proliferation, as determined by ELISA (human serum albumin), human B-globin/ng liver DNA and histology. **Results:** In an environment supporting cell proliferation, transplanted PHH underwent strong expansion ($2\log_{10}$ HSA increase already at 5 weeks) both in untreated mice and in animals receiving pegIFN±. In untreated mice, the overall intrahepatic HDV RNA level increased as PHH expanded ($\Delta 1.57\log_{10}$, w5), while HDV RNA levels per PHH remained unchanged. In contrast, overall intrahepatic HBV markers decreased during the first 5 weeks of cell division, resulting in an increased proportion of PHH appearing HDAg-positive but HBcAg-negative. Seven weeks of pegIFN± promoted stronger reduction of intrahepatic HBV DNA and RNA levels (median $2.7\log_{10}$ and $2.2\log_{10}$), compared to untreated group. Strikingly, pegIFNa treatment resulted in undetectable levels of HDV viremia ($\Delta > 3\log_{10}$, compared to untreated), HDV RNA and HDAg-positive PHH in the liver, despite high levels of chimerism. Strong induction of human IFN-responsive genes was confirmed in all mice receiving pegIFN±. **Conclusion:** In line with previous in vitro studies, HDV can persist in hepatocytes undergoing cell division in vivo but is potently inhibited by pegIFN± in PHH during cell expansion.

1220-C | HEALTHCARE RESOURCE UTILIZATION AND COSTS OF HDV INFECTION VS HBV MONOINFECTION ACROSS DISEASE STATES IN A HOSPITAL RECORDS DATABASE FROM SPAIN

Maria Buti[1], Marvin Rock[2], Meritxell Ascanio[3], Josep Darba[4] and Chong Hoon Kim[2], (1)Hospital Universitario Vall D'hebron and Ciberehd Del Instituto Carlos III, (2) Gilead Sciences, Inc., (3)Bcn Health Economics & Outcomes Research SL, (4)University of Barcelona

Background: Hepatitis delta virus (HDV), which requires the presence of hepatitis B virus (HBV) for transmission, results in the most severe form of viral hepatitis. This retrospective study compares healthcare resource utilization (HCRU) and costs of HDV infection vs HBV monoinfection by disease states in Spain. **Methods:** Patients aged ≥ 18 years with ≥ 1 *ICD-9/10-CM* diagnosis code for HDV or HBV between Jan 1,

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

2000 and Dec 31, 2019 (study period) were identified in the Spanish National Health System's Hospital Discharge Records Database (Conjunto Mínimo Básico de Datos). Patients with a first diagnosis between Jan 1, 2001 and Dec 31, 2018 and those with continuous enrollment for ≥ 12 months before and after first diagnosis were selected. Baseline (BL) characteristics and clinical comorbidities were recorded from the year before first diagnosis. Patient groups were propensity score matched (1:5) according to BL characteristics. Mean per patient per year (PPPY) HCRU and costs were compared within subgroups of liver disease severity. Descriptive statistics were summarized, and comparisons were made via generalized linear models. **Results:** Among 12,317 patients identified with HDV or HBV only, 756 met all inclusion criteria (HDV, n = 126; HBV only, n = 630). Patients' mean (SD) age was 41.7 (11.8) vs 41.2 (9.9) years in patients with HDV vs HBV only; 89.7% of patients in each group were male. Significantly greater proportions of patients with HDV vs patients with HBV only had compensated cirrhosis (CC; 25.4% vs 9.5%, $p < 0.0001$) or decompensated cirrhosis (DCC; 51.6% vs 20.6%, $p < 0.0001$). Mean time spent in each liver disease state was significantly shorter for patients with HDV vs HBV only. Mean (SD) length of hospital stay (days) was longer for patients with HDV vs HBV only for patients with CC (6.6 [2.7] vs 4.3 [1.8], $p = 0.04$), DCC (11.7 [4.7] vs 6.9 [3.8], $p = 0.03$), and liver transplantation (11.8 [3.0] vs 9.1 [3.4], $p = 0.04$). Mean pharmacy, inpatient, outpatient, and total costs PPPY were significantly higher for those with HDV vs HBV only and increased with disease state severity. **Conclusion:** In Spain, mean inpatient length of stay and total costs associated with HDV were higher than for patients with HBV only and increased with greater liver disease severity. These findings underscore the need for effective screening, diagnosis, and treatment of HDV to help reduce the clinical and economic burden of disease.

Table. Healthcare resource utilization and costs for patients with HDV infection vs HBV monoinfection in Spain

HCRU or cost[a]	Liver disease state severity				
	NC	CC	DCC	HCC	LT
Patients, n					
HDV infection	61	36	70	13	10
HBV monoinfection	211	201	295	40	29
Time spent in liver disease state, months, mean (95% CI)					
HDV infection	56.3 (25.3-82.6)	30.6 (20.0-81.0)	60.3 (19.6-81.0)	41.2 (20.7-81.4)	81.0 (67.5-94.5)
HBV monoinfection	75.5 (31.1-90.1)	63.2 (31.1-88.2)	87.9 (31.0-90.2)	91.4 (68.3-99.6)	89.3 (73.2-91.3)
P	.04	.03	.04	.03	.05
Length of hospital stay, days, mean (SD)					
HDV infection	4.5 (1.7)	6.6 (2.7)	11.7 (4.7)	13.6 (5.8)	11.8 (3.0)
HBV monoinfection	3.5 (1.4)	4.3 (1.8)	6.8 (3.8)	8.7 (3.2)	9.1 (3.4)
P	.08	.04	.03	.06	.04
Total costs, €, mean (SD)					
HDV infection	7,429 (3,279)	8,600 (3,299)	9,812 (3,642)	10,944 (4,248)	11,798 (4,872)
HBV monoinfection	4,115 (2,441)	5,563 (2,462)	6,610 (2,843)	7,543 (3,231)	8,399 (3,943)
P	<.0001	<.0001	<.0001	<.0001	<.0001

Note: HCRU was compared with a Poisson distribution generalized linear model, while costs were compared using gamma distribution generalized linear model; both models did not adjust for any variables.
[a]All HCRU and cost values are presented per patient per year.
CC, compensated cirrhosis; DCC, decompensated cirrhosis; HBV, hepatitis B virus; HCC, hepatocellular carcinoma; HCRU, healthcare resource utilization; HDV, hepatitis delta virus; LT, liver transplant; NC, no cirrhosis.

1221-C | HEPATIC TUBERCULOSIS: REAL WORLD EXPERIENCE FROM A TERTIARY CARE CENTRE

Souveek Mitra[1], Ranajoy Ghosh[1], Dipankar Mondal[1], Srijan Mazumdar[1], Kishalaya.[1] and Abhijit Chowdhury[2], (1)Ilds, (2)Institute of Post Graduate Medical Education & Research

Background: In developing countries, like India, where tuberculosis is endemic, diagnosis of hepatic tuberculosis often remains a challenge. Due to the lack of specific presenting symptoms and characteristic imaging findings, diagnosis is challenging. Invasive methods like liver biopsy, for detection of granuloma, classical for tuberculosis, often aids in the diagnosis. Another challenge, lies in the therapy of these patients, as often they have altered liver function tests, which preclude the uses of first line antitubercular therapy. We retrospectively reviewed, a series of hepatic tuberculosis, diagnosed in our institute. **Methods:** Between September of 2018 to January of 2023, we reviewed all cases that were diagnosed as a case of hepatic tuberculosis at our institute. Diagnosis of hepatic tuberculosis was made if the subjects fulfilled any of the following criteria 1) Liver biopsy showing classical caseating granuloma, pathognomic for tuberculosis 2) Identification of acid fast positive bacilli from liver tissue 3) Positive culture for tuberculosis. **Results:** During the period, we identified twenty two (22) subjects, fulfilling our diagnostic criteria. 16 of the total subjects (72.73%) were male. Mean age was 53 years. 28% of the subjects were diabetic. 23% of them were diagnosed cirrhotic beforehand. Of the cirrhotic subjects, 20% was hepatitis B positive, and 40% were having alcohol use disorder (AUD). Presenting symptoms of 27% of subjects were pyrexia of unknown origin (PUO), among them 33% had isolated elevation of alkaline phosphatase (ALP). 14% of the total subjects were asymptomatic, and was identified via histopathology. Indications for liver biopsies in two of them were isolated elevation of ALP, one of them underwent liver biopsy during work up for non

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

alcoholic fatty liver disease (NAFLD). 9% of the subjects presented with a focal liver space occupying lesion (SOL). All the cirrhotic subjects presented with either acute decompensation of cirrhosis (AD) / acute on chronic liver failure (ACLF) and in them, tuberculosis was postulated as an acute inciting event. 86% of subjects underwent liver biopsy, granuloma were identified in all of them. 10% of the samples were sent for cultures. Three (3) subjects, expired during the study period. Of them two were cirrhotic beforehand, and presented with ACLF. Mean time from symptom onset to start of therapy was 6.8 months. Standard 1st line quadruple therapy could only be offered to 27% of the subjects at the initiation. 63% of the subjects afterwards received complete 1st line therapy. **Conclusion:** Hepatic tuberculosis can present with a constellation of symptoms and signs. Identification and diagnosis, requires good clinical acumen. Tissue diagnosis aids in the diagnosis and must be offered to all suspected individual's. In subjects with underlying chronic liver disease, t = hepatic tuberculosis might precipitate acute decompensation and can often prove fatal.

f 1222-C | HEPATITIS DELTA TESTING TRENDS IN THE U.S. VETERANS AFFAIRS MEDICAL SYSTEM (2000-2022): AN ANALYSIS OF PATIENT AND PROVIDER-LEVEL PREDICTIVE FACTORS

Binu V John[1], Mahmoud Manouchehri Amoli[2], Robert J. Wong[3], Donna M. Evon[4], Bassam Dahman[2] and VALID group of investigators, (1)University of Miami and Miami VA, (2)Virginia Commonwealth University, (3)VA Palo Alto Healthcare System, (4)University of North Carolina

Background: Low prevalence of Hepatitis Delta Virus (HDV) infection in the US could be attributed to insufficient testing, which can result in an underestimation of true prevalence. This study aimed to identify prevalence and factors associated with HDV testing among participants with positive Hepatitis B surface antigen (HBsAg) in the Veterans Health Administration (VHA). **Methods:** This was a nationwide retrospective study involving all participants positive for HBsAg between 01/2000 and 12/2022 within the VHA. We identified those who were tested, and positive for HDV, and used a logistic regression model to identify patient and provider-level predictive factors associated with HDV testing. **Results:** Of 67,606 participants with a positive HBsAg, 4,661(6.9%) were tested at least once for HDV antibodies, of which 333 (7.1%) were positive (298 HDV RNA positive). The annual number of HDV antibody tests ordered in the VHA was stable from 2000 to 2015 (135-171 a year), increased by over 50% from that baseline in 2016-2017 (283 and 277 respectively), and more than doubled in 2018-2019 (451 and 446 respectively), before dropping during COVID-19 from 2020-2022 (231, 289 and 244 respectively). Participants in the Northeast (aOR 1.31, 95% CI 1.18-1.45, $p < 0.001$) were more likely, while those in the Midwest (aOR 0.69, 95% CI 0.60-0.79, $p < 0.001$) were less likely to undergo HDV testing. Participants received care at an academic VA (aOR 1.24, 95% CI 1.1-1.4, $p < 0.001$) or from a hepatology provider (aOR 1.43, 95% CI 1.29-1.60, $p < 0.001$) were more likely, while those under the care of a primary care provider were less likely to be tested for HDV (aOR 0.62, 95% CI 0.52-0.73, $p < 0.001$). Non-Hispanic Black people were less likely to be HDV tested (aOR 0.87, 95% CI 0.79-0.95, $p = 0.004$)-however, no difference in screening among other racial groups were observed. Participants with private insurance coverage (aOR 1.18, 95% CI 1.09-1.27, $p < 0.004$), and those Medicaid eligible (aOR 1.60, 95% CI 1.25-2.04, $p < 0.001$) were more likely to be tested, as were those on oral nucleotide/nucleoside therapy (aOR 1.58, 95% CI 1.45-1.72, $p < 0.001$), participants with cirrhosis (aOR 1.12, 95% CI 1.01-1.25, $p = 0.04$), and hepatic decompensation (aOR 1.28, 95% CI 1.10-1.49, $p = 0.002$). Lastly, HDV testing was positively associated with being tested for HBeAg, HBeAb, and HBcIgM. In contrast, HCV positive (aOR 0.90, 95% CI 0.81-0.98, $p = 0.02$) and HIV positive participants (aOR 0.78, 95% CI 0.69-0.87, $p < 0.001$) were less likely to be tested for HDV. **Conclusion:** While overall HDV screening rates have increased in the VHA, participants who are Black, living in the Midwest, receiving liver care from a primary care provider, those at high risk of HDV, as well as HIV or HCV positive patients are less likely to be tested for

HDV. These results highlight the need for refining testing strategies to increase HDV screening rates, especially among historically marginalized and high-risk populations.

1223-C | HEPATITIS DELTA VIRUS SCREENING STRATEGIES IN FRENCH UNIVERSITY HOSPITAL LABORATORIES: ADVOCACY FOR REFLEX TESTING IMPLEMENTATION

Segolene Brichler, CHU Avicenne, Pascale Trimoulet, CHU Pellegrin, Anne-Marie Roque-Afonso, CHU Paul Brousse, Jacques Izopet, CHU Purpan, Vincent Thibault, CHU Pontchaillou, Caroline Scholtès, CHU Croix-Rousse and Stephane Chevaliez, Service De Virologie, Hôpital Henri Mondor

Background: Infection with Hepatitis delta virus (HDV) leads to the most severe form of chronic viral hepatitis; unfortunately, screening rates are scarce in most areas and patients are often diagnosed at an advanced clinical stage. International guidelines recommend either a systematic HDV screening for all HBsAg-positive patients (EASL) or a risk-based approach (AALSD). In addition to perform HDV serology on medical prescription, some laboratories have implemented a "HDV reflex testing" protocol, consisting of the addition of a serological HDV test on all samples with a first HBsAg positive result. The aim of this cross-sectional study was to analyse the different strategies implemented in seven French university hospital laboratories and to compare their efficiency for HDV antibody (HDV-Ab) and viral load (HDV-VL) screening. **Methods:** All individual's with a positive HBsAg test referred for the first time between January 2018 and October 2022 were included. Patients replicate requests were removed. Total or IgG HDV-Abs were assayed with commercial tests, HDV-VL with in-house or commercial tests, and HDV genotype with partial sequencing (R0 region). **Results:** Of 459,644 consecutive individual's, 6,772 were tested HBsAg-positive for the first time (mean age 38.7, sex ratio 2.03). Testing for HDV-Abs was conducted on 5,749 patients (84.9%) and 364 of them were positive (6.3%, CI 95%: 5.7-7.0, mean age 40.9, sex ratio 2.36). HDV-VL was determined in 285 (78.3%) patients and 167 (58.6%, CI 95%: 52.8-64.2) had an active HDV infection. HDV-1 genotype was predominant (77%), followed by HDV-5 (19%). The screening rate was 46.6% in one centre (pre-reflex testing period), varied from 65.2% to 96.4% in laboratories with a manual add-on strategy (i.e. biologist-driven, 5 centres), and reached up to 99.2% when the HDV-Ab reflex testing is automatically set in the local

information system (2 centres). **Conclusion:** Even in this university hospital context, in a country with a recommendation to screen all HBsAg-positive patients, HDV is underdiagnosed with a prescription-only strategy. Both manual and automatic reflex testing are highly effective. Early identification of HBV-HDV infected patients allows a faster referral to hepatologists for adequate clinical management, especially in this era of new HDV treatments. This work strongly argues for changing public health policies and allowing laboratory-driven HDV reflex testing.

1224-C | HEPATITIS E RNA RESPONSE-GUIDED RIBAVIRIN TREATMENT IMPROVES SUSTAINED VIROLOGIC RESPONSE RATE COMPARED WITH A STANDAR D 12-WEEK REGIMEN IN IMMUNOSUPPRESSED PATIENTS

Guan-Huei Lee[1,2], Haoxing Lai[2], Zera Yingrui Te[2] and Margaret Li Peng Teng[3], (1)National University Hospital, (2)National University of Singapore, (3) National University Health System (NUHS)

Background: Hepatitis E virus (HEV) causes chronic hepatitis in immunosuppressed patients. Our earlier study revealed that the sustained virologic response rate (SVR) of 12-week ribavirin therapy for HEV infection was lower than expected. This study aims to compare the outcome of the standard 12-week of ribavirin treatment against a response-guided ribavirin treatment in immunosuppressed patients infected with HEV. **Methods:** We performed a retrospective analysis of all patients who had persistence of plasma HEV RNA for more than 3 months in NUH between 2012 to 2022. The study protocol is approved by NHG DSRB (reference: 2016/00250). Initially, most patients received standard 12-week ribavirin therapy, and subsequent patients were given response-guided ribavirin regimen, during which HEV RNA was monitored 4 weekly, and continued until it became undetectable for at least 8 weeks. Rapid virologic response (RVR) is defined as undetectable HEV RNA after 4 weeks of ribavirin therapy. SVR is defined as undetectable HEV RNA 24 weeks after completing treatment. Statistical analysis was carried out using OpenEpi online software. **Results:** Fifty immunosuppressed patients with HEV infection were reviewed. Thirteen were excluded due to spontaneous recovery or loss to follow-up before confirmation of SVR. Thirty-seven patients are included in the final analysis (6 liver transplant, 18 kidney transplant, 5 bone marrow transplant, and 8 steroid/chemotherapy). Thirteen patients received 12 weeks of ribavirin therapy, but only 8 patients achieved SVR (61.5%, all achieved RVR), and 5 relapsed, who then undergo retreatment. Remaining 24 patients required 12 weeks or more of treatment under response-guided regimen, of which 7 had prolonged viremia on continuous ribavirin for more than one year. Response-guided therapy results in all 24 patients achieving SVR, (100 % vs. 61.5%, Fisher exact test, $p = 0.006$), with 1 relapsed after > 6 months. Two-thirds (16 out of 24 patients) had positive HEV RNA at week 12, indicating a certainty of relapse if they had received the 12-week regimen. Achieving RVR followed by 8 weeks of consolidation predicts a good response for 12-week ribavirin regimen, whilst kidney transplant recipient, ribavirin dose reduction, and non-adherence to treatment contribute to longer treatment duration and relapse. **Conclusion:** HEV RNA response-guided treatment results in a higher treatment success rate than a fixed 12-week ribavirin regimen in immunosuppressed patients.

1225-C | HEPATITIS EDUCATION IN THE UNITED STATES' MEDICAL SCHOOL CURRICULA

Michelle Martin[1,2], Gerda Lescinskaite[2], Alexander Pan[1,3], Zeba Saiyad[2] and Adam E. Mikolajczyk[1,3], (1)UI Health, (2)UIC College of Pharmacy, (3)UIC College of Medicine

Background: The Viral Hepatitis National Strategic Plan documents the value of a collaborative provider workforce trained in the provision of hepatitis treatment and prevention to facilitate the United States' 2030 viral hepatitis elimination efforts. Physicians play a crucial role in viral hepatitis management, yet the Liaison Committee on Medical Education (LCME)

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

does not mandate minimum requirements for hepatitis content in medical curricula in the United States. **Methods:** Investigators developed a 19-item Qualtrics survey, validated by 6 colleagues, sent survey links to curricula content experts at 157 LCME-accredited medical colleges/schools in April-May 2023, and allotted 28 days for survey completion. Survey questions assessed the type, amount, and topics of viral hepatitis instruction provided to Doctor of Medicine students, and the hepatitis instructors' training/experience. We used descriptive statistics for analysis. Results: By 5/24/2023, 29 medical institutions across 20 states responded; 93% were 4-year programs, 52% public, with an average enrollment of 154 ± 56 students/class. 76% use both lecture and discussion for provision of hepatitis education, 14% use small group discussion only, and 10% lecture only. 90% of institutions provide required hepatitis education with 2.5 ± 1.1 lecture hours/program and 2.7 ± 1.5 discussion hours/program, while 10% of institutions also offer elective hepatitis coursework averaging 4.5 ± 1.5 lecture hours/program. The table lists the percent of schools who provide required hepatitis education on the listed topics. All schools teach hepatitis A-E epidemiology, hepatitis A-C serologies/diagnostics, and HBV vaccination. Nearly all teach HAV vaccination and HBIG. Instruction on HDV and HEV pharmacology and therapeutics was less than half the rates for HBV and HCV, and screening/linkage to care was more commonly taught for HBV and HCV than HDV. Over half of schools teach about HBV and HCV/HIV-coinfection. Drug interaction assessment instruction for HBV and HCV is provided at fewer than one-third of programs. A quarter of programs teach HCV donor(+) / recipient(-) solid organ transplantation. Few programs teach about the 2030 national hepatitis elimination goals and pipeline agents for HBV and HDV. Responders stated 70% of primary hepatitis instructors had at least one board certification (58% each Gastroenterology and Internal Medicine, 26% Infectious Disease, 21% Transplant Hepatology), 96% were full-time faculty, and 41% of the 17 instructors with clinical appointments spent 20-39% time on patient care. **Conclusion:** Survey results show similarities, variability, and gaps in topics devoted to hepatitis education across United States medicine curricula. Our data offer knowledge about the viral hepatitis education provided to Doctor of Medicine students who will soon be able to assist with nationwide hepatitis elimination efforts.

1226-C | HUMAN iPSC DERIVED HEPATOCYTE-LIKE CELLS SEEDED INTO INVERTED COLLOID CRYSTAL SCAFFOLDS AS A NOVEL ORGANOID MODEL FOR HEPATITIS D VIRUS INFECTION

Leer Shen, Qingxin Guo and Xiaohua Chen, Shanghai Sixth People's Hospital

Background: Hepatitis D virus (HDV) super-infection with Hepatitis B virus (HBV) is considered the most

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

severe form of viral hepatitis, affecting 4.5% of HBV-positive patients. However, current in vivo and in vitro models provided limited information about HDV infection and replication, which has impeded the development of effective therapies. Thus, we aimed to develop an HDV infected model on the basis of a novel liver organoid platform using human induced pluripotent stem cell (iPSC) and 3-D inverted colloid crystal (ICC) to study the HDV infection mechanism and antiviral drug responses. **Methods:** We first fabricated ICC following NG Soon Seng's protocol. Under proper culture conditions iPSCs can be differentiated to hepatocyte-like cells (HLCs) in the 21th day in vitro (Fig A), which were later cultured in the 3-dimensional ICC scaffolds. HLCs were inoculated with concentrating HBV and HDV supernatants in the presence of 4% Polyethylene Glycol 8000 (PEG8000) and 2% dimethyl sulfoxide (DMSO). Myrcludex B (100 nM) were administrated before and after HDV inoculation, and IFN-± (1000UI/ml) were administrated after HDV inoculation to evaluate their antiviral effects. **Results:** After the iPSC-derived HLCs were generated and seeded into ICC scaffolds, the function and transcriptomic characteristics of the organoid model were confirmed resembling human liver characteristics by immunofluorescence (Fig B). HDV antigen was assessed by quantitative RT-PCR and immunofluorescence after HDV inoculation (Fig C). HDV RNA was highly expressed in Huh7 overexpressed with NTCP after inoculated with the supernatant HDV particles collected from the HDV infected model (Fig D). The change of HDV RNA, IL-2, IL-4, IL-10, TNF-± and IFN-γ were shown in Figure E. We further found that Myrcludex B treatment before HDV inoculation demonstrated the most effective antiviral therapy compared with Myrcludex B and IFN-± administration after HDV inoculation (Fig F). **Conclusion:** This novel HDV infected model presents a valuable platform for the study of HDV infection mechanisms and antiviral drug responses.

1227-C | IMPACT OF HYPERGLYCEMIA ON HOSPITAL ADMISSIONS DUE TO PYOGENIC LIVER ABSCESS: A NATIONWIDE STUDY

Sajana Poudel[1], Ayusha Poudel[1], Karun Shrestha[2], Kalpana Ghimire[2], Prakriti Subedi[2], Sumina Rai[1], Anurag Adhikari[3] and Manoj Ghimire[4], (1)John H Stroger Jr. Hospital of Cook County, (2)St Barnabas Hospital, (3)New York City Health and Hospitals/ Jacobi, (4)Mayo Clinic

Background: Liver abscesses are one of the most common types of visceral abscess. Pyogenic liver abscesses usually develop in the context of biliary disease, portal pyemia of various causes, through arterial hematogenous seeding, or via direct spread. It is associated with high mortality and morbidity. In this study we aimed to determine the impact of hyperglycemia on clinical outcome, inpatient mortality and hospital stay of patients admitted with pyogenic liver abscess. **Methods:** Methods: All adult patients (age > 18 y) old with pyogenic liver abscess with or without hyperglycemia during hospital admission from 2016-2020 were identified from the Nationwide Inpatient Sample (NIS). Data on demographic information, baseline clinical characteristics, and outcome variables such as mortality, hospital length of stay, and total hospital charges were collected and analyzed. Statistical analysis was performed by using the survey procedures function in STATA v.17. Statistical significance was defined by the two-sided t-test with a p value < 0.05. **Results:** A total of 4,895 patients were included in the analysis, of which 445 (10%) had hyperglycemia at the time of admission. Patients with hyperglycemia were found to have a significantly higher prevalence of chronic kidney disease (16% vs. 8%, $p = 0.01$), hyperlipidemia (50% vs. 35%, $p = 0.009$), obesity (22% vs. 14%, $p = 0.03$), and biliary and pancreatic disease (34% vs. 24%, $p = 0.03$). Furthermore, patients with hyperglycemia had a higher incidence of septic shock (6.74% vs. 1.01%, $p < 0.001$) and a greater need for mechanical ventilation (6.74% vs. 1.12%, $p = 0.0001$) compared to those without hyperglycemia. However, there was no significant difference between the two groups in terms of mortality, mean length of hospital stays, and total hospital charges. **Conclusion:** The presence of hyperglycemia in patients admitted with pyogenic liver abscess is associated with an increased risk of developing septic shock and requiring mechanical ventilation. However, it does not appear to impact hospital mortality rates, the duration of hospitalization, or the financial costs associated with the hospital stay. Disclosures: The following people have nothing to disclose: Sajana Poudel, Ayusha Poudel, Karun

1228-C | IMPLEMENTATION CONSIDERATIONS FROM A MULTI-SITE PILOT OF HEPATITIS DELTA VIRUS SCREENING AMONG HEPATITIS B SURFACE ANTIGEN POSITIVE PATIENTS IN THE UNITED STATES OF AMERICA AND SPAIN

Bijou Hunt[1], Bindu Balani[2], Maggie Li[3], Nancy Glick[1], Chinwe Ogedegbe[2], Peter Gordon[4], Michelle Rose[5], Joshua Hayden[5], Su Wang[6], Christopher Co[7], Victor Liang[7], Sandeep Bhat[8], Anita Chang[7], Miguel Garcia-Deltoro[9], Enrique Ortega Gonzalez[9] and Maria Buti[10], (1)Sinai Chicago, (2)Hackensack Meridian Health, (3) Northwestern University, (4)Newyork-Presbyterian Queens, (5)Norton Healthcare, (6)Cooperman Barnabas, (7)Asian Health Services, (8)Family Health Centers at NYU Langone, (9)Hospital General Universitari De València, (10)Hospital Universitari Vall d'Hebron, Department of Medicine of the UAB (Universitat Autònoma de Barcelona), Spain

Background: Hepatitis Delta virus (HDV) screening has been recommended for individual's with chronic hepatitis B (HBV), though guidelines differ on universal (EASL, APASL) vs. risk-based approaches (AASLD, WHO). Uptake of these recommendations, however, has been suboptimal. In 2022, 8 sites based in the United States of America (US) and 2 based in Spain implemented universal HDV screening among patients testing positive for HBV surface antigen (HBsAg). We describe the process of implementing HDV screening across various settings and identify challenges to and recommendations for making changes to workflows. **Methods:** The ten sites (hospital (7); community health center (3)) are in urban areas across the contiguous US and eastern Spain (Figure 1). While the primary populations served varied in terms of race/ethnicity and socio-economic status, all sites served large immigrant populations and had robust, policy-driven HBV screening and linkage to care programs. **Results:** Sites fell into two categories when considering their laboratory processes (Figure 1). Reflex testing meant that all HBsAg positive results were automatically tested for HDV antibody (Ab) and in 4 of the 6 reflex sites, HDV Ab positive results were automatically tested for HDV ribonucleic acid (RNA). Add-on testing required manual orders for HDV Ab and RNA tests for HBsAg positive results. Between 4/22-2/23, across all sites, a total of 68,536 patients were tested for HBsAg with 514 (1.0%) testing positive in the US and 371 (2.1%) in Spain. Among them, 63% (n = 326) in the US and 99% (n = 369) in Spain were tested for HDV Ab with 3.4% HDV Ab positive and 1.2% (n = 4) HDV RNA positive in the US and 7.3% HDV Ab positive and 2.4% (n = 9) HDV RNA positive in Spain. **Conclusion:** A lack of HDV reflex testing at certain sites presented more potential for disruptions in workflow and may have resulted in HBV patients not being tested for HDV, possibly missing the opportunity for diagnosis. Additionally, for all sites, regardless of reflex status, insufficient samples often resulted in missed HDV testing if additional tubes were not collected. Though early in implementation process, recommendations for HDV screening may include a double reflex from HBsAg positive results to HDV Ab and subsequent HDV RNA testing. Additionally, laboratories should consider instituting reflex confirmatory testing, as is best practice for hepatitis C testing. Sufficient sample availability will be an important consideration.

Background: Hepatitis delta constitutes a global health problem affecting between 15 and 20 million people worldwide; with the recent introduction of Bulevirtide, the first antiviral for its treatment, and the imminent arrival of new antivirals against B virus, therapeutic options are expanded and may facilitate elimination strategies. Our aim has been to analyze the current status of undiagnosed hepatitis Delta in the South of Spain (Andalusia), and evaluate the efficacy and feasibility of hepatitis delta reflex testing. **Patients and Methods:** Ambispective (retro- and prospective) multicentre study in 17 hospitals in Andalusia. In the retrospective phase, we have analysed hepatitis delta diagnostic cascade, searching for HBsAg-positive patients, those in whom anti-delta antibody detection was performed, and those in whom HDV RNA detection was performed, extracting data from the laboratory information systems (LIS) of the participating centres (January 2018 to June 2022). From October 2022 to March 2023, all centres initiated the prospective phase in which reflex hepatitis delta (testing for anti-HDV in all HBsAg positive patients without a prior test) was implemented. **Results:** Regarding the retrospective phase, a total of 17872 HBsAg positive patients were analyzed; of those, anti-HDV was performed in 3287 (18%), and was positive in 178 patients (5,4%); HDV RNA was tested in 131 patients and, finally, 36 patients (1.1%) were identified as HDV-RNA positive. Data from the prospective phase are as follow: from a total of 3504 HBsAg positive patients, 927 had already been tested for anti-HDV; from the remaining 2577, 2150 (83%) were tested for anti-HDV, and from these 103 (4,8%) tested anti-HDV positive; HDV RNA was tested in 92/103 (89%) patients and, finally, 28 patients (1.3% of all HBsAg positive, 30,5% of HDV-RNA tested) were identified as HDV-RNA positive. **Conclusion:** Our retrospective data indicated an infra-diagnosis of HDV in Southern Spain: only a fifth of HBsAg positive patients had been screened for anti-HDV through the years 2018 to early 2022. We show here that implementing double reflex HDV testing is feasible and results in a very important increase in the detection of patients with HDV chronic infection. We believe this implementation will facilitate finding the “missing” hepatitis delta patients.

1230-C | IMPROVING ACCESS TO HDV TESTING USING DRY BLOOD SPOTS

Valerian Delagarde, Athenaïs Gerber, Samira Dziri, Dominique M Roulot, Emmanuel Gordien, Frederic Le Gal and Segolene Brichler, CHU Avicenne

Background: Hepatitis Delta Virus (HDV) is a small satellite virus infecting about 5% of HBV carriers that increases the risk of serious liver complications. New treatment options are now available but limited testing facilities in areas of high prevalence means most infections remain undiagnosed and patients receive suboptimal care. Developing local expertise is key but meanwhile tools such as Dry Blood Spots (DBS, *i.e.* filter paper used as a non-infectious transport and storage medium) can provide an easy and cheap way to link patients and testing facilities. This study aimed at defining new matrix specific thresholds for HDV virological tests on DBS. **Methods:** We conducted two complementary studies. Using our large collection, representative serum and plasma samples were put on DBS before being tested respectively for total anti-HDV antibodies (Diasorin Liaison XL) and for HDV viral load (VL, Abbott m2000/Eurobio EBX-004). Multiple storage conditions (2 weeks ambient, 2 weeks at -20°C and 5 weeks ambient) were tested, and two resuspension buffers were compared for RNA recovery. In parallel, other DBS were prospectively prepared using whole peripheral blood samples from patients attending our hepatology clinic, and the same analyses were performed. **Results:** The evaluation of the two resuspension solutions showed a slight advantage for PBS/0.01% NP40 (*vs* the Abbott m2000 lysis buffer) especially in samples with low VL. The finalized DBS protocol was set: 50µL of matrix/circle, dried for 2 hours and stored in opaque bags with desiccants. Each circle was resuspended in 500µL PBS/0.01% NP40 and agitated for 1 hour at room temperature. The serum arm had a 100% specificity and a good antibody titer correlation between paired serum/DBS for high positive samples. The reduced sensitivity noted for weak positive samples led to redefining the signal cut-off around 0.15 (to be adapted locally according to background noise). Similarly, plasma samples on DBS showed a 100% specificity and a good capacity in detecting and quantifying HDV RNA. However, sensitivity dropped to 50% for samples with low VL, 1000 IU/mL being the observed limit. The prospective whole peripheral blood study provided similar results. **Conclusion:** DBS can be useful for patient's management and epidemiological studies. Both serological and molecular testing showed high sensitivity and specificity when antibody titers and VL are high. A general reduction in signal means adapted cut-offs need to be used and specific care needs to apply for very early infections and patients under medication. Testing capillary blood on DBS will be critical to further develop this tool.

1231-C | INDEPENDENT ONLINE MEDICAL EDUCATION SIGNIFICANTLY IMPROVES PHYSICIAN KNOWLEDGE REGARDING THE BURDEN OF HEPATITIS DELTA VIRUS INFECTION AND BEST PRACTICE IN SCREENING AND DIAGNOSIS

Julia Duffey[1], Gillian Griffiths[1], Tatyana Kushner[2], Juan Mendive[3], Fabien Zoulim[4] and Maria Buti[5], (1)Webmd Global, (2)Icahn School of Medicine at Mount Sinai, New York, NY, (3)La Mina Primary Care Academic Centre Catalan Health Institute, (4)Hépatologie Unit, Hospices Civils De Lyon, Lyon University, Inserm, (5) Hospital Vall D'hebrón, and Ciberehd Del Instituto Carlos III, Barcelona, Spain

Background: Many patients infected with hepatitis delta virus (HDV), experience disease progression to cirrhosis and HCC more rapidly than mono-infected HBV patients.[1] Data regarding the burden and epidemiology of HDV are varied[2] due to the lack of screening of all patients with HBV. We assessed whether two online independent medical education activities could improve the knowledge and confidence of gastroenterologists regarding the burden of HDV and best practices in screening and diagnosis. **Methods:** For both activities the educational effect was assessed using a repeated-pairs design with pre-/post-assessment. Six multiple choice questions assessed knowledge, and two questions assessed confidence. Statistical tests to assess significance included: Paired samples t-test for overall average number of correct responses and confidence. McNemar's test for individual questions and learning objectives ($p < 0.05$). Cohen's d estimated the effect size impact on number of correct responses (< 0.20 modest, .20-.49 small, .59-.79 moderate, e .80 large). **Results:** From a total audience of 2450 gastroenterologists there were 317

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

assessment completers. Overall, there were significant knowledge gains ($p < 0.001$) for both educational activities. Specifically, there was a significant gain in knowledge regarding the prevalence of HDV in patients with HBV with a 289% relative change in the proportion of gastroenterologists answering the question correctly following education (pre 9%; post 35%; $p < 0.001$). Another notable gain in knowledge was reported for awareness of HDV screening guideline recommendations (relative change 104%; pre 27%; post 55%; $p < 0.001$). A significant increase in confidence was observed in gastroenterologist's ability to identify patients who should be screened for possible HDV infection with 51% increasing their confidence (confidence shift 113%; $p < 0.001$). **Conclusion:** With therapies for HDV either available or in late phase clinical trials it is important to understand the burden of HDV and best practice in screening and diagnosis so that more patients can benefit from treatment. Online medical education significantly improved gastroenterologist's knowledge and confidence regarding data on epidemiology, patient risk factors, diagnostic tests and screening guidelines recommendations. These findings highlight the importance of independent online medical education to facilitate best practice in screening and diagnosis to increase understanding of HDV epidemiology and reduce the disease burden.

1232-C | IS LIVER DISEASE A RISK FACTOR FOR SARS-COV-2 INFECTION? INSIGHTS FROM A RETROSPECTIVE COHORT STUDY

Martina Marano[1], Elisabetta Bretto[1], Roberta Lasco[1], Rosa Claudia Stasio[1], Marco Tizzani[1], Alona Mednikov[2], Yulia Troshina[2], Rossana Cavallo[2,3], Fabrizia Pittaluga[3], Giacomo Scaioli[4], Giulia Barbera[4], Giorgio Maria Saracco[1,2] and Alessia Ciancio[1,2], (1) Gastrohepatology Unit, Aou Città Della Salute e Della Scienza Di Torino, (2)University of Turin, (3) Microbiology Unit, Aou Città Della Salute e Della Scienza Di Torino, (4)Department of Public Health Sciences and Pediatrics, University of Turin

Background: Previous studies have already demonstrated the thrombogenic effect of inflammatory cascade in COVID-19 disease. Due to this and their fragility, patients with Chronic Liver Disease (CLD), were considered at increased risk of SARS-CoV-2 infection and developing a more severe COVID-19 disease than the general population. This study aims to evaluate if the prevalence of SARS-CoV-2 infection among CLD patients is higher than the general population, and to assess potential risk factors of SARS-CoV-2 infection and severe COVID-19 disease among CLD patients. **Methods:** A retrospective analysis was conducted on a cohort of 1000 patients with CLD of different etiology, attending the Hepatology outpatient clinics of the Molinette University Hospital of Turin, Italy, from August 2022 to April 2023. Demographic characteristics, anthropometric measurements, biochemical values, etiology and severity of liver disease, comorbidities, anti-SARS-CoV-2 vaccination and COVID-19 severity with related symptoms and therapy were analyzed by multivariate logistic and ordered logistic regression analyses. These parameters were compared with those of a population of subjects without liver disease living in Turin. **Results:** The mean age of the cohort was 61.7 (Standard deviation (SD) $\pm$13.3), 44.1% were females. Patients with CLD had a lower prevalence of infection than the general population of Piedmont (27.5% vs 43.8%). The results showed that vaccinated patients had a lower likelihood of getting SARS-CoV-2 (adjusted Odds Ratio (adjOR) 0.45, 95% Confidence Interval (CI) 0.31; 0.64) and of developing a severe disease (adjOR 0.28, 95% CI 0.15; 0.50). After adjusting for anti-SARS-CoV-2 vaccine status, patients with high-stage liver fibrosis or cirrhosis did not show a significant higher predisposition of SARS-CoV-2

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

infection or a symptomatic form, whereas hepatic steatosis was correlated with a higher probability of infection (adjOR 1.58, 95% CI 1.18; 2.13) and diabetes with a higher likelihood of severe disease (adjOR 4.55, 95% CI 1.77; 11.69). Conversely, the presence of ascites is a risk factor for SARS-CoV-2 infection (adjOR 2.59, 95% CI 1.09; 6.16). **Conclusion:** Unlike previous studies, this preliminary work suggests that, after adjusting for anti-SARS-CoV-2 vaccine status, liver cirrhosis is not associated with a higher risk of SARS-CoV-2 infection or the development of severe COVID-19 disease. Further studies are needed to validate the results and contribute to the comprehension of the potential linkage between COVID-19 and CLD.

Disclosures: The following people have nothing to disclose: Martina Marano, Elisabetta Bretto, Roberta Lasco, Rosa Claudia Stasio, Marco Tizzani, Alona Mednikov, Yulia Troshina, Rossana Cavallo, Fabrizia Pittaluga, Giacomo Scaioli, Giulia Barbera, Giorgio Maria Saracco, Alessia Ciancio

1233-C | LABORATORY-CONFIRMED HEPATITIS DELTA VIRUS PREVALENCE AND PATIENT CHARACTERISTICS AMONG COMMERCIALLY INSURED PATIENTS IN THE US

Robert J. Wong[1,2], Robert G. Gish[3], Ira M. Jacobson[4], Joseph K. Lim[5], Marvin Rock[6], Gary Leung[7] and Chong Hoon Kim[6], (1)VA Palo Alto Healthcare System, (2) Stanford University School of Medicine, (3)Hepatitis B Foundation, La Jolla, CA, (4)NYU Grossman School of Medicine, (5)Yale School of Medicine, New Haven, CT, (6)Gilead Sciences, Inc., (7)Rwe — Epidemiology, Gilead Sciences, Inc.

Background: Patients with hepatitis delta virus (HDV) infection have significantly increased risks of liver-related morbidity and mortality vs those with hepatitis B virus (HBV) monoinfection, yet data describing HDV epidemiology, particularly in the US, are limited. This study aims to evaluate the prevalence and incidence of laboratory-confirmed HDV infection among commercially insured adults with HBV in the US. **Methods:** Adults (≥ 18 y old) diagnosed with HBV infection (*ICD-9/10-CM*) or who had an HDV RNA test completed between Jan 1, 2015, and Dec 31, 2022 from the HealthVerity Database linked with Quest laboratory data were included. Overall, yearly, and state-level prevalence of lab-confirmed HDV infection, based on RNA test, were determined among all adults with HBV; incidence was calculated among patients who had HDV RNA− or anti-HDV− results prior to HDV RNA+ result. Annual prevalence was calculated based on the lifetime prevalence approach; adults with HDV RNA+ on or before the year of assessment were included. HDV RNA and anti-HDV test rates among HBV patients were reported. Baseline (12 mo pre-index) characteristics of laboratory-confirmed HDV or HBV only patients with at least 12 months pre- and post-index continuous enrollment were compared. **Results:** Among 1,217 commercially insured adults with lab-confirmed HBV infection between 2015–2022, 95 were HDV RNA+, corresponding to a prevalence of 7.8%; yearly prevalence ranged from 6.3%–11.3%. New lab-confirmed HDV infections accounted for 68 cases, an overall incidence of 5.7%; yearly incidence ranged from 0.5%–6.4%. When evaluated by state-level prevalence, the highest prevalence and incidence of HDV among patients with HBV was observed in New Hampshire and Iowa. Only 1.8% had RNA testing, while 11.3% had either RNA test or anti-HDV test among the HBV patients. Laboratory-confirmed adults with HDV and continuous enrollment (n = 15) were on average 44 years old; 47% were females, mean Charlson Comorbidity Index Score was 1.3, and 86.7% did not have any cirrhosis, hepatocellular carcinoma, or liver transplant during the baseline. **Conclusion:** Lab-confirmed HDV prevalence and incidence among US adults with HBV was 7.8% and 0.5% in 2022. Overall low rates of HDV testing among adults with HBV emphasize the need for increased efforts in screening, diagnosis, linkage to care, and timely treatment of HDV infection.

Figure. HDV Prevalence Among Adult HBV Patients With Commercial Insurance Between 2015-2022

1234-C | LIVER-RELATED COMPLICATIONS IN PATIENTS WITH HDV HIGHER THAN IN HBV MONO-INFECTED PATIENTS: A REGIONAL NYC BASED ASSESSMENT

Lauren Alpert[1], Xiaotao Zhang[1], Theresa Worthington[1], Marcia Lange[1] and Tatyana Kushner[2], (1)Icahn School

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of Medicine at Mount Sinai, (2)Icahn School of Medicine at Mount Sinai, New York, NY

Background: Hepatitis delta virus (HDV) is the most severe form of viral hepatitis, as it is associated with the most rapid progression to cirrhosis, liver failure, and hepatocellular carcinoma (HCC). Although New York City (NYC) has among the highest reported prevalence of HDV in the US, there is limited data on testing patterns, positivity rates, and disease outcomes in the NYC population. We evaluated the prevalence of liver-related health outcomes in NYC patients with HDV and HBV co-infection compared to patients with HBV mono-infection. **Methods:** This was a retrospective, longitudinal cohort study using data from the INSIGHT Clinical Research Network, a PCORNET database of approximately 19 million patients from 5 institutions across New York City. Individual's included in the study were identified based on a diagnosis code of HBV and/or HBsAg positive laboratory status. Among these patients, individual's with either a diagnosis code of HDV or positive HDV Ab and/or HDV RNA laboratory status were identified to indicate HDV co-infection. Multivariable logistic regression models were employed to evaluate adjusted OR of HDV infection on outcomes of cirrhosis, hepatocellular carcinoma, and liver transplantation. **Results:** We identified 36,494 patients with either laboratory evidence and/or diagnosis code evidence of HBV and 1637 patients with HDV. Patients with HDV were median age 50.2 (IQR:37.0, 62.0) at time of testing, 44% Asian, and 12% Hispanic ethnicity. Patient with HDV were more likely to have liver-related comorbidities including fatty liver (21.7% vs. 11.8%, $p < 0.0001$) and hepatitis C virus (HCV) (9.4% vs. 6.7%, $p < 0.0001$) (Table 1). Compared to patients mono-infected with HBV, patients co-infected with HDV had a higher prevalence of cirrhosis (23.5% vs. 5.6%, $p < 0.0001$), ascites (12.3% vs. 6.2%, $p < 0.0001$), and liver transplant (14.2% vs. 2.5%, $p < 0.0001$). In a multivariable regression analysis adjusted for age, gender, and liver-related comorbidity (i.e. fatty liver and HCV) co-infection with HDV was associated with cirrhosis (OR = 5.90, 95% CI: 5.00, 6.97), HCC (OR = 5.53, 95% CI: 4.49, 6.82) diagnoses, and liver transplant (OR = 7.47, 95%CI: 6.10, 9.15). **Conclusion:** In this diverse U.S. based cohort, ~5% of patients with HBV were co-infected with HDV. Patients with HDV were more likely to also have other liver-related comorbidities, including HCV and NAFLD. Patients co-infected with HDV had significantly increased risk of liver-related health outcomes, including cirrhosis, HCC, hepatic decompensation, and liver transplantation compared to those mono-infected with HBV. There is a clear need for HDV therapies in order to prevent progression of liver disease in patients with HDV.

Table 1. Demographic, clinical and liver disease characteristics of HDV versus HBV mono-infection

	TOTAL (n=36494)	HBV (n=34857)	HDV n=1637	p-value

f 1235-C | LOWER INCIDENCE OF HCC AND OTHER MAJOR ADVERSE LIVER OUTCOMES IN PEOPLE LIVING WITH HIV AND CHRONIC LIVER DISEASE: A POPULATION-BASED COHORT STUDY

Maurice Michel[1,2], Hannes Hagström[3,4], Linnea Widman[3], Piotr Nowak[3,5], Ying Shang[3], Jorn Schattenberg[2,6] and Axel Wester[3], (1)University of Mainz, (2)I. Department of Medicine, University Medical Centre Mainz, Germany, (3)Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden, (4) Unit of Hepatology, Department of Upper GI Diseases, Karolinska University Hospital, Stockholm, Sweden, (5) Unit of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden, (6)Metabolic Liver Research Program, I. Department of Medicine, University Medical Centre Mainz, Germany

Background: Chronic liver disease (CLD), including non-alcoholic fatty liver disease (NAFLD) and viral hepatitis, is common in people living with HIV (PLWH). However, there are limited data on whether HIV is associated with a different risk of major adverse liver outcomes (MALO) in patients with CLD. Therefore, the aim of this study was to examine the association

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

between HIV and MALO in patients with CLD. **Methods:** In this nationwide population-based cohort study, data were retrieved from the Swedish National Patient Register based on ICD-codes from patients with CLD and HIV (n = 2,375) or CLD without HIV (n = 144,346) between 1997 and 2020. MALO were defined according to the following diagnoses: ascites, bleeding varices, hepatorenal syndrome, portal hypertension, hepatocellular carcinoma (HCC), or liver transplantation. The cumulative incidence at 10 years follow-up was calculated while accounting for competing risks (non-MALO death). Incidence rates per 1000 person-years were compared between the exposure groups (HIV vs. no HIV) with Cox regression to estimate adjusted hazard ratios (aHR) and their 95% confidence intervals (CIs). Adjustments were made for age, sex, inclusion year, education, country of birth, cirrhosis, liver disease etiology, COPD, cancer, and metabolic comorbidities. **Results:** The majority of individual's in both groups were male, and the median age at baseline was lower in PLWH compared to HIV-negative individual's (41 y vs. 49 y). In both groups, the main etiology of CLD was viral hepatitis (PLWH: 91.7% vs. no HIV: 50.5%) followed by alcohol-related liver disease and NAFLD. At baseline, the prevalence of liver cirrhosis was lower in PLWH (2.9% vs. no HIV: 14.9%). The cumulative incidence of MALO:s at 10 years follow-up was lower in PLWH (5.0%, 95% CI 4.1-6.1 vs. 10.9%, 95% CI 10.7-11.0) (Figure). The incidence rate of MALO:s was significantly lower in PLWH (5.1, 95% CI 4.2-6.1) in comparison to those without HIV (13.1, 95% CI 12.9-13.3; aHR: 0.77, 95% CI 0.64-0.93). The incidence of the individual components of MALO were consistently lower in PLWH, with a significantly lower incidence of HCC in PLWH (1.5, 95% CI 1.1-2.1) than without HIV (3.4, 95% CI 3.3-3.5; aHR: 0.61, 95% CI: 0.43-0.86). **Conclusion:** The incidence of MALO was lower in PLWH and CLD, primarily due to a lower rate of HCC. These results may indicate that the close surveillance and improved treatment options of PLWH and CLD have affected liver-related outcomes.

1236-C | NATIONAL AND REGIONAL PREVALENCE OF HEPATITIS DELTA VIRUS AMONG COMMERCIALLY INSURED PATIENTS IN THE US

Robert J. Wong[1,2], Robert G. Gish[3], Ira M. Jacobson[4], Joseph K. Lim[5], Chong Hoon Kim[6] and Marvin Rock[6], (1)VA Palo Alto Healthcare System, (2)Stanford University School of Medicine, (3)Hepatitis B Foundation, La Jolla, CA, (4)NYU Grossman School of Medicine, (5)Yale School of Medicine, New Haven, CT, (6)Gilead Sciences, Inc.

Background: Patients with hepatitis delta virus (HDV) infection have increased risk of liver-related morbidity and mortality vs those with hepatitis B virus (HBV) monoinfection, yet data describing HDV epidemiology, particularly in the US, are sparse. This study aims to evaluate national and regional prevalence and incidence of HDV infection among commercially insured adults in the US. **Methods:** Adults (≥ 18 y old) diagnosed with HBV or HDV infection (*ICD-9/10-CM*) between Jan 1, 2014, and Dec 31, 2021, with continuous enrollment for ≥ 12 months before and after first diagnosis and ≥ 1 inpatient claim or ≥ 2 outpatient claims, each ≥ 30 days apart, were identified from the PharMetrics Database. Yearly and state-level prevalence of HDV infection were determined among (1) all commercially insured adults (Total) and (2) all adults with HBV; incidence was calculated among adults with no HDV infection diagnoses prior to the date of their first HDV claim. Annual prevalence was calculated based on the lifetime prevalence approach; adults diagnosed on or before the year of assessment were included. Comparisons between HDV and HBV cohorts used Mann-Whitney U tests for continuous and chi-square tests for categorical variables. **Results:** Among 74,937 commercially insured adults with HBV infection between 2015–2020, 1,422 had concurrent HDV infection identified, translating into a prevalence of 1.9%; the HDV prevalence among all commercially insured adults was 18.7 per million. Yearly HDV prevalence among patients with HBV ranged from 1.3%–1.9%. Newly diagnosed HDV infections among HBV patients accounted for 1,312 cases, with an overall incidence of 1.8%; the HDV incidence among all commercially insured adults was 17.3 per million. Yearly HDV incidence among HBV patients ranged between 0.2%–0.6%. The highest prevalence of HDV among adults with HBV was observed in Utah (4.1%), followed

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by New Hampshire (3.7%) and South Carolina (3.6%). Incidence was highest in Utah (4.1%), South Carolina (3.6%), and New Hampshire (3.2%). **Conclusion:** In a nationally representative US commercial claims database, the HDV prevalence among adults with HBV was 1.9%, and the prevalence of HDV among all commercially insured adults was 18.7 per million from 2015 to 2020. We observed significant regional differences in HDV prevalence, which was highest in Utah. Better describing HDV epidemiology will help guide healthcare resource planning and health policy as it relates to screening, diagnosis, and management of HDV.

Figure. HDV Incidence Among Adult HBV Patients With Commercial Insurance Between 2015–2020

HBV, hepatitis B virus; HDV, hepatitis delta virus.

1237-C | NO DETECTABLE RESISTANCE TO BULEVIRTIDE MONOTHERAPY THROUGH 96 WEEKS TREATMENT IN PATIENTS WITH CHRONIC HEPATITIS D

Soo Aleman[1], Yang Liu[2], Simin Xu[2], Silvia Chang[2], Ross Martin[2], Thomas Aeschbacher[2], Lindsey May[2], Savrina Manhas[2], Dong Han[2], Tahmineh Yazdi[2], Clarissa Martinez[2], Pui Yan Ho[2], Christopher Richards[2], Caleb Marceau[2], Dmitry Manuilov[2], John F. Flaherty[2], Evguenia Maiorova[2], Hongmei Mo[2], Heiner Wedemeyer[3] and Pietro Lampertico[4], (1)Karolinska University Hospital/Karolinska Institutet, Department of Infectious Diseases, (2)Gilead Sciences, Inc., (3) Hannover Medical School, (4)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: Bulevirtide (BLV) is a novel entry inhibitor that binds to the HDV entry receptor, sodium taurocholate cotransporting polypeptide (NTCP). Virologic resistance analyses at Week (WK) 24 and WK48 show no resistance to BLV in MYR301 (NCT03852719), an ongoing Phase 3 study in patients with chronic hepatitis D (CHD). Here, we describe the WK96 resistance analyses of this study. **Methods:** In this study, 49 and 50 participants with CHD were randomized to receive BLV 2 mg or 10 mg given subcutaneously once daily for 96 weeks, respectively, as monotherapy. Results for the delayed treatment for 48 weeks followed by BLV 10 mg/day for 48 weeks group are not included herein. Deep sequencing of the BLV-corresponding region in HBV preS1 and HDV antigen (HDAg), and phenotypic analysis using a primary human hepatocyte based in vitro infection inhibition assay were attempted for virologic non-responders (NR; HDV RNA decrease < 1 $\log_{10}$ IU/mL from baseline [BL] at WK96) and for participants with virologic breakthrough (VB; a ≥ 2 $\log_{10}$ IU/mL decrease in HDV RNA from BL for ≥ 2 consecutive visits followed by a ≥ 2 $\log_{10}$ increase from nadir for ≥ 2 consecutive visits; or ≥ 2 consecutive HDV RNA $\geq$ LLOQ if previously $<$ LLOQ for ≥ 2 consecutive visits). Virologic responder (VR) was defined as an undetectable HDV RNA or a decline in HDV RNA ≥ 2 $\log_{10}$ IU/mL from BL at WK96, and virologic partial responder (PR) was defined as a ≥ 1 but < 2 $\log_{10}$ IU/mL in HDV RNA from BL at WK96. **Results:** At WK96, of the 10 NRs that were observed at WK48, 1 became VR and achieved undetectable HDV RNA, 3 became PRs, and the remaining 6 NRs remained NRs. At WK96, there were 8 VBs, including 1 VB at WK48. In total, 14 of 99 (14%; BLV 2 mg, $n = 10$; BLV 10 mg, $n = 4$) participants qualified for resistance analysis at WK96, 6 of which were NRs and 8 which were VBs. By deep sequencing, no identical amino acid changes were identified in the BLV-corresponding region or HDAg from BL through WK96 in NRs/VBs. By phenotypic analysis, no change in sensitivity to BLV was observed in WK96 isolates versus BL isolates. Variants in the BLV-corresponding region and HDAg detected at BL were similarly present in NRs/VBs and VRs, and all remained susceptible to BLV in vitro. The BLV EC_{50} values from 116 BL samples in this study were similar across NRs/VBs, PRs, and VRs. **Conclusion:** There was no genotypic or phenotypic resistance to BLV monotherapy through 96 weeks of treatment.

1238-C | NON-INVASIVE FIBROSIS MARKERS FOR ASSESMENT OF LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS DELTA

Emin Bodakci, Muhammed Fatih Karakaya, Digdem Kuru Oz, Dilara Turan Gokce, Serkan Duman, Zeynep Melekoglu Ellik, Mesut Gumussoy, Sevinc Tugce Guvenir, Volkan Yılmaz, Ramazan Erdem Er, Hale Gökcan, Ayse Erden and Ramazan Idilman, Ankara University, Ankara, Turkey

Background: Non-invasive biochemical-based biomarkers and imaging methods are widely used to assess liver fibrosis in routine clinical practice. The accuracy of blood-based tests varies according to the underlying etiology of chronic liver disease. Magnetic resonance elastography (MRE) is significantly more accurate in assessing hepatic fibrosis in patients with chronic liver disease than other non-invasive techniques. However, data on patients with chronic delta hepatitis (CDH) are scarce. The aims of the present study were to evaluate the accuracy of MRE, vibration-controlled transient elastography (VCTE), and fibrosis-4 (FIB-4) in the assessment of liver fibrosis in patients with CDH. **Methods:** Between September 10, 2019 and March 9, 2023, 42 consecutive patients with CDH were included in the study. MRE, FIB-4, and TE were performed for liver stiffness measurements. **Results:** All 42 patients were Caucasian, their mean age was 51.8 ± 11.1 years, and their gender was predominantly female (60%). Among the patients, 52.4% of the patients were compensated, and 3 of them were decompensated. Median Child-Pugh and MELD scores were 5.0 and 6.5, respectively. The mean FIB-4 and APRI scores were 3.32 ± 2.92 and 1.15 ± 1.32, respectively. FIB-4 and APRI were calculated on the day when MRE was performed. The median liver stiffness values of VCTE and mean MRE were 10.95 kPa, (IQR: 5.20 - 15.7 kPa) and 3.98 ± 1.51 kPa, respectively. A significant positive correlation was found between MRE and VCTE ($r_s = 0.617$, $p < 0.001$). There was also a significant positive correlation between FIB-4 and the APRI ($r = 0.713$, $p < 0.001$). However, a moderate correlation existed between MRE and the FIB-4 ($r = 0.376$, $p = 0.014$) and between MRE and the APRI ($r = 0342$, $p = 0.026$). MRE and VCTE demonstrated a significant accuracy in the detection of clinical cirrhosis with an area under the ROC curve (AUC) of 0.855 (95% confident interval [CI]: 0.733 - 0.976, $p < 0.001$) and 0.841 (95%CI: 0.723 - 0.959, $p < 0.001$), respectively. **Conclusion:** In conclusion, MRE and TE accurately determine clinical cirrhosis in patients with CDH. These imaging methods can eliminate or reduce the number of liver biopsies for liver fibrosis assessments in such patients.

1239-C | OCCURRENCE OF LIVER-RELATED EVENTS IN INDIVIDUALS WITH HEPATITIS DELTA VIRUS: A SYSTEMATIC LITERATURE REVIEW

Laura E. Telep[1], Dominique M Roulot[2,3], Amanda W. Singer[1], Alice Stead[1], Ben L. Da[1], Grace Chee[1], Emily Kaiser[4], Max Lee[4], Patrick S. Reilly[4], Anand P. Chokkalingam[1] and Ira M. Jacobson[5], (1)Gilead Sciences, Inc., (2)Unité D'hépatologie, Assistance Publique-Hôpitaux De Paris, Hôpital Avicenne, (3) Université Paris-Est, U955, Inserm, (4)Costello Medical, (5)NYU Grossman School of Medicine

Background: Hepatitis delta virus (HDV) results in the most severe form of viral hepatitis and is associated with high risk of liver-related complications and mortality. We conducted a systematic literature review (SLR) to identify studies for a meta-analysis analyzing the incidence of liver-related events among patients with HDV infection. **Methods:** We searched online databases (MEDLINE, Embase, the Cochrane Library, and the University of York Center for Reviews and Dissemination) from Jan 1, 2000, to Dec 14, 2022, and relevant congress proceedings from 2021 and 2022. Bibliographies of identified SLRs and meta-analyses were also searched. Randomized controlled trials (RCTs), interventional non-RCTs, and observational studies reporting incidence of cirrhosis, hepatic decompensation, hepatocellular carcinoma (HCC), liver transplant (LT), and liver-related death in ≥ 20 patients (≥ 18 y of age) with HDV infection (positive HDV RNA or ≥ 2 positive anti-HDV tests ≥ 6 mo apart) were included. Quality of included studies was assessed using the JBI Prevalence Checklist. Study and patient characteristics, cumulative incidence, and incidence rates were extracted. **Results:** From 2,227 records identified, 47 publications reporting on 37 studies were included; from these studies, 32 unique data sets were extracted. The 47 publications were published between 2004 and 2022, and 57% (n = 27) were published from 2019 to 2022. While most (n = 19; 59%) of the 32 studies included < 100 patients, 5 included ≥ 200 (Figure). The majority of studies were retrospective cohort studies (n = 19; 59%), and the remaining were prospective cohort (n = 5; 16%), interventional non-RCT (n = 3; 9%), RCT (n = 3; 9%), and registry/database studies (n = 2; 6%). The most commonly reported outcomes were hepatic decompensation (n = 21 studies) and HCC (n = 20 studies). LT was reported in 15 studies, liver-related death in 13, and cirrhosis in 9. Consistent with variable follow-up times across studies (12 weeks–13 y), a wide range of cumulative incidence values were observed (cirrhosis, 15.6%–51.9%; decompensation, 0.0%–50.4%; HCC, 0.0%–16.3%; LT, 0.8%–26.9%; liver-related death, 0.0%–22.2%); only 2 studies reported incidence rates. **Conclusion:** The number of studies describing the natural history of HDV infection has grown in recent years but remains limited. Quantifying the incidence of liver-related events can improve our understanding of disease progression and inform interventions and treatment strategies to reduce the burden of HDV infection.

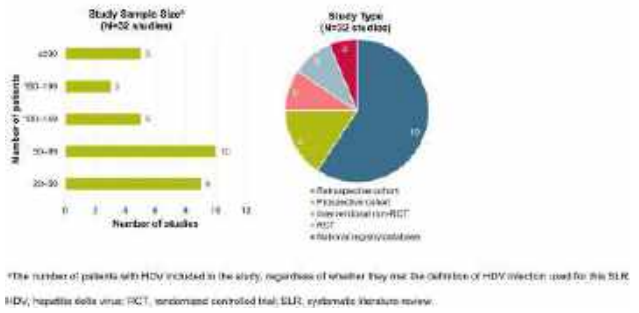

Figure. Characteristics of studies included in the SLR

*The number of patients with HDV included in the study, regardless of whether they met the definition of HDV infection used for this SLR.
HDV, hepatitis delta virus; RCT, randomized controlled trial; SLR, systematic literature review.

1240-C | PATTERN OF LIVER INJURY IN METHAMPHETAMINE USERS IN ACUTE HEPATITIS A AND UTILITY OF N-ACETYLECYSTEINE FOR TREATMENT

Ifrah Fatima[1], Vinay Jahagirdar[1], Noor Hassan[2], Islam Mohamed[1], Mohamed Ahmed[1], Jagadish Koyi[1], Jennifer Von Ende[1], Fouad Jaber[1], Kimberly Sanders[1] and Hassan Ghoz[1,3], (1)University of Missouri- Kansas City, (2)University of Missouri- Kansas City, Kansas City, MO, (3)University Health- Truman Medical Center

Background: Hepatitis A virus (HAV) is known to spread through the fecal-oral route from contaminated food, water, and person-to-person contact. The incidence of hepatitis A in the US has increased over the last decade, with the highest increase from 2017-2019. The total cases in Missouri were 1116 with 649 (58%) hospitalizations, during an outbreak from 09/01/2017 to 11/30/2022. Previous epidemiological studies from California, Kentucky, Michigan, and Utah have shown an association between Hepatitis A and drug use and homelessness. We aimed to identify the prevalence of drug use and its effect on outcomes in the Hepatitis A outbreak at our safety-net hospital. **Methods:** This a single-center retrospective study. Adult patients e 18 years with positive Hepatitis A IgM antibody were identified between March 2012-Feb 2022. Patients were classified into amphetamine-positive and negative groups. Patients with cirrhosis and hepatboiliary obstruction were excluded. Variables including age, total bilirubin, methamphetamine use, route of drug use, N-acetylcysteine use, length of stay, and mortality were identified. Chi-square and Fisher exact tests were used to compare categorical variables, and t-test for continuous variables. Multivariable logistic regression analysis was performed using Stata/SE 16.1. A two-tailed p value < 0.05 was considered statistically significant. **Results:** A total of 95 patients with acute Hepatitis A were identified. 55% (53) were found to have amphetamine use either by UDS or documented history. Among the amphetamine users, 73% were male and 70% were white. 54% (29) had concomitant use of other drugs and 28% (15) had an additional diagnosis of Hepatitis B or C. NAC was given to 28% (15) in the amphetamine users group vs 14%(6) in the non-users. Mean age (42.3 vs 50.3 years; $p = 0.01$) and BMI (25 vs 28; $p = 0.02$) were lower in the amphetamine positive group. Homelessness was higher and significant in the drug use group. (47% vs 5%; $p = 0.01$). The mean total bilirubin was comparable in the amphetamine-use group and non-users. (5.64 vs 4.37 g/dL; $p = 0.39$). On multivariate logistic regression, neither drug use ($p = 0.129$) nor use of NAC ($p = 0.9$) were significantly associated with length of stay or mortality. **Conclusion:** There is an increased prevalence of hepatitis A and

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

amphetamine use. Homelessness was significantly higher in the drug use group. The pattern of liver injury was similar and comparable in the two groups. Amphetamine use and treatment with NAC in acute hepatitis A did not significantly impact the length of stay or mortality. Future vaccination efforts towards these high-risk groups is needed.

Factor	Amphetamine +ve	Amphetamine -ve	p-value
Age	42.3 years	50.3 years	0.004
BMI	25.07 kg/m^2	28.13 kg/m^2	0.02
LOS	5.07 days	5.46 days	0.87
Bilirubin	5.64 mg/dL	4.37 mg/dL	0.39
Female	14 (27%)	19 (45%)	0.027

1241-C | PREVALENCE CLINICAL CHARACTERISTICS OF HEPATITIS DELTA VIRUS (HDV) INFECTED INDIVIDUALS IN BRITISH COLUMBIA

Valeriya Oleksandrivna Zaborska, Ubc, Alnoor Ramji, Division of Gastroenterology, University of British Columbia, BC, Canada, Edward V. Tam, Pacific Gastroenterology Associates, Vancouver, BC, Canada and Hin Hin Ko, University of British Columbia

Background: Globally, HDV is reported in 4.5-13% of chronic hepatitis B (CHB) patients. HDV and HBV co-infection is associated with progression to cirrhosis and higher risk of hepatocellular carcinoma (HCC). HDV prevalence in Canada is not fully elucidated. The purpose of the study was to describe the prevalence and clinical characteristics of HDV infection in CHB patients in a tertiary care centre. **Methods:** Retrospective study of HBsAg-positive patients > 18 years of age tested for HDV Ab between April 2013 and October 2022. Data collected included HDV Ab status, patient demographics, comorbidities, alcohol use, fibrosis stage, and therapies utilized. **Results:** Among 663 HBsAg-positive patients tested for HDV Ab,10/663 (1.5%, 95% CI 0.58-2.44) wereHDV-Ab (+), with 8/10 (80%, 95% CI 0.55-1.05) of those confirmed HDV RNA (+). Average age of HDV patients was 57.8 (95% CI 52.7-62.9) years, similar to HBV patients. Compared to HBV mono-infected patients, HBV-HDV co-infected patients were more likely to be male (90.0% vs 57.6%; $p = 0.04$), have decompensated liver disease (30.0% vs 1.4%; $p < 0.0001$) and less likely to be Asian (50.0% vs 80.9%; $p = 0.014$). One HBV-HDV co-infected patient was also HIV/HCV co-infected, and two had cleared HCV. One HDV patient had a known history of IVDU (10%, 95% CI 0.09 – 0.28). Mean ALT in HDV patients was 55.9, vs. 34.3 in HBV mono group ($p = 0.0508$). 50% of HDV patients consumed any lifetime alcohol compared to 31.9% of HBV mono-infected patients ($p = 0.22$). HDV patients were more likely to have liver stiffness measurements > 9.0 kPa 30% vs 8.9%, $p = 0.02$), and equally likely to have HCC 10% vs 2.5% ($p = 0.13$). **Conclusion:** The prevalence of HDV positivity in CHB patients in this tertiary care centre was 1.5%. Persons with HDV were more likely to be male, and have decompensated liver disease and less likely to be Asian than those with HBV mono-infection. Further studies to understand the burden of disease in other regions are needed.

Table 1.0: Comparison of demographics, alcohol use, hepatic outcomes, laboratory values, antiviral treatment experience, and co-morbidities in HBV mono-infected individuals (n =653) compared with HDV–HBV co-infected individuals (n = 10)

	HDV-HBV co-infected (n=10)	HBV Monoinfected (n=653)	p-value
Age	57.80 (95% CI 52.73-62.87, n=10)	52.95 (95% CI 51.93-53.98, n=653)	0.25

1242-C | RECENT INCREASE IN HEPATITIS CASES (ACUTE HEPATITIS OF UNKNOWN ORIGIN IN CHILDREN/HEPATITIS A/OTHER FOOD BORNE HEPATITIS) WORLDWIDE: A POSSIBLE COVID19 LINKAGE

Arvind Tomar, Pulmonary Medicine, Institute of Liver and Biliary Sciences Hospital and Nishul Rani, C.C.S. University Meerut, Uttar Pradesh, India

Background: In 2022, cases of acute hepatitis of unknown origin in children under 16 years, which are not associated with hepatitis viruses A-E, remained a cause for global concern and alarmed public health agencies. While the aetiology of these severe hepatitis cases is still under investigation, the leading hypothesis points to infection with a common adenovirus which was detected in 75% of confirmed cases with symptoms like abdominal pain, diarrhea and vomiting preceding severe acute hepatitis. In recent years, there has been also increase in enteric hepatitis infections in adults due to food borne viruses including hepatitis A virus, which led to serious public health problems worldwide. **Methods:** Concurrent and preceding to these reports, the emergence of novel SARS CoV2 virus led COVID 19 illness, a global pandemic as declared by World Health Organization (WHO) in early 2020, is accompanied by repeated and exuberant use of soap and alcohol-based sanitizers worldwide for cleaning the hands to curtail the virus transmission. Alcohol-based sanitizing agents considered as potent virucidal agents against enveloped viruses such as Hepatitis B virus, Herpes virus, SARS-CoV, and human immunodeficiency virus, whereas non-enveloped viruses like Adenovirus, Hepatitis A virus, Poliovirus and Norovirus exhibited medium to high level of resistivity against these disinfectants. Also, human innate cutaneous defense system i.e., RNases, an important barrier to prevent the entry of exogenous RNAs, may be compromised with these sanitizers and still be transmitting resilient non-enveloped enteric viruses such as adeno, hepatitis A virus and norovirus into the body. The children probably will be more prone for getting enteric viral infections because of typical playing/feeding habit and subsequent overreliance on alcohol-based sanitizers for cleaning the hands. **Results:** The possible linkage between COVID19 pandemic and emergence of frequent hepatitis A and acute hepatitis of unidentified etiology in children seems to be increased enteric viral infections in the wake of overuse and reliance on alcohol-based hand sanitizers which are considered less effective against non-enveloped viruses. **Conclusion:** In author's opinion, as SARS CoV2 infection is realized as an airborne infection, the unwarranted emphasis on alcohol-based sanitizers should now be guarded.

Virus Category	Examples	Resistance to disinfectant
Enveloped virus	Herpes Simplex virus, Human Immunodeficiency virus (HIV), Influenza, Coronavirus	Low
Non-enveloped virus	Adenovirus, Poliovirus, Norovirus, Parvovirus, Enterovirus	Medium to high

Disclosures: The following people have nothing to disclose: Arvind Tomar, Nishul Rani

1243-C | RECENT PREVALENCE AND CHARACTERISTICS OF PATIENTS WITH HEPATITIS DELTA VIRUS IN HOKKAIDO, JAPAN

Takashi Sasaki[1], Takashi Kitagataya[2], Masatsugu Ohara[1], Masato Nakai[3], Takuya Sho[1], Koji Ogawa[1], Goki Suda[1] and Naoya Sakamoto[1], (1)Hokkaido University Hospital, (2)Mayo Clinic, (3)Hokkaido University Hospital, Sapporo, Japan

Background: Approximately 300 million individual's worldwide carry the hepatitis B virus (HBV) infection,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

which remains a major cause of liver cirrhosis (LC) and hepatocellular carcinoma (HCC). Annually, 800,000 individual's die of HBV infection. Hepatitis delta virus (HDV) is an incomplete RNA virus that requires co-infection with HBV to replicate. Although HDV co-infection with HBV is a global health concern, the global prevalence of HDV infections remains unknown due to insufficient data in many countries. In Japan, HDV prevalence has not been updated for over 20 years. We aimed to investigate the recent prevalence of HDV infections in Japan. **Methods:** We screened 1,264 consecutive patients with HBV infection at the Hokkaido University Hospital between 2006 and 2022. Patients' serums were preserved and subsequently tested for HDV-antibody (immunoglobulin-G). Available clinical information was collected and analyzed. We compared the changes in liver fibrosis using the fibrosis-4 (FIB-4) index between propensity-matched patients with and without the evidence of anti-HDV antibodies and corrected for baseline FIB-4 index, nucleos(t)ide-analog administration, alcohol intake, sex, and age. **Results:** After excluding patients without properly stored serums and those lacking appropriate clinical information, 601 patients with HBV were included. Of these, 1.7% of patients had detectable anti-HDV antibodies. Patients with anti–HDV antibody serum positivity had a significantly higher prevalence of liver cirrhosis, significantly lower PT%, and a higher prevalence of human-immunodeficiency-virus co-infection than those who demonstrated serum anti-HDV antibody negativity. A propensity-matched longitudinal analysis revealed that liver fibrosis (FIB-4 index) progressed more rapidly in patients with positive results for anti–HDV antibody tests. Changes in FIB-4 index/year in patients tested positive for anti-HDV antibodies were more significant than in those with negative test results for anti-HDV antibodies (delta FIB-4 index/year were 0.22 and 0.03 in patients with and without anti-HDV antibody positive, respectively, $p = 0.006$). **Conclusion:** this study revealed that the recent prevalence of HDV infection in Japanese patients was 1.7% (10/601) among those with HBV infection. These patients experienced rapid progression of liver fibrosis. Therefore, a proper test for evaluating HDV infection in Japanese patients with HBV infection is required.

1244-C | REFLEX TESTING FOR HEPATITIS DELTA SCREENING : DOES IT CHANGE THE PREVALENCE? CITYWIDE EXPERIENCE

Alexia Gonzalez[1], Guillaume Penaranda[2], Souad Benali[3], Patrick Borentain[4], Patrick Dukan[5], Sandrine Thibeaut[6], Emmanuel Debono[6], Laurence Lecomte[7], Isabelle Portal[4], Olivia Pietri[6], Si Nafa Si Ahmed[8], Paul Castellani[3], Pierre Audoin[2], Xavier Adhoute[3], Marc Bourliere[7], René Gérolami[4] and Philippe Halfon[2,5], (1) Assistance Publique Hôpitaux De Marseille, Paris, France, (2)Laboratoire Alphabio-Biogroup, (3)Service Hépato-Gastroentérologie, Hôpital Saint-Joseph, (4) Assistance Publique Hôpitaux De Paris, Paris, France, (5)Hôpital Européen, (6)Hôpital Saint-Joseph, (7) Service Hépato-Gastro-Entérologie, Hôpital Saint-Joseph, (8)Hopital Saint Joseph

Background: The knowledge of Delta hepatitis prevalence is made difficult by the absence of reflex testing in the presence of a positive HBsAg. The aim of our study was to look at the prevalence of delta hepatitis (DH) in a city of 1.6 million inhabitants, between the university hospital (UH) where reflex testing was almost systematic (1) and two private structures (hospital with reference hepatology unit (HRH) and 25 city laboratories (CL)) where reflex testing was not systematic. **Methods:** From January 2019 to December 2022, we retrospectively analyzed in each facility the number of HBsAg tests requested, the prevalence of HBsAg, the number of delta serology tests requested in HBsAg-positive patients, the prevalence of DH, and the rate of delta RNA-positive patients and their characteristics (fibrosis, co-infection and treatment). **Results:** During the study period, 2,680,603 patients had blood test. 133,924 patients (5%) had HBsAg test (10% of patients in UH and HRH but 2,3% in CL). 3742 patients were HBsAg+ (2.8%) (2.7% in HU, 0,8% in HRH, 2% in CL). Among the 1792 newly HBsAg+ patients found in the study period, 998 patients (56%) had HDV antibody-(HDV-Ab) screening with huge variation according to site (84% in UH, 66% HRH, 21% in CL). 64 patients (6.4%) were HDV-Ab positive. The prevalence of varied according to site (7% in UH and HRH and 5% in CL $p = 0.6929$). 27 patients (2.7 %) were HDV RNA positive, 80% were male, mean age 44yo (SD15), 74% had advance fibrosis or cirrhosis and 3 patients (11%) were co infected by HIV. 4 patients died (2HCC and 1CCA), 9 patients were either loss of follow -up or refuse treatment and 15 patients have been treated by bulevirtide or NAPs. **Conclusion:** The prevalence of HDV was 6.4% among newly diagnosed HBsAg who had a HDV screening in our city with 15% of migrant's population. The prevalence did not change significantly according to the mode of Delta screening. Reflex testing

1245-C | SAFETY AND EFFICACY OF REP 2139-MG-BASED THERAPY IN AUSTRIAN PATIENTS WITH HBV / HDV COMPENSATED CIRRHOSIS WITH PRIOR FAILURE TO BULEVIRTIDE

Mathias Jachs[1], Thomas Reiberger[2], Michael Schwartz[3], Lorenz Balcar[4], Mattias Mandorfer[3], Michel Bazinet[5] and Andrew Vaillant[5], (1)Medical University of Vienna, (2)Cemm Research Center for Molecular Medicine of the Austrian Academy of Sciences, (3) Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, (4)Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, (5)Replicor Inc.

Background: REP 2139-Mg is a nucleic acid polymer (NAP) with demonstrated safety and antiviral efficacy in patients with HBV/HDV coinfection – including in compensated and decompensated cirrhosis (compassionate use program NCT05683548). **Methods:** REP 2139-Mg 250 mg s.c. qW and pegylated interferon (pegIFN) 90 μg s.c. qW were added to TDF/TAF in three patients with compensated HBV/HDV-induced cirrhosis and clinically significant portal hypertension (CSPH) who failed to respond to long-term BLV treatment. Weekly safety/antiviral efficacy evaluation was performed. Hepatic venous pressure gradient (HVPG) was measured at baseline and at week 12. **Results:** REP 2139-Mg was well tolerated with no related systemic adverse events. Injections were accompanied by grade 1 erythema and puritis in patient 2. Patient 1 is a Caucasian male (69 y.o., Child-A5, large varices, HVPG 17mmHg) with baseline HDV-RNA 3.28 $\log_{10}$ copies/mL and qHBsAg 1202 IU/mL. At week 17, antiviral response was not yet observed, however, HVPG decreased by 18% to 14 mmHg at week 12. Patient 2 is a Caucasian female (51 y.o., Child-A5, large varices, HVPG 14mmHg) with baseline HDV-RNA 4.97 $\log_{10}$ copies/mL and qHBsAg 626 IU/mL. Initial elevation of ALT (ALT_{max} 683 U/L) and bilirubin ($Bili_{max}$ 6.9 mg/dL) but stable INR were noted - similar as during her previous pegIFN exposure. Upon halting pegIFN at week 7, ALT and bilirubin steadily declined during continued REP 2139-Mg therapy. HDV-RNA declined to 710 IU/mL (-2.11 $\log_{10}$) and HBsAg declined to 8.29 IU/mL (-1.88 $\log_{10}$) at week 13. However, HVPG increased by 29% to 18 mmHg, most likely related to the pegIFN-associated hepatitis flare. Patient 3 is a Caucasian male (38 y.o., Child-A5, large varices, HVPG 22mmHg) with baseline HDV-RNA 4.52 $\log_{10}$ copies/mL and qHBsAg 922 IU/ml. An initial ALT flare (ALT_{max} 659 U/L) was observed with stable bilirubin and INR. At week 13, HDV-RNA declined to 7700 IU/mL (-0.63 $\log_{10}$) and HBsAg declined to 281 IU/mL. HVPG decreased by 19% to 18 mmHg at week 12. **Conclusion:** Subcutaneous weekly REP 2139-Mg in combination with TDF and low-dose pegIFN appears safe and effective against HBV/HDV infection in patients with compensated cirrhosis and CSPH, although the use of pegIFN warrants close clinical/laboratory monitoring. The reductions in HVPG observed in both patients with a hepatitis flare suggest a clinically meaningful amelioration of portal hypertension that may translate into a decreased risk of hepatic decompensation.

1246-C | SAFETY AND EFFICACY OF REP 2139-MG-BASED THERAPY IN FRENCH PATIENTS WITH PRIOR FAILURE TO PEGIFN AND OR BULEVIRTIDE

Marc Bourliere[1], Veronique Loustaud-Ratti[2], Christiane Stern[3], Souad Benali[4], Edouard Bardou-Jacquet[5], Laurent Alric[6], Lea Colombain[7], Magdalena Meszaros[8], Sophie Métivier[9], Michel Bazinet[10], Laurence Lecomte[1], Sandrine Francois[2], Cecilia De Freitas[3], Segolene Brichler[11], Athenaïs Gerber[11], Emmanuel Gordien[11], Stephane Chevaliez[12] and Andrew Vaillant[10], (1) Service Hépato-Gastro-Entérologie, Hôpital Saint-Joseph, (2)Service d'Hépato-Gastroentérologie, CHU De Limoges, (3)Service d'Hépatologie, Hôpital Beaujon, (4)Service Hépato-Gastroentérologie, Hôpital Saint-Joseph, (5)Service Des Maladie Du Foie, CHU De Rennes, (6)Service De Médecine Interne-Maladies Digestives, CHU Rangueil, Université Toulouse 3, (7) Centre Hospitalier De Perpignan, (8)CHU Montpellier, Montpellier, France, (9)Service d'Hepatologie, CHU Rangueil, Université Toulouse 3, (10)Replicor Inc., (11) CHU Avicenne, (12)Service De Virologie, Hôpital Henri Mondor

Background: REP 2139 blocks HBV subviral particle assembly and hepatitis delta antigen function, driving HBsAg loss in HBV infection and HBsAg / HDV RNA loss in HBV / HDV co-infection. Compassionate access to REP 2139-Mg is being provided under the Replicor Compassionate Access Program (RCAP, NCT05683548). The safety and efficacy of weekly SC injection of REP 2139-Mg in combination therapy is currently being assessed in cirrhotic patients with chronic HBV / HDV co-infection after failure on bulevirtide (BLV). **Methods:** Compassionate access to REP 2139-Mg has been approved by the ANSM in 15 patients with compensated cirrhosis at baseline who had either no response or viral escape of HDV RNA during 2 or 10mg BLV. Existing TDF was supplemented with 48 weeks of QW SC 250mg REP 2139-Mg and 90 μg pegIFN. Weekly safety evaluations were accompanied by virologic assessment every 4 weeks. **Results:** Data is currently available for 11 patients with at least 4 weeks of REP 2139-Mg exposure. REP 2139-Mg administration has been well tolerated, with transient grade 1 erythema reported in 6/11 patients. ALT flares > 5X baseline have been observed in 1 patient. ALT elevation at baseline present in 7 patients has declined or normalized in 5 patients. No evidence of liver decompensation or other AEs has been observed. Esophageal varices present in one patient have disappeared. HDV RNA response is observed in 9/11 patients, 1 with HDV RNA > 2 $\log_{10}$ IU/mL decline from baseline and 3 with undetectable HDV RNA. HBsAg decline is observed in 6/11 patients with declines of 1 $\log_{10}$, and 2 $\log_{10}$ IU/mL from baseline in 1 and 1 patient respectively and undetectable HBsAg in an additional 2 patients (both with anti-HBs seroconversion). Undetectable HDV RNA and HBsAg and HBsAg seroconversion have been stable after withdrawal of REP 2139-Mg and pegIFN for 10 and 3 months respectively in 2 patients after completion of 48 weeks of therapy. One of these patients has now had TDF withdrawn with HBV DNA remaining additionally undetectable for 2 months. **Conclusion:** Subcutaneous REP 2139-Mg is safe, and effective against HBV and HDV infection in combination with TDF and low dose pegIFN in patients with compensated cirrhosis and can salvage failure from BLV therapy.

1247-C | SCHISTOSOMA MANSONI-INDUCED OXIDATIVE STRESS TRIGGERS HEPATOCELLULAR PROLIFERATION

Verena Von Bülow, Nicola Buss, Jakob Lichtenberger, Lukas Härle, Christoph Gero Grevelding, Martin Roderfeld and Elke Roeb, Justus-Liebig-University, Giessen

Background: Schistosomiasis is a parasitic infection which globally affects more than 250 million people. There is compelling evidence that schistosome eggs, but not the adult worms evoke major tissue damage. *S. mansoni* eggs induce metabolic exhaustion and a strong redox imbalance, which is critical for hepatocellular DNA integrity. However, the impact of egg-induced oxidative stress for the regulation of cell cycle remains elusive. In this study, we investigated, whether oxidative stress provokes hepatocyte proliferation upon *S. mansoni* infection. **Methods:** Cell cycle, replication stress response, and proliferation were analyzed in *S. mansoni*-infected hamsters. Functional experiments were performed in a human hepatic cell line using quantitative real-time PCRs, western blotting, and BrdU assays. Major results were validated by means of human biopsies. **Results:** *Schistosoma mansoni* infection promoted an induction of licensing factors of DNA replication and cell cycle checkpoint cyclins of the G1/S transition in parallel with a DNA damage response. *S. mansoni* egg antigen-induced oxidative stress triggered an upregulation of cyclin D1 in hepatocytes, thus driving G1/S phase transition. At the same time oxidative stress caused downregulation of the cell cycle inhibitor $p27^{KIP1}$. Together, these conditions led to hepatocyte proliferation overcoming the G1/S phase transition. Ultimately, there is an increase in hepatocyte proliferation, which was reversed by the administration of the ROS scavenger L-glutathione. Moreover, human liver biopsies from a patient infected with *S. mansoni* demonstrated elevation of nuclear cyclin D1 in hepatocytes. Furthermore, in a hamster model of *S. mansoni* infection, we confirmed SEA-induced cell cycle progression. **Conclusion:** Hepatocellular proliferation is triggered by *S. mansoni* egg-induced oxidative stress in addition to paracrine mitogenic signals induced by the eggs.The current study demonstrates that *S. mansoni* infection, and in particular the soluble egg antigens, promote hepatocellular proliferation by oxidative stress and subsequent modulation of cell cycle regulation. It appears that these mechanisms contribute to the parenchymal damage caused by *S. mansoni* eggs, and that they may even be associated with malignancy

1248-C | SURGICAL MANIFESTATIONS OF HEPATOBILIARYPANCREATIC TUBERCULOSIS★

Daniel Ernest Laylay Florendo and Apolinario Ericson Berberabe, Philippine General Hospital

Background: Surgical hepatobiliary-pancreatic tuberculosis (HBPTB) has been documented in lieu of more effective therapies for tuberculosis. The documentation HBPTB is sporadic at most, with no large center studies to provide baseline data regarding this rare presentation of tuberculosis. A significant number of these studies draw conclusions based on clinical diagnosis alone with no histopathologic proof of tubercular involvement of the biliary tract and surrounding structures. This study aimed to determine the risk factors, diagnostic and therapeutic approach to surgical HBPTB patients at the Philippine General Hospital (UP-PGH) from January 1, 2014 to December 31, 2021 **Methods:** An institutional database was used to identify patients who underwent a surgical procedure for HBPTB. Patients were only included if there was biopsy or microbiologic proof of tuberculous involvement of the biliary tract or surrounding structures. Clinical data and corresponding outcomes were retrieved from the patient's medical

records. **Results:** Among the total 45 patients included in the study, the most common admitting diagnosis was either malignancy (35.6%) or tuberculosis (37.8%). The major risk factors identified include previous TB exposure (47.6%) and low albumin (60%). Most of the patients did not report any medical co-morbids (83.3%). The liver (37.8%) and the bile ducts (33.3%) were the most common organs involved. Six (6) patients presented with solid lesion and elevated tumor markers suspicious for malignancy; among these CA 19-9 was the most commonly elevated (5 out of 6). The most common surgical procedures done were 1) ultrasound-guided liver biopsy (26.7%), 2) biliary enteric anastomosis for diversion (22.2%) and 3) percutaneous transhepatic biliary drainage (15.6%). Most patients underwent a procedure with a therapeutic outcome (71.1%). There was a distinct preference for minimally invasive procedures such as ERCP or PTBD. Biliary enteric anastomosis was the most common procedure requiring a laparotomy. Average procedure time was 2 hours or less for 55.5%. Mean length of stay was 14.53 days with patients having a post-op stay of 7.47 days. There no mortalities but the identified morbidities were nosocomial pneumonia (6.67%), bacteremia (4.4%), surgical site infection and post-ERCP pancreatitis. **Conclusion:** Identifying which HBPTB patient requires surgery relies on recognition of the constellation of clinical, laboratory and imaging features. Minimally invasive approaches are the mainstay of treatment for surgical HBPTB, the goal of which may be to diagnose or provide symptom relief.

1249-C | THE EFFECT OF METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE ON LIVER FIBROSIS PROGRESSION AND REGRESSION IN VIRUS-RELATED LIVER DISEASE: A MULTICENTER LONGITUDINAL STUDY

Felice Cinque[1], Jovana Milic[2], Stefano Renzetti[3], Federico Motta[2], Jenny Bischoff[4], Dana Kablawi[5], Wesal Elgretli[6], Giulia Besutti[2,7], Giuseppe Mancini[2,7], Sara Esperti[2,7], Marianna Menozzi[2,7], Stefano Calza[3], Cristina Mussini[2,7], Valentina Menozzi[2,7], Maria Daria Di Trapani[2,7], Juergen Rockstroh[4], Giovanni Guaraldi[2,7] and Giada Sebastiani[1,8], (1)Mcgill University Health Centre, Montreal, Canada, (2)University of Modena and Reggio Emilia, Modena, Italy, (3)University of Brescia, Brescia, Italy, (4)University Hospital Bonn, Bonn, Germany, (5)Mcgill University Health Centre, (6)Mcgill University, Montreal, Canada, (7)Policlinico of Modena, Modena, Italy, (8)Mcgill University

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) is a definition of fatty liver not requiring the exclusion of secondary causes of liver diseases, such as HIV and viral hepatitis. Liver fibrosis is a dynamic process recognized as the main predictor of liver disease progression and mortality. We aimed to investigate the effect of MAFLD on liver fibrosis progression and regression in virus-related liver disease. **Methods:** We included people with HIV with and without coinfection with HCV and HBV and with at least two transient elastography examinations with controlled attenuation parameters (CAP) from three prospective cohorts in Canada, Italy and Germany. MAFLD was defined according to Eslam criteria: presence of hepatic steatosis (CAP > 248 dB/m), plus any among type 2 diabetes, overweight (BMI > 25 Kg/m^2) or two other metabolic abnormalities. Fibrosis progression was defined as development of significant liver fibrosis, defined as liver stiffness measurement (LSM) > 8 kPa, or transition to cirrhosis, defined as LSM > 13 kPa, for those with LSM > 8 but < 13 kPa at baseline. Fibrosis regression was defined as transition to no liver fibrosis, defined as LSM < 8 kPa, or to significant liver fibrosis for those with cirrhosis at baseline. Weight gain was defined as a 5% BMI increase in two consecutive visits. A continuous-time multi-state Markov model was used to describe transition across fibrosis stages. Cox regression model was used to identify predictors for liver fibrosis progression. **Results:** 1183 patients were included (median age 53 years, 77% males, median duration since HIV diagnosis 18 years, 25% HIV/HCV coinfected and 4% HIV/HBV coinfected). The baseline prevalence of MAFLD, significant liver fibrosis and cirrhosis was 47%, 14% and 6% respectively. During a median follow-up period of 3.5 years, two to six annual LSM were performed. The incidence rate of fibrosis progression and of fibrosis regression was 3.4 per 100 persons-year and 1.2 per 100 person-years, respectively. In Markov model, weight gain predicted fibrosis progression and prevented its regression (see Table). On multivariable Cox regression analysis, predictors of fibrosis progression were MAFLD (adjusted hazard ratio 2.50, 95% CI 1.06-5.89; $p = 0.036$) and weight gain (adjusted hazard ratio 2.65, 95% CI 1.32-5.26; $p = 0.006$), after adjusting for male sex, age, nadir CD4 cell count, coinfection with HBV and HCV and exposure to different classes of antiretroviral regimens. **Conclusion:** MAFLD and weight gain are the main drivers of liver fibrosis progression in virus-related liver disease, independently of HCV and HBV coinfection and antiretroviral therapy exposure. In the global effort for liver fibrosis screening in at-risk populations, metabolic health should be prioritized.

1250-C | THE NEED FOR CAREGIVER SUPPORT IN PATIENTS WITH HEPATITIS D VIRUS INFECTION: DESCRIPTIVE RESULTS FROM A CROSS-SECTIONAL STUDY IN ITALY, GERMANY, SPAIN AND THE US

Marvin Rock[1], Pietro Lampertico[2,3], Robert G. Gish[4], Nancy Reau[5], Heiner Wedemeyer[6], Maria Buti[7], Ankita Kaushik[1], Caroline Burk[1], Laura Mirams[8], Hilary Ellis[8], Teresa Taylor-Whiteley[8] and Alon Yehoshua[1], (1)Gilead Sciences, Inc., (2)University of Milan, (3)Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, (4) Hepatitis B Foundation, La Jolla, CA, (5)Rush Medical College, Chicago, IL, (6)Hannover Medical School, (7) Hospital Universitari Vall d'Hebron, Department of Medicine of the UAB (Universitat Autònoma de Barcelona), Spain, (8)Adelphi Real World

Background: Hepatitis D virus (HDV) is associated with accelerated progression to advanced liver disease compared to mono-infection with hepatitis B (Fattovich, et al. 2000). HDV may result in reduced health-related quality of life relative to other hepatitis infections (Buti et al., 2021). However, there is a lack of evidence regarding the caregiver burden associated with HDV. Novel questions were developed in this study to understand the need for caregiver support among patients living with chronic HDV who were not receiving any licensed HDV treatment. **Methods:** A cross-sectional survey was completed by adults with a physician confirmed diagnosis of chronic HDV in Italy, Germany, Spain, and the US between July-November 2022. The survey included questions that measured the impact of HDV including the need for caregiver support. Patients who were heavily immunocompromised, received interferon (IFN)/peg-IFN in the past six months, were diagnosed with human immunodeficiency virus or hepatitis C, or had received an organ transplant were excluded. Patients receiving any licensed HDV treatment were also excluded for this analysis. **Results:** Descriptive results were based on 168 patients who were not receiving treatment indicated for HDV

(demographics and clinical characteristics as per Table 1). Of these 168 patients 46 (27.4%) had received caregiver support. The percentage of patients who had received caregiver support rose to 62.5% in patients with a concomitant diagnosis of HCC, and 80.0% in patients with F4D cirrhosis. Most patients (93.5%) received care from people that lived with them; mainly the patient's spouse/partner (84.8%) as well as the patients' children (37.0%, 8.7% of whom were under 18) and other relatives (13.0%). The top 3 activities that patients received help with were preparing meals/cooking food (76.1%), emotional support (69.6%) and travelling out of home (65.2%). Some patients also received help with basic activities of daily living including getting dressed/washed (41.3%), getting in and out of bed (34.8%) and walking (28.3%). **Conclusion:** This study demonstrates a need for caregiver support in patients with HDV across a range of activities, with care mainly received from family members who live with them. The need for caregiver support is highest in patients at later stages of disease and in those with a concomitant HCC diagnosis. Newer treatment interventions which slow down disease progression could potentially ease the caregiver burden.

Table 1

		Overall sample	Non-cirrhotic	Cirrhotic		
			F0-F3	F4 Compensated	F4 Decompensated	Concomitant HCC (any fibrosis stage)

1251-C | TREATMENT WITH REP 2139-MG IN ASSOCIATION WITH TDF IN HDV DECOMPENSATED CIRRHOSIS IS SAFE AND EFFECTIVE IN A REAL-LIFE SETTING

Christiane Stern[1], Cecilia De Freitas[1], Michel Bazinet[2], Vincent Mackiewicz[3], Segolene Brichler[4], Emmanuel Gordien[4], Stephane Chevaliez[5], Marc Bourliere[6] and Andrew Vaillant[2], (1)Service d'Hépatologie, Hôpital Beaujon, (2)Replicor Inc., (3)Service De Virologie, Hopital Bichat, (4)CHU Avicenne, (5)Service De Virologie, Hôpital Henri Mondor, (6)Service Hépato-Gastro-Entérologie, Hôpital Saint-Joseph

Background: REP 2139-Mg blocks assembly and secretion of HBV subviral particles and hepatitis Delta antigen function, providing effects against both HBV and HDV infection. The objective of this study is to describe the safety and efficacy of REP 2139-Mg in CHD patients with decompensated cirrhosis. **Methods:** Compassionate use in three CHD patients with decompensated cirrhosis was approved by the ANSM in France. Scheduled therapy is 48 weeks of REP 2139-Mg 250 mg QW SC and TDF 245 mg QD PO. Clinical, biological, virological and imaging data were collected at baseline and every week for the first month, then every month. **Results:** SC administration of REP 2139-Mg has been well tolerated. No significant adverse events (including ALT elevation) have been observed to date. Patient 1 (Caucasian female, 56 y.o.) had portal hypertension and ascites (Child Pugh B8) with baseline HDV RNA 7.04 $\log_{10}$ IU/mL and HBsAg 1177 IU/mL. Reversal of ascites occurred at week 4, HBsAg loss at week 10, anti-HBs seroconversion at week 14 (increasing to 559 mIU/mL at week 42) and HDV RNA has been undetectable since week 20. Improvement of liver function (to Child A6) occurred during therapy. REP 2139-Mg has now been withdrawn. Patient 2 (African female, 56 y.o.) was listed for liver transplantation due to hepatocellular carcinoma (HCC). She had portal hypertension and ascites (Child Pugh C12), baseline HDV RNA of 3.64 $\log_{10}$ IU/mL and HBsAg of 4270 IU/mL. A significant reduction of ascites occurred at week 4 with marked reduction of edema and fatigue. Successful liver transplantation occurred after 10 weeks of therapy. HDV RNA became undetectable at week 6 and HBsAg was 1.75 IU/mL (anti-HBs 8 mIU/mL) prior to transplant. Explant histology was normal with well-differentiated HCC nodules and no vascular emboli. No ground glass hepatocytes were present. Patient 3 (African male, 47 y.o.) had portal hypertension, ascites, and hepatic encephalopathy (Child Pugh C10). Initial reversal of ascites relapsed with poor diet and diuretic discontinuation. Initial 2.7 $\log_{10}$ IU/mL decline in HDV RNA at week 11 was followed by mild rebound concomitant with perfusion of albumin following paracentesis. **Conclusion:** REP 2139-Mg is safe and well tolerated in CHD patients with decompensated cirrhosis. HBV-HDV functional cure appears achievable for the first time in this special population, which could prevent the need for liver transplant.

1252-C | UNDERSTANDING THE ANTIVIRAL EFFECTS OF PEGINTERFERON LAMBDA WITH AND WITHOUT RITONAVIR BOOSTED LONAFARNIB IN CHRONIC HEPATITIS D INFECTION

Christina Park[1], Julian Hercun[1], Harel Dahari[2], Ohad Etzion[3], Saeed S. Hamid[4], Edward J. Gane[5], Yoav Lurie[6], Farial Rahman[1], David Yardeni[7], Pallavi Surana[1], Colin Hislop[8], Ingrid Choong[8], Jeffrey Glenn[9], Theo Heller[10] and Christopher Koh[11], (1)National Institutes of Health, (2)The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, Highland Park, IL, (3)Saroka University Medical Center, Beer-Sheba, Israel, Beer-Shiva, Israel, (4)Aga Khan University Hospital, Karachi, Pakistan, (5)University of Auckland, (6)Shaare Zedek Medical Center, (7)Soroka University Medical Center, Mishmar Hanegev, Israel, (8) Eiger BioPharmaceuticals, Inc., (9)Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology & Immunology, Stanford School of Medicine, Stanford, California, USA, (10) Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (11) National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: Hepatitis Delta Virus (HDV) infection causes the most aggressive form of human viral hepatitis and lacks an approved FDA therapy. Various investigative therapies are in the pipeline including interferon-based therapy and therapies targeting viral assembly. We aim to compare different combinations of novel HDV therapies and assess their anti-HDV effectiveness. **Methods:** Viral kinetic data was analyzed from three phase-2 clinical trials (LOWR-3 [NCT02511431], LIMT-1 [NCT02765802], and LIFT-1 [NCT03600714]). LOWR-3 employed Ritonavir (RTV-100mg) boosted Lonafarnib (LNF-50/75/100mg) for 12-24 weeks. LIMT-1 employed 180mcg of PEGylated lambda interferon (L-IFN) weekly for 48 weeks. LIFT-1 combined 180mcg of L-IFN with RTV-100mg and LNF-100mg for 24 weeks. 12 weeks of HDV RNA data were analyzed, and the Wilcoxon tests and linear regression were used to assess all three studies. In subgroup analysis, patients who participated in both the LOWR-3 and LIFT-1 studies were analyzed to further assess the combinatory effects of therapy. **Results:** The baseline HDV RNA levels were similar between cohorts in all three studies and not significantly different with a *p*-value of 0.075. At 12 weeks of therapy, the median HDV RNA decline from baseline in LOWR-3 (LNF 100mg + RTV) was 0.52 log IU/mL ($p = 0.181$), LIMT-1 was 1.14 log IU/mL ($p = 0.012$), and LIFT-1 was 1.72 log IU/mL ($p < 0.0001$). The coefficients of the LOWR-3 (100mg), LIMT-1, and LIFT-1 linear regressions were -0.030 ($R^2 = 0.045$), -0.093 ($R^2 = 0.335$), and -0.123 ($R^2 = 0.630$), respectively. A model of additive effect of L-IFN paired with LNF+RTV has the coefficient -0.1229, which comes from adding LOWR-3 and LIMT-1 coefficients. The LIFT-1 coefficient of -0.1231 is very close to the additive effect model, suggesting that the combination of L-IFN and LNF+RTV has an effect that is equal to the sum of their individual effects. In the individual patient analysis across LOWR-3 and LIFT-1 studies (n = 12), HDV RNA responses at week 12 differed by a mean of 0.97 log IU/mL (SD = 0.88). Additionally, the median HDV RNA decline from baseline after 12 weeks of therapy in LOWR-3 was 0.92 log IU/mL ($p = 0.003$) and LIFT-1 was 2.11 log IU/mL ($p = 0.001$). The coefficients of the LOWR-3 (100mg), LIMT-1, and LIFT-1 linear regressions were -0.104 ($R^2 = 0.703$), -0.093 ($R^2 = 0.335$), and -0.268 ($R^2 = 0.737$) respectively. The additive effect model of L-IFN and LNF+RTV has the coefficient -0.196, based on adding LOWR-3 and LIMT coefficients. However, the LIFT-1 coefficient of -0.268 is 1.37 times more suggesting a true synergistic effect of L-IFN plus LNF +RTV therapy. **Conclusion:** The combination of L-IFN plus LNF+RTV suggests a synergistic effect against HDV by 12 weeks after initiation of therapy. These findings have important implications for designing the optimal therapy to treat HDV.

1253-C | UNSAFE SEXUAL PRACTICES PRIOR TO INCARCERATION, A HIGH-RISK FACTOR OF HEPATITIS B AND HIV INFECTION AMONG PRISONERS IN BLANTYRE, MALAWI

Shakira Chimberenga[1,2], Anastansia Mgawa[2], Grace James[3], Enock Jumbe[3], Marie-Claire Van Hout[4], Mulinda Nyirenda[2,5] and Isaac Thom Shawa[2,6], (1) Ministry of Health, Mzuzu Central Hospital, (2)Kamuzu University of Health Sciences, (3)Johns Hopkins Research Project, (4)Liverpool John Moore's University, (5)Ministry of Health, Queen Elizabeth Central Hospital, (6)University of Derby

Background: Hepatitis B and C viruses (HBV/HCV) are the major causes of liver diseases. Both HBV and HCV are primarily transmitted through contact with infected blood, and body fluids. Low and middle-income countries have a disproportionately high rate of chronic HBV and HCV especially in the HIV infected population. Prison settings are associated with substantial risk of HBV, HCV, and HIV acquisition and are a significant driver of blood-borne viruses among prisoners during detention and after release. The primary aim of this study was to assess the prevalence of HBV, HCV and HIV among those detained at Chichiri prison, that would provide insights into the highest risk factors associated with acquisition of hepatitis infection among prisoners in Malawi. **Methods:** 220 participants [86.4% males (n = 190/220), 13.6% females (n = 30/220) were enrolled at Chichiri prison. A structured questionnaire was used for collection of demographic details, assessment of knowledge, and risk factors for transmission of viral hepatitis in prison environment in Malawi. Serum samples were prepared and analyzed utilizing HBV, and HCV rapid assays. All positive samples were run on sandwich enzyme immunoassay (EIA). **Results:** The HBV prevalence was estimated at 8.6%; whereas HCV was not detected in the sample (0%). The HIV prevalence rate was 21%, and HBV/HIV co-infection prevalence was 11%. The majority (79.1%) of prisoners were incarcerated between 2017 and 2020. HBV/HIV co-infection was observed in 11% of the sample. **Conclusion:** This study confirms high prevalence of HBV among prisoners at Chichiri. Findings suggest that intra-prison viral hepatitis transmission was very minimal, possibly due to criminalisation of high-risk practices (injecting drug use, sex between men) for exposure to blood-borne viruses. Sexual transmission prior to incarceration was the highest risk factor for viral hepatitis and HIV. Prison environments present both challenges and opportunities for prevention and treatment of viral hepatitis and HIV infections. Absence of HCV markers reported in this study was expected since the HCV prevalence in general population was apparently very low. An exigent consideration of vertical and horizontal HBV transmission to be performed in future studies to provide further insights into the viral transmission dynamics.

1254-C | USEFULNESS OF A UNIQUE PAN-GENOTYPIC PANEL OF HDV SAMPLES TO COMPARE HDV RNA QUANTIFICATION KITS

Athenaïs Gerber, Valerian Delagarde, Pascale Leloup, Emmanuel Gordien, Frederic Le Gal and Segolene Brichler, CHU Avicenne

Background: Hepatitis delta virus (HDV) infects a non-negligible fraction of HBV chronically infected patients, and worsens the clinical prognosis. Beyond HDV antibody screening with a serological test, RNA detection and quantification is required to identify patients with an active HDV infection, and further assess the efficacy of antiviral treatment. A few RT-qPCR commercial kits are now available worldwide, but despite the distribution of the First WHO International Standard, results are not yet standardized. Our objective was to compare the HDV quantification results obtained with pipelines (extraction device – RT-qPCR kit – thermocycler) from several manufacturers, on a unique HDV panel representative of circulating genotypes. **Methods:** A panel of 24 plasma samples of various viral loads (VL) and genotypes was established and multiples aliquots of 1mL each were stored at -80° C. We first compared four complete pipelines recommended by the manufacturers; then, the same amplification kit (EurobioPlex EBX-071 on a CFX96 thermocycler) was used after RNA extraction with four different automated devices. Volumes of plasma sample and eluate in each extraction technique were taken in account to calculate VL results in IU/mL. **Results:** The panel consisted of 2 negative, 8 HDV-1 (of both African and European origin), 3 HDV-2, 2 HDV-4, 3 HDV-5, 2 HDV-6, 2 HDV-7 and 2 HDV-8 positive samples, with VL ranging from 2 to 5 log IU/mL (as quantified with EurobioPlex EBX-071 kit). Qualitative results were concordant for all samples on the 4 pipelines. Quantitative results were very similar between the EurobioPlex EBX-071 (Eurobio), the RealStar HDV RT-PCR (Altona) and the RoboGene HDV RNA Quantification 3.0 (AG Roboscreen) kits, with a mean difference < 0.2 log IU/mL, whatever the genotype and VL, but the EurobioPlex EBX-004 (Eurobio) kit systematically overestimated the VL by 1 log IU/mL. Compared to the results obtained with the m2000sp, changing the extraction device led to

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

a difference of -0.1, +0.2 and +0.5 log IU/mL (for EasyMag, Cobas 4800 and QiaSymphonySP respectively). **Conclusion:** Our results clearly show that standardized HDV VL results can be obtained with several RT-qPCR kits and pipelines now commercially distributed, but that not all kits are equivalent and that many factors can influence the final quantitative results. Using the same panel for comparison studies allows a rapid identification of concordant tests and participate to the ultimate goal of HDV quantification standardization.

1255-C | VALIDATION OF PROGNOSTIC SCORES FOR PREDICTING ACUTE LIVER FAILURE AND IN-HOSPITAL DEATH IN PATIENTS WITH DENGUE-INDUCED SEVERE HEPATITIS

Tongluk Teerasarntipan[1], Kessarin Thanapirom[1], Roongruedee Chaiteerakij[1], Piyawat Komolmit[1] and Sombat Treeprasertsuk[2], (1)Chulalongkorn University, (2)Chulalongkorn University, Bangkok, Thailand

Background: Acute liver failure (ALF) in dengue is rare but fatal. MELD score was generally used in predicting liver-related prognosis. However, the complex calculation might limit its applicability. Recently, simple prognostic scores, including the ALBI, EZ-ALBI and PALBI scores, have been developed in determining prognosis in various aspects of liver injury. Therefore, we aimed to validate prognostic scores for predicting ALF and in-hospital mortality in patients with dengue-induced severe hepatitis (DISH). **Methods:** We retrospectively reviewed 2,532 serology-confirmed hospitalized adult dengue patients during the 16-year study period (2007-2022) at the King Chulalongkorn Memorial Hospital, Thailand. Patients with DISH [n = 193 (7.62%)], defined as transaminases > 10 times from the normal reference level, and DISH with subsequent ALF, defined by the EASL 2017 criteria, were included. Univariate regression analysis was used to identify potential factors associated with adverse outcomes. Youden's index in conjunction with receiver operating characteristics (ROC) analysis was used to determine the best cut-off value of prognostic scores in predicting ALF and in-hospital death and area under ROC (AUROC) curves were compared using a paired data nonparametric ROC curve estimation. **Results:** Of the 193 DISH patients, 20 patients developed ALF (0.79%). Mortality rates in patients with ALF and without ALF were 60.0% (12/20) and 0.58% (1/173), respectively. Regression analysis showed that INR, bilirubin, albumin, and creatinine were independent laboratory markers associated with ALF and death. Liver prognostic scores had excellent performance predicting adverse outcome from DISH; MELD score > 15 predicted ALF with AUROC of 0.917, (90.0% sensitivity, 88.4% specificity) and MELD score > 18 predicted in-hospital death with AUROC of 0.823, (86.9% sensitivity, 89.1% specificity); EZ-ALBI score > -30 predicted ALF and death with AUROC of 0.835, (80.0% sensitivity, 72.2% specificity), and AUROC of 0.808 (76.9% sensitivity, 69.3% specificity), respectively; ALBI score > -2 predicted ALF and death with AUROC of 0.806, (80.0% sensitivity, 77.4% specificity), and AUROC of 0.799 (76.9% sensitivity, 74.3% specificity), respectively. PALBI score had the lowest but still good performance predicting adverse DISH outcomes (AUROC of 0.786 and 0.699 for ALF and death, respectively). A paired sample ROC curve estimation showed non-different performance between MELD score and EZ-ALBI score, in predicting ALF ($z = 1.688$, $p = 0.091$, 95%CI of -0.014-0.194) and in-hospital death ($z = 0.322$, $p = 0.747$, 95%CI -0.141-0.197). **Conclusion:** MELD score was the best predictor of ALF and death in DISH patients. EZ-ALBI score, a simple and easy-to-use score, had excellent predictive performance and therefore might be considered as an alternative tool to predict prognosis in dengue patients.

f 1256-C | VASCULAR REMODELING AND LIVER REGENERATION BEGIN EARLY AND PERSIST IN CHRONIC HEPATITIS D PROGRESSION

Maleeha F Ahmad[1], Moumita Chakraborty[1], Adekanyinsola Onitiri[1], Rownock Afruza[1], Nicole San-Dee Minerva[1], David E Kleiner[2], Christopher Koh[3] and Theo Heller[1], (1)Translational Hepatology Section, National Institutes of Health, (2)Laboratory of Pathology, National Cancer Institute, National Institutes of Health, (3)National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: Of all the viral hepatitides, delta virus is the most aggressive- carrying the highest risks for cirrhosis, decompensation, hepatocellular carcinoma, and mortality. Understanding chronic hepatitis delta's (CHD) ability to cause rapid and reproducible progression of liver disease will not only aid development of improved staging techniques and sorely needed therapeutics for CHD but will also allow for a deeper understanding of chronic liver disease (CLD) progression in general. Vascular and regenerative factors are of particular interest as potential key drivers of CLD progression. **Methods:** 42 treatment-naïve liver biopsies from CHD patients evaluated at the National Institutes of Health were staged according to the Ishak Fibrosis (IF) scale (IF 0-4: non-cirrhotic, IF 5-6: cirrhotic) and underwent immunofluorescent staining with vascular (Vascular Endothelial Growth Factor, VEGF; CD34) and regenerative markers (cytokeratins 7 and 19, CK7 and CK19; alpha-fetoprotein, AFP; CD133). Confocal microscopy was used to take images of each liver zone (Periportal, PP; Midlobular, ML; Pericentral, PC) and signal quantification was performed with FIJI. **Results:** Cirrhosis was significantly associated with male sex (11/12 cirrhotic patients, Fischer's exact $p = 0.036$), increased aspartate aminotransferase (AST) (median 64 vs 44.5 U/L, $p = 0.034$), decreased platelets (102 vs 174 K/mcL, $p = 0.0009$), increased liver stiffness (n = 27, 15.0 vs 9.95 kPa, $p = 0.022$), and increased hepatic venous pressure gradients (n = 34, 8.0 vs 4.5 mmHg, $p = 0.0057$). Higher CD34 expression was noted in non-cirrhotic vs cirrhotic PC regions (median: 2.27 vs 1.45, $p = 0.046$) and higher VEGF expression was observed in middle-stage (IF 3-4) vs cirrhotic PC zones (95.77 vs 41.64, $p = 0.018$). Higher CD133 expression was seen in middle- compared to early-stage PC regions (2.83 vs 0.82, $p = 0.037$). AFP expression was significantly higher in middle-stage vs cirrhotic ML regions (8.36 vs 2.18, $p = 0.042$). Lower CK19 expression was detected in cirrhotic vs early-stage (IF 0-2) PP regions (164.2 vs 305.1, $p = 0.044$). AFP and particularly CK7 were expressed notably in the PP zone, but did not statistically differ between disease stages, suggesting liver regeneration is occurring consistently throughout disease. CK7 and CK19 expression was also noted in the ML and PC regions, typically in middle-stage disease. **Conclusion:** CD34 and VEGF data suggest angiogenesis and vascular remodeling are prominent features even in early- and middle-stage CHD. CK7, CK19, CD133, and AFP results reveal that ductular reaction and liver regeneration take place in the PP region throughout the spectrum of CHD disease but that the ML and PC zones are also involved (most notably during middle-stage disease), indicating that liver regeneration begins earlier in the disease process and to a greater extent than perhaps was previously appreciated.

1257-C | VIR-2218 AND VIR-3434 THERAPY IS EFFICACIOUS IN PRECLINICAL MODELS OF HEPATITIS DELTA VIRUS INFECTION

Jiayi Zhou[1], Hannah Kaiser[1], Michael A. Schmid[2], Ashley N. Terrell[1], Davide Corti[2], Lisa A. Purcell[1], Florian A. Lempp[1] and Andreas S. Puschnik[1], (1)Vir Biotechnology, Inc., (2)Humabs Biomed SA, a Subsidiary of Vir Biotechnology, Inc.

Background: Chronic Hepatitis Delta Virus (HDV) infection represents the most severe form of viral hepatitis with limited treatment options. HDV is a satellite virus of Hepatitis B Virus (HBV) that depends on HBV-derived HBsAg for envelopment and viral dissemination. VIR-2218 is an investigational RNAi therapeutic that targets a highly conserved region within the HBV X open reading frame and demonstrates potent knockdown of all HBV transcripts, including HBsAg. VIR-3434 is an investigational monoclonal antibody targeting the antigenic loop of HBsAg, inhibiting viral entry, and reducing circulating HBsAg in preclinical models and in early-stage clinical trials. This study aims to investigate the antiviral effect of VIR-2218 and VIR-3434 on HDV infection in preclinical models. **Methods:** *In vitro* antiviral efficacy of VIR-2218 was determined in an HBV/HDV co-infection model of primary human hepatocytes (PHH). Secreted HBsAg was quantified using ELISA and secreted infectious HDV virions by re-infection of naïve Huh7-NTCP cells. *In vitro* neutralization potency of VIR-3434 was determined against HDV enveloped with HBsAg of eight different HBV genotypes. *In vivo*, efficacy of VIR-2218/VIR-3434 mono- and combination treatments were

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

evaluated in HBV/HDV co-infected liver-chimeric mice. **Results:** VIR-2218 treatment *in vitro* reduced HBsAg and secreted infectious HDV with picomolar efficacy. VIR-3434 neutralized HDV infection i*n vitro* with > 10,000-fold higher potency than Hepatitis B Immunoglobulins. Neutralization activity was pan-genotypic as tested with HDV enveloped with HBsAg of HBV genotypes A-H. Combination treatment of co-infected PHH with VIR-2218 and VIR-3434 reduced levels of infectious HDV virions. *In vivo*, mono-treatment with VIR-2218 or VIR-3434 decreased HBsAg and HDV RNA serum levels by > 0.5 log and > 1 log, respectively. Combination treatment reduced HBsAg and HDV RNA serum levels by > 2 log. **Conclusion:** VIR-2218 and VIR-3434 have previously shown antiviral efficacy against HBV infection in multiple *in vitro* and *in vivo* models. Due to the shared use of HBsAg by HBV and HDV, targeting HBsAg also reduces concurrent HDV infection. VIR-2218 and VIR-3434 exert antiviral efficacy against HDV as single agents and in combination by reducing HBsAg secretion, circulating HBsAg and HDV virions, as well as by blocking entry into hepatocytes. These data support the clinical development of VIR-2218 and VIR-3434 for treatment of patients with chronic HDV infection.

f 1258-C | YAP MEDIATES HIV-RELATED LIVER FIBROSIS

Shadi Salloum[1], Raymond T. Chung[1], Volney Spalding[2], Brian A Fellenstein[2], Andre Jeyarajan[2], Lishan Su[3], Nadia Alatrakchi[1], Wenyu Lin[1] and Guangming Li[3], (1)Massachusetts General Hospital and Harvard Medical School, (2)Massachusetts General Hospital, (3)University of North Carolina at Chapel Hill

Background: The successful implementation of antiretroviral therapy has shifted the focus of human immunodeficiency virus-1 (HIV-1) research towards the long-term effects of persistent, controlled infection. We and others have demonstrated that HIV accelerates liver fibrosis attributable to multiple etiologies, including HCV, HBV, and fatty liver disease. Evidence also suggests that HIV infection itself is associated with liver fibrogenesis. Recent studies have implicated Yes-Associated Protein 1 (YAP1) and the upstream lysophosphatidic acid (LPA)/PI3K/AKT pathway as critical regulators of hepatic fibrogenesis, and suggest a connection to HIV-related liver fibrosis. The aim of our study was to identify the relationship between YAP/PI3K/AKT pathway activation and HIV-related liver fibrosis. **Methods:** We examined the impact of HIV on the YAP pathway on serum samples as well as primary hepatic stellate cells (pHSC) and human hepatocytes (pHH) cultured directly from healthy donors. *Ex vivo* precision cut liver slices (PCLS) are also generated from patient samples which serve as transiently culturable tissue and facilitates the observation of HIV within the context of complete hepatic architecture. We also utilized a humanized mouse model (NRG-hu HSC mice) with both human liver tissue and immune system infected with HIV-1. The data was supplemented with both traditional *in vitro* models as well as a 3D spheroid system which supports crosstalk between hepatocytes and pHSCs. **Results:** Human serum samples analyzed via ELISA showed elevated levels of circulating YAP-related protein within HIV infected patients. PCLS and *in vitro* analysis of pHSCs, pHHs, and Huh7 cells (including mono and co-culture models (spheroids)) also showed that YAP-related and profibrotic genes were upregulated when exposed to HIV. In addition to upregulating YAP-regulated genes, the humanized mouse model developed histologically worsened fibrosis after infection with HIV. When Huh7 cells and pHSCs were each exposed to individual HIV proteins, gp120 was found to most closely reproduce the profibrotic program of the virus. Finally, lysophosphatidic acid receptor 1 (LPAR1), PI3K, and AKT inhibitors and knockout via siRNAs inhibitors abrogated the fibrotic effects of HIV exposure. **Conclusion:** We demonstrate through multiple lines of evidence that the LPAR/PI3K/AKT axis is vital for the activation of YAP

and hepatic fibrogenesis due to HIV infection. This novel mechanistic insight suggests new pharmacologic targets for treatment of liver fibrosis in persons living with HIV.

1300-C | A 20% DECREASE OF SERUM CHI3L1 INDICATES HISTOLOGICAL REGRESSION IN PATIENTS WITH CHRONIC HEPATITIS B DURING ANTIVIRAL TREATMENT

Tongtong Meng[1], Lin Wang[1], Jialing Zhou[1], Biaoyang Lin[2], Yameng Sun[1], Bingqiong Wang[1], Shuyan Chen[3], Xiaojuan Ou[1], Jidong Jia[1], Hong You[3] and Xiaoning Wu[1], (1)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (2)Zhejiang California International Nanosystems Institute (ZCNI) Proprium Research Center, Zhejiang University, Hangzhou Proprium Biotech Company Limited, Hangzhou, China, (3)Liver Research Center, Beijing Friendship Hospital, Capital Medical University

Background: Chitinase 3-like 1 (CHI3L1) is a marker for staging of liver fibrosis, however its dynamic change and the potential application of CHI3L1 as a non-invasive surrogate marker for liver fibrosis regression in patients with chronic hepatitis B (CHB) during antiviral treatment is unknown. **Methods:** Serum CHI3L1 levels were tested in treatment-naïve patients with CHB who performed liver biopsy before and at 78 weeks of entecavir-based therapy. Histological change at 78 weeks were evaluated with the Ishak score as well as the P-I-R score. Liver fibrosis regression was defined as the Ishak score decreased by ≥ 1 point or predominantly regression by P-I-R score if there was no change in Ishak score. Kruskal-Wallis test was used to compare the differences in absolute values or changes of CHI3L1 levels from the baseline to 78 weeks, chi-square test was used to compare the proportion of patients with decreased CHI3L1 levels during treatment. **Results:** A total of 131 CHB patients were enrolled with a median age of 36 (29, 43) years and 77.9% of them were males. There were 41 (31.3%), 29 (22.1%), and 25 (19.1%) patients staged at significant fibrosis (Ishak 3), advanced fibrosis (Ishak 4), and cirrhosis (Ishak 5 and Ishak 6) before treatment according to the Ishak score system. Totally 83 (63.4%) of patients achieved histological regression at 78 weeks, and 48 (36.6%) were classified to the non-regression group. The baseline characters were comparable between two groups. Median levels of CHI3L1 seemed similar in both groups at baseline and at each visit during treatment [at baseline, 26 weeks, 52 weeks, and 78 weeks were 87.57 (66.42, 115.24), 67.52 (51.06, 91.66), 66.73 (45.20, 97.47), 69.41 (47.52, 88.56) *vs.* 91.29 (61.99, 136.85), 73.28 (53.70, 111.97), 84.39 (54.54, 131.59), 74.21 (54.41, 97.57) ng/ml, respectively; $p = 0.330$~0.986]. However, both groups showed a significant decrease in CHI3L1 levels during treatment compared with pre-treatment. Besides that, the decrease was more remarkable in the regression group at 52 weeks of treatment (the median difference in CHI3L1 levels: -19.09 ng/ml *vs.* -1.94 ng/ml, $p = 0.039$; the median rate of change: -26.85% *vs.* -3.05%, $p = 0.039$). Furthermore, we found that the proportion of patients with CHI3L1 decline during treatment was higher in the regression group than in the non-regression group at 52 and 78 weeks of treatment (79.5% *vs.* 54.2%, $p = 0.004$; 80.7% *vs.* 58.3%, $p = 0.010$). In addition, the proportion of patients with a ≥ 20% decrease in CHI3L1 was significantly higher in the regression group than in the non-regression group at 52 weeks of treatment (56.6% *vs.* 35.4%, $p = 0.031$). **Conclusion:** Serum CHI3L1 levels decreased significantly during antiviral therapy in treatment-naïve CHB patients with liver fibrosis, a ≥ 20% decrease at 52 weeks could be a potential non-invasive surrogate marker of liver fibrosis regression.

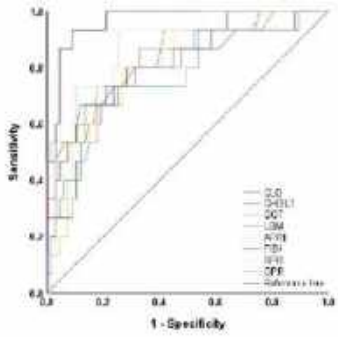
1301-C | A NONINVASIVE DIAGNOSTIC MODEL FOR LIVER CIRRHOSIS IN PATIENTS WITH HBV INFECTION BASED ON CHI3L1 AND ROUTINE CLINICAL PARAMETERS

Zhiwei Xie[1], Jinnian Lin[2], Chujing Li[1], Wenyu Wang[1], Songlian Liu[1], Honglian Bai[2], Jianping Li[1] and Yujuan Guan[1], (1)Guangzhou Eighth People's Hospital, Guangzhou Medical University, (2)The First People's Hospital of Foshan

Background: Chitinase-3 like-protein-1 (CHI3L1) is a chitinase-like protein that is expressed in various tissues, including the liver. This study aimed to investigate whether CHI3L1 could serve as a non-invasive diagnostic marker for assessing liver cirrhosis in patients with hepatitis B virus (HBV) infection. **Methods:** This study enrolled chronic hepatitis B (CHB) patients from Guangzhou Eighth People's Hospital and The First People's Hospital of Foshan. Inclusion criteria: age ≥ 18 years, HBsAg (+) ≥ 6 months, and HBV DNA (+). Patients with liver injury caused by factors such as HCV, HDV, or other etiologies were excluded. Serum CHI3L1 levels were measured using chemiluminescence enzyme-linked immunoassay. Liver biopsy was performed on patients who provided consent for liver puncture. Univariate and multivariate logistic regression analyses were conducted to identify independent predictors of liver cirrhosis and establish a diagnostic model. **Results:** Between November 2018 and July 2022, 152 patients with HBV infection were enrolled. They were divided into the CHB group (n = 115) and the liver cirrhosis (LC) group (n = 37). The median (interquartile) levels of serum CHI3L1 were 29.79 (21.68) ng/ml in the CHB group and 74.73 (75.66) ng/ml in the LC group. The difference between the two groups was statistically significant ($p < 0.001$). Among the 87 patients who underwent liver biopsy, the mean age was 38.14 ± 8.62 years; 58 (66.7%) were male; 28 (32.2%) were HBeAg (+); 69 were CHB and 18 were LC; 25 (28.7%) had fibrosis staging 0-1 (S0-1), 32 (36.8%) had S2, 11 (12.6%) had S3, and 19 (21.8%) had S4. CHI3L1 levels showed a gradual increase with the progression of fibrosis. Serum CHI3L1 expression levels were positively associated with liver stiffness measurement (LSM), aspartate aminotransferase-to-platelet ratio index (APRI), fibrosis-4 (FIB-4) index, gamma-glutamyl transferase-to-platelet ratio (GPR), and red cell distribution width-to-platelet ratio (RPR) ($p < 0.05$). The results of both univariate and multivariate logistic regression analyses indicated that CHI3L1, LSM, and GGT were independent predictors of liver cirrhosis in patients with HBV infection ($p < 0.05$). The diagnostic model was established as follows: CHI3L1/LSM/GGT (CLG) = 0.044 × CHI3L1 + 0.353 × LSM + 0.068 × GGT - 9.191. The receiver operating characteristic (ROC) curve demonstrated that CLG outperformed other non-invasive methods in diagnosing cirrhosis, with an area under the ROC curve (AUC) of 0.964 for liver cirrhosis diagnosis (Sensitivity: 0.933, Specificity: 0.910, cut-off value: -1.6314) (Figure 1). **Conclusion:** CHI3L1 levels were significantly higher in cirrhosis patients with HBV infection compared to non-cirrhosis patients. The CLG model exhibited a strong diagnostic efficacy for liver cirrhosis in patients with HBV infection, making it a precise non-invasive diagnostic index for clinical practice.



Markers	AUC	Specificity	Sensitivity
CLG	0.964	0.910	0.933
CHI3L1	0.825	0.716	0.800
GGT	0.821	0.881	0.667
LSM	0.844	0.821	0.733
APRI	0.803	0.731	0.800
FIB4	0.775	0.866	0.667
RPR	0.885	0.746	0.933
GPR	0.785	0.791	0.733

Figure 1. Diagnostic value of CLG, CHI3L1, LSM, GGT for distinguishing S0-S1 from S4 in patients with HBV infection. CLG(CHI3L1/LSM/GGT) = 0.044 × CHI3L1 − 0.353 × LSM + 0.068 × GGT-9.191; CHI3L1, Chitinase-3 like-protein-1; GGT, gamma-glutamyl transferase; LSM, liver stiffness measurement; APRI, aspartate aminotransferase-to-platelet ratio index; FIB-4, fibrosis-4 index; RPR, red cell distribution width to platelet ratio; GPR, gamma-glutamyl transferase to platelet ratio.

1302-C | ANALYSIS OF INTRAHEPATIC VIRAL RESERVOIR IN GAMBIAN CHRONICALLY INFECTED PATIENTS: CORRELATION WITH EMERGING SERUM VIRAL MARKERS AND FUNCTIONAL CHARACTERIZATION OF CLINICAL ISOLATES

Anaëlle Dubois[1,2], Sarah Heintz[1,2], Damien Cohen[1], Marie-Laure Plissonnier[1,3], Francoise Berby[1,2], Marintha Heil[4], Massimo Levrero[5], Fabien Zoulim[1,6,7,8], Yusuke Shimakawa[9], Maud Lemoine[10], Umberto D'Alessandro[11,12], Isabelle Chemin[1,2] and Barbara Testoni[1,3], (1)Cancer Research Center of Lyon (CRCL), Inserm U1052, Cnrs UMR5286, Lyon, France, (2) Institut D'hépatologie De Lyon, (3)Institut d'Hépatologie De Lyon, (4)Roche Molecular Diagnostics, (5) Department of Medicine Sciac and the Italian Institute of Technology (IIT) Center for Life Nanosciences (CLNS), University of Rome La Sapienza, Rome, Italy, (6) Hépatologie Unit, Hospices Civils De Lyon, Lyon University, Inserm, (7)Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France., (8) Hospices Civils De Lyon (HCL), Lyon, France, (9)Institut Pasteur, (10)Imperial College, London, (11)MRC Unit the Gambia, (12)School of Hygiene and Tropical Medicine, Banjul, the Gambia

Background: In Sub-Saharan Africa, hepatocellular carcinoma, one of the most common cancers in the region, is mainly attributable to HBV infection, which has a prevalence of 10% in the area. Mode of transmission, age of infection, and various genetic and environmental factors differ completely between Western, Asian and Sub-Saharan African populations. Therefore, data relating to the natural history of HBV infection in these patients are much needed. **Methods:** 96 untreated chronically HBV infected (CHB) patients were retrospectively selected from samples collected in The Gambia in the frame of the PROLIFICA program. Paired liver biopsy and serum samples were analyzed for serum HBV DNA, HBsAg, HBcrAg (Lumipulse CLEIA Assay) and alanine aminotransferase (ALT) levels. Liver total HBV DNA (tHBV DNA), cccDNA and 3.5Kb RNA were assessed by droplet digital PCR (ddPCR) and cccDNA transcriptional activity was calculated as 3.5Kb RNA/cccDNA ratio. Liver histology scores were also available. Serum HBV RNA (cirB-RNA) was quantified by the Roche HBV RNA investigational assay for use on the cobas® 6800 System (Scholtès, J Clin Virol 2022). **Results:** The large majority of patients were HBeAg(-), HBV genotype E and only 10% of them had ALT levels above twice the upper limit of normal. Median levels of serum HBV DNA were 2.9 (2.1-4.2) Log IU/ml and qHBsAg were 3.7 (2.5-4.9) Log IU/ml. All patients had quantifiable tHBV DNA in their liver, 90% had quantifiable cccDNA and 85% quantifiable 3.5Kb RNA. Results indicated the presence of two groups of patients with comparable cccDNA levels, but different transcriptional activity, which was not reflected in differences in the serum HBV DNA or qHBsAg levels. Eighty-five serum samples were available for HBcrAg and cirB-RNA quantification, which were detectable in 35 and 33 samples, respectively. Both markers were highly correlated with cccDNA levels which was confirmed also in the group of patients with low cccDNA transcriptional activity. Analysis of in vitro replicative capacity of clinical HBV isolates demonstrated a decreased HBsAg secretion associated with intracellular cytoplasmic accumulation at the endoplasmic reticulum. **Conclusion:** So far, this is the most comprehensive study evaluating the correlations between intrahepatic and serum HBV activity in people living with CHB in Sub-Saharan Africa. These data will contribute to a better understanding of the natural history of CHB and associated pathogenesis in this population.

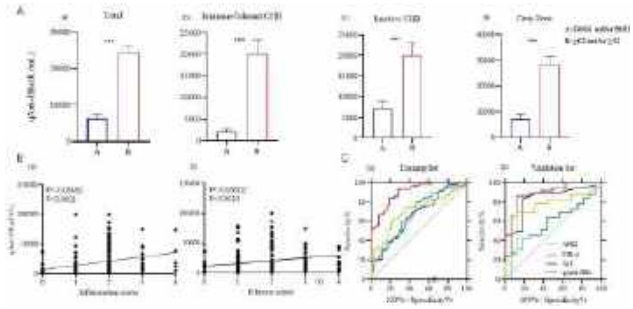
1303-C | ANTI-HBC QUANTIFICATION AS A BIOMARKER FOR IDENTIFYING SIGNIFICANT LIVER INJURY AMONG CHB PATIENTS WITH NORMAL ALT

Mingyang Feng, Xiaoyin Wang, Kehui Liu, Gangde Zhao, Weiliang Tang, Baoyan An, Lanyi Lin, Yezhou Ding and Hui Wang, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine

Background: Increased evidence demonstrates that there are still significant liver injuries in some CHB patients with normal ALT (CHB-NALT). In this study, we aim to investigate the correlation between hepatitis B core antibody quantification (qAnti-HBc) and the severity of hepatic pathological damage in CHB-NALT patients, as well as the feasibility of using it as a serum marker for identifying significant liver injury. **Methods:** CHB-NALT patients without antiviral therapy who underwent liver biopsy from Jan 2015 to Dec 2022 were retrospectively enrolled. The Scheuer scoring system was used to assess liver inflammation and fibrosis. The serum qAnti-HBc level was measured, using the newly developed double-sandwich immunoassay (Wantai, Beijing, China), calibrated in conjunction with the WHO standard (NIBSC, UK). **Results:** 212 CHB-NALT patients were enrolled for analysis. Based on the AASLD 2018 Hepatitis B guideline, 31% and 32% of these patients are in the Immune-Tolerant and inactive CHB phase respectively, whereas 37% were unable to be classified into any of the usual immune states, who were considered to be in the 'grey zone (GZ)'. 73% of these patients had significant liver injury. qAnti-HBc was significantly higher in CHB-NALT patients with significant liver injury than these without, regardless of the immune states (Fig. A). In addition, there was a positive correlation between liver injury scores and qAnti-HBc in these patients (Fig. B). In order to determine the feasibility of qAnti-HBc as a biomarker for identifying significant liver injury, these patients were randomly divided into two groups at a 3: 1 ratios, i.e., 159 subjects were assigned to the training cohort and the remaining 53 cases were assigned to the validation cohort. There was no significant difference in clinical characteristics between the two cohorts. In training cohort, the area under receiver operating characteristic curve (AUC) of qAnti-HBc level was 0.9037 (95% CI: 0.8498–0.9575, $p < 0.0001$) with a cut-off of 7585 IU/mL, the sensitivity and specificity were 0.8257 and 0.8056, respectively. By contrast, the AUC of ALT, FIB-4 and APRI was 0.6613, 0.6792 and 0.7101, respectively. In addition, similar results were obtained in the validation cohort (Fig. C). **Conclusion:** Serum qAnti-HBc level was associated with the severity of liver injury and might be served as a novel biomarker for identifying significant liver injury among CHB-NALT.



Disclosures: The following people have nothing to disclose: Mingyang Feng, Xiaoyin Wang, Kehui Liu, Gangde Zhao, Weiliang Tang, Baoyan An, Lanyi Lin, Yezhou Ding, Hui Wang

1304-C | APPLICATION OF NOVEL HEPATITIS B CORE ANTIGEN-SPECIFIC IMMUNOASSAYS TO MONITOR TREATMENT RESPONSE IN HBEAG POSITIVE CHRONIC HEPATITIS B

Pir Shah[1,2], Rene Geissler[3], Megha Patel[3], Khawaja Hassam[1], Satinder Pal Kaur[1], Mark Anderson[3], Gavin A Cloherty[3] and Daryl T. Y. Lau[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)University of Texas San Antonio, Texas, USA, (3)Abbott Laboratories, IL

Background: Non-invasive surrogate markers to evaluate changes in HBV cccDNA levels and transcriptional activities are important in monitoring treatment response without the need for liver biopsy. Two novel hepatitis B core antigen (HBcAg) immunoassays that specifically detect HBV DNA-containing particles (HBcAg) and phosphorylated non-HBV DNA-containing particles (P-HBcAg) were recently developed. We examined the kinetics of HBcAg and P-HBcAg in relation to on-treatment HBV DNA and RNA levels in 22 HBeAg (+) patients who were treated for an average 4.4 (2.2-6.7) years with nucleos(t)ide analogs (NUCs). **Methods:** This is a single center, retrospective study that selected HBeAg(+) patients on prolonged NUC therapy with available serial stored sera from baseline. The HBcAg and P-HBcAg assays are chemiluminescent microparticle immunoassays (CMIA) performed on a fully automated platform (ARCHITECT i2000SR). Specific monoclonal antibodies were used to capture phosphorylated or non-phosphorylated HBcAg, but not HBeAg, in circulation. The limit of quantification (LOQ) is 14 pg/ml for HBcAg and 4 pg/ml for P-HBcAg. Serum HBV RNA was measured using the Abbott RealTi*m*e 0.2 HBV RNA Research assay (Sensitivity: 1.65 log U/ml). Quantitation of HBsAg (qHBsAg) was

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

performed using ARCHITECT HBsAg assay (Sensitivity: 0.05 U/ml). **Results:** This was an Asian predominant (95%) cohort with HBV genotypes B and C. 10 (45%) achieved HBeAg loss after 2.7 (0.5-5) years of therapy and only 1 had HBsAg loss. Both groups with and without HBeAg loss had similar treatment duration (mean 4.5 vs. 4.3 y, $p = 0.4$) and pretreatment HBV DNA, RNA, HBcAg, P-HBcAg levels [Figure]. At baseline, HBV DNA correlated significantly with HBcAg ($r = 0.63$, $p < 0.001$); HBV RNA correlated equally well with HBcAg and P-HBcAg ($r = 0.79$ and 0.74 respectively, $p < 0.0001$). When HBV DNA was reduced to < 20 IU/ml in both groups, HBcAg was also suppressed to undetectable or low levels. At time of DNA < 20 IU/ml and at last follow up, both RNA and P-HBcAg levels were significantly lower for those who achieved HBeAg loss [Figure]. The on-treatment RNA and P-HBcAg (but not HBcAg) levels correlated closely at optimal DNA suppression ($r = 0.79$, $p < 0.0001$) and at last follow-up ($r = 0.87$, $p < 0.0001$). The qHBsAg levels were similar for those with and without HBeAg loss at baseline (3.4 vs. 3.5 log IU/ml, $p = 0.69$) and at last follow-up (3.3 vs. 3.4 log IU/ml, $p = 0.87$) excluding the single patient with HBsAg clearance. **Conclusion:** For HBeAg (+) patients with chronic hepatitis B, HBV DNA correlated significantly with HBcAg. Patients with treatment-induced HBeAg loss had differential differences in HBV RNA and P-HBcAg decline from those without, whereas the on-treatment qHBsAg titers cannot distinguish the 2 groups. P-HBcAg, together with HBV RNA, may serve as surrogate biomarker for HBV cccDNA and provides insight on its transcriptional status with prolonged NUC therapy or novel therapeutic agents.

1305-C | BIOMARKER-BASED IDENTIFICATION OF HIGH-RISK GROUPS FOR PRIMARY HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B PATIENTS UNDER THE NUCLEOS(T)IDE ANALOGUE TREATMENT

Kazuhiro Murai[1], Hayato Hikita[1], Emi Sometani[1], Satoshi Tanaka[2], Shinji Kuriki[1], Jihyun Sung[1], Akiyoshi Shimoda[1], Makoto Fukuoka[1], Satoshi Shigeno[1], Akira Nishio[1], Takahiro Kodama[3], Tomohide Tatsumi[3], Hidenori Toyoda[4], Yasuhito Tanaka[5] and Tetsuo Takehara[3], (1)Osaka University, Graduate School of Medicine, (2)National Hospital Organization, Osaka National Hospital, Osaka, Japan, (3)Osaka University Graduate School of Medicine, (4)Ogaki Municipal Hospital, (5)Graduate School of Medical Sciences, Kumamoto University

Background: Although nucleos(t)ide analogues (NUCs) treatment for chronic hepatitis B (CHB) reduces the risk of developing hepatocellular carcinoma (HCC), it does not completely suppress developing HCC. Clinical characteristics of CHB patients who developed primary HCC under NUC treatment are not clear. Recently, we reported that serum GDF15 level may be a predictor of developing primary HCC after direct-acting antiviral therapy in chronic hepatitis C patients. The aim of this study was to identify high-risk groups for primary HCC in CHB patients under NUC treatment by retrospective analysis of biomarkers including serum GDF15. **Methods:** Two hundred forty-two CHB patients for whom stored sera were available, who had treated with NUC for at least 1 year at the time of stored serum collection, whose HBV DNA levels in sera were less than 3.0 log IU/mL, and who had no history of HCC were included. Stored sera were used to measure GDF15 using ELISA and HBcrAg using immunoassay for total antigen including complex by pretreatment (iTACT) technology. **Results:** The median age of the patient cohort was 55 years old, and 144 patients (60.0%) were male. The median observation period was 123.1 months. Seventy-three (30.3%) were hepatitis B

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

envelope antigen (HBeAg) positive. The median hepatitis B surface antigen (HBsAg) was 3.2 log U/mL. HBcrAg (lower detection limit: 2.1 log U/mL) was quantified in 211 patients (87.2%) with the median of 4.2 log U/mL. GDF15 was quantified in 241 patients (99.6%) with the median of 0.86 ng/mL. During the observation period, 44 patients (18.2%) developed primary HCC, of which 13 were HBeAg positive. In multivariate analysis, gender (HR: 2.65 [1.18-5.96]), γ-GTP (HR: 1.01 per 1IU/L increase [1.003-1.011]), AFP (HR: 1.06 per 1ng/mL increase [1.02-1.09]), GDF15 (HR: 1.53 per 1ng/mL increase [1.04-2.12]), and FIB-4 index (HR: 1.27 per 1 increase [1.10-1.43]) were significant factors in the Cox proportional hazards model for factors related to the occurrence of primary HCC, while HBsAg, HBeAg, HBcrAg, and HBV DNA were not significant. When the median is defined as cut off value (0.858ng/mL), the cumulative HCC occurrence rate at 5/10 years was 12.4%/23.1% and 6.7%/9.2% in high GDF15 group and in low GDF15 group, respectively. **Conclusion:** Male sex, high γ-GTP, high AFP, high GDF15 and fibrosis progression were high risk factors for the occurrence of primary HCC in CHB patients under NUC treatment.

1306-C | CLINICAL APPLICATION OF NOVEL HIGHLY SENSITIVE HEPATITIS B SURFACE ANTIGEN AND HEPATITIS B CORE-RELATED ANTIGEN ASSAYS FOR MANAGEMENT OF HBV REACTIVATION

Takako Inoue[1], Takanori Suzuki[2], Takehisa Watanabe[3], Etsuko Iio[3], Katsuya Nagaoka[3], Hiroko Setoyama[3], Yoko Yoshimaru[3], Kentaro Matsuura[2] and Yasuhito Tanaka[3], (1)Nagoya City University Hospital, (2)Nagoya City University Graduate School of Medical Sciences, (3)Faculty of Life Sciences, Kumamoto University

Background: We developed a novel, highly sensitive hepatitis B core-related antigen assay (iTACT-HBcrAg) and described its utility for the diagnosis of HBV reactivation (J Hepatol, 2021). In Japan, iTACT-HBcrAg has gained pharmaceutical approval and is now available for clinical use. Meanwhile, hepatitis B surface antigen (HBsAg) assays with a higher sensitivity, such as iTACT-HBsAg, have also been developed as an alternative marker to HBV DNA. In this study, we examined the clinical application of iTACT-HBcrAg and iTACT-HBsAg to manage HBV reactivation. **Methods:** Between 2012 and 2022, 42 patients who were diagnosed with HBV-resolved infection before the introduction of systemic chemotherapy or immunosuppressive therapy were enrolled. Among them, the patients diagnosed with HBV reactivation and whose serial sera were stored were included in this study. Serial sera were measured with iTACT-HBcrAg (cut-off value: 2.1 log U/mL) and iTACT-HBsAg (cut-off value: 0.0005 IU/mL) and compared to the results of serum HBV DNA monitoring performed as the medical practice. The diagnostic criterion for HBV reactivation was detection of serum HBV DNA. This study was approved by the ethical review committee of our institute. **Results:** Thirty-three patients diagnosed with HBV reactivation during or after systemic chemotherapy or immunosuppressive therapy, and with quantitative detection of HBV DNA during the observation period, were selected. Their underlying diseases were hematopoietic malignancies in 22, non-hematopoietic malignancies in 4, autoimmune diseases in 5, and others in 2 patients. Of the 33 patients in which serum HBV DNA was detected quantitatively, iTACT-HBcrAg was detected early or simultaneously with the diagnosis of HBV reactivation in 85% (28/33), and was detected simultaneously or within 1 month of serum HBV DNA detection quantitatively in 94% (31/33). When iTACT-HBcrAg and iTACT-HBsAg were measured simultaneously, at least one of them was detected earlier or simultaneously with HBV DNA in 100% (33/33) (Figure). **Conclusion:** In this study, the usefulness of iTACT-HBcrAg for the diagnosis of HBV reactivation was

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

reproduced, and the addition of iTACT-HBsAg provided a higher diagnostic performance. iTACT-HBcrAg and iTACT-HBsAg are rapid tests (within 30 min) with comparable sensitivity to quantitative HBV DNA detection. Because they serve as a guide for administration of nucleos(t)ide analogues, they are useful for monitoring of HBV reactivation among outpatients.

Figure Comparison of iTACT-HBcrAg and HBsAg for management of HBV reactivation

1307-C | CLINICAL SIGNIFICANCE OF MAC-2 BINDING PROTEIN GLYCOSYLATION ISOMER IN KOREAN PATIENTS WITH CHRONIC HEPATITIS B: COMPARATIVE STUDY OF NON-INVASIVE MODALITY FOR DIAGNOSIS OF LIVER FIBROSIS

Jae-Sung Yoo[1], Hye Seon Kim[2], Jin Seoub Kim[2], Ji Min Kim[2], Ji Won Han[2], Pil Soo Sung[1], Si Hyun Bae[3], Jong Choi[1], Seung Kew Yoon[1] and Jeong Won Jang[1], (1) Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, Republic of Korea, (2)The Catholic University of Korea, Seoul, Korea, (3)The Catholic University of Korea

Background: Mac-2 binding protein glycosylation isomer (M2BPGi), one of the novel, non-invasive fibrosis markers, has been evaluated for assessing liver fibrosis in a multitude of studies. Nevertheless, there is a scarcity of data on its diagnostic accuracy of M2BPGi for liver fibrosis in patients with chronic hepatitis B (CHB). The aim of this study is to investigate the clinical value of M2BPGi in assessing liver fibrosis in comparison with existing tools for liver fibrosis screening. **Methods:** A total of 367 patients diagnosed with chronic hepatitis B between June 2016 and January 2022, at our liver units were entered in this study. Patients' medical records at the time of liver biopsy were retrospectively reviewed for determining M2BPGi, transient elastography (TE, FibroScan®), fibrosis-4 (FIB-4) index, and aspartate aminotransferase to platelet ratio index (APRI). Liver fibrosis on pathology was assessed based on METAVIR fibrosis scores. **Results:** Pathological liver fibrosis grades of the 367 patients (216 males and 151 females; 163 without hemato-oncologic disease) were classified as F0 (n = 59, 16%), F1 (n = 84, 23%), F2 (n = 40, 11%), F3 (n = 68, 19%) and F4 (n = 116, 32%). The median M2BPGi values for METAVIR fibrosis score F0, F1, F2, F3 and F4 were 1.9, 1.5, 1.4, 1.8, and 3.2 cutoff index (COI), respectively ($p < 0.001$). M2BPGi levels weak correlated with the METAVIR scores ($r = 0.295$, $p < 0.001$). The area under receiver operating characteristic (AUROCs) with M2BPGi for ≥ F2, ≥ F3 and F4, were 0.6161, 0.6581 and 0.6908, respectively. To identifying significant fibrosis (F2-4), both M2BPGi and TE were significantly better than FIB-4 and APRI. The AUROCs with M2BPGi, TE, FIB-4, and APRI for diagnosing cirrhosis were 0.7208, 0.8085, 0.5051, and 0.6011, respectively. When analyzed without hemato-oncologic patients, the predictive value of M2BPGi for assessing liver fibrosis slightly increased (AUROC 0.6944 for significant fibrosis; 0.7837 for cirrhosis), which was significantly better than that of FIB-4 and APRI. With multivariate analysis with several other non-invasive fibrosis indices, M2BPGi didn't remain significant for diagnosing ≥ F2, ≥ F3, F4 (OR: 0.96, 95%CI: 0.77-1.20, $p = 0.7$; OR: 1.05, 95%CI: 0.83-1.35, $p = 0.7$; OR: 1.14, 95% CI: 0.93-1.44, $p = 0.060$). However, M2BPGi Platelet ratio index (MPRI) was shown to be associated with ≥ F3 and F4 (OR: 1.41, 95%CI: 1.09-2.06, $p = 0.030$; OR: 1.43, 95% CI: 1.15-1.87, $p = 0.03$) in multivariate analysis. **Conclusion:** Serum M2BPGi together with TE is a reliable non-invasive tool for assessing liver fibrosis and better performs than FIB-4 and APRI. Its performance for assessing fibrosis appears to be more efficient among non-hemato-oncologic patients. Additionally, markers combined with

platelets and M2BPGi suggested the potential to enhance the capacity to predict liver fibrosis.

1308-C | COMPARISON OF ROBOGENE® 2.0 AND ALTOSTAR® ASSAYS FOR QUANTIFICATION OF PLASMA HDV RNA IN BULEVIRTIDE-TREATED PATIENTS WITH HDV RELATED CIRRHOSIS

Maria Paola Anolli[1], Sara Uceda Renteria[2], Elisabetta Degasperi[1], Floriana Facchetti[1], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Roberta Soffredini[1], Sara Monico[1], Ferruccio Ceriotti[2] and Pietro Lampertico[1,3], (1)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2)Virology Unit, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (3)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: Diagnosis and treatment of chronic hepatitis Delta (CHD) primarily depend on the quantification of HDV RNA, but there is considerable variability among different assays. The aim of this study was to compare two methods for measuring serum HDV RNA levels in Bulevirtide (BLV)-treated patients with HDV related cirrhosis. **Methods:** Frozen plasma from consecutive BLV treated-CHD patients were tested in a single-center retrospective study for HDV RNA levels by using two different quantification methods: Robogene® 2.0 (Roboscreen GmbH, Leipzig, Germany; CE-IVD-labeled; LOD 6 IU/mL) and AltoStar® HDV RT-PCR Kit 1.5 (Altona Diagnostics, Hamburg, Germany; RUO test, estimated LOD < 10 IU/mL). RNA extraction was performed according to the manufacturer indications: manual extraction with INSTANT Virus RNA/DNA kit (Analytik Jena AG, Jena, Germany) for Robogene® 2.0 and automated extraction with AltoStar® Purification Kit 1.5 (Altona Diagnostics GmbH) for AltoStar®. The extraction volume was 400 µl for Robogene® and 500 µl for AltoStar®. HDV genotype was determined by sequencing. **Results:** A total of 100 plasma samples collected from 44 BLV-treated CHD patients were analyzed: median age was 51 (29-77) years, 57% males, 93% of European origin, 100% with cirrhosis, 57% with gastroesophageal varices, 21% with hepatocellular carcinoma history, 100% under NUC, 98% HDV genotype 1, 95% HBeAg negative, 86% HBV DNA undetectable. Median ALT were 52 (12-310) U/L, HBsAg 3.7 (0.5-4.4) Log IU/mL. Median HDV RNA levels were 3.93 (0.70-6.60) *vs.* 4.49 (0.45-6.80) Log IU/mL by Robogene® 2.0 *vs.* AltoStar® ($p < 0.0001$). Correlation between the 2 tests was excellent (Figure, $R^2 = 0.9496$). HDV RNA levels were similar (Δ ± 0.5 Log) in 57 (57%) samples, while AltoStar® reported higher HDV RNA levels in 42 (42%) [Δ between +0.5 and +1 Log in 35; Δ between +1 and +2 Log in 7] samples. In one case AltoStar® reported lower HDV RNA levels (Δ < -0.5). Of the 6 (6%) target not detected (TND)/ < LOD samples by Robogene® 2.0, 3 tested > 10 IU/mL by AltoStar®. In contrast, all the 3 (3%) < 10 IU/mL samples by AltoStar® tested < LOD/TND by Robogene®. **Conclusion:** In BLV-treated patients, HDV RNA levels quantified by AltoStar® significantly correlated with those measured by Robogene® 2.0 but viremia resulted half a log IU/ml higher by the former assay.

