Hye Yeon Chon[1] Hyung Joon Yim[2] Su Jong Yu[3] JA KYUNG KIM[1] Sang Hoon Ahn[4] Yeon Seok Seo[5] Seung Up Kim[4] sang gyune kim[6], [1]Yongin Severance Hospital, Yonsei University College of Medicine, [2]Korea University Ansan Hospital, Korea University College of Medicine, [3]Seoul National University College of Medicine, [4]Yonsei University College of Medicine, [5]Korea University College of Medicine, [6]Soonchunhyang University Bucheon Hospital

Background: While the age-male-albumin-bilirubin-platelet (aMAP) score combined with liver stiffness (LS) measurement has shown promise in assessing liver fibrosis, its utility in predicting hepatocellular carcinoma (HCC) risk remains unexplored. This study evaluated the feasibility and predictive performance of combining the aMAP score with LS measurements for HCC in patients with chronic hepatitis B (CHB). **Methods:** We analyzed 944 CHB patients who initiated antiviral therapy (AVT) between May 2005 and July 2021 at five tertiary hospitals in Korea. All patients underwent baseline and 2- year vibration-controlled transient elastography (VCTE) assessments. The predictive accuracy of aMAP alone, and aMAP combined with LS for advanced fibrosis (aML_{af}), and aMAP combined with LS for cirrhosis (aML_c) was assessed using receiver operating characteristic (ROC) curve analysis, calibration plots, and decision curve analysis. **Results:** During a median follow-up of 47.7 months, 44 patients developed HCC, whose aMAP was significantly higher than that of the patients who did not develop HCC. The aML_{af} and aML_c models demonstrated superior predictive performance compared to conventional models, with AUROCs at 3 years of 0.843 and 0.839, respectively (both $P < 0.05$ versus PAGE-B and modified PAGE-B). In multivariate analysis, elevated aMAP (hazard ratio [HR] = 1.125, 95% confidence interval [CI] = 1.033-1.225), aML_{af} (HR = 1.049, 95% CI = 1.005-1.095), and aML_c (HR = 1.039, 95% CI = 1.008-1.071) were independent predictors for HCC development. Notably, no HCC cases occurred in the aML_{af} low-risk group during follow-up. **Conclusion:** The integration of aMAP score with LS measurements significantly improves HCC risk prediction in CHB patients receiving antiviral therapy. This combined model may enable more precise risk stratification and personalized surveillance strategies.

Syed Naqui Kazim[2] Shiv Kumar Sarin[1] Nirupma Trehanpati[1], [1]Institute of Liver and Biliary Sciences, [2]. Centre for Interdisciplinary Research in Basic Sciences, Jamia Millia Islamia, New Delhi, India

Background: HBsAg seroconversion is very low (5-6%) in hepatitis B virus (HBV) reactivation patients on anti-viral treatment. Underlying immune-metabolic mechanisms in seroconverters (SC) and non-seroconverters (NSC) remains poorly understood. We aimed to characterize the immune and metabolic landscape in SC and NSC at baseline and week 24 using single-cell RNA sequencing and validation by flowcytometry. **Methods:** Out of sixty seven hepatitis B reactivation (rHBV) patients (age 39 ± 13, ALT > 5XULN, HBV DNAlog10$^{4-8}$), twelve patients on anti-viral treatment were seroconverted after 24 weeks (anti-HBs > 10IU/ml). Single cell sequencing using BD rhapsody platform was performed in three seroconvertors (SC) and three non-seroconvertors (NSC) at baseline and 24 wks. Sequencing data was further validated by flow Immune-metabolic panel in five SC and sixteen NSC patients. **Results:** At baseline, there was no difference in HBV DNA and HBsAg levels in SC and NSC. Single-cell transcriptomic profiling revealed that at baseline CD8$^+$ T cell and monocyte compartment was increased (Fig1 A). T cell showed upregulation of CD69, IL32, TNF, GZMA, IL2RB, ATP2B4and KLRG1 indicating activated, cytolytic and metabolically functional T cells in SCs compared to NSCs (Fig1 B). In contrast, NSCs had elevated expression of CTLA4, PDCD1, LAG3, CD25 exhaustion markers (Fig1 A). At baseline, SC monocytes displayed a pro-inflammatory, M1-like profile characterized by increased TNFAIP3, IL1β, CXCL8, TNF, and TREM1, whereas NSC monocytes exhibited a suppressive phenotype with high TIM3 and CTLA4 expression (Fig1 C). By week 24, SCs maintained earlier gene expression and emerged with raised TPR, CD74, CXCL3 immune-metabolic genes. But NSCs had continuous exhaustion state with upregulated TOX and FOXP1 (Fig1 D). Further, immune metabolic profiling by flow cytometry in validation cohort showed higher Glut1, HK2, mTOR, and LDHB expressing naïve, central memory, and effector memory CD4$^+$ and CD8$^+$ T cell subsets in SCs (Fig1 E). **Conclusion:** Despite no diiference in HBV DNA and HBsAg levels, few reactivation patients clear the virus by host mediated immunity. Seroconversion is orchestrated by robust activated, cytolytic, metabolic T cells and M1 macrophage polarization. This data emphasised that exhausted phenotype of non-seroconverters can be restored by inducing metabolically active activated T cells.

1182 | EFFECT OF TOBEVIBART (VIR-3434) AND ELEBSIRAN (VIR-2218) MONOTHERAPY ON HEPATITIS B SURFACE ANTIGEN COMPOSITION IN PATIENTS WITH CHRONIC HEPATITIS B

Gregory Camus[1] Andrea Cathcart[1] Jonathan Seltmann[2] Thomas Berg[2] Hasan Imam[1] Andre Arizpe[1] Madlen Matz-Soja[2] Florian van Bömmel[3], [1]Vir Biotechnology, Inc., San Francisco, CA, USA, [2]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Germany, [3]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germa

Background: Tobevibart (VIR-3434) is an Fc-engineered monoclonal antibody targeting the conserved antigenic loop of HBsAg. Elebsiran (VIR-2218) is a small interfering RNA targeting the HBx region. Reductions in large (LHBs) and medium (MHBs) HBsAg during nucleos(t)ide analogue (NA) therapy have been linked to functional cure, likely reflecting covalently closed circular DNA (cccDNA) transcriptional activity. We investigated the effect of tobevibart and elebsiran, two agents with distinct modes of action, on

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

serum HBsAg isoforms in participants with predominantly HBeAg-negative chronic hepatitis B (CHB). **Methods:** Sera from the VIR-3434-1002 and VIR-2218-1001 trials were retrospectively analyzed. VIR-3434-1002 included three patient cohorts: Part B (n = 30; NA ≥ 2 months, baseline [BL] HBsAg < 3000 IU/mL), Part C (n = 23; NA ≥ 2 months, BL HBsAg ≥ 3000 IU/mL), and Part D (n = 16; no NA, BL HBV DNA ≥ 1000 IU/mL). Patients received a single subcutaneous dose of 6–300 mg tobevibart. VIR-2218-1001, cohort 1d (n = 15) received six doses of elebsiran over 20 weeks. HBsAg isoforms (LHBs, MHBs, HBsAg) were quantified via DiaSorin platform with specific monoclonal antibodies on days 1, 8, and 57 (VIR-3434-1002) or weeks 0, 24, and 44 (VIR-2218-1001). **Results:** In VIR-3434-1002, tobevibart significantly reduced LHBs and MHBs levels and MHBs proportions (%) in a dose-dependent manner, particularly in Part B. At day 8, LHBs and MHBs declined across all doses; MHBs proportions dropped from 3.8% to 0% ($p < 0.001$) in Part B and slightly rebounded to 0.7% by day 57. The strongest suppression was observed with the 300 mg dose. However, effects in patients with BL HBsAg > 3000 IU/mL were limited. In VIR-2218-1001, elebsiran led to a significant reduction in total HBsAg, LHBs, and MHBs levels (all $p < 0.001$) by week 24, with sustained suppression at week 44. MHBs proportions declined from 1.6% to 0% at end of treatment (EOT, $p < 0.001$) and to 0.2% at follow-up ($p = 0.007$). Patients with BL HBsAg < 3000 IU/mL showed sustained undetectable MHBs. **Conclusion:** Tobevibart led to significant reductions in LHBs and MHBs levels, and MHBs proportions in patients with BL HBsAg < 3000 IU/mL. Elebsiran, in contrast, effectively suppressed LHBs and MHBs with sustained undetectable MHBs regardless of HBsAg baseline levels. Our findings suggest differential effects of the two agents on cccDNA-related HBsAg expression and support further evaluation of LHBs and MHBs as predictors of functional cure.

1183 | SAFETY AND EFFECTIVENESS OF PEGINTERFERON ALFA-2B COMBINED WITH TENOFOVIR AMIBUFENAMIDE IN PATIENTS WITH CHRONIC HEPATITIS B

Ru-Yue Chen[1] Sheng-li Ma[2] Yu-Meng Zhu[3] Ya-jie Pan[1] Xue-Yan lv[1] Yue-Hang Wang[1] Zhuang-Zhuang Zhai[1] Xue-Jing Xue[1] Qing-Lei Zeng[1], [1]The First Affiliated Hospital of Zhengzhou University,Zhengzhou,China, [2]The People's Hospital of Yongcheng City,Henan, China, [3]The Luoyang Central Hospital,Henan,China

Background: Data on the combination of Peg-IFN α-2b and tenofovir amibufenamide (TMF) remain limited. This study aims to evaluate the safety and effectiveness of Peg-IFN α-2b combined with TMF in patients with CHB. **Methods:** Patients treated with TMF (25 mg/day) and Peg-IFN α-2b (180 μg/week) from January 2022 to May 2025 were retrospectively enrolled from three hospitals in Henan, China. This study included two groups: the switch combination group, consisting of patients who transitioned from nucleos(t)ide analog (NA) monotherapy to a combination of TMF and Peg-IFN α-2b; and the treatment-naive combination group, comprising patients who received TMF plus Peg-IFN α-2b as initial therapy. The primary endpoint of this study was the rate of hepatitis B surface antigen (HBsAg) loss at 48 weeks of treatment, the secondary endpoints were the rate HBV DNA undetectable (< 25 IU/mL) and safety profiles during treatment. **Results:** A total of 180 patients were enrolled, with 120 patients in the switch combination group and 60 patients in the treatment-naive combination group. The treatment period of NA monotherapy in switch group was 67.45 ± 35.36 months. At baseline, the age, HBV DNA, hepatitis B e antigen (HBeAg), HBsAg, alanine aminotransferase (ALT) levels of the patients in the switch combination group and treatment-naive combination group were 38.48 ± 0.89 vs. 37.20 ± 1.28 years ($p = 0.413$), 4.1 (2.6, 6.5) vs. 4.9 (3.1, 7.8) $\log_{10}$ IU/mL ($p = 0.169$), 255.0 (11.0, 406.6) vs. 304.9 (12.1, 459.7) PEIU/mL ($p = 0.536$), 2.63 ± 1.14 vs. 2.79+1.18 $\log_{10}$ IU/mL ($p = 0.370$), 34.10 ± 4.31 vs. 50.14 ± 6.62 U/L ($p = 0.037$), respectively; At 48 weeks of treatment (Figure 1), the HBV DNA undetectable rates were 99.17% (119/120) vs. 96.67% (58/60) ($p = 0.537$), the HBeAg clearance rates were 76.67% (23/30) vs. 42.86% (6/14) ($p = 0.026$), the HBsAg loss rates were 44.16% (53/120) vs 28.33% (17/60) ($p = 0.040$), in the switch combination group and treatment-naive combination group, respectively. Regarding laboratory abnormalities, the main adverse events during treatment were the ALT elevation (57.50% [69/120] vs. 33.33% [20/60], $p = 0.002$), leukopenia(46.67% [56/120] vs. 31.67% [19/60], $p = 0.054$), neutropenia(45.83% [55/120] vs. 28.33% [17/60], $p = 0.024$), thrombocytopenia (65.83% [79/120] vs. 40.00% [24/60], $p = 0.001$), in the switch combination group and treatment-naive combination group, respectively. Only one patient presented with elevated total bilirubin (39.2 μmol/L). No serious adverse events occurred. **Conclusion:** At week 48 of treatment, the switch combination group exhibited significantly higher rates of HBsAg loss and HBeAg seroconversion compared to the treatment-naïve combination group.

Both groups maintained a favorable overall safety profile throughout the treatment period. These findings suggest that initiating therapy with nucleos(t)ide analogs followed by combination with Peg-IFN α may be a reasonable and promising strategy to promote HBsAg loss.

1184 | ELEVATED SOLUBLE IMMUNE BIOMARKERS IN SUBJECTS WITH HBSAG LOSS AFTER TREATMENT WITH IMDUSIRAN AND IMMUNOTHERAPEUTIC AGENTS IN THE IM-PROVE I AND IM-PROVE II STUDIES

Sharie Ganchua[1] Christine Espiritu[1] Kevin Gray[1] Deana Antoniello[1] Man-Fung Yuen[2] Grace Lai-Hung Wong[3] Kosh Agarwal[4] Leonard Hooftman[5] Bethan Jones[5] Vicky Wheeler[5] Tilly Varughese[1] Karen Sims[1] Emily Thi[1], [1]Arbutus Biopharma, Warminster, PA, USA, [2]The University of Hong Kong, Queen Mary Hospital, Hong Kong, China, [3]The Chinese University of Hong Kong, Prince of Wales Hospital, Hong Kong, China, [4]King's College Hospital, London, UK, [5]Barinthus Biotherapeutics, Harwell, UK

Background: Functional cure of chronic hepatitis B (CHB) requires suppression of viral replication, reduction of HBV antigens and induction of anti-HBV immune responses. Imdusiran (IDR) is an *N*-Acetylgalactosamine–conjugated, pan-genotypic small interfering RNA that blocks all HBV RNA transcripts, resulting in suppression of viral replication and all viral antigens. IM-PROVE I and IM-PROVE II are Phase 2a studies assessing combination treatment of IDR with an immunotherapeutic in nucleots(t)ide analogue (NA) treated CHB subjects. IM-PROVE I assessed 24 weeks (W) of IDR lead-in followed by 12W or 24W of pegylated interferon alfa-2a (IFN) with or without additional IDR doses. IM-PROVE II assessed 24W of IDR lead-in followed by the immunotherapeutic VTP-300, VTP-300 + low dose nivolumab (LDN), or placebo. On-treatment comparison of soluble immune biomarker profiles of subjects from the IM-PROVE I and II studies is presented. **Methods:** Longitudinal plasma samples were collected from 105 subjects (n = 43 IM-PROVE I; n = 62 IM-PROVE II) through W48/end of treatment. Soluble immune biomarkers were assessed using Luminex multiplex panels (58 analytes). **Results:** Transient increases ($\geq$3 to 130-fold from baseline) in soluble immune biomarkers associated with immune activation, Th1 cell-mediated response, inflammation regulation and immune checkpoint proteins occurred during IDR lead-in in subjects in both IM-PROVE I and IM-PROVE II. Elevations of the same immune biomarkers were observed in all subjects who lost HBsAg ($\leq$LLOQ, $\leq$0.05 IU/mL) by W48 in IM-PROVE I and in 1 of 4 subjects in IM-PROVE II, with higher elevations in IM-PROVE I subjects. In subjects who had anti-HBs antibodies by W48, a greater breadth of elevated immune biomarkers occurred in IM-PROVE I compared to IM-PROVE II. For both IM-PROVE I and II studies, 63-76% of the subjects who experienced increases in soluble immune biomarkers on-treatment met the criteria for NA discontinuation and had baseline HBsAg levels of $\leq$1000 IU/mL. **Conclusion:** IDR treatment is associated with increases in soluble immune biomarkers in both IM-PROVE I and IM-PROVE II studies. In subjects who lost HBsAg and had anti-HBs antibodies, a greater breadth and magnitude of immune biomarker increases were observed in IM-PROVE I subjects compared to IM-PROVE II. In both studies, subjects who showed increases in soluble immune biomarkers on-treatment met NA discontinuation criteria

1185 | IMC-I109V, A SOLUBLE T CELL RECEPTOR (TCR) BISPECIFIC TARGETING HBSAG (ENVXCD3), IS TOLERABLE AND ACTIVE AGAINST HEPATITIS B IN A FIRST-IN-HUMAN (FIH) SINGLE ASCENDING DOSE (SAD) STUDY

Jeong Heo[1] Anca Streinu-Cercel[2] Mark Nelson[3] Stefan Bourgeois[4] YOUNG-SUK LIM[5] Paola Cicconi[6] Santiago Moreno-Guillen[7] Stephen Ryder[8] Jordi Navarro Mercade[9] Hyun Woong Lee[10] Jason Wustner[11] Adel Benlahrech[12] Kehmia Titanji[13] Lucy Dorrell[12] Man-Fung Yuen[14], [1]Pusan National University Hospital, Busan, Republic of Korea, [2]National Institute of Infectious Diseases "Prof. Dr. Matei Bals", Bucharest, Romania, [3]Chelsea and Westminster NHS Foundation Trust, UK, [4]ZAS Cadix, Antwerp, Belgium, [5]Asan Medical Center, Seoul, Republic of Korea, [6]Nuffield Department of Medicine, University of Oxford, Oxford, UK, [7]Hospital Universitario Ramón y Cajal, Madrid, Spain, [8]NIHR Biomedical Research Centre, Nottingham University Hospitals NHS Trust, Nottingham, UK, [9]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [10]Gangnam Severance Hospital, Seoul, Republic of Korea, [11]Immunocore LLC, Conshohocken, PA, USA, [12]Immunocore Ltd, Abingdon, UK, [13]Immunocore LLC, Gaithersburg, MD, USA, [14]Queen Mary Hospital, The University of Hong Kong, Hong Kong

Background: HBsAg seroclearance, a key biomarker of resolved chronic HBV (CHB), is rarely achieved with standard of care. IMC-I109V is a soluble high-affinity HBV-specific TCR anti-CD3 bispecific molecule that redirects non-exhausted T cells to kill HBV-infected hepatocytes presenting HLA-A*02:01-HBsAg peptide complexes. We conducted a FIH SAD study to assess the safety, tolerability, pharmacokinetic and pharmacodynamic (PD) activity of IMC-I109V in CHB. **Methods:** HLA-A*02:01-positive adults aged 18-65 with non-cirrhotic HBeAg-negative CHB on nucleos(t)ide analogue therapy and serum HBsAg <3000 IU/mL were enrolled in sequential ascending dose cohorts evaluating a single dose of IMC-I109V, given as an IV infusion on day 1. Tolerability and liver function tests were monitored over 24h post end of infusion (EOI) and through day 29. PD activity was determined from post-dose changes in serum ALT, HBsAg and IL-6. **Results:** Twenty participants (17 males, 3 females) were allocated to IMC-I109V at doses of 0.8 (n = 4), 2.4 (n = 2), 7 (n = 6) and 20 (n = 8) μg. In the 7-20 μg dose groups, 4 participants experienced transient systemic symptoms (Grade 1-2) with onset <24h post-EOI, which were followed by ALT elevations on day 2-3 (n = 3, Grade 1-2; n = 1, Grade 3) without alterations in bilirubin or prothrombin time. ALT changes resolved to Grade ≤1 within 14 days. One participant in the 20 μg group developed Grade 2 cytokine release syndrome that responded promptly to dexamethasone, resolving within 4 hours. Although this event did not meet dose-limiting toxicity criteria, it was classified as an SAE due to an extended hospital stay (<1 day). The observed AEs were consistent with the expected mechanism of action (MoA) of IMC-I109V, and their short duration with its rapid clearance (serum half-life ~14 hours). Small decreases in HBsAg were seen at lower doses, while at 7-20 μg doses, HBsAg reductions exceeding a pre-specified threshold of -0.2 $\log_{10}$ IU/mL were seen in 4 participants (maximum -0.85 $\log_{10}$, Figure), 3 of whom maintained reduced levels through day 29. Transient, dose-dependent elevations in serum IL-6 (median 6.5-fold at 7-20 μg doses), indicative of immune cell activation, accompanied the changes in ALT and HBsAg. **Conclusion:** IMC-I109V was associated with rapidly reversible MoA-related AEs in people with HBeAg-negative CHB. The FIH evidence for dose-

1186 | CHARACTERIZATION OF HIV/HBV CO-INFECTED PATIENTS ACHIEVING HIGH RATES OF HEPATITIS B SURFACE ANTIGEN LOSS IN THE ALLIANCE PHASE 3 CLINICAL STUDY

Caleb Marceau[1] Pamela Odorizzi[1] Nikita Kolhatkar[1] Thomas Aeschbacher[1] David Pan[1] June Wai Man Mung[1] Sophia Rahman[1] Michelle D' Antoni[1] Ross Martin[1] Scott Balsitis[1] Sharline Madera[1] Frida Ambramov[1] Jason Hindman[1] Hongmei Mo[1] Anchalee Avihingsanon[2], [1]Gilead Sciences, [2]Thai Red Cross AIDS Research Centre

Background: Sustained Hepatitis B virus S-Antigen (HBsAg) loss is a marker of Chronic Hepatitis B virus (CHB) functional cure but occurs in only ~1% of HBV monoinfected patients per year on nucleos(t)ide therapy. We sought to characterize patients achieving HBsAg loss after initiating tenofovir containing antiretroviral treatment for HIV/HBV co-infected participants on the ALLIANCE trial. **Methods:** A total of 241 treatment naïve HIV/HBV co-infected participants with HBV DNA (COBAS 6800) of $\geq$2000IU/ml were enrolled in the ALLIANCE trial from study start (May 2018) to study completion (March 2024). Longitudinal quantitative HBsAg and HBeAg levels were measured for participants achieving HBsAg-loss. HBsAg loss was indicated by a negative HBsAg test result as determined by immunochemiluminometric assay (ICMA $<$0.05 IU/ml). **Results:** Of the 241 participants enrolled 54 (22.4%) were HBeAg(-) and 187 (77.6%) were HBeAg (+) at baseline. 55 (22.8%) participants achieved HBsAg loss of which 6 (11%) and 49 (26%) participants were HBeAg(-) and HBeAg(+) respectively at baseline. Baseline quantitative HBsAg levels were measured for 38 participants achieving HBsAg loss on study (5 and 33 for HBeAg(-) and HBeAg(+) groups respectively). For the HBeAg(-) group, 3 participants had baseline HBsAg levels of less than 2 IU/mL, and 2 participants had baseline HBsAg levels of 52,438 IU/mL and 4,669 IU/mL. For the HBeAg(+) group, 3 participants had baseline HBsAg levels of less than 3,000IU/mL, and 30 participants had median baseline HBsAg levels of 83,859 IU/mL with a range of 4,642 IU/mL to $>$249,750 IU/mL. Kinetics from treatment initiation to HBsAg loss was fast with 23 participants (5 and 18 for HBeAg(-) and HBeAg(+) groups respectively) achieving HBsAg loss within 48 weeks. HBsAg loss rates by genotype (GT) were 9/26 (34.6%) for GT-A, 4/45 (8.9%) GT-B, 28/111 (25.2%) GT-C, 8/29 (27.6%) GT-D, 2/4 (50%) GT-F with the remaining 4/26 (15.4%) having undetermined GT. Additionally, HBsAg loss was associated with higher levels of ALT ($>$ULN) and CD4+ T-cell counts ($>$200 cells/µL) at baseline. **Conclusion:** TAF/TDF treatment in HIV/HBV co-infected participants on the ALLIANCE trial resulted in high rates and rapid HBsAg loss even with high baseline HBsAg levels in many participants. HBsAg loss was associated with higher baseline ALT and CD4+ T-cell counts and was more frequent in participants with HBV GT-A and HBV GT-F. These suggest a role for viral and immune factors in HBsAg loss which can inform CHB functional cure therapeutic strategies.

1187 | METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE INCREASES HEPATOCELLULAR CARCINOMA RISK IN CHRONIC HEPATITIS B: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hanah Lee[1] Eunju Kim[1] Jong-In Chang[1] Hyung Joon Kim[1], [1]Chung-Ang University

Background: The recent introduction of the nomenclature "metabolic dysfunction-associated steatotic liver disease (MASLD)" highlights the importance of cardiometabolic risk factors in liver disease. While MASLD is acknowledged as a significant contributor to liver-related morbidity, its impact on hepatocellular carcinoma (HCC) risk in chronic hepatitis B (CHB) remains controversial. This systematic review and meta-analysis aimed to evaluate the association between MASLD and HCC risk in CHB. **Methods:** Data from observational studies were collected through PubMed, EMBASE, and the Cochrane Library from inception to March 1, 2025. The primary outcome was the association between MASLD and HCC. **Results:** A total of 27 studies involving 329,798 patients with CHB were included. SLD including non-alcoholic fatty liver disease (NAFLD), metabolic dysfunction-associated fatty liver disease (MAFLD), and MASLD, was associated with an increased risk of HCC (OR 1.99, 95% CI 1.40–2.59, $I^2 = 76\%$). When stratified by disease classification, all SLD subtypes remained associated with an increased HCC risk (MASLD OR 1.85, 95% CI 0.49–3.20; MAFLD OR 1.92, 95% CI 0.38–3.46; NAFLD OR 2.04, 95% CI 1.27-2.82). In subgroup analyses, the association remained consistent in both Asian (OR, 1.90; 95% CI 1.19–2.60; $I^2 = 78\%$), and non-Asian regions (OR, 2.29; 95% CI 1.16–3.43; $I^2 = 81\%$), as well as in studies with a median follow-up duration of ≥ 5 years (OR, 2.32; 95% CI, 1.51–3.13), those excluding alcohol use (OR, 2.57; 95% CI, 1.36–3.78), and those using biopsy-proven steatosis (OR, 3.28; 95% CI, 1.66–4.90). Similar associations were observed in hospital-based (OR 2.0, 95% CI 1.32–2.69) and nationwide datasets (OR 1.22; 95% CI 0.96–1.49). When stratified by antiviral therapy (AVT) use, there was no association between SLD and HCC risk in the non-AVT group (OR 0.95, 95% CI 0.58-1.32), whereas a positive association was observed in the AVT group (OR 1.32, 95% CI 0.93-1.71). Finally, studies that included only steatohepatitis showed the strongest association with an increased HCC risk (OR 3.66, 95% CI 1.83-5.49). **Conclusion:** MASLD is associated with an increased risk of HCC in patients with CHB, particularly in those with steatohepatitis, highlighting the importance of identifying concomitant steatosis in CHB.

1188 | HBCRAG AND HBSAG KINETICS AFTER TREATMENT CESSATION: IMPLICATIONS FOR FUNCTIONAL CURE AND HEPATITIS FLARES

Yao-Chun Hsu[1] Ying-Nan Tsai[2] Jia-Ling Wu[3] Cheng-Hao Tseng[4] Tzu-Haw Chen[4] Mindie Nguyen[5] Jaw-Town Lin[4] Katsuya Nagaoka[6] Yasuhito Tanaka[6], [1]E-Da Hospital, I-Shou University, [2]E-Da Hospital, [3]National Cheng Kung University, [4]E-Da Hospital/I-Shou University, [5]Stanford University Medical Center, [6]Kumamoto University

Background: Circulatory levels of hepatitis B core-related antigen (HBcrAg) and hepatitis B surface antigen (HBsAg) are emerging biomarkers for managing chronic hepatitis B (CHB). Prior studies have

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

demonstrated end-of-treatment (EOT) levels of HBcrAg and HBsAg are associated with clinical outcomes after cessation of nucleos(t)ide analogue (NAs). However, the post-treatment cessation kinetics of these biomarkers remain unclear, and their associations with hepatitis flares and functional cure have not been elucidated. **Methods:** This is a multicenter center cohort study that prospectively enrolled adults with non-cirrhotic CHB who received first-line NAs for at least 2 years, and were HBeAg-negative with undetectable HBV DNA in serum before stopping the treatment. Highly sensitive iTACT assays were used to measure HBcrAg and HBsAg at treatment cessation and then every 6 months for up to 3 years. Functional cure was defined as HBsAg loss with undetectable HBV DNA, while hepatitis flares were defined as alanine aminotransferase (ALT) elevation above 5 times the upper limit of normal. The kinetics of HBcrAg and HBsAg were analyzed, and their associations with functional cure and hepatitis flares were evaluated using time-dependent models. **Results:** A total of 206 patients were enrolled, with a median age of 50.0 years (interquartile range [IQR], 42.1–58.7) and predominantly male (78.6%, n = 162). After a median treatment duration of 37.6 months (IQR, 36.7–47.8), the median EOT HBcrAg and HBsAg levels were 3.0 log U/mL (IQR, 2.3–3.9) and 2.7 log IU/mL (IQR, 1.5–3.1), respectively. During a median follow-up of 70.3 months (IQR, 41.8–103.5), 30 patients achieved functional cure, corresponding to a cumulative incidence of 16.0% (95% CI, 10.3–22.7%) at 8 years, and 68 patients developed hepatitis flares, with a 8-year cumulative incidence of 33.9% (95% CI, 26.9–41.0%). As illustrated in Figure 1, the ALT trajectories significantly differed according to EOT HBcrAg and HBsAg levels. Both HBcrAg and HBsAg significantly decreased over 3 years in patients without hepatitis flares. In contrast, patients who experienced flares showed no significant changes over time. Similarly, patients who achieved functional cure exhibited significant reductions in HBcrAg and HBsAg, whereas the levels remained unchanged in those without functional cure. In multivariable analyses, the time-varying HBcrAg level was more accurate than the HBsAg level in predicting ALT flares, while time-varying HBsAg was superior in forecasting functional cure. **Conclusion:** Dynamic reductions in HBcrAg and HBsAg levels were observed in patients with favorable outcomes following NA cessation. Comparative analyses revealed that HBcrAg was more effective in predicting hepatitis flares, whereas HBsAg better predicted functional cure. Monitoring both biomarkers may provide complementary information to tailor management strategies for the practice of finite NA therapy.

1189 | HIBIT-TAG ENABLES THE TRACKING OF POLYMERASE ACTIVITY IN HBV LIFE CYCLE

Wan Yu[1] Xinyu Du[2] Qiqin Lei[3] Tianhao Mao[4] Fengmin Lu[5] Ting Zhang[5] Xiangmei Chen[5] Huan Wang[3], [1]Zunyi Medical University, Guizhou, China., [2]Zhengzhou University, Zhengzhou, China., [3]Zunyi Medical University, Zunyi, Guizhou, China., [4]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, China., [5]School of Basic Medical Sciences, Peking University Health Science Center, China.

Background: Chronic hepatitis B (CHB) is still a major global health problem. As a critical rate-limiting enzyme in HBV replication, polymerase (Pol) plays an important role in HBV life cycle. However, the biological characteristics of Pol remain poorly understood due to technological limitations. Here in this study, we engineered

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

novel systems to achieve visual tracking and quantitative analysis of Pol using the unique features of HiBiT peptide tag. **Methods:** First, the 11-amino acid of HiBiT tag was inserted into the region between Spacer and TP regions of Pol protein to establish two different HBV Pol tracking systems, which called HBVcircle-HiBiT-Pol and prcccDNA/Cre-HiBiT-Pol, resepctively. Next, bioluminescence assay was employed to evaluate intra- and extracellular expression of HiBiT-Pol in HepG2 cells transfected with the above systems. Chemiluminescence assay was used to quantify HBeAg and HBsAg while qPCR was performed to measure HBV DNA levels in culture supernatants. Recombinant viral particles were collected from cell culture supernatant and purified by iodixanol density gradient centrifugation for compositional analysis. Finally, the infectivity of recombinant viral particles was validated using the HepG2-NTCP cell infection model. **Results:** HiBiT-tag was successfully expressed without compromising HBV replication efficiency in both the HBVcircle-HiBiT-Pol and prcccDNA/Cre-HiBiT-Pol. No significant differences were observed in HBsAg, HBeAg levels or HBV DNA replication efficiency between HiBiT-tagged and wild-type constructs. Consistent with these findings, intracellular core protein expression level and the ratios of L/M/S-HBs isoforms remained unaltered. Importantly, HiBiT-tag was specifically detected in viral particles likely included naked capsids, Dane particles, and pgRNA-containing virus-like particles. As expected, the tagged virions maintained infectivity in HepG2-NTCP cells with persistent HiBiT signals detected in subsequent viral progeny. **Conclusion:** A system for real-time visualization and quantitation of HBV polymerase was established, which enabled us to detect the dynamics of Pol protein in HBV life cycle.

1190 | THE ROLE OF ALIX AND VPS4A IN AUTOPHAGY AND ENDOSOMAL PATHWAYS AND THEIR RELATION TO HBV REPLICATION

Mengji Lu Jia Li[1], [1]University Hospital Essen, Essen, Germany

Background: Background & Aims: Autophagic and endosomal pathways coordinately contribute to hepatitis B virus (HBV) production. Alix and VPS4A are two important endosomal sorting complex required for transport (ESCRT) components involved in membrane scission. Previous studies showed that Alix and VPS4A participate in HBV replication and modulate the release of HBV particles. Yet, the mechanisms remain elusive. In the present study, we investigated the role of Alix and VPS4A in HBV biogenesis in the context of endosomal membrane trafficking and autophagy. **Methods:** Methods: We examined the production, trafficking, and release of HBV particles by using gene silencing and overexpression of wild-type (WT) and dominant-negative (DN) mutants of Alix and VPS4A in HBV replication cell models. **Results:** Results: Alix silencing increased the levels of intracellular HBV DNA and subviral particles (SVPs/HBsAg), extracellular HBsAg, and virions, while decreasing the secreted naked capsids. Alix silencing promotes HBsAg secretion along the early endosomes while it reduces HBsAg transported to late endosomes and autophagosomes. Alix silencing impairs autophagosome formation by activating the AKT/MTOR pathway and increasing autophagosome degradation in lysosomes. VPS4A silencing has minimal effects on HBV production, while DN VPS4A significantly blocks HBV secretion. DN VPS4A disrupts endosomal trafficking and HBsAg colocalization within early endosomes and late endosomes, while promoting autophagosome formation and lysosome activity, resulting in HBV degradation. **Conclusion:** Conclusion: Our findings demonstrate that the endosomal pathway plays a critical role in HBV progeny secretion, particularly when lysosomal activity is suppressed. Conversely, increased lysosomal function drives HBV degradation through the autophagosome-lysosome pathway.

1191 | INCREASED POSTOPERATIVE RISK IN CIRRHOTIC WOMEN WITH CHRONIC HEPATITIS B UNDERGOING HYSTEROSCOPIC SURGERY

Calvin Pan[1] Xiulan Li[2] Fuqiang Xu[2] Nan Wang[2] Yanmei Li[2] Yifan Wang[2] Yuxiang Zhou[2] Huadong Tang[2] Xin Liu[2] Ying Hou[2] Meina Bian[2] Qing Liu[2], [1]NYU Langone Health, NYU School of Medicine, [2]Beijing You'an Hospital, Capital Medical University, Beijing, China

Background: Patients with chronic hepatitis B (CHB) and cirrhosis face increased postoperative risks, especially those with decompensated disease due to impaired hemostasis, immune dysfunction, portal hypertension, and reduced liver synthetic function. However, limited data exist on outcomes following hysteroscopic surgery in this population. This study aimed to evaluate perioperative complications in CHB-related cirrhotic women undergoing hysteroscopic procedures, to guide preoperative assessment and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

perioperative management. **Methods:** This retrospective cohort study was conducted at a tertiary hospital between March 2012 and June 2024. It included consecutive women with mono-HBV infection who underwent hysteroscopic surgery. Cirrhotic and non-cirrhotic patients were matched 1:1 using propensity scores. The primary outcomes were perioperative and 30-day postoperative complications, including their frequency and severity, classified according to the Clavien-Dindo classification. Secondary outcomes included the identification of independent predictors of complications in cirrhotic patients using multivariate logistic regression based on preoperative variables. **Results:** A total of 196 patients were included after propensity score matching (98 with cirrhosis and 98 without). The mean age was 53.5 years, and 51.52% were postmenopausal. Preoperative characteristics, including age, BMI, and frequency of diabetes, were comparable between the two groups, though laboratory abnormalities were more prevalent in the cirrhosis group (Table 1). Among cirrhotic patients, the mean Child-Pugh score was 5.89 ± 1.59, with 55.1% (54/98) classified as decompensated. The most frequent complications were fever (5/196, 2.6%), abdominal pain (4/196, 2.0%), nausea or vomiting (4/196, 2.0%), and abdominal distension (4/196, 2.0%). Compared to the non-cirrhotic group, cirrhotic patients had a significantly higher overall complication rate (15.3% [15/98] vs. 9.2% [4/98], P = 0.008). Based on the Clavien-Dindo classification, cirrhotic patients had a significantly higher rate of Grade I complications (13.27% vs. 5.2%, P = 0.035), while Grade II (1.02% vs. 0%, P = 0.37) and Grade III (1.02% vs. 0%, P = 0.36) complication rates were not significantly different. No Grade IV or V complications occurred in the entire cohort. Notably, all complications were non-hepatic. Multivariate analysis did not identify significant preoperative predictors of postoperative complications in cirrhotic patients. **Conclusion:** Women with CHB-related cirrhosis undergoing hysteroscopic surgery have a significantly higher risk of mild, non-hepatic postoperative complications compared to non-cirrhotic women. Despite this elevated risk, no liver-related mortality was observed, suggesting that hysteroscopic surgery can be safely performed with appropriate perioperative monitoring in this population.

Table 1. Clinical characteristics of the participants and liver cirrhosis status

Variables, mean ±SD or (pecified	Entire cohort (n=196)	Group A Cirrhosis (n=98)	Group B Non-cirrhotic (n=98)	*P*-value between groups A vs B

1192 | SINGLE-CELL SEQUENCING REVEALS THE MECHANISM OF HBSAG CLEARANCE MEDIATED BY PD-1 INHIBITOR COMBINED WITH PEG-IFNA

Chenrui Liu[1] Yaping Li[1] Liu Yang[1] Meng Zhang[1] Shuangsuo Dang[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University

Background: While pegylated interferon-alpha (Peg-IFNα) remains a cornerstone for chronic hepatitis B (CHB) functional cure, more than 60% of patients fail to achieve HBsAg seroclearance after 48-week therapy. Although PD-1 blockade has shown promise in reversing immune dysfunction, its synergistic potential with Peg-IFNα remains underexplored. **Methods:** In this prospective cohort study (ChiCTR2400091948), 64 HBeAg-negative CHB patients without HBsAg clearance (<0.05 IU/mL) after 48-week Peg-IFNα therapy were stratified into two groups according to treatment preference : Treatment group (n = 33): Subcutaneous PD-1 mAb (1mg/kg Q12W) + ongoing Peg-IFNα + Nucleos(t)ide Analogues (NAs); Control group (n = 31): Continued Peg-IFNα therapy + NAs. Paired PBMC samples from 3 treatment group patients at baseline and Week 12 (post-PD-1 initiation) were collected for single-cell sequencing. ELISA quantification of 9 IFN-related proteins (IFIT1, MX1, IFI6, ISG15, OAS1, EIF2AK2, STAT1, IRF7, IFITM3) in all 64 patients at baseline, Week 12 and Week 24. **Results:** ELISA validation demonstrated no significant differences in baseline levels of nine interferon-related proteins between the treatment group and control group (P > 0.05 for all). At Week 24, the treatment group showed pronounced increases in ISG15 (45.38 ± 4.33 pg/mL vs. 36.50 ± 6.30 pg/mL, P < 0.001) and IRF7 (1481.90 ± 217.93 pg/mL vs. 1113.70 ± 401.35 pg/mL, P = 0.001). However, there was no significant change in the levels of the aforementioned proteins in the serum of the control group. Single-cell sequencing yielded 19 clusters, which were identified as 10 distinct cell types. Differential gene expression analysis across cell types before and after treatment

revealed that in three interferon non-responders treated with PD-1 inhibitors for 12 weeks, CD4+ T cells, CD8+ T cells, NK cells, and B lymphocytes exhibited significant upregulation of interferon signaling pathway-related genes (STAT1, IRF7, IRF9) and effector protein-coding genes induced by interferon (IFIT1, IFIT2, IFIT3, OAS1, OAS2, OAS3, MX1, MX2, ISG15, etc.). After enrichment analysis of up-regulated genes in various cell groups, it was found that the up-regulated genes were mainly related to antiviral immunity. **Conclusion:** CHB patients undergoing long-term Peg-IFNα therapy may exhibit insufficient activation of the interferon signaling pathway, which is a critical factor contributing to their low HBsAg clearance efficiency. However, the addition of PD-1 inhibitors can significantly enhance the biological efficacy of Peg-IFNα in these HBsAg-persistent patients by promoting the restoration of interferon pathway functionality and activating downstream effector genes. The combination therapy markedly elevated peripheral blood levels of ISG15 and IRF7.

1193 | HEPATITIS B VIRUS SP1CIRCLE DNA GENERATED FROM SP1 DOUBLE-STRAND LINEARIZED DNA COULD PROMOTE HBV REPLICATION

Liang Wang[1] Qianqian Jiang[2] Wan Yu[3] Ting Zhang[4] Xiaoping Wu[1] Xiangmei Chen[4] Fengmin Lu[4], [1]The First Affiliated Hospital, Jiangxi Medical College, Nangchang University, [2]Peking University People's Hospital, Peking University Hepatology Institute, [3]Zunyi Medical University, [4]School of Basic Medical Sciences, Peking University

Background: Spliced RNA 1 (SP1) is the most abundant spliced variant of the viral pregenomic RNA. The lack of hM region (nt2806-2994) of the HBV cis-acting sequence would prevent rcDNA formation and instead, lead to the generation of SP1 double-stranded linear DNA (SP1-derived dslDNA, SP1-dslDNA). It remains unknown whether SP1-dslDNA can undergo circularization through non-homologous end joining (NHEJ) to generate SP1circle DNA, a proceed similar to the NHEJ-mediated formation of cccDNA from wild-type HBV dslDNA. **Methods:** The SP1 variant (pcDNA3.1-SP1) was constructed using a plasmid containing integrated HBV DNA that mimics dslDNA, with nucleotides 2447-489 removed from the dslDNA. The purified SP1-dslDNA fragments (nt1818-3215/0-1827 with nt2447 to 489 removed) amplified by PCR were transfected into HepG2 cells. Subsequently, the extracted Hirt DNA was used for amplicon sequencing with primers targeting the head-to-tail junction region of SP1-dslDNA, if circulization occured. To further investigate its impact, SP1circle DNA was constructed by modifying an established HBV circle plasmid (a cccDNA mimic) through deletion of nucleotides 2447–489. In addition, its impact on HBV replication was investigated through co-transfection of SP1circle with HBVcircle plasmids (with the Pol protein tagged by a Hibit-tag) into HepG2 cells. **Results:** Via NHEJ, SP1-dslDNA could circularize to produce a series of indels sequence within the head-to-tail junction region in HepG2 cells. Notably, since a subset (~9.09%) of SP1circle DNAs retained functional BCP/CP promoters and partially intact preC/C ORF, both HBeAg and core proteins were detected without HBsAg or HBV DNA detected. Next, co-transfection of SP1circle and HBVcircle increased extracellular HBV DNA levels in the supernatant compared to co-transfection of HBVcircle with an empty vector. Luciferase reporter assays revealed that co-transfection with SP1circle enhanced polymerase (Pol) protein levels in both cellular lysates and supernatant. Western blot analysis showed that SP1 co-transfection significantly increased total and cytoplasmic TIAR protein levels, suggesting that SP1circle may promote HBV replication by upregulating TIAR expression which

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

inturn enhanced polymerase translation. **Conclusion:** SP1-dsIDNA could circularize through NHEJ to produce SP1circle which could express core protein, potentially enhancing HBV replication through TIAR mediated Pol protein translation.

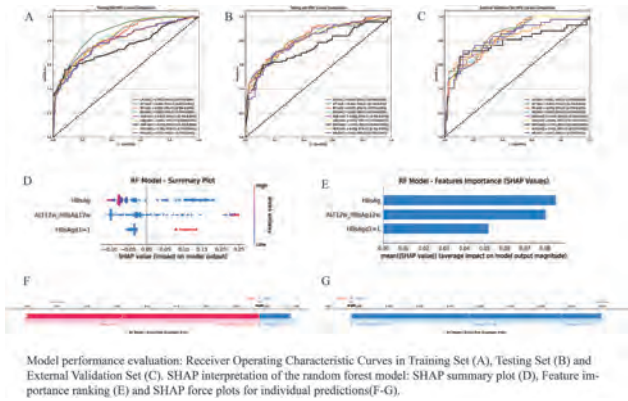
1194 | PREDICTING HBSAG SEROCLEARANCE AFTER 48 WEEKS OF PEGYLATED INTERFERON THERAPY IN INACTIVE CARRIERS: A MACHINE LEARNING APPROACH

Jianxia Dong[1] Shan Ren[1] Jing Zhao[1] Pengxuan Wu[1] Haitian Yu[1] Xinyue Chen[1] Sujun Zheng[1], [1]Department of Hepatology, Beijing YouAn Hospital, Capital Medical University, Beijing, China

Background: To investigate the predictors of hepatitis B surface antigen (HBsAg) seroclearance after 48 weeks of pegylated interferon (Peg-IFN) therapy in inactive HBsAg carriers (IHCs), and to develop a machine learning model to optimize clinical decision-making. **Methods:** A total of 777 IHC patients who received at least 48 weeks of Peg-IFN therapy were retrospectively enrolled from the multicenter "Hepatitis B Clinical Cure—Starlight Project" (STARHB) cohort in China. Least absolute shrinkage and selection operator (LASSO) regression and the Boruta algorithm were used to select predictive variables. Nine machine learning models were constructed, including logistic regression (LR), decision tree (DT), and random forest (RF). Model performance was evaluated using 10-fold cross-validation and externally validated in an independent cohort (n = 167) from three medical centers in Beijing. Shapley additive explanations (SHAP) were applied to interpret variable contributions. **Results:** The HBsAg seroclearance rate at week 48 was 29.9% (232/777). Key predictive factors included baseline HBsAg level, HBsAg decline at week 12, and the ratio of alanine aminotransferase (ALT) to HBsAg at week 12. The RF model demonstrated the best performance, with an area under the receiver operating characteristic curve (AUC) of 0.829 (95% confidence interval [CI]: 0.784–0.874) and specificity of 0.774 in the training set. In the external validation cohort, the AUC was 0.838 (95% CI: 0.759–0.917) with a specificity of 0.968. SHAP analysis indicated that baseline HBsAg level was the most important predictor. **Conclusion:** The RF model developed in this study accurately predicts HBsAg seroclearance in IHC patients receiving Peg-IFN therapy, offering a novel strategy for early identification of candidates with favorable response and for personalized treatment planning.



Model performance evaluation: Receiver Operating Characteristic Curves in Training Set (A), Testing Set (B) and External Validation Set (C). SHAP interpretation of the random forest model: SHAP summary plot (D), Feature importance ranking (E) and SHAP force plots for individual predictions(F-G).

1195 | CIRCULAR RNA SETD2 (CIRCSETD2) INCREASES DDX3 EXPRESSION TO INHIBIT AUTOPHAGY BY SPONGING MIR-181A-5P IN HEPATITIS B VIRUS INFECTION

MD ISMAIL[1] Teja Naveen Sata[1] Runa Nasrin Sheuly[1] Amrendra Kumar Sah[1] Srijita Paul[1] Gopal Sharma[1] Senthil Kumar Venugopal[1], [1]South Asian University

Background: Circular RNA (circRNA) is a covalently closed non-coding RNA produced by back-splicing mechanism. They act as competing endogenous RNA to modulate various cell functions and infections. Hepatitis B virus (HBV) utilizes cellular recycling mechanism autophagy for its proliferation. It modulates the expression of various host factors, such as non-coding RNAs and several host restriction factors to induce autophagy. Circular RNA SET domain containing 2 (circSETD2) was reported to inhibit hepatocellular carcinoma progression. However, its role in HBV infection is not yet established. A recent study showed that miR-181a-5p, upregulated in HBV, was sponged by circSETD2 in trophoblasts. Dead Box RNA helicase 3 (DDX3), a host restriction factor of HBV infection, was targeted by miR-181a-5p in HIV infection. In this study, we explored the role of circSETD2 in the modulation of miR-181a-5p and DDX3 in HBV infection. **Methods:**

CircSETD2 were cloned into pcDNA3.1(+) circRNA mini vector. $pHBV_{3.1}$, HBx plasmids were transfected into HepG2 or pCircSETD2 was transfected to HepG2.2.15 cells using Lipofectamine-2000 reagent. miR-181a-5p mimics and inhibitors were transfected in HepG2.2.15 cells using SiPORT NeoFX transfection reagent. After 48 hours, cells were collected for RNA and protein isolation. CircSETD2, HBx and miR-181a-5p expression were analysed by qPCR. DDX3 and autophagy markers ATG5, Beclin1 and LC3 II expression were analysed by Western blot. **Results:** The expression of circSETD2 was lower in HepG2.2.15 cells compared to HepG2 cells ($p \leq 0.005$). HBV and HBx transfection in HepG2 cells downregulated circSETD2 expression ($p \leq 0.05$). CircSETD2 transfection in HepG2.2.15 cells downregulated the expression of miR-181a ($p \leq 0.05$), whereas HBV and HBx transfection in HepG2 cells upregulated the expression of miR-181a-5p. miR-181a-5p mimics transfection in HepG2.2.15 cells resulted in downregulation of DDX3 and upregulation of ATG5, Beclin1 and LC3 II ($p \leq 0.05$). Conversely, miR-181a-5p inhibitor induced the expression of DDX3 and reduced the levels of ATG5, Beclin1 and LC3 II. Further, circSETD2 transfection in HepG2.2.15 cells led to the upregulation of DDX3 and downregulation of ATG5, Beclin1 and LC3 II ($p \leq 0.05$). **Conclusion:** The data suggested that HBV inhibits circSETD2 expression to enhance miR-181a-5p, which in turn inhibits DDX3, and the decreased DDX3 results in enhanced autophagy.

1196 | PROTEOMIC ANALYSIS OF SERUM EXTRACELLULAR VESICLES IDENTIFIES FIBULIN-3 AS A NOVEL PREDICTOR OF HCC IN CHB PATIENTS

Emi Sometani[1] Kazuhiro Murai[1] Takao Kitanaka[1] Takayuki Miyake[1] Shinji Kuriki[1] Jihyun Sung[1] Kazuki Maesaka[1] Satoshi Shigeno[1] Yuta Myojin[1] Kumiko Shirai[1] Yuki Tahata[1] Yoshinobu Saito[1] Takahiro Kodama[1] Hayato Hikita[1], [1]The University of Osaka

Background: Although nucleos(t)ide analog (NUC) therapy reduces the incidence of hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB), HCC can still develop even when HBV DNA is suppressed. Identifying predictive markers for HCC during NUC therapy is of significant clinical importance. In this study, we performed proteomic analysis of serum extracellular vesicle (EV) proteins and aimed to identify novel biomarkers predictive of HCC development. **Methods:** A total of 242 CHB patients were included in the study. All had stored serum samples available, had been treated with NUCs for at least one year at the time of sample collection, had serum HBV DNA levels below 3.0 log IU/mL, and had no prior history of HCC. We performed proteomic analysis of serum EV proteins using stored sera and identified candidate proteins predictive of HCC development. The serum levels of the identified candidate proteins were then measured using ELISA to evaluate their potential as predictive biomarkers. **Results:** The median age of the patient cohort was 55 years, and 144 patients were male. During the observation period, 44 patients (18.2%) developed primary HCC. Proteomic analysis identified five candidate EV proteins; EGF-containing fibulin-like extracellular matrix protein 1 (fibulin-3), vascular cell adhesion protein 1 (VCAM-1), Fibronectin, von Willebrand factor (vWF), Fibroblast growth factor-binding protein 2 (FGFBP2). The serum levels of all five candidate proteins were subsequently quantified by ELISA. Among these, fibulin-3 and VCAM-1 levels were extracted as significant factors in univariate analysis of the COX proportion hazards model. In multivariate analysis, gender (HR: 2.70 [1.21-6.05]), γ-GTP (HR: 1.01 per 1 U/L increase [1.004-1.011]), AFP (HR: 1.05 per 1ng/mL increase [1.01-1.08]), fibulin-3 (HR: 1.06 per 1μg/mL increase [1.02-1.11]), and FIB-4 index (HR: 1. 24 per 1-point increase [1.05-1.42]) were identified independent factors, while VCAM-1 was not. Serum Fibulin-3 levels had a median of 10.1 μg/mL. Using the Youden index, a cutoff value of 10.8 μg/mL was determined. The cumulative incidence of HCC was significantly higher among patients with fibulin-3 $\geq$ 10.8 μg/mL, AFP $\geq$ 3.0 ng/mL, γ-GTP $\geq$ 22 U/L, FIB-4 index $\geq$ 1.93, and male gender. Among patients with none or more than three of these five risk factors, the 10-year HCC cumulative incidence rates were 0% and 37.2%, respectively. **Conclusion:** Serum Fibulin-3 was identified as a biomarker for predicting HCC in CHB patients under NUC treatment.

1197 | IL-1B FROM PERIPHERAL BLOOD CD14+ MONOCYTES PREDICTS SERUM HBSAG DECLINE IN PATIENTS WITH CHRONIC HEPATITIS B

Satoshi Shigeno[1] Takahiro Kodama[1] Kazuhiro Murai[1] Hayato Hikita[1] Tomohide Tatsumi[1] Tetsuo Takehara[1], [1]Department of Gastroenterology and Hepatology, The University of Osaka, Graduate School of Medicine

Background: Although nucleotide analogs (NAs) suppress viral replication in patients with chronic hepatitis B (CHB), they rarely achieve HBsAg seroclearance. While a reduction in HBsAg levels is associated with seroclearance, the factors regulating HBsAg levels remain poorly understood. To advance toward a "functional cure," we investigated the host immune dynamics involved in the reduction of HBsAg levels. **Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from CHB patients who showed a decrease in serum HBsAg from $>1{,}000$ IU/mL to <100 IU/mL after over two years of NA therapy (declining group), and from those with persistently high levels ($>1{,}000$ IU/mL, persistent group). Single-cell RNA sequencing (scRNA-seq), targeting 397 immune-related genes, was performed to investigate immune cell dynamics. The findings were validated in an independent cohort of 32 patients and further extended to a long-term follow-up cohort of 45 patients, in whom cytokine levels were measured one year after initiation of NA therapy. In vitro analysis was performed with HBV-expressing cell line HepG2/2.2.15. **Results:** scRNAseq revealed ten distinct immune cell populations, with the monocyte cluster in the declining group exhibiting higher antigen presentation and phagocyte gene scores. Differential gene expression analysis revealed that IL-1β expression in the $CD14^+$ monocyte cluster was significantly higher in the declining group than in the persistent group. In the validation cohort, IL-1β expression level of isolated circulating $CD14^+$ classical monocytes was also significantly higher in the declining group. In vitro, treatment with recombinant IL-1β reduced the HBsAg levels in the supernatant of HepG2/2.2.15 in a dose-dependent manner. In ex vivo studies, stimulating $CD14^+$ monocytes with HBs antigen significantly increased IL-1β expression in the declining group. Finally, in the long-term follow-up cohort, serum IL-1β levels measured one year after initiation of NA therapy were significantly higher in the declining group, and multivariate analysis identified high serum IL-1β as independent predictors of HBs antigen decline. **Conclusion:** In CHB patients, differences in the IL-1β production capacity of peripheral blood classical monocytes might contribute to the decline of serum HBsAg levels during NA treatment.

1198 | HEPATOCELLULAR CARCINOMA SCREENING RATES AMONG INDIVIDUALS WITH CHRONIC HEPATITIS B IN A LARGE URBAN ACADEMIC CENTER

Cameron Adams[1] Terry Li[1] Feng Su[2], [1]New York University, [2]NYU

Background: Routine hepatocellular carcinoma (HCC) screening facilitates early cancer detection and improves survival among patients with chronic hepatitis B (HBV). However, screening adherence remains suboptimal due to patient, provider, and system-level barriers. The primary objective of this study was to identify barriers to screening by determining the proportion of ordered screening tests that were successfully completed among patients with chronic HBV at a large urban academic hospital. Our secondary objective was to determine the overall screening rate in the cohort and identify variables that differed between those who underwent screening and those who did not. **Methods:** Inclusion criteria were age ≥ 18 years, a diagnosis of chronic HBV, and established follow up with either primary care or gastroenterology/hepatology during the study period. Patients were excluded if they had a prior HCC diagnosis or a history of liver transplantation. Overall screening rate was determined by identifying the proportion of patients undergoing abdominal ultrasound, CT abdomen, or MRI ordered for screening purposes during a 1-year period from 10/01/2022 to 10/01/2023. Screening completion was defined as completion of the first ordered screening test during the study period. **Results:** A total of 330 individuals met inclusion criteria. Of 226 screening tests that were ordered, 204 (90%) were completed. The overall screening rate during the study period was 62%. The screening rate was significantly higher in individuals with cirrhosis compared to those without cirrhosis (83% vs 60%, $p = 0.024$). No significant difference was observed based on marital status, gender, insurance type, English fluency and type of imaging ordered. Patients under the care of a gastroenterologist or hepatologist had significantly higher screening rates compared to those not under specialist care (73% vs 26%, $p < 0.00001$). **Conclusion:** HCC screening rates among individuals with chronic HBV remain suboptimal. The vast majority of patients for whom a screening test is ordered proceed to completion of the test, suggesting that the barrier to screening may be at the level of providers ordering screening tests and/or linkage to care rather than lack of patient adherence to

1199 | NOVEL FIBROGENIC MACROPHAGE SUBPOPULATION DRIVES HBV-RELATED LIVER FIBROSIS AND OFFERS A TARGET FOR ANTIBODY THERAPY

Masaya Sugiyama[1] Aiko Sakai[2], [1]Japan Institue for Health Security, [2]Japan Institute for Health Security

Background: Chronic hepatitis B virus (HBV) infection has been demonstrated to lead to rapid progression of liver fibrosis and hepatocellular carcinoma (HCC), thus bypassing the traditional multistep carcinogenesis model. Despite its clinical significance, no effective antifibrotic therapies are currently available, making hepatic fibrosis a major unmet medical need. In the previous study, we utilized chimeric mice with human hepatocytes infected with HBV (HBV-chimeric mice) as a model of HBV-associated liver fibrosis. The aim of this study was to identify novel fibrogenic cell populations using single-cell RNA sequencing (scRNA-seq) of liver tissues from both HBV-chimeric mice and HBV-infected patients, and to explore potential therapeutic targets for fibrosis suppression. **Methods:** scRNA-seq was performed on liver tissues obtained from HBV-chimeric mice and human patients with chronic HBV infection. The resulting datasets were analyzed to identify cell populations associated with fibrosis progression and to characterize their gene expression profiles. The presence of these cell populations was validated through immunohistochemistry and fluorescence-activated cell sorting (FACS). To assess therapeutic efficacy, HBV-chimeric mice were treated with an anti-GPNMB monoclonal antibody, and hepatic fibrosis was evaluated after three months. **Results:** scRNA-seq analysis of HBV-chimeric mouse livers revealed a distinct macrophage subpopulation enriched in fibrotic regions. This macrophage subtype, characterized by $C1Q^+$/$GPNMB^+$/$CD68^+$ expression, was also identified in resected liver specimens from HBV-infected patients. The frequency of this subpopulation positively correlated with fibrosis stage in HBV cases but not in HCV-related liver disease. Functional inhibition of GPNMB with monoclonal antibodies in HBV-chimeric mice significantly reduced both fibrosis grade and the expression of fibrosis-associated genes after three months of treatment ($p < 0.05$). **Conclusion:** GPNMB-positive macrophages played a critical role in HBV-associated liver fibrosis. Targeting these cells with anti-GPNMB antibodies effectively suppressed fibrosis progression, underscoring their potential as a novel therapeutic target. These findings could provide a rationale for the development of antibody-based therapies for fibrotic liver diseases in patients with chronic HBV infection.

1200 | THE GLOBAL BURDEN OF ACUTE AND CHRONIC HEPATITIS B IN YOUNG AND MIDDLE-AGED ADULTS FROM 1990 TO 2021

Mohammed Youssef[1] MOHAMED A ELNAGGAR[2] Mohamed Eldesouki[3] Mona Ali[4] HESHAM ELGOUHARI[5] Sherif Elhanafi[6], [1]Hunt Regional Medical Center, [2]University of Connecticut, [3]New York Medical College at Saint Michael Medical Center, [4]Mansoura University Egypt, [5]texoma liver center, [6]Division of Gastroenterology, Texas Tech University Health Sciences Center El Paso

Background: Viral hepatitis B (Hep. B) is a significant health concern; it is one of the leading causes of chronic liver diseases and liver cancer worldwide. According to the WHO it is estimated that 254 million individuals worldwide are affected with chronic Hep B. In this study we aim to investigate the global incidence, mortality and disability-adjusted life years (DALYs) related to acute and chronic Hep B among Young and middle-aged adults. **Methods:** Global data were extracted from the GBD database for the age group between 15-49 years from 1990 to 2021. The total burden of hepatitis B includes acute Hep. B, chronic Hep. B including cirrhosis, and liver cancer due to hepatitis B. The primary outcome was the total Hep B related, mortality rate, and incidence rate. global trends were visualized using GBD derived mortality figures and graphs, with data further stratified by sex and by Socio-demographic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Index (SDI). **Results:** The total mortality rate of Hepatitis B in 1990 was 127.909 death vs 168,802.07 in 2021. The mortality rate decreased from 6.06 CI (5.34-6.98) per 100,000 in 1990 to 4.28 CI (3.65-4.91) per 100,000 in 2021. Gender specific data showed that males had a mortality rate of 9.32 CI (8.15-10.77) and 6.69 CI (5.70-7.75) per 100,000 in 1990 and 2021 respectively. Females had a lower mortality rate of 2.72 CI (2.29-3.22) and 1.80 CI (1.51-2.11) per 100,000 in 1990 and 2021 respectively. The incidence rate of Hep B in 1990 was 1,763.66 CI (1,307-2,259) per 100,000 and 1,171 CI (878.05- 1,530.09) per 100,000 in 2021. The DALYs decreased from 316.57 CI (278.22-362.66) in 1990 to 220.14 CI (190.66-250.97) in 2021 in this age group. The prevalence rate decreased from 6,470.26 CI (5,889- 7,178) per 100,000 in 1990 to 4,451 CI (4,058-4,912) per 100,000 in 2021. Low SDI countries had the highest Hep B mortality rate in 1990 and 2021 with rates of 8.52 CI (6.97-10.34) and 5.61 CI (4.61-6.71) respectively. High SDI countries had the lowest mortality rate in 1990 and 2021 with rates of 2.39 CI (2.05-2.73) and 1.28 CI (1.06-1.48) respectively. **Conclusion:** This study highlights a global decline in Hep B related burden among individuals aged between 15-49 from 1990-2021. This decline can be explained by improved prevention and treatment strategies. Despite this progress and the wide availability Hep B vaccine, males and low SDI countried suffered more for Hep B complications. Targeted public health efforts are needed to close these gaps and accelerate progress toward HBV elimination goals.

1201 | IMMUNE DYSREGULATION IN PREGNANT WOMEN WITH CHRONIC HEPATITIS B: IMPAIRED MDSC FUNCTION AND ENHANCED T CELL ACTIVATION

Xingfei Pan[1] Panpan Zhai[1] Li Pan[1] Xueting Ou[1] Liyang Zhou[1] Jun Huang[2] Calvin Pan[3,] [1]The Third Affiliated Hospital, Guangzhou Medical University, Guangzhou, China, [2]China Sino-French Hoffmann Institute, Guangzhou Medical University, [3]Guangzhou Medical University, Guangzhou, China; NYU Langone Health, NYU School of Medicine

Background: Myeloid-derived suppressor cells (MDSCs) are immature myeloid cells with potent immunosuppressive activity, particularly in chronic inflammatory conditions. However, limited data are available regarding MDSC activity in pregnant women with chronic hepatitis B (CHB). We aimed to compare the status of MDSCs in pregnant women with CHB versus healthy controls, focusing on their abundance and the expression of molecules and immune cells commonly associated with MDSC function. **Methods:** We prospectively enrolled mothers at a tertiary care hospital in China between May 6, 2024, and April 8, 2025, including both CHB-infected mothers and healthy controls. Clinical data, along with peripheral blood, umbilical cord blood, and placental samples, were collected at delivery. MDSC counts and subsets were analyzed by flow cytometry. We also measured molecules and immune cells commonly associated with MDSC function, including $CD4^+$ T cells, CD80, CD163, reactive oxygen species (ROS), arginase-1 (Arg-1), transforming growth factor-β (TGF-β), programmed death-ligand 1 (PD-L1), and interleukin-10 (IL-10). **Results:** Among 160 participants (CHB: n = 69; healthy: n = 91), the mean age was 33 years. In the CHB group, the median (IQR) HBV DNA level was 52.98 (29.00, 827.20) IU/mL; 18.84% were HBeAg-positive, and 30.43% received antiviral therapy. Compared to healthy mothers, those with CHB had significantly lower counts of neutrophils (11.57 vs. 10.22, $p = 0.01$) and monocytes (1.02 vs. 0.86, $p = 0.0007$). MDSC analyses revealed a significant reduction in the proportion of total MDSCs (54.2% vs. 38.4%, $p = 0.0002$), granulocytic MDSCs (51.5% vs. 25.8%, $p < 0.0001$), and expression of MDSC-associated markers (Figure 1), including CD163 (69.9% vs. 46.1%, $p < 0.0001$), ROS (52.43×10^4 vs. 36.24×10^4, $p = 0.006$), Arg-1 (7.370×10^4 vs. 4.45×10^4, $p < 0.0001$), TGF-β (78.4% vs. 65.9%, $p = 0.0005$), PD-L1 (48.9% vs. 39.0%, $p = 0.0019$), and IL-10 (53.8% vs. 33.5%, $p < 0.0001$). In contrast, $CD4^+$ T cell counts and CD80 expression were significantly elevated in the CHB group compared to controls. **Conclusion:** Compared to healthy pregnant women, those with CHB exhibited a marked reduction in MDSC abundance and immune-regulating function, as reflected by decreased expression of CD163, ROS, Arg-1, TGF-β, PD-L1, and IL-10. Conversely, $CD4^+$ T cell numbers and CD80 expression were increased. These immunologic shifts may influence the regulation of maternal-fetal immune tolerance in the context of chronic HBV infection.

1202 | INVESTIGATION OF CORE I97L MUTATION AND HOST IMMUNE RESPONSE INVOLVED IN FUNCTIONAL CURE OF CHRONIC HEPATITIS B

Takashi Honda[1] Kena Yamamoto[1] Kazuyuki Mizuno[1] Hisanori Muto[1] Shinya Yokoyama[1] Takanori Ito[1] Norihiro Imai[1] yoji ishizu[1] Yoshiki Murakami[2] Sachiyo Yoshio[3] Tatsuya Kanto[4] Hiroki Kawashima[1] Tetsuya Ishikawa[1], [1]Nagoya University Graduate School of Medicine, [2]Tokyo Medical Univesity/Asahi University, [3]National Institute of Global Health and Medicine, [4]National Center for Global Health and Medicine

Background: Functional cure (FC) is a treatment goal for chronic hepatitis B (CHB). We previously reported that the I97L mutation in the HBV core region reduces cccDNA production and is associated with FC. This study aimed to evaluate whether the core I97L mutation can predict FC in CHB and how it relates to host immune responses for viral clearance. **Methods:** Study 1: In 129 CHB patients, clinical and viral factors associated with FC were analyzed using the Cox proportional hazards model. Study 2: Peripheral blood mononuclear cells (PBMC) were obtained from 10 FC and 9 non-FC patients matched for clinical background, using the patients from Study 1. PBMCs were stimulated with peptides containing the amino acid sequence of the core region I97 (wild-type peptide) and core region I97L (mutant peptide), and the IFNγ-producing cell ratio was compared using Enzyme-Linked ImmunoSpot (ELISpot) assay (R&D Systems). HLA typing was also performed. Study 3: Serum cytokines were measured at baseline (Pre, from Study 1) and at the time of PBMC collection (Post, from Study 2). **Results:** In Study 1, both univariate and multivariate analyses identified HBsAg levels and I97L mutation as significant predictors of FC ($P < 0.001$, $P = 0.004$). In Study 2, PBMC in non-FC patients exhibited significantly higher IFN-γ responses to the wild-type peptide compared to the mutant peptide. While no significant HLA differences were observed between FC and non-FC groups, HLA-A*24:02 positivity rate was more frequent in I97L carriers (75.0%) as compared in wild-type (14.3%) ($P < 0.05$). In Study 3, the expression level of cytokine was not different at Pre. However, at the Post levels of CXCL9, CCL22, and TNF-α, were significantly lower in FC patients ($P < 0.05$). From pre- to post, significant changes were observed in CXCL9, CXCL11, CXCL13, CCL2, CCL15, and IL-4. Notably, CXCL9 levels decreased significantly in FC patients and correlated with the reduction in ALT. HLA-A*24:02 was enriched among patients with I97L mutation compared to the general Japanese population. IFNγ production in response to wild-type peptide correlated with elevated post-CXCL9 levels, especially in non-FC patients. **Conclusion:** The elimination of wild strains by the host's acquired immune response may have acted as a selective pressure leading to the emergence of the I97L mutation. This suggested core I97L mutation may be a valuable predictor for FC in addition to low HBs antigen levels.

1203 | UPDATE OF 96 WEEKS TENOFOVIR AMIBUFENAMIDE TREATMENT IN CHRONIC HBV-INFECTED PATIENTS WITH NORMAL ALANINE AMINOTRANSFERASE (THE PROMOTE STUDY)

Honglian Gui[1] Yingqiu Shen[2] Lin Tan[3] Qing Xie[1] Lihong Qu[2] Piao Hu[4] Feng Qian[5] Xiaoping Wu[6] Yuanwang Qiu[7] Sujun Zheng[8] Jiaojian Lv[9] Yunzhen Shi[10] Jun Li[11] Yongfang Jiang[12] Zhizhen Hu[13] Yan Huo[13] Fanru Nie[13] Weijian Huang[13], [1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [2]East Hospital Affiliated To Tongji University, [3]The Second People's Hospital of Fuyang, [4]Hangzhou Xiaoshan First People's Hospital, [5]The Fifth People's Hospital of Suzhou, Hospital of Infectious Diseases Affiliated to Soochow Univers, [6]The First Affiliated Hospital of Nanchang University, [7]Wuxi Fifth People's Hospital, [8]Beijing You 'an Hospital, Capital Medical University, [9]Lishui People's Hospital, [10]Dongyang People's Hospital, [11]Jiangsu Provincial People's Hospital, [12]The Second Xiangya Hospital of Central South University, [13]Jiangsu Hansoh Pharmaceutical Group Co., Ltd.

Background: The primary analysis of the PROMOTE study showed significant efficacy in chronic HBV-infected patients at 48 weeks with normal alanine aminotransferase (ALT) levels with favorable bone, renal and blood lipid safety profiles. Here we report a prespecified updated analysis after 96 weeks follow-up. **Methods:** Participants aged 18-65 diagnosed as chronic hepatitis B virus infection, with serum HBV DNA > 20IU/mL and normal ALT ($\leq$1×ULN [40 IU/L]) were randomly assigned to the TMF (25 mg/day) group or blank control group. Blood samples were analyzed for HBV DNA, HBsAg, HBeAg, and ALT levels, with the proportion of participants with serum HBV DNA levels < 20 IU/mL at week 96. **Results:** This analysis included 193 participants (93 TMF, 100 control). At 96 weeks, TMF treatment demonstrated significantly higher rates of HBV DNA suppression to < 20 IU/mL compared to control (78.49% vs 14.0%, $p < 0.001$). In patients with high baseline viral load (HBV DNA $\geq$8 log10 IU/mL), TMF treatment achieved HBV DNA < 2,000 IU/mL in 95.24% of patients (including 38.1% with HBV DNA < 20 IU/mL), compared with 5.56% (0 < 20 IU/mL) in controls. Among HBeAg-negative patients, TMF treatment demonstrated significantly higher rates of HBV DNA suppression to < 20 IU/mL (91.3% vs 18.31%; $p < 0.001$). Compared with the control group, TMF treatment resulted in a significant reduction in HBsAg levels from baseline (-0.29 vs -0.07 log10 IU/mL, $p < 0.001$), with this trend being similarly significant in the HBeAg-positive subgroup (-0.30 vs 0 log10 IU/mL, $p < 0.001$). Participants receiving TMF demonstrated significantly greater reductions in ALT levels compared with controls (-12.25% vs 6.25%, $p < 0.001$). This treatment effect was consistently observed in both HBeAg-positive (-10.81% vs 21.43%, $p = 0.007$) and HBeAg-negative (-13.01% vs 5.0%, $p = 0.008$) subgroups. Notably, one case of acute hepatitis with ALT flare (ALT > 5×ULN) unrelated to other causes occurred in the control group, while none were observed in the TMF group. No between-group differences were observed in creatinine levels, glomerular filtration rates, or lipid profiles. **Conclusion:** TMF demonstrated sustained potent antiviral efficacy, while maintaining favorable safety profiles and tolerability. TMF treatment appears to reduce the incidence of virus replication associated ALT flare. Long-term follow up are required to observe the benefit of outcome improvement after antiviral treatment in such population. Clinical trial Registry: NCT05797714.

1204 | THE ROLE AND MECHANISM OF THE HOST RESTRICTION FACTOR SLFN5 IN HEPATITIS B VIRUS TRANSCRIPTION AND REPLICATION

Ning Han[1], [1]Sichuan University

Background: Hepatitis B virus (HBV) infection remains a global health challenge, with current treatments unable to fully eradicate it. Host restriction factors (HRFs), especially those induced by interferons, play a key role in antiviral defense. Schlafen family member 5 (SLFN5), an interferon-α-inducible HRF, has shown antiviral activity against viruses like HIV-1 and herpes simplex virus. However, its role in HBV infection is unclear. This study aims to investigate SLFN5's function

in regulating HBV transcription and replication, offering potential for HRF-based antiviral therapies against HBV. **Methods:** Differentially expressed genes in HBV-infected dHepRG cells with or without interferon-α (IFN-α) treatment were analyzed by RNA sequencing and Interferome database integration. SLFN5 was identified as an IFN-α-inducible HRF, validated by qRT-PCR and western blotting. Its effect on HBV replication was evaluated in cell models through gain- and loss-of-function experiments, measuring HBV RNA, DNA, and antigens. *In vivo*, SLFN5 modulation was assessed using an AAV8-HBV mouse model. Mechanistic studies included promoter activity assays and pathway validation. **Results:** Transcriptomic analysis and the Interferome database identified SLFN5 as an interferon-α-inducible host restriction factor, upregulated in interferon-α-induced HBV-infected dHepRG cells, validated by qPCR and western blotting. SLFN5 overexpression suppressed HBV RNA, DNA, and antigens in multiple HBV models, while knockdown enhanced viral replication. *In vivo*, SLFN5 overexpression in an AAV8-HBV mouse model reduced HBV intermediates, serum HBsAg, and HBV DNA, whereas knockdown promoted replication. Mechanistically, SLFN5's antiviral effect was dependent on its C-terminal domain and the ATR/CHK1 pathway. SLFN5 knockdown increased ATR phosphorylation, and this effect was reversed by the ATR inhibitor AZD6738. **Conclusion:** This study shows that SLFN5 is significantly upregulated in HBV-infected cells following interferon treatment, potentially acting as a host restriction factor to inhibit HBV replication. SLFN5 overexpression suppresses HBV transcriptional replication. Specifically, SLFN5 restricts HBV replication through its C-terminal domain and by regulating the ATR/CHK1 signaling pathway.

1205 | ANTIVIRAL THERAPY FAILS TO RESOLVE IMMUNE DYSFUNCTION AND INFLAMMATORY SIGNALLING IN INNATE-LIKE CD8$^+$ T CELLS IN CHRONIC HEPATITIS B

Lung Yi Mak[1] Shue Xiong[2] Sebastian Deschler[3] Corrina Pade[2] Chanelle Fernandes[2] Tizong Miao[2] Gerard Hernandez-Mir[2] Yu Lei[2] Anna Riddell[4] Apostolos Koffas[2] Katrin Boettcher[3] Patrick Kennedy[2], [1]The University of Hong Kong, [2]Queen Mary University of London, [3]University of Tubingen, [4]Barts Health NHS Trust

Background: CD56+ CD8 T cells straddle the boundary between innate and adaptive immunity and are distinguished from other CD8 T cell subpopulations, exhibiting high NK receptor (NKR's) expression and exerting effector functions in a TCR-independent manner, associated with 'bystander' activation. Previous studies have recognised the role of bystander T cells correlating with liver inflammation. Evaluating this cell population may provide insights into reasons for immunological failure of novel therapies for chronic hepatitis B (CHB) cure. **Methods:** We studied blood-circulating CD8 T cells from treated and untreated (treatment-naïve) CHB patients compared to healthy controls (HC). The proportion of activated CD8 T cells, expression of NKRs, impact of free fatty acids (FFA's) and functional profile of these cells was analysed by multi-parameter flow cytometry. Transcriptomic analysis of CD8 T cells was also performed. **Results:** Activated (CD38+HLA-DR+) CD8 T cells expressing CD56 were significantly greater in CHB vs HC's, with a higher expression of NKRs (NKG2A, NKp30) on innate-like T cells (CD56+ CD8+). The percentage of CD56+ CD8 T cells expressing NKRs were greater in subjects with 'immune active' vs 'immune control' disease. Contrarily, CHB subjects undergoing antiviral therapy (AVT), exhibited a reduced percentage of CD56+ CD8 T cells, however their NKR expression remained significantly higher than in treatment-naïve patients. Undertaking transcriptomic analysis on sorted CD8 T cells, we noted mRNA expression of innate-like markers (KLRK1, NCR3) was higher in treated vs. untreated immune control patients indicating innate-like immune defects are not recovered by AVT.To determine cellular effector function, stimulation was undertaken with anti-CD3/CD28 (TCR-dependent) and IL-15 (TCR-independent). We noted IFNg production was similar on CD56+ CD8 T cells with either stimulation method, but TNFa production was greater following IL-15 stimulation, indicating a differential functional profile in a TCR-independent manner. Functional CD56+ CD8 T cells were more susceptible to FFA's as inflammatory mediators. **Conclusion:** We demonstrate the increased expression of CD56+ CD8 T cells expressing NKR's in CHB, signalling with TCR-independence, causing bystander activity with greater susceptiblity to inflammatory mediators. Further work analysing the impact of AVT in CHB and CHB-MASLD patients is underway, to guide the development of therapeutic targets in the functional cure program.

1206 | UTILIZING IMMUNOLOGIC AND METABOLIC MARKERS IN ASSESSMENT OF LOW-LEVEL VIREMIA IN PATIENTS WITH CHRONIC HEPATITIS B RECEIVING NUCLEOS(T)IDE ANALOGS

Xiaoyin Wang[1] Mingyang Feng[1] Kehui Liu[1] Wanqing Chi[2] Baoyan An[1] Lanyi Lin[1] Yezhou Ding[1] Xiaolin Wang[1] Hui Wang[1], [1]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [2]Department of Epidemiology of Microbial Diseases, Yale University School of Public Health

Background: Low-level viremia (LLV) is associated with disease progression and unfavorable clinical outcomes of chronic hepatitis B (CHB), including liver fibrosis, cirrhosis, and hepatocellular carcinoma. This study aims to analyze the clinical characteristics of CHB patients with LLV and evaluate the immunological status and metabolic differences between patients with maintained virologic response (MVR) and patients with LLV. **Methods:** We conducted a single-center retrospective study and analyzed clinical data from 270 patients with CHB after first-line nucleos(t)ide analogs (NAs) therapy over 48 weeks. Patients were divided into two groups: 90 MVR patients with HBV DNA < 10 IU/mL and 180 LLV patients with HBV DNA between 10 IU/mL and 2000 IU/mL. Demographic and clinical characteristics, serum cytokines levels and results of baseline serum non-targeted metabolomics were comprehensively compared. **Results:** Patients with LLV demonstrated significantly higher levels of ALT, AST, qHBsAg and percentage of HBeAg positivity compared to those with MVR after NAs therapy over 48 weeks ($p < 0.05$ for all). Dynamic cytokines levels were analyzed in 14 MVR patients and 15 LLV patients. LLV patients showed higher levels of serum IL-17 and TNF-α compared to those who achieved MVR, from baseline through the 96-week follow-up period ($p < 0.05$ for all). Serum IL-1β levels were significantly higher in LLV patients at baseline and 48 weeks post-NA therapy. ROC analysis indicated baseline serum IL-1β,IL-17 and TNF-α could predict the occurrence of LLV. The cut-off value for IL-1β was 12.45 pg/mL, with an AUC of 0.748, a sensitivity of 0.933 and a specificity of 0.571. The cut-off value for IL-17 was 3.85 pg/mL, with an AUC of 0.843, a sensitivity of 0.8 and a specificity of 0.857. The cut-off value for TNF-α was 10.9 pg/mL, with an AUC of 0.752, a sensitivity of 0.667 and a specificity of 0.786. Analysis of baseline serum non-targeted metabolomics were conducted in 20 MVR patients and 20 LLV patients. 101 different metabolites were detected in patients with MVR compared to those with LLV. The top three metabolites with significant differences were 4-amino-5-phenoxymethyl-4H-[1,2,4]triazole-3-thiol, triethylene glycoldimethacrylate and cycloastragenol. ROC analysis indicated potential predicative value for LLV of baseline 4-amino-5-phenoxymethyl-4H-[1,2,4]triazole-3-thiol (AUC 0.9225), triethylene glycoldimethacrylate (AUC 0.8750) and cycloastragenol (0.8600). **Conclusion:** Baseline serum IL-1β,IL-17 and TNF-α have potential value of LLV prediction. Baseline serum 4-amino-5-phenoxymethyl-4H-[1,2,4]triazole-3-thiol, cycloastragenol and triethylene glycoldimethacrylate are potential metabolic markers for prediction of LLV. This study indicates potential clinical application and further exploration of immunologic and metabolic markers in both prediction and disease management evaluation of LLV.

1207 | BRELOVITUG (BJT-778) BINDS A CONFORMATIONAL EPITOPE HIGHLY CONSERVED ACROSS HBV GENOTYPES

Craig Pace[1] Hilario Ramos[1] Jerome Deval[1] Nancy Shulman[1] Hassan Javanbakht[1], [1]Bluejay Therapeutics

Background: Brelovitug is a fully human highly potent, pan-genotypic IgG1 neutralizing monoclonal antibody that targets the HBsAg antigenic loop on the surface of both HBV and HDV virions. In this study, we mapped the brelovitug epitope and assessed the conservation of its epitope residues among global HBsAg sequences. **Methods:** The brelovitug epitope was mapped by evaluating its binding to a panel of HBsAg variants, including 60 variants bearing single alanine substitutions in the antigenic loop, and 44 naturally occurring HBsAg escape variants found in CHB patients. Plasmids encoding these HBsAg variants were transfected into Huh-7 cells, and brelovitug binding was quantified by ELISA, measuring the area under the curve (AUC) after capturing HBsAg from supernatants with a

polyclonal anti-HBsAg antibody. To control for differences in HBsAg expression, brelovitug binding to each variant was normalized to both polyclonal antibody binding and brelovitug binding to wild type HBsAg. Conservation of brelovitug epitope residues was determined from 29,987 HBsAg sequences spanning HBV genotypes A - H obtained from the HBV Database. **Results:** Brelovitug binding was substantially reduced for HBsAg alanine-scan variants I110A, G119A, Q129A, P142A, T143A, D144A, G145A, I150A, P151A and I152A. While brelovitug had substantially reduced binding when HBsAg residues I110, Q129, P142, T143 and D144 were substituted with alanine, it maintained wild type binding to the naturally occurring escape variants at these positions (I110L, Q129H, P142S, T143L and D144E). The only naturally occurring variants that displayed reduced brelovitug binding were those containing substitutions at G145A/E/R, P142/G145R, D144E/G145R and T132N/T143S substitutions. Across 29,987 global HBsAg sequences, conservation of the brelovitug epitope residues ranged from 98.2% at position G145 to 99.9% at positions I150, P151 and I152. **Conclusion:** HBsAg residues I/L110, G119, Q/H129, S/A132, P142, T/L/S143, D/E144, G145, I150, P151 and I152 are critical for brelovitug binding. These amino acids are highly conserved ($\geq$98.2%) among HBsAg from HBV genotypes A – H consistent with brelovitug's pan-genotypic neutralization activity in vitro. Therefore, brelovitug binds to a highly conserved epitope comprised of these residues, reinforcing its potential as a broadly effective therapeutic for chronic hepatitis B and D.

1208 | SUSTAINED REDUCTION OF HBV ANTIGEN LEVELS DURING THE 8-WEEK FOLLOW-UP PERIOD IN TREATMENT NA&IUML;VE (TN) OR CURRENTLY-NOT-TREATED (CNT) HBEAG-POSITIVE SUBJECTS WITH CHRONIC HEPATITIS B VIRUS INFECTION AFTER 96-WEEK 300 MG ALG-000184, WITH OR WITHOUT ENTECAVIR (ETV)

Man-Fung Yuen[1] Edward Gane[2] Kosh Agarwal[3] Hong Ren[4] Yanhua Ding[5] Alina Jucov[6] XieEr LIANG[7] Jia Xu[5] Alexei Haceatrean[6] Kha Le[8] Jennifer Rito[8] Lawrence Blatt[8] Sushmita Chanda[8] Tse-I Lin[8] Hardean E. Achneck[8] Jinlin Hou[7], [1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China, [2]Faculty of Medicine, University of Auckland, Auckland, New Zealand, [3]King's College Hospital, Institute of Liver Studies, London, United Kingdom, [4]The Second Affiliated Hospital of ChongQing Medical University, Chongqing, China, [5]The First Hospital of Jilin University, Changchun, China, [6]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University, [7]Nanfang Hospital, Southern Medical University, Guangzhou, China, [8]Aligos Therapeutics, Inc.

Background: ALG-000184-201 (NCT04536337) is a multi-centre phase 1 clinical trial conducted in healthy volunteers and TN/CNT subjects with chronic Hepatitis B virus infection. Previous data demonstrated favourable safety and potent antiviral effects with ALG-000184 $\pm$ ETV for $\leq$ 96 weeks. Here, we present HBV antigen data during treatment and the 8 weeks follow up (FU). **Methods:** TN or CNT HBeAg+ subjects received either 100 mg ALG-000184 + ETV for $\leq$ 24 weeks or 300mg ALG-000184 $\pm$ ETV for $\leq$ 96 weeks. Following completion of ALG-000184 dosing, subjects entered an 8-week follow-up period, during which only nucleos(t)ide analogues (NA) was administered. **Results:** Mean baseline levels were comparable in 100 mg ALG-000184 + ETV ($\leq$ 24 weeks, N = 8) and 300 mg ALG-000184 $\pm$ ETV ($\leq$ 96 weeks, N = 21), with HBsAg at 4.7 vs. 4.4 $\log_{10}$ IU/mL; HBeAg at 2.6 vs. 2.5 $\log_{10}$ PEI U/mL; and HBcrAg at 8.5 vs 8.3 $\log_{10}$ U/mL, respectively. At Week 24, a dose-dependent HBV antigen reduction was observed with mean reductions of HBsAg, HBeAg and HBcrAg of 0.5 vs 0.6 $\log_{10}$ IU/mL, 0.2 vs 0.6 $\log_{10}$ PEI U/mL and 0.6 vs 1.2 $\log_{10}$ U/mL in 100 mg ALG-000184 + ETV (n = 4) and 300 mg ALG-000184 $\pm$ ETV (n = 19), respectively. In the 16 subjects receiving 300 mg ALG-000184 $\pm$ ETV for 96 weeks, continuous mean reductions were observed in HBsAg, HBeAg and HBcrAg levels (0.9 $\log_{10}$ IU/mL, 1.5 $\log_{10}$ PEI U/mL, 2.2 $\log_{10}$ U/mL at Week 96, respectively). Notably, of these 16 subjects, HBV antigens changed minimally during the 8 weeks FU with mean reductions at FU Week 8 of 0.8 $\log_{10}$ IU/mL for HBsAg, 1.2 $\log_{10}$ PEI U/mL for HBeAg and 1.9 $\log_{10}$ U/mL for HBcrAg. **Conclusion:** 100 or 300 mg ALG-000184 $\pm$ ETV for $\leq$ 24 weeks or $\leq$ 96 weeks resulted in dose- and duration-dependent multi-log reductions in HBV antigens in TN/CNT HBeAg+ subjects. Additionally, sustained reductions in HBV antigens were observed during the 8-week post-ALG-000184 follow-up period after longer treatment with higher dose of 300 mg ALG-000184. This may indicate cccDNA depletion, associated with the CAM-E secondary mechanism of action.

1209 | INHIBITION OF HSPG2 EXPRESSION IMPAIRS HBV ENTRY AND REPLICATION THROUGH THE C-MET SIGNALING PATHWAY

Kazuhiro Murai[1] Tasuku Nakabori[1] Takao Kitanaka[1] Takayuki Miyake[1] Shinji Kuriki[1] Emi Sometani[1] Jihyun Sung[1] Satoshi Shigeno[1] Yoshinobu Saito[1] Takahiro Kodama[1] Hayato Hikita[1], [1]The University of Osaka, Graduate School of Medicine

Background: Hepatitis B virus (HBV) entry into hepatocytes depends on heparan sulfate proteoglycans (HSPGs) and the sodium taurocholate co-transporting polypeptide (NTCP), a bile acid transporter (BAT). Among HSPGs, we focused on HSPG2, which contributes to the binding of cMET and NK4, which is competitive antagonist against HGF. We examined the impact of HSPG2 suppression on HBV infection and explored the underlying mechanisms. **Methods:** Primary human hepatocytes isolated from humanized liver chimeric TK-NOG mice (HepaSH cells) were inoculated with HBV (500 genome equivalent (GEq)/cell) prepared by concentrating the culture supernatant of HBV genome-integrated cells (HepAD38.7). **Results:** Silencing HSPG2 expression with siRNA 3 days prior to HBV inoculation significantly reduced covalently closed circular DNA (cccDNA). The suppression of HSPG2 expression significantly increased cMET expression and decreased NTCP expression. The downregulation of NTCP expression induced by HSPG2 suppression was reversed by silencing c-MET. On the other hand, the suppression of NTCP expression did not alter the mRNA expression levels of HSPG2. Silencing NTCP expression with siRNA 3 days prior to HBV inoculation significantly reduced cccDNA. Suppression of both HSPG2 and NTCP expression had no additional effect on cccDNA reduction compared to the suppression of NTCP alone. Suppression of HSPG2 may inhibit HBV entry by downregulating NTCP expression via upregulation of c-MET. Suppression of NTCP expression 20 days after HBV inoculation did not reduce the expression levels of cccDNA, but the suppression of HSPG2 expression did. Given the possibility that HSPG2 suppression may influence HBV replication through mechanisms beyond entry inhibition, we investigated PPARγ, a host transcription factor known to activate HBV transcription. Suppression of HSPG2 upregulated cMET and pMET, and downregulated PPARγ. Suppression of PPARγ led to downregulation of NTCP, NR5A2 (a regulator of bile acid transporter expression), and CTNNB1, an upstream activator of NR5A2. Suppression of CTNNB1 downregulated NR5A2 and NTCP. The suppression of NR5A2 downregulated NTCP. It was suggested that cMET regulated NTCP expression via PPARγ, CTNNB1 and NR5A2. **Conclusion:** Suppression of HSPG2 expression was suggested to have an effect that suppress both HBV entry and replication via cMET signaling pathway.

Background: Bepirovirsen, an unconjugated antisense oligonucleotide that targets all hepatitis B virus (HBV) RNAs, is in Phase 3 development for chronic HBV infection. Data from B-Together (NCT04676724) indicated that a subset of participants on nucleos(t)ide analogs (NAs) achieved either a complete response (CR) or a partial response (PR) following 12 or 24 weeks of bepirovirsen and 24 weeks of pegylated interferon α-2a (Peg-IFN) sequential therapy. This response was sustained for 24 weeks following the end of Peg-IFN treatment. Participants with a CR or PR at the end of B-Together were eligible for the B-Sure long-term durability study (NCT04954859; ongoing). Here we present up to 2-year follow-up data on the durability of response for B-Together complete responders (CRs) and partial responders (PRs) who enrolled in B-Sure. **Methods:** CR was defined as both hepatitis B surface antigen (HBsAg) $<$ lower limit of quantification (LLOQ) andHBV DNA $<$ LLOQ (20 IU/mL), and PR as detectable HBsAg (LLOQ $<$ HBsAg $<$ 100 IU/mL) and HBV DNA $<$ LLOQ, at the end of B-Together. If eligible, participants discontinued NA 3 months into B-Sure ($\geq$ 9months from the end of bepirovirsen plus Peg-IFN sequential therapy) and were followed to determinethe achievement and durability of functional cure (HBsAg and HBV DNA $<$ LLOQ for a minimum of 24weeks off all HBV treatment). Adverse events (AEs) were recorded at each visit. **Results:** In total, 23 On-NA participants (13 CRs, 8 PRs and 2 non-responders) from B-Together were enrolled into B-Sure (Figure); mean age was 51.3 years. At entry into B-Together, 19 participants (83%) were hepatitis B e-antigen (HBeAg) negative, 16 (70%) had documented HBV infection $\geq$ 10 years, and 17 (74%) had HBsAg $\leq$ 1000 IU/mL. Three months after entry into B-Sure, 12/13 CRs discontinued NAs; 9/12 maintained CR to 6 months post NA cessation, thus achieving functional cure; the three losses in CR (3/12) were due to HBsAg reversion or study withdrawal. Additionally, 7/8 participants who had data up to 12 months post NA cessation maintained functional cure at the 12 month visit (i.e. functional cure for 6 months), and 2/2 participants who had data up to 18 months post NA cessation maintained functional cure at the 18 month visit (i.e. functional cure for 12 months; Figure). No CRs restarted NAs during B-Sure. Overall, 3/8 PRs discontinued NAs 3 months after B-Sure entry. None achieved functional cure, 2/3 participants maintained PR at 6 and 12 months post NA cessation; the one loss of PR was due to virological relapse (Figure). Among the 3 PRs who discontinued NAs, 1 restarted NA therapy by 9 months post NA cessation. No CRs/PRs who discontinued NAs had alanine aminotransferase (ALT) $\geq$ 2x upper limit of normal; 1 participant had HBV DNA $>$ 2000 IU/mL with no ALT increase. There were no new safety signals. **Conclusion:** These data provide evidence of the durability of functional cure for up to 1 year in CRs to sequential bepirovirsen plus Peg-IFN therapy. Funding: GSK (206882)

1211 | PREDICTING HBSAG SEROCLEARANCE IN PEG-IFNα TREATED CHRONIC HEPATITIS B PATIENTS PRESENTING WITH HIGH HBV DNA OR HBSAG LEVELS:A NOVE NOMOGRAM

Wentao Kuai[1] Liang Xu[2] Jiaxin Han[3], [1]Department of Hepatology, Tianjin Second People's Hospital, [2]Department of Hepatology, Tianjin Second People's Hospital, [3]Department of Hepatology,Tianjin Second People's Hospital

Background: Chronic hepatitis B (CHB) patients with unfavorable baseline markers(HBV DNA > 20 IU/mL and/or HBsAg > 1500 IU/mL) typically exhibit suboptimal responses to pegylated interferon-α (Peg-IFNα) therapy. However, a clinically relevant subset still achieves functional cure (HBsAg seroclearance). We developed and validated a dynamic, parameter-incorporated nomogram to predict 6-month, 12-month and 18-month HBsAg seroclearance in this challenging population, facilitating personalized treatment decisions. **Methods:** A prospective training cohort of 178 treatment-naïve CHB patients (HBV DNA > 20 IU/mL and/or HBsAg > 1500 IU/mL) was enrolled from Tianjin Second People's Hospital (July 2020–June 2024), randomly split into training (n = 124) and internal validation (n = 54) sets (7:3 ratio). An independent external cohort (n = 182) from Tianjin Third Central Hospital was used for geographical validation. LASSO-regularized Cox regression identified key predictors, and the final model was rigorously evaluated for discrimination (time-dependent AUC, C-index), calibration (Brier score), and clinical utility (decision curve analysis). Follow-up extended 3–6 months post-treatment to confirm seroclearance. **Results:** The derivation (n = 124), internal validation (n = 54), and external validation (n = 182) cohorts showed well-balanced baseline characteristics (all P > 0.05). LASSO-selected predictors included: Baseline HBsAg (log10 IU/mL; HR 0.741, 95%CI 0.62-0.89), 3-month HBsAg decline (log10 IU/mL; HR 0.256, 0.18-0.36), HBeAg seroconversion by month 3 (HR 0.469, 0.32-0.69), ALT flares

(1-2×ULN: HR 2.449, 1.8-3.3; >2×ULN: HR 2.306, 1.7-3.1). The nomogram achieved exceptional discrimination: Training cohort: C-index 0.929 (95%CI 0.90-0.95), time-dependent AUCs 0.981/0.913/0.946 at 6/12/18 months; Internal validation: C-index 0.886 (0.85-0.92), AUCs 0.947/0.940/0.839; External validation: C-index 0.946 (0.92-0.97), AUCs 0.958/0.932/0.961. Calibration curves demonstrated excellent agreement between predicted and observed probabilities. Kaplan-Meier analysis confirmed significantly faster HBsAg seroclearance in low-risk vs high-risk groups ($P < 0.001$). **Conclusion:** This dynamic nomogram represents the first validated tool integrating on-treatment virological responses to predict HBsAg seroclearance in CHB patients with unfavorable baseline markers. With superior accuracy and clinical applicability, it enables: Early identification of Peg-IFNα responders at month 3. The model's implementation could optimize therapeutic strategies and improve functional cure rates in this challenging patient population.

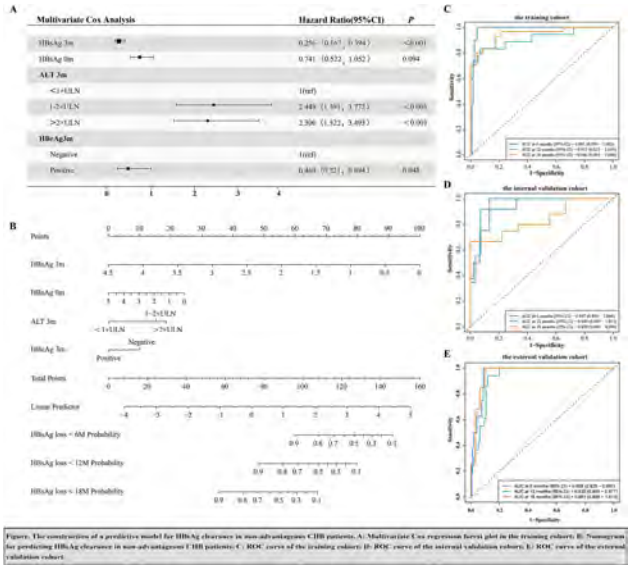

Figure. The construction of a predictive model for HBsAg clearance in non-advantageous CHB patients. A: Multivariate Cox regression forest plot in the training cohort; B: Nomogram for predicting HBsAg clearance in non-advantageous CHB patients; C: ROC curve of the training cohort; D: ROC curve of the internal validation cohort; E: ROC curve of the external validation cohort.

1212 | A VIRAL LOAD-BASED MODEL TO PREDICT HEPATOCELLULAR CARCINOMA AND ANTIVIRAL TREATMENT BENEFIT IN CHRONIC HEPATITIS B

Won-Mook Choi[1] Gi-Ae Kim[2] Jonggi Choi[1] Gwang Hyeon Choi[3] Yun Bin Lee[4] Dong Hyunn Sinn[5] Nae-Yun Heo[6] Sehee Kim[1] YOUNG-SUK LIM[1], [1]Asan Medical Center, University of Ulsan College of Medicine, [2]Kyung Hee University School of Medicine, [3]Seoul National University Bundang Hospital, Seoul National University College of Medicine, [4]Seoul National University, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, [6]Inje University Haeundae Paik Hospital, Inje University College of Medicine

Background: Chronic hepatitis B (CHB) remains a leading cause of hepatocellular carcinoma (HCC) worldwide. Early identification of high-risk individuals could enhance prevention strategies through timely initiation of antiviral therapy. However, current HCC risk prediction models do not simultaneously consider both untreated and treated CHB patients. This study aimed to develop and externally validate a risk score for non-cirrhotic CHB patients, incorporating the non-linear association between HBV DNA levels and HCC risk. **Methods:** A multivariable Cox regression analysis was performed using data from 5,865 treatment-naïve, non-cirrhotic CHB patients with baseline HBV DNA >2,000 IU/mL at Asan Medical Center in Korea. External validation was conducted in an independent cohort of 8,664 patients from 10 centers across Korea, Hong Kong, and Taiwan. **Results:** Over a median follow-up of 8.0 years, 398 patients (6.8%) in the derivation cohort developed HCC. Independent risk factors included male sex, older age, absence of antiviral therapy, lower platelet count, and moderate HBV DNA levels. A distinct parabolic relationship was observed between HBV DNA and HCC risk, with the highest risk at 6.0–7.0 $\log_{10}$ IU/mL (HR 4.99 compared to >8.0 $\log_{10}$ IU/mL; $p < 0.001$). Based on these five predictors, a 15-point risk model—the ASAN ALT-independent HBV-related HCC (ABC) score—was constructed, demonstrating strong discriminatory ability (c-index 0.83). In the external cohort, the ABC score outperformed existing models (PAGE-B, modified PAGE-B, and REACH-B) in both discrimination and calibration, effectively identifying high-risk patients who may benefit most from antiviral treatment. **Conclusion:** The ABC score offers an accurate and practical tool for assessing HCC risk in both untreated and treated CHB patients, reflecting the non-linear effect of viral load. This model supports personalized clinical decision-making regarding antiviral therapy initiation.

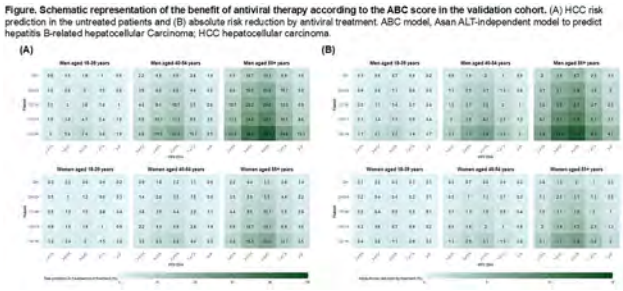

Figure. Schematic representation of the benefit of antiviral therapy according to the ABC score in the validation cohort. (A) HCC risk prediction in the untreated patients and (B) absolute risk reduction by antiviral treatment. ABC model, Asan ALT-independent model to predict hepatitis B-related hepatocellular Carcinoma; HCC hepatocellular carcinoma.

1213 | TRENDS IN DONOR-DERIVED HBV INFECTION IN LIVER TRANSPLANT PATIENTS

Dilara Hatipoglu[1] Emily Blumberg[1] Maarouf Hoteit[1] Ingi Lee[1] Therese Bittermann[2], [1]University of Pennsylvania, [2]Perelman School of Medicine

Background: Unexpected donor-derived hepatitis B virus (HBV) infection in liver transplant recipients is a clinically significant and incompletely understood complication. Identifying risk factors for de novo HBV is important, particularly in an era where maximizing organ utilization is critical to addressing organ shortage. **Methods:** We conducted a retrospective cohort study using United Network for Organ Sharing (UNOS) liver transplant registry data. We included adult ($\geq$ 18 years) liver transplant recipients between 2015 - 2024. To ensure an HBV-naïve population, recipients were excluded if they had HBV diagnosis or positive pre-transplant hepatitis B surface antigen (HBsAg), hepatitis B core antibody (anti-HBc), or nucleic acid testing (NAT). We also excluded recipients missing pre-transplant HBsAg or anti-HBc, and those without HBV follow-up data in the first year. Donors with positive or missing HBV markers were also excluded. The primary outcome was de novo HBV infection, defined as a new positive HBsAg or NAT within one year post-transplant in previously confirmed HBV-negative recipients. Multivariable logistic regression was performed with a priori selected variable based on clinical judgement and literature review. **Results:** A total 29,707 liver transplant recipients met inclusion criteria. We identified 238 (0.8%) cases of de novo HBV infection. Compared to uninfected patients, those with infection were more likely to receive grafts from younger donors (median age 35 vs 39, $p = 0.025$) and donors with a history of IV drug use (34.5% vs 18.8%, $p < 0.001$). In adjusted analysis, donor HCV NAT positivity (OR 1.84, 95% CI 1.24 – 2.73, $p = 0.002$) and HCV Ab +/NAT- status (OR 2.11, 95% CI 1.33 – 3.33, $p = 0.001$) were associated with higher odds of infection (Figure 1). Recipients transplanted after 2021, when universal donor HBV screening was implemented, had lower odds (OR 0.45, 95% CI 0.33 – 0.62, $p < 0.001$). **Conclusion:** We identified 238 cases of de novo HBV infection despite negative pre-transplant testing. Donor HCV exposure was strongly associated with recipient infection. These results suggest that a proportion of post-transplant patients develop donor derived infection despite negative serologies. Possible mechanisms include window period HBV exposure or possible HBV-HCV viral interference. These results support close post-transplant surveillance in increased risk organ recipients and inform risk-benefit discussions regarding HCV-exposed donor organ

1214 | INTRAHEPATIC IMMUNOPHENOTYPING OF PARTICIPANTS WITH CHRONIC HEPATITIS B RECEIVING BEPIROVIRSEN IN THE B-FINE STUDY REVEALS DIVERSE CHANGES IN IMMUNOLOGICAL STATUS

Adam Gehring[1] Yanal Ghosheh[1] Andre Boonstra[2] Nadia Alatrakchi[3] Upkar Gill[4] Boris Beudeker[2] Raymond Chung[3] Jordan Feld[1] Harry Janssen[2] Patrick Kennedy[4] Robert De Knegt[2] Leigh Felton[5] Lin-Ming Shen[6] Robert Elston[5] Dickens Theodore[7] Melanie Paff[7] Maria Agostini[8] Johannes Freudenberg[7] Yvonne Teo[7] Sorcha O'Byrne[5] Jenn Singh[7] Jill Walker[8], [1]Toronto Centre for Liver Disease, University Health Network, Toronto, ON, Canada, [2]Erasmus Medical Center, Rotterdam, The Netherlands, [3]Massachusetts General Hospital, Boston, MA, USA, [4]Queen Mary University of London, London, United Kingdom, [5]GSK, Stevenage, UK, [6]GSK, Waltham, MA, USA, [7]GSK, Collegeville, PA, USA, [8]GSK, San Francisco, CA, USA

Background: Bepirovirsen is an unconjugated antisense oligonucleotide under development for chronic hepatitis B virus (HBV) infection. Previous analyses have shown that bepirovirsen can stimulate the immune system; however, no studies to date have examined the

intrahepatic immune response. In the open-label Phase 2a B-Fine study (NCT04544956), we analyzed longitudinal liver fine needle aspirates (FNA) from participants (pts) with chronic HBV infection treated with bepirovirsen. **Methods:** Pts with chronic HBV infection on stable nucleos(t)ide analogs, with hepatitis B surface antigen (HBsAg) levels >100 IU/mL, received bepirovirsen 300 mg once weekly for 12 weeks (with loading doses on Days 4 and 11), then were followed for 24 weeks (until Week 36). This translational study focused primarily on assessing the effect of bepirovirsen on immunological and disease biomarkers in the liver and periphery, which was evaluated as an exploratory endpoint. RNA sequencing was performed on single cells (scRNA-seq) recovered from the liver by FNA (collected at baseline and up to 4 additional timepoints). Differential expression (DE) analysis was used to compare FNA from baseline and (a) timepoints proximal to the HBsAg nadir or (b) timepoints coinciding with HBsAg decline (i.e. HBsAg slope) to investigate putative immune drivers of HBsAg decline. The primary endpoint evaluated treatment efficacy, i.e. serum HBsAg loss (HBsAg concentration below the lower limit of quantification [LLOQ; 0.05 IU/mL]) at any time up to and including Week 12. **Results:** Overall, 11 pts completed the study. All major immune lineages (T, B, natural killer [NK], macrophages, monocytes, dendritic cells) were identified by scRNA-seq of liver FNA. Subclustering of major lineages included 12 T cell, 5 macrophage and 3 NK cell subclusters. DE analysis found pt-specific differences in immune gene expression between baseline and HBsAg nadir, and baseline and HBsAg slope, irrespective of response. Changes in the $CD56^{dim}$ and tissue-resident NK cell clusters indicated altered cell signaling (e.g. *FOS, CD247*) in some pts, although the impact on NK cell function was unclear. In total, 3 pts achieved the primary endpoint (including 1 sustained responder with HBsAg and HBV DNA 10 IU/mL and $1.5–<3\log_{10}$ IU/mL were obtained by 2 and 3 pts, respectively. Alanine aminotransferase increases >3 times the upper limit of normal were observed in 2 of 3 responders; these increases occurred in conjunction with HBsAg decline. **Conclusion:** Variable clinical, virological and immunological responses to bepirovirsen treatment were observed among pts with chronic HBV infection in this study. Overall, repeat FNA sampling captured activation of the immune compartment in the liver, regardless of response. Three pts achieved HBsAg loss following bepirovirsen treatment. Funding: GSK (212602).

1215 | INTRAHEPATIC AND PERIPHERAL IMMUNOPHENOTYPING OF PARTICIPANTS WITH CHRONIC HEPATITIS B RECEIVING BEPIROVIRSEN IN THE B-FINE STUDY STRONGLY SUGGESTS THAT BEPIROVIRSEN MAY TRIGGER A HUMORAL RESPONSE

Andre Boonstra[1] Adam Gehring[2] Yanal Ghosheh[2] Nadia Alatrakchi[3] Upkar Gill[4] Boris Beudeker[1] Raymond Chung[3] Jordan Feld[2] Harry Janssen[1] Patrick Kennedy[4] Robert de Knegt[1] Leigh Felton[5] Lin-Ming Shen[6] Robert Elston[5] Dickens Theodore[7] Melanie Paff[7] Naveen Prasad[5] Johannes Freudenberg[7] Yvonne Teo[7] Sorcha O'Byrne[5] Jenn Singh[7] Jill Walker[8], [1]Erasmus Medical Center, Rotterdam, The Netherlands, [2]Toronto Centre for Liver Disease, University Health Network, Toronto, ON, Canada, [3]Massachusetts General Hospital, Boston, MA, USA, [4]Queen Mary University of London, London, United Kingdom, [5]GSK, Stevenage, UK, [6]GSK, Waltham, MA, USA, [7]GSK, Collegeville, PA, USA, [8]GSK, San Francisco, CA, USA

Background: Recent evidence suggests a role for B cells in the immune response to hepatitis B virus (HBV) infection and bepirovirsen, an unconjugated antisense oligonucleotide. Here, we investigated how B cell and humoral responses are impacted by bepirovirsen, currently under development for chronic HBV infection. In the open-label Phase 2a B-Fine study (NCT04544956), we analyzed matched liver fine needle aspirates (FNA) and peripheral blood from participants (pts) with chronic hepatitis B infection treated with bepirovirsen. **Methods:** Pts with chronic HBV infection on stable nucleos(t)ide analogs, with hepatitis B surface antigen (HBsAg) levels >100 IU/mL, received bepirovirsen 300 mg once weekly for 12 weeks (with loading doses on Days 4 and 11), then were followed for 24 weeks (until Week 36). This translational study focused primarily on assessing the effect of bepirovirsen on immunological and disease biomarkers in the liver and periphery, which was evaluated as an exploratory endpoint. Biomarker analyses included RNA sequencing (RNA-seq) of whole blood and single cells recovered from the liver by FNA (collected at baseline and up to 4 additional timepoints thereafter), serum proteomics and flow cytometry on peripheral blood mononuclear cells (PBMCs). Differential expression analysis was used to (a) identify transcriptomic and proteomic changes in gene or protein expression in the periphery and (b) investigate putative immune mechanisms of HBsAg decline in the liver. The primary endpoint evaluated treatment efficacy, i.e. serum HBsAg loss (HBsAg concentration below the lower limit of quantification [LLOQ; 0.05 IU/mL]) at any time up to and including Week 12. **Results:** Overall, 11 pts completed the study. Single cell RNA-seq identified all major immune lineages, including 4 B cell and 3 plasma lineage subclusters; differential expression analysis suggested B cell activation in the liver, irrespective of response. Differential analysis of whole blood RNA-seq indicated immune activation (e.g. *CD80, CXCR6, MS4A1*) and immunoglobulin transcription (e.g. *IGHM*, *IGLC3*), consistent with a humoral response. Differential analysis of serum proteomics also indicated B cell activation (e.g. *CD22*, *FCRL2*). Flow cytometry of PBMCs showed an increase in frequency of $Ki67^+$ B cells, but no overall expansion in the $CD19^+$ compartment. Three pts achieved the primary endpoint, including 1 sustained responder with HBsAg and HBV DNA 3 times the upper limit of normal were observed in 2 of the 3 responders; these increases occurred in conjunction with HBsAg decline. **Conclusion:** The proteomic, transcriptomic (liver and peripheral) and flow cytometry data obtained from the B-Fine study strongly suggest that bepirovirsen triggers a humoral immune response in treated pts. Three pts achieved HBsAg loss following bepirovirsen treatment. Funding: GSK (212602)

1216 | A STUDY ON THE LONG-TERM CLINICAL OUTCOMES OF HBSAG DISAPPEARANCE IN CHB PATIENTS TREATED WITH INTERFERON

Wen Deng[1] Minghui Li[1] Yao Xie[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: To investigate the risk and influencing factors of long-term liver clinical outcomes in patients with hepatitis B surface antigen (HBsAg) conversion to negative after treatment with Pegylated interferon α (Peg-IFN α). **Methods:** A retrospective analysis was conducted on patients who achieved HBsAg disappearance and discontinued Peg-IFN α treatment at Beijing Ditan Hospital from October 2008 to December 2023. The baseline time was considered as the point of HBsAg conversion to negative and medication discontinuation, with the endpoint time being the first occurrence of liver adverse events (hepatocellular carcinoma (HCC) or ascites) or the last follow-up. The primary evaluation indicators included the incidence and influencing factors of long-term liver adverse events. The secondary evaluation indicators encompassed liver fibrosis, cirrhosis, and improvements in liver function indicators. **Results:** A total of 456 eligible patients were included for analysis. During the follow-up period of 70 (11-173) months, the incidence of liver adverse events, HCC, and ascites were 2.30%, 1.76%, and 0.55%, respectively. Advanced age and cirrhosis were significant influencing factors for liver adverse events after HBsAg disappearance and discontinuation (*HR* = 1.075, *95%CI* 1.028-1.125, *P* = 0.002; *HR* = 41.393, *95%CI* 4.773-358.958, *P* < 0.001). Compared with the time of HBsAg disappearance and discontinuation, the Aspartate Aminotransferase to Platelet Ratio Index (APRI) score significantly improved at the follow-up endpoint [0.53 (0.37, 0.86) *vs.* 0.25 (0.19, 0.35), *Z* = -15.765, *P* < 0.001]. Additionally, the percentage of patients with cirrhosis significantly decreased (5.62% *vs.* 0.86%, *P* < 0.001). **Conclusion:** Patients with HBsAg disappearance and discontinuation of medication have a lower risk of developing liver adverse events, with cirrhosis and advanced age identified as significant risk factors for these adverse events.

1217 | ★ EFFECT OF SWITCHING FROM PRIOR NUCLEOS(T)IDE ANALOGUE(S) TO TENOFOVIR ALAFENAMIDE ON LIPID PROFILE AND CARDIOVASCULAR RISK IN PATIENTS WITH CHRONIC HEPATITIS B

Witchayaporn Praguylertluck[1] Pimsiri Sripongpun[1] Apichat Kaewdech[1] Naichaya Chamroonkul[1], [1]Prince of Songkla University

Background: Tenofovir alafenamide (TAF) is recommended as the 1st line treatment of chronic hepatitis B (CHB). However, increased LDL-c in those who were switched from Tenofovir disoproxil fumarate (TDF) to TAF was observed. Whereas data regarding switching from other antiviral agents to TAF are limited. We investigated how switching to TAF affected lipid and cardiovascular outcomes in CHB patients. **Methods:** We conducted a prospective observational study including CHB patients who had to switch from their prior NUC to TAF according to the Thai national reimbursement policy in late 2022. All enrolled patients had lipid tests and transient elastography (TE) done at 0 and 48- week post-switch to TAF. Demographic data, prior NUC, liver biochemistry, controlled attenuated parameter (CAP) and liver stiffness (elastic modulus; E) data measured by TE were collected. The changes in lipid, Thai cardiovascular (CV) risk score, and TE results between 0 and 48-week were compared. **Results:** A total of 110 patients who were switched to TAF and completed 48-week follow-up were analyzed. The prior NUCs were as follows: 47 Lamivudine (LAM), 2 Entecavir (ETV), and 41 TDF-based. Baseline characteristics were similar between the three groups except for underlying disease of hypertension was more frequent and baseline total cholesterol levels were lower in the TDF-based group. At 48-week post-switch, the median LDL-c changes were -2.45, -5.9 and +8.8 mg/dL ($p < 0.001$), total cholesterol changes were -4.5, -4 and +17 mg/dL ($p < 0.001$), and weight changes were 0, 0, and +1 kg ($p = 0.010$) in the ETV, LAM, and TDF-based group, respectively. Whereas the changes in hepatic steatosis (measured by CAP), and liver stiffness (measured by E) as well as Thai CV risk score were not significantly different. No cardiovascular events occurred during follow-up. Results from the multivariable logistic regression analysis confirmed that TDF-based regimen at baseline, prior to the switch to TAF, was significantly associated with worsening LDL-c (defined by increase of LDL-c level or increase dose/intensity of lipid lowering agent) with an adjusted odds ratio of 3.84 (95%CI 1.55-10.22, $p = 0.005$), after adjusted with change in BMI, age, sex, and baseline coexisting hypertension. **Conclusion:** Significant increase in LDL-c and total cholesterol after switching to TAF were observed only in patients with prior TDF, but not in those with prior ETV or LAM. Careful monitoring of lipids after the switch may not universally needed. Data regarding long-term cardiovascular outcomes are warrant.

1218 | ASSESSMENT OF HCC RISK STRATIFICATION AND THE ROLE OF PRES1/2 DELETIONS DURING NUCLEOS(T)IDE ANALOGUE THERAPY IN CHRONIC HEPATITIS B

KOTARO DOI[1] Jun Inoue[2] Masashi Ninomiya[2] Akitoshi Sano[3] Mio Tsuruoka[2] Kosuke Sato[2] Kieshi Ouchi[2] KENGO WATANABE[2] Atsushi Masamune[2], [1]Division of Gastroenterology, Tohoku University Graduate School of Medicine, [2]Tohoku University Hospital, [3]Mayo Clinic, Rochester

Background: Hepatocellular carcinoma (HCC) remains a major concern in chronic hepatitis B (CHB) patients despite nucleos(t)ide analogue (NA) treatment. We previously reported that abnormal ALT levels (≥ 31 U/L) after 1 year of NA treatment were associated with HCC development. We also developed a FAL-1 score, based on the FIB-4 index and ALT at 1 year of NA treatment, to estimate HCC risk. However, the cause of persistent ALT abnormalities during NA treatment despite undetectable serum HBV DNA is unclear. Previous studies have suggested that deletions in the preS1/2 region of the HBV genome are associated with progression of liver fibrosis and HCC development, possibly through mitochondrial dysfunction and ER stress. The aim of this study was to validate the FAL-1 score compared to established HCC risk scores and to explore the association between preS1/2 deletion and ALT abnormalities during NA treatment. **Methods:** A cohort of 725 CHB patients from 23 centers was analyzed to compare the FAL-1 score with established

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

HCC risk scores (PAGE-B, mPAGE-B, APA-B, and aMAP). Additionally, 38 patients who received ETV, TDF, or TAF as first-line therapy and had preserved serum samples collected before NA treatment were evaluated. Total DNA was extracted from the samples and subjected to nested PCR targeting the preS1/2 region to detect deletions. Patients with deletion signals ≥40% of the total amplified signal were classified as the high-del group; others were classified as the low-del group. **Results:** In the 725-patient cohort, the 5-year HCC incidence was 11.3%, 7.2%, 11.9%, 10.1%, and 18.3% in the high-risk groups for PAGE-B, mPAGE-B, APA-B, aMAP, and FAL-1, and 1.0%, 0.8%, 5.0%, 2.5%, and 0.5% in the low-risk groups for each score. At 10 years, the HCC incidence was 22.1%, 15.3%, 35.4%, 15.9%, and 22.2%, in the high-risk groups, and 1.0%, 2.5%, 6.4%, 2.5%, and 0.5% in the low-risk groups. The FAL-1 low-risk group (n = 259, 35.9%) showed a low incidence of HCC over 10 years, whereas the high-risk group (n = 113, 15.7%) showed a relatively early occurrence of HCC within 5 years. In the preS1/2 deletion analysis, the preS1/2 region was successfully amplified in 37/38 patients (97.4%), and deletions were found in 18/37 (48.6%) patients. The ALT level after 1 year of NA treatment was significantly higher in the high-del group than in the low-del group (35 vs. 26 U/L, P = 0.021). The cumulative incidence of HCC was also significantly higher in the high-del group than in the low-del group (25% vs. 7% at 2 years, P = 0.027). The proportion of patients with a high FAL-1 score was significantly higher in the high-del group (P = 0.045). **Conclusion:** The FAL-1 score effectively identified CHB patients with a low long-term risk of HCC. PreS1/2 deletions are associated with persistent ALT abnormalities during NA treatment and elevated FAL-1 scores. Persistent ALT abnormalities despite virological suppression may reflect underlying viral factors and contribute to hepatocarcinogenesis.

1219 | CHARACTERIZATION OF THE FUNCTION AND PHENOTYPE OF NK CELLS IN PATIENTS WITH CHRONIC HEPATITIS B WHO ACHIEVED FUNCTIONAL CURE

Yuki Nakaya[1] Goki Suda[2] Kazumi Yamasaki[3] Kouichi Miura[4] Norie Yamada[5] Hirayuki Enomoto[6] Jun Inoue[7] Takashi Honda[8] Yosuke Osawa[9] Satoru Joshita[10] Daichi Onomura[1] Yuji Hoshi[1] Chunfeng Li[11] Evguenia Maiorova[11] Hongmei Mo[11] Kazumoto Murata[1], [1]Division of Virology, Department of Infection and Immunity, Jichi Medical University, [2]Department of Gastroenterology and Hepatology, Graduate School of Medicine, Hokkaido University, [3]Clinical Research Center, NHO Nagasaki Medical Center, [4]Division of Gastroenterology, Department of Medicine, Jichi Medical University, [5]Department of Internal Medicine, Center of Liver Diseases, Seizankai Kiyokawa Hospital, [6]Department of Gastroenterology, Hyogo Medical University, [7]Division of Gastroenterology, Tohoku University Graduate School of Medicine, [8]Department of Gastroenterology and Hepatology, Nagoya University Graduate School of Medicine, [9]Department of Gastroenterology, International University of Health and Welfare Hospital, [10]Department of Medicine, Yodakubo Hospital, [11]Gilead Sciences Inc

Background: Hepatitis B virus (HBV) is a global health concern as the causes of cirrhosis and liver cancer. HBV semi-permanently exists in the hepatocytes by generating covalently closed circular DNA (cccDNA) in the nuclei, hence the complete cure is currently impossible. The goal of therapies for chronic hepatitis B (CHB) has recently shifted toward the achievement of a functional cure (FC), which is defined as a dual state of sustained undetectable serum HBV DNA and hepatitis B surface antigen (HBsAg). Although it is reported that innate immunity may play a major role in anti-HBV effects, its detailed features in patients who achieved FC have not been clarified. Here, we characterized natural killer (NK) cells, a major component of innate immunity, in patients with FC. **Methods:** We studied NK cell receptor expression, cytotoxic activity, and IFN-γ production in peripheral blood mononuclear cells (PBMCs) from 41 patients who lost HBsAg within 1 year before this study (32 with FC and 9 with HBV DNA), 42 CHB patients (13 treatment-naïve and 29 with nucleos(t)ide analogs (NUC)), 17 inactive carriers (IC), and 15 healthy volunteers (HV). PBMCs were treated with or without interleukin (IL)-12 and IL-18 for 18 h, following stimulation with K562 cells with monensin for 5 h. NK cells defined as a subset of $CD3^-$ $CD56^+$ in the lymphocytes were analyzed by a multicolor fluorescence-activated cell sorting (FACS) LSRFortessa X-20. Median values of each group were compared, and statistical differences were determined by Mann-Whiteney U test. **Results:** The proportion of NK cells in PBMCs were significantly lower in CHB patients and IC than HV as well as FC (Figure 1A). Phenotypically, NK cells in patients with FC are related to lower expression of PD-1, an immune suppressive mediator, and higher expression of activation markers such as CD69, NKG2c, and NKp46 when compared with those of CHB patients, especially in the population of FcεRIγ-positive NK cells (conventional NK cells). The

frequency of functionally active NK cells characterized by expression of CD107a and IFN-γ in patients with FC was comparable to HV, and statistically higher than those of CHB patients and IC (Figure 1B, 1C). Of note, these trends were observed in patients with FC, but not in patients who lost HBsAg but had detectable HBV DNA. Interestingly, the cytotoxic activity and IFN-γ production in NK cells in CHB patients under treatment with NUC were not affected by the presence or absence of serum HBV DNA. In addition, NK cells were phenotypically and functionally similar between CHB patients and IC. **Conclusion:** NK cells are phenotypically and functionally impaired in CHB patients and IC but recovered only when CHB patients achieved both undetectable serum HBV DNA and HBsAg, suggesting that some of the products from cccDNA, other than serum HBsAg or HBV DNA, may affect the function of NK cells.

1220 | LONG-TERM HCC RISK AFTER NA WITHDRAWAL IN PATIENTS WITH CHRONIC HEPATITIS B – RESULTS: OF A GLOBAL COHORT STUDY (RETRACT-B)

Edo Dongelmans[1] Grishma Hirode[2] Florian van Bömmel[3] Rachel Wen-Juei Jeng[4] Rong-Nan Chien[5] Chien Hung Chen[6] Mai Kilany[2] Tung-Hung Su[7] Jia-Horng Kao[7] Wai-Kay Seto[8] Lilian Yan Liang[9] Dag Henrik Reikvam[10] Marte Holmberg[11] Arno Furquim d'Almeida[12] Margarita Papatheodoridi[13] Benjamin Maasoumy[14] Bettina Hansen[1] Anna Pocurull[15] Norah Terrault[16] Marc Ghany[17] Asgeir Johannessen[11] Anna Lok[18] Thomas Vanwolleghem[12] Sabela Lens[15] Markus Cornberg[14] Man-Fung Yuen[8] Grace Lai-Hung Wong[9] Milan Sonneveld[1] George Papatheodoridis[13] Thomas Berg[3] Yao-Chun Hsu[19] Jordan Feld[2] Harry Janssen[1], [1]Erasmus University Medical Center, [2]Toronto General Hospital/University of Toronto, [3]Leipzig University Medical Center, [4]Chang Gung Memorial Hospital, Linkou Medical Center, [5]Chang Gung Memorial Hospital Linkou Medical Center, [6]Kaohsiung Chang Gung Memorial Hospital, [7]National Taiwan University Hospital, [8]The University of Hong Kong, [9]The Chinese University of Hong Kong, [10]Oslo University Hospital, [11]University of Oslo, [12]Antwerp University Hospital, [13]Medical School of National and Kapodistrian University of Athens, [14]Hannover Medical School, [15]Hospital Clinic Barcelona, IDIBAPS and CIBEREHD, [16]Keck Medicine of University of Southern California, [17]NIH/NIDDK, [18]University of Michigan Medical Center, [19]E-Da Hospital/I-Shou University

Background: Continuous nucleos(t)ide analogue (NA) therapy is proven to reduce HCC risk in patients with chronic hepatitis B (CHB). However, the effect of stopping NA therapy on subsequent HCC risk is unknown. Therefore, our aim was to assess the long-term HCC risk after NA cessation in a large cohort. **Methods:** Data from patients enrolled in the RETRACT-B cohort study, a large global cohort including long-term follow up after NA withdrawal, were used. Patients with CHB were included if virally suppressed on NA-therapy, HBeAg negative and ALT < 5xULN at end of therapy (EOT). Patients with a co-infection, HCC diagnosed in the past or within 6 months after EOT and/or prior IFN-therapy within 1 year before NA cessation were excluded. The primary end-point was the overall cumulative HCC incidence after NA withdrawal, including HCC cases after resuming NA. Next, we assessed predictors for HCC using Cox regression, and assessed the performance of the PAGE-B score (age, sex and platelets < 1 year before EOT) for risk stratification (low/intermediate/high-risk: ≤9/10-17/≥18). **Results:** In total 2,027 patients were included. Mean (SD) age at EOT was 52 (±11) years, 72% were male, 81% was Asian,15% White, 4% Black, mean HBsAg at EOT was 2.7 (±0.8) log10 IU/mL, and 10% had a history of cirrhosis. Mean PAGE-B score at EOT (n = 1,279) was 12 (±5), low/intermediate/high-risk: 25%/54%/21%. In total, 41 patients (17 with a history of cirrhosis) developed HCC. The 10 year cumulative HCC incidence was 3.8%, being 10.7% in patients with a history of cirrhosis at EOT compared to 2.7% in patients without cirrhosis, p < 0.001. In patients with HCC, 85% was male, median age was 59 [53-67] years at EOT and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

median time until HCC diagnosis was 40 [17-86] months. Among HCC cases without cirrhosis at EOT (n = 24), 16 (67%) patients had known metabolic risk factors or steatotic liver disease at NA cessation. In multi-variate Cox Regression model, older age (aHR 1.08,p < 0.001), male sex (aHR 4.46,p = 0.019), lower platelets (aHR 0.99,p = 0.034) and history of cirrhosis (aHR 4.28,p = 0.001) were associated with increased HCC risks. Ethnicity, type of NA and HBsAg at EOT were not associated with HCC risk in univariate models (all p > 0.05). PAGE-B was highly effective in risk stratification, with a 10 year HCC risk of 0%/2.6%/10.5% for a low/intermediate/high-risk score (p < 0.001). **Conclusion:** Patients with CHB remain at risk of HCC after NA withdrawal (4% at 10yrs). Patients with a high PAGE-B score at EOT have the highest HCC risk (11% at 10yrs), while those with a low PAGE-B score had negligible HCC risks, and may not need HCC surveillance.

1221 | NEW SUBMISSIONA LONG-ACTING AQUEOUS NANOSUSPENSION OF VONAFEXOR PRODRUG ATTENUATES LIVER FIBROSIS DEVELOPMENT IN CCL_4 MOUSE FIBROSIS MODEL

Natalia Osna[1] Asrafi Sultana[1] Anup Pathania[1] Weimin Wang[1] Grace Bybee[1] Haritha Chava[1] Deanna Mosley[1] Christopher Bauer[1] Todd Wyatt[1] Larisa Poluektova[1] Benson Edagwa[1], [1]University of Nebraska Medical Center

Background: Chronic hepatitis B (CHB) leads to the development of end-stage liver disease. However, therapeutic targets are not well-characterized. A synthetic non-steroid, non-bile acid farnesoid X receptor agonist, Vonafexor (Von) is a promising candidate for liver fibrosis prevention. However, its short half-life requires daily administration. To address this limitation and enhance drug delivery into the liver, we modified Von into a lipophilic prodrug and then nanoformulated it into an aqueous nanosuspension stabilized by surfactants presented in other parenteral products (NM2Von). The prodrug formulation was designed to improve the therapeutic index and half-life of Von through slow nanoparticle dissolution, prodrug release, and hydrolysis mechanisms in addition to sustaining therapeutic drug levels in the liver. **Methods:** In vivo experiments were performed on HBV-replicating transgenic mice injected with carbon tetrachloride (CCl_4), 1 mg/g of body weight twice a week for 3 months. Mice were also administered intramuscular injections of 200 mg/kg NM2Von at weeks 1, 5, and 10, and then euthanized 24h after the last CCl_4 injection to collect blood and liver tissues. The drug efficacy was evaluated by pro-fibrotic genes (αSMA, *TIMP, Col1aA1,* $TGF\beta$) expression, immunohistology, and Sirius Red staining in liver tissue. The effectiveness of a long-acting formulation was also evaluated in vitro on hepatocytes, macrophages, and hepatic stellate cells (HSC, LX-2 cells). LX-2 cells were preactivated with TGFβ and then exposed to NM2Von to measure pro-fibrotic gene activation. **Results:** In vitro, NM2Von significantly attenuated pro-fibrotic gene activation in HSC. Monthly in vivo administration of NM2Von reduced liver fibrosis development in livers from HBV-replicating mice, as demonstrated by decreased activation of pro-fibrotic markers and collagen deposition in the liver. Additionally, while exposure to CCL4 increased PKC activity in liver tissue to induce TGFβ, NM2Von efficiently reversed it in male and female mice. **Conclusion:** Administered monthly, NM2Von reduced liver fibrosis development, presumably due to decreased activation of HSC. This indicates its potential efficacy in preventing/attenuating liver fibrosis, a frequent outcome of HBV infection. These promising preclinical data support the potential clinical

1222 | LOW RISK OF FIBROSIS PROGRESSION DURING THE IMMUNE TOLERANT PHASE IN CHRONIC HEPATITIS B PATIENTS

Lisa van Velsen[1] Mai Kilany[2] Norah Terrault[3] Terry Cheuk-Fung Yip[4] Karen Ho[5] Gabriele Ricco[6] Sabela Lens[7] Marc Ghany[8] Elena Vargas-Accarino[9] Stéphanie Narguet[10] Bettina Hansen[11] Tarik Asselah[10] Maria Buti[12] Yao-Chun Hsu[13] Xavier Forns[7] Maurizia Brunetto[14] Wai-Kay Seto[5] Man-Fung Yuen[5] Grace Lai-Hung Wong[4] Jordan Feld[2] Milan Sonneveld[1] Harry Janssen[1], [1]Erasmus University Medical Center, [2]Toronto General Hospital, [3]University of Southern California, [4]The Chinese University of Hong Kong, [5]The University of Hong Kong, [6]University Hospital of Pisa, [7]Hospital Clinic Barcelona, [8]NIH/NIDDK, [9]Hospital Universitari Vall d'Hebron, [10]Hôpital Beaujon, [11]Erasmus MC Rotterdam, [12]Hospital Valle Hebron, [13]I-Shou University, [14]University of Pisa

Background: Immune tolerant (IT) chronic hepatitis B patients (CHB) are considered to have a high viral load, and minimal inflammation and fibrosis. However, it remains unclear whether these patients continue to have minimal fibrosis over time. Therefore, we studied the risk of fibrosis progression in IT patients with CHB. **Methods:** This is a multicenter international cohort study containing data from a large cohort of mono-infected CHB patients from 12 sites in North America, Europe and Asia from the RADICAL-consortium. Baseline refers to the first clinic visit at the investigational site. Patients were strictly defined as IT if they persistently had 1) HBeAg-positivity, 2) ALT $\leq$40 U/L, 3) HBV DNA $\geq$5 logIU/ml and 4) METAVIR F0-1 during the first year after baseline (based on liver stiffness measurement [LSM] $<$8 kPa or biopsy). Fibrosis progression was defined as an increase to F2-4 in 2 consecutive fibrosis measurements or the last measurement based on LSM or biopsy. Cumulative incidences were obtained through Kaplan Meier method, censored for start of antiviral therapy (AVT). A sensitivity analysis was performed restricted to fibrosis progression during the IT phase (also censored for transition out of the IT phase which was defined as: HBeAg loss, ALT $>$40 U/L or HBV DNA $<$5 log IU/ml). Predictive factors were obtained through univariable Cox regression. **Results:** In total, 416 IT patients were included with a median age of 31 (IQR 24-40) years, 34% were male, 96% had an Asian ethnicity and 42% had a metabolic comorbidity. Median ALT and HBV DNA at baseline were 26 (20-30) U/L and 8.3 (8.0-8.7) log IU/mL. In total, patients were followed for a median of 131 (89-187) months, during which 61% patients started on AVT after a median of 57 (29-97) months. The median time to last fibrosis measurement was 70 (33-122) months. Overall, 11 patients progressed to F2-4 during follow-up. The cumulative 3-, 5-, 7- and 10-year incidences of fibrosis progression were 0.4%, 1.4%, 3.2% and 4.2%. Fibrosis progression was more likely in patients with a metabolic comorbidity (HR: 4.13, $p=0.036$) or an age $>$30 (HR: 9.60, $p=0.031$) years at baseline. Of the 11 patients with fibrosis progression prior to start of AVT, 7 patients progressed after transitioning out of the IT phase, and 4 patients progressed to F2-4 while persistently in the IT phase. The cumulative 3-, 5-, and 7-year incidences of fibrosis progression during the IT phase were 0.3%, 1.9% and 2.9%. One patient developed hepatocellular carcinoma (HCC). The cumulative 10-year incidence of HCC was 0.3%. **Conclusion:** IT patients exhibit a 4.2% risk of fibrosis progression and a 0.3% risk of HCC after 10 years of follow-up. The majority of fibrosis progression (64%) occurred after transitioning out of the IT phase. Thus, fibrosis progression and HCC are uncommon in patients who remain to have a strictly defined IT phenotype.

1223 | INVERTED U-SHAPED ASSOCIATION BETWEEN HEPATITIS B CORE-RELATED ANTIGEN AND HEPATOCELLULAR CARCINOMA INCIDENCE IN PATIENTS WITH CHRONIC HEPATITIS B

Ji Eun Han[1] Yoon Je Cho[1] Hyelynn Jeon[2] Hye Young Chang[3] Hyo Jung Cho[1] jaeyoun cheong[1] Hyun Woong Lee[3] Soon Sun Kim[1] Min Ji Son[1], [1]Ajou University School of Medicine, [2]Ajou University Medical Center, [3]Yonsei University College of Medicine, Gangnam Severance Hospital

Background: Despite advancements in antiviral therapy, chronic hepatitis B (CHB) remains a major global cause of hepatocellular carcinoma (HCC). Persistent high viral load drives disease progression, highlighting the need for a sensitive biomarker to assess viral activity. While antiviral therapy suppresses HBV DNA replication, it does not eliminate intrahepatic cccDNA, allowing residual transcriptional activity to persist. Hepatitis B core-related antigen (HBcrAg) reflects cccDNA transcription and may serve as a biomarker. This study aimed to investigate whether baseline HBcrAg levels can predict HCC development. **Methods:** This retrospective study included 204 CHB patients who initiated antiviral therapy between September 2015 and February 2023 at a tertiary center in Korea. Patients were followed for HCC development until October 2023, with a median follow-up duration of 5.5 years. HBcrAg levels were measured using a chemiluminescence immunoassay on the LUMIPULSE G12000 automated analyzer (Fujirebio, Tokyo, Japan). Baseline HBcrAg levels were categorized into tertiles: low (<5.17 log U/mL), moderate (5.17–6.87 log U/mL), and high (≥ 6.87 log U/mL). Kaplan-Meier and Cox regression analyses were performed. **Results:** HCC was diagnosed in 24 out of 204 patients. Kaplan-Meier analysis and the log-rank test revealed that patients in the moderate HBcrAg group (5.17–6.87 log U/mL) had the highest cumulative incidence of HCC during follow-up. The 5-year cumulative incidence of HCC was 8.4% (95% CI: 1.0–15.2) in the low HBcrAg group, 20.2% (8.6–30.3) in the moderate group, and 3.2% (0.0–7.5) in the high group (log-rank $P = 0.001$). Multivariable Cox regression analysis included the following covariates: age, sex, liver cirrhosis (LC), platelet count, total bilirubin, albumin, creatinine, FIB-4, HBeAg positivity, HBsAg, and HBcrAg. Higher total bilirubin (HR 1.90; 95% CI, 1.06–3.43, $P = 0.031$) and moderate HBcrAg levels (HR 5.29; 95% CI, 1.60–17.58, $P = 0.006$) were associated with an increased risk of HCC development. In contrast, a higher HBsAg level (HR 0.03; 95% CI, 0.00–0.53, $P = 0.016$) was associated with a lower risk of HCC development. **Conclusion:** These findings indicate that patients with pre-treatment moderate

HBcrAg levels exhibited the highest incidence of HCC during the follow-up period despite receiving antiviral treatment. Based on this trend, pre-treatment HBcrAg levels may serve as a potential biomarker for predicting the long-term risk of HCC.

