Background: Primary biliary cholangitis (PBC) remains incompletely characterized in large, population-based studies. Most available data come from academic centers, limiting generalizability and underrepresenting the broader spectrum of disease, treatment, and demographic diversity. Furthermore, the only well-validated algorithm for PBC was developed in a US Veterans Affairs cohort of predominantly men, limiting its applicability. This study aims to evaluate and compare three diagnostic algorithms to identify patients with PBC and to assess their performance across biopsied and non-biopsied populations. **Methods:** We retrospectively reviewed charts for patients using three different algorithms to identify patients with PBC. All algorithms included a diagnosis code PBC with the following:

1. Elevated alkaline phosphatase (AP);
2. Elevated AP + ursodeoxycholic acid (UDCA) prescription;
3. Elevated AP + UDCA + elevated anti-mitochondrial antibody (AMA).

We diagnosed patients with PBC according to the AASLD guidelines: 2 of the 3 – elevated AP, +AMA, or biopsy findings of PBC. Patients were identified as having PBC, not having PBC, having insufficient data to assess, or having probable PBC. Probable PBC was present when borderline findings were present. We also clarified if patients underwent biopsy confirmation or had overlap syndromes. Categorical variables were compared by chi-squared tests. **Results:** There were 860, 629, and 286 patients who were identified using algorithms 1, 2, and 3 respectively. Between 82-84% of patients were female and 53-58% were biopsied.

Using algorithm 1, 70% had definite PBC, 3% had probable PBC, and 12% had insufficient data (Figure). Using algorithm 2, 72% had definite PBC, 3% had probable PBC, and 7% had insufficient data. PBC Using algorithm 3, 80% had definite PBC, 4% had probable PBC, and 2% had insufficient data. When including only biopsied patients, all algorithms identified PBC in 90% of patients. In those without biopsy, algorithm 3 identifies PBC in 81% compared to 72% and 70% in algorithms 1 and 2, respectively.

In all algorithms, male patients were more likely to be misidentified as definite PBC. In all algorithms, patients were misidentified as PBC and instead had primary sclerosing cholangitis, other biliary diseases, or other liver diseases (usually autoimmune hepatitis). **Conclusion:** This study demonstrates that all three diagnostic algorithms effectively identified patients with PBC, with improving accuracy as additional clinical criteria are incorporated. Importantly, this study population includes mostly female patients, reflecting the known epidemiologic distribution of PBC and addressing a key limitation of the prior validated algorithm developed in a male-dominant cohort. These findings provide a framework for identifying PBC in larger datasets and support future efforts to further study disease patterns, treatment response, and clinical outcomes.

4537 | IMPACT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE ON HEPATOCELLULAR CARCINOMA RISK IN AUTOIMMUNE HEPATITIS

JIHYE LIM[1] Ye-Jee Kim[2] Sehee Kim[2] Ju Hyun Shim[3], [1]Yeouido St. Mary's Hospital, [2]Department of Gastroenterology, Liver Center, Asan Medical Center, University of Ulsan College of M, [3]Department of Clinical Epidemiology and Biostatistics, Asan Medical Center, University of Ulsan Col

Background: Few large-scale studies have investigated factors associated with the development of hepatocellular carcinoma (HCC) in patients with autoimmune hepatitis (AIH). This study aimed to determine the risk of HCC in AIH patients and associated risk factors, focusing on metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** We analyzed the claims data from the Korean National Health

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Insurance Service from 2007 to 2020. The study included 7,382 patients with AIH and a control group of 58,538 age- and sex-matched individuals, at a ratio of 1:8. We compared the incidence rates of HCC between these groups and investigated the risk factors of HCC. **Results:** During a median follow-up of 5.9 years, 160 AIH patients were diagnosed with HCC, resulting in an incidence rate of 3.60 per 1,000 person-years. The matched controls exhibited an incidence rate of 0.48 per 1,000 person-years. After adjustment, AIH patients had a 4.85-fold heightened risk of HCC compared to the control group (Figure 1A). Within the AIH cohort, the presence of coexisting MASLD further elevated the risk of HCC (Figure 1B), along with other factors such as older age, male sex, and decompensated liver cirrhosis, as observed in a two-year landmark analysis. The presence of concurrent extrahepatic autoimmune diseases did not affect the prognosis, while glucocorticoid treatment was associated with a decreased risk of HCC. **Conclusion:** Patients with AIH had an increased risk of HCC compared to matched controls, particularly those with coexisting MASLD. In addition to appropriate medical treatment, proactive interventions and lifestyle modifications for concurrent MASLD are recommended for these patients.

4538 | ALTERED THREE DIMENSIONAL (3D) INTRAHEPATIC BILIARY STRUCTURES VISUALIZED USING TISSUE CLEARING METHODS: IN HUMAN HEPATOBILIARY DISEASE

Motoko Sasaki[1] Yasunori Sato[2] Yasuni Nakanuma[3], [1]Kanazawa University, [2]Kanazawa university graduate school of medical sciences, [3]Fukui-ken Saiseikai hospital

Background: Various biliary lesions such as ductular reactions and biliary obstruction occur in human hepatobiliary diseases. Three-dimensional (3D) intrahepatic biliary structures may alter in such diseases, however, there are few studies on 3D-imaging of biliary structures in human hepatobiliary diseases. We took advantage of tissue clearing methods and light sheet fluorescence microscopy (LSFM) to analyze pathological changes in 3D-biliary structures in human chronic liver diseases. **Methods:** Twenty-eight autopsied liver tissues were obtained from 2 patients with primary biliary cholangitis [PBC] (both advanced stage), 5 with cirrhosis (hepatitis C-related, 2; metabolic dysfunction associated steatotic liver disease [MASLD], 3), 4 with mild fibrosis (F1/2; hepatitis B-related, 1; MASLD, 3) and 17 with nonspecific reactive change (NSR). Liver tissues were formalin-fixed, then cleared using Rapid and nondestructive tissue clearing system (RAP) or the clear, unobstructed brain/body imaging cocktails (CUBIC) methods. 3D-imaging of biliary structures were obtained using immunostaining with Alexa 488- or Alexa 647-labelled anti-CK19 and LSFM. A number (No.) of CK19-positive biliary components, No. of biliary components per portal tract, degrees of biliary networks in portal tract, anastomoses, bridging formation, meandering and caliber variation were evaluated semi-quantitatively on the image. **Results:** 3D-biliary structures in human hepatobiliary diseases were clearly visualized by tissue clearing methods and imaging by LSFM. No. of biliary components and No. of biliary components per portal tract were significantly increased in cirrhosis, compared to mild fibrosis and NSR ($p < 0.05$). Degrees of biliary networks in portal tract, anastomoses, bridging formation and meandering were significantly increased in cirrhosis, compared to PBC, mild fibrosis and NSR ($p < 0.01$). There was no significant difference in caliber variation among groups. It is of interest that No. of biliary components and other factors were not increased in PBC, even in the advanced stage. **Conclusion:** 3D-imaging using the tissue clearing methods may be a promising strategy to evaluate pathological alterations of human intrahepatic biliary structures in various human hepatobiliary diseases.

4539 | ANTIMICROBIAL THERAPY IN PRIMARY SCLEROSING CHOLANGITIS-INFLAMMATORY BOWEL DISEASE: REAL-WORLD EVIDENCE REVEALS CLINICAL RISKS DESPITE ALKALINE PHOSPHATASE IMPROVEMENT

Himaben Gohil[1] Lan Nguyen[1] Randy Cheung[1] Anthony Martinez[1], [1]University at Buffalo

Background: Primary sclerosing cholangitis (PSC) is closely linked to inflammatory bowel disease (IBD). The leaky gut theory proposes that disruption of the intestinal barrier in IBD allows microbial translocation to the biliary system, promoting hepatic inflammation

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and fibrosis. This gut-liver axis has driven interest in using oral antimicrobials to treat PSC. While some antibiotics have demonstrated biochemical benefits, their clinical impact remains unclear. To address this, we compared five oral antibiotics across PSC- and IBD-related outcomes using real-world multicenter data. **Methods:** We conducted a retrospective cohort analysis using TriNetX, a global database of healthcare organizations. Participants were adults over the age of 18 with both PSC and IBD. They were grouped based on exposure to vancomycin, rifaximin, metronidazole, minocycline, or azithromycin. The control group was not exposed to any of these antibiotics. Each group was propensity score-matched to the control based on demographics, comorbidities, medications, and baseline liver function labs. PSC outcomes included alkaline phosphatase (ALP) elevation, liver fibrosis, transplant, and hepatobiliary cancer. IBD outcomes included steroid use, hospitalization, IBD-related surgery, and death. Results shown in Table A are presented as risk differences, calculated as the percent risk of the outcome in the control group minus that in the treatment group. **Results:** All antimicrobials, except azithromycin, showed a statistically significant decrease in ALP elevation. Vancomycin was associated with higher risks of liver transplant, steroid use, hospitalization and death. Rifaximin not only raised the risk of liver fibrosis and transplant but also had the highest associated mortality. Metronidazole was linked to increased risks of liver transplant, steroid use, IBD-related surgery, and death. Minocycline had the greatest decline in ALP elevation and reduced IBD-related surgery risk but was linked to higher hepatobiliary cancer risk. Azithromycin was not significantly associated with any outcomes. **Conclusion:** Most antibiotics improved serum ALP; however, they failed to reduce and often worsened both PSC- and IBD-related outcomes. These findings highlight a disconnect between biochemical response and long-term clinical benefit thereby challenging the utility of antimicrobials for PSC. Future studies should explore optimal dosing or alternative therapies that improve both hepatic and intestinal outcomes.

Table A: PSC and IBD- related clinical outcomes of antimicrobial therapies in IBD patients

4540 | "IT'S MORE LIKE A DULL, ACHY PAIN THAT'S JUST CONSTANT": LIVER PAIN EXPERIENCES IN ADULTS WITH PRIMARY SCLEROSING CHOLANGITIS (PSC) TO INFORM MEASURE DEVELOPMENT

Donna Evon[1] Lauren Wright[2] Laura Mkumba[2] Nicole Lucas[2] Kaya Merkler[1] Ricky Safer[3] Joanne Hatchett[3] Rachel Gomel[3] Stephen Rossi[3] Mark Swain[4] Sasha Deutsch-Link[1] Bryce Reeve[2], [1]UNC Chapel Hill, [2]Duke, [3]PSC Partners Seeking a Cure, [4]University of Calgary

Background: An in-depth understanding of experiences with liver pain associated with chronic liver disease is virtually non-existent, especially for individuals living with PSC. The development of a PSC-specific liver pain measure suitable for clinical trials relies upon understanding key characteristics of liver pain in this population. **Methods:** Adults with PSC were recruited through the PSC Partners Patient Registry and hepatology experts in the U.S. Participants were phone screened for the presence of multiple PSC-related symptoms. Purposeful sampling was used to recruit a representative sample of 17 adults for in-depth qualitative interviews about key PSC symptoms experienced in the last month, including liver pain. Interviews were conducted virtually, audio-recorded, transcribed, and analyzed using NVivo software. **Results:** Ten out of 17 participants who reported liver pain as a prominent PSC symptom described their experiences in detail, while another three spontaneously mentioned liver pain during their interviews. Participants were, on average 43 years old (range: 27-65), 50% male, 60% white, 30% black, 10% asian and 30% had inflammatory bowel disease (IBD). Participants' experiences of their liver pain are found in the Table below. Participants described the location of PSC-associated liver pain generally in the right upper quadrant area, but said it can extend around the side and back. Eleven of 13 described liver pain as "stabbing" or "sharp." Eight described their pain as "achy" or "dull." The sharp/stabbing pain is typically brief, while the achy/dull pain is more persistent. All but one participant used the word "pain" to describe their sensations. Liver pain can "come

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and go" intermittently, happens at random, and seems unassociated with specific triggers. Some reported pain daily, others weekly, and most reported pain occurring outside of cholangitis attacks. Participants were able to differentiate PSC-related liver pain versus abdominal pain from other causes (including IBD) based on location and type of pain, timing, response to medications, and laboratory/clinical markers. Liver pain interfered with sleep and caused anxiety, but relative to fatigue and brain fog, it appears to interfere less with daily functioning. Participants tended to "*push through it.*" **Conclusion:** Dull/achy and sharp/stabbing liver pain may be more frequent and severe in symptomatic adults with PSC than previously recognized. These in-depth qualitative findings will inform the development of a de novo PSC-specific liver pain measure, inclusive of heterogeneity of experiences, and suitable for future PSC research studies.

TABLE. Participants' Descriptions of PSC-related Liver Pain

Attribute	Illustrative Liver Pain Quotes
Location	*"I feel it's like right underneath my right rib cage. Sometimes around to the right side, like stretching around to the right side of my torso."*
Quality	*"The sharp pain, it's like getting stuck with the needle but it's very short. The fact that it's so brief makes it not as bad."*
Quality	*"The dull pain around the whole liver area, that's more problematic honestly 'cause it's just like, it's a lot more uncomfortable 'cause it lasts for a while."*
Severity	*"Sometimes it's bad enough that I vocalize a bit of a scream, because it's very—it's just so—it's so out of nowhere. It's like surprising excruciating pain."*
Severity	*"It's a 10. It's like a knife. It's intense."*
Frequency	*"The liver pain more comes and goes. It's not an all-the-time pain."*
Frequency	*"I would say almost daily."*
Frequency	*"I probably have days where I don't have it, but I would say most days that I do."*
Interference	*"I do have trouble sleeping. Trying to get to a comfortable position if my liver's hurting on that right side, trying to get comfortable is not always easy."*
Interference	*"I don't like being reminded. I don't like being reminded of my disease, and I would say it causes me anxiety."*
Interference	*"It definitely makes it harder to be a fully engaged parent. I think putting our toddler to sleep, sometimes he climbs all over you and it's painful…."*
Resilient Coping	*"…I just try to ignore it and go about my day."*

4541 | PATHOGENIC MOLECULES IN AUTOIMMUNE LIVER DISEASE (AILD) AND ITS CORRELATION WITH DISEASE ACTIVITY AND SEVERITY

Sunil Taneja[1] Kannupriya.[1] Lekha Rani[1] Yaswant Kumar[1] Sweta Rose[1] Sonali Dagar[1] Savneet Singh[1] Balaraja S[1] Arpit Shastri[1] Ganesh CP[1] Muhammad Ashraf[1] Harjot Singh[1] Ashwin Vinod[1] Arka De[2] Nipun Verma[2] Madhumita Premkumar[1] Ranjana Minz[1] Ajay Duseja[1], [1]Postgraduate Institute of Medical Education & Research, [2]Postgraduate Institute of Medical Education & Research,

Background: The spectrum of Autoimmune Liver Disease (AILD) comprises of Autoimmune Hepatitis (AIH), Primary Biliary Cholangitis (PBC), Primary Sclerosing Cholangitis (PSC) and overlap disorders in varying presentations. The pathogenic molecules like T cell immunoglobulin and mucin domain-containing protein 3 (TIM-3), Lymphocyte Activation Gene-3 (LAG-3) stimulate the Cluster of Differentiation 24 (CD24) and has been found to be associated with increased hepatic inflammation causing liver injury. Hence targeting CD24 can be an alternative mechanism through which AIH can be regulated. This study aimed to characterize the expression of CD24, TIM-3, and LAG-3 on peripheral blood helper (CD4+) and cytotoxic (CD8+) T cells in AIH and overlap syndromes and correlate with disease activity and severity. **Methods:** 48 biopsy proven patients with AILD along with 7 healthy controls were recruited in the study. Patients were stratified into Asymptomatic AIH(n = 7), Acute AIH(n = 19), AIH with cirrhosis(n = 4), AIH-PSC overlap(n = 11), AIH-PBC overlap (n = 7) and 7 healthy control groups. Flow cytometry on peripheral blood samples was used to analyze the expression of CD24, TIM-3, and LAG-3 on CD4+ and CD8+ T cells. **Results:** A significant increase in CD8+ T cell percentage was observed in asymptomatic AIH compared to AIH-cirrhosis($p = 0.0408$) and acute AIH ($p = 0.0064$). TIM-3+CD4+ T cells were significantly higher in asymptomatic AIH compared to healthy controls($p = 0.0162$). LAG-3+CD4+ T cells were more abundant in AIH-cirrhosis, and CD24+CD4+ T cells were higher in AIH-PSC and acute AIH, although not statistically significant. In the CD8+ T cell subset, TIM-3+ expression was reduced across AIH groups compared to healthy controls, while CD24+CD8+ T cells were elevated in acute AIH and AIH-PSC subgroups. The T cell marker expression in AILD is shown in Table 1. **Conclusion:** Distinct patterns of immune checkpoint molecule expression on peripheral blood T cells were observed across AIH subtypes. In asymptomatic AIH, elevated TIM3+ CD4+ T cells indicate an exhaustion like state suggesting hyperactive immune system suggesting the immune system is more active, concurrently increased CD8+ T cell expression reflects the active immune surveillance and hepatocyte injury. Reduced CD8+ T cells in AIH cirrhosis can be due to fibrosis and T cell exhaustion. LAG-3 is marker of immune fatigue which is elevated in AIH cirrhosis suggesting long term inflammation in liver leading to cirrhosis. These findings support the potential of CD24, TIM-3, and LAG-3 as biomarkers for disease stratification and may guide future targeted therapeutic strategies in AIH.

4542 | ASSESSING THE RELATIONSHIP BETWEEN IMMUNOSUPPRESSANT MEDICATIONS AND COVID-19 PRESENCE AND SEVERITY IN AN AUTOIMMUNE HEPATITIS COHORT

Krish Rai[1] Jin Ge[2] Karla Lindquist[1] John Kornak[1], [1]UCSF, [2]University of California, San Francisco

Background: Due to their potential use of immunosuppressants (IS), patients with autoimmune hepatitis (AIH) may be at higher risk for poor outcomes with COVID-19 infections. This study leverages the National COVID Cohort Collaborative (N3C), a large multicenter electronic health record (EHR) database, to assess whether there are associations between IS type and the severity of COVID-19 in patients with AIH. **Methods:** We identified patients with AIH in the N3C database from 3/2020 through 3/2025 along with COVID-19 diagnoses as indicated by positive testing. We used logistic regressions adjusting for age, sex, race, region, and CLD etiology to determine associations between odds of COVID-19 diagnosis and IS classes (Prednisone, Azathioprine, Budesonide, Tacrolimus, Cyclosporine, and Cellcept). We used Cox proportional hazard models to determine associations between IS and death starting from March 2020 for the subset of AIH patients diagnosed with COVID-19. In addition to primary analyses, we conducted a subgroup sensitivity analysis testing for the association between IS classes and outcomes among patients with Model for End-Stage Liver Disease (MELD) 3.0 scores. P value <0.05 was considered significant for all models. **Results:** Of 16,553 AIH patients, 3,860 (23%) tested COVID-19 positive during the study period, and 4,956 (30%) had IS exposure. In our adjusted logistic regressions assessing for associations with COVID-19 diagnoses, we found an association between Prednisone (odds ratio [OR] 1.23, 95% CI [1.12 - 1.36] $p<0.01$), Budesonide (OR 1.38, 95% CI [1.18-1.62] $p<0.01$), and Tacrolimus exposure (OR 1.35, 95% CI [1.16-1.58] $p<0.01$). In our adjusted Cox regressions, amongst those diagnosed with COVID-19, we found Prednisone exposure (HR 0.83, 95% CI [0.67-1.03] $p=0.08$) but was slightly above the threshold to be associated with a decreased risk of death. Subgroup sensitivity analyses for patients with MELD 3.0 scores showed Prednisone (OR 1.25, 95% CI [1.06-1.48] $p<0.01$), Budesonide (OR 1.35, 95% CI [1.03-1.77] $p<0.01$), and Tacrolimus exposure (OR 1.34, 95% CI [1.04-1.72] $p<0.01$) to be associated with COVID-19 diagnoses. **Conclusion:** IS exposure that was statistically significant was positively associated with COVID-19 diagnosis (and varied between the IS). Further work involves determining the impact of vaccinations and advances in COVID-19 treatment on clinical outcomes in this population.

4543 | CHARACTERIZATION OF A COHORT OF PATIENTS WITH LATER-ONSET PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS (PFIC) FROM TWO US HEALTH SYSTEMS IDENTIFIED LEVERAGING NATURAL LANGUAGE PROCESSING (NLP)

Seema Meloni[1] Ravikumar Patel[1] Praveen Kumar-M[2] Sivaprakasam G[2] Gopinath Ashokkumar[2] Marie-Cecile Fournier[3] Danielle Dray[1] Fatine Elaraki[3], [1]Ipsen, Cambridge, MA, US, [2]nference, Cambridge, MA, US, [3]Ipsen, Boulogne-Billancourt, France

Background: Progressive familial intrahepatic cholestasis (PFIC) is a rare disease in which bile secretion is impaired, resulting in cholestasis. PFIC is classically diagnosed in early childhood, but emerging evidence suggests that some patients with PFIC variants experience later-onset disease. A major challenge in the later-onset disease is that the

presentation varies greatly, and the characteristics of those patients are not well understood. This study aimed to identify and characterize individuals diagnosed with PFIC, at 10 years of age or older, from electronic health record (EHR) data from two major medical health systems in the United States (US) to add to the knowledge base regarding the presentation of this disease. **Methods:** This is a non-interventional study leveraging de-identified data ranging from January 1, 2005 to November 15, 2024 from Mayo Clinic and Duke Health systems. Patients were identified using both structured and unstructured data, where natural language processing (NLP) was utilized to review unstructured data. Patients were included in the cohort if they had at least one relevant ICD code (ICD-9: 576.8, ICD-10: K76.8), unstructured instance of diagnosis, or presence of any genetic mutations reported in structured or unstructured data at any time. All records of identified patients underwent manual review to confirm diagnosis. The cohort was limited to those with first report of PFIC on or after 10 years of age and described using standard descriptive analytic methods. **Results:** In total, 43 patients (Mayo Clinic = 35; Duke Health = 8) were confirmed to have evidence of late-onset PFIC. Across the combined cohort, the majority were female (58.1%), White (65.1%), and not Hispanic/Latino (72.1%) (Table 1). The median age for first available record with mention of PFIC in the cohort was 26 years in the Mayo subset and 20 years in the Duke subset. While there was some variability in patient profiles between the two centers, the most frequent clinical characteristics documented in the combined cohort were: cholestasis (37.2%), pruritus (25.6%), cirrhosis (18.6%), and jaundice (16.3%). **Conclusion:** To our knowledge, this is the first study to leverage EHR from two large medical institutions to identify and characterize a cohort of patients with later-onset PFIC. These data will be valuable for furthering the understanding of patients with diagnosed PFIC and potentially aid in faster diagnosis of yet undiagnosed patients.

Table 1: Baseline and Clinical Characteristics of Patients Diagnosed with Later-Onset PFIC

Variable	Mayo Clinic (n=35)	Duke Health (n=8)	Combined (N=43)
Age (years) at first available record, median (IQR)	26.0 (18.0 - 31.0)	20.0 (16.7 - 24.3)	N/A
Sex, n (%)			
Male	12 (34.3)	6 (75)	18 (41.9)
Female	23 (65.7)	2 (25)	25 (58.1)
Race, n (%)			
White	25 (71.4)	3 (37.5)	28 (65.1)
Black	1 (2.9)	2 (25)	3 (7)
Asian	2 (5.7)	0 (0)	2 (4.7)
Other	3 (8.6)	1 (12.5)	4 (9.3)
Unknown	4 (11.4)	2 (25)	6 (14)
Ethnicity, n (%)			
Hispanic or Latino	5 (14.3)	1 (12.5)	6 (14)
Not Hispanic or Latino	26 (74.3)	5 (62.5)	31 (72.1)
Unknown	4 (11.4)	2 (25)	6 (14)
Clinical Abnormality, n (%)			
Cholestasis	11 (31.4)	5 (62.5)	16 (37.2)
Pruritus	7 (20)	4 (50)	11 (25.6)
Cirrhosis	6 (17.1)	2 (25)	8 (18.6)
Jaundice	6 (17.1)	1 (12.5	7 (16.3
End-stage liver disease	3 (8.6)	2 (25)	5 (11.6)
Splenomegaly	1 (2.9)	2 (25)	3 (7)
Portal hypertension	1 (2.9)	0 (0)	1 (2.3)

4544 | RETRIEVAL-AUGMENTED GENERATION ENABLED GENERATIVE PRE-TRAINED TRANSFORMERS FOR ACCESSIBLE AUTOIMMUNE LIVER DISEASES MANAGEMENT

Ernest Saenz[1] Jimmy Daza[2] Xiaoyun Xiong[1] Heike Bantel[3] Marcos Girala[4] Matthias P. Ebert[1] Florian van Bommel[5] Andreas Geier[6] Andres Gomez Aldana[7] Mario Alvares-da-Silva[8] Markus Peck-Radosavljevic[9] Ezequiel Ridruejo[10] Frank Tacke[11] Arndt Weinmann[12] Christel Weiss[1] Javier Pazó[13] Juan Turnes[14] Andreas Teufel[15], [1]Heidelberg university, [2]Medical Faculty Mannheim of Heidelberg University, [3]Hannover Medical School, [4]Universidad Nacional de Asuncion, [5]Leipzig University Medical Center, [6]University Hospital Wurzburg, [7]Texas Liver Institute, [8]Universidade Federal do Rio Grande do Sul, [9]Clinic Klagenfurt am Woerthersee, [10]Centro de Educacion Medica e Investigaciones Clínicas Norberto Quirno "CEMIC, [11]Charité - Universitätsmedizin Berlin, [12]University Medical Center of the Johannes Gutenberg-University Mainz, [13]Spanish Association for the Study of the Liver, [14]Galicia Sur Health Research Institute, [15]Division of Hepatology, Division of Clinical Bioinformatics, Department of Medicine II, Medical Facu

Background: Autoimmune liver diseases (AILDs), including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC), present diagnostic and management challenges due to their complex pathophysiology. Although large language models (LLMs) hold promise as clinical decision support tools, general-purpose models often lack domain-specific knowledge and may produce inaccuracies. This study aims to enhance LLM performance in AILD management by employing Retrieval-Augmented Generation (RAG) technology that integrates evidence-based clinical guidelines and FDA medication safety data. **Methods:** We developed three RAG-enhanced systems—HepaChat (custom GPT from the OpenAI platform), RAG-ChatGPT (GPT-4o), and RAG-Claude (Claude 3.5 Sonnet)—and compared their responses to a baseline of best-performing non-RAG LLM outputs. Responses were evaluated by ten board-certified hepatologists on a 1–10 Likert scale assessing clinical accuracy. Statistical analyses

included Kruskal-Wallis tests with Dunn's post-hoc comparisons, along with subgroup analyses by disease type and geographic region. **Results:** HepaChat achieved the highest overall mean score of 7.81 (SD = 1.35) and provided the best-rated answer for 40 questions, significantly outperforming RAG-ChatGPT (7.48, SD = 1.49), RAG-Claude (7.42, SD = 1.43), and the baseline (6.99, SD = 1.49; $p < 0.001$). Additionally, evaluators from the Americas assigned higher ratings (mean = 8.02) compared to those from Europe (mean = 7.03; $p < 0.001$). Notable deficiencies were observed in medication dosing accuracy, particularly in AIH management. **Conclusion:** RAG technology enhances the clinical utility of LLMs in managing autoimmune liver diseases. These findings show the potential utility of RAG-based decision support systems to improve diagnostic accuracy and accessibility, particularly in resource-limited settings.

4545 | ◆ FUNCTIONAL DIFFERENCES OF THE GUT MICROBIOME IN PRIMARY SCLEROSING CHOLANGITIS AND PRIMARY BILIARY CHOLANGITIS INFORM PATHOGENESIS AND THERAPEUTIC INTERVENTIONS

Marios Nikolaidis[1] Brian Juran[1] Bryan Mccauley[2] Erik Schlicht[1] Jackie Bianchi[1] Ahmad Ali[3] Elizabeth Atkinson[2] Grigorios Amoutzias[4] Konstantinos Lazaridis[1], [1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, [2]Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN, [3]Division of Gastroenterology and Hepatology, School of Medicine, University of Missouri, Columbia,MO, [4]Bioinformatics Laboratory,Department of Biochemistry and Biotechnology,University of Thessaly,Greece

Background: Primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) are rare immune-mediated cholestatic diseases with complex etiologies involving genetic factors, and environmental influences, including dysbiosis of gut microbiome. We aimed to define constitutional and functional elements of the gut microbiome relating to disease phenotypes and outcomes by performing a large, comprehensive, metagenomic analysis of PSC and PBC patients and matched controls. **Methods:** Stool samples from patients with PSC (n = 245), PBC (n = 280), and matched controls (PSC controls n = 245, PBC controls n = 278) underwent metagenomic sequencing to profile bacterial communities using the latest version of Genome Taxonomy Database. Microbial abundance comparisons were conducted with MaAsLin2 and ZicoSeq. Microbiome functional features, such as pathways and virulence factors were inferred with HUMANN3 and DIAMOND. Impact of bacterial species on risk of progression to hepatic decompensation was explored using Cox Regression. All statistical comparisons were adjusted for age and sex. **Results:** PSC and PBC patients had reduced microbial diversity featuring similar and distinct alterations in microbial abundance and virulence factors, along with significant alterations to overall microbial metabolism, including short-chain fatty acid (SCFA) and B-vitamin production. Regression analysis identified bacterial species associated with risk of hepatic decompensation in PSC, including potentially pathogenic *Streptococcus* species such as *S. vestibularis* (hazard ratio: 3.18) as well as protective species including *Alistipes shahii* (hazard ratio: 0.46), which is involved with butyrate production. Several species were also associated with risk of hepatic decompensation in PBC including *Acidaminococcus intestini* (hazard ratio: 4.45), although the number of events in PBC was limited. **Conclusion:** The gut microbiome of PSC and PBC patients are characterized by increased abundance of opportunistic pathogens and presence of virulence factors, coupled with disruption of beneficial microbial metabolism, such as that of short chain fatty acids. Notably, pathogenic microbial species were predictive of hepatic decompensation, whereas beneficial species had a protective effect. Future potential interventions for PSC and PBC might include dietary changes, probiotics and SCFA supplementation.

4546 | ◆ T CELL IMMUNE DYSREGULATION IN PROGRESSIVE LIVER DISEASE: A POTENTIAL CONTRIBUTOR TO CIRRHOSIS-ASSOCIATED IMMUNE DYSFUNCTION

Aenne Harberts[1] Rut Schatzschneider[1] Amanda Tolios[1] Thanh-Son Phan[1] Martina Sterneck[1] Ansgar Lohse[1] Samuel Huber[1] Julian Schulze Zur Wiesch[1] Felix Piecha[1] Peter Hübener[1], [1]University Medical Centre Hamburg-Eppendorf

Background: Cirrhosis-associated immune dysfunction (CAID) is characterized by systemic hyperinflammation and impaired immune responses in patients with advanced liver disease and favors infections and organ dysfunction. The role of cellular dysfunction of the adaptive immune system remains largely unknown. This study aims to delineate the networks of T cell function in acutely decompensated cirrhosis (AD) and acute-on-chronic liver failure (ACLF) and evaluate their association with systemic inflammation, disease severity, and outcome. **Methods:** 79 patients with liver cirrhosis (compensated cirrhosis (CC) n = 16, AD n = 27, ACLF n = 36) and 11 healthy controls (HC) were prospectively included in a single-center observational study. Plasma levels of immune checkpoint markers and T helper cytokines were assessed using a bead-based multiplex immunoassay. LPS-binding protein (LBP), sCD14, and intestinal fatty acid binding protein (iFABP) were measured via ELISA. PBMCs were isolated, and T cell phenotype and function were analyzed using flow cytometry. **Results:** Circulating levels of immune checkpoint markers (sCD25, CD86, PD-L1, Tim-3, and Galectin-9) progressively increased with advancing disease stages, particularly in ACLF, and correlated with markers of systemic inflammation, intestinal barrier dysfunction, and clinical disease severity scores. Patients who died within 90 days of study inclusion had significantly higher baseline levels of sCD25, CD86, Tim-3, and Galectin-9. Among patients with ACLF, those with an infection as the precipitating event showed significantly higher levels of Tim-3 and a trend toward elevated levels of other checkpoint markers compared to patients with alcohol-related or unidentified triggers. In severe ACLF, $CD4^+$ and $CD8^+$ T cells showed increased expression of Tim-3 and Lag-3 compared to patients with CC or DC. Notably, Tim-3 expression was particularly elevated on regulatory $CD4^+$ T cells. **Conclusion:** Progressive liver disease is marked by a significant upregulation of both circulating and cellular immune checkpoint markers, indicating T cell exhaustion and systemic immune dysregulation. Elevated levels of these markers are associated with infection-driven ACLF and predict poor short-term survival. The pronounced expression of checkpoint receptors, particularly Tim-3, in advanced disease stages highlights potential targets for immunomodulatory therapies aimed at overcoming cirrhosis-associated immune dysfunction.

4547 | ZONAL HEPATOCYTE VULNERABILITY AND MACROPHAGE REPROGRAMMING IN A MOUSE MODEL OF PORPHYRIA CUTANEA TARDA

CINDY E. AMENT, ABHISHEK MURTI, RASIKA PATKAR, SIMON BUCHER, NIKITA SAJAI, SAPHIA NGUYEN, MATTHEW CHOI, ARIS TAYCHAMEEKIATCHAI, BRUCE WANG, UCSF LIVER CENTER, UNIVERSITY OF CALIFORNIA, SAN FRANCISCO, CA, USA Cindy Ament[1] Abhishek Murti[1] Bruce Wang[1], [1]UCSF*

Background: Porphyria cutanea tarda (PCT) is the most common hepatic porphyria and results from

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

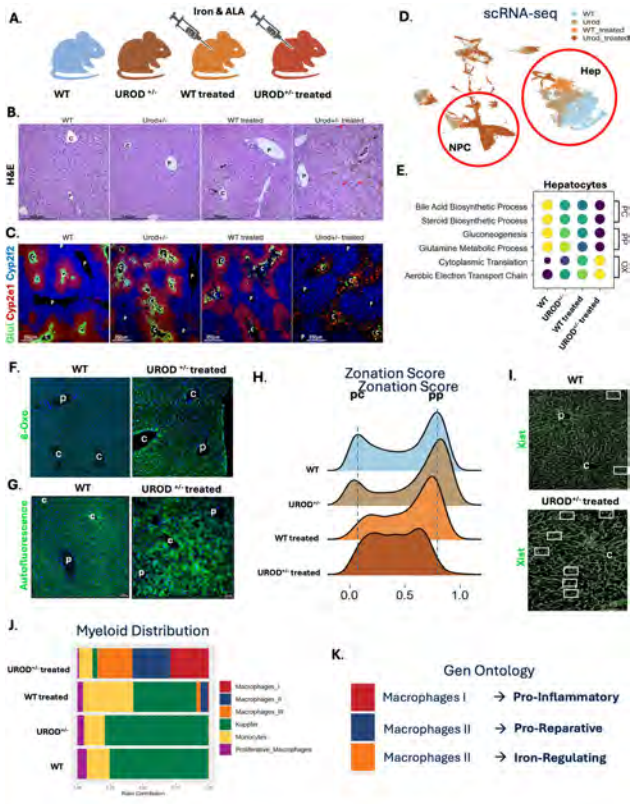
reduced activity of uroporphyrinogen decarboxylase (UROD), the fourth enzymatic step of heme biosynthesis. While individuals with UROD deficiency may remain asymptomatic, clinical disease is typically triggered by additional stressors that either increase heme demand or further impair UROD activity in hepatocytes. One of the most relevant triggers is hepatic iron overload, which promotes oxidative stress and enhances the functional inhibition of UROD. This creates a bottleneck in the pathway, leading to porphyrin accumulation. Epidemiological studies further suggest that patients with PCT are at increased risk of developing hepatocellular carcinoma (HCC), yet the cellular and spatial mechanisms by which chronic porphyrin accumulation drives liver injury and predisposes to cancer remain unknown and require further investigation. **Methods:** We employed a mouse model of PCT combining Urod haploinsufficiency ($Urod^{+/-}$) with iron and δ-aminolevulinic acid (ALA), a heme precursor that increases pathway flux, to induce porphyrin accumulation and hepatic stress. Liver pathology was analyzed using histology, immunofluorescence, and single-cell RNA sequencing (scRNA-seq) to characterize transcriptomic and cellular changes in hepatocytes and non-parenchymal cells (NPCs). **Results:** $Urod^{+/-}$ treated livers displayed selective pericentral hepatocyte injury, marked by oxidative DNA damage, loss of zonated metabolic function, and increased polyploidization. Hepatocytes progressively lost their spatial zonation signatures, with decreased expression of periportal and pericentral marker genes, while stress-related and translational programs were increasingly activated. Among NPCs, macrophages showed the strongest expansion. In addition to canonical Kupffer cells and monocytes, three novel macrophage populations were identified exclusively in $Urod^{+/-}$ treated livers. These included a subset expressing oxidative stress and iron metabolism genes, a reparative population, and a highly pro-inflammatory macrophage type. All three populations localized to areas of pericentral injury. **Conclusion:** Our findings reveal how porphyrin accumulation in the context of UROD deficiency disrupts liver homeostasis at multiple levels, driving spatially restricted hepatocyte dysfunction, metabolic disorganization, and the emergence of distinct injury-associated macrophage populations. By uncovering fundamental mechanisms of porphyrin-induced liver injury, our study provides critical insights into the pathogenesis of PCT and highlights cellular processes that may underlie the elevated cancer risk observed in affected patients. These results offer a framework for understanding porphyria-associated liver disease and identifying new targets for therapeutic intervention.



A) Experimental overview: $Urod^{+/-}$ treated mice receive iron and δ-aminolevulinic acid (ALA) to induce porphyrin accumulation and oxidative stress.
B) H&E staining reveals immune infiltration and iron accumulating Macrophages in $Urod^{+/-}$ treated livers.
C) Zonation markers (Cyp2f2, Cyp2e1, Glul) show loss of spatial gene expression in $Urod^{+/-}$ treated livers.
D) Single-cell transcriptomic analysis identifies major liver cell types and captures progressive hepatocyte reprogramming and myeloid expansion.
E) Gene ontology analysis reveals downregulation of metabolic functions and upregulation of stress and translation-related pathways.
F) 8-oxoG staining indicates oxidative DNA damage in pericentral hepatocytes.
G) Autofluorescence imaging shows porphyrin accumulation in pericentral zones.
H) Zonation score distribution based on scRNA-seq illustrates progressive loss of periportal and pericentral hepatocyte identity in $Urod^{+/-}$ treated livers.
I) FISH staining for *XIST* shows increased hepatocyte polyploidization in $Urod^{+/-}$ treated livers.
J) scRNA-seq identifies expansion of distinct macrophage subsets specific to $Urod^{+/-}$ treated livers.
K) Functional annotation of macrophage subtypes based on gene ontology analysis. Macrophage I was enriched for oxidative stress and iron-handling pathways, Macrophage II showed a reparative gene signature, and Macrophage III displayed a pro-inflammatory profile..

Ashish Datta[3] Yuan Zhuang[4] Scott Minchenberg[4] Deepika Deepika[3] Bruna Santos[3] Stephen Varghese Samuel[4] Yeshaswini Katkoori[3] Gyongyi Szabo[4], [1]Beth Israel Medical Center, Harvard Medical Centre, [2]BIDMC - Harvard Medical School, [3]Beth Israel Deaconess Medical Centre, [4]Beth Israel Deaconess Medical Center

Background: Alcohol-associated hepatitis (AH) features heightened pro-inflammatory responses in monocytes and neutrophils, complicated by immune exhaustion, infection susceptibility, and poor outcomes. Trained immunity, characterized by epigenetic reprogramming of innate immune cells by a primary insult, can lead to dysfunctional responses to subsequent secondary insults. We hypothesized that alcohol serves as the primary insult in AH, inducing trained immunity and impairing host defence against bacterial infection. **Methods:** Liver and peripheral blood mononuclear cells (PBMCs) from AH patients and healthy controls (HCs) were analysed. Female C57Bl/6 mice (10–12 weeks) received binge alcohol (5 g/kg/day) or saline for 4 days ("training"), followed by a 1-week rest. Mice were then given saline, LPS (5 mg/kg, i.p.), or E. coli (10^6 CFU), and euthanized after 9 hours. Bacterial burden (CFU) was assessed in liver, lung, and spleen. Single-nucleus RNA-seq and scATAC-seq were performed on liver tissue. Serum ALT and cytokines were measured by ELISA. Histone marks (H3K27ac, H3K9me) were evaluated by Western blotting and flow cytometry in liver immune cells and bone marrow (BM) progenitors. T cell activation was induced by CD3/CD28 crosslinking. **Results:** Alcohol-trained (AT) mice exhibited increased liver damage and pro-inflammatory cytokines (which ones) in response to LPS or E. coli, with reduced bacterial clearance in liver, lung, and spleen. AT mice showed increased monocyte and neutrophil activation in BM, circulation, and liver. Markers of trained immunity, H3K27ac and H3K9me, were enriched in monocytes/neutrophils from AH patients and AT mice. Multi-omic analysis of AT livers revealed unique neutrophil/monocyte clusters with proinflammatory transcriptional profiles (snRNA seq), chromatin accessibility changes (scATAC seq), and upregulation of immune exhaustion markers, particularly programmed cell death ligand 1 (PDL1). Both AH patients and AT mice exhibited increased PDL1 expression in circulating monocytes/neutrophils. Furthermore, neutrophils from AH patients suppressed autologous T cell proliferation and IFN-γ secretion, indicating an immunosuppressive phenotype. **Conclusion:** Our findings reveal a novel role for alcohol inducing trained immunity in monocytes and neutrophils of AH patients and alcohol-trained mice evidenced by altered transcriptomic and epigenetic profiles and impaired host defence. Alcohol-induced trained immunity may explain the paradox of increased inflammation and dysfunctional host defence in AH patients.

4549 | ◆ ANTI-MRPS27 ANTIBODIES AS A NOVEL BIOMARKER FOR AUTOIMMUNE HEPATITIS IDENTIFIED VIA COMPREHENSIVE HUMAN PROTEIN MICROARRAY PROFILING

JUN WADA[1] Kazumichi Abe[1] Naoto Abe[1] Tatsuro Sugaya[1] Yosuke Takahata[1] Masashi Fujita[1] Manabu Hayashi[1] Hiromasa Ohira[1], [1]Fukushima Medical University Department of Gastroenterology

Background: Autoantibodies such as antinuclear and anti-smooth muscle antibodies are frequently detected in autoimmune hepatitis (AIH), yet their limited disease specificity often complicates diagnosis. A human protein microarray comprising over 16,000 proteins synthesized via a wheat germ cell-free system enables comprehensive detection of novel autoantibodies, including those against membrane, cytoplasmic, and nuclear proteins. This study aimed to identify candidate autoantigens in AIH using a human protein microarray and to explore disease-specific autoantibodies relevant to diagnosis and pathogenesis. **Methods:** Autoantibody profiling identified mitochondrial ribosomal protein S27 (MRPS27) as a novel AIH-specific autoantigen. Anti-MRPS27 antibody levels were quantified by ELISA in sera from patients with AIH (n = 68), primary biliary cholangitis (PBC, n = 19), metabolic dysfunction-associated steatotic liver disease (MASLD, n = 39), chronic hepatitis C (CHC, n = 27), drug-induced liver injury (DILI, n = 18), post-treatment AIH (n = 36), and healthy controls (HC, n = 37). Clinical features and laboratory parameters were compared between anti-MRPS27-positive and -negative AIH patients, and longitudinal antibody titers were assessed. All AIH samples were collected prior to corticosteroid therapy. **Results:** Anti-MRPS27 levels were significantly higher in AIH (50.2 AU) than in PBC (9.3 AU), MASLD (12.8 AU), CHC (24.8 AU), DILI (19.8 AU), and HC (7.5 AU) (all $P < 0.01$). Using the HC mean + 3SD (48.5 AU) as cutoff, sensitivity, specificity, positive predictive value, negative predictive value, and AUROC were 42.7%, 94.3%, 78.3%, 77.2%, and 0.82, respectively. No significant associations were observed between anti-MRPS27 positivity and clinical features of AIH. However, anti-MRPS27 antibody titers remained elevated after treatment, with positivity observed in half of seronegative AIH cases. Notably, patients with high titers showed a lower proportion of liver-related events. MRPS27, a component of the mitochondrial small ribosomal subunit, is involved in cytochrome c oxidase activity essential for ATP production. Dysfunction may lead to hepatic energy loss and oxidative stress, contributing to chronic liver injury. This is the first report to propose an association between MRPS27 and AIH. **Conclusion:** Anti-MRPS27 antibody may serve as a novel and disease-specific biomarker for AIH, providing insights into pathogenesis and potential therapeutic targets.

4550 | ◆ IFRD1 ORCHESTRATES HEPATOCYTE METABOLISM AND MACROPHAGE INTERACTIONS TO FACILITATE LIVER REGENERATION

Taofei Zeng[1] Yabin Huang[1], [1]The First Affiliated Hospital of USTC

Background: Liver regeneration is a complex and tightly regulated process that relies on the coordinated interaction between hepatocytes and non-parenchymal cells; however, the underlying mechanisms remain incompletely understood. **Methods:** Using murine models of partial hepatectomy (PHx) and CCl_4-induced liver injury, we employed genetic knockout, adeno-associated virus-mediated overexpression, single-nucleus RNA-seq, ATAC-seq, and biochemical assays to dissect the function of IFRD1 in liver regeneration **Results:** Hepatocyte expression of IFRD1 is significantly upregulated during the early phase of regeneration. Genetic deficiency of IFRD1 impairs post-hepatectomy regeneration, while its overexpression enhances this process. IFRD1 is essential for maintaining hepatocyte β-oxidation and mitochondrial ATP production, stabilizing SLC25A5 levels through competition with the E3 ubiquitin ligase TRIM21. Furthermore, IFRD1-mediated ATP production facilitates chromatin remodeling in hepatocytes, which enhances CC/CXC chemokine expression, subsequently recruiting $CCR2^+$ monocytes and driving their differentiation into $GPNMB^+$ macrophages. Additionally, reduced liver expression of IFRD1 in acute liver failure patients suggests that IFRD1 may serve as a potential therapeutic target in liver diseases and regenerative medicine. **Conclusion:** IFRD1 acts as a metabolic-immune integrator in hepatocytes, orchestrating mitochondrial function and immune cell recruitment to promote liver regeneration. These findings highlight IFRD1 as a promising therapeutic target for enhancing liver repair and treating liver failure.