Nguyen, Stanford University Medical Center, Palo Alto, CA

Background: The coexistence of chronic hepatitis B (CHB) and hepatic steatosis (HS) is increasingly common, but the association of diabetes mellitus (DM) with hepatic inflammation and fibrosis is not well characterized. The aim of this study is to investigate the association of DM with significant hepatic inflammation and/or fibrosis in this population. **Methods:** This study consecutively enrolled CHB patients with concurrent HS who underwent liver biopsy from eight medical centers of China between April 2004 and October 2020. Univariable and multivariable logistic regression analyses were conducted to explore the association of DM with significant hepatic inflammation (Scheuer's system, grade [G] 2-4) and fibrosis (Scheuer''s system, stage [S] 2-4). **Results:** A total of 869 CHB patients with HS with available liver histology data were included in study analysis. The average age was 40.6 ± 10.4 years, 79.9% were male, and 8.2% (71 patients) had DM. The mean body mass index (BMI) was 24.9 ± 3.3 kg/m2 and the mean HBV-DNA was 5.3 ± 2.0 $\log_{10}$ IU/ml. About half (380 patients, 46.3%) were HBeAg-positive, and 5.9% (42 patients) were on antiviral therapy. Moderate and severe HS (grade 2-3) was present in 24.3% of patients (206 patients). The majority (529 patients, 60.9%) had significant inflammation (G2-4), and about half (431, 49.6%) had significant fibrosis (F2-4). Compared with non-DM patients, DM patients more likely had significant inflammation (76.1% vs 59.7%, $p = 0.02$) or significant fibrosis (76.1% vs 47.3%, $p < 0.001$). On multivariable logistic analysis adjusting for age, sex, BMI, HBV DNA, and HBeAg (model 1), DM was independently associated with significant inflammation (OR: 3.60; 95% CI: 1.56-8.33; $p = 0.003$) and significant fibrosis (OR: 4.08; 95% CI: 1.95-8.53; $p < 0.001$); We further adjusted for HS (model 2), and DM remained an independent factor associated with significant inflammation (OR: 3.38; 95% CI: 1.46-7.86; $p = 0.005$) and significant fibrosis (OR: 4.49; 95% CI: 2.08-9.72; $p < 0.001$) (Table). **Conclusion:** CHB patients with concurrent HS with DM was more than 3 times more likely to have significant hepatic inflammation and more than 4 times more likely to have significant fibrosis compared to non-DM patients, independent of the presence of HS, BMI, viral factors, and demographics. As liver inflammation and fibrosis are major predictors for future liver-related outcomes, collaboration between liver and metabolic specialists are needed to optimize the management of CHB patients with HS and DM. Keywords: chronic hepatitis B; nonalcoholic fatty liver diabetes; diabetes Mellitus; significant fibrosis; significant inflammation; risk factors

1310-C | EVALUATION OF A FULLY AUTOMATED HIGH-THROUGHPUT SEROLOGY ASSAY FOR DETECTION OF HDV INFECTION

Xiaoxing Qiu[1], Abbas Hadji[1], Ana Olivo[1], Austin Hodges[1], Carla Beertsen[2], Mark Anderson[3], Mary Rodgers[1] and Gavin A Cloherty[3], (1)Abbott Laboratories, (2)Academic Medical Center, (3)Abbott Laboratories, IL

Background: Hepatitis D virus (HDV) is a defective RNA virus requiring Hepatitis B virus (HBV) to produce infectious virus particles. Co-infection of HDV/HBV leads to increased mortality over HBV mono-infection. With new therapeutic drugs for HDV on the horizon, it has been suggested to expand current HDV screening efforts from risk based to universal screening of all HBsAg-positive individual's. Antibody to HDV is the serological marker of HDV infection and testing for HDV antibodies is recommended as the first line screening test of choice. Combining HDV antibody testing with reflex testing of HDV RNA can effectively identify patients with active infection for therapeutic treatments. The aim of this study is to evaluate the performance of a newly developed HDV antibody test, HDV Total Ig, on the fully automated and high-throughput Abbott ARCHITECT platform. **Methods:** An HDV panel, composed of 71 HDV RNA positive and 54 HDV RNA negative

Uganda/Cameroon samples previously determined using m2000 RealTime HDV RUO assay, was tested with both ARCHITECT HDV Total Ig (ARCHITECT HDV) and CE marked LIAISON XL Anti-HDV (LIAISON Anti-HDV). 600 healthy blood donors from the United States (US) were assessed with ARCHITECT HDV to determine assay specificity. A subset of 200 US donor samples was also tested with LIAISON Anti-HDV. **Results:** For the HDV panel, ARCHITECT HDV detected 67/71 RNA positive samples demonstrating comparable sensitivity ($p = 0.1336$) to the HDV RNA test with 94.4% positive agreement; sensitivity of LIAISON Anti-HDV was significantly lower ($p = 0.0412$) than the HDV RNA test with 91.5% (65/71) positive agreement. Notably, the 6 samples missed by either serology tests had low viral load ranged from 2.2-34.7 IU/ml, suggesting early seroconversion. For the 54 RNA negative samples, ARCHITECT HDV showed 76% (41/54) negative agreement with the RNA test, significantly greater ($p = 0.0003$) than the 43% (23/54) negative agreement of LIAISON Anti-HDV with the RNA test. Evaluation with the 600 US healthy blood donors showed 99.8% (599/600, 95%CI = 99.2-100.0) specificity for ARCHITECT HDV. Specificity of LIAISON Anti-HDV was 98.5% (197/200, 95%CI = 96.1-99.6) with the subset of 200 US donors. **Conclusion:** The newly developed ARCHITECT HDV Total Ig assay with enhanced sensitivity and specificity compared to current LIAISON Anti-HDV marketed in Europe offers a promising tool for universal screening of all HBsAg-positive persons.

Kennedy[3,4] and Fabien Zoulim[1,2,8,9], (1)Cancer Research Center of Lyon (CRCL), Inserm U1052, Cnrs UMR5286, Lyon, France, (2)Institut d'Hépatologie De Lyon, (3)Barts Liver Centre, Immunobiology, Blizard Institute, Barts, (4)The London School of Medicine & Dentistry, Queen Mary University of London, London, UK, (5)Roche Molecular Diagnostics, (6)Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France, (7) Department of Medicine Sciac and the Italian Institute of Technology (IIT) Center for Life Nanosciences (CLNS), University of Rome La Sapienza, Rome, Italy, (8) Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France., (9)Universite Claude Bernard Lyon 1

Background: Available therapies against Hepatitis B virus (HBV) infection effectively limit viral replication but rarely lead to intrahepatic viral elimination. Likely, new treatment strategies will involve the combination of direct antiviral and host targeting agents to reach elimination or durable inactivation of intrahepatic covalently-closed circular (ccc)DNA. To assist drug development, it will be essential to define early predictive markers of clearance of the viral reservoir, assessing their value in reflecting intrahepatic cccDNA levels and transcriptional activity. Fine needle aspirates (FNA) have recently emerged as a less invasive alternative to core liver biopsy (CLB), having already shown to be useful for investigating intrahepatic immune responses. However, quantification of HBV replicative parameters using FNAs remains to be explored. **Methods:** We compared HBV cccDNA and 3.5Kb RNA quantification by droplet digital PCR in paired FNA/CLB samples from patients with hepatitis B e antigen (HBeAg)+ chronic hepatitis ($n = 4$), HBeAg- chronic hepatitis ($n = 4$) and HBeAg- chronic infection ($n = 1$). One HBeAg+ patient was undergoing tenofovir treatment. **Results:** Our results demonstrated that this method allowed cccDNA quantification in all but one FNA/CLB pair, showing the highest levels in untreated HBeAg+ subjects, except for the tenofovir-treated patient. Similarly, 3.5-kb RNA was detectable in all but one FNA sample and showed higher levels in HBeAg+ patients. When comparing cccDNA and 3.5-kb RNA quantification in FNA vs CLB samples, no statistically significant differences were identified either when values were normalized over the total number of cells or over the relative expression of NTCP RNA as an estimation of hepatocyte content. Correlation of cccDNA quantified in both CLB and FNA positively correlated with serum viral load and HBcrAg with similar statistical significance. **Conclusion:** Altogether, we demonstrate the feasibility of assessing cccDNA pool and transcriptional activity in HBV-infected patients by combining FNA and ddPCR, thus supporting the use of FNA in early-stage clinical trials to evaluate the intrahepatic viral reservoir during the development of new antivirals and immunomodulatory agents.

1312-C | EXPLORING Mac2-BINDING PROTEIN GLYCOSYLATION ISOMER DIAGNOSTIC POTENTIAL FOR NON-INVASIVE TESTING OF LIVER DISEASE IN VIETNAMESE HBV PATIENTS

Thuy Pham, Dat Tan Ho and Nguyen Bao Toan, Medic Medical Center, Ho Chi Minh City- Vietnam

Background: The study aims to explore the value driven care approach of utilizing serum based Mac2-binding Protein glycosylation isomer (M2BPGi) as a novel biomarker for the early detection of liver fibrosis and monitoring of anti-viral treatment response in patients with chronic hepatitis B (HBV). Non-invasive testing is patient friendly, and this work aims to fill critical gaps to derive clinical decision cut-offs for liver fibrosis staging and track responses of patients during treatment. **Methods:** This is a cross sectional study involving 334 mono-infected chronic HBV patients. The study receives ethical approval from Medic Medical Center, Ho Chi Minh City, Vietnam. Treatment naïve patients were recruited with baseline M2BPGi taken, and additional serial measurements at 3 and 6-month intervals. M2BPGi is measured via an automated chemiluminescence immunoassay (Sysmex, Japan) using residual serum samples. Kruskal-Wallis tests were used to ascertain the statistical significance of M2BPGi for fibrosis staging and variations at different serial measurements. Area under the receiver operating characteristics (AUROC) curve was computed comparing M2BPGi levels with different biomarkers. A p-value of < 0.05 was considered statistically significant. **Results:** Baseline M2BPGi median levels provided specific cut-offs relevant for liver fibrosis staging in comparison with classical biomarkers and transient elastography (TE). Baseline levels were found to be highly correlative to TE results (Pearson, $\rho = 0.71$, p-value < 0.0001). Median M2BPGi levels were 0.73, 0.92, 1.57 and 3.19 cut-off index (C.O.I.) across F0-1, F2, F3 and F4 cases respectively. To ascertain the diagnostic potential, AUROC was computed among these cases addresses early disease and cirrhosis. Between F2 and F3 cases, AUROC was 0.79, which presents strong performance measurements to discriminate early liver disease cases. Furthermore, AUROC between cirrhotic cases and F3 was 0.88, suggesting M2BPGi can be clinically useful in distinguishing advanced liver disease. Serial M2BPGi measurements showed monotonic decreasing trends among the patient cohorts across different fibrosis stages. Median levels reduced by 35% at 6-month for M2BPGi and 10% using TE. Interestingly, TE at 3-month were non-significant for the treated patients but observed a reduction of 25% using M2BPGi. **Conclusion:** Within the current HBV cases, M2BPGi displayed excellent discriminatory levels among different fibrosis stages prior to treatment. This work is the first in Vietnam that extensively validated the marker with specific decision limits. As a non-invasive test, M2BPGi can be easily integrated into existing testing programs for concurrent profiling of liver disease in chronic HBV. Early diagnosis of fibrosis adds value to reduce healthcare burden and prevents disease progression. In comparison with TE, we observed a better dynamic range using M2BPGi when tracking treated cases.

1313-C | HEPATIC EXOSOMAL miR122 DECLINES DURING NUCLEOTIDE THERAPY IN HBV/HIV COINFECTED PERSONS

Susan D Rouster[1], Paul S Horn[2], Jason T Blackard[1], Marion G. Peters[3], Mark Anderson[4], Michael Stec[5], Gavin A Cloherty[4] and Kenneth E Sherman[1], (1) University of Cincinnati, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)UCSF, San Francisco, CA, (4)Abbott Laboratories, IL, (5)Abbott Laboratories

Background: New biomarkers of HBV infection provide additional insights into the biology of infection and treatment response. Circulating microRNA (miR) 122 enveloped in exosomes that are derived from the liver represents a potential novel biomarker of treatment response. **Methods:** ACTG 5127 was a Phase 2 treatment trial that enrolled HBV/HIV coinfected patients who were randomized to receive either tenofovir (TDF) or adefovir (ADV) for HBV suppression. Participants were followed for 48 weeks post-treatment initiation. Hepatic exosomal miR122 was isolated from serum using the Qiagen (Germantown, MD) miRNeasy Serum Advanced kit, with RNA spike-ins to monitor RNA isolation quality. RNA was then subjected to reverse transcription using the miRCURY LNA RT kit, including additional synthetic spike-ins to monitor cDNA synthesis and presence of inhibition. The resulting cDNA template was amplified by qPCR using the Qiagen miRCURY LNA SYBR Green kit and miRNA PCR assays for each target (spike-ins, reference miRNA [*C. eleg* miR39], and liver-specific miR122). Relative expression was determined using the $2^{-\Delta\Delta CT}$ method compared to the reference miRNA and reported as fold change from the healthy control group. Correlations were made with clinical characteristics, as well as HBV DNA, pgRNA, and qHBs antigen levels. **Results:** Baseline and week 48 timepoints were available for 35 study participants. The majority were male (91%), white non-Hispanic (52%), or black (33%). The groups were evenly randomized to receive either TDF or ADV. The mean baseline miR122 relative fold change was 49.5 $\pm$ 12.6. This declined to 10.9 $\pm$ 2.8 at week 48 post-treatment ($p < 0.003$ by paired t-test). The change negatively correlated with CD4 count (Pearson r = -0.422; $p = 0.021$) but not with HBV DNA, pgRNA, qHBsAg, or ALT. **Conclusion:** Liver-specific exosomal miR122 declines following HBV treatment in HBV/HIV coinfected persons but remains elevated compared to healthy controls. The correlation with CD4 suggests that immune status may be an independent predictor of hepatic miR122 in the setting of coinfection. Future studies will focus on the relationship between exosomal miR122 decline and functional cure status.

Background: Hepatitis B virus (HBV) infection remains a major public health problem. Several markers have been validated to monitor each phase of infection and its outcome. Hepatitis B core-related antigen (HBcrAg) is emerging as marker of virus replication. The aims of this study are to describe the variation of HBcrAg during each phase of HBV infection and its performance in predicting liver fibrosis levels and occurrence of hepatocellular carcinoma (HCC) compared to hepatitis B surface antigen (HBsAg) and HBV DNA in hepatitis B-e antigen (HBeAg) negative patients. **Methods:** among 273 HBV infected patients attending our center in the last year, 125 underwent HBcrAg dosage and represent our study population. In 33 of them the second determination was performed. Patients were classified according to the European Association for the Study of the Liver (EASL) phases of the HBV infection; we then compared HBeAg-negative chronically infected patients with those in other phases. For each patient we assessed demographics, virological data, comorbidities, stage of liver fibrosis, presence of HCC and antiviral treatment at the moment of the sampling. Equality of median test and multivariate linear regression analysis were performed to assess potential associations between HBcrAg levels and characteristics of the disease. **Results:** median age was 58 (IQR 45-66), 43% patients (n = 54) were female, 17% (n = 22) were cirrhotic, median liver stiffness was 6.4 kPa (IQR 4.6-10.7), 3% (n = 4) had HCC and 64% (n = 80) underwent NUC therapy. HBeAg-negative chronically infected patients (n = 83, 66%) showed significantly lower levels (median 2 log U/ml, IQR 1.9-3) of HBcrAg compared to the others (n = 42, 34%) (median 2.8 log U/ml, IQR 2-4.6; $p = 0.009$). HBcrAg levels did not differ significantly in patients with and without HCC (mean 2.2 log U/ml vs 2 log U/ml; $p = 0.347$). The multivariate linear regression analysis demonstrated that Fibroscan values were inversely related to HBcrAg ones ($p < 0.001$). After adjusting for age, sex and stage of fibrosis HBV DNA and HBsAg levels are directly related to HBcrAg ones ($p < 0.001$ each). **Conclusion:** in this ongoing study we demonstrate that the new HBcrAg biomarker can provide clinicians with reliable information on the HBV replication activity, especially in HBeAg negative chronic infected patients, in a non-invasive manner. In this prospective study HBcrAg seems to be useful to monitor the natural history of liver disease but further studies are needed to demonstrate if HBcrAg could predict occurrence of HCC or liver decompensation.

1315-C | HEPATITIS B VIRUS SURFACE ANTIGEN GLYCAN ISOMER (HBSAGGI) AS A NEW GLYCO-BIOMARKER TO DETECT INFECTIOUS HBV VIRIONS

Kiyohiko Angata[1], Maki Sogabe[1], Hisashi Narimatsu[1], Murata Ayato[2] and Takuya Genda[2], (1)Rcmg Inc., (2) Juntendo University Shizuoka Hospital

Background: Hepatitis B virus surface antigen (HBsAg) gene generates L-, M-, and S-HBsAg. In HBV patients' sera, non-infectious particles are much dominant than infectious particles containing HBV DNA (Dane particles). Dane particles contain all HBsAgs, but non-infectious particles mainly contain S-HBsAg. Thus, general HBsAg test using antibodies recognizing S-HBsAg does not always distinguish infectious and non-infectious subviral particles. *O*-glycosylated M-HBsAg was determined by mass spectrometry, because a lectin recognizing *O*-glycans could enrich DNA-containing particle. This study aimed to develop a new marker to measure infectious particles which contain *O*-glycosylated M-HBsAg [HBsAg glycan isomer (HBsAgGi)]. **Methods:** To generate HBsAgGi antibodies, glycopeptides modified with *O*-glycans were generated. To analyze the HBsAgGi antibody, Western blotting, immunostaining, and ELISA were performed. To characterize target particles of HBsAgGi, immunoprecipitated (IP) particles by HBsAgGi antibody was analyzed by qPCR and reverse-transcription PCR for quantifying HBV DNA and HBV RNA, respectively. Furthermore, a new HBsAgGi ELISA system measured sera of chronic hepatitis B (CHB) patients before and after nucleos(t)ide analog (NA) treatment to investigate clinical utility of the HBsAgGi. **Results:** PreS2 peptide with or without glycans generated genotype specific antibodies. For genotype C, HBsAgGi antibody recognized M-HBs but not L-HBs that is not modified with *O*-glycan on the PreS2. Mutations in *O*-glycosylation site or removal of *O*-glycans resulted in decrease of the recognition by HBsAgGi antibody. HBsAgGi localized in ER to Golgi in MHBs-expressing cells, suggesting generation of HBsAgGi through glycosylation pathway. Immunoprecipitation experiments confirmed that both HBV DNA- and HBV RNA-containing particles were collected by HBsAgGi antibody. In treatment naïve CHB patients, serum HBsAgGi level was higher in HBe-positive patients than HBe-negative patients at baseline. HBsAgGi levels were significantly correlated with the HBV DNA level ($p = 0.002$, n = 32). **Conclusion:** New HBsAgGi antibodies recognize HBV particles in genotype specific manner dependent on the presence of *O*-glycans in PreS2 domain. HBsAgGi specifically presents in minor infectious fraction of HBV virions containing HBV DNA or HBV RNA. Taken together with ELISA analysis of patients' sera, HBsAgGi would be a

Background: Stopping nucleos(t)ide analogue (NA) therapy is associated with functional cure (HBsAg loss) in a significant minority of patients with chronic hepatitis B (CHB). Novel biomarkers are needed to predict those at high chance of HBsAg loss and low risk of hepatitis flare. Hepatitis B core-related antigen (HBcrAg) is a composite of three proteins: HBcAg, HBeAg and a truncated precore protein (p22cr). **Methods:** The predictive utility of end of treatment (EOT) and off-treatment HBcrAg level was evaluated amongst patients previously enrolled in the published HBV-STOP study with 96 weeks of follow-up (non-cirrhotic HBeAg-negative CHB patients). 68 of 110 patients in the original study had stored serum available and were included. HBcrAg levels were analysed using the Lumipulse® G System (Fujirebio, Japan). The lower limit of detection and quantification of HBcrAg were 2 and 3 log U/mL, respectively. EOT (at NA cessation) and longitudinal HBcrAg levels were used to predict clinical outcomes. **Results:** At EOT, the median [IQR] age was 54 years [48-60], 54% were male, 82% were Asian, the median [IQR] EOT HBsAg titre was 703 [245-1878] IU/mL and the median ALT was and 24 [17-33] U/L. At EOT, 10/68 (15%) had undetectable HBcrAg, 18/68 (26%) had a detectable HBcrAg below the lower limit of quantification, 30 (44%) had a level between 3 and 4 log U/mL and 10 (15%) had a level above 4 log U/mL. An EOT HBcrAg level of $\geq$ 4 log U/mL strongly predicted biochemical relapse (80% vs 39%; OR = 6.55; $p < 0.05$) and hepatitis flare (80% vs 25%, OR = 11.47; $p < 0.005$; Figure 1). Longitudinal off-treatment HBcrAg levels also had predictive value with a HBcrAg level $\geq$ 4 (compared to EOT HBcrAg $\leq$ 2) demonstrating a strong association with subsequent hepatitis flare (HR = 31.9; $p < 0.005$). No patient who achieved HBsAg loss (n = 4) had a EOT HBcrAg level above 3 log U/mL (lower limit of quantification). **Conclusion:** High levels of HBcrAg ($\geq$ 4 log U/mL) were present in 15% of patients at EOT and this was a marker of increased risk of hepatitis flare. In patients with low or undetectable levels at EOT, rising levels of HBcrAg ($\geq$ 4 log U/mL) off-treatment were associated with subsequent hepatitis flare. HBcrAg is a clinically useful biomarker to predict patients who are at high risk of hepatitis flare after stopping NA and who should be encouraged to continue NA whilst awaiting new cure strategies.

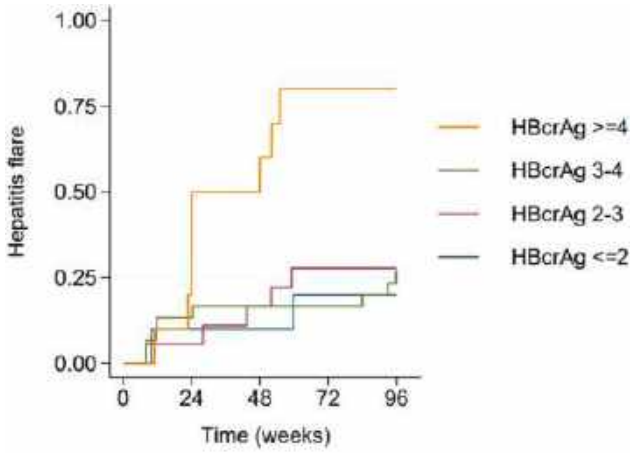

Figure 1. Cumulative incidence of hepatitis flare according to EOT HBcrAg level

1317-C | IMPACT OF HBEAG LOSS ON HEPATOCELLULAR CARCINOMA RISK IN PATIENTS WITH HBEAG-POSITIVE CHRONIC HEPATITIS B: A MULTICENTER STUDY IN SOUTH KOREA

Hyunjae Shin[1], Yunmi Ko[2], Youngsu Park[2], Jeayeon Park[2], Jeong-Hoon Lee[3], Won-Mook Choi[4], Seung Up Kim[5], Moon Haeng Hur[1], Min Kyung Park[2], Yun Bin Lee[1], Eun Ju Cho[2], Su Jong Yu[2], Yoon Jun Kim[6] and Jung-Hwan Yoon[2], (1)Seoul National University Hospital, (2)Seoul National University College of Medicine, (3)Seoul National University College of Medicine, Seoul, South Korea, (4)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, Seoul, South Korea, (5)Severance Hospital, Seoul, Republic of Korea, (6)Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea

Background: Antiviral treatment has been shown to reduce the risk of developing hepatocellular carcinoma (HCC) in patients with hepatitis B envelop antigen (HBeAg)-positive hepatitis. Nonetheless, whether the loss of HBeAg resulting from antiviral treatment has a beneficial effect on the risk of HCC remains uncertain. Our study aimed to investigate the impact of HBeAg loss timing on HCC development. **Methods:** HBeAg-positive chronic hepatitis B (CHB) patients who attended and were treated with antivirals at three tertiary centers in Korea from 2007 to 2021 were eligible for the study. Patients with cirrhosis, a normal alanine aminotransferase (ALT) level, HBeAg loss, or HCC occurrence within one year after initiation of

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

antiviral treatment were excluded from the study. The primary outcome of the study was the incidence of HCC, compared between the HBeAg-loss group and the HBeAg-maintained group using the inverse probability treatment weighting (IPTW) method. Landmark analysis and time-varying Cox analysis with multiple timepoints after the initiation of antiviral treatment were also performed as sensitivity analyses. **Results:** A total of 2,382 non-cirrhotic HBeAg-positive CHB patients were analyzed. Patients were followed for a median of 6.6 years, during which 64 patients (2.7%) developed HCC. In the IPTW-balanced population (Table 1), the HBeAg-loss group (HBeAg loss before 36 months after initiation of antiviral treatment) and the HBeAg-maintained group had a similar risk of developing HCC (hazard ratio [HR] = 0.89, 95% confidence interval [CI] = 0.47–1.68, $p = 0.72$ by Cox proportional hazard analysis, Table 1, $p = 0.85$ by log-rank test, Figure 1). Landmark analysis of HBeAg loss at different timepoints of 24 months (HR = 0.61, 95% CI = 0.21–1.77, $p = 0.36$), 36 months (HR = 0.99, 95% CI = 0.53–1.85, $p = 0.97$), 48 months (HR = 1.09, 95% CI = 0.61–1.96, $p = 0.77$), and 60 months (HR = 1.20, 95% CI = 0.68–2.10, $p = 0.53$) after initiation of antiviral treatment also showed an independent association with the development of HCC (Table 2). Stratification of groups by the timing of HBeAg loss also showed no difference of HCC development ($p = 0.2$ by log-rank test, Figure 2) **Conclusion:** This study implies that the timing of HBeAg loss was not associated with the risk of HCC in non-cirrhotic patients in the HBeAg-positive hepatitis phase. HBeAg positivity may be indicative of the early virologic phase of CHB, but it is not itself a substance associated with carcinogenesis.

1318-C | KINETICS OF QUANTITATIVE HBsAg DECLINE IN CHRONIC HEPATITIS B PATIENTS RECEIVING NUCLEOS(T)IDE ANTIVIRAL THERAPY

Yong Gyu Hyun, University of Toronto and Scott K. Fung, Toronto General Hospital, University of Toronto; University Health Network, Toronto, Ontario, Canada

Background: Nucleos(t)ide analog therapy (NA) is the standard of care for patients with chronic hepatitis B (CHB) infection. However, NA rarely leads to HBsAg seroclearance, which is considered as 'functional cure' and is associated with improved clinical outcomes. However, the optimal duration of NA among HBeAg-negative patients remains unclear and stopping NA as a strategy to cure HBV is controversial. The kinetics of HBsAg decline on NA has not been well studied in clinical trials but may help predict the duration of therapy required to achieve HBV cure. Therefore, the aim of this study was to determine the rate of HBsAg decline in order to predict time to functional cure in CHB patients on NA. **Methods:** Consecutive adult patients with CHB attending the Toronto General Hospital Liver Clinic from 2017-2022 who received NA as per current treatment guidelines were included. Baseline demographic, clinical and laboratory data including liver enzymes, quantitative HBsAg level (Abbott Architect, LLOQ 0.02 IU/ml), and HBV DNA (Roche TaqMan, LLOQ 10 IU/ml) were collected every 6 months during followup. Baseline HBsAg was compared with HBsAg level at the time of seroclearance or at last followup to analyze HBsAg kinetics and to estimate the rate of HBsAg loss. **Results:** Of 371 consecutive patients who were treated with NA (TDF 88%, ETV 9%, other 3%), the majority was male (67%), Asian (92%) with a mean age 57 yrs. Mean baseline HBsAg was 6754.6 IU/mL, 317 (86%) HBeAg-negative, and baseline HBV DNA 5.6 log IU/mL. Patients were divided into 3 categories according to HBsAg levels: low < 1000 IU/mL, 167 (45%) patients; intermediate 1000-10,000 IU/mL, 161 (44%); and high > 10,000 IU/mL, 43 (11%). Mean annual rate of HBsAg decline differed according to baseline HBsAg: low group declined 50.4 IU/mL; intermediate 446.8 IU/mL; and high 9851.5 IU/mL, ($p < 0.05$). Overall, annual average decline in HBsAg was 1034.7 IU/mL and HBsAg seroclearance was observed in 53 (14%) patients after a mean treatment duration of 5.2 years. Majority of HBsAg seroclearance occurred in patients in the low HBsAg group (87% low, 8% intermediate and 5% high). **Conclusion:** In this retrospective cohort study of CHB patients receiving long-term NA, the annual rate of HBsAg decline was slow but measurable at approximately 1000 IU/ml. The magnitude of HBsAg decline correlated with baseline HBsAg level. HBsAg seroclearance increased with

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prolonged duration of NA and was greatest among those with low HBsAg. These data demonstrate the utility of HBsAg kinetics and can predict time to functional cure for those receiving NA, although further studies are required.

1319-C | LOWER VIRAL DIVERSITY OF THE HEPATITIS B CORE GENE IS ASSOCIATED WITH A DECREASED LIKELIHOOD OF HBEAG CLEARANCE IN IMMUNE-TOLERANT PATIENTS

Tai-Chung Tseng, Chun-Jen Liu, Tung-Hung Su, Hung-Chih Yang, Pei-Jer Chen and Jia-Horng Kao, National Taiwan University Hospital

Background: Current criteria for defining immune-tolerant patients rely on serum ALT and HBV DNA levels. However, these markers can fluctuate, making it challenging to distinguish immune-tolerant patients from from immune-active individual's who may exhibit normal ALT levels temporarily. As viral quasispecies arise from the adaptation to selection pressure exerted by the host immune response, our objective was to investigate whether lower viral diversity could serve as an indicator to identify genuine immune-tolerant patients. **Methods:** We conducted a retrospective study involving 202 HBeAg-positive patients with HBV DNA levels exceeding 1 million IU/mL and ALT levels below the upper limits of normal defined by the AASLD guidelines. These patients were classified as immune-tolerant based on the AASLD criteria and were enrolled between 1985 and 1990. Throughout the HBeAg-positive stage, these patients remained untreated. The primary endpoint of the study was HBeAg seroclearance. Serum samples collected at enrollment were used to determine viral factors. Viral quasispecies of the hepatitis B core (HBc) gene were determined using deep sequencing, with the ability to detect viral variants as low as 0.1%. We defined high and low viral diversity using a cutoff of 0.005. **Results:** Among the 202 immune-tolerant patients, the mean age was 31.2 years, with 56.9% being male. A total of 13.3% of patients exhibited high HBc viral diversity. Over a mean follow-up period of 15.2 years, 88 patients achieved HBeAg seroclearance, resulting in an annual incidence of 2.9%. Univariable analysis demonstrated that older age and higher HBc diversity were associated with an increased probability of clearing HBeAg. Compared to patients with low HBc diversity, those with higher diversity had an elevated chance of clearing HBeAg, with a hazard ratio (HR) of 2.62 (95% CI: 1.58-4.36). Multivariable analysis revealed that higher HBc diversity remained an independent factor, with an HR of 2.32 (95% CI: 1.37-3.95), even after adjusting for age, sex, HBV DNA levels, and HBV genotype. This relationship remained significant, even when restricted to 165 immune-tolerant patients under the age of 40. **Conclusion:** In a cohort of immune-tolerant patients defined by HBV DNA and ALT levels according to the AASLD guideline, lower HBc viral diversity was associated with a reduced likelihood of clearing HBeAg. Deep sequencing-based determination of viral diversity may aid in the identification of genuine immune-tolerant patients.

1320-C | METABOLOMIC PROFILING TO PREDICT HISTOLOGIC PROGRESSION OF LIVER FIBROSIS IN PATIENTS WITH HIV AND HBV COINFECTION

Tzu-Hao (Howard) Lee, Baylor College of Medicine, Richard K. Sterling, Virginia Commonwealth University Health System, Joseph E Lucas, Vital Statistics, Wendy C King, University of Pittsburgh, Keyur Patel, University Health Network, Toronto, ON, Canada and Susanna Naggie, Duke Clinical Research Institute, Durham, NC

Background: Despite antiretroviral therapy (ART), some patients with HIV-HBV coinfection still have advanced fibrosis or fibrosis progression. Multiple metabolic pathways have been implicated in liver disease pathogenesis. Our study aims to discover expression patterns of circulating bioactive metabolites and their association with liver fibrosis in patients with HIV-HBV coinfection. **Methods:** This study cohort includes adults with HIV-HBV coinfection on ART recruited from eight Hepatitis B Research Network (HBRN) sites in North America. Clinical data, plasma samples, and liver biopsy were collected at entry, with paired liver biopsy obtained three or more years later. Serum samples within 24 weeks of the baseline liver biopsy were used to quantify 325 metabolites including fatty acids, amino acids, bile acids, and related intermediate metabolites. Metabolite expression was adjusted by clinical factors including sex, age, BMI, viral

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

loads, HCV/HDV coinfection, and medications for HIV, diabetes, and dyslipidemia to assess for association with (1) advanced fibrosis (Ishak fibrosis score greater than 3) in baseline liver biopsy and (2) worsening Ishak score on paired liver biopsy. We used generally applicable gene set enrichment (GAGE) pathway analysis to test for aggregate changes in the expression of metabolites grouped by predefined class. **Results:** 108 participants were included in the study, with a mean age of 50 years. 80% of participants had HBV DNA < 200 (IU/ml), and 92% had HIV RNA < 200 (copies/ml) with a median CD4 369 (cells/mm3). Ten participants (9.3%) had advanced fibrosis at baseline liver biopsy. In pathway analysis, metabolites in the amino acid class were associated with baseline advanced fibrosis (Table). 60 participants had paired liver biopsies (median 3.6 y apart) with 11 (18%) exhibiting fibrosis progression. Baseline serum expression of Dodecanedioic acid (DiCA [12:0]), cysteine synthesis indicator, and the sum of neurotransmitter expression (dopamine, histamine, and serotonin) was associated with fibrosis progression in the paired liver biopsy. In the pathway analysis, multiple classes of metabolites were associated with progression of fibrosis (Table). **Conclusion:** In participants with HIV-HBV coinfection, approximately 1 in 5 exhibited progression of fibrosis despite ART. We identified several baseline metabolites classes associated with the progression of liver fibrosis. Further discovery could elucidate pathways and biomarkers predictive of liver disease in this high-risk group.

Table: Metabolites classes associated with liver fibrosis and fibrosis progression in pathway analysis

Metabolites Classes and associated outcome	P-Value	Number of metabolites with positive correlation	Numbers of metabolites with negative correlation	*False discovery Rate
Baseline Liver Fibrosis				
Amino Acids	0.00248	3	7	7.9%
Liver Fibrosis Progression				
Triacylglycerols	<0.00001	226	16	<0.1%
Alcohols	0.00017	24	1	0.2%
Carboxylic Acids	0.00034	6	1	0.2%
Glycerophospholipids	0.00037	77	10	0.2%
Fatty Acids	0.00091	12	0	0.5%
Biogenic Amines	0.00100	6	3	0.5%
Epoxide	0.00377	1	2	1.5%
Hydroxyperoxide	0.00622	3	0	2.2%
Sugars	0.01573	0	1	5.0%
Acylcarnitines	0.02088	33	7	6.1%

* False discovery rate (FDR) is a control measure for high-throughput data. FDR is defined as the expected ratio of false positive classifications to the total number of positive classifications. For the purpose of novel hypotheses, an FDR of less than 10% is considered valid. We used Benjamini-Hochberg to control the false discovery rate.

1321-C | MIR-4461 ASSOCIATED WITH HEPATITIS B-DERIVED HEPATOCELLULAR CARCINOMAS

Aiko Sakai and Masaya Sugiyama, National Center for Global Health and Medicine

Background: The development of hepatocellular carcinoma (HCC) due to hepatitis B is difficult to predict. One reason is that its pathogenesis is not due to a persistent accumulation of inflammation. The molecular changes that occur in cells persistently infected with hepatitis B virus (HBV) are not clear on a cell-by-cell basis. The impact of those HBV-infected cells on the pathogenesis of the disease is also unknown. In this study, single-cell RNA-seq (scRNA-seq) analysis of HBV-infected cells was performed to investigate changes in gene expression on a single-cell basis. The molecules relating to HCC were identified and their functions were analysed. **Methods:** After the infection of primary hepatocytes with HBV, their scRNA-seq analysis was performed. scRNA-seq data were compared between HBV RNA-positive and negative hepatocytes (cell populations in the same environment) in one dish. The miR-4461 levels of HuH7 and HepG2 cells with and without HBV were identified and analyzed for cell proliferation, invasion and migratory capacity. Target genes to which miR-4461 bound were explored by in vitro assay. miR-44661 was quantified in HCC and non-HCC areas using resected liver tissue of hepatitis B and non-B/non-C. **Results:** Primary hepatocytes were infected with HBV and then scRNA-seq was performed. miR-4461 was significantly reduced in HBV-infected hepatocytes. miR-4461 expression was reduced when HBV replication plasmids were transfected into HuH7 and HepG2 cells. siRNA knockdown of miR-4461 enhanced the proliferation, invasive and migratory capacity of HuH7 and HepG2 cells. miR-4461 expression levels were confirmed in liver tissues from hepatitis B and non-B/non-C HCC patients. In non-B/non-C specimens, no difference of the miR-4461 expression was observed in both HCC and non-HCC areas compared to normal liver tissue. On the other hand, in hepatitis B specimens, the expression of miR-4461 was lower than that of normal liver ($p < 0.05$). in addition, the expression in HCC areas was lower than non-HCC areas ($p < 0.05$). Target genes of miR-4461 were explored using database and in vitro assay. Then, the FGA gene was one of the targets of miR-4461. **Conclusion:** The miR-4461 pathway was suggested to be associated with the establishment and pathogenesis of HBV infection. miR-4461 levels were reduced in liver tissue derived from hepatitis B, and a more significant reduction was observed in HCC area, suggesting that this pathway could be a useful biomarker for HBV-derived HCC.

1322-C | NON-INVASIVE EXPLAINABLE MACHINE LEARNING MODELS FOR ASSESSMENT OF SIGNIFICANT FIBROSIS IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Zhiyi Zhang[1], Huali Wang[2], Qun Zhang[3], Li Zhu[4], Shaoqiu Zhang[5], Yifan Pan[6], Jian Wang[5], Yuanwang Qiu[7], Chao Wu[1,5], Rui Huang[1,5] and Jie Li[1,5], (1) Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China, (2) Department of General Practice, Nanjing Second Hospital, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China, (3)Department of Infectious Diseases, Affiliated Zhongda Hospital of Southeast University, Nanjing, Jiangsu, China, (4)Department of Infectious Diseases, the Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China, (5)Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, (6) Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, Jiangsu, China, (7)Department of Infectious Diseases, the Fifth People's Hospital of Wuxi, Wuxi, Jiangsu, China

Background: Accurate assessment of significant fibrosis non-invasively is pivotal in managing patients with autoimmune hepatitis (AIH). This study aims to develop a non-invasive interpretable machine learning model for predicting significant fibrosis in AIH patients. **Methods:** A retrospective multi-center cohort of AIH patients who underwent liver biopsy was randomly divided, with 70% for model training and 30% for validation. Liver histology was assessed according to the Scheuer grading system and significant liver fibrosis was defined as stage S ≥ 2. Five machine learning algorithms (logistic regression, support vector machine, k-nearest neighbors, XGBoost, random forest [RF]) underwent ten-fold cross-validation. Models with the highest area under the receiver operating characteristic curve (AUC) were fine-tuned using grid search. Better models were retrained with the optimized parameters, performance was compared with APRI and FIB-4 on a test dataset. SHapley Additive exPlanation (SHAP) analysis explained predictions and assessed feature contributions. **Results:** A total of 261 AIH patients were included. Among the five models, XGBoost (AUC: 0.856, 95% confidence interval [CI]: 0.775-0.938) and RF (AUC: 0.885, 95% CI: 0.811-0.960) exhibited superior predictive performance, demonstrating their robust discriminative capabilities. The grid-search identified optimal hyperparameters for these two models. Retrained models achieved an AUC of 0.813 (95% CI: 0.698-0.929) for XGBoost and 0.790 (95% CI: 0.661-0.919) for RF on test dataset, significantly surpassing the performance of APRI (AUC: 0.546, 95% CI: 0.345-0.747) and FIB-4 (AUC: 0.632, 95% CI: 0.476-0.788). SHAP feature analysis revealed platelets, prothrombin time, and cholinesterase as the most influential factors in predicting significant fibrosis. **Conclusion:** The non-invasive interpretable machine learning models hold promise for predicting significant fibrosis in AIH patients. These models can aid clinicians in early identification of significant fibrosis for better management in AIH patients.

1323-C | O-GLYCOSYLATED MIDDLE-HEPATITIS B SURFACE ANTIGEN AS A NEW POTENTIAL BIOMARKER FOR CHRONIC HEPATITIS B: ASSOCIATION WITH HEPATOCELLULAR CARCINOMA AND QUANTITATIVE CHANGES WITH NUCLEOS(T)IDE ANALOG THERAPY

Taiki Okumura[1], Satoru Joshita[2], Takanobu Iwadare[1], Hiroyuki Kobayashi[1], Shunichi Wakabayashi[1], Yuki Yamashita[1], Takefumi Kimura[1] and Takeji Umemura[1], (1)Shinshu University Hospital, Matsumoto, Japan, (2) Yodakubo Hospital, Nagawa town, Chiisagata county, Japan

Background: A novel antibody recognizing O-glycosylated middle-hepatitis B surface antigen (HBsAgGi) can detect hepatitis B surface antigen (HBsAg) associated with hepatitis B virus (HBV) virions in patients with genotype C. This study investigated the association of HBsAgGi levels with clinical parameters, including other HBV markers and a history of hepatocellular carcinoma (HCC) development, in a cross-sectional cohort analysis (Study 1) in addition to the quantitative changes of HBsAgGi during nucleos(t)ide analog (NA) therapy in a longitudinal analysis (Study 2). **Methods:** HBsAgGi was measured by ELISA kits

Symbols: ƒ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(RCMG Inc.) using stored sera. A total of 124 patients were analyzed in Study 1. Among those, 36 patients receiving NA therapy were enrolled in Study 2 for quantitative comparisons between pre-treatment baseline and 48 weeks of NA treatment. **Results:** In Study 1, median age was 59 years, and 49 patients (39.5%) of subjects were male. Serum HBsAgGi was significantly associated with HBsAg ($r = 0.59$, $p < 0.001$). HBV DNA showed a higher correlation with HBsAgGi ($r = 0.29$, $p = 0.001$) than with HBsAg ($r = 0.28$, $p = 0.002$). After excluding 73 patients under NA treatment, HBV DNA continued to exhibit a higher correlation with HBsAgGi ($r = 0.43$, $p = 0.002$) than with HBsAg ($r = 0.39$, $p = 0.006$). Although HBsAgGi level was comparable between the HCC history (+) group (16 patients) and the HCC history (-) group (108 patients) ($p = 0.111$), the HBsAgGi/HBsAg ratio was significantly higher in the HCC history (+) group ($p = 0.011$). The patients were divided into 4 categories according to HBsAg and HBsAgGi titer according to the cut-off values of 3.0 log IU/mL and 3.0 log ng/mL, respectively. Multivariate testing using logistic regression analysis revealed low HBsAg and high HBsAgGi as an independent factor associated with HCC history (+) (hazard ratio: 4.20, 95% confidence interval: 1.34-13.12, $p = 0.014$). In Study 2, HBsAgGi was significantly decreased from baseline at 48 weeks of NA in the hepatitis B e antigen (HBeAg) (+) subgroup ($p = 0.005$), whereas HBsAg was comparable ($p = 0.051$). In contrast, HBsAgGi was similar between baseline and 48 weeks of NA in the HBeAg (-) subgroup ($p = 0.092$). **Conclusion:** In a cross-sectional analysis, HBsAgGi showed a stronger correlation with HBV DNA than did HBsAg, with the HBsAgGi/HBsAg ratio significantly associated with a history of HCC. Longitudinal analysis revealed that HBsAgGi was significantly decreased by 48-week NA therapy, suggesting its potential as a biomarker of HBV particles with HBV DNA.

1324-C | OPTIMIZED CUTOFF OF LIVER STIFFNESS MEASUREMENT FOR RULING IN SIGNIFICANT FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS B

Zhiyi Zhang[1], Li Zhu[2], Xingxiang Liu[3], Jian Wang[4], Shaoqiu Zhang[4], Xiaomin Yan[4], Yuanwang Qiu[5], Jie Li[1,4], Rui Huang[1,4] and Chao Wu[1,4], (1)Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China, (2)Department of Infectious Diseases, the Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, Jiangsu, China, (3)Department of Clinical Laboratory, Huai'an No. 4 People's Hospital, Huai'an, Jiangsu, China, (4) Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, (5) Department of Infectious Diseases, the Fifth People's Hospital of Wuxi, Wuxi, Jiangsu, China

Background: Accurate assessment of liver fibrosis is important in guiding therapeutic interventions and predicting prognosis in patients with chronic hepatitis B (CHB). Liver stiffness measurement (LSM) has emerged as a valuable non-invasive tool for evaluating the severity of fibrosis. However, the optimal cutoff of LSM values remains in debate. Therefore, we aim to identify the optimal cutoff value of LSM for ruling in/out significant fibrosis and cirrhosis among patients with CHB. **Methods:** We retrospectively collected the clinical data of a multi-center cohort of CHB patients who underwent liver biopsy along with LSM. Significant fibrosis and cirrhosis were defined as Scheuer fibrosis stage ≥ 2 and Scheuer fibrosis stage 4, respectively. The diagnostic performance of LSM in differentiating between various fibrosis stages was evaluated using the areas under the receiver operating characteristic curve (AUC). Subsequently, new cutoff values of LSM were identified in the training set using the grid-search method, ensuring a specificity and positive predictive value (PPV) of over 90% for ruling in, sensitivity of at least 90% and negative predictive value (NPV) of more than 95% for ruling out. The new cutoff values of LSM were subsequently validated in an internal and an external validation set. **Results:** A total of 332 individual's were enrolled in this study, with the training set consisting of 145 patients, 79 of whom with significant fibrosis. The internal and external validation sets included 31 and 38 patients with significant fibrosis, respectively. A strong correlation between LSM and the severity of fibrosis was found. The AUCs of LSM for predicting significant fibrosis were 0.753 in the training set, 0.839 in the internal validation set, and 0.811 in the external validation set. The optimal cutoff value of LSM for ruling in significant fibrosis was determined to be 9.8 kPa, exhibiting a specificity of 95.5%, a PPV of 93.3% and a misclassification rate of 7.6% in the training set, which is significantly superior to the cutoff of LSM ≥ 8 kPa recommended by the 2020 East Asia expert opinion with a specificity of 74.2%, a PPV of 73.8% and a misclassification rate of 25.8%. Furthermore, in the internal validation set, the optimal cutoff LSM value demonstrated a specificity of 96.8% and a PPV of 93.8%, while in the external validation set, it showed a specificity of 92.1% and a PPV of 94.0%. Importantly, the misclassification rate of the newly identified cutoff of LSM across all three datasets was below 10%.

However, the optimal cutoffs of LSM to rule out significant fibrosis or rule in/out liver cirrhosis could not be identified. **Conclusion:** The newly identified and validated cutoff value of ≥ 9.8 kPa for LSM to rule in significant liver fibrosis, coupled with a low misclassification rate, provides invaluable guidance for risk stratification, treatment decision-making, and long-term prognosis for CHB patients.

1325-C | PREDICATION VALUE OF SERUM O-GLYCOSYLATED HEPATITIS B SURFACE ANTIGEN LEVELS IN CHRONIC HEPATITIS B PATIENTS DURING ANTIVIRAL THERAPY

Bilian Yao[1], Qi Xu[1], Kiyohiko Angata[2], Hisashi Narimatsu[2] and Xinxin Zhang[1], (1)Ruijin Hospital, Shanghai Jiaotong University School of Medicine, (2) Research Core for Medical Glycoscience (RCMG) Inc

Background: Recent research has revealed that hepatitis B surface antigen (HBsAg) of Hepatitis B virus (HBV) Dane particles and non-infectious subviral particles (SVPs) can be distinguished by their *O*-glycosylation of the PreS2 domain of the middle HBsAg protein. This study aimed to evaluate the changes of serum *O*-glycosylated HBsAg levels in chronic hepatitis B patients treated with entecavir (ETV) or pegylated interferon ± (Peg-IFN±) treatment. **Methods:** Eighty-six treatment-naïve patients with genotype C CHB were retrospectively enrolled. The *O*-glycosylated HBsAg, HBsAg, HBeAg, HBV DNA, HBV RNA at baseline, weeks 4, 12, 24 and 48 after ETV or Peg-IFN± treatment were determined. Serum *O*-glycosylated HBsAg levels were semi-quantified by immunoassay using a monoclonal antibody against the *O*-glycosylated PreS2 domain of middle HBsAg. **Results:** At baseline, the serum *O*-glycosylated HBsAg levels were significantly correlated with the HBsAg ($R = 0.719, p < 0.001$), HBV DNA ($R = 0.485$, $p < 0.001$), HBV-RNA ($R = 0.460$, $p < 0.001$), and HBeAg ($R = 0.403, p = 0.03$) as well as with the HBsAg ($R = 0.564, p < 0.001$), HBeAg ($R = 0.556, p < 0.001$) in patients($n = 68$) who achieved undetectable HBV DNA. Serum *O*-glycosylated HBsAg, HBsAg, HBV RNA, HBV DNA levels were decreased after 48 weeks of antiviral therapy. A total of 60 patients achieved virological response (VR) and the area under the ROC curve (AUC) of baseline O-glycosylated HBsAg levels was 0.841 in predicting VR, which was superior to HBsAg (AUC = 0.815), HBV RNA (AUC = 0.704) or HBV DNA (AUC = 0.694) during ETV treatment. Similarly, AUC of baseline *O*-glycosylated HBsAg levels in predicting VR was 0.762, which was also higher than that of HBV RNA (AUC = 0.755), HBV DNA (AUC = 0.667) or HBsAg (AUC = 0.556) during Peg-IFN± treatment. The AUC of baseline *O*-glycosylated HBsAg levels in predicting 1 log IU/L decline in serum HBsAg levels after 48 weeks of antiviral therapy was 0.900, which was also higher than that of HBV DNA (AUC = 0.839), HBsAg (AUC = 0.700) or HBV RNA (AUC = 0.515) during Peg-IFN± treatment. **Conclusion:** During antiviral therapy, changes in serum *O*-glycosylated HBsAg levels may be indicative of combined levels of serum HBV DNA and RNA virions. The baseline serum *O*-glycosylated HBsAg level might provide a novel predictor of VR during ETV or Peg-IFN± treatment in CHB genotype C patients.

1326-C | PREDICTORS OF TREATMENT INITIATION AMONG HIGH-RISK AND GREY AREA CHRONIC HEPATITIS B PATIENTS IN A REAL-WORLD CLINICAL PRACTICE SETTING IN THE UNITED STATES

Mark A Schmidt[1], Yihe G Daida[2], Sacha Satram[3], Teresa M Kimes[1], Ana Gabriela Rosales[1], Sixiang Nie[2], Richard T Meenan[1], Judy L Donald[1], Michael A. Chattergoon[4] and Norah Terrault[5], (1)Center for Health Research, Kaiser Permanente Northwest, (2)Center for Integrated Health Care Research, Kaiser Permanente Hawaii, (3)Vir Biotechnology, (4)Vir Biotechnology, Inc, (5)University of Southern California, Los Angeles, CA

Background: Antiviral treatment of chronic hepatitis B virus (cHBV) infection is recommended for those patients with active disease who are at high risk of severe, long-term consequences. We sought to describe the initiation of cHBV treatment among a cohort of real-world patients in the United States, by demographic characteristics and treatment recommendation category. **Methods:** This retrospective, cohort analysis utilized electronic health records from large, integrated

health delivery systems in the US. Patients were included if they had e 2 positive labs, or 1 positive lab and 1 diagnostic code for cHBV, at least 6 months apart, between January 1, 2000 – December 31, 2015. Patients were followed until treatment initiation, disenrollment from the health plan, death, or December 31, 2020. The 2018 AASLD Hepatitis B Guidance was used to define "high-risk treatment indicated," "grey area," and "treatment not indicated" categories. Kaplan-Meier survival curves and Cox proportional hazards regression with associated hazard ratios [HR] and 95% confidence intervals [CI] estimated the predictors of treatment initiation by treatment recommendation category, adjusting for baseline patient characteristics. **Results:** Of 1,946 total untreated cHBV patients, 1,008 (52%) were male and 938 (48%) were female. There were 96 (5%) high-risk, 356 (18%) grey area, 269 (14%) not treatment indicated, and 1,225 (63%) patients with unknown treatment recommendation category. Of all untreated patients, 452 (23%) initiated treatment during the study period, including 57 (59%) high risk and 89 (25%) grey area patients. Females were 22% less likely to initiate treatment than males (HR 0.78; 95% CI 0.64-0.95); with no significant differences found by age or race. Compared to patients who were not treatment indicated, high-risk (HR 7.7, CI 5.0-11.7) and grey area (HR 1.9, CI 1.3, 2.8) patients were significantly more likely to initiate treatment, with mean (median) time to treatment initiation of 0.7 (0.2) and 2.8 (2.1) years, respectively (Figure). **Conclusion:** We observed a higher likelihood and faster rate of high-risk treatment eligible patients initiating treatment than grey area or treatment not indicated patients. However, almost two-thirds of patients lacked information necessary to classify treatment eligibility and over one-third of high-risk patients remained untreated throughout the study period. Thus, there remains considerable room for improvement in treatment strategies among high-risk cHBV patients. Figure: Kaplan-Meier curve of time to treatment initiation among untreated cHBV patients, by treatment recommendation category

Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2)Virology Unit, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (3)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: Accurate HDV RNA quantification is crucial for diagnosis and management of chronic hepatitis Delta, yet variability between assays exist. Aim of the study was to compare two methods to quantify HDV RNA in untreated and Bulevirtide (BLV)-treated CHD patients. **Methods:** Frozen plasma from consecutive untreated and BLV–treated CHD patients were tested in a single-center retrospective study with two quantification methods: Robogene HDV RNA Quantification Kit 2.0 (Roboscreen GmbH, Leipzig, Germany; LOD 6 IU/mL on 7500 Fast Real-Time PCR System [Applied Byosystem, Germany]) and EurobioPlex HDV PCR quantitative (Eurobio Scientific, France, LOD 100 IU/mL on CFX96™ real-time PCR detection system [Bio-Rad, USA]). RNA extraction was performed manually according to manufacturer indications: INSTANT Virus RNA/DNA kit (Roboscreen GmbH, Leipzig, Germany) for Robogene and NucleoSpin® Dx Virus Kit (Macherey-Nagel GmbH, Düren, Germany) for EurobioPlex. **Results:** 232 plasma samples from 127 CHD (69 untreated and 58 BLV-treated) patients were analyzed: age 52 (23-77) years, 54% males, 91% of European origin, 62% with cirrhosis, 75% under NUC, 96% HDV genotype 1, 87% HBeAg negative, 73% HBV DNA undetectable. ALT were 76 (6-743) U/L, HBsAg 3.8 (0.3-4.6) Log IU/mL. Overall, median HDV RNA levels were 3.78 (0.70-7.99) *vs.* 4.69 (2.00-8.19) Log IU/mL by Robogene 2.0 *vs.* EurobioPlex ($p < 0.0001$). Compared to Robogene 2.0, EurobioPlex reported similar HDV RNA levels ($\Delta \pm 0.5$ Log) in 66 (28%) patients, higher in 160 (69%) [Δ between +0.5 and +1 Log in 55; Δ between +1 and +2 Log in 98; $\Delta > 2$ in 7] and lower in 6 (3%) [Δ between -0.5 and -1 Log in all 6]. Among the 40 (17%) samples testing target not detected (TND) with Robogene 2.0, 73% tested TND with EurobioPlex, 13% tested < LOD, 15% tested positive (median HDV RNA 2.29 Log IU/mL). Of the 14 (6%) samples < LOD with Robogene 2.0, 79% were TND with EurobioPlex, 14% were < LOD and 1 positive (HDV RNA 3.03 Log IU/mL). 54 (23%) samples tested TND or < LOD with Robogene 2.0, 66 (28%) with EurobioPlex, respectively. In BLV-treated patients, virological response rates differed according to the assay: 25% of patients achieved HDV RNA < LOD/TND with Robogene 2.0, 33% with EurobioPlex. 14% of Robogene 2.0 negative patients tested positive with EurobioPlex (median HDV RNA 2.26 Log IU/ml). 33% of those negative with EurobioPlex tested positive with Robogene 2.0 (median HDV RNA of 1.91 Log IU/ml). We then tested 6 serum samples from the WHO standard: EurobioPlex read a median of 0.66 Log IU/mL more than the standard in 4/6 samples, Robogene 2.0 read a median of 0.20 Log IU/mL less than WHO standard in 5/6. **Conclusion:** HDV RNA quantification is significantly influenced by the assay, EurobioPlex reporting overall 1 Log higher viremia than Robogene 2.0. These results could significantly influence the clinical management of patients with CHD, being viral load a surrogate treatment endpoint in CHD.

1328-C | STREAMLINING THE DIAGNOSIS OF LIVER FIBROSIS TO REDUCE PATIENTS WITH INDETERMINATE RESULTS: A NOVEL ALGORITHM FOR CHB PATIENTS WITH CONCURRENT NAFLD

Xiaoming Xu[1], Fajuan Rui[1], Wenjing Ni[1], Chao Wu[1,2], Jeff Liang[3], Junping Shi[4], Yee Hui Yeo[5] and Jie Li[1,2], (1) Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China, (2)Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, (3)Cedars-Sinai Medical Center, Los Angeles, CA, (4)The Affiliated Hospital of Hangzhou Normal University, Hangzhou, Zhejiang, China, (5)Cedars-Sinai Medical Center, Culver City, CA

Background: Non-invasive tests (NITs) have been proposed as potential alternatives for the identification of patients at high risk of advanced fibrosis. However, they are limited by having a significant proportion of indeterminate results. Herein, we aimed to establish novel diagnostic algorithms to enhance the proportion of correct classification. **Methods:** From April 2004 to September 2021, treatment-naive patients with CHB patients with concurrent NAFLD, who underwent liver

biopsies from nine medical centers in China, were consecutively enrolled in this study. Fibrosis index based on four factors (FIB-4), aspartate aminotransferase to platelet ratio index (APRI), and NAFLD fibrosis score (NFS), as well as their combinations, were used to predict advanced fibrosis. Area under receiver operating characteristic (AUROC), sensitivities, specificities, and positive and negative predicted values were calculated. Subsequently, we computed the proportion of patients with the correct classification (the sum of true positives and negatives) for different combinations of NITs. **Results:** Among 926 treatment-naive CHB patients with concurrent NAFLD, 180 (19.44%) patients had advanced fibrosis. At the lower cut-off values, APRI exhibited the highest sensitivity of 65.56%, followed by FIB-4 (53.89%) and NFS (41.11%). At the higher cut-off values, NFS had the highest specificity of 97.99%, followed by FIB-4 (94.77%) and APRI (94.1%). Notably, APRI displayed the highest indeterminate rate of 30.99% compared to other NITs. The proportions of patients to receive a correct classification according to a single test were 64.7% for NFS, 64.1% for FIB-4, and 57.6% for APRI. When combining the test, the algorithm with NFS followed by APRI enabled most patients to receive a correct classification (73.7%), compared to FIB-4-NFS (71.3%), NFS-FIB-4(71.8%), FIB-4-APRI (71.0%), APRI-FIB-4 (70.5%), APRI-NFS(71.8%) . **Conclusion:** Our study highlights the superior performance of the combined NFS-APRI model in improving the proportion of correct classification. The findings has implications for optimizing referral pathways and provide an invaluable tool for primary care to facilitate targeted screening for liver fibrosis in CHB patients with concurrent NAFLD. **Keywords:** chronic hepatitis B; nonalcoholic fatty liver disease; advanced fibrosis; combined models; non-invasive tests

University of Valencia., (4)Hospital Universitario Vall D'hebron and Ciberehd Del Instituto Carlos III, (5)Marques De Valdecilla University Hospital, (6)Ciber De Enfermedades Hepáticas y Digestivas (CIBEREHD), (7)Hospital Universitario Cínico San Cecilio, (8)Hepatology Unit, Hospital Universitario La Paz, Spain, (9)Hospital Universitario De Canarias, (10) Complejo Hospitalario De Leon, (11)Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain, (12)Hospital Universitari Germans Trias I Pujol, Institut d'Investigació Germans Trias I Pujol (IGTP), (13)University Hospital Valme, (14)Hospital Universitario y Politécnico La Fe, (15)Vall D'hebron Research Institute (VHIR), (16) Hospital Universitario Central De Asturias, (17) Universidad De Valencia, (18)Galician Health Service, (19)Pharmacoeconomics & Outcomes Research Iberia (PORIB), (20)Puerta Del Hierro University Hospital, Madrid, Spain, (21)Marqués De Valdecilla University Hospital, Cantabria University, Idival, Santander, Spain, (22)Clinical and Translational Research in Digestive Diseases, Valdecilla Research Institute (IDIVAL)

Background: The SEPD (Spanish Association for Digestive Diseases), AEEH (Spanish Association for the Study of the Liver), SEIMC (Spanish Society of Infectious Diseases and Clinical Microbiology), SEIMC-GEHEP (Work-group for Viral Hepatitis) and AEHVE (Spanish Viral Hepatitis Elimination Alliance) agreed on a document at the beginning of 2022 to carry out a comprehensive diagnosis of viral hepatitis (B, C and D): a positive result in serology to detect viral hepatitis (HBV, HCV and HDV), as well as HIV, would trigger the analysis of the rest of the virus, including the viral load when necessary, from the same blood sample. This process would increase the diagnosis rate and it would reduce the time to be evaluated. Aim: To evaluate the situation in Spain regarding the comprehensive diagnosis of viral hepatitis in a single blood draw. **Methods:** A panel of experts prepared a structured survey disseminated through the Google Forms platform to all Spanish hospitals, public or private with teaching accreditation, with 200 beds or more. The survey was sent on 20th Oct 2022 and the reception of the results closed on 1st Dec. 2022. **Results:** Of the 130 hospitals with inclusion criteria, 48 responded (37% response rate, 34 centers > 500 beds). All centers have tools for the determination of HBV surface antigen, anti-HCV and HIV serology. 92% have a PCR technique for HBV/HCV. Only 67% of the centers have capacity for the determination of anti-HDV, and this drops to 31% for the detection of HDV-RNA; 88%, who do not have this technique, outsource it. The availability of Point-of-Care (POC) tests is low (21% of centers), GenXpert HCV (38%) and dry blood spot (38%) being the most frequent. Most of the POCs (90%) are supervised by Microbiologists and are always included in the clinical records. Reflex-test diagnosis is performed simultaneously in 88% of centers for HCV, 62% for HBV, 50% for HDV, and only 41% for HBV-HDV. Although 90% of centers believe that HBV and HCV serology should be performed on HIV-positive patients in the same sample, it is only done on 18% of HBsAg-positive and/or anti-HCV-positive subjects. When there is an active infection, any communication strategy is used in 38/48 (79%) of the hospitals (38 hospitals for HCV, 18 for HBV and 10 for HDV). The automated appointment arrangement is only available in 19% of the centers. Only 44.2% of the respondents believe that the determinations to reach a definitive diagnosis must be made with a single blood sample. **Conclusion:** Although most hospitals have the procedures to carry out a comprehensive diagnosis of viral hepatitis in a single analytical sample, this is used in less than 50% of cases for HBV/HDV. Alerts to maintain continuity of care are widely available for hepatitis C, but they need to be increased for HBV and HDV. Likewise, it is necessary to implement the devices for decentralized diagnosis.

1330-C | THE ROLE OF PREGENOMIC RNA IN RECURRENCE OF ADVANCED HEPATOCELLULAR CARCINOMA

Yifan Han[1], Jiali Pan[1], Hongyu Chen[1], Zhan Zeng[1], Xiaoyuan Xu[1] and Wengang Li[2], (1)Peking University First Hospital, (2)Fifth Medical Center of Chinese PLA General Hospital

Background: Previous studies have suggested that pregenomic RNA (pgRNA) could serve as a potential prognostic marker for early-stage HBV-related hepatocellular carcinoma (HCC). However, the significance of pgRNA in advanced HCC is not yet fully understood. Therefore, the objective of our study is to investigate the potential role of pgRNA in predicting the recurrence of advanced HCC and to assess the prognostic value of dynamic changes in pgRNA levels. **Methods:** A total of 55 treatment-naïve patients with HBV-related HCC at BCLC stage B or C were included in this study. Following the diagnosis, all patients underwent systemic therapy, including stereotactic body radiation therapy (SBRT) and immunotherapy combined with anti-angiogenic drugs. Additionally, all patients received antiviral treatment for HBV infection, and their HBV-DNA levels were negative prior to HCC treatment. Serum levels of pgRNA were tested in all 55 patients before HCC treatment, and 38 of them underwent a retest after 3 months of treatment. The quantification of pgRNA was performed using quantitative polymerase chain reaction (qPCR) analysis. The cumulative probability of HCC recurrence was assessed using the Kaplan–Meier method, and univariate and multivariate analyses were conducted using Cox proportional hazard models. **Results:** Table 1 summarizes the clinical characteristics of 55 patients with HBV-related HCC. The average age of the patients was 54 years, with 46 male patients and 48 patients presenting with cirrhosis. The majority of patients had Child–Pugh A (74.5%) and BCLC Stage C (81.8%). There were no significant differences in age, gender, BCLC stage, and number of lesions between the recurrence and non-recurrence groups. The actuarial rates of overall recurrence at six months and one year were 34.5% (95% CI: 20.7–46.0%) and 58.6% (95% CI: 41.2–70.9%), respectively. The median time to recurrence was 8 months. Univariate and multivariate analyses (Table 2) revealed that the serum level of pgRNA before HCC treatment ($p = 0.001$, HR [4.122, 1.765–9.629]), maximum tumor diameter ($p = 0.037$, HR [1.095, 1.006–1.192]), and total bilirubin ($p = 0.024$, HR [1.019, 1.002–1.035]) were independent risk factors for recurrence. Patients with a positive baseline serum pgRNA had a worse prognosis and a higher cumulative recurrence rate after systemic treatment(Figure 1). Among the 38 patients tested for pgRNA levels after 3 months of systemic therapy, those who were pgRNA-positive also exhibited a worse prognosis and a higher recurrence rate(Figure 2). **Conclusion:** Our study demonstrates that pgRNA serves as a valuable predictor of recurrence in advanced HCC. Furthermore, our findings suggest that continuous monitoring of pgRNA levels after treatment may hold predictive value for the recurrence of advanced HCC.

Genomic Research Center, Academia Sinica, (2)Linkou Chang Gung Memorial Hospital, (3)College of Medicine, National Cheng Kung University, (4)College of Medicine, National Taiwan University, (5)National Taiwan University Hospital, (6)National Cancer Institute

Background: Hepatitis B virus (HBV) infection is a leading cause of hepatocellular carcinoma (HCC). Clinical seromarkers, including the seroclearence of HBeAg, HBV DNA, and HBsAg, are used to monitor disease progression among chronic hepatitis B (CHB) patients. These markers have been shown to be predictive to HCC risk. However, risk assessment during the early stage of infection, when HBeAg is still present, remains challenging. **Methods:** In this study, we utilized advanced long-read sequencing techniques to examine HBV quasispecies variants in 439 HBeAg-positive CHB patients enrolled in the REVEAL-HBV cohort. We investigated quasispecies characteristics within three major genomic variation categories: viral complexity (quantified by Shannon entropy [SE]) of the Core gene, proportion of a protective combination of SNVs associated with HCC (protective-SNVs), and proportion of a combination of splicing variants (SP combination). Risks associated with quasispecies characteristics were assessed by Cox proportional hazards models, with HCC as the primary end point, adjusting for covariates. These characteristics were defined and evaluated to assess their potential for predicting HCC risk. **Results:** During an average follow-up period of 21.5 years, a total of 133 HCC cases were identified. In models without mutual adjustment, HBV quasispecies characteristics (specifically SE of Core, protective-SNVs, and SP combination) were found to be associated with risk of HCC (adjusted hazard ratios [adj. HR] for the highest quartile compared to the lowest quartile = 3.3, 0.1, and 3.1 respectively; all p values < 0.05). These associations remained statistically significant in models with mutual adjustment and persisted when incorporating a previously established REACH-B score. In addition, a combined model of the quasispecies characteristics demonstrated good discriminative ability for HCC risk with high performance (area under the curve [AUC] = 0.780; 95% CI = 0.735-0.825), which was higher than that of using REACH-B score alone (AUC = 0.729; 95% CI = 0.676-0.783), albeit not statistically significant (p for difference = 0.0531). When integrating the quasispecies markers and the REACH-B score, the performance in predicting true positive HCC cases was significantly higher (AUC = 0.809; 95% CI = 0.765-0.853; p for difference < 0.001) than using the REACH-B score alone. **Conclusion:** Our study demonstrated the potential of HBV quasispecies characteristics for HCC risk assessment during the early stage of HBV infection. These findings could contribute to the development of more effective strategies for HCC prevention and treatment.

Jiangsu, China, (19)Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China

Background: Although the endemic phenomenon of the superimposed chronic hepatitis B (CHB) on hepatic steatosis (HS) has been observed, few non-invasive tools are suitable for CHB patients with concurrent HS to evaluate the severity of liver fibrosis. To address the clinical need, a diagnostic model named PAP was previously developed to assess advanced fibrosis and cirrhosis for these patients. The PAP model was built on Gaussian naive bayes (GNB) by including prothrombin time (PT), albumin(ALB) and platelet (PLT). However, the stability and reproducibility of the PAP model were not clear across different categories. Therefore, the study aimed to test the PAP model performance in five subgroups. **Methods:** The study used data from a previous population-based cohort of 1,427 patients from nine clinical centers in China (NCT05766449). Patients were divided into five groups according to age (e 40 y and < 40 y), sex (males and females), alanine transaminase (ALT) levels (normal and elevated ALT), hepatitis B e antigen (HBeAg) status (positive and negative) and hepatitis B virus deoxyribonucleic acid (HBV DNA) level ($< 10^5$ and e 10^5 IU/mL) in both the training and validation cohorts. A web page was developed to score the PAP model. **Results:** In the training cohort (n = 1,063), the PAP model had the highest area under curves (AUCs) in patients with HBV DNA e 10^5 IU/mL at 0.827 (95% CI 0.749-0.905) for diagnosing advanced fibrosis (e S3) and 0.864 (95% CI 0.794-0.934) in patients aged e 40 years for identifying cirrhosis (= S4), while it performed modestly in patients with normal ALT levels in diagnosing advanced fibrosis (e S3) and cirrhosis (= S4), with AUCs between 0.558 and 0.711. In the validation cohort (n = 364), the PAP model had the highest AUC of 0.824 (95% CI 0.765-0.883) in patients with HBV DNA e 10^5 IU/mL, and the lowest AUC of 0.687 (0.619-0.755) in patients aged < 40 years for diagnosing advanced fibrosis (e S3). In diagnosing cirrhosis(= S4), the PAP model performed best in female patients, with an AUC of 0.954 (95% CI 0.902-1.000), while showing the poorest performance in patients with HBV DNA $< 10^5$ IU/mL, with an AUC of 0.771 (0.708-0.834). A web-page for fibrosis score calculation of the PAP model is freely at http://py.reallife-liver.com/. **Conclusion:** In CHB patients with concurrent HS, the PAP model remained its reproducibility for diagnosing liver advanced fibrosis and cirrhosis across various groups, hoping to serve as a novel diagnostic tool.

1333-C | A 10-YEAR STUDY OF PERINATAL HEPATITIS B VACCINATION TRENDS IN NEW YORK STATE AND THE IMPACT OF THE COVID-19 PANDEMIC

Clive Jude Miranda[1], Murad Hayatt Ali[2], Alexander Mark Carlson[3], Farhan Azad[2], Naren Srinath Nallapeta[2] and Anthony Dunning Martinez[4], (1)University at Buffalo, Buffalo, NY, (2)University at Buffalo, (3)University at Buffalo, Orchard Park, NY, (4)University of Buffalo

Background: Vaccination for hepatitis B virus (HBV) is recommended within 24-hours of birth for most neonates. The virus infects roughly 1000 neonates in the United States annually via vertical transmission from mother to infant. HBV vaccination is essential to prevent potentially lethal neonatal chronic infection. However, vaccination rates in the United States have been notably subpar, and the COVID-19 pandemic has further impaired timely and widespread vaccination initiatives. We aim to analyze trends in HBV vaccination in New York State over the past decade and investigate the extent to which the COVID-19 pandemic has influenced this. **Methods:** This retrospective cohort study investigated New York State neonates > 2000g who received birth hospitalization between 2012-2021. 143 hospitals in 45 counties were included. Counties were grouped into 4 Regional Offices (RO): Western (WRO); Capital District (CDRO); Metropolitan Area (MARO); Central New York (CYNRO). Annual HBV vaccination rates were analyzed in each county and trended over the 10-year period. The counties of Richmond, New York, Kings, Bronx, and Queens were absent in this study. **Results:** A total of 1,114,402

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hospitalized births were accounted for between 2012-2021 in the healthcare facilities in our study. After adjusting for healthy infants weighing > 2000g, 1,084,315 neonates were included in the cohort analysis. Of these neonates, a total of 883,893 (81.5%) were vaccinated for HBV within 24-hours of life over the 10-year period. When grouping counties by Regional Offices, a steady rise in average HBV vaccination rates was noted in MARO from 74% in 2012 to 78% in 2021. Rates in CDRO stayed steady between 85-89%. Interestingly, both WRO and CNYRO reached a peak vaccination rate in 2019 of 89% and 93% respectively, before both plummeting to 85% and 87% in 2021 (Figure 1). This period correlated with the COVID-19 pandemic during which New York City was an infection epicenter with overcrowded healthcare facilities and dwindling resources. Individual counties showed wide discrepancy in their 10-year vaccination trends from 2012 to 2021, with some showing impressive rises (Allegany: 52% to 81%; Nassau: 63% to 82%) and some falling precipitously (Madison: 97% to 47%; Erie: 83% to 69%). Despite this, heat maps show an overall increase in vaccination rates in New York State between 2012-2021 despite the pandemic (Figure 2). **Conclusion:** Despite the COVID-19 pandemic impacting healthcare access, resources, and personnel in New York State, the overall trend of neonatal HBV vaccination rates has demonstrated a steady rise since 2012. However, it is still not up to target levels. Further work is needed on promoting medical education and developing neonatal HBV vaccination regimens in the state.

1334-C | A 7th-YEAR INTERIM ANALYSIS OF PROSPECTIVE AND LONGITUDINAL KOREAN CHRONIC HEPATITIS B COHORT

Jae Seung Lee[1], Beom Kyung Kim[1], Hye Won Lee[1], Seung Up Kim[1], Do Young Kim[1], Sang Hoon Ahn[1], Sang Gyune Kim[2], Eun Young Cho[3], Young Mi Hong[4], Ki Tae Yoon[4], Yeon Seok Seo[5] and Jun Yong Park[1], (1) Yonsei University College of Medicine, Seoul, Republic of Korea, (2)Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Bucheon, Republic of Korea, (3)Wonkwang University College of Medicine, Iksan, Republic of Korea, (4)Pusan National University Hospital, Busan, Republic of Korea, (5)Korea University Anam Hospital, Korea University Medical College, Seoul, Korea, Republic of (South)

Background: We aimed to report the clinical outcome of Korean chronic hepatitis B (CHB) patients from a prospective longitudinal cohort. **Methods:** This cohort, supported by the Korea Disease Control and Prevention Agency (2022E190400), was established in 2015. Voluntarily enrolled patients with CHB serially provide their clinical data and blood samples during the ten-year follow-up. **Results:** From 2015 to 2022, 2949 patients (1812 male) with a mean age of 52.6 years participated in this study. Annual 16 mL of blood sampling was collected (median three times) from 1391 volunteers. Male patients had more smoking and hazardous alcohol intake ($p < 0.001$). At the enrollment, most patients were receiving antiviral therapy (AVT) (n = 2359, 80.0%), whereas 515 (17.4%) patients were AVT-naïve. Cirrhosis was noted in 646 (21.9%) patients. The most favored AVT regimen was tenofovir disoproxyl fumarate (TDF) (40.0%), followed by entecavir (33.0%). However, during the recent two years, an increasing proportion of patients are starting the first AVT with tenofovir alafenamide (5.9% to 13.5%) or besifovir dipivoxil maleate (2.8% to 7.5%). Most patients receiving AVT with a high-genetic barrier experienced a complete virologic response (more than 80% at week 48). Crudely, the incidence of an increase in chronic kidney disease stage ≥ 1 was significantly higher in TDF users than ETV users (7.56 vs. 4.56 per 100 person-years, $p < 0.001$). Hepatocellular carcinoma occurred in 33 (1.9%) patients after 50.3 months of median follow-up, most of which were within Milan criteria. Cirrhosis was independently associated with hepatocellular carcinoma occur (adjusted hazard ratio, 5.005, $p = 0.002$). **Conclusion:** This cohort study will evaluate long-term liver-related outcomes among Korean CHB patients. Future research using the cohort data and blood samples after the data purification could reveal the unmet needs to manage CHB.

1335-C | A HEPATOCELLULAR CARCINOMA RISK PREDICTION MODEL IN PATIENTS ACHIEVING HBsAg SEROCLEARANCE

Jonggi Choi[1], Hye Won Lee[2], Terry Cheuk-Fung Yip[3], Vincent Wai-Sun Wong[4], Young-Suk Lim[5], Henry Lik Yuen Chan[6], Sang Hoon Ahn[2] and Grace Lai-Hung C Wong[7], (1)Asan Medical Center, Seoul, Korea, Republic of (South), (2)Yonsei University College of Medicine, Seoul, Republic of Korea, (3)The Chinese University of Hong Kong, Hong Kong, 91, China, (4)The Chinese University of Hong Kong, Hong Kong, China, (5)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South), (6) Chinese University of Hong Kong, Hong Kong, China, (7)Prince of Wales Hospital

Background: The risk of hepatocellular carcinoma (HCC) decreases but remains present after HBsAg seroclearance in patients with chronic hepatitis B (CHB). The aim of this study was to determine the risk factors for HCC development and construct a prediction model to stratify the risk of HCC after HBsAg seroclearance. **Methods:** We analyzed CHB patients with confirmed HBsAg seroclearance, which was defined as HBsAg negativity by at least two consecutive tests, with a 6-month interval, regardless of hepatitis B surface antibody positivity. The primary outcome was the development of HCC following HBsAg seroclearance. A training cohort was derived from 3,476 patients at Asan Medical Center and Severance Hospital in Seoul, Republic of Korea, while 5,255 patients from the Chinese University of Hong Kong were used as an external validation cohort. A Cox model was used to determine the risk factors associated with HCC development in the training cohort. A prediction model for HCC risk with integer scores assigned to each risk factor based on the coefficient from the Cox model was built. The performance of the prediction model was evaluated using the time-dependent AUROC in predicting the 5- and 10-year risk of HCC. **Results:** In the entire cohort, 64.5% of the patients were male, the mean age at the time of HBsAg seroclearance was 55.4 years, and 17.1% had cirrhosis. During the 24,109 person-years (PYs) of follow-up, 102 patients developed HCC, resulting in an annual incidence of 0.43/100 PYs in the training cohort. Age ≥ 50 years (adjusted hazard ratio [AHR]: 2.8, $p < 0.001$), male gender (AHR: 3.81, $p < 0.001$), cirrhosis (AHR: 4.32, $p < 0.001$), and platelet count < 150,000 (AHR: 1.64, $p = 0.02$) were independently associated with an increased risk of HCC in multivariable analysis from the training cohort. Risk scores were assigned to age ≥ 50 years (2 points), male gender (3 points), cirrhosis (3 points), and low platelet count (1 point). Based on the sum of these points, the patients were categorized into low (0–3 points), intermediate (4–6 points), and high (≥ 7 points) risk groups, with incidences of HCC of 0.06, 0.41, and 1.37/100 PYs, respectively. The 5- and 10-year time-dependent AUROC of HCC in the training cohort were 0.782 and 0.827, respectively. In the validation cohort, 85 patients developed HCC with an annual incidence of 0.24/100 PYs. The incidences of HCC in the low-, intermediate-, and high-risk groups in the validation set were 0.07, 0.37, and 0.90/100 PYs, respectively. The 5- and 10-year time-dependent AUROC of HCC in the validation cohort were 0.785 and 0.771, respectively. **Conclusion:** Liver cirrhosis, age ≥ 50 years, male gender, and platelet < 150,000 at the time of HBsAg seroclearance were significantly associated with HCC development after HBsAg seroclearance. Our suggested model can be easily applied in the real world and aid in stratifying the risk of HCC after HBsAg seroclearance in patients with CHB.

1336-C | ADHERENCE TO HEPATOCELLULAR CARCINOMA SURVEILLANCE IN PATIENTS WITH CHRONIC HEPATITIS B IN A LOW ENDEMIC COUNTRY

Lesley Ann Patmore[1], Warshan K. Katwaroe[1], Daniel Van Der Spek[1], Sylvia Brakenhoff[1], Laurens van Kleef[1], Adriaan J. Van der Meer[2], Harry L. A. Janssen[2,3], Rob J. De Knegt[1], Bettina E. Hansen[2], Robert A. De Man[1] and Milan J. Sonneveld[1], (1)Erasmus MC, University Medical Center, (2)Erasmus MC, University Medical Center Rotterdam, (3)Toronto General Hospital Research Institute

Background: Hepatocellular carcinoma (HCC) surveillance in high risk patients with chronic hepatitis B (CHB) is associated with improved long-term outcomes, and is therefore recommended in all guidelines. However, adherence to HCC surveillance recommendations is often suboptimal. We aimed to study adherence rates and predictors of non-adherence to HCC surveillance recommendations in a low endemic country. **Methods:** We conducted a single-center retrospective cohort study of all patients with HBV mono-infection attending the outpatient clinic of a tertiary care center in the Netherlands. We assessed the medical records to assess eligibility for HCC surveillance based on the Dutch guidelines. Patients were considered eligible for HCC surveillance in case of one of the following criteria (1) presence of cirrhosis (2) positive family history for HCC (3) Asian males ≥ 40 years (4) Asian females ≥ 50 years and (5) all Sub-Saharan African patients ≥ 20 years. We compared adherence rates across risk groups (cirrhosis versus other indications) and across clinic types (dedicated viral hepatitis clinic versus general hepatology clinic). **Results:** A total of 480 patients were included, of whom 243 (50.6%) patients were considered eligible for HCC surveillance. Eligibility for HCC surveillance was based on presence of cirrhosis in 48 patients (10%). Of the 243 patients with an indication for HCC surveillance, 218 (89.7%) underwent surveillance. Adherence to surveillance was observed in all patients with cirrhosis, and in 87.2% of non-cirrhotic patients ($p = 0.009$). Among the chronic hepatitis B patients with a surveillance indication, 144 (59.3%) were seen at a dedicated viral hepatitis clinic. Dedicated viral hepatitis clinics had superior adherence rates to HCC surveillance guidelines compared to general hepatology clinics (95.1% versus 81.8%, $p < 0.001$), which was mostly accounted for by suboptimal adherence among non-cirrhotic patients (94.3% vs. 74.6% $p < 0.001$). **Conclusion:** The majority of patients with an indication for HCC surveillance were enrolled in an HCC surveillance program. Management at a dedicated viral hepatitis clinic was associated with superior adherence to HCC surveillance recommendations. These findings suggest that centralizing care for chronic hepatitis B in low incidence countries could potentially improve patient outcomes.

1337-C | ALL IN MODERATION: ASSESSING THE FREQUENCY OF GUIDELINE-BASED HEPATITIS B SCREENING IN THE MODERATE-RISK GROUP FOR HBV REACTIVATION PRIOR TO IMMUNOSUPPRESSIVE THERAPY

Joanne Lin, Humzah Iqbal, Jennifer Yoon, Alakh Gulati, Ratnali Jain and Marina M. Roytman, UCSF Fresno

Background: Hepatitis B virus reactivation (HBVr) is a syndrome associated with significant morbidity and mortality, reflecting the loss of immune control of the infection which can be due to stopping antiviral therapy or starting immunosuppressive medication. Immunosuppressive therapies are used to treat various conditions by many specialties including rheumatology, dermatology, oncology, and gastroenterology. Prior to starting immunosuppressive therapy, many clinical guidelines recommend screening for chronic hepatitis B (HBV). However, adherence in clinical practice varies. We sought to determine the frequency of complete guideline-based hepatitis B screening recommended by the American Gastroenterological Association (AGA) prior to the initiation of moderate-risk immunosuppressive therapy. **Methods:** Our retrospective study included 2443 patients over the age of 18 being treated with moderate-risk immunosuppressive therapy, which included tumor necrosis factor-alpha inhibitors, cytokine or integrin inhibitors, and tyrosine kinase inhibitors, from October 2020 to April 2021. Patients taking moderate-risk doses and duration of steroid therapy were not included. The following data were collected: gender, age, complete HBV serologies (hepatitis B surface antigen [HBsAg], hepatitis B core antigen [anti-HBc], hepatitis B surface antibody [anti-HBs]), the immunosuppressive regimen, and the indication for immunosuppression. **Results:** Of the 2443 patients, 33.2% were over the age of 65 and 63.2% were females. The most frequently used immunosuppressive therapy was adalimumab (33.8%), followed by etanercept (18.1%) and 2 or more medications (14.3%). The specialties that prescribed immunosuppressive therapies most often were rheumatology (51.6%), gastroenterology (23.4%), and dermatology (15.7%). Only 393 patients (16.1%) had complete HBV screening. Of the screening tests, HbsAg was tested in 44.8% of patients, anti-HBc in 33%, and anti-HBs in 20.6%. Gastroenterology completed HBV screening most frequently, followed by rheumatology, dermatology, other/mixed, and hematology/oncology. **Conclusion:** HBVr is a potentially life-threatening complication of immunosuppression but is preventable with appropriate pre-immunosuppression screening and antiviral therapy. Our study emphasizes the significant deficiencies in HBV screening even in moderate-risk patients and demonstrates that there are opportunities to improve provider adherence to HBV screening recommendations to prevent HBVr.

1338-C | AN INTEGRATED MODEL NURSE CLINIC TO PREVENT MOTHER-TO-CHILD TRANSMISSION (MTCT) OF HEPATITIS B VIRUS (HBV)

Amber C Yip[1], Cherry C Yung[1], Terry Cheuk-Fung Yip[2], Vincent Wai-Sun Wong[3] and Grace Lai-Hung C Wong[1], (1)The Chinese University of Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, 91, China, (3)The Chinese University of Hong Kong, Hong Kong, China

Background: Pregnant women with chronic hepatitis B virus (HBV) infection and high viral load (HBV DNA > 200,000 IU/mL) would be at higher risk to transmit the virus to their babies despite the universal HBV vaccination to neonates. An integrated model nurse clinic (IMNC) co-run by hepatologists and hepatitis nurses has been introduced since 2020 to prescribe perinatal tenofovir disoproxil fumarate (TDF) to mothers who are hepatitis B surface antigen (HBsAg) positive with high viral load (HBV DNA > 200,000 IU/mL) for the prevention of mother-to-child-transmission (MTCT) of HBV. We now report the outcomes of mothers who have attended this IMNC. **Methods:** This was a prospective single-center pilot programme in Prince of Wales Hospital, Hong Kong from February 2020 to December 2022. Pregnant women with HBV DNA > 200,000 IU/mL were identified. The uptakes of IMNC attendance and TDF use were captured. **Results:** We identified 284 women of childbearing age (18-40 y old) with HBV DNA > 200,000 IU/mL; 95 women (median age 34 y) were pregnant. 43 of 95 (45.3%) pregnant women attended IMNC during their pregnancy, and 77 of 95 (81.1%) pregnant women had received TDF during their pregnancy. The updates of IMNC attendance and TDF use increased from 67.7% and 87.1% respectively in 2020, to 76.2% and 90.9% respectively in 2021, but then dropped to 28.6% and 81.0% respectively in 2022 (when the outbreak of omicron variants of SARS-CoV-2 occurred in Hong Kong). **Conclusion:** The uptakes of IMNC attendance and hence TDF use increased in the first two years of the novel integrated model, but were significantly affected amid the omicron outbreak. Towards the end of the COVID-19 pandemics, this IMNC will keep playing an important role to prevent mother-to-child transmission of HBV in order to achieve hepatitis elimination.

Background: The association between prior antiviral therapy (AVT) and the risk of hepatocellular carcinoma (HCC) after HBsAg seroclearance has not been confirmed. This study aimed to assess the relationship between AVT and HCC risk and develop a prediction model to determine the likelihood of HCC occurrence after HBsAg seroclearance. In addition, long-term incidence of HCC and hepatic decompensation after HBsAg seroclearance was investigated. **Methods:** Patients with chronic hepatitis B who achieved HBsAg seroclearance between 2003 and 2022 were retrospectively reviewed for eligibility. Exclusion criteria for this study included patients who developed HCC before HBsAg seroclearance, or had a follow-up duration less than 6 months. The primary endpoint of the study was the occurrence of HCC, while the secondary endpoint was hepatic decompensation. Baseline characteristics of the patient groups were balanced using inverse probability of treatment weighting (IPTW). **Results:** Among 1,521 patients selected for statistical analysis, 84.2% (n = 1,280) achieved HBsAg seroclearance without AVT (spontaneous clearance group), while the remaining 15.8% (n = 241) achieved it after AVT (AVT-induced clearance group). During a median follow-up of 4.3 years, 37 patients (2.4%) developed HCC. AVT-induced clearance group had a significantly larger number of patients with alcohol consumption and cirrhosis, a lower platelet count, and a ALBI grade compared to the spontaneous clearance group (all $p < 0.05$). The incidence rate of HCC was comparable between the two groups ($p = 0.727$ by log-rank test). However, after IPTW, that was significantly higher in the spontaneous clearance group compared to the AVT-induced clearance group ($p = 0.014$ by log-rank test). In multivariate analysis, older age (aHR = 1.054), cirrhosis (aHR = 5.022), lower platelet count (aHR = 0.992), ALBI grade ≥ 2 (aHR = 5.340), and no previous AVT (aHR = 0.461) were independent predictors for the higher risk of HCC (all $p < 0.05$). The prediction model developed using these variables had AUC of 0.828 (95% CI 0.724-0.933) in the training group, and 0.801 (95% CI 0.719-0.882) in the validation group. The cumulative incidence of HCC was consistent 0-5 and 5-10 years after HBsAg seroclearance ($p = 0.30$). In total, 98 patients (6.5%) developed decompensation after HBsAg seroclearance, and the cumulative incidence of decompensation was persistent 0-5 and 5-10 years after HBsAg seroclearance ($p = 0.47$). In multivariable analysis, HBsAg loss for over 5 years was not associated with the risk of HCC (adjusted subdistribution hazard ratio [aSHR] 0.85, 95% CI 0.48-1.51, $p = 0.580$) or decompensation (aSHR 0.79, 95% CI 0.52-1.19, $p = 0.250$). **Conclusion:** The novel prediction model based on age, cirrhosis, platelet count, ALBI grade, and history of AVT is beneficial for determining the risk of HCC after HBsAg seroclearance. The risk of HCC and decompensation is consistent over time after HBsAg seroclearance.

Table. Risk scores for HCC development after HBsAg seroclearance

Variable	β	HR	95% CI	P value	Risk score

Medicine, (10)Chosun University, (11)Inje University Haeundae Paik Hospital, (12)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR, (13)The Chinese University of Hong Kong, Hong Kong, China, (14)State Key Laboratory of Translational Oncology, Department of Clinical Oncology, Sir Yue-Kong Pao Center for Cancer, the Chinese University of Hong Kong, (15)Genomic Research Center, Academia Sinica

Background: This study aimed to investigate and validate the relationship between serum hepatitis B virus (HBV) DNA levels and hepatocellular carcinoma (HCC) risk in non-cirrhotic chronic hepatitis B (CHB) patients without significant elevation in alanine aminotransferase (ALT) levels, for whom antiviral treatment is typically not recommended despite high HBV viremia. **Methods:** A total of 7,429 CHB patients from the Taiwanese REVEAL-HBV cohort and 7 centers in Hong Kong and Korea (validation cohort) were used to validate findings from 6,949 patients at a Korean center (derivation cohort). All were non-cirrhotic adults with ALT levels < 2x the upper limit of normal, not indicated for antiviral treatment. **Results:** During a median follow-up of 10.0 and 12.2 years in the derivation and validation cohorts, 435 and 467 incident HCC cases were identified, respectively. The relationship between baseline HBV DNA levels and HCC risk was linear in HBeAg-negative patients, inverse in HBeAg-positive patients, and non-linear parabolic in the entire population for both cohorts. The highest HCC risk was observed with moderate viral loads (around 6 $\log_{10}$ IU/mL). Compared to viral load d 3.0 $\log_{10}$ IU/mL, the adjusted HCC risk was 3.97 times higher with viral load 6.0-7.0 $\log_{10}$ IU/mL in the derivation cohort (95% CI, 2.80–5.63; $p < 0.001$) and 8.36 times higher with viral load 5.0-6.0 $\log_{10}$ IU/mL in the validation cohort (95% CI, 5.89–11.87; $p < 0.001$). These findings were consistent in patients with normal ALT levels and in a nested case-control study. **Conclusion:** HCC risk was highest with moderate HBV viral load (around 6 $\log_{10}$ IU/mL) in untreated, non-cirrhotic, adult CHB patients without significant ALT elevation. Antiviral treatment should be considered for these patients to reduce HCC risk.

1341-C | BENEFITS OF HEPATITIS B VIRUS (HBV) VACCINATION IN PATIENTS WITH CHRONIC LIVER DISEASES

Kaicen Wang[1], Timo Itzel[1], Jimmy Daza[1], Thomas Falconer[2], George Hripcsak[2], Jimyung Park[3], Jae Youn Cheong[3], Rae Woong Park[3], Matthias Ebert[1] and Andreas Teufel[1], (1)Medical Faculty Mannheim, Heidelberg University, (2)Columbia University Irving Medical Center, New York, NY, (3)Ajou University Graduate School of Medicine

Background: Hepatitis B vaccine has proven highly successful in preventing hepatitis B virus (HBV) infection and reducing consequential hepatitis B-related disease burden in the countries where vaccination has been implemented. However, few studies have reported the impacts of the hepatitis B vaccination in overall survival, particularly on patients with chronic liver disease (CLD) other than chronic hepatitis B. **Methods:** To investigate the efficacy of the hepatitis B vaccine on patients with chronic liver disease, a large USA cohort of 57.306 patients between 2000 and 2020 was obtained through the Observational Health Data Sciences and Informatics (OHDSI) consortium. **Results:** In the 20-year cohort of the Columbia University, 2.79% (1601/57306) of patients with chronic liver disease were reported as vaccinated. Overall, HBV-vaccinated patients with chronic liver disease had a significantly better survival ($p = 0.000$). Patients with liver cirrhosis also showed a significantly improved survival ($p = 0.000$). By investigating subgroups, particularly patients with chronic hepatitis C ($p = 0.000$), chronic non-alcoholic liver disease ($p = 0.000$), or both alcoholic and non-alcoholic-induced cirrhosis (both $p = 0.000$) all shared significant benefits from HBV vaccination ($p = 0.000$). These benefits showed no differences between gender. **Conclusion:** Our results demonstrated that vaccinated patients with different kinds of chronic liver diseases generally had significantly better survival when the use of Hepatitis B Surface Antigen vaccine was verified. However, as 97.21% (55706/57306) of the population were not reported as immunized, further efforts to improve the quality and comprehensiveness of medical records in chronic liver disease patients must be implemented.

1342-C | CHARACTERIZING CHRONIC HEPATITIS B VIRUS INFECTION PREVALENCE, GEOGRAPHIC DISTRIBUTION, AND FOLLOW-UP TESTING, ALAMEDA COUNTY, CALIFORNIA, 2017–2021

Emily Yette[1], Rachel Marusinec[1], Craig Conlon[1], Robert J. Wong[2] and Amit S. Chitnis[1], (1)Alameda County

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Public Health Department, (2)VA Palo Alto Healthcare System

Background: In the United States, chronic hepatitis B (CHB) virus infection predominantly affects ethnic minorities and vulnerable populations. We analyzed surveillance data to describe CHB prevalence, geographic distribution, and follow-up testing to guide prevention efforts in Alameda County. **Methods:** CHB cases from 2017–2021 were identified by > 2 positive hepatitis B virus (HBV) surface antigen (HBsAg), HBV e antigen (HBeAg), or HBV DNA tests > 6 months apart using data from the California Reportable Disease Information Exchange. CHB cases were stratified by age, race/ethnicity, census tract, zip code-based healthy places index (HPI), and federally-designated medically underserved areas (MUA). Lower HPI values represent less advantaged areas. Among CHB cases, we evaluated engagement with HBV care, which was defined as having at least annual testing with HBsAg, HBeAg, or HBV DNA, and stratified analyses by MUA status. Comparisons of CHB prevalence between groups utilized z-test; comparisons between MUA regions utilized chi-square testing. **Results:** Among a population of 1.53 million, 8122 CHB cases were identified; 5-year CHB prevalence was 0.53% (95% CI: 0.52%–0.54%). CHB prevalence was significantly higher among persons aged 50–69 years old than persons aged 30–49 years old (0.99%, 0.78%;$p < 0.01$) and Asians compared to Native Hawaiian/Pacific Islanders and African-Americans (1.21%, 0.56%, 0.18%;$p < 0.01$). CHB prevalence in the two lowest HPI quartiles was significantly higher than in the two highest quartiles (0.55% and 0.68%, 0.37% and 0.42%;$p < 0.01$). Geographic distribution of CHB prevalence by census tract and MUA identified areas within Alameda County that had < 1.0- to > 2.0-times overall County CHB prevalence is presented in the Figure. The 1933 CHB cases in MUA, compared to 5878 non-MUA cases, were significantly more likely to be African-American (7%, 3%;$p < 0.01$) and from the lowest HPI quartile (79%, 19%;$p < 0.01$). Among 6897 CHB cases eligible for e 1 year of follow-up, only 21% received annual testing, regardless of MUA status. **Conclusion:** CHB prevalence in Alameda County was 1.5-times higher than national estimates, and prevalence was highest among Asians and persons in more disadvantaged areas, with a high proportion of cases occurring in MUA. Only 21% of persons with CHB had annual testing, suggesting low engagement in CHB care. Analysis of local CHB surveillance data can guide public health efforts to improve outreach, CHB testing, and care.

1343-C | CHRONIC HBV INFECTION: IMPACT OF HDV COINFECTION AND IFN TREATMENT ON LIVER RELATED OUTCOMES AND MORTALITY IN THE MULTICENTER, PROSPECTIVE, OBSERVATIONAL ANRS CO22 HEPATHER FRENCH COHORT

Lucia Parlati, AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, Dmu Cancérologie Et Spécialités Médico-Chirurgicales, Service d'Hépatologie, Paris, France and ANRS/AFEF HEPATHER study group

Background: The HBV-HDV coinfection is the most severe viral hepatitis, with the higher rate of morbidity

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and mortality. New drugs available for HDV treatment will change the natural history of HBV-HDV coinfected patients. We aimed to analyze the prognosis of HBV-HDV coinfected patients and the impact of IFN on liver related outcomes and mortality. **Methods:** We conducted a multicenter, national, prospective, observational cohort study between August 2012 and April 2023. The incidences of liver related complications (decompensation of cirrhosis and HCC), liver transplantation and mortality were measured according to HDV status and IFN treatment in patients with chronic HBV infection. Relative risks (HR) were calculated with multivariate analysis. **Results:** Among 3,958 HBsAg-positive patients with a known HDV status, 205 (5.2%) were HDV positive; 135 (66 %) HBV-HDV coinfected patients were male with a median age of 43 (35-52) years, 151 (73.6%) were treated by IFN. Compared to mono-infected patients, HBV-HDV coinfected patients were younger (43 vs 45 years, $p = 0.01$), more often Africans (58 vs 43%, $p < 0.0001$) and cirrhotic (39 vs 13%, $p < 0.0001$). A history of HCC (6 vs 3 %, $p = 0.03$) and of cirrhosis decompensation (10 vs 3 %, $p < 0.0001$) was more prevalent in coinfected than in mono-infected patients at the inclusion. After a median follow-up of 5.9 (3.9 ;7.2) years, the incidences of death, liver transplantation, HCC and cirrhosis decompensation in HBV-HDV coinfected vs mono-infected patients were 1.6 (0.9-2.5) vs 0.9 (0.8-1.1)/100pyr ($p = 0.04$), 1.1 (0.55-1.86) vs 0.12 (0.08-0.18)/100pyr ($p < 0.0001$), 1.7 (1.0-2.6) vs 0.6 (0.5-0.7)/100pyr ($p = 0.0002$), 1.36 (0.76-2.24) vs 0.23 (0.17-0.30)/100pyr ($p < 0.0001$), respectively. Treatment by IFN in HBV-HDV coinfected was not associated with any of the outcomes. In multivariable analysis, the HBV-HDV coinfection (HR 2.70, 95%CI (1.55-4.70)) w/o effect modification by IFN, cirrhosis (HR 2.65, 95%CI (1.83-3.84), older age (HR 1.06, 95%CI (1.05-1.08) and diabetes (HR 1.56, 95%CI (1.02-2.40) were significantly associated with the occurrence of liver related complications, liver transplantation and mortality (Table 1). **Conclusion:** HDV coinfection increases the risk of liver-related complications, transplantation and death in HBV-infected patients. IFN did not improve significantly the outcomes of these patients, underlying the need of efficacious therapy in this population.

	n of events/pyrs	Hazard ratio	95% CI

1344-C | CHRONIC HEPATITIS B INFECTION IN PREGNANCY ASSOCIATED WITH IMPAIRMENT OF PATIENT-REPORTED OUTCOMES AND QUALITY OF LIFE

Yueying Deng[1,2], Yawen Geng[1,2], Shi Ouyang[1] and Calvin Pan Pan[1,3], (1)The Fifth Affiliated Hospital of Guangzhou Medical University, Guangzhuo, China, (2) North China University of Technology, Tangshan, China, (3)NYU Grossman School of Medicine

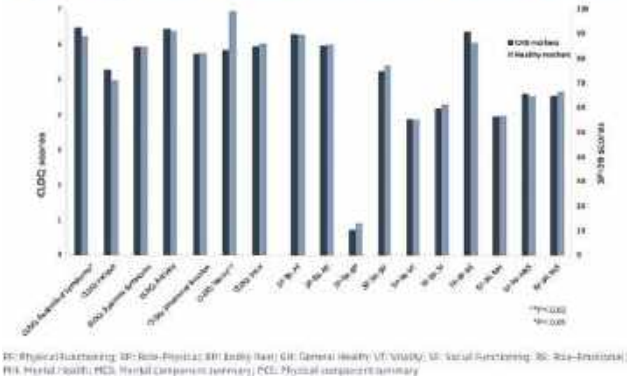
Background: The health-related quality of life (HRQoL) during pregnancy has not been well-elucidated in mothers with chronic hepatitis B (CHB). We aim to evaluate patient-reported outcomes (PROs) in CHB mothers and compare them with those of PROs from healthy mothers during pregnancy. **Methods:** We prospectively enrolled mothers from 4/1/2023 to 5/30/2023 at the outpatient clinic of a university medical center in China. Consecutive compensated CHB mothers and healthy mothers were invited to participate and complete the 36-item Short Form Survey (SF-36) and the Chronic Liver Disease Questionnaire (CLDQ). Covariates included pregnancy profiles, comorbidities or complications, laboratory parameters, and HBV virological variables. Data were compared between groups and risk factors for worse PROs were further analyzed by the multiple linear regression model.

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Results: Among 131 participants including 61 CHB and 70 healthy mothers, the mean (SD) age was 29.3 ± 3.7, median (range) gestational week 23 (16 - 39), 42% had health insurance, 39.7 % had gravidity count > 1, and 3.1 % had comorbidities. When comparing variables between CHB and healthy mothers, there were statistically significant differences in the mean (SD) age (29.4 ± 4.35 vs 27.1 ± 3.03, $p = 0.01$), percentage of full-time workers (59% vs 75%, $p = 0.04$), and median (IQR) gestational week when reporting the PROs (32 [24, 35] vs 23 [16.25, 32], $p = 0.001$). Other variables including the frequency of comorbidities or pregnancy complications, spouse's support, gravidity counts, insurance status, and living condition did not differ between the two groups. Their scores for PROs are shown in Figure 1. CHB mothers had a significant impairment of the PROs ($p < 0.05$) in CLDQ domains with abdominal symptoms and worry. However, the PROs based on SF-36 measurements of eight scales did not differ between groups, which included T-scores from the mental and physical component summary. In the multivariate analysis model, independent predictors of worse PROs in pregnant women were CHB infection, younger age, and lack of full-time employment. **Conclusion:** Pregnant mothers with CHB reported a significant HRQoL impairment from abdominal symptoms and worry when compared to healthy mothers. CHB infection, younger age, and lack of full-time employment are independent risk factors for worse PROs during pregnancy. Further interventions with consultation and patient support are warranted.

Figure 1. Comparison of CLDQ and SF-36 scores between CHB and healthy mothers



Disclosures: Calvin Pan Pan – Gilead: Grant/Research Support (research funding from ineligible companies should be disclosed by the principal or named investigator even if that individual's institution receives the research grant and manages the funds), No, No;

1345-C | CLINICAL IMPACT OF CONTINUATION VERSUS CESSATION OF ANTIVIRAL THERAPY IN HEPATITIS B "E" ANTIGEN-NEGATIVE CHRONIC HEPATITIS B: A MODELING STUDY WITH IMPLICATIONS FOR HEPATITIS B CURE

Amir M Mohareb[1], Ghideon Ezaz[2], Arthur Y Kim[3], Kenneth A. Freedberg[1], Anders Boyd[4] and Emily P Hyle[1], (1)Massachusetts General Hospital, (2)Mount Sinai Hospital, (3)Massachusetts General Hospital and Harvard Medical School, (4)Public Health Service of Amsterdam

Background: The AASLD HBV guidelines differ from other international HBV guidelines in recommending against stopping antiviral therapy in people with HBeAg-negative infection. Our objectives were to project long-term outcomes of treatment continuation versus cessation and to determine the threshold of HBsAg loss needed to counter the risks of cessation. **Methods:** We developed a Markov model of HBeAg-negative people with undetectable DNA receiving antiviral therapy in the US (age at model start, 51y). We simulated 4 strategies: (1) treatment continuation (Continue) and 3 cessation strategies in which treatment is stopped and then reinitiated within 5y for: (2) virologic relapse (Restart_VR); (3) clinical relapse (Restart_CR); or (4) hepatitis flare (Restart_HF). We simulated virologic relapse as an exponential decay function fit to observational data (65% incidence in 5y) with subsequent risk of clinical relapse and hepatitis flare. We estimated annual incidence on/off antiviral therapy of cirrhosis (0.3%/0.6%) and HCC (0.1%/0.25%) among people who remain HBsAg-positive. Following cessation, HBsAg loss occurs in 6-8% within 5y. Individual's with HBsAg loss have lower age-adjusted mortality and are assumed to have no incident cirrhosis or HCC. We projected cumulative incidence of HBsAg loss, cirrhosis, HCC, and life years from model start. We conducted one-way sensitivity analyses on cirrhosis/HCC incidence among people who remain HBsAg-positive off antiviral therapy (range, 0.4–1.5x base case) and incidence of HBsAg loss following antiviral cessation (range, 6-70% within 5y). **Results:** Treatment continuation would result in 13.0% cumulative incidence of HBsAg loss and an average of 28.41 life-years gained from model start (Table). Antiviral cessation strategies would more than double lifetime HBsAg loss compared with Continue. However, the cumulative incidence of cirrhosis and HCC would be higher following cessation. Survival would be lower at all time points with each of the antiviral cessation strategies compared with continuation. In sensitivity analysis, Continue would be preferred over Restart_VR unless off-therapy cirrhosis/ HCC incidence for people who

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

remain HBsAg-positive is less than 0.6x the base case (i.e., approaching the on-therapy incidence). In sensitivity analysis, Restart_VR would be preferred to Continue only when the probability of HBsAg loss surpasses a threshold of 46% among people stopping treatment, given other base case estimates. **Conclusion:** Continuing antiviral therapy would result in improved survival in people with HBV despite lower rates of HBsAg loss. These results support current AASLD guidelines, which generally discourage treatment cessation in chronic HBV. Novel therapies aimed at HBV cure would need to provoke higher rates of HBsAg loss than currently observed following cessation to have a survival benefit over treatment continuation.

Table: Model input parameters and simulated clinical outcomes associated with continuation versus cessation of antiviral therapy in people with HBeAg-negative chronic HBV with undetectable HBV DNA in the US

Model Input Parameters	Base Case Incidence Rate, events per 100 person-years		
Population	HBsAg Loss	Cirrhosis	HCC
HBsAg+ on Antiviral Therapy	0.5[1]	0.3[2]	0.1[2]
HBsAg+ off Antiviral Therapy	1.0[3]	0.6[4]	0.25[5]
HBsAg-negative	N/A	0%	0%
Model-Simulated Outcomes	**Clinical Outcomes Over Lifetime**		
Strategy	HBsAg Loss, cumulative	Cirrhosis, cumulative	HCC, cumulative	Life Years (from age 51y)
(1) Continue	13.0%	7.6%	4.7%	28.41
(2) Restart_VR	23.1%	9.5%	6.4%	28.00
(3) Restart_CR	25.7%	10.2%	7.0%	27.81
(4) Restart_HF	27.8%	11.1%	7.7%	27.72

1346-C | CONCURRENT NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) IN CHRONIC HEPATITIS B (CHB) HAS NO ADDITIVE EFFECT ON FIBROSIS PROGRESSION AND HEPATOCELLULAR CARCINOMA (HCC) DEVELOPMENT

Ngai-Moh Law, Yong Loo Lin School of Medicine, National University of Singapore; Changi General Hospital

Background: Concurrent Non-Alcoholic Fatty Liver Disease (NAFLD) among patients with Chronic Hepatitis B (CHB) is becoming a significant clinical problem with increasing NAFLD prevalence. The direct fibrotic effect of NAFLD in CHB leading to cirrhosis and development of Hepatocellular Carcinoma (HCC) despite antiviral therapy remained unexplored. **Methods:** We studied the presence of NAFLD among our CHB patients who are on long term follow up for a period of ten years. We risk stratified CHB patients based on fibrosis score on Transient Elastography (TE) with liver function test and measurement of HBV viral load at point of entry. We examined the development of NAFLD during the follow up period and correlated with progression of fibrosis and development of HCC. All patients had baseline TE and liver function test done at entry point of screening. Those with TE cut-off reading of $>=9.5$ kPa were considered as significant fibrosis i.e.F2 and above with antiviral treatment initiated. All patients were on regular six monthly follow up with blood tests and ultrasound of liver for detection of NAFLD and HCC surveillance. Repeat TE measurement to assess progression of liver fibrosis if indicated. Detection of NAFLD was based on conventional ultrasound criteria. Detection of HCC was confirmed by radiological imaging and serum alpha-fetoprotein. **Results:** 486 patients were included (mean age 54, range 25 to 85). 78 patients had LSM $>=9.5$kPa i.e., significant liver fibrosis. Among these patients, 27 had developed superimposed fatty liver with 2 HCC detected. In contrast, 51 patients had significant fibrosis without NAFLD and 9 had HCC during the 10 years follow up period, Chi-square statistic $=1.528$, p value $=0.22$, (NS at $p<0.05$). **Conclusion:** Our study showed that the prevalence of NAFLD among high risk CHB patients was 35%. Development of NAFLD did not increase the fibrosis staging if antiviral therapy was initiated. In addition, there is no increased risk of developing HCC even if patient has developed NAFLD during the follow up period.

Disclosures: The following people have nothing to disclose: Ngai-Moh Law

1347-C | COUNTRY-SPECIFIC SCREENING, PREVALENCE, AND IMMUNITY RATES FOR HEPATITIS B INFECTION IN THE UNITED STATES

Matt Sumethasorn[1], Christopher Wong[2], Norah Terrault[2] and Kali Zhou[3], (1)LAC+USC Medical Center, (2)University of Southern California, (3)University of Southern California, Los Angeles, CA

Background: Desegregated rates of hepatitis B virus (HBV) screening and prevalence in the United States (US) by birth country are largely unknown. This study provides current epidemiologic estimates of country- and region-specific HBV screening, prevalence, and immunity rates in a large US cohort enriched for foreign-born persons. **Methods:** Adults ≥ 18 with at least two outpatient primary care visits and a self-reported country of birth in the Los Angeles County Department of Health Services healthcare system from 2017 to 2021 were included. Country- and region-specific HBV screening rates were estimated as the proportion tested for HBsAg from all eligible persons. Age-adjusted HBV

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prevalence rates were estimated as the proportion with a positive HBsAg among screened. Among those who tested negative for HBsAg between ages 19-59, we examined frequency of HBsAb testing and HBV immunity rates defined as a HBsAb titer ≥ 12 U/L. Countries were grouped into six World Health Organization regions; countries with < 100 persons screened were only included in regional analyses. **Results:** The cohort included 202,868 adults from 174 unique countries; 86.2% from Region of the Americas, 6.8% from Western Pacific, 2.7% from European, 2.4% from Eastern Mediterranean, 1.1% from South-East Asian, and 0.8% from African Regions. Overall, 41.8% (41.5-42.0%) were screened for HBV and age-adjusted HBV prevalence was 0.9% (0.9-1.0%). 57.9% (57.6-58.3%) of uninfected had HBsAb testing, of which 29.9% (29.5-30.3%) were HBV immune. 40.3% (39.9-40.6%) of US-born were screened with HBV prevalence of 0.4% (0.3-0.5%) and immunity rates of 36.0% (35.3-36.7%); 42.7% of all foreign-born were screened with prevalence of 1.2% (1.1-1.3%) and immunity rates of 26.7% (26.2-27.2%). Rates of HBV screening were < 45% across all regions, with > 50% screened in only 2 countries. Prevalence varied from 0.3% in the Region of the Americas to 6.6% in the Western Pacific Region. ≥ 5% prevalence was observed among immigrants from Cambodia, China + territories, Ethiopia, North Korea, Myanmar, Nigeria, Thailand, and Vietnam (Figure). HBV immunity rates ranged from 9.1% (0.2-42.3%) from Chile to 77.8% (57.7-91.4%) from Myanmar. **Conclusion:** Suboptimal HBV screening and immunity across countries of birth suggest that previous strategies of risk-based screening failed to adequately identify those with HBV infection. Our data supports the recent CDC guideline shift to universal HBV screening and vaccination.

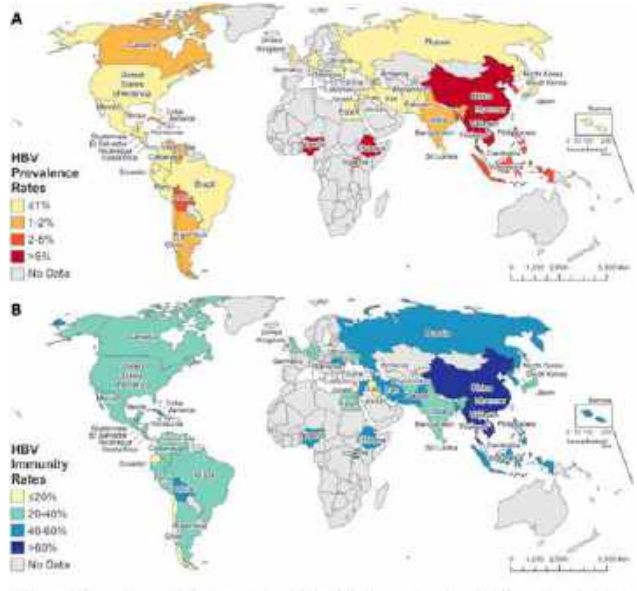

Figure 1. Prevalence of HBsAg positivity (A) and HBV immunity rates (B) by country of birth

1348-C | CROSS-CULTURAL COMPARISON OF DEMOGRAPHIC AND CLINICAL FACTORS OF KOREAN-AMERICAN AND KOREAN PATIENTS WITH CHRONIC HEPATITIS B

Hee-Soon Juon[1], Daniel Yang[1], Hie-Won L. Hann[2], Neung Hwa Park[3], Mimi Chang[4], Ho Bae[4] and Ann Klassen[5], (1)Thomas Jefferson University, (2)Thomas Jefferson University Hospital, Philadelphia, PA, (3) Ulsan University Hospital, (4)Coalition of Inclusive Medicine, (5)Drexel University

Background: Despite the high incidence of liver cancer related to hepatitis B virus (HBV) infection among foreign born Koreans, few studies have explored the differences in factors between immigrant Koreans and Koreans in host country. The purpose of this study is to describe and compare the sociodemographic and clinical characteristics between Korean American patients and Korean patients in South Korea living with chronic hepatitis B (CHB). **Methods:** We used data from two retrospective cohorts of CHB patients of Korean Americans (KAs) and South Koreans. Retrospective Medical Charts of the two cohorts were reviewed from 2016 to 2020. Categorical variables were compared using the Chi-square test and the Fisher test; continuous variables were compared using t-test. **Results:** Of a total of 1,194 patients (365 Korean Americans and 829 Koreans in South Korea), there were significant differences in age, gender, BMI, and health insurance status: KAs were older, were more likely to be female, and had a higher BMI than Koreans. About 92% of KAs had any types of health insurance, while all Koreans had national health insurance (100%). KAs were diagnosed with HBV for longer mean years compared to Koreans (28.43 years vs 14.35 years, $p < 0.001$). About 75% of KAs and 100% of Koreans had antiviral therapy ($p < 0.001$). KAs had higher rates

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of non-alcoholic fatty liver disease (NAFLD) than Koreans (34% vs. 21.6%, $p < 0.001$). KAs also had higher rates of hypertension (33.7% vs 13.5%, $p < 0.001$) and hyperlipidemia (35.6% vs 8.2%, $p < 0.001$) than Koreans. In contrast, Koreans had higher rates of liver cirrhosis than KAs (40% vs. 13.7%, $p < 0.001$). **Conclusion:** Intra-ethnic differences in demographic and clinical characteristics were found between KAs and South Koreans. Because unfamiliar sociocultural and clinical factors may influence the treatment of CHB, cultural differences and language barriers should be considered in CHB management strategies for Asian immigrants in the United States.

Table. Demographic and Clinical Characteristics of Korean American and Korean CHB patients (n =1,194)

Variable	Korean American cohort (n=365)	Korean cohort (n=829)	P-value
	N (%)	N (%)	
Age (mean±SD, range)	60.06±10.84 (39-84)	55.94±9.87 (23-87)	<.001
Median (Q1, Q3)	62 (53,67)	57 (50-63)	
Gender			.011
-Men	203 (55.6%)	521 (62.8%)	
-Women	162 (44.4%)	308 (37.2%)	
Having health insurance (=yes)	337 (92.3%)	829 (100%)	<.001[†]
BMI (mean±SD)	26.68± 4.82	23.79± 3.15	<.001
Median (Q1, Q3)	25.70 (23.40, 30)	23.63 (21.64,25.59)	
Time since HBV diagnosis (year) (mean±SD, range)	28.43 ±9.76	14.35 ±4.95	<.001
Median (Q1, Q3)	30 (22,36)	14 (11,17)	
Taking antiviral medication (=yes)	283 (77.5%)	829 (100%)	<.001[†]
NAFLD (=yes)	124 (34.0%)	178 (21.6%)	<.001
Liver cirrhosis (=yes)	50 (13.7%)	332 (40.0%)	<.001
Diabetes (=yes)	56 (15.3%)	117 (14.1%)	.578
Hypertension (=yes)	123 (33.7%)	111 (13.5%)	<.001
Hyperlipidemia (=yes)	130 (35.6%)	67 (8.2%)	<.001

1349-C | DELAYED DIAGNOSIS OF CHRONIC HEPATITIS B VIRUS (HBV) INFECTION INCREASES THE RISK OF HEPATOCELLULAR CARCINOMA (HCC): A TERRITORY-WIDE STUDY

Grace Lai-Hung C Wong[1], Vicki Wing Ki Hui[1], Yee-Kit Tse[1], Vincent Wai-Sun Wong[2] and Terry Cheuk-Fung Yip[1], (1)The Chinese University of Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, China

Background: World Health Organization (WHO) proposes to reduce of chronic viral hepatitis incidence and mortality of 90% and 65% respectively by 2030. Early diagnosis of chronic hepatitis B virus (HBV) infection is one of the cornerstones to reduce mortality by offering timely antiviral treatment and surveillance for complications. We aimed to incidence of delayed HBV diagnosis and the clinical outcomes of such patients. **Methods:** This was a territory-wide retrospective observational cohort study in Hong Kong. We identified subjects who had hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg), and HBV DNA checked in 2000-2022. Patients who had negative HBV results initially, then positive HBV results later were defined to have delayed HBV diagnosis. Incidence of hepatocellular carcinoma (HCC) was compared in patients who did or did not have delayed HBV diagnosis. **Results:** We identified 1,684,821 subjects who had HBV checked in 2000-2022, and 256,822 (15.2%) had positive results; of whom 10,015 (3.9%) had delayed HBV diagnosis. Delayed HBV diagnosis was more commonly observed in patients who had their first HBV assay performed in 2000-2010 compared to whose done in 2011-2022 (Figure). The patients were younger (median age 51 vs. 56 y), more likely to be men (49.9% vs.43.7%) and had higher 10-year incidence rate of HCC was 41.6% (95% CI 40.3%-42.9%) vs. 34.4% (95% CI 34.2%-34.7%) in patients who had delayed HBV diagnosis compared to those who did not have delayed HBV diagnosis (all $p < 0.001$). **Conclusion:** A small yet non-negligible proportion of patients had delayed HBV diagnosis, which is linked to higher risk of HCC. Repeated tests with more sensitive HBV assays should be offered to patients who are at risk of chronic HBV infection, in order to achieve early diagnosis, timely antiviral treatment and reducing HCC and hence mortality.

1350-C | DIFFERENCES IN LIVER DISEASE PROGRESS OF CHRONIC HEPATITIS B PATIENTS OF TWO COHORTS OF KOREAN AMERICAN AND SOUTH KOREAN

Hee-Soon Juon[1], Hie-Won L. Hann[2], Neung Hwa Park[3], Mimi Chang[4], Ho Bae[4], Daniel Yang[1] and Ann Klassen[5], (1)Thomas Jefferson University, (2)Thomas Jefferson University Hospital, Philadelphia, PA, (3) Ulsan University Hospital, (4)Coalition of Inclusive Medicine, (5)Drexel University

Background: In the treatment of chronic hepatitis B, patients were closely monitored their liver disease progress such as liver fibrosis, liver cirrhosis, or non-alcoholic fatty liver disease (NFALD). We aimed to describe and compare disease progression with two cohorts with chronic hepatitis B (CHB): Korean Americans and Koreans in South Korea. **Methods:** We used data from two cohorts of CHB patients: Korean Americans (KAs) and Koreans in South Korea. Retrospective medical histories from 2016-2020 of the two cohorts were reviewed. The binary outcomes of liver disease severity were included liver fibrosis (measured by FIB-4 > 2.67), diagnosis of liver cirrhosis, and NAFLD. Multiple logistic regression was used to examine the differences of cohort after controlling age, gender, education, marital status, current drinking, BMI, time since HBV diagnosis (years). **Results:** Among 827 CHB patients (365 Korean Americans and 462 Koreans), KAs had higher rates of NAFLD than Koreans (34% vs. 21.4%, $p < 0.001$). In contrast, Koreans had higher rates of liver cirrhosis than KAs (42.2% vs. 13.7%, $p < 0.001$). There were no differences in FIB-4. In multivariate analysis, KAs had higher odds of having NAFLD than Koreans (aOR = 2.15, 95% CI: 1.34-3.47). In contrast, Koreans had higher odds of having liver cirrhosis than KAs (aOR = 6.41, 95% CI: 3.65-11.24). In addition, BMI and education were associated with NAFLD, while age and current drinking were associated with liver cirrhosis. **Conclusion:** Intra-ethnic differences in liver disease progress were found between KAs and Koreans. Because these differences in clinical characteristics may influence the treatment of CHB, clinicians should consider different CHB management strategies for KA cohort and Korean cohort.

Table 1. Comparison of liver disease severity of two cohorts of chronic hepatitis B patients: Korean Americans and Koreans in South Korea (n=827)

	Korean Americans N=365	Koreans N=462	p-value
	N(%)	N(%)	
Liver fibrosis (FIB-4 >2.67)	40 (11.2%)	60 (14.0%)	.238
NAFLD (=yes)	124 (34.0%)	98 (21.4%)	<.001
Liver cirrhosis (=yes)	50 (13.7%)	195 (42.2%)	<.001

Figure 1. Comparison of two cohorts: results from multivariate analysis (n=827), 2020

1351-C | EFFICACY AND SAFETY OF TENOFOVIR ALAFENAMIDE FUMARATE VERSUS TENOFOVIR DISOPROXIL FUMARATE IN PREVENTING MOTHER-TO-CHILD TRANSMISSION OF HBV: A PROSPECTIVE COHORT STUDY

Liuqing Yang[1], Li Zhang[2] and Yingxia Liu[1], (1)The Third People's Hospital of Shenzhen, (2)Fudan University

Background: Tenofovir disoproxil fumarate (TDF) is most commonly used for pregnant women in preventing mother-to-child transmission (MTCT) of HBV in the world. However, tenofovir alafenamide fumarate (TAF) has been gradually initiated for preventing MTCT due to its better safety profile. This head-to-head study aimed to compare the efficacy and safety of TAF and TDF for the prevention of MTCT of HBV. **Methods:** Pregnant women with chronic HBV infection and high viral load (HBV DNA e 200,000 IU/ml) were enrolled from January 2019 to January 2022 in The Third People's

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Hospital of Shenzhen. They could choose to receive TDF 300 mg/d or TAF 25 mg/d from gestational weeks 24–32 until delivery. Infants received immunoprophylaxis. All mothers and infants were followed up at postpartum month 1, 7, 12. The primary efficacy endpoints were the decrease in viral load and MTCT rates at month 7~12. The primary safety endpoints were the changes in liver and renal function of mothers, the infants' growth parameters. **Results:** There were 66 mothers in TAF group and 115 mothers in TDF group respectively. A total of 181 infants were delivered, all of whom were single births. 137 mothers and infants completed 12 months follow-up. The levels of HBV-DNA decline in TDF-treated mothers were compared with those in TAF-treated mothers before delivery (3.56 log10IU/ml vs 3.13 log10IU/ml, $p > 0.05$). The HBsAg positive rate was 0% in all infants. The TAF group was well tolerated during treatment. No adverse events such as cholestasis or renal impairment, and none of them reported drug related nausea and vomiting. However, 10 cases of gastrointestinal discomfort were reported in TDF group, but they did not discontinue or switch until delivery. In TAF group, 6 mothers had ALT elevation after delivery and restarted TAF treatment; in TDF group, 10 mothers had ALT elevation after delivery and 8 of them restarted TAF treatment. All mothers returned to normal ALT. Additionally, no significant differences were observed for serum creatinine levels between two groups. No congenital defects, malformations or neurodevelopmental disorders occurred in the infants of both groups. There was no significant difference in height, weight and head circumference between the two groups at postpartum month 12 and all were in the normal range. **Conclusion:** The efficacy and safety of TAF for the prevention of MTCT of HBV were similar with TDF.

Table. Infants' growth parameters between TAF group and TDF group

Parameters	TAF (n=57)	TDF (n=77)	p value
At 1 month			
Weight, kg	4.38±0.58	4.27±0.51	0.208

1352-C | EPIDEMIOLOGY OF HEPATITIS B VIRUS INFECTION IN ENDEMIC AREA OVER THE PAST 15 YEARS AND THE INFLUENCE OF COVID-19 INFECTIONS

Jeong-Ju Yoo, Soonchunhyang University Bucheon Hospital, Dong Hyeon Lee, Seoul National University, Jae Young Jang, Soonchunhyang University College of Medicine and Log Young Kim, National Health Insurance Service

Background: The purpose of this study is to investigate the epidemiological changes of chronic hepatitis B (CHB) and the impact of COVID-19 over the past 15 years in Korea, an HBV endemic area. **Methods**: We used the National Health Insurance Service claims data on hepatitis B patients from 2007 to 2021. In addition, in order to compare the characteristics of the hepatitis B group, a 4-fold control group adjusted for age and gender was set using the propensity score matching analysis. **Results**: Excluding the COVID period, the number of patients with CHB has continuously increased for 15 years. The average age of the CHB patient group increased every year, and the male dominance pattern gradually decreased. In addition, the proportion of patients taking antiviral drugs increased in both men and women. When classified according to the severity of liver disease, the proportion of hepatocellular carcinoma (HCC), liver cirrhosis, and decompensation showed a decreasing trend, while the proportion of liver transplants continuously increased. Patients with CHB had significantly higher medical and drug costs than the control, especially when they developed decompensation, HCC, or liver transplantation. Patients with CHB had more comorbidities such as osteoporosis, chronic kidney disease, and diabetes than the control, and the rate of taking concomitant medication was significantly higher. During the COVID period, the number of outpatient visits and overall medical costs in the HBV group significantly decreased compared with control. **Conclusion**: The epidemiology of chronic hepatitis B in HBV endemic area has changed over the past 15 years in terms of prevalence, severity, medical costs, and comorbidities. In addition, COVID-19 showed an effect of reducing healthcare utilization in patients with chronic hepatitis B compared to controls.

1353-C | EPIDEMIOLOGY, TREATMENT PATTERN, AND SURVIVAL IN CANADIAN PATIENTS WITH CHRONIC HEPATITIS B RELATED HEPATOCELLULAR CARCINOMA

Yashasavi Sachar[1], Carla S. Coffin[2], Abdel-Aziz Shaheen[2], Anna Manko[3], Stephen E. Congly[3], Alnoor Ramji[4], Sheikh Rahman[1], John Talia[5], David Kah Heng Wong[6], Scott K. Fung[7], Curtis Cooper[8], Mang M. Ma[9], Jeyani Jeyaparan[1], Robert Bailey[10], Gerald Y. Minuk[11], Alexander Wong[12], Karen E. Doucette[9], Magdy Elkhashab[13], Philip Wong[14] and Mayur Brahmania[3], (1) University of Western Ontario, (2)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, (3)University of Calgary, (4)University of British Columbia, (5)University of Toronto, (6)Department of Medicine, University of Toronto, Toronto, ON, Canada, (7)Toronto General Hospital, Toronto, Ontario, Canada, (8)The Ottawa Hospital, Ottawa, ON, Canada, (9) Department of Medicine, University of Alberta, Edmonton, AB, Canada, (10)Bailey Health Center, Edmonton, AB, Canada, (11)Department of Internal Medicine, University of Manitoba, MB, Canada, (12) University of Saskatchewan, (13)Toronto Liver Center, Toronto, Ontario, Canada, (14)Department of Medicine, McGill University Health Centre, Montreal, QC, Canada

Background: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and the second-most frequent cause of malignancy-associated death. Chronic hepatitis B (CHB) infection is the leading cause of developing HCC. We aimed to describe and evaluate the outcomes of CHB-HCC patients in Canada, addressing a paucity of such data in large North American patient populations. **Methods:** Data was collected from January 1, 2012, to December 31, 2022, from a cross-sectional cohort of subjects mono-infected with CHB and HCC (per AASLD guidance) from the Canadian HBV Network - a national consortium involving 10 Canadian provinces and 19 academic and community hospitals. Descriptive analysis and Chi-square modeling were used to develop statistical outcomes for the comparison of cohorts. Statistical analyses were done in R (version 4.1.1). **Results:** Of the 6711 CHB patients who met inclusion criteria, 232 (3.5%) developed HCC. The median age for the HCC cohort was 65 years (IQR 57-73) with a population of 80% male and 71% Southeast Asian (SEA) patients. The HCC cohort had a median HBV DNA of log 3.67 IU (IQR1.86-5.62), and 16% of HCC patients had a positive HbeAg status (vs 47% in the CHB group, $p < 0.0001$). Relative to the CHB cohort, the CHB-HCC cohort had a higher proportion of male (80% vs 55%; $p < 0001$) and SEA patients (71% vs 55%; $p < 0001$). A greater number of HCC patients were born in an endemic region (63% vs 40%; $p < 0001$). 92% of HCC patients had advanced liver disease (minimum Fibrosis Stage 3 or known diagnosis of cirrhosis). A greater proportion of HCC patients underwent antiviral treatment with Tenofovir (50.9% vs 19.7%; $p < 0.0001$), Lamivudine (19.8% vs 12.2%; $p = 0.0012$), and Entecavir (23.3% vs 5.8%, $p < 0.0001$). HCC patients were followed for a median 15 months (IQR 2-69) prior to diagnosis, and a median 41 months (IQR 19-87) post-diagnosis. 53% of patients were diagnosed with HCC as part of surveillance protocols. The median lesion number was 1(IQR 1-1), with a median lesion size of 2.5cm (IQR 1.7-4.0). HCC diagnoses skewed towards early-stage BCLC 0-A disease (81%). There was an overall 84% survival rate post-HCC diagnosis during follow-up. Overall, 38% of patients received ablation, 16% received TACE, 25% underwent resection, 17% underwent a liver transplant, 8% required systemic therapy, and 6% received palliative therapy. Patient treatment was compared to recommendations per BCLC with an 82% treatment concordance. **Conclusion:** In this large multi-ethnic cohort of patients with CHB-HCC, the majority of patients were detected with early-stage HCC and received treatment with curative intent, resulting in excellent survival rates, likely driven by surveillance practices in tertiary centers.

1354-C | EVALUATION OF HEPATITIS D SCREENING PATTERNS AND OUTCOMES AMONG HEPATITIS B PATIENTS IN AN ACADEMIC MEDICAL CENTER

Dilara Hatipoglu, Massachusetts General Hospital, Philadelphia, PA and Raymond T. Chung, Massachusetts General Hospital and Harvard Medical School

Background: Coinfection of hepatitis D virus (HDV) and hepatitis B virus (HBV) is associated with more severe outcomes compared to monoinfection. Consistent screening and care are essential to identify this patient population, especially in light of recent treatment advancements. **Methods:** This study utilized data from the Mass General Brigham Research Patient Data Registry, focusing on a cohort of patients with hepatitis B who were screened for hepatitis D at Massachusetts General Hospital between 2011 and 2021. Manual chart review was conducted to collect relevant data, and statistical analysis was performed using unpaired t-tests. **Results:** Among 7,861 patients with chronic hepatitis B; only 737 (9.4%) were screened for hepatitis D. Of 641 reviewed patients, 48% were tested for HDV antibody only, 37% for HDV RNA only, 14% for both antibody and RNA, and the remainder tested with IgM antibody and antigen. There were 32 (4.9%) patients diagnosed with hepatitis D. Screening strategies used in this group included 28% HDV antibody only, 16% HDV RNA only, 53% antibody and RNA, and 3% for IgM antibody and RNA. Among those tested for HDV antibody and RNA, 44% tested positive for both. Interferon treatment was administered to five patients (16%), two had sustained response, 1 failed treatment, and two discontinued due to side effects. Comparing outcomes between HDV positive and negative patients, no significant difference in mortality (12.5% vs. 11.7%, $p = 0.89$, CI -0.12 to 0.11) or rates of hepatocellular carcinoma (12.5% vs. 7%, $p = 0.26$, CI -0.15 to 0.039) was observed. However, higher rates of cirrhosis (43.8% vs. 19.4%, $p = 0.0009$, CI -0.39 to -0.10) and hepatitis C co-infection (46.9% vs. 18.4%, $p < 0.0001$, CI -0.43 to -0.14) were found in patients with chronic hepatitis D. Interestingly, patients with HDV were less likely to fit HDV screening recommendations outlined by the AASLD guidelines (75% vs. 92%, $p = 0.0013$, CI 0.065 to 0.27). Fibrosis screening rates, including liver biopsy, elastography, or Fibrotest, were similar between the two groups (50.0% vs. 49.9%, $p = 0.99$, CI -0.18 to -0.178). **Conclusion:** This study highlights the lack of screening for HDV and variability in screening decision-making and serology selection for hepatitis D within a single hospital system. Given the disparity in outcomes among patients with HDV infection, the establishment of more standardized screening guidelines is crucial to

1355-C | FEASIBILITY AND EFFECTIVENESS OF REFLEX TESTING IN PERFORMING HEPATITIS DELTA SEROLOGY IN HBSAG+ PATIENTS

Albert Tran, Anne De Monte, Valerie Giordanengo, Regine Truchi and Laurence Ollier, Archet Hospital

Background: Several studies have shown that screening for the hepatitis Delta virus (HDV) was not optimal: between 30 and 50% in HBsAg positive patients (HBsAg+). The virology laboratory of the Nice University Hospital Center (CHU) has been carrying out HDV reflex testing (HDV RT) for several years in patients with HBsAg+ screening. **Methods:** This work assesses the feasibility and effectiveness of HDV RT within the different departments of our University Hospital. HDV RT consists of systematically adding HDV serology to HBsAg+ patients if the latter was not requested by the prescriber. In the event of an insufficient quantity of sample, the virology laboratory contacts the clinical department to obtain a second sample in order to carry out HDV screening. **Results:** From 01/01/2021 to 12/31/2021, 17364 HBsAg screenings were carried out at the CHU. 182 HBsAg screenings were positive, corresponding to 138 patients (58 F and 80 M). 80 among 138 patients (58%) were screened for the first time at the CHU and 58 patients (42%) were already known to be positive. Among the 80 HBsAg+ patients screened for the first time in our center, HDV serology was immediately prescribed by the department for 12 patients (15%). HDV serology could be added to the first sample for 38 patients (47%) and performed after obtaining a second sample for 18 patients (23%). Thus, 68 of the 80 HBsAg+ patients (85%) had an HDV serology result available, including 56 following reflex testing carried out by the virology laboratory. The operating procedure of the HDV serology is carried out by the different CHU departments is shown in the figure below. Among these 68 HBsAg+ screened for HDV, HDV serology was positive for 4 patients (6%), with HDV replication detected in 3 of them. Concerning the 58 patients already known to be HBsAg+ at the CHU, HDV serology was already available or prescribed from the outset for 49 patients (85%). The reflex testing made it possible to search for co-infection with HDV for 7 additional patients (12%), with a total of 97% of patients screened for HDV. **Conclusion:** HDV reflex testing is feasible at the level of an university establishment and makes it possible to optimize the search for HDV co-infection in different departments, including departments not specialized in the management of viral hepatitis.

Background: Antiviral therapy is effective in suppressing hepatitis B virus (HBV) replication and reducing hepatocellular carcinoma risk. However, studies on adherence to guidelines for HBV treatment globally are sparse. We aimed to determine the treatment evaluation, eligibility, and initiation rates of patients with chronic hepatitis B (CHB) in a real-world multinational patient cohort using the American Association for the Study of Liver Diseases (AASLD) guidelines for HBV. **Methods:** We performed a retrospective cohort study of treatment-naïve patients with CHB in the REAL-B registry, an observational chart review registry at 26 study centers (Japan, Korea, Hong Kong, Taiwan, Singapore, US, Spain, Romania, and Argentina). We then determined the proportions of patients who received complete evaluation (HBV DNA, ALT, and HBeAg), subsequently met AASLD treatment criteria, and initiated treatment at any time during the study period. We also identified factors associated with receiving complete evaluation and treatment using multivariable Cox regression analysis. **Results:** We included 12,692 adult patients with treatment-naïve CHB: 58.3% male, mean age 47.1 ± 13.7 years, 95.0% Asian, 50.2% from Asia, and 8.6% with baseline cirrhosis. Overall, 28.7% (3641 patients) of the cohort received complete evaluation. Among those with complete evaluation, 22.8% (831 patients) met AASLD treatment criteria, and 78.5% of these treatment-eligible patients initiated antiviral therapy. Notably, there were significant disparities in both the evaluation and treatment rates by geographic region and ethnicity, with patients from non-Asia less likely to have complete evaluation compared to those from Asia (21.3% vs. 36.0%, $p < 0.001$) but more likely to initiate treatment (85.0% vs. 75.4%, $p = 0.001$). However, Asia Asian had a higher rate of complete evaluation compared to US Asian (36.0% vs. 18.6%, $p < 0.001$) but a lower rate of treatment initiation (75.4% vs. 84.5%, $p = 0.010$) (Figure 1). In

multivariable analysis adjusting for age, sex, and geographic region, patients from non-Asia were about 60% less likely than those from Asia to have complete evaluation (adjusted hazards ratio [aHR]: 0.44, 95% CI: 0.41-0.48, $p < 0.001$), but there was no significant association in antiviral therapy initiation by region (aHR: 1.08, 95% CI: 0.91-1.27, $p = 0.390$). **Conclusion:** In this multinational real-world study, we found significant geographic and ethnic differences in the treatment evaluation and initiation rates, likely reflecting differences in local practice and reimbursement policies. Additional studies with a larger geographic representation are needed to assess global CHB treatment landscape.

Figure 1. Treatment evaluation, eligibility, and initiation rates by (A) Asia and Non-Asia regions and (B) US Asian and Asia Asian at any time during study follow-up.

1357-C | HBV TREATMENT CAN REDUCE RISK OF KIDNEY DISEASE AMONG PATIENTS WITH HEPATITIS B, YET TREATMENT IN THE US REFLECTS INEQUITIES IN CARE

Kaori L Ito[1], Yuqing Zhang[1], Biao Li[1], Jinfeng Liu[1], Andrew King[2], Leland J. Yee[1], Frida Abramov[1], Catherine Frenette[1], John F. Flaherty[1] and Vladislav A

Malkov[1], (1)Gilead Sciences, Inc., (2)Scripps Clinic Torrey Pines

Background: Kidney disease (KD) can be comorbid with chronic hepatitis B virus (HBV) infection, and untreated HBV is associated with increased risk of KD (Ning et al., 2017). We used a large electronic medical record (EMR) database to examine whether patients with HBV are at greater risk for developing KD vs those without HBV and identified factors placing patients at risk. We also explored the effect of using oral antiviral (OAV) treatment on the risk of developing KD. **Methods:** Data were queried from the IQVIA Ambulatory EMR (2006–2020). Propensity score matching and Cox proportional hazards were performed for all comparisons. Time to development of KD was assessed in patients with/without HBV, where age of KD onset served as a proxy for time to KD. KD was defined as worsening of eGFR/UACR or ≥ 1 ICD code. Hypertension, diabetes, and obesity were evaluated as concomitant risk factors for KD. The association between KD and cirrhosis in untreated patients aged ≥ 55 years was evaluated using FIB-4 (≥ 3.25) and cirrhosis ICD codes. The risk of KD with OAV use was assessed in patients with HBV age ≥ 55 with HBV DNA, ALT, or liver disease codes. **Results:** Compared with matched controls, patients with HBV were more likely to develop KD (hazard ratio [HR], 2.18 [95% CI, 1.89, 2.50]). Most events occurred after age 55. Patients with HBV with comorbid risks were more likely to develop KD (HR, 1.99 [1.71, 2.30]; Figure). Neither cirrhosis nor FIB-4 score ≥ 3.25 was associated with KD (cirrhosis HR, 1.18 [0.65, 2.15]; FIB-4 HR, 1.21 [0.59, 2.52]). Treated patients were at lower risk of developing KD (HR, 0.61 [0.42, 0.88]) compared with untreated patients; however, only 17% of patients with HBV received treatment. Stratification analyses showed that African American (AA) patients were more likely to have at least 1 risk factor for KD (Figure) yet were underrepresented in the treated group; only 10% of AA and 11% of White patients with HBV received treatment, whereas 20% of Asian patients with HBV received treatment. **Conclusion:** Patients with HBV, especially older patients with comorbid risks, were at higher risk of developing KD relative to matched controls. KD was observed even in the absence of cirrhosis, suggesting that HBV infection may directly induce renal tissue injury. Our results show that OAVs may decrease the risk of developing KD in patients with HBV, yet inequities in treatment were observed. These results require further investigation.

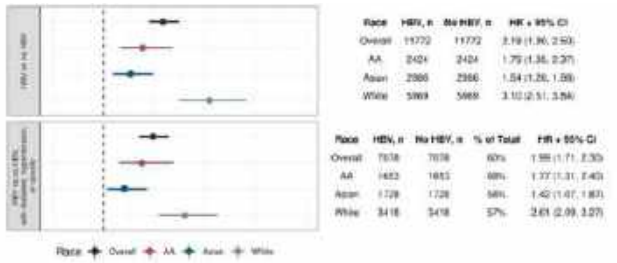

Figure. Hazard ratios for kidney disease in patients with and without chronic HBV by race. Patients with chronic HBV, particularly those with hypertension, diabetes, or obesity, were more likely to develop kidney disease.
AA, African American; HBV, hepatitis B virus; HR, hazard ratio. % in Total calculated as number of patients with hypertension, diabetes, or obesity within each race divided by total number of patients within each race category.

1358-C | HBV VIRAL REPLICATION MARKERS AND HEPATIC FIBROSIS IN UNTREATED CHRONIC HBV INFECTION WITH AND WITHOUT HIV COINFECTION IN ZAMBIA

Michael Vinikoor[1,2], Samuel Bosomprah[1], Edford Sinkala[3], Bright Nsokolo[4], Taonga Musonda[3], Kalongo Hamusonde[5], Debika Bhattacharya[6], Georg M. Lauer[7], Raymond T. Chung[8], Lloyd Mulenga[9], Gilles Wandeler[5] and Guy Muula[1], (1)Centre for Infectious Disease Research in Zambia, (2)University of Alabama at Birmingham, (3)University of Zambia, (4)Levy Mwanawasa Medical University, (5)University of Bern, (6)University of California, Los Angeles, (7) Massachusetts General Hospital and Harvard Medical School, (8)Massachusetts General Hospital, Harvard Medical School, (9)Zambian Ministry of Health

Background: To inform novel curative therapies for patients with HBV/HIV coinfection, a more nuanced understanding is needed of HIV's impact on hepatitis B virus (HBV) natural history. Prior analyses of HBV/HIV coinfection had small and selected groups of patients or occurred in the context of HIV cohorts with limited focus on liver endpoints. Because HBV and HIV care is often siloed, direct comparisons between people with coinfection and HBV monoinfection have been scarce. In adults in Zambia, we analyzed pre-therapy viral and liver markers of chronic HBV with and without HIV coinfection across a range of CD4 counts. **Methods:** In Lusaka, Zambia, where adult HIV prevalence is 12% and chronic HBV prevalence is 6%, we analyzed baseline data from an HBV clinical cohort study. Adults (18+ years) with chronic HBV infection, with and without HIV, prior to the start of antiviral therapy were included in analysis. To reduce selection bias created by later diagnosis (i.e., with advanced liver disease) of HBV versus HIV in Africa, we excluded participants with HBV diagnosed on clinical suspicion. We assessed HBV DNA levels, hepatitis B e antigen, CD4 (if coinfection), and liver disease (transient elastography [TE], serum alanine aminotransferase). In multivariable analyses, we evaluated the association of HIV overall and then we considered the level of CD4 count to assess heterogeneity. **Results:** Among 713 adult (>18 y) participants analyzed, the median age was 33 years, 63.0% were male, and 433 had HBV/HIV coinfection. HBV DNA was >2,000 IU/ml for 311 (51.0%) and 227 (32.5%) were HBeAg-positive. 15.5% had advanced fibrosis or cirrhosis. In coinfection, the median CD4 count was 200 cells/mm^3. HIV coinfection was overall associated with 5-fold increased HBV DNA levels (adjusted geometric mean ratio, 5.78; 95% confidence interval, 2.29-14.62) and 2 times the odds of HBeAg-positivity (adjusted odds ratio, 2.54; 95% CI, 1.59-4.08). However, these associations were significant only at CD4 counts 100-350 and <100 cells/mm^3 but not at CD4 >350. HIV was not associated with markers of fibrosis or ALT, either overall or by CD4 strata. **Conclusion:** In the context of HIV, acceleration of HBV natural history likely depends on the degree and duration of immune suppression. Thus, HBV immunity may be less affected in patients with HBV/HIV coinfection who started antiretroviral therapy at high CD4 count. A better understanding is needed of mechanisms of increased liver-related mortality in people with HBV/HIV coinfection.

1359-C | HEPATITIS DELTA VIRUS SUPERINFECTION INCREASES THE RISK OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC HEPATITIS B VIRUS

Mohamed I Elsaid[1], Khalid Mumtaz[2], Na Li[2], Demond Handley[1], Joanna Jianing[1], Bipul Gnyawal[1] and Vinod K. Rustgi[3], (1)The Ohio State University College of Medicine, (2)The Ohio State University, Wexner Medical Center, (3)Rutgers Robert Wood Johnson School of Medicine

Background: Hepatocellular Carcinoma (HCC) incidence and mortality continue to rise in the United States despite the declining trends in numerous other cancers. While the hepatitis delta virus (HDV) has been shown to increase the risk of adverse hepatic manifestations, research on the association between HDV and HCC risk has yielded mixed results. In addition, most of the research on this topic has focused on Chronic Hepatitis B Virus CHBV/HDV coinfection, with limited studies on HBV-HDV superinfection. We aim to examine the association between CHBV-HDV superinfection and the risk of HCC in patients with CHBV. **Methods:** Using the MarketScan® Commercial Claims databases from January 1, 2008, to December 31, 2017, we combine claims data from the inpatient admissions and outpatient services records to identify patients with CHBV using ICD-9 and 10 codes. HBV-HDV superinfected patients were defined as new HDV diagnoses over 90 days from the first date of CHBV diagnosis. HDV status was modeled as a time-varying covariate to account for the effects of the wait time between the date of CHBV diagnosis and the first record for HDV diagnosis. Inverse probability of treatment weighted Cox proportional hazard models were used to assess the adjusted risks of HCC for CHBV mono-infection versus CHBV-HDV superinfection. **Results:** The study included 36,689 adults with CHBV (53.7% males, average age 45 y), of which 1,633 had CHBV-HDV superinfection. The average time from CHB diagnosis to HBV-HDV superinfected was 26.2 months. During the study period, 201 patients developed HCC. The median follow-up was 19 months. The risk of HCC was significantly higher in super- vs. mono-infected patients (1.4% vs. 0.5%; $p < 0.001$). The incidence rate of HCC was more than 2.5-fold higher in super- vs. mono-infected patients (6.7 vs. 2.3 per 1000 Person-years %; $p < 0.001$). The adjusted risk of cirrhosis was significantly higher super- vs. mono-infected patients hazard ratio (HR) of 2.64 (95% CI 2.11–3.28). In the fully adjusted models, HDV superinfection was associated with a 93% increase in the risk of HCC (HR, 1.93; 95% CI, 1.20–2.97) relative to CHBV mono-infection. **Conclusion:** Our comprehensive analysis of a large commercial claims database suggests a markedly increased risk of HCC in patients with CHBV-HDV superinfection compared to those with CHBV mono-infection. These findings underscore the crucial importance of early diagnosis, surveillance, and targeted intervention strategies for HBV-HDV superinfected patients.

1360-C | HIGH RISK, HIGH REWARD: EVALUATING THE FREQUENCY OF GUIDELINE-BASED HEPATITIS B SCREENING IN THE HIGH-RISK GROUP FOR HBV REACTIVATION PRIOR TO IMMUNOSUPPRESSIVE THERAPY

Joanne Lin[1,2], Humzah Iqbal[1], Jennifer Yoon[1], Alakh Gulati[1], Ratnali Jain[1] and Marina M. Roytman[1], (1)UCSF Fresno, (2)Temple University

Background: Hepatitis B virus reactivation (HBVr) is a syndrome associated with significant morbidity and mortality, reflecting the loss of immune control of the infection which can be due to stopping antiviral therapy or starting immunosuppressive medication. Immunosuppressive therapies are used in the management of many rheumatologic and dermatologic conditions, malignancies, and inflammatory bowel diseases. Multiple guidelines recommend screening for chronic hepatitis B (HBV) prior to initiating immunosuppressive drug therapy. Adherence to these guidelines in clinical practice is variable. We sought to determine the frequency of complete guideline-based HBV screening prior to the initiation of immunosuppressive therapy in patients in the high-risk group based on the American Gastroenterological Association (AGA) classification. **Methods:** Our retrospective study included 305 patients over the age of 18 taking high-risk immunosuppressive therapy, which included B cell-depleting agents and anthracycline derivatives, from October 2020 to April 2021. Patients prescribed high-risk doses and duration of steroid therapy were not included. The following data were collected: gender, age, complete HBV serologies (hepatitis B surface antigen [HBsAg], hepatitis B core antigen

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

[anti-HBc], hepatitis B surface antibody [anti-HBs]), the immunosuppressive regimen, and the indication for immunosuppression. **Results:** Of the 305 patients, 45.6% were over the age of 65 and 68.9% were females. The most frequently used immunosuppressive therapy was rituximab (64.3%), followed by doxorubicin (26.2%), 2 or more medications (8.2%), ofatumumab (1%) and epirubicin (0.3%). The specialties that prescribed immunosuppressive therapies most often were hematology/oncology (63.3%), rheumatology (22.6%), neurology (7.9%), dermatology (3.3%), and 2 or more specialties (3%). Only 83 patients (27.2%) had complete HBV screening. Of the screening tests, HBsAg was tested in 66.9% of patients, anti-HBc in 48.5%, and anti-HBs in 31.8%. Hematology/oncology completed HBV screening most frequently, followed by rheumatology, neurology, two or more specialties, and dermatology. **Conclusion:** HBVr is a potentially life-threatening complication of immunosuppression but is preventable with appropriate pre-immunosuppression screening and antiviral therapy. Our study highlights the stark deficiencies in HBV screening in high-risk patients and emphasizes the opportunities to improve provider adherence to HBV screening recommendations to prevent HBVr.

1361-C | IMPACT OF COVID-19-RELATED PUBLIC HEALTH MEASURES ON TESTING FOR HEPATITIS B IN BRITISH COLUMBIA, CANADA: AN INTERRUPTED TIME SERIES ANALYSIS

Richard L Morrow[1,2], Sofia R. Bartlett[2], Mike Irvine[1], Mawuena Binka[3], Jean Damascene Makuza[1], Dahn Jeong[2], Jason Wong[1], Amanda Yu[1], Julia Li[1], Stanley Wong[1], Maria Jose Alvarez[1], Mel Krajden[1] and Naveed Zafar Janjua[1,2], (1)BC Centre for Disease Control, (2) University of British Columbia, (3)British Columbia Centre for Disease Control

Background: Public health measures implemented in response to the coronavirus disease 2019 (COVID-19) pandemic disrupted healthcare services internationally. We aimed to assess the impact of COVID-19-related public health policies on hepatitis B (HBV) testing among residents of British Columbia (BC), Canada. **Methods:** We used interrupted time series analysis with administrative health data from the province's COVID-19 Cohort to estimate changes in testing for HBV following an initial phase of COVID-19-related public health policies. The study period included a pre-policy period (January 2017 to February 2020), a 3-month transition period during restrictive early COVID-19-related public health measures (March to May 2020), and 3 follow-up periods (June to December 2020, January to December 2021, and January to December 2022). Models with a linear trend term and adjustment for seasonality and autocorrelation were used to estimate the absolute and percentage difference between actual and predicted monthly HBV surface antigen testing, HBV DNA testing, and HBV e-antigen testing during each follow-up period. **Results:** We observed both short-term and sustained impacts on HBV testing. The monthly rate of HBV surface antigen testing was 15.6% lower than predicted in June to December 2020 (73 fewer individual's tested each month per 100,000 population; 95% CI 61 to 86) and declined further to 24.1% lower than predicted in 2022. However, this decrease was attenuated among women 19 to 44 years of age, which may reflect prenatal HBV testing. The monthly rate of HBV DNA testing was 12.0% lower than predicted in June to December 2020 (7 fewer individual's tested each month per 100,000 population; 95% CI 5 to 8) and was 11.9% lower than predicted in 2022. The number of individual's with an e-antigen test was 5.3% lower than predicted in June to December 2020 (27 fewer individual's tested each month; 95% CI 4 to 52) and was 7.4% lower than predicted in 2022. **Conclusion:** The period following the introduction of public health measures related to COVID-19 has been associated a decrease in HBV testing relative to the predicted level in the short term and over a longer period. It is important to better understand and develop strategies to address this sustained impact on HBV testing.

1362-C | IMPACT OF FATTY LIVER (FL) ON VIROLOGIC (VR), BIOCHEMICAL (BR), AND COMPLETE RESPONSE (CR) AMONG PATIENTS WITH CHRONIC HEPATITIS B (CHB) TREATED WITH NUCLEOS(T)IDE ANALOGS (NA): A REAL-B STUDY

Angela Chau[1], Ming-Lun Yeh[2], Pei-Chien Tsai[2], Huy N. Trinh[3], Cheng-Hao Tseng[4], Yao-Chun Hsu[4], Takanori Ito[5], Keigo Kawashima[6], Takanori Suzuki[6], Toru Ishikawa[7], Akito Nozaki[8], Kaori Inoue[9], Yuichiro Eguchi[9,10], Haruki Uojima[11], Hiroshi Abe[12], Hirokazu Takahashi[9], Tsunamasa Watanabe[13], Makoto Chuma[8], Masatoshi Ishigami[5], Joseph Hoang[1], Mayumi Maeda[1], Chung-Feng Huang[2], Chia-Yen Dai[2], Jee-Fu Huang[14,15], Wan Long Chuang[2], Ramsey Cheung[1], Ming-Lung Yu[2,16] and Mindie H. Nguyen[1], (1)Stanford University Medical Center, (2)Kaohsiung Medical University, (3)San Jose Gastroenterology, (4)E-Da Cancer Hospital, I-Shou University, (5)Nagoya University Graduate School of Medicine, (6)Nagoya City University Graduate School of Medical Sciences, (7) Saiseikai Niigata Hospital, (8)Yokohama City University Medical Center, (9)Saga University Hospital, (10) Locomedical Eguchi Hospital, (11)Kitasato University School of Medicine, (12)Shinmatsudo Central General Hospital, (13)St. Marianna University School of Medicine, (14)Kaohsiung Medical University Hospital, (15)Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, (16)National Sun Yat-Sen University

Background: NA therapy can reduce disease progression in chronic hepatitis B (CHB) patients. However, there is limited data on treatment response among patients with concurrent fatty liver (FL) and CHB, including viral suppression (VR), biochemical response (BR), and complete response (CR) rates. Therefore, we aimed to compare the outcomes of NA therapy between FL-CHB and non-FL CHB groups. **Methods:** A retrospective real-world cohort study of adult CHB patients treated with either entecavir or tenofovir from 12 sites (U.S., Taiwan, and Japan) was conducted. FL was diagnosed by imaging. Propensity score matching (PSM) was used to balance the FL-CHB and non-FL CHB groups. The Kaplan-Meier method was used on the matched cohort to compare 5-year cumulative rates of VR, BR, and CR, stratified by FL-CHB vs. non-FL CHB. Univariable Cox proportional hazard regression was performed on the matched cohort to identify independent factors associated with VR, BR, and CR. **Results:** We analyzed 1693 adult CHB patients (452 FL-CHB; 1241 non-FL CHB). The mean ($\pm$ SD) follow-up was 4.1 ($\pm$ 3.8) years before PSM and 3.5 ($\pm$ 2.8) years after PSM. At baseline before PSM, FL-CHB patients had higher BMI (25.6 vs. 23.9, $p<0.001$), platelet count (240.7 vs. 203.9 10^3/ L, $p<0.001$), and ALT (103 vs. 87 IU/L, $p=0.004$). FL-CHB patients were more likely to be HBeAg-positive (32.8% vs. 25.9%, $p=0.007$), and were less likely to have cirrhosis (9.6% vs. 34.1%, $p<0.001$) or high FIB-4 (25.2% vs. 37.5%, $p<0.001$). Baseline characteristics between the FL and non-FL CHB groups became similar after matching on age, BMI, diabetes mellitus, cirrhosis, platelets, ALT, HBV DNA, HBeAg positive, and FIB-4. On follow-up before PSM, FL-CHB patients had a lower 5-year cumulative VR rate (84.4% vs. 89.9%, $p=0.0017$) and

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

5-year cumulative CR rate (80.2% vs. 85.1%, $p = 0.020$), as well as a slightly lower 5-year cumulative BR rate (90.3% vs. 92.3%, $p = 0.068$) (Table 1). However, after PSM with the two groups balanced well, FL and non-FL CHB patients had similar 5-year cumulative VR (91.5% vs. 89.9%, $p = 0.21$), BR (97.7% vs. 96.9%, $p = 0.34$), and CR rates (89.9% vs. 86.8%, $p = 0.099$) (Table 1). We found no statistically significant association between FL and VR (HR = 1.14, CI: 0.93-1.40, $p = 0.22$), BR (HR = 1.09, CI: 0.90-1.32, $p = 0.37$), or CR (HR = 1.19, CI: 0.96-1.47, $p = 0.11$) in the PSM-matched cohort. **Conclusion:** Among diverse real-world NA-treated CHB patients, while FL patients had higher baseline ALT levels than non-FL patients, FL was not independently associated with response to NA therapy.