1224 | PERSISTENT DISPARITIES AND DIVERGING TRENDS: STATE-LEVEL AND REGIONAL HEPATITIS B BURDEN IN THE UNITED STATES, 1990-2021

Thanathip Suenghataiphorn[1] Kanachai Boonpiraks[2] Pojsakorn Danpanichkul[3] Narathorn Kulthamrongsri[4], [1]Yale/Griffin Hospital, [2]University of Kansas Medical Center, [3]Texas Tech University Health Sciences Center, [4]thames.kulthamrongsri@gmail.com

Background: Hepatitis B virus (HBV) infection remains a significant cause of morbidity and mortality in the United States. While national progress in prevention has occurred, understanding state-level and regional variations over time is crucial for effective public health strategies. We aimed to characterize the trends in HBV prevalence, incidence, mortality, and disability-adjusted life years (DALYs) across US states and Census Divisions from 1990 to 2021. **Methods:** We analyzed state-level data for the United States and the District of Columbia from 1990-2021 using estimates from the Institute for Health Metrics and Evaluation (IHME) Global Burden of Disease (GBD) study. We extracted all-ages rates per 100,000 population for HBV Prevalence, Incidence, Deaths, and DALYs. Trends were visualized for each state and aggregated by US Census Division (using unweighted state averages). States ranking in the top 5 for each metric based on 2021 rates were identified and highlighted. Analyses were performed using R statistical software. **Results:** From 1990 to 2021, HBV prevalence and incidence rates generally declined across most US states, although substantial state-level heterogeneity persists. States including New Mexico, West Virginia, Kentucky, Alaska and Indiana frequently appeared in the top 5 for highest prevalence and/or incidence rates in 2021. In stark contrast, HBV death and DALY rates demonstrated concerning *increasing* trends in numerous states over the same period. States consistently ranking highest for mortality and DALYs in 2021 included West Virginia, New Mexico, Kentucky, Indiana, and Tennessee. Regional analysis revealed significant disparities; Pacific, West South Central, and East South-Central divisions generally exhibited higher average death and DALY rates compared to New England and North Central divisions throughout the study period, with particularly steep increases noted in the East South Central and West South-Central divisions for mortality and morbidity metrics. **Conclusion:** Despite decades of prevention efforts reflected in declining HBV incidence and prevalence, significant geographic disparities in HBV burden persist across the US. The alarming divergence, with rising HBV-related mortality and DALY rates in several states and regions, underscores an urgent need for targeted, state-specific interventions focused on improving linkage to care, management of chronic HBV infection, and addressing the drivers of HBV-related liver disease progression and mortality.

1225 | DUAL ORAL THERAPY TARGETING FUNCTIONAL CURE OF CHRONIC HEPATITIS B: SYNERGISTIC EFFECTS OF SAG-524 AND A NOVEL CAPSID ASSEMBLY MODULATOR

Takehisa Watanabe[1] Sanae Hayashi[2] Yutaka Furutani[3] YAN ZHAOYU[2] Shintaro Ogawa[2] Chang Wu[2] Hiroki Inada[2] Satoshi Narahara[2] Katsuya Nagaoka[2] Hiroko Setoyama[2] Yasuhito Tanaka[2], [1]Kumamoto University, Japan, [2]Kumamoto University, [3]The Jikei University School of Medicine, Department of Laboratory Medicine

Background: The SAG-524, which we are developing, acts as an HBV RNA destabilizer by inhibiting PAPD5, a noncanonical poly(A) polymerase stabilizing HBV RNA. Inhibition of PAPD5 disrupts protective RNA tailing, promoting HBV RNA degradation and reducing HBsAg and HBcrAg production. This study aimed to evaluate the combined effects of SAG-524 and a novel capsid assembly modulator (CAM: CBT-209) and explore the potential for clinical application by testing anti-HBV effects *in vitro* and *in vivo*. **Methods:** *In vitro*, we first conducted preliminary studies in HepAD38 cells to assess the combination effects of SAG-524 and CAM. Next, we treated HBV-infected PXB cells with SAG-524 (1 μM), CBT-209 (10 μM), or ETV (0.1 nM), either alone or combined with SAG-524, for 15 days and compared their anti-HBV activities. *In vivo*, we administered SAG-524 (20 mg/kg/day, BID) and CBT-209 (20 mg/kg/day, BID) either alone or together to HBV-infected human liver chimeric mice (PXB mice) by oral administration for four weeks, then evaluated serum HBV markers and intrahepatic HBV-cccDNA. **Results:** *In vitro*, SAG-524 and CAM combination strongly suppressed HBV RNA in HepAD38 cells. In PXB cells, SAG-524 alone reduced extracellular HBV DNA by over 1 log copies/mL, and combining with CBT-209 or ETV resulted in an additional 1 log copies/mL reduction. Monotherapy with CBT-209 or ETV resulted in only slight reduction of extracellular HBsAg and HBcrAg. Northern blot showed decreased HBV RNA with SAG-524 alone and further reduction when combined with CBT-209 or ETV. Southern blot showed HBV replication was suppressed by SAG-524 alone and reduced below detection with combination therapy. *In vivo*, the combination therapy with SAG-524 and CBT-209 resulted in the most potent suppression of HBV markers. Serum HBV DNA was decreased by 4.4 log IU/mL in both the CBT-209 monotherapy group and the combination group; notably, one animal in the combination group achieved undetectable levels. Serum HBsAg was reduced by more than 2.5 IU/mL with SAG-524 or CBT-209 alone, but in the combination group, all animals showed levels below 0.5 IU/mL, demonstrating the strongest HBsAg suppression. Furthermore, the combination group exhibited a 3.2 log U/mL reduction in serum HBcrAg, and the greatest suppression of intrahepatic cccDNA levels was also seen with combination therapy. **Conclusion:** This study demonstrates that combination therapy with SAG-524 and CBT-209 exhibits potent anti-HBV activity, leading to marked reductions in HBV DNA, HBsAg, and HBcrAg levels. These findings suggest that dual oral therapy with SAG-524 and CBT-209 holds promise as a strategy to achieve a functional cure for chronic hepatitis B.

1226 | UNDERSTANDING QUALITY-OF-LIFE IMPACTS OF HEPATITIS DELTA VIRUS

Beatrice Zovich[1] Shreya Koirala[1] Chari Cohen[1], [1]Hepatitis B Foundation

Background: Hepatitis delta virus (HDV) is the most severe form of viral hepatitis and can cause rapid progression to serious liver disease. It is estimated that 5% of people living with chronic hepatitis B globally also have HDV. Despite potential disease severity, little has been documented about the effects of HDV on quality of life. This mixed-methods study attempted to capture the ways in which HDV shapes daily life for those living with the virus around the world. **Methods:** A survey was created using Qualtrics, with questions developed *a priori* through literature review. The survey was disseminated through social media, newsletters, Google ads, and website postings. Qualitative in-depth interviews were conducted virtually with those who indicated interest in participating from the survey. Interview data were analyzed via Dedoose using grounded theory to describe QoL impacts. **Results:** Seventy-two respondents from 25 countries completed the survey, with the largest representation from Pakistan, the United States, and the Philippines. A third of respondents (31%) were between 35 and 44 years of age, and 27% were between 45 and 54 years of age. Just under three quarters (71%) were male. 70% experienced symptoms, most commonly fatigue (69%), abdominal pain (41%), muscle or joint pain (38%), and loss of appetite (38%). 27% ranked their symptoms as a 7 on a severity scale from 1-10. Around half had been prescribed treatment for hepatitis B and 65% for HDV. A total of 13 individuals participated in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

qualitative interviews. Most were male with an average age of 42 years, and half were from the U.S. and Pakistan. Interview participants described difficulty concentrating, impacts on job performance, frequent anxiety, depression and despair, fear, hope for a cure, and concerns about stigma. Strained communication with providers, issues with access to treatment and care, and financial struggles due to the disease were also expressed. **Conclusion:** A hepatitis delta diagnosis can reverberate across all areas of an individual's life. As approved HDV treatments become available and testing becomes more widespread, it is important to raise awareness of these numerous physical and psychosocial impacts, especially in terms of how they differ from hepatitis B mono-infection. This will help us holistically address patient health and improve quality of life for those diagnosed with HDV.

Polonovski CS 70001, 59 037 Lille Cedex, France, [24]Gastroenterology Department, University Hospital of Nantes, Nantes, France, [25]Service d'Hépato-Gastroentérologie, CHU de la Guadeloupe, F-97159 Pointe-à-Pitre Cedex, France, [26]Unité de Santé Publique, Hôpital Saint-Antoine, Assistance Publique-Hôpitaux de Paris, [27]Hopital Saint Joseph

Background: Accurate data on liver-related complications and mortality in HDV-HBV patients versus HBV patients remain scarce. This study explores the prognosis of HDV-HBV patients within the ANRS CO22 HEPATHER French cohort. **Methods:** We conducted a multicenter, nationwide, prospective observational cohort study from August 2012 to April 2023. The incidence of hepatic events (cirrhosis decompensation and HCC), liver transplantation and mortality was assessed based on HDV status, HDV RNA detectability and liver fibrosis. HBV-HDV patients were compared to a matched population of HBV patients, with matching performed based on sex, age, and center of care (1:5 matching ratio applied). **Results:** Our cohort included 185 HDV patients, matched to 925 HBV patients. The median age was 43 years (Q1-Q3: 34-51), with a majority (66%) being male. Compared to HBV patients, those with HBV-HDV were more often of African origin (56% vs. 41%, $p < 0.0001$) and had a higher prevalence of advanced fibrosis at inclusion (45% vs. 14.2%, $p < 0.0001$), particularly those with detectable HDV RNA ($n = 100$) (54.4% vs. 38.9%, $p = 0.0009$). HDV patients had a poorer prognosis. The incidence rates (per 1,000 person-years) of death, HCC, cirrhosis decompensation, and liver transplantation were significantly higher in HBV-HDV patients compared to HBV patients: 15 (9–25) vs 5 (3–7) ($p = 0.0003$), 16 (9–26)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

vs 3 (1.75–5) ($p < 0.0001$), 14.8 (8–24) vs 1.4 (0.6–3) ($p < 0.0001$), and 10.8 (5–19) vs 0.8 (0.2–1.9) ($p < 0.0001$), respectively. Patients with detectable HDV RNA had a significantly higher incidence of hepatic decompensation compared to those with undetectable HDV RNA: 27.4 (15–45) vs 0 (0–8) per 1,000 person-years ($p = 0.0002$) and a lower survival rate free from hepatic complications. A mediation analysis shows that approximately 50% of the effect of HDV coinfection on HCC or mortality is mediated by fibrosis (indirect effect), meaning that HDV leads to increased fibrosis, which in turn elevates the risk of HCC or death. The remaining 50% of the effect of HDV co-infection appears to be independent of fibrosis (direct effect) (Table1). **Conclusion:** HDV coinfection increases the risk of hepatic events and death in HBV patients. Controlling HDV infection may have a dual benefit: an immediate reduction in risk through the direct effect, and a longer-term benefit through the reduction of fibrosis and its associated risks.

Table 1. Estimated direct (NDE) and indirect (NIE) effects of HDV co-infection on liver outcomes: mediation by fibrosis

Outcome	NDE (HR) [95% CI]	NIE (HR) [95% CI]	Total Effect (HR) [95%CI]	Proportion Mediated	P value (NDE)	P value (NIE)
Death	1.66 [0.8 – 3.43]	1.685 [1.3 – 2.19]	2.797 [1.29 – 6.05]	50.7% [24.1 – 177.1%]	0.171	<0.001
HCC	2.361 [1.11 – 5.04]	2.31 [1.74 – 3.06]	5.453 [2.43 – 12.24]	49.4% [31.6 – 86.3%]	0.026	<0.001
Decompensated cirrhosis	4.159 [1.44 – 12]	2.171 [1.58 – 2.99]	9.027 [2.98 – 27.31]	35.2% [23.1 – 52.8%]	0.008	<0.001
Liver transplantation	4.761 [1.47 – 15.37]	2.845 [1.92 – 4.22]	13.542 [3.93 – 46.62]	40.1% [29.1 – 55.9%]	0.009	<0.001

1228 | SAFETY AND PHARMACOKINETICS OF BJT-628, AN ORALLY AVAILABLE LIVER-TARGETED HBV TRANSCRIPT INHIBITOR FOR THE TREATMENT OF CHRONIC HEPATITIS B IN HEALTHY VOLUNTEERS

Edward Gane[1] Christian Schwabe[2] Jeff Zablocki[3] Nancy Shulman[3] Raj Bhardwaj[4] Joelle Batonga[4] Hassan Javanbakht[3] Susanna Tan[3], [1]University of Auckland, Auckland, New Zealand, [2]New Zealand Clinical Research, Auckland, New Zealand, [3]Bluejay Therapeutics, Inc., California, USA, [4]Certara, Inc., New Jersey, USA

Background: BJT-628 is a liver-targeted small molecule inhibitor that targets the noncanonical poly(A) polymerases, PAPD5, and 7. These host enzymes are thought to support the hepatitis B virus by stabilizing HBsAg viral mRNA transcripts through polyadenylation. BJT-628 is a pro-drug that undergoes enzymatic hydrolysis upon absorption into systemic circulation and generates the active metabolite BJT-338. Its liver-targeted design enhances drug concentrations in the liver while minimizing systemic exposure and therefore may improve therapeutic specificity and reduce potential off-target effects. In pre-clinical studies, BJT-628 led to a significant reduction in HBsAg levels in an HBV infection mouse model. **Methods:** In the single ascending dose (SAD) part, a single dose of BJT-628 was evaluated in 3 cohorts (35, 105, and 315 mg), as well as food effect with a high-fat diet. In the multiple ascending dose (MAD) part, 14 days of daily dosing with BJT-628 were evaluated in 2 cohorts (35 mg and105 mg). Each cohort contained 8 healthy volunteers randomized 3:1 to oral BJT-628 or matching placebo. Safety evaluation included the incidence of treatment emergent adverse events (TEAEs), laboratory assessments, vital signs, ECGs, and physical examinations. Plasma pharmacokinetics (PK) of BJT-628 and active metabolite BJT-338 are summarized using non-compartmental analysis. Blinded data are presented. **Results:** In both the SAD and MAD portions of the study, TEAEs were observed in 24/48 (50.0%) participants. All TEAEs were Grade 1 or 2 severity. The most common TEAEs were headache

(6/48, 12.5%) and dyspepsia (4/28, 8.3%). No serious adverse events, clinically significant vital signs, physical and neurological exam, ECGs, or laboratory abnormalities were observed. PK was characterized by rapid absorption of both BJT-628 prodrug and BJT-338 active metabolite. Under single and multiple dose fasted PK conditions, pro-drug and metabolite AUC and Cmax increased dose proportionally. Peak and overall exposure increased by 30-44% under fed conditions. After 14 days of dosing, minimal accumulation was observed for pro-drug and active metabolite. Half-life was short for pro-drug and active metabolite, not impacted by dose, and were comparable between single and multiple dosing (approximately 0.9-1 and 1.4-1.6 hours, respectively). **Conclusion:** Single and multiple doses of BJT-628 in healthy volunteers were safe and well tolerated. BJT-628 dosing in CHB patients is anticipated.

1229 | ALCOHOL SUPPRESSES TYPE I IFN RESPONSES IN HBV INFECTION VIA RIG-I AND STING PATHWAY INHIBITION

Anup Pathania Larisa Poluektova[1] Natalia Osna[1],
[1]University of Nebraska Medical Center, Omaha, NE, USA

Background: Chronic hepatitis B virus (HBV) infection can progress to severe liver diseases, including cirrhosis and hepatocellular carcinoma, with alcohol consumption further exacerbating disease progression. Despite this clinical association, the mechanisms by which alcohol influences HBV pathogenesis and impairs host antiviral immunity remain poorly understood. In this study, we investigated the effects of ethanol and its metabolites on HBV replication and innate immune responses, focusing on the nucleic acid sensing pathways RIG-I/MAVS and cGAS/STING. **Methods:** We used hepatocyte-based models (HepAD38, HepG2.2.15) and HBV-infected primary human hepatocytes (PHHs) to study ethanol effects. Ethanol metabolism was simulated using an acetaldehyde-generating system (AGS), comprising yeast alcohol dehydrogenase (ADH), NAD^+, and 50 mM ethanol. HBV replication was measured via viral RNA, DNA, covalently closed circular DNA (cccDNA), HBsAg, and HBcAg levels. Innate immune responses were assessed by analyzing RIG-I/MAVS and cGAS/STING signaling, STAT1 phosphorylation, type I IFN production, and ISG expression (e.g., APOBEC3B, 3G). **Results:** Exposure to ethanol or AGS significantly increased HBV RNA, DNA, cccDNA, HBsAg, and HBcAg levels in hepatocytes. In HBV-infected PHHs, similar elevations in viral markers were noted following ethanol treatment. Mechanistically, ethanol and HBV co-treatment suppressed the expression of RIG-I, MAVS, and cGAS in PHHs and AGS-treated HepAD38 and HepG2.2.15 cells. Phosphorylation of IRF3, induced by poly(I:C) stimulation, was diminished in HBV+ cells exposed to ethanol, leading to impaired production of IFN-β and type I IFNs. Type I IFNs are crucial for STAT1 phosphorylation, which subsequently induces the activation of antiviral ISGs. We observed that ethanol also inhibited STAT1 phosphorylation and downregulated the expression of APOBEC3B and APOBEC3G. Furthermore, ethanol exposure in IFNα-stimulated HepAD38 and PHH cells increased the expression of ZBP1, a key innate immune sensor and regulator of inflammatory cell death. **Conclusion:** Ethanol exposure enhances HBV replication and disrupts antiviral immunity by suppressing RIG-I/MAVS and cGAS/STING pathways and downstream IRF3 and STAT1 signaling, impairing ISG induction. Concurrently, ethanol enhances ZBP1 expression, potentially priming infected hepatocytes for inflammatory cell death, thereby contributing to HBV persistence and liver disease progression.

1230 | EFFICACY OF PEGINTERFERON α-2B TREATMENT IN HBV-INFECTED CHILDREN AGED &LE;5 YEARS: SUBGROUP ANALYSIS FROM A LARGE-SCALE, PROSPECTIVE STUDY (SPROUT PROJECT)

Hongfei Zhang[1] Qing He[2] Wenxian Ouyang[3] Shuangjie Li[3] Yilan Zeng[4] Hong Zhang[4] Jia Shang[5] Fang Wang[2] Lijuan Ouyang[6] Yujing Tang[6] Xiaogua Liu[7] Pengfei Xu[7] Hongxia Zhou[8] Hui Lv[9] Xiaorong Mao[10] Hong Wan[11] Rendong Wei[12] Shuangsuo Dang[13] Chen Pan[14] Riying Lv[15] Zhenkun He[16] Yahui Liu[17], [1]Beijing Chen Jumei Foundation, China, [2]Shenzhen Third People's Hospital, China, [3]Hunan Children's Hospital, China, [4]Public Health Clinical Center of Chengdu, China, [5]Henan Provincial People's Hospital, China, [6]Xiamen Hospital of Traditional Chinese Medicine, China, [7]Xi'an Children's Hospital, China, [8]The Infectious Diseases Hospital of Handan City, China, [9]Shandong Public Health Clinical Center, China, [10]The first hospital of lanzhou university, China, [11]Lanzhou Second People's Hospital, China, [12]Qingdao Sixth People's Hospital, China, [13]The Second Affiliated Hospital of Xi'an Jiaotong University, China, [14]Mengchao Hepatobiliary Hospital of Fujian Medical University, China, [15]Guigang City People's Hospital, China, [16]Huaihe Hospital of Henan University, China, [17]Kuitun Hospital of Yili Kazakh Autonomous Prefecture, China

Background: Current evidence regarding antiviral therapy for pediatric HBV infection remains limited. We aimed to explore the efficacy and safety of different antiviral strategies for HBV-infected children, and a stratified analysis was conducted on children in the lower age group (3-5 years old). **Methods:** This was a prospective, multicenter real-world study (NCT05792761) that enrolled three types of HBV-infected children aged 3-18 years, including treatment-naïve, NA-experienced and normal ALT level populations. All patients received NA monotherapy or combined with peginterferon α-2b (PegIFNα-2b, Pegbing®, Xiamen Amoytop Biotech Co., Ltd.) for 96 weeks. Data from 158 children aged 3-5 years treated with PegIFNα-2b for 48 weeks were analysed. **Results:** Among the 158 pediatric patients, 57.0% were male, 86.7% were HBeAg positive and 89.5% were HBV DNA positive. Patients were divided into an ALT normal group (n = 86) and an ALT abnormal group (n = 72). The mean baseline HBsAg levels were 4.0 and 3.8 $\log_{10}$ IU/mL, HBeAg were 2.7 and 2.3 $\log_{10}$ COI, and HBV DNA were 6.2 and 5.8 $\log_{10}$ IU/mL in the two groups, respectively. 71.5% of patients were treatment-naïve patients. Both in total population and treatment-naïve patients, the ALT abnormal group obtained greater HBsAg declines, reaching 2.64 and 2.45 $\log_{10}$ IU/mL at week 48, respectively, compared with 1.74 and 1.88 $\log_{10}$ IU/mL in the ALT normal group. In the total population, HBsAg loss rates in the ALT abnormal and normal groups at week 48 were 37.5% and 11.6%, respectively ($p = 0$), and HBeAg loss rates were 31.7% and 11.7%, respectively ($p = 0.004$). 29.2% and 23.0% of patients in the ALT abnormal group achieved HBsAg seroconversion and HBeAg seroconversion by week 48, significantly higher than 9.3% and 7.8% in the ALT normal group ($p = 0.001$ and 0.012). The HBsAg response in the ALT abnormal group was also significantly better than in the ALT normal group among the treatment-naïve patients, with HBsAg loss rates of 32.2% and 11.1% ($p = 0.007$) and HBsAg seroconversion rates of 27.1% and 9.3% at week 48, respectively. HBeAg loss (27.85 vs. 14.0%, $p = 0.086$) and seroconversion (18.5% vs. 8.0%, $p = 0.116$) rates were not statistically different between the two groups. An increase in ALT levels was also observed in the ALT normal group during the treatment. **Conclusion:** HBV-infected children aged 3-5 years treated with PegIFNα-2b achieved high HBsAg and HBeAg loss rates, especially those with abnormal ALT, with both rates exceeding 30% after 48 weeks. Younger children with abnormal ALT can better pursue functional cure based on PegIFNα therapy.

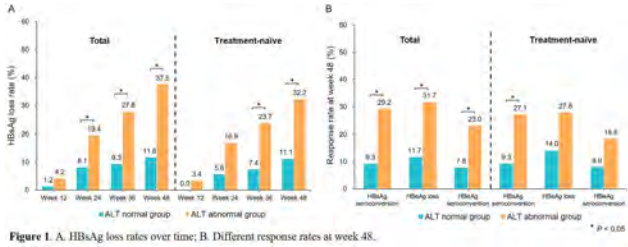

Figure 1. A. HBsAg loss rates over time; B. Different response rates at week 48.

1231 | GLS4 INHIBITS HEPATITIS B VIRUS INFECTION BY ACTIVATING THE INTERFERON SIGNALING PATHWAY

lingzhu zhao[1] SIDUO XU[2] Zhiqiang Wei[3] Xueyu Wang[3] Zhenggang Yang[3] Min Zheng[3], [1]The First Affiliated Hospital, College of Medicine, Zhejiang, [2]the first affiliated hospital, college of medicine,zhejiang university, [3]the first affiliated hospital, college of medicine, zhejiang university

Background: Nearly 300 million people worldwide still have chronic hepatitis B virus (HBV) infection despite preventive vaccinations. Current treatment can control HBV replication but do not lead to functional cure. The formation of normal HBV nucleocapsid is a critical step in sustaining the HBV life cycle. GLS4, a novel heteroaryldihydropyrimidine (HAP) compound, can induce aberrant non-capsid polymers of HBV, resulting in pgRNA encapsulated abnormally for reverse transcription, thereby inhibiting the secretion of HBV virions. However, it is unknown whether exposure to the cytoplasm of pgRNA activates innate immunity in hepatocytes. Thus, the effects of GLS4 on innate immune were investigated in human hepatoma cell lines. **Methods:** RNAseq of normal and GLS4 treatment group was performed on Hep G2.2.15 to detect related changes in gene expression. Western blotting, qRT-PCR and immunofluorescence were used to investigate the effects of GLS4 treatment on the innate immune of HBV-infection hepatoma cell line HepG2 and HBV-replicating cell line HepG2.2.15. **Results:** KEGG analysis of RNAseq data showed that HBV-related pathway was enriched, and the expression of interferon receptors were significantly up-regulated. In two human hepatoma cell lines, GLS4 increased RNA receptor RIG-I expression and caused phosphorylation of interferon regulatory factor 3 (IRF3), which promoted the transcription of interferon, thereby activating the JAK-STAT signaling pathway and increasing expression of antiviral proteins such as OAS1. In addition, knockdown of OAS1 significantly reversed the inhibitory effect of GLS4 on HBV replication. **Conclusion:** This study suggests that GLS4 inhibits HBV replication by not only disrupting the correct assembly of the nucleocapsid, but also activating the interferon signaling pathway.

1232 | PHARMACOLOGICAL ACTIVATION OF LUBAC SYNERGIZES WITH IFNα TO INHIBIT HBV REPLICATION VIA IRF9 M1-LINKED UBIQUITINATION

peng chen[1] Yuxin Zhou[1] Zheyu Dong[1] Yuqing Shao[1] Qiuyue Ye[2] Yadong Wang[1] Libo Tang[3] yongyin li[1], [1]Nanfang Hospital, Southern Medical University, [2]Afiliated Hospital of Guizhou Medical University, [3]Nanfang Hospital, Southern Medical Univerisity

Background: Combination therapy with interferon-alpha (IFNα) is a promising strategy for chronic hepatitis B virus (HBV) infection; however, the underlying mechanisms remain largely unclear. The linear ubiquitin assembly complex (LUBAC), composed of HOIP, HOIL-1, and SHARPIN, is the only E3 ligase that generates linear (M1-linked) ubiquitination and plays a critical role in antiviral response. This study aims to elucidate LUBAC's regulatory function in IFNα responsiveness and explore pharmacological strategies that enhance IFNα-based combination therapy. **Methods:** We systematically evaluated IFNα's effects on LUBAC activity by liver tissues from the patients with chronic HBV infection, HBV mouse models and HBV-infected cell lines. The role of LUBAC in IFNα treatment efficacy and HBV suppression was evaluated both *in vitro* and *in vivo*. Mechanistic studies were conducted using chromatin immunoprecipitation-quantitative PCR (ChIP-qPCR), RNA sequencing, and Western blot. The synergistic antiviral effect of pharmacological LUBAC activation combined with IFNα was tested in cell lines and multiple HBV mouse models. **Results:** IFNα treatment specifically upregulated M1-linked ubiquitination in hepatocytes, with minimal effects on other ubiquitin linkages. HOIL-1 knockdown, which impaired LUBAC function, enhanced HBV replication, as evidenced by increased levels of HBV DNA, HBeAg, HBsAg in HBV-replicating cell lines and in a mouse model established by hydrodynamic injection (HDI) of the 1.2×HBV plasmid. Notably, HOIL-1 knockdown substantially diminished the antiviral efficacy of IFNα both *in vitro* and *in vivo*. In contrast, HOIL-1 overexpression not only inhibited HBV replication but also synergized with IFNα to enhance antiviral responses. Mechanistically, ChIP-qPCR revealed that IFNα promoted IRF9 binding to the *HOIL-1* and *HOIP* promoters, thereby upregulating the expression of *HOIL-1*, *HOIP* and M1-linked ubiquitin. In turn, HOIL-1 interacted with IRF9 to mediate its M1-linked ubiquitination, facilitating IRF9 nuclear translocation and subsequent induction of interferon-stimulated genes. Importantly,

pharmacological activation of LUBAC by TNFα promoted IRF9 M1-linked ubiquitination and nuclear translocation, synergizing with IFNα to amplify antiviral efficacy. **Conclusion:** Our findings establish LUBAC as a critical amplifier of IFNα antiviral responses by promoting IRF9 M1-linked ubiquitination and nuclear translocation. These results propose LUBAC-targeted pharmacologic activation as a novel strategy to boost IFNα efficacy, especially in IFNα-nonresponsive HBV patients.

1233 | DE NOVO DIAGNOSIS OF HBV AND HDV INFECTIONS IN HARM REDUCTION AND MIGRANT SUPPORT CENTERS IN SPAIN: PROSPECTIVE RESULTS: FROM THE DESCRIBE STUDY

Pablo Ryan[1] Antonio Madejon[2] Jorge Valencia[1] Sabela Lens[3] Xavier Forns[3] Javier García-Samaniego[4], [1]Hospital Universitario infanta Leonor, Ciber de Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, [2]Unidad de Hepatología, Hospital Universitario La Paz., [3]Hepatology Department, Hospital Clínic, Universidad de Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spai, [4]Hepatology Unit. Hospital Universitario La Paz. IdiPaz. Madrid, Spain

Background: Epidemiological surveillance of HBV and HDV infections is particularly important in populations with limited engagement with healthcare systems. Identifying the prevalence of HDV coinfection is clinically relevant, as persistent HDV replication is associated with increased liver-related mortality. DESCRIBE is a retrospective/prospective program to analyze the prevalence of HDV infection in two major urban settings in Spain. We previously describe the serologic and active HDV infection (retrospective, AASLD 2023). This prospective phase focused on individuals without a prior diagnosis of HBV or HDV, attending a harm reduction centers: a mobile harm reduction unit operating in informal settlements and migrant centers in Madrid, and a fixed-site harm reduction center in Barcelona. **Methods:** Between 2023 and 2024, individuals without known HBV or HDV infection were recruited from two locations: (1) a mobile harm reduction program in Madrid covering "Cañada Real" shantytown and centers serving undocumented migrants (n = 439), and (2) the fixed-site harm reduction center "La Mina" in Barcelona (n = 276) HBsAg was assessed using rapid diagnostic tests followed by confirmatory assays. In HBsAg-positive individuals, anti-HDV and HDV-RNA were tested to determine HDV exposure. **Results:** Fifty-nine individuals tested positive for HBsAg via rapid testing. Twelve of them (20%) were considered false positives based on confirmatory assays, resulting in an HBsAg prevalence of 47/715 (6.6%). Most HBsAg-positive individuals were male (42/47; 91%) with a mean age of 31.4 years, 66% were from sub-Saharan Africa, 23% from Europe, 4% from Asia, and 4% from Latin AmericaEight (17%) reported intravenous drug use; 2 were coinfected with HIV and 5 with HCV. The vast majority of HBsAg-positive cases were were identified in Madrid, in the migrant centers (46/47). Only 1/47 (2%) patients tested positive for anti-HDV, but HDV RNA was undetectable (no active HDV infection). **Conclusion:** In this cohort of high-risk individuals without prior serological testing or regular contact with healthcare services, chronic HBV infection prevalence was 6.6%. Surveillance and preventive efforts should prioritize populations from African origin. HDV seroprevalence was very low (2% of HBsAg-positive), and no active HDV infection was found.

Janssen[4] Milan Sonneveld[2], [1]Gilead Sciences, Inc., Foster City, CA, USA, [2]Erasmus University Medical Center, Rotterdam, The Netherlands, [3]Gilead Sciences, Inc., Foster City, CA, USA; Redsen Limited, Tring, UK, [4]Erasmus University Medical Center, The Netherlands; Toronto Centre for Liver Disease, Canada

Background: Individuals with hepatitis B virus (HBV) infection have an increased risk of hepatocellular carcinoma (HCC) and other liver-related complications. HBV coupled with metabolic comorbidities (MCs) may further increase the risk of liver-related events (LREs). Here, we investigate the impact of MCs on the risk of developing LREs in US patients with chronic HBV infection. **Methods:** This observational cohort study used closed US medical claims data (HealthVerity Marketplace™; Oct 2015–Dec 2024) from individuals aged ≥18 with chronic HBV infection (index date set to first inpatient or first of two outpatient claims). LREs included cirrhosis, liver decompensation, HCC, and liver transplant. Patients were excluded if there was evidence of LREs or other forms of chronic liver disease, or human immunodeficiency virus, prior to index. The earliest record of each MC (diabetes mellitus [DM], hypertension, hyperlipidemia, and overweight/obesity) was identified using all available data. Incidence of any LRE during follow-up (composite outcome) was examined among individuals with individual MCs. Adjusted hazard ratios (aHRs) are presented using overlap weights to balance demographics, comorbidities, and prescriptions (including nucleos[t]ide analogs) in the 6 months prior to index. Individuals who developed an MC during follow-up prior to experiencing an LRE were censored (primary analysis) or switched to the MC cohort (sensitivity analysis; not shown). **Results:** Out of 292,349,478 individuals, 259,305 had chronic HBV infection; 147,987 had evidence of an MC. In the primary analysis, some individual MCs were associated with an increased risk of LREs (aHR [95% confidence interval]; DM: 1.34 [1.15–1.55]; hypertension: 1.32 [1.12–1.55]), while others demonstrated no association (hyperlipidemia: 0.88 [0.77–1.01]; overweight/obesity: 0.92 [0.80–1.05]; Table 1). Findings were similar for the cirrhosis and liver decompensation outcomes (not shown). No exposures were associated with significantly increased risk of HCC or liver transplant. Findings were similar in the sensitivity analysis. **Conclusion:** Among individuals with HBV, those with evidence of DM or hypertension had an increased risk of LREs. Future studies are needed to understand the underlying mechanisms of these combined exposures and the impact of treatment on improving HBV outcomes.

Table 1. Liver-related events among individuals with HBV infection and metabolic comorbidities compared to those with HBV infection alone

Metabolic comorbidities	Population (unweighted)	Population (weighted)	Number of events	Per 100 PY	IR (95% CI)	Unadjusted HR (95% CI)	Adjusted HR* (95% CI)
No diabetes mellitus	47,809	7,295	1,756	1,360.72	1.29 (1.23–1.35)	1.00	1.00
Diabetes mellitus	12,006	7,293	726	309.29	2.35 (2.18–2.53)	1.78 (1.63–1.94)	1.34 (1.15–1.55)
No hypertension	38,013	7,295	1,140	1,052.80	1.08 (1.02–1.15)	1.00	1.00
Hypertension	21,248	7,290	1,267	573.51	2.21 (2.09–2.34)	2.03 (1.87–2.20)	1.32 (1.12–1.55)
No hyperlipidemia	31,013	10,634	1,022	784.48	1.30 (1.22–1.39)	1.00	1.00
Hyperlipidemia	26,702	10,626	1,284	730.99	1.76 (1.66–1.88)	1.38 (1.27–1.50)	0.88 (0.77–1.01)
No overweight/obesity	42,805	10,308	1,658	1,154.09	1.44 (1.37–1.51)	1.00	1.00
Overweight/obesity	16,296	10,302	713	415.46	1.72 (1.59–1.85)	1.17 (1.07–1.27)	0.92 (0.80–1.05)

Liver-related events is a composite outcome, comprising cirrhosis, liver decompensation, HCC, and liver transplant outcomes. Outcomes are only included if they were recorded after ≥185 days (~6 months) of follow-up. Individuals who developed a metabolic comorbidity during follow-up, prior to having an outcome, were censored. (a) Adjusted hazard ratios are presented using overlap weights to balance demographics, comorbidities, and prescriptions (including nucleos[t]ide analogs) in the 6 months prior to index. CI: confidence interval; HBV: hepatitis B virus; HCC: hepatocellular carcinoma; HR: hazard ratio; IR: incidence rate; PY: patient-years.

1235 | ASSESSMENT OF TRADITIONAL AND NOVEL VIROLOGIC MARKERS AS PREDICTORS OF FUNCTIONAL CURE AND HBEAG LOSS WITH PEGYLATED INTERFERON IN CHRONIC HEPATITIS B: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ying Zhang[1] Longfei Wang[1] Jing Chen[1] Mindie Nguyen[2] Qi Zheng[1], [1]The First Affiliated Hospital of Fujian Medical University, [2]Stanford University Medical Center

Background: Functional cure (loss of HBsAg) rates remain unsatisfactory after pegylated interferon (PEG-IFN) therapy for chronic hepatitis B. To guide PEG-IFN therapy, this study evaluates the role of virological markers

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to identify patients with higher likelihood of functional cure and/or hepatitis B e antigen (HBeAg) loss or seroconversion. **Methods:** A systematic search of PubMed, Embase, Cochrane Library, and Web of Science up to November 2023 identified studies on virological markers predicting functional cure and HBeAg loss after PEG-IFN therapy. Predictive effectiveness was assessed using the summary receiver operating characteristic curve (SROC). **Results:** We analyzed 38 studies (8,289 patients). HBsAg decline at week 24 had the highest area under receiver operating characteristic curve (AUROC) (0.89) and sensitivity (0.88) for predicting functional cure, while baseline HBsAg had a comparable AUROC (0.86) and highest specificity (0.79), with both being significantly better than baseline hepatitis B core-related antigen and hepatitis B virus (HBV) RNA (all $P < 0.001$). For HBeAg loss or seroconversion, HBV DNA, HBV RNA, HBeAg, and HBeAg decline at week 12, as well as HBV DNA and HBeAg decline at week 24, all exhibit comparable predictive value (AUROC = 0.75–0.78). HBV RNA and HBeAg at week 24 showed optimal sensitivity (0.87), and HBeAg decline at week 12 had the highest specificity (0.83). **Conclusion:** HBsAg decline at week 24 and baseline HBsAg levels are better predictors of functional cure than novel virologic markers, while on-treatment HBV RNA and HBeAg levels and dynamic changes are the most reliable indicators for HBeAg loss.

1236 | KINETIC CHARACTERIZATION OF HBV ACUTE INFECTION AND HEPLISAV-B TREATMENT IN RAAV-HBV MOUSE MODEL

Aarim Khan[1] James Ahodantin[2] Louis Shekhtman[1] Jiapeng Wu[2] Lydia Tang[3] Shyam Kottilil[2] Harel Dahari[1] Lishan Su[2], [1]Loyola University Chicago, [2]University of Maryland School of Medicine, [3]University of Maryland, Baltimore

Background: Heplisav-B (Dynavax Technologies Corporation) is a new FDA approved 2-dose hepatitis B vaccine with a CpG adjuvant with higher rates of seroprotection. Here, we sought to characterize the kinetics of serum hepatitis B viral genome (HBV DNA), hepatitis B surface antigen (HBsAg), hepatitis B e-antigen (HBeAg), anti-HBs antigen IgG (IgG), and alanine aminotransferase (ALT) in rAAV-HBV infected mice with and without Heplisav-B, for 25 weeks. **Methods:** Ten rAAV-HBV infected mice were included. Heplisav-B was administered in 6 mice at weeks 4 and 8 post infection (p.i.). Blood samples were collected every 2 weeks until 25 weeks p.i. Kinetic phases were identified by linear regression. For simplicity we present mice per group as an agglomerate mouse. A plateau is defined as not different than slope 0 ($p > 0.05$). **Results:** In the unvaccinated agglomerate mouse (Fig. 1A), HBV DNA and HBsAg had a multiphasic increase consisting of a rapid first phase increase during the first 2 weeks p.i. (median doubling time, $t_2 = 0.64$ days), followed by a slower increase phase ($t_2 = 13$ days) until 16 weeks p.i., after which HBV-DNA levels plateaued at 8.90 log(ge/ml) until end of the experiment (EOE). HBsAg paralleled HBV DNA increase kinetic phases reaching a plateau at 0.11 log(ng/ml). IgG remained close to the assay detection level until 16 weeks p.i., after which it increased ($t_2 = 4.8$ days) to 2.46 log(U/ml) by EOE. ALT remained at pre-infection levels until EOE. In the vaccinated agglomerate mouse (Fig. 1B), a first phase increase ($t_2 = 0.64$ days) in HBV DNA was seen, that was followed by a second phase decline (half-life, $t_{1/2} = 3.5$ days) after the 1st dose of Heplisav-B was administered at 4 weeks p.i. and until the 2nd dose at week 8 p.i. This was followed by a third phase increase ($t_2 = 19$ days) starting from 8 weeks p.i. until EOE. HBsAg decreased (median $t_{1/2} = 3.2$ days) beginning at 4 weeks p.i. until 8 weeks p.i. to below detection, where it remained until EOE. IgG saw a steady increase ($t_2 = 6.4$ days) after 4 weeks p.i., then plateaued after 12 weeks p.i. HBeAg increased up to vaccination at week 4 and then declined slowly until week 12 and remained unchanged until EOE. Notably, at the end of the experiments vaccinated mice had a median 1.96 log lower HBV-DNA ($p = 0.034$), 3.76 log lower HBsAg ($p = 0.02$), 0.51 log lower HBeAg ($p = 0.04$) and 1.18 log higher IgG ($p = 0.04$) than unvaccinated mice, demonstrating vaccine effectiveness. **Conclusion:** HBV infection in rAAV-HBV infected mice is highly dynamic despite the absence of HBV spread. Minimum serum HBV DNA t1/2 in mice was estimated to be 3.5 days. Heplisav-B demonstrated effective therapeutic potential to suppress HBsAg in the rAAV-HBV infected mouse model. The infection kinetics presented here is an important step in characterizing this experimental model system so that it can be effectively used to elucidate the dynamics of the HBV life cycle and thus possibly reveal effective therapeutic vaccine effects.

1237 | THE IMPACT OF METABOLIC-ASSOCIATED FATTY LIVER DISEASE ON THE TREATMENT EFFICACY OF PEGYLATED INTERFERON-BASED THERAPY IN PATIENTS WITH CHRONIC HEPATITIS B

Jiaxin Han[1] Wentao Kuai[1] Minghui Zeng[1] Yuqin Li[1] Lianxin Xu[1] Huiling Xiang[2] Liang Xu[1], [1]Tianjin Second People's Hospital, [2]Tianjin Third Central Hospital

Background: To investigate the impact of metabolic-associated fatty liver disease (MAFLD) on therapeutic efficacy, lipid metabolism, and clinical outcomes in chronic hepatitis B (CHB) patients with HBV DNA > 20IU/mL receiving pegylated interferon (Peg-IFN) antiviral therapy. **Methods:** A retrospective cohort study was conducted, enrolling 620 CHB patients with HBV DNA > 20IU/ml treated with Peg-IFN at the Department of Hepatology, Tianjin Second People's Hospital and Tianjin Third Central Hospital from December 2020 to December 2024. Participants were categorized into a CHB-only group (n = 373) and an MAFLD-CHB comorbid group (n = 247). Propensity score matching (1:1) was applied to balance baseline characteristics. LASSO-COX regression identified independent predictors of CVR and HBsAg clearance. Flow cytometry was employed to monitor immune cell subsets and cytokine profiles. **Results:** After propensity score matching, 247 patients were included in each group. The CHB group demonstrated significantly higher cumulative CVR rates at multiple timepoints (3 months: 36.84% vs 24.54%,P = 0.041; 12 months:77.19% vs 62.72%,P = 0.013; end of treatment:78.94% vs 65.45%,P = 0.019; end of follow-up: 80.7% vs 68.18%,P = 0.026) and a shorter median time to first CVR (4.5 vs. 5.8 months, P = 0.025). LASSO-COX regression identified HBV DNA levels (HR:0.486,95%CI:0.297-0.793,P = 0.004), MAFLD comorbidity (HR:0.736,95%CI:0.550-0.986,P = 0.040), HBsAg levels (HR:0.808,95%CI:0.706-0.926,P = 0.002), triglycerides (HR:0.793,95%CI:0.661-0.951,P = 0.012), and HBeAg positivity (HR:0.611,95%CI:0.433-0.862,P = 0.005) as independent predictors of CVR. Although HBsAg clearance rates increased over time in both groups, no significant intergroup differences were observed (16.6% vs. 15.4% at follow-up, P > 0.05). Kaplan-Meier analysis revealed no difference in median time to HBsAg clearance (Log-rank P = 0.2). Notably, six independent predictors of HBsAg clearance were identified: baseline HBV DNA levels (adjusted HR = 0.651, 95% CI 0.507–0.835; P < 0.001), HBsAg titers at 3-month follow-up (adjusted HR = 0.368, 95% CI 0.305–0.443; P < 0.001), baseline LDL-C concentrations (adjusted HR = 0.609, 95% CI 0.460–0.807; P < 0.001), baseline fasting glucose levels (adjusted HR = 0.409, 95% CI 0.254–0.660; P < 0.001), 3-month γ-GGT activity (adjusted HR = 1.004, 95% CI 1.002–1.007; P < 0.001), and baseline HDL-C levels (adjusted HR = 4.320, 95% CI 2.185–5.933; P < 0.001). Immunological profiling demonstrated significantly lower CD4+/CD8+ T lymphocyte ratios (1.1% vs. 1.4%, P < 0.05) and elevated IL-10 levels (3.1 vs. 2.2, P < 0.05) in the MAFLD-CHB group. **Conclusion:** MAFLD comorbidity may delay virological response, prolong time to first CVR, and promote liver fibrosis progression in CHB patients undergoing Peg-IFN therapy, potentially mediated through decreased CD4+/CD8+ T lymphocyte ratios and elevated IL-10 levels.

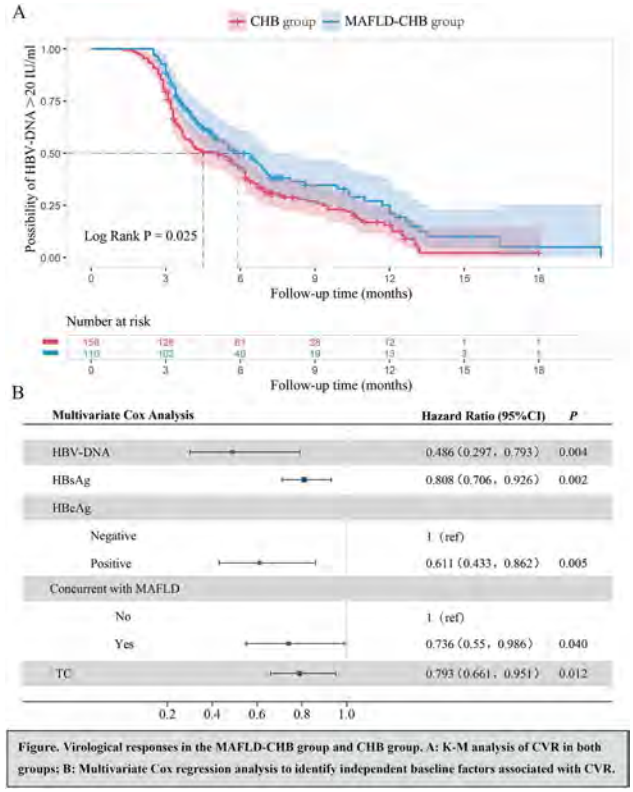

Figure. Virological responses in the MAFLD-CHB group and CHB group. A: K-M analysis of CVR in both groups; B: Multivariate Cox regression analysis to identify independent baseline factors associated with CVR.

1238 | THE EFFECT OF PEG-IFNA2B ON THE METABOLIC STATUS OF CHB COMBINED WITH MASLD

Baiguo Xu[1] Aili Fan[2] Jiawen Feng[2] Lei Liu[1] Jia Lian[1] Huiling Xiang[1] Qing Ye[1], [1]Department of Hepatology of The Third Central Hospital of Tianjin, China, [2]The Third Central Clinical College of Naikai University, China

Background: The proportion of chronic hepatitis B patients with MASLD is increasing. Peg-IFNα2b is one of the core drugs for CHB antiviral therapy, and its mechanism of action involves not only direct inhibition of virus replication, but also immune regulation and inflammation regulation. However, previous studies have mostly focused on the antiviral efficacy of interferon, with limited attention paid to its impact on improving host metabolic status. This study aims to reveal the potential regulatory effect of interferon on metabolic syndrome in patients with CHB through long-term follow-up observation of the dynamic changes in metabolic parameters such as blood lipids, blood glucose, uric acid, BMI, and waist circumference treated with interferon. **Methods:** This is a prospective observational study. The patients with CHB who met the indications of antiviral treatment of the Guidelines were collected as the research objects, and were followed up for at least 48 weeks. The therapeutic effect and impact on metabolic related indicators of Peg-IFNα2b and nucleotide analogs (NA), as well as the combination therapy group were analyzed. **Results:** There are 585 CHB patients who meet the inclusion criteria, including 322 patients combined with MASLD. The group with MASLD had higher BMI, CAP, TG, LDL and serum uric acid values at baseline ($p < 0.05$). Compared with NA group, patients treated with Peg-IFNα2b showed a significant decrease in waist circumference, BMI, CAP and LDL at the 48 weeks ($p < 0.05$). There is not much difference in blood sugar and uric acid between the two groups. In the Peg-IFNα2b based treatment process, there was no significant statistical difference in virological indicators, including HBsAg and HBVDNA, between CHB without MASLD and CHB with MASLD group at 48 weeks. No difference was found in the clinical cure rate between the two groups. 45 patients achieved clinical cure, including 20 cases combined with MASLD. All cured patients were treated with Peg-IFNα2b based therapy (Peg-IFNα2b alone or combined with NA). **Conclusion:** There was no doubt that Peg-IFNα2b treatment plays an important role in the clinical cure of CHB, and it also significantly improves waist circumference, BMI, CAP, LDL and metabolic disorder of chronic hepatitis B combined with MASLD.

1239 | MATHEMATICAL MODELING QUALITATIVELY RECAPITULATES HBV DNA AND HBV RNA RESPONSE UNDER NUCLEOS(T)IDE ANALOGUE OR NUCLEIC ACID POLYMERS MONOTHERAPY

Ashish Goyal[1] Scott Cotler[2] Yuji Ishida[3] Chise Tateno[3] Kazuaki Chayama[4] Alexander Ploss[5] Andrew Vaillant[6] Harel Dahari[1], [1]Loyola University Chicago, [2]Loyola University Health System, [3]PhoenixBio Co., Ltd., [4]Hiroshima Institute of Life Sciences, [5]Princeton University, [6]Replicor Inc.

Background: We (Hershkovich et al. Antiviral Res. 2025;234:106061) and others reported that while serum HBV DNA dramatically declined from pre-treatment levels in chronic HBV-infected patients treated with nucleos(t)ide analogue (NA), HBV RNA largely remained unchanged. In contrast, we observed a decline in both HBV DNA and HBV RNA during nucleic acid polymers (NAPs) monotherapy (Jansen et al. J Hepatology;2015(62):S250). Here, we aimed to develop a mathematical model that can explain the difference in these kinetic pictures. **Methods:** The modeling approach taken here was inspired by our previous work that successfully recapitulated HBV DNA kinetics during acute infection in humanized mice (Goyal et al. Hepatology;2023:78(S1):S530-S531). This previous model included accumulation of intracellular covalently closed circular DNA (cccDNA; accumulation up to 5 cccDNA per infected cell), production of encapsidated pregenomic RNA (pgRNA) from cccDNA in a saturated manner (i.e., Michaelis–Menten equation) and production of relaxed circular DNA (rcDNA) from pgRNA in a linear fashion. The model also included secretion of encapsidated

pgRNA and rcDNA as serum HBV RNA and serum HBV DNA, respectively. We assumed that steady state serum HBV RNA levels are approximately ~2log lower than HBV DNA levels as was observed in patients treated with ETV (Fig. 1A) or NAPs (Fig. 1B). Treatment effects were further simulated by assuming that NAs block reverse transcriptase (RT) with 95% efficacy whereas NAPs block the secretion of both serum HBV RNA and HBV DNA with an efficacy of 95%. **Results:** Our model simulations qualitatively recapitulate HBV DNA and HBV RNA response under ETV monotherapy (Fig. 1A) by assuming that ETV mainly acts as a RT inhibitor which drives a steep serum HBV DNA decline. Moreover, serum HBV RNA remains unchanged due to slower conversion of pgRNA to rcDNA, which results in excess intracellular HBV RNA compared to HBV DNA. We assumed that NAPs block secretion of both HBV DNA and HBV RNA (in addition to subviral particles – to be included in more comprehensive models) from infected cells to explain in part the decline in both HBV DNA and HBV RNA under NAPs monotherapy treatment (Fig. 1B). **Conclusion:** Modeling results suggest that serum HBV RNA remains largely unchanged during treatment with NAs due to excess intracellular HBV RNA in comparison to intracellular HBV DNA.

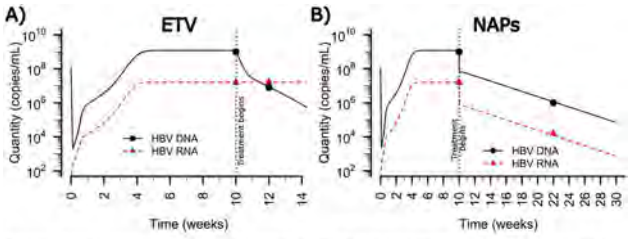

Figure 1: Model simulations (lines) of serum HBV DNA and HBV RNA during acute infection and post-treatment initiation indicated by vertical dotted lines. Modeling HBV kinetics during monotherapy with **(A)** entecavir (ETV) or **(B)** REP2139-Ca (NAP) treatment. Circles represent measured HBV DNA and HBV RNA data as reported by Jansen et al. J Hepatology;2015(62):S250.

1240 | PEGINTERFERON ALPHA-2B AND NUCLEOS(T)IDE ANALOGS COMBINATION THERAPY FOR CHRONIC HEPATITIS B PATIENTS WITH HIGH HBSAG LEVEL AT THE END OF TREATMENT (52 WEEKS) FROM ONGOING CREATED EXCELLENT STUDY

Wenhua Zhang[1] Haitao Tang[1] Qinghua Lu[2] Haifang Cao[2] Tingxia Chao[1] Fengmei Wang[1] Wenling Jia[1] Chunhui Liang[1] Feng Ren[3] Hongfei Zhang[4], [1]Gansu Wuwei Tumour Hospital, Wuwei, China, [2]The 4th People's Hospital of Qinghai Province, Xining, China, [3]Beijing Youan Hospital, Capital Medical University, Beijing, China, [4]Jumei Doctor Group Medical (Shenzhen) Co., Ltd, Shenzhen, China

Background: Chronic hepatitis B (CHB) patients with HBV DNA 1500 IU/mL (Non-preferred population for clinical cure, NPPCC). **Methods:** The CREATED EXCELLENT study (ChiCTR2400081073) is a multicenter, prospective, positive-controlled study. CHB patients with NAs treated for ≥3 months and HBsAg >1500 IU/mL were enrolled and divided into two groups. The NAs monotherapy group continued to receive their original NAs (ETV/TDF/TAF/TMF) treatment, while the PegIFNα-2b+NAs group received PegIFNα-2b (180 μg/week) in addition to NAs. The total treatment period was 52 weeks, and all participants were followed up for 24 weeks after the end of treatment (EOT). **Results:** A total of 682 patients (NAs monotherapy group, n=330; PegIFNα-2b+NAs group, n=352) were included. At baseline, there were 170 patients with HBsAg between 1500 and 3000 IU/mL (NAs group: 21.81%, PegIFNα-2b +NAs group: 27.84%), 133 patients with HBsAg between 3000 and 6000 IU/mL (NAs group: 18.23%, PegIFNα-2b +NAs group: 20.68%), 90 patients with HBsAg between 6000 and 9000 IU/mL (NAs group: 12.11%, PegIFNα-2b +NAs group: 14.24%); and 289 patients with HBsAg greater than 9000 IU/mL (NAs group: 47.91%, PegIFNα-2b+NAs group: 37.23%). The baseline average HBsAg level in the NAs group was 18767.23 ± 5623.33 IU/mL and in the PegIFNα-2b+NAs group was 17346.91IU/mL ($P > 0.05$). After 52 weeks of treatment, the average HBsAg level of the NAs group was 16963.92 ± 5127.89 IU/mL and the PegIFNα-2b+NAs group was 3589.40 ± 1223.47 IU/mL($P <$ HBsAg < HBsAg < HBsAg **Conclusion:** Compared with NAs monotherapy, PegIFNα-2b combined with NAs therapy for the treatment of NPPCC (HBsAg >1500 IU/mL) rapidly reduced HBsAg levels, and increased the number of PPCC (HBsAg <1500 IU/mL), thereby providing a new treatment strategy for CHB patients with high-level HBsAg to achieve clinical cure.

1241 | EFFECT OF FINITE DURATION PEGINTERFERON ALPHA-2B WITH OR WITHOUT NUCLEOS(T)IDE ANALOGUES ON LONG-TERM PROGNOSIS IN CHRONIC HEPATITIS B: PRELIMINARY 24-WEEK RESULTS: FROM THE MULTICENTER REAL-WORLD &LDQUO;VISION&RDQUO; STUDY IN CHINA

Qing-Lei Zeng[1] Hongyu Zhang[1] Yaqing Liu[2] Guoqiang Zhang[3] Haiyan Chen[4] Chuanwen Chen[5] Yuzhong Wang[6] Guifu Shi[7] Zujiang Yu[1] hongxia liang[1], [1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, China, [2]The First People's Hospital of Shangqiu, Shangqiu, Henan, China, [3]Luoyang Central Hospital, Luoyang, Henan, China, [4]Xinyang Central Hospital, Xinyang, Henan, China, [5]Shangcheng County People's Hospital, Xinyang, Henan, China, [6]The Fifth People's Hospital of Anyang, Anyang, Henan, China, [7]Zhumadian Central Hospital, Zhumadian, Henan, China

Background: Optimizing antiviral strategies and achieving a functional cure remain major challenges in the management of chronic hepatitis B (CHB). Loss of hepatitis B surface antigen (HBsAg) and achievement of a functional cure are associated with reduced risks of cirrhosis and hepatocellular carcinoma. This study aimed to evaluate the long-term effects of a finite duration of peginterferon alpha-2b (Peg-IFN α-2b) with or without nucleos(t)ide analogues (NAs) in patients with CHB (The Vision Study). **Methods:** This was a multicenter, prospective, observational real-world study. Eligible patients received either NA monotherapy or a combination of Peg-IFN α-2b (PegBing®) plus NA. All patients who completed treatment in accordance with Chinese CHB Guidelines were followed for at least five years to compare long-term outcomes between the two regimens. This analysis focuses on patients who had completed 24 weeks of treatment. **Results:** A total of 23 patients in the NA monotherapy group and 186 patients in the Peg-IFN α-2b + NA group were included. The mean ages were 40.2 ± 8.20 and 40.9 ± 9.70 years ($p = 0.7330$), and the proportion of males was similar between groups: 60.9% (14/23) vs. 60.8% (113/186) ($p = 0.991$). In the NA monotherapy group, 2, 14, 3, and 4 patients received entecavir (ETV), tenofovir alafenamide (TAF), tenofovir disoproxil fumarate (TDF), and tenofovir amibufenamide (TMF), respectively. In the Peg-IFN α-2b + NA group, 64, 56, 43, and 23 patients received Peg-IFN α-2b plus ETV, TAF, TDF, and TMF, respectively. At baseline, 39.1% (9/23) and 31.2% (58/186) of patients were HBeAg-positive ($p = 0.2451$). Mean levels of HBV DNA, HBsAg, and alanine aminotransferase (ALT) were 3.216 ± 2.066 vs. 3.264 ± 2.201 $\log_{10}$ IU/mL ($p = 0.9444$), 2.981 ± 1.101 vs. 2.743 ± 1.289 $\log_{10}$ IU/mL ($p = 0.3971$), and 27.92 ± 19.74 vs. 38.30 ± 42.04 U/L ($p = 0.2451$) in the NA and Peg-IFN α-2b + NA groups, respectively. After 24 weeks of treatment, HBeAg loss was observed in 0% (0/9) vs. 31.2% (15/58) of patients ($p = 0.193$). Mean HBV DNA, HBsAg, and ALT levels were 1.917 ± 0.725 vs. 1.829 ± 0.779 $\log_{10}$ IU/mL ($p = 0.7690$), 2.840 ± 1.270 vs. 2.032 ± 1.668 $\log_{10}$ IU/mL ($p = 0.0294$), and 26.74 ± 13.06 vs. 57.20 ± 44.99 U/L ($p = 0.0015$), respectively. Additionally, after 24 weeks of treatment, a >1 $\log_{10}$ IU/mL reduction in HBsAg levels was observed in 4.3% (1/23) of patients in the NA monotherapy group, compared to 30.1% (56/186) in the Peg-IFN α-2b + NA group ($p = 0.009$), and the HBsAg loss was achieved in 4.3% (1/23) vs. 6.5% (12/186) of patients ($p = 1.000$). The treatment was well tolerated, with no severe adverse events reported. **Conclusion:** These findings suggest that a HBsAg loss may be attainable with currently approved antiviral agents, even following a fixed 24-week treatment course, warranting further long-term investigation.

1242 | MATHEMATICAL MODELING SUGGESTS THAT 2 MG/DAY BULEVIRTIDE MONOTHERAPY EFFICACY IS SUBOPTIMAL IN MOST HDV-INFECTED PATIENTS WITH COMPENSATED CIRRHOSIS AND CSPH

Adquate Mhlanga[1] Louis Shekhtman[1] Ori Wasserman[1] Ashish Goyal[1] Elisabetta Degasperi[2] Maria Paola Anolli[3] Sara Colonia Uceda Renteria[2] Dana Sambarino[2] Marta Borghi[2] Riccardo Perbellini[2] Floriana Facchetti[2] Annapaola Callegaro[2] Scott Cotler[1] Harel Dahari[1] Pietro Lampertico[4], [1]Loyola University Chicago, [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]Department of Pathophysiology and Transplantation, University of Milan, [4]University of Milan

Background: We recently identified HDV kinetic patterns in 18 patients with compensated cirrhosis and clinically significant portal hypertension (CSPH) treated with the entry inhibitor bulevirtide (BLV) for 48 weeks and found that a biphasic decline was most prevalent (JHEP Rep. 2023;6(2):100966). We aim to further characterize HDV, HBsAg and ALT kinetics under 96 weeks of BLV (2 mg/day) monotherapy in these patients and 20 additional patients to provide insights into HDV-host dynamics and evaluate BLV efficacy in blocking infection (η) via mathematical modeling. **Methods:** 38 patients were included. All patients received nucleos(t)ide analogues for HBV. Blood samples were collected at weeks 0, 4, 8, 16, 24, 32, 40, 48 and every 12 weeks thereafter. We developed a mathematical model that includes HDV-free and HDV-infected HBsAg-producing hepatocyte dynamics to explain observed HDV, ALT and HBsAg kinetics using a nonlinear mixed-effects approach. Kinetic patterns were characterized and the critical drug efficacy (CDE) was estimated for each patient, such that for $\eta >$ CDE, HDV is ultimately cleared (i.e., cure), while $\eta <$ CDE results in a new lower viral plateau or viral breakthrough. **Results:** 6 patients were non-responders (less than 1.6 log HDV decline from baseline). After an initial decline, the 32 responder patients exhibited 4 different kinetic patterns (Fig. 1): a flat partial response (Fig. 1A), where the viral kinetics reached a new lower plateau (FPR, n = 18); a biphasic response (Fig. 1B) with a second slower phase of HDV decline (BP, n = 2); a viral breakthrough (Fig. 1C) marked by a 1.6 log HDV kinetic increase from nadir (VB, n = 6); and a triphasic kinetic pattern (Fig. 1D) marked by a plateau or slight increase followed by a 2nd decline in viral kinetics reaching LLD (TP, n = 6). ALT normalization was reached in 29 patients (76%) at a mean 11.9 (95% CI: 5.9 – 17.9) weeks. HBsAg remained at pre-treatment levels (Fig. 1). The model reproduced the observed HDV, ALT and HBsAg kinetic patterns well in all responders (Fig. 1A, B and C), excluding the 6 TP patients (Fig. 1D). Modeling indicated that BLV inhibited infection of hepatocytes with overall efficacy 82% (95% CI: 65 – 92%) and estimated a HDV-infected cell $t_{1/2}$ of 6.93 (95% CI: 3.94 – 9.92) days. BLV efficacy (η) was $<$ CDE in 16 FPR and all VB cases. Modeling explained VB by an increase of susceptible cells (i.e., HDV-free hepatocytes), ALT normalization by a decline in HDV-infected cells, and stable HBsAg by an overall constant number of HBsAg-producing hepatocytes during treatment. **Conclusion:** The HDV FPR and VB observed in patients during 96 weeks of BLV is consistent with the modeling prediction that the efficacy of BLV 2 mg/day is $<$ CDE to achieve HDV cure in many patients with compensated cirrhosis and CSPH. Higher BLV doses or its combination with other anti-HDV drugs might potentially raise treatment efficacy to $>$ CDE to achieve cure. Explaining the HDV triphasic pattern requires further study.

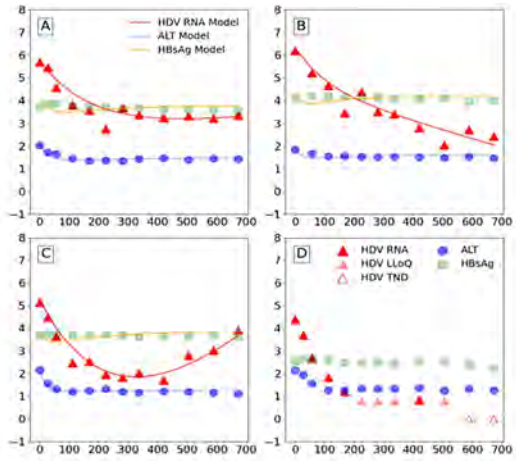

Figure 1. Measured kinetics (symbols) and modeling best curve fits (lines) in representative responder patients with a flat partial viral response (**A**), biphasic viral decline (**B**), viral breakthrough (**C**), and triphasic viral response (**D**). Estimated BLV efficacy in blocking infection (η) and death/loss of HDV-infected cells (δ) in A, B and C were (η = 90%, δ = 0.045 day^{-1}), (η = 96%, δ = 0.05 day^{-1}), and (η = 75%, δ = 0.08 day^{-1}), respectively. Modeling was not performed in triphasic (D). HDV RNA was measured using Robogene 2.0 (lower limit of detection, LLD = 6 IU/mL). ALT normalization was defined as 41 and 59 U/L for women and men, respectively.

historically been challenging. We developed methods to launch HBV infection in chimeric huFNRG mice from recombinant (r)cccDNA. We here aimed to quantify the launch efficiencies and use the most efficient method for deep mutational scanning (DMS) of the HBsAg antigenic loop to identify anti-HBs antibody resistant variants. **Methods:** To quantitatively compare launch methods, we engineered the viral genome to contain silent mutant barcodes. We created DNA pools containing silent mutants that were spiked into wildtype (WT) DNA at 1:2 ratios ranging from 1:1000 to ~1:500,000. We measured the efficiency of various launch methods, including direct intrahepatic injection (IHI), by deep sequencing viral DNA from serum and quantifying the barcodes. We then synthesized a rcccDNA library containing >4000 codon variants within the antigenic loop open reading frame (ORF) to screen for resistance to a neutralizing antibody. **Results:** The IHI method was the most efficient method, launching 8,000 rcccDNA molecules in all mice tested and 64,000 in most mice. The antigenic loop DMS library, or WT control rcccDNA, was launched by IHI, and once viremia was established, huFNRG mice were injected with anti-HBs or control antibodies. In the presence of control antibody, many variants were enriched consistently between mice, illustrating that variants other than WT can spread more efficiently in the absence of an adaptive immune system. Treatment with anti-HBs suppressed WT viremia for the duration of the experiment, whereas viremia continued to rise in 3 out of 5 mice infected with the variant library. In animals with breakthrough viremia, many G145 variants could propagate in the presence of anti-HBs, with G145Q, G145S and G145R encoding variants being the most prevalent. Interestingly, 4 of 6 arginine codons were present, while the 2 arginine codons that create a stop codon in the overlapping polymerase ORF were not detected. These results highlight that the DMS library enables more efficient discovery of mutants compared to WT virus and illustrate restraints imposed by the overlapping ORFs. **Conclusion:** The IHI technique efficiently initiates HBV infection from thousands of rcccDNA molecules in parallel, enabling high-throughput characterization of HBV variant fitness and direct-acting antiviral resistance *in vivo*.

Background: Functional cure of chronic hepatitis B (CHB) requires suppression of HBV replication, antigens and induction of anti-HBV immune responses. Imdusiran (IDR) is an *N*-Acetylgalactosamine–conjugated, pan-genotypic small interfering RNA that blocks all HBV RNA, resulting in suppression of viral replication and all antigens. IM-PROVE I is a Phase 2a study assessing combination treatment of IDR with pegylated interferon alfa-2a (IFN) in HBeAg-negative nucleots(t)ide analogue (NA) treated CHB subjects. After a 24-week (W) IDR-lead-in, subjects received 12 or 24W of IFN with or without additional IDR doses. HBV genotypes (GT) are known to influence response to IFN, with the greatest HBsAg declines in GT A and the lowest response for GT C in HBeAg-negative patients. The association of GT with HBsAg response during IFN treatment with IDR dosing and clinical outcomes for subjects in IM-PROVE I is presented. **Methods:** Baseline plasma samples from 43 subjects were used to determine HBV GT by ultra-deep sequencing or serology (IMMUNIS® HBV GT EIA by Institute of Immunology Co). Data on percentages of patients achieving HBsAg decline during IFN treatment (defined as HBsAg decrease from W28 through W40 for 12W IFN cohorts or W52 for 24W IFN cohorts), functional cure and NA discontinuation criteria (DC) are presented

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with respect to subjects with different HBV GTs. **Results:** The mean (SD) age across subjects was 45.3 (6.4) and 28% were female. The overall GT distribution across subjects was GT A 9.3%, GT B 32.6%, GT C 44.2%, GT D 11.6% and GT E 2.3%. 53.4% of subjects had baseline HBsAg <1000 IU/mL and 4.3% were GT A, 43.5% GT B, 30.4% GT C, 17.4% GT D and 4.3% GT E. During IFN treatment, 10 subjects experienced HBsAg declines: 10% were GT A, 50% GT B, and 30% GT C. Of the 10 IFN responsive subjects, 5 went on to achieve functional cure off all treatment following NA DC. Of these 5 subjects, 4 were GT B or C. 10 additional subjects met NA DC criteria for HBsAg response and achieved HBsAg <100 IU/mL: 40% were GT B, 40% GT D and 20% GT C; these subjects NA DC but did not achieve functional cure by end of study. **Conclusion:** In this limited dataset, the majority of subjects who achieved HBsAg response during IFN treatment with or following IDR dosing were GT B or C. These findings contrast with historical data from IFN therapy and suggest that IDR may enhance IFN responsiveness in CHB patients with specific HBV GTs. Further studies in larger cohorts are warranted to confirm these observations.

Background: Although previous studies have shown good durability of HBsAg loss, the durability of functional cure remains to be investigated. We aimed to assess the long-term durability of functional cure in patients who achieved by peginterferon alpha-2b (PegIFNα-2b). **Methods:** Patients who achieved functional cure (maintain HBsAg loss and HBV DNA undetectable for 24 weeks follow-up after all drugs discontinuation) at the end of a phase 3 trial (NCT04846491) were enrolled in cohort 1 of this long-term follow-up study (NCT06707922) and observed for 5 years. In the preliminary phase 3 trial, nucleos(t)ide analogue (NA)-experienced patients were randomized to receive tenofovir disoproxil fumarate (TDF) monotherapy (group 1), TDF combined with PegIFNα-2b (Pegbing®, Xiamen Amoytop Biotech Co., Ltd.) 180 μg/week (group 2) or 90 μg/week (group 3); after 48 weeks of TDF treatment, patients in group 1 either continue TDF monotherapy (group 1a) or add PegIFNα-2b 180 μg/week (group 1b). Treatment-naïve patients were also included to receive TDF combined with PegIFNα-2b 180 μg/week (group 4). The treatment period was 144 weeks and the follow-up was 24 weeks. PegIFNα-2b were given intermittently in cycles. **Results:** A total of 88 patients who achieved functional cure were enrolled in cohort 1 of this follow-up study, including 32, 23, 29 and 4 patients from groups 2, 1b, 3 and 4 of the preliminary phase 3 trial, respectively, and no patients from group 1a. The mean age of NA-experienced patients in groups 2, 1b and 3 ranged from 36.1 to 41.5 years, with 58.6% to 82.6% being male. For treatment-naïve patients in group 4, the mean age was 30.5 years and 25% were male. By 104 weeks of follow-up, 90.6% (29/32), 87.0% (20/23), 89.7% (26/29) and 100% (4/4) of patients maintained functional cure in groups 2, 1b, 3 and 4, respectively (Figure 1). All patients who relapsed had HBsAg reversion while maintaining HBV DNA negativity. Only one patient in group 3 experienced HBV DNA reactivation (≥ 20 IU/mL) at 52 weeks of follow-up but returned undetectable by 104 weeks of follow-up. **Conclusion:** PegIFNα-2b combination therapy induced durable functional cure, with maintenance rates of approximately 90% in NA-experienced patients and 100% in treatment-naïve patients at 104 weeks of extended follow-up. Only one transient HBV DNA relapse was observed in the low-dose PegIFNα-2b group. PegIFNα-based therapy enables sustained functional cure and safe discontinuation of all drugs.

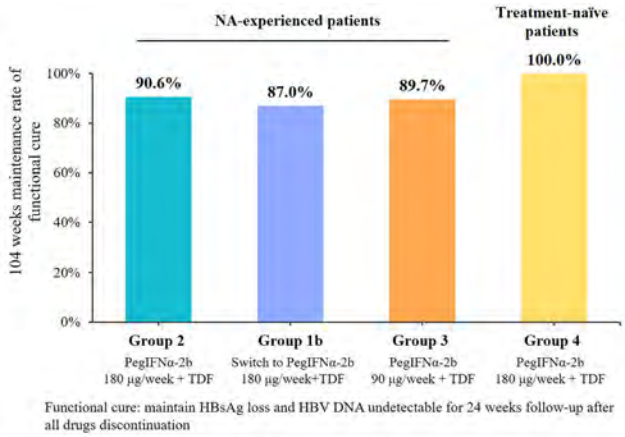

Figure 1. 104 weeks maintenance rate of functional cure in each group.

Background: Chronic hepatitis B (CHB) is a major public health concern, and patients with compensated cirrhosis are at risk for significant liver complications. Pegylated interferon alpha-2b (Peg-IFN-α-2b) combined with nucleos(t)ide analogs (NAs) has shown promise in enhancing antiviral efficacy and improving liver fibrosis. The CHESS-SAVE score is a noninvasive approach to assess decompensated event risk: (CHESS-SAVE score = 0.036*stiffness-0.152*albumin-0.011*platelets +1.177*[Varices: 0 if absent, 1 if present], where stiffness is in kPa, albumin in g/L, and platelets in$\times 10^5$/L. Score $<$-1.5 = low risk, <0 = medium risk, ≥ 0 = high risk). This study compared liver stiffness, virological response, and safety between patients (low/medium CHESS-SAVE risk) receiving Peg-IFN-α-2b + NAs vs. NAs alone. **Methods:** This prospective, non-randomized observational study included 201 patients in the CHESS-SAVE guided group (Peg-IFN-α-2b + NAs) and 238 patients in the control group (NAs alone). Patients were followed for 48 weeks, with liver stiffness assessed via transient elastography and adverse drug reactions monitored. **Results:** Baseline characteristics were comparable (Table 1). Liver stiffness in the CHESS-SAVE group decreased from 11.8 kPa to 9.7 kPa at week 24 (change: -2.1 kPa, $p < 0.05$), while the control group decreased from 12.7 kPa to 11.2 kPa (change: -1.5 kPa, $p < 0.05$). No significant difference in reduction between groups ($p > 0.05$, Figure 1). By week 48, CHESS-SAVE group stiffness decreased to 9.6 kPa (-2.2 kPa), and the control group to 10.1 kPa (-2.6 kPa), with no significant difference. HBsAg clearance occurred in 5 patients in the CHESS-SAVE group vs. 0 in the control group($p < 0.05$). HBV-DNA was fully suppressed in both groups. One patient in the treatment group withdrew due to mental symptoms. Adverse events: CHESS-SAVE group: 7 (3.5%) neutropenia, 1(0.5%) granulocytosis,30(14.9%) mild thrombocytopenia,4(2.0%)severe thrombocytopenia.21(10.4%)bilirubin increase $\leq$ 2ULN,1(0.5%) $>$ 2ULN. Control group:1(4.2%) neutropenia,20(8.4%) mild thrombocytopenia, 6(2.5%) severe thrombocytopenia.40 (16.8%)bilirubin increase $\leq$ 2ULN,7(2.9%) $>$ 2ULN.Neutropenia was significantly higher in the CHESS-SAVE group ($p < 0.05$), but other cytopenias showed no significant differences. Bilirubin elevation incidence was not higher in the CHESS-SAVE group. **Conclusion:** The addition of Peg-IFN-α-2b to NAs therapy demonstrated a higher HBsAg clearance rate, and liver stiffness can also be decreased after treatment. Serious adverse reactions were rare in patients with compensated hepatitis B virus-related cirrhosis whose CHESS-SAVE scores were low and medium risk.

Table 1. Baseline data

1247 | HEPATITIS D SEROPOSITIVITY IS ASSOCIATED WITH HIGHER PREMATURE MORTALITY AMONG HEPATITIS B SURFACE ANTIGEN CARRIERS IN THE UNITED STATES: DATA FROM NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (NHANES) 2011-2018

Zobair Younossi[1] James Paik[2] George Papatheodoridis[3] Veronica Nguyen[4] Pietro Lampertico[5] Rafael Esteban-Mur[6] Saleh Alqahtani[7] Zohal Zekrya[8] Linda Henry[9] Maria Buti[10], [1]The Global Liver Council, [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, [3]First Academic Department of Gastroenterology, Medical School of National and Kapodistrian Univer, [4]Inova Health System, [5]University of Milan, [6]Hospital Universitario Vall d'Hebron, [7]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King, [8]Beatty Liver and Obesity Research Program, Inova Health System Falls Church, VA, [9]The Global NASH Council, [10]Hospital Valle Hebron

Background: Hepatitis D virus (HDV), a satellite virus of hepatitis B virus (HBV), can be associated with a severe disease course. The outcomes of HDV patients in the U.S. is not well understood. We aimed to assess the clinical outcome of HDV positive subjects among adults with HBV using a nationally representative data from the U.S. **Methods:** We analyzed data from adults ($\geq$18 years) in NHANES 2011–2018, linked to the National Death Index through 2019. According to CDC, we defined current or past HBV infection as Anti-HBc Antibody positive (HBcAb-positive). We also considered HBsAg carriers as a separate group. HDV was determined by anti-HDV antibody assessed among HBsAg and Anti HBcAb positive individuals. Premature mortality was defined as death ($<$75/80 years for men/women). Age-standardized mortality rates (per 1,000 person-years [PY]) were calculated using the 2000 U.S. standard population. **Results:** Among 23,825 adults (mean age 46.8 years, 48.2% male, 64.2% non-Hispanic White, 11.5% non-Hispanic Black, 8.9% Mexican American, 6.4% other Hispanic, 5.6% Asian, 18.2% foreign-born), the prevalence of HBcAb-positive was 4.4% (95% CI: 3.92%-4.88%) while HBsAg carrier was 0.32% (95% CI: 0.25%–0.38%). Among those with positive Anti-HBc, 2.7% (95% CI: 1.67%-3.67%) were positive for anti-HDV. In multivariable logistic regression, HBsAg carrier state was associated with being Asian (OR: 10.44, 95% CI: 6.05–18.02), black (OR: 5.81, 95% CI: 3.23–10.47), foreign-born (OR: 4.68, 95% CI: 2.48–8.82), and those with a history of injection drug use (OR: 9.81, 95% CI: 3.18–30.24). Compared to HBsAg carriers without HDV, those with anti-HDV were more likely to be older ($\geq$65 years: 29.3% vs. 11.0%), female (56.9% vs. 40.0%), white (29.1% vs. 9.5%), and college degree (43.8% vs. 19.3%) ($p<0.05$). Over 736 PY of follow-up, age-standardized premature mortality rates for HBsAg carrier were 5.19 per 1,000 PY. Compared to HBsAg carriers without HDV, those with anti-HDV had significantly higher premature mortality rates (14.57vs. 2.89 per 1,000 PY, $p=0.04$). Repeating this analysis for HBcAb-positive with anti-HDV vs. without anti-HDV, indicated that premature mortality was 14.57 vs. 3.98 per 1000 PY ($p=0.172$). **Conclusion:** In the U.S., HDV co-infection is associated with higher premature mortality in HBsAg carriers. Identification of HDV infected individuals will be important to better manage these patients in clinical practice.

1248 | DIFFERENTIATION OF HBV CAPSID ASSEMBLY MODULATORS BASED ON STABILIZATION OF CORE PROTEIN OLIGOMERIZATION AND RESIDENCE TIME

Cheng Liu[1] Yannick Debing[2] Dieudonné Buh Kum[1] Hannah Vanrusselt[2] Andreas Jekle[1] Hyunsoon Kang[1] Hua Tan[1] Qingling Zhang[1] Abel Acosta Sanchez[3] Pierre Raboisson[2] Julian Symons[1] Lawrence Blatt[1] Leonid Beigelman[1] David Smith[1] Sandrine Vendeville[2] Jerome Deval[1], [1]Aligos Therapeutics, [2]Aligos Belgium BV, [3]Novalix

Background: Despite the availability of vaccines against hepatitis B virus (HBV), no curative therapies are available for the estimated 300 million people worldwide who are chronically infected. Capsid assembly modulators (CAMs) are a promising new class of potential HBV antivirals. ALG-000184 is a prodrug of ALG-001075, a novel capsid assembly modulator leading to the formation of empty capsids (CAM-E). ALG-000184 has demonstrated best-in-class reductions of HBV DNA, RNA, HBsAg, HBeAg and HBcrAg in CHB patients. However, the lack of quantitative and predictive biochemical assays limits the characterization of novel and potent CAM-E compounds. Therefore, a novel jump dilution assay was designed to assess the capsid disassembly and the residence time of CAM compounds. **Methods:** Cellular antiviral activity was assessed in HepG2.117 and HepAD38 cells using intracellular HBV DNA as a readout. Cellular core immunostaining (spotting) assay, quenching assay, negative-staining electron microcopy and a thermal shift assay were used to measure and classify capsid assembly. Capsid disassembly and residence time of compounds were assessed in jump dilution assays. Compound pharmacokinetics were studied in AAV-HBV-transduced C57Bl/6 mice. **Results:** We determined that a subset of CAMs was able to trigger HBV core protein (Cp) oligomerization under denaturing conditions, leading to the hypothesis that CAMs might have heterogenous stabilizing effects on capsid assembly. We designed a novel jump dilution assay to measure the effect of CAMs on the intrinsic stability of pre-assembled capsids over time. While less potent first-generation CAMs did not significantly impede capsid disassembly, capsid stability increased up to 4 days with the most potent compounds, including ALG-001075, the parent of ALG-000184. We found that target residence time measured with the jump dilution assay correlated with cell-based antiviral potency for CAM-Es. In AAV-HBV mice expressing HBV Cp to high levels in the liver, CAMs with long residence times demonstrated excellent liver exposures. **Conclusion:** We developed a novel jump dilution assay to assess the biochemical potency/residence time of CAM compounds. Our results demonstrate that the stability of Cp oligomerization and target residence time are important parameters for the characterization of next-generation CAMs.

Hospital, Guangzhou Medical University, [24]Beijing Friendship Hospital Capital Medical University, [25]The First Hospital of Lanzhou University, [26]Nanjing Drum Tower Hospital, [27]The First Hospital of Wenzhou Medical University, [28]Tongren Hospital Shanghai Jiao Tong University School Of Medicine, [29]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [30]Shanghai Fifth People's Hospital, [31]Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, [32]Third Hospital of Hebei Medical University, [33]Jiangsu Hansoh Pharmaceutical Group Co., Ltd.

Background: Tenofovir amibufenamide (TMF) is widely utilized in the Chinese mainland for the treatment of chronic hepatitis B (CHB). In a phase III, double-blind, randomized controlled trial, TMF demonstrated non-inferior antiviral efficacy compared to tenofovir disoproxil fumarate (TDF), along with superior bone and renal safety profiles. Subsequent phase IV extension studies further revealed sustained therapeutic benefits over five years. This study aimed to evaluate the impact of 5-year treatment on bone mineral density (BMD) and to identify potential risk factors associated with BMD decline. **Methods:** All participants continued to receive oral TMF (25 mg, daily), including those who had previously switched from two years of TDF treatment during the phase III study. BMD at the lumbar spine (L1-L4), as assessed by dual energy X-ray absorptiometry, was analyzed over five years of treatment ([144+] 96 weeks). The Z-score (adjusted by age, sex and race) has been adopted in BMD evaluation as it can reflect non-physiological and non-age-related bone loss. BMD decline was defined as a decrease in Z-score of $\geq$ 0.5 from baseline at week (144+) 96. Odds ratio (OR) was calculated by multivariate logistic regression. **Results:** At week (144+) 96, 584 patients had available BMD data, and 315 (53.9%) patients showed an increase in lumbar spine Z-score. Although BMD in the TDF group was significantly lower than in the TMF group at week 96, this reduction in BMD associated with TDF treatment had recovered after switching to TMF treatment up to week (144+) 96. BMD decline was observed in 114 (19.5%) patients, including 75 (12.8%), 35 (6.0%), and 4 (0.7%) with decrease in Z-score of 0.5-1, 1-2 and $\geq$2, respectively. The distribution in decrease levels of Z-score was comparable in TMF group and TDF-to-TMF group. Notably, baseline HBV DNA $\geq$8 log10 IU/mL was found to be an independent risk factor for BMD decline (OR = 1.850, 95% CI: 1.103-3.103, p = 0.020). The following were also risk factors: serum calcium (OR = 46.133, 95% CI: 4.246-501.265, p = 0.002), parathyroid hormone (OR = 1.010, 95% CI: 1.002-1.018, p = 0.014), C-terminal telopeptide of type 1 collagen (OR = 5.103, 95% CI:1.319-19.735, p = 0.018) and baseline Z-score (OR = 1.575, 95% CI: 1.249-1.986, p < 0.001). **Conclusion:** After five years of treatment, half of the patients had an increased BMD Z score and the other decreases may be related to risk factors such as baseline high viral load and high serum calcium.

1250 | CHANGES OF ALBUMIN FUNCTION IN HBV-RELATED LIVER DISEASES

Mengqi Li[1] Wenyu Li[2] Qi Wang[1] Hong Zhao[1] Yidi Ge[1] Jingjing Wang[1] Haijun Yang[2] Wen Xie[1], [1]Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, [2]Department of Chemistry, Tsinghua University, Beijing, China

Background: Hepatitis B virus (HBV) infection is a major global public health challenge that can lead to liver fibrosis, cirrhosis, and hepatocellular carcinoma. In cirrhotic patients, not only are albumin levels decreased, but its functionality may also undergo significant changes. Currently, there is no universally accepted method for testing albumin function. Electron paramagnetic resonance (EPR) technology has gained widespread attention for its ability to assess albumin binding capacity in various diseases. However, the application of EPR technology in HBV-related diseases remains limited, particularly in the Chinese population. Therefore, this study aims to investigate the changes in albumin function at different disease stages and the relationship between albumin function and clinical indicators in HBV-related liver diseases. **Methods:** This study utilized EPR technology with 16-doxyl stearic acid (16-DSA) as a spin probe to test plasma samples from age- and gender-matched healthy controls, chronic

hepatitis B patients, HBV-related cirrhosis patients, and hepatocellular carcinoma patients. The results were analyzed using both spectral fitting and direct measurement methods. **Results:** This study tested 120 plasma samples from four age- and gender-matched groups: 30 healthy controls, 30 chronic hepatitis B patients, 30 hepatitis B-related cirrhosis patients, and 30 hepatocellular carcinoma patients. The results showed a significant reduction in albumin binding function in the HBV-related cirrhosis and hepatocellular carcinoma groups, particularly in the Child-Pugh C group (Figure 1). Additionally, a significant positive correlation was confirmed between the h_{-1}/h_0 ratio obtained through direct measurement and the proportion of free components derived from spectral fitting, supporting h_{-1}/h_0 ratio potential as a simple and reliable alternative indicator for assessing albumin function. The h_{-1}/h_0 ratio also correlated with several clinical indicators reflecting liver function, coagulation function, and inflammation, suggesting its potential value in evaluating disease severity. **Conclusion:** This study found a significant decline in albumin binding function in the HBV-related cirrhosis and hepatocellular carcinoma groups and confirmed that the h_{-1}/h_0 ratio effectively reflects albumin's binding ability, potentially serving as an important supplementary indicator for clinical evaluation.

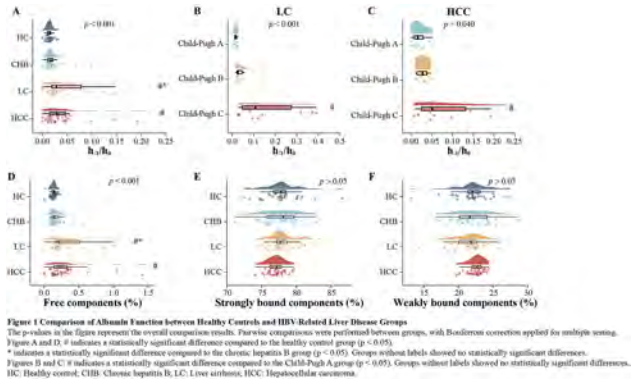

Figure 1 Comparison of Albumin Function between Healthy Controls and HBV-Related Liver Disease Groups
The p-values in the figure represent the overall comparison results. Pairwise comparisons were performed between groups, with Bonferroni correction applied for multiple testing.
Figure A and D: # indicates a statistically significant difference compared to the healthy control group ($p < 0.05$).
* indicates a statistically significant difference compared to the chronic hepatitis B group ($p < 0.05$). Groups without labels showed no statistically significant differences.
Figures B and C: # indicates a statistically significant difference compared to the Child-Pugh A group ($p < 0.05$). Groups without labels showed no statistically significant differences.
HC: Healthy control; CHB: Chronic hepatitis B; LC: Liver cirrhosis; HCC: Hepatocellular carcinoma.

1251 | CAPSID ASSEMBLY MODULATOR ALG-001075 PREVENTS CCCDNA FORMATION AND HBV DNA INTEGRATION IN VITRO

Jordi Verheyen[1] Hannah Vanrusselt[1] Tse-I Lin[1] Zhili Wang[2] Selena Lin[2] Ying-Hsiu Su[2] Stéphane Plaisance[3] Jin Hong[4] Julian Symons[5] Lawrence Blatt[4] Andreas Jekle[4] Yannick Debing[1], [1]Aligos Belgium BV, [2]JBS Science, [3]VIB Nucleomics Core, [4]Aligos Therapeutics, Inc., [5]Aligos Therapeutics

Background: The hepatitis B virus (HBV) capsid assembly process has emerged as a key target for the treatment of chronic hepatitis B (CHB). ALG-000184 is a prodrug of ALG-001075, a novel capsid assembly modulator leading to the formation of empty capsids (CAM-E). ALG-000184 has demonstrated best-in-class reductions of HBV DNA, RNA, HBsAg, HBeAg and HBcrAg in CHB patients. Here, we investigated the effects of ALG-001075 on HBV cccDNA formation and HBV DNA integration in vitro. **Methods:** HBV cccDNA was quantified in HBV-infected HepG2-NTCP cells using Southern blot and digital PCR (dPCR). Production of double-stranded linear DNA (dslDNA), which can lead to HBV DNA integration, and relaxed circular DNA (rcDNA) from HBV-expressing HepG2.117 cells was investigated using Southern blot and PNA clamp-based qPCR. The level of HBV DNA integration after HBV infection of HepG2-NTCP cells was quantified using genomic DNA isolation, HBV sequence enrichment, next-generation sequencing and subsequent identification of HBV-host junctions. **Results:** ALG-001075 substantially reduced cccDNA formation when added together with the viral inoculum in a dose-dependent fashion, as confirmed by Southern blot, dPCR and antigen quantification, through its secondary mechanism of action. This was not the case for nucleos(t)ide analogs entecavir and tenofovir. ALG-001075 also potently and dose-dependently inhibited production of both rcDNA and dslDNA through its primary mechanism, thereby reducing the precursor pool available for HBV DNA integration. Direct quantification of HBV DNA integrations in HBV-infected cells over a relatively short period of time (14 days) showed pronounced reductions in the number of detected host-viral junctions, with superior reductions observed for ALG-001075 compared to nucleos(t)ide analogs. **Conclusion:** ALG-001075 demonstrated potent prevention of HBV cccDNA formation and HBV DNA integration, further confirming its best-in-class properties and superiority over commonly used nucleos(t)ide analogs.

1252 | SIGNIFICANCE OF HBV RNA IN PATIENTS WITH HEPATITIS B HEPATOCELLULAR CARCINOMA

Ning Lin[1] Guangming Li[2] Zhan Zeng[3] Yifan Han[4] Huiying Rao[5] Gongming Zhang[2] yanyan yu[1] Xiaoyuan Xu[4], [1]Department of Infectious Diseases, Peking University First Hospital, Beijing, China, [2]Department of General Surgery Center, Beijing Youan Hospital, Capital Medical University, China, [3]Department of Infectious Diseases, Peking University First Hospital, Beijing, China, [4]Department of Gastroenterology, Peking University First Hospital, Beijing, China, [5]Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China

Background: According to the Chinese expert consensus, serum hepatitis B virus (HBV) RNA levels can reflect hepatic cccDNA transcriptional activity and correlate with patients' virological response and prognosis. HBV RNA is recommended to be used for clinical testing. However, the significance of HBV RNA in patients with HBV-related hepatocellular carcinoma (HCC) is not clear. In this study, we investigated the significance of HBV RNA levels in tumor development and recurrence in HBV-related HCC patients. **Methods:** HBV- related HCC patients who underwent hepatectomy were retrospectively enrolled from June 2020 to April 2023 in Beijing Youan Hospital (LL-2024-127-K). Detection of HBV RNA in serum was defined as positive. Patients were divided into HBV RNA positive and negative groups. Patients' gender, age, antiviral treatment, preoperative serologic and virologic markers, and tumor characteristics were collected. The observation endpoint was 2-year recurrence after hepatectomy in patients with hepatocellular carcinoma. Kaplan–Meier curves was used to analyze the relationship between HBV RNA and recurrence. Statistical significance was set at $p < 0.05$. **Results:** The study included 80 patients with HBV- related HCC. The mean age was 55.8 years old and 38.7% patients was HBV RNA positive. In HBV RNA-positive patients, the recurrence rate at 24 months was 42.3% and the median recurrence-free survival (RFS) time was 9 months. In HBV RNA-negative patients, the recurrence rate at 24 months was 42.1% and the median RFS time was 12 months. 25.0% HBV-positive patients have multiple tumors, more than HBV-negative patients. No significant difference in tumor diameter and Ki-67 between HBV RNA-positive and negative patients. Patients with microvascular invasion (MVI) 1 and with Edmondson-Steiner IV (II vs IV,III vs IV,P **Conclusion:** HBV- related HCC patients with HBV RNA positive are prone to multiple tumors and faster recurrence. Patients with microvascular invasion and poorly differentiated tumors have higher HBV RNA levels. HBV RNA monitoring is relevant in tumorigenesis and recurrence in patients with HCC to some extent.

1253 | HEPATITIS B VACCINATION AWARENESS AND IMMUNITY IN THE UNITED STATES: GAPS BETWEEN PERCEPTION AND PROTECTION

Giovanni Roldan[1] Prowpanga Udompap[2] Jesse Fletcher[1] Timothy Davie[1], [1]University of Minnesota, [2]Minneapolis VA Medical Center

Background: Hepatitis B virus (HBV) remains a public health concern and HBV vaccination is fundamental to the WHO's HBV elimination targets. However, population awareness of immune protection and adherence to vaccination remain poorly characterized. We aimed to evaluate self-reported HBV vaccination status and discordance with serologic immunity in a nationally representative U.S. sample. **Methods:** We analyzed adults aged $\geq$20 years from NHANES 2017–2020 with available HBV vaccination history and serologic data on HBV surface antibody (HBsAb), core antibody (HBcAb), and surface antigen (HBsAg). Serologic immunity was defined as HBsAb-positive with HBcAb-negative and HBsAg-negative. Self-reported vaccination status was classified as complete, partial, unvaccinated, or unknown. Discordance was defined as a mismatch between reported vaccination and serologic immunity. National estimates were calculated using survey weights. **Results:** Among 216.9 million U.S. adults (mean age 48.0 years, 52.2% female, 64.5% non-Hispanic White), 66.1 million reported complete vaccination (30.5%), yet only 48.1% of those demonstrated serologic immunity. Conversely, 10.2% of the 112.3 million adults who denied HBV vaccination were immune, approximately 11.5 million people. Discordance affected 45.8 million people (21.1%). Rates were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

highest among adults aged 20–39 (32.4%, 95% CI: 29.3–35.6%), followed by 40–59 (18.5%) and ≥60 years (9.8%). Asian adults had the highest discordance (25.8%, 95% CI: 22.5–29.2%), while multi-racial individuals had the lowest (15.9%, 95% CI: 11.8–20.2%), the only statistically significant difference across racial groups. Although point estimates suggested higher discordance among adults below the poverty line (25.1%) compared to those with high income (20.0%), and among U.S.-born (21.6%) versus foreign-born individuals (19.0%), these differences were not statistically significant. Importantly, regardless of etiology, only 23.7% of adults with liver stiffness ≥15 kPa and 10.8% of those with FIB-4 > 2.67 reported complete HBV vaccination, with serologic immunity similarly low at 13.8% and 12.8%, respectively **Conclusion:** In this nationally representative cohort, over half of the adults who reported complete HBV vaccination lacked serologic immunity, while 1 in 10 unvaccinated adults were unknowingly HBV protected. Discordance between perceived vaccination and actual immunity affected over one in five adults, with the highest rates observed among younger adults and Asian populations. These gaps in awareness and protection highlight critical opportunities for targeted education, catch-up vaccination, and targeted outreach in national HBV elimination efforts.

1254 | REAL-WORLD TREATMENT RATES WITH NUCLEOS(T)IDE ANALOGS (NA) IN PATIENTS WITH HEPATOCELLULAR CARCINOMA (HCC) AND HEPATITIS B VIRUS (HBV) INFECTION: A POPULATION-BASED U.S. STUDY

Taotao Yan[1] Sally Tran[1] Guillermo Daniel Molina[1] Xinrong Zhang[1] Tyler Wong[1] Ramsey Cheung[1] Mindie Nguyen[1], [1]Stanford University Medical Center

Background: NA therapy is a key strategy for preventing the development of HCC in patients with chronic HBV infection. NA treatment is also associated with reduced recurrence rates and improved overall survival in HBV patients with established HCC (HBV-HCC). However, unlike HBsAg+ patients with cirrhosis which by itself a criteria for antiviral treatment independent on HBV DNA or liver enzyme levels, HCC by itself is not a criteria for antiviral treatment in most major guidelines leading to undertreatment. We aimed to quantify NA treatment rate among HBV-HCC to identify potential factors associated with no treatment. **Methods:** We conducted a study of adult patients with HCC using the Truven Health MarketScan Research Database, a database comprised of approximately 250 million U.S. residents with private health insurance (2007-2022). The primary outcome was the proportion of HBV-HCC patients who received NA treatment at any time. **Results:** We analyzed 3208 HBV-HCC patients (mean age 58 years, 81.2% male, and 68.7% cirrhosis, 69.8% with at least one gastroenterology or infectious disease [GI/ID] specialty visit, and 69.8% with receipt of HCC therapy). Only one-third (34.5%) of patients received NA in total (21.4% initiating treatment prior to HCC diagnosis, 8.9% at the time of HCC diagnosis, and 4.2% after diagnosis). NA treatment rate has increased from about 30% in 2013 or earlier to 53.1% in 2017 then remained at about 50% thereafter (Figure 1). NA treatment rates were significantly lower in females (30.5 vs. 35.5%, $P = 0.02$), patients aged >60 years (28.6 vs. 39.2%, $P < 0.001$), and those with compensated or decompensated cirrhosis compare to noncirrhosis (36.0 vs. 22.5 vs. 45.5%, $P < 0.001$). Patients without NA treatment were more likely to have preferred provider organization (PPO) insurance, a history of alcohol use, or viral hepatitis C co-infection. Patients who had GI/ID specialty visit after HCC diagnosis were more likely to receive NA treatment compared to those who had specialty visit prior to HCC diagnosis or no specialty visit at any time (40.3 vs. 34.6 vs. 30.2%, $P < 0.001$). **Conclusion:** The rate of antiviral treatment in patients with HBV-HCC was markedly suboptimal even among this cohort of HCC patients with

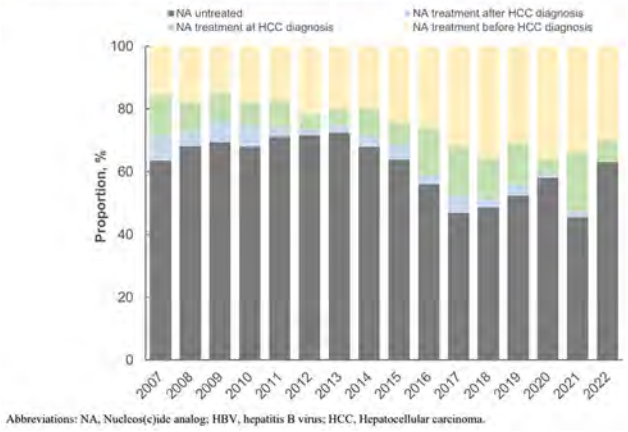
private health insurance in the U.S., with only about 30% receiving NA therapy overall and 50% in the more recent era 2015 and after. As effective and well tolerated NAs are now available in low cost generics, much more efforts are needed to increase patient and provider awareness of the potential benefits of NA which may help increase treatment rates and improve patient survival. Inclusion of HCC as an antiviral treatment criteria would also help increase treatment rates.

Figure 1. Temporal trends in the receipt of NA treatment among patients with HBV-related HCC.



Abbreviations: NA, Nucleos(t)ide analog; HBV, hepatitis B virus; HCC, Hepatocellular carcinoma.

1255 | INCIDENCE AND DETERMINANTS OF ACHIEVING HBSAG < 100 IU/ML IN HBEAG-NEGATIVE CHB PATIENTS WITH NUCLEOS(T)IDE ANALOGUE TREATMENT

Jian Wang[1] Chao Wu[1] Rui Huang[1], [1]Nanjing Drum Tower Hospital

Background: Hepatitis B serum antigen (HBsAg) < 100 IU/mL is a key criterion of partial cure and an important threshold of stopping nucleos(t)ide analogues (NAs) therapy with a finite therapeutic strategy for chronic hepatitis B (CHB). We aimed to investigate the incidence and associated factors of achieving HBsAg < 100 IU/mL in hepatitis B e antigen (HBeAg)-negative CHB patients with NAs treatment. **Methods:** This study retrospectively included 996 HBeAg-negative CHB patients who received first-line NAs treatment with baseline HBsAg levels > 100 IU/mL from five sites in China. The cumulative incidence of achieving HBsAg < 100 IU/mL was evaluated using Kaplan-Meier and the associated factors was identified by the Cox regression analysis. **Results:** A total of 69 patients (6.9%) achieved HBsAg < 100 IU/mL during a median follow-up of 28.8 months. The 5-year cumulative incidence of HBsAg < 100 IU/mL was 13.97% (95%CI: 10.42%-17.38%). Among these, 94.2% (65/69) of the patients who achieved HBsAg < 100 IU/mL also had undetectable HBV DNA, representing a 5-year incidence of 13.15% (95% CI: 9.66-16.50%). Baseline HBsAg < 3 Log_{10}IU/mL (HR = 19.66, 95% CI: 8.84-43.71; P < 0.001) and HBV DNA < 4 Log_{10}IU/mL (HR = 2.47, 95% CI: 1.48-4.13; P = 0.001) were independently associated with a significantly higher likelihood of achieving HBsAg < 100 IU/mL. Patients with both baseline HBsAg < 3 Log_{10}IU/mL and HBV DNA < 4 Log_{10}IU/mL exhibited a 5-year incidence of HBsAg < 100 IU/mL of 58.73%, compared to 3.91% in those with HBsAg ≥ 3 Log_{10}IU/mL and HBV DNA ≥ 4 Log_{10}IU/mL. **Conclusion:** Few HBeAg-negative CHB patients achieved HBsAg < 100 IU/mL with first-line NAs therapy. The combination of baseline HBsAg and HBV DNA levels enables identification of patients with higher probability of achieving HBsAg < 100 IU/mL during NAs treatment and may benefit from a finite-duration therapeutic strategy.

1256 | CONCOMITANT MASLD INCREASES HBSAG SEROCLEARANCE IN CHRONIC HEPATITIS B PATIENTS ON ANTIVIRAL THERAPY

Yan Dai[1] Ke Jin[1] Xinhe Sun[2] Jun Li[1], [1]First Affiliated Hospital of Nanjing Medical University, [2]Xiamen Amoytop Biotech Co., Ltd.

Background: The impact of metabolic dysfunction-associated steatotic liver disease (MASLD) comorbidity on the cure rate of chronic hepatitis B (CHB) remains unclear. This study aimed to investigate the effect of MASLD on the therapeutic outcomes of CHB. **Methods:** A total of 262 CHB patients without significant liver fibrosis receiving nucleos(t)ide analogues (NAs) and/or pegylated interferon alpha (PEG-IFNα) antiviral therapy were enrolled. They were divided into a CHB+MASLD group (n = 152) and a CHB group (n = 110). The impact of MASLD on antiviral response in CHB patients was evaluated by comparing the HBsAg seroclearance rates, using Kaplan-Meier survival analysis and logistic regression analysis between the two groups. **Results:** Compared to the CHB group, the CHB+MASLD group demonstrated a significantly increased HBsAg seroclearance rate (21.7% vs 10.9%, P = 0.03). The median time to HBsAg seroclearance was 41.1 (34.0 - 48.0) weeks in the CHB group and 29.6 (26.4 - 48.8) weeks in the CHB+MASLD group. Although seroclearance time was shorter in the CHB+MASLD group, the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

difference was not statistically significant (P = 0.39). Within the CHB+MASLD group, patients with baseline HBsAg levels ≤100 IU/ml achieved seroclearance at a significantly higher rate than those with levels >100 IU/ml (41.1% vs. 12.3%, P < 0.001). The CHB+MASLD group also exhibited a higher HBsAb seroconversion rate compared to the CHB group (7.2% vs. 3.6%), although this difference lacked statistical significance (P = 0.28), which might be attributed to the small number of cases. Kaplan-Meier survival analysis indicated significantly higher likelihood of HBsAg seroclearance in CHB+MASLD group (Log Rank P = 0.047). Logistic regression analysis revealed that the CHB+MASLD group had 2.3-fold higher odds of achieving HBsAg seroclearance compared to the CHB group (95% CI: 1.11–4.62, P = 0.025). **Conclusion:** Concomitant MASLD increases HBsAg seroclearance in CHB patients undergoing antiviral therapy, particularly with baseline HBsAg ≤100 IU/ml. Large-scale multicenter studies are warranted to explore metabolic influences on HBsAg clearance and to elucidate the underlying mechanisms.

1257 | CYTOKINE PROFILING DISTINGUISHES CLINICAL FORMS OF ACUTE HBV INFECTION: INSIGHTS INTO ALF PATHOGENESIS

NEW SUBMISSION, *Davide De Battista[1] Ronald Engle[1] Jody Rule[2] Eric Chu[3] Sandra Kendra[1] Soichi Takeda[1] Hanh Nguyen[1] Zhaochun Chen[1] Dean Follmann[3] William Lee[2] [1]Hepatic Pathogenesis Section, Laboratory of Infectious Diseases, NIAID, NIH, [2]Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center at Dallas, [3]Biostatistics Research Branch, Division of Clinical Research, NIAID, NIH*

Background: Acute liver failure (ALF) caused by HBV is one of the most dramatic clinical syndromes, occurring in ~1% of patients with acute hepatitis B (AVHB). The mechanism underlying the development of ALF, and how it relates to milder forms remain unclear. Access to serum samples from the US Acute Liver Failure Study Group and Hepatitis B Research Network allowed us to investigate virus-elicited immune responses by analyzing the longitudinal cytokine profile in serial serum samples from patients with different outcomes of acute HBV infection, including ALF subtypes. **Methods:** We analyzed 231 serial serum samples from 49 well-characterized HBV patients: 7 with early- onset ALF (<10d onset of encephalopathy, HE), 11 late-onset ALF (>10d HE), 7 acute liver injury (no HE, ALI), 11 with ALF secondary to acute flare of chronic hepatitis B (reactivation–CHBALF), and 13 with AVHB. Longitudinal clinical and virological data were obtained for each patient. Genotype A predominated across all groups. Serum concentration of 19 cytokines was measured using high-multiplexing quantitative CodePlex proteomic assay. **Results:** Cytokines were classified as type 1 (IP-10, MIP-1ß, IL-8, IFN-gamma, TNF-alpha, MIP-1alpha, granzyme B, IL-1ß, IL-15), type 2 (MCP-1, IL-4, sCD137, IL-7, IL-6, IL-10), and growth factors (EGF, GM-CSF, PDGF-BB, VEGF). Distinct cytokine patterns correlated with disease severity and clinical outcome. At admission, within the ALF group, early ALF cases showed the highest expression of both type 1 (TNF-alpha, MIP-1alpha, IFN-gamma) and type 2 cytokines (IL-4, IL-7, sCD137) compared to late ALF and CHBALF. AVHB showed the highest levels of type 1 cytokines, especially IP-10, but the lowest type 2 cytokines. ALI showed an intermediate cytokine pattern between AVHB and early ALF. Notably, the restricted cytokine profile seen in late ALF and CHBALF correlated with the highest rates of mortality (82% and 88%, respectively) with IL-8 uniquely elevated in CHBALF. Over time, type 1 cytokines (IP-10, MIP-1ß, and IFN-gamma) declined in AVHB, whereas no changes were seen in ALF subtypes. Growth factor levels did not differ significantly among groups. **Conclusion:** This study reveals distinct cytokine signatures across the three major forms of HBV-associated ALF, consistent with the hypothesized different pathogenic mechanisms. Notably, a restricted cytokine profile in late ALF and CHBALF was associated with poor prognosis, raising the possibility of a direct cytopathic role of HBV in these cases.

1258 | COMPARATIVE LONG-TERM OFF-TREATMENT OUTCOMES IN HBEAG-NEGATIVE CHRONIC HEPATITIS B: PROPHYLACTIC THERAPY IN CANCER PATIENTS VS. FINITE THERAPY IN NON-CANCER PATIENTS

Hsin-Che Lin[1] Yen-Chun Liu[2] Wei Teng[3] Chao-Wei Hsu[1] Rachel Wen-Juei Jeng[4] Rong-Nan Chien[1,]
[1]Chang Gung Memorial Hospital, Linkou branch, Taoyuan, Taiwan, [2]Chang Gung Memorial Hospital, Linkou main branch, [3]Linkou Chang Gung Memorial Hospital, [4]Chang Gung Memorial Hospital, Linkou Medical Center

Background: Guidelines recommend finite prophylactic nucleos(t)ide analogue (NUC) therapy for cancer patients with chronic hepatitis B (CHB) receiving chemotherapy. However, the long-term outcomes after stopping Nuc therapy, such as clinical relapse or changes in HBsAg kinetics, and their relationship with immunosuppressive agents or cytotoxic drugs, remain unclear. We aim to investigate the off-NUC clinical course focusing on relapse and HBsAg loss between prophylactic (cancer) and non-cancer CHB patients after NUC therapy. **Methods:** Non-cirrhotic, HBeAg-negative CHB patients with cancer who discontinued prophylactic NUC 6 months after the end of chemotherapy (C/T-CHB cohort) were compared to non-cancer HBeAg-negative CHB patients treated with finite Nuc per APASL guidelines (CGMH off-Nuc cohort). Clinical relapse (CR) was defined as HBV DNA $\geq$2000 IU/mL with ALT $>$ 2 times the upper limit of normal (ULN). Hepatic decompensation (HD) was defined as total bilirubin $\geq$2 mg/dL and INR $\geq$1.5, with or without ascites or encephalopathy. Multivariate Cox regression was performed to evaluate the hazard of off-Nuc CR in the C/T-CHB cohort. One to one propensity score matching (PSM) was performed based on age, sex, NUC agent, pretherapy HBV DNA, and ALT and HBsAg at end of treatment (EOT). Kaplan-Meier and log-rank tests were used to compare outcomes. **Results:** Among 126 C/T CHB and 1815 CGMH off-Nuc patients, the C/T-CHB group had fewer males (46% vs. 79%; $P < 0.001$), and lower pretreatment HBV DNA (3.1 vs. 6.2 $\log_{10}$ IU/mL; $P < 0.001$), lower ALT (25 vs. 160 U/L; $P < 0.001$), and shorter treatment duration (42 vs. 156 weeks, $P < 0.001$). Multivariate Cox regression showed a lower risk of CR in the C/T CHB group [adjusted HR: 0.38; 95% CI: 0.22-0.66, $P < 0.001$], after adjusting for age, sex, prior treatment, Nuc agent, pretherapy HBV DNA, treatment duration and EOT HBsAg. In the matched cohort (n = 99 per group, median follow-up: 3.7 years), the 5-year cumulative CR incidence was lower in the C/T-CHB group (29% vs. 71%, $p < 0.01$). Relapse severity was also lower (ALT $\geq$10x ULN: 5% vs. 23%, $P < 0.01$; ALT $\geq$1000 IU/mL: 0 vs. 8%, $p = 0.01$). HD incidence was low in both groups (5-year: 3.3% vs.4.7%, $P = 0.71$). HBsAg loss was four times more frequent in the C/T-CHB group (5 years: 6.7% vs. 1.8%, $p = 0.097$), though not statistically significant. **Conclusion:** HBeAg-negative non-cirrhotic CHB patients with cancer had a lower incidence and severity of clinical relapse after stopping NUC therapy than non-cancer patients. A trend toward higher HBsAg loss in the cancer group warrants further immunological investigation.

1259 | MACHINE LEARNING MODEL INTEGRATING BIOMARKERS FOR PREDICTING HBSAG SEROCLEARANCE IN PEGYLATED INTERFERON-A (PEG IFN-A)-TREATED CHB PATIENTS

Jie Li[1] Sisi Zhou[2] Shengxia Yin[1] Chao Wu[1] Xin Tong[1],
[1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University,China, [2]Nanjing Drum Towel Hospital Clinical College of Nanjing Medical University,China

Background: Hepatitis B virus (HBV), affecting an estimated 292 million chronic carriers globally, remains a significant public health challenge. Standard treatments for chronic HBV, including pegylated interferon-α (PEG IFN-α) and nucleos(t)ide analogues (NUCs), have distinct merits and drawbacks. While PEG IFN-α yields higher HBeAg and HBsAg seroconversion rates, its clinical utility is hampered by inconsistent patient responses. Thus, the aim of this study was to identify significant proteins as pre-treatment predictors for assessing PEG IFN-α efficacy and develop a predictive model based on machine learning for chronic hepatitis B (CHB) patients treated with PEG IFN-α. **Methods:** This retrospective cohort included 49 CHB patients who received PEG IFN-α either as monotherapy or in combination with NUCs. Serum protein expression profiles at baseline were comprehensively analyzed by mass spectrometry, integrated with machine learning algorithms including random forest, gradient-boosted decision trees, extreme gradient boosting, and support

vector machines. A predictive model for HBsAg seroclearance was developed using Lasso feature selection followed by logistic regression modeling. Model performance was evaluated by the Receiver Operating Characteristic (ROC) curve. **Results:** A total of 49 CHB patients treated with PEG IFN-α for 48 weeks were enrolled for analysis, of whom 14 patients achieved HBsAg seroclearance. Forproteomic analysis, age-matched male patients with (n = 12) and without (n = 12) HBsAg seroclearance were selected. These 24 patients were randomly split into training and internal validation sets in a 1:1 ratio. The logistic regression model incorporating three significant proteins, including suprabasin (SBSN), mesoderm development protein (MESD), and EZRI, was established for HBsAg seroclearance prediction. These three proteins indicated that neutrophil-related immune mechanisms are pivotal for HBsAg seroclearance for CHB patients undergoing PEG IFN-α therapy. The model demonstrated achieved an ROC of 0.984 in the training set and 0.964 in the internal validation set, showing good predictive performance. **Conclusion:** This study identifies blood-derived proteomic biomarkers that predict early HBsAg seroclearance in CHB patients before initiating interferon therapy. These findings offer clinically actionable prognostic indicators, potentially enabling personalized interferon-based strategies.

Figure Predictive performance of the logistic regression model based on key proteins for HBsAg seroclearance in CHB patients treated with PEG IFN - α.

Note: CHB, chronic hepatitis B; PEG IFN - α, pegylated interferon-α.

A. Protein expression heatmap

The expression patterns of proteins are shown in 24 age-matched male CHB patients (12 with and 12 without HBsAg seroclearance) after 48-week PEG IFN - α treatment. Different colors represent varying expression levels, with red indicating up - regulation and blue indicating down - regulation.

B. Protein relative importance bar plot

The relative importance of different proteins are displayed. Suprabasin (SBSN), mesoderm development protein (MESD), and EZRI are key proteins with relatively high importance scores.

C. Receiver operating characteristic (ROC) curve

The performance of the logistic regression model was constructed based on SBSN, MESD, and EZRI. The orange and red line represents the ROC of 0.984 and 0.964 in the the training and internal validation sets, respectively.

1260 | CHARACTERISTICS AND HEALTHCARE RESOURCE USE OF PATIENTS RECEIVING CARE FOR CHRONIC HEPATITIS B VIRUS INFECTION IN THE US: A CROSS-SECTIONAL SURVEY

Anna Coutinho[1] Chris Bell[1] Fritha Hennessy[2] Tia Pennant[2] Daniel Graham[2] Fraser Barrable[2], [1]GSK, [2]Adelphi Real World

Background: Limited data exist on patients actively seeking care for chronic hepatitis B virus [cHBV] infection, which impacts an estimated 1.6mn people in the United States [US]. Characteristics and healthcare resource use [HRU] of patients receiving care for cHBV in real-world practices are described. **Methods:** Data were drawn from the Adelphi Hepatitis Disease Specific Programme™, a cross-sectional survey with retrospective data collection of a convenience sample of physicians and their patients with cHBV in the US from Jun 2024 – Feb 2025. Specialists and primary care physicians provided patient characteristics, treatment, diagnostic tests, and HRU for up to 6 adult patients with cHBV infection. Data were analyzed descriptively and stratified by treatment status (naïve vs. treated — nucleos[t]ide analogue [NA] and/or pegylated interferon [Peg-IFN]), payer type, and race/ethnicity. **Results:** Overall, 69 physicians reported on 461 patients with cHBV infection: mean, standard deviation [SD] age: 47.0 (13.5) years; 58% male; 45% White, 28% Black or African American, 20% Asian; 50% Commercial, 27% Medicaid, 10% Medicare. Although physicians judged most patients (86%) to have mild liver disease, a high proportion (70%) received antiviral treatments, of which 94% had NAs and 8% Peg-IFN. cHBV biomarkers were tested in approximately half (HBV viral load, ALT and AST) to a third (hepatitis surface or e-antigen) of the sample, with an average of 2 tests conducted among those tested in the year prior to the survey date (Table). Antiviral-treated patients had a higher proportion tested (35%–60% vs. 21%–47%) and had a higher number of tests (Table). Testing rates were higher for Commercial (32%-56%) and Medicaid (35%-64%) but lower for Medicare patients (20%-51%). Except for HBV viral load, Asian patients had lower testing rates in general vs White or Black patients (Table). Treated patients had a higher mean (SD) number of physician visits than treatment-naïve patients, particularly with hepatologists (2.7 [1.5] vs 1.8 [0.4]) and infectious disease specialists (3.8 [2.4] vs 2.0 [1.3]). Differences were also noted by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

payer type and race/ethnicity in HRU rates (Table). **Conclusion:** Patients with cHBV infection managed in real-world US practices are most likely to be those currently receiving treatment. Less than half are receiving biomarker or liver function tests regardless of treatment status, payer type, or race/ethnicity, highlighting gaps in the current standard of care.

1261 | ASSOCIATION OF HBV VIRAL MARKERS AND HCC RISK IN HBV-RELATED CIRRHOSIS PATIENTS UNDER LONG-TERM ENTECAVIR THERAPY

Tung-Hung Su[1] Hung-Hsuan Pan[1] Tsung-Hui Hu[2] Wan Long Chuang[3] Wei-Wen Su[4] Chun-Che Lin[5] Cheng Yuan Peng[6] Chia-Chi Wang[7] Yao-Chun Hsu[8] Yi-Wen Huang[9] Kuo-Chih Tseng[10] Chih-Lin Lin[11] Sheng-Shun Yang[12] Fat-Moon Suk[13] Shih-Jer Hsu[1] Tsung-Ming Chen[14] Ming-Jong Bair[15] Cheng-Kuan Lin[16] Tai-Chung Tseng[17] Jia-Horng Kao[1], [1]National Taiwan University Hospital, Taipei, Taiwan, [2]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [3]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Changhua Christian Hospital, Changhua, Taiwan, [5]Chung Shan Medical University Hospital, Taichung, Taiwan, [6]China Medical University Hospital, Taichung, Taiwan, [7]Taipei Tzuchi Hospital, the Buddhist Tzuchi Medical Foundation, Taipei Taiwan, [8]E-Da Hospital, Kaohsiung, Taiwan, [9]Cathay General Hospital Medical Center, Taipei, Taiwan, [10]Buddhist Tzu Chi General Hospital, Da-Lin Branch, Chiayi, Taiwan, [11]Ren-Ai Branch, Taipei City Hospital, Taipei, Taiwan, [12]Taichung Veterans General Hospital, Taichung, Taiwan, [13]Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, [14]Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan, [15]Mackay Memorial Hospital, Taitung, Taiwan, [16]Far Eastern Memorial Hospital, Taipei, Taiwan, [17]National Taiwan University Hospital

Background: The risk of hepatocellular carcinoma (HCC) is reduced but not eliminated after nucleos(t)ide analogue (NA) therapy in chronic hepatitis B (CHB) patients. We aimed to investigate the role of HBV RNA, hepatitis B core-related antigen (HBcrAg), and quantitative hepatitis B surface antigen (qHBsAg) in predicting HCC in cirrhotic CHB patients receiving long-term entecavir therapy. **Methods:** This retrospective cohort study included patients with CHB-related cirrhosis who had been under entecavir for a median duration of 6.2 years from medical centers in Taiwan. Serum levels of HBV RNA, HBcrAg, and qHBsAg were quantified by automated assays. Correlation among viral markers was assessed using Pearson correlation coefficients. Multivariable Cox proportional hazards regression models were used to identify predictors for HCC development and sustained detectability of HBV RNA. **Results:** Overall, 451 CHB-related cirrhosis patients were included. The mean age was 60, the median HBV RNA level was 0.7 (log_{10} copies/ml), the median HBcrAg level was 3.2 (log_{10} U/ml), and the median qHBsAg level was 2.4 (log_{10} IU/mL). After a median follow-up of 3.3 years, 55 patients developed HCC. There was a positive correlation between HBV RNA and HBcrAg (r = 0.4515). Among patients with undetectable HBV DNA, 55.3% still had detectable HBV RNA. After adjustment for confounding factors, higher gamma-glutamyl transferase (γ-GT) levels (hazard ratio [HR], 1.01; 95% confidence interval [CI], 1.00–1.01), positive HBeAg (HR, 2.29; 95% CI,1.16-4.54), detectable HBV DNA (HR, 2.41; 95% CI, 1.11–5.21), HBcrAg > 3.23 log_{10} U/ml (HR, 1.75; 95% CI, 1.10–2.77) and shorter ETV treatment duration (HR, 0.88; 95% CI, 0.79–0.97) significantly predicted sustained HBV RNA detectability. In multivariate analysis, age (HR: 1.04, 95%CI: 1.01-1.07), FIB-4 (HR: 1.11, 95%CI: 1.02-1.22) and AFP levels (HR: 1.01, 95% CI: 1.00-1.01) were predictive of the development of HCC, while serum HBV RNA, HBcrAg, and qHBsAg were not. **Conclusion:** Among CHB-related cirrhotic patients receiving 6-year entecavir therapy, higher γ-GT and HBcrAg levels, positive HBeAg, detectable HBV DNA, and shorter duration of ETV treatment were associated with sustained HBV RNA detectability. Older age, higher FIB-4 index, and elevated AFP levels were associated with increased risk of HCC development, while serum levels of HBV RNA, HBcrAg, and qHBsAg were not predictive of HCC.

1262 | EPIGENETIC EDITORS TARGETING CHRONIC HEPATITIS B ACHIEVE HBV SURFACE ANTIGEN LOSS WITH A SINGLE COURSE OF TREATMENT IN MULTIPLE HBV MOUSE MODELS

Glen Acosta[1] Rayman Choo-Wing[1] Arogya Khadka[1] Lenka Hoffman[1] Christina Blinn[1] Christine Waters[1] Jeremy Zeitler[1] Taesun Eom[1] Shefal Parikh[1] Padma Malyala[1] Yesseinia Anglero-Rodriguez[1] Sarah Voytek[1] Jenny Marlowe[1] John Xiong[1], [1]nChroma Bio

Background: Current treatments for chronic hepatitis B rarely achieve functional cure due to persistent viral expression from covalently closed circular DNA (cccDNA) and integrated HBV DNA (intDNA) in infected hepatocytes. nChroma Bio is developing epigenetic editors, a novel therapeutic modality that leverages DNA methylation to silence target genes at the level of transcription without cutting or nicking the DNA, aimed at permanently silencing both cccDNA and intDNA to improve the rate of functional cure for HBV patients. **Methods:** To demonstrate the therapeutic potential of epigenetic editors for HBV, a prototype HBV-targeting editor was tested in two HBV mouse models, a transgenic model (Genotype A) and the AAV-HBV model (Genotype D), with 6-months of follow up. Further optimization of the editor construct, LNP formulation, and mRNA/gRNA ratios resulted in nomination of a development candidate, CRMA-1001, for further testing in the HBV mouse models. **Results:** A single dose of the prototype epigenetic editor targeting HBV demonstrated >2 $\log_{10}$ reduction in hepatitis B surface antigen (HBsAg) and circulating HBV DNA in both Tg- and AAV-HBV mouse models for $>$ 6 months post dose. At the same dose level, CRMA-1001 showed ~10-fold greater HBV antigen suppression than the prototype editor in both models, demonstrating greatly enhanced in vivo potency. In AAV-HBV mice, a single dose of CRMA-1001 produced dose-dependent, durable (at least 6 months), and substantial suppression of HBV biomarkers (up to a 3.5 $\log_{10}$ reduction in HBsAg) without tolerability issues at doses up to 2 mg/kg. Notably, a significant portion of animals receiving ≥ 0.5 mg/kg achieved undetectable HBsAg (10–70% for 0.5 to 2 mg/kg) and HBV DNA (20–90% for 0.5 to 2 mg/kg). A three-dose regimen at 1 mg/kg further improved outcomes, with 90% of mice achieving no detectable HBsAg, HBeAg or HBV DNA. CRMA-1001 was also shown to be compatible with Entecavir, and combination therapy led to deeper, more durable HBV DNA suppression. **Conclusion:** In vivo pharmacology studies in clinically relevant HBV mouse models demonstrate the therapeutic potential of epigenetic editing to effectively and durably silencing viral expression from both episomal and integrated forms of HBV DNA.

1263 | EFFICACY AND SAFETY OF SWITCHING TENOFOVIR DISOPROXIL FUMARATE TO TENOFOVIR ALAFENAMIDE IN CHRONIC HEPATITIS B PATIENTS WITH MULTIDRUG RESISTANCE

Jaehong Jeong[1] Jae Seung Lee[1] Dong Yun Kim[1] Sang Hoon Ahn[1] Jun Yong Park[1], [1]Yonsei University College of Medicine

Background: Tenofovir disoproxil fumarate (TDF) monotherapy effectively suppresses viral replication in patients with multidrug-resistant chronic hepatitis B (CHB). However, TDF use is associated with risks of kidney dysfunction and osteopenia. We conducted this prospective, randomized, open-label study to compare the efficacy and safety of switching from TDF to tenofovir alafenamide (TAF) in these patients. **Methods:** TDF-treated patients with CHB and multidrug resistance (e.g., resistance to more than two non-potent nucleos(t)ide analogs or to entecavir) were enrolled between 2021 and 2023. During the 96-week follow-up, patients in TAF-switch group changed from TDF to TAF at baseline, while those in the TDF-maintained/TAF-switched group continued TDF for 48 weeks before switching to TAF. **Results:** Baseline characteristics—including age, body mass index, HBeAg positivity, estimated glomerular filtration rate (eGFR), and bone mineral density (BMD) of spine and hip—did not significantly differ between the TDF-maintained/TAF-switched group (n = 13) and the TAF-switch (n = 30) group. Virologic responses were maintained in all patients. At 48 weeks, the TAF-switch group exhibited an increasing trend in eGFR, while the TDF-maintained/TAF-switched group showed a decreasing trend, yielding a statistically significant between-group difference (2.17 vs. -2.42 mL/min/1.73m^2, P = 0.045). However, at week 96, the difference was no longer significant due to recovery of eGFR in the TDF-maintained/TAF-switched group (0.34 vs. 2.15 mL/min/1.73m^2, P = 0.927). Spine BMD significantly increased from baseline in the TAF-switch group at week 48 (0.972 vs. 0.936 g/cm^2, P < 0.001), with a statistically significant between-group difference in percentage change (3.97% vs. 1.54%, P = 0.034). Hip BMD showed an increasing trend over 96 weeks in the TAF-switch group, whereas in the TDF-maintained/TAF-switched group, it initially declined but improved after switching to TAF. Between-group differences in hip BMD at weeks 48 and 96 were not statistically significant (P = 0.371 and 0.463, respectively). **Conclusion:** Switching from TDF to TAF in patients with multidrug-resistant CHB maintained virologic suppression and mitigated declines in renal function and bone mineral density.

1264 | FUNCTIONAL ANALYSIS OF FUMARYLACETOACETATE HYDROLASE IN MEDIATING ANTI-HBV AND ANTI-TUMOR EFFECTS

Shouichi Namikawa[1] Takuto Nosaka[1] Yosuke Murata[1] Yu Akazawa[1] Tomoko Tanaka[1] Kazuto Takahashi[1] Tatsushi Naito[1] Masahiro Ohtani[1] Yasunari Nakamoto[1], [1]University of Fukui

Background: Chronic hepatitis B (CHB), caused by the hepatitis B virus (HBV), is a leading cause of hepatocellular carcinoma (HCC) worldwide. We established a hepatitis B virus (HBV) infection assay system using primary human hepatocytes and extracted fumarylacetoacetate hydrolase (FAH) as a host factor gene that regulates viral life cycle by RNA microarray analysis (PLoS ONE 2025). In this study, we functionally investigated the anti-HBV and anti-tumor effects of FAH using resected hepatocellular carcinoma (HCC) tissues and HBV-stably transfected HCC cell lines. **Methods:** In 111 resected HCC specimens, immunohistological staining intensities of FAH and ki67 in tumor and non-tumor areas were determined by H-score using inform (akoya), and the correlation between FAH and ki67 was investigated. FAH index was calculated by H-score of tumor/non-tumor areas, and analyzed for correlation with recurrence and prognosis. In vitro, the 1.3 mer HBV genomes of genotype C2 with basic core promoter and/or pre-core mutations (wt/wt; Low transcription, mu/mu; High t.) were stably transfected into HepG2 cells, HepG2.1-E10 (Low t.) and HepG2.D11 (High t.) were established. FAH vector and siRNA were transfected, and HBsAg, HBV-DNA, HBV-RNA measurements, proliferation assay, apoptosis assay, and sphere formation assay were performed. RNA expression was analyzed for 205 anti-tumor and anti-viral related genes using TaqMan custom array plates.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Results: The H-score of FAH in resected HCC specimens was significantly lower in tumor areas than in non-tumor areas (ΔH-score = -10.99, $p < 0.05$). The expression intensities of FAH and ki67 were inversely correlated ($p < 0.05$). Recurrence and survival rates were better in the patient group with higher FAH index ($p < 0.05$). In HepG2.D11 and HepG2.1-E10, HBsAg was increased with FAH knockdown and decreased with FAH overexpression compared to controls. Furthermore, FAH knockdown decreased cell proliferative activity, apoptosis, and increased spheres, while FAH overexpression inhibited cell proliferation, induced apoptosis, and decreased spheres. FAH overexpression increased the expression of CDKN2B, CHECK1, and CCND1 (cell cycle regulation), increased the expression of SMAD3, FAS, and BAX (apoptosis induction), and decreased the expression of NANOG and SALL4 (stem cell function). **Conclusion:** Evaluation of FAH and ki67 expression in HCC tissues and functional analysis in HBV-stably transfected HepG2 cells suggested that the FAH gene may contribute to HBV reduction, cell proliferation inhibition, apoptosis induction and stem cell function inhibition. The hepatocyte host factor FAH may be a candidate for a new therapeutic strategy for viral carcinogenesis that exhibits both anti-tumor and anti-HBV effects.

1265 | CHRONIC KIDNEY DISEASE PROGRESSION IN PATIENTS WITH CHRONIC HEPATITIS B ON TENOFOVIR ALAFENAMIDE VERSUS ENTECAVIR

Lilian Yan Liang[1] Terry Cheuk-Fung Yip[1] Jimmy Che-To Lai[1] Vincent Wong[1] Grace Lai-Hung Wong[1], [1]the Chinese University of Hong Kong

Background: Tenofovir alafenamide (TAF) is a prodrug of tenofovir. Tenofovir has been associated with a slightly increased risk of renal impairment. We aimed to evaluate the progression of chronic kidney disease (CKD) over 12 months in patients with chronic hepatitis B (CHB) receiving TAF and entecavir (ETV). **Methods:** This is a retrospective cohort study in Hong Kong. CHB patients who were initially treated with TAF or ETV were included. The baseline was defined as the start date of treatment. CKD progression was defined as an increase in CKD stage of at least one stage for at least three consecutive months. **Results:** After propensity score matching, 305 TAF-treated and 1460 ETV-treated CHB patients were included in the analysis. Their baseline estimated glomerular filtration rate were 84.4 $\pm$ 21.5 and 85.2 $\pm$ 21.6 mL/min/1.73 m2, respectively. During the 12-month follow-up duration, 28 TAF-treated and 116 ETV-treated patients developed CKD progression. The corresponding 12-month cumulative incidence (95% confidence interval) of CKD progression were 9.2% (5.9% - 12.4%) in TAF-treated and 8.0% (6.6% - 9.3%) in ETV-treated patients ($p = 0.492$). In the Kaplan-Meier curve, the cumulative incidence of CKD progression in TAF-treated patients was comparable with that of ETV-treated patients ($p = 0.49$). **Conclusion:** CHB patients treated with TAF had a comparable risk of renal impairment to that of ETV-treated patients.

1266 | SINGLE-ARM META-ANALYSIS AND SYSTEMATIC REVIEW ON CLINICAL CURE OF CHRONIC HEPATITIS B AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: IMMUNOREGULATORY MECHANISMS AND CLINICAL TRANSLATIONAL INSIGHTS

He Ma[1] Bo Feng[1], [1]Peking University People's Hospital

Background: The quest for a functional cure for chronic hepatitis B (CHB) remains an elusive objective. Hematopoietic stem cell transplantation (HSCT) may elicit viral clearance by immunological remodelling in recipients with positive-HBsAg; however, the factors that determine its effectiveness are yet unknown. **Methods:** Nine trials (308 patients) were subjected to single-arm meta-analysis (R4.2.2 "meta" package) in accordance with PRISMA/Cochrane criteria. Heterogeneity was addressed via random-effects models (I2 = 87.1%). Subgroup analysis accounted for donor HBsAb/recipient HBeAg impacts. **Results:** The total HBsAg clearance rate was 26% (95% CI:14% to 39%), greater than that of standard therapies. Notably, HBsAb-positive donors had significantly enhanced clearance (55% vs. 8%, p < 0.01). HBeAg-negative recipients fared better (29% vs. 2%). In patients who achieved HBsAg loss, HBsAb-positive donors and HBeAg-negative recipients are the most prevalent types (10/11). Sensitivity analysis confirmed robustness; publication bias was nonsignificant (Egger' s p = 0.271). **Conclusion:** Depending on the recipient' s HBeAg and the donor' s HBsAb status, HSCT shows promise as a treatment for CHB. HBsAb-positive donors and HBeAg-negative recipients should be given priority in order to maximize results, which may also provide new immunological therapeutic strategy for functional cure of CHB.

1267 | COMPARATIVE RENAL SAFETY OF TENOFOVIR ALAFENAMIDE VS TENOFOVIR DISOPROXIL FUMARATE IN CHRONIC HEPATITIS B: A KOREAN NATIONWIDE STUDY

JIHYE LIM[1] Ji won Yang[2] Ye-Jee Kim[3] Hwa Jung Kim[3] Jonggi Choi[4], [1]Yeouido St. Mary's Hospital, [2]Department of Gastroenterology, Liver Centre, Asan Medical Centre, University of Ulsan College of Me, [3]Department of Clinical Epidemiology and Biostatistics, Asan Medical Centre, University of Ulsan Coll, [4]University of Ulsan, Asan Medical Center

Background: The long-term renal safety of tenofovir-based therapy in patients with chronic hepatitis B virus (HBV) infection remains uncertain, particularly regarding end-stage kidney disease requiring renal replacement therapy (RRT). We investigated the comparative risk of renal dysfunction between tenofovir alafenamide (TAF) and tenofovir disoproxil fumarate (TDF). **Methods:** We identified treatment-naïve adult patients with chronic HBV infection who initiated TAF or TDF between 2017 and 2020 from the Korean National Health Insurance Service. After 1:1 propensity score (PS) matching, we compared the incidence of RRT and chronic kidney disease (CKD) between the two groups. **Results:** Among 46,663 eligible patients (TAF: n = 16,885; TDF: n = 29,778), the median follow-up duration was 2.61 years (interquartile range, 1.52–3.75). During this period, 25 patients in the TAF group underwent RRT, with an incidence rate of 0.56 per 1,000 person-years (PYs), compared to 108 patients in the TDF group, with an incidence of 0.96 per 1,000 PYs. Although the cumulative risk of RRT was lower in the TAF group, the difference was not statistically significant (crude hazard ratio [HR], 0.74; 95% confidence interval [CI], 0.47–1.16; Figure 1a). In the propensity score–matched cohort (n = 31,218), the adjusted HR for RRT in the TAF group compared to the TDF group was 0.67 (95% CI, 0.40–1.10; Figure 1b). Male sex, older age, hypertension, cirrhosis, and current smoking were associated with an increased risk of RRT. Regarding CKD, the TAF group showed a higher crude incidence (HR, 1.26; 95% CI, 1.01–1.57), which was attenuated after adjustment (HR, 1.20; 95% CI, 0.93–1.56). **Conclusion:** In conclusion, our study suggests that the type of tenofovir used did not significantly affect the risk of RRT or CKD, while the overall incidence of RRT in patients with tenofovir remained higher than that of the general population. Male patients, older patients, and those with hypertension or cirrhosis are at elevated risk of renal complications, requiring careful renal function monitoring to improve long-term outcomes.