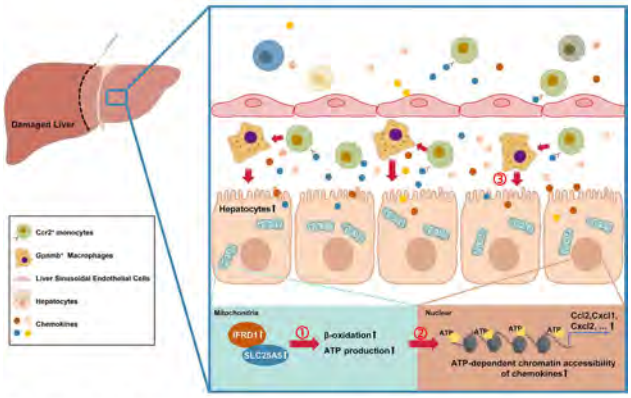
Graph Abstract



This study reveals that the nutrient-deprived microenvironment resulting from the substantial energy demands during liver regeneration induces an increase in IFRD1 levels. This upregulation facilitates the binding of IFRD1 to the mitochondrial transporter SLC25A5, thereby enhancing lipid β-oxidation and ATP production. As a crucial energy molecule, ATP not only enhances hepatocyte function but also fuels chromatin remodeling complexes, enabling the opening of chromatin and regulating the transcription of chemotactic genes. This mechanism facilitates the recruitment of $Ccr2^{+}$ monocytes and then transfer lipid-associated macrophages (LAMs) to the liver, where they exert protective functions, and promote liver regeneration. We delineate a novel IFRD1-SLC25A5-ATP-GPNMB^{+} monocyte-derived macrophage signaling axis that mediates the interaction between hepatocytes and monocyte-derived macrophages to drive hepatocyte proliferation

4551 | ◆ HEPATOCYTE IRE1α-XBP1S AXIS PREVENTS PRO-METASTATIC NICHE FORMATION THROUGH METABOLIC REWIRING OF INFLAMMATORY MONOCYTES

Jiajie Hou[1], [1]*QIMR Berghofer Medical Research Institute*

Background: As unfolded protein response (UPR) signal transducers, inositol-requiring enzyme 1α (IRE1α) and the downstream spliced form of X-Box Binding Protein 1 (XBP1s) have been identified as tumor promotors in multiple mouse models. However, clinical trials of IRE1α antagonism so far have not yielded encouraging results from metastatic cancer patients. While hepatocyte IRE1α-XBP1s axis has been linked to both tumorigenesis and metabolic homeostasis, it remains largely unknown how it affects tumor progression in a non-cell autonomous manner. Given the importance of non-tumoral hepatocytes under the circumstance of liver metastases, it is imperative to reexamine the significance of hepatocyte IRE1α-XBP1s signaling during pro-metastatic niche formation. **Methods:** Genetically modified mice (*Ern1*$^{flox/flox}$;*Alb*^{Cre}, *Xbp1*$^{flox/flox}$;*Alb*^{Cre}, and *Ccr2*$^{-/-}$) were employed for generating liver metastasis models. Pharmacological inhibitors targeting the IRE1α-XBP1-glutamine pathway or antibodies neutralizing specific immune subsets were administrated to tumor-bearing mice. High-throughput flow cytometry and single-cell RNA-sequencing were utilized to discern the liver myeloid compartment. While primary hepatocytes and monocytes were isolated for in vitro stimulation or in vivo reconstitution, multiplex immunohistochemistry was applied to validate the hepatocyte-monocyte interaction in mouse and human liver metastases. **Results:** Genetic ablation of IRE1α or XBP1 in non-tumoral hepatocytes exacerbated liver metastasis without disturbing immunosurveillance. Single-cell RNA sequencing identified a group of inflammatory monocytes (IM) that were significantly enriched in the IRE1α-deficient peritumor liver. Loss of IRE1α or XBP1 activated a non-canonical Forkhead box O1 (FoxO1)-glutamine synthetase (GS) pathway, endowing the non-tumoral hepatocytes with the metabolic activity to secrete glutamine, which was found necessary and sufficient for IM fitness. Patient survival with liver metastases was negatively correlated with such hepatocyte-IM interaction. As for mice, glutamine blockade efficiently reduced IM and disrupted the pro-metastatic niche in the liver. **Conclusion:** The hepatocyte IRE1α-XBP1s axis inhibits liver metastasis by reprograming metainflammation shaped in the pro-metastatic niche, which provides an organ-specific dimension for targeting cancer-promoting inflammation.

4552 | EPSTEIN-BARR VIRUS STATUS AS A PREDICTOR OF PRIMARY SCLEROSING CHOLANGITIS IN INFLAMMATORY BOWEL DISEASE

Mohamed Nadeem[1] *prabhat kumar*[2] *Shilpa Junna*[3] *Mohamad-Noor Abu-Hammour*[1], [1]*Cleveland Clinic Foundation,* [2]*Virginia Commenwealth University,* [3]*Cleveland Clinic*

Background: The role of Epstein-Barr virus (EBV) infection in the development of Primary sclerosing cholangitis (PSC) and liver complications in inflammatory bowel disease (IBD) remains unclear. EBV has been associated as trigger for various autoimmune liver diseases. This study evaluated whether EBV serum or tissue positivity or recent EBV infection in IBD patients is associated with increased risks of PSC, cirrhosis, liver transplantation, hepatic decompensation, and mortality. **Methods:** Using a global electronic health record network (TriNetX), adult patients diagnosed with IBD (Crohn's disease or ulcerative colitis) were identified and categorized into EBV-positive (EBV+) who have had recent infection or active infection, and EBV-negative (EBV–) cohorts based on documented EBV laboratory results within one year before or five years after their IBD diagnosis. Patients were classified as EBV + if they had at least one documented positive result for any of the following assays: early-diffuse IgG antibody, EBV DNA (quantitative or qualitative), EBV

nuclear antibody, EBV viral capsid antibody IgM, EBV antigen in tissue (immunostain), or EBV viral capsid IgA. Patients with pre-existing PSC, organ transplants, chronic hepatitis, or HIV were excluded. Cohorts were balanced for demographics, comorbidities, and ongoing IBD therapies through 1:1 propensity-score matching. Outcomes were followed for up to ten years post-index, and odds ratios (ORs) with 95 % confidence intervals (CIs) were calculated. **Results:** After matching, there were 3219 patients in each cohort. PSC developed in 1.8 % of EBV-positive patients versus 0.6 % of EBV-negative patients (OR = 3.32, 95 % CI 1.95–5.64; p < 0.0001). Cirrhosis occurred in 4.4 % versus 1.2 % (OR = 3.67, 95 % CI 2.57–5.23; p < 0.0001), and liver transplantation in 1.9 % versus 0.3 % (OR = 6.10, 95 % CI 3.12–11.97; p < 0.0001). EBV-positive patients also showed higher odds of hepatic decompensation (8.4 % vs 4.0 %; OR = 2.19, 95 % CI 1.77–2.72; p < 0.0001) and all-cause mortality (8.3 % vs 5.5 %; OR = 1.55, 95 % CI 1.27–1.88; p < 0.0001). **Conclusion:** EBV infection in IBD patients is significantly associated with increased risks of PSC, cirrhosis, hepatic decompensation, liver transplant, and mortality. These findings highlight the importance of EBV status as a potential predictor for development of PSC and of adverse hepatic outcomes in IBD, underscoring the need for vigilant monitoring of EBV-positive IBD patients.

Baseline Characteristics

Characteristic	EBV-Positive IBD (n=3,219)	EBV-Negative IBD (n=3,219)	P-Value
Demographics			
Age at Index (mean ± SD)	35.6 ± 20.5	35.9 ± 20.2	0.613

4553 | TIME-RESOLVED HEPATIC SINGLE-CELL SEQUENCING DURING LIVER FIBROSIS REGRESSION IDENTIFIES DISTINCT &LSQUO; REGRESSIVE&RSQUO; MACROPHAGE SUB-POPULATIONS

Katharina Bonitz[1] Thomas Sorz-Nechay[2] Henriette Horstmeier[2] Vlad Taru[2] Oleksandr Petrenko[2] Katja Sommer[2] Benedikt Hofer[2] Benedikt Simbrunner[2] Kerstin Zinober[2] Hubert Scharnagl[3] Michael Trauner[2] Stefan Kauschke[4] Peng Sun[4] Eric Simon[4] Philipp Schwabl[2] Thomas Reiberger[2], [1]Medical University Vienna, [2]Medical University of Vienna, [3]University Hospital Graz, [4]Boehringer Ingelheim Pharma GmbH & Co.KG, Biberach an der Riss

Background: Liver fibrosis regression has been described in both clinical and experimental settings. However, the molecular changes from a fibrotic to a regressive environment in hepatic and immune cell populations remain incompletely understood. **Methods:** Fibrosis was induced in mice with carbon tetrachloride (CCl_4) for 12 weeks (peak), followed by a period of 3, 7 or 14 days (D3, D7 or D14) of regression after CCl_4-cessation. Healthy controls received olive oil (OO). Portal pressure (PP), collagen proportionate area (CPA) and liver transaminases (AST, ALT) were assessed at each time point. Hepatic single-cell isolates were sequenced with 10x Chromium Flex technology. The obtained single-cell dataset was analyzed using Seurat. **Results:** At peak (vs. OO), fibrosis (CPA: 3.83 ± 0.61 vs. 0.53 ± 0.12%), PP (7.32 ± 0.49 vs. 4.75 ± 0.46 mmHg), and liver injury (AST: 1666 ± 2485 vs. 51 ± 20 U/L; ALT: 1406 ± 3117 vs. 30 ± 8 U/L) were significantly increased (all $p < 0.05$), confirming fibrosis and portal hypertension. CPA (2.89 ± 0.29 %), PP (6.18 ± 0.38 mmHg), and transaminases (AST: 61 ± 13 U/L; ALT: 44 ± 11 U/L) significantly regressed ad D14 (all $p < 0.05$). Major hepatic cell populations were retrieved by single-cell sequencing. Subclustering macrophages revealed seven subpopulations: Four Clec4f+ Vsig4+ Kupffer-cell subpopulations, including a cluster of embryonically-derived macrophages that were depleted during fibrogenesis and did not recover during regression, and a putative regressive macrophage subpopulation with enrichment over the course of regression.
Three monocyte-derived subpopulations were identified, including an infiltrating population with low expression of residency markers and two Cd9+ Trem2+ scar-associated macrophage (SAM) clusters. The two SAM clusters were enriched at peak fibrosis and subsequently depleted within 3 days of regression (“fibrotic SAMs”) or more gradually depleted throughout regression (D3-D14, “regressive SAMs”). The fibrotic SAMs were major

producers of Tgfb1, while the regressive SAMs highly expressed Mmp12, indicating an important role in matrix remodeling. Both SAM populations further expressed Ctss at high levels. **Conclusion:** The murine CCl_4-cessation model allows investigation of liver fibrosis regression at single-cell resolution. Our analysis underlines the dual role of SAMs as drivers of both progression and regression and points towards a complex interplay of myeloid-derived cells in liver fibrosis regression.

4554 | HEPATOCYTE HUMANIZATION IN AN SRG RAT MODEL AFTER PARTIAL HEPATECTOMY

Yohan Kim[1] George McClung[1] Cecilia Wright[1] David Tischfield[1] Eleanna Kaffe[1] Kelley Weinfurtner[1] Terence Gade[1], [1]Perelman School of Medicine at the University of Pennsylvania

Background: Rodent models often fail to recapitulate human liver metabolism and regeneration, limiting their translational utility for liver cancer research. We aimed to establish human liver chimerism in immunodeficient SRG rats (Sprague Dawley Rag2/Il2rg–/–) which lack functional rodent T, B, and NK cells. **Methods:** SRG rats were treated with retrorsine (30–45 mg/kg i.p. x 2 doses) to inhibit rodent hepatocyte proliferation, followed by 70–80% partial hepatectomy (PH). Immediately after PH, rats received an intrasplenic injection of 3×10^6 viable human hepatocytes (HL rats, n = 5) or saline control (n = 5). Liver regeneration was monitored based on MRI volumetrics at weeks 2, 6, and 12 and normalized to body weight. Blood samples were taken by saphenous vein bleeds for biochemical analysis and bile acid profiling. At necropsy, liver tissue was fixed for histological analyses and snap-frozen for human-specific proteomic analysis. **Results:** MRI demonstrated significantly greater liver regeneration post-PH in HL rats compared to controls at weeks 2 (3.34 ± 0.35% vs 2.81 ± 0.13%, p = 0.0034) and 6 (3.11 ± 0.23% vs 2.62 ± 0.13%, p = 0.0439). Normalized liver weight at necropsy 12 weeks post-PH corroborated the MRI findings (4.49 ± 0.36% vs 4.10 ± 0.21%, p = 0.0185). Serum ALT and bilirubin levels were decreased over time, indicating efficient replacement of the lost liver tissue. Immunohistochemistry for human-specific lipoprotein A (LPa) and for Histidine-Ammonia-Lyase (HAL) demonstrated widespread (~50%) human hepatocyte engraftment in the central area (LPa+) and in the portal area (HAL+) of the liver. Bile acid profiling at weeks 6 and 12 demonstrated significant shifts toward human-specific metabolic patterns in HL rats, including increased glycine-conjugated bile acids, decreased taurine-conjugated bile acids with a ratio of Glycine-BA/Taurine-BA = 3 at 12 weeks and substantially reduced rodent-specific muricholic acids. Lipid profiling revealed higher LDL/HDL ratio (1.51) in HL rat compared to control rat (0.36), closely resembling the human LDL/HDL profile (1.45), indicating human-specific lipid metabolism. **Conclusion:** This preliminary study establishes a foundational step toward creating a highly translational humanized rat model capable of supporting human hepatocyte engraftment, and human-specific liver metabolism. These findings provide crucial evidence supporting the feasibility and potential of this humanized rat model as a robust platform for future translational studies, specifically enabling precise modeling of human liver biology and the evaluation of novel therapeutic strategies in liver injury models.

4555 | ROLE OF MYELOID-SPECIFIC MITOGEN-ACTIVATED PROTEIN KINASE PHOSPHATASE 1 (MKP1) IN SEXUAL DIMORPHISM TO ENDOTOXIN RESPONSE

Mary Nancy Walter[1] Diego Montoya-Durango[1] Seamus Pugh[1] Yali Wang[1] Walter Rodriguez-Alvarez[1] Jingwen Zhang[1] Craig McClain[1] Leila Gobejishvili[1], [1]University of Louisville

Background: Gut-derived microbial products like endotoxin drive hepatic inflammation and injury. We have previously shown that alcohol significantly down-regulated the expression of hepatic mitogen-activated protein kinase phosphatase 1 (MKP1). We further showed that MKP1 deletion in hepatocytes resulted in increased alcohol-induced liver injury in mice, demonstrating the role of hepatocyte-specific MKP1 in liver damage. However, the role of myeloid-specific MKP1 in liver injury has never been investigated. Given the significant role of MKP1 phosphatase in the regulation of MAPK kinases and inflammation, we examined the effect of myeloid-specific MKP1 deletion on endotoxin-induced inflammation and liver injury. **Methods:** Myeloid-specific MKP1 knockout mice (MSKO) were generated using LysMCre and MKP1 floxed (f/f) mice on C57Bl/6 background. 12-week-old male and female MKP1 MSKO and their wild type counterparts (f/f) mice were injected with 3mg/kg endotoxin (E. coli-derived lipopolysaccharide, LPS) and sacrificed after 24 hours. Plasma levels of liver injury markers were analyzed. MesoScale Discovery multiplex platform was used for plasma cytokine quantification. Immune cells isolated from the liver were used for flow cytometry and gene expression analysis by RT qPCR. Statistical analysis was completed with Two-way ANOVA. **Results:** Endotoxin administration resulted in liver injury in MSKO male and female mice but had no significant effect in f/f mice. However, female MSKO mice demonstrated increased endotoxin-induced liver injury compared to male MSKO mice. 24 hours after injection plasma levels of inflammatory cytokines returned to baseline levels in f/f mice. Meanwhile, MSKO mice exhibited a sustained response, as shown by elevated levels of cytokines IL-1β, IL-4, KC-GRO, IL-10, IL-33, and TNFα. Additionally, plasma levels of inflammatory markers IFNγ, IL-5, IL-6, and IL-12p70 were elevated in female MSKO mice compared to f/f females. Gene expression analysis of immune cells isolated from the livers of female MSKO mice showed significant increases in mRNA expression of pro-inflammatory cytokines *Il6* and *Ccl2* following LPS injection. Flow cytometry analysis showed no significant changes in proportions of NKT cells, B cells, and CD4+ T cells between the genotypes regardless of treatment. However, MKP1 depletion was associated with significant changes in the ratio of infiltrating macrophages to resident Kupffer cells in female mice after LPS injection. **Conclusion:** Deletion of MKP1 in myeloid cells resulted in increased LPS-induced liver injury and sustained systemic inflammation in both male and female mice. However, MKP1 deletion in myeloid cells had a more profound effect in female mice.

4556 | KV1.3 REGULATES MACROPHAGE IMMUNE FUNCTION THROUGH THE PI3K/AKT PATHWAY TO ALLEVIATE METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

BAOMING WU[1], [1]Pharmacy of School/Anhui Medical Univeristy

Background: The progression of metabolic dysfunction-associated steatohepatitis (MASH) is closely associated with macrophage-mediated inflammatory responses. The voltage-gated potassium channel Kv1.3 plays a critical role in regulating macrophage function; however, its specific role and mechanism in MASH remain unclear. This study aimed to investigate the therapeutic effect of Kv1.3 blockade on MASH and elucidate its underlying mechanism, particularly through the PI3K/AKT signaling pathway in modulating macrophage activity. **Methods:** A Western diet (WD)-induced mouse model of MASH was established, and adeno-associated virus AAV8-Kv1.3-shRNA was used to knock down hepatic Kv1.3 expression. The effects on hepatic steatosis, inflammation, and macrophage infiltration were evaluated. In vitro, an inflammatory model was constructed using LPS-stimulated RAW264.7 macrophages, and cells were treated with the Kv1.3 inhibitor ShK-186 to assess inflammatory cytokine (IL-6, TNF-α) production and migratory capacity. The GEO dataset (GSE167523) and RNA-seq were utilized to identify and validate the involvement of the PI3K/AKT signaling pathway in Kv1.3-mediated regulation of macrophage function. **Results:** Kv1.3 expression was significantly upregulated in WD-induced MASH mouse livers. Hepatic Kv1.3 knockdown markedly alleviated liver injury, steatosis, and inflammatory responses. In vitro, ShK-186 inhibited LPS-induced macrophage migration and inflammatory cytokine production, and significantly reduced phosphorylation of the PI3K/AKT pathway. These effects were partially reversed by the PI3K agonist 740Y-P, further confirming that Kv1.3 attenuates macrophage migration and inflammation by downregulating PI3K/AKT phosphorylation. **Conclusion:** This study is the first to demonstrate that Kv1.3 regulates macrophage inflammatory response and migration via the PI3K/AKT signaling pathway, thereby influencing MASH progression. Hepatic knockdown of Kv1.3 significantly improves MASH-related pathological features, supporting Kv1.3 as a potential therapeutic target for MASH.

4557 | CANCER NEUTROPHIL ENCYCLOPEDIA: A DEEP DIVE INTO ANTIGEN-PRESENTING WARRIORS

Yingcheng Wu[1] Qiang Gao[2], [1]Fudan University, [2]Fudan University Zhongshan Hospital

Background: Neutrophils, the most efficient defenders against pathogens, are essential for tumor microenvironment balance and homeostasis. However, given their plasticity and short half-life which made them too fragile to be profiled, it poses complex challenges regarding how neutrophils are imprinted and adapt specific fates across cancers. **Methods:** Here we designed a one-two-punch sorting strategy, generated the neutrophil atlas from 225 samples of 144 patients from 17 cancer types, and further developed a computational pipeline to recover both shared and specific transcriptional programs. **Results:** Unexpectedly, neutrophils harbored extraordinary complexity composed of 10 cell states and showed sharp tissue or phenotypic specialty. We observed and verified that cancer neutrophils are dramatically arranged along tumor-specific terminal differentiation paths such as inflammation, angiogenesis and antigen-presenting. In particular, the antigen-presenting program was associated with better patient outcomes in the majority of cancers. Such a program can be evoked by leucine metabolism and is dependent on mitochondrial remodeling, acetyl-CoA generation, and preferable epigenetic histone H3K27ac modification. Functionally, antigen-presenting neutrophils invoked expanded T cell response and neoantigen-specific reactiveness. We finally designed the antigen-presenting neutrophil immunotherapy (adoptive transferring and leucine diet) which fine-tunes the microenvironment balance and fuels anti-PD-1 immunotherapy. **Conclusion:** In summary, these data not only lay the groundwork for future neutrophil research, and open the black box of neutrophil state divergence across cancers, but also unravel minimally invasive therapeutic opportunities including adoptive transferring antigen-presenting neutrophils.

4558 | DIFFERENTIAL MODULATION OF BONE MARROW- AND LIVER-DERIVED DENDRITIC CELL FUNCTION BY HEPATIC ISCHEMIA-REPERFUSION- DERIVED EXOSOMES

Cindy Avalos de Leon[1] Suguru Mitsufuji[1] Alan Zahorchak[1] Hamza Yazdani[2] David Geller[2] Angus Thomson[1], [1]Thomas E. Starzl Transplantation Institute, [2]University of Pittsburgh Medical Center

Background: Exosomes play pivotal roles in intercellular communication, facilitating delivery of proteins and nucleic acids to proximal and distal cells. They are elevated in the circulation following liver ischemia-reperfusion injury (IRI). Dendritic cells (DC) are key regulators of innate and adaptive immunity and have been found to influence experimental liver IRI and transplant outcomes. DCs that reside in the liver exhibit tolerogenic properties. Here, we examined the influence of liver-derived exosomes from IRI and control livers on DC phenotype, exosome uptake, and T cell immunostimulatory function. **Methods:** Male C57BL/6 (B6) mice underwent 70% hepatic warm ischemia for one hour, followed by six hours of reperfusion. Liver exosomes (<150 nm) were isolated by ultracentrifugation and iodixanol gradient purification and characterized via nanoparticle tracking analysis, Western blot, and flow cytometry. Liver-resident conventional DCs (LDC) were purified following liver perfusion *in situ* and collagenase digestion, while bone marrow-derived DCs (BMDC) were differentiated from precursors *in vitro* with GM-CSF and IL-4. The DCs were incubated for 24 hours with PKH26-labeled exosomes and evaluated for exosome uptake using imaging flow cytometry. Cell phenotype was assessed by flow cytometry, and DC function determined in allogeneic mixed leukocyte reactions (MLR) and by cytokine quantification. Levels of intercellular adhesion molecule-1 (ICAM-1) and lymphocyte function-associated antigen-1 (LFA-1) expression were also analyzed in both BMDC and LDC to explore mechanisms contributing to exosome uptake. **Results:** Exosome levels were significantly increased in the liver following IRI. Purified liver IRI-derived exosomes, enriched in canonical markers (CD9, CD63, and CD81), enhanced BMDC maturation, as evidenced by upregulation of co-stimulatory CD80 and CD86, and significantly enhanced ability to induce allogeneic CD4+ and CD8+ T cell proliferation and secretion of IFNγ, TNFα, and IL-17A in MLR compared with control liver exosomes. In contrast, LDC did not exhibit phenotypic changes or an altered capacity to stimulate allogeneic T cells, despite exposure to IRI-derived exosomes under the same conditions. Imaging flow cytometry confirmed that BMDC internalized significantly more exosomes than LDC. Notably, BMDC expressed higher levels of ICAM-1 compared to LDCs, suggesting a potential mechanism for their greater exosome uptake capacity. **Conclusion:** These novel findings reveal a differential capacity of liver exosomes released following IRI to affect the phenotype and stimulatory function of BMDC versus LDC. This response may be linked to differential exosome uptake, potentially mediated by ICAM-1/LFA-1 interactions. The refractory response of LDC to liver IRI exosomes may contribute to modulation of tissue injury and alloimmune reactivity following liver transplantation.

4559 | DONOR-DERIVED EXTRACELLULAR VESICLES HAVE IMMUNOLOGICAL PROPERTIES DEPENDENT ON LIVER AGE AND DONOR TYPE

Heather Jennings[1] Peter Chlebeck[1] Brooke Miller[1] Grace Heise[1] Mia Levitsky[1] Bret Verhoven[1] David Al-Adra[1], [1]University of Wisconsin

Background: Liver transplantation is the best treatment for end-stage liver disease, but immunological rejection can reduce both graft and recipient lifespan. Older livers or those procured from donation after circulatory death (DCD) are associated with increased ischemia-reperfusion injury, which may be associated with increased rejection. Donor-derived extracellular vesicles (EVs) can operate in this process by promoting immune activation or suppressing it, primarily through their miRNA cargo. Normothermic ex vivo liver perfusion (NEVLP) provides the opportunity to simulate physiological conditions and allow collection and analysis of EVs derived from standard, older, and DCD livers. We hypothesize older and DCD livers will produce inflammatory EVs. **Methods:** Livers isolated from rats aged 8–12 weeks were used for standard and DCD NEVLP and rats aged at least 21 weeks were used for older donor NEVLP. Cryogenic electron microscopy (cryo-EM) was used to identify the presence of EVs in perfusate samples. Nanosight tracking analysis (NTA) determined the size and number of EVs. EV miRNA was isolated and sequenced. Mixed lymphocyte reaction (MLR) experiments were performed, adding pooled $5x10^7$, $5x10^8$, and $5x10^9$ EVs to quantify the immune effects of EVs from each group

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in a dose-dependent manner. **Results:** Cryo-EM confirmed the presence of EVs in samples taken after 4 hours of NEVLP. NTA data demonstrated older and DCD livers respectively produced 11.5x and 4.7x more EVs than standard livers after 1 hour of NEVLP and older and DCD livers produced 5.9x and 2.6x more EVs than standard livers after 4 hours of NEVLP, respectively. Principal Components Analysis of miRNAs clustered the older liver EV miRNAs within the standard liver cluster area, while DCD liver EV miRNAs were separate. MLR results indicate that higher concentrations of standard liver EVs suppress the immune response, whereas older and DCD liver EVs enhance it. **Conclusion:** DCD and older livers release more EVs than standard livers during NEVLP, with DCD livers having a distinct population of miRNAs. The RNA cargo in the older liver EVs appear similar to that of the standard livers, but do not suppress an immune response at higher concentrations as seen with the standard liver EVs. DCD EVs also increased the immune response at higher concentrations. These results help elucidate the role that donor graft EVs can play in rejection and may present novel targets for immune response modulation.

4560 | HEPATIC INFARCTION, AN INFREQUENTLY ENCOUNTERED COMPLICATION OF HELLP SYNDROME: A CASE REPORT

Jill Bhavsar[1] Manjusha Das[1], [1]Wellstar Cobb Medical Center

Background: HELLP syndrome (defined as: hemolysis, elevated liver enzymes and low platelet) is a relatively uncommon pregnancy related disease. Most cases occur in third trimester and have strong association with preeclampsia, while some have more "atypical" presentations. This case highlights the importance of carefully distinguishing HELLP syndrome from other diseases, and initiating prompt treatment to prevent further complications. **Methods:** A 32 year old female with pertinent past history of systemic lupus erythematosus (SLE) on plaquenil, and aplastic anemia secondary to idiopathic thrombocytopenic purpura (ITP) with prior splenectomy was admitted for preterm premature rupture of membranes at 35 weeks and 5 days of gestation. She endorsed mild right sided abdominal pain on admission and was found to have liver enzyme elevation and worsening thrombocytopenia (84,000 cells/microL), with elevated LDH at 251 units/L, low hemoglobin at 9.7 g/dL and low haptoglobin < 10 mg/dl concerning for HELLP syndrome during the 3rd trimester of pregnancy. The peak aspartate aminotransferase and alanine aminotransferase (AST and ALT) was 600 IU/L and 934 IU/L respectively 2 days postpartum. The peak alkaline phosphatase (ALP) was 720 IU/L a few days before delivery. MRI abdomen/pelvis was notable for multiple nonspecific areas of hypoenhancement in the liver with the largest lesion in the left lateral hepatic lobe measuring 5.9 x 4.6 cm, a region of hepatic infarction. Due to concerns for worsening hepatic failure she was transferred to a liver transplant center. **Results:** HELLP syndrome complicates about 0.2-0.8% of all pregnancies. The placental factors and vasoactive substances induce an enhanced inflammatory state and endothelial damage in the liver which leads to increased formation of microthrombi, ischemia of the hepatocytes and ultimately liver failure. In 70-80% of cases it co-exists with pre-eclampsia, however about 15% of HELLP syndrome patients have no association with pre-eclampsia and present without hypertension or proteinuria.

Occasionally, HELLP syndrome can be worsened by the development of hepatic infarction, subcapsular hematoma, or hepatic rupture. Hepatic infarction occurs in less than 1% of HELLP patients and has mortality rate of 16%. Thus, in a patient with right upper quadrant pain and significant elevation of liver enzymes; bedside ultrasound, CT or MRI imaging should be obtained to establish a prompt diagnosis and a timely treatment plan, which often includes surgical interventions such as hepatic resection or liver transplantation. **Conclusion:** This case highlights severe, rare presentation of HELLP syndrome (without hypertension or proteinuria) developing hepatic infarction which has high morbidity and mortality; emphasizing the need for close monitoring of liver function test for all HELLP patients and early diagnosis with aggressive management.

4561 | INJURED LIVER-RELEASED MIR-122 LEADS TO ERYTHROCYTE PHAGOCYTOSIS VIA THE ACTIVATION OF TLR7

Yingyun Gong[1] Yingjing Zou[2] Moran Hu[1] Hai Huang[1] Ke Zen[3] Hongwen Zhou[1] Hongwei Liang[4], [1]Nanjing Medical University, [2]Nanjing Medical University; China Pharmaceutical University, [3]Nanjing University, [4]China Pharmaceutical University

Background: Anemia is a prevalent complication in patients with advanced chronic liver disease, with prevalence ranging from 50% to 87%. The specific mechanism by which liver disease results in erythrocytopenia remains unclear, underscoring the necessity for further investigation. **Methods:** To investigate the influence of liver injury on erythrocytopenia, subjects with liver diseases and age- and sex-matched healthy volunteers were enrolled. Both AFLD and NAFLD mouse models were induced for further investigation, and genetic mouse models were also applied accordingly. Erythrocytes were isolated from human and mouse whole blood samples. Flow cytometry and Immunofluorescence were used for surface staining. **Results:** We first demonstrated that injured liver-released miR-122 could bind with Toll-like receptor 7 (TLR7) to alter the morphology and CD47 distribution of erythrocytes, which results in erythrophagocytosis. Knockout of either miR-122 or TLR7 could block erythrophagocytosis in AFLD and NAFLD mouse models. Furthermore, a miR-122 inhibitor rescued this phenotype. **Conclusion:** These findings represent a novel mechanism of anemia caused by advanced chronic liver disease. The inhibition of miR-122 in patients may prove to be an effective strategy for the prevention or retardation of anemia.

4562 | A MICROBIAL METABOLITE REDUCES ALCOHOL-INDUCED INFLAMMATION VIA DUAL MODULATION OF NF-&KAPPA;B AND INTERFERON PATHWAYS

Adam Kim[1] Yurui Zheng[1] Nicholas Handali[1], [1]UConn Health

Background: Chronic alcohol consumption alters innate immune signaling leading to a hyper pro-inflammatory state. Preliminary data from our lab found that in both patients and murine models of alcohol-associated liver disease, immune cells have imbalanced innate immune gene regulation, with elevated pro-inflammatory nuclear factor kappa B (NF-κB) responses and significantly reduced interferon signaling. Interferon signaling is essentially protection from viruses but also regulation of anti-inflammatory pathways. We wanted to find a molecule that could stimulate the interferon pathway and reduce NF-κB activation to rebalance innate immune signaling in the liver and immune cells of ALD patients. **Methods:** We utilized THP1-Dual cells, a human monocyte-derived cell line that has been genetically engineered with dual reporter systems. These cells allow the simultaneous monitoring of NF-κB and Interferon Regulatory Factor (IRF) activation via alkaline phosphatase and luciferase secretion respectively.

To identify novel drugs that modulate these pathways, we challenged THP1-Dual cells with +/- LPS (100pg/ml) to simulate chronic inflammation observed in patients. After 24 hours, cells were then treated with a single compound from a library of microbial metabolites. After another 24-hours we collected supernatant to measure alkaline phosphatase and luciferase. **Results:** While we identified a number of molecules capable to shifting these two signaling pathways in different ways, one microbial metabolite, 4-Hydroxyphenylacetic acid (4-HPAA), led to a downregulation of NF-κB and an upregulation of IFN pathway activity, only in monocytes challenged with LPS. This suggests that 4-HPAA may be a molecule that can specifically rebalance innate immune signaling during inflammation. To test this, we used the NIAAA-model of alcohol-associated hepatitis where 4-HPAA was added to the Lieber-DiCarli diet. We found that 4-HPAA was able to significantly reduce liver damage and qPCR results show an increase in interferon signaling in EtOH fed animals. **Conclusion:** These findings provide insight into the potential application of 4-HPAA as a therapeutic agent targeting alcohol-induced inflammation.

important in liver transplantation. ATP is a source of energy and abundant in the cell. However, ATP is released into extracellular space and acts as a damage associated molecule patten (DAMP) during cell injury. P2X7 is a receptor of extracellular ATP (eATP) and activates immune cells thorough eATP ligation. In this study, we will reveal the role of P2X7 in liver IRI and demonstrate the potential therapeutic capacity of eATP-P2X7 axis. **Methods:** 8–10-week-old wild type (WT) or P2X7 KO male mice, NOD.129P2 background, were subjected to liver IRI. After 6 hr reperfusion, the mice were euthanized and liver injury assessed by serum ALT. A740003 were intraperitoneally injected 1 hr before applying ischemia for P2X7 blockade or eATP hydrolysis. The expression levels of IL-6, TNF-α and IL-1β in IRI induced liver was evaluated by RT-PCR and western blot. WT and P2X7 KO splenocytes were stimulated with LPS for 18 hr for assessing the impact of P2X7 deficiency in IL-6, TNF-α and IL-1β production. **Results:** P2X7 KO mice displayed significant lower serum ALT compared with WT mice after liver IRI injury (KO/WT: $1530 \pm 584/7544 \pm 3442$ U/L, $P < 0.001$). The expression of IL-6, TNF-α and IL-1β in IRI induced liver was significantly lower in P2X7 KO mice. A740003 treatment reduced serum ALT after the liver IRI compared with untreated mice (A740003/untreated: $39280/323 \pm 1452$ U/L, $P < 0.001$). IL-6, TNF-α and IL-1β expression in IRI induced liver were significantly lower in A740003 treated mice compared with PBS treated control mice. IL-6, TNF-α and IL-1β production by P2X7 KO splenocytes were significantly lower compared with those of WT splenocytes. **Conclusion:** P2X7 deficiency reduced inflammatory cytokine production and protected liver from IRI. P2X7 blockade could be a treatment option for liver IRI.

4564 | FUNCTIONAL VARIANTS OF THE IFNL4 DRIVE ISG EXPRESSION WITH SECONDARY EFFECTS ON LIPID METABOLISM IN THE HEALTHY LIVER

Keisuke Fukutomi[1] Alexis Moore[1] Sabitree Shahi[1] Vicky Chen[2] Marc Ghany[3] Barbara Rehermann[1],
[1]Immunology Section, Liver Diseases Branch, NIDDK, National Institutes of Health, [2]Integrated Data Sciences Section, Research Technologies Branch, NIAID, National Institutes of Health, [3]Clinical Hepatology Research Section, Liver Diseases Branch, NIDDK, National Institutes of Health

Background: Interferon lambda 4 (IFNL4) is an ancestral protein that is produced in the presence of the rs368234815-ΔG allele, while the alternate rs368234815-TT allele results in a frameshift that abrogates IFNL4 production. The IFNL4-encoding rs368234815-ΔG allele has been associated with decreased disease progression in chronic HCV infection and metabolic dysfunction-associated steatohepatitis, but the mechanisms are not known. **Methods:** To investigate the effect of IFNL4 on hepatocytes and intrahepatic immune responses in the absence of any HCV-mediated effects, we performed single-cell RNA-seq analysis of liver biopsies from 14 patients five years after treatment-induced HCV clearance with direct acting antivirals. No patient had substantial liver inflammation (ALT, median: 27 (IQR, 19-31.5) U/L; mean HAI score 2, Ishak fibrosis score 1). Genotyping for rs368234815 and rs117648444 was performed. **Results:** Twelve patients encoded IFNL4 (rs368234815-ΔG/ΔG or -ΔG/TT, and rs117648444-G/G). Two of these encoded a functionally attenuated IFNL4 with a P to S substitution at IFNL4 position 70 (rs117648444-A/G). Two patients did not encode IFNL4 (rs368234815-TT/TT). Single-cell RNA sequencing analysis revealed significantly higher expression of interferon-stimulated genes (ISGs, *MX1*, *IFITM1*, *OAS1*, and *ISG15)* in hepatocytes and liver sinusoidal endothelial cells (LSECs) of patients who encoded IFNL4 than in those who did not. Patients with a functionally attenuated IFNL4 had significantly lower ISG expression than those with conserved IFNL4 but higher ISG expression than those without IFNL4. In hepatocytes, increased ISG expression was associated with enriched pathways for fatty acid degradation (*ACAA2*, *ACAT1, ACADM*, *ACADVL*, *GCDH, ACOX1, CPT2*), while steroid biosynthesis (*LSS*, *MSMO1*, *TM7SF2*, and *FDFT1*) was reduced (KEGG database). Differential ISG expression extended to all intrahepatic immune cell populations, even though IFNLR1 expression is restricted to neutrophils and dendritic cells. These findings suggest secondary type I and II IFN responses, which were confirmed by Hallmark gene enrichment analysis. CD4 and CD8 T cell activation pathways were enriched (Hallmark gene set) despite reduced antigen processing and presentation pathways in macrophages (GO analysis). **Conclusion:** Functional variants of the *IFNL4* gene increase ISG expression in LSECs and hepatocytes, and liver immune cells with a secondary effect on lipid metabolism.

4565 | EFFICACY OF THE CLM-022, AN INHIBITOR OF THE NLRP3 INFLAMMASOME, IN IN VIVO AND IN VITRO PATHOGEN-ASSOCIATED MOLECULAR PATTERNS (PAMPS)-INDUCED DISEASE MODELS

Guillaume Vidal[1] Alexandra Caron[1] Hana El Khatib[1] Maryse Malysiak[1] Valérie Daix[1] Simon Debaecker[1] Manon Clarisse[1] Dean Hum[2] Bart Staels[3] Sakina Sayah Jeanne[1], [1]Genfit, [2]GENFIT CORP, [3]University Lille 2

Background: Inflammation and hepatocyte cell death are common elements in the pathogenesis of most chronic liver diseases leading to fibrosis, cirrhosis and liver failure. Zhao et al. (2025) recently identified a previously unrecognized pathogenic role of Gasdermin-D (GSDMD)-elicited pyroptosis in regulating the immune microenvironment in HBV-ACLF (hepatitis B virus-acute on chronic liver failure) liver tissue. Pyroptosis is regulated by inflammasomes which are intracellular multiprotein complexes also expressed in both parenchymal and non-parenchymal cells of the liver. In response to danger signals such as PAMPs, inflammasomes activate caspase-1, release IL-1β and IL-18. The aim of this work was to characterize the mechanism of NLRP3 inhibition by CLM-022 and evaluate its protective activity in models of PAMP-induced inflammation. **Methods:** Drug Affinity Responsive Target Stability (DARTS) assay was performed to assess the mechanism of action of CLM-022 on inflammasome inhibition. Inhibition of cytokines production was assessed in LPS stimulated human whole blood cells. For in vivo studies, polymicrobial sepsis was induced by caecal ligation and puncture (CLP). **Results:** CLM-022 binds to the NLRP3 protein, thereby preventing NLRP3 inflammasome complex assembly. In human whole blood assay, CLM-022 strongly inhibits IL-1β, IL-6 and TNF-α production when added concomitantly and after LPS stimulation (IC_{50} ~135nM - 121nM, 363nM - 456nM, 283nM - 380nM, in co- and post-treatment, respectively). In the mice murine sepsis model CLM-022 confers protection from gut leakage-induced mortality at 1 mpk, orally administered, once daily for 7 days. **Conclusion:** Although further experiments are needed to fully understand how CLM-022 improved survival in septic mice, at a minimum, it seems to be mediated by regulation of the innate immune response. These results further support the development of CLM-022 in advanced liver disease including ACLF

4566 | MICRONUTRIENT CHANGES IN A MURINE MODEL OF CCL_4-INDUCED CHRONIC LIVER DISEASE

Jeffrey Singer[1] Dillon Kunkle[1] Eric Skaar[1], [1]Vanderbilt University Medical Center

Background: Micronutrient deficiency is a well-recognized complication of chronic liver disease owing to the central role the liver plays in organismal metabolism. Additionally, patients with decompensated cirrhosis are more prone to invasive bacterial infections. Despite the co-incidence of these two well-known observations in the same patient population, it is unclear if nutritional deficiency is a causal factor for increased infection risk in patients with chronic liver disease. **Methods:** To address this question, we aimed to develop a murine model of micronutrient deficiency in chronic liver disease which could then be subjected to infection. We implemented the well-studied model of chronic liver injury using carbon tetrachloride (CCl_4) injection for 8 weeks. Following fibrosis induction, we analyzed tissue and serum with inductively-coupled plasma mass spectrometry and real-time gene expression analysis to evaluate for changes in trace metal and selenium homeostasis. **Results:** As expected, mice treated for 8 weeks with CCl_4 developed advanced fibrosis compared to those treated with corn oil vehicle. We found robust differences across treatment groups in both male and female mice in multiple trace metals and selenium in the serum and liver as well as gene expression changes in the liver and duodenum that support a biologically significant role for these observed differences. Interestingly, no differences were observed in serum or liver iron levels despite gene expression changes suggesting altered iron homeostasis. **Conclusion:** We conclude that chronic CCl_4-induced fibrosis disrupts host nutritional metal homeostasis and this model is well-suited for mechanistic probing of how micronutrition status impacts infection susceptibility in chronic liver disease. Insights from future studies may offer a roadmap to preventing infections in highly susceptible patients.

4567 | MACRO-ASPARTATE AMINOTRANSFERASE IN A PATIENT WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Helena Steffens[1] Isabella Solaroli[1] Mark Cervinski[1] Jeffrey Adler[1], [1]Dartmouth Hitchcock Medical Center

Background: Macro-aspartate aminotransferase (macro-AST) is a rare phenomenon in which auto-antibodies bind circulating AST, reducing AST clearance, leading to AST concentrations that are not reflective of a disease process. The condition can lead to diagnostic ambiguity and unnecessary tests. Herein, we report a case of macro-AST for a patient referred to the gastroenterology department for evaluation of a pancreatic cyst incidentally discovered on ultrasound performed because of an elevated AST found on routine blood work. **Methods:** A 61-year-old man with type II diabetes mellitus and metabolic dysfunction-associated steatohepatitis (MASH) presented to the gastroenterology clinic for evaluation of a pancreatic cyst. However, this issue was incidental, and was discovered on an abdominal ultrasound that had been performed because of an elevated AST (384 U/L, reference interval $\leq$ 39 U/L).
On interview he recalled that his AST had been elevated to 800 U/L at an outside facility five months prior. Subsequent general serologic testing for chronic liver disease was performed, and was found unremarkable. Of note, CK was also performed and was 80 U/L (reference interval 0-200 U/L). Despite this, his AST remained elevated at 280 U/L. Notably, the patient's ALT, alkaline phosphatase, and fractionated bilirubin had been, and all remained within reference intervals. **Results:** At this time, macro-AST testing was performed. Testing involved affinity chromatography utilizing agarose beads coated with protein A/G with high affinity for human IgG. AST activity was measured before and after column elution. For a patient with macro-AST, the AST activity should mirror the pattern of IgG. The figure below (Figure 1) demonstrates the patient's AST activity (blue line) was lower than the control (orange) after binding to the column, indicating that most of the AST was bound by antibodies. Activity spiked with elution buffer, which is consistent with macro-AST. **Conclusion:** An isolated elevation in AST might be the result of macro-AST. Recognition of this phenomenon might save a patient unnecessary testing for liver disease.

4568 | NEW SUBMISSION PERIPHERAL LYMPHOCYTES IN HUMAN LIVER HEPATOCELLULARCARCINOMA: A NEW DRUGGABLE TARGET AS WELL AS BIOMARKER TO HELP DIAGNOSIS AND PREDICT IMMUNOTHERAPY RESPONSE

Andrea Dalbeni[1] Rosa Lombardi[2] Vincenzo Di Maria[1] Paola Dongiovanni[3] Marica Meroni[4] Stefania CAnè[5] Antonio Vella[6] Moris Sangineto[7] Massimo Pettoello Mantovani[8] Maria Rosa Pastore[9] GAETANO SERVIDDIO[7] david sacerdoti[10] Anna Ludovica Fracanzani[11], [1]AOUI Verona, [2]University of the Study of Milan, [3]SC Medicina Indirizzo Metabolico, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Mila, [4]Fondazione Ca' Granda OMP Milano, [5]The Veneto Institute of Oncology IOV-IRCCS, Padua, Italy., [6]Section of Immunology, Azienda Ospedaliera Universitaria Integrata (AOUI), Verona, Italy., [7]Liver Unit, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy., [8]European Pediatric Association, Union of National European Pediatric Societies and Associations, [9]Unità Operativa Complessa di Pediatria, Fondazione IRCCS "Casa Sollievo della Sofferenza", San Gi, [10]Liver Unit, Medicine Department, University of Verona, [11]University of Milan

Background: Hepatocellular carcinoma (HCC) represents the second leading cause of cancer-related death worldwide, developing from a chronic liver disease, characterized by inflammation and fibrosis, derived from either viral insult (e.g. HBV and HCV), metabolic syndrome (MASLD), plus alcohol abuse (MetALD) or other causes. Over the past decade, immune

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

checkpoint inhibitors (ICI) have revolutionized the treatment of HCC adding to previous treatments. Despite the remarkable advances, the criteria and guidelines for patient selection are missing and insufficient. Therefore, identify the immunological features in different etiologies and properties to support patient eligibility is *a sine qua non* for the improvement of therapeutic efficacy and for the development of a solid, personalized medicine approach. Aims of our study are define phenotypically, lymphocytes cells trough flow cytometry (FACS) in patients with HCC BCLC B/C with different aetiologies and in a subgroup of patients, treated with ICI, the aim is to identify their contribution to response. **Methods:** Liver-resident immune cells, in particular γδT cells 8 (CD4-CD8-), CD8 and CD4 lymphocytes, neutrophils, Kpuffer cells and macrophages were assessed by FACS in 159 patients. Liver specimens from adult patients with either diagnosis of MASLD including previous HCV with metabolic factors (100) or viral (HBV/HCV) infection (41) or alcohol abuse (18) stratified according to the HCC stage.

We performed Kruskal Wallis or Anova with post hoc to establish the difference between aetiologies and trough Machine Learning, XGBoost with SHAP, we determined which lymphocytes make a difference in prediction and accuracy of the model ($AUC > 0.8$). Using Leave-One-Out Cross-Validation (LOOCV) we selected the patients with features able to predict response to systemic treatment. **Results:** We documented differences in neutrophiles, monocytes, CD4 and CD8 and ratio and NK between the different aetiologies. In particular CD8 CD57+ (exhausted cell), NK and CD4 discriminates viral vs MASLD (AUC 0.8), while CD4-8-, NKt, and CD4 +8+ MASLD vs MetALD (AUC 0.83).

Also combing HCC stage (B or C) with lymphocytes, we documented a difference between viral and MASLD/MetALD. ($p < 0.05$) in CD8+CD57+.

We selected patients who received ICI considering all lymphocyte populations and correlated them to objective response rate (ORR). Throught LOOCV we identified CD8+57+, IGD+ CD27- and CD4-CD8- like top 3 features (AUC 0.84, precision 0.8, recall 0.7). **Conclusion:** For the first time this study identifies in blood in patients with HCC different lymphocytes population that could be a future target of immune therapies and moreover featured CD8+57+ named also exhausted cell and CD4-8- as biomarker of response to ICI treatment.