Table 1. Cumulative 5-year virologic response (A), biochemical response (B), and complete response (C), by FL-CHB vs. non-FL CHB.

A. Cumulative viral suppression rates

Follow up	6 month	1-year	2-year	3-year	4-year	5-year	*P*-value
Overall cohort							
FL-CHB	29.7%	41.7%	59.0%	71.4%	81.4%	84.4%	0.0017
Non-FL CHB	35.1%	49.7%	66.6%	77.1%	85.6%	89.9%	
PSM-matched cohort							
FL-CHB	26.7%	40.1%	60.4%	76.3%	89.0%	91.5%	0.21
Non-FL CHB	26.7%	43.2%	57.3%	67.4%	81.8%	89.9%	

B. Cumulative biochemical response rates

Follow up	6 month	1-year	2-year	3-year	4-year	5-year	*P*-value
Overall cohort							
FL-CHB	51.4%	65.6%	79.2%	85.6%	88.5%	90.3%	0.068
Non-FL CHB	51.6%	68.6%	82.9%	87.6%	90.6%	92.3%	
PSM-matched cohort							
FL-CHB	59.7%	73.8%	87.8%	93.7%	95.9%	97.7%	0.34
Non-FL CHB	52.9%	70.8%	88.0%	91.4%	95.9%	96.9%	

C. Cumulative complete response rates

Follow up	6 month	1-year	2-year	3-year	4-year	5-year	*P*-value
Overall cohort							
FL-CHB	21.9%	35.0%	52.7%	66.4%	76.3%	80.2%	0.020
Non-FL CHB	24.8%	39.0%	59.2%	70.6%	79.6%	85.1%	
PSM-matched cohort							
FL-CHB	21.4%	35.0%	55.5%	73.3%	86.1%	89.9%	0.099
Non-FL CHB	19.6%	33.4%	52.7%	62.6%	77.8%	86.8%	

Virologic response: undetectable HBV DNA; Biochemical response: ALT normalization (<25 IU/L for females, <35 IU/L for males); Complete response: undetectable HBV DNA plus ALT normalization

1363-C | INFLUENCE OF VIRAL LOAD AND FIBROTIC BURDEN ON HEPATOCELLULAR CARCINOMA RISK AT PHASE CHANGE TO IMMUNE-ACTIVE PHASE IN CHRONIC HEPATITIS B

Ho Soo Chun[1,2], Minjong Lee[1,2], Hye Ah Lee[3], Jihye Kim[4], Han Ah Lee[1,2], Hwi Young Kim[1,2], Tae Hun Kim[1,2], Eileen L. Yoon[5], Dae Won Jun[6], Sang Hoon Ahn[7,8], Seung Up Kim[9,10] and Yoon Jun Kim[4], (1) Department of Internal Medicine, Ewha Womans University College of Medicine, Seoul, South Korea, (2) Department of Internal Medicine, Ewha Womans University Medical Center, Seoul, South Korea, (3) Clinical Trial Center, Ewha Womans University Seoul Hospital, Seoul, Korea, Republic of (South), (4) Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea, (5)Department of Internal Medicine, Hanyang University College of Medicine, Seoul, South Korea, (6)Hanyang University College of Medicine, (7)Department of Internal Medicine, Yonsei University College of Medicine, (8)Yonsei Liver Center, Severance Hospital, Seoul, South Korea, (9)Yonsei University College of Medicine, Seoul, Republic of Korea, (10)Severance Hospital, Seoul, Republic of Korea

Background: Recent studies reported that moderate hepatitis B virus (HBV) DNA levels are significantly associated with hepatocellular carcinoma (HCC) risk in hepatitis B e antigen (HBeAg)-positive, non-cirrhotic patients with chronic hepatitis B (CHB). We assessed

the association of baseline viral load and fibrotic burden with the risk of HCC development in CHB patients entering the immune-active (IA) phase. **Methods:** This multicenter cohort study recruited 3,589 HBeAg-positive, non-cirrhotic CHB patients who started antiviral treatment with entecavir or tenofovir disoproxil fumarate at IA phase transitioned from immune-tolerant (IT) phase in twenty-three tertiary university-affiliated hospitals of South Korea (2012–2020). Significant liver fibrosis was defined as fibrosis-4 index (FIB-4) > 3.25. Multivariable analysis using the Cox proportional hazards model was performed. **Results:** Sixty (1.7%) patients developed HCC (median follow-up, 5.4 y). Patients who developed HCC were significantly older and showed a significantly higher proportion of diabetes, lower platelet counts, and higher FIB-4 levels than those who did not (n = 3,525, 98.3%) (all $p < 0.05$). The HCC risk was highest at moderate HBV DNA levels (5.00–7.99 $\log_{10}$ IU/mL) and significant liver fibrosis. In multivariable analysis, moderate HBV DNA levels was independently associated with the increased risk of HCC development (adjusted hazard ratio [aHR] = 2.55, 95% confidence interval [CI] = 1.32–4.91, $p = 0.005$). After adjustment for FIB-4 levels, similar result was maintained (moderate HBV DNA levels: aHR = 2.68, 95% CI = 1.40–5.13; FIB-4 > 3.25: aHR = 7.63, 95% CI = 3.05–19.09; all $p < 0.05$). **Conclusion:** Moderate HBV DNA levels and significant liver fibrosis at the time of phase change from IT to IA phase was significantly associated with the risk of HCC development during potent antiviral therapy in patients with CHB.

Table. Predictors of HCC development

1364-C | INTERIM RESULTS OF A PROGRAM TO NARROW GAP BETWEEN IN ACCORDANCE WITH GUIDELINES AND CONSENT TO TREAT CHB POPULATION IN EAST OF CHINA (GATE STUDY)

Shaoqiu Zhang[1], Jian Wang[1,2], Xiaomin Yan[1], Li Wang[1], Zhaoping Zhang[1], Sufang Lu[1], Yuxin Chen[3], Jie Li[1,2], Rui Huang[1,2] and Chao Wu[1,2], (1)Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, (2)Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, Jiangsu, China, (3)Department of Laboratory Medicine, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China

Background: Antiviral treatment may decrease risk of cirrhosis, liver failure, and hepatocellular carcinoma in patients with chronic hepatitis B (CHB). However, the rates of antiviral treatment are suboptimal in treatment-eligible CHB patients. We aimed to dissect the barriers to antiviral treatment and conduct a program to increase the treatment rate of treatment-eligible CHB patients. **Methods:** We established a retrospective cohort and a prospective cohort of treatment-naïve CHB patients from January 2019 to October 2021 and from November 2021 to February 2023, respectively. Treatment-naïve patients who fulfilled with indications for antiviral treatment according to Chinese 2019 CHB guidelines were recommended to initiating antiviral treatment. A standardized questionnaire survey was conducted via telephone or clinic follow-up visit to learn treatment status of patients and discover the possible treatment barriers. A program with integrated intervention strategies, including the development of online medical education and the design of follow-up alert system, was implemented to narrow Gap between in Accordance with guidelines and consent to Treat CHB population in East of China (GATE) and improve the treatment uptake. **Results:** Before the implement of integrated intervention strategies, 1134 treatment-eligible CHB patients were included in the retrospective cohort and 71.08% of patients received antiviral treatment. Of the treatment-eligible patients, 22.05% patients were not suggested to receive treatment by their physicians; 6.88% patients refused the treatment due to varying personal concerns, including concerns about long period of treatment, treatment efficacy and adverse effects and high cost, and potential pregnancy plan. After the GATE program with integrated strategies implemented, 252 patients were enrolled in the prospective cohort and there was an 8.68% (from 71.08% to 79.76%, $p = 0.005$) increase in rate of antiviral treatment. The proportion of patients

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

not suggested to receive treatment by their physicians decreased from 22.05% to 10.71% ($p < 0.001$). **Conclusion:** One of the major treatment barriers was a lack of adherence to guidelines for CHB in physicians. There remains a need to educate physicians regarding guidelines for CHB. The integrated intervention strategies achieved increased antiviral treatment rate in treatment-eligible CHB patients. This approach could be an important strategy to improve treatment uptake of CHB patients.

1365-C | IS NASH THE FASTEST GROWING CAUSE OF LIVER CANCER IN CHINA?

Liying Ren, Dongbo Chen, Shaoping She, Pu Chen, Guixin Li, Yao Yang and Hongsong Chen, Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease

Background: Although NASH, progressing from non-alcoholic fatty liver disease (NAFLD), has become an important component of the etiology of liver cancer worldwide. However, in many countries and regions, viral hepatitis, particularly hepatitis B virus (HBV), remains the dominant cause of liver cancer. **Methods:** We collected the data from the GBD 2019, which includes mainland of China and Taiwan Province, prevalence and incidence rate per 100,000 person-years were calculated. **Results:** Data from mainland of China and Taiwan Province from 1990 to 2019 showed that HBV is still the most common cause of liver cancer in these regions, and the incidence is still high. Compared to HBV, the proportion of liver cancer cases caused by HCV, NASH, and alcohol in mainland of China has remained relatively stable. This suggests HBV is currently still the main cause of liver cancer. However, the incidence of HBV-related liver cancer in mainland of China has not decreased despite effective control of hepatitis B. From 2000 to 2019, the incidence of hepatitis B in mainland of China presented a downward trend, which may be closely related to the widespread use of the hepatitis B vaccine. Although the incidence of liver cancer in mainland of China showed a downward trend from 1990 to 2010 with the control of hepatitis B, the incidence of liver cancer has been increasing since 2010. Through the analysis of the etiology of liver cancer, we found that the incidence of HBV-related liver cancer in mainland of China has been on the rise since 2010, and its rate of increase far exceeds that caused by hepatitis C, alcohol, or NASH. In Taiwan Province, the incidence of liver cancer caused by various etiologies has decreased yearly. Moreover, the results stratified by age showed that the number of HBV-related liver cancer cases among individual's under 20 years of age remains very low in both mainland of China and Taiwan Province; in mainland of China, the number of cases among individual's over 20 years of age has continued to increase over the past decade, but in Taiwan Province, it has remained relatively stable over time. Therefore, the population mainly affected by the rising incidence of HBV-related liver cancer in mainland of China is hepatitis B patients older than 20. **Conclusion:** In summary, the widespread use of the hepatitis B vaccine has undoubtedly played an outstanding role in liver cancer prevention and control, especially among children and adolescents. However, the incidence of HBV-related liver cancer among adults in mainland of China has continued to rise, which may be the reason for the continuous increase in the total number of liver cancer cases. Although the popularization of liver cancer screening methods and the extension of life expectancy make this growth reasonable to some extent, we still need to increase public awareness and prevention of hepatitis B and carry out health education and monitoring for populations in high-risk countries and regions such as China.

1366-C | LONG TERM HEPATITIS B CARE IN TORONTO, CANADA: A SINGLE CLINICIAN EXPERIENCE

David Kah Heng Wong, University of Toronto

Background: There is debate about whether clinical care of patients with chronic HBV should be simplified such that most, if not all, patients are treated indefinitely. The Liver Clinic in Toronto, Canada was first established by Jenny Heathcote in 1979. The patients in this clinic had universal free access to healthcare providers and investigations including all blood tests and medical imaging. An electronic medical record (EMR) on QuadraMed platform that was used from 2007. At the time, all patient records were individually reviewed and transferred from paper records to electronic records. Blood tests from Jan 2010 performed at labs in Ontario were accessible by Connecting Ontario. DW philosophy of care for hepatitis B: 1. Not all with HBV would benefit from antiviral treatment and 2. antiviral therapy need not be indefinite - stopping treatment might be beneficial. On June 4, 2022, the clinic moved to a commercial EMR (Epic). **Methods:** All current patient records were individually reviewed by DW and migrated to Epic EMR since June 4, 2022. Specific diagnoses were recorded in Medical History using ICD-10 codes that allowed analyses using the SlicerDicer module of Epic. **Results:** From Jun 4, 2022 to May 21, 2023, 2443 patients have been assessed by DW. From this clinic, 1115 had chronic HBV infection (HBsAg positive > 6 mo) and 1 had acute HBV infection. Of those with chronic HBV infection, mean age was 54 (range 18 to 97). N = 30 were co-infected with HIV. Self-identified racial identity was as follows: Chinese 528, White 145, Vietnamese 129, Black 71, Filipino 53, Indian 31, Korean 27, Middle-East 14, Other Asian 54. Of those with chronic infection, only 37 (3.3%) were HBeAg positive,19 (1.7%) were in the Immune Tolerant phase. An additional 79 had functional cure of chronic HBV infection. Antiviral treatment included Tenofovir based therapies 232 (includes N = 12 on TAF), Entecavir 220, Lamivudine 20, No treatment 650 (58.3%). Severity: history of HCC 65, ascites 11. Two individual's died during this time period: first was an Asian man at age 78, presented Mar 2023 with hypotension and large HCC and new diagnosis of hepatitis B, passed on Apr 2023. Second was a Tibeten woman at age 82, who presented with ascites in 2020 from untreated hepatitis B. Entecavir started in Aug 2020, aggressive HCC detected in Oct 2022, passed April 2023. **Conclusion:** Chronic HBV infection is a lifelong infection. Only 41.7% of this cohort were on antiviral therapy. With regular monitoring in a specialty clinic, mortality risk is low and predominately from advanced age-related comorbidity (personal observation). Only 2 deaths were noted in this study period, both referred to the clinic with end stage disease. The required monitoring was facilitated through electronic resources that are not universally available to most in Ontario, creating healthcare disparity even within the same health district.

1367-C | LONG-TERM FOLLOW-UP OF PATIENTS WITH INCIDENTALLY DETECTED ASYMPTOMATIC HEPATITIS B

Mithun Sharma[1], Anand V. Kulkarni[1], Nagaraja Rao Padaki[2], Sowmya T R[1], Shantan Venishetty[1], Manasa Alla[1], Rajesh Gupta[1] and Nageshwar D Reddy[1], (1)Aig Hospitals, Hyderabad, India, (2)Asian Institute of Gastroenterology, Hyderabad, Telangana, India

Background: Incidentally detected asymptomatic hepatitis B (IDAHB) is found in 2.3% of subjects in India during routine screening, with an overall prevalence of 1.46%. Labeling these patients of chronic hepatitis B infection as inactive carriers have long

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

resulted in misinformation to patients leading to laxity in follow-up. This study was designed to find out the natural history of these patients who presented to a tertiary care center **Methods:** All patients with IDAHB were counseled with written documentation on the need to follow up with alanine aminotransferase(ALT), ultrasound abdomen (USG), and alpha-fetoprotein every six months and to report if there is an elevation of ALT > 70 for males and > 50 for females or if there are any abnormalities on the USG. The research coordinator will make a call if there is no update for greater than six months. **Results:** 740 patients were enrolled for follow-up from 2014 to 2017 and were followed up till January 2023. The mean duration of follow-up was 8.6 ± 3.8 years. 230(32.67%) patients defaulted in follow-up at a mean of 2.4 ± 1.2 years. 98 (13.24%) of the patients at the end of the follow-up term had converted to chronic hepatitis B requiring anti-viral therapies with a mean duration of 4.8 ± 2.1 years. The incidence of onset of hepatocellular carcinoma(HCC) was 13(1.75%) in patients on regular screening and was found in 11/240(4.58%) of those who did not follow the screening protocol. On inquiry, the majority of patients (45%) who defaulted in regular follow-up reported a belief that the disease would not spread, while an additional 21.2% reported unwillingness to spend money on conditions that did not cause symptoms. **Conclusion:** IDAHB patients become eligible for antiviral therapy on follow up, and lack of awareness of the disease despite proper counseling may hinder the detecting these patients. In addition, HCC develops more patients of even IDAHB who are not on the screening program.

1368-C | NATURAL HISTORY OF CHRONIC HBEAG NEGATIVE INFECTION AMONG THE ANRS CO22 HEPATHER COHORT

Lucia Parlati, AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, Dmu Cancérologie Et Spécialités Médico-Chirurgicales, Service d'Hépatologie, Paris, France and ANRS/AFEF HEPATHER study group

Background: Natural history of patients with HBeAg-negative chronic infection (HBeAg-CI) remains unclear regarding the loss of HBsAg, the need for treatment and their outcome. **Methods:** Among the 5174 HBs patients enrolled in the ANRS CO22 Hepather French national prospective cohort between Q3 2012 and Q4 2015, 1162 patients with HBeAg-CI were studied with a median follow-up of 5.8 years (IQR 4-7.2). At inclusion all patients had normal ALT < 40 IU/ml and HBV DNA < 2000 IU/ml. All patients were untreated and never treated by NUCs or Interferon during their past history. At inclusion, the median age was 41.9 yo (33.6-53,4). 50.4% were male. 54.8% were from African origin, 9.4% from Asia, 27.1% from Europe and 8.8% from other origins. 95% had F0-F2 fibrosis stage, 5.2% had past or current excessive alcohol consumption, 14.6% had obesity and 6.0% had diabetes. **Results:** 66 patients (5.6%) lost HBsAg. No clinical liver complications were observed. Geographical origins were not associated with HBsAg loss (7.0% for European, 5.4% for Africans, 5.5% for Asians and 4.0% for other origins). During follow-up, 1083 patients remained untreated and 79 patients (7.0%) started treatment with NUCs. Among the 1083 untreated patients, 18 died, including one death from liver end-stage disease in a patient with other cofactors alcohol and obesity. 3 patients had a hepatocellular carcinoma, 2 of them with other cofactors (overweight, diabetes and alcohol). Among the 79 patients treated, 6 died, two of them of hepatic causes, one of them with other cofactors (alcohol and HCC). The cumulative incidence per 1000 person-years (pyrs) (CI95%) of HCC, hepatic decompensation (HD), all cause of deaths (ACD), and liver related deaths (LRD), are given in the table and compared with those of 2698 chronic HBeAg negative hepatitis (HBe-Ag-CH) patients followed in the Hepather cohort. **Conclusion:** In this large cohort of HBeAg negative infection patients followed for more than 6 years, 5.6% lost HBsAg, 93% remained untreated with very low incidence of adverse events confirming the current EASL and AASLD guidelines recommendations.

Events	Population	Incidence per 1000 pyrs (CI95%)	Incidence ratio (CI95%)	p
HCC	HBe-Ag-CI untreated (n=1079)	0.5 (0.1-1.5)	1	
	HBe-Ag-CI treated (n=78)	2.0 (0.1-11.1)	3.8 (0.1-47.1)	0.322
	HBeAg-CH (N=2614)	2.9 (2.1-3.9)	5.4 (1.7-27.4)	**<0.001**
HD	HBe-Ag-CI untreated (n=1077)	0.2 (0.0-1.0)	1	
	HBe-Ag-CI treated (n=76)	0.0 (0.0-7.5)	0.0 (0.0-450.2)	0.920
	HBeAg-CH (N=2605)	1.1 (0.6-1.7)	6.1 (0.9-254.8)	**0.036**
ACD	HBe-Ag-CI untreated (n=1083)	3.1 (1.9-5.0)	1

1369-C | NATURAL HISTORY OF DISEASE PROGRESSION IN PATIENTS WITH CHRONIC HEPATITIS B USING A LARGE NATIONWIDE POPULATION-BASED DATABASE

Nobuharu Tamaki, Masayuki Kurosaki, Yutaka Yasui, Kaoru Tsuchiya, Hiroyuki Nakanishi and Namiki Izumi, Musashino Red Cross Hospital

Background: Disease progression in patients with chronic hepatitis B remains unclear, especially in untreated patients. In this study, we aimed to investigate disease progression (hepatocellular carcinoma [HCC] development and decompensation) in patients with chronic hepatitis B using a large nationwide database. **Methods:** We used a large claims database established by the Japan Medical Data Center (JMDC Co., Ltd. Tokyo, Japan). The database consists of claims from medical institutions and annual health checkup data. Annual health checkup results consist of age, gender, physical examination, medical history, blood test results, and questionnaire information for smoking and alcohol habits. Claims data contains diagnostic ICD code, prescription, procedure/treatment code, etc. The database contains records of approximately 14 million insured persons. Among these patients, 3 million patients who have health checkup data from 2016 to 2021 were examined. Of these, 16,676 persons with chronic hepatitis B disease (based on ICD code) were included. The occurrence of new decompensation (encephalopathy, ascites, variceal bleeding) and HCC during the observation period was examined. **Results:** The mean age of the 16676 patients was 51.4 years and 69.2% were male. 3575 (21.4%) were taking nucleic acid analogs (NA). New decompensation occurred in 503 patients (3.0%) and new HCC in 116 patients (0.7%) during the observation period. The 3- and 5-year HCC incidence rates were 0.9% and 1.1%, and the 3- and 5-year decompensation rates were 2.1% and 2.9%. The 5-year HCC incidence was 3.1% and 0.6% in patients with and without NA, respectively. Although patients with NA had a significantly higher incidence of HCC, HCC was also observed in patients without NA. Age, male gender (hazard ratio [HR]:1.7), NA administration (HR:5.3), and alanine aminotransferase (ALT) every 10 IU/L (HR:1.12) were significant factors associated with the development of HCC. The 3- and 5-year decompensation rates were 4.1% and 5.2% in patients with NA and 1.5% and 2.1% in patients without NA, respectively. The significant factors associated with decompensation were age, male gender (HR: 1.4), NA administration (HR: 2.4), and ALT every 10 IU/L (HR: 1.16). In patients without NA, HCC development rates were equivalent in patients with ALT > 30, 20-30, and < 20 IU/L. Regarding the development of decompensation in patients without NA, the decompensation development was significantly higher in patients with ALT > 30 IU/L than those with ALT 20-30, and < 20 IU/L ($p < 0.01$). **Conclusion:** NA was introduced in high-risk cases for the prevention of HCC and decompensation, while a small number of cases without NA also developed HCC and decompensation, suggesting the need for further verification of the identification of high-risk groups and the criteria for NA administration.

1370-C | NEXT-GENERATION SEQUENCING OF HBV GENOTYPES CIRCULATING IN CHILE AMONG HAITIAN IMMIGRANTS AND CHILEAN PATIENTS; IDENTIFICATION OF POTENTIAL ESCAPE MUTANTS

Javier Uribe[1], Ruth Núñez[1], Karla Pino[1], Jorge Vera[1], Marcelo Lopez-Lastra[1], Alejandro Soza[1] and Francisco Fuster[2], (1)Pontificia Universidad Católica De Chile, (2) Hospital Gustavo Fricke

Background: Hepatitis B virus (HBV) infection presents different genotypes, viral variants, and escape mutants that can influence disease progression and vaccination response. HBV's prevalence and molecular characteristics in Haitian immigrants to Chile are poorly understood. This study aimed to describe the specific HBV genotypes infecting Haitian immigrants in Chile and compare them with Chilean isolates using next-generation sequencing (NGS). **Methods:** A total of 32 subjects were included in the study, comprising 8 Haitian immigrants and 24 Chileans. HBV viral DNA was sequenced using NGS, with a mean Phred score > 32, indicating high precision (> 99.9%). The raw FASTQ files were taxonomically classified using Kraken2, aligned with BWA, and variant detection was performed with LoFreq. Variants were annotated using SnpEff, and escape mutations were identified using geno2pheno. Genotyping, sub-genotyping, and serotyping were conducted using geno2pheno, HBVseq, and HBV Serotyper tools. **Results:** Chilean patients were predominantly infected with HBV genotype F1 (23 subjects) and genotype D4 (1 subject). In contrast, Haitian immigrants presented genotypes A1 (1 subject), E (1 subject), and F1 (3 subjects). Mutations were identified in preS1, preS2, S, P, X, preC, and C genes, with some representing previously reported escape mutations. Specifically, in the 'a' determinant (codons

121-147 of the S gen), the immunodominant portion of the HBsAg, 50 different mutations were found, and they were equally detected in the Haitian and Chilean populations (75%). **Conclusion:** This study revealed distinct HBV genotypes and potential viral escape mutants among Haitian immigrants and Chilean patients, highlighting the importance of understanding the molecular dynamic of HBV infection in different populations within a country. These findings could inform public health policies and optimize vaccination strategies for marginalized groups, such as Haitian immigrants in Chile.

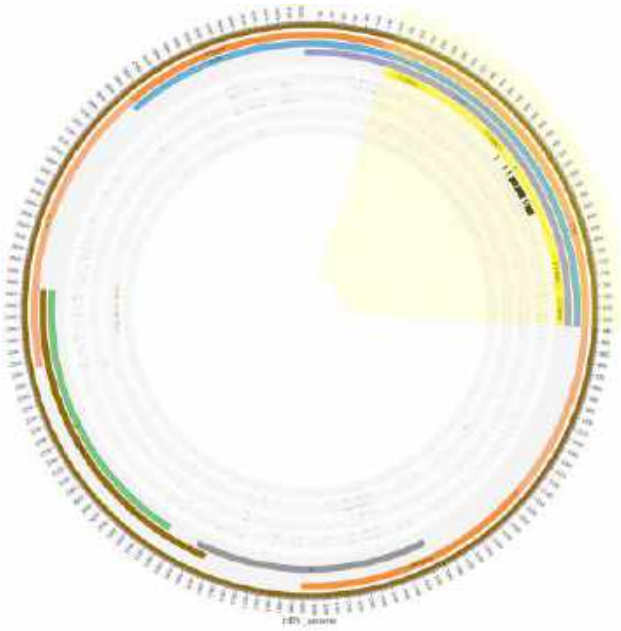

Figure 1. Variations found along the Hepatitis B virus genome in samples from Haitian individuals. The concentric circles represent, from the inside out, the variants (red stripes) found for samples 456, 413, 401, 357, 351, 204, and 75; the codons where an escape variant has been described (black stripes); the annotation of the virus proteins; and the positions along the genome. The variations shown (red stripes) are a sub-selection of the total variants, with a frequency ≥ 1% and excluding synonymous variations, insertions, and deletions. P-TP, polymerase terminal domain; P-Spacer, polymerase spacer domain; P-RT, reverse transcriptase domain; P-RNaseH, ribonuclease H activity; S-TMM, transmembrane sites 1,2,3,4 of the S protein.

1371-C | NON-ALCOHOL FATTY LIVER DISEASE IN A PROSPECTIVE NATIONAL COHORT OF HEPATITIS B PATIENTS WITH SUBOPTIMAL RESPONSE TO ANTIVIRAL THERAPY

Wen Xie, Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, Lihua Cao, The Third Hospital of Qinhuangdao City, Hebei, China, Shuangsuo Dang, The Second Affiliated Hospital of Xi'an Jiaotong University, Shaanxi, China, Liying Zhu, The Second Affiliated Hospital of Harbin Medical University, Heilongjiang, China, Dongliang Yang, Union Hospital Affiliated to Tongji Medical College, Huazhong University of Science and Technology, Hubei, China, Yueyong Zhu, The First Affiliated Hospital of Fujian Medical University, Fujian, China, Xiaoguang Dou, Shengjing Hospital Affiliated with China Medical University, Liaoning, China, Zhiliang Gao, The Third Affiliated Hospital of Sun Yat-Sen University, Guangdong, China, Binbin Chen, Guangzhou Eighth People's Hospital, Guangzhou Medical University, Xinxin Zhang, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Yuming Wang, Chongqing Public Health Medical Center, Chongqing, China, Yan Liu, Department of Infectious Diseases, the Fifth Medical Center of Chinese PLA General Hospital, Beijing, China, Ting Zhang, Center of Liver Diseases Division, Beijing Ditan Hospital, Capital Medical University, Beijing, China and Calvin Pan Pan, New York University Langone Medical Center, Flushing, NY

Background: The non-alcohol fatty liver disease (NAFLD) had been reported in 27% of Chinese adults with chronic hepatitis B (CHB). Although coexisting NAFLD was associated with a significantly higher frequency of HBsAg seroclearance in virologically quiescent CHB, the risk of dual etiologies on outcomes and the efficacy of antivirals have not been fully characterized in CHB with persistent viremia on antiviral therapy. We aimed to compare the differences in clinical features between CHB with and without NAFLD in this subpopulation. **Methods:** In a cross-sectional prospective study from 9/3/2021 to 3/20/2023, CHB adults with a suboptimal response (SOR) to antivirals (who met the 2017 EASL guideline definition for the SOR) were enrolled from 11 centers (Hepatitis B Research Network) in China. NAFLD was identified by fibroscan with the controlled attenuation parameter (CAP) ≥ 238 dB/m. We explored the possible roles of NAFLD in these patients by comparing clinical characteristics between the two sub-groups (presence *vs.* absence of NAFLD), including disease activity (alanine aminotransferase [ALT] or aspartate aminotransferase [AST] as a surrogate), virological profile, and fibrosis. **Results:** Among 90 patients enrolled (Table 1), all were viremic

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and currently adhered to the antiviral therapy without genotypic resistance (96% taking entecavir, 1% tenofovir-DF, and 3% second-line antivirals), the median age was 39 years, 64% male, 82% HBeAg (+), and 47% had significant viremic levels (HBV DNA > 2000 IU/mL). Only 6% and 1% of them reported a history of NAFLD and diabetes, respectively. At enrollment, 43% (39/90) of them had CAP e 238 dB/m and received the NAFLD diagnosis (38.5% [15/39], 46.1% [18/39], and 15.4% [6/39] were mild, moderate, and severe steatosis, respectively). CHB patients with NAFLD had a significantly higher mean body mass index (BMI: 25.5 *vs.* 21.9 kg/m^2; $p < 0.001$), higher median ALT levels (34.7 *vs.* 24.0 U/L; $p = 0.004$), higher median AST levels (23.7 *vs.* 21.0 U/L; $p = 0.02$), and higher frequency of HBV DNA > 2000 IU/mL (64.1% *vs.* 33.3%; $p = 0.04$). **Conclusion:** We observed a high frequency of NAFLD (43%) in CHB patients with SOR to antiviral therapy. The presence of NAFLD was associated with high levels of ALT or AST, BMI > 25 Kg/m^2, and HBV DNA > 2000 IU/mL. Because of the association between NAFLD and death from cancer or cardiovascular events, identifying NAFLD and managing adverse metabolic profiles are critically important in CHB patients with viremia on antiviral therapy, which already carries a high risk for liver cancer. Grant support: Gilead Science, Inc.

1372-C | NON-LINEAR ASSOCIATION OF BASELINE VIRAL LOAD WITH ON-TREATMENT HEPATOCELLULAR CARCINOMA RISK IN CHRONIC HEPATITIS B★

Won-Mook Choi[1], Gi-Ae Kim[2], Jonggi Choi[3], Gwang Hyeon Choi[4], Yun Bin Lee[5], Dong Hyun Sinn[6] and Young-Suk Lim[1], (1)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South), (2)Kyung Hee University School of Medicine, (3)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, (4)Seoul National University Bundang Hospital, Seoul National University College of Medicine, (5)Seoul National University College of Medicine, (6)Samsung Medical Center

Background: The association between baseline pretreatment serum hepatitis B virus (HBV) DNA levels and on-treatment hepatocellular carcinoma (HCC) risk remains controversial in chronic hepatitis B (CHB) patients. We aimed to investigate the association between baseline HBV viral load and on-treatment HCC risk in non-cirrhotic CHB patients. **Methods:** Using a multicenter historical cohort study including 4,693 non-cirrhotic adult patients with HBeAg-negative and HBeAg-positive CHB who initiated antiviral treatment, HCC risk was estimated by baseline HBV viral load as a categorical variable. **Results:** During a median of 7.6 years of antiviral treatment, 193 patients developed HCC (0.53 per 100 person-years). Baseline HBV DNA level was independently associated with on-treatment HCC risk in a non-linear, parabolic pattern. Patients with moderate baseline viral loads (5.00–7.99 $\log_{10}$ IU/mL) exhibited the highest HCC risk (adjusted hazard ratio [aHR], 2.60; 95% confidence interval [CI], 1.61–4.22; $p < 0.001$), followed by those with low viral loads (3.30–4.99 $\log_{10}$ IU/mL; aHR, 1.66; 95% CI, 0.88–3.12; $p = 0.11$). Patients with high viral loads (e 8.00 $\log_{10}$ IU/mL) presented the lowest HCC risk. Particularly, patients with baseline HBV DNA levels 6.00–6.99 $\log_{10}$ IU/mL had the highest on-treatment HCC risk (aHR, 3.36; 95% CI, 2.00–5.65; $p < 0.001$) compared to those with baseline HBV DNA levels e 8.00 $\log_{10}$ IU/mL. These findings were more prominent among younger patients (< 45 y) and those with

less advanced hepatic fibrosis. **Conclusion:** Patients with moderate baseline viral load, particularly around 6 log_{10} IU/mL, demonstrated the highest on-treatment HCC risk, despite long-term antiviral treatment. Early initiation of antiviral treatment, tailored to viral load, should be considered to minimize HCC risk in non-cirrhotic adult CHB patients.

Figure. Adjusted hazard ratio for the on-treatment HCC risk by baseline HBV DNA levels in CHB patients treated with entecavir or TDF.
Hazard ratio plot adjusted for age, sex, platelet count, HBeAg-positivity, levels of ALT, and FIB-4 index with HBV DNA level of 6.00 log_{10} IU/mL as a reference.
The black line represents the point estimates, and the grey zone indicates 95% confidence intervals.
ALT, alanine aminotransferase; CHB, chronic hepatitis B; FIB-4, fibrosis-4; HBeAg, hepatitis B e antigen; HBV, hepatitis B virus; HCC, hepatocellular carcinoma; TDF, tenofovir disoproxil fumarate.

1373-C | PREDICTORS FOR HIGH LEVELS OF VIREMIA AT DELIVERY IN CHB MOTHERS WITHOUT INDICATIONS FOR ANTIVIRAL PROPHYLAXIS UP TO GESTATIONAL WEEK 32

Shi Ouyang[1], Yawen Geng[1,2], Tingting Peng[1] and Calvin Pan Pan[1,3], (1)The Fifth Affiliated Hospital of Guangzhou Medical University, Guangzhuo, China, (2) North China University of Technology, Tangshan, China, (3)NYU Grossman School of Medicine

Background: International guidelines recommend antiviral prophylaxis initiated at gestational weeks of 24-28 for chronic hepatitis B (CHB) mothers with high levels of viremia (HLV), i.e., HBV DNA > 200,000 IU/mL to prevent vertical transmission. In mothers without HLV during the first and second trimesters, the frequency of developing HLV at delivery and missing the opportunity for antiviral prophylaxis has not been elucidated. We aimed to study the incidence of HLV before delivery and predictors in mothers without HLV before gestational week 32. **Methods:** In a retrospective cohort study at a university medical center in China from 1/2020 to 9/2022, consecutive CHB mothers who had HBV DNA tested before and after gestational week 32 were eligible. We excluded those with HLV before or at gestational week 32, or taking antiviral therapy at any time during pregnancy. Mothers with and without HLV after gestational week 32 were identified and compared for their baseline parameters obtained at the earliest visit with virological tests during pregnancy. We analyzed the frequency and predictors for HLV occurring after gestational week 32 until delivery. **Results:** We enrolled 251 mothers. At baseline, the mean (SD) age was 30.7 (±4.3) years, the median (range) gestational week was 17 (12-24), five percent was HBeAg (+), and the median (IQR) HBV DNA was 99 (99, 242) IU/mL (Table 1). All mothers had HBV DNA < 200,000 IU/mL before or at gestational week 32, and three percent (8/251) of them presented with HBV DNA > 200,000 IU/mL after gestational week 32. When comparing mothers with and without HLV before delivery, there were statistically significant differences in several baseline variables including HBV DNA tests performed at the time of median (IQR) gestational weeks (14.5 [13.3, 15.8] vs 17.0 [15.0, 20.0]; $p = 0.02$), HBeAg positive status (38% [3/8] vs 4% [9/243], $p = 0.004$), and median (IQR) HBV DNA levels (5,802 [410; 56,575] vs 99 [99,189] IU/mL; $p < 0.001$). **Conclusion:** Three percent of CHB mothers without HLV before or at 32 weeks of pregnancy progressed to the status of HBV DNA > 200,000 IU/mL before delivery, which increased the risk for HBV vertical transmission. HBeAg positive status, HBV DNA levels ranging from 2 to 4 log_{10} IU/mL, and testing HBV DNA in the 1st trimester without repeating it thereafter were the risk factors. Close monitoring of mothers with these features or considering preemptive antiviral prophylaxis before gestational week 32 might be necessary to reduce the risk of transmission.

Table 1. Baseline characteristics of mothers at the time of the first HBV virological testing

Variables presented as median (IQR) or specified	All patients (n=251)	Mothers with stable HBV DNA levels (n=243)	Mothers with HLV after 32 weeks of pregnancy (n=8)	P-values
Age, mean ±SD - year	30.7 ± 4.3	30.8 ± 4.3	28.0 ± 3.2	0.07
Age ≥30 years, n (%)	148/251 (59)	140/243 (60)	2/8 (25)	0.07
Gestational week of testing HBV DNA	17.0 (15.0, 20.0)	17.0 (15.0, 20.0)	14.5 (13.3, 15.8)	0.02
Gravidity count >1, n (%)	194/251 (77)	192/243 (79)	2/8 (25)	0.15
Multiparous, n (%)	3/251 (1)	3/243 (1)	0/8 (0)	>0.99
AST - U/L*	15.6 (13.6, 19.7)	15.6 (13.5, 19.6)	18.8 (13.5, 24.4)	0.55
ALT - U/L*	14.2 (9.6, 18.8)	13.9 (9.5, 18.3)	19.1 (12.2, 25.0)	0.13
Dyslipidemia, n (%)	99/195 (51)	96/189 (51)	3/6 (50)	>0.99
HBeAg positivity, n (%)	12/251 (5)	9/243 (4)	3/8 (38)	0.004
HBV DNA levels - IU/mL†	99 (99, 242)	99 (99, 189)	5802 (410, 56575)	<0.001
HBV DNA detectable, n (%)	94/251 (38)	86/243 (35)	8/8 (100)	<0.001
FIB-4#	0.58 (0.47, 0.75)	0.59 (0.47, 0.75)	0.49 (0.41, 1.01)	0.59

*AST and ALT normal ranges are 13-35U/L and 7-40 U/L, respectively.
†When HBV DNA level <100 IU/mL (lowest level of quantitation in the laboratory, data imputed as HBV DNA=99 IU/mL.
FIB-4 data were collected from 87 and 4 mothers with stable viremia levels and those with HLV, respectively.

1374-C | PREDICTORS OF HBsAg SEROREVERSION IN PATIENTS ACHIEVING SERUM HBsAg LOSS WITH PEGYLATED INTERFERON-BASED THERAPY

Na Gao[1], Haishi Wu[1], Huiying Yu[1], Jing Zhang[1], Zhishuo Mo[1], Qiyi Zhao[1,2,3] and Zhiliang Gao[1,2,3], (1) Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-Sen University, (2)Guangdong Key Laboratory of Liver Disease Research, the Third Affiliated Hospital of Sun Yat-Sen University, (3)Key Laboratory of Tropical Disease Control (Sun Yat-Sen University)

Background: HBsAg loss is a well-accepted treatment endpoint for chronic hepatitis B. However, it is unclear whether nucleos(t)ide analogue (NUC) consolidation confers clinical benefits after HBsAg seroclearance with pegylated interferon-based therapy, especially in HBsAg seroreversion and HBsAb production. **Methods:** Patients with CHB who achieved serum HBsAg loss with pegylated interferon (PEG-IFN)-based therapy were enrolled and followed up 96 weeks. HBsAg loss was confirmed by two or more consecutive negative-qualitative HBsAg results. The primary endpoint was HBsAg seroreversion. Secondary endpoint was virological relapse. Using multivariable logistic regression analysis, we determined factors associated with HBsAg seroreversion. **Results:** 215 patients achieving HBsAg seroclearance were enrolled in the present study including 164 and 51 patients in the none-NUC consolidation group and NUC consolidation group, respectively. In NUC consolidation group, patients received (quartile [Q] 1, Q3, 23.00, 96.00) weeks oral NUCs therapy. There were no significant difference of gender, treatment time of PEG-IFN to attain HBsAg loss ($p = 0.744$), consolidation treatment time of PEG-IFN ($p = 0.658$), serum ALT ($p = 0.681$), serum HBsAb($p = 0.052$), compensated cirrhosis ($p = 0.064$) at the baseline of follow-up and also the HBsAg level before PEG-IFN treatment ($p = 0.979$). The age in NUC consolidation group was older than none-NUC consolidation group[(44.61 ± 7.84) vs. (39.89 ± 8.33), $p < 0.001$]. At week 96, the rate of HBsAg seroreversion (20.12% vs. 24.49%, $p = 0.414$) and virological relapse (7.83% vs 7.84%, $p = 1.000$) were similar between the none-NUC consolidation group and NUC consolidation group. Furthermore, HBsAb production rate during 96-week follow-up in patients with negative HBsAb at ceasing time of PEG-IFN did not display statistical discrepancies between the none-NUC consolidation and NUC consolidation groups(62.86% vs. 58.82%, $p = 0.779$). For patients with positive serum HBsAb at ceasing time of PEG-IFN, sustainable positive HBsAb rate during 96-week follow-up showed no statistical significance between the two groups (77.17% vs. 69.70%, $p = 0.373$). HBsAb titer at ceasing PEG-IFN therapy was independent predictors of HBsAg seroreversion (odds ratio [OR] 0.419, 95% confidence interval [CI]: 0.272–0.645, $p < 0.001$). **Conclusion:** NUC consolidation therapy were not significantly associated with HBsAb production and HBsAg seroreversion in patients achieving serum HBsAg loss with PEG-IFN-based therapy.

1375-C | PREDICTORS OF HEPATITIS FLARE AND INITIATION OF ANTIVIRAL THERAPY IN NUCLEOS(T)IDE-NAÏVE CHRONIC HEPATITIS B IN GREY ZONE

Yunjeong Lee and Jin-Wook Kim, Seoul National University Bundang Hospital

Background: Chronic hepatitis B (CHB) patients without significant liver inflammation, i.e., immune-tolerant or HBeAg-negative inactive carrier phase, are followed without nucleos(t)ide analogs (NAs) until transaminase level elevates. A substantial number of patients show low/normal transaminase with persistent viremia, known as "grey zone" phase. It is unclear, however, which patients in grey zone have high probability of hepatitis-flare. This study aimed to investigate the clinical and laboratory characteristics which may predict the hepatitis flare and becoming initiated of antiviral therapy in nucleos(t)ide-naïve patients with low/normal transaminase level (both AST/ALT < 80 U/L), along with HBV DNA levels > 2,000 IU/mL in HBeAg-negative and > 20,000 IU/mL in HBeAg-positive CHB. **Methods:** We reviewed nucleos(t)ide analogue-naïve, noncirrhotic CHB patients with low/normal transaminase level (both AST/ALT < 80 U/L) seen at our hospital between April 2003 and April 2023. 467 HBeAg-positive patients with HBV DNA level > 20,000 IU/mL and 2,008 HBeAg-negative patients with HBV DNA level > 2,000 IU/mL were included in our analysis. The Cox regression model was used to

identify the factors associated with initiation of antiviral therapy throughout the follow-up period in each group. Age, gender, serum AST, ALT, albumin, prothrombin time (INR), bilirubin, platelet counts, HBsAg level as well as the HBV DNA level were tested. **Results:** In the HBeAg-negative CHB, lower serum albumin (hazard ratio [HR] = 0.45, 95% confidence interval [CI]: 0.31–0.65, p value = 0.00) and prolonged prothrombin time (HR = 4.37, 95% CI: 1.40–13.61, p value = 0.01) along with higher serum ALT and HBV DNA level were associated with the initiation of antiviral therapy. In contrast, there were no statistically significant independent factors associated with initiation of antiviral therapy other than higher baseline serum AST levels in HBeAg-positive CHB. **Conclusion:** Decreased serum albumin level and prolonged prothrombin time along with high baseline HBV DNA levels were predictive of the hepatitis flare and initiation of NA therapy in HBeAg-negative grey zone CHB patients. In HBeAg-positive grey zone, only elevated baseline AST levels were associated with hepatitis flare.

1376-C | PRE-EXISTING AND NEWLY-DEVELOPED METABOLIC DYSFUNCTIONS INCREASE THE RISKS OF CIRRHOSIS AND ITS COMPLICATIONS IN CHRONIC HEPATITIS B PATIENTS

Shang-Chin Huang[1,2,3], Tung-Hung Su[4], Tai-Chung Tseng[2], Chi-Ling Chen[3], Shih-Jer Hsu[2], Chen-Hua Liu[4], Sih-Han Liao[5], Chun-Ming Hong[4], Ting-Yuan Lan[6], Hung-Chih Yang[2], Chun-Jen Liu[4], Pei-Jer Chen[4] and Jia-Horng Kao[4], (1)National Taiwan University Hospital Bei-Hu Branch, Taiwan, (2)National Taiwan University Hospital, Taiwan, (3)National Taiwan University College of Medicine, (4)National Taiwan University Hospital, (5) National Taiwan University Cancer Center, Taipei City, Taiwan, (6)National Taiwan University Hospital Hsin-Chu Branch

Background: Cirrhosis is the major adverse outcome of chronic hepatitis B (CHB). We aimed to explore the impact of pre-existing and newly-developed metabolic comorbidities on the risks of cirrhosis and its complications in CHB patients. **Methods:** Patients with CHB were consecutively recruited at the National Taiwan University Hospital. The presence of metabolic dysfunction (MD) was based on the criteria of type 2 diabetes mellitus (DM), overweight/obesity, or e two other metabolic risk abnormalities. Patients were categorized into MD and non-MD groups based on these criteria. **Results:** From 2006 to 2021, 11,647 treatment-naïve non-cirrhotic CHB patients were included with a median follow of 5.2 years. Patients in the MD group (n = 6,360) had older age and lower HBV DNA levels than non-MD patients (n = 5,287). After adjustment for clinical and viral factors, MD patients had significantly higher risks of cirrhosis (adjusted hazard ratio [aHR]: 1.75, 95% confidence interval [CI]: 1.42 – 2.16, $p < 0.001$) and cirrhotic complications (aHR: 2.51, 95% CI: 1.31 – 4.84, $p = 0.006$) than non-MD patients, with a dose-dependent effect of MD on cirrhosis (aHR: 1.45 per MD increase, 95% CI: 1.31 – 1.60, $p < 0.001$) and the complications (aHR: 1.63 per MD increase, 95% CI: 1.24 – 2.14, $p < 0.001$). Furthermore, in patients without pre-existing DM, the newly-developed DM during the follow-up additively increased the risk of cirrhotic complications (aHR: 2.13, 95% CI: 1.04 – 4.37, $p = 0.040$). The MD group with hepatic steatosis had a higher risk of cirrhosis than the steatosis-only non-MD group in a dose-dependent manner (aHR: 1.46 per MD increase, 95% CI: 1.23 – 1.72, $p < 0.001$). Sensitivity analyses, including the inverse probability of treatment weighting (IPTW) and multiple imputation, confirmed the robustness of these results. **Conclusion:** Concurrent and newly-developed metabolic dysfunctions increase the risks of cirrhosis and cirrhotic complications in CHB patients, independent of hepatic steatosis. Identifying and managing metabolic comorbidities in CHB are thus critical to prevent liver disease progression.

1377-C | PREVALENCE AND INCIDENCE OF OSTEOPENIA AND OSTEOPOROSIS IN PATIENTS WITH CHRONIC HEPATITIS B: A COHORT STUDY IN SOUTH KOREA

Hye Won Lee[1,2,3], Sungshin Kwon[4], Yeo Rae Moon[5], Hyunjung Ahn[5], Juyeon Lee[5] and Sang Hoon Ahn[1,2,3], (1)Yonsei Liver Center, Severance Hospital, Seoul, South Korea, (2)Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea, (3)Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, South Korea, (4) Gilead Sciences Korea, Ltd., Seoul, South Korea, (5) Kakao Healthcare Corp., Seoul, South Korea

Background: Despite recent findings that patients with chronic hepatitis B (CHB) had higher risk of osteoporosis/fracture,[1] awareness of metabolic bone diseases in patients with CHB is low among hepatologists. Assessment of bone health may be beneficial in evaluating and monitoring treatment plans for patients with CHB. Here, we report the epidemiology and risk factors associated with osteopenia/osteoporosis in CHB patients in South Korea. **Methods:** This retrospective cohort study included patients ≥ 19 years with or without CHB who went through bone mineral density (BMD) testing at least twice and with their first BMD test date in 2005–2021 at Severance Hospital. Patients with liver cancer prior to the first BMD test, hepatitis C infection at baseline, or a follow-up observation period of < 6 months from the first BMD test were excluded. Demographic factors (i.e., age, sex), and comorbidities for CHB and non-CHB patients were matched at a 1:4 ratio based on propensity scores. Univariate and multivariate Cox proportional hazards regression models were used to estimate the hazard ratios (HRs) and their 95% confidence intervals (CI) for assessing the risk of osteoporosis. **Results:** Overall, the incidence rate of osteopenia/osteoporosis in CHB and non-CHB patients was 25.8% and 28.7%, respectively. After propensity matching, 275 CHB patients (mean age: 57.8 y) and 1,100 non-CHB patients (mean age: 57.9 y) who had normal BMD in the first BMD test were further analyzed. In the second BMD test, 73.8%, 24.7%, and 1.5% of CHB patients and 70.7%, 26.5% and 2.8% of non-CHB patients, had normal BMD, osteopenia, and osteoporosis, respectively. Significant risk factors (HR [95% CI]) for osteoporosis in CHB patients were age (1.00 [1.00–1.00]), body mass index (BMI) ≥ 25 (0.65 [0.50–0.84]), chronic kidney disease (2.10 [1.50–2.80]), and proton pump inhibitor use (0.78 [0.62–0.99]) based on the multivariate analysis. The difference between the cumulative hazard for patients with or without CHB was not statistically significant ($p = 0.97$; Figure 1). **Conclusion:** In this cohort, CHB patients showed similar risks of osteopenia/osteoporosis compared to non-CHB patients. In addition to providing closer monitoring for CHB patients with greater bone disease risk, further studies of bone disease in CHB patients may help to understand the factors that impact bone health in CHB patients.

1378-C | PREVALENCE OF HDV INFECTION AND LIVER DISEASE SEVERITY IN A LARGE COHORT OF HBsAg POSITIVE PATIENTS IN TWO BIG URBAN ÁREAS IN SPAIN

Pablo Ryan[1,2], Sabela Lens[3,4], Antonio Madejon[4,5], Jorge Valencia[1,2], Ana Martínez-Alcocer[3,4], Guillermo Cuevas[1,2], Xavier Forns[3,4] and Javier Garcia-Samaniego[4,5], (1)Hospital Universitario Infanta Leonor, Madrid, Spain, (2)Ciber De Enfermedades Infecciosas (CIBERINFEC), (3)Idibaps - Hospital Clínic, Barcelona, Spain, (4)Ciber De Enfermedades Hepáticas y Digestivas (CIBEREHD), (5)Hepatology Unit, Hospital Universitario La Paz, Spain

Background: The prevalence of hepatitis delta virus (HDV) infection in patients with chronic HBV infection varies across studies. The aims of the study were to assess the prevalence of HDV and to investigate the impact of HDV viremia in the severity of hepatic disease. **Methods:** A retrospective study was conducted in 3 hospitals from the two biggest cities in Spain (Madrid and Barcelona). Sociodemographic data was collected, and the medical records of patients with hepatitis B were also reviewed. All participants had a positive hepatitis B surface antigen (HBsAg). The prevalence of HDV was calculated and a descriptive analysis of patients with HDV infection was performed. The data were collected using REDCap. **Results:** Of 2241 HBsAg-positive participants, the prevalence of HDV coinfection was 4.5% (103/2241) and 39% of HDV-positive individual's had active HDV replication (detectable HDV-RNA). The median age was 54 (47-61) years, 65 (63%) were male and 35% were non-native. Main risk factors for HBV/HDV were unknown route (64%), intrafamilial transmission (18%), intravenous drug use (14%) and men who had sex with men who engaged in unsafe sexual behaviors (3%). Of the 103 patients with HBV/HDV coinfection, 16 (16%) had been exposed to HCV and 14 (14%) were coinfected with HIV. Regarding liver disease severity, 11% had advanced liver fibrosis (F3) and 51 (50%) had cirrhosis (F4), based on transient elastography or liver biopsy. Of those with liver cirrhosis and according to the Child-Pugh score, patients were classified as: A (26%), B (34%) and C (40%). Of these patients, 19 (18%) were on the waiting list for liver transplantation and 10 (10%) had been diagnosed with a hepatocellular carcinoma. Ten patients (14%) had received pegylated interferon, but of these, 7 patients still had detectable HDV-RNA. In a multivariate regression analysis, the only variable associated with liver cirrhosis was the presence of detectable HDV-RNA (OR 8.1 [95% CI, 2.9-22.7] $p < 0.001$). **Conclusion:** The prevalence of HDV infection in HBsAg positive patients in a large urban Spanish cohort was 4.5 %. The presence of cirrhosis was very common, particularly in patients with detectable HDV-RNA. Only a minority had had past exposure to IFN-based therapies.

1379-C | PREVALENCE OF HEPATITIS B AND D VIRUS AMONG A NATIONALLY REPRESENTATIVE INSURED POPULATION IN THE UNITED STATES

Norah Terrault[1], Sacha Satram[2], Michael A. Chattergoon[3], Christopher Dieyi[4], Jason Maynard[4], Radhika Trivedi[4], Richard Coppola[4] and Nancy Reau[5], (1)University of Southern California, (2)Vir Biotechnology, (3)Vir Biotechnology, Inc, (4)Statinmed, LLC, (5)Rush Medical College, Chicago, IL

Background: Hepatitis D virus (HDV) is an incomplete human RNA virus that requires chronic hepatitis B (HBV) infection for replication. HDV is the most severe

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

form of viral hepatitis and presents as a co-infection (simultaneous infection) or superinfection (acquired infection) with HBV. The true prevalence of HBV and HDV remains unclear in the United States (US), given that HBV is not a nationally reportable condition, and many prevalence estimates rely on small studies from special high-risk subpopulations. The aim of this study is to provide updated prevalence estimates for HBV and HDV using a large, population-based administrative claims database. **Methods:** This cross-sectional, prevalence study used data from an all-payer claims database, from January 1, 2014 to December 31, 2022. The database contains information on 80% of the US insured population. Prevalence of HBV was defined among all patients in the database (N = 278,679,590), while prevalence of HDV was defined among patients with HBV. Patients with HBV and HDV were identified by the presence of ≥ 2 International Classification of Diseases 9th/10th Clinical Revision (ICD-9/-10-CM) diagnoses codes, at least 1 month apart to exclude rule out diagnoses (i.e. patients screened but not diagnosed). Baseline demographic characteristics (age at diagnosis, sex, US residential region, and race) were assessed. **Results:** The prevalence of HBV was 0.2% (n = 548,722). The majority of HBV patients were adults (aged 18+ years; 99%), male (54%), located in the Northeast (36%), and enrolled under Medicaid (42%). Where race information was available (34%), most were White (48%) or Asian (36%). Among the patients with HBV, the prevalence of HDV was 2.8% (n = 15,065), with the majority being adults (97%), male (52%), located in the North central region (42%), and enrolled under Medicaid (56%). Among those with available race information (38%), most were White (43%) or Black (34%). **Conclusion:** This is the largest study to date on the diagnosed prevalence of HBV and HDV in the US and provides further support of a previously reported 3% overall prevalence of HDV among HBV patients. A robust definition of HBV and HDV that required confirmation of at least 2 diagnostic codes on medical claims is a strength of this study and adds to the existing sparse literature on disease burden of HDV in the US.

1380-C | PREVALENCE, CLINICAL AND VIROLOGICAL CHARACTERISTICS AND SHORT-TERM PROGNOSIS OF HEPATITIS DELTA INFECTION AMONG HIV/HBV COINFECTED PATIENTS IN NOUAKCHOTT, MAURITANIA

Hélène Le Guillou-Guillemette[1,2], Adeline Pivert[1,2], Ahmed ElBara[3], Mazouz Vall[4], Cindy Ng Wing Sang[1], Pascal Veillon[1], Alexandra Ducancelle[1,2], Mohamed Abdallahi Bollahi[3], Francoise Anne Caroline Lunel-Fabiani[1,2] and Mohamed Hemeyine[5], (1)Angers University Hospital, Angers, France, (2)Angers University, Angers, France, (3)Institut National De Recherche En Santé Publique, Nouakchott, (4)Centre De Traitement Ambulatoire, Nouakchott, (5)Institut National D'hépato-Virologie, Nouakchott

Background: Patients living with HIV infection (PLWH) are at risk of acquiring HBV and HDV. The present study aimed to determine the prevalence and characteristics of HIV-HDV-HBV tri-infection in comparison with HIV-HBV coinfection and to estimate severities and outcomes of associated liver diseases in Mauritanian PLWH. **Methods:** 292 consecutive HBsAg-positive PLWH were included. Anti-HDV antibodies (Ab) and HBV and HDV viral loads were determined. APRI, FIB-4 and FibroScan were used to evaluate liver disease. **Results:** The anti-HDV Ab prevalence was 37% and HDV RNA was positive in 40.7% of patients. At inclusion, for almost all variables studied, including FIB-4 and APRI scores, no significant differences were found between anti-HDV-Ab positive or negative patients. Significant differences were also absent at end-of-follow-up FibroScan examinations. However, after a mean follow-up of 24.55 ± 8.01 months, a highly significant worsening of APRI and FIB-4 scores was found in the group of patients with follow-up (n = 217). Moreover, patients with HDV showed more severe liver disease progression. **Conclusion:** In a substantial Mauritanian cohort of PLWH, we found high HDV prevalence and worsening liver disease. In high-risk countries, screening for HDV and providing appropriate treatment and follow-up are warranted in PLWH.

1381-C | PROJECT ECHO IMPLEMENTING CASE BASED PROVIDER TRAINING FOR HEPATITIS B TO REDUCE HEALTH DISPARITIES

Catherine Freeland[1], John Bruckbauer[2], Evangeline Wang[1], Anousha Qureshi[1], Katherine Huynh[3], Myra Rutland[4], Jonathan M. Fenkel[5], Jessie Torgersen[6], Kenneth D. Rothstein[7], Robert G. Gish[8] and Chari Cohen[1], (1)Hepatitis B Foundation, (2)Thomas Jefferson University College of Population Health Science, (3)Fairmount Primary Care Center Gmc, (4) Spectrum Health Services, (5)Thomas Jefferson University Hospital, (6)University of Pennsylvania Perelman School of Medicine, (7)University of Pennsylvania Health System, (8)Hepatitis B Foundation, La Jolla, CA

Background: In the United States, 2.4 million people are living with chronic hepatitis B, but less than 20% are aware of their status. Screening and vaccination uptake remains low among adult U.S. populations. Comprehensive hepatitis B education and testing remains low at the primary care level. The Project ECHO (Extension for Community Health Outcomes) seeks to simplify complex hepatitis B epidemiology and enhance medical knowledge competency on hepatitis B testing, treatment, and management among primary care providers and public health professionals through case-based learning modules, best practices, and interactive discussions delivered by experts in the field. This study assesses the impact of the ECHO sessions on provider training to deliver efficient and specialized care to test, treat, and manage hepatitis B. **Methods:** The hepatitis B ECHO uses the ECHO model (all teach all learn) collaborative learning model of case-based learning. Hepatitis B Project ECHO hosts monthly hour-long sessions for an international audience. Each session features a didactic session followed by a case presentation with feedback and discussion. Sessions are evaluated through pre- and post-test surveys to assess provider knowledge and confidence gained following each session. Qualitative data is also captured to assess provider satisfaction. To assess provider knowledge and satisfaction, survey results from the 2021 and 2022 sessions were used to report the mean change in reported scores from survey participants. The Wilcoxon signed-rank test was performed to evaluate the change in scores from pre- to post-session survey results. SPSS statistical software was used for analysis. **Results:** A total of 20 Hepatitis B ECHO sessions took place in 2021 and 2022 with an average attendance of 40 participants in each session. From the statistical analysis, average scores from post testing demonstrate a significant growth in confidence and hepatitis B related knowledge following each session (Figure 1). Results of the Wilcoxon Rank Test indicated a statistically significant difference in the scores from pre to post. Analysis of scores before and after each session identified increased competency, with changes from pre to post ranging between 22% to 27% in growth (Table 1). Qualitative data demonstrated positive feedback from attendees who completed the survey describing it as “a great source for learning” and “a wonderfully diverse participant group that lends well to comprehensive discussion.” **Conclusion:** Hepatitis B provider training is limited in its availability and gaps in provider knowledge related to hepatitis B have been demonstrated within the literature. The Hepatitis B ECHO fills the gap in provider training and demonstrates the value of mentored, case-based, didactic learning as well as an interest and need for ongoing support for primary care providers to improve testing, treatment and management for hepatitis B.

Table 1. Change in scores before and after using Wilcoxon Rank Test from the HBV Provider ECHO evaluation.

Survey Question	Survey Question	Pre-test Median	Post-test Median	Z score	p value	Pre-Test: Reporting “Competency” or higher (%)	Post-Test: Reporting “Competency” or higher (%)	Change from Pre to Post (%)
Question 1	Question 1	4	4	-4.874	<.001	61	83	22
Question 2	Question 2	3	4	-4.625	<.001	47	69	22
Question 3	Question 3	3	4	-5.374	<.001	42	69	27
Question 4	Question 4	3	4	-4.75	<.001	36	59	24
Question 5	Question 5	3	4	-4.951	<.001	48	70	22

1382-C | PROJECTED BURDEN OF NEWLY DIAGNOSED CHRONIC HEPATITIS B IN HONG KONG TOWARDS 2030

Vicki Wing-Ki Hui[1], Grace Lai-Hung C Wong[1], Yee-Kit Tse[1], Vincent Wai-Sun Wong[2] and Terry Cheuk-Fung Yip[3], (1)The Chinese University of Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, China, (3)The Chinese University of Hong Kong, Hong Kong, 91, China

Background: Chronic Hepatitis B (CHB) is a major public health concern, particularly in Hong Kong, where approximately 7% of the population is affected. The World Health Organization (WHO) aims to eliminate hepatitis B by 2030, making it essential to understand the disease burden and treatment adoption among CHB patients. In this study, we sought to estimate the disease burden in Hong Kong from 2023 to 2030. **Methods:** This territory-wide retrospective observational cohort study was conducted in Hong Kong. We identified subjects who had hepatitis B surface antigen, hepatitis B e antigen, and Hepatitis B virus (HBV) DNA tested between 2000 and 2022. Vector autoregression and autoregressive integrated moving average were utilized to forecast the HBV incidence rate, with the optimal granularity identified as a three-month interval. Health expenditure per capita, total visitor arrivals, and death counts were considered in forecasting. The yearly HBV incidence rate is approximated by the number of patients with the first HBV positive case divided by the number of patients with the first HBV assay checked. **Results:** Between 2000 and 2022, 1,684,821 patients who had undergone HBV testing were identified, with 256,822 (15.2%) yielding positive results. Over the 23-year period, newly diagnosed HBV patients between 2011-2022 had a higher average age of 57.3 $\pm$ 14.7, compared to 44.9 $\pm$ 17.1 for those diagnosed between 2000-2004. The majority of patients were male (129,367, 57%). Projections indicate that the incidence rate of HBV is expected to decrease by 36% from 0.11 to 0.04 between March 2023 and December 2030. **Conclusion:** Our study suggests that Hong Kong is on track to achieve the WHO's goal of hepatitis B elimination by 2030, leading to improved public health and reduced healthcare costs. The projected decrease in the incidence rate of HBV highlights the effectiveness of public health measures and increased awareness of the disease. The government-sponsored hepatitis B vaccination program in Hong Kong has played a significant role in reducing the prevalence of HBV among younger generations, which is consistent with the observation that newly diagnosed patients are older. Figure: Projected HBV incidence rate from 2023 to 2030.

1383-C | RECOMPENSATION TIMEFRAME AND STABILITY IN TREATMENT-NAÏVE HBV-RELATED DECOMPENSATED CIRRHOSIS

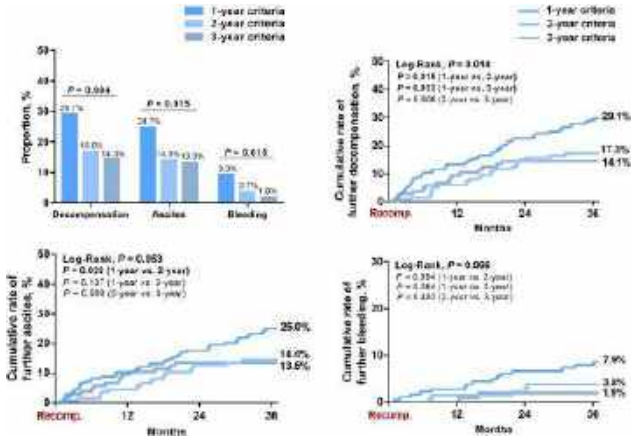
Zhiying He[1], Bingqiong Wang[1], Xiaoning Wu[1], Zhongjie Hu[2], Chunqing Zhang[3], Yanqin Hao[4], Yongfeng Yang[5], Yan Huang[6], Wei Rao Sr.[7], Jing Wang[8], Shuai Xia[1], Jialing Zhou[1], Xiaojuan Ou[1], Jidong Jia[1] and Hong You[9], (1)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (2)Capital Mecical University Beijing Youan Hospital, (3)Provincial Hospital Affiliated to Shandong First Medical University, (4)The First Hospital of Shanxi Medical University, Taiyuan, China, (5)The Second Hospital of Nanjing, Affiliated to Medical School of South East University, Nanjing, China, (6)Department of Infectious Diseases, Xiangya Hospital, Central South University, Changsha, Hunan, China, (7)Division of Hepatology, Liver Disease Center, the Affiliated Hospital of Qingdao University, (8)Inner Mongolia University of Science and Technology, (9)Liver Research Center, Beijing Friendship Hospital, Capital Medical University

Background: Recompensation could be achieved by effective etiological treatment in patients with HBV-related decompensated cirrhosis. However, the timeframe criteria to define recompensation and its stability has not been well clarified. **Methods:** In this retrospective multicenter study, treatment-naïve HBV-related decompensated patients were enrolled at first decompensating event of ascites and/or variceal bleeding in 8 participating hospitals. Further complications and clinical characteristics were collected every 6 months to 6 years of antiviral treatment. Recompensation was defined as maintaining free of decompensation for at least 1 year, along with stable improvement of liver function within Child-Pugh A and/or MELD < 10. The timeframe criteria for recompensation were further subclassified according to the different time interval within the first 3 years since first decompensation: 1 year (1-year criteria), 2 years (2-year criteria) and 3 year (3-year criteria). Stablility of recompensation was determined as free of decompensation and maintenance of liver function following recompensation. **Results:** A total of 243 patients were included for analysis with a median follow-up duration of 64.8 months. Among them, there were 192 (79.0%), 147 (60.5%) and 110 (45.3%) patients met the criteria for recompensation according to 1-year, 2-year and 3-year criteria ($p < 0.001$), respectively. In recompensated patients, the 5-year cumulative rate of second decompensation was significant higher in the 1-year criteria group compared to the 2-year and 3-year criteria groups (35.0% vs. 22.9% and 12.3%, $p < 0.05$). During an extended 3-year follow-up period after recompensation in recompensated patients, the rate of further decompensation was highest in 1-year criteria group with a rate of 29.1%, which was 17.3% and 14.1% in 2-year and 3-year criteria groups (1-year vs. 2- and 3-year criteria, $p < 0.05$; 2-year vs. 3-year criteria: $p > 0.05$), respectively. The proportion of stable recompensation was lower in 1-year criteria group compared to 2-year and 3-year criteria (52.7% vs. 63.2% vs. 68.6%), and the difference was only observed between the 1-year and 3-year criteria groups ($p = 0.009$). Thus, compared to 1-year criteria recommended in Baveno VII

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

consensus, using 2- or 3-year criteria resulted in a higher proportion of stable recompensation. **Conclusion:** In treatment-naïve HBV-related decompensated patients, maintaining free of decompensation for at least 2 years was highly recommended to define recompensation.



Disclosures: The following people have nothing to disclose: Zhiying He, Bingqiong Wang, Xiaoning Wu, Zhongjie Hu, Chunqing Zhang, Yanqin Hao, Yongfeng Yang, Yan Huang, Wei Rao, Jing Wang, Shuai Xia, Jialing Zhou, Xiaojuan Ou, Jidong Jia, Hong You

1384-C | REGIONAL DIFFERENCES IN HEPATITIS DELTA SEROPREVALENCE AND EPIDEMIOLOGY IN PORTUGAL: DATA FROM THREE CENTERS

Mariana Ferreira Cardoso[1], Isabel Garrido[2], Verónica Gamelas[3], Henrique Coelho[1], Maria Inês Canha[3], Guilherme Macedo[2], Filipe Calinas[3] and Alexandra Martins[1], (1)Hospital Professor Doutor Fernando Fonseca, (2)Centro Hospitalar Universitário S. João, (3) Centro Hospitalar Universitário Lisboa Central

Background: Data about seroprevalence and clinical features of hepatitis delta virus (HDV) infection in Portugal are scarce. We aimed to perform a combined analysis of three cohorts of patients followed in Hepatology clinics for hepatitis B virus (HBV) infection regarding HDV seroprevalence, to characterize seropositive patients, and to compare their epidemiology in the 3 groups. **Methods:** We included data from two hospitals in Lisbon metropolitan area, including one in the city center (HSAC) and one serving the districts of Amadora and Sintra (HFF), as well as a third hospital in Porto (CHUSJ). The cohort from HSAC refers to consecutive patients followed for chronic HBV infection between January 2018 and December 2019. In HFF, patients followed for HBV between 2012 and 2022 were included. In CHUSJ, all HBV patients who had been tested for HDV between 2010 and 2020 were studied. SPSS was used for statistical analysis. Fischer exact test and t-student test were used to compare groups ($p < 0.05$ was considered significant). **Results:** HDV serology data were available in 196/349 (56%) HBV patients from HSAC, 665/835 (80%) from HFF and 580 from CHUSJ, adding up to 1441 patients. HDV seroprevalence was 28/196 (14.3%) in HSAC, 43/665 (6.5%) in HFF and 20/580 (3.4%) in CHUSJ, resulting in a pooled seroprevalence of 91/1441 (6.3%). Considering the group of 91 seropositive patients, 68% were male and mean age was 43 ± 11 [20-68] years. A high proportion of patients originated from African countries (47%), 88% of which from Guinea-Bissau, while 38% originated from Portugal, 12% from Central and Eastern Europe, and 3% from American and Asian countries. Most patients were HBeAg negative at diagnosis (91%). RNA data was available in 43 patients and was positive in 11 (26%), of which 8 had been genotyped: 7 patients as GT5 and one as GT1. Advanced chronic liver disease was present in 36% of patients and 5 (6%) presented liver cancer (hepatocellular carcinoma: 4; cholangiocarcinoma: 1). When comparing Lisbon area (HSAC and HFF) to Porto (CHUSJ), HDV seroprevalence was higher in Lisbon (8.3% vs 3.4%, $p < 0.0001$). A higher proportion of seropositive patients were immigrants from endemic areas in Lisbon than in Porto (70% vs 30%, $p = 0.002$), while intravenous drug use (IDU) was more common in the cohort from Porto (55% vs 14%, $p < 0.0001$). In Lisbon area, HFF had the strongest influence of immigration, with 84% of seropositive patients originating from endemic areas, compared to 46% in HSAC ($p = 0.001$). Age (43.3 vs 41.8 y, $p = 0.582$) and gender (65% vs 80% male, $p = 0.154$) did not differ in Lisbon and Porto. **Conclusion:** Pooled HDV seroprevalence in 1441 patients followed for HBV in three portuguese centers was 6.3%. Seroprevalence was higher in Lisbon than in Porto. In Porto, IDU was the most common source of HDV transmission, while in Lisbon, and particularly in HFF, immigration from endemic countries played a major role.

1385-C | RELATIONSHIP BETWEEN PRESENCE OF METABOLIC DYSFUNCTION ASSOCIATED FATTY LIVER DISEASE AND CHANGE IN LIVER STIFFNESS IN INDIVIDUALS WITH CHRONIC HEPATITIS B

Lesley Ann Patmore[1], Kirsi Van Eekhout[2], Ozgur Mustafa Koc[3], Rob J. De Knegt[1], Harry L. A. Janssen[4,5], Matthijs Kramer[3], Willem Pieter Brouwer[6], Pieter Honkoop[7], Joep De Bruijne[8], Greet Boland[8], Robert A. De Man[6], Bart Takkenberg[2] and Milan J. Sonneveld[1], (1)Erasmus MC, University Medical Center, (2)Amsterdam University Medical Center, Amsterdam, Netherlands, (3)Maastricht University Medical Center, (4)Erasmus MC, University Medical Center Rotterdam, (5)Toronto General Hospital Research Institute, (6)Erasmus MC, University Medical Center, Rotterdam, Netherlands, (7)Albert Schweitzer Hospital, (8)Utrecht Umc

Background: Recent studies suggest that presence of metabolic dysfunction associated fatty liver disease (MAFLD) is associated with an increased risk for liver-related events in individual's with chronic hepatitis B (CHB). This might be due to more rapid progression of liver fibrosis in individual's co-affected by CHB and MAFLD. Therefore, we studied the association between presence of MAFLD and change in liver stiffness over time in individual's with CHB. **Methods:** We conducted a multicenter retrospective cohort study of mono-infected individual's with CHB who underwent at least two liver stiffness measurements (LSM) with FibroScan. MALFD was defined as presence of hepatic steatosis (based on histology, controlled attenuation parameter or ultrasound) in combination with metabolic dysfunction (diabetes, overweight or hypercholesterolemia and hypertension). We studied the change in LSM from the first LSM to the most recent LSM and defined a significant increase/decrease of ≥ 1 kPa from baseline. **Results:** We analyzed 1376 individual's with a median age of 40 years (interquartile range [IQR] 31-49). MAFLD was present in 359 (26.1%) individual's. The median LSM at baseline was and at last follow-up was 5.6 kPa (IQR: 4.4–7.4) and 5.1 kPa (IQR 4.1–6.5); with a median follow-up time of 4.7 years (IQR 2.6–7.7). Individual's co-affected by MAFLD had a significantly higher LSM compared to individual's without MAFLD (8.0 kPa vs. 6.6 kPa $p = 0.003$). An increase in LSM was observed in 283 (20.5%) individual's, with a significantly higher proportion among individual's with MAFLD versus those without MAFLD (25% vs. 18%, $p = 0.008$). 682 (49.6%) individual's initiated antiviral therapy, of whom 181 (26.5%) had MAFLD ($p = 0.707$). Antiviral therapy was associated with a significant decrease in LSM (72.1% vs. 53.1% $p < 0.001$). Individual's with MAFLD were significantly less likely to achieve a decrease in LSM (57.9% vs 67.8%, $p = 0.001$). An increase in LSM was observed in 128 individual's (18.7%) who initiated antiviral therapy. MAFLD was associated with a significantly higher risk of LSM increase (27% vs. 15%, $p < 0.001$), and the absolute increase in LSM was also higher among individual's with MAFLD (4.9 vs. 3.5 kPa, $p = 0.01$). In multivariable logistic regression analysis, adjusting for duration of follow-up, baseline HBV DNA and ALT levels, higher age (odds ratio [OR] 1.02, $p = 0.008$), higher LSM at baseline (OR 1.302, $p < 0.001$) and MAFLD (OR 1.516, $p = 0.010$) were significantly associated with an increased risk of LSM progression. **Conclusion:** Individual's with CHB co-affected by MAFLD are more likely to experience an increase in LSM during follow-up. While initiation of antiviral therapy was associated with a decline in LSM in the overall population, such a decrease was less frequently observed among individual's with CHB and MAFLD, and MAFLD was an independent risk factor for liver stiffness increase despite initiation of antiviral therapy.

1386-C | RE-VACCINATION AGAINST HEPATITIS B IN PREVIOUS NON-RESPONDERS FOLLOWING HEPATITIS C ERADICATION

Jesse Powell[1], Spencer Goble[1] and Jose D. Debes[2], (1)Hennepin Healthcare, (2)University of Minnesota

Background: Rates of immunization against hepatitis B virus (HBV) among individual's with chronic hepatitis C virus (HCV) are low and patients with chronic HCV infection do not respond to HBV vaccination as efficiently as non-infected patients. We assessed if HCV treatment resulted in improved response after re-vaccination for HBV. **Methods:** Adult patients who previously did not respond to HBV vaccine were prospectively recruited for re-vaccination after HCV eradication with direct acting antivirals (DAAs). Vaccine response was evaluated by obtaining hepatitis B surface antibody (HBsAb) one month following completion of either the ENGERIX-B or HEPLISAV-B vaccine series. **Results:** A total of 34 patients were enrolled. The median age at time of re-vaccination was 61.5 years (IQR 55-65 y). The majority of patients were male (68%) and Black (59%). The median time from completed HCV treatment to first dose of re-vaccination was 18 months (IQR 8-30 mo). HBsAb testing was performed in 31/34 re-vaccinated patients with 21 reactive (67.7%), 8 non-reactive (25.8%) and 2 equivocal results (6.5%). There were no significant differences in HBsAb reactivity based on age, sex, race, or ethnicity. Presence of advanced fibrosis, being on hemodialysis, HIV co-infection and presence of hepatitis B core antibody also did not significantly impact development of HBsAb following re-vaccination. **Conclusion:** Most prior HBV vaccine non-responders responded to re-vaccination after treatment of HCV. We suggest considering HBV re-vaccination in individual's post DAA treatment. Our results have important public health implications.

1387-C | RISK FACTORS FOR THE DEVELOPMENT OF HEPATOCELLULAR CARCINOMA AFTER ANTIVIRAL THERAPY FOR CHRONIC HEPATITIS B PATIENTS

Junjie Chen[1], Tienan Feng[2] and Xinxin Zhang[1], (1) Ruijin Hospital, Shanghai Jiaotong University School of Medicine, (2)Shanghai Jiao Tong University School of Medicine

Background: It is widely believed that antiviral therapy can reduce the occurrence of hepatocellular carcinoma (HCC) related to chronic hepatitis B (CHB). However, there are still some CHB patients developing HCC during or after antiviral treatment. This study aims to investigate the risk factors for the development of HCC after antiviral therapy in CHB patients. **Methods:** We selected CHB patients who received their first antiviral therapy and completed follow-up from April 2006 to March 2023 in our hospital. All patients were divided into two groups: the HCC group (patients who developed HCC) and the control group (patients who did not develop HCC). Baseline data, including age, gender, initial liver cirrhosis status, routine blood biochemistry, virological examinations, and imaging results (ultrasound, CT, MRI, etc.) were collected. Univariate and multivariate analyses were performed, and a regression model was established using a nomogram for prediction. **Results:** A total of 1450 patients were included, with a median follow-up time of 60 months and a maximum follow-up time of 144 months. During the follow-up period, 32 cases of HCC occurred. The HCC group had significantly lower baseline platelet (PLT) counts, older age, and a higher proportion of pre-existing liver cirrhosis compared to the control group ($p < 0.001$). The levels of γ-glutamyl transferase(γ-GT) and alpha-fetoprotein (AFP) at baseline were higher in the HCC group than in the control group ($p < 0.01$). The HCC group also had a higher proportion of males, higher HBeAb-positive rate, lower albumin (ALB) levels, higher alkaline

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

phosphatase (ALP) levels, and higher total bilirubin (TBil) levels ($p < 0.05$). There were no significant differences between the two groups in terms of HBeAg-positive rate, HBV DNA levels, HBsAg levels, HBcAb levels, and alanine transaminase (ALT) levels. Multivariate analysis revealed that pre-existing liver cirrhosis, male gender, and older age were independent risk factors for HCC development ($p < 0.05$). Besides, higher levels of γ-GT and lower PLT counts at baseline were also identified as risk factors for HCC occurrence ($p < 0.05$). A predictive model for HCC was constructed using baseline liver cirrhosis status, gender, age as independent risk factors, and ALB, HBeAb, γ-GT, TBil, and PLT count as covariates. The model had an area under the curve (AUC) of 0.85 [0.77-0.92], sensitivity of 0.78 [0.60-0.91], and specificity of 0.78 [0.76-0.80]. **Conclusion:** These findings suggest that pre-existing liver cirrhosis, the male and older age at baseline were risk factors associated with HCC, clinicians should monitor closely and intervene early to reduce the incidence of HCC in those CHB patients. Additionally, in high-risk patients for HCC, attention should be given to γ-GT and PLT counts.

1388-C | SCREENING FOR ISOLATED HEPATITIS B CORE ANTIBODIES IN GREATER PHILADELPHIA

Catherine Freeland[1], Vivek Sreepathi[2], Evangeline Wang[1], Jonathan M. Fenkel[3], Richard W Hass[2], Kenneth D. Rothstein[4], Jessie Torgersen[5], Robert G. Gish[1] and Chari Cohen[1], (1)Hepatitis B Foundation, (2) Thomas Jefferson University College of Population Health Science, (3)Thomas Jefferson University Hospital, (4)University of Pennsylvania Health System, (5)University of Pennsylvania Perelman School of Medicine

Background: Approximately 2.4 million individual's are living with chronic hepatitis B in the U.S., but less than 20% are diagnosed. Isolated anti-hepatitis B core (IAHBc) antibodies indicate serology in an individual that is positive for anti-HBc antibodies, while negative for surface antigen (HBsAg) and surface antibodies (anti-HBs). Excluding anti-HBc from HBV screening tests makes interpreting screening results challenging and fails to identify a population of patients at risk for hepatitis B reactivation and increased liver cancer risk. This study assesses the prevalence and risk factors associated with anti-HBc and IAHBc among people at high risk for hepatitis B in Philadelphia at community-based screening events. **Methods:** Individual's from communities at high risk for HBV were offered free hepatitis B triple panel screening (HBsAg, anti-HBc, and anti-HBs) between September 2022 and December 2022. Individual's were recruited through community partners and social service organizations serving known high-risk communities. Participants completed an informed consent and brief demographic survey to assess risk factors, followed by a blood draw. Participants received results within two weeks and were provided linkage to care according to test results. Chi-square tables and Firth logistic regression were used to define demographic factors associated with positive anti-HBc and IAHBc. **Results:** Participants (n = 177) were screened for HBsAg, anti-HBs, and anti-HBc. This study detected anti-Hbs in 58.2% (n = 103) of participants, of whom 63.1% also had detectable anti-HBc. Overall, 50.8% of participants had detectable anti-Hbc (63.1% prior exposure (65/103), 12.6% IAHBc (13/103), and 11.7% (12/103) current infection). The prevalence of IAHBc was 7.3% (n = 13). Participants born in the Western Pacific (5.5) and Africa (12.1) have increased odds of anti-HBc versus American-born participants. Individual's born in Africa had 7.93 greater odds for IAHBc than those born in American and odds that were multiplied by 1.01 for every 1-year increase in age. There were no differences in odds based on whether an individual reported being vaccinated, had health insurance, or had a primary care provider. **Conclusion:** Our data show a high burden of IAHBc within high-risk and often hard-to-reach communities. Much of Philadelphia's high-risk HBV population may have been missed due to IAHBc during screening programs, implying an increased risk of reactivation as well as HCC. Triple panel screening should be incorporated into all HBV screening programs, in accordance with current universal screening guidelines, to ensure a comprehensive picture of the disease burden and reduce the risk of misdiagnosis or further liver complications. This recommendation is within the currently updated hepatitis B universal screening guidelines from March of 2023 and should be implemented within practice, particularly in communities at high-risk for HBV.

1389-C | SOCIODEMOGRAPHIC, BEHAVIORAL, AND CLINICAL CHARACTERISTICS DIFFERENTIATED IN PHYSICAL FUNCTION AMONG CHRONIC HEPATITIS B PATIENTS OF KOREAN AMERICANS

Hee-Soon Juon[1], Ann Klassen[2], Mimi Chang[3], Julia Katcher[1] and Hie-Won L. Hann[4], (1)Thomas Jefferson University, (2)Drexel University, (3)Coalition of Inclusive Medicine, (4)Thomas Jefferson University Hospital, Philadelphia, PA

Background: Although physical function is an important patient outcome, little is known about physical function in chronic hepatitis B (CHB) patients. The purpose of this study to identify subgroups of Korean American CHB patients based on their level of physical function; determine which sociodemographic, behavioral, and clinical factors were associated with subgroup membership; and determine if these subgroups differed on moderate physical activity. **Methods:** Latent class analysis was used to identify groups of CHB patients (n = 365) with distinct physical function profiles. Patients were assessed using the Physical Component Summary (PCS) score from the Short Form 12. Differences, among the groups, in factors were evaluated using multinomial logistic regression. ANOVA was used to examine the differences in moderate physical activity by subgroup. **Results:** Four groups of CHB patients with distinct functional classes were identified: Well Below (8%), Below (21%), Above (12%), well Above (59%) normative PCS scores. Compared with those in the Well Above class, those in the Well Below class were more likely to being older, being female, not married, having poor spoken English proficiency, current smoker, and having a higher level of comorbidity. Two characteristics differentiated Below class and Well Above class: being older and having a higher level of comorbidity. Compared with the Well Above class, patients in the other three classes had significantly lower regular exercise ($p < 0.017$). **Conclusion:** This is the first study to use a person-centered analytic approach to identify subgroups of Korean American CHB patients with distinct physical function profiles. About one third of CHB patients reported significant decrements in physical function which led to lack of regular exercise. Clinicians can assess for those characteristics associated with poorer functional status to identify high-risk patients and initiate appropriate interventions.

1390-C | STATUS OF ANTI-HEPATITIS B ANTIBODY TITER IN ADULTS AND FACTORS ASSOCIATED WITH LOW TITER LEVEL: A RETROSPECTIVE STUDY IN A TERTIARY HOSPITAL IN WV, U.S.A.

Tewodros Ayele, Marshall University

Background: Hepatitis B (HBV) vaccine programs have reduced the global incidence of hepatitis B & hepatocellular carcinoma. Immunity lasts for about 35 years, however there are patients who either remain unimmune or lose immunity over time, putting them at risk for infection. In this study, we examined post-vaccination HBs antibody level & factors associated with low titers in adult patients. **Methods:** A cross sectional study was used to assess the status of hepatitis B antibody titer in patients who were tested between 2018 & 2022 in a tertiary hospital. A total of 2248 patients with antibody titer test results were retrieved. In depth chart review of 800 randomly selected patients was done. Descriptive & logistic regression analysis were used to find possible risk factors for low titers. **Results:** In 2248 patients, the median age was 40 (18-89). 2043 (90.9%) where White. The mean anti-HBs antibody titer level was 165.99 (0.10-4000); 1170 (52%) had titers < 10 mIU/mL. In patients aged 18-35, 402 (44.1%) had titers < 10 mIU/mL. Out of the 800 randomly selected patients, median age was 40 (18-85); 488 (61.5%) Female; 761 (95.8%) White. In patients aged 18-35, 113 (45.6%) had titers < 10 mIU/mL. Median BMI was 29.0 (13.3-141.0). 501 (63.1%) had ≥ 1 comorbidity. 502 (63.2%) used tobacco, 227 (28.6%) used alcohol, & 337 (42.4%) used other substances. 241 (30.4%) had documented HBV vaccination. 228 (28.7%) patients had hepatitis C; 36 (4.5%) had HIV. HIV was significantly associated with immunity (OR = 0.221 95%CI 0.049-0.999). Four other factors had clinically significant but not statistically significant association with antibody titer: substance abuse (OR = 2.393 95%CI 0.917-6.246), alcohol abuse (OR = 1.792 95%CI 0.852-3.769), obesity (OR = 1.782 95%CI 0.801-3.963), & female gender (OR = 0.503 95% CI 0.248-1.020). **Conclusion:** A large portion of young adults have low antibody titers. Those with levels < 3.2 were likely unexposed to the vaccine, while those with levels 3.2 & 10 were likely vaccinated, however lost immunity over time. HIV was associated with higher antibody titers likely due to guideline recommendations for boosters while substance use, alcohol use, & obesity were associated with low titers. These factors may become statistically significant with increased sample sizes. Larger studies may be beneficial, as some of these groups, particularly substance use, are not part of current recommendations for assessing post-vaccination immunity.

1391-C | TENOFOVIR ALAFENAMIDE FUMARATE WAS EFFECTIVE AND SAFE IN PREVENTING MOTHER-TO-CHILD TRANSMISSION OF HEPATITIS B VIRUS: A MULTICENTER PROSPECTIVE COHORT STUDY IN SOUTHWEST CHINA(INTERIM ANALYSIS)

Yan Zhu[1], Dan Wang[2], Jie Xia[1], Guohong Deng[3], Qiong Tan[2], Fang Chen[1], Yi Wu[3], Shilian Li[1], Xuqing Zhang[4], Baofang Zhang[5], Fang Zeng[6] and Qing Mao[3], (1)Department of Infectious Diseases, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China, (2)Department of Obstetrics and Gynecology, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China, (3)Department of Infectious Diseases, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China., (4)Department of Infectious Diseases, the Third Affiliated Hospital of Chongqing Medical University, China, (5)Department of Infectious Diseases, Affiliated Hospital of Guizhou Medical University, Guiyang, China, (6)Department of Infectious Diseases, Wushan County People's Hospital of Chongqing, China

Background: Evidence of Tenofovir alafenamide fumarate(TAF) for the prevention of HBV mother-to-child transmission(MTCT) is limited. Our study aimed to evaluate the effectiveness and safety of TAF in preventing MTCT in Southwest China. **Methods:** In this multicenter prospective study, chronic HBV infected pregnant women with HBsAg(+), HBeAg(+) and HBV DNA > 200,000 IU/ml were enrolled in 4 hospitals in Southwest China. TAF was given to all the pregnant mothers from 24-29 weeks' gestation until 4 to 6 weeks postpartum, and then followed up to 7 to 9 months after infants were born. All the infants received standard immunoprophylaxis with Hepatitis B hyper-immune globulin(HBIG) within 12 hours of birth and hepatitis B vaccination at birth, 1 month and 6 months old. The primary endpoint was HBsAg positive rate at 7-9 months of age in the infants. **Results:** From Apr. 2021 to Apr. 2022, a total of 128 pregnant women were enrolled and 69 mothers and 69 infants completed 7 to 9 months postpartum follow-up. Basic characteristics are showed in Table 1. The HBsAg positive rate was 0% at 7-9 months in all children who completed immunoprohylaxis. Body weight, height and head circumferences were comparable with national standards. No infant had congenital defects and growth retardation. At delivery, maternal mean HBV DNA levels were significantly reduced (from baseline 7.22 ± 1.20 $\log_{10}$ IU/mL to 3.76 ± 0.91 $\log_{10}$ IU/mL, $p = 0.000$) and 95.7%(66/69) of mothers had HBV DNA < 200,000 IU/mL, including 46.4%(32/69) with HBV DNA < 500 IU/mL. ALT, AST, serum creatinine maintained normal before and after TAF treatment. TAF was well tolerated during mean duration of 24-29 weeks of TAF treatment. The most common AEs were weakness(1%) and fatigue(3%). No pregnant woman discontinued TAF treatment due to AE. **Conclusion:** TAF was determined to be effective and safe for both mothers and infants and the MTCT rate is 0%. Therefore, TAF will be an appropriate choice for HBV infected pregnant women for preventing MTCT.

1392-C | THE APPLICATION OF RISK SCORES IN PREDICTION OF HCC IN CHRONIC HEPATITIS B PATIENTS WITH HBsAg SEROCLEARANCE

Rachel Wen-Juei Jeng[1,2], Mei-Hung Pan[3], Chien-Jen Chen[3], Hwai-I Yang[3] and REVEAL-HBV team, (1)Chang Gung Memorial Hospital, Linkou Medical Center, (2)College of Medicine, Chang Gung University, Taiwan, (3)Genomic Research Center, Academia Sinica

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Several scores were developed and validated based on HBsAg-positive chronic hepatitis B patients (CHB). However, their ability to predict hepatocellular carcinoma (HCC) development after HBsAg seroclearance (SC) remains unknown. This study aims to compare the REACH-B, CAG, CAMD, RWS, and NGM scores with Yang's score (*J Hepatol. 2022 Sep;77(3):632-641*), derived from Korean CHB patients who experienced SC, to predict subsequent HCC occurrence. Additionally, we will investigate whether changes in the REACH-B score at SC, compared to the score upon entry to the REVEAL cohort, impact HCC development after HBsAg seroclearance. **Methods:** The REACH-B score, CAG score, CAMD score, RWS score, and NGM score were calculated for a total of 632 REVEAL-CHB patients who experienced HBsAg seroclearance. These scores were estimated using the patients' characteristics at the time of entry into the REVEAL study as well as at the time of SC. On the other hand, Yang's score was only estimated at the time of SC. To assess the predictability of HCC, the area under the reciprocal operating curve (AUROC) was calculated. HCC diagnosed was ascertained using National Cancer Registry database. A *p*-value of less than 0.05 was considered statistically significant. **Results:** Out of 632 CHB patients who achieved SC, 29 patients were diagnosed with HCC over a median follow-up of 17.5 years. The AUROC values for predicting overall, 5-year, 10-year, and 15-year HCC using Yang's score were 0.6207, 0.8883, 0.7261, and 0.7004, respectively. These values were comparable to those obtained using the REACH-B score, which was estimated either at study entry (0.6491, 0.7856, 0.6985, and 0.6865, respectively) or at the time of seroclearance (0.5903, 0.8040, 0.7171, and 0.6973, respectively). Similar predictive performance was observed for the GAG score, CAMD score, RWS score, and NGM score, except for the RWS score at study entry, which was less effective than Yang's score for predicting HCC at 5 years (AUROC: 0.6389 vs. 0.8883, $p = 0.0118$). When comparing the REACH-B scores at the time of cohort entry and seroclearance, it was found that 83.5% of the 540 patients with an initial score < 9 remained in the low-risk group (group 0), while 16.5% progressed to the intermediate-risk group at the time of seroclearance (group 1). Among the 92 patients with an initial score between 9 and 17, 51.1% transitioned to the low-risk group (group 2), while 48.9% remained in the intermediate-risk group (group 3). The occurrence of HCC was highest in group 3 (15.6%), followed by group 2 (6.4%), group 1 (4.5%), and lowest in group 0 (3.3%). **Conclusion:** The risk prediction scores derived from HBsAg seropositivity cohort has comparable HCC predictability as that derived from HBsAg loss cohort. Patients whose REACH-B score reduced at time of SC also have reduced HCC risk.

f 1393-C | THE EFFECT OF ANTIVIRAL TREATMENTS IN PATIENTS WITH CHRONIC HEPATITIS B OF NEAR-CUTOFF ALT LEVELS: A REGRESSION DISCONTINUITY DESIGN STUDY

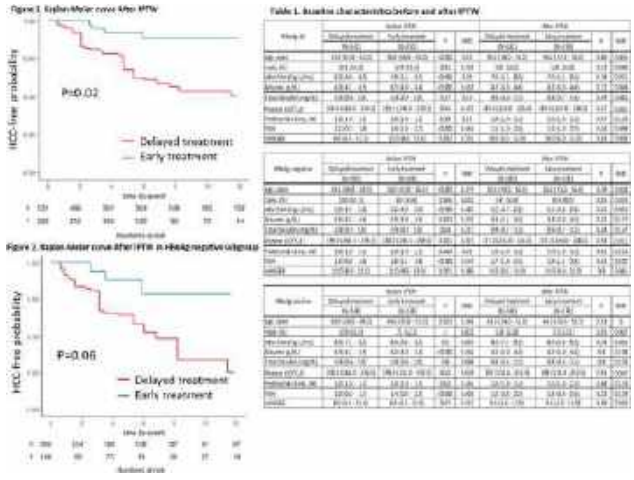
Hyunjae Shin[1], Yunmi Ko[2], Youngsu Park[2], Jeayeon Park[2], Moon Haeng Hur[1], Min Kyung Park[2], Yun Bin Lee[1], Eun Ju Cho[2], Su Jong Yu[2], Yoon Jun Kim[3], Jung-Hwan Yoon[2] and Jeong-Hoon Lee[4], (1)Seoul National University Hospital, (2)Seoul National University College of Medicine, (3)Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea, (4)Seoul National University College of Medicine, Seoul, South Korea

Background: Antiviral treatment reportedly reduces the risk of hepatocellular carcinoma (HCC) development in patients with chronic hepatitis B (CHB). However, it is controversial whether antiviral treatment would be beneficial for patients with high serum HBV DNA and modestly elevated alanine aminotransferase (ALT) levels. We aimed to examine the effect of antiviral treatments on patients with serum ALT levels around 80 U/L, which is the Asian-Pacific treatment threshold. **Methods:** Consecutive non-cirrhotic CHB patients with serum HBV DNA **e** 2,000 IU/mL and an ALT level around the threshold (i.e., 60–100 U/L) were included from a tertiary hospital in Korea. With an ALT cutoff of 80 U/L, regression discontinuity design (RDD), a quasi-experimental impact evaluation method, was utilized. Patients were classified into two groups: those with ALT levels of 80–100 U/L who initiated antiviral treatment within a year (the early treatment group) and those with ALT levels of 60–80 U/L of ALT level who did not begin antiviral treatment within a year (the delayed treatment group). The primary outcome was the HCC development. According to the assumptions of RDD, two groups were

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

assumed to have comparable characteristics, including unmeasured confounders, except for ALT level and timing of antiviral initiation. Inverse probability treatment weighting (IPTW) method of two groups were applied to rebalance the remaining unbalanced baseline characteristics. **Results:** A total of 781 non-cirrhotic CHB patients were analyzed. During a median of 7.1 (interquartile range = 3.2–11.8) years of follow-up, 24 patients (3.1%) developed HCC. Baseline ALT levels were lower in the delayed treatment group (median = 68 U/L, interquartile range = 64–73 U/L) than in the early treatment group (median = 89 U/L, IQR = 84–94 U/L). After employing IPTW, baseline characteristics except for ALT level were well-balanced (Table 1). In the IPTW-balanced population, the early treatment group had a significantly lower risk of HCC than the delayed treatment group (hazard ratio [HR] = 0.23, 95% confidence interval [CI] = 0.08–0.73, $p = 0.02$ by log-rank test; Figure 1). In the subgroup analysis, the HRs of the HBeAg-negative (HR = 0.29, 95% CI = 0.08–1.05, $p = 0.06$; Figure 2) and HBeAg-positive (HR = 0.19, 95% CI = 0.02–1.87, $p = 0.15$) subgroups were similar, although neither result reached statistical significance. **Conclusion:** This finding of RDD study suggests that antiviral treatments is associated with lower of HCC development among patients with near-cutoff ALT levels and active HBV replication. Further study is warranted to lower the treatment threshold of ALT level in CHB patients.



Disclosures: The following people have nothing to disclose: Hyunjae Shin, Yunmi Ko, Youngsu Park, Jeayeon Park, Moon Haeng Hur, Min Kyung Park, Yun Bin Lee, Eun Ju Cho, Su Jong Yu, Yoon Jun Kim, Jung-Hwan Yoon, Jeong-Hoon Lee

1394-C | THE IMPACT OF CHANGING HBV TREATMENT ELIGIBILITY ON PORTION ELIGIBLE FOR TREATMENT BY REGION, 2024

Devin Razavi-Shearer, Ivane Gamkrelidze, Kathryn Razavi-Shearer, Alexis Voeller and Homie Razavi, Center for Disease Analysis Foundation

Background: As countries and regions begin to expand eligibility guidelines for hepatitis B virus (HBV) it is important to understand the potential impact that this will have on healthcare systems. We aimed to quantify the portion of HBV infections eligible for treatment under different guidelines at the regional level in 2024. **Methods:** The Polaris Observatory maintains and annually updates 170 country specific PRoGReSs Models. The PRoGReSs Model is a fully dynamic HBV disease burden and transmission Markov model. This model considers the impact of diagnosis, treatment, and all prophylaxis measures on the incidence and disease burden of hepatitis B. The models were then used to estimate the impact of 10 different scenarios altering cut-offs for viral load, ALT, and age. **Results:** Models were populated for 170 countries, 97 of which received feedback from country experts, 54 were based on published data, and 19 used extrapolated prevalence data. Lowering the eligible age has little impact on the portion of HBV-positive individual's eligible for treatment in EURO, PAHO, and WPRO (Table 1). However, lowering the age cut-off had the largest impact in the AFRO. When the viral load threshold for eligibility was lowered it had a large impact on the total number and proportion eligible in every region. Lowering the viral load cut-off from **e** 20,000 IU/mL to **e** 2000 IU/mL increased eligibility by 37% in the AFRO region whereas the same change would increase eligibility by only 18% in the WPRO region (Table 1). Removing ALT (greater than upper limit of normal) from eligibility criteria had the largest impact on proportion eligible. Removing ALT > ULN increased the number of HBV infections eligible for treatment in 75–100% across the regions analysed (Table 1). **Conclusion:** Expanding treatment eligibility will result in many more individual's being eligible for treatment. However, there is great variation on the impact of changing specific thresholds will have by region dependent on the historical vaccination coverage, current age structure, and HBV genotype. Even with expansion in treatment criteria the biggest hurdles yet to overcome remain increasing the share of infected individual's who are diagnosed and linked to care. This will require an increase in awareness regarding HBV, including that it is a virus that cause liver cancer, and a mobilization of resources centring primary health care workers on all fronts.

1395-C | THE IMPACT OF HEPATIC STEATOSIS ON RESPONSE OF ANTIVIRAL THERAPY IN CHB PATIENTS: A META-ANALYSIS

Lili Liu[1], Hong Li[1], Daqiong Zhou[1], Xiaofei Du[1], Lixia Qiu[1], Shan Liang[1], Xiaohui Liu[1], Lixia Ma[1], Xinhuan Wei[1], Haiqing Guo[1], Shanshan Xu[1], Yang Zhang[1], Yali Liu[1], Jing Zhang[2] and Zhenhuan Cao[1], (1)Beijing Youan Hospital Capital Medical University, Beijing, China, (2) Beijing Youan Hospital, Capital Medical University

Background: Hepatitis B virus (HBV) infection combined with nonalcoholic fatty liver disease (NAFLD) is very common. However, it remains unclear whether hepatic steatosis affects the antiviral efficacy in patients with chronic hepatitis B (CHB). **Methods:** We searched the literature from PubMed, EMBASE, Cochrane library and Web of Science from inception to July 22, 2022. Data were collected and meta-analysis was performed using fixed or random models. **Results:** A total of 14 studies with 2591 CHB patients were included. CHB patients combined with steatosis had lower alanine transaminase (ALT) normalization rates when treated with nucleoside analog (NA) at 48 and 96 weeks (60% vs. 72% and 62% vs. 74%, $p < 0.001$), but the difference was not statistically significant with pegylated interferon (PEG-IFN) treatment. HBV DNA suppression rates were lower in patients with hepatic steatosis treated with NA and PEG-IFN at week 48 (64% vs. 76%, $p < 0.001$ and 39% vs. 45%, $p = 0.043$), while there was no significant difference at week 96 treated with NA. The clearance rates of hepatitis B e antigen (HBeAg) and hepatitis B surface antigen (HBsAg) were higher with PEG-IFN than with NA. There were no significant differences in HBeAg and HBsAg clearance rates between CHB patients with and without steatosis treated with NA or PEG-IFN at week 48. **Conclusion:** Hepatic steatosis did not impose a significant effect on NA and PEG-IFN treatment efficacy. Perhaps hepatic steatosis reduced HBV DNA suppression in the short time with NA therapy, but this effect disappeared with longer treatment duration. Studies on the antiviral efficacy of hepatic steatosis on PEG-IFN are rare and more studies are needed, especially for long-term treatment.

Table. The association of hepatic steatosis with 48-week and 96-week ALT normalization rate, HBV DNA suppression rate, HBeAg clearance rate and HBsAg clearance.

	Studies (n)	Participants (n)	CHB with steatosis vs without steatosis	Pooled RR (95% CI)
48-week antiviral response				
ALT normalization	All:9 NA*:6 PEG-IFN*:4	1714 1270 444	**54% vs 67%** **60% vs 72%** 42% vs 59%	**0.79 (0.70-0.90)** **0.83 (0.76-0.91)** 0.77 (0.51-1.16)
HBV DNA suppression	All:13 NA*:9 PEG-IFN*:5	2449 1955 494	**57% vs 66%** **64% vs 76%** **39% vs 45%**	**0.86 (0.81-0.92)** **0.87 (0.81-0.93)** **0.80 (0.64-0.99)**
HBeAg clearance	All:10 NA*:7 PEG-IFN:3	1043 824 219	21% vs 27% 16% vs 23% 35% vs 37%	0.83 (0.66-1.04) 0.78 (0.58-1.04) 0.94 (0.65-1.36)
HBsAg clearance	PEG-IFN: 2	139	8% vs 6%	1.26 (0.41-3.92)
96-week antiviral response				
ALT normalization	NA: 4	1001	**62% vs 74%**	**0.82 (0.74-0.91)**
HBV DNA suppression	NA: 5	1175	71% vs 76%	0.93 (0.84-1.04)
HBeAg clearance	NA: 4	469	32% vs 36%	0.90 (0.70-1.15)
HBsAg clearance	NA: 2	282	4% vs 4%	1.11 (0.37-3.37)

*29.5% of the patients were treated with PEG-IFN and 70.5% with NA in one study, separate analysis according to treatment modality.
†29.5% of the patients were treated with PEG-IFN and 70.5% with NA in one study, results were included in the NA group analysis.
ALT, alanine transaminase; CI, confidence interval; HsBAg, hepatitis B surface antigen; HBeAg, hepatitis B e antigen; NA, nucleoside analog; PEG-IFN, pegylated interferon; RR, relative risk.

limited settings. A crucial milestone is achieving 80% treatment coverage among eligible individual's. Currently, high risk of disease progression determines antiviral treatment eligibility for chronic hepatitis B virus (HBV). In order to inform the updating of the 2015 WHO recommendations on who to treat, a systematic review and meta-analysis was undertaken to estimate the incidence rate of clinical outcomes in untreated, non-cirrhotic people with HBV, stratified by HBV DNA levels and alanine transaminase (ALT) levels at baseline. **Methods:** We searched PubMed, Embase, Web of Science, and the Cochrane Library for cohort studies published up to 6th Feb 2023. Two reviewers independently screened the titles and abstracts and extracted data from full-text articles. Outcomes included cirrhosis, hepatocellular carcinoma (HCC), and liver-related mortality. The pooled incidence rates of each outcome were stratified by the baseline viral load (< 2,000, 2,000-20,000, 20,000-200,000, and **e** 200,000 IU/mL) or ALT levels (1x, 1-2x, **e** 2x ULN). A meta-analysis using a generalized linear mixed model was performed. **Results:** Of 13,124 identified and screened studies, 80 were included. In low viral load strata - HBV DNA < 200 IU/mL and < 2,000 IU/mL, the pooled incidence of HCC (per 100 person-years) was low: 0.129 (95% CI: 0.090-0.183) and 0.161 (0.103-0.253) respectively. In viral load strata above 2,000 IU/mL, there was a clear dose-response relationship: 0.267 (0.213-0.334), 0.732 (0.592-0.905), and 0.923 (0.679-1.256) when HBV DNA were 2,000-20,000, 20,000-200,000, and **e** 200,000 IU/mL, respectively ($p < 0.01$, Figure). A similar relationship was observed for the incidence of cirrhosis and liver-related mortality. HCC incidence was low (0.094 (0.045-0.196)) in individual's with persistently normal ALT. There were only 12 studies in children, and we did not observe any clear association between viral loads at baseline and clinical outcomes. **Conclusion:** This represents the most comprehensive global systematic review and meta-analysis to date of the natural history of chronic HBV infection. The incidence rates of cirrhosis and HCC were low in those with HBV DNA < 2000 IU/ml. There was paucity of data for the natural history of chronic HBV in the paediatric population, and this is a priority for further research.

Figure. Incidence rates of liver-related deaths, HCC, and cirrhosis by baseline HBV DNA levels.

1397-C | THE SHARE OF TOTAL HBV INFECTIONS BY AGE AT THE GLOBAL AND REGIONAL LEVEL, 2022

Devin Razavi-Shearer, Ivane Gamkrelidze, Kathryn Razavi-Shearer, Alexis Voeller and Homie Razavi, Center for Disease Analysis Foundation

Background: As we move closer to the 2030 date set for the elimination of viral hepatitis as a public health threat, information is needed to guide countries towards strategies that will be most impactful. Due to the diversity of nations, their historical and current programs, there exists great heterogeneity in the burden of hepatitis B virus (HBV). One way this can be understood, and targeted is through the share of infections by age. This provides insights into what has worked and what still needs to be done. We aimed to quantify the share of HBV infections at the global and regional level in 2022. **Methods:** The Polaris Observatory maintains and annually updates 170 country specific PRoGReSs Models. The PRoGReSs Model is a fully dynamic HBV disease burden and transmission Markov model. This model considers the impact of diagnosis, treatment, and all prophylaxis measures on the incidence and disease burden of hepatitis B. **Results:** Models were populated for 170 countries, 97 of which received feedback from country experts, 54 were based on published data, and 19 used extrapolated prevalence data. Globally, just over 11% of all HBV infections were found to be among those aged **d** 20 years of age, with over 50% of cases being among those aged 30-54 (Figure 1). The AFRO region stands out with 25% of all HBV infections being in ages **d** 20 years and 14.4% in the EMRO region, compared to 2.5% in the WPRO and EURO regions. On the other hand, the WPRO and EURO regions show a very low number of HBV infections in younger age groups with a peak of infections among those aged 35-39 due to a long history of birth- and three-dose HBV vaccinations. The peak share of infections in the oldest population is in the PAHO region with the 40-44 age group representing 11.9% of all infections in that region. **Conclusion:** These data provide evidence for policy makers to use on multiple fronts. In the regions in which

there remains a high burden of pediatric HBV infections, it is clear that more needs to be done to support prevention programs, particularly elimination of mother to child transmission. These regions will also face large burdens of HBV-related morbidity and mortality for years to come. However, regions with a higher share of prevalence among older individual's have been successful in prevention but will still have a large number of individual's in need of screening and treatment to prevent liver cancer and mortality in the shorter term.

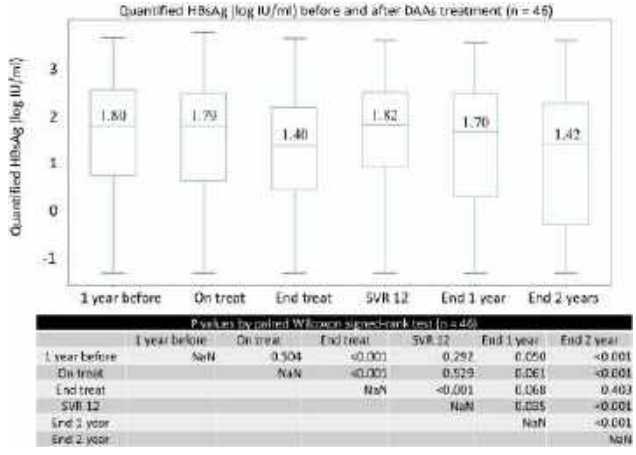
1398-C | VIGOROUSLY DYNAMIC CHANGES OF HEPATITIS B SURFACE ANTIGEN AFTER DIRECT-ACTING ANTIVIRALS TREATMENT AMONG HEPATITIS C VIRUS AND HEPATITIS B VIRUS CO-INFECTED PATIENTS

Chenger Hsu[1], Yen-Chun Liu[1], Ya-Ting Cheng[2], Yi-Chung Hsieh[3], Rachel Wen-Juei Jeng[3], Chun-Yen Lin[3], Rong-Nan Chien[3] and I-Shyan Sheen[3], (1)Chang Gung Memorial Hospital, Linkou Medical Center, (2)Linkou Chang Gung Memorial Hospital, Linkou Branch, Taiwan, (3)Linkou Chang Gung Memorial Hospital

Background: Direct-acting antivirals (DAAs) achieved high sustained virologic response (SVR) rate in patients co-infected with hepatitis C virus (HCV) and hepatitis B virus (HBV). Whether HBsAg level reduction will be accelerated after SVR remained unknown. This study aims to investigate this issue by comparing the longitudinal dynamic changes of quantitative HBsAg (qHBsAg) level before, during and after DAAs treatment. **Methods:** CHC patients with HBV co-infection who received DAA treatment and achieved SVR12 between March 2015 and December 2019 in Chang Gung Memorial Hospital, Linkou branch were prospectively enrolled. qHBsAg level was assayed at 1 year before DAA, at start of DAA, end-of-treatment, SVR and 1, 2 years after DAA treatment. The qHBsAg was quantified by Roche Elecsys HBsAg II quantitative assay detection range 0.05 - 52000 IU/mL. **Results:** A total of 46 CHC patients with SVR and with all timepoint qHBsAg assessment available were included in the analysis. The median age was 63.2 years, 25 patients (54.3%) were male. The kinetics of qHBsAg level before DAA to start of DAA (SOT), during DAA (from end-of-treatment(EOT) to SOT) and from EOT to SVR 12 were -0.01, -1, and 0.9 $\log_{10}$ IU/mL/year, respectively. Rapid decline of HBsAg (>1 $\log_{10}$IU/mL/year) was observed in 50% of patients during DAA treatment but the phenomenon is not sustained and 19 of these 23 (83%) rapid HBsAg decline patients rebound from nadir while the rest remain declining and 2 patients achieved HBsAg <0.05 by EOT and sustained till SVR 12. Interestingly, HBsAg median level drop from 1.82 $\log_{10}$ IU/mL (SVR 12) to 1.70 $\log_{10}$ IU/mL by EOT 1-year and 1.42 $\log_{10}$ IU/mL by EOT 2-year. Rapid HBsAg decline was observed in 6.5% of the CHC/CHB-SVR patients (Figure 1). By 2-year follow-up after EOT, 7 patients (16%) achieved HBsAg loss. **Conclusion:** Eradication of HCV by DAA leads to a temporal rapid reduction of HBsAg level during DAA therapy and rebound in most patients by SVR12. HBsAg decline appeared to be increased after SVR 12 than that before SVR 12. This phenomenon may reflect the different durability of the restored anti-HBV immunity during DAA and after SVR12.



P values by paired Wilcoxon signed-rank test (n = 46)

1399-C | A MEDIATION ANALYSIS OF DYNAMIC PROCESS OF HEPATOCELLULAR CARCINOMA DEVELOPMENT IN CHRONIC HEPATITIS B PATIENTS WITH ANTIVIRAL TREATMENT

Minjoo Cho[1], Jonggi Choi[1], Yeojin Lee[1], Hyeyeon Hong[1], Jiwon Yang[1], Sung Won Chung[1], Won-Mook Choi[1], Danbi Lee[1], Ju Hyun Shim[2], Kang Mo Kim[2], Young-Suk Lim[3], Han Chu Lee[1] and Seungbong Han[4], (1)Asan Medical Center, Seoul, Korea, Republic of (South), (2)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, (3)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South), (4)Korea University

Background: Antiviral treatment in chronic hepatitis B (CHB) patients without cirrhosis is determined by ALT levels and HBV DNA levels to prevent disease progression. We performed a mediation analysis to examine the dynamic process of hepatocellular carcinoma (HCC) development in CHB patients treated with antiviral treatment. **Methods:** A total of 4,832 patients with CHB who received with entecavir or tenofovir disoproxil fumarate at Asan Medical Center, Seoul, Korea were analyzed retrospectively. The association between HBV DNA levels and the on-treatment ALT normalization or VR were analyzed by multiple logistic regression. A mediation analysis was conducted to see whether these on-treatment ALT normalization or VR mediate the association between the pre-treatment HBV DNA levels and the HCC risk. **Results:** The mean age was 48.3 years, and 62.0% were men. HBeAg was positive in 59.3% and cirrhosis was present in the 52.5% of the patients. On-treatment ALT normalization was achieved in 4,635 (95.9%) patients during the study period. At 1 year of antiviral treatment, patients with pre-treatment HBV DNA levels **e** 8 log10 IU/mL showed the highest rate of on-treatment ALT normalization (81.8%), whereas those with pre-treatment HBV DNA levels of 6.0-6.99 log IU/mL showed the lowest rate of on-treatment ALT normalization (69.9%). A total of 4,511(93.4%) achieved VR during the overall treatment period. The rate of VR at 1 year of antiviral treatment was proportionally increased as the pre-treatment serum HBV DNA level decreases. HCC occurred in 455 patients with an annual incidence of 1.61/100 person-years. Pre-treatment HBV DNA levels of 6.0-6.99 (adjusted hazard ratio: 2.08, 95% CI: 1.43–3.04, $p < 0.001$) showed the highest risk of HCC development after adjusting for confounders. Indirect effect of the 6.00–6.99 log IU/mL HBV DNA group or the HBV DNA group (< 5 log IU/mL) through the on-treatment ALT normalization were statistically significant, which was smaller than direct effect. This indicates that indirect mediation effect of on-treatment ALT normalization on the risk of HCC is negligible. Regarding the association between the pre-treatment HBV DNA level, VR, and the HCC risk, indirect and direct effect of the pre-treatment HBV DNA groups through the VR were also negligible. **Conclusion:** The present study demonstrated three important aspects; 1) CHB patients with pre-treatment serum HBV DNA levels of 6-7 had the highest risk of HCC development. 2) this group of patients showed the lowest rate of on-treatment ALT normalization at 1 year of antiviral treatment. 3) the risk of HCC development in patients with CHB was mainly determined by the pre-treatment serum HBV DNA levels rather than achievement of intermediate outcomes by antiviral treatment.

Disclosures: The following people have nothing to disclose: Minjoo Cho, Jonggi Choi, Yeojin Lee, Hyeyeon Hong, Jiwon Yang, Sung Won Chung, Won-Mook Choi, Danbi Lee, Ju Hyun Shim, Kang Mo Kim, Young-Suk Lim, Han Chu Lee, Seungbong Han

1400-C | ACUTE HEPATITIS FLARES AFTER CESSATION OF NUCLEOS(T)IDE ANALOGUES ARE ASSOCIATED WITH LOWER RATES OF HBsAg SEROCLEARANCE IN PATIENTS WITH CHRONIC HEPATITIS B

Ying-Nan Tsai[1,2], Jia-Ling Wu[3], Cheng-Hao Tseng[1,2], Yi Ling Wu[4], Jaw-Town Lin[4], Mindie H. Nguyen[5] and Yao-Chun Hsu[1,2], (1)E-Da Cancer Hospital, I-Shou University, (2)I-Shou University, (3)National Cheng Kung University, (4)E-Da Hospital, I-Shou University, (5) Stanford University Medical Center, Palo Alto, CA

Background: Patients with hepatitis B virus (HBV) infection frequently experience acute hepatitis flares after stopping nucleos(t)ide analogue (NA) treatment. These flares could precipitate liver failure but they are also thought to promote hepatitis B surface antigen (HBsAg) seroclearance, which is one of the major rationales for NA cessation. We aimed to evaluate and clarify the association between acute hepatitis flares and subsequent HBsAg seroclearance following NA cessation in patients with chronic hepatitis B (CHB). **Methods:** This retrospective, multi-center cohort study systematically reviewed all CHB patients who received NA treatment in a healthcare system in Taiwan. We included adults who discontinued NA therapy between April 01, 2004, and May 24, 2022, who had at least one year of continuous treatment before discontinuation. Patients with malignancy, hepatic insufficiency (defined by jaundice and coagulopathy), or viral

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

coinfections were excluded. A hepatitis flare was defined as a serum level of alanine aminotransferase (ALT) > 5 times the upper limit of normal (ULN; 40 U/L). The primary outcome was HBsAg seroclearance during the post-NA cessation period. We estimated the incidence of HBsAg seroclearance using a competing risk analysis, factoring in death or retreatment as informative censoring events. The occurrence of ALT flares was evaluated as a time-dependent variable in the multivariable-adjusted sub-distribution hazard regression models. **Results:** A total of 854 eligible patients (median age of 53.2 y, 74.6% male) were enrolled. The median duration of NA therapy was 34.7 (interquartile range [IQR], 31.0-38.5) months and the majority (63.4%) of patients used entecavir. During a median post-NA cessation follow-up of 3.7 years (IQR, 1.4-6.3), HBsAg seroclearance occurred in 51 patients, at an average annual rate of 1.48% (95% confidence interval [CI], 1.10-1.95%) and a cumulative incidence of 13.8% (95% CI, 10.20-18.05%) at 10 years. Of the 175 patients who experienced acute ALT flares, 6 (3.43%) subsequently cleared HBsAg. Conversely, 45 of 679 patients (6.63%) without ALT flares achieved HBsAg seroclearance. In the multivariable-adjusted model, occurrence of ALT flares was associated with a lower incidence of HBsAg seroclearance (sub-distribution hazard ratio, 0.24; 95% confidence interval, 0.09-0.64). Furthermore, the peak serum ALT level post NA cessation was significantly lower in patients achieving HBsAg seroclearance (median, 77 U/L; IQR, 42-136) compared to those who did not achieve HBsAg seroclearance (median, 127 U/L; IQR, 47-341; $p < 0.0001$) (Figure 1). **Conclusion:** Acute ALT flares are associated with a lower incidence of subsequent HBsAg seroclearance in CHB patients who discontinued NA therapy. Therefore, ALT flares following NA cessation should not be viewed as a "desirable" event and treatment cessation should be avoided in patients at risk of withdrawal flares.

1401-C | AIR POLLUTION MIGHT IMPEDE ALT NORMALIZATION IN CHRONIC HEPATITIS B PATIENTS TREATED WITH NUCLEOTIDE/NUCLEOSIDE ANALOGUES

Tyng-Yuan Jang, Kaohsiung Medical University

Background: Biochemical response is an important prognostic indicator in chronic hepatitis B (CHB) patients receiving nucleotide/nucleoside analogues (NAs). However, the effects of air pollution in alanine aminotransferase (ALT) normalization remain elusive. **Methods:** This longitudinal study recruited 80 hepatitis B e antigen (HBeAg)–negative CHB patients who received NAs. ALT levels were measured during the first year of anti-HBV therapy. Normal ALT levels were defined as < 19 U/L for females and < 30 U/L for males, and the risk factors associated with ALT abnormalities were analyzed. The daily estimations of air pollutants (particulate matter **d** 2.5 μm in diameter ($PM_{2.5}$), nitrogen dioxide (NO_2), ozone (O_3), and benzene) were aggregated into the mean estimation for the previous month based on the date of recruitment (baseline) and 1 year later. **Results:** Sixteen patients (20.0%) had a baseline ALT > 40 U/L; overall, 41 (51.6%) had an abnormal ALT (**e** 19 U/L for females and **e** 30 U/L for males). After 1 year of NA therapy, 75 patients (93.8%) had undetectable HBV DNA levels. Mean post-treatment ALT levels were significantly lower than mean pre-treatment levels (21.3 U/L vs 30.0 U/L, respectively; $p < 0.001$). The proportion of patients with a normal ALT was also significantly higher after versus before treatment (71.2% vs. 51.2%, respectively; $p = 0.001$). The strongest factors associated with ALT abnormality after 1 year of NA treatment were body mass index (odds ratio [OR], 1.28; 95% confidence interval [CI], 1.05–1.54; $p = 0.01$). and ozone level (OR, 1.11; 95% CI, 1.02–1.22; $p = 0.02$). **Conclusion:** Among HBeAg-negative CHB patients with relatively low viral loads, 1 year of NA treatment improved ALT levels after the adjustment for confounding factors and increased the proportion of patients with normal ALT levels. Air pollution affects the efficacy of ALT normalization.

Background: End of treatment (EOT) HBsAg levels < 100 IU/mL identify patients most likely to achieve a favorable outcomes after nucleo(s)tide analogue (NUC) withdrawal. Various strategies are being explored to increase the number of patients achieving HBsAg levels below this threshold, but it is unclear whether the outcomes of patients who achieved on-treatment HBsAg decline to < 100 IU/mL are comparable to outcomes in patients who already had low HBsAg levels at the start of antiviral treatment. **Methods:** We identified chronic hepatitis B patients who discontinued NUC monotherapy and had available information on pretreatment and EOT HBsAg levels in an international multicentre database. We studied the association between pretreatment HBsAg levels and on-treatment HBsAg decline with the cumulative probability of clinical relapse (defined as the occurrence of either HBV DNA > 2,000 IU/mL with ALT > 2x the upper limit of normal) and HBsAg loss at 192 weeks of post-treatment follow-up. **Results:** We enrolled 746 patients, the majority of whom were Asian (92%), HBeAg negative at start of treatment (69.6%) and treated with entecavir (61%). Pretreatment HBsAg levels were < 100/100-1000/ > 1000 IU/mL in 68/198/480 patients. Patients with higher pretreatment HBsAg levels had a higher risk of clinical relapse (HR 1.224, $p < 0.001$) and a lower chance of off-treatment HBsAg loss (HR 0.473, $p < 0.001$). After a median of 157 (IQR: 156 - 165) weeks of treatment, HBsAg decline from pretreatment to EOT was < 1 log IU/mL in 545 (73%), 1-2 log IU/mL in 149 (20%) and > 2 log IU/mL in 52 (7.0%). Patients who had achieved > 2 log decline from pretreatment to EOT had a significantly lower probability of post-treatment clinical relapse (38% vs 59%, $p < 0.001$) and a significantly higher chance of HBsAg loss (32.5% vs 4.6%; $p < 0.001$) when compared to patients who experienced < 1 log on-treatment decline. Among the 678 patients with a pretreatment HBsAg level > 100 IU/mL, 106 (15.6%) achieved HBsAg < 100 IU/mL at EOT. Patients who achieved an EOT HBsAg level < 100 IU/ml had a significantly lower risk of clinical relapse (33.4% vs 62.1%; $p < 0.001$) and a significantly higher chance of HBsAg loss (31.1% vs 2.4%; $p < 0.001$). Finally, outcomes at 192 weeks of follow-up were similar for patients with high pretreatment HBsAg levels who achieved a decline to < 100 IU/mL during treatment when compared to patients who already had HBsAg levels < 100 IU/mL at start of treatment (clinical relapse: 26.1% versus 33.4% [$p = 0.202$] and HBsAg loss: 36.5% versus 32.6% [$p = 0.915$], see figure).

Conclusion: An on-treatment decline of HBsAg levels to < 100 IU/mL was associated with excellent outcomes after NUC cessation. These findings support the exploration of novel strategies to reduce viral antigen levels in order to facilitate safe NUC withdrawal.

1403-C | ASSOCIATION OF LOW-DOSE ASPIRIN USE WITH RISK OF HEPATOCELLULAR CARCINOMA AND GASTROINTESTINAL BLEEDING IN PATIENTS WITH HBV-RELATED CIRRHOSIS: A LANDMARK ANALYSIS

Mi Na Kim[1], Geun U Park[2], Jae Seung Lee[1], Hye Won Lee[1], Beom Kyung Kim[1], Seung Up Kim[1], Jun Yong Park[1], Do Young Kim[1] and Sang Hoon Ahn[1], (1)Yonsei University College of Medicine, Seoul, Republic of Korea, (2)Clinical and Translational Hepatology Laboratory, Seongnam, Seongnam, Korea, Republic of (South)

Background: The use of aspirin in hepatocellular carcinoma (HCC) prevention is still uncertain in patients with hepatitis B virus (HBV)-related cirrhosis. In addition, results regarding whether the risk of gastrointestinal (GI) bleeding is associated with aspirin use in patients with HBV related cirrhosis are controversial. Accordingly, we investigated the association between aspirin use and the risks of HCC and GI bleeding in HBV-related cirrhosis patients using a nationwide cohort. **Methods:** We conducted a 3-year landmark analysis using nationwide cohort data from the National Health Insurance Service of South Korea. Patients with diagnosed with compensated HBV-related cirrhosis in 2005-2017 were included. Patients who were prescribed aspirin for at least 90 days consecutively during the 3-year exposure period were classified as the aspirin-treated group. A propensity-score matching analysis was applied to balance the aspirin-treated and untreated groups. Using Cox proportional hazard regression analysis, we estimated the risks of HCC and GI bleeding, accounting for competing events. **Results:** A total of 12,687 patients (608 aspirin-treated and 12,079 untreated) were included in the analysis. During a median of 7.6 years of follow-up, HCC developed in 219 (36.0%) patients of the aspirin-treated group and 4,265 (35.3%) patients of the untreated group. After multivariate adjustment, the aspirin-treated group showed a significantly lower risk of HCC than the untreated group (adjusted hazard ratio [aHR] = 0.84, 95% confidence interval [CI] = 0.73-

0.96; $p = 0.013$). GI bleeding developed in 157 (25.8%) of the aspirin-treated group and 2,072 (17.2%) of the untreated group. The aspirin-treated group showed a significantly higher risk of GI bleeding than the untreated group (aHR = 1.21, 95% CI = 1.03-1.43; $p = 0.021$). After propensity-score matching, the cumulative incidence rate of HCC was significantly lower in the aspirin-treated group than the untreated group ($p = 0.022$, log-rank test). Whereas, the cumulative incidence rate of GI bleeding was significantly higher in the aspirin-treated group than the untreated group ($p = 0.040$, log-rank test). The aspirin-treated group showed a significantly lower risk of HCC and higher risk of GI bleeding than the untreated group after propensity-score matching (both $p < 0.05$). **Conclusion:** In patients with HBV-related cirrhosis, the aspirin-treated group showed a significantly lower risk of HCC than the untreated group, whereas the risk of GI bleeding was significantly higher in the aspirin-treated group.

Background: Bulevirtide (BLV) has been approved by EMA for treatment of chronic compensated hepatitis D virus (HDV) infection, however predictors of response are still unknown. **Methods:** Consecutive compensated HDV cirrhotic patients treated with BLV 2 mg/day monotherapy were retrospectively enrolled in a multicenter Italian real-life study (HEP4Di). Clinical, biochemical and virological features at BLV start and during treatment were collected. Virological response (HDV RNA undetectable or **e** 2-log decline *vs.* baseline), biochemical response (ALT < 40 U/L) and combined response (biochemical + virological) were assessed. HDV RNA was quantified locally (Robogene 2.0 [LOD 6 IU/mL] in 71% of the patients). **Results:** 97 HDV cirrhotic patients receiving BLV monotherapy up to 96 weeks were included: at BLV start, median age was 52 (29-77) years, 53% males, 100% CPT score A, 9% HIV-positive, 52% with oesophageal varices, 19% with history of previous

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ascites, 11% with active HCC, 97% on NUC. Median ALT were 80 (26-1,074) U/L, liver stiffness measurement (LSM) 17.4 (6.4-68.1) kPa, platelets 83 (17-330) x10^3/mm^3, HBsAg 3.7 (0.8-4.5) Log IU/mL and HDV RNA 5.1 (1.2-7.6) Log IU/mL. At BLV treatment weeks (W) W24, W48, W72 and W96, rates of virological response were 53%, 70%, 75% and 80%, respectively, and HDV RNA was undetectable in 16%, 15%, 38% and 33% patients. Biochemical response was achieved by 65%, 74%, 81% and 67% at W24, W48, W72 and W96, respectively, while rates of combined response were 38%, 59%, 63% and 67%. By univariate logistic regression analysis, baseline viremia was the only factor associated with the achievement of virological response: indeed, HDV RNA levels < 5 LogIU/mL predicted HDV RNA < 1000 IU/mL (OR 3.33, 95% CI 1.19-9.26, $p = 0.02$) and < 100 IU/mL (OR 7.30, 95% CI 2.49-21.41, $p = 0.0003$) at week 24, while HDV RNA levels < 4 LogIU/mL were associated with HDV RNA < 100 IU/mL at week 24 (OR 7.37, 95% CI 2.21-24.60, $p = 0.001$). Conversely, none of the other baseline clinical features (age, sex, albumin, platelets, presence of varices, ALT values, bile acids) were associated with virological response, and none of the baseline clinical/virological features predicted biochemical or combined response. **Conclusion:** In HDV compensated cirrhotic patients treated with BLV monotherapy, baseline viremia is the only factor associated with early virological response at week 24. Week 48 data will be presented at the meeting.

Background: Current guidelines recommend using TAF or entecavir as alternative first-line therapy in patients with risk factors for TDF-associated toxicities. We evaluated the safety of TAF, including in patients switched from TDF to TAF, who were considered to be at risk for adverse bone and/or renal effects from TDF based on EASL guidelines. **Methods:** In two similarly designed Phase 3 studies, HBeAg-positive (N = 873) and HBeAg-negative (N = 425) patients were initially randomized (2:1) to TAF 25 mg QD vs TDF 300 mg QD in a double-blind (DB) phase for up to 3 years, after which all patients received TAF during the open-label (OL) extension phase (ie, TAF vs TDF→TAF). Safety results were pooled for bone (serial DXA scans at hip/spine and serum bone biomarkers) and renal (eGFR by Cockcroft-Gault [$eGFR_{CG}$] and urinary biomarkers of tubular function) parameters assessed over 8 years in the subsets with or without baseline risk factors for TDF use: age > 60 y, osteoporosis at hip/spine by t-scores, $eGFR_{CG}$ < 60 mL/min, urine albumin-to-creatinine ratio > 30 mg/g, or serum phosphorus < 2.5 mg/dL. **Results:** Of 1298 randomized and treated patients, 239 (18%; 151 TAF and 88 TDF→TAF) had at least 1 risk factor. Baseline demographics were similar between treatment groups: 29% with age > 60 y, 60% male, 40% with $eGFR_{CG}$ < 90 mL/min, and 6% and 36% with osteoporosis at hip and spine, respectively. A greater median decline in

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

eGFR was seen in TAF-treated patients with risk factors at Year 8 (−8.3 vs −4.6 ml/min) compared to those without. In the TDF→TAF groups, a greater degree of recovery was noted in those with risk factors switched at Year 2 vs Year 3 (Figure). In the TAF group, mean % decline in hip BMD at Year 8 was small regardless of risk factor status. In the TDF→TAF groups, mean % increases occurred after switching to TAF with changes that were similar to the TAF group at Year 8, supporting sustained reversibility of TDF-associated bone loss. Consistent changes were seen in proteinuria markers and serum bone biomarkers. **Conclusion:** Long-term TAF treatment showed favorable renal and bone tolerability in patients with and without baseline risk factors for TDF use supporting guideline recommendations.

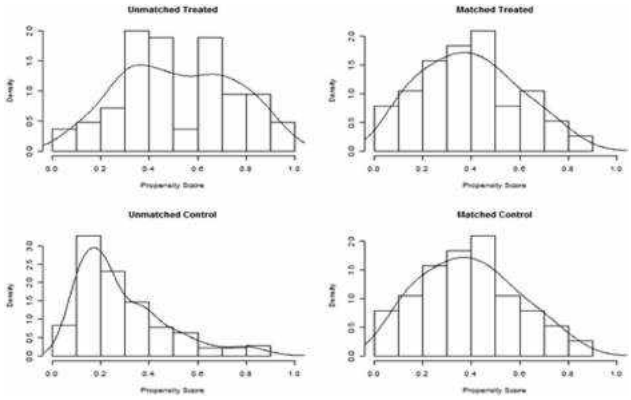
1406-C | CHRONIC HEPATITIS B (CHB) PATIENTS WITH NORMAL ALT MAY HAVE IMPROVED LONG-TERM OUTCOMES AFTER ANTIVIRAL THERAPY

Zhihong Liu, Jianning Jiang and Cailian Cai, The First Affiliated Hospital of Guangxi Medical University

Background: With the improved efficacy and accessibility of antiviral agents as well as the concerns about disease progression, there is a hot discussion on whether HBeAg-negative chronic hepatitis B (CHB) patients with normal alanine aminotransferase (ALT) and positive HBV DNA should be treated. However, studies on long-term outcomes of antiviral therapy in CHB patients with normal ALT are still lacking. **Methods:** 256 cases of HBV infection in the antiviral therapy group of our study cohort from January 2008 to January 2021 were retrospectively enrolled. Patients with normal ALT at baseline were assigned to the study group (n = 61), alT1-2 ×ULN at baseline were assigned to the control group 1 (n = 62), ALT > 2×ULN were assigned to the control group 2 (n = 58), and were recieved NAs antiviral therapy. The above three groups were incorporated into the treatment group, and 256 subjects who were not treated with antiviral therapy were included in the historical control group by propensity score matching with gender, age and baseline HBeAg as factors. The occurrence of cirrhosis or liver cancer was the endpoint, and no endpoint event was observed until the last follow-up. SPSS 20.0 software package was used for statistical analysis, and lifetime table method was used to calculate the cumulative progression rate and the annual incidence of end-point events (cirrhosis, liver cancer, death). Analysis of variance was used to compare measurement data between the three

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

groups. **Results:** 182 (71.1%) of the 256 patients in the study group were male. The mean follow-up time was 3.13 years. In the historical control group, there were 190 males (74.2%) with a mean follow-up of 3.63 years. The annual incidence of cirrhosis was 2.24% in the treatment group and 5.6% in the historical control group ($p < 0.05$). The annual incidence of liver cancer in the treatment group and the historical control group was 0.4% and 3.2%, respectively ($p < 0.05$).The annual incidence of cirrhosis in the study group,the control group 1 and the control group 2 were 1.97%, 1.56% and 1.09%, respectively ($p > 0.05$). **Conclusion:** Patients with positive serum HBV DNA, regardless of ALT level, active antiviral therapy is beneficial to delay and reduce the occurrence of liver failure, cirrhosis, HCC and other complications, improve the patients' quality of life , and prolong their survival time.



Disclosures: The following people have nothing to disclose: Zhihong Liu, Jianning Jiang, Cailian Cai

1407-C | COMPARABLE RISK OF RENAL DYSFUNCTION BETWEEN ENTECAVIR AND TENOFOVIR ALAFENAMIDE IN PATIENTS WITH CHRONIC HEPATITIS B

Jiwon Yang[1], Yeojin Lee[1], Hyeyeon Hong[1], Sung Won Chung[1], Minjoo Cho[1], Won-Mook Choi[2], Danbi Lee[1], Ju Hyun Shim[3], Kang Mo Kim[3], Young-Suk Lim[4], Han Chu Lee[1] and Jonggi Choi[3], (1)Asan Medical Center, Seoul, Korea, Republic of (South), (2)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, Seoul, South Korea, (3)Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, (4)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South)

Background: A previous study suggested a higher higher risk of renal function decline with entecavir (ETV) compared to tenofovir alafenamide (TAF) in treatment-naïve patients with chronic hepatitis B (CHB). However, the sample size was limited. This study aimed to compare the risk of renal dysfunction between ETV and TDF in a large-scale hospital cohort of treatment-naïve CHB patients. **Methods:** A total of 3,343 treatment-naïve patients with CHB who received with ETV or TAF at Asan Medical Center, Seoul, Republic of Korea were included. The primary outcome was chronic kidney disease (CKD) progression, defined as an increase in CKD stage by at least one stage. CKD stage was based on the estimated glomerular filtration rate (GFR), determined using the CKD-EPI equation. Patients below 18 years old, with a history of hepatocellular carcinoma or other malignancies, baseline eGFR < 60 ml/min, or follow-up duration < 3 months were excluded. Multivariable Cox models were used to evaluate factors associated with CKD progression. Propensity score (PS) matching was conducted to minimize baseline characteristic differences and compare the primary outcome. **Results:** Of the 3,343 patients, 2,635 (78.8%) received ETV and 708 (21.2%) received TAF. The mean age was 49.0 years in the ETV group and 49.3 years in the TAF group. Cirrhosis was present in 52.4% of the ETV group and 38.1% of the TAF group. Baseline median eGFR was significantly lower in the ETV (81.0 mL/min) than TAF group (90.0 mL/min). The prevalence of hypertension and diabetes was higher in the ETV group (5.9% and 7.9%) than TAF group (4.0% and 4.4%). Over 18,806 person-years (PYs) of observation, 207 patients experienced CKD progression, resulting in an annual incidence of 1.10 / 100 PYs. Multivariable analysis identified hypertension, diabetes, and increasing age as significant factors for CKD progression. However, treatment with TAF compared to ETV was not independently associated with the risk of CKD progression (adjusted hazard ratio: 0.87, 95% confidence interval: 0.46–1.66, $p = 0.68$). PS matching generated 586 matched pairs and baseline characteristics were comparable between the two groups. CKD progression occurred in 36 patients treated with ETV (3,358 PYs of observation) and in 10 patients treated with TAF (1,008 PYs of observation). The annual incidence of CKD progression was 1.10 / 100 PYs in the ETV group and 0.99 / 100 PYs in the TAF group, without a statistically significant difference ($p = 0.08$). **Conclusion:** In contrast to previous report, the risk of renal dysfunction did not significantly differ between ETV and TAF in this larger historical cohort with sufficient long-term follow-up period.

1408-C | COMPARABLE SAFETY AND EFFICACY OF TENOFOVIR ALAFENAMIDE WITH TENOFOVIR DISOPROXIL FUMARATE IN PREGNANT WOMEN: SYSTEMATIC REVIEW WITH META-ANALYSIS

Ruojing Wang, Xiaoli Zhang, Shan Fu, Yali Feng, Yingren Zhao, Jinfeng Liu and Tianyan Chen, First Affiliated Hospital of Xi'an Jiaotong University

Background: Tenofovir alafenamide (TAF) has been administered extensively in patients with hepatitis B virus (HBV) or human immunodeficiency virus (HIV). Mother-to-child transmission (MTCT) is one of the main transmission routes for HBV and HIV. Whereas, data about TAF in pregnant women was insufficient. To further evaluated the safety and effectiveness of TAF during pregnancy and direct clinical practice, we conducted a review and meta-analysis. **Methods:** Two reviewers independently searched randomized controlled trials and nonrandomized trials concerning peripartum TAF administered in MEDLINE (PubMed), Embase, Cochrane library, Clinical Trials.gov, Wanfang, and Chinese National Knowledge Infrastructure (CNKI), without language restriction, published from inception to March 10, 2023. The search terms covered HBV (or HIV), TAF, and pregnancy. We enrolled the studies concerning pregnant women with HBV or HIV infection receiving TAF during pregnancy. The following outcomes should be reported: the MTCT rate, the incidence of congenital malformations in new-borns, and the changes in serum creatinine levels during and after treatment. **Results:** Nine studies involving 1359 pregnant women were included for final analyses. Among the 6 studies of HBV infected pregnant women, the pooled rate of MTCT was zero in pregnant women administered with TAF (N = 513). Similarly, the pooled MTCT rate was also zero in the study of pregnant women with HIV infection receiving antiviral therapy containing TAF regimen. Further compared with pregnant women receiving tenofovir disoproxil fumarate (TDF), risk differences of TAF for congenital malformations was 0.00 (-0.01-0.02, $p = 0.61$) in HBV-infected pregnant women receiving TAF. Among all HBV-infected pregnant women treated with TAF, only one case of congenital malformations was reported. Additionally, among HIV-infected pregnant women, the odds ratio of birth defects for the TAF-containing antiviral regimens compared with the TDF-containing antiviral regimens was 1.02 (0.46, 2.27, $p = 0.96$). Moreover, among HBV-infected pregnant women, the mean difference of serum creatinine level between TAF group and the TDF group were comparable, -1.22 (-0.28, 0.36, $p = 0.13$) at delivery and -1.11 (-2.87, 0.65, $p = 0.22$) at 6 months after delivery, respectively. **Conclusion:** In pregnant women with HBV or HIV infection, the administration of TAF or TAF-containing antiviral regimens can effectively prevent MTCT. Compared with TDF or TDF-containing regimen, TAF or TAF-containing regimen presents comparable safety in mothers and infants.

1409-C | COMPARISON OF THE EFFECTS OF ENTECAVIR AND TENOFOVIR ALAFENAMIDE ON KIDNEY FUNCTION IN CHRONIC HEPATITIS B: PROPENSITY SCORE MATCHED RETROSPECTIVE COHORT STUDY

Eunjee Lim and Jin-Wook Kim, Seoul National University Bundang Hospital

Background: Since the treatment of chronic hepatitis B involves long-term medication, it is crucial to take into account the potential negative effects of the drugs when choosing the appropriate treatment. Long-term treatment with nuleos(t)ide analogues (NAs) such as adefovir or tenofovir disoproxil fumarate (TDF) may impair renal function in chronic hepatitis B (CHB). Entecavir (ETV) and tenofovir alafenamide (TAF) are known to be safer than adefovir or TDF for renal function, but insufficient research has been conducted comparing the renal effects of these two drugs. Therefore, we retrospectively investigated the effect of TAF or ETV on estimated glomerular filtration rate (eGFR) in chronic hepatitis B patients. **Methods:** This study evaluated propensity score (PS)-matched 268 treatment-naive patients with CHB who had been treated with either ETV (n = 83) or TAF (n = 185) between 2017 and 2021. Changes in renal functions were monitored over a period of 36 months (at baseline, 6, 12, 18, 24, 30 and 36 mo). Patients were excluded if they had used any nucleotide analogue other than those two specific drugs, received preemptive therapy for drug treatment, had a baseline HBV DNA level below 27 unit/ml confirmed as negative, had no previous HBV DNA or eGFR data before starting the drug, had a follow-up duration of less than 90 days,

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

had experienced sepsis or received an organ transplant, had a history of alcohol-related liver disease or cancer including HCC, had HCV co-infection or were diagnosed with ESRD. Propensity score matching was conducted using age, sex, baseline HBV DNA level, baseline creatinine (Cr) level, baseline eGFR-CKD-EPI level, systolic blood pressure (SBP), platelet count (PLT), total bilirubin, prothrombin time (PT, INR), albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT) and presence of portal systemic encephalopathy (PSE)/ascites/diabetes mellitus (DM)/dyslipidemia (DL). **Results:** The baseline mean eGFR was 100.31 ml/min/1.73 m2 vs. 101.31 ml/min/1.73 m2 in the ETV and TAF groups, respectively ($p = 0.63$). Comparison of eGFR between ETV group and TAF group during follow-up showed no significant differences at 6 months (101.46 vs 100.34, $p = 0.67$), 12 months (101.74 vs 100.24, $p = 0.65$), 18 months (94.85 vs 99.61, $p = 0.18$), 24 months (92.30 vs 97.24, $p = 0.21$), 30 months (92.34 vs 96.08, $p = 0.39$) and 36 months (94.08 vs 96.98, $p = 0.66$), respectively. Furthermore, there was no significant difference in annual changes in eGFR (ETV -1.38 vs TAF -2.04, $p = 0.5708$) and 1-stage progression of CKD stage at study endpoints between the two treatment groups (ETV 10.8% vs TAF 18.8%, $p = 0.21$). **Conclusion:** There was no significant difference in eGFR-CKD-EPI between the ETV and TAF treatment groups over a 36-month period in NAs-naive CHB patients. Further research is required to establish the long-term effect of ETV and TAF on kidney function.

Changes in eGFR with the use of ETV or TAF

eGFR, ml/min/1.73m² (number of patients)	ETV	TAF	P-value
baseline	100.31 (83)	101.31 (185)	0.6285
at 6 month	101.46 (46)	100.34 (134)	0.6746
at 12 month	101.74 (38)	100.24 (113)	0.6529
at 18 month	94.85 (31)	99.61 (93)	0.1804
at 24 month	92.30 (26)	97.24 (69)	0.2073
at 30 month	92.34 (16)	96.08 (49)	0.3925
at 36 month	94.08 (12)	96.98 (36)	0.6631

f 1410-C | COMPARISON OF THE EFFECTS OF ENTECAVIR AND TENOFOVIR DISOPROXIL FUMARATE ON RECURRENCE OF HEPATOCELLULAR CARCINOMA AFTER CURATIVE RESECTION IN CHRONIC HEPATITIS B

Eunjee Lim and Jin-Wook Kim, Seoul National University Bundang Hospital

Background: Antiviral therapy with nuleos(t)ide analogues (NAs) may reduce the risk of hepatocellular carcinoma (HCC) recurrence after curative resection in patients with chronic hepatitis B (CHB). However, it is not fully elucidated whether entecavir (ETV) or tenofovir disoproxil fumarate (TDF) provide a comparable beneficial effect on postoperative recurrence of HCC. Therefore, we investigated the effect of TDF or ETV on recurrence of HCC after curative surgery in chronic hepatitis B patients. **Methods:** This retrospective cohort study analyzed 553 patients who received either ETV (n = 339) or TDF (n = 214) after curative resection of HCC. The curative surgery included hepatectomy, lobectomy, sectionectomy, segmentectomy, and tumorectomy. The recurrence was confirmed based on positive imaging studies. We used Kaplan-Meier estimation to assess HCC recurrence, and used a multivariable-adjusted Cox proportional hazard model to adjust covariates between the two groups. **Results:** The median age of patients was 61 years (ETV group 62 y, TDF group 59 y) and 78% were male (ETV group 76%, TDF group 82%). The median follow-up duration was 32 months (ETV group 33 mo, TDF group 32 mo). The cumulative HCC recurrence rate was 9, 21, 27 and 38% after 12, 24, 36 and 60 months, respectively. By multivariable-adjusted analysis, more recurrence was observed with younger patients (hazard ratio[HR] = 0.970, 95% CI = 0.955-0.986, p value = 0.000), male (HR = 1.704, 95% CI = 1.117-2.600, p value = 0.013), lower albumin level (HR = 0.543, 95% CI = 0.389-0.757, p value = 0.000) and use of TDF compared to ETV (HR = 0.612, 95% CI = 0.434-0.864, p value = 0.005). **Conclusion:** This study showed that TDF treatment was associated with a significantly lower risk of HCC recurrence following curative surgery compared to ETV treatment among patients with CHB.

1411-C | EFFECTIVENESS AND SAFETY OF SWITCHING TENOFOVIR DISOPROXIL FUMARATE AND ENTECAVIR TO TENOFOVIR ALAFENAMIDE FUMARATE (TAF) IN VIROLOGICALLY SUPPRESSED CHRONIC HEPATITIS B VIRUS-INFECTED PATIENTS WITH ONE-MINUTE OSTEOPOROSIS RISK TEST

Hui Li[1], Chunmei Li[1], Jia Wei[1], Yunhua Liu[1], Ming Gong[1], Ruyi Zhang[2], Jiawei Geng[2], Hongyan Wang[3], Zhijian Yu[3], Zi Wang[1] and Xiang Liu[1], (1)Hospital of Yunnan University, (2)The First Hospital of Yunnan Province, (3)Xiehe Shenzhen Hospital of Huazhong University of Science and Technology

Background: Long-term antiviral treatment is necessary for chronic hepatitis B (CHB) patients and treatment safety is imperative for these patients. However, there is still lack of a rapid and convenient method to identify CHB patients at high risk of osteoporosis before initiating antiviral treatment. One-minute osteoporosis risk test(Figure 1) was recommended to screen early high-risk patients by international osteoporosis foundation (IOF). Previous studies showed tenofovir alafenamide (TAF) has shown efficacy non-inferior to that of tenofovir disoproxil fumarate (TDF) with improved renal and bone safety. We aimed to evaluate the feasibility of the one-minute osteoporosis risk test as well as the effectiveness and safety among virologically suppressed CHB patients switching to TAF. **Methods:** In this multiple, prospective study, CHB patients who had been receiving TDF or ETV for at least 48 weeks with HBV DNA less than 20 IU/ml for more than 6 months were screened by one-minute osteoporosis risk test. Patients at high risk of osteoporosis and then diagnosed with osteopenia or osteoporosis by dual-energy X-ray absorptiometry (DEXA) were enrolled. Safety in bone and bone turnover markers and antiviral efficacy of TAF were assessed respectively at 24 and 48 weeks. **Results:** 84.95% (175/206) CHB patients screened by one-minute osteoporosis risk test were at risk of osteoporosis. 85.71% (150/175) of them were diagnosed with osteopenia by DEXA. A total of 138 patients were included for analysis.92(62.3%) patients were male, and 46 (37.7%) patients were female, with a mean age of 45 years old. HBV DNA was suppressed at 48 weeks with 88% (35/40) in the prior ETV group, and 90% (88/98) in the prior TDF group. BMD of the lumbar spine (L1-L4) in patients switching from TDF to TAF was improved at 24 weeks (1.03 ± 0.11 vs 0.97 ± 0.12, $p = 0.001$) than baseline. Serum Propeptide of type I procollagen (PINP) and serum beta-C-terminal telopeptides of type 1 collagen (CTX) declined at 24 weeks after switching from TDF to TAF compared with baseline (50.35 ± 18.90 vs 63.65 ± 19.17, $p = 0.016$ and 0.21 ± 0.13 vs 0.32 ± 0.10, $p = 0.017$). BMD, PINP, and CTX in the prior ETV group maintained stable compared with baseline (Table 1). **Conclusion:** Osteoporosis risk should be paid closely attention to during lone-term nucleot(s)ide analogue treatment. One minute test of osteoporosis risk could rapidly identify most CHB patients at risk of osteoporosis. It is convenient and we recommend this test for early screening in CHB patients before initiating antiviral treatment. Our results also demonstrated that there is improvement in bone safety after switching to TAF in virologically suppressed CHB patients with osteoporosis.

1412-C | EFFICACY AND RENAL SAFETY IN CHRONIC HEPATITIS B PATIENTS ON TENOFOVIR ALAFENAMIDE

Lilian Yan Liang[1], Vicki Wing Ki Hui[1], Terry Cheuk-Fung Yip[2], Jimmy Che-To Lai[1], Yee-Kit Tse[1], Henry Lik Yuen Chan[1], Vincent Wai-Sun Wong[1] and Grace Lai-Hung C Wong[3], (1)The Chinese University of Hong Kong, (2) The Chinese University of Hong Kong, Hong Kong, 91, China, (3)Medical Data Analytics Centre (MDAC), the Chinese University of Hong Kong

Background: Tenofovir alafenamide (TAF) is a novel prodrug of tenofovir. We aimed to evaluate the antiviral effectiveness and renal safety in those chronic hepatitis B (CHB) patients on TAF treatment during the first 12 months of follow-up. **Methods:** This is a retrospective cohort study. TAF-treated CHB patients who were previously treated naïve were included. The baseline was defined as the start date of TAF treatment. Chronic kidney disease (CKD) progression was defined as an increase in the CKD stage of at least one stage for at least three consecutive months. **Results:** We analyzed 296 treatment-naïve CHB patients on TAF treatment, among whom 181 (61.1%) patients are males and their mean age was 59 ± 14 years old. The median TAF treatment duration was 17 months. The proportion of patients with undetectable hepatitis B virus (HBV) DNA increased from 37.9% to 78.1% ($p < 0.001$). The majority of patients achieved alanine transaminase (ALT) normalization at 12 months (71.1%) compared with that of baseline (50.3%) ($p < 0.001$). The number of patients with estimated glomerular filtration rate (eGFR) **e** 90, between 60 and 90, and < 60 mL/min/1.73 m^2 were 97 (42.4%), 91 (39.6%) and 42 (18.3%) at baseline and 86 (37.4%), 98 (42.6%) and 46 (20.0%) at 12 months, respectively ($p = 0.067$) (Figure). 28 (9.4%) patients experienced CKD progression during the first 12 months of follow-up. **Conclusion:** The use of TAF improves the virological and biochemical responses with comparable kidney function during the first 12 months of follow-up.

assessed the virological and serological responses of Peg-IFN α-2b alone or in combination with tenofovir disoproxil fumarate (TDF) therapies for HBV postpartum women with low HBsAg level. **Methods:** Postpartum patients received TDF during pregnancy or treatment-naïve with HBsAg **d** 3000 IU/mL were included in this study (No.ChiCTR 2200058096). All of them received at least 48 weeks of Peg-IFN α-2b therapy after delivery. The primary endpoint was HBsAg clearance rate at the end of the treatment (EOT). Clinical and laboratory data and adverse events (AEs) were collected. **Results:** A total of 42 HBV postpartum women were included and half of them had already received TDF during pregnancy. The mean age was 32.4 (± 3.4) years and 38 (90.5%) patients were HBeAg-negative. The mean initial treatment time of Peg-IFN α-2b was 9.4 (± 4.3) months after delivery. Till now, 34 (81.0%) patients completed treatment, and the data of these patients were analyzed. At EOT, 41.2% (14/34) patients achieved HBsAg clearance and 35.3% (12/34) achieved HBsAg seroconversion. The median treatment time for HBsAg clearance was 24.5 (14.5-39.5) weeks and the median HBsAb level in patients with HBsAg seroconversion was 339.3 (107.2-633.2) IU/L. The median baseline HBsAg level in patients with HBsAg clearance was significantly lower than those without HBsAg clearance (271.6 IU/mL vs. 956.9 IU/mL, $p = 0.002$), and the decline degrees of HBsAg at 12th and 24th week from baseline were significantly higher than those without HBsAg clearance (99.8% vs. 43.0%, $p = 0.000$; 100% vs. 70.1%, $p = 0.000$), while the baseline ALT and HBV DNA levels were not significantly different. 90.0% (9/10) patients with HBV DNA-positive at baseline converted to HBV DNA-negative at EOT. Three patients discontinued Peg-IFN α-2b therapy due to AEs, which included abnormal thyroid function (2/3) and thrombocytopenia (1/3). **Conclusion:** Peg-IFN α-2b monotherapy or combined with TDF treatment in HBV postpartum women with low HBsAg levels can obtain relatively high HBsAg clearance rate. The baseline HBsAg level and on-treatment HBsAg declines at 12/24 weeks might be valuable predictors of HBsAg clearance at EOT.

TABLE Baseline and on-treatment characteristics of the 34 postpartum women who completed the therapy

Characteristics	HBsAg Clearance Group (N=14)	HBsAg Persistence Group (N=20)	P value
Age, year, mean (± sd)	33.0 (± 3.6)	32.1 (± 3.2)	0.585
Initial time of Peg-IFN α-2b after delivery, months, median (IQR)	11.0 (6.8-11.3)	9.0 (6.3-11)	0.560
Peg-IFN α-2b plus TDF	10 (71.4%)	10 (50.0%)	0.218
Baseline			
HBV DNA-positive	4 (28.6%)	6 (30.0%)	0.698
HBV DNA Level, log_{10}IU/mL, mean (± sd)	3.4 (± 0.9)	3.4 (± 0.4)	0.862
ALT Level, IU/L, median (IQR)	20.6 (14.4-32.2)	16.7 (13.5-20.5)	0.090
HBsAg level, IU/mL, median (IQR)	271.6 (76.9-665.0)	956.9 (538.2-1673.8)	0.002*
HBsAg decline from baseline, %, median (IQR)			
At 12th week of treatment	99.8% (98.9%-100%)	43.0% (-7.5%†-73.0%)	0.000*
At 24th week of treatment	100% (99.9%-100%)	70.1% (31.1%-95.7%)	0.000*

†The negative sign means the HBsAg level was elevated from baseline.
*P≤0.05 was considered statistical significance.