1268 | QUANTIFICATION AND EVALUATION OF INTRAHEPATIC HBV DNA AND CCCDNA IN HBV ASSOCIATED HEPATOCELLULAR CARCINOMA

Jin Li[1] Yuanlang Ji[2], [1]The Affiliated Infectious Diseases Hospital of Soochow Unive, [2]Suzhou Medical College, Soochow University

Background: In 2022, hepatitis B resulted in an estimated 1.1 million deaths, mostly from cirrhosis and hepatocellular carcinoma (HCC). Almost 50% of all cases of HCC are associated with chronic infection with HBV. HBV cccDNA binds to histones to form the viral mini-chromosome and serves as the template for the transcription of all HBV mRNAs, which is a key factor in viral persistence infection. Several studies have investigated the HBV cccDNA level in HCC and matched non-cancerous tissues but the results are still inconclusive. Given that HBV virological factors have been linked to HCC development, the expression levels and clinical significance of HBV DNA and cccDNA in liver tissues require further investigation. **Methods:** This study collected 40 HBV-HCC patients, including serum samples, liver carcinoma tissues and matched peritumoral tissues. Quantitative PCR was used to measure HBV DNA and cccDNA levels in liver carcinoma tissues and matched peritumoral tissues, and their correlations with tumor markers and disease progression were assessed. According to TNM staging, 16 HBV-HCC patients were assigned into TNM 0 group and 24 HBV-HCC patients were assigned into TNM 2-4 group. Additionally, 31 HBV-HCC patients without lymphovascular invasion (LVI) belonged to LVI 0 group, and 9 patients with LVI enrolled into LVI 1 group. **Results:** Significant correlations were observed between HBV DNA levels in carcinoma tissues (HBV DNA-ca) and cccDNA-ca ($r = 0.38$, $p = 0.0155$), HBV DNA in peritumoral tissues (HBV DNA-pa) ($r = 0.57$, $p = 1.32E-04$) and cccDNA-pa ($r = 0.34$, $p = 0.0311$). The cccDNA-ca levels demonstrated positive associations with HBV DNA-pa ($r = 0.55$, $p = 2.70E-04$) and cccDNA-pa ($r = 0.51$, $p = 8.83E-04$), while cccDNA-pa was significantly correlated with HBV DNA-pa ($r = 0.60$, $p = 3.85E-05$). Notably, all viral markers (HBV DNA-ca, cccDNA-ca, HBV DNA-pa, cccDNA-pa) exhibited strong positive correlations with TNM staging ($r > 0.4$, $p < 0.01$). Furthermore, cccDNA-ca, HBV DNA-ca, and cccDNA-pa showed significant associations with LVI and alpha-fetoprotein (AFP) levels ($r > 0.35$, $p < 0.05$) (Figure 1). Comparative analysis revealed higher HBV DNA-ca, cccDNA-ca, HBV DNA-pa, and cccDNA-pa levels in TNM stages II–IV group compared to TNM stage 0 group (Figure 2). Similarly, cccDNA-ca, HBV DNA-pa, and cccDNA-pa levels were elevated in LVI-positive (LVI 1) than in LVI-negative (LVI 0) group (Figure 3). **Conclusion:** This study highlights significant correlations between HBV DNA and cccDNA levels in liver carcinoma tissues and matched peritumoral tissues of HBV-HCC patients. These levels were closely associated with TNM staging and tumor progression. Monitoring HBV DNA and cccDNA in liver tissues may provide valuable insights for evaluating disease progression and prognosis of HBV-HCC patients.

1269 | AN EGCG-LOADED FERRITIN NANODRUG INDUCING HBSAG CLEARANCE FOR HBV THERAPY

Yixin Dong[1] Xizhi Yin[1] Xiangru Shan[2] Chuanlong Zhu[1], [1]The First Affiliated Hospital of Nanjing Medical University, [2]China Pharmaceutical University

Background: Hepatitis B virus (HBV) infection remains a serious threat to global health. Current antiviral therapies are often associated with systemic side effects or drug resistance, highlighting the need for developing more effective HBV treatment strategies. As the most abundant viral antigen in the bloodstream, hepatitis B surface antigen (HBsAg) serves as a key therapeutic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

target. The elimination of HBsAg might substantially enhance HBV treatment efficacy. In this study, we designed a novel ferritin-based nanodrug to induce HBsAg clearance through ferritinophagy, and evaluated its antiviral activity. **Methods:** HBsAg-affinity peptides were modified on the outer surface of the human H chain ferritin nanocage, named HA, to enable its ability to bind HBsAg in the cytoplasm. And encapsulated EGCG molecules within the ferritin cage (HE) to enhance complete autophagy. The interaction of HA and HBsAg was verified by surface plasma resonance (SPR) analysis. And the effects of HE on HBsAg were characterized by Western blot (WB). We then evaluated the antiviral efficacy of these ferritin-based nanodrugs by determining levels of HBsAg, HBeAg, and HBV DNA. **Results:** Structural characterization confirmed the successful preparation of functionalized ferritin nanocages (HA), which maintained the characteristic 12-nm spherical morphology as verified by DLS and TEM. SPR analysis demonstrated special binding between HA and HBsAg, with an equilibrium association constant (KD) of 37.8 nM. WB analysis indicated significant LC3-II accumulation (1.6-fold increase) and NCOA4 down-regulation (26% reduction) after treatment with HA, indicating that HBsAg clearance was relied on the ferritinophagy of HA, and this process could be effectively promoted by EGCG. Importantly, the EGCG-loaded nanodrug (HE) exhibited strongest antiviral efficacy compared to individual HA or EGCG treatments, reducing extracellular HBeAg levels by 20%, HBsAg levels by 40%, and HBV DNA by 37% in HepAD38 cell lines. **Conclusion:** The results demonstrate the great potential of our ferritin-based nanodrug as a novel HBV treatment agent. This nanodrug was confirmed to directly bind HBsAg and effectively induce HBsAg clearance through the ferritin-mediated ferritinophagy process under the promotion of EGCG, suggesting a promising new therapeutic strategy for HBV infection.

1270 | OPTIMIZING HBV COMBINATION THERAPY: DUAL TARGETING OF INTRACELLULAR REPLICATION AND EXTRACELLULAR VIRIONS WITH ENTECAVIR AND HBVZ10

Yong-Yuan Zhang[1] Bai-Hua Zhang[1] YUANPING ZHOU[2] Steve Horrigan[3] Jianming Hu[4] Fabien Zoulim[5], [1]HBVtech, Rockville, MD, [2]Nafang Hospital, Southern Medical University, Guangzhou, China, [3]Noble Life Sciences Inc, Sykesville, MD, [4]Department of Microbiology and Immunology, Penn State College of Medicine, Hershey, PA, [5]UMR PaThLiv U1350, INSERM, Université Claude Bernard Lyon 1, Lyon, France

Background: Current combination therapies for chronic hepatitis B (CHB) focus on intracellular inhibitors, such as NAs, RNAi, or capsid modulators, but these regimens, like NA monotherapy, fail to fully suppress HBV replication. Consequently, low levels of virions are continuously released, initiating new rounds of infection and replenishing cccDNA pool. However, these virions can be neutralized by extracellular blockers like anti-HBs Ab. Durable blockade of virion spread requires sustained high levels of anti-HBs Ab. In CHB, a lack of detectable anti-HBs Ab stems from the immune system's limited capacity to produce enough Ab to match the large circulating HBsAg pool. To overcome this, we developed HBVZ10, a novel HBV therapy candidate that employs an optimized AAV8 vector to deliver human anti-HBs Ab genes to muscle cells, enabling sustained and high-level Ab production beyond B cells. This study evaluated whether pairing entecavir (ETV) with HBVZ10 enhances HBsAg seroclearance. **Methods:** HBV infected chimeric mice received either ETV monotherapy (18 weeks, starting day 42 pi, baseline viremia ~7.5 log) or combination therapy with a single HBVZ10 dose (2.5×10^{10} genome copies) plus ETV. Mice were monitored for 9 more weeks after stopping ETV. Endpoints included kinetic serum HBsAg levels and average hepatic rcDNA and cccDNA levels at termination (day 231 pi), assessed by sampling each liver 20 times. **Results:** A single 2.5×10^{10} dose of HBVZ10 achieved anti-HBs Ab titers $\geq$100,000 mIU/mL, sustained for at least 200 days. Eight of 9 mice in the combination group achieved progressive HBsAg clearance to undetectable levels, compared to only 1 of 10 in the monotherapy group ($p = 0.033$). HBV relapse occurred after ETV withdrawal in the ETV only group but was largely prevented in the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

combination group, resulting in approximately 10-fold and 100-fold reductions in hepatic rcDNA and cccDNA levels, respectively. **Conclusion:** Sustained high-level anti-HBs Ab expression from HBVZ10 complements ETV by durably blocking new rounds of infection including HBV relapse with released virions. Meanwhile, ETV inhibits virion production, thus enhancing the efficiency of HBVZ10-mediated neutralization. This synergistic mechanism improves efficiency for both cccDNA elimination and HBsAg seroclearance. Thus, combining an intracellular replication inhibitor (ETV) with a durable extracellular virion blocker (HBVZ10) may offer a superior regimen compared to all intracellular inhibitors-based combinations.

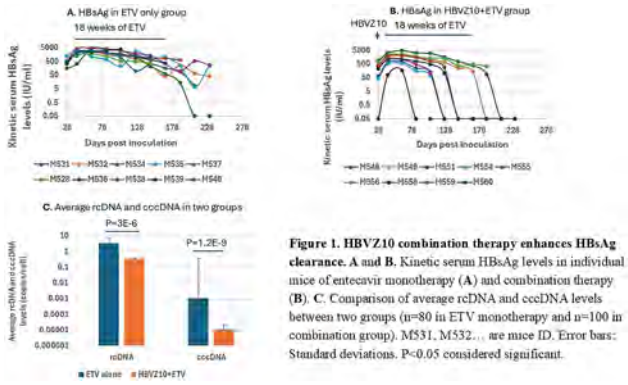

Figure 1. HBVZ10 combination therapy enhances HBsAg clearance. A and B. Kinetic serum HBsAg levels in individual mice of entecavir monotherapy (**A**) and combination therapy (**B**). **C.** Comparison of average rcDNA and cccDNA levels between two groups (n=80 in ETV monotherapy and n=100 in combination group). 1271 | INVESTIGATING HBSAG-SPECIFIC MEMORY T CELL RESPONSES IN VACCINE-INDUCED LONG-TERM IMMUNE PROTECTION AGAINST HBV

Margaux Bossis[1] Diane Biron[2] Phuong-Ha Le[2] Nour Nasser[3] Fanny Onodi[4] Emilie Artru[4] Abdellah Mansouri[5] Georg Lauer[6] Tarik Asselah[7] Pierre Tonnerre[4], [1]Institut de Recherche Saint-Louis, Université Paris Cité, Inserm U1342, Paris, France, [2]Institut de Recherche Saint-Louis, Université Paris-Cité, Inserm U1342, Paris, France., [3]Université Paris Cité, Centre de Recherche sur l'Inflammation, Inserm U1149, CNRS ERL8252, Paris, Fr, [4]Institut de Recherche Saint-Louis, Université Paris-Cité, Inserm U1342, Paris, France, [5]INSERM U1149, [6]Division of Gastroenterology, Massachusetts General Hospital, Boston, Massachusetts, USA, [7]Hôpital Beaujon

Background: Hepatitis B virus (HBV) remains a significant global health burden, despite the availability of a highly effective prophylactic vaccine. The mechanisms underlying vaccine-induced long-term immune protection, particularly the role of memory T cells, remain incompletely understood. Here, we investigate the presence and phenotype of HBsAg-specific memory T cells in individuals with a history of HBV vaccination to elucidate their contribution to durable immunity. **Methods:** We analyzed peripheral blood samples from twenty HLA-A*02-positive healthy donors with history of HBV vaccination. Spectral flow cytometry combined with unsupervised bioinformatics analysis was used to characterize HBsAg-specific $CD8^+$ T cells. These were identified using HLA-A*02:01-restricted MHC class I multimers targeting immunodominant HBsAg peptides, as well as through Intracellular Cytokine Staining (ICS) and Activation-Induced Marker (AIM) assays following stimulation with HBsAg peptide pools. Influenza A virus (IAV)-specific multimers and peptide pools served as comparative controls. **Results:** HBsAg-specific $CD8^+$ T cells were detected in 11 out of 20 donors (55%), indicating that a substantial proportion of vaccinated individuals retain detectable antigen-specific memory T cells long after immunization. Phenotypic analysis revealed that, in contrast to influenza-specific memory $CD8^+$ T cells —which exhibited a mixed effector-memory and EMRA profile ($CCR7^-CD45RA^{+/-}$)— HBsAg-specific T cells predominantly displayed a "naïve-like" memory phenotype ($CD45RA^+CCR7^+CD62L^+KLRG1^-$). This phenotype is characteristic of long-lived memory T cells capable of maintaining homeostatic quiescence while preserving the ability to mount robust responses. Functional assays confirmed that upon antigen re-exposure, these cells could expand and secrete pro-inflammatory cytokines, including TNF-α and IFN-γ, supporting their role in effective recall responses. **Conclusion:** Our findings demonstrate that HBsAg-specific $CD8^+$ T cells with a distinct naïve-like memory phenotype persist long-term following HBV vaccination. These cells retain proliferative and functional capacity, suggesting a role in durable vaccine-induced immunity, identifying a potential correlate of long-term protection and providing insight to guide future HBV-targeted immunotherapies.

1272 | STUDY ON THE ROLE OF NK CELLS IN INTERMITTENT INTERFERON THERAPY

Minghui Li[1] Yao Xie[1] Xiaoyue Bi[2] Weihua Cao[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]Beijing Ditan Hospital, Capital Medical University; Beijing Huairou Hospital

Background: To investigate changes in the phenotype and frequency of natural killer (NK) cells during intermittent interferon (IFN) therapy in patients with chronic hepatitis B (CHB) and explore their relationship with clinical outcomes. **Methods:** CHB patients were categorized into three groups based on antiviral treatment status: a treatment-naïve group, an IFN-treated plateau group, and an oral nucleos(t)ide analog antiviral therapy group. The treatment-naïve group received IFN therapy. Patients in the plateau group (experiencing stalled HBsAg decline during IFNα therapy) discontinued IFNα and resumed it after a 12–24-week IFN-free interval. The oral therapy group continued their original regimen. Viral and serological data were collected from the treatment-naïve group at baseline, 4 weeks, and 12–24 weeks of IFN therapy. For the plateau group, data were collected at IFN discontinuation, after the 12–24-week interval, and after 12–24 weeks of IFN retreatment. Peripheral blood mononuclear cells (PBMCs) were isolated at follow-up timepoints, and NK cell phenotypes/frequencies were analyzed via multicolor flow cytometry. **Results:** A total of 207 CHB patients were enrolled: 68 in the treatment-naïve group, 50 in the HBsAg plateau group, and 89 in the oral therapy group. At baseline, the plateau group exhibited significantly lower CD56dim and higher CD56bright NK cell frequencies compared to the treatment-naïve group (all $P < 0.001$), with both subsets showing functional suppression. During IFN therapy, the treatment-naïve group showed declining HBsAg levels. CD56dim frequencies decreased significantly at 4 and 12–24 weeks ($P = 0.024$ and $P < 0.001$, respectively), alongside reduced activating receptors NKG2D (at 4 weeks, $P = 0.021$) and NKG2C (at 12–24 weeks, $P < 0.001$), and increased inhibitory receptor NKG2A ($P < 0.001$). CD56bright frequencies rose, with elevated NKG2A and NKG2D ($P < 0.01$). In the plateau group, CD56bright frequencies decreased during the 12–24-week IFN-free interval ($P = 0.008$) but increased after IFN retreatment ($P = 0.001$). The activating marker CD69 rose during the interval ($P = 0.018$) and declined post-retreatment ($P = 0.006$). CD56dim frequencies showed nonsignificant fluctuations, but inhibitory NKG2A increased significantly post-retreatment ($P = 0.001$). **Conclusion:** IFN therapy reduces the cytotoxic CD56dim subset and enhances the cytokine-secreting CD56bright subset, with activity modulated by multiple factors. The plateau phase may be associated with this shift, reflecting NK cells' dual role in immune regulation and inflammatory control.

Francisco, [8]Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, [9]Los Angeles General Medical Center, Los Angeles, CA

Background: Hispanic individuals with chronic hepatitis B (HBV) in the United States (US) represent an understudied population with respect to hepatocellular carcinoma (HCC) risk. To address this paucity of data, we established a multi-center national cohort to characterize US Hispanics living with chronic HBV and estimate the incidence of HCC. **Methods:** We conducted a retrospective cohort study of Hispanic adults with chronic HBV from eight US sites, identified by positive hepatitis B surface antigen (HBsAg) and EMR-reported Hispanic ethnicity. Clinical, demographic, and laboratory data were abstracted from EMR. Cohort entry was date of HBsAg testing. We used Kaplan-Meier analysis to evaluate our primary outcome, i.e., the cumulative incidence (CI) of HCC, per AASLD criteria, overall and stratified by cirrhosis status and PAGE-B score; we excluded those diagnosed with HCC within 3 months of positive HBsAg as prevalent HCC in incidence analysis. **Results:** 784 patients were included, including 55% foreign-born (30% Mexico, 18% Central America, and 4% South America), 12% US-born and 33% unknown. Median age was 50 years (IQR 39–59); 62% were male, and among those with known status, 76% were HBeAg-negative, 57% inactive carriers, with median HBV DNA of 357 IU/mL (IQR 0-17,686). 46% received antiviral therapy and 22% had cirrhosis. Co-morbid conditions included 26% with MASLD, 12% AUD, 11% HCV, and 26% HIV. Over median follow-up of 4.7 years (IQR 1.6-9.1), 32 patients developed HCC, 15 of which prevalent. HCC cases were older (56 vs 49 years), more male (81% vs 62%), and cirrhotic (93% vs 19%), with higher median liver enzymes and lower platelets and albumin (all $p < 0.05$). 4%, 21%, and 75% of cases were in the low-, medium-, and high-risk PAGE-B groups, respectively. The 1-, 5-, and 10-year CI of HCC was 0.5%, 1.8%, and 4.4%, respectively, increasing to 2.2%, 7.5%, and 16.8% among those with cirrhosis. The overall incidence rate of HCC was 4.3 per 1000 person-years (2.8-6.5). CI differed by PAGE-B score, with a 1-, 5-, 10-year CI for those with high-risk PAGE B score of 1.1%, 4.8%, and 7.9% (See Figure). **Conclusion:** In this multi-center cohort of US Hispanics with chronic HBV, incidence of HCC was low overall, but significantly higher in those with cirrhosis or high-risk PAGE-B group. Nearly half of HCCs were prevalent, suggesting delayed HBV screening or possibly referral bias. These findings are critical to informing HCC surveillance strategies for this group.

1274 | INDUCTION OF STRONG ANTI-HBV IMMUNE RESPONSES IN IMMUNOSUPPRESSED MICE BY NASAL ADMINISTRATION OF HBS/HBC CONTAINING ANTIGEN

Toyoki Shimamoto[1] Osamu Yoshida[1] Ryo Yano[1] Yuki Okazaki[1] Atsushi Yukimoto[1] Yoshiko Nakamura[1] Takao Watanabe[1] Masashi Hirooka[1] Yoshio Tokumoto[1] Masanori Abe[1] Yoichi Hiasa[1], [1]Ehime University

Background: Liver transplanted patients due to HBV related diseases require a lifelong nucleos(t)ide analogue medication and HBIG administration to prevent HBV recurrence. We have developed a nasal administrative vaccine containing HBs/HBc antigen, named CVP-NASVAC. CVP-NASVAC demonstrated stronger immunogenicities compared with conventional HB vaccine, because CVP-NASVAC induced anti-HBs and HBcAg specific CTL in HBV carriers who are regarded as immune-tolerogenic status against HBV. In this study, we hypothesized that CVP-NASVAC might induce anti-HBV immune responses in immune-suppressed condition and protect liver transplanted patients from HBV recurrence. **Methods:** Immunosuppressed mice (IS) and immunocompetent mice (IC) were developed by injecting either tacrolimus (2mg/kg/day) or PBS (PBS) intraperitoneally into 8-10 week old C57BL6 male mice 1 week before start vaccination (-1 week). CVP-NASVAC (HBsAg 1mg, HBcAg 1mg, intranasally) or conventional HB vaccine (conv HB, HBsAg 1mg, subcutaneously) were administrated into IS or IC for total 3 times (0, 2, 4 week). 4th dose of CVP-NASVAC was added at 9 week in IS with CVP-NASVAC group. Then mice were sacrificed at 10 weeks for evaluating anti-HBV immune responses such as, IgG-type-anti-HBs (CLEIA), IgG-type-anti-HBc (ELISA), HBcAg specific CTL (ELISPOT). **Results:** CVP-NASVAC induced similar levels of IgG-type-anti-HBs in IC compared with conv HB vac. Although there was no significant difference in IgG-type-anti-HBs titers between CVP-NASVAC and conv HB after 3 doses in IS, 4th dose of CVP-NASVAC in IS significantly raised IgG-type-anti-HBs titers and positivity. CVP-NASVAC, but not conv HB, induced IgG-type-anti-HBc and IFN-γ producing HBcAg specific CTL in both IC and IS. **Conclusion:** CVP-NASVAC induced anti-HBV immune responses in immunosuppressed condition and could be a treatment option for preventing HBV recurrence after liver transplantation due to HBV related diseases.

1275 | IDENTIFICATION OF SERUM MIRNAS CHARACTERISTIC OF CASES OF CHRONIC HEPATITIS B THAT ACHIEVE FUNCTIONAL CURE

Yoshiki Murakami[1] Takashi Honda[2] Yuichirou Harada[3] Shinya Yokoyama[2] Kenta Yamamoto[2] Takanori Ito[4] Norihiro Imai[2] yoji ishizu[2] Masahiko Kuroda[3] Hiroki Kawashima[2], [1]Tokyo Medical Univesity/Asahi University, [2]Nagoya University Graduate School of Medicine, [3]Tokyo Medical University, [4]Nagoya University

Background: The current treatment goal for chronic hepatitis B (CH) is functional cure (FC) through the disappearance of HBsAg. We analyzed the expression patterns of serum miRNAs in CH and FC and attempted to develop a method to predict cases that will improve from CH to FC. **Methods:** Analysis 1: Total RNA was extracted from serum of 11 FC cases, 13 CH cases, and 3 CH cases with HBV DNA less than 3 log/IU among CH cases (hereafter CHL), and miRNA expression analysis was performed by small RNA-sequencing. Support vector machines (SVM) were used to determine a function that would enable classification between CH, and FC. Analysis 2: Six cases of CH undergoing follow-up were analyzed. Three cases improved from CH to FC, and three cases remained in CH. miRNA expression analysis and amino acid analysis of the core region were performed. **Results:** Analysis 1: Expression level of 17 miRNAs with False Discovery Rate (FDR) < 0.05 in the comparison among FC, CHL, and CH, was identified. Three miRNAs with FDR < 0.05 were also identified in the comparison between the FC and CH groups. Correlated with the amount of HBV DNA, the expression of three miRNAs, miR-455-5p, 192-5p, and 125b-5p, was increased, while the expression of miR-125a-5p was decreased. Three miRNAs (miR-455-5p, 192-5p, and 125b-5p) whose expression showed a positive correlation with HBV DNA quantity were obtained, while miR-125a-5p showed a negative correlation. Two decision trees for miR-99a-5p and miR-342-3p were able to efficiently distinguish between FC and CH based on SVM. Analysis 2: As CH improved to FC, the expression of miR-454-3p and 590-3p increased in all three cases, and the expression of four miRNAs (miR-574-5p, 361-3p, 483-5p, 194-5p) decreased. Expression of miR-485-3p was decreased in cases that improved from CH to FC, and expression increased in cases that remained CH. In all cases of FC improvement, the 97th amino acid sequence in the core region was initially wild type, but mutated from I to L upon improvement to FC. **Conclusion:** Patients with chronic HBV infection showed specific miRNA expression patterns according to disease type (CH, CHL, FC), and disease differentiation was possible using SVM based on miRNA

expression patterns. It was shown that miRNAs that show different expression patterns according to the clinical course can be used to predict clinical course (FC improvement prediction).

1276 | BASELINE RATES OF PERINATAL HEPATITIS B SCREENING AND VACCINATION IN PHILADELPHIA OBSTETRIC CLINICS PRIOR TO THE UNIVERSAL TRIPLE SCREENING ERA

M. Elle Saine[1] Julia Szymczak[2] William Short[1] Celeste Durnwald[1] Robert Gross[1] Vincent Lo Re III[1] Jessie Torgersen[3], [1]Hospital of the University of Pennsylvania, [2]University of Utah School of Medicine, [3]University of Pennsylvania Perelman School of Medicine

Background: Prenatal care is a key opportunity to screen patients for hepatitis B virus (HBV), link them to care or vaccination, and prevent perinatal transmission. In 2023, the US Centers for Disease Control and Prevention recommended all adults receive a one-time HBV triple panel screening to identify those in need of vaccination. Baseline metrics of HBV screening and vaccination are needed among pregnant patients to understand how to optimize implementation of these interventions. **Methods:** We conducted a retrospective cohort study using electronic health records among all pregnant patients with a first prenatal visit at two outpatient obstetrics clinics in Philadelphia between January 2018 and December 2022, with 12 months of follow-up post-delivery. Only the first eligible pregnancy during this period was included. Outcomes were: 1) completion of HBV surface antigen (HBsAg) screening during pregnancy, 2) completion of one-time HBV triple panel screening (HBsAg, core antibody [anti-HBc], surface antibody [anti-HBs]), and 3) receipt of ≥1 dose of HBV vaccine (among patients without laboratory evidence of HBV immunity) within the follow-up period. Univariate logistic regression analyses evaluated factors associated with HBV vaccination. **Results:** Among 11,853 pregnant patients, 9,782 (82.5%) completed HBsAg screening during pregnancy; 6,227 (63.6%) during the first trimester. Overall, only 82 (0.69%) patients underwent triple screen prior to delivery; 30 (36.6%) were nonimmune. Additionally, 663 patients had a history of anti-HBs testing prior to delivery, of whom, 245 (36.9%) had a negative (229 [34.5%]) or indeterminant (16 [2.4%]) test. Among 11,802 patients without laboratory evidence of immunity, 51 (0.4%) received ≥1 dose of HBV vaccine during pregnancy or post-partum follow-up, and 13 (25.5%) completed the HBV vaccine series within the follow-up period. Receipt of HBV vaccination did not differ by age, race, clinic, provider type, or Medicaid status (Table 1). **Conclusion:** Prior to universal HBV screening recommendations, fewer than 1% of pregnant patients had documented HBV triple panel screening before delivery. HBsAg screening rates in the two outpatient practices were high, suggesting feasibility of triple panel implementation within existing clinical workflows. Among patients without demonstrated HBV immunity, vaccination rates were very low. Future research is needed to evaluate uptake of universal HBV triple panel screening and optimize vaccination during pregnancy and post-partum care.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Patients with cHBV infection may experience ALT flares spontaneously, or due to treatment initiation or discontinuation, likely caused by stimulation of the immune system against infected hepatocytes. We assessed 1) the association between pre-/on-treatment ALT flares and both HBsAg loss and clinical outcomes among a diverse US population; 2) potential risk factors for these flares. **Methods:** Retrospective study conducted using the Optum® de-identified electronic health record dataset (2012–2019) among patients with cHBV infection in the US. Marginal structural models estimated the association between ALT flares and clinical outcomes accounting for time-varying confounding; adjusted odds ratios (aOR) and 95% confidence intervals (CI) were reported. A Cox proportional hazards regression model was used to assess risk factors for ALT flares. **Results:** Among 14,328 cHBV patients (pre-treatment) with no co-infection, 2,298 initiated treatment (on-treatment cohort; 46% Asian, 59% men, 29% HBeAg-positive, mean age 48 years). 364 (2.5%) patients experienced ≥ 1 pre-treatment ALT flare and 84 (3.7%) ≥ 1 on-treatment flare. On-treatment ALT flares were associated with HBsAg loss and HBeAg loss (aOR [95% CI]: 15.3 [4.5, 51.8] and 3.7 [1.9, 7.3], respectively), but not with clinical outcomes (hepatic decompensation, aOR: 1.3 [0.5, 3.7]; hospitalization, aOR: 0.7 [0.3, 1.6]); death, aOR: 1.3 [0.5, 3.4]). Pre-treatment ALT flares were associated with spontaneous HBsAg loss (aOR: 2.4 [1.2, 5.1] and also associated with an increased risk of hepatic decompensation (aOR: 2.7 [1.7, 4.2]), hospitalization (OR: 1.5 [1.04, 2.2]), and death (OR: 3.8 [2.4, 6.2]), likely due to disease progression among untreated patients. Risk factors for pre-treatment ALT flare included male sex, history of flares, metabolic syndrome, liver fibrosis, compensated cirrhosis (CC) and decompensated liver disease (DLD). Risk factors for on-treatment flare included younger age, white race, history of flares, liver fibrosis, CC and DLD. **Conclusion:** Understanding the risk factors and consequences of ALT flares in patients with cHBV infection is critical for providing optimal care. In line with literature, on-treatment flares were associated with HBsAg and HBeAg loss. Flares occurring before treatment initiation were associated with long-term clinical outcomes, while no association with adverse clinical outcomes was observed for flares occurring during treatment. Funding: GSK Study 217283.

1278 | EXPOSURE TO TENOFOVIR ALAFENAMIDE AND TENOFOVIR DISOPROXIL FUMARATE AND THE RISK OF HEPATOCELLULAR CARCINOMA

W. Ray Kim[1] YOUNG-SUK LIM[2] Harry Janssen[3] Sang Hoon Ahn[4] Ira Jacobson[5] Masashi Mizokami[6] Grace Lai-Hung Wong[7] Frida Abramov[8] Leland Yee[8] Hongyuan Wang[8] Catherine Frenette[8] Scott Fung[9] Patrick Marcellin[10] Wai-Kay Seto[11] Kosh Agarwal[12] Jinlin Hou[13] Seng Gee Lim[14] Jia-Horng Kao[15] Maria Buti[16], [1]Division of Gastroenterology and Hepatology, Mayo Clinic College of Medicine, Rochester, MN, USA, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Erasmus University Medical Center, The Netherlands; Toronto Centre for Liver Disease, Canada, [4]Yonsei University College of Medicine, Seoul, Republic of Korea, [5]Division of Gastroenterology and Hepatology, NYU Langone Health, New York, NY, USA, [6]Genome Medical Sciences Project, National Center for Global Health and Medicine, Ichikawa, Japan, [7]The Chinese University of Hong Kong, Hong Kong, [8]Gilead Sciences, Inc., Foster City, CA, USA, [9]Toronto General Hospital, University of Toronto, Toronto, ON, Canada, [10]Service d'Hépatologie, Hôpital Beaujon, Clichy, France, [11]The University of Hong Kong, Hong Kong, [12]Institute of Liver Studies, King's College Hospital, London, United Kingdom, [13]Nanfang Hospital of Southern Medical University, Guangzhou, China, [14]National University Health System, Singapore, [15]National Taiwan University College of Medicine, National Taiwan University Hospital, Taipei, Taiwan, [16]Hospital Universitari Vall d'Hebron, Barcelona; Ciberehd del Instituto Carlos III, Madrid, Spain

Background: Nucleos(t)ide analogs have been associated with reduced risk of hepatocellular carcinoma (HCC) in patients with hepatitis B virus (HBV) infection. Many, though not all, studies have suggested that tenofovir-based therapies are more effective than entecavir in reducing HCC risk. Here, we examine HCC risk based on exposure to tenofovir alafenamide (TAF) vs tenofovir disoproxil fumarate (TDF) in patients with chronic hepatitis B. **Methods:** Data from four pivotal phase 3 trials were pooled to examine the association between TAF/TDF exposure and HCC occurrence. These included Studies 102 and 103, in which patients were randomized (2:1) to TDF vs adefovir dipivoxil (ADV) for 48 weeks, followed by open-label TDF (up to 8 years' total treatment [384 weeks]), and Studies 108 and 110, in which patients were randomized (2:1) to TAF vs TDF for up to 144 weeks, followed by open-label TAF (up to 8 years' total treatment). HCC occurrence was classified as an adverse event and assessed as part of routine care (hepatic ultrasonography conducted in Studies 108 and 110). The outcome variable in the uni- and multi-variate Cox proportional hazards analyses was HCCs occurring after 48 weeks of treatment initiation or switching (ADV to TDF), as HCCs occurring within the timeframe may be considered to have pre-existed. This design allows consideration of predictor variables at baseline and up to 48 weeks without a concern for immortal time bias. Exposure to TAF vs TDF was the main predictor variable and was captured by the total TAF exposure time/(total TAF exposure time + total TDF exposure time), with values ranging between 0 (TDF only) and 1 (TAF only). **Results:** In total, 2,273 patients (Studies 102/103: n = 641; Studies 108/110: n = 1,632) were included in the pooled analysis. By Year 8, 46 (2.0%) patients had developed HCC (9 cases occurred within the first 48 weeks and were excluded). Table 1 presents the results of the univariate and multivariate Cox proportional hazards analyses. In the univariate model, sex, age, cirrhosis, normalization of alanine aminotransferase (ALT) levels at Week 24, and exposure to TAF vs TDF were significantly associated with decreased HCC risk. In the final multivariate analysis, exposure to TAF vs TDF was significantly associated with a 70.0% reduction in HCC risk compared to TDF (hazard ratio = 0.30). Independently, ALT normalization at Week 24 was also significantly associated with decreased HCC risk. **Conclusion:** Long-term TAF treatment was associated with a greater reduction in HCC risk than TDF treatment. Differences in study design, population, and timing should be considered, and real-world data may help to confirm these findings.

Table 1. Factors associated with HCC development (Cox regression analysis)

Parameter	Univariate		Multivariate	
	HR (95% CI)	p	HR (95% CI)	p
Sex, male vs female	2.93 (1.14–7.51)	0.0255	4.14 (1.57–10.93)	0.0041

1279 | SEX AND AGE-BASED CLINICAL HETEROGENEITY IN HIGH HBV DNA PATIENTS

Jie Liu[1] Jia Li[1] Guifeng Li[2], [1]Department of Hepatology, Tianjin Second People's Hospital, [2]The Second People's Hospital Affiliated to Tianjin

Background: High HBV DNA level is a crucial predictor of adverse long-term outcomes in chronic hepatitis B (CHB). Despite similarly high viral loads, patients may differ significantly in liver inflammation (ALT), fibrosis progression, and clinical outcomes. This heterogeneity's relationship to age and sex, particularly in females, and its implications for mother-to-child transmission (MTCT) remain unclear. Understanding these nuances is vital for accurate risk stratification and tailored antiviral treatment. **Methods:** We retrospectively analyzed 420 CHB patients with HBV DNA $>$ 10^7 IU/mL. Demographics, education, marital status, residence, occupation, reproductive history, and MTCT prevention practices were recorded. Patients were stratified by sex and age group to identify clinical variations and their potential causes. Special focus was given to female patients' MTCT characteristics. **Results:** The cohort (217 males, 203 females) showed a similar age distribution between sexes, with a mean age of 38.14 $\pm$ 9.50 years for males and 38.32 $\pm$ 9.75 years for females (P = 0.870). Overall ALT abnormality was significantly higher in males compared to females. Specifically, males had higher median ALT (71 vs. 49 U/L, $P < 0.001$), CAP (231 vs. 211 dB/m, $P = 0.005$), and LSM (6.5 vs. 6.1 kPa, $P = 0.040$). Stratified by age, females aged 50-60 exhibited higher LSM and CAP values, whereas HBsAg and HBeAg levels declined with age. Conversely, younger males displayed higher ALT levels that decreased with age; similarly, viral markers decreased progressively. Among females, higher educational attainment (college level and above) correlated significantly with lower child HBV infection rates ($P = 0.010$). Younger mothers (< 30 years) had higher child infection rates compared to older mothers (mean age 27 vs. 31, $P = 0.024$). **Conclusion:** Significant heterogeneity exists among high-HBV DNA CHB patients, with pronounced sex and age-related differences. Elevated ALT in older females correlates with fatty liver, coinciding with increased fibrosis. Higher maternal education and younger maternal age are associated with reduced and increased MTCT, respectively. Personalized clinical management strategies considering sex, age, and social determinants are essential to optimize patient outcomes and prevent vertical transmission.

Table 1. Baseline characteristics of chronic HBV patients with high viral load, stratified by sex.

	Total (n=420)	Male (n=217)	Female (n=203)	*P*
Age (years)	38.23 ± 9.60	38.14 ± 9.50	38.32 ± 9.75	0.870
HBV DNA (lg) (IU/mL)	7.60 (7.30, 7.80)	7.70 (7.30, 7.80)	7.60 (7.40, 7.70)	0.760
HBsAg (IU/mL)	30,109.00 (9,902.00, 55,855.00)	32,063.00 (9,902.00, 55,855.00)	27,844.00 (9,902.00, 55,855.00)	0.740
HBeAg (S/CO)	1,320.00 (887.00, 1,597.00)	1,411.00 (887.00, 1,597.00)	1,392.00 (887.00, 1,597.00)	0.560
ALT (U/L)	59.00 (30.00, 123.00)	71.00 (30.00, 123.00)	49.00 (25.00, 71.00)	<0.001
AST (U/L)	41.00 (25.00, 71.00)	43.00 (25.00, 71.00)	36.00 (25.00, 71.00)	0.080
CAP (dB/m)	223.00 (195.00, 257.00)	231.00 (195.00, 257.00)	211.00 (195.00, 257.00)	0.005
LSM (kPa)	6.40 (5.10, 9.20)	6.50 (5.10, 9.20)	6.10 (5.10, 9.20)	0.040

Note. Data are presented as mean ± standard deviation (age) or median (interquartile range, IQR) for non-normally distributed variables. Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; CAP, controlled attenuation parameter; HBeAg, hepatitis B e antigen; HBsAg, hepatitis B surface antigen; HBV DNA, hepatitis B virus deoxyribonucleic acid (log₁₀ IU/mL); LSM, liver stiffness measurement; S/CO, signal-to-cutoff ratio. Statistical comparisons were performed using the Mann–Whitney U test.Statistical comparisons were performed using the Mann–Whitney U test for continuous variables or chi-square test for categorical variables. *P*-values <0.05 were considered statistically significant.

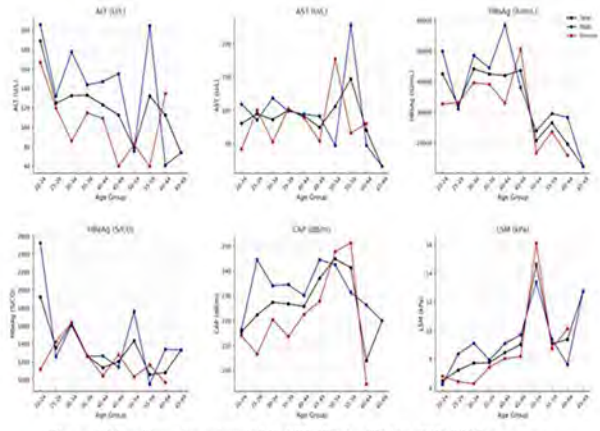

Figure 1. Mean biomarker values (ALT, AST, HBsAg, HBeAg, CAP, LSM) across age groups, stratified by sex.

1280 | HEPATITIS B VIRUS REACTIVATION IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES RECEIVING CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY

Abdullah Shaikh[1] Khalis Mustafayev[1] Filippos Koutroumpakis[1] Joanne arvelaez Pascucci[1] Hao Chi Zhang[1] Krina Patel[1] Sairah Ahmed[1] Harrys Torres[1], [1]The University of Texas MD Anderson Cancer Center

Background: Chimeric antigen receptor T-cell therapy (CAR-T) targeting CD19 or B-cell maturation antigen has been associated with hepatitis B virus reactivation (HBVr), but there are limited data on HBVr after CAR-T in patients with hematological malignancies. We studied the incidence, characteristics, and management of HBVr in this patient population. **Methods:** We retrospectively identified adult lymphoma and myeloma patients with a history of resolved or chronic HBV who received CAR-T between 1/1/2015 and 8/31/2024. Patients with false reactive HBV core antibody (HBcAb), false reactive HBV surface antigen (HBsAg), or incomplete HBV DNA data were excluded. Resolved HBV was defined as negative HBsAg with positive HBcAb; chronic HBV, as positive HBsAg for $\geq$6 months with positive HBcAb; and occult HBV, as negative HBsAg with detectable HBV DNA. HBVr was defined per the 2018 AASLD guidelines. The risk of HBVr was categorized as low ($<$1%), moderate (1-10%), or high ($>$10%). **Results:** Of the 71 HBV-infected patients who received CAR-T during the study period, 30 were included in the analysis (Figure 1). The patients' characteristics are given in Table 1. Most patients were men (20 [67%]), were over age 65 (17 [57%]), had large B-cell lymphoma (19 [63%]), received axicabtagene ciloleucel (axi-cel; 17 [57%]), had resolved HBV (20 [67%]), and were evaluated by HBV specialists (22 [73%]). The median follow-up time after CAR-T was 30 months (interquartile range, 45 months). Most patients with resolved HBV (19/20 [95%]) or chronic HBV (9/10 [90%]) were on HBV prophylaxis; the most common antivirals were entecavir (75%) and tenofovir alafenamide (21%). Only 1 patient (3%), who had resolved HBV, developed HBVr. This patient received rituximab-based therapy followed 1 month later by axi-cel. Approximately 1 week after completing CAR-T, he developed HBVr with low-grade viremia ($<$10 IU/mL) while receiving entecavir, which was continued with no further episodes of HBVr. Two patients (1 with resolved HBV, and 1 with occult HBV with intermittent low-grade viremia), who were closely monitored by HBV specialists, did not receive HBV prophylaxis after CAR-T; neither developed HBVr. **Conclusion:** CAR-T poses a low to moderate risk of HBVr in infected patients with hematologic malignancies. HBV prophylaxis can prevent HBVr in this patient population. However, a select group of patients with HBV can be closely monitored without HBVr prophylaxis.

1281 | METABOLIC EFFECTS AND CARDIOVASCULAR DISEASE RISKS OF TDF OR TAF IN PATIENTS WITH CHRONIC HEPATITIS B:A SYSTEMATIC REVIEW AND META-ANALYSIS

Peng Hu[0] Yuan-hai Zhou[0], [0] The First Affiliated Hospital of Chongqing Medical University

Background: The effects of Tenofovir Disoproxil Fumarate (TDF) or Tenofovir Alafenamide (TAF) on lipid profiles have been observed in chronic hepatitis B (CHB) treatment. However, the metabolic features and their impact on cardiovascular risk remain unclear. We conducted a systematic review and meta-analysis to evaluate these effects. **Methods:** We searched for studies from four major databases (PubMed, Web of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Science, EMBASE, and the Cochrane Library) that reported the effects of TDF or TAF on metabolism and cardiovascular disease risk. The changes in metabolic parameters and 10-year atherosclerotic cardiovascular disease (ASCVD) risk were compared with baseline in the TDF and TAF treatment groups. Extracted data were analyzed with the random-effects model or the fixed-effects model. Potential sources of heterogeneity were investigated using sensitivity and subgroup analyses. **Results:** A total of 19 studies including 19,396 CHB patients (12,067 in TDF-only group, 5423 in TAF-only group, and 1906 in TDF-switched group) were included in this meta-analysis. We found that both TAF and TDF treatment mildly increase the 10-year ASCVD risk. The TAF treatment showed significant increases in body weight, with no significant effects were observed on lipid levels or blood glucose. While TDF treatment has a lipid-lowering effect and caused weight loss. Subanalyses emphasized the impact of changing antiviral treatment strategies on metabolism. We found an increased risk of dyslipidemia and body weight gain after switching from TDF to TAF treatment. **Conclusion:** Although TAF and TDF treatments exhibit different metabolic characteristics, both mildly increase the risk of cardiovascular disease.

1282 | UBIQUITINATION OF NTCP AT RESIDUE K340 IS A CRITICAL DETERMINANT FOR NTCP ENDOCYTOSIS AND HEPATITIS B VIRUS (HBV) INFECTIO

Monique Appelman[1] Anh Nguyen[2] Andreas Oswald[3] Aaron Lucko[3] Coen Paulusma[4] Ulrike Protzer[3] Stan van de Graaf[5], [1]UMC Utrecht, [2]Amsterdam UMC, [3]Institute of Virology, Technical University of Munich / Helmholtz Munich, [4]Tytgat Institute for Liver and Intestinal Research, [5]Amsterdam UMC, Tytgat Institute for Liver and Intestinal Research

Background: The sodium taurocholate co-transporting polypeptide (NTCP), the main hepatic uptake transporter of conjugated bile salts, has been identified as the docking receptor required for the hepatitis B and D virus (HBV/HDV) entry. The mechanism of NTCP-dependent internalization of HBV/HDV into hepatocytes is, however, poorly understood. We investigated the contribution of posttranslational modification of NTCP on transporter endocytosis as well as HBV docking and infection. **Methods:** NTCP ubiquitination was determined by immunoprecipitation of wild-type NTCP ($NTCP^{WT}$). To identify amino acids involved in NTCP ubiquitination, lysine residues (K) in the C-terminus of NTCP were substituted by arginine (R). HepG2 cells overexpressing NTCP mutants were assessed for protein levels, bile salt uptake activity, NTCP endocytosis and HBV infectivity. TAK-243 was used to assess global ubiquitination effects on uptake activity and HBV infection in $NTCP^{WT}$ HepG2 and HepaRG cells. **Results:** NTCP is ubiquitinated. Compared to $NTCP^{WT}$, the $NTCP^{K340R}$ mutant showed reduced ubiquitination, suggesting that this is the main ubiquitination target within NTCP. Furthermore, $NTCP^{K340R}$ had increased NTCP membrane abundance, coinciding with enhanced bile salt uptake. Notably, $NTCP^{K340R}$ endocytosis was strongly impaired. HBV-derived myr-preS1 peptide binding to $NTCP^{K340R}$ -expressing cells remained intact, increasing the total cellular binding of preS1 peptides-$NTCP^{K340R}$ plasma membrane abundance. Nevertheless, HBV infection of $NTCP^{K340R}$-expressing HepG2 was strongly reduced compared to $NTCP^{WT}$. In line with this, TAK-243 treatment reduced cellular ubiquitination levels and increased the bile salt uptake while reducing the HBV infection. **Conclusion:** The lysine residue at position 340 plays a crucial role in NTCP ubiquitination. Interfering with NTCP ubiquitination resulted in impaired NTCP endocytosis and a concomitant reduction in HBV infection. Our study directly shows that NTCP-mediated endocytosis is critical for HBV entry into the liver.

Li[5] Chunhui Yang[1] Youmin Yang[6] Jing Xu[4] Min Xu[1] He Xie[1] Shilin Li[1] Raymond Chung[3] Xianding Wang[7] Limin Chen[1] Wenyu Lin[3], [1]Institute of Blood Transfusion, Chinese Academy of Medical Sciences and Peking Union Medical College, [2]The Second People's Hospital of Fuyang City, Fuyang 236015, Anhui, China, [3]Massachusetts General Hospital and Harvard Medical School, [4]The Second People's Hospital of Fuyang City, [5]The First Affiliated Hospital of Anhui Medical University, Hefei, [6]Institute of Urology/Kidney Transplant Center, West China Hospital, Sichuan University, [7]West China Hospital, Sichuan University

Background: Chronic hepatitis B (CHB) is a major etiology of liver cirrhosis. We previously found that pyruvate, a key intermediate in many metabolic pathways, increases HBV replication. However, the mechanism by which pyruvate mediates HBV-induced liver fibrosis is not well characterized. We hypothesize that HBV induces liver fibrosis through a pyruvate-peroxisome proliferator-activated receptor α (PPARα) - reactive oxygen species (ROS) pathway. **Methods:** We evaluated HBV-induced fibrogenesis in HBV HepAD38, HBV-infected NTCP-HepG2 cells, and hepatic stellate cell lines (HSC, LX2) in mono- and co-culture models, as well as in sera from CHB patients, HBV carrier mouse, HBV-Transgenic mouse (HBV-Tg), humanized liver mouse, and human precision-cut liver slice (PCLS) models. Cells were cultured in medium without pyruvate. Infectious HBV viral particles (HBVvp) were purified from HepAD38 supernatant (HBVsup). We evaluated the effects of the PPARα agonist fenofibrate, the PPARα antagonist GW6471, PPARa RNAi knockdown, and the ROS inhibitor diphenyliodonium chloride (DPI) on HBV-induced liver fibrosis. HBV replication and the expression of pyruvate, PPARα, TGF-β1, and liver fibrosis-related genes were monitored by qRT-PCR, Western blot, or ELISA. **Results:** We found that HBV increased pyruvate levels and fibrosis-related gene expression in both HBV-infected hepatocytes and patient sera. Supernatants from HBV-infected cells (HBVsup) and pyruvate supplementation independently and additively increased expression of profibrotic genes (TGF-β1, TIMP-1, COL1A1, and α-SMA), activated ROS production, and inhibited PPARα expression. Notably, PPARα inhibition and siRNA knockdown increased ROS production and profibrogenic gene expression, while activation of PPARα blocked HBVsup- and pyruvate-induced ROS generation and fibrogenesis. ROS was confirmed to be downstream of PPARα-related fibrogenesis, as ROS inhibition abrogated HBVsup-, pyruvate supplementation-, or PPARα inhibition-induced liver fibrosis. **Conclusion:** HBV infection induces pyruvate production and decreases PPARα expression, leading to increased ROS generation and liver fibrosis. Pyruvate and PPARα represent novel targets for antifibrotic therapeutic development in CHBV.

Background: Peginterferon alpha (PegIFNα)-based therapy has been proven to promote HBsAg loss and enable functional cure in patients with chronic hepatitis B. However, the efficacy of PegIFNα retreatment remains to be explored. Our study specifically evaluated the efficacy of PegIFNα-2b retreatment in patients who initially responded well in a phase 3 trial. **Methods:** This is a long-term follow-up study (NCT06707922) of a randomized controlled phase 3 trial (NCT04846491). At the end of the phase 3 trial, nucleos(t)ide analogue (NA)-experienced patients with HBsAg decline ≥ 1 $\log_{10}$ IU/mL and HBsAg level < 100 IU/mL, as well as treatment-naïve patients with HBsAg decline ≥ 1.5 $\log_{10}$ IU/mL and HBsAg level < 1500 IU/mL were enrolled in cohort 2. All patients initially received treatment with PegIFNα-2b (Pegbing®, Xiamen Amoytop Biotech Co., Ltd.)180 μg/week combined with tenofovir alafenamide fumarate (TAF) for 72 weeks, after which all drugs were discontinued and patients were followed up to 5 years. PegIFNα-2b was given intermittently in cycles (8 weeks of treatment + 4 weeks of interval, repeating every 12 weeks). Here, we report the results of the 60-week analysis in cohort 2. **Results:** A total of 47 NA-experienced patients and 15 treatment-naïve patients were included in cohort 2. The average ages of the two populations were 42.5 and 34.5 years, and 85.1% and 66.7% were male. The mean baseline HBsAg level of NA-experienced patients was 13.04 IU/mL, and HBeAg and HBV DNA were negative in all patients. Treatment-naïve patients had mean baseline HBsAg and HBeAg levels of 269.56 IU/mL and 2.24 COI, respectively, with 73.3% were HBeAg negative and 100% were HBV DNA undetectable. HBsAg levels significantly declined in both patients as treatment progressed. By week 60, the mean reduction in HBsAg from baseline amounted to 1.29 and 1.10 $\log_{10}$ IU/mL in NA-experienced and treatment-naïve patients, respectively (Figure 1a). 48.9% (23/47) of NA-experienced patients and 33.3% (5/15) of treatment-naïve patients achieved HBsAg loss at week 60 (Figure 1b), while the HBsAg seroconversion rates were 32.5% (13/40) and 23.1% (3/13), respectively. Among four treatment-naïve patients with HBeAg positive, one achieved HBeAg loss and seroconversion. **Conclusion:** Nearly 50% of NA-experienced patients and over 30% of treatment-naïve patients still achieved HBsAg loss after retreatment with PegIFNα-2b. Patients with good initial responses to PegIFNα have great chance to pursure functional cure by retreatment with PegIFNα.

[88]Hospital universitario Vall d'Hebron, [89]Hospital Universitario y Politécnico La Fe, [90]Hospital Universitario Príncipe de Asturias, [91]Hospital Germans Trias i Pujol

Background: The quantification of hepatitis B surface antigen (qHBsAg) provides essential information on disease phase and residual viral activity. Its relevance is even greater in the context of new therapeutic agents aimed at achieving a functional cure for HBV. Despite its clinical value, the implementation of qHBsAg in Clinical Microbiology (CM) laboratories, as well as awareness of its practical applications, remains limited. This study aims to assess the level of implementation and awareness of the use of qHBsAg in CM labs in Spain, in order to identify barriers and opportunities for its standardization and optimal integration into the management of chronic HBV infection. **Methods:** A cross-sectional, observational, and descriptive study was conducted between March and April 2025 through a survey distributed to CM labs in Spain. The questionnaire collected information on the implementation of qHBsAg, the methodologies used, the number of HBsAg-positive patients, and the main barriers to its application. In centers where the test was available, additional data on quantitative results were requested, categorized into predefined ranges. **Results:** A total of 91 responses were received from 118 CM labs invited. Only 37.4% of centers reported performing qHBsAg. Among non-quantifying centers, 86% did not refer samples to external laboratories, and the most frequently reported reason was a lack of clinical demand (46.4%). Other barriers included lack of equipment and resources, often in combination. Hospital number of beds were significantly associated with implementation ($p = 0.041$): no hospital with < 200, 23.3% with 200-500, 44.9% with 500-1000, and 62.5% with ≥ 1000 beds performed quantification. Regarding geographical distribution, quantification rates varied between autonomous communities but showed no statistically significant differences, possibly due to uneven representation across regions. Among centers that perform qHBsAg, 57.6% do so only after a positive result from a qualitative screening result, 27.3% upon specific request, and 15.2% use the quantitative assay as the initial test. Notably, 69.7% of these centers report the result proactively to the requesting physician, and 81.8% dilute samples above the upper quantification limit to obtain the exact value. In the past year, 40.7% of quantified determinations were below 100 IU/mL, while 27.1% exceeded 3000 IU/mL. **Conclusion:** The survey results show that HBsAg quantification remains underutilized in CM labs in Spain, with limited implementation and heterogeneous practices among centers. The findings help identify specific barriers—such as perceived low demand and lack of integration within clinical care pathways—and provide a solid foundation for designing educational and organizational interventions to support the effective implementation of qHBsAg in routine clinical practice.

1286 | HIV CO-INFECTION WORSENS INPATIENT OUTCOMES IN HEPATITIS B: A NATIONWIDE ANALYSIS WITH SOCIODEMOGRAPHIC INSIGHTS

Iqra Qazi[1] Fnu Versha[1] Sunita Devi[1] Harika Chintalapalli Patta[1] Nigil Thaimuriyil[1], [1]Baptist Hospitals of Southeast Texas

Background: Chronic hepatitis B virus (HBV) infection affects millions worldwide and is a leading cause of cirrhosis and hepatocellular carcinoma. When co-infection with human immunodeficiency virus (HIV) occurs, the clinical course of HBV can worsen due to impaired immune control, accelerated liver disease progression, and complex treatment interactions. Despite these known risks, the inpatient impact of HIV co-infection in HBV-positive patients remains underexplored in large-scale datasets. Moreover, HIV and HBV disproportionately affect populations already facing structural disadvantages, including racial minorities, individuals with low income, and those reliant on public insurance. Understanding how both clinical and social factors shape hospitalization outcomes in this co-infected population is essential to guiding equitable and evidence-based care. **Methods:** We conducted a retrospective cross-sectional analysis using the Nationwide Inpatient Sample (2018–2022). Adult hospitalizations with HBV and HIV infection were identified using ICD-10-CM codes. The primary exposure was HIV co-infection among HBV-positive patients. Outcomes included in-hospital mortality, sepsis, ICU-level care (defined by procedure codes for mechanical ventilation or vasopressor use), length of stay (LOS), and total hospital charges. Multivariable survey-weighted logistic and linear regression models were used to assess associations between HIV co-infection and outcomes, adjusting for age, sex, race, insurance status, income quartile by ZIP code, comorbidities, and hospital characteristics. **Results:** Among an estimated 204,705 hepatitis B–related hospitalizations in the United States from 2018 to 2022, approximately 12,130 (5.9%) involved documented HIV co-infection. Compared to HBV-only patients, those with HIV were younger, more likely to be male, Black, Medicaid-insured, and reside in lower-income ZIP code quartiles. After adjusting for demographic, clinical, and hospital-level factors, HIV co-infection was independently associated with significantly worse outcomes. Co-infected patients had higher odds of in-hospital mortality (adjusted odds ratio [aOR] 1.48; 95% CI: 1.22–1.80; $p < 0.001$), sepsis (aOR 1.88; 95% CI: 1.68–2.09; $p < 0.001$), and ICU-level care (aOR 1.28; 95% CI: 1.08–1.51; $p = 0.003$). Additionally, co-infection was associated with longer hospital stays (+1.7 days; $p < 0.001$) and 28% higher total hospital charges ($p < 0.001$). **Conclusion:** HIV co-infection is associated with significantly worse inpatient outcomes among hepatitis B patients, including higher mortality, sepsis, ICU use, and healthcare costs. These findings highlight the need for integrated clinical management and attention to social risk factors in this high-risk population.

Variable	HBV only (n = 204,705)	HBV + HIV (n = 12,130)	p-value
Age, mean (95% CI)	55.3 (55.1–55.5)	51.3 (50.8–51.8)	<0.001
Female (%)	43.5	19.4	<0.001
Black (%)	22.3	56.0	<0.001
Medicaid as primary payer (%)	29.4	39.1	<0.001
Diabetes (%)	28.7	16.5	<0.001
Hypertension (%)	51.4	47.7	0.0009
Congestive Heart Failure (%)	17.6	19.3	0.059
Lowest-income ZIP quartile (%)	30.6	46.9	<0.001
Large hospital bed size (%)	57.8	65.8	<0.001
South hospital region (%)	28.1	17.7	<0.001
In-hospital mortality (%)	4.4	5.5	0.0126
Sepsis (%)	14.1	22.4	<0.001
ICU proxy (vent/pressor) (%)	6.4	8.7	<0.001
Length of stay, mean (days)	5.4 (5.3–5.4)	7.1 (6.9–7.3)	<0.001
Total charges, mean (USD)	$95,482.00	$109,048.00	<0.001

1287 | TOWARDS THE ELIMINATION OF MOTHER-TO-CHILD TRANSMISSION OF HEPATITIS B VIRUS IN HONG KONG: INSIGHTS FROM A POST-VACCINATION SEROLOGIC TESTING PROGRAM

Vivien Tsui[1] Chin Man Poon[2] Zenith Hin Yam Wu[2] Bonnie Chun Kwan Wong[2] Jeffrey Cing Hon Lai[1], [1]Hospital Authority, Hong Kong, China, [2]Special Preventive Programme, Centre for Health Protection, Department of Health, Hong Kong, China

Background: Hong Kong has implemented comprehensive measures to prevent mother-to-child transmission (MTCT) of hepatitis B virus (HBV), including universal antenatal HBsAg screening, universal neonatal hepatitis B vaccination, and hepatitis B immunoglobulin administration for at-risk newborns, all with a coverage of >98%. In Aug 2020, antiviral prophylaxis for pregnant women with high viral load (HBV DNA >200000 IU/mL) was introduced in public hospitals. In 2022, a post-vaccination serologic testing (PVST) program was launched to identify infants with immunoprophylaxis failure (IF) or inadequate immune response. This study explores potential factors contributing to residual MTCT, which might inform gaps in current prevention strategies. **Methods:** The PVST program covered infants born to HBV-infected women from Oct 2020 onwards, who received tests for HBsAg and anti-HBs at 9-12 months of age after completing the primary hepatitis B vaccination series. HBsAg-positive infants were referred to pediatricians, where clinical review on maternal factors, including HBV status awareness, viral load, antiviral prophylaxis eligibility, and treatment adherence, was conducted to identify possible factors associated with IF. **Results:** From Jan 2022 to Dec 2024, 2806 infants were enrolled in the PVST program. Nine (0.3%) tested positive for HBsAg, including one set of twins. All eight mothers were aware of their HBV status during antenatal care. Three (37.5%) mothers were unaware of their eligibility for antiviral prophylaxis, as they received antenatal care either before the implementation of the prophylaxis program or outside the program's coverage. One (12.5%) mother had an HBV DNA of 162000 IU/mL, below the prophylaxis threshold. One (12.5%) mother who was on long-term tenofovir treatment self-discontinued treatment during pregnancy. Three (37.5%) mothers eligible for antiviral prophylaxis either refused or did not adhere to the regimen. **Conclusion:** The absence of completed maternal antiviral prophylaxis in all MTCT cases underscores its critical role in minimizing residual HBV transmission risk in Hong Kong. Achieving the vision of a hepatitis B-free generation necessitates strengthening territory-wide healthcare provider training in HBV management and targeted public education to improve prophylaxis uptake and adherence. Furthermore, the IF in an infant born to a mother with HBV DNA below the current treatment threshold warrants a critical review and evaluation of the prophylaxis initiation criteria.

1288 | HISTOLOGICAL CHARACTERISTICS AND CLINICAL OUTCOMES OF HBEAG-NEGATIVE CHRONIC HBV INFECTION PATIENTS WITH UNDETECTABLE HBV DNA

Lin Weijia[1] Rongrong Ding[1] Shuangshuang Sun[1] Liang Chen[1], [1]Shanghai Public Health Clinical Center

Background: The research on the histological characteristics and clinical outcomes of the liver in patients with chronic hepatitis B virus (HBV) infection who are negative for HBeAg-negative and whose HBV DNA cannot be detected is still insufficient. This study aims to explore the histological characteristics and clinical outcomes of the liver of this type of patients. **Methods:** A total of 275 treatment-naive HBeAg-negative patients with chronic HBV infection who underwent liver biopsy in Shanghai Public Health Clinical Center from January 2010 to July 2022. Patients were categorized into two groups based on HBV DNA status: HBV DNA-negative (n = 168) and HBV DNA-positive (n = 107). The lower limit of HBVDNA detection was 500 IU/mL. The clinical characteristics and liver histological distribution of the two groups of patients were compared. This study defines pathological grade ≥ G2 or/and stage ≥ S2 as significant liver histological changes (SLHC), G0-1 and S0-1 as mild liver histological changes. Longitudinal follow-up was conducted for 100 patients with mild liver histological changes. APRI ≥ 1.5, FIB-4 ≥ 3.25, or liver stiffness measurement (LSM) ≥ 8.0 kPa were defined as the presence of significant liver fibrosis. The Kaplan-Meier curve was used to analyze the cumulative occurrence risk of significant liver fibrosis and HBsAg clearance. **Results:** There was no significant difference between HBVDNA-negative and positive patients in Age, Male, ALT, AST, GGT, TBIL, ALB, PT, WBC, PLT, APRI, and FIB-4 ($P > 0.05$). The serum HBsAg level in the HBV DNA negative group was significantly lower than that in the positive group (2.87 vs. 3.11 $\log_{10}$ IU/ml, $P = 0.031$). Among the overall population, significant liver histological changes accounted for 27.3%, and there was no significant difference between the two groups (26.2% in the HBV DNA negative group vs. 29.0% in the positive group, $P > 0.05$). The cumulative

incidence of significant liver fibrosis showed no statistically significant difference between the two groups (Log-rank $P = 0.362$, HR = 0.490, 95%CI = 0.102-2.369). The HBsAg clearance rate was slightly higher in the HBV DNA negative group, but there was no significant difference between the two groups (Log-rank $P = 0.075$). **Conclusion:** In HBeAg-negative chronic HBV infection patients, there was no significant difference in the significant liver histological changes, the cumulative risk of significant liver fibrosis, and HBsAg clearance between patients with undetectable and positive HBV DNA. Compared with patients with positive HBV DNA, patients with undetectable HBV DNA had lower serum HBsAg levels and slightly higher serum HBsAg clearance rates.

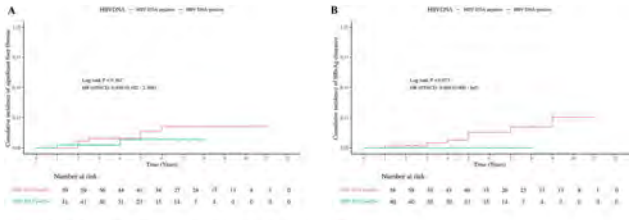

Figure 2 Cumulative incidence of significant liver fibrosis (A), HBsAg clearance (B).

1289 | BRIDGING THE GAP BETWEEN ACIP GUIDELINES AND PRACTICE: IMPROVING HEPATITIS B VACCINATION RATES IN INTERNAL MEDICINE RESIDENT CLINICS

Mohammad Adam[1] Ehsan Sha'ban[2] Ameen Awad[2] Abdelsabour Hassan[2] Himil Mahadevia[2] Julie Banderas[2] David Wooldridge[2], [1]University of Missouri - Kansas City School of Medicine, [2]University of Missouri-Kansas City

Background: Chronic hepatitis B virus (HBV) infection remains a major public health concern in the United States, contributing to cirrhosis, hepatocellular carcinoma, and liver-related mortality. Despite a highly effective vaccine, only 30% of adults aged ≥19 years had completed the hepatitis B vaccination series by 2018. In response to rising incidence, the Advisory Committee on Immunization Practices (ACIP) updated its guidelines to recommend universal adult vaccination for individuals aged 19–59. Yet, vaccination rates remain suboptimal. At our institution, baseline data from 2020 showed hepatitis B vaccine utilization among eligible outpatients was <1%, underscoring a critical gap in preventive care. We aimed to increase vaccine ordering rates among eligible patients in two internal medicine resident clinics by 30%. **Methods:** A QI intervention was conducted from September 2024 to March 2025 in two university-affiliated outpatient clinics. Strategies included interactive lectures, weekly educational emails, meme-based messages via Telegram, and visual workstation reminders. Vaccine utilization rate (orders among eligible patients) was the primary outcome. Hepatitis B surface antigen (HBsAg) screening orders were tracked as a process measure reflecting HBV status assessment. A balancing measure assessed inappropriate vaccine orders (e.g., for previously vaccinated or infected patients). Resident knowledge was evaluated via pre- and post-intervention surveys, which also explored perceived barriers to vaccination. **Results:** Hepatitis B vaccine utilization increased tenfold from 0.4% in November to 4.1% in February. Monthly vaccine orders rose from 1 to 11. HBsAg screening improved from 0.7% (2/289) to 3.8% (10/264). No inappropriate vaccine orders were recorded. Survey participation remained stable (24 pre vs. 27 post), with correct knowledge responses increasing from 38% to 76%, and incorrect responses dropping from 74 to 32. Residents identified competing clinical priorities (53%), patient hesitancy (32%), uncertainty about prior vaccination (9%), and insurance issues (6%) as major barriers. **Conclusion:** Following updated ACIP guidelines, our targeted QI strategy improved hepatitis B vaccine uptake in resident-run outpatient clinics. Educational outreach, reminder systems, and workflow optimization enhanced provider knowledge and vaccination behavior. Sustained improvement will require continued focus on guideline awareness, patient engagement, and efficient vaccination record review.

1290 | ECONOMIC BURDEN OF NON-CIRRHOTIC PATIENTS WITH CHRONIC HEPATITIS B VIRUS INFECTION IN THE UNITED STATES

Anna Coutinho[1] Kiran Rai[2] Amisha Patel[2] Thomas Jennison[2] Rosie Hulme[2] Vera Gielen[3] Seth Anderson[3] Christopher Bell[1], [1]GSK, [2]Adelphi Real World, [3]GSK (at time of study)

Background: While the long-term complications of chronic hepatitis B virus [cHBV] infection are well-recognized, the disease is considered as manageable with limited data on the economic burden of non-cirrhotic patients. This study described the costs and healthcare resource utilization [HRU] of patients with non-cirrhotic cHBV infection in the US. **Methods:** This retrospective cohort study used administrative claims data from the Merative™ MarketScan® Database. Patients were indexed on the chronologically first cHBV diagnosis occurring between Jan 2017–Jun 2022. Included patients were aged ≥18 years, had continuous eligibility ≥12 months prior to (baseline) and ≥3 months after index, and without liver disease progression or co-infection (HIV, HCV or HDV) at baseline. All-cause HRU per year and costs per patient per year [PPPY] (2022 USD) were evaluated from the index date until the earliest date of liver disease progression or the end of follow-up. Data were analyzed descriptively overall, by treatment status with nucleos(t)ide analogues [Nas]/Peg-interferon [IFN] and newly- or previously- diagnosed status. **Results:** A total of 7,466 patients were included: mean (standard deviation [SD]) age 47.1 (12.1) years; 53.2% female; mean (SD) follow-up of 2.6 (1.8) years; 37.8% newly diagnosed. Overall, 31.3% of patients were treated with NAs/IFN during follow-up, higher in previously vs newly diagnosed patients (42.5% vs. 12.8%). Total mean (SD) costs were $24,230 (88,409) PPPY with treated patients having higher costs versus untreated patients ($32,240 vs $20,115). Hospitalization ($11,922 untreated vs $10,105 treated) and ER visit costs ($487 untreated vs $414 treated) did not differ by treatment status; however, untreated patients had a higher proportion with hospitalizations and ER visits whereas treated patients had more lab and imaging tests (Table). Newly diagnosed patients had higher total mean costs PPPY ($29,798 vs $20,845) and had a higher proportion with hospitalizations and ER visits and lower proportion with lab or imaging tests than previously diagnosed patients (Table). **Conclusion:** Despite the uncomplicated nature of non-cirrhotic cHBV infection, economic burden is high. Results demonstrate a disparity in cHBV infection management with potential opportunities for improving care among those untreated and newly diagnosed.

Table. All-cause Healthcare Resource Use and Costs of Non-Cirrhotic Patients with cHBV

	Overall (n=7,466)	NA/IFN Treated (n=2,534)	Not Treated with NA/IFN (n=4,932)	Newly diagnosed (n=2,823)	Previously diagnosed (n=4,643)
All-cause healthcare costs PPPY (2022 USD), mean (SD)					
Total	$24,230 (88,409)	$32,240 (99,096)	$20,115 (82,088)	$29,798 (114,846)	$20,845 (67,237)
Medical	$18,955 (83,983)	$21,571 (92,687)	$17,612 (79,115)	$25,667 (110,342)	$14,875 (62,423)
Pharmacy	$5,274 (16,214)	$10,669 (17,950)	$2,503 (14,487)	$4,130 (19,231)	$5,970 (14,025)
All-cause HRU					
Inpatient, n (%)	2,558 (34.3%)	576 (22.8%)	1,980 (40.1%)	1,419 (50.3%)	1,139 (24.5%)

1291 | ISOGENIC STUDIES OF BASAL CORE PROMOTER AND PRECORE MUTANT VARIANTS ACROSS HEPATITIS B VIRUS GENOTYPES

Leon Seifert[1] Georgios Dangas[2] Yingpu Yu[1] Chenhui Zou[1] Catherine Freije[1] Xupeng Hong[1] Mengyin Zhang[1] Corrine Quirk[1] Yichen Zhou[3] Kosuke Ogata[4] Charles Rice[1] William Schneider[1] Eleftherios Michailidis[5] Ype De Jong[3], [1]The Rockefeller University, New York, NY, USA, [2]Department of Pediatrics, Emory University, Atlanta, [3]Weill Cornell Medicine, New York, NY, USA, [4]Kyoto University, Kyoto, Japan, [5]Department of Pediatrics, Emory University, Atlanta, GA, USA

Background: Studying isogenic hepatitis B virus (HBV) mutants in human hepatocyte chimeric mice remains a major challenge. Infection efficiency using cell culture-derived virus is limited, and patient serum samples

typically contain heterogeneous viral populations. To overcome these limitations, we developed a method to initiate HBV infection via intrahepatic injection of recombinant HBV cccDNA into human hepatocyte chimeric mice (*HBV rcccDNA launch*), enabling the study of viral variants with isogenic controls. We applied this method to investigate basal core promoter (BCP; A1762T/G1764A) and precore (PC; G1896A) mutants in HBV genotypes A, C and D. **Methods:** We generated isogenic, infectious viral stocks of wild-type (WT), BCP-, and PC-mutant variants in HBV-A, HBV-C and HBV-D using the HBV rcccDNA launch method. These stocks were used to infect human hepatocyte chimeric mice, and key viral parameters (HBV DNA, HBsAg, HBeAg) were monitored over time. Liver samples were collected and human hepatocytes were isolated at peak serum viremia. These HBV-infected, mouse-passaged primary human hepatocytes (mpPHHs) were then cultured to assess interferon (IFN) responses using pulse-SILAC proteomics. **Results:** Using HBV rcccDNA launch, we generated viral stocks with defined viral sequences corresponding to either WT or isogenic mutant variants, allowing for direct comparisons of HBV mutant variant in a controlled genetic background. These isogenic variants remained genetically stable, showing neither reversion back to WT nor acquisition of additional mutations. Consistent with clinical observations, no HBeAg secretion was observed in PC-mutant infection, while BCP-mutant infection led to an ~90% reduction of HBeAg serum levels compared to WT. The WT, BCP- and PC-mutant variants showed distinct viral kinetics that were genotype-dependent: in HBV-A and HBV-D, BCP-mutant infection showed a more rapid increase in serum viremia compared to WT and PC-mutant infection. In contrast, in HBV-C an accelerated increase in serum viremia was observed only in the presence of both mutations (PC/BCP double-mutant). Transcriptomic and proteomic studies uncovered unique, variant-specific profiles both in harvested liver tissue and in the pre-infected, IFN-stimulated mpPHHs. **Conclusion:** The BCP mutation, alone or in combination with the PC mutation, accelerates viral infection kinetics in human hepatocyte chimeric mice, and primary human hepatocytes display distinct responses to BCP- and PC-mutant infection. These findings promise to enhance our understanding of how these HBeAg lowering variants may contribute to liver disease progression in chronic HBV infection.

1292 | ADHERENCE PATTERNS TO ANTIVIRAL THERAPY IN OLDER ADULTS WITH HEPATITIS B: INSIGHTS FROM GROUP-BASED TRAJECTORY MODELING

Javeria Khalid[1] *Jieni Li*[1] *Rajender R Aparasu*[1],
[1]*University of Houston*

Background: Over one million people in the U.S. live with chronic hepatitis B (CHB), with a considerable percentage being older adults. The effectiveness of first-line nucleoside analogs (NAs) is significantly influenced by treatment adherence; however, evidence on longitudinal adherence patterns is limited. Therefore, we aim to examine adherence trajectories of NAs and identify predictors of non-adherence among older adults with CHB. **Methods:** This retrospective cohort study included continuously enrolled Medicare enrollees aged 65 years and older with CHB from 2014-2019. We included incident users of first-line NAs (including entecavir [ETV], tenofovir disproxil fumarate [TDF] and tenofovir alafenamide [TAF]) for CHB. Monthly adherence was evaluated using the proportion of days covered (PDC). Longitudinal patterns of adherence were discerned by group-based trajectory modeling (GBTM) over a 12-month follow-up period. The predictors of adherence trajectories were analyzed by a multinomial logistic regression model, accounting for sociodemographic and clinical factors as per the Andersen Behavioral Model. **Results:** Among 3,317 incident users of NAs, the mean age was 72.6 years, and 57.85% were male. GBTM identified three distinct adherence patterns: consistently adherent (57.1%), gradual decline in adherence (25%), and rapid decline in adherence (17.9%). The consistently adherent patients varied across the individual NAs (54.13% of ETV, 58.32% of TDF, and 71.91% of TAF). In the multinomial logistic regression model, using consistently adherent group as reference, compared to patients initiated on ETV, those prescribed with TAF had lower odds of being in the gradual decline (OR = 0.59; 95% CI: 0.43–0.81) and rapid decline groups (OR = 0.49; 95% CI: 0.34–0.72). African American patients had higher likelihood of belonging to the gradual (OR = 1.38; 95% CI: 1.05–1.82) and slow decline groups (OR = 1.52; 95% CI: 1.11–2.09), while Asian patients had lower odds for gradual decrease in adherence decline (OR = 0.70; 95% CI: 0.54–0.90). Lower likelihood of gradual decline was also observed among patients with HIV (OR = 0.62; 95% CI: 0.42–0.92), hepatocellular carcinoma (OR = 0.61; 95% CI: 0.38–0.98), and compensated cirrhosis (OR = 0.75; 95% CI: 0.58–0.98). **Conclusion:** Approximately two-thirds of older adults with CHB consistently adhered to NAs, and both clinical and demographic factors were associated with rapid and slow decline of adherence.

1293 | HBSAG SCREENING AND RISK FACTORS IN A NATIONWIDE PRIVATE LABORATORY PROGRAM

Liliana-Simona Gheorghe[1] Irma Csiki[1] Mihaela Ghioca[1] Mirela Chitul[1] Razvan Cerban[1] Carmen Ester[1] Roxana Saizu[1] Speranta Iacob[1], [1]Fundeni Clinical Institute

Background: Chronic viral hepatitis continues to exert a significant burden on public health in Romania. The RE-LINK project explores the potential of private laboratory networks to contribute to the national hepatitis elimination strategy through structured screening and reflex testing. This abstract presents the results of the prospective phase, focused on HBsAg testing and associated comorbidities in 8,188 adults from predefined risk groups. **Methods:** From January to March 2025, 8,188 individuals were tested for HBsAg, anti-HCV and anti-HDV antibodies in a national private laboratory chain. All HBsAg-positive patients underwent reflex testing for anti-HDV antibodies and HBV DNA, and a standardized questionnaire collected information on risk factors, comorbidities and socioeconomic status. **Results:** The overall HBsAg positivity rate was 3.03%, with detectable HBV viremia in 77% of cases. Anti-HDV antibodies were positive in 1.6% of HBsAg-positive patients. Only 5.4% of tested persons were vaccinated against HBV. HBsAg was more prevalent in men (3.84%) than women (2.62%) ($p = 0.014$). The median age was significantly higher in HBsAg-positive vs. negative individuals (57 vs. 54 years; $p = 0.002$). The key factors associated with HBsAg positivity ($p < 0.05$) included: knowledge of elevated transaminases ($p < 0.0001$), low platelet count ($p < 0.0001$), diabetes mellitus ($p = 0.03$), cardiovascular disease ($p = 0.0016$), neurological/psychiatric disorders ($p = 0.036$), frequent hospitalizations (≥ 2/year) ($p = 0.0042$), history of blood transfusions ($p = 0.017$), incarceration history ($p = 0.032$), known STIs ($p = 0.033$), HIV infection ($p = 0.038$), family history of hepatitis B/C/D ($p < 0.0001$), previous residence in orphanages/institutions ($p = 0.024$), abortion history ($p < 0.0001$), alcohol consumption above risk thresholds ($p = 0.012$). **Conclusion:** The RE-LINK prospective screening study confirms that private laboratory networks can serve as scalable platforms for viral hepatitis detection and linkage to care. This dataset provides the most extensive evidence to date of clinical and demographic risk associations for HBsAg positivity in Romania. Integration of such structured screening with reflex testing in national policy frameworks could accelerate HBV and HDV micro-elimination and reduce complications through earlier identification of high-risk individuals.

1294 | MITOCHONDRIAL STRESS IN PATIENTS WITH CHRONIC HEPATITIS B-RELATED HEPATOCELLULAR CARCINOMA

Abdellah Mansouri[1] Luis Correa[1] Manon Van den heede[1] Dorothy Tonui[2] Margaux BOSSIS[3] Stéphanie Narguet[4] Adel HAMMOUTENE[1] Nathalie BOYER[5] Pierre Tonnerre[3] Valerie PAradis[2] Tarik Asselah[6], [1]INSERM U1149, Centre de Recherche sur l'Inflammation, Université de Paris Cité, Paris, France., [2]INSERM U1149, Centre de Recherche sur l'Inflammation, Université de Paris Cité, Paris, France, [3]Institut de Recherche Saint-Louis, Université Paris-Cité, Inserm U1342, Paris, France., [4]Assistance Publique Hôpitaux de Paris, Hôpital Beaujon, Clichy-92110, France, [5]Assistance Publique Hôpitaux de Paris, Hôpital Beaujon, Service d'Hépatologie, Clichy, France, [6]Hôpital Beaujon

Background: Hepatitis B virus (HBV) interacts with hepatic mitochondria and increases liver oxidative stress. We hypothesized that HBV-induced mitochondrial stress might account for the pathophysiology of hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB). **Methods:** Fifty (50) mono-infected patients with CHB and HCC and 25 healthy controls were included in the study. Liver mitochondrial DNA (mtDNA) damage was screened by long PCR, Southern blot and Slot blot analysis. The expression of the mtDNA-encoded cytochrome *c* oxidase subunits 1 (MT-CO1), Parkinson-juvenile disease protein 2 (PRKN), Phosphatase and Tensin-Induced Putative Kinase-1 (PINK1), Lon Peptidase 1 (LONP1), mitochondrial chaperonins HSPD1 and HSPA9, as well as liver pro-inflammatory cytokines TNF-alpha and IL6 mRNA was investigated by Western-blotting and/or Reverse Transcriptase-quantitative PCR. In vitro, the HBV antigen HBx was expressed in hepatocarcinoma HepG2 cells, treated or not with cisplatin (CDDP), and mitochondrial parameters, Jun-c NH2 terminal Kinase 1 (JNK1) activation as well as apoptosis features were investigated. **Results:** Whereas 100% of patients with HCC exhibited multiple

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

mtDNA deletions, only 11% of the controls of comparable age ($kc^2 = 6.4$; $p < 0.01$) carried a single common mtDNA deletion. Significant decreases were observed in patients with HCC as compared to controls for the mtDNA-encoded MT-CO1 (0.69 ± 0.28 and 1.33 ± 0.85, *p < 0.001*), nuclear DNA-encoded HSPA9 (0.44 ± 0.21 and 1.13 ± 0.21, *p < 0.001*), HSPD1 (0.82 ± 0.25 and 1.80 ± 0.66, *p < 0.05*), LONP1 (0.80 ± 0.17 and 1.09 ± 0.32, *p < 0.05*), PRKN (0.44 ± 0.28 and 1.11 ± 0.38, *p < 0.0001*), and PINK1 (0.52 ± 0.06 and 1.16 ± 0.28, *p < 0.0001*). Liver TNFalpha mRNA was 1.53 ± 0.2 and 0.79 ± 0.14 (*p < 0.05*) and IL6 mRNA was 6.98 ± 0.88 and 1.36 ± 0.19 (*p < 0.05*) in patients with HCC and controls, respectively. Protein levels of MT-CO1, LONP1, PRKN, and PINK1 significantly decreased in patients HCC compared to the healthy controls. In vitro, HBx confers resistance to CDDP-induced JNK1 activation and to hepatocarcinoma HepG2 cells apoptosis. **Conclusion:** Diverse mtDNA damages were associated with alterations in mitochondrial function, mitochondrial unfolded protein response, mitophagy and liver inflammation in patients with CHB and HCC. Hbx antigen seems to confer chemo-resistance to CDDP in HepG2 cells.

1295 | EXPANSION OF DYSFUNCTIONAL MEMORY B CELLS IS ASSOCIATED WITH HEPATITIS FLARES AND DISEASE ACTIVITY IN CHRONIC HEPATITIS B

Thi Kim Duyen Nguyen[1] Yen-Chun Liu[2] Hsiang-Wei Huang[2] Chia-Wei Lin[2] Jian He Fan[2] Wei-Ting Ku[1] Cheng-Heng Wu[2] Rachel Wen-Juei Jeng[2] Chun-Yen Lin[2], [1]Chang Gung University, [2]Chang Gung Memorial Hospital, Linkou Medical Center

Background: Atypical memory B cells (atMBC) are a functionally impaired subset of B cells with enhanced pro-inflammatory cytokine profile that expand in chronic immune activation, including chronic hepatitis B (CHB). However, the clinical significance of atMBCs in CHB remains poorly understood. This study aims to elucidate the role of atMBCs in CHB by examining their relationship with hepatitis flare and virological parameters. **Methods:** A total of 42 patients with CHB were prospectively enrolled, including NA-treated (n = 30) and treatment-naïve (n = 12) subjects. Patients represented a spectrum of disease activity and ALT levels. Hepatitis flare was defined as ALT > 5 times the upper limit of normal (ULN). Six subsets of B cells in peripheral blood mononuclear cells were analyzed by flow cytometry. Clinical parameters, including ALT, HBV DNA, and quantitative HBsAg levels were collected at the time of sampling. Linear regression and Spearman correlation analysis were applied when necessary with statistical significance defined as $p < 0.05$. **Results:** The frequencies of atMBCs and activated memory B cells (actMBC) were significantly increased in CHB patients who were experiencing hepatitis flares compared to normal ALT CHB patients ($p = 0.003$ and $p = 0.0104$, respectively). The frequency of atMBCs was not associated with age and gender. AtMBCs and actMBCs were highly correlated with each other ($r = 0.7639$, $p < 0.0001$). atMBCs were positively associated with HBV DNA levels ($p = 0.0392$), but not with HBsAg levels ($p = 0.1806$). In contrast, actMBCs demonstrated a significant positive correlation with HBsAg levels ($p = 0.0182$). Classical memory B cells (cMBC) and naïve B cells were reduced in patients with hepatitis flare, although the differences were not statistically significant ($p = 0.342$ and $p = 0.1952$, respectively). Interestingly, the ratio of atMBC/actMBC was numerically significantly higher in patients with ALT > 5x ULN than patients with normal ALT (median: 4.112 vs. 2.547, $p = 0.0811$). This observation suggests that a higher grade of inflammation is associated with a stronger tendency toward the development of atMBC. **Conclusion:** Hepatitis flare in CHB is associated with an increase in both atypical and activated memory B cells. Moreover, a higher grade of liver inflammation correlates with a stronger tendency toward the development of atypical memory B cells. This implies that functionally exhausted atypical memory B cells might play an important role in patients with high grade of inflammation.

1296 | IMPACT OF INTERFERON RETREATMENT ON ACHIEVING HBSAG CLEARANCE IN PREVIOUSLY TREATED CHRONIC HEPATITIS B PATIENTS: IDENTIFICATION OF PREDICTIVE FACTORS AND CONSTRUCTION OF A PREDICTION MODEL

Huiling Xiang[1] Jun Li[2] Yanchao Fu[1] fei yan[2] Jing Chen[2] Qin Du[3] Qing Ye[1] Jing Liang[1] Chao Yang[1] Jiayin Wang[1], [1]Department of Gastroenterology and Hepatology, Tianjin University Central Hospital, [2]The Third Central Clinical College of Tianjin Medical University, Tianjin University Central Hospita, [3]Nankai University Affiliated Third Central Hospital, Tianjin University Central Hospital

Background: To explore predictive indicators for achieving HBsAg clearance in chronic hepatitis B (CHB) patients undergoing retreatment with interferon after initial non-response, providing evidence for clinical selection of responder populations. **Methods:** This single-center retrospective cohort study enrolled CHB patients and those with compensated cirrhosis who failed to achieve HBsAg clearance after first-line interferon therapy between January 2017 and April 2025. All participants received retreatment with pegylated interferon α-2b (Peg-IFNα-2b) monotherapy or combination therapy with nucleos(t)ide analogs (NAs), with a median follow-up of 48 weeks. The primary endpoint was HBsAg clearance (defined as HBsAg <0.05 IU/mL). Candidate variables were screened via univariate Cox proportional hazards regression analysis, optimized using least absolute shrinkage and selection operator (LASSO) regression, and core variables were identified through multivariate Cox regression analysis. A prediction model was constructed, and its discriminative ability was evaluated using Kaplan-Meier survival curves. **Results:** A total of 135 patients (median age 40.0 years, 74.1% male) with prior interferon non-response were included. Among them, 28 (20.74%) achieved HBsAg clearance after retreatment. Univariate, LASSO, and multivariate Cox regression analyses identified three independent predictors: HBsAg decline during initial interferon therapy (hazard ratio [HR] = 2.050), baseline HBsAg level at retreatment initiation (HR = 0.518), and treatment-free interval duration (HR = 1.015). The prediction model incorporating these variables demonstrated strong discriminative performance (area under the curve [AUC] = 0.930), with sensitivity of 92.6% and specificity of 80.5%. The Harrell's C-index was 0.904 (95% CI: 0.865–0.944). Stratification by nomogram scores revealed significantly higher cumulative HBsAg clearance rates at 48 weeks in high-score groups (≥ 74 points) compared to low-score groups (71.4% vs. 20.3% vs. 1.3%, log-rank $P < 0.001$) **Conclusion:** Retreatment with interferon can achieve HBsAg clearance in 20.74% of CHB patients who previously failed interferon therapy. Baseline factors including greater HBsAg reduction during initial therapy, lower HBsAg levels at retreatment initiation, and longer treatment-free intervals are associated with favorable outcomes. The proposed scoring system effectively identifies optimal candidates for interferon retreatment.

Jun Song[2] Hae Lim Lee[1] Chang Wook Kim[3] Jung Hyun Kwon[2], [1]The Catholic University of Korea, College of Medicine, [2]The Catholic University of Korea, [3]Uijeongbu St. Mary's Hospital

Background: Between September 2020 and January 2025, a total of 519 hepatocellular carcinoma (HCC) patients who met the eligibility criteria and received A-B treatment were included in the study. Among them, 260 patients (50.1%) had underlying hepatitis B virus (HBV) infection, and 85 patients (32.7%) received combination therapy with RT. The primary endpoints evaluated were progression-free survival (PFS) and overall survival (OS). scRNA-seq datasets from GSE156625, GSE149614, and GSE151530 were obtained with metadata extracted from the corresponding publications. **Methods:** Between September 2020 and January 2025, a total of 519 HCC patients who met the eligibility criteria and received A-B treatment were included in the study. Among them, 260 patients (50.1%) had underlying HBV, and 85 patients (32.7%) received RT combination therapy. The primary endpoints evaluated were progression-free survival (PFS) and overall survival (OS). scRNA-seq datasets from GSE156625, GSE149614, and GSE151530 were obtained with metadata extracted from the corresponding publications. **Results:** The median follow-up duration was 7.6 months. In A-B monotherapy, no significant differences were observed in PFS and OS between those with HBV-related HCC and others (7.56 vs. 7.19 months, $P = 0.7410$ and 4.04 vs. 4.93 months, $P = 0.5369$, respectively). However, in RT combination group, HBV-related HCC group demonstrated a trend toward improved OS (9.03 vs. 8.02 months, $P = 0.0300$). Among HBV patients, antiviral therapy was associated with a prolonged OS (11.90 vs. 7.23 months, $P = 0.0890$). scRNA-seq data from three datasets, comprising 43 patients and 88,572 cells, were collected and analyzed. Single-cell transcriptomic analysis revealed an increase in SPP1+ endothelial cells (ECs), suggesting enhanced non-VEGF-mediated angiogenesis in the HBV group. Consistently, pathway analysis indicated a downregulation of VEGF receptor expression in HBV-associated HCC. In cancer cells, HBV-related HCC had increase in inflammatory signatures with downregulation of VEGF ligand expression. **Conclusion:** The efficacy of A-B in HCC may be influenced by underlying etiology and treatment combination. While no significant differences in survival outcomes were observed between HBV-related and non-HBV-related HCC patients receiving monotherapy, HBV-related HCC exhibited improved OS when combined with RT. Additionally, antiviral therapy was associated with a trend toward prolonged survival in HBV patients. Mechanistic analysis using scRNA-seq revealed an increase in VEGF-independent endothelial cells, suggesting a shift toward non-VEGF-mediated angiogenesis in HBV-related HCC, accompanied by downregulation of VEGF receptor expression. These findings highlight potential differences in angiogenic pathways between HBV and non-HBV HCC, which may influence responses to VEGF-targeted therapy and provide insights for optimizing treatment strategies.

1298 | A NUCLEOSOME SWITCH PRIMES HEPATITIS B VIRUS INFECTION

Robert Schwartz[1], [1]Weill Cornell Medicine

Background: Chronic hepatitis B virus (HBV) infection is a global health problem causing significant liver disease and hepatocellular carcinoma. After viral entry, the HBV genome is shuttled into the nucleus and repaired from a partially double-stranded, relaxed circular DNA into a fully double-stranded, covalently closed circular DNA (cccDNA). The cccDNA rapidly becomes populated with host histone octamers and serves as the primary template for viral transcription. The viral protein HBx has a paradoxical relationship to cccDNA transcription during the earliest stages of infection. HBx induces the degradation of the host Smc5/6 complex, which otherwise would transcriptionally silence cccDNA, but is absent from the mature virion and must be expressed *de novo* in freshly infected hepatocytes. HBx is thought to be the earliest-expressed viral gene, with its transcript most abundant in the first 24 hours after HBV infection.

Moreover, the interplay between cccDNA chromatin state and viral transcription kinetics remains poorly understood despite its potential importance to the establishment of active chronic infection. **Methods:** Traditional genetic and cell biology approaches lack the temporal and biochemical resolution necessary to characterize this critical intermediate in HBV infection establishment. To surmount these difficulties, we developed a method to generate recombinant cccDNA minichromosomes in a chemically defined system, allowing us to characterize its biophysical properties and map nucleosome occupancy on the chromosome. **Results:** We apply biochemical techniques to demonstrate that chromatin assembly on cccDNA is spatially defined and critical for HBx mRNA expression, but not other viral transcripts. This is further confirmed in native HBV infection using transcriptomic and MNase-seq analysis. Finally, we demonstrate that small molecule-mediated disruption of nucleosome integrity is sufficient to inhibit HBx transcription, cccDNA content, and viral infection in hepatocytes. **Conclusion:** In summary, we show that cccDNA chromatin structure specifically regulates HBV RNA transcription and how when disrupted inhibits and alters HBV infection.

1299 | THE CLINICAL EFFICACY OF TENOFOVIR ALAFENAMIDE RE-TREATMENT IN CHRONIC HEPATITIS B PATIENTS WITH CLINICAL RELAPSE AFTER DISCONTINUATION OF ORAL ANTIVIRAL THERAPY

Tung-Hung Su[1] Yao-Chun Hsu[2] Yu-Jen Fang[3] Chih-Lin Lin[4] Chia-Chi Wang[5] Kuo-Chih Tseng[6] Chi-Yi Chen[7] Jia-Horng Kao[8], [1]National Taiwan University Hospital, [2]I-Shou University, [3]National Taiwan University Hospital, Yun-Lin Branch, Yun-Lin, Taiwan, [4]Department of Gastroenterology, Ren-Ai Branch, Taipei City Hospital, Taipei, Taiwan, [5]Taipei Tzuchi Hospital, the Buddhist Tzuchi Medical Foundation, Taipei, Taiwan, [6]Buddhist Tzu Chi General Hospital, Da-Lin Branch, Chiayi, Taiwan, [7]Chia-Yi Christian Hospital, [8]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Background: Retreatment is frequent in patients with chronic hepatitis B (CHB) who developed clinical relapse after cessation of oral antiviral therapy. Whether retreatment using the original regimen or switching to tenofovir alafenamide (TAF) would be beneficial remains unclear. We aimed to investigate the clinical effectiveness of switching to TAF after clinical relapse. **Methods:** This multicenter study enrolled CHB patients who experienced clinical relapse after discontinuing entecavir or tenofovir disoproxil fumarate [TDF] and switched the regimen to TAF for 48 weeks of retreatment. The primary endpoint was the rate of virological remission (HBV DNA <20 IU/mL), and the secondary endpoints were the rate of ALT normalization (<41 U/L), the change of HBsAg level, renal function, body weight, and lipid profiles. **Results:** The CHANGE (Chronic Hepatitis b patients switch to tAf after discontinuation of Nucleoside analoGuE) study (NCT04496882) included 48 patients previously treated with entecavir ($n=27$) or TDF ($n=21$) for a median duration of 3.2 years. At TAF retreatment, the median age was 48 years, 12.5% was HBeAg positive and HBV DNA was 6.5 $\log_{10}$ IU/mL. The virological remission rate was 58%, 77%, and 77% at 24, 36, and 48 weeks of therapy. The ALT normalization rate was 77%, 90%, and 85%, respectively. After 48-week TAF therapy, both their median HBsAg (3.3 to 2.7 $\log_{10}$ IU/mL, $P<0.001$) and HBcrAg (6.1 to 3.2 $\log_{10}$ IU/mL, $P<0.001$) declined significantly. Four of 6 (67%) HBeAg-positive patients cleared their HBeAg. There was a significant reduction of liver fibrosis by M2BPGi level (0.88 to 0.63 C.O.I., $P<0.001$). There was a significantly increase of serum creatinine (0.85 to 0.89 mg/dL, $P=0.022$), T-CHO (179 to 187 mg/dL, $P=0.019$), TG (81 to 94 mg/dL, $P=0.016$), and LDL (105 to 118 mg/dL, $P<0.001$), and a significantly reduction of HDL (59 to 55 mg/dL, $P=0.049$), while their body weight remained stable. The change of T-CHO, TG, and HDL after 48-week TAF therapy were insignificant if patients switched from TDF to TAF. The compliance was $>90\%$ and no significant adverse events were reported. **Conclusion:** TAF re-treatment after off-therapy relapse is safe and effective in viral suppression, ALT normalization, and liver fibrosis improvement. The renal function and lipid profiles should continue to be monitored.

Figure 1. The serial HBV serological and virological markers after retreatment of TAF in patients who experienced off-therapy flare of chronic hepatitis B.

1300 | REDUCING READ TIME OF POINT-OF-CARE TEST DOES NOT AFFECT DETECTION OF HEPATITIS B AND CORRELATES WITH HBSAG LEVELS

Judit Romero[1] ARIADNA RANDO-SEGURA[2] amanda beatriz Cohn[1] Xavier Major[3] Elena Vargas-Accarino[1] Adriana Palom[1] Juan Carlos Ruiz Cobo[4] Mar Riveiro-Barciela[4] Maria Buti[4], [1]Vall Hebron Research Institute, [2]Liver Pathology Laboratory, Microbiology and Biochemistry Department, Vall d'Hebron Clinical Laborat, [3]Programme on Addictions, HIV, Sexually Transmitted Infections and Viral Hepatitis, Public Health Ag, [4]Hospital Universitari Vall d'Hebron

Background: Global elimination of hepatitis B virus (HBV) requires improved diagnosis, particularly in resource-limited settings. Point-of-care (POC) HBsAg test are valuable for identification of HBV infection in community settings, particularly in areas with limited access to healthcare services. We investigated whether individuals with high levels of HBsAg could be identified using a shorter reading time (standard: 15–20 minutes), and potentially avoiding the need for HBV DNA testing where unavailable. **Methods:** Patients with past or current HBV infection and healthy controls were included between January and May 2025. Quantitative HBsAg was measure by a commercial assay (Elecsys HBsAg II, Roche) and qualitative HBsAg by rapid point-of-care (POC) test (Determine HBsAg 2, Abbott; LOD: 0.1 IU/mL). HBV-DNA was quantified by real-time PCR with the COBAS 6800 system (LOD: 10 IU/mL). Whole blood from finger-prick samples was tested immediately, and time to positive result was recorded. **Results:** Overali,133 patients were tested: 117 HBsAg-positive, 4 with past HBV infection and 12 healthy controls. Among HBsAg-positive subjects, 55 presented HBsAg $\leq$1,000 and 62 subjects $>$1,000 IU/mL. All HBsAg-positive patients had a positive POC result at a mean time of 2.27 $\pm$ 2.04 minutes. Test reading time was strongly negatively correlated with HBsAg levels (Pearson's r = –0.808, $p < 0.001$) (figure 1). Patients with HBsAg $\leq$1,000 IU/mL had a longer reading time than those with $>$1,000 IU/mL (3.5 $\pm$ 2.4 vs 1.16 $\pm$ 0.43 minutes, $p < 0.001$). HBV-DNA was detected in 59 cases, but no significant difference was found in POC reading times between those with detectable and undetectable HBV-DNA (N = 58) (1.37 vs 1.5, $p = 0.085$). However, inactive carriers (n = 20), defined as HBsAg $\leq$1,000 IU/mL and HBV-DNA $<$2,000 IU/mL, showed longer reading times compared to chronic hepatitis B (CHB, n = 10) (2.82 vs 1.09, $p = 0.005$). Using a 90-second cut-off, the test identified CHB (HBsAg $>$1000 IU/mL and $>$2000 IU/mL HBV DNA) with 80% sensitivity and 88% specificity (PPV 95.6% and NPV 57%) and at 60 seconds the sensitivity was 30%, specificity 100% (87.7% PPV and 100% NPV). All 4 patients with past infection and 12 healthy carriers tested negative on the capillary POC test. **Conclusion:** The wait time for the HBsAg rapid POC blood test can be reduced from 15-20 min to 5 min and continue to reliably identify patients with HBV infection. Shortening the test time could increase high-throughput screening, and reduce loss to follow-up.

1301 | EARLIER AND MORE SEVERE RELAPSE AFTER NUCLEOS(T)IDE ANALOGUE DISCONTINUATION IN HBEAG-POSITIVE CHRONIC HEPATITIS B PATIENTS

Yen-Chun Liu[1] CHIEN-WEI PENG[1] Rachel Wen-Juei Jeng[1] Rong-Nan Chien[1], [1]Chang Gung Memorial Hospital, Linkou Medical Center

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: HBeAg-positive and -negative chronic hepatitis B (CHB) represent distinct immunovirological phenotypes. However, many studies of finite nucleos(t)ide analogue (Nuc) therapy have analyzed them together, potentially obscuring the impact of baseline HBeAg status on off-Nuc outcomes. This study aimed to compare the incidence, timing, and severity of relapses after finite Nuc therapy between pretherapy HBeAg-positive and -negative patients. **Methods:** CHB patients who stopped Nuc therapy per APASL criteria (HBV DNA undetectable $\geq$1 year; HBeAg loss for $\geq$1 year) were analyzed. Clinical relapse (CR) was defined as ALT $\geq$2 times upper limit of normal (xULN) and HBV DNA $\geq$2000 IU/mL. Severe flare was defined as ALT $\geq$1000 U/L, total bilirubin $\geq$3.5 mg/dL or CR with hepatic decompensation (HD: total bilirubin $>$ 2mg/dL and INR $\geq$1.5). CR incidence, timing, and severity were compared between HBeAg-positive and -negative patients before and after propensity score matching (PSM) by age, sex, pretherapy ALT, HBV DNA, and end-of-treatment (EOT) HBsAg. Cox regression was used to identify predictors of severe flare. **Results:** A total of 286 HBeAg-positive and 2355 HBeAg-negative patients were analyzed (median follow-up: 4.6 years). CR occurred in 60% vs. 67%, respectively. HBeAg-positive patients had higher ALT at CR (345 vs. 244 U/L, $p<0.01$), more ALT $\geq$10$\times$ ULN (48% vs. 37%, $p<0.01$), higher HBV DNA at CR (7.3 vs. 5.7 $\log_{10}$ IU/mL), earlier relapse (34 vs. 39 weeks, $P<0.01$), and higher CR-related mortality (2% vs. 0.3%, $p=0.04$). After PSM ($n=265$/group), baseline characteristics were balanced. HBeAg-positive patients still had higher peak ALT, (345 vs. 269 U/L), HBV DNA at CR (7.3 vs. 6.4 $\log_{10}$IU/mL), and HD incidence (3% vs. 0%) (all $p<0.05$). The 2-year cumulative incidence of severe flare was higher in HBeAg-positive patients before and after PSM (pre: 11% vs. 8%, $p=0.02$; post: 11% vs. 7%, $p=0.12$), while CR rates post PSM were comparable (58% vs. 66%, $p=0.20$). In multivariate analysis, pretherapy HBeAg positivity (aHR: 1.6), cirrhosis (aHR: 1.8), ALT $\geq$5$\times$ ULN (aHR: 1.8), and non-entecavir use (aHR: 1.7) independently predicted severe flare among off-Nuc CR patients. **Conclusion:** HBeAg-positive CHB patients experience earlier and more severe relapses after finite NUC therapy. Off-therapy outcomes should be stratified by baseline HBeAg status, with intensified monitoring recommended for those with cirrhosis, pretherapy flare, or non-entecavir use.

1302 | IDENTIFICATION OF FDA-APPROVED COMPOUNDS THAT SUPPRESS HBS ANTIGEN THROUGH LIBRARY SCREENING

Kazuhiro Murai[1] Akiyoshi Shimoda[1] Takao Kitanaka[1] Takayuki Miyake[1] Shinji Kuriki[1] Emi Sometani[1] Jihyun Sung[1] Satoshi Shigeno[1] Kumiko Shirai[1] Yuki Tahata[1] Yoshinobu Saito[1] Takahiro Kodama[1] Hayato Hikita[1],
[1]The University of Osaka, Graduate School of Medicine

Background: Hepatitis B surface antigen (HBsAg), a structural protein of the hepatitis B virus (HBV), plays a role in the development of hepatocellular carcinoma and immune exhaustion, thereby facilitating chronic infection. Current anti-HBV therapy, nucleos(t)ide analogue (NUC) have little effect on HBsAg. We aim to discover novel agents that reduce HBsAg using an FDA-approved compound library and to define the mechanisms responsible for their efficacy. **Methods:** A library of 1134 FDA-approved drugs was screened on HepG2.2.15.7 cells, HBV genome integrated cells, at 9.9 μM for 7 days. After incubation, HBsAg levels in the supernatant and cell viability were measured. Compounds reducing viability by more than 1 standard deviation (SD) were excluded; those reducing HBsAg by more than 1.5 SD were selected as candidates. These were retested at 5 and 0.5 μM. Compounds reducing HBsAg at both doses were selected as final candidates. To explore the mechanism, final candidates were tested on HepG2.2.15.7 and HBV-inoculated (1000 genome equivalent/cell) primary human hepatocytes from TK-NOG mice (HepaSH cells). **Results:** A total of 126 compounds were excluded from further analysis due to their cytotoxic effects. Six compounds were identified as candidate compounds with HBsAg levels decreased. Among them, only ethacridine and auranofin significantly reduced HBsAg levels at both 5 μM and 0.5 μM concentrations. Using HepaSH cells, while ethacridine did not decrease HBsAg, auranofin decreased HBsAg. Auranofin did not reduce the levels of hepatitis B e antigen (HBeAg), HBV DNA in the supernatant, or pregenomic RNA (pgRNA). In addition, Western blotting did not show a change in intracellular HBsAg by auranofin. Transmission electron microscopy revealed more vesicles within the endosomes of auranofin-treated HepaSH cells than those of untreated HepaSH cells. Western blotting showed that auranofin treatment enhanced protein expression of Galectin-3, a marker of damaged lysosomes. Immunofluorescence staining demonstrated co-localization of HBsAg with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Galectin-3. It is suggested that auranofin-induced lysosomal damage led to the accumulation of Galectin-3, which co-localized with HBsAg, resulting in the suppression of extracellular HBsAg secretion. **Conclusion:** FDA approved drug library screening identified auranofin which suppresses HBsAg levels.

1303 | IMPACT OF BASELINE HBEAG STATUS ON HBV OUTCOMES IN THE ALLIANCE STUDY

Anchalee Avihingsanon[1] Chee Loon Leong[2] Chien-Ching Hung[3] Sasisopin Kiertiburanakul[4] Man-Po Lee[5] Hui Liu[6] Sharline Madera[6] Jason Hindman[6] Taisheng Li[7], [1]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Hospital Kuala Lumpur, Kuala Lumpur, Malaysia, [3]National Taiwan University Hospital & National Taiwan University College of Medicine, Taipei, Taiwan, [4]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [5]Queen Elizabeth Hospital, Hong Kong, China, [6]Gilead Sciences, Inc., Foster City, CA, USA, [7]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: Baseline (BL) hepatitis B e-antigen (HBeAg) status has been associated with differential hepatitis B virus (HBV) treatment responses in individuals with HBV monoinfection. In treatment-naïve adults with HIV-1 and HBV co-infection, the ALLIANCE study demonstrated that bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) achieved superior HBV DNA suppression compared to dolutegravir plus emtricitabine/tenofovir disoproxil fumarate (DTG+F/TDF) at Week (W) 48, with sustained improvements through W144. This subanalysis assessed HBV virologic outcomes by BL HBeAg status. **Methods:** ALLIANCE (NCT03547908) was a randomized, double-blind, active-controlled Phase 3 clinical study. Here we present data from participants who received B/F/TAF through W144 ($\geq$96 weeks of blinded treatment + 48-week optional open-label extension [OLE]), and in participants who switched to B/F/TAF after $\geq$96 weeks of DTG+F/TDF through OLE W48. BL demographics, HBV DNA $<$29 IU/mL, ALT normalization (2018 AASLD criteria), HBeAg loss/seroconversion and surface antigen (HBsAg) loss/seroconversion at W96 and OL W48, were assessed by BL HBeAg status using Missing = Excluded (M = E) approach. **Results:** Among 241 participants, 54 (22.4%) enrolled with BL HBeAg-, median age 38, 89% male; 187 (77.6%) enrolled with BL HBeAg+, median age 31, 98% male. BL HBeAg status was comparable across treatment groups. At W96, all participants with BL HBeAg- achieved HBV DNA $<$29 IU/mL regardless of treatment group while 74.7% and 70.3% of those with BL HBeAg+ achieved the same on B/F/TAF and DTG+F/TDF, respectively. In BL HBeAg+, W96 HBeAg loss/seroconversion were 41%/34.9% on B/F/TAF and 20.9%/16.5% on DTG+F/TDF; and HBsAg loss/seroconversion for BL HBeAg- and HBeAg+ were 18.5%/11.1% and 27.2%/9.9% and 4.5%/4.5% and 17.8%/7.8%, respectively. ALT normalization was 93.3% (BL HBeAg-) and 72.5% (BL HBeAg+) on B/F/TAF, and 50.0% and 64.7% on DTG+F/TDF, respectively. At OLE W48, BL HBeAg- participants exhibited higher HBV DNA suppression rates across treatment groups compared to HBeAg+, with continued HBe/sAg loss/seroconversion and ALT normalization observed through OLE W48. **Conclusion:** In HIV/HBV co-infected individuals who started tenofovir-containing combination ART, BL HBeAg- correlated with greater HBV suppression when compared to BL HBeAg+ through 144 weeks. Continued improvements in HBe/sAg loss/seroconversion and/or ALT normalization persisted through 144 weeks of tenofovir-containing combination ART in both BL HBeAg- and BL HBeAg+.

Virologic and Immunologic Outcomes Through W144 (M=E)

Randomized Phase: W96				
	B/F/TAF		**DTG+F/TDF**	
HBeAg status at baseline[a] n/N (%)	+ **N=90**	- **N=29**	+ **N=97**	- **N=25**
HBV DNA < 29 IU/mL	62/83 (74.7)	27/27 (100.0)	64/91 (70.3)	22/22 (100.0)
HBeAg loss	34/83 (41.0)	NA	19/91 (20.9)	NA
HBeAb seroconversion	29/83 (34.9)	NA	15/91 (16.5)	NA
HBsAg loss	22/81 (27.2)	5/27 (18.5)	16/90 (17.8)	1/22 (4.5)
HBsAb seroconversion	8/81 (9.9)	3/27 (11.1)	7/90 (7.8)	1/22 (4.5)
ALT normalization (2018 AASLD)[b]	29/40 (72.5)	14/15 (93.3)	22/34 (64.7)	5/10 (50.0)
W144 (W48 Open-Label Extension Phase)[c]				
	B/F/TAF		**Switch From DTG+F/TDF to B/F/TAF**	
HBeAg status at baseline[a] n/N (%)	+ **N=90**	- **N=29**	+ **N=72**	- **N=17**
HBV DNA < 29 IU/mL	60/81 (74.1)	25/25 (100)	55/66 (83.3)	16/16 (100)
HBeAg loss	26/58 (44.8)	NA	8/47 (17.0)	NA
HBeAb seroconversion	17/58 (29.3)	NA	6/47 (12.8)	NA
HBsAg loss	13/58 (22.4)	3/13 (23.1)	3/55 (5.5)	0/15 (0)
HBsAb seroconversion	8/58 (13.8)	3/13 (23.1)	0/55 (0)	0/15 (0)
ALT normalization (2018 AASLD)[b]	28/38 (73.7)	13/14 (92.9)	11/18 (61.1)	2/7 (28.6)

[a]Baseline in randomized phase is defined as the first dose date of randomized study drug (ie, B/F/TAF, DTG+F/TDF). Baseline in open-label extension phase is defined as the first dose date of B/F/TAF in the randomized phase for B/F/TAF group, the first dose date of B/F/TAF in the extension phase for switch from DTG+F/TDF to B/F/TAF group. [b]Reduction in ALT to ≤ ULN for participants with ALT > ULN at baseline, based on American Association for the Study of Liver Diseases 2018 criteria, where ULN is 25 U/L for females and 35 U/L for males. [c]OLE W48 corresponds to W144 for B/F/TAF group and W48 for DTG+F/TDF to B/F/TAF group.

1304 | LONG-READ TRANSCRIPTOMIC LANDSCAPE OF LIVER BIOPSIES FROM PATIENTS FUNCTIONALLY CURED OF CHB

Bei Jiang[1] Jia Li[1] Lili Zhao[1] Minghui Li[2] Fengmin Lu[2], [1]Tianjin Second People's Hospital, [2]Peking University

Background: HBsAg seroclearance is considered the hallmark of hepatitis B virus infection resolution. Nonetheless, about 5-10% of patients who achieved functional cure with pegylated interferon–based regimens subsequently experience HBsAg seroreversion. Therefore, an in-depth characterization of the HBV transcriptomic landscape in liver tissue would improve our understanding on the virological charateristics for sustant HBsAg seroclearance in patients with functional cure of chronic hepatitis B. **Methods:** HBV transcripts in the liver tissue from four patients(patient2-5)who have achieved HBsAg seroclearance following NA/Peg-IFNα combination therapy were analyzed via long-read transcriptome sequencing through Nanopore sequencing. In parallel, an interferon treatment naïve patient was recruited as control (patient1). The sequencing reads were subjected to quality control, and then aligned to the HBV ayw genotype using minimap2. The alignment results were visualized using R. **Results:** Analysis of polyadenylation status revealed the entirely lack of classical polyadenylation (0%) in both the untreated patient (P1) and the cured patient (P2) with intrahepatic HBsAg-positive staining, which suggested the viral transcripts were originated from the integrated HBV DNA. In contrast, the cured, hepatic HBsAg-negative group (P3-P5) showed a small fraction (1.2%) of classically polyadenylated HBV RNA, indicating a minor contribution from cccDNA, though transcripts from integrated HBV DNA still predominated. Further analysis revealed that the 2.1kb HBsAg RNA in the untreated control (P1) was the most abundant species (61%), followed by the 2.4kb HBsAg RNA (9%), while the 0.7kb RNA constituted a minor fraction (0.4%). A same pattern of 2.4/2.1kb HBsAg RNA was observed in patient (P2) with liver HBsAg-positive with 0.7kb RNA abundancy at 2%. For the cured group (P3-P5), the 0.7kb RNA species was notably more abundant, representing 33% of the HBV RNA reads, though the 2.1kb HBsAg RNA accounted for 37% of transcripts and undetectable (0%) 2.4kb HBsAg RNA. **Conclusion:** Long-read sequencing demonstrated that low-level HBV transcripts, predominantly transcribed from integrated viral DNA, persist in hepatic tissue despite serologic HBsAg clearance. Accordingly, vigilant surveillance for virologic relapse is especially critical when immunosuppressive therapy is anticipated or underway in those functional cured CHB patients.

1305 | NOVEL, HIGH-SENSITIVE IMMUNOASSAYS FOR PHOSPHORYLATED AND NON-PHOSPHORYLATED HBCAG DETECTION

Rene Geissler[1] Megha Patel[1] Michael Berg[1] Gavin Cloherty[1], [1]Abbott

Background: Current HBV guidelines for treatment eligibility are based on HBV DNA viral load levels. Specifically, for HBV infected patients with DNA levels ≥2,000 IU/ml (HBeAg-) or ≥20,000 IU/ml (HBeAg+), antiviral therapies are recommended. However, HBV molecular assays to monitor HBV DNA levels are often unavailable or unaffordable in low- and middle-income countries (LMIC). We previously developed two novel HBcAg immunoassays to specifically detect non-phosphorylated HBcAg as surrogate marker for HBV DNA-containing particles (referred as HBcAg) and phosphorylated HBcAg (referred as P-HBcAg), which represents

non-HBV DNA-containing particles. HBcAg and P-HBcAg correlate best with HBV DNA as compared to HBV core-related antigen (HBcrAg). Here, we describe improved P-HBcAg/HBcAg assays with superior performance and higher sensitivity that should enable decisions to put patients on antiviral therapy. **Methods:** The improved P-HBcAg and HBcAg assays use specific monoclonal antibodies to capture and detect either non-phosphorylated or phosphorylated HBcAg that are secreted from HBV infected hepatocytes into the blood stream. P-HBcAg and HBcAg signals are measured as relative light units (RLUs). We analyzed single timepoint specimens from HBV infected patients with viral loads ranging from 10^2 to 10^8 HBV DNA IU/ml. **Results:** Several factors were optimized, including new monoclonal antibodies, to increase the limit of quantification (LOQ) for P-HBcAg and HBcAg, respectively. Serial dilutions of specimens from HBV infected patients revealed that P-HBcAg could be detected at HBV DNA levels as low as 60 IU/ml. HBcAg, which represents infectious HBV DNA-containing particles and is the least abundant antigen, is still detectable at HBV DNA levels as low as 1,000 IU/ml. **Conclusion:** The ability to specifically detect low abundant P-HBcAg/HBcAg levels at the lower limit of HBV DNA levels that qualify for treatment eligibility provides additional insights for disease staging. The assays have the potential to be made available at lower cost compared to molecular assays and are more easily deployable in low- and middle-income countries where HBV diagnosis and verification of response to therapies are most needed.

1306 | DYNAMICS OF GENE EXPRESSION IN THE HUMANIZED LIVER INFECTED WITH PRECORE AND BASAL CORE PROMOTER MUTATED HBV

Takuro Uchida[1] Kei Mori[1] Haruna Noguchi[1] Tomoko Tokumaru[1] Tomoko Saito[1] Masao Iwao[1] mie arakawa[1] Mizuki Endo[1] Masataka Tsuge[2] Kazuaki Chayama[3] Kazuhiro Mizukami[1], [1]Oita University, [2]Hiroshima University Hospital, [3]Hiroshima Institute of Science

Background: Mutations within the precore (PC) and basal core promoter (BCP) regions of the HBV genome are associated with fulminant hepatitis and HBV reactivation. We previously reported that PC and BCP mutations were associated with enhanced viral replication and cell death induced by ER stress using HBV infection models, indicating these mutations might be associated with liver damage in patients with fulminant hepatitis or HBV reactivation (Uchida et al, *Hepatology*, 2023). In previous study, RNAseq revealed the molecular characteristics in PC/BCP mutant HBV infection. Herein, we assessed dynamics of the expression of the genes which is up- or down-regulated in PC/BCP mutated HBV infection. **Methods:** Mice with humanized livers were infected with either wild-type (HBV-wt) or mutant-type PC/BCP HBV (HBV-mt/mt) and sacrificed at various phase of HBV replication. Three HBV-infected mice were assigned for each time points. The top 10 genes extracted from RNAseq in humanized liver infected with PC/BCP mutated HBV were investigated. As a control, uninfected mice were prepared. **Results:** HBV-mt/mt-infected mice without human albumin reduction (indicating human hepatocyte loss) were sacrificed at the four time points (average serum HBV DNA levels were 6.36, 7.71, 9.9, and 10.7 log copies/ml, respectively). HBV-mt/mt-infected mice with human hepatocyte loss were also sacrificed (HBV DNA levels was 10.6 log copies/ml). For HBV-wt infection, the mice were sacrificed at the time that serum HBV DNA level was 6.09, 7.33, 7.56, and 9.3log copies/ml, respectively. HBV-mt/mt infected mice showed higher replication compared with HBV-wt infection. The expression of FST, DDB2, PHLDA3, and GDF15 was stable in HBV replication phase and excessively increased at and after peak of viremia. CES and FAM111B expression was down-regulated only in HBV-mt/mt mice at and after the peak of viremia. GPC3 expression was down-regulated in mice infected with both HBV-wt and HBV-mt/mt with higher viremia over 9 log copies of HBV DNA levels. **Conclusion:** HBV infection induce the change of gene expression in HBV-infected hepatocytes, and the dynamics of gene expression was different between HBV-mt/mt infection and HBV-wt infection. This difference might be affected the phenotype for liver diseases. Further study is needed to clarify the pathophysiology of hepatitis B.

Background: The long-term clinical benefits of interferon (IFN)-based therapy compared to nucleos(t)ide analogue (NA) monotherapy in HBeAg-positive chronic hepatitis B (CHB) have not been well defined. This study aimed to evaluate the cumulative incidence of new-onset cirrhosis, serological responses, and hepatocellular carcinoma (HCC) development between these treatment strategies. **Methods:** Two independent cohorts of non-cirrhotic, HBeAg-positive CHB patients were analyzed: a treatment-naïve cohort (n = 686) and an NA-experienced cohort (n = 531). Patients received either IFN-based therapy or NA monotherapy. Propensity score matching (PSM) was employed to minimize intergroup heterogeneity. The primary endpoint was the cumulative incidence of new-onset cirrhosis. **Results:** After PSM, the 10-year cumulative incidence of new-onset cirrhosis was significantly lower in the IFN-based therapy group compared to the NA monotherapy group in both the treatment-naïve (3.3% vs 20.0%, $p = 0.005$) and NA-experienced (4.9% vs 20.9%, $p = 0.034$) cohorts. IFN-based therapy also resulted in significantly higher serological response rates across both cohorts, including HBeAg loss (treatment-naïve: 84.7% vs 55.6%; NA-experienced: 60.4% vs 43.6%, both $p < 0.001$) and HBsAg loss (treatment-naïve: 14.3% vs 5.7%, $p = 0.006$; NA-experienced: 10.2% vs 1.3%, $p < 0.001$). Subgroup analysis showed that patients receiving IFN-based therapy who achieved HBeAg loss within 96 weeks had the greatest long-term benefits, with lower cirrhosis incidence and higher HBsAg loss rates. Although the incidence of HCC was lower in the IFN-based group, the difference did not reach statistical significance (both $p > 0.05$). **Conclusion:** IFN-based therapy provides superior long-term benefits over NA monotherapy in reducing cirrhosis risk and enhancing serological responses in HBeAg-positive CHB patients.

1308 | RETROSPECTIVE ANALYSIS OF B-CLEAR STUDY HBSAG LEVELS WITH THE ULTRASENSITIVE LUMIPULSE HBSAG ITACT ASSAY AND ASSOCIATION WITH RESPONSE AND RELAPSE

Scott Speer[1] Yasuhito Tanaka[2] Jerome Bouquet[3] Jennifer Cremer[4] Gift Nyamundanda[5] Lauren Maynard[5] Maria Agostini[3] Dickens Theodore[4] Rob Elston[5] Jill Walker[3], [1]GSK, Collegeville, PA, USA, [2]Department of Gastroenterology and Hepatology, Kumamoto University, Kumamoto, Japan, [3]GSK, South San Francisco, CA, USA, [4]GSK, Durham, NC, USA, [5]GSK, Stevenage, Hertfordshire, UK

Background: Bepirovirsen is an unconjugated antisense oligonucleotide in development for chronic hepatitis B virus (HBV) infection that has been shown to reduce hepatitis B surface antigen (HBsAg). The B-Clear Phase 2b study used the CE marked Roche Elecsys HBsAg II quant II (clinical trial test [CTT]) assay to measure HBsAg reductions. In this post hoc analysis, we explored whether the in-development Fujirebio Lumipulse iTACT HBsAg (iTACT) assay could support modeling of response or relapse in participants (pts) with chronic HBV infection receiving bepirovirsen. **Methods:** B-Clear randomized pts with chronic HBV infection on or not on nucleos(t)ide analogs to receive up to 300 mg bepirovirsen weekly for 12 or 24 weeks with or without loading doses.[1] Responders were pts who achieved HBsAg < limit of detection (LOD; 0.05 IU/mL) and HBV DNA < lower limit of quantification (LLOQ; 20 IU/mL) for 24 weeks after planned bepirovirsen treatment end in the absence of rescue medication. Non-responders did not achieve this endpoint, and a subset of those were relapsers who achieved HBsAg < LOD and HBV DNA < LLOQ at any time point but did not maintain HBsAg or HBV DNA loss. Samples from responders, non-responders, and relapsers at Weeks 9, 17, 23, and off-treatment Weeks 4, 12, and 24 (N = 50 pts, N = 300 samples) were analyzed using the iTACT HBsAg assay (LLOQ = 0.0005 IU/mL). For both assays, a linear mixed effects model evaluated the association of HBsAg with response. Logistic and/or multinomial regression models evaluated the association of HBsAg with response or relapse. **Results:** Both assays showed a strong association between HBsAg and response over time; the overall p value for all time points was the same (0.0011; Table). The iTACT assay provided quantitative

values for 165/183 (90%) of samples that were < LLOQ with the CTT. The relative associations with response and relapse for the iTACT and CTT assays (area under the receiver operating characteristic curves; higher percentages indicate better discrimination) were 75% vs 62% [Week 17 response], 74% vs 64% [Week 17 relapse], 72% vs 58% [Week 23 response], and 80% vs 64% [Week 23 relapse], respectively. **Conclusion:** The iTACT HBsAg assay provides additional data with improved resolution to support pharmacokinetic/pharmacodynamic modeling. However, further studies with larger sample sizes and additional time points are needed to confirm the findings.

1309 | THE RATE OF OCCULT HEPATITIS B VIRUS INFECTION IN HIGH ENDEMIC AREAS - VALUE IN EVALUATING LIVER FIBROSIS AND THE ROLE OF HBCRAG

Thuy Pham[1] Dat Ho[1] Toan Nguyen[1,] [1]Medic Medical Center

Background: Aim: Vietnam is a high epidemiological area of hepatitis B virus with high rates of cirrhosis and liver cancer. Among those, occult hepatitis B virus infection (OBI) plays an important but it is easily neglected. Therefore, the purpose of the study is to invests: -OBI rate in HBsAg negative, and AntiHBc positive subjects. -To evaluate the degree of liver fibrosis in these patients. -The role of HbcrAg. **Methods:** Research subjects and methods: Cross-sectional retrospective, random screening of 1492 subjects, HBsAg negative, AntiHBc positive subjects were tested for HBV DNA using polymerase chain reaction (PCR) amplification technique to determine the OBI rate. These subjects were also evaluated for liver fibrosis and tested for HBcrAg. **Results:** Results: Among 1492 subjects, there were 537 (35.99%) cases of HBsAg negative and AntiHBc positive. These patients were tested for HBV DNA to determine the OBI rate, accounting for 7.26% (39/537), average age was 49 ± 12, female was 49.72% (267/537). In the OBI group, F1 fibrosis was 7.69% (3/39), F2 was 15.38% (6/39), F3 was 30.76% (12/39), and F4 was 47.36% (18/39). There were 2 HCC patients with F4 fibrosis, accounting for 5.12% (2/39). When quantifying HBcrAg, 53.84% were greater than 2 log U/mL and less than or equal to 3 log U/ml, 46.15 % (18/39) were greater than 3 log U/mL, 2 HCC patients had HBcrAg greater than 3 log U/mL. All patients in the group of HBsAg negative, AntiHBc positive with non-OBI had F1 liver fibrosis and only 7.22% (36/498) patients had HBcrAg greater than 2 log U/mL. **Conclusion:** It is necessary to screen for OBI in the group of patients with HBsAg negative, AntiHBc positive, pay attention to patients with higher liver fibrosis score (F3, F4), HBcrAg greater than 2 log U/mL, and patients with clinical manifestations of HCC. **Disclosures:** Thuy Pham: Nothing to Disclose, Dat Ho: Nothing to Disclose, Toan Nguyen: Nothing to Disclose

1310 | FREQUENCY, AGE, CHARACTERISTICS, AND OUTCOMES OF SEROLOGICAL STATUS TRANSITION IN HBEAG-NEGATIVE CHB PATIENTS: INSIGHTS FROM THE HEPCARE LONG-TERM LONGITUDINAL COHORT

Ci Song[1] Jie Jiang[2] Siyu Wang[1] Chengxiao Yu[3] Wentao Yao[1] Jiao Qian[2], [1]Nanjing Medical University, [2]Jiangsu Provincial Center for Disease Control and Prevention, [3]The First Affiliated Hospital of Nanjing Medical University

Background: Serological transitions toward functional or partial cures in HBeAg-negative chronic hepatitis B (ENCHB) patients are crucial for understanding the natural history of HBV, evaluating antiviral treatment efficacy, and assessing the long-term risks of adverse outcomes. This study analyzed serological transition patterns, the incidence and characteristics of functional and partial cures, and their impact on long-term

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

outcomes in ENCHB patients. **Methods:** In this multicenter, long-term prospective HEPCARE cohort, 4,010 ENCHB patients were followed from 2012 to 2023. Functional cure was defined as sustained HBsAg loss and undetectable HBV DNA during follow-up, which were categorized as "gold medalists". Partial cure was defined as sustained undetectable HBV DNA, categorized as "silver medalists". Patients with unchanged serological status were classified as persistent ENCHB. **Results:** After a median follow-up of 10.69 years, 288 and 949 patients were classified as gold and silver medalists respectively, with annual incidence rates of 0.88% for functional cure and 3.83% for partial cure. Most gold medalists (67.7%, 195 patients) first experienced HBV DNA seroclearance, followed by HBsAg loss. Among the patients who achieved partial cure, 112 experienced HBV DNA reactivation. Regardless of baseline HBV DNA levels, antiviral therapy significantly increased the incidence of partial cure by age 50 ($P < 0.001$), but had no significant effect on functional cure. The gold and silver groups showed statistically lower HBV DNA levels compared to the persistent ENCHB group at baseline, while serum ALT and AST levels exhibited a significant decline from 2016. Furthermore, the long-term risk of adverse outcomes (i.e. all-cause and liver-related mortality, cirrhosis, and hepatocellular carcinoma) was similar between the gold and silver groups, both of which showed significantly reduced risks compared to the persistent ENCHB group. **Conclusion:** Functional and partial cures are key milestones in the management of ENCHB, significantly reducing disease progression and mortality. Dynamic monitoring of serological markers can help improve both short- and long-term outcomes.

1311 | SYSTEMATIC REVIEW AND META ANALYSIS OF HEPATOCELLULAR CARCINOMA RISK IN HISPANIC AND LATIN AMERICAN PATIENTS WITH CHRONIC HEPATITIS B

Jonathan Lim[1] Ariel Lee[2] Gisela Butera[3] Sungyoung Auh[1] Kali Zhou[2] Christine Hsu[1], [1]National Institute of Diabetes and Digestive and Kidney Diseases, [2]Keck Medicine of USC, [3]National Institutes of Health Library

Background: Hepatocellular carcinoma (HCC) incidence in chronic hepatitis B (CHB) varies by race. Current AASLD guidelines recommend HCC screening in African or African American individuals at earlier ages and in males and females with CHB aged > 40 years and > 50 years, respectively, from endemic regions. HCC incidence in Hispanic and Latin American CHB is not well studied, and surveillance in this group is not specifically addressed. This systematic review evaluates overall HCC incidence in Hispanics and Latin Americans with CHB. **Methods:** A systematic review was conducted using PubMed, Embase, CENTRAL, Web of Science, and LILACS to search for eligible observational cohort studies and randomized-control trials prior to February 4, 2025. Eligible studies included Hispanic and/or Latin American adults (greater than or equal to 18 years old) with CHB. Outcomes evaluated include HCC and mortality incidence. Two reviewers (AL and JL) independently extracted data and performed risk of bias assessments using a tool developed and validated by Hoy et al. 2012, with discrepancies resolved by CH. Statistical analysis was performed using the R package “metarate”. Heterogeneity was assessed using Cochrane’s Q-test and quantified by I^2. **Results:** 2395 studies were screened, with 84 studies eligible for full-text review. 75 studies were excluded due to wrong outcomes, study populations, study designs, and duplication. 9 observational studies were included in the meta-analysis: 5 from the US, 3 from Brazil, and 1 across multiple countries. The overall pooled HCC incidence rate for Hispanic/Latin American CHB patients was 1.08 (95% CI 0.51-1.66) per 100 patient-years (pt-yrs). The I^2 was 80%, suggestive of a large amount of heterogeneity. After excluding a study conducted among only CHB patients with cirrhosis, the HCC incidence rate decreased to 0.87 (95% CI 0.43-1.31) per 100 pt-yrs. Influential analyses showed that when removing one study with 100% co-infected HIV (human immunodeficiency virus), the overall pooled incidence rate was similar (1.25 [95% CI 0.59-1.91] per 100 pt-yrs). When removing one study with 100% co-infected hepatitis D, effect estimates also remained similar (1.01 [95% CI 0.40-1.63] per 100 pt-yrs). The incidence of all-cause mortality using 4 studies was 1.98 (95% CI 0.92-3.05) per 100 pt-yrs. **Conclusion:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The calculated HCC incidence rate in Hispanic/Latin American CHB patients is similar than other at-risk populations and above the threshold of $>0.2\%$ per year where screening for HCC becomes recommended for CHB patients from endemic areas. This suggests the need for screening in this population, and further prospective studies are needed to confirm the observed rate.

1312 | IMMUNE COMPLEXES OF BJT-778 ENHANCE CROSS-PRESENTATION OF HBSAG AND ACTIVATION OF CD8+ T CELLS

Adam Gehring[1] Loghman Salimzadeh[2] Stuti Shah[2] Danie La[2] Hilario Ramos[3] Leesun Kim[3] Nancy Shulman[3] Hassan Javanbakht[3], [1]Toronto Centre for Liver Disease, Schwartz-Reisman Liver Research Centre, Toronto, Canada, [2]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada, [3]Bluejay Therapeutics, Inc., Redwood City, United States

Background: Chronic hepatitis B (CHB) is characterized by persistently high levels of hepatitis B surface antigen (HBsAg), which contribute to the dysfunction of HBV-specific T cells. BJT-778 is a fully humanized IgG1 monoclonal antibody that targets the antigenic loop of HBsAg and is currently in Phase 1/2 clinical development for chronic hepatitis B and D. We previously demonstrated that BJT-778 enhances the uptake of HBsAg by professional antigen-presenting cells (APCs) through the formation of immune complexes (ICs), leading to improved activation of CD4+ T cell responses. However, its capacity to promote cross-presentation and activation of CD8+ T cells has not yet been investigated. **Methods:** CD14+ monocytes isolated from healthy HLA-A02+ donors were loaded with either recombinant HBsAg or CHB serum-derived HBsAg in the presence or absence of BJT-778 to form ICs. Cells were differentiated into monocyte-derived dendritic cells (moDCs) and matured with R848, sCD40L, and IFNγ. Mature DCs were co-cultured with an HLA-A02-restricted HBsAg-specific CD8+ T cell clone. Antigen-specific responses were measured via IFN-γ ELISpot. **Results:** Formation of HBsAg ICs using BJT-778 significantly enhanced activation of CD8+ T cells compared to antigen alone. This enhancement was observed with both recombinant and serum-derived HBsAg, demonstrating the capacity of BJT-778 ICs to drive cross-presentation of diverse antigen sources. Across multiple CHB patient sera tested, BJT-778 ICs consistently increased the magnitude of IFN-γ production by CD8+ T cells, indicating improved cross-priming efficiency. In contrast, antigen alone or healthy control sera showed minimal CD8 T cell activation. **Conclusion:** BJT-778 not only enhances the uptake of HBsAg by antigen-presenting cells but also facilitates efficient cross-presentation to CD8+ T cells. These findings expand the mechanistic understanding of BJT-778 beyond CD4+ T cell activation, demonstrating its ability to boost HBV-specific CD8+ T cell responses. Together, the data support combining BJT-778 with immunomodulators to enhance both HBV-specific CD4 and CD8 T cell immunity.

INC., [3]Department of Internal Medicine, College of Medicine, Pusan National University and Biomedical Rese, [4]University of Auckland, Grafton, New Zealand

Background: A functional cure for Chronic Hepatitis B (CHB), defined as sustained loss of HBsAg, is a key treatment goal. N-linked glycosylation modification at N146 of HBsAg resulted in two forms of HBsAg: glycosylated (GpS) or unglycosylated (pS). In most CHB patients, the ratio of serum pS to GpS is 1:1 since glycosylation site N146 is not fully utilized. Host-dependent glycosylation of HBsAg may affect immune recognition, protein folding, and viral secretion. However, the relationship between HBsAg decline and HBsAg glycosylation levels is poorly understood in CHB patients. In this study, the association between GpS levels and HBsAg decline in CHB patients was investigated. **Methods:** Baseline (BL) serum samples were randomly selected from CHB patients in two similarly designed phase 3 studies of tenofovir alafenamide and/or tenofovir disoproxil fumarate: GS-US-320-0108 (HBeAg-negative) and GS-US-320-0110 (HBeAg-positive). Western blot analysis was used to quantify GpS and pS band intensities, from which pS/GpS ratios were calculated. Quantitative HBsAg levels were measured every 12 weeks through week 144, and every 24 weeks until week 384. HBsAg decline was analyzed from BL to week 384. BL sequences were analyzed to detect mutations at N146 glycosylation site. Pearson correlation was used to calculate P value if not stated. **Results:** A total of 66 patients, including 48 HBeAg+ and 18 HBeAg-, with HBV genotypes (GTs) distributed as follows: GTA (N = 11), GTB (N = 24), GTC (N = 30), and GTF (N = 1) were analyzed. BL pS/GpS ratios ranged from 0.23 to 4.03. HBsAg decline at week 48 varied from 0 to 6.19 log. An average pS/GpS ratio for HBeAg+ CHBs (1.99) was higher than that for HBeAg- CHBs (1.07, $P < 0.0001$, Student t test). A significant positive correlation was found between BL pS/GpS ratio and HBsAg decline at week 48 ($r = 0.57$, $p < 0.0001$), in HBeAg+ ($r = 0.52$, $p = 0.0002$) but not in HBeAg- patients ($r = -0.13$, $p = 0.6$). Similar correlations persisted from weeks 96 to 196 ($r > 0.5$, $p < 0.001$). For example, the largest HBsAg decline from baseline (6.19 log) was observed at week 48 in a patient with BL pS/GpS as 2.95. GT-specific correlations were checked for GTA ($r = 0.59$, $p = 0.056$), GTB ($r = 0.60$, $p = 0.002$), and GTC ($r = 0.51$, $p = 0.0045$). Patients who achieved HBsAg loss ($N = 12$) had higher pS/GpS ratios compared to those who did not ($N = 54$, $P = 0.0103$, Student t test) (Figure 1A). Among those who achieved HBsAg loss, faster S loss kinetics were associated with higher pS/GpS ratios (Figure 1B). No mutations at N146 glycosylation site were found in any samples at BL. **Conclusion:** The higher proportion of unglycosylated HBsAg correlated with faster HBsAg decline in HBeAg+ patients suggesting BL pS/GpS ratio could serve as a potential biomarker for predicting treatment response in HBeAg+ CHB patients. Further studies are warranted to elucidate the underlying mechanism of this correlation. **Disclosures:** Chunfeng Li: Nothing to Disclose, ANDREW LOPEZ: Nothing to Disclose, Nadine Peinovich: Nothing to Disclose, Savrina Manhas: Nothing to Disclose, Yu Hu: Nothing to Disclose, Jiani Li: Nothing to Disclose, Christopher Richards: Gilead Sciences: Employee, Caleb Marceau: Gilead Sciences: Employee, Ross Martin: Gilead Sciences: Employee, Jeong Heo: Gilead: Grant/Research Support, Roche: Speaking and Teaching, Yuhan: Speaking and Teaching, Abbvie: Speaking and Teaching, AstraZeneca: Advisor, Oncolys Japan: Grant/Research Support, Surrozen: Advisor, MedVir: Advisor, Edward Gane: Aligos Therapeutics: Advisor, Aligos Therapeutics: Advisor, Assembly Biosciences: Advisor, Assembly Biosciences: Advisor, AbbVie: Speaking and Teaching, AbbVie: Speaking and Teaching, Intellia Therapeutics: Advisor, Intellia Therapeutics: Advisor, Tune Therapeutics: Consultant, Tune Therapeutics: Consultant, Precision Bio: Advisor, Precision Bio: Advisor, Virion Therapeutics: Advisor, Virion Therapeutics: Advisor, Gilead Sciences: Advisor, Gilead Sciences: Advisor, GSK: Advisor, GSK: Advisor, AusperBio: Advisor, Aligos Therapeutics: Advisor, Aligos Therapeutics: Advisor, Assembly Biosciences: Advisor, Assembly Biosciences: Advisor, AbbVie: Speaking and Teaching, AbbVie: Speaking and Teaching, Intellia Therapeutics: Advisor, Intellia Therapeutics: Advisor, Tune Therapeutics: Consultant, Tune Therapeutics: Consultant, Precision Bio: Advisor, Precision Bio: Advisor, Virion Therapeutics: Advisor, Virion Therapeutics: Advisor, Gilead Sciences: Advisor, Gilead Sciences: Advisor, GSK: Advisor, GSK: Advisor, AusperBio: Advisor, Frida Abramov: Nothing to Disclose, Hongmei Mo: Nothing to Disclose, Evguenia Maiorova: Nothing to Disclose

1314 | IDENTIFICATION OF HOST FACTORS INVOLVED IN INDUCING FUNCTIONAL CURE

Takashi Honda[1] Yuichirou Harada[2] Shinya Yokoyama[1] Kena Yamamoto[1] Takanori Ito[1] Norihiro Imai[1] yoji ishizu[1] Masahiko Kuroda[2] Hiroki Kawashima[1] Yoshiki Murakami[3], [1]Nagoya University Graduate School of Medicine, [2]Tokyo Medical University, [3]Tokyo Medical Univesity/Asahi University

Background: The primary objective of existing therapies for chronic hepatitis B (CH) is to achieve hepatitis B surface antigen (HBsAg) clearance, indicative of a functional cure (FC). We have reported that the 97th amino acid mutation in the core region is associated with FC, but the cellular factors involved remain unclear. This study aimed to identify cellular factors associated

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with FC induction. **Methods:** Serum samples from six patients with CH—three who achieved FC and three who remained in CH—were prepared. For cases in which CH progressed to FC during follow-up, the specimen taken at the first visit was defined as preFC, and the specimen taken after FC was defined as postFC. For cases in which CH remained CH during follow-up, the specimen taken at the first visit was defined as preCH, and the specimen taken most recently was defined as postCH. These sera were co-cultured with primary human hepatocytes (PHHs) for 12 days. After cell culture, we analyzed the expression of miRNA, mRNA, and protein in PHHs, bioinformatically identified miRNAs and target genes and also analyzed miRNA expression derived from cell supernatants. **Results:** In patients who improved from CH to FC, expression of miR-489-3p significantly increased after the transition. Expression of genetic suppressor element 1 (GSE1), a target gene of miR-489-3p, was suppressed. Overexpression of miR-489-3p suppressed HBV replication. Comparison of preCH and preFC, expression of miR-20a-5p and miR-186-5p in preFC was significantly higher than preCH. miR-20a-5p and miR-186-5p targeted Rho GTPase-activating protein 12 (ARHGAP12) and RELA proto-oncogene, NF-kB subunit (RELA), respectively. Overexpression of these miRNAs or silencing of the corresponding target genes with siRNA suppressed HBV replication. Analysis of culture supernatants revealed that four miRNAs (miR-6747-3p, 3193, 101-5p, and let-7e-3p) were differentially expressed depending on whether cases improved to FC or remained in CH, and six additional miRNAs (miR-4504, 128-1-5p, 660-3p, 501-5p, 449a, and 4526) were expressed only in either FC or CH. **Conclusion:** This study established an in vitro experimental model to improve the transition of CHB to FC using patient serum, and identified the cellular factors involved in FC induction. The miRNAs and target genes obtained herein may provide useful therapeutic targets to induce FC. Cell supernatant miRNAs may serve as potential diagnostic markers for FC.