4569 | ◆ HIGH SALT DIET EXACERBATES LIVER FIBROSIS AND MODULATES IMMUNE RESPONSES IN MOUSE MODELS

Amalia Tzoumpa[1] Joanna Picó[1] Yin Huang[1] Beatriz Lozano[1] Pedro Zapater[1] Jose Manuel Gonzalez Navajas[1], [1]Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL)

Background: Liver cirrhosis is characterized by inflammation and fibrosis, with the immune system playing a crucial role in progression. Evidence suggests dietary salt can modulate immune responses and immune-mediated diseases. The interplay between dietary factors, immune cells, and liver tissue highlights the importance of understanding how high salt intake may contribute to liver pathology. This study evaluated the hepatic immunomodulatory effects of salt and its impact on liver injury and fibrosis in mouse models. **Methods:** C57BL/6 male mice were fed either normal diet (ND) or a high salt diet (HSD) (4% NaCl) for one week and were then additionally subjected to CCl_4 or vehicle injections (2 mL/kg) twice weekly for three weeks to induce liver fibrosis. At the end point, mice were sacrificed and liver tissue and blood were analyzed by flow cytometry, elisa, qpcr and histology. In addition, hepatocytes from both groups of mice were isolated for ex vivo experiments. **Results:** All mice receiving CCl_4 injections exhibited liver injury and fibrosis. Although HSD alone did not induce hepatic damage or immune cell infiltration, it exacerbated CCl_4-induced injury and fibrosis, as evidenced by increased necrotic areas, the expression of fibrosis-related genes (Acta2, Fn1, and Timp1) and immunohistochemistry of alpha smooth muscle actin. Additionally, $CD68^+$ staining indicated elevated macrophage infiltration in the HSD group upon liver injury. Furthermore, flow cytometry analysis demonstrated a significant increase in hepatic CD4+ IL17+ (Th17 cells), CD4+ IL17+ TNFα+ cells, and pro-inflammatory Th17-like Tregs (Foxp3+ IL17+ cells) in HSD-fed mice, suggesting a Th17-skewed immune response. Moreover, HSD promoted the expansion of cDC2 dendritic cells, which are known to facilitate Th17 differentiation, and upregulated MHC II expression on macrophages, further supporting a pro-inflammatory microenvironment that can facilitate activation of T cells. Mechanistically, hepatocytes isolated from mice exposed to HSD showed elevated production of IL-6 and IL-1β, which was associated to an increase in mitoROS, NF-κB and NLRP3 inflammasome activation. Additionally, we analysed the effect of conditioned medium (CM) from hepatocytes previously exposed to

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

high NaCl conditions in T cell differentiation. Our observations revealed that CM from hepatocytes pre-treated with NaCl specifically exacerbated Th17 differentiation. **Conclusion:** In conclusion, HSD exacerbates liver injury and fibrosis by facilitating Th17-mediated inflammation. Our findings indicate that HSD induces a pro-inflammatory response in hepatocytes, potentially through mitoROS/NLRP3 activation, and affects T cell differentiation via signals derived from hepatocytes. This study offers evidence for future investigations into potential therapeutic strategies targeting the salt-induced inflammatory cascade in liver disease.

4570 | ◆ TARGETING MONOCYTE TLR8 AS AN ANTI-INFLAMMATORY THERAPY IN DECOMPENSATED ADVANCED CHRONIC LIVER DISEASE

Malgorzata Grzelka[1] Roseanne Khawaja[1] Alejandro Brenes[1] Ailish McCafferty-Brown[1] Daniel Dugger[2] Guiguan Jia[2] Nandhini Ramamoorthi[2] Andrew Thorley[2] Jonathan Fallowfield[1] Prakash Ramachandran[1], [1]The University of Edinburgh, [2]Genentech

Background: Decompensated advanced chronic liver disease (dACLD) is associated with significant morbidity and mortality. Beyond transplantation, current therapies for dACLD do little to change its natural history. Systemic inflammation (SI) is associated with adverse outcomes in dACLD and anti-inflammatory therapies have been proposed as a treatment strategy. However, the molecular mechanisms underpinning SI in dACLD remain unclear. We aimed to define cellular and molecular drivers of SI to identify new candidate therapeutic targets for dACLD. **Methods:** Blood and clinical phenotyping data were collected from patients with dACLD, compensated ACLD (cACLD), non-ACLD or healthy controls. Serum cytokines were measured using immunoassay. Immunophenotyping was performed using spectral flow cytometry. Monocytes were isolated for mass spectrometry and functional assays. TLR8 agonist activity was assessed by serum treatment of TLR8-reporter HEK cells. Human liver single-cell RNA-seq (scRNAseq) data was analysed using R. **Results:** Serum inflammatory cytokines increased in dACLD patients and positively correlated with MELD-Na score, liver frailty score and liver stiffness. Flow cytometry showed a reduction in cytotoxic CD8+ T cells between cACLD and dACLD but no numerical differences in circulating monocytes. However, monocytes in dACLD exhibited a more pro-inflammatory profile with elevated CD9, CD64 and CD63 expression, enhanced phagocytosis capacity and increased production of IL-1β and TNF-α. Unbiased proteomics revealed significantly augmented expression of the endosomal toll-like receptor 8 (TLR8) in dACLD monocytes compared to cACLD (Figure 1A), whilst serum analysis using TLR8-reporter HEK cells demonstrated increased circulating TLR8 ligand activity with more advanced liver disease (Figure 1B). Analysis of scRNAseq confirmed that TLR8 expression is specific to myeloid cells and increased in CLD livers. Treatment of dACLD monocytes, using either the specific TLR8 inhibitor CU-CPT9a or the dual TLR7/8 inhibitor Enpatoran, reduced expression of pro-inflammatory cytokines IL-1β, IL-6 and TNF-α. **Conclusion:** Our comprehensive immunophenotyping data demonstrate monocyte activation as a key regulator of SI in dACLD and identifies TLR8 activity as a driver of this process, with elevated monocyte TLR8 expression and serum TLR8 ligand activity observed in dACLD patients. Crucially, the TLR8 pathway is druggable, highlighting this as a tractable therapeutic target to abrogate SI in dACLD.

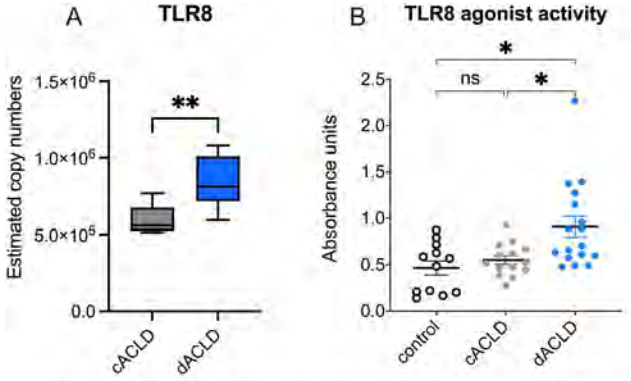

Figure 1 A. Mass spectrometry revealed significantly higher TLR8 in dACLD compared to cACLD in CD14+ monocytes; B. Treatment of TLR8 reporter HEK cells with human serum demonstrated significantly higher endogenous TLR8 ligand activity in dACLD compared to cACLD and control.

4571 | ◆ IMPACT OF PEDIATRIC AGE CUTOFFS ON US LIVER TRANSPLANT ALLOCATION: A REGRESSION DISCONTINUITY DESIGN

Tomohiro Tanaka[1] George Wehby[2] Michael Jones[2] David Axelrod[3], [1]University of Iowa School of Medicine, [2]University of Iowa, College of Public Health, [3]University Hospitals

Background: Currently, U.S. liver transplant (LT) organ allocation policy prioritizes allografts recovered from pediatric donors (< 18 years) for candidates < 12 years, followed by those aged 12–17 and then adults ≥ 18. The impact of these age-based allocation cutoffs on access to LT and waitlist mortality was retrospectively evaluated. **Methods:** U.S. national transplant registry data from 2/4/20 to 12/31/23 was analyzed using person-day as the unit of analysis to assess outcomes for LT candidates listed between ages 12 and 24 to evaluate the age 18 threshold, and between ages 6 and 18 for the age 12 threshold. Sharp regression discontinuity (RD) designs embedded in pooled regression models were applied at both age cutoffs based on current OPTN policy. Primary outcomes were receipt of a top five liver organ offers and the probability of undergoing deceased donor transplantation (DDLT). The exposure was organ offer prioritization defined by PELD score for each age. RD plots were generated (Figure A–D). Poisson and logistic regression analyses were used to model offer rates and DDLT probability, adjusting for MELD exception status and covariates. Age was defined as actual daily age for the 12-year threshold model and age at listing for the 18-year threshold model. **Results:** A total of 301,783 person-day observations from 1,521 unique candidates were analyzed, including 122,947 waitlisted observations impacted by the age 12 threshold and 187,766 affected by the age 18 threshold. The age 12 threshold did not significantly impact organ offer rates (Figure A); however, transplant probability was lower for candidates > 12 years old (Figure B). Patients over 12 had a relative risk of 1.06 (95% CI: 0.90 to 1.26) and an odds ratio of 0.61 (95% CI: 0.40 to 0.92), favoring those under 12. Age above the 18-year threshold was associated with a significant decline in both organ offers and transplant probability (Figures C and D), with a relative risk of 0.86 (95% CI: 0.76 to 0.98) and an odds ratio of 0.55 (95% CI: 0.46 to 0.95), respectively. Additional RD models evaluating offer-related metrics, including the proportion of donors under age 18, use of brain-dead donors, and organ acceptance rates, also showed significant declines in access for patients above the age thresholds. **Conclusion:** Current age-based allocation cutoffs at 12 and 18 years create significant discontinuities in LT access in the U.S. The disadvantage experienced by adolescent and young adult candidates was particularly significant near the cutoff age. Future allocation refinements should reconsider these age-based transitions to ensure more fair access across all age groups.

4572 | ◆ LARGE-SCALE PROTEOMIC STUDY REVEALS TOTAL SERUM IGG AS A CANDIDATE NOVEL DIAGNOSTIC BIOMARKER IN GESTATIONAL ALLOIMMUNE LIVER DISEASE

Katie Rose Conover[1] Priya Rolfes[1] Kathryn Kilpatrick[1] Anthony Saviola[1] Sarah Taylor[2], [1]University of Colorado, [2]Columbia University Medical Center

Background: Gestational alloimmune liver disease (GALD) is a leading cause of neonatal acute liver failure (ALF) with high mortality, particularly if treatment with intravenous immunoglobulin (IVIG) and exchange transfusion (ET) is not initiated early. However, diagnosis of GALD remains challenging. We aim to identify novel non-invasive diagnostic biomarkers for GALD. **Methods:** We obtained serum samples from GALD (n = 10) and non-GALD (n = 15) cases with neonatal ALF from the NIDDK Pediatric Acute Liver Failure study biorepository. Mass spectrometry and IgG enzyme-linked immunosorbent assay (ELISA) were run on all samples. Proteomic analysis (MetaboAnalyst, Enrichr) was conducted in patients without prior IVIG or ET treatment (n = 18); proteomic analysis by outcome included the full cohort (n = 25). Statistical analysis was performed using Pearson's chi-squared, Mann-Whitney *U* and Student's t-test. **Results:** Age of liver failure onset and serum collection did not differ between

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

groups ($p > 0.05$ for both). Although not reaching statistical significance, a greater proportion of GALD patients died (67% vs 30%) and fewer were transplanted (0% vs 30%). After excluding post-IVIG/ET cases, GALD cases demonstrated robust upregulation of immunoglobulin heavy and light chains (Figure 1A). ELISA confirmed significant increase in total serum IgG in untreated GALD cases ($p = 0.005$) with an area under receiver operating curve of 0.903 to predict GALD vs non-GALD ALF ($p = 0.007$, Figure 1B,C). Importantly, IgG level did not correlate with age ($r = -0.07$, $p = 0.74$). Pathway analysis showed upregulation of classical antibody-mediated complement activation pathways in GALD (adjusted $p = 3.9e\text{-}13$) and scavenging by class A receptors in non-GALD (adjusted $p = 1.2e\text{-}6$). Several proteins reflecting liver synthetic and regenerative function, including factor levels, alpha-fetoprotein, angiotensinogen and fibrinogen were significantly decreased in GALD cases with poor outcome (raw $p < 0.05$). **Conclusion:** Differentially expressed serum proteins between GALD and non-GALD neonatal ALF reflect understood pathogenic mechanisms involving complement activation and decreased liver synthetic proteins particularly in GALD infants with poor outcome. Total serum IgG may be significantly increased in GALD due to maternal placental transfer of pathogenic antibodies that destroy fetal hepatocytes. Total serum IgG should be explored prospectively as a non-invasive GALD diagnostic biomarker.

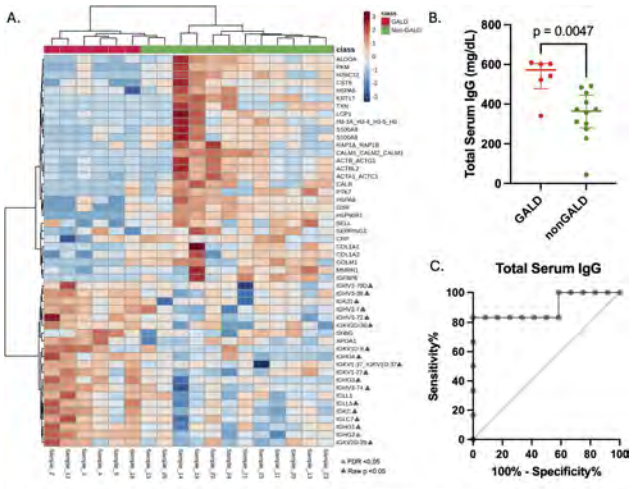

Figure 1. Results from proteomic analysis comparing gestational alloimmune liver disease (GALD) and non-GALD neonatal acute liver failure cases, which excluded patients who received intravenous immunoglobulin or exchange transfusion prior to serum collection. **(A)** Heatmap showing top 50 differentially expressed proteins between groups. Colored triangles notate immunoglobulin heavy and light chains that are significantly increased in GALD vs non-GALD cases via Student's t-test. **(B)** Total serum IgG from enzyme-linked immunosorbent assay (ELISA) is significantly higher in GALD vs non-GALD cases (p=0.005). **(C)** Area under the receiver operating curve is 0.903 to predict GALD vs non-GALD neonatal acute liver failure (p=0.007).

4573 | ◆ EARLY CHANGES IN THE FECAL MICROBIOTA ARE ASSOCIATED WITH PEDIATRIC METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Sarah Maxwell[1] Lu Yang[1] Abdur Rahim Khan[1] James Bayrer[1] Philip Rosenthal[1] Emily Perito[1] Jennifer Price[1] Janet Wojcicki[1], [1]University of California, San Francisco

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is the most common pediatric liver disease in the US. Alterations in the gut-liver axis leading to intestinal dysbiosis contribute to MASLD development. Pediatric MASLD severity has been linked to alterations in the fecal microbiota, with prior studies showing decreased bacterial diversity and different microbial abundance in children with MASLD compared to those without MASLD. However, no studies have examined whether fecal microbial composition in early childhood is associated with MASLD risk later in childhood. We characterized the gut microbiome in Latino infants and preschool children who later developed MASLD and compared it to those without MASLD. **Methods:** In a longitudinal cohort of 87 Latino babies, stool samples were collected at 6 months, 1, 2, and 3 years of age. MASLD was assessed between 5-8 years of age and defined by BMI $> 85\%$ and alanine aminotransferase $\geq 95\%$ for age and gender (≥ 25.8 IU/L for boys, ≥ 22.1 IU/L for girls). Stool microbial communities were profiled using 16s ribosomal RNA sequencing, and analyzed for alpha diversity (via linear regression-based t-tests), beta diversity (via PERMANOVA), and differential taxonomic abundance (via ANCOM-BC) to assess associations with later MASLD, adjusting for potential confounders. **Results:** Of the 87 babies, 46% were boys, 52% were of Mexican origin, 33% had overweight/obesity, and 8% developed MASLD in early childhood. Compared to healthy children, children with later MASLD exhibited lower α-diversity at 1 year of age (Shannon diversity index, $p = 0.041$) and showed distinct overall microbial community composition (beta diversity) at 6 months ($p = 0.037$, $R^2 = 0.11$) and 2 years ($p = 0.04$, $R^2 = 0.07$). We observed a lower abundance of *Erysipelatoclostridium* and a higher abundance of *Bifidobacterium* in children with MASLD with greatest differences up until 2 years of age (FDR < 0.1) (Figure 1). By 3 years of age, there were no microbial differences between children who developed MASLD and those who did not. **Conclusion:** Differences in fecal microbiota were identified as early as 6 months of age in children who later developed MASLD compared to those who did not. Exposures prior to 3 years of age may be critical for future development of MASLD. Our finding of a greater abundance of *Bifidobacterium* in

children with MASLD contrasts with previous studies that found a reduced amount of *Bifidobacterium* in children with MASLD and requires further investigation.

4574 | ◆ INTESTINAL ALISTIPES PUTREDINIS ALLEVIATES METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE BY REGULATING SECONDARY BILE ACID HOMEOSTASIS

Yan Ni[1] Weixing Zhao[1] Huiying Wang[1] Ana Liu[1] Shuangjiang Liu[2], [1]Children's Hospital, Zhejiang University School of Medicine, [2]State Key Laboratory of Microbial Technology, Shandong University

Background: Disruption of the gut microbiota leads to dysregulation of secondary bile acid (BA) metabolism, exacerbates intestinal inflammatory responses, and accelerates the onset and progression of metabolic dysfunction-associated steatotic liver disease (MASLD). However, the key gut bacteria associated with secondary BA metabolism, their metabolic functions, and mechanistic roles in MASLD remain to be fully elucidated. **Methods:** This study enrolled 149 children, including MASLD patients, individuals with simple obesity (OB), and healthy controls (HC). Metagenomic sequencing and targeted metabolomics were employed to characterize gut microbiota profiles and BA metabolism. Utilizing the NCBI database, we established a reference database of protein sequences for gut microbial metabolic enzymes, with a focus on identifying and screening key bacteria that express metabolic enzymes of secondary BA metabolism. In vitro anaerobic culture and animal intervention experiments were further conducted to validate the metabolic functions of key bacteria and their therapeutic potential in MASLD. **Results:** Key findings revealed decreased expression

of bile salt hydrolase (BSH) in the gut microbiota of MASLD patients, with Cluster I bacteria showing strong disease association. Targeted metabolomics analysis demonstrated an elevated ratio of conjugated BAs to unconjugated BAs in the serum of MASLD patients. Among BA subtypes, the taurolithocholic acid/lithocholic acid (TLCA/LCA) ratio exhibited the most significant alterations across groups and correlated strongly with alanine aminotransferase (ALT) levels. Differential analysis identified *Alistipes putredinis* (AP) within Cluster I as the most dynamically altered species between OB and MASLD groups, which had been validated in two independent cohorts. Mediation effect analysis further indicated that AP influenced the ALT level by modulating conjugated LCA hydrolysis. In vitro anaerobic culture confirmed the BSH activity of AP. Moreover, AP supplementation significantly attenuated high-fat diet induced MASLD progression in mice and restored BA homeostasis. Finally, transcriptome sequencing analysis showed significant enrichment of the JAK-STAT signaling pathway and helper T cell differentiation pathways in both intestinal and hepatic tissues. This suggests that these pathways may serve as the key signaling pathways mediating immune regulation in the gut-liver axis. **Conclusion:** In conclusion, our findings demonstrate that reduced gut microbial BSH expression in MASLD was partially compensated by AP, which enhanced TLCA/LCA balance and ameliorated MASLD phenotypes. These findings deepen our understanding of microbial-metabolic crosstalk in MASLD pathogenesis and provide a scientific foundation for targeting BA metabolism in MASLD prevention and therapy.

4575 | ◆ CLINICAL PRESENTATION, OUTCOMES, AND MANAGEMENT OF BSEP DEFICIENCY WITH TRUNCATED MUTATIONS: A COHORT STUDY OF PFIC2 PATIENTS AT A HIGH-VOLUME PEDIATRIC LIVER TRANSPLANT CENTER

Mohammad Shagrani[1] Kishwer Kumar[1] Alexandra Aldana[1] Ali syed Akhturl Hassan[1] Dalal Albugami[1] Sateesh Maddirevula[1] Saleh Alqahtani[1] Ehab Abufarhaneh[1] Saad Alghamdi[1] Waleed Alhamoudi[2] Bandar Mohammed H Aljudaibi[1] Massimo Malago[1] Dieter Broering[3], [1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital and Research Centre, Riyadh Saudi Arabia, [3]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: This study aimed to evaluate the clinical presentation, laboratory findings, outcomes, and interventions in patients with Bile Salt Export Pump (BSEP) deficiency, specifically focusing on those with truncated mutations in the ABCB11 gene (BSEP3). **Methods:** The cohort consisted of 25 patients diagnosed between 2010 and 2023, with data on demographics, clinical features, laboratory results, and treatment outcomes. A comprehensive analysis of clinical symptoms, laboratory markers, and therapeutic interventions was performed to assess disease progression and management strategies. **Results:** The cohort had a median birth year of 2018, with 48% male patients, all originating from consanguineous relationships. The median age at presentation was 3.05 years, with pruritus observed in 60% of patients. Laboratory findings revealed significantly elevated serum bile acids (median 190 μmol/L), bilirubin (median 151 μmol/L), and liver enzymes (ALT median 389 IU/L, AST median 386 IU/L). Notably, 16% of patients developed hepatocellular carcinoma (HCC), and there were notable deficiencies in fat-soluble vitamins (D, A, and E). Liver transplantation was required for 80% of patients, with a median age of 1.9 years at transplantation. Post-transplant mortality was low, but disease recurrence occurred in 10% of cases. **Conclusion:** The findings highlight the aggressive nature of PFIC2 due to truncated BSEP mutations, with early liver transplantation being essential for survival. The study underscores the limited efficacy of current medical therapies for BSEP3 patients and emphasizes the importance of early intervention, close monitoring for HCC, and management of nutritional deficiencies. Despite successful liver transplantation, the risk of disease recurrence remains a significant challenge. Regular screening and tailored therapeutic strategies are crucial for improving long-term outcomes.

4576 | ◆ CHARACTERISTICS AND OUTCOMES OF FONTAN ASSOCIATED LIVER DISEASE IN CHILDREN FROM A MULTICENTER - INITIAL ANALYSIS OF 8 CENTERS IN USA

Chaowapong Jarasvaraparn Henry Lin[1] Sindhu Pandurangi[2] Kim Liss[3] Steven Lobritto[4] Adebowale Adeyemi[5] Sara Kathryn Smith[6] Amal Aqul[7] R. Mark Payne[8] Katryn Furuya[9] Wikrom Karnsakul[6] Jean Molleston[10], [1]Oregon Health and Science University, [2]UT Southwestern, Children's Medical Center Dallas, [3]Washington University School of Medicine, [4]Columbia University, [5]Nemours Children's Hospital, Delaware, [6]Johns Hopkins University, [7]University of Texas Southwestern Medical Center, [8]Pediatric Cardiology, Indiana University School of Medicine, [9]UNIVERSITY OF WISCONSIN - MADISON, [10]Indiana University School of Medicine

Background: Fontan associated liver disease (FALD) is a universal sequela of the Fontan procedure. In this study, we aimed to 1) characterize severity of pediatric FALD, 2) evaluate non-invasive markers of liver fibrosis, and 3) describe long-term outcome of FALD in children. **Methods:** This is a multi-center study (PED-FALD) collecting data prospectively and retrospectively since January 2020 of FALD patients aged 10- 20 years. All imaging, cardiac catheterization, and transient elastography were collected. Laboratory tests were collected within 6 months of the liver biopsy. Liver histologic data was abstracted from the pathology reports and utilized the congestive hepatic fibrosis score (stage 0-4). **Results:** 251 patients with Fontan procedure were identified at 8 centers with mean age at 14.3 ± 3.3 years and mean age at Fontan procedure of 3.7 ± 1.7 years. The majority were male (153; 61%), and white (129; 51%). 51 patients (20%) had liver biopsy with the most common indication being surveillance (44; 86%). 24 patients (47%) had stage 3 or 4 liver fibrosis, and 9 patients (18%) had stage 4 liver fibrosis (cirrhosis) from liver biopsy. Patients with biopsy proven cirrhosis had significantly lower platelet count and higher GGT than patients without cirrhosis (155.5 vs. 202.8 x10^3/uL; p = 0.03 and 78.6 vs. 49.2 units/L; p = 0.04, respectively). There was significant correlation between liver fibrosis score and non-invasive fibrosis markers (FIB-4, Forn's index; Spearman 0.28, p = 0.05, 0.48, p = 0.05), and free hepatic venous pressure (0.4, p = 0.03). There was no significant association with histologic severity and liver stiffness measurements from FibroScan or elastography. 242 patients (96%) had imaging and only 15 patients (6%) had cirrhosis from imaging, including 9 from ultrasound, 1 CT, and 5 MRI. 5 patients died (2%), 37 patients were diagnosed with failing Fontan (15%) and 24 patients (10%) ended up with isolated heart transplant. **Conclusion:** This is the first multi-center study in children with FALD with ongoing data registry. Lower platelet counts and high GGT are good markers of cirrhosis. Overall, there was a low mortality rate at 2%. The fact that only 20% of the children in this study underwent liver biopsy demonstrates the need for more sophisticated measures of liver injury. The PED-FALD network will help us understand how to monitor progression of the disease and to optimize treatment decisions in children with FALD.

4577 | ◆ EXCELLENT OUTCOMES IN PEDIATRIC RECIPIENTS OF ABO-INCOMPATIBLE LIVER TRANSPLANTW: AN ANALYSIS OF THE SPLIT REGISTRY

Sarah Bedoyan[1] Bridget Whitehead[2] James Squires[3] Sarah Anderson[4] Ravinder Anand[4] Jeff Mitchell[4] Catherine Chapin[2] The Society of Liver Transplantation[5], [1]University of Pittsburgh Medical Center, [2]Ann & Robert H. Lurie Children's Hospital of Chicago, [3]UPMC Children's Hospital of Pittsburgh, [4]Emmes, [5]n/a

Background: Pediatric liver transplant (LT) waitlist mortality remains high due to shortage of suitable grafts. Accepting an ABO-Incompatible (ABO-I) LT is a strategy to address this issue but has been theorized to have higher rates of vascular and biliary complications and worse outcomes compared to ABO-Compatible (ABO-C) LT. Additionally, variability in ABO-I protocols among centers has not been described. We present an analysis of ABO-I LT patient outcomes using the SPLIT registry and characterize differences in clinical practice. **Methods:** Patients enrolled in SPLIT who received an ABO-I LT between 2011-2022 were eligible. ABO-I patients were matched to ABO-C patients by Status 1A/1B and PELD/MELD score, which resulted in final comparison of 157 ABO-I to 783 ABO-C patients. Separately, a web-based survey was sent to SPLIT investigators to determine whether a center performed ABO-I LTs and identify practice variability. **Results:** ABO-I LT recipients spent significantly less time on the waitlist compared to ABO-C recipients (mean 2.1 months vs. 3.1 months, p-value < 0.001). The ABO-I cohort required more parenteral nutrition (30.6% vs. 18.0%, $p = 0.021$), ventilator assistance (21.7% vs. 12.1%, $p = 0.001$) and ICU care at time of LT (37.6% vs. 26.1%, $p = 0.002$). In the first 30 days post-LT biliary complications were more common in the ABO-I group (12.1% vs. 11.3%, $p < 0.001$), but there were no differences in vascular complications, rates of rejection, or patient and graft survival. Long-term patient and graft survival was equivalent between ABO-I and ABO-C groups (Figure 1).

Survey response rate was 63% (26/46). 17/26 (59%) centers reported performing ABO-I LT, most (53%) considering this option only for children $\leq$ 2 years of age. 46% of centers utilize pre-LT desensitization (rituximab, plasmapheresis, IVIG) and 59% adjust post-LT immunosuppression for ABO-I recipients. Post-LT desensitization is implemented for all patients at 24% of centers and based on anti-ABO antibody titers at 43% of centers. **Conclusion:** Patient and graft survival rates are equivalent between matched ABO-I and ABO-C LT recipients. Some complications may be more common in the ABO-I LT group, however this group was also sicker at time of LT. ABO-I LT is an option that should be considered for children awaiting LT to reduce waitlist mortality. Variability in institutional practices regarding listing and management of ABO-I LT recipients represents an opportunity for future comparative effectiveness studies.

4578 | ◆ ETHICAL CHALLENGES IN PEDIATRIC LIVER TRANSPLANT SELECTION RELATED TO PATIENT AND CAREGIVER SOCIAL DETERMINANTS OF HEALTH: A NATIONAL SURVEY OF CLINICIAN PERSPECTIVES

Danielle Rabinowitz[1] Eliza Lee[1] Christy Cummings[1] Jenna Simes[1] Scott Elisofon[2] Andrew Wehrman[2] Katherine Sweeny[2] Stacy Kahn[1] Christine Lee[1], [1]Boston Children's Hospital, [2]Boston Childrens Hospital

Background: Disparities exist in pediatric liver transplantation in the United States. While prior research has demonstrated inequities in time-to-listing and in waitlist and post-transplant outcomes, clinician perspectives on the role of patient and family social determinants of health (SDoH) on decision-making in pediatric liver transplant selection remain unknown. **Methods:** A national, cross-sectional, mixed methods survey was distributed via email to pediatric liver transplant committee members between June and November 2024.

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The survey assessed institutional voting practices and ethical issues related to SDoH. Quantitative analysis was conducted with summary statistics and multiple linear and logistic regression (Stata v16); free-text responses were qualitatively coded (NVivo v15). **Results:** Of 550 invited participants, 162 (29.4%) completed the survey. Most were transplant hepatologists/gastroenterologists (41.4%), women (70.4%), and white race (77.2%). Listing decisions were typically made via verbal vote (90.1%), with conflicts resolved through further discussion (77.2%), ethics committee consultation (19.8%), or granting the transplant surgeon the tie-breaker vote (16.0%). Transplant surgeons and hepatologists were viewed as most influential in listing decision-making. Clinician moral distress regarding SDoH-related concerns was moderate (5.71 ± SD 2.39/10), with higher distress levels reported by psychosocial providers ($p = 0.006$), transplant hepatologists/gastroenterologists ($p = 0.042$), and women ($p = 0.022$); moral distress among late-career as compared with early-career professionals trended toward significance ($p = 0.087$). Key SDoH concerns included patient/caregiver non-adherence and mental health issues/substance use, housing instability, and insurance status. Ethics committees (53.7%) and child protective services (79.6%) were often involved when non-medical factors created barriers to listing. Qualitative data showed that for pediatric patients, SDoH are not absolute contraindications but often delay listing, require team collaboration, and create post-transplant challenges. **Conclusion:** Patient and family SDoH factors influence decision-making in pediatric liver transplant selection and contribute to clinician moral distress. To promote justice, advocacy should focus on optimizing patient and family support from the listing phase onward, integrating ethics education for clinicians, and adapting more balanced decision-making frameworks.

Table 1. Multiple linear and logistic regression models assessing reported moral distress and moral distress frequency related to the impact of patient and family SDoH factors on pediatric liver transplant listing decision-making

4579 | ◆ HISTOLOGICAL INJURY PATTERNS IN CHILDREN WITH DRUG-INDUCED LIVER INJURY

Ivan Gonzalez[1] Jean Molleston[1] Naga Chalasani[2] Jiezhun Gu[3] Huiman Barnhart[3] Victoria Shakhin[4] Robert Fontana[5] David Kleiner[6], [1]Indiana University, [2]Indiana University Medical Center, [3]Duke Clinical Research Institute, [4]C. S. Mott Children's Hospital, [5]University of Michigan Hospitals and Health Centers, [6]National Cancer Institute, Bethesda

Background: Pediatric drug induced liver injury (DILI) is rare cause of morbidity and mortality. Liver biopsy can be a valuable part of causality determination and injury severity assessment. There is limited literature regarding histology of DILI in children. **Methods:** Drug-Induced Liver Injury Network database from 2004-2025 was queried for high causality cases in children (< 18 years) with centrally reviewed liver biopsies. Descriptive statistics were used. **Results:** Out of 2711 DILI cases in the database, 88 (3.2%) were from children. 22 were high causality and had liver tissue centrally reviewed. Mean age was 13.8 (range 1.7-17.9) years, 16 (73%) were female; none were known to have underlying chronic liver disease. There were 21 needle biopsies and 1 explant. Causative agents were minocycline (5), azithromycin (3), atomoxetine (3), lamotrigine (2), and nicotine, drospirenone/estradiol, Trikafta, carbamazepine, doxycycline, infliximab, amoxicillin, amoxicillin/clavulanate, and isoniazid (1 each). The median time from DILI onset to biopsy was 16 days (range:13-40), and 32% were treated with steroids (9% at biopsy). Fifteen (68%) had hepatocellular, 4 (18%) mixed and 3 (14%) cholestatic biochemical pattern at onset. Severity was moderate-hospitalized or severe in more than half. The biopsies showed diverse patterns of injury, similar in spectrum to reported patterns in adults: 6 with cholestatic hepatitis, 5 each with acute (lobular) and chronic (portal) hepatitis, 3 with acute (bland) cholestasis and 2 with minimal findings. The explant showed bridging and multi-acinar necrosis with regenerative nodule formation. Inflammatory activity varied, with 6 cases each of minimal and mild, 3 of moderate and 5 of severe inflammation (Ishak Histology Activity Index). 3 cases, including the explant, had bridging fibrosis. 9 (41%) had increased eosinophils, 7 (32%) had increased plasma cells and 7 (32%) had microgranulomas; 27% had steatosis. Three cases had

endothelialitis of either portal or central veins. One biopsy showed bile duct loss. 5 of 20 children (20%) with 6 month follow up had evidence of chronic liver injury. **Conclusion:** Children with DILI experienced similar range of pathology as seen in adults, with both hepatocellular and cholestatic liver injury represented. Eosinophilia was seen in less than half, and plasmacytosis in one third of biopsies. While most cases showed mild injury overall, a few showed severe inflammation, necrosis, or bridging fibrosis.

4580 | ◆ BSEP PROTEIN DERIVED FROM CODON-OPTIMIZED HUMAN ABCB11 MRNA IMPROVES BILE ACID TRANSPORT IN BSEP-DEFICIENT HUMAN-INDUCED HEPATOCYTES AND MOUSE MODEL

Karis Kosar[1] Aitaro Takimoto[1] Lupe Sierra[2] Henry Law[2] Esthelle Hoedt[2] Akihiro Asai[1] Maggie Wright[2], [1]Cincinnati Children's Hospital Medical Center, [2]Ultragenyx Pharmaceutical Inc.

Background: Bile Salt Export Pump (BSEP) is a critical transporter of bile acids in hepatocytes encoded by the *ABCB11* gene. Pathogenic variants in *ABCB11* result in functional BSEP deficiency, leading to severe hepatocellular cholestasis, known as Progressive Familial Intrahepatic Cholestasis (PFIC). BSEP deficiency often requires a liver transplant for patient survival; thus, a treatment that restores BSEP activity in a patient's native liver has the potential offer a novel disease-modifying. We sought to test the functional efficacy of an mRNA-LNP approach as one such therapeutic option. **Methods:** *ABCB11* mRNA candidates were screened in primary human hepatocytes for expression intensity and half-life of the BSEP protein. A codon-optimized, pseudo-uridine-modified human *ABCB11* mRNA (named UX123) was selected as the best candidate. We established a cholestasis model in mice lacking BSEP (BSEP-KO) by feeding them a diet containing 0.1% CA and 0.3% G-CDCA. They were treated with 4 mg/kg UX123 encapsulated in lipid nanoparticles up to 5 times over 15 days. BSEP protein, liver size, and blood and liver bile acid levels were assessed. In vitro, BSEP-deficient hepatocytes derived from human induced pluripotent stem cells (iHep) were transfected using lipofectamine with titrating doses of *ABCB11* mRNA. BSEP protein level, capacity of bile transport in Transwell culture system and cell injury were assessed. **Results:** In mouse studies, UX123 treatment led to a significant reduction in the level of multiple bile acid species, as well as a reduction in liver to body weight ratio when comparing treated BSEP-KO mice to vehicle controls. In in vitro models, we found that treatment with *ABCB11* mRNA rescued bile acid transport and prevented bile acid-induced cell injury compared to untreated iHep. We also found that UX123 rescued BSEP deficiency in iHep at surprisingly low levels of BSEP protein expression, suggesting that a relatively small amount of mRNA delivery can induce effective BSEP in the cholestatic liver. **Conclusion:** This proof-of-concept study demonstrates that mRNA-LNP therapy can restore BSEP function in BSEP-deficient hepatocytes in vitro and in vivo. These data provide a foundation for clinical translation and establish a benchmark for minimal effective BSEP expression.

4581 | MULTICENTER REPORT OF EXCELLENT OUTCOMES FOLLOWING LIVER TRANSPLANT IN SICKLE CELL DISEASE IN CHILDREN AND YOUNG ADULTS

Pamela Valentino[1] Steven Lobritto[2] Juliet Emamaullee[3] Helen Te[4] Ryan Chadha[5] Vani Gopalareddy[6] Mary Alice Boulware[6] William Kitchens[7] Ryan Himes[8] Rima Fawaz[9], [1]University of Washington, [2]Columbia University, [3]Keck Medical Center of USC, [4]University of Chicago Medical Center, [5]Mayo Clinic, Jacksonville, FL, [6]Levine Children's Hospital at Advocate Health, [7]Emory University, [8]Ochsner Clinic Foundation, [9]Yale University

Background: Sickle cell disease (SCD) is associated with hepatopathy: a myriad of acute and chronic liver conditions due to sequalae from intrahepatic red blood cell sickling and increased delivery of bilirubin from hemolysis. Progression to cirrhosis and end-stage liver disease is under recognized and liver transplantation is rarely

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

offered; a characterization of transplant management outcomes is lacking in the literature. **Methods:** Multicenter review of patients with SCD (Hemoglobin (Hb) SS or SC) who underwent liver transplantation (LT) between 2010-2020. **Results:** There were 6 patients with SCD who underwent LT at a median age of 16 years (IQR 13,24); 50% female, 83% Black and 17% Hispanic, 67% HbSS and 33% HbSC. SCD therapies employed included hydroxyurea (83%), chronic pRBC transfusion therapy (67%), iron chelation therapy (33%), and RBC exchange transfusions (17%). Gallstone disease with ERCP and cholecystectomy was required in 67%. LT was provided for one patient with biliary atresia (BA) with a non-draining Kasai portoenterostomy at 5 months of age and one patient in acute liver failure (ALF) at 18 years of age. Patients with cirrhosis (4) included 2 with sclerosing cholangitis, 1 with autoimmune hepatitis, and 1 with recurrent cholangitis episodes. Overall time on the waitlist was 32 days (IQR 26,36); median calculated MELD/PELD at LT was 30 (IQR 25,30). Immunizations had been updated prior to LT in 83%. Preoperatively, 1 patient received a pRBC transfusion, 2 patients underwent exchange transfusion, and 1 underwent plasmapheresis; pre-LT HbS was 24g/dL in these cases. In those without transfusion therapy pre-LT, HbS was 7.9, 13 and 20 g/dL. All patients received a deceased donor (DD) whole graft except the infant with BA received a DD split graft. All patients underwent Roux-hepaticojejunostomy apart for the one with ALF who received a duct-to-duct biliary reconstruction. Immunosuppression included corticosteroids and tacrolimus/cyclosporine in all patients. No thymoglobulin was used, however 2 patients received basiliximab and 3 received mycophenolate mofetil. All patients received parenteral anticoagulation initially. There were no vascular or biliary complications in the first year. Hepatic vein stenosis was diagnosed in one patient 2 years postLT and one patient developed a dominant biliary stricture 3 years postLT. Acute T cell rejection was observed in 2 and de novo plasma cell rich rejection was observed in 1. One patient died at 8 years post-LT due to hemorrhage; no retransplants during a median 3 years of follow up. **Conclusion:** Liver transplantation can be successful in patients with SCD. Survival outcomes and the rates of transplant complications are similar to those reported in other LT recipients. Further studies are required to identify optimal management strategies.

4582 | MOLECULAR SUBTYPES RELATED TO GLUCOSE METABOLISM AND LACTIC ACID METABOLISM AND THEIR PROGNOSTIC CHARACTERISTICS IN HEPATOCELLULAR CARCINOMA

Fengsheng Dai[1] Yi Wang[1] MaoYun Liu[1] sheng wang[1] Cheng Zhang[1] Jiale Lu[1] Yuqin Xie[1] DeWei Li[1] Hui Li[1], [1]Chongqing University Cancer Hospital

Background: Hepatocellular carcinoma (HCC) is a malignant tumor with a high incidence worldwide, with occult onset and rapid progression. The onset of HCC is usually accompanied by liver dysfunction, leading to metabolic reprogramming, which includes sugar metabolism and the production of large amounts of lactic acid. However, the effects of carbohydrate metabolism and lactic acid metabolism on HCC have not been fully clarified. This study aimed to develop a new molecular subtype based on carbohydrate metabolism-related genes (CRGs) and lactate metabolism-related genes (LMRGs) and to identify characteristics that predict the prognosis and treatment outcomes of HCC patients. **Methods:** scRNA-seq and clinical HCC data were downloaded from the TCGA and GEO databases. CRGs and LMRGs are from the Molecular Signature Database. Differential expression analysis was performed via the R software package DESeq2. Molecular subtype classification was performed via unsupervised clustering. Predictive characteristics were determined via univariate Cox regression, random forest, LASSO, and multivariate Cox regression analyses. Finally, in vitro and in vivo experiments were used to verify the impact of the key gene HPX on the biological function of HCC tumors. **Results:** We classified 365 HCC patients into 2 molecular subtypes and were able to clearly distinguish their prognosis. The C2 subtype is associated with a worse prognosis, with a lower proportion of CD4+ T cells, and the expression of immune checkpoint genes is generally elevated in C2 patients with severe immune dysfunction. We subsequently constructed a predictive model, the CLM score, which can effectively predict the prognosis of HCC patients and the efficacy of immunotherapy. The CLM scores were verified in the GSE14520, GSE151530 and IMvigor210 datasets. Patients with high CLM scores showed high infiltration of activated CD4+ T cells and other cells in the immune microenvironment. Finally, in vitro cell experiments confirmed that HPX can inhibit the proliferation, migration and invasion of HCC cells. **Conclusion:** We constructed new molecular subtypes related to carbohydrate metabolism and lactate metabolism and revealed their immunological and genetic characteristics. We have also developed a CLM scoring system that can be used to predict the prognosis and efficacy of immunotherapy in patients with HCC.

4583 | RESTORATION OF PORTAL CIRCULATION IN CHILDREN WITH CONGENITAL PORTOSYSTEMIC SHUNTS RESULTS: IN SPONTANEOUS INVOLUTION OF HEPATIC MASSES

Riccardo Superina[1] Matthew Switalski[1] Esther Ro[1] Ian Gelarden[1] Anita Gupta[2], [1]Ann and Robert H. Lurie Children's Hospital of Chicago, [2]Nationwide Children's Hospital

Background: Congenital portosystemic shunts (CPSS) may be associated with benign or malignant liver lesions. In this study, we describe the evolution of liver masses that take place after surgical ligation of shunts and restoration of portal circulation to the liver. **Methods:** A retrospective review was done of all patients diagnosed with CPSS in the 25 years from 1999-2024 at a single pediatric center. MR and CT were used for radiological characterization of lesions. Liver biopsies were reviewed by two pediatric pathologists utilizing light microscopy and molecular characterization. Serial MRI following ligation was used to document changes in the number and size of the lesions. Lesions were grouped according to pathological diagnosis and changes in size documented. Age at procedure was compared between those with lesions and those without using a Mann-Whitney U test. Lesion sizes at pre-op and 1-year post-op were compared using paired t-tests. **Results:** One hundred fifteen patients with CPSS were included. Thirty-two (27.8%) had liver masses. The median (interquartile range) age in years of children with masses was significantly higher than those without masses at diagnosis: median 12.2 IQR (4.4-15.8) and median 4.2 IQR (1.9-10.4) respectively ($p = 0.001$) Six patients had 1 lesion, 18 had between 2 and 10, and 8 had more than 10 lesions. Twenty-three patients underwent 35 needle, wedge, or excisional biopsies. Biopsies were diagnostic of 23 hepatocellular adenomas (HCA), 21 with β-catenin activation, of which 12 were confirmed to have pathogenic CTNNB1 mutations. Two had HNF1α inactivation alone, and 4 lesions expressed both mutations. There were 3 hepatocellular carcinomas (HCC) and 4 FNH or regenerative nodules. The three patients with HCC were transplanted, and all other patients underwent closure of the CPSS. Of the patients with HCA, 6 lesions were resected, five underwent a significant reduction in size and 7 resolved completely within a year of shunt ligation ($t(11) = 9.1$, $p < 0.001$, Cohen's $d = 0.69$). All 4 patients with FNH underwent spontaneous resolution or decrease in size ($t(3) = 6.7$, $p = 0.006$; Cohen's $d = 0.48$). All patients are alive and well at the end of the observation period. **Conclusion:** HCA and FNH lesions involute completely or reduce in size within two years of surgery. Patients with CPSS associated hepatic lesions including β-catenin mutated HCA may be safely treated solely with shunt ligation and careful observation.

Table 1. Outcomes of Lesions with Follow-up Imaging by Diagnosis

	Shrunk	Resolved	Resected	Total
HCA				
β-catenin activated	3	4	4	11
β-catenin activated, HNF1α inactivated	0	1	0	1
β-catenin activated, Inflammatory type	2	3	2	7
HNF1α inactivated	0	0	0	0
FNH	2	2	0	4

4584 | RECTUS FEMORIS MUSCLE QUANTITY AND QUALITY IS ASSOCIATED WITH PEDIATRIC LIVER-RELATED OUTCOMES, INCLUDING LIVER TRANSPLANTATION (LT) AND MORTALITY

Christopher Chu[1] Victor Yu[2] Cameron Willis[3] Jennifer Dodge[3] Sindhura Kasturi[2] Patricia Acharya[2] David Rigual[2] Norah Terrault[3], [1]Rady Children's Hospital, [2]Children's Hospital Los Angeles, [3]University of Southern California

Background: Sarcopenia predicts morbidity and mortality in adults with end-stage liver disease. However, data on sarcopenia and liver-related outcomes in children remain limited. We examined ultrasound (US) measurements of the readily accessible rectus femoris muscle in children with chronic liver disease (CLD) and the outcome of liver failure (Liver Transplantation [LT] or death). **Methods:** Prospective cohort of participants ≤18 years with CLD with US measures for 4 sonographic parameters of the rectus femoris muscle [cross-sectional area (CSA), muscle thickness (MT), fascicle length (FL) and echogenic intensity (EI)], and baseline anthropometrics including mid-upper arm circumference (MUAC) and BMI. Outcomes were liver failure,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

decompensation (GI bleed, ascites, hepatic encephalopathy, hyperammonemia, hepatopulmonary or hepatorenal syndrome, LT), and hospitalization within one year. Associations of US muscle parameters and outcomes were explored by logistic regression. **Results:** Of 66 participants (43.9% male; median age 7.5 years [IQR 1.7-13.6], 19.5% malnourished [by BMI z-score] and 44% had advanced fibrosis/cirrhosis [F3/F4]), 22 (33.3%) developed liver failure within 1 year. Participants with liver failure were younger and had lower MUAC z-scores but were similar by sex, and BMI z-score. Increasing quantitative muscle parameters (CSA, MT, FL) were associated with decreasing odds of liver failure (all $p < 0.01$) whereas increasing EI to MT ratio was associated with increasing odds of liver failure ($p = 0.002$). These associations remained after adjusting for advanced hepatic fibrosis status (all $p < 0.05$, except EI) but were attenuated with age and fibrosis-adjustment (Table 1).

Within 1 year, 35 (53.0%) were hospitalized and 6 decompensated (16.2% of the 37 compensated at baseline). Odds of hospitalization were lower with increases in quantitative muscle parameters (CSA, MT, and FL) (all $p < 0.05$), but only FL was statistically significant after age- and fibrosis-adjustment ($p = 0.04$). Sample size was too small for statistical analysis of decompensation. **Conclusion:** This study is the first to assess ultrasound-based muscle measurements in children with chronic liver disease in relation to clinical outcomes. Younger age and decreased CSA, MT and FL of the rectus femoris muscle are associated with liver failure whereas greater EI to MT ratio was associated with decreased odds of liver failure—although not statistically significant after adjusting for age and fibrosis status. Lastly, increasing fascicle length was associated with lower hospitalization risk even after adjusting for age and fibrosis status suggesting that this ultrasound parameter may be an important measure for risk stratification. This study highlights the role that muscle health may have in transplant waitlist outcomes and warrants further investigation.