1414-C | EFFICACY AND SAFETY OF TENOFOVIR ALAFENAMIDE (TAF) AT 2 YEARS IN CHILDREN AND ADOLESCENTS WITH CHRONIC HEPATITIS B (CHB)

Kathleen B. Schwarz[1], Jorge A. Bezerra[2], Byung Ho Choe[3], Chuan-Hao Lin[4], Frida Abramov[5], Hongyuan Wang[5], Yang Liu[5], John F Flaherty[5], Daniela Pacurar[6], Kyung Mo Kim[7], Ilsiyar Khaertynova[8], Dr Shalimar[9], Jia-Feng Wu[10], Manish Tandon[11], Philip Rosenthal[12], Viacheslav Morozov[13], Étienne M. Sokal[14] and Mei Hwei Chang[15], (1)University of California San Diego, Rady Children's Hospital San Diego, (2)University of Texas Southwestern Medical Center, (3)Kyungpook National University School of Medicine and Kyungpook National University Children's Hospital, (4)Children's Hospital Los Angeles, (5)Gilead Sciences, Inc., (6)Carol Davila University of Medicine and Pharmacy, (7)Asan Medical Center Children's Hospital, University of Ulsan, Seoul, Korea, Republic of (South), (8)Kazan State Medical University, (9)All India Institute of Medical Sciences, India, (10)National Taiwan University Hospital, (11)M.V. Hospital and Research Centre, (12) University of California San Francisco, (13)Hepatolog Medical Company, (14)Cliniques Universitaires Saint-Luc, (15)National Taiwan University and Children Hospital

Background: TAF, a novel prodrug of tenofovir, has shown noninferior efficacy with superior bone and renal safety compared to tenofovir disoproxil fumarate in randomized trials in adults with CHB. The US FDA has recently approved TAF for treatment of CHB in patients aged 12 and older and weighing **e** 35 kg with compensated liver disease, based on Week (W) 24 findings from a randomized, double-blind, placebo (PBO)-controlled trial (GS-US-320-1092; NCT02932150) in children and adolescents. Here we report W96 (2 y) findings from this study. **Methods:** CHB patients 12 to < 18 y and **e** 35 kg body weight (Cohort 1; adolescents) and 6 to < 12 y weighing **e** 25 kg (Cohort 2, Group 1; children), with HBV DNA **e** 2×10^4 IU/mL, ALT **e** 1.5 × ULN (30 U/L), and creatinine clearance (eGFR; Schwartz method) **e** 80 mL/min/1.73m^2 were randomized (2:1) to TAF 25 mg or matching PBO once daily (QD) for 24 weeks followed by an open-label (OL) extension phase where all patients received TAF 25 mg

QD through W240 (ie, TAF vs PBO→TAF). At W96, efficacy was assessed by proportion with HBV DNA < 20 IU/mL, serologic, and biochemical responses. Safety assessments included adverse events (AEs) and serious AEs (SAEs) during OL and changes in bone mineral density (BMD) by DXA, eGFR, and resistance surveillance. **Results:** 88 patients were randomized and treated (adolescents: n = 70 [TAF 47, PBO 23]; children: n = 18 [TAF 12, PBO 6]). Overall, mean (range) age and BMI were 14 (7-17) y, and 20.0 (13.6-29.4) kg/m^2; 58% male, 66% Asian, 99% HBeAg-positive, 68% with HBV DNA **e** 8 $\log_{10}$ IU/mL; median (Q1, Q3) ALT was 66 (52,103) U/L, and 22% had prior nucleos(t)ide use. Forty-four percent were HBV genotype (GT) D, with 24%, 23%, and 7% being GT C, B, and A, respectively. Results at W96 vs W48 showed increasing proportions with HBV DNA < 20 IU/mL in both groups: TAF (61% vs 37%) and PBO→TAF (48% vs 21%). In the TAF group, there was a trend for higher viral suppression in adolescents vs children at W96: 64% vs 50%. Most AEs were mild-moderate; no patient had a Grade 3 or 4 AE or serious AE related to study treatment, and none discontinued TAF due to an AE. At W96, changes from baseline in BMD and in eGFR for the TAF vs PBO→TAF groups were similar (Table), and no participant had eGFR < 90 mL/min/1.73m^2. Resistance to TAF was not detected through W96. **Conclusion:** Increasing rates of viral suppression were seen in pediatric CHB patients treated with TAF for 2 years, while the safety profile remained favorable.

Table. Efficacy and safety outcomes at Week 96

	TAF (N=59)	PBO→TAF (N=29)
HBV DNA <20 IU/mL, n (%)*	36/59 (61)	14/29 (48)
ALT normalization (AASLD)*#	30/56 (54)	16/28 (57)
HBeAg loss, n/N*	14/58 (24)	5/29 (17)
HBsAg loss, n/N*	1/59 (2)	0/29
Change from BL in eGFR, mL/min/1.73m^2, median (Q1, Q3)**	-13 (-30, 12)	-11 (-21, 2)
% Change from BL in Spine BMD, mean (SD) **	+6.4 (8.99)	+7.6 (11.10)
% Change from BL in Whole Body BMD (minus head), mean (SD)**	+6.6 (6.80)	+7.1 (7.13)

BL, baseline
*Missing = Failure analysis
#Includes only patients with ALT >ULN at baseline; AASLD ULN: 30 U/L
**Observed data
All TAF vs PBO→TAF comparisons were P>0.05

1415-C | EFFICACY AND SAFETY OF TENOFOVIR ALAFENAMIDE FOR 48 WEEKS IN HBEAG-POSITIVE CHB PATIENTS: A REAL-WORLD, MULTICENTER COHORT STUDY

Jiajia Han[1], Jiming Zhang[2], Yongmei Zhang[2], Yao Zhang[2], Yifei Guo[2], Feifei Yang[2], Richeng Mao[2] and Xueyun Zhang[2], (1)Huashan Hospital, Fudan University, (2)Fudan University

Background: There is a limited number of real-world studies investigating the efficacy of tenofovir alafenamide (TAF) in China. Nucleotide analogues (such as tenofovir disoproxil fumarate) have been reported to exhibit additional immunoregulatory effects compared to nucleoside analogues. But there are few clinical studies to explore the immunoregulatory effects of TAF, and a lack of prospective cohort studies evaluating serum cytokine changes during treatment. We conducted a multicenter prospective cohort study to assess the efficacy and safety of TAF, HBsAg and cytokines profile was also conducted during 48-week TAF treatment for chronic hepatitis B virus (HBV) infection. **Methods:** We performed a multicentre, prospective real-world study in China, which enrolled 98 HBeAg positive, treatment-naïve CHB patients with baseline HBV DNA > 2×10^4/mL. The enrolled patients were treated with TAF for 48 weeks. Blood samples were collected at 0, 12, 24 and 48 weeks to detect HBsAg level, cytokines (IFN-λ3, IP-10, IL-12, IL-21, IL-10) in patient serum. **Results:** A total of 98 patients were included. The medium levels of baseline HBV DNA and HBsAg were 7.7 $\log_{10}$ IU/mL and 4.3 $\log_{10}$ IU/mL, respectively. After 48 weeks of TAF treatment, HBsAg declined significantly by a median level of 0.53 log10 IU/mL. Among the patients, 28.6% experienced a decline in HBsAg of more than 1 $\log_{10}$ IU/mL, while no patient achieved HBsAg clearance. Additionally, 12 patients (12.2%) achieved HBeAg clearance, 52 patients (53.1%) achieved the complete virological response (HBV DNA **d** 20 IU/mL), and ALT normalization (the American Association for the Study of Liver Diseases criteria) in 56.5% of patients after 48 weeks of treatment. Compared with baseline, there were small mean increases in serum creatinine at week 48 (mean change 0.03 mg/dL [0.01-0.05], $p = 0.006$), with almost no change in blood phosphorus and calcium. During the 48-week treatment, IP-10 declined significantly from baseline to 48 weeks (0W, 12W, 24w, 48w median: 671.3 vs 431.3 vs 287.3 vs 269.5 pg/mL, $p < 0.001$). Similarly, IFN-λ3 slightly decreased during 48-week treatment. IL-12, IL-21 and IL-10 remained stable and did not show significant changes. Based on multivariate analysis, it was found that the baseline IP-10 > 1000 pg/mL was an independent predictor of complete virological response at 48 weeks (OR = 5.26, 95% CI:1.27-21.71, $p = 0.022$). Moreover, baseline HBsAg > 4.6 $\log_{10}$ IU/mL , ALT > 299 U/L and IP-10 > 680 pg/mL were independently related with the decline in HBsAg of more than 1 $\log_{10}$ IU/mL after 48 weeks. **Conclusion:** HBsAg declined significantly after 48-week TAF treatment. TAF demonstrated good renal safety during the 48-week treatment period. Moreover, baseline IP-10 level may be related with antiviral efficacy.

1416-C | EFFICACY AND SAFETY OF TENOFOVIR ALAFENAMIDE IN THE TREATMENT OF DECOMPENSATED CIRRHOTIC PATIENTS WITH CHRONIC HEPATITIS B

You Deng[1], Shuqian Zhang[1], Wenya Chen[1], Jiashuo Li[1], Mengqi Li[1], Qi Wang[1], Hong Zhao[1], Bing Qiao[2] and Wen Xie[1], (1)Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (2) Qingdao Sixth People's Hospital

Background: Hepatitis B viral (HBV) infection is a leading cause of liver cirrhosis and hepatocellular carcinoma (HCC) worldwide. Tenofovir alafenamide (TAF) is a new antiviral drug approved for the treatment of chronic HBV (CHB) infection. However, the effect of TAF therapy on viral suppression and hepatic function in CHB patients with decompensated cirrhosis remains unknown. This study aims to evaluate the efficacy and safety of TAF treatment in CHB patients with decompensated cirrhosis. **Methods:** Decompensated CHB patients with ascites were enrolled and provided 25 mg/day of TAF. Treatment outcomes were evaluated after 24 weeks of treatment, including clinical events, virological, serological, and biochemical responses. **Results:** Among the 182 recruited patients, 126 have completed the 24-week study thus far. At week 24, an undetectable HBV-DNA level was achieved in 56.3% (71/126) of patients, and ALT normalization was observed in 76.2% (96/126) of patients. Additionally, 69 (54.8%) patients experienced resolution of ascites. During the study, one patient died, three patients developed HCC, six patients developed gastroesophageal variceal bleeding, and five patients

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

developed hepatic encephalopathy. After 24 weeks of TAF treatment, significant improvements were observed in CTP [7.0 (6.0-9.0) vs. 6.0 (5.0-7.0), $p < 0.001$], MELD [11.4 (9.2-13.8) vs. 9.4 (8.3-12.3), $p < 0.001$], FIB-4 [5.2 (2.8-8.5) vs. 4.1 (2.2-7.0), $p = 0.003$], bilirubin [23.9 (16.5, 34.8) μmol/L vs. 18.9 (14.1, 25.8) μmol/L, $p < 0.001$], INR [1.31 (1.20, 1.51) vs. 1.21 (1.13, 1.33), $p = 0.001$], albumin (36.8 ± 7.74 g/L vs. 40.6 ± 6.69 g/L, $p < 0.001$), and ALT [30.3 (19.0, 51.6) IU/L vs. 24.8 (18.5, 33.7) IU/L, $p = 0.009$]. Meanwhile, TAF treatment was associated with a significant increase in blood lipid levels (total cholesterol: 3.64 ± 0.97 vs. 4.10 ± 1.18, $p = 0.004$; high density lipoprotein cholesterol: 1.02 ± 0.43 vs. 1.19 ± 0.37). There was no significant difference in eGFR (102.0 (88.5, 110.6) mL/min vs. 103.6 (91.8, 111.0) mL/min, $p = 0.364$). **Conclusion:** TAF treatment demonstrates efficacy in improving virological and liver function outcomes in CHB patients with decompensated cirrhosis. Further studies are needed to confirm the long-term efficacy and safety of TAF in this patient population.

1417-C | EFFICACY COMPARISON OF HIGH GENETIC BARRIER NUCLEOS(T)IDE ANALOGUES IN TREATMENT-NAÏVE CHRONIC HEPATITIS B PATIENTS: A NETWORK META-ANALYSIS

Hyun Yang[1], Si Hyun Bae[1], Jaejun Lee[2], Ahlim Lee[1], Pil Soo Sung[3], Jeong Won Jang[3], Jong Choi[2] and Seung Kew Yoon[3], (1)The Catholic University of Korea, (2) College of Medicine, the Catholic University of Korea, (3)Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, Republic of Korea

Background: Chronic HBV infection is a major cause of liver cirrhosis that may progress to hepatocellular carcinoma (HCC). Four high genetic barrier nucleos(t)ide analogues (NA) for CHB, namely entecavir (ETV), tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF), and besifovir dipivoxil maleate (BSV) have been established. The aim of this study is to investigate the efficacy of four high genetic barrier NAs using a network meta-analysis of randomized trials and propensity score matched cohorts. **Methods:** Systematic search was performed using PubMed, Cochrane library, and EMBASE and included randomized controlled trials and cohort studies that used propensity score matching. Studies on treatment-naïve CHB patients treated with ETV, TDF, TAF, or BSV were included. Outcomes included alanine aminotransferase normalization and HBeAg seroclearance at week 48 and undetectable HBV DNA at week 48 and 96. The ROB2.0 and ROBANS-I tools were used for quality assessment of included studies. Network meta-analysis was performed to synthesize the results. **Results:** In total, 13,822 patients from 15 studies were included. In terms of 48- and 96-week virologic response, TDF was ranked best and outperformed ETV with statistical significance (odds ratio 1.46, $p < 0.001$). ETV was ranked first for 48-week biochemical response and outperformed TDF (odds ratio 0.76, $p = 0.028$). In the sensitivity analyses, 48-week virologic responses from randomized-controlled trials were compiled, and the same trend toward the superiority of TDF over ETV was found (odds ratio = 1.51, $p = 0.030$). **Conclusion:** Four high genetic barrier NAs were compared and TDF and TAF were more likely to achieve a virologic response after 48 weeks and ETV provided a superior biochemical response after 48 weeks. Additional studies with longer treatment durations and large-sample studies are needed to determine the benefit of each of these drugs.

1418-C | FACTORS ASSOCIATED WITH A LACK OF VIRAL SUPPRESSION IN CHRONIC HBV (CHB) PATIENTS AFTER 8 YEARS OF TREATMENT WITH TENOFOVIR ALAFENAMIDE (TAF) OR TENOFOVIR DISOPROXIL FUMARATE (TDF) FOLLOWED BY TAF TREATMENT

Edward J. Gane[1], Maria Buti[2], Scott K. Fung[3], Henry Lik Yuen Chan[4], Namiki Izumi[5], Wan Long Chuang[6], Sang Hoon Ahn[7], Rajiv M. Mehta[8], Selim Gurel[9], Frida Abramov[10], Leland J. Yee[10], Hongyuan Wang[10], Roberto Mateo[10], John F. Flaherty[10], Xiaoli Ma[11], Calvin Q. Pan[12], Young-Suk Lim[13] and Patrick Marcellin[14], (1) University of Auckland, (2)Hospital Universitario Vall D'hebron and Ciberehd Del Instituto Carlos III, (3) Department of Medicine, University of Toronto, Toronto, ON, Canada, (4)The Chinese University of Hong Kong, (5)Department of Gastroenterology and Hepatology, Japanese Red Cross Musashino Hospital, (6) Kaohsiung Medical University Hospital, Kaohsiung Medical University, (7)Department of Internal Medicine, Yonsei University College of Medicine, (8)Nirmal Hospital, (9)Uludağ University Department of Gastroenterology, (10)Gilead Sciences, Inc., (11) Hahnemann University Hospital, (12)NYU Langone Health, New York University Grossman School of Medicine, (13)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South), (14)Hôpital Beaujon, Aphp, University of Paris

Background: We have previously shown that in CHB patients treated with TAF, or with TDF followed by roll-over to TAF, high rates of viral suppression (**e** 91%) were achieved and maintained at Week 384 (Year 8), with no emergence of antiviral resistance. Although only a small proportion of patients did not suppress, we sought to characterize factors associated with virologic failure after 8 years of treatment in a cohort of patients enrolled in two large Phase 3 studies. **Methods:** Pooled on-treatment data from two similarly designed Phase 3 studies (GS-US-320-0108; HBeAg-negative) and (GS-US-320-0110; HBeAg-positive) were included in this analysis. Briefly, patients were randomized (2:1) to TAF 25 mg QD vs TDF 300 mg QD in a double-blind (DB) phase for up to 3 years, after which all patients received TAF during the open-label (OL) extension phase (ie, TAF and TDF→TAF groups). Patients were assessed by the proportions with or without HBV DNA < 29 IU/mL (COBAS® AmpliPrep/ COBAS® TaqMan® HBV Test, v2.0) at Week 384. Demographic and disease characteristics and other factors potentially influencing treatment response (eg, adherence) were evaluated by univariate and multivariate logistic regression analyses. **Results:** Of 1298 randomized and treated patients, 895 (69%) remained on study treatment at Week 384. Forty-two of 895 (4.7%; TAF 29/600 [4.8%] and TDF→TAF 13/295 [4.4%]) had HBV DNA **e** 29 IU/mL at Week 384, and of these, 38 (90%) had achieved HBV DNA < 29 IU/mL, and 4 (10%) had achieved HBV DNA between 29 and < 2000 IU/mL at least once; no patient had a viral nadir **e** 2000 IU/mL. Characteristics of patients with HBV DNA < 29 vs **e** 29 IU/mL at Week 384 are shown in the Table. Disproportionally more nonsuppressed patients were younger in age, male, White, HBeAg-positive, genotype (GT) A or D, nucleos(t)ide-experienced, and baseline viral load and serum ALT were higher. Treatment assignment and study drug adherence (by pill count) did not differ between groups. By multivariate analysis, predictors of HBV DNA **e** 29 IU/mL were: GT A infection (OR 95% CI, 3.24 [1.13, 9.26]; $p = 0.028$); GT D infection (4.03 [2.06, 7.91]; $p < 0.001$), and age < 50 y (4.78 [1.45, 15.71]; $p = 0.010$). **Conclusion:** After 8 years of TAF or sequential TDF and TAF treatment, virologic failures were uncommon. HBV GT A or D infection and younger age were independently associated with lack of suppression.

Table. Characteristics of CHB Patients With/Without Viral Suppression at Week 384

Factor n (%)	HBV DNA <29 IU/mL (n = 853)	HBV DNA ≥29 IU/mL (n = 42)
Treatment group		
TAF	571 (67)	29 (69)
TDF→TAF	282 (33)	13 (31)
Age <50 years	610 (72)	39 (93)
Male	540 (63)	35 (83)
Race		
Asian	683 (80)	27 (64)

1419-C | FDA APPROVED DRUG LIBRARY SCREENING TO IDENTIFY COMPOUNDS THAT REDUCE HBS ANTIGEN

Akiyoshi Shimoda[1], Hayato Hikita[1], Kazuhiro Murai[1], Shinji Kuriki[1], Emi Sometani[1], Jihyun Sung[1], Makoto Fukuoka[1], Satoshi Shigeno[1], Akira Nishio[1], Takahiro Kodama[2], Tomohide Tatsumi[2], Hiroshi Suemizu[3] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2)Osaka University Graduate School of Medicine, (3)Central Institute for Experimental Animals

Background: Hepatitis B surface antigen (HBsAg), a component protein of hepatitis B virus (HBV), is suspected to be related to liver carcinogenesis or immune exhaustion that contributes to persistent infection. Current anti-HBV therapy, nucleos(t)ide analogue (NUC) have little effect on HBsAg. In this study, it is aimed to search for novel treatment to reduce HBsAg by FDA approved drug library screening and to elucidate its mechanism. **Methods:** Library screening with FDA approved drugs consisting of 1134 compounds was performed on HepG2.2.15.7 cells, HBV genome-integrated cells. The screening was conducted at a concentration of 9.9μM for 7 days. After 7 days incubation, the level of HBsAg in the supernatant and cell viability were measured. Compounds that reduced cell viability by more than 1 standard deviation (SD) were excluded. The compounds that decreased the level of HBsAg in the supernatant by more than 1.5 SD were selected as candidate compounds. The candidate compounds were validated at concentrations of 5 and 0.5 μM with the same time course. Compounds that significantly reduced the supernatant HBsAg at both concentrations were selected as final candidate compounds. To elucidate the mechanism of HBsAg reduction, HepG2.2.15.7 cells and HBV-inoculated (1000 genome equivalent/cell) primary human hepatocytes isolated from humanized liver chimeric TK-NOG mice (HepSH cells) were treated with final candidate compounds. **Results:** Total 126 compounds were excluded because their cell viability was below 1 SD. Out of the remaining 1008 compounds, 6 compounds were identified as candidate compounds with HBsAg levels decreased by more than 1.5 SD. Among them, only ethacridine and auranofin significantly decreased HBsAg in the supernatant at the both concentrations of 5 and 0.5 μM. Using HBV-inoculated HepSH cells, while ethacridine did not decrease HBsAg, auranofin decreased HBsAg. Hepatitis B envelope antigen (HBeAg), HBV-DNA in the supernatant or intracellular pregenomic RNA (pgRNA) was not decreased by auranofin. In addition, Western blotting did not show intracellular HBsAg decrease by auranofin. In a transmission electron microscopy image, many vesicles in the endosome were detectable in auranofin-treated HepSH cells inoculated with HBV, but not in untreated HepSH cells inoculated with HBV, suggesting that auranofin suppresses HBsAg secretion from the endosome. **Conclusion:** FDA approved drug library screening identified auranofin which suppresses HBsAg levels.

Background: Liver fibrosis in patients with chronic hepatitis B (CHB) could be regressed with successful antiviral therapy. However, the long-term clinical benefits of fibrosis regression have not been fully elucidated. This study investigated the association between biopsy-proven fibrosis regression by P-I-R score with liver-related events (LREs) in CHB patients. **Methods:** Patients with on-treatment liver biopsy and significant fibrosis/cirrhosis (Ishak **e** stage 3) were enrolled in this study. Fibrosis regression was evaluated according to the P-I-R score of the Beijing Classification. LREs was defined as decompensations, hepatocellular carcinoma (HCC), liver transplantation, or death. Cox proportional hazards model was used to determine associations of fibrosis regression with LREs. **Results:** A total of 733 patients with Ishak stage 3/4 (n = 456, 62.2%) and cirrhosis (Ishak stage 5/6, n = 277, 37.8%) by on-treatment liver biopsy were enrolled. According to P-I-R score, fibrosis regression, indeterminate and progression were observed in 314 (42.8%), 230 (31.4%) and 189 (25.8%) patients, respectively. The 7-year cumulative incidence of LREs was 4.1%, 8.7% and 18.1% in regression, indeterminate and progression, respectively (Log-rank, $p < 0.001$). Compared with progression, patients with fibrosis regression had a lower risk of LREs (adjusted HR = 0.40, 95%CI: 0.16-0.99, $p = 0.047$), followed by indeterminate (adjusted HR = 0.86, 95%CI: 0.40-1.85, $p = 0.691$). Specifically, this favorable association was also observed in patients with cirrhosis or low-level platelet counts ($< 150 \times 10^9$/L). **Conclusion:** Antiviral therapy-induced liver fibrosis regression assessed by P-I-R score is associated with reduced liver-related events. This study strengthened the utility of histologic fibrosis regression assessed by on-treatment P-I-R score as surrogate endpoints for clinical events in patients with HBV-related fibrosis or early cirrhosis.

1421-C | Immunotherapy Impact on HBsAg Reduction in Chronic Hepatitis B with HCC: Diminished by Corticosteroid Co-administration

TeWei Tseng[1], Wei Teng[1,2], Po-Ting Lin[1,2], Chung-Wei Su[1,2], Rachel Wen-Juei Jeng[1,2] and Chun-Yen Lin[1,2], (1)Linkou Chang Gung Memorial Hospital, (2)College of Medicine, Chang Gung University, Taiwan

Background: In a recent phase I clinical trial, chronic hepatitis B (CHB) patients treated with 0.3 mg/kg/dose of Nivolumab, a PD1 inhibitor, showed a mean decline of 0.30 $\log_{10}$ IU/ml in HBsAg levels at week 12 and a 4.5% loss of HBsAg after 6 months. However, our study reported in ILC 2023 found that using anti-cancer doses of ICI did not result in greater HBsAg reduction or higher HBsAg loss compared to CHB patients with HCC (CHB-HCC) who received TKIs. Importantly, the common use of corticosteroids among HCC patients undergoing immunotherapy, which can increase HBV replication and reactivation, may influence the inconsistent decline/loss rate of HBsAg between clinical trials and real-world ICI treatment in CHB-HCC patients. To investigate this further, we aim to compare HBsAg kinetics between CHB-HCC patients receiving ICI or TKI anti-cancer treatment, while excluding patients prescribed steroids. **Methods:** Retrospectively enrolled were CHB-HCC patients who received Nivolumab (2-3 mg/kg/dose) or Atezolizumab (1200 mg/dose) plus Bevacizumab (5-10 mg/kg/dose) as ICI therapy, or Sorafenib (400-800 mg/day) as TKI therapy, between 2012 and 2023. Only patients with a follow-up > 8 weeks were included, while those with prior systemic cancer treatments or concurrent steroid administration during ICI or TKI therapy were excluded. Propensity score matching (PSM) was employed to balance baseline differences (age, gender, ALT, BCLC stage, HBV DNA level, and NUC coadministration status) between the two groups in a 1:1 ratio.

HBsAg levels were measured and compared at the initiation of anti-cancer therapy and the second timepoint > 8 weeks post-treatment. HBsAg reduction magnitude was estimated using the formula [$\log_{10}$ (HBsAg level at second timepoint) – $\log_{10}$ (HBsAg level at the start of anti-cancer treatment)] / (HBsAg estimated interval, in years). **Results:** After PSM, there were 10 patients in each group. The median duration of ICI or TKI treatment was 12.8 weeks and 12.8 weeks, respectively. The median interval of two timepoints HBsAg measurement were 12.0 vs. 15.8 weeks in ICI versus TKI arms ($p = 0.10$). Characteristics at study entry including HBsAg levels at the start of treatment were comparable between both groups (Table). The ICI group had higher HBsAg reduction magnitude than TKI [median: 0.30 vs -0.07 ($\log_{10}$IU/ml/year), $p = 0.04$)], with a numerically higher proportion of rapid HBsAg decline (> 0.5 $\log_{10}$IU/ml/year) 4/10 vs 1/10, $p = 0.30$) and HBsAg loss rate (1/10 vs 0/10, $p = 1.00$). **Conclusion:** Upon excluding the influence of corticosteroids, a notable reduction in HBsAg was observed in CHB-HCC patients receiving ICI, compared to those treated with TKI. The administration of corticosteroids during anti-cancer therapy may hinder the impact of ICI on HBsAg reduction.

Background: Antiviral therapy reduces HCC risk in patients with CHB, particularly with TDF or entecavir. TAF, a novel prodrug of tenofovir, is a first-line recommended treatment for CHB and has shown efficacy comparable to TDF with higher rates of ALT normalization and no resistance. In an integrated analysis of 2 global Phase 3 studies, we evaluated HCC incidence and risk at 8 years (Week 384) in CHB patients treated solely with TAF and those treated initially with TDF and then switched to TAF for up to

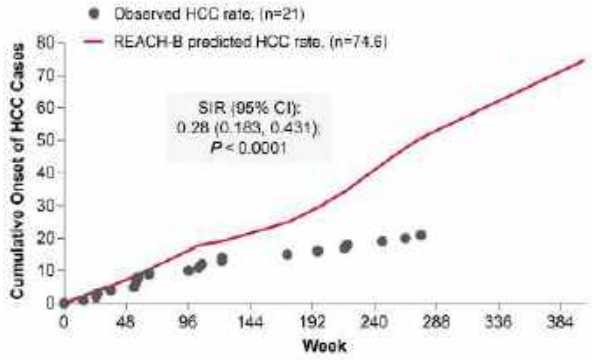
6 years (y). **Methods:** In 2 similarly designed studies, HBeAg-positive (n = 859) and -negative (n = 439) CHB patients with HBV DNA **e** 20,000 IU/mL and ALT > 60 U/L (males) or > 38 U/L (females) were randomized (2:1) to TAF 25 mg or TDF 300 mg given once daily in a double-blind (DB) phase for up to 3 y, followed by open-label (OL) TAF through Y8. HCC was assessed by local standards of care and by hepatic ultrasonography introduced after Week 96 and performed at 6-month intervals. Three validated models (REACH-B, aMAP, and mPAGE-B) were utilized to assess HCC risk by initial treatment assignment and collectively. Using the REACH-B model, standard incidence ratios (SIRs) for HCC (observed vs model-predicted HCC rates) were calculated; for aMAP and mPAGE-B, shifts in baseline risk for HCC were determined at Week 384. **Results:** Through Y8, HCC was diagnosed in 21/1298 patients (1.6%; TAF 1.4% [12/866]; TDF→TAF 2.1% [9/432]; $p = 0.33$ by logrank test)—11 in DB/10 in OL phase. Eight of 21 HCC cases were in cirrhotic patients. Median (Q1, Q3) time to HCC onset was 729 (388, 1373) days (TAF 1291 [397, 1629], TDF→TAF 460 [180, 729] days). Advanced age, male gender, and cirrhosis (defined as FibroTest **e** 0.75) were more common in HCC vs non-HCC patients ($p < 0.05$). Proportionately more HCC patients were HBV genotype C (76% vs 47%) and had BL HBV DNA between 6 to **d** 8 $\log_{10}$ IU/mL (57% vs 38%). With treatment over 8 y, by REACH-B, HCC incidence was significantly reduced (21 observed vs 74.6 predicted; SIR [95% CI] 0.28 [0.183-0.431]; $p < 0.0001$; Figure). Of patients predicted to be low risk for HCC at BL, nearly all remained low risk at Y8 by aMAP (98%) and mPAGE-B (97%), and substantial proportions estimated to be medium or high risk at BL shifted to a lower risk at Y8 (aMAP: 45% and 72%; mPAGE-B: 27% and 51%, respectively). **Conclusion:** CHB patients treated with TAF alone or switched from TDF to TAF for up to 8 y showed a reduced observed vs predicted risk for HCC development.

Observed vs Predicted HCC Cases in Patients Treated With Continuous TAF or Being Switched From TDF to TAF Through Year 8



HCC, hepatocellular carcinoma; SIR, standardized incidence ratio for observed cases vs predicted cases based on the REACH-B model; TAF, tenofovir alafenamide; TDF, tenofovir disoproxil fumarate.

1423-C | IMPROVEMENT OF NON-INVASIVE FIBROSIS TESTS IN HDV CIRRHOTIC PATIENTS WITH CLINICALLY SIGNIFICANT PORTAL HYPERTENSION RESPONDING TO BULEVERTIIDE MONOTHERAPY

Elisabetta Degasperi[1], Maria Paola Anolli[1], Sara Uceda Renteria[2], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Floriana Facchetti[1], Sara Monico[1], Mirella Fraquelli[3], Andrea Costantino[3], Ferruccio Ceriotti[2] and Pietro Lampertico[1,4], (1)Division of Gastroenterology and Hepatology, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (2)Virology Unit, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (3)Division of Gastroenterology and Endoscopy, Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, (4)CRC "a. M. and a. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan

Background: In patients with chronic hepatitis B or C, non-invasive fibrosis tests (NITs) have demonstrated significant improvement following antiviral treatment, whereas little is known about patients with chronic hepatitis Delta treated with Bulevirtide (BLV) monotherapy. **Methods:** Consecutive HDV patients with compensated cirrhosis and clinically significant portal hypertension (CSPH) according to Baveno VII criteria with a virological response (**e** 2 Log HDV RNA decline *vs.* baseline) to BLV monotherapy 2 mg/day up to 96 weeks were enrolled in this single-center study. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/mL). AST to Platelet Ratio Index (APRI), Fibrosis-4 (FIB-4) Index and liver stiffness-spleen size-to-platelet ratio score (LSPS) were calculated from clinical variables recorded on-therapy. Liver (LSM), spleen (SSM) stiffness measurement performed both by transient elastography (Fibroscan®) and point shear-wave elastography (ElastPQ) were also assessed on-treatment every 24 weeks. **Results:** 46 HDV cirrhotic patients with a virological response to BLV were included: pre-treatment, median age was 52 (30-77) years, 59% males, ALT 98 (30-1,074) U/L, platelets 78 (17-217) $x10^3/mm^3$, 54% with varices, spleen 15 (9-25) cm, CPT-A 100%, HDV RNA 5.2 (2.4-6.9) Log IU/mL. During BLV monotherapy [median 48 (range 8-96) weeks], serological NIT significantly improved at all timepoints, APRI decreasing from baseline 3.5 (0.6-16.5) to 1.2 (0.3-4.5) at week 96 ($p < 0.001$), and FIB-4 from 6.1 (1.3-28.1) to 4.1 (1.2-9.0) ($p = 0.003$). LSM decreased from baseline 17.2 (6.4-68.1) to 13.8 (5.4-54.3) kPa at week 48 ($p = 0.001$) and LSPS from baseline 4.1 (0.5-23.7) to 3.8 (0.3-14.3) at week 48 ($p = 0.001$), whereas no other significant changes were observed throughout weeks 48 and 96. Conversely, other NITs did not significantly modify from baseline to week 96: liver ElastPQ 14.3 (4.2-35.2) *vs.* 10.9 (7.0-22.3) kPa ($p = 0.54$); SSM 50.3 (19.7-100) *vs.* 47.9 (21.2-97.9) kPa ($p = 0.69$), Spleen ElastPQ 36.9 (12.8-114) *vs.* 30.6 (17.4-51.8) kPa ($p = 0.31$). Five patients underwent liver transplantation (HCC n = 3; liver decompensation n = 2) and one patient died of liver unrelated causes. **Conclusion:** In HDV compensated cirrhotic patients with CSPH and a virological response to BLV monotherapy, long-term treatment led to a statistically significant improvement of serological fibrosis NITs, liver stiffness and LSPS.

1424-C | INCIDENCE AND RISK FACTORS FOR LOW LEVEL VIREMIA IN CHRONIC HEPATITIS B PATIENTS RECEIVING ANTIVIRAL TREATMENT

Imran Hasanoğlu, Ankara Yildirim Beyazit University Ankara Bilkent City Hospital, Ankara, Turkey, Hatice Rahmet Guner, Ankara City Hospital, Ankara, Turkey, Esra Yerlikaya Zerdali, Istanbul Haseki Training and Research Hospital, Selma Tosun, Bozyaka Training and Research Hospital, Yusuf Onlen, Mustafa Kemal University Medical Faculty, Figen Yildirim, Antalya Training and Research Hospital, Tuba Turunc, Adana City Hospital, Ozgur Gunal, Samsun Training and Research Hospital, Ayse Batirel, Kartal Lutfu Kirdal City Hospital, Selcuk Kaya, Karadeniz Technical University Medical Faculty, Deniz Ozkaya, Bakircay University Cigli Training and Research Hospital, Nilsun Altunal, Umraniye Training and Research Hospital, Fehmi Tabak, Cerrahpasa University Cerrahpasa Medical Faculty and HEPBTURKEY Study Group

Background: Although there may not be many options in the treatment of chronic hepatitis B (CHB), the available antiviral agents have demonstrated the ability to suppress HBV DNA replication and reduce the risk of liver-related complications. Nevertheless, despite long-term antiviral therapy, some patients continue to experience low-level viremia (LLV) which is defined as HBV DNA < 2000 IU/ml. In this study, we aimed to evaluate the incidence and the factors that influence low-level LLV in patients with CHB receiving antiviral treatment. **Methods:** This multicenter retrospective observational study included clinical data from CHB patients who had received antiviral treatment for at least one year from January 2010 to April 2023. Univariate and multivariate logistic regression analyses were conducted to investigate the risk factors for LLV. **Results:** A total of 1826 patients from 32 centers included in the study. At the end of 1 year, incidence of LLV was 14.2%. To evaluate the risk factors for LLV, patients were divided into two groups as LLV and sustained virological response (SVR). Results of the univariate and multivariate logistic regression analyses are given in are given in Table 1. Multivariate logistic regression analyses showed that patients with HBeAg positive serostatus and pretreatment HBV DNA levels > 1.000.000 IU/ml has increased risk for LLV. No significant difference was observed between patients receiving entecavir and tenofovir in terms of LLV. **Conclusion:** Studies have demonstrated that a significant proportion of CHB patients, ranging from 20.0% to 40, maintain LLV. Results of this study emphasize that patients with HBeAg positive serostatus or pretreatment HBV DNA > 1.000.000 IU/ml has higher risk for LLV and should carefully monitored and the incidence of LLV was similar in entecavir and tenofovir treatments.

University, (2)The Third People's Hospital of Taiyuan, Taiyuan, China, (3)Shandong Provincial Hospital Affiliated to Shandong University, (4)Fudan University

Background: Interferon (IFN)-based therapies are considered effective in functional cure and reducing hepatocellular carcinoma (HCC) risks in patients with chronic hepatitis B (CHB). However, in practice, IFN-based therapies are less used in cirrhotic patients and have limited evidence. We aimed to evaluate the safety and effects of interferon-based therapy in CHB patients with cirrhosis, based on large scale real-word data from China. **Methods:** The analysis was conducted in the data from a multi-center, prospective real-world study (OASIS Project) from China. This project recruited patients with CHB from 32 provinces in China. Participants in OASIS Project received either IFN-based therapy or Nuc therapy, and would be followed up for five years. We made this analysis at the time-point of 2.5 years from project initiation, and in the subgroup of patients with cirrhosis. **Results:** A total of 1944 cirrhotic patients with complete baseline information was included in this analysis, of which 920 received IFN-based therapies and 1024 received Nuc therapy. Most of patients (897, 97.5%) in IFN group are classified as Child–Pugh class A at baseline, and the rest (23, 2.5%) are classified as Child–Pugh class B, while in Nuc group, there are 930 (90.8%), 79 (7.7%) and 15 (1.5%) patients in Child–Pugh class A, B and C, respectively. In IFN group, 72 (7.8%) patients had ALT elevation above 3 ULN, significantly higher than that in Nuc group (15[1.5%], $p < 0.0001$), and 17 (1.8%) had bilirubin elevation over 2ULN. None of them resulted in irreversible injury or liver failure yet. Up to this analysis, 2(8.7%) patients in IFN group child-pugh classification improved from B class to A class, and all those originally classified as A class stayed the same. No progression or decompensation happened in either group. A total of 971 participants reached 48-week follow-up visit and 386 reached 96-week follow-up study at the timepoint of analysis. In participants with HBsAg < 1500IU/ml, the HBsAg loss rates of IFN-based therapy were higher than in Nuc group at 48 weeks (11.2% vs 2.9%, $p = 0.008$) and 96 weeks (19.4% vs 4.8%, $p = 0.047$). However, in patients with HBsAg **e** 1500IU/ml, IFN-based therapies could not improve HBsAg loss rates significantly from Nuc either at 48 weeks (2.7% vs 1.4%, $p = 0.62$) or 96 weeks (6.7% vs 3.7%, $p = 0.366$). For HBV DNA suppression and HBeAg loss, patients in two group had no significant difference. There were 8 cases developed HCC within 144 weeks. The cumulative HCC incidence was lower in IFN-based treatment group than Nuc treatment group (0.14% vs 1.05 %) but not statistically significant after adjusting covariates including age, gender and baseline HBsAg level ($p = 0.0612$), and the HR of IFN-based therapy for HCC was 0.264 (95%CI 0.065-1.065) compared with Nuc therapy (Figure 1). **Conclusion:** IFN-based therapies are safe in CHB patients with child-pugh A cirrhosis, and more effective in terms of functional cure and HCC risk reduction.

Background: Tenofovir alafenamide (TAF) has similar efficacy and fewer safety concerns than tenofovir disoproxil fumarate (TDF) in the treatment of patients with chronic hepatitis B (CHB). Switching from TDF to TAF improves biochemical response and renal safety; however, long-term real-world data are limited. The aim of this study was to assess the effectiveness and safety outcomes for both treatment-naïve and experienced CHB patients treated with TAF for up to four years. **Methods:** This multicenter, retrospective, observational cohort study consisted of consecutive CHB patients aged 18 years and older who from March 2017 initiated or switched to a fixed dose of TAF, 25mg orally once daily. Primary outcomes were viral suppression (VR: HBV DNA < 10 IU/mL), ALT normalization (BR: ALT < 35/25 U/L men/women), and complete response (CR: viral plus biochemical response) within four years. Safety assessments included changes in estimated glomerular filtration rate (eGFR) and serum phosphorus level. **Results:** We enrolled 578 eligible patients: 115 treatment-naïve and 463 treatment-experienced. In the treatment-naïve group, the mean age was 56.5 ± 13.1, 53.0% were male, 25.2% were HBe-antigen positive, and 13.9% had cirrhosis. In the four-year follow-up, the proportions of VR and BR were 77.5%/66.3%, 87.7%/75.3%, 89.8%/78.5%, 92.5%/80.6%, and 94.3%/83.3% at month 6, year 1, year 2, year 3, and year 4, respectively. The proportions of CR also longitudinally increased, to 59.0%, 70.7%, 71.6%, 73.5%, and 75.6%, at month 6, year 1, year 2, year 3, and year 4, respectively ($p < 0.01$). eGFR significantly decreased during the first 6 months (79.3 to 77.0 mL/min/1.73m^2, $p < 0.01$); however, it did not change significantly after 6 months of TAF therapy. Moreover, 9.3% of treatment-naïve patients experienced hypophosphatemia (< 2.5 mg/dL). In the treatment-experienced group, the mean age was 57.9 ± 12.6, 62.0% were male, and 14.9% had cirrhosis. All had been treated with entecavir (n = 200), TDF (n = 135), or a combination of nucleos(t)ide analogues (n = 128) before switching to TAF. Sixty-five (14.0%) had HBV DNA > 20 IU/mL at baseline. In the four-year follow-up, the proportions of VR and BR increased, to 95.7%/81.1%, 96.3%/80.9%, 97.8%/83.2%, 97.8%/82.1%, and 98.9%/83.5% at month 6, year 1, year 2, year 3, and year 4, respectively. The proportions of CR also significantly increased, to 81.4%, 81.4%, 83.8%, 82.7%, and 84.6%, at month 6, year 1, year 2, year 3, and year 4, respectively ($p < 0.01$, compared to baseline). For patients who switched from a TDF-containing regimen to TAF, eGFR significantly improved during the first 6 months (+3.1 mL/min/1.73m^2) ($p < 0.01$). **Conclusion:** In this 4-year real-world cohort, TAF had a potent virological and biochemical effect for treatment-naïve and experienced patients with CHB. Moreover, patients who switched from TDF to TAF can benefit from TAF therapy in terms of improvement of renal function.

1427-C | LONG-TERM FOLLOW-UP OF WOMEN RECEIVING TENOFOVIR ALAFENAMIDE DURING PREGNANCY TO PREVENT MATERNAL HBV TRANSMISSION

Wan-Hsin Wen[1,2], Chun-Jen Liu[3], Ming-Wei Lai[4], Ming-Chieh Tsai[5], Shu-Chi Mu[6], Kuang- Chun Hu[7], Rong-Nan Chien[4], Chien-Nan Lee[8], Huey-Ling Chen[9] and Mei-Hwei Chang[10], (1)Cardinal Tien Hospital, (2)Fu-Jen Catholic University, (3)National Taiwan University Hospital, (4)Linkou Chang Gung Memorial Hospital, (5) Hsinchu Cathay General Hospital, (6)Shin Kong Wu Ho-Su Memorial Hospital, (7)Mackay Memorial Hospital, (8)National Taiwan University College of Medicine and Hospital, (9)National Taiwan University, Taipei, Taiwan, (10)National Taiwan University, College of Medicine

Background: Tenofovir alafenamide (TAF), a newer generation of tenofovir with less renal and bone toxicity, has been demonstrated to have a favorable effectiveness and safety profile in preventing maternal HBV transmission in studies with a follow-up duration of no longer than 12 months. Long-term data is lacking. This study reports on the long-term liver outcomes of women who received TAF during pregnancy to prevent maternal HBV transmission. **Methods:** Women included in this study were the participants in our prospective cohort (ClinicalTrials.gov, NCT 03695029) on TAF treatment in pregnancy from 3rd trimester until 2 weeks postpartum. At baseline, all pregnant women were hepatitis B e antigen (HBeAg)-positive and had a viral load above 6.0 log10 IU/mL. Serum alanine aminotransferase (ALT) and HBV viral load were measured at baseline, delivery, 1, 2, 4, 6, and 12 months postpartum, and subsequently at 12-month intervals. HBeAg was checked at delivery, 6, and 12 months postpartum,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

followed by 12-month intervals thereafter. The hazard ratios for HBeAg clearance with 95% confidence intervals (CI) were determined using a Cox proportional hazards model adjusted with multiple covariates. **Results:** The analysis included 78 women. The median follow-up duration after delivery was 23.8 months (range, 12 to 50.6 mo). Postpartum, 21 (26.9%) women continued or resumed antiviral nucleos(t)ide analog (NA) treatment, including two who received short-term TAF treatment for subsequent pregnancies. At baseline, six (7.7%) pregnant women had ALT elevations above 40 U/L. During the follow-up period, ALT elevations above 40 U/L were observed in 7.7%, 56.4% and 16.7% of the women at delivery, during 1-6 months postpartum, and at 1 year postpartum. Of the 78 subjects, 9 (11.5%) cleared HBeAg, including one became HBeAg negative at the time of delivery, while 8 cleared HBeAg during the postpartum follow-up period. After adjustment for maternal age, baseline ALT, ALT flare within 6 months postpartum, ALT flare at one year postpartum, and NA treatment during follow-up, we found that mothers with ALT > 40 IU/L at delivery were more likely to clear HBeAg than mothers with normal ALT at delivery (hazard ratio, 16.80; 95% CI, 2.38 to 118.71; $p = 0.005$). None of these women experienced progression to liver failure, cirrhosis, or cancer. **Conclusion:** Highly viremic women receiving TAF during pregnancy to prevent maternal HBV transmission had high rates of ALT elevations during 1-6 months postpartum, and some continued or resumed antiviral therapy. An ALT flare greater than 40 IU/L at delivery serves as an independent predictor of HBeAg clearance.

1428-C | MATHEMATICAL MODELING OF HBV KINETICS IN HUMANIZED MICE SUGGESTS THAT NA BLOCKS NOT ONLY RCDNA PRODUCTION BUT ALSO PGRNA SYNTHESIS

Ashish Goyal[1], Yuji Ishida[2,3], Chise Tateno[3,4], Andrew Vaillant[5], Scott J. Cotler[1], Kazuaki Chayama[3,6,7] and Harel Dahari[1], (1)Loyola University Chicago, (2)R&D, Phoenixbio Co., Ltd., (3)Hiroshima Institute of Life Sciences, (4)Phoenixbio Co., Ltd., (5)Replicor Inc., Montreal, Canada, Montreal, QC, Canada, (6)Riken Center for Integrative Medical Sciences, (7) Collaborative Research Laboratory of Medical Innovation, Hiroshima University

Background: Nucleos(t)ide analogue therapy (NA) for hepatitis B was recently suggested to be multifunctional based on the observed decline of both serum HBV DNA and pregenomic RNA (pgRNA) in patients (Hepatology. 2021;74(3):1708-1709). We aim to provide insights into NA modes of action in chimeric urokinase type plasminogen activator (uPA)/severe combined immunodeficiency (SCID) mice reconstituted with humanized livers using a mathematical modeling approach. **Methods:** We first employed a modeling selection approach to identify a mathematical model that best reproduced the observed multiphasic serum HBV kinetics from de-novo infection to a steady state of viremia in humanized mice (Hepatology. 2018;68(2):473-484). Models that were explored assumed: (1) basic viral dynamic model without intracellular dynamics, (2) extended models that included intracellular covalently closed circular DNA (cccDNA; accumulation up to 5 cccDNA per infected cell), and relaxed circular DNA (rcDNA) with or without pgRNA and with or without saturation (i.e., Michaelis–Menten equation) in pgRNA and/or rcDNA production. The best model found in Fig. 1A was then used to fit the viral kinetics observed in 21 humanized mice (Fig. 1B) that were treated with lamivudine (LAM) for 14 days after reaching viral steady state (J Virol.2021;24;95(14):e0049220). We fit the models to the observed serum viral data using a population, nonlinear mixed-effects approach. **Results:** The multiphasic serum viral kinetics from de-novo infection to steady state were successfully recapitulated using an extended model that included pgRNA synthesis in a saturated manner from cccDNA and the synthesis of rcDNA from pgRNA by HBV reverse transcriptase, (RT) [Fig. 1A, solid line]. When we assumed that LAM inhibits both RT and pgRNA synthesis, the model fit the observed viral kinetics during LAM treatment better (Fig.1B, solid line) than when we assumed that LAM inhibits RT alone (Fig. 1B, dashed line). The estimated dual LAM inhibition efficacy of rcDNA and pgRNA synthesis which best fit the viral kinetics following LAM treatment were 81% (95% CI: 80%-83%) and 93% (95% CI: 89%-95%), respectively. **Conclusion:** Modeling suggests that intracellular saturated pgRNA synthesis plays a pivotal role in reproducing the observed multiphasic viral kinetics from infection to steady state in humanized mice. The use of a model that includes intracellular HBV dynamics to reproduce viral kinetics under LAM treatment predicts potential upstream NA interactions affecting intracellular pgRNA synthesis in addition to rcDNA synthesis.

1429-C | NO DETECTED RESISTANCE TO TENOFOVIR ALAFENAMIDE (TAF) THROUGH 96 WEEKS OF TREATMENT IN CHILDREN AND ADOLESCENTS WITH CHRONIC HEPATITIS B

Philip Rosenthal[1], Mei-Hwei Chang[2], Jorge A. Bezerra[3], Yang Liu[4], Dong Han[4], Simin Xu[4], Caleb Marceau[4], Tahmineh Yazdi[4], Lindsey May[4], Robert Li[4], Savrina Manhas[4], Pui Yan Ho[4], Clarissa Martinez[4], Nadine Peinovich[4], Silvia Chang[4], Ross Martin[4], Evguenia Maiorova[4], Hongmei Mo[4], Frida Abramov[4], John F. Flaherty[4] and Kathleen B. Schwarz[5], (1)University of California San Francisco, (2)National Taiwan University, College of Medicine, (3)University of Texas Southwestern Medical Center, (4)Gilead Sciences, Inc., (5)University of California San Diego, Rady Children's Hospital San Diego

Background: Tenofovir alafenamide (TAF) is approved for use in adults with chronic hepatitis B (CHB) and no resistance has been detected through 8 years of treatment. Here, we describe the resistance analyses at Week 96 of a Phase 2 study evaluating TAF for the treatment of children and adolescents aged 6 to < 18 years with CHB. **Methods:** A total of 88 adolescents (n = 70) and children (n = 18) with CHB were randomized (2:1) to receive TAF 25 mg once daily or matching placebo (PLB) in Cohort 1 (aged 12 to < 18 years weighing **e** 35kg) and Cohort 2 Group 1 (aged 6 to < 12 years weighing **e** 25kg) in a double-blind fashion for 24 weeks followed by open-label TAF through Week 240 (ie TAF or PLB-TAF). HBV pol/RT deep sequencing was conducted for participants with HBV DNA **e** 69 IU/mL at Week 96. Virologic breakthrough (VB) was defined as HBV DNA **e** 69 IU/mL after achieving < 69 IU/mL or a **e** 1.0-$\log_{10}$ increase from nadir for 2 consecutive visits; participants meeting these criteria at only 1 visit were classified as having a virologic blip. Viremia was defined as having persistent HBV DNA **e** 20 IU/mL over the course of treatment. Phenotypic analysis using recombinant HBV in HepG2 cells was performed for those with VB, conserved site substitutions, or same polymorphic substitutions emergent in > 1 participant. **Results:** At Week 96, 24 of 88 (27%) participants (TAF 8, PLB-TAF 9 in Cohort 1; TAF 4, PLB-TAF 3 in Cohort 2 Group 1) qualified for resistance analysis due to persistent viremia (n = 19) or VB (n = 5). The number of participants who qualified for resistance analysis decreased compared to Week 48 (43 of 88, 49%). Of the 24 participants who qualified for sequencing at Week 96, 1 had conserved site substitution, 3 had polymorphic site substitutions, 15 had no change from baseline, and 5 were unable to be sequenced due to low level HBV DNA. At Week 96, 2 participants qualified for phenotypic analysis due to conserved site change (n = 1) or virologic breakthrough (n = 1) and both the baseline as well as the Week 96 isolates remained sensitive to TAF in vitro. **Conclusion:** Fewer participants qualified for resistance analysis with continued TAF treatment. The majority of participants qualified for sequence analysis due to persistent viremia (79%) and most had no sequence change from baseline. No substitutions associated with resistance were detected in children and adolescents with CHB treated with TAF for up to 96 weeks.

Table. Week 96 Sequence Analysis

Category	Cohort 1 (12 to <18 years weighing ≥35kg)		Cohort 2, Group 1 (6 to <12 years weighing ≥25kg)	
	TAF (N=47)	PLB-TAF (n=23)	TAF (n=12)	PLB-TAF (n=6)
Qualified for Sequence Analysis at Week 96	8 (17%)	9 (39%)	4 (33%)	3 (50%)
Virologic breakthrough	2	2	1	0
Virologic blip	0	0	0	0
Viremia	6	7	3	3
Sequence Analysis Results at Week 96				
Conserved Site Substitution(s)	0	0	0	1
Polymorphic Site Substitution(s)	1	1	1	0
No Change from Baseline	6	5	2	2
Unable to Sequence	1	3	1	0

1430-C | NO RESISTANCE TO TENOFOVIR ALAFENAMIDE (TAF) IN ADULT, HBEAG-POSITIVE AND HBEAG-NEGATIVE PARTICIPANTS WITH CHRONIC HEPATITIS B INFECTION TREATED WITH TAF FOR UP TO 8 YEARS.

Roberto Mateo[1], Henry Lik Yuen Chan[2], Patrick Marcellin[3], Calvin Pan Pan[4], Tahmineh Yazdi[1], Silvia Chang[1], Dong Han[1], Lindsey May[1], Caleb Marceau[1], Christopher Richards[1], Savrina Manhas[1], Pui Yan Ho[1], Robert Li[1], Simin Xu[1], Clarissa Martinez[1], Yang Liu[1], Nadine Peinovich[1], Andrew Lopez[1], Frida Abramov[1], John F. Flaherty[1], Hongmei Mo[1], Namiki Izumi[5], Maria Buti[6], Dr Shalimar[7] and Young-Suk Lim[8], (1)Gilead Sciences, Inc., (2)Chinese University of Hong Kong, Hong Kong, China, (3)Beaujon Hospital, (4)NYU Grossman School of Medicine, (5)Department of Gastroenterology and Hepatology, Japanese Red Cross Musashino Hospital, (6)Hospital Universitario Vall D'hebron and Ciberehd Del Instituto Carlos III, (7)All India Institute of Medical Sciences, New Delhi, (8)Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South)

Background: Tenofovir alafenamide (TAF) has shown similar efficacy and improved safety profiles for treatment of patients with chronic hepatitis B (CHB) compared to tenofovir disoproxil fumarate (TDF). We have previously shown no resistance to TDF after 8 years, and TAF resistance has not been detected after up to three years of treatment in CHB patients. Here we report results from annual resistance surveillance from years 3 through 8 of TAF treatment. **Methods:** Two randomized, double-blind (DB), active-controlled trials to evaluate TAF treatment of hepatitis e antigen (HBeAg)-negative (Study GS-US-320-0108) and HBeAg-positive (Study GS-US-320-0110) participants with CHB were conducted over 8 years (384 weeks). Sequence analysis of the pol/RT region was attempted for any participant who experienced a viral breakthrough, viral blip, or persistent viremia with HBV DNA **e** 69 IU/mL at annual intervals and for any participant who discontinued study drug with HBV DNA **e** 69 IU/mL. Participants that developed substitutions at conserved pol/RT sites or at polymorphic residues (if observed in **e** 2 participants within the study) were also phenotyped against TAF. **Results:** Out of 1298 participants enrolled in both studies, the percentage of participants who qualified for resistance analysis annually from Week 144 (Year 3) to Week 384 (Year 8) remained low (range 1.7 – 8.4%). Among those qualifying for sequencing, the proportions with persistent viremia progressively declined with time, with only 3 participants being persistently viremic by Year 8. The viral load of these 3 participants at baseline was $> 10^8$ $\log_{10}$ IU/mL and declined over time but did not reach 69 IU/mL. During the 5-year open-label period where all participants received TAF, conserved site substitutions in the HBV viral pol/RT were observed in 13 participants. Polymorphic site substitutions present in **e** 2 participants in the study were observed in 10, 6, 18, 8 and 6 participants at Weeks 192, 240, 288, 336 and 384, respectively. Phenotypic analysis showed that viruses containing those substitutions had TAF EC_{50} fold-change values in the range 0.21-1.85, compared to baseline (below the assay cut-off of 2-fold). **Conclusion:** Overall, no resistance to TAF was detected in adult CHB participants with positive or negative HBeAg who received TAF therapy for up to 8 years. These findings support the use of TAF as long-term viral suppressive therapy in patients chronically infected with HBV regardless of their HBeAg status.

1431-C | NUC-INDUCED RAPID DECLINE IN HEPATITIS B SURFACE ANTIGEN BELOW LOW LEVELS LEADS TO SURFACE ANTIGEN SEROCLEARANCE IN PATIENTS TREATED WITH LONG-TERM AND CONTINUOUS NUCLEOS(T)IDE ANALOGUES.

Tetsuya Hosaka[1], Fumitaka Suzuki[1], Mariko Kobayashi[1], Shunichiro Fujiyama[1], Yusuke Kawamura[1], Hitomi Sezaki[2], Norio Akuta[1], Yoshiyuki Suzuki[1], Satoshi Saitoh[1], Yasuji Arase[1], Kenji Ikeda[1] and Hiromitsu Kumada[1], (1)Toranomon Hospital, (2) Toranomon Hospital, Tokyo, Japan

Background: Long-term nucleos(t)ide analogues (NUCs) treatment improve the prognosis in chronic hepatitis B (CHB) patients. However, hepatitis B surface antigen (HBsAg) seroclearance rates are still low by NUC treatment. Therefore, some new antiviral agents targeting the great reduction in HBsAg are now developing, combined with NUC treatment. It is important to investigate the underlying mechanisms of HBsAg reduction and seroclearance during long-term NUC treatment. **Methods:** We conducted a retrospective cohort study of 1696 patients who received nucleos(t)ide analogues (NUCs) including lamivudine, entecavir and tenofovir for more than three years in our institute. Almost all patients received continuous NUC treatment until HBsAg seroclearance. Serum HBsAg levels were quantified at annual time points from baseline to last visits by the commercial assay (lower limit of quantification = 0.05 IU/mL) in the regular visits or from their stored serum samples. "Rapid decline" in HBsAg levels was defined as over 0.3 log IU/mL/year reduction 3 years after starting with NUC. We examined the association between the kinetics of on-treatment HBsAg levels and subsequent HBsAg seroclearance in chronic hepatitis B (CHB) patients treated with long-term and continuous NUCs. **Results:** During follow-ups of median 12.6 years, 128 patients achieved HBsAg seroclearance (5.9/1,000 person-years), and rapid decline in HBsAg occurred in 527 patients (31%). Median time from baseline when rapid decline occurred was year 7. Cumulative incidences rates of rapid decline were 12% at year 5, 27% at year 10, 40% at year 15, and 49% at year 20, respectively. 36% of patients with rapid decline had HBsAg < 100 IU/mL at the rapid decline, 37% had HBsAg **e** 100 and < 500, and 28% had HBsAg **e** 500. Next, we evaluated HBsAg seroclearance rates since rapid decline occurred in patients with rapid decline stratified by HBsAg levels at the rapid decline. Cumulative HBsAg seroclearance rates from the rapid decline were significantly greater in patients with HBsAg **e** 100 IU/mL (group 1) than those with HBsAg **e** 100 and < 500 (group 2), and **e** 500 (group 3) (Figure). 5-year HBsAg seroclearance rates from the rapid decline were 41% in group 1, 11% in group 2 and 3% in group 3, despite of continuous NUC treatment. Median reductions in HBsAg 3 years after the rapid decline were -0.55 log IU/mL in group 1, -0.30 in group 2, and -0.11 in group 3 (p trend < 0.001). Median ALT levels at the rapid decline were 20 IU/L in group 1, 21 in group 2 and 25 in group 3 (p trend = 0.027). Factors with the occurrence of rapid decline below HBsAg < 100 were baseline low HBsAg levels, baseline HBeAg negativity and male using multivariable Cox regression. **Conclusion:** When the rapid decline below HBsAg < 100 occurred in continuous NUC, subsequent HBsAg seroclearance rates were relatively high, and HBsAg reduction was durable. Further investigation is needed to find out this mechanism.

1432-C | NUCLEOS(T)IDE ANALOGUES HELP PRESERVE LIVER VOLUME IN CHRONIC HEPATITIS B PATIENTS WITH LOW VIRAL LOAD

Yunjeong Lee and Jin-Wook Kim, Seoul National University Bundang Hospital

Background: The ultimate goal of treatment for chronic hepatitis B (CHB) is to halt progression of liver injury and to prevent the development of hepatocellular carcinoma. Since these long-term outcomes are not readily obtainable, surrogate markers, i.e., transaminase and viral load, are used both as a response marker and an indication of nucleos(t)ide analogue (NA) therapy. Hepatic volumetry has been used for the planning of liver transplantation and liver resection. Previous studies have also suggested that liver volume can predict prognosis in chronic viral hepatitis. This study aimed to test whether liver volume may serve as a response marker in CHB patients with low HBV DNA level (< 2000 IU/mL) and persistently low AST/ALT level (both < 80 U/L), for whom current guidelines do not recommend initiation of NA therapy. **Methods:** We retrospectively examined CHB patients with a low HBV DNA level (< 2000 IU/mL) and persistently low transaminase level (both ALT and AST < 80 U/L), either with or without maintenance of NA therapy, who underwent computed tomography (CT) scans seen between April 2003 and February 2023. A total of 131 were categorized into on-NA group (n = 63) and NA-untreated group (n = 68). Whole-liver volume quantification on their initial and latest follow-up CT images was performed using a semiautomatic 3-dimensional multiplanar reconstruction tool within the DICOM Viewer Pro edition 64-bit version (Inobitec, Moscow, Russia). We used the two-sample Wilcoxon rank-sum (Mann-Whitney) test to determine the effect of NUCs on the subsequent change in liver volume using Stata/SE 14.0. **Results:** At baseline, on-NA group had significantly lower HBV DNA level with higher serum AST/ALT level with more HbeAg positivity than NUC-untreated group. Otherwise, there was no statistically significant difference in age, gender, other laboratory data, initial liver volume or interval between the CT scans. Liver volumes in NA-untreated group decreased more with time than those in on-NA group (-71 ± 170 mL vs. +35 ± 193 mL, $p = 0.00$; Figure). When compared according to HBV DNA levels regardless of history of NUC use, patients with undetectable HBV DNA level (< 60 UL/mL, n = 64) showed more preserved liver volume than those with higher HBV DNA titers (60 ~ 2000 UL/mL, n = 67) (+1 ± 195mL vs. -40 ± 181 mL, $p = 0.02$). **Conclusion:** In CHB patients with low/normal transaminases and low HBV DNA, treatment with NUC therapy was associated with preservation of liver volume. Also, the loss of liver volume was significantly larger in low viremia patients (60 ~ 2000 IU/mL) than those with undetectable HBV DNA level (< 60 IU/mL). Our data suggests that liver volume may serve as a new response indicator to NA therapy, and that suppression of low viremia may contribute to preservation of liver volume in CHB with low/normal transaminases and low HBV DNA who are not currently indicated for NA therapy.

Background: Nucleo(s)tide analogue (NUC) withdrawal is being explored as a novel means of increasing HBsAg loss in patients with chronic hepatitis B, but has been associated with a significant risk of severe viral rebound and hepatitis flares. End-of-treatment (EOT) HBsAg levels < 100 IU/mL are associated with favorable outcomes after therapy withdrawal. Unfortunately, the majority of patients potentially eligible for therapy withdrawal do not have such low HBsAg levels. We studied whether off-treatment HBV DNA and HBsAg levels can be used to guide further management in these patients. **Methods:** Chronic hepatitis B patients with HBsAg levels > 100 IU/mL at the time of NUC cessation who were still HBsAg positive and without clinical relapse or retreatment at follow-up week 24 (FU W24) were identified in an existing multicenter database. The association between HBsAg and HBV DNA levels at FU W24 with subsequent clinical relapse (defined as HBV DNA > 2,000 IU/mL + ALT > 2x ULN or retreatment) and HBsAg loss was studied through univariable analyses using the Kaplan-Meier method, as well as multivariable Cox regression analysis adjusting for other potential predictors. **Results:** We enrolled 509 patients, 85% Asian, 29% pretreatment HBeAg positive, and 60% treated with entecavir. At 192 weeks of subsequent follow-up, the cumulative probability of clinical relapse and HBsAg loss were 56% and 5.1%. Patients with higher HBV DNA levels at FU W24 had a higher risk of clinical relapse (hazard ratio [HR] 1.550, $p < 0.001$) and a lower chance of HBsAg loss (HR 0.572, $p < 0.001$). Similarly, patients with higher HBsAg levels at FU W24 had a higher risk of clinical relapse (HR 1.379, $p < 0.001$) and a lower chance of HBsAg loss (HR 0.162, $p < 0.001$). Patients with both HBsAg < 100 IU/mL and HBV DNA < 100 IU/mL (n = 22) at FU W24 had excellent outcomes (13% clinical relapse and 53% HBsAg loss at 192 weeks of subsequent follow-up, see figure). Amongst patients with both HBsAg > 100 IU/mL and HBV DNA > 100 IU/mL (n = 308), clinical relapse rates were very high (68% at 192 weeks), and HBsAg loss rates were dismal (< 1% at 192 weeks). Findings were consistent in multivariable analysis.

Conclusion: Among CHB patients with HBsAg > 100 IU/mL at EOT, HBsAg and HBV DNA levels at FU W24 predict outcomes during subsequent follow-up. Presence of HBsAg < 100 IU/mL with HBV DNA < 100 IU/mL at FU W24 is associated with a low risk of subsequent clinical relapse and excellent chances of HBsAg loss. Retreatment should be considered for all patients with both HBsAg > 100 IU/mL and HBV DNA > 100 IU/mL due to high clinical relapse rates and virtually no chance of HBsAg loss.

1434-C | PEGINTERFERON ALFA-2b PLUS TDF TREATMENT IN ADULTS WITH HBEAG-POSITIVE CHRONIC HEPATITIS B VIRUS INFECTION: A PILOT, OPEN-LABEL, PROSPECTIVE COHORT STUDY

Min Liu[1], Lili Zuo[1], Yuting Zhang[1], An Xiao[1], Yilan Wang[1], Bing Bu[1], Jiayi Chen[1], Ling Zhu[1], Wei Yue[1], Jiawei Geng[1] and Xueshan Xia[2], (1)The First People's Hospital of Yunnan Province, (2)Kunming University of Science and Technology

Background: Expanding antiviral therapy to benefit more patients with chronic HBV infection and optimizing treatment to improve prognoses are two main objectives in current guidelines. However, the guidelines do not recommend antiviral therapy for HBeAg-positive chronic HBV infection (immune-tolerant, IT) patients. Currently, existing literature is sparse on the clinical efficacy for IT adults. This study aims to evaluate the efficacy and safety of the combination of peginterferon alfa-2b (PEG-IFNα-2b) and Tenofovir disoproxil fumarate (TDF) in IT adults. **Methods:** This is a pilot, open-label, prospective cohort study from May 2019 to October 2022. Treatment-naive adults aged 18 to 60 years in immune-tolerant phase were recruited and divided to three groups as their willing. Patients in combination therapy group received PEG-IFNα-2b for 12 weeks followed by TDF "add-on" for 36 weeks, TDF monotherapy group received TDF for 48 weeks and control group received follow-up only (Figure 1A). The primary endpoints were HBeAg loss rate and the proportion of patients achieving qHBsAg < 3000 IU/mL at the end of treatment (EOT). The secondary endpoints were HBsAg loss rate and proportion of patients with HBV DNA **d** 10 IU/mL at EOT. **Results:** 247 patients were enrolled. At baseline, there was no significant difference in the epidemiological, biochemical, serological and virological indicators among groups. The median age was 28 years, 34.82% were male, and nearly all were genotype B or C. Of the 73 patients in the combination therapy group, 5.48% achieved HBeAg loss, 46.58% achieved HBsAg < 3000 IU/mL, 71.23% had HBV DNA **d** 10 IU/mL, and 4.11% achieved HBsAg loss at EOT. Of 121 patients in the TDF monotherapy group, only 0.83% achieved HBeAg loss,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

2.48% achieved HBsAg < 3000 IU/mL, 52.07% obtained HBV DNA **d** 10 IU/mL, and none had HBsAg loss. In the control group, none met any endpoints (Figure 1B). No serious adverse events were observed in the study. **Conclusion:** A lead-in strategy of 12 weeks of PEG-IFNα-2b followed by TDF "add-on" for 36 weeks had good efficacy in IT adults. We emphasize the need for more multicenter large sample randomized trials in the future to verify whether the combination antiviral therapy strategy for IT patients is associated with good outcomes or reduced risk of end-stage liver disease.

1435-C | PEGINTERFERON ALFA-2b PLUS TDF TREATMENT OF HBEAG-NEGATIVE CHRONIC HEPATITIS B PATIENTS IN INDETERMINATE PHASE: A PILOT, OPEN-LABEL, PROSPECTIVE COHORT STUDY

Min Liu[1], Yuting Zhang[1], Lili Zuo[1], An Xiao[1], Wei Yue[1], Bing Bu[1], Yilan Wang[1], Jiayi Chen[1], Ling Zhu[1], Jiawei Geng[1] and Xueshan Xia[2], (1)The First People's Hospital of Yunnan Province, (2)Kunming University of Science and Technology

Background: Many chronic hepatitis B (CHB) patients cannot be clearly classified into natural history phases of chronic HBV infection, which were defined as "indeterminate phase (IP)" patients. However, it is unclear whether the antiviral treatment indications should be expanded for IP patients. This study aims to evaluate the efficacy and safety of the combination therapy of peginterferon alfa-2b (PEG-IFNα-2b) and Tenofovir disoproxil fumarate (TDF) in HBeAg-negative IP patients. **Methods:** This is a pilot, open-label, prospective cohort study from May 2019 to October 2022. Treatment-naïve CHB patients aged 18-60 years with HBeAg-negative, qHBsAg > 3000 IU/mL and normal ALT were enrolled and divided into three groups according to their willing. Combination therapy group received PEG-IFNα-2b for 12 weeks followed by TDF "add-on" for 36 weeks, TDF monotherapy group received TDF for 48 weeks and control group were followed-up without any antiviral treatment (Figure 1A) . The primary endpoint was the proportion of patients achieving qHBsAg < 1500 IU/mL at the end of treatment (EOT), and the secondary endpoint was HBsAg loss at EOT. **Results:** 261 IP patients were enrolled. At baseline, there was no significant difference in the epidemiological, biochemical, serological and virological indicators among the groups. In the combination therapy group, 55.06% (49/89) achieved HBsAg < 1500 IU/mL and 4.49% (4/89) achieved HBsAg loss at EOT. In the TDF monotherapy group and control group, none met these endpoints (Figure 1B). Patients achieving qHBsAg < 1500 IU/mL in the combination therapy group had significantly higher mean ALT levels at week 12/24 compared to those with qHBsAg **e** 1500 IU/mL ($p = 0.04$; $p = 0.002$, Figure 1C). Week 12/24 ALT > 2 × baseline were associated with higher rates of qHBsAg < 1500 IU/mL at EOT (97.96% and 73.47%, respectively). No serious adverse events were observed in the study. **Conclusion:** A lead-in strategy of 12 weeks of PEG-IFNα-2b followed by TDF "add-on" for 36 weeks had good efficacy in HBeAg-negative IP patients

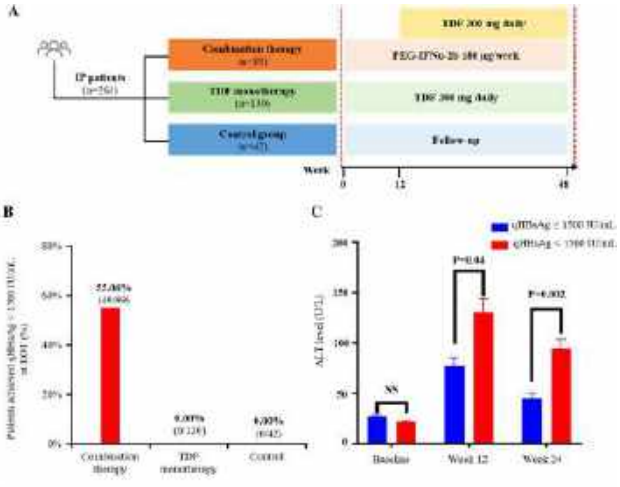

Figure 1

1436-C | PREDICTIVE VALUE OF AGE ON LIVER HISTOLOGICAL CHANGES IN CHB PATIENTS WITH NORMAL ALT LEVELS

Xuefu Chen, Xiaodan Luo, Yifan Yang, Ren Chen, Xiaoping Chen and Xiaoming Chen, Guangdong Provincial People's Hospital

Background: The 2022 China HBV guideline recommends antiviral therapy for CHB with normal ALT levels, HBV DNA (+), and age > 30 years (B1). This study aimed to analyze the role of age in liver histological changes in CHB patients with normal ALT levels, using the presence of moderate to severe liver injury as an indication for initiating antiviral therapy. **Methods:** This retrospective study included CHB patients with normal ALT levels who were treatment naive and had undergone liver biopsy in Guangdong Provincial People's Hospital between Jan. 2010 and Dec. 2019. Inclusion criteria : age between 16 and 70 years (Y), HBsAg (+) > 6 months, ALT **d** 40 U/L, and HBV DNA > 20 IU/ml. Exclusion criteria: liver injury caused by HCV, HDV or other factors, and severe heart comorbidities et al. Patients were categorized as having either mild (G < 2 and/or S < 2) or moderate to severe (G **e** 2 and/or S **e** 2) liver injury based on liver histological changes. All patients have signed consent for liver puncture. The Wilcoxon rank-sum test and Pearson $\chi 2$ test were used to compare differences in quantitative and qualitative data between groups, respectively. The kappa coefficient was used to evaluate the sensitivity (SEN%) and specificity (SPE%) of each indicator for liver histological changes. Statistical analyses were performed using SAS 9.4 and MedCalc. **Results:** 648 CHB patients were included,375 (57.9%) were male, mean age was 37.7 ± 11.3 Y, 444 (68.5%) were > 30 Y, 316 (48.8%) were HBeAg (+), mean HBV DNA was 5.65 ± 1.84Log_{10}IU/mL, 581 (90.0%) had HBV DNA **e** 2000 IU/ml, mean ALT was 26.0 ± 7.6U/L, 365(56.3%) **e** 30 (male)/19(female)U/L ; 305 (47.1%) had moderate to severe liver injury. Comparing the mild and moderate to severe liver injury groups, the proportion of patients > 30 Y was higher in the moderate to severe group than in the mild group (72.5% vs. 65.0%, $p = 0.042$), and the proportion of patients with ALT **e** 30/19 U/L was higher in the moderate to severe group than in the mild group (61.0% vs. 52.2%, $p = 0.024$). When evaluating the SEN and SPE of clinical indicators for moderate to severe liver histological changes, the results were as follows: for age > 30 Y, SEN was 72.46, SPE was 34.99; for ALT **e** 30/19 U/L, SEN was 60.98, SPE was 47.81; for HBV DNA **e** 2000 IU/mL, SEN was 89.18, SPE was 9.91. Combining age > 30 Y with other indicators further increased the SEN. For age > 30 Y and ALT **e** 30/19 U/L, SEN and SPE is 87.54 and 17.78, respectively. For age > 30 Y and HBV DNA **e** 2000 IU/mL, SEN and SPE is 97.70 and 2.62, respectively. Three indicators combined, SEN 98.36, SPE 1.75. (Figure 1) **Conclusion:** Age > 30 Y can be a good predictor for the liver tissue damage in CHB patients with normal ALT levels, which is very meaningful for initiating antiviral treatment in this population. This study supports the use of ALT thresholds of 30 U/L for male and 19 U/L for female for antiviral therapy. Combining age > 30 Y with HBV DNA **e** 2000 IU/ml or ALT **e** 30/19 U/L can further improve the sensitivity of evaluating the degree of liver tissue damage.

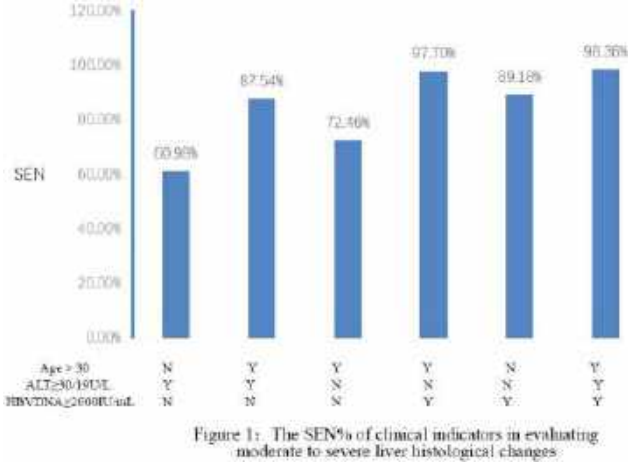

Figure 1: The SEN% of clinical indicators in evaluating moderate to severe liver histological changes

Background: Pegylated interferon-α (Peg-IFN-α) therapy is currently considered a promising treatment option for achieving clinical cure of chronic hepatitis B (CHB) patients. In this study, we aimed to identify biomarkers associated with clinical cure and off-treatment hepatitis B surface antigen (HBsAg) relapse in CHB patients with low HBsAg levels. **Methods:** Chronic hepatitis B patients with HBeAg-negative and HBsAg < 2000 IU/mL who were treated with Peg-IFN-α alone or in combination with nucleotide analogs for 48-96 weeks were enrolled in our study. The serum levels of hepatitis B core-related antigen (HBcrAg), HBsAg, and hepatitis B surface antibody (HBsAb) were dynamically examined. **Results:** A total of 101 patients were enrolled, 40.59% (41/101) achieved HBsAg clearance, and 33.66% (34/101) achieved HBsAg seroconversion at the end of treatment (EOT). The baseline HBsAg level was strongly associated with the probability of HBsAg clearance, specifically when HBsAg < 210.10 IU/mL, there will be a 69.8% conversion rate after 48 weeks of treatment with IFN. Additionally, for patients with baseline HBsAg > 210.10 IU/mL, baseline HBcrAg levels < 3.90 log10 U/mL predicted 69.3% of HBsAg clearance, with positive and negative predictive values of 38.71% and 87.88%, respectively. Nine of 41 patients who achieved HBsAg clearance experienced HBsAg relapse during a follow-up time of 114.00(49.00-217.00) weeks. There was a significant difference of EOT HBcrAg levels between the patients with HBsAg relapse and those without (3.96 ± 0.57 log10 U/mL vs 3.25 ± 0.65 log10 U/mL, $p < 0.05$). An EOT HBcrAg level > 3.8 log10 U/mL indicated a recurrence rate of 79.3%. When combined with HBsAb (**d** 51.50 IU/L) at EOT, predictive value for off-treatment HBsAg relapse was up to 84%, with positive and negative predictive values of 66.67% and 85.71%, respectively. **Conclusion:** HBcrAg and HBsAg can be used to predict the possibility of clinical cure, while HBcrAg and HBsAb are closely related to off-treatment HBsAg relapse following Peg-IFN-α therapy in patients with CHB and low HBsAg. Specifically, when the baseline level of HBsAg is less than 210.10 IU/mL, pegylated interferon-α is strongly recommended. When the baseline level of HBsAg is over 210.18 IU/mL, levels of HBcrAg should be tested, and patients should be treated if HBcrAg is less than 3.90 log10 U/mL. When levels of HBcrAg are over 3.8 log10 U/mL after treatment, close follow-ups are recommended to reduce relapse.

1438-C | RETREATMENT WITH TENOFOVIR ALAFENAMIDE FOR 48 WEEKS SIGNIFICANTLY REDUCES LIVER FIBROSIS, QUANTITATIVE HBsAg AND HBCRAG LEVELS

Tung-Hung Su, National Taiwan University Hospital, Yao-Chun Hsu, I-Shou University, Yu-Jen Fang, National Taiwan University Hospital, Yun-Lin Branch, Chih-Lin Lin, Ren-Ai Branch, Taipei City Hospital, Taipei, Taiwan, Chia-Chi Wang, Taipei Tzuchi Hospital, the Buddhist Tzuchi Medical Foundation, Taipei, Taiwan, Kuo-Chih Tseng, Department of Internal Medicine, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chi-Yi Chen, Ditmanson Medical Foundation Chiayi Christian Hospital, Chia Yi, Taiwan and Jia-Horng Kao, National Taiwan University Hospital, Taipei, Taiwan

Background: Achieving function cure and reducing liver fibrosis are important goals in management of chronic hepatitis B. Mac-2 binding protein glycosylation isomer (M2BPGi) is a novel marker for liver fibrosis. Hepatitis B core related antigen (HBcrAg) reflects intrahepatic cccDNA of HBV and its transcriptional activity. Little is known the dynamic change of these two markers after retreatment by tenofovir alafenamide (TAF) at hepatitis relapse after discontinuation of prior entecavir or tenofovir disoproxil fumarate (TDF) therapy. **Methods:** This prospective multicenter CHANGE (Chronic Hepatitis b patients switch to tAf after discontinuation of Nucleoside analoGuE) study (NCT04496882) is enrolling patients who experienced off-therapy (TDF or entecavir) clinical relapse and switch them to TAF for retreatment for 48 weeks in Taiwan. The primary endpoint was the rate of virological remission (HBV DNA < 20 IU/mL), and the secondary endpoints include the change of HBsAg, HBcrAg and M2BPGi levels. **Results:** As of April 30 2023, 47 patients were enrolled and 42 patients were included in this biomarker evaluation (discontinuation of prior TDF: entecavir = 21:21). At retreatment, the median age was 49 years and 5 were HBeAg positive. After 48-week of therapy, the virological remission and ALT normalization (< 41 U/L) rate were 77% and 88%, respectively. Among 30 patients who completed 48-week TAF therapy, there is a significant decline of HBsAg (0.6 $\log_{10}$ IU/mL, $p < 0.001$) and 6 patients (6/30, 20%) had achieved a favorable HBsAg response (**d** 100 IU/mL). There was a significant reduction of liver stiffness measured by M2BPGi (0.93 to 0.59 C.O.I., $p < 0.001$), FIB-4 index (1.62 to 1.20, $p < 0.001$) and HBcrAg levels (6.05 to 3.50 $\log_{10}$ IU/mL, $p < 0.001$), especially in HBeAg-negative patients (5.70 to 3.20 $\log_{10}$ IU/mL,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

$p < 0.001$). **Conclusion:** Switching to TAF retreatment for 48 weeks after off-TDF or entecavir relapse is effective in viral suppression, reduction of quantitative HBsAg and HBcrAg levels, ALT normalization and liver stiffness improvement.

Figure 1. The comparison of variables of 30 patients who completed 48-week TAF retreatment

Variables	Week 0	Week 48	P
Age, year	48	49	<0.001
Male	18 (60)		
BW, kg	66 (55-72)	69 (55-73)	0.178
Fibroscan, kPa	6.2 (4.3-7.0)	5.0 (4.0-5.5)	0.076
HBeAg positive	5 (16.7)	2 (6.7)	0.424
HBV DNA, log_{10} IU/mL	6.6 (5.5-7.5)	1.0 (1.0-1.1)	<0.001
HBsAg, log_{10} IU/mL	3.3 (2.9-3.7)	2.7 (2.3-3.3)	<0.001
AST, U/L	91 (52-179)	25 (22-31)	<0.001
ALT, U/L	192 (98-344)	23 (19-30)	<0.001
Platelet, k/uL	227 (202-247)	228 (183-251)	0.156
FIB-4 index	1.62 (1.01-2.55)	1.20 (0.84-1.70)	<0.001
Cre, mg/dL	0.8 (0.7-1.0)	0.9 (0.7-1.0)	0.049
eGFR, mL/min/1.73 m^2	96 (84-105)	89 (83-99)	0.026
T-CHO, mg/dL	177 (163-195)	187 (171-209)	0.010
TG, mg/dL	80 (69-97)	94 (72-124)	0.005
HDL, mg/dL	60 (50-66)	55 (46-66)	0.046
LDL, mg/dL	100 (84-113)	110 (99-139)	<0.001
M2BPGi, C.O.I.	0.93 (0.59-1.39)	0.59 (0.45-0.83)	<0.001
HBcrAg, log_{10} U/mL	6.05 (4.43-7.00)	3.50 (2.30-3.95)	<0.001
HBeAg positive	7.00 (7.00-7.00)	4.70 (4.60-5.10)	0.1003
HBeAg negative	5.70 (4.10-6.80)	3.20 (2.00-3.50)	<0.001

Data are expressed as median (interquartile range) or number (percentage). By Wilcoxon signed-rank test, or the Fisher's exact test.

1439-C | SELF-DISCONTINUATION DURING NUC THERAPY IN HBEAG-NEGATIVE CHRONIC HEPATITIS B PATIENTS: A NOT UNCOMMON BUT PERILOUS SITUATION

Rachel Wen-Juei Jeng[1,2], Chenger Hsu[2], Chia-Ling Wu[2], Chung-Wei Su[1], Yen-Chun Liu[2], Rong-Nan Chien[1,2] and Yun-Fan Liaw[1,2], (1)College of Medicine, Chang Gung University, Taiwan, (2)Chang Gung Memorial Hospital, Linkou Medical Center

Background: In real-world practice, self-discontinuation and loss to follow-up (LTFU) during long-term antiviral treatment are not uncommon. Chronic hepatitis B (CHB) patients who self-discontinue treatment without proper monitoring face risks of delayed retreatment and hepatic decompensation/hepatic failure. Limited information exists on the incidence and factors associated with self-discontinuation/LTFU. This study explores the issue using a multi-institutional electronic medical record database (CGRD). **Methods:** We recruited HBeAg-negative CHB patients who received ETV or TDF for **e** 3 months between Jan 2004 and Nov 2021 at Chang Gung Memorial Hospital's branches in Taipei, Linkou, and Taoyuan, selected from CGRD. Exclusions included patients on Nuc for prophylaxis related to chemotherapy or immunosuppressants, with co-infections (HCV, HIV, or HDV), or diagnosed with HCC within 5 years before antiviral treatment. Self-discontinuation/LTFU was identified as patients failing to refill medication for **e** 2 consecutive months, verified through medical chart review. Logistic regression analysis identified factors associated with self-discontinuation. Hepatic decompensation (HD) was determined using ICD codes (ICD-9: 572.2, 789.5, 578.0, 578.9, 456.0, 456.2 or ICD-10: K72.9, K72.91, R18.8, K92, K92.2, I85.01, I85.11, I86.4). HD events after Nuc discontinuation in non-retreated patients or within 1 year during retreatment were considered associated with Nuc discontinuation. Comparison was made between self-discontinuation and scheduled withdrawal. **Results:** A total of 3358 HBeAg-negative CHB patients with 4217 treatment courses were included. Over a median treatment duration of 2.4 (IQR: 1.1-3) years, 341 self-discontinuation/LTFU events were identified, with annual incidence rates of 3.02% and cumulative rates of 8.61%, 13.23%, and 19.97% at 3, 5, and 10 years. Most self-discontinuation events (38.4%) occurred within the first year. Factors associated with self-discontinuation events included age (< 40 or **e** 70) [age 40-69 as referent: < 40, aOR: 2.10 ; **e** 70, aOR: 1.65], liver cirrhosis (aOR: 2.04), prior treatment experienced (aOR: 0.61), pretherapy ALT levels (< 2X ULN as referent, 2-5X ULN: aOR: 0.72, > 5X ULN: aOR: 0.78), and use of ETV (TDF as referent, aOR: 1.36). During median follow-up of 2.5 years (IQR: 1.3-5.4), 49 (2.1%) of 2,321 patients who stopped Nuc experienced off-Nuc HD events, primarily among cirrhosis patients (96%). Self-stop/LTFU patients had significantly higher HD incidence (7.3% vs. 1.2%, $p < 0.0001$) than scheduled stopped patients. **Conclusion:** Self-discontinuation/LTFU increased with the duration of Nuc therapy, reaching 8.61% and 19.97% within 3 and 10 years, respectively. Among these cases, 7.3% were

complicated by HD. It is crucial to prioritize education and establish a tele-call back service to prevent such events and mitigate the associated adverse outcomes.

f 1440-C | STABLE RECOMPENSATION IN ENTECAVIR-TREATED HEPATITIS B PATIENTS WITH DECOMPENSATED CIRRHOSIS★

You Deng[1], Haiyan Kang[2], Huiling Xiang[3], Yuemin Nan[4], Jinhua Hu[5], Qinghua Meng[6], Xiaoyuan Xu[7], Jilian Fang[8], Jie Xu[9], Xiaoming Wang[10], Hong You[10], Qi Wang[1], Hong Zhao[1], Jidong Jia[11] and Wen Xie[1], (1) Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (2)Shijiazhuang Fifth Hospital, Shijiazhuang, China, (3)Tianjin Third Central Hospital, Tianjin, China, (4)Third Hospital of Hebei Medical University & Hebei Key Laboratory of Mechanism of Liver Fibrosis in Chronic Liver Disease, (5)The Fifth Medical Centre of Chinese PLA General Hospital, Beijing, China, (6)Beijing Youan Hospital Capital Medical University, Beijing, China, (7)Peking University First Hospital, (8)Peking University People's Hospital, Beijing, China, (9)Peking University Third Hospital, Beijing, China, (10)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China, (11)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China

Background: Recompensation is achievable in certain chronic hepatitis B (CHB) patients with decompensated cirrhosis who are treated with nucleos(t)ide analogues (NAs).However, the understanding of stable recompensation in these patients remains limited. **Methods:** This study was based on a multicenter, prospective study of CHB patients with decompensated cirrhosis who were enrolled at the onset of ascites as the first decompensated event and treated with entecavir for 120 weeks. At week 120, out of the recruited 283 patients, 159 achieved recompensation and 124 did not. These patients were further followed up until the occurrence of a second decompensation event or until March 2023. Recompensation was defined by the Baveno VII definition and the criteria of stable improvement in liver function tests reported by us. **Results:** Out of the initial 283 patients, 165 patients were followed beyond week 120, with a further median follow-up time of 240 (192-288) weeks. Among the 101 patients who achieved recompensation by week 120, 87 (86.1%) did not experience any subsequent decompensated events; 4 patients were diagnosed with HCC, 2 patients developed variceal bleeding, 2 patients developed moderate-severe ascites, and 6 patients died. In contrast, among the 64 patients who did not achieve recompensation by week 120, 27 (42.2%) did not experience any further decompensated events (achieved recompensation); 4 patients were diagnosed with HCC,1 patient developed variceal bleeding, 10 patients developed moderate-severe ascites, and 22 patients died. **Conclusion:** In CHB patients with decompensated cirrhosis, approximately 86% of those who achieved recompensation by week 120 maintained stable recompensation during the next 120 (72-168) weeks of antiviral therapy. Furthermore, recompensation was attained in the next 120 (72-168) weeks in 42% of patients who did not achieve it by week 120. Besides, patients undergoing recompensation also need to pay attention to the monitoring of hepatocellular carcinoma.

Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan 430030, China, (2)State Key Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (3) The First Affiliated Hospital of Nanchang University, (4) Department of Infectious Diseases, Xiangya Hospital, Central South University, Changsha, Hunan, China, (5) Wuhan Seventh Hospital, Department of Hepatology, Wuhan, China, (6)Department of Liver Disease, Shanghai Public Health Clinical Center, Fudan University, Shanghai, China, (7)Department of Infectious Diseases, Shulan Hospital, Affiliated to Shulan International Medical College, Zhejiang Shuren University, Hangzhou, China, (8)Institute and Department of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology

Background: Tenofovir alafenamide (TAF) has been approved for the treatment of chronic hepatitis B (CHB). We aimed to assess the effectiveness and safety of TAF-based therapy in treatment naïve (TN) or experienced (TE) CHB patients. **Methods:** This multicenter, prospective, real-word study included 500 CHB patients treated with TAF monotherapy or combining with entecavir (ETV) for 144 weeks. Virological and biochemical responses and safety were evaluated (clinicaltrial.gov: NCT03752658). **Results:** 404 patients (TN, 146; TE, 258) with available data were included in this interim analysis. 13.6% had cirrhosis at baseline. All TN patients and 164 TE patients received TAF alone, and 94 TE patients received TAF plus ETV. Of TN patients, 88.7% achieved virological response (HBV DNA < 20 IU/mL) at week 96. 81.8% achieved biochemical response (ALT < 40 U/L) at week 96. Among TE patients switching to TAF, virological response rate was significantly increased, from 67.8% at baseline to 91.7% at week 96 ($p < 0.05$), and biochemical response rate was 79.7% at baseline and 92.1% at week 96. Among TE patients receiving TAF+ETV, virological response rate was significantly increased from 42.0% at baseline to 91.3% at week 96 ($p < 0.05$), and biochemical response rate was significantly increased from 80.0% at baseline to 92.9% at week 96 ($p < 0.05$). Of 75 TE patients with low level viremia at baseline (HBV DNA < 2000 IU/mL), 61 achieved virologic response at week 96. Among patients with estimated glomerular filtration rate (eGFR) below 90 mL/min/1.73m^2 at baseline, eGFR was significantly improved at week 96 ($p < 0.05$). Total cholesterol levels significantly increased at week 96 ($p < 0.05$). TAF-based therapy was well-tolerated. **Conclusion:** TAF-based therapy was effective in both TN and TE CHB patients, as well as those with low level viremia. TAF therapy show a sustained improvement in renal glomerular function in patients with prior impaired renal function.

1442-C | TENOFOVIR ALAFENAMIDE FUMARATE THERAPY IN HEALTHY HBsAg CARRIERS: PRELIMINARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Qiumin Luo, Wenxiong Xu, Xiangyong Li, Chan Xie and Liang Peng, Third Affiliated Hospital of Sun Yat-Sen University

Background: At present, antiviral therapy for healthy HBsAg carriers is still controversial. This study is to evaluate the safety and efficacy of tenofovir alafenamide fumarate (TAF) in these subjects. **Methods:** It is a prospective randomized controlled trial and the protocol has been published (BMJ Open. 2021;11: e048410). In brief, the subjects enrolled were healthy HBsAg carriers, defined as positive HBV DNA (> 20 IU/ml in HBeAg (+), and 20-2000 IU/ml in HBeAg (-)), normal ALT, Fibroscan < 5.8 KPa, without family history of cirrhosis or hepatocellular carcinoma. Participants were randomly divided into treatment group (treated with TAF) and control group in a 1:1 ratio. More details of the study protocol can be seen in the previous article mentioned above. **Results:** 122 patients were enrolled by May 15, 2023, including 61 HBeAg (+) cases (30 treated with TAF, 31 without treatment) and 61 HBeAg (-) cases (29 treated with TAF, 32 without treatment). 20 cases in TAF group and 17 in control group have been followed up to 24 weeks in HBeAg (+) cohort, while 22 and 17 cases in HBeAg (-) cohort. Baseline characteristics were similar between TAF group and control group in HBeAg (+) cohort, as well as in HBeAg (-). The mean HBV DNA values of TAF group and control group in HBeAg (+) cohort at baseline were 7.85 and 8.03 $\log_{10}$IU/ml respectively, while those in HBeAg (-) were 2.74 and 2.60 $\log_{10}$IU/ml. No severe adverse effects and no significant changes in ALT, Cr, CHI3L1 and Fibroscan were observed in each arm. HBV DNA was < 10 IU/ml in 2 out of 20 HBeAg (+) patients and 18 out of 22 HBeAg (-) patients after treatment for 24 weeks. The HBeAg (+) and HBeAg (-) TAF groups showed an average decrease of 4.24 and 2.57 $\log_{10}$IU/ml in HBV DNA at 12w after treatment, respectively. While at

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

24w, HBV DNA decreased by a mean of 5.24 log_{10}IU/ml in the HBeAg (+) TAF group. The virological changes were shown in Figure 1. **Conclusion:** The preliminary results indicated that TAF was safe in healthy HBsAg carriers. HBV DNA decreased rapidly at the first 12 weeks of treatment in both HBeAg (+) and HBeAg (-) groups. HBsAg changed little in this study. However, HBsAg reduction from baseline was greater in the HBeAg (+) group than HBeAg (-). PgRNA increased in HBeAg (+) cases after 24 weeks of antiviral therapy, and this trend should be monitored during treatment extension. The number of patients followed up to 48 weeks was insufficient to make a valid statistic. More results will be reported in the near future.

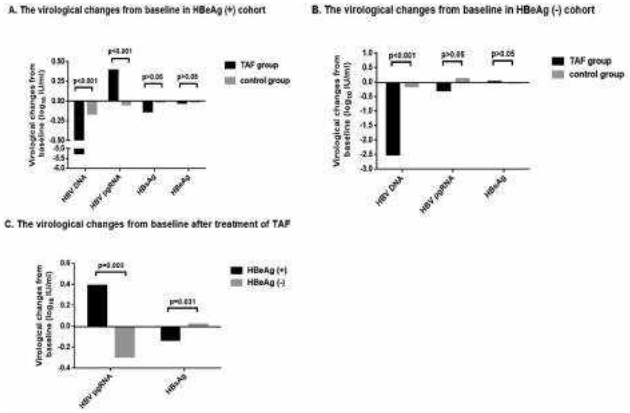

Figure 1. Changes in virological indices from baseline in each group at 24 weeks.

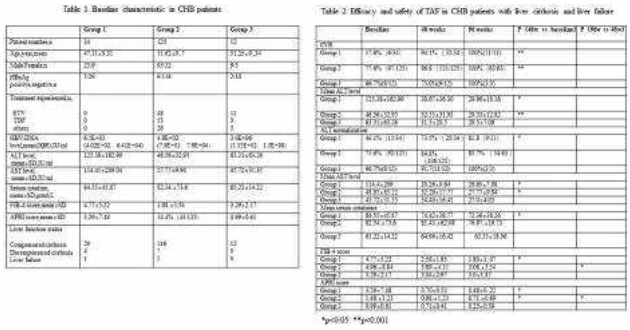
1443-C | TENOFOVIR ALAFENAMIDE FUMARATE WAS EFFECTIVE AND SAFE FOR CHB PATIENTS WITH LIVER CIRRHOSIS: A REAL-WORD EVIDENCE IN CHINA

Lufeng Li[1], Zhonglan You[1], Jing Wang[1], Guohong Deng[1], Baoyan Xu[1], Yan Zhu[2], Jie Xia[1] and Qing Mao[1], (1)Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China, (2) Department of Infectious Diseases, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China.

Background: Previous studies showed antiviral treatment(AVT) improves clinical outcomes in patients with chronic hepatitis B (CHB). However evidence of AVT for patients with liver cirrhosis or end-stage liver disease was limited. We aimed to evaluate the efficacy and safety of Tenofovir alafenamide fumarate(TAF) for CHB patients with liver cirrhosis (LC)or liver failure(LF). **Methods:** Cirrhotic CHB patients receiving TAF treatment were retrospectively enrolled(cirrhosis was diagnosed by imaging examinations and clinical symptoms). Complete virological response rate(CVR, (defined as serum HBV DNA < 50 IU/mL), ALT normalization (defined as ALT < 42 U/L) rate, AST level, FIB-4 and APRI score were also observed. Safety profiles including liver function and renal function were collected. **Results:** From Jan.2020 to Dec.2022, a total of 171 CHB patients with LC or LF receiving TAF were enrolled. The patients were divided into three groups: Group 1(n = 37) was treatment-naïve patients receiving TAF and group 2(n = 125) was treatment experienced patients receiving TAF. Group 3(n = 12) was treatment experienced patients receiving TAF in combination with ETV. 92%(157/171) of patients had compensated cirrhosis(CC), 6.4%(11/171) had decompensated cirrhosis(DCC) and 1.8%(3/171) of patients had LF. Baseline characteristics were showed in Table 1. 100% of the patients achieved CVR after 96 weeks of TAF or TAF +ETV treatment, regardless of treatment experience. A total of 10 patients with DCC and 1 patient with liver failure improved to CC after 96 weeks treatment. Mean ALT and AST level decreased during treatment in each group. And the rate of ALT normalization improved significantly in group 1 at 48 weeks compared with baseline(from 44.1% to 73.5%, $p = 0.013$). Other groups had numerically increase for ALT normalization rate after 48 weeks and 96 weeks treatment. Serum creatinine was significantly reduced after 48 weeks of TAF treatment in group 1(from 84.55 ± 45.87 μmol/L to 74.42 ± 38.77 μmol/L, $p = 0.006$) and remained stable in the other groups. Mean FIB-4 and APRI scores also decreased during treatment(Table 2). No drug-related AEs or SAEs were observed during the follow-up period. **Conclusion:** TAF was effective and safe for CHB patients with liver cirrhosis or liver failure, regardless of previous treatment.



Disclosures: The following people have nothing to disclose: Lufeng Li, Zhonglan You, Jing Wang, Guohong Deng, Baoyan Xu, Yan Zhu, Jie Xia, Qing Mao

1444-C | TENOFOVIR ALAFENAMIDE SWITCHING THERAPY IN KIDNEY TRANSPLANT RECIPIENTS WITH CHRONIC HBV INFECTION – MIDTERM ANALYSIS OF A PROSPECTIVE STUDY

Teng-Yu Lee, Hsin-Ju Tsai, Cheng-Hsu Chen, Sheng-Shun Yang, Ming-Ju Wu, Tung-Min Yu, Chung-Hsin Chang, Szu-Chia Liao, Mu-Chi Chung and Hsien-Fu Chiu, Taichung Veterans General Hospital

Background: Kidney transplant recipients (TKRs) with chronic HBV infection may be indicated for tenofovir alafenamide (TAF) switching therapy, however the related studies remain limited. We aimed to assess the effects of TAF switching therapy in KTRs. **Methods:** In this prospective cohort study (ClinicalTrials.gov: NCT05410496), KTRs who were indicated for TAF switching therapy, such as concerns in virological response, biochemical response, drug compliance, or safety to the used HBV antivirals, were enrolled. Following conditions were excluded: (1) End stage renal disease (eGFR < 15 mL/min/1.73m^2); (2) Co-infected with HIV or HCV; (3) Any active malignancies; (4) Pregnant or breast-feeding women; (5) Known allergy to tenofovir-contained regimens. After switching to TAF therapy, any treatment-related adverse effects (TRAEs) and the changes in virological responses, renal function, bone mineral density, and drug adherence were prospectively recorded. **Results:** Until May 17, 2022, two patients early withdrew from this study due to non-TRAEs, and 31 patients who were followed up for more than 24 weeks were included for this mid-term analysis. In the per-protocol analysis, median age was 58.9 (IQR: 53.1-64.6) years, and 24 (77.4%) patients received entecavir before switching to TAF. Seventeen (54.8%) and 14 (45.2%) patients were classified in the chronic kidney disease stage 1&2 and 3&4, respectively. After 24-week TAF therapy, more patients achieved undetectable serum HBV DNA (96.8% vs. 77.4%; $p = 0.031$) and ALT normalization (80.6% vs. 67.7%; $p = 0.125$). The changes in renal parameters were not significant, including serum creatinine (1.18 [IQR: 0.97-1.52] vs. 1.15 [IQR: 0.95-1.42] mg/dL), eGFR (61.1 [IQR: 50.5-80.4] vs. 60.3 [IQR: 51.3-79.2] mL/min/1.73 m^2), urine fractional excretion of phosphate (17.6 [IQR: 13.2-23.4] vs. 16.4 [IQR: 12.5-20.8]), urine β2 microglobulin-to-creatinine ratio (3.1 [IQR: 1.3-11.1] vs. 4.0 [IQR: 1.3-27.1]), and urine albumin-to-creatinine ratio (21.6 [IQR: 11.2-205.0] vs. 22.6 [IQR: 7.2-102.8]). The changes in bone mineral density were not significant (Trabecular bone score: 1.37 [IQR: 1.28-1.44] vs. 1.36 [IQR: 1.30-1.43]). Evaluated by Morisky 8-item questionnaire at week 24, more patients achieved the full scores to HBV antivirals (100% vs. 77.4%; $p = 0.014$). **Conclusion:** TAF switching therapy is effective and safe to TKRs, and medication adherence can be significantly improved.

1445-C | THE CLINICAL EFFECTIVENESS AND SAFETY OF TENOFOVIR ALAFENAMIDE FOR HBV-INFECTED PATIENTS WITH SIGNIFICANT VIREMIA AND MILDLY ELEVATED ALANINE AMINOTRANSFERASE

Pin-Nan Cheng, National Cheng Kung University Hospital, Ming-Lung Yu, Kaohsiung Chang Gung Memorial Hospital, Yao-Chun Hsu, I-Shou University and Chun-Jen Liu, National Taiwan University Hospital

Background: Treatment for chronic hepatitis B virus (HBV) infected patients with significant viremia and

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

mildly elevated alanine aminotransferase (ALT) is controversial. In this study, we aimed to investigate the efficacy and renal safety of tenofovir alafenamide (TAF) and also to evaluate the nature course of untreated patients. **Methods:** Patients with chronic HBV infection with HBV DNA > 2000 IU/mL of HBeAg negative or HBV DNA > 20000 IU/mL of HBeAg positive, naive to any antiviral treatment, and an ALT level between 1-2 folds of ULN within one year before entering study were enrolled in this phase IV study (NCT04674423). Liver biopsy was suggested and liver histology was assessed by histology activity index (HAI) of Knodell necroinflammation scoring system and fibrosis stage of Metavir scoring system. TAF treatment was commenced for those patients exhibited significant liver injury, which was defined as HAI > = 4 or Metavir fibrosis stage 2 or 3. For patient with HAI < 4 or Metavir fibrosis stage < 2 or not agree to receive liver biopsy, periodic follow-up including biochemical, hematology, and virological tests were conducted. Liver stiffness measurement (LSM) by FibroScan at enrollment and at week 48 was performed for each patient. **Results:** In total, 62 patients with mean age of 55.5 years and 31 females were enrolled. Of these patients, 22 received TAF treatment and 40 patients received periodic follow-up. Baseline characteristics of the two groups were comparable except significantly higher values of AST, ALT, LSM, and FIB-4 score in TAF treated patients. Following a 48-week TAF treatment, 21 patients (21/22, 95.5%) achieved undetectable HBV DNA and 16 patients (16/22, 72.2%) had normal ALT. Comparing with baseline values, significant reduction of AST, ALT, LSM, and FIB-4 score were observed. In periodic follow-up group, AST, ALT, and LSM remained stationary while FIB-4 was significantly increased at week 48 (Fig.1). Impact of TAF on renal parameters were also examined and revealed that urine phosphate, urine protein, serum creatinine and phosphate, and eGFR (MDRD equation) at baseline and at week-48 were similar between two groups of patients. In TAF treatment group, no significant changes of these parameters were present before and after 48-week treatment. **Conclusion:** A 48-week TAF treatment could effectively suppress HBV replication, normalize ALT, improve liver stiffness and FIB-4 score, and maintain renal parameters in patients with significant HBV viremia and mildly elevated ALT.

Disclosures: Pin-Nan Cheng – Gilead Sciences: Grant/ Research Support (research funding from ineligible companies should be disclosed by the principal or named investigator even if that individual's institution receives the research grant and manages the funds), No, No;

1446-C | THE EFFECTS OF NUCLEOS(T)IDE ANALOGUES ON LIPID PROFILES IN TREATMENT-NAÏVE CHRONIC HEPATITIS B PATIENTS

Mengqi Li[1,2], Lin Zhu[1,2], You Deng[1,2], Xiaoping Jiang[1,2], Shuqian Zhang[1,2], Ligai Liu[1,2], Hong Zhao[1,2], Qi Wang[1,2] and Wen Xie[1,2], (1)Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (2)National Center for Infectious Diseases, Beijing, China

Background: International guidelines have approved entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide fumarate (TAF) as first-line oral antiviral nucleos(t)ide analogues (NA) for the treatment of chronic hepatitis B (CHB). However, there is still controversy surrounding the effects of these medications on lipid metabolism. This study aimed to clarify the impact of ETV, TDF, and TAF on lipid metabolism in patients with CHB. **Methods:** This retrospective cohort study included 156 patients with CHB who initiated treatment with ETV, TDF, or TAF after a minimum of 96 weeks between July 2020 and March 2023 at Beijing Ditan Hospital, Capital Medical University. To minimize selection bias, the effects of these treatments on the lipid profiles of the CHB patients were evaluated after propensity score matching (PSM). One-to-one pair matching was performed by nearest-neighbor matching without replacement. Propensity scores were estimated based on baseline

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

characteristics, including age, sex, and lipid profiles. PSM was performed using a caliper width set at 0.2 times the standard deviation of the logit of the propensity score. **Results:** After PSM, the study cohorts were divided into three separate groups for analysis: 37:37 (TDF: ETV), 33:33 (TDF: TAF), and 48:48 (ETV: TAF). After 96 weeks of follow-up, the TAF group demonstrated significantly higher levels of total cholesterol (TC) and low-density lipoprotein (LDL) at 96 weeks compared to the TDF group (TC 4.76 [4.13, 5.39] vs. 3.93 [3.47, 4.63], $p = 0.004$; LDL 2.96 [2.44, 3.43] vs. 2.50 [1.92, 2.99], $p = 0.028$). Additionally, the TAF group exhibited significantly higher levels of TC and triglycerides (TG) at 96 weeks compared to the ETV group (TC: 4.89 [4.52, 5.45] vs. 4.54 [3.95, 4.97], $p = 0.016$; TG: 1.31 [0.92, 1.85] vs. 0.94 [0.75, 1.38], $p = 0.011$). However, no significant differences in lipid profiles were observed between the ETV and TDF groups after 96 weeks of follow-up. Furthermore, among the 156 patients, none of them exhibited **e** Grade 3 lipid abnormalities at 96 weeks. Additionally, there were only a few cases of Grade 2 lipid abnormalities, with one patient in the ETV group, one patient in the TDF group, and three patients in the TAF group. **Conclusion:** After 96 weeks of treatment, TAF may lead to increased lipid levels compared to ETV and TDF. The impact of such lipid metabolism abnormalities on the clinical outcomes of patients requires further exploration.

f 1447-C | THE EFFICACY AND SAFETY OF PROPHYLACTIC TENOFOVIR ALAFENAMIDE TO PREVENT HBsAg-POSITIVE CANCER PATIENTS UNDERGOING CHEMOTHERAPY FROM HBV REACTIVATION- AN INTERIM REPORT OF A PROSPECTIVE TRIAL

Po-Yueh Chen[1], Hung-Da Tung[2], Ching-Chu Lo[3], Jow-Jyh Huang[3], Kuo-Chih Tseng[4], Chih Wei Tseng[4], Yu-Jen Fang[5], Jyh-Jou Chen[2] and Chi-Yi Chen[1], (1) Ditmanson Medical Foundation Chiayi Christian Hospital, (2)Department of Internal Medicine, Chi Mei Medical Center, Liouying, Tainan, Taiwan, (3)St. Martin De Porres Hospital - Daya, Chiayi, Taiwan, (4) Department of Internal Medicine, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, (5) National Taiwan University Hospital, Yun-Lin Branch

Background: Hepatitis B reactivation had been noted in HBsAg-positive patients undergoing chemotherapy and could result in hepatic decompensation or even mortality. Prophylactic use of nucleos(t)ide analogues (NUCs) had been proved to lower the incidence of HBV reactivation in patients receiving highly risky immunosuppressants. We aim to prospectively evaluate the efficacy and safety of prophylactic tenofovir alafenamide (TAF) in HBsAg-positive cancer patients undergoing chemotherapy. **Methods:** This prospective trial was conducted in middle-south part of Taiwan and we aimed to enroll 150 patients. Individual's aged 20 years or more with positive HBsAg would be enrolled when scheduled systemic chemotherapy was confirmed. All participants would receive 25mg TAF daily for 48 weeks and the first dose would be given less than 7 days prior to start of chemotherapy. The HBV DNA level would be checked at baseline, week 4, 12, 24, 36, and 48 after TAF use. The primary endpoint is the rate of HBV reactivation during prophylactic use of TAF. HBV reactivation is defined as either HBV DNA increase 2 logs compared to the baseline level or 3 log of HBV DNA in patient with previously undetectable level. **Results:** One hundred and seven patients were screened from Jun 2021 to Apr 2023 and 82 patients were enrolled. The mean age of all patients was 55.5 years old and 41 (50%) patients were male. The baseline mean HBV DNA level was 3.7 (log IU/ml) and the mean value of liver stiffness was 7.49 kPa. Among the 82 patients, the most common cancer type was breast cancer (35.4%, 29/82). Cisplatin-containing regimens were prescribed in 23 patients (28.0%, 23/82) and 6 patients (7.3%, 6/82) ever received rituximab. Of 82 patients with a mean follow-up of 7.8 months, one

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patient (1.2%, 1/82) had experience of virologic HBV reactivation due to poor drug adherence. Among 30 patients with complete 48-weeks of TAF prophylaxis, 26 patients (86.7%, 26/30) were with undetectable HBV DNA and decreased liver stiffness from baseline to 48th week was also found (7.49 kPa to 6.89 kPa). Acute kidney injury (serum creatinine > 1.5 x baseline) was noted in 2 patients (2.4%, 2/82) and all of them received cisplatin-based regimens. The eGFR level and serum phosphate were stationary from baseline to 48th week of TAF treatment. The safety profiled show that 36 patients (43.9%, 36/82) had adverse effects. Five patients were expired due to progression of underlying malignancies. Serious adverse effects were found in 18 patients (21.9%, 18/82), however, none was resulted from TAF. No adverse effect induced drug discontinuity or death was found. The most common adverse effects were nausea (35.3%, 29/82) and vomit (15.9%, 13/82). **Conclusion:** Tenofovir alafenamide (TAF) is an effective and tolerable antiviral agent to prevent HBV reactivation in cancer patients with positive HBsAg undergoing chemotherapy.

f 1448-C | THE EFFICACY OF ANTIVIRAL THERAPY AT PREVENTING CLINICAL OUTCOMES IN HBV-INFECTED PEOPLE AT DIFFERENT BASELINE VIRAL LOAD AND ALT LEVELS: A GLOBAL SYSTEMATIC REVIEW & META-ANALYSIS★

Yu Ri Im[1], Si Emma Chen[2], Rukmini Jagdish[3], Daniela Yucuma[2], Arthur Rakover[2], Zakary Ismail Warsop[4], Roger Chou[5], Philippa Easterbrook[6] and Yusuke Shimakawa[2], (1)University of Oxford, (2)Institut Pasteur, (3)St George's Hospital, London, United Kingdom, (4)Imperial College London, (5)Oregon Health & Science University, (6)World Health Organization

Background: In 2015, the WHO issued its first clinical guidelines for management of chronic HBV infection (CHB), recommending antiviral therapy in non-cirrhotic people with a baseline viral load (VL) of **e** 20,000 IU/mL and abnormal alanine transaminase (ALT) levels. It is not known whether antiviral therapy is also efficacious in groups with lower VL. To inform the development of updated WHO guidelines and expanded treatment criteria, we conducted a systematic review and meta-analysis and provided summary estimates of the efficacy of antiviral therapy in groups stratified by baseline VL (< 2000, 2000-20,000, 20,000-200,000, **e** 200,000 IU/mL) and ALT levels. **Methods:** We searched PubMed, Embase, Web of Science, and the Cochrane Library for randomized controlled trials (RCTs) and non-randomized studies of anti-HBV therapy versus placebo or no treatment. Treatment efficacy needed to be reported in groups stratified by baseline VL for inclusion. Random-effects meta-analysis was performed to pool risk ratios from RCTs and adjusted hazard ratios (HR) from observational studies. Risk of bias was assessed with the Cochrane ROB2 and Newcastle-Ottawa scales and the quality of the evidence with GRADE. **Results:** Of 13,124 records identified, 30 RCTs and 12 observational studies met inclusion criteria. 22 (52%) studies were from Asia, 0 (0%) from Africa, 2 (5%) from North America, and 7 (17%) from Europe. 21 (50%) studies were in adults > 18 years and 13 (31%) in those < 18 years. Most studies (86%) only reported outcomes for groups with VL > 20,000 IU/mL. Only one RCT and five observational studies (14%) reported results for groups with VL < 20,000 IU/mL (n = 5 for < 2000, n = 1 for 2000-20,000). Overall, the pooled HR of HCC for treated vs. untreated groups was 0.72 (95%CI 0.43-1.20; only one study), 0.45 (0.14-1.46; only one study), 0.17 (0.06-0.50; only one study), 0.48 (0.26-0.91; 3 studies, I2 = 31.4%), 0.44 (0.19-1.03; only one study), and 0.40 (0.17-0.9; 2 studies) for the groups with baseline viral load < 2,000, 2,000-20,000, 20,000-200,000, 200,000-2M, 2M-20M, and 20M-200M IU/mL, respectively. These and other outcomes are summarised in table 1. The quality of evidence supporting treatment efficacy was very low or low for the lower VL strata (< 2000, 2000-20,000) and ranged from very low to high for the higher VL strata. **Conclusion:** Only one RCT evaluated the efficacy of antiviral therapy in patients with VL < 2000 IU/mL and only five non-randomized studies in patients with VL 2000-20,000 IU/mL. Within these limitations, we observed a tendency for an interaction between higher VL and higher treatment efficacy for a range of clinical, histological, virological, and biochemical outcomes. Our findings highlight the urgent need for RCTs of antiviral therapy to establish treatment

1449-C | THE EFFICACY OF ANTIVIRAL THERAPY FOR HBV-INFECTED CHILDREN: A MULTICENTER REAL-WORLD STUDY (SPROUT PROJECT) - AN INTERIM ANALYSIS

Hongfei Zhang[1], Hong Zhang[2], Wenxian Ouyang[3], Yilan Zeng[2], Shuangjie Li[3], Jia Shang[4], Qing He[5], Fang Wang[5], Hongxia Zhou[6] and Lijuan Ouyang[7], (1)Jumei Doctor Group Medical (Shenzhen) Co., Ltd, Shenzhen, China, (2)Public Health Clinical Center of Chengdu, Chengdu, China, (3)Hunan Children's Hospital, Changsha, China, (4)Henan Province People's Hospital, Zhengzhou, China, (5)The Third People's Hospital of Shenzhen, Shenzhen, China, (6)The Infectious Diseases Hospital of Handan, Handan, China, (7)Xiamen Traditional Chinese Medicine Hospital, Xiamen, China

Background: In China, approximately 30% to 50% of HBV transmission occurs through the mother-to-infant, and nearly 2 million children are HBsAg-positive. Children infected with HBV, if not treated timely, not only affect their healthy growth, but also have a significant risk of disease progression, making them a huge additional population for adult chronic hepatitis B. We aimed to investigate the efficacy and safety of different antiviral strategies for HBV-infected children. **Methods:** This is a multicenter real-world study in China, three types of HBV-infected children were enrolled, including treatment-naïve, NA-treated and normal ALT level population. All patients were 3-18 years old and HBsAg positive, they received NA monotherapy or in combination with peginterferon α-2b for 96 weeks according to the willing of their own or guardian (NCT05792761). Data on those who have completed at least 48 weeks of treatment before April 13, 2023 were analyzed. **Results:** A total of 197 children who met the inclusion criteria and completed 48 weeks of treatment were analyzed (NA monotherapy group, n = 13; combination therapy group, n = 184). The average age was 7.7 years, and 56.9% were male, 89.8% were HBeAg positive and 90.3% were HBV DNA positive. The mean baseline HBsAg, HBV DNA and HBeAg were 3.59, 6.14 $\log_{10}$ IU/mL and 2.48 $\log_{10}$ COI, respectively. 50.8% (100/197) of patients were treatment-naïve chronic hepatitis B. In the total population, the HBsAg loss rate at 48 weeks was 25.0% in combination therapy group, while 7.7% in NA monotherapy group. In treatment-naïve patients, the HBsAg loss rates were 30.1% and 0% in combination therapy group and NA monotherapy group, respectively (Figure 1A). During the treatment course, the mean HBsAg gradually decline in both groups, but was significantly greater in combination therapy group, reaching 1.6 and 1.8 $\log_{10}$ IU/mL at 48 weeks in total and treatment-naïve population, respectively (Figure 1B). For the total population, 19.6% in combination therapy group and 0% in NA monotherapy group achieved HBeAg loss at 48 weeks, while 71.2% and 66.7% achieved HBV DNA negative. For treatment-naïve population, the HBeAg loss rates were 22.1% in combination therapy group and 0% in NA monotherapy group, while the HBV DNA negative rates were 67.1% and 60.0% (Figure 1A). Both therapies were well-tolerated. **Conclusion:** HBV-infected children can achieve significant higher HBeAg loss and HBsAg loss chance in peginterferon α-2b combination group, although HBV DNA negative can be well obtained in both groups. Therefore, peginterferon α-based strategies can help pediatric patients better pursue functional cure.

1450-C | USEFULNESS OF FIB-4 INDEX AND ALT AT 1 YEAR OF NUCLEOS(T)IDE ANALOG TREATMENT FOR PREDICTION OF HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B PATIENTS

Jun Inoue[1], Takehiro Akahane[2], Tomoo Kobayashi[3], Osamu Kimura[4], Kosuke Sato[5], Masashi Ninomiya[1], Tomoaki Iwata[1], Satoshi Takai[6], Norihiro Kisara[7], Toshihiro Sato[8], Futoshi Nagasaki[9], Masahito Miura[10], Takuya Nakamura[11], Teruyuki Umetsu[12], Akitoshi Sano[13], Mio Tsuruoka[1], Masazumi Onuki[1], Satoko Sawahashi[14], Hirofumi Niitsuma[1], Atsushi Masamune[1] and THERME Study Group, (1)Tohoku University Graduate School of Medicine, (2)Japanese Red Cross Ishinomaki Hospital, (3)Tohoku Rosai Hospital, (4) South Miyagi Medical Center, (5)Tohoku University Graduate School of Medicine, Sendai, Japan, (6)Iwaki City Medical Center, (7)Japan Community Health Care Organization Sendai South Hospital, (8)LC Clinic, (9) Sendai City Hospital, (10)Omagari Kousei Medical Center, (11)Yamagata City Hospital Saiseikan, (12) Kesennuma City Hospital, (13)Tohoku University Graduate School of Medicine, Sendai-shi, Japan, (14) Tohoku University Graduate School of Medicine, Sendai city, Miyagi, Japan

Background: Patients with chronic hepatitis B virus (HBV) infectionare at risk for liver cirrhosis and hepatocellular carcinoma (HCC). The incidence of HCC has been reported to be reduced with nucleos(t)ide analogs (NAs), but patients on such antiviral treatments are still at risk for HCC.The aim of this study was to evaluate the dynamics of a non-invasive marker of liver fibrosis, the FIB-4 index, for predicting the development of HCC. **Methods:** Among a total of 882 chronically HBV-infected patients who were treated with NAs (lamivudine, entecavir, tenofovir disoproxil fumarate or tenofovir alafenamide fumarate as a 1st line therapy), 472 patients without a history of HCC whose FIB-4 was obtained at baseline and 1 year of treatment were evaluated for the incidence of HCC. **Results:** The median age was 54 years and 303 (64.2%) were male. 147 patients (31.1%) were HBeAg positive and 350 patients (74.2%) were treated with entecavir as the 1st line NA. Of 417 patients whose HBV genotypes were determined, 36.9% and 61.2% were genotype B and C, respectively. The median FIB-4 index was 2.00 and the median observation period after starting NAs was 72 months. The median FIB-4 index at year 1 was 1.57 and had decreased significantly from the baseline ($p < 0.001$), but the reduction was small at 2 years or later. When a receiver operating characteristic (ROC) analysis of FIB-4 was performed to predict HCC within 5 years, the area under the curve of FIB-4 at 1 year was higher than that at baseline (0.676 vs. 0.599). The HCC incidence was significantly higher in patients with FIB-4 **e** 1.58 at 1 year than in those with FIB-4 < 1.58 (14.8% vs. 3.6% at 10 years, $p < 0.001$). In addition, alanine aminotransferase (ALT) at year 1 was included in the analysis. An ROC curve was plotted for the HCC incidence at year 5 and, based on the Youden index, the ALT cut-off was set at 31. When a FAL-1 score was evaluated as an applicable number of FIB-4 **e** 1.58 and ALT **e** 31 as 0, 1 and 2, the risk of HCC was significantly higher in patients with score 2 than in those with score 1 or score 0 (24.1% vs. 9.8% vs. 0.7% at 10 years, $p < 0.001$). **Conclusion:** This study showed that chronic hepatitis B patients with FIB-4 index **e** 1.58 and ALT **e** 31 at year 1 of NA had a high risk of HCC, and conversely, those with low FIB-4 index and low ALT at year 1 had a minimal risk. The FAL-1 score can stratify the HCC risk and may be useful for individualized HCC surveillance planning.

Locarnini[2] and Aileen Rubio[1], (1)Clearb Therapeutics, (2)Victorian Infectious Diseases Reference Laboratory

Background: We have previously identified a murine monoclonal antibody (mAb) 4G2 that binds specifically to a key loop 1 epitope within the Hepatitis B surface antigen (HBsAg) and demonstrates anti-viral activity in the hydrodynamic tail vein injection (HDI) mouse model of persistent HBV infection (EASL poster # 2543, 2023). This antibody was humanized onto human IgG1 backbone to support the clinical development of a therapeutic antibody approach in Chronic Hepatitis B (CHB) patients. **Methods:** Humanized versions of the 4G2 mAb were developed by grafting the CDRs from the murine 4G2 into human IgG1 acceptor to obtain three light and heavy chains. These were paired with each other to create nine humanized candidates which were recombinantly expressed and purified from CHO cells. Binding to CLB-405 (HBsAg with multiple loop1 epitopes) using SPR and ELISA methods identified the strongest binding candidate 4G2 (3-2) which was tested for anti-viral activity in the HDI model [Chou H-H et al. 2015. PNAS 112(7) pp2175]. These mice were administered a single 400 μg dose of 4G2 (3-2) by intravenous injection and monitored for serological markers of HBsAg and HBV DNA over time, as well as liver HBsAg and Hepatitis B core antigen (HBcAg) immunohistochemistry at the end of study. **Results:** The humanized candidates successfully bound CLB-405 thereby retaining the binding affinity of the murine 4G2 mAb. A single injection of 4G2 (3-2) at 400 μg resulted in an average reduction of 1.67 log IU/ml HBsAg at peak response (4 d post-dose antibody administration). The number of animals with undetectable HBsAg was 1/8 in placebo and 8/8 in 4G2 (3-2) groups. A rebound in HBsAg level was observed one week post dose in a subset of animals. Seroclearance of HBsAg resulted in clearance of HBsAg and HBcAg positive cells in the liver. This data was comparable with the effect observed from treatment with the parent murine 4G2 mAb (EASL poster # 2543, 2023), for which multiple dosing data showed enhanced efficacy in all treated mice. **Conclusion:** Serotherapy using humanized 4G2 (3-2) mAb was highly efficacious in the HDI HBV persistent murine model with rapid serum HBsAg decline and clearance in a subset of animals, followed by clearance of infected hepatocytes. Multiple injections of 4G2 (3-2) were not tested in this model due to likelihood of formation of anti-drug antibodies associated with species mismatch. These findings further support the clinical development of 4G2 (3-2) for the treatment of CHB.

Background: Pradefovir is a liver-targeted prodrug of adefovir, a nucleoside/nucleotide analogue with antiviral activity against hepatitis B virus (HBV) DNA polymerase. From the Phase 2 trial, we had the results that Pradefovir and TDF exhibited comparable reductions in HBV DNA levels. All treatments were safe and well tolerated. This phase 3 study aimed to further confirm the efficacy and safety of pradefovir versus tenofovir disoproxil fumarate (TDF) of long-term drug use. **Methods:** This ongoing randomized, double-blind, non-inferiority, phase 3 study was conducted at 58 sites in China. Patients with chronic HBV infection were randomly assigned (2:1) to receive either 45 mg daily pradefoivr mesylate(PDV) or 300 mg daily TDF with matching placebo. Patients were stratified according to hepatitis B e-antigen (HBeAg) status and previous treatment experience. The patients with compensated cirrhosis were lower than 20% in over roll. The primary efficacy endpoint was defined as the proportion of patients who's HBV DNA level were less than 29 IU/mL at week 48. The pre-specified non-inferiority margin was 12%. All participants who received one dose of the study drug were included in the primary intention to treat efficacy and safety analyses with pre-specified renal and bone endpoints at the 48 weeks. **Results:** 1170 patients were screened ; 912 eligible patients were randomized and 908 patients received study drug. The baseline characteristics were well balanced between groups. In the HBeAg positive group, 444 patients received PDV and 222 patients received TDF; at week 48, 264 (59.5%) patients who received PDV and 136 (61.3%) patients who received TDF reached HBV DNA less than 29IU/ml; the virologic success rate was similar between the two groups with difference -1.8% [-9.7% to 6.1%]. In the HBeAg negative group, 162 patients received PDV and 80 patients received TDF. At week 48, 150 (92.6%) patients who received PDV and 72 (90.0%) who received TDF reached HBV DNA less than 29IU/ml; the virologic success rates were similar between the two groups with difference 2.6%[-5.1% to 10.3%]. Through 48 weeks, there were significantly less adverse events assessed related to the study drug by the investigator were reported (with differences of 62.9% *vs* 67.9% ($p = 0.0415$) of PDV *vs* TDF); the rates of the most common adverse events reported were similar between the two groups. Patients in PDV group demonstrated a significantly lower trend of decrease in bone mineral density at both hip and spine, and a smaller decrease in sCCR at week 48, especially in the elderly patients (older than 40 y) ; which suggested patients with PDV had a more favorable long-term renal and bone safety profile. **Conclusion:** These findings suggest that the efficacy of Paladofovir 45mg QD is equal to or better than TDF 300mg, and the safety of Paladofovir 45mg QD has significant advantages, which can be used in the treatment of HBeAg-positive or HBeAg-negative adult patients with chronic hepatitis B.

1453-C | ADENINE BASE EDITING SILENCES HBsAg EXPRESSION AND INHIBITS HEPATITIS B VIRAL REPLICATION IN HBV MOUSE MODELS

Elena M Smekalova[1], Anuj Kumar[2], Emmanuel Combe[2], Selam Dejene[1], Chao-Ying Chen[1], Dominique Leboeuf[1], Maria Guadalupe Martinez[2], Luis A Barrera[1], Giuseppe Ciaramella[1], Michael S Packer[1], Barbara Testoni[2], Francine Gregoire[1] and Fabien Zoulim[3,4,5,6], (1)Beam Therapeutics, Cambridge, MA, USA, (2) Cancer Research Center of Lyon, Inserm, U1052, Lyon, France, (3)Cancer Research Center of Lyon (CRCL), Inserm U1052, Cnrs UMR5286, Lyon, France, (4) Hospices Civils De Lyon (HCL), Lyon, France, (5) University of Lyon, Umr_S1052, Ucbl, 69008 Lyon, France, (6)Hépatologie Unit, Hospices Civils De Lyon, Lyon University, Inserm

Background: The hepatitis B virus (HBV) covalently closed circular (ccc)DNA serves as a template for viral replication. It is not targeted efficiently by nucleos(t)ides analogues nor by small molecules in development. HBV DNA also integrates into the human genome. Integrated HBV DNA contributes to Hepatitis B surface antigen (HBsAg) expression, which inhibits HBV-specific immune responses. Adenine Base Editors (ABEs) can convert A™T to G™C within DNA in a guide RNA-dependent manner, and thus can directly modify the HBV genomic elements responsible for viral persistence. **Methods:** Guide RNAs (gRNAs) were designed such that, when paired with an ABE, they lead to missense mutations in HBV genes or disrupt regulatory elements in the HBV genome. Transfection of ABE-encoding mRNA and HBV-targeting gRNAs was performed to evaluate their antiviral efficacy *in vitro* in HBV-infected HepG2-NTCP cells and primary human hepatocytes (PHH), as well as in PLC/PRF/5 cells with naturally integrated HBV DNA. *In vivo* antiviral effect was assessed after lipid nanoparticle (LNP)-mediated delivery of the ABE mRNA and HBV targeting gRNAs in two animal models: HBV-circle mouse model and HBV-infected liver-humanized mice. **Results:** Adenine base editing enabled robust HBV cccDNA editing and reduction of the corresponding viral markers in HepG2-NTCP and PHHs. Furthermore, *HBs*-targeting gRNAs robustly inhibited HBsAg expression in PLC/PRF/5 cells. In the HBV-circle mouse model, intravenous injection with base editing reagents formulated in LNPs resulted in a complete loss of HBsAg and profound sustained reduction in the serum HBV DNA. In HBV-infected humanized mice, base editing enabled 1log (90%) sustained reduction in HBsAg and 1.3log (>90%) reduction in the serum HBV DNA. **Conclusion:** Combined, the data indicate that base editing can silence HBsAg expression and abrogate HBV replication *in vitro* and *in vivo*. Figure: Loss of HBsAg and HBV replication inhibition in HBV-circle mouse model. 3-4 log sustained HBsAg reduction in ABE / HBV gRNA treated group > 4 weeks after a single injection with LNP/ABE&gRNA; HBV replication is reduced in entecavir treated mice, and then rebounds when the treatment is discontinued (positive control); sustained reduction in serum HBV DNA in base editing treated groups; no HBV rebound.

1454-C | AN EFFECTIVE STRATEGY TO REDUCE HBsAg LEVEL WITHOUT DIRECT INHIBITION OF INTRACELLULAR HBsAg SYNTHESIS IN HBV INFECTED HUMANIZED MICE

Bai-Hua Zhang[1], Yong-Yuan Zhang[1], Yuanping Zhou[2], Ben Tempel[1], Todd Parsley[3] and Fabien Zoulim[4], (1) Hbvtech, (2)Nanfang Hospital, (3)Noble Life Sciences, (4)Hépatologie Unit, Hospices Civils De Lyon, Lyon University, Inserm

Background: The current strategy to reduce serum HBsAg is to inhibit cellular HBsAg synthesis using siRNA/ASO drugs that show an average < 2log serum HBsAg reduction. cccDNA is the major HBsAg transcription template. We have reported spontaneous cccDNA loss from infected cells in humanized livers of chimeric mice. Thus, cccDNA loss and ongoing HBsAg secretion could lead to clearing HBsAg in the infected cells. We hypothesize that an effective strategy to reduce serum HBsAg to an undetectable level is to block cccDNA replenishment with a sustained high level of anti-HBs antibody. We have developed a new HBV drug candidate HBVZ10 that uses an optimized AAV vector to deliver human anti-HBs antibody genes into muscle cells. HBVZ10 expresses sustained high levels of anti-HBs antibody after a single injection. We evaluated the efficacy in reducing cellular and serum HBsAg levels by blocking de novo infection-mediated cccDNA replenishment. **Methods:** HBV infected chimeric mice were divided into 4 groups, including 1 untreated control and 3 groups treated with HBVZ10 combined with 12-weeks of entecavir administered at different timepoints post infection. Serum HBsAg, HBeAg, HBV DNA, and anti-HBs were analyzed in serial blood samples. Average intrahepatic HBV DNA levels were determined using qPCR and dPCR after random sampling of each liver 20 times. **Results:** High Anti-HBs antibody levels were expressed by HBVZ10 and reached and sustained > 100,000mIU/ml in all treated mice during the experiment period. All HBVZ10 treated mice responded with serum HBsAg reduction. Baseline HBsAg in the 8 of 11 treated mice who survived long enough ranged from 2000 to 10,000IU/ml among 7 mice and was 58IU/ml in the last mouse, and became undetectable in all 8 mice after 3-5log progressive reduction by day 162 pi (Figure 1). Progressive serum HBsAg reduction was closely paralleled with progressive serum HBeAg decline, implying that progressive serum HBsAg reduction reflects progressive HBV clearance in the livers, which was confirmed by a 3-4 log lower intrahepatic HBsAg, rc, and cccDNA levels from mice who achieved undetectable serum HBsAg compared to untreated controls. **Conclusion:** HBsAg can be efficiently cleared from infected cells through secretion, provided the replenishment of depleted cccDNA pool is prevented. Blocking of cccDNA replenishment with HBVZ10 is more effective in reducing both cellular and serum HBsAg levels than the reported direct inhibition of cellular HBsAg synthesis in the same animal model.

1455-C | ANALYSIS OF HBV GENOTYPE ASSOCIATION TO SEQUENTIAL BEPIROVIRSEN AND PEGYLATED INTERFERON TREATMENT RESPONSE IN PATIENTS WITH CHRONIC HBV INFECTION (PHASE 2b B-TOGETHER STUDY)

Scott D. Speer[1], Jerome Bouquet[2], Leigh Felton[3], Thomas Greene[1], Jill Walker[2], Dickens Theodore[4], Melanie Paff[1] and Susan Dixon[3], (1)GSK, Collegeville, PA, USA, (2)GSK, South San Francisco, CA, USA, (3) GSK, London, UK, (4)GSK, Durham, NC, USA

Background: Bepirovirsen (BPV; GSK3228836) is an antisense oligonucleotide that targets a conserved 20 nucleotide sequence within HBV pregenomic RNA and mRNAs. B-Together is a phase 2b trial (NCT04676724) assessing the efficacy and safety of sequential treatment of up to 24 wk BPV followed by up to 24 wk of pegylated interferon (PegIFN) in patients with CHB. We present the HBsAg response for patients by viral genotype. **Methods:** Multicenter, randomized, open-label study in patients with CHB who were receiving concomitant stable nucleos(t)ide analogue (NA) therapy. Patients were randomized (1:1) to receive BPV 300 mg weekly either for 24 wk (Arm 1) or 12 wk (Arm 2). A loading dose of BPV was given on days 4 and 11. For eligible patients, BPV treatment was followed by up to 24 wk of PegIFN. Patients were followed for 24 weeks (OT-WK24) after the planned end of treatment (EOT). B-Together recruited patients in 11 countries encompassing Asia, Europe, North America, and South Africa. Genotype was determined by HBV RNA sequencing and/or investigator report. **Results:** Six different genotypes (GT) were observed: A, B, C, D, E, and H, with GT-C (24%) and GT-D (9%) observed most frequently. All patients maintained concomitant NA therapy throughout the study, resulting in low/undetectable RNA/DNA and a high proportion of undetermined genotypes (51%, 28/55 for Arm 1; 49%, 26/53 for Arm 2). Arm 1: GT-C (24%, 13/55 patients) was most frequently observed, followed by GT-D (9%, 5/55), GT-A (5%, 3/55), GT-E (5%, 3/55), and GT-B (4%, 2/55). Patients with GT-D virus had the lowest mean HBsAg level at baseline (2.97 log IU/mL) and GT-B the highest (3.76 log IU/mL). Arm 2: GT-C (25%, 13/53 patients) was most frequently observed, followed by GT-A (11%, 6/53), GT-D (9%, 5/53), GT-E (4%, 2/53), and GT-B (2%, 1/53). The patient with GT-B virus had the lowest mean HBsAg level at baseline (2.95 log IU/mL) and GT-D the highest (3.74 log IU/mL). Treatment response: Treatment response 24 wk after planned EOT by GT is shown in Table 1. **Conclusion:** BPV treatment followed by PegIFN resulted in substantial HBsAg reduction ($>$1log IU/mL) in all genotypes, and the primary endpoint (PE; HBsAg and HBV DNA $<$ LLOQ for 24 wk after planned EOT, in the absence of rescue therapy) was achieved in GT-A, C, D, E. Few genotype differences were observed between Arm 1 and Arm 2, which may be attributed to the small sample size and low genotype data availability. Funding: GSK (209348; NCT04676724)

Table

BPV 24 wk (Arm #1) N = 55						
Genotype	A	B	C	D	E	Undetermined

1456-C | APPARENT VIROLOGICAL CURE OF HBV INFECTION BY THE NOVEL CAPSID/CGAS BIFUNCTIONAL MOLECULE LW231 IN AAV-HBV MICE

Ning Zhang, Anran Qian and Zhe Wang, Longwood Biopharma

Background: Current cHBV treatment options have a low incidence of functional cure. Combination therapy including direct-acting antivirals and immunomodulators is a promising approach to achieve cHBV cure. Here, we present preclinical studies of a novel bifunctional molecule LW231, which can simultaneously modulate HBV capsid assembly and activate cGAS-STING pathway. **Methods:** The effect of LW231 on HBV capsid assembly and cGAS expression was studied *in vitro*. The activity of LW231 were tested both *in vitro* and *in vivo*. The AAV-HBV mice were randomly divided into six groups: vehicle, LW231 (bid at 50, 100, and 200 mg/kg), ETV (qd at 0.1 mg/Kg) and combination group (100 mg/Kg LW231 with ETV). HBV virological markers in blood and liver tissue were detected. **Results:** *In vitro* study: LW231 enhanced the formation of empty capsids. LW231 also dose-dependent promoted the expression of cGAS in HepG2.2.15 cells, but the effect was absent in HepG2 cells. LW231 demonstrated potent activity across HBV genotypes A-J ($EC_{50}=8$ - 60 nM, $CC_{50}>100$ μM). *In vivo* study: After treated with LW231 for 42 days in the AAV-HBV mice, the mean declines in HBV DNA was 0.2, 2.2 and 2.3 logs, in HBsAg was 0.3, 0.8, 0.5 logs, in HBeAg was 0.08, 1.1, 0.7 logs comparison to pretreatment levels in mice dosed with 50, 100 and 200 mg/kg LW231, respectively. LW231 (100 mg/Kg, the optimal dose for HBsAg and HBeAg reduction) single treatment continued to show a decrease in serum HBV DNA (-3.4 logs), HBsAg (-1.2 logs) and HBeAg (-1.9 logs) levels on day 112. LW231/ETV combination treatment synergistically reduced the HBV DNA level (-5.5 logs) but not HBsAg (-1.3 logs) and HBeAg (-1.9 logs) levels on day 112. In comparison, ETV treatment showed no effect on HBsAg and HBeAg levels despite its potent inhibition of HBV DNA. Encouragingly, the serum HBV DNA, HBsAg and HBeAg levels did not rebound after 8-weeks off-treatment in both LW231 treatment groups, while serum HBV DNA levels in the ETV-treated mice rapidly rebounded. Liver tissues analysis showed that LW231 treatment completely cleared of $HBcAg^+$ and $HBsAg^+$ hepatocytes and markedly decrease the level of liver HBV DNA (-2.8, -3.2 logs for single and combination groups respectively) on day 112, and there was no rebound following 8-weeks recovery period. **Conclusion:** These preclinical studies showed the bifunctional properties of LW231 and demonstrated that LW231 treatment achieve apparent virological cure of HBV infection in AAV-HBV mice.

1457-C | ASSESSMENT OF REGIONAL IMPACT ON THE PHARMACOKINETICS OF VIR-2218 (BRII-835) IN SUBJECTS WITH CHRONIC HEPATITIS B VIRUS INFECTION

Yali Zhu[1], Sneha Gupta[2], Chunming Li[1], Chong Zhu[1], Xiaofei Chen[1], Weihong Liu[1] and Ji Ma[1], (1)Brii Biosciences, (2)Vir Biotechnology, Inc

Background: VIR-2218 (also referred as BRII-835) is an investigational, N-acetylgalactosamine (GalNAc)–conjugated RNA interference (RNAi) therapeutic that targets a region of the hepatitis B virus (HBV) genome that is common to all HBV viral RNA transcripts. VIR-2218 is in clinical development for treatment of chronic HBV infection in multiple trials over different regions as a single agent or in combination with other treatment modalities. Here we report the potential effect of region on VIR-2218 pharmacokinetics (PK) via cross-study comparison. **Methods:** VIR-2218-1001 is a Phase 1/2 single and multiple ascending dose study at multiple sites in Asia-Pacific (APAC) region excluding mainland China. Parts B (HBeAg-) and C (HBeAg+) of the study evaluated 2 SC injections of 20 to 200 mg VIR-2218 4 weeks apart (Q4W) as a single agent in subjects with HBV infection. VIR-2218-1005 is a Phase 2 study in mainland China; each subject with HBV infection with HBeAg- (Part One) or HBeAg+ (Part Two) received 2 SC injections of 50 or 100 mg VIR-2218 Q4W. PK exposures at same dose levels (50, 100 mg) between the two studies were log-transformed and statistically analyzed using a mixed effects model, with study region as a fixed effect. For each dose level and dosing day separately, geometric least square mean (GLSM), geometric mean ratio (GMR), and 90%CI are calculated. **Results:** In study VIR-2218-1001, 24 subjects received VIR-2218 of which 23/24 (95.8%) were Asian ethnicity enrolled in the APAC region. In study VIR-2218-1005, all 16 subjects receiving VIR-2218 were of Asian ethnicity enrolled in mainland China. PK profiles in subjects with HBV infection are generally similar between APAC region and mainland China. No accumulation of BRII-835 in plasma was evident after a second dose. Subjects with HBeAg- or HBeAg+ had similar PK profiles, and thus were combined for each

study. Statistical analysis demonstrated no clinically meaningful differences in PK exposure between the two study populations in different regions. The GMRs were 82.5-110% and 90%CIs for GMR encompass 100%, though with wide range due to small sample size and data variability. Comparable safety and HBsAg reduction profiles were also observed between the two studies. **Conclusion:** Chinese ethnic background from mainland China has no apparent impact on the PK of VIR-2218, which could serve as a bridge to support mainland China's participation in future global trials for further evaluation of VIR-2218.

Background: Hepatitis delta (HDV) infection is the most severe form of viral hepatitis. Bulevirtide (BLV), a first-in-class entry inhibitor, is approved in Europe for the treatment of chronic hepatitis delta (CHD). Here we describe the baseline (BL) demographics and clinical characteristics of patients included in the BLV clinical program. **Methods:** A pooled analysis was conducted on BL data collected from 4 CHD trials that enrolled patients from 7 countries in Europe, including the Phase 2 studies MYR202 (NCT03546621), MYR203 (NCT02888106), and MYR204 (NCT03852433), and the Phase 3 study MYR301 (NCT03852719). Patients with compensated liver disease, alanine aminotransferase (ALT) > 1×ULN but < 10×ULN, with/without prior nucleos(t)ide analogue therapy were included. Key exclusion criteria included total bilirubin **e** 34.2 µmol/L, current or prior hepatic decompensation (history or within the last 2 y, depending on study), and recent interferon (IFN) use (duration depending on study). Patients were categorized into terciles based on BL ALT and HDV RNA for comparison. Fisher's exact test and ANOVA test were used for univariate analysis as appropriate. **Results:** 532 CHD patients were included; age, mean (SD) years, was 40 (9); 65% were male; 87% were White; 10% had BMI **e** 30 kg/m^2; and 10% were HBeAg+. 46% of patients (244 of 532) had prior IFN therapy. The BL mean (SD) HDV RNA viral load was 5.3 (1.3) $\log_{10}$ IU/mL, and 94% of the cohort was Genotype (GT) HDV-1. The majority of patients (95%) had elevated ALT, median (Q1, Q3), of 87 (60, 131) U/L. The mean liver stiffness (LS) was 13.8 (8.1) kPa with 38% of the cohort having cirrhosis. On subgroup analysis, those with higher BL ALT were more often of male sex ($p < 0.0001$) and had higher LS ($p = 0.0003$; Table). Further, those with higher BL HDV RNA were more often HBeAg+ ($p = 0.0052$) and had higher ALT ($p = 0.0313$) and HBsAg levels ($p < 0.0001$). 319

patients (60%) with CHD were treated with BLV monotherapy alone (92 BLV 2 mg; 32 BLV 5 mg; 195 BLV 10 mg), while 145 patients (27%) were treated with BLV + pegylated IFN (PEG; 65 [12%] BLV 2 mg + PEG; 15 [3%] BLV 5 mg + PEG; 65 [12%] BLV 10 mg + PEG). 68 patients (13%) were controls (no treatment) for the duration of the study. **Conclusion:** This is a large, pooled analysis including 532 CHD patients enrolled in past and ongoing BLV trials from Europe. The population identified here is predominantly male, White, and GT HDV-1. Those with higher BL ALT are more likely to be male with higher LS while those with higher HDV RNA are more likely to be HBeAg+ with higher ALT and HBsAg levels.

Table. Subgroup Analysis by ALT and HDV RNA Terciles

Subgroup Analysis by ALT Terciles			
	ALT < 69 (T1) (N = 175)	69 ≤ ALT ≤ 112 (T2) (N = 180)	ALT > 112 (T3) (N = 177)

1459-C | BASELINE NUCLEOTIDE POLYMORPHISMS WITHIN HBV TARGET SITE IN CHRONIC HEPATITIS B SUBJECTS DO NOT IMPACT HBsAg REDUCTIONS MEDIATED BY RNA INTERFERENCE THERAPEUTIC AB-729

Christine Espiritu, Holly M Micolochick Steuer, Andrzej Ardzinski, Varun Sharma, Timothy Eley, Karen Sims, Amy C.H. Lee, Rene Rijnbrand, Andrea Cuconati, Nagraj Mani, Angela M. Lam, Michael J Sofia and Emily P Thi, Arbutus Biopharma, Warminster, PA

Background: AB-729 is a *N*-Acetylgalactosamine (GalNac) conjugated small interfering RNA (siRNA) currently being investigated for the treatment of chronic hepatitis B virus (HBV) infection. In clinical study AB-729-001, mean HBsAg declines from baseline ranged from 1.8 to 2.6 $\log_{10}$ across all cohorts by end of treatment. Here we report the characterization of AB-729 HBV target site variants identified from the HBVdb database as well as from sequence profiling of the AB-729 target site at baseline in chronic hepatitis B (CHB) subjects enrolled in AB-729-001. The impact of identified target site variants on HBV fitness and AB-729 activity was assessed in a transient transfection cell model of HBV. **Methods:** CHB subjects were administered single doses (60mg, 90mg, or 180mg) or multiple doses (60mg or 90mg every 4, 8 or 12 weeks) of AB-729. At baseline, prior to AB-729 administration, HBV RNA extracted from plasma was reverse transcribed, subjected to PCR amplification and ultra deep sequencing (UDS) of the HBx region. Additionally, sequences from the HBVdb database were screened for AB-729 target site variants. To determine the impact of identified AB-729 target site variants on viral fitness and AB-729 activity, point mutations were introduced into an HBV plasmid by site-directed-mutagenesis and transfected into HepG2 cells. Viral fitness and AB-729 activity were determined by comparing inhibitory activity in variants versus wildtype. **Results:** Analysis of HBV sequences from the HBVdb database identified changes in 8 nucleotide positions (G1577A, T1580A, C1582G, C1587T, G1588A/C/T, C1589A/G, T1590G and T1591C) with **e** 0.5% prevalence in any one HBV genotype or **e** 0.3% prevalence in at least two genotypes. UDS analysis from 31 subjects at baseline showed target site conservation in 23 subjects (74.2%). Single nucleotide polymorphisms (SNPs) were observed at positions 1590 and 1593 at > 15% read count frequency at baseline. *In vitro* analysis of these variants showed viral fitness to be > 50% of wildtype, with no decrease in sensitivity to AB-729. **Conclusion:** SNPs in the AB-729 HBV target site were identified in sequences obtained from a publicly available database and were observed at baseline in some CHB subjects in AB-729-001. *In vitro* testing in an HBV cell-based model confirm retention of AB-729 activity against tested variants, suggesting that these SNPs have no apparent influence on individual or mean HBsAg declines observed in subjects treated with AB-729.

1460-C | BEPIROVIRSEN HAS INTRINSIC INNATE ACTIVITY, DISTINCT FROM THAT OF OTHER ANTI-SENSE OLIGONUCLEOTIDES

Megan Ermler[1], Kristen Jones[1], Amitabh Das[1], Anne DeHart[1], Nicholas Galwey[1], Melanie Paff[2] and Shihyun You[2], (1)GSK, (2)GSK, Collegeville, PA, USA

Background: Bepirovirsen (BPV) is an anti-sense oligonucleotide (ASO) that is in phase 3 clinical trials for chronic hepatitis B (CHB). Previously, we have reported that BPV induces innate immune activation in human PBMCs and also specific activity in transgenic hTLR8 mice (Shanghai Model Organisms Center, Inc.), but not in wild type mice. Here, we investigate whether bepirovirsen is unique in its mechanism for innate immune activation compared to other ASOs, and whether presence of HBV mRNA via infection alters innate activity in the hTLR8 transgenic mouse model. **Methods:** WT littermate control and transgenic hTLR8 mice were dosed with BPV, other ASOs (including a scrambled, a minimally inflammatory, and a TLR9 activating ASO), or control treatments. Mice were euthanized four hours after dosing and plasma protein and liver RNA cytokine levels were examined. To investigate the impact of HBV infection on innate immune response to bepirovirsen, WT littermate control and transgenic hTLR8 mice were infected with 1x10^11 viral genome per mouse of AAV-HBV for at least 30 days prior to study start. Mice were stratified based on HBsAg levels prior to dosing. **Results:** BPV had a distinct profile of innate immune activation compared to the other ASOs tested. Levels of TNF-α and IL-6 were significantly higher in hTLR8 mice dosed with BPV than in those dosed with scrambled ASO (TNFα: $p < 0.0001$; IL-6: $p = 0.0169$) or the non-inflammatory ASO 104838 ($p = 0.025$, $p = 0.0346$). BPV induced TNF-α and IL-6 in hTLR8 mice but not in WT mice, whereas ASO 421856 (activates through TLR9) induced TNF-α and IL-6 in

both hTLR8 and WT mice. Additionally, AAV-HBV infection of both WT and hTLR8 transgenic mice had no impact on cytokine protein production by BPV treatment within four hours post-dose. **Conclusion:** The innate immune activity of BPV in hTLR8 transgenic mice is distinct from that from another ASO known to induce TLR9 activity, suggesting that the BPV-mediated innate response is more specific to human TLR8. Interestingly, infection of either WT or hTLR8 transgenic mice with AAV-HBV does not impede, enhance, or alter the innate immune protein response observed with BPV treatment.

1461-C | CHARACTERIZATION OF THE DIRECT ANTIVIRAL EFFECT OF REP 2139 ON HDV REPLICATION

Simone Fonte[1,2], Marie-Laure Plissonnier[1,3], Maud Michelet[1,2], Matthieu Blanchet[4,5], Patrick Labonte[6], Andrew Vaillant[7] and Massimo Levrero[1,3,8,9,10], (1) Cancer Research Center of Lyon (CRCL), Inserm U1052, Cnrs UMR5286, Lyon, France, (2)Institute d'Hépatologie De Lyon, Lyon, France, (3)Institut d'Hépatologie De Lyon, (4)Replicor Inc., (5)Inrs – Institut Armand Frappier, Institut National De La Recherche Scientifique, Laval, Canada, (6)Inrs-Centre Armand-Frappier Santé Biotechnologie, (7) Replicor Inc., Montreal, Canada, (8)Department of Hepatology, Croix Rousse Hospital, Hospices Civils De Lyon, France, (9)University of Lyon Claude Bernard 1 (UCLB1), Lyon, France, (10)Department of Medicine Sciac and the Italian Institute of Technology (IIT) Center for Life Nanosciences (CLNS), University of Rome La Sapienza, Rome, Italy

Background: REP 2139 blocks the assembly and secretion of HBV subviral particles, an effect which also blocks envelopment of the Hepatitis D Virus (HDV) ribonuclear protein (RNP) and secretion of HDV from infected cell. A previous phase II study and current compassionate use of REP 2139 in Hepatitis B Virus (HBV) / HDV infection have shown an early and more robust antiviral response toward HDV RNA than as compared to HBsAg, suggesting a second, upstream and direct acting antiviral mechanism. Here we have investigated the direct antiviral activity of REP 2139 in relevant HDV cell infection models *in vitro*. **Methods:** Restoration of REP 2139 endosomal release *in vitro* employed the UNC 7938-based method previously described (Blanchet et al., Antiviral Res 2019; 164: 97). Clinical supply of REP 2139-Mg (lot FAB-22-0001) was used for dosing in HDV infected HepG2-NTCP cells and primary human hepatocytes (PHH) at (10 genome equivalents/cell). REP 2139-Mg was diluted in normal saline before addition to tissue culture. Intracellular HDV viral genome levels were assessed in cell lysates by quantitative RT-PCR. The association of HDV RNA and Hepatitis Delta Antigen (HDAg) to form the HDV ribonucleoprotein (HDV RNP) was monitored by anti-HDAg RNA immunoprecipitation (RIP) followed by HDV specific RT-PCR (Abeywickrama-Samarakoon N et al., Nat Commun. 2020; 11: 419). **Results:** A single dose of REP 2139-Mg reduced intracellular HDV viral genome levels by ~1 $\log_{10}$ in HepG2-NTCP and PHH cells at 400nM and 600nM respectively. Loss of antiviral activity at higher doses could be recovered by increasing UNC 7938 concentration, indicating that the efficiency of endosomal release of REP 2139 into cells is a process influenced by endosomal concentration of REP 2139 and the dose of UNC 7938 used. A single dose of REP 2139-Mg also reduced the intranuclear association of HDV RNA with HDAg in both HepG2-NTCP and PHH by ~60% (@ 600nM) and 65% (@ 400nM), respectively. **Conclusion:** REP 2139 has a direct acting antiviral effect against HDV RNA replication which may involve blocking HDV RNA interaction with HDAg during the morphogenesis of HDV RNP. These antiviral effects bear further investigation and may explain the more rapid decline of HDV RNA versus HBsAg in human studies.