1315 | EFFICACY COMPARISON OF NUCLEOS(T)IDE ANALOGUES MONOTHERAPY VERSUS COMBINATION THERAPY WITH PEG-IFNA AT 48 WEEKS IN PATIENTS WITH CHRONIC HEPATITIS B AND LOW-LEVEL VIREMIA: A PROSPECTIVE STUDY

Shiyu Wang[1] Minghui Li[1] Ziyu Zhang[1] Xinxin Li[1] Wen Deng[1] Xin Wei[1] Linmei Yao[1] Zixuan Gao[1] Shuojie Wang[1], [1]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University

Background: Low-level viremia patients with chronic hepatitis B is closely associated with the progression of liver fibrosis, development of decompensated cirrhosis, hepatocellular carcinoma (HCC) risk, and reduced long-term survival rates. Through a 48-week prospective cohort study, we compared the efficacy of nucleos(t)ide analogues (NAs) monotherapy versus combination therapy with pegylated interferon-alpha (Peg-IFNα) in CHB patients with low-level viremia. **Methods:** Patients with chronic hepatitis B (CHB) and low-level viremia (HBV DNA: 20–2000 IU/mL) who had persistently positive HBV DNA after 48 weeks of nucleos(t)ide analogue (NAs) therapy at Beijing Ditan Hospital (January 2022 to December 2024) were enrolled. Clinical data from two groups—those receiving NAs + Peg-IFNα(n = 272) and NAs (n = 90)—were prospectively analyzed to evaluate antiviral efficacy at 48 weeks and compare therapeutic outcomes. **Results:** At 48 weeks of treatment, the HBeAg seroclearance rates in the NAs + Peg-IFNα group and NAs group were 44.97% (76/169) and 50.00% (30/60), respectively ($P = 0.746$). The complete virologic response rates were 26.84% (73/272) versus 15.56% (14/90) ($P = 0.03$), and the HBsAg loss rates were 15.44% (42/272) compared to 2.22% (2/90) ($P = 0.004$). The median baseline ALT levels were 27.00 (18.15, 38.85) U/L in the NAs + Peg-IFNα group and 28.30 (20.00, 43.00) U/L in the NAs group. ALT levels in the NAs + Peg-IFNα group were significantly higher than those in the NAs group at 12, 24, 36, and 48 weeks, peaking at 12 weeks. Additionally, AST levels in the NAs + Peg-IFNα group remained consistently higher than those in the NAs group at all time points (12, 24, 36, and 48 weeks) ($P < 0.05$). The median baseline HBsAg levels were 3.36 (2.49, 3.78) $\log_{10}$ IU/mL in the NAs + Peg-IFNα group and 3.28 (2.52, 3.81) $\log_{10}$ IU/mL in the NAs monotherapy group. At baseline, the NAs + Peg-IFNα group showed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

numerically higher HBsAg levels compared to the NAs group, though this difference was not statistically significant (Z = -0.24, P = 0.814). At subsequent time points, the median HBsAg levels in the NAs + Peg-IFNα group remained lower than those in the NAs group, but these differences also lacked statistical significance (P > 0.05). By week 48, both HBsAg and HBV DNA levels were significantly reduced compared to baseline in both treatment groups. At baseline, the median HBV DNA level in the NAs + Peg-IFNα group was 1.81 $\log_{10}$ IU/mL compared to 1.75 $\log_{10}$ IU/mL in the NAs group (P > 0.05). By week 24 of treatment, the median HBV DNA level in the NAs + Peg-IFNα group was numerically lower than that in the NAs group, though this difference also did not reach statistical significance(1.38 $\log_{10}$ IU/mL vs. 1.43 $\log_{10}$ IU/mL)(P > 0.05). **Conclusion:** In the optimized treatment of patients with low-level viremia (LLV), the NAs + Peg-IFNα regimen demonstrated significantly higher rates of complete virologic response and HBsAg loss compared to NA monotherapy optimization strategies.

1316 | STUDY ON THE EFFECTIVENESS AND SAFETY OF TAF IN THE TREATMENT OF ELDERLY CHB PATIENTS IN CHINA

Jie Tan[1] Huiling Fu[2] Lizhen Chen[1] Xinjie Hao[2] Tao Liu[2] Yuhong Dong[2] Jun Yu[2] Jianping Duan[2] Jinjin Li[2] Haifeng Zhang[2] Qingxi Wang[2] Zhaohui Wang[2] Yuwen Song[1] Bing Qiao[2] He Wang[2] Weili Cui[2] Shijing Gao[2] Jingjing Guo[2] Wei Zhao[2] Yong Zhou[2] Yongning Xin[3], [1]Qingdao Hospital, University of Health and Rehabilitation Sciences (Qingdao Municipal Hospital), [2]Qingdao Public Health Clinical Center, [3]Qingdao Hospital, University of Health and Rehabilitation Sciences (Qingdao Municipal Hospital)

Background: Tenofovir alafenamide fumarate (TAF) has significant antiviral effects and favorable safety in patients with chronic hepatitis B (CHB). This study aimed to investigate the effectiveness and safety of TAF in elderly (60 years and older) CHB patients and to clarify the impact of TAF on bone and renal health. **Methods:** A total of 201 CHB patients aged 60 years and older who received TAF antiviral treatment in multiple hospitals in Qingdao, China from June 2021 to December 2023 were included. The indicators at baseline, 24 weeks, 48 weeks, 72 weeks and 96 weeks were collected and analyzed. **Results:** A total of 187, 175, 162, and 54 elderly CHB patients completed the 24, 48, 72 and 96-week follow-ups, respectively. Compared with the baseline period, significant improvements in bone mineral density (BMD) was observed in both the lumbar spine (-0.91SD vs. -0.73SD, P = 0.011) and femoral neck (-1.03SD vs. -0.91SD, P = 0.017) at week 96. Compared with the baseline level, at week 96, there were no significant changes in BUN (5.60mmol/L vs. 5.24mmol/L, P = 0.642), creatinine (70.21umol/L vs. 68.32umol/L, P = 0.151), and eGFR (85.28mL/min/1.73m² vs. 85.56mL/min/1.73m², P = 0.873). At any time, there were no significant changes in urinary protein, α1-MG, β2-MG, or URBP. The HBV DNA undetectable (lower limit of detection is 20IU/ml) rate was 83.58% at baseline, and with the prolonged use of TAF, HBV DNA undetectable rate increased to 87.70%, 93.75%, 96.82%, and 98.15% at weeks 24, 48, 72, and 96, respectively. Compared with baseline, HBsAg levels significantly decreased at week 48 (1045.68IU/ml vs. 856.15IU/ml, PP < 0.01). **Conclusion:** After 2 years of TAF treatment in CHB patients aged 60 years and older, the BMD of the lumbar spine and femoral neck significantly improved, and the renal function was stable. The HBV DNA undetectable rate gradually increased, and the HBsAg levels significantly decreased.

1317 | EFFICACY OF NAS IN COMBINATION WITH PEG-IFN FOR FUNCTIONAL CURE IN PATIENTS WITH CHB: A META-ANALYSIS OF RCTS

Yaqin Zhang[1] Yao Xie[1] Minghui Li[1], [1]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University

Background: The goal of treating chronic hepatitis B (CHB) is to achieve functional cure. We aimed to evaluate the efficacy of the combination of nucleoside (acid) analogues (NAs) and pegylated interferon (Peg-IFN) on the functional cure of CHB patients at the EOT and at the EOF. **Methods:** PubMed, Embase, and Web of Science were searched systematically up to March 15, 2025. Sixteen RCTs on CHB patients receiving combination or monotherapy were included. **Results:** Compared with NAs treatment, the NAs combined with Peg-IFN treatment group significantly improved HBsAg clearance rate (RR: 14.05, 95% CI 6.13-32.20) and HBsAg seroconversion rate (RR: 12.82, 95% CI 5.08-32.33) at the EOT. Moreover, compared with NAs treatment, the NAs combined with Peg-IFN treatment group significantly improved HBsAg clearance rate (RR: 7.70, 95% CI 4.24-13.98), HBsAg seroconversion rate (RR: 11.93, 95% CI 5.14-27.67) at the EOF. However, compared with Peg-IFN monotherapy, the combination therapy group did not show any improvement in HBsAg clearance rate, HBsAg seroconversion rate, and the rate of qHBsAg decrease >1 log10 IU/mL at the EOT and the EOF. Moreover, in terms of safety, the Peg-IFN monotherapy group showed more ALT flares (ALT $> 5 \times$ ULN) during the treatment process. **Conclusion:** Compared with NAs therapy, Peg-IFN combined with NAs therapy significantly improves functional cure rate. However, combination therapy shows no additional advantage over Peg-IFN monotherapy in achieving functional cure. The Peg-IFN monotherapy group has a higher incidence of ALT flares than the combination therapy group.

1318 | MULTIMODAL SPATIAL PROFILING OF LIVER BIOPSIES FROM INDIVIDUALS WITH CHRONIC HBV INFECTION REVEALS A PREVIOUSLY UNDESCRIBED POPULATION OF HBV-INTEGRATED HEPATOCYTES

SANGEETHA MAHADEVAN[1] Ricardo Ramirez[1] Hatef Mehrabian[1] CHRISTINA MOON[1] APOORVA MOHAN[1] Edith Vaquero[1] Rosanna Win[1] Subhra Chaudhuri[1] Hsiu-Chun Chuang[1] Kai-Hui Sun[1] Abhishek Aggarwal[1] Anjali Rao[1] Scott Balsitis[1] Simon Fletcher[1] Meghan Holdorf[1] Li Li[1] Lauri Diehl[1], [1]Gilead Sciences, Inc.

Background: HBV cccDNA+ and HBV-integrated (iHBV) hepatocytes are both present in the livers of individuals with chronic hepatitis B (CHB), and recent studies have indicated that elimination of both HBV+ cell populations is required for functional cure. To better understand these cell populations, we combined Spatial Transcriptomics (ST), single-nucleus RNA-Seq (snRNA-Seq), chromogenic in situ hybridization (CISH), and multiplex immunofluorescence (mIF) with machine learning methods to profile archival liver biopsy samples from CHB patients. Six commercially-procured liver tissue sections ($n=2$ healthy, $n=4$ CHB) and 6 core-needle biopsies from study GS-US-174-0149 ($n=4$ CHB baseline, $n=2$ CHB Tenofovir Disoproxil Fumarate-treated) were profiled by 10X Visium CytAssist using the Human Transcriptome panel with the addition of custom-designed probes targeting HBV. Serial FFPE sections were analyzed by CISH (viral RNA) and mIF (HBsAg, HBV core), which were used to train machine learning classifiers. In addition, snRNA-Seq was performed on $n=1$ healthy and $n=3$ CHB samples. **Methods:** Six commercially-procured liver tissue sections ($n=2$ healthy, $n=4$ CHB) and 6 core-needle biopsies from study GS-US-174-0149 ($n=4$ CHB baseline, $n=2$ CHB Tenofovir Disoproxil Fumarate-treated) were profiled by 10X Visium CytAssist using the Human Transcriptome panel with the addition of custom-designed probes targeting HBV. Serial FFPE sections were analyzed by CISH (viral RNA) and mIF (HBsAg, HBV core), which were used to train machine learning classifiers. In addition, snRNA-Seq was performed on $n=1$ healthy and $n=3$ CHB samples. **Results:** HBV RNA and DNA were successfully co-detected alongside human transcripts using custom spike-in of HBV-specific probes into a ST panel. Spots containing cccDNA+ hepatocytes (HBs+, HBc+, HBx+, rcDNA+ RNA by ST) had increased immune cell (e.g., T cell, B cell) and type II interferon transcriptional signatures compared to iHBV (HBs+, HBx+, HBc-, and rcDNA- RNA by ST) or uninfected hepatocytes. Integrated analysis identified a population of iHBV hepatocytes which were HBcAg- and HBsAg- by mIF but HBs RNA+ by ST and CISH. These iHBV cells produced similar levels of HBs RNA as iHBV cells which were HBsAg+ by mIF, but were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

spatially distinct and exhibited a peri-portal zonal bias in the liver. At the individual cell level, a higher percentage of HBV + cells was also detected by snRNA-seq than by mIF. **Conclusion:** Our findings indicate the presence of a previously undescribed population of HBV-integrated hepatocytes which may suggest higher intrahepatic viral burden than previously described.

1319 | POLICY MATTERS: A SUCCESS STORY IN HEPATITIS B TREATMENT ACCESS FOLLOWING REIMBURSEMENT POLICY CHANGE

Rahmet Guner[1] Imran Hasanoglu[1] Nazlim Demir[2] Ozlem Altuntas Aydin[3] Derya Ari[4] Oguz Karabay[5] Esra Zerdali[6] Yusuf Hayran[2] SILA AKHAN[7] Birsen Asena Emre[3] Meral Akdoğan Kayhan[4] Sibel Yildiz Kaya[8] Asli Vatan[5] Deniz Kakalicoglu Ozden[9] Tugba Arslan Gulen[10] Asli Haykir Solay[11] Bilger Cavus[12] Dilek Yıldız Sevgi[13], [1]Ankara Yildirim Beyazit University Bilkent City Hospital, [2]Selcuk University Faculty of Medicine, [3]University of Health Sciences Basaksehir Cam and Sakura City Hospital, [4]Ankara Bilkent City Hospital, [5]Sakarya University Faculty of Medicine, [6]Istanbul Haseki Education and Research Hospital, [7]Kocaeli University Faculty of Medicine, [8]Istanbul University Cerrahpasa Faculty of Medicine, [9]University of Health Sciences Haseki Sultangazi Education and Research Hospital, [10]Adana City Hospital, [11]Ankara Etlik City Hospital, [12]Istanbul University Istanbul Faculty of Medicine, [13]Hamidiye Etfal Education and Research Hospital

Background: On November 2, 2024, a revised reimbursement policy in Türkiye partially removed the requirement for liver biopsy in the treatment of chronic hepatitis B (CHB), aiming to improve access to antiviral therapy. This study aimed to evaluate the policy's comprehensive impact on treatment initiation rates, antiviral drug choices, age-specific effects, and projected economic benefits in the context of hepatitis B elimination goals. **Methods:** We retrospectively analyzed data from 1,035 CHB patients across 18 tertiary centers. Patients were categorized into two periods: pre-policy change (Nov 2, 2023 – Nov 1, 2024; n = 583) and post-policy change (Nov 2, 2024 – May 1, 2025; n = 452). The primary outcome was the proportion of patients initiating therapy without biopsy. Interrupted time series (ITS) analysis assessed changes in trend and level post-policy and multilevel logistic regression examined center-level variability and interaction by age <40 years, ALT, AST, and FIB-4. Economic projections assumed a biopsy cost of $250. **Results:** The proportion of patients initiating treatment without biopsy increased from 27.6% pre-policy change to 68.6% post-policy change (RR = 2.48; p < 0.0001). ITS confirmed a significant immediate increase of +41.3 percentage points (p < 0.001) (Fig. 1). In multivariable analysis, the post-policy change period was independently associated with higher odds of initiating treatment without biopsy (aOR = 6.90; 95% CI 5.05–9.43), with a significant interaction for patients under 40 years (aOR = 0.33; p = 0.002). No significant changes were observed in antiviral preferences (entecavir, TDF, TAF; all p > 0.30). FIB-4 had limited discriminatory power for biopsy decisions (AUC = 0.42). Avoidance of 189 biopsies in the study cohort resulted in projected savings of $47,250, with an estimated national annual cost benefit between $6 million and $30 million. **Conclusion:** The recent reimbursement policy change in Türkiye has substantially improved access to antiviral therapy for CHB by reducing dependency on invasive liver biopsies. This shift has led to a simplified clinical workflow, reduced procedural burden on patients, and yielded considerable cost savings. The marked increase in treatment initiation, especially among patients previously deterred by biopsy requirements, highlights the real-world impact of policy-driven interventions.

1320 RELINK: GETTING HEPATITIS B AND C PATIENTS BACK INTO CARE IN MARYLAND AND VIRGINIA | A COMMUNITY-ROOTED OUTREACH STRATEGY BUILT ON CULTURAL TRUST, REAL RELATIONSHIPS, AND LESSONS LEARNED THE HARD WAY

Yanhong Zou[1] Sandra Marrero-Ashford[1], [1]Hepatitis B Initiative of Washington, D.C. Inc.

Background: Too many people are diagnosed with Hepatitis B or C and never make it to treatment. They fall through the cracks—because of a disconnected phone, stigma, addiction, or simply because no one followed up. The ReLink Project was created to find them again—and bring them back. We focused on: 1. Immigrant communities with a high Hepatitis B and Hepatitis C burden. 2. People who use drugs and those who are unstably housed are at the highest risk for untreated HCV. **Methods:** 1. 470 individuals with HBV and 410 with HCV were identified in Maryland and Virginia. 2. Outreach by trained CHWs from the same communities. 3. Contact via phone, clinic, email, message, letter, rehab centers, shelters. 4. Data tracked: contact success, current care status, and new linkage. **Results:** Key Rusult: Population-based insights. 1.Vietnamese Clients(HBV & HCV). 1)Highest care retention. 2)Tested with trusted provider (Dr. Tran). 3)CHW (Jennifer) was there at testing and follow-up. 2. Mongolian Clients(HBV & HCV). 1)Language alignment, but fewer stayed in care. 2)Tested through HBI, but no ongoing provider relationship. 3)Many had moved or become unreachable. 3.African Immigrant Clients (HBV). 1)Higher rate of declined care. 2) Barriers: stigma, mistrust, spiritual beliefs. 4.U.S.-Born Clients (HCV). 1)Least reachable. 2)Most from harm reduction or recovery centers. 3)Many lost phones or relapsed, but all who were reached accepted care. Lesson Learned. 1. Main barrier: Disconnected numbers, no response, missing contact information, and relocated. 2. Key win: 100% of reachable HCV clients who needed care accepted linkage. 1)Referrals don't work without relationships. 2)CHWs must be assigned at diagnosis, especially in rehab and shelter settings. 3) Clients need someone to walk them into care, not just give them the address. 4)Contact info decays quickly—we need faster follow-up and better systems. What We are Building Next. 1. CHW-led in-person outreach is now active. 2. AI-powered follow-up system (launching 2026) to help track disconnected clients. 3. Deep partnerships with community clinics and rehab programs. 4. Continued investment in relationship-first engagement. **Conclusion:** The Relink Project's findings emphasize the need for a systems-level approach to hepatitis care that focuses on swift engagement, continued support, and removing barriers to healthcare access. As the project progresses, efforts will focus on refining the CHW model and exploring technological solutions to streamline follow-up. Ultimately, the project illustrates that overcoming obstacles in healthcare requires persistence, cultural humility, and coordinated support. By diligently following up and reconnecting every patient to care, regardless of time passed or challenges faced, we can improve our lives and make meaningful progress in the fight against viral hepatitis. These lessons broadly apply to linkage-to-care efforts for other diseases, especially in underserved populations.

	HBV	HCV
Total Patients	470	410
Succsfully Contacted	75%(349)	43%(172)
Already in Care/Treated	85% (298 of 439 contacted)	94% (162 of 172 contacted)
Newly Linked to Care	20(8.9%)	10(0%)

1321 | END-OF-THERAPY HBSAG, HBCRAG, AND HBV RNA PREDICT 8-YEAR OUTCOMES AFTER NUCLEOS(T)IDE ANALOGUE CESSATION IN CHRONIC HEPATITIS B

Meng-Ju Lin[1] Tung-Hung Su[1] Chun-Jen Liu[1] Hung-Chih Yang[1] Jyh-Ming Liou[1] Tai-Chung Tseng[1] Chen-Hua Liu[1] Chun-Ming Hong[1] Pei-Jer Chen[1] Jia-Horng Kao[1], [1]National Taiwan University Hospital

Background: Nucleos(t)ide analogues (NA) are the cornerstone for the treatment of hepatitis B virus (HBV)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

infection. Finite NA therapy has been proposed to facilitate hepatitis B surface antigen (HBsAg) clearance; however, virological relapse (VR, HBV DNA > 2000 IU/mL) and clinical relapse (CR, VR and ALT > 2-fold upper limit of normal) are common. The role of quantitative HBsAg, hepatitis B core-related antigen (HBcrAg), and HBV RNA to predict outcomes after NA cessation remained undetermined. **Methods:** Non-cirrhotic chronic hepatitis B (CHB) patients who discontinued NA therapies in a tertiary medical center were prospectively enrolled. The serum at the end-of-therapy (EOT) was collected to quantify HBsAg, HBcrAg, and HBV RNA. The patients were monitored prospectively at the 1st, 3rd, and every 3 months after treatment cessation to monitor HBV DNA and alanine aminotransferase (ALT) levels. HBsAg, HBcrAg, and HBV RNA levels were logarithmically transformed or categorized for univariate and multivariable analyses to predict VR, CR, and HBsAg seroclearance. **Results:** Overall, 260 patients (39.6% initially HBeAg-positive) were included, and 194 (74.6%) fulfilled the Asian Pacific Association for the Study of the Liver (APASL) guidance for stopping NAs. Before NA cessation, 156 (60.0%) patients received entecavir, 81 (31.1%) received tenofovir-based therapies, and the rest received other NAs or combination therapies. The median treatment and follow-up duration were 37 months and 7.9 years. At EOT, HBV RNA levels were <5, 5–10, and ≥ 10 copies/mL in 39.2%, 25.0%, and 35.8% of patients, respectively. At the end of follow-up, 229 (88.1%) and 148 (56.9%) patients developed VR and CR, respectively, and 23 (8.8%) patients developed HBsAg seroclearance. Multivariable Cox regression analysis showed age (adjusted HR [aHR]: 1.02, 95% CI: 1.00-1.03, P = 0.024), tenofovir use (aHR: 1.61, 95% CI: 1.21-2.14, P = 0.001), HBsAg (aHR: 1.26, 95% CI: 1.04-1.53, P = 0.018), and HBV RNA (aHR: 1.69, 95% CI: 1.46-1.95, P < 0.0001) significantly predicted VR. Age (aHR: 1.02, 95% CI: 1.00-1.04, P = 0.012), HBcrAg (aHR: 1.26, 95% CI: 1.05-1.50, P = 0.012), and HBV RNA (aHR: 1.34, 95% CI: 1.14-1.57, P = 0.0003) predicted CR. EOT HBV RNA $\geq$ 10 copies/mL conferred higher risk of VR (2.16-fold) and CR (1.57-fold) than HBV RNA $\leq$ 10 copies/mL. EOT HBV RNA detectability ($\geq$ 5 or < 5 copies/mL) stratifies the risk of HBsAg seroclearance; however, HBsAg level (aHR: 0.23, 95% CI: 0.14-0.36, P < 0.0001) was the only factor strongly associated with HBsAg seroclearance in multivariable analysis. EOT HBV RNA remained predictive of VR and CR in patients who met the APASL criteria. **Conclusion:** VR and CR are frequent after NA cessation. In a cohort including both HBeAg-positive and -negative patients, whether or not they met the APASL stopping criteria, EOT HBsAg, HBcrAg, and HBV RNA predicted subsequent relapses. A low HBsAg level at EOT was the strongest predictor of subsequent HBsAg seroclearance.

1322 | ANALYSIS OF IMMUNE RESPONSES IN HIV/HBV CO-INFECTED PATIENTS EXPERIENCE HBSAG LOSS AFTER TDF/TAF-BASED ANTIVIRAL THERAPY IN THE ALLIANCE CLINICAL STUDY

David Pan[1] Nikita Kolhatkar[1] Pamela Odorizzi[1] Caleb Marceau[1] Rod Dunbar[2] Daniel Verdon[2] Scott Balsitis[1] Sharline Madera[1] Frida Abramov[3] Jason Hindman[1], [1]Gilead Sciences, [2]University of Auckland, [3]Gilead Sciences, Inc.

Background: A functional cure for chronic hepatitis B (CHB), defined by hepatitis B s antigen (HBsAg) loss and sustained HBV DNA suppression, is rarely achieved, even with long-term antiviral therapy. In the phase 3, randomized, double-blind ALLIANCE trial, treatment-naïve adults co-infected with HIV-1/HBV received either bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) or dolutegravir (DTG) + emtricitabine/tenofovir disoproxil fumarate (F/TDF). HBsAg loss/seroconversion rates were significantly higher, particularly with B/F/TAF, than those reported in TDF or TAF HBV monoinfection studies. This analysis aimed to further characterize immune responses in participants who achieved HBsAg loss through at least 144 weeks of follow-up. **Methods:** A sub-study analysis of the ALLIANCE trial evaluated plasma collected from 48 participants (HBsAg loss (n = 25), non-HBsAg loss (HBsAg +, n = 23)). The two cohorts were balanced based on treatment, demographic, and viral parameters. Plasma samples were collected longitudinally from baseline, pre- and post HBsAg loss, pre- and post- HBsAg antibody seroconversion (if detected), end of treatment, open-label

extension (OLE), and ALT flare (if detected). Chemokine and cytokine levels were quantified using multiplex ELISA (O-link). Peripheral blood mononuclear cells (PBMCs) were collected from 31 participants during the OLE phase (HBsAg loss (n = 16), non-HBsAg loss (n = 15)) and were used to characterize HBV-specific T cell responses using a 2-color Fluorospot (IFNg/granzyme B). **Results:** Peripheral inflammatory cytokines and chemokines decreased after initiation of antiviral treatment in all participants regardless of HBsAg loss when compared to their baseline cytokine profile. While not statistically significant, tissue-homing cytokines, CXCL9, CXCL10 and CXCL11 trended higher at the time of HBsAg loss when compared to those who remained HBsAg+. HBV-specific T cell responses trended higher in HIV/HBV co-infected participants with HBsAg loss and were skewed towards hepatitis B core antigen specificity. **Conclusion:** This sub-analysis of HIV/HBV coinfected participants treated with B/F/TAF suggests that antiviral treatment results in an overall reduction in systemic inflammation irrespective of HBsAg loss. However, modest increases in HBV-specific T-cell responses and increases in tissue homing chemokines were observed in those who achieved HBsAg loss, indicating a potential role for immune activation in promoting functional cure.

1323 | DOSE-DEPENDENT BUT ATTENUATED RISK OF INTRAHEPATIC CHOLESTASIS OF PREGNANCY WITH INCREASING HBV DNA LOAD IN MOTHERS WITH CHRONIC HEPATITIS B

Jinjuan Wu[1] Jing Zhang[1] Xiaoyan Sha[1] Calvin Pan[2]

[1]Guangzhou Women and Children's Medical Center, Guangzhou Medical University, China, [2]NYU Langone Health, NYU School of Medicine

Background: Chronic hepatitis B virus (HBV) infection remains prevalent among women of childbearing age in China. Intrahepatic cholestasis of pregnancy (ICP), a liver disorder occurring in late pregnancy, is linked to adverse perinatal outcomes. Although HBV has been proposed as a risk factor for ICP, the association between HBV DNA levels and ICP remains unclear. **Methods:** We conducted a retrospective case-control study of 71,342 pregnant women who delivered at Guangzhou Women and Children's Medical Center between January 2019 and November 2021. Intrahepatic cholestasis of pregnancy (ICP) was diagnosed based on elevated total bile acid levels (> 10 μmol/L), with or without pruritus or abnormal liver function tests. Women with ICP were compared to those without (controls) to assess potential risk factors. HBV infection status and, for those infected, HBV DNA levels, along with other clinical characteristics, were extracted from medical records. Multivariate logistic regression was performed to assess the association between HBV infection or HBV DNA levels and ICP, adjusting for maternal age, gallbladder disease, pancreatic disorders, hepatitis C, cirrhosis, and the use of assisted reproductive technology. **Results:** Among 1,075/71,342 women diagnosed with ICP, HBV prevalence was significantly higher than in women without ICP (12.3% vs. 4.1%, P < 0.01). After adjusting for potential confounders, HBV infection was associated with increased ICP risk (adjusted odds ratio [aOR] 3.14; 95% CI: 2.60–3.80). To examine the relationship between HBV DNA levels and ICP risk, mothers were categorized into five groups based on their hepatitis B surface antigen (HBsAg) status and HBV DNA load. Group 0 included 18,429 women without HBV infection and served as the reference group. Group 1 comprised 130 women with HBV DNA levels less than 10^3 IU/mL, group 2 included 404 women with HBV DNA levels between 10^3 and $< 10^5$ IU/mL, group 3 included 471 women with HBV DNA levels between 10^5 and 10^7 IU/mL, and group 4 included 356 women with HBV DNA levels of 10^7 IU/mL or higher. The risk of ICP increased in a dose-dependent manner with rising HBV DNA levels, peaking in group 3 (aOR 9.44; 95% CI: 5.97–14.90). However, this elevated risk was not observed in group 4 (Table 1), where HBV DNA levels were $\geq 10^7$ IU/mL (aOR 1.55; 95% CI: 0.82–2.92). **Conclusion:** HBV infection is an independent risk factor for ICP. The relationship between HBV DNA levels and ICP is nonlinear, with peak risk at intermediate viral loads (10^5–10^7 IU/mL), possibly reflecting immune activity during the immune-clearance phase. Pregnant women with moderate HBV DNA levels may benefit from closer monitoring for ICP and related complications.

Table 1. Odds Ratios and 95% Confidence Intervals for Developing ICP in HBV-Infected Women and Subgroup Analyses

Variables	Crude OR (95% CI)	Adjusted OR (95% CI) [‡]
Hepatitis B infection		
No	1(reference)	1(reference)
Yes	3.24 (2.69,3.90)	3.14 (2.60-3.80)
HBV DNA levels		
Non-HBV infected cases	1 (reference)	1 (reference)
Hepatitis B infected cases		
- HBV DNA ≤1,000 IU/mL	3.03 (2.40,3.83)	2.96 (2.34,3.76)
- HBV DNA >3log10 to ≤ 5log10 IU/mL	3.30 (2.12,5.14)	3.22 (2.06,5.03)
- HBV DNA >5log10 to ≤ 7log10 IU/mL	9.82 (6.26,15.41)	9.44 (5.97,14.90)
- HBV DNA >7log10 IU/mL	1.64 (0.87,3.08)	1.55 (0.82,2.92)

Abbreviations: OR = odds ratio; CI = confidence interval.

[‡] Adjusted for maternal age, pancreatic disease, hepatitis C, gallbladder disorders, and use of assisted reproductive technology

1324 | CLINICAL TRIALS FOR CURING CHRONIC HEPATITIS B: A COMPREHENSIVE ANALYSIS OF DESIGN PRINCIPLES AND THEIR IMPACT ON TRIAL PERFORMANCE

Lichen Shi[1] Hao Wang[1] Cheng Huang[1] Yifan Du[2] Hong You[1] Jidong Jia[1] Yuanyuan Kong[1], [1]Beijing Friendship Hospital, Capital Medical University, [2]Capital Medical University Affiliated Beijing Friendship Hospital

Background: The development of novel agents for chronic hepatitis B (CHB) has rapidly evolved, but only with a few candidates progressing to phase III trials. This study aimed to systematically analyze the key elements of clinical trial design for curing CHB and evaluate their impact on the trial performance. **Methods:** We conducted a systematic review of clinical trial registries (ClinicalTrials.gov, WHO Clinical Trials Registry Platform, and Chinese Clinical Trial Registry) and publications (PubMed, Embase, and the Cochrane Library) for CHB cure trials. The relationship of the design characteristics and the performance of the trials were analyzed with Cox regression and meta-analysis. **Results:** A total of 244 trials and 23 publications involving 1,798 patients were included. Phase I clinical trials had a completion rate of 65.5%, with 38.7% advancing to phase II. For phase II trials, the completion rate was 48.9%, only with 4.3% advancing to phase III. Novel trial designs were adopted by 30.3% of the CHB clinical trials. Smaller sample size significantly was associated with higher completion rates in both phase I (HR: 0.980, 95% CI: 0.966–0.994) and phase II trials (HR: 0.994, 95% CI: 0.988–0.999). Shorter treatment duration was associated with higher completion rates only in phase I trials (HR: 0.992, 95% CI: 0.986–0.998). Meta-analysis of early-phase trials showed that direct-acting antivirals (SMD: 5.43, 95% CI: 0.22–10.64) were superior to control groups in achieving HBV cure. **Conclusion:** This study demonstrates that smaller sample sizes and shorter treatment durations are significantly associated with higher completion rates in early-phase trials. These findings highlight the importance of optimizing trial design to facilitate the development of cure therapy for CHB.

1325 | EVALUATION OF FIBROSIS STATUS IN TREATMENT-NAIVE HEPATITIS B PATIENTS WITH LOW LEVEL VIREMIA USING MR ELASTOGRAPHY AND NONINVASIVE FIBROSIS SCORES: FIB-4 AND APRI HAVE INSUFFICIENT EFFICACY IN DETECTING EARLY-STAGE FIBROSIS

Osman Dogan[1] Ilkay Idilman[2] Beyza Atay[3] Abdurrahman Ozkan[3] Bengi Öztürk[3] Taylan Kav[3] onur keskin[3], [1]Hacettepe University School of Medicine Department of Internal Medicine, [2]Hacettepe University School of Medicine Department of Radiology, [3]Hacettepe University School of Medicine Department of Gastroenterology

Background: This study aimed to evaluate the fibrosis status of hepatitis B virus (HBV) carriers with low viral load using MR elastography and noninvasive fibrosis scores. **Methods:** Treatment-naive HBV patients with HBV DNA levels <2000 IU/ml, normal liver function tests and abdominal ultrasonography findings were included in the study. Retrospectively, patients were classified into two groups: Those with persistently low HBV DNA levels (<2000 IU/mL) over the past two years were defined as the "true inactive carrier group", while those with at least two HBV-DNA values between 2000-20000 IU/mL were classified as the "gray zone group". Non-invasive liver fibrosis scores including FIB-4, NFS, APRI, GUCI, HUI, BARD, FORNS, CDS, LOK index were calculated for all patients. The presence or absence of liver fibrosis was determined according to the kPA levels, which is the liver stiffness measurement obtained from MR elastography (MRE). **Results:** The study included 79 treatment-naive HBV patients (mean age: 54.06 $\pm$10.8; 42 M/ 37 F) who met the inclusion criteria. Based on liver stiffness measurements (LSM) obtained by MRE, 55 patients (68%) had normal stiffness values (<2.5 kPa) 16 patients (20%) showed mildly increased stiffness (2.5-3.0 kPa), and 8 patients (9%) had LSM values between 3.0-3.5 kPa,consistent with stage 1-2 fibrosis. No cases of advanced fibrosis or cirrhosis were identified. The mean liver stiffness in the gray zone group was significantly higher than in the true inactive carrier group (2.75 ± 0.81 vs. 2.31 ± 0.39 kPa; p:0.007). Among the commonly used noninvasive fibrosis scores, weak but statistically significant correlations were observed between the BARD score, NFS, HUI and the liver stiffness value (kPA) obtained by MRE (r: 0.24; $p<0.01$, 0.33; $p<0.01$ and 0.37; $p<0.01$, respectively). In contrast, APRI and FIB-4 scores did not correlate with liver stiffness values measured by MRE (p:0.20 and p:0.14, respectively).The FIB-4 score was able to detect only 5 of 24 patients with fibrosis and/or inflammation based on MRE findings, failing to detect

early- stage fibrosis in the remaining 19 patients. In 9 of 55 patients in whom fibrosis was not detected by MRE, the FIB-4 score was found to be compatible with moderate fibrosis (sensitivity 70.7%, specificity 35%, positive predictive value 83% and negative predictive value 20.3%). Sensitivity of the APRI score in detecting the absence of fibrosis was 70%, specificity was 50%, with a positive predictive value 98% and a negative predictive value 4%. **Conclusion:** Noninvasive fibrosis scores have limited effectiveness in detecting early-stage fibrosis in HBV patients with low viral load. Imaging methods should be considered for the evaluation of liver fibrosis in this patient population.

1326 | ENHANCING CHRONIC HEPATITIS B CARE THROUGH HOSPITAL-BASED MANAGEMENT INTERVENTIONS: THE "HOT WAVE PROJECT" EXPERIENCE

Jia Chen[1] Qiumin Luo[1] Yeqiong Zhang[1] Wenqi Shi[1] Chan Xie[1] Zhiliang Gao[1] Zifeng Liu[1] Liang Peng[1], [1]Third Affiliated Hospital of Sun Yat-sen University

Background: Hepatitis B virus (HBV) infection remains a significant global health challenge, with effective management being crucial to prevent severe liver complications. This study evaluates the impact of the "Hot Wave Project," a series of process-oriented interventions implemented at The Third Affiliated Hospital of Sun Yat-sen University in China, on improving key management metrics for HBV patients. **Methods:** Starting in 2022, the "Hot Wave Project" was initiated, which included: education on HBV-related knowledge for doctors in non-infectious disease departments, laboratory report reminders for HBsAg-positive patients to be referred to the infectious disease clinic, various forms of patient education, dedicated personnel for patient follow-up, and big data monitoring of HBV infection data within the hospital. Data on HBsAg screening rates, antiviral treatment rates among HBsAg-positive patients, regular follow-up rates, and referral rates from non-infectious disease departments were collected and compared between 2021 and 2024. **Results:** From 2021 to 2024, the total number of HBsAg screenings at the hospital increased from 129,655 (screening rate 11.75%) to 154,989 (screening rate 15.25%). The overall antiviral treatment rate for HBsAg-positive patients improved from 71.00% in 2021 to 80.25% in 2024 ($P < 0.0001$). The regular follow-up rate for these patients rose from 59.96% to 61.50% ($P < 0.0001$). In non-infectious disease departments, the referral rate of HBsAg-positive patients to the infectious disease clinic increased from 9.26% in 2021 to 17.87% in 2024 ($P < 0.0001$). This increase contributed to an overall improvement in the antiviral treatment rate for these patients, which rose from 34.47% in 2021 to 59.63% in 2024. Specifically, in 2021, the antiviral treatment rate was 31.42% for patients who were not referred and 64.37% for those who were referred. By 2024, these rates had increased to 56.86% and 72.39%, respectively. **Conclusion:** The implementation of the "Hot Wave Project" significantly enhanced the treatment accessibility and management of HBV patients at The Third Affiliated Hospital of Sun Yat-sen University in China. Continued efforts and further studies are essential to maintain these improvements and assess their long-term impact.

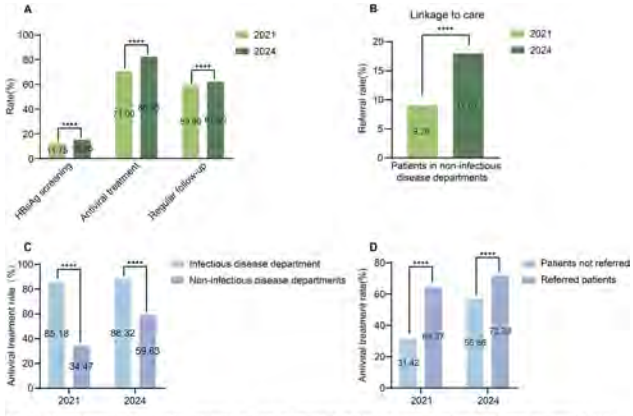

Figure 1. (A) The hospitalwide HBsAg screening rate, antiviral treatment rate, and regular follow-up rate for HBsAg-positive patients in 2021 and 2024. (B) The referral rate ofHBsAg-positive patients from non-infectious disease departments in 2021 and 2024. (C) The antiviral treatment rates in infectious disease and non-infectious disease departments in 2021 and 2024. (D) The differences in antiviral treatment between referedand non-referred patients in non-infectious disease departments in 2021. ****, Chi-square test $p < 0.0001$.

Zeng Shengtao[3] ZUO Weize[4] WU Xu[5] Wang Xiaozhong[1], [1]Traditional Chinese Medical Hospital Affiliated to Xinjiang Medical University, [2]The Second Affiliated Hospital of Xi'an Jiaotong University, [3]Yili Prefecture Xinhua Hospital, [4]The first affiliated hospital of shihezi university medical college, [5]The Fourth Clinical Medical College of Xinjiang Medical University

Background: Tenofovir alafenamide fumarate (TAF) has shown excellent efficacy and safety in the treatment of chronic hepatitis B (CHB), but research data in patients with decompensated cirrhosis remain limited. This study aims to investigate the efficacy and safety of TAF in CHB patients with decompensated cirrhosis. **Methods:** This is a retrospective-prospective, multicenter, real-world clinical study enrolling patients with decompensated hepatitis B cirrhosis who receive daily TAF 25 mg treatment, with a planned follow-up period of at least 48 weeks. The primary endpoint is the HBV DNA negativity rate (< 20 IU/ml) at 48 weeks, while the secondary endpoint is the ALT normalization rate at 48 weeks. Other endpoints include changes from baseline in HBsAg, Child-Pugh (CTP) score, and Model for End-Stage Liver Disease (MELD) score. Safety is also analyzed, including drug-related adverse events (AEs) / serious adverse events (SAEs), and clinical outcomes such as liver transplantation, hepatocellular carcinoma (HCC), mortality, renal function, and lipid abnormalities. **Results:** By May 12, 2025, a total of 106 patients (72 males, 34 females; mean age: 53.5 ± 9.26 years) were enrolled from 6 medical centers, among whom 46 completed 48-week follow-up. After 48 weeks of TAF treatment, the HBV DNA negativity rate increased from 57.55% at baseline to 96.65% (*P < 0.001*), while HBsAg, ALT, and AST levels significantly decreased compared with baseline (all *P < 0.05*). For ALT normalization rate, when using gender-specific criteria (" < 30 U/L for males, < 19 U/L for females"), no significant change was observed compared with baseline (*P > 0.05*); however, when using the uniform criterion " < 40 U/L for both genders", the normalization rate increased significantly (*P < 0.01*). The proportion of patients with Child-Pugh (CTP) score B/C significantly decreased from 60.38% (64/106) at baseline to 30.43% (14/46) at week 48 (*P = 0.004*). Renal function indicators (serum creatinine [Scr], β2-microglobulin [β2-MG], eGFR) and lipid profiles were not significantly affected during treatment. During follow-up, 3 patients developed HCC, while no drug-related adverse events (AEs) / serious adverse events (SAEs), liver transplantation, or mortality were observed. **Conclusion:** TAF demonstrated favorable efficacy and safety in the treatment of CHB patients with decompensated cirrhosis.

Characteristics	Baseline (n=106)	24Weeks (n=33)	48Weeks (n=46)	Statistical value	P

Army Medical University, [3]The First Hospital of Jilin University, [4]Henan Provincial People's Hospital, [5]Jilin Hepatobiliary Disease Hospital, [6]The Sixth People's Hospital of Shenyang, [7]The Second Hospital of Nanjing, [8]Henan Provincial Infectious Disease Hospital, [9]The First Affiliated Hospital of Nanchang University, [10]Chizhou People's Hospital, [11]Qingyuan People's Hospital, [12]Shanghai Tongren Hospital, [13]Shanghai HEP Pharma Co., Ltd, [14]Shanghai HEP Pharma Co. Ltd.

Background: Current clinical practice can hardly eliminate HBV from the host completely because of the persistent reservoir of covalently closed circular DNA (cccDNA) in hepatocyte nucleus. It remains a major challenge in achieving a sterilizing cure for chronic hepatitis B (CHB). Although Pegylated interferon (PEG-IFN) may promote cccDNA degradation via immune modulation, its clinical effect is insufficient to terminate chronic HBV infection. Targeting cccDNA replenishment through inhibition of viral entry offers a complementary mechanism and may have synergistic effects if combined with PEG-IFN. This phase II trial evaluated the efficacy and safety of combining the HBV entry inhibitor hepalatide with PEG-IFN alpha-2a in CHB patients. **Methods:** In this multicenter, randomized, double-blind study (NCT04426968), 96 treatment-naïve CHB patients received daily subcutaneous hepalatide (2.1 mg, 4.2 mg, 6.3 mg) or placebo, in combination with weekly PEG-IFN (180 μg) for 24 weeks. Virological response was defined as a ≥ 2 $\log_{10}$ IU/mL reduction in HBV DNA or HBV DNA < 20 IU/mL. Virological parameters, including serum HBV DNA, HBsAg, HBV pgRNA, and intrahepatic cccDNA quantification in liver biopsies, were assessed at baseline and week 24. Safety and tolerability were closely monitored. **Results:** At week 24, virological response rates were significantly higher in the 4.2 mg hepalatide group (87.5%, 95%CI: 67.64–90.34, $p = 0.0248$) compared to placebo (58.3%, 36.64–77.89). Notably, cccDNA became undetectable in 33.3% (1/3) and 40.0% (2/5) of patients receiving 4.2 mg and 6.3 mg hepalatide, respectively, while remaining detectable in all placebo-treated patients. Despite persistent HBsAg expression, which may derive from integrated HBV DNA rather than cccDNA, this reduction was accompanied by a notable decline in serum pgRNA. At week 24, mean (SD) change in pgRNA from baseline in the 4.2 mg group reached -3.15 (1.93) $\log_{10}$ copies/mL, compared to -2.52 (1.79) in the placebo group. Hepalatide demonstrated a favorable safety profile with only mild injection-site reactions. **Conclusion:** PEG-IFN may promote cccDNA degradation via immune activation, while entry inhibitors block its replenishment by preventing new HBV infection. The combination of hepalatide and PEG-IFN demonstrated measurable intrahepatic cccDNA reduction, supporting a potential strategy for depleting the HBV reservoir. These findings warrant validation in larger studies to further explore their potential contribution to achieving a sterilizing cure for CHB.

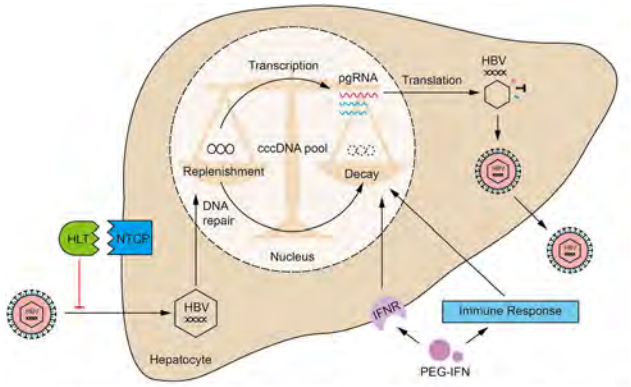

Figure 1. Mechanism of Hepalatide (HLT) and the equillibrium of cccDNA pool. HLT blocks HBV entry, halting cccDNA replenishment, while PEG-IFN accelerates cccDNA decay—shifting the cccDNA balance toward eventual pool exhaustion.

1329 | HERACLIS_BLV_D: PERSISTENCY AND ADHERENCE TO REAL-LIFE THERAPY WITH BULEVIRTIDE (BLV) IN CHRONIC HEPATITIS D (CHD)

Dimitra Lakiotaki[1] Margarita Papatheodoridi[1] Vasilios Sevastianos[2] Kalliopi Zachou[3] Dimitrios Christodoulou[4] John Koskinas[5] Melanie Deutsch[5] Alexandra Alexopoulou[5] Ioannis Elefsiniotis[6] Christos Triantos[7] Elena Gigi[8] Theodoros Androutsakos[1] Dimitrios Karagiannakis[1] Iliana Mani[5] Dimitrios Dimitropoulos[9] Maria Mela[10] Emmanouil Sinakos[8] Spyros Michopoulos[11] Konstantinos Mimidis[12] Nikolaos Papadopoulos[13] Athanasios Kontos[9] Christos Veteranos[10] Dimitrios Lymperopoulos[10] George Giannoulis[3] Vasilios papadimitropoulos[5] Evdoxia Avramopoulou[7] Alkistis Papatheodoridi[11] Spyridon Pantzios[14] Larisa Vasilieva[5] Hariklia Kranidioti[5] Emmanouil Koullias[5] Nikolaos Psichos[4] Paraskevi Fytili[1] John Vlachogiannakos[1] Evangelos Cholongitas[1] Spilios Manolakopoulos[5] Ioannis Goulis[8] George Dalekos[3] George Papatheodoridis[1], [1]General Hospital of Athens "Laiko", Medical School of National &

Kapodistrian University of Athens, [2]General Hospital of Athens "Evangelismos";, [3]General University Hospital of Larissa, [4]University General Hospital of Ioannina, [5]General Hospital of Athens "Hippokratio", [6]General and Oncology Hospital of Kifisia "Agioi Anargyroi", [7]University General Hospital of Patras, [8]General Hospital of Thessaloniki "Hippokratio", Aristotle University of Thessaloniki, [9]Agios Savvas Hospital, [10]General Hospital of Athens "Evangelismos", [11]General Hospital of Athens "Alexandras", [12]University General Hospital of Alexandroupolis, [13]401 General Army Hospital of Athens, Greece, [14]General and Oncology Hospital of Kifisia "Agioi Anargyroi"

Background: BLV has been approved for the treatment of CHD, but real-world data on persistency/adherence is lacking. We aimed to assess the rates and predictors of persistency/adherence to long-term BLV therapy as well as the effects on response rates in CHD. **Methods:** HERACLIS_BLV_D study (NCT05928000) included adult CHD patients who started BLV 2 mg/day and were followed according to standard clinical practice. HDV RNA was assessed by PCR at central lab (sensitivity <100 IU/ml). Virological response (VR) was defined as HDV RNA undetectable (complete VR) or decline >2 log and biochemical response (BR) as normal ALT (≤ 40 IU/L). Persistency was defined by absence of BLV discontinuation considered as no executed BLV prescription for >3 months at the end of follow-up. Adherence was determined by the rates of monthly prescriptions of BLV boxes of 30 vials (percentage of executed prescriptions over certain months divided by the number of months). **Results:** In total, 76 patients were included [age 50 ± 12 years, males 49%, migrants 72%, PWIDs 7%, BMI 25 ± 4 kg/m², liver stiffness 15.9 ± 9.5 kPa, cirrhosis 59%). VR/BR rates were 73%/71% at 12 and 93%/74% at 24 months. Thirteen (17%) patients discontinued BLV (none for adverse events); 5/76 (7%) in the 1st, 5/71 (7%) in the 2nd and 3/54 (6%) in the 3rd year. Of the 13 patients who discontinued BLV (migrants 77%, cirrhosis 54%), 4 died of liver disease (decompensated cirrhosis:3, cholangiocarcinoma:1), 1 died of lung cancer and 8 were lost to follow-up. VR was achieved in 7 and BR in 5 of 10 patients who discontinued BLV and were tested at ≥ 6 months. In patients on therapy, mean adherence was 97 ± 7% in 1st year declining to 93 ± 13% in 2nd and 91 ± 17% in 3rd year ($P \leq 0.010$). No patient characteristic was associated with poor (<90%) or good (≥ 90%) adherence to BLV therapy. Patients with poor vs good adherence had lower relevant response rates (1st year – VR: 40% vs 77%, $P = 0.108$; complete VR: 40% vs 61%, $P = 0.392$ & 2nd year – VR: 60% vs 97%, $P = 0.033$; complete VR: 40% vs 87%, $P = 0.040$; BR: 40% vs 78%, $P = 0.103$). **Conclusion:** In real-life, 6-7% of CHD patients may discontinue BLV therapy annually for several reasons including death, often despite satisfactory responses and good tolerability. Adherence to BLV therapy is excellent in the 1st year, but its mean rate declines in the 2nd and 3rd year remaining however >90%. Poor (<90%) adherence cannot be predicted, but it negatively affects the VR rates emphasizing the need for interventions to improve long-term treatment retention.

1330 | CAM-E AND CAM-A COMPOUNDS DIFFERENTIALLY AFFECT PHOSPHORYLATED AND NON-PHOSPHORYLATED HEPATITIS B CORE PROTEIN IN VITRO

Rene Geissler[1] Hannah Vanrusselt[2] Jordi Verheyen[2] Tse-I Lin[2] Lawrence Blatt[3] Julian Symons[4] Andreas Jekle[3] Megha Patel[5] Gavin Cloherty[1] Yannick Debing[2], [1]Abbott, [2]Aligos Belgium BV, [3]Aligos Therapeutics, Inc., [4]Aligos Therapeutics, [5]Abbott Laboratories

Background: Phosphorylation of hepatitis B core protein (HBc) plays a key role in HBV capsid formation. Empty particles have hyperphosphorylated HBc and DNA-containing particles contain very low levels of phosphorylated HBc. Capsid assembly modulators (CAMs) bind to HBc and modulate the assembly of viral capsids. This study explored the nuanced roles of CAM-E and CAM-A compounds in modulating the dynamics of HBc phosphorylation states, by specifically quantifying both phosphorylated (P-HBcAg) and non-phosphorylated core (HBcAg) proteins, emphasizing the differential impacts of the CAM classes on viral particle formation. **Methods:** A combination of in vitro assays and quantitative analyses was employed to evaluate the effects of CAM-E and CAM-A compounds on HBc phosphorylation states. HepAD38 cells and HBV-infected primary human hepatocytes were treated with different CAMs and nucleoside analogs. Medium and cell lysates were collected after 7 days of culture and used for the P-HBcAg and HBcAg chemiluminescent microparticle immunoassays (CMIA). Specific chemotypes were tested to compare their efficacy and to identify potential mechanistic variations among CAM compounds. **Results:** CAM-Es significantly reduced HBcAg levels, affecting DNA-containing particles both intra- and extracellularly. P-HBcAg levels, representing empty particles, increased correspondingly. CAM-A treatment also reduces HBcAg levels similarly to CAM-E. However, at high CAM-A concentrations, P-HBcAg levels decreased; while at lower concentrations, they increased. Similar patterns were observed across different CAM chemotypes with minor variations. Nucleos(t)ide analogs showed no effect on HBcAg and P-HBcAg over the time course of these experiments. **Conclusion:** These findings confirm that the distinct mechanisms of action of CAM-E and CAM-A compounds are reflected in HBc phosphorylation states and their subsequent effects on viral particle dynamics. The observed concentration-dependent effects of CAM-A compounds on P-HBcAg levels suggest a nuanced interaction that may involve capturing P-HBcAg in intracellular aggregates at higher concentrations. The lack of direct impact by nucleos(t)ide analogs on HBcAg and P-HBcAg levels is in line with their known mechanism of action and underscores the specificity of CAMs in targeting HBc.

1331 | COMBINED MUTATIONS OF HEPATITIS B VIRUS BASAL CORE PROMOTER AND PRECORE REGION CORRELATE WITH IMMUNE-MEDIATED VIRAL CONTROL AND LIVER DAMAGE

Zhao Zhou[1] Guangxin Yu[1] Guiwen Guan[1] Danli Yang[2] Xiangmei Chen[1] Fengmin Lu[1], [1]Peking University, [2]Peking Univeristy

Background: It has been known that basal core promoter (BCP) and/or precore (PC) region mutations favor persistent hepatitis B virus (HBV) infection via facilitating viral immune evasion and viral replication during the disease progression of chronic hepatitis B (CHB). **Methods:** Serum samples were extracted from 153 CHB patients to detect mutations in HBV BCP and PC region by targeting amplicon sequencing. Mutation rates of single sites and combined mutations were calculated by self-written scripts. **Results:** Among the 129 identified mutation sites, the prevalence of 84 sites and the mean mutation rates of 103 sites were found decreased in HBeAg negative patients when compared to HBeAg positive ones. Among the 14 high-rate ($\geq$ 10%) mutation sites, most of them existed in combined mutations which were much more common in HBeAg negative patients. Further analysis showed that mutation rate of some high-rate mutation sites and their combined mutations were closely associated with

patients' clinical indicators. In HBeAg-positive patients, HBV DNA level was correlated negatively with the rate of A1762T, G1764A, A1846T and G1896A but were positively correlated with inflammation markers, including ALT and AST. Mutation rates of some combined mutations constructed by the aforementioned four sites were also correlated negatively with HBV DNA levels but positively with inflammation markers (Figure1). These correlations weakened or disappeared in HBeAg-negative patients. **Conclusion:** This study helps for better understanding the role of mutations and combined mutations in BCP/PC region and their interaction with host immune in disease progression. It suggested that it was the selection of host immune, as reflected by the active hepatic inflammatory damage, that leaded to the accumulation of single site mutations and combined mutations with characteristics of facilitating immune evasion and viral replication.

1332 | APOLIPOPROTEIN C3 ELEVATION IN ISOLATED MAFLD VERSUS HBV CO-INFECTION: DISTINCT METABOLIC PHENOTYPES AND CLINICAL IMPLICATIONS

Kong Xiangsha[1] Lin Zhang[1] Danli Ma[1] Wei Zhang[1], *[1]Peking University People's Hospital*

Background: Metabolic-associated fatty liver disease (MAFLD) and Chronic Hepatitis B virus (HBV) infection are prevalent global chronic liver diseases. Altered immune homeostasis in both diseases may contribute to hepatocellular carcinoma (HCC) progression. Understanding mechanisms of HBV-MAFLD coexistence is crucial for targeted therapies, particularly given HBV's potential impact on MAFLD lipid metabolism and steatosis. This study investigates the HBV co-infection effects on lipid profiles, hepatic steatosis, and metabolic impairments in MAFLD patient. **Methods:** Study Population Retrospective analysis of patients diagnosed with MAFLD (based on predefined criteria) between January 2021 - 2023. Data collection Demographics/anthropometrics (age, gender, weight, BMI, waist/hip circumference); lipid profile (TC, TG, HDL-C, LDL-C); glucose; liver enzymes (ALT, AST, GGT); apolipoproteins (ApoA1, ApoB, ApoC3); HBV serology were collected. Hepatic steatosis/fibrosis assessed via ultrasound and FibroScan. Statistical analysis Continuous variables were compared using one-way ANOVA, categorical variables with χ^2 tests. Statistical significance was defined as $p < 0.05$. **Results:** Clinical characteristics MAFLD with HBV cohort ($n = 72$) was older than isolated MAFLD group ($n = 110$) (median 47 vs. 43.5 years, $p = 0.039$), with more patients aged ≥ 50 years (44.44% vs. 36.36%). Isolated MAFLD patients had higher BMI (27.56 vs. 25.09 kg/m², $p = 0.01$), greater prevalence of class I obesity (25.45% vs. 6.94%), and higher rates of central obesity (males: 45.8% vs. 28.8%; females: 60.5% vs. 25.0%). Metabolic and Hepatic Parameters Isolated MAFLD group showed elevated ApoB (0.813 vs. 0.761 g/L, $p = 0.025$) and ApoC3 (11.77 vs. 10.39 mg/dL, $p = 0.040$). Hepatocellular injury was more severe: ALT (64 vs. 29 U/L), AST (39 vs. 26.5 U/L), and γ-GGT (52 vs. 32 U/L) were more higher in isolated MAFLD group ($p < 0.001$). Median CAP showed no significant difference between the two groups (Isolated MAFLD group: 314.5 dB/m vs. MAFLD with HBV group: 305 dB/m, $p = 0.359$). The proportion of patients with moderate/severe steatosis (CAP ≥ 300 dB/m) was higher in the NAFL group (37.3% vs. 22.2%), but this difference did not reach statistical significance ($p = 0.910$). **Conclusion:** Isolated MAFLD presents a metabolically driven phenotype (younger age, severe obesity, central obesity) characterized by ApoC3-driven dyslipidemia (promoting hepatic lipogenesis) and elevated ApoB, correlating with significant liver injury consistent with metabolic steatohepatitis (MASH). In contrast, MAFLD-HBV patients are older with milder obesity and attenuated metabolic dysregulation, suggesting HBV influences progression via non-metabolic pathways.

1333 | IMPROVEMENT OF HEPATIC STEATOSIS AND ITS ASSOCIATION WITH HBSAG CLEARANCE IN CHRONIC HEPATITIS B PATIENTS RECEIVING PEGYLATED INTERFERON-ALPHA THERAPY

MINGMING ZHANG[1] Huan Liu[1] Juan Liao[2] Dongmei Zhang[2] Min He[2] Libo Yan[2] Lingyao Du[2] Hong Tang[2], [1]West China Hospital of Sichuan University, [2]Center of Infectious Disease, West China Hospital

Background: Hepatic steatosis is frequently observed in chronic hepatitis B (CHB) patients and has been implicated in modulating host immune responses and antiviral efficacy. Pegylated interferon-alpha (PegIFNα) is a finite-duration therapy capable of inducing functional cure. However, the interaction between hepatic steatosis and treatment response to PegIFNα remains inadequately characterized. This study aimed to evaluate longitudinal changes in hepatic fat content during PegIFNα treatment and investigate its association with HBsAg clearance. **Methods:** We conducted a retrospective cohort study of 162 CHB patients treated with PegIFNα (180 μg/week) for ≥48 weeks between April 2020 and April 2021. All patients had prior nucleos(t)ide analog therapy for ≥3 months. Hepatic steatosis was quantified using controlled attenuation parameter (CAP) by transient elastography and stratified as follows: S0 (CAP <248 dB/m, n=91), S1 (248–267 dB/m, n=40), S2 (268–279 dB/m, n=11), S3 (≥280 dB/m, n=20). HBsAg levels, CAP, and BMI were assessed at baseline and every 12 weeks. The primary outcomes were HBsAg seroclearance at week 48 and change in CAP. Correlation between CAP reduction and HBsAg loss was assessed using Pearson's correlation. **Results:** At baseline, increasing steatosis severity was significantly associated with older age, male sex, and higher BMI (all $p<0.001$). After 48 weeks of PegIFNα therapy, the overall HBsAg clearance rate was 40.6% (66/162). Group-specific clearance rates were 46.2% (42/91) in S0, 32.5% (13/40) in S1, 27.3% (3/11) in S2, and 50.0% (10/20) in S3. Despite greater hepatic fat burden, S3 patients exhibited the highest clearance rate, comparable to the non-steatotic S0 group. CAP levels significantly decreased in all steatosis groups, with the greatest absolute reduction in S3 (−32.7 dB/m, $p<0.0001$), followed by S2 (−31.1 dB/m, $p=0.006$), and S1 (−22.5 dB/m, $p<0.0001$). S0 showed no significant change in CAP ($p=0.68$). BMI decreased across all groups (mean Δ−1.0 kg/m², $p<0.001$). A moderate positive correlation was observed between CAP reduction and HBsAg clearance rate across the four groups (Pearson's $r=0.46$), though this did not reach statistical significance ($p=0.11$), possibly due to small subgroup sizes. Baseline BMI was not predictive of CAP improvement ($r=0.12$, $p=0.14$) or HBsAg loss ($r=0.08$, $p=0.31$). **Conclusion:** PegIFNα therapy in CHB patients results in not only significant serological responses but also measurable metabolic benefits, particularly reduction in hepatic steatosis. Importantly, patients with severe baseline steatosis achieved comparable or even superior HBsAg clearance rates to those without steatosis, challenging assumptions about steatosis-related treatment resistance. These findings suggest that improvements in liver fat content may support immune-mediated HBsAg clearance and highlight the potential dual benefit of PegIFNα in serological and metabolic domains.

1334 | SURVEY ON THE AWARENESS AND CLINICAL APPLICATION OF THE " GUIDELINES FOR THE PREVENTION AND TREATMENT OF CHRONIC HEPATITIS B (CHINESE VERSION 2022)" AMONG CHINESE CLINICIANS

Yuanyuan Kong[1] Yujie Guo[2] Yujuan Guan[3] Xuan Liang[4] Zhongjie Hu[5] Xiaobo Lu[6] Mingqin Lu[7] Yongfeng Yang[8] Meifang Han[9] Hong You[1] Zhiyun Yang[2] Jidong Jia[1], [1]Beijing Friendship Hospital, Capital Medical University, [2]Beijing Ditan Hospital, Capital Medical University, [3]Guangzhou Eighth People's Hospital, Guangzhou Medical University, [4]The Sixth People's Hospital of Shenyang, [5]Beijing YouAn Hospital, Capital Medical University, [6]The First Affiliated Hospital of Xinjiang Medical University, [7]The First Affiliated Hospital of Wenzhou Medical University, [8]The Second Hospital of Nanjing, Nanjing, [9]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology

Background: To evaluate clinicians' awareness and current status of clinical practice regarding the HBV guidelines set by the Chinese Society of Hepatology and Chinese Society of Infectious Diseases (CSH/CSID, 2022 version). **Methods:** From July 19 to December 31, 2024, a self-developed electronic questionnaire was distributed via the WeChat mini-program to collect data from Chinese 1,588 clinical physicians nationwide on their knowledge and practices regarding 18 questions across three domains: testing and referral, diagnosis and treatment, and follow-up. **Results:** Among all respondents, only 350 clinicians correctly understood all the updated key points of antiviral indications and treatment for special populations in the Chinese HBV Guidelines (2022 version), with an overall awareness rate of just 22.0%. The actual proportion of

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients with HBV DNA positivity and age >30 years receiving antiviral treatment ranged from 20% to 40%. For patients with HBV DNA positivity and either liver cirrhosis or a family history of hepatocellular carcinoma (HCC), the proportion receiving antiviral treatment ranged from 80% to 100%. Follow-up rates for patients at 1 year, 3 years, and 5 years gradually declined, ranging from 70% to 90%, 25% to 45%, and 25% to 45%, respectively. These declines were associated with factors such as insufficient time for follow-up management by clinicians, patients' lack of awareness about the disease, and poor adherence to follow-up. **Conclusion:** There is a gap between clinicians' awareness and practice of the Chinese HBV Guidelines (2022 version). It is recommended to further strengthen the standardized management and training of the entire process of "detection, diagnosis, treatment, and management" for patients with chronic hepatitis B in healthcare institutions to promote the implementation of the guidelines.

1335 | HEPATITIS B SCREENING IN AN URBAN SAFETY-NET HEALTH SYSTEM BEFORE AND AFTER CHANGES TO CDC GUIDELINES

Karlyn Tunnell[1] *Kathryn Thompson*[1] *Lesley Miller*[1], [1]*Emory University School of Medicine*

Background: Before 2023, the Centers for Disease Control and Prevention (CDC) recommended screening for hepatitis B (HBV) only in individuals at increased risk. In 2023, these guidelines were updated to recommend screening all adults at least once in their lifetime and more frequently for those at increased risk. The recommended screening tests include three serologic tests: hepatitis B surface antigen (HBsAg), hepatitis B core antibody (HBcAb), and hepatitis B surface antibody (HBsAb). There is a gap in the literature regarding how these recommendations have impacted clinical practice. Our study examined screening rates at primary care centers across a single health system before and after the changes in CDC guidelines. **Methods:** We conducted a retrospective analysis of patients across 10 primary care centers within Grady Health System in Atlanta, Georgia two years preceding the changes in CDC guidelines (March 10, 2021-March 10, 2023) and two years following the changes in CDC guidelines (March 11, 2023-March 10, 2025). We examined screening rates, demographic data, and various HBV risk factors as defined by the CDC. Descriptive statistics and independent two-sample t-tests were used to identify differences in screening rates before and after the guideline change. **Results:** There was a statistically significant increase in HBV screening rates among all patients seen in primary care clinics after the change in guidelines. Screening with any component of the three-part serologic test increased from 14.13% to 19.55% (p-value <0.001), and screening with all three components increased from 7.59% vs 12.01% (p-value <0.001). However, there was no statistically significant change in screening rates among patients with identified HBV risk factors. Notably, patients with liver disease were screened at a statistically significantly lower rate after the CDC guidelines changed (13.57% vs 10.13%, p-value 0.024). In contrast, patients without any documented risk factors were screened at a statistically significantly higher rate after the CDC guidelines changed (66.42% vs. 71.33%, p-value <0.001). **Conclusion:** Our study demonstrated an overall increase in HBV screening rates after the updated CDC guidelines. Notably, the increase was almost exclusive to groups without any identified risk factors. This study highlights the need for targeted interventions to enhance routine screening, especially in patient populations at highest risk for HBV.

1336 | COMBINED ASSESSMENT OF PRES1 AND HBV RNA FOR PREDICTING HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS B PATIENTS RECEIVING ENTECAVIR THERAPY

Hatsue Fujino[1] Masataka Tsuge[1] Yusuke Johira[1] Ryoichi Miura[1] Yasutoshi Fujii[1] Atsushi Ono[1] Eisuke Murakami[1] Tomokazu Kawaoka[1] Daiki Miki[1] Shiro Oka[1], [1]Hiroshima University

Background: Prediction of hepatocellular carcinoma (HCC) risk in patients with chronic hepatitis B (CHB) is important for determining appropriate treatment strategies. PreS1 is involved in viral infectivity and replication, while HBV RNA reflects viral transcriptional activity. However, the relationship between these markers and their respective impacts on HCC risk remain unclear. This study aimed to evaluate the clinical utility of PreS1 and HBV RNA levels for predicting HCC risk after initiation of entecavir (ETV) therapy. **Methods:** A total of 87 treatment-naïve CHB patients who started ETV therapy were enrolled (median age: 49 years; median observation period: 8.7 years). Serum PreS1 antigen levels were quantified by ELISA using a PreS1-specific antibody, and HBV RNA levels were measured using the Roche cobas 6800 HBV RNA Investigational Assay. **Results:** A significant correlation was observed between baseline PreS1 and HBV RNA levels ($r = 0.610$, $P < 0.001$). However, no correlation was found between the reductions in these markers after ETV initiation. At 1 year, patients with lower PreS1 or HBV RNA levels showed significantly higher rates of HBV DNA suppression compared to those with higher levels ($P = 0.001$ and $P < 0.001$, respectively). Notably, the group with both low PreS1 and low HBV RNA levels achieved HBV DNA suppression most rapidly. Interestingly, a significant reduction in HBsAg levels was observed in patients with high HBV RNA levels ($P = 0.003$). Based on baseline PreS1 and HBV RNA levels, patients were stratified into four groups. The group with low PreS1 and high HBV RNA showed the highest incidence of HCC, followed by the group with high PreS1 and low HBV RNA. **Conclusion:** The combined assessment of PreS1 and HBV RNA levels may allow for more accurate stratification of antiviral response and HCC risk in CHB patients. In particular, patients with low PreS1 and high HBV RNA levels are at the highest risk of developing HCC and may require intensive monitoring and early therapeutic intervention.

1337 | CROSS-SECTIONAL ASSOCIATION BETWEEN AWARENESS OF HEPATITIS B INFECTION STATUS AND HEALTH-RELATED BEHAVIORS: NHANES 2013 TO 2020

Samandika Saparamadu[1] Elizabeth A. Platz[1] Oshozimhede E Iyalomhe[2], [1]Johns Hopkins Bloomberg School of Public Health, [2]University of Maryland

Background: In the United States, hepatitis B virus (HBV) infection prevalence is higher among individuals born outside the U.S. (1.28% vs. 0.15%), with the highest burden observed among non-Hispanic Asians (3.85%). The national HBV elimination plan aims to increase awareness of the infection status from 50% to 90% by 2030. Awareness of HBV infection may be associated with health-related behaviors, including asymptomatic screening and symptomatic testing. Using nationally representative data, we aimed to: (a) examine associations between socio-demographic factors (race/ethnicity and immigration status) and HBV infection status and awareness categories; and (b) evaluate whether health-related behaviors differ across these categories independent of other factors. **Methods:** In this cross-sectional analysis of 18,250 participants aged >20 years in the National Health and Nutrition Examination Survey cycles 2013 – 2020, we categorized participants based on serology and awareness of HBV infection status: current HBV and aware, current HBV and unaware, past HBV infection, and negative for HBV. We generated a health-related behavior score (0-8) using eight variables capturing health care service utilization, self-motivated, and self-directed health behaviors. We estimated the prevalence ratio (PR) of a favorable health-related behavior score ($>=6$ considered favorable) and 95% confidence intervals (CI) comparing HBV infection status and awareness categories to those negative for HBV using Poisson regression. **Results:** Current HBV infection, irrespective of awareness, was more prevalent among non-Hispanic Asians and immigrants ($p < 0.001$). The only socio-demographic and health-related behaviors that were not associated with HBV status and awareness categories were healthcare utilization, diet, sleep,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and supplement use. The prevalence of favorable health-related behavior scores differed by HBV status and awareness categories in unadjusted analyses ($p < 0.001$). However, after adjusting for socio-demographic and other covariates, no statistically significant differences were observed when comparing individuals with current HBV infection (aware: PR = 0.60; 95% CI: 0.29–1.22; unaware: PR = 1.22; 95% CI: 0.90–1.65) or past infection (PR = 0.90; 95% CI: 0.82–1.00) to uninfected individuals (Table 1). **Conclusion:** After adjusting for confounding variables, engagement in favorable health-related behaviors did not differ significantly by HBV infection or awareness status. Although current infections were more prevalent among non-Hispanic Asians and immigrants, awareness status was not associated with a higher likelihood of favorable health-related behaviors. These findings underscore challenges to achieving 90% awareness and the need for targeted interventions in high-risk groups. We suggest further evaluating the underlying assumptions in the HBV elimination strategy to ensure its feasibility.

Table 1: *Multivariable-adjusted association of HBV infection status and awareness of infection categories with a favorable health-related behavior score*, NHANES 2013-2020 (pre-pandemic).*

Variable	Level	Exponentiated Beta**	Lower CI	Upper CI

1338 | CAPSID ASSEMBLY MODULATOR ALG-001075 BINDS AND DIRECTLY TARGETS HBEAG

Jordi Verheyen[1] Hannah Vanrusselt[1] Thomas Klein[2] Tse-I Lin[1] Cheng Liu[3] Julian Symons[4] Lawrence Blatt[3] Andreas Jekle[3] Yannick Debing[1], [1]Aligos Belgium BV, [2]2bind GmbH, [3]Aligos Therapeutics, Inc., [4]Aligos Therapeutics

Background: The hepatitis B virus (HBV) capsid assembly process has emerged as a key target for the treatment of chronic hepatitis B (CHB). ALG-000184 is a prodrug of ALG-001075, a novel capsid assembly modulator leading to the formation of empty capsids (CAM-E). ALG-000184 has demonstrated best-in-class reductions of HBV DNA, RNA, HBsAg, HBcrAg and HBeAg in CHB patients. ALG-000184 induced an immediate 0.4 $\log_{10}$ PEI U/mL reduction in the first two weeks of treatment of HBeAg-positive patients, suggesting a potential direct effect of ALG-001075 on HBeAg. **Methods:** The impact of ALG-001075 and other CAMs on the HBeAg biogenesis was studied using transient HBeAg expression in Huh7 cells and stably transfected HepG2 cells, with plasmids encoding either wild-type or T33N-mutated HBeAg. The effect on HBeAg secretion was assessed utilizing a Chemiluminescent Immunoassay (CLIA) to determine EC_{50} values, while a Western blot analysis was conducted to characterize the impact of ALG-001075 on HBeAg and its precursors. Interactions between CAMs and purified, fluorescently labeled HBeAg were further investigated using a biophysical spectral shift assay. **Results:** ALG-001075 and other CAMs strongly reduced the levels of secreted HBeAg in the absence of other HBV proteins, suggesting a direct effect on HBeAg. EC_{50} values for HBeAg inhibition were considerably higher than for HBV DNA inhibition but strongly increased upon introduction of the T33N mutation into HBeAg, indicating a similar binding site to the HBV core protein. Western blot analysis showed CAMs also impacted the HBeAg precursor (p22), contributing to HBeAg secretion inhibition. Finally, biophysical analysis through spectral shift confirmed direct binding of ALG-001075 and other CAMs to wild-type HBeAg but not to the HBeAg T33N mutant. **Conclusion:** ALG-001075 demonstrated direct binding to HBeAg and pronounced in vitro reductions in secreted HBeAg levels, in line with clinical observations for its prodrug ALG-000184, suggesting direct inhibition of HBeAg as a third mechanism of action for ALG-001075. Although the direct HBeAg effect requires higher compound concentrations than the primary and secondary effects of CAMs, the high pharmacokinetic exposure achieved with prodrug ALG-000184 and relative HBeAg-targeting potency of parent ALG-001075 likely enable the clinical observation of this effect.

1339 ASSESSING THE FREQUENCY OF HEPATITIS DELTA VIRUS SCREENING IN PATIENTS WITH CHRONIC HEPATITIS B | RESULTS FROM AN INTERACTIVE DECISION SUPPORT TOOL APP IN ALIGNMENT WITH AASLD GUIDANCE

Carley Yawn[1] Zachary Schwartz[1] Paul Kwo[2,] [1]Clinical Education Alliance, [2]Stanford University Medical Center

Background: The 2018 American Association for the Study of Liver Diseases (AASLD) guidance recommends risk-based screening for hepatitis delta virus (HDV) in patients with chronic hepatitis B (CHB). Key risk indicators include (1) coinfection with hepatitis C virus (HCV) and/or HIV and (2) low HBV DNA levels plus elevated alanine aminotransferase (ALT) levels, among other clinical factors. However, these criteria can be complex to apply in real-world settings, potentially contributing to under-screening. Amid a growing trend toward universal HDV screening, tools that simplify guideline interpretation may be helpful. To support healthcare professionals (HCPs) in identifying patients who meet screening criteria, the Hep B Consult point-of-care app was developed to provide patient-specific recommendations based on user-entered clinical data. **Methods:** We analyzed real-world data from the Hep B Consult app from March 3, 2023, to May 13, 2025. The evaluation focused on CHB cases where HCPs had selected AASLD as their preferred guideline. Cases were deemed eligible for HDV screening if they met the criteria established by AASLD: • Scenario 1: HCV and/or HIV coinfection. • Scenario 2a: low or unknown HBV DNA level AND ALT > ULN or unknown. • Scenario 2b: low or unknown HBV DNA level AND healthcare workers at elevated risk (no ALT level required). Patient cases were then categorized by whether HDV screening was completed (HDV antibody listed as positive or negative) or incomplete (HDV antibody status unknown). **Results:** Among 2170 patient cases entered by HCP learners selecting AASLD as their preferred guideline, 430 cases met criteria for HDV screening, but 48 (34.4%) of these had no HDV screening information. Among these 430 cases where HDV screening was indicated, 158 cases had positive HDV antibody. Among these, 21 (13.3%) lacked follow-up HDV RNA testing. These cases suggest missed opportunities for early detection and intervention in a high-risk population. **Conclusion:** This analysis highlights a significant care gap: More than one third of CHB patient cases meeting AASLD guidance–based criteria for HDV screening were not screened, and follow-up HDV RNA testing was often missed. These findings may highlight the difficulty HCPs face in identifying whom to screen based on complex risk-based criteria. As the field considers a shift toward universal HDV screening, our data suggest current practices fall short. Broader integration of tools like Hep B Consult may support improved guideline adherence and enhance patient outcomes.

1340 | DIFFERENT IMPACT OF HBV GENOTYPE ON HBSAG DECLINE KINETICS DURING AND AFTER NUCLEOS(T)IDE ANALOGUE THERAPY IN HBEAG-NEGATIVE CHRONIC HEPATITIS B

Rachel Wen-Juei Jeng[1] Chien-Hung Chen[2] Yen-Chun Liu[1] Rong-Nan Chien[1], [1]Chang Gung Memorial Hospital, Linkou Medical Center, [2]Kaohsiung Chang Gung Memorial Hospital

Background: In HBeAg-negative chronic hepatitis B (CHB), serum HBsAg kinetics serve as a surrogate marker for functional cure. While host and viral factors influencing HBsAg decline during nucleos(t)ide analogue (Nuc) therapy have been identified, genotype-specific differences in HBsAg kinetics across treatment phases remain unclear. We investigated whether HBV genotype (GT) differentially modulates HBsAg reduction during active Nuc treatment and after treatment cessation. **Methods:** A total of 614 non-cirrhotic HBeAg-negative CHB patients [GT-B: 535 (87.1%), GT-C: 79 (12.9%)] treated with finite-course Entecavir (ETV) or Tenofovir Disoproxil Fumarate (TDF) according to APASL stopping criteria at Chang Gung Memorial Hospital (CGMH)-Linkou, Taiwan, were included. HBsAg levels were assessed at the start of treatment (SOT), end-of-treatment (EOT), and last follow-up. Two propensity score–matched (PSM) cohorts were constructed: PSM-cohort 1 (n = 158) for on-treatment analysis (matched by age, sex, treatment-naïve status, Nuc agent, and SOT ALT, HBV DNA, and HBsAg levels); and PSM-cohort 2 (n = 132) for off-treatment analysis (matched by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

EOT age, sex, Nuc agent, and baseline laboratory parameters). Generalized linear regression was used to identify predictors of HBsAg reduction. A multivariable linear mixed model (LMM) was employed to evaluate genotype-by-phase interaction. External validation was conducted in an independent cohort of 701 patients [GT-B: 541 (77.2%), GT-C: 160 (22.8%)] from CGMH-Kaohsiung. **Results:** In PSM-cohort 1, patients with GT-B exhibited significantly greater on-treatment HBsAg reduction compared to those with GT-C (–0.21 vs. –0.05 $\log_{10}$ IU/mL/year, $p < 0.001$). In PSM-cohort 2, GT-C patients demonstrated a significantly faster off-treatment decline (–0.22 vs. –0.08 $\log_{10}$ IU/mL/year, $p = 0.001$) and a higher HBsAg loss rate (15.2% vs. 0%, $p = 0.001$). Similar trends were observed in the external validation cohort. In the full cohort, GT-B ($\beta = 0.194$, $p < 0.0001$), older age at SOT, and higher SOT ALT, HBV DNA, and HBsAg levels were independently associated with a greater on-treatment HBsAg decline. For off-treatment decline, GT-C ($\beta = -0.1669$, $p = 0.0057$), younger EOT age, and lower HBsAg at EOT were independent predictors. A LMM confirmed a significant genotype-by- phase interaction ($p = 0.0144$), indicating that HBV genotype differently modulates HBsAg reduction kinetics across treatment phases (Figure). Following Nuc cessation, GT-C patients exhibited accelerated HBsAg decline, whereas GT-B patients showed stable HBsAg levels. **Conclusion:** HBV genotype modulates HBsAg reduction kinetics in a phase-specific manner. GT-B is associated with a greater decline during Nuc therapy, whereas GT-C shows enhanced off-Nuc HBsAg reduction and subsequent HBsAg loss. These findings underscore the need for genotype-specific immunologic studies to elucidate underlying mechanisms.

1341 | INTEGRATED PLASMA PROTEOMICS AND METABOLOMICS IDENTIFY FIBROSIS-LINKED SIGNATURES IN HBEAG-NEGATIVE NAIVE CHB PATIENTS WITH LOW HBSAG

Ravinder Singh[1] NUPUR SHARMA[1] Neha Sharma[1] Sadam Bhatt[1] Archana Rastogi[1] Shiv Kumar Sarin[1] Nirupama Trehanpati[1], [1]Institute of Liver and Biliary Sciences

Background: HBsAg levels indicate viral activity and immune control in HBeAg-negative, treatment-naive chronic hepatitis B patients, but associated molecular changes remain unclear. This study integrates plasma proteomics and metabolomics to identify distinct molecular signatures linked to HBsAg levels, revealing disease heterogeneity and potential biomarkers. **Methods:** We recruited thirty-treatment-naive HBeAg-negative chronic hepatitis B (nCHBV) patients were stratified into Group I ($HBsAg^{low}$, $n = 10$; HBsAg < 2000 IU/mL) and Group II ($HBsAg^{high}$, $n = 20$; HBsAg > 2000 IU/mL, HBV DNA > 2000 IU/mL, ALT $> 1.2\times$ULN) and healthy control (HC, $n = 10$). Liver histopathological scoring, plasma cytokine profiling, proteomic and metabolomic analyses were performed. **Results:** Total nCHBV patients compared to HC, plasma proteomics pathway enrichment analysis showed significant activation of immune and fibrosis-related pathways, including complement cascade (C3/C5), $\alpha4\beta7$ integrin, TLR signaling, and fibrin clot formation compared to healthy controls. Key discriminatory proteins APCS, HBD, SAA2, and S100A8 were markedly elevated ($FC > 4$, $p < 0.05$). Metabolomic analysis revealed increased levels of S-adenosylmethionine, glutamic acid, and indolepyruvate, linked to arginine and tryptophan metabolism ($FC > 1.5$, $p < 0.05$). Further, nCHBV $HBsAg^{low}$ compared to $HBsAg^{high}$ subgroups, pathway enrichment analysis showed upregulation of IL-4 signaling, platelet activation/degranulation, PTP1B signaling, ECM interactions, and fibrin clot formation ($FC > 2$, $p < 0.05$). $HBsAg^{low}$ specific proteins included ARG1, S100A9, S100A8, and PLEK ($FC > 10$, $p < 0.05$). Metabolomic profiling showed elevated dihydrofolic acid and 5-methoxyindoleacetate in HBsAglow, indicating altered folate and tryptophan metabolism ($FC > 1.5$, $p < 0.05$). Integrated proteomic-metabolomic data in $HBsAg^{low}$ indicated coordinated TLR4 signaling activation, enhanced fibrin clot formation, and disrupted tryptophan metabolism, correlating with plasma cytokines CXCL8, CXCL11, CXCL12 levels and liver fibrosis severity. The ARG1, S100A9, S100A8, and PLEK panel

demonstrated highest diagnostic accuracy for identifying HBV patients at risk of subclinical inflammation and fibrosis (FC > 10, p < 0.05). **Conclusion:** Integrated multiomics and cytokine analysis identified inflammation- and fibrosis-associated proteins and metabolites specific to nCHBV-HBsAg^{low} patients, which should be closely monitored for disease progression using a proteomics panel including ARG1, S100A9, S100A8, and PLEK.

1342 | MMP-9 SUPPRESSES THE ANTI-HBSAG B CELL RESPONSE DURING CHRONIC HBV INFECTION

Dongliang Yang[1] Dilhumare Ablikim[2] Yuhan Chen[2] Mengxiao Zhao[2] Yanqin Du[2] Xuecheng Yang[2] Mengji Lu[3] Xin Zheng[2] Jia Liu[2], [1]Depart. Infectious Disease, Union Hospital of TJMC, HUST, [2]Department of Infectious Diseases, Union Hospital, Tongji Medical College, HUST, [3]Institue for Virology, University Hospital of Essen, University of Duisburg-Essen, Essen, Germany

Background: Our previous research indicated that Matrix Metalloproteinase (MMP)-9, together with MMP-2, are involved in the regulation of intrahepatic anti-HBV effector T cell responses in acute self-limiting HBV infection. However, it remains unclear if MMP-9 also plays a role in regulating anti-HBV immune responses and mediating HBV clearance in the scenario of chronic HBV infection. **Methods:** We employed MMP-9 gene knockout (KO) and RNA interference techniques in chronic HBV replication mouse models. **Results:** The absence of MMP-9 in FVB mice led to significantly accelerated clearance of Hepatitis B surface antigen (HBsAg) in peripheral blood and increased production of Hepatitis B surface antibody (HBsAb) in pAAV-HBV1.2 or BPS plasmids hydrodynamic injection (HDI) mouse models. Adoptive transfer of spleen immune cells from MMP-9 KO mice to wild-type mice could also accelerate serum HBsAg clearance and enhance HBsAb production in the pAAV-HBV1.2 HDI mouse model, suggesting that the anti-HBV effect of MMP-9 KO is mainly mediated by immune cells. RNA-seq analysis showed that MMP-9 KO significantly induced enrichment of genes related to the B-cell receptor signaling pathway in the splenocytes of mice post pAAV-HBV1.2 HDI compared to wild-type mice. MMP-9 KO mice also showed significantly enhanced B cell activation, as well as increased numbers of germinal B cells and follicular helper CD4+ T cells infiltration in the liver post pAAV-HBV1.2 HDI compared to wild-type mice. In vivo knockdown of MMP-9 expression by RNAi also resulted in significantly accelerated serum HBsAg clearance in wild-type FVB and C57BL/6 mice post pAAV-HBV1.2 HDI. **Conclusion:** MMP-9 may play a role in negatively regulating anti-HBV B cell responses during chronic HBV infection. Targeting MMP-9 could serve as a novel strategy for the treatment of chronic HBV infection.

1343 | CHARACTERISTICS ASSOCIATED WITH SUBSPECIALTY CARE WITHIN A HEPATITIS B VIRUS (HBV) COHORT AT A TERTIARY CARE URBAN HOSPITAL

Lindsay Matthews[1] Yedidya Saiman[2], [1]Temple University, [2]Lewis Katz School of Medicine at Temple University

Background: Hepatitis B virus (HBV) has a prevalence in the US around 0.4%. Those with chronic infection remain at risk for complications including cirrhosis and hepatocellular carcinoma (HCC), and require subspecialty care due to complexities with management and cancer screening. We aim to evaluate the roughly 1,300 patients within our hospital system with HBV to determine patient characteristics that are associated with subspecialist follow-up. **Methods:** Patients 18 years and older with a positive hepatitis B surface antigen (HBsAg) from January 2011-November 2022 were included. We obtained demographic data, medical and social history, laboratory and imaging data. We compared the medical and social characteristics between the cohorts who followed with subspecialty care, primary care, and those without any follow up care to determine characteristics associated with subspecialty care and examined hepatocellular carcinoma screening rates. **Results:** Our cohort includes 1,314 patients with a positive HBsAg. Of those, 666 (50.7%) had any follow-up (PCP or subspeciality), and 450 (34%) had subspecialty follow-up (1+ visit with gastroenterology, hepatology, or infectious disease). Among the 450 with any follow-up, those who engaged in subspecialty care were older (50 vs 45 years, $p = 0.019$), and had higher rates of end-stage liver disease (30.7% vs 9.6%, $p < 0.001$) and elevated FIB4 (18.9% vs 7.0%, $p < 0.001$). There were similar rates of drug use (26.9% vs 29.8%, $p = 0.45$), housing insecurity (2.2% vs 2.5%, $p = 0.78$), and HIV (11.1% vs 13.6%, $p = 0.36$).

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Although there were similar rates of obtaining hepatitis C antibody (83.9% vs 74.3%, p = 0.22), those in subspecialty care were more likely to have had at least one alphafetoprotein AFP (79.3% vs 20.8%, p < 0.001). **Conclusion:** Subspecialty care in chronic HBV is associated with improved screening and identification of severe liver disease but likely reflects referral bias. Importantly, patients facing social barriers, including drug use and housing insecurity, can and do access subspecialty care when connected. Primary care, emergency, and inpatient settings are crucial referral points and should be leveraged to promote specialist engagement. Interventions such as electronic consults or proactive referrals from primary care may improve HBV care delivery in underserved populations.

1344 | LONGITUDINAL CHANGES IN FIB-4 INDEX AND RISK FACTORS FOR FIBROSIS PROGRESSION IN UNTREATED HEPATITIS B VIRUS CARRIERS: A MULTICENTER STUDY

KENGO WATANABE[1] Jun Inoue[1] Takehiro Akahane[2] Hiroaki Haga[3] Tomoo Kobayashi[4] Satoshi Takai[5] Shinichiro Minami[6] Kojiro Kataoka[7] Mami Kida[8] Toshihiro Sato[9] Noriyuki Obara[10] Masashi Ninomiya[1] Mio Tsuruoka[11] Kosuke Sato[1] Keishi Ouchi[1] KOTARO DOI[1] Tomoya Sasazaki[1] Hirofumi Niitsuma[1] Yoshiyuki Ueno[3] Atsushi Masamune[1], [1]Tohoku University Graduate School of Medicine, [2]Japanese Red Cross Ishinomaki Hospital, [3]Faculty of Medicine, Yamagata University, [4]Tohoku Rosai Hospital, [5]Iwaki City Medical Center, [6]Akita University Graduate School of Medicine, [7]Japanese Red Cross Sendai Hospital, [8]Kurihara Central Hospital, [9]LC Clinic Sendai, [10]JCHO Sendai Hospital, [11]Tohoku University Hospital

Background: According to the guideline of the Japan Society of Hepatology, antiviral therapy is recommended for patients with chronic hepatitis B who have both HBV DNA ≥ 3.3 log IU/mL and ALT ≥ 31 U/L. However, patients who do not meet these criteria may still develop fibrosis and have an increased risk of hepatocellular carcinoma over time. The objective of this multicenter study was to evaluate fibrosis progression using longitudinal changes in the FIB-4 index in nucleos(t)ide analogue (NA)-untreated HBV carriers and to identify associated clinical risk factors. **Methods:** We retrospectively enrolled HBsAg-positive patients who were first seen in 2019 and had not received prior NA therapy. Annual FIB-4 index values were calculated, and follow-up was terminated if treatment was initiated. The slope of FIB-4 change (S1) was divided by the age-related physiological slope (S2), and the ratio of S1 to S2 (S1/S2) was defined as a fibrosis progression grade. Cases with S1/S2 ≥ 2.0 were considered as fibrosis progressors. Patients with baseline FIB-4 ≥ 4.0, other diseases causing thrombocytopenia, or follow-up < 3 years were excluded. **Results:** Of the 584 cases from 10 institutions, 452 patients were included in the study (median age: 58 years; 48% male; median ALT: 21 U/L; platelet count: 21.1×10^4/μL; HBV DNA: 2.9 log IU/mL; baseline FIB-4: 1.34; median follow-up: 7 years). Fibrosis progression occurred in 25.4% of patietns. Patients were stratified into four groups based on HBV DNA (cutoff: 3.3 log IU/mL) and ALT (cutoff: 31 U/L): Group a: high DNA/high ALT (n = 48); Group b: high DNA/low ALT (n = 121); Group c: low DNA/high ALT (n = 68); Group d: low DNA/low ALT (n = 215). The median fibrosis progression grades were 0.77, 0.95, 0.61, and 1.15, respectively; group d had the highest grade. In a multivariate analysis, high HbA1c levels were significantly associated with progression in group d (odds ratio [OR] 2.67, P = 0.045), while a higher platelet count predicted progression in group b (OR 1.10, P = 0.006). Interestingly, steatosis was associated with increased progression in patients with HBV DNA ≥ 4.0 log IU/mL (2.80 vs. 0.64, P = 0.007), whereas it was associated with reduced progression in those with DNA < 4.0, (0.52 vs. 1.08, P = 0.004). **Conclusion:** Fibrosis can progress in patients with HBV infection, even when ALT and HBV DNA levels were low, particularly when HbA1c is elevated. In patients with high HBV DNA levels and low ALT levels, fibrosis may still progress despite normal platelet counts. Furthermore, the impact of fatty liver varies by HBV DNA level, suggesting a need to revisit treatment strategies and consider proactive interventions for high-risk subgroups.

1345 | POSITIVITY OF HIGH-SENSITIVITY HBSAG TEST, NOT PREVIOUS HBV INFECTION, INDICATES POOR PROGNOSIS IN PATIENTS WITH NON-HBV-RELATED HCC

Naohiro Yasuura[1] Goki Suda[1] Masatsugu Ohara[1] Daisuke Yokoyama[1] Shoichi Kitano[1] Takatsugu Tanaka[1] Akimitsu Meno[1] Takashi Kitagataya[1] Masato Nakai[1] Takuya Sho[1] Naoya Sakamoto[1], [1]Hokkaido University Faculty of Medicine and Graduate School of Medicine

Background: The prognostic impact of previous-HBV-infection (pHBV) in non-HBV-related hepatocellular carcinoma (non-HBV HCC) remains unclear. Recently a high-sensitivity HBs antigen test has been developed. The prevalence and significance of high-sensitivity HBs antigen positivity (hHBsAg+) in non-HBV HCC patients with pHBV have not been fully clarified. **Methods:** We retrospectively screened patients with newly diagnosed non-HBV HCC (standard HBsAg-test negative) from April 2000 to March 2023. Patients with insufficient clinical information or positive HBV-DNA were excluded. We evaluated the prevalence, characteristics and prognostic impact of pHBV and hHBsAg+ in non-HBV HCC. We compared three groups as follows: Group 1 – without pHBV, Group 2 - with pHBV and without hHBsAg+, and Group 3 – with pHBV and hHBsAg+. **Results:** A total of 401 non-HBV HCC patients were included (288 with pHBV/113 without pHBV). pHBV did not affect overall survival (OS). Among non-HBV HCC patients with pHBV, 11.8% (34/288) were hHBsAg+ and had more advanced stages of HCC, higher AFP levels, higher vascular invasion rates. Comparison of OS among 3 groups revealed significantly shorter OS in Group 3 (66.4, 56.6, and 19.3 months in Groups 1, 2, and 3, respectively ; $p = 0.036$). Multivariate Cox regression indicated that only Group 3 was significantly and independently associated with shorter OS (HR: 2.044, $p = 0.011$) in addition to BCLC stage, Child-Pugh grade, platelet counts, AST, and AFP. Subgroup analysis in patients with non-B-non-C aetiology HCC revealed that Group 3 had significantly shorter OS than the other groups (OS: 66.4 months vs 44.6 months vs 11.4 months, $p = 0.035$) and, multivariate Cox regression indicated that only Group 3 was significantly and independently associated with shorter OS (HR: 2.954, $p = 0.005$). Subgroup analysis in patients with non-B-non-C aetiology and BCLC stage B/C/D HCC revealed that Group 3 had significantly shorter OS than the other groups (OS: 44.5 months vs 20.9 months vs 5.9 months, $p < 0.001$) and, multivariate Cox regression indicated that only Group 3 was significantly and independently associated with shorter OS (HR: 7.426, $p < 0.001$). **Conclusion:** In patients with non-HBV-related HCC, hHBsAg+ is significantly and independently associated with poor prognosis. This association is particularly evident in HCC patients with NBNC aetiology and advanced HCC. These findings have potential utility in the clinical management of and therapeutic strategies for patients with non-HBV-related HCC.

1346 | IDENTIFICATION OF HBV CURE PATIENTS BY HBV RNA AND HBV GENOME COVERAGE MAP IN PLASMA

Daryl Lau[1] Selena Lin[2] Hsin-Ni Liu[3] Zach Heimer[2] Rohullah Rasikh[1] Mati Ullah[1] Khawaja Hassam[4] Mansoor Rahman[1] Zhili Wang[2] Ying-Hsiu Su[5], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, [2]JBS Science, Inc., Doylestown, PA, United States, [3]The Baruch S Blumberg Institute, Doylestown, PA, United States, [4]Lahey Hospital and Medical Center, [5]Baruch S. Blumberg Institute

Background: Despite prolonged NUC therapy, the rate of functional cure, defined as HBsAg loss and transcriptionally silent cccDNA, remains low. In HBeAg (-) CHB, most of the HBsAg is derived from integrated HBV DNA (iDNA). Some may have achieved either non-replicative cccDNA or cccDNA depletion but still have HBsAg from iDNA. We applied our liquid biopsy biomarker that estimates intrahepatic HBV DNA genome coverage and serum HBV RNA as cccDNA surrogate markers to determine potential cure among

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

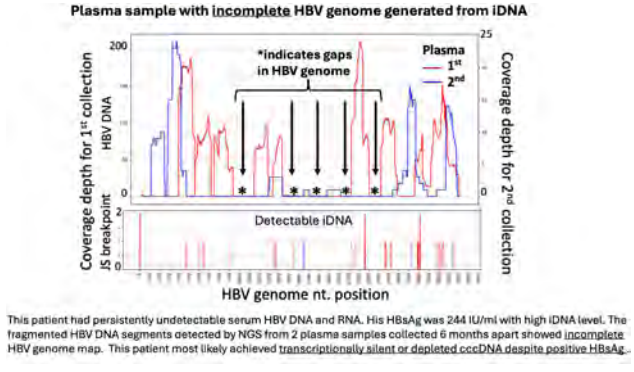
HBeAg(-) CHB patients with various HBsAg levels. **Methods:** We utilized the HBV-targeted Next Generation Sequencing (NGS) platform and *ChimericSeq* bioinformatics to quantify iDNA and construct genome map with fragmented HBV (fHBV) DNA on plasma samples from 83 HBeAg(-) CHB patients. Samples with incomplete HBV DNA genome coverage likely had cccDNA depletion as illustrated in Figure. Second-generation HBV RNA assay (LOD 0.49 U/ml) was by Abbott Diagnostics. 73 patients on continuous NUC for at least 3 years with undetectable or <10 IU/ml serum HBV DNA were selected. Among them, 5 achieved HBsAg loss (<0.05 IU/ml) and 69 had HBsAg levels between 0.4 and $>25{,}000$IU/ml. In addition, 10 patients with spontaneous HBsAg clearance were included. **Results:** 78 (94%) of this cohort were Asians and 51 (61%) were male. The mean age was 53 (range: 27 to 79) years. All the subjects had detectable plasma iDNA. HBsAg was positively correlated with iDNA ($r=0.23$, $p=0.016$) and fHBV DNA ($r=0.27$, $p=0.003$). This finding suggested that most of the HBsAg was derived from iDNA. There was no significant correlation between HBV RNA and HBsAg ($p=0.24$). 11 (73%) subjectswith HBsAg <0.05 IU/ml had undetectable HBV RNA and partial HBV DNA genome coverage. In addition, 5 subjects with HBsAg ranged from 1.5 to 244 IU/ml also had undetectable HBV RNA and partial HBV coverage. By using the criteria of both undetectable serum HBV RNA and partial HBV genome coverage, 16 (19%) of this cohort most likely achieved transcriptionally silent cccDNA or cccDNA depletion. Their detectable fHBVDNA would have been derived from iDNA. **Conclusion:** HBsAg can be derived from cccDNA and iDNA; currently, there is no diagnostic test to distinguish the sources of HBsAg. By applying undetectable HBV RNA and partial HBV DNA genome coverage criteria, we were able to identify patients who had potentially achieved HBV cure regardless of their HBsAg levels. This encouraging surrogate liquid biopsy for "HBV cure" need to be further validated.



This patient had persistently undetectable serum HBV DNA and RNA. His HBsAg was 244 IU/ml with high iDNA level. The fragmented HBV DNA segments detected by NGS from 2 plasma samples collected 6 months apart showed incomplete HBV genome map. This patient most likely achieved transcriptionally silent or depleted cccDNA despite positive HBsAg.

1347 | INTEGRATIVE CLINICAL AND MOLECULAR RISK SCORE FOR PREVENTION OF HBV-RELATED HCC

Hiroyuki Suzuki[1] Hiroaki Kanzaki[1] Naoto Fujiwara[2] Jingxuan Chen[1] Courtney Katz[1] Soumith Paritala[1] Ece Janet Dinc[1] Subhojit Paul[1] Sumit Mishra[1] Jeon Lee[1] Hsiao-Ling Huang[3] Ming-Chin Yu[4] Tsung-Han Wu[3] Vera Kim[5] Venancio Alves[5] Flair Jose Carrilho[5] Suzane Ono[5] Adam Yopp[1] Amit Singal[1] Emilie Crouchet[6] Thomas Baumert[6] Sen-Yung Hsieh[3] Yujin Hoshida[1], [1]University of Texas Southwestern Medical Center, [2]Mie University, [3]Chang Gung Memorial Hospital, [4]New Taipei Municipal TuCheng Hospital, [5]University of São Paulo School of Medicine, [6]University of Strasbourg

Background: Patients with HBV-related chronic liver disease remain at risk even with the use of antiviral therapies. Clinical variable-based scores such as PAGE-B score have been proposed for HCC risk precision in patients with HBV-related chronic liver disease. However, there is still room for improvement to refine risk stratification and early detection of HBV-related HCC. **Methods:** We defined and validated multi-omic molecular signatures (transcriptome including viral-host fusion transcripts, single nucleotide polymorphisms [SNPs] in coding regions, somatic DNA mutational signature, and somatic DNA mutations with predicted functional consequence) associated with time to incident HCC development and validated their outcome association in total of 111 patients with HBV-related cirrhosis (median follow-up 9.3 years; IQR 3.4–12.3 years). These candidate molecular signatures were integrated with PAGE-B. The HBV-specific transcriptomic signature was used for *in silico* screening of compounds that favorably modulated the HBV HCC risk signatures. Candidate compounds were tested in two models: an *in vitro* cell-based model (cPLS), inducible for the prognostic liver signature (PLS) we previously reported, and an *ex vivo* organotypic culture of precision-cut liver slice (PCLS) derived from HBV-infected patients. **Results:** In the derivation set including 39 HBV cirrhosis patients, we defined a 95-gene transcriptomic signature, which was associated with fibrogenic molecular pathways among several others. In addition, DNA mutational signatures related to reactive oxygen species-induced DNA damage were associated with HCC risk. Spatial mapping of these signatures on liver tissue samples is currently underway. No ~ marginal association was observed for SNPs previously reported for HCC risk association. These HCC risk-associated molecular signatures were integrated with PAGE-B score, and evaluated

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in independent validation sets, including a longitudinal cohort (n = 42) and a case-control series (n = 30). The integrative score was associated with HCC risk on the longitudinal cohort (Firth-adjusted HR, 16.2; 95% CI, 1.9-135.7) and the case-control series (Firth-adjusted OR, 12.3; 95% CI, 1.1-1705.8). Two candidate compounds were identified as potential chemopreventive agents to improve high-risk pattern of the molecular signatures. Their assessment in the cPLS and PCLS models are currently ongoing. **Conclusion:** An integrative clinical and molecular risk score for HBV-related HCC showed promising performance in our preliminary validation studies, which warrants further validation. The score may also serve as a companion biomarker for the candidate chemoprevention agents.

1348 | COVID-19 PANDEMIC INTENSIFIED AGE AND SEX DISPARITIES IN DIAGNOSTIC AND HEPATIC EVENT INCIDENCES IN INDIVIDUALS WITH CHRONIC HEPATITIS B

Grace Lai-Hung Wong[1] Vicki Hui[1] Mandy Lai[1] Jimmy Che-To Lai[2] Vincent Wong[2] Terry Cheuk-Fung Yip[2], [1]Medical Data Analytics Centre, State Key Laboratory of Digestive Disease, The Chinese University of, [2]The Chinese University of Hong Kong

Background: Age and sex significantly influence the diagnosis and outcomes of chronic hepatitis B (CHB). Lockdowns amid the COVID-19 pandemic might have further exacerbated the impact. This study evaluated the secular trends in diagnostic rates of chronic hepatitis B virus (HBV) infection and the incidences of hepatic events, focusing on disparities by age and sex region over two decades before, during, and after the COVID-19 pandemic. **Methods:** Individuals with CHB were identified from a territory-wide database from year 2000 to 2024. Age- (18-30, 30-40, 50-60, 60-70, 70-80, >80 years) and sex-stratified diagnostic rates of HBV in 2000-2024 were calculated based on the number of individuals tested annually, Incidences of hepatic events, including hepatocellular carcinoma, decompensating events, and liver transplantation, were calculated among HBV-infected individuals. **Results:** A total of 276394 individuals were diagnosed with HBV. Newly diagnosed HBV rates increased over time across all age groups, with the most dramatic increase observed in patients of 50-59 years old, from 0.36% [0.34%–0.39%] in 2000 to 3.31% [3.31%–3.42%] in 2021, dropped to 3.11% [2.98%–3.25%] in 2022, then bounced back to 9.82% [9.44%–10.19%] in 2024. Men had consistently higher diagnostic rates for HBV than women: it peaked in 2021 for both sexes – 2.84% [2.77%–2.91%] in men and 2.56% [2.50%–2.62%] in women; dropped to 2.83% [2.75%–2.91%] in men and 2.56% [2.50%–2.62%] in women in 2022, then bounced back to 8.19% [7.97%–8.41%] in men and 6.90% [6.71%–7.09%] in women in 2024. Incidence of hepatic event increased significantly with age over time; it was highest in patients of 70 years or older, rising from 15.00% [14.30%–15.71%] in 2000 to 55.32% [53.76%–56.89%] in 2023 dropped to 44.32% [42.21%–46.44%] in 2024. Men had consistently more hepatic events than women; it peaked in 2022 for both sexes – 22.06% [21.37%–22.74%] in men and 15.76% [15.14%–16.37%] in women (Figure). **Conclusion:** Newly diagnosed HBV rates showed substantial increases, particularly among middle-aged males. Hepatic event rates rose with age, especially in older males. Such disparities have been intensified amid COVID-19 pandemic, and mostly relieved toward the end of the pandemic.

1349 | A MARKOV MODEL COST THRESHOLD ANALYSIS OF POTENTIAL HEPATITIS B VIRUS CURE REGIMENS IN THE U.S

Grace Lai-Hung Wong[1] Boyu Yang[2] Jimmy Che-To Lai[1] Vincent Wong[1] Robert Wong[3] Anna Lok[4] Terry Cheuk-Fung Yip[1], [1]The Chinese University of Hong Kong, [2]Medical Data Analytics Centre, State Key Laboratory of Digestive Disease, The Chinese University of, [3]VA Palo Alto Healthcare System, [4]University of Michigan Medical Center

Background: Various hepatitis B virus (HBV) cure regimens are actively undergoing clinical development and will soon be available for regulatory approval. Patients without liver cirrhosis who fulfill the current treatment criteria may further benefit from functional cure of HBV. We aimed to evaluate the treatment cost-effective thresholds with different anticipated success rates of functional cure for a potential HBV cure regimen in the U.S. using a Markov model, with long-term oral nucleos(t)ide analogue (NUC) treatment as a reference. **Methods:** The base case is a 50-year-old man with non-cirrhotic hepatitis B e antigen-negative hepatitis with serum HBV DNA suppressed for at least one year with oral NUC treatment. We used a Markov model to simulate patients' progression through a discrete series of health states, comparing a functional cure to current practice with long-term NUC treatment. Outcomes from the model included lifetime costs of treatment, monitoring and medical management; quality-adjusted life-years (QALYs); and risk of clinical endpoints (compensated and decompensated cirrhosis, hepatocellular carcinoma [HCC], liver transplantation and death). The threshold incremental cost-effectiveness ratio (ICER) was set at USD100,000. **Results:** Compared with current long-term NUC treatment, a functional cure regimen with a 30% success rate in the base case patient would yield 18.69 QALYs (0.38 QALY gained compared with long-term NUC) per patient. Cost-effectiveness analyses suggest that a functional cure regimen could be cost-effective at a one-time treatment cost under US$66,708. Corresponding one time treatment costs and QALYs gained (vs. long-term NUC) are estimated at US$44,205 and 0.25 QALYs, US$89,210 and 0.51 QLAYs, US$111,712 and 0.64 QALYs for a potential HBV treatment with functional cure rates of 20%, 40%, and 50%, respectively (Table). **Conclusion:** A Markov model-based cost-effectiveness analysis demonstrates that a hypothetical HBV cure regimen with a 30% functional cure in aforementioned base case could be cost-effective if less than US$66,708. Cost-effectiveness thresholds and QALYs gained would vary depending on patient characteristics, liver disease severity, and actual treatment success rates.

Table. Life-long per person quality-adjusted life-years (QALYs) gained and threshold costs of a functional cure regimen with different anticipated success rates of functional cure compared with current long-term antiviral treatment.

	Cure rate 20%	Cure rate 30%	Cure rate 40%	Cure rate 50%
Long-term antiviral treatment				
QALYs (years)		18.31		
Drug cost with current antivirals (US$)		5,891		
Medical Management cost (US$)		108,508		
Functional cure				
QALYs (years)	18.56	18.69	18.82	18.95
QALYs gained (years)	0.25	0.38	0.51	0.64
Drug cost with current antivirals (US$)	4,539	4,013	3,487	2,961
Medical Management cost (US$)	90,701	81,570	72,438	63,307
Treatment cost-effective threshold (US$)	44,205	66,708	89,210	111,712

Base case: A 50-years-old man with non-cirrhotic hepatitis B e antigen-negative hepatitis with serum HBV DNA suppressed for at least one year with oral nucleos(t)ide analogue (NUC) treatment.

1350 | ASSOCIATION OF HBSAB LEVEL CHANGES WITH HEPATIC OUTCOMES IN NON-CIRRHOTIC CHB PATIENTS FOLLOWING HBSAG LOSS

Wen Deng[1] Yao Xie[1] Minghui Li[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: The relationship between changes in hepatitis B surface antibody (HBsAb) levels and liver-related adverse events following hepatitis B surface antigen (HBsAg) clearance remains unclear. This study aimed to investigate the association between HBsAb level dynamics and hepatic adverse outcomes in non-cirrhotic patients after HBsAg loss. **Methods:** Patients achieving HBsAg seroclearance after pegylated interferon-alpha (Peg-IFNα) therapy at Beijing Ditan Hospital, Capital Medical University from October 2008 to December 2023 were retrospectively analyzed. Patients were stratified into four groups according to baseline HBsAb levels: negative (<10 mIU/mL), low (10-100 mIU/mL), moderate (100-1000 mIU/mL), and high (≥ 1000 mIU/mL) groups. During follow-up, they were further categorized into declining, stable, and increasing groups based on HBsAb titer dynamics. The primary endpoint was the incidence of liver-related adverse events following HBsAg seroclearance. **Results:** A total of 390 patients were included, with a median age of 38.00 years (32.00-44.00) and a median follow-up duration of 53.50 months (11.00-173.00). Liver-related adverse events were observed in 4 cases (1.03%), all occurring in the HBsAb-declining group (4/131, 3.05%), while no events were detected in either the HBsAb-stable (0/120) or HBsAb-increasing (0/139) groups ($P=0.017$). A significant inverse correlation was found between HBsAb level dynamics and the incidence of hepatic adverse events ($rs=-0.125$, $P=0.014$). **Conclusion:** Declining HBsAb levels following HBsAg seroclearance may be associated with an increased risk of liver-related adverse events.

1351 | NEW SUBMISSION: A LONG-ACTING LIPOPHILIC TFV PHOSPHONATE PRODRUG SUSTAINS SUPPRESSION OF HBV REPLICATION

Natalia Osna[1] Samiksha Raut[1] Grace Bybee[1] Haritha Chava[1] Mojisola Ogunnaike[1] Weimin Wang[1] Anup Pathania[1] Howard Gendelman[1] Larisa Poluektova[1] Benson Edagwa[1], [1]University of Nebraska Medical Center

Background: Chronic hepatitis B (CHB) treatment requires daily oral therapy with Tenofovir (TFV) prodrugs, TFV disoproxil/TFV alafenamide- fumarates (TDF/TAF), or entecavir. Treatment cessation leads to HBV reactivation, underscoring the significance of adherence to therapy. Since long-acting formulations improve treatment outcomes, we developed an amino acid-free hydrophobic and lipophilic crystalline phosphonate TFV prodrug named M5TFV. M5TFV is scalable, cost-effective, and as efficacious as M1TFV, another injectable long-acting TFV prodrug that we previously reported (Sci Adv, 2023). Now, we address the mechanisms by which M5TFV nanosuspension (NM5TFV) sustains suppression of HBV replication in hepatocytes. **Methods:** M5TFV was synthesized and nanoformulated as an aqueous nanosuspension using Tween 20 and PEG 3350 as the stabilizing surfactants. In vivo, experiments were performed on HBV transgenic (TG05) mice administered a single intramuscular injection of NM5TFV at 200 and 400 mg/kg TFV equivalents. HBV viral load in blood was tested weekly until the HBV DNA rebound occurred. For in vitro studies, HepAD38 cells were treated with NM5TFV, 25 μM, 8h, followed by incubation in a medium for 48h. HBV DNA and cccDNA were determined by qPCR. After IFNα signaling induction (400 IU, 6h), interferon-stimulated genes (ISGs), ISG15, OAS1, and APOBEC3G were measured by RT-PCR. **Results:** At the two doses evaluated in mice, NM5TFV exhibited >2.5 log 10 reduction in HBV DNA, lasting over two months after a single injection, with a rebound at 12 weeks, similar to NM1TFV. Exposure of HepAD38 cells to NM5TFV reduced HBV DNA and cccDNA levels 2-fold.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

HepAD38 cells co-cultured with human monocyte-derived macrophages (MDMs) did not potentiate NM5TFV's suppression of HBV DNA/cccDNA, suggesting that intracellular M5TFV prodrug is efficiently activated in infected HepAD38 cells, independent of MDM active drug transfer. Also, in HepAD38 cells and precision-cut liver slices from Tg05 mice, the suppression magnitude of HBV DNA by NM5TFV was the same. NM5TFV (unlike NM1TFV) did not increase the induction of ISGs by IFNα. **Conclusion:** NM5TFV exhibited significant anti-viral activity by directly suppressing HBV DNA and cccDNA in infected hepatocytes, with no ISG activation. Notably, a single intramuscular well-tolerated injection of NM5TFV sustained HBV DNA suppression in HBV-replicating mice for at least ten weeks. Thus, NM5TFV is a perfect long-acting candidate for CHB treatment.

1352 | SINGLE-CELL DISSECTION OF THE IMMUNE LANDSCAPE IN HBV-ASSOCIATED HEPATOCELLULAR CARCINOMA REVEALS VIRAL-DRIVEN IMMUNE DYSFUNCTION

PeiChing Chang[1], [1]National Yang Ming Chiao Tung University

Background: Chronic HBV infection creates a unique tumor microenvironment (TME) in hepatocellular carcinoma (HCC), yet the mechanisms linking viral persistence to immune suppression remain unclear. **Methods:** To dissect this complexity, we performed single-cell RNA sequencing (scRNA-seq) on HBV-associated HCC specimens and uncovered a cellular ecosystem shaped by chronic viral exposure and immune exhaustion. Analysis of over 20,000 single-cell transcriptomes revealed heterogeneous immune and tumor compartments, including diverse $CD8^+$ T-cell states and transcriptionally distinct HBV-infected HCC subpopulations. **Results:** Notably, we identified an unexpected trajectory of $CD8^+$ T-cell states spanning naïve-like, memory, and exhausted phenotypes, ending with progenitor-exhausted T cells. A stem-like precursor population, previously thought to precede terminal exhaustion, was instead positioned at the terminal end of the differentiation axis, suggesting alternative exhaustion pathways shaped by chronic viral exposure. Moreover, cell-cell interaction analysis uncovered selective immunoregulatory interactions between HBV-enriched tumor subsets and dysfunctional T-cell populations, implicating temporally regulated mechanisms of immune evasion. **Conclusion:** Together, these findings reveal the intricate interplay between HBV-infected HCC cells and T cells, highlighting virus-associated immunosuppressive dynamics that may inform future immunotherapeutic strategies in virally driven cancers.

1353 | EFFICACY AND RISK FACTORS OF PEGINTERFERON ALFA-2B MONOTHERAPY IN INITIAL TREATMENT OF PATIENTS WITH HBEAG NEGATIVE CHRONIC HEPATITIS B

Jing Chen[1] Lin Jianmei[1], [1]Sichuan Provincial People's Hospital

Background: To evaluate the efficacy of initial treatment with peginterferon alfa-2b (peg-IFN alfa-2b) monotherapy in patients with HBeAg negative chronic hepatitis B (CHB), and explore the factors affecting the clearance of hepatitis B surface antigen. **Methods:** This study included 47 HBeAg negative CHB patients from December 2019 to December 2024, who were treatment-naïve with a serum HBsAg < 100IU/ml. These patients had a willingness to receive interferon treatment, and after thorough examination to rule out relevant contraindications and sufficient communication, they received peg-IFN alfa-2b monotherapy. Serum HBsAg, HBV DNA, biochemical changes and adverse reactions during treatment were monitored every 3 months. These patients had treated for at least 24 weeks, of which 32 patients had completed 48 weeks of treatment. **Results:** The average age of these patients was 40.6 years, with 34 males accounting for 72.3%. After 24 weeks of treatment, average HBsAg level decreased from a baseline level of 30.4 ± 31.5 IU/ml to 6.0 ± 13.9 IU/ml, and 26 patients (55.3%) achieved surface antigen clearance. Univariate analysis suggested that lower HBsAg levels at baseline and 4 weeks, baseline HBV DNA < 100IU/ml, and HBsAg seroconversion at 12 weeks were associated with HBsAg clearance at 24 weeks. However, multivariate analysis indicated that lower HBsAg levels at baseline and 4 weeks were independent predictors of HBsAg clearance at 24 weeks. Among patients who completed 48 weeks of treatment, 81.3% achieved HBsAg clearance. Overall, the treatment was well tolerated. **Conclusion:** The lower the baseline HBsAg level, the greater the probability of HBsAg clearance in patients receiving initial interferon monotherapy.

1354 | IMPACT OF HEPATITIS B SURFACE ANTIBODY (ANTI-HBS) LEVEL AT HEPATITIS B SURFACE ANTIGEN (HBSAG) SEROCLEARANCE ON LONG-TERM RISK OF HBSAG SEROREVERSION

Terry Cheuk-Fung Yip[1] Jimmy Che-To Lai[1] Mandy Lai[1] Vincent Wong[1] Henry Lik-Yuen Chan[2] Grace Lai-Hung Wong[1], [1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, [2]Department of Internal Medicine, Union Hospital, Hong Kong

Background: The impact of anti-HBs seroconversion and anti-HBs level at the time of HBsAg loss on the durability of nucleos(t)ide analogues (NA)-induced HBsAg loss remains unclear. We examined the role of anti-HBs status and level on the risk of HBsAg seroreversion in patients with chronic hepatitis B who achieved NA-induced HBsAg loss, with spontaneous HBsAg loss as a reference. **Methods:** A retrospective territory-wide cohort of adult patients with chronic hepatitis B virus monoinfection who achieved NA-induced or spontaneous HBsAg loss from 2000-2022 was identified from an electronic health database in Hong Kong. Patients with HBsAg loss after liver transplantation, no HBsAg test results after HBsAg loss, malignancies, and immunosuppressant use were excluded. Patients were followed from HBsAg loss to HBsAg seroreversion, 6 months after the last HBsAg test, death, last follow-up (Dec 31, 2024), or 10 years, whichever earlier, with death as a competing event. **Results:** Of 6,269 patients, 1,250 had NA-induced HBsAg loss (mean age 55 ± 13 years, 29% women, 8.4% cirrhosis, 33.2% positive anti-HBs); and 5,019 had spontaneous HBsAg loss (mean age 57 ± 13 years, 43% women, 1.8% cirrhosis, 32.7% positive anti-HBs). In 1,250 patients with NA-induced HBsAg loss, 891 continued to receive NA therapy for a median of 12.3 (IQR 5.9-24.6) months after HBsAg loss. At a median follow-up of 3.9 (2.1-7.1) years after HBsAg loss, 78 (6.2%) and 318 (6.3%) developed HBsAg seroreversion after NA-induced and spontaneous HBsAg loss, respectively. Positive anti-HBs at HBsAg loss was not associated with a lower risk of HBsAg seroreversion after NA-induced HBsAg loss (adjusted subdistribution hazard ratio [asHR] 0.71, 95% CI 0.37-1.35, $p = 0.291$) but was protective against HBsAg seroreversion after spontaneous HBsAg loss (asHR 0.58, 95% CI 0.40-0.86, $p = 0.006$). Compared to low-detectable anti-HBs level (10-100 mIU/mL), an anti-HBs level ≥ 100 mIU/mL was not associated with a further reduced risk of HBsAg seroreversion in patients with NA-induced HBsAg loss (asHR 0.80, 95% CI 0.15-4.31, $p = 0.791$) or spontaneous HBsAg loss (asHR 1.16, 95% CI 0.53-2.53, $p = 0.707$) (Figure). In patients with NA-induced HBsAg loss, undetectable HBV DNA at HBsAg loss (asHR 0.28, 95% CI 0.21-0.36) was associated with a lower risk of HBsAg seroreversion. **Conclusion:** Anti-HBs seroconversion does not add to the durability of NA-induced HBsAg loss. A higher anti-HBs level may not confer additional protection against HBsAg seroreversion.

1355 | QUANTITATIVE HBSAG LEVELS REMAINED ELEVATED WITH PROLONGED NUCLEOS(T)IDE ANALOGUE THERAPY OVER 10 YEARS

Syed Bilal Shah[1] Saeed Ahmad[1] Ashraf Ullah[2] Nicole Lue[2] Umar Iqbal Javid Choudhary[2] NAEEM KHAN[3] Mati Ullah Dad Ullah[4] Daryl Lau[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, [2]Beth Israel Deaconess Medical Center,Harvard Medical School, [3]Beth Israel Deaconess Medical Center, [4]University of Oklahoma Health Sciences Center

Background: The current treatment goal for chronic hepatitis B (CHB) is functional cure with HBsAg loss but it is seldom achieved with current nucleos(t)ide analogue (NUC) therapy. some patients on prolonged NUC may benefit from alternative treatment strategies. In this study, we evaluated the levels of quantitative HBsAg (qHBsAg) in both HBeAg (+) and (-) CHB patients with long-term NUC therapy. **Methods:** This is a retrospective study conducted at a single tertiary liver center. Patients who received NUC therapy for >1 year and achieved persistently undetectable (UD) or <10 IU/ml HBV DNA were selected. They must have qHBsAg by Quest Diagnostics at their last clinic visit. Most patients started therapy >5 years ago before qHBsAg was available in our center. Statistical analysis was by GraphPad Prism. **Results:** 206 [66 HBeAg (+), 140 HBeAg (-)] CHB patients with predominantly (91%) Asians were included. [Table 1] HBeAg (+) patients were younger, had higher pretreatment HBV DNA levels (6.8 vs 4.6 log IU/ml, $p<0.0001$), and longer treatment duration (11.9 vs. 9.1years, $p=0.0005$). Cirrhosis was present in 5 HBeAg(-) and none of the HBeAg(+) patients. 2 HBeAg(-) patients without cirrhosis had HCC after 2 and 8 years on NUC therapy respectively. There was a weak negative correlation ($r = -0.17$, $p=0.03$) between qHBsAg levels and treatment duration in the HBeAg (-) group but not in the HBeAg (+) group ($r = -0.06$, $p=0.62$). At last follow-up visit, 7 (5%) HBeAg(-) and 1 (1.5%) HBeAg(+) patients had qHBsAg <0.05 IU/ml but only 4 had UD qualitative HBsAg. Those had therapy for >15 years, the mean qHBsAg levels were 3.3 and 3.4 log IU/ml for HBeAg(-) and (+) patients respectively. [Figure] The mean and median qHBsAg values were similar for shorter treatment durations in both groups. HBsAg remained >1000 IU/ml after 1-5, >5-10, and >10 years of NUC therapy in 59%, 32%, and 32% of HBeAg(-); 57%, 58%, and 58% of HBeAg(+) patients respectively. Among the HBeAg(+) patients, 38 (58%) had HBeAg loss. The pretreatment HBV DNA levels were similar between those with (6.77 log) and without (6.99 log) HBeAg loss ($p=0.6$). The last follow up qHBsAg titers were also similar (3.45 log vs.3.7 log, $p=0.15$). **Conclusion:** After long-term continuous NUC therapy for greater than 10 years, qHBsAg remained >1000 IU/ml in over 30% and 50% of the HBeAg(-) and HBeAg(+) CHB patients despite optimal HBV DNA suppression. Only 8 (3.9%) patients achieved qHBsAg <0.05 IU/ml. These findings could inform patient selection for alternative treatment options as new therapeutic agents become available for definitive HBV control.

Table. Demographic and Clinical features

	HBsAg(-) (n=140)	HBeAg (+) (n=66)	P value
Male (n,%)	67 (47.9%)	30 (45.5%)	NS
Asian (n,%)	122 (87%)	65 (98%)	NS
Age (year; mean, range)	56.8 (33.7-80.9)	47.6 (32.4-70.3)	<0.0001
Pretreatment HBV DNA (log IU/ml; mean, range)	4.6 (1.5-8)	6.8 (3-9)	<0.0001
Pretreatment HBV DNA (log IU/ml) 1-5 years NUC >5-10 years NUC >10-15 years NUC >15 years NUC	(p=0.54) 4.4 4.5 5.1 4.1	(p=0.56) 6.8 7.2 7.3 5.9	
NUC treatment duration (year; mean, range)	9.1 (1.1-24.8)	11.9 (1.4-23.9)	0.0005
Pretreatment cirrhosis (n,%)	5 (3.6%)	0 (0%)

1356 | CHANGES IN CX3CR1 EXPRESSION IN DENDRITIC CELLS DURING INTERFERON INTERMITTENT THERAPY IN CHB PATIENTS

Minghui Li[1] Yao Xie[1] Liu Yang[2] weihua cao[1] Wen Deng[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]BeijingDitanHospital, CapitalMedicalUniversity;TheSecondAffiliatedHospital of Xi'anJiaotongUniversity

Background: The emergence of a plateau phase characterized by slow decline in hepatitis B surface

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

antigen (HBsAg) during Interferon (IFN) therapy represents a critical challenge contributing to suboptimal treatment outcomes. As central antigen-presenting cells initiating antiviral immunity, the functional status of dendritic cells (DCs) directly impacts the effectiveness of IFN therapy. The chemokine receptor CX3CR1 plays a pivotal role in DC migration to inflamed tissues and co-localization with T cells. This study aimed to investigate the association between the onset of the HBsAg decline plateau phase and the expression of CX3CR1 on peripheral blood DCs in patients with CHB receiving IFN therapy. **Methods:** Patients included were divided into CHB group (CHB without any antiviral treatment before), NAs group (treated with NAs) and P group (IFN treated and plateau arriving). After perfecting the baseline related examination, the patients in the P group were retreated with IFN after 12-24W of IFN intermission. For patients in the CHB group and NAs group at baseline; patients in P group at baseline when IFN was stopped, 12-24W of IFN intermission and 12-24W of IFN retreatment, the percentage of $CX3CR1^+$ DCs and the CX3CR1 MFI of $CX3CR1^+$ DCs were collected. **Results:** 49 patients in CHB group, 47 patients in NA group and 47 patients in the P group were included. At baseline, the percentage of $CX3CR1^+$ cells in pDC, the percentage of $CX3CR1^+$ cells in mDC and the CX3CR1 MFI of $CX3CR1^+$ mDC, the CX3CR1 MFI of $CX3CR1^+$ mDC2, the percentage of $CX3CR1^+$ cells in DN mDC and the CX3CR1 MFI of $CX3CR1^+$ DN mDC in the P group were significantly lower than those in the NA group and CHB group. 35 patients in P group were followed up for 12-24W of IFN intermission. The $CX3CR1^+$ cells in DN mDC and CX3CR1 MFI of $CX3CR1^+$ DN mDC increased significantly; 11 patients in the P group were followed up until 12-24W of IFN retreatment, and the data of three follow-up points were obtained. It was found that the percentage of $CX3CR1^+$ cells in DN mDC and CX3CR1 MFI of $CX3CR1^+$ DN mDC all showed a trend of increasing first and then decreasing. **Conclusion:** The plateau phase of slow HBsAg decline during IFN therapy in CHB patients may be associated with insufficient expression of CX3CR1 on peripheral blood DCs, particularly on CD141/CD1c double negative myeloid dendritic cells (DN mDCs).

1357 | HEPATITIS B VIRUS REACTIVATION IN INFLAMMATORY BOWEL DISEASE PATIENTS ON BIOLOGICS: A SYSTEMATIC REVIEW OF RISK AND PREVENTION

Yu An Lin[1] Lan Nguyen[2] Mohammed Ayyad[1] Paul Gaglio[1], [1]Rutgers NJMS, [2]University at Buffalo

Background: Biologic therapies are widely used in inflammatory bowel disease (IBD), but hepatitis B virus (HBV) reactivation remains a concern, particularly in patients with chronic or resolved infection. While this risk is better characterized in other autoimmune conditions, data specific to IBD are limited. This systematic review therefore evaluates HBV reactivation risk in IBD patients on biologics, stratified by HBV serostatus, prophylaxis use, and biologic agent. **Methods:** We searched PubMed, Embase, and Scopus (1996–2024) for studies describing HBV reactivation in IBD patients receiving biologics. Of 1,489 screened articles, nine studies (seven full-text articles, two abstracts) were included, encompassing retrospective and prospective designs across diverse geographic regions. Extracted data included HBV serologic status, antiviral prophylaxis use, biologic agents, and reactivation outcomes. **Results:** Among patients with chronic HBV, reactivation was more frequent in the absence of prophylaxis (20/121, 16.5%). In resolved HBV cases, reactivation was rare (2/242, 0.8%) and occurred only without prophylaxis. Prophylaxis was associated with a lower incidence of reactivation: 80% (16/20) of reactivations occurred without it, while 20% (4/20) occurred despite it. All reported reactivations involved anti-TNF agents. Specifically, reactivations occurred in 11.1% (7/63) patients on infliximab and 7.7% (2/26) patients on adalimumab. Meanwhile, certolizumab (n = 6) and golimumab (n = 2) were less frequently used and not implicated in any reactivation. No reactivation was observed among the 17 patients treated with ustekinumab. Only two studies reported HBV screening prior to biologic initiation, with baseline testing applied in just 44.3% (5,425/12,244) of patients. Across four studies, prophylaxis was also underused, prescribed in only 45.1% (69/153) of chronic HBV patients despite elevated risk. **Conclusion:** IBD patients with chronic HBV infection face a measurable risk of reactivation during biologic therapy, especially without prophylaxis. Reactivation in resolved HBV is rare but possible. While anti-TNF agents were linked to all reactivation cases, data are insufficient to compare risk across biologic classes. Therefore, larger prospective studies are needed to clarify these risks and guide

prevention strategies. Routine HBV screening and risk-based prophylaxis were underutilized, although they remain essential for safe biologic use in IBD, along with multidisciplinary coordination.

1358 | COMPARISON OF THE IMPACT OF TENOFOVIR ALAFENAMIDE AND ENTECAVIR ON HEPATITIS B SURFACE ANTIGEN DECLINE AND FACTORS INFLUENCING PARTIAL HBSAG RESPONSE AFTER 96 WEEKS OF CONTINUED THERAPY

shanfei ge[1] Yuliang Zhang[1] Shipeng Ma[1] Liang Wang[1] Xin Wan[1] Yulun Tang[1] Qian Liu[1], [1]The First Affiliated Hospital of Nanchang University

Background: Hepatitis B surface antigen (HBsAg) serological clearance is a critical therapeutic goal in the treatment of chronic hepatitis B (CHB). Although nucleos(t)ide analogues (NAs) suppress viral replication effectively, their impact on HBsAg loss remains suboptimal. Tenofovir alafenamide (TAF), a novel prodrug of tenofovir with improved hepatocyte delivery and one of the recommended first-line treatment for CHB has demonstrated favorable efficacy and safety profile. However, the comparative data on HBsAg levels between TAF and entecavir (ETV) remains limited. This study aimed to evaluate HBsAg decline and identify predictors of partial serological response after 96 weeks of ETV or TAF treatment in treatment-naïve CHB patients. **Methods:** This was a single-center retrospective study that enrolled treatment-naïve CHB patients initiated on ETV or TAF for at least 48 weeks from September 2019 to March 2025. Propensity score matching (PSM) was applied to balance baseline characteristics. HBsAg partial serological response was defined as a $\geq$ 1 log IU/mL decline from baseline. The precentage decline of HBsAg was calculated using the formula: (post-treatment HBsAg concentration - baseline HBsAg concentration) / baseline HBsAg concentration*100%. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of HBsAg partial serological response after 96 weeks. The area under the receiver operating characteristic curve (AUC) was used to evaluate the predictive value of these factors for HBsAg partial serological response. **Results:** After PSM, yielding 105 matched pairs in ETV and TAF treatment group. The baseline characteristics were well balanced between ETV and TAF groups ($P > 0.05$). At 48 weeks, the median percent decline of HBsAg was significantly higher in the TAF group compared to the ETV group [-2.53% (-10.13%, 0.24%) vs -4.92% (-14.23%, -1.78%), $Z = -2.55$, $P = 0.011$]. At 96 weeks, 17 out of 89 patients (19.10%) who continued ETV or TAF treatment achieved HBsAg partial serological response. Multivariate logistic regression showed that baseline HBsAg levels (OR = 278.70, 95% CI: 2.82–27552.73, $P = 0.016$) and the percent decline of HBsAg at 48 weeks (OR = 0.79, 95% CI: 0.64–0.96, $P = 0.021$) were independent predictors of achieving HBsAg partial serological response after 96 weeks of treatment. ROC analysis demonstrated that both baseline HBsAg levels (AUC = 0.913, 95% CI: 0.850–0.975, $P < 0.001$) and the percent decline of HBsAg at 48 weeks (AUC = 0.908, 95% CI: 0.814–1.000, $P < 0.001$) were strong predictors of HBsAg partial serological response at 96 weeks. **Conclusion:** Compared to ETV, TAF significantly reduced HBsAg levels. Baseline HBsAg levels and the percent decline of HBsAg at 48 weeks are independent and effective predictors of HBsAg partial serological response after 96 weeks treatment, supporting their role in guiding individualized CHB treatment strategies.

Background: Humanized liver mouse models are of significant value in studying human hepatocyte-specific functions and liver diseases. URG mice, which are highly immunodeficient mice with a TetOn-regulated uPA transgene, can be induced liver damage by expressing uPA gene specifically in the liver upon Doxycycline administration, allowing the engraftment of exogenous hepatocytes including human's. Although URG mice have the advantages of easy breeding, good health status, early experiments showed that the human hepatocyte replacement rate was rarely more than 50%, or the human serum albumin (HSA) content rarely exceeded 6 mg/mL. Despite continuous induction with Dox, the chimeric rate tended to decline after 8 weeks transplantation. Here reports that optimizing the protocol for preparing Hu-URG (URG mice transplanted primary human hepatocytes) significantly increased the chimerism that supports high infection of HBV. **Methods:** The Dox induction scheme after the transplantations in URG mice was changed from a fixed concentration of Dox in drinking water, intending to cause a chronic liver damage. The diet for URG mice was changed from breeding feed to a low-fat feed with $<4\%$ crude fat content. HSA content measurement and immunohistochemical staining were employed to exhibit the chimerism of human hepatocytes. Liver tissues were collected from five Hu-URG mice approximately 10 weeks post-PHH transplantation for RNA-seq analysis alongside PHHs. HuURG mice then were inoculated with different sources of HBV and detected for viral indicators in the serum and livers. **Results:** After optimization, the HSA contents in Hu-URG significantly increased, the highest up to 15 mg/mL. IHC analysis showed that the positive staining areas of human albumin, CK-18, CYP3A4, etc., in the liver sections could occupy up to 95%, and uniformly distributed in every lobe. In Hu-URG mice that did not change to low-fat diet, human hepatocytes usually accumulated a large amount of fat as showed in the sections, and became steatotic after 8 weeks of transplantation. The low-fat feed significantly reduced lipid droplet liver sections, and enable the HSA level stable nearly 12 months. HuURG mice were easily infected with HBV isolates either from clinical hepatitis B patient serum, HBV transgenic mouse serum, or HepAD38 cell culture supernatant, producing long-term high viremia. RNA-seq results indicate that in the livers of Hu-URG, the genes related to human drug-metabolizing enzymes, glucose metabolism, lipid metabolism, and coagulation factors are highly similar to those in PHHs in terms of both types and expression levels. **Conclusion:** The use of low-fat feed can improve the steatosis of engrafted human hepatocytes, increase chimerism and extend the stable period. The optimized Hu-URG mouse model supports long-term stable infection of various genotypes of HBV, providing an ideal in vivo model for HBV biological research and evaluation of anti-hepatitis B drugs.