Table 1. Age- and Fibrosis-Adjusted Logistic Regression Model of Ultrasound Measures as Predictor of Liver Failure Hospitalization

Muscle Measure	Liver Failure		Hospitalization	
	Odds Ratio (95% CI)	p-value	Odds Ratio (95% CI)	p-value
Cross-Sectional Area*	0.50 (0.11 – 2.17)	0.35	0.38 (0.10 – 1.39)	0.14
Muscle Thickness*	0.63 (0.21 – 1.86)	0.40	0.52 (0.22 – 1.23)	0.14
Fascicle Length*	0.61 (0.21 – 1.78)	0.36	0.36 (0.14 – 0.93)	0.04
Echogenic Intensity*	1.62 (0.71 – 3.74)	0.25	1.18 (0.59 – 2.36)	0.64
Echogenic Intensity/Muscle Thickness	1.14 (0.89 – 1.47)	0.29	1.14 (0.88 – 1.48)	0.34

4585 | SIGNIFICANT INCREASE IN DONOR-DERIVED CELL-FREE DNA LEVELS IN PEDIATRIC LIVER TRANSPLANT RECIPIENTS WITH REJECTION COMPARED TO NORMAL LIVER HISTOLOGY

Andres Rivera[1] Bridget Whitehead[1] Batul Kaj-Carbaidwala[1] Alyssa Kriegermeier[1] Catherine Chapin[1], [1]Ann & Robert H. Lurie Children's Hospital of Chicago

Background: Donor-derived cell-free DNA (dd-cfDNA) is a promising noninvasive biomarker of rejection in adult liver transplant (LT) recipients, but its utility in children remains unknown. We aimed to determine the relationship between peripheral blood dd-cfDNA and histologic findings in pediatric LT recipients undergoing for-cause and surveillance liver biopsies. **Methods:** Prospective single-center study of pediatric LT recipients $\geq$ 6 months of age undergoing for-cause and surveillance liver biopsies 6/5/2024–4/25/2025. Biopsies were classified into 3 histologic groups: rejection (AR) (T-cell mediated, chronic, and plasma-cell rich), acute dysfunction non rejection (ADNR), or normal liver (NL). Peripheral blood at time of liver biopsy was collected for dd-cfDNA analysis. **Results:** 42 subjects were enrolled, 64% ($n = 27$) female, with median age 14.5 years (IQR 10.9-17.0) and 9.5 years (IQR 5.0-13.7) post LT. 74% of grafts were technical variant and 31% were living donor. 17 (40%) biopsies were for-cause and 25 (60%) were surveillance. There were 18 patients in the AR group (12 T-cell mediated, 4 chronic, 1 plasma-cell rich, 1 T-cell mediated and biliary stricture), 8 ADNR (all non-specific inflammation), and 16 NL. There were no differences in dd-cfDNA by graft or donor type. Patients undergoing for-cause biopsies had increased dd-cfDNA compared to surveillance biopsies (median 22.6% vs 10.5%, $p = 0.007$). ALT, AST, and GGT were higher in the AR compared to other groups ($p < 0.001$ for all comparisons). Median dd-cfDNA values were significantly higher in the AR compared to the NL group (20.2% vs 7.5%, $p = 0.02$) (Figure 1A). There was a moderate positive correlation between dd-cfDNA and ALT values for the AR group (Pearson $r = 0.53$). Receiver operator characteristic curve analyses for dd-cfDNA were statistically significant with AUC value 0.73 for AR vs NL ($p = 0.02$, 9.0% cutoff) and AUC = 0.70 for AR vs non-AR (NL+ADNR) ($p = 0.03$, 18.4% cutoff) (Figure 1B). All patients in the NL group had liver enzymes $\leq$1.5xULN at time of surveillance

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

biopsy, but 6 (38%) had dd-cfDNA levels that would classify them as acute rejection based on published adult LT thresholds (AR vs non-AR 15%). **Conclusion:** Dd-cfDNA levels are significantly increased in pediatric LT recipients with biopsy-proven rejection and may be a useful biomarker of graft injury. More data is needed in pediatric patients to determine the predictive value of this test, pediatric-specific cut-offs, and the significance of elevated values in the NL group.

4586 | THE CONTEXT-DEPENDENT ROLE OF CELLULAR SENESCENCE IN BILIARY ATRESIA

Katie Rose Conover[1] Franziska Lammert[2] Eric Katz[3] Ronald Sokol[1] Sarah Taylor[1], [1]University of Colorado School of Medicine, [2]University Hospital Aachen, [3]University of Colorado

Background: Cellular senescence supports tissue repair but if dysregulated can contribute to disease, in part by immune cell modulation. Increased senescence is present in biliary atresia (BA), but its role in disease progression remains poorly defined. We aimed to explore immune-senescent cell networks based on BA disease stage and patient outcome. **Methods:** We used multiplex histology to identify cell densities in liver tissue (cholangiocytes: CK19; senescence: P21; T regs: CD3, FOXP3; TREM2+ macrophages [Mφ]: CD68, TREM2) in BA at diagnosis (BADx, n = 17), BA at transplant (BATx, n = 22), cholestatic controls (CC, n = 13), and non-cholestatic controls (NCC, n = 7). Targeted serum proteomics detected 61 senescence-associated secretory proteins (SASPs) and 39 BA-related proteins in BADx (n = 12), BATx (n = 12), CC (n = 12) and NCC (n = 10). Statistical analysis compared all groups and BA groups by outcome (survival with native liver $\geq$ 2 years [favorable outcome] vs $<$ 2 years [poor outcome]). **Results:** Among all groups, cholangiocyte density was highest in the BA groups ($p = 0.02$), but there were no significant differences in senescent or immune cell subsets. BADx with favorable outcome had greater senescent cholangiocytes ($p = 0.01$), TREM2+ Mφ ($p = 0.01$), and T reg densities ($p = 0.04$). Total Mφs, TREM2+ Mφs, and T regs correlated with senescent cells ($r = 0.654$, $r = 0.761$, $r = 0.639$ respectively, $p < 0.05$ for all). Among all groups, 30 SASPs and 17 BA-associated proteins significantly differed (p adj < 0.05). Nine of 10 SASPs differing between BADx and BATx were higher at transplant (p adj < 0.05, FC > 1.5, Figure 1A). BADx patients separated discreetly by outcome (Figure 1B). Of the top 20 proteins driving this separation (Figure 1C), most (9 of 11) SASPs were associated with poor outcome. Pathway analysis revealed BADx patients with poor outcome had IL-6/JAK/STAT3 activation (p adj 7.45 e-7), which is known to regulate oxidant-induced senescence in fibroblasts. BADx patients with favorable outcome had HIF-1a stabilization (p adj 0.02), which could be related to increased antioxidant gene expression. **Conclusion:** In BADx, liver tissue senescence is associated with favorable outcome, while SASPs are associated with poor outcome and progress over disease course. Our data highlight the dynamic and context-dependent nature of senescence. Impaired redox homeostasis may modulate senescence and contribute to discrepant BA outcomes, warranting exploration of senescent cell driven oxidative-stress modulating therapies.

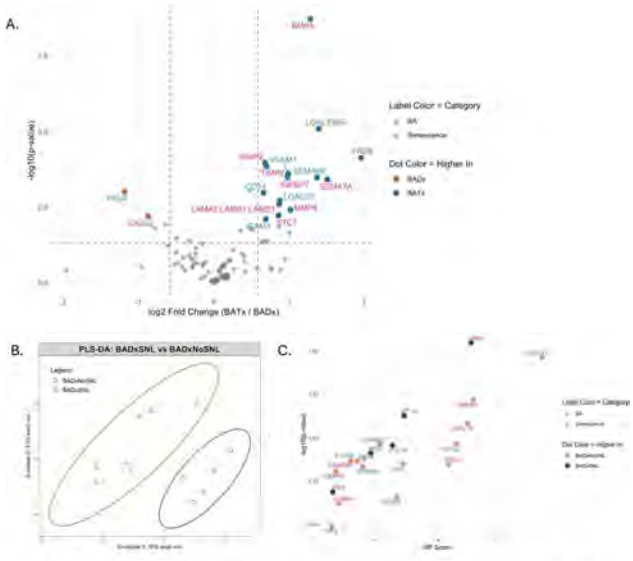

Figure 1. (**A**) Volcano plot displaying differentially expressed proteins in biliary atresia (BA) at diagnosis versus transplant (FDR <0.05, fold change >1.5). Nine of the 10 senescence-associated secretory proteins that differ are higher at transplant. (**B**) Partial least squares discriminant analysis (PLS-DA) plot with 95% confidence intervals shaded, showing separation of BA at diagnosis with favorable (survival with native liver ≥2 years) versus poor (survival with native liver <2 years) outcome. (**C**) Variable importance in projection (VIP) plot showing the top 20 proteins contributing to the PLS-DA plot in (B). Most senescent proteins are higher in BA at diagnosis with poor outcome.
BADx: BA at diagnosis, BATx: BA at transplant, BADxNoSNL: BA at diagnosis with survival with native liver <2 years (poor outcome), BADxSNL: BA at diagnosis with survival with native liver ≥2 years (favorable outcome)

4587 | ALTERED T CELL PROFILE MAY CONTRIBUTE TO THE IMMUNE DYSREGULATION IN CHILDREN WITH PORTAL HYPERTENSION: A PILOT STUDY

Tengfei Si[1] huihong yu[2] Qing Shao[3] Bethany Tucker[4] Eirini Kyrana[5] Yun Ma[6] Tassos Grammatikopoulos[7], [1]Zhejiang University School of Medicine, [2]Department of Gastroenterology, The Second Affiliated Hospital, Chongqing Medical University, [3]King's College London, [4]Institute of Liver Studies, King's College, London, United Kingdom, [5]Paediatric Liver, GI & Nutrition Centre, King's College Hospital NHS Trust, London, United Kingdom., [6]Institute of Liver Studies, King's College London, United Kingdom, [7]King's College Hospital

Background: While portal hypertension (PHT) is associated with elevated pro-inflammatory cytokines, T cell immune alterations in pediatric PHT remain understudied. This study provides a comprehensive analysis of T cell phenotypic and functional changes in children with PHT. **Methods:** Forty-four children with PHT (chronic liver disease (CLD)-related PHT, n = 27; portal vein thrombosis (PVT)-related PHT, n = 17) and 15 paediatric controls without liver disease were prospectively recruited. Six paired blood samples (peripheral and central blood) were collected. Plasma and peripheral blood mononuclear cells (PBMCs) were isolated from blood. Immune markers, cytokines, and chemokines were detected, and T cell phenotyping and functional testing were performed using ELISA or multiparameter flow cytometry. Statistical analysis was conducted to assess group differences and correlations with liver parameters such as stiffness using GraphPad Prism (version 9). **Results:** CLD-related PHT patients showed reduced T cell counts and elevated CD39/CD38 expression in CD8+ and DN T cells. Both PHT groups had higher CD39 expression and increased IFN-γ but reduced IL-10 production in non-CD8 T cells, along with elevated exhausted CD4 T cells (PD-1$^+$CD39$^+$). PVT-related PHT uniquely showed CXCR3 downregulation in DN T cells and CCR4 upregulation in CD4+ T cells. Soluble CD25 was decreased, while PD-L1, IFN-γ, and TNF-α were elevated and correlated with liver stiffness in CLD-related PHT. Portal CXCL9 levels were higher than peripheral and associated with CXCR3$^+$ T cell recruitment, though these central T cells showed reduced pro-inflammatory and cytotoxic capacity. **Conclusion:** CLD-related PHT in children is linked to more profound T cell dysregulation and inflammation, suggesting immune mechanisms may contribute to disease progression and represent potential therapeutic targets.

4588 | SPATIAL MOLECULAR IMAGING REVEALS AN EVOLVING INFLAMMATORY INFILTRATE AND PROLIFERATING STEM-LIKE CELLS WITH LIVER DISEASE PROGRESSION IN BILIARY ATRESIA (BA)

Tyler Yasaka[1] Mylarappa Ningappa[2] Chethan Ashokkumar[2] Stefan Scholz[2] Simon Horslen[2] Joseph Glessner[3] Hakon Hakonarson[3] Rakesh Sindhi[2], [1]University of Pittsburgh, [2]Children's Hospital of Pittsburgh of UPMC, Hillman Center for Pediatric Transplantation, [3]Center for Applied Genomics (CAG), Children's Hospital of Philadelphia, University of Pennsylvania

Background: To define architectural and immunological-inflammatory landscape of liver disease progression in BA. **Methods:** Residual formalin-fixed-paraffin embedded sections were obtained from normal pre-perfusion donor liver, and biopsies at portoenterostomy (PE) from a child with native liver survival (BA-PE-NLS), and at PE (BA-PE (prog) and liver transplantation (BA-LT) from a child with progressive BA. Spatial molecular imaging was performed with 6000 genes on the CosMx platform (Nanostring). Cell-specific genes were used to enumerate hepatocytes, cholangiocytes, stellate cells, macrophages, neutrophils, B-cells and T-cells. **Results:** A total of 301742 cells were visualized across 326 fields of view (FOVs), 0.25mm by 0.25 mm each, averaging 75435 cells across 81 FOVs in each of four biopsies.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Spatial molecular images (Figure 1) revealed progressive increases in cell proportions ($p < 0.001$), from normal to BA-PE-NLS, BA-PE (prog) and BA-LT for cholangiocytes (0.9%, 3%, 6%, 10%), stellate cells (6%, 14%, 10%, 28%) and B-cells (1%, 1%, 2%, 5%). Macrophages (3%, 11%, 21%, 10%), neutrophils (3%, 2%, 4%, 3%) and T-cells (0.1%, 1%, 2%, 2%) peaked in BA-PE (prog). A novel cell population with upregulated proliferation (PCNA, MCM6) replicative stress (CHEK2, CHEK1, MSH1), epithelial (EPCAM), cytoskeletal/cholangiocytic (MYH9, TMSB4X, TUBB, KRT7, KRT19) and hepatoblast markers (HNF1, HNF4) also increased progressively and suggested a less differentiated stem-like cell which made up $< 1\%$ of cells in normal and BA-PE-NLS, increased 10-fold to 3% in BA-PE (prog) ($p < 0.001$) and declined to $< 1\%$ in BA-LT. Among 1442 upregulated genes in this stem-like cell, 18 were ciliary planar polarity effectors (CPLANE, e.g. ADD3) and 27 were non-CPLANE genes (e.g., MCM6, KIF23) with known BA-associated common and rare variants, respectively (PMID: 37572794). **Conclusion:** Replicative stress, stemness and upregulated developmental BA susceptibility genes, and a monocyte-rich inflammatory infiltrate are demonstrable at portoenterostomy in the BA liver which progresses to cirrhosis and transplantation, but not in the liver with non-progressive BA. Increasing B-cell infiltrates with disease progression suggest possible autoimmune damage, which requires further study.

4589 | PROTECTIVE EFFECTS OF BUTYRATE ALONG THE GUT LIVER AXIS IN A MURINE MODEL OF PARENTERAL NUTRITION

Colin Shearn[1] Aimee Anderson[1] Michael Devereaux[1] Ronald Sokol[2], [1]University of Colorado Anschutz Medical Campus, [2]University of Colorado School of Medicine

Background: Using a mouse model of Parenteral Nutrition Associated Cholestasis (PNAC) in which PN infusion results in increased liver injury and ileal dysfunction replicating human PNAC, we have recently shown that administration of parenteral nutrition results in discordant expression of circadian transcription factors between the ileum and liver. Dietary supplementation of short chain fatty acids such as butyrate are known to improve intestinal barrier function and ameliorate hepatic injury in mice. The aim of this study was to examine the protective effect of sodium butyrate on PN-induced hepatic injury and uncoupling of the gut-liver circadian axis. **Methods:** WT adult C57/B6 mice were exposed to Chow or continuous soy oil lipid emulsion-based total PN infusion +/- inclusion of sodium butyrate (9mM) through a central venous catheter for 4 days. Water was provided ad libitum, but no nutrients were provided enterally. On d4, mice were sacrificed at 7AM, serum harvested, and ileal and hepatic tissue obtained. From tissue samples, relative expression of CR transcription factors, Fxr signaling and gut permeability were assessed. **Results:** Administration of 4d PN increased hepatic injury (AST, ALT) and inflammatory cytokine mRNA expression which was ameliorated by addition of sodium butyrate. In the liver, butyrate significantly suppressed *Nr5a2* (LRH1), *Abcg5*, *Abcb11* (BSEP) mRNA expression, but did not have a significant effect on *Abcc2* which was already suppressed by PN. Concurrently, butyrate supplementation normalized PN-altered hepatic mRNA expression of *Nr1d1* (Reverba), *Nfil3, Npas2, Cry1, Cry2, Bhlhe40* (Dec1) and *Bhlhe41* (Dec2) but did not have an effect on *Arntl* (Bmal), *Clock*, *Per1* or *Per2*. In cultured Huh7 cells, butyrate supplementation mimicked hepatic effects. In the ileum, with the exception of *Arntl* and *Bhlhe41*, butyrate suppressed PN-dependent increases in circadian transcription factor expression. Finally, addition of butyrate reversed PN-dependent changes in intestinal permeability and suppressed ileal HDAC signaling. **Conclusion:** Dysregulation of circadian regulatory machinery is in part due to uncoupling of the gut-liver circadian axis. Supplementation of Butyrate into the PN solution ameliorates PN-dependent hepatic injury, improves gut permeability and restores expression of Nr1d1. Thus, the use of short chain fatty acids for preventing or treating PNAC deserves further investigation.

4590 | BASILIXIMAB DOSING IN PEDIATRIC LIVER TRANSPLANTATION (LT) RECIPIENTS: STARZL NETWORK EXPERIENCE

Or Steg Saban[1] Nadya Nalli[1] Evelyn Hsu[2] Anna Peters[3] Steven Lobritto[4] Catherine Chapin[5] Frank DiPaola[6] Regino Gonzalez-Peralta[7] Emily Perito[8] James Squires[9] George Mazariegos[9] Vicky Ng[10], [1]The Hospital for Sick Children, Toronto, ON, Canada., [2]Seattle Children's and the University of Washington, PO Box 5371/OB.9.640, Seattle, WA 98155, USA., [3]Cincinnati Children's Hospital Medical Center, [4]Columbia University Irving Medical Center, New York, NY, USA., [5]Ann and Robert H. Lurie Children's Hospital of Chicago, [6]University of Virginia, UVA Health Children's Health, Charlottesville, VA., [7]AdventHealth for Children, [8]University of California, San-Francisco, USA., [9]Children's Hospital of Pittsburgh, [10]Hospital for Sick Children

Background: A recent audit of immunosuppression induction protocols for infants and children undergoing liver transplantation (LT) at Starzl Network for Excellence in Pediatric Transplantation (SNEPT) centers identified two approaches to basiliximab dosing: fixed dose by body weight (FDBW,10 mg for patients <35 kg, 20 mg for ≥ 35 kg) or body surface area dosing (BSAD, 12 mg/m² per dose, maximum 20 mg). Given limited clinical evidence favoring either approach, we aimed to compare short-term outcomes of FDBW versus BSAD basiliximab dosing in pediatric LT recipients. **Methods:** This retrospective multicenter study analyzed SNEPT records of children receiving basiliximab induction following isolated LT (2005- 2024). Outcomes assessed were center-determined T-cell mediated rejection (TCMR), serum creatinine, readmissions in the first year, and mortality at three intervals: transplant-to-discharge, discharge to 6-months, and 6-12 months. Fisher's exact test compared categorical variables; Mann-Whitney U test compared group means of nonrelated samples. A nearest-neighbor propensity score matching (PSM) approach was utilized, matching in a 1:2 ratio with a calliper of 0.1, based on age, days until discharge, weight, and height at LT. Outcomes were analyzed using the Mantel-Haenszel chi-square test for categorical variables and generalized estimating equations for continuous variables. **Results:** A total of 191 pediatric LT recipients (for indications of Biliary Atresia (21%), primary liver malignancy (14%) and metabolic disease (14%)) at 8 SNEPT sites received basiliximab induction, with 155 (81%, 50% female, median age 40 months (IQR 10–172)) receiving FDBW and 36 (19%, 42% female, median age 25 months (IQR 9-67)) receiving BSAD. Median basiliximab dose was significantly lower in the BSAD group (5.9 mg, IQR 4.7–8.2) compared to FDBW (10 mg, IQR 10–20; $p<0.001$). TCMR during the initial LT admission occurred in 16/155 (10%) receiving FWBD and 4/36 (11%) receiving BSAD ($p = 1.0$). Seventy FWBD patients were matched to 35 BSAD patients, showing comparable baseline characteristics and confirming no difference in TCMR prevalence during the initial LT admission (BSAD: 3/35 [8.6%] vs. FWBD: 7/70 [10%], $p = 0.9$). Other outcomes are presented in Table 1. **Conclusion:** Children receiving BSAD of basiliximab after LT were exposed to lower doses than those receiving FWBD. Lower TCMR rates were observed in the BSAD group at 6–12 months. These findings suggest that BSAD may serve as an effective and resource-efficient alternative for immunosuppression induction in pediatric LT, potentially reducing both immunosuppression exposure and associated costs. Prospective studies are warranted to further evaluate its clinical and economic benefits.

This abstract is submitted on behalf of STARZL Network.

Table 1: Short-Term Clinical Outcomes Before and After Propensity Score Matching in Patients Receiving BSAD vs. FDBW Basiliximab Induction

	BSAD (n=36)	FDBW (n=155)	P
Results Before PSM			
Days till discharge	19.5 (15-35)	19 (13-35)	0.48
TCMR by discharge	4 (11)	16 (10)	1
TCMR discharge- 6 mo	5 (14)	21/126 (16.7)	0.8
TCMR 6-12 mo	0	20/118 (17)	0.008
Readmissions 6 mo	18/35 (51)	98/138 (71)	0.03
Readmissions 6-12 mo	14/35 (40)	94/124 (76)	<0.001
Creatinine 6 mo (mg/ dL)	0.28 (0.2-0.36, n=34)	0.4 (0.25-0.7, n=119)	0.001
Creatinine 12 mo	0.33 (0.24-0.4, n=35)	0.4 (0.3-0.7, n=110)	0.004
Results After PSM	(n=35)	(n=70)	
TCMR by discharge	3 (8.6)	7 (10)	0.9
TCMR discharge to 6 mo	4 (11.4)	8/59 (13.6)	0.98
TCMR 6-12 mo	0	10/57 (17.5)	0.02
Readmissions 6 mo	17/34 (49)	48/64 (69)	0.02
Readmissions 6-12 mo	14/34 (40)	50/60 (71)	<0.001
Death by 6 mo	0	0	
Death by 12 mo	0	3 (4.3)	0.54
Creatinine 6 mo (mg/ dL)	0.28 (0.2-0.36)	0.3 (0.2-0.5)	0.01
Creatinine 12 mo (mg/dL)	0.33 (0.24-0.4)	0.34 (0.22-0.5)	0.1

Note: Data presented as n (%) or median and interquartile range. Abbreviations: BSAD, body surface area dose; FDBW, fixed dose by body weight; TCMR, T-cell mediated rejection; PSM, propensity score matching.

4591 | ANTISENSE OLIGONUCLEOTIDE-MEDIATED UPREGULATION OF JAGGED-1 EXPRESSION AMELIORATES DISEASE PHENOTYPES IN AN ALGS MOUSE MODEL

Lingdi Zhang[1] Nima Niknejad[1] Jian Li[1] Lansha Peng[1] Surendra Jain[1] Rich Thai[1] Ye Xu[1] Xing xian Yu[1] Yanfeng Wang[1] Xuehai Liang[1], [1]ARNATAR THERAPEUTICS INC

Background: Alagille Syndrome (ALGS) is a rare autosomal dominant multisystem disorder, primarily affecting the liver, with potential involvement of the heart and other organs. Hepatic manifestations, including cholestasis due to bile duct paucity, often result in progressive liver dysfunction and life-threatening complications. Current treatment are largely supportive and symptomatic, without directly addressing the underlying genetic etiology, highlighting a significant unmet clinical need. In approximately 95% of ALGS cases, pathogenic variants in the *JAG1* gene lead to haploinsufficiency and impaired bile duct morphogenesis during early development. Thus increasing Jag1 protein levels provides a promising approach to treat ALGS from the root cause. **Methods:** To enhance JAG1 protein expression, antisense oligonucleotides (ASOs) were developed using Arnatar's ACT-UP1 platform, which boosts translational efficiency. ASOs were delivered to normal and ALGS patient-derived cells via transfection or free uptake, and JAG1 protein levels were measured by Western blot. Off-target effects were assessed through Western blotting of predicted proteins and transcriptome-wide RNA sequencing. In vivo studies in BALB/c and ALGS diease mice with *Jag1* heterozygous knockout were performed by 2–3 subcutaneous injection of the ASOs, followed by analysis of liver JAG1 protein levels and bile duct structure. Tolerability was evaluated in mice, neonatal ALGS models, rats, and non-human primates. **Results:** The optimized ACT-UP1 ASO, ART4, increased JAG1 protein levels by 40–80% across stable cell lines from humans, mice, rats, and monkeys. In ALGS patient-derived cells, ART4 elevated JAG1 levels 1.4- to 1.7-fold post-transfection. Western blot or RNA sequencing detected no off-target effects, confirming high specificity. In vivo, ART4 (1–6 mg/kg) increased JAG1 expression by 34–100% in mice, rats, and monkeys, with upregulation effects lasting 30–60 days. Functional assays confirmed Notch pathway activation. In neonatal *ALGS* disease mice, three weekly doses of ART4 improved JAG1 expression, bile duct architecture, somatic growth, and liver biomarkers (bile acids, bilirubin, ALT/AST). No safety issues were observed across species, even at higher doses. **Conclusion:** ART4 is a first-in-class, potentially disease-modifying ASO that specifically upregulates

JAG1, promotes bile duct development, and reduces liver toxicity with durable efficacy and a strong safety profile in animal models. These preclinical findings support its potential to transform ALGS treatment by directly targeting its genetic cause.

4592 | SURGICAL CORRECTION OF EXTRAHEPATIC PORTAL VEIN OBSTRUCTION AND CONGENITAL PORTOSYSTEMIC SHUNTS IMPROVES NEUROCOGNITIVE OUTCOMES IN CHILDREN USING THE NIH TOOLBOX COGNITION BATTERY AND A SCALE OF ADAPTIVE FUNCTIONING

Frank Zelko[1] Matthew Switalski[1] Katherine Brandt[2] Riccardo Superina[2], [1]Ann and Robert H. Lurie Children's Hospital of Chicago, [2]Ann and Robert H. Lurie Children's Hospital of Chicago

Background: Portal venous flow anomalies in children can impair neurocognitive outcomes. Surgery to improve portal blood flow is an effective option for mitigating these effects, yet its impact upon cognition has not been adequately studied. **Methods:** Children with portal vein flow anomalies were studied for cognitive and adaptive functioning pre- and post-corrective surgery. We utilized a novel technology, the NIH Toolbox Cognition Battery (NTCB), to measure cognitive outcomes, along with a parent questionnaire of adaptive functioning, the Adaptive Behavior Assessment System (ABAS). Both measures were administered before surgery and at 6-months follow up. The NTCB produced a Fluid Cognition Index (FCI) and a Vocabulary (VOC) score, and the ABAS produced a General Adaptive Composite (GAC), each measure having a mean value of 100 (SD 15) in the general population. These measures were examined in children with either 1) Extrahepatic portal vein obstruction (EHPVO) or 2) Congenital Portosystemic shunt (CPSS). **Results:** Thirty-four children were tested: 22 with EHPVO and 12 with CPSS. Of the 22 with EHPVO, 12 received portal vein revascularization via meso-Rex bypass (MRB) and 10 received distal splenorenal shunt (DSRS). Twelve children with CPSS were treated by shunt ligation. Baseline age was 10.2 years (SD 5.36). 18 (53%) were female and 8 (24%) were non-white. 24 subjects completed follow up assessments 6 months after surgery. Single-sample t-tests indicate that at baseline the combined sample scored significantly below the population mean on all 3 neurocognitive variables: FCI (M = 80.29, SD = 16.05) t(32) = -7.05, p < .0001; VOC (M = 94.27, SD = 15.36) t(32) = -2.14, p = .039; and GAC (M = 89.62, SD = 14.77) t(33) = -4.10, p = .0003. Paired-samples t-tests comparing the performances of the 24 subjects who returned for 6-month follow up revealed statistically significant increases from baseline to 6 month follow up on FCI t(20) = 2.33, p < .0306 and VOC t(21) = 2.23, p = .0365, with mean values/SDs presented in Figure 1. **Conclusion:** Our results indicate that children with impaired portal venous flow experience significant neurocognitive dysfunction, with effect sizes suggesting that fluid cognitive abilities are especially vulnerable. The adverse impact of portal vein flow anomalies upon fluid cognition and vocabulary performance is significantly improved by surgical correction.

4593 | UNCOVERING HIDDEN RISK: CYP450 GENOTYPES REVEAL SUSCEPTIBILITY TO LIVER INJURY IN CYSTIC FIBROSIS PATIENTS ON CFTR MODULATORS

Sarah Lowry Adamitis[1] Wikrom Karnsakul[1] Christopher Hartley[1], [1]Johns Hopkins University

Background: Cystic Fibrosis (CF) is no longer a uniformly fatal childhood disease thanks to CFTR modulators. Patients are now living longer, healthier lives. Many CFTR modulators are metabolized through hepatic cytochrome P450 (CYP) enzymes in the liver endoplasmic reticulum, especially CYP3A4 and CYP3A5, which are polymorphic and known to influence drug exposure, toxicity, and interactions. While a CYP3A4 Neg/Neg variant is a normal phenotype, the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

CYP3A4*22 variant has been found in 5-7% of the Caucasian population, linked to lower hepatic CYP3A4 expression and activity. Slow metabolizers with this variant may be at risk for drug accumulation and subsequent drug-induced liver injury (DILI). By integrating pharmacogenomic testing into clinical care, we explore the feasibility of a precision model to proactively identify patients at risk for hepatic adverse events. **Methods:** A pilot cross sectional study recruited CF patients at Johns Hopkins who have been treated with CFTR modulators. Pre-existing liver conditions other than CF were excluded. 4 patients had known mild CF related liver disease. While elevated transaminases are classified as hepatocellular injury, hyperbilirubinemia, increased alkaline phosphatase and gamma-glutamyl transferase as cholestatic damage. We aimed to assess whether any CYP3A4 and CYP3A5 genotypes are associated with liver enzyme elevations in pediatric CF patients receiving CFTR modulators. **Results:** 11 patients were in the study. 4 of 7 patients without prior liver disease had elevations of transaminases while on CFTR modulators. All patients with elevated transaminases carried the CYP3A4*22 variant, associated with decreased CYP enzymatic activity and slower drug metabolism. Notably, those with CYP3A4 *22/- (heterozygosity) or *1/*1 in combination with CYP3A5 *3/*3 (poor metabolizers) demonstrated significant hepatocellular injury. Intermediate CYP3A5 metabolizers alone did not exhibit liver enzyme elevations, suggesting a role for CYP3A4 dysfunction in this DILI phenotype. Of 4 patients with CFLD, 2 had persistent transaminitis but did not lead to liver decompensation. **Conclusion:** Hepatocellular injury pattern is more common among suspected patients with DILI from CFTR modulators. This study is among the first to link specific CYP3A4 genotypes (especially CYP3A4 *22 carriers) to liver enzyme elevations in CF patients on CFTR modulators. These findings point to a pharmacogenetic vulnerability in a population of long-term CF survivors. As CF care transitions into adulthood, understanding each patient's metabolic fingerprint could ensure that the success story of CFTR modulators is not compromised by silent hepatic toxicity.

Table 1: Genotype and Phenotype Profiles of CF Patients on CFTR Modulators

3A4 Genotype	3A4 Phenotype	3A5 Genotype	3A5 Phenotype	AST	ALT	Known Liver Disease	Age (years)	Gender
*1/*1	Normal	*3/*3	Poor	162	358	no	21	F

4594 | BENEFICIAL EFFECTS OF PARABACTEROIDES GOLDSTEINII AND ITS METABOLITES ON THE THERAPEUTIC POTENTIAL FOR CHOLESTATIC LIVER DISEASE

Huey-Ling Chen[1] Shu-hao Hsu[2] Huey-Huey Chua[1] Bang-Yu Liou[1] Chia-Ray Lin[1] Ya-Hui Chen[1] Tzu-Hsien Yang[2] Mei-Hwei Chang[3] Yen-Hsuan Ni[1], [1]National Taiwan University College of Medicine and Children's Hospital, [2]National Taiwan University College of Medicine, [3]National Taiwan University

Background: The homeostasis of gut microbiota is pivotal to maintaining the physiological liver-gut axis and affect development of liver disease. We have discovered *Parabacteroides goldsteinii* (*P goldsteinii)* improved cholestasis in a strain of Bsep *(abcb11)* knockout mice with more severe jaundiced phenotype. However, the detailed mechanism involved in therapeutic effect of *P goldsteinii* is not known. **Methods:** Adult male Bsep *(abcb11)* knockout mice were treated with *P goldsteinii*. Liver biochemistry and pathology were assessed. The liver transcriptome of Bsep knockout mice with *P goldsteinii* treatment were investigated by RNA sequencing. The secreted metabolite profile of *P goldsteinii* was analyzed by UHPLC-MS/MS. The *in vitro* effects of *P goldsteinii*-secreted metabolites were test by organoids derived from biliary duct cells. **Results:** Bsep knockout mice treated with *P. goldsteinii* (PG) showed improvement in cholestasis, as evidenced by decreased serum bilirubin levels and restored biliary structures, including proliferative cholangiocytes expressing increased interleukin-6 during the recovery phase. RNA sequencing revealed upregulation of genes related to cell proliferation and downregulation of genes associated with inflammation and bile duct damage. UHPLC-MS/MS analysis identified liquiritigenin, a liver-protective metabolite, as one of the secreted compounds from *P. goldsteinii*. To evaluate its effects, we used bile duct–derived organoids that form spheroids with a central lumen. Treatment with *P. goldsteinii*-secreted metabolites and liquiritigenin promoted organoid proliferation. Furthermore, liquiritigenin-treated organoids showed increased expression of CK-19 and MYC, markers of cholangiocyte differentiation and proliferation. **Conclusion:** Our results suggest that *P. goldsteinii* treatment alleviates liver injury by reducing inflammation and promoting cellular proliferation. Metabolites secreted by *P. goldsteinii*, including liquiritigenin, enhance the proliferation and differentiation of bile duct–derived organoids.

4595 | LONG-TERM SAFETY OF CHILDREN FOLLOWING MATERNAL TAF OR TDF USE DURING PREGNANCY FOR THE PREVENTION OF MOTHER-TO-CHILD TRANSMISSION OF HBV

Kai-Chi Chang[1] Ming-Wei Lai[2] Chun-Jen Liu[1] Shu-Chi Mu[3] Yu-Chun Chen[1] Jin-Chung Shih[1] Mei-Hwei Chang[4] Huey-Ling Chen[4], [1]National Taiwan University Hospital, [2]National Chang Gung University Hospital, [3]Shin Kong Wu Ho-Su Memorial Hospital, [4]National Taiwan University

Background: The long-term effects of in utero exposure to maternal Tenofovir Alafenamide (TAF) for the prevention of mother-to-child transmission (MTCT) of hepatitis B virus (HBV) remain unclear. This study investigates the long-term outcomes of children born to mothers who received TAF or Tenofovir Disoproxil Fumarate (TDF) during pregnancy to prevent perinatal HBV transmission. The aim is to assess the children's growth and biochemical development over time. **Methods:** A cohort of 257 infants born to mothers treated with TAF or TDF was enrolled and followed for up to 2–5 years post-delivery. Of these, 166 infants were born to mothers treated with TDF, and 91 were born to mothers treated with TAF. Annual follow-up visits were conducted, with each child evaluated 1–3 times. Assessments included HBV serological markers (HBsAg and anti-HBs), as well as developmental and biochemical indices such as serum calcium (Ca), phosphorus (P), creatinine (Cr), and bone alkaline phosphatase (BAP). **Results:** The mean age at follow-up for children exposed to TAF and TDF was 3.12 ± 0.94 and 4.01 ± 1.36 years, respectively. The TDF group belonged to an earlier cohort, resulting in an older average age at follow-up. Z-scores for weight and height were comparable between the two groups. Biochemical evaluations revealed that Ca, P, Cr, and BAP levels remained within normal ranges across all children, with no significant differences between groups. A high persistence rate of anti-HBs positivity was also observed. **Conclusion:** Maternal use of TAF or TDF during pregnancy is not associated with adverse effects on child growth or renal and bone biochemistry during early life. Continued follow-up is essential to confirm the long-term safety and efficacy of prenatal antiviral therapy.

4596 | INVESTIGATION OF ASSOCIATIONS BETWEEN VARIANTS IN MRGPRX4 AND PEDIATRIC CHOLESTATIC PRURITUS

Minna Rodrigo[1] Daphne Chun-Che Chien[2] Ryo Kawamoto[2] Nathachit Limjunyawong[3] Tony Rajborirug[4] Xinzhong Dong[2] Wikrom Karnsakul[5], [1]University of Maryland School of Medicine, [2]Department of Neuroscience, Johns Hopkins University School of Medicine, [3]Center of Research Excellence in Allergy and Immunology, Faculty of Medicine Siriraj Hospital, Mahid, [4]Johns Hopkins University Bloomberg School of Public Health, [5]Johns Hopkins University

Background: Cholestatic pruritus is a common and often debilitating symptom in various pediatric liver diseases, including Alagille syndrome, progressive familial intrahepatic cholestasis (PFIC), biliary atresia, and primary sclerosing cholangitis (PSC), with a complex and poorly understood pathogenesis. Recent evidence implicates the Mas-related G protein-coupled receptor X4 (MRGPRX4)—a bile acid receptor expressed in human dorsal root and trigeminal ganglia—as a potential mediator of cholestatic pruritus. Although *MRGPRX4* harbors multiple single nucleotide variants (SNVs), their role in modulating cholestatic pruritus, particularly in pediatric patients, remains unexplored. **Methods:** We conducted a case-control study at a single pediatric tertiary care center, enrolling patients with Alagille syndrome, PFIC, biliary atresia, and PSC. Cases were defined as individuals with a history of pruritus; controls had no reported pruritus. Clinical data included peak total and fractionated bile acid levels, total bilirubin, and direct bilirubin. Targeted sequencing of the *MRGPRX4* coding region was performed to evaluate associations between SNVs and pruritus status. **Results:** Among 36 participants (17 cases, 19 controls), peak total bile acid level ($p = 0.0038$), peak cholic acid level ($p = 0.0004$), peak chenodeodxycholic acid ($p = 0.0095$), and peak direct bilirubin ($p = 0.0497$) were significantly higher among patients with pruritus compared to those without pruritus. All participants harbored at least one coding-region SNV in *MRGPRX4*. Eleven unique SNVs were identified, with recurrent variants at positions p.Phe8-Leu, p.Asn25Lys, p.Val47Val, p.Tyr54Cys, p.Ala182Val, and p.Tyr215Tyr. While no single SNV was significantly associated with pruritus overall, the Tyr54Cys variant was found exclusively in individuals with severe pruritus when it occurred as the sole variant. **Conclusion:** The functional significance of

MRGPRX4 variants remains unknown. However, the Tyr54Cys variant may alter receptor interaction with ligands and enhance itch signaling when unaccompanied by other SNV's, potentially via altered bile acid binding or receptor activation threshold, which may contribute to cholestatis pruritus. Further investigation, including functional assays, is warranted to elucidate the mechanistic and clinical relevance of this variant in cholestatic pruritus.

4597 | INFLUENCE OF MASLD SUBTYPES DURING PREGNANCY ON ADVERSE NEONATAL OUTCOMES: RESULTS: FROM A PROSPECTIVE COHORT OF OVER 1000 MATERNAL-INFANT PAIRS

Cecilia Katzenstein[1] Nina Rodriguez[1] Lauren Alpert[1] Jeanette Rios[1] Priyanka Singh[1] Kim Le[1] Rachel Meislin[1] Sonam Rosberger[1] Keith Sigel[1] Rhoda Sperling[1] Emily Jane Gallagher[1] Norah Terrault[2] Jaime Chu[3] Tatyana Kushner[4], [1]Icahn School of Medicine at Mount Sinai, [2]University of Southern California, [3]Icahn School of Medicine at Mount Sinai (ISMMS), [4]Weill Cornell Medicine

Background: MASLD has been established as a risk factor for adverse neonatal outcomes (ANOs) such as preterm birth. However, MASLD encompasses various subtypes and their specific impacts on neonates remain unclear. Given that gestational diabetes (GDM) is a known risk factor for ANOs such as large for gestational age (LGA) and hypoglycemia, we aimed to determine whether maternal MASLD with dysglycemia (MASLD +DG) confers compounded neonatal risk beyond MASLD or DG alone. **Methods:** In this prospective study we evaluated the prevalence of MASLD defined by steatotic liver disease detected on ultrasound and/or fibroscan at 18-32 weeks gestation and metabolic comorbidities (diabetes mellitus (DM), obesity based on pre-pregnancy BMI, chronic hypertension, or hyperlipidemia). Patients with MASLD were further subtyped by evidence of DG, defined as history of GDM (known indicator of metabolic risk and increased odds of developing DM), current GDM, positive 1- or 3-hour glucose tolerance test (GTT), and prediabetes (A1c in pregnancy), in addition to pre-gestational DM. Incidence of ANOs were compared between the MASLD+DG subgroup and other groups. **Results:** Among 1291 participants, 206 (16%) were found to have MASLD in pregnancy; mean age was 30 years (SD = 5.3), and 62% identified as Hispanic. Of neonates born to mothers with MASLD, 3% were very/extremely preterm (born before 32 weeks gestation), 6% were LGA, and 19% had hypoglycemia (Figure 1). Among MASLD participants, 76 (37%) had evidence of DG. There was no statistical difference in rates of advanced maternal age ($\geq$ 35 years) across groups. MASLD+DG showed a stronger association with very/extremely preterm birth compared to MASLD without DG (5.3% vs 1.5%, $p = 0.016$), remaining significant after excluding obese patients (6.5% vs 1.6%, $p = 0.042$). DG alone was not associated. Similarly, MASLD+DG was more strongly associated with LGA (15.2% vs 4.1%, $p < 0.001$) and higher mean Fenton percentiles (54% vs 44%, $p < 0.001$) than the general MASLD cohort, even after excluding patients with obesity (16.6% vs 4.5%, $p = 0.005$; 57.4% vs 44.7% $p = 0.025$). Incidence of LGA was higher in DG alone than the rest of the cohort (12.8% vs 1.9%, $p < 0.001$), though rates were lower than than MASLD+DG. Finally, neonatal hypoglycemia was also more common MASLD+DG than MASLD without DG (47.6% vs 19%, $p < 0.001$), also after excluding obese patients (47.8% vs 21%, $p = 0.002$). Though DG alone showed higher rates of neonatal hypoglycemia than the rest of the cohort (40.8% vs 14.5%, $p < 0.001$), the incidence was lower than in MASLD+DG. **Conclusion:** MASLD+DG confers distinct risks for ANOs including preterm birth, LGA, and neonatal hypoglycemia. The presence of MASLD+DG was a stronger predictor than DG alone or MASLD alone, even when excluding patients with obesity. These findings suggest there should be consideration of GDM or abnormal GTT (already routinely assessed) in risk stratification to guide the counseling and management of MASLD in pregnancy.

4598 | CYP2C70-DEFICIENT MICE EXHIBIT AGE-DEPENDENT LIVER INJURY AND UNFOLDED PROTEIN RESPONSE (UPR) ACTIVATION

Ryan Shaw[1] Paul Dawson[2] Saul Karpen[3] Brian LeCuyer[4] Richard Green[1] Alyssa Kriegermeier[5], [1]Northwestern Feinberg School of Medicine, [2]Emory University School of Medicine, [3]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [4]Ann & Robert H. Lurie Children's Hospital of Chicago, [5]Ann and Robert H. Lurie Children's Hospital of Chicago

Background: Cholestatic liver diseases are the most common indication for liver transplantation in children and lack effective medical therapies to prevent disease progression. An accumulation of toxic bile acids causes hepatic injury, increases endoplasmic reticulum (ER) stress, and triggers the unfolded protein response (UPR). Our prior cholestasis studies demonstrate impaired expression of the hepatic X-box binding protein 1 (XBP1) and other UPR pathways leads to liver injury in neonatal compared to adult mice. However, traditional murine cholestatic models have limited translational value due to the less toxic, hydrophilic bile acid composition of mice. Thus, we employed Cyp2c70 knockout (KO) mice which have a hydrophobic bile acid profile closely resembling that of humans to investigate age-related ER stress, liver injury and UPR activation in the setting of cholestasis. **Methods:** Female Cyp2c70 KO mice and heterozygous controls were assessed at ages 10 days, 3 weeks and 8 weeks. Serum liver chemistries were analyzed, and hepatic gene expression was assessed using quantitative PCR (qPCR). **Results:** At 10 days, serum alanine transaminase (ALT), alkaline phosphatase (ALP), and bile acid (BA) levels were normal in KO mice, indistinguishable from controls. However, by 3 weeks, KO mice exhibited significantly elevated liver functional tests (LFTs) compared to controls. At 8 weeks, serum ALT levels in KO mice were markedly increased compared to controls (346 $\pm$ 157 U/L vs 42 $\pm$ 11 U/L, $p = 0.0027$). Serum bile acid concentrations were also higher in KO mice compared to controls (38 $\pm$ 18 vs $<$ 5 μmol/L, $p = 0.0022$). Hepatic X-box binding protein 1 spliced form (*Xbp1s*) was comparable between KO and controls at 10 days and remained unchanged at 3 weeks. By 8 weeks, hepatic *Xbp1s* expression was ~ 2-fold higher in KO mice ($p = 0.0241$) compared to controls. Additionally, hepatic death receptor 5 (*Dr5*) mRNA expression showed no difference between KO and controls at 10 days but increased by ~10-fold in KO mice at both 3 and 8 weeks ($P = 0.008$ and 0.013, respectively). Lastly, hepatic C/EBP homologous protein (*Chop)* gene expression consistently trended or was significantly higher in KO mice across all ages. **Conclusion:** Neonatal Cyp2c70 KO mice exhibit age-dependent liver injury with serum liver chemistries and UPR-related gene expression similar to controls. In contrast, there are significantly higher serum liver injury markers and enhanced hepatic UPR activation by 3 to 8 weeks. These data, using a human-like bile acid mouse model, further support our previous murine cholestatic studies which demonstrate age-dependent changes in UPR activation and liver injury markers. Cyp2c70 KO mice may provide a more clinically relevant model to test therapeutic interventions for cholestatic liver diseases, including potential UPR targets.

4599 | VARIANTS IN MDR3 AND KIF12 GENES: NATURAL HISTORY OF CHOLANGIOPATHIES AND LIVER TRANSPLANTATION; A SINGLE CENTER EXPERIENCE

Mohammad Shagrani[1] Kishwer Kumar[1] Alexandra Aldana[1] Ali Syed Akhtarul Hassan[1] Dalal Albogami[1] Sateesh Maddirevula[1] KRIS ANN MARQUEZ[2] Saleh Alqahtani[1] Ehab Abufarhaneh[1] Saad Alghamdi[1] Waleed Alhamoudi[1] Bandar Mohammed H Aljudaibi[1] Massimo Malago[1] Dieter Broering[1], [1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital and Research Center. Riyadh, Saudi Arabia

Background: Cholangiopathies represent a diverse group of chronic liver diseases characterized by progressive damage to the bile ducts, often leading to liver failure and the need for transplantation. Genetic factors play a crucial role in the pathogenesis of many cholangiopathies. Among these, variants in the *MDR3* (ABCB4) and *KIF12* genes have been increasingly recognized as significant contributors to disease development and progression. *MDR3* encodes a phospholipid transporter essential for bile formation, while *KIF12* is involved in ciliary function and biliary epithelial integrity. Understanding the natural history of cholangiopathies associated with these genetic variants is critical to improving diagnosis, management, and transplant outcomes. This study aims to characterize the clinical progression of patients with *MDR3* and *KIF12* variants and assess their outcomes following liver transplantation. **Methods:** We conducted a large-scale genomic investigation involving 299 pediatric patients (from 279 families) presenting with intrahepatic cholestasis. Exome sequencing was performed as a first-tier diagnostic test to identify likely causal genetic variants. Clinical data including gender, bile acid levels, and presenting symptoms were collected. Liver transplantation records from 2011 to 2024 at our center were reviewed to assess transplantation rates and outcomes in patients diagnosed with PFIC3 and KIF12-related cholangiopathy **Results:** In a cohort of 299 pediatric patients (279 families) with intrahepatic cholestasis, exome sequencing identified likely causal variants in 135 families. Among these, 80 patients were diagnosed with PFIC3 and 12 with KIF12-related disease. In the PFIC3 group, there were 43 females and 37 males, with a median bile acid level of 196 μmol/L (range 7–560), 59 patients reported a history of pruritus. The KIF12 group included 6 females and 6 males, with a median bile acid level of 209.5 μmol/L (range 72–423), and the predominant clinical feature was portal hypertension.