Baumert[4,5], (1)Inserm Umr_S1110, Institute of Viral and Liver Disease, (2)Aligos Belgium BV, Leuven, Belgium, (3)Aligos Therapeutics, (4)University of Strasbourg, France, (5)University of Strasbourg, Inserm, Institut De Recherche Sur Les Maladies Virales Et Hépatiques Umr-S1110, 67000 Strasbourg, France

Background: Despite a preventive vaccine, almost 300 million people suffer from a chronic hepatitis B virus (HBV) infection. Therapies controlling HBV replication exist but do not lead to functional cure of chronic hepatitis B. HBV core protein (HBc) is the building block of the HBV nucleocapsid and it modulates almost every step of the HBV life cycle. Class A capsid assembly modulators (CAM-As) represent attractive direct antiviral agents (DAAs). These compounds impair HBV replication by blocking pgRNA encapsidation and inducing HBc aggregation due to aberrant nucleocapsid structures. We previously showed that CAM-A RG7907 treatment leads to an unexpected sustained HBsAg reduction and loss of infected hepatocytes via apoptosis in an AAV-HBV mouse model. In this study we present further insights into the mechanism of action of the CAM-A compound, RG7907 **Methods:** We investigated the impact of RG7907 treatment on HBc aggregation, cell survival, and transcriptomic reprogramming in HBc-expressing hepatoma cell lines (HepG2) and primary human hepatocytes (PHH) as well as in the HBV-replicating cell line HepAD38 **Results:** RG7907 induced extensive HBc-aggregation-dependent cell death both in hepatoma cells and in primary hepatocytes. Transcriptomic analyses revealed the activation of specific host pathways such as apoptosis, inflammation, and the interferon response. The induction of apoptosis-related gene expression was validated in HBc-expressing HepG2 and PHH as well as in HepAD38. We also observed activation of an interferon response in HepAD38 suggesting the potential activation of the innate immunity upon CAM-A treatment **Conclusion:** CAM-A-dependent HBc aggregation drives cell death via activation of host specific pathways such as apoptosis and the inflammatory and innate immunity responses. These results shed light on a previously unknown mechanism of action specific to CAM-A compounds.

1463-C | CLINICAL VALIDATION OF AN ORALLY-DELIVERED, SYSTEMICALLY ACTIVATED TLR7 AGONIST TO BOOST HOST IMMUNE RESPONSE TO CHRONIC VIRAL DISEASES, INCLUDING HEPATITIS B VIRUS

Curtis L. Scribner[1], Charlotte R. Lemech[2], Christopher Argent[2], Richard Daniels[3] and James R Appleman[3], (1) Curtis L. Scribner, (2)Scientia Clinical Research, Ltd, (3) Primmune Therapeutics

Background: PRTX007 is a novel, clinical stage TLR7 agonist prodrug that can be used in multiple indications, including as part of a functional cure for chronic hepatitis B virus (HBV) infection. Using phase 1 single ascending dose (SAD) and multiple ascending dose (MAD) healthy volunteer (HV) data, we show its safety profile and immunomodulatory activity are optimal for clinical use. All synthetic non-nucleoside TLR7 agonists activate NF-κB and have failed clinically in chronic viral infection settings. In contrast, nucleoside-based TLR7 therapies have shown benefit in clearing HBsAg. PRTX007 is an orally administered prodrug of PRX034, a nucleoside-based TLR7 agonist, that elicits an optimal pattern of systemic immune induction in non-human primates and in humans. There is no evidence of NF-kB-mediated systemic inflammation at drug levels that stimulate IFN-responsive pathways and corresponding downstream cellular processes. **Methods:** This was a phase 1, single-center, prospective, randomized, double-blind, placebo-controlled study of 9 SAD and 4 MAD cohorts of PRTX007 given orally every other day (QOD) to adult HVs. Primary objectives were safety and tolerability. Secondary objectives were evaluation of pharmacokinetics (PK) and pharmacodynamics (PD). In total, 104 of the 130 HVs received the study drug. **Results:** PRTX007 was well-tolerated with no grade 3 or higher AEs and no dose modifications or discontinuations due to treatment-related AEs. The PKs of PRTX007 and PRX034 are well-behaved, with a planned short half-life and exposure increasing proportionally with PRTX007 dose without accumulation upon repeated dosing (QOD) in the 300, 400, and 750 mg dose cohorts. Coordinated expression of IFN stimulated genes and genes known to be related to

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

TLR7 agonism was observed in immune cells in blood in all HVs. There was no change in expression of NF-kB regulated gene products. Increases in IL-1RA, MCP-1 and IP10 in plasma were observed. IL-6, TNFα, and IL- 1b remained essentially unchanged from pretreatment levels. **Conclusion:** PRTX007 was well tolerated, with mostly mild AEs and no SAEs. Activation of the innate and adaptive immune responses were observed without systemic increases in proinflammatory factors. Sustained immune pressure and extended PD response was demonstrated with oral QOD doses. These data demonstrate the suitability of PRTX007 for investigation in combination therapy for curative treatment of chronic HBV infection.

1464-C | DEEP IMMUNOPHENOTYPING ANALYSIS OF PBMC FROM THE BEPIROVIRSEN PHASE 2a STUDY

Jared Delahaye[1], Cory Knudson[1], Thea Hogan[2], Esther Perez Garcia[2], Irene Del Molino Del Barrio[2], Elizabeth Moore[1], Jennifer Singh[1], Dickens Theodore[3], Melanie Paff[1], Shihyun You[1] and Avijit Ray[1], (1)GSK, Collegeville, PA, USA, (2)GSK, Stevenage, UK, (3) GSK, Durham, NC, USA

Background: Bepirovirsen is an antisense oligonucleotide (ASO) targeting all hepatitis B virus (HBV) RNAs, and currently in Phase 3 development for chronic HBV infection. Phase 2 studies have demonstrated that bepirovirsen treatment induces loss of hepatitis B surface antigen (HBsAg) in a subset of participants (pts) as well as inducing serum immune activation. Here we sought to evaluate pts peripheral blood mononuclear cells (PBMC) post-hoc using deep immunophenotyping by high parameter flow cytometry from the Phase 2a study (NCT02981602), which included a 4-week treatment period. **Methods:** The samples included placebo-treated and bepirovirsen-treated pts (25 total pts) who experienced high (>2.0log), partial (>0.2 to **d** 2.0log) or no (**d** 0.2log) HBsAg reduction at a range of timepoints, which allowed us to detect changes in immune cells in blood during and following the treatment period. **Results:** During bepirovirsen treatment, pts with high HBsAg reduction had a greater proportion of PD1+ CD8 T cells compared with no HBsAg reduction pts, and there were also trends for elevated Granzyme B+ CD8 T cells at Day 15. After treatment, it was observed that high reduction pts had elevated TCF1+ CD4 and CD8 T cells, and there were trends for increased effector memory and Ki67+ CD4 T cells than no reduction pts. **Conclusion:** While the small sample size and high variation in this dataset limit our conclusions, this analysis provides a first glimpse of cellular immune characterization during bepirovirsen treatment. Our results suggest that pts with high HBsAg reduction may mount an enhanced T cell response with signs of superior proliferative potential after treatment. We will apply similar approaches to subsequent clinical studies to further elucidate immune responses in bepirovirsen-treated pts. Funding: GSK (study 205695; NCT02981602)

Background: Bulevirtide (BLV), a novel entry inhibitor, is approved in Europe for chronic hepatitis delta (CHD) treatment. Early results from a Phase 1b/2a study (MYR201) reported no correlation with antidrug antibody (ADA) development and the efficacy, safety, or pharmacokinetic (PK) profile of BLV. The potential for ADA development with BLV treatment was assessed in an integrated analysis of results from 2 Phase 2 studies (MYR203, MYR204) and 1 Phase 3 study (MYR301). **Methods:** The incidence of ADA development (ADA+) was defined as ADA negativity or missing at baseline with subsequent ADA positivity at any postbaseline visit and for this analysis was evaluated following BLV alone (2 or 10 mg) given subcutaneously once daily for 48W. Impact of ADA development on efficacy (virologic response [VR, defined as undetectable HDV RNA or decrease by **e** 2 $\log_{10}$ IU/mL from baseline], biochemical response [BR, defined as alanine aminotransferase (ALT) normalization], and combined response [CR; VR +BR]), safety, and PK were explored. W48 efficacy pooled data from MYR203 and MYR301, while adverse event and PK data were pooled across all 3 studies. **Results:** For the W48 efficacy analysis, 128 CHD patients showed similar incidences of ADA+ status among patients treated with BLV 2 or 10 mg (15/64 [23%] and 14/64 [22%]). VR for ADA+ vs ADA− patients was similar at BLV 2 mg (ADA+, 10/15 [67%] vs ADA−, 34/49 [70%]) and higher with BLV 10 mg (ADA+, 13/14 [93%] vs ADA−, 38/50 [76%]), respectively (Table). BR rates were similar by ADA status for both BLV 2 mg (ADA+, 9/15 [60%] vs ADA−, 27/49 [55%]) and BLV 10 mg (ADA+, 8/14 [57%] vs ADA−, 26/50 [52%]). Rates of CR among ADA+ and ADA− patients were similar among dose groups: BLV 2 mg, ADA+, 7/15 (47%) vs ADA−, 23/49 (47%); BLV 10 mg, ADA+, 7/14 (50%) vs ADA−, 23/50 (46%). BLV exposure (area under the plasma concentration-time curve [AUC]) between ADA+ and ADA− patients was similar for 2 mg, AUC_{ratio} (90% CI) = 1.22 (1.00-1.51) and for 10 mg, 1.12 (0.96-1.32). Of 177 patients in the safety analysis, among ADA+ patients, the rates of Grade 3 or higher treatment-emergent adverse events (TEAE) or hypersensitivity TEAEs were not higher and did not lead to BLV discontinuation. **Conclusion:** Development of ADA to BLV monotherapy did not impact efficacy, safety, or PK of BLV in CHD patients. Effect of ADAs on efficacy and safety of BLV will continue to be monitored in ongoing studies.

Background: PD-1/PD-L1 antibody-based therapies have demonstrated success in the treatment of liver cancer and have exhibited potential for effecting functional cure of chronic hepatitis B (CHB). However, the systemic immune-related adverse events (irAEs) associated with PD-1/PD-L1 antibodies can be life threatening, due to their long half-lives. Our first-generation liver targeted PD-L1 small molecule inhibitor, ALG-093702, activated PBMC from an HBV-infected patient *ex vivo* with similar activity to durvalumab and demonstrated *in vivo* antitumor efficacy in a human PD-L1 MC38 subcutaneous mice model. Further optimization led to our next generation liver targeting PD-L1 small inhibitor, ALG-094103, which has similar *in vitro* potency to ALG-093702 with excellent oral bioavailability. **Methods:** Biochemical interaction of PD-1/PD-L1 and PD-L1 dimerization were assessed by AlphaLISA®. Cellular activity was measured using a co-culture assay of PD-1 expressing Jurkat NFAT luciferase T cells with PD-L1 expressing CHO cells. Pharmacokinetic (PK) and tissue distribution studies were performed in C57BL/6 mice. *In vivo* PD-L1 target occupancy was assessed at 6 hours of post single dose in the humanized-PDL1 MC38 subcutaneous mouse model. **Results:** ALG-094103 is a novel liver targeted oral PD-L1 small molecule which inhibits the PD-1/PD-L1 axis similarly to PD-L1 antibodies. ALG-094103 has *in vitro* potency similar to ALG-093702 and a non-liver targeted PD-L1 small molecule inhibitor, INCB086550. In mice, ALG-094103 exhibited significantly improved oral bioavailability compared to ALG-093702 and INCB086550. In a mouse tissue distribution study, ALG-094103 showed higher liver concentrations vs. other tested tissues (liver/lung ratio of 17) at 12 hours after a single dose. In the *in vivo* PD-L1 target occupancy model, oral dosing of ALG-094103 at 50 mg/kg demonstrated higher PD-L1 target occupancy than oral dosing of INCB086550 at 150 mg/kg and IV dosing of durvalumab at 5 mg/kg. **Conclusion:** We have discovered a novel liver targeted oral PD-L1 small molecule inhibitor, ALG-094103, with similar *in vitro* potency to ALG-093702 and INCB08655, and with significantly improved oral bioavailability. ALG-094103 will be further evaluated as a potential candidate for drug development.

1467-C | EFFICACY AND SAFETY OF COMBINATION TREATMENT OF TLR7 AGONIST TQA3334 AND ANTI-PD-L1 TQB2450 IN VIRALLY SUPPRESSED CHRONIC HEPATITIS B PATIENTS: A PILOT RCT PHASE II STUDY (OCEAN cure05 STUDY)

Ting Wu[1], Di Wu[1], Yuying Chen[1], Da Huang[1], Zhize Yuan[1], Peng Wang[2], Zhongnan Xu[3], Shuna Wang[3], Dandan Huo[3], Weiming Yan[1], Meifang Han[1], Qin Ning[4] and Xiaojing Wang[5], (1)State Key Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan 430030, China, (2)State Key Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (3)Chia Tai Tianqing Pharmaceutical Group Co., Ltd, (4)Institute and Department of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, (5)Tongji Medical College and State Key Laboratory for Diagnosis and Treatment of Severe Zoonostic Infectious Disease, Huazhong University of Science and Technology

Background: Curing chronic hepatitis B (CHB) relies on the orchestration of innate and adaptive immunity in addition to profound viral replication suppression. TQA3334 is a selective toll-Like Receptor-7 (TLR-7) agonist and activates innate immune to induce specific cytokines and chemokines to inhibit hepatitis B virus (HBV), such as IFN-α and IFN-inducible protein-10. TQB2450, a PD-L1 antibody, inhibits PD-1/PD-L1 axis and rouses adaptive immune response to HBV. This phase II study (OCEAN cure05 Study) aimed to evaluate the efficacy and safety of nucleos(t)ide analog (NA) and TQA3334 combined with/without TQB2450 in CHB patients. **Methods:** Totally 24 viral-suppressed (250 **d** IU/ml HBsAg **d** 5000 IU/ml, HBV DNA < 100 IU/ml) CHB patients were randomized to receive NA (monotherapy, n = 6), NA+TQA3334 (dual therapy, n = 9) or NA+TQA3334+TQB2450 (triple therapy, n = 9). In each cohort, the hepatitis B e antigen (HBeAg)-positive and HBeAg-negative patients were enrolled in a ratio of 1:2. TQA3334 (1.2mg or 1.5mg, QW) and TQB2450 (400mg, Q3W) were administrated for 24 weeks, and NA was given throughout 24-week treatment and 24-week follow-up. The HBsAg (Roche Elecsys, lower limit of quantification = 0.05 IU/ml) reduction and adverse events (AEs) were evaluated. **Results:** One patient in dual therapy arm withdrew at week 6 due to personal reasons, and

23 patients completed the study. At the end of treatment (EOT), 4 (66.67%), 5(62.5%) and 8 (88.89%) patients received NA monotherapy, dual therapy and triple therapy had a reduction in HBsAg from baseline. Compared to NA monotherapy and dual therapy, triple therapy was associated with greater HBsAg reduction at EOT (0.04 ± 0.08, 0.04 ± 0.16, and 0.37 ± 0.50 log10 IU/ml). HBsAg reduction > 0.5 log10 IU/ml (n = 3) and HBsAg declined to < 100 IU/ml (n = 2) were only observed in triple therapy arm. In triple therapy group, high dose TQA3334 administration had a prominent HBsAg reduction (0.46 vs 0.32 log10 IU/ml) at EOT. The maximum HBsAg reduction in this study was 1.4 log10 IU/ml with a baseline HBsAg of 2767 IU/ml and administration of 1.5mg TQA3334. After TQA3334 and TQB2450 discontinuation, HBsAg remained lower than those of EOT in 62.5% (5 of 8) and 66.6% (6 of 9) of patients received dual therapy and triple therapy respectively at the end of follow-up (EOF). Treatment related AEs were developed in 5 patients received dual therapy and 8 patients received triple therapy. The grade 1 thyroiditis was the most common immune-related AEs in patients received TQB2450. Two grade 3 AEs (neutropenia in dual therapy group and elevated creatine phosphokinase in triple therapy group) were reported. However, all the events were resolved before EOF. No serious AE or death reported in current study. **Conclusion:** The combination of NA, TQA3334 and TQB2450 induced greater and more durable HBsAg decline in viral-suppressed CHB patients with good safety and tolerability. Moreover, high dose of TQA3334 promoted HBsAg reduction in triple therapy.

Background: JNJ-73763989 (JNJ-3989) reduces hepatitis B surface antigen (HBsAg) in chronic hepatitis B (CHB) patients, but seroclearance remained rare; functional cure may require adding an immune modulator. Approved treatments have limited effects on HBsAg and hepatitis B e antigen (HBeAg) in immune-tolerant patients with CHB. The phase 2 REEF-IT study (NCT04439539) assessed the safety and efficacy of PegIFN-α2a add-on to JNJ-3989 ± JNJ-6379+NA in treatment naïve HBeAg+ CHB patients with alanine transaminase (ALT) < 2× upper limit of normal (ULN). **Methods:** Patients received JNJ-3989 200 mg Q4W +NA ± JNJ-6379 250 mg QD, for 36–52 weeks (induction phase) followed by 12 weeks of PegIFN-α2a 180 mcg QW add-on (consolidation phase). Primary endpoint is proportion of patients with HBsAg seroclearance after 24 weeks after stopping of all treatment (NA stopped based on criteria at end of treatment [EOT]) Changes in viral markers (HBsAg,

HBV DNA, HBeAg) at EOT, with available Follow-up Week 24 (FU24) data, are presented. **Results:** 54 patients were enrolled (mean age 34 y; 69% with HBV DNA > 10^7 IU/mL and normal ALT); 49 (91%) completed EOT; 28 (52%) reached FU24. At EOT, mean (SE) HBsAg change from baseline (BL) was –3.61 (0.18) $\log_{10}$ IU/mL (Table). Mean (SE) HBV DNA change from BL was 6.24 (0.20) $\log_{10}$ IU/mL and 7/48 (15%) patients had HBeAg seroclearance. At FU24, mean (SE) HBsAg change from BL was –2.92 (0.37) $\log_{10}$ IU/mL (Table) and 21/28 (75%) patients on NA had HBV DNA < lower limit of quantitation. 10/54 (19%) patients had at least transient HBsAg sero-negativity; 7 remained HBsAg negative at the last available time point. Transient ALT and HBV DNA increases occurred during PegIFN-α2a add-on. Many patients showed increased HBsAg decline during or after PegIFN-α2a add-on. Treatments were generally safe and well tolerated with no serious adverse events (AEs) during treatment or, AEs leading to treatment discontinuation, or death; 3/49 (6%) and 0 patients experienced grade 3 and 4 AEs, respectively. **Conclusion:** In these treatment-naïve, HBeAg positive and mainly immune-tolerant patients, adding PegIFN-α2a increased HBsAg declines after levels were reduced by JNJ-3989. 19% of patients achieved transient HBsAg sero-negativity and 15% lost HBeAg.

Table. HBsAg change from baseline and thresholds achieved.

Study time point	N	Mean (SE) HBsAg change from baseline, $\log_{10}$ IU/mL	HBsAg threshold achieved, n (%)			HBsAg reduction from baseline threshold achieved, n (%)		
			<100 IU/mL	<10 IU/mL	<1 IU/mL	≥2 $\log_{10}$ IU/mL	≥3 $\log_{10}$ IU/mL	≥4 $\log_{10}$ IU/mL
End of induction* phase	47	–2.85 (0.13)	23 (48.9)	11 (23.4)	3 (6.4)	38 (80.9)	16 (34.0)	6 (12.8)
EOT (end of consolidation† phase)	49	–3.61 (0.18)	33 (67.3)	20 (40.8)	13 (26.5)	44 (89.8)	30 (61.2)	19 (38.8)
FU24‡	28	–2.92 (0.37)	12 (42.9)	8 (28.6)	7 (25.0)	15 (53.6)	9 (32.1)	7 (25.0)

EOT, end of treatment; FU24, Follow-up Week 24; HBsAg, hepatitis B surface antigen; ULN, upper limit of normal; SE, standard error.
*Includes JNJ-3989+NA±JNJ-6379 treatment phase.
†Includes 12 weeks with PegIFN-α2a added to JNJ-3989+NA treatment.

1469-C | EVALUATING THE EFFICACY OF PEGYLATED IFN-LAMBDA AND IFN-ALFA TREATMENTS ON HBV AND HDV INFECTIONS IN HUMANIZED MICE

Sarah Duehren[1], Takuro Uchida[2,3], Masataka Tsuge[3,4], Nobuhiko Hiraga[3], Abu Fahad Abbasi[1], Ohad Etzion[5], Jeffrey Glenn[6], Christopher Koh[7], Theo Heller[7], Scott J. Cotler[1], Kazuaki Chayama[8,9,10] and Harel Dahari[1], (1) The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, (2)Department of Gastroenterology, Faculty of Medicine, Oita University, Yufu, Japan, (3)Research Center for Hepatology and Gastroenterology, Hiroshima University, Hiroshima, Japan, (4)Department of Gastroenterology, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan, (5)Soroka University Medical Center, Beer-Sheba, Israel, (6)Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology & Immunology, Stanford School of Medicine, Stanford, California, USA, (7)Liver Diseases Branch, Niddk, Nih, USA, (8)Collaborative Research Laboratory of Medical Innovation, Hiroshima University, (9)Riken Center for Integrative Medical Sciences, (10)Hiroshima Institute of Life Sciences

Background: We recently reported that the early kinetics of HDV decline with pegylated IFN-λ (Lambda) therapy in chronic HDV-infected patients [Hepatology.2023;77(6):2093-2103] was dramatically greater than with pegylated IFN-α (Alfa) therapy [Hepatology.2014;60(6):1902-10]. We investigated HDV RNA, HBV DNA, HBsAg and human albumin (hAlb) kinetics during Lambda and Alfa treatment in chimeric urokinase type plasminogen activator (uPA)/severe combined immunodeficiency mice reconstituted with humanized livers. The aim was to compare the antiviral efficacy of Lambda and Alfa in humanized mice that lack an adaptive immune response. **Methods:** Thirteen mice from 3 separate studies were treated twice weekly with 30 μg/kg of either Alfa (n = 7) or Lambda (n = 6) for either 12 weeks (n = 10) or 13 weeks (n = 3). Ten mice were coinfected with HBV and HDV, and 3 were superinfected (HBV infection followed by HDV after 10 weeks). HBV DNA, HDV RNA, and hAlb levels were measured weekly, and HBsAg levels were measured biweekly. **Results:** Baseline median levels of HBV DNA, HDV RNA, hAlb, and HBsAg were 8.8 log IU/mL (interquartile range, IQR 0.2), 9.8 IU/mL (IQR 0.5), 6.9 log ng/mL (IQR 0.12) and 4.0 IU/mL (IQR 0.35), respectively. Baseline values were similar between mice treated with Alfa vs. Lambda, or superinfection vs. coinfection. One mouse treated with Alfa died after 1 week and was excluded from analysis. The remaining 12 mice (Alfa n = 6; Lambda n = 6) had analysis of on treatment kinetics. Regardless of type of IFN, HDV RNA had a longer delay in decline than HBV DNA, with medians of 3 (n = 6, IQR 1.18) weeks and 1 (n = 5, IQR 0.02) day, respectively (Fig. 1A and B). Thereafter, mice treated with Alfa experienced a significantly greater decline in HBV DNA ($p < 0.049$, Fig.1A), HDV RNA ($p < 0.041$, Fig.1B), and HBsAg ($p < 0.017$, Fig.1C), starting at weeks 9, 6, and 5 after initiation of treatment, respectively, until end of treatment (EOT). Overall, the magnitude of decline from baseline to EOT for HBV DNA was significantly greater than that of HDV RNA, with medians of 1.55 (IQR 1.18) and 0.79 (IQR 0.98) log IU/mL, respectively ($p = 0.013$), with no association with hAlb levels which remained approximately at baseline values (Fig.1D). **Conclusion:** In contrast to our findings in immune competent patients (ibid), Alfa was more effective than Lambda in decreasing HBV DNA, HDV RNA, and HBsAg during treatment in humanized mice that lack of an adaptive immune response, suggesting that Alfa induces stronger innate immune responses than Lambda. The respective roles of the combined innate and adaptive immune systems in the antiviral efficacy of Alfa and Lambda against HBV and HDV requires further study.

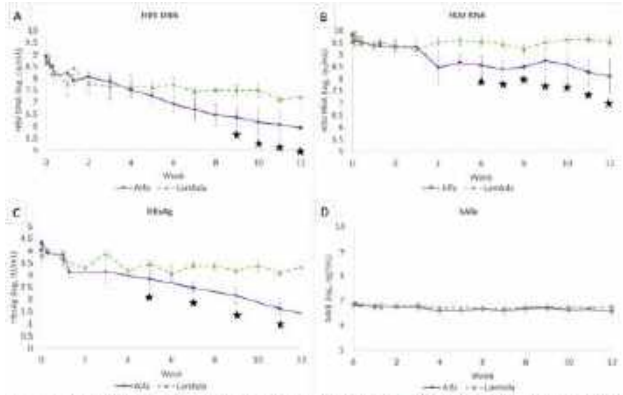

Figure 1. Median levels throughout Alfa or Lambda treatment in rDNA uPA/SCID humanized mice. Solid line= Alfa treatment; Dashed line= Lambda treatment; Error bars=interquartile range; Black stars= timepoint where Alfa median viral level is significantly ($p<0.05$) different from Lambda. There were no differences between Alfa and Lambda or co-infection and superinfection for hAlb throughout treatment. The kinetic picture includes one super-infected mouse that died after 7 weeks of Lambda treatment.

1470-C | GENOME-WIDE LOSS-OF-FUNCTION GENETIC SCREEN IDENTIFIES THE VULNERABILITY OF HBV-INTEGRATED HEPATOMA CELLS

Makoto Fukuoka[1], Takahiro Kodama[2], Hayato Hikita[1], Jihyun Sung[1], Akiyoshi Shimoda[1], Satoshi Shigeno[1], Kazuhiro Murai[1], Akira Nishio[1], Kunimaro Furuta[1], Tomohide Tatsumi[1] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2)Osaka University Graduate School of Medicine

Background: There are about 250 million people chronically infected with hepatitis B virus (HBV) worldwide. HBV is often integrated into the host genome and promotes hepatocarcinogenesis. In this study, we searched for the therapeutic vulnerability of HBV-integrated liver cancer cells using forward genetic screen. **Methods:** Loss-of function screen was performed in HepG2 and HBV-integrated HepG2.2.15 cells expressing SpCas9 cDNA using a pooled genome-wide clustered regularly interspaced short palindromic repeats (CRISPR) library. Genomic DNAs were extracted from these cells at immediately after the library infection (D2) and after 2-week culture (D14). They were sequenced to determine the abundance of each gRNA by a next-generation sequencer. Genes whose gRNA abundance significantly decreased in HepG2.2.15 cells but not in HepG2 cells were extracted using the MAGeCK algorithm. **Results:** We identified 38 genes potentially involved in the vulnerability of HBV-integrated cancer cells. We focused on 4 genes (BCL2L1, VPS37A, INSIG2, and CFLAR) that showed significant reductions of gRNA abundance. siRNA-mediated mRNA inhibition or CRISPR-mediated genetic deletion of INSIG2 significantly impaired cell proliferation in HepG2.2.15 cells but not in HepG2 cells. Its inhibitory effect was alleviated by co-transfection of siRNAs targeting HBV in HepG2.2.15 cells. INSIG2 inhibition suppressed the pathways related to cell cycle and DNA replication in HepG2.2.15 cells. INSIG2 inhibition downregulated CDK2 levels and delayed the G1-to-S transition in these cells. CDK2 inhibitor suppressed cell cycle progression in HepG2.2.15 cells and INSIG2 inhibition did not suppress cell proliferation in the presence of CDK2 inhibitor. **Conclusion:** INSIG2 inhibition induced cell cycle arrest in HBV-integrated hepatoma cells in CDK2-dependent manner, and thus might be a potential therapeutic for HBV-associated liver cancer.

1471-C | HBV IMMUNE CHECKPOINT RECEPTOR CD33 (SIGLEC-3) IS A PROMISING THERAPEUTIC TARGET FOR CHRONIC HEPATITIS B INFECTION

Pei-Shan Sung[1,2], Chieh-Ju Lee[3], Yi-Hsiang Huang[3], Chang-Ru Wu[4] and Shie-Liang Hsieh[1], (1)Academia Sinica, (2)Academia Sinica, Taoyuan City, Taiwan, (3)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, (4)Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University

Background: Currently, approximately 300 million people worldwide suffer from chronic hepatitis B (CHB), and the primary treatment option is antiviral nucleos(t)ide analogues. However, these treatments are seldom successful in stimulating the generation of anti-HBsAg antibody (HBsAb) that can effectively cure patients. In our previous study, we reported that CD33 (Siglec-3) serves as an immune checkpoint that triggers immunotolerance by binding to the sialic acid of HBsAg (hepatitis surface antigen). In CHB patients, a distinct group of B cells expressing CD33 was observed. Given the immune suppressive role of CD33, the hypothesis was that CD33 could be suppressing the production of HBsAb in B cells. **Methods:** We created a high-affinity antagonistic monoclonal antibody against CD33 (clone 4H33A) using a phage display platform. We evaluated its effectiveness in inducing HBsAb production by incubating it with PBMC and B cells from CHB patients. Subsequently, we analyzed the B cell subsets in PBMCs through flow cytometry after exposing them to 4H33A. We examined if there is a positive correlation between the level of HBsAg and HBV DNA in the blood and the production of HBsAb induced by 4H33A. Additionally, we calculated the correlation between HBV DNA, HBsAg, $CD33^+$ B cells percentage, and the response to anti-CD33 mAb that triggers HBsAb production. Furthermore, we established a hydrodynamic injection mouse model in which we administered AAV/HBV1.2 and AAV/HBV1.2-Y132A (HBcAg mutant strain) in wild-type (WT) and human CD33 transgenic mice (hCD33 Tg). We aimed to investigate whether the presence or absence of human CD33 affects the clearance of HBsAg and the efficacy of 4H33A in vivo. **Results:** Our results showed that the anti-CD33 monoclonal antibody 4H33A effectively induced the production of HBsAb in ex vivo assays, as demonstrated by PBMC/B cell ELISPOT and ELISA analyses. Additionally, after incubation for 5 days, 4H33A reduced the percentage of $CD33^+S100A9^+$ B cells, activated memory B cells, and atypical memory B cells. Furthermore, a positive correlation was observed between higher levels of HBV DNA and $CD33^+$ B cells

and a better response to the anti-CD33 monoclonal antibody 4H33A in promoting HBsAb production in ex vivo assays. In human CD33 transgenic mice, the presence of human CD33 extended the persistence of HBsAg, whereas treatment with the anti-CD33 monoclonal antibody 4H33A led to the clearance of HBsAg. **Conclusion:** Targeting CD33, which acts as an immune checkpoint receptor for HBV-induced immune tolerance, shows great potential as a strategy for reactivating the host's immune system to eliminate HBV in patients with CHB.

1472-C | IMPACT OF HBCAG SPECIFIC CTL ON HBsAg REDUCTION AFTER NASAL ADMINISTRATIVE THERAPEUTIC VACCINE TREATMENT IN CHRONIC HEPATITIS B PATIENTS

Kana Shiraishi, Ehime University Graduate School of Medicine

Background: The treatment goal of chronic hepatitis B (CHB) is HBs antigen (HBsAg) elimination, however it is difficult to achieve the goal with interferon and nucleos(t)ide analogues (NAs). We have developed a nasal administrative therapeutic vaccine containing HBs/HBcAg mixed viscosity enhancer (CVP-NASVAC). We conducted clinical trials of CVP-NASVAC against CHB and reported its capacities of HBsAg reduction and anti-HBs induction. In this study, we explored the immunological mechanism of CVP-NASVAC on HBsAg reduction. **Methods:** Fifty CHB patients (21 with NAs and 29 without NAs) participated in our clinical trial. Participants received total 10 doses of CVP-NASVAC via nose. We investigated the rate of HBsAg reduction/loss, anti-HBs induction including IgA-type by ELISA, and HBcAg-specific CTL by ELISPOT. The data or samples were obtained up to 54 months after the end of treatment. **Results:** At the 18 months after CVP-NASVAC administration, HBsAg was reduced in 64.7% (11/17) patients with NAs and 75.0% (15/20) without NAs, and HBsAg loss was observed in 1/21 with NAs and 3/29 without NAs. Anti-HBs was induced in 14.3% (3/21) with NAs and 42.9% (12/28) without NAs. IgA type anti-HBs titer and the number of HBc-specific interferon γ producing CTL were significantly elevated after CVP-NASVAC treatment in both with and without NAs. Interestingly, significant correlation was observed between the CTL increase and HBsAg reduction in CHB patients with NAs ($p < 0.005$). **Conclusion:** HBcAg-specific CTL induction might be an important immunological mechanism for reducing HBsAg in CHB patients under NAs treatment.

Background: Bulevirtide (BLV) is a novel entry inhibitor that is approved in Europe as therapy for patients with chronic hepatitis D (CHD). The impact of BLV on noninvasive tests (NITs) has not been fully explored. **Methods:** A longitudinal analysis was conducted using pooled data from Phase 2 MYR204 (NCT03852433) and Phase 3 MYR301 (NCT03852719) studies. The change in ALT, FIB-4, APRI, and liver stiffness measurements (LSM) was assessed in CHD patients treated with BLV monotherapy (2 and 10 mg) for 96 weeks (W). The change of NITs across HDV RNA virologic response groups at 96W were also compared:

viral responders (VR, defined as undetectable HDV RNA or **e** 2-$\log_{10}$ IU/mL decline from baseline [BL]), partial VR (PVR, defined as **e** 1-$\log_{10}$ IU/mL but < 2-$\log_{10}$ IU/mL decline from BL), and nonresponders (NR, defined as < 1-$\log_{10}$ IU/mL decline from BL). Results are reported as median (Q1, Q3) unless otherwise stated. **Results:** In total, 149 CHD patients treated with BLV monotherapy (49 BLV 2 mg, 100 BLV 10 mg) were included in this analysis. At BL across the total cohort, the ALT was 93 (64, 136) U/L, gamma-glutamyl transferase was 51 (28, 73) U/L, FIB-4 was 1.7 (1.3, 2.5), APRI score was 1.0 (0.7, 1.6), and LSM was 11.4 (8.8, 15.5) kPa. The mean (SD) HDV RNA and platelet count were 5.2 (1.3) $\log_{10}$ IU/mL and 164 (51.0) 10^9/L. In the total cohort, improvements were seen in ALT and NITs at W96: ALT change from BL, −55 (−97, −25) U/L; W96 ALT, 34 (26, 44) U/L; FIB-4 change from BL, −0.4 (−0.9, −0.1); W96 FIB-4, 1.2 (0.9, 1.9); APRI change from BL, −0.5 (−1.0, −0.2); W96 APRI, 0.5 (0.3, 0.8); LSM change from BL, −3.3 (−6.1, −1.3) kPa; and W96 LSM, 7.7 (5.8, 11.1) kPa. Improvements in ALT and NITs were seen across all viral-response groups including PVR (n = 15) and NR (n = 11) at 96W, with continued declines between 48 and 96W in most cases (Figure 1). Among PVR, changes from BL were: ALT, −57 (−148, −29) U/L; FIB-4, −0.3 (−0.6, 0.2); APRI, −0.6 (−0.9, 0.0); and LSM, −2.5 (−4.3, −1.1) kPa. Among NR, changes from BL were: ALT, −63 (−102, −14) U/L; FIB-4, −0.4 (−1.4, 0.0); APRI, −0.6 (−1.5, 0.0); and LSM, −2.5 (−6.3, −1.7) kPa. **Conclusion:** Treatment of CHD patients with either dosage of BLV monotherapy through 96W resulted in longitudinal improvements in NITs, with greater improvement in the first 48W. These improvements were seen even among those without viral response.

Figure 1. Improvements in ALT, FIB-4, APRI, and LSM Through Week 96 by Viral Response Category
(A) LSM, (B) ALT, (C) APRI, (D) FIB-4
Values expressed in median (Q1, Q3)
ALT, alanine aminotransferase; LSM, liver stiffness measurement; PVR, partial viral responders (defined as ≥1-$\log_{10}$ IU/mL but <2-$\log_{10}$ IU/mL decline from baseline but not undetectable); NR, non-viral responders (NR, defined as <1-$\log_{10}$ IU/mL decline from baseline); VR, viral responders (undetectable HDV RNA and/or ≥2-$\log_{10}$ IU/mL decline from baseline)

Perron, Michael A. Walker, William Delaney, Min Zhong and Ken Zhang, Assembly Biosciences, Inc., South San Francisco, CA

Background: Interferon alpha (IFNα) has immunomodulatory and broad antiviral activities and has been shown to lead to HBV surface antigen (HBsAg) clearance (functional cure) in a subset of patients. However, the poor tolerability of injectable, systemically administered IFNα limits its clinical use. To overcome these limitations, we are optimizing a class of small molecule IFNα receptor (IFNAR) 2 agonists. Here we report the preclinical profiling of selected orally bioavailable small molecules that mimic an IFNα response *in vitro* and *in vivo*. **Methods:** The half-maximal effective concentrations (EC_{50}s) for HBV and HCV inhibition were measured in infected primary human hepatocytes (PHHs) and Huh-7 replicon cells by HBeAg enzyme-linked immunosorbent assay (ELISA) and reporter activity, respectively. Time- and dose-dependent interferon-stimulated gene (ISG) induction in PHHs was assessed by gene expression analysis. *In vitro* cytokine secretion from human peripheral blood mononuclear cells (PBMCs) was assessed by ELISA. The phosphorylation pattern of STATs was evaluated in hepatoma cells by ELISA and Western blot. Compound concentrations and ISG induction in the liver and serum/PBMCs were determined in mouse pharmacokinetic and pharmacodynamic (PK/PD) studies, respectively. **Results:** Novel small molecules were identified with distinct structural elements that inhibited HBV (EC_{50} = 0.8–11.7 mM) and HCV (EC_{50} = 0.008–0.2 mM) in a dose-dependent manner. A representative compound induced ISGs in PHHs at 0.1, 1, and 10 mM dose-dependently. Furthermore, at 10 μM compound, the ISG induction strongly correlated with 1000 IU/mL IFNα at 6 h and 24 h post-treatment (R^2 = 0.91 and 0.83, respectively). Cytokine secretion and STAT phosphorylation patterns induced by the small molecules also mimicked IFNα treatment in PBMCs and human hepatoma cells. PK/PD studies demonstrated that a representative compound has a liver-to-plasma ratio of approximately 5- to 7-fold at 6 h and 24 h post-dosing in mice treated with 100 mg/kg and efficiently induced ISGs, mimicking the ISG profile induced by 60,000 IU murine IFNα in a dose- and time-dependent manner (R^2 = 0.60–0.77 between 0.1–100 mg/kg). **Conclusion:** Novel, orally bioavailable small molecules are able to activate IFN signaling *in vitro* and *in vivo* and inhibit HBV replication in PHHs. Lead optimization is ongoing with the objective of nominating a development candidate for treatment of chronic HBV.

Background: Hepatitis B surface antigen (HBsAg) loss is key to achieving functional cure of chronic hepatitis B virus (HBV) infection. In the B-Clear study, 24-week treatment with 300 mg bepirovirsen (BPV), an antisense oligonucleotide, induced sustained HBsAg and HBV DNA loss in 9–10% of participants (pts) with chronic

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

HBV infection, with higher response rates in pts with lower HBsAg levels. This analysis examined characteristics of those with HBsAg decline to below the lower limit of quantification (LLOQ; 0.05 IU/mL). **Methods:** B-Clear was a Phase 2b, randomized study in pts with chronic HBV infection on stable nucleos(t)ide analog (NA) therapy (On-NA; N = 227) or not on NA therapy (Not-on-NA; N = 230). Pts received up to 300 mg BPV once weekly for 12 or 24 weeks with/without loading dose. Primary endpoint was the proportion of pts who achieved HBsAg and HBV DNA < LLOQ, sustained for 24 weeks after BPV treatment end in the absence of newly initiated antiviral treatment. A pre-specified modified primary endpoint permitted 'blips', i.e., single-timepoint increases in HBsAg or HBV DNA **e** LLOQ in the off-treatment period after becoming unquantifiable. This post hoc analysis explored pts who had a blip at any timepoint (on- or off-treatment), categorized as: 1) no blip (no HBsAg increase following HBsAg < LLOQ); 2) reached HBsAg < LLOQ then had **e** 1 blip but maintained HBsAg < LLOQ at all subsequent timepoints; 3) HBsAg increase at last off-treatment visit (potentially maintained HBsAg loss); 4) blip then sustained HBsAg increase (rebound). Treatment groups were pooled. **Results:** There were 22 pts with no blips (group 1: 12 On-NA, 10 Not-on-NA), 9 pts (group 2: 3 On-NA, 6 Not-on-NA) with **e** 1 blips and subsequently maintained HBsAg loss, 4 pts (group 3: 2 On-NA, 2 Not-on-NA) with HBsAg increase at the last visit, and 12 pts (group 4: 8 On-NA, 4 Not-on-NA) with blips then a rebound. Example pt profiles are shown in Figure. Numerical differences in pt characteristics between groups were observed but pt numbers were small. **Conclusion:** In this initial exploration, there were comparable number of pts with sustained HBsAg loss versus those with blips; however, low pt numbers limit interpretation of pt characteristics. Pts who had a blip were comparably split between those who rebounded, and those who maintained or potentially maintained HBsAg loss. Further investigation into the durability of effect with respect to blips is needed. Funding: GSK (study 209668)

1476-C | IS IT USEFUL TO ADD PEG-IFN IN POOR RESPONDER PATIENTS TO BULEVIRTIDE 2 MG? RESULTS FROM THE FRENCH MULTICENTER EARLY ACCESS PROGRAM

Victor De Ledinghen[1], Marie-Noelle Hilleret[2], Sophie Métivier[3], Louis D'Alteroche[4], Christiane Stern[5], Xavier Causse[6], Si Nafa Si Ahmed[7], Eric Billaud[8] and Juliette Foucher[1], (1)CHU Bordeaux, Bordeaux, France, (2) CHU Grenoble, (3)Service d'Hepatologie, CHU Rangueil, Université Toulouse 3, (4)CHU Tours, (5) Service d'Hépatologie, Hôpital Beaujon, (6)CHU Orléans, (7)Hopital Saint Joseph, (8)CHU Nantes

Background: Significant HDV RNA decline was observed in HBV/HDV patients who received 48 weeks of Bulevirtide (BLV) in monotherapy or in combination with PEG-interferon α 2a (PEG-IFNα) in the French early access program. However, some patients are poor virological responder. No data are available of adding PEG-IFN in poor responders to 2 mg BLV. The aim of this analysis was to evaluate the efficacy and safety of the adjunction of PEG-IFN in poor responder patients to BLV 2 mg. **Methods:** 11 patients (male 63.7%, mean age 37 y, cirrhosis 27.3%, median HDV-RNA at inclusion (day 0 BLV) 6.81 log_{10} IU/mL, after a median time of treatment with BLV 2 mg of 6 (extremes:3-12) months, with chronic HBV/HDV infection, with compensated cirrhosis/severe fibrosis or moderate fibrosis with elevated ALT levels, were included in this study. Patients received BLV 2mg qd sc in combination with PEG-IFNα once weekly sc (90 to 180 mg). **Results:** No specific side-effects were reported. At Day 0 of adjunction of PEG-IFN, median HDV RNA was 5.21 log_{10}IU/ml and median ALT level 46 IU/L (4/10 patients had ALT level < 40 IU/L). Median decline of HDV RNA between day 0 BLV and day 0 PEG-IFN was -1.57 log_{10} IU/ml (extremes: -2.49 - +1.2), 8/11 patients (72.7%) with < 2 log_{10} decline. Main results (per protocol analysis) are indicated in Table. At M6 and M12, median HDV-RNA was 1.98, and 0 log_{10} IU/ml. All cirrhotic patients had undetectable HDV-RNA. Only three patients (without cirrhosis) did not have undetectable HDV-RNA after 12 months of BLV + PEG-IFN. Among them, one patient received only 3 months of PEG-IFN. The two other patients had less than 1 log_{10}decline between day 0 BLV and day 0 PEG-IFN. **Conclusion:** In this first real-world cohort of HDV patients, weekly administration of PEG-IFN in poor responder patients to BLV 2 mg was safe and well tolerated. More than 2 out of 3 patients had undetectable HDV-RNA after 12 months of combined therapy. These preliminary results should be confirmed but are an encouraging option for poor responder patients to BLV 2 mg.

1477-C | MATHEMATICAL MODELING OF HDV RNA, ALT AND HBsAg KINETICS SUGGESTS A DUAL MODE OF ACTION OF PEGINTERFERON LAMBDA: THE LIMT-1 STUDY

E. Fabian Cardozo-Ojeda[1,2], Sarah Duehren[1], Scott J. Cotler[1], Saeed S. Hamid[3], Yoav Lurie[4], Edward J. Gane[5], Anat Nevo-Shor[6], David Yardeni[6], Ingrid Choong[7], Jeffrey Glenn[8], Harel Dahari[1] and Ohad Etzion[6], (1)The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, (2) Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Research Center, Seattle, USA, (3) Aga Khan University Hospital, Karachi, Pakistan, (4) Shaare Zedek, Jerusalem, Israel, (5)Auckland Clinical Studies, (6)Soroka University Medical Center, Beer-Sheba, Israel, (7)Eiger BioPharmaceuticals, Inc., (8) Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology & Immunology, Stanford School of Medicine, Stanford, California, USA

Background: The recent LIMT-1 study demonstrated the safety and efficacy of Peginterferon Lambda (Lambda) monotherapy for chronic HDV (Hepatology.2023;77(6):2093-2103). Here we sought to predict Lambda mechanisms of action and efficacy using mathematical modeling of measured HDV RNA, ALT and HBsAg kinetics. **Methods:** 33 chronic HDV infected patients participated in the LIMT-1 study of Lambda 120 μg (n = 19) or 180 μg (n = 14), administered once weekly by subcutaneous injection for 48 weeks, with 24 weeks of follow-up. All were on entecavir or tenofovir treatment throughout the study. Samples were measured at baseline at weeks 1, 2 and 4 and every four weeks during and post Lambda therapy. 11 participants were excluded from analysis due to treatment null response (n = 3), HDV below detection at baseline (n = 3), or Lambda discontinuation. We evaluated models with or without proliferation of hepatocytes and Lambda blocks virus production and/or mediates death of HDV-infected cells. **Results:** We identified a mathematical model with hepatocyte proliferation that best describes HDV, ALT and HBsAg kinetics. The model recapitulates the three main HDV kinetic patterns under Lambda: (i) viral suppression, i.e., viral decline below limit of quantification, LOQ (n = 12, Fig. 1a), (ii) viral decline followed by a plateau above LOQ, termed flat-partial response (n = 3, Fig. 1b), and (iii) viral decline followed by a rebound not related to Lambda-dose reduction (n = 7, Fig. 1c). Modeling predicted that in participants with viral suppression Lambda blocks viral production with a median e = 98.6% efficacy (IQR: 81.6%-99.3%). The model reproduced the flat-partial response (Fig. 1b) and rebound (Fig. 1c) kinetic patterns, with a median suboptimal efficacy of e = 68.0% (IQR: 46.8%-92.0%), which was below each patient's critical drug efficacy (e_c) needed to reach viral suppression. Modeling predicted that viral rebound can occur during suboptimal therapy, if the number of hepatocytes susceptible to HDV infection (target cells) increases during therapy. To reproduce the ALT flares (Fig. 1a) the model estimated that Lambda increases the death rate of HDV-infected cells by a median of 1.7-fold (ranging from 1- to 6.7-fold, Fig. 1). Assuming that HBsAg levels were proportional to the sum of the infected target cells, the observed stability of HBsAg was explained by no significant change in the sum of HDV-infected and target cell number that produce HBsAg under Lambda therapy due to hepatocyte homeostasis. **Conclusion:** This study provides, for the first time, a dynamic description of HDV RNA, ALT and HBsAg response under Lambda monotherapy. Modeling suggests that Lambda blocks HDV viral production and mediates an increase in the death of HDV-infected cells that requires further study.

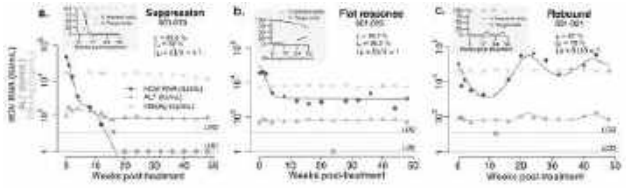

Figure 1. Illustrative examples of best model fits during Lambda therapy. (a) HDV suppressed below the limit of detection, (b) flat-partial response of HDV, and (c) HDV RNA decline followed by a rebound to pre-treatment levels. The grey inset figure on the top-left of each panel describes the model prediction of the percentage of infected and target hepatocytes (solid and dashed lines, respectively). Model predictions are represented by the dark, medium and light grey solid lines. ε describes the Lambda effectiveness in reducing virus production; ε_c denotes the critical drug efficacy; $\varepsilon > \varepsilon_c$ leads to virus suppression and $\varepsilon < \varepsilon_c$ leads to flat-partial response or rebound (μ=0)%, represents the fold increase in the death rate of infected cells mediated by Lambda. HDV clearance from blood and HDV-infected hepatocytes basal death rates were fixed to 0.43 day^{-1} and 0.65 day^{-1}, respectively. LOQ: limit of quantification (14 IU/mL) and LOD: limit of detection (1 IU/mL). The model was simultaneously fit with measured HDV, ALT, and HBsAg kinetic data using a nonlinear mixed-effects approach.

1478-C | MECHANISTIC PK/PD MODELING AND SIMULATION OF BEPIROVIRSEN, HBsAg, AND ALT AFTER SEQUENTIAL BEPIROVIRSEN-PEGYLATED INTERFERON A-2a THERAPY TO INFORM PHASE 3 STUDY DESIGN: B-TOGETHER STUDY

Amir Youssef[1], Mohamed Ismail[2], Donald E Mager[2,3], Mindy Magee[1], Susan Dixon[4], Dickens Theodore[5], Melanie Paff[6] and Ahmed Nader[1], (1)Clinical Pharmacology Modeling and Simulation, GSK, Collegeville, PA, USA, (2)Enhanced Pharmacodynamics LLC, Buffalo, NY, USA, (3) Department of Pharmaceutical Sciences, University at Buffalo, SUNY, Buffalo, NY, USA, (4)Development Clinical Sciences Hepatology/GI, GSK, Stevenage, Hertfordshire, UK, (5)GSK, Durham, NC, USA, (6)GSK, Collegeville, PA, USA

Background: Bepirovirsen (BPV; GSK3228836), an antisense oligonucleotide, inhibits all HBV RNAs resulting in reduction of hepatitis B surface antigen (HBsAg) levels. BPV monotherapy (300 mg for 24 weeks [wks]) met its primary endpoint (PE) (HBsAg < LLOQ and HBV DNA < LLOQ) in 9% of participants (pts) in B-Clear who remained on stable nucleos[t]ide (NA) analogs. A pharmacokinetic (PK)/pharmacodynamic (PD) model, previously developed for BPV monotherapy, was adapted to describe the changes in HBsAg after BPV-Pegylated Interferon α-2a (PegIFN) sequential therapy in B-Together. The model simulated HBsAg responses under different study designs, populations, and dose regimens. **Methods:** In B-Together, BPV (300 mg) was administrated weekly for 12 or 24 wks (with loading doses on Days 4 and 11), followed by 24 wks of PegIFN 180 mcg weekly for 24 wks to pts on stable NA therapy. The PE was assessed 24 wks after the end of PegIFN treatment. The effect of PegIFN in preventing relapse in pts who achieved virologic response (VR; HBsAg < LLOQ) at BPV treatment end was added to the model. The probability of a PegIFN effect (being sensitive to PegIFN) was estimated based on observed differences in achieving PE between Phase 2b study 209668 (B-Clear) and sequential BPV-PegIFN Phase 2b study 209348 (B-Together). ALT changes after both BPV and PegIFN were captured in the model. Simulations were conducted to describe response in all pts receiving sequential BPV-PegIFN treatment. **Results:** The model accurately captured the time-course of HBsAg and ALT after sequential BPV-PegIFN treatment; incorporation of B-Together data confirmed previous findings on predictors of response. Only baseline HBsAg was a statistically significant and clinically relevant predictor of response for BPV. Increase of ALT after BPV was described through an indirect mechanism (through reduction in HBsAg) whereas increase in ALT after PegIFN was captured in the model by a direct drug effect. Simulation results for 24- and 12-week arms are presented in the Table. **Conclusion**: The PK/PD model described HBsAg and ALT changes after sequential BPV-PegIFN treatment. Simulation results were generated to predict response rates for different study designs, populations, and dosing regimens. Funding: GSK (study 209348)

Table: Summary of simulated HBsAg response for different study design and dosing regimens in CHB participants with baseline HBsAg ≤3000 IU/mL assuming a PegIFN sensitivity of 24%*

		Participants with HBsAg response** (%)	
Study Design	Bepirovirsen dosing regimen	EOT	EOS
All participants receive PegIFN at end of BPV treatment	Bepirovirsen 300 mg weekly x 24 weeks with LD, then Peg-IFN 180 µg weekly x 24 weeks	27.7	24.8
	Bepirovirsen 300 mg weekly x 12 weeks with LD, then Peg-IFN 180 µg weekly x 24 weeks	24.4	21.5

*PegIFN sensitivity is defined as probability of preventing relapse in participants who achieved VR at the end of BPV treatment calculated as observed differences in achieving PE between Phase 2b study 209668 (B-Clear) and sequential BPV-PegIFN Phase 2b study 209348 (B-Together).
**HBsAg response defined as being below LLOQ = −1.3 $\log_{10}$ IU/mL (0.05 IU/mL)

BPV, bepirovirsen; CHB, chronic hepatitis B; EOT, end of PegIFN treatment (Week 36 or Week 48); EOS, end of study (60 weeks post end of BPV treatment: Week 72 or Week 84); HBsAg, hepatitis B surface antigen; LD, loading dose; LLOQ, lower limit of quantification; PE, primary endpoint; PegIFN, pegylated interferon; VR, virologic response; wk, week.

1479-C | PANGENOMIC ANTIVIRAL EFFECT OF REP 2139 IN CRISPR/Cas9 ENGINEERED CELL LINES EXPRESSING HEPATITIS B VIRUS HBsAg

Lena Angelo[1], Matthieu Blanchet[1,2], Andrew Vaillant[2] and Patrick Labonte[1], (1)Inrs-Centre Armand-Frappier Santé Biotechnologie, (2)Replicor Inc.

Background: Hepatitis B virus remains a global health problem with 296 million people living with chronic infection who are at increased risk of developing liver inflammation, cirrhosis and hepatocellular carcinoma. Subviral particles (SVP) are produced in large excess over Dane particles in patients and are the major source of HBsAg. SVPs inhibit /exhaust the immune response to HBV infection. Re-establishment of immune control of HBV (functional cure) requires the clearance of HBsAg from blood of patient. Nucleic acid polymers (NAPs) inhibit the assembly/release of SVP, resulting in rapid clearance of HBsAg from circulation *in vivo* and *in vitro* and in human studies. However, their efficacy has only been demonstrated in limited genotypes in phase IIA clinical trials. HBV exists as nine main genotypes (A to I), and our study assesses the activity of the lead NAP, REP 2139, in the most prevalent genotypes (A, B, C, D, E, G), which account for over 96% of chronic HBV infection. **Methods:** HBsAg ORFs from the previously mentioned genotypes were inserted into the AAVS1 safe-harbor of HepG2 cells using CRISPR/Cas9 knock-in. A cell line producing the D144A vaccine escape mutant was also engineered. The secretion of HBsAg into these new genotype cell lines (GCLs) was confirmed by immunofluorescence and ELISA. The antiviral activity of REP 2139 was then assessed in these GCLs by evaluating HBsAg secretion in the supernatant by ELISA. **Results:** The results show an efficient inhibition of HBsAg secretion in all GCLs. We demonstrate that REP 2139 exerts an antiviral effect in all genotypes and serotypes tested in this study, including in the vaccine escape mutant D144A. EC_{50} for REP 2139 against every genotype assessed in this study was in the nanomolar range, which is in line with previous *in vitro* and clinical studies. **Conclusion:** CRISPR/Cas9 was used to create in vitro HepG2-derivative cell lines expressing HBsAg from various genotypes and serotypes. Our results suggest that REP 2139 has a pangenomic antiviral effect, as well as an antiviral effect for vaccine escape mutants.

1480-C | PHARMACOKINETICS AND SAFETY OF VIR-2218 MONOTHERAPY IN ADULT CIRRHOTIC PARTICIPANTS WITH MODERATE HEPATIC IMPAIRMENT

Li Wang, Michael A. Chattergoon, Sophia Elie, Pan Wu, George Hristopoulos, Sneha Gupta and Maribel Reyes, Vir Biotechnology, Inc

Background: VIR-2218 is an investigational, N-acetyl-galactosamine (GalNAc)–conjugated, double-stranded RNA interference (RNAi) therapeutic that targets a region of the hepatitis B virus (HBV) genome that is common to all HBV viral RNA transcripts. VIR-2218 is in clinical development for the treatment of chronic HBV and HDV infection. We have previously demonstrated that VIR-2218 administered every 4 weeks at 200 mg subcutaneously (SC) results in sustained reductions in HBsAg. Here, we report the pharmacokinetics (PK) and safety of VIR-2218 in cirrhotic participants who have hepatic impairment (HI) with Childs-Pugh-Turcotte Class-B (CPT-B) score. **Methods:** VIR-2218-V107 (NCT05484206) is a Phase 1, open-label, single-dose parallel-group study. Adult participants with CPT-B HI and healthy participants (HV) were demographically matched. Participants received a single SC dose of VIR-2218 at 200 mg. Blood samples were collected up to 8 weeks and pooled urine samples were collected over 72 hours post-dose to measure the concentrations of VIR-2218 and its major metabolite, AS(N-1)3'VIR-2218. PK parameters were estimated using non-compartmental analysis in WinNonlin®. Safety and tolerability were monitored throughout the study. **Results:** Eight (8) cirrhotic participants with CPT-B HI and 8 HV were enrolled. The geometric mean ratios (GMR) of C_{max}, AUC_{last} and AUC_{inf} of VIR-2218 in CPT-B participants (test) vs. HV (reference) were 1.7, 2.1 and 1.9, respectively. Similarly, the GMR of C_{max} and AUC_{last} of VIR-2218 major metabolite AS(N-1)3'VIR-2218 in CPT-B participants vs. HV were 2.1 and 2.4, respectively. Accordingly, fraction of VIR-2218 and metabolite excreted in urine were higher in CPT-B participants vs. HV. Two SAEs of thrombocytopenia (Grade 4) in 1 participant were reported and resolved within 7 days with platelet transfusion. They were consistent with underlying cirrhosis and were considered unrelated to VIR-2218. There were no clinical cardiovascular events. **Conclusion:** A single dose of VIR-2218 at 200 mg was generally well tolerated in participants with moderate CPT-B HI. VIR-2218 exposures were higher in CPT-B participants vs HV. However, based on collective PK and safety data, no

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

dose adjustment is warranted for VIR-2218 in CPT-A and CPT-B participants. PK and safety from a single dose of VIR-2218 support continued evaluation of 200 mg VIR-2218 in participants with HBV and HDV infection with up to moderate CPT-B HI.

1481-C | PRECLINICAL CHARACTERIZATION OF THE NOVEL, ORALLY BIOAVAILABLE NTCP INHIBITOR A7387

Ellen Strängberg[1], Britta Bonn[1], Phuong Phan[1], Ivana Uzelac[1], Ingemar Starke[1], Runa Pal[2], Ashwani Gaur[2], Ramesh Kangarajan[2], Shivendra Singh[2], Santosh Kulkarni[2], Paul A. Dawson[3] and Erik Lindström[1], (1) Albireo Pharma, Inc., (2)Syngene International Ltd., (3) Emory University

Background: Na^+-taurocholate co-transporting polypeptide (NTCP) is a hepatocyte sinusoidal membrane bile acid (BA) transporter. In addition to its major role in hepatocellular clearance of BAs, NTCP is used by hepatitis B and D viruses (HBV, HDV) to enter and infect human hepatocytes. We evaluated the effects of A7387 on the inhibition of BA uptake and HBV entry. **Methods:** NTCP and the related BA transporter apical sodium-dependent BA transporter (ASBT) from human were expressed in cell lines. Inhibition by A7387 was studied using [^{3}H]taurocholate as substrate. Cryopreserved human hepatocytes infected with a clinical isolate of HBV were used for infection experiments. Two female non-human primates (NHPs) were dosed with A7387 via oral gavage at dose levels of A7387 ranging between 3−30 mg/kg once daily for 5 days. Total serum, urine, and fecal BAs were analyzed enzymatically and A7387 plasma concentrations were assessed via liquid chromatography−tandem mass spectrometry. The oral pharmacokinetics of A7387 was also studied in mice, rats, and dogs. **Results:** A7387 had half-maximal inhibitory concentration (IC_{50}) values of 3.4 and 193 nmol/L vs human NTCP and ASBT, respectively. A7387 prevented HBV infection of human hepatocytes with an IC_{50} of 13.5 nmol/L without affecting cell viability. In NHPs, plasma exposure of A7387 increased with dose, and serum BAs increased in a dose-dependent manner in response to oral dosing of A7387 on both Day 1 and Day 5. Doses of 10 and 30 mg/kg A7387 evoked increases in serum BAs lasting for at least 8 hours on both Day 1 and Day 5. Serum BAs returned to baseline at 24 hours post-dose in response to 10 mg/kg A7387 while still being elevated in response to 30 mg/kg A7387. Urine excretion of BAs tended to increase in response to A7387 compared with vehicle, while the levels of fecal BAs did not change. Levels of the BA synthesis biomarker 7-alpha-hydroxy-4-cholesten-3-one (C4) did not change in response to A7387 after 5 days of repeated dosing. Good oral bioavailability was demonstrated in the pharmacokinetic studies across all species. **Conclusion:** A7387 is a highly potent, selective, orally available NTCP inhibitor with potential in HBV/HDV infection and cholestatic diseases.

1482-C | PRECLINICAL RESISTANCE PROFILE AND ANTIVIRAL ACTIVITY OF THE BEST-IN-CLASS CAM-E ALG-001075, THE PARENT COMPOUND OF ALG-000184

Yannick Debing[1], Abel Acosta Sanchez[2], Hannah Vanrusselt[1], Dieudonné Kum[3], Lars Degrauwe[1], Tse-I Lin[1], Julian Symons[3], Lawrence M. Blatt[3], Leonid N. Beigelman[3] and Andreas Jekle[3], (1)Aligos Belgium BV, Leuven, Belgium, (2)Novalix, Leuven, Belgium, (3) Aligos Therapeutics, Inc., South San Francisco, CA, USA

Background: The hepatitis B virus (HBV) capsid assembly process has emerged as a key target for the treatment of chronic hepatitis B (CHB). ALG-000184 is a prodrug of ALG-001075, a novel capsid assembly modulator leading to the formation of empty capsids (CAM-E). ALG-000184 has demonstrated best-in-class reduction of HBV-DNA, HBV-RNA and HBsAg in CHB patients. Here, we provide an update on the preclinical antiviral activity and viral resistance profile of ALG-001075. **Methods:** Antiviral activity on HBV DNA was determined in HepG2.2.15 and HepG2.117 cells using quantitative PCR, with and without 40% human serum. HepG2 cells were transfected with plasmids encoding an overlength HBV genome with amino acid mutations known to confer viral resistance to CAMs and nucleos(t)ide analogs. **Results:** ALG-001075 is a potent inhibiter of HBV DNA production in HepG2.2.15 and HepG2.117 cells with EC_{50}/EC_{90} values of 0.53/1.84 nM and 0.63/3.17 nM respectively. Inclusion of 40% human serum resulted in an average 5-fold shift in antiviral activity. ALG-001075 retains potent antiviral activity against isolates from HBV genotypes A-J. To date, T33N is the only mutation identified that mediates a major loss of activity of ALG-001075 (28-fold compared to wild-type), while T33P and V124G exhibit minor resistance in vitro (6- to 8-fold). F23Y, P25A, L37F, Y38F, I105L, I105T, T109I, F110I, Y118F and T128I did not substantially alter the antiviral activity of ALG-001075 (**d** 3-fold shift). ALG-001075 retained activity against mutations conferring resistance to the nucleos(t)ide analogs tenofovir, entecavir and lamivudine. **Conclusion:** With sub-nanomolar activity in cell-based assays, ALG-001075 is among the most potent CAM-E compounds reported to date and displays a favorable preclinical resistance profile thereby warranting further development as a potential best-in-class CAM-E.

1483-C | PROLONGED (> 24 WEEK) DOSING WITH THE ORAL CAM-E COMPOUND ALG-000184 RESULTS IN MULTI-LOG REDUCTIONS IN HEPATITIS B SURFACE ANTIGEN, HBV DNA, AND HBV RNA LEVELS IN UNTREATED E ANTIGEN POSITIVE SUBJECTS WITH CHRONIC HEPATITIS B

Jinlin Hou[1], Yanhua Ding[2], Xieer Liang[1], Jia Xu[2], Man-Fung Yuen[3], Edward J. Gane[4], Kosh Agarwal[5], Junqi Niu[2], Min Wu[6], Kha Le[6], Christopher Westland[6], Maida Maderazo[6], Genevieve Harrington[6], Lawrence M. Blatt[6], Leonid N. Beigelman[6], Sushmita Chanda[6], Tse-I Lin[6] and Matthew McClure[6], (1)Nanfang Hospital of Southern Medical University, (2)The First Hospital of Jilin University, (3)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR, (4)Faculty of Medicine, University of Auckland, (5) Institute of Liver Studies, King's College Hospital, (6) Aligos Therapeutics, Inc.

Background: ALG-000184 is a prodrug of ALG-001075, a novel, pan-genotypic CAM-E (empty capsids) with picomolar potency in vitro. **Methods:** ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled Phase 1b study (NCT04536337) evaluating the safety, pharmacokinetic, and antiviral activity profiles of oral daily dosing with ALG-000184 in heathy volunteers (**d** 7 d) and subjects with chronic hepatitis B (**d** 48 weeks). These profiles have previously been reported to be favorable for dosing x **d** 24 weeks. Here we report emerging safety and antiviral activity data after dosing > 24 weeks in ongoing Part 4 cohorts, which are evaluating the antiviral activity of 300 mg ALG-000184 in untreated HBeAg+ CHB subjects. Available additional data will be presented at the conference. **Results:** To date, 5 untreated HBeAg+ subjects have been dosed with 300 mg ALG-000184 + Entecavir (ETV) for > 24 weeks, with all 5 subjects dosing for 32 weeks. All subjects are Asian, genotype B/C, and receiving background ETV; they have the following mean baseline levels: ALT 29.2 U/L, HBV DNA 8.1 log_{10} IU/mL, HBV RNA 6.9 log_{10} copies/mL, and HBsAg 4.3 log_{10} IU/mL. Long term

ALG-000184 dosing has been well tolerated with no serious adverse events (AEs) reported and no subjects requiring discontinuation of study drug. All treatment emergent AEs (TEAEs) in these subjects were Grade 1 or 2 in severity except in one subject who experienced a Grade 4 TEAE of ALT elevation, which peaked at 416 U/L (10.1xULN) on Day 171. This event is currently improving despite continued dosing with ALG-000184 and the study's safety oversight committee assessed it as not being related to drug toxicity. No concerning laboratory, ECG, vital sign, or physical examination findings or trends have been identified. Among these 5 subjects, 4 subjects have demonstrated a > 1.1 $\log_{10}$ IU/mL decline in HBsAg levels with a maximum HBsAg decline of 1.9 $\log_{10}$ IU/mL (figure 1). All patients had HBV DNA level declines of **e** 5 $\log_{10}$ IU/mL, with 1 suppressed below the limit of detection. All patients had HBV RNA levels declines **e** 2 $\log_{10}$ IU/mL and all were below the limit of detection. **Conclusion:** Dosing of untreated HBeAg+ CHB subjects for > 24 weeks with 300 mg ALG-000184 on an ETV background therapy has been well tolerated and resulted in multi-$\log_{10}$ reductions in HBsAg, DNA, and RNA. The associated declines in HBsAg levels suggest a potential secondary mechanism of action of CAM-Es. Dosing of more subjects and for longer durations to better understand the risk-benefit profile of ALG-000184 is currently ongoing.

1484-C | PROTEIN EXPRESSION ASSOCIATED WITH ALANINE AMINOTRANSFERASE INCREASE DURING BEPIROVIRSEN TREATMENT: ANALYSIS OF THE B-CLEAR STUDY

William Jordan[1], Jennifer Singh[1], Shihyun You[1], Ji Won Cremer[2], Robert Elston[3], Jared Delahaye[1], Johannes Freudenberg[1], Melanie Paff[1] and Dickens Theodore[2], (1)GSK, Collegeville, PA, USA, (2)GSK, Durham, NC, USA, (3)GSK, Stevenage, Hertfordshire, UK

Background: In the Phase 2b B-Clear study, 300 mg bepirovirsen (BPV; an antisense oligonucleotide) for 24 weeks induced sustained hepatitis B surface antigen (HBsAg) and hepatitis B virus (HBV) DNA loss in 9–10% of participants (pts) with chronic HBV infection. Transient alanine aminotransferase (ALT) increases occurred in association with HBsAg reduction. This post hoc analysis evaluated protein expression according to HBsAg response and presence of ALT increase in the first 12 weeks of treatment. **Methods:** Pts were categorized based on HBsAg response. For pts achieving HBsAg < lower limit of quantification (LLOQ), number of days to first reach LLOQ was quantized into three categories: early (< 47.3 d), intermediate (47.3–63.5 d), and late (> 63.5 d) responders. Pts not reaching LLOQ were classed as null (< 0.5 log HBsAg reduction) or partial (> 0.5 log reduction but not reaching LLOQ) responders. Presence or absence of ALT increase (ALT > 3 times upper limit of normal [women: > 99 IU/L; men: > 120 IU/L] at any timepoint) among these response categories was examined. Differential protein expression analysis comparing pts with ALT increase vs no increase was performed within each HBsAg response group. Expression of the proteins identified from each grouped comparison was evaluated over time and pathway analysis of differentially expressed proteins was performed. **Results:** Occurrence of an ALT increase was associated with overall response and rate of HBsAg decline, with a significant difference in the frequency of ALT increases in BPV responders vs null responders (~40% vs ~2%). Within BPV responders reaching LLOQ, ALT increases were significantly more likely in early vs late responders. Multiple proteins were consistently upregulated in pts with ALT increase, differentiating them from those with no increase across HBsAg response categories (false discovery rate **d** 0.1). Pathway analysis of post-baseline upregulated proteins found associations with pathways involved in interferon gamma signaling and drug metabolism, highlighting potential association of immune activation with ALT increase. Some proteins upregulated in pts with ALT increases (e.g., CXCL10, CXCL9, IL10) were also found to be associated with timing of ALT increase in the previous Phase 2a study (NCT02981602). **Conclusion:** This analysis identified a subset of proteins that were correlated with ALT increase during BPV treatment. Funding: GSK (study 209668; NCT04449029)

1485-C | RECOMBINANT MOSAIC HBV CAPSID PARTICLES FOSTER ADAPTIVE IMMUNITY AGAINST THE MOST PREVALENT HBV GENOTYPES BY THERAPEUTIC VACCINATION

Shubhankar Ambike[1], Julia Sacherl[1], Alexander Seidler[1], Arie Geerlof[2], Anna Kosinska[1,3], Sophia Schreiber[1], Frank Thiele[1], Tanja Bauer[1,3], Michael Nassal[4], Anne Schütz[5] and Ulrike Protzer[3], (1)Institute of Virology, School of Medicine, Technical University of Munich and Helmholtz Munich, Germany, (2)Institute of Structural Biolology, Helmholtz Munich and Technical University of Munich, Germany, (3)German Center for Infection Research, Munich Partner Site, Germany, (4) University Hospital Freiburg, Internal Medicine 2/ Molecular Biology, University of Freiburg, Germany, (5) Faculty of Chemistry and Pharmacy, Ludwig Maximilian University of Munich, Germany

Background: Hepatitis B virus (HBV)-specific B- and T-cell responses are key to cure HBV. TherVacB, a heterologous protein-prime/modified vaccinia virus Ankara (MVA) vector-boost therapeutic vaccine was developed to activate both HBV-specific B- and T-cell responses. For a worldwide use, vaccine components should cover all major circulating HBV genotypes A-E. We have therefore previously developed MVA-HBVac, a boost vector covering B- and T-cell epitopes of all major HBV genotypes. To prime HBV core-specific CD4 + and CD8+ T cells, we designed a novel, recombinant, mosaic HBV capsid particle consisting of genotype C (gtC) and D (gtD) core proteins to activate CD4+ and CD8+ T-cell responses against the different HBV genotypes. **Methods:** Under individual promoters, open reading frames encoding a full-length gtD and a C-terminally truncated gtC HBV core protein were cloned into a single inducible bacterial expression vector. Using Western blotting, the expression of both core proteins in *E. coli* was confirmed. Self-assembling capsid particles were purified using ion-exchange chromatography. Structural characterization of purified mosaic capsid particles was performed with ELISA, native agarose gel electrophoresis, pull-down assay, electron microscopy and NMR spectroscopy. **Results:** Structural analysis confirmed the occurrence of fully functional HBV mosaic capsid particles comprising of core proteins from both the genotypes. Antigen-presenting cells primed with the mosaic capsid particles could *in vitro* activate HBV core-specific TCR-grafted T cells differentially recognizing genotype A, C and/or D epitopes. Immunization of mice with the mosaic capsid particles in a heterologous protein-prime/MVA-boost scheme resulted in strong core-specific antibody and T-cell responses. The assessment of stability of mosaic capsid in various conditions, exhibited their suitability for long-term storage and clinical application. **Conclusion:** We successfully designed and expressed highly functional and immunogenic mosaic capsid particles from a single vector that can now be used in *TherVacB* clinical trials. Our approach provides a promising treatment strategy to cure chronic hepatitis B targeting all major circulating HBV genotypes worldwide.

Research, (9)Institute for Medical Virology, (10)Gilead Sciences, Inc., (11)Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, University Hospital of Pisa, (12)University Hospital Frankfurt, Department of Medicine

Background: Patients with chronic HDV (CHD) treated with 2 or 10 mg bulevirtide (BLV) showed superior responses at week (W)48 vs controls based on the combined response (CR) endpoint of virologic response (VR; a **e** 2-$\log_{10}$ decline from baseline [BL]) or undetectable HDV RNA and biochemical response (BR; ALT normalization). BR is a widely accepted endpoint for HDV antiviral effect, but optimal VR criteria are unclear. We explored the relationship between BR and VR criteria with BLV treatment. **Methods:** A pooled analysis of W48 BLV (2 and 10 mg) data from 2 Phase 2 and 1 Phase 3 study was performed. Rates of VR, VR +BR (ALT **d** upper limit of normal [ULN]), and VR+partial BR (ALT **d** 1.5×ULN) were determined using HDV RNA cutoffs for VR and the recommended VR definition. Subanalyses were performed to identify predictors of no BR in those with viral control at W48. **Results:** Included were 229 CHD patients: 64 on BLV 2 mg, 165 on 10 mg; 64% were male, 86% White, and 40% had cirrhosis. At BL, mean (SD) age and HDV RNA were 41 (8) y and 5.2 (1.4) $\log_{10}$ IU/mL. Median (Q1, Q3) ALT and liver stiffness were 84 (61, 127) U/L and 11.8 (8.7, 16.2) kPa; 25% had ALT **d** 1.5×ULN. At W48, VR ranged from 18% to 87% (Figure); 54% (123) achieved BR; 79% (180) met the standard VR definition, representing 85% (105/123) of BRs. Achieving **e** 1-$\log_{10}$ decline in HDV RNA was the most sensitive predictor of BR, representing 94% (116/123) of BRs. CR:VR ratios were consistent across VR cutoffs. Subgroup analysis showed 95/163 (58%) achieved HDV RNA < 1000 IU/mL at W48 and achieved BR. BRs were less likely to have cirrhosis but were otherwise comparable to non-BRs at BL. A similar mean change in HDV RNA level was seen in BRs and non-BRs at W48. Using HDV RNA < 1000 IU/mL at W48 (with exclusion of HBV DNA **e** LLOQ, normal ALT, or HDV RNA < 1000 IU/mL at BL), 30 patients had BR, and 19 did not. Assessment of non-BRs showed ALT improvements following control of HDV viremia in all but 3 patients; 16 non-BRs had partial BR at W48. Likely etiology for the lack of BR: cirrhosis (n = 7), nonalcoholic fatty liver disease (n = 8), and HBV reactivation (n = 1). **Conclusion:** Using a less stringent cutoff than the standard definition captures additional cases of BR/partial BR. **e** 1-$\log_{10}$ decline in HDV RNA was sufficient to predict BR in 94% of patients. Conversely, for those achieving HDV RNA < 1000 IU/mL, most had ALT normalization; in those without BR, other etiologies could usually be identified, although histologic evaluation should be considered.

1487-C | SAG-COMP, A NOVEL RNA DESTABILIZER, SPECIFICALLY DESTABILIZES HBV-RNA AND EXHIBITS POTENT ANTI-HBV ACTIVITY AND SAFETY.

Takehisa Watanabe[1], Sanae Hayashi[1], Yan Zhaoyu[1], Katsuya Nagaoka[2] and Yasuhito Tanaka[3], (1) Kumamoto University, (2)Faculty of Life Sciences, Kumamoto University, (3)Kumamoto University Hospital, Kumamoto, Japan

Background: Nucleic acid analogues (NAs), currently used as approved drugs for HBV treatment, are excellent agents with potent activity against HBV-DNA but poor efficacy against HBs antigen (HBsAg). In addition, the therapeutic efficacy and tolerability of peginterferon are unsatisfactory. Therefore, this study aims to develop a novel drug with a novel mode of action (MoA) against HBV and good tolerability. **Methods:** Drug screening from 30,000 library compounds using HepG2.2.15 cells and HBV-infected PXB cells was performed to optimize the hits that reduced the amount of HBsAg in the culture supernatant, especially those with potent anti-HBV activity, to obtain SAG compounds (SAG-comp; IC50 = 1.4 nM). The MoA of SAG was evaluated by Northern blotting, BRIC assay, NRO assay, and poly(A) assay. *In vivo* efficacy and safety were evaluated in animal models. **Results:** SAG-comp treatment shortened polyA and significantly destabilized pgRNA and PreS/S mRNA in HepG2.2.15 cells, but did not affect GAPDH mRNA, suggesting that destabilization may have occurred specifically for HBV-RNA. SAG-comp did not suppress transcription. Knockdown of PAPD5 with siRNA attenuated the effect of SAG-comp, suggesting that PAPD5 may be involved in MoA of SAG-comp. Knockdown of ELAVL1, an RNA-binding protein, decreased HBV-RNA, however, double knockdown of PAPD5 and ELAVL1 attenuated the siELAVL1-induced decrease in HBsAg, suggesting that PAPD5 may be directly and/or indirectly involved in the effect of ELAVL1. The efficacy of SAG-comp alone or in combination with NAs when administered orally was evaluated in human liver chimeric mice. The results showed that SAG-comp alone reduced HBsAg (minimum effective dose; 6 mg/kg/day) and in combination

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with NAs markedly reduced both serum HBsAg and HBV-DNA. Furthermore, the safety examination in mice and monkeys showed that the SAG compound had no apparent toxicity. **Conclusion:** The SAG-comp, a novel anti-HBV therapeutic agent, is an orally available and well-tolerated drug that potently suppresses HBsAg. It can destabilize HBV-RNA and may induce functional cure in combination therapy with NA.

1488-C | SCREENING OF LOW-MOLECULAR COMPOUNDS THAT INHIBIT BINDING OF ENVELOPE AND CAPSID OF HEPATITIS B VIRUS

Kosuke Sato[1], Jun Inoue[1], Masashi Ninomiya[2], Akitoshi Sano[1], Mio Tsuruoka[2], Satoko Sawahashi[1] and Atsushi Masamune[2], (1)Tohoku University Hospital, (2)Tohoku University Graduate School of Medicine

Background: An unmet need in patients with chronic hepatitis B virus (HBV) infection is for treatment that enables efficient viral elimination, which requires the development of therapies with novel mechanisms of action. HBV replicates in infected hepatocytes, and binding of PreS1/S2 on the N-terminus of large HBs (LHBs) to the HBc protein-forming nucleocapsid is thought to be necessary for the HBV envelope formation, and an inhibition of this binding may be a target for anti-HBV drugs. In this study, we aimed to identify compounds with the above binding inhibition effects that could be used as therapeutic agents. **Methods:** A high-throughput screening method that measures the binding of LHBs and HBc was established using the NanoBRET system (Promega), which measures the fluorescent signal generated when the two proteins are in close proximity. Using HepG2 cells, we examined where specific proteins are tagged to optimize the NanoBRET assay. Next, we screened low-molecular compounds from our library that inhibit the binding of LHBs to HBc using the high throughput screening method as the 1st screening. The hit compounds were added to HepG2.2.15.7 cells, which are HBV-expressing cells, and HBV DNA levels in the culture supernatant after immunoprecipitation with anti-HBs antibody were measured by RT-PCR and HBsAg by CLIA as the 2nd screening. In addition, we tested the dose-dependent anti-HBV effects of compounds (1, 3, 10, 30 and 100 μM) that reduced HBV DNA levels in the above experiments. **Results:** The combination that resulted in the highest fluorescence signal intensity in BRET was when the NanoLuc was tagged to the N-terminus of the LHBs protein and the HaloTag was tagged to the N-terminus of the HBc protein. After the 1st screening, 33 of the 3200 compounds (10 μM) reduced the BRET signal to less than 60% of the positive control. All of them maintained cell viability of more than 80% and were considered to have low cytotoxicity. In the 2nd screening, 5 of these hit compounds (compound A-E) reduced HBV DNA compared to the positive control. When we tested the hit compounds at different concentrations that maintained cell viability, 30 μM compound A inhibited HBV DNA to 40.4% of control, 100 μM compound B inhibited to 29.6%, 10 μM compound C inhibited to 32.5% and 3 μM compound D inhibited to 72.5%. **Conclusion:** We have identified lead compounds that might inhibit the binding of LHBs and HBc. Further studies are required for clinical application.

Disclosures: Jun Inoue – AbbVie: Grant/Research Support (research funding from ineligible companies should be disclosed by the principal or named investigator even if that individual's institution receives the research grant and manages the funds), No, Yes;

1489-C | THE ROLE OF NUCLEOPORIN 50 IN HEPATITIS B VIRUS REPLICATION

Wei-LUN Tsai[1], Wei-Chih Sun[1], Tsung Hsien Chang[2] and Chia-Ming Lu[1], (1)Kaohsiung Veterans General Hospital, (2)National Defense Medical Center, Taipei, Taiwan

Background: There remained no effective therapy to cure HBV. Nuclear transport is essential for the replication of many viruses in their life cycles. But the role of nuclear transport in HBV replication remained unclear. The aim of the study is to investigate the influence of Nucleoporin (Nup) 50 on HBV replication. **Methods:** The HBV infected HepG2-hNTCP-C4 cells

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

will be used in the experiments. Short hairpin RNA (shRNA) or siRNA mediated knock-down of Nup50 will be done. Quantification of supernatant HBsAg and HBV DNA and intracellular cccDNA, pgRNA will be performed. Immunofluorescence assay (IFA) will be conducted. **Results:** We screened many molecules associated with nuclear transport in hepatocytes and investigated their impacts on HBV replication. We found that shRNA against Nup50 reduced supernatant HBsAg and HBV DNA and cellular cccDNA and pgRNA with good knockdown efficiency and similar cell viability compared with negative control in HBV infected HepG2-hNTCP-C4 cells. siRNA mediated knock-down against Nup50 also decreased supernatant HBsAg and HBV DNA secretion and cellular cccDNA in HBV infected HepG2-hNTCP-C4 cells with good knock-down efficiency of Nup50 and similar cell viability compared with negative control. IFA also found that HBV core Ag was decreased in the nucleus in HBV infected HepG2-hNTCP-C4 cells after treatment with siRNA against Nup50. **Conclusion:** Inhibition of Nup50 significantly reduced HBV replication in HBV infected HepG2-hNTCP-C4 cells. We plan to further investigate the molecular mechanism of Nup50 and HBV replication. Our data is promising and Nup50 may be a new therapeutic target for future anti-HBV treatment.

1490-C | TREATMENT EMERGENT BEPIROVIRSEN BINDING SITE NUCLEOTIDE POLYMORPHISMS IN PHASE 2b B-CLEAR STUDY

Jerome Bouquet[1], Robert Elston[2], Phil Yates[2], Shihyun You[3], Ji Won Cremer[4], Geoff Quinn[2], Fiona Campbell[2], Melanie Paff[3] and Dickens Theodore[4], (1)GSK, South San Francisco, CA, USA, (2)GSK, Stevenage, Hertfordshire, UK, (3)GSK, Collegeville, PA, USA, (4) GSK, Durham, NC, USA

Background: Bepirovirsen (BPV; GSK3228836) is an antisense oligonucleotide that targets a conserved 20-nucleotide sequence within HBV pregenomic RNA and mRNAs. B-Clear is a Phase 2b study (NCT04449029) assessing the efficacy and safety of 12 or 24 weeks (wks) of BPV treatment (tmt) in participants (pts) with chronic hepatitis B (CHB). This analysis assessed the association of BPV binding site single nucleotide polymorphism (SNP) detected in post-baseline samples and the impact on end of tmt (EOT) and end of study (EOS) hepatitis B surface antigen (HBsAg) serum level reduction. **Methods:** Multicenter, randomized, partial-blind study in pts with CHB who were either receiving concomitant stable nucleos(t)ide analogue therapy (On-NA) or were not receiving NA (Not-on-NA). Pts were randomized (3:3:3:1) to receive BPV 300 mg weekly either for 24 weeks (Arm 1); for 12 wks then 150 mg for 12 wks (Arm 2); for 12 wks then placebo (PBO) for 12 wks (Arm 3); or PBO for 12 wks then BPV 300 mg for 12 wks (Arm 4). Next-generation sequencing of HBV DNA or RNA was used. A SNP was reported if the frequency was **e** 5% compared to wild type. A SNP was considered tmt-emergent if it was reported at any post-baseline visit but not at baseline. This post-hoc analysis explored the relationship between resistance mutation and response in pts with non-response (NR; < 1 log decline), partial response (PR ; > 1 log decline, did not reach LLOQ) or breakthrough/relapse (detected after reaching LLOQ on-/off-tmt) for HBsAg or HBV DNA. **Results:** Post-baseline sequence information was available for 49/226 (22%) On-NA pts and 137/229 (60%) Not-on-NA pts. BPV binding site SNPs were detected in 16/186 (8.6%) pts. Three tmt-emergent SNPs were in On-NA pts and 5 were detected in Not-on-NA pts, across all tmt arms. The most common tmt-emergent SNP was C9A (n = 4/8, 50%). Tmt-emergent SNPs occurred in 4 NR and 4 PR, but were not detected in pts with breakthrough/relapse. **Conclusion:** Tmt-emergent SNPs within the BPV binding site were detected at similar frequency in Not-on-NA vs On-NA, were infrequent across tmt arms, and observed in NR and PR only. The % SNP were low and did not exceed 34%. In vitro fitness and drug susceptibility evaluation of tmt-emergent SNPs are needed to better understand potential resistance. Larger studies are also needed to confirm these findings. Funding: GSK (study 209668)

Table. Treatment-emergent SNP not present at >5% at baseline

1491-C | UNDERSTANDING THE INTERPLAY BETWEEN HDV RNA, HBV DNA AND HBsAg DURING LONAFARNIB-BASED THERAPY VIA MATHEMATICAL MODELING: THE LOWR HDV-1 STUDY

Adquate Mhlanga[1], Rami Zakh[2,3], Sarah Duehren[1], Alexander Churkin[3], Vladimir Reinharz[4], Danny Barash[2], Jeffrey Glenn[5], Ohad Etzion[6], Scott J. Cotler[7], Cihan Yurdaydin[8] and Harel Dahari[1], (1)The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, (2)Department of Computer Science, Ben-Gurion University, Beer-Sheva, Israel, (3)Department of Software Engineering, Sami Shamoon College of Engineering, Beer-Sheva, Israel, (4)Department of Computer Science, Universit´e Du Qu´Ebec ´a Montr ´Eal, Montr´Eal, Canada, (5)Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology & Immunology, Stanford School of Medicine, Stanford, California, USA, (6)Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (7)Loyola University Chicago, (8)Department of Gastroenterology and Hepatology, Koç University Medical School,

Background: The frequent samples obtained in the LOWR HDV-1 study (Hepatology.2018;67(4):1224-1236) provide a unique opportunity to analyze and mathematically model the interplay among HDV RNA, HBV DNA, and HBsAg during lonafarnib (LNF)-based therapy. **Methods:** Fifteen patients (n = 3 per group) received LNF-based therapy (i) LNF 200mg twice daily (BID) for 12 weeks, (ii) LNF 300mg BID for 12 weeks; (iii) LNF 100mg thrice daily for 5 weeks; (iv) LNF 100mg BID + ritonavir (RTV) 100mg once daily for 8 weeks; or (v) LNF 100mg BID + pegIFNα 180g once weekly for 8 weeks. Kinetic data were measured on days 0, 1, 2, 3, 7, 14 and 28 and then every 4 weeks during treatment. Modeling was performed using a recently developed HDV/HBV mathematical model (Mathematics. 2022;10 (20):3917) that was extended herein to include HBsAg kinetics. **Results:** Median baseline HDV RNA, HBV DNA, and HBsAg were 6.53 log IU/mL [interquartile, IQR:1.96], 2.67 log IU/mL [IQR:1.69] and 3.90 log IU/mL [IQR:0.42], respectively. After a delay of 0 to 2 days, all patients experienced a rapid 1st HDV decline phase (median slope of 0.14 log/day [IQR:0.06]), followed by a viral plateau (flat-partial response, FPR, n = 8; Fig.1A), a 2nd slower decline (0.04 log/day [IQR:0.02]) phase (biphasic, BP; n = 6;Fig.1B and C), or viral rebound (n = 1, not shown). LNF combination therapy with RTV or pegIFNα was associated with a BP HDV decline. LNF monotherapy was associated with FPR (n = 7) that was followed by a rebound in 4/7. In contrast, none of the patients who received combination therapy experienced HDV rebound. In all dosing groups except the pegIFNα group, at least one patient experienced an HBV DNA increase (Fig.1A and B). HBsAg levels did not change throughout treatment (Fig.1). The extended HBV/HDV model reproduced the observed kinetics in all patients (Fig.1). Modeling indicated that the 1st HDV decline phase represents the HDV half-life (median 1.3 d [IQR:0.42]) and the efficacy of treatment in blocking HDV production (median 97% [range: 67% - 99%]), which was similar under all treatments. The 2nd phase of HDV decline in BP patients was represented in the model by an additional (time-dependent) efficacy increase in blocking HDV production with rate reaching a maximal efficacy of 99.98% (range:97.44%-99.995%). The increase in HBV DNA was explained by ~2-fold increase in HBV production rate corresponding to the HDV decline. The stability of HBsAg suggests no change in HBsAg-producing cell number under all treatments. **Conclusion:** The similar antiviral response observed with LNF monotherapy and LNF with RTV or pegIFNα indicates that combination therapies do not increase treatment efficacy in blocking HDV production during the initial 1st phase decline. However, LNF with RTV or pegIFNα was associated with a BP response and lack of HDV rebound, which can be explained by LNF combination therapy augmenting HDV blocking production efficacy in a time dependent manner.

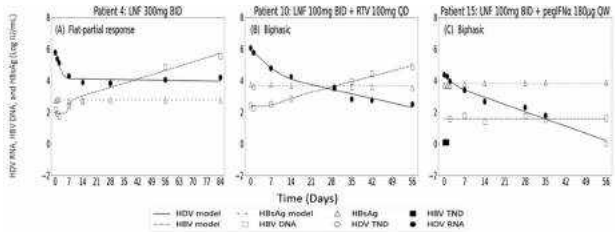

Figure 1: Representative kinetic patterns and mathematical modeling curves. (A) HDV flat-partial response, (B) biphasic HDV decline with HBV DNA increase, (C) biphasic HDV decline with no change in HBV DNA. TND, target not detected.

1492-C | ALANINE AMINOTRANSFERASE TO QUANTITATIVE HBsAg RATIO INDEPENDENTLY PREDICTS LONG-TERM HBsAg SEROCLEARANCE AFTER ENTECAVIR CESSATION IN CHINESE HEPATITIS B PATIENTS

Ryan Hin-Man Leung[1], Rex Wan-Hin Hui[1], Lung Yi Mak[1,2], Kevin Sze Hang Liu[1], Danny Ka-Ho Wong[1,2], James Fung[1,2], Wai-Kay Seto[2,3,4] and Man-Fung Yuen[2,5], (1)Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, (2)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR, (3) Department of Medicine, School of Clinical Medicine, the University of Hong Kong, (4)Department of Medicine, the University of Hong Kong-Shenzhen Hospital, Shenzhen, China, (5)Department of Medicine, Queen Mary Hospital, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, Hong Kong, China

Background: Nucleos(t)ide analogue cessation in chronic hepatitis B (CHB) may induce hepatitis B surface antigen (HBsAg) seroclearance. Good predictors at end-of-treatment (EOT) to predict long-term HBsAg seroclearance are needed. **Methods:** This study followed up Chinese CHB patients from two studies of entecavir cessation from Queen Mary Hospital, Hong Kong. The first study (n = 80) did not have inclusion criteria for quantitative HBsAg (qHBsAg), and the second (n = 114) recruited patients with qHBsAg < 200 IU/ml. All patients were non-cirrhotic, hepatitis B e-antigen negative, with undetectable HBV DNA (< 20 IU/ml) at EOT. They had close monitoring for 48 weeks with regular HBV DNA, qHBsAg and alanine aminotransferase (ALT) measurements, and were resumed on entecavir if HBV DNA > 2000 IU/ml. After 48 weeks, the patients were reviewed every 6 months, regardless of whether entecavir was resumed. **Results:** 194 patients (63.4% male, median age 55.6, on entecavir for a median of 47.2 mo) were recruited. The median (interquartile range) ALT and qHBsAg at EOT were 23.0 (18.0-31.0) U/L and 104.5 (30.8-616.0) IU/ml respectively. 139 (71.6%) patients had EOT qHBsAg < 500 IU/ml. 151 (77.8%) patients developed HBV DNA > 2000 IU/ml and were resumed on entecavir by week 48. After follow up for 70.7 (51.0-118.2) months, 28 (14.4%) patients had HBsAg seroclearance at 29.3 (12.3-47.7) months after EOT. EOT qHBsAg predicted HBsAg seroclearance in univariate analysis (HR 0.993 [95%CI 0.989-0.998], $p = 0.007$), and this association trended towards significance in multivariate analysis (HR 0.997 [95%CI 0.993-1.000], $p = 0.075$), possibly due to the low and narrow EOT qHBsAg range limiting statistical power. EOT ALT (HR 1.029 [95% CI 1.000-1.059], $p = 0.049$) and not resuming entecavir (HR 5.525 [95% CI 2.283-13.333], $p < 0.001$) were predictors of HBsAg seroclearance in multivariate analysis. The ratio of ALT/qHBsAg (conceptually viewed as the intensity of immune-mediated response per IU/mL of HBsAg) at EOT and week 6 after EOT independently predicted HBsAg seroclearance (Figure 1A-1B; EOT: HR 1.007 [95%CI 1.001-1.012], $p = 0.018$; Week 6: HR 1.033 [95%CI 1.015-1.052], $p < 0.001$), regardless of whether entecavir was later resumed. The ALT/qHBsAg ratio at EOT and week 6 achieved area-under-curve of 0.800 (95%CI 0.736-0.854) and 0.879 (95%CI 0.812-0.928) in predicting HBsAg seroclearance respectively. **Conclusion:** While the utility of ALT/qHBsAg ratio in predicting long-term HBsAg seroclearance needs further validation, it may be particularly useful in patients who are more likely to require early resumption of antivirals after treatment cessation.

1493-C | ANTIVIRAL THERAPY REDUCES HEPATOCELLULAR CARCINOMA BY AMELIORATING ER STRESS, IMPROVING MITOCHONDRIAL DYSFUNCTION AND RESTORING AUTOPHAGY ACTIVITY IN A HYBRID HBV-ASSOCIATED HCC MOUSE MODEL

Jaw-Ching Wu[1], Yuh-Jin Liang[2,3,4], Yu-Wei Chiou[2], Wei Teng[5], Chin-Wei Lin[2] and Chien-Wei Su[6], (1)Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, (2)Taipei Veterans General Hospital, (3)Institute of Clinical Medicine, National Yang Ming Chiao Tung University, (4)Translational Research Division, Medical Research Department, Taipei Veterans General Hospital, (5)Linkou Chang Gung Memorial Hospital, (6)Taipei Veterans General Hospital, Taipei, Taiwan

Background: The role of hepatis B virus (HBV) in metabolic dysfunction and their interaction on hepatocellular carcinoma (HCC) development are unclear. Nucleos(t)ide analogues (NUCs) treatment reduces HCC incidence. The indication of antiviral treatment in HBV carriers with normal or minimally elevated ALT levels remains debated. MicroRNA-122 (miR-122) regulating fatty acid and cholesterol metabolism, is shown downregulated as hepatitis and HCC progressed. miR-122 as a tumor suppressor and its reciprocal inhibition with HBV highlight its role in HCC development. **Methods:** We generated a mouse model with a single copy of *Mir-122* by hybridizing an HBV transgenic mouse with a homozygous *Mir-122* knockout mouse. The hybrid mouse strain had 89% HCC incidence. The hybrid mice had been characterized by various experiments before and after antiviral therapy. Short-term NUCs treatments were to compare the withdrawal virological relapses between tenofovir disoproxil fumarate (TDF) and entecavir (ETV). And long-term therapies were to compare the reduction of HCC incidence. **Results:** The model exhibited early-onset hepatic steatosis, progressive liver fibrosis, and impaired late-phase autophagy without ALT elevation until HCC development. Metabolomics and microarray analysis identified impaired lipid metabolism, inflammation, and genomic instability, as early as 4-8 months. A combination of the Warburg effect, reduced TCA cycle flux, energy deficiency, and impaired free radical scavenging resulted in liver injury and HCC development. Hybrid mice demonstrated faster virological relapse (VR) one month after cessation of TDF

compared to that in ETV. Trace amount of residual HBV replication intermediates in the liver tissues of the TDF group, but not in the ETV groups. Longterm antiviral therapy reduced HCC incidence by 30-35% by improving endoplasmic reticulum stress, enhancing lysosomal degradation of P62 of autophagy, and inhibiting CHOP-mediated apoptosis. There was no significant difference in the reduction of HCC between the two treatment groups, but both groups had significantly lower HCC incidences than that that in the control group. **Conclusion:** This study highlights a novel mechanism of liver injury caused by HBV-induced mitochondrial dysfunction and autophagy hijacking, leading to metabolic dysregulation, prolonged ER stress, and cell death. It provides mechanistic explanation and therapeutic rationale for HBV carriers with normal or minimally elevated ALT levels.

1494-C | CHARACTERISTICS OF GUT MICROBIOTA ASSOCIATED WITH FUNCTIONAL CURE IN CHRONIC HEPATITIS B PATIENTS WITH HBEAG-NEGATIVE; POSSIBLE INHIBITION OF HEPATITIS B VIRUS BY BUTYRATE-PRODUCING BACTERIA

Takashi Honda[1], Asako Murayama[2], Yosuke Inukai[1], Hisanori Muto[1], Shinya Yokoyama[1], Kenta Yamamoto[1], Takanori Ito[1], Norihiro Imai[1], Yoji Ishizu[1], Masatoshi Ishigami[1], Sachiyo Yoshio[3], Tetsuya Ishikawa[1], Hiroki Kawashima[1] and Takanobu Kato[2], (1)Nagoya University Graduate School of Medicine, (2)National Institute of Infectious Diseases, (3)The Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine

Background: Hepatitis B virus (HBV) infects approximately 320 million people worldwide and is difficult to eradicate. Achieving functional cure (FC) is the ultimate goal, however, factors contributing to FC are poorly understood. We investigate the impact of gut microbiota in chronic hepatitis B patients who achieved FC. **Methods:** Of 105 HBeAg-negative patients with chronic hepatitis B, 70 patients were enrolled excluding cirrhosis, hepatocellular carcinoma, and those receiving nucleoside analogue. The gut microbiome was evaluated in patients who achieved FC and compared with patients with a high titer HBV DNA (**e** 3.3 log IU/mL) [High Titer (HT) group] or patients with a low titer of HBV DNA (< 3.3 logs IU/mL) [Low Titer (LT) group]. The HBV infection system of the cell culture-generated HBV (HBVcc) was used to assess the effects of short-chain fatty acids (SCFAs) including butyric acid produced from identified gut microbiota. **Results:** There was no difference in α and β diversity of gut microbiota in the FC group compared to patients in other groups, but there was a significantly higher relative abundance of bacteria that produce SCFAs, including butyric acids, such as *Bifidobacterium breve* and *Coprococcus catus (Lachnospiraceae)* in patients of the FC group. Furthermore, the relative abundance of both *C. catus* and *B. breve* was gradually higher in sequence from the HT group to the LT group and FC group. In vitro study indicated that butyric acid treatment reduced the production of HBsAg in HBVcc infected cells at a concentration of 1.0mM. The most effective phase of the treatment with butyric acid was identified to be during the culture of infected cells. **Conclusion:** Our study suggested that bacteria that produce SCFAs, including butyrate, are associated with FC in HBeAg-negative patients with hepatitis B through the direct inhibition of HBV replication by butyric acid.

1495-C | COMBINATION OF SINGLE-CELL AND BULK RNA-SEQ REVEALS IMMUNE CHARACTERISTICS OF NK CELLS IN DIFFERENT STAGES OF CHRONIC HBV INFECTION

Yuwei Liu and Junqi Niu, The First Hospital of Jilin University

Background: Natural killer (NK) cells are important effector cells of the antiviral immune response. In hepatitis B virus (HBV) infection, NK cells display altered changes in phenotypes and functions. This study was designed to explore the immune characteristic alternation of NK cells in different stages of chronic HBV(CHB) infection. **Methods:** NK cell single-cell RNA sequencing (ScRNA-seq) data (GSE182159) from patients with CHB infection were analyzed, including 6 immune tolerant (IT), 5 immune active (IA), 3 chronic

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

resolved (CR), and 6 healthy controls. NK cell clusters and subtypes were identified by Seurat pipeline and pseudotime analysis. The functions of different hepatic NK cell subtypes were investigated by enrichment analyses. The bulk RNA-seq data (GSE125686) from CD56+NK cells combined with the scRNA-seq data were analyzed to explore transcriptome profile changes and potential regulatory transcription factors (TFs) of NK cells in the distinct stage of CHB infection by hdWGCNA and WGCNA analysis. **Results:** Compared to healthy controls, CHB patients showed a significant decrease in hepatic NK cells, especially in the IA phases, as well as peripheral blood NK cells, especially in the CR phases. In addition, impaired expression of cytotoxic genes in hepatic NK cells was observed in the IT patients. Subclustering and pseudotime analysis revealed two subtypes of hepatic NK cells, conventional NK (cNK) cells and liver resident NK (LrNK) cells with different phenotypes and functions. The proportion of cNK cells was significantly decreased whereas LrNK cells were increased in all phases of CHB infection. Finally, Four TFs related to IT phases (YBX1, ID2, CNBP, and HOPX) and six TFs (BACH2, MYC, NFKB2, SMAD3, IRF8, and RERE) related to the IA phases were identified in the hepatic NK cells. **Conclusion:** Our research dissected the immune characteristic of NK cells and identified TFs involved in the transcriptional regulation of NK cells in different CHB infection stages, which provided novel insight into the mechanisms of antiviral immunity in CHB infection.

1496-C | DEFICIENCY OF SCAP INHIBITS HBV PATHOGENESIS VIA ACTIVATION OF THE INTERFERON SIGNALING PATHWAY

Grace Naswa Makokha[1], Hiromi Abe-Chayama[2], Clair Nelson Hayes[3] and Kazuaki Chayama[1], (1)Collaborative Research Laboratory of Medical Innovation, Hiroshima University, (2)Hiroshima University, Japan, (3)Hiroshima University

Background: Hepatitis B virus (HBV) infects the liver and is a major risk factor for liver cirrhosis and hepatocellular carcinoma. Currently, interferons and reverse transcriptase inhibitors are useful for treatment of HBV but they have substantial side effects and drug resistance, respectively. Approaches for an effective cure for the virus are thwarted by the limited knowledge on virus-host interactions. The purpose of this study is to identify novel host factors that may support the lifecycle of the HBV virus. **Methods:** Host molecules involved in HBV lifecycle were identified by a genome-wide siRNA based screening in primary human hepatocytes. Overexpression and knockdown were performed to investigate the role of the proteins. Gene expression was measured by PCR whereas protein was determined by immunoblotting. HBV infection was performed by inoculum derived from the serum of an HBV-infected patient. HBV DNA was quantified by immunoprecipitation. HBs and HBe antigens were measured by ELISA. Interferon activity was blocked by an interferon receptor blocking antibody. **Results:** We identified SCAP as a novel host factor that regulates HBV replication. SCAP which stands for **s**terol regulatory element-binding protein (SREBP) **c**leavage-**a**ctivating **p**rotein is an integral membrane protein located in the endoplasmic reticulum. The protein plays a central role in controlling lipid synthesis and uptake by cells. We found that gene silencing of SCAP significantly inhibited HBV production through activation of interferons (IFNs) and interferon stimulated genes (ISGs). Consequently, ectopic expression of SREBP-2, a downstream effector of SCAP in SCAP deficient cells inhibited the IFNs/ISGs expression thereby restoring HBV production. Importantly, treatment of SCAP deficient cells with an interferon blocking antibody also rescued HBV infection. Our results suggest that SCAP via its downstream effector SREBP2 participates in HBV replication through an effect on the interferon production. This observation was further characterized by an increase in HBV production through ectopic expression of SREBP2 compared to control in the parental HepG2-NTCP cells. **Conclusion:** We highlight a previously undocumented role of the cellular sterol pathway controlled by SCAP via the SREBPs in regulating IFN hemostasis to limit HBV infection of hepatocytes. These results may shed light on development of new antiviral strategies against HBV.

1497-C | DEVELOPMENT OF A NOVEL HUMAN HEPATOMA CELL LINE SUPPORTING REPLICATION OF RECOMBINANT HBV GENOME WITH A REPORTER GENE AND PRODUCING INFECTIOUS RECOMBINANT HBV

Shotaro Kawase, Masaya Funaki, Tetsuro Shimakami, Kazuyuki Kuroki, Masaki Kakuya, Reona Suzuki, Koji Matsumori, Taro Kawane, Mika Yoshita, Ariunaa Sumiyadorj, Kazuhisa Murai, Kouki Nio, Masao Honda and Taro Yamashita, Kanazawa University

Background: For the development of antiviral agents to eliminate hepatitis B virus (HBV), an HBV cell culture system that can easily monitor HBV infection is needed. We reported an HBV infection monitoring system using a luminescent 11-amino-acid reporter (HiBiT) by inserting the HiBiT-coding sequence at the N-terminus of PreS1 in a 1.2-fold plasmid encoding a genotype C HBV genome. A recombinant cell culture-derived virus (HiBiT-HBVcc) prepared by transient transfection of this plasmid into HepG2 cells was infectious only to primary human hepatocytes, not to HepG2-NTCP cells. To update the previous system, we established a new HepG2 cell line supporting stable replication of the HiBiT-containing HBV genome and characterized this cell line. **Methods:** We inserted the HiBiT-coding sequence at the C terminus of HBV PreS1 into the plasmid encoding a genome length of genotype D HBV. Following transfection of this plasmid into HepG2 cells, several HepG2 cell clones which integrated the HBV genome into its genome were selected using the appropriate antibiotics. The cell line showing the highest extracellular HiBiT activity, designated as HepG2-B4 cells, was used for further characterization. **Results:** HepG2-B4 cells could be maintained in the presence of 2% DMSO without cell splitting by day 42 after seeding. Extracellular HiBiT activity, as well as the amounts of HBV markers in the supernatants such as HBV-DNA, HBsAg and HBcrAg, kept increasing until day 42. Entecavir or tenofovir treatment reduced extracellular HiBiT activity and HBV-DNA amount in a dose dependent manner. Covalently closed circular HBV-DNA was detected by Southern blot analysis. Furthermore, the supernatants of HepG2-B4 cells were concentrated, then tested for the ability to infect naïve HepG2-NTCP cells and primary human hepatocytes. HiBiT-HBVcc from HepG2-B4 cells could infect both naïve HepG2-NTCP cells and primary human hepatocytes as extracellular HiBiT activity showed continuously increasing and treatment upon infection by an HBV entry inhibitor, bulevirtide, inhibited the increase of HiBiT activity. **Conclusion:** The HepG2-B4 cells stably supported replication of the recombinant HBV genome containing a HiBiT genome and produced an infectious recombinant virus. HBV replication and infection can be easily assessed by measuring extracellular HiBiT activity. Thus, this cell line itself and HiBiT-HBVcc from HepG2-B4 cells can be a powerful tool to develop wide ranges of direct-acting antivirals.

1498-C | GENOMIC LANDSCAPE OF NON-HODGKIN LYMPHOMA PATIENTS WITH CURRENT OR PAST HEPATITIS B VIRUS INFECTIONS

Moon Haeng Hur[1], Jeayeon Park[1], Youngsu Park[1], Yunmi Ko[1], Hyunjae Shin[1], Min Kyung Park[1], Yun Bin Lee[1], Eun Ju Cho[1], Jeong-Hoon Lee[2], Yoon Jun Kim[3], Jung-Hwan Yoon[1] and Su Jong Yu[1], (1)Seoul National University College of Medicine, (2)Seoul National University College of Medicine, Seoul, South Korea, (3) Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea

Background: Hepatitis B virus (HBV) infection is a risk factor for non-Hodgkin lymphoma (NHL). By evaluating the genomic landscape of patients with NHL, we aimed to assess the effect of current or past HBV infections on the development of NHL. **Methods:** Patients who were diagnosed with NHL and underwent targeted next-generation sequencing (NGS) for NHL tissue at Seoul National University Hospital between 2019 and 2022 were consecutively enrolled. Patients confirmed with Hodgkin lymphoma or those without clinical information were excluded. Targeted NGS was performed for 166 NHL-related genes, including *MYD88*, *MYC*, and *ATM*, to detect single nucleotide variant (SNV). Current and past HBV infections were defined by a positive HBV surface antigen (HBsAg) and a positive HBV core antibody (HBcAb) with a negative HBsAg, respectively. The incidence of SNV was compared among three groups (i.e., control group vs. current HBV infection group vs. past HBV infection group). **Results:** A total of 252 patients were included for analysis and 87 (34.5%) were diagnosed with diffuse large B-cell lymphoma. According to the HBsAg and HBcAb positivity, patients were classified into three groups: control ($n = 129$), current HBV infection group ($n = 23$), and past HBV infection group ($n = 100$). The incidence of *MYD88* (control vs. current HBV infection vs. past HBV infection: 14.0% vs. 34.8% vs. 30.0%; $p = 0.005$), *PIM1* (16.3% vs. 34.8% vs. 29.0%; $p = 0.03$), and *MYC* (3.1% vs. 8.7% vs. 12.0%; $p = 0.03$) gene

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

mutation was significantly higher in the current or past HBV infection group compared to the control group. On the other hand, the current HBV infection group showed significantly higher incidence of *ATM* (4.7% vs. 13.0% vs. 0%; $p = 0.004$), *BCL10* (3.9% vs. 17.4% vs. 6.0%; $p = 0.046$), and *BIRC3* (0.8% vs. 13.0% vs. 0%; $p = 0.003$) gene mutation than the other two groups. **Conclusion:** Although current or past HBV infections share some of the gene mutations associated with the development of NHL, current HBV infection exhibited other distinct gene mutations. These findings are expected to reveal the genomic pathways of NHL associated with HBV infection.

1499-C | HBsAg EXPRESSION DOES NOT AFFECT THE HEPATOCYTE RESPONSE TO PEGYLATED INTERFERON AS ANALYZED BY SPATIAL TRANSCRIPTOMICS OF LIVER TISSUE

Nehna Abdul Majeed[1], Regina Umarova[2], Ahmad Alawad[2], David E Kleiner[3], Barbara Rehermann[4] and Marc G. Ghany[5], (1)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (2)National Institute of Diabetes and Digestive and Kidney Diseases, (3)Laboratory of Pathology, National Cancer Institute, Bethesda, MD, (4)Niddk, National Institutes of Health, (5)National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: Treatment with pegylated interferon (Peg-IFN) results in hepatitis B surface antigen (HBsAg) loss in only 1-3% of patients with chronic hepatitis B. **Aim:** To evaluate whether HBsAg expression affects the hepatocyte response to Peg-IFN, we performed spatial transcriptomics on paired liver biopsies pre- and 6 hours post-Peg-IFN treatment of patients with chronic hepatitis B. **Methods:** Peg-IFN was added for 24 weeks to ongoing nucleotide analogue treatment in 13 patients with suppressed HBV DNA. A clinical response was defined as **e** 2 $\log_{10}$ IU/mL decline in HBsAg level at end of treatment. Paired liver biopsies pre- and 6 hours post-initial dose of Peg-IFN were stained with anti-HBs to distinguish HBsAg positive (+) from HBsAg negative (-) hepatocytes. Digital spatial profiling was used to select HBsAg (+) and (-) regions of interest (ROI) followed by transcriptomic analysis. Analysis of differentially expressed genes (DEG) and gene set enrichment were performed utilizing Hallmark gene sets. **Results:** One Peg-IFN responder with 2.6 $\log_{10}$ and 2 non-responders with 0.3 and 0 $\log_{10}$ IU/mL decline in HBsAg levels, respectively, were studied. In total, 17 HBsAg (+) and 19 HBsAg (-) ROIs were analyzed. Minimal change in gene expression post-Peg-IFN was observed in one non-responder. Using an absolute DEG-fold change of > 2, comparing post- to pre-PEG-IFN injection analyzing all ROIs, independent of HBsAg staining, there were 52 DEGs, the majority of which were upregulated interferon stimulated genes (ISGs). Comparing HBsAg (+) to HBsAg (–) hepatocytes post- to pre-PEG-IFN, there were 42 upregulated genes common to both (majority of DEGs were ISGs), 32 genes unique to HBsAg (+) hepatocytes and 17 to HBsAg (-) hepatocytes. Finally, comparing HBsAg (+) and HBsAg (–) hepatocytes post- to pre-pIFN in the responder to the non-responder with no change in HBsAg level, there were 14 common DEGs (majority ISGs) and 59 genes unique to the responder (majority were upregulated ISGs) and 12 unique to the non-responder (majority non-ISGs). **Conclusion:** The presence of HBsAg does not substantially influence intrahepatic response to PEG-IFN. Rather, the intrahepatic response to Peg-IFN is highly variable among patients with responders displaying a greater breadth of DEGs (primarily ISGs) compared to non-responders.

1500-C | HBsAg LOSS DURABILITY AND RATES OF HBsAg SEROREVERSION IN PATIENTS WITH CHRONIC HBV INFECTION, A SYSTEMATIC LITERATURE REVIEW

Vera Gielen[1], Supriya Desai[2], Mounika Adepu[2], Shayon Salehi[1] and Anadi Mahajan[2], (1)GSK, Brentford, UK, (2) Bridge Medical Consulting, London, UK

Background: Functional cure, defined as hepatitis B surface antigen (HBsAg) and HBV DNA undetectable after completion of all treatment, is regarded as the elevated treatment endpoint for patients with chronic HBV (CHB) infection, but is rarely achieved. HBsAg seroclearance is associated with greater reduction in risk of hepatocellular carcinoma than HBV DNA suppression alone. Limited data is available on durability of functional cure and/or HBsAg loss. The objective of this study is to identify data on durability of HBsAg loss, rates of HBsAg seroreversion and factors associated with these. **Methods:** A systematic review of studies in people with CHB infection was conducted. Searches were performed in MEDLINE® and Embase® (January 2000 to October 2022), with hand searches of relevant congress abstracts (2020–2022) and

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

bibliographic and grey literature searches. Outcomes included durability of HBsAg loss, rate of HBsAg seroreversion and predictors of HBsAg seroreversion. Clinical trials and observational studies were included. **Results:** In total, 36 studies (26 observational, 10 clinical trials) were identified. There was considerable heterogeneity among the studies by study design, geography, follow-up, sample size, study population, treatment and treatment cessation before or after HBsAg loss. Durability of HBsAg loss at predefined timepoints was only reported in observational studies. This varied by type of therapy and was mostly observed by 48 weeks; nucleos(t)ide analogues (NA, 88%-96%), interferon (IFN)-containing regimens (69%-80%) and untreated patients (~98%) with similar trends over extended follow-up. These data are consistent with the data on HBsAg seroreversion rates. Although data were limited to 5 studies, significant predictors of HBsAg seroreversion included type of therapy (IFN, 2 studies), duration of consolidation < 12 weeks (NA 1 study; IFN 2 studies), HBeAg-positive (vs. HBeAg-negative) at baseline (IFN 1 study). Anti-HBs seroconversion and levels were associated with durability of HBsAg loss in 2 studies; this was inconclusive in another. Age, alanine transaminase (ALT), duration of NA or IFN and NA cessation (vs NA continued) did not predict HBsAg seroreversion. **Conclusion:** HBsAg loss is durable with most HBsAg seroreversion occuring within 48 weeks after HBsAg loss. More research is needed to determine the role of consolidation therapy, other biomarkers and factors that might predict HBsAg seroreversion, as limited data is available. Funding: GSK (study 219256)

1501-C | HBV INDUCES LIVER FIBROSIS THROUGH A PYRUVATE-PPARA-ROS-DEPENDENT PATHWAY

Xiaoqiong Duan[1], Shasha Li[2], Min Xu[3], Shilin Li[1], Andre Jeyarajan[3], Charlotte Warner[3], Yujia Li[1], Min Xu[1], Chunhui Yang[1], Wenting Li[4], Tuo Shao[3], Pei-Jer Chen[5], Raymond T. Chung[3], Limin Chen[1] and Wenyu Lin[4], (1) Institute of Blood Transfusion, Chinese Academy of Medical Sciences and Peking Union Medical College, (2)The Second People's Hospital of Fuyang City, (3) Massachusetts General Hospital and Harvard Medical School, (4)Massachusetts General Hospital, Harvard Medical School, (5)National Taiwan University Hospital

Background: Chronic hepatitis B (CHB) is a major cause of liver fibrosis and hepatocellular carcinoma (HCC). We previously found that pyruvate, a key intermediate in metabolic pathways, increases HBV replication. Pyruvate supplementation suppressed peroxisome proliferator-activated receptor α (PPARα) expression and increases reactive oxygen species (ROS) production as well as expression of profibrotic related genes. However, the mechanism by which pyruvate mediates HBV-induced liver fibrosis is still not well characterized. **Methods:** We studied HBV-induced fibrogenesis through pyruvate in HBV HepAD38, HBV infected NTCP-HepG2 cells, an hepatic stellate cell line (HSC, LX2), primary human hepatocytes (PHHs), HBV carrier mouse model and CHB patients. Cells were cultured in medium without pyruvate. Infectious HBV viral particles (HBVvp) were purified from HepAD38 supernatant (HBVsup). HBV carrier mouse was generated by hydrodynamic injection of pAAV/HBV1.2 plasmid though the tail vein into wild-type C57BL/6. We evaluated the effects of the PPARα agonist fenofibrate and of the PPARα antagonist GW6471 RNAi knockdown, as well as the ROS inhibitor diphenyliodonium chloride (DPI) on HBV induced liver fibrosis. HBV replication and expression of pyruvate, PPARα, TGF-β1, and liver fibrosis related genes were monitored by qRT-PCR, Western blot, or ELISA. **Results:** Pyruvate levels were significantly increased in HBV-infected NTCP-HepG2 cells, HepAD38 cells, HBV carrier mouse model, and CHB patients. Pyruvate supplementation further increased HBV-induced liver fibrosis through suppressed PPARα and subsequently activated ROS in NTCP-HepG2 and LX2 cells. PPARα antagonist or siRNA increased HBV-induced ROS production and profibrotic gene expression in NTCP-HepG2 and LX2 cells. In contrast, PPARα agonist or ROS inhibitor DPI abrogated HBV and pyruvate induced fibrogenesis and PPARα inhibition. We found that DPI did not affect PPARα expression, indicating that PPARα lies upstream of ROS regulation. **Conclusion:** We conclude that HBV promotes liver fibrogenesis through a pyruvate-PPARα-ROS-dependent pathway. These findings clarify the mechanisms underlying HBV-induced liver fibrosis and provide alternate strategies to monitor, prevent and treat HBV-related liver disease. Pyruvate and PPARα may be novel targets for antifibrotic therapeutic development in CHBV.

1502-C | HEPATITIS B VIRUS HIJACK HOST TRIM26 TO AVOID PROTEASOME-DEPENDENT DEGRADATION OF VIRAL CORE PROTEIN

Kazumoto Murata[1], Yuki Nakaya[1], Tsutomu Nishizawa[1], Daichi Onomura[1], Tomoko Yamagata[1], Hiromi Morita[1] and Hironori Nishitsuji[2], (1)Jichi Medical University, (2)Ujita Health University School of Medicine

Background: Hepatitis B virus (HBV) is a life-threatening infectious virus involving a risk of cirrhosis and hepatocellular carcinoma. Current treatments such as nucleos(t)ide analogs or interferon (IFN) for chronic HBV infection safely control its replication and reduce the risk of disease progression; however, these treatments cannot eliminate HBV and novel treatment-strategies are required. We have previously done a small interfering RNA (siRNA) screening to identify most important host factors for HBV replication. Among these factors, we focused on the tripartite motif-containing protein 26 (TRIM26) because TRIM 26 is reported to down-regulate IFN regulatory factor 3 which is a key element for immunological responses against HBV. **Methods:** Human hepatoma cell lines with sodium taurocholate co-transporting polypeptide (HepG2/NTCP, Huh7/NTCP), PXB cells derived from chimeric mice with human primary hepatocytes and HEK293 cells were used. Protein expressions were examined by western blotting or co-immunoprecipitation (Co-IP). In cyto-ubiquitination assay was conducted by transfection of FLAG-tagged core, TRIM 26 or their mutants together with HA-tagged ubiquitin. Proximity ligation assay was used for intracellular interaction of each protein. **Results:** siRNA-mediated TRIM26 knockdown (KD) inhibited HBV DNA and RNA levels in HBV-infected human hepatoma cell lines as well as human hepatocytes (PXB cells). Therefore, we examined whether TRIM26 downregulated IFN responses during HBV infection, but no down-regulation of type I or type III IFN as well as some IFN-stimulated genes were observed by TRIM26 KD. To examine the other possibilities that TRIM26 modulates HBV protein function, we conducted Co-IP for TRIM26 and each HBV protein. Co-IP clearly demonstrated that both exogenous and endogenous TRIM26 physically interacted with HBV core protein (HBc), but not polymerase nor HBX, through the TRIM26 SPRY domain. Next, we analyzed whether TRIM26 affects HBc ubiquitination since TRIM26 is an E3 ubiquitin ligase. A proteasome inhibitor, MG132, significantly increased HBc protein levels in a dose-dependent manner in HEK293T cells transfected with HBc-FLAG expression plasmid. However, unexpectedly, TRIM26 KD promoted HBc ubiquitination and HBc degradation was inhibited by exogenous TRIM26 in a dose-dependent manner. Furthermore, RING domain deleted TRIM26 mutant (TRIM26ΔR), which interacted with HBc but did not have an ability to inhibit the ubiquitination of HBc, acted as dominant negative of TRIM26 and promoted HBc ubiquitination, suggesting that sequestration between TRIM26 and HBc induces HBc degradation by proteasome. **Conclusion:** We found that HBV hijacked TRIM26 to avoid the proteasome dependent HBc degradation for effective viral replication. The interaction between TRIM26 and HBc might be a novel therapeutic target against HBV infection.

Background: HBV-cccDNA can produce microRNAs that bind target mRNAs to inhibit post-transcriptional gene expressions. Hepatitis B Virus-Encoded MicroRNA 3 (HBV-miR-3) has recently been reported to control the replication of HBV and regulate host gene expressions in HCC. Factor Inhibiting HIF-1 (FIH-1), also named Hypoxia Inducible Factor 1 Subunit Alpha Inhibitor (HIF1AN), Hydroxylates hypoxia-inducible factor 1-alpha (HIF-1α) to repress transcription of vascular endothelial growth factor A (VEGFA). It is interesting that in 3'-UTR of FIH-1, there is target sequence of HBV-miR-3.we aimed to elucidate the role of HBV-miR-3 in promoting HBV-related HCC angiogenesis. **Methods:** stem-loop qPCR was used to detect the expression of HBV-miR-3 in HBV-related HCC tissues and survival analysis was conducted. The expression of VEGFR2 in HCC tissues was detected by qPCR and its correlation with HBV-miR-3 was analyzed. HepG2 cells were transfected with HBV-miR-3 agomir, HepG2.2.15 cells were transfected with HBV-miR-3 antagomir, and the expression levels of FIH-1, HIF-1α and VEGFA were detected. A co-culture model of HepG2/HepG2.2.15 and human umbilical vein endothelial cells (HUVEC) was established to analyze the effect of HepG2 cells transfected with HBV-miR-3 agomir or HepG2.2.15 cells transfected with HBV-miR-3 antagomir on HUVEC tube formation. The binding site and nucleic acid sequence of HBV-miR-3 targeting FIH-1 mRNA 3'-UTR were verified by luciferase reporter assay. HepG2 and HepG2.2.15 cells were used to establish a mouse tumor-bearing model; HBV-miR-3 agomir and antagomir were injected into the tumors and the expression of FIH-1, HIF-1α, VEGFA and VEGFR2 were analyzed. **Results:** HBV-miR-3 expression was significantly correlated with angiogenesis related genes VEGFR2 and FIH-1. This suggests that HBV-miR-3 may participate in HBV-related HCC angiogenesis. In vitro, HBV-miR-3 agomir repressed HCC cell FIH-1 expression and promoted HIF-1α and VEGFA expression, resulting in increased human umbilical vein endothelial cell (HUVEC) lumen formation; HBV-miR-3 antagomir induced HCC cell FIH-1 expression and inhibited HIF-1α and VEGFA expression, resulting in decreased HUVEC lumen formation. There results suggest that HBV-miR-3 affect angiogenesis of HBV-related HCC by up-regulating HIF-1α/VEGFA expression. The binding site of HBV-miR-3 to 3'-UTR of FIH-1 mRNA was also confirmed by luciferase activity assay. The effect of HBV-miR-3 regulating tumor angiogenesis was also confirmed by mouse tumor bearing model. These data indicates that HBV-miR-3 regulates angiogenesis of HBV-related HCC by targeting 3'-UTR of FIH-1 mRNA to promote angiogenetic signaling. **Conclusion:** HBV-miR-3 promotes HBV-related HCC angiogenesis by repressing FIH-1 post-transcription and it may be a new mechanism by which HBV promotes angiogenesis in HBV-related Hepatocellular Carcinoma.

1504-C | HYPEREXPRESSION OF INNATE-LIKE MARKERS ON ACTIVATED T CELLS, CONSISTENT WITH IMMUNOPATHOLOGY IN CHRONIC HEPATITIS B IS NOT FULLY REVERSED WITH ANTIVIRAL THERAPY

Lung Yi Mak[1,2], Apostolos Koffas[2], Sabina Wellington[2], Sophie Stretch[2], Anna Riddell[3], Man-Fung Yuen[1], Patrick T. Kennedy[2] and Upkar Singh Gill[2], (1)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR, (2)Blizard Institute, Barts and the London SMD, Qmul, (3)Department of Virology, Barts Health NHS Trust, London

Background: There is renewed focus on the importance of non-specific bystander T cells as contributors to hepatic immunopathology in chronic hepatitis B (CHB). It is key to ascertain further details on this understudied immune cell population to provide insights into the reasons for immunological failure of novel therapies for CHB cure. We studied the phenotypic innate-like properties of global CD4 and CD8 T cells in treatment naïve and experienced patients with CHB compared to healthy controls (HC) to determine any differences and correlated these with clinical parameters. **Methods:** Forty-six subjects (47.8% male, median age 39.5 y) were studied [CHB; 20, HC; 26]. The proportion of activated (HLA-DR+) T cells was determined along with the expression of NK cell receptors

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

(NKRs), markers of T cell differentiation and residency by multi-parameter flow cytometry. The impact of antiviral therapy in a cohort of CHB subjects was also analysed [median tenofovir treatment duration 7.6 years; median ALT: 43 (range: 31-72) U/L; median HBV DNA: 7.1 log IU/ml at treatment initiation]. **Results:** The overall proportion of HLA-DR+ T cells was higher in CHB patients compared to HCs, and significantly higher on CD4 T cells (3.1% vs 1.3%, $p = 0.041$). T cell expression of CXCR6 (0.7% vs 0.3%, $p = 0.010$) and the NKRs, NKG2A (4.4% vs 1.7%, $p = 0.015$) and NKp30 (2.0% vs 0.9%, $p = 0.023$) was increased in CHB, consistent with immunopathology. We noted augmented expression of NKG2A and CD56 (both $p < 0.0001$) on the activated (HLA-DR+) proportion of CD8 T cells compared to their HLA-DR- counterparts. On analysingCHB subjects undergoing antiviral therapy, the expression of NKRs [NKG2A: CD4; 35.4% vs 2.2% & CD8; 28.4% vs 3.6% (both $p < 0.001$); NKG2D: CD4; 79.6% vs. 2.4% & CD8; 20% vs 5.9% (both $p < 0.01$); NKp30: CD4; 2.9% vs 0.7% & CD8; 3.3% vs 0.5% (both $p < 0.01$)] and the residency marker CXCR6 (CD4; 10.6% vs 0.4%, $p < 0.0001$, CD8; 2.4% vs 0.3%, $p = 0.011$) remained significantly higher in those on antiviral therapy, despite undetectable HBV DNA and ALT normalisation, compared to those CHB treatment naïve patients with bona-fide immune control, indicating that the bystander innate like immune defects are not recovered by current antiviral therapy. **Conclusion:** CHB is associated with increased non-specific innate like activated T-cells, potentially causing immunopathology. Antiviral therapy is unable to reverse these immune cell defects suggesting the need for earlier treatment or add on therapies to achieve CHB cure. Further work is being undertaken to determine the functionality of these innate-like cells in this setting.

1505-C | IDENTIFICATION OF NOVEL ANTIVIRAL HOST FACTORS BY FUNCTIONAL GENE EXPRESSION ANALYSIS USING IN VITRO HBV INFECTION ASSAY SYSTEMS

Takuto Nosaka, Tatsushi Naito, Yu Akazawa, Kazuto Takahashi, Hidetaka Matsuda, Masahiro Ohtani and Yasunari Nakamoto, University of Fukui

Background: Nucleos(t)ide analogs are effective antivirals that reduce hepatitis B virus (HBV) DNA but do not cure HBV infection due to the persistence of covalently closed circular DNA (cccDNA). We established a human hepatocyte HBV infection system and reported that IFN-γ regulates HBV cccDNA via STAT1-related pathway (Hepatol Res. 2020, 2022). In this study, using *in vitro* HBV infection systems, novel antiviral host factors that regulate the cccDNA and their molecular mechanisms were investigated by gene knockdown methods and functional gene expression analysis. **Methods:** The 1.3-mer HBV genome plasmid (genotype C2) with core promoter A1762T/G1764A and precore G1896A mutation was transfected into HepG2 cells and "HepG2.D11 clone" was established. The supernatant containing HBV was added to primary human hepatocytes (PXB cells). siRNA knockdown experiments and RNA microarray were performed. Gene expression was analyzed with GeneSpring GX software and Gene Set Enrichment Analysis. Single-cell RNA sequencing (scRNAseq) data from the Human Protein Atlas (HPA) for 30 major tissues/organs was analyzed. **Results:** In STAT1 knockdown experiment, HBsAg, intracellular HBV DNA, and cccDNA were decreased in PXB cells, whereas HBsAg and HBV DNA were increased in HepG2.D11 cells [HBV DNA (PXB-siSTAT1/HepG2.D11-siSTAT1), 0.51/1.91 folds; $p < 0.05$]. RNA microarray analysis showed that 65 genes expression was changed in PXB-siSTAT1 cells (> 2.0 folds, 42 genes; < 0.5 folds, 23 genes). The siRNA screening experiments of these 65 genes in PXB cells showed that knockdown of two anti-HBV candidate genes, fumarylacetoacetate hydrolase (FAH) and Nicotinamide N-methyltransferase (NNMT), increased HBsAg and cccDNA [HBsAg (PXB-siFAH/-siNNMT), 1.58/1.33 folds; $p < 0.05$]. In HepG2.D11 cells, knockdown of FAH and NNMT also increased HBsAg and HBV DNA ($p < 0.05$). To investigate the cells expressing FAH and NNMT, scRNAseq showed that both FAH and NNMT were highly expressed in the liver, particularly in hepatocytes. In these two candidate genes, FAH is the enzyme which catalyzes the hydrolysis into fumaric acid. In HepG2.D11 cells, dimethyl fumarate reduced HBsAg and HBV DNA (HBV DNA, 0.72 folds; $p < 0.05$). **Conclusion:** We identified novel antiviral host factors, FAH and NNMT, that reduce HBV cccDNA levels using *in vitro* HBV infection assay systems in primary human hepatocytes. A couple of undefined host factors were found to contribute to the control of viral infection independently of STAT1 by comprehensive functional screening.

1506-C | IL-21 AND CD4+ T CELL-DERIVED IFN-GAMMA SYNERGISTICALLY ENHANCE HBSAB PRODUCTION IN INFANTS WITH INTRAUTERINE HBV ANTIGEN EXPOSURE

Yanchen Ma, Xiaoyi Liu, Haonan Lou, Weiying He, Qingqing Pan, Libo Tang and Yongyin Li, State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University

Background: The humoral immune response is widely acknowledged for its crucial role in protecting against pathogens. However, the specific characteristics of the humoral immune response to HBV-related antigens encountered during intrauterine exposure remain poorly understood. **Methods:** Twenty-seven cord blood from pregnant women with chronic hepatitis B virus (HBV-PW) and 9 cord blood from healthy pregnant women (HC-PW) as controls were enrolled. The frequency and phenotype of B cells and $CD4^+$T cells were assessed using flow cytometry. Functional responses of HBV-specific B cells were quantified through B cell ELISPOT assays and ELISA. In vitro co-culture experiments were conducted to investigate the role of $CD4^+$ T cells in facilitating HBV-specific B cell responses. **Results:** Cord blood B cells from HBV-PW were capable of producing anti-HBs and anti-HBc, whereas cord blood B cells from HC-PW did not show

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

detectable levels (Figure A). Additionally, a higher proportion of plasmablast and switched memory B cells in cord blood from HBV-PW was found (Figure B). Upon stimulation with HBsAg in vitro, cord blood B cells from HBV-PW demonstrated an increased expansion of plasmablast (Figure C). Cord blood $CD4^+$ T cells could also promote the production of HBsAb, and we found that cord blood $CD4^+$ T cells exhibited higher production of IFN-γ from HBV-PW (Figures D and E). Blockade of IFN-γ production from $CD4^+$ T cells markedly decreased the proportion and absolute count of plasmablast in cord blood and reduced supernatant levels of anti-HBs (Figure F). IFN-γ alone was insufficient to effectively promote the differentiation of B cells into plasmablast and induce anti-HBs production, but in the presence of IL-21, it effectively facilitated these processes (Figure G). **Conclusion:** B cells of infants can generate HBV-specific responses upon exposure to intrauterine HBsAg, and IFN-γ secreted by $CD4^+$ T cells enhances HBV-specific responses of cord blood B cells in the presence of IL-21. These findings contribute to our knowledge of fetal humoral immunity and provide evidence that fetal B cells can respond to HBV-related antigens encountered in utero.

1507-C | IMMUNE CORRELATES OF HDV CLEARANCE IN HDV/HBV COINFECTED INDIVIDUALS

Arshi Khanam[1], Ameer Abutaleb[2], Alip Ghosh[1], Furkan Kaysin[3], Cihan Yurdaydin[4] and Shyam Kottilil[1], (1) Institute of Human Virology University of Maryland, (2) Department of Surgery, George Washington University Medical Faculty Associates, (3)Department of Gastroenterology and Hepatology, Koç University Medical School, (4)Koc University School of Medicine

Background: Chronic hepatitis delta virus (CHD) infection causes the most severe form of viral hepatitis due to rapid progression towards end-stage liver disease leading to high mortality. In the presence or absence of antivirals, a very few patients resolve the infection in chronic hepatitis B/D coinfection (CHB/CHD-coinfection). An enhanced understanding of what derives the resolution of CHD infection is critical to project future therapeutic strategies. Here, we aimed to investigate hepatitis D virus (HDV)-specific T cell responses to determine the immune correlates of HDV clearance. **Methods:** We collected the peripheral blood from CHB/CHD-coinfected patients who did (n = 11, CHD-resolved) or did not (n = 39, CHD-viremic) clear CHD infection and compared them with patients who cleared both CHB/CHD infection (CHB/CHD-resolved n = 3). Circulating T cell phenotype and HBs/HDAg-specific responses were tested with overlapping peptides. Bulk RNAseq and scRNAseq were used to delineate transcriptional profiles of CD4/8 T cells associated with HDV clearance. **Results:** CHB/CHD-resolved patients constituted higher frequencies of effector memory cells with less expression of exhaustion markers including PD-1, CTLA4 and TIGIT in both CD4 and CD8 T cell compartment than those of CHD-resolved (CD4:$p = 0.04$, CD8:$p = 0.02$) and CHB/CHD-coinfection ($p = 0.003$, $p = 0.001$). Further, flow cytometry screening identified higher activation of these cells with improved HDV-specific CD4/CD8 T cells responses in terms of IFN-γ (CD4:$p = 0.001$, CD8: $p = 0.0003$), TNF-α (CD4:$p = 0.0001$, CD8:$p = 0.0008$) and IL-21 (CD4:$p = 0.02$, CD8: $p =$ ns) secretion and cytotoxic functions in CHB/CHD-resolved infection followed by CHD-resolved in comparison to CHB/CHD-coinfection, which display significantly limited functional activity. HBsAg-specific functional responses were also improved in patients who cleared CHD and CHB/CHD infection; however, the recovery was lower than HDV-specific responses and seemed inadequate to clear CHB infection, suggesting robust HDV-specific T cell responses may hold the capacity not only to clear CHD but CHB infection as well. Polyfunctional CD4 and CD8 T cells coproducing IFN-γ, TNF-α, IL-2 and IL-21, and exhibiting cytotoxic potential against HDV were mainly present in CHB/CHD-resolved infection while a

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

very few patients with resolved CHD and CHB/CHD-coinfection established polyfunctional T cells and these patients were specifically those with significantly raised ALT levels. Transcriptional profiling demonstrated distinct adaptive immune responses that defined HDV clearance. **Conclusion:** HDV clearance is associated with higher frequencies of effector T cells producing robust HDV-specific cytokine secretory response while reflecting a transcriptional profile implying a broad anti-HDV peripheral immunity. Hence, these results may guide distinct correlates that define HDV functional cure with antiviral therapeutics.

1508-C | IMMUNE PROFILING OF HBV-ASSOCIATED HEPATOCELLULAR CARCINOMA (HCC) IDENTIFIES TWO DISTINCT IMMUNE SUBTYPES

Davide De Battista[1], Rylee Yakymi[1], Evangeline Scheibe[1], Shinya Sato[1], Sandra Kendra Raini[1], Tovah Markowitz[2], Justin Lack[2], Roberto Mereu[3], Cristina Manieli[3], Fausto Zamboni[3] and Patrizia Farci[1], (1)Hepatic Pathogenesis Section, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, (2)NIAID Collaborative Bioinformatics Resource, National Institute of Allergy and Infectious Diseases, National Institutes of Health, (3)Liver Transplantation Center, Azienda Ospedaliera Brotzu

Background: Despite significant advances in immunotherapy, there is limited information on the HBV HCC tumor microenvironment (TME). Taking advantage of a unique series of liver specimens from patients with HBV HCC, we characterized the TME that may provide important clues to identify patients who could benefit from immunotherapy. **Methods:** We analyzed multiple paired liver samples from 10 well-characterized Caucasian patients with HBV HCC, comprising 20 liver specimens from the tumor and 20 from the nontumorous tissue, obtained at the time of liver transplantation or partial hepatectomy. We performed an extensive immunohistochemistry (IHC) analysis of immunologic markers, including CD3, CD4, CD8, CD20, CD56, CD163, PD-1, and a-SMA. Each marker was scored semi-quantitatively (score 0-4). IHC was combined with RNA-seq performed on paired tumor and nontumor tissue. **Results:** Analysis of immune cells identified two distinct tumor subtypes: immune-high and immune-low. Half of the tumors were immune-high. They were characterized by clusters of infiltrating B cells and T cells expressing PD1. Immune-high tumors also showed a significantly higher expression of a-SMA in stromal cells compared to the immune-low. The number of NK cells and macrophages were similar between the two subtypes. Outside the tumors, the distribution of the immune markers was similar in the 2 subtypes. Next, we compared tumor versus nontumor in both subtypes to identify differentially expressed genes. Immune-high tumors had a significantly higher proportion of upregulated genes (45%) compared to the immune-low tumors where only 19% of genes were upregulated. Most upregulated genes detected exclusively in immune-high tumors were related to cell cycle regulation (e.g., *CCNA2, CDK4, E2F7, E2F8, HDAC11, HDAC6, MKI67, TGFB3*). Direct comparison between immune-high and immune-low tumors showed that the immune-high was characterized by an enrichment of upregulated genes involved in anti-inflammatory pathways (e.g., WNT/Ca+ pathway, IL-10 signaling) and downregulated genes involved in pro-inflammatory pathways (e.g., Neuroinflammation Signaling Pathway, Th1 Pathway, TREM1 Signaling, Pathogen Induced Cytokine Storm Signaling Pathway). **Conclusion:** Immune profiling identified two subtypes in HBV-HCC with distinct molecular signatures. Immune-high tumors are characterized by abundant tumor-infiltrating immune cells, but upregulation of genes related to anti-inflammatory pathways.

1509-C | IMPAIRED CROSSTALK BETWEEN HEPATOCYTES AND MACROPHAGES INCREASES HBV INFECTIVITY: THE EFFECTS OF ETHANOL METABOLISM

Natalia Osna[1,2] and Murali Ganesan[1,2], (1)University of Nebraska Medical Center, (2)Veterans Affairs Nebraska-Western Iowa Health Care System

Background: Hepatitis B virus (HBV) causes about 10% of chronic hepatitis (CHB), which is estimated as high as 250 million patients worldwide, with an annual death rate of 800,000. Alcohol abusers have a higher exposure rate to HBV and a subsequent acquisition of chronic infection. However, the complex interactions between alcohol and HBV infection remain unclear. HBV is not cytotoxic and infects only hepatocytes. Innate immunity, specifically, the activation of anti-viral interferon-stimulated genes (ISGs) prevents HBV spread and persistence. Here, we hypothesize that ethanol metabolism impairs extracellular vesicles

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(EVs)-mediated crosstalk between hepatocytes and macrophages leading to impairment of anti-viral ISG response, thereby increasing HBV infectivity in hepatocytes. **Methods:** Tg05 HBV-replicating mice were fed control and ethanol liquid diets for 10+1 day (NIH model). Hepatocytes were isolated by collagenase perfusion, and the induction of ISGs (APOBEC3G, ISG15, and OAS1) has been ex vivo done by IFN type 1 on plated hepatocytes. We also used HBV +HepG2.2.15 and HBV- HepG2 cells exposed to the acetaldehyde-generating system (AGS) as well as human monocyte-derived macrophages (MDMs). **Results:** In ethanol-fed Tg05 mice, there was a decrease in anti-viral ISG activation due to suppression of IFNα-induced STAT1 phosphorylation (Western Blot), which increased HBV DNA (ddPCR), HBV RNA (RT-PCR), and HBcAg (IF staining) in hepatocytes Similar results were obtained in HBV+ HepG2.2.15 cells exposed to AGS. When MDMs were treated with supernatants (sups) from HepG2.2.15 cells exposed to AGS (but not with sups from control HBV+ or AGS-exposed HBV-hepatocytes), they showed reduced activation of ISGs by IFNα. These effects were absent when the EVs release from AGS-HepG2.2.15 cells was blocked by GW4869 inhibitor, suggesting that HBV is transferred to MDMs via sup-containing EVs with HBV DNAs and RNAs as part of their cargo. Importantly, sups from MDMs activated by EVs derived from control HepG2.2.15 cells reversed AGS-impaired ISG induction and an increase in HBV markers in AGS-exposed HBV+ cells, while sups from MDMs activated by EVs secreted by AGS-HepG2.2.15 cells were not protective **Conclusion:** Ethanol metabolism in HBV+ hepatocytes suppresses anti-viral ISG activation to enhance HBV infectivity which in the presence of acetaldehyde cannot be protected by EV-mediated crosstalk between these cells and hepatocyte EV-activated macrophages.

Disclosures: The following people have nothing to disclose: Natalia Osna, Murali Ganesan

1510-C | INHIBITION OF VIRAL REPLICATION CAN EFFECTIVELY REDUCE THE EXPRESSION OF HBV INTEGRATION BUT THE CLEARANCE OF FN1 EXON REGION INTEGRATION IS HARD BY LONG-TERM ETV TREATMENT

Xiajie Wen[1], Hong You[2], Ju-Tao Guo[3], Fengmin Lu[4] and Jidong Jia[1], (1)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (2)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, (3)Baruch S. Blumberg Institute, (4)Peking University Health Science Center

Background: Integrated HBV DNA is the main source of serum HBsAg in HBeAg negative patients. Due to the inability of current antiviral therapy to directly clear the integrated HBV DNA, the clearance of serum HBsAg remains one of the clinical challenges. This study explored the profile of transcriptionally active HBV DNA integration during the long-term ETV or ETV combine IFN-α treatment and the characteristics of transcriptionally active HBV DNA was identified during the antivirus treatment. **Methods:** Liver biopsies and paired blood samples were obtained from CHB patients at baseline, 78 and 260 weeks after the treat. There are 16, 16 and 22 patients at each time points were finial included in the study, and among them 10 patients had series liver biopsy and blood test. Serum HBV markers, including HBV DNA, HBsAg and HBeAg were longitudinally assessed. No less than 40ng total RNA obtained from each sample, and RNA-seq was carried out. HIVID2 was used for the identification of HBV integration expression fragment. **Results:** After 78 weeks antivirus therapy, the replication of HBV was inhibited the mean level of serum HBV DNA decreased from to 6.91to 0.54(lg IU/mL), at the same time the HBV integration expression decreased 12.25 times compare with the baseline. However, no further significant decline of HBV integration expression was observed at week 260. The analysis of HBV breakpoints showed that more breakpoint or splicing set were detected in HBsAg expression region peeked at 458nt. The proportion of integrated expression occurring in FN1 greatly increases from 0.06% to 31.39% between baseline and week 260. **Conclusion:** Long term antivirus therapy can significantly benefit the patients by decrease the expression of integrated HBV DNA, however, the HBV breakpoint or splicing sit in s-HBsAg expression region near 458nt linking to FN1 gene might help the integrated hepatocytes gain survival and became one of the hard to clear integration express type.

1511-C | INITIAL EVALUATION OF IMMUNE COMPLEX BINDING IN A PHASE 1 SAFETY AND TOLERABILITY STUDY OF CHRONIC HBV PARTICIPANTS GIVEN A SINGLE DOSE OF VIR-3434

Rachel Wong[1], Hasan Imam[1], Julia Di Iulio[1], Amin Momin[1], Yi-Pei Chen[1], Andrea L. Cathcart[1], Gregory Camus[1], Andre Arizpe[1], Sneha Gupta[2], David Sun[1],

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Daniel Cloutier[1], Ann Arvin[1], Kosh Agarwal[3], Man-Fung Yuen[4], Heiner Wedemeyer[5] and Edward J. Gane[6], (1) Vir Biotechnology, Inc., (2)Vir Biotechnology, Inc, (3) Institute of Liver Studies, King's College Hospital, (4) State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR, (5)Hannover Medical School, (6)Faculty of Medicine, University of Auckland

Background: VIR-3434 is an investigational Fc-engineered human monoclonal antibody targeting the conserved antigenic loop of HBsAg in development for the treatment of chronic hepatitis B (CHB). Here, we report immune complex (IC) detection in participants with CHB given a single dose of VIR-3434. **Methods:** VIR-3434-1002 is a randomized, double-blind, placebo-controlled phase 1 single ascending dose study that evaluated the safety, tolerability, antiviral and immunologic activity of VIR-3434. In Parts B and C, participants received nucleos(t)ide reverse transcriptase inhibitors (NRTIs) for **e** 2 months prior to study entry and had baseline HBsAg levels < 3,000 and **e** 3,000 IU/mL, respectively. In Part D, participants were not on NRTIs and had baseline HBV DNA **e** 1000 IU/mL with any HBsAg level allowed. Participants in Parts B-D receiving 300 mg VIR-3434 subcutaneously were monitored for immunologic activity for 8 weeks after drug administration. Cell associated ICs were detected by flow cytometry using an anti-HBsAg antibody that can bind HBsAg complexed with VIR-3434. **Results:** 18 participants enrolled in Parts B-D received a single dose of 300 mg VIR-3434. Among these participants, 17 were analyzed for IC detection. 6/17 participants had detectable ICs on neutrophils and/or CD16+ monocytes in peripheral blood samples at one and/or two weeks after VIR-3434 administration. Preliminary analysis showed that participants with higher baseline HBsAg were more likely to have detectable ICs at any of the post-baseline visits. **Conclusion:** Initial evaluation of peripheral blood samples from participants in this study given 300 mg VIR-3434 validated the immune complex binding detection assay. These data provide proof of concept that VIR-3434 forms complexes with HBsAg and targets these immune complexes to immune cells in participants with CHB. Furthermore, a temporal relationship between IC detection and HBsAg reduction was observed. These findings support the continued development of VIR-3434 for functional cure of participants with CHB Infection.

Georg M. Lauer[6], Raymond T. Chung[6], Gilles Wandeler[7], Debika Bhattacharya[8], Paul Kelly[1], Nadia Alatrakchi[6] and Michael Vinikoor[9], (1)University of Zambia, (2)Massachusetts General Hospital, (3) Massachusetts General Hospital, Harvard Medical School, (4)Levy Mwanawasa Medical University, (5) Centre for Infectious Disease Research in Zambia, (6) Massachusetts General Hospital and Harvard Medical School, (7)University of Bern, (8)University of California, Los Angeles, (9)University of Alabama at Birmingham

Background: Liver fine needle aspiration (FNA) has potential as a longitudinal research procedure for HBV immunology in the context of current and future therapies, but in low- and middle-income countries, its feasibility, patient acceptability, and safety are not established. We report on our initial use of longitudinal liver FNA in Zambia. **Methods:** Adults with treatment-naïve chronic HBV monoinfection or HBV/HIV coinfection enrolled. At enrollment and 1 year of antiviral therapy, following safety labs and ultrasound, Zambian hepatologists performed percutaneous liver FNAs (4 passes/visit) with ultrasound guidance using a 25g Quincke-type needle. After red blood cell (RBC) depletion, cells were loaded fresh in a Seq-well array. At a collaborating US laboratory, cDNA libraries were created, sequenced (NovaSeq 6000), and analyzed. FNA acceptability was based on completion of a second FNA and qualitative interviews. Safety was based on adverse events. **Results:** Of 113 participants (59-HBV/HIV and 54-HBV only), 103 completed pre-FNA safety tests, and of them, 10 (9.7%) had a contraindication to FNA (high INR, thrombocytopenia, or liver lesions). Of the remaining 93, 86 (92.5%) had an enrollment FNA. So far, 14 of the 29 (48.3%) who reached 1 year have completed a repeat FNA, 13 are waiting to schedule it, and only 2 declined. FNA sample quality was good as a median of 27,257 non-RBC immune cells per FNA pass were counted, and among 400 FNA passes, only 3.1% had few/no cells. Sequencing of an initial 12 cDNA libraries yielded 7,992 high-quality cells. We consistently captured major lymphoid and myeloid immune cell types in each patient, including neutrophils and small numbers of macrophages, hepatocytes, and hepatic stellate cells. In interviews, satisfaction with the clinical care provided in the cohort made the pain and anxiety of the liver FNA, which were typically short-lived, very acceptable. Post-FNA, the majority of participants reported pain that was treated with paracetamol, no patient developed vital sign changes during post-procedure monitoring, and 99% were allowed home after 1-2 hours. One participant was admitted for 24-hour observation due to severe pain but no major complications were found. **Conclusion:** In an HBV cohort in Zambia, longitudinal liver FNAs for HBV immunology research were feasible, acceptable, and safe. HBV clinical and translational research in Africa has potential to contribute to global scientific objectives within the cure agenda.

1513-C | LOSS OF HEPATITIS B VIRUS HBEAG CONTRIBUTES TO IMMUNE ESCAPE FROM CD8+ T CELLS DIRECTED AGAINST THE CORE-PROTEIN

Maximilian Damagnez[1], Tatjana Schwarz[2], Christopher Menne[1], Smarands Gliga[1], Hans Bock[1], Johannes Ptok[1], Dennis F.G. Remst[3], Tom Luedde[1], Mirjam H.M. Heemskerk[3] and Joerg Timm[1], (1)Düsseldorf University Hospital, (2)Charite, (3)Leids Universitair Medisch Centrum

Background: Epitopes in the hepatitis B virus core region are important targets of HBV-specific CD8$^+$ T-cell responses. Importantly, there are two different viral proteins in HBV-infected hepatocytes from which these epitopes can be processed and presented to T cells. One is the core protein itself, which is translated from the pregenomic mRNA and is required for nucleocapsid formation. The other is the N-terminally extended precore protein, which is translated from the precore mRNA and further processed and secreted as HBeAg. HBeAg status is an important marker of disease stage and prognosis in hepatitis B. While HBeAg-positive chronic infection is characterized by high viral loads and weak or undetectable CD8$^+$ T-cell responses, the transition to HBeAg-negative infection is associated with activation of HBV-specific CD8$^+$ T-cells. However, it is unclear whether epitopes processed by HBeAg contribute to the CD8$^+$ T cell response and whether the loss of HBeAg may be driven by CD8$^+$ T cell selection pressure. Here, we investigated whether mutations that reduce HBeAg production reduce epitope abundance and thereby contribute to CD8$^+$ T cell immune escape. **Methods:** Different variants of covalently closed circular HBV DNA (cccDNA), including HBV genotypes A and D with and without substitutions in the basal core promoter region, the precore start codon and at position G1896, were produced in vitro and transfected into HLA-A*02-positive HepG2-NTCP cells. Cells transfected with cccDNA were used as targets for CD8$^+$ Jurkat reporter cells carrying TCRs specific for HLA-A*02 restricted epitopes in core or HBsAg. **Results:** HepG2 cells transfected with different genotype A and D cccDNA showed reproducible secretion of HBeAg and HBsAg. These cells were effectively targeted by HBV-specific CD8$^+$ reporter cells, indicating processing and presentation of sufficient amounts of the core peptide for T-cell activation. As expected, the G1896A substitution, which changes the core position W28 to a stop codon, reduced supernatant HBeAg levels without affecting HBsAg levels or intracellular core protein levels. Importantly, the G1896A substitution resulted in an almost complete loss of activation of the HBV-specific CD8$^+$ reporter cells, suggesting that in the absence of HBeAg, the amount of the remaining core epitope was insufficient for CD8$^+$ T cell activation. In the control, the targeting of the epitope in HBsAg was not altered. **Conclusion:** Despite the contribution of HBeAg to an immunologically tolerant state of HBV infection, we find evidence that HBeAg-derived epitopes contribute to the presented peptide repertoire in a model system. Accordingly, when tolerance is broken and CD8$^+$ T cells are activated, mutations associated with loss of HBeAg production appear to contribute to immune escape.

1514-C | MECHANISM OF A1762T/G1764A MUTATION IN PROMOTING HBV REPLICATION BY AFFECTING HBV TRANSCRIPTOME

Danli Yang[1], Xiangmei Chen[1] and Fengmin Lu[1,2], (1)Peking University, (2)Peking University People's Hospital

Background: Chronic hepatitis B virus (HBV) infection is still a major public health problem worldwide. The A1762T/G1764A mutation, one of the most common mutations in HBV basal core promoter, is associated with the progression of chronic HBV infection. However, the effect of this mutation on HBV replication remains controversial. Thus, we aimed to systematically address the effect of A1762T/G1764A mutation on HBV replication and explore the underlying mechanisms. **Methods:** To study the effect of the mutation on HBV viral replication, the prcccDNA-A1762T/G1764A mutant plasmid was constructed based on the prcccDNA/pCMV-Cre recombinant plasmid system and transfected into Huh-7 or HepG2 cells. Meanwhile, hydrodynamic injection was conducted. Chemiluminescence detection kit for the quantitative determination of HBsAg or HBeAg, qPCR, Western blot, Southern Blot and Northern blot were used to evaluate the impact of mutation on HBV replication. 5'-RACE assay and full-length transcriptome sequencing were performed to analyze the effect of the mutation on HBV transcripts. Dual luciferase reporter assay was conducted to detect the effect of the mutation on the transcriptional activity of P protein. Additionally, the transcription factors that mediated the A1762T/G1764A mutation to promote viral replication were explored through ChIP-qPCR assay. **Results:** Compared with the wild-type group, A1762T/G1764A mutation promotes HBV replication and suppresses HBeAg production in vitro and in vivo. Southern Blot and Northern Blot also indicated significantly higher intracellular levels of HBV rcDNA, replication intermediates, dslDNA, as well as intracellular HBV 3.5 kb RNA. RT-qPCR and 5'-RACE

showed that A1762T/G1764A mutation relatively upregulated the transcription of pgRNA, while downregulated the transcription of preC RNA, which were further confirmed the full-length transcriptome sequencing results. More than that, a proportion of sub-pgRNAs with the potential to express HBV polymerase was also upregulated by A1762T/G1764A mutation. Further ChIP-qPCR assay showed that A1762T/G1764A mutation created a functional HNF1α binding site in BCP region, and overexpression of HNF1α enhanced the effect of A1762T/G1764A mutation on HBV. **Conclusion:** Our findings revealed A1762T/G1764A mutation selectively regulate preC RNA, pgRNA and sub-pgRNA transcription which hints it as an indicator for management of CHB patients, and provide HNF1α as a new target for curing HBV infected patients.