1360 | UNCOVERING THE OVERUSE: A HOSPITAL-WIDE ANALYSIS OF UNNECESSARY HBSAG RETESTING

Rahmet Guner[1] Ebrar GÜNEY[1] Imran Hasanoglu[1] Ahmet Sertçelik[1] Ayşe Kaya[1] Fatma Eser[1] Muge Ayhan[1] Bedia Dinç[1] Bircan Kayaaslan[1], [1]Ankara Bilkent City Hospital

Background: Achieving the global goal of viral hepatitis elimination requires not only effective screening strategies but also the rational use of healthcare resources. Despite clear diagnostic guidelines, repeated hepatitis B surface antigen (HBsAg) testing without clinical indication is frequently observed in hospital settings, potentially leading to increased laboratory burden, unnecessary costs, and misallocation of resources. **Methods:** This retrospective descriptive study analyzed all adult patients who underwent HBsAg testing at a tertiary care hospital between January 1, 2022, and December 31, 2023. Demographic characteristics and the number of test requests per patient were evaluated. In patients who had more than one HBsAg test, the time interval between repeat tests was calculated and stratified by the requesting clinical department. An interval of 14 days or less was considered potentially inappropriate based on clinical guidelines. Categorical data were reported as frequency, percentage, and odds ratio (OR) with 95% confidence intervals (CI); continuous variables were expressed as median and interquartile range (IQR). **Results:** Of the 558,730 patients tested for HBsAg, 45% were male. The median age was 45.0 years (IQR: 29.0–74.0). While the overall median number of HBsAg tests per patient was 1.0, 32.6% of patients underwent repeat testing, with one patient receiving as many as 40 tests. In this subgroup, a total of 331,386 HBsAg tests were ordered. Significant variation was observed in the frequency

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and timing of repeat testing across departments. Intensive care units had the highest proportion of early repeat tests (≤14 days) at 79.9% (OR: 10.59, 95% CI: 9.89–11.34), followed by neurology (70.5%, OR: 6.38), and pulmonology (65.3%, OR: 5.01). In contrast, departments such as ophthalmology (9.7%, OR: 0.29), ENT (12.3%, OR: 0.37), and microbiology (27.3%, reference group) had significantly lower early repeat testing rates. **Conclusion:** Our findings demonstrate a high rate of potentially unnecessary repeat HBsAg testing in several clinical departments, particularly in acute care settings. These practices contribute to inefficient resource utilization and may undermine efforts to streamline viral hepatitis screening. Interventions focused on clinician education, electronic test ordering restrictions, and audit-feedback mechanisms are needed to promote more judicious test use, reduce redundancy, and align with public health goals for hepatitis elimination.

1361 | RISK FACTORS FOR LOW VIRAL LOAD IN CHB PATIENTS RECEIVING NAS

Ziyi Zhang[1] Xijie Zhao[1] Rong Mu[1] Rongjiong Zheng[1] Xiaobo Lu[1], [1]The First Affiliated Hospital of Xinjiang Medical University

Background: Low viral load (LLV) refers to a situation where HBV DNA remains persistently or intermittently at a level of 20-2000 IU/mL in patients with chronic hepatitis B (CHB) after receiving first-line nucleoside (acid) analogues (NAs) treatment for at least 48 weeks. Studies have shown that LLV is associated with the progression of liver fibrosis and an increased risk of liver cancer, but the prevalence and risk factors of LLV in the real world remain unclear. This study aims to analyze the prevalence of LLV and its risk factors among CHB patients receiving NAs treatment. **Methods:** A total of 1,582 patients with chronic hepatitis B (CHB) who received standard first-line nucleos(t)ide analogues (NAs) (entecavir/tenofovir disoproxil fumarate/tonofovir alafenamide fumarate) for more than 48 weeks were retrospectively included. The patients were divided into the low-level viremia (LLV) group (HBV DNA 20 - 2000 IU/mL), the complete virological response (CVR) group (HBV DNA < 20 IU/mL), and the virological non-response group (HBV DNA ≥ 2000 IU/mL) based on the virological response at 48 weeks of treatment. Baseline clinical data were collected, and multivariate Logistic regression analysis was used to identify the risk factors for LLV. According to the research purpose, only the LLV group and the CVR group were included for comparative analysis. **Results:** A total of 1582 patients completed the follow-up. The mean age was (47.6 ± 11.6) years, with 61.3% being male. The mean hepatitis B virus DNA level was 5.3 Log10 IU/ml. The incidence of LLV was 19.72% (312/1582). The baseline HBV DNA level in the LLV group was significantly higher than that in the CVR group (6.61 ± 0.9 vs 5.12 ± 1.1 Log10 IU/mL, p < 0.001), but there were no statistical differences in gender, platelets, ALT, ALB, TBIL, AFP, etc. (p > 0.05 for all). Multivariate analysis showed that age > 50 years (OR = 1.53, 95% CI: 1.30-1.80, p = 0.001), baseline HBeAg positive (OR = 2.87, 95% CI: 1.80-4.57, p < 0.001), HBsAg ≥ 8000 IU/mL (OR = 2.73, 95% CI: 2.15-3.49, p < 0.001), and HBV DNA ≥ 6 Log10 IU/mL (OR = 1.41, 95% CI: 1.06-1.88, p=0.019) were independent risk factors for LLV. **Conclusion:** Patients over 50 years old, with high HBsAg/HBV DNA levels and HBeAg positivity significantly increase the risk of LLV after NAs treatment for CHB. It is necessary to strengthen virological monitoring for high-risk groups and explore optimized treatment strategies.

1362 | THE BIDIRECTIONAL REGULATION BETWEEN USP20 AND HBSAG AND ITS POTENTIAL IMPACT ON HEPATITIS B VIRUS IMMUNE EVASION

Anxing Niu[1] Jin Liu[1] Wenhui Tu[2] Feng Qian[1] Li Zhu[1] Chuanwu Zhu[1], [1]The Affiliated Infectious Diseases Hospital of Soochow University, [2]Taizhou Municipal Hospital

Background: The persistent expression of hepatitis B surface antigen (HBsAg) is a hallmark of chronic HBV infection and a major barrier to achieving functional cure. Research indicates that the host ubiquitination system regulates HBsAg stability, with ubiquitination promoting its proteasomal degradation, while the virus may counteract this by utilizing deubiquitinating enzymes (DUBs). However, the specific regulatory molecules (such as E3 ubiquitin ligases/DUBs), mechanisms of viral-host interactions, and epigenetic regulatory networks remain unclear. Understanding these mechanisms will provide a theoretical foundation for therapeutic strategies aimed at HBsAg degradation. This study aimed to identify key DUBs regulating HBsAg stability and elucidate the regulatory relationship between USP20 and HBsAg as well as its potential impact on HBV infection. **Methods:** A DUB overexpression library was screened in HepG2.2.15 cells. USP20-HBsAg interaction was validated via co-immunoprecipitation (Co-IP). USP20's regulatory effects on HBsAg stability were assessed through cycloheximide (CHX) chase experiments and ubiquitination assays. HBsAg-mediated USP20 degradation was examined using proteasome/lysosome inhibitors. NF-κB pathway activity was evaluated by measuring phosphorylated p65 (p-p65) levels in HMC3 cells. **Results:** USP20 was firstly identified as a specific DUB regulating HBsAg, and their interaction between USP20 and HBsAg was confirmed by Co-IP. USP20 upregulated endogenous (pHBV1.3-induced) and exogenous (Myc-HBsAg) HBsAg in a dose-dependent manner, while USP20 knockdown remarkably Inhibited HBsAg expression. USP20 overexpression prolonged the half-life of HBsAg, whereas USP20 knockdown accelerated its degradation, indicating that USP20 can stabilize HBsAg via deubiquitination pathway. Ubiquitination assays indicated that USP20 significantly inhibited polyubiquitination modification of HBsAg, and the effect could be reversed by knockdown of USP20 or the inhibitor GSK2643943A. HBsAg gradient transfection specifically downregulated USP20 (but not USP33, a member of the homologous family), and the regulation was independent of ubiquitin-proteasome or the autophagy-lysosome pathways. Functional experiments of NF-κB pathway showed that USP20 overexpression significantly enhanced the LPS-induced p-p65 levels, while HBsAg co-expression could inhibit this pathway activation by degrading USP20. **Conclusion:** This study reveals a bidirectional USP20-HBsAg regulatory axis: USP20 stabilizes HBsAg to promote viral persistence, while HBsAg degrades USP20 to inhibit NF-κB-driven antiviral immunity. Targeting this dynamic equilibrium may offer novel strategies for HBV functional cure.

1363 | CHARACTERIZATION OF VARIOUS GENOTYPE HBV CARRIER MOUSE MODELS GENERATED BY AAV VECTOR DELIVERY

Zhenchuan Miao[1] Ming Yin[1], [1]Beijing Vitalstar Biotechnology Co., Ltd

Background: Functional cure (also known as clinical cure) is the ideal treatment goal recognized by the prevention and treatment guidelines for chronic hepatitis B (CHB). Hepatitis B virus (HBV) includes at least 8 genotypes and more variants, which cause different symptoms in infected individuals with different genetic backgrounds. To develop new effect drugs and realize personalized treatment for this disease, it is necessary to establish clinically relevant animal models of HBV infection. AAV-HBV mouse model prepared by injection of rAAV viral vectors carried the entire HBV genome demonstrate a good HBV carrier and useful in anti-HBV drug evaluation in vivo. According to previous studies, especially with genotype B, it's particularly difficult to maintain long-term stable virological indicators when constructing AAV-HBV.This study aims to compare the virological indicators, hepatic damage, and immune tolerance characteristics of models established by injecting different doses of AAV-HBV constructed with 1.3 fold length of HBV genome sequences of different genotypes into mice (especially with genotype B), in order to explore the implications of the models for hepatitis B research and new therapy development. **Methods:** Different doses of genotypes B, C, and D AAV-HBV were injected into C57BL/6 and immunodeficient NPG mice, and the levels of HBV DNA, HBsAg, HBeAg in serum of the mice were measured. **Results:** The levels of viremia indicators in the mouse models established by each type of AAV-HBV were dose-dependent. Genotype D AAV-HBV could establish a stable HBV carrier state at an injection dose even as low as 1E8 vg/mouse, while genotype C AAV-HBV could only maintain HBV viremia in immunocompetent mice at an injection dose more than 2E9 vg/mouse. Lower dose C-type AAV-HBV deliveries only sustained viremia for a few weeks in the mice, while in immunodeficient mice, HBV viremia remained stable. It was found difficult for Type-B AAV-HBV to establish a stable HBV infection state in immunocompetent mice even at dose of 1E11 vg/mouse, except for using a mutant Type-B HBV sequence. Interestingly, the highly immunodeficient mice (NPG) injected with 1E11 vgs of AAV-HBV of subtypes B/C/D, genotypes B and D easily maintained stable virological indicators, while genotype C was relatively difficult to sustain. **Conclusion:** The efficiency of establishing AAV-HBV mouse models varies with HBV genomes of different genotypes, and the levels of HBV viremia are related to the capacity of HBV antigens to induce immune tolerance, in addition

to the viral replication efficiency. The decline in HBV virological indicators in the model is due to immune clearance. The ability of each genotype of HBV to induce immune tolerance in mice is in an order of D > C > B. The results suggest that the polymorphism of HBV antigens is related to the different clinical characteristics of hepatitis B.

1364 | SAFETY AND EFFECTIVENESS OF TENOFOVIR AMIBUFENAMIDE FOR PREGNANT WOMEN WITH CHRONIC HEPATITIS B

Ru-Yue Chen[1] Yan-Qin Ai[2] Ya-Jie Pan[1] Xue-Yan Lv[1] Yue-Hang Wang[1] Zhuang-Zhuang Zhai[1] Xue-Jing Yu[1] Qing-Lei Zeng[1], [1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [2]Xuchang Central Hospital, Xuchang, Henan, China

Background: There are currently no studies on the safety and effectiveness of tenofovir amibufenamide (TMF) in pregnant women with chronic hepatitis B (CHB). This study aims to investigate the safety and efficacy of TMF in this population. **Methods:** The clinical data of women of childbearing age who took TMF tablet (25mg per day, orally after meals) and became pregnant were retrospectively collected from January 2022 to February 2025. The changes of hepatitis B virus (HBV) markers, biochemistry, blood routine and other parameters and adverse events were analyzed at baseline, during pregnancy, and within 7 months after delivery, and the infants' growth indexes at birth and 7 months of age and the effect of hepatitis B immunization were also analyzed. **Results:** This study included a total of 21 women of reproductive age and the 21 infants they gave birth to (Figure). (1) At baseline (pregnancy -12 [-17.5, -7.5] weeks), the median age, HBV DNA, and alanine aminotransferase (ALT) levels were 30 (25.5, 33) years, 6.9 (1.4, 7.9) $\log_{10}$ IU/mL, and 120 (53, 200) U/L, respectively. Among them, 17 cases were hepatitis B e antigen (HBeAg) positive. Routine blood tests, renal function, and other indicators were all normal. (2) During pregnancy, maternal HBV DNA and ALT levels gradually decreased, with median values at delivery of 0 (0, 0) $\log_{10}$ IU/mL and 17 (15, 27.5) U/L, respectively. Additionally, hemoglobin and serum creatinine levels showed a gradual decline, while the estimated glomerular filtration rate (eGFR) showed an increasing trend. (3) At 7 months postpartum, HBeAg seroconversion occurred in 3 cases (17.6% [3/17]), all patients had HBV DNA levels below the lower limit of detection (< 25 IU/mL), the median ALT level was 16 (13.5, 19) U/L, and hemoglobin, serum creatinine, and eGFR levels returned to baseline. (4) The main adverse events during maternal treatment were nausea (85.7% [18/21]), anorexia (61.9% [13/21]), and fatigue (42.9% [9/21]). The main complication was premature rupture of membranes (14.2% [3/21]). (5) At birth, the infants had a median gestational age of 38.5 (38.5, 40) weeks, with 12 males. There were no cases of preterm or post-term birth, no birth defects or malformations. The Apgar score at 1 minute after birth was 9 (9, 10). Growth indicators (height, weight, and head circumference) were all normal. All newborns received standard HBV immunoprophylaxis, and 11 (52.4%) were breastfed. (6) At 7 months of age, all infants had normal growth indicators, and all were hepatitis B surface antigen negative. The median level of hepatitis B surface antibody was 490 (222, 675) mIU/mL. **Conclusion:** This study preliminarily suggests that TMF treatment for pregnant women with chronic hepatitis B has favorable maternal and infant safety and effectiveness profiles. Combined with the hepatitis B immunization, it can successfully prevent HBV mother-to-child transmission. Future studies with larger sample sizes are needed to validate this conclusion.

1365 | PERIOPERATIVE RISKS AND PREDICTORS OF COMPLICATIONS IN HBV-RELATED CIRRHOSIS PATIENTS UNDERGOING GYNECOLOGIC LAPAROSCOPY

Nan Wang[1] Xiulan Li[1] Fuqiang Xu[1] Yanmei Li[1] Yifan Wang[1] Yuxiang Zhou[1] Huadong Tang[1] Xin Liu[1] Ying Hou[1] Meibian Bian[1] Calvin Pan[2] Qing Liu[1,] [1]Beijing You'an Hospital, Capital Medical University, Beijing, China, [2]NYU Langone Health, NYU School of Medicine

Background: Liver cirrhosis is a well-established risk factor for postoperative complications and liver-related mortality. However, data on the safety of gynecological laparoscopic surgery in cirrhotic patients remain limited, particularly in those with chronic hepatitis B (CHB). This study aimed to evaluate perioperative risks and complications in CHB-related cirrhotic patients undergoing gynecological laparoscopic surgery to inform clinical decision-making. **Methods:** This retrospective cohort study was conducted at a tertiary care university center in China between March 2012 and June 2024. CHB patients who underwent gynecological laparoscopic surgery during this period were included, excluding those with HIV or HCV coinfections. Cirrhotic and non-cirrhotic patients were matched 1:1 using propensity scores. Primary outcomes were perioperative and 30-day postoperative complications, including frequency and severity (Clavien-Dindo classification). Secondary outcomes included the identification of independent predictors of complications in cirrhotic patients through multivariate logistic regression of preoperative variables **Results:** A total of 94 patients were included, with a mean age of 52.5 years; 45.7% were postmenopausal. Baseline characteristics were comparable between groups, except for laboratory abnormalities, which were more frequent in the cirrhotic group (Table 1). The mean (SD) Child-Pugh score of cirrhotic patients was 6 ± 1 (43% classified as decompensated). The most common complications were pyrexia (12/94, 12.8%), abdominal distension (7/94, 7.4%), and external genital swelling (4/94, 4.3%). Postoperative complications occurred significantly more often in cirrhotic patients than in non-cirrhotic patients (40.4% [19/47] vs. 8.5% [4/47], $p < 0.01$). However, the rates of moderate to severe complications (Clavien-Dindo Grades II–IV) did not differ significantly between groups: Grade I (21.3% vs. 4.3%, $p = 0.01$), Grade II (14.9% vs. 2.1%, $p = 0.06$), and Grades IV–V (4.3% vs. 2.1%, $p > 0.99$). Notably, no complications were liver-specific. Elevated bilirubin levels and older age were independently associated with a higher frequency and severity of complications. **Conclusion:** Gynecological laparoscopic surgery in patients with HBV-related cirrhosis carries a higher risk of mild postoperative complications, particularly in patients with older age or elevated bilirubin. No liver-related mortality was observed. While the procedure appears generally safe, vigilant postoperative monitoring is warranted in this population.

1366 | HBSAG DECREASES IN A BIPHASIC MANNER AFTER LIVER TRANSPLANTATION AND HBIG MAINLY ENHANCES THE FIRST PHASE DECLINE

Leeor Hershkovich[1] Sara Battistella[2] Louis Shekhtman[1] Anna Pocurull[2] Thais Leonel[2] Sergio Rodriguez-Tajes[2] Yilliam Fundora[2] Sabela Lens[2] Sofía Pérez-Del-Pulgar[2] Scott Cotler[3] Harel Dahari[1] Xavier Forns[2], [1]Loyola University Chicago, [2]Liver Unit, Hospital Clínic, IDIBAPS, University of Barcelona, [3]Loyola University Health System

Background: Differences in HBsAg kinetics following liver transplantation (LT) between patients receiving nucleos(t)ide analogues (NUC) plus hepatitis B immunoglobulin (HBIG) and NUC alone have not been well characterized. Here we aim to mathematically model very frequent HBsAg kinetics during and after LT in patients treated with NUC with or without HBIG and assess the impact of HBIG on HBsAg kinetics. **Methods:** Between 2020 and 2023, 7 HBV LT recipients were prospectively enrolled. All patients were being treated with NUC preceding and after LT, of whom 3 patients additionally received HBIG during surgery and subsequently every 24 hours for 1 week

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

after LT (Fig. 1). We developed a mathematical model to explain HBsAg clearance, and to explore the impact of HBIG on HBsAg clearance during graft reperfusion. The model includes an initial rate constant (c_0), an extended decline rate constant (c_{RP}), and a constant *k* controlling the transition from c_0 to c_{RP}. We further incorporated blood transfusion into our model to account for dilution of circulating HBsAg. **Results:** At the beginning of the anhepatic phase, the median HBsAg level was 1.32 log IU/mL (IQR 1.08-1.94). All four NUC alone patients had an insignificant change in HBsAg during the anhepatic phase (Fig 1A). One out of 3 HBIG patients had sufficient data during the anhepatic phase (Fig. 1B) and showed a significant decline (~1.2 log). Baseline HBsAg at the beginning of reperfusion was 1.11 log IU/mL (IQR 0.90-1.42). Six of the 7 participants experienced a decline in a biphasic manner, consisting of an initial rapid decline followed by a slower and continuous decline until reaching negativity (Fig. 1 C-D). Modeling indicated a shorter HBsAg $t_{1/2}$ in HBIG participants (median 0.8 [IQR 0.5-2.0] hours vs. 2.0 hours [IQR 1.2-5.4]), however the decline rate of the slower phase was not different, with a median $t_{1/2}$ of 96.5 hours. **Conclusion:** Participants receiving HBIG achieved HBsAg negativity quicker than those who did not (median 5 days vs 6 months). Our model suggests that HBIG has an impact at the beginning of reperfusion, increasing the slope and duration of the initial phase of HBsAg decline, allowing patients to reach negativity faster, although HBsAg became undetectable in all patients over time. The observed initial rapid HBsAg decrease immediately post-reperfusion can at least in part due to HBsAg removal from circulation by hepatocytes, whereas the 2nd slower decrease phase likely represents a more physiological clearance rate of HBsAg from circulation as estimated during drug perturbation (Fig. 1C-D, gray area).

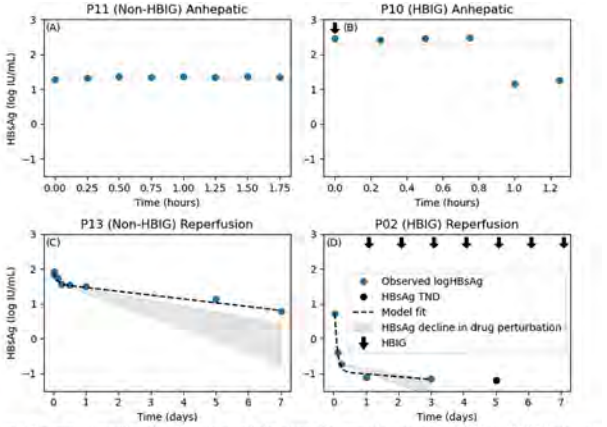

Figure 1: Representative patients for anhepatic/reperfusion phase of treatment (rows) and non-HBIG and HBIG (columns). Black arrows indicate timing of HBIG dosing, dashed line is the line of best fit in our mathematical model, and the gray area is the IQR of HBsAg estimated $t_{1/2}$ from a previous study (under anti-HBsAg drug perturbation of chronic infected patients) [PMID 32398799]. All participants were negative for or had very low levels of HBV DNA at the start of therapy (not shown).

1367 | EFFICACY OF NAS COMBINED WITH PEGIFNA-2B IN CHRONIC HEPATITIS B PATIENTS WITH / WITHOUT METABOLIC-RELATED FATTY LIVER DISEASE: A MULTICENTER, PROSPECTIVE REAL-WORLD STUDY

Guo Feng[1] Huxi baiheti[1] Dou Jing[1] Zeng Shengtao[2] Da Xin[3] Lu Xiaobo[4] Wu Yanqin[5] Maimaitiaili ·Tuerxun[6] Zhang Yongping[7] Wang Zhuanguo[1] Maimaitijiang ·Wubuliaishan[8] Wang Jun[9] Yue Yonghong[1] Wang Xiaobo[1] Chen Min[10] Ma Yan[1] Sayilaxi ·Jieensinue[1] Ning Zhonghui[1] Xu Qiang[1] Wang Hongfeng[1] Ni Ka[1] Ailifeire ·Abulajiang[1] Zhang Rong[1] WU Xu[11] Wang Xiaozhong[1], [1]Traditional Chinese Medical Hospital Affiliated to Xinjiang Medical University, [2]Yili Prefecture Xinhua Hospital, [3]Kelamayi Center Hospital, [4]The First Affiliated Hospital of Xinjiang Medical University, [5]Bazhou People's Hospital, [6]The First People's Hospital of Kashgar, [7]People's Hospital of Xinjiang Uygur Autonomous Region, [8]Hotan Infectious Diseases Hospital, [9]The First People's Hospital of Aksu Prefecture, [10]Changji Branch Hospital, First Affiliated Hospital of Xinjiang Medical University, [11]The Fourth Clinical Medical College of Xinjiang Medical University

Background: Functional cure is now an achievable and ideal goal of hepatitis B virus (HBV) treatment. However, the antiviral efficacy in chronic hepatitis B (CHB) patients with and without metabolic-related fatty liver disease (MAFLD) remains controversial. The purpose of this study was to evaluate the difference in hepatitis B surface antigen (HBsAg) clearance rate between CHB patients with and without MAFLD treated with PegIFNα-2b combined with NAs, and to provide a reference for clinical treatment. **Methods:** This is a prospective, multicenter, real-world clinical study. CHB patients with or without MAFLD treated with NAs for more than 6 months, HBeAg negative, HBsAg $\leq$ 1500 IU/mL, HBV DNA positive or negative, ALT $< 5 \times$ ULN were included. All patients were treated with PegIFNα-2b combined with NAs for 48 weeks. The primary outcome was the difference in HBsAg clearance rate between CHB patients with and without MAFLD at 48 weeks. Secondary outcome was the proportion of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

participants with HBsAg decline > 1 lg IU/mL. Other outcomes included the proportion of participants with HBV DNA undetectable, changes in body mass index (BMI), liver function biomarkers and blood routine. Safety was also assessed. **Results:** A total of 528 CHB patients with or without MAFLD from 10 centers were included in this study from December 1, 2022 to May 15, 2025. Of these, 128 patients (63 with MAFLD and 65 without MAFLD) had completed 48 weeks of treatment. The HBsAg clearance rates at 24 and 48 weeks were 26.98% (17/63) and 33.33% (21/63) in CHB patients with MAFLD, and 32.31% (21/65) and 38.46% (25/65) in CHB patients without MAFLD. The differences between the two groups were not statistically significant (all P values > 0.05). Both groups showed significant reductions in HBsAg levels from baseline to 24 and 48 weeks (all P values P values > 0.05). By week 48, the proportions of CHB patients with MAFLD and without MAFLD achieving an HBsAg decline > 1 lg IU/mL were 42.86% and 50.77%, respectively (P > 0.05). After 48 weeks of treatment, the proportion of patients with HBV DNA undetectable reached 100% in both groups. CHB patients with MAFLD had a higher baseline BMI and ALT compared to those without MAFLD, and BMI decreased significantly with prolonged treatment in both groups. ALT and AST in the two groups were significantly higher than baseline at 24 weeks (P > 0.05), and decreased at 48 weeks. **Conclusion:** MAFLD has no impact on HBsAg clearance in CHB patients treated with NAs combined with PegIFNα-2b.

◆ 1368 | LINKING PERSONS WITH A HISTORY OF EXPERIENCING HOMELESSNESS TO HEPATITIS C VIRUS (HCV) TREATMENT BY ESTABLISHING DATA EXCHANGE BETWEEN A PUBLIC HEALTH HCV REGISTRY AND A HOMELESS SERVICES AGENCY — LOS ANGELES COUNTY, JANUARY–MAY, 2025

Prabhu Gounder[1] Jennifer Paul[2] Sophie Varma[1] Mirna Ponce Jewell[1] Heidi Behforouz[2], [1]Los Angeles County Department of Public Health, [2]Los Angeles County Department of Health Services

Background: In 2024, there were an estimated 75,312 persons experiencing homelessness (PEH) in Los Angeles (LA) County. One study estimated that 27% of PEH in the Skid Row area of LA had hepatitis C virus (HCV) infection. Although HCV is curable, it can be challenging to treat PEH until food and housing insecurity are addressed. Housing for Health (HFH) is a County program that provides supportive housing for PEH. We describe a pilot data exchange collaboration between LA County Department of Public Health (DPH) and HFH to identify and link PEH to HCV care. **Methods:** Clinical laboratories in LA are required to report positive anti-HCV antibody and all HCV polymerase chain reaction results to DPH; data management is conducted to relate all test results to unique persons to create a HCV registry. Persons with a positive anti-HCV antibody or PCR test and no corresponding negative PCR result classified as having potentially untreated HCV. We cross-referenced the DPH Countywide HCV registry with the HFH client list to identify persons with potentially untreated HCV. We worked with the assigned HFH case managers (CM) to reach out to clients interested in HCV treatment and make an appointment with their clinical provider. **Results:** In January 2025, we cross-referenced 26,073 HFH clients against the DPH HCV registry and identified 1,463 (6%) persons with potentially untreated HCV (1123 HCV PCR positive, 340 anti-HCV positive). Of the 104 HFH clients with untreated HCV who we targeted for initial outreach, 45 (43%) were unreachable because they were discharged from HFH before linkage with a provider or did not have an assigned CM. Of the 60 clients assessed by a CM, 18 (30%) declined treatment; 34 (81%) of 42 clients interested in treatment were linked to their provider, 8 (24%) of 34 clients linked to provider had a subsequent negative HCV PCR while 14

(41%) initiated HCV treatment, and 6 (42%) of 14 clients initiating HCV treatment completed it as of May 2025. **Conclusion:** It is challenging to conduct phlebotomy in the street and treat HCV in unhoused persons. This pilot program demonstrated the potential for identifying PEH with HCV through data exchange with a Public Health HCV registry that eliminated the need for repeat testing for HCV screening/confirmation. Partnering with a County homeless services agency allowed for treating HCV by leveraging existing resources. This data-to-action model for partnering with Public Health to support linkage to HCV care can be adapted for other high prevalence populations who are disconnected from the health system, such as local jails or harm reduction clinics.

◆ 1369 | GLOBAL TREATMENT RATES AND IMPACT OF DIRECT-ACTING ANTIVIRALS (DAA) ON SURVIVAL AND CANCER RECURRENCE IN PATIENTS WITH HEPATITIS C VIRUS-RELATED HEPATOCELLULAR CARCINOMA (HCV-HCC): A SYSTEMIC REVIEW AND META-ANALYSIS OF 81 STUDIES AND 22,474 PATIENTS

Taotao Yan[1] Takanori Ito[2] Tsukasa Yasuda[2] Takaya Suzuki[2] Michael Le[1] Rui Huang[3] Yu Shi[4] Haruki Uojima[1] Vy Nguyen[1] Xiangrong Gao[1] Zhiwen Fan[1] Ramsey Cheung[1] Mindie Nguyen[1], [1]Stanford University Medical Center, [2]Department of Gastroenterology & Hepatology, Nagoya University Hospital, Nagoya, Japan, [3]Nanjing Drum Tower Hospital, [4]1Division of Gastroenterology and Hepatology, Stanford University Medical Center

Background: Direct-acting antivirals (DAAs) is recommended for all patients with viremic HCV infection except those with limited life expectancy. Data on DAA treatment rate and its impact on long-term clinical outcomes remains under-characterized. We aimed to estimate DAA treatment rates among HCV-HCC patients and compare the incidence of overall mortality and HCC recurrence in DAA-treated and untreated HCV-HCC patients using a systematic review and meta-analytic approach. **Methods:** We searched PubMed, Embase, and the Cochrane library for eligible studies from inception until Jan 15, 2025. Primary outcomes were the pooled proportion of HCV-HCC patients who received DAA at or after HCC diagnosis and the pooled incidence of overall mortality and HCC recurrence per 100 person-years by DAA treatment status in patients with HCV- HCC using random effect models. **Results:** We initially identified 3784 potential articles and included a total of 81 eligible studies (19 reporting on DAA treatment rate, 49 on overall survival, and 60 on HCC recurrence) involving 22,474 patients from 13 countries/regions. The pooled DAA treatment rate was 36.2% overall (95% CI 36.7-46.3%, $I^2 = 98.5\%$) among 12,771 HCV-HCC patients from 19 studies, with no significant difference by geographic region: 32.4% in America, 40.2% in Europe, 40.4% in Asia, and 35.7% in Africa ($P = 0.90$) (Table 1). In meta-regression adjusting for study year and study setting, HCC cure (vs. active HCC) was significantly associated with higher DAA treatment rate ($P = 0.04$). The pooled incidence of overall mortality was 5.2 (95% CI: 3.4–7.0; $I^2 = 94.3\%$) in 10,074 DAA-treated patients compared to 23.8 (95% CI: 13.4–34.1; $I^2 = 99.3\%$) in 7,468 untreated patients, $P < 0.001$; with similar trends in subgroup analyses among those with cirrhosis (2.8 vs. 16.7, $P = 0.003$), curative HCC (3.3 vs. 12.2, $P < 0.001$), and active HCC (20.9 vs. 57.5, $P = 0.09$). The pooled incidence of HCC recurrence based on data from both comparative and noncomparative studies was 17.9 (95% CI: 15.1-20.7; $I^2 = 96.4\%$) in 6,983 DAA-treated patients as compared to 20.8 (95% CI: 14.9-26.7; $I^2 = 99.3\%$) in 2,051 untreated patients, $P = 0.36$. However, the incidence of HCC recurrence was significantly lower in DAA-treated patients among 4,191 patients from 23 comparative studies (13.5 vs. 20.8, $P = 0.03$) and in 497 treated vs. 633 untreated propensity score matched patients from 6 of these studies (11.8 vs. 20.9, $P < 0.001$). DAA treatment was significantly associated with reduced overall mortality (pooled adjusted hazard ratio [aHR] 0.39) and reduced HCC recurrence (pooled aHR 0.47), both $P < 0.001$. **Conclusion:** DAA-treated HCV-HCC patients had 4 times lower overall mortality and about half HCC recurrence rates but only one-third across major world regions received this beneficial therapy, highlighting the need for better access to DAA prescription and treaters as well as increased patient and provider awareness.

◆ 1370 | NATIONAL POPULATION-BASED HEPATITIS C SCREENING AND ELIMINATION PROGRAMME IN LITHUANIA: WHAT RESULTS: HAVE WE ACHIEVED?

Limas Kupcinskas[1] Veceslavas Zaksas[2] Alexis Voeller[3] Artur Kozlov[2] Jurate Sabaliene[2] John Ward[4] Janina Petkeviciene[5] Juozas Kupcinskas[5], [1]Lithuania University of Health Sciences, [2]National Health Insurance Fund under the Ministry of Health, Vilnius, Lithuania, [3]Center for Disease Analysis Foundation, Lafayette, Colorado, United States, [4]Coalition for Global Hepatitis Elimination, Decatur, United States, [5]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: In Lithuania National HCV screening program started in May, 2022. General practitioners (GPs) received special promoting fee for serological HCV antibody testing: 1. For people born between 1945 and 1994 (once in a lifetime) and 2. For people who inject drugs (PWID) or HIV-positive people (annual testing). This initiative is the first in Central and Eastern Europe. The aim of this study was to assess the results of the first 34 months of the programme and evaluate the different scenarios for achieving the WHO 2030 targets. **Methods:** GPs invited people to perform a serum blood test for HCV antibodies. Anti-HCV+ patients were referred to a gastroenterologist or infectologist for HCV RNA testing, and if result was positive, direct-acting antiviral (DAA) therapy was prescribed. Information about patients was obtained from the National Health Insurance Fund. The Markov disease progression model elaborated by the CDA Foundation was used to assess HCV elimination progress. The data from the 2022-2023 screening were used as inputs. Three scenarios were developed: the 'Base' scenario - return to pre-screening program level in 2023 and 2 scenarios with different extents of treatment. **Results:** At the beginning of 2022, about 1.8 million people born in 1945-1994 lived in Lithuania. Between May 5, 2022 and February 28, 2025, from this population 1362472 people (75.7%) were tested for HCV antibodies. Anti-HCV+ were found in 1.28% of cases. In the risk group, 8396 PWID and/or HIV+ people were screened, of whom 28.9 % were seropositive. Among anti-HCV+ persons 83.8% was from population and 16.2 % from risk groups. Specialists consulted 58% anti-HCV+ persons and viremia was detected in 53,1 %. Among anti-HCV+ persons from population specialist consulted 63%, but only 29% from risk group ($p < 0.001$). During 34-month (May 2022- February 2025) period 3 times more HCV patients were treated with DAA than during the same period before starting of the program (7577 vs 2470). The Markov disease progression model to assess HCV elimination progress showed the following scenarios: Scenario 1: if the same number of patients are treated as before the screening, the WHO targets will not be reached. Scenario 2: treating 70% of infected patients will meet most but not all WHO targets. Scenario 3: by treating all infected patients by 2030, the WHO target will be met by saving 150 lives and preventing 90 new cases of decompensated cirrhosis and 120 cases of hepatocellular carcinoma. **Conclusion:** In a European country with a moderate HCV seroprevalence, a population-based screening program is feasible and the number of patients treated has increased more than 3-fold in the first 34 months. Current status of the program predict that till 2030 country will meet most but not all WHO targets (the second scenario). Special measures to increase motivation and compliance of risk group patients to

◆ 1371 | THE IMPACT OF VIRAL CLEARANCE BY DIRECT-ACTING ANTIVIRAL ON PROGNOSIS AND LIVER-RELATED EVENTS IN HEPATITIS C VIRUS-RELATED DECOMPENSATED CIRRHOSIS

Yuki Tahata[1] Hayato Hikita[1] Yoshihito Uchida[2] Atsunori Tsuchiya[3] Seiichi Mawatari[4] Hidekatsu Kuroda[5] Daiki Miki[6] Nobuharu Tamaki[7] Yoichi Hiasa[8] Masaru Enomoto[9] Goki Suda[10] Taro Yamashita[11] Hiroshi Yatsuhashi[12] Hitoshi Yoshiji[13] Masato Nakamura[14] Taro Takami[15] Hisamitsu Miyaaki[16] Yasuhiro Asahina[17] Kanji Yamaguchi[18] Kentaro Matsuura[19] Ryosuke Tateishi[20] Yasunari Nakamoto[21] Eiji Kakazu[22] Shuji Terai[23] Masahito Shimizu[24] Yoshiyuki Ueno[25] Norio Akuta[26] Takahiro Kodama[1] Tomomi Yamada[27] Tetsuo Takehara[28], [1]Osaka University Graduate School of Medicine, [2]Saitama Medical University, [3]Faculty of Medicine, University of Yamanashi, [4]Kagoshima University Graduate School of Medicine and Dental Sciences, [5]Iwate Medical University, [6]Graduate School of Biomedical and Health Sciences, Hiroshima University, [7]Musashino Red Cross Hospital, [8]Ehime University Graduate School of Medicine, [9]Osaka Metropolitan University, [10]Graduate School of Medicine, Hokkaido University, [11]Kanazawa University, [12]National Hospital Organization Nagasaki Medical Center, [13]Nara Medical University, [14]Graduate School of Medicine, Chiba University, [15]Yamaguchi University Graduate School of Medicine, [16]Nagasaki University of Graduate School of Biomedical Sciences, [17]Institute of Science Tokyo, [18]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, [19]Nagoya City University Graduate School of Medical Sciences, [20]The University of Tokyo, [21]Faculty of Medical Sciences, University of Fukui, [22]National Center for Global Health and Medicine, [23]Niigata University, [24]Gifu University, [25]Yamagata University, [26]Toranomon Hospital, [27]Osaka University Hospital, [28]Kansai Rosai Hospital

Background: Sustained virologic response (SVR) can be achieved by direct-acting antiviral (DAA) therapy in approximately 90% of patients with hepatitis C virus (HCV)-related decompensated cirrhosis. However, the impact of SVR on prognosis and liver-related events in this population remains unclear. **Methods:** A total of 206 patients with HCV-related decompensated cirrhosis who initiated 12-week sofosbuvir and velpatasvir (SOF/VEL) therapy between February 2019 and December 2021 at 31 Japanese institutions were included. Decompensated cirrhosis was defined as Child-Pugh class B (CP-B) or CP-C, or CP-A with a history of decompensating events. The observation period began at the initiation of SOF/VEL. We evaluated liver transplantation (LT)-free survival, cumulative incidence of decompensating events requiring hospitalization, and de novo hepatocellular carcinoma (HCC). Decompensating events were defined as ascites, encephalopathy, variceal bleeding, spontaneous bacterial peritonitis, sepsis and acute kidney injury. SVR was defined as undetectable serum HCV-RNA at 12 or 24 weeks after the end of therapy (EOT). **Results:** The median age was 68 years; 9.7%, 75.7%, and 14.6% of patients were CP-A, CP-B and CP-C, respectively. The SVR rate was 91.3%. During a median follow-up of 43.7 months from the start of SOF/VEL, 44 patients died (19 liver failure, 10 HCC, 2 variceal bleeding, 13 non-liver-related causes), and 4 underwent LT. The 3- and 5-year LT-free survival rates were 82.9% and 69.0%, respectively. Multivariate Cox proportional hazard analysis identified virologic response and CP class at 12 weeks after the EOT as significant factors. The 3-year LT-free survival rates were 86.2% and 50.0% in patients with SVR and virologic failure, respectively ($p = 0.001$). Decompensating events occurred in 51 patients (ascites was the most common event), with 3- and 5-year incidence rates of 21.8% and 32.0%. In multivariate Cox proportional hazard, virologic response, baseline variceal status, and CP class were significant predictors; the 3-year incidence rates were 19.7% and 68.7% in patients with SVR and virologic failure, respectively ($p = 0.008$). Among 117 patients without prior HCC, 26 developed de novo HCC, with a 3-year cumulative incidence of 17.4%. In multivariate Cox proportional hazard analysis, baseline AFP level was significant, while virologic response was not. The 3-year HCC incidence rates were 17.0% and 25.0% in patients with SVR and virologic failure, respectively ($p = 0.292$). **Conclusion:** In patients with HCV-related decompensated cirrhosis, viral clearance through DAA therapy was associated with improved LT-free survival and a reduced incidence of decompensating events. However, the development of HCC may still occur in SVR patients, and careful surveillance is required.

◆ 1372 | MOLECULAR CONVERGENCE OF POST-SVR HEPATOCELLULAR CARCINOMA WITH MASLD/MASH- AND ALD-ASSOCIATED HCC

Fukiko Kawai-Kitahata[1] Yasuhiro Asahina[1] Sei Kakinuma[1] Kento Inada[1] Tomohiro Mochida[1] KEIYA WATAKABE[1] Tsubasa Nobusawa[1] Taro Shimizu[1] Jun Tsuchiya[1] Masato Miyoshi[1] Shun Kaneko[1] Miyako Murakawa[1] Sayuri Nitta[1] Mina Nakagawa[1] Daisuke Ban[1] Shinji Tanaka[1] Shinya Maekawa[2] Nobuyuki Enomoto[3] Ryuichi Okamoto[1], [1]Institute of Science Tokyo, [2]University of Yamanashi, [3]University of Yamanahsi

Background: In hepatitis C patients, the contribution of metabolic factors—linked to MASLD/MASH—to hepatocarcinogenesis remains poorly understood, particularly after viral eradication. We compared gene profiles of hepatocellular carcinoma (HCC) between HCV-SVR, steatotic liver disease (SLD), and HCV-non-SVR patients. **Methods:** This study analyzed 126 resected HCCs from patients with HCV and SLD, classifying them as HCV-SVR (n = 22), HCV-non-SVR (n = 56), and SLD (n = 48). Deep sequencing of 2910 hotspots in 55 cancer-related genes was conducted to examine mutations and copy number variations in both cancerous and background liver tissues. **Results:** The HCV-SVR group comprised more patients who consumed alcohol (45.5% vs. 15.7%, p = 0.008); were obese (54.5% vs. 17.9%, p = 0.002); and had dyslipidemia (18.2% vs. 3.6%, p = 0. 029) and hyperuricemia (18.2% vs. 3.6%, p = 0.029) than HCV-non-SVR group. Mutational profiling of the HCV-SVR HCC showed significantly lower alteration rates of *AXIN1* (13.6% vs. 42.9%, p = 0.016), *ARID2* (9.1% vs. 39.3%, p = 0.013), and *TP53* (9.1% vs. 32.1%, p = 0.030) than HCV-non-SVR patients. Compared with HCV-non-SVR-HCC, SLD-HCCs exhibited significantly lower rates of *TERT* promoter mutations (62.5% vs. 85.7%, p = 0.004); *ARID2* alterations (12.5% vs. 39.3%, p = 0.003); and *AXIN1* alterations (12.5% vs. 42.9%, p = 0.002). HCV-SVR/MASH/MASLD/ALD-HCC had significantly lower alteration rates of the Wnt/β-catenin (41.4% vs. 60.7%, p = 0.048) and chromatin remodeling pathways (27.1% vs. 48.2%, p = 0.026) than HCV-non-SVR-HCC. Furthermore, shorter disease free survival was significantly associated with *AXIN1* alteration (HR 0.43, p = 0.003); Wnt/β-catenin pathway alteration (HR 0.49, p = 0.005); tumor number ≥ 2 (HR 0.44, p = 0.004); TMN stage (p = 0.014); vascular invasion (HR 0.43, p = 0.001); differentiation (p = 0.014); and serum DCP level (HR 1.00, p < 0.001) in 102 patients who underwent hepatectomy as the initial curative treatment for primary HCC. **Conclusion:** HCC that develops ≥ 5 years after SVR was associated with features of metabolic disease and SLD in the nontumorous liver. Furthermore, our comprehensive genetic analysis revealed that the genetic features of HCV-SVR HCC were similar to those of MASH/MASLD-HCC and ALD-HCC. These findings suggested that these diseases share molecular subtypes and that the treatment response may be strongly associated with hepatic steatosis and cardiometabolic factors.

◆ 1373 | SOFOSBUVIR-BASED REGIMEN ACHIEVED HIGH VIROLOGICAL RESPONSE IN NON-GENOTYPED HCV PATIENTS FROM A GENOTYPE 3 HIGH-PREVALENCE REGION OF SOUTHWEST CHINA: A RETROSPECTIVE COHORT STUDY (SAIN-C)

Liu Li[1] Mei Li[2] Rui-Ling Liu[3] Fu-Zhen Xie[4] Ming Fang[2] Xing-Qiang Gao[5] Li-Hua Li[6] Chun-Xia Dao[7] Rui-Ling Hui[8] Chang-Xian Lu[9], [1]Kunming Third People's Hospital, Yunnan Province, China, [2]Fuyuan County People's Hospital, Yunnan Province, China, [3]Xuanwei People's Hospital, Yunnan Province, China, [4]Gengma County People's Hospital, Yunnan Province,China, [5]Luoping County People's Hospital, Yunnan Province, China, [6]Xishuangbanna People's Hospital, Yunnan Province, China, [7]Menglian County People's Hospital, Yunnan Province, China, [8]Qujing First People's Hospital, Yunnan Province, China, [9]Lincang People's Hospital, Yunnan Province, China

Background: To leverage a simplified strategy without genotype test in high-prevalence regions of hepatitis C virus (HCV) genotype 3 (GT3) infection, and explore the efficacy of sofosbuvir(SOF)-based regimen for chronic hepatitis C (CHC) patients with unknown genotypes. **Methods:** CHC patients who visited hospitals including Kunming Third People's Hospital in Yunnan province were retrospectively included. Patients were treated with Sofosbuvir/Velpatasvir (SOF/VEL) or Ledipasvir/Sofosbuvir (LDV/SOF) ± Ribavirin(RBV) for 12 weeks. The sustained virological response after 12 weeks of follow-up after the end of treatment(SVR12) between genotype-tested and the untested group were compared. **Results:** From January 2022 to December 2024, a total of 2445 cases were enrolled from 9 hospitals including 4 county-level primary hospitals and 5 city-level hospitals. Baseline characteristics: average age of 52.6 ± 15.4 years, with 1295 males (53.0%) and 2066 farmers (84.5%). 1208 cases (49.4%) were in the untested genotype group. Mean level of HCV RNA was 6.08 ± 1.09 IU/mL. 64 cases (2.6%) already had cirrhosis before treatment initiation. After 12 weeks off-treatment, totally 2377 cases achieved SVR12 (97.2%), with 1187 cases in genotype-untested group (98.3%) and 1190 cases in genotype-tested group(96.2%). No significant difference could be found between two groups. For patients with SOF/VEL, 97.1%(1941/1998) achieved SVR12, including 98.4%(1145/1164) in genotype-untested group and 95.4% (796/834) in genotype-tested group . For SOF/VEL+RBV regimen, 97.1% achieved SVR12, with 98.4% (1145/1164) in genotype-untested group and 95.4%(796/834) in genotype-tested group. For patients treated with LDV/SOF, SVR12 rate was 99% (304/307), with 96.4% (27/28) in genotype-untested group and 99.3%(277/279) in genotype-tested group . **Conclusion:** SOF-based regimen could achieve high SVR regardless of genotype testing, even in high-prevalence regions of HCV GT3 infection. We believe this simplified strategy could be considered for genotype testing unavailable areas.

◆ 1374 | OUTCOMES OF DIRECT ACTING ANTIVIRAL AGENTS IN CHRONIC HEPATITIS C PATIENTS WITH PRE-EXISTING HEPATOCELLULAR CARCINOMA

Hyun Young Woo[1] Ki Youn Yi[1] Young Joo Park[1] Jeong Heo[1], [1]Pusan National University Hospital

Background: Chronic hepatitis C (CHC) is a significant global health issue and a well-known risk factor for hepatocellular carcinoma (HCC). The advent of direct-acting antivirals (DAAs) has revolutionized hepatitis C treatment by achieving high rates of viral clearance and improving liver function. However, the benefits of DAAs for patients with pre-existing HCC—particularly regarding recurrence, progression, and overall survival—remain controversial. The aim of our study was to assess the outcome of various direct acting antiviral agents for CHC patients with pre-existing HCC. **Methods:** In this real-world observational study, we recruited chronic hepatitis C patients with pre-existing HCC who was treated with DAAs after diagnosis of HCC. Patients were administered various DAAs; daclatasvir+asunaprevir, sofosvubir+ribavirin, sofosbuvir+daclatasvir, ledipasvir/Sofosbuvir ± ribavirin, ombitasvir/Paritaprevir/Ritonavir and Dasabuvir ± Ribavirin, glecaprevir/pibrentasvir, velpatasvir/Sofobuvir ± ribavirin. The primary efficacy endpoint was sustained virological response at post-treatment week 12 (SVR12). Adverse events (AEs) during treatment, overall survival, HCC recurrence after HCV treatment was also evaluated. **Results:** This study included 105 patients (mean age, 67 ± 9.87, male, n = 67) with HCV

genotypes 1b (n = 64), 2 (n = 41). 17.1% (n = 18) had a Child-Pugh score of B. BCLC HCC stage is A in 68, B in 28 and C in 9 patients and 41 (39%) patients have viable HCC at the start of HCV treatment. Thirty-one patients had prior HCV treatment experience, including 25 with interferon based treatment, 5 with DAAs. SVR12 rates were 92.3% (ITT, 97/105) and 93% (mITT, 94/101). SVR12 for each DAAs was shown Table 1. AEs occurred in four patients but improved with symptomatic treatment. HCC was recurred or progressed during or after DAAs treatment in 80 patients and median time to progression was 10.8 months (95% CI, 3.01-18.59) months). Overall survival after DAAs treatment was 66.7% and median survival was 81.2 months (95% CI 62.41-99.99). In multivariate analysis, viable HCC at the start of HCV treatment (p = 0.003), BCLC HCC stage (p = 0.015) and ribavirin use (p = 0.001) are significantly associated with overall survival. **Conclusion:** This study demonstrated that the DAAs achieved favorable treatment outcomes and was well tolerated in CHC patients with pre-existing HCC. HCC tumor stage, presence of viable HCC and ribavirin use was significantly associated with survival.

Table 1. SVR12 in each direct acting antiviral agents

	SVR12, % (N)	SVR12, % (N)
daclatasvir+asunaprevir	91.7 (22/24)	91.7 (22/24)
sofosvubir+ribavirin	78.9 (15/19)	78.9 (15/19)
ledipasvir/Sofosbuvir ±ribavirin	75 (6/8)	100 (6/6)
sofosbuvir+daclatasvir	87.7 (7/9)	88.9 (7/8)
ombitasvir/Paritaprevir/Ritonavir and Dasabuvir ± Ribavirin	100 (10/10)	100 (10/10)
glecaprevir/pibrentasvir	100 (13/13)	100 (13/13)
velpatasvir/Sofobuvir ± ribavirin	100 (20/20)	100 (20/20)

◆ 1375 | OCCULT HEPATITIS C VIRUS INFECTION ACCELERATES NON-HEPATOCELLULAR CANCER DEVELOPMENT BY AUGMENTING REGULATORY B CELLS: A 15-YEAR PROSPECTIVE COHORT STUDY

Ming-Ling Chang[1], [1]Department of Gastroenterology and Gastroenterology

Background: How occult hepatitis C virus (HCV) infection (OCI) affects the prognosis of chronic hepatitis C patients with sustained virological responses (SVRs) following anti-HCV therapy remains elusive. **Methods:** A 15-year prospective study of 509 SVR patints who had been assessed for OCI, defined as HCV RNA detectable in peripheral blood mononuclear cells (PBMCs) but undetectable in serum, was conducted. **Results:** Of 509 SVR patients, 139 (27.3%) had OCI. Two (1.4%) male OCI patients developed relapse of HCV infection with a duration of 4 years (direct-acting antiviral-treated SVR) and 10 years (interferon-based therapy-treated SVR), respectively. A higher non-hepatocellular (non-HCC) cancer cumulative incidence was noted in patients with than those without OCI (23.07% vs. 11.74%, $p = 0.002$); most non-HCC cancers occurred before SVR [before SVR (18% vs. 10.5%, $p = 0.004$); after SVR (5.9% vs. 2.2%, $p = 0.032$)], while the HCC cumulative incidences were comparable between patients with and without OCI (6.15% vs. 5.1%, $p = 0.405$). OCI was independently associated with non-HCC cancer development (95%CI hazard ratio: 1.042~ 3.268). Of OCI patients, most HCV RNAs existed in the B cells of PBMC. Higher rates of interleukin-10 (IL10)-regulatory B cell (Breg) (CD19+ CD24hi CD27+ cells) (17.39+/-8.00 % vs. 11.55+/-5.63 %, $p = 0.013$) and naive regulatory T cell (Treg) (CD4 +Foxp3+CD45RA+ cells)(11.21 +/- 7.24 vs. 4.76 +/-2.24%, $p = 0.012$) but lower rates of B cells (3.45 +/-1.16 % vs. 4.72 +/-1.63%, $p = 0.01$) and memory Treg (CD4+Foxp3+CD45RA- cells) (88.56+/-7.23 vs. 95.24+/-2.25%, $p = 0.011$) were noted in SVR patients with than those without OCI. While tumor immune cell proportion and cancer cell proliferation activities were comparable between the patients with and without OCI. **Conclusion:** During a 15-year follow-up, about one third of the SVR patients harbored OCI, in which HCV parasitizes B-cells to downregulate B-cells but upregulate Bregs, this scenario might accelerate non-hepatic oncogensis, as early as before SVR.

Jordan Feld[2] Milan Sonneveld[1], [1]Erasmus University Medical Center Rotterdam, [2]Toronto General Hospital, [3]King's College Hospital, [4]Queen Mary University of London, [5]Hannover Medical School, [6]University of Barcelona, [7]niversidad Autonoma de Madrid and CIBERehd, [8]University of British Columbia, [9]Link University of Rome, [10]IRCCS Azienda Ospedaliero-Universitaria di Bologna, [11]Tor Vergata University Rome, [12]ASST Ospedale Niguarda Milan, [13]University of Padova, [14]University Hospital Padua, [15]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico Milan, [16]University of Pisa Medical School Hospital, [17]AOU Città della Salute e della Scienza di Torino, [18]RCCS Azienda Ospedaliera-Universitaria di Bologna

Background: Direct acting antiviral (DAA) therapy results in high rates of sustained virological response (SVR) even in patients with decompensated hepatitis C virus (HCV) cirrhosis. However, these patients remain at risk for liver-related events (LREs). We aimed to assess the incidence and risk factors for LREs in patients with decompensated HCV cirrhosis who have achieved SVR. **Methods:** We conducted an international multicenter retrospective cohort study including patients with decompensated HCV cirrhosis (Child-Turcotte-Pugh (CTP) ≥ 7 and/or history of decompensation) treated with DAAs. Patients aged ≥ 65, and those that developed HCC or underwent liver transplantation (LT) before SVR were excluded from analyses. LREs were defined as the first of a composite of HCC, LT or death. Predictive factors were assessed by multivariable Cox regression (MVA) adjusting for age, sex, diabetes mellitus (DM), current or history of alcohol use disorder (AUD), creatinine, bilirubin, albumin, platelets and INR at moment of SVR. A risk score was constructed by adding the obtained hazards through MVA. **Results:** We included 612 patients with a median age of 54 (IQR 49-59) years, 70% was male, 49% had AUD, 22% had DM, and the median MELD score at the time of SVR was 11.0 (8.9-13.0). Median follow-up time after SVR was 21 (8-33) months. In total, 235 LREs were recorded in 193 (32%) patients (59 HCC, 57 LT and 119 deaths). The 1-, and 3-year cumulative incidence of LREs were 18% and 44% in the overall cohort. The presence of DM (aHR: 1.5, $p = 0.020$), AUD (aHR: 1.5, $p = 0.011$), higher bilirubin (aHR for bilirubin 20-40 umol/L: 1.4, aHR for > 40 umol/L: 1.8, $p = 0.026$) and lower albumin (aHR for albumin 28-35g/L: 2.0, aHR for albumin < 28g/L: 3.4, $p < 0.001$) levels were independently associated with an increased risk of LREs. Patients were subsequently allocated to a low-risk group (no risk factors), intermediate risk (risk points > 0 & < 4) and high risk (≥ 4 risk points). In the overall cohort, 12% of patients had a predicted low risk, 61% a predicted intermediate risk and 27% a predicted high risk of LREs. Amongst patients with no risk factors, the cumulative 1-year incidence of LREs was 2%, compared to 17% and 25% in those at intermediate and high risk ($p < 0.001$). The cumulative 3-year incidence of LREs was 21/39/61% in patients at low/intermediate/high predicted risk (Figure 1). Similar findings were observed when further decompensation was added as an outcome. When applying the score on HCC, the cumulative 1-, and 3-year incidences were 0/6/10% and 12/16/23% in patients at low/intermediate/high predicted risk ($p = 0.145$). **Conclusion:** Patients with decompensated HCV cirrhosis remain at high risk of HCC, liver transplant and death despite SVR. A simple risk score based on the presence of DM, AUD, elevated bilirubin and lower albumin can be used to identify patients at highest risk, who could potentially benefit from stringent surveillance and evaluation for LT.

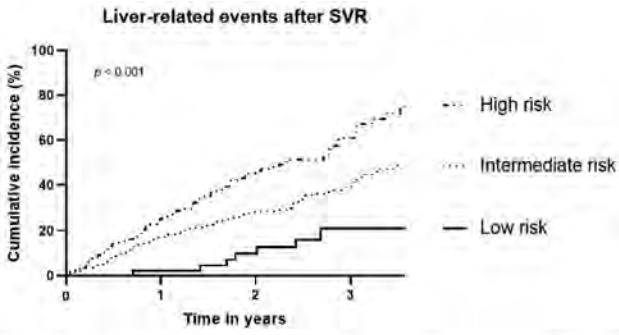

Figure 1. Cumulative incidence of liver-related events in patients with decompensated cirrhosis who achieved SVR stratified for a predicted high, intermediate and low-risk.

◆ 1377 | INCIDENCE AND RISK FACTORS FOR HEPATOCELLULAR CARCINOMA AFTER SUSTAINED VIROLOGIC RESPONSE CHANGE OVER TIME IN PATIENTS WITH HEPATITIS C VIRUS TREATED WITH DIRECT-ACTING ANTIVIRAL

Yuki Tahata[1] Hayato Hikita[2] Yasutoshi Nozaki[3] Hisashi Ishida[4] Atsushi Hosui[5] Masanori Miyazaki[6] Ryotaro Sakamori[7] Kazuyoshi Ohkawa[8] Nobuyuki Tatsumi[9] Fumihiko Nakanishi[10] Yoshinori Doi[11] Takayuki Yakushijin[12] Mitsuru Sakakibara[13] Kazuho Imanaka[14] Naruyasu Kakita[15] Sadaharu Iio[16] Yuichi Yoshida[17] Kumiko Shirai[2] Kazuhiro Murai[2] Yuki Makino[2] Yoshinobu Saito[2] Yoshinobu Saito[2] Takahiro Kodama[2] Tetsuo Takehara[3], [1]Osaka University Graduate School of Medicine, [2]Osaka University Graduate School of Medicine, [3]Kansai Rosai Hospital, [4]Ikeda Municipal Hospital, [5]Osaka Rosai Hospital, [6]Osaka Keisatsu Hospital, [7]National Hospital Organization Osaka National Hospital, [8]Osaka International Cancer Institute, [9]Japan Community Healthcare Organization Osaka Hospital, [10]National Hospital Organization Osaka Minami Medical Center, [11]Otemae Hospital, [12]Osaka General Medical Center, [13]Yao Municipal Hospital, [14]Itami City Hospital, [15]Kaizuka City Hospital, [16]Hyogo Prefectural Nishinomiya Hospital, [17]Suita Municipal Hospital

Background: We previously reported that the incidence and risk factors for hepatocellular carcinoma (HCC) after sustained virologic response (SVR) change over time in hepatitis C virus (HCV) patients treated with interferon-based therapy. However, whether these patterns also apply to patients treated with direct-acting antiviral (DAA) remains unclear. **Methods:** This study included 3,049 HCV-infected patients without a history of HCC who initiated DAA therapy between September 2014 and December 2022 and achieved SVR at 26 Japanese hospitals. SVR was defined as undetectable serum HCV-RNA at 24 weeks after the end of therapy. FIB-4 index of 3.25 or more was defined as patients with advanced liver fibrosis. The observation period began at SVR confirmation. Annual HCC incidence rate was evaluated separately for patients with and without advanced liver fibrosis. Segmented regression analysis was performed to identify a change point in the trend of HCC occurrence. Risk factors associated with HCC occurrence after SVR were examined by Cox proportional hazard analysis before and after the identified joinpoint. **Results:** The median age was 69 years, and 1,240 patients (41%) were diagnosed as having advanced liver fibrosis. During a median follow-up of 51.6 months from SVR, 118 and 32 patients developed de novo HCC occurrence in patients with and without advanced liver fibrosis, respectively. The 7-year cumulative HCC incidence rates after SVR were 13.4% in patients with advanced liver fibrosis and 2.5% in those without ($p < 0.001$). Among patients with advanced liver fibrosis, annual HCC incidence rates at 1, 2, 3, 4, 5, and 6 years after SVR were 2.7%, 3.1%, 1.8%, 1.5%, 0.9%, and 2.4%, respectively, suggesting a possible decline followed by a rise in incidence. In contrast, annual HCC incidence rates remained below 0.5% throughout the observation period in patients without advanced liver fibrosis. Segmented regression analysis identified a joinpoint at 4.5 years after SVR in patients with advanced liver fibrosis. Risk factors for HCC occurrence were therefore analyzed separately for the early phase (≤ 4 years) and the late phase (> 4 years) after SVR. In multivariate analysis, male sex ($p = 0.027$), higher gamma-glutamyl transpeptidase (GGT) level at SVR ($p < 0.001$), lower albumin level at SVR ($p = 0.013$), and higher AFP level at SVR ($p < 0.001$) were significantly associated with HCC occurrence in the early phase. In the late phase, only higher GGT level at SVR ($p = 0.021$) was significantly associated with HCC

occurrence in univariate analysis. **Conclusion:** In patients with advanced liver fibrosis, HCC incidence decreases for up to 4 years following SVR but may increase thereafter. Risk factors for HCC occurrence appear to differ between the early and late phase after SVR.

◆ 1378 | SAFETY AND EFFICACY OF 8-WEEKS GLECAPREVIR/PIBRENTASVIR IN PERSONS WITH ACUTE HEPATITIS C IN GERMANY AND AUSTRIA

Carolina Russo[1] Johannes Hülsenbeck[1] Christoph Boesecke[2] Axel Baumgarten[3], [1]AbbVie Deutschland GmbH & Co. KG, Wiesbaden, Germany, [2]Department of Medicine I, University of Bonn, Bonn, Germany, [3]Center for Infectiology, Berlin, Germany

Background: Although recommended by international guidelines current direct-acting antivirals (DAAs) for chronic hepatitis C are not approved for the treatment of acute HCV infection. In high-risk populations, initiating HCV treatment immediately after diagnosis is critical to prevent onward transmission. Previously, safety and efficacy of 8-weeks Glecaprevir/Pibrentasvir (G/P) was presented in 286 participants with acute hepatitis C (AASLD 2024 abstract #5031). This exploratory analysis aims to confirm the efficacy and safety of G/P in persons with acute hepatitis C enrolled in Germany and Austria. **Methods:** A post-hoc analysis of safety and efficacy of 8-weeks G/P was carried out in a subset of participants enrolled in Germany and Austria from a single-arm, prospective phase 3b study (NCT04903626) in adults with acute/recent HCV infection (Table 1) who had not previously been treated for current infection. **Results:** 79 participants were enrolled and treated in Austria (N = 7) and Germany (N = 72) between September 7, 2021, and August 26, 2024. 96.2% of participants were male with a median age of 44.0 years (IQR: 37.0 - 54.0 years) and baseline HCV RNA of 5.65 $\log_{10}$ IU/mL (IQR: 4.09 - 6.53 $\log_{10}$ IU/mL). Genotype 1, 3 and 4 infections were present in 66.2%, 10.8% and 23.0% of participants, respectively. 59.9% of participants had current alcohol use, 62.0% had a history of illicit drug use within 12 months prior to treatment (illicit injection drug use, 20.3%), and 62.0% had HIV co-infection (HIV-1 RNA < 20 copies/mL, 89.8%). The main risk behaviors for current acute HCV infection were unprotected sexual activity with other male(s) (78.5%) or multiple partners (58.2%), shared non-injection drug use equipment (20.3%) or drug-injection equipment (19.0%). Sustained virologic response at 12-weeks post-treatment (SVR12) rates were 94.9% in ITT and 100% in mITT analysis, without virologic failures, relapses or reinfections. During treatment none of the 79 participants experienced an adverse event (TEAE) leading to G/P discontinuation or serious TEAE related to G/P. 97.6% (41/42) of participants who had baseline ALT > 3× ULN showed normal ALT at final treatment visit. **Conclusion:** In this high-risk, sexually very active population with acute hepatitis C in Germany and Austria 8-weeks G/P was safe and highly effective, regardless of HIV co-infection and drug/alcohol use supporting its implementation as a key strategy toward achieving the WHO HCV elimination goal.

Table 1. Study Protocol Eligibility Criteria for Acute/Recent HCV Infection

Physician diagnosis of acute HCV infection	
AND	
Quantifiable HCV RNA at screening	
AND	
At least one of	Negative anti-HCV antibody, HCV RNA, and/or HCV core antigen followed by a positive HCV RNA or HCV core antigen all within an 8-month period prior to screening
	Negative anti-HCV antibody, HCV RNA, and/or HCV core antigen followed by a positive HCV RNA or HCV core antigen all within an 11-month period prior to screening AND Risk behavior for HCV infection within 6 months prior to positive HCV RNA or HCV core antigen
	Clinical signs and symptoms compatible with acute hepatitis (ALT >5×ULN and/or jaundice) in the absence of a history of chronic liver disease or other cause of acute hepatitis and positive HCV RNA or HCV core antigen all within an 8-month period prior to screening AND Risk behavior for HCV infection within 6 months prior to positive HCV RNA or HCV core antigen
	Negative anti-HCV antibody with a positive HCV RNA or HCV core antigen within a 5-month period prior to screening

ALT, alanine aminotransferase; HCV, hepatitis C virus; RNA, ribonucleic acid; ULN, upper limit of normal.

◆ 1379 | GENDER AND SOCIOECONOMIC-BASED DISPARITIES IN HEPATITIS C TREATMENT AND CURE RATES IN AN EMERGENCY DEPARTMENT-BASED SCREENING AND TREATMENT PROGRAM

Christian Rhudy[1] Daniel Moore[1] Lindsey Sheehan[2] Afomia Gelan[1] Morgan Stacey[3], [1]University of Kentucky HealthCare, [2]UK HealthCare, [3]University of Kentucky Medical Center

Background: Hepatitis C (HCV) remains a public health issue, with particularly high prevalence and mortality rates in Kentucky. To address this, University of Kentucky HealthCare (UKHC) implemented an emergency department (ED)-based screening and treatment program, UK-CURES (Cascade Utilizing Routinized screening through treatment to Eliminate Syndemics), which improved diagnosis and treatment attachment rates at the institution. However, the extent to which UK-CURES addressed sociodemographic-based disparities in HCV outcomes, particularly gender-based disparities, has not been fully investigated. **Methods:** This was a retrospective, cross-sectional study including patients screening HCVRNA positive at a UKHC ED between July 2018 and December 2023. Patients missing gender data were excluded, and only the patient's first HCV RNA positive screening (index date) at UKHC was considered. Demographic data including age group, gender, ethnicity/race, payor type as well as HIV and hepatitis B lab values, and diagnoses of opioid use (ICD-10-CM F 11*) were collected. Outcomes of interest included HCV treatment orders or negative HCVRNA results within the one-year post-index period. Association of sociodemographic attributes with outcomes was assessed using univariable logistic regression. Significant univariable predictors were included in adjusted multivariable models for each outcome. **Results:** 97,386 patients were screened for HCV, of which 4,723 (4.9%) were HCV RNA positive (female n = 1,636, 34.6%; male n = 3,087, 65.4%). Adjusted odds of treatment orders (male referent, OR 0.94, 95%CI 0.76-1.17) and negative HCVRNA results (OR 1, 95%CI 0.73-1.24) within one year did not differ significantly between male and female patients. Patients with self-pay or other insurance were significantly less likely to attach to treatment (commercial referent, OR 0.18, 95%CI 0.1-0.34) or have a negative HCVRNA result at one year (OR 0.25, 95%CI 0.13-0.41). Notably, patients receiving treatment through the UK-CURES program had significantly higher odds of receiving treatment orders (OR 4.96, 95%CI 3.84-6.4). **Conclusion:** No notable gender disparities were observed in HCV treatment ordering or cure rates, suggesting that UK-CURES ED-based screening and treatment may address any existing disparities. Lower odds of treatment and cure were observed in self-pay patients, suggesting disparities attributable to financial barriers to care exist and need to be addressed.

◆ 1380 | CUMULATIVE REVIEW OF SOFOSBUVIR/VELPATASVIR EXPOSURE IN PREGNANT WOMEN WITH HEPATITIS C VIRUS FROM A PHARMACOVIGILANCE SAFETY DATABASE

Stacey Scherbakovsky[1] Catherine Chappell[2] Chelsea Elwood[3] Yachna Sahi[4] Frederick Pitts[4] Lauren Liu[4] Catherine Frenette[5] Tatyana Kushner[6], [1]Gilead Sciences, Inc, [2]University of Pittsburgh; Magee-Womens Research Institute, [3]Medical Lead Oak Tree Clinic and Antimicrobial Stewardship BC Women's Hospital and Health Centre, [4]Gilead Sciences, [5]Gilead Sciences, Inc., [6]Weill Cornell Medicine

Background: The prevalence and incidence of hepatitis C virus (HCV) in women of childbearing age and pregnant individuals has increased nearly tenfold over the last 20 years, paralleling rising infection rates among young adults. While no direct-acting antiviral (DAA) therapies are approved for use in pregnancy, animal studies provide encouraging safety data. Clinical studies, including the Phase 4 Safety, Tolerability, and Outcomes of Velpatasvir/SofosbuviR in Treatment of Chronic Hepatitis C Virus during Pregnancy (STORC) study, are ongoing to validate safety data for the routine use of DAAs in pregnancy. **Methods:** The cumulative review included safety data reported from Feb 2016 to June 2024 to the Gilead Pharmacovigilance database. Data included pregnancy exposures and outcomes from clinical trials, spontaneous post-marketing reports,

solicited sources and the literature. These data were analyzed for timing of treatment initiation/discontinuation, whether SOF/VEL treatment was completed, if sustained virologic response (SVR) was achieved, pregnancy outcomes, congenital anomalies and vertical transmission. **Results:** A total of 335 pregnancy cases (337 pregnancies [2 sets of twins]) associated with SOF/VEL use were reported from spontaneous sources (216), clinical studies (66), solicited sources (46) and the literature (7). Case distribution included the USA (62%), Europe, Canada, Asia, and Australia. The median age was 30.5 years (range: 19-52), with ethnicity data available for 83 of 335 cases. Of 123 pregnancies with documented outcomes, 74 (60.2%) resulted in live births, 28 (22.8%) experienced spontaneous abortions and 21 (17.1%) underwent elective or induced abortions. Of the 74 live births, 62 (82.6%) had normal outcomes (caesarean and full-term deliveries), while 10 (13.5%) involved congenital anomalies and two (2.7%) were premature births at 30 and 33 weeks without anomaly. Congenital anomalies ranged from specific physical abnormalities to renal malformations, melanocytosis and intrauterine growth restrictions, spontaneous abortions were confounded with illicit drug use, concomitant medications not recommended in pregnancy, or other concurrent illnesses, both lacking sufficient data to link them to SOF/VEL use. **Conclusion:** The high rate of congenital anomalies is notable in the reported live births, but spontaneous reporting systems inherently risk under-reporting (63.5% with unknown or pending outcomes) and reporting bias. These cumulative data add to the body of evidence of the use of SOF/VEL in pregnancy and underscore the importance of further safety data.

◆ 1381 | NO IMPACT OF RASS ON THE HIGH EFFICACY OF BEM AND RZR IN COMBINATION: RESISTANCE ANALYSIS FROM A PH 2 STUDY IN HCV-INFECTED PATIENTS

Qi Huang[1] Dawei Cai[1] Shannan Lynch[1] Keith Pietropaolo[1] Xiao-Jian Zhou[1] Sergey Izmailyan[1] Maria Arantxa Horga[1] Janet Hammond[1] Nancy Agrawal[1] Jean-Pierre Sommadossi[1], [1]Atea Pharmaceuticals, Inc.

Background: Bemnifosbuvir (BEM) and ruzasvir (RZR) are potent pan-genotypic inhibitors of HCV NS5B and NS5A, respectively. A Phase 2 open-label study evaluated the efficacy/safety of BEM+RZR for 8 weeks in 275 HCV-infected patients (NCT05904470). SVR12 was 98% (99% in non-cirrhotics; 88% in compensated cirrhotics [CC]) in the primary Per-Protocol Treatment-Adherent Population (study-drug adherent). Detailed analyses were conducted of Next-Generation Sequencing (NGS) results for 14 patients in the overall population who experienced virological failure (VF), and *in vitro* phenotyping results, to establish clinical resistance profiles. **Methods:** NGS was performed at baseline and at failure for the 14 VF patients. For phenotypic analyses of potential HCV NS5A and NS5B RASs observed in baseline and on/post-treatment, single or linked RASs were engineered back to specific (sub)genotype replicons and EC_{50} fold shifts were determined in transient replicon assays. **Results:** Analysis of viral kinetics and plasma drug exposures across the whole study population indicated that the majority of VFs were due to treatment adherence issues, especially in NC. 6/7 of the NC subjects with VF were not study-drug adherent, and 4/6 developed high resistance to RZR. For the NS5A gene, 7/14 patients had pre-existing primary NS5A RASs and 5 of these 7 carried baseline NS5A RASs that were further enriched at VF, often acquiring additional RASs. Phenotyping results showed these linked NS5A RASs confer high resistance to RZR. The other 2 of these 7 carried low resistance NS5A at baseline, with additional NS5A substitutions emerging at VF, which did not confer RZR resistance alone or linked with NS5A RASs. 3/14 patients with no known NS5A RASs at baseline had high resistance RASs emerging at VF. The other 4/14 patients with no baseline NS5A RASs did not have new substitutions at VF. For the NS5B region, no primary BEM C223 substitutions or SOF S282T were detected at baseline or VF. Some NS5B substitutions emerged or were enriched, but the impact on BEM or SOF activities was minimal in transient replicon assays. Results indicate BEM viral resistance is not developing rapidly, consistent with earlier studies. **Conclusion:** The combination of BEM/RZR in this phase 2 study showed strong antiviral activity against all tested HCV genotypes (GT 1-4). VK and PK data indicated most VFs were due to poor adherence and resulted from NS5A resistance to RZR. BEM/RZR is currently in phase 3 development.

1382 | HEPATITIS C CARE CASCADE USING DIRECT ACTING ANTIVIRAL MEDICATIONS IN RURAL NEW YORK STATE FROM 2013-2023; A RETROSPECTIVE STUDY

Zoi Papalamprakopoulou[1] Melissa Scribani[2] Nicole Krupa[2] Paul Jenkins[2] Jennifer Victory[2] Wendy Brunner[2] Michael Cain[1] Arpan Dharia[1] Daniel Freilich[3] Andrew Talal[1], [1]Division of Gastroenterology, Hepatology, and Nutrition, University at Buffalo, NY 14203 USA, [2]Bassett Research Institute, Bassett Medical Center, 1 Atwell Road, Cooperstown, NY 13326 USA, [3]Department of Internal Medicine, Division of Infectious Diseases, Bassett Medical Center, 1 Atwell

Background: Hepatitis C virus (HCV) infection is higher in rural areas, yet access to HCV care remains more limited. We evaluated the HCV care cascade during the first decade of direct-acting antiviral (DAA) use in the primary care setting at Bassett Healthcare Network in rural New York State (NYS). **Methods:** We used retrospective electronic health record data to construct eleven annual testing cohorts (2013-2023) based upon HCV antibody testing date. Eligible patients were primary care patients aged 18-79 years. We summarized the annualized average HCV care cascade using frequencies and weighted percentages. We conducted subgroup analyses of people with opioid use disorder (OUD) versus those without OUD using chi-square. Using ANOVA, we compared changes in the HCV care cascade before and after reflex HCV RNA testing implementation in 2017 and universal HCV screening recommendations for all adults introduced in 2020. **Results:** The primary care population was 72,615 individuals, 96.4% white, 44.6% male, and 4.2% had OUD. We illustrate the annualized average HCV care cascade from 2013-2023 for both the total primary care population and the subgroup with OUD (Fig). Of the total and OUD populations, 5.0% and 8.2%, respectively, had HCV serostatus assessed. Among those tested, HCV seropositivity occurred in 2.8% and 17.5% of the total and OUD populations, respectively. Among the total population, we observed the highest HCV seropositivity (4.65%) among individuals aged 20-39 years. Among 96 HCV-seropositive individuals in the total population, 95.8% (92/96) underwent HCV RNA testing. Of those tested, 40.2% (37/92) were HCV RNA-positive. Among them, 45.9% (17/37) initiated DAAs, and 81.3% (13/16) achieved HCV cure. People with OUD had higher HCV RNA-positivity compared to those without OUD (51.3% vs. 35.7%, respectively) ($p < 0.0001$), suggesting more active disease and infectivity, and lower DAA initiation rates (35.7% vs. 57.7%, respectively) (Fig). RNA testing rates increased following implementation of RNA reflex testing in 2017 ($p = 0.0333$); HCV antibody testing increased following implementation of universal HCV screening in 2020 ($p < 0.0001$). **Conclusion:** While HCV case identification improved following the implementation of RNA reflex testing and universal screening policies, opportunities exist to improve HCV detection and DAA treatment initiation in rural NYS. Expanding DAA access for people with OUD is critical to improving rural HCV care and public health.

1383 | DECENTRALIZATION IN ACTION: T&UUML;RKIYE&RSQUO;S POLICY-DRIVEN EXPANSION OF HEPATITIS C TREATMENT TO SECONDARY CARE

Imran Hasanoglu[1] Rahmet Guner[1] Mehmet Cabalak[2] Burak Kizilcay[3] Mustafa Muhammed Gulhan[4] Ummu Sena Sari[5] Islim Tuba Ozkaya[6] Meral Bayar[7] Unal Cagir[8] Cigdem Toruner Ineli[9] Armagan Toy[10] Ragip Sariismailoglu[11] Gozde Akkiraz Bac[12] Imran Icel Yildirim[13] Fidan Dogan[14] Tansu Yamazhan[15], [1]Ankara Yildirim Beyazit University Bilkent City Hospital, [2]Mustafa Kemal University Hospital, [3]Arnavutkoy State Hospital, [4]Duzce Ataturk State Hospital, [5]Ankara 29 Mayis State Hospital, [6]Mersin Toros State Hospital, [7]Silivri State Hospital, [8]Nevsehir State Hospital, [9]Kepez State Hospital, [10]Seyhan State Hospital, [11]Sivas Numune Hospital, [12]Menemen State Hospital, [13]Sultanbeyli State Hospital, [14]Ceyhan State Hospital, [15]Ege University Faculty of Medicine

Background: The primary challenge in hepatitis C elimination now lies in identifying and engaging individuals who remain undiagnosed or untreated. In response to a recent policy change in Turkiye allowing hepatitis C treatment prescriptions by secondary care physicians, a national meeting was held to promote region-specific action plans for screening, diagnosis, and treatment, contributing to national hepatitis C elimination goals. This initiative aimed to address that critical gap by empowering frontline healthcare providers and expanding access to care. **Methods:** A total of 45 physicians from 41 hospitals across 23 provinces participated. Each physician was tasked with implementing locally tailored interventions. Post-meeting, 27 physicians from 27 unique centers submitted data on their activities, including community outreach, prison-based screening, addiction center screening, and retrospective hospital records reviews. A standardized form collected data on the number of patients screened, diagnosed, and treated. **Results:** Among the 45 physicians who attended the national hepatitis C elimination meeting, 27 provided data from their local efforts. Across all efforts, 296,404 individuals were screened. The overall anti-HCV positivity rate was 1.4%, with HCV RNA testing performed in 64.3% of anti-HCV positive individuals. Among those tested, 27.8% were HCV RNA positive. In total, 734 patients were found to be HCV RNA positive, and 544 (74.1%) began treatment. Of the HCV RNA positive individuals, 257 (35.0%) were identified through prison screenings and 473 (64.4%) through retrospective hospital data. Similarly, of the patients treated, 256 (47.1%) came from prison screenings and 284 (52.2%) from hospital records screenings, highlighting the challenges of engaging retrospectively identified patients in care. These outcomes are presented in detail in Figure 1, which illustrates the distribution of HCV RNA positive cases and treatment initiation according to screening type. **Conclusion:** This decentralized national initiative has shown early success in identifying and treating hepatitis C cases in both high-risk populations and individuals identified through hospital-based screening efforts. The involvement of secondary care hospitals has played a key role in broadening access to diagnosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and therapy, demonstrating the positive impact of recent policy changes. However, suboptimal HCV RNA testing rates among anti-HCV positive individuals, particularly in retrospective screenings, and challenges in linking diagnosed patients to timely treatment reveal persistent gaps in the care cascade.

1384 | ASSOCIATION BETWEEN HEPATITIS C VIRUS INFECTION AND CARDIOVASCULAR DISEASE: A NATIONWIDE, POPULATION-BASED COHORT STUDY IN SOUTH KOREA

Juneyoung Lim[1] Min Kyung Park[2] Eun Sun Jang[3] seungteak Lee[1], [1]Seoul national university Bundang hospital, [2]Seoul National University Hospital, [3]Seoul National University College of Medicine

Background: Chronic hepatitis C virus (HCV) infection has been increasingly associated with cardiovascular disease, but population-based evidence remains limited. This study aimed to evaluate the independent association between HCV infection and cardiovascular outcomes using a nationwide, population-based cohort in South Korea, with general population-matched controls. **Methods:** Using the National Health Insurance Service (NHIS) database of South Korea, we identified patients newly diagnosed with HCV between 2009 and 2022 who were ≥20 years old. Each HCV patient was matched with six non-HCV individuals from the general population using 1:6 matching based on age and sex. The primary outcome was the incidence of major adverse cardiovascular events (MACE), including ischemic heart disease, stroke, and peripheral arterial disease. Cox proportional hazards models were used to estimate hazard ratios, adjusting for age, sex, medication use, and comorbidities. A competing risk model additionally accounted for death and liver transplantation. **Results:** The final cohort included 30,467 HCV patients and 182,802 age- and sex-matched controls. Baseline characteristics were well balanced (mean age: 48.8 years; male proportion: 53.9% in both groups). Over the follow-up period, MACE occurred in 6,594 HCV patients and 23,258 controls. During the follow-up period, 19,265 patients developed MACE (incidence rate: 10.0 per 1,000 person-years). Before adjustment for covariates, HCV infection was associated with a 25% increased risk of MACE compared to the matched control group (hazard ratio [HR] 1.25, 95% confidence interval [CI]: 1.20–1.30, $P < 0.001$). In the adjusted model—including income, comorbidities, medication use, BMI, alcohol consumption, and smoking—HCV infection was independently associated with increased MACE risk (adjusted HR 1.21, 95% CI: 1.16–1.25, $P < 0.001$). This association remained significant in the competing risk model (adjusted HR 1.18, 95% CI: 1.14–1.23). **Conclusion:** This nationwide, general population-matched cohort study provides strong evidence that HCV infection is an independent risk factor for cardiovascular disease. These findings highlight the need for cardiovascular risk monitoring in HCV patients and further research on potential prevention strategies.

1385 | FROM DISCOVERY TO CURE — WHERE ARE WE NOW? MORTALITY TRENDS IN CHRONIC HEPATITIS C: AN ANALYSIS OF THE CDC WONDER DATABASE (1999–2024)

Ashraf Ullah[1] Mati Ullah Dad Ullah[2] Syed Bilal Shah[3] Naveed Ali[4] Rohullah Rasikh[5] Umar Iqbal Javid Choudhary[6] Hamnah Tayyab[7], [1]Guthrie Robert Packer Hospital, Pennsylvania, [2]University of Oklahoma Health Sciences Center, [3]Beth Israel Deaconess Medical Center, [4]Khyber Teaching Hospital, Pakistan, [5]Landmark Medical Center, Rhode Island, [6]The Good Samaritan Medical Center, [7]Guthrie Robert Packer

Background: Hepatitis C virus (HCV)-related cirrhosis was the leading cause of liver-related mortality, morbidity, and liver transplantation before the introduction of direct-acting antiviral (DAA) therapies. Since their introduction in 2014, DAAs have revolutionized the management of HCV by making it a curable disease. Despite these breakthroughs, hepatitis C remains a significant public health burden in the United States, particularly among historically underserved populations. Understanding mortality trends over time can provide critical insight into the effectiveness of public health interventions and identify persistent healthcare disparities **Methods:** We analyzed mortality data for the U.S from the CDC WONDER database, focusing on cirrhosis as the underlying cause of death and HCV as a contributing cause. Age-adjusted mortality rates (AAMRs) per 100,000 were calculated, and trends were analyzed using Joinpoint regression, focusing on annual percentage changes (APCs) from 1999 to 2023. **Results:** Between 1999 and 2024, there were 175,712 deaths from HCV cirrhosis. AAMRs increased from 2.92 in 1999 to 3.79 in 2013; however, after the introduction of DAA, a significant decline occurred, with AAMRs decreasing from 3.77 in 2014 to 2.3 in 2024, representing an 8.2% annual decrease. Males consistently had higher AAMRs than females. Among males, AAMRs rose by 1.5% annually from 1999 to 2014, but declined by 9.0% annually from 2014 to 2021. For females, AAMRs rose by 1.4% annually until 2013, followed by a decline of 8.8% annually from 2014 to 2019. Racial disparities persisted: non-Hispanic American Indian/Alaska Native populations had the highest mortality rate in 2022 (5.12 per 100,000), followed by Hispanics (2.45), non-Hispanic Black (2.40), non-Hispanic White (1.74), and non-Hispanic Asian populations (0.82). After 2013, mortality rates began to decline across all racial groups, with the steepest decline seen in non-Hispanic Black populations (APC: -11.0%). Geographically, metropolitan areas saw the most significant reductions in mortality rates, especially large metro areas (APC: -10.2%). Mortality rates for HCV were found to be highest for the male gender, age group 55-74 years, American Indians or Alaskan Natives, the West US Census Region, and Medium to small metropolitan areas. Geographically, states in the top 90th percentile for HCV-associated mortality included the District of Columbia, Oklahoma, Oregon, California, New Mexico, and Washington. **Conclusion:** The introduction of DAA therapies has led to a significant decline in mortality from HCV-related cirrhosis. However, racial minorities, particularly non-Hispanic American Indian/Alaska Native and Black populations, continue to experience disproportionately high mortality rates. Addressing healthcare access disparities remains crucial.

1386 | RE-LINKING HEPATITIS C PATIENTS TO CARE: A QUALITY ASSURANCE INITIATIVE FROM THE CALGARY LIVER UNIT

Ofodile Joe-Uzuegbu[1] Mayur Brahmania[1] Stephen Congly[1] Yashasavi Sachar[2] Morgan Koczkur[1] Carla Coffin[1] Mark Swain[3] Henry Nguyen[3] Abdel-Aziz Shaheen[1], [1]University of Calgary Cumming School of Medicine, Calgary, AB, [2]Western University, [3]University of Calgary

Background: Despite the availability of curative treatment for the hepatitis C virus (HCV), gaps in post-treatment follow-up limit progress toward elimination. At the Calgary Liver Unit (CLU)—a tertiary referral center serving over 1.5 million people in Alberta, Canada—patients with chronic HCV receive multidisciplinary care and treatment plans that include confirmatory sustained virologic response (SVR) testing. This quality assurance (QA) project aims to systematically identify and relink these patients to confirm SVR and reduce long-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

term liver disease risk. **Methods:** A retrospective chart review was conducted for patients seen at the CLU between 2015 and 2024 who tested HCV antibody-positive. Using Alberta's integrated clinical information systems, patients were categorized by treatment status. Individuals who had no record of SVR testing or never initiated treatment, and were not known to be deceased or ineligible, were flagged for follow-up. Patients were contacted via telephone, email, or letter to offer re-engagement in care and confirmatory RNA testing. Responses were recorded using a secure platform. Summary statistics were compiled for QA monitoring. **Results:** Among 2,923 HCV Ab-positive patients, 329 were deceased and 104 were ineligible, leaving 2,490 eligible for follow-up. Of these, 2,099 (95.8%) had documented SVR and outreach was attempted in 91 (4.2%) without known SVR. In total, 29 (31.8%) were successfully contacted, 17 (58.6%) agreed to re-engage in care through scheduled clinical consultations or HCV RNA testing to confirm SVR. Of the 17 re-engaged, 10 were male, and the mean age was 56.6 years. The mean ALT and bilirubin were 43.4 U/L (IQR 18-46) and 10.9 µmol/L (IQR 6-10), respectively. In contrast, the 12 contacted patients who declined re-engagement had a higher mean age of 62.4 years, with a mean ALT of 78.2 U/L (IQR 30-97.5) and bilirubin of 11.4 µmol/L (IQR 5.8-15.3). Reported reasons for not achieving SVR among the 29 contacted included being unaware of diagnosis (n = 2), personal choice to defer care (n = 5), incarceration (n = 1), health-care access barriers (n = 2), and incomplete treatment (n = 3), while several patients declined to provide a reason. **Conclusion:** This QA initiative demonstrates a structured relinkage strategy's feasibility and early impact for HCV patients lost to follow-up. Successful re-linkage was feasible in > 50% of those contacted, with older age and higher ALT noted in those who declined follow-up. Future interventions will extend this approach to community-based primary care settings, advancing scalable models for HCV elimination across Alberta by 2030.

1387 | PREVALENCE OF ANTI-HCV ANTIBODIES IN AT-RISK PATIENTS IN HOSPITAL SETTINGS IN COLOMBIA: A MULTICENTER STUDY

Javier Hernandez-Blanco[1] Juan Ignacio Marin Zuluaga[2] Ismael Yepes[3] Diana Chávez Bejarano[4] Alfredo Spath[5] Yanette Suarez[6] Monica Tapias[7] Patricia Reyes Pabón[8] DianaD Escobar[9] Oscar Beltran[10], [1]Colombian Hepatology Association, University of Magdalena., [2]Colombian Hepatology Association, University of Antioquia, [3]Colombian Hepatology Association, University of Cartagena, [4]Clinical Epidemiology Program, University Foundation of Health Sciences – FUCS., [5]Gilead Medical Department, [6]Colombian Hepatology Association, San Ignacio University Hospital, [7]Colombian Hepatology Association, Santafé de Bogotá Foundation, [8]Colombia Clinic, [9]Colombian Hepatology Association, Valle de Lili Foundation, [10]Colombian Hepatology Association, Universidad del Rosario

Background: Hepatitis C virus (HCV) remains a global health burden, with millions chronically infected and at risk of cirrhosis, hepatocellular carcinoma, and death. Despite the availability of curative direct-acting antivirals (DAAs), diagnosis and treatment coverage remain low, particularly in low- and middle-income countries. In Colombia, less than 1% of estimated HCV cases receive treatment. Micro- elimination strategies, including opportunistic screening in hospital settings, may help close diagnostic gaps, especially among at-risk populations. This study aimed to estimate the prevalence of HCV infection through targeted rapid antibody testing in Colombian hospitals and to evaluate the feasibility of linkage to care for positive cases. Keywords: Hepatitis C, Opportunistic Screening, Prevalence, Risk Factors, Hospitals. **Methods:** We conducted a multicenter, cross-sectional study in six hospitals across Colombia, targeting adults (≥ 18 years) attending inpatient, emergency, outpatient, and laboratory services. Participants with risk factors for HCV were screened using the Bioline™ anti-HCV rapid test at the point of care, after

informed consent. Reactive cases were referred to as specialist evaluation and HCV RNA confirmation (PCR). The study included pre- and post-test counseling and structured pathways to support treatment linkage. Data was collected using an electronic case report form (CRF) and analyzed with R software using descriptive statistics and chi-square tests. Data were collected from December 2023 to April 2025. **Results:** Among 18,480 screened individuals, 18 tested positives for anti-HCV antibodies, yielding a prevalence of 0.097% (95% CI: 0.058%–0.154%). The median age was 51 years (IQR: 37.7–63.3), and 68.9% were female. Most were covered by the contributory health regime (56%), and outpatient care was the most frequent recruitment setting (31.1%). The highest positivity rate occurred in the Magdalena region (66.7%). Significant associations were found with intravenous (16.7%, $p = 0.0022$) and intranasal drug use (16.7%, $p = 0.0429$). Orthopedic (38.9%) and gynecological surgeries (22.2%) showed higher positivity but lacked statistical significance. No significant links were found with comorbidities. **Conclusion:** Opportunistic hospital-based screening for HCV in Colombia is feasible and can identify undiagnosed cases, particularly among people with drug use history. Despite low overall prevalence, significant associations with behavioral risk factors underscore the need to maintain focused screening approaches. This strategy also proved effective in initiating linkage to care, supporting national efforts toward HCV micro-elimination. Expansion of similar models may accelerate progress toward WHO's 2030 elimination goals in low-prevalence settings.

1388 | PROLINK-C: LEVERAGING LABORATORY INFORMATION SYSTEMS TO RECAPTURE HCV PATIENTS LOST TO FOLLOW-UP &MDASH; A MULTICENTER STUDY FROM SOUTHERN SPAIN

Federico Garcia[1] Alberto Vázquez Blanquiño[1] Ana Fuentes[1] Clara de Asís Morales Domínguez[2] Ana Belén Pérez[2] Francisco Franco Álvarez de Luna[3] Lucía Chaves Blanco[1] Lucía Pérez Rodríguez[1] Marta Illescas[1] Jaime Borrego-Jiménez[4] Teresa Cabezas[5] ISABEL VICIANA[6] José Manuel Azcona[7] Antonio Sampedro[8] Jesús Machuca[9] Inmaculada López[10] Carmen Lozano[11] Natalia Montiel Quezel-Guerraz[12] Carolina Freyre[13] Francisco Javier Casas-Ciria[14] Cesar del Prado[15], [1]Hospital Universitario Clínico San Cecilio, [2]Hospital Universitario Reina Sofía, [3]Hospital Universitario Juan Ramón Jiménez, [4]Hospital Universitario de Poniente, [5]Hospital Universitario Torrecárdenas, [6]Hospital Universitario Virgen de la Victoria, [7]Hospital Universitario Santa Ana, [8]Hospital Universitario Virgen de las Nieves, [9]Hospital Universitario Infanta Elena, [10]Hospital Universitario Costa del Sol, [11]Hospital Universitario Virgen del Rocío, [12]Hospital Universitario Puerta del Mar, [13]Hospital Universitario de Puerto Real, [14]Hospital Universitario de La Línea, [15]Hospital Universitario Punta de Europa

Background: Hepatitis C remains a major global health concern, and the World Health Organization has prioritized its elimination. In Spain, locating individuals lost to follow-up (LTFU) after a positive HCV antibody result is essential for elimination strategies. However, conventional retrieval methods have shown limited success. We present the results of an innovative "opportunistic" retrieval strategy integrated into routine healthcare workflows. **Methods:** This multicenter pilot study was conducted across several hospitals in southern Spain. It evaluated the performance of an automated "opportunistic" retrieval strategy embedded in each hospital's Laboratory Information System (LIS). A daily process generated lists of patients with previous positive anti-HCV antibody results and a currently available serum sample collected for any clinical purpose. Medical records were systematically reviewed to confirm evidence of sustained virologic response (SVR) or prior antiviral therapy. In cases without documented SVR, HCV RNA testing was performed using the available serum sample, avoiding the need for new sample collection or direct patient contact. Follow-up and linkage to care outcomes were subsequently monitored through electronic health record (EHR) review. **Results:** From May 22, 2023, to April 31, 2025, 3,222 anti-HCV-positive patients were identified. Of these, 2,859 (88.7%) had documented SVR and no reinfection risk. Among the remaining 363, HCV RNA testing was feasible in 359, identifying 124 active infections (34.5%), representing 3.8% of the total screened cohort. The majority of viremic individuals were male (71%) with a median age of 59 years (IQR 54–65). Among viremic cases, 62% had previously disengaged from care prior to achieving SVR, and 38% lacked any confirmatory RNA testing. Referrals originated from Primary Care (65%), Hospital Services (19%), and Emergency Departments (16%). All viremic cases were flagged to referring clinicians. Of the 124 patients, 66% (82) attended follow-up appointments; among them, 62% (51/82) initiated antiviral therapy, 14 declined treatment, and 17 missed their appointments. **Conclusion:** This study supports the feasibility and

clinical utility of a LIS-based "opportunistic" strategy to recapture HCV patients lost to follow-up. By leveraging existing laboratory data and clinical encounters, this model facilitates reintegration into the HCV care cascade without requiring proactive patient outreach, thereby strengthening real-world elimination efforts.

1389 | HEPATITIS C VIRUS TESTING AND FOLLOW-UP FOR PERINATALLY EXPOSED INFANTS IN NORTH CAROLINA: FINDINGS FROM THE UNIVERSITY OF NORTH CAROLINA RELINK PROGRAM

Cory Spencer[1] Lauryn Ursery[2] Carl Seashore[3] Peyton Thompson[3], [1]University of North Carolina School of Medicine, [2]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [3]University of North Carolina, Chapel Hill, USA

Background: Hepatitis C Virus (HCV) infections are increasing among reproductive-aged persons in the United States. It is estimated that 6-7% of perinatally exposed infants acquire an HCV infection, yet, as many as 70% of perinatally exposed infants are not tested or linked to appropriate care. As a part of the University of North Carolina (UNC) Relink Program, we identified, followed, and linked to care infants perinatally exposed to HCV in North Carolina. **Methods:** We searched UNC Health records (15 hospitals, 15.6% of statewide births) for infants perinatally exposed to HCV from the period May 2023-June 2024. After confirming exposure status, we reviewed infant medical records to collect demographic information and assess whether exposure status and appropriate testing recommendations were documented in hospital discharge summaries. HCV-exposed infants were then followed over time to monitor testing completion, and the families of infants untested at an age >6 months old were contacted via phone or MyChart for linkage to testing and care. Data were collected in REDCap, and summary statistics were computed in R. **Results:** We identified 79 HCV-exposed infants across North Carolina from May 2023-June 2024, 75 of whom had full medical records available. Most exposed infants were born in central North Carolina (54.7%; n = 41), 86.7% (n = 65) were born to Medicaid-insured persons, and 52% (n = 39) were born to persons with a diagnosed opioid use disorder. HCV exposure was documented in the infant's hospital discharge summary and added to the infant's problem list in 93.3% (n = 70) and 64% (n = 48) of cases, respectively. Recommendations for HCV testing were made in the infant's discharge summary in 64% (n = 48) of cases. Midway through the study period (in November 2023), the CDC published updated guidance recommending that all perinatally exposed infants be tested for HCV RNA at 2-6 months old. Among the 51 exposed births occurring after this date, recommendations for follow-up testing were made in 66.7% (n = 34) of infant discharge summaries, and 91.2% (n = 31) of these recommendations referenced the updated testing guidelines. Less than half (41.3%; n = 31) of all exposed infants completed HCV RNA testing without intervention from the program's relinkage activities. Twenty-one of these infants had a known testing date, and the majority (80.9%, n = 17) of tests were completed within the recommended timeframe of 2-6 months. Two infants (6.4% of those tested) were HCV-infected. Relink contact efforts have resulted in 11 additional infants being linked to care, of whom none have tested positive for HCV to date. **Conclusion:** Infants perinatally exposed to HCV are lost to follow-up at high rates in North Carolina. While exposure status is typically well-documented in infant discharge summaries, follow-up testing guidelines are less consistently noted and carried out. Findings suggest the need for further interventions to ensure appropriate testing and care.

Background: HCV undiagnosed infection is particularly critical among populations of special interests, including patients hospitalized for mental disorders. They are more likely to engage in hazardous behaviours that are risk factors for communicable diseases. These factors include a high prevalence of intravenous drug use, homelessness, incarceration, and limited access to routine medical care. Additionally, the psychiatric symptoms themselves, such as reduced awareness, impaired judgment and possible less care for somatic health, may contribute to high-risk behaviours that facilitate HCV transmission. The epidemiology of HCV among patients with mental disorders seems to by insufficiently characterized, partly due to the lack of routine HCV screening in psychiatric settings. **Methods:** The Polish HCV initiative was a comprehensive cross-sectional research study conducted in Poland from 2021 to 2023, focusing on individuals hospitalized for mental health in 24 facilities. It is estimated that the study population covered over 7% of patients hospitalized due to the mental diseases. The main objective was to conduct HCV screening and collect data on prevalence and risk factors associated with HCV infection. Diagnosis of HCV infection was confirmed through positive HCV antibody screening and subsequent nucleic acid testing (NAT). Participants were interviewed by healthcare professionals, who administered a detailed questionnaire to collect the necessary data. All patients diagnosed with HCV infection were offered on-site treatment or were referred to the outpatient clinic. **Results:** The multivariate analysis identified intravenous drug use as the primary factor contributing to a positive HCV RNA test, with an odds ratio of 9.36 (95% CI: 6.09–14.39; $p < 0.001$). The presence of diagnosed and treated liver disease was also identified as a significant risk factor, with an odds ratio of 6.25 (95% CI: 4.16–9.38; $p < 0.001$).The odds ratio for blood transfusions prior to 1992 was 2.62 (95% CI: 1.30–5.29; $p = 0.007$). A recorded diagnosis of mental and behavioural disorders due to psychoactive substance abuse (ICD-10 F10-F19) had an OR of 1.802 (95% CI: 1.23–2.63; $p = 0.002$). This finding indicates that the most frequently reported group in the analysed population is also the group with the substantially increased high-risk of HCV. Those who had ever been in prison exhibited a diminished yet still markedly elevated risk of HCV infection, with an OR of 1.61 (95% CI: 1.08–2.41, $p = 0.020$). This finding reflects the heightened risk of HCV infection associated with incarceration. **Conclusion:** The prevalence of anti-HCV and HCV RNA in 1.8% and 1.3% of psychiatric patients respectively is about three times higher than in the general population in Poland. Systematic, integrated, and destigmatized approaches can facilitate better health outcomes for this vulnerable group, aligning with the goal of HCV elimination by 2030.

Background: HCV-related cirrhosis is a major cause of hepatocellular carcinoma (HCC), and liver-related mortality. The advent of DAAs has dramatically improved treatment outcomes, with high SVR rates. However, despite viral eradication, the post-treatment prognosis remains heterogeneous. Reliable biomarkers are urgently needed to identify patients at high risk for adverse liver-related outcomes. We previously demonstrated that serum GDF15 levels are associated with the development of HCC and decompensated events in patients with metabolic dysfunction-associated steatotic liver disease. In the present study, we aimed to evaluate whether serum GDF15 levels could serve as a prognostic biomarker for liver-related events in patients with HCV-related cirrhosis after viral clearance. **Methods:** Patients with HCV-related cirrhosis were treated with DAAs at 38 institutions in Japan between February 2019 and December 2021. Data were prospectively collected and retrospectively analyzed. The study was conducted in accordance with the Declaration of Helsinki and approved by the institutional review boards of participating centers (IRB No. 18431). Liver-related events—defined as the occurrence of HCC, hepatic decompensation, or liver-related death—were used as endpoints. Sera from registered patients were stored at –80°C at each institution, and GDF15 concentrations were measured using an enzyme-linked immunosorbent assay (ELISA) specific for human GDF15. **Results:** A total of 478 patients achieved SVR following DAA therapy. Among them, serum samples from 256 patients were available for GDF15 measurement. Of these, 162 patients without a prior history of HCC (HCC-naïve) were included in the final analysis. Median observation periods were 36.1 months (IQR: 16.6-52.7) and liver-related events were occurred in 36 patients. Patients who developed liver-related events during follow-up had significantly higher GDF15 levels at the time of end of treatment (EOT) (3.68 vs. 2.54 ng/mL) compared to those without events. In multivariable Cox proportional hazards analysis, the GDF15 level at EOT was identified as an independent risk factor for event occurrence from age and serum AFP level at baseline (hazard ratio: 1.15, $p < 0.05$). Applying a previously established cutoff of 1.75 ng/mL at EOT, patients with higher GDF15 levels had significantly lower event-free survival. While the cumulative event rate at two years was 17.9 % in the high-GDF15 group, no events occurred in the low-GDF15 group during the first two years of follow-up. **Conclusion:** Serum GDF15 levels are associated with liver-related events in patients with HCV-related cirrhosis who achieve SVR. GDF15 may serve as a valuable prognostic biomarker for identifying high-risk individuals in this population, thereby facilitating improved post-treatment surveillance and management strategies.

[1]National Institute of Health, [2]NIH/NIDDK, [3]National Institute of Diabetes, Digestive, [4]National Institutes of Health, [5]National Cancer Institute, Bethesda

Background: Almost all persons with chronic hepatitis C (CHC) can be cured with direct acting antiviral (DAA) agents. Previous studies have demonstrated regression of hepatic fibrosis following sustained virologic response (SVR) using interferon-based regimens. However, data on histological outcomes with DAA therapy are limited. **Methods:** Adult persons cured of CHC with a DAA regimen with a pre-treatment liver biopsy were prospectively enrolled in a longitudinal follow-up study for 480 weeks. Participants are followed every 24 weeks, undergo annual HCC screening if non-cirrhotic at baseline or every 24 weeks if cirrhotic, annual transient elastography and a follow-up biopsy at week 240 (Wk240). Biopsies were reviewed by one hepatopathologist using the modified histology activity index (HAI) for inflammation, the Ishak fibrosis score for fibrosis, and a 0–4 steatosis scale based on the percentage of hepatocytes with fat. Histological improvement was defined as a ≥ 2 point decrease in HAI score with no worsening of fibrosis. Paired t-test was used to compare histologic scores and liver stiffness measurements (LSM) between baseline and Wk240. **Results:** A total of 121 subjects were enrolled of whom 46 reached Wk240. This is an interim analysis of 41/46 subjects who completed the Wk240 follow-up biopsy (5 subjects declined liver biopsy). Liver tissue was insufficient for scoring in 3 subjects. Mean age at baseline was 59 ± 9 years, 26 were male, 27 White, 2 Asian, 9 Black, 3 other. HCV genotype 1 accounted for 75% of infections, and 75% received sofosbuvir/velpatasvir. Mean baseline ALT was 95 ± 52 U/L, and mean LSM was 12.5 ± 7.5 kPa. Median duration between biopsies was 8.5 years. Pre-therapy mean total HAI and Ishak fibrosis scores were 8 ± 2 and 3 ± 2, respectively and at Wk240 2 ± 1 and 2 ± 2. SVR was durable, with undetectable HCV RNA confirmed a median of 23 times in follow-up. At Wk240, 32 (84%) showed histologic improvement (of whom 13 (34%) had HAI ≤ 3 and Ishak 0), 1 (3%) remained stable, and 5 (13%) worsened (in all cases inflammation improved by ≥ 3 points but fibrosis increased by 1 stage likely representing sampling error). LSM correlated weakly with fibrosis stage on liver biopsy at both baseline ($r^2 = 0.32$, $p < 0.001$) and post-treatment ($r^2 = 0.22$, $p = 0.003$). **Conclusion:** A majority of patients with CHC showed histologic improvement with substantial (mean 6-point) reduction in inflammation and 37% with complete resolution of fibrosis over 8.5 years after achieving SVR with DAA therapy.

1393 | EFFECTIVE RE-ENGAGEMENT OF HEPATITIS C PATIENTS: A MULTICENTER STUDY BASED ON LABORATORY RECORDS IN ARGENTINA

Fernando Cairo[1] MANUEL BARBERO[1] IGNACIO ROCA[2] LUCIA NAVARRO[1] Nicolas Dominguez[1] OMAR GALDAME[1] AYELEN TRILLO[3] Esteban Gonzalez Ballerga[4] DANIEL CALFUNAO[5] RODRIGO BELLONI[3] ADRIAN BOLOGNA[3] ANDREA CURIA[4] MELINA SUSANA[4] SILVIA BORZI[6] STEFANIA BURGOS[6], [1]HOSPITAL EL CRUCE, [2]HOSPITAL L CRUCE, [3]HOSPITAL SAN MARTIN, [4]HOSPITAL DE CLINICAS, [5]HOSPITAL CASTRO RENDON, [6]HOSPITAL ROSSI

Background: Hepatitis C virus (HCV) remains a significant cause of global morbidity despite the availability of highly effective direct-acting antivirals (DAAs). In Argentina, fragmented healthcare access and a high prevalence of advanced liver disease

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

underscore the need for re-engagement strategies to achieve HCV elimination. This study aimed to assess the effectiveness of a multicenter re-engagement program for HCV patients lost to follow-up in high-complexity healthcare settings. **Methods:** A multicenter prospective study (March–November 2024) analyzed blood samples from five hospitals to identify HCV antibody-positive patients. Positive cases were contacted to confirm viremia, undergo clinical evaluation, and initiate treatment. Data collected included re-engagement rates, fibrosis staging (FibroScan), genotype distribution, treatment regimens, and sustained virologic response (SVR) rates. Statistical analyses were performed using chi-square tests to compare positivity rates, genotypes, and treatments. **Results:** Among 206,053 samples, 3,334 (1.62%) tested positive for HCV antibodies, and 2,149 (64.5%) were potentially eligible for re-engagement. Non-re-engagement causes included deaths (419), previous cure (741), and liver transplants (25). Positive cases were 54.16% male ($p = 0.03$). A total of 422 patients (19.6%) were successfully re-engaged, of whom 311 (73.8%) exhibited advanced fibrosis ($\geq$F2). Genotype distribution was as follows: 1a (22.00%), 1b (18.99%), 2 (8.24%), 3 (18.72%), 4 (8.13%), and data not obtained (24.92%). No significant difference was found between genotype 3 and others ($p = 0.3$). Among re-engaged patients, 167 initiated treatment with Sofosbuvir/Velpatasvir (70.08%) or Glecaprevir/Pibrentasvir (29.92%) ($p = 0.12$). The overall SVR12 rate was 97.98% among treated patients. SVR4 was assessed in 112 patients, showing a 100% correlation with SVR12. Among re-engaged patients, 15% were unaware of their positive result, 10% were unaware of the existence of effective treatments, and 64% were unaware of disease progression. **Conclusion:** This program successfully re-engaged HCV patients lost to follow-up, achieving high SVR12 rates and demonstrating the utility of SVR4 as an early predictor of treatment success. A significant proportion of patients were unaware of their diagnosis, available treatments, or disease progression. The majority of treated patients had advanced fibrosis, highlighting the need for proactive strategies targeting high-risk populations. These findings underscore the necessity of establishing elimination programs in countries with complex healthcare systems like Argentina.

1394 | LONG-TERM BENEFITS FOLLOWING HEPATITIS C VIRUS TREATMENT THROUGH FACILITATED TELEMEDICINE; EXPERIENCES OF PEOPLE WHO USE DRUGS FIVE YEARS AFTER ACHIEVING A SUSTAINED VIROLOGICAL RESPONSE

Zoi Papalamprakopoulou[1] Tin Dang[2] Christopher Gonzalez[2] Colin Tedesco[3] Paul Updike[3] Christina Corl[3] Arpan Dharia[1] Noelia Hernandez[2] Martin Shapiro[2] Elaine Wethington[4] Andrew Talal[1], *[1]University at Buffalo, [2]Weill Cornell Medicine, [3]Catholic Health, [4]Cornell University*

Background: Facilitated telemedicine hepatitis C virus (HCV) treatment integrated into opioid treatment programs (OTPs) has shown high effectiveness and patient satisfaction among people with opioid use disorder (OUD). However, the long-term impact of a sustained virological response (SVR) obtained through facilitated telemedicine remains unexplored. We examined people with OUD perspectives on an SVR obtained through facilitated telemedicine. **Methods:** We conducted two focus group discussions (FGDs) with nine participants at least five years after achieving an SVR through facilitated telemedicine in OTPs (New York State, 2018–2020). Eligibility criteria included individuals aged at least 18 years who had previously achieved SVR through this model, remained actively enrolled in an OTP, and were able to provide informed consent. We identified a list of potential FGD participants from those who had participated in a randomized clinical trial of facilitated telemedicine. We used a semi-structured interview guide and thematically analyzed transcripts. **Results:** Participants had a mean age of 52.6 years (standard deviation = 13.7), 66.6% (6/9) were male, and 88.8% (8/9) identified as White. We identified three FGD themes each corresponding to pre-, during, or post-intervention (see Figure): (1) attitudes toward HCV and barriers to treatment among people with OUD, (2) embracing telemedicine HCV care integrated into OTPs, and (3) experiencing long-term benefits from facilitated telemedicine across all aspects of HCV care and overall well-being. Participants described feeling shame and fearful disclosing their HCV status prior to seeking care. Barriers to care included competing priorities, perceiving HCV as low-priority medical comorbidity, and third-party payer coverage restrictions (Theme 1). Participants valued telemedicine for its convenience and ability to overcome transportation barriers. Many preferred the empathetic telemedicine

clinicians and appreciated the one-stop shop approach (Theme 2). At least five years post intervention, participants reported lasting benefits of achieving an SVR, including enhanced HCV knowledge, improved sobriety, and improvement in whole health (Theme 3). **Conclusion:** At least five years post achieving an SVR, people with OUD reported improved sobriety, overall well-being, and sustained satisfaction with telemedicine-based HCV care. These findings highlight the sustained impact of both an SVR and the care delivery model.

1395 | PROVIDER EDUCATION AND TRENDS IN ANTEPARTUM HEPATITIS C VIRUS SCREENING FROM 2021 – 2025 AT AN ACADEMIC MEDICAL CENTER IN CHICAGO

Michelle Martin[1] Evan Brownsberger[1] Christin Jogan[1] Nina Mai[1] Amal Al-Bayati[1] Katie Kaczmarski[1],
[1]University of Illinois Chicago Retzky College of Pharmacy

Background: Perinatal hepatitis C virus (HCV) transmission presents a public health concern that threatens HCV elimination efforts. The American College of Obstetricians and Gynecologists (ACOG) updated its clinical practice guidelines for antepartum HCV screening in 2021 and 2023; they recommend universal screening for each pregnancy. Our study aims to evaluate antepartum HCV screening trends at an academic medical center in Chicago from 2021 – 2025 after the provision of maternal health provider education in 2024 – 2025. **Methods:** We conducted a retrospective cohort study of antepartum HCV screening rates at our institution from 2021 – 2025. Patients were included if they were 18 years or older with a pregnancy end date in March or April of each year. Data collected from the electronic health record included infectious diseases screening, age, race/ethnicity, insurance, and gravida. We compared the HCV screening rate difference between subsequent years using a z-test to analyze difference in proportions. We used logistic regression to assess relationships among patient characteristics and HCV screening in 2025. Pharmacists delivered antepartum HCV screening education to clinicians with in-person slide presentations at two maternal health department meetings and via an emailed link to the slides in 2024 – 2025. **Results:** From 2021 – 2025, most antepartum patients were 20 – 29 years old, Black, non-Hispanic, and had Medicaid as their payor. The antepartum HCV screening rate was 38.8% prior to the 2021 ACOG HCV screening practice advisory, and 71.0% in 2025 post-provider education. HCV screening rates increased from 38.8% to 49.5% between 2021-2022 ($p = 0.015$), from 49.5% to 49.6% between 2022-2023 ($p = 0.975$), from 49.6% to 55.5% between 2023-2024 ($p = 0.068$), and from 55.5% to 71% between 2024-2025 ($p = 0.008$). See Table 1 for additional 2025 patient characteristics. In 2025, patients who had HBV surface antigen screening had higher odds of HCV screening than those without HBV screening [OR = 55.02 (95% CI 26.03–112.81); $p < 0.001$], and patients with commercial insurance were more likely to be screened for HCV than those with Medicaid coverage [OR = 3.40 (95% CI 1.07–5.40); $p = 0.034$] (Table 2). Thirty-nine physicians of the 71 total maternal health providers attended one of two live education sessions on antepartum HCV screening. As of 5/29/2025, 28 of the 71 clinicians had opened the link to the education slides. **Conclusion:** The highest numeric and percent increases in antepartum HCV screening occurred from 2024 to 2025, in the same year that pharmacists offered HCV screening education to the maternal health clinicians. The second highest increase in HCV screening was from 2021 to 2022, after the 2021 ACOG HCV advisory. Despite improvements from 2021 – 2025, a gap remains between our institution's antepartum HCV screening rate and the guideline-advised universal screening; this necessitates further quality improvement research and education.

1396 | TRACING CHILDREN WITH SILENT HEPATITIS C IN THE UK

Clare Rayner[1] Rachel Cockayne[2] Carla Lloyd[3] Stephen Corcoran[3] Monica Mitcham[3] William Irving[1] Ruth Simmons[4] Annabel Powell[4] Deirdre Kelly[3],
[1]Birmingham Chidlren's Hospital, [2]Birmingham Women's and Children's, [3]Birmingham Children's Hospital, [4]UKHSA (United Kingdom Health Security Agency)

Background: Hepatitis C (HCV) infection is asymptomatic in children & young people (CYP) but carries long term risks of chornic liver disease, and therefore, these CYP need to be identified. Direct-acting antiviral (DAAs) drugs (licensed 2020 for CYP) provide effective cure making the World Health Organisation's (WHO) 2030 elimination target achievable. In the United Kingdom (UK), an HCV+ve test is legally 'notifiable' with cases reported to a government agency (UKHSA). Since 2022 the national paediatric Multi-Disciplinary Team Operational Delivery Network (pMDT ODN) has worked with UKHSA to Track & Trace CYP with HCV to ensure they are appropriately treated & managed. **Methods:** 1086 CYP (<18 yrs) HCV+ve between 2004 to 2019 were identified by UKHSA. Initially 481/1086 were shared with ODN in March 2022. Outcomes were determined via written & telephone communications with primary care providers (PCP); laboratory cross-checks; working with hospital specialists; & re-testing. **Results:** Of 481/1086 cases, 50 were adults leaving 431 CYP to trace. Current HCV status was ascertained in 418 (97%). Seventy-six (17.9%) had been RNA+ve & treated. In 13 cases the outcome is unknown (left UK, adopted or refused tests) (See Flow Chart-image 1). Challenges in case-finding were tracking patients, obtaining test results, & refusals to re-test. In view of the long-term health consequences of HCV, & available treatment it is essential to overcome these challenges. Obtaining re-test results was achieved by repeated cross-checking with laboratory systems, PCP & treating specialists, proving time intensive. For CYP requiring new tests, PCP & family education was provided by a specialist nurse who engaged with families to reduce stigma & support testing. A 'GP Champion' identified those who had changed GP, emigrated or been adopted. Adopted CYP in UK receive a new identity that cannot be shared at present. **Conclusion:** Tracing and treating children with HCV is essential but complex. We have successfully traced & treated 97% of CYP with a reported HCV+ve test despite significant barriers. Recommendations include dedicated track & trace staff (coordinator, GP Champion, specialist nurse), systems for transfer of neonatal HCV test records to PCPs, education for PCPs on the importance of retesting & robust laboratory systems which ensure that positive neonatal tests are followed-up until negative. Discussions are ongoing with adoption agencies to act as intermediaries to trace those CYP who have been adopted with a new identity. Our cohort provides valuable lessons for systems change to assist WHO's 2030 elimination plan.

1397 | NAKED-EYE DETECTION OF UNAMPLIFIED HCV RNA IN CLINICAL SPECIMENS USING A DUAL-PROBE MAGNETIC NANOPARTICLE SYSTEM WITH ENZYME-MEDIATED SIGNAL AMPLIFICATION

Wei Hou[1], [1]Translational Medicine Research Center, School of Clinical Medicine, Qilu Medical University, CHINA

Background: Hepatitis C virus (HCV) infection continues to pose a significant global health challenge, with chronic cases potentially advancing to cirrhosis and hepatocellular carcinoma. Although nucleic acid amplification tests (NAATs) are regarded as the gold standard for HCV RNA detection in the current era of direct-acting antiviral (DAA) therapies, their dependence on sophisticated instrumentation and high operational costs limits accessibility, particularly in resource-limited regions. In response to this need, we present an innovative nanoparticle-based biosensing platform that enables visual detection of unamplified HCV RNA through a combination of magnetic separation and enzyme-amplified colorimetric readout. **Methods:** Our developed biosensor integrates several key innovations, utilizing a dual-probe magnetic nanoparticle system that employs genotype-independent oligonucleotides targeting both the 5'UTR and NS3 regions of the HCV genome. This ensures specific viral RNA capture from serum samples. The methodology consists of three critical components: (1) A dual-probe magnetic nanoparticle system that captures HCV RNA with high specificity; (2) An alkaline phosphatase (ALP)-activated click chemistry cascade that generates colorimetric signals through copper-mediated aggregation of gold nanoparticles (AuNPs); (3) Target-dependent AuNP aggregation produces a visible color transition (from red to blue) that correlates with viral load, allowing for naked-eye detection. **Results:** Validation with 120 clinical specimens demonstrated an impressive 99.2% concordance with RT-qPCR results, alongside 100% specificity and complete genotype inclusivity. This establishes our platform as a viable alternative for point-of-care HCV screening. **Conclusion:** The cost-effective design and stability at ambient temperatures make this biosensor particularly suitable for use in low-resource settings. Furthermore, the modular architecture allows for rapid adaptation to detect other bloodborne pathogens (e.g., Dengue, Zika) through simple modifications of probe sequences, positioning this technology as a versatile diagnostic platform for global infectious disease surveillance.

1398 | BEMNIFOSBUVIR AND RUZASVIR PROVIDED AS A FIXED-DOSE-COMBINATION DEMONSTRATES HIGH RELATIVE BIOAVAILABILITY TO THEIR INDIVIDUAL FORMULATIONS AND CAN BE DOSED WITH NO REGARD TO FOOD

Xiao-Jian Zhou[1] Brett Smith[2] Maureen Montrond[3] Keith Pietropaolo[3] Bruce Belanger[3] Shannan Lynch[3] Dayle James[3] Maria Arantxa Horga[3] Janet Hammond[3], [1]Atea Pharmaceuticals, Inc, [2]Altasciences, [3]Atea Pharmaceuticals, Inc.

Background: Bemnifosbuvir (BEM) and ruzasvir (RZR) are potent pan-genotypic inhibitors of the HCV NS5B polymerase and NS5A protein, respectively. BEM/RZR is in phase 3 development for the treatment of chronic HCV using a fixed-dose-combination (FDC) of the two investigational drugs, each containing 275 mg BEM and 90 mg RZR. We report results from a phase 1 study evaluating the relative bioavailability (rBA) of the FDC to the individual formulations of BEM and RZR in healthy participants. The study also determined the effect of a high-fat/high-calories (HFHC) meal or famotidine on the pharmacokinetics (PK) of BEM/RZR FDC (NCT06204679). **Methods:** This adaptive study evaluated the rBA of FDC prototypes to BEM/RZR formulations and the effect of food or famotidine. The study initially enrolled 24 participants who received a single dose of 550 mg BEM (2x275 mg tablets) and 180 mg RZR (2x90 mg capsules) on an empty stomach as reference. The study continued with 24 participants who received a single dose of 550 mg BEM /180 mg RZR as 2xFDC tablets on an empty stomach and after a HFHC meal according to a randomized design. Participants further received two doses of 20 mg famotidine approximately 12h apart, with 2xFDC tablets dosed on an empty stomach together or 2h after the second dose of famotidine. Intensive PK sampling was performed over 144h and plasma concentrations of BEM and metabolites and RZR were quantitated using validated bioanalytical methodologies. **Results:** Treatment-emergent adverse events were infrequent and generally mild. Based on total plasma exposure (AUCinf), the FDC showed high rBA of 86.8, 89.0 and 113% respectively for BEM, its nucleoside metabolite AT-273 (plasma surrogate for the active intracellular triphosphate metabolite AT-9010) and RZR, respectively. An HFHC

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

meal increased the AUCinf of BEM, AT-273 and RZR by 8.6, 11.1 and 38.5%, respectively. When dosed simultaneously, famotidine did not affect the total plasma exposure of BEM, AT-273 or RZR with geometric mean ratios ranging from 95.8%-103%. **Conclusion:** The BEM/RZR FDC was safe and well-tolerated when dosed without or with food or with famotidine. BEM/RZR FDC demonstrated a high rBA to the BEM and RZR individual reference formulations. A HFHC meal or simultaneously co-administered famotidine had no meaningful effect on plasma exposure of the FDC. Study results support use of the BEM/RZR FDC in the ongoing and future clinical trials. **Disclosures:** Xiao-Jian Zhou: Nothing to Disclose, Brett Smith: Nothing to Disclose, Maureen Montrond: Nothing to Disclose, Keith Pietropaolo: Nothing to Disclose, Bruce Belanger: ATEA Pharmaceuticals: Employee, Shannan Lynch: Atea Pharmaceuticals: Employee, Dayle James: Nothing to Disclose, Maria Arantxa Horga: Nothing to Disclose, Janet Hammond: Nothing to Disclose

1399 | MICRO-ELIMINATION OF HEPATITIS C (HCV) IN A LARGE AND RISKY POPULATION OF DIABETIC PATIENTS BY COLLABORATIVE CARE SYSTEM

Tsung-Hui Hu[1] Yung-Hsiang Lin[2] Rong-Nan Chien[3] Lay San Lim[4] Chia-Yu Chang[2] Te-Sheng Chang[5] Yu-Ling Lu[6] Ming-Ling Chang[7] Soh-Ching Ng[8] Chih-Lang Lin[9], [1]Division of Hepato-Gastroenterology,Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [2]Division of Endocrinology and Metabolism,Chiayi Chang Gung Memorial Hospital, Chiayi, Taiwan., [3]Taiwan National Hepatitis C Program Office, Ministry of Health and Welfare, Taipei, Taiwan, [4]Division of Endocrinology and Metabolism,Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan., [5]Division of Hepato-Gastroenterology,Chiayi Chang Gung Memorial Hospital, Chiayi, Taiwan., [6]Division of Endocrinology and Metabolism, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan., [7]Liver Research Unit, Linkou Chang Gung Memorial Hospital and University, Taoyuan, Taiwan, [8]Division of Endocrinology and Metabolism,Keelung Chang Gung Memorial Hospital, Keelung, Taiwan., [9]Division of Hepato-Gastroenterology,Keelung Chang Gung Memorial Hospital, Keelung, Taiwan.

Background: Previous studies have indicated a higher prevalence of type 2 diabetes mellitus among populations that are seropositive for the hepatitis C virus (HCV) infection and vice versa, particularly in individuals with cirrhosis. Various mechanisms have been suggested to explain the link between HCV and diabetes, primarily through the development of insulin resistance. However, there is a lack of reliable data on the prevalence of HCV in diabetic populations and outcomes after HCV treatment. HCV micro-elimination approach, which focuses treatment on DM population was also rarely reported. We aim to conduct HCV elimination for a large population with diabetes mellitus and follow up outcomes after HCV treatment. **Methods:** We conducted a study at four medical centers in Chang Gung Memorial Hospital of Taiwan (Linkou, Keelung, Chiayi, and Kaohsiung). Taking the diabetic cases in the shared care system from 2021 to 2023 as the tracking generation. Several meetings were held among hepatologists and endocrinologists from the four medical centers to improve the HCV screening process and to establish a strong linkage for diagnosis and treatment of HCV. The achievement rate of HCV care cascade, the coverage of treatment, and outcome after treatment rate were analyzed. Data on sugar and lipid profiles, renal and liver function panels, HCV antibody (HCV-Ab), HCV RNA, and urine albumin creatinine ratio (UACR) were retrieved retrospectively from these patients' electronic medical records. **Results:** Among 46,601 patients with diabetes in the shared care system, 37,159 had been screened for HCV antibodies, and 2,974 were found to be HCV seropositive, resulting in an HCV screening rate of 79.74% and a prevalence of hepatitis C virus seropositivity of 8.74%. 2697 of 2974 (90.68%) patients were linked to HCV RNA testing, with a positive HCV RNA of 62.88% and viremic (1696 patients). Overall, 1601 of 1696 have received anti-viral therapies (either IFN based or DAA treatment). The coverage of treatment was high as 94.39%. For patients treated and achieved a sustained viral response, significant improvements in HbA1C levels (7.4$\pm$1.5 to 7.1$\pm$1.3; $P < 0.001$), liver biochemical tests ($P < 0.001$), and the APRI and FIB-4 indices ($P < 0.001$) were observed after treatment. However, there was no improvement of serum creatinine, eGFR, as well as urine albumin creatinine ratio (UACR) before and after HCV treatment. **Conclusion:** In the present study, the prevalence of hepatitis C virus seropositivity in the diabetic population is 8.74%, which is about two to three times of general population in Taiwan. HCV is a significant issue in the diabetic population that we recommend an elimination program of HCV is mandatory to get the benefits following HCV treatment and to facilitate global HCV elimination.

1400 | HISTOPATHOLOGICAL FEATURES AND EIGHT-WEEK TABLET-SPLIT SOFOSBUVIR/VELPATASVIR TREATMENT FOR YOUNG CHILDREN WITH ACUTE HEPATITIS C: A CASE SERIES STUDY

Ru-Yue Chen[1] Ya-Jie Pan[1] Yan-Qin Ai[2] Xue-Yan Lv[1] Yue-hang Wang[1] Zhuang-zhuang Zhai[1] Xue-Jing Yu[1] Qing-Lei Zeng[1], [1]Department of Infectious Diseases, The First Affiliated Hospital of Zhengzhou University, China, [2]Department of Infectious Diseases, Xuchang Central Hospital, Xuchang, Henan Province, China

Background: The clinical and therapeutic research on acute hepatitis C (AHC) in children under 5 remains scarce. **Methods:** Two 4-year-old children (Nos. 1 and 2) acquired hepatitis C virus (HCV) infection through unsafe injections and were diagnosed with AHC. Both children displayed no clinical symptoms and signs. Liver biopsies were performed prior to initiating an 8-week regimen of half-dose sofosbuvir/velpatasvir (200/50mg [1/2 tablet, tablet-split], a total of one bottle of Epclusa® for each child) once daily. The adverse events, HCV RNA levels, liver function, complete blood counts, renal function, lipid profiles, and other relevant parameters were monitored through week 12 post-treatment. The primary endpoint was sustained virologic response at 12 weeks (SVR12) post-treatment, and the secondary endpoint was the safety profiles. **Results:** Child No. 1 had an HCV RNA level of 1500 IU/mL and an alanine aminotransferase (ALT) level of 316 U/L, abdominal ultrosound showed splenomegaly, and the liver biopsy indicated mild hepatitis and moderate fibrosis (G1S2, Figure). Child No. 2 had an HCV RNA level of 2300 IU/mL and an ALT level of 15 U/L, and the liver biopsy indicated moderate hepatitis and mild fibrosis (G2S1, Figure). HCV genotyping revealed that both children were infected with genotype 1b. After 1 week of treatment, Child No. 1's HCV RNA level decreased to 49.2 IU/mL, with ALT normalization; and Child No. 2 had undetectable HCV RNA and ALT normalization. By week 2, Child No. 1 had undetectable HCV RNA. Finally, both children achieved SVR12, and no specific adverse events were observed during treatment or follow-up period; additionally, blood counts, renal function, lipid profiles, and electrolyte levels maintained normal. At SVR 24, child No. 1's spleen had returned to normal size. **Conclusion:** In conclusion, young children with AHC may exhibit significant liver injury, and eight-week sofosbuvir/velpatasvir appears safe and effective. Future larger sample size studies are needed to confirm the safety and efficacy of this approach.

1401 | THE CLINICAL EPIDEMIOLOGY AND TREATMENT OF ACUTE HEPATITIS C CAUSED BY UNSAFE CLINICAL PRACTICES

Ru-Yue Chen[1] Yan-Qin Ai[2] Ya-Jie Pan[1] Xue-Yan Lv[1] Yue-Hang Wang[1] Xue-Jing Yu[1] Zhuang-Zhuang Zhai[1] Qing-Lei Zeng[1], [1]The First Affiliated Hospital of Zhengzhou University,Zhengzhou,China, [2]Xuchang Central Hospital, Xuchang,Henan,China

Background: Compared to chronic hepatitis C, acute hepatitis C (AHC) is more difficult to detect and therefore less likely to be treated in a timely manner. This study reports the clinical epidemiological characteristics, treatment, and outcomes of AHC caused by unsafe clinical practices. **Methods:** From 2023 to 2024, an outbreak of hepatitis C caused by unsafe clinical practices occurred at a clinic in Xuchang City, Henan Province, China. The local government and Center for Disease Control and Prevention screened 630 individuals. Through comprehensive epidemiological and virological assessments, 72 adolescents and adults aged 5 years and older were identified as having AHC. Among them, 47 AHC patients agreed to receive a 12-week course of direct-acting antiviral (DAA) therapy. The criterion for evaluating treatment efficacy was sustained virological response (SVR) 12, defined as undetectable hepatitis C virus (HCV) RNA 12 weeks after completion of therapy, meanwhile, the safety profiles were closely monitored. **Results:** Among the 72 patients with detectable HCV RNA, 38 (52.8%) patients were male, 71 (98.6%) patients tested positive for HCV antibodies. The mean age was 62.5 (54.0, 72.0) years, with 4 (5.6%) patients aged 5-12 years, 4 (5.6%) patients aged 13-18 years, and 64 (88.8%) patients aged over 18 years. The mean HCV RNA level was 5.60 $\pm$ 1.64 $\log_{10}$ IU/mL, genotype 1b accounted for 87.5% (63/72), 2.8% (2/72) of patients with genotype 2a,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and 9.7% (7/72) of patients were not tested for genotype. Among the 37 patients with alanine aminotransferase (ALT) results, the mean ALT level was 143.0 (61.8, 378.7) U/L, and 31 (83.8%) had elevated ALT levels. Only 8 (11.1%) patients presented with significant clinical symptoms (Table 1). Among the 47 patients who received DAA therapy, the regimens used were as follows: sofosbuvir/velpatasvir in 24 patients (33.3%), emitasvir/sofosbuvir in 20 patients (27.8%), ledipasvir/sofosbuvir in 2 patients (2.8%), and coblopasvir/sofosbuvir in 1 patient (1.4%). Notably, 100% (47/47) of DAA-treated patients achieved SVR 12. For the 25 untreated patients, reasons for non-treatment included financial constraints, advanced age with impaired mobility, and unspecified refusal. A standardized recall and follow-up program was subsequently initiated for these untreated patients, among 7 patients who were successfully recalled to date, with 2 patients achieved spontaneous clearance, 4 patients maintaining stable or slightly elevated HCV RNA levels, and 1 patient showing a decrease in HCV RNA levels from 5.26 to 3.41 $\log_{10}$ IU/mL. **Conclusion:** This outbreak highlights the risks of unsafe clinical practices and the importance of early detection and treatment of AHC. DAA therapy was highly effective, with all treated patients achieving SVR12. Strengthened infection control and timely intervention are crucial to preventing similar events.

Table 1 Baseline demographics and characteristics

Parameters	n=72
Age, years	62.5(54.0, 72.0)

1402 | HEPATITIS C IN PREGNANCY: EVALUATING SCREENING AND MANAGEMENT PRACTICES IN A RURAL POPULATION

Aleena Moin[1] Benyam Addissie[2] Lifang Zhang[3] Sara Gaines[1] Alberto Unzueta[1], [1]Geisinger Medical Center, [2]University of Rochester, [3]Department of Population Health Sciences, Geisinger Medical Center, Danville PA

Background: Hepatitis C (HCV) is now one of the most prevalent blood-borne infections, with 65% percent of infections impacting persons 20-39 years old. Rates of HCV amongst women giving live birth doubled during 2009-2014. Current guidelines now recommend hepatitis C (HCV) testing for every pregnancy, a shift from the previously recommended risk-based testing. We sought to investigate the current HCV screening practices amongst all pregnant women in our rural health system in order to identify gaps in screening practice and evaluate success of treatment. **Methods:** This was a retrospective study utilizing electronic health records from the Geisinger Health system. We evaluated all pregnancy encounters for women > 18 years between 2019 to 2023 to investigate the following AIMS: 1) Assess the health system's compliance of HCV screening guidelines by reviewing every pregnancy encounter during the study window for HCV antibody testing 2) Report the incidence of new HCV infection as delineated by positive HCV antibody and HCV RNA tests 3) Determine the rate of hepatology referral for all known positive pregnancy encounters and 4) Quantify success of treatment. **Results:** From 2019 to 2023, 23,253 pregnancies encounters were documented within our rural health system. 20,747 (89.22%) of these encounters were screened for HCV per guidelines, whereas 2506 (10.78%) of encounters had no testing. There were 478 positive HCV antibody tests and 280 positive RNA tests. 150 (53.57%) of HCV viremic patients were referred to Hepatology to be treated after their pregnancy, but only 69 (46%) initiated an appointment. In total, 91 out of 280 (32.5%) of all known positive HCV RNA cases successfully initiated HCV treatment with sustained viral response in all treated patients. Three were lost to follow up. **Conclusion:** Our retrospective study showed opportunities for improvement in both screening and linking to treatment of HCV infection for pregnant women. This was the first

phase of initiatives and will now serve as the basis for future intervention. Our rural health system has demonstrated adequate success (89.22%) in screening for HCV with every pregnancy, as recommended per guidelines, but referral to and initiation of HCV treatment in the postpartum period as well as success in treatment, are identified as areas of future improvement. We intend to evaluate how initiation of HCV treatment is impacted by subsequent pregnancies, breastfeeding, active drug use, incarceration and other social determinants of health.

	Yes	No	Total
Hep-C antibody test in any trimester, n (%)	20,747 (89.22%)	2,506 (10.78%)	23,253
Hep-C antibody positive in any trimester, n (%)	478 (2.30%)	20,269 (97.70%)	20,747
Hep-C RNA test positive, n (%)	280 (40.46%)	412 (59.54%)	692
Hep-C RNA positive referral, n (%)	150 (53.57%)	130 (46.43%)	280
Initiate Hep-C doctor visit after referral, n (%)	69 (46.0%)	81 (54.0%)	150
HCV Treated, n (%)	91 (32.38%)	189 (67.5%)	280

1403 | DEVELOPMENT OF B-CELL LYMPHOMA AFTER TREATMENT OF HEPATITIS C WITH DIRECT-ACTING ANTIVIRAL AGENTS

Omar Zuhdi[1] Amanda Rigdon[1] Paola Campillo[1] Muhammad Ghabra[1], [1]Lakeland Regional Health Medical Center

Background: According to reports from the World Health Organization, more than 170 million people are infected with chronic hepatitis C worldwide, leading to complications including chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma. Remarkable advances in hepatitis C treatment have been made in recent years with the introduction of direct-acting antiviral agents (DAA's) allowing for viral eradication in greater than 98% of patients with hepatitis C. While DAA's have provided significant benefit for patients with HCV, development of B-cell lymphoma following HCV clearance with DAAs have rarely been reported in the literature. **Methods:** A systematic literature search was conducted using PubMed, Scopus, and ScienceDirect to retrieve studies from inception up to May 2025. Studies describing late-onset B-cell lymphoma after hepatitis C clearance with direct-acting antiviral agents, and no previous history of B-cell lymphoma were extracted. According to PRISMA guidelines, two reviewers completed the initial title and abstract screening, full text review, and data extraction. **Results:** Three case series and five case reports, describing 12 patients treated for hepatitis C with direct-acting antiviral agents, who subsequently developed B-cell lymphoma, were found in the current literature. The average age of the included patients was 66 years, ranging from 52-81 years of age. Sofosbuvir-based HCV therapy was used in 81% of patients, including sofosbuvir-ribavirin and sofosbuvir-ledipasvir regimens. Diffuse large B-cell lymphoma was the most common type of B-cell lymphoma among patients following hepatitis C treatment with direct-acting antiviral agents at 58.3% of patients, followed by mantle cell lymphoma (16.7%), and marginal zone lymphoma (16.7%). 42% of patients developed lymphoma within three months of HCV clearance with direct-acting antiviral agents, 33% within 3-12 months, and 25% of patients after more than 12 months. Most cases responded well to rituximab-based chemotherapy, composed of R-CHOP or similar chemotherapy regimens with complete lymphoma regression in 25% of patients, and partial lymphoma response in 41.7% of patients, and the rest of patients without fully reported responses. **Conclusion:** While direct-acting antiviral agents have provided significant benefit for patients with hepatitis C, such as prevention of liver cirrhosis and hepatocellular carcinoma, reports in recent years have described development of B-cell lymphoma after HCV clearance with direct-acting antiviral agents. Increased monitoring of patients for B-cell lymphoma following direct-acting antiviral agents treatment for HCV can allow for earlier diagnosis resulting in earlier initiation of treatment and improvement in patient outcomes.