Between 2011 and 2024, 865 pediatric liver transplantations were performed at our center, with 196 cases attributed to PFIC. Of these, 55 patients diagnosed with PFIC3 underwent liver transplantation, and 6 patients with KIF12-related cholangiopathy required transplantation. **Conclusion:** Exome sequencing serves as an effective first-tier diagnostic tool for pediatric intrahepatic cholestasis, facilitating precise genetic diagnosis in nearly half of the cases. PFIC3 and KIF12 variants contribute significantly to the disease burden, with PFIC3 patients commonly presenting with pruritus and KIF12 patients exhibiting portal hypertension. Liver transplantation remains a crucial treatment for severe cases, particularly in PFIC3 and KIF12-related cholangiopathies, underscoring the importance of early genetic diagnosis and specialized management in this population.

4600 | SLOW PROGRESSION OF LIVER STIFFNESS IN FONTAN-ASSOCIATED LIVER DISEASE IN CHILDREN

Anna Mania[1] Katarzyna Mazur-Melewska[1] Magdalena Figlerowicz[1], [1]Department of Infectious Diseases and Child Neurology

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Fontan-associated liver disease (FALD) represents a significant and emerging concern in the management of pediatric patients who have undergone the Fontan procedure (FP) for congenital heart defects. Altered hemodynamics, chronic hypoxia, and increased venous pressure associated with the Fontan circulation lead to liver injury and progressive fibrosis. This study aims to evaluate the clinical abnormalities and disease progression in children with FALD. **Methods:** The study included 31 children (18 girls) who underwent FP due to inborn heart defects. Children were evaluated every 12 months in the hepatology clinic for the following 3 years. Physical examination, blood CBC, ALT, AST, ALP, and GTP levels, and shear-wave elastography were evaluated during each visit. FIB-4 and APRI scores were calculated based on the laboratory results. All children received ursodeoxycholic acid in the dose of 15 mg/kg during the study period **Results:** The study group included 18 girls and 13 boys; median age 10 years (IQR 6-12). Various congenital heart defects were noted. The median time from FP was 6 years (IQR 3.25-8.00). On baseline evaluation, 14 children who underwent FP >6 years ago were significantly older (median 12 vs 6 years; $p=0.0004$), had higher FIB-4 (8.98 vs 5.53; $p=0.04$) and liver stiffness (9.0 vs 6.6 kPa; $p=0.026$). During the observation period of 3 years, no significant progression was observed in FIB-4 (6.35 vs 6.47; $p=0.68$) and liver stiffness (6.4 vs 6.9; $p=0.91$). Similar observations were made in the group >6 years after FP – FIB-4 (9.51 vs 9.74; $p=0.91$) and liver stiffness (9.2 vs 9.8; $p=0.67$). **Conclusion:** Liver stiffness is significantly higher in children who underwent FP >6 years ago. However, no significant progression was observed during the study period. Further studies are necessary to elucidate the direct influence of UDCA on the progression of FALD in children.

4601 | THE CLINICAL SPECTRUM OF PORTO-SINUSOIDAL VASCULAR DISEASE IN PAEDIATRICS: A SINGLE CENTRE REVIEW

Marumbo Paul Mtegha[1], [1]Leeds Children's Hospital

Background: Porto-sinusoidal vascular disease (PSVD) is a condition which affects the portal venules and sinusoids in the absence of cirrhosis[1]. Knowledge about PSVD natural history is still limited[2,3,4]. We aimed to describe the characteristics of children affected with PSVD, as well as their histological findings and clinical outcomes. **Methods:** We performed a retrospective review of children with native liver biopsy samples suggestive of PSVD from January 2019 to October 2024. **Results:** Forty-eight patients fit the diagnostic criteria of PSVD as described by Gottardi et al.[1] with 64.6% ($n=31$) having associated portal hypertension (PHT) and 35.4% ($n=17$) without PHT. The most common reason for referral to hepatology was isolated elevated transaminases in non-PHT group, hypersplenism and portal hypertensive bleed in the PHT group (table 1). There were no significant differences between the histological features found on both groups, apart from a higher prevalence of perisinusoidal fibrosis in those with PHT ($p=0.018$). The non-PHT group had a higher median ALT of 61 (IQR 35, 213) at presentation when compared to the PHT group ($p=0.021$). During the follow up period no significant adverse events were observed in non-PHT group, while 2 children developed hepatopulmonary syndrome and 3 underwent liver transplantation in the PHT group. Of those with PHT, 16 had evidence of portal vein thrombosis (PVT) with cavernous transformation at presentation and 2 developed PVT during the follow up period. **Conclusion:** In summary, PSVD is a condition with variable phenotypic presentation and disease course. Those without PHT, mostly presenting with isolated elevated transaminases, appear to have a milder disease course, while those with PHT can have poor outcomes. Prospective studies are required to improve our understanding of the disease course and identify those at risk of progressing to PHT and developing adverse outcomes.

4602 | PREVALENCE OF SUCCESSFUL TREATMENT WITHDRAWAL IN CHILDREN&RSQUO;S WITH AUTOIMMUNE HEPATITIS

Saurabh Singh[1] Bikrant Biharilal Raghuvanshi[1], [1]ILBS

Background: There is lack of systemic data on withdrawal of immunosuppression and the relapse after treatment withdrawal in children with autoimmune hepatitis (AIH). The present study was planned to analyze the clinical, biochemical and histological characteristics of children with AIH undergoing treatment withdrawal **Methods:** All children (< 18 years) presenting between Jan 2011- Jan 2022 and diagnosed as AIH based on simplified criteria were included. Data of all patients in whom treatment was withdrawn was extracted through HIS (hospital information system). Treatment was stopped in children having biochemical remission for atleast 24 months along with histological remission (HAI < 5 and no cirrhosis). **Results:** 212 patients presenting in study period, 30 had documented biochemical remission for more than 24 months. Of these, 24 consented for liver biopsy and all 24 showed histological remission and absence of cirrhosis. Immunosuppression (steroid and azathioprine) were withdrawn in them after consent. In addition, 4 patients stopped their immunosuppression on their own without a repeat liver biopsy. Hence, a total of 28 children underwent treatment withdrawal.(Table 1)

Four patients (14.2%) had relapse after 2,4, 6 and 12 months of immunosuppression withdrawal, respectively. All relapses were within one year of withdrawal therefore strict follow up is needed post withdrawal in first year **Conclusion:** Withdrawl of Immunosupressant is feasible and safe with maintenance of long term off treatment remission in a select cohort of children having Autoimmune Hepatitis

4603 | PREDICTING RESPONSE TO ODEVIXIBAT TREATMENT AND COMPARISON BETWEEN CLASSICAL TYPES AND RARER FORMS OF CHILDREN WITH PFIC

Angelo Di Giorgio[1] Marco Sciveres[2] Maurizio Fuoti[3] PierLuigi Calvo[4] Mara Cananzi[5] Ana Lleo[6] Simona Gatti[7] Giuseppe Indolfi[8] Annalisa Madeo[9] Claudia Mandato[10] Federica Nuti[11] Chiara Zanchi[12] Greta Carioli[13] Arianna Ghirardi[14] Emanuele Nicastro[15] Lorenzo D'Antiga[15], [1]Hospital Santa Maria Misericordia; University of Udine, [2]ISMETT IRCCS, Palermo; Liver Unit, Bambino Gesù Children Hospital, Rome, [3]Pediatric Gastroenterology and Endoscopy Unit, University Department of Pediatrics, Children's H, [4]Pediatric Gastroenterology Unit, Regina Margherita Children's Hospital, Turin, Italy, [5]Unit of Gastroenterology, Digestive Endoscopy, Hepatology, Padua, Italy, [6]IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy, [7]Department of Pediatrics, Università Politecnica delle Marche, Ancona, Italy, [8]Meyer Children's Hospital, IRCCS;, [9]Pediatric Gastroenterology Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy, [10]Department of Medicine, Pediatrics Section, University of Salerno, Italy, [11]Department of Paediatrics, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [12]IRCCS Burlo Garofolo, Trieste, Italy;, [13]FROM Research Foundation, Hospital Papa Giovanni XXIII, Bergamo, Italy;, [14]FROM Research Foundation, Hospital Papa Giovanni XXIII, Bergamo, Italy, [15]Paediatric Hepatology and Transplantation, Hospital Papa Giovanni XXIII, Bergamo, Italy

Background: In our previous study we reported efficacy of odevixibat treatment (OT) in a real-world cohort of children with progressive familial intrahepatic cholestasis (PFIC). Here we aim to compare the response to treatment in children with classical types of PFIC versus rare forms and identify the best cut-off of sBA reduction predicting the response to OT at 6 months. **Methods:** We reviewed data on children with PFIC prospectively enrolled and treated with odevixibat for 6 months. We divided the patients into 2 groups (classic types vs rarer forms) and compared. ROC analysis was performed to calculate the best cut-off of sBA reduction associated with improvements in pruritus scale of -1 point at 6 months (defined as *pruritus responders*). **Results:** 24 patients [median age 6.6 years (3.7-12.1), M/F = 11/13] were enrolled; All had high sBA levels [median value of 317 μmol/ (82-369)] and 22/24 (92%) had pruritus.

16 patients (67%) had classic PFIC types [FIC-1 deficiency (PFIC-1) = 2; BSEP deficiency (PFIC-2) = 11; MDR3 deficiency (PFIC-3) = 3; 8 patients (33%) had rarer forms [TJP2 deficiency (PFIC-4) = 5; FXR deficiency (PFIC-5) = 1; MYO5B (PFIC-6) = 1; ZFYVE19 (PFIC-9) = 1]. At baseline, median values of age [6.6 years (4.2-11.6) in classic types vs 6.3 (3.0-9.7) in rarer forms], sBA levels [317 μmol/L (88-367) vs 290 μmol/L (77-364) in rarer forms] and prevalence of pruritus (88% vs 100% in rarer forms) were similar in both groups ($p > 0.05$).

After 6 months of treatment, 75% of patients were sBA responders, 73% were pruritus responders; 30% required dose escalation. Comparing the two groups, percentages of sBA responders were 63% in classic types vs 100% in rarer forms of PFIC ($p = 0.06$); for pruritus responders: 59% in classic types vs 100% in rarer forms ($p = 0.05$).

On ROC analysis, reductions of sBA levels $\geq 48\%$ from baseline value at 1st month and $\geq 52\%$ at 3rd month were associated with improvements of pruritus scale (-1point) at 6 months (*pruritus responders*) (1st month: ROC-AUC 0.771; SE = 0.75, SP = 0.83; 3rdmonth: ROC-AUC 0.885; SE = 0.81, SP = 1.00). **Conclusion:** In our cohort, the majority of patients responded well to odevixibat treatment; higher percentages of response were recorded among children with rarer forms.

Reduction of sBA levels of around 50% from baseline value at 1 and 3 months is associated with a full response to OT at 6 months. This information could be useful to plan prosecution or prompt discontinuation of treatment after 6 months of odevixibat.

4604 | DISTINCT GUT MICROBIOTA AND METABOLOMIC SIGNATURES ASSOCIATED WITH THE ABSENCE OF HEPATIC STEATOSIS IN OBESE AND OVERWEIGHT CHILDREN

Kai-Chi Chang Chia-Ray Lin[1] Bang-Yu Liou[1] Huey-Ling Chen[2], [1]National Taiwan University Hospital, [2]National Taiwan University

Background: Obesity or overweight is a significant risk factor for children to develop hepatic steatosis in pediatric population. However, some children who meet BMI or z-score criteria for obesity or overweight do not have fatty liver. Their gut microbiota and its derived metabolites warrant further investigation. **Methods:** We enrolled obese or overweight children aged 6-18 years and performed ultrasonography to screen hepatic steatosis. Children with normal BMI z score were recruited as control group. Anthropometric data were measured, and fasting blood samples were analyzed for liver biochemistry, lipid profiles, uric acid and metabolomics. Stool sample were collected for gut microbiota analysis using full-length 16S rRNA gene sequencing. Serum samples were analyzed using ultra-high-performance liquid chromatography with mass spectrometry. **Results:** Twenty-eight obese children (median age 9.0 years, range 8.2–14.9 years), and six age-matched healthy control were enrolled. The median BMI z score were 1.92 and 0.39 in obese/overweight group and control group, respectively.

Their age, alanine aminotransferase, triglyceride, uric acid, and bile acid were comparable. Obese/overweight children exhibited higher total cholesterol (169 mg/dL vs. 124 mg/dL, p = 0.029) and low-density lipoprotein levels (105.5 mg/dL vs. 58.5 mg/dL, p = 0.039) compared to the control group.

Among the 28 cases in the obesity/overweight group, 7 showed no hepatic steatosis on sonographic examination, while the remaining 21 demonstrated mild to moderate steatosis. The alpha and beta diversity of the gut microbiota differed significantly among the control group, the obesity/overweight-with-steatosis group, and the obesity/overweight-without-steatosis group (p = 0.008 and p = 0.003, respectively; Figure 1A, 1B). Additionally, the shannon index was lowest in the obesity/overweight-with-steatosis group and showed a trend toward difference compared to the obesity/overweight-without-steatosis group (p = 0.06; Figure 1A). Linear discriminant analysis (LDA) effect size analysis revealed that *Bifidobacterium bifidum* and *Bacteroides ovatus* were significantly enriched in the control group compared to both obesity group. To identify metabolites potentially associated with protection against hepatic steatosis, we compared serum metabolites between the obesity/overweight-with-steatosis and obesity/overweight-without-steatosis groups. We found that 2-hydroxycinnamic acid and citrulline were highly associated with obesity in the absence of steatosis. **Conclusion:** Our results suggest that the microbiota and the derived metabolites may play a role in modulating liver health in obese children. Protecting factors for steatotic liver disease warrants further investigation to better understand individual susceptibility and to develop therapeutic strategies for hepatic steatosis.

4605 | DISCREPANCIES IN STANDARDIZED ASSESSMENT AND DISEASE BURDEN OF PRURITUS IN BILIARY ATRESIA

Natasha Dilwali[1] Rozanne Groen[2] Alex Brenner[2] Nadia Ovchinsky[2] Jennifer Vittorio[2], [1]Johns Hopkins University, [2]NYU Grossman School of Medicine

Background: Pruritus is a debilitating symptom in cholestatic liver diseases, yet remains understudied in biliary atresia (BA). Evidence from other pediatric subspecialties suggests a gap between caregiver-reported symptoms and provider documentation, raising concerns about under-recognition. Although validated tools exist to assess cholestatic pruritus and its impact on quality of life, they are not routinely used in clinical practice. The goal of this study is to evaluate provider

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

screening practices for pruritus and compare them with caregiver-reported experiences in children with BA. **Methods:** A cross-sectional survey was conducted among caregivers and providers of pediatric patients with BA. Caregivers of children ≥6 months were recruited via the Biliary Atresia Research and Education (BARE) network and NYU Langone clinics. Providers were recruited through the international Pediatric Gastroenterology ListServ. Separate surveys assessed demographics, medication use, and pruritus-related experiences. Descriptive statistics summarized responses, and comparisons were made between caregiver and provider perspectives. **Results:** Of 67 provider respondents, 35.8% (n = 24) had managed more than 20 BA patients in the past five years; 59.7% (n = 40) were hepatologists. While 85.2% reported routinely screening for pruritus, this was more common among hepatologists (97.1%) than gastroenterologists (69.2%). 27% of hepatologists and none of the gastroenterologists used validated assessment tools. Discrepancies emerged between provider perceptions and caregiver reports. While 65.1% of providers believed pruritus disrupted sleep for both children and caregivers, only 42.9% (24/56) of caregivers recalled being asked about sleep. Differences were also observed in reported pruritus locations: hepatologists most frequently identified the ears (67.6%), gastroenterologists cited generalized pruritus (73.1%), while caregivers most commonly reported the legs (30.3%), with fewer describing generalized itching (18.2%). **Conclusion:** A disconnect exists between provider perceptions and caregiver-reported experiences of pruritus in children with BA. Although screening is frequently reported, use of validated tools is limited, particularly among gastroenterologists. These discrepancies may contribute to under-recognition of symptoms such as sleep disruption. Broader adoption of standardized assessment methods and targeted education may improve symptom recognition and management in this vulnerable population.

4606 | ODEVIXIBAT RAPIDLY REDUCES PRURITUS AND SERUM BILE ACIDS IN CHILDREN WITH BILIARY ATRESIA AND CHRONIC CHOLESTASIS FOLLOWING KASAI PORTOENTEROSTOMY

Emanuele Nicastro[1] Angela Marino[1] Lorenza Matarazzo[1] Fernanda Cristofori[2] Ruggiero Francavilla[2] Gabriella Nebbia[3] Giulia Paolella[3] Alessandro La Rosa[4] Annalisa Madeo[4] Antonio Marseglia[5] Eleonora Severi[1] Lorenzo D'Antiga[1] Angelo Di Giorgio[1], [1]ASST Papa Giovanni XXIII, Bergamo, Italy, [2]Pediatric Hospital Giovanni XXIII, Bari, Italy, [3]Ospedale Maggiore Policlinico, Milan, Italy, [4]IRCCS Giannina Gaslini, Genoa, Italy, [5]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy

Background: Biliary atresia (BAtr) is a major cause of neonatal cholestasis, and the most common indication to pediatric liver transplantation. Children surviving with native liver after Kasai portoenterostomy (KPE) may present chronic cholangiopathy, residual cholestasis, and fibrotic progression. Ileal Bile Acid Transporter (IBAT) inhibitors have not been studied in these patients. We assessed safety and efficacy of Odevixibat in BAtr children with cholestatic pruritus. **Methods:** Odevixibat was administered at a dosage of 40 μg/kg/d QD. Complete pruritus response was defined as a score ≤1 of the 0-to-4 points Pruritus Global Impression Scale (PGIS). Serum bile acid (sBA) response was defined as sBA decrease ≥50%, and was defined complete in presence of total sBA ≤75 μmol/L. **Results:** Seven children [4 females, median age 7.5 years (range 1.1-11.5), KPE performed at 67 (60-95) days of life] were included. Five had liver fibrosis (≥12 kPa) at transient elastography, and 4 clinically evident portal hypertension; mean baseline bilirubin was 2.2 ± 1.3 mg/dL. All the patients had a complete pruritus response after a median time of 2 weeks, with a PGIS score decreasing from 2.8 ± 0.8 (baseline) to 1.1 ± 1 (week 2, $p = 0.003$), and 0.2 ± 0.4 (week 16, $p < 0.001$). Likewise, all had sBA response, which was complete in 6 of them. sBA decreased from 239 ± 115 (baseline) to 85 ± 122 (week 2, $p = 0.005$), and 57 ± 19 μmol/L (week 24, $p = 0.052$), with a median decrease of -75% (range: -55% to -86%). Transient grade 1 diarrhea was recorded in one patient. **Conclusion:** This is the first report of Odevixibat in children with BAtr. Odevixibat is highly effective and safe in cholestatic pruritus in children with BAtr and residual cholestasis after KPE.

4607 | PREDICTORS OF BIOCHEMICAL REMISSION FOR PEDIATRIC AUTOIMMUNE HEPATITIS IN NORTH AMERICAN MULTICENTER LEARNING HEALTH NETWORK

Mary Ayers[1] Cyd Castro-Rojas[2] Rebekah Karns[2] Leina Alrabadi[3] Heli Bhatt[4] Kate Cheng[5] Ranita Datta[6] Nitika Gupta[7] Jennifer Halma[8] Sakil Kulkarni[9] Shelby Mecklenborg[10] Katelyn Saarela[11] Emily Rothbaum Perito[5] Alexander Weymann[12] Mandy Zhu[2] James Squires[13] Alexander Miethke[2] Amy Taylor[2], [1]UPMC Children's Hospital of Pittsburgh, [2]Cincinnati Children's Hospital Medical Center, [3]Stanford/Lucile Packard Childrens Hospital, [4]University of Minnesota Children's Hospital, [5]University of California, San Francisco, [6]Children's Hospital of Atlanta, [7]Emory University School of Medicine, [8]Children's Mercy Hospital, [9]Washington University in St. Louis, [10]University of Cincinnati, [11]Seattle Children's Hospital, [12]Nationwide Children's Hospital, [13]Children's Hospital of Pittsburgh

Background: Poor outcomes in pediatric-onset Autoimmune Hepatitis (AIH) can lead to liver transplant before adulthood. Biochemical remission at 6 months after AIH diagnosis is associated with event-free survival in adults. We evaluated a diverse multi-center retrospective cohort of children with AIH in the Autoimmune Liver disease Network for Kids (A-LiNK) to determine factors associated with 6- and 12-month biochemical remission. **Methods:** This retrospective study included children 2-21 years old diagnosed with AIH without concurrent liver disease at 9 A-LiNK centers between 2010-2020 with $\geq$12 months of follow-up. Biochemical remission was defined as normalization of serum aminotransferases (AST and ALT) for age/sex. Baseline predictors for remission were computed using Wilcoxon rank-sum and Fisher's exact tests. P-values were corrected for multiple testing using false discovery rate (FDR), with FDR $<$ 0.05 significant. **Results:** 216 children and adolescents with AIH, 67% were female; 71% White, 21% Black; with 90% non-Hispanic. (TABLE 1) Median age at AIH diagnosis was 13.2 years, with 69% type 1, 15% type 2, and 16% seronegative. Biochemical remission rates were 62% at 6 months and 73% at 12 months. Lower FIB4, a fibrosis biomarker, was associated with remission at both 6 and 12 months. Lower BMI Z-score, higher platelets, and lower INR were associated with 12-month remission.

Durable remission—normal transaminases by month 9 sustained at month 12—occurred in 61% of 165 patients. Twenty-one percent never achieved remission, and 18% achieved temporary remission. Durable remission was associated with higher initial dose of prednisone per body weight (1 vs 0.7 mg/kg/day, p = 0.0009, FDR = 0.016), especially in children with initial GGT $>$ 50 IU/L (OR = 3.31, p = 0.0017). Nondurable remission was associated with higher BMI at 12 months (22.6 vs 19.2 kg/m2, p = 0.011, FDR = 0.088) and increased prednisone dose at 12 months (10 vs 5mg, p = 0.013, FDR = 0.088). Baseline and 12-month doses of azathioprine were not associated with remission. **Conclusion:** This is the largest pediatric multi-center AIH cohort in North America, with similar 6- and 12-month remission rates as previously described in single-center studies. These findings suggest higher induction doses of prednisone are associated with durable remission, regardless of induction azathioprine dose. Comparative effectiveness studies are needed to determine best induction regimens to achieve early biochemical remission.

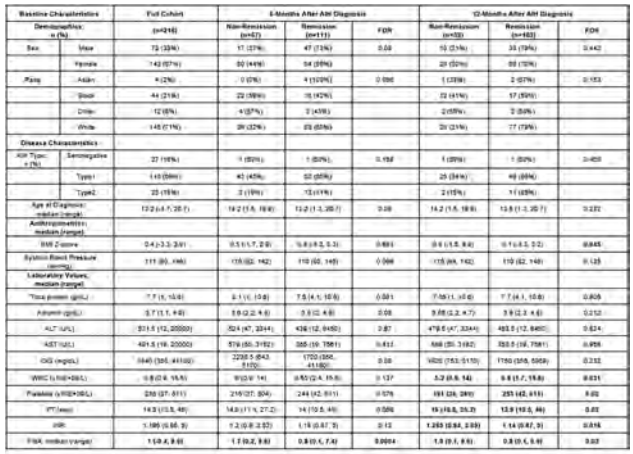

Table 1: Baseline characteristics of 216 children with AIH diagnosed between 2010-2021 at 9 A-LiNK centers. Continuous variables are displayed as median and range.

4608 | TITLE: EPIDEMIOLOGICAL CHARACTERISTICS OF CHILDREN WITH WILSON DISEASE: A SINGLE-CENTER EXPERIENCE FROM BRAZIL

Rafaella Karen Sousa Monterlei[1] Camila Oliveira Hansen[2] Ana Leticia Fernandes Coelho de Oliveira[3]

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Gabriel Nuncio Benevides[3] Mirella Cristiane de Souza Bolognini[3] Maria Tereza Guiotti[3], [1]ICr HC FM USP - The University of São Paulo (USP), [2]ICr HC FM USP - The Univervisity of São Paulo, [3]ICr HC FM USP - The University of São Paulo

Background: Background:: Wilson's disease (WD) is an autosomal recessive disorder of copper metabolism caused by mutations in the ATP7B gene, leading to toxic accumulation of copper in the liver, brain, and other organs. Clinical manifestations range from asymptomatic to severe hepatic or neuropsychiatric presentations. This study aims to describe the epidemiological and clinical follow-up data of pediatric WD cases at a single center in Brazil. **Methods:** Methods:: A retrospective, descriptive review of medical records was conducted for pediatric patients diagnosed with WD between 2010 and 2025 at a tertiary care center in Brazil. **Results:** Results:: Twenty-six patients with WD were included, with a minimum follow-up of 12 months. The mean age at first consultation was 9.4 years; 53.8% were female. Genetic testing was performed in 14 out of 26 patients (53.8%), and all had diagnostic mutations identified in the ATP7B gene. The most common initial presentations were incidental transaminase elevation (46.1%) and positive family screening (30.7%). Additional findings included hepatomegaly (15.3%), jaundice (7.6%), neuropsychiatric symptoms (3.8%), and acute liver failure (3.8%). Kayser-Fleischer rings were present in 34.6%, and brain MRI abnormalities were noted in 23%. Liver biopsy, performed in 7 patients, showed significant fibrosis (F2/F4) in 71.3%. At diagnosis, mean ceruloplasmin and serum copper levels were 5.5 mg/dL (96% $<$10 mg/dL) and 47 mcg/dL, respectively. Urinary copper excretion increased from 229 mcg/24h at diagnosis to 421 mcg/24h at the latest follow-up. Laboratory markers showed significant improvement between the first and last visits: AST (107.5→39.6 U/L), ALT (169.5→61.8), GGT (85→41.3), ALP (318.7→202.8), total bilirubin (1.05→0.66 mg/dL), and INR (1.33→1.18). At last follow-up, 61.5% were adhering to a low-copper diet. Treatment was initiated at a mean age of 9.6 years. Most patients were on penicillamine (96.1%), vitamin B6 (73%), and zinc (11.5%). The most common regimen was penicillamine + B6 (69.2%), with average doses of 16.2 mg/kg/day for penicillamine, 1.6 mg/kg/day for zinc, and 0.85 mg/kg/day for B6. Treatment adherence remained high (88.2% initially vs. 75% at last visit). Adverse effects decreased over time (32%→11.5%), primarily gastrointestinal symptoms and neutropenia, most of which resolved in follow-up visits. **Conclusion:** Conclusion:: This study underscores the importance of early diagnosis and long-term treatment adherence in pediatric WD. Clinical and laboratory improvements were strongly associated with therapy, reinforcing the value of continuous monitoring to prevent disease progression and manage treatment-related adverse effects.

4609 | EPIDEMIOLOGICAL AND GENETIC CHARACTERISTICS OF CHILDREN WITH ALAGILLE SYNDROME: A SINGLE-CENTRE EXPERIENCE FROM BRAZIL

Rafaella Karen Sousa Monterlei[1] Camila Oliveira Hansen[2] Maria julia Soares Barbosa[2] Ana Luiza de Aquino Oliveira[2] Mirella Cristiane de Souza Bolognini[2] Maria Tereza Guiotti[2], [1]ICr HC FM USP - The University of São Paulo (USP), [2]ICr HC FM USP - The University of São Paulo

Background: Alagille syndrome (ALGS) is a rare autosomal dominant disorder with multisystem involvement and variable expression. It typically presents in the first 3 months of life, often with cholestasis and pruritus. Most patients carry JAG1 mutations, fewer have NOTCH2 variants. Diagnosis is challenging due to phenotypic variability. We reviewed clinical and genetic findings in Brazilian patients from a single tertiary center. **Methods:** A retrospective and descriptive study was carried out by reviewing medical records of children with ALGS, at single-centre in Brazil in the period from 2001 to 2025. **Results:** 36 patients with ALGS were analyzed, with 72.2% being male. The mean age of symptom onset was 4 months. Among the 19 patients who underwent liver biopsy, ductopenia was present in 16 cases (84.2%) and absent in 3, two of whom were under 6 months old. Regarding fibrosis staging: F0 in 61.1%, F1 in 22.2%, F2 in 5.5%, F5 in 11.1%. 24 patients performed genetic analyses. JAG 1 mutations were identified in 23, but NOTCH 2 mutation was not analysed. Neonatal cholestasis was observed in 77.7%. Typical facies and congenital heart disease were each present in 88.8%, being pulmonary artery stenosis/hypoplasia 78.1%. Additional findings included cognitive impairment (36.1%), short stature (52.9%), nephropathy (41.6%), ophthalmologic abnormalities (47.2%) most commonly posterior embryotoxon (94.1%) and vertebral anomalies in 61%, mainly butterfly vertebrae (77.2%). Pruritus was present in 42.3% at the first visit and 53.1% at the last, though intensity was not recorded. Use of antipruritic medications increased from 33.3% to 80.5%, due to the presence of cholestasis. Medications used were ursodeoxycholic acid, rifampicin, sertraline, cholestyramine and hydroxyzine. Until now, we still do not have the possibility of prescribing any IBAT for our patients.

Three patients (8.3%) underwent ileal exclusion, with 2 showing improvement in pruritus. Comparing mean laboratory parameters from the first and last consultation: direct bilirubin levels decreased from 4.19 mg/dL to 3.72, GGT decreased from 768.7 to 354.4 U/L, AST/ALT decreased from 190.7/184.5 to 152.1/167.1 U/L. Two patients (5.5%) required liver transplantation. **Conclusion:** This study highlights the variability of clinical features and multisystem involvement in ALGS. Neonatal cholestasis, pruritus, typical facies, and cardiac anomalies were frequent. The findings reinforce the need for early recognition and multidisciplinary care. **Disclosures:** Rafaella Karen Sousa Monterlei: Nothing to Disclose, Camila Oliveira Hansen: Nothing to Disclose, Maria julia Soares Barbosa: Nothing to Disclose, Ana Luiza de Aquino Oliveira: Nothing to Disclose, Mirella Cristiane de Souza Bolognini: Nothing to Disclose, Maria Tereza Guiotti: Nothing to Disclose

4610 | CLINICAL OUTCOMES OF LIVER TRANSPLANTATION IN PEDIATRIC MAPLE SYRUP URINE DISEASE AND DOMINO LIVER RECIPIENTS AT KING FAISAL SPECIALIST HOSPITAL AND RESEARCH CENTER- SAUDI ARABIA

Mohammad Shagrani[1] Kishwer Kumar[1] Alexandra Aldana[1] Ali Syed Akhtarul Hassan[1] Dalal Albugami[1] Sateesh Maddirevula[1] Saleh A Alqahtani[1] Ehab Abufarhaneh[1] Bandar Mohammed H Aljudaibi[1] Massimo Malago[1] Dieter Broering[1], [1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia

Background: Maple Syrup Urine Disease (MSUD) is a rare genetic disease affecting branched chain amino acid metabolism in the liver. Treatment is primarily lifelong protein restriction to prevent devastating neurologic complications; however, compliance is difficult, and severe metabolic crises can still be triggered by acute illness. Elective liver transplantation offers a metabolic cure for classical MSUD patients. An additional benefit is that the explanted MSUD liver can subsequently be transplanted into a *non-MSUD* patient, effectively curing the "domino" recipient's liver disease as well, since the enzymatic deficiency of the MSUD liver can be compensated by other organs in the recipient. The purpose of this retrospective study is to investigate the long-term clinical outcomes of liver transplantation in pediatric MSUD patients and their domino recipients. **Methods:** Data was collected of all the pediatric genetically confirmed MSUD patients and their non-MSUD domino recipients who underwent liver transplantation at KFSHRC between September 1, 2011 and August 31, 2024. **Results:** MSUD patients: 31 pediatric MSUD patients underwent liver transplant at our center. Demographics and complications of these patients are represented in Table 1. Out of the two MSUD patients who required re-transplantation, the first patient underwent liver transplantation at the age of 4 years. Transplant was complicated by biliary stricture followed by chronic rejection and required Re liver transplantation.

The second patient was 9 years old at the time of liver transplantation and developed out flow obstruction. and required Re Liver Transplantation on day 44 of post Liver Transplantation.

Domino liver recipients

Of the 31 explanted MSUD livers, 25 (80%) were utilized for domino transplant, 4 (16%) went to adult domino recipients.

Total 25 patients received MSUD domino livers. Four (16%) of the domino recipients developed ACR. Two (8%) domino recipients required re-transplantation, first one due to primary graft failure and second one due to hepatic artery thrmbosis. There were 2 (8%) mortalities, first one died due to brian herniation and second one died due to cardiac complication secondary to coronary artery disease.

For the majority of domino recipients, post-transplant BCAA levels were mildly elevated but later normalized. Further studies are ongoing on long-term patient and graft outcomes. **Conclusion:** Liver transplantation successfully prevents metabolic crisis in MSUD patients.

Domino MSUD livers are good source of grafts to expand the donor pool thereby decreasing the wait time and wait list mortality.

Table 1	MSUD Patients (n=31)	MSUD Liver Recipients (n=25)
Mean Age at Transplant (yrs), range	4 (range: 5 months - 15 years)	Peciatric: 5.5 years (range: 6 months – 13.5 years); Adults: 31 41, 65 years
Male (%) / Female (%)	13 (42%) / 18 (58%)	9 (36%) / 16 (64%)
Blood Group (%)		
A	8 (26%)	7 (28%)
AB	1 (3%)	1 (4%)
B	4 (13%)	5 (20%)
O	18 (58%)	12 (48%)
Complications (%)		
Acute Cellular Rejection	7 (22%)	4 (16%)
Vascular Complications	3 (10%)	21
Biliary Stricture	1 (3%)	1
Required Re-transplantation	2 (6%)	2 (8%)
Mortality	N/A	2 (8%)

4611 | CHOLANGIOCYTE REGULATES MACROPHAGE ACTIVATION THROUGH FIBRONECTIN-INTEGRIN INTERACTION

Wenqi Li[1] Ashley Fonseca-Mejia[1] Reena Mourya[1] Pranavkumar Shivakumar[1] Jorge Bezerra[1], [1]University of Texas Southwestern Medical Center

Background: Macrophage has been known to contribute to the pathogenesis of biliary atresia (BA). However, the mechanisms by which macrophages interact with cholangiocytes to promote biliary injury and fibrosis are poorly understood. Here, we investigated the molecular crosstalk used by cholangiocytes to induce macrophage inflammatory cytokine production. **Methods:** Mouse cholangiocyte organoids (mCOs) derived from common bile ducts of BALB/c mice were cocultured with murine macrophages (Raw 264.7 cell line) in Matrigel and analyzed by flow cytometry after 24 and 48 hours of culture. In transwell assays, macrophages and mCOs were separated by 0.4um membrane to block cell-cell interaction. For RNA-seq analysis, mCOs and macrophages were separated by fluorescence-activated cell sorting (FACS) before submitted for sequencing. Ligand-receptor analysis was done using CellChat. Human cholangiocyte organoids (hCOs) from livers of BA patients (BACOs) and normal donors (NCOs) were cocultured with human embryonic stem cell (hESC)-derived macrophages before analysis by flow cytometry. **Results:** Macrophages cocultured with mCOs increased TNFa, IL6 and iNOS expression, which were boosted when macrophages were primed by LPS for 3h. Coculture using transwell assays to block cell-cell interaction reduced TNFa, IL6 and iNOS expression, indicating cell-cell contact is required for enhanced macrophage activation. RNA-seq analysis of sorted macrophages and sorted cholangiocytes post coculture was performed and ligand-receptor interaction using CellChat predicted fibronectin (Fn, ligand on cholangiocyte) and ITGA5/ITGB1 (receptor on macrophages) as the most likely interaction within the coculture. Flow cytometry validated cholangiocyte as the main source of Fn. Macrophages treated with Fn showed increased TNFa expression. This effect was mitigated by either Fn inhibition with RGDS peptide or ITGA5-ITGB1 double knockdown (DKD) using siRNA. In human, Fn, ITGA5 and ITGB1 expression were increased in BA livers, and Fn expression was increased in BACOs vs NCOs. Coculture BACOs with hESC-derived macrophages increased IL6 and IL8 expression compared with NCOs. **Conclusion:** Cholangiocytes induce macrophage inflammatory cytokine production through Fn-ITGA5/ITGB1 interaction. In Biliary atresia, diseased cholangiocytes induce enhanced macrophage inflammatory cytokine production through increased fibronectin production. **Disclosures:** Wenqi Li: Nothing to Disclose, Ashley Fonseca-Mejia: Nothing to Disclose, Reena Mourya: Nothing to Disclose, Pranavkumar Shivakumar: Nothing to Disclose, Jorge Bezerra: Nothing to Disclose

4612 | OUTCOMES OF CONGENITAL PORTOSYSTEMIC SHUNT CLOSURE: EARLY SINGLE-CENTRE INTERVENTIONAL RADIOLOGY EXPERIENCE

Marumbo Paul Mtegha[1], [1]Leeds Children's Hospital

Background: Congenital portosystemic shunts (CPSS) are rare vascular malformations comprising abnormal portovenous connections that bypass the liver, potentially causing hepatic encephalopathy and other complications. Traditionally managed surgically, interventional radiology (IR) provides minimally invasive alternatives. **Methods:** Retrospective cohort study of consecutive patients from 2006-2024 who underwent CPSS closure using radiological techniques. **Results:** Twenty patients (50% male) with a median age of 7.6 years ($\pm$4.5, range 1–15) underwent shunt closure, with a median follow-up of 2.6 years ($\pm$1.8, range 0–6). Most patients presented incidentally with 1 patient presenting with pulmonary hypertension as their primary pathology. Comorbidities included cardiac abnormalities (65%), neurological conditions (25%), chromosomal abnormalities (10%), and syndromic conditions (10%). Technical success, defined as complete shunt occlusion at final follow-up, was achieved in 18 patients (90%). Single-stage closure was performed in 15 patients (75%), while 3 (15%) required $\geq$2 procedures. Devices used included vascular plugs, cardiac septal occlusion devices, stent grafts and embolisation coils, or a combination of devices. Two patients experienced complications: one patient had two episodes of device migration, successfully retrieved, and one patient experienced acute portal vein thrombosis requiring thrombolysis. No patients developed clinically significant portal hypertension. **Conclusion:** IR closure of CPSS is an effective alternative to surgery, with a high technical success rate and low complication risk. Expanding the spectrum of devices used can provide a minimally invasive treatment option for a wider cohort of patients.

4613 | LIVER CELL-SPECIFIC UNFOLDED PROTEIN RESPONSE GENE EXPRESSION IS LOWER IN NEONATAL COMPARED TO ADULT MICE

Alyssa Kriegermeier[1] Brian Lecuyer[1] Richard Green[2], [1]Ann and Robert H. Lurie Children's Hospital of Chicago, [2]Northwestern University

Background: The unfolded protein response (UPR) is a protective response which decreases ER stress. The UPR has ER stress sensors IRE1α/XBP1, PERK and ATF6 which activate their downstream targets. We previously published that young mice have attenuated hepatic XBP1 pathway activation in response to bile acid feeding and pharmacologically induced ER stress, and that expression of this pathway is decreased in human pediatric cholestatic liver disease explants. Additionally, using whole liver RNA-Seq and qPCR, we have also demonstrated that following bile duct ligation (BDL), neonatal mice have decreased expression of UPR pathways. In this study, we sought to elucidate the liver cell-specific age-dependent differences in UPR activation at baseline and during obstructive cholestasis. **Methods:** Female C57BL/6 neonatal (10 day) and adult (8-10 week) mice underwent BDL or sham laparotomy (SL) for 7 days. Serum LFTs and single-nuclei RNA-seq (snRNA-seq) was performed and cell specific (hepatocyte, cholangiocyte, stellate cell) gene expression of *Xbp1, Atf6* and *Perk* and 60 canonical UPR genes were analyzed. Pathway and enrichment analysis utilizing TRRUST was performed utilizing Metascape. **Results:** After BDL, neonatal mice have higher serum alkaline phosphatase (1336 +/- 380 vs 481 +/- 174 U/L, $p < 0.001$) compared to adult mice, with no significant differences in SL mice. After BDL, neonatal mice have significantly decreased hepatocyte-specific expression of *Xbp1* (2-fold, padj < 3x10^-92), *Atf6* (1.8-fold, padj < 2x10^-185) and *Perk* (1.5-fold, padj < 9x10^-17) compared to adult mice, and expression of 31 canonical UPR genes were significantly decreased while 3 genes were increased. Cell-specific analysis of cholangiocytes and stellate cells revealed a decrease of 5 and 14 UPR genes, respectively. Enrichment analysis identified XBP1 is one of the most significant (-log10(P) = 3.1) transcription factors associated with the hepatocyte-specific differentially expressed genes between adults and neonates after BDL (Fig.1), which was not found after SL. After SL, 47 UPR targets were decreased and 3 were increased in hepatocytes, 6 were decreased in cholangiocytes, and 18 were decreased in stellate cells in neonatal compared to adult mice. **Conclusion:** Neonatal mice have higher alkaline phosphatase after BDL compared to adult mice. A greater number of UPR genes are significantly decreased in neonatal compared to adult hepatocytes after BDL. Neonatal cholangiocytes and stellate cells also had diminished UPR gene expression, though less so than hepatocytes. Notably, these decreases in hepatic UPR target expression profiles were also seen in SL operated neonatal compared to adult mice supporting impaired UPR activation at baseline in young mice. We hypothesize this impaired UPR activation in young mice at baseline may predispose to the injury seen the setting of cholestasis and therefore be a potential target for therapeutic intervention.

4614 | LAURIC ACID MITIGATES DUCTULAR REACTION, OXIDATIVE STRESS AND HEPATOCYTE SENESCENCE IN A MOUSE MODEL OF INFLAMMATORY CHOLANGIOPATHY

Swati Ghosh[1] Michael Devereaux[1] Colin Anderson[1] Angelo D'Alessandro[1] David Orlicky[1] Ronald Sokol[1], [1]University of Colorado School of Medicine

Background: Inflammatory cholangiopathies are associated with bile ductular reaction, macrophage activation and hepatocyte senescence. We showed that lauric acid (LA), a medium chain fatty acid precursor of the LRH1 agonist DLPC, was hepatoprotective in cholestasis. In this study we examined the mechanism of LA protection in the DDC cholangiopathy mouse model. **Methods:** Mice were administered a 0.1% DDC diet for three days with or without 20% LA dietary supplementation. *In vitro* studies used cultured hepatocytes and cholangiocytes. **Results:** Mass spectrometry-based metabolomics analyses of DDC liver revealed marked accumulation of toxic bile acids, oxidative stress markers, and mitochondrial fatty acid perturbations, with a marked ductular reaction on histology;

upregulated mRNA expression of *CCL2* in hepatocytes and macrophages from DDC liver; elevated serum CCL2 (ELISA); and upregulated senescence genes. Oxidative injury was confirmed by increased lipid peroxides and nitric oxide in DDC liver. Increased *CCL2* expression was associated with the recruitment of pro-inflammatory monocyte-like macrophages (F4/80^{+}LY6C^{+}). All of these alterations were prevented in the LA supplemented-DDC mice. Furthermore, hepatocytes isolated from DDC mice showed increased expression of oxidative stress genes and lipogenic gene markers, which were significantly reversed by LA supplementation, concomitant with upregulation of genes that promote mitochondrial function. To determine if CCL2 could activate hepatocyte senescence pathways, primary mouse hepatocytes exposed to CCL2 showed STAT1 activation and downstream senescence gene expression (e.g., *Cdkn1b, Cdkn1a*); senescence was confirmed by β-galactosidase staining. Furthermore, ChIP assay in hepatocytes from DDC mice demonstrated direct STAT1 binding to the ***Cdkn1b*** promoter, implicating CCL2-STAT1 signaling in senescence induction. LA treatment in DDC mice prevented this binding. In co-culture of Huh7 cells with H69 cholangiocytes exposed to DDC, DLPC—the active LA-derived LRH-1 agonist—suppressed DDC-induced senescence in Huh7 cells measured by expression of ***CDKN1a*** and ***CCL2.*** **Conclusion:** LA supplementation reduced hepatic inflammation/ductular injury and hepatocyte senescence and oxidative stress in DDC mice in conjunction with inhibition of the CCL2-STAT1 axis which promotes senescence. These studies support activating LRH1 signaling by dietary LA as a protective strategy for inflammatory cholangiopathies.

4615 | ACTIVATION OF REGULATORY MACROPHAGES BY LRH1 AGONIST DLPC MEDIATES REVERSAL OF CHOLESTATIC INJURY IN THE PRIMARY SCLEROSING CHOLANGITIS MOUSE MODEL

Swati Ghosh[1] Michael Devereaux[2] David Orlicky[2] Yonghua Zhuang[2] Ronald Sokol[2], [1]University of Colorado Denver Anschutz Medical Campus, [2]University of Colorado School of Medicine

Background: Primary sclerosing cholangitis (PSC) is a progressive inflammatory cholangiopathy marked by chronic biliary inflammation and limited treatment options beyond liver transplantation. Dysregulated immune responses are central to its pathogenesis. Previously we showed that the liver receptor homolog-1 (LRH-1) agonist, dilauroyl phosphatidylcholine (DLPC), was protective in a mouse cholestasis model involving parenteral nutrition. This study was conducted to determine if DLPC mitigates injury in a mouse PSC model and its effects on immunosuppressive regulatory macrophages (Mregs), which are associated with the resolution of inflammation and tissue repair. **Methods:** A murine model of PSC used 14-day diet containing 0.1% diethyl 1,4-dihydro-2,4,6-trimethyl-3,5-pyridinedicarboxylate (DDC mice). A group of DDC mice also received intravenous DLPC 30 mg/kg/day for 14 days through a central venous catheter. **Results:** DDC mice exhibited markedly elevated serum AST, ALT, ALP, bilirubin, total bile acids, and a pronounced ductular reaction on histology; all were significantly improved or reversed by DLPC treatment. To assess macrophage phenotypes in DDC mouse liver, RNA-seq of flow-sorted CD45^{+}F4/80^{+} Kupffer cells showed that DDC induced pro-inflammatory and macrophage-like monocyte markers. In contrast, DLPC-treated DDC mice exhibited increased expression of restorative, lipid-associated, and regulatory macrophage (Mreg) gene signature markers, including ***IL10***. ATAC-seq revealed reduced chromatin accessibility at Mreg-related loci in DDC mice; accessibility was restored by DLPC, indicating reactivation of Mreg transcriptional programs. DLPC treatment in DDC mice also induced hepatic phosphorylation of ERK, a known activator of Mregs. To study these effects *in vitro*, cultured bone marrow-derived macrophages (BMDMs) were treated with overnight with DLPC (10 μM) or the known Mreg activator adenosine (100 μM) ± LPS (100 ng/mL) for 4 hr. qPCR analysis showed that DLPC in the presence of LPS, like adenosine, significantly upregulated IL-10, inhibited pro-inflammatory macrophage activation, and promoted Mreg polarization. **Conclusion:** LRH-1 activation by DLPC fosters Mreg activation and confers hepatoprotection in a murine model of PSC through mechanisms involving ERK signaling and IL-10 production. These findings support LRH-1 agonists as promising candidates for immunoregulatory therapy in PSC and related cholangiopathies.