1515-C | MOLECULAR EPIDEMIOLOGY OF HEPATITIS B VIRUS IN PEOPLE WITH AND WITHOUT HIV COINFECTION IN ZAMBIA, SOUTHERN AFRICA

Bright Nsokolo[1], Andreas Walker[2], Taonga Musonda[1], Edford Sinkala[3], Nadia Alatrakchi[4], Guy Muula[5], Paul Kelly[6], Annie Kanunga[5], Debika Bhattacharya[7], Gilles Wandeler[8], Georg M. Lauer[4], Raymond T. Chung[4], Joerg Timm[2] and Michael Vinikoor[9], (1)University of Zambia, (2)Heinrich Heine, (3)University Teaching Hospital, Lusaka, (4)Massachusetts General Hospital and Harvard Medical School, (5)Centre for Infectious Disease Research in Zambia, (6)Queen Mary University of London, (7)University of California, Los Angeles, (8)University of Bern, (9)University of Alabama at Birmingham

Background: Data are lacking on HBV's natural history in Africa, including host genetics, environmental exposures, and viral factors. The impact of different HBV genotypes found in Africa (A1, D, and E) is poorly understood, including in the context of HIV, a common coinfection in the region. We sequenced HBV in a unique clinical cohort in Zambia and analyzed viral differences by genotype and HIV coinfection status. **Methods:** We analyzed HBV viremic samples from a clinical cohort that recruited treatment-naïve adults (age 18+ years) with HBV/HIV coinfection and HBV monoinfection at 3 hospitals in Lusaka. Participants with coinfection were identified at enrollment into HIV care. Counterparts with HBV alone were identified due to both clinically-driven (i.e., signs/symptoms) or routine HBsAg testing. At enrollment, we measured liver transaminases, hepatitis B e antigen, and HBV DNA (plus CD4 count in HIV coinfection). When HBV DNA was > 500 IU/ml, the complete HBV genome was amplified in two fragments and sequenced on the Nanopore platform. **Results:** Sequencing results from 220 adults with HBV DNA > 500 IU/ml were analyzed. Their median age was 33.2 years, 65 (29.5%) were women, 60 (27.3%) had HIV coinfection, and in participants with coinfection, the median CD4 count was 137 cells/mm^3. HBV genotype A1 (gtA) and genotype E (gtE) were equally frequent (105 vs. 115); however, HIV coinfection was more common in participants with gtE than gtA (33.9% vs 20.0%; $p = 0.02$). Interestingly, gtE isolates displayed less phylogenetic clustering and genetic distance than gtA (median patristic distance, 0.019 vs. 0.011; $p < 0.0001$), consistent with more recent and local transmission of gtE in the population. The stop codon in the pre core region associated with HBeAg loss was detected in 42.6% of the gtE isolates, but was nearly absent in gtA. Notably, in gtE this HBeAg variant was less frequent in HBV/HIV coinfection compared to HBV alone (38.4% vs. 70.1%; $p = 0.0014$), consistent with less immune pressure in the context of HIV. **Conclusion:** In Zambia, two HBV genotypes are circulating and may have unique transmission patterns. Whereas different gtA isolates were seemingly introduced on multiple occasions and continued to spread through the population, it appears that gtE is a more endemic form of HBV in this region and is still transmitted. Association of HIV with gtE may reflect shared transmission networks between HIV and gtE.

1516-C | PATHOGENESIS OF FLARES IN LIVER INFLAMMATION IN HEPATITIS B VIRUS-INFECTED WOMEN DURING AND AFTER PREGNANCY

Keisuke Fukutomi[1], Akira Nishio[1], Sharika Hasan[1], Pir Shah[2], Mukarram Jamat Ali[2], Karen J. Campoverde Reyes[2], Jonathan H. Badger[3], Giorgio Trinchieri[3], Daryl T. Y. Lau[2] and Barbara Rehermann[1], (1)Niddk, National Institutes of Health, (2)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (3)Center for Cancer Research, National Cancer Institute

Background: Pregnant women with chronic hepatitis B are at increased risk of liver inflammation. Here, we examined whether changes in the immune system and the gut microbiome during pregnancy play a role in the pathogenesis of these disease flares. **Methods:** Blood and stool samples from 18 women with chronic hepatitis B (12 without and 6 with NUC treatment) and 3 uninfected women were collected in each trimester of pregnancy and at two and six months postpartum. Increased ALT activity was defined as above the upper limit of normal and twice the baseline value in the respective patient. Plasma levels of cytokines, chemokines and soluble markers of immune cell activation, were assessed by Mesoscale assay. Gut microbial composition was determined by 16S ribosomal RNA amplicon sequencing. **Results:** Seven (58%) treatment-naïve and 2 (33%) NUC-treated patients developed perinatal hepatic flares. While plasma levels of soluble CD163, inflammatory cytokines, and chemokines increased during hepatic flares, IL-22 and IFN-γ levels increased prior to a postpartum hepatic flare in one case. Plasma levels of IL-27, a cytokine produced by the trophoblast, increased in the 3rd trimester even in women with normal ALT levels. The fecal microbiota of hepatitis B virus-infected patients with and without NUC therapy had a lower α-diversity (inverse Simpson index) than those of uninfected controls. 16S rRNA amplicon analysis and principal component analysis revealed patient-specific clustering of the microbiota. To identify predictive factors for postpartum hepatic flares, we compared 16S rRNA DNA data from patients with and without a postpartum hepatic flare (four patients per group). The gut microbiota of those with a hepatic flare was significantly different from those without a hepatic flare and the difference was maintained at all study time points. **Conclusion:** A postpartum ALT increase was preceded by an IL-27, and/or IL-22 and IFN-γ increase during pregnancy in some cases. The composition of the fecal microbiota was found to be patient- rather than time-point-dependent and differed between patients with and without postpartum liver disease flares.

1517-C | PD-1 INHIBITOR-BASED THERAPIES COULD LEAD TO A DIVERSITY OF VIRAL KINETICS IN CANCER PATIENTS WITH CONCOMITANT HBV INFECTION

Yingfu Zeng, Xinhua Li and Yutian Chong, The Third Affiliated Hospital of Sun Yat-Sen University

Background: Previous studies have shown that blockade of programmed cell death-1 (PD-1) or programmed cell death- Ligand-1 (PD-L1) may improve anti-HBV responses in vitro and woodchuck models. However, due to the fact that PD-1/PD-L1 inhibitors are still under clinical trials, clinical data on their effects or side-effects in the treatment of chronic HBV infection is limited. Therefore, we aimed to observe the changes of serum HBsAg and HBV DNA levels in cancer patients concomitant with HBV infection ongoing PD-1 inhibitor-based therapies and identify the risk factors associated with HBsAg fluctuations and HBV reactivation (HBVr). **Methods:** A retrospective study including HBsAg-positive cancer patients (n = 677) who received PD-1 inhibitors between July 2019 and December 2022 was undertaken. The primary study endpoint was the significant changes of serum HBsAg during treatment, which was defined as serum HBsAg levels were more than 3 folds higher/lower than the baseline after receiving PD-1 inhibitors. The secondary study endpoint was

HBVr, which was defined by the American Association for the Study of Liver Diseases (AASLD) 2018 hepatitis B guidelines. The incidence of HBsAg loss and immune-related adverse events (irAEs) were also investigated. Univariable and multivariable analysis were performed to identify the risk factors for significant serum HBsAg fluctuations and HBVr. **Results:** Due to insufficient attention been paid to the detection of serum HBsAg levels in cancer patients by clinicians, only 121 patients were eligible according to the inclusion criteria of this study (as shown in Fig 1). With concurrent use of antiviral agents, we noticed that most patients with baseline serum HBsAg range between 50 and 500 IU/ml experienced a statistically significant decrease in serum HBsAg levels ($Z = -3.2767$, $p = 0.001$) after PD-1 inhibitor exposure (as shown in Fig 2), viral replication can be inhibited effectively in most patients undergoing anti-tumor therapies. HBsAg loss, HBVr and irAEs were developed in 6 patients (4.96%), 6 patients (4.96%) and 14 patients (11.57%), respectively. Multivariable analysis showed baseline serum HBsAg less than 100 IU/ml ($p = 0.01$) was the only significant risk factor for HBsAg decrease, irAEs occurrence was the only significant risk factor for HBVr ($p = 0.03$), while no risk factors were identified for HBsAg increase. **Conclusion:** PD-1 inhibitor combined with NAs may exert therapeutic potential for chronic HBV infection in cancer patients, attention also should be paid to the risk of HBVr and irAEs.

1518-C | PRECORE MUTATION PROMOTES CHRONIC HEPATITIS B DISEASE PROGRESSION VIA ENHANCED VIRAL REPLICATION AND ABERRANT CORE PROTEIN EXPRESSION

Guixin Li[1], Danli Yang[2], Hongsong Chen[1], Xiangmei Chen[2] and Fengmin Lu[2,3], (1)Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, (2)Peking University, (3)Peking University People's Hospital

Background: Naturally occurred precore (PC, G1896A) and basal core promoter (BCP, A1762T/G1764A) mutations are prevalent in chronic hepatitis B (HBV)- infected patients. Numerous studies have focused on the role of these mutations in viral replication and disease progression but the conclusion remains ambiguous. This study aimed to explore the effects of PC mutation alone or BCP+PC combined mutations on virus replicative capacity, infectivity and pathogenicity. **Methods:** We searched Pubmed, Embase and Cochrane library to include studies about association of PC mutant with HBV DNA, liver cirrhosis or hepatocellular carcinoma up to June 18, 2022. Transfected or infected cell models and animal models were used. **Results:** Meta-analyses showed that serum HBV DNA load of patients without G1896A mutant was 0.37 $\log_{10}$copies/mL (2.34 foldchange) higher than those with PC mutant among HBeAg-positive patients, whereas it was 0.87 $\log_{10}$copies/mL (7.41 foldchange) lower than those with the mutant among the HBeAg-negative patients. Moreover, PC mutant was closely relevant with liver cirrhosis and hepatocellular carcinoma compared to well-stratified controls. Next, we found that PC mutation enabled preC RNA to serve pgRNA-like function, expressing Core and P protein, to promote HBV replication in transfected cell and mouse models. And compared to PC mutation alone, BCP+PC mutations could further elevated HBV DNA level. Consistently, PC and BCP+PC mutations decreased infectivity but increased replicative capacity in HepG2-NTCP cells and human liver chimeric mice. RNA sequencing of livers in chimeric mice implied BCP+PC mutants suppressed host IFN signaling pathways in human hepatocytes, which might account for elevated cccDNA level. Importantly, accumulation of core proteins likely led to severe human hepatocyte degeneration and cytoplasmic vacuolation via endoplasmic reticulum stress and TNF signaling pathway, which might in turn induce the compensatory proliferation

indicated by enhanced cell cycle and hippo pathways in mouse livers of BCP+PC group. **Conclusion:** PC and/or BCP mutations enhanced HBV replication *in vitro* and *in vivo*, but the association of PC mutant with higher HBV DNA level was observed solely in HBeAg-negative patients. PC mutant was closely associated with advanced liver diseases in chronic HBV-infected patients. BCP and PC combined mutations might induce severe hepatocyte damage via enhanced viral replication and aberrant core protein expression in human liver chimeric mice.

1519-C | SUPPRESSION OF HSPG2 EXPRESSION INHIBITS HBV ENTRY AND REPLICATION VIA INCREASED cMET EXPRESSION

Kazuhiro Murai[1], Hayato Hikita[1], Tasuku Nakabori[1], Shinji Kuriki[1], Emi Sometani[1], Jihyun Sung[1], Akiyoshi Shimoda[1], Makoto Fukuoka[1], Satoshi Shigeno[1], Akira Nishio[1], Takahiro Kodama[2], Tomohide Tatsumi[2], Hiroshi Suemizu[3] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2)Osaka University Graduate School of Medicine, (3)Central Institute for Experimental Animals

Background: Hepatitis B virus (HBV) entry into hepatocyte requires heparan sulfate proteoglycans (HSPGs) and NTCP, which is a bile acid transporter (BAT). Among HSPGs, we focused on HSPG2, which contributes to the binding of HGF fragments and cMET. We investigated the effect of HSPG2 suppression on HBV infection and its mechanism. **Methods:** Primary human hepatocytes isolated from humanized liver chimeric TK-NOG mice (HepaSH cells) were inoculated with HBV (500 genome equivalent (GEq)/cell) prepared by concentrating the culture supernatant of HBV genome-integrated cells (HepAD38.7). **Results:** The suppression of HSPG2 expression with siRNA 3 days before HBV inoculation significantly decreased the expression levels of covalently closed circular DNA (cccDNA). The suppression of HSPG2 expression significantly increased cMET expression and decreased NTCP expression. The suppression of NTCP expression by the suppression of HSPG2 expression was cancelled by the suppression of cMET. On the other hand, the suppression of NTCP expression did not alter the mRNA expression levels of HSPG2. The suppression of NTCP expression with siRNA 3 days before HBV inoculation significantly decreased the expression levels of cccDNA. The suppression of both HSPG2 and NTCP expression had no additional effect on cccDNA reduction compared to the suppression of NTCP alone. The suppression of HSPG2 may inhibit HBV entry by suppressing NTCP expression through upregulation of cMET expression. The suppression of NTCP expression 20 days after HBV inoculation did not reduce the expression levels of cccDNA, but the suppression of HSPG2 expression did. Considering the possibility that the suppression of HSPG2 expression may have other mechanisms to affect HBV replication than HBV entry inhibition, we focused on PPARγ, a host transcription factor that activates HBV transcription. The suppression of HSPG2 upregulated cMET and downregulated PPARγ. The Suppression of PPARγ downregulated NTCP, NR5A2, which regulates BAT expression, and CTNNB1, an activator of NR5A2. The Suppression of CTNNB1 downregulated NR5A2 and NTCP. The suppression of NR5A2 downregulated NTCP. It was suggested that cMET regulated NTCP expression via PPARγ, CTNNB1 and NR5A2. **Conclusion:** Suppression of HSPG2 expression was suggested to have an effect that suppress both HBV entry and replication via increased cMET expression.

1520-C | SUPPRESSION OF MIR-451a TRIGGERS A MYC DEPENDENT OVERPRODUCTION OF ONCOMIR-126-5p LEADING TO ACTIVATION OF Β-CATENIN SIGNALING AXIS BY IMPEDING DKK1 THAT PROMOTES CHEMO-RESISTANCE TO HEPATOCELLULAR CARCINOMA CELLS.

Anannya Chakraborty[1], Sanjana Banerjee[1], Swagata Majumdar[1], Indrashish Dey[1], Amit Ghosh[1], Suchandrima Ghosh[1], Sayantani Bhowmik[1], Abhijit Chowdhury[2], Simanti Datta[1] and Soma Banerjee[1], (1)Institute of Post Graduate Medical Education and Research, (2)Institute of Post Graduate Medical Education & Research

Background: Despite availability of vaccine against Hepatitis B virus, chronic hepatitis B (CHB) is a global health threat and the major underlying risk factor for the development of Hepatocellular Carcinoma (HCC). Chemo-resistance is the major obstacles in the current treatment modalities of HCC. This study explored the role of oncogenic transcription factor MYC on the deregulation of microRNA and its impact on chemo-resistance

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

of HCC. **Methods:** Transcriptome-analysis/qRT-PCR/Bio-informatics/Luciferase assay/ELISA/Immuno-blotting/Chromatin-Immuno-precipitation/Transfection/Cell proliferation/ Apoptosis/ Migration/ Chemo-sensitivity assay, etc. were employed as required. **Results:** Transcriptome analysis of GSE 94660 that includes liver tissue of 21 HBV-HCC and 21 adjacent normal revealed that 52 oncogenic transcription factors (TF) were upregulated in HCC. Among which MYC was observed as one of the most overexpressed TFs. Subsequently, it was observed that MYC could activate the expression of endothelial growth factor 7 (EGFL7) intron derived miRNA, miR-126-5p, which was previously established as biomarker of HCC. ChIP-assay further confirmed the binding of MYC to the promoter of EGFL7/miR-126. HBX protein of HBV was the activator of MYC oncoprotein. Target prediction and pathway analysis with validated targets in transcriptome data revealed WNT signaling pathway was the most targeted pathway of this miRNA. Luciferase assay and western blot analysis showed that each protein of β-catenin destruction complex (GSK3β/ APC/AXIN) and DKK1, inhibitor of Wnt-β catenin pathway were impeded by miR-126-5p. Restoration of miR-126-5p in Huh7/Snu449 augmented the chemoresistance to 5FU/ sorafenib and triggered proliferation and stemness in HCC cells as MYC/OCT4/NANOG/CD44 was overproduced in the milieu and followed a feedback loop. The expression of MYC was observed to be maintained by a tumor suppressor miRNA, miR-451a in HCC. **Conclusion:** These results highlighted that targeting oncogenic transcription factor may be useful in the clinical management of HCC patients.

1521-C | TARGETED VIRAL ADAPATION GENERATES A SIMIAN-TROPIC HEPATITIS B VIRUS THAT INFECTS MARMOSET CELLS

Yongzhen Liu[1], Thomas R. Cafiero[1], Debby Park[1], Abhishek Biswas[1], Benjamin Y. Winer[1], Cheul H. Cho[2], Yaron Bram[3], Vasuretha Chandar[3], Aoife K. O'Connell[4], Hans P. Gertje[4], Nicholas Crossland[4], Robert E. Schwartz[3] and Alexander Ploss[5], (1)Princeton University, (2)Visikol, Inc., (3)Weill Cornell Medicine, NY, (4)Boston University, (5)Princeton University, Princeton, NJ

Background: Hepatitis B virus (HBV) only infects humans and chimpanzees, posing major challenges for modeling HBV infection and chronic viral hepatitis. The major barrier in establishing HBV infection in non-human primates lies at incompatibilities between HBV and simian orthologues of the HBV receptor, sodium taurocholate co-transporting polypeptide (NTCP). **Methods:** Phylogenetic analysis among NTCP orthologues from Old World monkeys (OWM), New World monkeys (NWM) and prosimians were performed. Myristoylated preS1[2-48]-FITC peptides of HBV or woolly monkey HBV (WMHBV) were used for viral binding assays by fluorescence confocal microscopy and flow cytometry. HepG2 cells expressing different NTCP orthologues and mutagenesis analysis were used for HBV binding, entry, and infection assays. AlphaFold NTCP structure prediction was used for analyzing the structural basis. Sucrose density gradient centrifugation and transmission electron microscopy were employed for HBV/WMHBV preS1[1-48] chimeric virus characterization. Self-assembling co-cultures of primary marmoset hepatocytes (PMH) and murine non-parenchymal stromal cells were established to maintain the highly differentiated phenotype of primary hepatocytes for HBV, WMHBV and HBV/ WMHBV preS1[1-48] chimeric virus infection. Marmoset induced pluripotent stem cell (iPSC)-derived hepatocyte-like cells were developed for HBV and HBV/WMHBV preS1[1-48] infection. Southern blot, HBV cccDNA qPCR, multiplexed HBV RNA in situ hybridization (ISH), HBc and NTCP immunohistochemistry (IHC) were used to determine the infection. **Results:** Our results suggest R158G enables binding of preS1 to OWM-NTCP, whereas G158R abrogates preS1 binding to NWM-NTCP, underscoring that G158 is necessary for HBV binding while residues 84-87 are functional for HBV internalization. We also found L165 is another important residue to accelerate HBV infection by stabilize NTCP structure. More importantly, structure analysis among wild type NTCPs from OWM and NWM suggests marmoset has the lowest root mean squared deviation compared with hNTCP. We replaced residues 1-48 of HBV preS1, the key regions mediating HBV entry, with the equivalent WMHBV sequence that differs by 16 AAs, yielding a chimeric virus termed HBV/WMHBV preS1[1-48] which has similar biophysical properties with HBV. Functionally, HepG2 cells expressing marmoset-NTCP, primary marmoset hepatocytes and induced marmoset pluripotent stem cell-derived hepatocyte-like cells support HBV and more efficient woolly monkey HBV (WMHBV) infection. Adapted chimeric HBV genome harboring residues 1-48 of WMHBV preS1 led to a more efficient infection than wild-type HBV in primary and stem cell derived marmoset hepatocytes. **Conclusion:** Our data demonstrate that minimal targeted simianization of HBV can break the species barrier in small NHPs, paving the path for an HBV primate model.

1522-C | TENOFOVIR ALAFENAMIDE FUMARATE IN TREATMENT-NAÏVE CHRONIC HEPATITIS B PATIENTS WITH HISTOLOGICALLY CONFIRMED LIVER FIBROSIS: A 48-WEEK EFFICACY AND SAFETY RESULTS

Jialing Zhou[1], Xiaoning Wu[2], Chuanwu Zhu[3], Jiming Zhang[4], Ping Li[5], Tao Han[6,7], Huiguo Ding[8], Chenghai Liu[9,10], Wen Xie[11], Qing Xie[12], Yali Zong[13], Tongtong Meng[2], Xiaojuan Ou[2], Hong You[14] and Jidong Jia[2], (1) Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (2)Liver Research Center, Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center of Digestive Diseases, Beijing, China, (3)The Fifth People's Hospital of Suzhou, (4)Fudan University, (5)Department of Hepatology, Tianjin Second People's Hospital, Tianjin, China, (6)Tianjin Third Central Hospital, Tianjin, China, (7)Tianjin Medical University, Tianjin Union Medical Center Affiliated to Nankai University, (8)Department of Gastroenterology and Hepatology, Beijing You'an Hospital, Capital Medical University, Beijing, China, (9) Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, (10)Shanghai Key Laboratory of Traditional Chinese Clinical Medicine, (11) Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, (12)Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, (13) The Ninth Hospital of Nanchang, (14)Liver Research Center, Beijing Friendship Hospital, Capital Medical University

Background: The antiviral efficacy of tenofovir alafenamide (TAF) in both control trials and real-world studies are well documented in patients with chronic hepatitis B (CHB). However, its histological effect on liver fibrosis is still unknown. Therefore, we conducted a single arm study to investigate anti-fibrotic effect of 96 weeks of TAF. In this interim analysis, we present the effect of 48-week treatment with TAF on liver fibrosis evaluating by non-invasive methods. **Methods:** Treatment-naïve CHB patients with histologically confirmed liver fibrosis patients were prospectively recruited from 10 tertiary hospitals in China (NCT04939441). Virological responses (VR: HBVDNA < 20 IU/ml), alanine aminotransferase (ALT) normalization (< 40 IU/L) and noninvasive indicators including LSM, aspartate aminotransferase-to-platelet ratio index (APRI) and Fibrosis 4 Score (FIB-4) were used to assess liver fibrosis at every 24 weeks during treatment. Safety profiles covered estimated glomerular filtration rate (eGFR), bone density and lipid profiles at 48 weeks. **Results:** A total of 100 CHB patients were enrolled. At baseline, The mean age of the cohort was 42.2 ± 10.3 years and 59% of the subjects were male. There were 47, 30 and 23 patients staged at F2, F3 and F4 respectively according to Metavir score system before treatment. VRs at 12, 24 and 48 weeks were 34%, 49% and 74%, respectively. ALT normalization rates were 61% and 75% at 24 and 48 weeks, respectively. LSM, APRI and FIB-4 significantly declined ($p < 0.001$) at 48 weeks. LSM decreased from 9.6 to 6.8 kPa at 48 weeks with a steep decline in the first 24 weeks and then a gradual decline. There were 73.1% patients had LSM decrease, especially 44 patients (47.3%) decreased at least 30% of LSM at 48 weeks. Changes of APRI and FIB-4 were similar to LSM. From baseline to week 12, the median changes in eGFR, using the *CKD-EPI* equation, showed transient and mild reduction. There was no statistically significant in hip and spine BMD and lipid profiles (TG, TC, HDL and LDL) from baseline to week 48. During the 48-week treatment, five cases of serious adverse event occurred. **Conclusion:** TAF had good efficacy in virological response, biochemical response and safety profiles. More importantly, the study demonstrated that TAF could well reverse hepatitis B liver fibrosis by using non-invasive indicators.

1523-C | THE BCL6/Blimp1 AXIS REGULATES FOLLICULAR T CELLS TO PROMOTE HBEAG SEROCLEARANCE IN PATIENTS WITH HBEAG-POSITIVE CHRONIC HEPATITIS B

Shuo Li[1,2], Xiaoke Li[1,2], Xiaobin Zao[1,2], Hongbo Du[1,2], Da'Nan Gan[1,2] and Yong'An Ye[1,2], (1)Dongzhimen Hospital, Beijing University of Chinese Medicine, (2) Institute of Liver Diseases, Beijing University of Chinese Medicine

Background: T cells exert both protective and pathogenic effects in CHB. Follicular T cells, a particular subgroup of T cells that express the C-X-C pattern chemokine receptor 5 (CXCR5), have gained attention in recent years due to unique characteristics and potential impact on the immune response in chronic hepatitis B (CHB). This study aimed to investigate the role of the BCL6/Blimp1 axis in regulating follicular T cells and improving the seroclearance of hepatitis B e antigen (HBeAg) in CHB patients. **Methods:** Flow cytometry was conducted using circulating peripheral blood mononuclear cells (PBMCs) obtained from 15 healthy controls (HCs) and 40 patients with CHB. These patients exhibited different HBeAg responses (seroclearance response [SR] and non-seroclearance response [NR]) following a 96-week regimen of Entecavir (ETV). The potential correlations between the frequency of follicular T cells, clinical parameters, and relevant serum cytokines (IL-10, IL-21, IFN-γ, and TNF-α) expression were assessed. The mRNA and protein expression levels of BCL-6, Blimp-1, IL-21, and IFN-γ were evaluated by quantitation PCR and western blotting analyses, respectively. **Results:** The frequencies of $CD4^+CXCR5^+$ T follicular helper (TFH) cells and $CD8^+CXCR5^+$ T follicular cytotoxic cells (TFC) were significantly higher in HBeAg-positive CHB patients compared with HCs. Compared with the NR patients, there was an increase in the frequencies of TFH and TFC and a decrease in the frequency of $CD4^+CD25^+$ regulatory T cells (Tregs) in SR patients. The subgroups of TFH and TFC were analyzed. Compared with the NR patients, $ICOS^+CXCR5^+CD4^+$ TFH and $CD127^+CXCR5^+CD8^+$ TFC were significantly higher in SR patients. The SR patients showed higher levels of IL-21 and IFN-γ than the NR patients. Additionally, BCL-6, IL-21, and IFN-γ expression were significantly upregulated, while Blimp-1 expression was downregulated in SR patients. **Conclusion:** The BCL6/Blimp1 axis regulates follicular T cells to promote HBeAg seroclearance in patients with HBeAg-positive CHB. These findings may contribute to a better understanding of the function of follicular T cells and provide a potential immunotherapeutic target for chronic HBV infection.

Background: Hepatitis B is a common infectious disease in humans and is associated with significant morbidity and mortality. The hepatitis B virus (HBV) encodes three transmembrane surface proteins of distinct sizes (HBsAg L,M,S) which contribute to the viral envelope and also assemble into capsid-free subviral particles/filaments (SVPs) that are secreted in massive amounts to potentiate infection. Currently the cellular mechanisms by which these SVPs are secreted from the host are unclear. Therefore, the **GOAL** of this study was to define the precise hepatocellular trafficking pathway utilized to support HBsAg (SVP) secretion. **Methods:** High resolution confocal microscopy and a novel mCherry-tagged HBsAg-probe were applied to a HepG2 cell line stably expressing the small surface antigen (SHBsAg), as well as HBV-infected primary human hepatocytes (PHH). The truncated SHBsAg-GFP/mCherry probe was constructed and characterized to observe SHBsAg trafficking in live cells, an approach that has been unsuccessful to date. Secretion of SHBsAg was also monitored by Western blot analysis and a chemiluminescence immunoassay. **Results:** Detailed imaging of both HepG2 and PHH cell models indicates that the SHBsAg transits directly from the ER to the late endosomal compartments including the multivesicular body (MVB) and lysosome while bypassing the Golgi apparatus. This unique SHBsAg secretory pathway was compared within the HepG2 and PHH models that were co-transfected with the vesicular stomatitis virus G (VSV-G) protein, well known to utilize a canonical ER to Golgi to surface pathway. Importantly, in both fixed and live cells the VSV-G protein was observed to transit from the ER-Golgi-surface while the SHBsAg trafficked directly from ER to MVBs, including autophagic LC3 positive structures. To further test for a direct ER to autophagosome SHBsAg pathway, we applied an siRNA knockdown approach to target autophagosome/ER-Phagy receptors/adaptors and found that disruption of this pathway resulted in reduced secretion and an intracellular accumulation of SHBsAg as a result of treatment with the lysosome inhibitor Baf-A1. **Conclusion:** this study indicates that in both HepG2 and PHH cell models the SHBsAg particles bypass the canonical ER-Golgi secretory pathway and instead are transited directly to the autophagic/MVB pathway via an ER-phagy process. These findings along with the development of a novel tagged bio-probe will facilitate the study and understanding of HBV infection.

1525-C | THE IMPACT OF SINGLE-NUCLEOTIDE VARIANTS AND SURFACE ANTIGEN MUTATION ON THE DEVELOPMENT OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC HBV INFECTION

Yuh-Jin Liang, Taipei Veterans General Hospital; National Yang Ming Chiao Tung University

Background: Nucleos(t)ide analogues (NUC) therapy has shown efficacy in reducing hepatocellular carcinoma (HCC) incidence in HBV carriers with normal or mildly elevated ALT levels. Our previous study also identified mitochondrial dysfunction as a novel mechanism in HBV-related liver disease, particularly in carriers with secretion-defective Pre-S/S deletion mutants. Additionally, a genome-wide high-throughput analysis revealed HBV single-nucleotide variants (SNVs) associated with HCC development. **Methods:** In a separate report presented at this conference, our research team conducted a longitudinal case-control study to assess the predictive value of SNVs in the Pre-S/S region and the role of antiviral therapy in patients not meeting current treatment guidelines (ALT < 80 U/L or HBV DNA < 2000 IU/ml). This report investigates the impact of Pre-S/S region SNVs on mitochondrial function, calcium homeostasis, and HBV DNA retention/secretion in HCC cell lines. Methods included Seahorse XF real-time ATP rate assay, calcium imaging, quantitative PCR, and western blot. **Results:** HCC-associated SNVs generally led to ATP depletion, with genotype C SNVs, such as G530A and T724C, affecting mitochondrial ATP production and genotype B SNVs, such as A2889G and C3097A, impairing glycolysis-driven ATP production. Genotype C SNVs also correlated with higher ROS production and lower mitochondrial membrane potential. Calcium imaging revealed that T53C SNV and Pre-S/S region deletion-expressing cells exhibited elevated basal calcium levels and reduced calcium buffering capacity. Furthermore, T53C SNV and Pre-S/S deletion demonstrated higher intracellular retention of HBV DNA and HBsAg, accompanied by increased ER stress and unfolded protein response. **Conclusion:** Our findings suggest heterogeneity in the pathogenic role of HBV SNVs, with secretion-defective mutants, such as T53C and Pre-S/S deletion, inducing ER stress, impairing mitochondrial function, and reducing ATP production, while secretion-efficient SNVs, such as A293G and G633A, may enhance viral replication and infectivity. In a separate report presented at this conference, our research team also revealed that inhibition of late-phase autophagy by HBV contributes to liver injury and the development of HCC. Further investigations will assess the impact of these SNVs on autophagic and lysosomal activity.

1600-A | ASSESSMENT OF PORTAL SYSTEM HEMODYNAMICS FOR THE PREDICTION OF PORTAL VEIN THROMBOSIS IN CIRRHOSIS – A SYSTEMATIC REVIEW AND META-ANALYSIS

Marko Kozyk[1], Suprabhat Giri[2], Ankita Singh[3], Kailash Kolhe[4], Akash Roy[5] and Kateryna Strubchevska[1], (1) Corewell Health William Beaumont University Hospital, (2)Nizam's Institute of Medical Sciences, (3)Seth GS Medical College and Kem Hospital, (4)Narayana Hospital, (5)Apollo Hospitals, Kolkata

Background: The pathogenesis of portal vein thrombosis (PVT) in cirrhosis is multifactorial, with altered hemodynamics being proposed as a possible contributor. The present systematic review was conducted to study the role of assessment of portal hemodynamics for the prediction of PVT in patients with cirrhosis. **Methods:** Three databases (Medline, Embase, and Scopus) were searched from inception to February 2023 for studies comparing portal venous system parameters in patients with cirrhosis developing PVT with those not. Results were presented as mean difference (MD) or odds ratio (OR) with their 95% confidence intervals (CI). **Results:** A total of 31 studies (patients with cirrhosis: 19 studies, patients with cirrhosis undergoing splenectomy: 12 studies) were included. In patients with cirrhosis, portal vein diameter (PVD), splenic length, and splenic thickness were significantly shorter in those without PVT than those developing PVT with a MD of -1.62 (-2.51 to -0.73) cm, -1.17 (-1.59 to -0.75) cm, and -0.97 (-1.19 to -0.74) cm, respectively. On pooling the data from multivariable analyses of the included studies, a larger portal vein diameter was a significant predictor of PVT in patients with cirrhosis without or with splenectomy with OR 1.74 (1.12 – 2.69) and OR 1.55 (1.26 – 1.92), respectively (Figure 1). With each 1 cm increase in the PVD, there was 1.7 times higher odds of developing PVT in cirrhotics. On the other hand, portal vein velocity (PVV) was significantly higher in those not developing PVT than those developing PVT, with an MD of 5.23 (4.86 to 5.60) cm/s. A lower PVV was a significant predictor of PVT in cirrhotics without or with splenectomy with OR 0.93 (0.91 – 0.96) and OR 0.71 (0.61 – 0.83), respectively. With each 1 cm/s reduction in PVV, there was 1.1 times higher odds of developing PVT in cirrhotics. A PVV of < 15 cm/s was the most commonly used cut-off for the prediction of PVT. Patients developing PVT also had a significantly higher splenic length, thickness, and splenic vein velocity. **Conclusion:** The assessment of portal hemodynamic parameters at baseline evaluation in patients with cirrhosis may predict the development of PVT. Further studies are required to determine the optimal cut-offs for various parameters.

1601-A | EVALUATION OF RESPONSE TO HIGH-DOSE INTRAVENOUS VITAMIN K ADMINISTRATION

April Chapman[1], Jason Yerke[2], Mollie Lumpkin[2], Michael Rudoni[2], Christina C. Lindenmeyer[2], Aanchal Kapoor[2], Lu Wang[2] and Stephanie Bass[2], (1) Intermountain Health St. Vincent Healthcare, (2) Cleveland Clinic

Background: In addition to its use in the correction of clotting factor deficiencies and reversal of warfarin-induced bleeding, high-dose intravenous (IV) vitamin K (phytonadione) (IVK) is often used to lower INR in patients with cirrhosis to "challenge" INR elevation in the setting of nutritional deficiency. Limited data exists supporting repeat dosing. This study sought to characterize differences in responders and non-responders to high-dose IVK to guide dosing strategies. **Methods:** This was a subgroup analysis of patients with cirrhosis from a previously published case-control study of hospitalized adults (**e** 18 y) who received IVK 10 mg daily for 3 days for treatment of coagulopathy, defined as an international normalized ratio (INR) of > 1.5. Patients with an INR < 1.5 or **e** 30% lower than baseline after the first dose of IVK were considered responders and compared to non-responders. The primary outcome was change in INR over time with subsequent doses. A linear mixed-effects model (LMM) compared reduction of INR at follow-up time points between groups. Secondary outcomes included factors associated with response to IVK and incidence of safety events. **Results:** 455 patients with were included; 151 were

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

IVK responders. Most patients were white (n = 335, 75%) males (n = 238, 52%) with a mean age of 53 ± 14 years. Most patients had alcohol-related cirrhosis (n = 249, 55%), with a mean MELD score of 25.3 (95% CI 18.9-31.2). INR decreased from 1.94 (adjusted least square mean from LMM, 95% CI 1.88-2.00) to 1.67 (1.63-1.71); a 16% reduction from baseline to day 3 (11.9-20.2%). In responders, the largest INR decrease occurred from 1.91 at baseline (95% CI 1.82-2.0) to 1.48 on day 1 (1.43-1.54) and to 1.39 on day 3 (1.34-1.44). In non-responders, INR changed from 1.96 at baseline (95% CI 1.89-2.03) to 1.84 on day 3 (1.79-1.89). Predictors of response included lower weight, compensated cirrhosis, cirrhosis etiologies other than alcohol, and lower bilirubin. There was a low incidence of anaphylactoid events. Risk of bleeding was not assessed. **Conclusion:** In this subgroup analysis of patients with cirrhosis, the overall adjusted change in INR over 3 days was 0.3 with minimal variation between responders and non-responders. In responders, the largest reduction in INR occurred after the first dose and minimal change occurred with subsequent doses. Future studies may serve to characterize patient populations who would benefit from sequential daily IVK versus single dosing.

1602-A | MULTIDISCIPLINARY CARE IMPROVES SURVIVAL IN PATIENTS WITH SPLANCHNIC VEIN THROMBOSES

Dina Zaret[1], Dahniel Sastow[1], Tyler Italiano[1], Thomas Schiano[2], Rahul Patel[1], Douglas Tremblay[1] and Adam Winters[1], (1)Icahn School of Medicine at Mount Sinai, (2)Recanati/Miller Transplantation Institute at Mount Sinai

Background: Splanchnic vein thromboses (SVT) are complications of liver cirrhosis as well as underlying hypercoaguable states, notably myeloid proliferative neoplasms. When treatment is indicated, anti-coagulation is the mainstay of therapy. Procedural intervention, such as transjugular intrahepatic portosystemic shunt placement, is reserved for patients with ischemic or portal hypertensive complications. The management of SVTs is complex and requires weighing the risk and benefit of any intervention carefully. Multidisciplinary input from hematology, hepatology and interventional radiology (IR) is often solicited for this population. The aim of this study is to identify the rates of multidisciplinary care and its impact on patient survival. **Methods:** We queried our imaging database to identify patients with possible splanchnic vein thrombosis based on imaging report. We evaluated 307 consecutive patients with a multi-phasic cross-sectional imaging report from 2013 to present. 196 cases had a confirmed SVT. We recorded if the patients had been evaluated by hepatology, hematology, and/or IR after their SVT diagnosis. Overall survival (OS) was estimated via Kaplan Meier method. To account for immortal time bias, a landmark analysis was also performed. **Results:** Of the 196 patients with a confirmed SVT, 170 (87%) had portal vein thromboses. 22 (11%) had hepatic vein thromboses, 44 (22%) had splenic vein thromboses, and 77 (39%) had mesenteric vein thromboses. Of these, 84 patients (43%) had thrombosis at multiple sites. A majority of patients (73%) were seen by hepatology after their diagnosis, as well as by hematology (60%), and by IR (59%). A total of 149 patients (77%) were seen by a specialist within 1 month of their diagnosis. Only 61 patients (31%) saw all three specialists. After a median follow up of 22.7 months, 27 patients died. The median OS of patients seen by all three specialties was significantly longer (Not Reached [NR]) as compared to those seen by 2 or less specialties (32.0 mo, Figure). The landmark analysis demonstrated similar results. **Conclusion:** Most patients diagnosed with an SVT were seen by a specialist in hematology, hepatology, or IR. However, only a third of patients saw physicians from all three specialties. Increasing multidisciplinary care for patients with SVTs between hematology, hepatology, and IR may improve mortality. Multidisciplinary pathways to facilitate interdisciplinary communication may greatly impact outcomes among patients with SVTs.

1603-A | QUALITY IMPROVEMENT AND EDUCATION PROJECT IMPROVES HOUSE STAFF CONFIDENCE AND PERFORMANCE IN ORDERING AND INTERPRETING ROTATIONAL THROMBOELASTOMETRY FOR PATIENTS WITH COAGULOPATHY OF END STAGE LIVER DISEASE

Alexander N. Scherer[1,2], Mary Clare McGregor[1], Jaquelyn F. Fleckenstein[1] and Daniel Reynolds[1], (1) Washington University School of Medicine in St. Louis, (2)Indiana University School of Medicine

Background: In patients with end stage liver disease (ESLD), INR values do not predict bleeding risk nor reflect dynamic changes in coagulopathy. Rotational thromboelastometry (ROTEM) is an alternative, real-time test of hemostasis performed on whole blood. ROTEM-based transfusion strategies have reduced transfusions, costs, and transfusion reactions in ESLD patients prior to procedures or during bleeding. One barrier to using such a strategy is provider familiarity with ordering and interpreting ROTEM tests. We implemented a quality improvement (QI) and education project to improve house staff knowledge of indications for and interpretation of ROTEM in ESLD patients. **Methods:** We implemented an education and QI project in an ICU setting at a single tertiary care center over six months. We provided educational resources in the form of a monthly lecture, infographics in work areas (Fig. 1), and an online literature review. House staff voluntarily responded to assessments before and after their ICU rotations. The primary outcome was confidence in ordering and interpreting ROTEM in ESLD patients. The secondary outcome was correctly ordering and interpreting test results in case-based questions. **Results:** Forty-one of 72 eligible participants (57%) completed at least one pre- or post-rotation assessment and 65 percent ordered at least one ROTEM test during their rotation. House staff confidence ordering (2.1/5 vs. 3.5/5, $p = 0.0001$) and interpreting (1.8/5 vs. 3.3/5, $p = 0.0001$) ROTEM tests increased significantly after their rotations. In case-based questions, correctly ordering ROTEM testing significantly improved after the rotation (80% vs. 100%, $p = 0.025$); however, there was no change in interpretation of the results (60% vs. 67%, $p = 0.78$). PGY-1 residents were less confident ordering ($p = 0.008$) and interpreting ($p = 0.02$) testing compared to senior residents before rotations, but afterward had no differences from their peers in confidence scores or case-based questions. **Conclusion:** This education and QI project significantly improved trainee confidence and performance in ordering ROTEM testing in ESLD patients, and also improved confidence in interpreting the results. ROTEM-based transfusion strategies for ESLD patients have shown promise, but more data with clinical endpoints are needed to apply this technology broadly. Collecting such data may be possible after first improving provider understanding of how to order and act on ROTEM results at the bedside.

1604-A | REEVALUATING THE SIGNIFICANCE OF INR IN LIVER CIRRHOSIS: COLLABORATIVE DECISION-MAKING WITH INTERVENTIONAL RADIOLOGY FOR OPTIMAL PARACENTESIS

Adalberto Guzman[1], Evelyn Calderon Martinez[1], Anas Atrash[1], Wern Lynn Ng[1], Fernanda Ibarra[2] and Douglas M. Levin[3], (1)UPMC, (2)Woodhull Medical and Mental Health Center, (3)Ohio State University, Columbus, OH, United States

Background: The liver plays a critical role in the production of nearly all clotting factors and their inhibitors. Despite having mean INR values above > 3, patients with acute liver failure or cirrhosis typically experience minimal changes in their in vivo coagulation profiles. In patients with liver disease, PT and INR calculations do not strongly correlate with more advanced and specific assessments of coagulation status, such as those obtained through the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

use of thromboelastography (TEG). TEG serves as an alternative to measures like bleeding time, PT, and INR calculations in individual's with hepatic dysfunction whose healthcare provider wishes to evaluate a genuine coagulation profile that accurately reflects their in vivo clinical presentation. **Methods:** A collaborative effort between interventional radiology, internal medicine and gastroenterology with the introduction of thromboelastography (TEG) was proposed. **Results:** In our community practice, a significant number of patients (76%) hospitalized for acute decompensated cirrhosis or acute liver failure presented with an INR above 1.5, necessitating diagnostic or therapeutic paracentesis for abdominal ascites. However, due to concerns about elevated INR levels, only a fraction (23%) of these patients received timely paracentesis. It is worth noting that extensive research has consistently demonstrated minimal risk of bleeding associated with paracentesis, ranging from 0% to 0.99%. Nevertheless, the primary factor preventing patients from receiving timely paracentesis was the apprehension surrounding bleeding risks associated with elevated INR levels. To overcome these concerns, a multidisciplinary approach involving interventional radiology ,internal medicine and hepatology was implemented to perform thromboelastography in patients with INR levels above 1.5 and advanced liver disease. Out of the 72 patients included in the study, an overwhelming majority (approximately 98.3%) exhibited normal coagulation profiles as indicated by the thromboelastography results. Consequently, following the introduction of thromboelastography and a collaborative decision-making process involving interventional radiology, internal medicine, and gastroenterology teams, the rate of paracentesis within 12 hours saw a remarkable increase from 23% to 77%. **Conclusion:** Furthermore, this study reaffirms the inherent ability of individual's with liver cirrhosis to restore their hemostasis With the implementation of thromboelastography and the collaborative efforts of interventional radiology, internal medicine, and gastroenterology, the significant increase in the rate of paracentesis within 12 hours showcases the positive impact of evidence-based decision-making on patient care, ensuring timely and appropriate interventions.

1605-A | ROTATIONAL THROMBOELASTOMETRY PREDICTS FUTURE BLEEDING EVENTS IN PATIENTS WITH CIRRHOSIS

Natasha Janko[1,2], Ammar Majeed[1,2], Isabella Commins[1], Paul J. Gow[3,4], William W. Kemp[1] and Stuart Keith Roberts[1], (1)Alfred Health, (2)Monash University, (3)Austin Health, (4)University of Melbourne

Background: Patients with cirrhosis of the liver are in a delicate state of rebalanced haemostasis and are at risk of developing both bleeding and thrombotic complications. Conventional haemostatic tests are unable to predict bleeding and thrombosis in these patients. We aimed to explore the role of Rotational Thromboelastometry (ROTEM) in predicting bleeding and thrombotic events in patients with cirrhosis. **Methods:** We conducted a prospective cohort study of patients with cirrhosis at two metropolitan hospitals. All patients underwent ROTEM analysis and were then followed to record any bleeding and thrombotic events. Univariate and multivariate logistic regression analyses were performed to explore associations with bleeding and thrombotic events. **Results:** Nineteen of the 162 patients recruited experienced a bleeding event within one year of ROTEM analysis. On univariate analysis, maximum clot firmness (MCF) using both EXTEM and INTEM tests was significantly reduced in patients who had a bleeding event, compared to those who did not (50mm vs 57mm, $p < 0.01$ and 48mm vs 54mm, $p < 0.01$, respectively). In addition, on univariate analysis, clotting time (CT) in the INTEM test was prolonged in the bleeding group (214 sec vs 198 sec, $p = 0.01$). After adjusting for age, gender, presence of clinically significant portal hypertension, use of beta-blockers, bilirubin, albumin, creatinine, INR and MCF_{EX}, only MCF_{EX} (HR 0.22, 95% CI; 0.05 – 0.90, $p = 0.04$) remained a significant predictor of a bleeding event within one year follow-up (see Table 1). In contrast, there was no association found between ROTEM parameters and development of thrombosis within a one-year period. **Conclusion:** ROTEM may provide a useful tool in predicting future bleeding events in patients with cirrhosis. Larger studies are required to further validate this finding and explore its application in clinical practice.

Table 1. Multivariate logistic regression analysis of factors associated with bleeding events within one year of follow-up.

Patient characteristics	Adjusted-HR (95% CI)	p - value
Age (years)	0.98 (0.94 - 1.02)	0.39
Gender (female)	1.74 (0.56 – 5.37)	0.34
CSPH	1.06 (0.16 – 6.78)	0.95
Beta-blocker use at baseline	2.18 (0.65 – 7.33)	0.21
Bilirubin (mcmol/L)	1.01 (0.99 – 1.01)	0.11
Albumin (g/L)	0.95 (0.84 – 1.07)	0.41
Creatinine (mcmol/L)	1.01 (0.99 – 1.04)	0.27
INR	1.04 (0.22 – 4.83)	0.97
EXTEM MCF	**0.22 (0.05 – 0.90)**	**0.04**

CSPH, clinically significant portal hypertension; INR, international normalised ratio; MCF, maximum clot firmness.

1606-A | ROTATIONAL THROMBOELASTOMETRY PREDICTS TRANSPLANT-FREE SURVIVAL IN PATIENTS WITH LIVER CIRRHOSIS

Natasha Janko[1,2], Ammar Majeed[1,2], Isabella Commins[2], Paul J. Gow[3,4], William W. Kemp[2] and Stuart Keith Roberts[2], (1)Monash University, (2)Alfred Health, (3)University of Melbourne, (4)Austin Health

Background: There is emerging evidence that Rotational Thromboelastometry (ROTEM) is superior to conventional haemostatic tests, such as INR in the assessment and management of bleeding risk in patients with cirrhosis. Whether or not ROTEM may also be useful in assessing prognosis in patients with advanced liver disease is still unknown. We aimed to explore the role of ROTEM in predicting transplant-free survival in patients with cirrhosis. **Methods:** We conducted a prospective cohort study of patients with cirrhosis at two metropolitan hospitals. All patients underwent ROTEM analysis at baseline and were followed until death, liver transplant or the end of follow-up (28/2/2023). Univariate and multivariate Cox regression analyses were performed to explore associations with transplant-free survival and first episode of hepatic decompensation. **Results:** Between Apr 2018-Oct 2021, a total of 162 patients with cirrhosis were recruited and followed for a median of 42 months. During follow-up, 36 patients died and seven underwent liver transplant. On univariate analysis, maximum clot firmness (MCF) using both EXTEM and INTEM tests was significantly reduced in the death/liver transplant group, compared with the survivor group (52 vs 57, $p = 0.02$ and 51 vs 55, $p = 0.01$, respectively). After adjusting for age, gender, presence of clinically significant portal hypertension, hepatocellular carcinoma, care setting, bilirubin, sodium, creatinine, only albumin (HR; 0.92, 95% CI; 0.85 – 0.99, $p = 0.02$) and MCF_{EX} (HR 0.96, 95% CI; 0.92 – 0.99, $p = 0.03$) remained significant predictors of transplant free survival. The optimal cut-off of MCF_{EX} to predict transplant-free survival, as calculated with the Youden index, was 58mm with a sensitivity of 0.79 and specificity of 0.44. A Kaplan Meier curve (see Figure 1) shows that patients with a baseline MCF_{EX} of less than 58mm have a significantly lower transplant-free survival than those patients with an MCF_{EX} equal to or greater than 58mm (HR 0.40, 95% CI = 0.19 – 0.84, $p = 0.015$). Of the 101 patients who had not previously experienced hepatic decompensation, 20 developed a first hepatic decompensation event during follow-up after a median (IQR) of 19 months (4–31 mo). After adjusting for age, gender, presence of clinically significant portal hypertension, HCC, albumin, creatinine, INR, platelets and MCF_{EX}, only albumin (HR 0.86, 95% CI 0.75 – 0.98, $p = 0.02$), platelet count (HR 1.01, 95% CI 1.00-1.02, $p = 0.02$) and MCF_{EX} (HR 0.82, 95% CI = 0.74 – 0.92, $p < 0.01$) remained significant predictors of first episode hepatic decompensation. **Conclusion:** ROTEM may be useful in assessing survival and first episode hepatic decompensation in patients with cirrhosis. Further research is needed to determine the clinical utility of ROTEM parameters as prognostic markers in patients with cirrhosis.

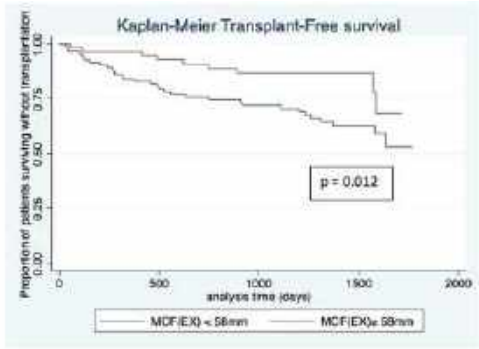

Figure 1. Kaplan Meier curve of transplant free survival according to MCF_{EX} cut-off of 58mm (Youden index-optimised cut-off). Proportion of patients surviving without liver transplantation during the follow-up period.

1607-A | SAFETY OF DIRECT ORAL ANTICOAGULATION VERSUS WARFARIN IN CIRRHOTIC PATIENTS WITH PORTAL VEIN THROMBOSIS AND SIGNIFICANT THROMBOCYTOPENIA

Julton Tomanguillo Chumbe[1], Mark Ayoub[2], Lauren Searls[2], Frank Annie[2], Harleen Chela[2], Nadeem Anwar[1] and Ebubekir Daglilar[1], (1)West Virginia University - Charleston Area Medical Center, Charleston, WV, (2)Charleston Area Medical Center/ WVU Charleston Division

Background: In the treatment of portal vein thrombosis, direct oral anticoagulation (DOAC) such as Apixaban or Rivaroxaban have proven to be equally effective as warfarin. Nonetheless, patients with cirrhosis frequently exhibit significant thrombocytopenia ($< 50*10^3$/uL), a condition that poses management challenges due to safety concerns when administering anticoagulation. This study aims to compare the safe use of reduced dosage DOAC versus warfarin in treating PVT among patients with cirrhosis. **Methods:** Adult patients 18 years and older with the diagnosis of cirrhosis with and without the presence of significant

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

thrombocytopenia, as defined by platelet count less than 50*10^3/uL, were identified using TriNetX between 2012 and 2023. TriNetx includes a total of 106 different healthcare organizations from 14 different countries. Patients with cirrhosis and thrombocytopenia on DOAC or warfarin within 1-month after the diagnosis of PVT were divided into two cohorts; the first cohort comprised patients receiving 50% reduced-dose DOAC (Apixaban or Rivaroxaban) and platelet between 30 and 49*10^3/uL, and a second cohort was patient on warfarin and platelet value were greater and equal than 50*10^3/uL. We compared the rate of mortality and significant bleeding such as intracranial bleeding and gastrointestinal bleeding between propensity-matched (PSM) pairs of patients. **Results:** 2,121 patients with cirrhosis and PVT were included in this analysis. Of these 16% (n = 338) had a platelet level between 30 and 49*10^3/uL and received a reduce-dose of DOAC, and 84% (n = 1,783) were on warfarin and had platelet level **e** 50*10^3/uL. The raw data showed that the patients on DOAC were significant younger (60.6 ± 12.3 vs 64.5 ± 12, $p < 0.0001$), and had a higher rate of diabetes (49.11% vs 40.58%, $p = 0.003$). Subsequently, two well-matched cohorts were created using a 1:1 propensity-scored matching model (337/337). No significant difference was noted between the two groups in the rate major bleedings at 6 or 12 months. At 6-months intracranial hemorrhage (2.96% vs 2.96%, $p = 1.00$), gastrointestinal bleeding (7.12% vs 8.60%, $p = 0.47$), and over-all mortality (19.28% vs 14.54%, $p = 0.10$). At 12-months intracranial hemorrhage (2.96% vs 2.96%, $p = 1.00$), gastrointestinal bleeding (9.19% vs 10.38%, $p = 0.60$), and over-all mortality (22.84% vs 17.50%, $p = 0.08$). **Conclusion:** The use of 50%-reduce dose of DOAC in patient with cirrhosis and platelets levels between 30-49*10^3/uL was not significantly associated with major bleedings such as intracranial hemorrhage, gastrointestinal bleeding, or mortality up to 12 months when compared with patient with platelets **e** 50*10^3/uL and on warfarin.

1608-A | THE ASSOCIATION BETWEEN HEPATIC DYSFUNCTION AND COAGULOPATHY IN PATIENTS PRESENTING WITH SHOCK LIVER: AN INSTITUTIONAL REVIEW

Simone A Jarrett[1], Jordan Carty[1], Sahana Tlto[1], Brenda Chiang[1], Bruce Casipit[1], Alexander Prendergast[1], Jose Martinez Manzano[1], Isaac Ogunmola[1], Otoniel Ysea-Hill[1], Ahmer Khan[1], Kevin Robinson[1], Dominic E Jarrett[2], Sujani Yadlapati[3], Kevin B Lo[1], Zurab Azmaiparashvili[1] and Victor J. Navarro, Md[1], (1)Albert Einstein Medical Center, (2)University of the West Indies, Mona, (3)Cooper University Hospital

Background: Patients with shock liver, either ischemic or congestive, often have prolongation of the INR. The objective of this study is to examine whether the INR correlates with bleeding in patients with shock liver. **Methods:** This retrospective cohort study analyzed a sample of 232 patients by using ICD codes 9 and 10 to identify cases of ischemic hepatitis and congestive hepatopathy. Out of the initial sample,135 patients were excluded after review of the medical record due to factors such as hemorrhage as the cause of liver injury before diagnosis of ischemic hepatitis, missing INR values, and prior cirrhosis. Major bleeding was defined by the presence of a clinically identifiable bleeding source that was fatal or associated with a drop in hemoglobin levels by 2g/dl or transfusion of at least 2 units of packed red blood cells, or involvement of critical anatomical sites. These sites included gastrointestinal, intracranial, intraspinal, intraocular, retroperitoneal, intraarticular, pericardial, intramuscular with compartment syndrome. All other clinically apparent bleeding were considered minor bleeding. Admission and peak INR values were compared between patients with major bleeding, minor bleeding, both major & minor bleeding and those who did not experience bleeding events. Statistical analysis of the data was performed using chi-squared tests, Wilcoxon signed rank tests, and independent T-score tests. **Results:** Among the patients with shock liver, 84% had a clinical diagnosis of ischemic hepatitis, while 16% had congestive hepatopathy. Two-thirds of the patients (68%) already had liver injury upon admission, while 32% developed it during their hospital stay. Cardiac arrest was the leading cause of liver injury (40%), followed by cardiogenic shock (30%), sepsis (19%), and other causes (11%). With regards to bleeding events, 15% of the patients experienced major bleeding, and 22% had minor bleeding events. The combined rate of major and minor bleeding was 41%. The median INR upon admission was 1.5 (1.2-2.1) while the peak INR during hospitalization was 2.6 (1.7-4.2). There was no significant difference in INR values between patients with major bleeding and those without. (See table 1) **Conclusion:** The INR did not predict bleeding events in those with ischemic hepatitis or congestive hepatopathy. The degree of coagulopathy as reflected by INR values were not directly associated with bleeding events

Table 1. INR values stratified according to presence or absence of bleeding

Median(IQR)	Major bleeding	Without bleeding	p value
Admission INR	1.4(1.1-1.9)	1.5(1.3-2.1)	0.48
Peak INR	2.6(1.8-4.6)	2.5(1.6-4.1)	0.63
	Minor bleeding	Without bleeding	
Admission INR	1.6(1.2-2.2)	1.5(1.2-2.1)	0.60
Peak INR	2.5(1.8-4.1)	2.6(1.6-4.3)	0.86
	Major/Minor Bleed	Without bleeding	
Admission INR	1.4(1.2-2.1)	1.5(1.3-2.1)	0.40
Peak INR	2.6(1.8-4.4)	2.5(1.6-3.9)	0.40

1609-A | TREATMENT OF PORTAL VEIN THROMBOSIS IN CIRRHOSIS IS ASSOCIATED WITH MINIMAL BENEFIT: A RETROSPECTIVE CONTROLLED STUDY

Abraham Z Cheloff[1], Joshua L Ross[2], Jenny L Engelman[2], Luke J Bonanni[2], Joshua D Kirschenbaum[2], Gabriel Fuligni[2], Naveena Luke[3], Yasmeen Mardi[2] and Patrick Grant Northup[4], (1)NYU Langone Health, New York, NY, (2)NYU Grossman School of Medicine, (3)NYU Langone Health, (4)NYU Langone Health, Saint Petersburg, FL

Background: The benefit of treating portal vein thrombosis (PVT) in patients with cirrhosis has not been proven. The aim of this study was to compare clinically meaningful endpoints in patients with cirrhosis and PVT who undergo different treatment strategies. **Methods:** Patients with established cirrhosis and PVT were retrospectively identified using electronic medical records from a single referral center and analyzed in three groups based on treatment course: 1) Anticoagulants, 2) TIPS or vascular interventional therapies, 3) Supportive care only. Groups were analyzed for clinically meaningful endpoints including death, transplantation, complete PVT resolution, and progression of PVT to complete obstruction of the portal vein. Analyses were adjusted for demographics, severity of liver disease, portal hypertension, and extent of initial PVT. **Results:** 222 patients were included. 112 were treated with anticoagulants, 80 with TIPS, and 30 with supportive care. 40 (18%) presented with cavernous transformation of the PV, 28 (13%) with complete obstruction of the PV, and the remainder with partial obstruction. Patients with a history of prior bleeding were offered anticoagulation less often than other groups ($p < 0.001$). Conversely, patients who presented with cavernous transformation ($p = 0.02$), older age (63 vs. 57, $p = 0.04$), and higher MELD score (13 vs. 10, $p = 0.02$) were offered supportive care more often. Of 154 (69% of total) patients presenting with partial or minimal obstruction of the PV, 132 (86%) remained patent regardless of whether targeted PVT therapy or supportive care was chosen (Figure 1). Initial PV patency (OR 11.9, 95%CI 5.7-24.9, $p < 0.0001$) was the only significant factor predicting PV patency at the end of follow up. MELD ($p = 0.24$), prior portal hypertensive bleeding ($p = 0.74$), patient age ($p = 0.35$), and treatment vs. supportive care ($p = 0.10$) were not predictive of PV patency at the end of follow-up. In 68 (30.6% of total) patients presenting with complete PV obstruction or cavernous transformation, 22 (34.4%) patients achieved some level of patency of the PV at the end of follow up but treatment arm had no impact on eventual patency ($p = 0.08$). In an adjusted competing risks analysis, lack of patency of the PV was directly correlated with death (HR 3.7, 1.3-10.4, $p = 0.01$) but treatment directed at the PV clot was not (HR 0.8 0.3-2.3, $p = 0.66$). **Conclusion:** In patients with cirrhosis and partial PVT, progression of clot to the point of complete occlusion is uncommon and treatment of the clot with TIPS or anticoagulation showed little benefit in the clinically meaningful outcomes including final PV patency and survival. Prospective, randomized studies investigating the benefit of thrombosis directed therapies in this population are needed.

f 1610-A | VARIATIONS IN PRACTICE IN PATIENTS WITH PORTAL VEIN THROMBOSIS AND ESOPHAGEAL VARICES: AN INTERNATIONAL SURVEY STUDY

Brandon G. Mui, Lauren T. Grinspan and James F. Crismale, Icahn School of Medicine at Mount Sinai

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Portal vein thrombosis (PVT) is common in cirrhosis. While current guidelines recommend anticoagulation for PVT in patients with cirrhosis, there exists no consensus regarding treatment protocols. The primary aim of this study is to better discern practice patterns surrounding anticoagulation and variceal hemorrhage prophylaxis in PVT patients and to assess guideline concordance. **Methods:** A questionnaire was created using RedCap and then distributed to practice sites across Canada and the USA. The survey included questions that assessed provider knowledge and attitudes regarding the management of PVT and prevention of portal hypertensive bleeding in such patients. **Results:** 136 of 237 (57%) providers responded to our survey. Most respondents identified as hepatologists (54%) and gastroenterologists (26%). Apixaban (47%) was the preferred anticoagulation agent. Providers were "more likely" to start anticoagulation if the patient was listed for liver transplantation (84%), symptomatic (91%), and in the setting of superior mesenteric vein thrombosis (92%) but were less likely to start anticoagulation among patients with a history of severe bleeding or thrombocytopenia. For the primary prophylaxis of variceal hemorrhage, practice was variable with 44% of responses discordant from Baveno VII guideline recommendations with an appreciable proportion of providers preferring combination therapy with endoscopic variceal ligation and beta-blockers over guideline-recommended monotherapy (see Table). There were significant differences in the timing of anticoagulant initiation among patients with symptomatic versus asymptomatic PVT. Most providers start anticoagulation prior to endoscopic investigation and eradication of varices among patients with symptomatic PVT versus asymptomatic PVT (65% vs. 23%, $p < 0.001$). Similarly, a greater proportion of providers immediately restart anticoagulation following band ligation among patients with symptomatic versus asymptomatic PVT (24% vs. 15%, $p = 0.01$). Practice patterns were similar between hepatologists and non-hepatologists. Notable differences included a greater tendency to initiate anticoagulation prior to endoscopic eradication of varices among patients with asymptomatic PVT (41% vs. 21%, $p = 0.04$), and a reduced tendency to start anticoagulation in the inpatient setting (10% vs. 52%, $p < 0.001$). **Conclusion:** There is consensus amongst providers on the factors that influence the decision to initiate/hold anticoagulation in PVT patients, often in alignment with guidelines. However, a wide variation in practice was observed regarding primary prevention of variceal hemorrhage in patients with cirrhosis and recent PVT and the use of endoscopic surveillance prior to anticoagulation. Several practice tendencies contrary to guidelines were identified in this study, highlighting the need for more efficacy-safety data on PVT treatment in cirrhosis.

Table. Approach to variceal hemorrhage prophylaxis treatment in patients with recent PVT

	Child-Pugh A		Child-Pugh B or C		High risk of bleeding	
Prophylaxis	Small/No Red Signs	Large or Red Signs	Small/No Red Signs	Large or Red Signs	Large or Red signs AND Plt < 50k	Large or Red signs AND past history of life-threatening bleed
None	43%	0%	4%	0%	3%	3%
NSBB	53%	48%	51%	15%	19%	5%
EVL	1%	24%	22%	26%	16%	10%
NSBB+EVL	4%	29%	24%	60%	62%	82%

1611-A | LIVER ENDOTHELIAL Gimap5 IS REQUIRED TO MAINTAIN HEPATOCYTE ZONATION

Shanin Chowdhury, Chigoziri Konkwo, Kaitlyn Lee, Caroline Tippett, Joseph Brancale and Silvia M. Vilarinho, Yale School of Medicine, New Haven, CT

Background: Liver zonation is the spatial organization of metabolic and physiological functions across the liver lobule, which is critical to maintaining hepatic homeostasis and function. Emerging research suggests that signals originating from liver endothelial cells (LECs) play a critical role in maintaining hepatic parenchymal homeostasis and zonation. Our group discovered that rare bi-allelic loss-of-function mutations in *Gimap5* cause nodular regenerative hyperplasia and consequently non-cirrhotic portal hypertension. Moreover, we demonstrated that LECs express *Gimap5*, which is critical to maintain liver endothelial cell homeostasis. Hence, we postulated that endothelial Gimap5 is required to maintain hepatocyte zonation and function. **Methods:** We used loss-of-function (LOF) Gimap5 mice and Gimap5 sufficient littermate controls to conduct histological and protein studies to characterize hepatocyte zonation using zone 1 and zone 3 specific markers over the course of 3 to 8 weeks of age. These markers were established zonation markers such as E-Cadherin for zone 1, arginase-1 for zones 1/2, and glutamine synthetase and Cyp2e1 for zone 3. Single-cell RNA sequencing of enriched hepatocytes from 8-week-old LOF Gimap5 and WT littermate control mice was also performed. **Results:** Our data shows that zonation can be established and maintained up to 6 weeks-old but is disrupted by 8 weeks of age in LOF Gimap5 mice as compared to WT controls. In LOF Gimap5 mice, we observed an expansion of epithelial marker E-cadherin around the periportal region, and a reduction of zone 3 markers on pericentral region, such as glutamine synthetase and Cyp2e1. Furthermore, single-cell RNA sequencing data revealed that hepatocytes from

Gimap5 LOF livers exhibit distinct transcriptional profiles compared to wild-type hepatocytes, resembling immature hepatocytes. **Conclusion:** Our study uncovers a crucial role of liver endothelial Gimap5 to maintaining adult hepatocyte zonation, highlighting the importance of the endothelial cell compartment in liver homeostasis.

1612-A | CARDIOPULMONARY DYSFUNCTION AND ITS CORRELATION WITH DISEASE SEVERITY IN PORTO-SINUSOIDAL VASCULAR DISEASE

Harish Gopalakrishna[1], Maria Mironova[2], My-Le Nguyen[3], Gracia Viana[4], Gayatri Nair[5], David E Kleiner[6], Christopher Koh[7], Vandana Sachdev[3] and Theo Heller[1], (1)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (2)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, (3)NHLBI, National Institutes of Health, (4)University of Maryland Medical Center, (5) Medstar Georgetown University Hospital, (6)Laboratory of Pathology, National Cancer Institute, National Institutes of Health, (7)National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: Porto-sinusoidal vascular disease (PSVD) encompasses a group of hepatic vascular disorders affecting portal venules and sinusoids in the absence of cirrhosis. PSVD patients develop portal hypertension and associated complications including variceal bleeding, hepatic encephalopathy, and ascites. Cardiopulmonary complications of portal hypertension including hepatopulmonary syndrome and porto-pulmonary hypertension are well described in cirrhotic cohorts but not in PSVD patients. We aim to explore echocardiography findings of cardiopulmonary dysfunction in PSVD patients and its association with clinically significant portal hypertension (CSPH). **Methods:** We included a prospective cohort of 44 biopsy proven PSVD patients followed under the natural history protocol (NCT02417740) who underwent transthoracic echocardiogram with agitated saline study. Intrapulmonary shunting was defined as presence of microbubbles in the left atrium after at least four heartbeats. Porto-pulmonary hypertension (PoPH) was defined as elevated tricuspid regurgitation velocity (TRV) > 2.8 m/sec. All patients underwent liver stiffness measurement (LSM) using transient elastography, and investigations to evaluate for CSPH. CSPH was defined by presence of one specific feature as per BAVENO VII criteria. **Results:** Among the 44 subjects, 3 with intracardiac shunting were excluded; of the remaining 41 subjects, 17 (41%) had intrapulmonary shunting, 5 (12%) had PoPH and 3 (7%) had both features. AST/ALT ratio (1.28 vs 1.05, $p = 0.01$) and LSM (13.3 kPa vs 8.3 kPa, $p = 0.02$) were significantly higher in patients with shunting. A composite score combining LSM > 10 and AST/ALT ratio > 1 performed with specificity of 83%, negative predictive value (NPV) of 74% and positive predictive value (PPV) of 69% in predicting presence of shunting. Patients who met the composite score criteria had 6.4 (1.4-22.1) times higher odds of having shunting ($p < 0.001$). Patients with CSPH had higher left ventricular diastolic volume (124 ml vs 97 ml, $p = 0.04$), left atrial volume (64.5 ml vs 46 ml, $p = 0.01$), left atrial volume index (34.4 m^2 vs 23.1 m^2, $p < 0.01$), and left atrial dimension (40 mm vs 33 mm, $p < 0.001$) compared to patients without CSPH. **Conclusion:** Intra-pulmonary shunting, which is a feature of hepatopulmonary syndrome can be seen in PSVD patients especially in those with CSPH. A combination of AST/ALT ratio and LSM can be useful in risk stratification for HPS prior to developing hypoxia. Similar to decompensated cirrhotic patients, features suggestive of diastolic dysfunction can be seen in PSVD patients with CSPH. Collectively, these findings suggest screening patients with PSVD for cardiopulmonary dysfunction.

Background: Non-cirrhotic portal hypertension (NCPH) is a spectrum of chronic liver diseases, characterized by increased portal pressures in absence of cirrhosis. The progression and pathophysiology of the disease is not fully explored. We aimed to explore magnetic resonance imaging (MRI) features of NCPH and correlate those with histologic findings. **Methods:** Patients with known NCPH or at risk for NCPH by the virtue of underlying disease were enrolled in a single center prospective study NCT02417740. Patients with cirrhosis and other liver diseases were excluded. Clinically significant portal hypertension (CSPH) was diagnosed by presence of portosystemic collaterals (PSS), varices, including esophageal varices (EV) and/or portal hypertensive gastropathy. All patients had an initial liver biopsy. Blood work and abdominal MRI were repeated every 6-12 months. MRI images were reviewed by an expert radiologist. **Results:** 25 patients were included in the analysis: 21 (84%) had CSPH, while 4 (16%) had no CSPH. Majority of patients with CSPH were males (62%), mean age was 51 ± 11 years. Patients without CSPH were mostly females (75%), median age 42 years. Most common underlying disease in both groups was common variable immunodeficiency (36%), followed by autoimmune and hematological disorders. 5 (24%) patients had no underlying disease identified. Most frequent findings on liver biopsy in both cohorts were perisinusoidal fibrosis (48% of all biopsies), nodular regenerative hyperplasia (48%), obliterative portal venopathy (36%), and sinusoidal dilation (20%). 71 MRIs were performed in this cohort, with a median follow-up time between MRIs of 12 months. Features of baseline MRIs are displayed in Table 1. Patients with CSPH had large splenic volumes, liver macronodularity, caudate lobe hypertrophy along with atrophy of segment IV, and significant dilation of portal and splenic veins when compared to patients without CSPH. Specific features of portal hypertension included ascites, mostly mild, esophageal varices and gastric varices, and PSS: portal (81%), splenic (76%), mesenteric (19%) and recanalization of umbilical or periumbilical vein (14%). Follow-up MRI was available for 3 patients without CSPH and 16 patients with CSPH. Patients without CSPH had no substantial changes. On the follow-up MRI more patients with CSPH developed splenic infarcts (21% vs 14%), liver macronodularity (81% vs 69%), abrupt tapering of portal vein branches (44% vs 25%), and PSS (81% vs 75%), none of which reached statistical significance. **Conclusion:** The presence of MRI findings that are common in patients with cirrhosis and NCPH may be misleading in the diagnosis of NCPH. It is important to augment the imaging diagnosis with liver histology and have a high suspicion of NCPH when a patient has a known NCPH-predisposing condition.

1614-A | IMPACT OF TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT ON BUDD-CHIARI SYNDROME: ANALYSIS OF THE NIS DATABASE

Xheni Deda[1], Khaled Elfert[2], Hazem Abosheaishaa[3] and Ahmad Hassan Ali[1], (1)Missouri University Hospital, (2)St. Barnabas Hospital, Bronx, NY, (3)Icahn School of Medicine at Mount Sinai

Background: Budd-Chiari syndrome (BCS) is a rare disorder characterized by hepatic venous flow obstruction or narrowing. If left untreated, BCS can lead to

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

serious complications. Treatment options include anticoagulation, endovascular interventions, transjugular portosystemic shunt (TIPS) placement, and orthotopic liver transplantation. This study aims to examine the outcomes of TIPS in BCS using the National Inpatient Sample (NIS) database, contributing to our understanding of its effectiveness and safety as a therapeutic intervention. **Methods:** This study utilized a retrospective analysis of data from the NIS database, covering the period from 2016 to 2020, including patients diagnosed with BCS. Patient demographics, baseline comorbidities, liver-related complications, in-hospital mortality, LOS, total hospital cost, and other hospitalization outcomes were collected. Univariate analysis and multivariate analysis were performed to investigate factors associated with TIPS performance. **Results:** A total of 1,070 patients diagnosed with BCS were included. Among them, 105 patients underwent TIPS placement, while 965 patients did not receive TIPS. Comparison between the two groups revealed that patients who underwent TIPS placement were younger, with a mean age of 39.3 years compared to 48.6 years in the non-TIPS group ($p < 0.01$). Patients in the non-TIPS group had a higher prevalence of baseline comorbidities, including diabetes (17.1% vs 0; $p = 0.034$) and hypertension (42.5% vs 19.0%; $p = 0.036$). Regarding liver-related complications, the TIPS group had a higher incidence of portal pressure complications such as ascites (81.0% vs 53.4%; $p < 0.01$), hepatorenal syndrome (9.5% vs 2.6%; $p = 0.08$), and SBP (4.8% vs 2.1%; $p = 0.43$). Conversely, portal vein thrombosis (PVT) was more common in the non-TIPS group (26.9% vs 23.8%; $p = 0.75$). No significant differences were found between the groups in terms of in-hospital mortality, length of stay (LOS), and total hospital cost. However, patients in the TIPS group had a higher prevalence of acute liver failure (28.6% vs 13%; $p = 0.05$) and acute kidney failure (42.9% vs 23.3%; $p = 0.05$), which likely served as indications for TIPS placement (table 1). Multivariate logistic regression analysis revealed that ascites was independently associated with TIPS performance. **Conclusion:** Our findings indicate that TIPS was predominantly performed in younger patients with a higher incidence of ascites, acute liver and kidney failure, which likely influenced the decision for intervention. However, there were no significant differences in in-hospital mortality, length of stay, and total hospital cost between the TIPS and non-TIPS groups. The comparable outcomes achieved by the TIPS group, despite having a higher incidence of complications, provides evidence for the effectiveness of TIPS in improving clinical outcomes.

Table 1. Liver related complications and in-hospital outcomes

Section, National Institutes of Health, (4)National Institutes of Health, Rockville, MD, (5)Clinical Research Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, (6)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (7)Laboratory of Pathology, National Cancer Institute, National Institutes of Health

Background: Porto-sinusoidal vascular disease (PSVD) is caused by a myriad of diseases broadly classified into pre-sinusoidal, sinusoidal and post-sinusoidal. Liver synthetic function in PSVD is preserved, making identification of disease severity a challenge. Down trending platelet count and increasing spleen size are considered markers of disease progression. Though decreased thrombopoietin (TPO) production and splenic sequestration are observed to be the cause for thrombocytopenia in cirrhosis, the reason for the down trending platelet count in PSVD is unclear. **Aim:** The study sought to investigate the factors influencing the platelet count in PSVD. **Methods:** Patients enrolled in a natural history protocol for PSVD were screened (NCT02417740). Of the total 43 patients, 27 with portal hypertension (PHT) and 8 with a known disease predisposing to PSVD were included in the analysis. This also included 3 patients who had undergone splenectomy. Biochemical and imaging data were obtained from the most recent visit. Liver biopsies were obtained at study entry. ELISA assays were performed in stored sera to explore the influence of liver related (TPO, neuraminidase), portal vein related (vWF, ADAMTS13), inflammation related (IL-6, CD-40, Pselectin) and spleen related factors. Graph Pad software version 9.2.0 was utilized for data analysis. **Results:** The median age was 54.5 years (range, 21.26-75.3) with 31 White, 2 Multiracial and 2 African American. Hypogammaglobulinemia (CVID/XLA) was present in 21 patients (60%). All had liver biopsies and 15 patients were noted to have nodular regenerative hyperplasia. Median platelet count was 84k/ul and median spleen height ratio (SHR) was 1.0mm/cm. In the 27 patients with PHT, SHR, CD-40 and P selectin significantly correlated with platelet count on univariable analysis, and only CD-40 significantly correlated on multivariable analysis. Similar results were observed after exclusion of splenectomized patients. Patients with and without PHT were compared and the difference in platelet count, spleen height ratio (SHR), direct bilirubin, INR, vWF, ADAMTS13, CD40 and Pselectin were significantly correlated with PHT (Table 1). **Conclusion:** The declining platelet count in PSVD is considered a marker of disease progression. TPO level was expected to be elevated as liver synthetic function is preserved in PSVD. However, TPO levels were lower than previously published in chronic hepatitis C patients. Our findings do not suggest low thrombopoietin or splenic sequestration to be the leading causes of declining platelet count in PSVD. The finding of only CD-40 correlating significantly with platelet count in PHT on multivariable analysis suggests endothelial activation as a major cause of thrombocytopenia in PSVD. Future studies are needed to identify reliable factors to predict disease severity and progression of PSVD.

f 1616-A | POTENT AND ORALLY ACTIVE DUAL GPBAR1/CYSLT1R MODULATOR PROTECT FROM VASCULAR DYSFUNCTION IN A MOUSE MODEL OF NAFLD

Michele Biagioli[1], Silvia Marchianò[1], Cristina Di Giorgio[1], Martina Bordoni[1], Rachele Bellini[1], Carmen Massa[1], Ginevra Urbani[1], Rosalinda Roselli[2], Eleonora Distrutti[3], Angela Zampella[2] and Stefano Fiorucci[1], (1) University of Perugia, (2)University of Naples, Federico II, (3)Azienda Ospedaliera Di Perugia

Background: Several mediators are involved in the development of liver inflammation and fibrosis in NAFLD/NASH patients. Among these targets, the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

cysteinyl leukotriene receptor 1 (CysLT1R) and the bile acid receptor GPBAR1 have been shown to be involved in disease development in several animal models of NAFLD/NASH. CysLT1R and GPBAR1 are expressed by the liver resident macrophages, the Kupffer cells and the HSC. Thus, although CysLT1R promotes an inflammatory response, GPBAR1 agonists attenuate the production of inflammatory mediators, suggesting that CysLT1R antagonists might synergize with GPBAR1 agonists in reducing liver inflammation. Additionally, the two receptors are expressed by several metabolically active tissues, including the white adipose tissues (WAT) exerting antagonistic effects on adipocytes. Based on this background, we have developed a molecule, CHIN117, with dual activity: CysLT1R antagonist and GPBAR1 agonist. In a previous study we demonstrated that CHIN117 exerted beneficial effects on the liver when administered in a mouse model of NASH. However, it is increasingly recognized that CV-related events represent the main cause of death in patients with NAFLD, strongly suggesting that management of NAFLD/NASH should include the treatment of the CVD component of the disease. Whereas CysLT1R and GPBAR1 are also expressed on the vascular epithelium could represent an interesting therapeutic target for the management of NASH-related CVDs. To evaluate the effect of CHIN117 on the vascular component of NASH, we administered the new compound in a mouse model of atherosclerosis. **Methods:** Apolipoprotein E deficient mice ($ApoE^{-/-}$), a standard model of atherosclerosis, were fed with HFD-F alone or with BAR501 for 14 weeks and then sacrificed. The aortic rings, aorta and liver were isolated and analyzed. **Results**: Analysis of the aortas from $ApoE^{-/-}$ mice fed with HFD-F for 14 weeks showed severe wall thickening accompanied by the formation of atherosclerotic plaques of various sizes. Inhibition of CYSLT1R activity and simultaneous activation of GPBAR1 by CHIN117 alleviated the disease in a dose-dependent manner. CHIN117 reduced the thickness of the aorta and the number of atherosclerotic plaques. Furthermore, analysing the type of plaques, it was evident that the highest dose of CHIN117 (30 mg/kg/day) completely reversed the formation of plaques larger than 3 mm, which are the ones that are more likely to break. To further analyse the effects of the administration of the new compound, we performed an RNAseq analysis on the aorta of the mice of the various experimental groups. The data obtained showed that CHIN117 reduced the expression of many genes belonging to inflammatory pathways thus exerting an anti-inflammatory effect on the aortas. **Conclusion:** A novel dual CYSLT1R antagonist and GPBAR1 agonist CHIN117 exert beneficial effect dose-dependent versus NASH-associated vascular disease.

1617-A | SURVIVAL OF NON-TRANSPLANTED PATIENTS WITH HEPATOPULMONARY SYNDROME (HPS)

Kathryn Teresa del Valle[1], Hilary Megan DuBrock[1] and Michael J. Krowka[2], (1)Mayo Clinic, (2)Mayo Clinic Rochester, Rochester, MN

Background: Hepatopulmonary syndrome (HPS) is the most common pulmonary vascular complication of liver disease, affecting 20-30% of patients with advanced liver disease. It is characterized by abnormal arterial oxygenation due to intrapulmonary vasodilatation. The majority of patients with HPS experience complete resolution following liver transplant (LT) and have a similarly favorable prognosis to non-HPS LT recipients. Therefore, HPS is considered an indication for LT, and patients with severe or very severe HPS ($PaO2 < 60$ mmHg) are eligible for Model for End Stage Liver Disease (MELD) exception points. On the contrary, patients with HPS who do not undergo LT have historically been shown to have poor outcomes. We sought to evaluate recent survival among patients with HPS who do not undergo LT in our center's large patient database. **Methods:** We performed a retrospective cohort study evaluating patients with moderate to very severe HPS in our single-site, academic center. We included patients diagnosed in 2005 and later with HPS and PaO2 **d** 70 mmHg. We excluded patients diagnosed with HPS before 2005. Survival in the non-transplanted cohort was analyzed using Kaplan Meier methods. **Results:** Since 2005, 151 patients in our database were diagnosed with HPS with initial PaO2 **d** 70 mmHg. 78/151 (52%) patients did not undergo LT, and the remaining 73/151 (48%) did. The 78 patients who did not undergo LT were included in our final

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

analysis, with year of diagnosis ranging from 2005 through 2023. Five-year survival was 14% (11/78). Overall survival curve of the cohort is depicted in Figure 1. Mean PaO2 at time of HPS diagnosis was 56 mmHg ± 9mmHg. Of these, 47/78 (60%) have died. 19/78 (24%) patients remain living, and 12/78 (15%) have been lost to follow-up. **Conclusion:** Overall survival for patients with HPS who do not undergo LT remains poor since 2005, with five-year survival 14%. Additionally, mean PaO2 at time of diagnosis was 56 mmHg, consistent with severe HPS and potentially suggestive of delays in HPS diagnosis. Our findings underscore the importance of facilitating LT whenever feasible for patients with HPS and also the unmet need for targeted medical therapies for those who are not eligible for LT.

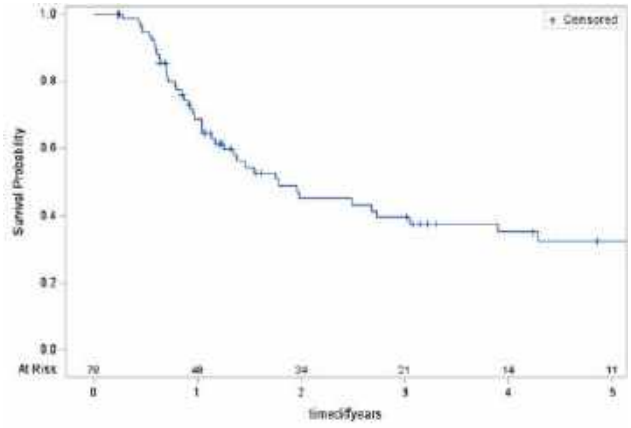

Figure 1: Survival in Patients with HPS who Do Not Undergo LT

1618-A | THE OUTCOMES OF PORTAL VEIN THROMBOSIS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA WHO UNDERWENT LOCOREGIONAL THERAPY

Cristina Batarseh[1], Asahi Hoque[1], Karim Osman[1], Joseph Cappuccio[1], Judy Alrukby[1] and Amir Ahmed Qamar[2], (1)Lahey Hospital and Medical Center, (2) Lahey Clinic Medical Center

Background: Portal vein thrombosis (PVT) incidence is thought to be higher in hepatocellular carcinoma (HCC). Locoregional therapies (LRT) play a major role in managing the majority of HCC cases. They are used to prolong survival, bridge to transplant, or for down-staging when the tumor burden exceeds transplant criteria. In this study, we aim to develop further understanding of the outcomes of developing PVT in patients with HCC who underwent LRT. Specifically, we will examine rates of hepatic decompensation, mortality and access to LRT. **Methods:** Patients with HCC who underwent liver transplant evaluation at our institution from 2015 to 2022, were retrospectively reviewed. We included adult patients (age > 18 y) with a clear diagnosis of HCC made by multiphasic computed tomography, magnetic resonance imaging or liver biopsy. Portal vein thrombosis was defined by partial or complete occlusion of the portal venous flow due to luminal thrombus. Exclusion criteria included: unclear diagnosis of HCC, portal vein tumor thrombosis or portal vein compression by neoplasm. Baseline data was obtained at time of HCC diagnosis. Patients were followed from baseline until last follow up or death. Patients were divided into two cohort groups depending on the presence or absence of PVT. Censoring occurred at the time of last follow up. Cumulative incidence of outcomes was determined by the Kaplan-Meier method. Data was analyzed using SPSS software. The study was approved by the institutional IRB. **Results:** A total of 116 patients with HCC were included, among which 27.6 % had PVT. Age, gender, tumor burden, variceal bleeding, ascites, and MELD-Na were similar between the two groups. However, patients in PVT group had higher proportion of hepatic encephalopathy (HE) (p-value < 0.006), and use of non-selective beta-blockers (p-value 0.04) as shown in table (1). The median number of LRT performed in patients with and without PVT was 1 (1-2) and 2(1-2), respectively (p-value 0.02) table (1). Regardless of the presence or absence of PVT, the most performed LRT was transcatheter hepatic artery chemoembolization (TACE), followed by stereotactic body radiotherapy (SBRT), then percutaneous ablation therapy (PCA) as illustrated in table (2). Kaplan Meier survival analysis showed no difference in mortality between the groups. **Conclusion:** The presence of PVT in patients with HCC is associated with higher rates of HE and lower numbers of LRT. However, there was no significant difference in survival rates. Further studies with larger sample size are required to validate our results.

1619-A | VASCULARIZED LIVER ORGAN-ON-A-CHIP: STEP FORWARD IN UNDERSTANDING LIVER PHYSIOLOGY

Subia Bano[1], Parinita Agrawal[1], Anupriya Mehra[1], Shanthini Kannan[1], Nisha Rajendran[1], Suvro Kanti Chowdhury[1], Joseph Christakiran Moses[1], Wenson David Rajan[1], Satish Nadig[1,2], Sonal Asthana[1,3], Ajith V Kamath[1], Arun Chandru[1] and Tuhin Bhowmick[1], (1) Pandorum Technologies, (2)Feinberg School of Medicine, (3)Aster CMI Hospital

Background: Human relevant 3D liver organoid models are instrumental in understanding healthy liver functions and pathophysiology, although inclusion of functional vasculature in such models remains a challenge. Micro-physiological systems (MPS) such as organ-on-chip (OOC) with functional vasculature offer real-time monitoring, high-throughput screening, and human-relevant pathophysiological responses. The proposed model exploits the potential of the OOC platform by encapsulating healthy liver organoids and advancing vasculature development in biomimetic matrix. **Methods:** Multicomponent liver organoids (400-450 μm diameter in size) comprised of primary hepatocytes, endothelial (HUVEC), and MSCs were encapsulated in photo-responsive biomimetic matrix in the central channel of a perfusion chip. HUVECs were seeded in side perfusion channels. Angiogenic cocktails (VEGF, FGF, PMA, S1P) was introduced on day 3 into the perfusion channels to create concentration gradient. Cellular viability (CTG and Live/Dead assay) and hepatocyte functionality (albumin ELISA) were assessed. Cell specific biomarkers expression were checked by immunofluorescence staining. The vascular network tube length and numbers were quantified using ImageJ software[1]. **Results:** Matrix embedded liver organoids were observed until 2 weeks in OOC platform (Aim biotech chip)[2]. Organoids showed good cellular viability and functionality of hepatocytes. Angiogenic cocktails triggered endothelial cells sprouting and formation of vascular network between the organoids as well as endothelial monolayer in the perfusion channel of the OOC. The embedded organoids retained the functionality of hepatocytes, indicated by albumin secretion (ELISA), CYP3A4 and albumin biomarker expression. Endothelial tube formation was confirmed with CD31 expression while MSCs were checked via CD90 biomarker expression. Quantitative analysis of vascular network indicated angiogenic cocktails promoted 3-fold increase in tube length and 2.5-fold increase in branch numbers compared to control. **Conclusion:** The current OOC platform with multicomponent liver organoids successfully supported the formation of a functional vascular network. The preserved functionality of cells in organoids showcases the robustness of this OOC platform under angiogenic stimulation. Importantly, our work reveals the potential of such platform towards the advancement of disease modelling and drug screening. References: 1. 1700-A | A STUDY OF ACUTE LIVER INJURY ASSOCIATED WITH ORNIDAZOLE: ANALYSIS OF 82 CASES IN TÜRKIYE

Ilker Turan[1], Esra Nur Nur Durmazer[1], Sezgin Vatansever[2], Ali Rıza Calıskan[3], Murat Harputluoglu[4], Cumali Efe[5], Ramazan Idilman[6], Emin Bodakci[7], Zeki Karasu[1], Ulus S. Akarca[1] and Fulya Gunsar[1], (1)Ege University Faculty of Medicine, Izmir, Turkey, (2)Katip Celebi University ,Faculty of Medicine ,Izmir, (3) Adiyaman University Faculty of Medicine, Adiyaman, Turkey, (4)Inonu University Faculty of Medicine, Malatya, (5)Harran University Faculty of Medicine, Sanliurfa, (6)Ankara University, Ankara, Turkey, (7) Ankara University Faculty of Medicine, Ankara, Ankara, Turkey

Background: Ornidazole-induced acute liver injury has been described in a few case reports and series. The aim of this study was to examine the characteristics and outcomes of patients diagnosed with acute liver injury associated with ornidazole. **Methods:** Between December 2006 and March 2023, the clinical and laboratory data of patients diagnosed with acute liver injury associated with ornidazole were analyzed in six centers

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in Türkiye. The endpoints were defined as death, liver transplantation, and post-transplantation mortality. **Results:** Out of the identified 82 patients, 62 (75.6%) were female, with a mean age of 46 years. Among them, 44 patients had used ornidazole alone, while 38 had used it in combination with other medications. The most common symptoms were jaundice (83%), darkening of urine (65%), nausea/vomiting (40%), and abdominal pain (22%). The mean peak levels of ALT, AST, ALP, GGT, total bilirubin, and INR were 1190 IU/L, 1124 IU/L, 234 IU/L, 236 IU/L, 17.6 mg/dL, and 1.75, respectively. Hepatocellular pattern of liver injury was observed in most patients (mean R [ALT/ULN ÷ ALP/ULN] 12 ± 0.7). Nine patients (10.9%) developed liver failure as a severe consequence of liver injury. Four patients died, and five patients underwent transplantation. Two transplant recipients died. One patient developed chronic hepatitis. Multivariate logistic regression analysis showed that INR level was a predictor of severe outcomes (OR: 337,059, $p = 0.0029$). **Conclusion:** This study demonstrates that ornidazole, either alone or in combination with other drugs, can cause severe drug-induced liver injury, and that INR level can predict poor outcomes.

Disclosures: The following people have nothing to disclose: Ilker Turan, Esra Nur Nur Durmazer, Sezgin Vatansever, Ali Rıza Calıskan, Murat Harputluoglu, Cumali Efe, Ramazan Idilman, Emin Bodakci, Zeki Karasu, Ulus S. Akarca, Fulya Gunsar

f 1701-A | AN OPTIMIZED STEROID STEPWISE DOSE REDUCTION THERAPY FOR CHRONIC DRUG-INDUCED LIVER INJURY WITH OR WITHOUT AIH-LIKE FEATURES: A RANDOMIZED PROSPECTIVE OPEN-LABEL TRIAL

Ang Huang[1,2], Yun Zhu[1], Shuhong Liu[1], Zherui Liu[1], Qingsheng Liang[1], Jun Zhao[1], Binxia Chang[1], Jing-Feng Bi[1], Xingran Zhai[1], Ning Li[1], Hui Tian[1], Lin Han[1], Yingjie Zhuang[1], Guang-Ju Teng[1], Wei Zhang[3], Ying Sun[1], Dong Ji[1], Jingmin Zhao[1] and Zhengsheng Zou[1], (1)Fifth Medical Center of PLA General Hospital, (2) First Medical Center of PLA General Hospital, (3)Peking University

Background: The use of corticosteroids to treat patients with chronic drug-induced liver injury (DILI) is an important challenge. Our previous study showed that patients with chronic DILI significantly benefit from the 48-week steroid stepwise reduction (SSR) therapy. However, it is unclear whether a shorter course steroid therapy is effective. The aim of this study was to assess if the short-term (36-week) SSR for patients with chronic DILI can achieve similar efficacy and safety to 48-week SSR. **Methods:** This was a randomized prospective open-label trial. Eligible patients were randomly assigned (1:1) either to 36-week SSR group or 48-week SSR group. Liver biopsies were performed at baseline and at the end of treatment period. The primary outcome was the proportion of patients with sustained biochemical response (SBR). The secondary outcomes were improvement in liver histology, time to biochemical normalization, and safety. **Results:** Of 90 participants, 84 (87.5%) completed the trial. The patients were predominantly female (68.9%), aged > 40 years (78.6%), and had a hepatocellular injury pattern of DILI (53.4%). After treatment, SBR was 92.9% in the 36-week SSR group compared with 95.2% in the 48-week SSR group by PPS analysis ($p = 1.000$). Significant histological improvements in both histological activity (93.1% vs. 92.9%, $p = 1.000$) and fibrosis (41.4% vs. 46.4%, $p = 0.701$) were observed in 36-week SSR and 48-week SSR group. There was also no difference in biochemical normalization time between the two groups. No severe adverse events were observed during the trial. **Conclusion:** Both 36-week SSR and 48-week SSR demonstrate similar efficacy in biochemical response and histological improvements with good safety, which support 36-week SSR as a preferable therapeutic choice. (ClinicalTrials.gov, NCT03266146)

1702-A | CHARACTERIZATION OF A LIVER INJURY OUTBREAK IN 2022 AFTER INGESTION OF THE FROZEN FRENCH LENTIL AND LEEK CRUMBLE FOOD PRODUCT

Gina Choi[1], Jawad Ahmad[2], Victor J. Navarro, Md[3], Swan N. Thung[2], Ikhlas Khan[4], Bharathi Avula[4], Huiman Barnhart[5] and Andrew Stolz[6], (1)David Geffen School of Medicine at UCLA, (2)Icahn School of Medicine at Mount Sinai (ISMMS), (3)Albert Einstein Medical Center, Doylestown, PA, (4)University of Mississippi, (5)Duke University, Durham, NC, (6) University of Southern California, Los Angeles, CA

Background: In April 2022, French Lentil and Leek Crumble (FLLC), a new frozen food, was introduced online as part of a meal subscription plan. Soon thereafter, widespread anecdotal reports of acute gastrointestinal symptoms with liver injury were reported, leading to its voluntary withdrawal in June 2022, after shipment of 28,000 preparations. **Aim:** To report the clinical features, liver test abnormalities, liver histology, and initial chemical analysis of 17 patients with FLLC associated liver injury, enrolled in the Drug Induced Liver Injury Network (DILIN). **Methods**: Analysis of patients enrolled in the DILIN prospective study in 2022 with suspected FLLC associated liver injury. **Results:** The mean age was 41 years, 76% female, mean BMI of 24kg/m^2, and all were Caucasian without underlying liver disease. The median latency to onset was 5 days with 18 days to resolution. In some cases, abdominal pain proportional to the amount of FLLC consumed was observed. Regarding symptoms, 29% had jaundice, 35% nausea, 29% fever, 41% abdominal pain, 35% itching, and none had rash. The median initial serum ALT was 369 U/L, AST 117 U/L, alkaline phosphatase 176 U/L, and total bilirubin 2.7 mg/dL (see Table 1). The mean time to peak injury was 2 days. 53% had a hepatocellular pattern of liver injury at presentation, with the rest mixed or cholestatic. 24% of patients were hospitalized and there were no fatalities or transplants. Liver biopsy in one subject revealed mild ductular reaction, mild lymphocytic and eosinophilic portal inflammation with preserved bile ducts and no interface hepatitis. There was mild lobular necroinflammation without steatosis, granulomatous reaction or cholestasis, consistent with acute hepatitis of unknown etiology. Four FLLC samples underwent chemical analysis and no amatoxins, phallotoxins, aflatoxins, microcystins, or pyrrolizidine alkaloids were identified within limits of detection (10-25 ppb) and the heavy metals (As, Pb, Hg, Cr, Cd) were within acceptable limits. Phylogenetic analysis confirmed the presence of *Tara spinosa*, the source of Tara flour. Since removal of the product from the market, no further subjects have been enrolled into the DILIN. **Conclusion:** Ongoing studies will seek to identify the presumed hepatotoxin in addition to host factors, including genetic variants, which may predispose to liver injury.

Table 1: Clinical Features and Presentation

	N = 17
Mean Age	41

1703-A | CLINICAL CHARACTERISTICS AND HLA ASSOCIATIONS OF AZITHROMYCIN INDUCED LIVER INJURY

Dina Halegoua-De Marzio[1], Caroline Conlon[2], Jawad Ahmad[3], Huiman Barnhart[4], Robert J. Fontana[5], Marwan S. Ghabril[6], Paul H. Hayashi[7], David E Kleiner[8], William M. Lee[9], Yi-Ju Li[4], Joseph Odin[10], Andrew Stolz[11], Raj Vuppalanchi[12], Victor J. Navarro, Md[13] and for the Drug Induced Liver Injury Network (DILIN), (1)Sidney Kimmel Medical College at Thomas Jefferson Unversity, (2)Thomas Jefferson University Hospital, (3)Icahn School of Medicine at Mount Sinai (ISMMS), (4)Duke University, Durham, NC, (5) University of Michigan Hospitals and Health Centers, (6) Indiana University, (7)FDA, (8)Laboratory of Pathology, National Cancer Institute, National Institutes of Health, (9)University of Texas Southwestern Medical Center, (10)Icahn School of Medicine at Mount Sinai, New York, NY, (11)University of Southern California, Los Angeles, CA, (12)Indiana University School of Medicine, (13) Einstein Medical Center

Background: Azithromycin (AZ) is a widely used macrolide antibiotic with a favorable safety profile, yet drug induced liver injury (DILI) has been reported. Our aim is to characterize the clinical features, outcomes, and human leukocyte antigen (HLA) associations in patients with AZ DILI. **Methods:** We evaluated individual's with definite, highly likely or probable AZ DILI enrolled by the US Drug Induced Liver Injury Network (DILIN). HLA typing was performed using an Illumina MiSeq platform. Analysis of HLA alleles was performed by Fisher's exact test to compare allele frequency (AF) in AZ DILI cases and population controls assembled from five dbGaP GWAS datasets. **Results:** Thirty cases (4 definite, 14 highly likely, 12 probable) of AZ DILI were included. These represent 2% of adult and 7% of pediatric high causality DILI cases enrolled in DILIN between 2004 and 2022 (n = 1635). Median age was 46 years (range 1-78). 83% were white. 60% were female. 17% had pre-existing liver disease. Median duration of use was 5 days (range 2-8 d) and latency was 18.5 days (range 2-65 d). 73% were jaundiced at presentation. The DILI pattern was hepatocellular in 60%, cholestatic in 27%, and mixed in 13%. Ten cases (33%) were considered severe or fatal, with 90% having hepatocellular injuries. Two patients (7%) required liver transplantation and one patient with chronic liver disease died of hepatic failure. Chronic liver injury developed in 17% of patients, of which 80% had hepatocellular injuries at onset. Of the 5 children included, 3 were hospitalized; 1 required transplantation; 1 suffered a severe cutaneous reaction; and 2 developed chronic liver injury. Of the 13 liver biopsies reviewed, 6 had acute or chronic hepatitis, 6 had cholestatic injuries, 4 had zone 3 to multiacinar necrosis, and 1 had severe ductopenia. HLA-DQA1*03:01 showed a significantly increased prevalence in AZ DILI versus population controls after correction for multiple testing (AF: 0.29 vs 0.11, p = 0.001, FDR = 0.03). The increased prevalence was non-significant when compared to other DILI cases (AF = 0.16, p = 0.053, FDR 0.50). **Conclusion:** AZ DILI can lead to significant morbidity and mortality in both adult and pediatric populations. Hepatocellular injury pattern and pediatric incidence were associated with worse outcomes. HLA-DQA1*03:01 was significantly more prevalent in AZ cases than in the population. However, this allele was not specific to AZ DILI compared with DILI caused by other drugs.

1704-A | CLINICAL FEATURES AND OUTCOME OF LIVER INJURY INDUCED BY IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH ADVANCED MALIGNANCIES

Takanori Ito[1], Takafumi Yamamoto[1], Kazuyuki Mizuno[1], Shinya Yokoyama[1], Norihiro Imai[1], Kenta Yamamoto[1], Yoji Ishizu[1], Takashi Honda[1], Satoshi Yasuda[2], Hidenori Toyoda[2], Masatoshi Ishigami[1] and Hiroki Kawashima[1], (1)Nagoya University Graduate School of Medicine, (2) Ogaki Municipal Hospital

Background: The clinical course of immune checkpoint inhibitor (ICI)-induced immune-mediated hepatotoxicity (IMH) differs significantly from that of classical drug-induced liver injury and varies widely among individual's. In this study, we aimed to clarify the clinical characteristics and outcomes in patients with IMH. **Methods:** We evaluated the characteristics and clinical course of IMH in 2071 patients treated with ICIs for advanced malignancies between September 2014 and March 2023. **Results:** During a median observation period of 298 days, 81 (3.9%) patients developed IMH (**e** Grade 3). Of these, 31 (38.3%) patients had a pathological diagnosis by liver biopsy. The number of ICI types were anti-PD-1 or PD-L1 antibody (Ab), anti-CTLA-4 Ab monotherapy/anti-PD-1, and anti-CTLA-4 Ab combination were 60, 7, and 14 patients, respectively. The median time from the first administration of ICI to the onset of IMH (**e** Grade 3) was 50 (range; 1-531) days. The liver-injury patterns were hepatocellular (n = 38), mixed (n = 16), or cholestatic (n = 27), respectively. The neutrophil-to-lymphocyte ratio (NLR), neutrophil count ($P < 0.01$), and CRP ($P < 0.05$) were significantly higher in IMH patients with cholestatic and mixed patterns than those with hepatocellular patterns ($P < 0.01$). Thirty-eight patients (37%) had immune-related adverse events (irAE) other than IMH during follow-up periods, the common type of were endocrine disorders (n = 12). Forty-six patients (56.8%) were treated with prednisolone (PSL), 7 patients with PSL/mycophenolate mofetil. The therapeutic response to PSL in the hepatocellular injury pattern was better than in mixed/cholestatic patterns. ICIs were re-administered in 21 patients (25.9%), and only one patient had a flare-up of liver injury, and seven patients developed irAEs in other organs. Immune-related sclerosing cholangitis (irSCs) was observed in 7 patients (8.7%), and as previously reported, the PSL response was poor. **Conclusion:** For the diagnosis of IMH, it is necessary to determine the treatment strategy according to the type of liver injury after excluding irSCs which is refractory to PSL treatment. Additionally, when ICI is re-administered after IMH occurrence, it is necessary to be aware not only of IMH recurrence but also of the occurrence of irAEs in other organs.

1705-A | COMPARISON OF THE IMMUNE-MEDIATED LIVER INJURY INDUCED BY IMMUNE CHECKPOINT INHIBITORS IN CASES WITH HEPATOCELLULAR CARCINOMA AND OTHER MALIGNANT TUMOR

Yan Wang[1], Liwei Liu[2], Mengyu Zhao[1], Wei Chen[1] and Xinyan Zhao[1], (1)Beijing Friendship Hospital, Capital Medical University, Beijing, China, (2)Beijing Youan Hospital Capital Medical University, Beijing, China

Background: Whether the incidence of immune-mediated liver injury induced by immune checkpoint inhibitors (ILICI) between liver carcinoma and other tumor are not well understood. We aim to compare the incidence of ILICI and clinical characteristics between the liver carcinoma and the other malignancies. **Methods:** Patients treated with immune checkpoint inhibitors at Beijing Friendship Hospital were retrospectively reviewed and categorized into liver carcinoma group and other malignant tumor group. The demographic and laboratory data, and mortality between the two groups were compared. Patients with liver carcinoma were further grouped into no liver injury, immune-mediated liver injury and other reasons caused liver injury groups. The demographic and laboratory data, and mortality among these three groups were compared. **Results:** A total of 109 liver carcinoma and 1247 other tumor cases were included, including 501 gastrointestinal malignancies, 348 pulmonary malignancies, 126 urological tumors and 272 other malignancies. All the cases were treated with anti-programmed death (PD)-1 or anti PD-L1. No difference of total ICIs cycles was found between the liver carcinoma and other malignancies group (2(1,6) vs. 3 (2,6) cycles, $p = 0.053$). Not surprisingly, the baseline alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma glutamyl transpeptidase (GGT), total bilirubin (TB) of cases with liver carcinoma were significantly higher than those with other malignancies. More cases in the liver carcinoma

Symbols: ᶠ, Poster of Distinction; ★, Foundation Award Recipient

group experienced acute liver injury of any reason (36 (33.0%) vs. 287 (23.0%), p = 0.019). However, the incidence of immune medicated liver injury of the two groups were similar (6 (5.5%) vs. 61 (4.9%), p = 0.777). No difference of mortality was found between the two groups. Furthermore, no difference of mortality was found between the cases with liver carcinoma who has no liver injury, immune mediated liver injury and any other causes induced liver injury (2 (2.7%) vs. 1 (16.7%) vs. 3 (10.0), p = 0.159). **Conclusion:** The incidence of immune medicated liver injury of the two groups were similar despite that more cases in the liver carcinoma group experienced acute liver injury of any reason. No difference of mortality was found between the liver carcinoma and other tumor groups.

1706-A | DAPAGLIFLOZIN ALONE AND IN COMBINATION ATTENUATES CISPLATIN-INDUCED HEPATOTOXICITY BY MITIGATING OXIDATIVE STRESS : A PRE-CLINICAL STUDY.

Mohamed Farook[1], Mohammed Moin Khan[1], Anuradha Nair[1], Sofiya Khan[1], Nirmal Binu[1], Mohamed Yehya[1], Shakta Mani Satyam[2], Laxminarayana Kurady Bairy[2] and Abdul Rehman[2], (1)Ras Al Khaimah Medical and Health Sciences University, (2)Faculty Supervisors-Departments of Pharmacology and Pathology, Rakcoms, Rakmhsu

Background: The world wide prevalence of liver diseases is rising due to the lack of effective preventive or treatment measures. This study aimed to investigate the anticipated hepatoprotective potential of Dapagliflozin alone and in combination with Silymarin against Cisplatin-induced hepatotoxicity in Wistar rats. **Methods:** 30 adult Wistar rats were randomly divided into five groups (n = 6/group): Group I- Normal control, Group II-Negative control, Group- III- Positive control (Silymarin), Group IV- Dapagliflozin and Group V- Dapagliflozin + Silymarin. Hepatotoxicity was induced in Group II to Group V rats by administering Cisplatin per week for seven weeks. Serum ALT, AST, Total Protein,inflammatory cytokines, Heme oxygenase -1, Superoxide dismutase were estimated and H&E staining of the liver was performed. **Results:** Hepatotoxicity was significantly ($p < 0.05$) marked in negative control compared to normal control rats. Both silymarin and dapagliflozin alone and in combination significantly ($p < 0.05$) decreased serum ALT, AST, inflammatory cytokines and oxidative stress markers compared to negative control. **Conclusion:** The present study revealed that dapagliflozin alone and in combination with silymarin attenuates cisplatin-induced hepatotoxicity by mitigating oxidative stress.

1707-A | DEUBIQUITINATING ENZYME JOSD1 MITIGATES PROTEOTOXIC HEPATOCELLULAR INJURY VIA THE SOCS1 PATHWAY

Saheli Chowdhury, Abhishek Sen and Partha Chakrabarti, Csir-Indian Institute of Chemical Biology

Background: Aberrant protein homeostasis and accumulation of intracellular hyperubiquitylated proteins are histopathological signatures in a multitude of chronic liver diseases. Aim of this study is to identify novel deubiquitinating enzymes (DUB) that could reverse pathological ubiquitylation and consequently mitigate the proteotoxic liver injury. **Methods:** Proteasomal inhibitor MG132 was used to induce proteotoxicity in HepG2 cells for assaying with 96 human DUB siRNA library to identify target DUBs modulating proteotoxic stress. DUB JOSD1 was identified and validated for protection against cell death by multiple *in vitro* assays. JOSD1 interacting proteins were analyzed by immunofluorescence microscopy and co-immunoprecipitation. JOSD1 mutant clones were generated by site directed mutagenesis. Knockdown and overexpression of Josephin domain-containing protein 1 (JOSD1) was done using adenovirus and adeno-associated virus (AAV) respectively in primary mouse hepatocytes and in mouse liver. **Results:** Screening of DUB unearthed

JOSD1 as one of the targets for reducing hepatocyte apoptosis under proteotoxicity. The hepato-protective role of JOSD1 was further validated by overexpression and knockdown of JOSD1 both *in vitro* and *in vivo*. Mechanistically, under proteotoxic stress JOSD1 accumulates and localizes to the plasma membrane where it binds, deubiquitinates and stabilizes suppressors of cytokine signaling 1 (SOCS1). Correspondingly, enzymatically inactive JOSD1^{C36A} mutant was neither able to mitigate cell death nor modulate the levels of its interacting partners. **Conclusion:** Our study thus unveils a candidate DUB, JOSD1, as a potent target of proteotoxicity induced hepatocellular apoptosis and proposes a mechanism for its protective action via the SOCS1 pathway.

1708-A | EFFECTS OF ELEXACAFTOR/TEZACAFTOR/IVACAFTOR ON MARKERS OF LIVER FIBROSIS IN ADULTS WITH CYSTIC FIBROSIS

Olivia Portolese[1], Marc Bilodeau[2], Hélène Castel[1], Bernard E. Willems[1], Genevieve Huard[3], Catherine Vincent[2], Annick Lavoie[1] and Julian Hercun[1], (1)Centre Hospitalier De L'université De Montréal, Montréal, QC, Canada, (2)Centre De Recherche Du Centre Hospitalier De L'université De Montréal (CRCHUM), (3)Centre Hospitalier De l'Université De Montréal

Background: Cystic fibrosis (CF) is a genetic disease caused by a mutation in the CFTR gene, the most common being F508del. While lung involvement is predominant, it is estimated that 30% of adults will have cystic fibrosis liver disease (CFLD). Elexacaftor/tezacaftor/ivacaftor (ETI) modulates the F508del mutated protein and improves respiratory outcomes. Although ETI can cause increases in liver enzymes, it has the potential to improve long term liver outcomes as the CFTR protein is located on cholangiocytes. The aim of this study was to determine the short term and long-term effects of ETI on liver outcomes in adults with CF. **Methods:** This is a retrospective descriptive cohort including all adults with CF currently treated with ETI by the Respirology Division of the Centre hospitalier de l'Université de Montréal. Clinical data were collected prior to treatment initiation and on-therapy. Liver fibrosis was assessed by transient elastography (TE); a threshold of 6.8 kPa was used to define CFLD based on previous findings. For each patient, Fib4 and APRI scores were calculated using standard formulas; values of 1.3 and 0.7 were respectively used as thresholds for increased fibrosis. **Results:** The cohort included 154 patients, 51.3% male, with an average age at treatment initiation of 37. One patient had a prior liver transplant. Four (2.6%) patients had imaging findings compatible with cirrhosis. Only 3 (2%) patients had thrombopenia and 8 (5%) had splenomegaly. Baseline liver tests prior to initiating ETI were within normal limits in all but 6 patients presenting with an ALT > 1.5 times the upper limit of normal (ULN) and only case of elevated bilirubin. Thirty-one patients had a pre-treatment TE measurement: their average measure was 6.8 kPa (3.3-24.2 kPa). 29% were considered as having CFLD. Five patients had elevated Fib4 and only 1 elevated APRI scores. Over an average follow-up of 9 months (range 1 – 28), 26 patients (16.8%) had at least one episode of ALT > 1.5 x ULN and 4 presented with increased bilirubin (unconjugated in all cases). Three patients had treatment interruptions for liver related causes, with 1 patient successfully resuming therapy. There was one reported death (non-liver related). The average APRI increased from 0.20 to 0.32 ($p = 0.0001$) and Fib4 from 0.62 to 0.72 ($p = 0.07$): the former remained significant on paired analysis (Wilcoxon test < 0.0001). In 15 patients with paired measures, average TE decreased significantly from 6.8 to 6.1 kPa ($p = 0.01$). In patients with a baseline elevated TE score, measurement improved by 1.3 kPa on average. **Conclusion:** Severe drug-induced liver injury was infrequent in this cohort. Serum markers of fibrosis increased while remaining within normal range. However, TE values decreased, a potentially encouraging finding suggesting improvement in liver fibrosis. Additional long-term follow-up is required to determine trends in TE and explain the discrepancy with serological markers of fibrosis.

1709-A | HIGHER INCIDENCE OF STATIN-INDUCED RHABDOMYOLYSIS IN PATIENTS WITH CIRRHOSIS COMPARED WITH THE GENERAL POPULATION: A RETROSPECTIVE COHORT STUDY

George Chen[1], Meagan Alvarado[1], Elizabeth Cohen[1], Kara Ventura[1] and Uyen To[2], (1)Yale University, New Haven, CT, (2)Yale School of Medicine, New Haven, CT

Background: Statins have been shown to reduce portal hypertension and liver decompensation in patients with advanced chronic liver disease. However, the safety profile of statins in cirrhosis has not been investigated extensively. Although statin-induced rhabdomyolysis (SIR) events in cirrhosis have been reported by multiple case reports, their incidence and associated risk factors are unknown. To this end, we conducted a retrospective cohort study of SIR in patients with cirrhosis in a large United States healthcare system. **Methods:** We evaluated patients with cirrhosis in the Yale New Haven Health System (YNHHS) in Connecticut, USA from January 2012 to March 2023. The YNHHS electronic health record (EHR) was queried using Slicer Dicer, a data exploration tool in the Epic EHR system, to identify patients with cirrhosis who were prescribed statins and developed rhabdomyolysis following initiation of statin therapy. Patient charts were manually reviewed to confirm SIR diagnosis. Demographic and clinical data, including age, sex, race, ethnicity, etiology of cirrhosis, Child-Pugh score, Model for End-Stage Liver Disease (MELD) score, statin type and dose, and hospitalization status were extracted from patient charts. Categorial variables were compared using Chi-square tests at a significance level of < 0.05. **Results:** Among 20,251 patients diagnosed with cirrhosis, 8,239 (41%) were prescribed statins. A total of 15 patients developed SIR, with a cumulative incidence of 0.2%. Demographic and clinical characteristics are provided in Table 1. The majority of patients diagnosed with SIR (mean age of onset: 60 ± 13 y) were male (87%) and white (60%). A significantly higher proportion of SIR events occurred in patients with decompensated cirrhosis (0.87) compared to compensated cirrhosis ($p = 0.005$). Patients had a mean Child-Pugh score of 8.4 and MELD score of 19.5. Eleven patients (73%) were prescribed high-intensity statins, while the remaining four patients were on moderate-intensity statin therapy ($p = 0.002$). A significantly larger percentage of SIR events occurred in the outpatient setting (80%) compared to inpatient ($p = 0.02$). **Conclusion:** To our knowledge, this is the first cohort study to assess the risk of SIR in patients with cirrhosis. The cumulative incidence of SIR in cirrhosis was 0.2%, 20-fold higher than the estimated 0.01% risk of SIR in the general population. The safety profile of statins should be carefully weighed against their potential benefits on liver outcomes, particularly in patients with decompensated cirrhosis and those prescribed high-intensity statin therapy. Additional studies investigating risk factors associated with SIR in cirrhosis are warranted.

Table 1: Demographic and clinical characteristics of patients with cirrhosis diagnosed with statin-induced rhabdomyolysis

Demographic characteristics	
Age (mean±SD)	60±13 years
Sex	
Male	87%
Female	13%

1710-A | IMPACT OF CLINICAL TRIAL DATA QUALITY ON FDA DRUG-INDUCED LIVER INJURY RISK ASSESSMENT IN NEW DRUG AND BIOLOGIC APPLICATIONS

Ling Lan[1], Mark I. Avigan[2] and Paul H. Hayashi[1], (1) FDA, (2)Food and Drug Adminstration

Background: One or two jaundiced hepatocellular DILI cases in clinical programs can significantly impact the

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

benefit-risk assessment of a study drug; therefore, much depends on the completeness and accuracy of submitted data. Aim: To characterize the impact of liver injury data quality on new drug and biologics license application (NDA/BLA) reviews requiring FDA DILI Team assessment. **Methods:** We retrospectively assessed 22 applications for which the FDA DILI Team was consulted from 12/2021 to 3/2023. We assessed the quality of case level data by how many applications required information requests to obtain more data about individual subjects suspected of having DILI. For study level data, we identified applications having deficiencies in laboratory datasets used to generate eDISH (hepatocellular DILI screening) plots. **Results:** Seventy-seven percent (17/22) applications involved new molecular entities; and 86% (19/22) were approved. Labeling had DILI-related warnings and precautions in 84% (16/19) of the approved drugs. The DILI Team had to request more complete case level data in nearly all applications (95%, 21/22). The most common inadequacies were unclear evaluation testing for non-DILI causes, incomplete narratives, unclear concurrent medications, lack of chronologic lab results by table or graphics, and lack of follow-up. DILI Team analyses alleviated DILI concerns in three NDAs/BLAs once complete data were obtained. However, we found two applications with significant study level data limitations including missing local lab results, upper limit normal values, and units (i.e., U/L, mg/dL) that led to subjects meeting Hy's Law lab criteria being incorrectly plotted outside of Hy's Law quadrant in eDISH plots. These study level limitations were only discovered when manually cross-checking study reports and case level data with study level datasets. **Conclusion:** Case level data in applications are often inadequate to assess DILI attribution. Missing lab results from study level data can undermine eDISH as a sensitive screening tool. The extent of incorrect eDISH plotting across applications may be larger than captured in our analysis. Clearer communication between the FDA and drug sponsors throughout drug development is needed so that pre-specified means and expectations are set for collecting DILI-related data. Routine cross-checking of case and study level laboratory data by computer programming may be beneficial.

1711-A | IV AMIODARONE INFUSION INDUCED ACUTE HEPATOTOXICITY AND LIVER FAILURE

Tulsi Patel, Christianacare Hospital

Background: IV amiodarone is commonly indicated for rate control in hemodynamically stable arrhythmias, including atrial fibrillation. Existing literature reports the development of acute hepatotoxicity from IV amiodarone infusions in patients with reduced EF. We report a case of amiodarone induced acute hepatitis in the setting of cardiogenic shock where the patient also developed multi-organ failure, including acute liver failure. **Methods:** This is a 63 year old male with history of atrial fibrillation who presented with dyspnea and found to be in atrial fibrillation with rapid ventricular rate requiring admission for heart failure. Of note, initial transaminitis(AST 71, ALT 85) was thought to be due to some degree of congestive hepatopathy. Rate control with IV metoprolol was unsuccessful so he was loaded with 150mg IV amiodarone followed by continuous infusion. He received 1020 mg of amiodarone during the initial 22 hours of hospitalization. He eventually developed cardiogenic shock (lactic acid 10.6, CVP 22, SvO2 58%, Fick cardiac output 4.1) and acute renal failure requiring renal replacement therapy. Repeat labs revealed AST > 10000, ALT > 5000 and INR 5.7, peaking at 9.4. Ischemic hepatitis alone could not explain the trajectory of the transaminitis, especially with optimization of cardiogenic shock. Acute hepatitis and acute liver failure (evidenced by coagulopathy and hepatic encephalopathy) were suspected to be due to IV amiodarone. Transaminitis drastically improved within 24 hours of stopping amiodarone and near normalized within 1 week. N-acetylcysteine was initiated 48 hours after development of ALF for possible mortality benefit. **Results:** Hepatotoxicity due to oral amiodarone is a commonly known side effect. Less commonly encountered is the development of acute hepatitis or ALF from IV amiodarone. The mechanism by which this develops is not yet understood. Some literature (Rhodes et al., 1993) suggests that it is related to formulation of the IV infusion with Polysorbate 80. The pattern of injury described on liver pathology appears different in IV amiodarone hepatotoxicity compared to its oral counterpart; described as a pattern of injury similar to ischemic hepatitis. It is possible this could be in part due to the fact that these patients are receiving IV amiodarone for acute arrhythmias impending hemodynamic instability. One study (Nasser et al., 2013) suggests that reduced LV systolic function leads to prolongation of the half life of its metabolite. Further research needs to be conducted in order to assess if the level of injury is dose dependent. **Conclusion:** The mechanism for IV amiodarone induced hepatitis and ALF is not known yet. However, it seems to be a common theme that all of these patients have some degree of reduced left ventricular systolic function. Further research needs to be conducted to identify if there are prognostic factors that can predict this adverse event.

1712-A | OPTIMIZING DILI DETECTION AND MANAGEMENT IN CLINICAL TRIALS FOR PATIENTS WITH ELEVATED AMINOTRANSFERASE LEVELS AT BASELINE

Michael Merz, Self-Employed, Don C. Rockey, Medical University of South Carolina, Hans L. Tillmann, East Carolina University; Greenville VA Health Care Center, Gerd A Kullak-Ublick, University Hospital Zurich, Zurich, Switzerland; Novartis, Anna Fettiplace, Astrazeneca and John F. Marcinak, Abbvie, Inc.

Optimizing DILI detection and management in clinical trials for patients with elevated aminotransferase levels at baseline **Background:** Drug-Induced Liver Injury (DILI) can be a serious problem during clinical development, especially in patients with abnormal baseline liver chemistry, such as in cancer or NASH patients. For patients with normal baseline ALT, there are established ALT thresholds triggering action ('action levels'), e.g. dose interruption or discontinuation; however, no consensus is yet available for thresholds in patients with abnormal baseline ALT. To address this, we developed a simple mathematical model using established ALT thresholds for patients with normal baseline ALT to calculate action levels in multiples of the upper limit of normal (ULN) for patients with abnormal baseline ALT. We then applied the model, as an example, to inclusion and action thresholds typically used in oncology studies, with 20 x ULN as maximum action level triggering permanent drug discontinuation. **Methods:** As per intercept theorem, on two parallel lines intersected by at least three lines, intersecting at a point outside the parallels, the ratio of two segments on one line equals the ratio of the corresponding segments on the parallel line. We used this theorem to translate ALT action levels in patients with normal baseline into action levels in patients with abnormal baselines (detailed derivation see Figure 1). **Results:** Calculation of action levels for patients entering clinical trials with abnormal ALT (i.e., 1 - 3 x ULN or 3 - 5 x ULN) at baseline, using intercept theorem, expressed in multiples of ULN and rounded up, results in the three projected action levels ($al_{1\text{-}3}$) presented below, along with action levels for patients with normal ALT at baseline: Normal ALT at baseline **d** ULN:

- al_1: 3
- al_2: 5
- al_3: 10

Abnormal ALT at baseline > 1 - 3 x ULN

- al_1: 5
- al_2: 7
- al_3: 11

Abnormal ALT at baseline > 3 - 5 x ULN

- al_1: 7
- al_2: 8
- al_3: 12

Thus, protocols placing action levels for ALT in patients with normal baseline at 3, 5 and 10 x ULN, respectively, for increased monitoring, dose interruption or drug discontinuation can use the above derived values to assign appropriate ALT action levels to patients with abnormal ALT at baseline. For example, a patient with a normal baseline may have drug interrupted at 5 x ULN, whereas a patient with a baseline ALT of 2 x ULN will reach interruption at 7 x ULN, resulting in the degree of permitted ALT elevation before interruption being proportional to the baseline ALT value. **Conclusion:** Here, we demonstrate an innovative method to create action levels for patients with abnormal baseline ALT levels. The resulting algorithm is simple, transparent, and provides grouped ALT threshold values without the need to calculate patient-specific multiples of baseline values. This logical, structured approach provides clear and practical guidance for hepatotoxicity management in clinical trials.

Figure 1: Derivation of action levels for patients with abnormal baseline ALT (lower parallel) from thresholds for patients with near normal baseline ALT (upper parallel).

1713-A | OUTCOMES IN WOMEN WITH CHRONIC LIVER DISEASE UNDERGOING INFERTILITY TREATMENT

Meera Garriga, Monika Sarkar and Marcelle Cedars, University of California, San Francisco

Background: Women with cirrhosis commonly have amenorrhea and subfertility, although data on the the safety and success of assisted reproductive technology (ART) across the spectrum of chronic liver diseases (CLDs) are limited, undermining appropriate pre-conception counseling in women with liver disease. Here, we report reproductive and liver-related outcomes following ART in women with CLD as compared to women without liver disease. **Methods:** We conducted a retrospective analysis of all adult women undergoing ART at our center from 2010-2022. CLD cases were matched to non-CLD controls by age at ART and ART protocol (to ensure consistency in hormonal exposure). Medical history and ART protocols were extracted from the electronic health record. Outcomes of interest included response to controlled ovarian stimulation, embryo fertilization rate, implantation rate, live birth rate, change in liver enzyme levels or hepatitis viral load. Chi-squared and t-tests were used to compare dichotomous and continuous

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

variables, respectively. **Results:** We identified 54 women with CLD who underwent 100 oocyte retrievals and 64 oocyte transfers between 2010-2022 at our center. Mean age at retrieval and transfer was 39.1 and 39.2 years, and were similar across CLD cases and controls (all $p > 0.05$). The most common causes of CLD were chronic hepatitis B (CHB) (46%), non-alcoholic fatty liver disease (NAFLD) (28%) and benign hepatic lesions (19%). Two patients had autoimmune hepatitis and one had alcoholic cirrhosis. There were no significant differences between CLD and non-CLD groups in number of oocytes retrieved (12.2 vs 13.0), or rates of embryo fertilization (0.69 vs 0.69), implantation (0.45 vs 0.47) or live birth (0.34 vs 0.33) (all $p > 0.05$). Notably, on subgroup analysis by type of CLD, the mean number of oocytes retrieved in patients with CHB was numerically lower compared to controls (12.8 vs 14.5, $p = 0.43$), though rates of embryo fertilization, implantation and live birth were similar. Among women with available liver tests, a rise in liver enzymes was observed during 4/73 (5.6%) cycles in patients with NAFLD, AIH, and CHB. The median (IQR) peak AST was 121.5 IU/L (86-157 IU/L) and median (IQR) peak ALT was 85 IU/L (59-185 IU/L). Among 20 women with CHB, one had rise in viral load from ~12,000 to 1 million IU/mL and concurrent rise in ALT from 18 to 53. OHSS occurred in no patients with CLD and in 1 non-CLD control. 5 patients with CLD (3 CHB, 1 NAFLD, 1 liver lesion) developed hypertension in pregnancy, compared to only one non-CLD control. There were no maternal deaths. **Conclusion:** women with CLD had similar ART outcomes to patients without CLD, and liver-related complications were uncommon. While reassuring, the absolute number of oocytes retrieved may be lower in some patients with CLD. Routine family planning discussions and consideration of early referral for ART planning may help to improve pregnancy potential in reproductive-aged women with CLD.

1714-A | OVERWHELMING CYTOCHROME P450 ISOENZYME ACTIVITY GENERATING DRUG-INDUCED LIVER INJURY RESULTING IN FULMINANT LIVER FAILURE

Jose R. Russe[1], Islam Abdelhamid[1], Raphael Meier[2], Georgeta Giblen[1] and Anurag Maheshwari[1], (1)Institute for Digestive Health and Liver Disease at Mercy Medical Center, (2)University of Maryland Medical Center

Background: Fulminant liver failure (FLF) is a severe and rapidly progressive form of liver injury with a high mortality rate without liver transplantation; drug-induced liver injury (DILI) is the leading cause in developed countries. The following case of FLF due to DILI is suspected to be caused by the synchronous use of multiple medications metabolized by the same liver enzyme cytochrome P450 (CYP450). **Methods:** In June, a 41-year-old Caucasian female started paroxetine for anxiety and depression and trazodone for insomnia. Although she improved in July, she noted poor focus and decreased concentration and started lisdexamfetamine. In August, after unrelenting abdominal symptoms, a colonoscopy found lymphocytic colitis, and she began budesonide. Finally, around September, she had COVID managed with molnupiravir. **Results:** A month later, she was severely ill, and biochemistry (BCH) showed elevated liver enzymes (LFTs)l; aspartate transferase (AST) 37 x upper limit of normal (ULN), alanine transaminase (ALT) 36 x ULN, elevated alkaline phosphatase (ALP), and normal bilirubin (TB) (Figure 1A). In November, imaging showed acute hepatitis, splenomegaly, and ascites; budesonide was stopped. A week later, she was hypotensive, dyspneic, and jaundiced; new BCH showed AST 50 x ULN, ALT 36 x ULN, ALP 6 x ULN, and TB of 5.3 with a model for end-stage liver disease score (MELDs) of 26 (Figure 1B). A liver biopsy (LBx) showed submassive necrosis, inflammation, interface hepatitis, and duct-sparing poorly-formed granulomas, suggesting drug-induced injury (Figure 1C-I). Therefore, all prior medications were stopped. Days later, she had MELDs of 29, TB of 13.6, and encephalopathy; her continued deterioration prompted a liver transplant. An explant LBx confirmed chronic hepatitis with massive eosinophils and grossly nodular inflamed liver consistent with drug-induced liver injury (Figure 1J-K). **Conclusion:** The pathophysiology of DILI begins when medications processed by CYP450 and its isoenzymes, including CYP1A2, CYP2D6, and CYP3A4, that metabolize the aforementioned drugs, produce metabolites that damage the liver. The resulting substrates inhibit, induce, or compete for the same enzymes resulting in an overwhelming accumulation of toxins directly injuring hepatocytes and ultimately leading to FLF. When co-medicating, if DILI is suspected, immediate cessation, close monitoring, and prompt action are crucial to prevent severe complications such as FLF.

1715-A | POPULATION LEVEL EXPOSURE ESTIMATES TO 4 POTENTIALLY HEPATOTOXIC HDS BOTANICAL PRODUCTS: RESULTS FROM THE NHANES 2017-2018 COHORT

Alisa Likhitsup, University of Michigan, Vincent Chen, University of Michigan Medical Center and Robert J. Fontana, University of Michigan Medical Center, Ann Arbor, MI

Background: Herbal and dietary supplements (HDS) such as green tea extract (GTE), turmeric, and Garcinia account for 20% of drug hepatotoxicity cases in the US. Our study was to determine the characteristics of individual's who consume 4 potentially hepatotoxic botanical products from the NHANES 2017-2018 cohort. **Methods:** The Dietary Supplement database of NHANES 2017-2018 was queried. Exposure to 4 potentially hepatotoxic botanical ingredients including turmeric, GTE, Garcinia cambogia, and black cohosh were identified by reviewing the constituent ingredients listed in the product names and labels. Total US exposure estimates were calculated based on 2020 U.S. Census data. **Results:** Among the 5,850 adults, 56.7% reported using **e** 1 HDS products within the past 30 days, 11.3% used **e** 1 botanical products, and 210 (4.78%) reported using at least one of the 4 botanicals of interest. Amongst the 210 adults, mean age was 52.5 ± 1.3 years, 54.7% female, and 64.7% White. A turmeric containing product was used in 151 patients, GTE products in 72 patients, Garcinia products in 15 and black cohosh products in 10. Compared to the 2,649 NHANES patients with no HDS use, patients taking these 4 products were significantly older, more likely female, had higher education, higher income, and non-smokers ($p < 0.01$ Table 1). They were also more likely to have underlying hypertension, diabetes, hyperlipidemia, arthritis, or cancer diagnosis. Multivariable analysis identified age 40-59 years (OR 3.6, $p < 0.001$), age 60 years or older (OR 5.2, $p < 0.0001$), some college (OR 9.5, $p = 0.009$), college graduates or above (OR 15, $p = 0.002$), hyperlipidemia (OR 2.8, $p = 0.005$), arthritis (OR 2, $p = 0.01$), and non-smokers (OR 1.9, $p = 0.026$) as associated with consumption of these 4 botanicals. Among turmeric and GTE users, 85% reported using on their own accord and 15% were recommended by a health provider. The most common reasons to use turmeric and GTE, respectively, were to improve/maintain health (62.3% & 68%), prevent health problems (26.5% & 26.4%), nutrition supplement (25.8% & 47.2%), and for metabolic or heart health (11.3% & 15.2). In addition, 36.4% used turmeric for muscle/joint or arthritis and 19.4% used GTE for weight loss. When extrapolating to the general US population, an estimated 15.7 million of US adults used at least of these 4 potentially hepatotoxic botanical products; 11.5 million used turmeric and 3.95 million used GTE. **Conclusion**: Over 15 million U.S. adults consumed potential hepatotoxic botanical products containing turmeric, GTE, Garcinia or black cohosh. Older age, higher education, present of arthritis or hyperlipidemia, and non-smokers were associated with potential hepatotoxic HDS products use.

1716-A | RUCAM HAD BETTER AGREEMENT WITH DILIN EXPERT OPINION COMPARED TO RECAM FOR BONAFIDE DILI IN A RETROSPECTIVE COHORT

Adam Seth Myer, Jacob A Ciricillo, Askanda Osman, Farrah Rahim and Amoah Yeboah-Korang, University of Cincinnati

Background: RECAM, a revised, electronic version of RUCAM, was better than RUCAM at diagnostic extremes in two large prospective DILI registries. RECAM requires more extensive serologic evaluation to exclude alternative diagnoses, and has heavy penalties for missing serologic data. Limited data exists comparing RECAM versus RUCAM agreement with the gold standard DILIN expert opinion in retrospective databases. The primary aim of this study was to compare RECAM versus RUCAM agreement with DILIN expert opinion in a retrospective cohort. **Methods:** All EMR encounters were searched for potential DILI using ICD-10 codes for toxic liver injury between 10/1/2015 and 9/30/2019. Clinically significant liver injury was defined as: 1) AST **e** 5 x ULN, 2) ALT **e** 5 x ULN, 3) ALP **e** 2 x ULN, 4) total bilirubin **e** 2.5 mg/dL, or 5) INR **e** 1.5. Gold standard DILIN expert opinion scores were assigned to each case (1/2/3 = probable-DILI, 4/5 = non-DILI). RUCAM and RECAM scores were calculated for probable-DILI cases. Among probable-DILI, agreement between RECAM and DILIN expert opinion were compared to RUCAM and DILIN expert opinion. **Results:** Among 766,930 patients searched, 127 unique patients met inclusion criteria with 70 (55.1%) cases adjudicated as probable-DILI using DILIN expert opinion. The most frequent suspect drugs were antimicrobials (41.9%), herbal and dietary supplements (9.5%), and antineoplastic (8.1%). Mean age was 48.8 ± 16.9, 55.7% female, and 78.6% Caucasian. Pattern of liver injury was 48.6% hepatocellular, 30% cholestatic, and 21.4% mixed. Liver biopsy was completed in 25.4%. There were missing serological data for anti-HAV IgM (12.9%), anti-HBcore antibody (14.3%), anti-HCV (55.7%), anti-HEV IgM (71.4%), autoimmune markers (ANA, ASMA, IgG) - 32.9%, CMV IgM (84.3%), CMV PCR (65.7%), EBV IgM (71.4%), EBV PCR (68.6%), HSV IgM (85.7%), and HSV PCR (70%). RUCAM classified 65.7% of probable-DILI as probable or highly probable while RECAM classified 38.6% of probable-DILI as probable or highly probable ($p = 0.0023$). **Conclusion:** In a retrospective cohort of consecutive probable-DILI cases from a single center with incomplete viral and autoimmune serologies, RUCAM had better agreement with DILIN expert opinion compared to RECAM. Future efforts should focus on educating providers about the complete serologic evaluation needed for DILI diagnosis.

1717-A | SIRT7 PROTECTS AGAINST OXALIPLATIN INDUCED LIVER INJURY VIA MAINTAINING NRF2 STABILIZATION AND ACTIVATION

Tingzi Yu, Cong Ding, Bohao Liu, Wenbin Tang, Wang Zhiqiang and Zhuan Li, Hunan Normal University

Background: Oxaliplatin (Oxa) is the core therapeutic agents which widely used for treatment of advanced stage of colorectal cancer patients, but it occasionally causes hepatotoxicity characterized by sinusoidal dilatation, hepatic plate atrophy and venular obstruction. Studies have suggested that oxidative stress and stellate cell activation are associated with Oxa induced liver injury. SIRT7 (sirtuin-7) is a NAD^+-dependent class III histone deacetylases (HDAC III), which mediates multiple biological processes such as lipid metabolism and cellular homeostasis. Whether SIRT7 plays role in Oxa induced liver injury remains unclear. **Methods:** Hepatocyte specific SIRT7 knockout mice (Alb-Cre SIRT7) were generated by crossing $SIRT7^{flox/flox}$ mice with Alb-Cre mice. Adeno-associated virus (AAV8)-TBG vectors were used for modulating hepatic gene expression *in vivo*. Mice were receiving Oxa (4mg/kg) interperitoneally daily for 12 days. Liver injury were accessed by ALT and histology, changes of proteins and mRNA were evaluated by WB and qRT-PCR. **Results:** Oxa administration caused elevation of ALT, hepatocyte parenchymal damage, sinusoidal dilation, and inflammation. Alb-Cre SIRT7 mice showed enhanced liver ALT elevation, inflammation and hepatocyte parenchymal damage after Oxa. We further demonstrated that SIRT7 regulates Nrf2 protein levels and activity. Knockdown SIRT7 led to decrease of Nrf2 protein expression, nuclear translocation and transcriptional activity, and increased intracellular ROS accumulation and apoptosis in response to various types of

oxidative stress including acetaminophen (APAP) and hydrogen peroxide (H_2O_2). Mechanistically, SIRT7 interacts with Nrf2 and stabilizes Nrf2. In primary SIRT7 knockout hepatocyte, we observed decreased Keap1/Nrf2 binding when compare with WT. Most importantly, we found that both Nrf2 agonists (Oltipraz) and AAV8-TBG mediated overexpression of NRF2 in Alb-Cre SIRT7 mice alleviated Oxa induced elevation of ALT, hepatocyte parenchymal damage, sinusoidal dilation, and inflammation. **Conclusion:** We identify previously unidentified protective role of SIRT7 in chemotherapy drugs induced liver injury via acting as a positive regulator of Nrf2 protein level and activation.

1718-A | THE IMPACT OF MEDIUM CHAIN TRIGLYCERIDE KETOGENIC DIET ON LIVER MITOCHONDRIA AND CYP2E1

Abigail S. Ryan[1], Kelly R. Misare[1], Joseph McQuail[2], Fiona Hollis[2] and Jessica H. Hartman[1], (1)Medical University of South Carolina, (2)University of South Carolina

Background: The ketogenic diet (KD) is a high fat, low carbohydrate diet that causes elevated levels of blood ketones due to increased fatty acid metabolism as a response to decreased glucose levels. Under these conditions, the liver produces ketone bodies that are metabolized for energy. A particularly effective variation of this diet is the medium chain triglyceride ketogenic diet (MCT-KD) which is comprised mainly of caprylic and capric acids (8 and 10 carbons). **Methods:** Rats (male and female, young and old rats) were fed a MCT-KD or a caloric-matched control diet for eight weeks, and reached maximal levels of plasma beta-hydroxybutyrate within one week. Liver mitochondrial fractions were tested for reaction rates of complexes I-IV of the mitochondrial electron transport chain. Western blot analyses were performed to quantify concentrations of CYP2E1, cytochrome c oxidase, and endoplasmic reticulum membrane oxidoreductase. HepG2 and CYP2E1-transduced HepG2 cell lines were cultured in low glucose media spiked with ketone bodies to determine the effect of CYP2E1 expression on cellular survival. **Results:** We found that MCT-KD caused a decrease in complex I and IV activity in young male and female rats but not old rats. No significant differences were observed between keto and control groups in complexes II and III. In western blot experiments, consistent and dramatic > 3-fold upregulation of CYP2E1 was observed in all rat livers from the MCT-KD group, regardless of sex or age. Similarly, we observed a ~2-fold increase in levels of the coenzyme P450 oxidoreductase. In *in vitro* experiments with HepG2 cells, cellular survival was decreased in low glucose media with and without the addition of ketone bodies, and was rescued by CYP2E1 expression, but there was no significant response to changes in the ketone concentration. **Conclusion:** The results of this study reveal a dramatic effect of the MCT-KD on liver mitochondria and the expression of CYP2E1. MCTs are likely substrates for CYP2E1, and metabolites formed in this pathway could contribute to the physiological effects of the diet. Ongoing and future studies are determining the importance of this pathway in MCT-KD safety and efficacy.

1719-A | BH3-ONLY PROTEINS REGULATE HEPATOCYTE APOPTOSIS AND APOPTOSIS-RELATED LIVER INJURY

Shinnosuke Kudo[1], Hayato Hikita[1], Yoshinobu Saito[1], Takahiro Kodama[2], Tomohide Tatsumi[1] and Tetsuo Takehara[2], (1)Osaka University, Graduate School of Medicine, (2)Osaka University Graduate School of Medicine

Background: Continuous hepatocyte apoptosis with the activation of pro-apoptotic Bcl-2 family proteins, Bak/Bax, is observed in various chronic liver diseases like non-alcoholic steatohepatitis (NASH). BH3-only proteins, upstream of the core Bcl-2 family proteins, can activate Bak and Bax, and we previously reported that BH3-only proteins, Bid and Bim, were involved in regulating hepatocyte apoptosis. However, the whole participations of BH3-only proteins in regulation of hepatocyte integrity remain unclear, and we aimed to reveal their roles. **Methods:** As a model of chronic liver injury with Bak/Bax activation, we generated hepatocyte-specific Bcl-xL(-/-) Mcl-1(+/-) mice, which showed massive hepatocyte apoptosis and severe elevation of serum ALT levels at the age of 6 weeks. We crossed these mice with Bid, Bim, and Puma KO mice to examine the role of BH3-only protein, Puma. **Results:** Bid-/- Bim-/- Puma-/- Bcl-xL(-/-) Mcl-1(+/-) mice showed significantly lower levels of serum ALT and smaller number of TUNEL positive hepatocytes than Bid-/- Bim-/- Puma+/+ Bcl-xL(-/-) Mcl-1(+/-) mice. These findings showed that Puma had a role of inducing hepatocyte apoptosis. On the other hand, serum ALT levels of Bid-/- Bim-/- Puma-/- Bcl-xL(-/-) Mcl-1(+/-) mice were significantly higher than those of Bak-/- Bax(-/-) Bcl-xL(-/-) Mcl-1(+/-) mice, and this suggested there

were other sensor proteins involved in hepatocyte apoptosis. In Vitro study, we immortalized Bim-/- Bid-/- Puma-/- Bcl-xL flox/flox Mcl-1flox/flox mouse primary hepatocyte and doxycycline-dependent Cre recombinase was expressed by pLenti-iCre-Neo. Among other BH-3 only proteins, Bad, Bmf and Noxa, only Noxa knockdown significantly suppress doxycycline-induced apoptosis and improved the cell viability. We next generated Bid-/- Bim-/- Puma-/- Noxa-/- Bcl-xL flox/flox Mcl-1flox/flox tamoxifen-inducible Albumin Cre mice by using CRISPR/Cas9 technology. Serum ALT levels and caspase3/7 activity, and the number of TUNEL positive hepatocytes in Bid-/- Bim-/- Puma-/- Noxa-/- mice significantly decreased compared with Bid-/- Bim-/- Puma-/- mice. These results showed that, in addition to Bid, Bim, and Puma, Noxa had an inducing role of Bak/Bax activation. We finally examined the role of Puma and Noxa in apoptosis related chronic liver disease, NASH. In NASH mice fed with Western diet, Noxa expression levels in their livers increased, while Puma expression levels did not change. In addition, Noxa expression levels strongly increased in liver specimens from NASH patients, and serum ALT levels of NASH patients were positively correlated with expression levels of Noxa in their livers. **Conclusion:** In addition to Bid and Bim, Puma and Noxa participate in Bak/Bax dependent hepatocyte apoptosis, and the activation of Noxa in hepatocyte may be associated with the pathophysiology of human NASH.

1720-A | FATTY LIVER DISEASE AND ALTERED HEPATIC ENERGY METABOLISM CAUSED BY ENVIRONMENTAL TOXICANT MIXTURES ARE SEX-DEPENDENT

Yuan Hua, Oluwanifemi Esther Bolatimi, Jianzhu Luo, Ngozi Victoria Adiele, Tyler C Gripshover, Walter Watson and Banrida Wahlang, University of Louisville, Louisville, KY

Background: Epidemiologic studies have demonstrated that exposure to 'forever chemicals' such as organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs) were associated with elevated liver enzymes, indicative of liver injury. However, effects and mechanisms related to how 'mixtures' of such chemicals induce liver injury are still largely unknown. Thus, the study's objective is to investigate the sex-dependent effects of OCPs and PCBs, using chlordane and PCB126 as model compounds, in the context of fatty liver disease and metabolic disruption in a diet-induced obesity model. **Methods:** Male and female C57BL/6 mice were fed a high-fat diet (HFD) and administered either vehicle control or chlordane(20 mg/kg)+PCB126(20μg/kg) over a 12-week period. Tissues and plasma were collected at euthanasia for downstream analyses. **Results:** Female mice generally had lower fat content, but higher spleen and cecal weights *vs.* males. With regards to steatosis, females exhibited lower hepatic lipid accumulation (steatosis), confirmed by H&E staining and quantification of hepatic triglycerides, and could be attributed to estrogenic-protective effects with HFD feeding. However, compared to their sex-matched controls, mixture-exposed females showed elevated plasma alanine transaminase (ALT), increased liver weight and hepatic cholesterol levels, and trend for downregulated HDL, implicating liver injury and dyslipidemia . Moreover, exposure to the toxicant mixture decreased physical activity (assessed using metabolic chambers) in females. In contrast, mixture-exposed males had lower hepatic GSH/GSSG levels, suggesting oxidative stress. Chlordane+PCB126 exposure resulted in insulin resistance in both sexes. In terms of receptor activation, chlordane+PCB126 activated hepatic xenobiotic receptors, namely CAR (*Cyp1b10*) and AHR (*Cyp1a2*) but PXR (*Cyp3a11*) was activated only in males, implicating how sex+HFD interactions impact these receptors as potential drivers of toxicant-induced hepatic metabolic disruption and possibly injury. **Conclusion:** While females were more susceptible to steatosis, males were prone to oxidative stress, and glucose metabolism was impacted in both sexes with exposure. Toxicant-sex-HFD interactions also regulated receptor activation outcomes. Further assessment of off-liver targets including the gut microbiome and adipose tissue will help understand how these toxicant mixtures impact multi-organ toxicity in driving fatty liver disease.

1721-A | PRELIMBIC 5-HT6 RECEPTORS REGULATE ANXIETY IN CCL4 MODEL OF LIVER INJURY: EVIDENCE FROM BEHAVIOR, ELECTROPHYSIOLOGY, AND NEUROCHEMISTRY

Yuming Zhang and Jiao Guo, Department of Anesthesiology, Shaanxi Provincial People's Hospital

Background: Acute or chronic liver injury is associated with hyperammonemia which triggers several emotional disorders such as anxiety. Carbon tetrachloride (CCl4), is a potent hepatotoxic agent and extensively utilized to induce hepatotoxicity-related anxiety in rodent models. Unfortunately, an effective treatment for anxiety-like behaviors induced by CCl4 is yet to be found. Recent

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

studies indicate that the prelimbic cortex (PrL) is involved in the pathophysiology of anxiety. PrL is innervated by 5-HT fibers, and the 5-HT system is regarded as a crucial role in anxiety. Our previous results demonstrated the PrL 5-HT_6 receptors regulated anxiety-like behaviors in Parkinson's rats. Thus, we speculate that the PrL 5-HT_6 receptors also may function in regulating anxiety-like behaviors induced by CCl4. **Methods:** CCl4 dissolved in olive oil was administered in the model rats by intraperitoneal (i.p) route before induction of anxiety. The sham-operated group received an equal volume of vehicle solution in the same schedule. Behavioral, electrophysiological, neurochemical and morphological methods were utilized to identify the role of PrL 5-HT_6 receptors in CCl4-induced anxiety. **Results:** Intra-PrL injection of 5-HT_6 receptor agonist WAY208466 induced anxiogenic responses in sham-operated rats, and injection of antagonist SB258585 showed anxiolytic effects. Interestingly, WAY208466 increased the expression of anxiolytic behaviors in model rats, and SB258585 produced anxiogenic responses. Neurochemical results showed that intra-PrL injection of WAY208466 and SB258585 decreased or increased DA, 5-HT and NA levels in the mPFC, amygdala, habenula and vHip in both rats, respectively. WAY208466 increased the firing rate of PrL GABA-ergic interneurons in both rats, while SB258585 decreased the firing rate of the interneurons. Compared to sham-operated rats, the duration of WAY208466 and SB258585 action on the firing rate of GABA-ergic interneurons was markedly prolonged in model rats. The CCl4 did not change the co-localization of PrL 5-HT_6 receptors and GABA-ergic interneurons. These findings indicate that PrL 5-HT_6 receptors are involved in the regulation of anxiety-like behaviors, which ascribe to changes in DA, 5-HT and NA levels in the limbic and limbic-related brain regions. Additionally, the findings suggest that the CCl4 leads to a hypersensitization of PrL 5-HT_6 receptors on GABA-ergic interneurons. **Conclusion:** Our study is the first to identify the role of PrL 5-HT_6 receptors in CCl4-induced anxiety. Present findings pave the way for more advanced and specific theories on the treatment of neuropsychiatric disorders in liver injury.

1722-A | RECHALLENGE EPISODES IN DRUG-INDUCED LIVER INJURY: AN ANALYSIS OF CASES IN TWO PROSPECTIVES REGISTRIES ACCORDING TO EXISTING DEFINITIONS

José María Pinazo Bandera[1], Ismael Alvarez-Alvarez[1], Hao Niu[2], Inmaculada Medina-Cáliz[2], Enrique Del Campo-Herrera[2], Aida Ortega-Alonso[2], Mercedes Robles-Díaz[2], M I Lucena[3], Nelia Hernandez[4], Fernando Oscar Bessone[5], Miren Garcia Cortes[2] and Raul J. Andrade[1], (1)University Hospital Virgen De La Victoria, Ibima Plataforma Bionand, Universidad De Málaga, Málaga, Spain. Centro De Investigación Biomédico En Red Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain, (2)University Hospital Virgen De La Victoria, Ibima Plataforma Bionand, Universidad De Málaga, Málaga, Spain. Centro De Investigación Biomédico En Red Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain., (3)Universidad De Málaga, Málaga, Spain, (4)Clínicas Hospital, Montevideo, Uruguay, (5) Centenario Hospital, Rosario National University, Rosario, Argentina

Background: Positive drug-induced liver injury (DILI) rechallenge has been traditionally related to higher severity. We analyse the clinical presentation, outcome and main drugs related with positive rechallenge in two prospective DILI registries. **Methods**: Cases from the Spanish and Latin American DILI registries were included. Demographics, clinical and biochemical parameters of cases with positive rechallenge were compared with those cases with single episode of DILI. **Results**: Of 1,410 patients with idiosyncratic DILI, 64 cases had positive rechallenge (4.5%). Patients with positive rechallenge had shorter duration of therapy and latency than cases with a first episode of DILI ($p < 0.001$). In addition, aspartate transaminase (AST) levels were significantly increased in patients with positive rechallenge when compared to those with a single episode (median 10 vs. 6.4 times the upper limit of normal, respectively; $p = 0.025$). Patients who rechallenged showed a longer time until normalization of liver parameters compared to cases with a first episode (median 138 vs. 93 d, respectively; $p = 0.022$) (Table). There were not significant differences in terms of fatal outcomes. The main drug implicated in positive rechallenge was amoxicillin-clavulanate ($n = 11$, 17.2%), followed by antituberculous drugs ($n = 4$, 6.2%), and by diclofenac and Herbalife® products ($n = 3$, 4.7%). Indeed, antiinfectives ($n = 20$, 31.2%), and herbal products and dietary supplements and NSAIDs (both $n = 7$, 11%) were the most common pharmacological groups. Most reexposure events were unintentional (72%) with lack of previous hepatotoxicity diagnosis being the main reason (70%), while self-medication (disregarding medical recommendations) constituted 9% of cases. **Conclusion**: Episodes of positive rechallenge were characterized by increased AST levels and shorter duration of therapy and latency. Furthermore, these cases had a prolonged recovery. Clinicians should be aware about the possibility of facing a DILI episode in patients with hypertransaminasemia with unknown etiology.

1723-A | REVEALING THE ROLE OF PHOSPHATIDYLETHANOLAMINE METHYLTRANSFERASE IN ALD AND NAFLD PATHOGENESIS USING MULTI-OMICS ANALYSES

Isin T Sakallioglu[1], Sathish Kumar Perumal[2,3], Madan Kumar Arumugam[2,3], Murali Ganesan[2,3], Natalia Osna[2,3], Karuna Rasineni[2,3], Robert Powers[1] and Kusum K. Kharbanda[2,3], (1)University of Nebraska-Lincoln, (2)University of Nebraska Medical Center, (3) Veterans Affairs Nebraska-Western Iowa Health Care System

Background: Our previous studies indicated that impaired phosphatidylcholine (PC) generation via the phosphatidylethanolamine methyltransferase (PEMT)-mediated methylation of phosphatidylethanolamine (PE) is a common feature in the development of alcohol- and non-alcohol-associated liver diseases (ALD and NAFLD, respectively). Indeed, spontaneous development of hepatic steatosis is observed in both male and female 3-month-old PEMT knockout (KO) mice, which progresses to inflammation and pericellular fibrosis by 6 months of age. No such pathology is seen in age-and gender-matched wildtype (WT) mice. **Methods:** To further gain mechanistic insights into the importance of PEMT, we conducted a multi-omics analyses on livers of 6-month-old PEMT KOs of both genders and their age-matched WTs using Waters Xevo G2-XS Quadrupole Time of Flight with optimized separation methods. **Results:** The metabolomic and lipidomic data yielded 8074 and 7983 spectral features respectively, proteomics data yielded 2634 proteins. The resulting unsupervised principal component analysis (PCA) model yielded a clear separation between the groups. The supervised orthogonal projection to latent structures discriminant analysis (OPLS-DA) model validated using a permutation test was determined to be of high quality given R^2 (0.92), Q^2 (0.89), and $p < 0.02$. These results indicated that the PEMT KOs exhibit a significant differences in the ~*Ome* compared with their respective WTs. The tight clustering of the quality control samples in the center of the scores plot testified to the high quality of ~*Ome* data set. In total, 60 metabolites, 40 lipids and 600 proteins were significantly different amongst the groups. Metabolomics enrichment analysis identified amino acids, peptides, purines, pyridines and sulfonic acid pathways as being the most altered upon PEMT loss. Lipidomics enrichment analysis identified increases in diacylglycerides (2.2-fold, $p < 0.001$), triacylglycerides (753-fold, $p < 0.001$) and PE (7.2-fold, $p < 0.001$) in livers of KO irrespective of gender compared with their respective WT counterparts. Further, while an overall ~3.5-fold increase in PC was evident, we observed a significant decrease in those species with a shorter chain length in the KOs. Proteomics pathways enrichment analysis identified alterations in glycolysis, gluconeogenesis, pyruvate and tryptophan metabolism in PEMT KOs. **Conclusion:** Taken together, our study further establishes the important role of PEMT in maintaining liver function homeostasis and in preventing development of liver disease even in the absence of second hits (alcohol/high-caloric intake). Since genetic loss-of-function PEMT polymorphism is common, such individual's should be cautioned about the potential for spontaneous development of liver disease and to abstain from alcohol and/or high-caloric intake.