1404 | HIGH SVR RATES ACHIEVED WITH SIMPLIFIED MONITORING IN JAPANESE PATIENTS WITH HCV INFECTION TREATED WITH SOFOSBUVIR/VELPATASVIR: A PROSPECTIVE MULTICENTER STUDY

Goki Suda Masaru Baba[1] Yoshiya Yamamoto[2] Katsumi terashita[3] Jun Ito[4] Tomoe Kobayashi[5] Tetsuhito Muranaka[6] Naoki Kawagishi[7] Takashi Kitagataya[8] Masatsugu Ohara[7] Masato Nakai[7] Takuya Sho[7] Naoya Sakamoto[9], [1]Japan Community Health Care Organization (JCHO) Hokkaido Hospital, [2]Department of Gastroenterology and Hepatology, Hakodate Municipal Hospital, Hakodate, Hakodate, Japa, [3]Keiwakai Ebetsu Hospital, [4]National Hospital Organization Hokkaido Medical Center, [5]Tomakomai City Hospital, Hokkaido, Japan, [6]Department of Internal Medicine Wakkanai City Hospital, [7]Hokkaido University, [8]Department of Gastroenterology and Hepatology, Hokkaido University Graduate School of Medicine, [9]Graduate School of Medicine Hokkaido University

Background: The advent of DAAs targeting viral proteins has revolutionized the treatment of HCV infection, making nearly all infected individuals eligible for therapy and achieving SVR rates exceeding 95%. Despite this, some patients with confirmed HCV infection defer regular outpatient visits. Given the excellent safety and efficacy profile of DAAs, simplified monitoring with reduced visit frequency may offer a practical alternative, as has been reported overseas. However, in Japan, where elderly patients and those receiving polypharmacy are common, real-world evidence on the safety and efficacy of minimal monitoring remains scarce. Sofosbuvir/velpatasvir, a pan-genotypic DAA regimen, has demonstrated high efficacy and safety and was recently approved for use in patients with chronic hepatitis C and compensated cirrhosis in Japan. Nevertheless, domestic real-world data are still limited. In a previous clinical trial involving 37 patients, visits were scheduled at treatment initiation and at weeks 2, 4, 8, and 12, leaving the utility of simplified monitoring unclarified. This prospective multicenter study aimed to evaluate treatment efficacy and safety under simplified monitoring conditions, specifically focusing on the impact of having fewer than two outpatient visits from treatment initiation to SVR12. **Methods:** This prospective multicenter study included patients who initiated treatment after January 2023 and completed at least 24 weeks of follow-up by May 2025. Primary endpoints were SVR12, safety, and the relationship between the number of outpatient visits and treatment outcomes. **Results:** As of May 2025, 51 patients had reached 12 weeks post-treatment. The median age was 67.0 years; 31 were male and 20 female. HCV genotypes included genotype 1 (n = 18), genotype 2 (n = 32), and one indeterminate case. One patient discontinued treatment at week 9 due to suspected pregnancy, but still achievedwhile achieving SVR12[1] . One otherThe another onepatients was lost to follow-up. Among the remaining 49 patients, all achieved SVR12. Thus, the SVR rate was 98% (50/51) in the intention-to-treat (ITT) analysis and 100% (49/49) in the per-protocol analysis. The number of outpatient visits from treatment initiation to SVR12 ranged from 1 to 7, with a median of 3.0. Notably, in 30 patients who had three or fewer visits, SVR rates were 100% in both ITT and per-protocol analyses. **Conclusion:** This prospective, real-world study suggests that treatment with sofosbuvir/velpatasvir in Japanese patients with chronic hepatitis C—predominantly elderly individuals—can achieve high SVR rates even under minimal monitoring. These findings support the feasibility of simplified monitoring strategies in clinical practice

1405 | CHARACTERISTICS OF 930 PATIENTS WITH CHRONIC HEPATITIS C: A 7-YEAR REAL-WORLD COHORT FROM A TERTIARY CENTER IN GREECE

CHARIKLEIA KRANIDIOTI[1] Olga Anagnostou[2] Pinelopi Antonakaki[2] Spyros Siakavellas[3] Maria Manolakopoulou[4] Nikolaos Tsiamperas[4] Christiana Charalambous[4] Eleni Myrto Trifylli[4] Georgios Kontos[5] Nikolaos Papadopoulos[6] MARIA MELANIE DEUTSCH[4] Spilios Manolakopoulos[4], [1]National & Kapodistrian University of Athens Medical School, [2]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, "Hippocration", [3]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, "Hippocration, [4]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, "Hippocration", [5]2nd Department of Internal Medicine, National and Kapodistrian University of Athens,"Hippocration", [6]2nd Department of Internal Medicine, 401 General Army Hospital of Athens

Background: The advent of direct-acting antivirals (DAAs) has made the elimination of hepatitis C a realistic public health objective. While people who inject drugs (PWID) represent the highest-risk group, a substantial proportion of HCV-infected individuals in Greece appear to originate from the general population with no prior history of substance use (non-PWID). Aim of this study was to identify differences in the demographic and clinical profiles of PWID and non-PWID with chronic hepatitis C in a real-world Greek large cohort. **Methods:** All patients with chronic HCV infection considered eligible for DAA therapy between 2015–2022 at a tertiary liver center were retrospectively identified. Demographic, clinical, and laboratory data were retrieved from medical records. Liver stiffness measurements (LSM) by elastography were performed prior to treatment initiation. Cirrhosis was defined based on clinical, laboratory, and/or LSM values >12 kPa. **Results:** A total of 930 patients were included; 69.8% were male, with a median age of 52 years. At baseline, 9.2% had decompensated liver disease. PWID represented 56.8% of the cohort (n = 528). PWID were younger (47.1 ± 9.8 vs. 56.9 ± 13.1 years, $p < 0.001$) and had lower BMI (24.4 ± 4.4 vs. 26.4 ± 4.7 kg/m², $p < 0.001$) compared to non-PWID. Non-PWID had higher rates of diabetes (13.6% vs. 2.7%), hypertension

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(14.8% vs. 7.6%), decompensated liver disease (13.5% vs. 6.1%), and higher liver stiffness (13.9 ± 10.9 vs. 10.9 ± 7.7 kPa, p = 0.001). LSM > 9 kPa was observed in 57.4% of non-PWID versus 40% of PWID. Genotype 3 infection was more common in PWID (64% vs. 30%, p < 0.001). Treatment and outcome data were available for 853 patients. Sofosbuvir/velpatasvir (39%), glecaprevir/pibrentasvir (19.5%), and elbasvir/grazoprevir (13.2%) were the most used regimens. Sustained virologic response (SVR) rates were similar in both groups (PWID: 92%, non-PWID: 94%). All reinfection cases (n = 8) occurred in PWID during the 7-year follow-up. **Conclusion:** PWID and non-PWID with HCV infection in Greece display distinct clinical profiles that do not affect SVR rates but may influence long-term management. Non-PWID are older, have more features of metabolic syndrome, and demonstrate more advanced liver fibrosis at baseline. The number of patients with advanced liver disease and metabolic syndrome raise the importance of surveillance for hepatocellular carcinoma during next years.

1406 | 'REACHING IN, REACHING OUT': TRACING CHILDREN OF HEPATITIS C POSITIVE WOMEN PRISONERS

Rachel Cockayne[1] Hayley Allen[2] Carla Lloyd[2] Sean Cox[3] Julia Sheehan[3] Caroline Foster[4] Deirdre Kelly[1], [1]Birmingham Women's and Children's NHS Trust, [2]Birmingham Women and Children's NHS Trust, [3]The Hepatitis C Trust, [4]Imperial College Hospital London

Background: Hepatitis C virus (HCV) infection is a major global health problem in adults & children which may cause serious & life-threatening damage to the liver. HCV Global Elimination by 2030 remains a target for the World Health Organisation & NHS England. Vertical transmission is the main cause of HCV infection in children. It is vital that there is an effective pathway to trace, test and treat children of mothers living with HCV (LWHCV). Identification of people in prisons LWHCV is an integral part of the HCV elimination agenda given the disproportionate burden of infection amongst residents. The aim of the 'Reaching In, Reaching Out'(RIRO) prison project is to develop & pilot pathways to trace and test children of HCV +ve women prisoners as they may be at risk of HCV. **Methods:** The pilot project was launched in 3 English female prisons with mother & baby units. The team worked with The Hepatitis C Trust & Healthcare teams to identify & counsel mothers LWHCV. Identification of women prisoners LWHCV was via prison database & arrival reports. Inclusion criteria: All women tested on entry to prison who are HCV+ve (RNA and/or Ab) & have children. Women who. * were pregnant/ breastfeeding. * do/ do not have parental responsibility (PR). Exclusion criteria: Women who. * declined to engage in the project. * were medically unfit to approach (mental health concerns). Consent forms were developed, information governance cleared & ethics achieved. Demographic details, dependents & family contacts were collected directly from women. **Results:** (See table 1). Jan-April 2025. 1642 women were incarcerated in 3 pilot sites: 1244 tested; 242 were Ab+ve, 34 RNA+ve. 30 women engaged with the RIRO team. 13 continue to be followed up. Preliminary challenges and lessons learnt: * Women prisoners may be vulnerable, so reassurance & building trust is imperative to working with them. * Accessing women may be difficult in a secure setting as lockdowns are common. * Discussing family is emotive & complex, requiring confidential private communication. * The high turnover of individuals at prison sites necessitates community follow up. * Effective partnership working is key **Conclusion:** A significant proportion of females in prison are HCV Ab +ve. It is vital to trace their children & offer testing. Pathways have been drafted, tested & adapted. Challenges have been highlighted & learning from the pilot will support the ongoing tracing of children & the roll out of RIRO into the remaining 9 English women's prisons.

Table 1: HCV status of women in 3 prison pilot sites & outcome of engagement with RIRO project (Jan-April 2025) (n=1643)

n	Status
1643	Women incarcerated at 3 pilot sites
1244/1643	Women HCV tested • 242 Ab +ve • 34 RNA +ve
198/ 1244	Women approached/ spoken to about RIRO project

30/198	Women engaged with RIRO
	• 8 Released from prison
	• 3 Didn't have children
	• 2 Declined to be part of RIRO
	• 3 Children not at risk/ low risk (i.e. HCV after children born)
	• 12 For further follow up
	  • 8 Have children: more details required
	  • 4 Dependents unknown, details required
	• 1 Child's details obtained, follow up in progress
	• 1 deemed medically unsuitable

1407 | A NOVEL SCORE FOR PREDICTING RETURN TO DRINKING AFTER ALCOHOLIC HEPATITIS

Wanzhu Tu[1] Qing Tang[1] Srinivasan Dasarathy[2] Suthat Liangpunsakul[1] Gyongyi Szabo[3] Craig McClain[4] Ramon Bataller[5] Arun Sanyal[6] Thomas Cotter[7] Mack Mitchell[8] Vijay Shah[9] Samer Gawrieh[1] Richard Sterling[6], [1]Indiana University, [2]Cleveland Clinic, [3]Beth Israel Deaconess Medical Center, [4]University of Louisville, [5]University of Pittsburgh, [6]Virginia Commonwealth University, [7]UT Southwestern Medical Center, [8]University of Texas Southwestern Medical Center, [9]Mayo Clinic Rochester

Background: Alcohol-associated hepatitis (AH) carries significant morbidity and mortality, with longer-term outcomes depending on alcohol cessation. The High-Risk Alcohol Relapse (HRAR) scale has been used to predict return to drinking (RTD) following liver transplantation (LT), but its use in patients with AH not undergoing LT is untested. We evaluated the performance of HRAR and developed a new model for improved predictive accuracy. **Methods:** Using data from a prospective observational cohort of patients hospitalized for AH, we calculated HRAR scores based on duration of heavy drinking, number of drinking days, and number of prior inpatient admissions for alcohol treatment. We constructed a new score to quantify the probability of RTD within 200 days after hospitalization using a generalized additive model (GAM) to capture nonlinear and interacting influences of the predictors for improved performance. In addition to the HRAR score components, the new model also included MELD, Ethnicity, Race, Age, Gender, and Education (MERAGE). In GAM, two key components of the HRAR score, the typical numbers of daily drinks and drinking days in the past 30 days, were included as a bivariate function to accommodate their nonlinear and interactive effects. Data were split 70% vs 30% for training and validation of the MERAGE score. **Results:** The study cohort included 347 patients with AH, of whom 98 (28%) had RTD within 200 days of follow-up. The mean age was 44.6 years, 43.2% were female, and 84.3% were non-Hispanic Whites. The mean baseline MELD score was 24.5. Compared to those stayed abstinent, the RTD group had greater numbers of daily drinks (12.7 vs. 9.7; $p = 0.01$) and more drinking days (21.3 vs. 13.6; $p < 0.001$), greater total number of drinks in the past 30 days (242.4 vs. 133.6; $p < 0.001$), and slightly lower baseline MELD (23.3 vs. 24.9; $p = 0.06$). GAM analysis showed RTD risk was higher in those with more than 20 drinking days, especially for those with greater daily intake. Youden Index was used to select a threshold value for the MERAGE score (optimal threshold = 0.242). The MERAGE score outperformed HRAR in the training and validation datasets (Table). In the validation set, the MERAGE had an area under the ROC curve of 0.69 vs 0.54 in the HRAR score (optimal threshold = 1.5). Compared to HRAR, the MERAGE score also had improved sensitivity, positive & negative predictive values, as well as the overall predictive accuracy. **Conclusion:** RTD results from multiple clinical and behavioral factors whose nonlinear and interacting influences may determine the level of risk. The novel MERAGE score, expanded upon the HRAR score, shows potential for improved accuracy in predicting return to drinking. Independent validation in a broad patient population is needed to establish its practical utility.

Table. Performance of the HRAR and MERAGE scores in predicting return to drinking by 200 days after hospitalization for alcohol-associated hepatitis

Score	Sensitivity	Specificity	PPV	NPV	Accuracy	AUROC
Training sample (70%)						
HRAR	0.48	0.64	0.36	0.75	0.60	0.55
MERAGE	0.83	0.64	0.49	0.90	0.69	0.78
Validation sample (30%)						
HRAR	0.38	0.65	0.24	0.78	0.59	0.54
MERAGE	0.71	0.60	0.34	0.88	0.62	0.69

Notes: PPV -positive predictive values; NPV – negative predictive values; AUROC – area under the receiver characteristic curve.

1408 | HCV MEDICATION TURNAROUND TIME USING SPECIALTY MAIL ODER PHARMACY VS. LOCAL PHARMACY

Paulina Deming[1] Carly Cloud Floyd[1] Savannah Gold[2] Michelle Iandiorio[3], [1]University of New Mexico Health Sciences Center, [2]Truman Health Services, [3]University of New Mexico Health Sciences Center; Truman Health Services

Background: Despite the removal of the prior authorization (PA) requirement for hepatitis C virus (HCV) treatment for New Mexico (NM) Medicaid, insurances often restrict directly acting antivirals (DAAs) dispensing to their own or contracted mail order specialty pharmacy. The purpose of this analysis was to determine DAA turnaround time before removal of the PA in July 2024? and after for patients with Medicaid insurance prescribed DAAs by the University of NM's Truman Health Services (THS), comparing mail order pharmacy to THS's in-house pharmacy turnaround time. **Methods:** Adults >18 years of age with NM Medicaid insurance seen >1 time at THS for confirmed HCV and prescribed DAAs were included. Time to DAA receipt from initial prescription was assessed through a retrospective analysis of DAA prescription data from the electronic health record, THS pharmacy's fill records, and clinic medication room logs for meds shipped from mail order pharmacy. Turnaround time for mail order pharmacies was determined by calculating the number of days from the date of prescribing DAA to the date received at THS. Turnaround time for THS's on-site pharmacy was determined by calculating the number of days from date prescribed to date ready for pick up. Turnaround time calculations excluded weekends and holidays. DAAs sent directly to the patient or those never picked up were excluded from the turnaround time calculation. **Results:** Preliminary data between Jan. 1, 2023 and Dec. 31, 2024 indicate 138 patients at THS initiated DAA therapy. The use of external mail order pharmacy was required for 53 patients but 6 (11%) never returned to THS to start treatment. The average time to DAA receipt was 8.5 days (range 5-17). THS pharmacy was able to fill 85 prescriptions, with 49 prescriptions filled in the 18 months prior to PA removal (average of 2.7 fills/month) and 36 in the first 6-months after removal of the PA (average of 6 fills/month). When allowed to fill on-site the average time to DAA at THS was 1.67 days pre-PA removal and decreased to <1 day after removal of the PA. In contrast, time from prescription to DAA receipt with specialty mail order pharmacy averaged

13.58 days (range 5-14 days) before the PA removal and after PA removal was 11.36 days (range 4-25 days). **Conclusion:** Requiring the use of specialty mail-order pharmacy delays access to HCV treatment, even after removing the PA requirement.

1409 | VERTICAL TRANSMISSION OF HEPATITIS C VIRUS RUNS IN FAMILIES: HAVING A CHILD INFECTED INCREASES THE RISK OF FUTURE VERTICAL TRANSMISSION

Andrew Mendlowitz[1] Jennifer Flemming[2] Tatyana Kushner[3] Wenbin Li[4] Zoë Greenwald[5] William Wong[6] Camelia Capraru[1] Mia Biondi[7] Jordan Feld[1], [1]Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, [2]Queen's University Cancer Research Institute, [3]Weill Cornell Medicine, New York, New York, USA, [4]ICES, Queen's University, Kingston, Ontario, [5]University of Toronto, Toronto, Ontario, Canada, [6]University of Waterloo, Waterloo, Ontario, [7]York University, Toronto, Ontario, Canada

Background: While vertical transmission is the predominant route of pediatric hepatitis C virus (HCV) acquisition, few studies have examined how having an infected child may affect the risk of future vertical transmission. **Methods:** We conducted a population-based retrospective cohort study linking infants born from 2007 to 2021 to individuals with chronic HCV infection in Ontario, Canada. Families were defined as those in which two or more infants were born to the same individual, with at least one infant tested for HCV during a follow-up period of at least two years. HCV testing was defined as a record of an antibody (Ab) test after 18 months of age and/or an RNA test at any time. Transmission was defined as a record of Ab-positivity or RNA testing after 18 months of age, or RNA-positivity at any time. We quantified and compared the association between vertical HCV transmission and the presence or absence of an infected sibling. Factors associated with transmission were identified using mixed-effects logistic regression, adjusting for within-family clustering, family size, and relevant covariates. **Results:** A total of 1,101 infants were included from 432 families (median of 2 infants per family, IQR: 2–3). Among these, vertical transmission occurred in 85 (7.7%) children, from 72 families (16.7% with at least one child affected). The maximum number of children who acquired HCV within a single family was 2. The incidence of vertical transmission was 22.2% (95% CI: 15.1%–30.8%) in children with an HCV infected sibling compared to 6.0% (95% CI: 4.6%–7.7%) among those without ($p < 0.0001$). After adjustment, having an infected sibling (adjusted odds ratio (aOR) = 4.30; 95% CI: 2.53–7.33) and a record of substance use prior to the pregnancy (aOR = 1.92; 95% CI: 1.15–3.21) were associated with a higher likelihood of vertical transmission. Additionally, increasing age of the birthing parent (per year) (aOR = 1.06; 95% CI: 1.02–1.11) was modestly associated with a higher likelihood. **Conclusion:** The data show that vertical HCV transmission was markedly more frequent to those with an infected sibling. Increased transmission rates to siblings may relate to higher parental viral load or possibly anatomical factors. The recognition that once vertical transmission occurs there is a higher risk of it recurring in future pregnancies is important for parents and providers, and may support treatment in pregnancy to prevent additional transmission.

1410 | LONG-TERM RESTORATION OF HCV-SPECIFIC CD4+ T CELL IMMUNITY FOLLOWING DAA-MEDIATED CLEARANCE OF CHRONIC HCV INFECTION

Tetiana Pozniak[1] Arshi Khanam[2] Shyam Kottilil[3] Poonam Mathur[4] Alip Ghosh[4], [1]Institute of Human Virology School of Medicine University of Maryland, Baltimore, [2]Institute of Human Virology University of Maryland School of Medicine, [3]Institute of Human Virology, University of Maryland School of Medicine, [4]Institute of Human Virology, University of Maryland School of Medicine

Background: The advent of direct-acting antivirals (DAAs) has revolutionized the treatment of chronic hepatitis C virus (HCV) infection, leading to sustained virologic response (SVR) in over 95% of cases. Despite this success, the long-term effects of HCV clearance on T cell-mediated antiviral immunity remain unclear, particularly concerning the restoration of immune function and protection against reinfection. **Methods:** We conducted a longitudinal study using 14 PBMC samples from participants enrolled in the CHROME study (NCT03823911) with chronic HCV infection who achieved SVR following DAA treatment. Peripheral blood mononuclear cells (PBMCs) were collected at baseline and more 60 weeks post-treatment (>SVR60). We assessed serum proinflammatory markers (IP-10, MIP-1B, TNFα, IL-1B, GRO) and evaluated HCV-specific inflammatory cytokine responses in CD4+ and CD8+ T cells after HCV-specific peptides stimulation. Additionally, we analyzed activation (CD38, HLADR) and inhibitory (PD1, TIGIT, 2B4) marker expression and mitochondrial function in T cell subsets (mitoSOX, JCR/JCG). **Results:** At >SVR60, significant reductions were observed in serum IP-10, MIP-1B, and TNFα levels, indicating decreased systemic inflammation. CD4+ T cells exhibited enhanced HCV-specific cytokine production, particularly within activated CD38+ and CD38+HLADR+ subsets, with increased frequencies of TNFα+, IFNγ+TNFα+, IL-2+, and IL-21+ cells. Notably, these subsets also demonstrated reduced expression of inhibitory receptors PD1 and TIGIT and a significant increase in the mitochondrial membrane potential (JCR/JCG) in a CD4+CD38+ T cells, indicating improved mitochondrial function. There were no significant changes in the level of ROS. In contrast, CD8+ T cells showed no significant changes in cytokine production or phenotypic markers at >SVR60 compared to baseline. **Conclusion:** One-year post-DAA therapy, patients exhibited restoration of HCV-specific CD4+ T cell responses, characterized by enhanced cytokine production, decreased inhibitory receptor expression in activated T-helper cells and improved mitochondrial function of CD4+ T cell. However, CD8+ T cell responses remained unchanged, suggesting a different timeline for immune recovery. Recovery of HCV specific CD4+ T cell function may prevent of reinfection in high-risk individuals after SVR.

1411 | PREVALENCE AND CLINICAL SIGNIFICANCE OF LOW HCV RNA LEVELS IN KOREAN PATIENTS WITH CHRONIC HEPATITIS C INFECTION: A MULTICENTER PROSPECTIVE COHORT STUD

Juneyoung Lim[1] seungteak Lee[1] Min Kyung Park[2] Eun Sun Jang[3], [1]Seoul national university bundang hospital, [2]Seoul National University Hospital, [3]Seoul National University College of Medicine

Background: The clinical significance of low HCV RNA levels in chronic hepatitis C infection remains unclear, particularly in relation to treatment response and long-term outcomes. This study aimed to estimate the proportion of low viral titer patients, and to evaluate the sustained virologic response (SVR) and clinical outcomes, including hepatocellular carcinoma (HCC) incidence and composite liver-related events, in patients with low (<3000 IU/mL) versus high (≥3000 IU/mL) HCV RNA levels. **Methods:** We analyzed data from a multicenter prospective cohort collected from nine tertiary centers in Korea between 2007 and 2024. Patients with chronic HCV infection were classified into low RNA titer (HCV RNA <3000 IU/mL) and high RNA titer (HCV RNA ≥3000 IU/mL) groups. Baseline cirrhosis status and SVR rates after interferon (IFN) or direct-acting antiviral (DAA) treatment were compared. Clinical outcomes were assessed by analyzing HCC incidence and composite liver-related events, which included decompensated liver cirrhosis, liver transplantation, HCC, and death. Statistical analyses included odds ratios (ORs) for baseline characteristics, while Kaplan-Meier survival analysis and Cox proportional hazards regression were used to evaluate clinical outcomes. **Results:** A total of 2,297 patients were included. The median age was 60.0 years (IQR: 51.0–69.0), and 48.9% were male. Among them, 105 (4.6%) were in the low RNA titer group, while 2,192 (95.4%) were in the high RNA titer group. Baseline characteristics, including age ($p = 0.79$) and sex distribution ($p = 0.82$), did not significantly differ between groups. Cirrhosis prevalence was also similar (OR: 0.80, 95% CI: 0.53–1.20, $p = 0.28$). SVR rates among IFN-treated patients were 62.5% (5/8) in the low RNA titer group and 70.2% (193/275) in the high RNA titer group ($p = 0.70$). In the DAA-treated group, SVR rates were 93.5% (29/31) and 95.2% (1075/1129), respectively ($p = 0.66$). For the composite event analysis, 1,799 patients were analyzed over a median follow-up of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

60 months (IQR: 31–95), with 191 events occurring. The high RNA titer group had an HR of 1.14 (95% CI: 0.56–2.31, p = 0.72), showing no significant difference between the groups (Figure 1A). For HCC incidence, 1,876 patients were analyzed over a median follow-up of 60 months (IQR: 31.75–95), during which 124 patients developed HCC. The high RNA titer group showed a hazard ratio (HR) of 0.71 (95% CI: 0.35–1.45, p = 0.35) compared to the low RNA titer group (Figure 1B) **Conclusion:** In Korean HCV patients, the proportion of low HCV RNA levels was less than 5%, and they had comparable SVR rates and clinical outcomes to those with high RNA levels following IFN or DAA treatment. Although these patients are minor, they include cases with decompensated cirrhosis and HCC, underscoring the need for careful clinical assessment and active treatment.

1412 | MILESTONE-BASED INCENTIVES IMPROVE HEPATITIS C TREATMENT COMPLETION IN AN UNDERSERVED POPULATION: A PILOT STUDY

Aaron Skiles[1], [1]University of New Mexico

Background: Chronic hepatitis C virus (HCV) infection remains a significant public health concern, particularly among underserved populations. While highly effective antiviral therapies are available, completion rates remain suboptimal due to various barriers, including social determinants of health and limited access to care. Behavioral economics research suggests that small, structured incentives can motivate health-related behaviors. This pilot study explores whether milestone-based incentives can improve treatment adherence and achievement of sustained virologic response (SVR) in patients undergoing HCV treatment within a safety-net healthcare system. **Methods:** A prospective cohort study was conducted at the University of New Mexico Truman Health Services HCV clinic. Approximately 50 patients initiating HCV treatment were enrolled. Participants received up to $200 in merchandise card incentives for completing five treatment milestones: (1) New Patient Visit, (2) Baseline Labs, (3) Start of Treatment, (4) Post-Treatment Visit, and (5) SVR12 Labs (12 weeks post-treatment). Surveys administered during clinic visits collected demographic and social data, including access to transportation, housing, phone, insurance, and medication for opioid use disorder (MOUD). Clinical data, such as fibrosis scores and genotype, were also collected. Data were securely stored in compliance with HIPAA regulations and IRB-approved protocols. **Results:** Patients completing all five milestones and three surveys demonstrated higher SVR rates compared to baseline comparisons at the clinical site for year prior. Commonly reported barriers included transportation difficulties (60%), phone/housing instability (50%), and reliance on government assistance (70%). The majority of participants rated the gift card incentives as "Important" or "Very Important" motivators for treatment adherence. Notably, SVR rates were achieved even among participants with multiple social risk factors. **Conclusion:** Structured, milestone-based incentives are feasible and in certain patient groups are effective in improving HCV treatment adherence and SVR rates among underserved populations. Early identification of social determinants of health and integration of support services are critical to enhancing treatment outcomes. This model is low-cost, scalable, and holds promise for reducing disparities in HCV care. Further research with larger sample sizes and longitudinal follow-up is recommended. Study was completed when SVR-4 was not a recommendation and same-day start of treatment with removal of state Medicaid prior authorization allows for start-of-treatment same-day in many cases, so outcomes may be different now with current treatment protocols.

Pacheco[1] Javier García-Samaniego[6], [1]Biochemistry Department, Medicine Faculty, Universidad Autónoma de Madrid (UAM), Madrid, Spain, [2]Unidad de Hepatología, Hospital Universitario La Paz., [3]Centro Nacional de Biotecnología (CNB), Madrid, Spain, [4]Hepatology Unit. Hospital Universitario La Paz. IdiPaz. Madrid, Spain, [5]Oncology Service. Hospital Universitario La Paz. IdiPaz. Madrid, Spain, [6]Hepatology Unit. Hospital Universitario La Paz. IdiPaz. Madrid., Madrid, Spain

Background: Previous studies in cell models show that treatment with sofosbuvir (SOF) induces cell cycle modifications mediated by increased levels of epidermal growth factor receptor (EGFR) (Bojkova, 2020), vascular endothelial growth factor (VEGF) and platelet-derived growth factor receptor beta (PDGFRB) (Atif, 2022), DUSP1 or MET. The aims of thos work was to analyse the effect of sofosbuvir treatment on the levels and activity of Aurora kinase B (AURKB), an enzyme involved in cell cycle control, and its relationship with changes in cell proliferation, viability and migration, in an in vitro cell model. **Methods:** Cultures of Huh7 and Huh7.5 hepatoma cell lines were treated with SOF (C22H29N3FO9P) or daclatasvir (DCV) (BMS-790052) at different doses. AURKB expression levels of each culture were analysed by qPCR and Western-Blot. For cell proliferation assays, trypan-blue stained cells were counted using the Cell-dropTM (DeNovix). Cell viability was analysed by metabolic activity-MTT assays. Finally, cell migration capability was measured by wound assays. Results from SOF- or DCVtreated cultures were expressed in all cases as percentage induction with respect to untreated cells. **Results:** Protein and mRNA expression assays in SOF-treated Huh7 and Huh7.5 hepatocarcinoma cells showed significant increases of more than 25% in AURKB expression over untreated cells. Proliferation analysis of both cell lines showed that treatment with 5 mM doses of SOF for 72 hours induced increases in cell proliferation, which became statistically significant after 336 hours of treatment. Metabolic activity-MTT assays showed that cell viability of cultures treated with 5 mM SOF for 336 hours was higher. Finally, in Huh7 cells treated with 5 μM SOF, cell migration was observed to increase by 36% after 72h of treatment. All SOF-induced effects were reversed in the presence of AZD1152, an inhibitor of AURKB activity, confirming that they were exerted through the AURKB pathway. Finally, no differences were observed in any of the parameters studied between untreated control cells and cells treated with DCV at different doses. **Conclusion:** These results suggest that SOF can induce cell cycle modifications through AURKB activation in in vitro cell models. The effect of these changes in vivo (hepatitis C patients treated with SOF) should be analysed, taking into account that HCV eradication may induce an increase in AURKB per se, due to the inhibitory effect that the viral core protein exerts on AURKB activity.

1414 | MODELING SUGGESTS THAT UNDETECTABLE HCV RNA AT WEEKS 1 OR 2 OF DAA THERAPY COULD IDENTIFY ADULTS WITH RECENT HCV FOR SHORTER TREATMENT DURATION

Ashish Goyal[1] Tatyana Kushner[2] Kimberly Page[3] Ohad Etzion[4] Scott Cotler[1] Gail Matthews[5] Harel Dahari[1] Marianne Martinello[5], [1]Loyola University Chicago, [2]Weill Cornell Medicine, [3]University of New Mexico, [4]Soroka University Medical Center, [5]The Kirby Institute

Background: Identifying individuals with recent hepatitis C virus (HCV) infection (duration <12 months) who could be cured with short duration direct-acting antiviral (DAA) therapy would support efforts to reach World Health Organization (WHO) HCV elimination goals. Shorter treatment could improve adherence, decrease loss to follow-up, and reduce cost in key populations such as people who inject drugs (PWID) and pregnant women. Using a computational modeling approach, we previously demonstrated that undetectable HCV by day 14 among people with chronic HCV may shorten duration of DAA therapy by 4-5 weeks while achieving $>90\%$ cure (J Hepatol 2024 vol. 80(S1):S832). The efficacy of a similar approach among people with acute and recent HCV receiving glecaprevir-pibrentasvir (GLE-PIB) is unknown. **Methods:** In the TARGET3D study which evaluated HCV treatment in recently acquired HCV, 23 and 30 participants received 4 and 6 weeks of GLE-PIB, respectively (PMID: 31652357 and 37771545). Characterization of viral-host parameters, DAA efficacy in blocking HCV production, and treatment outcomes were available from previous modeling based on ~300 patients receiving DAA (Math Biosci 2022,343:108756). 100,000 parameter combinations of viral-host and treatment parameters were generated and viral kinetic profiles under GLE-PIB 300-120mg daily were simulated using a multiscale model. Each simulation represented an *in silico* patient with recent HCV receiving GLE-PIB. The time to cure (TTC) for each *in silico* patient with recent HCV, defined as time to reach <1 HCV viral copy in 15L of extracellular body fluid (i.e. $V = 7\text{x}10^{-5}$ IU/ml) was then estimated using mathematical modeling simulations. TTC of <8 weeks (56 days) of GLE-PIB indicates the potential for reduction in treatment duration. **Results:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The *in silico* recent HCV population closely matched HCV kinetics of the 53 trial participants; 74% of the *in silico* population had undetectable HCV RNA (< 10 IU/ml) at week 2, similar to 68% among TARGET3D participants. Modeling suggested that if HCV RNA was undetectable on or before day 14, 95% of people with recent HCV infection could be cured with GLE-PIB for 6 weeks (Fig.1A). The median predicted TTC was 24 days (IQR = 19-29 days), with 71% reaching TTC at ≤ 4 weeks (Fig.1B). Among the *in silico* population, 32% had undetectable HCV RNA at day 7, of whom 89% were predicted to achieve cure with GLE-PIB for 4 weeks (Fig.1C); the median predicted TTC was 19 days (IQR = 16-22 days) (Fig.1D). **Conclusion:** Mathematical modeling suggested that most people with recent HCV treated with GLE-PIB will have undetectable HCV RNA by week 1 or 2 and could have their treatment duration reduced by 2-4 weeks. This could improve treatment access, facilitate HCV elimination, and reduce cost, particularly in key populations most affected by HCV, such as PWID.

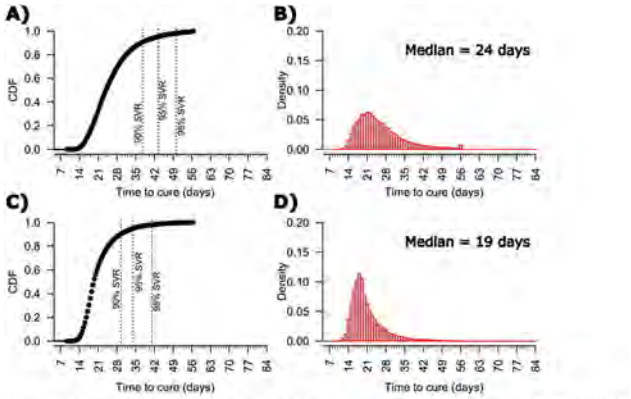

Figure 1: (A) Cumulative Distribution Function (CDF) and (B) frequency distributions of the time to cure (TTC) for ~40,000 *in silico* acute patients with undetectable HCV RNA (<10 IU/mL) at week 2. (C) Cumulative Distribution Function (CDF) and (D) frequency distributions of the time to cure (TTC) for ~32,000 *in silico* acute patients with undetectable HCV RNA (<10 IU/mL) at week 1.

1415 | THE USE OF DIRECT-ACTING ANTIVIRALS TO ENHANCE ACCESS TO CANCER CLINICAL TRIALS FOR PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION AND CANCER

Khalis Mustafayev[1] Joanne arvelaez Pascucci[1] Aung Naing[1] Sheeba Thomas[1] Krina Patel[1] Naveen Pemmaraju[1] Naval Daver[1] Ying Jiang[1] Eduardo Yepez Guevara[1] Harrys Torres[2], [1]The University of Texas MD Anderson Cancer Center, Houston, Texas., [2]The University of Texas MD Anderson Cancer Center

Background: Most cancer patients with chronic hepatitis C virus (HCV) infection are excluded from cancer clinical trials because of their active infection. The use of direct-acting antivirals (DAAs) to eradicate HCV and allow access to cancer clinical trials has not been studied. We aimed to evaluate the safety and efficacy of using DAAs to increase access to cancer clinical trials in patients with chronic HCV infection and advanced cancer. **Methods:** HCV-infected cancer patients seen at MD Anderson Cancer Center from January 1, 2016, through February 28, 2025, were enrolled in a prospective observational study. Patients initially excluded from cancer clinical trials but ultimately enrolled after DAA treatment were defined as cases. Patients treated with DAAs but never enrolled in cancer clinical trials were defined as controls. A 1:1 matching between cases and controls was performed, with matching based on the cancer type and stage, history of > 3 lines of chemotherapy, and presence of cirrhosis. Predictors of overall survival (OS) and progression-free survival (PFS) were evaluated using multivariable Cox regression analysis. The primary outcomes were the safety and efficacy (sustained virologic response [SVR]) of DAAs. The secondary outcomes were OS and PFS. **Results:** We studied 150 consecutive HCV-infected patients with any type of cancer, including 75 cases and 75 matched controls. In both groups, most patients were men, were White, were non-cirrhotic, and had HCV genotype 1 (Table). Adverse events occurred in 36 of 150 patients (24%), including 17 of 75 cases (23%) and 19 of 75 controls (25%). Five patients (3%), 1 case, and 4 controls, had grade 3-4 adverse events, none of them related to DAAs. The SVR rate was 92% (138/150) overall, 96% (72/75) in cases, and 88% (66/75) in controls. Median OS was 61 months in cases and 59 months in controls, and median PFS was 30 months in cases and 42 months in controls. Among patients with long-term follow-up, cases had better OS than controls (hazard ratio 0.20; 95% CI 0.07–0.56; p = 0.002). Achieving an SVR was significantly associated with better PFS (hazard ratio 0.46; 95% CI 0.24–0.89; p = 0.02). The rate of cancer-related deaths was significantly lower among cases (53% [40/75] vs. 69% (52/75); p = 0.04). **Conclusion:** Participating in a cancer clinical trial after DAA treatment enhances survival for patients with cancer and chronic HCV infection.

1416 | RE-ENGAGEMENT TO RESCUE THERAPY WITH SOFOSBUVIR/VELPATASVIR/VOXILAPREVIR IN HEPATITIS C AFTER DIRECT-ACTING ANTIVIRAL FAILURE

Wonseok Kang[1] Ki Tae Yoon[2] sang gyune kim[3] Moon Young Kim[4] Jae Yoon Jeong[5] Hyung Joon Yim[6] Byoung Kuk Jang[7] Soo Young Park[8] Tae Hee Lee[9] Seung Up Kim[10], [1]Samsung Medical Center, [2]Pusan National University Yangsan Hospital, [3]Soonchunhyang University Bucheon Hospital, [4]Yonsei University Wonju College of Medicine, [5]Ewha Womans University Mokdong Hospital, [6]Korea University Ansan Hospital, [7]Keimyung University School of Medicine, [8]Kyungpook National University Hospital, [9]Konyang University College of Medicine, [10]Yonsei University College of Medicine

Background: Sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) became available in South Korea in late 2022, enabling rescue therapy for patients with chronic hepatitis C who had failed previous direct-acting antiviral (DAA) treatment. This study aimed to re-engage patients who were lost to follow-up after DAA failure. **Methods:** A prospective observational study was conducted at 10 tertiary medical centers in South Korea. Investigators identified patients who had previously received DAA therapy at each center and screened them for eligibility for SOF/VEL/VOX. Eligible patients were reached through phone outreach by investigators for re-engagement. SOF/VEL/VOX was administered to patients who provided written informed consent, and treatment response was assessed. **Results:** Among 4,439 patients who had received DAAs, 58 (1.3%) were lost to follow-up after treatment failure. Of these, 45 patients (77.6%) were eligible for SOF/VEL/VOX. Nineteen patients (42.2%) were successfully reached, and 8 (42.1%) returned for an in-person visit. Written informed consent was declined or withdrawn by 3 patients due to financial concerns or advanced age. Ultimately, 5 patients (62.5%) initiated SOF/VEL/VOX treatment, and all achieved a sustained virologic response at 12 weeks post-treatment. **Conclusion:** The introduction of SOF/VEL/VOX in Korea enabled the re-engagement of patients lost to follow-up after DAA failure and facilitated successful rescue therapy.

1417 | EFFECT OF DIRECT ACTING ANTIVIRAL TREATMENT ON HEPATIC STEATOSIS IN PATIENTS WITH CHRONIC HEPATITIS C

WonKyung Cho[1] Tom Ryu[2] Jae Young Jang[2] Young Chang[3] Soung Won Jeong[2] Young Deok Cho[2], [1]Long Island Jewish Forest Hills Hospital, Northwell Health, [2]Digestive Disease Center, College of Medicine, Soonchunhyang Univesity, [3]Soonchunhyang University

Background: Hepatic steatosis is a common comorbidity in chronic hepatitis C virus (HCV) infection, linked

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to accelerated liver disease progression and increased risk of hepatocellular carcinoma. With the advent of direct acting antivirals, HCV cure rate has exceeded 90%, and prognosis has improved drastically. However, the effect of direct acting antivirals on pre-existing liver pathologies, in particular hepatic steatosis is not well elcuidated. This study investigates steatosis evolution following DAA therapy and identifies associated clinical factors. **Methods:** We conducted a retrospective cohort study of 212 HCV-infected patients treated with DAAs between January 11, 2015, and December 31, 2022 at a tertiary medical center in South Korea. Steatosis was evaluated using controlled attenuation parameter (CAP) scores from FibroScan at baseline and 6 months post-treatment (SVR-24). Improvement was defined as ≥ 1 grade decrease in steatosis; worsening as ≥ 1 grade increase. Hepatic Steatosis Index (HSI) and laboratory profiles were also assessed. Adjusted odds ratio was calculated using multivariable logistic regression to identify predictors of steatosis improvement. **Results:** At baseline, 26.9% of patients exhibited hepatic steatosis (S1: 11.8%, S2: 8.5%, S3: 6.6%). Following SVR-24, 54.3% of patients with baseline steatosis showed improvement, 36.9% remained stable, and 8.7% worsened. Median CAP scores significantly decreased post-treatment ($p < 0.001$), while HSI slightly declined but remained above fatty liver threshold. Baseline liver function parameters and lipid panel tests were not associated with steatosis improvement. Lipid profiles showed increased total cholesterol and LDL levels post-SVR. Multivariable analysis revealed that advanced baseline steatosis (S2 OR 2.48, $p = 0.021$; S3 OR 2.20, $p = 0.028$) and high baseline HCV RNA load ($> 800{,}000$ IU/mL; OR 2.40) were independent predictors of steatosis improvement. **Conclusion:** DAA-induced HCV eradication led to hepatic steatosis improvement in over half of patients with baseline steatosis, especially among those with high viral load and advanced steatosis. These findings suggest that viral and burden may influence steatosis regression. Despite normalization of liver enzymes, metabolic parameters such as HSI and LDL remained elevated, underscoring the need for continued metabolic risk management post-SVR. Prospective studies with longer follow-up and histologic validation are warranted to confirm these findings and assess long-term impact on liver outcomes.

1418 | SOFOSBUVIR BASED REGIMENS ARE EFFECTIVE FOR HEPATITIS C TREATMENT IN PATIENTS WITH END-STAGE RENAL DISEASE IN REAL-LIFE SETTING

Radha Dhiman[1] Ajay Kumar Mishra[2] Dharmendra Bhadauria[2] Surender Singh[2] Anupma Kaul[2] SUMIT RUNGTA[3] Harshita Katiyar[2] Manas Behera[2] Monika Yachha[2] Narayan Prasad[2] Amit Goel[2], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [3]King George's Medical University, Lucknow, India

Background: Sofosbuvir is a major drug in directly acting antiviral (DAA) drug regimens for HCV treatment. In patients with chronic kidney disease (CKD) and estimated glomerular filtration rate (eGFR) < 30 mL/min, the experience of sofosbuvir (SOF) based regimens is limited. We report real-life experience of treating a cohort of CKD patients with eGFR < 30 mL/min using sofosbuvir based regimens. **Methods:** Adults CKD patients who had eGFR < 30 ml/min and detectable HCV RNA were included in the study ($n = 262$). They were treated with full dose SOF (400 mg) in combination with either Velpatasvir (VEL) 100 mg or Daclatasvir (DAC) 60 mg. Regardless of DAA combination, those without cirrhosis or decompensated cirrhosis were treated for 12 and 24 weeks respectively. Those with compensated cirrhosis were treated for 12 (SOF/VEL) or 24 (SOF/DAC) weeks. Primary outcome measure was proportion of participants who could achieve sustained virological response after 12 weeks (SVR12) of treatment completion. **Results:** 271 infection episodes (262 new- or 9 re-infections) in 262 participants (men 74.1%; age 42 [32-52] years; on hemodialysis 231/262 [88.2%]; dialysis duration 15 [9-25] months; no-cirrhosis 221, 84.4%; HCV RNA(log10) 7.4 [3.6-9.1]) were treated with either SOF/DAC (201; 74.2%) or SOF/VEL (70; 25.8%). SVR12 could be tested for 226 (SOF/DAC 171, SOF/VEL 55) of 271 episodes (83.4%). Overall, SVR12 was achieved for 215 treatment episodes (intention-to-treat [ITT] analysis 215/271, 79.3%; per-protocol [PP] analysis 215/226, 95.1%). SVR12 was not affected by presence of cirrhosis (ITT no-cirrhosis 79.9% vs cirrhosis 76.2%, $p = 0.144$; PP cirrhosis 88.9% vs no-cirrhosis 96.3%, $p = 0.058$), DAA combination used for treatment (ITT SOF/DAC 94.7% vs SOF/VEL 96.4%, $p = 0.626$; PP

SOF/DAC 80.6% vs SOF/VEL 75.7%%, p = 0.404), or hemodialysis status (ITT dialysis 79.7% vs no-dialysis 77.5%, p = 0.234; PP dialysis 94.4% vs no-dialysis 100%, p = 0.175). Eleven patients (9 SOF/DAC, 2 SOF/VEL; 7 non-cirrhosis, 4 cirrhosis) failed to achieve SVR (4.9%). Six of the nine retreatment episodes (8 second episode and 1 third episode after 8[4-13.5] and 6 months after SVR12) were tested for SVR12 and five achieved SVR12. **Conclusion:** Sofosbuvir in combination with daclatasvir or velpatasvir are highly and equally effective against HCV in CKD patients with eGFR below 30 mL/min.

1419 | EVALUATING PROGRESS TOWARD HEPATITIS C ELIMINATION IN THE UNITED KINGDOM: A REAL-WORLD ANALYSIS USING NATURAL LANGUAGE PROCESSING

Mahd Siddiqi[1] Saima Ajaz[1] Mohammad Al-Agil[1] Kosh Agarwal[1], [1]Kings College Hospital, London, United Kingdom

Background: The UK has made significant strides in hepatitis C virus (HCV) control through national screening initiatives and the broad rollout of direct-acting antivirals (DAAs). These efforts support the WHO's goal to eliminate HCV as a public health threat by 2030. However, most countries remain off track, with only 12 countries globally, including the UK, projected to meet elimination targets. Our aim was to provide a real-world overview of HCV diagnoses, treatment patterns, and clinical outcomes before and after national screening and treatment initiatives were introduced. We assessed the impact of these programmes on key clinical endpoints, including cirrhosis, hepatocellular carcinoma (HCC), liver transplantation, and all-cause mortality. **Methods:** This study involved the retrospective analysis of electronic health records (EHRs) from patients with HCV RNA-positive at King's College Hospital, London, between the years 2013 and 2023. Structured and unstructured clinical data were extracted using CogStack, a natural language processing (NLP) platform. Variables included yearly new diagnoses, demographics, fibrosis level (LSM), liver function tests, cirrhosis status, DAAs treatment initiation, and clinical outcomes (mortality, HCC, liver transplant). Statistical analysis identified trends and factors influencing HCV incidence and clinical outcomes over the decade, coinciding with broader public health screening and elimination efforts. **Results:** Using CogStack, we identified 10,171 HCV RNA-positive patients. The cohort had a male predominance (62% male, 38% female). Ethnicity distribution was: White (58.6%), Unknown (20.1%), Black (12.6%), Other (5.3%), Asian (3.7%), and Mixed (0.3%). Evidence of cirrhosis was found in 2,696 patients (27.3%), 1,256 (12.7%) had documented HCC, and 226 (2.3%) underwent liver transplantation. Annual HCV RNA-positive diagnoses declined significantly, from 2,123 in 2013 to 291 in 2023, an 86.3% reduction, with a compound annual decline of 18.0%. Similarly, cirrhosis fell from 321 to 72 (–77.6%; –14.0% annually), HCC from 195 to 63 (–67.7%; –10.7%), and transplants from 35 to 15 (–57.1%; –8.1%). The Mann–Kendall test confirmed significant monotonic declines for all outcomes (RNA $\tau = -0.85$, $p < 0.001$; cirrhosis $\tau = -0.56$, $p = 0.020$; HCC $\tau = -0.53$, $p = 0.029$; transplant $\tau = -0.56$, $p = 0.020$). **Conclusion:** The marked downward trends in HCV diagnoses and related liver complications over the past decade highlight the success of the UK's coordinated screening and DAA treatment programmes in moving toward WHO elimination goals. Importantly, the use of CogStack's proved critical in rapidly harnessing both structured and narrative clinical data, offering a scalable model for ongoing surveillance and optimisation of public health strategies.

1420 | REAL-WORLD OUTCOMES OF SOFOSBUVIR/VELPATASVIR IN A VARIETY OF HEPATITIS C PATIENT POPULATIONS: A RETROSPECTIVE COHORT STUDY

Hyun Young Woo[1] Jeong Heo[1] Young Joo Park[1] Ki Youn Yi[1], [1]Pusan National University Hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Sofosbuvir/velpatasvir (SOF/VEL) has revolutionized the treatment of hepatitis C virus (HCV) by providing a promising option for virus elimination across various patient groups. However, there is a need for more comprehensive real-world studies to assess its efficacy and safety specifically in the Korean population with chronic hepatitis C (CHC), where diverse clinical scenarios and patient characteristics may influence treatment outcomes. The aim of our study was to assess the effectiveness and safety of SOF/VEL-based treatment for CHC patients in Korea. **Methods:** In this real-world observational study, we recruited patients at tertiary hospital in South Korea. Patients were administered SOF/VEL (400/100mg) ± ribavirin (RBV) once daily for 12 weeks or 24 weeks. The primary efficacy endpoint was sustained virological response at post-treatment week 12 (SVR12). Adverse events (AEs) were evaluated during treatment. **Results:** This study included 87 patients (median age, 65, male, n = 50) with HCV genotypes 1 (1a+1b, n = 52), 2 (2, 2b, 2a/2c, n = 34) and 1b&2b (n = 1), as well as two cases of HBV coinfection and two cases of HIV coinfection. 46% (n = 40) of the patients included in this study had cirrhosis, 8.0% (n = 7) had a Child-Pugh score of B, and 25.3% (n = 22) were diagnosed with hepatocellular carcinoma (HCC). BCLC HCC stage is A in 4, B in 11 and C in 7 patients and 18 patients have viable HCC at the start of HCV treatment. Thirty-one patients had prior HCV treatment experience, including three with interferon (IFN) based treatment, 20 with direct acting antivirals (DAA) treatment, and eight with DAA treatment after failing IFN therapy. Among them, 98.6% [86/87, intention to treat (ITT)] and 100% [86/86, modified ITT (mITT)] received SOF/VEL. At the end of treatment, 95.4% (ITT, 83/87) and 100% (mITT, 83/83) of patients had undetectable HCV RNA. SVR12 rates were 90.8% (ITT, 79/87) and 98.7% (mITT, 79/80). In the mITT analysis, SVR12 for patients with cirrhosis and HCC was 100% and 100%. AEs occurred in eight patients but improved with symptomatic treatment. Twenty-eight patients received SOF/VEL + RBV, and among them, eight had their RBV dose reduced; however, all achieved a 100% SVR12. **Conclusion:** This study demonstrated that the SOF/VEL ± RBV achieved excellent treatment outcomes and was well tolerated in Korean patients with CHC, despite a significant proportion of patients having cirrhosis or HCC

1421 | WOMEN OF CHILDBEARING AGE WITH UNTREATED OR INCOMPLETELY DIAGNOSED HEPATITIS C VIRUS: INTERIM RESULTS: OF A PROSPECTIVE COHORT AND LINKAGE-TO-CARE PROGRAM

Mai Sedki[1] Matthew Caliz[2] Jeff McKinney[2] Jennifer Price[2] Katrina Alcantara[2] Tasha Toliver[2] Michael Helle[2] Rena Fox[3], [1]University of California San Francisco, Stanford University, [2]University of California San Francisco, [3]University of California, San Francisco

Background: Women of childbearing age living with hepatitis C virus (HCV) are a population for whom timely diagnosis and pre-pregnancy antiviral treatment is important to reduce vertical transmission and improve long-term maternal outcomes. Two studies found younger women were less likely to progress through the HCV care cascade than the general HCV population. We identified a prospective cohort of adult women age 18-50 with HCV viremia or incompletely diagnosed HCV and implemented a targeted intervention to improve linkage to care among these patients. **Methods:** Using the electronic medical record (EMR), we identified adult women of childbearing age, defined as age 18–50, seen between 2020–2024 at a large urban health system, with either 1) a quantified or detected HCV RNA at most recent testing, or 2) a reactive HCV antibody without HCV RNA testing. Cirrhosis was identified by ICD-9/10 code followed by chart review of clinical notes. Two trained navigators reviewed any non-searchable EMR data from external systems and excluded patients with more recent negative HCV RNA results. Navigators placed ≥3 phone calls to contact patients to offer updated HCV testing and linkage with HCV specialists. No study incentives were provided. Interim results are presented. **Results:** The initial query identified n = 138 patients. After manual review of external laboratory data, the cohort consisted of 72 of whom 56% were White and 62% had Medi-cal insurance. Only 5 had a primary care provider, 60 (85%) were viremic, 11 (15%) were Ab+ without RNA testing, and 5 had cirrhosis. To date, 33 (46%) have been successfully contacted; among these, 22 agreed to a video visit, 19 visits have been scheduled, 13 visits have been completed, and 4 have started DAA treatment. Reasons for no-shows/cancelled appointments (n = 6) included evictions, accidents, drug use, lack of phone service, homelessness, and other stressors. **Conclusion:** Finding and treating women with untreated and incompletely diagnosed HCV is achievable. Our EMR algorithm identified those with HCV RNA+ or HCV Ab+ without RNA testing and we increased accuracy with outside RNA results. Our outreach successfully contacted almost half of the cohort by phone and to date, 30% of the patients who linked to care have initiated DAA therapy. Major psychosocial stressors were the primary

1422 | METABOLIC IMPLICATIONS OF HDL-C/APOA1 RATIO IN HCV-INFECTED PATIENTS: A COMPARATIVE ANALYSIS OF DIABETIC AND NON-DIABETIC PATIENTS FOLLOWING SUSTAINED VIROLOGICAL RESPONSE

Irina Duport-Dodot[1] Mihai Dodot[2] Irina Sirbulescu[3] Isabela Staicu[1] anca negru[4] Anca Saran[4] Smaranda Gata[5] Laurentiu Stratan[6] Catalin Tiliscan[7] Adrian Gabriel MARINESCU[8] Sorin Arama[9] Victoria Arama[10], [1]INBI "Prof. Dr. Matei Bals, [2]UMF, I.C Fundeni, [3]INBI Prof. Dr. Matei Bals, [4]UMF "Carol Davila", INBI "PRof. Dr. Matei Bals", [5]INBI "PRof. Dr. Matei Bals", [6]UMF "Carol Davila", INBI Prof. Dr. Matei Bals, [7]UMF "Carol Davila", INBI "PRof. Dr. Matei Bals, [8]UMF "Carol Davila", INBI "Prof Dr. Matei Bals, [9]UMF "Carol Davila", INB I "PRof. Dr. Matei Bals", [10]UMF "Carol Davila, INBI "Prof. Dr. Matei Bals"

Background: The HDL-Cholesterol (HDL-C) to apolipoprotein A1 (ApoA1) ratio reflects both HDL-C levels and its functional quality. A decreased ratio indicates dysfunctional HDL, which is linked to higher cardiovascular and metabolic risks, particularly in the context of chronic inflammation and type 2 diabetes (T2DM). This ratio is considered to offer greater prognostic value compared to HDL-C levels alone, underscoring its importance in the field of hepatology and overall metabolic health. **Methods:** This study assessed HDL-C and ApoA1 ratio changes in chronic hepatitis C (HCV) infected patients with and without T2DM one year after sustained virological response (SVR). Statistical analysis used SPSS 22, with Chi-squared and t-tests, considering $p < 0.05$ as significant. **Results:** We conducted a retrospective study on 100 HCV-infected patients treated with direct-acting antivirals (DAAs), which were administered according to the national protocols, at the National Institute for Infectious Diseases, Prof. Dr. Matei Bals, Bucharest, between September 2016 and August 2019. The study group was divided into two subgroups according to the presence of T2DM. We evaluated the kinetics of HDL-C and the ApoA1 ratio across the two groups as a marker of lipid metabolism evolution. The study group consisted of 57 females and 43 males. The mean age at treatment initiation was 63 years $\pm$ 9.1 years. All patients were assessed at the initiation of treatment and one year after. At the initiation of the IFN-free treatment, the mean HDL-ApoA1 ratio in the study population was 33.06 $\pm$ 6.86. The diabetic group had a lower ratio than the non-diabetic group (29.6 vs 35.1, $p = 0.124$). One year after treatment completion, the mean HDL-C and ApoA1 ratio was 36.07 $\pm$ 7.25, with an overall increase of 3.22 $\pm$ 7.63. One year after treatment completion, the T2DM patients maintained a significantly lower mean ratio than the non-diabetic patients (33.2 versus 39.04, $p = 0.01$). The increase in HDL-C–ApoA1 ratio was higher in the nondiabetic group compared to the diabetic group (6.36 versus 0.5, $p = 0.14$). **Conclusion:** This study found that the ratio of HDL-C to ApoA1 increased one year following HCV treatment, with non-diabetic patients exhibiting a more significant improvement compared to those with T2DM. This indicates that diabetes might impede lipid recovery even after eradicating HCV infection, highlighting the importance

of continued metabolic management. Monitoring HDL-C and ApoA1 ratio kinetics after antiviral therapy can provide more accurate insights into metabolic risk stratification in these populations.

1423 | PREDICTION RISK SCORE FOR DEVELOPMENT OF HEPATOCELLULAR CARCINOMA IN COMPENSATED ADVANCED CHRONIC HEPATITIS C AFTER SUSTAINED VIROLOGICAL RESPONSE

Sirajuk Khongviwatsathien[1] Tawesak Tanwandee[2], [1]Siriraj Hospital, [2]Siriraj Hospital/Mahidol University

Background: Hepatocellular carcinoma (HCC) remains a major cause of cancer-related mortality in patients with chronic hepatitis C virus (HCV) infection, even after achieving sustained virological response (SVR). Current guidelines recommend lifelong HCC surveillance in individuals with compensated advanced chronic liver disease (cACLD) following SVR. However, this approach imposes a considerable burden on healthcare systems. Stratifying HCC risk using simple, noninvasive tools may enhance the efficiency of surveillance, particularly by identifying low-risk patients who may not require routine screening. **Methods:** We conducted a retrospective study of patients with cACLD due to chronic HCV infection who achieved SVR following treatment with direct-acting antivirals (DAAs) at Siriraj Hospital between 2013 and 2023. Patients with a history of HCC or a follow-up duration of less than 12 months were excluded. Four noninvasive scoring systems—FIB-4, APRI, ALBI, and aMAP—were calculated at 12 weeks post-treatment. Predictive performance for HCC development at 1, 3, 5, and 8 years was assessed using ROC curve analysis (AUC), and Cox regression was used to identify associations with HCC development. Optimal aMAP score cutoffs were determined using Youden's J-statistic. **Results:** Out of 2,971 patients screened, 571 met the inclusion criteria. During a median follow-up of 4.59 years, 78 patients (13.7%) developed HCC, with an annual incidence of 3.12% (95% CI: 2.50–3.80). Among all models, aMAP demonstrated the highest predictive performance (AUC = 0.74; 95% CI: 0.67–0.80). Patients were stratified into three risk categories based on aMAP scores: low risk (< 55) with no HCC cases observed, intermediate risk (55–60) with an annual incidence of 0.01–2.42%, and high risk (> 60) with an annual incidence of 2.43–6.42%. Our study suggests that an aMAP score < 55 effectively excludes patients from the need for routine HCC surveillance. This threshold aligns with previous findings that identified a cutoff of < 50 as low risk across various cACLD etiologies (Fan et al., J Hepatol, 2020). The slightly higher cutoff in our cohort may reflect improvements in liver status after SVR specific to HCV-related cACLD. **Conclusion:** Our findings demonstrate that the aMAP score provides the strongest predictive performance (AUC = 0.74) compared to FIB-4, APRI, and ALBI. An aMAP cutoff of < 55 can reliably exclude cACLD HCV patients from post-SVR HCC surveillance. Adoption of this threshold may safely reduce the number of patients requiring routine surveillance, easing the strain on healthcare resources. If validated in other HCV-specific cohorts, this revised cutoff could inform future surveillance guidelines.

Diagnostic accuracies for the detection of de novo HCC at 1-, 3-, 5-, and 8-year follow-up, and the predictive performance of the four noninvasive scoring systems (NSS).

NSS* (3 months after EOT)	1-Year FU AUC (95% CI)	3-Year FU AUC (95% CI)	5-Year FU AUC (95% CI)	Overall HCC, 8-Year FU AUC (95% CI)
FIB-4	0.64 (0.49-0.78)	0.69 (0.59-0.79)	0.69 (0.60-0.78)	0.69 (0.61-0.78)
APRI	0.61 (0.46-0.75)	0.67 (0.57-0.77)	0.65 (0.56-0.75)	0.66 (0.57-0.75)
ALBI	0.59 (0.44-0.73)	0.67 (0.58-0.76)	0.66 (0.57-0.74)	0.65 (0.56-0.74)
aMAP	0.74 (0.62-0.85)	0.76 (0.68-0.83)	0.74 (0.67-0.82)	0.74 (0.67-0.80)

* Noninvasive scoring system calculated at 3 months after end of treatment

1424 | FACTORS ASSOCIATED WITH HEPATITIS C INFECTION IN SUB-SAHARAN AFRICA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Nkengeh Tazinkeng[1] Sonia Yonta Kenne[2] Jan René Nkeck[3] Monela Ntonifor[4] Fatima Elmustafa[5] Ryan Tanjoh[6] Ephesians Anutebeh[7] Yasmin Osman Ali[8] Adedeji Adenusi[9] David Makanga[7] Lydia Lantum Dzeenyuy[10] Cameg-Brenda Meriki[11] Emmanuel Agyemang[7] Noon Altijani[12] Valirie Ndip Agbor[13], [1]Rutgers/Newark Beth Israel Medical Center, [2]Centre Hospitalier de l'Estran, Pontorson, France, [3]Faculty of Medicine and Biomedical Sciences, University of Yaoundé I, Cameroon, [4]North Carolina Agricultural and Technical State University, North Carolina, USA, [5]Henry Ford Hospital System, Michigan, USA, [6]South Liverpool & Birkenhead GP training program, Mersey and West Lancashire Hospitals NHS Trust, UK, [7]Rutgers/Newark Beth Israel Medical Center, New Jersey, USA, [8]Hennepin Healthcare, Minnesota, USA, [9]One Brooklyn Health-Interfaith Medical Center, New York, USA, [10]Faculty of Health Sciences, University of Buea, Cameroon, [11]Faculty of Health Sciences, University of Bamenda, Cameroon, [12]Postgraduate Team, Education Centre, Liverpool University Hospitals NHS Foundation Trust, UK, [13]Department of Clinical Sciences,Global Health Trials Unit, Liverpool School of Tropical Medicine,UK

Background: Despite the advances in diagnosis and treatment of Hepatitis C virus (HCV) infection, there is still a growing trend in incidence in low-middle income countries where universal screening programs and linkage to care still face severe financial and logistical complexities. With lack or insufficient domestic funding, there is a need for targeted screening programs among high-risk groups. Previous evidence on the determinants of HCV in sub-Saharan Africa (SSA) has been limited by small sample sizes. This systematic review and meta-analysis investigated the factors associated with HCV infection in SSA. **Methods:** Following the PRISMA guidelines, we conducted a comprehensive search on MEDLINE, Embase, Global Health Library, and Africa-specific databases (AFROLIB, African Index Medicus and African Journals Online) for articles published in English from inception of the databases to 27 October 2024. Random-effects meta-analytic models were used to calculate pooled log-transformed odds ratios (ORs) and their variances to evaluate the determinants of HCV infection. Heterogeneity across studies was assessed using the I^2 statistic and Cochran's Q test. **Results:** We included 72 studies with a total sample of 1,094,104 participants. Most included studies were cross-sectional studies (65/72) and were published between 2011 and 2020 (45/72). East (n = 30) and West Africa (n = 24) had the most publications, with Ethiopia (n = 19), Nigeria (n = 6) and Ghana (n = 9) contributing the most publications.The following factors were associated with significantly higher odds of HCV infection: sharing razors (pooled OR 4.2, 95% confidence interval: 1.3–13.8), history of blood transfusion (2.5, 1.5–4.2), History of dental procedures (4.6, 2.3–9.1), history of STI (2.4,1.5–3.8), and HIV infection (2.1, 1.6–2.9). **Conclusion:** This study suggests that HCV transmission in SSA is multifactorial and driven by household and health-care related exposures. These insights highlight the importance of strengthening infection prevention practices in healthcare and community settings and the need for targeted public health interventions such as education, screening and access to treatment for high risk individuals.

1425 | PREDICTORS OF REINFECTION AMONG PARTICIPANTS IN A HEPATITIS C TREATMENT TRIAL IN RURAL KENTUCKY

Jennifer Havens[1] Takako Schaninger[2] Michelle Lofwall[1] Sharon Walsh[1], [1]University of Kentucky College of Medicine, [2]University of Kentucky Medical Center

Background: Direct acting antivirals (DAAs) have revolutionized treatment for hepatitis C virus (HCV) infections. However, treatment delivery is disjointed in the United State (U.S.), especially among marginalized groups in under resourced areas. The purpose of the current analysis was to examine the factors associated with HCV reinfection among participants in an HCV treatment trial. **Methods:** Patients (n = 380) consented to participate in the Kentucky Viral Hepatitis Treatment (KeY Treat) trial, a test and treat model of care in a rural Appalachian county in the U.S. Most consenting participants (n = 368) initiated sofosbuvir/velpatasvir and 22.3% were lost-to-follow-up (LTFU) during the treatment phase. Sustained Virologic Response (SVR-12) was achieved by 306 participants, who represent the sample for the current analysis. Participants were tested using the Xpert HCV VL fingerstick assay at 6- and 12-months post-SVR to determine reinfection and Cox proportional hazards models were used to model reinfection. **Results:** Fourteen reinfections were detected corresponding to a reinfection rate of 4.3 per 100 person years (95% Confidence Interval: 2.5, 7.3). Most (85%) reinfections were detected within a year of SVR. Males were nine times more likely to be reinfected than females ($p < 0.001$). Injecting drugs during the period between SVR and follow-up was predictive of reinfection (adjusted Hazard Ratio [aHR]: 7.35, 95% Confidence Interval [CI]: 2.46, 21.9), as was being incarcerated prior to or at the time of reinfection. Enrollment in a medication for opioid use disorder (MOUD) program was protective against reinfection (aHR: 0.24, 95% CI: 0.07, 0.67). **Conclusion:** The low overall HCV reinfection rates observed in this study support engaging people who inject drugs in DAA treatment. Consistent with the literature, a significant risk factor for reinfection was ongoing injection drug use after cure. Given that MOUD decreases injection opioid use and MOUD engagement was protective against reinfection herein, we call for increasing access to DAA treatment within MOUD treatment programs, including MOUD programs in carceral settings. The recently updated U.S. recommendations for establishing cure at four weeks post-treatment (SVR4) versus 12 (SVR12) will encourage earlier counsel around safe injection practices and engagement in MOUD to prevent reinfection.

1426 | UNCOVERING THE URBAN-RURAL HIDDEN BURDEN OF HEPATITIS C: A POPULATION-BASED STUDY IN SOUTHERN ITALY

Torre Pietro[1] Silvana Mirella Aliberti[1] Tommaso Sarcina[1] Mariano Festa[1] Chiara D'Amore[1] Giuseppe D'Adamo[2] Michele Gambardella[3] Antonella Santonicola[1] Gaetano Manzi[1] Mario Masarone[1] Mario Capunzo[1] Marcello Persico[1], [1]University of Salerno, Italy, [2]Internal Medicine, Umberto I Hospital, ASL SA, [3]Infectious Disease Unit, San Luca Hospital, ASL SA

Background: Although major advances in treatment have made it possible to cure HCV infection today, this disease still represents a significant global challenge, as WHO hepatitis C elimination targets are not achievable in most countries, mainly due to the high number of undiagnosed people. The primary objective of this study was to estimate the hidden burden of chronic HCV infection across the vast territory of the province of Salerno (Campania region), in Southern Italy. **Methods:** Records of patients with confirmed diagnosis of chronic HCV infection between 2015 and 2022, limited to residents of the province of Salerno, were retrieved from the prescribing centers active in that area. Age, sex, municipality of residence, HCV genotype, and liver fibrosis stage were considered in the analysis. The estimate of the hidden burden was achieved by considering observed and expected prevalence of active infection, derived from regional and national benchmarks. Municipalities were classified as urban or rural based on the resident population. **Results:** Between 2015 and 2022, a total of 3528 confirmed cases of chronic HCV infection were identified across 138 municipalities in the Province of Salerno. Patient characteristics showed a marked predominance of older individuals (mean age of 63 years), a slight male predominance (54%), about 50% of patients diagnosed with advanced liver disease (F3–F4), and genotype 1b as the most prevalent. The hidden burden of active HCV cases increased with age, except for the younger age group, and was greater in rural areas than in urban ones. Multivariable logistic regression showed that older age, urban residence, and genotype 1b were significant predictors of F3–F4 fibrosis at the time of diagnosis. **Conclusion:** To reach HCV elimination goals, targeted interventions in underdiagnosed areas are crucial. Addressing the hidden

burden of HCV, however, requires more than just expanded screening coverage; it necessitates a deep knowledge of the complex interplay between health system accessibility, past exposure risks, and the sociocultural contexts that shape hepatitis C diagnosis, linkage-to-care, and treatment. Our municipal-level classification system, coupled with the estimate of hidden cases, could offer a replicable model for supporting precision public health strategies.

1427 | ★ HCV DAA PRESCRIBING PATTERNS AMONG SPECIALISTS AND NON-SPECIALISTS IN ONTARIO, CANADA, FROM 2017-2024

Mia Biondi[1] Andrew Mendlowitz[2] Camelia Capraru[3] Jordan Feld[3], [1]York University, Viral Hepatitis Care Network, [2]Toronto General Research Institute, Viral Hepatitis Care Network, University Health Network, [3]Viral Hepatitis Care Network, University Health Network

Background: As of 2018 in Canada, fibrosis eligibility restrictions for HCV direct acting antivirals (DAAs) were removed. While there was a large uptake in treatment among patients awaiting alternatives to interferon-based therapy, prescribing in Canada has continued to decrease each year since. While efforts to expand treatment to non-specialists have intensified; it is unclear whether this has occurred. We evaluated prescribing patterns of DAAs by specialty provider type in Ontario from 2017-2024, the largest province in Canada. **Methods:** The IQVIA database was used to assess DAA dispending from 2017-2024. Year, molecule, prescriber type, and first three digits of the pharmacy postal code were available. Specialties were collapsed into: Gastroenterology/Hepatology (G/H), Microbiology/Infectious Diseases (M/ID), Internal Medicine (IM), Family Medicine/General Practitioner (FM/GP), Nurse Practitioner (NP), Pediatrics, and other. We used linear regression to assess prescribing trends. **Results:** Total DAA prescriptions in Ontario in 2017 were 6027, which decreased to 4185 in 2020, had a slight rebound in 2021 and 2022, and went down to 4116 in 2024. Most specialties had decreased prescribing in 2020, with peak years in 2017-2018 and have gone down each year since, apart from NPs (Figure 1). After adjusting for specialty, prescribing volume showed a significant year-to-year decline of 63.2 (95%CI: 18.9 to 107.6; $p < 0.05$). Specialty-specific trends showed G/H volumes with the highest decline of 206.5 (95%CI: 104.2 to 308.7; $p < 0.05$) per year, followed by IM with 101.9 (95% CI: 42.7 to 161.2; $p < 0.05$) per year. In contrast, NP volumes increased over time, by 105.6 (95%CI: 9.8 to 201.4; $p < 0.05$) per year; for over a quarter of all prescriptions in the province by 2024. From 2017-2024, there were a total of only 31 prescriptions by pediatricians, despite estimates ~200-1000 children living in Ontario with HCV. **Conclusion:** In Ontario, all specialities have been able to prescribe since the public funding of DAAs. Despite efforts to engage FM/GPs in programmatic approaches to screen and treat HCV, prescribing continues to decrease; concerning as FMs/GPs largely lead OAT and methadone programs. Prescribing amongst NPs has increased, likely due to NP-led outreach, virtual care, and prescribing in community health centres. While this demonstrates the value of engaging NPs, sustained and expansion of prescribing is required by other types of providers to reach elimination.

1428 | THE MAJORITY OF PATIENTS WITH HEPATITIS C NOT ACHIEVING SVR CAN BE SUCCESSFULLY RETREATED WITH FIRST-LINE REGIMENS: RESULTS: FROM A MULTIDISCIPLINARY TEAM APPROACH TO GUIDE TREATMENT DECISIONS

Stephen Barclay[1] Alison Boyle[1] Fiona Marra[1] Erica Peters[1] Emma Thomson[1] Samantha Shepherd[1] Janice McAvennie[1] Elaine Reilly[1], [1]NHS Greater Glasgow and Clyde

Background: Amongst people who inject drugs, sustained viral response (SVR) bloods following HCV treament may not always be available. Subsequent positive RNA tests may represent treatment failure, or reinfection. We discuss such cases in a Multidisciplinary Team (MDT) setting, using assessment of reinfection risk factors and compliance, testing for NS5A resistance (RAVs), and (where available) comparison of pre and post treatment viral sequences, to judge the likelihood of reinfection vs treatment failure, and hence the necessity for first or second-line antiviral regimens. We report treatment outcomes from this approach. **Methods:** From an HCV database, patients not achieving SVR with an initial DAA regimen, who received one or more subsequent DAA regimens were identified. Patients with a genotype switch (confirming reinfection) were excluded. Treatment completion, reinfection risk factors, NS5A resistance testing, nature of subsequent treatments (1st vs 2nd line) were recorded, along with the outcome of each retreatment. **Results:** 243 patients were identified. 12/243 (4.9%) were excluded due to genotype switch. 65/231 (28.1%) had incomplete initial treatment. 139 (60.2%) had end of treatment response (EOTR) with subsequent positive RNA, 20 (8.65%) were positive at end of treatment, with the remainder positive at first test beyond end of treatment (SVR timepoint or later). A total of 263 retreatments were given, 176 (66.9%) 1st line (103 glecaprevir/pibrentasvir, 28 sofosbuvir/velpatasvir, 20 grazoprevir/elbasvir, 18 sofosbuvir/ledipasvir, 7 others) and 87 (33.1%) 2nd line (76 sofosbuvir/velpatasvir/voxilaprevir, 11 others).98 (37.2%) had documented risk factors for reinfection. 183 (69.6%) had RAV testing prior to treatment, 64 (34.9%) of which were positive. Intention to treat SVR rate was 199/263 (75.7%); 129/176 (73.3%) 1st line vs 70/87 (80.4%), $p = 0.20$. Excluding 19 with incomplete treatment, 7 reinfections and 21 with missing SVR data, per protocol SVR rate was 199/216 (92.1%); 129/141 (91.5%) 1st line vs 70/75 (93.3%) 2nd line, $p = 0.22$. **Conclusion:** An MDT approach to treatment failure, combined with resistance testing where available, allows for the majority of patients to be retreated with 1st line DAA regimen, with comparable rates of SVR to those treated with 2nd line regimens.

1429 | CLINICAL CHARACTERISTICS AND RISK FACTORS OF HCV GT3 PATIENTS IN QINGHAI PROVINCE

Faying Li[1] Guoying Yu[1], [1]Infectious Disease Specialized Hospital of Qinghai Province

Background: Qinghai is a province in China with a high incidence of hepatitis C virus (HCV). The epidemiological characteristics of HCV genotype 3 (GT3) have not been clearly defined. The purpose of this study is to investigate the clinical characteristics of patients with HCV GT3 in Qinghai, and to lay the groundwork for developing appropriate prevention and treatment measures in the furture. **Methods:** A total of 755 HCV patients who tested positive for HCV antibodies and HCV RNA and had successful polymerase chain reaction (PCR) gene sequencing were prospectively enrolled at the Infectious Disease Specialized Hospital of Qinghai Province between January 2023 and December 2024. The clinical characteristics of patients with HCV GT3 were analyzed and independent risk factors for cirrhosis were identified using multifactorial regression modeling. **Results:** The prevalence of HCV GT3 in Qinghai Province showed an increasing trend (33.1%, 250/755), with HCV GT 3b being the most common subtype (71.6%, 179/250). Most HCV GT3 patients were significantly male (78.8%, 595/755), aged 40-60 years (89.6%, 677/755), and unemployed farmers (87.6%, 662/755). The main route of transmission was intravenous drug addiction (49.6%, 375/755). Compared with non-HCV GT3 patients, HCV GT3

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients had a higher incidence of cirrhosis (39.6% [99/250] vs. 16.4% [83/505], p **Conclusion:** In recent years, the infection rate of HCV GT3 patients in Qinghai has increased, predominantly of subtype 3b and it has been significantly associated with cirrhosis. It is recommended that high-risk populations be screened and that early treatment with pan-genotypic direct antiviral agents be used to improve prognosis.

1430 | IS SVR4 TESTING AN ACCEPTABLE ALTERNATIVE MEASURE OF HCV CURE IN RE-TREATED PATIENTS FOLLOWING DAA FAILURE? A SVR4/12 CONCORDANCE EVALUATION FROM THE POLARIS CLINICAL TRIALS

Stacey Scherbakovsky[1] Marc Bourliere[2] Stephen Shafran[3] Meena Bansal[4] Stuart Gordon[5] Stefan Zeuzem[6] Candido Hernandez[1] Renee-Claude Mercier[1] Kyle Hammond[7] Liyun Ni[1] Ira Jacobson[8], [1]Gilead Sciences, Inc, [2]Hopital Saint Joseph, [3]University of Alberta, [4]Icahn School of Medicine at Mount Sinai (ISMMS), [5]Henry Ford Health System, [6]University Hospital Goethe-University, [7]Gilead Sciences, Inc., [8]NYU Hepatology Associates

Background: Guidance from AASLD/IDSA and EASL have endorsed treatment simplification as part of a global call to action for HCV elimination. Within this simplification strategy, AASLD/IDSA has recently developed a New Algorithm for Hepatitis C Point of Care Testing and Treatment, in which SVR4 is an acceptable alternative measure of HCV cure for people without cirrhosis or prior DAA exposure. However, we hypothesize that SVR4 could also apply to vulnerable patients with prior DAA exposure, to help reduce the risk of patients being lost to follow-up (LTFU). For this reason, we evaluate the SVR4/12 concordance of sofosbuvir/velpatasvir/voxilaprevir (S/V/V) in randomized clinical trials (RCTs). The POLARIS studies included patients who had previously been treated with a DAA and failed.[1,2]. **Methods:** HCV RNA data from patients in the registrational POLARIS-1, -2, -3 and -4 RCTs evaluating treatment with S/V/V for 8 and 12 weeks were evaluated. SVR was defined as patients with HCV RNA less than the lower limit of quantification (15 IU/mL) using the COBAS TaqMan HCV Test v2.0. Only patients with both SVR4 and SVR12 data were included in the concordance analysis. **Results:** 1,056 patients were evaluated for concordance from the POLARIS (1-4) trials: 611 treated with 8 weeks of S/V/V (POLARIS 2,3) and 445 with 12 weeks of S/V/V (POLARIS 1,4). In the 8-week group, 583 (95.4%) patients achieved both SVR4 and SVR12 (True Positive), giving a 100% sensitivity and 98.8% positive predictive value (PPV) [7 patients achieved SVR4 but failed SVR12]. In the 8-week group, 21 patients failed to achieve both SVR4 and SVR12 (True Negative), showing a 75% specificity and 100% negative predictive value (NPV). In the 12-week group, 431 patients achieved both SVR4 and SVR12, showing 100% sensitivity and 98.9% PPV [5 patients achieved SVR4 but failed SVR12]. In the 12-week group, 9 patients failed both SVR4 and SVR12, showing a 64.3% specificity and 100% NPV. **Conclusion:** HCV treatment with S/V/V can be infrequent in the real world and achieving SVR4 is highly predictive of HCV cure. This earlier time point to confirm HCV cure may be particularly important in persons at high-risk to be LTFU.

1431 | PREVALENCE AND TRENDS OF HEPATITIS C VIRUS INFECTION AMONG PREGNANT WOMEN IN XI'AN, CHINA: AN 11-YEAR RETROSPECTIVE STUDY

Yingli He[1] gengwen liu[2] Wenjuan Shi[3] Qiao Zhang[1], [1]The First Affiliated Hospital of Xi'an Jiaotong University, [2]Xi'an People's Hospital (Xi'an Fourth Hospital), [3]Lanzhou Second People's Hospital

Background: Understanding the prevalence and temporal trends of hepatitis C virus (HCV) infection in pregnant women is critical for guiding prevention and elimination strategies. This study aimed to assess the seroprevalence and viremia rate of HCV among pregnant women in Xi'an, China, over an 11-years period. **Methods:** We conducted a retrospective analysis of pregnant women who admitted to the Obstetrics and Gynecology Specialized Hospital of Xi'an between January 2014 to December 2024. All patients underwent either quantitative or qualitative anti-HCV detection, and HCV RNA detection was performed for those who were anti-HCV positive. Trends in anti-HCV positivity and HCV RNA positivity were analyzed across two time periods: the first five years (2014.1.1-2019.6.30) and the second five years (2019.7.1-2024.12.31). **Results:** A total of 133,765 pregnant women were screened, of which 693 (0.518%) tested positive for anti-HCV, with a median age of 30 years (IQR: 28-33). The anti-HCV seroprevalence increased significantly increased from 0.46% (279 cases) in the first five years to 0.56% (414

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cases) in the second five years (P = 0.006). Among the anti-HCV positive women, 478 (68.98%) underwent HCV RNA testing,of whom 73 (15.27%) were HCV RNA positive, with a median age of 29 years (IQR: 27-32). Notably, the HCV RNA positive rate declined significantly from 23.08% (45/195) in the first five years to 9.89% (28/283) in the second five years (P = 0.000).However, a substantial proportion (31.03%, 215 cases) of anti-HCV positive women did not receive confirmatory HCV RNA testing, highlighting a critical gap in the diagnostic cascade. **Conclusion:** The findings of this study demonstrate a rising trend in anti-HCV seroprevalence while a declining trend in HCV viremia, possibly reflecting the improvements in awareness,screening and access to treatment for hepatitis C patients in China. However there remains significant gap for improvement in the diagnostic cascade. To support the action plan of HCV elimination in Shaanxi Province, a recall program targeting both anti-HCV positive and HCV RNA-positive individuals is currently being implemented to increase HCV RNA testing uptake and facilitate timely linkage to treatment with Direct-Acting Antivirals (DAAs), supporting the ongoing efforts to eliminate HCV in Shaanxi province.

1432 | HCV REINFECTION AFTER DAA THERAPY AMONG HIV/HCV-COINFECTED INDIVIDUALS IN THE COUNTRY OF GEORGIA: A NATIONAL COHORT STUDY, 2015-2024

Otar Chokoshvili[1] Lali Sharvadze[2] Natia Dvali[2] Pati Gabunia[2] Marine Karchava[2] Vladimer Getia[3] Lana Gatserelia[2] Revaz Metchurtchlishvili[2] Marine Ezugbaia[2] Akaki Abutidze[2], [1]T. Tsertsvadze Infectious Diseases and AIDS Center., [2]T. Tsertsvadze Infectious Diseases AIDS and Clinical Immunology Research Center, Tbilisi, Georgia, [3]National Center for Diseases Control and Public Health of Georgia

Background: Although direct-acting antivirals (DAAs) are highly effective in curing HCV infection in nearly all HIV/HCV-coinfected individuals, high rates of reinfection may impede efforts to eliminate HCV in this population. In 2015, with technical support of US CDC and commitment from Gilead Sciences to donate DAAs, Georgia launched the world's first hepatitis C elimination program, providing free access to DAAs to all patients, including HIV/HCV co-infected persons. We aimed to study rates of HCV reinfection among after sustained virological response (SVR) among HIV patients in the country of Georgia. **Methods:** A retrospective cohort study included HIV-positive adult patients treated with DAAs during 2015-2024 and who achieved SVR, defined as undetectable HCV RNA 12 weeks post-treatment. Patients were followed until their last HCV RNA measurement performed through December 31, 2024. Reinfection was defined as detectable HCV RNA after SVR. Data were extracted from Georgia's National HIV/AIDS Health Information System, a real-time, countrywide registry of HIV care and treatment. Rate of Reinfection was calculated per 100 person-years (PY) of follow-up. **Results:** During the study period 1,046 HIV/HCV co-infected patients achieved SVR. 764 (73.0%) were screed for HCV reinfection. Among them 679 (88.9%) were men and 531 (69.5%) had a history of injecting drug use (IDU). The median age was 51 (IQR:11) years. Patients were followed for median 3.3 (IQR: 6.2) years, contributing to 3,567 PY of follow-up. 43 (5.6%) patients had HCV reinfection with an overall incidence rate of 1.2 per 100 PY. The median time to reinfection was 4.3 years (IQR: 2.7). 40 out of 43 patients with reinfection had history of IDU. Three reinfections occurred among men who have sex with men (MSM). **Conclusion:** HIV positive IDUs are at high risk of HCV reinfection following successful DAA therapy, reinforcing the critical need for targeted prevention strategies. Greater engagement of patients in harm reduction services is crucial to prevent reinfection risks, particularly in this vulnerable population and achieve HCV elimination targets.

1433 | DEVELOPMENT OF NESTED-RPA BASED DIAGNOSTIC PLATFORM FOR THE IDENTIFICATION OF HCV RNA USING CRISPR/CAS13A SYSTEM

Senthil Venugopal[1] Teja Naveen Sata[1] Amrendra Kumar Sah[1] MD ISMAIL[1] Dr Shalimar[2] Baibaswata Nayak[2], [1]South Asian University, [2]All India Institute of Medical Sciences, New Delhi

Background: Chronic hepatitis C virus (HCV) is the second major hepatic viral burden after HBV. Screening tests are not widely accessible among high-risk populations worldwide. CRISPR-based detection platforms employing isothermal amplification methods have emerged as novel low-cost technology with high specificity and sensitivity. Cas13a, a class 2 type VI RNA targeting Cas protein, majorly employs collateral cleavage against single-stranded RNA. Cas13a detects the target RNA through its cis-cleavage, which is further activated to trans-cleave the fluorophore quencher

(FQ)-labelled ssRNA reporter and illuminate detectable fluorescent signals. **Methods:** Leptotrichia wadei (Lwa) cas13a was expressed and purified. Nested-Recombinase Polymerase Amplification (Nested-RPA) was implemented to produce T7 RNA polymerase appended amplicons of conserved HCV regions at 42°C and 37°C. Corresponding crRNAs have been designed against amplified regions and produced using In-Vitro Transcription (IVT). With T7 RNA polymerase, the Nested-RPA-amplified HCV templates are transcribed into ssRNAs, which are further used in detection assay containing expressed Cas13a protein, crRNA, and fluorescent probes. This detection was performed in the kinetic format of the microplate reader. **Results:** LwaCas13a was expressed in Rosetta2(DE3)pLysS strain and was purified using the strep tag. Conserved regions among Indian HCV genomes are selected as targets of detection. Nested RPA was performed using primers against the HCV RNA-dependent RNA polymerase (RdRp) region. CRISPR RNAs were produced using T7 RNA polymerase. The detection assay was optimized with HCV 3a genotype RNA. This system can detect HCV RNA as low as 1000 copies [1.65 femtomolar (fM)]. This system also successfully detected the HCV RNA as low as 1000 copies from the human serum samples. **Conclusion:** This approach can be utilized as an alternative in rural areas. At the same time, with high sensitivity for rapid detection of HCV, it could be used as a novel, low-cost diagnostics platform for identifying HCV RNA.

1434 | HEPATITIS C VIRUS (HCV) RNA POINT-OF-CARE TESTING IN A TRIBAL HEALTH SETTING: IMPLEMENTATION, CHALLENGES, AND LESSONS LEARNED

Jorge Mera[1] Kendra Lewis[1] Savana Christy[1] Andrea Blair[1] Ashley Comiford[1], [1]Cherokee Nation Health Services

Background: American Indian/Alaska Native populations have disproportionately high hepatitis C (HCV) rates and mortality. In 2015, Cherokee Nation Health Services launched an HCV elimination program that cured 99% of treated patients but achieved treatment initiation in under 60% of diagnoses. A 2023 expansion added community point-of-care (PoC) antibody screening, improving detection but requiring clinic visits for HCV RNA confirmation. To address delays and follow-up loss, CNHS was and early adopter of the FDA-approved PoC HCV RNA testing in fall 2024. The purpose of this study was to assess the effectiveness of using the PoC HCV RNA test to increase linkage to care and treatment initiation among a high-risk population, both in clinical and community settings. **Methods:** Using the Cepheid® Xpert HCV RNA platform, CNHS implemented PoC testing in tribal clinics and three community sites: a harm reduction program, a substance use recovery center, and a tribal specialty clinic. Adults (18+) visiting these sites who consented were eligible. Participants received incentives for screening and treatment initiation, and peer recovery support was available at community sites. Those testing positive were offered treatment at the tribal clinic if AI/AN or referred to external providers if non-AI/AN. Data from CNHS electronic health records and program reports were analyzed using descriptive statistics to assess test uptake, result validity, and treatment initiation. **Results:** From October 30, 2024, to May 23, 2025, overall 416 individuals were offered testing; 349 (83.9%) accepted, and 327 samples were adequate for analysis. Of those, 277 (84.7%) yielded valid results, with 26 testing HCV RNA-positive (9.4%). Twelve individuals were AI/AN, of whom nine initiated HCV direct acting antiviral agents (DAAs) treatment. Among 14 non-AI/AN positives, only one initiated HCV DAAs treatment. Sample collection challenges caused 15.3% invalid results, which improved over time with deeper-gauge lancets, hydration, and warming techniques. Incentives and peer support increased testing and linkage, but HCV treatment access for non-AI/AN individuals remained a barrier. **Conclusion:** PoC HCV RNA testing successfully identified undiagnosed infections and enabled same-day referrals, as well as HCV DAAs treatment initiation, addressing a critical gap in the HCV care continuum. As the first high-risk, community-based implementation program of its kind in this population, the findings offer valuable insights for scaling up HCV elimination strategies.

PoC HCV RNA by Location (October 30, 2024 - May 23, 2025)

Location	Test Offered	Accepted/ Collected	Tested	Test Valid	RNA Not-Detected	RNA Detected	Test Invalid

1435 | HCV TESTING AND LINKAGE-TO-CARE PRACTICES IN A TERTIARY HOSPITAL IN SOUTHERN ITALY UNDERSCORE THE NEED FOR ROUTINE SCREENING AND TREATMENT PROGRAMS

Torre Pietro[1] Enrica Serretiello[1] Giuseppe Di Siervi[1] Emilia Vaccaro[1] Mariano Festa[1] Tommaso Sarcina[1] Luigi Gallo[1] Mario Masarone[1] Pasquale Pagliano[1] Gianluigi Franci[1] Marcello Persico[1], [1]University of Salerno, Italy

Background: Direct-acting antivirals (DAAs) have had an extraordinary impact on curing and limiting the spread of HCV infection. According to that, screening programs have been established worldwide to achieve ambitious goals, including an 80% reduction in HCV incidence and a 65% reduction in HCV-related mortality by 2030. This study aimed to assess, within a large community tertiary hospital in Southern Italy, the proportion of HCV testing among inpatients and, subsequently, the proportion of positive patients referred for treatment. This analysis was also performed to identify any differences over the years and to provide evidence to support the need for more targeted and extensive future screening initiatives. **Methods:** This retrospective analysis was conducted at the University Hospital of Salerno in the Campania region, Italy, covering the period from 2016 to 2023. Hospital admissions data and the numbers of patients tested for anti-HCV antibodies (anti-HCV) and HCV-RNA were extracted from hospital information systems. The proportion of patients with active infection who received DAA therapy was also considered. **Results:** Within the specified time frame, about 320000 patients were admitted to the Hospital for various medical conditions. Among these, 116478 (36.4%) were tested for anti-HCV, and out of these, 4214 (3.6%) were found positive. This value showed an overall decreasing trend over the years (2016: 4.0%, 2017: 4.3%, 2018: 4.1%, 2019: 4.1%, 2020: 4.1%, 2021: 3.0%, 2022: 2.8%, 2023: 3.1%). Stratification by age showed that the highest anti-HCV positivity was found in the 71-80 age group. Among anti-HCV positive patients, 2120 (50.3%) underwent HCV-RNA testing (which means that a high percentage, 49.7%, were not tested for active infection). 1450 out of 2120 (68.4%) tested positive for HCV-RNA, with a decreasing trend over time (70.8% in 2016 vs. 60.0% in 2023). The percentage of patients with active infection who underwent DAA therapy was approximately 60%, though this value varied annually. **Conclusion:** HCV testing and linkage-to-care should be reinforced also in the hospital setting, where a routine screening program might be suggested for all hospitalized patients. In addition, a specific program of testing for active HCV infection and its treatment, under the guidance of an expert liver specialist, should be suggested to promote an appropriate and aware approach to find and cure as many HCV-infected individuals as possible.

1436 | RELINK HCV PATIENTS WITH LIMITED HEALTH CARE RESOURCE TO CARE

Tsung-Hui Hu[1] Chih-Chao Yang[2] Wei-Wen Su[3] Yen-Po Yeh[4], [1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [2]Changhua Hospital, Ministry of Health and Welfare, Changhua, Taiwan, [3]Changhua Christian Hospital, Changhua, Taiwan, [4]Changhua Public Health Bureau, Changhua, Taiwan

Background: Taiwan is reported to have one of the highest prevalence rates of HCV in North-East Asia, around 3%. Changhua is among one of the higher HCV prevalent counties in Taiwan, around 3.25% in 2018. Nine townships located in the remote area of Changhua have highest average HCV prevalence ($>8\%$) but with limited health care resources and frequently have no access to GI/hepatologists to care for their HCV. This is evidenced by 30% of anti HCV positive population was not linked to HCV RNA diagnosis for subsequent management. We aim to conduct a novel approach to relink this vulnerable group with positive anti-HCV is of pressing need in order to achieve WHO's goal of diagnosis and treatment. **Methods:** Changhua Public Health Bureau (CHPHB) officials has established a comprehensive population level data on HCV screening rate, diagnosis rate and treatment rate with the following steps: 1. CHPHB will coordinate efforts to perform call back through phone call, mail and physical visit. 2. CHPHB will set up telemedicine facility/station at health centers 3. Called back patients will have telemedicine visit (at health centers on site) with GI/hepatologists at station set by CHPHB. 4. Primary care physicians at health centers will be advised on decision making by GI/hepatologists with telemedicine. 5. HCV treatment decision will be driven at the physician's discretion and patients will be treated onsite. **Results:** The date of enrollment of first subject was on Dec 1, 2023. The follow up was analyzed at the end of Nov 30, 2024. The total target of 3112 patients with previous positive anti-HCV patients. Among them, 213 people have received HCV RNA test (68.2%). 870 people were found to be with detectable HCV RNA (41.0%). 751 people have received and completed direct antiviral agents (DAA) treatment (86.3%). Furthermore, we also target 457 patients who were with detectable HCV RNA, but have

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

not received any treatment in the past. Under this program, 341 patients (74.6%) have received DAA treatment during the program. The causes of failure to re-link were mostly due to refuse from patients (32.6%), and unreachable communication (15.9%). **Conclusion:** For patients living in limited health care resource to car, the re-ling program (by telemedicine) provided an effective and successful methods for further cascade of care of HCV patients.

1437 | EVALUATING HEPATITIS C TREATMENT ATTACHMENT RATE FOLLOWING IMPLEMENTATION OF AN EMERGENCY DEPARTMENT-BASED PHARMACIST-LED TREATMENT PROGRAM

Benjamin Coy[1] Timothy Tatchell[1] Christian Rhudy[1] Jacob Johnson[1] Matthew Zeltner[1] Lindsey Sheehan[2], [1]University of Kentucky Healthcare, [2]UK HealthCare

Background: Emergency department (ED) screenings have identified high hepatitis C (HCV) prevalence in Kentucky. However, many patients are not ultimately linked to care due to high rates of loss to follow up with traditional specialist referral models. UK-CURES (University of Kentucky - Cascade Utilizing Routinized screenings to Eliminate Syndemics) was implemented as a novel pharmacist-led model to treat HCV patients through simplified treatment guidelines . The goal of UK-CURES is to improve direct acting antiviral (DAA) initiation in ED patients with HCV. **Methods:** This was a single center, retrospective cohort review of patients who screened HCV RNA positive at one of two ED sites from 10/1/2022 - 4/1/2024. Patients ineligible for HCV treatment per AASLD guidelines were excluded. Patients were grouped as pre- or post-implementation based upon an initial screening date before or after 7/1/2023. Patient demographics and dates of service, including screening and first DAA dispense date were collected. The primary outcome was treatment attachment at 30 days, defined as a dispense of a DAA within 30 days of the ED screening. Secondary outcomes included attachment within 90 and 180 days, as well as days to treatment initiation. Significant differences in pre- and post-implementation cohorts were assessed by Pearson's chi square or Fischer's exact test (categorical) and the Mann Whitney U test (numeric) as appropriate. **Results:** 814 patients met inclusion criteria (pre-implementation n = 404; post-implementation n = 410). There were no significant differences in age, sex, race, and payor type between pre- and post-implementation cohorts. Treatment attachment at 30 days was significantly higher in the post-implementation period (pre 1%, n = 1; post 21.2%, n = 87; $p < 0.0001$). Significant differences were also observed in attachment at 90 days (pre 6.4%, n = 26; post 27.6%, n = 113; $p < 0.0001$) and 180 days (pre 10.9%, n = 44; post 31.2%, n = 128; $p < 0.0001$). The median days to treatment was 105 days sooner in the post-implementation group (25 days; pre 130 days; $p < 0.0001$). **Conclusion:** Implementing a pharmacist-led ED program to engage and workup patients with HCV greatly improves treatment attachment rate. Proactive resolution of clinical and logistical barriers at point-of-care can reduce loss to follow-up in patients with HCV.

1438 | CLINICAL OUTCOME OF HCV INFECTION IN CHILDREN: AN ANALYSIS BASED ON SIX CASES OF HCV INFECTED CHILDREN

Guoying Yu[1] Faying Li[1] Jie Ma[2], [1]Infectious Disease Specialized Hospital of Qinghai Province, [2]Infectious Disease Specialized Hospital of Qinghai Province.

Background: Previous studies have reported that HCV direct-acting antiviral(DAA) drugs can be used to treat pediatric and adolescent patients with HCV infection, including those aged 3-12 years and those aged 12 years and older, with favorable efficacy and safety. In this study, we analyzed the clinical data of six pediatric patients with HCV infection to investigate their clinical characteristics, disease prognosis, and management strategies. **Methods:** Data were collected from six pediatric patients with HCV patients who received screening, diagnosis, treatment and follow-up at the Infectious Disease Specialized Hospital of

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Qinghai Province between January 2022 and December 2024. The patients had completed follow-up for at least six months. Their clinical characteristics, diagnoses, and treatment outcomes were analyzed. **Results:** Six pediatric patients were retrospectively enrolled. The male to female ratio was 1:1 (three males and three females). The median age was 11.5 years. Two patients (33.33%) were attributed to vertical mother-to-child transmission. The diagnosis was confirmed by abnormal ALT levels in four patients (66.67%). All were treatment-naïve patients, with a mean HCV RNA of 6.35×10^5IU/mL at baseline. Genotype 2a was predominant (83.33%, five out of six cases), and one case had an undetectable genotype. The median ALT and AST at baseline were 58U/L and 41U/L, respectively, and there were no cirrhotic patients. The time from HCV diagnosis to treatment initiation was 6-18 months. Four patients received sofosbuvir and velpatasvir for 12 weeks, while the other two received ledipasvir and sofosbuvir for the same duration. All achieved 100% SVR12. No adverse events were reported during treatment. **Conclusion:** This small, single-center clinical study confirms the need for early treatment of pediatric patients with HCV infection to prevent serious liver-related complications caused by long-term infection. There is an urgent need to establish an integrated pathway of screening, diagnostic, and treatment pathway for pediatric patients with HCV infection.

1439 | CLINICAL PERFORMANCE OF A NOVEL DUAL ANTIGEN-ANTIBODY ASSAY FOR HCV SCREENING: A STEP TOWARD SIMPLIFYING THE DIAGNOSTIC CASCADE

Takako Inoue[1] Hiroko Setoyama[2] Takehisa Watanabe[2] Takanori Suzuki[3] Katsuya Nagaoka[2] Etsuko Iio[2] kentaro matsuura[3] Yasuhito Tanaka[3], [1]Nagoya City University Hospital, [2]Kumamoto University, [3]Nagoya City University Graduate School of Medical Sciences

Background: A timely diagnosis is critical for HCV elimination; however, delays in confirmatory testing continue to be a major barrier to effective patient care. Elecsys HCV Duo (HCV Duo) is a novel one-step immunoassay that simultaneously detects anti-HCV antibodies (anti-HCV) and HCV core antigen (HCV-Ag) in under 30 minutes. This study evaluated the clinical utility of HCV Duo in identifying active HCV infection in Japan and assessed its potential to streamline the diagnostic workflow. **Methods:** (1) A total of 373 serum samples from chronic hepatitis C (CHC) patients were analyzed (120 HCV RNA-positive, 253 HCV RNA-negative). The sensitivity of Duo/anti-HCV was evaluated in comparison with conventional anti-HCV assays to determine its diagnostic accuracy. The sensitivity and specificity of Duo/HCV-Ag were assessed using HCV RNA as the reference standard. (2) HCV RNA distributions were assessed in 153 untreated CHC patients diagnosed between 2019 and 2023. (3) Trends in HCV RNA testing and detection rates over 5 years were examined (n = 3,213). **Results:** Duo/anti-HCV demonstrated 100% sensitivity. Duo/HCV-Ag showed 99.2% specificity and 55.0% overall sensitivity, increasing with viral load: 20.5% ($\leq$4.0 log IU/mL), 33.3% (4.1–5.5), and 87.3% ($\geq$5.6). Among untreated CHC patients (n = 153), HCV RNA levels were distributed as follows: 2.6% $\leq$4.0, 26.1% between 4.1–5.5, and 71.2% $\geq$5.6 log IU/mL—indicating that most cases fall within the Duo/HCV-Ag detectable range (Figure). Over the past 5 years, a total of 3,213 quantitative HCV RNA tests were submitted, showing a decreasing trend (1,246 in 2019 to 328 in 2023) and a cumulative detection rate of 9.4%. **Conclusion:** HCV Duo enables rapid, point-of-care identification of active HCV infection with high specificity and strong sensitivity at clinically relevant viral loads. It serves as a frontline screening tool, particularly valuable in emergency care, preoperative evaluations, and short-stay admissions, where rapid diagnosis is critical. This assay may help overcome key barriers in the HCV cascade of care, particularly in non-specialist settings. By combining antibody and antigen detection in a single step, HCV Duo eliminates the need for separate confirmatory testing, potentially increasing diagnostic follow-up and treatment initiation. By streamlining the diagnostic process, HCV Duo can minimize delays, reduce patient burden, and enhance early linkage to care, improving overall treatment outcomes. Integrating this assay into broader screening programs could play a pivotal role in accelerating national HCV elimination efforts.

1440 | UNIQUE HCV AND HBV/HDV RE-LINKING PROGRAM IN ITALY

Alessandra Mangia[1] Valeria Piazzolla[1] Luca L'Erario[2] Mattia Lopez[3] Laura Solito[4] Daniela De Biasi[5] Gianluca Carone[6] Giovanni Manica[7] Antonio Camodeca[8] Antonio Napolitano[1] Maria Maddalena Squillante[1] Angelo L'erario[9], [1]Fondazione Casa Sollievo della Sofferenza IRCCS, [2]Laboratorio Dell'Olio Trani, [3]Laboratorio di Analisi Cliniche Palazzo s.r.l., [4]Laboratorio analisi dott. Francesco Solito S.r.l, [5]C.M.D. Analisi s.r.l., [6]Laboratorio Analisi Rosanna Santoro S.r.l., [7]Laboratorio d'analisi Paolo VI s.r.l., [8]Laboratorio di Analisi San Giorgio, [9]Sapienza University

Background: Despite the advances in HCV therapy, HCV continues to lead to approximately 400.000 deaths annually and HBV was associated with 550.000 deaths, in 2019. After diagnosis, not all patients are treated. Re-linking to care represents one of the main focusses to achieve HCV and HBV elimination. In Italy, re-linkage is hampered by Data Privacy rules which we overcome by designing our project to be conducted in collaboration with private laboratories. The aims is to explore the efficiency of a dedicated re-linking program conducted in collaboration with hub private laboratories managing in their turn spoke laboratories and covering an area of 7500 Km2 in Puglia. **Methods:** From 06/2024 to the present, our centre coordinated 10 hub laboratories with the help of Telehealth across the 6 provinces of our region. Recall activities, promoted by private laboratories, focused on patients aged 50-85 years who have been tested during the last 10 years and found to be HCVAb or HBsAg positive. Only the results on HCV infection will be reported here. The project will be completed at the end of 2025. When HCVAb positive, patients were offered counselling, DAA prescription and monitoring by Telehealth. The primary endpoint is the number of patients re-linked, out of patients HCVAb positive. The secondary endpoint, SVR after 12 weeks of SOF/VEL. **Results:** Overall, of 1582 possible candidates, only 398 were eligible for contact. Of them 95 (23.8%) had died. Overall 303 HCVAb positive individuals were identified, 66 could not be reached, 22 were not interested in treatment. With the remaining 215 HCVAb positive responding to the call, the study retrieval rate was 54%. These patients were 59% male and had a mean age of 68.6+/-12.9 yrs. Fifty five (18.1%) were HCV RNA positive. Differences between HCV RNA +or- in the Table. Overall, 51 patients, representing 23.7% of the seropositive patients reached out at the different laboratories, have been re-linked to treatment with 100% SVR so far. **Conclusion:** Our study shows that re-linkage in Italy is possible. The 54% retrieval rate of HCVAb patients, among subjects 50-85 years old, was higher than that of other EU countries. Education and information programs are needed to increase this rate. Re-linkage to care was 23.7%. Among HCV RNA+ve patients identified, 16% had low PLT counts. Efficient programs are required to allow patients with past HCV diagnosis to complete the HCV care cascade. Acknowledgments: This study was partially founded by Gilead Sciences.

	AntiHCV+ve HCV RNA negative (n=160)	AntiHCV+ve HCV RNA positive (n=55)	P value

1441 | FIB-4 PREDICTS LONG-TERM OUTCOMES AFTER SVR IN HCV PATIENTS WITH CIRRHOSIS: GONE BUT NOT TO BE FORGOTTEN

Anas Aljabi[1] Husam Mikati[1] Reena Cherian[1] Shawn Lewis[1] Leah Blatzer[1] Richard Sterling[1], [1]Virginia Commonwealth University

Background: While the use of direct-acting antivirals (DAA) for chronic hepatitis C virus (HCV) has high sustained virologic response (SVR) in patients with cirrhosis, they remain at risk for developing hepatic decompensation or hepatocellular carcinoma (HCC). This analysis aimed to assess the engagement in care and development of decompensation or HCC after SVR in those with cirrhosis among our HCV treatment cohorts: Department of Corrections (DOC) vs non-DOC (University) HCV treatment clinics. **Methods:** All subjects treated with DAA since 2014 across the clinics were prospectively followed in our HCV treatment registry. Demographic and clinical data were recorded. Cirrhosis was defined by transient elastography, imaging, or clinical criteria. Outcomes (decompensation or HCC) were extracted from the electronic health record. The proportion who remained in care, underwent post-treatment HCC surveillance imaging, or developed decompensation (ascites, hepatic encephalopathy (HE), portal hypertensive bleeding, or jaundice) was compared between DOC and non-DOC groups. **Results:** 2240 patients with cirrhosis were included in this analysis: baseline mean age 54 yrs, ALT 72 U/L, FIB-4 3.9, 76%

male, 58% White/40% Black, 4% HIV, 81% genotype 1, and 51% treated in the DOC via Telemedicine. Those treated in the DOC vs non-DOC had lower FIB-4 (2.8 vs 5.1; $p < .0001$) and lower SVR (89% vs 94%; $p < .0001$) due to increased lost to follow-up prior to SVR-12 visit (9% vs 1%; $p < .0001$). Among the cohort, follow-up data were available in 1477 (65%). Of these, HCC surveillance was higher in non-DOC vs DOC clinic (81% vs 63%; $p < .0001$). HCC developed in 7.8% and decompensation in 13% of which 85% developed ascites, 61% HE, 30% bleeding, and 25% jaundice (bilirubin > 1.5 mg/dL). Patients followed in the non-DOC clinic had higher HCC (9.6% vs 1.8%; $p < .0001$) and decompensation (11.8% vs 3.6%; $p < .0001$). After adjusting for age, SVR, and treatment setting (DOC vs non-DOC), FIB-4 was highly predictive of HCC ($p < .0001$) or decompensation ($p < .0001$). The optimal pre-DAA FIB-4 that predicted post-SVR HCC or decompensation was 3.7 (AUROC 0.78). **Conclusion:** While SVR is high in patients with cirrhosis, development of HCC and decompensation can happen and are associated with higher pre-treatment FIB-4. Therefore, adherence to AASLD guidelines on continued follow-up of patients with high FIB-4 is needed to monitor for the development of HCC or decompensation after SVR in those with elevated FIB-4.

1442 | HEPATITIS C IN PRISONS: MAINTAINING VIGILANCE IS ESSENTIAL

Veronica Patiño[1] Jose Dominguez[2] Carolina Broco[3] Andrea Robredo[3] Sofia Cid[2] Yolanda Mendez[3] Luis Tulleuda[2] María Gonzalez[2] Rubén Diez[3] Francisco Jorquera[3], [1]Complejo Asistencial Universitario de León, [2]León Penitentiary Center, [3]Complejo asistencial universitario de Leon

Background: The World Health Organization (WHO) has set a goal to eliminate hepatitis C as a public health threat by 2030. Spain, through the implementation of its National Strategic Plan for the Management of Hepatitis C, has emerged as a global leader in the treatment of HCV, with the highest number of patients treated per million inhabitants. Prisons historically exhibit a high prevalence of HCV (15-30%), have experienced a dramatic reduction in infection rates, similar to those observed in the general population ($< 0.3\%$) after interventions. One such initiative, the Jailfree project at El Dueso prison, demonstrated the efficacy of comprehensive screening and treatment strategies. However, recent difficulties in healthcare staffing in prisons, the impact of the COVID-19 pandemic have limited current epidemiological surveillance. In this context, updated data on HCV prevalence among inmates are crucial. **Methods:** This study aimed to evaluate the current prevalence of HCV at the León Penitentiary Center. An observational, cross-sectional study was conducted in May 2024. Following an educational session provided by the Gastroenterology Department of the University Hospital of León, inmates were invited to participate in voluntary screening for HBV, HCV, and HIV using a rapid diagnostic test. Individuals with positive serology underwent confirmatory viral load testing and, if viremic, were referred for specialist care and offered direct-acting antiviral (DAA) therapy. Data were analyzed using IBM SPSS Statistics, with results expressed as mean $\pm$ standard deviation; statistical significance was defined as $p < 0.05$. **Results:** Of 854 inmates, 274 (32.1%) participated. The average age was 41.53 $\pm$ 11.29 years; 86.5% were male. Anti-HCV antibodies were identified in 25 participants (9.12%), with no significant sex difference. HCV-seropositive individuals were significantly older than seronegatives (50.6 $\pm$ 6.62 vs. 40.6 $\pm$ 11.2 years, $p < 0.001$). Among the seropositive group, 7 male individuals (mean age 52.7 years) had detectable HCV RNA, indicating active infection. These cases represented 28% of seropositives and 2.55% of the total study sample. All viremic participants received DAA treatment. The prevalence of active HCV infection among inmates in León remains significantly higher than in the general population. While overall trends reflect progress, these findings underscore the ongoing need for systematic test-and-treat strategies in correctional settings. Structural challenges—particularly healthcare staffing shortages and reduced surveillance post-pandemic—must be addressed to prevent setbacks and support sustained elimination efforts. **Conclusion:** The current HCV prevalence among inmates at the León Penitentiary Center exceeds that of the general population. Maintaining systematic screening and immediate antiviral treatment within prisons is essential for achieving HCV elimination goals.

◆ 1443 | HEPATIC STIFFNESS, NEUROVASCULAR COUPLING, AND WORKING MEMORY: AN MRE-DRIVEN EXPLORATION OF LIVER-BRAIN CROSSTALK

Jie Li[1] Zhuoru Jiang[1] Futao Chen[1] Wenjing Ni[1] Bing Zhang[1] Jun Chen[2], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [2]Mayo Clinic

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) has become the primary cause of chronic liver disease in younger adults. Alarmingly, MASLD may disrupt brain function even without cirrhosis. Magnetic resonance elastography (MRE) quantifies liver stiffness, yet its neurological implications in non-cirrhotic younger patients with MASLD remain unclear. This study aimed to demonstrate that higher liver stiffness affects brain health in young patients with non-cirrhotic MASLD. **Methods:** This was a prospective cohort involving 78 MASLD outpatients without cirrhosis [median age 26 years, (18-33)]. Using the Mayo criteria defining 2.5 kPa as the threshold for normal liver or inflammation, patients were stratified by MRE into low liver stiffness (LLS, MRE < 2.5 kPa, n = 38) and high liver stiffness (HLS, MRE ≥ 2.5 kPa, n = 40) groups. Participants underwent neuropsychological assessments, hepatic MRE, and multimodal brain magnetic resonance imaging (MRI), including resting-state fMRI and arterial spin labeling (ASL) for cerebral blood flow (CBF) and regional homogeneity (ReHo) analyses. Neuro-imaging data were processed using SPM12, with voxel-wise comparisons and global CBF-ReHo coupling analyses. T-tests and non-parametric methods were used for statistical analyses, adjusted for age and education. **Results:** HLS patients exhibited reduced global CBF-ReHo coupling ($p = 0.044$) and increased CBF/ReHo ratio in the right temporal pole (TPOsup) (voxel $p < 0.001$, cluster-level FWE-corrected, Figure 1A-B), suggesting that compensatory hyperperfusion maintains neural efficiency under metabolic stress. Functional connectivity decreased in the left superior temporal gyrus (STG) in HLS (cluster $p < 0.05$, Figure 1C). The CBF/ReHo ratio in the right temporal pole was correlated with digit span backward performance (r = 0.263, $p = 0.020$), while STG connectivity was correlated with auditory verbal learning (AVLT) (r = 0.235, $p = 0.038$, Figure 1D). No significant CBF or ReHo differences were found at the voxel level. **Conclusion:** Elevated liver stiffness in non-cirrhotic MASLD is associated with disrupted neurovascular coupling and functional connectivity in young patients, highlighting the extrahepatic manifestations of metabolic liver disease.

Figure 1. (A) Reduced global CBF-ReHo coupling in patients with high liver stiffness. (B) Differences in CBF/ReHo ratio between the two groups. (C) Brain regions showed significant differences in functional connectivity between the two groups (voxel $p<0.001$, cluster $p<0.05$, cluster-level FWE corrected). (D) Correlations between clinical indexes and CBF/Reho and functional connectivity values in the two groups. CBF, cerebral blood flow; Reho, regional homogeneity; FC, functional connectivity; HLS, high liver stiffness; TPOsup.R, right temporal pole; STG.L, left superior temporal gyrus; AVLT, auditory verbal learning.

◆ 1444 | HEPATOCYTE AGING SIGNATURE FROM RNASEQ IS SIGNIFICANTLY ASSOCIATED WITH HISTOLOGIC SEVERITY IN HUMAN MASLD, INDEPENDENT OF CHRONOLOGIC AGE

Rajesh Dutta Tae-Hwi Schwantes-An[1] Kuo Du[2] Liuyang Wang[2] Marco Abreu[1] Callie Zaborenko[1] Xiuqing Guo[3] Jerome Rotter[3] Cynthia Guy[2] Brent Neuschwander-Tetri[4] Arun Sanyal[5] Luca Lotta[6] Niek Verweij[6] Naga Chalasani[7] Anna Mae Diehl[2], [1]Indiana University School of Medicine, Indianapolis, IN, [2]Duke University, [3]Lundquist Institute, Torrance, CA, [4]Saint Louis University, Saint Louis, MO, [5]Virginia Commonwealth University, [6]Regeneron Genetics Center, Regeneron, PA, [7]Indiana University Medical Center

Background: Aging is a risk factor for progressive metabolic dysfunction-associated steatotic liver disease (MASLD) and thus aging signatures might be used as tools to identify mechanisms that drive MASLD progression. Previously, we developed an Aging Hepatocyte Gene Signature (AHGS) by comparing transcriptomic profiles of hepatocytes from healthy young and old male mice and found that AHGS was enriched in human MASLD livers in parallel with disease severity. However, that analysis did not control for potential confounding factors, including age itself. **Methods:** We applied AHGS to bulk RNA-seq data from a demographically balanced cohort of 502 patients enrolled in the NASH Clinical Research Network (NASH-CRN). This cohort was nearly twice the size of our previous cohort and our analysis adjusted for age, sex, race, and ethnicity to evaluate the independent associations between AHGS and MASLD histological severity. AHGS scores were calculated using gene set variation analysis (GSVA) on bulk RNA-seq data. Logistic regression models, adjusted for demographic variables, assessed associations between AHGS and fibrosis (≥ 3 vs. < 3), NAS (≥ 4 vs. < 4), lobular and portal inflammation, steatosis, hepatocellular ballooning, and Mallory's hyaline. **Results:** Higher AHGS scores were significantly associated with multiple histologic features indicative of more severe MASLD. Patients with higher AHGS scores had over twice the odds of having advanced fibrosis (OR = 2.36, p = 3.95E-14) compared to those with lower scores, even after adjusting for age and other demographic factors. Similarly, the likelihood of NAS ≥ 4, reflecting more severe disease activity was nearly doubled (OR = 1.90, p = 7.19E-10). Higher AHGS was also associated with increased lobular inflammation (OR = 1.71), portal inflammation (OR = 1.93), and hepatocellular ballooning (OR = 1.61), all features of progressive hepatic damage. While the association with steatosis was more modest (OR = 1.29, p = 6.11E-03), it remained statistically significant. Biopsies of patients with higher AHGS were nearly twice as likely to show Mallory's hyaline (OR = 1.99), which reflects proteostasis, a hallmark of aging. **Conclusion:** Hepatocyte aging-associated transcriptional programs are strongly linked to MASLD histological severity, independent of chronological age and other co-variates. Progressive MASLD involves degenerative processes driven by aging-sensitive mechanisms.

◆ 1445 | TREATMENT-INDUCED LIVER FAT REDUCTION ASSESSED BY MRI-PDFF IS STRONGLY ASSOCIATED WITH HISTOLOGICAL ENDPOINTS IN NON-CIRRHOTIC MASH CLINICAL TRIALS: A META-ANALYSIS

Kusha Mohammadi[1] Quang Nguyen[1] Tejasv Bedi[1] Selin Somersan-Karakaya[1] Stefanie Hectors[1] Gavin Imperato[1] Ifeanyichukuw Anidi[1] Emily Labriola-Tompkins[1] Muhammad Effendi[1] Katie Tuckwell[1] Sonya Aziz-Zaman[1] Jutta Miller[1] Aris Baras[1] Gary Herman[1] Dinko Gonzalez-Trotter[1] Rong liu[1] Thomas Norton[1] David Lederer[1], [1]Regeneron Pharmaceuticals, Inc.

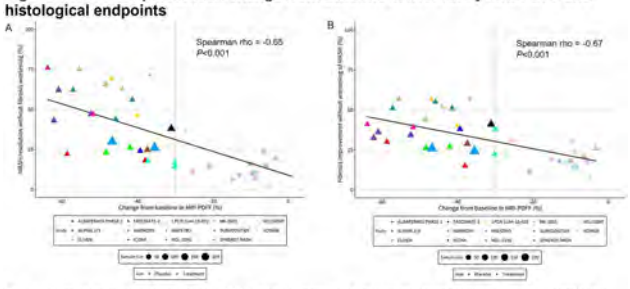
Background: Several clinical trials have evaluated the effect of therapeutics on both liver fat and histological response in metabolic dysfunction–associated steatohepatitis (MASH). Magnetic resonance imaging–derived proton density fat fraction (MRI-PDFF) offers a feasible and non-invasive method to assess the efficacy of MASH therapeutics if a strong correlation exists between liver fat change and histological response. This systematic meta-analysis of randomized clinical trials describes the association between treatment-induced change in liver

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

fat by MRI-PDFF and histological responses in participants with MASH and fibrosis. **Methods:** Following PRISMA guidelines, we conducted a search in Cochrane, EMBASE, and clinicaltrials.gov for all non-cirrhotic MASH trials up to April 10, 2025. Key inclusion criteria were phase 2 or 3 trials in adults ($\geq$18 years old) with change from baseline in MRI-PDFF data and $\geq$1 histology endpoint reported in a peer-reviewed journal or conference abstract. Histology endpoints included MASH resolution without fibrosis worsening, and fibrosis improvement without MASH worsening. We assessed the strength of the relationship between treatment-induced changes in MRI-PDFF and histological responses using Spearman correlation coefficients and linear regression. **Results:** Fourteen studies were included, comprising ~2600 participants. The analyses showed that the treatment-related reduction from baseline in liver fat by MRI-PDFF was strongly associated with a higher rate of MASH resolution without fibrosis worsening (Spearman rho = -0.65, $P<0.001$; Figure). In addition, treatment-related changes in liver fat by MRI-PDFF were also associated with fibrosis improvement without MASH worsening (Spearman rho = -0.67; $P<0.001$). A 30% reduction from baseline in liver fat by MRI-PDFF resulted in an estimated response rate of 31.1% (95% CI: 26.5–35.7%) for MASH resolution without worsening fibrosis and 30.3% (95% CI: 27.1–33.5%) for fibrosis improvement without MASH worsening. **Conclusion:** Treatment-related reductions in liver fat assessed by MRI-PDFF are strongly associated with both MASH resolution without fibrosis worsening as well as fibrosis improvement without MASH worsening in patients with non-cirrhotic MASH with fibrosis. These findings support change from baseline in liver fat by MRI-PDFF as a meaningful endpoint in non-cirrhotic MASH.

Figure. Relationships between change from baseline in liver fat by MRI-PDFF and histological endpoints



The mean percent change from baseline in MRI-PDFF and the percentage of patients with a histological response are reported in the figures. Each point represents a separate intervention where multiple doses or dose regimens were tested within a study. The size of the point reflects the approximate number of participants in the treatment arm. For scenarios in which the number of participants was different for individual endpoints, the larger number was chosen as the sample size. The color depicts an individual study eligible for the meta-analysis. The triangles represent active treatment arms, and the circles represent placebo arms. The black line is a simple linear regression through the studies.

◆ 1446 | A TCF21-MIMETIC SMALL MOLECULE SERVES AS A NOVEL DRUG CANDIDATE FOR STEATOHEPATITIS AND FIBROSIS BY ALTERING THE FUNCTIONAL FEATURES AND CELLULAR CROSSTALK OF HEPATIC STELLATE CELL

Takayo Yanagawa[1] Noriaki Hirayama[2] Harumi Ogawa[2] Sachie Nakao[2] Mayumi Watanabe[2] Hideaki Sumiyoshi[2] Hiromi Miura[1] Masato Ohtsuka[1] Masayuki Tanaka[1] Yumi Iida[1] Misaki Higashiseto[1] Shigeyuki Shichino[3] Kouji Matsushima[3] Kota Tsuruya[4] Yoshitaka Arase[1] Yusuke Mishima[1] Tatehiro Kagawa[4] Yutaka Inagaki[1], [1]Tokai University School of Medicine, [2]Graduate School of MedicineTokai University, [3]Tokyo University of Science, [4]Tokai University

Background: Despite the recent approval of the first drug and the ongoing clinical trials for metabolic dysfunction-associated steatohepatitis (MASH), no drug is available that directly suppresses liver fibrosis in MASH. We previously identified Tcf21 as a deactivation factor of activated hepatic stellate cells (HSCs). Subsequently, we identified several Tcf21-mimetic small molecules that act as Tcf21 agonists to suppress progression of liver fibrosis. Adeno-associated virus-mediated *Tcf21* transfer not only suppressed progression of liver fibrosis, but also restored the hepatic lobular structure and function. However, it was unknown whether and how Tcf21-induced HSC deactivation *per se* exerts such antifibrotic and tissue repair actions. In the present study, we examined the effect of the hit Tcf21-mimetic molecule (YT0300) on progression of experimental steatohepatitis and explored the molecular mechanisms by which Tcf21 mimetic-induced HSC deactivation accelerates tissue repair of the fibrotic liver. **Methods:** The effect of YT0300 treatment was examined using the streptozotocin and high fat diet-induced murine MASH model. The fate of YT0300-induced deactivated HSCs was monitored using the type I collagen gene-driven mTFP1 reporter mice induced by tamoxifen administration. Single cell RNA sequencing was performed using cells obtained from the tracing mice that were repeatedly injected with carbon tetrachloride with or without YT0300 treatment.

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Cellular crosstalk was examined by CellChat analysis. **Results:** Administration of YT0300 suppressed both the activity of steatohepatitis and the extent of liver fibrosis in the MASH model mice. Expression of steatohepatitis signature genes such as *Adamtsl2*, *Thbs2*, and *Igfbp7* was down-regulated in the mTFP1-positive deactivated HSCs from YT0300-treated mice. YT0300 treatment also suppressed gene expression of neurotrophin 3, an autocrine fibrogenic signal, and increased expression of midkine that accelerates liver regeneration, in the HSC population. Furthermore, YT0300 administration induced a unique subset of macrophages expressing tissue repair- (*Arg1*, *Sdc1*) and angiogenesis-related genes (*Vegfa*), and enhanced crosstalk between the VEGF-expressing macrophages/HSCs and liver sinusoidal endothelial cell (LSEC) expressing VEGF receptors. Consistently, some of the mTFP1-positive deactivated HSCs in YT0300-treated mice formed a network with LSEC present in liver parenchyma. There were no differences in the peripheral blood cell counts or biochemical parameters such as alanine aminotransferase, albumin, and creatinine between the control and YT0300 groups. **Conclusion:** YT0300 treatment not only suppressed steatohepatitis and fibrosis, but also accelerated tissue repair of the fibrotic liver. Tcf21 mimetic-induced deactivation of HSCs may provide a novel option for treating MASH fibrosis by orchestrating cellular crosstalk in the fibrotic liver.

1447 | MORTALITY AND LIVER-RELATED OUTCOMES OF SGLT2 INHIBITORS IN PATIENTS WITH MASLD, OBESITY, AND DIABETES: A 3-YEAR COHORT STUDY

Mohamad-Noor Abu-Hammour[1] Barish Eren[1] Walid Hazem[2] Mohamad Mahdi Osman[1] Mohammad Alabbas[1] Leandro Sierra[1] Hussam Kawas[1] Omar Sims[1] Dian Chiang[3], [1]Cleveland Clinic Foundation, [2]University Hospitals, [3]Cleveland Clinic

Background: Metabolic-associated steatotic liver disease (MASLD) patients are at elevated risk for cardiovascular and hepatic complications. Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have shown benefits beyond glycemic control, with recent studies revealing potential hepatic benefits. This study aimed to evaluate the 3-year outcomes of SGLT2i treatment in patients with MASLD/MASH and T2DM. **Methods:** Using the TriNetX global research network, we conducted a retrospective cohort analysis involving adult patients diagnosed with MASLD/MASH, obesity (BMI ≥ 30 kg/m²), and T2DM receiving SGLT2i ($n = 73,811$) and compared to a control cohort not on SGLT2i ($n = 73,811$). Using propensity score matching, we balanced cohorts for demographics, comorbidities, medications, and laboratory values. Outcomes evaluated over three years included cirrhosis development, hepatocellular carcinoma (HCC), all-cause mortality (ACM), and all-cause hospitalizations (ACH). **Results:** Compared to the non-SGLT2i group, the SGLT2i cohort were associated with significantly lower risks of ACM (3.7% vs. 6.2%; HR 0.537, 95% CI 0.512-0.563, $p < 0.001$) and ACH (24.2% vs. 25.5%; HR 0.872, 95% CI 0.854-0.890, $p < 0.001$). However, patients on SGLT2i were associated with a slightly higher risk of cirrhosis development (10.0% vs. 8.9%; HR 1.063, 95% CI 1.028-1.099, $p < 0.001$). No significant differences in HCC risk were noted between the two cohorts (HR 1.079, 95% CI 0.965-1.207, $p = 0.183$) **Conclusion:** In patients with MASLD/MASH, T2DM, and obesity, treatment with SGLT2 inhibitors were associated with significantly reduced mortality and hospitalizations compared to non-users. Increased risks of cirrhosis warrant continued vigilance and further investigation to fully elucidate the hepatic safety profile of SGLT2 inhibitors.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Current guidelines recommend screening for MASLD beginning at age 10 years. Hispanic youth are known to be at increased risk and severity of MASLD, but few studies have included children under the age of 10 years, despite this increased risk. The aim of this study was to test for MASLD and risk factors in prepubertal Hispanic children. **Methods:** This was a prospective cohort of Hispanic/Latino children aged 6–9 years recruited from the community (NCT05292352). Children were of Hispanic/Latino heritage and without known chronic diseases as reported by their parent. Consented participants underwent MRI-PDFF for hepatic steatosis, comprehensive anthropometrics and phlebotomy for clinical labs and DNA for genotyping. Genotyping for *PNPLA3* rs738409 was performed. **Results:** Of 170 participants (mean age 7.9 years SD 1.1, 57% male), 27% were categorized as normal weight, 18% were overweight, and 55% were in the obese category for BMI. The frequency of the *PNPLA3* genotype was 15.6% CC, 51.4% CG and 31.9% GG. Overall, 34.6% of children had hepatic steatosis (HS) defined as an intrahepatic fat content ≥5% and 22% had elevated ALT. HS was most prevalent among those with a *PNPLA3* GG polymorphism (56.5%), elevated ALT (78.8%), obesity (55.3%), and in boys (41.4%). Controlling for age and sex, children with obesity were 11 times more likely to have HS (OR 11.31, CI 4.0–40.7). Those with *PNPLA3* GG were 9.2 times more likely to have HS compared to CC (OR 9.24, CI 2.42–42.8). **Conclusion:** MASLD onset may occur earlier than previously thought and delays in screening until age 10 years may miss important opportunities to interrupt the progression. The presence of obesity and *PNPLA3* risk genotype are strong predictors for MASLD, even in children as young as 6 years old. This evidence supports lowering the age of screening in Hispanic/Latino children and particularly for those who have obesity.

1449 | AN ASSOCIATION OF COVERT HEPATIC ENCEPHALOPATHY WITH NON-ELDERLY AND MASLD IN PATIENTS WITH LIVER CIRRHOSIS AND HEPATOCELLULAR CARCINOMA: DATA-MINING ANALYSES

Dan Nakano[1] Takumi Kawaguchi[1] Tsubasa Tsutsumi[1] Ryuki Hashida[1] Keisuke Amano[1], [1]Kurume University School of Medicine

Background: Covert hepatic encephalopathy (CHE) is a complication of liver cirrhosis that contributes to impaired quality of life, increased risk of falls, and traffic accidents. While hyperammonemia and decreased hepatic reserve are established risk factors, recent attention has turned to additional variables such as age and metabolic dysfunction-associated steatotic liver disease (MASLD). This study aimed to characterize the clinical profiles associated with CHE in patients with liver cirrhosis. **Methods:** This was a retrospective observational study. We enrolled 195 patients with chronic liver disease (female/male 60/135, mean age 68.0 years, ALBI Grade 1/2/3 76/105/12) without overt hepatic encephalopathy and under 80 years of age. CHE was diagnosed using the Stroop test. SLD was diagnosed with abdominal ultrasound. Factors associated with CHE, including age, sex, BMI, serum albumin, glucose metabolism, SLD, and ammonia, were investigated using logistic regression analysis and decision-tree analysis. **Results:** CHE was observed in 36.4% (71/195) of all patients. The CHE group, compared to the non-CHE group, was younger, had a higher BMI, a higher prevalence of SLD, and lower serum albumin. Multivariate logistic regression analysis identified age (<65 years old: Odds Ratio [OR] 4.57, 95% Confidence Interval [CI] 2.29–9.13, $p < 0.001$), MASLD (OR 1.95, 95%CI 1.01–53.76, $p = 0.0456$), and the presence of hepatocellular carcinoma (HCC) (OR 0.245, 95%CI 0.08–0.71, $p = 0.0096$) as independent factors for CHE. In the decision-tree analysis, age was the initial classifier. For patients <65 years old, the second classifier was MASLD; 90.5% of those with MASLD had CHE. For patients ≥65 years old, the second classifier was the presence of HCC. Among those with HCC, the third classifier was serum ammonia level; 31.6% of patients with serum ammonia ≥80 μg/dL had CHE. **Conclusion:** The pathophysiological profiles associated with CHE differ by age. In patients

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

<65 years, MASLD was a dominant factor, whereas in those ≥65 years, HCC status and ammonia levels were more relevant. These findings suggest that age-specific factors contribute to the development of CHE and underscore the importance of MASLD as an emerging risk factor in non-elderly cirrhotic patients.

1450 | IMPACT OF AGE-ADJUSTED SKELETAL MUSCLE INDEX AND MODEST ALCOHOL USE ON LIVER STEATOSIS AND FIBROSIS IN MALE MASLD

Jung Hee Kim[1] JangHan Jung[1], [1]Hallym university

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a highly prevalent condition closely linked to obesity and metabolic risk factors, with a disease spectrum ranging from simple steatosis to advanced fibrosis. This study aimed to investigate the clinical, body composition, and biochemical factors associated with hepatic steatosis and advanced fibrosis severity, with particular emphasis on the role of skeletal muscle index (SMI), visceral fat area (VFA), and light alcohol consumption. **Methods:** A total of 174 male participants diagnosed with MASLD were evaluated. Hepatic steatosis and fibrosis were assessed using controlled attenuation parameter (CAP) and liver stiffness measurement (LSM, kPa), respectively. Body composition was assessed via bioelectrical impedance analysis. Univariate and multivariate regression analyses were performed to identify factors independently associated with steatosis and fibrosis severity. Subgroup analyses were conducted according to alcohol consumption. **Results:** The mean age of participants was 40.0 ± 10.4 years, and the median BMI was 28.8 kg/m². Severe hepatic steatosis was independently associated with alcohol intake (<30 g/day; OR 1.22, 95% CI 1.03–1.44, p = 0.020), higher age-adjusted SMI (z score) (OR 1.82, 95% CI 1.23–2.70, p = 0.003), and elevated triglyceride levels (OR 1.01, 95% CI 1.00–1.02, p = 0.009). Among non-drinkers, SMI remained a significant predictor of severe steatosis. A positive correlation was observed between SMI (z score) and CAP values (R = 0.328, p < 0.001).For advanced hepatic fibrosis, multivariate analysis identified elevated SMI (z score) (OR 1.84, 95% CI 1.14–2.96, p = 0.013) and increased aspartate aminotransferase (AST) levels (OR 1.04, 95% CI 1.02–1.05, p < 0.001) as independent risk factors, whereas light alcohol consumption (OR 0.068, 95% CI 0.01–0.71, p = 0.025) and higher platelet count (OR 0.99, 95% CI 0.97–1.00, p = 0.016) were associated with lower odds of advanced fibrosis. A significant positive correlation was also found between SMI and fibrosis severity (p = 0.001). Additionally, participants reporting light alcohol intake had significantly higher CAP scores (p = 0.018) but lower LSM values (p = 0.007) compared to non-drinkers. **Conclusion:** In men with MASLD, higher age adjusted SMI (z score) was independently associated with both severe steatosis and advanced fibrosis. Light alcohol intake increased steatosis but was linked to lower fibrosis severity.Notably, the consistent association of higher SMI with both steatosis and fibrosis severity suggests a potential role of muscle mass quality or myosteatosis in MASLD pathogenesis, warranting further investigation for tailored risk stratification and management.

1451 | PNPLA3 MRNA SILENCING WITH ALN-PNP REDUCES LIVER FAT IN PATIENTS WITH MASLD HOMOZYGOUS FOR PNPLA3 P.I148M

Selin Somersan-Karakaya[1] Stefanie Hectors[1] George Kalliolias[1] Emily Labriola-Tompkins[1] Tejasv Bedi[1] Kusha Mohammadi[1] Zaira Yunus[1] Jenna Octavio[1] David Workman[1] SeungHwan Lee[2] Simona Podgrabinska[1] Eriks Smagris[1] Viktoria Gusarova[1] Thomas Norton[1] Rong liu[3] Dinko Gonzalez Trotter[1] David Lederer[1] Gary Herman[1] Aris Baras[1], [1]Regeneron Pharmaceuticals, Inc., [2]Seoul National University Hospital, [3]regeneron

Background: Homozygote carriers for the patatin-like phospholipase domain-containing protein 3 (PNPLA3) p.I148M variant have increased liver fat and a higher risk of liver-related disease and mortality compared to wild type. We hypothesized that silencing PNPLA3 messenger RNA

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(mRNA) with ALN-PNP, an investigational N-acetylgalactosamine-conjugated RNA interference therapeutic targeting PNPLA3 mRNA, would be well tolerated, and reduce liver fat in patients who are PNPLA3 p.I148M homozygotes with metabolic dysfunction–associated steatotic liver disease (MASLD). **Methods:** In a pooled interim analysis of 2 phase 1 studies conducted in the USA and South Korea, we analyzed 30 adult PNPLA3 p.I148M homozygotes with baseline liver fat $\geq$ 8.5% by magnetic resonance imaging–derived proton density fat fraction (MRI-PDFF) who had received study drug and had $\geq$1 evaluable post-baseline MRI-PDFF assessment. Participants were randomized 1:1:1:1 to receive a single dose of ALN-PNP 200 mg, 400 mg, or 800 mg, or placebo. The primary endpoint was the incidence and severity of treatment-emergent adverse events (TEAEs). Liver fat was assessed by MRI-PDFF at Weeks 6, 12, 24, and 36 post-single dose treatment. **Results:** At baseline, mean liver fat by MRI-PDFF was 18.3%, 16.9%, 18.2%, and 17.1% in the 200 mg (n = 8), 400 mg (n = 7), and 800 mg (n = 7), and placebo (n = 8) groups, respectively. ALN-PNP reduced liver fat from baseline by 48.0%, 37.2%, and 46.8% by Week 12 in the 200 mg, 400 mg, and 800 mg groups, respectively, compared to 11.9% for placebo (Figure). In the 800 mg group, the reduction in liver fat was sustained to Week 24. There were no serious adverse events, TEAEs leading to study discontinuation, or deaths. **Conclusion:** In this single-dose study, ALN-PNP was well tolerated at all dose levels tested and reduced liver fat in PNPLA3 p.I148M homozygotes with MASLD by up to 48%.