4617 | EVALUATING THE IMPACT OF GENETIC DIAGNOSIS IN PEDIATRIC LIVER TRANSPLANTATION: A RETROSPECTIVE COHORT STUDY OF 179 CHILDREN AT A SINGLE CENTER

Erika Minonne[1] Angelo Corso Faini[2] Cristina Chiadò[3] Giulia Brach Del Prever[2] Francesco Tito[2] Lucio Queiroz[1] Luigi Marchionni[1] Silvia Catalano[4] Marco Spada[5] Michele Pinon[3] Renato Romagnoli[6] Antonio Amoroso[2] Pier Luigi Calvo[3] Silvia Deaglio[2], [1]Department of Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, USA, [2]Immunogenetics and Transplant Biology Unit, University of Turin, Italy, [3]Pediatric Gastroenterology Unit, University of Turin, Italy, [4]General Surgery, Liver Transplant Center, University of Turin, Italy, [5]Pediatric Inborn Errors of Metabolism, Department of Pediatrics, University of Turin, Italy, [6]General Surgery, Liver Transplant Center, Unversity of Turin, Italy

Background: Many pediatric liver diseases continue to be diagnosed at a late stage or without a clear understanding of their underlying molecular basis, leading to liver transplantation without a definitive diagnosis. This study aimed to assess the role of genetic testing in enhancing diagnostic accuracy in this patient population. **Methods:** This retrospective study included 179 pediatric patients (<18 years) who underwent liver transplantation at Molinette Hospital in Turin between 1996 and 2023. Patients were categorized into eight diagnostic groups: biliary atresia (37.4%, n = 67), metabolic disorders (19.6%, n = 35), liver tumors (12.3%, n = 22), membrane transport defects (8.9%, n = 16), genetic syndromes/malformations (5.6%, n = 10), autoimmune diseases (4.5%, n = 8), ciliopathies (3.4%, n = 6), and other conditions (8.4%, n = 15). Demographic, clinical, and surgical data were retrospectively collected from medical records and transplant registries. Genetic analysis was performed using Next-Generation Sequencing (NGS) on peripheral blood DNA, through clinical exome sequencing (CES). Variants were classified according to ACMG guidelines and validated using international databases (ClinVar, OMIM, GnomAD). Survival and risk analyses were performed using Kaplan-Meier estimates and Cox regression models. **Results:** The median age at transplantation was 2.9 years, with a balanced sex distribution (50.3% male) and a predominance of Caucasian patients (92.2%), followed by Asian (3.3%), African (1.7%), and other ethnicities (2.8%). Genetic testing was indicated in 78 cases (43.6%), performed in 66/78 (84.6%), and conclusive in 56/66 (84.9%). Diagnostic yield was 100% in metabolic disorders, membrane transport defects, and ciliopathies; 50% in genetic syndromes/malformations; and 33.3% in the "other" group. No testing was performed in autoimmune or neoplastic diseases. Survival analysis showed a significant association with disease category ($p = 0.029$): biliary atresia had the best outcome (>90% at 20 years), while liver tumors had the worst (~80% at 5 years). No significant impact on survival was found for age at transplant, HLA-DR matching, or crossmatch testing ($p = 0.42$; $p = 0.36$; $p = 0.17$). **Conclusion:** NGS improves diagnostic accuracy by identifying relevant genetic variants, potentially optimizing therapies and improving survival and quality of life.

4618 | ABCB4 MUTATIONS IN CHILDREN FROM NORTH INDIA: DISTINCT CLINICAL PROFILES AND DECOMPENSATION RISK IN PATIENTS WITH BIALLELIC VERSUS MONOALLELIC VARIANTS

Chennakeshava Thunga[1] Suvradeep Mitra[1] alisha babbar[1] Raghav Lal[1] Sadhna Lal[1], [1]PGIMER, Chandigarh

Background: Progressive Familial Intrahepatic Cholestasis Type 3 (PFIC-3), caused by *ABCB4* mutations, exhibits a variable clinical spectrum and can progress to end-stage liver disease (ESLD). This study aimed to evaluate the clinical, biochemical, and histological profiles of pediatric patients with *ABCB4* mutations, with a focus on genotype-based differences and predictors of hepatic decompensation. **Methods:** In this prospective study (January 2022–March 2025), children (<18 years) with *ABCB4* mutations presenting to a tertiary center in North India were enrolled. Patients were categorized into Group 1 (homozygous or compound heterozygous mutations) and Group 2 (heterozygous mutations). Decompensation was defined as the presence of ascites, gastrointestinal bleeding, and/or encephalopathy. Clinical, laboratory, and histological features were compared across both groups and between compensated and decompensated patients. **Results:** Among 24 patients (58.3% male), 12 had homozygous, 2 compound heterozygous, and 10 heterozygous mutations. Median age at symptom onset

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was 17 months, and at presentation, 50 months. Jaundice and pruritus were present in 70.8%, while ascites and variceal bleed occurred in 16.6% each. Group 1 had a significantly higher rate of decompensation compared to Group 2 (64.3% vs. 20%, $p = 0.04$), along with higher baseline GGT ($p = 0.009$) and lower leukocyte and platelet counts, suggesting hypersplenism. At 6 months and last follow-up (median 28.5 months), Group 2 showed better bilirubin and coagulation profiles. Decompensated patients presented at an older age ($p = 0.03$), with larger spleens ($p = 0.006$), more prominent varices ($p = 0.01$), and higher bilirubin levels across all time points. Histologically, they demonstrated significant ductular reaction ($p = 0.02$), ductular cholestasis ($p = 0.004$), and had higher mortality (54.5%, $p = 0.003$). Twenty-six distinct *ABCB4* variants (80.76% missense) were identified, including one novel mutation (c.1558C > T). One Group 2 patient progressed to sclerosing cholangitis with ESLD. **Conclusion:** Children with heterozygous *ABCB4* mutations may exhibit milder disease but are still at risk of severe progression. Decompensation is associated with worse clinical and histological features and poorer outcomes, highlighting the need for long-term monitoring and early risk stratification

Comparison of Clinical, Laboratory and genetic parameters between Homozygous and heterozygous ABCB4 mutations

Parameters	Homozygous/Compound heterozygous mutation (N=14)	Heterozygous mutation (N=10)	Significance*
General Characteristics			
Male Gender	8 (57.1%)	5 (50%)	1.00
Age at symptom onset in months (IQR)	36 (6, 102)	10.5 (5, 72)	0.48

4619 | SPERMIDINE MODULATES IMMUNE NETWORKS AND REDUCES SEVERITY OF LIVER INJURY IN THE MOUSE MODEL OF BILIARY ATRESIA

Kathryn Kilpatrick[1] Eric Katz[1] Colin Shearn[2] Matthew Burchill[3] William Janssen[4] Ronald Sokol[5] Sarah Taylor[6], [1]University of Colorado, [2]University of Colorado Denver, [3]University of Colorado - Anschutz, [4]National Jewish Health, [5]University of Colorado School of Medicine, [6]Children's Hospital Colorado

Background: Biliary atresia (BA) is a fibroinflammatory disease of infants without medical therapies to slow disease progression. The polyamine spermidine (SPD) plays a critical role in driving anti-inflammatory macrophage polarization; however, it's role in BA remains poorly defined. We used the mouse model of Rhesus Rotavirus (RRV) induced BA to define the mechanism by which SPD may reduce hepatic injury in BA. **Methods:** Wild-type Balb/c neonatal mice received intraperitoneal (IP) RRV (murine BA) or saline (SLN; controls) within the first day of life (DOL 0) followed by IP SLN or SPD on DOL4, 6, 8, and 10, resulting in 4 experimental groups: 1) RRV-SLN, 2) RRV-SPD, 3) SLN-SLN, 4) SLN-SPD. Whole liver tissue was collected on DOL12 for histologic evaluation of liver injury (Ishak score), gene expression, and flow cytometry. Flow cytometry identified CD4+ and CD8+ T cells, Ly6g + neutrophils, F4/80^{hi}CD11b^{lo} tissue-resident macrophages (Kupffer cells, KC), and F4/80^{lo}CD11b^{hi} monocyte-derived macrophages (MoM). Statistical analyses included Student's t-test (Ishak score) and ANOVA with Bonferroni. **Results:** Comparison of Ishak scores between murine BA groups showed reduced severity of hepatic injury in RRV-SPD vs RRV-SLN mice (mean 10 vs 6.1, $p < 0.001$, Figure 1A). Among all groups, RRV-SPD mice had reduced whole liver expression of the pro-inflammatory genes *Il6*, *Il33*, *Ccl2*, and *Il1β* ($p < 0.05$ for all, Figure 1B) whereas levels of *Il10, Ifng,* and *Tnfa* did not differ. RRV-SPD mice also had decreased levels of the pro-fibrotic gene *Tgfb1* ($p = 0.03$). Flow cytometry analysis of CD45+ live cells demonstrated reduced frequency of MoM and increased MoM MHCII mean fluorescence intensity (MFI) in RRV-SPD vs RRV-SLN mice ($p < 0.001$ for both). In contrast, there were no significant differences in KC frequency or KC MHCII MFI between murine BA groups. Among other immune cell subsets, RRV-SPD had an increase in the proportion of neutrophils

($p < 0.001$) but no difference in the proportion of CD4+ or CD8+ T cells. **Conclusion:** Cumulatively, our data support the premise that SPD improves hepatic injury in murine BA by reducing hepatic inflammation and stimulating anti-inflammatory MHCII-positive MoM polarization. Ongoing studies will define the functional significance of SPD-driven changes in macrophage phenotype and immune cell networks. Findings from our work may support SPD as a potential therapeutic target in infants with BA.

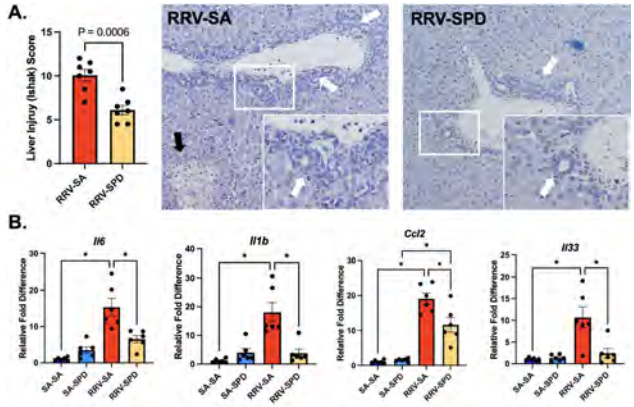

Figure 1. A. Histologic injury by Ishak Score is reduced in murine BA (RRV) mice treated with spermidine (SPD) vs saline (SA) at DOL12 (n=7 per group). H&E images show lower portal inflammatory infiltrate (white arrows) and reduced parenchymal necrosis (black arrow) in SPD-treated mice. **B.** Whole liver tissue gene expression shows significant reduction in the pro-inflammatory genes *Il6*, *Il1b*, *Ccl2*, and *Il33* after SPD treatment. *p<0.05 for multiple comparisons.

4620 | CHARACTERIZING COGNITIVE DEFICITS AND NEUROINFLAMMATION IN A NOVEL MOUSE MODEL OF PEDIATRIC TYPE C HEPATIC ENCEPHALOPATHY

Kathryn Rhodes[1] Juliet Venter[1] Jace Tyson[1] Mihika Patankar[1] Yubo Wang[1] Patrick Mireles[1] Brandy Routh[1] Kiersten Bell[1] Laura Fonken[1] Sharon DeMorrow[1], [1]The University of Texas at Austin

Background: Background: Hepatic encephalopathy (HE) describes the neurological deficits arising from liver impairment. Children with chronic liver disease are at a heightened risk for long term consequences of HE if an episode coincides with crucial neurodevelopmental periods. Little is known about the pathology of pediatric HE, nor the long-term consequences, due to a lack of a suitable rodent model of pediatric HE. The aim of the current work was to establish a rodent model of Type C HE in juvenile mice that will allow for the temporal assessment of the impact of an episode of HE on subsequent brain function. **Methods:** Methods: C57/Bl6 mice at postnatal day 14 were injected with 0.2 µL/kg (ip) CCl_4 or corn oil (vehicle) 3 times per week for 8 weeks. Blood ammonia was assessed to monitor liver function over time. Behavioral assessments for cognition, neuromuscular ability, balance, and learning and memory were performed during weeks 6 and 7 of treatment. Liver pathology was assessed via serum chemistries and standard histological assessments. Microglia morphology was visualized by Iba-1 immunoreactivity, and the number of glia, soma size and cellular complexity or branching of the cells were assessed. **Results:** Results: Blood ammonia levels were significantly increased in CCl_4-treated mice at all time points and markers of liver pathology were consistent with chronic liver disease. CCl_4-injected mice displayed i) hyperammonemia in brain tissue; ii) neuromuscular deficits (decreased grip strength and time and distance on the Rota-rod); iii) impairment in well-being (nest building assay); iv) deficits in balance and presence of ataxia (balance beam test); and v) impairment in learning and memory (novel object recognition). Furthermore, there was an increase in the number of microcroglia in the frontal cortex, cerebellum and hippocampus in both male and female mice after CCl_4 injection. Closer assessment of microglia morphology showed a significantly larger soma size and reduced branching, consistent with a reactive and amoeboid shape. **Conclusion:** Conclusions: Treatment of juvenile mice with CCl_4 resulted in impaired cognitive and neurological function, hyperammonemia and increased microglia reactivity. This model allows for further investigation of brain recovery patterns, impacts of HE on a developing brain, and pathology of pediatric HE.

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) comprises a heterogeneous group of rare autosomal recessive disorders characterized by cholestasis, which frequently progresses to end-stage liver disease and often requires liver transplantation. **Methods:** To describe the clinical and epidemiological profile, as well as the outcomes, of patients with PFIC undergoing liver transplantation in order to characterize this population. Retrospective descriptive study of patients with PFIC who underwent liver transplantation before the age of 18 between 2000 and 2025 at the Instituto da Criança (FMUSP). Data analyzed included clinical, genetic, surgical, and outcome information extracted from medical records. **Results:** Among 21 patients followed for PFIC, 15 underwent liver transplantation. Of those transplanted, 33% were male and 66.6% were diagnosed with PFIC type III. The mean ages at symptom onset and at transplantation were 23.7 and 70.9 months, respectively. Pre-transplant clinical manifestations included diarrhea (20%), growth retardation (33.3%), and pruritus (73.3%). After transplantation, the prevalence of diarrhea increased to 33.3%, while growth retardation showed improvement, with mean height z-scores changing from -2.23 before to -1.6 after transplantation. Regarding pre-transplant disease severity, 46.6% of patients were classified as CHILD B, with mean PELD/MELD and corrected PELD/MELD scores of 20.1 and 59, respectively. Cadaveric donors accounted for 73.3% of the transplants. The overall survival rate was 93.3%, with a current mean post-transplant survival of 149 months. Regarding complications, 93.3% of patients experienced at least one, with rejection being the most common (66.6%), classified as chronic (30%), acute (60%), and hyperacute (10%). Only 13.3% required retransplantation, and there was one recorded death in the cohort. **Conclusion:** This study demonstrates that liver transplantation significantly improves clinical conditions such as pruritus and growth retardation in patients with PFIC. Despite the high incidence of rejection, post-transplant survival is favorable, with a survival rate of 93.3% and an average follow-up of nearly 12 years. These findings support the efficacy of liver transplantation as a therapeutic option for this severe and progressive disease.

4622 | LIVER ELASTOGRAPHY IN PEDIATRIC PATIENTS WITH ALAGILLE SYNDROME RECEIVING MARALIXIBAT THERAPY: A REAL-WORLD SINGLE-CENTER STUDY

Aglaia Zellos[1] Paraskevi Galina[2] Evaggelia Lykopoulou[2] Zoi Chatzikonstantinou[3] Daphne Margoni[2] Angeliki Moudaki[2] Elissavet Georgiadou[2] Irini Batsis[1] Maria Rogalidou[4] Christina Kanaka-Gantenbein[1], [1]National and Kapodistrian University of Athens Medical School, Greece, [2]Agia Sophia Children's Hospital, Athens Greece, [3]Mitera Children's Hospital, Athens Greece, [4]Agia Sophia Children;s Hospital, Athens Greece

Background: Patients with Alagille syndrome (ALGS) exhibit progressive liver fibrosis. While Maralixibat, an ileal bile acid transporter (IBAT) inhibitor, has demonstrated efficacy in reducing pruritus and cholestasis in ALGS patients aged >2 months. However, its impact to disease progression and liver fibrosis remains to be characterized. Our aim is to assess the effectiveness of Maralixibat in cholestasis, and liver fibrosis in children with genetically confirmed ALGS and persistent cholestatic pruritus, managed at the Hepatology clinic of a single tertiary referral center. **Methods:** This prospective observational study included patients with ALGS receiving Maralixibat at an initial dose of 190 mcg/kg in week 1, followed by 380 mcg/kg daily. All patients had previously been treated with ursodeoxycholic acid, rifampicin, hydroxyzine, and fat-soluble vitamins, which were continued during the study. Pruritus assessment using the Itch(RO) questionnaire, liver biochemical parameters, and 2D shear wave liver elastography (2D-SWE) were performed at baseline and during follow-up. Elastography was performed by a single experienced pediatric radiologist using LOGIQ E9 and P9 US systems by GE Healthcare[â]. Metavir stage fibrosis corresponding to KPa pediatric cut offs (Galina et al. *Pediatr Radiol* 2021), as follows: 4.7 KPa (F1), 5.8 KPa (F2), 8.7 KPa (F3), 10.3 KPa (F4). **Results:** Seven children (4 females, 3 males; median age 8 years) received Maralixibat for a median duration of 18 months (range: 3–27 months). All had refractory severe pruritus at baseline, despite multidrug therapy. After treatment with Maralixibat, the median Itch(RO) score significantly decreased from 4.0 (IQR: 3.5–4.0) to 1.0 (IQR: 1.0–2.0) after treatment ($p = 0.026$). One patient was able to discontinue rifampicin and hydroxyzine following clinical improvement. Median serum bile acid levels declined

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significantly from 90.0 μmol/L (IQR: 72.5–107.5) from baseline to 48.8 μmol/L (IQR: 32.3–66.0) during follow-up ($p = 0.016$). Liver stiffness, measured by 2D SWE elastography, showed a decreasing trend from a median of 8.6 kPa (IQR: 7.4–15.0) to 7.2 kPa (IQR: 7.0–10.6), although the change was not statistically significant ($p = 0.116$), Figure 1. There was no progression of liver fibrosis in 5/7 patients. No serious liver-related events noted in 6/7 patients (1 patient with established cirrhosis, 2D-SWE 20 KPa, improved pruritus but underwent liver transplantation). No patient discontinued treatment due to adverse events.

Conclusion: In this real-world cohort study, children with ALGS who responded to Maralixibat and improved pruritus and serum bile acid levels, showed a favorable trend of decreasing values in liver elastography over time. Although the sample size is small, the effect of Maralixibat seems promising on mitigating disease progression and merits further investigation with recruitment of more patients and a longer follow-up period.

Figure 1. Liver elastography over time in patients with Alagille syndrome treated with maralixibat.

4623 | ROLE OF LIVER TRANSPLANTATION IN MANAGING PEDIATRIC ORGANIC ACIDEMIAS: A SINGLE-CENTER EXPERIENCE

Mohammad Shagrani[1] Kishwer Kumar[1] Alexandra Aldana[1] Ali Syed Akhtarul Hassan[1] Dalal Albogami[1] Sateesh Maddirevula[1] KRIS ANN MARQUEZ[2] Saleh Alqahtani[1] Bandar Mohammed H Aljudaibi[1] Massimo Malago[1] Dieter Broering[1], [1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital And Research Center, Riyadh Saudi Arabia

Background: Organic acidemias are a group of rare inherited metabolic disorders characterized by defects in the breakdown of amino acids, leading to the accumulation of toxic organic acids in the body. These metabolic imbalances can cause severe and life-threatening complications, including metabolic acidosis, developmental delays, and multi-organ damage.

Liver transplantation has emerged as a promising therapeutic option for certain organic acidemias. By replacing the defective liver with a healthy donor organ, transplantation can restore critical enzymatic activity, reduce toxic metabolite accumulation, and significantly improve clinical outcomes. This intervention has the potential not only to enhance metabolic stability but also to improve the quality of life and survival rates in affected patients. **Methods:** To evaluate the clinical indications, outcomes, and long-term benefits of liver transplantation in patients with organic academia (Propionic acidemia and Methymelanic academia), with the aim of determining the necessity and timing of transplantation as a definitive treatment to improve metabolic control and reduce disease-related complications. **Results:** Between 2011 and 2024, a total of 865 pediatric liver transplantations were performed at our center. Of these, 127 patients (14.7%) were diagnosed with metabolic disorders. Among the metabolic group, 35 patients underwent liver transplantation for Propionic Acidemia (PPA), and 4 patients were transplanted for Methylmalonic Acidemia (MMA).

In the PPA cohort, 46% were male and 54% female. All patients received living donor liver transplants, with 91% from living-related donors and 9% from unrelated donors. The median carnitine level before liver transplantation was 19 μmol/L (range 12.7–23), which decreased to a median of 9.9 μmol/L (range 7–11.2) after transplantation. From a complication standpoint, one patient developed hepatic artery thrombosis, another experienced a biliary leak, and one patient required re-transplantation. Acute cellular rejection (ACR) was reported in 9% of the PPA cases.

In the MMA group, 75% were female and 25% male. All patients underwent living donor liver transplantation from living-related donors. The median methylmalonic acid level prior to transplantation was 398 μmol/L (range 389–436), which reduced to a median of 106 μmol/L (range 106–177) post liver transplantation. No complications were observed in this group. Additionally, two domino liver transplants were successfully performed using explanted livers from MMA patients. **Conclusion:** Liver transplantation significantly improves metabolic control and clinical outcomes in pediatric patients with Propionic Acidemia and Methylmalonic Acidemia. The procedure is safe with manageable complications and offers a promising treatment option for these metabolic disorders.

4624 | LYMPHATIC INTERACTION WITH AND TRAFFICKING OF IMMUNE CELLS IS ALTERED IN CHOLESTASIS

Alyssa Goldberg[1] William Hollenbach[2] Beth Tamburini[2], [1]Children's Hospital Colorado, [2]University of Colorado, School of Medicine

Background: The liver lymphatic system supports organ health by draining interstitial fluid and immune cells to the lymph node. Patients with primary sclerosing cholangitis have increased lymphatic vessel density in the liver. These findings are replicated in murine models of cholestasis and are associated with increased immune cell infiltrate into the liver. Our study evaluates changes in immune cell populations in the liver and how they correlate with changes in trafficking of immune cells to liver draining lymph nodes. **Methods:** Using flow cytometry, we evaluate immune cell phenotypes in the liver and in liver draining lymph nodes of mdr2*(Abcb4)*-/- mice and correlated with histologic findings including liver injury and fibrosis. To evaluate how changes in immune cell populations correlate with transcriptional changes in the whole liver, we perform RNA extraction and RT-PCR on whole liver tissue from mdr2-/- mice. *In vitro*, we treat cells with pro-inflammatory cytokine IFNg and bile acid to evaluate lymphatic endothelial cells specific expression of markers of immune regulation including immune-checkpoints, and chemokines. **Results:** Liver lymphatics are expanded in a murine model of cholestasis and expansion is associated with an increase in activated T cells both in the liver and in the liver draining lymph node. However, notably while there are fewer Tregs in the liver of mdr2-/- mice, there are more Tregs in the liver draining lymph node. In whole liver PCR, we note an increase in expression of CCL21 and of PD-L1 important for lymphatic recruitment of immune cells and checkpoint inhibition of T cells, respectively. We also demonstrate upregulation of PD-L1 along with chemokines CXCL9,10&11 in lymphatic endothelial cells *in vitro* in response to treatment with IFNg and bile acids. **Conclusion:** This study demonstrates disruptions in immune cell drainage to the liver draining lymph nodes in cholestasis. Our *in* vitro data also suggests that the intrahepatic lymphatic endothelial cells are able to directly respond to the immune-rich and cholestatic environment. In turn, lymphatic endothelial cells may have increased expression of immune checkpoint molecules and chemokines to drive changes in immune cell within the liver by cell-cell signaling and trafficking through the lymphatics by chemokines. These changes in lymphatics may contribute to the liver inflammation and injury in cholestatic liver disease.

4625 | HEPATOBLASTOMA PATIENT-DERIVED ORGANOIDS, A TOOL FOR PERSONALIZED MEDICINE?

Elise Lelou[1] Abhishek Murti[1] Simon Bucher[1] Saphia Nguyen[1] Matthew Choi[1] Soo-Jin Cho[1] Amar Nijagal[1] Bruce Wang[1], [1]University of California, San Francisco

Background: Hepatoblastoma (HB) is the most common primary pediatric liver cancer. Among childhood tumors, HB has one of the highest mortality rates because 20% of HB cases are high-risk and result in death or require liver transplantation. Efforts to better characterize HB and identify high-risk cases of tumors have been hampered by the high heterogeneity within tumors. Improvement in HB treatment has been limited by the lack of model systems for high-risk HB. We recently used single-cell RNA sequencing to identify

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and characterize multiple tumor cell type signatures. We developed 3D-cultured Patient-Derived Organoids (PDO) from freshly resected HB and showed that they retain patient-specific features even after long-term culture. **Methods:** PDO lines from either HB cryopreserved or fresh tissues were cultured in 3D Matrigel droplets using HB growth media for up to 10 passages. Freshly isolated tumor cells and early and late passage (passages 4 and 10, respectively) PDO cells were characterized with single-cell RNA sequencing. The dataset was analyzed using Scanpy in Python. **Results:** We successfully developed 9 PDO lines out of 14 patient HB tumor tissues that can be maintained in 3D long-term culture after multiple passages. From fresh tissues, the success rate of PDO development is 77.78% (7 PDOs out of 9 tumor tissues). These PDO have distinct morphology from one patient to another that stays stable through multiple passages. Using single-cell RNA sequencing, we showed that PDO retain gene expression profiles similar to their freshly isolated parent tumor cells. Early and late passage gene expression profiles from the same patient PDO also remain similar and stable. **Conclusion:** Hepatoblastoma PDO lines grown in long-term 3D culture retain patient-specific features and cell subtypes from their freshly isolated parent tumor cells. This PDO model system will be used for the development of high-throughput drug screening on PDO grouped by HB tumor subtypes to target high-risk HB tumor cells.

4626 | CHARACTERIZATION OF THE USE OF ANTI-THYMOCYTE GLOBULIN (RABBIT) FOR ALLOGRAFT REJECTION IN PEDIATRIC LIVER TRANSPLANT RECIPIENTS: A SINGLE CENTER EXPERIENCE

Krupa Mysore[1] Dana Cerminara[2], [1]Baylor College of Medicine, [2]Texas Children's Hospital/Baylor College of Medicine

Background: Acute T-cell mediated rejection (TCMR) and antibody mediated rejection (AMR) can pose treatment related challenges in pediatric liver transplant (LT) recipients. Although corticosteroids are used to treat TCMR; children can develop steroid refractory TCMR (SRR). Untreated or recurrent rejection can lead to chronic rejection (CR). Rabbit anti-thymocyte globulin (rATG) is a polyclonal antibody that binds to cell surface antigens to cause T-cell depletion. Limited data exists for the use of rATG for allograt rejection in pediatric LT. We describe the use of rATG in Texas Children's Hospital (TCH), a large pediatric LT center. **Methods:** This study is a retrospective chart review of children aged 0-18 years who received deceased donor LT at TCH. We searched the electronic medical records for children who had for-cause liver biopsy for allograft rejection and received rATG between January 1, 2014 and December 31, 2024. During this period 383 patients underwent LT at TCH. Our center uses tacrolimus and methylprednisone for induction, and tacrolimus for maintenance immunosuppression. Patients received prophylaxis against opportunistic infections for 6 months after rATG treatment. **Results:** 23 patients received 25 courses of 1.5 mg/kg/dose rATG, median 6 doses per patient. Median age at LT was 29.5 months. Median time for rATG was 1.5 years post-LT. Indications for rATG included SRR (n = 14, 56%), AMR (n = 9, 36%), and CR (n = 2, 8%). In the SRR group, 13 patients (93%) had an improvement in ALT, while 10 (71%) had an improvement in GGT. In the AMR group, 9 patients (100%) had improvement both in ALT and GGT. All patients in AMR group also received concurrent antibody-directed therapies. Mean % improvement from baseline in ALT was 56 and 76, and GGT 50 and 98 at one and six months respectively after rATG (Figure 1). Mean absolute lymphocyte count was < 300/uL at end of rATG treatment. None of the patients had adverse events related to medication administration. Neither patient who received rATG for CR had biochemical improvements. Three patients ultimately died, two due to complications related to chronic rejection, and one due to worsening allograft function from biliary strictures and sepsis. **Conclusion:** We conclude that there is a good response to rATG in children with SRR and AMR after LT and is overall well tolerated.

4627 | THE FARNESOID X RECEPTOR REGULATES CIRCADIAN TRANSCRIPTION FACTOR EXPRESSION ALONG THE GUT-LIVER AXIS DURING PARENTERAL NUTRION

Colin Shearn[1] Aimee Anderson[1] Michael Devereaux[1] Ronald Sokol[2], [1]University of Colorado Anschutz Medical Campus, [2]University of Colorado School of Medicine

Background: We have developed a mouse model of Parenteral Nutrition Associated Liver Disease (PNAC) in which PN infusion results in liver injury and discordant expression of circadian regulatory genes (CR) between the ileum and liver. The aim of this study was to examine the effect of an Farnesoid X Receptor (FXR) agonist on PN-induced dysregulation of ileal and hepatic CR genes, FXR signaling and bile acid homeostasis. **Methods:** WT mice were exposed to continuous soy oil lipid emulsion PN infusion +/- the FXR agonist GW4064 (30mg/kg/d) through a central venous catheter for 4d. Water was provided ad libitum, but no nutrients were provided enterally. On d4, mice were sacrificed at 7AM, and serum, ileal and hepatic tissue obtained. From tissue samples, mRNA expression of CR genes, FXR signaling and gut permeability were assessed. In primary hepatocytes, the impact of an FXR agonist on CR gene expression was determined. **Results:** Administration of 4d PN increased hepatic injury and inflammatory cytokine expression which was ameliorated by GW4064. In the liver, GW4064 treatment increased expression of *Nr1d1* corresponding to suppression of *Nr1f1*, *Nfil3* and *Bmal*. In addition, GW4064 increased expression of *Nr0b2*, prevented PN-dependent increases in *Nr5a2* and *Abcg5* but had no effect on *Abcb11*, *Abcc2*, *Cyp7a1*, *Cyp7b1*, *Cyp8b1* or *Cyp27a1* mRNA expression. In the ileum, GW4064 increased *Nfil3* and *Bmal* and suppressed *Per2* mRNA expression but had no additional effect on FXR target genes *Fgf15*, *Nr0b2*, *Slc51a* (OSTa), *Slc10a2* (ASBT) which were already increased by PN. Activation of FXR restored normal gut permeability by normalizing *Ocln* and *Cldn1* expression. Interestingly, compared to the PN only group, GW4064+PN increased ileal FXR expression suggesting that agonist driven FXR activation prevents PN-induced feedback inhibition of FXR expression. Supporting *in vivo* data, in mouse primary hepatocytes, treatment with obeticholic acid (OCA) for 24hr increased Nr1d1 expression, Fxr binding to the *Nr1d1* promoter and Bmal binding to the *Nr1h4* (FXR) promoter with corresponding decreased Bmal expression. **Conclusion:** Dysregulation of CR machinery is partly due to uncoupling of the gut-liver circadian axis. FXR activation ameliorates PN-induced hepatic injury, gut permeability and restores *Nr1d1* expression. Thus, FXR is a direct regulator of CR transcription factor expression and the use of FXR agonists as a mechanism for restoring normal gut-liver CR expression deserves further investigation.

4628 | EFFECT OF GENERAL ANESTHESIA ON LIVER AND SPLEEN STIFFNESS MEASUREMENTS FOR PREDICTING HIGH-RISK VARICES IN CHILDREN WITH BILIARY ATRESIA

Shinya Yokoyama[1] Takashi Honda[1] yoji ishizu[1] Norihiro Imai[2] Takanori Ito[1] Kenta Yamamoto[1] Chiyoe Shirota[1] Takahisa Tainaka[1] Satoshi Makita[1] Masanao Nakamura[1] Hiroo Uchida[1] Hiroki Kawashima[1], [1]Nagoya University, [2]Nagoya University Graduate School of Medicine

Background: In biliary atresia (BA), portal hypertension and esophagogastric varices (EGVs) can develop even after Kasai portoenterostomy (KP). Early identification of high-risk varices (HRVs) is crucial to prevent variceal bleeding. Two-dimensional shear wave elastography (2D-SWE) enables noninvasive assessment of liver stiffness (LS) and spleen stiffness (SS), which are useful surrogates for portal hypertension. However, in young children, measurement conditions are often unstable due to inability to cooperate with breath-holding and movement artifacts caused by crying. This study evaluated whether performing LS and SS measurements under general anesthesia improves diagnostic accuracy for HRVs in children with BA. **Methods:** Subjects were prospectively enrolled patients with biliary atresia (BA), aged $\leq$15 years, who had undergone Kasai portoenterostomy (KP) and were scheduled for screening esophagogastroduodenoscopy (EGD). LS and SS were measured using 2D-SWE in both the awake and anesthetized states. HRVs were defined based on specific endoscopic findings. Diagnostic performance was assessed using receiver-operating characteristic (ROC) curves and area under the curve (AUC). Correlation between awake and anesthetized values was analyzed using Spearman's rank correlation coefficient. **Results:** Among 39 patients analyzed, The majority of cases (35 cases, 89.7%) had preserved liver function classified as Child-Pugh A. No patients with poor liver function (Child-Pugh C) were included. Girls accounted for 66.7% (26 cases) of the study population. HRVs were identified in 19 (48.7%). The median age was 4 years. In the HRVs group compared with the non-HRVs group, awake-LS, awake-SS, and anesthesia-LS were significantly higher: 2.23 vs. 1.81, 4.40 vs. 3.46, and

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

2.56 vs. 1.79 m/s, respectively. Anesthesia-SS did not show a significant difference between the two groups (4.13 vs. 3.67 m/s, P = 0.112). The area under the curve (AUC) for awake-LS, awake-SS, and anesthesia-LS were 0.757, 0.775, and 0.797, respectively. Awake-LS and anesthesia-LS showed a strong positive correlation (ρ = 0.881), while awake-SS and anesthesia-SS had a weak one (ρ = 0.422). **Conclusion:** Awake LS, awake SS, and anesthesia LS all demonstrated good predictive accuracy for HRVs in children with BA. However, SS measured under general anesthesia showed greater variability and reduced predictive value. These discrepancies may be attributed to changes in circulatory dynamics associated with anesthetic agents or mechanical ventilation. Further studies are warranted to evaluate whether LS and SS measurements under mild sedation provide more reliable values compared to those obtained in the awake state in the pediatric population.

Correlation coefficient of measurements between awake and anesthetized states for (a) liver stiffness and (b) spleen stiffness

4629 | ELEVATED BILE ACIDS DECLINE AFTER SURGICAL LIGATION OF EXTRAHEPATIC CONGENITAL PORTOSYSTEMIC SHUNT

Lisa Keys[1] Riccardo Superina[1], [1]Ann and Robert H. Lurie Children's Hospital of Chicago

Background: Congenital portosystemic shunts (CPSS) are rare vascular malformations in which mesenteric venous circulation is shunted bypassing the liver. This may result in impaired hepatic clearance of bile acids. We postulate that restoration of portal blood to the liver results in improved clearance of serum bile acids. This study assesses pre-and post-operative bile acid levels to determine the metabolic impact of surgical intervention in pediatric patients with CPSS. **Methods:** Electronic medical records of children diagnosed with CPSS were reviewed at a single pediatric hospital. Demographic and clinical information were collected. Those with available with pre- and post-op total serum bile acid levels between July 1, 2023, and January 21, 2025, were selected for inclusion in the analysis. A paired t-test was performed to compare pre-operative and post-operative levels. Statistical significance was defined as $p < 0.05$. Analysis was conducted using R (4.3.1). **Results:** Seven children were included in our study. The mean age at surgical treatment was 6.5 years (± 5.15). Pre-operative total serum bile acids were elevated with a mean value of 101.7, ±69.9 (reference range ≤ 6.8 umol/L). Post-operative total serum bile acids decreased to mean 10.1, ± 9.3). This decrease was statistically significant: $t(6) = 2.99$, $p < 0.024$, with an effect size of -1.66 (Cohen's d). Four (57%) patients achieved decreased levels to normal levels after ligation while 3 (43%) patients achieved a decrease in total serum bile acid after surgical ligation but not within the reference range. **Conclusion:** Total serum bile acids significantly decreased following surgical closure of CPSS ($p < 0.024$) where 4/7 patients achieved normalization and 3/7 patients achieved an improvement. This finding supports the role of surgical intervention in restoring hepatic bile acid metabolism and mitigating systemic effects of shunting. Prior studies have largely focused on anatomical correction, with limited data on metabolic recovery; our findings help fill this gap. Future studies should explore long-term bile acid trends and the utility of bile acids as a biomarker for post-operative monitoring.

4630 | HEPATIC PARENCHYMAL RESPONSE TO INTERFERON GAMMA IN MOUSE MODEL OF FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

Tamir Diamond[1] Michelle Lau[2] Sara Hughes[1] Sarah Mccuaig[1] Niansheng Chu[1] Em Elliott[1] Portia Kreiger[1] Edward Behrens[1], [1]The Children's Hospital of Philadelphia, [2]The Children's Hospital of Phaildelphia / Rowan Medical School

Background: Hepatic inflammation is a common feature of Hemophagocytic Lymphohistiocytosis (HLH). In the mouse model of familial HLH (FHL) hepatic tissue response to interferon gamma (IFNg) results in hepatocellular injury, endotheliitis and increase in CD8+ effector T-cell and CD11b+/Ly6C^{hi} inflammatory monocyte (iMonos) infiltration. However, which parenchymal population responding to IFNg contributes to liver injury in FHL remains unknown. We hypothesized that parenchymal cells- hepatocytes, liver sinusoidal endothelial cells (LSEC) and Kupffer Cells (KC), are the main responders to IFNg perpetuating liver injury in FHL. To test this we conditionally deleted the IFNg receptor (IFNgR) in hepatocytes and LSECs in the perforin 1 deficient (*Pf1-/-*) FHL model and performed in vitro assays assessing KC response to IFNg. **Methods:** For in vivo experiments *Prf1-/-* mice were crossbred to IFNgR floxed mice and then crossbred with a conditional hepatocyte (HepΔIFNgR) or endothelial (LSECΔIFNgR) knock-out (KO) using albumin-cre and Ve-cadherin-cre mice respectively. *Prf1-/-* IFNgR WT *(Prf-/-)*, HepDIFNgR and LSECDIFNgR were infected with Lymphocytic Choriomeningitis Virus (LCMV) to induce FHL physiology according to established protocols. Immunophenotyping was done by histological assessment, biomarkers of hepatocyte injury, serum cytokines and flow cytometry. To assess Kupffer Cell (KC) response to IFNg as part of pathogenesis of liver injury, IFNg unresponsive hepatocytes and KC that were either IFNg responsive (KC WT) or unresponsive (KC ΔIFNgR) were isolated. Cells were cultured for 48 hours with 10ng/mL of IFNg in media and viability of hepatocytes was measured using DAPI by flow cytometry. **Results:** LSECΔIFNgR mice had smaller liver (Figure 1A) and spleen size (Figure 1B) compared to *Prf-/-* with trend of reduction of hepatocellular (ALT) (Figure 1C) and vascular injury (LDH) (Figure 1D) that were not statistically significant. There were no differences between *Prf-/-*, HepΔIFNgR and LSECΔIFNgR in serum cytokines, population of infiltrating lymphocytes or degree of liver injury histologically. LSECΔIFNgR mice had less anemia accompanied by reticulocytosis (Figure 1E and F). This could be secondary to LSECΔIFNgR affecting all endothelial cells rather than a LSEC-bone marrow physiology but requires further studies. IFNg treated hepatocytes co-cultured with KCΔIFNγR tended to have higher viability (Figure 1G). **Conclusion:** There is minimal contribution of the hepatocyte and LSEC response to IFNg in murine FHL hepatitis. In vitro assays suggests a contribution of IFNg responsive KC to hepatocellular injury in FHL. Therefore, further studies focusing on the KC response to IFNg will be beneficial in further delineating the pathophysiology of FHL hepatitis.

Background: The elimination of hepatitis C virus (HCV) infection as a public health threat according to goal established by the World Health Organization, is impossible to achieve without micro-elimination in children. The pediatric population gained the opportunity to be treated with direct-acting antivirals much later than adults so knowledge and experience in this area is modest. Our study aimed to analyze the use of glecaprevir/pibrentasvir (GLE/PIB), one of the pangenotypic options recommended in children, which provides the shortest possible duration of therapy. **Methods:** All consecutive children treated with 8-weeks GLE/PIB regimen for chronic HCV infection between 2022 and 2024, whose data were collected retrospectively through the Epi-2-Ped national multicenter database, were included in the analysis. **Results:** The study population consisted of 42 patients with a median age of 10.5 years, predominantly girls (61.9%) divided into age ranges of 3-5 years, 6-11 years and 12-18 years, comprising 6, 16 and 20 patients, respectively. More than 70% of all children were in the reference weight range according to the BMI-for-age percentile, obesity was diagnosed only in the oldest group in as many as 25% of children. Other comorbidities were present in two patients, renal disease and bronchial asthma. All children were treatment-naïve, nearly half of them (47.6%) were infected with genotype 1b, which was the most common in each age group. The advancement of liver disease by non-invasive elastography was assessed in 36 children, with half of them showing no fibrosis (18/50%). Eight-weeks GLE/PIB therapy was completed in all patients as planned, and the cure rate calculated in the per-protocol population was 100% (39/39). Three girls were considered lost to follow-up, one from the 6-11 age range and two from the oldest group. Adverse events were rare and mild, occurring in 4 children, only in the oldest age group. **Conclusion:** Eight-week GLE/PIB therapy in children is well tolerated and highly effective in all age ranges and regardless of gender. Its use in routine clinical practice will bring the ambitious goal of eliminating HCV worldwide a step closer.

4632 | DIAGNOSTIC YIELD OF LIVER BIOPSY VS. GENETIC TESTING IN CHILDREN

Ashraf Alsahafi[1] Salma Almadani[1] Tahani Asiri[1] Jumanah Abdulaziz[1] Mohammad Hasosah[1], [1]King Abdullah Specialized Children Hospital

Background: Liver biopsy and genetic testing are essential tools for evaluating patients with liver disease. However, their diagnostic yield and contributions may vary by age group. This study aims to describe liver diseases in infants (≤ 1 year) compared to children (> 1 year) and to compare the diagnostic utility of liver biopsy and genetic testing in each group. **Methods:** This retrospective study included pediatric patients who underwent liver biopsy and genetic testing for suspected liver disease at King Abdulaziz Medical City, National Guard Hospital, Jeddah, Saudi Arabia. Descriptive statistics were used to summarize the findings and compare the age groups. **Results:** All infants (16) had abnormal liver biopsy findings, and genetic testing was positive in 68.8%. The most common final diagnoses were genetic/metabolic liver disease (37.5%), followed by biliary atresia, hematologic liver disease, and idiopathic liver disease, which occurred with equal frequency (12.5%). The most frequent biopsy pattern was cholestatic (37.5%), followed by neonatal giant cell hepatitis (31.3%) and biliary cirrhosis (12.5%). Jaundice was the most common presenting symptom (81.25%).

In the children group (30), liver biopsy revealed abnormal findings in 90%, while genetic testing showed positive results in 70%. The most frequent diagnosis was genetic/metabolic liver disease (26.7%), followed by infectious liver disease and malignancy (10%). Biopsy findings revealed chronic hepatitis (20%), followed by fatty liver and granulomatous/infectious diseases at similar percentages (13.3%). The majority were asymptomatic with laboratory/imaging abnormalities (46.66%), followed by hepatomegaly (30%) and jaundice (16.7%).

Jaundice was significantly more common in infants compared to asymptomatic presentations in children ($P = 0.001$). There was no significant difference between age group regarding the positivity of genetic testing ($P = 0.93$). Among all patients who underwent liver biopsy and genetic testing, 93.5% had abnormal liver biopsy findings, and 67.4% of these also had positive genetic testing results ($P = 0.236$). See figure **Conclusion:** Liver biopsy and genetic testing are complementary and provide significant insights into the evaluation of pediatric liver disease. Although clinical presentations

4633 | EFFICACY OF CUSTOMIZED STEROID BASED PROTOCOL IN POST KASAI- BILIARY ATRESIA

Anmol Anmol[1] Seema Alam[2] Rajeev Khanna[3] Vikrant Sood[3] Bikrant Biharilal Raghuvanshi[4], [1]Institute of liver and biliary sciences/trainee, [2]Professor, [3]additional professor, [4]associate professor

Background: Role of steroids as adjunct therapy for improving post kasai portoenterostomy outcomes of biliary atresia remains controversial. **Methods:** In this analysis 122 infants with biliary atresia who underwent Kasai surgery at our centre were included. Post-operatively three persistent pale stool on three consecuitive days was considered as marker of poor biliary drainage and steroid was administered as per protocol at 3mg per kg orally and gradually tapered off over period of 6 weeks. Analysis of successful biliary drainage after portoenterostomy (defined as serum bilirubin <2mg/dL) was primary endpoint. **Results:** 122 patients (65 vs 57 in Steroid group (SG) vs Historical cohort (HC)) where 66% were boys. The age at Kasai was 79 versus 80 days ($p=0.075$), total bilirubin was 9.7 versus 9.9 mg /dl ($p=0.371$), albumin was 3.7 versus 3.5 g% ($p=0.003$) and LSM was 12.3 kPa versus 26.25 kPa ($p=0.001$) in the SG versus HC respectively. Jaundice clearance rate was seen in 60% in SG vs 43% in HC ($p=0.146$).The jaundice cleared in 66 days versus 80 days in SG versus HC ($p=0.223$). The NLS was comparable in both the groups. The median values of age at Kasai was 77 versus 81 days ($p=0.017$), total bilirubin was 9.9 versus 9.5 mg /dl ($p=0.319$), albumin was 3.89 versus 4 g% ($p=0.682$) and LSM was 10.9 kPa versus 16.1 kPa ($p=0.036$) in the SG successful versus SG unsuccessful respectively. Amongst the 20 SG successful group below 70 days the jaundice clearance rate was 75%. **Conclusion:** Lower age at Kasai and LSM were significantly associated with jaundice clearance. Jaundice clearance rate is significantly higher among those who received steroids and had age at Kasai below 70 days.

4634 | IMPACT OF CONCURRENT EXTRAHEPATIC AUTOIMMUNE DISORDERS ON OUTCOME OF PEDIATRIC AUTOIMMUNE LIVER DISEASE

Anmol Anmol[1] Rajeev Khanna[2] Seema Alam[3] Vikrant sood[2] Bikrant Biharilal[4], [1]Institute of liver and biliary sciences/trainee, [2]Additional professor, [3]professor, [4]associate professor

Background: Concurrent extrahepatic autoimmune disorders (CEAID) are present in 21-48% of pediatric autoimmune liver disease (AILD). There is controversial evidence of the effect of CEAID or celiac disease on long-term outcome of AILD. In view of limited data from Indian subcontinent, we aimed to study the prevalence of CEAID and its effect of outcome of AILD. **Methods:** All consecutive patients under-18 year of age with a diagnosis of autoimmune hepatitis (AIH) or autoimmune sclerosing cholangitis/overlap (ASC/overlap) were studied retrospectively. Presence and proportion of various CEAIDs were studied. Outcome was studied in terms of survival with native liver (SNL) or death or liver transplantation (LT). **Results:** There were 230 patients (124 girls), mean age 10.3 $\pm$ 4.3 years with AILD. Prevalence of CEAID was 40.4%. Autoimmune hemolytic anemia (60.2%), celiac disease (19.4%), inflammatory bowel disease (7.5%), hypothyroidism (4.3) were the common CEAIDs. CEAID was not associated with type of AIH, ASC/overlap or antibody positivity ($p=$ NS). Poor outcome (death or LT) was seen in 36 (16.9%) of 212 children on follow-up and was unrelated to the presence of CEAID. On subgroup analysis, celiac disease was the only CEAID which was associated with poor SNL (HR = 3.422; 95% CI 1.396-8.391, $p=0.012$). **Conclusion:** CEAID are present in 40% of pediatric AILD. Celiac disease, but not other CEAID, is associated with poor SNL in children with AILD.