Beier[1], (1)University of Pittsburgh, (2)University of Louisville, Louisville, KY, (3)Pittsburgh Liver Research Center

Background: Vinyl chloride (VC), a common environmental pollutant, directly causes liver injury at high exposure levels, but lower concentrations (i.e., < OSHA limits), which do not overtly damage the liver, can also enhance injury due to overnutrition. Previous work from this lab showed that VC induces endoplasmic reticulum (ER) stress, and impairs mitochondrial (mt) function. ER- and mt-stress are often linked events; for example, the unfolded protein response (UPR) releases factors that subsequently protect mitochondria from mt-stress and dysfunction. Here, a more detailed analysis of the underlying molecular underpinnings was performed and yielded insight the potential impact of VC exposure crosstalk between these ER- and mt-stress. **Methods:** C57Bl/6J mice were exposed to VC (sub-OSHA standard: < 1 ppm), or air for 6 hrs/d, 5 d/wk for up to 12 wks. Mice were fed Western diet (WD) to induce experimental NAFLD, or control diets (CD). Plasma and liver samples were collected for determination of injury and mitochondria were isolated for respirometry, analysis of mt-(dys)function and mt-proteome via LC-MS/MS. **Results:** As previously observed, VC exposure enhanced experimental NAFLD caused by WD feeding. The major effect appeared to impact hepatic metabolic function versus other mechanisms (e.g., inflammation). Under these conditions VC exposure exacerbated ER stress, coupled with mitochondrial oxidative damage and dysfunction. Respirometry indicated that mitochondria from VC-exposed mice had impaired electron transport chain (ETC) function. Despite an observed decrease in mt respiration, proteomic analysis indicated that VC exposure actually increased expression of several proteins associated with Gene Ontology (GO) terms for ETC (e.g., GO:0005746 and GO:0022900). In contrast, the mitochondrial level of key UPR-mediated proteins that protect against mitochondrial damage was decreased. For example, VC strongly decreased mitochondrial levels of GRP78 (also known as BiP), which has been shown to protect mitochondrial function during ER stress. **Conclusion:** Taken together, these data suggest that VC causes mitochondrial dysfunction via mechanisms that are mediated, at least in part, by failed crosstalk between the ER and mitochondrial during nutrition overload. These results further shed light on the observation that mitochondria appear to be the key target of injury during low-level VC exposure.

1725-A | THE NA+/K+-ATPASE AND THE NA+-K+-2CI- CO-TRANSPORTER AS POTENTIAL METABOLIC REGULATORS IN RESPONSE TO HYPERAMMONEMIA IN ASTROCYTES

Carlos Pérez-Monter, Lilia Noriega and Alma Estanes-Hernández, Incmnsz

Background: Hepatic encephalopathy (HE) is characterized by hyperammonemia derived from impairment of ammonia (NH_4^+) clearance capacity of the liver. Within central nervous system (CNS), astrocytes produce glutamine (Gln) by conjugating NH_4^+ and glutamate (Glu). Gln is exported to glutamatergic neurons in order to produce glutamate. During hyperammonemia, increased levels of Gln can enter mitochondria, where its converted into Glu by glutaminase-1, and then to alpha-ketoglutarate, fueling the Krebs cycle and releasing NH_4^+ in the process. Mitochondrial excess of NH_4^+ alters the internal pH and disable several protein complexes, including those related with electron transport; thus, altering the metabolic homeostasis. In addition, the $NH4^+$ ion strongly activates Na^+/K^+-ATPase and the Na^+-K^+-2Cl co-transporter in the cell membrane. Activation of both proteins consumes large quantities of intracellular ATP, leading the astrocyte to a condition of energy starving. Our main aim here was to determine whether astrocyte Na^+/K^+-ATPase and Na^+-K^+-2Cl co-transporter pharmacological inhibition, improves the metabolic status under hiperammonemia in astrocytes. Specifically, we focus on oxygen consumption rate (OCR) to evaluate mitochondrial function and extracellular acidification rate (ECAR) as an indirect measure of glycolytic activity. **Methods:** The astrocytoma C8-S cell-line was incubated in standard conditions (DMEM with 10% FBS and 1% penicillin/streptomycin/37°C/5% CO_2/95% O_2). Cells were seeded at $4x10^4$ cells/well in a 96 well plate. Twenty hours later, cells were exposed to Na^+-K^+-2Cl (50mM) or Na^+/K^+-ATPase (10mM), inhibitors (Bumetanide and Digoxyn, respectively) for 3hrs. Next, cells were exposed to NH_4Cl 10 mM for 24hrs. We then performed a XF Mito Stress test on a Seahorse Analyzer (Agilent). Na^+/K^+-ATPase and Na^+-K^+-2Cl proteins, were also evaluated by immunostaining after exposure to inhibitors. **Results:** NH_4Cl did not affect mitochondrial function, but increased basal glycolysis (12.7 ± 0.32 vs 15.63 ± 0.37, $p < 0.001$) and glycolytic capacity (12.73 ± 0.39 *vs* 15.45 ± 0.41 $p < 0.01$) of C8-S astrocytes, and this response is Gln-dependent. However, Bumetanide and Digoxyn treatment did not affect the glycolytic capacity nor basal glycolysis under hyperammonemia (ECAR of 15.45 ± 0.40 *vs* 15.14 ± 0.46 for Bumetanide and 15.45 ± 0.40 *vs* 14.95 ± 0.44 for Digoxyn). In addition,

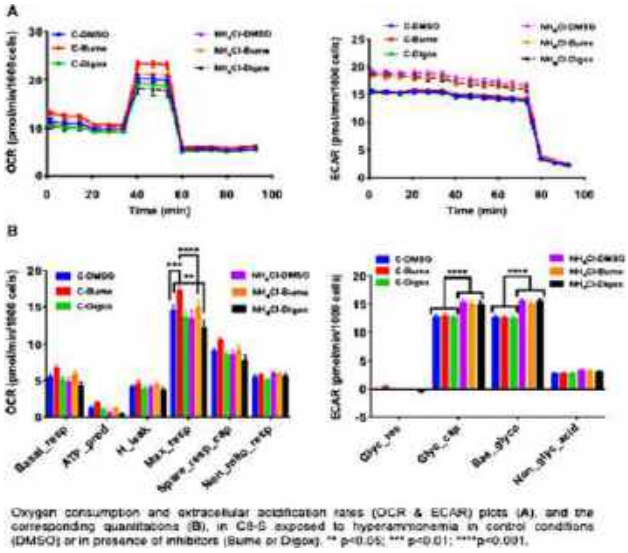
Bumetanide significantly increased maximal respiration (OCR of 14.62 ± 0.68 vs 17.33 ± 0.58, $p < 0.01$) only in basal conditions, suggesting an improvement of mitochondrial function. Corrected total cell fluorescence (CTCF) signal indicates that Bumetanide diminished the Na^+-K^+-2Cl co-transporter expression, while Digoxyn has the opposite effect on Na^+/K^+-ATPase protein expression. **Conclusion:** Altogether, our data indicates that maximal respiration is regulated by both inhibitors, Bumetanide and Digoxyn, under hyperammonemia



Oxygen consumption and extracellular acidification rates (OCR & ECAR) plots (A), and the corresponding quantitations (B), in C8-S exposed to hyperammonemia in control conditions (DMSO) or in presence of inhibitors (Bume or Digox). ** p<0.05; *** p<0.01; ****p<0.001.

1726-A | THE STRUCTURAL BASIS OF IMMUNOLOGICALLY-MEDIATED GREEN TEA [GT] -INDUCED LIVER INJURY.

David A. Ostrov[1], James Line[2], Danmeng Li[1], Serat-E Ali[2], Sophie Grice[2], Dean J. Naisbitt[2] and Herbert L. Bonkovsky[3], (1)University of Florida, (2)University of Liverpool, (3)Atrium Health Wake Forest Baptist

Background: Green tea [GT] is used as a beverage and extracts of GT are used as popular dietary supplements. Epigallocatechin-3-O-gallate (EGCG) is an abundant polyphenol in GT and has been implicated in GT-induced liver injury. Recent studies have shown striking associations between GT-induced liver injury and presence and expression of the *HLA-B*35:01*[1]. This association suggests a model in which immunogenic structures are recognized by *HLA-B*35:01*-restricted T cells. The **aims** of this study were to 1) understand structural interactions between EGCG and *HLA-B*35:01*, and 2) determine if immunogenic structures are generated as a result of such putative interactions by measuring T cell responsiveness to EGCG in individual's that express *HLA-B*35:01*. **Methods:** We refolded *HLA-B*35:01* and β_2-microglobulin *in vitro* in the presence of high and low affinity peptides, in the presence or absence of EGCG. We characterized refolded complexes by gel filtration chromatography. The immunogenicity of EGCG was measured with peripheral blood mononuclear cells from *HLA-B*35:01* positive and negative healthy donors ($n = 3$). **Results:** Peptide binding was required for generation of complexes of *HLA* in the presence of EGCG. A peptide with low affinity for *HLA-B*35:01* (LRAREEAY, estimated affinity for *HLA-B*35:01* $K_d = 5.3$ μM) formed complexes with *HLA-B*35:01* and β_2-microglobulin in the presence of EGCG, but not in the absence of EGCG. EGCG stabilized the interaction between a low affinity peptide and *HLA-B*35:01*. EGCG stimulated T cells from *HLA-B*35:01* positive and negative healthy donors. **Conclusion:** These data suggest a model in which EGCG forms direct interactions with *HLA-B*35:01* to produce immunogenic structures on hepatocytes. Since thermostability profiles of *HLA-B*35:01* differ drastically depending on bound ligands,[2] these data suggest that EGCG has the potential to form stabilizing intermolecular contacts with loosely bound peptide and *HLA-B*35:01*. Because T cell responses to EGCG were also observed in individual's lacking HLA-B*35:01, our results are consistent with recent data that showed that GT-induced liver damage can occur in individual's lacking *HLA-B*35:01*,[1] suggesting that EGCG has the potential to bind additional *HLA* molecules. In this model, pathogenic T cells cause liver damage by specific recognition of *HLA*-bound EGCG. We speculate that such a model likely also plays a role in other immune-mediated responses to many compounds, including drugs and other components of herbal and dietary supplements.

1727-A | A MULTICENTER STUDY OF THE DIAGNOSTIC AND PROGNOSTIC UTILITY OF AUTOANTIBODIES IN HIGH-GRADE IMMUNE CHECKPOINT INHIBITOR HEPATITIS

Michael Li[1], Alexander Vogel[2], Jordan S Sack[2], Lawrence Fong[1], Jennifer C. Lai[3], Shilpa Grover[2] and Stephen D. Zucker[2], (1)University of California, San Francisco, (2)The Brigham and Women's Hospital, (3) University of California-San Francisco

Background: Similarities exist between immune checkpoint inhibitor (ICI) hepatitis and autoimmune hepatitis (AIH), though the role of well-described serological markers of AIH like antinuclear antibodies (ANA), smooth muscle antibodies (SMA), total IgG level, and liver-kidney microsome type 1 antibodies (anti-LKM1) in the evaluation of ICI hepatitis is unclear. **Methods:** We conducted a multicenter retrospective cohort study of patients with grade ≥ 3 (ALT > 200 U/L) ICI hepatitis. ANA/SMA/anti-LKM1 positivity was defined as ≥ 1:40, and ANA/SMA ≥ 1:80 were considered strongly positive. The primary outcome was time to ALT normalization (defined as ≤ 40 U/L). The secondary outcome was time to all-cause death; this outcome was assessed in the subgroup of patients with melanoma to avoid confounding of long-term survival due to different cancer types. **Results:** Of 294 study patients who developed high-grade ICI hepatitis, 180 (61%) received testing for at least one autoantibody; 49% had melanoma, and anti-PD-1 monotherapy was the most common ICI regimen (45%). The sensitivities of ANA and SMA were 45% (75/165) and 21% (28/135), respectively. The median IgG level among 105 tested patients was 814 [IQR 669, 1045] mg/dL, and only two patients had an elevated IgG > 1600 mg/dL. Only one patient out of 77 tested positive for anti-LKM1. After multivariable adjustment using Cox regression, ANA-positivity was associated with faster ALT normalization (HR 1.32, 95% CI 1.00-1.73, p = 0.047) and SMA-positivity was associated with slower ALT normalization (HR 0.63, 95% CI 0.46-0.85, p = 0.003) (Figure A). When assessing survival, ANA-positivity had no effect on long-term all-cause mortality. However, SMA-positive patients experienced reduced all-cause mortality compared to SMA-negative patients (median not reached vs 2.9 years, log-rank p = 0.036; Figure B). After adjusting for age and combination CTLA4/PD-1 therapy, SMA-positivity remained significantly associated with reduced risk of death (HR 0.32, 95% CI 0.11-0.93, p = 0.037). **Conclusion:** ANA and SMA have moderate and low sensitivity for high-grade ICI hepatitis, though the prognostic implications of ANA- or SMA-positivity suggest that testing for these autoantibodies may be useful. IgG and anti-LKM1 do not appear to have any diagnostic utility in ICI hepatitis. SMA-positivity was associated with improved long-term cancer survival, though further studies are needed to investigate this effect.

(ISMMS), Huiman Barnhart, Duke University, Durham, NC, Alfred Sidney Barritt IV, University of North Carolina, Herbert L. Bonkovsky, Atrium Health Wake Forest Baptist, Robert J. Fontana, University of Michigan Hospitals and Health Centers, Paul H. Hayashi, FDA, Christopher Koh, National Institute of Diabetes and Digestive and Kidney Diseases, Nih, Jose Serrano, National Institute of Diabetes, Bethesda, MD, United States, Averell H. Sherker, NIH/NIDDK and Raj Vuppalanchi, Indiana University School of Medicine

Background: The Drug Induced Liver Injury Network (DILIN) enrolls patients with injury from drugs, and herbal and dietary supplements (HDS). Aim: To define features of HDS induced liver injury (HILI) enrolled in DILIN **Methods:** Among a total of 1780 high-confidence cases (definite, highly likely, probable) enrolled between 2004 and 2021, 325 (18%) were due to HDS. HILI cases were grouped as due to bodybuilding (BB) or non-bodybuilding (non-BB) agents based on purpose for use. **Results:** Since 2004, the majority of HILI was due to non-BB agents (239: 73%) which were most frequently used for weight loss (23%). Since 2010, the number and proportion of BB-HILI cases fell ($p < 0.001$ for trend) while those of non-BB-HILI rose ($p = 0.03$ for trend) (figure). BB HILI cases were younger than non-BB HILI and drug injury cases; median ages 32 vs 46, and 54 years ($p < 0.001$). BB HILI occurred almost exclusively in men (97%), compared with non-BB HILI (60%) and drug injury (61%). Most HILI patients were white (75%). Non-BB HILI had a higher rate of Latinos (21%), compared to BB-HILI (12%) and drug injury (8%) ($p < 0.001$). BB and Non-BB HILI had longer median latencies (71 and 68 d) than drugs (41 d, $p < 0.001$), and BB HILI was more likely to present with jaundice ($p < 0.001$). Peak median ALT levels were highest in non-BB HILI (1252 U/L), compared with BB HILI (560 U/L) and drugs (964 U/L) ($p < 0.001$) while peak median bilirubin levels were highest in BB HILI (10 mg/dL vs 5.0 and 6.5 mg/dL, $p < 0.001$). Median time to return of peak bilirubin and ALT levels to normal was longest for BB HILI (median 70 and 106 d) vs non-BB HDS (35 and 71 d) and drugs (29 and 62 d; $p < 0.01$). None of the 86 BB-HILI cases died or required liver transplant (LT), compared to 27 (11%) of non-BB-HILI cases (10, 4% deaths; 17, 7% LTs) and 196 (13%) of drug cases (152, 10% deaths; 44, 3% LTs) $p = 0.001$. Persistent liver test abnormalities at 6 months were more frequent among drug compared to non-BB and BB cases (18% vs 12% and 9%: $p < 0.05$). **Conclusion:** HILI accounts for an increasing proportion of DILIN cases; BB HILI becoming less and non-BB HILI more frequent, the latter particularly among Latinos. Changes in HILI may reflect changes in US population characteristics and the increasing use of HDS for conditions such as obesity not responsive to or in lieu of other treatments.

for their efficacy and safety profile. Acute, idiosyncratic liver injury from CS occurs, but is rare and typically mild to moderate in severity and self-limited in course. **Methods:** We sought to characterize the clinical, biochemical features and HLA associations of liver injury attributed CS in the DILIN prospective study. **Results:** Between 2004 and Nov 2, 2022, a total of 2347 cases of drug-induced liver injury (DILI) were enrolled in the prospective DILIN study and had 6 months of follow up and formal adjudication. 1854 cases were scored as being probable, highly likely or definite DILI, 58 of which (3%) were attributed to different CS, including cefazolin (n = 40), cephalexin (n = 4), ceftriaxone (n = 3), cefdinir (n = 3), cefuroxime (n = 3) and 5 others with one each. Characteristic clinical features of CS DILI were a self-limited, mixed or cholestatic hepatitis arising 1 to 4 weeks after starting and often several weeks after stopping the antibiotic. Most striking was the phenotype of cefazolin and other parenteral cephalosporins given as a single dose with onset of jaundice, fatigue and itching 1 to 3 weeks later. HLA sequencing performed on 57 CS cases revealed a significant association with HLA-A*02:01, an allele also found to be linked to amoxicillin and amoxicillin/clavulanate [A/C] DILI (PMID: 36496055). The association was strongest with cefazolin with an allele frequency [AF] 51% and carriage frequency [CF] 78% compared to population-based AF of 23% and CF of 39% (Figure). Other A/C related HLA and genetic variants (HLA-B*15:18, DRB1*15:01, ERAP2 [rs1363907] and PTPN22 [rs2476601]) were not increased in frequency with CS liver injury. The HLA-A*02:01 association found with cefazolin was not found in the 17 other CS cases [AF 0.31]. The clinical features of cefazolin cases with and without HLA-A*02:01 were similar, although the cases with the allele tended to be more severe (81% vs. 44% with either moderate-hospitalized or severe by DILIN. **Conclusion:** The cephalosporins are rare causes of liver injury and have a self-limited, mixed/cholestatic hepatitis that arises after a short course of therapy. Most cases are due to cefazolin which has an HLA association similar but not identical to amoxicillin and A/C.

1730-A | DEVELOPMENT OF ACUTE LIVER FAILURE AND MORTALITY IN PATIENTS WITH DRUG-INDUCED LIVER INJURY: A RISK FACTORS ANALYSIS.

Fatima Higuera De La Tijera[1], José Antonio Velarde-Ruiz Velasco[2], José Miguel Córdoba-Reyes[1], Lydia Aurora Mercado[2], Juan Manuel Aldana-Ledesma[2], Alfredo Servin-Caamaño[1] and José Luis Pérez-Hernández[3], (1)Hospital General De México "Eduardo Liceaga", (2)Hospital Civil De Guadalajara "Fray Antonio Alcálde", (3)Hospital General De Mexico "Eduardo Liceaga"

Background: Drug-induced liver injury (DILI) can cause acute liver failure (ALF) or death. DILI is an exclusion diagnosis. No specific therapy is available. Aim: To describe the main characteristics of patients with DILI, and to identify risk factors to develop ALF and death. **Methods:** An observational, retrospective cohort study including patients with DILI diagnosis, identified between January 2006 to January 2023 in two medical centers. Univariate and multivariate regression models were performed to identify risk factors associated with ALF and death. **Results:** 110 patients were included, 84(76.4%) women, 42.6 ± 14.1 year-old; according to *R-value* 43(39.1%) had cholestasis, 38(34.5%) hepatocellular injury, and 29 (26.4%) mixed; 42(38.2%) were obese; 35 (31.8%) developed ALF; 11 (10%) died. The most frequent DILI causal agents were: antibiotics 35.6%, herbal and dietary supplements (HDS) 29.1%, immunosuppressive agents 7.2%, statins 6.4%, oral antimycotics 5.5%, AINEs 4.5%, carbamazepine 3.6%, anti-tuberculous drugs 2.7%, contraceptives 1.8%, oral dermatological agents 1.8%, antineoplastic 0.9%, valproate 0.9%. Some patients received empirical therapy to treat DILI: 11 (10%) received ursodeoxycholic acid (UDCA), 26 (23.6%) S-adenosylmethionine (SAMe), 25 (22.7%) vitamin E, and 30 (27.3%) metadoxine (MTD). In the univariate analysis, the following were risk factors for ALF: hepatocellular injury (OR 16.7, 95%CI: 4.9-56.7, $p < 0.0001$), HDS (OR 8.7, 95%CI: 3.4-22.1, $p < 0.0001$), obesity (OR 3.2, 95%CI: 1.4-7.4, $p = 0.006$). Other factors like gender, and treatment with MTD, vitamin E, UDCA, or SAMe were not significant. In the adjusted multivariate analysis, just hepatocellular injury was a risk factor to develop ALF (see Table). In the univariate analysis, the following were risk factors for death: developing of ALF (OR 70.9, 95CI%: 4.0-1247.4, $p < 0.0001$), hepatocellular injury (OR 60.6, 95%CI: 3.5-1064.4, $p < 0.0001$), HDS (OR 35.0, 95%CI: 4.2-288.5, $p = 0.001$), obesity (OR 20.9, 95%CI: 2.6-170.7, $p < 0.004$). Gender, vitamin E, MTD, SAMe, and UDCA were not significant. In the adjusted multivariate analysis, the development of ALF was the most relevant risk factor associated with death, also there was a tendency to significance with the presence of obesity (see Table). **Conclusion:** Antibiotics and HDS were the most frequent agents related to DILI. The hepatocellular injury was related to the development of ALF, and ALF is related to death. No empirical therapy was useful to prevent ALF or death.

Adjusted multivariate model: Risk factors related to the development of ALF in patients with DILI

Variable	*p*	OR	95% CI	
			Inferior	Superior
Obesity	0.09	2.4	0.9	6.7
Herbal and dietary supplements	0.50	1.7	0.4	7.3
R-value (Cholestasis)	0.02	-	-	-
Mixed type	0.07	3.5	0.9	14.1
Hepatocellular	0.01	10.4	1.9	56.0
Constant	< 0.001	0.07		

Adjusted multivariate model: Risk factors related to death in patients with DILI

Variable	*p*	OR	95% CI	
			Inferior	Superior
Obesity	0.05	11.7	1.0	143.5
ALF	0.002	18.7	17.1	31.8
Herbal and dietary supplements	1.0	1.0	0.5	20.2
R-value	1.0	-	-	-
Constant	1.0	0.000	-	-

ALF, acute liver failure; CI, confidence interval; DILI, drug induced liver injury; OR, odds ratio.

1731-A | EFFECT OF VARIATION IN ALANINE AMINOTRANSFERASE (ALT) AND TOTAL BILIRUBIN (TB) UPPER LIMITS OF NORMAL (ULN) ON THE EVALUATION OF HEPATOCELLULAR DRUG-INDUCED LIVER INJURY (DILI) IN CLINICAL TRIALS

Chih-Hao Huang, Ling Lan, Paul H. Hayashi and Y. Veronica Pei, FDA

Background: Increased ALT and total bilirubin based on multiples of ULN identify potential DILI of concern in clinical trials (e.g., Hy's Law cases). However, ALT ULNs vary across laboratories and have increased over time. Variability in ALT and TB ULNs may hinder consistent identification of DILI cases. Using a fixed, acceptable, and lower ALT ULN may impact potential DILI case identification. **Methods:** We identified 121 clinical trials submitted to the FDA in 2022 that enrolled subjects > 18 years old with baseline ALT < 1.5 times trial reported ULN. We used descriptive statistics to summarize the distribution of trial reported ULNs for ALT and TB across all 121 trials. In addition to using trial reported ULNs of ALT and TB, we examined the number of subjects in each eDISH (Hepatocellular DILI screening) plot quadrants using a published reference for ALT (Kwo PY et al. Am J Gastro 2017) and fixed TB at 33 U/L and 1.25 mg/dL, respectively. **Results:** Maximum post-baseline and ULN ALT and TB values from 63,016 subjects across the 121 trials were analyzed. We excluded clinically unfeasible values for ALT (> 50,000 U/L) and TB (> 100 mg/dL). The maximum number of unique ALT and TB ULNs reported in a single trial were 54 and 41, respectively. Median value of trial reported ALT ULNs was 43 U/L (range = 0.6 to 306 U/L) with 85.9% of the reported ULN values > 33 U/L. Median value of trial reported TB ULNs was 1.23 mg/dL (range = 0.000076 to 16.6 mg/dL) with 23.9% of trial reported ULN values > 1.25 mg/dL. Using ALT ULN of 33 U/L and TB ULN of 1.25 mg/dL resulted in identification of 23 additional cases in Hy's Law quadrant (33.3% increase) and 828 additional cases (86.3% increase) in Temple's Corollary quadrant compared to using trial provided ULNs. (Figure) **Conclusion:** Current reported ALT and TB ULNs from clinical trials vary widely. Most trial reported ALT values were also coupled with ALT ULNs higher than 33 U/L, which led to a lower frequency in subject identification on eDISH plots of either Hy's Law or Temple's Corollary quadrants compared to using a fixed ALT ULN of 33 U/L and TB ULN of 1.25 mg/dL. Variability of ALT ULN can affect eDISH's function as a DILI screening tool and DILI assessment in clinical rials may benefit from standardized, uniform TB ULN and lower fixed ALT ULN. Assessment for potential DILI cases based on trial reported ULNs may result in missed cases of DILI. Gender-based ALT and TB ULN values should also be considered for DILI analysis.

1732-A | ESTIMATING THE INCIDENCE OF IDIOSYNCRATIC DRUG-INDUCED LIVER INJURY

Jay H. Hoofnagle, Niddk, Rockville, MD, Einar Stefan Bjornsson, Landspitali University Hospital, Reykjavik, Iceland, Vincent Chen, University of Michigan Medical Center, Huiman Barnhart, Duke University, Durham, NC and Don C. Rockey, Medical University of South Carolina

Background: Idiosyncratic drug-induced liver injury (DILI) is rare, occurring at rates of 1:100 to 1:1,000,000 exposed-persons. However, the incidence of liver injury from individual agents is rarely known. Using the relative rates of the major causes of DILI in the DILIN Prospective Study (NCT NCT00345930) and the known rate for amoxicillin/clavulanate (43/100,000) from a population-based study from Iceland, we sought to estimate the incidence of the major causes of idiosyncratic DILI. **Methods**: DILIN has enrolled cases of suspected DILI in the United States (US) since 2004. Cases were carefully assessed, followed for at least 6 months, and then adjudicated for causality. The estimated incidence of DILI (*EID*) was calculated for all prescription medications with 5 or more cases adjudicated as definite, highly likely or probable. The average yearly usage of drugs was extracted from https://clincalc.com/. *EID* was calculated based upon relative number of cases in DILIN due to the agent (Drug X) to those of amoxicillin/clavulanate and adjusted for the

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

yearly usage relative to A/C using the following formula: *EID* (Drug X) = *EID* (A/C) x [No cases of X ÷ No cases A/C] x [yearly usage of *A/C* ÷ yearly usage of *X*]. **Results:** As of 2021, 55 drugs were implicated in at least 5 cases of DILI in DILIN. Data on prescription usage was available for 33 of the drugs. The *EID*, as expressed as number of patients given a prescription for each case, ranged from 1:1,000 to 1:250,000 (Table). Drugs with the highest *EID* (1:1000-1:5000) included amoxicillin/clavulanate, trimethoprim/sulfamethoxazole (TMP/SMZ), nitrofurantoin, phenytoin, and carbamazepine. Drugs with moderately high *EID* (1:5000-1:10,000) included levofloxacin, moxifloxacin, lamotrigine, valproate, and diclofenac. Classic anticonvulsants such as pheytoin and carbamazepine had a relatively high *EID* (< 1:10,000). Importantly, among drugs with the lowest EID are included the statins (all 4 statins had an *EID* > 1:50,000). Some antibiotics had a high *EID* (sulfonamides, fluoroquinolones), while others had a low EID (amoxicillin, cephalexin, doxycycline). Because of lack of data on usage, *EID* could not be calculated for drugs not among the top 300 prescribed in the US or for those given parenterally. **Conclusion:** The calculated *EID* for DILI of commonly prescribed drugs clearly demonstrates substantial differences for DILI incidences with different drugs. Although these are rough estimates that rest upon assumptions about the relative rates and ability to detect DILI between different drugs (and between the US and Iceland), the *EID* provides informative rates for these rare events and likely explains why the risk of DILI may be missed in registration trials of new drugs which may enroll fewer than 1,000-3,000 patients.

Table: Estimated Risk of Liver Injury

No	Agent	No Cases in DILIN	Average No Pts Exposed/Year	Cases/ 100,000 Pts	Estimated Incidence (1:)
1	Amox/Clavulanate	189	4,558,138	43.0	2,326
2	TMP/SMZ	77	3,404,743	23.5	4,264
3	Nitrofurantoin	68	2,390,226	29.5	3,390

1733-A | IMMUNE CHECKPOINT INHIBITOR THERAPY FOR HCC IS ASSOCIATED WITH INCREASED INCIDENCE OF HEPATOTOXICITY, COMPARED TO SORAFENIB

Elsie Ennin[1], Niharika Mallepally[2], Layla Shojaie[1], Myra Ali[3], Sean Dewberry[3], Melissa Trieu[3], Kali Zhou[2], Jeffrey A Kahn[2], Jennifer L. Dodge[4] and Lily Dara[2], (1) Department of Medicine, Keck School of Medicine, University of Southern California, (2)Division of Gastrointestinal and Liver Diseases, Keck School of Medicine, University of Southern California, (3)Keck School of Medicine, University of Southern California, (4)USC Research Center for Liver Disease, Keck School of Medicine, University of Southern California

Background: Immune checkpoint inhibitors (ICIs) are approved systemic therapy for many malignancies including HCC. The impact of chronic liver disease and HCC on the incidence of immune-mediated liver injury from checkpoint inhibitors (ILICI) is unknown. Sorafenib drug induced liver injury (DILI) occurs in 1-3% of HCC patients. No direct comparison has been made of hepatotoxicity rates between ICI and sorafenib in HCC. **Methods:** We retrospectively identified patients with HCC who received 1 of 5 ICI regimens indicated for HCC, patients with various non-HCC cancers who received the same ICI drugs, and HCC patients who received sorafenib between 2010-2020. The primary outcome was grade **e** 3 liver injury (AST/ALT > 5X upper limit of normal) with ICI (ILICI) or sorafenib (DILI) with incidence (Clopper-Pearson 95% confidence intervals (CI)) compared using the Fisher's exact test. Logistic regression estimated odds ratios (OR) for hepatotoxicity. **Results:** We identified 530 patients, 129 (24%) HCC-ICI, 256 (48%) non-HCC ICI and 145 (27%) HCC-Sorafenib (mean age 65 (SD ± 12), autoimmune disorders 3%). Compared to non-HCC ICI,

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

HCC-ICI and HCC-Sorafenib were more often male (57%, 82%, 77%), Hispanic (14%, 35%, 34%), and cirrhotic (1%, 85%, 88%). ILICI incidence was higher for HCC-ICI (11%, CI 6-18) vs non-HCC ICI (4%, CI 2-6, p = 0.006) and DILI in HCC-Sorafenib (3%, CI 1-8, p = 0.02) with incidence highest for nivolumab+ipilimumab (HCC-ICI 42%, CI 15-72 vs non-HCC 10%, CI 3-24; p = 0.02). On multivariate regression, ILICI was independently associated with HCC (OR 3.9, CI 1.5-10.3, p = 0.005) and nivolumab+ipilimumab (OR 8.0, CI 2.9-22.0, p < 0.001). ILICI was elevated in patients who received atezolizumab + bevacizumab (OR 2.7, CI 0.7-9.9, p = 0.13) and/or had autoimmune disorders (OR 3.6, CI 0.7-19.6, p = 0.14), though not statistically significant. In HCC cases, liver injury remained elevated for ICI vs. sorafenib (OR 6.6, CI 1.8-25.0, p = 0.005) and potentially for autoimmune disorders (OR 1.8, CI 0.97-3.3, p = 0.07). Among the 19 HCC cases with DILI, those with ICI vs. sorafenib had higher median peak serum AST (353 vs 172, p = 0.03) and ALT (250 vs 109, p = 0.04). **Conclusion:** We identified an elevated risk of liver injury in ICI treated patients with HCC that exceeded the risk in ICI treated non-HCC cancers and sorafenib treated HCC cancers. The use of nivolumab + ipilimumab was specifically associated with increased odds of ILICI. Notably, our data suggests autoimmune disorders may also increase risk of developing ILICI though more research is needed to confirm these findings in a larger population. HCC patients treated with ICIs should be monitored closely as they are at higher risk of decompensation than are their non-ICI counterparts.

1734-A | PREDICTING STEROID-REFRACTORY IMMUNE CHECKPOINT INHIBITOR HEPATITIS: DEVELOPMENT AND EXTERNAL VALIDATION OF THE NOVEL SUNLIT MODEL AND IDENTIFYING A CUTOFF FOR BIOCHEMICAL NONRESPONSE AFTER STEROID TREATMENT

Michael Li[1], Jordan S Sack[2], Alexander Vogel[2], Lawrence Fong[1], Stephen D. Zucker[2], Shilpa Grover[2] and Jennifer C. Lai[3], (1)University of California, San Francisco, (2)The Brigham and Women's Hospital, (3) University of California-San Francisco

Background: Immune checkpoint inhibitor (ICI) hepatitis is one of the most frequent severe immune-related adverse events (irAEs) caused by cancer immunotherapy. Many patients have inadequate response to corticosteroids, but there are limited data regarding predictors of steroid-refractory ICI hepatitis and when to initiate additional immunosuppression. **Methods:** We conducted a multicenter, retrospective cohort study of cancer patients who developed grade 3-4 ICI hepatitis. The SUNLIT (Steroid UNresponsive Liver Immune Toxicity) model was derived using LASSO regression in a training set of 222 patients (Boston cohort) and then externally validated in 72 patients (San Francisco cohort). **Results:** Out of 294 patients, 80 (27%) developed steroid-refractory hepatitis, and 91% of these patients received mycophenolate mofetil. Steroid-refractory patients had higher peak ALT (median 703 vs 368 U/L, p < 0.001) and longer time to ALT normalization (median 57 vs 35 d, log-rank p < 0.001; Figure A) compared to steroid-responsive patients. The SUNLIT model included five pre-steroid treatment variables: pre-existing liver disease, alcohol use, liver metastasis, combination anti-CTLA4/PD1 therapy, and prior irAE of any organ system. SUNLIT had good discrimination for development of steroid-refractory hepatitis, with c-statistics of 0.79 (95% CI 0.73-0.86) and 0.82 (95% CI 0.71-0.93) in the training and validation sets, respectively. The median percent change in ALT after 7 days of steroid treatment differed significantly between steroid-refractory and responsive patients (-12% [IQR -40%, +24%] vs -58% [-73%, -40%], p < 0.001). As a single predictor of steroid-refractory disease, the percent change in ALT after 7 days of steroids had a c-statistic of 0.83, and the optimal cutoff based on maximizing the J statistic was -30% (sensitivity 68%, specificity 85%). Early additional immunosuppression **d** 7 days of steroid initiation was associated with faster ALT normalization in steroid-refractory patients (median 44 vs 63 days, log-rank p < 0.001, Figure B; adjusted HR 2.46, 95% CI 1.41-4.27, p = 0.001). **Conclusion:** The SUNLIT model uses

baseline variables to predict development of steroid-refractory ICI hepatitis and can identify high-risk patients who require frequent lab monitoring while receiving high-dose steroid treatment. We propose that patients who do not demonstrate at least a 30% improvement in ALT after 7 days of steroid treatment should initiate additional immunosuppression.

1735-A | PREDICTORS OF HEPATIC ENCEPHALOPATHY AMONG ADULTS ADMITTED WITH ACETAMINOPHEN POISONING.

Omar Almetwali, Marshall University School of Medicine, Renuka Verma, Guru Gobind Singh Medical School, Kamleshun Ramphul, Independent Researcher, Hemamalini Sakthivel, One Brooklyn Health System/ Interfaith Medical Center Program and Tejas Vijay Joshi, Marshall University

Background: Acetaminophen poisoning is a medical emergency that requires prompt and effective management to mitigate the risk of serious complications including hepatic encephalopathy (HE). The aim of this project is to construct a machine learning model to evaluate and predict the risk of impending HE by taking into account signs and sociodemographic determinants that predispose patients at risk to developing HE. **Methods:** Patients (aged ≥ 18 y) admitted with acetaminophen poisoning (Without a pre-existing diagnosis of liver cirrhosis) were included in our patient sample. Patient population was derived from the 2016-2020 National inpatient census. Prognostic factors predisposing to HE were studied via logistic regression models. **Results:** We found 132040 hospitalizations involving acetaminophen poisoning amongst adults in the United States that matched our selection criteria, of which 11985 (9.1%) cases reported events of hepatic encephalopathy. Multiple patient attributes and comorbidities were considered. Factors such as Charlson Comorbidity index score ≥ 4 (aOR 23.179, $p < 0.01$), Cardiogenic shock (aOR 1.574, $p < 0.01$), history of alcohol abuse (aOR 1.158, $p < 0.01$), history of drug use (aOR 1.06, $p = 0.045$), hypertension (aOR 1.081, $p < 0.01$), acute kidney injury (aOR 1.864, $p < 0.01$) and weekend admissions (aOR 1.18, $p < 0.01$) showed a higher predisposition of reporting hepatic encephalopathy. On the contrary, patients aged over 60 (vs. ages < 60, aOR 0.802, $p < 0.01$), diabetic (aOR 0.584, $p < 0.01$), peripheral vascular disease (aOR 0.46, $p < 0.01$), smoking history (aOR 0.822, $p < 0.01$), chronic kidney disease (aOR 0.477, $p < 0.010$), African American (vs. Caucasian, aOR 0.657, $p < 0.01$) and covered by Medicaid (vs. Medicare, aOR 0.876, $p < 0.01$) reported lower incidence of HE. **Conclusion:** Our study highlighted the role of various contributing factors attributed with inducing HE in the setting of acetaminophen poisoning. While the data did show a direct correlation between some of the aforementioned variables and the risk of developing HE, our study was unable to ascertain the exact dose and timeline between drug ingestion and onset of HE. Further studies can help evaluate the potential relationship between such variables and possible changes in outcomes.

Table 1. Predictors of hepatic encephalopathy in adults following acetaminophen poisoning

Patient characteristics and risk factors	95% Confidence interval		aOR	p-value
	Lower	Upper		
Age ≥60	0.746	0.862	0.802	**<.001**
Charlson Comorbidity Index ≥4	22.012	24.407	23.179	**<.001**

1736-A | PREVALENCE AND RISK FACTORS ASSOCIATED WITH DRUG-INDUCED LIVER INJURY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A 28-YEAR SINGLE CENTER EXPERIENCE

Asif Ali Hitawala[1], Zerai Manna[2], Yenealem Temesgen-Oyelakin[2], Elaine Poncio[2], Christopher Koh[1], Sarfaraz Hasni[2] and Theo Heller[3], (1)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (2) National Institute of Arthritis and Musculoskeletal and Skin Diseases, (3)Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health

Background: Patients with systemic lupus erythematosus (SLE) may require multiple medications for disease control. Drug-induced liver injury (DILI) is an important cause of hepatic injury (HI) in these patients, sometimes requiring therapy modification. We assessed prevalence and risk factors of the same. **Methods:** A retrospective longitudinal single center study was conducted from 1994-2022. Inclusion: 1) Age **e** 18 years; 2) Diagnosis of SLE based on 1997 American College of Rheumatology revised criteria. Exclusion: Patients with either < 3 visits or < 6 months of follow-up. Demographic, laboratory, medication and liver histology data were obtained from the electronic medical records. Prescriber notes were queried to identify patients with DILI. The patients were initially divided into those with and without HI, followed by HI secondary to DILI or another cause. The groups were then compared to identify risk factors. Chi-square test was used for comparing categorical variables, while Kruskal-Wallis test was used for numerical variables. P-value < 0.05 was considered statistically significant. **Results:** Out of 1106 patients, 636 patients were included in the final cohort, with median duration of follow-up of 9.7 yrs (4.15-16.96). There were 82 deaths, but only six patients had documented cause of death (all non-liver related). Mean age was 53.85 yrs (±15.31) and majority were females (555, 87.26%). About half the patients (303, 47.64%) developed HI during follow-up and majority (230, 75.91%) did not have an identifiable cause. Of the remaining 73 patients, 14 patients, all females, were suspected or diagnosed with DILI. The most common drug implicated was azathioprine (5 cases), followed by cyclophosphamide (2 cases), with 1 case each of a Janus-Kinase inhibitor (trial drug), methotrexate, meropenem, trimethoprim-sulphamethoxazole and enoxaparin. No drug could be identified in two patients. One patient had a liver biopsy suggestive of DILI, although no drug could be implicated. The rest were diagnosed clinically. There were no deaths recorded in the DILI group. Patients with DILI were younger but had similar body mass index (BMI). They had longer duration of follow-up than those without HI, but similar to those with other causes of HI. They had higher liver enzymes, direct bilirubin, prothrombin time, ferritin and C-reactive protein but lower albumin. Interestingly, these patients had higher anti-ribonucleoprotein antibody levels. In addition, they were more likely to be exposed to hydroxychloroquine, azathioprine, methotrexate and corticosteroids. **Conclusion:** HI is common in SLE, and the cause is often unknown. DILI remains an important cause of HI, and its risk increases in patients on multiple medications, emphasizing the importance of avoiding polypharmacy. Higher anti-ribonucleoprotein antibody levels may be helpful in identifying these patients, although further research is needed.

Table 1: Baseline Characteristics

1737-A | RISK OF DRUG-INDUCED LIVER INJURY WITH REMDESIVIR, MOLNUPIRAVIR AND RITONAVIR-BOOSTED NIRMATRELVIR IN PATIENTS WITH CHRONIC LIVER DISEASE

Binu V John[1], Dustin R Bastaich[2], K Rajender Rajender Reddy[3], Ashwani K. Singal[4], Bassam Dahman[2] and VALID group of investigators , (1)University of Miami and Miami VA, (2)Virginia Commonwealth University, (3)University of Pennsylvania, (4)University of South Dakota

Background: COVID-19 remains the sixth most common cause of death in the United States in 2023, and patients with chronic liver disease (CLD) remain at risk. Approved antivirals may be potentially hepatotoxic, while there is limited data on their safety in CLD. This study aimed to determine the risk of drug induced liver injury (DILI) with remdesivir, ritonavir boosted nirmatrelvir, and molnupiravir, in a large national cohort of participants with CLD. **Methods:** This was a retrospective cohort study of 152,917 Veterans with CLD who developed SARS-CoV-2 infection between 3/1/2020 and 12/31/2022. Participants receiving remdesivir (n = 22,444), ritonavir-boosted nirmatrelvir (n = 6535), or molnupiravir (n = 2564) within 7 days of a positive SARS-Co-V-2 PCR were compared with untreated participants with COVID-19 (n = 121,374) after controlling for potential confounders. The outcomes included mild (peak ALT > 2 times upper limit of normal [ULN]), and moderate (ALT > 5-fold ULN) elevations at 60-days from baseline values. The outcomes were modeled using multivariable Poisson regression accounting for follow-up time and adjusting for age, sex, race, BMI, Charleston Comorbidity Index, diabetes, smoking, hypertension, COPD, AUDIT-C, severity of COVID-19, and baseline lab results (ALT, AST, ALP, total bilirubin, platelet count, and creatinine). **Results:** The overall study participants were predominantly male (n = 139,978, 91.5%) and white (n = 70,436, 46.1%), with a median age of 68.6 years (IQR 15.7). The most common etiology of liver disease was NAFLD (n = 122,191, 79.9%), followed by alcohol (n = 13,468, 8.8%), and HCV (n = 11,789, 7.7%), and 9,572 (6.3%) individual's had cirrhosis. Participants who received remdesivir had a 1.19-fold higher likelihood of mild elevations in ALT (95% CO 1.14-1.24, p < 0.0001) but a lower likelihood of moderate ALT elevations (aHR 0.86, 95% CI 0.79-0.94, p = 0.001). Exposure to ritonavir-boosted nirmaltrevir was associated with a lower likelihood of mild (aHR 0.69, 95% CI 0.61-0.78, p < 0.0001) and moderate (aHR 0.59, 95% CI 0.40-0.85, p = 0.005) ALT elevations. There was no association of molnupiravir with mild (aHR 0.92, 95% CI 0.78-1.09, p = 0.36) or moderate (aHR 0.61, 95% CI 0.34-1.07, p = 0.08) elevations in ALT. **Conclusion:** In this large study of Veterans with CLD, anti-virals used to treat COVID-19 had a favorable hepatic safety profile. Compared to an untreated COVID-19 cohort, molnupiravir and ritonavir-boosted nirmatrelvir treated group did not have an increased rate of elevations in ALT, while remdesivir use was associated with only mild ALT elevations.

1738-A | SIGNIFICANT HEPATIC FIBROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS WAS NOT ASSOCIATED WITH DURATION OF TREATMENT OR CUMULATIVE DOSE OF METHOTREXATE

Masoud Moghtaderi[1], Mohammad Ali Nazarinia[2], Saeedeh Shenavandeh[2], Elham Aflaki[2] and Maryam Moini[3], (1)Gastroenterohepatology Research Center, Shiraz University of Medical Sciences, (2)Shiraz University of Medical Sciences, (3)University of Ottawa

Background: Methotrexate (MTX) has been one of the main agents used for treatment of Rheumatoid Arthritis (RA) for years. Drug-induced liver injury is one of the concerns in patients on long term treatment with MTX. Based on guidelines, patients on MTX are recommended to be monitored for liver tests abnormalities and fibrosis for those on long term treatment. However, the correlation between cumulative dose of MTX and increased risk of hepatic fibrosis has been questioned by more recent studies. **Methods:** In this prospective study, 120 adult patients with RA receiving treatment with MTX for more than 6 months were recruited from Rheumatology clinics of Shiraz University of Medical Sciences and underwent liver assessment. Patients with known chronic liver disease except for fatty liver were excluded. Complete history and physical exam were done by hepatologist. Full profile liver testing, viral hepatitis serology, CBC, ultrasound and Vibration Controlled Transient Elastography (VCTE) through FibroScan were performed. **Results:** Ninety-four participants (93.6% female, mean age 53.4 ± 10.4 y) completed the study. Of them, 42.6% had received MTX for more that 10 years and in 45.7% cumulative dose of MTX was more than 4 grams. History of type 2 diabetes was reported in 17%. None of the patients had a positive serology for Hepatitis B antigen or Hepatitis C antibody, but in 5.6% Hepatitis B core antibody was positive. Ultrasound reported fatty liver in 60.6% of patients and in only one patient features of chronic liver disease were reported. VCTE was technically feasible in 74 patients. Of those, 8.1% had significant hepatic fibrosis (F **e** 2) and 35 (47.3%) had significant hepatic steatosis (S **e** 2). Body Mass Index (BMI) was significantly higher in patients in whom VCTE failed. Duration of MTX use and cumulative dose of MTX did not have statistically significant associations with significant fibrosis ($P = 0.862$ and $P = 0.983$). In multiple linear regression analysis, BMI ($P = 0.23$) and AST/PLT ratio ($P = 0.22$) were identified as independent predictors for significant hepatic fibrosis. BMI was identified as an independent risk factor for significant hepatic steatosis ($P < 0.001$). **Conclusion:** In this study, the population of patients with RA on MTX, using VCTE as a non-invasive test, no significant correlation was observed between duration of treatment or cumulative dose of MTX and significant hepatic fibrosis.

1800-A | ALBI (ALBUMIN-BILIRUBIN) SCORE AS A USEFUL PREDICTOR OF PORTAL HYPERTENSION AND HEPATIC ENCEPHALOPATHY IN PATIENTS WITH HEPATITIS C CIRRHOSIS

Miriam Mercedes Sanchez[1], Gail Fernandes[2], Natalie Nguyen[2], Stephanie Paduano[2], Geovanny Manuel Gutierrez-Brito[2], Quynh-An Phan[2], Destny Agubuzo[2], Chukwuma Egwim[2] and Victor Ankoma-Sey[2], (1)Liver Associates of Texas, (2)Liver Associates of Texas, P.a.

Background: Hepatitis C Virus (HCV) infection remains a global health problem that can progress to liver cirrhosis. Patients with cirrhosis are subject to a variety of complications related to portal hypertension. The ALBI score has been mainly investigated as a non-invasive method to evaluate liver dysfunction and assess prognosis in patients with hepatocellular carcinoma (HCC). The aim of our study is to determine if there is a correlation between the ALBI score and portal hypertension and ALBI score and hepatic encephalopathy in patients with cirrhosis due to HCV. **Methods:** A retrospective study was conducted for all patients diagnosed with chronic hepatitis C from September 1, 2018, to May 1, 2021, at Liver Associates of Texas, P.A., clinics in Houston, TX. Individual's with chronic hepatitis C (CHC) were identified as patients with a positive anti-HCV antibody and detectable HCV RNA with or without elevated liver transaminases. Patients with chronic liver diseases secondary to causes other than HCV infection were not included. The ALBI score was calculated using the formula: ALBI score = (log10 bilirubin × 0.66) - (albumin × 0.085). A multivariate binomial logistic regression model was employed to demonstrate the correlation of the ALBI score with the presence of portal hypertension and hepatic encephalopathy. A p-value of less than 0.05 was considered significant. **Results:** The study comprised 61 patients diagnosed with cirrhosis due to CHC, of which 43.3% were identified with portal hypertension and 35.6% with a history of hepatic encephalopathy. The ages ranged from 37 to 80 years, with a mean of 61.5 years. ALBI scores were found to positively correlate with the presence of portal hypertension ($p = 0.023$) and hepatic encephalopathy ($p = 0.038$) in patients with cirrhosis secondary to HCV infection. Using a cut-off value of 25%, the ALBI score resulted with a sensitivity of 92.3% and specificity of 8.82% for portal hypertension in patients with HCV cirrhosis. **Conclusion:** This study shows a positive correlation between the ALBI score and both portal hypertension and hepatic encephalopathy in patients with cirrhosis due to chronic HCV infection. This correlation must be further studied in larger populations to determine its prognostic value. The ALBI score only uses two standard laboratory parameters, making it easier to calculate compared to other well-known scoring systems available to assess the severity of liver dysfunction. A high ALBI score may be used as a screening tool to exclude portal hypertension in patients with cirrhosis due to HCV infection. Further studies are needed for a larger cohort of patients to further study the sensitivity and specificity value of the ALBI score in this setting.

1801-A | AN ARTIFICIAL INTELLIGENCE MODEL FOR PREDICTION OF HEPATOCELLULAR CARCINOMA DEVELOPMENT AFTER ORAL ANTIVIRAL THERAPY IN PATIENTS WITH CHRONIC HEPATITIS C★

Yu Rim Lee[1], Hyun Young Woo[2], Jung Gil Park[3], Min Kyu Kang[3], Jeongeun Song[4], Jang Byoung Kuk[5], Young-Oh Kweon[6], Won Young Tak[7], Se Young Jang[1], Soo Young Park[1], Chang-Hyeong Lee[4], Byung Seok Kim[4], Jaeseok Hwang[8], Woo Jin Chung[5], Jeong Heo[9] and Keun Hur[6], (1)School of Medicine, Kyungpook National University, (2)Pusan National University, (3) Yeungnam University College of Medicine, (4)Daegu Catholic University School of Medicine, (5)Keimyung University School of Medicine, (6)Kyungpook National University, (7)College of Medicine, Kyungpook National University, (8)Keimyung university, (9)Department of Internal Medicine, College of Medicine, Pusan National University, Busan, South Korea

Background: Hepatocellular carcinoma (HCC) can still occur after achieving a sustained virologic response (SVR) to direct-acting antiviral (DAA) therapy in patients with hepatitis C. Several models have been developed to predict risk of hepatocellular carcinoma (HCC) in patients with chronic hepatitis C. We aimed to develop an artificial intelligence-assisted prediction model of

HCC risk. **Methods:** A total of 3,489 HCV patients who treated with DAAs and had achieved SVR from ten hospitals in South Korea were included in this study. HCC risk prediction models were developed using machine learning including Decision tree and Gradient Boosting. **Results:** Age, platelet, AST, ALT, bilirubin, and albumin at baseline and 1 year after treatment were determined to be important factors predicting HCC risk. Prediction models using these parameters at baseline and 1 year after treatment was showed good predictive abilities (AUROC values of 0.83 to 0.86). This model showed significantly better discrimination than previous models. **Conclusion:** HCC risk prediction models using machine learning including Decision tree and Gradient Boosting accurately predicted the risk of HCC in patients with chronic hepatitis C who have achieved SVR with DAAs.

1802-A | APPLICATION OF LIVERFAST BIOMARKERS TO EVALUATE LONGITUDINAL HEPATIC FIBROSIS AND INFLAMMATION AFTER HCV CURE

Mati Ullah Dad Ullah[1], Arjun P. Kelaiya[1], Rohullah Rasikh[1], Mehdi Sakka[2], Rana Alkouri[2], Mukarram Jamat Ali[1], Hao Wei Chen[1], Iman Waheed Khan[1], Mina Choudhry[1], Muhammad Ashar Ali[1], Maxime Deregnaucourt[2], Dominique Bonnefont-Rousselot[2,3], Mona Munteanu[4], Ronald Quiambao[4] and Daryl T. Y. Lau[1], (1)Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, (2)Metabolic Biochemistry Department, Pitié-Salpêtrière Hospital, Public Assistance Paris Hospitals,Aphp Sorbonne University, France, (3)Pharmacy Training and Research Unit (UFR), Paris Cité University; Cnrs, Inserm, Utcbs, France, (4)Fibronostics US Inc, USA

Background: HCV infection is a leading cause of cirrhosis and hepatocellular carcinoma (HCC). Direct antiviral agents (DAA) therapy is associated with > 95% sustained virological response (SVR). It is important to identify patients who continue to be at risk for HCC and liver disease progression after HCV cure. In this study, we applied LIVERFASt to evaluate changes in hepatic fibrosis and inflammation post-DAA therapy and to identify risks for liver disease complications after achieving SVR. **Methods:** This is a retrospective cohort study in a single tertiary liver center. Patients who achieved DAA-induced HCV cure with > 1 year follow up and had serial stored sera from pretreatment were selected. LIVERFASt ™ (Fibronostics) fibrosis and inflammation activity scores were computed for each sample. APRI and FIB-4 scores were correlated with the LIVERFASt fibrosis scores at baseline. Medical chart review was performed to record demographics, HCC, hepatic decompensation, and comorbid liver conditions. **Results:** A total of 40 patients with a follow-up period of 37(17-62) months post-DAA were included. This male predominant (62.5%) cohort had 26 (65%) White, 9(22.5%) Black and 3(7.5%) Asian; 34 (85%) had HCV genotype 1. 28(70%) patients had advanced F3-4 fibrosis prior to treatment. The baseline LIVERFASt fibrosis scores correlated with APRI ($r = 0.56$, $p < 0.0001$) and FIB-4 ($r = 0.48$, $p = 0.001$). At follow up, 23(58%) had **e** 1 stage fibrosis regression, 3 (7.5%) had progressive fibrosis and 14(35%) had no change including 4 with F0-F1 at baseline [Figure 1a]. Prior to therapy, 16(70%) and 8(47%) patients with and without subsequent fibrosis regression had inflammation Activity (A) score **e** 1 grade respectively ($p = 0.15$). At last follow up, 22(96%) patients with fibrosis regression had no inflammation (A = grade 0). In contrast,10(59%) of those without fibrosis regression continued to have inflammation (A = grade 1)

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

[Figure 1b]. 9(23%) patients developed de-novo HCC between 2.1 and 5.8 years after HCV cure; 8 (F3 = 2, F4 = 6) had advanced fibrosis prior to DAA. At the time of HCC diagnosis, 5 had no fibrosis regression and 1 had progressed to cirrhosis; 4(67%) continued to have inflammation. 3 HCC patients who had fibrosis regression without inflammation had at least 1 episode of hepatic decompensation prior to DAA. Among the remaining 6 non-HCC patients with active inflammation at follow up, 4 had unchanged fibrosis and 2 had fibrosis progression. 3 had pre-existing cirrhosis with portal hypertension, 2 continued active alcohol use and 1 developed autoimmune hepatitis. **Conclusion:** LIVERFASt has prognostic values in monitoring inflammation and fibrosis after HCV cure. Patients who continue to have advanced fibrosis and persistent inflammation after HCV cure remain at risk for HCC and require regular HCC surveillance. Other liver conditions must be considered for those with active hepatic inflammation or progressive fibrosis after successful DAA therapy.

1803-A | EARLY READ-TIME PERFORMANCE OF THE ORAQUICK® HCV RAPID ANTIBODY ASSAY FOR THE EXCLUSION OF HCV VIREMIA

Jessie Torgersen[1], Rebecca Russell[2], Julia Gasior[1], Dena Carbonari[1], Nancy Aitcheson[1], David Smookler[3], Camelia Capraru[3], Bettina E. E. Hansen[4], Jordan J. Feld[5] and Vincent Lo Re III[1], (1)University of Pennsylvania Perelman School of Medicine, (2) University of Pennsylvania Health System, (3)Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, Toronto, Canada, (4)Toronto General Hospital University Health Network, Rotterdam, Netherlands, (5)Toronto General Hospital Research Institute

Background: Rapid point-of-care tests for hepatitis C virus (HCV) allow for testing and linkage to care for difficult-to-reach populations. The OraQuick® rapid HCV antibody lateral flow immunoassay (OQ) detects anti-HCV antibodies in blood with results finalized after 20 minutes. Prior work has suggested OQ-positivity beyond 5 minutes could identify people who do not have current HCV viremia; however, these observations have not been externally validated. **Methods:** We conducted a single-center cohort study between June 2021-April 2023 to evaluate the performance of OQ early reading time for the exclusion of HCV viremia among patients with reactive HCV antibody. Consenting adult inpatients and outpatients were screened for HCV antibody using OQ, and those with positive results were tested for HCV RNA. Patients were excluded if there was clinical evidence to suggest likely acute HCV infection. The OQ was used according to the manufacturer's instructions. The presence of both control and test bands was evaluated and recorded at every minute between 5-10 minutes, then at 20- and 40-minutes following dipstick insertion. Performance of an early reading time of the OQ assay was evaluated against the standard-of-care HCV RNA completed as part of routine clinical care. The proportion of participants identified by positive OQ were compared by HCV viremic status. **Results:** The OQ was completed by 155 participants (69.6% male; 18.1% HIV+; median age, 54.3 y) with reactive HCV antibody, including 109 (70.3%) with HCV viremia. Among HCV viremic patients, 105/109 (96%) had a positive OQ by 5 minutes and 108 (99%) had a positive result by 7 minutes. In contrast, 18/46 (39%; $p < 0.0001$) and 22/46 (47.8%; $p < 0.0001$) of HCV non-viremic patients had a positive OQ by 5 and 7 minutes, respectively (Table 1). Among the 25 participants with a negative OQ at 7 minutes, 24 (96%) were HCV non-viremic. The one HCV viremic patient not identified by OQ by 7 minutes was profoundly immunosuppressed due to recent critical illness and HIV; after excluding this participant, both the sensitivity and negative predictive value of the OQ by 7 minutes improved to 100%. Among patients with a positive OQ, there was no time threshold that accurately identified only participants with HCV viremia. **Conclusion:** A negative OQ by 7 minutes reliably excludes HCV viremia, which may reduce the need for RNA testing and improve throughput. Early results (by 7 minutes) cannot be used to exclusively identify viremia and should be used with caution in those with severe immunosuppression or if acute HCV is suspected.

1804-A | HCC PREDICTION MODELS EFFECTIVELY ASSESS THE RISK OF HCC IN CHRONIC HEPATITIS C PATIENTS WITHOUT ADVANCED FIBROSIS AFTER ORAL ANTIVIRAL THERAPY: A MULTICENTER STUDY

Yu Rim Lee[1], Hyun Young Woo[2], Jung Gil Park[3], Min Kyu Kang[3], Jeongeun Song[4], Byoung-Kuk Jang[5], Young-Oh Kweon[6], Won Young Tak[7], Se Young Jang[1], Soo Young Park[1], Keun Hur[6], Chang-Hyeong Lee[4], Byung Seok Kim[4], Jaeseok Hwang[8], Woo Jin Chung[5], Jeong Heo[9], Nae-Yun Heo[10], Seung Ha Park[10], Junsik Yoon[11] and Yang Hyun Baek[12], (1)School of Medicine, Kyungpook National University, (2)Pusan National University, (3)Yeungnam University College of Medicine, (4)Daegu Catholic University School of Medicine, (5)Keimyung University School of Medicine, (6)Kyungpook National University, (7)College of Medicine, Kyungpook National University, (8)Keimyung university, (9)Department of Internal Medicine, College of Medicine, Pusan National University, Busan, South Korea, (10)Inje University Haeundae Paik Hospital, (11) Busan Paik Hospital, (12)Dong-a University College of Medicine

Background: The current guidelines recommend lifelong ultrasound surveillance for chronic hepatitis C patients with advanced fibrosis or cirrhosis after achieving SVR with DAA therapy. However, there are limited studies on the risk of HCC in patients without advanced fibrosis. Therefore, we aimed to identify high risk group for HCC development using HCC prediction models. **Methods:** This study included 1,839 chronic hepatitis C patients without advanced chronic liver disease from 10 tertiary hospitals who were treated with DAA. Advanced fibrosis was defined as LSM **e** 10 kPa, FIB-4 > 3.25, or APRI **e** 1.5 at baseline. The predictors of HCC occurrence and predictive ability of HCC risk scores were assessed. **Results:** During a median follow-up of 2.8 years, 28 (1.5%) patients developed HCC at a median of 2.77 years. The mean age was 56 years, and 852 (46.3%) patients were male. When the patients were divided into HCC and non-HCC groups, patients who developed HCC during follow-up were significantly older, and had lower platelet count and albumin level before antiviral treatment. In addition, patients who developed HCC had a higher FIB-4 score ($P < 0.001$). Comorbidities, such as diabetes and hypertension, were more common among patients with HCC than those without HCC ($P < 0.05$). In multivariate analysis, old age, platelet count, albumin level, and

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

sodium level before treatment were significantly associated with the occurrence of HCC (all $P < 0.05$). The high-risk group defined by previously published HCC prediction models showed a significantly high HCC occurrence. This finding was observed in most validated HCC prediction models including aMAP and mPAGE-B, and the incidence of HCC ranged from 1.5% to 7.4% at 3-years and from 3.8% to 24.2% at 5-years at SVR in high-risk patients (Figure). HCC rarely occurred during the first 5-years of follow-up in low and intermediate-risk patients defined by HCC risk scores. **Conclusion:** HCC risk models effectively assess the risk of HCC in chronic hepatitis C patients without advanced fibrosis after achieving SVR. Therefore, even in patients without advanced liver fibrosis before treatment, surveillance should be considered if they are included in the high-risk group of the HCC prediction model.

1805-A | IMPACT OF COVID ON PREVALENCE HEPATITIS C IN FRANCE : 5 SCREENING HCV ACTIONS, BEFORE, DURING AND AFTER COVID-19

Juliette Pont[1], Pascal Melin[2], Laurence Garbet[3], Veronique Monot[4], Jacky Sainty[3], Solange Bresson[5] and AASLD Authors group', (1)SOS Hepatites, (2) Hospital, (3)Sos Hepatites, (4)CHU Dijon, (5)CHU Besançon

Background: In France, it has been estimated that at least 90 000 people are unaware of their HCV infection. Many reports indicated declines in hepatitis C virus (HCV) testing during covid crisis. But, what are the consequences for new contaminations in France? The aim is to compile and analyze the results of 5 roadtrips between March 2020 until the end of 2021 to compare results before Covid, during crisis and one year after is a way to see if they're different. **Methods:** A team made up of caregivers and peers has been carrying out roadtrips for several years to screen people who use drugs (PWUDs) for hepatitis C. Around the same number of people seen, drug users, same addiction centers, the results are absolutely comparable. **Results:** First roadtrip : done during the pre-COVID-19 period (October 2019), 108 HCV antibodies done, 12 RNA + tests with POC, prevalence 11%. Second roadtrip: October 2020, after first confinement, 112 HCV antibodies, 10 RNA + tests, prevalence 9%. Third and forth roadtrip: April and October 2021, after a year and half crisis, results are : 97 and 92 HCV antibodies tests respectively and 3 RNA tests + for each, prevalence 3% and 3,26% respectively. Fifth roadtrip: after Covid, 75 antibodies VHC antibodies tests, 8 RNA+, prevalence 10,7%. Before Covid, during the preliminary interviews, very few drug users said they share injection equipment. They were much more at the last roadtrip, after crisis. Behaviors have changed? Harm reduction centers were more closed during Covid-19? Difficulties to move with the confinements? Hard to say, but results speak for themselves. **Conclusion:** Achieve elimination hepatitis C by 2030 is not certain when if an event like Covid-19 seems to reactivate the epidemic. the years to come will show if behaviors return to the way they were before covid

1806-A | INVOLVEMENT OF CIRCULATORY CELL-FREE MITOCHONDRIAL DNA IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION: BEFORE AND AFTER CLEARANCE

Rownock Afruza[1], Adekanyinsola Onitiri[1], Moumita Chakraborty[1], Nicole San-Dee Minerva[1], Maleeha Ahmad[1], Rabab Ali[1], Kareen Hill[1], Grace Zhang[1], Elizabeth Townsend[1], Lisa Scheuing[1], Jenna Leigh Oringher[1], Elliot Levy[2], Ohad Etzion[1], David E Kleiner[3], Christopher Koh[4] and Theo Heller[1], (1)Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (2)Radiology & Imaging Sciences Department, Clinical Center, National Institutes of Health, (3)Laboratory of Pathology, National Cancer Institute, National Institutes of Health, (4) National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: Disruption of mitochondrial functions, increased reactive oxygen species production and apoptosis, and decreased mitochondrial DNA content along with inflammation are often associated with HCV infection. We have previously shown the central role of mitochondria and peroxisomes in hepatic metabolic dysregulation during HCV infection and advanced fibrosis. The aim of this project is to investigate the role of circulatory cell free mtDNA (ccfmtDNA) during HCV infection and after clearance in both cirrhotic and non-cirrhotic groups. **Methods:** Peripheral blood was collected before (HCVi, $n = 29$) and after DAA therapy (SVR, $n = 23$), and from healthy controls ($n = 13$) (NCT02400216). Cell-free DNA was extracted from peripheral plasma and used for calculating mtDNA copy numbers via qPCR. Total mtDNA copy numbers were calculated using the average copy numbers for human mitochondrial genes: NADH dehydrogenase 1 (*ND1*), NADH dehydrogenase 6 (*ND6*), Cytochrome C Oxidase III (*COXIII*) and ATP synthase 5A1 (*ATP5A*1). For significance, all $p < 0.05$. **Results:** ccfmtDNA copies were significantly lower in both HCVi and SVR compared to healthy controls. Interestingly, a significant reduction of ccfmtDNA copy numbers in HCVi cirrhotic compared to HCVi non-cirrhotic indicates an effect of fibrosis on mitochondria. ccfmtDNA copy numbers correlated with serum inflammatory (CRP; spearman $r = 0.374$), angiogenesis (Tie-2; spearman $r = 0.374$), and complement (C5a; spearman $r = 0.5327$) markers during HCVi. A correlation was noted between ccfmtDNA copy numbers and c3a (spearman $r = 0.75$, $p = 0.06$) in HCVi cirrhotics, suggesting a relationship between C3a pathway and ccfmtDNA during advanced fibrosis. After SVR, there were correlations between ccfmtDNA copy numbers and serum growth factors (TGFb; $r = 0.4722$ and PDGF-AA; $r = 0.582$) as well as with serum vascular injury marker (sICAM-1; $r = 0.626$), all of which may play a role in tissue repair. There was a significant reduction of ccfmtDNA copy numbers in SVR compared to HCVi. mtDNA copy numbers were not different between SVR non-cirrhotic and cirrhotic, although they were lower in both compared to HCVi non-cirrhotic. **Conclusion:** HCV infection impairs mitochondrial function and lowers copy number of

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ccfmtDNA compared to healthy controls. A decrease in ccfmtDNA copy number in cirrhotic compared to non-cirrhotic during HCV infection links mitochondrial dysfunction with severe fibrosis. In SVR, there was no increase of ccfmtDNA copy numbers, suggesting regulatory mechanisms other than HCV infection. Elucidation of these mechanisms has potential therapeutic implications beyond chronic HCV infection.

1807-A | POSITIVE RATES OF AUTOANTIBODIES IN CHRONIC HEPATITIS C PATIENTS BEFORE AND AFTER DAA THERAPY: A PROSPECTIVE, MULTICENTER STUDY IN SOUTH KOREA

Su Hyun Choi and Sook-Hyang Jeong, Seoul National University Bundang Hospital

Background: Hepatitis C Virus (HCV) infection causes extrahepatic diseases, involving B-cell dysregulations and autoantibody (autoAb) production. This study aimed to investigate the positive rates of 4 conventional autoAbs (anti-nuclear, anti-smooth muscle, anti-LKM type1, and anti-mitochondrial; ANA, ASM, Anti-LKM1, and AMA, respectively) in the patients with chronic HCV infection (CHC) at 2-time points of pretreatment (PreTx) and at 12 weeks after the end of treatment for evaluation of sustained virological response (SVR) of direct-acting antiviral (DAA) therapy, and compared to those in healthy controls. **Methods:** Using a prospectively collected plasma obtained from 201 CHC patients (median age 62, 49.8% of female, 7.5% of cirrhosis) enrolled in 8 hospitals before and after DAA therapy, ANA, ASM, Anti-LKM1, and AMA were detected by indirect immunofluorescence with cutoff level of 1:80, 1:10, 1:10 and 1:10, respectively, according to the manufacturer's protocols. As a control group, plasma samples from 127 healthy person representative of age and sex standardized Korean adult population (median age 55, 49.6% of female) were obtained from a biobank. The prevalence of these autoAbs was compared between CHC patients at PreTx. and healthy controls, and between at PreTx and at SVR in CHC patients. In addition, clinical variables associated with ANA positivity were analyzed using multivariate logistic analysis. **Results:** The positive rate of ANA in CHC patients was significantly higher than that in healthy controls (32.3% vs 21.3%, $p = 0.032$) however, ASM (2.0% vs 2.4%), LKM1 (0% vs 0%), and AMA (0% vs 0.79%) were not. In CHC patients, ANA positivity at PreTx tended to decrease at SVR (32.3% vs 23.9%, $p = 0.059$) In healthy controls, ANA positivity was higher in females than males regardless of age, while in CHC patients, ANA positivity was not associated with sex, but higher globulin level. HCV RNA titer was significantly lower in the any-autoAb positive group (5.69) than the negative group (median 5.69 vs 6.10 log10 IU/mL, $p = 0.046$), though not an independent factor in multivariate analysis.
The 37 (57%) patients among 65 ANA-positive CHC at PreTx maintained positive at SVR, and 11 (8%) patients among 136 ANA-negative CHC at PreTx converted positive at SVR. In CHC patients who maintained or converted ANA-positive at SVR, were older (67 vs 59, $p = 0.013$) with higher proportion of cirrhosis or HCC (27% vs 17.9%, $p = 0.032$). **Conclusion:** In this prospective study, Korean CHC patients showed higher ANA positivity than controls, and PreTx ANA positivity decreased after SVR. However, about half of the ANA-positive CHC patients remained in ANA-positive state and less than 10% of ANA-negative patents turned out to be positive after SVR, mostly older age with higher portion of cirrhosis or HCC.

Mitsuhiro, Department of Materials Science and Technology, Graduate School of Industrial Science and Technology, Tokyo University of Science, Tokyo, Japan

Background: We previously developed a novel technology for extraction and enrichment of HCV antigen using a thermo-sensitive smart polymer (NIPAAm-co-HIPAAm-co-SAKIPAAm (Patent: 2019/2002) as a point of care testing which has the same diagnostic accuracy as the gold standard PCR (1). The laboratory-based Roche COBAS®TaqMan® HCV test is able to detect and measure HCV RNA down to 15 international units per ml (IU/ml) with > 99% sensitivity. Our aim is to determine the target limit of detection (LOD) of this technology. **Methods:** We predefined 60 serum samples subdivided to three groups according to HCV viral load distribution in log 10 IU/ml by (Cobas ampliprep/TaqMan®, Roche); 20 samples with viral load from 500 up to 1000 IU/ml., 20 samples with viral load from 100 up to 500 IU/ml., 20 samples with viral load from < 100 IU/ml. **Results:** Extraction and enrichment of HCV antigen using a thermo-sensitive smart polymer (NIPAAm-co-HIPAAm-co-SAKIPAAm) in all 60 samples yields positive results. The lowest HCV viral load of the study samples is 36 IU/ml. **Conclusion:** The novel thermo-sensitive smart polymer technology was able to detect very low viremia which could be used as an accurate point of care test for diagnosis of HCV viremia when validated in multicentre studies of different ethnicities and genotypes. References: Shiha et al., A novel technology for diagnosis of HCV viremia using thermo sensitive smart polymer: pilot study of a point of care test of HCV compared to polymerase chain reaction test (PCR).Hepatol Int (2023) 17:S1–S267

1809-A | ZONAL DISTRIBUTION OF MITOCHONDRIAL AND PEROXISOMAL DAMAGE IN CHRONIC HEPATITIS C VIRUS INFECTION AND CIRRHOSIS WITH MITOCHONDRIAL RECOVERY AFTER CLEARANCE

Moumita Chakraborty[1], Maleeha Ahmad[1], Adekanyinsola Onitiri[1], Rownock Afruza[1], Nicole San-Dee Minerva[1], Rabab Ali[1], Elliot Levy[2], Ohad Etzion[3], David E Kleiner[4], Christopher Koh[5] and Theo Heller[1], (1)Translational Hepatology Section, Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, (2) Radiology & Imaging Sciences Department, Clinical Center, National Institutes of Health, (3)Soroka University Medical Center, Beer-Sheba, Israel, (4) Laboratory of Pathology, National Cancer Institute, Bethesda, MD, (5)National Institute of Diabetes and Digestive and Kidney Diseases, Nih

Background: HCV-infected individual's have been shown to have metabolic alterations predominantly localized to mitochondria and peroxisomes. However, the changes in these organelles across different zones of the liver before and after HCV clearance is unclear. Aim: To understand the changes in mitochondria and peroxisomes across liver zones before and after HCV clearance in non-cirrhotic vs cirrhotic patients. **Methods:** HCV patients had a liver biopsy before Phase 1 (n = 29), and 1 year after DAA therapy Phase 2 (n = 23) (NCT02400216). Immunofluorescence staining was performed on the liver biopsies (Phase 1 Non-Cirrhotic/Cirrhotic and Phase 2 Non-Cirrhotic/Cirrhotic). ATP5A, a classical marker for mitochondria, and Catalase, for peroxisomes, were utilized. Image segmentation analyses were then performed on the confocal microscopy images using LABKIT, a FIJI plugin, to analyze the particle count in the hepatocytes for these two markers. All the images were normalized by the number of nuclei. Mann-Whitney U test ($p < 0.05$) was used for marker comparison between groups. **Results:** Phase 1 cirrhotic patients when compared with non-cirrhotic patients exhibited significantly reduced expression of both ATP5A ($p = 0.007$) and Catalase ($p = 0.03$) in zone 1 hepatocytes, but no significant difference in zone 2 hepatocytes. After clearance of HCV, Phase 2 non-cirrhotic patients showed a significant increase of ATP5A in both zone 1 ($p = 0.0003$) and zone 2 ($p = 0.002$) hepatocytes when compared with Phase 1 non-cirrhotic patients. The Catalase expression was still low in zone 1 ($p = 0.003$) hepatocytes and no significant difference was observed in Zone 2 hepatocytes. Interestingly, when ATP5A levels of Phase 2 cirrhotic patients were compared to Phase 1 cirrhotic patients, significantly elevated levels were observed in both zone 1 ($p = 0.02$) and zone 2 ($p = 0.01$) hepatocytes, while there were no significant changes in Catalase expression. **Conclusion:** ATP5A and Catalase expression in HCV-infected patients are affected in a zonal pattern suggesting the greatest perturbations in the most metabolically active zone, zone 1 and in the patients with the greatest disease progression, those with cirrhosis. Intriguingly, after DAA therapy, there was an increase in ATP5A but a decrease in Catalase expression in zone 1, suggesting improvement of mitochondrial but not peroxisomal function after SVR. These findings suggest that peroxisomes and mitochondria are differentially affected in different liver zones before and after HCV clearance. This has relevance and implications for metabolic function of the liver as disease progresses, suggesting mitochondrial rescue as a possible therapeutic target.

1810-A | A GLOBAL SURVEY OF PHYSICIAN KNOWLEDGE ABOUT MANAGEMENT OF CHRONIC HEPATITIS C

Mohamed El-Kassas, Endemic Medicine Department, Faculty of Medicine, Helwan University, Ain Helwan, Cairo, Egypt, Yusuf Yilmaz, Department of Gastroenterology, School of Medicine, Recep Tayip Erdogan University, Rize, Turkiye, Chun-Jen Liu, National Taiwan University Hospital, Marlen Ivon Castellanos Fernandez, Institute of Gastroenterology, University of Medical Sciences of Havana, Cuba, Wah Kheong Chan, University of Malaya, George V. Papatheodoridis, Medical School of National & Kapodistrian University of Athens, Athens, Greece, Mohammed Ahmed Medhat Nasr, Assiut University, Fatema Nader, Center for Outcomes Research in Liver Diseases, Andrei Racila, Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, VA, Maria Stepanova, Center for Outcomes Research in Liver Diseases, Washington, DC, Zobair M. Younossi, Inova Health System and The Global Nash Council

Background: Knowledge about disease management can affect patient outcomes. Recent advances in treatment of chronic hepatitis C virus (HCV) may have affected the physicians' awareness and knowledge of HCV guidelines. **Methods:** Providers who treat HCV patients were asked to complete a specifically designed 48-question survey about HCV practice, familiarity with guidelines, attitudes, perception, self-efficacy, and barriers of treatment. **Results:** 183 physicians completed the survey: 32% hepatologists, 39% gastroenterologists, 12% internal medicine, 16% infectious diseases specialists, mean 18 $\pm$ 11 years in practice, seeing median (IQR) 50 (20 - 250) patients with HCV annually. When asked to mention all the HCV treatment guidelines they know (95% at least one), guidelines by AASLD, EASL, APASL and WHO were mentioned by 72%, 84%, 11% and 28%. The most common source of guideline knowledge was Internet (48%) then conferences (23%). The most commonly followed guideline was EASL (46%) followed by AASLD (23%). Of the survey completers, 50% reported regularly attending workshops, conferences, or training courses about HCV treatment mostly organized by AASLD, EASL, and UCHID (10-12% each). 91% believed that guidelines for HCV treatment are based on sound evidence but 39% reported inconsistencies; while 90% reported feeling well-informed about guidelines for HCV treatment. There were 94% who believed that post-treatment follow-up is effective for early detection of HCC, cirrhosis, and other complications among treated HCV patients, and 93% recommend their patients to continue with post-treatment follow-up. Regarding specific knowledge, 61% were aware that in patients with advanced fibrosis and cirrhosis, HCV eradication reduces the rate of decompensation but does not abolish the risk of HCC. Before treatment, 79% reported assessing fibrosis stage using only non-invasive tests (NITs), and 12% reported using both NITs and a biopsy. After treatment, 65% of providers ask their non-cirrhotic patients with SVR-12 to repeat ALT and HCV RNA assessments later, 96% would explain the risk of reinfection to patients from high-risk populations, and 87% recommend annual HCV RNA testing to those populations. Overall, 86% believed that there is a need for following up patients who achieved SVR, with the most commonly recommended periods being 6 months for non-cirrhotic and 3 months for cirrhotic patients; however, hepatologists and gastroenterologists more commonly believed that there was no need to follow-up non-cirrhotic patients (49% vs. 28% others). Finally, $<5\%$ reported not telling their HCV patients about post-treatment follow-up or not discussing its potential benefits. **Conclusion:** Participating physicians appear well aware of the current guidelines for treatment and post-treatment follow-up for HCV. Awareness could be lower among providers working in community clinics and/or in locations with limited resources.

Imma Valls[6], Carla Ventosa[7], Juan Carlos Ruiz Cobo[8], Mar Riveiro[8] and Maria Buti[9], (1)Vall D'hebron Research Institute (VHIR), (2)CAP Trinitat Vella, (3) CAP Río De Janeiro, (4)CAP Chafarinas, (5)CAP Sant Andreu, (6)CAP San Rafael, (7)CAP Guineueta, (8)Vall D'hebron Universitary Hospital, (9)Hospital Universitari Vall d'Hebron, Department of Medicine of the UAB (Universitat Autònoma de Barcelona), Spain

Background: The WHO proposed the elimination of viral hepatitis as a public health threat by 2030. In order to achieve this goal 90% of patients with hepatitis C need to be diagnosed and 80% of these individual's need to be treated. In Spain, it is described that the prevalence of anti-HCV+ and HCV-RNA+ is 0.85% and 0.22% respectively in the general population attending the primary care centers but little data are available on the HCV testing rates. The aim of this study was to assess the percentage of individual's screened for hepatitis C in the primary care centers of the Barcelona northern area and the rates of HCV detection. **Methods:** Retrospective search in the microbiology database of the Barcelona northern area primary care centers to assess the percentage of patients screened for hepatitis C and the percentage of patients anti-HCV+ and HCV-RNA +. Medical records of those HCV-RNA+ patients are being reviewed to identify lost to follow-up patients and link them to care. **Results:** HCV testing data from 2022 were analyzed from six primary care centers from the northern area of Barcelona. A total of 64,985 individual's attended these primary care centers and had a blood test. From these 64,985 patients, only 4,929 (7.6%) were screened for anti-HCV. Anti-HCV antibodies were detected in 96 (1.9%) and HCV-RNA was performed by reflex testing in 70 (73%) of these patients. Nine patients were HCV-RNA+, accounting for 9.37% of the anti-HCV+ patients and a 0.2% of the 4,929 screened patients. 61 patients had indetectable HCV-RNA but 32 (53%) of these 61 patients were previously treated for hepatitis C. Patients with antibodies anti-HCV were 57% male with a median age of 55 years, with basal median AST and ALT of 23 and 25 IU/L respectively and basal FIB-4 and APRI of 1,26 and 0,25, respectively. The 9 positive cases were 77% female, with a median age of 68 years, with basal median AST and ALT of 32,5 and 29 IU/L respectively and basal FIB-4 and APRI of 1,4 and 0,3, respectively. **Conclusion:** A low percentage of individual's are screened for hepatitis C in primary care centers. The majority of those tested positive for anti-HCV antibodies are not viremic.

1812-A | CASCADE OF CARE FOR CHRONIC HEPATITIS C IN SOUTH KOREA: A STUDY ON TREATMENT UPTAKE AND BARRIERS

Sang Bong Ahn[1], Dae Won Jun[2], Joo Hyun Oh[3] and Eileen Yoon[2], (1)Nowon Eulji Medical Center, (2) Hanyang University College of Medicine, (3)Eulji Medical Center

Background: The World Health Organization has set ambitious targets for the elimination of hepatitis C virus (HCV) by 2030, aiming to diagnose 90% of people with HCV and treat 80% of those diagnosed. However, significant barriers hinder progress in accessing affordable HCV testing, direct-acting antiviral (DAA) treatment, and effective patient linkage to HCV care. The HCV care cascade plays a crucial role in improving treatment rates. This study aims to examine the cascade of care for chronic hepatitis C patients in South Korea and identify factors impeding treatment.

Methods: We conducted an analysis using data from the Korea Disease Control and Prevention Agency, which registered 8,810 patients with chronic hepatitis C in 2019. We collected and analyzed baseline characteristics, income levels, healthcare facility utilization, actual treatment status, comorbidities, and laboratory test results. **Results:** The proportions of patients diagnosed at primary, secondary, and tertiary healthcare facilities were 26%, 53%, and 21%, respectively. Among all diagnosed patients, 41% did not receive actual treatment. Treatment rates were 11.5% at primary healthcare facilities and 47.3% and 59.4% at secondary and tertiary healthcare facilities, respectively, for patients diagnosed at these respective levels. Among patients diagnosed at primary healthcare facilities, 60% were referred to higher-level facilities, and 80% of those referred received treatment. Treatment rates did not significantly differ by region, but the lowest income group (below 25%) exhibited lower treatment rates. However, income level did not show a proportional relationship with treatment rates. Treatment rates were also lower for elderly patients, those with underlying comorbidity, and patients with liver cirrhosis. **Conclusion:** Treatment uptake for chronic hepatitis C in South Korea falls below optimal levels, posing a challenge to achieving the goal of HCV elimination. Efforts are needed to address barriers that reduce treatment rates and improve the cascade of care for HCV patients.

1813-A | CHANGES OF ADIPONECTIN-LEPTIN RATIO IN CHRONIC HEPATITIS C PATIENTS BEFORE AND AFTER DAA THERAPY: A PROSPECTIVE, MULTICENTER STUDY IN KOREA

Jung Hoon Yoo, Seoul National University Bundang Hospital and Gwang Hyeon Choi, Seoul National University Bundang Hospital, Seoul National University College of Medicine

Background: Some studies suggested an increase of hepatic steatosis after achieving sustained virological response (SVR) in patients with chronic hepatitis C. Recently, adiponectin-leptin (A-L) ratio is proposed as a predictor of CVD risk. Therefore, we investigated the plasma levels of A-L ratio in the Korean chronic hepatitis C patients treated with DAA at 3 time points of pretreatment (PreTx), end-of treatment (EOT) and SVR12. **Methods:** Using a prospectively collected 179 plasma samples at the 3 time points from 179 patients with chronic hepatitis C virus (HCV) infection who were treated with direct acting antivirals (DAAs) (mean age 59.9, 50.3% of female, 29.7% of cirrhosis) enrolled in 8 hospitals from Mar 2020 to Jan 2022, adiponectin and leptin levels were measured and compared. In addition, factors related to low A-L ratio < 0.5, which can be considered high cardiometabolic risk, were analysed. **Results:** All 179 patients achieved SVR12. The A-L ratio showed negative association with pretreatment HCV RNA ($R = -0.28$, $p = 0.017$) and body mass index (BMI, $R = -0.5$, $p < 0.001$). The median plasma leptin level showed a transient increase of leptin level at EOT compared to PreTx (6.0, 6.6, and 6.0 ng/mL, respectively). The median plasma adiponectin level showed a significant decrease at SVR12 than PreTx level (4.0, 4.1, and 3.5 ug/mL, respectively). The median A-L ratio showed a significant decrease at EOT and SVR12 than preTx level (0.63, 0.63, and 0.56, respectively) The proportion of high CV risk groups with an A-L ratio < 0.5 significantly increased to 39.1%, 44.1%, and 47.2% at PreTx, EOT and SVR12, respectively ($p = 0.006$). Among normal A-L group ($n = 109$), pretreatment A-L ratio (OR 0.33, $p = 0.024$) and BMI is independently associated with transition to low A-L ratio group at SVR12 (OR 1.23, $p = 0.048$). **Conclusion:** During DAA therapy and achieving SVR, plasma A/L ratio tended to decrease, suggesting potential CV risk after DAA treatment.

1814-A | CHEMOPREVENTIVE EFFECT OF METFORMIN AND STATIN ON RISK OF HEPATOCELLULAR CARCINOMA AMONG CHRONIC HEPATITIS C PATIENTS WHO FAILED TO ANTIVIRAL THERAPY

Pei-Chien Tsai[1], Chung-Feng Huang[1], Ming-Lung Yu[1,2] and T-COACH Study Group, (1)Hepatobiliary Section, Department of Internal Medicine, and Hepatitis Center, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, (2)School of Medicine and Doctoral Program of Clinical and Experimental Medicine, College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-Sen University, Kaohsiung, Taiwan

Background: Chronic hepatitis C (CHC) patients who failed antiviral therapy are at high risk of hepatocellular carcinoma (HCC), especially among patients with diabetes mellitus (DM). We aimed to investigate if metformin or/and statin can reduce HCC risk among CHC patients with DM and/or hyperlipidemia (HLP) who failed antiviral therapy. **Methods:** CHC patients who failed interferon-based therapy were enrolled in a large-scale, multicenter cohort in Taiwan (T-COACH). HCC 1.5-year after interferon-based therapy was identified by linking to the cancer registry databases from 2003 to

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

2019. After considering death and liver transplant as competing risks, Gray's cumulative incidence method and Cox subdistribution hazards for HCC development were used. **Results:** Of 2,779 CHC interferon-failed patients, 480 (17.3%) developed new-onset HCC after antiviral therapy. Patients with DM who did not use metformin had a 1.5-fold higher risk of HCC, while those with HLP who used statins had a 47% lower risk of HCC. We redefined HCC risk levels as high-, intermediate-, and low-risk based on the risk number of DM risk [DM non-metformin] and lipid risk [HLP non-statin or non-HLP]. Annual incidence rates of HCC were 519.7 per 10,000 person-years for patients with both risks, 275.2 for patients with only lipid risk, and 117.7 for patients with only sugar risk or no risk. After adjusting for confounding factors, patients with both risks had a 3-fold higher risk of developing HCC, while patients with only lipid risk had a 2-fold higher risk compared to patients with only sugar risk or no risk. **Conclusion:** Among non-SVR CHC patients, metformin use in DM patients or statin use in HLP patients significantly reduced HCC risk after antiviral therapy. A simple risk score based on DM non-metformin use at high risk and HLP statin use at low risk could predict the new-onset HCC among those patients.

1815-A | COLLABORATIVE IN-HOSPITAL HCV MICRO-ELIMINATION MODEL AND CALL BACK STRATEGY FOR DIAGNOSED BUT UNTREATED PATIENTS IN CHINA

Chunfang You, Yangyang Pu, Wei Deng, Jing Tang, Chunqi Zheng, Xuerong Wang, Yibei Li, Dan Song, Jie Wang and Juan Tang, The First People's Hospital of Zigong, Sichuan, China

Background: We explored an in-hospital and outside hospital model targeting HCV elimination in a tier 3 city in China. The study aimed to evaluate the HCV screening, linkage to care and treatment outcomes with Sofosbuvir/Velpatasvir(SOF/VEL) treatment. **Methods:** The First People's Hospital of Zigong City initiated the collaborative HCV micro-elimination model (in-hospital action plan and call-back program). For the in-hospital patients, all the inpatients and outpatients received HCV screening. Those with anti-HCV positive results would come out pop-up window by operation systems to remind patients to infectious disease (ID) department to receive HCV RNA testing and receive 12-week SOF/VEL treatment if HCV viremic (Figure 1). On the other side, for all the individual's with anti-HCV positive result but untreated, the local primary community hospital called them back. Free HCV RNA testing and HCV education was provided. HCV viremic patients could be linked to the ID specialists once confirmed. With pre-treatment assessment, patients could receive reimbursed SOF/VEL within 1 day. Rate of screening, diagnosis and linkage to treatment would be report back to CDC (Figure 2). **Results:** For in-hospital action plan, a total of 26,235 patients received HCV screening from January to April 2023 and 492 anti-HCV positive individual's were identified. 92%(453/492) patients received HCV RNA testing. 165 patients were HCV viremic and 82.4%(136/165) initiated SOF/VEL treatment. All the patients were under treatment period and follow-up. Before in-hospital model established, only 49.8%(147/295) patients received HCV RNA testing and 74 were HCV RNA positive. The rate of link-to-treatment was only 55.4%(41/74), and 97.6%(40/41) achieved SVR12 after SOF/VEL treatment. For the call-back program, during January to April 2023, a total of 23%(500/2200) patients with anti-HCV(+) were re-linked to care and received HCV RNA testing. 38%(189/500) were HCV RNA positive. 21%(40/189) patients initiated SOF/VEL treatment. **Conclusion:** Screening number and rate of link-to-treatment were significantly improved after cooperation model established. This model could help targeting HCV elimination in low-level cities.

1816-A | COMPARISON OF HEPATITIS C VIRUS ANTIBODY SCREENING STRATEGIES IN VARIOUS COMMUNITY AND CLINICAL SETTINGS IN ONTARIO, CANADA

Grishma Hirode[1], Brett Wolfson-Stofko[1], Aaron Vanderhoff[1], Camelia Capraru[1], Joel Karkada[1], David Smookler[1], Steven M Friedman[2], Kathy Bates[3], Tony Mazzulli[4,5], Joshua V. Juan[6], Hemant A. Shah[1], Bettina E. Hansen[7], Harry L. A. Janssen[7], Mia Biondi[1,8] and Jordan J. Feld[1], (1)Toronto Centre for Liver Disease/ Viral Hepatitis Care Network (VIRCAN), University Health Network, Toronto, Canada, (2)Department of Emergency Medicine, University Health Network, Toronto, Canada, (3)Emergency Department, Toronto Western Hospital, University Health Network, Toronto, Canada, (4)Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Canada, (5)Department of Microbiology, University Health Network/Mount Sinai Health System, Toronto, Canada, (6)Albany Medical Clinic, Albany, NY, (7)Erasmus MC, University Medical Center Rotterdam, (8)School of Nursing, York University, Toronto, Canada

Background: Extensive hepatitis C virus (HCV) screening and linkage to care with ongoing patient engagement is vital to prevent transmission and progression to advanced liver disease. Current strategies largely focus on risk-based and population-based screening rather than testing modality. We aimed to analyze the effectiveness of different types of HCV antibody (Ab) testing including point-of-care tests (POC), dried blood spot collection cards (DBS), and phlebotomy-based serologic tests (ST) conducted in a large, real-world cohort across diverse clinical and community settings in Ontario, Canada. **Methods:** Cross-sectional study of individual's who completed HCV Ab testing at various centers in partnership with the Viral Hepatitis Care Network (VIRCAN). HCV RNA testing used DBS for POC and DBS Ab, and phlebotomy-based tests for ST (no reflex testing). Similar to ST, turnaround time for DBS was ~2 weeks for Ab and RNA. Test settings included primary care or HIV pre-exposure prophylaxis clinics (PC/PrEP), emergency department or walk-in clinics (ED/walk-in), one-time screening events (SE), community outreach programs (CO), and drug treatment centres (DC). **Results:** Among 26,478 individual's HCV Ab tested, 36% were POC, 9% were DBS, and 55% were ST (figure). By setting, SE, CO, and AC largely used POC (**e** 95%), PC/PrEP used ST (92%), and ED/walk-in used a combination of POC (38%) and DBS (62%). Overall HCV Ab prevalence was 5.4% (n = 1,431); 13% among POC, 3% among DBS, and 0.9% among ST. Among HCV Ab positives, 62% were newly identified infections of which 79% were POC (n = 708), 7% were DBS (n = 58), and 14% were ST (n = 122). After an HCV Ab positive test, POC and DBS had higher proportions of RNA tests completed compared to ST. After an HCV RNA positive test result, POC had better engagement in the cascade of care compared to DBS, particularly in setting the first appointment across settings. No linkage to care data was available for ST. **Conclusion:** POC and DBS are feasible and effective alternatives to conventional screening methods and improve linkage to care. POC Ab testing was most effective for identifying new HCV Ab infections but POC and DBS both improved HCV RNA testing compared to ST. Quicker turnaround using POC likely increased patient engagement by efficiently setting up the first appointment after an RNA positive result. Given that the type of Ab test was closely related to setting and available resources, matching the optimal Ab screening modality to the test setting will be critical to reach elimination targets.

1817-A | COMPLEXITY OF HCV PATIENTS ATTENDED AT ADDICTION SETTING IN REAL-WORLD PRACTICE. RESULTS FROM COMPLEXADIC STUDY

Francisco Pascual Pastor[1], Rosario Ballesta Gómez[2], Juan Jesus Ruiz[3], Joan Colom[4], María Yébenes[5] and Miguel Angel Casado[5], (1)Socidrogalcohol, (2)Jefatura De Inclusión Social y Gestión Del Conocimiento De La Agencia De Servicios Sociales y Dependencia De Andalucía, (3)Centro Provincial De Drogodependencias (CPD) De Málaga, Diputación De Málaga, (4) Subdirector General De Adicciones, VIH, Its y Hepatitis Víricas. Agència De Salut Pública De Catalunya. Generalitat De Catalunya, (5)Pharmacoeconomics & Outcomes Research Iberia (PORIB)

Background: To achieve WHO HCV elimination is necessary to target people who use drugs. Complexadic study aimed to describe the profile of user with HCV at addiction center (AC) to understand their special needs and to guide it toward HCV elimination. **Methods:** Anonymous, online, cross-sectional survey aimed at healthcare professionals (HP) from AC with experience in addictive disorders patients in Spain. All addiction specialists belonging to AC that attended at least 50 drug users/year were considered. The survey collected characteristics of HCV patients attended at AC and their patient´s journey. The survey questions were answered by HP based on their last 3 years of experience, without reviewing the patient's medical record. **Results:** Eighty questionnaires were included in the analysis. More than half (58%) of users with HCV were on opioid substitution treatment and 28% were injecting drug users. The main illegal substances consumed were cannabis (53%) and heroin (45%). The mean age of the patients was 45 years; 85% were men. 51% presented psychiatric comorbidities: major depressive disorder (36% of patients), anxiety (35%) and personality disorders (31%). The most frequent organic pathologies were pulmonary disease and HIV (both 23%) and heart disease (10%). Polypharmacy was common, with 67% of patients receiving 3 or more medications. 49% take more substances or medications than they say at the first visit. According to the most important characteristics of HCV medication that could have an impact on adherence and persistence of addiction patients, HP highlighted efficacy even if the

patient forget any dose, number of tablets per day and treatment duration (50.8%, 35.8% and 26.2% of professionals rated each characteristic individually, respectively). When HP were asked about the combined characteristics of HCV medication that best suited the addiction patient profile, 77.5% selected the therapeutic option of one tablet/day, with or without meal co-administration for 12 weeks, while the remining 22.5% selected the option of 3 tablets/day (single dose), with meal co-administration, for 8 weeks ($p < 0.001$). **Conclusion:** HCV drug users present a complex profile, including organic, addictive, and psychosocial problems that require an interdisciplinary approach. HCV treatment simplifications would be key to favour treatment adherence and persistence. Integrating AC into the health circuit is key to achieve the elimination of HCV in these patients

1818-A | CONQUERING HEPATITIS VIA MICRO-ELIMINATION (CHIME) PROGRAM FOR CHRONIC HEPATITIS C INFECTION IN HIGH-RISK POPULATIONS IN HONG KONG: FINAL RESULTS

Lung Yi Mak[1], Wai Pan To[2], Vivien Tsui[2], Ka-Yin Hui[2], Trevor Kwan-Hung Wu[2], Anthony Kwok[2], Kwan-Lung Ko[2], Danny Ka-Ho Wong[1], Siu-Yin Wong[2], Kevin Sze Hang Liu[1], Wai-Kay Seto[3] and Man-Fung Yuen[4], (1) Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, (2)The University of Hong Kong, (3)Department of Medicine, School of Clinical Medicine, the University of Hong Kong, (4)State Key Laboratory of Liver Research, the University of Hong Kong, Hong Kong SAR

Background: To achieve elimination of hepatitis C virus (HCV) infection, targeted screening of HCV among high-risk groups is a reasonable approach. We aimed to screen for HCV and provide linkage to care (LTC) for high-risk populations in Hong Kong. **Methods:** Between 2019 and 2021, we initiated the Conquering Hepatitis vIa Micro-Elimination (CHIME) program involving outreach visits to halfway house or drug rehabilitation centers run by non-governmental organizations in Hong Kong. Subjects with history of illicit drug use, needle sharing, or prior imprisonment were included. We performed point-of-care (POC) test for antibody to HCV (anti-HCV), and reflex HCV RNA testing by formal venipuncture. Viraemic subjects were invited to attend the LTC clinic for counselling and treatment with direct acting antiviral (DAA). **Results:** 22 site visits were conducted and 396 subjects were screened. A total of 229 subjects had positive POC (57.8% anti-HCV+), while 187 subjects were found to have HCV infection (47.2% RNA+). Among 187 viraemic subjects, 128 (68.4%) attended LTC (median waiting time: 23.9 weeks) and 59 (31.6%) defaulted the clinic visits. The median age was 50 (interquartile range, 43-57), with 93% male; 79.7% reported needle sharing. All of them were smokers and heterosexual, with the majority of them having multiple sexual partners (74.3%), being unmarried (69.5%), heavy drinkers (53.1%), and with history of tattoos (54.7%). All of them were willing to receive DAA treatment, although only 44.5% was aware of HCV infection prior to the program. The most predominant genotype was 6 (58.6%) (Figure 1A). Two-thirds (70.3%) had abnormal alanine aminotransferase (ALT) and 16.4% subjects were cirrhotic (defined by liver stiffness **e** 12.5 kPa at transient elastography, with only 1 being Child Pugh class B/C). Co-infection with hepatitis B virus was found in 4.7%. Post-treatment blood was checked in 102 subjects (default rate 20.3%), with sustained virological response (SVR) achieved in 97.1% (99/102); Figure 1B. No serious side effects were reported, and 90% achieved normalization of ALT after DAA. **Conclusion:** The CHIME program successfully identified high risk populations with HCV in Hong Kong. The prevalence of chronic HCV is > 45% with distinct socio-demographic features. Although these subjects are prone to non-engagement, for those who were successfully linked to the care system, all had high intention to receive treatment which resulted in a high rate of SVR. Figure legend: 1A: Genotype distribution among HCV+ subjects attending the LTC clinic 1B: Proportion of subjects with active HCV infection, being linked to care, and achieved SVR12

1819-A | COST-EFFECTIVENESS AND HEALTH-RELATED OUTCOMES OF ONE-TIME SCREENING AND TREATMENT FOR HEPATITIS C IN KOREAN POPULATION: A PILOT PROJECT FOR HEPATITIS C SCREENING

Young Chang, Soonchunhyang University

Background: As a part of a pilot project for early detection of hepatitis C patients in Korea, hepatitis C screening was temporarily performed in 56-year-old general population in Korea. This study investigated the cost-effectiveness of one-time screening and treatment strategy for hepatitis C patients as compared to no screening or risk-based screening strategies. **Methods:** From September 1, 2020 to October 31, 2020, 56-year-old general Korean population received hepatitis C virus (HCV) antibody (Ab) tests at the national general health checkup, followed by HCV RNA tests for HCV Ab-positive subjects as a confirmatory test. To model different screening and treatment strategies for hepatitis C patients, a Markov disease progression model with screening and treatment decision tree was used. The screening strategies included "Scree-all", "Risk-based screening", and "No screening" strategies followed by treatment. Treatment strategies included 8 or 12 weeks of ledipasvir/sofosbuvir and 8 weeks of glecaprevir/

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

pibrentasvir. Model inputs were primarily sourced from the results of the hepatitis C screening pilot project, and from published literature. **Results:** A total of 133,705 subject, 104,918 subjects received hepatitis C screening test with acceptability of screening rate of 78.47%. Of the 104,918 examinees, 792 cases (0.75%) were positive for HCV Ab and 189 cases (0.18%) were positive for HCV RNA. The acceptability of treatment is estimated to be 70.34% based on the results of the survey. In cost-effective analyses, the screen-all strategy led to the lowest rates of advanced liver disease events. When screening with the screen-all strategy, compared to the no-screening strategy, compensated cirrhosis was expected to decrease by 50%, decompensated cirrhosis by 48%, hepatocellular carcinoma by 49%, liver transplantation by 43%, and death by 49%. The incremental cost-effectiveness ratio (ICER) of the screen-all strategy compared to the no screening strategy was $7,258/quality-adjusted life-year (QALY), which was much lower than the cost-effectiveness threshold of gross domestic product per capita, $31,846. When compared with the risk-based strategy, the screen-all strategy was consistently cost-effective with ICER of $7,080/QALY. In both deterministic and probabilistic sensitivity analyses, the cost-effectiveness of the screen-all strategy over the no screening or risk-based screening strategies was robust in all situations. **Conclusion:** Screening all 56-aged Korean population once followed by effective treatment is expected to reduce the incidence of adverse liver disease and is cost-effective when compared with risk-based screening or no screening.

1820-A | DEVELOPMENT AND VALIDATION A RISK MODEL OF HEPATOCELLULAR CARCINOMA FOR PATIENTS WITH ADVANCED FIBROSIS AND CIRRHOSIS WHO ACHIEVED SUSTAINED HCV CLEARANCE

Shanshan Xu[1], Lixia Qiu[1] and Jing Zhang[2], (1)Beijing Youan Hospital Capital Medical University, Beijing, China, (2)Beijing Youan Hospital, Capital Medical University

Background: Hepatitis C patients with advanced fibrosis or cirrhosis are at high risk of developing hepatocellular carcinoma (HCC) even after sustained virological response (SVR). Clinical guidelines recommend lifelong screening for HCC every six months, which places a heavy burden on them. We aimed to stratify the risk of HCC accurately and refine the current screening strategy. **Methods:** A total of 551 adult hepatitis C patients with baseline advanced fibrosis or cirrhosis after SVR were included and followed-up every six months. The patients were randomized into a derivation cohort (70%, n = 385) and an internal validation cohort (30%, n = 166). A total of 221 similar patients from another hospital served as the external validation cohort. Demographic data, medical history, and laboratory results were recorded. HCC was diagnosed using radiography, alpha-fetoprotein (AFP), or liver histology. Advanced fibrosis and cirrhosis were diagnosed by liver stiffness measurement (LSM) or clinical manifestations. **Results:** The derivation cohort's median follow-up period was 66.60 ± 12.28 months, during which 37 (9.61%) patients developed HCC. Older age (HR: 1.08, 95% CI 1.01-1.15, $p = 0.029$), male gender (HR: 2.41, 95% CI 1.15-5.03, $p = 0.020$), baseline serum albumin levels (HR: 0.88, 95% CI 0.82-0.94, $p = 0.000$), and LSM (HR: 1.02, 95% CI 1.00-1.05, $p = 0.032$) were all independent predictors of HCC development. The derivation cohort's Harrell's C-index was 0.81. The time-dependent AUROC of the model at 3-, 5- and 7-year were 0.84 (95% CI 0.80-0.88), 0.83 (95% CI 0.79-0.87) and 0.81 (95% CI 0.77-0.85), respectively ($p > 0.05$). Patients could be classified as low, intermediate, or high risk based on the prediction model. The three groups had annual HCC incidence rates of 0.18%, 1.29%, and 4.45%, respectively ($p < 0.05$). **Conclusion:** We developed and validated a model for predicting HCC risk in patients with advanced fibrosis or cirrhosis at baseline and after SVR. The model can stratify patients based on their HCC risk and, as a result, determine an appropriate screening strategy based on their HCC risk.

1821-A | DIFFERENCES IN BASELINE CHARACTERISTICS OF DIRECT ACTING ANTIVIRAL (DAA)-TREATED GREEK HCV PATIENTS ACCORDING TO SOURCE OF INFECTION

Spyros Siakavellas[1], Charikleia Kranidioti[1], Anastasia Kourikou[1], Charalampos Karageorgos[1], Anestis

Goulas[1], Sofia Vasileiadi[1], Georgios Kontos[1], Nikolaos Papadopoulos[1], Maria Melanie Deutsch[1], Spilios Manolakopoulos[1] and Heraclis Authors Group, (1) Geniko Nosokomeio Athinon "Hippokratio" Athens, Greece

Background: With the introduction of direct-antiviral medication (DAAs), eradication of HCV infection is considered now an achievable goal. While people with history of drug use (PWHD) form the most common population at risk for the infection, in Greece historically there has been a significant proportion of patients arising from the general population with no prior drug use. These two different subgroups exhibit different characteristics, that may be pertinent in the management of HCV infection and long-term follow up. The aim of this study was to identify potential differences in the makeup of these two HCV patient subgroups. **Methods:** The HERACLIS cohort, is the largest national HCV registry of patients treated with DAAs in tertiary liver centers from 2015 until 2022. Clinical data and characteristics were obtained from medical records, while transient elastography (TE) measurements and APRI and FIB-4 score calculations were conducted at baseline. Patients were followed up initially for the duration of their treatment. **Results:** 680 patients were included in the study, 70.9% (n = 482) of them were men with median age 50.8 years old and 13.6% of these had decompensated liver disease at DAA initiation. 62% (n = 422) of this cohort were PWHD, while the rest had been infected in another manner (nonPWHD). When comparing these two populations, PWHD were younger in age (47.3 ± 9.8 vs 56.3 ± 12.8 years, $p < 0.001$) and with lower BMI (24.3 ± 4.2 vs 26.1 ± 4.6 kg/m2, $p < 0.001$). NonPWHD cases had more often diabetes (4.9% vs 1.3%, $p < 0.001$), hypertension (10.7% vs 8.8%, $p < 0.001$) as well as decompensated liver disease (8.0% vs 5.6%, $p < 0.001$). This was also reflected by TE measurements (14.6 ± 11.1 vs 11.3 ± 7.9 kPa, $p = 0.001$) and FIB-4 score calculations (2.8 ± 2.6 vs 2.2 ± 4.0 vs, $p < 0.001$) but not by the APRI score. Moreover, PWHD patients tended to have been more often infected with genotype 3 (36.8% vs 8.8%, $p < 0.001$) while for other genotypes no such stark differences were observed. There was no significant variance observed regarding DAA regimen use but non-PWHD patients tended to suffer more often from adverse events secondary to DAA treatment (1.6% vs 0.3%, $p = 0.001$). **Conclusion:** The Greek PWHD and non-PWHD populations of HCV patients seem to exhibit different baseline characteristics which may be relevant to treatment selection and long-term follow up regimens. The main differences observed imply the concomitant presence of an element of metabolic syndrome in the non-PWHD cohort with a subsequent potential effect on the degree of underlying liver fibrosis.

Disclosures: The following people have nothing to disclose: Spyros Siakavellas, Charikleia Kranidioti, Anastasia Kourikou, Charalampos Karageorgos, Anestis Goulas, Sofia Vasileiadi, Georgios Kontos, Nikolaos Papadopoulos, Maria Melanie Deutsch, Spilios Manolakopoulos

1822-A | ETHNIC DISPARITIES IN HCV-RELATED EXTRAHEPATIC MANIFESTATIONS: A POPULATION-BASED STUDY IN BRITISH COLUMBIA, CANADA

Dahn Jeong[1], Stanley Wong[2], Héctor Alexander Velásquez García[1,3], Prince Asumadu Adu[3], Jean Damascene Makuza[1], Sofia R. Bartlett[1,3], Eric M. Yoshida[1], Alnoor Ramji[4], Mawuena Binka[3], Amee R. Manges[1,3], Mohammad Ehsanul Karim[1,5], Amanda Yu[2], Maria Jose Alvarez[2], Mel Krajden[1,2] and Naveed Zafar Janjua[1,2], (1)University of British Columbia, (2)BC Centre for Disease Control, (3)British Columbia Centre for Disease Control, (4)Division of Gastroenterology, University of British Columbia, BC, Canada, (5)St. Paul's Hospital

Background: Chronic hepatitis C virus (HCV) infection often leads to extrahepatic manifestations (EHMs). The risk of EHMs may vary among different ethnic groups due to biological differences and socioeconomic disparities. We examined the differing risk of EHMs in people with chronic HCV, focusing on people of East Asian and South Asian backgrounds in British Columbia (BC), Canada. **Methods:** Using the BC Hepatitis Testers Cohort (BC-HTC) comprising ~1.3 million people tested for HCV from 1990-2015 with linked health administrative data, we identified those diagnosed with chronic HCV infection by March 31, 2020. Participants were followed from their first HCV diagnosis date until incident EHM, death, or study end date (March 31, 2021). We assessed incident chronic kidney disease (CKD), type 2 diabetes (DM), major adverse cardiac events (MACE) and neurocognitive disorders (NCD; dementia, delirium and Alzheimer's disease) using ICD-9/10 diagnostic and procedure codes and treatment dispensation data. Ethnicity was determined based on first and last name using a name recognition software (> 98% specificity for East and South Asian). Persons with prevalent conditions were excluded from analysis for the specific EHM. Cumulative incidence rates were calculated for each ethnic group (East Asian, South Asian, and Other) by HCV treatment status. Multivariable cause-specific competing risk models were used to estimate EHM risks, adjusting for time-varying HCV treatment status, competing mortality risk, and baseline sociodemographic and clinical characteristics. **Results:** The study included 1,372 East Asians, 1,390

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

South Asians and 37,680 persons of other backgrounds diagnosed with chronic HCV in the BC-HTC. Incident EHMs were more frequent among untreated individual's overall, except for type 2 diabetes. Untreated South Asians had the highest EHM rates per 1000 person-years: CKD (Other 9.1, East Asian 12.5, South Asian 17.3); DM (Other 5.0, East Asian 8.4, South Asian 11.4); MACE (Other 11.6, East Asian 15.0, South Asian 16.2); NCD (Other 9.2, East Asian 9.1, South Asian 10.8). In the multivariable models, compared to untreated Others, untreated South Asians had a higher risk of CKD (adjusted cause-specific hazard ratio [aCSHR] 1.26, 95%CI 1.01-1.57), while treatment reduced the risk for all groups. South Asians had the highest risk of DM (untreated aCSHR 2.03, 95%CI 1.50-2.74; treated aCSHR 1.87, 95%CI 1.50-2.34), compared to untreated Others. East Asians had a lower risk of MACE and NCD compared to Others. **Conclusion:** In British Columbia, East and South Asians with chronic HCV had a differing risk of developing EHMs, particularly elevated for chronic kidney diseases and type 2 diabetes. HCV treatment was able to reduce the risk for incident CKD and MACE but not for type 2 diabetes among South Asians. Tailored interventions and screening programs may benefit East and South Asians living with HCV infection.

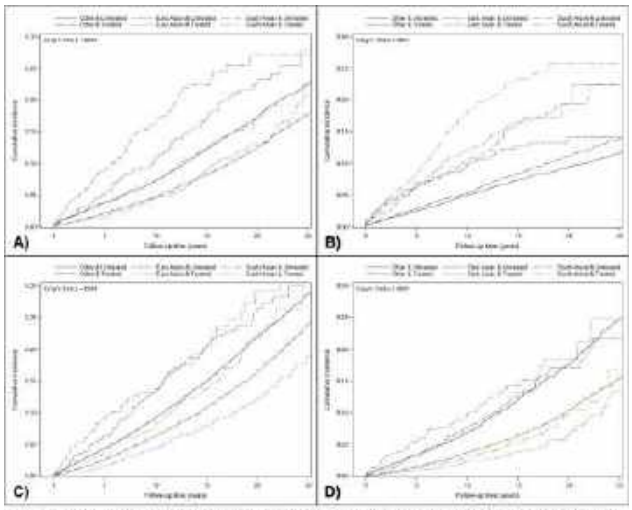

Figure 1. Cumulative incidence curves by ethnicity and treatment status for A) chronic kidney diseases, B) type 2 diabetes, C) major adverse cardiac events, D) neurocognitive disorders, among people diagnosed with chronic HCV infection in British Columbia, Canada

1823-A | EVALUATION OF AN OPT-OUT UNIVERSAL HEPATITIS C SCREENING PROGRAM IN THE EMERGENCY DEPARTMENT AND URGENT CARE AT A SINGLE VA HEALTHCARE SYSTEM

Huy Ha[1], Yash Motwani[1,2], Jenna H Kawamoto[1], Neaka Mohtashemi[1,2], Cassandra Coleman Lautredou[1,2], Arpan Arun Patel[1,2], Manuel Celedon[1,2] and Debika Bhattacharya[1,2], (1)Greater Los Angeles VA Healthcare System, (2)University of California, Los Angeles

Background: Universal Hepatitis C Virus (HCV) Screening in the US was recommended in 2020. The objectives of this study were to characterize the HCV care cascade in the Emergency Department following implementation of an opt-out universal HCV screening program in the Emergency Department and Urgent Care Center (ED/UCC) at the Veteran's Affairs Greater Los Angeles Healthcare System (VAGLAHCS), identify barriers to linkage to care, and determine associations of HCV viremia. **Methods:** The assessment period was from September 2021 to September 2022. Baseline characteristics of those who were HCV antibody (Ab) positive were collected, and we identified barriers to linkage to care in those with HCV viremia. We performed Fisher's exact and Chi-square tests to determine associations for HCV viremia. **Results:** 850 Veterans accepted HCV screening. Of the Veterans, 13% (112/850) were HCV Ab positive, and 26% (29/112) had HCV viremia. Of those who were Ab positive, 96% (108/112) were male, 45% (50/112) were White, 42% (47/112) were African American and only 44% (49/112) had stable housing. Regarding comorbid substance use disorder diagnoses, 19% (21/112) had previous or current opioid use disorder, 43% (48/112) had previous or current stimulant use disorder (stimulant UD), and 32% (36/112) had

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

previous or current alcohol use disorder. Ever having a stimulant UD ($p = 0.015$) was associated with HCV viremia. Of those who had HCV viremia, 65% (19/29) were scheduled with the Infectious Disease (ID) and/or Gastroenterology (GI) clinics, 28% (8/29) were evaluated by ID/GI and 10.3% (3/29) were initiated on HCV therapy. The most common reason for non-linkage to care was the inability to reach the Veteran after discharge in 62% (18/29). **Conclusion:** During a 12-month pilot of opt-out universal ED/UCC HCV screening in a Los Angeles VAMC ED, the HCV Ab prevalence was 13% (112/850), higher than in other similar cohorts. A quarter of those Veterans had active HCV infection. In univariate analysis, ever having a stimulant use diagnosis was associated with HCV viremia. Inability to reach Veterans after discharge was common and led to non-linkage to care. This study highlights the importance of point of care HCV screening and subsequent rapid linkage to care, given the high loss to follow up rates. Future research should focus on novel HCV linkage to care interventions for ED patients that minimize immediate loss to follow up.

1824-A | EXPLORING HEPATITIS C VIRUS TRANSMISSION AMONG PEOPLE WHO INJECT DRUGS AND MEN WHO HAVE SEX WITH MEN: RARE AND LIMITED RISK GROUPS IN JAPAN

Zayar Phyo[1], Ko Ko[1], Aya Sugiyama[1], Tomoyuki Akita[1], Kazuaki Takahashi[1], Satoshi Tanaka[2], Ryotaro Sakamori[2] and Junko Tanaka[1], (1)Department of Epidemiology, Infectious Disease Control and Prevention, Graduate School of Biomedical and Health Sciences, Hiroshima University, Japan, (2)National Hospital Organization, Osaka National Hospital, Osaka, Japan

Background: In Japan, people who injects drugs (PWID) and men who have sex with men (MSM) represent small and rare. Although Japan is on track for elimination of hepatitis C virus (HCV) by the World Health Organization's (WHO) 2030 goal, the epidemiology of HCV among PWID and MSM is very limited and poses a remaining challenge. Therefore, this study aimed to examine the potential existence of cross-transmission of HCV infection among PWID and MSM in Japan. **Methods:** This retrospective cohort study was jointly conducted by Hiroshima University and Gastroenterology Department of National Hospital Organization, Osaka, Japan. We recruited HCV infected patients treated at the hospital between January 2009, and February 2023. Patients who visited the hospital from June 2022 to February 2023 were recruited prospectively with informed consent, while patients who had not visited the hospital until June 2022 were recruited retrospectively through opt-out system. We recruited all patients with either PWID or MSM, or both whereas patients with neither PWID nor MSM were randomly recruited. Stored serum samples collected before anti-HCV treatment was analyzed at Hiroshima University. HCV RNA was extracted, full core region (576 base-pairs) was sequenced by Sanger method and genotype distribution was determined by phylogenetic analysis. The study was approved by the Ethics Review Committee of Hiroshima University and Osaka National Hospital. **Results:** The subjects were divided into four groups: 26 Non-MSM PWID, 14 MSM PWID, 22 MSM Non-PWID, and 42 Non-MSM Non-PWID. Out of 104 samples, 94 could be amplified and sequenced. The most common genotype in Non-MSM PWID was 2a (58%), while in MSM PWID, MSM Non-PWID, and Non-MSM Non-PWID groups, it was 1b (82%, 53%, and 73%, respectively). By phylogenetic analysis, cluster cases were found in MSM group regardless of drug abuse (MSM PWID and MSM Non-PWID) but no cluster

case was found in PWID group regardless of homosexuality (MSM PWID and Non-MSM PWID). **Conclusion:** This study explored that MSM group had same HCV transmission route regardless of PWID status, but transmission route was differed in PWID group regardless of MSM status. MSM status determined the transmission route among PWID. Our study suggests that prioritizing control measures on MSM is more crucial than on the PWID for achieving HCV elimination in Japan.

1825-A | HEALTH OUTCOMES OF HEPATITIS C DIRECT-ACTING ANTIVIRALS: BEYOND REAL LIFE SUSTAINED VIRAL RESPONSE DATA

Gloria Sanchez Antolín, Carmen Alonso Martín, Carolina Almohalla Álvarez, Irene Peñas Herrero and Felix Garcia Pajares, Hospital Universitario Rio Hortega

Background: Hepatitis C (HCV) infection was the leading cause of liver transplantation worldwide, causing significant mortality associated with end-stage liver disease. The appearance in 2015 of HCV direct-acting antivirals (DAAs) for the treatment of Hepatitis C with an efficacy close to 100% has changed the natural history of hepatitis C. Its economic impact conditioned the prioritization of its use, initially in more severe patients. Health results of DAA treatment have been described, such as reducing the liver transplant waiting list, but there are no studies on the impact of DAAs on the activity of health systems. The aim of our study is to find out if new DAA-based treatments for hepatitis C have had an impact on the outcomes of a healthcare system. We analyzed the evolution of hospital discharges of patients with a primary diagnosis of hepatitis C, hospital discharges for hepatocellular carcinoma, and hospital discharges for other causes with an additional diagnosis of hepatitis C. **Methods:** The number of hospital discharges from 2012 to 2022 was analyzed, selecting patients with hepatitis C as primary or secondary diagnosis. The information of the admitted patients was obtained from the minimum basic set of hospital discharge data. We also analyzed the average number of discharges due to hepatocellular carcinoma or bile duct neoplasm in the same period and compared the average number of discharges for the period 2012-2015 with the average for 2016-2020. **Results:** Hospital discharges associated with HCV infection decreased progressively from 2015 to 2022. The average number of discharges in the period 2012-2015 was significantly higher than that of 2016-2020 for patients admitted for any reason with a diagnosis of hepatitis C associated (2327.5 vs. 1505.2, $p < 0.005$). The mean number of discharges due to hepatocarcinoma and cholangiocarcinoma was also significantly higher in the first period (95.5 vs. 72.8, $p < 0.05$). The % variation of hospital discharges compared to 2012 was -32.74% in 2015, -40.93% in 2016, -44.84 in 2017, -55.52% in 2018, -53.38 in 2019 and -61 .57% in 2020. The average age ranged from 54 years old in the 2012-2015 period to 57 in the 2016-2020 period. **Conclusion:** The introduction of direct-acting antivirals (DAAs) for the treatment of chronic hepatitis C infection (HCC) has led to a significant decrease in the number of hospital discharges for hepatitis C-related diseases. The variation in hospital discharges since 2012 represents a drop of up to 60% in 2022. A progressive decrease in the number of discharges due to hepatocellular carcinoma and other causes with an additional diagnosis of HCV was also demonstrated. Most of the hospital discharges of patients with HCV due to other causes were classified in ICD10 group 9: diseases of the digestive system, followed by group 1: infectious and parasitic diseases, and group 2: neoplasms. Our study demonstrates the efficacy of DAAs on health outcomes.

1826-A | HEPATITIS C CIRRHOSIS IS ASSOCIATED WITH AN INCREASED RISK OF DEVELOPING GASTROESOPHAGEAL REFLUX DISEASE AND ITS COMPLICATIONS: RESULTS FROM A NATIONAL HEALTHCARE DATABASE

Samantha Mathialagan[1], Benjamin Liu[2] and Gengqing Song[2], (1)Metrohealth/Case Western Reserve University, (2)Case Western Reserve University/Metrohealth

HEPATITIS C CIRRHOSIS IS ASSOCIATED WITH INCREASED RISK OF DEVELOPING GASTROESOPHAGEAL REFLUX DISEASE AND ITS COMPLICATIONS: RESULTS FROM A NATIONAL HEALTHCARE DATABASE Samantha, Mathialagan[1] MD, Benjamin Liu[1] MD, Gengqing Song[1] MD [1]Department of Medicine, Case Western Reserve University/MetroHealth **Background:** Gastroesophageal reflux disease (GERD) related symptoms frequently occur in patients with liver disease, yet limited data is available on the impact of liver cirrhosis on the development of GERD and its complications in patients with chronic hepatitis C viral infection. Our study aimed to evaluate whether patients with cirrhosis secondary to hepatitis C virus were at increased risk of developing GERD, esophagitis, Barrett's esophagus and esophageal strictures, compared to

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients with hepatitis C who had not developed cirrhosis. **Methods:** To study this, we utilized TriNetX, a global health research platform, to develop a retrospective query across 55 healthcare organizations in the United States. The control group and treatment group consist of patients at index event who meet the criteria of chronic viral hepatitis C, or hepatitis C virus RNA in serum or plasma. Patients in the treatment group were eligible for inclusion if they met the criteria for cirrhosis and one of the criteria for chronic hepatitis C and were excluded if they had a diagnosis of hepatic failure or ascites. Patients in the control group were excluded if they had liver cirrhosis. Propensity score matching performed between cohorts controlled for GERD risk factors, including alcohol use, nicotine dependence, T1DM, T2DM, hormone replacement therapy, and hormonal contraceptive for systemic use. We assessed primary outcomes: esophagitis, GERD, esophageal stricture, Barrett's esophagus with and without dysplasia. Odds ratios were calculated within the TriNetX Analytics Platform with significance set at a 2-sided P value < 0.05. **Results:** After propensity matching, there were a total of 91,444 patients in both the treatment and control cohorts. Patients with hepatitis C cirrhosis were more likely to experience GERD (OR 1.088; 95% CI 1.064 - 1,114), erosive esophagitis (OR 1.365; 95% CI 1.273 - 1.444), esophageal stricture (OR 1.336; 95% CI 1.206 - 1.479), and Barrett's esophagus without dysplasia (OR 1.440; 95% CI 1.319 - 1.573), and Barrett's esophagus with dysplasia (OR 1.510; 95% CI 1.191 - 1.913) compared to the control group chronic hepatitis C patients without cirrhosis, ($p < 0.0001$). **Conclusion:** Our findings suggest that cirrhosis resulting from chronic hepatitis C infection is associated with an increased odds of developing GERD and its complications, including esophageal strictures and Barrett's esophagus. Additional research studies are required to elucidate the relationship between cirrhosis in patients with chronic hepatitis C virus and the development of esophagitis.

1827-A | HEPATITIS C ELIMINATION IN NANFANG HOSPITAL - PROACTIVE MANAGEMENT TO PREVENT LOSS OF EVERY HEPATITIS C PATIENT

Yuyuan Xu, Suling Chen, Chunxiu Zhong, Junhua Yin and Jie Peng, Nanfang Hospital, Southern Medical University

Background: The World Health Organization has set a goal of eliminating the threat of hepatitis C by 2030. The challenge lies in identifying patients and connecting them to treatment. Hospitals play a crucial role in it. Previous data showed that anti-HCV antibody positive rate of inpatient was 0.88%, higher than general population. Our hospital has established a dedicated team to realize hepatitis C elimination in hospital. **Methods:** Led by the Department of Infectious Diseases, Liver Disease Center at Nanfang Hospital, various departments collaborated on the project. The Liver Disease Center took the lead in developing the core program for proactive management of hepatitis C within the hospital. The key components included daily follow-up by the dedicated hepatitis C team at the Liver Disease Center, expanded screening within the hospital, recalled of previously patients, enhanced disease awareness among non-specialists and patients, established hepatitis C clinics, and more (Figure 1). Multiple departments, channels, and approaches were employed to facilitate comprehensive management of hepatitis C patients starting from the screening stage. **Results:** From March 2021 to March 2023, a total of 5,588,406 outpatient visits and 300,203 discharges were recorded. Anti-HCV antibody was performed on 154,404 individual's, HCV screening rate was 2.62% (154,404/5,888,609). Among them, 1,683 individual's tested positive for Anti-HCV antibody, with a positivity rate of 1.09% (1,683/154,404). It is worth noting that the anti-HCV antibody positivity rate in our hospital (screening data) is higher than 0.43%, the anti-HCV antibody (+) rate in China. The top 10 departments where anti-HCV antibody (+) were identified were as follows: Liver Disease Center (18%), Cardiology (11%), Orthopedics (11%), Gastroenterology (7%), Hepatobiliary Surgery (7%), Interventional Radiology (7%), Neurology (7%), Geriatrics (7%), General Surgery (5%), and Hematology (4%). The HCV RNA detection rate was 80.69% (1,358/1,683), slightly below the year 2025 target of 90% set in our country. 497 individual's tested positive for HCV RNA; the HCV RNA (+) rate was 36.60% (497/1,358). Treatment was initiated in 465 individual's, the treatment rate was 93.56% (465/497), surpassing the target of **e** 80% set in the national action plan. 462 individual's achieved virological cure, with a sustained virologic response rate of 99.35% (462/465). During the implementation process, 99 individual's were lost to follow-

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

up, with the outpatient loss-to-follow-up rate of 16%, higher than the inpatient (2%). **Conclusion:** Currently, hepatitis C treatment rate and the cure rate in our hospital have met the target, but the antibody screening rate and the RNA testing rate still need to be further improved. It is crucial for us to address the issue of loss to follow-up among hepatitis C patients in the outpatient clinic.

1828-A | HEPATITIS C VIRUS INFECTION AND COVID-19 INPATIENT MORTALITY

Spencer Goble, Hennepin Healthcare and Jose D. Debes, University of Minnesota

Background: The impact of chronic hepatitis C virus (HCV) infection on outcomes in patients with COVID-19 remains unclear as studies have showed mixed results. We performed a United States nationwide study to determine if a history of HCV infection impacted outcomes in those hospitalized with COVID-19. **Methods:** We retrospectively assessed hospitalizations for COVID-19 in the year 2020 using the National Inpatient Sample database. ICD-10 codes were used to establish a primary diagnosis of COVID-19 and to determine patients with a history of HCV infection including those with documented chronic infection, acute infection, and HCV carriers. Our study did not include HCV treatment data. Outcomes were compared between those with and without a history of HCV using logistical regression analysis, controlled for age, sex and Charlson Comorbidity Index. **Results:** A total of 1,050,720 hospitalizations for COVID-19 were identified, 8,040 (0.8%) of which occurred in individual's with history of HCV. Those with a history of HCV were younger (mean age 62.1 y vs 64.8 y, $p < 0.001$) more likely to be men (68.2% vs 52.9%, $p < 0.001$), Black (35.2% vs 18.3%, $p < 0.001$) and had a higher burden of comorbid diseases. Mortality (OR = 1.04, 95% CI: 0.90-1.22, $p = 0.549$) and intubation (OR = 1.14, 95% CI: 0.98-1.33, $p = 0.092$) showed an increased trend in those with a positive history for HCV after adjusting for confounders, but the differences were not statistically significant. Mortality was increased in the HCV cohort when it was restricted to those with cirrhosis (adjusted OR = 1.42, 95% CI: 1.05-1.91, $p = 0.023$). **Conclusion:** While cirrhosis increases mortality in those hospitalized with COVID-19, HCV in the absence of cirrhosis does not appear to be a risk factor for COVID-19 related mortality. Disclosures: The following people have nothing to disclose: Spencer Goble, Jose D. Debes

1829-A | HEPATOCELLULAR CARCINOMA RISK IN SPONTANEOUSLY CLEARED HEPATITIS C PATIENTS

Asif Ali Hitawala[1], Elizabeth C. Wright[1], Tomilowo Abijo[1], Kyong-Mi Chang[2], David E. Kaplan[2] and Christine C Hsu[3], (1)National Institute of Diabetes and Digestive and Kidney Diseases, Nih, (2)Division of Gastroenterology and Hepatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA, (3)National Institute of Health

Background: A quarter to a third of patients who acquire hepatitis C infection spontaneously clear. Despite rapid clearance, epigenetic changes of hepatocytes occur and persist. The impact of short-term HCV infection on long-term hepatic outcomes such as hepatocellular carcinoma (HCC) is unknown. We therefore evaluated the long-term HCC risk and associated risk factors in a spontaneously cleared HCV cohort. **Methods:** This is a retrospective study of patients from US Veterans Administration (VA) from 1999-2022 who achieved spontaneous SVR, defined as presence of positive anti-HCV antibody but negative HCV RNA without treatment at the time of initial diagnosis. We excluded patients with baseline diagnosis of cirrhosis, primary biliary cholangitis, primary sclerosing cholangitis, hemochromatosis, alpha-1 antitrypsin, and autoimmune hepatitis, HIV, chronic Hepatitis B, < 1 year of follow-up, HCC within 1 year after diagnosis and missing baseline FIB-4 values. The final cohort was created after further excluding patients with concomitant NAFLD (defined as 2 sets of elevated liver enzymes 6 mo apart with metabolic risk factors) or alcohol use disorder (AUD, based on AUDIT-C **e** 4), and the these were analyzed separately. Univariable and multivariable analyses were performed using Cox proportional hazards model, with FIB-4 as a time-varying variable. All analyses were done using SAS (SAS Institute), and p-value < 0.05 was considered statistically significant. **Results:** Out of 21,154 patients, 421 developed HCC (1.99%) with mean follow-up of 10 ± 5.3 yrs. After excluding patients with NAFLD and AUD, 93 out of 5,882 patients developed HCC at a rate

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of 0.15 per 100 patient-years, with mean follow-up of 10.9 ± 5.4 yrs. On univariable analysis, Hispanic race, elevated baseline ALT and AST, and max FIB-4 within 1 year of initial diagnosis > 1.45 were associated with increased risk of developing HCC. On multivariable analysis, Hispanic race, elevated ALT, max FIB-4 within 1 year of 1.45-3.24 and > 3.25 were associated with increased risk of HCC, even on a time varying scale. In comparison, the rate of HCC of spontaneously cleared HCV patients with NAFLD or AUD was 0.15 and 0.33 per 100 patient-years, respectively, with age **e** 55 years, elevated baseline ALT and AST and FIB-4 **e** 1.45 as significant risk factors in univariable and multivariable analyses for both the latter cohorts. Interestingly, anti-Hepatitis B core antibody positivity was not a significant risk factor for HCC in any cohort. **Conclusion:** There continues to be an increased HCC risk in patients of Hispanic race and those with baseline elevated ALT and FIB-4 levels in patients who have spontaneously cleared HCV. Hence, in patients with baseline elevated FIB-4 > 1.45, Hispanic race, elevated liver enzymes, additional risk-stratification for chronic liver disease and HCC risk is recommended.

Table 1: Univariable and Multivariable Analyses of the Final Cohort

Variable	Univariable Analysis N (%)	N Events	Rate/100 pt-years	HR (95% CI)	p-value	Multivariable Analysis with Stepwise Selection HR (95% CI)	p-value	Time Varying Analysis with Backward Selection HR (95% CI)	p-value

Hospital, Instituto De Biomedicina De Sevilla, Ciberehd, University of Seville, Sevilla, Spain

Background: #HepCityFree is an action launched by the Spanish Alliance for Viral Hepatitis Elimination (AEHVE) to promote the commitment of cities on the elimination of hepatitis C. The goal of the study is to evaluate the response of the Spanish cities to #HepCityFree since its launch in 2020. **Methods:** Compilation of the processes of adherence to #HepCityFree initiated or completed by Spanish cities and the population they cover. Both the constitution and activities developed by the local committees (LC), as well as other awareness results obtained through #HepCityFree were analysed. **Results:** Until November 28, 2022, there are 17 cities adhered to #HepCityFree by agreement of the Government bodies of their Town Halls (Plenary or Governing Boards), which add up to a population of about 7.5 million people. The cities are: Sevilla, Valencia, Santander, Gijón, Granada, Alcoy, Vigo, Madrid, Santiago de Compostela, Ferrol, Pontevedra, León, Córdoba, Salamanca, Écija, Málaga and A Coruña. Moreover, there are another 10 cities completing the process of accession, that add up to another 1.7 million people and 21 LC coordinators (hepatologists and microbiologists) who participate in meetings with council governments for accession and/or starting actions. #HepCityFree has got the support of the Public Health Commission of the Spanish Federation of Municipalities and Provinces (FEMP), which will promote it among their cities from 2023. AEHVE is also involved in the elimination plans of two regional Spanish governments, published in 2022, and incorporated their strategic lines for local entities in accordance with the objectives of #HepCityFree, which has also received the recognition from the Health Commission of the Spanish Parlament. Seven cities (Sevilla, Madrid, Écija, Santander, Ferrol, Vigo and Alcoy) have already designed and/or started their respective roadmaps that include, among others, micro-elimination actions in centers attending vulnerable persons under local jurisdiction (immigrants, homeless, IDUs), review of medical records, telemedicine, training and awareness. All of these have allowed the screening of more than 3,800 patients. **Conclusion:** The commitment of cities with the elimination of hepatitis C is feasible and viable despite the fact that health service responsabilities depend on the Regional Governments rather than councils. In addition, there is a high predisposition of the councils with this AEHVE action, as demonstrated by the high number of cities involved to #HepCityFree. Specific roadmaps are currently being defined for each council, through direct actions in local centers that attend vulnerable groups.

1831-A | HIGH HCV REINFECTION RATE IN A COMMUNITY-BASED COHORT OF PEOPLE WHO INJECT DRUGS (PWID) IN IMPHAL, INDIA

Ashwini Kedar[1], Mihili P. Gunaratne[2], Aylur K. Srikrishnan[1], Allison M. McFall[2], Shanta Chingtham[1], Pradeep Amrose[1], Jiban J. Baishya[3], Archit K. Sinha[1], Shruti H. Mehta[2] and Sunil S. Solomon[3], (1)Y.R. Gaitonde Centre for AIDS Research and Education, (2) The Johns Hopkins Bloomberg School of Public Health, (3)The Johns Hopkins University School of Medicine

Background: In order to achieve WHO elimination targets, PWID, who bear a disproportionate burden of hepatitis C virus (HCV) need to be treated, cured and subsequently supported with harm reduction services to prevent reinfection. To date, most data on HCV

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

reinfection derive from clinical trial samples or PWID on medication for opioid use disorder (MOUD) and may underestimate reinfection rates in the community. We characterize HCV reinfection among PWID who were cured through a community-based treatment program in the northeastern Indian city of Imphal, which has the most comprehensive harm reduction program in India. **Methods:** 1,370 PWID with documented evidence of sustained virologic response (SVR) following direct acting antiviral (DAA) therapy were screened for a longitudinal cohort between April 2021 – November 2022. HCV RNA was quantified at baseline and semi-annual follow-up visits. We present reinfection incidence rates with the period at risk calculated from the date the participants achieved SVR to the baseline visit date. Reinfection date was the mid-point period for those reinfected. Correlates of HCV reinfection were estimated using Poisson regression. **Results:** Median age of the 1,267 with available HCV RNA data was 30 years, 4% were women, and 12% were HIV co-infected. At baseline, 51% reported injecting, 24% reported MOUD use and 25% syringe service programs (SSP) use. Overall, 315 cases of reinfection were documented over 2,395 person-years of follow-up (incidence rate: 13.2 per 100 person years [PY] [95% CI: 11.8, 14.7]). Reinfection was significantly higher among men vs. women (13.6 vs. 4.5 per 100 PY; $p < 0.05$) and among HIV-negative vs. people living with HIV (13.9 vs. 6.4 per 100 PY; $p < 0.01$); incidence of reinfection was highest among those 18-24 years old (20.0 per 100 PY; Figure). In multivariable regression, age was independently associated with reinfection risk (incidence rate ratio for 18–24 vs. 45–54 years = 5.2 [95% CI: 2.7, 9.8]). Neither MOUD nor SSP use was associated with reduced reinfection risk in multivariable analysis. **Conclusion:** We observed a high reinfection rate among PWID in this Indian city, highlighting gaps in engagement in harm reduction and other preventive services. The particularly high incidence among younger PWID reinforces that programs must be tailored to individual needs to reach all those at risk and maintain the gains towards HCV elimination that have been achieved by expanded DAA-based treatment.

1832-A | HYBRID AGENT-BASED AND VIRAL KINETICS MODELING OF HEPATITIS C MICRO-ELIMINATION AMONG PEOPLE WHO INJECT DRUGS WITH DIRECT-ACTING ANTIVIRALS IN METROPOLITAN CHICAGO

Eric Tatara[1], Louis Shekhtman[2,3], Nicholson T Collier[1], Basmattee Boodram[4], Jonathan Ozik[1] and Harel Dahari[3], (1)Consortium for Advanced Science and Engineering, University of Chicago, Chicago, Il; Decision and Infrastructure Sciences, Argonne National Laboratory, Argonne, IL, USA, (2)Network Science Institute, Northeastern University, Boston, MA, USA, (3) The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, (4)Division of Community Health Sciences, School of Public Health, University of Illinois at Chicago

Background: Persons who inject drugs (PWID) are at high risk for acquiring and transmitting hepatitis C virus (HCV) infection. Direct-acting antiviral (DAA) therapy leads to high cure rates among PWID, however high rates of reinfection after cure and may require multiple DAA treatments to reach the World Health Organization's (WHO) goal of HCV elimination by 2030. In this modeling study we use an agent-based model (ABM) with a kinetic model of HCV transmission via syringe sharing to show that continued courses of DAA treatment among networks of HCV infected PWID is required to achieve elimination in a large population of PWID from Chicago, IL, and surrounding suburbs. **Methods:** We extended our previously developed agent-based Hepatitis C Elimination in PWID (HepCEP) model [PLoS One. 2022 Mar 10;17(3):e0264983] to identify and optimize DAA therapy scale-up and treatment strategies. We previously used a fixed probability (1%) of HCV transmission through syringe sharing among infected PWID [ibid]. The updated HepCEP model uses a mathematical model to determine transmission probabilities relative to the HCV RNA titers of needle/syringe-sharing donors. Individual temporal viral load profiles are sampled from unique distributions for acute and chronic naïve and reinfected individual's, and for individual's undergoing DAA treatment. We compared the rates of new chronic infections using the fixed and variable HCV transmission models for different combination(s) of DAA enrollment and frequency of DAA treatment courses. **Results:** When DAA retreatment limitations are not imposed, annual

DAA enrollment rates of > =5% of the PWID population are able to achieve elimination using a fixed HCV transmission probability of 1% (Figure 1A). The updated model, that accounts for in host viral kinetics, shows that elimination is possible only for DAA enrollment rates > =7.5% and that the elimination goal is shifted later by several years (Figure 1B). The large increase in new chronic infections apparent (Figure 1A and B) is due to reinfections among recently cured PWID. When a retreatment limitation is imposed such that PWID are only eligible for four total DAA treatments (after cure and reinfection), the fixed HCV transmission model again shows that elimination is feasible for DAA enrollment rates of > =5% (Figure 1C), while the updated model shows that elimination is not possible for DAA enrollment rates up to 10% of the PWID population (Figure 1D). **Conclusion:** The updated HepCEP model simulations underscore the importance of DAA scale-up without any re-treatment prohibition to achieve significant reductions in HCV incidence when the rates of reinfection among PWID networks are high. An unbiased DAA scale-up of >7.5% (or 75 per 1000 PWID) is projected to achieve the WHO target of 90% HCV incidence reduction by 2030 using the updated kinetic model of HCV transmission probability.

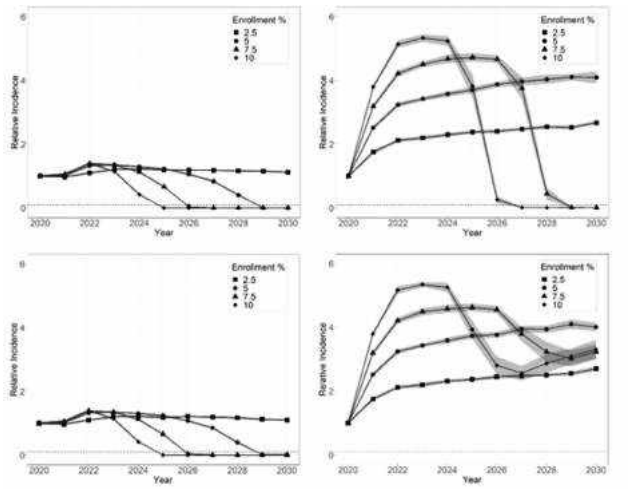

Figure 1. Projected HCV mean incidence of new chronic infections among PWID relative to the predicted 2020 incidence during with no restriction on DAA treatment frequency for the (**A**) HepCEP model with fixed 1% HCV transmission probability, and for the (**B**) Updated HepCEP model that accounts for in host viral kinetics and transmission probabilities. Mean incidence of new chronic infections when DAA treatment is limited to four times per individual for the (**C**) fixed 1% HCV transmission probability, and for the (**D**) Updated HepCEP model transmission probabilities. Enrollment percent is DAA rate (e.g., enrollment of 10% is treatment of 100 per 1000 PWID per year). The ribbons represent the 95% confidence interval around the mean of 20 simulation runs. The horizontal dashed line represents the WHO 2030 goal of 90% reduction in the incidence rate.

1833-A | IDENTIFYING THE POPULATION AT RISK OF HCC IN NON-ACLD CHRONIC HEPATITIS C PATIENTS CURED BY DIRECT-ACTING AGENTS: A STRATEGIC APPROACH

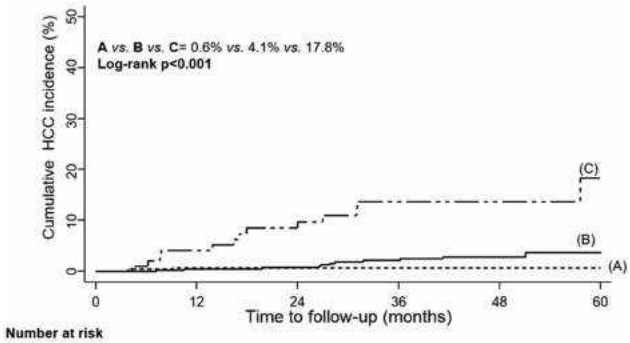
Yen-Chun Liu[1,2], Ya-Ting Cheng[1,2], Yi-Cheng Chen[1,2], Rachel Wen-Juei Jeng[1,2], Chun-Yen Lin[1,2], Rong-Nan Chien[1,2], Dar-In Tai[1,2], I-Shyan Sheen[1,2] and Yi-Chung Hsieh[1,2], (1)Chang Gung Memorial Hospital, Linkou Branch, Taiwan, (2)College of Medicine, Chang Gung University, Taiwan

Background: HCC surveillance is recommended for chronic hepatitis C (CHC) patients with advanced fibrosis (F3) or cirrhosis (F4) after successful viral eradication, according to clinical guidelines. However, the risk of hepatocellular carcinoma (HCC) persists in CHC patients without advanced fibrosis or cirrhosis. The objective of this study is to identify the risk factors for HCC in patients with pre-treatment FIB-4 scores below 3.25 and develop a scoring system to stratify the population that would benefit from HCC surveillance after achieving sustained virological response (SVR). **Methods:** We enrolled chronic hepatitis C patients from Chang Gung Memorial Hospital who achieved HCV eradication using direct-acting antiviral agents (DAA) during 2015 to 2020 and had pretherapy FIB-4 scores available. Patients with a history of prior HCC before DAA therapy were excluded. Cox regression analysis was performed to assess the occurrence of HCC, and predictive scores were derived based on adjusted hazard ratios. The cumulative incidences of de novo HCC were calculated using the Kaplan-Meier method. **Results:** Out of the 1597 patients enrolled, 1065 (67%) had pre-DAA FIB-4 < 3.25, with a mean age of 59 years and 43% being male. Over a median follow-up period of 43 (IQR:31-52) months, 27 of the 1065 non-ACLD patients developed de-novo HCC, resulting in an annual incidence of 0.76% person-year. By multivariate Cox regression analysis, it was revealed that male [adjusted hazard ratio (aHR): 4.262 (95% CI: 1.781-10.198), p = 0.001] and FIB-4 **e** 2.5 [aHR: 4.125 (1.864-9.126), p < 0.001] were two independent factors associated with HCC in patients with FIB-4 < 3.25. We derived a non-ACLD-HCC score = 1 x (Male: 1, Female: 0) + 1 x (FIB-4 **e** 2.5: 1, < 2.5: 0), which ranged from 0-2.The 5-year cumulative HCC incidences for scores 0, 1 and 2 were 0.6%, 4.1% and 17.8%, respectively (annual incidences: 0.18%, 0.71%, 3.76% person-year; log-rank p < 0.001) (Figure). Applying the same annual incidence threshold for HCC surveillance in CHB (0.2%/year), patients with a predictive score **e** 1 should undergo

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

HCC surveillance even after SVR. Notably, 10% of non-ACLD patients with a predictive score of 2 (FIB-4 **e** 2.5 plus male) had significantly higher HCC risks compared to those with predictive scores < 2 (annual incidence: score = 2 vs. < 2: 3.76% vs. 0.43% person-year, $p < 0.01$). **Conclusion:** A simple scoring system utilizing the FIB-4 cut-off of 2.5 and gender can identify 10% of non-ACLD CHC-SVR patients with a predictive score of 2 who are at higher risk of HCC. These patients should be considered for inclusion in an HCC surveillance program.



Sex	Score	FIB-4	Score
Female	0	<2.5	0
Male	1	≥2.5	1

1834-A | IMPACT OF COVID-19-RELATED PUBLIC HEALTH MEASURES ON HEPATITIS C TREATMENT INITIATION IN BRITISH COLUMBIA, CANADA: AN INTERRUPTED TIME SERIES ANALYSIS

Richard L Morrow[1], Mawuena Binka[2], Julia Li[3], Mike Irvine[3], Sofia R. Bartlett[1], Stanley Wong[3], Dahn Jeong[1], Jean Damascene Makuza[3], Jason Wong[3], Amanda Yu[3], Maria Jose Alvarez[3], Mel Krajden[3] and Naveed Zafar Janjua[1,3], (1)University of British Columbia, (2) British Columbia Centre for Disease Control, (3)BC Centre for Disease Control

Background: Previous research highlighted that testing for hepatitis C (HCV) in the Canadian province of British Columbia (BC) decreased immediately following the introduction of public health measures to address the coronavirus disease 2019 (COVID-19) pandemic in March 2020, but recovered to near prior levels later in 2020. In this analysis, we aimed to assess the impact of COVID-19-related public health measures on HCV treatment initiation in BC. **Methods:** We conducted an interrupted time series analysis using administrative health data from the province's COVID-19 Cohort to estimate changes in HCV treatment initiation following the introduction of COVID-19-related public health measures in March 2020. The study period included a 24-month pre-policy period (April 2018 to March 2020) and 3 follow-up periods (April to December 2020, January to December 2021, and January to December 2022). As the pre-policy trend in HCV treatment initiation was non-linear, we used a generalized additive model with a smoothing function for the pre-policy trend, a binary variable for a post-policy level change, a smoothing function for a post-policy trend change, and a smoothing function to adjust for seasonality. The model also adjusted for autocorrelation. We calculated the absolute difference in the number of individual's initiating HCV treatment estimated by the model compared to predicted (or counterfactual) levels based on the pre-policy trend. **Results:** HCV treatment initiation was characterized by a declining trend during the pre-policy period and decreased to a level of approximately 200 patients initiating treatment per month by early 2020. After March 2020, HCV treatment initiation fell abruptly and then resumed a decreasing trend that gradually rose above the predicted (i.e., counterfactual) trend. Due to this pattern, an estimated 176 fewer patients than predicted initiated HCV treatment during April to December 2020 and 104 fewer patients than predicted initiated treatment in 2021, while the number of patients initiating treatment showed an increase of 351 patients compared to the predicted level in 2022. **Conclusion:** Following the introduction of COVID-19-related public health measures in March 2020, HCV treatment initiation initially fell but gradually rose above levels predicted by the pre-policy trend in BC. Further investigation is needed to assess the distributional impacts of these trends.

Figure 1. Number of individuals initiating HCV treatment in BC following the start of COVID-19-related policies (estimated vs counterfactual based on pre-policy trend)

1835-A | IMPLEMENTATION OF UNIVERSAL HEPATITIS C VIRUS SCREENING IN A TERTIARY CARE CANCER CENTER

Harrys A. Torres, Khalis Mustafayev, Ruston Juneau, Jessica P. Hwang, Lan Sun Wang, Georgios Angelidakis, Bruno P. Granwehr, Eduardo Yepez Guevara and Anita K. Ying, The University of Texas MD Anderson Cancer Center

Background: The prevalence of chronic hepatitis C virus (HCV) infection in the general United States (US) population is **d** 1%. Oncologic professional societies recommend universal HCV screening for cancer patients. Here we describe our experience implementing universal HCV screening at MD Anderson Cancer Center (MDACC), one of the largest cancer centers in the US. **Methods:** In October 2016, universal HCV screening with HCV antibody (anti–HCV) was initiated at MDACC for all new outpatients by implementing widespread provider education and the use of newly created electronic health records (EHR) orders (SmartSets) and automated reminders (best practice alerts or BPA). Only solid tumor patients were targeted, as hematologic cancer patients were already being screened for HCV before the study period. The primary outcomes of the study were the proportion of patients who were screened for HCV and then linked to HCV care. Epic's Reporting Workbench business intelligence tools were used. Statistical significance was defined as $p < 0.05$ on Chi-square analysis. **Results:** Between April 2016 and April 2023, 85,836 cancer patients were screened for HCV. Among them, 56,075 (65.3%) patients had solid tumors and were further analyzed. The prevalence of reactive anti-HCV was 2.3% (1,300/56,075 patients). The highest HCV prevalence rates were seen in patients with gastrointestinal (5.6%), head and neck (3.97%), and thoracic cancers (3.97%). The screening was performed by using SmartSets (39,332 patients or 45.8%) followed by BPAs (10,972 patients or 12.8%). Universal screening led to the identification of 1,300 new outpatients. Most of them were linked to HCV care (765/1,300 or 59%) and treated (425/562 or 76%) (Figure 1). The majority of patients achieved a sustained virologic response (414/425 or 97%). There was a continuous increase in screening over time, except during the peak of the COVID-19 pandemic. The proportion of new patients screened increased between the first 6 months before the study implementation and the last 6 months of the study period (10.1% vs 34.4%, $p < 0.001$). **Conclusion:** The prevalence of HCV remains higher in cancer patients compared to the general population. Universal HCV screening can be successfully implemented in cancer hospitals using an EHR-based multi-pronged approach. This strategy can be implemented in cancer centers nationwide to contribute to HCV elimination targets.

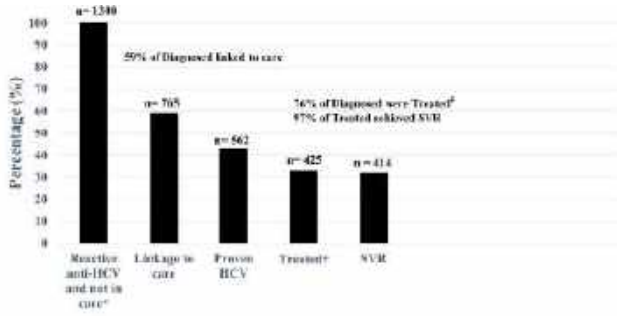

Figure 1. Cascade of care for solid tumor patients with chronic HCV infection during the post-implementation phase of universal HCV screening
Abbreviations: HCV, hepatitis C virus; SVR, sustained virologic response.
* 370 (28%) were lost to follow-up, 72 (6%) not chronically infected, and 93 (7%) died.
† 322 patients (25%) were treated before arriving at MDACC, and 103 patients (8%) were treated at MDACC.
‡ 137 HCV-infected patients (24%) were not treated, 103 of them because of progressive cancer, 28 patients were lost to follow-up, and 6 patients were not treated to avoid drug-drug interactions.

1836-A | IMPROVING THE HCV CARE CASCADE AMONG IMMIGRANTS IN CANADA THROUGH LINKAGE TO CARE AND TREATMENT SUPPORTS: A COST-EFFECTIVENESS ANALYSIS

Ana Maria Passos-Castilho[1,2,3], Anna Lucie Fournier[1,2,3,4], Feng Tian[5], Karim Abou Nader[2], Jordan J. Feld[6], Beate Sander[7,8], William W. L. Wong[5] and Christina Greenaway[2,3,9], (1)Joint First Authors, (2)Lady Davis Institute, Jewish General Hospital, Montreal, Canada, (3)Mcgill University, Montreal, Canada, (4) Caen University Hospital, Caen, France, (5)University of Waterloo, Waterloo, Canada, (6)Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, Toronto, Canada, (7)Toronto General Hospital Research Institute, University Health Network, Toronto, Canada, (8)Ices, Toronto, Canada, (9)Division of Infectious Diseases, Jewish General Hospital, Montreal, Canada

Background: High uptake in the care cascade for all groups will be necessary to achieve hepatitis C virus (HCV) elimination. We used decision analysis modelling to assess the cost-effectiveness of systematic HCV screening interventions among new immigrants to Canada, with or without linkage to care and treatment supports, compared to the status quo of limited screening. **Methods:** We modelled a hypothetical cohort to reflect the 341,180 immigrants admitted as permanent residents in Canada in 2019 as of country of origin, age, and sex distribution. Adult immigrants from **e** 2% HCV-prevalence countries were included in the main cost-utility analysis (N = 30,270). A Markov model was used to estimate costs, quality-adjusted life years (QALYs), decompensated cirrhosis (DC) and hepatocellular carcinoma (HCC) cases, and liver-related deaths (LRD) over a lifetime horizon. Linkage to care and treatment supports included interpreters, peer navigators, written educational material, and text-message reminders. Input parameters and costs were obtained from the literature, including Canadian costs. We used the healthcare payer perspective, with costs expressed in 2020 Canadian dollars, and future costs and outcomes discounted at an annual rate of 1.5%, according to Canadian guidelines. We performed one-way and probabilistic sensitivity analysis (PSA), and tested alternative scenarios of 1% (N = 107,414) and 0% (N = 279,465) HCV prevalence threshold. **Results:** Compared to the status quo, screening with linkage to care and treatment supports averted 13.8 [95% uncertainty range (UR) 9.2-17.5] DC, 11.0 (6.9-14.0) HCC cases, and 20.2 (13.1-23.4) LRD per 1000 persons screened (Table). It was estimated to cost an additional $1,027,042 ($355,830-$1,201,290) and result in 259 (214-280) additional QALYs; translating to an incremental cost-effectiveness ratio (ICER) of $3957 per QALY. While screening without supports also improved outcomes, it was more costly and less effective than with care supports (extended dominance; ICER $4837 vs. no screening). Screening with care supports was cost-effective (< $50,000 per QALY gained) in 100% of PSA simulations (n = 100), compared to no screening. It was also cost-effective in alternative prevalence threshold scenarios of 1% (ICER $4003) and 0% (ICER $4230) compared to no screening. As health events among immigrants from **e** 2% prevalence countries accounted for only 37.9% of outcomes in the entire simulated cohort, screening with care support for all adult immigrants averted an additional 613 DC, 586 HCC cases, and 998 LRD, overall, compared to the **e** 2% threshold. Screening with care support for all vs. **e** 2% prevalence averted 3.7 vs. 1.5 DC, 3.3 vs. 1.2 HCC cases, and 5.8 vs. 2.2 LRD per 1000 newly arrived adult immigrants. **Conclusion:** Systematic mass HCV immigrant screening with linkage to care and treatment supports can greatly reduce DC and HCC cases, and LRD, and improve quality of life while being cost-effective.