Figure. Single doses of ALN-PNP or placebo were administered to homozygous PNPLA3 p.I148M carriers with MASLD. Liver fat changes were evaluated by MRI-PDFF at multiple timepoints. At Week 12, ALN-PNP reduced liver fat by 48.0%, 37.2%, and 46.8% in the 200 mg, 400 mg, and 800 mg groups, respectively, compared to baseline. The analysis was based on the natural log-transformed MRI-PDFF values then exponentially back-transformed onto the original scale to give geometric percent changes in MRI-PDFF from baseline. Mean ±SE are shown.

1452 | THE RELEVANCE OF DATA-DRIVEN MASLD CLUSTERS AND THEIR RELATIONSHIP WITH MASH AND ADVANCED FIBROSIS IN PATIENTS WITH TYPE 2 DIABETES FROM THE QUID-NASH COHORT

Laurent Castera[1] Tiphaine Vida-Trecan[2] Pauline Manchon[3] Anais Vallet-Pichard[4] Sebastien Czernichow[5] Dominique Roulot[6] Valerie Paradis[7] Catherine Postic[8] Jean-Baptitste Julla[2] Etienne Larger[4] Bernard van Beers[9] Helene Fontaine[1] Thierry Poynard[10] Pierre Bedossa[11] Stanislas Pol[12] Dominique Valla[1] Cedric Laouenan[13] Francois Pattou[14] Jean-Francois Gautier[2], [1]Dept of Hepatology, Hopital Beaujon, AP-HP, Clichy, France, [2]Dept of Diabetology, Hopital Lariboisière, AP-HP, Paris, France, [3](DEBRC), Hôpital Bichat, AP-HP, Paris, France, [4]Dept of Diabetology, Hopital Cochin, AP-HP, Paris, France, [5]Dept of nutrition and obesity, Hôpital Européen Georges Pompidou, AP-HP, Paris, France, [6]Unit of Hepatology, Hopital Avicenne, AP-HP, Bobigny, France, [7]Dept of Pathology, Hopital Beaujon, AP-HP, Clichy, France, [8]Université Paris Cité, Institut Cochin, CNRS, Inserm, Paris, France., [9]Dept of Radiology, Hopital Beaujon, AP-HP, Clichy, France, [10]Pitié-Salpêtrière Hospital, Paris, France, [11]Liverpath, Paris, France, [12]Dept of Hepatology, Hopital Cochin, AP-HP, Paris, France, [13]DEBRC, Hôpital Bichat, AP-HP, Paris, France, [14]Dept of General and Endocrine Surgery, CHU de Lille, Lille, France

Background: MASLD exhibits considerable variability in clinical outcomes. Recently, two distinct types of clinically relevant data-driven MASLD clusters were identified: liver-specific and cardiometabolic (Raverdy et al., Nat Med, 2024 / PMID: 39653777). Despite having similar liver phenotypes at baseline, these clusters have different underlying biological profiles and clinical trajectories. Currently, there is a lack of data on patients with type 2 diabetes (T2D), who are at high risk of MASLD/MASH cirrhosis and its

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

complications. The present study aimed to explore the distribution of MASLD clusters and their relationship with MASH and advanced fibrosis (F3F4) in patients with T2D from the multicenter prospective Quid-NASH cohort (NCT03634098). **Methods:** Cluster analysis was performed using the partitioning around medoids method based on six clinical variables: age, BMI, HbA1c, ALT, LDL-cholesterol, and triglycerides. The cohort included 415 patients with T2D and MASLD (ALT >20/30 IU/L in females & males, respectively) attending diabetes clinics. Liver biopsies were centrally reviewed by a single expert pathologist (PB). **Results:** Clusters were determined in 383 patients (median age 60 years; male 51%; BMI 32 kg/m^2; HbA1c 7.4%; ALT 48 IU/L; LDL-cholesterol 0.8 g/l; triglycerides 1.66 g/l; MASH 55%; F3F4 36%). Figure 1A shows that three clusters were identified. Cluster 1 (Control) included 31% of patients. Cluster 2 (Cardiometabolic, CM) included 64% of patients (vs. 11% in the original study) and had the highest levels of HbA1c and triglycerides. Cluster 3 (Liver-specific, LS) included 5% of patients (vs. 7%) and had the highest ALT levels and the youngest age. Despite the marked differences between the clusters, CM and LS clusters had a higher prevalence of MASH than Control cluster (66.7% and 65.3% vs. 30.8%, respectively; $p < 0.01$) and CM had a higher prevalence of F3F4 (41.2% vs. 26.7%; $p = 0.02$) than Control cluster (Figure 1B). These findings are consistent with those reported in the original study. **Conclusion:** In this large, homogeneous cohort of patients with T2D and MASLD, our findings show that the cardiometabolic cluster accounted for two-thirds of cases, whereas the liver-specific cluster was minimal. Both clusters were associated with a higher prevalence of MASH and advanced fibrosis in the cardiometabolic cluster. These findings may be important for the future stratification of T2D patients in MASH therapeutic trials.

Figure 1A. Distribution of clusters in the Quid-NASH cohort (n=383)

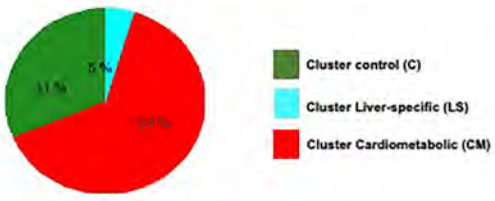

Figure 1B. Prevalence of MASH and F3F4 according to the clusters

1453 | RATIONALE AND DESIGN OF THE FIBROLITE STUDY EVALUATING SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF AFIMKIBART IN PATIENTS WITH ADVANCED LIVER FIBROSIS

Mazen Noureddin[1] Daniel Dugger[2] Steven Levitte[2] Valentina D'Arienzo[3] Sarah Williams[4] Vaibhavi Patel[4] KT Park[2] Jorge Ross Terres[2], [1]Houston Research Institute and Houston Methodist Hospital, Houston, Texas, USA, [2]Genentech, Inc., a member of the Roche Group, South San Francisco, CA, USA, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [4]Roche Products Ltd, Welwyn Garden City, Hertfordshire, UK

Background: Cirrhosis due to metabolic dysfunction-associated steatohepatitis (MASH) is increasingly a cause of liver transplantation and hepatocellular carcinoma (HCC). While resmetirom is approved for the treatment of MASH with moderate to advanced fibrosis (F2–F3), a significant unmet need remains for patients with compensated cirrhosis (F4) for reversal of cirrhosis, prevention of liver decompensation, HCC, and transplantation. Afimkibart (RO7790121/RG6631) is a fully human monoclonal antibody against tumor necrosis factor-like ligand 1A (TL1A), which acts as a key amplifier of inflammatory and fibrotic signaling pathways activated in disease states, through its receptor death receptor 3. **Methods:** The FIBROLITE

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

study (NCT06903065) is a single-arm, open-label study to evaluate the safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity and activity of afimkibart in 50 participants with advanced MASH fibrosis (F3–F4) in the USA and Mexico. Participants will be administered afimkibart via 10-week intravenous induction regimen followed by subcutaneous administration for a total of 52 weeks. Key inclusion criteria include a body mass index of 25–45 kg/m², and MASH fibrosis (F3–F4) confirmed by transient elastography ($\geq$12.0 kPa to $\leq$25.0 kPa) and biopsy staging within 12 months of baseline or Enhanced Liver Fibrosis (ELF) score of $\geq$9.8 to $\leq$11.3 at screening. Key exclusion criteria include decompensated liver disease, non-MASH causes of liver disease, and significant alcohol consumption. **Results:** The study population is expected to represent MASH patients with F3–F4 advanced fibrosis/compensated cirrhosis. The primary outcome is the safety of afimkibart in advanced liver disease. Secondary outcomes are the PK profile and activity of afimkibart in patients with MASH fibrosis (F3–F4). The PK profile will be investigated by measuring circulating concentrations of afimkibart at specified timepoints. FIBROLITE will leverage the utility of non-invasive tests (NITs) to evaluate the antifibrotic activity of afimkibart in F3–F4 MASH by measuring change from baseline to week 52 in liver stiffness by transient elastography, serum levels of propeptide of type III collagen, serum ELF test, and fibroinflammation by iron-corrected T1 magnetic resonance imaging mapping. **Conclusion:** If an acceptable safety and PK/PD profile for afimkibart is demonstrated, a larger, placebo-controlled follow-up study in people with MASH and advanced fibrosis may be undertaken. The data obtained from NITs could elucidate the anti-fibrotic potential of afimkibart as well as the potential for composite NIT assessments in MASH therapy development.

Background: Metabolic dysfunction and alcohol-related liver disease (MetALD) is a phenotype of steatotic liver disease characterized by moderate alcohol consumption coexisting with cardiometabolic risk factors. The pathogenesis of MetALD remains incompletely understood. Lipotoxicity, driven not only by lipid quantity but also specific lipid composition changes, is central to the pathology of steatotic liver disease. To clarify the role of lipotoxicity in pathogenesis of MetALD, we conducted a lipidomics analysis on liver tissues and serum samples from patients with MetALD and compared these lipid profiles with those from metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD). **Methods:** Thirty-two biopsy-proven patients were classified according to Delphi consensus criteria into MASLD ($n = 24$), MetALD ($n = 4$), and ALD ($n = 4$). Lipidomics profiling was performed using liquid chromatography-mass spectrometry. Lipid species differing significantly ($p < 0.05$) between MASLD and ALD groups were selected via one-way ANOVA, resulting in 59 lipid species. Principal component analysis, K-means clustering, and Euclidean distance analysis within the principal component space were applied to determine whether MetALD lipid profiles were more similar to MASLD or ALD. **Results:** No significant differences were observed among groups regarding age, sex, body mass index, skeletal muscle index, blood biochemistry, controlled attenuation parameter, liver stiffness, or NAFLD activity score. Principal component plots indicated that MetALD lipid profiles occupied an intermediate position between MASLD and ALD groups in both liver tissues and serum. However, K-means clustering placed MetALD profiles predominantly within the MASLD cluster. MetALD liver lipids such as lysophosphatidylserines, non-dihydrosphingomyelins, phosphatidylcholines, phosphatidylglycerols, and sphingomyelins were more similar to MASLD profiles. Conversely, multiple bis(monoacylglycero) phosphates, specific alpha-hydroxy ceramides, lactosylceramides, and triacylglycerols exhibited profiles closely resembling those of ALD. Although clustering and distance analyses indicated a general clustering proximity of MetALD to MASLD, several individual lipid species exhibited profiles that closely resembled those observed in ALD, particularly in pathways implicated in ceramide metabolism and hepatocellular injury. **Conclusion:** MetALD exhibits an intermediate lipidomic profile between MASLD and ALD, with an overall resemblance to MASLD. However, certain lipid species implicated in pathways such as ceramide metabolism, which are considered important in alcohol-associated liver injury, appear to align more closely with ALD, suggesting a pathophysiological overlap that contributes to disease development of MetALD.

1455 | GM60106: A NOVEL CLINICAL TREATMENT FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

WON-IL CHOI[1] Sungmin Song[2] Peter Goughnour[2] Won Hee Lee[3] Hee Jong Lee[2] Byung-Kwan Jeong[3] Wonsuk Choi[3] Jun Yong Park[4] Hail Kim[3] Jin Hee Ahn[5], [1]Jeonbuk National University Medical School, [2]JD Bioscience Inc., [3]Korea Advanced Institute of Science and Technology, [4]Yonsei University College of Medicine, [5]Gwangju Institute of Science and Technology

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), and its progressive form, metabolic dysfunction-associated steatohepatitis (MASH), represent a growing global health burden with a high unmet need for improved therapies. 5-Hydroxytryptamine receptor 2A (5HT2A) has emerged as a potential target for modulating lipid metabolism and fibrogenesis in the liver. Here, we characterize a peripherally restricted 5HT2A antagonist called GM-60106, and report Phase 1 safety and tolerability data (ClinicalTrials.gov: NCT05517564). **Methods:** The efficacy of GM-60106 on MASLD/MASH and liver fibrosis was evaluated in multiple murine models, including STZHFD model, CCL4-induced fibrosis model, and bile duct ligation (BDL) model. Histological analysis included steatosis, lobular inflammation, hepatocyte ballooning, and fibrosis. Phase 1 trial design of GM-60106 is a randomized, double-blind, placebo-controlled study to evaluate single and multiple ascending doses in healthy adults and individuals with elevated MASLD/MASH markers. The trial comprises three parts: • Part A (single ascending dose, SAD): 64 participants across 8 cohorts. • Part B (multiple ascending dose, MAD): 24 participants across 3 cohorts, once-daily doses for 14 days. • Part C (MAD): 8 participants with elevated disease markers, once-daily dosing for 28 days. **Results:** The expression of 5HT2A increased in hepatocytes upon high-fat diet feeding and in hepatic stellate cells during their activation. GM-60106 reduced lipid accumulation, inflammation, and hepatic fibrosis in STZHFD mouse model. GM-60106 also reduced hepatic fibrosis in both

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

CCL4-induced fibrosis model and BDL model. In a comparative study, GM-60106 showed superior efficacy in reducing MASLD/MASH progression and hepatic fibrosis compared to Resmetirom. In the Phase 1 trial, GM60106 was well-tolerated with no dose-limiting toxicities observed. Among participants with baseline liver fat content $>12\%$ (MRI-PDFF), liver fat reductions of up to 76% were observed after 28 days of treatment. Notably, the participant with a 76% reduction in liver fat showed no accompanying weight loss, indicating a direct hepatic effect of GM-60106 independent of systemic weight changes. **Conclusion:** GM-60106 demonstrated significant efficacy in preclinical models by mitigating lipid accumulation, inflammation, and fibrosis, outperforming current alternatives like Resmetirom. The Phase 1 clinical study further validated its safety and tolerability, highlighting GM-60106 as a promising candidate for long-term treatment strategies aimed at addressing the unmet needs of patients with MASLD. These findings support the continued clinical development of GM-60106 as a potentially first-in-class therapeutic candidate for the treatment of MASLD/MASH.

1456 | ACCURACY OF NONINVASIVE TESTS IN ASSESSING LIVER FIBROSIS IN THE GENERAL POPULATION: A LARGE-SCALE PROSPECTIVE MULTICENTER STUDY

Jing Zhao[1] Shanghao Liu[2] Jianxiang Song[1] Hui Shi[3] Xibin Liu[4] Yijun Tang[5] Puqiang Liu[6] Xiao Liang[7] Huizhen Fan[8] Qing He[9] Yilin Zhang[2] Yong Pan[10] JianSong Ji[11] Manguo Zhao[12] Hui Yang[13] Yang Bo[14] Shuli Hao[15] Tongqin Han[16] Yongyi Zeng[17] Guo Zhang[18] Qiang Yan[19] Rong Hu[3] Haiying Feng[4] Pinglei Pan[1] Zhongji Meng[5] Jianping Zhang[6] Yongfen Zhu[7] Jianwen Sheng[8] Fengjuan Chen[9] Ruyu Liu[10] Yanru Xie[11] Lingxiao Wang[12] Junhong Yang[12] Yan Yang[12] Yajuan Zhao[13] Jing Wang[14] Youfang Gao[15] Yuxia Qi[16] Wenjuan Wang[18] Zhaowei Tong[19] Gao-Jun Teng[2] Zhenyu Dai[1] Xiaolong Qi[2], [1]Affiliated Yancheng Hospital, School of Medicine, Southeast University, [2]Zhongda Hospital, Medical School, Southeast University, [3]The First People's Hospital of Lian yungang, [4]Huanghua People's Hospital, [5]Taihe Hospital, Hubei University of Medicine, [6]Puxian People's Hospital, [7]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, [8]Yichun People's Hospital, [9]Shenzhen third People's Hospital, [10]Beijing Ditan Hospital, Xuzhou Hospital, Capital Medical University, [11]Lishui Central Hospital, The Fifth Affiliated Hospital of Wenzhou Medical University, [12]Baiyin Central Hospital, [13]The Second Affiliated Hospital of Guangzhou Medical University, [14]General Hospital of Ningxia Medical University, [15]Bozhou People's Hospital, [16]Qingdao Public Health Clinical Center, [17]Mengchao Hepatobiliary Hospital of Fujian Medical University, [18]Guangxi Hospital Division of The First Affiliated Hospital, Sun Yat-sen University, [19]Huzhou Central Hospital

Background: Reliable and broadly applicable non-invasive tests (NITs) are essential for the early identification of liver fibrosis in the general population. This study aimed to evaluate the diagnostic performance of established NITs in predicting liver fibrosis among the general population. **Methods:** The LiverHealth project is a large, ongoing, prospective, community-based cohort study conducted in China among individuals aged 18 years and older, in which all participants underwent liver stiffness measurement (LSM) using transient elastography (Fibroscan). A total of 10,893 participants from seven regions in China—Haizhou District, Yandu District, Maojian District, Huanghua City, Yiyang New District, Qiantang District, and Puxian County—were enrolled between September 2024 and April 2025. Baseline demographic, anthropometric, and biochemical data were collected to compute multiple NIT scores, including LiverRisk, MAF-5, FIB-4, APRI, NFS, BARD, SAFE, Forns, Fibrosis Index, FibroIndex, and AAR. Liver fibrosis stages were defined based on LSM thresholds: ≥ 8.0 kPa for clinically significant liver fibrosis, ≥ 10.0 kPa for suggestive compensated advanced chronic liver disease (cACLD), ≥ 12.0 kPa for advanced fibrosis, and ≥ 15.0 kPa for highly suggestive cACLD. Diagnostic accuracy was assessed using the area under the receiver operating characteristic curve (AUC), with comparisons conducted using the DeLong test. **Results:** MAF-5 and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

LiverRisk scores demonstrated the highest diagnostic accuracy across all fibrosis thresholds. For clinically significant liver fibrosis, MAF-5 showed an AUC of 0.76 (95% CI: 0.74-0.79) and LiverRisk 0.75 (95% CI: 0.73-0.77), with no significant difference ($p = 0.122$). For suggestive cACLD (LSM $\geq$ 10.0 kPa), AUCs were 0.83 (95% CI: 0.80-0.87) for MAF-5 and 0.81 (95% CI: 0.78-0.85) for LiverRisk ($p = 0.109$). In detecting advanced fibrosis, both scores performed similarly: MAF-5 had an AUC of 0.86 (95% CI: 0.82-0.91) and LiverRisk 0.85 (95% CI: 0.80-0.90; $p = 0.478$). For highly suggestive cACLD, the AUCs were 0.87 (95% CI: 0.81-0.93) for MAF-5 and 0.88 (95% CI: 0.82-0.94; $p = 0.676$). Furthermore, MAF-5 demonstrated significantly superior performance in predicting clinically significant liver fibrosis and suggestive cACLD compared to the other nine non-invasive scores, with the exception of LiverRisk (all $p < 0.05$). **Conclusion:** Simple noninvasive tests can effectively identify individuals in the general population who are at risk of liver fibrosis. In this large-scale prospective community-based cohort in China, we found that MAF-5 and LiverRisk scores demonstrated the highest overall diagnostic accuracy.

1457 | MIRICORILANT, A SELECTIVE GLUCOCORTICOID RECEPTOR MODULATOR, REPROGRAMS HEPATIC GENE NETWORKS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Rafael Mayoral Monibas[1] Jan Kroon[1] Hazel Hunt[1] Aprille Espinueva[1] William Guyer[1] Kavita Juneja[1], [1]Corcept Therapeutics

Background: The hormone cortisol, which regulates metabolism and stress, has been implicated in the development and progression of metabolic dysfunction-associated steatohepatitis (MASH). Miricorilant (MIRI) is an orally delivered, nonsteroidal selective glucocorticoid receptor modulator (SGRM). In a phase 1b study, patients with presumed MASH treated with MIRI 100 mg twice weekly had a 28.2% mean reduction in liver fat content, with improvements in hepatic, lipid, and glycemic markers (Alkhouri et al. *Hepatology* 2024). This study aims to explore MIRI's mechanism of action by determining its effects on gene expression in human cells in vitro. **Methods:** Transcriptomic profiling was conducted in HepaRG cells, a human bipotent progenitor cell line that can differentiate into hepatocyte-like cells. Steatosis was induced by culturing cells in an oleic acid-rich medium for 7 days. Short-term treatment (8 hours) and sub-chronic treatment (5 days) with MIRI 400 nM (171.36 ng/mL) or vehicle

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was performed, and RNA-sequencing was used to assess gene expression changes induced by MIRI. **Results:** MIRI induced a dual regulatory signature with distinct temporal dynamics. At the early time point (8 hours), MIRI treatment led to the upregulation of genes involved in lipid transport (APOA4, APOA5, CREB3L3), ketogenesis (HMGCS2), bile acid synthesis (CYP7A1), and antioxidant defense (GPX2). Balanced chemokine regulation (increased CXCL8/decreased CXCL13) indicates modulation of hepatocyte pathways for immune cell recruitment, while reducing chronic inflammatory signals. Genes associated with cell cycle and proliferation (AURKB, TOP2A, KIFC1, KIF4A, KIF14) were downregulated. Following sub-chronic treatment with MIRI for 5 days, prolonged upregulation of APOA4, CREB3L3, GPX2, and VNN1 suggested continued enhancement of lipid handling and antioxidant defense. Downregulation of CYP51A1 and gluconeogenic G6PC1 and PCK2 genes suggested longer-term reduction in steatosis and improved glucose metabolism. Downregulation of WNT6 supported reduced fibrogenesis. **Conclusion:** MIRI selectively modulated key genes in pathways that regulate hepatic steatosis, metabolism, oxidative stress, inflammation, and fibrosis. These findings provide insights into MIRI's molecular mechanism of action, potentially informing future therapeutic strategies. The ongoing phase 2b MONARCH trial (NCT06108219) is further evaluating MIRI in patients with biopsy-confirmed or presumed noncirrhotic MASH.

Figure. Miricorilant induced significant transcriptional changes in human hepatocyte-like cells under steatotic conditions

1458 | PREDICTION OF STEATOTIC LIVER DISEASE: MACHINE LEARNING-BASED STUDY IN TAIWAN

Chia-Yen Dai[1] Tzu-Chun Lin[2] Hon-Yi Shi[3] Pei-Chien Tsai[4] Ming-Lun Yeh[5] Chung-Feng Huang[5] Jee-Fu Huang[5] Ming-Lung Yu[2], [1]Kaohsiung Medical University Hispital, Kaohsiung Medical University, Kaohsiung, Taiwan, [2]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [3]Kaohsiung Medical University, [4]Kaohsiung Medical University Hospital, Medical University, Kaohsiung, Taiwan, [5]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Kaohsiung

Background: In Taiwan, NAFLD affects approximately one-third of the population. Closely associated with metabolic disorders, non-alcoholic steatotic liver disease (SLD) have been a major disorder of liver diseases which may induce severe liver complications and substantially increase the risk of hepatocellular carcinoma. The integration of artificial intelligence (AI) into medical research has facilitated the extensive application of machine learning (ML) in predicting liver disease risk and treatment outcomes. This study aimed to apply ML algorithms to a community-based cohort in southern Taiwan to identify key risk factors for SLD and to develop predictive models with clinical applicability. **Methods:** Data were derived from community health examinations, and we colleced demographic features and clinical parameters including height, weight, waist circumference, systolic blood pressure (SBP), and diastolic blood pressure (DBP), aspartate aminotransferase (AST), alanine aminotransferase (ALT), triglycerides (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), and low-density lipoprotein cholesterol (LDL-C) levels. Five ML algorithms were evaluated: logistic regression (LR), random forest (RF), K-nearest neighbors (KNN), adaptive boosting (AdaBoost), and extreme gradient boosting (XGBoost). Model performance was assessed using accuracy, precision, recall, F1 score, and the area under the receiver operating characteristic curve (AUROC). **Results:** A total of 7,700 participants were included (39.2% male; mean age 50.9 $\pm$ 14.9 years). The Synthetic Minority Over-sampling Technique (SMOTE) was employed to balance SLD and non-SLD groups (n = 3,850 each). The dataset was randomly divided into training (80%) and testing (20%) subsets, with no significant differences observed between groups. Among all models, XGBoost achieved the highest performance, with an accuracy of 91.66%, precision of 91.78%, recall of 91.54%, F1 score of 91.65%, and AUROC of 96.92%. Feature importance analysis identified LDL-C, body mass index (BMI), triglycerides (TG), age, and waist circumference as the most

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

influential predictors of SLD. **Conclusion:** ML algorithms, particularly XGBoost, demonstrated high accuracy in predicting SLD and effectively identified key clinical predictors. These findings may enhance early diagnosis and facilitate the development of targeted intervention strategies in the management of SLD.

TABLE 1 Comparison of the machine learning (ML) model performance metrics following bootstrapping (N=7,700)

Training dataset (n=6,160)					
Model	Accuracy (95% CI)	Precision (95% CI)	Recall (95% CI)	F1 score (95% CI)	AUROC (95% CI)

1459 | QUTAN HUOXUE FORMULA INHIBITS MASH PROGRESSION BY REGULATING CYP1B1-MEDIATED ARACHIDONIC ACID METABOLISM

Jing Zhou[1], [1]Ning bo NO.2 hospital, Zhejiang, China

Background: The incidence of metabolic dysfunction-associated steatohepatitis (MASH) is rising annually, posing a significant threat to global health. However, effective therapeutic agents remain lacking. Qutan Huoxue Formula (QTHXF), an empirically developed traditional Chinese medicine formula, has demonstrated efficacy in reducing hepatic lipid deposition and inhibiting MASH progression. **Methods:** An MASH model was established in C57BL/6 mice via 16 weeks of high-fat diet (HFD) feeding. QTHXF was administered for 6 weeks as an intervention. Changes in body weight, liver weight, hepatic lipid deposition, and biochemical indices were monitored. Hepatic alterations at the gene and metabolic levels were assessed using transcriptomics and metabolomics analyses. In vitro, palmitate was used to induce steatosis in hepatocytes, and siRNA-mediated knockdown was employed to validate the mechanism of drug action. **Results:** QTHXF significantly reduced body weight, liver weight, hepatic steatosis, serum levels of alanine aminotransferase, triglycerides, and total cholesterol, as well as NASH scores and reactive oxygen species (ROS) levels in MASH mice. Transcriptomic sequencing revealed that differentially expressed genes regulated by QTHXF were significantly enriched in ROS-related pathways, with CYP1B1 identified as a key gene. QTHXF directly targeted CYP1B1 and markedly suppressed its expression in hepatocytes. Metabolomic analysis indicated that QTHXF suppressed the activation of hepatic arachidonic acid metabolism pathways. In vitro experiments further validated the mechanism involving QTHXF regulation of CYP1B1-mediated arachidonic acid metabolism. **Conclusion:** Qutan Huoxue Formula inhibits MASH progression by attenuating hepatic oxidative stress through the regulation of CYP1B1-mediated arachidonic acid metabolism. Our findings provide a novel strategy for the clinical treatment of MASH.

1460 | INCREASED HEPATIC MICROARTERIES AND COLLAGEN DEPOSITION IN ACINAR ZONE 1 ARE ASSOCIATED WITH CLINICALLY SIGNIFICANT PORTAL HYPERTENSION CAUSED BY METABOLIC ASSOCIATED STEATOTIC LIVER DISEASE

Zhengxin Li[1] Yayun Ren[2] Xiao Teng[3] Dean Tai[3] Jörn Schattenberg[4] Chenghai Liu[5], [1]Gongli Hospital of Shanghai Pudong New Area, [2]Hangzhou Choutu Tech. Co., Ltd [3]HistoIndex, [4]Department of Internal Medicine II, Saarland University Medical Center, [5]Shuguang Hospital, Shanghai University of Traditional Chinese Medicine

Background: Metabolic-associated steatotic liver disease (MASLD) is one of the common causes of clinically significant portal hypertension (CSPH). The occurrence of CSPH is often accompanied by severe complications such as bleeding and ascites. Early identification of CSPH remains challenging. This study aims to investigate histological correlates of CSPH in MASLD to develop pathological markers for early risk stratification. **Methods:** Eighty-five needle biopsy samples with MASLD were collected from Shuguang

Hospital and Medical Center of the Johannes Gutenberg-University. The risk of CSPH was based on Baveno VII consensus. According to liver stiffness measurement(LSM) and platelet(PLT) count, patients were divided into two groups: no CSPH risk(LSM **Results:** Fibrosis stages (NASH-CRN) in the high CSPH risk group included F1 (n = 2), F2 (n = 3), F3 (n = 8), and F4 (n = 5); the no CSPH risk group showed F1 (n = 21), F2 (n = 37), and F3 (n = 9) (no F4 cases). Compared to the no CSPH risk group, the high CSPH risk group had higher levels of arterial density (19.73 ± 10.98 vs. 13.12 ± 12.71, P < 0.05) and CPA in acinar zone 1(1.59 ± 0.70 vs. 0.90 ± 0.68, P **Conclusion:** Arterial proliferation, collagen deposition in acinar zone 1 and loss of central veins were associated with CSPH in MASLD, suggesting potential utility as pathological markers for early CSPH screening.

1461 | EFFECT OF MODERATE AND SEVERE HEPATIC IMPAIRMENT ON PHARMACOKINETICS, SAFETY AND TOLERABILITY OF PEGOZAFERMIN AFTER SUBCUTANEOUS ADMINISTRATION

Eric Lawitz[1] Leo Tseng[2] Kemal Balic[2] Hank Mansbach[2] Mildred Gottwald[2] Madhavi Rudraraju[3], [1]Texas Liver Institute, [2]89bio, Inc., [3]Pinnacle Clinical Research

Background: Hepatic impairment may alter the pharmacokinetics (PK) of therapeutic agents, potentially impacting safety and necessitating dose adjustments. This study assessed the PK, safety and tolerability of pegozafermin, a long-acting glycoPEGylated analog of fibroblast growth factor 21 (FGF21), in subjects with moderate and severe hepatic impairment (HI) from any etiology, including those with metabolic dysfunction-associated steatohepatitis (MASH). PK data will enable dosing recommendations in patients with varying degrees of HI. **Methods:** This multicenter, open-label,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

parallel-group, single-dose, PK study enrolled subjects with moderate (n = 8) and severe (n = 6) hepatic impairment (including 2 MASH subjects in each category), according to the Child-Pugh classification, and 12 healthy control subjects matched by age, sex, and body weight. All subjects received a single SC dose of pegozafermin (30 mg) via prefilled syringe. Blood samples for PK analysis were collected at predetermined intervals over 3 weeks. PK parameters, including AUC and Cmax, were determined using non-compartmental methods and compared across groups. Log-transformed PK parameters were analyzed using a statistical model, analysis of covariance (ANCOVA). The geometric least-square (LS) means and mean ratios for each group were calculated to evaluate the effect of HI on pegozafermin exposure. As part of the exploratory objectives, pharmacodynamic (PD) endpoints, including lipid panel and adiponectin levels, were evaluated as changes from baseline to Day 8. Safety and tolerability profile was also assessed. **Results:** Overall, PK profiles were similar between subjects with HI and healthy controls (Figure 1). The geometric LS mean ratios for AUC and Cmax remained within the standard bioequivalence range (80 – 125%), indicating that systemic exposure to pegozafermin is not substantially altered in subjects with moderate or severe HI. Furthermore, compared to other etiologies of cirrhosis, the presence of MASH did not appear to alter PK parameters in a meaningful way. PD biomarkers showed favorable changes at Day 8. The SC administration of pegozafermin was well tolerated across all degrees of hepatic impairment, with no new or unexpected safety signals observed. Mild to moderate gastrointestinal disorders were the most common treatment-emergent adverse events, occurring in 6 of the 26 subjects (23.1%). **Conclusion:** Pegozafermin was safe and well tolerated across subjects with HI. Moderate and severe HI, including the presence of MASH, had no clinically meaningful effect on PK profile or parameters of pegozafermin. Based on these findings, no dose adjustment is warranted in patients with HI.

1462 | STEATOTIC LIVER DISEASE IS AN UNFAVORABLE PROGNOSTIC FACTOR OF THE RECURRENCE FOLLOWING RESECTION IN EARLY-STAGE ORAL SQUAMOUS CELL CARCINOMA

Hidetoshi Nomura[1] Reiichiro Kondo[1] Jingo Kusukawa[1] Jun Akiba[1], [1]Kurume University School of Medicine

Background: Steatotic liver disease (SLD), especially metabolic dysfunction-associated steatotic liver disease (MASLD), is getting a lot of interest in the association with the prognosis of extrahepatic diseases. It has been reported that MASLD as a risk

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

factor for recurrence after resection in early esophageal cancer and early gastric cancer. However, the relationship between SLD/ MASLD and prognosis for oral squamous cell carcinoma (OSCC) is uninvestigated. The aim of this study is to investigate the association of SLD and MASLD with the risk of recurrence after resection in early-stage OSCC. **Methods:** We retrospectively analyzed 93 patients who underwent resection for Tis (carcinoma in situ) or T1 (maximum diameter < 2 cm, depth of invasion < 5 mm) OSCC between 2017 and 2024. There were 24 of Tis and 69 of T1. The mean age was 68.3 years, with a male-to-female ratio of 49:44. Smoking history and alcohol consumption history were present in 21 patients and 20 patients, respectively. SLD was assessed using the preoperative Hepatic Steatosis Index (HSI), with HSI $\geq$ 30 defined as SLD. MASLD was defined based on the presence of SLD (HSI ≥ 30) and concomitant metabolic factors. Data on metabolic factors (body mass index [BMI] $>$ 23 kg/m^2, impaired glucose tolerance, hypertension, dyslipidemia) and blood laboratory results were extracted from preoperative records. Impaired glucose tolerance, hypertension, and dyslipidemia were present in 59 patients, 51 patients, and 31 patients, respectively. The median follow-up period was 1219 days. **Results:** 50 patients were classified into the SLD group (HSI $\geq$ 30), and 43 into the non-SLD group (HSI $<$ 30). The SLD group had a significantly higher BMI than the non-SLD group (24.54 ± 2.57 vs. 20.71 ± 3.15, $p < 0.01$). MASLD was identified in 32 cases. In univariate analysis for recurrence after resection, HSI $\geq$ 30 (Hazard Ratio [HR] 2.79, $p < 0.04$), MASLD (HR 3.14, $p < 0.01$), and positive surgical margin (HR 4.19, $p < 0.01$) had a statistically significant impact. Kaplan-Meier curves confirmed that the SLD group showed significantly worse recurrence-free survival (RFS) compared to the non-SLD group (log-rank test $P < 0.03$). Similarly, patients with MASLD exhibited significantly worse RFS than those without MASLD ($p < 0.01$). Neutrophil-to-lymphocyte (N/L) ratio ($R = 0.36$, $p < 0.01$) and CRP ($R = 0.36$, $p = 0.02$) were decreased along with increase of HSI. There were no significant differences between the SLD and non-SLD groups regarding age, sex, smoking history, alcohol consumption history, T classification, or positive surgical margin status, eGFR, and γGTP. **Conclusion:** SLD/ MASLD is a significant risk factor for recurrence following resection in Tis and T1 oral squamous cell carcinoma. These findings highlight a potential link between liver health, metabolic dysfunction, and oral cancer prognosis. SLD may be associated with immunoinflammatory responses and involved in patient prognosis.

1463 | BEYOND THE AIRWAY: THE POSSIBLE HEPATIC COST OF CPAP IN OBSTRUCTIVE SLEEP APNEA

Muhammad Ali Ibrahim Kazi Hasan Kamal[1] Akshay Sharma[1] Nirav Agrawal[1] Adrien Mazer[1] Sanmeet Singh[1], [1]Anne Arundel Medical Center

Background: Obstructive sleep apnea (OSA) is a prevalent disorder marked by repeated upper airway obstruction, leading to intermittent hypoxia and systemic inflammation, which contribute to metabolic, cardiovascular, and liver-related complications. While continuous positive airway pressure (CPAP) therapy improves oxygenation and has proven cardiovascular benefits, its effect on hepatic outcomes such as NASH and cirrhosis remains unclear. Given the shared pathophysiology between OSA and metabolic liver disease, this study aimed to evaluate the incidence of NASH and liver complications in CPAP users versus non-users using a propensity-matched cohort design. **Methods:** We conducted a retrospective cohort study utilizing data from patients who underwent sleep testing and were diagnosed with OSA. Two cohorts were established: one group that initiated CPAP therapy and one that did not. Patients were matched 1:1 using propensity score matching for age, sex, ethnicity, race, and Charleston Comorbidity Index (CCI). Outcomes assessed included the development of NASH, varices, hepatic encephalopathy, ascites, and cirrhosis. Risk differences and risk ratios (RR) with 95% confidence intervals (CI) were calculated for each outcome. **Results:** A total of 204,616 patients were included in the analysis, with 102,308 patients in each matched cohort. Patients with OSA who used CPAP had a significantly higher risk of developing the following outcomes compared to those who did not use CPAP • NASH: CPAP 2.2% vs. No CPAP 1.7%. • RR: 1.288 (95% CI: 1.211–1.370), $p < 0.001$. • Varices: CPAP 0.8% vs. No CPAP 0.6%. • RR: 1.211 (95% CI: 1.093–1.342), $p < 0.001$. • Hepatic Encephalopathy: CPAP 0.5% vs. No CPAP 0.3%. • RR: 1.623 (95% CI: 1.408–1.871), $p < 0.001$. • Ascites: CPAP 3.0% vs. No CPAP 2.1%. • RR: 1.441 (95% CI: 1.364–1.522), $p < 0.001$. • Cirrhosis: CPAP 3.0% vs. No CPAP 2.5%. • RR: 1.212 (95% CI: 1.150–1.276), $p < 0.001$ **Conclusion:** In this large-scale propensity-matched cohort study, CPAP use in patients with OSA was associated with an increased risk of developing nonalcoholic steatohepatitis (NASH) and liver-related complications, including varices, hepatic encephalopathy, ascites, and cirrhosis. While CPAP therapy is well established for improving cardiovascular and respiratory outcomes, these findings suggest that CPAP alone may not adequately mitigate the hepatic risks linked to OSA. The observed associations could reflect underlying disease severity, lifestyle factors, or limitations in CPAP adherence. Given the rising prevalence of OSA and its association with systemic inflammation, oxidative stress, and metabolic dysfunction, further

research is needed to explore the interplay between CPAP adherence, OSA severity, and lifestyle modifications to optimize hepatic outcomes in this high-risk population.

1464 | CARDIOVASCULAR DISEASE RISK IN METABOLIC ASSOCIATED FATTY LIVER DISEASE: A MULTICENTER PROPENSITY-MATCHED LONGITUDINAL ANALYSIS

Ahmed Salem[1] Sarah Meribout[1] Mohammed Abusuliman[2] Mohamed Eldesouki[3] Avleen Kaur[4] Hazem Abosheaishaa[5] Sherif Elhanafi[6] Aaron Tokayer[1], [1]Maimonides Medical Center, [2]Henry Ford Hospital, [3]New York Medical College at Saint Michael Medical Center, [4]Sunny Upstate University Medical Center, [5]Mount Sinai Queens, [6]Texas Tech University Health Science Center El Paso

Background: Metabolic associated fatty liver disease (MAFLD) is increasingly recognized as a systemic metabolic condition. While it has been associated with cardiovascular disease (CVD), the long-term real-world magnitude of this risk remains underexplored. Aim: To assess the incidence and predictors of major adverse cardiovascular events (MACE) in patients with MAFLD compared to matched non-MAFLD controls. **Methods:** We conducted a retrospective multicenter cohort study using TriNetX, a U.S.-based network of longitudinal electronic health records. Adults ($\geq$18 years) diagnosed with MAFLD (ICD-10: K76.0) from Jan 1, 2010, to Dec 31, 2023, were included. Exclusion criteria: prior MI, stroke, cardiovascular procedures, alcohol-related liver disease, viral hepatitis, or cirrhosis at baseline. Controls were matched 1:1 for age, sex, BMI, diabetes, hypertension, dyslipidemia, tobacco use, and use of statins or antiplatelets. The primary outcome was 5-year incidence of MACE: MI, stroke (ischemic or hemorrhagic), and cardiovascular death. Adjusted hazard ratios (aHR) were estimated via Cox models controlling for metabolic syndrome, HbA1c, and medications. Kaplan-Meier analysis illustrated cumulative risk. **Results:** After matching, 48,552 patients (24,276 per group) were included. Mean age: 57.4 years; 52.8% female. Median follow-up: 5.2 years. MAFLD patients had significantly higher 5-year MACE incidence: • MACE: 13.7% vs 8.4% ($p < 0.001$). • MI: 5.9% vs 3.7%; aHR 1.56 (95% CI: 1.39–1.74). • Stroke: 4.4% vs 2.9%; aHR 1.51 (95% CI: 1.32–1.73). • CV death: 3.5% vs 1.9%; aHR 1.88 (95% CI: 1.55–2.29). Statin use was protective in both groups (aHR 0.67; 95% CI: 0.56–0.80). Sensitivity analyses confirmed findings across subgroups by diabetes, sex, LDL, and BMI. Kaplan-Meier curves showed divergence by 24 months, with sustained separation over 5 years. **Conclusion:** MAFLD is independently linked to increased long-term risk of MI, stroke, and cardiovascular death. These real-world findings support classifying MAFLD as a systemic disease and underscore the need for early cardiovascular screening, aggressive risk management, and statin therapy.

Background: Comprehensive understanding of the prevalence of steatotic liver disease (SLD) and liver fibrosis in the general population is essential for shaping effective public health policies aimed at reducing the future burden of cirrhosis and liver cancer. China bears the world's highest burden of chronic liver disease, yet population-level epidemiological data remain limited. This study aimed to determine the prevalence of SLD and liver fibrosis in the general Chinese population. **Methods:** The LiverHealth project is a large, ongoing, prospective, community-based cohort study conducted in China among individuals aged 18 years and older, in which all participants underwent controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) assessment using transient elastography (Fibroscan). Between September 2024 and April 2025, participants were enrolled from seven sites across China: Haizhou District, Yandu District, Maojian District, Huanghua City, Yiyang New District, Qiantang District, and Puxian County. Comprehensive data collection included standardized questionnaires, anthropometric measurements, and laboratory tests. Logistic regression analysis was performed to identify risk factors associated with SLD and liver fibrosis. SLD was graded by CAP values: ≥248 dB/m (≥S1, mild or above), ≥268 dB/m (≥S2, moderate or above), and ≥280 dB/m (S3, severe). Fibrosis stages were defined by LSM thresholds: ≥6.0 kPa (≥F1, mild or above), ≥8.0 kPa (≥F2, moderate or above), and ≥10.0 kPa (≥F3, advanced fibrosis or above). **Results:** A total of 11,721 participants were included, with a median age of 49 years (IQR: 36.0–59.0), and 48.5% (n = 5,687) were male. The prevalence of ≥S1, ≥S2, and S3 was 43.06%, 30.35%, and 24.07%, respectively. The prevalence of ≥F1, ≥F2, and ≥F3 was 19.23%, 4.37%, and 1.65%, respectively. Additionally, 24.90% of individuals were identified with metabolic dysfunction-associated steatotic liver disease (MASLD) and 1.66% met criteria for metabolic and alcohol-related liver disease (MetALD). The prevalence of SLD and fibrosis varied significantly by sex and age groups (Figure 1A–1D). Individuals who were male, or had obesity, diabetes, hypertension, dyslipidemia, ≥2 metabolic risk factors, or elevated liver enzymes, or decreased platelet counts showed significantly higher prevalence of all grades of steatosis and fibrosis. Multivariate analysis further identified obesity, male, hypertension, diabetes, and elevated alanine aminotransferase or aspartate aminotransferase as independent risk factors associated with both SLD and fibrosis. **Conclusion:** High prevalence of SLD and liver fibrosis was identified in the general adult population in China. These findings underscore the urgent need for effective population-based screening and prevention strategies to mitigate the future burden of cirrhosis and liver cancer.

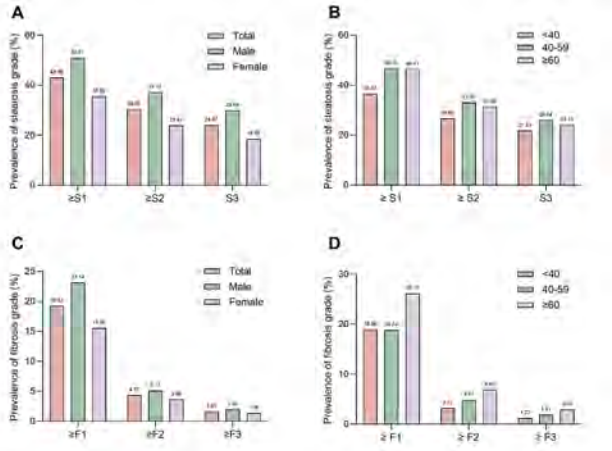

Figure 1. Prevalence of steatotic liver disease (SLD) and fibrosis by sex and age groups.

(A) SLD prevalence (≥S1, ≥S2, S3) in the overall population and by sex.

(B) SLD prevalence across age groups (<40, 40–59, ≥60 years).

(C) Fibrosis prevalence (≥F1, ≥F2, ≥F3) in the overall population and by sex.

(D) Fibrosis prevalence across age groups (<40, 40–59, ≥60 years).

1466 | UNIQUE SEX-SPECIFIC ASSOCIATIONS OF METABOLIC AND HORMONAL FACTORS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Norah Terrault[1] Jennifer Dodge[1] Laura Wilson[2] Ayako Suzuki[3], [1]university of Southern California, [2]Johns Hopkins University, [3]Duke University

Background: Biologic sex is known to influence disease onset, progression, and treatment response in many diseases. Understanding risk factors for MASH from non-MASH in persons with MASLD is essential, as MASH is associated with higher risk of fibrosis progression and need for targeted therapeutic interventions. Here, we sought to examine sex-specific clinical, metabolic and hormonal related factors associated with disease severity in MASLD. **Methods:** Cross-sectional study of participants (N = 1595 women, 1002 men; randomly split 80:20 into derivation and test sets) with biopsy-proven MASLD. The key outcome was borderline/definite MASH. Explanatory variables included laboratory parameters, metabolic and clinical comorbidities, and menopausal status/synthetic estrogen use. Numeric variables were treated as continuous or categorical depending on their relationship with the outcome. Sex-stratified multivariable models were developed in the derivation sets using two statistical approaches, logistic and elastic net regression. Optimal models were selected for men and women based on clinical utility and performance in the test sets assessed via area under the receiver operating curve (AUC) and the interaction of sex with model-identified variables assessed. **Results:** Among participants (median age 52 yrs, 72.4% White, 33.5 median BMI, 39.5% and 31.5% with prediabetes/diabetes, 51.3% low alcohol use), 49.9% had significant fibrosis and 57.1% met criteria for MASH. Women were 65.8% postmenopausal; 10.9% reported estrogen use. Model discrimination was strong across sexes: women 0.803–0.804, men 0.794-0.825. For MASH, elevated AST and HbA1c were consistently associated with increased odds in both sexes (TABLE). In women, additional associations were lower platelets, higher GGT, and absence of estrogen therapy at menopause, whereas in men, higher BMI, elevated triglycerides, and low alcohol consumption were additional associations. Interaction testing identified statistically significant interactions for sex with age (p = 0.02), alcohol use (p = 0.005), BMI (p = 0.02), with ALT approaching significant (p = 0.06). **Conclusion:** Unique sex-specific associations with MASH severity were identified, highlighting the importance of studying MASLD through a sex-specific lens inclusive of hormonal influences, both to advance knowledge regarding the pathogenic underpinnings of disease severity as well as developing more effective, personalized approaches to MASH diagnosis and management.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Patients with metabolic dysfunction and alcohol-related liver disease (MetALD) and coexisting diabetes mellitus (DM) are at increased risk of morbidity and mortality, particularly with poorly controlled glycemia. However, optimal inpatient glucose management in this population remains unclear. Current guidelines generally recommend a liberalized glucose target of <180 mg/dL, but whether stricter control improves clinical outcomes has not been studied. **Methods:** In this study, 107 hospitalized patients with MetALD and DM were stratified based on fasting glucose levels ranging from 100–180 mg/dL in 10 mg/dL increments. Baseline characteristics and rates of inpatient complications—including ascites, hepatic encephalopathy, esophageal variceal bleeding (EVB), acute kidney injury (AKI), and infection—were analyzed in relation to fasting glucose levels. Significance was assessed via analysis of variance (ANOVA), with $p<0.05$ considered significant. Data are reported as mean $\pm$ SEM. **Results:** The average patient age was 53 $\pm$ 11.5 years of age, with a mean BMI of 30.3 $\pm$ 8.6 kg/m², daily alcohol use of 302 $\pm$ 39 grams, and a median MELD score of 14 (IQR 8.5–20.5). Patients with glucose levels <140 mg/dL had lower—but not statistically significant—rates of ascites (26.2% vs 41%, $p=0.13$), encephalopathy (35.3% vs 47.6%, $p=0.2$), AKI (26.1% vs 35.7%, $p=0.3$), and infections (26.1% vs 19%, $p=0.4$), though this difference was small and not statistically significant. However, EVB was significantly lower in those with glucose <140 mg/dL compared to higher levels (13.8% vs 33.3%, $p=0.02$). Above 150 mg/dL, the incidence of EVB remained lower but did not reach statistical significance (16.9% vs 30.5%, $p=0.13$). **Conclusion:** Our findings demonstrated that in hospitalized persons with MetALD and DM, a fasting glucose level <140mg/dl was associated with a lower rate of ascites, encephalopathy, and AKI and a significantly lower rate of EVB. Our study suggests maintaining glucose levels <140mg/dl in this patient population may minimize complications. Considering that diabetic patients with advanced liver disease are known to have a propensity toward hypoglycemia due to low glycogen stores and poor ability to liberate stored glucose, maintaining a stricter glycemic control while avoiding hypoglycemia might benefit patients and improve clinical outcomes.

1468 | RISK OF PYOGENIC LIVER ABSCESS AND ITS CLINICAL COMPLICATIONS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A NATIONWIDE COHORT STUDY

Na Ryung Choi[1] Hanah Lee[2] Hyungmi An[3] Jae Yoon Jeong[4] Hwi Young Kim[5], [1]Ewha Womans University Mokdong Hospital, [2]Department of Internal Medicine, Chung-Ang University Hospital, [3]Department of Statistics and Data Science, Korea National Open University, [4]Department of Internal Medicine, Ewha Womans University Mokdong Hospital, [5]Division of Gastroenterology and Hepatology, University of Nebraska Medical Center

Background: Pyogenic liver abscess (PLA) is a severe infectious disease with significant morbidity and mortality and the incidence of pyogenic liver abscess (PLA) is rising in South Korea. This study investigated the association between metabolic dysfunction-associated liver disease (MASLD) and PLA incidence, as well as the risk of PLA complications. **Methods:** We analyzed data from 2,951,003 adults aged 40–64 years who underwent health examinations between 2009 and 2010, as recorded in the Korean National Health Insurance Service database. Hepatic steatosis was defined as a fatty liver index ≥ 30, and MASLD was identified based on established criteria. Participants were categorized into five mutually exclusive groups: (1) MASLD, (2) MASLD with increased alcohol intake (MetALD), (3) MASLD with other combined etiology, (4) alcohol-associated liver disease with cardiometabolic risk factors (ALD with CMRF), and (5) non-steatotic liver disease (non-SLD). Cox proportional hazards models were used to assess the risk of PLA and its complications. Additionally, changes in MASLD status over a four-year follow-up period were evaluated for their impact on PLA risk. **Results:** Over a median follow-up of 13 years (IQR 13–14), PLA occurred in 3,152 individuals with MASLD (N = 881,466) and 3,169 individuals without any SLD (N = 1,797,978). The incidence rate of PLA was 27.2 vs. 13.3 per 100,000 person-years in the MASLD and non-SLD group, respectively. MASLD was significantly associated with an increased risk of PLA (HR: 1.53, 95% CI: 1.45–1.61) and its complications (HR: 1.72, 95% CI: 1.27–2.33) compared to non-SLD. In the 4-year follow-up analysis, individuals with persistent MASLD had the highest risk of PLA (HR: 1.61, 95% CI: 1.39–1.74), followed by those who MASLD regressed to non-SLD (HR: 1.38, 95% CI: 1.23–1.53) and who developed MASLD during follow-up (HR: 1.27, 95% CI: 1.13–1.43) compared to individuals without any SLD at both baseline and follow-up. Other SLD categories, including MetALD, MASLD with other combined etiologies, and the ALD group, also showed a higher risk of PLA compared to the non-SLD group. **Conclusion:** MASLD was significantly

associated with an increased risk of PLA and its complications, with the highest risk observed in individuals with persistent MASLD in a large-scale cohort study using South Korea's National Health Insurance data. Given the global increase in MASLD prevalence, pyogenic liver abscess could be considered as a differential diagnosis in patients presenting with suspected infection.

Cumulative incidence of liver abscess according to the (A) MASLD and (B) SLD stauts.

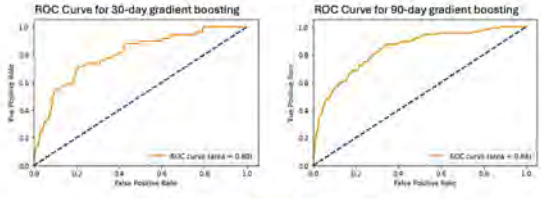
1469 | PATIENTS WITH DIABETES AT HIGH RISK OF UNDIAGNOSED ADVANCED LIVER FIBROSIS ARE AT INCREASED RISK OF POSTOPERATIVE MORTALITY AFTER ELECTIVE SURGERY

Christen Ong[1] Chloe Yitian Guo[1] Daniel Yan Zheng Lim[2] Yiying Pei[2] Bochao Jiang[2] Chanda Ho[2] Kevin Kim Jun Teh[2] Yong Mong Bee[3] Hairil Rizal[4] Chee-Kiat Tan[2] George Boon Bee Goh[2], [1]Yong Loo Lin School of Medicine, National University of Singapore, [2]Dept of Gastroenterology and Hepatology, Singapore General Hospital, [3]Dept of Endocrinology, Singapore General Hospital, [4]Dept of Anaesthesiology, Singapore General Hospital

Background: Diabetes mellitus is a common comorbidity in patients undergoing elective surgery and they may have MASLD with advanced fibrosis. It is unknown whether the preoperative FIB-4 score relates to postoperative mortality risk, and whether this risk is well estimated by existing risk models for cirrhotic patients (MELD-Na, VOCAL-Penn). Hence, we evaluated whether a high-risk preoperative FIB-4 score of >2.67 predicts postoperative mortality in diabetic patients without known advanced fibrosis or cirrhosis undergoing elective surgery. In addition, using machine learning (ML) methods, we developed new risk models incorporating FIB-4 score and evaluated them against current mortality risk prediction models. **Methods:** We analyzed 8,437 diabetic patients with FIB-4 scores from the PASAR database, a large perioperative database from a major Asian academic medical center. Median age was 65.00 (IQR 57.00 – 72.00) and 57.67% were males. Logistic regression models evaluated association between high FIB-4 scores and postoperative mortality at 30 and 90 days. Other variables included patient demographics, comorbidities, hepatic steatosis index, organ system undergoing surgery, and operative risk. Further predictive modelling was done using ML models (random forests, gradient boosting, multilayer perceptron). All models were evaluated alongside MELD-Na and VOCAL-Penn scores using the overall cohort, as well as the subgroup of patients with high-risk FIB-4 scores. SHAP analysis was used to identify key predictors in ML models. **Results:** A high-risk FIB-4 score was significantly associated with both 30-day (OR 2.46, 95%CI 1.73–3.48, $p<0.001$) and 90-day postoperative mortality (OR 2.15, 95%CI: 1.65–2.79, $p<0.001$). In the overall cohort, gradient boosting model had the best performance (30-day AUROC: 0.80, 95%CI 0.74–0.86), outperforming MELD-Na (30-day AUROC 0.66, 95%CI 0.56–0.75) and VOCAL-Penn (30-day AUROC 0.59, 95%CI 0.55–0.61). Key independent predictors included FIB-4 score category, hepatic steatosis index and preoperative white blood cell count. In the high FIB-4 subgroup, novel ML models also surpassed MELD-Na and VOCAL-Penn in overall performance. **Conclusion:** A high-risk FIB-4 score is associated with increased 30- and 90-day postoperative mortality in diabetic patients undergoing elective surgery. These patients may benefit from specialist referral for preoperative optimization. As existing risk scores do not perform well in such patients, we propose using novel ML-based risk scores instead.

Figure 1. Comparison and visualization of model performance



Model AUROC for 30-day postoperative mortality

	Logistic Regression	Random Forest	Gradient Boosting	Multilayer Perceptron	MELD-Na	VOCAL-Penn
AUROC	0.72	0.79	0.80	0.76	0.66	0.59

Model AUROC for 90-day postoperative mortality

	Logistic Regression	Random Forest	Gradient Boosting	Multilayer Perceptron	MELD-Na	VOCAL-Penn
AUROC	0.78	0.79	0.84	0.72	0.69	0.64

Highest scoring model for each metric is marked in green.

1470 | TRANSCRIPTOMIC REGULATION OF E2F1 IN MASLD PROGRESSION IN AFRICAN AMERICANS

Tanmoy Mondal[1] Coleman Smith[2] Christopher Loffredo[3] Ruth Quartey[1] Charles Howell[4] Brent Korba[3] Zaki Sherif[1] Gail Nunlee-Bland[1] Leanna Rucker[5] Gemeyel Moses[1] Somiranjan Ghosh[1], [1]Howard University, [2]Georgetown University Hospital, [3]Georgetown University, [4]Howard University Hospital, [5]MedStar Georgetown University Hospital

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is a chronic liver condition characterized by hepatic fat accumulation that can progress to advanced stages of liver disease. The prevalence of MASLD in the US has risen to 30% as of 2023. However, African Americans (AAs) paradoxically exhibit a significantly lower MASLD prevalence (13%) despite higher rates of obesity, Type 2 Diabetes, and hyperlipidemia. This unsolved trend underscores the need to investigate ethnic-specific mechanisms in the underlying susceptibility, heterogeneity, and progression of MASLD. *E2F1*, a key metabolic regulator and fibrogenic marker, modulates fatty acid oxidation and plays a critical role in lipid biosynthesis, including hepatic steatosis. Our preliminary research revealed the dysregulation of *E2F1* pathways in blood samples in AA MASLD patients, suggesting a link to their unique metabolic phenotype. Relying on these findings, our pilot study aims to elucidate the role of *E2F1* in MASLD progression among AAs through transcriptomic and clinical analyses. **Methods:** We collected whole blood from clinically identified MASLD patients and healthy AA cohorts (total n = 24, MASLD n = 16, Control n = 8 with matched age, gender). Participants' sociodemographic and medical histories were recorded. RNA sequencing was performed, followed by Ingenuity Pathway Analysis (IPA) to identify significant pathways and the biofunctions. *E2F1* expression and its regulatory up- and downstream genes, and their expression, were validated by custom TaqMan qRT-PCR Arrays (*E2F* and *TGFB* signaling pathways). **Results:** Transcriptomic analysis in AAs MASLD patients revealed significant (p value < 0.05) downregulation of key *E2F1*-regulated genes, including *CCNA1*, *CDK2*, and multiple HDACs (*HDAC1, HDAC4, HDAC5, and HDAC7*), which are involved in *hepatocyte proliferation*, *chromatin remodeling*, and *fibrogenesis.* Network analysis also indicated the activation of *TP53*, *CDKN2A*, *cyclin E*, and RB complex, suggesting a transcriptional profile that may suppress hepatic fibrosis, hence reflecting a protective regulatory mechanism. **Conclusion:** Our pilot study suggests a unique, possibly protective, E2F1-associated signature in AAs that may contribute to their lower MASLD prevalence despite metabolic risk. These preliminary findings highlight distinct *E2F1*-driven networks that may underlie ethnic differences in MASLD progression, emphasizing the need for further large-scale studies for validation.

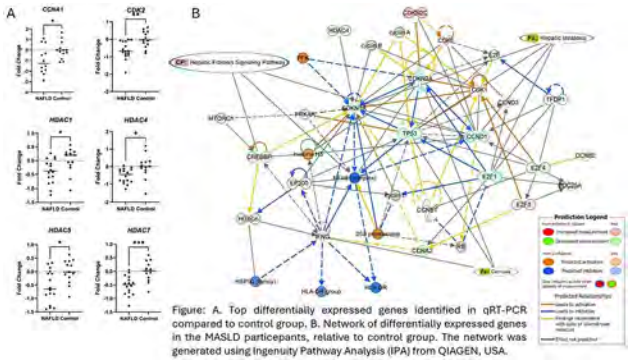

Figure: A. Top differentially expressed genes identified in qRT-PCR compared to control group. B. Network of differentially expressed genes in the MASLD particepants, relative to control group. The network was generated using Ingenuity Pathway Analysis (IPA) from QIAGEN, USA.

1471 | CLINICAL, HISTOLOGICAL AND BILE ACIDS PROFILE FEATURES OF LEAN METABOLIC-ASSOCIATED FATTY LIVER DISEASE

Jie Liu[1] Lili Zhao[1] Jia Li[1], [1]Department of Hepatology, Tianjin Second People's Hospital

Background: The incidence rate of (metabolic-associated fatty liver disease) MAFLD is increasingly significant, along with lean MAFLD. Lean MAFLD can also lead to cirrhosis and liver cancer. However, little is known about the clinical, histological and metabolomic features of lean MAFLD patients. **Methods:** Current study enrolled consecutive MAFLD patients and available liver biopsy results. Patients were stratified by body mass index(BMI) into two groups for the comparison of their clinical and histological variables, which included

1472 | THE FADS2 RS174583 RISK ALLELE ALTERS THE HEPATIC PHOSPHOLIPID PROFILE AND CONTRIBUTES TO FIBROSIS PROGRESSION IN MASLD

Shunsuke Ikejima[1] Kazuyoshi Kon[1] Hyeon-Cheol Lee-Okada[2] Kumiko Arai[1] Kyoko Fukuhara[1] Reiko Yaginuma[1] Kei Ishizuka[1] Hiroo Fukada[1] Akira Uchiyama[1] Shunhei Yamashina[1] Takehiko Yokomizo[3] Kenichi Ikejima[1], [1]Juntendo University Graduate School of Medicine, [2]Juntendo University School of Medicne, [3]Juntendo University School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) develops from a combination of genetic predisposition and acquired factors such as overeating, aging, and physical inactivity. While PNPLA3 single nucleotide polymorphisms (SNPs) are widely known to be associated with MASLD onset, their impact on disease progression remains insufficiently understood. We have previously suggested that SNPs in fatty acid desaturase (FADS) genes may influence the progression of steatohepatitis. In this study, we investigated the association between the risk allele of FADS2 and both intrahepatic lipid composition and fibrosis progression in MASLD. **Methods:** We analyzed 48 patients with biopsy-proven MASLD between January 2021 and September 2024. Patients were divided into two groups: those with non-progressive fibrosis (stage 0–2, n = 32) and those with advanced fibrosis (stage 3–4, n = 16). Genotyping for PNPLA3 (rs738409), MBOAT7 (rs641738), TM6SF2 (rs58542926), FADS1 (rs174556), and FADS2 (rs174583) was performed using TaqMan PCR. Lipidomic analysis of liver tissues from 24 MASLD patients was conducted using LC/MS. **Results:** A higher frequency of PNPLA3 GG and FADS2 TT genotypes—both known as risk alleles—was observed in the progressive group. The combined PNPLA3-GG/FADS2-TT genotype was significantly more frequent in the progressive group than in the non-progressive group (43.8% vs. 12%). Multivariate logistic regression adjusting for age and sex demonstrated that the PNPLA3-GG/FADS2-TT genotype was an independent risk factor for fibrosis progression (odds ratio 7.2). Lipidomic profiling revealed that patients with the FADS2-TT genotype had significantly decreased levels of phosphatidylcholine species containing 16:0/20:3n-9 and 18:0/18:3n-6, as well as lysophosphatidylcholine with sn-2_20:4, compared with those with CC or CT genotypes. Conversely, LPE_sn-1_16:1 was increased in FADS2-TT carriers. Diacylglycerol and triacylglycerol species were unaffected by the FADS2 genotype. Notably, LPE_04_sn-1_16:1 showed a positive correlation with both age and fibrosis stage (r = 0.42 and 0.34, respectively), whereas PC 16:0/20:3n-9 and 18:0/18:3n-6 levels were negatively correlated with the serum branched-chain amino acid to tyrosine ratio (r = –0.32 and –0.31, respectively), a marker of metabolic disturbance in advanced liver disease. **Conclusion:** The FADS2 risk allele promotes MASLD progression via altered hepatic phospholipid composition, characterized by reduced polyunsaturated PC and LPC and increased monounsaturated LPE. These shifts impair membrane function, enhance inflammation, and progress fibrosis. Co-inheritance of FADS2-TT and PNPLA3-GG further increases fibrosis risk, suggesting a synergistic genetic effect. FADS2 polymorphisms contribute to MASLD severity by modulating hepatic lipid profiles, particularly in the presence of PNPLA3 risk alleles.

1473 | WHERE IS THE MASLD?: THE DIFFICULTY OF IDENTIFYING PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE WITHIN A GLOBAL DATABASE

Taylor Seacor[1] Garrick Gu[1] Anita Krishnarao[2], [1]University of Massachusetts Chan Medical School, [2]UMass Memorial Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the most common etiologies of cirrhosis and leading indications for liver transplantation worldwide. The prevalence of MASLD is estimated to be 30-40%, and early diagnosis is necessary to prevent liver disease progression and decompensation. The multi-step diagnostic criteria and the various labels for MASLD have created complexity in identifying these patients within a large clinical database. The purpose of this study is therefore to highlight the innate difficulty of capturing patients with MASLD via database query which hinders our ability to study this patient population and offer therapeutic interventions on a larger scale. **Methods:** We identified adult patients with MASLD using a global de-identified database, TriNetX, consisting of 158 million patients originating from 167 healthcare organizations and 21 countries. ICD-10 coding was then used to evaluate the overall prevalence of MASLD which included ICD codes for fatty liver, hepatic steatosis, MASH, NASH, and NAFLD. We then applied the ICD-10 coding to high risk populations which included patients with type II diabetes mellitus or obesity as defined by a BMI $\geq$ 30. **Results:** Less than 2% of patients had a diagnosis of MASLD when applying ICD-10 coding to the overall database. There was also a lack of MASLD diagnoses among high risk subgroups who had concomitant type 2 diabetes or obesity. Only 7% of patients with underlying type 2 diabetes and only 4% of patients with a BMI $\geq$ 30 were diagnosed with MASLD via ICD-10 coding within the database. We found similar Results: when querying the electronic health record for our multicenter hospital system which revealed a diagnosis of MASLD in less than 1% of the population which includes a liver transplantation center. We were able to identify up to 23% of patients with MASLD in those with concomitant type 2 diabetes and 16% of patients with MASLD in those with BMI $\geq$ 30. **Conclusion:** This study confirms the difficulty of identifying patients with MASLD in a large clinical database. Even when targeting high risk cohorts with a diagnosis of type 2 diabetes or obesity, the prevalence of MASLD diagnoses based on ICD-10 coding remains incredibly low compared to estimates of global disease burden. This issue likely stems from the multi-step diagnostic criteria for MASLD and recently updated terminology. This review emphasizes the need for greater screening and diagnostic efforts, particularly in high risk subgroups, as well as an adoption of consistent ICD coding for MASLD. This would not only promote our ability to perform retrospective studies in this population but would also allow for more effective identification of patients who could benefit from emerging therapies and clinical trial enrollment.

1474 | EXPLORING OPTIMAL GLYCEMIC CONTROL IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) AND DIABETES: A RETROSPECTIVE PROPENSITY-MATCHED COHORT ANALYSIS

Saad Ahmed[1], [1]Northwell Health NS-LIJ

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is now recognized as the most prevalent liver disease globally, paralleling rising rates of obesity, hypertension, and diabetes. Despite hemoglobin A1c (A1c) being a key diagnostic and predictive marker in MASLD, the optimal A1c target remains unclear. Previous studies in other chronic diseases suggest tighter glycemic control may not always confer survival benefit. This study investigates the association of different A1c targets with liver-related outcomes and mortality in MASLD patients with diabetes. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network. Adults $\geq$18 years with a diagnosis of both MASLD and diabetes (2004–2024) were identified (n = 523,912). Two A1c-based cohorts were created: Cohort 1 (A1c $<$6%) and Cohort 2 (A1c 6–7%). After one-to-one propensity score matching on age, sex, race, BMI, hypertension, and hyperlipidemia, 101,678 patients remained in each cohort. Outcomes assessed over five years included new-onset cirrhosis, hepatocellular carcinoma (HCC), and all-cause mortality. Kaplan-Meier survival analyses and risk metrics were calculated. All outcomes were measured over a 5-year follow-up period. Patients with prior diagnosis of the outcome were excluded from each respective analysis. **Results:** After matching, baseline characteristics were well-balanced between Cohort 1 and Cohort 2. Compared to Cohort 2 (HbA1c 6.0-7.0%), Cohort 1 (HbA1c $<$6.0%) had significantly higher risks of developing cirrhosis (5.8% vs 3.6%; RR 1.61, 95% CI 1.55-1.68; HR 1.69, 95% CI 1.62-1.76), HCC (0.8% vs 0.5%; RR 1.58, 95% CI 1.42-1.77; HR 1.67, 95% CI 1.50-1.87), and all-cause mortality (11.9% vs 7.5%; RR 1.58, 95% CI 1.53-1.63; HR 1.67, 95% CI 1.62-1.72). All p-values $<$0.0001. **Conclusion:** In patients with MASLD and diabetes, targeting an A1c of 6–7% was associated with significantly lower rates of cirrhosis, HCC, and all-cause mortality compared to tighter glycemic control (A1c

< 6%). These findings challenge conventional assumptions favoring stricter glucose targets in this population. Potential explanations include reduced hypoglycemia risk, polypharmacy burden, and the unique metabolic stressors in MASLD. Future prospective studies are warranted to refine glycemic targets and identify optimal therapeutic strategies in MASLD management.

Outcome	Cohort 1 (A1c <6%)	Cohort 2 (A1c 6–7%)	Risk Difference	Risk Ratio (95% CI)	P-value
Cirrhosis	5,377 / 92,540 (5.8%)	3,497 / 96,940 (3.6%)	2.2%	1.611 (1.545–1.679)	<0.0001
Hepatocellular Carcinoma (HCC)	818 / 100,946 (0.8%)	518 / 101,250 (0.5%)	0.3%	1.584 (1.419–1.768)	<0.001
All-Cause Mortality	12,068 / 101,383 (11.9%)	7,642 / 101,444 (7.5%)	4.4%	1.365 (1.295–1.437)	<0.0001

1475 | HIGHER HEMOGLOBIN TARGETS LINKED TO REDUCED DECOMPENSATION IN PATIENTS WITH CIRRHOSIS AND CORONARY ARTERY DISEASE

Saad Ahmed[1], [1]Northwell Health NS-LIJ

Background: A hemoglobin goal of 8 has been recommended for patients with an acute GI bleed and a history of CAD. Further, numerous studies have explored transfusion goals for patients that are critically ill or have ACS. However, the literature is sparse for hemoglobin goals for patients with a diagnosis of cirrhosis and CAD. This is of interest as patients with cirrhosis are prone to anemia, which can exacerbate disease. Likewise, 30% of patients have both CAD and cirrhosis. Thus, the goal of this project is to compare transfusion goals (7 vs 8) for patients with CAD and cirrhosis in 5 year progression to decompensating events and mortality. **Methods:** This was a retrospective cohort study conducted using the TriNetX database and the US Collaborative Network, which includes healthcare information records from 60 healthcare organizations. Two cohorts were generated for patients with both CAD and cirrhosis: group 1 with hemoglobin goal between 7-8 and group 2 with hemoglobin goal greater than 8. These cohorts were propensity matched to age of diagnosis, sex and race. This generated two cohorts each with 10,977 patients and were examined for risk and Kaplan-Meier analysis. **Results:** At the end of the 5 year period, 1,073 patients in cohort 1 (22.3%) developed ascites compared to 1,170 patients in cohort 2 (15.8%) This corresponded to a risk difference of 0.065% (P = 0.00) and a risk ratio of 1.408 (95% CI 1.307, 1.517). Next, 238 patients in cohort 1 (2.3%) and 189 patients in cohort 2 (1.8%) developed variceal bleeding. The risk difference was 0.05% (p = 0.009) with a risk ratio of 1.285 (95% CI 1.064, 1.553). 686 patients in cohort 1 (7.3%) developed HE compared to 616 in cohort 2 (6%). The risk difference was 1.3% (p = 0.00) and risk ratio was 1.216 (95% CI 1.094, 1.351). Lastly, 6,067 patients in cohort 1 (57.1%) and 2,782 in cohort 2 (25.6%) experienced mortality. Here, the risk difference was 31.5% (p = 0) and a risk ratio of 2.232 (95% CI 0.302, 0.327). **Conclusion:** We found a hemoglobin goal of at least 8 was associated with a lower rate of decompensating events and mortality. This likely is due to improved oxygen carrying capacity and organ perfusion when compared to restrictive transfusions. Greater hemoglobin can mitigate the harmful effects of hyperdynamic circulation, such as increased portal pressures, and improve hepatic decompensation. This is vital for patients with cirrhosis who are prone to hypotension and poor perfusion due to the vasodilatory effects of the disease. Our findings are consistent with the literature as anemia has been noted to be associated with hepatic decompensation. Further, iron supplementation has shown to be beneficial in mitigating the progression of cirrhosis. Ultimately, our study is unique as there have been numerous trials to study transfusion thresholds, but none have included patients with cirrhosis. Further investigation should also be conducted to reveal the mechanism of these results and the effects of different types of anemia.

1476 | DOACS AND ANTIPLATELETS IN MASLD: ARE WE TARGETING FIBROSIS BY ACCIDENT?

Syeda Najwa Hussain[1] Pinelopi Manousou[1] Maria Kalafateli[1] Michael Yee[1] Mark Thursz[1] Tanya Jayakar[1] Atputhan Kuralarasu[1] Mary Olayiwola[1] Ali Abdul Hussein[1] Azeem Hassan[1], [1]Imperial College London

Background: Emerging evidence suggests anticoagulation therapy, including direct oral anticoagulants (DOACs) and antiplatelet agents, may exert antifibrotic effects in chronic liver disease through inhibition of hepatic stellate cell activation and profibrotic signalling

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

pathways. However, data in metabolic dysfunction-associated steatotic liver disease (MASLD) remain limited. Our aim was to explore whether DOAC or antiplatelet therapy influences liver fibrosis severity in patients with MASLD, as a surrogate for potential antifibrotic effects. **Methods:** In a retrospective cross-sectional study of 314 MASLD patients from a single tertiary centre, fibrosis severity was assessed using transient elastography (TE, liver stiffness measurement (LSM) $\geq$ 8 kPa for advanced fibrosis). Patients were stratified by DOAC or antiplatelet use at the time of TE. Patients on DOACs or antiplatelet therapy were compared with a diabetes- and BMI-matched cohort. The proportion of patients with advanced fibrosis and differences in LSM were compared across groups. **Results:** Among 314 patients, 83 (26.4%) received DOACs and 101 (32.2%) received antiplatelet therapy. The proportion of advanced fibrosis was lower in the DOAC group (47.0%) than in the non-DOAC group (58.9%), though not statistically significant ($p = 0.061$). Similarly, the median LSM in DOAC users (7.6 kPa) was lower than in non-DOAC users (9.0 kPa). For antiplatelet users, the proportion of advanced fibrosis (56.4%) was comparable to non-antiplatelet users (55.4%), with no significant difference in median LSM values ($p = 0.882$). Notably, FIB-4 scores were significantly higher in both DOAC ($p = 0.048$) and antiplatelet ($p = 0.017$) groups compared to respective controls, though these differences were likely driven by age, rather than platelet counts. **Conclusion:** This study suggests a potential trend towards reduced fibrosis severity in MASLD patients receiving DOAC therapy, aligning with preclinical data on anticoagulation's antifibrotic effects. Antiplatelet therapy did not demonstrate a similar trend. Randomised clinical trials are needed to clarify the antifibrotic potential of anticoagulation in MASLD and to disentangle the confounding effects of comorbidities.

1477 | FATTY LIVER INDEX AS A LONG-TERM PREDICTOR OF METABOLIC DYSFUNCTION: A 10-YEAR FOLLOW-UP IN A JAPANESE POPULATION

Yoshitaka Arase[1] Yusuke Mishima[1] Kota Tsuruya[1] Tatehiro Kagawa[2], [1]Tokai University School of Medicine, [2]Tokai University

Background: Steatotic liver disease encompasses hepatic fat accumulation and highlights the contribution of coexisting metabolic dysfunction. Fatty liver index (FLI), which is calculated using waist circumference, body mass index, and levels of γ-glutamyl transferase and triglycerides, is a simple surrogate marker for hepatic steatosis. This study aimed to evaluate whether baseline FLI can predict the development of metabolic dysfunctions including diabetes mellitus, dyslipidemia, and hypertension over a 10-year period. **Methods:** We analyzed data from 6,381 Japanese individuals (median age: 54 years [range: 23–83]; 58.1% men) who underwent annual health checkups at our center in both 2008 and 2018. Participants were stratified into FLI quartiles: T1 (0.39–6.09), T2 (6.10–14.41), T3 (14.42–32.30), and T4 (32.31–98.63). Age-adjusted logistic regression was used to calculate odds ratios (ORs) for incident metabolic dysfunction, using T1 as the reference. Receiver operating characteristic analysis was performed to identify optimal FLI cut-off values for predicting each outcome. The incidence of new events was determined based on both electronic medical records and a self-reported questionnaire survey. **Results:** Baseline FLI was significantly higher in men than women (22.7 vs. 7.1, $P < 0.01$). FLI values positively correlated with the number of cardiometabolic risk factors ($P < 0.01$). Over the 10-year follow-up, incident cases included 260 of diabetes mellitus (186 men), 1,181 of dyslipidemia (631 men), and 1,657 of hypertension (1,039 men). Compared with the T1 group, the ORs (95% CI) for incident diabetes mellitus were 1.57 (0.90–2.75) in T2, 3.05 (1.83–5.07) in T3, and 7.30 (4.53–11.80) in T4 group ($P < 0.01$). For dyslipidemia, ORs were 1.50 (1.22–1.83), 1.63 (1.33–1.99), and 2.62 (2.17–3.18); for hypertension, 1.47 (1.21–1.78), 2.13 (1.75–2.60), and 3.74 (3.03–4.63) (all $P < 0.01$). Optimal FLI cut-off values varied by sex: for diabetes mellitus, 23.8 (area under the curve: 0.683) in men and 16.5 (0.738) in women; for dyslipidemia, 25.1 (0.626) in men and 5.15 (0.652) in women; and for hypertension, 16.9 (0.621) in men and 4.43 (0.622) in women. **Conclusion:** Elevated FLI was significantly associated with increased risk of developing metabolic dysfunction over a 10-year period. FLI may serve as a practical and accessible predictor, and sex-specific cut-off values could help tailor screening and prevention strategies for cardiometabolic diseases.

1478 | MACHINE LEARNING-BASED SURVIVAL ANALYSIS AND RISK STRATIFICATION FOR HEPATOCELLULAR CARCINOMA PATIENTS WITH CONCURRENT MASLD UNDERGOING SURGICAL RESECTION

Henry Sheng[1] Chun-Ting Ho[2] Chia-Jung Ho[3] Wei-Yu Kao[4] Yi-Hsiang Huang[3] Teh-la Huo[3] Ming-Chih Hou[3] Jaw-Ching Wu[5] Chien-Wei Su[3], [1]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Taipei Veterans General Hospital/NYCU, [3]Taipei Veterans General Hospital, [4]Taipei Medical University Hospital, [5]National Yang Ming Chiao Tung University

Background: To identify prognostic factors for hepatocellular carcinoma (HCC) patients with concurrent metabolic dysfunction-associated steatotic liver disease (MASLD) and to assess the performance of novel machine learning (ML)-based survival analysis models in predicting outcomes and stratifying risk. **Methods:** A total of 478 treatment-naïve HCC patients with MASLD diagnosed at Taipei Veterans General Hospital between 2016 and 2023 were retrospectively analyzed. Patients were randomly divided into a training cohort (n = 336) and a validation cohort (n = 142). Baseline characteristics did not differ significantly between cohorts. The primary endpoint was overall survival (OS). Non-invasive biomarkers and pathological features obtained at diagnosis were involved in a Cox proportional-hazards (COX PH) model as appropriate categorical or continuous covariates to identify independent prognostic factors. Prognostic models were developed in the training cohort using Extreme Gradient Boosting (XGBoost), Random Survival Forest (RSF), Decision Tree (DT), and Logistic Regression (LR). Hyper-parameters were optimized via 5-fold cross-validation by maximizing Harrell's concordance index (C-index) in the training set. Model performance was validated in the validation cohort and compared based on C-index, time-dependent AUROC (td-AUROC), and endpoint-specific predictive accuracy. Shapley Additive Explanations (SHAP) were used to identify key predictors in the ML-based models. Kaplan-Meier (KM) survival analysis was performed to validate the ability of the models to stratify patient risk groups. **Results:** After a median follow-up of 38.0 months (interquartile range 10.0–68.0 months), 50 patients had died, and the 5-year OS rate was 76.9%. Independent risk factors for OS included serum aspartate transaminase (AST), alanine transaminase (ALT), and steatohepatitis status. Among the ML-based models, XGBoost demonstrated the best performance in C-Index = 0.736, td-AUROC : year 1 = 0.811, year 2 = 0.660, year 3 = 0.668, year 4 = 0.765, year 5 = 0.764, predicting OS (AUROC 0.740, 95% CI: 0.636-0.844), outperforming RSF, DT, and LR. SHAP analysis highlighted pathological tumor size, FIB-4 grade, Barcelona Clinic Liver Cancer classification (BCLC), serum AST, and alpha-fetoprotein (AFP) level, as the five most influential variables in the XGBoost model. KM survival analysis confirmed the XGBoost model's robust ability to stratify patients into distinct risk groups in both training and validation cohort (log-rank p = 0.0021). **Conclusion:** ML-based survival analysis, particularly XGBoost, provided accurate prognostic predictions and risk stratification for HCC patients with concurrent MASLD. These tools could support individualized treatment planning and optimize disease management strategies.

1479 | LIPID-RELATED INSULIN RESISTANCE INDICES FOR THE DIAGNOSIS OF NON-ALCOHOLIC FATTY LIVER DISEASE IN CHINESE ADULTS

Weihua Cao[1] Yao Xie[1] Minghui Li[2], [1]Beijing Ditan Hospital, Capital Medical University, [2]Beijing Ditan Hospital, Capital Medical University,

Background: The non-invasive evaluation indicators for diagnosing and screening non alcoholic fatty liver disease (NAFLD) remain limited. We aim to analyze the diagnostic efficacy of lipid related insulin resistance markers in NAFLD patients with metabolic abnormalities. **Methods:** A retrospective cohort study was conducted, including NAFLD patients with metabolic abnormalities (NAFLD-MA group), non-NAFLD patients with metabolic abnormalities (Non-NAFLD-MA group), and NAFLD patients without metabolic abnormalities (NAFLD-nonMA group) all underwent liver biopsy. Five indices, namely homeostasis model assessment of

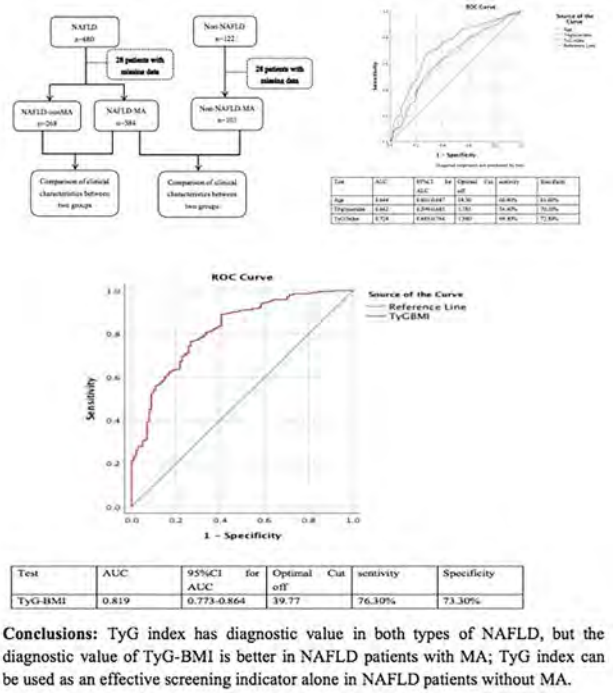
insulin resistance (HOMA-IR), lipid accumulation product (LAP), triglyceride glucose index (TyG), visceral obesity index (VAI), and triglyceride/high-density lipoprotein cholesterol (TG/HDL-C), were analyzed and compared for their relationships with NAFLD based on logistic regression. The area under the curve (AUC) of receiver-operating characteristic (ROC) curve was used to evaluate the diagnostic capability of these indicators for NAFLD. **Results:** In total, 384 NAFLD-MA cases, 101 Non-NAFLD-MA cases, 268 NAFLD-nonMA cases were enrolled. In NAFLD-MA group, BMI, obesity rate, metabolic syndrome rate, glycaemia, triglycerides, ALT, AST, GGT, HOMA-IR, LAP, VAI, TyG index and TG/HDL-C were higher than those in Non-NAFLD-MA group; Logistic regression showed that BMI and TyG index are independent risk factors for NAFLD. ROC curves analysis showed that the AUC was calculated for TyG-BMI 0.819 (95% CI 0.773–0.864), and the optimal cut-off for NAFLD detection was TyG-BMI 39.77 (sensitivity 76.30%; specificity 73.30%). For NAFLD patients with or without metabolic abnormalities, logistic regression analysis showed that Age, Triglycerides, and TyG index were independent risk factors, ROC curves analysis results showed that the AUC was calculated for TyG index 0.724 (95% CI 0.685–0.764) . The optimal cut-off for NAFLD with detection was TyG index 1.580 (sensitivity 69.30%; specificity 72.30%). **Conclusion:** TyG index has diagnostic value in both types of NAFLD, but the diagnostic value of TyG-BMI is better in NAFLD patients with metabolic abnormalities; TyG index can be used as an effective screening indicator alone in NAFLD patients without metabolic abnormalities.



Test	AUC	95%CI for AUC	Optimal Cut off	sentivity	Specificity
TyG-BMI	0.819	0.773-0.864	39.77	76.30%	73.30%

Conclusions: TyG index has diagnostic value in both types of NAFLD, but the diagnostic value of TyG-BMI is better in NAFLD patients with MA; TyG index can be used as an effective screening indicator alone in NAFLD patients without MA.

1480 | A HEAD-TO-HEAD COMPARISON OF MASLD WITH MAFLD DIAGNOSTIC CRITERIA IN LONGITUDINALLY ESTIMATING THE RISK OF ACUTE CARDIOVASCULAR EVENTS IN STEATOTIC LIVER DISEASE PATIENTS: A REAL-LIFE PRELIMINARY OBSERVATION

Mario Romeo[1] Fiammetta Di Nardo[1] Annachiara Coppola[1] Giuseppina Martinelli[1] Claudio Basile[1] Carmine Napolitano[1] Paolo Vaia[1] Luigi Maria Vitale[1] Alessandro Federico[1] Marcello Dallio[1], [1]University of Campania Luigi Vanvitelli

Background: Two years after the Delphi consensus-proposed revolution in the nomenclature and diagnosis of Steatotic Liver Disease (SLD), the benefits of adopting Metabolic dysfunction-associated steatotic liver disease (MASLD) rather than Metabolic dysfunction-associated fatty liver disease (MAFLD) diagnostic criteria in defining the cardiovascular risk of SLD patients have never been longitudinally evaluated in real-life. We aimed to compare MASLD and MAFLD criteria in estimating the 3-year risk of Acute Cardiovascular Event (ACE) occurrence in not-lean (NL) and lean (L) SLD patients. **Methods:** We retrospectively analyzed the anthropometrical, biochemical, clinical, Liver Stiffness Measurement (LSM), and controlled attenuation parameter (CAP) data stored in the University Hospital (UH)-official Health Documents Digitization Archive of 2136 SLD patients admitted to UH "Luigi Vanvitelli" (period: January 2015- May 2022), and followed up for 3 years. After excluding individuals with incomplete data/other causes justifying SLD, based on baseline Body Mass Index (BMI), patients were subdivided into "L" (BMI <25 kg/m2) (n:224) and "NL" (n:797) and, subsequently, by applying MAFLD and MASLD criteria, in NL-MASLD (n:206), NL-MASLD/MAFLD (n:481), NL-MAFLD (n:110), and L-MASLD (n:69), L-MASLD/MAFLD (n:98), L-MAFLD (n:57) (Figure). The collected ACEs were: Acute Myocardial Infarction, Acute Coronary Syndrome, Ictus cerebri, and Transient Ischemic Attack. **Results:** At baseline, NL- and L-patients with relative groups substantially presented similar features, except for higher Homeostatic-Model-Assessment-for-Insulin-Resistance (HOMA-IR) (p: 0.04) and high-sensitivity-C-reactive protein (hs-CRP) (p: 0.03) in L-SLD. CAP-assessed steatosis severity and LSM-determined fibrosis severity prevalence were not significantly different across the groups, both in NL and L-patients. Longitudinally, compared to MASLD, MAFLD diagnostic criteria better estimated the 3-year risk of ACEs occurrence in NL [HR: 1.316, C.I. 95%: 1.024-

1.495, p:0.025], and not in L [p: 0.071] patients. Multivariate competing risk analysis (adjusted for sex, age, diabetes, drug administration, baseline fibrosis severity) revealed diabetes (aHR: 2.113, C.I. 95%: 1.981-2.434, p: 0.001), hsCRP (aHR: 1.441; C.I. 95%: 1.232-1.775; p: 0.02), and HOMA-IR (aHR: 1.228; C.I. 95%: 1.152-1.893; p: 0.03) as associated with ACE occurrence in NL-MAFLD (Figure). **Conclusion:** MAFLD criteria better estimate the 3-year ACE occurrence risk in NL-SLD patients.

◆ 1481 | HOTSPOT MUTATIONS IN TGF-β/SMAD3/4 AND SPTBN1 REVEAL NEW ROLES IN ALCOHOL AND OBESITY INDUCED HCC

Lopa Mishra[1] Puja Ghosh[1] Krishanu Bhowmick[1] Mathew Brandon[1] Bibhuti Mishra[1] Kazufumi Oshiro[2] Lopa Mishra[1], [1]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory, [2]Feinstein Institutes for Medical Research

Background: Hepatocellular carcinoma (HCC) continues to rise at an alarming rate in the US and globally. Analyses of human cancers The Cancer Genome Atlas, reveals TGF-β pathway alterations in nearly 40% of HCC and GI cancers (Korkut Cell Systems 2016). Recurrent TGF-β pathway hotspot mutations occur in SMAD3 (R268C), SMAD4 (R360H, G385S, E174fs), and the Smad adaptor SPTBN1 (D1089Y, N32Y). Recently we observed that endogenous toxins such as lipids can modulate TGF-β to generate cancers, and these can be blocked (Cell Reports 2024). We hypothesized that the mutations could provide new insight into how toxins such as alcohol modulate protumorigenic switches in TGF-β signaling. **Methods:** SMAD3 (R268C), SMAD4 (R360H, G385S, E174fs) and SPTBN1 (D1089Y, N32Y) point mutations were introduced using CRISPR/Cas9 gene editing (Phenogenomics), to generate viable mouse models for these. Mice were placed on a normal diet vs a western diet with binge alcohol (GAN diet + 10% glucose + binge alcohol at 4.5 g/kg) for ≥24 weeks. Phenotypic characterization included immunohistochemistry, RNA-seq, co-immunoprecipitation, and metabolomic profiling. **Results:** SMAD3-R268C mice showed resistance to GAN/ethanol-induced obesity and diabetes, SMAD4-R360H mice develop a large liver and colon cancer. SPTBN1-D1089Y mice developed multiple HCCs. Metabolomic profiling showed the following (Supplementary Table 1): Reduced triglyceride levels in SPTBN1 mutant mice. In contrast, SMAD3 models had hypertriglyceridemia, visceral adiposity, and insulin resistance. Enhanced lipolysis was observed in epididymal white adipose tissue (eWAT) from SMAD4 and SPTBN1 mutants, in crosstalk lipolysis. Mechanistic studies confirmed that SPTBN1 mutations impair SMAD3 binding, and SMAD3/4 mutations disrupt oligomerization, leading to altered TGF-β transcriptional outputs, including suppression of key targets such as PAI-1, COL1A1, SNAIL1, P21, and P15—fostering metabolic dysregulation, fibrosis, and oncogenesis. **Conclusion:** Our approach reveals that pathogenic variants of SMAD3, SMAD4, and SPTBN1 differentially impact TGF-β signaling, metabolic homeostasis, and liver tumorigenesis. These findings provide mechanistic insight into the pathogenesis of alcohol induced MASH and HCC and may inform future therapeutic strategies targeting the SPTBN1-SMAD3/4 axis in liver disease.

Table 1: Metabolomic profiling of Phenogenomic mice

	WT	SMAD3$^{R268C/+}$	SMAD4$^{R360H/+}$	SPTBN1$^{D1089Y/+}$	SPTBN1$^{N32Y/+}$

◆ 1482 | UNDERSTANDING ICU STAYS IN ALCOHOL-ASSOCIATED LIVER DISEASE: BRIDGING DISEASE-SPECIFIC MODELING AND CLINICAL KNOWLEDGE

Sue Hyon Kim[1] Jiyoun Song[1] Sang Bin You[1] Se Hee Min[1] Marina Serper[2], [1]University of Pennsylvania, [2]University of Pennsylvania Health System

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Decompensated alcohol-associated liver disease (ALD) is marked by severe systemic manifestations often requiring critical care. Prior machine learning (ML) studies predicting ICU length of stay (LOS) have overlooked sociodemographic and ALD-specific factors, leaving a gap in understanding the full scope of ICU stays for patients with ALD. We compared different ML algorithms to determine the optimal model for predicting ICU LOS among this population, emphasizing disease-specific features for model optimization and interpretation. **Methods:** We used the MIMIC-IV database of 4,277 ICU admissions for ALD patients after excluding ICU deaths. To simplify patient deterioration predictions and resource management decisions, we defined a binary outcome of an extended ICU stay ($\geq$4 days) based on clinical and financial benchmarks. Per our intended use case, we included readily available features for prompt care planning and resource allocation following ICU admission. Three ML algorithms—logistic regression, Random Forest (RF), and Extreme Gradient Boosting—underwent cross-validation and testing. Feature importance analysis and model optimization were performed to achieve optimal balance between accuracy and practical utility. **Results:** Mean LOS was 3.4 ± 5.6days, with 24.9% exceeding 4 days. More than 70% of ALD patients were White males in their 50s. RF demonstrated the best performance for predicting extended ICU stays (AUC = 0.718). Reducing features to top 10 key predictors enhanced model interpretability but compromised performance (AUC = 0.704). Subsequent optimization using disease-specific features, such as MELD-Na scores and AST/ALT ratios, slightly improved performance (AUC = 0.707). While mean blood pressure and heart rate were key predictors consistent with other patient populations, our model underscored ALD-specific variables, such as liver enzymes (ALT, AST), ascites-related infection and electrolyte imbalances (WBC, sodium), coagulation dysfunction (PTT, PLT), and hepatorenal syndrome measures (Cr, BUN). **Conclusion:** Our model successfully classified extended ICU stays by integrating ALD-specific features. The development process of our model lays a foundation for creating predictive models tailored to ALD, which can support proactive planning, reduce caregiver uncertainty, and optimize resource allocation in the early stages of ICU admission. Future studies should expand on our approach to incorporate additional subtle features and test them in a demographically diverse sample of ALD patients.

1483 | ◆ ALCOHOL-INDUCED PHENOTYPIC CHANGES IN LYMPHATIC ENDOTHELIAL CELLS DRIVE TH17-MEDIATED LIVER INFLAMMATION

Young-Ri Shim[1] Yilin Yang[1] Jain Jeong[1] Matthew McConnell[1] Teruo Utsumi[1] Yasuko Iwakiri[1], [1]Yale University

Background: Alcohol-associated hepatitis (AH) involves severe inflammation and immune dysregulation. The lymphatic system modulates immune cell activity and resolves inflammation by regulating immune cell trafficking via lymphatic endothelial cells (LyECs), which secrete chemokines and cytokines. However, how ethanol affects LyEC-immune cell crosstalk remains unknown. We hypothesize that ethanol reprograms LyECs toward a dysfunctional, pro-inflammatory phenotype, enhancing immune cell recruitment and Th17 differentiation, thereby exacerbating AH. **Methods:** Mice were fed a 5% ethanol-containing Lieber-DeCarli diet for 10 days, followed by a single ethanol binge (5 g/kg; NIAAA model). Human primary hepatic and dermal LyECs were treated with 100 mM ethanol and co-cultured with peripheral blood mononuclear cells (PBMCs) from healthy donors to assess immune cell profiles by flow cytometry. To validate these findings in human disease, we analyzed a single-cell RNA-seq (scRNA-seq) dataset (GSE136103 **Results:** In ethanol-fed mice, $CD3^+$ T cells were enriched around LyECs and increased 1.43-fold ($p < 0.05$), showing

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

a significant correlation with lymphatic vessel density ($r^2 = 0.61$, $p < 0.0001$), suggesting enhanced LyEC-T cell interactions. Ethanol exposure also upregulated several chemokines in LyECs ($p < 0.05$), including CXCL10 (3.7-fold), CCL2 (2.4-fold), and CCL21 (4-fold), all of which are known to attract immune cells. In co-culture assays, ethanol-treated LyECs increased the migration of $CD4^+$ T cells and monocytes expressing CXCR3 and CCR7 (1.42- and 1.38-fold, respectively; $p < 0.01$), but not neutrophils, $CD8^+$ T cells, or B cells, indicating selective recruitment. Recruited $CD4^+$ T cells also exhibited higher CXCR3 expression compared to controls ($p < 0.05$), highlighting an enhanced CXCL10–CXCR3 axis. Furthermore, ethanol-treated LyECs promoted Th17 differentiation with a 31% increase ($p < 0.05$), accompanied by elevated expression of Th17-polarizing cytokines, including IL6, TGFB1, IL1B, and IL23A (1.9–2.1-fold; $p < 0.05$). These findings further suggest that ethanol reprograms LyECs to promote inflammatory T cell responses. Consistently, scRNA-seq analysis of liver tissue from alcoholic cirrhosis patients confirmed an expanded population of Th17 cells ($IL17A^+CXCR3^+CD4^+$). Mechanistically, ethanol activated PI3K/Akt signaling, increasing phospho-Akt 3-fold ($p < 0.01$). PI3K inhibition with wortmannin suppressed chemokine expression by >50% and reduced T-cell CXCR3 by 20% (both $p < 0.01$). **Conclusion:** Ethanol drives LyEC reprogramming through PI3K/Akt activation, enhancing the expression of chemokines and Th17-promoting cytokines. This leads to increased $CD4^+$ T cell recruitment and Th17 differentiation, thereby exacerbating AH. These findings uncover a previously unrecognized role for LyECs in promoting immune dysregulation in alcohol-associated liver disease.

1484 | ◆ PHOSPHATIDYLETHANOL TESTING: REAL-WORLD PATTERNS, DEMOGRAPHIC AND CLINICAL CORRELATES

Pranay Nadella[1] William Oles[2] Wei Zhang[3] Jay Luther[3] Russell Goodman[3] Esperance Schaefer[1], [1]Brigham and Women's Hospital, [2]Harvard Medical School, [3]Massachusetts General Hospital

Background: Phosphatidylethanol (PEth) is a widely used biomarker for alcohol use, but interpretation may vary by patient factors and the clinical relevance of current cutoffs is uncertain. We examined the distribution of PEth values across a large healthcare network and the associations between PEth and demographics, lab markers, clinical outcomes, and self-reported alcohol use. **Methods:** We conducted a retrospective cohort study of 4,892 adults with ³1 PEth 16:0/18:1 result from January 2022-August 2024 within the Mass General Brigham system. Linear regression assessed associations between PEth and demographic characteristics, AST, LDL, A1c, hospital encounters, length of stay, and self-reported alcohol use. **Results:** 60% of patients had negative PEth (<20 ng/mL). Among positives, the median was 251 ng/mL. Among those, 18% had moderate (20–200 ng/mL) and 22% heavy (>200 ng/mL) alcohol use (Figure 1A). PEth was directly associated with AST ($\beta = 2.75$, $p < .001$) and inversely with age ($\beta = -5.98$, $p < .001$), BMI ($\beta = -5.58$, $p = .019$), and income ($\beta = -0.0009$, $p = .010$). Black patients had higher PEth than White patients ($\beta = 286.23$, $p < .001$). No differences by gender were observed (Figure 1B). Compared to those with a negative PEth result, those in PEth quartiles 1 or 2 had a similar number of encounters ($\beta = 0.30$, $p = .25$), while those in quartiles 3 or 4 had significantly more hospital encounters ($\beta = 2.21$, $p < .001$). Compared to patients with negative PEth, those in PEth quartiles 2 ($\beta = -2.02$, $p = .023$), 3 ($\beta = -3.41$, $p < .001$), and 4 ($\beta = -5.12$, $p < .001$) had shorter average lengths of stay. PEth did not correlate well with self-reported alcohol intake, and 31% of patients with positive PEth reported no alcohol use. In each quartile, the mean self-reported drinks per week were 5.6, 6.3, 7.8, 13.0 and 20.8, for negative, Q1 (20-79ng/mL), Q2 (80-251ng/mL), Q3 (252-710ng/mL), and Q4 (>710ng/mL), respectively (Figure 1C). Less than 3% of the variation in PEth was explained by self-reported drinks per week ($R = .15$, $p < .001$). When we included an interaction term for sex, we found that the relationship between PEth and self-reported alcohol use was weaker for females compared to males ($p = .018$) (Figure 1D). **Conclusion:** In a real-world population, PEth values were substantively higher than has previously been reported. We identified several key demographic associations, notably a decline with increasing age, and, concordant with current epidemiology, we found that PEth values in women were similar to men. Self-reported alcohol use poorly predicted PEth values in all groups, with a weaker correlation in women, suggesting that women are even less likely to accurately self-report alcohol intake. Taken together, the demographic disparities and limited agreement with self-report suggest PEth may better detect unhealthy alcohol use and reveal unmet care needs.

◆ 1485 | OPTIMAL CORTICOSTEROID USE TO MITIGATE MORTALITY AND INFECTION IN PATIENTS WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS: LESS IS MORE

Abdelhaleem Sideeg[1] Mahima Tyagi[2] Fatima Elmustafa[3] Nimish Thakral[4] Mangesh Pagadala[5] Mohamed Elfeki[6] Winston Dunn[7] Ashwani Singal[2], [1]Virginia Mason Medical Center, [2]University of Louisville, [3]Henry Ford Hospital System, [4]University of Kentucky Medical Center, [5]Liver Institute -Methodist Dallas Medical Center, [6]University of South Dakota Sanford School of Medicine, [7]University of Kansas Medical Center

Background: Lille score is a validated tool to assess response to treatment and guide corticosteroid (aCS) use in severe alcohol-associated hepatitis (AH). However, its use in clinical trials has been inconsistent. We conducted a meta-analysis to compare mortality and infection outcomes in trials using Lille-guided CS therapy vs. those not guided by Lille score. **Methods:** Randomized controlled trials (RCTs) since the introduction of Lille score in 2007 and using CS in at least one arm were analyzed. Pooled data on mortality and infection (at 28, 90, and 180 d) are reported as odds ratios (OR) with 95% confidence intervals (CI). **Results:** A total of 21 steroid-treated arms from 12 trials (n = 2077) were included in this analysis. Of these, 2 studies used Lille score to guide treatment (n = 327), of which one study compared fixed vs. tapered CS regimen. Compared to patients receiving CS guided by Lille score, the mortality was higher in CS exposed group not guided by Lille score by about 5.2, 1.8, and 2.0 folds at 28, 90, and 180 d respectively (Table 1). However, the infection rates were similar at all the time points. 90-d infection rate was lower when comparing a) responders vs. non-responders with Lille guided CS use (23.3 vs. 40%), OR (95% CI): 0.46 (0.25-0.82), P = 0.009; b) non-Lille guided CS use vs. non-responders with Lille guided use (17.3 vs. 40%), 0.52 (0.31-0.87), P = 0.013; and c) tapered (10 mg per week) vs. fixed dose for 3 weeks in responders with Lille guided CS use (19.7 vs. 33.3%), 0.50 (0.28-0.88), P < 0.001. **Conclusion:** Lille-guided corticosteroid use in severe alcohol-associated hepatitis is associated with lower 28-day, 90-day, and 180-day mortality as compared to fixed 28-d of treatment. After one week of treatment in clinical care and trials, corticosteroids should be stopped in non-responders and tapered over 3 weeks (10 mg per week) in responders to mitigate the infection risk.

Table 1 Mortality and infection rate at 28, 90, and 180-d comparing two studies with Lille guided use of corticosteroids (CS) with 10 studies using CS not guided by Lille score.

	Lille guided CS use Event rate (95% CI)	Not guided by Lille Event rate (95% CI)	OR (95% CI)
28-d death	2.7 (0.7-10.3)	17.1 (14.4-20.1)	5.17 (1.26-21.26). P<0.001
90-d death	16 (13-19.6)	39.5 (27.4-53.1)	1.75 (1.26-2.44), P<0.001
180-d death	27 (21.5-33.3)	40.9 (34.0-48.3)	1.96 (1.09-3.50), P=0.023
28-d infection	12.6 (9.0-17.3)	18.1 (11.8-26.7)	0.88 (0.55-1.23), P=0.339
90-d infection	26.4 (21.3-32.1) [N=1]	22.1 (18.9-25.8) [N=1]	0.84 (0.60-1.17), P=0.308
180-d infection	18.1 (13.6-23.9) [N=1]	34.3 (24.4-45.8) [N=5]	1.16 (0.69-1.97), P=0.574

Hsu[9] Sheila Eswaran[10] Haripriya Maddur[11] Kirti Shetty[12] Neil Mehta[13] Michael Lucey[5] Ryan Gill[13] Norah Terrault[4], [1]Keck School of Medicine, [2]UCSF, [3]National Cancer Institute, Bethesda, [4]University of Southern California, [5]University of Wisconsin, [6]Ochsner Clinic, [7]University of Maryland, [8]Houston Methodist JC Walter Transplant Center, [9]National Institute of Diabetes, Digestive, [10]Rush University Medical Center, [11]College of Medicine Tucson, [12]University of Maryland, Baltimore, [13]University of California, San Francisco

Background: The natural history of alcohol-associated hepatitis (AH) by histopathology is not well-understood, due to the impracticality of repeat liver biopsies in this patient population. Using liver explants from patients undergoing early (i.e. less than 6 months from last alcohol consumption) liver transplantation for AH, combined with drinking history, we sought to identify novel histologic subgroups and assess their association with time from last alcohol consumption. **Methods:** Adults who underwent liver transplantation for AH between 2007-2019 among 9 ACCELERATE-AH sites were included. Histologic features from representative liver explant slides were assessed for consensus by 3 expert pathologists. Hierarchical cluster analysis (Gower's distance with partitioning around medoids) was used to identify histologic subgroups based on histologic features only: steatohepatitis (macrosteatosis grade, neutrophilic infiltration, Mallory-denk bodies, ballooned hepatocytes), fibrosis (Laennec stage, extent of pericellular fibrosis, presence of evolving fibrosis), bilirubinostasis, ductular reaction (CK7), and regeneration (EpCAM). Missing histology data were imputed by chained random forests. After histologic features were identified, the association of time from last alcohol consumption for each cluster was then assessed by linear regression. **Results:** Among 128 patients (70% male, median MELD at transplant of 39, median time from last alcohol consumption of 51 days), we identified 3 distinct histologic clusters (Cluster 1: n = 54; Cluster 2: n = 31; Cluster: n = 43). All clusters had similar demographic and clinical characteristics (e.g. age, sex, MELD score, pre-transplant steroid treatment). Cluster 1 had the most dominant features of steatohepatitis (26 vs. 13 vs. 12% for grade 3 macrosteatosis; 68 vs. 19 vs. 16% marked neutrophil infiltration), and least for fibrosis (6 vs. 32 vs. 33% with stage 4C fibrosis), bilirubinostasis (22 vs. 60 vs. 61% with extensive bilirubinostasis), and regeneration vs. Clusters 2 and 3. Cluster 2 (vs. Cluster 3) had predominance of ballooned hepatocytes (100 vs. 0%) and Mallory-Denk bodies (97 vs. 51%), but otherwise had similar features of macrosteatosis, bilirubinostasis, fibrosis and regeneration. All clusters had a similar degree of ductular reaction. Cluster 1 (mean of 47 [95%CI 37-56] days) was associated with the shortest interval from last alcohol consumption vs. Cluster 2 (mean of 76 [95%CI 63-89] days) and Cluster 3 (75 [95%CI 64-85] days) (Figure). **Conclusion:** Time from last alcohol consumption was associated with distinct clustering of histologic features, providing a view of the natural history of histologic AH. These results suggest that steatohepatitis may resolve and fibrosis evolve faster than previously thought for patients with severe AH. These results can inform clinical practice and trial design.

FIGURE. Percentage of patients (y-axis) vs. time from last alcohol consumption (x-axis) among 3 histologic clusters

◆ 1487 | INCREASING RATES OF PHARMACOTHERAPY PRESCRIPTIONS FOR ALCOHOL USE DISORDER AFTER LIVER TRANSPLANTATION: AN ANALYSIS OF EPIC COSMOS DATA

Oren Fix[1] Hersh Shroff[2] Sasha Deutsch-Link[2], [1]University of North Carolina at Chapel Hill, [2]UNC Chapel Hill

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Pharmacotherapy for patients with alcohol use disorder (AUD) has been shown to increase abstinence and complement psychosocial treatments for relapse prevention; however, most gastroenterologists and hepatologists are uncomfortable prescribing medications for AUD (MAUD) in patients with alcohol-associated liver disease (ALD). Data on MAUD after liver transplantation (LT) are extremely limited. **Methods:** We conducted a retrospective study using deidentified patient data from Epic Cosmos, a dataset created in collaboration with a community of Epic health systems representing 300 million patient records from over 1700 hospitals and 40,000 clinics. Inclusion criteria were LT recipients 18 years or older transplanted in the US between 1/1/2015 and 12/31/2023 with a diagnosis of ALD (ICD-10-CM K70.xx). The primary indication for LT is not available in Cosmos, which limited our ability to confirm that ALD was the primary indication for LT. We included results of ethanol biomarkers (phosphatidylethanol, urine ethyl glucuronide, serum ethanol) any time after LT and MAUD prescriptions (baclofen, naltrexone, acamprosate) within 1 year after LT. Linear regression was used to assess trends in MAUD prescriptions over time. **Results:** 17,975 patients were included in the study cohort (representing 56% of all US liver transplants during the period). Average age was 54 $\pm$11 years at the time of LT and 31% were female. 72% had a documented concomitant diagnosis of an alcohol-related disorder (ICD-10-CM F10.xx). Of 6,168 (34%) patients with an available ethanol biomarker test, 913 (15% of available tests) were positive for an ethanol metabolite. During the study period, 3.4% of patients were prescribed a MAUD within 1 year after LT (1.9% baclofen, 0.84% naltrexone, 0.85% acamprosate). MAUD prescriptions increased significantly during the study period, from 16 (2.0% of LT recipients) in 2015 to 164 (6.2%) in 2023 ($P = .001$) (see Figure). Baclofen prescriptions increased from 1.8% in 2015 to 2.0% in 2023 ($P = .255$). Naltrexone increased from 0.8% in 2018 to 1.9% in 2023 ($P = .093$). Acamprosate increased from 1.0% in 2021 to 2.9% in 2023 ($P = .324$). Data for naltrexone before 2018 and acamprosate before 2021 are unavailable because of small numbers. **Conclusion:** Despite proven efficacy, rates of MAUD prescriptions in LT recipients with a history of ALD remain low. However, overall MAUD prescriptions increased significantly during the study period. Statistically significant trends in individual medications were not observed, likely due to low numbers of prescriptions. The increasing rates of MAUD prescriptions may reflect increased provider awareness and comfort with AUD pharmacotherapy in LT recipients.

◆ 1488 | SEX-SPECIFIC RISK THRESHOLDS OF BINGE DRINKING FREQUENCY FOR ADVANCED FIBROSIS IN THE UNITED STATES

Winston Dunn[1] Juan Pablo Arab[2] Luis Antonio Diaz[3] Ashwani Singal[4] Marco Arrese[5] Naim Alkhouri[6], [1]University of Kansas Medical Center, [2]Virginia Commonwealth University, [3]University of California San Diego, [4]University of Louisville, [5]Pontificia Universidad Catolica de Chile School of Medicine in Santiago, [6]Summit Clinical Research

Background: The 2023 steatotic liver disease (SLD) nomenclature has defined metabolic dysfunction-associated alcohol-related liver disease (MetALD) and alcohol-associated liver disease (ALD) based on average daily alcohol intake. However, binge drinking patterns have not yet been incorporated into these definitions. We aimed to assess the relationships between the frequency of binge drinking and advanced fibrosis using nationally representative data. **Methods:** We included adults ($\geq$18 years) from the NHANES 1999–2020 cohort, excluding individuals with viral hepatitis. Alcohol intake was assessed through standardized questionnaires, capturing both average daily drinking and the frequency of binge drinking in the past year (defined as $\geq$4 drinks for women and $\geq$5 drinks for men on a single occasion). Advanced fibrosis was defined as FIB-4 $\geq$2.67. We first quantified the association between MetALD and ALD-level average daily drinking and advanced fibrosis, adjusting for demographic and metabolic risk factors. We then scanned the full range of binge drinking frequency to identify cutpoints that produced comparable adjusted odds ratios for advanced fibrosis. **Results:** Among 43447 eligible participants, 770 men (2.4%) and 559 women (1.8%) had advanced fibrosis. The adjusted odds ratio of MetALD-level daily drinking (2.50, 95% CI:

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

1.76–3.50) and ALD-level daily drinking for advanced fibrosis (5.82, 95% CI: 3.27–10.3) were used as reference. A total of 8,486 men (45.4%, representing 50.3 million U.S. adults) and 4,471 women (22.0%, representing 26.8 million) reported some level of binge drinking (Figure). Among women binge drinking as infrequently as twice per year conferred a risk equivalent to MetALD-level daily drinking, while monthly bingeing matched the risk of ALD-level daily drinking (Figure). Beyond monthly frequency, the risk increased exponentially. Men exhibited a higher threshold for harm: monthly bingeing approximated the risk of MetALD-level daily drinking, while daily bingeing approached the risk seen with ALD-level daily drinking (Figure). **Conclusion:** The risk of advanced fibrosis due to binge drinking differs substantially between sexes. Women face elevated risk even at low binge frequencies—comparable to the risk from MetALD-level daily drinking—whereas men require more frequent binge patterns to reach comparable risk. These findings support a sex-specific approach to MetALD and ALD definitions and highlight the need to incorporate binge drinking frequency into clinical risk stratification and public health messaging.

◆ 1489 | THE GUT MICROBIOTA FINGERPRINT OF SEVERE ALCOHOLIC LIVER DISEASE: FROM SPECIES-LEVEL CHARACTERISTICS TO A DIAGNOSTIC MODEL FOR SAH

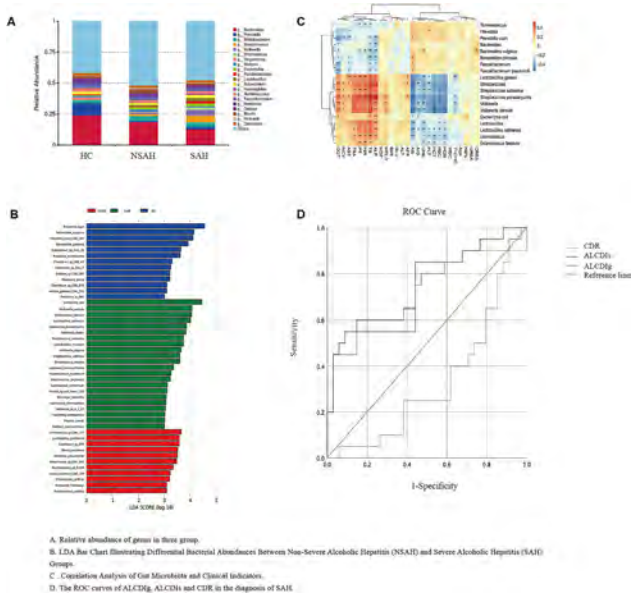
Yifan Xu[1] Song Yang[1] HUICHUN XING[1], [1]Beijing Ditan Hospital,Capital Medical University

Background: Patients with alcohol-related liver diseases exhibit intestinal microbiota dysbiosis, which becomes progressively more pronounced as the severity of the disease escalates. In the present study, patients with alcohol-related liver diseases at varying stages of disease progression were recruited. Additionally, potential species associated with the disease were further explored, and specific parameters reflecting intestinal microbiota dysbiosis in alcohol-related liver diseases were established, thereby providing novel insights for clinical diagnosis and therapeutic strategies. **Methods:** This study adopted a case-control design, enrolling healthy individuals (Healthy control, HC) as the control group. The intestinal microbiota profiles of patients with alcohol-related liver cirrhosis (ALC) were systematically analyzed. Furthermore, ALC patients were categorized into two subgroups: non-severe alcoholic hepatitis (NSAH) and severe alcoholic hepatitis (SAH), based on the severity of their alcoholic hepatitis. The differences in microbiota composition between the NSAH and SAH groups, as well as their associations with clinical parameters, were comprehensively evaluated. **Results:** Significant alterations in the intestinal microbiota are observed in patients with ALC. At the genus level, the abundance of *Streptococcus*, *Lactobacillus*, *Veillonella*, and *Enterococcus* was elevated in patients with ALC. Further analysis revealed

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

that the species *Enterococcus faecium*, *Streptococcus salivarius*, *Lactobacillus salivarius*, and *Veillonella parvula* were enriched in both ALC and SAH patients, while *Bacteroides vulgatus* and *Prevotella copri* were depleted. Based on these findings and their clinical relevance, combined with the enterotype characteristics of healthy individuals, two dysbiosis indicators were established: the genus-level alcohol-related liver cirrhosis dysbiosis index (ALCDIg) [(*Enterococcus* + *Streptococcus* + *Lactobacillus* + *Veillonella*) absolute abundance / (*Prevotella* + *Bacteroides*) absolute abundance] and the species-level ALCDIs [(*Enterococcus faecium* + *Streptococcus salivarius* + *Lactobacillus salivarius* + *Veillonella parvula*) absolute abundance / (*Prevotella copri* + *Bacteroides vulgatus*) absolute abundance]. The area under the curve (AUC) for ALCDIg was 70.9% (95% confidence interval: 55.6%-86.2%), with a sensitivity of 60% and specificity of 86%. For ALCDIs, the AUC in severe alcoholic hepatitis was 75.4% (95% confidence interval: 61.4%-89.5%), with a sensitivity of 85% and specificity of 53%. Higher ALCDIs values indicate more severe dysbiosis, making this parameter useful for evaluating dysbiosis in patients with ALC. **Conclusion:** Changes in intestinal microbiota are closely related to the progression of Alcohol-related liver disease,liver cirrhosis dysbiosis indicator (ALCDIg) can be used to evaluate the intestinal dysbiosis in patients with ALD.



A. Relative abundance of genus in three group.
B. LDA Bar Chart Illustrating Differential Bacterial Abundances Between Non-Severe Alcoholic Hepatitis (NSAH) and Severe Alcoholic Hepatitis (SAH) Groups.
C. Correlation Analysis of Gut Microbiota and Clinical Indicators.
D. The ROC curves of ALCDIg, ALCDIs and CDR in the diagnosis of SAH.

◆ 1490 | ALCOHOL-ASSOCIATED LIVER DISEASE EXHIBITS HIGHER CUT-POINTS OF LIVER STIFFNESS MEASUREMENT TO STAGE ADVANCED FIBROSIS COMPARED TO METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Wei Wang[1] Stephen Hoang[2] Luis Díaz[3] Juan Pablo Arab[2], [1]Saint Mary's Hospital, Trinity Health of New England, [2]Virginia Commonwealth University School of Medicine, [3]University of California San Diego

Background: Vibration-controlled transient elastography (VCTE) is a non-invasive technique for assessing liver fibrosis, yet the optimal cut-points to stage fibrosis differ among chronic liver diseases (CLDs). Although steatotic liver disease (SLD)—comprising alcohol-associated liver disease (ALD) and metabolic dysfunction-associated steatotic liver disease (MASLD)—is the most common CLD, evidence directly comparing disease-specific VCTE thresholds is scarce. Therefore, this study aimed to quantify the differences in VCTE cut-offs required to detect each fibrosis stage in ALD versus MASLD. **Methods:** We conducted a systematic review and meta-analysis, including studies that used liver stiffness measurements (LSMs) by VCTE to define cut-points for all fibrosis stages in adults with MASLD or ALD. We searched PubMed and the Cochrane Library from January 2008 to March 2025. Between-group comparisons of threshold values for each fibrosis stage were performed using Student's t-tests. Optimal numeric cut-points were identified by maximizing Youden's J. All statistical analyses were conducted in R. **Results:** A total of 79 studies were included in our study. The reference standard was liver biopsy and/or magnetic resonance elastography. Studies of ALD patients demonstrated significantly higher median LSMs for advanced stages: F3 (ALD 14.1 kPa vs MASLD 9.65 kPa, $p = 0.0012$) and F4 (ALD 20.8 kPa vs MASLD 12.6 kPa; $p = 3.5\times10^{-5}$) (Figure 1A). However, no significant differences were observed for F0–1 or F2. The boundary separating F2 vs F3 was 11.8 kPa in ALD vs 9.2 kPa in MASLD, while it was 16.6 kPa vs 10.0 kPa for F3 vs F4, respectively (Figure 1B). **Conclusion:** Our findings demonstrate that patients with ALD may require substantially higher VCTE cut-offs to accurately diagnose advanced fibrosis (F3-F4) compared to those with MASLD. This disease-specific variation underscores the risk of misclassification if uniform thresholds are applied across SLD subtypes.

◆ 1491 | IMPACT OF ACUTE KIDNEY INJURY ON 28- AND 90-DAY MORTALITY IN PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS: A META-ANALYSIS

frhaan zahrawi[1] Omar Alwan[2] Mohamed Alharami[3] Fawzy Naga[4] Basile Njei[5] Wajahat Mehal[5] Bubu Banini[5], [1]Franciscan Health, Olympia Fields, IL, USA, [2]Hamilton Medical Center, Dalton, GA, USA, [3]Henry Ford Warren, Warren, MI, USA, [4]Faculty of Medicine, Alexandria University, Alexandria, Egypt, [5]Yale University

Background: Acute kidney injury (AKI) is a common and serious complication in patients with alcohol-associated hepatitis (AH). AKI is associated with increased short term mortality in patients with AH. We aimed to quantify the pooled impact of AKI on 28-day and 90-day all-cause mortality in patients with AH. **Methods:** We performed meta-analyses to determine 28-day and 90-day mortality in patients with AH with versus without AKI. Data from four studies (n = 1,937) were pooled. Odds ratios (ORs) were estimated using common-effect and random-effect models. Heterogeneity was assessed using Cochran's Q, I^2, and τ^2 statistics. For 90-day mortality, a sensitivity analysis was conducted by excluding one outlier study to evaluate the robustness of the findings and reduce heterogeneity. **Results:** At 28 days (k = 4; n = 1,937; AKI = 782; non-AKI = 1,155), the common-effect model showed an OR of 3.19 (95% CI: 2.55; 4.00; p = < 0.0001) and the random-effects model showed an OR of 3.33 (95% CI: 2.28–4.88; p < 0.0001), indicating a more than threefold increased mortality risk, with sabstantial heterogeneity (I^2 = 73.3%) (Figure 1A). For 90-day mortality (k = 4; n = 1,937; AKI = 782; non-AKI = 1,155), the common-effect model OR was 2.49 (95% CI: 2.03; 3.05; p = < 0.0001) and the random-effects OR was 3.94 (95% CI: 1.40–11.09; p = 0.0093) with high heterogeneity (I^2 = 85.7%) primarily driven by one outlier study (OR = 26.22) (Figure 1B). After excluding this outlier (k = 3; n = 1,834), the random-effects OR was 2.39 (95% CI: 1.70–3.36; p < 0.0001) with reduced heterogeneity (I^2 = 62.7%) (Figure 1C). **Conclusion:** AKI significantly increases 28- and 90-day mortality in patients with AH. The mortality risk is stronger at 28 days compared to 90 days, suggesting a potential attenuation of the effect over time. Sensitivity analyses excluding an outlier study confirmed the 90-day mortality estimates and reduced heterogeneity. These findings highlight the critical prognostic impact of AKI and emphasize the need for early detection and targeted management strategies to improve patient outcomes.

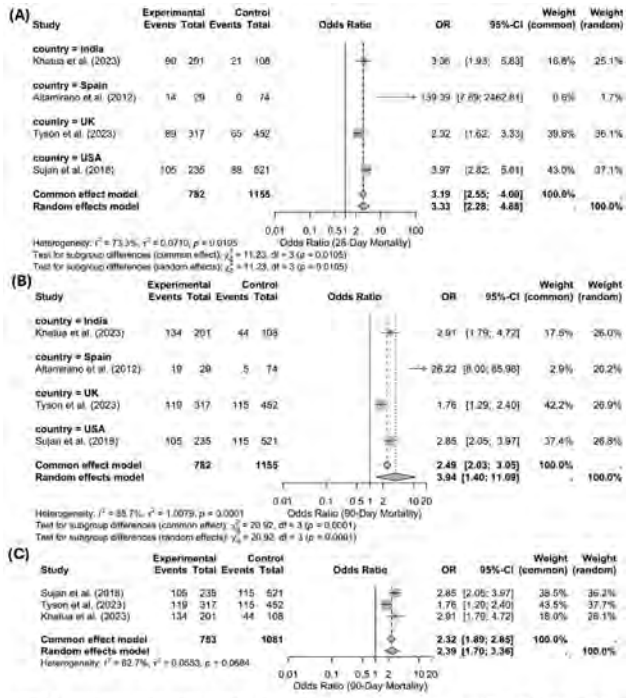

Figure 1. Odds ratios of all-cause mortality for patients with alcohol associated hepatitis with versus without acute kidney injury. (A) 28-day mortality risk (OR = 3.33; I^2 = 73.3%), (B) 90-day mortality risk (OR = 3.94; I^2 = 85.7%), (C) 90-day mortality risk after exclusion of one outlier to reduce heterogeneity (OR = 2.39; I^2 = 62.7%)

◆ 1492 | WHEN PETH GETS AN AUDIT-C - IMPLICATIONS ON CLASSIFICATION, MISCLASSIFICATION AND OUTCOMES IN STEATOTIC LIVER DISEASE

Puneet Puri[1] Thuy-duyen Vu[2] Vinod Aggarwal[3] HoChong Gilles[4] Michael Fuchs[5], [1]Virginia Commonwealth University, Richmond VA Medical Center, [2]Central Virginia VA Health Care System, [3]MedAugment, [4]McGuire Veterans Affairs Medical Center, [5]Central Virginia VA Healthcare System

Background: Integration of alcohol use in steatotic liver disease (SLD) is a critical step to understand the role and impact of alcohol on liver health and conical outcomes. We therefore investigated the concordance of currently used approaches Alcohol Use Disorders Identification Test (AUDIT-C) and Phosphatidylethanol (PEth) testing, and their impact on mortality. **Methods:** This cross-sectional study on a large national cohort of US Veterans with data from Veterans Affairs Corporate Data Warehouse was used for patients that had PEth test (11/2014 to 6/2022), and mortality outcome through 1/2024. Using ICD-9/10 codes we identified patients with and without cirrhosis, and alcohol use disorder. AUDIT-C cutoffs of 0 (no alcohol use); 1–3 for men/1–2 for women (low-risk drinking); $>=4$ for men / $>=3$ for women (high-risk drinking) were used. PEth (ng/ml) levels <35 (PEth_MASLD), 35-210 (PEth_MetALD) and >210 (PEth_ALD) classified SLD spectrum. Primary outcome of PEth and AUDIT-C concordance was evaluated, and its impact on death was examined using survival Cox-regression Fit Cox Model with Fixed Predictors only, and relative risk analyses. **Results:** Among 3153 patients with PEth test, 652 had AUDIT-C = 0 (No alcohol use). Of these, 85% had PEth level $>=35$, and 40% >210 (ALD range). Significant discordance in cutoffs for AUDIT-C and PEth risk classification for MASLD, MetALD and ALD was noted (Fig 1A). On Cox-regression analysis, PEth_MetALD had 16.8% lower risk of death compared to PEth_ALD ($p=0.03$, 95% CI 0.7-0.98, Fig 1B). No significant differences between PEth-MASLD compared to PEth_-MetALD and PEth_ALD cohorts, both in patients with and without cirrhosis. Surprisingly, among high-risk alcohol group based on AUDIT-C, PEth_MetALD cohort (35-210 ng/ml) had 38% lower risk of death compared to PEth_MASLD (<35 ng/ml, $p=0.03$, RR 0.61, 95% CI 0.4-0.94). In contrast to the published literature for AUDIT-C and PEth based mortality risk, no increased death rates were observed in our cohort likely due to discordant risk classification. **Conclusion:** Vast discrepancy between PEth test and AUDIT-C scores exists with significant risk of misclassifying new steatotic liver disease groups. These can have potential impact on natural history, outcomes and wasted resources in diagnostics and therapeutic development. Future carefully planned prospective studies with great attention to accurate measures and classification are warranted.

◆ 1493 | SEMAGLUTIDE REDUCES HEPATIC CYP2E1 LEVELS IN MICE INDEPENDENT OF ETHANOL INTAKE AND INCREASES BLOOD ETHANOL CONCENTRATIONS

frhaan zahrawi[1] Suyavaran Arumugam[1] Bubu Banini[1] Wajahat Mehal[1], [1]Yale University

Background: The glucagon-like peptide 1 receptor (GLP-1R) agonist semaglutide acts centrally in the brain and modulates ethanol intake and ethanol-induced transcriptional and metabolic changes in the liver. GLP-1R agonism reduces key ethanol metabolizing enzymes, including Cyp2e1. Our goal was to establish if semaglutide can reduce ethanol metabolizing enzymes independent of the reduction in ethanol intake, and if this affects blood ethanol concentrations. **Methods:** We examined the effect of GLP-1R agonism in the absence of food and ethanol intake. C57BL/6N mice ($n = 25$) were separated as follows: Group 1 ($n=4$) – chow diet; Group 2 ($n=5$) – chow diet with semaglutide; Group 3 ($n=8$) control followed by 16-hour fast ; Group 4 ($n=8$) semaglutide followed by16-hour fast. In groups 2 and 4 mice received a single subcutaneous dose of 30 nmol/kg of semaglutide. At 16 h mice were euthanized, and liver tissues were collected and mRNA and protein levels of Cyp2e1 assayed. To test if GLP-1R agonism affects blood ethanol levels, a second experiment with a single fixed dose of ethanol (2.5 g/kg) was administered by gavage or intraperitoneally, and serum ethanol concentrations were measured at 30min, 90 min, 150min, 270min and 330min. **Results:** Hepatic *Cyp2e1* gene expression and protein levels were significantly reduced in mice treated with GLP-1R agonist compared to control mice. In the ethanol gavage experiment, male

mice showed a significant P <0.001 difference in ethanol levels between the groups at times 30, 90, 150 min p $=$ 0.002 with a mean difference of -36mg/dl (SE 8.5) (Fig. 1 A). This was repeated in female mice which also showed a significant P <0.01 difference in ethanol levels between the groups at times 30, 90, 150 min with a mean difference of -29mg/dl (SE 7.8) (Fig. 1 B). Similarly GLP-1RA showed a significant P <0.001 difference in ethanol levels between the groups at times 30, 90, 150 min with a mean difference of -70mg/dl (SE 13.4) after intraperitoneal administration of ethanol (Fig. 1 C). **Conclusion:** GLP-1R agonism results in a reduction in hepatic Cyp2e1, independent of changes in ethanol intake. This would be predicted to reduce ethanol metabolism and result in elevated plasma ethanol levels, and this was seen after oral and intraperitoneal ethanol. If confirmed in humans, this may have important clinical implications.

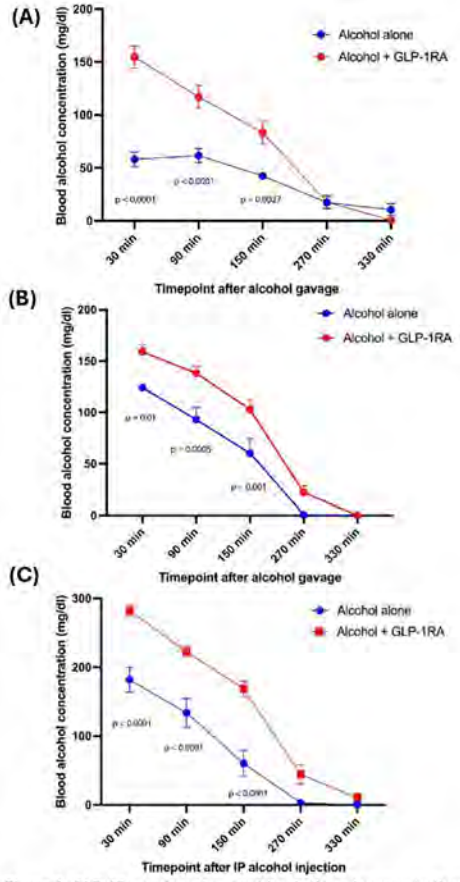

Figure 1. GLP-1R agonism elevates blood ethanol concentrations.
(A) Blood ethanol levels (BAC) were significantly higher at 30, 90, and 150 minutes after ethanol gavage in GLP-1RA vs. control in male mice.
(B) Similar increase in BAC were significant in female mice with GLP-1RA vs. control.
(C) Similar increase in BAC was significant after Intraperitoneal ethanol administration.

◆ 1494 | METABOLIC SIGNATURES OF BILE ACID AND SPHINGOLIPID DYSREGULATION IN ALCOHOL-ASSOCIATED HEPATITIS AND CIRRHOSIS

Grayson Way[1] Lianyong Su[1] Derrick Zhao[1] Yun-Ling Tai[1] NAN WU[1] Zhihong Yang[2] Jing Ma[2] THEMIS THOUDAM[2] Kristina Chandler[2] Suthat Liangpunsakul[2] Arun Sanyal[1] Phillip Hylemon[1] Hongkun Lu[1] Huiping Zhou[1], [1]Virginia Commonwealth University, [2]Indiana University

Background: Alcohol-associated liver disease (ALD) comprises a spectrum from heavy drinking (HD) without liver injury to alcohol-associated hepatitis (AH) and alcohol-associated cirrhosis (AC). The metabolic factors driving progression from HD to AH or AC remain incompletely understood. Bile acids (BAs) and sphingolipids are critical signaling molecules that regulate hepatic metabolism and immune responses, yet their potential interplay in ALD pathogenesis remains largely unexplored. **Methods:** Patients with AH and AC were recruited from the hepatology clinic at Indiana University. The study was approved by the Indiana University Institutional Review Board. Serum samples from 11 healthy controls (HC), 11 HD, 12 AC, and 9 AH patients were analyzed by LC-MS/MS to quantify 44 BAs and 28 major sphingolipid species. Hepatic gene expression data from the public dataset GSE143318 were reanalyzed to assess genes involved in BA and sphingolipid metabolism. **Results:** Total serum BA levels were significantly elevated in AC and AH patients, particularly glycine- and taurine-conjugated BAs ($p < 0.01$). Taurine conjugation was markedly increased in AC and AH compared to HC and HD (total taurine/total BA, all $p < 0.01$), especially in primary BAs such as TCDCA and TCA. In contrast, HD patients had a higher glycine/total BA ratio than HC and AH ($p < 0.05$). Deoxycholic acid (DCA) levels were significantly reduced in AC and AH, though lithocholic acid (LCA) was unaffected. All alcohol-consuming groups had a lower DCA percentage of total BA compared to HC. Only AC and AH patients exhibited decreased DCA/cholic acid (CA) ratios ($p < 0.05$). While total sphingolipid levels were similar across groups, serum sphingosine-1-phosphate (S1P) and C24:0 ceramide were significantly reduced in AH and AC. Gene expression analysis revealed downregulation of *CERS2* and *CERS4*, key enzymes for very-long-chain ceramide biosynthesis, and dysregulation of BA transporters, including downregulation of NTCP (*SCL10A1*) and BSEP (*ABCB11*). **Conclusion:** Patients with AC and AH exhibit distinct alterations in BA conjugation and sphingolipid metabolism. HD patients exhibit significantly higher glycine conjugation ratios of bile acids, which may indicate either an early step in disease progression or a protective finding. These findings suggest a mechanistic link between disrupted bile acid and sphingolipid homeostasis in the progression of ALD.

◆ 1495 | HSD17B13 EXPRESSION IS INCREASED IN BALLOONED HEPATOCYTES FROM PATIENTS WITH STEATOTIC LIVER DISEASE (SLD) AND CAN BE THERAPEUTICALLY TARGETED BY GSK4532990 IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE (ALD)

Nikhil Vergis[1] Young Kul Jung[2] Francisco Jorquera Plaza[3] William Sanchez[4] Hirotoshi Ebinuma[5] Stefano Fagiuoli[6] Elisa Pose Méndez[7] Patrick Weston[8] Jonathan Fallowfield[9] Timothy Kendall[9] Lara Murray[10] Robert Egger[10] Luis Vale Silva[11] Sourabh Bhide[11] Felix Frauhammer[11] Dmytro Dvornikov[11] Nils Kurzawa[11] Stuart Kendrick[12] Theresa Fleming[12] Stephen Atkinson[12], [1]GSK, London, UK, [2]Korea University College of Medicine, Seoul 02841, Republic of Korea, [3]Digestive Diseases, Complejo Asistencial Universitario de León, España, [4]Floridain Clinical Research, Miami Lake, FL, USA, [5]International University of Health and Welfare Narita Hospital, Chiba, Japan, [6]University of Milan Bicocca, Milan, Italy, [7]Hospital Clinic and Institut d'Investigacions Biomediques August Pi I Sunyer, Barcelona, Spain, [8]Synergy Healthcare of Tampa, FL, USA, [9]Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, UK, [10]PathAI, Boston, MA, USA, [11]GSK, Heidelberg, Baden-Württemberg, Germany, [12]GSK, Stevenage, UK

Background: Ballooned hepatocytes are pathognomonic of steatohepatitis and are prominent in ALD. Loss-of-function *HSD17B13* variants are associated with lower amino-transferase levels and reduced progression of SLD. Histopathology studies indicate that these variants may

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

protect against hepatocyte ballooning. We enabled spatial transcriptomics of ballooned hepatocytes using machine learning-guided morphological identification. We also show the potential for therapeutic silencing of *HSD17B13* using GSK4532990, a GalNAc-conjugated siRNA, with preliminary open-label safety data from the ongoing STARLIGHT P2 study in ALD (NCT06613698). **Methods:** Liver biopsies from 9 patients with SLD underwent spatial transcriptomics (Xenium, 10X Genomics) followed by H&E staining and Liver Explore deployment (for research use only; not for diagnostic use). Differential gene expression between Liver Explore predicted "ballooned hepatocytes" and "normal hepatocytes" was used to generate a ballooning gene expression signature. Three independent cohorts profiled by either single-nucleus or bulk transcriptomics with matched histopathology ballooning scores were used to validate the transcriptomic signature. In STARLIGHT, 11 ALD participants (8 Child-Pugh [C-P] A; 3 C-P B cirrhosis) received a single dose of GSK4532990 and were followed to week 8 (W8) for safety. **Results:** Ballooned vs morphologically normal hepatocytes showed increased *HSD17B13* expression (Log_2 fold change: 0.56, adj.p-value <0.03). A 6-gene ballooning signature, including *HSD17B13*, correlated with ballooning scores in a snRNAseq ($p=0.0568$) and two bulk RNAseq (both $p<0.001$) datasets. In STARLIGHT, all 11 participants completed all visits. Two participants experienced liver-related events, both with C-P A liver impairment at baseline. Events were adjudicated unlikely to be related to GSK4532990 and were conservatively managed to resolution. C-P A participants had ALT 55 (35–117) vs 39 (13–53) IU/L and AST 120 (180–73) vs 80 (144–53) IU/L, despite consistent alcohol consumption during follow-up (PEth 758 [427-1273] vs 796 [417–1169] μg/L) at baseline vs W8, (median [IQR]; Fig. 1). **Conclusion:** *HSD17B13* expression is increased in ballooned hepatocytes. Preliminary data from the ongoing STARLIGHT ALD study have not identified safety concerns from a single dose of GSK4532990. There was a trend toward reduced aminotransferases, despite ongoing alcohol consumption, that may correspond to improvements in hepatocyte ballooning.