4635 | OUTCOMES IN CHILDREN WITH BILIARY ATRESIA POST LIVER TRANSPLANT AT A HIGH VOLUME PAEDIATRIC LIVER TRANSPLANT CENTRE

Mohammad Shagrani[1] Kishwer Kumar[2] Alexandra Aldana[2] Ali Syed Akhtarul Hassan[2] Dalal I Albogami[2] Sateesh Maddirevula[2] Saleh Alqahtani[2] Bandar Mohammed H Aljudaibi[2] Massimo Malago[2] Dieter Broering[2], [1]King Faisal Specialist Hospital and Research Centre, [2]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia

Background: Liver transplant (LT) has played a significant role in improving outcomes of children with Biliary Atresia. In Saudia Arabia, the lack of centralisation and awareness often leads to delays in presentation. There is no data on outcomes of post-transplant patients with biliary atresia in Saudi Arabia. We aim to analyse our short and medium term outcomes post liver transplantation. **Methods:** We performed a retrospective analysis of medical records of those patients that were transplanted for biliary atresia between 2011 - 2024. Demographic data were collected and tabulated. Complications rates were analysed. **Results:** Between January 2011 and December 2024 we performed a total of 845 liver transplants, of which 116 were for Biliary Atresia.

Of these, Isolated BA was 88% (n = 90) and Syndromic Biliary Atresia (22%, n = 26). Majority were living related, 92% (with no donor mortality), Cadaveric 8% and Domino transplantation 3%. Recipients post-operative surgical complications consisted of hepatic artery thrombosis (1%, n = 2), Biliary strictures (10%, n = 12), Portal vein thrombosis (12%, n = 14), Hepatic vein stenosis (1.7%, n = 2). Retransplantation was performed in 2 patients. Two patients died in the early post operative period, due to TMA and uncontrolled bleeding. Sepsis was the most common cause of mortality in patients at peripheral hospitals. The 1, 5 and 10 year patient survival rates were 97%, 96% and 93% respectively. **Conclusion:** Liver transplant outcomes among patients with BA are excellent in Saudia Arabia. There is a need to improve our network structure to post transplant patients living in remote and rural areas. Moreover, introduction of centralisation of care will certainly improve outcomes.

4636 | CLINICAL AND GENETIC CHARACTERIZATION OF CHILDREN WITH SEVERE OBESITY: ASSOCIATIONS WITH MAFLD/MASH

Cherise Ali[1] Wikrom Karnsakul[2] Ann Scheimann[1], [1]Johns Hopkins University School of Medicine, [2]Johns Hopkins University

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) is the most common cause of pediatric liver disease with links to insulin resistance and early obesity. Those with syndromic or monogenic obesity with abnormal insulin signaling, hyperphagia, and severe obesity may be at greater risk for liver disease. This study evaluates the relationship between genetic variants and liver involvement in a broad pediatric cohort with severe early-onset obesity using the Prevention Genetics Uncovering Rare Obesity (PGURO) genetic screening panel. **Methods:** IRB-approved retrospective data collection in children with BMI $\geq$97th% with genetic screening with PGURO panel. Patients were divided into two groups based on abnormal liver findings. GraphPad Prism software was used to conduct statistical comparisons between groups using t-tests or Mann-Whitney U tests for continuous variables and Fisher's exact tests for categorical variables, as appropriate. **Results:** Data from 46 children was collected. Group 1 (abnormal liver) (n = 28) had higher mean age (6.5 $\pm$ 3.4 vs. 5.3 $\pm$ 2.9yrs,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

$p = 0.08$), male sex (82% vs 26%, $p < 0.001$), and white ethnicity (45% vs. 9%, $p = 0.027$). Transaminases were elevated in Group 1 (AST: 42IU [24.5–67.5] vs. 21IU [19.0–24.0], ALT: 68IU [32.0–98.0] vs. 20IU [14.5–24.5]; $p < 0.001$ for both). Comorbidities (obstructive sleep apnea (OSA), prediabetes, type 2 diabetes (T2DM), and hyperlipidemia) and gene variants were higher in Group 1 vs. Group 2 ((OSA: 57% vs. 56%; prediabetes: 36% vs. 17%; T2DM: 25% vs. 6%; hyperlipidemia 43% vs. 17%), (BBS1: 32% vs. 17%), (BBS9: 29% vs. 11%), (ALMS1: 21% vs. 6%), (PCSK1: 18% vs. 6%), (MC4R: 18% vs. 0%)), but there was no statistical significance (all $p > 0.1$). In total, 24 of 46 patients (52%) had findings of hepatomegaly with higher prevalence in Group 1 (20/28) vs. Group 2 (4/18) which was statistically significant ($p < 0.01$). **Conclusion:** Children with severe obesity and liver involvement (MAFLD/MASH) demonstrated expected higher aminotransferases accompanied by initial findings of PGURO screening variants though current genetic screening results were not significant likely due to sample size. Further study is warranted to ascertain whether PGURO screening should be incorporated into evaluation of obese children with liver disease.

Background: Variants in Adenosine Triphosphate-binding Cassette, subfamily B, member 4 (ABCB4) lead to decreased functional expression of multidrug resistance protein (MDR3), leading to a spectrum of genetic cholestatic disorders ranging from mild cholestasis to biliary cirrhosis with portal hypertension (PHTN). The study objectives were to describe the clinical and biochemical characteristics, genotype, and their correlation with phenotype and outcomes of patients with ABCB4 variants. **Methods:** Clinical, biochemical, histological, and follow-up data were collected from a national registry of genetic intrahepatic cholestasis. All children (0- 18 years) with clinical cholestasis and homozygous, compound heterozygous, and heterozygous variants in ABCB4 were included. The genotype was classified as mild (heterozygous missense), moderate (heterozygous protein-truncating mutation (PTM), biallelic missense variants), or severe (biallelic PTM, compound heterozygous PTM and missense). Outcome was defined as native liver survival (NLS), death, or liver transplantation (LT) at the most recent follow-up. **Results:** ABCB4 variants were the second most common variant (108/448, 24.1%), leading to genetic intrahepatic cholestasis in the registry (23 centres). These included 68 homozygous, 24 compound heterozygous, and 16 heterozygous patients. Variants were classified as mild in 13 (12%), moderate in 50 (46%), and severe in 45 (41.7%). Jaundice was the most common clinical presentation, affecting 90 (83.3%), with the median age of onset being 36 months (IQR: 11.8 - 66). 34 (31.5%) completely cleared their jaundice with ursodeoxycholic acid. Pruritus developed in 66 (61.1%), with 18 having pruritus refractory to medical therapy. 47 (43.5%) developed ascites at a median age of 66 months (IQR: 48 – 120). Clinically evident PHTN (CEPH) was present in 69 (63.9%), while 20 (18.5%) had variceal bleed. Nine (8.3%) died, 38 (35.2%) received LT, while 61 (56.5%) were surviving with their native liver at a

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

median age of 60 months (IQR: 35.3 – 108). The majority of patients had been listed for LT due to ascites (37, 82.2%), persistent jaundice (25, 55.6%), and uncontrolled PHTN (24, 53.3%). The median age at death and LT were 73 (IQR: 55 – 83.5) and 79 (59.8 – 144) months, respectively. Severe genotype (adjusted OR: *5.89, 95% CI: 2.01–17.25, p = 0.001)*, variceal bleed (adjusted OR: *4.32, 95% CI: 0.93–20.11, p = 0.062)*, pruritus (adjusted OR: 3.22, 95%CI: 1.07–9.72, p = 0.038), and high bilirubin (adjusted OR: *1.11, 95% CI: 1.01–1.22, p = 0.025)* at the latest follow-up were independent predictors of poor outcome on logistic regression analysis. **Conclusion:** ABCB4 variants are a common cause of genetic intrahepatic cholestasis in children. Around 44% of children die or receive LT by a median age of 79 months. Genotype (presence of ≥1 PTM), variceal bleed, presence of pruritus, and persistent high bilirubin are predictors of poor outcome.

Univariate and Cox multivariate regression analysis to identify the predictors of outcome in patients with ABCB4 (MDR3) variants (Good outcome: Survival with native liver; Poor outcome: Death or Liver transplantation):

Parameter	Poor Outcome (n = 47)	Good outcome (n = 61)	Significance (non-parametric) p value	Logistic regression analysis (Odds ratio, 95%CI), p value
Genotype categorization			<0.001	*Severe vs other genotypes: aOR: 5.89 (2.01 – 17.25), p = 0.001*
Mild	2 (4.3%)	11 (18%)		
Moderate	15 (31.9%)	35 (57.4%)		
Severe	30 (63.8%)	15 (24.6%)		
Gender				*
Male	28 (59.6%)	34 (55.7%)	0.700	
Jaundice	45 (95.7%)	45 (73.8%)	0.003	*
Age at onset of jaundice (months)	42 (21.5 – 66)	24 (6 – 66)	0.034	Not significant in LRA
Pruritus	34 (%)	32 (%)	0.047	3.22 (1.07 – 9.72), p = 0.038
Age of onset in pruritus (months)	30 (14.3 – 48.5)	23.5 (10.3 – 57.5)	0.339	*
Ascites	42 (89.4%)	5 (8.2%)	< 0.001	*
Age at onset of ascites (months)	67 (46.5 – 120)	66 (47 – 107.5)	0.945	*
CEPH	46 (97.9%)	23 (37.7%)	<0.001	*
Variceal Bleed	15 (31.9%)	5 (8.2%)	0.002	*4.32 (0.93 – 20.11), p = 0.062*
Bilirubin (mg/dl)	6.6 (3.7 – 15.8)	3 (1.2 – 6.1)	< 0.001	*1.11 (1.01 – 1.22), p = 0.025*
INR	1.5 (1.21 – 2.2)	1.13 (1.03 – 1.3)	<0.001	Not significant in LRA

4638 | ◆ DECODING CILIARY DYSFUNCTION IN HEPATOBILIARY DEVELOPMENT: MECHANISTIC INSIGHTS INTO BILIARY ATRESIA PATHOGENESIS

Prasanna Ramachandran[1] Wolfram Goessling[2], [1]Boston Children's Hospital, [2]Massachusetts General Hospital/Harvard Medical School

Background: Biliary atresia (BA) is a life-threatening pediatric liver disease marked by progressive bile duct obstruction, liver fibrosis, and eventual failure. Despite being the leading indication for pediatric liver transplantation, the underlying mechanisms of BA remain poorly understood. Emerging evidence suggests primary cilia – vital organelles for cellular signaling – play a critical role in liver development and biliary epithelial cell (BEC) integrity. Aberrations in cilia-associated pathways, including Hedgehog (Hh), Wnt, and Notch, have been implicated in BA pathogenesis. Notably, pathogenic variants in ciliary genes occur in over 30% of BA patients, and liver-specific knockout of the ciliary gene polycystin-1-like 1 (*PKD1L1*) replicates features of BA in a mouse model. How *PKD1L1* deficiency disrupts ciliary function and hepatobiliary development is unknown. **Methods:** To investigate the role of primary cilia in hepatobiliary development, we employed a zebrafish (*Danio rerio*) model, leveraging its conserved liver development pathways and optical clarity allowing for direct visualization of early hepatobiliary development *in vivo*. We performed morpholino-mediated knockdown of *pkd1l1* and confirmed dose-dependent effects. We employed high-resolution spinning-disk confocal microscopy to visualize phenotypic consequences on hepatobiliary structures using transgenic reporters (*fabp10a:CFP* labeling hepatocytes; *tp1:GFP* labeling BECs). We also visualized ciliogenesis and ciliary architecture using a cilia-specific reporter (*arl13:GFP*), and measured transcriptional responses to *pkd1l1* deficiency by qRT-PCR from dissected livers. **Results:** Knockdown of *pkd1l1* resulted in severe hepatobiliary malformations, including a 60% reduction

in BEC density, fragmented biliary networks, and a 2.1-fold expansion in hepatocyte populations, mimicking the cholangiopathy observed in BA (Figure 1). High-resolution imaging revealed significant structural disorganization and misorientation of cilia in *pkd1l1*-deficient BECs. Transcriptomic analysis confirmed aberrant Hh signaling activation (Figure 2). These findings directly link ciliary dysfunction to disrupted biliary tree development. **Conclusion:** Our study highlights the pivotal role of primary cilia in maintaining hepatobiliary integrity and elucidates how *pkd1l1* deficiency amplifies Hh signaling to drive biliary dysmorphogenesis. By pinpointing specific mechanisms underlying BA pathogenesis, these results lay the groundwork for targeted therapies aimed at mitigating ciliary-driven bile duct damage in pediatric patients. Ongoing efforts, including single-cell and spatial transcriptomic analyses, aim to further dissect intrahepatic and extrahepatic gene expression changes in *pkd1l1*-deficient livers.

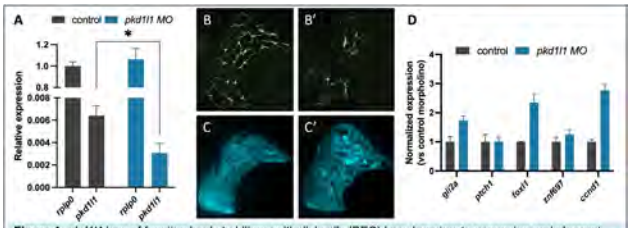

Figure 1. *pkd1l1* loss of function leads to biliary epithelial cells (BEC) loss, hepatocyte expansion and aberrant Hedgehog signaling. **A**: *pkd1l1* morpholino (MO) knockdown in dissected livers at 72 hours post-fertilization (hpf) validated by qPCR. *rplp0* internal control. Plotted mean +/- SD of 3 independent trials, 10 livers per genotype per trial. * P<0.05. **B-B'**: Decreased BECs and network density in *pkd1l1* MO compared to control MO. BECs marked by *lp1:mCherry*. **C-C'**: Hepatocyte expansion, increased liver volume in pkd1l1 MO relative to control MO. Hepatocytes marked by *fabp10a:cfp*. B-C: Dual-tagged reporter fish were imaged at 96 hpf. D: **D**: Hedgehog (Hh) signaling is activated in *pkd1l1*-deficient livers. Hh-responsive transcription factor *gli2a* and transcriptional targets *ptch1*, *foxl1*, *znf697* and *ccnd1* were assayed by qRT-PCR from dissected livers of control and *pkd1l1* morpholino (MO)-injected embryos at 120 hpf. Plotted mean +/- SD from 2 independent trials, 10 livers per genotype per trial.

4639 | ◆ CARDIOMEMS PULMONARY ARTERY PRESSURE MEASUREMENTS ARE ASSOCIATED WITH CONGESTIVE HEPATOPATHY IMAGING FINDINGS

Chelsea Pan[1] Liviu Klein[1] Shweta Motiwala[1] Jin Ge[2], *[1]University of California, San Francisco, [2]University of California, San Francisco*

Background: Hepatic congestion is an asymptomatic sequelae of right ventricular dysfunction that is often first recognized on abdominal imaging. CardioMEMS is an implantable pulmonary artery pressure (PAP) sensor used in the management of chronic heart failure (HF). In this hypothesis generating study, we evaluated whether pulmonary artery diastolic (PAD) pressure measured by CardioMEMS is associated with imaging findings consistent with hepatic congestion. **Methods:** We analyzed 43 patients with HF and CardioMEMS at the University of California, San Francisco. We extracted all structured clinical and demographic variables, abdominal imaging available, and average PAD pressure over 6 months prior to abdominal imaging. We annotated imaging reports with the number of findings that may be suggestive of congestive hepatology (defined as hepatomegaly, splenomegaly, dilated hepatic veins, dilated inferior vena cava, heterogeneous enhancement, increased echogenicity, and ascites). We used multivariable logistic regression (adjusted for age, gender, race/ethnicity, HF etiology, left ventricular ejection fraction (LVEF), and MELD-XI score) to associate PAD pressure with abnormal imaging findings. **Results:** Of the 34 patients with abdominal imaging available, the median age was 53 years (IQR 30), 73% were male, 58% were non-white, 79% had nonischemic cardiomyopathy, 64% had reduced LVEF, and 15% had left ventricular assist devices. The median MELD XI score was 13 (IQR 11) and median PAD pressure was 23mmHg (IQR 9). In this cohort, ultrasound was more sensitive in detecting abnormal imaging findings, with the most common abnormal findings being hepatomegaly and increased echogenicity. Adjusted multivariable logistic regression showed that each 1mmHg increase in PAD pressure was associated with a 1.4-odds of an abnormal imaging finding (95%CI 1.04-1.85, $p < 0.05$). PAD pressure above a threshold of 20mmHg was associated with 2+ abnormal abdominal imaging findings. **Conclusion:** This hypothesis generating pilot study showed that PAD measurements are associated with hepatic imaging findings. Given that the CardioMEMS system can provide longitudinal PAP readings, we hypothesize that quantifying right heart pressures and PAP pressures over time may allow for more accurate assessment of the development of congestive hepatopathy in HF patients.

4640 | ◆ RATES OF PORTAL VENOUS THROMBOSIS IN CIRRHOTICS WITH OR WITHOUT CLOTTING DISORDERS: A 7-YEAR NATIONWIDE STUDY

Andrej Sodoma[1] James Pellegrini[2] Samuel Greenberg[3] Ana Rivera[2] Mary Thomas[4] Jaspreet Singh[4], [1]Northwell, [2]NUMC, [3]Stony Brook, [4]SSUH

Background: Cirrhotics are considered to have a high risk of thrombotic events. A common thrombotic event in this group is portal venous thrombosis (PVT). One is decreased liver-synthesized factors in the coagulation cascade and increased endothelial-derived clotting factors. Current research states that inherited hemostatic disorders do not predict the development of PVT. **Methods:** In this study, various thrombophilias were analyzed: activated protein C resistance (APCR), prothrombin gene mutation (PTM), paroxysmal nocturnal hemoglobinuria (PNH), other thrombophilia (OT), and disseminated intravascular coagulation (DIC). The National Inpatient Sample (NIS) from 2015-2021 was used to identify patients diagnosed with cirrhosis with or without thrombophilias using the International Classification of Disease (ICD) 10 codes. Records were weighted per the NIS algorithm to produce accurate population estimates. Cirrhotic patients with or without thrombophilia were analyzed for baseline characteristics. Various primary outcomes were analyzed, which included PVT, death, acute kidney injury (AKI), acute myocardial infarction (AMI), shock, and composite outcomes. Secondary outcomes were analyzed, which included transjugular intrahepatic portosystemic shunt (TIPS) during hospitalization, length of stay (LOS), and hospital charges. **Results:** A weighted total of 2,391,389 patients with cirrhosis without a known coagulation pathology, 4,075 patients with cirrhosis and APCR, 425 patients with cirrhosis and PTM, 175 patients with cirrhosis and PNH, 14,155 patients with cirrhosis and DIC. Cirrhotic patients with PTM had the highest odds of developing PVT (OR (95% CI): 2.848 (2.24-3.62) APCR, 8.801 (5.471-14.157) PTM, 4.286 (3.708-4.955) OT, 2.904 (0.908-9.286) PNH, 1.744 (1.49-2.04) DIC). Cirrhotic patients with DIC had higher odds of death (OR (95% CI): 24.748 (22.82-26.839) DIC), AKI (7.458 (6.82-8.155), AMI (3.205 (2.801-3.667)), shock (21.454 (19.793-23.254)), and overall worse outcomes (15.912 (14.127-17.922)). Secondary outcomes were analyzed, which included higher odds of TIPS during hospitalization for cirrhotic patients with DIC (1.913 (1.369-2.674)). In turn, cirrhotic patients with DIC had greater lengths of stay (LOS) (5.270 (4.759-5.781)) and greater hospital charges (168463 (147901-189024)). **Conclusion:** Patients with cirrhosis and thrombophilic disorders had higher odds of developing PVT, which supports the role of alterations in coagulation factors as predictive factors in the development of PVT.

Table 2: Outcomes for Patients Admitted for PVT in Cirrhotics Stratified by Clotting Disorder

Groups	PVT	Death	AKI	AMI	Shock	Composite	Previous Liver Transplant	Liver Transplant	TIPS	LOS

4641 | PORTAL VENOUS SYSTEM ANEURYSMS: MAYO CLINIC EXPERIENCE OF NATURAL HISTORY, TREATMENT AND OUTCOMES

Eliabe Abreu[1] Chloe Hemm[2] Abigail Fickel[2] Christopher Kigongo[2] Todd Rasmussen[2] Jill Colglazier[2] Manal Abdelmalek[1], [1]Mayo Clinic Rochester, [2]Mayo Clinic, Rochester, MN

Background: Portal vein system aneurysms (PVSAs) are rare, yet the most common (prevalence 0.06-0.6%) visceral venous aneurysms in the general population. PVSAs are typically asymptomatic and incidentally discovered. Due to their rarity, the natural history and management of PVSAs are not well defined. Herein, we report the world's largest cohort study of PVSAs with the aim of defining the characteristics, natural history, and outcomes of surgical vs medical interventions. **Methods:** Using an AI-based system, we searched the Mayo Clinic Enterprise electronic medical record from 1/1/2000 through 1/1/2025 for terms "portal vein aneurysm", "splenic vein aneurysm", and "mesenteric vein aneurysm". Data was manually abstracted and recorded into REDCap. Descriptive analyses were performed. **Results:** From 2000 to 2025, 120 patients [female (55%), White (95%), with a median age of 63 (IQR 51-73) years] were diagnosed with PVSAs. Median follow-up was 51 (IQR 21.75-112) months. Most common comorbidities included arterial hypertension (42.9%), chronic liver disease (32.8%), and cirrhosis (28.6%). Initial diagnosis was made following

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

computed tomography (CT) in 65% of patients, with 54.6% being an incidental finding. 45.4% of patients presented with symptoms, of which the primary symptom was abdominal pain (66.7%). The PVSAs included intrahepatic portal vein branch (25.8%), splenic vein (24.2%), and body of the main portal vein (22.5%), with median diameters of 22 mm, 25 mm, and 35 mm, respectively. Splenomegaly was observed in 30.5% of patients, portal hypertension in 19.5%, and intraluminal thrombosis at initial presentation in 16.9%. Management consisted of conservative 'wait and watch' (90%), anti-coagulation (7.5%), and surgical repair (10%, with 1 case at presentation and 11 during follow-up). After diagnosis, 79.2% had follow-up imaging. While follow-up imaging triggered a change in management in 26.3% (n = 25/95), only 9.2% of patients had thrombosis of PVSA, and 87.5% experienced no unfavorable outcomes. **Conclusion:** PVSA is a rare entity, mainly idiopathic, and largely incidental finding on abdominal imaging. The overwhelming majority of patients have no associated clinical outcomes during follow-up. A non-surgical approach and potentially prophylactic antiplatelet therapy to prevent PV thrombosis may be considered. Multicenter longitudinal studies are warranted.

4642 | CLINICAL FEATURES AND RISK FACTORS OF PORTO-SINUSOIDAL VASCULAR DISEASE WITH CHRONIC GAMMA-GLUTAMYL TRANSFERASE ELEVATION

Weihua Cao[1] Yao Xie[2] Minghui Li[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]Beijing Ditan Hospital, Capital Medical University,

Background: In clinical practice, a significant number of patients presented with unexplained and recurrent gamma-glutamyl transferase (GGT) elevation. This study aimed to explore the clinical characteristics and risk factors of porto-sinusoidal vascular disease (PSVD) with persistent GGT elevation. **Methods:** This retrospective study included patients with unexplained persistent GGT elevation who underwent liver biopsy at Beijing Ditan Hospital between January 2014 and April 2025. Persistent GGT elevation was defined as three consecutive measurements within the past year exceeding twice the upper limit of normal (ULN). Patients were excluded if they exhibited concurrent elevations in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and/or alkaline phosphatase (ALP) exceeding 1.5 times the ULN at the time of biopsy, or if they had known etiologies for GGT elevation. Additional exclusion criteria included excessive alcohol consumption, active infectious diseases, malignancies, or other systemic disorders affecting hepatic function. Demographic data and clinical histories were collected. Patients were stratified into two groups based on the latest diagnostic criteria for PSVD: patients with GGT elevation $\geq 2\times$ULN confirmed as PSVD (PSVD group), and patients with GGT elevation $\geq 2\times$ULN without PSVD (Non-PSVD group). Clinical features and risk factors were analyzed to identify features specific to PSVD with persistent GGT elevation. **Results:** A total of 313 patients with unexplained persistent GGT elevation were enrolled, all of whom underwent liver biopsy. Based on biopsy results indicating whether PSVD was the etiology of GGT elevation, patients were categorized into PSVD and non-PSVD groups. Among them, 191 patients (61.02%) were diagnosed with PSVD, while 122 patients (38.98%) without PSVD in Table 1. Compared to the non-PSVD group, the PSVD group exhibited significantly lower white blood cell (WBC) counts ($p < 0.001$), neutrophils (NE#, $p = 0.005$), and hemoglobin (HGB) levels ($p = 0.050$). Additionally, the PSVD group had lower ALT ($p < 0.001$), AST ($p < 0.001$), and GGT levels ($p = 0.006$). Prothrombin Activity (PTA, $p < 0.001$), AFP ($p = 0.002$), and liver stiffness measurement (LSM, $p = 0.001$) were also lower in the PSVD group, while the international normalized ratio (INR) was higher ($p < 0.001$) in Table 1. Compared to the non-PSVD group, the PSVD group exhibited a higher proportion of patients with GGT < 173 U/L ($p = 0.012$) and LSM < 7.4 kPa ($p = 0.029$) in Table 2. Logistic regression analysis demonstrated that WBC [OR 1.238, 95%CI (1.083-1.416), p=0.002], PTA [OR 1.033, 95%CI (1.013-1.053), p=0.001], GGT < 173U/L [OR 1.730, 95%CI (1.060-2.823), p=0.028], and LSM < 10kPa [OR 2.169, 95%CI (1.237-3.803), p=0.007] emerged as independent risk factors for PSVD diagnosis in patients with persistent unexplained elevated GGT in Table 3. **Conclusion:** Patients with unexplained persistent GGT elevation diagnosed with PSVD exhibited lower WBC, PTA, GGT, and LSM. WBC, PTA, GGT < 173U/L, and LSM < 10 kPa were identified as independent risk factors for PSVD in Patients with unexplained persistent GGT elevation, providing critical diagnostic insights for individuals with unexplained persistent GGT elevation.

4643 | PORTO-SINUSOIDAL VASCULAR DISORDER: NATURAL HISTORY AND LONG-TERM OUTCOME

Elisa Farina[1] Alessandro Loglio[2] Guido Colloredo[3] Aurelio Sonzogni[4] Federica Cerini[5] Camilla Severgnini[6] Lisa Licini[1] Paola Tebaldi[1] Paolo Marra[1] Andrea Gianatti[1] Stefano Fagiuoli[1] Mauro Viganò[1], [1]ASST Papa Giovanni XXIII, Bergamo, Italy, [2]ASST Papa Giovanni XXIII, [3]Policlinico San Pietro, Ponte San Pietro, Italy, [4]ASST Bergamo Est, Seriate, Italy, [5]University of Milan, San Giuseppe Hospital, Milan, Italy, [6]School of Medicine, University of Milan Bicocca, Milan, Italy

Background: Porto-sinusoidal vascular disease (PSVD) represents a heterogeneous group of histopathological lesions and clinical phenotypes that may be associated with portal hypertension (PH). Aim of the study was to determine the long-term outcome and it prognostic factors in a large multicenter cohort of PSVD patients. **Methods:** All adult patients with a histologically diagnosed PSVD between 2002 and 2024 from three Italian referral Centres were retrospectively included at the time of diagnosis and followed up until May 2025. **Results:** Among the 284 patients [56% male, 45 (18-75) years-old, 95% Caucasian, 7% BMI > 25 kg/m^2, 64% ALT > ULN, 78% GGT > ULN, 12% platelets < 150*10^3/mmc, 6% with hematological diseases, 16% spleen ≥ 13 cm, 9% with esophageal varices (EV)] the majority 264 (93%) have never reported liver-related events before diagnosis while 20 (7%) had already developed at least one complication: 7 (3%) EV bleeding, 8 (3%) ascites, 9 (3%) portal vein thrombosis (PVT), which led to the Transjugular Intrahepatic Portosystemic Shunt (TIPS) placement in 4 (1%) patients. Overall, at diagnosis 67 (24%) patients (PH group) presented with PH features, i.e. platelets < 150*103/mmc, spleen ≥ 13 cm, EV, portosystemic collaterals at imaging, ascites while the remaining (n = 221) were classified as the noPH group. No significant histological differences were identified between the two groups. After a median follow-up of 5.5 (0-22) years, ALT > ULN, GGT > ULN and platelets < 150*10^3/mmc were present in 46%, 66% and 18% of patients, respectively; eight (3%) patients had liver disease progression (3 HCC, 4 EV bleeding, 5 decompensation, 2 PVT) [5.4% (95%CI: 2.5-11.2) 10-yr cumulative risk], requiring TIPS placement in 2 and liver transplantation in one. Occurrence of liver disease progression was significantly higher in the PH-group compared to noPH group (12% vs 0%, p < 0.001). In the PH-group the 10-yr cumulative risk of liver disease progression was 22% (95%CI: 11-47). **Conclusion:** In our study, conducted in a large cohort of PSVD patients, only those presenting with features of portal hypertension at diagnosis exhibited a high rate of liver disease progression, whereas patients without PH experienced an uneventful long-term follow-up.

4644 | UDCA DOES NOT IMPROVE LIVER ENZYMES IN PATIENTS WITH OBLITERATIVE PORTAL VENOPATHY – AN OBSERVATIONAL COHORT COMPARISON STUDY

Ahmed Elhawary[1] Joshua Onuiri[1] Swan Thung[2] Pruthvi Patel[1] Gene Im[3], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS), [3]Center for Liver Disease and Transplantation, Division of Digestive and Liver Diseases Columbia Univ

Background: Obliterative portal venopathy (OPV) is an increasingly recognized histopathologic lesion on liver biopsy that belongs to a heterogenous group of liver conditions known as idiopathic noncirrhotic portal hypertension (INCPH). Currently, there is no independent, liver-specific treatment for OPV. However, there are anecdotal reports that ursodeoxycholic acid (UDCA) may have a beneficial effect. The aim of this study was to evaluate the effect of UDCA treatment in patients with OPV and abnormal liver enzymes. **Methods:** In this single-center observational study, consecutive patients with biopsy-proven OPV and abnormal liver enzymes were identified from 2015-2025 using a pathology registry with clinicodemographic, histologic, laboratory, and radiologic data collected and censored at 1 year from diagnosis. Cohort comparisons were performed between patients treated with UDCA and those without treatment. Exclusion criteria included concomitant liver diseases like viral hepatitis and steatotic liver disease

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and < 1 year follow-up. The primary endpoint was change in liver enzymes from baseline to 1-year follow-up. The secondary endpoint was normalization of liver enzymes. Statistical analyses were performed in R version 4.5.0. **Results:** Over the 10-year study period, 176 patients were identified with biopsy-proven OPV, of which 74 (42%) lacked follow-up data, 20 (11%) had normal liver enzymes at biopsy, and 13 (7%) diagnosed at liver transplant explant, leaving a total of 69 (39%) patients with OPV and abnormal liver enzymes at biopsy for study inclusion. Thirty of these patients were treated with UDCA (median 13.3 mg/kg [11.8-14.1] and 39 without treatment (controls). Overall patient characteristics were median age 51 years [38.5-61], 54% male, and diverse race (29% Afro-Caribbean, 29% White). The primary indications for liver biopsy were portal hypertension and abnormal liver enzymes. Patient characteristics of the unmatched UDCA and control groups were similar except for higher rates of INCPH in the control group (Table 1). Overall, baseline median AST, ALT, and ALP levels were 42 U/L (27-72.5), 45 U/L (32-67.5), and 164 U/L (118.5-214), respectively. Median changes from baseline after 1-year of UDCA treatment in AST, ALT, and ALP were -17% [-50-40], -27% [-56-30], and -4% [-29-15], respectively. There were no significant differences in these liver enzyme changes compared with the control group, $p > 0.05$ for all. Normalization rates of liver enzymes were similar between the UDCA and control groups: AST 58%, 67%; ALT 44%, 50%, and ALP 12%, 13%, respectively; $p > 0.05$ for all. After adjusting for the presence of portal hypertension, there was no difference in change in liver enzymes between the 2 groups. **Conclusion:** UDCA did not improve or normalize liver enzymes in patients with OPV. Similar rates of liver enzyme improvement over time were seen in both groups that warrant further study.

Characteristic	UDCA Group (n=30)	Control Group (n=39)	P value

4645 | PREDICTORS OF NON-VARICEAL COAGULOPATHIC BLEEDING IN ACUTE DECOMPENSATION OF CIRRHOSIS PATIENTS USING MACHINE LEARNING

Chhagan Bihari[1] Shvetank Sharma[2] Ankit Bhardwaj[3] Dr. Ashish Maheshwari[2] Shiv Mudgal[4] Ramesh Huda[5] Shiv Kumar Sarin[3], [1]Institute of Liver and Biliary Sciences, [2]Institute of Liver and Biliary Sciences Delhi, [3]Institute of Liver and Biliary Sciences, Delhi, [4]AIIMS Deoghar, [5]ICMR-NIIRNCD Jodhpur

Background: Non-variceal-coagulopathic bleeding (NVCB) is common and carries high morbidity in cirrhosis patients with acute decompensation (AD). Sepsis, acute kidney injury, antibiotics, albumin infusions, and concurrent comorbidities can contribute to deranged coagulation. We aimed to decipher the predictors of NVCB events in hospitalized patients with AD, using machine learning. **Methods:** This investigation comprised patients admitted with AD between January 2019 and December 2024. Patients with ACLF and recent variceal bleeds were excluded. Baseline demographic, clinical, prior decompensation, comorbidities, etiology, laboratory tests, Rotational Thromboelastometry (ROTEM) assays, and fibrinogen were analyzed. Documentation of evolving complications, specifically sepsis and acute kidney injury (AKI), was done for the initial seven days post-admission. Major NVCB incidents, both post-procedural and spontaneous hemorrhages, were recorded up to 60 days. Logistic Regression (LR), XGBoost, Multiple Linear Regression (MLR), Random Forest, and the h2o-AutoML framework were utilized to predict NVCB risk using fastml in R. Models were trained on the initial 80% of cases and validated on the remaining 20% for the performance matrices after feature selection and hyperparameter optimization to enhance model performance. **Results:** 6697 cirrhosis with AD admitted at ILBS were included {Mean age 48 ± 13 yr., male (85%), common etiologies alcohol (49%) and MASLD (23%), MELD 28.7 ± 10.2}, and 38% had prior decompensation. Altogether, 736 (10.9%) patients experienced NVCB; 228 (3.5%) procedure-related and 508 (7.4%) spontaneous. NVCB had slightly higher INR (2.3 ± 1 *vs.* 2.1 ± 1, $p = 0.07$) and comparable platelets, $p = 0.23$). Area Under the Receiver Operating Characteristic Curve (AUROC) for different models (Table), it was highest, 0.83 for LR-Bayesian Information Criterion (bic) for distinguishing NVCB. The accuracy ranged from 0.79 for the Random Forest and 0.92 for the LR (bic) models. The sensitivity was also highest (0.90) for the LR (bic). LR (bic) and XGBoost had similar specificity (0.92 and 0.93, respectively). All models showed high specificity for identifying non-bleeders, with h2o AutoML performing the highest

(0.97). The LR (bic) model was the best fit for all the matrices, with prior decompensation, AKI grade > 1, lower hemoglobin, and lesser ExtemA10, and ExtemCFT ($p < 0.001$ each) as discriminatory parameters for NVCB. The following equation for NVCB in AD was formulated based on this model = (Prior Decompensation*0.6) + (AKI > 1*0.3)-(Hemoglobin*0.8)-(ExtemA10*0.2)-(ExtemCFT*0.15)-0.8. **Conclusion:** Logistic regression (bic) analysis revealed that baseline ROTEM- ExtemA10, ExtemCFT, prior decompensation, AKI grade > 1, and low hemoglobin levels are significant indicators of NVCB in AD. It would help the clinician to stratify the patients who are likely to develop NVCB for their better management.

Table: Comparison of Models predicting Non-Variceal Coagulopathic Bleed in Cirrhosis with AD

Model Type	AUC	Accuracy	Sensitivity	Specificity	F1Score	Precision	P value
Logistic Regression	0.83	0.92	0.90	0.92	0.40	0.26	<0.001
XGBoost	0.83	0.85	0.37	0.94	0.44	0.54	<0.001
h2o AutoML	0.79	0.90	0.32	0.97	0.41	0.57	<0.001
Random Forest	0.76	0.79	0.44	0.83	0.32	0.25	<0.001
Multiclass Regression	0.71	0.86	0.51	0.91	0.46	0.43	<0.001

4646 | BODY ADIPOSITY AS A RISK FACTOR FOR PORTAL VEIN THROMBOSIS IN PATIENTS WITH CIRRHOSIS

Isabel Campos-Varela[1] Carlos Cespedes[2] Ester Palacio[2] Sergi Quiroga[2] Cristina Dopazo[2] Guillermo Cardenas[3] Monica Pons[2] Victor Vargas[2] Lluis Castells[2] Macarena Simon-Talero[2], [1]Hospital Universitario Vall d'Hebron, [2]Hospital Universitary Vall d'Hebron, Barcelona, Spain, [3]HPB Surgery

Background: Alterations in adipose tissue compartments have been related to impaired outcomes in cirrhotic patients. A decreased subcutaneous adipose tissue has been associated with poor clinical outcomes and complications of portal hypertension. The role of the adipose tissue in the development of portal vein thrombosis (PVT) is unclear. **Methods:** Unicentric prospective study. Cirrhotic patients who underwent an abdominal computed tomography for any reason (June/2020-April/2024) were included. Body composition index were quantified at the 3rd lumbar vertebra; visceral adipose tissue index (VATI), subcutaneous adipose tissue index (SATI), visceral to subcutaneous adipose tissue index (VRS), and muscle attenuation were measured. Myosteatosis was later calculated. Adipose tissue compartments were measured by bioimpedance; visceral fat area (VFA), total body fat (TBF) and % were evaluated. Different multivariate (MV) models were explored. Patients with tumoral PVT were excluded. Patients with and without PVT were compared. **Results:** 245 cirrhotic patients were included (74.3% men), median age 62 yo. Child-Pugh (A:45%; B:42%, C:13); 35% with ascites, 11% with hepatic encephalopathy. Primary reasons for cirrhosis were alcohol-related liver disease (43%), metabolic disease (22%) and hepatitis C virus (20%). Hepatocellular carcinoma was present in 34%. 42 (17%) had PVT. Median body mass index was 27.7 kg/m^2, without differences between groups. Patients with PVT had a larger waist perimeter (108 cm vs.104 cm, $P = 0.09$) and were more frequently smokers (43% vs. 29%, $P = 0.08$). Gastroesophageal varices and/or portal hypertensive gastropathy were present in 83% and 71% of patients with and without PVT ($P = 0.10$). Platelet count was significantly lower in patients with PVT (73,000 vs. 104,000, $P = 0.02$). Spleen size was larger in patients with PVT (15.5 cm vs. 14.0 cm, $P = 0.02$). Patients with PVT showed a tendency to have higher SATI and VATI, (SATI; 97.3 cm^2/m^2 vs. 62.1 cm^2/m^2, $P = 0.21$), (VATI; 59.8 cm^2/m^2 vs. 49.5 cm^2/m^2, $P = 0.56$). VRS and muscle attenuation, were similar between groups ($P = 0.77$ and $P = 0.95$). The prevalence of myosteatosis was similar between groups (45% vs. 46%). VFA and total TBF had a tendency to be higher among patients with PVT (VFA; 101.4 cm^2 vs. 79.9 cm^2, $P = 0.11$) and (TBF; 25.5 kg vs.21.4 kg, $P = 0.05$). The proportion of fat was higher in patients with PVT (33% vs. 28%, $P = 0.10$). MV models adjusted for sex and Child-Pugh is showed in table, demonstrating a higher significant risk of PVT in those patients with a greater adipose tissue compartment and greater portal hypertension ($P < 0.05$). **Conclusion:** A larger adipose tissue compartment, and a greater portal hypertension were independently associated with PVT in patients with cirrhosis. This might reflect the inflammatory/prothrombotic role of adiposity, that might be an added risk factor to portal hypertension for the development of portal vein thrombosis in cirrhotic patients.

Table. Multivariate analysis of factors associated with portal vein thrombosis.

	Viscera fat (BIA)		Body Fat (BIA)		% Body Fat (BIA)		SATI		VATI	
	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P
Visceral fat area	1.01 (1.00-1.01)	0.047								
Total body fat			1.03 (1.01-1.06)	0.02						
% Body fat					1.04 (1.01-1.07)	0.04				
SATI							1.01 (0.99-1.01)	0.08		
VATI									1.01 (0.98-1.02)	0.07
Spleen size	1.13 (1.02-1.23)	0.02	1.11 (1.01-1.23)	0.03	1.12 (1.02-1.24)	0.02	1.12 (1.02-1.24)	0.02	1.13 (1.03-1.25)	0.01
Smoker	1.90 (0.91-3.96)	0.09	1.93 (0.91-4.06)	0.09	2.00 (0.95-4.20)	0.07	2.00 (0.95-4.17)	0.07	2.05 (0.99-4.28)	0.06

*Adjusted for sex, Child-Pugh score.

4647 | INVESTIGATING THE MOLECULAR UNDERPINNINGS AND PATHOBIOLOGY OF NODULAR REGENERATIVE HYPERPLASIA OF THE LIVER

Anne Mentzinger[1] Anubha Seth[1] Joseph Brancale[1] Sarah Platt[1] Shanin Chowdhury[1] Chigoziri Konkwo[2] Silvia Vilarinho[1], [1]Yale University, [2]Icahn School of Medicine at Mount Sinai

Background: Chronic liver disease (CLD) affects nearly one billion people worldwide, contributing to significant morbidity, mortality, and healthcare burden. While alcohol and metabolic dysfunction-associated liver disease account for many cases, the etiology of CLD remains unknown in a substantial subset of patients. By studying patients with non-cirrhotic portal hypertension of unclear etiology, our research group identified GIMAP5, a small GTPase, as essential for maintaining liver sinusoidal endothelial cell (LSEC) identity. Bi-allelic loss-of-function mutations in *GIMAP5* result in LSEC capillarization, nodular regenerative hyperplasia, and portal hypertension in both mice and humans. We aim to investigate the signaling pathway(s) driving hepatocyte proliferation in Gimap5-deficient livers. **Methods:** We studied Gimap5 deficient ($Gimap5^{sph/sph}$) and Gimap5 sufficient mice at 3 and 8 weeks. Single-cell RNA sequencing (scRNA-seq) was used to analyze the expression of liver regeneration pathway-related genes, including *Hgf*, *Il6*, *Wnt2*, *Tnf*, *Jag2* in liver endothelial cells. In addition, we crossed $Gimap5^{sph/sph}$ mice with TCF/Lef-GFP reporter mice to visualize and study Wnt/b-catenin signaling activity *in vivo* using confocal microscopy. **Results:** $Gimap5^{sph/sph}$ mice exhibited a 16-fold increase in Ki67-positive hepatocytes compared to wild-type controls, consistent with increased proliferation. scRNA-seq data showed upregulation of *Il6* and *Jag2* and downregulation of *Wnt2* and *Hgf* in liver endothelial cells from Gimap5-deficient mice compared to Gimap5 sufficient controls. Gimap5 deficient mice also show decreased glutamine synthetase (GS) expressing-hepatocytes. Preliminary data from $Gimap5^{sph/sph}$ x TCF/Lef-GFP reporter mice revealed detectable TCF/LEF activity in zone 3 GS positive hepatocytes at 3 and 8 weeks, as assessed through confocal microscopy. **Conclusion:** Our results demonstrate that *Il6* and *Jag2* mRNA are upregulated in liver endothelial cells isolated from Gimap5-deficient mice. Although expression of Wnt agonists is downregulated in Gimap5 deficient liver endothelial cells, preliminary data indicates detectable TCF/LEF activity in hepatocytes in Gimap5 deficient mice.

4648 | DUAL CHOLATE SHUNT TEST IDENTIFIES PATIENTS AT RISK FOR PORTAL HYPERTENSION AND WORSENING HEMODYNAMICS IN TWO COHORTS WITH FONTAN-ASSOCIATED LIVER DISEASE

Maarouf Hoteit[1] Yuli Kim[1] Daniel Ganger[2] Michael McRae[3] Jack Rychik[4] Joanne Imperial[5] Gregory Everson[6], [1]Hospital of the University of Pennsylvania, [2]Northwestern Memorial Hospital, [3]Custom DX Solutions LLC, [4]Children's Hospital of Philadelphia, [5]HepQuant, LLC, [6]HepQuant

Background: Fontan-associated liver disease (FALD) is a hepatopathy in individuals who have undergone Fontan surgery for single ventricle disease. FALD is inadequately characterized by existing laboratory and imaging methods. We previously reported the flow-dependent and liver-specific clearance of cholate in two separate cohorts of adults with Fontan circulation (FC). We combined these cohorts, characterized liver function and shunting, and compared the results in patients with FALD to healthy controls without liver disease. **Methods:** 50 adults with FC were studied: 35 from University of Pennsylvania (UPENN) (Kim et al. 2025) and 15 from Northwestern University (NU) (Lemmer et al. 2019). The dual cholate shunt test (HepQuant SHUNT V2.0) involves intravenous dosing of 13C-cholate and oral dosing of d4-cholate followed by blood samples collected at 20 and 60 min and quantification of cholate concentrations by LC-MS/MS. Hepatic filtration rates (HFR) from portal and systemic circulations were measured, and portal-systemic shunting (SHUNT%) and disease severity index (DSI) were calculated from HFRs. Healthy individuals ($n = 50$) served as controls. **Results:** Test parameters demonstrated worse function and more shunting in patients with FC versus healthy controls, with median (IQR) values of 17.1 (15.4–19.2)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

versus 10.9 (7.6–12.9) for DSI and 28.3% (20.8%–34.9%) versus 20.3% (17.1%–22.8%) for SHUNT% (all $p < 0.001$). Liver function was characterized according to DSI and SHUNT% (Figure). In the figure, the reference lines for DSI represent the normal range ≤ 11.6 (mean + 1 SD of healthy lean controls), low risk for large varices > 11.6 to ≤ 18.3 ($\leq 4.7\%$ probability), moderate risk for large varices > 18.3 to ≤ 24 ($\leq 10.8\%$ probability), and high risk for large varices > 24 ($> 10.8\%$ probability). SHUNT% $> 30\%$ and DSI > 18.3 correspond to the 95% sensitivity cutoffs for large varices (Hassanein et al. 2024). Twenty-three (46%) subjects with FALD had SHUNT% $> 30\%$, which was previously associated with greater risk for clinical outcome (Kittelson et al. 2024). **Conclusion:** The dual cholate shunt test detected reduced hepatic function and increased portal-systemic shunting in patients with FALD relative to controls. Given the relationship to large varices and clinical events, SHUNT% $> 30\%$ may potentially be predictive for liver-related outcomes in FALD.