Table: Cost-effectiveness results and health events with various HCV screening strategies per 1000 adult immigrants screened at different country of origin HCV prevalence thresholds.

HCV prevalence	Strategy	Cost, $ (95% UR)	QALYs (95% UR)	DC (95% UR)	HCC (95% UR)	LRD (95% UR)
≥2%	No screening	14,874,998 (1,915,167-59,344,891)	28,113 (27,887-28,406)	16.6 (13.4-20.9)	14.2 (11.0-17.9)	25.1 (23.3-27.7)

1837-A | INCIDENCE AND ASSOCIATIONS OF HCV REINFECTION IN THE ERA OF DIRECT ACTING ANTIVIRALS. THE RECARE STUDY

Sofia Vasileiadi[1], Olga Anagnostou[2], Kanellos Koustenis[1], Maria Manolakopoulou[1], Charalampos Karageorgos[1], Anestis Goulas[1], Charikleia Kranidioti[1], Spyros Siakavellas[1], Emilia Hadziyannis[1], Maria Melanie Deutsch[1] and Spilios Manolakopoulos[1], (1) Geniko Nosokomeio Athinon "Hippokratio" Athens, Greece, (2)Okana Greece

Background: The introduction of highly effective direct acting antivirals (DAAs) has dramatically changed practice against HCV infection with high therapy uptake and high response rates; one may argue for higher reinfection rates. Reinfection rates especially in high risk populations could become a significant barrier in the strategy of HCV elimination. Our aim is to explore the HCV reinfection rate after successful HCV therapy with DAAs in a cohort of people who use drugs (PWUD) and define factors associated with reinfection. **Methods:** We included patients with chronic compensated hepatitis C who had history of past or current illicit drug use. All had been treated successfully with DAAs in our tertiary center between 2014-2021. SVR was defined with serum HCV RNA no detectability 3-12 months after the end of treatment. All patients were contacted at least one year after end of treatment via phone call and were invited for follow up visit where serum HCV RNA levels, liver function tests and transient elastography were performed. Parameters regarding socioeconomic status and drug use habits, were also recorded. Detectable serum HCV RNA after achieving SVR was defined as reinfection. 223 patients were called twice; 94 of them did respond. **Results:** 129 patients (78.3% men) were included in this preliminary analysis. Median age was 52 (range 34-73) years and 18.6%(n = 24) had evidence of cirrhosis. 58.1%(n = 75) were unemployed, 58.9%(n = 76) were single and 25.6%(n = 33) had been incarcerated at some point in the past. 65%(n = 84) attended a substitution or therapeutic community program for drug use, with 30.2%(n = 39) reporting drug use in the last 12 months, of which 38.5%(n = 15) shared syringes/other paraphernalia, while 41%(n = 16) reported intravenous drug use. We identified 9 reinfections during 309.9 PY of follow-up, yielding a reinfection rate of 2.9/100 PY. HCV genotypes in reinfected patients were different compared to baseline pretherapy ones. We found that the reinfection group included younger (43 ± 5 vs 52 ± 8 y,$p = 0.001$) patients, the majority (n = 8, 88.9%) of them under the age of 50, and with a concomitant history of having been imprisoned (67% vs 23%,$p = 0.003$). Moreover, people in the reinfection group reported longer total history of intravenous drug use (24 ± 7 vs 14 ± 8 y,$p = 0.002$), more often active drug use in the past 12 months (89% vs 26%, $p < 0.001$), intravenous drug use (67% vs 9%,$p < 0.001$) and shared syringes/paraphernalia (89% vs 31%, $p < 0.001$). Reinfection was also significantly associated with HIV co-infection (44% vs 0%,$p < 0.001$) and cannabis consumption (78% vs 38%,$p = 0.02$). **Conclusion:** Our prospective study clearly showed that HCV reinfection rates after SVR with DAAs were higher among younger patients who continued high risk behaviors. These data highlight the importance of close follow-up for PWUD with widespread testing, harm reduction interventions and sustained linkage to health care services.

Background: Sustained virological response (SVR) by direct-acting antivirals (DAA) may reverse the hypercoagulable state associated with HCV cirrhosis. However, whether DAA-driven SVR reduces the risk of portal vein thrombosis (PVT) is unclear. We evaluated the incidence and predictive factors of *de-novo*, non-tumoral PVT in HCV cirrhosis after SVR. **Methods:** DAA-treated cirrhosis patients consecutively enrolled in the multicentric PITER cohort since 2014 were prospectively evaluated. A group of untreated patients (n = 448) were included as propensity-matched (inverse probability weighting) controls for PVT development. Kaplan-Meier analysis and competing risk regression analysis were performed to evaluate the PVT incidence and predictive factors. **Results:** The 3-year PVT weighted cumulative incidence rate was significantly lower in SVR+ patients than in untreated controls (1.3% vs. 2.4%, $p < 0.0001$). During a median follow-up of 38.3 (IQR 25.1-48.7) months, of 1609 consecutive DAA-treated patients with cirrhosis who achieved the SVR, 32 (2.2%) developed PVT. Patients who developed PVT had more severe liver disease as reflected by a lower platelet (PLT) count, higher bilirubin and a more frequent history of decompensation. In a multivariable model, considering death and liver transplantation as competing risk events, adjusting for the use of non-selective beta-blockers (NSBBs) and PLT count < 120.000/µl, pre-treatment ALBI grade > 2 (subHR: 4.02; CI95% 1.24-13.04) and presence of esophageal varices (subHR: 8.58; CI95% 3.37-21.82) were independent PVT predictors. Notably, patients who developed PVT have no significant improvement in portal hypertension severity and liver function tests after the SVR. There was a significant variation ($p < 0.001$) in the post-SVR *vs* baseline PLT, albumin, and bilirubin levels in patients who did not develop PVT, whereas in those who developed PVT no significant improvements were observed for all variables evaluated ($p > 0.05$). ALBI grade > 2, evaluated within the first year after the end of treatment and the presence of esophageal varices, adjusted for NSBBs and post SVR PLT count < 120.000/µl, remained associated with *de-novo* PVT (subHR: 5.5; CI95% 1,67-18.13 and subHR: 9.32; CI95% 3.16-27.53, respectively). **Conclusion:** SVR is associated with a significant reduction in the risk of PVT. Patients with more advanced liver disease prior and after viral eradication by DAA treatment remained at risk of PVT.

1839-A | INCREASED RISK OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CONCURRENT HEPATITIS C VIRUS INFECTION AND METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE AFTER ACHIEVING SUSTAINED VIROLOGIC RESPONSE WITH DIRECT-ACTING ANTIVIRALS

Chen-Hua Liu[1], Yu-Jen Fang[2], Chi-Yi Chen[3], Wei-Yu Kao[4], Chih-Lin Lin[5], Pin-Nan Cheng[6], Sheng-Shun Yang[7], Yu-Lueng Shih[8], Shang-Chin Huang[9], Tung-Hung Su[1], Tai-Chung Tseng[10], Chun-Jen Liu[1], Pei-Jer Chen[1] and Jia-Horng Kao[1], (1)National Taiwan University Hospital, (2)National Taiwan University Hospital, Yun-Lin Branch, (3)Ditmanson Medical Foundation Chiayi Christian Hospital, Chia Yi, Taiwan, (4)Taipei Medical University Hospital, (5)Renai Branch, Taipei City Hospital, Taipei, Taiwan, (6)National Cheng Kung University Hospital, Taiwan, (7)Taichung Veterans General Hospital, (8)Tri-Service General Hospital, (9)National Taiwan University Hospital Bei-Hu Branch, Taipei City, Taiwan, (10)National Taiwan University Hospital, Taiwan

Background: Data are limited regarding the risk of hepatocellular carcinoma (HCC) in patients with concurrent hepatitis C virus (HCV) infection and metabolic dysfunction-associated fatty liver disease (MAFLD) who achieve sustained virologic response (SVR) with direct-acting antivirals (DAAs). **Methods:** We retrospectively analyzed a prospective cohort assessing the risk of HCC in patients with HCV after achieving SVR_{12} with DAAs at eight academic centers in Taiwan. MAFLD was defined as the presence of hepatic steatosis with a controlled attenuation parameter (CAP) of 248 dB/m or more, in combination with type 2 diabetes mellitus (DM), overweight or obesity, or lean/normal weight. Baseline characteristics, including age, sex, stage of hepatic fibrosis, fibrosis index based on four parameters (FIB-4), albumin-bilirubin (ALBI) grade, were also assessed at the time point of SVR_{12}. The cumulative incidence rates between patients with or without concurrent MAFLD were calculated using Kaplan-Meier methods and were compared by log-rank tests. Multivariate Cox regression model, which was shown as hazard ratio (HR) with 95% CI, to assess the association between the risk of HCC and factors of interest. **Results:** A total of 2018 patients were included in the study. After a median of post-SVR_{12} follow-up of 4.5 years, 164 (8.1%) of them developed HCC. Patients with concurrent MAFLD had a significantly higher cumulative incidence rate of HCC than those without MAFLD (Log-rank test, $p < 0.001$)(Figure 1). Among patients with concurrent MAFLD, those with type 2 DM had a significantly higher cumulative incidence rate of HCC than those with overweight or obesity, or lean/normal weight (Log-rank test, $p = 0.005$). Multivariate Cox regression analysis revealed that age > 50 years (HR: 5.26 [95% CI: 2.80-9.88], $p < 0.001$), male (HR: 2.38 [95% CI: 1.71-3.32], $p < 0.001$), cirrhosis (HR: 4.98 (95% CI: 3.33-7.45, $p < 0.001$), ALBI grade (HR: 1.89 [95% CI: 1.23-2.92], $p < 0.001$), and MAFLD (HR: 1.96 (95% CI: 1.39-2.76, $p < 0.001$) were associated with HCC in patients achieving SVR_{12} with DAAs. **Conclusion:** In addition to age, sex, cirrhosis, and ALBI grade, patients who achieved SVR_{12} with DAAs had an independently higher risk of HCC during post-SVR_{12} follow-up if they had concurrent MAFLD, particularly for type 2 DM.

1840-A | INTERIM RESULTS OF AN AUTOMATED ELECTRONIC MEDICAL RECORD-BASED ALERT SYSTEM FOR THE MICRO-ELIMINATION OF HEPATITIS C – A SINGLE CENTER-BASED EXPERIENCE

Hee Yeon Kim[1], Sung Won Lee[1], Jung Hyun Kwon[1], Chang Wook Kim[1], Se Hyun Cho[1], Heechul Nam[1], Hyun Yang[1], Keungmo Yang[1], Do Seon Song[1], U Im Chang[1], Jin Mo Yang[1], Hae Lim Lee[1], Soon Woo Nam[1], Soon Kyu Lee[1], Seok-Hwan Kim[1], Myeong Jun Song[1], Pil Soo Sung[2], Ji Won Han[1], Jeong Won Jang[1], Si Hyun Bae[1], Jong Choi[3] and Seung Kew Yoon[1], (1)The Catholic University of Korea, (2)The Catholic University Liver Research Center, Department of Biomedicine & Health Sciences, College of Medicine, the Catholic University of Korea, (3)College of Medicine, the Catholic University of Korea

Background: The diagnostic process and linkage to care continue to represent the primary obstacles impeding the micro-elimination of the hepatitis C virus (HCV). This study aimed to evaluate the effectiveness of integrating an automated electronic medical record (EMR)-based alert system in a tertiary referral center. **Methods:** The analysis included 2,234 patients who tested positive for HCV

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

antibodies between July 2009 and October 2022. Starting from June 2021, an EMR-based alert system was implemented to remind physicians to conduct HCV RNA testing for patients with a history of positive HCV tests but no confirmatory HCV RNA test or recent positive HCV test result. **Results:** Out of the 172,241 patients who underwent anti-HCV testing during the study period, 2,234 patients (1.3%) tested positive for anti-HCV. After excluding patients previously diagnosed with HCV and those with a follow-up duration of less than 2 days, 2,033 patients were included in the analysis. Before the introduction of the automated EMR-based alert system, 60.7%(1077/1773) of the patients underwent HCV RNA testing following the initial positive anti-HCV result. Among them, 48.1% (518/1077) were confirmed to have HCV infection. Among the patients who did not undergo the HCV RNA confirmatory test following the initial positive anti-HCV result, 58 patients received the HCV RNA test after repetitive positive anti-HCV results. Notably, 3.1%(20/638) of patients who did not undergo the HCV RNA confirmatory test within our hospital were diagnosed with HCV elsewhere. Among 198 patients who had not undergone HCV RNA test before EMR-based alert system and had been followed up after alert system, 31.3% (62/198) were tested following the alert notification, resulting in confirmation of 12 new HCV infections. After incorporating an EMR-based alert system, 66.9%(174/260) of anti-HCV-positive patients were ordered an HCV RNA test, with 27.6%(48/174) confirmed cases. **Conclusion:** The integration of an EMR-based alert system for HCV microelimination improved RNA testing rates in new anti-HCV positive patients and diagnosis of previously missed HCV infection in a hospital-based setting. However, further modification and promotion of EMR-based alert system is needed to enhance HCV confirmation rates.

1841-A | LONG TERM OUTCOMES OF CIRRHOTIC PATIENTS WITH CHRONIC HEPATITIS C VIRUS AFTER ACHIEVING SUSTAINED VIROLOGIC RESPONSE

Justin Canakis[1], Reid Schalet[1] and Marc Siegel[2], (1) The George Washington University School of Medicine and Health Sciences, (2)George Washington University School of Medicine and Health Sciences

Background: Achieving sustained virologic response (SVR) with direct acting antivirals can lead to improvement in liver-related events (LREs) and non-liver-related events (NLREs). Most studies have explored the long-term outcomes of patients treated with interferon-based therapy and do not describe the outcomes in patient with hepatitis C virus (HCV)-related cirrhosis. There this is little data describing the long-term outcomes of patients with advanced fibrosis and cirrhosis after being treated with HCV directly acting agents (DAAs). Our aim was to assess to long term outcomes of liver related disease and non-liver related disease in patients with HCV-related cirrhosis following SVR after therapy with DAAs. **Methods:** We conducted a retrospective, observational cohort study of 248 patients who had received treated for Hepatitis C from 2008-2021. All patients had confirmed HCV by PCR and were treated with DAAs for 8, 12, or 24 weeks or as clinically indicated. Inclusion criteria included either confirmed cirrhosis on liver biopsy or stage F4 on transient elastography and platelet count less than 150 in order to weed of Fibroscans that were artificially elevated. We then conducted retrospective chart reviews of all cirrhotic patients successfully treated with DAAs and explored if they were diagnosed with hepatocellular carcinoma (HCC), esophageal varices, non-Hodgkins lymphoma (NHL), diabetes mellitus (DM), myocardial infarction (MI), or thyroid disease after treatment. We also reviewed performance of esophagogastroduodenoscopies (EGDs) and radiographic screenings for HCC to determine the incidence of variceal monitoring and HCC screening. **Results:** 59 patients (24%) had cirrhosis diagnosed by liver biopsy or transient elastography. 36 patients (61%) were men. The average age was 59.5 years. The average duration of HCV infection was 30 years (range 6 to 50 y). 62.7% never had an EGD, 22% had one EGD, and 15% had two or more EGDs. Esophageal varices were detected in 7 patients (32%) of patients who were screened. Regarding HCC screening with abdominal ultrasounds, 37.3% had no ultrasound performed, 28.8% had one,

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and 34% had greater than two. (Table 2). 15.3% of patients had an MRI performed and 18.7% had a CT scan for HCC screening (Tables 3 and 4). Regarding long term health outcomes, 4 patients (6.8%) were diagnosed with HCC, no patients was diagnosed with NHL, 10 patients developed diabetes, 2 patients had a MI, and 2 developed thyroid disease. **Conclusion:** Patients with HCV-related cirrhosis remain at substantial risk for developing liver-related and non-liver-related events after achieving SVR with DAA therapy. However, our cohort revealed sub-optimal rates of surveillance for HCC and esophageal varices.
Disclosures: The following people have nothing to disclose: Justin Canakis, Reid Schalet, Marc Siegel

1842-A | LONG-TERM PROGNOSIS AFTER DIRECT ACTING ANTIVIRALS TREATMENT WITH HEPATITIS C VIRUS ERADICATION

Masayuki Kurosaki[1], Nobuharu Tamaki[2] and Namiki Izumi[2], (1)Inserm UMR1149, Department of Hepatology, AP-HP Hôpital Beaujon, (2)Musashino Red Cross Hospital

Background: Almost all patients with chronic hepatitis C can achieve sustained virologic response (SVR) with direct-acting antiviral (DAA) treatment. However, the long-term prognosis after SVR remains unclear. The aim of this study was to evaluate the prognosis of patients who achieved SVR. **Methods:** In this nationwide prospective study involving 12 hospitals of the Japanese Red Cross Liver Study Group, a total of 5665 patients who achieved SVR with DAA treatment were enrolled. Liver-related and non-liver-related mortality were evaluated. The change in mortality was also evaluated. **Results:** The median (interquartile range) follow-up was 3.4 (2.2-5.0) years, and 293 patients (5.1%) died during follow-up. Among these patients, 108 patients died due to liver-related events and 185 patients died due to non-liver-related events. Among patients with non-liver-related death, 41, 47, 10, 8, 12, 32, and 35 patients died due to cardiovascular disease, gastrointestinal cancer, lung cancer, hematologic malignancy, other cancer, infectious disease, and other causes of death, respectively. The 1-, 3-, and 5-year all-cause mortality rates were 0.4%, 2.9%, and 6.2%, respectively. Similarly, the 1-, 3-, and 5-year liver-related mortality rates were 0.1%, 1.0%, and 2.1%, respectively. The proportion of liver-related deaths at 1, 3, and 5 years was 26%, 47%, and 38%, respectively. Liver-related mortality did not decrease over at least five years of follow-up. When patients were stratified by fibrosis stage, the 5-year mortality rates in patients with advanced fibrosis (defined by FIB-4) and those without advanced fibrosis were 10.3% and 3.5%, respectively. In patients with advanced fibrosis, the 5-year mortality rates for liver-related and non-liver-related events were 4.4% and 5.1%, respectively. Similarly, in patients without advanced fibrosis, the 5-year mortality rates for liver-related and non-liver-related events were 0.8% and 2.5%, respectively. The mortality rates for liver-related and non-liver-related events were equivalent in patients with advanced fibrosis, whereas in patients without advanced fibrosis, liver-related mortality is low and attention should be paid to non-liver-related mortality. **Conclusion:** In patients who achieved SVR, liver-related mortality did not decrease after at least five years of follow-up, and regular surveillance must be continued. In patients with advanced fibrosis, the risk of liver-related and non-liver-related mortality was high, and regular surveillance for liver-related and non-liver-related events is needed. In patients without advanced fibrosis, the risk of death was higher for non-liver-related events than for liver-related events.

1843-A | LOW PREVALENCE OF HEPATITIS C (HCV) VIREMIA WITH POPULATION-BASED SCREENING IN AN URBAN SAFETY-NET HOSPITAL

Melissa Osborn Jenkins[1,2], Peter Greco[1,2], David Kaelber[1,2], Nicholas Riley[1,2], James Misak[1,2], Michael Gierlach[1] and Ann Avery[1,2], (1)Metrohealth Medical Center, (2)Case Western Reserve University School of Medicine

Background: CDC recommends one-time HCV screening for all adults **e** 18 years old, due to a rise in HCV incidence in persons aged 20-39 fueled by the opioid epidemic. To facilitate this recommendation, we instituted bulk ordering of HCV testing in the electronic health record (EHR) for those meeting eligibility criteria. A pilot study of bulk HCV ordering at our hospital led to a 70% increase in completion of HCV screening compared to usual care (health maintenance reminder with provider-driven orders). **Methods:** Eligible patients were adults aged 18-79 who were enrolled in primary care with a visit in the last 12 months and had no prior HCV test or history of HCV. Patients were excluded if “deceased” in the EHR, had a positive HCV RNA in the EHR, had an appointment in Liver Clinic, or had a diagnosis of chronic HCV, cirrhosis secondary to HCV, or hepatitis C antibody (Ab) positive on their problem list. Bulk orders were placed over 1 year in batches ~ 1000 every other week

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by the study team. Patients received a single mailed letter or electronic message through the patient portal advising them of the recommendation and rationale for testing, as well as instructions for completion. Results were delivered to the study team for follow up of positive results, including informing patients of the diagnosis and linking them for HCV care. **Results:** Over the course of 1 year, a total of 28753 bulk orders for HCV Ab were placed, with invitations sent via patient portal (21419 (74.5%)) or mailed letter (7330 (25.5%)). Of those invited, 7795 (27.1%) completed testing within 1 year (Table). Out of the 41 patients with a reactive HCV Ab, 21/41 (51.2%) had a negative HCV RNA. 19/41 (46.3%) had a detectable HCV RNA. 1 person did not have HCV RNA testing due to inadequate sample. The overall prevalence of chronic HCV was 19/7795 (0.2%). Among 19 patients with +HCV RNA, 14 (74%) were successfully linked to HCV care and 10 (53%) have achieved cure (SVR12) to date. **Conclusion:** The overall prevalence of undiagnosed HCV in our primary care population was low (0.2%), compared to recent studies in our system (4%) or the US (0.8%). Our prior screening initiatives among high-risk patients (birth cohort, jail, emergency department) likely account for the low prevalence in patients targeted by the current intervention. The linkage-to-care rate among those identified was high, and over half have been successfully treated thus far. Although prevalence was low, bulk ordering was an easy intervention that identified patients who might not otherwise be tested, and whose treatment can help reach the 2030 goal of HCV elimination.

Table Characteristics of tested population (n= 7795)

Gender	
Male	2750 (35.2%)
Female	4923 (63.2%)
Nonbinary/Transgender/Other/Not disclosed	119 (1.5%)
Race	
White	4700 (60.2%)
Black	2187 (28.0%)
Asian	247 (3.1%)
American Indian/Alaska Native	37 (0.5%)
Native Hawaiian/Pacific Islander	18 (0.2%)

1844-A | OPTIMIZING METHADONE PROVIDER LOCATIONS FOR REDUCING SYRINGE SHARING BEHAVIOR AND HCV TRANSMISSION RISK AMONG PERSONS WHO INJECT DRUGS IN METROPOLITAN CHICAGO

Eric Tatara[1], Qinyun Lin[2], Jonathan Ozik[1], Marynia Kolak[2], Nicholson T Collier[1], Dylan Halpern[2], Luc Anselin[2], Harel Dahari[3], Basmattee Boodram[4] and John Schneider[5], (1)Decision and Infrastructure Sciences Division, Argonne National Laboratory and Consortium for Advanced Science and Engineering, University of Chicago, (2)University of Chicago, Center for Spatial Data Science, Chicago, IL, (3)The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois, USA, Highland Park, IL, (4)Division of Community Health Sciences, School of Public Health, University of Illinois at Chicago, (5)Department of Infectious Disease, Uchicago Medicine

Background: Ensuring that individual's have access to treatment and medication for opioid use disorder (MOUD), such as methadone, is crucial for enhancing health outcomes by mitigating the risks of infection and overdose associated with injecting drugs. However, the distribution of MOUD resources is influenced by intricate social and structural factors, leading to nuanced patterns that expose underlying disparities in social and spatial contexts Persons who inject drugs (PWID) face a heightened vulnerability to acquiring and transmitting hepatitis C virus (HCV) infection. PWID receiving MOUD treatment experience a decrease in the frequency of daily injection episodes where they share syringes with others. By reducing individual instances of syringe sharing, the cumulative probability of HCV transmission can be significantly diminished. **Methods:** The HepCEP agent-based model [PMID: 32624641], a validated tool for analyzing syringe sharing behaviors among PWID in metropolitan Chicago, Illinois, U.S.A., was used to assess actual (real-world) and hypothetical scenarios involving different levels of social and spatial inequity in methadone provider access. Synthetic spatial distributions, representative of varying geographic patterns of methadone provider locations and population

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

characteristics, were used to demonstrate corresponding variations in population-level health outcomes (Figure 1). Through simulation studies, we examined the impact of adherent methadone treatment on reducing syringe sharing behaviors among PWID. **Results:** Irrespective of the assumptions regarding methadone access and the distribution of providers, the redistribution of methadone providers consistently leads to certain areas experiencing inadequate access to MOUDs. In all scenarios, there were regions with limited access, underscoring the significant challenge posed by the scarcity of providers in the area. Need-based distributions closely resemble the actual distribution of providers (Figure 1), suggesting that the current spatial arrangement of methadone providers already aligns with the local demand for MOUD resources. **Conclusion:** The influence of the spatial distribution of methadone providers on the frequency of syringe sharing is contingent upon access. In situations where substantial structural obstacles hinder access to methadone providers, it is most effective to distribute providers in close proximity to areas characterized by the highest need, as determined by the geographical density of PWID.

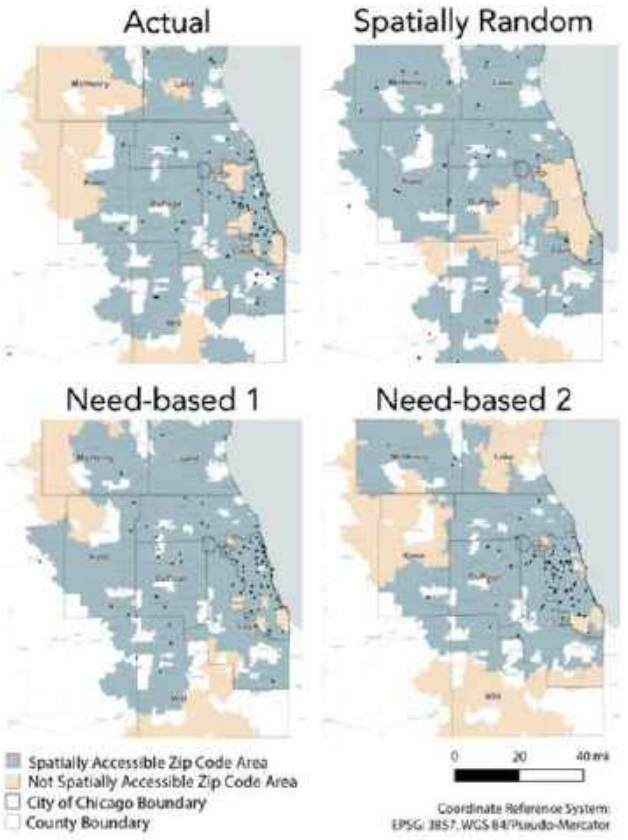

Figure 1. Spatial access to methadone providers for the actual scenario and three counterfactual distribution scenarios. Each dot represents the location of a single methadone provider. City of Chicago and collar county borders are indicated. Spatial access to methadone providers is calculated as distance to nearest provider to the center of each zip code area. Zip codes areas are not identified as accessible if there is no provider within a mile of its geographic center.

1845-A | PERSISTENT PRURITUS ASSOCIATED WITH WORSE QUALITY OF LIFE IN PATIENTS WITH CHRONIC HEPATITIS

Mei Lu[1], Lora Rupp[2], Christina Melkonian[2], Sheri Trudeau[2], Yihe G Daida[3], Mark A Schmidt[4] and Stuart C. Gordon[5], (1)156 Pocatello Rd, (2)Henry Ford Health, (3)Kaiser Permanente Hawai'I, (4)Kaiser Permanente Northwest, (5)William Beaumont Hospital

Background: Pruritus—itching—is common with liver disease, but its prevalence and severity among US patients with chronic hepatitis B and C (HBV, HCV) are not well-documented. A subset of patients from the Chronic Hepatitis Cohort Study (CHeCS) were surveyed to examine pruritus prevalence, persistence, and management, and the impact on patients' quality of life (QoL). **Methods:** The validated Pruritus Numeric Rating Scale (NRS) was used to assess pruritus intensity; patients who reported a score **e** 3 in the last 30 days were invited to participate in a 6-month study using the validated SF-36 questionnaire. A general regression model (univariate followed by multivariable modeling) was used to analyze associations between pruritus intensity and eight dimensions of QoL. **Results:** Among 1654 patients (HBV = 358, HCV = 1296, HBV/HCV = 6), pruritus prevalence was significantly higher among patients with HCV than those with HBV (44% vs 35%; $p < 0.05$ excluding HBV/HCV). A total of 123 patients (21 HBV and 102 HCV) with pruritus agreed to participate in a 6-month questionnaire-based study; 72% were **e** 60 years, 50% were men, 25% were Black, 22% had compensated cirrhosis, 15% had decompensated cirrhosis, and 66% had BMI > 25. Mean NRS was 4.9–5.3. QoL responses for social functioning and emotional well-being were relatively high (70–72 points), but responses for energy/fatigue were lower (50–51 points). Rates of antiviral treatment were higher in HCV patients (92%, SVR rate 99%) and 71% in patients with HBV patients (with 43% receiving ongoing treatment). Multivariable analyses showed no significant effect of either hepatitis type or antiviral treatments on itch. Antihistamine treatment was associated with severe itch. Higher NRS was associated with significantly reduced QoL across all eight dimensions analyzed (Table 1; negative coefficients indicate worse QoL, positive values indicate improvement). The strongest association was between increased itching and the

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

impact of pain on QoL; for each additional point in the NRS, QoL changed by -3.33 units (95%CI -4.46, -2.20). There was a similar effect on the role of physical limitations on QoL (-3.20, 95%CI -5.34, -1.07). Each unit increase in NRS was also associated with a 2 to 3-unit decline in reported QoL for the remaining dimensions of emotional well-being, general health, physical function, energy/ fatigue, social functioning, and the impact of emotional health. **Conclusion:** Pruritus affects a large proportion of viral hepatitis patients, regardless of antiviral treatment status. Improved treatment options are needed to address the significant negative impact of itch on their

1846-A | REDUCTION OF DISEASE BURDEN IN KOREAN PATIENTS WITH CHRONIC HEPATITIS C RECEIVING DIRECT-ACTING ANTIVIRALS: A NATIONWIDE, MULTICENTER, RETROSPECTIVE COHORT STUDY

Seung Up Kim[1], Won Sohn[2], Sang Hoon Ahn[1] and Young Seok Kim[3], (1)Yonsei University College of Medicine, Seoul, Republic of Korea, (2)Sungkyunkwan University School of Medicine, (3)Soon Chun Hyang University

Background: Direct-acting antivirals (DAAs) improve the prognosis of patients with chronic hepatitis C (CHC). This study investigated whether DAA treatment improves the disease burden by ameliorating the fibrotic burden in Korean patients with CHC. **Methods:** A nationwide, multicenter, retrospective cohort study was conducted that included patients with CHC recruited from 29 tertiary academic institutes in South Korea. The primary outcome was disease burden, assessed using the measure disability-adjusted life years (DALYs), with age weighting and discounting in untreated and DAA-treated groups. Improvement of fibrotic burden after DAA treatment was assessed using the APRI score and FIB-4 index. The clinical outcomes were hepatocellular carcinoma, liver transplantation, decompensation, or death. **Results:** Between January 2007 and December 2022, data from 11,726 patients with CHC, including

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

8,464 (72%) treated with DAAs, were analysed. During the follow-up period (median 27.5 mo), 469 patients died (353 [10.8%] in the untreated group, 116 [1.4%] in the DAA-treated group), 586 developed hepatocellular carcinoma (343 [10.5%] in the untreated group, 243 [2.9%] in the DAA-treated group), 580 developed decompensation (372 [11.4%] in the untreated group, 208 [2.5%] in the DAA-treated group), and 18 underwent liver transplantation (8 [0.2%] in the untreated group, 10 [0.1%] in the DAA-treated group). The multivariable analyses showed that DAA-treated group significantly reduced mortality, HCC risk, and decompensation development compared to the untreated group (hazard ratio [HR] = 0.22, 95% confidence interval [CI] 0.17-0.27; HR = 0.47, 95% CI 0.39-0.58; and HR = 0.31, 95% CI 0.26-0.37, respectively) (all $p < 0.001$). The APRI-based DALY estimate was significantly lower in the DAA-treated group than in the untreated group (mean 5.0 ± 2.9 vs. 5.9 ± 3.8 y, $p < 0.001$), as was the FIB-4-based DAL estimate (mean 5.7 ± 2.7 vs. 6.3 ± 3.5 y, $p < 0.001$). The difference between the two groups with respect to either the APRI- or FIB-4-based DALYs was highest in patients 40–60 years of age. **Conclusion:** DAA treatment significantly improved the clinical outcomes of CHC patients and reduced the disease burden, by improving the fibrotic burden after DAA treatment.

1847-A | RISK FACTORS FOR LIVER-RELATED OUTCOMES AFTER SUSTAINED VIROLOGIC RESPONSE TO DIRECT ACTING ANTIVIRALS IN PATIENTS WITH CHRONIC HEPATITIS C

Seung Up Kim, Severance Hospital, Seoul, Republic of Korea, Won Sohn, Sungkyunkwan University School of Medicine, Sang Hoon Ahn, Yonsei University College of Medicine, Seoul, Republic of Korea and Young Seok Kim, Soon Chun Hyang University

Background: Direct acting antivirals (DAAs) is the mainstay of antiviral therapy for patients with chronic hepatitis C (CHC). We investigated risk factors for liver-related outcomes after sustained virologic response (SVR) to DAAs in patients with CHC. **Methods:** This multicenter, retrospective, nationwide cohort study consisted of 1,248 patients with CHC who were seen at 29 expert hepatology centres in Korea from January 2015 to December 2022 and who achieved SVR after DAA therapy. The primary outcome was the development of liver-related events (LREs) after SVR, including all-cause death, hepatocellular carcinoma (HCC), decompensation, or liver transplantation. The fibrotic burden at baseline and at SVR was assessed using transient elastography (TE) and the FIB-4 index. **Results:** The mean age of the patients was 59.8 years and 58% (n = 722) were male. The prevalence of genotypes 1 and 2 was 52% and 46%, respectively. The mean liver stiffness value was 11.6 ± 9.8 kPa at baseline and 8.8 ± 7.5 kPa at SVR. LREs developed in 77 (6.2%) patients and consisted of death in 13, HCC in 34, decompensation in 44 and liver transplantation in 2 patients. The multivariable analysis showed that TE-defined cirrhosis at baseline (liver stiffness **e** 14.5 kPa; hazard ratio [HR] = 2.56; 95% confidence interval [CI] 1.30–5.07) and FIB-4-defined advanced fibrosis stage at SVR (> 3.25) (HR = 3.24; 95% CI 1.45–7.22) were independently associated with an increased risk of developing LREs (all $P < 0.05$), together with male sex (HR = 1.99; 95% CI 1.26–3.14) and lower serum albumin level at SVR (< 4.0 g/dL) (HR = 1.87; 95% CI 1.12–3.13) (all $P < 0.05$). **Conclusion:** The fibrotic burden decreased in patients with CHC after DAA treatment. However, the risk of developing LREs remained even after SVR. Our study showed that an assessment of fibrotic burden before and after DAA treatment is required for predicting outcomes in patients with DAA-treated CHC who achieve SVR.

Ahn[1] and Seung Up Kim[1,2], (1)Yonsei University College of Medicine, Seoul, Republic of Korea, (2) Severance Hospital, Seoul, Republic of Korea, (3) Yonsei Liver Center, Severance Hospital, Seoul, South Korea, (4)Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, South Korea

Background: A lack of awareness disturbs proper linkage to care for hepatitis C virus (HCV) infection in patients undergoing surgery. Therefore, we aimed to evaluate the status of HCV screening, confirmation, and treatment rates in patients undergoing surgery in the era of pan-genotypic direct-acting antivirals (DAAs). Additionally, we established and tested an EMR-based automatic alert system for the detection of patients with HCV infection. **Methods:** Patients who underwent surgery in a tertiary academic center between 2019 and 2021 were eligible for this retrospective study. The testing and positivity rates for anti-HCV antibodies and HCV RNA were sequentially analyzed. Additionally, an EMR-based automatic alert system for patients with positive anti-HCV within 3-years before surgery who had yet to be referred to hepatologists was adopted in January 2022 to help surgical departments adequately consult these patients to hepatologists before discharge. **Results:** Between 2019 and 2021, 96894 patients (40121 males, 41.4%) who underwent surgery under general anesthesia were recruited. The median age of the study population was 55.0 years. Of 83920 (86.6%) patients who tested anti-HCV antibody, 576 (0.7%) patients showed positive results with a higher proportion of diabetes mellitus (32.6% vs. 18.5%), hypertension (50.5% vs. 28.6%), liver cirrhosis (13.2% vs. 1.7%) and unfavorable laboratory test results (all $P < 0.05$). HCV RNA was confirmed in 215 (37.3%) patients, with a 20.5% (n = 44) positivity rate. HCV RNA confirmation was required in 266 of 361 (73.7%) patients without HCV RNA test results. Of 44 patients, 42 (95.5%) were referred for treatment, and 29 (69.0%) treatable patients were successfully treated using DAA. HCV RNA confirmation rates were higher in the hepatobiliary and transplant surgery (76.6%) than in the other surgery parts (25.0–33.5%). The newly established automatic alert system alarmed 449 (0.6%) patients from 75,724 discharges after surgery between January 2021 and April 2023. However, only 101 (22.5%) patients were referred to hepatologists even after the automatic notification to the surgical departments. **Conclusion:** Many patients who tested positive for anti-HCV antibodies for surgery still failed to be linked for proper management in the era of pan-genotypic DAA. The attenuated awareness, which continued even after applying an EMR-based automatic alert system, suggests the necessity of comprehensive education with forceful referral or retrospective call-back approach without infringing on the patient's legal privacy.@

1849-A | SIMPLIFIED HEPATITIS C DIAGNOSIS AND TREATMENT STRATEGY ON OUTPATIENT CARE FOR PEOPLE LIVING WITH HIV : A PILOT STUDY IN SOUTHWEST CHINA

Xiao Li[1,2], Xinping Yang[2], Quanying He[2], Yunqiu Yang[2], Shifang Liu[2], Lin Gui[2], Xingqiong Chen[2], Mei Liu[2], Jie Yang[2], Qiong Huang[2], Yanjiang Xu[2], Lihong Gong[2], Xiao Song[1,2], Canzhu Shang[1,2] and Huiqin Li[2], (1) Kunming Medical University,Kunming, Yunnan, China, (2)Yunnan Provincial Infectious Disease Hospital, Kunming, Yunnan, China

Background: The simplification of current hepatitis C (HCV) diagnostic algorithms and service delivery is very crucial to achieving the WHO goal by 2030. To increase timely diagnosis and improve the linkage to care in people living with human immunodeficiency virus (PLWH), HCV reflex testing and a call-back strategy was implemented in a outpatient-clinic of a territorial hospital in Southwest China. **Methods:** The pilot study was conducted in two phases. In Phase 1 (Jan 2022 ~ Oct 2022), the traditional approach to HCV diagnosis including at least 3 visits was adopted. The coordinating

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

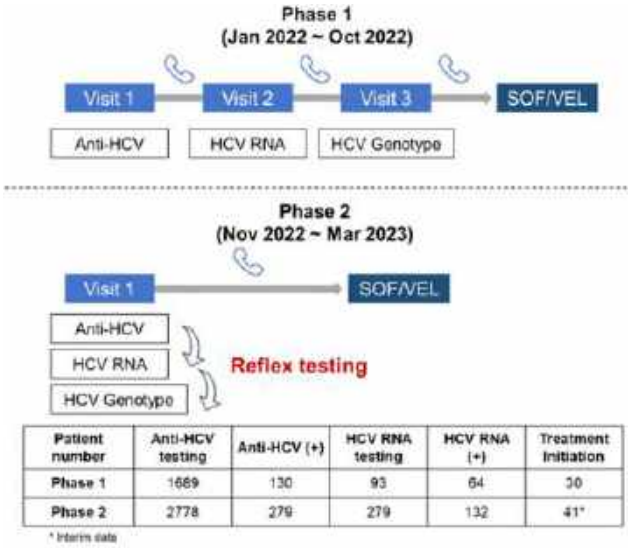
nurses followed up each testing result and called the patients with positive result back for the next visit. In Phase 2(Dec 2022 ~ Mar 2023), reflex testing for HCV RNA and genotype was implemented which only required one visit to confirm HCV diagnosis (Figure 1). 12-week Sofosbuvir/Velpatasvir regimen was administered to HCV viremic patients, and weight-based ribavirin was added for genotype 3 patients. **Results:** In phase 1, a total of 1689 PLWH were included during 10-month study period. With close follow-up by coordinating nurses, 93 anti-HCV positive patients came back for HCV RNA testing and the RNA diagnostic rate was only 71.5% (93/130). Genotype distribution: 10.0% (3/30)GT1b, 33.3% (10/30) GT3a ,43.3% (13/30) GT3b,10.0% (3/30) GT6n ,3.3% (1/30)GT6xa. 30 HCV viremic patients initiated SOF/VEL treatment and achieved SVR12. In phase 2, totally 2778 PLWH were included during 4-month period. The patients of Phase 2 with the "one-visit for diagnosis" strategy, the RNA diagnostic rate increased to 100% (279/279).Phase 2 Genotype distribution: 19.5% (8/41)GT1b, 26.8% (11/41) GT3a ,31.7% (13/41) GT3b,4.8%(2/41)GT6a,12.1% (5/41) GT6n ,2.4% (1/41) GT6u,one person genotyping was not detected. Compared with the Phase 1, the mean time from screening to treatment initiation was shorten from 144 days(144.47 ± 47.29) to 61 days (61.46 ± 25.59), $p < 0.01$. **Conclusion:** The application of the reflex testing significantly increased HCV diagnosis rate and efficiently improved the HCV care cascade efficiently in the HIV outpatient clinic. The simplified HCV diagnosis and treatment strategy could be scaled up for HIV services in China.



Patient number	Anti-HCV testing	Anti-HCV (+)	HCV RNA testing	HCV RNA (+)	Treatment initiation
Phase 1	1689	130	93	64	30
Phase 2	2778	279	279	132	41*

Disclosures: The following people have nothing to disclose: Xiao Li, Xinping Yang, Quanying He, Yunqiu Yang, Shifang Liu, Lin Gui, Xingqiong Chen, Mei Liu, Jie Yang, Qiong Huang, Yanjiang Xu, Lihong Gong, Xiao Song, Canzhu Shang, Huiqin Li

1850-A | SPECIFIC RISK GROUPS FOR HCV INFECTION: SCREENING DATA FROM LATVIA

Ieva Tolmane[1,2], Ieva Siksaliete[3], Inga Upmace[4], Inga Bulmistre[5], Agita Jeruma[1], Inga Azina[1] and Baiba Rozentale[1], (1)Riga East University Hospital, (2) University Og Latvia, (3)Riga Stradins University, (4) Balthiv, (5)Diseases Prevention and Control Center

Background: There are 58 million people living with chronic hepatitis C virus according to WHO data published in 2021. Hepatitis C has lead to approximately 290 000 deaths worldwide in 2019 mainly due to liver cirrhosis and hepatocellular carcinoma. According to previous population screening studies done in Latvia, there is a 2,4% anti-HCV prevalence. There is an anti-HCV screening done in Latvia's psychiatry hospitals reviled a prevalence of 6,8%. The aim of this study was to analyse screening, demographic and risk factor data regarding HCV infection in social care centres and shelters in Latvia. **Methods:** The study was done from October 2020 till October 2022 by HIV Prevention Point employees. Data were obtained using HCV rapid antigen tests and a questionnaire. The participants answered questions concerning demographics and risk factors like sexual activity, intravenous (IV) narcotic use and incarceration. 2838 tests were done in 46 social care centres (SCC) during 61 testing visits. 349 tests were done in 6 shelters during 13 testing visits. Data were analysed using MS Excel and IBM SPSS. **Results:** The mean age in SCC was 58 years (range 16 - 102) and 56 years in shelters (range 20 – 81). 10,3% of SCC residents noted that they were sexually active during the last 12 months. 19% of those who were sexually active used a condom. 5.6% admitted incarceration and 1.2% had IV narcotic use. In shelters 32.7% have been sexually active during the last 12 months of whom 31.6% used condoms. 26.9% admitted incarceration and 6.8% had IV narcotic use. 5.4% of performed tests in SCC were positive for anti-HCV and 12% in shelters. 11% had a history of IV narcotic use ($p < 0.001$) and 21.3% have been incarcerated ($p < 0.001$) of those with a positive anti-HCV test in SCC. 25% had a history of IV narcotic use ($p < 0.001$) and 46.9% have been incarcerated ($p = 0.008$) of those with positive anti-HCV test in shelters. And it is significantly higher rate in comparison to persons not been incarcerated or IV drug users in both groups. **Conclusion:** Residents of SCC and shelters in Latvia have a 2- and 5-times higher prevalence respectively of anti-HCV than the general population of Latvia. However, when compared to Latvia's psychiatry hospitals prevalence is lower in SCC and higher in shelters. The key risk factors in both populations of this study were highlighted as previous incarceration and IV narcotic use. These findings

Background: Although the WHO strategy has the goal to eliminate the hepatitis C virus (HCV) as a public health threat by 2030, the existence of national strategies is variable worldwide. We aimed to assess the establishment of different policies and strategies to

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

eliminate HCV in the Americas. **Methods:** We conducted a 23-item survey about HCV infection among gastroenterologists and hepatologists in the Americas. Questions were classified into four categories: policies and civil society (1 question), diagnosis (6 questions), care management (14 questions), and monitoring systems (2 questions). The survey was carried out using an electronic form between November 2022 – May 2023. Data were collected in a spreadsheet, revised by two independent reviewers, and compared with governmental institutions, regulatory agencies, scientific societies, and scientific publications. We estimated an index obtained from a regression scoring method through exploratory analysis, and row values were normalized from 0 to 100 using a min-max method. **Results:** We obtained 52 responses from 19 out of 21 countries targeted. The median HCV-related policies index was 51.4 [IQR: 27.3–70.1]. The lower establishment of HCV-related policies was observed in Ecuador (0.0), Honduras (6.6), and Costa Rica (9.8), while the highest performance was observed in Argentina (94.1), Colombia (94.7), and Canada (100) (Figure A). Fifteen (78.9%) countries have adopted a national strategic plan to eliminate HCV. Three (15.8%) countries have universal screening for HCV infection (Figure B). After a positive HCV serological test, 10 (52.6%) countries perform reflex testing to confirm HCV diagnosis using the same sample. However, only 7 (36.8%) countries have an alert system for the requesting physician. Twelve (63.2%) countries have a direct referral system for specialized care of HCV-positive cases. There is universal access to direct-acting antivirals (DAAs) in 15 (78.9%) countries. Universal access to DAAs was not widely available in Cuba, Ecuador, Venezuela, and the United States. Seven (36.8%) countries have generic DAAs available. Only 3 (15.8%) countries perform a retrospective search for HCV-positive cases that could have been lost to follow-up. **Conclusion:** Although most countries have adopted a national strategic plan to eliminate HCV, there are several issues and barriers to elimination in the Americas.

School of Medicine, (2)VA Greater Los Angeles Healthcare System, (3)Greater Los Angeles VA Healthcare System, (4)University of California, Los Angeles

Background: Veterans experiencing homelessness (VEH) face multiple barriers to Hepatitis C (HCV) diagnosis and treatment. We implemented and evaluated a novel universal HCV screening, care linkage, and treatment program for Veterans living at a tiny shelter encampment on the West Los Angeles Veterans Affairs campus. **Methods:** We implemented a low-barrier HCV treatment program for VEH in January 2022 that involved clinical dashboard evaluation and universal HCV screening, a novel e-consult direct-to-treatment program facilitated by pharmacists and referral to Infectious Diseases (ID)/Gastroenterology (GI) clinics (if ineligible for e-consult), and extensive engagement by providers. Veterans admitted to the encampment were assessed for HCV Antibody (HCV Ab) positivity and viremia via a local clinical dashboard developed from the National Hepatitis C Registry and universal HCV screening. Subsequent Veterans with HCV viremia were linked to care via an e-consult program, resulting in immediate treatment or referral to a liver clinic. Direct-acting antivirals (DAA) were delivered weekly to Veterans by medical teams. HCV RNA levels were obtained 12 weeks after the end of treatment (SVR12) to assess for treatment efficacy. Demographics, medical history, healthcare visits, and HIV and Hepatitis B (HBV) serologic results were abstracted from the electronic health record. **Results:** Of the 372 Veterans admitted since January 1, 2022, 59 (16%) had a positive HCV Ab. None had co-infection with HBV, and one had co-infection with HIV. Forty-eight percent (28/59) had HCV viremia. The median age for Veterans with HCV viremia was 64 years; all were male, 36% (11/28) were Black, 11% (3/28) were Hispanic, and 54% (15/28) were White. HCV linkage to care occurred in 75% (21/28) of Veterans (18 via e-consult, 3 via clinic referral). DAA initiation occurred in 71% (20/28). Of those who initiated DAA therapy, were not lost to follow-up, and had SVR12 results, 7 Veterans (100%) achieved SVR. Of Veterans with positive HCV Ab, 56% percent (34/59) were immune to Hepatitis B, and 80% (47/59) were immune to Hepatitis A. Of the 22 patients not immune to HBV, immunization was initiated at the encampment in 32% (7/22) of Veterans. **Conclusion:** In a small cohort, we demonstrate the feasibility of encampment-based HCV screening for VEH and high linkage to care and SVR rates. We also show the successful incorporation of other ID screening and immunization.

1853-A | SUPPORTING HCV ELIMINATION THROUGH MEDICAL EDUCATION TOURS PROJECT IN SOUTHWEST CHINA

Chunmei Li, Jia Wei and Hui Li, Hospital of Yunnan University

Background: Awareness of HCV disease and treatment rate were still very low in the resource-constrained rural/remote areas. We aimed to evaluate the effectiveness of medical education tours for health care providers (HCPs) disease awareness and the HCV link-to-care rates in county hospitals in Yunnan, China **Methods:** HCV disease specialists from Affiliated Hospital of Yunnan University and Health Commission of Yunnan province gave medical speeches including HCV disease knowledge training, update of HCV guideline and government policy of HCV elimination work among different cities in Yunnan for different levels of hospitals. HCV awareness questionnaires were provided to each attendee before and after education to assess the baseline knowledge and effectiveness of education. With the guidance of experts, HCV micro-elimination model in each area was carried out after education tour. **Results:** From Sep.2022 to Apr. 2023, a total of 5 viral hepatitis education speaker tours were held. Above 500 primary HCPs including Infectious Disease (ID) department and non-ID departments received the education from 11 counties in Yunnan Province (Figure 1). 146 HCPs completed paired surveys before and after education and disease awareness rates were increased significantly after education (Figure 2). In-hospital referral process of anti-HCV positive individual's from non-ID departments to ID department was improved in 14 county hospitals. Before the education tour project, 2237 patients received HCV screening from Jan 2022 to Aug 2022. After the project, 3167 patients received HCV antibody screening from Sep 2022 to Apr 2023. The rate of link-to-diagnosis rate before and after education was 81% (212/261) and 85% (351/431) respectively. The rate of link-to-treatment was increased from 70% (94/134) to 79% (200/253) after education (Figure 3) **Conclusion:** Medical education tours could raise the HCV disease awareness of local HCPs and improved the HCV screening and linkage to care in rural/remote areas.

1854-A | SURVIVAL, REJECTION AND EXTRA-HEPATIC MANIFESTATIONS FROM TRANSPLANTATION OF HEPATITIS C + HEARTS: A QUATERNARY CENTER EXPERIENCE

Ritika M. Mazumder, Sarah Khan, Qijun Yang, James Bena, Omar T. Sims and William D. Carey, Cleveland Clinic

Background: Donor organ shortages have consistently afflicted the field of solid organ transplantation. Although direct-acting antiviral (DAA) therapy has enabled successful use of HCV+ organs with favorable initial results, long-term outcome data beyond 12 months post-transplant remains insufficient. This study aimed to assess mortality, rejection rates, and extrahepatic manifestations of Hepatitis C in aviremic recipients of HCV+ hearts. **Methods:** This retrospective cohort study included all adult heart transplants at our center between January 2018 and September 2022. **Results:** A total of 256 heart transplant patients (23 HCV+ donors, 233 HCV- donors) were included. All recipients were HCV aviremic prior to transplant. Over a 4-year follow-up period, there was no statistical difference in survival between HCV+ and HCV- heart recipients (90% vs 89%, p = 0.89, Figure 1). Similarly, a multivariate proportional hazard model of survival showed that donor HCV status was not associated with death (HR 0.81, p = 0.78, Table 1). None of the patients developed fibrosing cholestatic hepatitis. No definitive extra-hepatic manifestations of HCV were noted in HCV+ heart recipients, including nephropathy, neuropathy, cryoglobulinemia or dermatitis. Rates of acute cellular rejection, chronic rejection and antibody-mediated rejection for HCV+ heart recipients were 96%, 13% and 0% respectively. All but one patient developed HCV viremia after receiving an HCV+ organ (96%), and the majority were treated with glecaprevir/pibrentasvir (86%). All viremic patients achieved sustained virologic response with one round of treatment. The median time to HCV clearance was 11.8 (6.0, 13.0) weeks. HCV genotypes 1a (45%) and 3 (32%) were the most prevalent. None of the patients contracted HBV or HIV infections from their high-risk donors. **Conclusion:** For heart transplant recipients, donor HCV status is not associated with mortality over 4 years. Nearly all patients with HCV+ donors acquired HCV and 100% of those infected were cured with a single 12-week course of DAA therapy. Extrahepatic effects of HCV were not encountered. Ongoing work at our institution aims to examine rejection rates in all heart recipients, enabling fair comparisons. Overall, our data suggests long-term safety in utilizing HCV+ hearts for enlarging the pool of limited organs. Future studies may examine variations of DAA therapy, such as shorter treatment durations and preemptive treatment strategies.

1855-A | SUSTAINED VIROLOGIC RESPONSE 4 WEEKS AFTER HEPATITIS C TREATMENT HAS A HIGH SENSITIVITY AND POSITIVE PREDICTIVE VALUE FOR CURE

Gia Landry[1,2,3], Frederic McCall III[3], Elizabeth N. Britton[4], Lisa Chang[3] and Kristina Larson[3], (1)Ochsner Health, (2)Louisiana State University, (3)Louisiana Department of Health, (4)Louisiana Department of Health/ Office of Public Health

Background: The United States is starting its plan for nationwide hepatitis C virus (HCV) elimination. Louisiana (LA) is one of a few states to have a statewide HCV elimination program. One part of a successful elimination program will be the sustained virologic response (SVR) rates. It can be difficult in these public health initiatives to have patients get SVR testing 12 weeks after treatment. Therefore, we designed this study to see if SVR 4 weeks after HCV treatment is adequate for determining HCV cure in a large, HCV elimination program. **Methods:** All persons in LA on Medicaid who completed HCV treatment from July 15, 2019 – October 31, 2022 were analyzed. HCV treatment completion was determined by Medicaid claims data. SVR4 and SVR12 were defined as having a negative HCV RNA test 3-6 weeks and **e** 10 weeks after HCV treatment, respectively. SVR data is based on those with SVR testing. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for SVR4 were calculated using SVR12 as the definition of cure. **Results:** There were 9,582 persons who completed treatment for HCV. 599 persons (6%) had SVR4 testing, 6,669 (70%) had SVR12 testing and 408 (4%) had both SVR 4 and SVR12 testing. SVR4 testing was done at a median of 5 weeks (range of 4-6) and SVR12 testing at a median of 22 weeks (range 12-187). 558 (93%) people achieved SVR4 and 5,976 (90%) people were cured based on SVR12. The test characteristics of SVR4 (Table 1) show a sensitivity of 97% and a positive predictive value of 98%. **Conclusion:** LA's HCV elimination program shows that HCV cure rates can be high (90%) in a public health initiative focused on a more complex Medicaid population. Capturing SVR12 data may be a challenge as only 70% of people had SVR12 testing completed. Although only 4% had SVR4 testing, it is not currently standard of practice, but the sensitivity and PPV were very high, 97% and 98%. This suggests that SVR4 could be used to determine HCV cure. It should be captured more systematically in future elimination programs, as it may be easier to get SVR4 testing done since it is closer to the time of treatment when people are still focused on their HCV as opposed to 12 months later. In fact, many people did not have SVR12 testing done until closer to 22 weeks after treatment was completed. SVR4 may be a better alternative to SVR12 going forward, but additional studies are needed.

Table 1. SVR4 Test Characteristics

	SVR12 Achieved (Cured)	SVR12 Failed (Not Cured)	
SVR4 Achieved	378	6	PPV= 98%
SVR4 Failed	12	12	NPV= 50%
	Sensitivity= 97%	Specificity=67%	

PPV= Positive Predictive Value

NPV= Negative Predictive Value

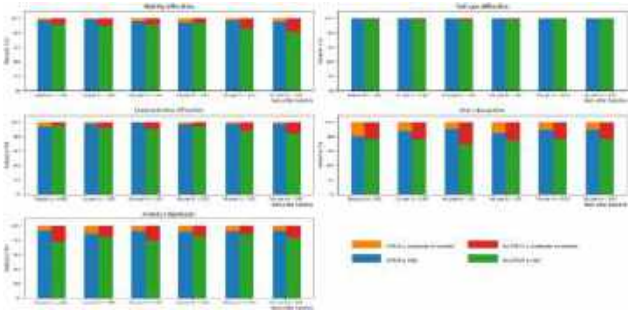
1856-A | SUSTAINED VIROLOGIC RESPONSE IMPROVED THE LONG-TERM HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC HEPATIC C: A PROSPECTIVE NATIONAL STUDY IN CHINA

Rui Huang, Peking University People's Hospital and Huiying Rao, Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis

Background: Chronic hepatitis C virus (HCV) infection can severely impair health-related quality of life (HRQoL) in patients. Although achieving sustained virologic response (SVR) is known to improve HRQoL, there is currently a lack of long-term longitudinal studies in real-world settings. We conducted the study to investigate the trends in HRQoL among HCV patients, and to assess the longitudinal impact of antiviral therapy on their well-being. **Methods:** We conducted a prospective observational study at 28 hospitals across China in adults diagnosed with chronic HCV infection. Sociodemographic, clinical characteristics as well as EQ-5D questionnaires were collected. To assess the associations between these variables and changes in HRQoL over time, we applied generalized estimating equation (GEE) models. **Results:** Our study included 456 patients, with a median age of 46.5 years (interquartile range: 36.5-57.0), of which 262 (57.5%) were males and 44 (9.6%) had cirrhosis. Among the 335 patients (73.5%) who received antiviral therapy, 61.8% achieved SVR24. The baseline EQ-5D utility and EQ-VAS were 0.916 ± 0.208 and 80.6 ± 13.0,

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

respectively. At baseline, there was no significant difference in EQ-5D utility scores between patients with and without SVR (0.959 ± 0.077 and 0.913 ± 0.215, $p = 0.241$), but as the proportion of patients achieving SVR increased over time, these differences became significant. Moreover, EQ-VAS scores were significantly higher in patients with SVR compared to those without SVR, both at baseline and during the follow-up period (baseline: 86.2 ± 12.0 and 80.2 ± 13.0, $p = 0.013$; 5th year: 88.2 ± 11.2, $p = 0.000$). Figure 1 illustrates the proportions of patients who reported moderate or severe problems in individual domains of EQ-5D during follow-up, stratified by SVR status. The differences in proportions between patients with and without SVR became significant over time, particularly in the domains of mobility (MO) and usual activities (UA) (5th year: MO, 8[4.8%] & 8[18.6%], $p = 0.032$; UA, 4 [2.4%] & 7 [16.3%], $p = 0.021$). A higher proportion of patients without SVR reported pain or discomfort compared to those with SVR (1st year: 21[12.2%] & 39[23.9%], $p = 0.005$; 2nd year: 20[9.9%] & 39 [20.2%], $p = 0.000$; 3rd year: 29[15.3%] & 28 [25.0%], $p = 0.047$; 4th year: 19 [10.9%] & 18[22.8%], $p = 0.027$). Using GEE estimation, we found that achieving SVR24 was positively associated with EQ-5D utility ($\beta = 0.039$, 95% CI [0.023, 0.056], $p = 0.000$) and EQ-VAS ($\beta = 5.317$, 95% CI [4.198, 6.438], $p = 0.000$) over time. Age, residence, marital status, occupation, income, cirrhosis and genotype also significantly influenced long-term changes in patients' quality of life. **Conclusion:** Our study suggested that SVR improved long-term HRQoL in HCV patients. Certain sociodemographic factors, as well as the presence of cirrhosis and genotype, significantly influenced long-term changes in patients' quality of life.



Disclosures: The following people have nothing to disclose: Rui Huang, Huiying Rao

1857-A | SUSTAINED VIROLOGICAL RESPONSE REDUCES RISK OF PORTAL VEIN THROMBOSIS IN HEPATITIS C PATIENTS WITH CIRRHOSIS

Humberto Gonzalez[1], Stuart C. Gordon[2], Yihe G Daida[3], Mark A Schmidt[4], Yueren Zhou[1], Trueman Wu[1], Lora Rupp[1], Sheri Trudeau[1] and Mei Lu[5], (1)Henry Ford Health, (2)Henry Ford Health and Wayne State University School of Medicine, Detroit, MI, USA, (3) Kaiser Permanente Hawai'I, (4)Kaiser Permanente Northwest, (5)156 Pocatello Rd

Background: Portal vein thrombosis (PVT) is a relatively common complication of liver cirrhosis. Prevalence estimates ranging from 10–25% of cirrhotic patients, but there are few studies investigating whether treatment of underlying liver disease affects risk of PVT. We used data on patients with cirrhosis and a history of chronic hepatitis C (HCV) infection to evaluate the impact of antiviral treatment status (treated or untreated) and treatment response (sustained virological response [SVR] or treatment failure) as well as patient demographic and clinical characteristics on risk of PVT. **Methods:** Patients were drawn from the multisite, US-based Chronic Hepatitis Cohort Study. PVT events were identified using ICD-CM codes. Events were excluded if they occurred < 1 month before or < 5 months after other thrombotic events (eg, deep vein thrombosis), malignant neoplasm, gastrointestinal inflammatory conditions (eg pancreatitis), pregnancy/ hormone therapy, or major abdominal surgery. Risk for PVT was assessed using a discrete survival model that include both fixed covariates (age, race, sex, history of thrombotic events, malignant neoplasm, gastrointestinal inflammatory conditions, pregnancy/hormone therapy, and major abdominal surgery) and time-dependent variables (BMI, compensated/decompensated cirrhosis, and treatment status/ response). Time-dependent propensity score weighting was used to address treatment selection bias. Patients were followed until liver transplant (if applicable) or last encounter; death was considered a competing risk. **Results:** A total of 6098 HCV patients with cirrhosis were included, among whom 39% (1798) received antiviral therapy and 55% (2956) achieved SVR; 116 patients developed PVT across 10 years of follow-up. SVR significantly reduced risk of PVT compared to no treatment (aHR = 0.29) and treatment failure (aHR = 0.12). Compared to no treatment, treatment failure was associated with more than twice the risk of PVT (aHR = 2.35). Sex and race were significantly associated with PVT: female patients had lower risk than male patients (aHR = 0.83]; Black patients were at 50% higher risk than whites (aHR = 1.5). Other significant risk factors included BMI (aHR = 0.70 [< 25 vs 25-30] and aHR = 0.85 [25–30 vs **e** 30), and history of malignancy (aHR = 1.75); Decompensated cirrhosis increased risk more than 8-fold (aHR = 8.06). **Conclusion:** In adjusted analyses, SVR from either interferon-based or direct-acting antiviral therapy is significantly and strongly associated with lower risk of PVT among HCV patients with cirrhosis. Male sex, Black race, and increasing BMI were associated with increased risk. Future studies to elucidate possible mechanisms for these observations are warranted.

1858-A | THE RELATIONSHIP OF VADOC INMATES WITH HEPATITIS C AND THE BARRIERS PREVENTING THE INITIATION OF DAA TREATMENT

Lisa Carpenter, Temple University, Shawn Lewis, Virginia Commonwealth University and Richard K. Sterling, Virginia Commonwealth University Health System

Background: To achieve global elimination of the hepatitis C virus (HCV), providing treatment to marginalized populations (e.g., incarcerated individual's) is necessary. The prevalence rate of HCV in the prison population ranges from 12-31%, compared to 1.8% for nonincarcerated individual's. Oral direct-acting antiviral (DAA) treatment is 96% effective at achieving a sustained virologic response (SVR) and can be administered over 8-12 weeks, with a significant decrease in side effects when compared to previous HCV treatments. Notwithstanding the availability of DAA treatment many prisons fail to treat all inmates who have HCV. The purpose of this study was to investigate the barriers in the Virginia Department of Corrections (VADOC) preventing the initiation of DAA treatment for inmates diagnosed with HCV. **Methods:** In this retrospective cohort study designed as a secondary analysis for the quality improvement of HCV treatment, data was collected from electronic medical records (EMR) of VADOC inmates who were referred for HCV treatment but did not start. Barriers were gathered from medical provider and VADOC staff notation in EMRs then grouped by common theme to assess frequencies. Statistical analyses were used to examine associations between treatment groups based on prison level data and demographics; no treatment = 135, initiated treatment = 2,062. **Results:** Of the inmates who had not initiated DAA treatment there were 124 (91.9%) males and 11 (8.1%) females. The mean age was 50 years old, with 44 Black (32.6%) and 89 White (65.9%) individual's. Of the 39 prisons, 26 prisons had 1 or more inmates who had not initiated DAAs (6.1% of total), ranging from 1-15 inmates per prison. Missing lab

results (42.2%), limited time remaining in an inmate's sentence (23.7%), and missing follow-up appointments (20.0%) had the highest frequency for preventing treatment initiation. In addition, there is a significant association between prison location and treatment initiation (Chi-square $p < 0.0001$), further defined by prison regional location and population size. **Conclusion:** With the increase in frequency of prison-initiated barriers, further investigation of prison policy and functionality is necessary to address the gap in HCV treatment initiation. Moreover, screening requirements for HCV treatment at the clinical level need to be addressed. These findings will improve our understanding of healthcare barriers in prisons, mitigating treatment delay to achieve HCV global elimination.

1859-A | THE RISK OF HEPATOCELLULAR CARCINOMA DEPENDING ON LIVER CIRRHOSIS IN PATIENTS WITH CHRONIC HEPATITIS C: A NATIONAL COHORT STUDY

Jong-In Chang[1], Gi Hyeon Seo[2], Eunju Kim[1], Young Youn Cho[1] and Hyung Joon Kim[1], (1)Department of Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea, (2)Health Insurance Review and Assessment of Service, Seoul, Korea

Background: Current direct-acting antiviral (DAA) treatments for the hepatitis C virus achieve high rates of sustained virological response, thus improving clinical outcomes. Chronic hepatitis C patients are at-risk for hepatocellular carcinoma (HCC) even after DAA treatment. Limited national data exist on the long-term clinical course of DAA use and whether surveillance is needed depending on liver cirrhosis in Korean patients with chronic hepatitis C. **Methods:** This is a population-based retrospective cohort study using the database of the Health Insurance Review and Assessment Service in Korea. A total of 16,344 adult patients who were newly administered Ledipasvir/sofosbuvir or Glecaprevir/pibrentasvir between 2016 and 2021 without a previous history of HCC were included in the analysis. The primary outcome was the incidence of HCC after DAA treatment in patients with and without cirrhosis. The secondary outcome was whether there were differences in HCC incidence by gender and age group. **Results:** The average age of 16,344 patients was 59.4 years, males were 46.9%, the average follow-up period was 23.5 months, and 2,928 (17.9%) patients had liver cirrhosis. The incidence of HCC per 1,000 patient-years was 9.38 in all patients, 3.68 in non-cirrhotic patients, and 33.17 in cirrhotic patients. In both patients with and without cirrhosis, age **e** 65 and male gender were associated with the incidence of HCC in each subgroup. **Conclusion:** Even after DAA treatment, the risk of HCC remains high in patients with chronic hepatitis C with cirrhosis, whereas the risk is significantly lower in patients without cirrhosis. These results may support the argument that DAA treatment is important before cirrhosis in patients with chronic hepatitis C and that HCC surveillance is necessary continuously after DAA treatment in patients with cirrhosis.

1860-A | ADDITION OF NEUTROPHIL-TO-LYMPHOCYTE RATIO TO PRE-DAA FIB-4 TO PREDICT DE NOVO LIVER COMPLICATIONS IN HEPATITIS C

Chun-Ming Hong[1], Tung-Hung Su[2], Shih-Jer Hsu[1], Tai-Chung Tseng[1], Chen-Hua Liu[2], Hung-Chih Yang[1], Jia-Horng Kao[2], Pei-Jer Chen[2], Pin-Nan Cheng[3], Cheng-Yuan Peng[4], Chun-Yen Lin[5], Han-Chieh Lin[6], Yi-Hsiang Huang[7], Chi-Yi Chen[8], Chih-Lin Lin[9], Pei-Chien Tsai[10], Chia-Yen Dai[10], Wan-Long Chuang[11], Jee-Fu Huang[11], Chung-Feng Huang[10], Ming-Lun Yeh[10], Ming-Lung Yu[11] and Chun-Jen Liu[2], (1)National Taiwan University Hospital, Taiwan, (2)National Taiwan University Hospital, (3)National Cheng Kung University Hospital, Taiwan, (4)China Medical University Hospital, Taiwan, (5)Linkou Chang Gung Memorial Hospital, (6)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, (7)Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, (8)Ditmanson Medical Foundation Chiayi Christian Hospital, Chia Yi, Taiwan, (9)Renai Branch, Taipei City Hospital, Taipei, Taiwan, (10)Hepatobiliary Section, Department of Internal Medicine, and Hepatitis Center, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, (11)Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Direct-acting antiviral agents (DAAs) can achieve high sustained virologic response (SVR) in chronic hepatitis C (CHC) patients; yet a proportion of patients still experience de novo liver complications even after SVR. Identification of risk factors is clinically important. FIB-4 index is a useful noninvasive tool to assess fibrosis, while neutrophil-to-lymphocyte ratio (NLR) is a biomarker for systemic inflammation. Our study tried to investigate that whether the addition of

NLR can increase the prediction power of pre-DAA FIB-4 for de novo liver complications such as ascites, hepatic encephalopathy, variceal bleeding, or HCC after SVR. **Methods:** We recruited patients via the platforms of The Taiwan HCV Registry (TACR) and National Health Insurance Registry Database. The inclusion criteria were patients who achieved SVR12 after DAA therapy and were followed for at least 24 months after SVR12. **Results:** Totally 7657 patients were recruited from 2013/12/25 to 2018/12/31. Among these 7657 patients, 3674 patients (48.0%) were FIB-4 > 3.25 and 491 patients (6.4%) were NLR > 4 before DAA therapy. 2281 (29.8%) had prior treatment. 5115 patients (66.8%) were infected with genotype 1, followed by genotype 2 (2269 patients, 29.6%). After two-year of follow-up after SVR 12, 214 patients (2.8%) developed de novo liver complications. Among these 214 patients, 11 (5.1%) were coinfected with HBV. 163 patients (76.2%) were FIB-4 > 3.25 and 17 patients (7.9%) were NLR > 4 at baseline. The cumulative incidence of de novo liver complications in patients with FIB-4 > 3.25 and NLR > 4 was the highest while the cumulative incidence in FIB-4 < 3.25 and NLR < 4 was the lowest. The addition of NLR did not differentiate the cumulative incidence in patients with either FIB-4**f** 3.25 or FIB-4 > 3.25. **Conclusion:** The overall incidence of de novo liver-associated complications after SVR is low during short-term follow-up. Pre-DAA FIB-4 is associated with de novo liver complications after SVR, though the addition of pre-DAA NLR does not increase the prediction power.

1861-A | BEMNIFOSBUVIR AND RUZASVIR ARE POTENT HCV DAAS WITH FAVORABLE ANTIVIRAL PROFILES AGAINST MAJOR HCV NS5A AND NS5B RAVS SUPPORTING USE IN COMBINATION

Qi Huang, Steven Good, Dawei Cai, Nancy Agrawal and Jean-Pierre Sommadossi, Atea Pharmaceuticals, Inc.

Background: Bemnifosbuvir (BEM), an oral prodrug of a guanosine nucleotide analog, has demonstrated highly potent pan-genotypic best-in-class *in vitro* and clinical antiviral activities against all hepatitis C virus (HCV) genotypes (GTs 1-4) tested. Ruzasvir (RZR), a potent NS5A inhibitor, has shown broad genotypic *in vitro* antiviral activities (EC_{50} **d** 10 pM) against GTs 1-6. Viral resistance has emerged as an important consideration for direct-acting antiviral (DAA) drug use since it may impact effectiveness for treatment of HCV infection. We aim to profile the antiviral activity of each of BEM and RZR against a panel of previous NS5A Resistance-Associated Variants (RAVs) selected *in vitro* or identified in HCV patients who have failed treatment with currently available DAAs. **Methods:** The antiviral effects of BEM, RZR and current Standard of Care (SOC) DAAs sofosbuvir and velpatasvir (component of EPCLUSA) against a set of selected, clinically relevant NS5A and NS5B RAVs were determined in transient replicon assays. **Results:** BEM is at least 10-fold more potent than sofosbuvir (SOF) across all genotypes tested and is not resistant to sofosbuvir RAVs (S282T, L159F/S282T, Figure 1A). BEM also retains antiviral activity against all GT1a and GT3a NS5A RAVs tested (Figure 1B). In GT- 1a, RZR is 10-fold more potent than velpatasvir (VEL), and it retains single-digit pM antiviral activity against RAVs (M28V +Q30R, M28T+T64A, L31M+H58P) selected by previous NS5A inhibitors, while velpatasvir is 10 time less potent against selected double mutants (M28V+Q30R, M28T+T64A). In GT-3a, the most difficult to treat genotype, RZR is 6 times more potent than velpatasvir, and retains sub-nM potency against NS5A RAVs (such as A30K, Y93H) which were treatment-emergent in HCV GT3 patients failing DAAs (Figure 1C). The combination of BEM and RZR resulted in additive to synergistic antiviral effects. The antiviral potency of RZR is not affected by signature RAVs emerging with

other classes of HCV DAAs against NS3/4A protease and NS5B polymerase (nucleoside and non-nucleoside) inhibitors. **Conclusion:** Given the highly potent pan-genotypic antiviral activity of BEM and RZR, the high resistance barrier of BEM, the complementary mechanisms of action of BEM and RZR, the clinically demonstrated safety and efficacy of each agent when administered individually, and the lack of drug-drug interaction(DDI) between BEM and RZR, combination treatment with these two agents for HCV infections is highly attractive and is currently being evaluated in a Phase 2 clinical trial. The combination of BEM/RZR should have a more compelling antiviral profile against major HCV NS5A RAVs than current SOCs.

1862-A | CHARACTERISTICS OF HEPATITIS C VIRUS RESISTANCE IN A TERTIARY CENTER IN FRANCE – A 6 YEARS EXPERIENCE

Simona Tripon[1], Mira Kayal[1], Aurélie Velay[1], Thibaut Goetsch[1], Francois Habersetzer[1], Robert Bader[2], Dominique Paya[1], Martine Alt-Tebacher[1], Izabelle-Ana Amaritei[3], Frederic Chaffraix[1], Carine Wiedemer[1], Thomas F. Baumert[4] and Michel Doffoel[1], (1)Nouvel Hôpital Civil, Hôpitaux Universitaires De Strasbourg, (2) Hôpital Emile Muller, Groupement Hospitalier Régional Mulhouse Sud Alsace (GHRMSA), (3)Hôpital Louis Pasteur, Colmar, (4)Institut Hospitalo-Universitaire (IHU), Pôle Hépato-Digestif, Hôpitaux Universitaires De Strasbourg, 67000 Strasbourg, France

Background: Despite the excellent efficacy of direct-acting antiviral (DAA), in some patients, virological failure can occur associated with resistance –associated substitutions (RASs). This study aimed to describe the RASs characteristics and evaluate clinical factors associated with RASs selection after 6 years of experience with DAA treatment, in a tertiary center in France. **Methods:** We performed a retrospective analysis based on data presented at the multidisciplinary team meetings of our tertiary care center between July 2015 and August 2021. From a total of 1593 patients, 55 experienced RAS mutations. The RASs in non-structural protein (NS)3, NS5A, and NS5B were determined by direct sequencing. **Results:** In our population, 64% of patients had a 1st generation DAA, 36% -2nd DAA generation as the first line treatment, 9% had **e** 2 lines of DAA regiments and 16% had INF before DAA. According to the RASs : 81% were NS5A, 38% NS3, 7% NS5B and 22% were mixed NS5A+NS3. Y93H and L31M in NS5A were more frequently detected in 47% and 18% of patients, respectively V170I in NS3 in 24%. Patients with cirrhosis had more frequent genotype 1b, 50% vs. 16% ($p = 0.013$) and NS3 –RASs 53.3% vs. 20% ($p = 0.024$). Y93H-RAS in NS5A was more present in older patients (> 60 y) 60% vs. 40% ($p = 0.06$) and after 1st generation DAA regimens, 52 %vs 48% ($p = 0.04$). NS5A RASs was associated with HCV genotype 3 ($p = 0.04$). Moreover, in multivariate logistic regression adjusted analyses, having genotype 3 seem to be more associated with NS5A RAS, aOR 5.57 95%CI 0.79-39.17; $p = 0.08$). **Conclusion:** In our cohort, failure to DAA treatment leads to more frequent RASs in the NS5A region, especially in patients with genotype 3 HCV infection.

Vanderbilt University Medical Center, (2)The Medical University of South Carolina, (3)University of Rochester Medical Center, (4)Ochsner Health

Background: The practice of transplanting solid-organs from hepatitis C virus (HCV) Nucleic Acid Testing (NAT)+ donors into HCV-negative recipients has become more prevalent as supporting data continues to emerge. Given the high sustained virologic response (SVR) rates of direct-acting antivirals (DAAs), little data exists regarding retreatment strategies for patients that fail to achieve SVR. This multi-site case series describes HCV-negative solid-organ transplant (SOT) recipients that failed DAA therapy following HCV NAT+ SOT, retreatment strategies, and subsequent SVR rates. **Methods:** This was a multi-site retrospective case series of patients that failed DAA treatment following HCV NAT+ SOT between September 2016 and September 2022 at three tertiary medical centers in the United States. **Results:** Nine patients were included (male, 78%; white, 78%; median [interquartile range (IQR)] age 66 years [57-70]) and are described in Table 1. The majority received an HCV NAT+ kidney (78%), just over half were genotype 1 (56%), and sofosbuvir/velpatasvir (SOF/VEL) x12 weeks was the initial DAA course most frequently (44%) prescribed. Baseline resistance testing was not completed. The median [IQR] time to treatment initiation following SOT was 26 days [20-40]. Two patients (ID 6, ID 9) never achieved a viral load of < 15 IU/mL or undetectable and 2 patients (ID 2, ID 5) never achieved normalization of alanine transaminase (ALT) while receiving the initial DAA course. The median [IQR] time to retreatment following positive viral load was 28 days [18-73]. The majority (67%) received retreatment with sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) x12 weeks. One patient (ID 5) prescribed SOF/VEL/VOX + ribavirin (RBV) x12 weeks with emergent M28I/K and L31L/P mutations failed to achieve a viral load of < 15 IU/mL or undetectable or normalization of ALT during 12 weeks of treatment. Treatment was extended to 24 weeks and SVR achieved. One patient (ID 8) prescribed SOF/VEL/VOX x12 weeks failed to achieve a viral load of < 15 IU/mL or undetectable until week 11 of treatment. Treatment was extended to 24 weeks and SVR achieved. Only 1 patient (ID 6) failed to achieve SVR following DAA retreatment with SOF/VEL/VOX x12 weeks. This patient was retreated with sofosbuvir (SOF) + GLE/PIB + RBV x24 weeks and achieved SVR. **Conclusion:** HCV-negative patients that failed DAA therapy following NAT+ HCV SOT are described. All patients achieved SVR following one or more DAA retreatment courses.

Table 1. Treatment Characteristics and HCV Test Results of HCV-Negative Patients that Failed DAA Therapy Following NAT+ HCV SOT

1864-A | DIRECT-ACTING ANTIVIRALS HAVE SUBSTANTIALLY MODIFIED THE PROFILE OF CHRONIC HEPATITIS C PATIENTS WITH CIRRHOSIS IN SOUTH CHINA: A MULTICENTER STUDY

Jianping Li[1], Songlian Liu[1], Ying Tan[1], Wenyu Wang[1], Shi Ouyang[2], Ganqiu Lin[1], Aiqi Lu[1], Binbin Chen[1], Zhiwei Xie[1], Chunlan Zhang[1], Yujuan Guan[1] and Xujing Liang[3], (1)Guangzhou Eighth People's Hospital, Guangzhou Medical University, (2)The Fifth Affiliated Hospital of Guangzhou Medical University, Guangzhuo, China, (3)The First Affiliated Hospital of Jinan University

Background: In patients with cirrhosis due to hepatitis C virus (HCV), a sustained virologic response (SVR) to antiviral therapy is associated with reductions in the incidence of hepatic decompensation, hepatocellular carcinoma, all-cause mortality and liver-related mortality. We aimed to evaluate the efficacy, safety and changes in noninvasive tests (NITs) in this population in South China. **Methods:** This retrospective multicenter study enrolled patients with Chronic hepatitis C (CHC) and cirrhosis who were treated with Direct-acting antivirals (DAAs). Patients with decompensated cirrhosis (DCC) received additional ribavirin (RBV). In the cases where RBV was not tolerated, the treatment duration was extended to 24weeks according to the guideline. Virological indicators, liver and renal function indexes were assessed at baseline, the week 4, the end of treatment, and 12 weeks of follow-up. **Results:** A total of 128 patients were enrolled from Jan. 2016 to Dec. 2022. The patients were from Guangzhou Eighth People's Hospital, The First Affiliated Hospital of Jinan

University, and The Fifth Affiliated Hospital of Guangzhou Medical University. 66 cases had compensated cirrhosis (CC) and 62 cases had DCC. Baseline characteristics were showed in Table 1. All patients completed the treatment, primarily with the regimen of Sofosbuvir and Velpatasvir. RBV was used in 81 (63.3%) patients. At the end of treatment, undetectable levels of HCV RNA were achieved in 125 cases (97.7%). The SVR12 rate was 94.5%. The SVR12 rates were high across genotypes (GT) with 100% for GT 1, GT 2 and GT unknown, 92.9% for GT 3a, 90.3% for GT 3b, and 93.5% for GT 6a. With different Child-Turcotte-Pugh (CTP) scores, the SVR12 rates were 97.0% for CTP A, 90.2% for CTP B, and 95.2% for CTP C. Notably, patients with CC showed significant improvements in ALB (from 40.7 ± 4.2 to 44.3 ± 3.7 g/L) ($P < 0.001$), ALT (from 81.6 ± 67.4 to 30.7 ± 24.8 U/L) ($P < 0.001$), APRI (from 1.6 ± 1.2 to 0.7 ± 0.5) ($P < 0.001$) and FIB-4 (from 3.9 ± 2.2 to 2.7 ± 1.5) ($P = 0.002$) after treatment. Additionally, patients with DCC showed a significant improvement in CTP score after treatment. All 66 CTP A patients remained in CTP A, while in the group CTP B, 22 (53.7%) improved to CTP A, 18 (43.9%) remained in CTP B and 1 (2.4%) worsened to CTP C. In the group CTP C, 9 (42.6%) improved to CTP A ,10 (47.6%) improved to CTP B, and 2(9.5%) remained in CTP C. Renal function remained stable throughout the treatment. The most common adverse events were fatigue (21.9%) and anemia (19.5%). 7 cases relapsed, 4 of them were successfully rescued and achieved SVR12, while 3 cases were lost to follow-up. **Conclusion:** This study shows that DAA treatment has good efficacy and safety in CHC with cirrhosis. Patients with CC show significant improvements in ALB, ALT, APRI and FIB-4 scores after treatment. Patients with DCC show a significant improvement in CTP score after treatment.

Table 1 Baseline Characteristics

	CTP A	CTP B	CTP C	Total
N	66	41	21	128
Age(year)	54.8±8.6	52.0±9.7	55.7±8.1	54.1±8.9

1865-A | DRUG DRUG INTERACTIONS BETWEEN ANTIPSYCHOTICS AND PANGENOTYPIC DAA IN PATIENTS RECEIVING OPIOID SUBSTITUTE THERAPY

Chihhao Chang[1,2], Yea-Yuan Chang[3,4,5], Han-Ting Wei[6,7] and Chien-Chun Wang[5], (1)Division of Gastroenterolog, Taipei City Hospital, Zhongxiao Branch, (2)Division of Gastroenterology, Taipei City Hospital, Linsen, Chinese Medicine and Kunming Branch, (3)Department of Teaching and Research, Taipei City Hospital, (4)Division of Infectious Disease, Taipei City Hospital Renai Branch, (5)Division of Infectious Disease, Taipei City Hospital Linsen, Chinese Medicine and Kunming Branch, (6)Department of Psychiatry, Taipei City Hospital Linsen, Chinese Medicine and Kunming Branch, (7)Kunming Prevention and Control Center, Taipei City Hospital

Background: Previous studies have shown high efficacy associated with new generation of pangenotypic direct acting antivirals (DAAs). Despite having high cure rate and well tolerated safety profile, DAAs are linked to potential drug drug interactions (DDI) with concomitant medications. Patients received opioid substitute therapy and infected with HCV are often prescribed with antipsychotics as comedication. The aim of current study is to describe the efficacy of pangenotypic DAA in Asian patients who receive opioid replacement therapy and assess their associated risk of DDI with antipsychotics. **Methods:** This is a retrospective observational study reviewing HCV adult patients treated in two addiction centers between Jan 2020 and Dec 2021 with pangenotypic DAAs. Demographic variables collected including age, baseline fibrosis, presence of ongoing recreational drug use, neurological comorbidities, type of DAA prescribed and presence or absence of psychiatric co-medication. DDI between concomitant medication and DAA were assessed using Liverpool database. Baseline demographic and clinical characteristics were summarized using descriptive statistics. **Results:** A total of 160 patients were included, 119 patients received SOF/VEL and 41 patients received GLE/PIB. Patient characteristics: mean age of 49 years, 39% patients had positive urine test for recent recreational drug use, 69 % received methadone maintenance therapy. The distribution of HCV genotypes- GT 6 (39%), GT 1a (19%), GT 1b (19%), GT 2 (12%), GT 3 (7%). 140 patients completed DAA treatments and had SVR 12 obtained; the SVR 12 per protocol was 98%. Eighty-eight patients (55%)

received psychotropics during HCV treatment and 28% received antipsychotics. The most prescribed antipsychotics were mirtazepine (50%), quetiapine (39%), and agomelatine (20%). There were no DDI between SOF/VEL and prescribed antipsychotics while DDI occurs in 16% (5/31) of patients treated with GLE/PIB with antipsychotics. (Table 1) **Conclusion:** Current study showed pangenotypic DAAs are effective in Asian HCV population receiving opioid substitute therapy. Similar to western data, antipsychotics are frequently prescribed in this cohort. SOF/VEL is associated with lower incidence of DDI with CNS drugs compared to GLE/PIB. A careful evaluation of DDI prior to DAA initiation is important to minimize potential risk and optimize treatment outcome.

Incidence of DDI between DAAs and CNS drugs

1866-A | EFFECTIVENESS AND SAFETY OF SOFOBUVIR/VELPATASVIR/VOXILAPREVIR AS A RESCUE THERAPY FOR CHRONIC HEPATITIS C PATIENTS WITH FAILED PREVIOUS DIRECT-ACTING ANTIVIRALS TREATMENT IN SOUTHWEST CHINA

Yan Guo, Yan Zhu, Jianqiong Guo, Yanyan Wu, Qing Mao, Jie Xia and Ming Liu, Department of Infectious Diseases, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China.

Background: The effectiveness and safety of sofobuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) as a rescue therapy for chronic hepatitis C (CHC) patients in China who failed previous direct-acting antivirals (DAA) treatment remains limited. **Methods:** Patients with hepatitis C who failed previous DAA receiving SOF/VEL/VOX for rescue therapy from Jan. 2022 to Mar. 2023 were recruited. The primary efficacy endpoint was the sustained virological response at post-treatment week 12 (SVR12). Clinical and laboratory data and adverse events (AEs) were collected during treatment period. **Results:** A total of 12 CHC patients receiving SOF/VEL/VOX rescue therapy were collected. The median age was 51 (48-58) years, and 8 patients (66.7%) were males. 8 patients (66.7%) had drug injection history and 2 of them were co-infected with HIV. 6 patients (50.0%) had liver cirrhosis. The previous failed DAA regimen include sofosbuvir/velpatasvir (SOF/VEL, n = 9, 75.0%), sofosbuvir plus coblopasvir (SOF plus CLP, n = 3, 25.0%). The median interval between virological relapse and previous DAA cessation was 9 (3-11) months. The median HCV RNA was 6.5 (5.9-6.9) $\log_{10}$IU/mL at baseline of rescue therapy and the most common HCV GT was GT 3b (n = 10, 83.3%). All patients with GT 3b received SOF/VEL/VOX plus ribavirin (RBV) combination therapy, and the other 2 patients received SOF/VEL/VOX monotherapy. Till now, 9 patients completed 12 weeks of SOF/VEL/VOX treatment and 12 weeks of follow-up, 2 patients were still under treatment, and 1 patient was lost to follow-up. All the 9 patients who completed the 12 weeks of SOF/VEL/VOX treatment achieved SVR12. Median ALT significantly declined from 134.7 (51.0-262.5) IU/L at baseline to 25.5 (9.6-40.4) IU/L at the end of treatment ($P = 0.013$). No special AE was reported during treatment and no patient discontinued treatment. **Conclusion:** SOF/VEL/VOX was effective and well-tolerated for difficult-to-treat DAA experienced CHC patients in China, including those with GT3b and cirrhosis.

Table Baseline characteristics of patients treated with SOF/VEL/VOX

Characteristics	Patients (N=12)
Age, year, median (IQR)	51 (48-58)
Male	8 (66.7%)
Previous failed DAA regimen	
SOF/VEL	9 (75.0%)
SOF plus CLP	3 (25.0%)
Rescure DAA regimen	
SOF/VEL/VOX	2 (16.7%)
SOF/VEL/VOX plus RBV	10 (83.3%)
HIV coinfection	2 (16.7%)
HCV RNA, $\log_{10}$IU/mL, median (IQR)	6.5 (5.9-6.9)
HCV genotype	
3b	10 (83.3%)
2a	1 (8.3%)
6a	1 (8.3%)
Liver cirrhosis	6 (50.0%)
White blood cell count, 10^9cells/L,median (IQR)	5.1 (4.2-6.4)
Hemoglobin, g/L, median (IQR)	143.5 (138.5-153.3)
Platelet count, 10^9cells/L,median (IQR)	140 (82-170)
ALT, IU/L, median (IQR)	134.7 (51.0-262.5)
Total bilirubin, umol/L, median (IQR)	15.3 (8.9-23.0)
Albumin, g/L, median (IQR)	41.0 (37.7-43.9)

1867-A | EFFICACY AND SAFETY OF SOF/VEL TREATMENT IN RECENTLY ACQUIRED HEPATITIS C VIRUS INFECTION AMONG PEOPLE LIVING WITH HUMAN IMMUNODEFICIENCY VIRUS: A SINGLE-CENTER STUDY IN SOUTHWEST CHINA

Qing Lin[1], Zhenglin Wang[1], Xiaohui Cheng[1], Fang Wang[1], Zheng Tang[1], Xinyue Huang[2], Zehu Deng[1] and Yiping Yang[1], (1)The People's Hospital of Jiulongpo District ,Chongqing,China, (2)Tongguanyi Town Health Center of Jiulongpo District, Chongqing,China

Background: HIV/HCV coinfection is a global health problem with overlapping modes of transmission. Epidemic outbreaks of recently acquired HCV infection in people living with HIV (PWLH) have been observed globally. However, little is known about the diagnosis and treatment of recently acquired HCV in PWLH in China. **Methods:** We retrospectively reviewed the recently acquired HCV patients in the HIV outpatient clinic of People's Hospital of Jiulongpo District, Chongqing from May 2021 to January 2023. **Results:** In total, 42 recently acquired HCV patients were identified from the PLWH cohort (n = 1623). All the patients were anti-HCV negative upon HAART initiation and were symptomatic or abnormal liver function during routine visits and confirmed HCV infection by Anti-HCV and HCV RNA testing. The baseline characteristics are summarized in table 1. 40(95%) patients who were taking EFV/TDF/3TC or AZT/3TC/LPVr switched to B/F/TAF regimen before anti-HCV treatment. All the patients received 12-week SOF/VEL (400 mg sofosbuvir plus 100 mg velpatasvir) treatment, weight-based ribavirin was added for genotype 3 patients. All the patients completed anti-HCV treatment and follow up. At post-treatment week 12, 42 (100%) patients were HIV RNA undetectable, 41 (98%) achieved HCV sustained virological response (SVR), and ALT concentrations declined into the normal range in 36 (86%) patients. The only patient who didn't achieve SVR12 was a 46-year-old male with HCV genotype 3. The 5 HBV/HCV/HIV co-infection patients maintained HBV DNA undetectable during treatment. SOF/VEL treatment was well tolerated. No serious adverse event (AE) reported, and no patient discontinued treatment prematurely due to AE. **Conclusion:** The 12-week treatment with SOF/VEL was well tolerated and highly effective in recently required HCV infection in PWLH. Regular HCV screening and prompt anti-HCV treatment might effectively prevent HCV transmission in PWLH.

1868-A | EFFICACY AND SAFETY OF SOFOSBUVIR/VELPATASVIR WITH OR WITHOUT RIBAVIRIN IN HCV-INFECTED CHINESE PATIENTS: A PROSPECTIVE COHORT STUDY

Jiayi Wang[1], Lingyao Du[1], Chen Zhou[1], Yilan Zeng[2], Enqiang Chen[1], Dong-Mei Zhang[1], Xing Cheng[1], Xiaona Song[1], Ning Han[1], Miao Liu[1], Han Chen[1] and Hong Tang[1], (1)Center of Infectious Diseases, Division of Infectious Diseases in State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, Sichuan 610041, China, (2)Public Health Clinical Center of Chengdu, Chengdu, Sichuan 610041, China

Background: Sofosbuvir/velpatasvir (SOF/VEL) is a highly effective pan-genotype, one single tap antiviral regiment in patients chronically infected with hepatitis C virus (HCV). But real-world data on its efficacy and safety remains scarce in Southwest China, a region with diverse HCV genotypes (GT), especially high proportion of HCV GT3. **Methods:** In this prospective observational cohort study, we recruited patients from West China Hospital and Public Health Clinical Center of Chengdu in Southwest China. Patients included adults chronically infected with any HCV genotype, either with or without cirrhosis, HCC, HIV/HBV coinfection. Patients were administered with a single table regimen SOF / VEL (400/100 mg) once daily for 12 weeks, with or without ribavirin (RBV). The usage of RBV was depended on GT3, cirrhosis and poor liver function. All

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

HCV patients reaching 12 weeks post-treatment were assessed for SVR12 (defined as HCV RNA less than 15 IU/mL at 12 weeks after treatment cessation). Adverse events (AEs) were also evaluated during treatment. **Results:** This study included 452 patients. HCV genotype: GT1 40.3% (182/452), GT2 7.3% (33/452), GT3 37.4% (169/452), GT6 11.3% (51/452) and GT uncertain 3.8% (17/452). RBV was administrated to 36.7% (166/452) patients. The overall SVR12 rate was 99.1% (448/452). The SVR12 for patients infected with HCV GT3, patients with cirrhosis or HCC, or patients with HBV/HIV coinfections was 99.4% (168/169), 100% (62/62), and 97.6% (40/41), respectively. The SVR12 was 98.8% (164/166) for patients who had received RBV. Among patients who received RBV, 88.0% (146/166) were infected with HCV GT3, 18.1% (30/166) had cirrhosis, and 7.2% (12/166) were coinfected with HBV/HIV. After SOF/VEL ± RBV therapy, ALBI representing liver function showed a significant decrease from baseline to SVR12(-2.91 *vs.* -3.11 $P < 0.001$), while both FIB4 (3.67 *vs.* 2.81, $P = 0.004$) and APRI (1.42 *vs.* 0.71, $P < 0.001$) used for liver fibrosis evaluation also showed a significant decrement from baseline to SVR12. None of the involved patients experienced any grade 3-5 AEs. **Conclusion:** Although included high proportion of patients with HCV GT3b, cirrhosis, HCC, or HBV/HIV coinfections, SOF/VEL with or without RBV was highly effective and well tolerated in patients with chronic HCV infection in Southwest China.

1869-A | EFFICACY OF SOFOSBUVIR/VELPATASVIR/VOXILAPREVIR IN NAÏVE CHRONIC HEPATITIS C PATIENTS: REAL LIFE STUDY

Hatice Rahmet Guner, Ankara Yildirim Beyazit University Ankara Bilkent City Hospital, Ankara, Turkey, Tansu Yamazhan, Ege University Medical Faculty, Izmir, Turkey, Oguz Karabay, Sakarya University Medical Faculty, Ayse Inci, Istanbul Training and Research Hospital, Gurdal Yilmaz, Karadeniz Technical University Medical Faculty, Ozlem Altuntas Aydin, Basaksehir Cam Ve Sakura City Hospital, Yesim Caglar, Balikesir University Medical Faculty, Ilknur Senel, Giresun University Medical Faculty, Arzu Altuncekic Yildirim, Ordu University Medical Faculty, Esra Yerlikaya Zerdali, Istanbul Haseki Training and Research Hospital, Bengu Gireniz Tatar, Izmir Tepecik Training and Research Hospital, Fehmi Tabak, Cerrahpasa University Cerrahpasa Medical Faculty and HEPCTURKEY Study Group

Background: Pan-genotypic Sofosbuvir/Velpatasvir/Voxilaprevir (SOF/VEL/VOX) for 8-12 weeks has been shown highly effective, safe, and well-tolerated in treating patients with chronic hepatitis C (CHC)) in POLARIS studies, however, there are no real-world setting data are available especially in treating naïve patients. This is the first opportunity from all over the world to demonstrate SOF/VEL/VOX efficacy and safety in Real World setting for the naive patients. **Methods:** On June 1, 2022, Turkey's reimbursement guidelines for CHC treatments were updated. With this change, SOF/VEL/VOX was approved to use pan-genotypically for noncirrhotic naïve patients, cirrhotic naïve patients, treatment experienced patients for 8, 12 and 12weeks respectively. The patients who treated with SOF/VEL/VOX were included in a database within the scope of the HEP-C II TURKEY STUDY. We presented preliminary results of naïve CHC patients. **Results:** Of the 127 patients 92.9% (n = 118) were naïve and 9 were treatment experienced, 48 naïve patients (40.7%) were treated with 8 weeks of SOF/VEL/VOX. Of these 48 patients 45.8% were female, median age was 59.5 (24-85), 70.0% were genotype 1 and 95.5% were genotype 1b, 2.1% were compensated cirrhotic. Median HCVRNA at the time of diagnosis were 918.000 IU/mL (19.426 – 10.000.000). Undetectable HCVRNA levels at the 1st month, end of the of treatment were 83.3% and 100% respectively and the rate of response, SVR12 were 97.9% (47/48). One relapsed patient was genotype 4. Median ALT levels were 32.0, 19.0 and 15.5 IU/L at diagnosis, end of the treatment and at the SVR12 follow-up respectively. There were not any treatment interruption or adverse event leading to treatment cessation. **Conclusion:** SOF/VEL/VOX combination treatment is safe and presenting high SVR12 rates for the naïve CHC patients, further results with the high number of patients will be needed to prove this preliminary results.
Disclosures: The following people have nothing to disclose: Hatice Rahmet Guner, Tansu Yamazhan, Oguz Karabay, Ayse Inci, Gurdal Yilmaz, Ozlem Altuntas Aydin, Yesim Caglar, Ilknur Senel, Arzu Altuncekic Yildirim, Esra Yerlikaya Zerdali, Bengu Gireniz Tatar, Fehmi Tabak

Crook[13], Penny North-Lewis[14], Rebecca Cooper[15], Carla Lloyd[2] and Graham R. Foster[16], (1)Birmingham Women's & Children's Hospital NHS Trust and University of Birmingham, (2)Birmingham Women's and Children's Hospital, (3)Leeds Teaching Hospitals NHS Trust, Leeds Children's Hospital, (4)King's College Hospital, (5)Nottingham University, (6)Institute of Liver Studies, Kings College Hospital, London, United Kingdom, (7)North Manchester General Hospital, (8) Great Ormond Street Hospital, (9)Cardiff and Value University, (10)Chelsea and Westminster Hospital, London, United Kingdom, (11)Imperial College Hospital, London, (12)St George's Hospital,London, (13)King's College Hospital, London, (14)Leeds General Infirmary, (15)Children's Liver Disease Foundation, (16)Queen Mary University Hospital

Background: Hepatitis C virus (HCV) infection is a major global health problem in adults & children. Direct Acting Anti-viral therapies (DAA) achieve cure rates of 99% in adults and adolescents, were licensed for children 3–12 yrs in 2020. Prescribing and reimbursement for HCV therapy is centralized in England by NHS England (NHSE)r To ensure equitable access, safe & convenient supply during COVID lockdown, a virtual national treatment pathway for children with HCV in England & Wales which provided care to children nearer to home, was established in April 2021. We evaluated its feasibility, efficacy & treatment outcomes. **Methods:** A paediatric Multidisciplinary Team Operational Delivery Network (pMDT ODN), funded & supported by NHSE, with relevant paediatric specialists provided a single point of contact for referrals. Referral & treatment protocols were agreed for HCV therapy approved by MHRA. On referral the pMDT ODN agreed the most appropriate DAA therapy based on clinical presentation, genotype, patient preferences, & ability to swallow tablets. Treatment was prescribed in association with the local paediatrician & pharmacist, with no need for families to travel to national centres. All children in England & Wales were eligible for NHS funded therapy. Referral centres were approved by the pMDT ODN to dispense medication with funding reimbursed by NHSE. Demographic, clinical data, treatment outcomes, Sustained viral response at 12 weeks (SVR12) and 12m (12mSVR) were collected. Feedback on feasibility & satisfaction on the pathway was sought from referrers. **Results:** 92 children referred April 2021 to March 2023: 85–England; 7–Wales; median (range) age: 8.7 years (3–16); 49 (53%) male; with genotypes 3(45); 1 (45); 2 (3) and 4 (4). Route of transmission where known was vertical; No child had cirrhosis. DAA therapy prescribed Sofosbuvir/Ledipasvir (Harvoni): tablets (33); granules (11) Glecaprevir/Pibrentasvir (Maviret) : tablets (6) ; granules (7) Sofosbuvir/Velpatisvir (Epclusa) : tablets (33) ; granules (2) 68 were treated, 62 completed treatment & cleared virus; 53 achieved SVR 12; 22 achieved 12m SVR Referrers found the virtual process easy to access, valuing opportunity to discuss their patient's therapy with the virtual MDT & many found it educational. There were initial difficulties in providing the medication due to manufacturing delays for granule formulations and pharmacy issues such as confusion with adult packaging. **Conclusion:** The National HCV pMDT ODN delivers high quality treatment & equity of access for children & young people, 3– 18 yrs with HCV in England and Wales, enabling care close to home with 100% cure rates and contributing to the goal of eliminating HCV in the UK by 2025

1871-A | ESTABLISHMENT OF A STANDARDIZED CLINICAL PATHWAY TO HCV : PRIMARY HOSPITAL CONTRIBUTE HCV ELIMINATION

Guo Li[1], Gao Bihua[1], Wu Wenbin[1] and Cailian Cai[2], (1) Beihai City People's Hospital, (2)Guangxi Medical University

Background: There is a big gap in HCV awareness and it is a big challenge to HCV elimination ,esp. in primary care physicians(PSP) in China. We aimed to work out a standardized clinical pathway for HCV patients screening -diagnosis and treatment in a primary hospital. We collaborate with other departments, including non-ID clinical departments and clinical laboratories and IT departments on this. **Methods:** We initiated the HCV elimination project in primary hospitals 6 months ago. We conducted education forums for PCP and produced soerials for them on this topic. We have increased awareness of HCV and HCV linkage to care,including free diagnosis, lectures, dissemination of information and other forms of publicity. We havme education mate also worked with the IT department to build a platform for the project. All in-hospital patients at high risk of HCV infection are alerted through the system to undergo HCV screening with HCV-Ab testing. All the patients with HCV-Ab (+) will be reminded to complete the HCVRNA testing by the clinical lab and referred to hepatologists automatically. Once the hepatologists are given the request, they should make a diagnosis and conduct appropriate treatment for the patients promptly. **Results:** Over the

past 6 months, 90% (24220/26912) patients were screened for HCV-Ab, including in-hospital and clinic, 0.41% (111/26912) of them are HCV-Ab (+), 36.9% (41/111) of them accepted HCVRNA test and 53.6% (22/44) were diagnosed with HCV infection, 81.82% were treated with DAA. The rate of diagnosis and treatment has increased significantly compared to the last years (53.4% vs. 14.9%; 81.82% vs. 8.4%). **Conclusion:** Establishment of standardized clinical pathways in collaboration with non-ID departments can approach HCV elimination in primary hospitals.

1872-A | EVALUATION OF HEPATITIS C TREATMENT AND CARE MODEL IN PRIMARY HEALTHCARE CENTERS IN THE COUNTRY OF GEORGIA

Tengiz Tsertsvadze[1,2], Nikoloz Chkhartishvili[1], Akaki Abutidze[1,2], Lali Sharvadze[2,3], Senad Handanagic[4], Shaun Shadaker[4], Ekaterine Adamia[5] and Tamar Gabunia[5], (1)Infectious Diseases, AIDS and Clinical Immunology Research Center, (2)Ivane Javakhishvili Tbilisi State University, (3)Hepatology Clinic Hepa, (4) Centers for Disease Control and Prevention, Division of Viral Hepatitis, National Center for HIV, Hepatitis, Std&tb Prevention, (5)Ministry of IDPs from the Occupied Territories, Labour, Health and Social Affairs of Georgia

Background: In April 2015, with a partnership with Gilead Sciences and technical assistance from U.S. CDC, Georgia launched the world's first hepatitis C elimination program. By the end of April 2023, more than 82,000 patients with current hepatitis C virus (HCV) infection initiated treatment, achieving > 98% cure rates. Broad access to direct acting antivirals (DAAs) resulted in rapid increase in treatment uptake in 2016, which has since declined due to barriers in diagnosis and linkage to care. To address this issue Georgia initiated service decentralization in 2018 by integrating HCV screening and treatment in primary healthcare centers (PHCs). We report preliminary results of an integrated model of HCV care in PHCs **Methods:** By April 30, 2023, a total of 10 PHCs were providing HCV care services throughout the country. The integrated model was based on "one stop shop" approach, where patients receive all HCV screening, treatment and care services in selected PHCs. PHCs provided care to HCV treatment-naïve patients with no or mild fibrosis (FIB-4 score < 1.45) using simplified diagnostics and a treatment monitoring approach, while persons with advanced liver fibrosis/cirrhosis were referred to specialized clinics. Patients received Sofosbuvir/Ledipasvir and/or Sofosbuvir/Velpatasvir for 12 weeks. Sustained virologic response (SVR) was defined as undetectable HCV RNA at 12-24 weeks after end of therapy. The Extension for Community Healthcare Outcomes (ECHO) telemedicine model was used to train and support primary healthcare providers. Regular teleECHO videoconferencing was conducted to provide primary care providers with advice and clinical mentoring. **Results:** Among persons diagnosed with current HCV infection, 1,756 were evaluated for FIB-4 score. A total of 1,159 patients initiated treatment, and of them 1,075 (92.8%) completed treatment. Of 1,051 patients eligible for SVR testing, 835 (79.4%) had been tested at the time of analysis, and 821 (98.3%) achieved SVR. **Conclusion:** Our study shows the feasibility and effectiveness of integrating a simplified HCV diagnostic and treatment model in PHCs. Countrywide expansion of this model is warranted to bridge the gaps in the HCV care continuum and ensure high rates of treatment uptake towards achieving elimination targets.

Background: Eradication of HCV infection requires elimination of this infection among people who inject drugs (PWID). However, the number of patients screened and treated for hepatitis C in PWID remains low. Many patients are lost of follow-up after serological diagnosis. The measurement of the viral load by rapid RT-PCR from capillary blood (Xpert® HCV Viral Load Fingerstick) allows to obtain a result in 1 hour. Measuring the evolution of the annual incidence of rapid PCR in our centers was used to define the evolution of HCV infection in these addiction centers. The objective of our study was to measure the annual incidence of C viral load over the last 2 years in anti HCV-positive PWID followed up in 3 French Harm reduction centers and Needle exchange structures (CAARUD/CSAPA) and the proportion of patients treated annually. **Methods:** From March 1, 2021, all HCV seropositive PWID (previously known positive for serology or determined using a Rapid Antigenic Detection Testing (RADT) targeting HCV, HBV, and HIV) followed in 3 CAARUD/CSAPA (2 in Nice, 1 in Marseille) were offered a rapid RT- PCR using the molecular Point of Cares Testing (POCT) (Xpert HCV Viral Load Fingerstick). If the HCV PCR was positive, treatment was proposed. **Results:** From March 2021 to February 2023 , 303 PWID were included :183 during the first year (March 2021 to February 2022) and 120 during the second year (March 2022 to February 2023): 80 % men with an average age of 44 years, 65 without social rights, 68 with precarious housing and 42 homeless, 143 declared having injected: heroin, crack, other, 119 inhaled: cocaine, crack, other, 167 having multiple addictions which cannabis 75 and drugs 52 and 180 excessive alcohol consumption. 153 were receiving substitution treatment. HCV serology was documented in 180/ 183 PWID seen during the first year and in 118 /120 PWID seen during the second year and was positive in respectively 85 (47 %) and 60 (51%) of them. During the first year 82/85 anti-HCV+ PWID agreed to perform a rapid RT-PCR which was positive in 29, i.e. annual incidence of 16%. Anti-HCV treatment was initiated in 18 of the 29 patients whose RT-PCR was positive. During the second year 59/60 anti-HCV+ PWID agreed to perform a rapid RT-PCR which was positive in 25, i.e. annual incidence of 21% and treatment was initiated in 12 of the 25 PCR positive patients. 6/11 in the first and 12/25 in the second year of the PCR positive patient could not be treated because they did not have access to social rights. **Conclusion:** The annual incidence of C viral load over the last 2 years in anti HCV-positive PWID followed up in 3 French Harm reduction centers remain relatively high . The introduction of rapid PCR allow a virological diagnosis in almost all anti-HCV+ PWID . Despite the implementation of rapid PCR, there is still a long way to go to achieve viral eradication in these centers. To achieve this goal it would be necessary to treat all PCR positive PWID.

f 1874-A | FREQUENCIES OF UNUSUAL HCV GENOTYPES AND SUBTYPES IN EUROPEAN DAA-EXPERIENCED PATIENTS AND REAL-WORLD RETREATMENT OUTCOMES

Julia Dietz[1], Christiana Graf[1], Peter Buggisch[2], Andreas E. Kremer[3], Beat Muellhaupt[4], Johannes Vermehren[5], Kai-Henrik Peiffer[1], Georg Dultz[5], Tony Bruns[6], Andreas Geier[7], Janina Trauth[8], Thomas Discher[8], Kerstin Port[9], Katja Deterding[9], Christoph Berg[10], Thomas Berg[11], Christophe Moreno[12], Stefan Zeuzem[1] and Christoph Sarrazin[1,13], (1)Goethe University Hospital, (2)Institute for Interdisciplinary Medicine IFI, (3)Department of Gastroenterology and Hepatology, University Hospital Zürich, Zürich, Switzerland, Zurich, Switzerland, (4)University Hospital Zurich, (5) Department of Internal Medicine 1, University Hospital, Goethe University, Frankfurt, Germany, (6)University Hospital Aachen, (7)Department of Hepatology, University of Würzburg, Würzburg, Germany, (8)Justus Liebig University Giessen, (9)Medizinische Hochschule Hannover, (10)University Hospital Tübingen, (11) University Hospital of Leipzig, (12)CUB Hôpital Erasme, (13)St. Josefs-Hospital Wiesbaden

Background: The approval of direct acting antivirals (DAAs) has revolutionized treatment of chronic HCV infection and the WHO has set the goal to eliminate HCV by 2030. However, sustained virological response (SVR) rates were lower in patients with unusual HCV genotypes (GT), which are uncommon in industrialized countries, and second generation DAAs are not available in low-income countries. This study investigated the prevalence of unusual GT and resistance-associated substitutions (RASs) among European DAA failure patients. **Methods:** A total of 1376 patients with DAA treatment failure were identified from the European Resistance database between 2014 and 2023 and included in the study. We amplified and sequenced the HCV NS3, NS5A and NS5B genes and re-evaluated subtypes sequence-based. RASs that conferred > 2-fold increased DAA susceptibility were analyzed. **Results:** The frequency of unusual subtypes among DAA-failure patients was 4% (60/1376). The majority of

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients with unusual GT were infected with unusual GT4 subtypes (47%, 28/60; subtypes 4b, 4c 4f, 4n, 4o, 4r, 4v) and GT3 subtypes (25%, 15/60; 3b, 3g, 3h, 3i, 3k). Among them, GT4r (n = 17) and GT3b (n = 8) were the most frequent, which were detected especially after failure to LDV/SOF (GT4r) or after DCV/SOF or VEL/SOF failure (GT3b), respectively. In addition, 12% (7/60) of DAA failures were infected with unusual GT6 (6e, 6f, 6n, 6r), 10% (6/60) with GT1 (1c, 1e, 1l) and 3% each (2/60) with GT2k and GT5a, respectively. Most patients (78%, n = 47/60) with unusual GT had failed to first generation DAA treatment (LDV/SOF, DCV/SOF, 2D/3D, SOF/RBV, GZR/EBR), whereas only 22% (13/60) had not responded to second generation DAAs (VEL/SOF, G/P). NS5A RASs at positions 28, 30 and 31 were common in patients with unusual GT1 (100%, n = 5/5), GT3 (80%, n = 12/15), GT4 (96%, 24/25) after NS5A inhibitor (NS5Ai) failure. Y93H was detected in only 16% (7/43) of patients with unusual GT after NS5Ai failure, whereas typically > 70% of patients with GT1b or GT3a harboured Y93H after NS5Ai failure. Overall, 75% (45/60) of patients had started retreatment, most with VOX/VEL/SOF (n = 27), and across all regimens 95% (40/42 with completed follow-up) had achieved SVR. **Conclusion:** Of European DAA failure patients, 4% were infected with an unusual HCV genotypes. Retreatment with second generation regimens resulted in an SVR rate of 95%. The limited global availability of these regimens could result in HCV elimination targets being delayed.

1875-A | HEPATITIS C VIRUS SUSTAINED VIROLOGIC RESPONSE (SVR) RATES ARE DISSIMILAR FOR PATIENTS WHO RECEIVED A SINGLE 84-DOSE FILL OF SOFOSBUVIR / VELPATASVIR COMPARED TO PATIENTS WHO RECEIVED A 28-DOSE PRESCRIPTION WITH TWO REFILLS

Frederic McCall III[1], Gia Landry[2], Lisa Chang[1], Jessica Fridge[1], Billy Robinson[3] and Elizabeth N. Britton[4], (1) Louisiana Department of Health, (2)Ochsner Health, Baton Rouge, LA, (3)LSU, (4)Louisiana Department of Health/ Office of Public Health

Background: The goal of Hepatitis C Virus (HCV) elimination has been prioritized globally by the World Health Organization and the United States has begun its planning for nationwide elimination. Louisiana (LA) stands out as one of the few states that has implemented a comprehensive HCV elimination program throughout the state. Due to the global Covid-19 pandemic and difficulty accessing in-person care, LA Medicare allowed prescribers to write 84-dose fills to limit patients from leaving home and to limit barriers to treatment. In this abstract we are examining how prescribing methods may effect cure rates. **Methods:** All persons in LA on Medicaid who initiated HCV treatment from July 15, 2019 – October 31, 2022 were analyzed. Test of Cure (TOC) is defined as the HCV RNA test result **e** 84 days after anticipated last HCV medication dose. Cure is defined as an undetectable TOC result. Treatment failure is defined as a detectable TOC result. **Results:** Of the 10,673 LA Medicaid patients analyzed, 9,049 (84.78%) of the patients were prescribed a 28 dose prescription with two refills and 1,624 (15.22%) of the patients were prescribed a single 84 dose fill of medication. Of those prescribed a 28-

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

dose fill with two refills and filled at least one dose; 6017 (66.5%) received an TOC. 5,433(60.0%) had a documented cure in LA Medicaid records, and 584(6.5%) had a documented treatment failure in LA Medicaid records. 7,819 of the 9,049 (86.4%) picked up all 84 doses. For those who filled an 84-dose prescription; 716 (44.1%) received a TOC. 602 (37.1%) had a documented cure in LA Medicaid records and 114 (7.0%) had a documented treatment failure in LA Medicaid records. 100% of claims picked up all 84 doses of medication. Please see the table for more detailed data. **Conclusion:** While patients who were prescribed a 28 dose-fill with 2 refills were more likely to have a documented TOC compared to those prescribed a single 84-dose fill, treatment failure rates were similar between the two groups (6.5% vs 7.0%). Cure rates are drastically lower in the 84 dose fill group, but that is largely driven by the decrease in TOC testing for that group. When considering only those who did receive a TOC, cure rates are 84.1% for those with a single 84 dose fills and 90.3% for those with a 28-dose fill with 2 refills. TOC with positive HCV RNA results may also be contributed to reinfection instead of treatment failure as some TOC labs were not obtained until years after treatment. Over a third of the medicaid claims had documented Opioid or Substance use disorder in their records, which may have also contributed to reinfection of HCV and makes us consider reinfection of HCV instead of true treatment failure. Overall, low return rates for TOC limited the data we have, and the small proportion of those who were prescribed a single 84-dose fill limit the power of the data we collected. Further studies may help direct future elimination efforts in how to most effectively prescribe HCV medications to improve TOC and cure rates.

f 1876-A | HEPATOCELLULAR CARCINOMA ASSOCIATED WITH CHRONIC HEPATITIS C, CLINICAL PROFILE, MANAGEMENT OUTCOMES AND SURVEILLANCE STRATEGY OF THE PUNJAB HCV MODEL: REAL WORLD DATA FROM THE PUBLIC HEALTH PERSPECTIVE

Madhumita Premkumar[1], Radha K. Dhiman[2], Radhika Srinivasan[3], Arka De[3], Ajay K. Duseja[4], Pankaj Gupta[3], Naveen Kalra[3], Ekta Gupta[5], Gagandeep Singh Grover[6], Anchal Sandhu[3], Harish Bhujade[3], Sreedhara B Chaluvashetty[3], Manoj Kumar[7], Sunil Taneja[4], Sahaj Rathi[3], Nipun Verma[4], Suvradeep Mitra[3], Divya Khosla[3], Jasvinder Nain[3], Vishesh Kumar[3], Prerna Sharma[3] and Surender Singh[3], (1)Postgraduate Institute of Medical Education & Research, Chandigarh, India, (2)Sanjay Gandhi Postgraduate Institute of Medical Sciences, (3)Post Graduate Institute of Medical Education and Research, (4)Post Graduate Institute of Medical Education and Research, Chandigarh, India, (5)Institute of Liver and Biliary Sciences, (6)Punjab Government, (7)Institute of Microbial Technology (CSIR-IMTECH)

Background: The Punjab HCV Model, a decentralized multicentric public health cohort, has resulted in cure rates of 91.6% using free-of-charge generic direct-acting antiviral agents (DAAs) in patients with chronic hepatitis C (CHC) infection. Real world data on the risk of hepatocellular carcinoma (HCC) in CHC patients with or without cirrhosis, and benefit of surveillance in a population-based cohort is needed to guide health policy. **Methods:** The association of hepatocellular carcinoma with CHC at first enrolment, clinical course, outcomes and new incidence of HCC following post sustained virological response (SVR-12) surveillance was assessed between December 2017 and December 2022. The treatment given and outcomes were recorded (Figure1). **Results:** Of the 51865 viremic patients with CHC in the Punjab Model cohort, 652 patients with HCC at 1st presentation were reported, of whom 287 referred patients (mean age 63.6 ± 11.1 years, 58.5% men median MELDNa 15.6, 15.5% non-cirrhotic, mean ALBI score: -1.9, median AFP 160 ng/ml) managed at the nodal centre PGIMER, Chandigarh were enrolled. The patients with HCC were classed as BCLC stage A (53,18.5%), B (79,27.5%), C (27,9.4%) and D(128,44.6%). About 22% had decompensation including ascites(20.9%) and variceal bleeding (3.2%), at enrolment. HCC characteristics were as follows; 193, 67.2%-single nodule, mean size as 4.4 ± 2 cm, 50 (17.4%)-tumoral portal vein thrombosis. The SVR-12 was 87.1%, which is lower than the Punjab cohort cure rate of 91.6%. 220 (76.4%) patients died, and 7 (2.4%) underwent liver transplantation.

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Ablative procedures included radiofrequency ablatio (7), microwave ablation (5) and cryoablation (2). In intermediate HCC, transarterial (TA) chemoembolization (95), transarterial radioembolization (32), bland embolization (2) and stereotactic body radiation (SBRT-6) were done. Patients with advanced HCC received sorafenib (20.9%), lenvatinib (14.6) following or in combination with locoregional therapy. Independent predictors of mortality were BCLC Stage C or D (aHR 1.03 ,95%CI:1.008-1.28, $P = 0.002$, age(aHR 1.3 ,95% CI:1.2-1.8,$P < 0.01$ and baseline MELD. (aHR 1.5 , 95% CI:1.2-1.8, $P = 0.022$). New incidence of HCC was detected in 29/6516 (0.45%) cirrhotic patients following SVR-12; during a follow-up period of 35.5months (24-48months). Better overall survival [(median 28.2 (interquartile range; IQR 18.5-45) vs 20.2 (IQR 12.5-40) months); $P < 0.01$], higher chance of curative intent therapy [15 (48.3 %) vs 14(4.8%); $P < 0.001$] and earlier BCLC stage was noted in those on surveillance than in those with HCC at enrolment, suggesting clinically meaningful lead time and better outcomes with the surveillance. **Conclusion:** The Punjab HCV Model demonstrates patients with CHC should remain on strict HCC surveillance following virological cure to provide survival benefit. The population cohort data provides unique insight to manage HCV-HCC and guides future heath policy.

1877-A | INCIDENCE OF LIVER ENZYME ELEVATION IN HCV-NONVIREMIC RECIPIENTS WHO UNDERWENT THORACIC ORGAN TRANSPLANTATION WITH HCV-VIREMIC ORGANS

Melanie Cabezas[1], Erin Parkinson[2], Basem Alkurdi[2], Rashid Syed[2], Kawtar Al Khalloufi[2], Nyingi Kemmer[2], Saurabh Agrawal[2] and Miguel H. Malespin[2], (1) University of South Florida, Tampa, FL, (2)Tampa General Hospital

Background: The use of HCV-viremic donor organs in HCV-nonviremic recipients has helped address the shortage in available donor grafts. Despite the risk of HCV transmission, there is a high rate of sustained viral response (SVR) with direct-acting antiviral (DAA) agents. While fibrosing cholestatic hepatitis and liver failure is rare, the incidence of liver enzyme elevation in the post-operative period and prior to initiation of DAA therapy has not been described in patients undergoing thoracic organ transplantation. **Methods:** This retrospective single center study evaluated patients who underwent lung or heart transplantation with an HCV-viremic organ from April 2019 to August 2022. Hepatitis B surface antigen or HIV antibody positive recipients were excluded. Lamivudine was initiated in patients who received hepatitis B core antibody positive organs. The degree of liver enzymes elevation was classified as mild (ALT > 1 to < 3x the upper limit of normal (ULN) and/or total bilirubin (TB) < 2x ULN), moderate (ALT 3-5x ULN and/or TB 2-4x ULN) or severe (ALT > 5x ULN and/or total bilirubin > 4x ULN). All patients were evaluated for DAA therapy post-transplant. **Results:** 44 patients underwent transplantation with an HCV-viremic donor heart (n = 18) or lung (n = 26) during the study period. 57% were male with a mean age of 58 years of age. 9% of donor organs were hepatitis B core antibody positive. HCV viremia occurred universally post-transplant with genotype 1A being the most prevalent (73%). Elevation in liver enzymes also occurred in all patients post-operatively (25% mild, 34% moderate, 41% severe). Of the patients with severe elevation in liver enzymes, n = 19 (95%) occurred while critically ill in the ICU. No patients underwent liver biopsy. Three patients died from etiologies unrelated to hepatitis C exposure

Symbols: f , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prior to initiation of DAA therapy. The median time between transplantation and initiation of HCV therapy was 42 days. All patients who underwent DAA therapy reached SVR. **Conclusion:** Post-transplant liver enzyme elevation occurs commonly in patients who undergo thoracic transplantation with HCV-viremic organs. Moderate to severe levels of enzymes elevation can present in critically ill patients, but are not associated with poor hepatic outcomes. This study is the first to describe the incidence of liver enzyme elevation in this population and further supports the utility of HCV-viremic organs in patients awaiting heart and lung transplantation.

1878-A | INDIVIDUALIZED HCV TREATMENT FOR PWIDS ON OPIOID AGONIST THERAPY LED TO EXCELLENT ADHERENCE THROUGHOUT THE COVID19 PANDEMIC

Caroline Schwarz[1,2], Angelika Schütz[3], Raphael Schubert[3], Michael Schwarz[2], Anika Jenke[3], David Josef Maria Bauer[1,2], Lukas Burghart[1,2], Benjamin Steinwender[3], Enisa Gutic[1], Thomas Reiberger[2,4], Hans Haltmayer[3] and Michael Gschwantler[1,5], (1)Klinik Ottakring, (2)Medical University of Vienna, (3)Suchthilfe Wien Ggmbh, (4)Cemm Research Center for Molecular Medicine of the Austrian Academy of Sciences, (5) Sigmund Freud University

Background: Directly observed therapy (DOT) with DAAs (direct-acting antivirals) is successful in eliminating HCV in PWIDs (people who inject drugs) on opioid agonist therapy (OAT): DAAs are prescribed via a low-threshold facility (LTF), and supervised DAA administration alongside OAT is performed at a pharmacy or LTF. In PWIDs with good adherence, DOT distribution intervals may be extended from daily to once weekly. We present one of the scarce HCV elimination projects for PWIDs that was continued throughout the COVID19 pandemic using the concept of DOT. **Methods:** We included 239 PWIDs on OAT starting DOT with DAAs 03/2020-10/2022 ("COVID" period), and a control group of 441 PWIDs receiving DOT 09/2014-03/2020 ("pre-COVID" period). We compared socio-economic characteristics, DOT distribution intervals, and SVR12 (sustained virologic response at week 12) rates of the two groups. **Results:** Pre-COVID, 348 (78.9%) PWIDs underwent daily DOT, while 19 (4.3%) and 74 (16.8%) were on 2-3 times/week and once weekly OAT/DAA dispensation schedules, respectively. During COVID, merely 75 (31.4%, $p < 0.001$) PWIDs were on daily OAT/DAA distribution, while 60 (25.1%, $p < 0.001$) and 104 (43.5%, $p < 0.001$) had 2-3 times/week and once weekly intervals, respectively. Missed visits (59 [0.8%] vs. 84 [0.4%] pre-COVID; $p = 0.239$) and SVR12 rates (167/168 [99.4%] vs. 402/405 [99.3%] pre-COVID according to modified intention-to-treat analysis; $p = 0.849$) were comparable among the groups. Loss of follow-up after end of treatment was more frequent during COVID (28.5% vs. 7.5% pre-COVID; $p < 0.001$), while mortality was similar (1.3% vs. 0.7% pre-COVID; $p = 0.444$). During COVID, socioeconomic status was equal or lower than pre-COVID (unemployment: 83.7% vs. 67.3%, $p = 0.967$; homelessness: 38.5% vs. 35.1%, $p = 0.227$; habitual alcohol consumption: 29.3% vs. 10.7%, $p < 0.001$; ongoing intravenous drug use: 64.0% vs. 57.8%, $p = 0.616$). No treatment interruptions or COVID19-associated deaths occurred among the study cohort. **Conclusion:** Initially, DOT was established to overcome suboptimal adherence to medical therapy in PWIDs with frequent ongoing substance use disorder, high prevalence of psychiatric comorbidities, and low socioeconomic status. Our data suggest that DOT is highly effective even with extended OAT/DAA dispensation intervals. The success of DOT seems to depend on the streamlined linkage to care and access to DAA achieved via a single visit to an LTF rather than the strict daily supervised ingestion of OAT/DAA.

1879-A | LACK OF PHARMACOKINETIC DRUG-DRUG INTERACTION BETWEEN BEMNIFOSBUVIR AND RUZASVIR IN HEALTHY PARTICIPANTS

Xiao-Jian Zhou[1], Gaetano Morelli[2], Maureen Montrond[3], Shannan Lynch[3], Keith Pietropaolo[3], Bruce Belanger[3], Arantxa Horga[3] and Janet Hammond[3], (1) Atea Pharmaceuticals, Inc., Boston, MA, United States, (2)Altasciences Clinical Research, (3)Atea Pharmaceuticals, Inc.

Background: Bemnifosbuvir (BEM) and ruzasvir (RZR) are potent, pan-genotypic inhibitors of HCV NS5B polymerase and NS5A protein, respectively. Combinations of BEM with daclatasvir, and RZR with uprifosbuvir were safe and well-tolerated, and independently achieved high sustained virologic response rates (SVR) in HCV-infected participants. *In vitro*, BEM is 10 times more potent than sofosbuvir and retains activity against sofosbuvir-resistant mutations. BEM and RZR exhibited synergistic anti-HCV activity *in vitro.* Cumulative data suggest that, while having a low drug-drug interaction (DDI) potential, the combination of BEM and RZR could be highly efficacious with a shorter treatment duration in a broad patient population. Here we report the results from a pharmacokinetic (PK) DDI study between BEM and RZR in healthy participants. **Methods:** Two groups of healthy participants (n = 16/group) were enrolled and received BEM 550 mg once daily (QD) or RZR 180 mg QD, alone, for 6 days. Starting on day 7, both groups received BEM+RZR QD for 12 days. Dosing occurred under fasting conditions from days 1-12 and with a low- or moderate-fat meal from days 13-18. Intensive PK sampling was performed over 24 h on days 6, 12 and 18, and plasma concentrations of BEM and metabolites and RZR were quantitated using validated bioanalytical methodologies. DDIs were assessed by comparing PK results on day 12 (combined) to day 6 (alone), whereas food effect assessed by comparing PK results on day 18 (fed) to day 12 (fasted). **Results:** All subjects completed the study. Adverse events were mild and non-serious. Co-administered RZR did not significantly alter the plasma PK of BEM: Maximum plasma concentration (Cmax) and area under the curve (AUC) of the parent drug of BEM (AT-511) and the circulating nucleoside metabolite AT-273, surrogate of the intracellular active triphosphate metabolite of BEM, were similar between BEM dosed alone and in the presence of RZR. Likewise, co-administered BEM had no marked effect on the plasma PK of RZR. In addition, a low- and moderate – fat meal did not affect the plasma exposure

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of AT-273 while slightly increased that of RZR. **Conclusion:** This study reports the first combination results of BEM and RZR in humans. The study drugs were well tolerated. Plasma PK of BEM and RZR was not altered when co-administered, indicative of a lack of PK DDI between the two drugs, and also the absence of a food effect. These results support the evaluation of a combination of these highly potent molecules as a potential novel combination for the treatment of HCV.

1880-A | LONG-ACTING TREATMENT FOR HEPATITIS C: HIGH ACCEPTABILITY AND FEASIBILITY AMONG PROVIDERS AND POLICYMAKERS IN LOW- AND MIDDLE-INCOME COUNTRIES

Neil Gupta[1], Lindsey Hiebert[1], Katherine Sun[1], Susan Swindells[2], Renae Furl[2], Kimberly Scarsi[2], Joelle Dountio Ofimboudem[3], Ethel D Weld[4], David L. Thomas[5] and John W. Ward[1], (1)The Task Force for Global Health, (2)University of Nebraska Medical Center, (3)Treatment Action Group, (4)Johns Hopkins University School of Medicine, (5)Johns Hopkins School of Medicine

Background: Although treatment for hepatitis C virus (HCV) with daily oral antiviral regimens is highly efficacious, suboptimal linkage and adherence may limit treatment success, particularly in patients with socioeconomic barriers or co-morbidities. Long-acting treatment (LAT) formulations are currently under early development as a strategy to improve HCV treatment outcomes. However, provider acceptability and health system feasibility for HCV LAT in low- and middle-income countries (LMICs) have not been evaluated. **Methods:** We conducted an online survey of HCV treatment prescribers and policymakers in LMICs regarding acceptability and feasibility of potential HCV LAT formulations, including one-time intramuscular injection, subdermal implant, and transdermal patch. Respondents were solicited from October 2022 to February 2023 via social media and targeted communications to provider networks, professional societies, and governmental contacts. **Results:** Overall, 122 providers and 50 policymakers from 42 LMICs completed the survey. Among providers, 113 (93%) expressed willingness to prescribe LAT, of which 63 (56%) would prescribe LAT for all patients and 50 (44%) would prescribe LAT based on risk factors or patient preference. If efficacy, safety, and cost were similar, 88 (72%) providers preferred LAT compared to oral treatment, of which 59 (67%) preferred injection, 21 (24%) preferred patch, and 8 (9%) preferred implant. Only 24 (20%) would still prescribe LAT if it were more costly than oral treatment. Reasons ranked most important for prescribing LAT were improved patient satisfaction or quality of life and improved adherence or treatment success. Patient characteristics ranked most important for prescribing LAT were non-routine engagement in medical care, HIV co-infection, previous HCV treatment failure, marginalized socioeconomic or ethnic background, incarceration, or housing instability. In regression analysis, no provider characteristics were associated with preference for LAT over oral treatment. Among policymakers, 42 (84%) reported high likelihood that LAT would be included in treatment guidelines and 39 (79%) reported high likelihood LAT would ultimately be included in national drug formularies (78%) if efficacy, safety, and cost were similar to oral treatment. **Conclusion:** There was high acceptability and perceived feasibility of HCV LAT if provided at comparable efficacy, safety, and cost as current oral treatment. Further characterizations of optimal patient populations, treatment settings, patient preferences, and health system preparedness are critical to inform development of HCV LAT options.

Gonzalez-Peralta[15], (1)Texas Children's Hospital, Baylor College of Medicine, (2)Cook Children's Health Care System, (3)University of Pennsylvania and the Children's Hospital of Philadelphia, (4)Pediatric and Liver Unit, Meyer Children's University Hospital Irccs, (5)The Pediatric Institute, Cleveland Clinic and Cleveland Clinic Children's, (6)University of California, San Francisco, (7)Children's Hospital Los Angeles, University of Southern California, Los Angeles, CA, (8)Johns Hopkins University School of Medicine, (9)King's College Hospital, (10)Nationwide Children's Hospital, the Ohio State University Wexner Medical Center, (11) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (12)Pediatric Liver Center, Johns Hopkins University School of Medicine, (13)Gilead Sciences, Inc., (14)The Royal Children's Hospital Melbourne, (15)Adventhealth Medical Group Pediatric Gastroenterology

Background: Direct-acting antivirals (DAAs) have revolutionized the treatment landscape for children with chronic hepatitis C virus (HCV) infection compared with pegylated interferon + ribavirin (RBV), which has suboptimal efficacy, extensive side effects, and negative impacts on growth. DAAs have shown high sustained virologic response (SVR) rates and favorable safety profiles in children, but data describing long-term outcomes are limited. Herein, we describe final follow-up data from study GS-US-334-1113 (NCT02510300) describing virologic outcomes and effects on growth and sexual development in children with chronic HCV infection. **Methods:** Children with chronic HCV infection who received sofosbuvir (SOF)+RBV, ledipasvir (LDV)/SOF ± RBV, SOF/velpatasvir (VEL), or SOF/VEL/voxilaprevir (VOX) in prior clinical trials were eligible to enroll in this 5-year registry study. Study baseline for enrollees was the day of their last visit in the parent trial. Every 6 to 12 months, we assessed the durability of SVR by measuring HCV RNA, and we evaluated the effects of DAAs on growth and sexual development by measuring weight, height, and body mass index (BMI) percentiles and z-scores (calculated using the 2000 CDC reference charts) and Tanner pubertal stage. **Results:** A total of 461 patients were enrolled between October 2015 and June 2021; 20% were treated with SOF+RBV, 42% with LDV/SOF ± RBV, 34% with SOF/VEL, and 4% with SOF/VEL/VOX in parent trials. Among 426 patients with **e** 1 postbaseline measurement, 58% were female, 80% were White, and the HCV genotype (GT) distribution was 66% GT1, 9% GT2, 21% GT3, 3% GT4, and 1% GT6. At enrollment, the median age (range) was 12 (3–18) years, and the mean (SD) weight, height, and BMI z-scores were 0.2 (1.23), −0.2 (1.05), and 0.4 (1.12), respectively. The median (range) follow-up was 193 (9–325) weeks. All but 2 patients achieved SVR in parent trials, and 100% of these patients maintained SVR throughout the registry study, with a median (range) SVR duration of 207 (30–341) weeks. Treatment with SOF-based DAAs had little impact on growth at week 240, and the mean changes (SD) in z-scores for weight, height, and BMI were 0.1 (0.71), 0.0 (0.67), and 0.1 (0.70), respectively. DAA treatment did not impact sexual development as assessed by Tanner stage. **Conclusion:** HCV treatment with SOF-based regimens resulted in durable SVR in children and had no impact on growth or sexual development up to 5 years posttreatment.

Yoshiyuki Ueno[8], Takahiro Kodama[1], Tomohide Tatsumi[1] and Tetsuo Takehara[1], (1)Osaka University Graduate School of Medicine, (2)Osaka University, Graduate School of Medicine, (3)Okayama University, Faculty of Medicine, Dentistry and Pharmaceutical Sciences, (4)Musashino Red Cross Hospital, (5) Nagoya City University Graduate School of Medical Sciences, (6)Iwate Medical University, (7)Nagasaki Medical Center, (8)Faculty of Medicine, Yamagata University, Yamagata, Japan

Background: Approximately 90% of hepatitis C virus (HCV) patients with decompensated cirrhosis can achieve sustained virologic response (SVR) by direct-acting antiviral (DAA) treatment. However, the long-term survival and hepatocellular carcinoma (HCC) development in patients with decompensated cirrhosis following DAA treatment is unclear. **Methods:** This study included 99 of the 102 patients who participated in the Japanese phase 3 trial on the effect of sofosbuvir and velpatasvir (SOF/VEL) with or without ribavirin (RBV) treatment in HCV patients with decompensated cirrhosis and who agreed to a long-term follow-up study. In the trial, patients started SOF/VEL with or without RBV treatment for 12 weeks between January 2017 and August 2017 at 33 Japanese hospitals. Decompensated cirrhosis was defined as Child-Pugh class B (CP-B) or CP-C at screening. We collected laboratory and clinical data at baseline, end of the treatment (EOT), 12 weeks after the EOT, 24 weeks after the EOT, 1 year after the EOT and every 1 year thereafter. Incidence rates of and baseline factors associated with overall survival and HCC development after DAA treatment were examined by Cox proportional hazard analysis. **Results:** The median age was 67 years, 40% of the patients were male, and seven patients had a history of HCC. The proportions of patients with CP-A, CP-B and CP-C at baseline were 12%, 77%, and 10%, respectively. The median observation period of this study was 58.7 months from the start of DAA. The percentage of patients with CP-A after starting DAA treatment was 22.2% (20/90) at the EOT, 43% (33/77) at 1 year after the EOT, 48% (36/75) at 3 years after the EOT, and 54% (27/50) at 5years after the EOT. Nineteen patients died, and the 3-year and 5-year overall survival rates were 92.4% and 76.6%, respectively. On multivariate analysis, higher γ-glutamyl transpeptidase levels (hazard ratio (HR): 1.020, $p = 0.009$), higher total bilirubin levels (HR: 1.941, $p < 0.001$), and lower albumin levels (HR: 0.164, $p = 0.010$) were significant baseline factors for overall survival after DAA treatment. For HCC development, 34 patients experienced HCC occurrence, and three patients experienced HCC recurrence. Cumulative HCC occurrence and HCC recurrence rates at 3 years were 28.4% and 57.1%, respectively. On univariate analysis, the presence of a history of HCC (HR: 2.898, $p = 0.050$) and lower albumin levels (HR: 0.363, $p = 0.025$) were significant baseline factors for HCC development after DAA treatment. **Conclusion:** In patients with decompensated cirrhosis, improvement in liver function is maintained over the long term after DAA treatment, and long-term survival is favorable. On the other hand, the risk of HCC development is high even after DAA treatment, continuous HCC surveillance is necessary in the long term.

1883-A | MARCHING TOWARDS ELIMINATION: REDUCTIONS IN COMMUNITY VIRAL LOAD IN A RURAL APPALACHIAN COUNTY WITH AN ONGOING HCV TREATMENT TRIAL

Jennifer Havens[1], Takako Schaninger[2], Michelle Lofwall[1], April Young[3], Michele Staton[1], Hannah Fraser[4], Peter Vickerman[4] and Sharon Walsh[1], (1) University of Kentucky College of Medicine, (2) University of Kentucky Medical Center, (3)University of Kentucky College of Public Health, (4)Bristol Medical School

Background: As we march towards the 2030 hepatitis C virus (HCV) elimination goal set forth by the World Health Organization, innovative programs are necessary to reach those at greatest risk for transmitting the virus. The Kentucky Viral Hepatitis Treatment (KeY Treat) project sought to enroll chronically infected individual's in a treatment trial where medical care and medication (sobosbuvir/velpatasvir) were provided free of charge in a rural Appalachian Kentucky county. **Methods:** The goal of this analysis was to determine the potential effectiveness of the KeY Treat intervention in reducing community viral load by examining the proportion of viremic individual's screening for study participation over time. We hypothesized that the proportion of viremic individual's would decrease over time as those achieving SVR in the community increased. Multiple logistic regression was utilized to analyze the proportion of viremic individual's by time (seven 6-month periods), adjusting for prior knowledge of HCV exposure, people who inject drugs (PWID), gender and age. **Results:** 748 screened in-person for the study; of those, 76.9% (n = 575) were anti-HCV-positive. Of the Ab-positive 64.9% (n = 373) were

Symbols: ƒ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

viremic and the proportion of viremic individual's significantly decreased over time ($p < 0.001$). In the multivariable model, compared to the first six months of recruitment (pre-COVID), the odds of being viremic were significantly lower at all follow-up periods, but especially the final 6 months of recruitment, from October 2022 to March 2023 where the odds were 69% lower. Age and PWID status were not associated with the presence of a chronic infection, but women were 39% less likely to be viremic at screening than men. **Conclusion:** These data point to a reduction in the proportion of viremic individual's over time, suggesting that the community viral load may have been significantly reduced as a result of an increase in the number of cured individual's in the county. These results held even after adjustment for PWID, gender and age. Continued treatment of those at greatest risk for HCV viral transmission is necessary to eliminate the virus from this high-risk community.

Background: Sofosbuvir/Velpatasvir (SOF/VEL) is a curative treatment for hepatitis C virus (HCV) infection. In France, prescribing rights were extended in May 2019 to non-specialists including physicians working in prisons, addiction centers, and psychiatric hospitals. For rapid treatment initiation, a Test and Treat (TnT) approach is followed, with severe patients (cirrhosis, treatment failures, comorbidities) referred to specialists. The main objective of this study was to evaluate the effectiveness and safety of the SOF/VEL TnT strategy for 12 weeks in HCV patients after prescription expansion. **Methods:** This French, multi-center, prospective, non-interventional study included adults with chronic HCV infection, treated with SOF/VEL for 12 weeks by specialists or non-specialists. Study data (e.g., patient characteristics, fibrosis evaluation) were collected from patients' medical records. The primary endpoint was the proportion of patients with sustained virologic response 12 weeks after end of treatment (SVR12). Secondary endpoints included safety profile, time between diagnostic tests and treatment start, and demographic characteristics of patients treated with SOF/VEL. **Results:** A total of 363 patients met the eligibility criteria and received at least one dose of SOF/VEL. Median age was 53.99 years (range, 19.8 to 88.7)

and 233 (64.2%) patients were male. Among them, 282 (77.7%) were treated by specialists, 81 (22.3%) by non-specialists. The specialist group had more patients with comorbidities (29.4% vs 8.6%) and advanced fibrosis (26.5% vs 18.9%), whereas the non-specialist group had more patients reporting alcohol consumption (62.9% vs 42.8%) and drug abuse (53.1% vs 10.8%). Among patients eligible for SVR12 analysis (300 patients), SVR12 rate was 98.3% (95%CI, 95.79%-99.35%) in the specialist group and 98.3% (95%CI, 91.14%-99.71%) in the non-specialist group. Overall, adverse events considered related to SOF/VEL occurred in 16 patients (specialist group, 7; non-specialist group, 9). One event in the non-specialist group led to treatment discontinuation. Median time between PCR positive test and treatment was 30 days in both groups. Median time between fibrosis evaluation by Fibroscan and treatment was longer in the non-specialist group (24 d vs 13 d). FIB-4 was also calculated and median time to treatment was 25 days in both groups. **Conclusion:** This study shows that non-specialists successfully treat chronic HCV infection with SOF/VEL for 12 weeks with a TnT approach. SOF/VEL prescription expansion could therefore be considered in other countries as a tool to reach WHO HCV elimination targets by 2030.

1885-A | PEER EDUCATION AND PSYCHOLOGICAL INTERVENTION FOR HCV ELIMINATION AMONG HIGH-RISK GROUPS: A PROSPECTIVE REAL WORLD STUDY IN METHADONE CLINIC

Shan Shi[1], Likui Wei[1], Hangfeng Liu[1], Ruyi Luo[1], Lanjuan Li[1], Rongjian Li[2], Cailian Cai[3], Xiaoting Li[3] and Minghua Su[3], (1)Nanning Red Cross Hospital, (2) Guangxi Zhuang Autonomous Region Center for Disease Control and Prevention, (3)The First Affiliated Hospital of Guangxi Medical University

Background: HCV elimination in methadone clinic is very important in China. But it is still a big challenge in patient education. Peer education and psychological interventions may be a strategy for health promotion in this population for HCV infection. We aim to explore a new model for HCV elimination in methadone clinic in Guangxi Province of China (Connection Project) **Methods:** A multi-collaborative approach was used for MT patients and HCV patients were recruited from methadone clinics from October 2022 to April 2023. The cooperation network consists of local centers for Disease Control and Prevention (CDC) and hepatology hospital and methadone clinics. The CDC is responsible for funding and building the patient network. Leaded by CDC, hepatologists collaborate with the health care professionals (HCPs) from methadone clinics, including physicians and nurses. Hepatology specialists educate methadone providers about HCV disease and conduct DAA treatment and follow-up for HCV RNA positive patients. Methadone health care providers are responsible for HCV antibody screening, HCV RNA testing, providing psychological intervention to patients, inviting the patients who have been cured of HCV treatment to communicate with patients who have not been treated for HCV, and facilitating referral of patients to receive treatment at MT or hepatologists for DAA treatment. **Results:** 3 HCV educations for HCPs (84 participants) and 12 psychological intervention classes for patients (120 participants) were conducted in one pilot methadone clinic of the Connection Project totally. 1,500 learning education materials were produced and handed out for the project. At the methadone clinic, there were 412 patients. The mean age was 50.28 (+/-7.19) years, 80.8% were male, 95% had medical insurance, 5% had cirrhosis. Most of them have comorbidities, including HIV infection, mental illness and diabetes. 96% (395/412) of them are HCV-Ab (+), and 58% (231/395) are HCV RNA (+) The main genotypes were 3b and 6a (30% and 30% respectively). Within six months of the start of the program, 38 patients had been referred and 27 had received HCV antiviral treatment, and they are still in the process of treatment and follow-up. Others are on the waiting list for health insurance approval. **Conclusion:** Peer education may be a strategy to HCV elimination in methadone clinics. Psychological intervention plays a key role in referral. The model is being extended to other methadone clinics in the province to help HCV elimination. Disclosures: The following people have nothing to disclose: Shan Shi, Likui Wei, Hangfeng Liu, Ruyi Luo, Lanjuan Li, Rongjian Li, Cailian Cai, Xiaoting Li, Minghua Su

1886-A | PEOPLE WITH HIV/HCV CO-INFECTION HAVE COMPARABLE SVR AND IMPROVEMENTS IN LIVER FUNCTIONS USING MINIMAL MONITORING STRATEGY: SECONDARY ANALYSES FROM THE MINMON TRIAL

Emmanuel Thomas, Miami, Dimas Kliemann, Hospital Nossa Senhora Da Conceição - Ghc, Kevin Wongsodirdjo, Cbar | Harvard T.H. Chan School of Public Health, Tanyaporn Wansom, Baylor College of Medicine, Estevão Nunes, Instituto Nacional De Infectologia, Laura Smeaton, Harvard School of Public Health, Susanna Naggie, Duke Clinical Research Institute, Durham, NC, David L. Wyles, Denver Health Medical Center, Sunil S. Solomon, The Johns Hopkins University School of Medicine and Mark S. Sulkowski, Johns Hopkins Medicine

Background: Simplified HCV treatment strategies allow for greater access in many settings. Current AASLD/IDSA simplified guidelines suggest that persons with HIV (PWH) are eligible for this approach. We compared markers of liver disease before and after treatment in both people with HCV only and HIV & HCV (HIV/HCV) treated using a minimal monitoring approach. **Methods:** ACTG A5360 was a single-arm, open-label trial to evaluate safety/efficacy of a minimal monitoring (MINMON) approach to HCV therapy in HCV treatment-naïve persons from 5 countries who had no evidence of decompensated cirrhosis. All participants received 84 tablets of sofosbuvir/velpatasvir at entry with the next scheduled in-person visit being at Week 24 to ascertain sustained virologic response (SVR). ALT, FIB-4 and Liver Stiffness Measurement by Fibroscan® (optional) were measured at baseline and week 24. Distribution of changes in ALT between baseline and SVR by HIV status were summarized; changes in FIB-4 and LSM were also quantified. Analyses included 379 of 399 participants who achieved SVR. **Results:** Median age of 379 participants was 47 years and 35% were assigned female sex at birth, 41% had HIV and 8% had compensated cirrhosis. SVR in HCV and HIV/HCV were 95.3% and 94.6%, respectively. The median ALT at baseline was 53 IU/L for the entire cohort. Overall, ALT had a median change

Symbols: ᶠ , Poster of Distinction; ★, Foundation Award Recipient

© 2023 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of -33 IU/L (IQR: -70, -19); improvements were similar in each group based on HIV status (Table 1). FIB-4 median change of -0.10 (IQR: -0.39, 0.09) and -0.11 (IQR: -0.53, 0.07) in HCV and HIV/HCV, respectively. In the subset of 142 patients with LSM, the median score changed from 6.4 kPa at baseline to 5.4 kPa at SVR. **Conclusion:** Among participants treated with minimal monitoring, these data suggest similar improvement in liver disease measured among people with and without HIV. Cumulatively with the SVR data, these data further strongly support the inclusion of PWH for curative HCV treatment using minimal or simplified monitoring strategies as indicated in recent guidelines.

Table 1: Change in ALT from baseline to SVR stratified by HIV-coinfection status.

		HIV-1 Status		
		HIV/HCV (N=157)	HCV only (N=222)	Total (N=379)
ALT at Baseline	Median (Q1, Q3)	56 (38, 99)	52 (33, 91)	53 (35, 97)
ALT at SVR	Median (Q1, Q3)	21 (15, 30)	18 (12, 21)	18 (13, 25)
ALT Change from Baseline to SVR	Median (Q1, Q3)	-33 (-69, -19)	-33 (-70, -18)	-33 (-70, -19)

Background: The prognosis of cirrhosis is clearly stratified by Child-Pugh (CP) class. Although direct-acting antiviral (DAA) treatment has recently been used to eliminate hepatitis C virus (HCV), it is not clear whether CP class stratifies the prognosis of decompensated cirrhotic patients treated with DAA. **Methods:** This study prospectively registered 206 HCV-associated decompensated cirrhotic patients who started DAA from February 2019 to December 2021 at Japanese institutions. Decompensated cirrhosis was defined as CP-B or CP-C or CP-A with previous decompensating events. All patients were treated with sofosbuvir and velpatasvir (SOF/VEL) for 12 weeks. Factors associated with liver transplantation (LT)-free survival and changes in CP class after SOF/VEL treatment were examined. **Results:** The median age was 68 years, and the proportions of patients with CP-A, CP-B and CP-C were 10%, 76% and 15%, respectively. The sustained virologic response rate was 91% in an intention-to-treat fashion. During 28 months from the start of SOF/VEL, 26 patients died (13 liver failure, 4 hepatocellular carcinoma, 1 varix rupture, 8 non-liver-related cause) and two patients underwent LT. The 3-year LT-free survival rate was 83%. In a multivariate Cox proportional hazards model, alanine aminotransferase level ($p = 0.046$), creatinine level ($p = 0.001$) and CP-C at 12 weeks after the end of treatment (EOT) ($p < 0.001$) were significantly associated with LT-free survival after SOF/VEL treatment, while baseline CP class was not. The 3-year LT-free survival rates were 91%, 86% and 52% for patients with CP-A, CP-B and CP-C at 12 weeks after the EOT, respectively (CP-A vs. CP-B; $p = 0.269$, CP-A vs. CP-C; $p < 0.001$, CP-B vs. CP-C; $p < 0.001$), indicating that not becoming to CP-C at 12 weeks after the EOT is important for patient prognosis. We evaluated CP changes in 193 patients for whom CP class both at baseline and 12 weeks after the EOT could be assessed. Among 17 patients with baseline

CP-A, two deteriorated to CP-B, but no patients deteriorated to CP-C at 12 weeks after the EOT. Among 150 patients with baseline CP-B, 60 improved to CP-A and seven deteriorated to CP-C at 12 weeks after the EOT. Among 26 patients with baseline CP-C, one and 14 improved to CP-A and CP-B, respectively, and 11 remained in CP-C at 12 weeks after the EOT. When we examined baseline factors associated with CP-C at 12 weeks after the EOT among patients with CP-B or CP-C at baseline, the presence of hepatic encephalopathy ($p = 0.020$) and total bilirubin levels ($p = 0.002$) were significant in multivariate logistic regression analysis. **Conclusion:** The prognosis of decompensated cirrhotic patients who underwent DAA treatment was clearly stratified by CP class at 12 weeks after the EOT. Baseline hepatic encephalopathy and total bilirubin levels were associated with CP-C at 12 weeks after the EOT.

Background: The country of Georgia launched the world's first national hepatitis C elimination program in April 2015. Key strategies include nationwide screening, active case finding, linkage to care, decentralized care, and provision of treatment for all persons with hepatitis C virus (HCV) infection, along with effective prevention interventions. The elimination program aims to achieve the following targets: a) diagnose 90% of HCV-infected persons, b) treat 95% of those diagnosed, and c) cure 95% of those treated. We report progress toward elimination targets of the elimination program. **Methods:** The estimated number of persons with HCV infection was based on a 2015 population-based national seroprevalence survey, which showed that 5.4% of the general adult population had current HCV infection (approximately 150,000 persons). We analyzed data in the national HCV screening and treatment databases during April 2015-April 2023. **Results:** As of April 30, 2023, 157,198 adults screened positive for HCV antibodies. Of those, 130,955 (83.3%) received HCV RNA or core antigen testing, of whom 102,354 (78.2%) tested had current HCV infection, and 82,203 (80.3%) of them initiated treatment. Of 58,074 persons who were evaluated for sustained virologic response (SVR), 57,478 (99.0%) had no detectable HCV RNA. Based on the 90-95-95 program goals, Georgia has diagnosed 68.2% of the estimated 150,000 adults with current HCV infection, treated 64.1% of the target 128,250 (95% of 150,000), and cured 47.2% of the target 121,837 (95% of 128,250). Treatment effectiveness was comparable among persons with advanced fibrosis (FIB-4 score F3 or F4) with 98.4% achieving SVR, and among patients with mild or no liver fibrosis (FIB-4 score **d** F2), SVR = 99.3%, $p < 0.0001$. **Conclusion:** Georgia has made substantial progress towards eliminating hepatitis C. Over 68% of persons with current HCV infection have been diagnosed, and most

have initiated treatment and experienced high cure rates regardless of fibrosis status. Challenges remain in identifying and linking to care persons with current HCV infection in Georgia. The Nationwide integrated, decentralized model of HCV treatment, which is already implemented in many locations, will be critical to improve linkage to care and close gaps in the HCV cascade of care.