4649 | PORTAL VEIN THROMBOSIS (PVT) INCREASES SHORT-TERM MORTALITY AMONG HOSPITALIZED DECOMPENSATED CIRRHOSIS PATIENTS IN A GLOBAL COHORT

Ashok Kumar Choudhury[1] Florence Wong[2] Patrick Kamath[3] Jacob George[4] Qing Xie[5] Mark Topazian[6] Hailemichael Mekonnen[7] Peter C Hayes[8] Ramazan Idilman[9] Mario Alvares-da-Silva[10] Aldo Torre[11] Wai-Kay Seto[12] Danielle Adebayo[13] Zhujun Cao[5] Aabha Nagral[14] K Rajender Reddy[15] Sumeet Asrani[16] Neil Rajoriya[17] Marco Arrese[18] Sevda Aghayeva[19] Mithun Sharma[20] Maria González Huezo[21] Adrian GADANO[22] Hasan Basri Yapici[23] Nabil Debzi[24] Jawaid Shaw[25] Somaya Albhaisi[26] José Luis Pérez Hernández[27] Yingling Wang[28] Feng Peng[29] LIN LIN WEI[30] CE Eapen[31] Hiang Keat Tan[32] James Fung[12] Ruveena Rajaram[33] Kessarin Thanapirom[34] Haydar Adanir[35] Adam Doyle[36] Dr. Shalimar[37] Minghua Su[38] Dinesh Jothimani[39] Yijing Cai[40] Rene Male Velazquez[41] Wei Wang[42] Michael Gounder[43] Cameron Gofton[44] Sezgin Barutcu[45] Busra Haktaniyan[46] Alberto Farias[47] Aloysious Aravinthan[48] Chinmay Bera[49] Surender Singh[50] SUNIL TANEJA[51] Dibyalochan Praharaj[52] Anil Arora[53] Akash Roy[54] Arun Valsan[55] Ningping Zhang[56] Wanqin Zhang[56] Fuchen Dong[57] hai li[57] Jing Liu[58] Hong Tang[59] Libo Yan[59] Dan Xu[60] Zhiliang Gao[60] Haibing Gao[61] Qunfang Rao[62] Beiling Li[63] Jinjun Chen[63] Yanyun Zhang[64] Huan Deng[65] Peng Hu[66] Jian Wang[67] Jie Li[67] Dominik Bettinger[68] Michael Schultheiss[68] Christian Labenz[69] Simon Johannes Gairing[69] Belimi Allah[24] Alaa M Mostafa[70] Yasser Fouad[70] Berecha Alemu Kereta[71] Abate Shewaye[72] Kaleb Assefa Berhane[72] Suresh Venkatachalapathy[73] Rosemary Faulkes[74] Damien Leith[75] Ewan Forrest[75] Nafisa F.I.M. Background: Portal Vein Thrombosis (PVT) in cirrhosis is multifactorial and is associated with poorer clinical outcomes thank those without PVT. However, determinants of PVT development and its impact on outcomes in hospitalized patients with cirrhosis, and variations across global regions is unclear. **Methods:** The multi-national CLEARED consortium enrolled prospective, non-electively admitted patients with cirrhosis without HCC, 30-days post-discharge follow-up. PVT was diagnosed on routine radiological and was analysed in relation to demographics, aetiology, clinical presentation, mode of decompensation, complications, course in hospital and survival at 30-days post discharge across all 6 continents. **Results:** A total of 7721 patients with predominant aetiology of alcohol (3185,41.3%) followed by MASH/Cryptogenic (1881,24.4%), HBV (1496, 19.4%), HCV (873,11.3%) and Autoimmune (790,10.2%) were included. PVT was seen in 773(10.01%) patients, more among NASH/Cryptogenic (11.9%), HCV (12.25%) and alcohol (7.25%) aetiology. The admission CTP and MELD Na score was comparable PVT prevalence was high among diabetics (37.4% vs 28.9%). Alcohol cirrhosis had a lower risk of PVT [OR 0.64 (0.54, 0.78), $p < 0.001$] and is independent of disease severity score. PVT prevalence is highest in high (11.1%) followed by middle (9.6%) and low (9.1%) WHO income countries. The regional variations, with PVT prevalence being high in Africa or Middle East (13.8%), followed by North America (11.8%), South America (10%), China (9.5%), Europe/Australia (9.4%) and India (6.2%). Cirrhosis with PVT had more frequent hospital visits (53.3% vs 47.4%), history of prior HE, ascites, hydrothorax, variceal bleed and infection in the preceding 6 months. PVT risk in multivariate analysis- MASH/ cryptogenic etiology of cirrhosis, history of prior ascites, variceal bleed, HE or hydrothorax. On admission, patients with PVT had more infection (25.9% vs 20.8%, $p = 0.001$), GI bleed (30 % vs 26.5%, $p = 0.04$) and HE (34.1% Vs 29.6%, $p < 0.001$). During the hospital course, they had higher AKI (34.4% vs 30.8%, $p = 0.04$) and grade3-4 HE (14.9% vs 11.4%, $p = 0.003$). The 30-day mortality (22.1% vs 18%, $p = 0.001$), 30-day re-admission (33.3% vs 28.4%, $p = 0.01$) and 30-day transplant (8% vs 5.5%, $p = 0.01$) were also higher with PVT. In multivariate (MV) analysis, 30-day mortality increased significantly in presence of PVT [OR = 1.47 (1.15, 1.87), $p < 0.001$]. **Conclusion:** In a prospective global cohort of hospitalized patients with cirrhosis, PVT was seen in 10% of cases, more often among those with diabetes, or MASH/Cryptogenic cirrhosis and was associated with higher in-hospital complications, re-admission and greater mortality even when the CTP or MELD Na score were comparable. Inpatients with cirrhosis and PVT deserve special focus and monitoring during and after discharge from the hospital.

Background: Abernethy syndrome or congenital extrahepatic portosystemic shunt (CEPS), is a rare vascular malformation where portal blood bypasses the liver and drains directly into the systemic circulation. It may present as type I (complete shunt, absence of intrahepatic portal branches) or type II (partial shunt, hypoplastic but patent intrahepatic portal branches) and is frequently associated with multisystem anomalies. **Methods:** Medical record review of a case series involving eight patients. **Results:** In our analysis of 8 pediatric cases, average age at diagnosis was 4,3 years, with a predominance of male (75%). Most patients were classified as type IB (62.5%), type II (25%) and type IA (12.5%). Hepatic tumors were present in 62.5% of patients: focal nodular hyperplasia (FNH) (20%), adenoma (20%), both FNH and adenoma (40%) and hepatoblastoma (20%). Clinical presentations included: pruritus, abdominal pain, jaundice, cholestasis, and hepatopulmonary syndrome. Two patients showed only mild liver enzyme changes and signs of cardiac decompensation. Cardiac malformations were present in 75% of cases, including atrial septal defect, atrial isomerism and atrial septal aneurysm. Gastrointestinal malformations were identified in 50%, including situs inversus, small pancreas, polysplenia and imperforate anus. Genitourinary anomalies were found in two patients and one with VACTERL syndrome. Skeletal, vascular and neurological abnormalities were noted, especially autism spectrum disorder and developmental delays (62.5% both), epilepsy and corpus callosum hypoplasia. Pulmonary involvement included pulmonary hypertension (50%), pulmonary shunt, recurrent pneumonias and tracheomalacia. The average blood ammonia level decreased from 91.53 to 69.91 μmol/L over follow-up. The response to lactulose in cases of hyperammonemia was variable. Tumor marker evaluation showed isolated or combined elevation of AFP and CA 19-9 in two patients, being one of them with hepatoblastoma. Liver transplant was needed in one case due to hepatopulmonary syndrome. Chronic liver disease or cirrhosis was present in 37.5% cases. Associated diagnoses included obesity, hypothyroidism, gallstones, dyslipidemia, vitamin D deficiency and various congenital syndromes. **Conclusion:** Early diagnosis and a multidisciplinary approach are critical for managing potentially life-threatening complications and improving clinical outcomes.

4651 | MICE WITH CONGENITAL PORTOSYSTEMIC SHUNT ARE PREDISPOSED TO KETOACIDOSIS INDUCED BY DIETARY β-HYDROXYBUTYRATE SUPPLEMENTATION

Beng San Yeoh[1] Piu Saha[1] Bina Joe[1] Matam Vijay-Kumar[2], [1]University of Toledo, College of Medicine and Life Sciences, [2]University of Toledo

Background: Portosystemic shunt (PSS) is an aberrant intrahepatic vein that shunts blood from portal vein directly into systemic circulation, bypassing the liver. In humans, PSS can either manifest as a congenital defect that affect ~1 in 30,000 newborns or develop spontaneously in adults with portal hypertension or cirrhosis. We previously reported the sporadic occurrence of PSS as a congenital defect among C57BL/6J mice, and that PSS mice are uniquely predisposed to cholestatic liver injury when fed on a compositionally defined (aka purified) diet. In this study, we investigated whether an intervention that increases circulating levels of the anti-inflammatory ketone body, β-hydroxybutyrate (βOHB), could confer protection against liver injury. **Methods:** C57BL/6J mice were screened for serum total bile acids $\geq$ 40 μM as a biomarker of PSS. Eight-weeks-old female non-PSS and PSS mice were given drinking water (n = 5) supplemented with 20% v/v of 1,3-butanediol, a precursor of βOHB. Body weight was monitored. Serum alanine transaminase (ALT), aspartate transaminase (AST) and βOHB, and urinary pH were measured. The experiment was repeated with another group of non-PSS and PSS female mice (n = 5) given 1,3-butanediol with or without 1% sodium bicarbonate in drinking water. **Results:** 1,3-butanediol supplementation induced a transient body weight loss in both non-PSS and PSS mice. While non-PSS mice regained their baseline body weight after day 5, PSS mice continued to lose body weight. PSS mice were moribund by day 10 and had to be euthanized. Serum ALT and AST were elevated in 1,3-butanediol-treated PSS, but not non-PSS, mice, suggesting that their morbidity was associated with liver injury. Histological analyses further revealed the presence of hepatic microvesicular steatosis, an indicator of liver injury, only in PSS mice. Circulating BHB levels were elevated in both groups of mice given 1,3-butanediol, *albeit* such elevation was greater in PSS mice. Moreover, the urinary pH was lower in PSS mice suggesting that they may be in a state of ketoacidosis. Mitigation of ketoacidosis via co-supplementation of sodium bicarbonate alleviated the loss in body weight and morbidity of 1,3-butanediol-treated PSS mice.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: Taken together, our study demonstrates that mice with PSS were intolerant to a ketogenic challenge, induced via supplementation of 1,3-butanediol. Our findings concurred with prior reports that humans with PSS are at greater risk of developing lactic and/or metabolic acidosis. Thus, we envision that our mouse model of congenital vascular defect could be further leveraged to decipher the mechanism underpinning the PSS-acidosis link.

4652 | THROMBOELASTOGRAPHY-GUIDED TRANSFUSIONS ARE SAFE AND MUST BE INCORPORATED IN CLINICAL PRACTICE ROUTINELY FOR PATIENTS WITH CIRRHOSIS UNDERGOING NEUROSURGICAL INTERVENTIONS

Rachana Domudala[1] Sameera Vattipalli[1] Siddharth Chavali[1] Vyshnavi Lingareddy[1] Anand Kulkarni[2], [1]AIG Hospitals, [2]Asian Institute of Gastroenterology

Background: Neurosurgical procedures are challenging in patients with cirrhosis due to the perceived risk of bleeding complications. Thromboelastography (TEG)-guided transfusions have been widely used in transplant settings, but their role in neurosurgical interventions is less well understood, which we aimed to assess. **Methods:** In this retrospective study, we included patients with cirrhosis who underwent neurosurgical interventions for any reason. All the patients underwent TEG as part of the preoperative assessment. Blood product transfusions were administered based on TEG results, with specific thresholds for Fresh Frozen Plasma (FFP), cryoprecipitate, and platelets.The primary outcome was concordance between TEG- and CCT-predicted transfusion needs. Secondary outcomes included hematoma expansion and reoperation within 48 hours. **Results:** A total of 18 patients who underwent 20 neurological interventions from March 2021 to January 2023 were included in the analysis. The mean age was 54.5 $\pm$ 9.6 years, with a male predominance (90%). The majority of patients (83.3%) were in Child-Pugh class C, followed by Child B (16.7%), and had a mean MELD-Na score of 19.45 $\pm$ 5.3. Out of 20 procedures (for intracranial haemorrhage-66.7%) performed, 70% had discordant transfusion predictions between TEG and CCT and only 30% were concordant. In our cohort, FFP transfusions were avoided in 57% of patients with elevated INR levels. Among those who did require FFP, 17% were identified through the use of TEG. Additionally, platelet transfusions were avoided in 37.5% of patients despite thrombocytopenia (platelet counts $<$ 100,000). Conversely, TEG indicated the need for a platelet transfusion in one patient with a normal platelet count. Postoperative interval imaging revealed no bleeding complications, and none of the patients developed transfusion-related complications. Only one patient needed re-surgery due to the persistent mass effect of hematoma. **Conclusion:** TEG-guided transfusions are safer than CCT-based transfusions in patients with cirrhosis undergoing neurosurgical interventions. It could reduce unnecessary blood product use and associated complications, supporting the growing evidence for viscoelastic testing in cirrhosis patients.

4653 | FLOW CYTOMETRY-BASED ISOLATION OF PLATELET-DERIVED MICROPARTICLES FROM PLASMA AND THEIR FUNCTIONAL INTERACTION WITH LIVER ENDOTHELIAL AND STELLATE CELLS

Nima Fattahi[1] Yasuko Iwakiri[1] Matthew McConnell[1], [1]Yale University

Background: The involvement of platelet-derived microparticles (PMPs) in liver pathophysiology is increasingly recognized, but current isolation techniques have limited their study. This study aims to establish a standardized pipeline for PMP isolation from banked plasma and to define their uptake by liver cells. **Methods:** PMPs were isolated from banked human plasma using flow cytometry. A size- and antigen-based gating strategy was applied using 180–1300 nm size calibration beads and the platelet-specific marker CD41. Microparticles within the 100–1000 nm range and positive for CD41 were sorted. Flow cytometry was also conducted on fresh platelet-rich plasma, stored platelets from the blood bank, and frozen plasma with isotype controls to confirm population specificity. Electron microscopy (EM) was used to validate PMP morphology and structure. PMPs were generated in parallel by thrombin or collagen treatment of purified platelets, and internalization of PMPs was assessed in liver sinusoidal endothelial cells (LSECs), and hepatic stellate cells (HSCs) using confocal imaging. **Results:** Flow cytometry of banked patient plasma stained with anti-CD41 and spiked with 180-1300 nm calibration beads revealed two populations of CD41+ particles. Flow cytometry of expired platelets from the Yale-New Haven Hospital blood bank along with fresh platelet-rich plasma revealed the larger population to be consistent

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with intact platelets, and the smaller population to be consistent with PMPs. Detergent (Triton X-100) treatment of banked plasma and subsequent flow cytometry confirmed that the smaller particles were of cellular origin. The CD41+ microparticles were then sorted. Electron microscopy confirmed the presence of small, spherical vesicles (~100–600 nm) consistent with intact PMPs. To demonstrate the interactions of PMPs with liver cells, thrombin or collagen-generated PMPs from purified platelets were co-cultured with LSECs and HSCs, which internalized PMPs into both cytoplasm and nucleus, confirming the role of PMPs in crosstalk between platelets and liver cells. A higher proportion of HSC images demonstrated internalized PMPs compared with those showing PMPs outside the cell (0.50 vs 0.20, $p < 0.001$), whereas with LSECs the proportions of cell images with PMPs visualized inside and outside the cell were not significantly different (0.66 vs 0.63, $p = 0.71$), suggesting a higher avidity of HSCs for PMPs. **Conclusion:** We established a validated, reproducible method for isolating platelet-derived microparticles from plasma using flow cytometry and electron microscopy. This approach enhances the feasibility of identification and isolation of PMPs for study across a wide variety of liver disease present in biorepositories. PMP internalization into endothelial and stellate cells suggests their potential mechanistic roles in liver disease.

4654 | UTILITY OF LIVER STIFFNESS MEASUREMENT AS AN EARLY PREDICTOR OF TREATMENT RESPONSE IN BUDD-CHIARI SYNDROME

Ankita Singh[1] Sakshi Koli[2] Akash Shukla[1], [1]Seth GS Medical College & KEM Hospital, [2]Seth GSMC & KEM hospital

Background: Management of Budd-Chiari Syndrome (BCS) with conventional guidelines recommend a stepwise intervention based on clinical response. This study aims to evaluate the utility of early variations in liver stiffness measurements (LSM) to predict treatment response in patients with BCS. **Methods:** Consecutive patients diagnosed with BCS and willing to participate in the study were enrolled between April 2024 to April 2025. Liver and splenic stiffness values were measured using Fibroscan 630 Xpert at presentation and day 2, 5 & 7 after initiation of medical therapy (anticoagulation and diuretics) or vascular intervention. Response was assessed using APASL criteria. **Results:** A total of 23 patients were enrolled: 7 (30.4%) were newly diagnosed and started on medical therapy alone, while 16 (69.6%) had previously received anticoagulation and underwent radiologic intervention due to non-response to treatment. Of the 7 newly diagnosed patients, 2 subsequently underwent vascular intervention and were followed similarly. Mean baseline LSM was 47 $\pm$ 20kPa in patients treated with anticoagulation; and 58.7 $\pm$ 13.5 kPa in those undergoing radiologic intervention. At 48 hours post-treatment, LSM values were: 38.7 $\pm$ 23 kPa in the anticoagulation group and 29.4 $\pm$ 16.6 kPa in the intervention group. Mean LSM value five days after vascular intervention was 27.6 $\pm$ 11.4 kPa. Radiologic intervention led to an immediate and sustained reduction in liver stiffness values by around 50%, while anticoagulation alone resulted in approximately 18% reduction from baseline. Statistically significant difference in absolute reduction in liver stiffness values at 48 hrs was noted between the two groups (34.5kPa vs 7.8kPa; $p = 0.006$). On multi-variate analysis, there was a significant association of reduction in LSM with response ($p = 0.005$) but not with baseline LSM ($p = 0.7$). The predicted probability of response with 50% reduction in LSM using logistic regression was 0.96. **Conclusion:** Radiological interventions are associated with a more rapid decline in LSM in patients with BCS as compared to medical therapy alone. Reduction in LSM correlates with response. A 50% reduction in LSM at day 5 is a strong predictor of treatment response.

4655 | ◆ ELEVATED ALT IS MORE PREDICTIVE OF ADVERSE MATERNAL OUTCOMES THAN THROMBOCYTOPENIA SEVERITY IN HELLP SYNDROME: AN ANALYSIS OF OVER 40,000 PATIENTS

Kate Solpari[1] Priyanka Gaur[1] Olivia Blocker[1] Emma Leipsner[1] Scarlet Yang[1] Tatyana Kushner[1], [1]Weill Cornell Medical College

Background: HELLP syndrome (Hemolysis, Elevated Liver enzymes, Low Platelets) is a severe pregnancy complication with significant maternal morbidity. We investigated whether the severity of thrombocytopenia and liver enzyme elevations in individuals with HELLP predicts adverse maternal outcomes. **Methods:** Using the TriNetX research network, pregnant women with HELLP syndrome and no prior chronic liver disease were stratified into cohorts based on laboratory values: severe (platelets $<50{,}000/\mu L$) versus moderate thrombocytopenia (platelets 50,000-100,000/μL); severe ($>5\times$ ULN) versus moderate ALT elevation (2-5× ULN); and combined severe versus moderate derangements. Propensity score matching balanced demographics and comorbidities, and adjusted risk ratios were calculated for pregnancy- and liver-related outcomes. **Results:** Of 5,701,108 pregnancies in the TriNetX database, we identified 47,156 (0.8%) female patients with HELLP syndrome, aligning with prior global estimates. The cohort was predominantly composed of White (62.4%), Hispanic or Latino (16.4%), and Black (14.3%) individuals with a mean age at pregnancy of 30 ± 6 years; comorbidities included hypertension (32%) and diabetes mellitus (11%). Propensity score matching yielded balanced cohorts for thrombocytopenia ($n = 2{,}663$ per group), ALT elevation ($n = 5{,}175$), and combined derangements ($n = 6{,}051$), with a median follow-up of 1,090–1,357 days. Severe thrombocytopenia increased risks of DIC (3.7% vs 2.0%, RR 1.90, $p < 0.001$); severe ALT elevation was associated with increased risks of hepatic failure (0.9% vs 0.3%, RR 3.142, $p < 0.001$), DIC (1.3% vs 0.6%, RR 2.03, $p < 0.001$), ICP (4.5% vs 2.2%, RR 2, $p < 0.001$), pre-eclampsia (85.4% vs 80.3%, RR 1.07, $p < 0.001$), and PPH (11.8% vs 9.5%, RR 1.24, $p < 0.001$); combined severe derangements demonstrated strong associations with hepatic failure (0.8% vs 0.3%, RR 2.53, $p < 0.001$), DIC (1.8% vs 0.9%, RR 2.00, $p < 0.001$), ICP (4.5% vs 1.9%, RR 2.37, $p < 0.001$), PPH (12.3% vs 10.2%, RR 1.20, $p < 0.001$) and pre-eclampsia (85.3 vs 80.7%, RR 1.06, $p < 0.001$), yet lower risk of future liver fibrosis (0.2% vs 0.4%, RR 0.45, $p = 0.034$) (Figure 1). A trend toward higher risk of liver transplant did not reach statistical significance (0.3% vs 0.2%, RR 1.39, $p = 0.369$). **Conclusion:** ALT elevation in the context of HELLP was more predictive of adverse maternal hepatic and obstetric outcomes than severe thrombocytopenia. Stratifying HELLP syndrome by laboratory severity may facilitate early risk detection for both adverse hepatic and obstetric events.

4656 | ◆ ROTEM-DEFINED HYPOCOAGULABILITY PREDICTS NON-PORTAL HYPERTENSIVE BLEEDING IN CIRRHOSIS

Kymentie Ferdinande[1] Jochen Decaestecker[2] Charlotte De Vloo[2] Laurence Seynhaeve[2] Sarah Raevens[3] Helena Degroote[4] Inge Van haute[5] Katrien Devreese[6] Hans Van Vlierberghe[3], [1]University of Padova, [2]AZ Delta Rumbeke, Gastroenterology and Hepatology, [3]Ghent University Hospital, Gastroenterology and Hepatology, [4]University Hospital of Brussel, Gastroenterology and Hepatology, [5]AZ Delta Rumbeke, Laboratory Medicine, [6]Ghent University Hospital, Department of Laboratory Medicine

Background: Patients with acute-on-chronic liver failure (ACLF) often demonstrate preserved thrombin generation (TG), with simultaneously hypocoagulable profiles on rotational thromboelastometry (ROTEM). The clinical relevance of these findings to non-portal hypertensive (NPH) bleeding risk remains undefined, limiting evidence-based bleeding prevention strategies. **Methods:** In this case-control study with a prospective three-year follow-up, we assessed haemostatic profiles in 215 patients categorized as stable cirrhosis (SC, $n = 122$), acute decompensation (AD, $n = 53$), and ACLF ($n = 40$). We evaluated conventional coagulation tests, factors/inhibitors, ROTEM parameters, and TG ($\pm$thrombomodulin), and analyzed their associations with NPH bleeding, thrombotic events, and liver-related mortality. **Results:** Disease severity, according to Child-Pugh (CP) and MELD-Na scores, increased progressively across patient groups ($P < 0.001$). TG analysis revealed that ACLF patients had a shorter lag time but reduced thrombin potential compared to SC/AD; these differences were normalized by thrombomodulin. ROTEM parameters showed marked hypocoagulable features in ACLF vs SC/AD, while AD and SC were comparable. Hypocoagulability (≥ 5 abnormal ROTEM parameters) was present in 1.8% of SC, 8.3% of AD, and 22.2% of ACLF patients ($P < 0.001$ for SC vs ACLF); hypercoagulability was rare (2.8% in ACLF). ROTEM and TG parameters correlated significantly with MELD-Na and CP scores ($P < 0,001$).

NPH bleeding occurred in 8.4% of patients, more frequently in ACLF (30.8%, $P < 0.001$) and AD (18.9%, $P = 0.011$) versus SC (5.7%). Patients with NPH bleeding had more severe liver disease (higher CP and MELD-Na scores), higher rates of AD/ACLF (33,3% and 38,9%), and more frequent ROTEM-defined hypocoagulability (31.3% vs 4.5%, $P = 0.02$). Multivariate analysis identified ROTEM-defined hypocoagulability as an independent predictor of NPH bleeding (OR 12.93, $P = 0.041$). Thrombotic events (7.0%) were not linked to hemostatic parameters.

Non-survivors had more pronounced coagulation abnormalities: 12.8% of non-survivors had hypocoagulability versus 3.3% in survivors ($P = 0.011$). Lower ETP in TG was a significant risk factor for liver-related mortality (OR 0.958, $P = 0.002$). **Conclusion:** Coagulation abnormalities in cirrhosis parallel disease severity, with NPH bleeding events clustering in AD and ACLF. ROTEM-defined hypocoagulability independently predicts NPH bleeding in cirrhosis and may serve as a valuable tool for NPH bleeding risk stratification in acutely ill cirrhotic patients.

INDEX

The Liver Meeting: 2025 Subject Categories

ACUTE LIVER FAILURE AND ARTIFICIAL LIVER SUPPORT

A Phase I Clinical Trial Of The Hepacure Bioartificial Liver System For Acute-On-Chronic Liver Failure 0022
Activation Of A Tumor Suppressor P53 Drives Acute Liver Failure Via Upregulation Of Leukemia Inhibitory Factor (LIF) 4119
Beyond Acetaminophen: An Umbrella Review Of N-Acetylcysteine In Non- Acetaminophen-Induced Liver Failure 4121
Bystander Activation Of Cytotoxic CD8 T Cells As A Mechanism For Indeterminate Pediatric Acute Liver Failure 0208
Clinical Profile, Prognostic Factors And Outcomes In Acute Liver Injury Due To Yellow Phosphorus/Metal Phosphide Poisoning: A Large Real-World Cohort Analysis 4108
Combination With Glucocorticoids During Artificial Liver Support System Treatment Does Not Improve The Survival Rate Of Acute-On-Chronic Liver Failure Patients: A Retrospective Cohort Study 4116
Demographic And Clinical Characteristics Of Pediatric Drug-Induced Acute Liver Failure: A National Inpatient Analysis 4115
Dlgap5 Promotes Acute Liver Injury Via Pyroptotic Hepatocyte Inflammasome-Driven Macrophage Metabolic Reprogramming And M1 Polarization 0017
Drug-Induced Liver Injury Is More Than Drugs- The Role Of Metabolic And Viral Comorbidities- Case Of Tinospora Cordifolia (Giloy) 0018
Efficacy, Safety And Prognostic Factors Of Dual Plasma Molecular Adsorption System Combined With Plasma Exchange On Acute-On-Chronic Liver Failure:A Single-Center Retrospective Cohort Study 4120
Enhancement Of Liver Regeneration In Mice Through Ddx3X-Cd36 Pathway- Mediated Promotion Of Hepatic Lipid Accumulation 4111
Expandable, Functional Hepatocytes Derived From Primary Cells Enable Liver Therapeutics 4105
Factors Contributing To Technical Success And Its Predictors In Transjugular Liver Biopsy 4118
Indications And Outcomes For Patients Delisted For Emergency Liver Transplant In Acute Liver Failure – A Single Centre Review Over 30 Years 4113
Lipopolysaccharide Binding Protein As A Potential Predictive Biomarker For Acute Kidney Injury Onset In Cirrhosis 4106
Liver-Targeted Delivery Of Human Platelet Lysate-Derived Hydrogels promote Hepatocyte Proliferation, Angiogenesis And Survival In Post- Hepatectomy Liver Failure 4104
Novel Predictors Of 30-Day Mortality In Acute Liver Failure: A Multi- Center Acute Liver Failure Study Group (ALFSG) Cohort Analysis 4109
Spatiotemporal-Omics Reveals The Role Of Mlxipl+ Hepatocytes In Liver Repair In Acute Liver Injury Mice 4122
Trem2 Deficiency Exacerbates Acute Liver Failure By Impairing Macrophage Efferocytosis Via Disruption Of S100A4-Mediated Glycolysis 4107
Targeting Albumin Binding Function To Describe Removal Of Protein-Bound Toxins In Personalized Extracorporeal Therapies 4114
Targeting Rac1 As A Novel Strategy To Reduce Inflammation And Liver Damage In Acute Liver Failure 4112
The Combined Engineering Of HLA Gene Disruption And Bcl2 Augmentation For Human Liver Organoid-Based Extracorporeal Support System In Treating Liver Failure 4117
Therapeutic Plasma Exchange In Patients With Acute Liver Failure: A Randomized Controlled Trial 0019
Treatment Of Alcoholic Liver Disease And Liver Failure Using A Novel 3D- Printed PLG-Based Implantable Therapy 4110
Using Artificial Intelligence/ Machine Learning For Early Prediction Of Response To Plasma Exchange In Pediatric Acute Liver Failure 0020

ACUTE ON CHRONIC LIVER FAILURE

A HDL-Based Cirrhosis Risk Score Improves The Prediction Of Short-Term Mortality In Acutely Decompensated Cirrhosis 4149

A Longitudinal Analysis Of Clinical Trajectories And Prognostic Outcomes In Patients With Acute-On-Chronic Liver Failure (ACLF) 0028
A Simple Machine Learning Model Considering Serum Bilirubin, PT-INR And Age Can Accurately Predicts The Risk Of Early Renal Failure In Patient Of Acute On Chronic Liver Failure (ACLF) 4131
AARC Score Predicts Survival Outcomes Better Than Other Scores In Patients With Acute On Chronic Liver Failure Patients Having Histopathologically-Proven Mild Liver Fibrosis 4166
Ask1 Inhibitor SRT-015 Reduces Systemic Inflammation While Promoting Immune Defense Mechanisms In Preclinical In Vitro And In Vivo Models Related To ACLF 4171
Anti-Microbial Resistance Patterns In Acute-On-Chronic Liver Failure And Its Impact On Clinical Outcome 4150
Combination Of MELD Score With Neutrophil-To-Lymphocyte Ratio Predicts In-Hospital Mortality In Acute-On-Chronic Liver Failure 4176
Combination Of Novel Plasma Metabolites And Wearable-Derived Physiologic Parameters Provide High Prognostic Value For Risk Of Hospitalization For Patients With Cirrhosis 4159
Development And Validation Of An Explainable Machine Learning Model For Predicting Invasive Fungal Infection In Acute-On-Chronic Liver Failure Within 28 Days 4147
Development And Validation Of The ATANGO Organ Failure Score For Diagnosis And Prognosis Of Acute-On-Chronic Liver Failure In Global Cohorts 4137
Direct Chemical Reprogramming Of Urine-Derived Stem Cells From ACLF Patients Into Functional Hepatocyte-Like Cells For Liver Injury Therapy 4140
Disparities In Liver Transplant Evaluation For Acute-On-Chronic Liver Failure: The Impact Of Race And Sex 4157
Dose-Dependent Risk Of Hepatic Encephalopathy With Chronic PPI Use In Cirrhosis: A Multicenter Cohort Analysis 4161
Drug-Induced ACLF (DI-ACLF) Associated With A High Mortality In Patients With MAFLD: A Multicenter Cohort Study From The AARC Registry 4130
Dynamic Changes In Spleen Stiffness Predicts Outcome Of ACLF Patients By Day-7 - A Prospective Study[Nct06069284] 4143
Dynamic Changes In The A-TANGO Organ Failure Score Over 7-Days Accurately Defines Mortality And Could Be Used As A Surrogate End Point In Clinical Trials 4133
Establishing A Rank-Ordered Heirarchy Of ACLF Related Mortality Risk Associated With Organ Support In Real World Clinical Practice 4136
Evaluation Of The Validity And Reliability Of The Glim Criteria In Diagnosing Malnutrition Among Outpatients With Liver Cirrhosis 4174
Effect Of VS-01 On Systemic Inflammation And Liver Injury In A Rat Model Of Endotoxemia 4162
Efficacy And Safety Of Tenofovir Amibufenamide Fumarate In Patients With Acute-On-Chronic Liver Failure: A Multi-Center, Prospective Cohort Study 4139
Efficacy Of Nitazoxanide (NTZ) On Systemic Inflammation And Organ Function In Disease Models Of Acute-On-Chronic Liver Failure (ACLF) When Administered Post-ACLF Trigger 4165
Elevated Fibrin Degradation Product Level Predict Poor Outcomes In Hepatitis B Virus-Related Acute-On-Chronic Liver Failure Patients Treated With Artificial Liver Support System Therapy 4170
Empiric Versus Pre-Emptive Antifungal In Acute-On-Chronic Liver Failure With Suspected Invasive Fungal Infections: A Pragmatic Randomized Controlled Trial With Machine Learning 4129
Frailty Is Associated With The Development Of Acute-On-Chronic Liver Failure In Patients With End-Stage Liver Disease 0024
From Colonization To Infection: Clinical Consequences Of Multidrug- Resistant Organisms In Cirrhosis In The ICU 4158
Gut Microbial Succession And Escalating Antibiotic Resistance From Chronic Hepatitis B To Acute-On-Chronic Liver Failure: A Metagenomic Study 4124
HDL-C, Cholesterol And The ALT/HDL-C Ratio Are Predictors Of Survival In Patients With Acute-On-Chronic Liver Failure 4141
Hepatic Dysfunction And Hepatic Failure Cutoffs In Cirrhosis Patients With ACLF 0023
High Risk Readmission Following Discharge Home From Expedited Liver Transplant Evaluation 4144
IL-37 Combined With IL-22 Could Serve As A Therapeutic Strategy For ACLF With The Effect Of Both Inhibiting Systemic Inflammation And Promoting Liver Regeneration 4123
Identification And Validation Of Receptor-Interacting Protein Kinase 3 As A Prognostic Biomarker To Guide Personalized Therapy In Acutely Decompensated Cirrhosis: A Multicohort Validation Study 4128
Identification Of Plasma Extracellular Vesicle Microrna Profiles As Diagnostic And Prognostic Biomarkers For HBV-Associated Acute-On-Chronic Liver Failure 4164

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Impact Of Frailty And Obesity On Hospital Length Of Stay After Liver Transplantation 4177
Impact Of Hepatic Encephalopathy On Prognosis In Cirrhotic Patients With Acute Decompensation: The Crucial Role Of Underlying Liver Function And Coagulation Failure 4134
Impact Of Liver Transplant And Therapeutic Plasma Exchange On Clinical Outcomes In ACLF Patients With And Without Infection: A Propensity Score-Matched Study From The AARC Database 4151
Impact Of Pre-Procedural Coagulopathy Reversal On Clinical Outcomes Following Paracentesis Or EGD In Patients With Cirrhosis And INR >3: A Propensity Score-Matched Study 0027
Infection Rather Than Bile Acid Levels Predict Mortality In Alcohol Associated Acute On Chronic Liver Failure 4146
Liver Cirrhosis Is Associated With Increased Prevalence Of Intestinal Polyps In Rheumatoid Arthritis: A Retrospective Analysis 4179
Liver Frailty Index Is Associated With Decreased Recovery In Egfr After Liver Transplantation 4132
Longitudinal Single-Cell Multimodal Analysis Reveals The Dynamic Immune Mechanisms Underlying HBV-ACLF Progression 4163
Macrophage Polarization Mediated By The Interactions Of Hypoxia- Inducible Factor 1α And CBP/P300 Interacting Trans-Activator Plays An Important Role In Disease Progression Of Hepatitis B Virus-Related Acute-On-Chronic Liver Failure 4138
New Submission The Albumin-Bilirubin (ALBI) Score Predicts Kidney Failure And Mortality In Patients With Alcohol Related Acute On Chronic Liver Failure- An Analysis From The AARC 4142
Noncanonical Inflammasome-Triggered Pyroptosis Exacerbates Coagulopathy In Acute-On-Chronic Liver Failure Via Releasing Histone H3 And Enhancing Tissue Factor Activity 4172
Nutritional Support Intervention In Patients With Hepatitis B Virus- Related Acute-On-Chronic Liver Failure At Nutritional Risk: A Randomized Controlled Clinical Trial 4126
Nutritional Intervention For Patients With Liver Failure Reduces The Risk Of Clinical Complications 4135
Performance Of The China-CLIF Framework In Acute-On-Chronic Liver Failure: A Multi-Cohort Study Across All Aetiologies 4148
Presence Of Sepsis Is Associated With Increased Risk Of Acute Variceal Bleeding And Increased Moratlity In Patients With Acute-On-Chronic Liver Failure: A Propensity-Matched Multinational Cohort Of The APASL ACLF Research Consortium (AARC) 4168
Prognostic Models And Infection-Related Mortality In ACLF: A Prospective Mexican Cohort Study 4182
Real-World Data On Acute-On-Chronic Liver Failure: Implications For Clinical Management And Policy 4181
Role Of Age And Frailty In Mortality Among Patients With Cirrhosis: A 5- Year Population-Based Analysis 4154
Secondary SBP Prophylaxis Worsens Survival Without Affecting Liver Transplant Rates In Veterans With Cirrhosis Followed After Their First Decompensation 4125
Single-Nucleus Transcriptomics Identifies A $Cd44^{+}$ regenerative hepatocyte subpopulation in hepatitis B virus-related acute-on-chronic liver failure 4173
Systemic And Multi-Organ Inflammation Patterns Across The Spectrum Of Experimental And Human Cirrhosis And Acute-On-Chronic Liver Failure 4152
Systemic Challenges In Managing Acute-On-Chronic Liver Failure (ACLF) In The U.S.: Diagnostic Delays, Referral Barriers, And Fragmented Post- Discharge Care 4127
Targeting Stress Inducible Hsp90 Reduces Extracellular Matrix And Ameliorates Liver Fibrosis 4180
Temporal Trends In Outcomes And Burden Of Acute-On-Chronic Liver Failure (ACLF) Among Patients With Cirrhosis In The United States: A Nationwide Analysis 0026
The Linoleic Acid-Derived Leukotoxin 9,10-Dihome Drives Immunosuppression In Patients With Acute-On-Chronic Liver Failure 4160
Timing Matters: Delayed Antibiotic Therapy Increases Mortality In Patients With ACLF. A Single-Center Retrospective Study 4169
Title- To Study The Efficacy Of Intravenous Neostigmine In Resolution Of Acute GI Paralysis In Critically Ill Cirrhosis- Prospective Observational Study (NCT- 06462872)New Submission 4156
Transcription And Translation Of Human Endogenous Retrovirus (HERV)- Derived Elements Defines Post-Transplant Alloimmune Hepatitis 4178
Transjugular Intrahepatic Portosystemic Shunt In Older Adults: Highlighting Risks In A High-Risk Population 0025
Treatment Of Hepatorenal Syndrome-Acute Kidney Injury (HRS-AKI) With Titratable 4167

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Norepinephrine Outside Of Intensive Care Unit (ICU): A Single Center Experience
Using Machine Learning To Accurately Predict The 90 Day Prognosis Of Acute-On-Chronic Liver Failure Based On Liver Reserve Function And Clinical Features 4175
Window For Plasma Exchange (PLEX) In Alcohol-Related ACLF (Kyoto Consensus): PSM Analysis Of 1-Year Survival With PLEX (With Low Dose Steroid) Vs Standard Medical Treatment 4145

ADVANCED PRACTICE PROVIDERS (NP, PA, RN, PHARMD, ETC.)
BEHAVIORAL AND QUALITY ISSUES

Barriers And Facilitators To Engaging In Alcohol Treatment Among Persons With Alcohol-Associated Liver Disease: A Mixed-Methods Systematic Review 2164
How The Cause Of Liver Failure Shapes The Post-Transplant Journey: Patient-Reported Outcomes Across Etiologic Categories 2159

PRACTICE ISSUES

ACLF – The Advanced Practice Provider Experience From A Liver ICU 2162
Impaired Working Memory In Individuals With Metabolic Dysfunction- Associated Steatotic Liver Disease (MASLD) And Fatigue 2160
Liverpal: A Formative Evaluation Of A Longitudinal Specialty-Aligned Palliative Care Intervention For Hospitalized Patients With Advanced Liver Disease (Advld) 2161
Navigating The Hepatitis C Care Cascade With Advanced Practice Provider And Electronic Health Record In An Urban Emergency Department And Outpatient Clinics 2163
Reduced Health-Related Quality Of Life Predicts Unfavorable Outcomes In Patients With Advanced Hepatocellular Carcinoma Treated With Atezolizumab And Bevacizumab.New Submission 2165
Title: Improving Access To Alcohol Use Disorder Pharmacotherapy In Hepatology: A Quality Improvement Initiative 0038

ALCOHOL-ASSOCIATED LIVER DISEASES: CLINICAL AND EXPERIMENTAL

A Deadly Combination? Exploring The Burden Of Septicemia In Patients With Alcoholic Liver Disease In The United States (1999–2023) 1590
A Novel Program For Management Of Alcohol Use Disorder In A Liver Transplant Program 1646

LIVER FIBROGENESIS AND NON-PARENCHYMAL CELL BIOLOGY

BASIC FIBROSIS RESEARCH AND STELLATE CELL BIOLOGY

A Novel Proteomics Strategy To Identify Natural Substrates Of Aminopeptidases In Human Cirrhosis 3344
Alkbh5 Ameliorates Hepatic Fibrosis By Regulating The Pi3K-Akt-Foxo3A Signaling Axis 3361
Atp-Citrate Lyase In Hepatic Stellate Cells Promotes Liver Fibrosis In Response To Chemical Injury 3383
Absence Of Mir-122 In Mice Triggers Pathological Regeneration And Liver Failure In Fibrotic Conditions 3335
Activated Hepatic Stellate Cells (Ahscs) Are Essential For The Proliferation Of Zone 3 Hepatocytes During Recovery From Toxic Liver Injury In Mice 0056
Activation Of The Integrin αV-Yap-Ctgf Axis In Lsecs Promotes Liver Fibrogenesis In Congestive Hepatopathy 3380
Adoptive Transfer Of Marco^{+} Macrophages Attenuate Liver Fibrosis and Suppress ECM Gene Expression in Hepatic Stellate Cells 3377
Baicalein Induces Hepatic Stellate Cell Senescence Via Inhibiting Glycolysis By Cebpz/P53/Hk2 Signaling Pathway To Inhibit Liver Fibrosis 3362
Cd146 Promotes The Progression Of Hepatic Fibrosis Via Activation Of The P38-Mapk Signaling Pathway 3420
Constitutive Mas1 G Protein-Coupled Receptor Participates In The Pathogenesis Of Liver Fibrosis 3394
Development Of A Yap Protac With Anti-Fibrotic Potential 0053
Effect Of Mesenchymal Stromal Cell-Derived Extracellular Vesicles Purified By Phosphatidylserine Affinity Method On A Murine Model Of Liver Fibrosis 3384
Fgf-21 Agonism Blocks The Ability Of Human Palmitate Stimulated Hepatocytes To Activate Human Hsc In A Klotho Dependent Manner 3350
Fibrosis Microenvironment After HBsAg Clearance Is Associated With HCC Recurrence In HBV Patients 3345
Five Anti-Fibrotic Micrornas Enriched In Extracellular Vesicles Derived From Mesenchymal Stem Cells Suppress Hepatic Stellate Cell Fibrogenesis Via Downregulation Of Rhoa Signaling 3404
From Trials To Targets: Hydronidone'S Mechanistic Role In Reversing Hepatic Fibrosis 3403
Functional Role Of Nicotinamide N-Methyltransferase In Hepatic Stellate Cell Activation And Liver Fibrosis 3364
Fut8-Mediated Core Fucosylation Of Sparc Drives Hepatic Fibrosis Via Collagen Crosslinking And Tgf-β Signaling 3367
Glycolysis-Derived Carbons Acetylate Histones To Promote Hepatic Stellate Cell Activation And Subsequent Murine And Human Liver Fibrosis 3389
HIV Coinfection Exacerbates HBV-Induced Liver Fibrogenesis Via An Exosomal Mir-103A-3P Dependent Pathway 3401
Hepatic Stellate Cell Notch Contributes To Liver Fibrosis In Metabolic Dysfunction-Associated Steatohepatitis 0052
Heterozygous G153D Mutation Of Lysyl Oxidase Like-1 Gene Is Associated With Liver Fibrosis Non-Regression 3354
Hot And Cold Liver Fibrosis Reflect Opposing Hepatocellular Carcinoma Trajectories In Experimental Metabolic Dysfunction-Associated Steatohepatitis 0054
Identification Of Tbx20 As A Mediator Of Hepatic Stellate Cell Memory And Plasticity 3379
Identification Of Novel Drivers Of Hsc Activation And Fibrogenesis Through Leveraging Complementary Proteomic Analysis 3382
Impact Of Extracellular Matrix Stiffness On Temporal Dynamics Of Hepatic Stellate Cell Activation In Vitro 3409
Inhibition Of Mitochondrial Fumarase (Fh1) Results In Release Of Mitochondrial Dna And Hsc Activation 0055
Inhibition Of Neutrophil Extracellular Trap Formation By Anticoagulation Attenuates Liver Fibrosis And Identifies Cystatin B As A Potential Target For Antifibrotic Therapies 3336
Liver Mesenchymal Stromal Cells (Lmscs) Reduce Hepatic Stellate Cell (Hsc) Migration And Ex Vivo Human Liver Fibrosis 3388
Ly6Clow Macrophages Mitigate Liver Fibrosis Via Galectin-9-Mediated Tim-3 Activation 3415

Predicting Cardiovascular Outcomes After Transjugular Intrahepatic Portosystemic Shunt (Tips) Using Machine Learning: An Alta Group Study 2318
Prediction Of Incident Overt Hepatic Encephalopathy Using Measures Of Minimal Hepatic Encephalopathy: The Pro-Mhe Study 2288
Predictors And Significance Of Elevated Lipase In Patients Undergoing Expedited Liver Transplant Evaluation 2351
Predictors Of Hypolgycemia In Individuals With Cirrhosis Without Diabetes 2457
Predictors Of In-Hospital Mortality In Patients With Cirrhosis: A Multicenter Retrospective Study From Ethiopia 2471
Prehabilitation Improves Physical Fitness Metrics Prior To Liver Transplantation And Expands The Pool Of Transplant-Eligible Patients 2292
Proton Pump Inhibitor Use And Risk Of Hepatic Encephalopathy In Cirrhotic Patients: A Meta-Analysis Of Observational Studies 2332
Reduced Risk Of Hepatic Decompensation And Overall Mortality In Patients With Compensated Cirrhosis And Statin Therapy: A Propensity Score- Matched Analysis Of A Population Based Cohort Of 14,034 Adults 2291
Rifaximin Monotherapy Is Superior To Lactulose Monotherapy In Reducing The Risk Of Hepatic Encephalopathy Recurrence: Insights From A Subgroup Analysis By Baseline Characteristics 2347
Rifaximin Monotherapy Reduces The Risk Of New-Onset Hepatic Encephalopathy And Mortality Compared To Lactulose Monotherapy In Compensated Cirrhosis: A Real-World Propensity-Matched Study 2294
Rifaximin Use Is Associated With Reduced Mortality And Hospitalizations In Cirrhotic Patients: A Global Cohort Study 2371
Rising Sepsis-Related Mortality In Cirrhotic Patients In The United States (1999–2020): A CDC WONDER Analysis 2369
Risk Factors And Prediction Model For Sarcopenia In Patients With Cirrhosis Undergoing Transjugular Intrahepatic Portosystemic Shunt 2479
Risk Factors For Infection After Tips 2328
Risk Of Serious Infection And Mortality In Patients With Compensated Cirrhosis And Decompensated Cirrhosis 2399
Sarciram: A Pilot Study On The Impact Of Hydroxiram D Supplementation On Sarcopenia In Patients With Liver Cirrhosis 2321
Safety Of Testosterone Supplementation In Men With Cirrhosis And Hypogonadism: A Propensity Score-Matched Study From A Multinetwork Study 2432
Sarcopenia Is Associated With Worse Inpatient Outcomes And Increased Procedure Utilization In Hospitalized Cirrhotic Patients: A Nationwide Analysis 2448
Secondary Spontaneous Bacterial Peritonitis Prophylaxis Is Associated With A Higher Rate Of Sbp Recurrence In Non-Cirrhotic Patients: A Propensity-Matched Analysis Using A Nationwide Emr Database 2415