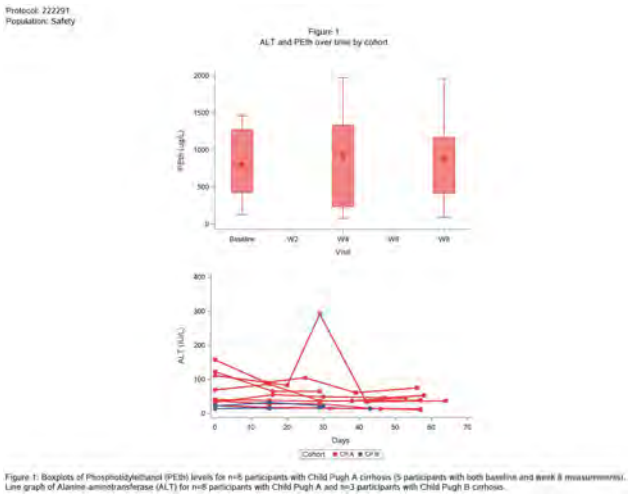

Figure 1: Boxplots of Phosphatidylethanol (PEth) levels for n=8 participants with Child Pugh A cirrhosis (5 participants with both baseline and week 8 measurements). Line graph of Alanine aminotransferase (ALT) for n=8 participants with Child Pugh A and n=3 participants with Child Pugh B cirrhosis.

◆ 1496 | IMPACT OF ABSTINENCE ON LIVER STIFFNESS MEASUREMENT IN ALCOHOL-ASSOCIATED LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Wesley Chow[1] Derek Wong[2] Ganeev Singh[1] Garrett Teskey[1] Lee Luniewski[1] Leah Puglisi[3] Samantha Bagsic[3] Paul Pockros[3] Julio Gutierrez[3], [1]Scripps Mercy Hospital, [2]Oregon Health Science University, [3]Scripps Clinic

Background: Alcohol-associated liver disease (ALD) has become a leading cause of liver failure, hepatocellular carcinoma, and liver-related mortality. While clinical guidelines emphasize cessation, the short-term impact on liver fibrosis remains poorly defined. In this study, we aimed to assess changes in liver stiffness measurement (LSM) using vibration controlled transient elastography (VCTE) following abstinence in patients with alcohol use disorder (AUD). **Methods:** A systematic review and meta-analysis was conducted using observational studies from MEDLINE, EMBASE, and Cochrane through November 2024. We included adults with AUD who underwent detoxification and had paired baseline and follow-up LSM. Pooled effect sizes and changes in LSM were calculated while stratified by alcohol abstinence and relapse. Subgroup analyses examined associations with BMI >25 kg/m^2 and baseline LSM >12.1 kPa. Studies reporting liver biopsy data were qualitatively reviewed. **Results:** A total of 1,557 AUD patients who initiated abstinence and completed paired VCTE were identified across 11 observational studies after screening 6,620 articles. Pooled LSM decreased in 12/13 follow-up cohorts but

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

contained large pooled standard deviations. The estimated pooled effect size LSM was –0.0013 kPa/day (95% CI: –0.0030 to 0.0005; p = 0.153). Estimated mean LSM difference was -1.95 kPa at 7 days, -2.30 kPa at 28 days, and -2.76 kPa after 56 days of continued abstinence. Alcohol relapse occurred in 114/267 patients at 30 days, 82/160 patients at 56 days, and 29/64 patients after 56 days follow up. Amongst alcohol relapse patients, 3/6 studies noted an increased kPa from baseline with mean changes of +0.086 kPa at 28 days and +0.40 kPa after 56 days. In the BMI-based subgroup model, LSM declined by -0.0027 kPa/day (SE = 0.0014; p = 0.0505; 95% CI: -0.0053 to 0.0000). In studies with a baseline BMI > 25, LSM declined by -0.1159 kPa (SE = 0.0765; p = 0.1298; 95% CI: -0.2658 to 0.0340). In the baseline liver stiffness subgroup model, LSM declined by -0.0017 kPa/day (SE 0.0009; 95% CI -0.0035 to 0.0002; p = 0.075). In studies with a baseline LSM > 12.1 kPa, LSM declined by -0.0838 kPa (SE 0.0681; 95% CI -0.2172 to 0.0497; p = 0.22). Four studies provided variably reported liver biopsy data. **Conclusion:** This systematic review and meta-analysis determined LSM declined following alcohol cessation, but pooled estimates were not statistically significant due to high inter-study variability. No similar trend was observed in the relapse group. The high BMI subgroup demonstrated a marginal reduction in LSM which did not reach statistical significance. The studies reporting liver biopsy results were inconsistent and prevented pooled analysis. These findings suggest early changes in inflammation and fibrosis after alcohol cessation may be detectable by VCTE; however, further studies are needed to clarify the trajectory and reliability of regression.

◆ 1497 | PREMATURE MORTALITY ACROSS THE STEATOTIC LIVER DISEASE (SLD) SPECTRUM IS DRIVEN BY BINGE DRINKING AND METABOLIC CONDITIONS

Zobair Younossi[1] James Paik[2] Shira Zelber-Sagi[3] Fatema Nader[4] Ariana Nader[5] Rand Jamal Alkalbani[2] Amolika Gupta[2] Manuel Reyes[2] Kathryn Hobbs[2] Saleh Alqahtani[6] Linda Henry[1], [1]The Global NASH Council, [2]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, [3]Tel-Aviv Sourasky Medical Center, [4]Center for Outcomes Research in Liver Diseases, CORLD, [5]Center for Outcomes Research in Liver Disease, [6]Liver, Digestive, and Lifestyle Health Research Section, and Organ Transplant Center of Excellenc

Background: Outcomes across SLD spectrum [metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic and alcohol-related liver disease (MetALD), and alcohol-related liver disease (ALD)] are influenced by both alcohol use and metabolic conditions (MCs). We assessed the association of MCs and alcohol use patterns with premature mortality across SLD subtypes. **Methods:** Using NHANES data (1988–2014) linked to mortality (follow-up 2019), we identified SLD by ultrasound or a validated U.S. Fatty Liver Index and classified participants as MASLD, MetALD, or ALD per the 2023 consensus. Alcohol intake was corrected to match U.S. per capita consumption.Participants were categorized as abstainers (< 12 drinks lifetime), former drinkers (≥ 12 drinks lifetime but < 12 drinks in past year), low (> 0 but < 20/30 g/day for women/men [W/M]), moderate (20–49.9/30–59.9 g/day), or heavy (≥ 50/60 g/day)

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

drinkers. Active binge drinking was defined as ≥5 drinks/day in prior year. History of binge drinking was defined as ever consuming ≥5 alcoholic drinks/day. Premature mortality (death ≤80/75 years W/M), age-standardized to the 2000 U.S. population (per 1,000 person-years), was evaluated across SLD subtypes, accounting for sociodemographic factors, alcohol use (including binge drinking), and MCs (type 2 diabetes [T2D], hypertension [HTN], hyperlipidemia, and obesity), with non-SLD abstainers as reference group. **Results:** Of 27,091 participants, 79.8% had ≥1 MC; 7.8% were non-SLD abstainers, while 27.1%, 3.4% and 3.6% had MASLD, MetALD, and ALD. History of binge drinking was reported by 10.4% of SLD [ALD (26.3%), MetALD (11.9%), and MASLD (10.8%)]. Age-standardized premature mortality rates were highest in ALD (13.3), followed by MetALD (8.6), and MASLD (7.3), and lowest in non-SLD abstainers (2.7). In sociodemographic-adjusted models, all SLD subtypes had a higher risk of premature mortality while after adjusting for MCs, only ALD remained significant. In fully adjusted models, binge drinking was independently associated with an increased risk of premature mortality (Table 1). Other predictors included obesity, T2D, HTN, smoking, older age, male sex, and low education/income. **Conclusion:** Premature mortality risk varies across SLD spectrum. In MASLD and MetALD, MCs (T2D, HTN) and history of binge drinking are key drivers. In ALD, binge drinking amplifies mortality risk beyond the impact of MCs alone. These findings underscore the need to target both alcohol use and MCs in managing SLD.

Table 1. Hazard Ratios for Premature Mortality by SLD Subclassification

	Sociodemographic-adjusted Model		Fully Adjusted Model		Fully Adjusted M Active Smok
	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)

◆ 1498 | CHARACTERIZING SEX DIFFERENCES IN LIVER-RELATED COMPLICATIONS AMONG PATIENTS HOSPITALIZED FOR ALCOHOL-RELATED CONDITIONS

Elina Stoffel[1] Elizabeth Verna[1] Caroline Rutherford[1] Katherine Keyes[1], [1]Columbia University Medical Center

Background: Women with alcohol use disorder (AUD) are at increased risk of medical complications compared with men at comparable levels of consumption. Alcohol consumption, high-risk drinking and alcohol-related liver disease (ALD) have also increased more rapidly among woman than men. However, sex-specific patterns in AUD-related hospitalizations and liver-related outcomes remains understudied. **Methods:** We conducted a retrospective study of 1,138 patients >18 years admitted to Columbia University Medical Center from 1/2020 to 9/2024 with alcohol-related diagnoses. Eligible patients were those with their first inpatient admission with an alcohol related ICD code after 1/2020. Patient characteristics, test results and outcomes were extracted from the electronic medical record. Statistical analyses included Fisher's exact test, Pearson's Chi-squared test, Wilcoxon rank sum test. Statistical analyses were performed using R. **Results:** 1,138 patients were analyzed, 237 (21%) were female and 900 (79%) male. Baseline demographics and comorbidities were similar between men and woman except men were more likely to be Hispanic (46% vs 24%, $p < 0.001$), had higher rates of diabetes (10% vs. 5.5%, $p = 0.003$) and lower rates of CKD. At index presentation, most patients (60%) were admitted with alcohol intoxication or AUD-related diagnoses. Women were more likely than men to present with ALD (35% vs. 26%, $p = 0.003$), while non-liver alcohol-related diagnoses (such as pancreatitis or gastritis) were similarly distributed between sexes (13% vs. 11%). Cirrhosis at initial presentation (33% vs 26%; $p = 0.04$), markers of liver decompensation including ascites (30% vs 20%; $p < 0.001$) and hepatic encephalopathy (11% vs. 5%; $p = 0.014$), rates of inpatient liver transplant consult (33% vs. 20%; $p < 0.001$) and referral at discharge (61% vs. 48%; $p = 0.024$). rates of liver transplant (13% vs 8.2%, $p = 0.021$) and all-cause mortality (12% vs 7.1%, $p = 0.018$) were all significantly higher among women than men. **Conclusion:** Women are more likely to present with severe liver-related complications of alcohol use and experienced higher rates of advanced liver disease, need for liver transplantation, and mortality on their index hospitalization. These findings suggest potential disparities in disease recognition and care, highlighting the need for earlier identification and tailored management of alcohol-related liver disease in women.

◆ 1499 | LONG-TERM IMPACT OF ALCOHOL CONSUMPTION PATTERNS ON LIVER FIBROSIS PROGRESSION

Sanjana Verma[1] FNU Baimaji[1] Shruti Mehta[1] Gregory Kirk[1] David Thomas[1] James Hamilton[1] Jing Sun[1] Po-Hung (Victor) Chen[1], [1]Johns Hopkins University

Background: Limited data are available regarding the long-term effects of alcohol consumption on liver fibrosis. Understanding how variations in alcohol use may impact liver health can guide clinical counseling and public health messaging. Our study quantifies the associations between different alcohol consumption patterns and the progression of liver fibrosis over a 14-year period. **Methods:** Our data came from the ALIVE Study, a community-based prospective cohort of people with a history of injection drug use. We included study participants from 2006 to 2020 who completed at least two annual visits. Group-based trajectory modeling of longitudinal AUDIT-C (Alcohol Use Disorders Identification Test - Consumption) scores classified participants into distinct patterns of alcohol consumption. We utilized a gamma-distributed generalized linear mixed model to compare longitudinal changes in liver fibrosis, measured as liver stiffness (LS) through transient elastography, across the alcohol consumption groups. Our model specified the alcohol consumption group, follow-up time, and their interaction as fixed effects, along with subject-specific random intercepts and random time slopes. We adjusted the model for age, sex, race, HIV serostatus, HBsAg, anti-HCV, comorbidities, and substance and tobacco use. **Results:** We analyzed 1790 participants (33% women, 82% Black, median age 42.1 years) with a median follow-up of 7.1 years (IQR: 2.5, 12.1). Six alcohol consumption patterns emerged: consistent minimal use (group 1), consistent low-risk use (group 2), gradual decline from low/moderate-risk use (group 3), consistent moderate-risk use (group 4), gradual decline from high-risk use (group 5), and consistent high-risk use (group 6) (Figure A). The overall predicted mean LS were highest in group 6 (10.90 kPa; 95% CI: 9.81, 11.99) and group 4 (9.02 kPa; 95% CI: 8.51, 9.53). Compared to group 6, the predicted mean LS was 20%, 21%, 25%, and 24% lower in groups 1, 2, 3, and 5, respectively (all $P < 0.05$). Additionally, LS increased significantly over time in group 6 (0.42 kPa/year; 95% CI: 0.24, 0.59) and group 4 (0.11 kPa/year; 95% CI: 0.03, 0.19), but not in the other groups. Model-predicted trajectories of mean LS depicted increasing separation between groups over time (Figure B). Group 6 showed a continuous increase and maintained the highest LS throughout, followed by group 4. The remaining four groups had minimal changes over time. **Conclusion:** Participants who consistently engaged in high-risk alcohol use had the highest levels of LS, which continued to rise over time. Conversely, those who gradually decreased their alcohol consumption, as well as those who consistently maintained minimal or low-risk use, showed little to no change in LS. Our findings highlight the importance of promoting alcohol cessation or reduction to support long-term liver health.

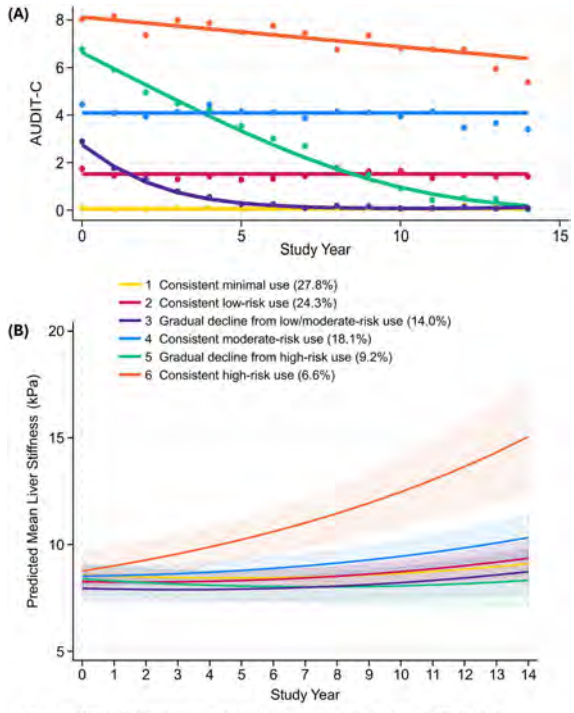

Figure. (A) Alcohol consumption trajectories and prevalences, **(B)** Model-predicted mean liver stiffness over study years, stratified by trajectory groups

◆ 1500 | GUT-BRAIN AXIS: EMERGING THERAPEUTIC TARGET FOR ALCOHOL USE DISORDER IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE

Prabha Bhandari[1] Abdelhaleem Sideeg[2] Sheel Patel[3] Hanna Blaney[4] Mohamed Elfeki[5] Chencheng Xie[6] Talal Bhatti[7] Ashwani Singal[8], [1]Mobile Infirmary Medical Center, [2]Virginia Mason Medical Center, Seattle, WA, United States, [3]University of Louisville, Louisville, KY, United States, [4]MedStar Georgetown University Hospital, Washington, DC, United States, [5]University of South Dakota Sanford School of Medicine, [6]University of South Dakota, [7]Northwell Health, NY Manhasset, [8]University of Louisville

Background: Gut-brain axis dysfunction contributing to systemic inflammation and alcohol-related behaviors is an emerging therapeutic target for alcohol use disorder (AUD) and for alcohol-associated liver disease (ALD). **Methods:** We systematically reviewed randomized clinical trials (RCTs) on gut-brain modulation in individuals with AUD with or without liver disease. Therapies targeted a) gut dysbiosis using Fecal Microbiota Transplant (FMT), prebiotics (inulin), and probiotics, and b) neurohormonal agents like Glucagon-Like Peptide-1 (GLP-1) receptor agonists, and ghrelin receptor. Studies were identified through PubMed, Google Scholar, Web of Science, and Embase up to 2025. **Results:** Of the nine included RCTs, five (n = 16 to 50) targeted gut dysbiosis. Of these, three studies included subjects with ALD (cirrhosis, moderate AH, and severe AH in one each) while two studies included AUD subjects without liver disease. These interventions showed benefits on behavioral (alcohol craving, consumption, relapse), psychological (anxiety, sociability), biochemical (MELD score and liver enzymes), and systemic inflammation. However, the magnitude and consistency of benefits varied across studies. Four RCTs targeting GI hormones included AUD subjects without liver disease, three using GLP-1 receptor agonists and one using ghrelin. Of the three studies using GLP-1 receptor agonists (n = 48-151) two showed a reduction in alcohol use while the decrease in alcohol use did not reach statistical significance in one study. RCT using intravenous ghrelin (n = 18) showed reduction in inflammatory markers, suggesting its potential anti-inflammatory effect. However, blocking the ghrelin receptor in the presence of alcohol did not produce significant changes in systemic inflammation. **Conclusion:** The current evidence supports gut-brain axis as a potential dual therapeutic target with benefits for both AUD and ALD. Large multicenter randomized controlled studies are needed to examine therapies targeting gut-brain axis in patients with AUD and ALD.

S.N	Study	Intervention	Sample Size	Study Duration	Primary Outcomes Measured and Key Findings
A	**Therapeutics targeting Gut Dysbiosis in AUD**				
1	Bajaj et al. (2020)	Fecal Microbiota Transplant (FMT)	20 patients with alcohol cirrhosis	6 months	↓alcohol craving/consumption (p=0.02) and improvement in cognition & quality of life
2	Amadieu et al. (2021)	Inulin Supplementation	50 participants with AUD	17 days	Improved sociability and ↑BDNF (Brain derived neurotrophic factor) (p=0.04) which has negative correlation with alcohol craving score (r=-0.67, p<0.001).
3	Vatsalya et al. (2023)	Probiotics (Lactobacillus rhamnosus GG)	46 patients with moderate AAH	6 months	Significant ↓in drinking levels to social or abstinence level (p<0.001) and liver injury (MELD and AST/ALT ratio)
4	Mennig et al. (2023)	Probiotic Supplement (Seed DS-01® Daily Synbiotic)	16 non-treatment -seeking heavy drinkers	30 days + 1 month washout	No significant change in plasma biomarker levels from probiotic use. Higher alcohol use was associated with ↑ IL-6, IL-8, and MCP-1.
6	Philips et al. (2022)	FMT vs. corticosteroids	35 patients with severe AAH	3 years	FMT↓ ascites, HE, infections (p<0.05), relapse (28.6%); longer abstinence (p=0.04); ↑ 3-yr survival (65.7%) (p=0.052), ↑ Bifidobacterium, ↓ Acinetobacter
B	**Therapeutics targeting Gut derived hormones in AUD**				
1	Farokhnia et al. (2020)	IV ghrelin vs. placebo	18 participants with AUD	2 lab sessions, 1 week apart	Ghrelin↑alcohol self-administration (+25%, p = 0.04), earlier initiation (p = 0.01), and enhanced brain activation in amygdala and reward regions.
2	Klausen (2022)	Exenatide	127 AUD patients	6 months	↓ heavy drinking days (p= 0.37)
3	Probst (2023)	Dulaglutide	151 participants with A	12 weeks	↓alcohol consumption by 29% (p=0.04)
4	Handershot (2025)	Semaglutide	48 AUD patients	10 weeks	↓alcohol self-administration (p=0.01), Significantly ↓ drinks per drinking day (p=0.04), and weekly alcohol craving (p=0.01)

◆ 1501 | EPIGENETIC CHANGES IN ALCOHOL EXPOSED HEPATOCYTES DRIVE PATHOGENIC HEPATOCYTE-MACROPHAGE FEEDBACK LOOP LEADING TO LOSS OF LIVER FUNCTION

Kruti Nataraj[1] Michael Schonfeld[1] Samson Mah[1] Steven Weinman[1] Irina Tikhanovich[1], [1]University of Kansas Medical Center

Background: Alcohol-associated liver disease (ALD) is a major cause of alcohol related mortality. Previously we identified KDM5B as a key driver of alcohol induced epigenetic changes involved in ALD development, however, the mechanism behind KDM5B-induced pathological changes is not established. **Methods:** *Kdm5b* flox/flox female mice were fed a Western diet and 20% alcohol in the drinking water for 8-16 weeks (WDA). To induce KDM5B knockout, mice received $2x10^{11}$ genome copies of AAV8-CMV-Cre, AAV8-TBG-Cre or AAV8-control. Liver fibrosis was evaluated by Sirius Red and COL1A1 staining and hydroxyproline measurement. Gene expression changes were assessed with RNA-seq analysis. To test the role of myeloid C/EBPβ, Cebpb fl/fl or Cebpb fl/fl Lyz2-Cre mice were fed WDA for 16 weeks. To test the role of recruited monocyte-derived macrophages we used *Ccr2* KO mice. **Results:** We found that *Kdm5b* knockout prevented alcohol-induced liver fibrosis, inflammation and alcohol-induced loss of liver syntetic function in female mice. These changes were in part mediated by hepatocyte to non-parenchymal cell communication changes. KDM5B in hepatocytes promoted CCL-2 and CCL-5 expression in hepatocytes, resulting in a shift in liver macrophage composition. KDM5B promoted an increase in monocyte-derived macrophages infiltration and a loss of mature Kupffer cell phenotype. Moreover, we found that the loss of liver function was dependent on hepatocyte to macrophage communication feedback loop. KDM5B in hepatocytes inhibited macrophage C/EBPβ expression which in turn resulted in loss of mature Kupffer cells phenotype and prevented Kupffer cells' ability to support hepatocyte differentiation, ultimately leading to loss of liver synthetic function. CCL-2/CCR2 mediated monocyte infiltration further exacerbated liver inflammation and hepatocyte de-differentiation. **Conclusion:** KDM5B-dependent alcohol-induced epigenetic changes in hepatocytes drive pathogenic cell-cell communication leading to alcohol-induced loss of liver function in ALD. **Disclosures:** Kruti Nataraj: Nothing to Disclose, Michael Schonfeld: Nothing to Disclose, Samson Mah: Nothing to Disclose, Steven Weinman: Nothing to Disclose, Irina Tikhanovich: Nothing to Disclose, Nothing to Disclose

1502 | DIVERGING TRENDS IN INCIDENCE OF ALCOHOL USE DISORDER AND ALCOHOL-ASSSOCIATED LIVER DISEASE: A 28-YEAR POPULATION-BASED COHORT STUDY

Kamalpreet Hara[1] Alberto Calleri[1] TIFFANY WU[1] Blake Kassmeyer[1] Patrick Kamath[1] Vijay Shah[1] Douglas Simonetto[1], [1]Mayo Clinic Rochester

Background: Alcohol use disorder (AUD) and alcohol-associated liver disease (ALD) are major public health burdens. ALD encompasses conditions such as alcohol-associated hepatitis (AAH) and cirrhosis and is the leading cause of liver-related morbidity and mortality. This study examines the incidence trends of AUD and ALD over a 28-year period in Olmsted County, Minnesota. **Methods:** We conducted a retrospective population-based cohort study using data derived from the Rochester Epidemiology Project. From 1995-2023, incident cases of AUD and ALD were identified using ICD codes and only the first-ever diagnosis was included. Incidence rates were calculated in 5-year intervals and age- and sex-adjusted to the 2020 US census population, expressed as cases per 100,000 person-years to evaluate the temporal trends. **Results:** We identified 22,754 individuals with AUD and 1,895 with ALD. The median age at diagnosis was 37.5 years (IQR, 25.5, 51.8) for the AUD cohort and 52.5 years (IQR, 42.9,61.6) for the ALD cohort. Women comprised 34.9% of the AUD and 28.5% of the ALD cohort. Among ALD cases, 963 (50.8%) had AAH, 1,003 (53%) had cirrhosis. Age- and sex-adjusted AUD incidence rates showed a notable overall decline, peaking during 1995–1999 at 631.2 per 100,000 (95% CI, 610.2–652.3) and declining to 399.5 per 100,000 (95% CI, 384.3–414.6) in 2020–2023. Sex-stratified analyses revealed a 31% reduction in women (from 389.1 to 269.8) and a 40% reduction in men (from 882.8 to 531.7), though rates remained higher in men throughout. In contrast, ALD incidence increased steadily, rising from 41.9 (1995-1999) to 65.5 (2020-2023) per 100,000 over the study period. This rise was especially pronounced among women, whose incidence nearly doubled (88% increase), from 19.2 to 36.3 per 100,000. Among men, incidence increased by 45%, from 66.0 to 95.9 per 100,000. While AUD incidence declined among younger adults (20-39) after 2015, ALD incidence rose in this age group during the same time-period. **Conclusion:** This 28-year population-based cohort study reveals contrasting trends, with a decline in AUD diagnosis in recent years, while ALD cases have continued to rise, particularly among women and younger adults. These opposing trajectories may reflect a shift toward more hazardous patterns

of alcohol consumption concentrated among fewer individuals and/or delayed or under recognized AUD diagnosis. Further research is needed to better understand the factors driving these trends.

1503 | ALCOHOL USE DISORDER, LIVER DECOMPENSATION, AND MORTALITY RISK ACROSS CIRRHOSIS ETIOLOGIES: A POPULATION-BASED STUDY.

Samer Gawrieh[1] Wanzhu Tu[1] Maaz Arif[1] Lauren Nephew[2] LaKeisha Boyd[1] Yang Li[1] Naga Chalasani[3] Eric Orman[2] Archita Desai[1], [1]Indiana University School of Medicine, [2]Indiana University, [3]Indiana University Medical Center

Background: The impact of alcohol use disorder (AUD) on cirrhosis outcomes across different etiologies remains unclear. Using contemporary real-world data, we evaluated the impact of AUD diagnosis on the risk of decompensation and mortality in patients with cirrhosis due to different etiologies including alcohol-associated liver disease (ALD). **Methods:** The Indiana Cirrhosis Cohort is a population-based longitudinal cohort which includes 13,264 adults diagnosed with cirrhosis between 2018 and 2020, followed from initial diagnosis to death, liver transplant (LT), or last follow up. Baseline demographics, comorbidities, and cirrhosis characteristics were collected. AUD diagnosis was made based on ICD10 F10.x. Outcomes included decompensation (ascites, encephalopathy, variceal bleeding), LT, and death. Kaplan–Meier and log-rank tests assessed transplant free survival (TFS); Multivariable Cox regression was used to examine time from diagnosis to decompensation and from decompensation to LT, death or last follow-up, by AUD status. **Results:** The cohort had mean (SD) age of 59 (12) years, 53% men, 87% White, and median follow-up 1,506 (IQR 894–2071) days. AUD diagnosis was observed in 30% of the cohort, 67% of ALD cirrhosis, and 16% of non-ALD cirrhosis. Patients with AUD diagnosis were younger (54 vs 62 years), more frequently men (67% vs 48%), Black (12 vs 7%), had Medicaid (61% vs 38%), not married (69% vs 52%), had higher baseline rates of ascites (18% vs 12%), encephalopathy (26% vs 9%), variceal bleeding (3% vs 1%), and had more frequently in the preceding year at least one emergency room visit (57% vs 40%) and hospitalization (51% vs 32%) vs those without AUD diagnosis ($P < 0.01$ for all). Among those without decompensation at entry ($N = 10,398$), AUD diagnosis had no impact on the decompensation risk in patients with ALD cirrhosis ($P = 0.5$). In those with non-ALD cirrhosis, AUD was associated with higher decompensation risk (HR 1.19, 95% CI 1.03, 1.38, $P = 0.016$, Fig 1A). During follow-up, patients with AUD diagnosis had lower LT rates (4% vs 8%) but similar mortality (36% vs 35%) vs those without AUD. TFS did not differ by AUD diagnosis ($P = 0.48$, Fig 1B); and these findings remained consistent after adjusting for cirrhosis etiology (ALD vs non-ALD). **Conclusion:** AUD diagnosis is associated with higher risk of decompensation in non-ALD cirrhosis. However, once decompensation occurred, AUD diagnosis was not independently associated with TFS regardless of liver disease etiology.

1504 | PHYSICAL ACTIVITY REDUCES THE RISK FOR DEMENTIA WITH REDUCED ALCOHOL CONSUMPTION IN ALCOHOL RELATED LIVER DISEASE (ALD): A LARGE POPULATION BASED ANALYSIS

Amy Attaway[1] Nicole Welch[1] Annette Bellar[1] Muaz Alsabbagh Alchirazi[1] fnu Shashi Kant[1] Peter Bazeley[1] Dan Rotroff[1] Takhar Kasumov[2] Srinivasan Dasarathy[1], [1]Cleveland Clinic, [2]NEOMED

Background: Alcohol consumption and ALD are contributors to brain histomorphometric changes,neurodegenration, and cognitive decline with limited therapies. Physical activity reduces the risk for dementia while simultaneously decreasing alcohol cravings/consumption. We hypothesized that physical activity mediates a reduction in alcohol consumption to cognitive decline in a large community based population analysis. **Methods:** Using a cross-sectional design of the UK Biobank (n = 393,223), we conducted a Mendelian randomization to determine the causal effect of alcohol use on physical activity and cognitive decline. Alcohol consumption data per week was obtained by self-report. Summed metabolic minutes of physical activity per week were determined based on metabolic equivalent of tasks (METs). Cognitive decline (dementia) was determined by self-report or ICD10 codes. We used a single nucleotide polymorphism (SNP) associated with alcohol risk (rs1260326, Glucokinase Regulator, GCKR) as the instrumental variable to assess the effect of alcohol consumption on physical activity. We then performed a mediation analysis to determine whether summed minutes of activity per week (treatment) influences alcohol consumption per week (mediator) to impact the risk of dementia (outcome). Statistical analyses were performed using Mendelian-Randomization and mediation R packages (4.5.0). **Results:** Our analysis included 47.8% male participants, with an overall average age (SD) of 59.2 (8.1) years. Within the cohort, 92.6% were current drinkers, 3.4% were former drinkers, and 4% were never drinkers. For current drinkers, the average (SD) alcohol consumed was 8.4 (10.2) drinks per week. To determine whether alcohol use influenced physical activity, we performed a Mendelian randomization to predict alcohol use adjusted for age and sex. We determined a statistically significant inverse effect where higher genetically predicted alcohol use was associated with lower physical activity (β coefficient -2.13, std. error 2.01, $p = 0.036$). Mediation analysis was used to determine the direct and indirect effects of physical activity on dementia risk using models adjusted for age, sex, and BMI and showed that physical activity significantly reduced dementia risk directly (ADE or Average Direct Effect: β coefficient -6.40e-08, 95% CI: -1.15e-07-0.00, $p < 0.001$), and indirectly (ACME or Average Causal Mediation Effect: β coefficient -8.75e-06, 95% CI: -1.29e-05-0.00, $p < 0.001$) by mediating a reduction in alcohol consumption. **Conclusion:** We show that physical activity is associated with reductions in dementia both directly and indirectly (by mediating alcohol consumption). Our data lay the foundation for prospective studies to determine whether targeted exercise interventions to reduce alcohol consumption can also decrease the risk for cognitive decline/dementia in patients with ALD and alcohol use disorder.

Takashi Honda[2] Hiroki Kawashima[2], [1]Nagoya University, [2]Nagoya University Graduate School of Medicine, [3]Tianjin Medical University Cancer Institute and Hospital

Background: Fas-associated factor family member 2 (Faf2), a lipid droplet- and endoplasmic reticulum-associated protein, regulates the post-translational degradation of apolipoprotein B in hepatocytes. A recent genome-wide association study linked Faf2 variants to alcohol-associated liver disease (ALD), yet its functional role in ALD pathogenesis remains undefined. Aim: To delineate the hepatocyte-specific role of Faf2 in the development of ALD using a murine model. **Methods:** Hepatocyte-specific Faf2 knockout (Faf2-LKO) mice were generated by crossing *Faf2$^{flox/flox}$* mice with *Albumin-Cre* transgenic mice. Faf2-LKO and littermate controls were subjected to a chronic ethanol feeding plus single binge gavage protocol. Tissues and blood were collected nine hours post-gavage. Liver histology was assessed by hematoxylin and eosin (H&E) and Sirius Red staining; serum transaminases and lipid profiles were measured. RNA sequencing of liver tissues was performed to uncover Faf2-regulated transcriptional networks. Given prior observations of sexual dimorphism, both sexes were analyzed. **Results:** Ethanol exposure in Faf2-LKO male mice resulted in significantly increased liver-to-body weight ratios and elevated serum free fatty acid and free cholesterol levels compared to controls, while Faf2-LKO females showed no differences in tissue weights or serum lipids. Aspartate transaminase and alanine transaminase levels were comparable between genotypes in both sexes. Histological analysis using H&E staining revealed prominent Zone 2 steatosis in Faf2-LKO males and widespread azonal steatosis in Faf2-LKO females compared with respective controls. Fibrosis quantification by Sirius Red staining showed no significant differences. Transcriptomic profiling identified 828 and 1,215 differentially expressed genes in Faf2-LKO males and females, respectively. Gene set enrichment analysis revealed downregulation of steroid and alcohol metabolism pathways in males, whereas IL-1 and cytokine signaling pathways were upregulated in females. **Conclusion:** Hepatocyte-specific deletion of Faf2 promotes sex-dependent hepatic steatosis and distinct transcriptional responses to ethanol exposure. These findings establish Faf2 as a novel modulator of ALD pathogenesis.

1506 | EXPLANT HISTOLOGY OF METALD RESEMBLES AC MORE THAN MASLD

Priyanka Singh[1] Smruti Rath[1] Thomas Schiano[1] Gene Im[2], [1]Mount Sinai Hospital, [2]Columbia University Irving Medical Center

Background: Steatotic liver disease (SLD) includes alcohol-associated cirrhosis (AC), alcohol-associated hepatitis (AH), metabolic dysfunction-associated liver disease (MASLD), and the newly created metabolic and alcohol-associated liver disease (MetALD). Data regarding histological findings for MetALD are lacking. This study aims to assess histological differences among SLD subgroups and determine whether histological findings in MetALD more closely resemble AC or MASLD. **Methods:** A retrospective cohort study was performed on patients who underwent liver transplant (LT) for SLD at Mount Sinai Hospital from 1/1/2012-1/1/2023. MetALD cases were reclassified from prior AC or MASLD designations based on current consensus. Explant histology reports from each liver transplant case were reviewed for key terms reflecting defining histologic features of MASLD and AC. Chi square analyses were used to compare MetALD to the SLD subgroups. **Results:** Over the 11-year study period, 405 LT for SLD were performed at our center, with MetALD being the least common with 28 (7%), followed by AH 114 (28%), AC 126 (31%), and MASLD 137 (34%). Patients with co-morbid liver diseases or diagnoses of HCC were excluded. Of the LT for MetALD recipients, 22 (79%) and 6 (21%) were originally classified as AC and MASLD, respectively. 14% of MASLD, 12% of AC, and 18% of MetALD histology reports mentioned hepatocellular carcinoma (HCC). Mallory-Denk bodies were mentioned in 51%, 37% and 54% of MASLD, AC, and MetALD cases respectively. Although not significant, MetALD (50%) had more findings of ductular reaction compared to MASLD (34%) and AC (32%) (MASLD/MetALD: 2.46, $p = 0.17$; AC/MetALD: 3.35, $p = 0.07$). MetALD (61%) had a significantly higher rate of fibrous septa compared to MASLD (4%) (61.50, $p < 0.001$) and AC (4%) (60.25, $p < 0.001$). MetALD (29%) also had the highest rate of mention of iron deposition compared to AC (25%) and MASLD (12%), with a significant difference compared to MASLD (5.34, $p = 0.02$). Neutrophil-rich inflammation was mentioned at significantly higher rates in MetALD (7%) than MASLD (0.73%) (5.36, $p = 0.02$). There was no significant difference between MetALD (11%) and MASLD (27%), or AC (21%) for mention of burnt-out steatohepatitis. **Conclusion:** MetALD histology showed greater frequency of features typical of AC, including iron deposition, neutrophilic infiltration, and fibrous septa, compared to MASLD. Trends toward increased HCC, Mallory-Denk bodies, and ductular reaction suggest that

both metabolic and alcohol-related injury in MetALD may lead to more severe hepatic insult. Larger studies are needed to further explore these findings.

Table 1. Histologic findings in the steatotic liver diseases

	MASLD (n= 137)	MetALD (n=28)	AC (n = 126)	AH (n = 114)	MetALD vs MASLD Chi-Square Statistic	MetALD vs MASLD P-value	MetALD vs AC Chi-Square Statistic	MetALD vs AC P-value

1507 | UNCOVERING THE DIVERSE ROLES OF LIVER MACROPHAGES IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS

Yang Wang[1] Yukun Guan[1] Dechun Feng[1] Luca Maccioni[1] Maria A Parra[2] Brandon Peiffer[2] Bryan Mackowiak[1] Takashige Kuwabara[3] Kiyoshi Mori[4] Masashi Mukoyama[3] Ramon Bataller[5] Zhaoli Sun[2] Bin Gao[1], [1]NIH/NIAAA, [2]Johns Hopkins University School of Medicine, Baltimore, [3]Kumamoto University Graduate School of Medical Sciences, [4]Shizuoka General Hospital, [5]Hospital Clinic, Barcelona, Spain

Background: Patients with alcohol-associated cirrhosis (AC) may develop severe alcohol-associated hepatitis (sAH), a disease with high short-term mortality. Our previous studies have demonstrated that sAH, but not AC livers, are infiltrated with high number of self-sustaining IL-8$^+$ neutrophils that likely drives the transition from AC to sAH. Monocyte-derived macrophages (MoMFs) also infiltrate the liver in sAH, but their roles remain largely obscure. **Methods:** In this study,we employed scRNA-seq, bulk RNA-seq, and multiplex immunofluorescence analyses to characterize liver macrophages in AC and sAH patients. Several experimental models of alcohol-induced liver injury were used to examine the roles of several population macrophages in mice. **Results:** In the current study, we characterized liver macrophages in sAH and AC. Our data revealed a marked reduction of Kupffer cells, while MoMFs were increased in sAH and AC. Single-cell RNA Seq analyses identified several populations in both AC and sAH including *C1Q*$^+$, *S100A8*$^+$, *APOE*$^+$, *TNF*$^+$ and *VSIG4*$^+$ macrophages, with sAH containing unique *C1Q*$^+$ macrophages potentially playing a role in removing apoptotic neutrophils in sAH. *C1Q*$^+$ macrophages also express a large number of genes involved in phagocytosis, pro-inflammatory, anti-inflammatory functions, suggesting that *C1Q*$^+$ macrophages have diverse functions in sAH. The roles of *C1Q*, *S100A8,* and *APOE* were further examined in experimental models of alcohol-induced liver injury. Our data revealed that *C1q* KO mice and macrophage-specific *S100a8* KO mice had similar alcohol-induced liver injury and hepatic neutrophil infiltration, while *Apoe* KO mice developed much more severe liver injury than WT mice following chronic-plus-binge ethanol challenge. **Conclusion:** Taken together, sAH and AC are infiltrated with multiple populations of macrophages playing diverse functions to drive chronic disease progression. Unique *C1Q*$^+$ macrophages in sAH play a compensatory role in removing dead cells but may also promote inflammation in sAH.

1508 | NON-ABSORBABLE ANTIBIOTICS WORSEN ALCOHOL-ASSOCIATED LIVER DISEASE IN GASTRIC ACID–SUPPRESSED MICE

Fernanda Raya Tonetti[1] Hui Han[1] Mitchell Schubert[2] Masoumeh Sikaroodi[3] Patrick Gillevet[3] Sonja Lang[4] Münevver Demir[5] Wilfred van der Donk[6] Jasmohan Bajaj[7] InTeam Consortium[8] Cynthia Hsu[1] Cristina Llorente[9], [1]Department of Medicine, University of California San Diego, La Jolla, CA, [2]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, VA, [3]Microbiome Analysis Center, George Mason University, Manassas, VA, [4]Faculty of Medicine, University of Cologne, Cologne, Germany, [5]Campus Virchow Clinic, Charité University Medicine, Berlin, Germany, [6]University of Illinois at Urbana-Champaign, Urbana, IL, USA, [7]Virginia Commonwealth University, [8]InTeam Consortium, [9]University of California, San Diego

Background: Proton pump inhibitors (PPIs), which suppress gastric acid secretion, promote intestinal dysbiosis and liver disease progression in mice and humans by facilitating the expansion of intestinal *Enterococcus faecalis* and its translocation to the liver. *E. faecalis* produces cytolysin, a two-subunit exotoxin, that causes hepatocyte death. Fecal cytolysin in

patients with alcohol-associated hepatitis (AH) predicts mortality, while targeted bacteriophage therapy reduces liver damage in humanized mice colonized with AH patient-derived microbiota. This study investigated whether gastric acid suppression-related dysbiosis and treatment with non-absorbable antibiotics targeting Gram-positive bacteria could modulate alcohol-associated liver disease (ALD) progression. **Methods:** Female *Atp4a*$^{SI/SI}$ mice, with inhibited gastric acid secretion, and WT littermates received the Lieber DeCarli diet for 9 weeks. Fecal DNA was extracted for 16S rRNA sequencing. A subset of *Atp4a*$^{SI/SI}$ mice received daily oral gavage of vancomycin (100 mg/kg) and bacitracin (273 mg/kg) during the last 4 weeks. Fecal 16S rRNA sequencing on AH patients (n = 44) with and without PPI use was analyzed from the multicenter InTeam cohort. **Results:** Alcohol-fed *Atp4a*$^{SI/SI}$ mice had increased Gram-positive taxa (*Aerococcus*, *Lactobacillus*, *Enterococcus*, and *Streptococcus*). *E. faecalis*-derived cytolysin was present and functional in *Atp4a*$^{SI/SI}$ and PPI-treated mice. Intriguingly, non-absorbable antibiotics targeting Gram-positive bacteria worsened ethanol-induced steatohepatitis, with elevated transaminases, steatosis, and increased expression of *Cxcl1*, *Cxcl2*, *Tnfa*, *Ccl5*, and *Tgfb1*. Although bacterial overgrowth declined to WT levels, with reductions in *A. viridans*, *Enterococcus*, and *Lactobacillus*, increases in *Streptococcus*, *Enterobacteriaceae*, *Parasutterella*, and *Helicobacter* were observed. Antibiotic-treated *Atp4a*$^{SI/SI}$ mice exhibited increased bacterial translocation to the liver. Similarly, PPI use in patients with AH correlated with increased *Enterococcus* and *Streptococcus* and higher 30-day mortality. Testing *in vitro* therapeutic strategies, we found that dipalmitoylphosphatidylcholine reduced cytolysin hemolysis, and caspase-1/11 inhibitors reduced cytolysin activity in primary mouse hepatocytes. **Conclusion:** Gastric acid suppression combined with non-absorbable antibiotics worsens ALD by disrupting gut microbiota and promoting bacterial translocation, underscoring the need for cautious use.

1509 | ETHANOL DECREASES CPT2-MEDIATED CARNITINE CATABOLISM TO PROMOTE STEMNESS IN ALCOHOLIC HEPATOCELLULAR CARCINOMA

Ronghua Jin[1] *Xiaoxue Yuan*[1] *Yang Wang*[1] *Song Yang*[1] *Wenqian Geng*[1] *Xi Wang*[1], [1]*Beijing Ditan Hospital, Capital Medical University*

Background: Alcoholic Liver Cancer (ALC) is a liver disease resulting from prolonged excessive alcohol consumption. Chronic alcohol abuse can lead to pathological changes such as fatty liver, alcoholic hepatitis, and cirrhosis, which may eventually progress to Hepatocellular Carcinoma (HCC). Globally, liver cancer is one of the leading causes of cancer-related deaths, and alcoholic liver cancer, as a specific type, is particularly prevalent in regions with high alcohol consumption. The incidence of alcoholic liver disease is notably high in certain Asia-Pacific countries (such as China, Japan, and South Korea) and Eastern Europe, where the burden of liver cancer is also significant. Early diagnosis of alcoholic liver cancer remains challenging, and effective treatment methods are still lacking. Therefore, early diagnosis and further research into the molecular mechanisms of alcoholic liver cancer are crucial for improving survival rates. This not only helps to elucidate the pathogenesis of liver cancer but also provides a theoretical foundation for developing new treatment strategies. **Methods:**
CPT2 expression levels were analyzed using the TCGA database. Immunofluorescence staining was conducted on liver tissue sections from patients with alcoholic liver disease. RNA and protein were extracted from the liver tissues of patients with alcoholic liver cancer (ALC), and CPT2 expression levels were evaluated. HepG2 cells were treated with 200 mM ethanol, followed by the detection of mRNA and protein levels, as well as transcriptome sequencing. **Results:** Analysis of the TCGA database reveals a significant reduction in CPT2 expression in liver cancer patients. Immunofluorescence staining demonstrates that the progression of alcoholic liver disease is associated with a marked decrease in CPT2 expression. In comparison to adjacent normal tissues, both mRNA and protein levels of CPT2 are considerably lower in alcoholic liver cancer tissues. At the cellular level, ethanol exposure significantly diminishes CPT2 expression. Transcriptome sequencing indicates that post-ethanol treatment, genes are predominantly enriched in the Hippo pathway and cancer stem cell regulatory pathways. **Conclusion:** The high incidence and low cure rate of alcoholic liver cancer present a substantial challenge to global public health. This study reveals that ethanol reduces CPT2 expression and subsequently decreases CPT2-mediated carnitine catabolism, thereby promoting stemness

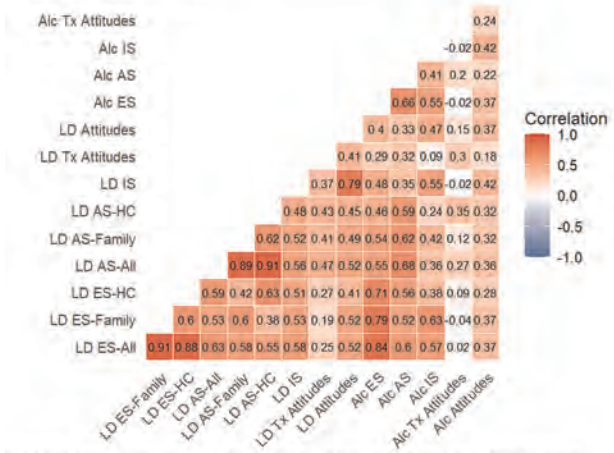
1510 | DEVELOPMENT AND VALIDATION OF THE LIVER DISEASE STIGMA SCALE (LDSS)

Wei Zhang[1] Kelly Hsu[2] Edward Wu[1] Ellen Zhen[1] Ana Ivkovic[1] Heidi Yeh[1] Emily Bethea[1] Sarah Wakeman[1] Russell Goodman[1] Esperance Schaefer[3] Jay Luther[1] Nneka Ufere[1] Raymond Chung[1] Annie Fox-Galalis[4], [1]Massachusetts General Hospital, [2]Tufts University School Of Medicine, [3]Brigham and Women's Hospital, [4]MGH Institute of Health Professions

Background: Liver disease stigma is an underrecognized barrier to equitable care. Patients with liver disease, particularly those with alcohol-associated liver disease (ALD), may experience stigma from both family and healthcare providers. Patients with ALD may internalize (apply negative stereotypes to the self) or anticipate stigma (worry about being the target of discrimination), contributing to delayed treatment, poor engagement and limited access to transplant. Despite growing attention to this issue, no validated instrument currently exists to measure liver disease–specific stigma across key stigma domains. We developed and validated the Liver Disease Stigma Scale (LDSS) to address this gap. **Methods:** Guided by stigma theory (Earnshaw & Chaudoir; Link & Phelan) and prior qualitative findings, we adapted the Substance Use Stigma Mechanisms Scale (SU-SMS) to measure stigma in the context of liver disease. The LDSS includes items assessing internalized, anticipated, and experienced stigma in both family and healthcare providers. Ten additional items were developed to capture liver disease–specific experiences. The survey was completed by 221 adults with liver disease, including 133 (60%) with ALD and 88 (40%) with non-alcohol-related etiologies. The sample was 55.5% male, with 56.0% diagnosed with cirrhosis. Exploratory factor analysis with oblimin rotation was used to confirm factor structure, and internal consistency was assessed using Cronbach's alpha. Convergent validity was assessed by examining associations between LDSS subscale scores and external measures of alcohol-related stigma (SU-SMS), as well as measures of attitudes toward AUD, ALD, and their respective treatments. **Results:** Each stigma domain (internalized, anticipated, and experienced) of the LDSS demonstrated strong internal consistency (Cronbach's alpha $>$ 0.85 in pilot testing), and an exploratory factor analysis confirmed the presence of theoretically consistent constructs (e.g., internalized liver stigma, anticipated stigma from healthcare providers, experienced stigma from family). LDSS subscale scores showed strong convergent validity, with moderate to strong positive correlations with stigma related to alcohol use and negative attitudes towards their AUD, ALD and respective treatments, supporting the scale's potential to identify patients at risk for care disengagement. (Figure). **Conclusion:** The LDSS is the first multidimensional instrument designed to assess liver disease–specific stigma. Its strong psychometric properties and theoretical grounding support its utility for stigma research and intervention development in hepatology, particularly for identifying stigma-related barriers and tailoring care for patients with alcohol-associated liver disease.

Figure: Correlation heatmap showing associations between liver disease stigma (LDSS) subscales, alcohol-related stigma (SU-SMS), and treatment-related attitudes. Diagonal self-correlations (e.g., a scale correlated with itself) are 1.0 but are not shown here due to the lower-triangular format.



LD: Liver disease, Alc: Alcohol, Tx: treatment, AS; anticipated stigma, IS: Internalized stigma, ES; Experienced stigma, HC: healthcare providers

1511 | EFFICACY AND SAFETY OF BOVINE COLOSTRUM IN THE TREATMENT OF SEVERE ALCOHOL-ASSOCIATED HEPATITIS: A MULTICENTER DOUBLE-BLIND, PLACEBO-CONTROLLED RANDOMIZED TRIAL

Sandeep Sidhu[1] Omesh Goyal[2] Ajay Duseja[3] Shalimar Shalimar[4] Sandeep Nijhawan[5] Dharmesh Kapoor[6] Harsh Kashyap[7] Prasanna Samuel[8] Saravanaraj Karuppasamy[9], [1]Christian Medical College & Hospital. Ludhiana, [2]Dayanand Medical College & Hospita, [3]Post Graduate Institute of Medical Education & Research, Chandigarh, [4]All India Institute of Medical Sciences, New Delhi, [5]Sawai Man Singh Medical College, Jaipur, [6]Global Hospital, Hyderabad, [7]Dayanand Medical College & Hospital, Ludhiana, [8]Christian Medical College, Vellore, [9]Christian Medical College, Vellore

Background: Severe alcohol-associated hepatitis is associated with hepatocyte necrosis, inflammation, paradoxical immune exhaustion and leaky gut,. The leading cause of mortality is bacterial infection with multi-organ failure. Corticosteroids provide only a short-term survival benefit in this disease. Bovine colostrum, rich in immunoglobulins and lactoferrin, neutralizes endotoxin and repairs the leaky intestinal mucosal barrier. We aimed to study the efficacy and safety of bovine colostrum in severe alcohol-associated hepatitis. **Methods:** This multicenter, double-blind study included patients with "probable" severe alcohol-associated hepatitis. Patients were registered with the "Trans European Network for Clinical Trials Services" They received 20 grams of freeze-dried bovine colostrum (n = 89) or placebo (Pasteurized milk powder) (n = 85) three times daily for four weeks. The primary outcome was survival at 90 days. Secondary outcomes included survival at 30 days, changes in liver pathobiology, serum cytokines, and episodes of sepsis over one month from baseline. Sensitivity Analysis: Relative Risk (RR) of mortality - Unadjusted and Adjusted (For Centre, Acute Kidney Injury, and Ascites grade) was performed for Actual Observed Outcomes, Best-case scenario and Worst-case scenario assumptions. Grades of Severity of the Adverse Events were as per the Common Terminology Criteria for Adverse Events, Version 5.0. Statistical analysis was done using IBM SPSS v.22.0 and R (version 4.3.1) **Results:** Survival at 90 days was significantly higher - 89.9% (80/89) in the colostrum arm [Model of End Stage Liver Disease score - 30.2 (Interquartile Range: 27.9-33.4)] compared to 57.6% (49/85) in the placebo arm [Model of End-Stage Liver Disease score - 31.5 (Interquartile Range: 27.9-34.2)] ($p < 0.0001$) - Hazard Ratio 0.18, 95% Confidence Interval: 0.09 - 0.38, ($p < 0.001$). Restricted mean survival time was 26.8 days longer in the colostrum arm ($p < 0.001$). The experimental arm had significantly higher survival ($p < 0.0001$), a decrease in serum endotoxin ($p < 0.001$), tumor necrosis factor-alpha levels ($p = 0.01$), and sepsis episodes ($p = 0.04$) at one month. Unadjusted RR for mortality was 0.24, $p < 0.001$; Adjusted RR was 0.22, $p < 0.001$- normal outcomes, unadjusted RR was 0.17, $p < 0.001$; the adjusted RR was 0.22, $p < 0.001$ - best case scenario, RR risk was 0.37 $p < 0.001$, adjusted RR was 0.42 $p < 0.01$ - worst-case scenario. The Relative Risk of mortality was lower in Colostrum arm. Serious adverse events were equivalent in both groups. **Conclusion:** Bovine colostrum significantly improved 90- and 30-day survival in patients with very severe alcohol-associated hepatitis by reducing serum endotoxin levels and tumor necrosis factor-alpha, as well as decreasing the frequency of sepsis episodes and improving gut integrity (decreased endotoxemia). Most deaths occurred in the first month in our study as in all Indian studies due to sepsis with few deaths later.

1512 | IMPACT OF PREVENTION STRATEGIES ON MORBIDITY AND MORTALITY AMONG PEOPLE WITH ALCOHOL USE DISORDERS IN FRANCE: A MODELLING STUDY (MOENA PROJECT)

Abbas MOURAD[1] Maria Patrizia Carrieri[1] Fabienne Marcellin[1] Marc Bourliere[2] Julien Mancini[1] Camelia Protopopescu[1], [1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Économiques & Sociales de la Santé, [2]Département d'hépatologie et Gastroentérologie, Hôpital Saint Joseph, Marseille, France

Background: Harmful alcohol use is a major cause of cirrhosis and hepatocellular carcinoma (HCC). This study uses mathematical modelling to assess the impact of different combinations of prevention strategies on changes in the prevalence and incidence of alcohol-related cirrhosis, HCC and mortality among people with alcohol use disorders (AUD) in France. **Methods:** A Markov model was developed to simulate disease progression to alcohol-related cirrhosis, HCC, and death between 2026 and 2035 among adult people with AUD in France. At each annual cycle, individuals can move between different health states depending on their clinical status and the prevention or care interventions received. The model was first parameterized during the 2000-2025 period using multiple data sources, and its outputs were validated against existing data on AUD prevalence in 2021, as well as cirrhosis prevalence/incidence and HCC incidence in 2017–2018. The model estimates the prevalence/incidence of alcohol-related cirrhosis, HCC, and mortality under 4 scenarios: S0: baseline scenario (no intervention); S1: S0+ a relative increase in the screening rate of harmful alcohol use and brief interventions in primary care varying from 25% to 100% (baseline rate: 16.8%); S2: S1 + a relative increase in access to AUD treatments of 25% to 100% (baseline rate: 48%); S3: S2 + a relative increase of 25% to 100% in the HCC screening rate (baseline rate: 20.7%). **Results:** Figure1 presents the model results on the number of cases averted for the alcohol-related cirrhosis prevalence, incidence, and HCC per million individuals with AUD, and of HCC-related deaths per million individuals with cirrhosis over the period 2026-2035. Application of S1 (vs S0) would avoid 35 to 478 cases of prevalent cirrhosis, 11 to 149 new cases of cirrhosis, as well as 1 to 10 new HCC cases in 2035. Application of S2/S3 (vs S0) would avoid 117 to 554 cases of prevalent cirrhosis, 35 to 160 new cases of cirrhosis, and 3 to 12 new HCC cases in 2035. The application of these scenarios also makes it possible to avoid a cumulative number of HCC deaths over 10 years of 0 to 14 cases for S1, 3 to 19 cases for S2 and 108 to 437 cases for S3 (vs S0). **Conclusion:** The combined implementation of prevention strategies, including early screening of AUD and HCC, and improving access to AUD treatments, could significantly reduce the prevalence and incidence of alcohol-related morbidity and mortality among people with AUD in France over a relatively short period.

1513 | DIGITAL PHENOTYPING CAPTURES REGRESSION OF LIVER FIBROSIS IN ALCOHOLIC CIRRHOSIS IN PARALLEL WITH ABSTINENCE-INDUCED CLINICAL IMPROVEMENT

Adelina Horhat[1] Adi Lightstone[2] Li Chen[3] Horia Stefanescu[4] ioana Rusu[4] Vincent Leroy[5] Marika Rudler[6] Leila Kara[7] Vlad Ratziu[8] Mathieu Petitjean[3], [1]Hopital Henri Mondor, Créteil, France, [2]PharmaNest,

New Jersey, USA, [3]PHARMANEST, [4]University of Medicine and Pharmacy "Iuliu Hatieganu," Cluj-Napoca, Romania, [5]Assistance publique-Hopitaux de Paris, [6]Hospital Pitié-Salpêtrière, [7]ICAN Institute for Cardiometabolism and Nutrition, [8]Service D' Hepatogastroenterologie (FR)

Background: Conventional pathology (CP) has limited ability to document fibrosis regression in cirrhosis. AI-assisted digital pathology (DP) detects changes in fibrotic matrix not captured by CP, offering enhanced sensitivity for tracking fibrosis dynamics. In pts with alcoholic cirrhosis prolonged abstinence induces clinical improvement which may reflect partial fibrosis regression. We applied the automated FibroNest™ single-fiber DP (PharmaNest, Princeton, USA) to assess fibrosis phenotype changes after alcohol abstinence in patients with severe alcoholic hepatitis (SAH). **Methods:** Paired liver biopsies from 9 pts (7 men) with histologically confirmed SAH (Maddrey ≥ 32) and a control liver biopsy after alcohol abstinence (6-15 months) were included. Tissue sections stained with Masson's Trichrome were processed using an AI-powered FibroNest™ DP platform. Composite scores of collagen quantity, morphometry (fiber shape and size) and fibrosis architecture (structural organization) were integrated into a Phenotypic Fibrosis Composite Score (Ph-FCS) to assess overall fibrosis severity and describe fibrosis temporal changes. **Results:** Median age was 47 yrs, bilirubin 5.2 mg/dL, INR 1.84, Maddrey DF 67, MELD 20. 8 pts had confirmed cirrhosis, 7 had ascites, 6 esophageal varices, median HVPG 16 mmHg (range 12-19). 7 patients were treated with corticosteroids. After confirmed abstinence the clinical condition improved: Child (A5/B7, 8/1 pts), no clinical ascites, median reduction in MELD 10, Bilirubin 3.6 mg/dl, INR 0.6, HVPG 5 mmHg. Despite unchanged cirrhosis stage in all pts at follow-up biopsy, there was measurable fibrosis regression with the mean Ph-FCS decreasing from 4.8 (se 0.27) at baseline to 3.6 (se 0.39) at follow-up ($p = 0.01$). Most pronounced improvements were observed in collagen deposition (5.83 to 3.42, $p < 0.01$) and fiber morphometry (2.36 to 1.2, $p = 0.001$). Mean PhFCS decrease was larger with longer duration between biopsies: -1.72 ($>$1yr, $N = 5$) vs -0.53 ($<$1yr). In contrast, architecture scores showed greater variability and smaller changes, suggesting that architectural remodeling may lag behind matrix regression. **Conclusion:** DP overcomes limitations of CP by showing fibrosis regression after alcohol abstinence, in parallel with clinical improvement. These results confirm the reversibility of fibrosis at the cirrhotic stage and highlight the value of AI-powered sensitive quantification of fibrosis regression for monitoring and therapeutic evaluation.

1514 | EXTRACELLULAR VESICLES (EVS) FROM INFLAMED LIVER SINUSOIDAL ENDOTHELIAL CELLS (LSECS) PROMOTE ALCOHOL-ASSOCIATED HEPATITIS THROUGH ACTIVATING FIBROGENIC AND LIPOGENIC PATHWAYS

Young-Ri Shim[1] Yasuko Iwakiri[1], [1]Yale University

Background: Liver sinusoidal endothelial cells (LSECs) are essential for maintaining the hepatic microenvironment through their barrier, signaling, and scavenging functions. In alcohol-associated hepatitis (AH), LSECs undergo pathological changes, characterized by dysfunction and inflammatory activation, which may impact cellular crosstalk and promote liver injury. We hypothesized that in severe AH, dysfunctional and inflammatory LSECs release extracellular vesicles (EVs) that reprogram hepatocytes and hepatic stellate cells (HSCs) toward proinflammatory, lipogenic, and fibrogenic phenotypes, thereby amplifying disease progression. **Methods:** LSECs and their EVs from control and AH mice were provided by the University of Southern California's Integrative Liver Cell Core (R24AA012885). These AH mice were fed chow (control) or a hybrid high-fat diet (HCFD) for 2 weeks, followed by 8 weeks of intragastric ethanol infusion (~27 g/kg/day) with weekly binge doses (3.5–5 g/kg), and developed elevated ALT levels (274 ± 36 U/L) and histological features of PMN infiltration, ductular reaction, and fibrosis. We examined LSECs and EVs by RNA-seq and small RNA-seq analyses, respectively. The effects of LSEC-derived EVs on hepatocytes (GSE259058) and HSCs (GSE176042) were evaluated. **Results:** LSECs from AH mice exhibited inflammatory signature, with significant upregulation of *Il1b* (3.52-fold), *Il15* (5.38-fold), *Ccl3* (10.14-fold), *Ccl4* (5.02-fold), and *Ccl5* (3.19-fold) (all $p < 0.01$). Markers of capillarization were also elevated, including Vwa1 (2.28-fold), Vwf (1.4-fold), CD34 (4.09-fold), and Fabp5 (2.53-fold) (all $p < 0.05$). Genes associated with membrane trafficking and EV biogenesis, such as Anxa1, Anxa2, and Anxa6, were significantly upregulated (1.99–2.58-fold; all $p < 0.01$). EVs isolated from AH-LSECs were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

enriched in miR-320-5p (1.54-fold) ($p < 0.05$) and miR-155-5p (1.52-fold) ($p < 0.05$). Target gene analysis revealed that predicted miR-155-5p targets were upregulated in HSCs and hepatocytes, including ATCA1 in HSCs (2.49-fold; $p < 0.05$) and MET and FOS in hepatocytes (1.75- and 8.83-fold, respectively; $p < 0.01$). Predicted targets of miR-320-5p involved in lipid metabolism, such as LEPR and SCD1, were also markedly increased (17.46- and 17.74-fold; $p < 0.05$), consistent with a lipogenic shift. **Conclusion:** In severe AH, LSECs acquire a capillarized and inflammatory phenotype accompanied by increased release of EVs. These EVs, enriched in miR-155-5p and miR-320-5p, promote fibrogenic activation of HSCs and lipogenic/oncogenic reprogramming of hepatocytes. These findings highlight LSEC-derived EVs as active mediators of disease progression and suggest they may represent a novel therapeutic target in alcohol-associated hepatitis. **Disclosures:** Young-Ri Shim: Nothing to Disclose, Yasuko Iwakiri: Nothing to Disclose

1515 | ALCOHOLIC HEPATITIS IS ASSOCIATED WITH DISTINCT PHENOTYPIC CHANGES OF THE HEPATIC FIBROTIC MATRIX AS EVIDENCED BY QUANTITATIVE DIGITAL PATHOLOGY: IMPLICATIONS FOR DIAGNOSIS AND PROGNOSIS

Marika Rudler[1] Adi Lightstone[2] Li Chen[2] Charlotte Bouzbib[1] Leila Kara[3] Dominique Thabut Damais[4] Frederic Charlotte[1] Vlad Ratziu[5] Mathieu Petitjean[2], [1]Hospital Pitié Salpêtrière, [2]PHARMANEST, [3]ICAN, [4]Hospital Pitié Salpetriere, [5]Service D' Hepatogastroenterologie (FR)

Background: Alcoholic hepatitis (AH) is a severe form of alcohol-related liver injury which is defined histologically by non-specific findings and occurs often in patients (pts) with cirrhosis. We investigated whether the extracellular matrix presents distinct phenotypic changes in pts with AH that could substantiate the diagnosis and derive specific diagnostic or prognostic biomarkers. **Methods:** Pts with clinical suspicion of severe AH, Maddrey discriminant function (MDF) ≥ 32 underwent transjugular liver biopsy for histological confirmation. Biopsies stained with Masson's Trichrome were analyzed using FibroNest^{TM}, a high-resolution single-fiber digital pathology platform, to quantify fibrosis traits grouped into three sub-phenotypes: collagen quantity, fiber morphometry, and architectural complexity. These traits were aggregated into Ph-FCS, a continuous fibrosis severity biomarker. Divergent fibrosis traits between pts with (AH+) and without (AH-) histologically confirmed AH were also calibrated into a Ph-AHS specific AH biomarker. **Results:** 61 pts (45 men) were included, mean age 52 yrs (sd 12.4), MELD 26 (sd 5.7), Bilirubin 14.9 mg/dl (sd 10), MDF 73 (range 34-177). All pts had cirrhosis and 50 had histologically confirmed AH. The Ph-AHS was higher in the 50 AH+ pts than in the 11 AH- (median 4.86 vs 3.24, $p = 0.002$) indicating a distinct fibrosis phenotype in AH. The most discriminative fibrosis traits were related to collagen deposition and fiber morphometry. Ph-AHS had a AUROC of 0.80 (95% CI:0.66–0.91) for the diagnosis of AH with 68% sensitivity, and 91% specificity at an optimal cutoff of 4.51. In contrast the overall fibrosis Ph-FCS biomarker was lower but not significantly different between AH+ and AH- pts: (mean 5.3 vs. 5.9 in HAA+, $p = 0.053$), with an AUROC of 0.69 (95% CI:0.53–0.84), suggesting comparable overall fibrosis burden despite underlying phenotypic differences. Pts with AH who survived free of liver transplantation at 3 months ($N = 30$) had a marginally lower median Ph-FCS (3.2 vs 4.0, $p = 0.04$), suggesting a more severe fibrotic phenotype in non-survivors. **Conclusion:** In pts with alcohol-related liver disease, the occurrence of AH coexists with distinct phenotypic remodeling of the fibrotic matrix. DP can identify these changes and quantify them with a new digital biomarker score, Ph-AHS which could improve the diagnosis of AH. In these patients with advanced disease the fibrosis amount is only a weak predictor of survival.

1516 | PRE-TRANSPLANT SOBRIETY PREDICTS WHEN, NOT IF, PATIENTS RETURN TO ALCOHOL USE AFTER LIVER TRANSPLANT

Sienna Li[1] Kelly Hsu[2] Sophie Van Tulder[3] Maria Diaz Soto[4] Maria Cote[3] Natalia Payan[3] Sofia Baptista[3] Eric Przybyszewski[3] Ana Ivkovic[3] Mladen Nisavic[3] Wei Zhang[3] Heidi Yeh[3] Emily Bethea[3], [1]University of Washington, [2]Tufts University School of Medicine, [3]Massachusetts General Hospital, [4]Beth Israel Medical Center

Background: Alcohol-associated liver disease (ALD) remains the leading indication for liver transplantation (LT). Biomarker-based testing offers greater reliability than self-reported data in detecting return to alcohol use (RAU) and plays a critical role in informing clinical decisions. However, further research is warranted to assess pre-transplant sobriety as a predictor of RAU and post-transplant survival. **Methods:** We conducted a single center, retrospective, cohort study of all adult (>18 years) patients with ALD who received a LT between 2016-2022. Medical records were queried for demographics, psychosocial variables, pre-transplant sobriety duration and one-year post transplant mortality. Logistic regression was used to correlate these factors with post-transplant RAU, defined as a positive urine ethyl glucuronide (EtG), urine ethyl sulfate (EtS), or serum phosphatidylethanol (PEth). **Results:** 194 LT recipients, with median age 59 years, were majority white (91%), male (72%), unemployed (61%), with English as their preferred language (97%). 125 (64%) patients were tested for biomarkers during the post-transplant period, and 52 (27% of all patients, 42% of those tested) tested positive for one or more alcohol biomarkers at least once. Median follow-up time from date of transplant was 43 months (IQR 29-63). Median time to RAU was 24 months by PEth (IQR 13-40), 7.5 months by EtG/EtS (IQR 3-17), and 9.5 months by either test (IQR 3-20). A multivariable regression analysis showed no significant association between pre-LT sobriety duration and post-LT RAU. However, survival analysis identified a shorter time to RAU for patients with <6 months ($p < .0001$) and 6-12 months ($p < .0001$) of pre-LT sobriety, compared to those with >12 months sobriety. There was no difference in one-year post-LT mortality between patients with <6 months and those with >6-month pre-LT sobriety. **Conclusion:** We observed that one-year mortality and RAU outcomes were not impacted by pre-transplant sobriety duration, supporting evolving standards that favor individualized risk assessment over fixed abstinence periods. However, shorter pre-LT sobriety (<6 months) was associated with shorter time to RAU and thus a useful factor in identifying candidates who may benefit from increased psychosocial and addiction support during the early peri-transplant period.

1517 | THE INTRACELLULAR COMPLOSOME: C5-MEDIATED MACROPHAGE REPROGRAMMING IN ALD

Shannon Twardy[1] Laura Saba[2] Rebecca McCullough[3], [1]Univeristy of Colorado, Anschutz Medical Campus, [2]University of Colorado Anschutz Medical Campus, [3]University of Colorado - Anschutz

Background: Complement activation and hepatic macrophages play critical roles in the pathogenesis of alcohol-associated liver disease (ALD). Complement activation has been observed in ALD patients and ALD preclinical models, resulting in C5a-mediated immune activation via C5aR1. While traditionally described as a serum-operative system, evidence supports a cell-autonomous, intracellular complement system (complosome). Here, we characterize the C5 complosome in hepatic macrophages and determine if phenotypic responses observed in ALD occur in a C5 complosome dependent manner. It is our working hypothesis that ethanol increases mitochondrial C5aR1 (mtC5aR1) localization and intracellular C5a binding to mtC5aR1 contributes to inflammatory phenotypes including

macrophage polarization, cytokine production, and impaired phagocytosis in hepatic macrophages that contribute to hepatocellular damage. **Methods:** Liver explants from patients with Alcohol-associated hepatitis (AH) and healthy donors were profiled for complosome expression using VSIG4 and CD68 as markers of hepatic macrophages for multispectral imaging. In a preclinical model of ethanol accelerated fibrosis, CD45+ enriched hepatic cells were subjected to single cell sequencing. Immortalized mouse Kupffer Cells (ImKCs) were cultured with 50mM ethanol and challenged with ethanol and/or 10ng/mL lipopolysaccharide (LPS) for up to 24 hours. To determine if responses to ethanol and/or LPS were C5 complosome dependent, C5 and C5aR1 KO ImKCs were generated. Mouse hepatocytes (AML12 cells) were cultured with and without ethanol and conditioned media (CM) from ethanol- and LPS-treated ImKCs and Nile Red staining was used to assess neutral lipid accumulation. **Results:** Expression of C5aR1 was increased in CD68+ cells in AH explant tissue. *In vivo*, expression of c5ar1 was enriched by ethanol feeding in all identified macrophage clusters. C5 complosome component expression was increased after EtOH and LPS exposure in ImKCs. Ethanol increased mtC5aR1 localization in a time-dependent manner. Ethanol and LPS exposure enhanced pro-inflammatory markers and secretion of pro-inflammatory mediators and suppressed anti-inflammatory markers and phagocytosis. C5 or C5aR1 KO ImKCs suppressed pro-inflammatory polarization and cytokine production and restored anti-inflammatory marker and phagocytosis. Hepatocytes cultured with ethanol and CM from stimulated WT ImKCs had enhanced lipid accumulation, that was completely suppressed in hepatocytes cultured with CM from C5 or C5aR1 KO ImKCs. **Conclusion:** Macrophage expression of C5aR1 is conserved among AH patients and in preclinical models of ALD. These data highlight a novel function of complement as a mediator of macrophage effector function and contributor to hepatocellular injury. This may suggest a feasible mechanism by which macrophages are more responsive to pathogens following alcohol exposure.

1518 | WHEN IS LIVER TRANSPLANT FOR ALCOHOL-ASSOCIATED HEPATITIS TOO EARLY?

Claire Durkin[1] Therese Bittermann[2], [1]University of Pennsylvania, [2]Perelman School of Medicine

Background: Early liver transplant (LT) for severe alcohol-associated hepatitis (AAH) has been increasing in prevalence over the past decade. Although AAH is associated with high mortality, 10-28% of patients evaluated for LT for AAH experience hepatic recompensation. The goal of this study was to characterize the clinical outcomes of patients awaiting LT and patient factors associated with waitlist mortality in AAH. **Methods:** This was a retrospective cohort study of the United Network for Organ Sharing database of adults ($\geq$ 18 years) waitlisted for first time, single organ LTs for AAH from 1/1/2018 to 12/31/2024. AAH was identified based on primary and secondary diagnoses codes on initial LT application. Transplantation and waitlist drop-out were identified using registration removal codes. Demographic and clinical characteristics were compared by reason for waitlist removal (i.e., death, transplantation, clinical improvement, or other reason) using chi-squared tests for categorical and Kruskal-Wallis tests for continuous variables. Logistic regression was used to evaluate risk factors for mortality within 28-days of LT waitlisting, adjusting for patient characteristics on initial transplant application. **Results:** Of the 2,704 patients waitlisted for AAH during the study period, 2,111 (83.4%) underwent LT and 206 (8.1%), 119 (4.7%), and 95 (3.8%) were removed from the waitlist due to death/deterioration, clinical improvement, or other reasons, respectively. By comparison, waitlist mortality of acute liver failure patients was 19.7% and of other non-AAH patients was 16.9%. Patients transplanted for AAH had short wait times with a median duration from listing-to-LT of 5 (interquartile range [IQR] 3-10) days. Approximately half (46.3%) of transplanted patients had no or mild ascites and no or grade 1-2 encephalopathy and half (45.2%) had intact renal function (i.e., eGFR $\geq$ 60 and not on dialysis) at listing. Patients who died/deteriorated awaiting LT experienced longer wait times with a median wait of 12 (IQR 5-32) days. Patients delisted due to clinical improvement tended to be younger and with lower initial MELD scores (both $p < 0.001$), remaining on the waitlist for an average of 270 (IQR 146-461) days. No difference in waitlist mortality rates were observed across MELD scores < 40 ($p = 0.624$, Figure 1A). On multivariable analysis, 28-day waitlist mortality was not different for listing MELD scores 25-34 and 40+ vs 35-39 as reference (all $p > 0.05$, Figure 1B). **Conclusion:** Patients with AAH undergo LT with significantly higher frequency and lower waitlist mortality compared to national averages. The prolonged waiting time prior to removal due to clinical improvement may suggest that a subset of patients are transplanted too early and not offered the opportunity to recover. MELD-based waitlisted prioritization may not be appropriate in AAH as it does not accurately stratify risk of waitlist mortality for many patients.

1519 | EVALUATING SEMAGLUTIDE AND LIFESTYLE INTERVENTIONS IN A NOVEL DIETARY RAT MODEL OF METABOLIC AND ALCOHOL-RELATED LIVER DISEASE WITH ADVANCED FIBROSIS

María Martínez Gómez[1] Imma Raurell[2] Maria de la Serra Cusidó Sabidó[3] Sophia Christina Parks[4] Joan Genescà[5] María Martell[6] Meritxell Ventura-Cots[7] Juan M Pericàs[5], [1]Liver Disease Group, VHIR; UAB; CIBERehd, [2]Liver Disease Group, VHIR; Liver Unit, VHUH; CIBERehd, [3]Liver Disease Group; VHIR; UAB, [4]Liver Disease Group; VHIR, [5]Liver Disease Group, VHIR; Liver Unit, VHUH; UAB; CIBERehd, [6]Liver Disease Group; VHIR; Liver Unit, VHUH; UAB; CIBERehd, [7]Liver Disease Group, VHIR; Liver Unit, VHUH; UAB

Background: Metabolic and alcohol-associated liver disease (MetALD) was recently proposed as a distinct entity however its natural history and therapy remain largely unknown. GLP-1 receptor agonists, approved for type 2 diabetes and obesity - major MetALD risk factors - have been evaluated for both metabolically and alcohol induced liver injury (MASLD and ArLD, respectively). Our aim was to develop a translational dietary rat model of MetALD with advanced fibrosis and portal hypertension (PH) to test therapeutic interventions and compare MetALD features to those of MASLD. **Methods:** The model was 20-week long, with interventions starting at week 16 (Fig.1). At the end of the study, liver hemodynamics, histology (fibrosis, ductular reaction, macrophage infiltration), biochemical markers, gene/protein expression, and immune profiling by multiplex assay were assessed. **Results:** Compared to CD, MASLD and MetALD showed an increase in body weight, dyslipidemia, AST, ALT, intrahepatic insulin resistance, steatosis, fibrosis, portal pressure (PP), ductular reaction, and macrophage infiltration, along with pro-inflammatory cytokines. Advanced fibrosis rates were higher in MetALD than MASLD (75% vs. 58.3%), but the difference was not statistically significant. Regarding interventions, semaglutide treatment induced significant weight loss in all groups (2-25%), regardless of dietary intervention or alcohol cessation. Gene analyses revealed restored insulin sensitivity after dietary intervention, independent of alcohol or semaglutide. Steatosis regressed from S3 to S1 in 50% of individuals when the diet was removed. All interventions reduced advanced fibrosis ratios showing a greater reduction in the group combining diet and alcohol removal with semaglutide ($p < 0.001$). PP and IHVR were significantly reduced in groups receiving semaglutide, whereas diet withdrawal, reaching values comparable to controls. Semaglutide alone did not significantly improve fibrosis or PP (Fig 1). **Conclusion:** Our MetALD model replicates key features of metabolic and alcohol-induced liver injury, including advanced fibrosis and PH. Adding semaglutide to diet and alcohol cessation significantly improved steatohepatitis, fibrosis, and PH. No major histopathological differences between MetALD and MASLD were found. Further research is needed to identify biomarkers distinguishing these conditions.

1520 | START DOMAIN-CONTAINING PROTEIN 10 MODULATES RECEPTOR TYROSINE-PROTEIN KINASE ERBB-2 -MEDIATED LIPOGENESIS IN ALCOHOL-ASSOCIATED LIVER DISEASE

Manisha Dagar[1] Youngyi Lim[2] Swati Chandla[2] Monica Justo[2] Sion Lee[2] Maria Lauda Tomasi[2], [1]Cedars Sinai Medical Center, [2]CEDARS-SINAI MEDICAL CENTER

Background: In developed countries, alcoholic steatohepatitis (ASH) is major risk factor for liver cirrhosis and hepatocellular carcinoma (HCC). Recently, receptor tyrosine-protein kinase erbb-2 (ErbB2) (transmembrane receptors with tyrosine kinase activity) has been described in ASH and correlated with severity of inflammation and signs of longstanding liver injury. StAR-related lipid transfer domain containing 10 (StarD10), a phospho protein that positively regulates ErBb2 signalling pathway. We recently reported that ethanol administration lowers StarD10 phosphorylation leading to increased plasma membrane fluidity and induced ErbB2 activity in alcohol-induced breast cancer. This study aims to investigate whether phosphorylation of StarD10 regulates lipogenesis via ErbB2 in alcohol-associated liver disease (AALD). **Methods:** NIAAA mice livers and primary mouse hepatocytes. Western blot and immunoprecipitation. Duolink proximity Ligation assay (PLA) and immunofluorescence. Lipids binding and membrane fluidity assays, Phospho-peptide mapping, CRISPR-Cas9 gene editing, triglyceride and cholesterol assay. **Results:** Alcohol increased StarD10 and ErbB2 expression in NIAAA livers as well as in ethanol-treated hepatocytes. Surprisingly, alcohol also promoted StarD10 and ErbB2 physical interaction in vitro and in vivo at the plasma membrane. StarD10 was found to bind all phosphatidylinositides species (PIPs), specifically PIP(3,4)2, PIP (4,5)2 and PIP(3,4,5)3, and ethanol treatment increased it further. Ethanol-induced ErbB2 transactivation leads to PIP2 to PIP3 phosphorylation by phosphoinositide 3-Kinase (PI3K) that correlates with increased mTOR pathway in ALD. StarD10 overexpression induced SrebF1 level as well as its downstream lipogenic target genes such as FASN and ACC1. Additionally, phospho-peptide mapping revealed an overall decrease in StarD10 phosphorylation, except for one unique hyperphosphorylation residue, serine 7 (S7). CRISPR gene editing of S7 led to significant reduction in lipid accumulation, even in the presence of ethanol. These findings suggest that StarD10 binds to and may transport or stabilize PIPs leading to de novo lipogenesis. **Conclusion:** This study suggests a potential role for StarD10-induced mTOR pathway via PIPs to cause liver steatosis upon alcohol treatment. It also opens a wide field of research about functional implications of StarD10 and ErbB2 cross-talk deducing possible therapeutic strategies in ALD.

1521 | IMPACT OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS ON ALCOHOL CONSUMPTION AND LIVER-RELATED OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Bernardo Moraes[1] Igor Boechat Silveira[2] Gabriel Leite[1] Gustavo Leite[1] Nathalia Lana[1] Guilherme Cançado[3], [1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil., [2]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil., [3]Hospital das Clínicas da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have shown promising results in reducing alcohol intake and impacting liver-related outcomes, mostly in patients with alcohol use disorder (AUD). However, their clinical benefit in this setting is debated and no prior meta-analysis has addressed the significance of these recent findings. **Methods:** We conducted a systematic review and meta-analysis to evaluate whether GLP-1RAs use is associated with reduced alcohol intake, alcohol-related events and liver-related outcomes, compared to non-use. Alcohol-related events included incident or recurrent AUD diagnosis, hospitalization or treatment due to AUD. Liver-related outcomes included progression to alcohol-related liver disease, hepatic decompensation, hepatocellular carcinoma, liver transplant or portal hypertension. A comprehensive search of PubMed, Embase, and CENTRAL was performed in May 2025. We included randomized controlled trials (RCTs) and observational studies comparing GLP-1RAs use versus non-use. Two reviewers independently screened studies, extracted data, and assessed risk of bias using RoB 2 tool for RCTs and ROBINS-I for cohort studies. A random-effects meta-analysis was conducted using

restricted maximum-likelihood estimation. Standardized mean differences (SMDs), incidence rate ratio (IRRs) or hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated for primary and secondary outcomes. **Results:** Eight studies (3 RCTs, 5 observational) including 101,770 patients on GLP-1RAs and 114,335 controls were included. The primary outcome of daily alcohol intake was reported in 3 RCTs with 162 patients on GLP-1RAs and 164 controls. In the pooled analysis, GLP-1RAs use was not associated with reduced alcohol intake (SMD -0.17; 95% CI: -0.39, 0.04; I^2 = 0.0%). However, this negative finding was not sustained in subsequent analyses. Eight observational studies including 101,608 patients on GLP-1RAs provided data for the secondary outcomes. GLP-1 RAs use was associated with reduced alcohol-related events (HR 0.56; 95% CI: 0.48, 0.65; I^2 = 63.6%) and reduced liver-related outcomes (IRR 0.65; 95% CI: 0.50, 0.85; I^2 = 0.0%). **Conclusion:** This pioneering meta-analysis outlines the impact of GLP-1RAs use on reducing alcohol-related events and liver-related outcomes, despite no observed change in daily alcohol intake. Alongside ongoing trials, further RCTs are needed to evaluate the role of GLP-1RAs in modulating alcohol use and its impact on liver function.

1522 | PLASMA SIGNAL REGULATORY PROTEIN-A, A POTENTIAL BIOMARKER TO PREDICT CORTICOSTEROID RESPONSE AND PROGNOSIS IN PATIENTS WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS.

Ethan Steele[1] David Malicote[1] Josiah Hardesty[1] Craig McClain[1] Samer Gawrieh[2] Srinivasan Dasarathy[3] Wanzhu Tu[2] Ramon Bataller[4] Gyongyi Szabo[5] Vijay Shah[6] Arun Sanyal[7] Suthat Liangpunsakul[2] Mack Mitchell[8] Ashwani Singal[1], [1]University of Louisville, [2]Indiana University, [3]Cleveland Clinic, [4]Barcelona Clinic, [5]Beth Israel Deaconess Medical Center, [6]Mayo Clinic Rochester, [7]Virginia Commonwealth University, [8]University of Texas Southwestern Medical Center

Background: Alcohol-associated hepatitis (AH) has a high short-term mortality in patients with severe episode (sAH) with a MELD score > 20. Corticosteroids (CS), the only available drug for patients with sAH is a suboptimal treatment, as 40-50% of patients are ineligible and a response (CS-R) rate of 50-60% in those who are eligible to receive CS. Further, response can only be determined after using CS for at least 7-d (Lille Score < 0.45), with a risk of bacterial and fungal infections especially in non-responders to CS (CS-NR). Signal regulatory protein alpha (SIRPA) is an immune cell receptor that regulates efferocytosis and inflammatory responses. Cleavage of SIRPA from its ADAM10 depends upon macrophage polarization, with its cleavage and release into the plasma in pro-inflammatory or M1 macrophage. The role of SIRPAa has not been studied in patients with AH. **Methods:** In a prospective cohort of sAH patients (2019-2024) enrolled in the Alchep Network study and treated with CS, plasma samples before CS exposure were analyzed by ELISA for cytokines and SIRPA levels (ng/mL). Patients were followed for up to 180 days from the time of CS treatment. **Results:** Of 134 sAH patients treated with CS, 88 (mean age 46.4 yrs., 39% females, 86% NH White, mean MELD 23.7, mean CTP score 10.4, mean albumin 2.56, mean WBC 9.7) with available Lille score at d-7 were analyzed. CS-R (n = 52) vs. NR (n = 36) were younger with lower MELD (22.6 vs. 25.4), BUN (11.9 vs. 18.8), and WBC (8.6 vs. 11.3). Baseline mean plasma SIRPa levels were higher in CS-NR vs. CS-R (216.6 vs. 176.2, Fig. 1A). Controlling for WBC and MELD score, SIRPA level predicted CS-R with OR (95% CI): 0.9 (0.98-1.00), P = 0.048. A total of 18 (20.5%), 29 (33%), and 32 (36.4%) died by 28, 90, and 180-d respectively. Stratifying the data at a median SIRPA level of 187, probability of survival at d-180 was higher in 44 patients with SIRPA levels < 187 vs. ≥ 187 ng/mL (Fig. 1B). In a Cox regression model controlled for MELD score, WBC, SIRPA, and Lille score, strongest predictor of death at d-180 was Lille score at d-7, with HR (95% CI) of 16.6 (2.8-99.7), p = 0.002. **Conclusion:** Plasma SIRPA is a potential biomarker to predict CS-R, and can personalize CS use in patients with sAH. Future pre-clinical studies are suggested to examine how loss of SIRPA expression or its cleavage contributes to AH pathogenesis. Prospective clinical studies are suggested to validate SIRPA as a biomarker in use of CS in patients with sAH.

1523 | LONGITUDINAL TRANSITIONS BETWEEN ALCOHOL CONSUMPTION LEVELS IN US ADULTS: INSIGHTS FROM THE PATH STUDY

Olajide Adekunle[1] Andrew Brouwer[2] Ha Tran[1] Yihua Yue[1] Michael Rothberg[1] Phuc Le[1], [1]Cleveland Clinic, [2]University of Michigan

Background: Changes in alcohol consumption over time may reveal important opportunities for early intervention, yet little is known about the frequency and direction of these transitions among adults (≥ 18 years) in the United States. **Methods:** Using Waves 1-7 (2013–2023) of the Population Assessment of Tobacco and Health study, we developed a Markov multistate transition model and estimated transition rates between alcohol use states for adults, accounting

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

for survey weights. We excluded pregnant women and participants with one observation for alcohol use or missing data. We defined drinking states based on WHO risk levels depending on grams of alcohol consumed per day: abstinent (<1 g/day), low (male, 1-40 g/day; female, 1-20 g/day), medium (male, >40-60 g/day; female, >20-40 g/day), high (male, >60-100 g/day; female, >40-60 g/day), and very high risk (male, >100 g/day; female, >60 g/day). Transition rates were used to estimate annual transition probabilities overall and by age, sex, and race/ethnicity. **Results:** We included 19,323 participants with 110,164 observations of alcohol use. Among the participants, 63.5% and 22.0% belonged to 18-34 and 35-54 age groups, respectively, 53.2% were female, 54.9% were non-Hispanic White, 21.7% Hispanic and 15.2% non-Hispanic Black. Among abstainers, 84.0% remained abstinent after one year, while 15.3% transitioned to low-risk drinking. Most people in the low-risk state either remained in low risk (74.7%) or became abstinent (20.9%). In contrast, participants in higher-risk categories were less likely to remain at the same use level. More than 50% of medium-risk and 63% of high-risk alcohol drinkers reduced their consumption. Among people in the very high-risk state, many decreased their drinking, with the most common transition (34%) being to the low-risk category. Transitions among abstinent and low-risk individuals showed minimal variation by demographic characteristics. However, in medium- or other higher risk groups, men, White participants, and those aged 35–54 were more likely to maintain or increase use compared to women, non-White participants, and other age groups. **Conclusion:** While abstinent and low-risk individuals largely maintained their low-risk status, those in higher-risk categories tended to reduce consumption over time. However, demographic differences in transitions were more pronounced among higher-risk groups. Targeted interventions are needed to support sustained reduction in alcohol use.

1524 | CHARACTERIZATION OF PLASMA PEPTIDOMIC SIGNATURES INVOLVED IN THE GUT-IMMUNE-LIVER AXIS OF THE EARLY-STAGE ALCOHOL-ASSOCIATED LIVER DISEASE

Anjali Kumari[1] Mukesh Kumar Sriwastva[1] Christine Dolin[1] Michael Merchant[1] Gavin Arteel[2] Maiying Kong[1] Melanie Schwandt[3] Joris Verster[1] Venkatakrishna Jala[1] Ashwani Singal[1] Craig McClain[1] Vatsalya Vatsalya[1], [1]University of Louisville, [2]University of Pittsburgh, [3]NIAAA

Background: The clinical presentation of early-stage alcohol-associated liver disease (eALD) has recently been described. However, the pathological biomarkers involved in the gut-immune-liver (GIL) axis and corresponding peptidomic changes have not yet been described. This study characterizes the role of liver pathology in the GIL axis, the corresponding novel biomarker response, and the identification of signature peptidomic. **Methods:** Forty-two adult male and female subjects were classified as healthy controls (HC, n = 6), alcohol use disorder (AUD, Gr.1, n = 10), or eALD (Gr.2, n = 26). Comprehensive metabolic panel (CMP), complete blood count (CBC), coagulation (PT+INR). Plasma samples collected were used for the detection of biomarkers for gut dysfunction, proinflammatory cytokines, and liver cell death markers (keratin 18, K18), and for peptide extraction for LC-MS/MS analysis. Differentially expressed peptides were identified and correlated. Pathway and protein-protein interaction analyses were performed to elucidate underlying biological processes. **Results:** Liver injury in Gr.2. was marked by clinical and statistically significant elevations in liver injury markers, AST (aspartate transaminase, 3~fold, $p = 0.013$), ALT (alanine transaminase, $p < 0.01$) values compared to Gr.1. Novel biomarkers of eALD (LPS [lipopolysaccharide], +sCD14 [soluble cells of differentiation 14], TNF-α [tumor necrosis factor-alpha], IL1-β [interleukin 1-beta], and K18 ratio [M65/M30]) were significantly dysregulated (Fig. 1a). Key peptides associated with gut permeability, immune activation, and liver cell death and injury (fibrinogen, collagen fragments) were statistically significantly and uniquely different between groups (Fig. 1b). Compartment-specific GIL axis analysis showed corresponding significant changes ($p < 0.05$) between the two groups: FIB-A (gut), COLA1, THRB, and FIB-B (immune), and FIB-B (liver) (Fig. 1b). **Conclusion:** We found that the characteristic feature of eALD that

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

distinguishes it from AUD is the progression of liver injury. The specific changes identified by the gut alterations and proinflammatory cytokine response could be consequential in the higher necrosis, contributing to the unique GIL axis alterations in eALD. Differentiation in the biomarkers' activity was supported by the subtle, albeit significant, changes in the representative proteomic changes. Plasma peptidomic signatures effectively distinguish eALD from AUD.

1525 | SERUM FERRITIN AND ADVERSE LIVER OUTCOMES IN PATIENTS WITH METALD: AN NHANES-BASED ANALYSIS

Sheena Bhushan *Kris Kowdley*[1], [1]*Liver Institute Northwest*

Background: Metabolic Dysfunction-associated Alcohol-related Liver Disease (MetALD) is a newly defined subgroup of patients with Metabolic Dysfunction-associated Steatotic Liver Disease (MASLD) who also consume moderate amounts of alcohol which is defined as 20-50 g/day for women and 30-60 g/day for men. It has been shown in experimental studies that even moderate amount of alcohol can suppress hepcidin synthesis in the liver, leading to dysregulation of iron homeostasis, and subsequent hepatocellular injury and fibrosis. However, the clinical significance of iron biomarkers in metALD has never been evaluated at a population level. The aim of this study is to evaluate the association between elevated serum ferritin (SF) and transferrin saturation (TSAT) and clinical outcomes in individuals with metALD. **Methods:** Data were obtained from the 2017-2018 National Health and Nutrition Examination Survey (NHANES), comprising of 4,438 participants. A total of 67 individuals met the diagnostic criteria for metALD defined as a CAP $\geq$ 288 dB/m and moderate alcohol intake (20-50 g/day in women and 30-60 g/day in men). Elevated SF was defined using gender-specific thresholds of $>$450 ng/mL for men and $>$300 ng/mL for women. Primary outcomes included advanced fibrosis (kPa $\geq$ 11.7), elevated ALT, mortality, hepatocelluar carcinoma (HCC) and cirrhosis (kPa $\geq$ 12.5). Statistical Analyses were conducted using Mann-Whitney U and chi-square tests. Logistic regression was used to adjust for age, sex, BMI, diabetes, triglycerides and HDL. **Results:** An elevated SF level was present in 22.2% of metALD patients and was associated with significantly higher liver stiffness (+2.03 kPa, $p=0.001$) and a trend toward advanced fibrosis (OR 2.20, $p=0.108$), cirrhosis (OR$=$2.20, $p=0.108$) and elevated ALT (OR 2.68, 95% CI 0.47-4.62, $p=0{,}007$). Elevated TSAT ($>$45%) also showed a trend toward higher rates of advanced fibrosis (20.0% vs. 6.5%) and ALT elevation (80% and 37.1%). **Conclusion:** Elevated SF levels are associated with increased liver stiffness and a trend toward advanced fibrosis and cirrhosis. These findings support the potential utility of iron biomarkers as non-invasive indicators of disease progression in patients with metALD.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Current published research establishes Baclofen as the gold standard of AUD treatment in patients with cirrhosis. Increasingly Naltrexone is being found to be safe and effective in this population. This study compares an emerging therapy Naltrexone against the gold standard in early cirrhotic (CTP $\leq$ 9) patients. **Methods:** Sixty-four patients with alcohol dependence and cirrhosis were enrolled and randomly assigned (1:1) to receive either Baclofen (10 mg TDS; n = 32) or Naltrexone (50 mg OD; n = 32) using block randomisation (block size: 10), with allocation and blinding managed by the trial coordinator. Medications were administered for 12 weeks and entrusted to a family member to ensure adherence and monitor side effects. Post-treatment assessments included AUDIT scores, obsessive-compulsive behaviours, cravings, binge drinking episodes, abstinence rates, and liver-related clinical and biochemical parameters. **Results:** After 12 weeks, both Baclofen and Naltrexone reduced AUDIT-12 scores in alcohol-dependent cirrhotic patients (12.61 $\pm$ 3.43 vs. 11.63 $\pm$ 3.86; $p = 0.288$). Baclofen more effectively reduced obsessive thoughts (OCD-O: 8.31 $\pm$ 1.10 vs. 10.25 $\pm$ 1.16; $p < 0.001$), while Naltrexone better reduced compulsive behaviour (OCD-C: 6.97 $\pm$ 1.12 vs. 9.66 $\pm$ 0.83; $p < 0.001$) and binge episodes (0.44 $\pm$ 0.87 vs. 2.06 $\pm$ 2.27; $p = 0.001$). Abstinence was higher with Naltrexone (65.6% vs. 43.8%; $p = 0.131$). Liver function was comparable (CTP: 6.44 $\pm$ 1.39 vs. 6.59 $\pm$ 1.45; MELD: 10.97 $\pm$ 3.60 vs. 11.84 $\pm$ 2.79; $p > 0.05$). Both drugs were effective and safe, with Baclofen favouring reduction in obsession and Naltrexone showing better outcomes in abstinence and binge control. **Conclusion:** Baclofen is more effective for obsessive thoughts, while Naltrexone is better for compulsive behaviours and binge drinking. No significant difference in abstinence rates was found, suggesting both treatments are viable options for managing alcohol dependence in early cirrhotic patients. Further studies with larger sample sizes are needed.

1527 | LONG-TERM BENEFITS OF MENTAL HEALTH FOLLOW-UP IN PATIENTS HOSPITALIZED FOR ALCOHOLIC HEPATITIS

Ahmed Ibrahim[1] Don Rockey[1] Mohamed Eldesouki[2],
[1]Medical University of South Carolina,
[2]New York Medical College at Saint Michael Medical Center

Background: Mental health disorders, including depression, anxiety, and PTSD, are common in patients with alcohol-associated liver disease and may influence recovery after alcoholic hepatitis (AH). However, the impact of post-discharge mental health (MH) follow-up on long-term outcomes in this population requires further investigation. **Methods:** We used the TriNetX Research Network to examine adult patients ($\geq$ 18 years) hospitalized with a first episode of AH between 2010 and 2024. Patients were stratified based on whether or not they had MH follow-up within 90–180 days post-discharge, defined as $\geq$ 1 of the following: (1) outpatient psychiatry or psychology visit, (2) initiation of psychotropic medication (e.g., SSRIs, antipsychotics), or (3) enrollment in alcohol/substance use counseling. The primary outcome was all-cause mortality. Secondary outcomes included liver-related decompensation (ascites, hepatic encephalopathy, variceal bleeding), and 1-year hospital readmission. Propensity score matching (PSM) was used to balance baseline characteristics. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). **Results:** A total of 70,397 patients hospitalized with a first episode of alcoholic hepatitis were identified; 17,201 had documented post-discharge MH follow-up, and 53,196 did not. The majority of patients were White males, with similar age distributions. At baseline, those in the MH follow-up group had higher aminotransferases and bilirubin, and lower platelet counts. After matching, each cohort had 14,613 patients (mean [SD] age, 49 [12] years; 35% women), and were evenly matched in baseline characteristics and laboratory parameters. Patients with MH follow-up had significantly lower rates of all-cause mortality (11% vs 18%; HR, 0.52; 95% CI, 0.49–0.53; $p < 0.001$), hospital readmissions (50% vs 65%; HR, 0.59; 95% CI, 0.54–0.63), and liver-related decompensation events including ascites (7% vs 12%; HR, 0.54; 95% CI, 0.50–0.60), hepatic encephalopathy (13% vs 20%; HR, 0.54; 95% CI, 0.50–0.58), and variceal hemorrhage (2% vs 3%; HR, 0.81; 95% CI, 0.69–0.94). Rates of esophageal and gastric varices were also significantly lower in the MH follow-up group. **Conclusion:** Post-discharge MH follow-up after hospitalization for AH is associated with improved long-term outcomes, including lower mortality, reduced relapse, and fewer liver-related complications. These findings highlight the importance of integrating psychiatric care into the routine management of patients recovering from AH.

1528 | MLCK REGULATED PLATELET CYTOSKELETAL DYNAMICS ENHANCE NEUTROPHIL CROSSTALK TO FACILITATE LIVER INFLAMMATION AND INJURE

Li Zuo[1] Juan Wang[2] Hua Wang[1], [1]Anhui Medical University, [2]the First Affiliated Hospital of Anhui Medical University

Background: Alcohol-related liver disease (ALD) is a major global cause of liver-related mortality, but its underlying pathogenic mechanisms remain incompletely understood. Emerging evidence suggests platelet activation may play a critical role in ALD progression, yet the molecular drivers and cellular consequences of this process are undefined. **Methods:** We employed electron microscopy, flow cytometry, and intravital two-photon microscopy to assess platelet activation and intrahepatic aggregation in ALD mouse models. Antiplatelet therapy (aspirin/clopidogrel) and platelet-specific Mylk knockout mice were used to evaluate functional consequences. Single-cell RNA sequencing characterized alcohol- and myosin light-chain kinase (MLCK)-dependent shifts in hepatic cell populations. In vivo dynamic imaging quantified platelet-neutrophil interactions, while mechanistic studies defined roles for CXCL7-CXCR2 signaling, mitochondrial transfer, and Piezo1-mediated Ca^{2+}/calmodulin activation of MLCK. **Results:** We demonstrate that platelet activation and intrahepatic aggregation are markedly elevated in ALD mice, correlating with cytoskeletal reorganization, pseudopod formation, and granule release. Antiplatelet therapy (aspirin/clopidogrel) attenuates hepatic inflammation and lipid accumulation, impeding disease progression. Mechanistically, myosin light-chain kinase (MLCK) emerges as a key regulator: its gene-knockout reduces platelet activation and aggregation, ameliorating ALD pathology. Single-cell sequencing reveals alcohol- and MLCK-dependent shifts in hepatocyte, platelet, and neutrophil subpopulations. Crucially, in vivo dynamic imaging identifies enhanced platelet-neutrophil interactions in portal regions, mediated by CXCL7-CXCR2 ligand-receptor binding and cytoskeleton-driven mitochondrial transfer. Activated platelets release functional mitochondria to neutrophils, triggering neutrophil extracellular traps (NETs) formation and inflammatory mediator release, processes disrupted in platelet-specific Mylk knockout mice. MLCK activation is driven by Piezo1-mediated Ca2+ influx and calmodulin signaling, linking mechanical cues to platelet hyperactivation. **Conclusion:** This work establishes MLCK as a central hub coordinating platelet-neutrophil crosstalk and cytoskeletal dynamics in ALD. Platelets emerge as active instigators of hepatic inflammation via mitochondrial transfer and NETosis, with MLCK integrating mechanical (Piezo1) and chemical (CXCL7) signals. Targeted inhibition of MLCK or platelet-neutrophil interactions represents a novel therapeutic strategy. Our findings redefine platelets as dynamic contributors to ALD pathogenesis, opening new avenues for mechanistic and translational research.

1529 | AN INTERIM UPDATE FROM THE DALLAS DIONYSUS STUDY - AN ONGOING PROSPECTIVE OBSERVATIONAL COHORT OF EARLY-STAGE METABOLIC AND ALCOHOL-ASSOCIATED LIVER DISEASE (METALD) AND ALD PATIENTS

Elias Rady[1] Hamza Dahshi[2] Ahmad Anouti[1] Bill Zhang[1] Courtney Roberts[3] Thomas Kerr[1] Amit Singal[1] Mack Mitchell[1] Thomas Cotter[1], [1]University of Texas Southwestern Medical Center, [2]Case Western Reserve University School of Medicine, Medical Scientist Training Program, [3]University of Texas Southwestern Medical School

Background: A significant proportion of patients constantly shift between steatotic liver disease (SLD) entities (MASLD, metALD, ALD) revealing a limitation of the cross-sectional nature of the 2023 AASLD nomenclature. Considering current and lifetime alcohol use as a cofactor, while accounting for the important modulating effect of metabolic co-morbidities and genetic predisposition, can help address this. Focusing on early-stage metALD/ALD is also critical, as most are diagnosed at advanced disease stages at a time when limited treatment options are available. We present our interim baseline findings from the Dallas Dionysus Study - a prospective early-stage metALD/ALD observational cohort study. **Methods:** From September 2024 to date, 70 adults with early-stage metALD/ALD and current/recent alcohol use were enrolled at UT Southwestern Medical Center and Parkland Health. Baseline surveys on demographics, co-morbidities, alcohol history, psychosocial constructs, and SDOH were administered by trained staff. Clinical assessments included anthropometrics, transient elastography, phosphatidylethanol (PEth), HbA1c, lipids, and genotyping for SLD-associated variants. A chi-square test assessed concordance between self-report alcohol use (via Timeline Follow Back (TLFB)) and PEth levels, categorized using established clinical cutoffs. **Results:** Of the 70 patients, 60 (85.7%) were male with a median age of 54.6 years (IQR 25.3) [Table1]. Alcohol use disorder, diagnosed by SCID, was present in 49 (70%). Median PEth was 318 ng/mL (IQR 909). Metabolic comorbidities were prevalent, with 92.9% of patients having at least one. Median liver fibrosis was 7.8 kPa (IQR 8.7) and median CAP scores 263 dB/m (IQR 83). Out of 11 patient who reported abstinence, 9 had a positive PEth ($\geq$ 20). There was significant discordance between TLFB and PEth ($p < 0.01$), with 21 of 42 patients (50%) underreporting their alcohol consumption. Several patients were below the metALD alcohol threshold at the time of enrollment. **Conclusion:** While self-report alcohol use remains a cornerstone in metALD/ALD management, it is important to integrate objective biomarkers such as PEth to improve classification accuracy. This is of particular importance for study candidate selection for SLD clinical trials. Upon healthcare engagement, many patients reduce alcohol consumption, highlighting that community engagement strategies may be critical to enhance metALD/ALD clinical trial recruitment.

1530 | NEIGHBORHOOD SOCIOECONOMIC DISADVANTAGE (AREA DEPRIVATION INDEX) AND REFERRAL TO LIVER TRANSPLANT IN PATIENTS WITH ALCOHOL RELATED LIVER DISEASE

Islam Mohamed[1] Mohamad Ali Ibrahim[2] Nagham Ramadan[2] Sherry Fares[2] Caroline Ankoma-Sey[2] Mazen Elsheikh[2] Megha Bhongade[2] Manal Hassan[3] Kumar Jalal[2], [1]The Cleveland Clinic Foundation-Fairview hospital, [2]Baylor College of Medicine, [3]The University of Texas MD Anderson Cancer Center

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Alcohol- associated liver disease (ALD) has become the leading indication for liver transplantation in the USA. The Area Deprivation Index (ADI) is a validated metric of neighborhood-level socioeconomic disadvantage, incorporating income, education, employment, and housing. These factors were independently described as barriers to access to liver transplant. The aim of this study is to identify the factors associated with access to listing in each ADI category. **Methods:** In this retrospective cohort we included patients with alcohol related liver disease (ALD) referred for evaluation for liver transplantation in 2022-2024 at Baylor College of Medicine. We included patients (> 18 y.o.) with referred ALD candidates. Excluded patients with other liver cirrhosis, incomplete records and who lost follow-up. ADI was assigned based on ZIP code and categorized into tertiles based on national percentiles. Univariable and Multivariable logistic regressions were used to evaluate the association between ADI categories, demographic, and clinical factors with access to liver transplant waitlist. **Results:** Of 192 included in the study; 30 (15.6%) patients in Low ADI, 93(48.4%) in Moderate ADI and 69(35.9%) patients in High ADI referred to our center for evaluation of liver transplantation. Mean age hovered around 52 years, p = 0.627. Higher alcohol gm/ in high ADI (mean 907 g/ week) vs. low (710 g/week), p = 0.097. In univariate analysis, among patients from low ADI areas, alcohol-related legal issues (HR: 3.52; 95% CI: 1.25–9.94; p = 0.018) and smoking (p = 0.041) were significantly associated with denial of listing. In the multivariate model, MELD-Na remained an independent predictor of listing, p = 0.001. In the moderate ADI group, univariate analysis identified male gender (p < 0.001), lower hemoglobin (p = 0.005), BMI (p = 0.039), and smoking (p = 0.030) as significant predictors. Multivariable analysis confirmed female gender (p = 0.022), lower hemoglobin (p = 0.005), and insurance status (p = 0.014) as independent predictors of listing, in addition to MELD-Na (p = 0.001). For patients from high ADI areas, family history of alcohol use disorder (AUD) was the only significant univariate and multivariable predictor (HR: 2.88; 95% CI: 1.13–7.35; p = 0.026), along with platelet count (HR: 0.99; 95% CI: 0.985–0.999; p = 0.025) and MELD-Na (HR: 1.05; 95% CI: 1.00–1.10; p = 0.050) (Figure 1). **Conclusion:** Neighborhood socioeconomic disadvantage is associated with distinct and context-specific barriers to liver transplant waitlist access among patients with ALD. While MELD-Na was a consistent predictor across all groups, factors such as alcohol-related legal issues, female gender, anemia, and family history of AUD significantly influenced listing decisions in certain ADI strata. These findings highlight the importance of incorporating social determinants of health into the evaluation of liver transplants to promote equitable access.

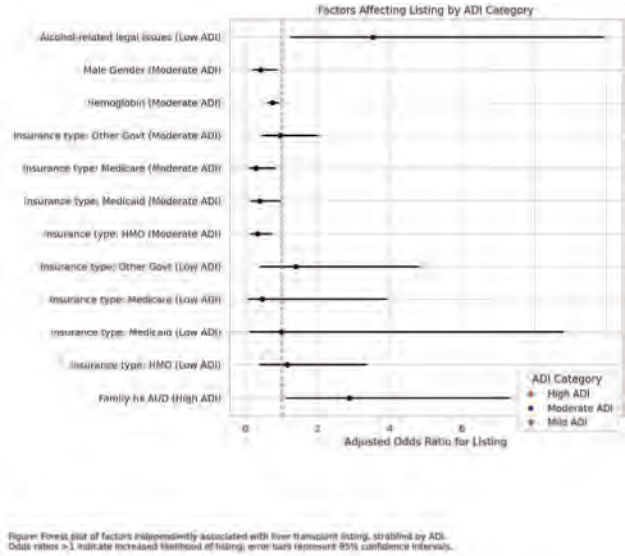

Figure: Forest plot of factors independently associated with liver transplant listing, stratified by ADI. Odds ratios >1 indicate increased likelihood of listing; error bars represent 95% confidence intervals.

Figure Legend:
Figure 1: Forest plot illustrating factors independently associated with liver transplant listing stratified by Area Deprivation Index (ADI) categories (Low, Moderate, High). The outcome is listing for liver transplantation. Adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) are shown for variables that remained significant in multivariate analysis for each ADI group. Notably, Insurance type was a significant predictor in the moderate ADI group, while family history of alcohol use disorder (AUD) was predictive in the high ADI group. Female gender and lower hemoglobin levels were associated with reduced likelihood of listing in the moderate ADI group.

1531 | IMPACT OF A SUBSTANCE USE NAVIGATION PROGRAM ON CLINICAL OUTCOMES IN PATIENTS WITH ALCOHOLIC HEPATITIS

James Vu[1] Robert Pecha[1] Jordan Holliday[1] Gregory Maynard[1] Connor Reilly[1] Daniel Colby[1] Aimee Moulin[1] Lydia Aye[1] Vikrant Rachakonda[2], [1]University of California Davis Medical Center, [2]University of California Davis

Background: Only alcohol abstinence has been shown to improve long-term survival in alcohol-associated hepatitis (AH). In February 2020, our institution implemented an inpatient Substance Use Navigation (SUN) program to support abstinence through motivational interviewing, pharmacotherapy, and linkage to ambulatory rehabilitation programs. The aim of the current study was to assess the effect of SUN consultation on clinical outcomes in AH. **Methods:** This was a

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

retrospective cohort study of patients admitted with AH from July 2017 to September 2024, stratified into pre-SUN (N = 152), SUN consulted (SUN+, N = 180), and SUN non-consulted (SUN-, N = 250) groups. Primary outcomes included 90-day transplant-free survival and 30-day readmission rates. Secondary analyses examined demographic and clinical predictors of non-SUN referral. **Results:** Patients who received SUN consultation were significantly younger [40 (IQR 34 – 52) years vs. 47 (39 – 57) years pre-SUN vs. 45 (37 – 54) years SUN-, $p < 0.001$], with higher MELD 3.0 than pre-SUN but lower MELD 3.0 than non-consulted patients [25 (20-30) vs. 23 (17-29) pre-SUN vs. 29 (24 – 34) SUN-, $p < 0.001$]. Intensive care unit (ICU) admission, ascites, hepatic encephalopathy, and gastrointestinal bleeding were more common in SUN non-consulted patients; however, multivariable logistic regression models demonstrated that only ascites [OR 0.396 (95% CI 0.250 – 0.626), $p < 0.001$] and ICU admission [OR 0.417 (95% CI 0.250 – 0.698), $p = 0.001$] were associated with reduced likelihood of SUN consultation. Kaplan Meier analysis demonstrated significantly longer 90-day transplant-free survival in SUN consulted patients compared to SUN non-consulted and pre-SUN groups [86 (IQR 84 – 88) vs. 69 (65 – 73) vs 79 (75 – 83) days, respectively; $p < 0.001$ by log-rank test]. Multivariable Cox models showed that SUN consultation was associated with reduced 90-day mortality independent of MELD 3.0 [HR 0.309 (95% CI 0.172 – 0.556), $p < 0.001$]. No difference in 30-day readmission rates was observed across cohorts. **Conclusion:** Implementation of a structured SUN program was associated with improved 90-day transplant-free survival in patients hospitalized with AH, independent of liver disease severity. Those with more severe presentation were less likely to receive a SUN consultation. These findings support the role of early substance use intervention in AH.

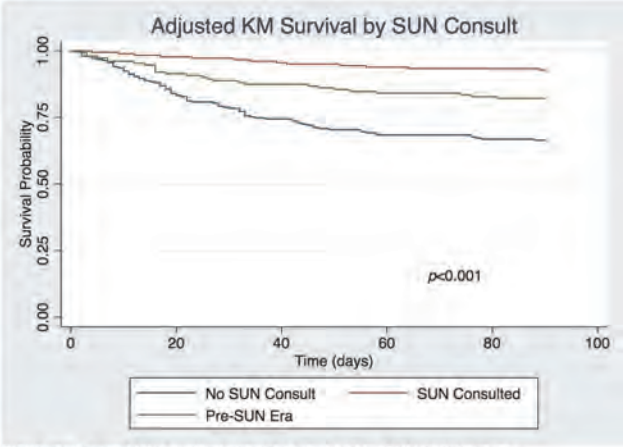

Figure 1: Kaplan Meier survival estimates stratified by SUN consult status.

1532 | CLINICAL CHARACTERISTICS AND INFLUENCING FACTORS OF RECOMPENSATION IN DECOMPENSATED ALCOHOLIC LIVER CIRRHOSIS

jingyuan zhou[1] Jia Zhou[1] Hongqin Xu[1] Yanhang Gao[1],
[1]The First Hospital of Jilin University

Background: Cirrhosis is a severe global liver disease, with alcoholic cirrhosis accounting for a significant proportion and the number of patients showing an upward trend. Traditionally, decompensated cirrhosis was considered irreversible, but the recent concept of recompensation has brought hope to patients. Currently, research on recompensation in decompensated alcoholic cirrhosis is relatively scarce, especially regarding the analysis of influencing factors and construction of prediction models. Therefore, this study aims to explore its clinical characteristics and establish a recompensation prediction model to provide evidence for clinical decision-making, thereby improving patients' prognosis and quality of life. **Methods:** A retrospective analysis was performed on 226 patients with alcoholic cirrhosis who experienced their first acute decompensatory event and initiated etiological treatment. Clinical data, laboratory indices, and imaging findings were comprehensively collected. Multiple evaluation indicators were used, and statistical analyses were conducted via SPSS 26.0, R software, etc., to screen relevant influencing factors and construct a recompensation prediction model. **Results:** 1、Abstinence significantly influenced the disease progression of patients with decompensated alcoholic cirrhosis. Whether patients abstained from alcohol ($P = 0.028 < 0.05$) was an important risk factor for recurrent acute decompensatory events. Strict abstinence promoted recompensation. 2、Among 206 patients with strict abstinence, the recompensation rate was 34.0%. Ascites occurred in over 90% of patients during the first acute decompensatory event of alcoholic cirrhosis. Patients with multiple acute decompensatory events ($\chi^2 = 18.486$, $P < 0.001$) or combined infections ($\chi^2 = 14.099$, $P < 0.001$) were less likely to achieve recompensation, and the more infection sites, the more unfavorable the outcome. 3、In laboratory tests, the recompensation group outperformed the persistent decompensation group in multiple aspects, including blood routine, coagulation function, and biochemical

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

indices. For portal hypertension analysis, the portal vein diameter (PVD) and the proportion of portal hypertension collateral circulation in the recompensation group were significantly lower than those in the persistent decompensation group ($P < 0.05$). Six scoring systems—Model for End-Stage Liver Disease (MELD), MELD 3.0, Child-Pugh score, neutrophil-to-lymphocyte ratio (NLR), red blood cell distribution width-to-platelet count ratio (RPR), and albumin-bilirubin score (ALBI)—showed differences between the two groups ($P < 0.05$). 4、Univariate Logistic regression identified multiple factors associated with recompensation. After excluding collinearity via multivariate analysis, multivariate Logistic regression showed that CHE ($P = 0.003$), PVD ($P < 0.001$), and NLR ($P = 0.016$) were predictive factors for recompensation in decompensated alcoholic cirrhosis. FBG ($P = 0.065$) showed a P-value close to statistical significance, indicating potential influence. 5、The Nomogram prediction model based on cholinesterase (CHE), PVD, NLR, and fibrinogen (FBG) exhibited high accuracy, with an AUC of 0.849, sensitivity of 75.7%, and specificity of 86.0%. The Hosmer-Lemeshow test ($P = 0.1197 > 0.05$) confirmed good goodness-of-fit and accuracy. **Conclusion:** 1、Abstinence is the core factor for controlling disease progression and promoting recompensation in decompensated alcoholic cirrhosis. Patients with strict abstinence had a significantly lower recurrence rate of acute decompensatory events than relapsing drinkers. 2、The recompensation rate among strictly abstinent patients was 34.0%. Ascites occurred in $>90\%$ of patients during the first acute decompensation. Multiple decompensatory events, combined infections, and more infection sites were detrimental to recompensation. 3、Cholinesterase (CHE), portal vein diameter (PVD), and neutrophil-to-lymphocyte ratio (NLR) are key predictive factors for recompensation, with fibrinogen (FBG) showing potential influence. Patients with CHE >3113.50 U/L, fibrinogen >2.58 g/L, NLR. 4、The Nomogram model based on CHE, PVD, NLR, and FBG demonstrates excellent accuracy and discriminative ability, serving as a valuable tool for predicting recompensation probability with promising clinical application prospects.

1533 | DYNAMIC CHANGES OF HEPATIC MACROPHAGES UPON CESSATION OF ALCOHOL CONSUMPTION IN MICE

Isabel Aranzazu Pulido Ruiz[1] Kyle Yuquimpo[1] Ayobami Dare[1] Ann Wozniak[1] Irina Tikhanovich[1] Steven Weinman[1], [1]University of Kansas Medical Center

Background: Alcohol cessation improves the prognosis of alcohol associated liver disease (ALD), but even after abstinence, recovery is slow and incomplete. A better understanding of the mechanisms of recovery could lead to new therapies. Kupffer cells (KC) and liver infiltrating macrophages (IM) change during ALD development, but how they change in after alcohol cessation has not been determined. The aim of this study was to determine the change of liver macrophages after alcohol cessation and how these might contribute to disease recovery. **Methods:** C57BL/6J and *Ms4a3*-Cre x CAG-TdT mice were fed high-fat western diet with 10%-20% alcohol in drinking water for 16 weeks (WDA diet). They were transitioned to a chow/water diet for 3, 7, or 28 days. Liver and blood were collected for histology, qPCR, western blot, and flow cytometry. **Results:** At the end of WDA feeding, liver macrophages consisted of an equal mixture of KCs and IMs. Transition forms, both KC and IM, with intermediate properties, were present. They expressed genes characteristic of lipid associated macrophages (LAMs) such as *Gpnmb*, *Trem2*, and *Cd9*) and localized primarily in crown-like structures (CLS). Following alcohol cessation, there was a rapid change in liver macrophage populations. Within 3 days there was a 78% decrease in KC *Clec4f* expression and by 7 days there was a 5-10-fold increase in IM genes such as *Cx3cr1* and *Lyz2*. Lineage tracing with *Ms4a3*-TdT mice that express TdT only in bone marrow derived cells confirmed that by 7 days, embryonic emKCs had been replaced by new moKCs. Alcohol cessation also resulted in about a 2-fold increase in CLS number and by 7 days the cells composing the CLS changed from GPNMB+VSIG4- LAMs to GPNMB+ VSIG4+ LAM-like KCs. In situ zymography showed that post alcohol cessation, the CLS became sites of high collagenase activity, and this was associated with an increase in *Mmp12* expression. **Conclusion:** Just like the situation when alcohol is started, sudden alcohol withdrawal induces an immediate change in liver macrophage populations with replacement of emKCs by new moKCs, changes in the cellular composition of crown-like structures, and an increase in MMP expression in a CLS-associated population of LAM-like KCs. These KC-like CLS cells may be involved in fibrosis remodeling. Further studies are needed to define the role that these novel resolution macrophages play in disease resolution or lack thereof.

1534 | MYOSTEATOSIS IS CLOSELY ASSOCIATED WITH SARCOPENIA AND WORSE SHORT-TERM OUTCOMES IN MALE PATIENTS WITH ARLD IN CHINA

Yu Zhang[1] Song Yang[1], [1]Beijing Ditan Hospital of Capital Medical University

Background: The burden of alcohol-related liver disease (ARLD) is increasing in China. Patients with ARLD are more likely to have comorbid muscle damage, such as myosteatosis and sarcopenia, which may impair their survival. This study aimed to evaluate the relationship between the prognoses of patients with ARLD and myosteatosis, identified using the mean muscle attenuation. **Methods:** We conducted a prospective multicenter study involving 308 hospitalized patients with ARLD. Sarcopenia and myosteatosis were evaluated using computed tomography scans. The 6-month cumulative incidence of relevant events was assessed by competing risk analysis. We used Cox proportional hazards regression models to evaluate the impact of sarcopenia and myosteatosis on mortality. **Results:** At enrolment, 116 (37.66%) patients presented with isolated myosteatosis, 21 (6.82%) with isolated sarcopenia, 99 (32.14%) with combined sarcopenia and myosteatosis and 72 (23.38%) patients showed no muscle changes. The 6-month cumulative incidence of death in patients with either sarcopenia and myosteatosis (13.13%) was over twice that of patients without muscle changes (4.16%), or with isolated myosteatosis (5.17%), and was significantly higher than that of patients with isolated sarcopenia (9.5%). Multiple Cox regression analysis showed that visceral adipose tissue area、subcutaneous adipose tissue area、VA-TI (visceral adipose tissue index)、SA-TI (subcutaneous adipose tissue index) and TBiL (total bilirubin) were independent prognostic factors of 6-month survival with hazard ratios (95% confidence intervals) of 0.923 (0.876-0.972), 1.075 (1.015-1.139), 1.277 (1.101-1.481), 0.801 (0.684-0.937), and 1.016 (1.003–1.029), respectively. **Conclusion:** Myosteatosis, whether alone or combined with sarcopenia, is highly prevalent in patients with ARLD and is associated with significantly worse short-term outcomes. Early diagnosis and intervention of myosteatosis, are important for optimizing the management of patients with ARLD.

1535 | ROLE OF KUPFFER CELL SPP1 IN ALCOHOL-ASSOCIATED LIVER DISEASE

Nithyananthan Subramaniyam[1] Hui Han[1] Xiaodong Ge[1] Sai Santosh Babu Komakula[1] Jeongwoo Park[1] Dan Lantvit[1] Grace Guzman[1] Natalia Nieto[1], [1]University of Illinois at Chicago

Background: Alcohol-associated liver disease (AALD) is a leading cause of chronic liver disease worldwide, with rising incidence and limited treatment options beyond alcohol cessation and liver transplantation. Secreted phosphoprotein-1 (SPP1) is a glycoprotein involved in immune regulation and tissue repair. Since Kupffer cells express high levels of SPP1, the aim of this work was to investigate the role of Kupffer cell-derived SPP1 in AALD. **Methods:** We analyzed publicly available human alcoholic hepatitis datasets for *SPP1* expression. To induce early AALD, 12-week-old male and female *Clec4f.Cre* (control), *Spp1* Knock-in in Kupffer cells ($Spp1^{KI\ KC}$), *Alb.Cre* (control), and arginase 2 knock-out in hepatocytes ($Arg2^{\Delta Hep}$) were fed a

control or ethanol Lieber-DeCarli diet for six weeks. Histopathological scores and parameters of liver injury were analyzed. **Results:** Transcriptomics analysis showed increased expression of *SPP1* mRNA in hepatic macrophages from ASH patients, which was validated by co-localization studies ($SPP1^{+}CD68^{+}$) in liver biopsies, compared to healthy individuals. Ethanol increased hepatic steatosis, liver-to-body weight, ALT activity, and triglycerides in *Clec4f.Cre* mice, but they were all reduced in $Spp1^{KI\ KC}$ mice. Moreover, qPCR analysis demonstrated that multiple genes involved in lipid metabolism were downregulated by ethanol in $Spp1^{KI\ KC}$ mice. Notably, minimal changes were found in adipocyte size in all ethanol-fed mice. We previously showed that $SPP1^{High}$ macrophages protect against MASH by increasing oncostatin M (OSM), which signals hepatocytes through its receptor (OSMR) to activate arginase-2 (ARG2) and enhance mitochondrial fatty acid oxidation. Therefore, we evaluated their expression and found a significant increase in OSM, OSMR, and ARG2 in $Spp1^{KI\ KC}$ compared to *Clec4f.Cre* mice. To test the involvement of ARG2 in AALD, *Alb.Cre* and $Arg2^{\Delta Hep}$ mice were fed the Lieber-DeCarli diets. Ethanol induced hepatic steatosis, inflammation, ALT activity, and triglycerides in $Arg2^{\Delta Hep}$ mice, but they were all reduced in *Alb.Cre* mice. $Arg2^{\Delta Hep}$ mice also showed reduced mitochondrial copy number and lower complex I expression. **Conclusion:** Kupffer cell-derived SPP1 protects against ALD by enhancing hepatocyte lipid metabolism via the OSM–OSMR–ARG2 axis.

1536 | GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST IS A PROMISING DUAL TARGET FOR METABOLIC LIVER DISEASE AND ALCOHOL USE

Sheel Patel[1] Fatima Elmustafa[2] Sara Nassar[3] Hanna Blaney[4] Harpreet Kaur[5] Winston Dunn[6] Ashwani Singal[1], [1]University of Louisville, [2]Henry Ford Health System, [3]Mansoura University Hospital, [4]Georgetown University, [5]Allegheny Health Network, [6]University of Kansas Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction and alcohol-associated liver disease (MetALD), and alcohol-associated liver disease (ALD) are major contributors to chronic liver disease worldwide, with overlapping pathophysiology. Combined metabolic dysfunction and alcohol use disorder (AUD) accelerate liver injury, with a higher risk for cirrhosis and complications. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) improve cardiometabolic risk profile and have also shown potential in reducing alcohol consumption. This systematic review aims to evaluate the influence of GLP-1 RAs on both alcohol use and liver-related outcomes. **Methods:** A systematic search using Web of Science, PubMed, and Embase identified 1,085 studies using terms related to GLP-1 RAs, liver disease, and alcohol use. Randomized control trials (RCTs) and observational studies assessing the effects of GLP-1 RAs on alcohol use and liver outcomes were screened, with inclusion limited to studies with >10 participants. **Results:** Of 22 studies reviewed, nine using different GLP-1RAs for variable treatment duration and follow-up were analyzed (Table 1). Of three RCTs ($n=48$ to 151) in subjects with AUD, semaglutide reduced self-reported alcohol use, dulaglutide lowered alcohol intake in current drinkers, while exenatide had no significant effect on heavy drinking days. Observational data from four studies ($n=58$ to 1470) in patients with liver disease (MetALD in 3 and MASLD in 1) showed semaglutide or tirzepatide to reduce decompensation in one study and reduce alcohol use in the other three studies. The remaining two observational studies using large databases showed GLP-1 RAs in AUD subjects reduced the risk of hospitalization in one and alcohol intoxication in the other study. **Conclusion:** GLP-1 receptor agonists are a promising therapy for liver diseases driven by metabolic dysfunction, including those with MetALD. Large scale RCTs are needed to substantiate their role in reducing alcohol use and in treating alcohol use disorders.

1537 | INCREASED FGF21 MEDIATES ALCOHOL-INDUCED METABOLIC ALTERATIONS IN TGR5-DEFICIENT MICE

SHIFAT-E FERDOUS[1] TITILAYO OLOTU[1] SHannon Boehme[1] Matthew Dilts[1] Jessica Ferrell[1], [1]Northeast Ohio Medical University

Background: Takeda G-protein coupled receptor 5 (TGR5), a bile acid activated receptor, exhibits organ-specific differential effects on metabolism, proliferation and inflammation. We recently reported that *TGR5*$^{-/-}$ mice were protected from alcohol-induced liver injury via upregulation of fibroblast growth factor 21 (FGF21). FGF21, a liver-derived hormone, plays a crucial role in lipid and glucose metabolism. FGF21 is upregulated in response to alcohol intake and suppresses alcohol consumption in a negative feedback mechanism involving liver, adipose tissue and brain. Here, we tested the hypothesis that *TGR5*$^{-/-}$ mice would voluntarily drink less ethanol, and we investigated the molecular mechanisms involved. **Methods:** Male and female *TGR5*$^{-/-}$ mice and their respective wild-type control (WT) mice were subjected to a two-bottle choice protocol with 10% ethanol and water, along with standard chow-diet for 2 weeks. Upon termination, we assessed metabolic, inflammatory and thermogenic pathways in liver, adipose tissue and brain. **Results:** Both male and female *TGR5*$^{-/-}$ mice exhibited reduced preference for ethanol compared to WT controls, which was accompanied by significantly increased circulating FGF21. Body weight and ethanol metabolizing enzymes (ADH, ALDH2) were unaltered, though female mice drank more ethanol than male mice. Interestingly, liver triglycerides were only reduced in male *TGR5*$^{-/-}$ mice, while liver cholesterol was increased in female *TGR5*$^{-/-}$ mice, possibly due to the overall increased ethanol consumption in female mice. Expression of browning, thermogenesis, and lipolysis genes (*Prdm16, Pparg, Pgc1a, Leptin, Atgl*), in white adipose tissue was increased in male *TGR5*$^{-/-}$ mice. In the hypothalamus expression of genes mediating satiety and glucose uptake (*Npy, Agrp, Glut2, Insr*) were also increased only in male *TGR5*$^{-/-}$ mice. As food intake between genotypes was not altered, these data may indicate sexual dimorphism in hypothalamic regulation of caloric intake and energy use in the context of ethanol consumption. Mechanistically, the source of hepatic FGF21 upregulation in *TGR5*$^{-/-}$ mice may be due to increased STAT5 protein expression, which will be further investigated. **Conclusion:** *TGR5*$^{-/-}$ mice have endogenously increased FGF21 levels that suppress voluntary drinking. The sex-specific differences in liver, adipose, and hypothalamic metabolism, as well as the molecular mechanism directing FGF21 expression in *TGR5*$^{-/-}$ mice, are under investigation.

1538 | PREVENTING NUCLEAR PROHIBITIN 1 DEPLETION PROTECTS AGAINST ALCOHOL-ASSOCIATED LIVER INJURY AND SENSITIZATION TO COLORECTAL LIVER METASTASIS

Jyoti Chhimwal[1] Lucia Barbier Torres[2] Sonal Sinha[1] Maria Lauda Tomasi[1] Shelly Lu[1], [1]Cedars Sinai Medical Centre, [2]Cedars-Sinai Medical Center

Background: Prohibitin 1 (PHB1) is a multifunctional protein with roles in mitochondrial function, gene regulation, and stress responses largely determined by its subcellular localization. We reported hepatic PHB1 is downregulated in cholestatic liver injury and liver cancer and reduced hepatic PHB1 expression sensitizes the liver to colorectal liver metastasis (CRLM) via matrix metalloproteinase 7 (MMP-7) induction. Whether PHB1 is dysregulated in alcohol-associated liver disease (ALD) is unknown. Here, we investigated whether ethanol disrupts PHB1 localization and examined the implications of these changes. **Methods:** We employed both in vitro and in vivo ALD models and confirmed the key finding using liver samples from alcoholic hepatitis (AH) patients. Primary mouse hepatocytes were treated with 100 mM ethanol for 24 hours, and mice were subjected to the NIAAA protocol. To examine how ethanol impacts CRLM, we used a modified NIAAA protocol (18 days of ethanol feeding without the terminal binge) and pair-fed controls that had intrasplenic injection of MC38 cells on day 4 of feeding and imaged up to day 14. PHB1's nuclear export signal (NES) peptide was used to inhibit PHB1 nuclear export. PHB1 content was measured in subcellular fractions by immunoblotting and immunohistochemistry (IHC), while liver injury, inflammatory and oxidative stress responses were evaluated using enzyme assays, qRT-PCR, IHC, and immunoblotting. **Results:** We found a marked depletion of cytosolic and nuclear PHB1, but mitochondrial PHB1 was protected in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

murine ALD, ALD-CRLM, and human AH. Ethanol treatment increased the interaction of PHB1 with CRM1 (aka Exportin 1) and PHB1-NES lowered their interaction and prevented ethanol-mediated nuclear PHB1 depletion. This resulted in protection from ethanol-mediated lowering of GSH level and expression of its rate-limiting enzyme. PHB1-NES also protected from induction of oncogenes known to be suppressed by PHB1, including c-MYC, MAFG, c-MAF, and MMP-7. Further, PHB1-NES protected from increased serum ALT/AST levels, inflammatory cytokines and oxidative stress in NIAAA mice. Lastly, ethanol feeding markedly sensitized to CRLM and this was completely blocked by PHB1-NES co-treatment. **Conclusion:** Ethanol consumption increased the interaction of PHB1 with CRM1, resulting in PHB1 nuclear depletion. Preventing nuclear PHB1 depletion by the PHB-NES peptide protected against ALD and ethanol-mediated sensitization to CRLM.

1539 | NALTREXONE VS ACAMPROSATE IN ALCOHOL USE DISORDER WITH ALCOHOL-ASSOCIATED CIRRHOSIS: A PROPENSITY-MATCHED REAL-WORLD ANALYSIS OF MORTALITY AND MORBIDITY

Ali Shaat Karim Osman[1] Raza Malik[1], [1]Lahey Hospital & Medical Center

Background: Alcohol use disorder (AUD) in individuals with alcohol-associated cirrhosis (AC) is commonly treated with medications such as naltrexone and acamprosate; however, data on their safety and effectiveness in this population remain limited. This study aimed to compare the risks of all-cause mortality, hospital admissions, hepatic encephalopathy (HE), acute kidney injury (AKI), and gastrointestinal bleeding (GIB) among patients with AUD and AC treated with naltrexone versus acamprosate. **Methods:** A retrospective cohort analysis was conducted using the TriNetX Global Collaborative Network on 04/23/2025, comprising 147 healthcare organizations. Patients ≥ 18 years old with AC and concurrent AUD were included and stratified by the following: Cohort 1 (N = 6,258) were prescribed naltrexone, and Cohort 2 (N = 4,719) were prescribed acamprosate. Individuals < 18 years old and those on disulfiram or topiramate were excluded from the study. Patients were matched 1:1 using propensity score matching based on demographics and MELD-related laboratory values, resulting in 4,508 matched pairs (Figure). The index event was defined as the first occurrence of naltrexone in Cohort 1 and the first occurrence of acamprosate in Cohort 2. Outcomes, identified via International Classification of Diseases (ICD) codes, assessed the incidence of GIB, HE, hospital admissions and death over a 5-year period. Risk analyses and Kaplan-Meier survival estimates were employed. **Results:** Following matching, treatment with naltrexone was associated with a significantly lower incidence of HE (20.3% vs. 24.3%; RR 0.84; 95% CI 0.76–0.93; $p = 0.001$), AKI (19.7% vs. 22.1%; RR 0.89; 95% CI 0.81–0.98; $p = 0.02$), and all-cause mortality (19.3% vs. 22.8%; RR 0.85; 95% CI 0.78–0.92; $p < 0.001$) compared to acamprosate. The hazard ratio for mortality was 0.794 (95% CI 0.726–0.869; $p < 0.001$), indicating a 20.6% reduction in the hazard of death with naltrexone (Figure). The proportional hazards assumption was satisfied ($p = 0.766$), confirming the stability of this effect over time. Median survival was longer and the 5-year survival probability was higher in the naltrexone group (64.2% vs. 57.5%; $p < 0.001$). There were no statistically significant differences in the incidence of GIB (11.6% vs. 13.0%; RR: 0.89; 95% CI 0.78–1.01; $p = 0.065$) or hospital admissions (7.5% vs. 8.1%; RR: 0.93; 95% CI 0.79–1.09; $p = 0.372$). **Conclusion:** Among patients with AUD and AC, treatment with naltrexone was associated with lower rates of all-cause mortality, HE, and AKI compared to acamprosate over a 5-year period. Limitations of the study include reliance on ICD codes, inability to differentiate liver-related from non-liver-related mortality, and inability to ascertain medication adherence. Nonetheless, the results support naltrexone as a potentially safer pharmacologic option in this high-risk population. Further prospective studies are warranted to validate these findings.

1540 | THE FIBROSIS NON-INVASIVE TEST PANEL (FIB-NIT): A NOVEL PANEL OF THREE NON-INVASIVE BIOMARKERS FOR EVALUATING FIBROSIS DYNAMICS THROUGH INDIVIDUAL COMPONENTS OF FIBROGENESIS (PRO-C3), FIBROLYSIS (CTX-III), AND CLINICAL OUTCOMES (PRO-C6) IN PATIENTS WITH VARYING SEVERITY OF ALCOHOL-RELATED LIVER DISEASE

Andressa de Zawadzki[1] Maja Thiele[2] Stine Johansen[2] Ida Villesen[2] Peter Andersen[2] Ida Spedtsberg[2] Morten Karsdal[1] Aleksander Krag[3] Diana Leeming[1], [1]Nordic Bioscience, [2]Odense University Hospital, [3]University of Southern Denmark

Background: Persistent and excessive alcohol intake induces damage to the liver, impairing its ability to properly regenerate, potentially leading to alcohol-related liver disease (ALD). Non-invasive tests (NITs) quantifying the dynamics of the extracellular matrix (ECM) remodeling and disease activity may be important for patient prognosis. We aimed to investigate the above-mentioned utility of the serologically assessed FIBrosis Non-Invasive Test panel (FIB-NIT) consisting of three single markers that can describe fibrogenesis (PRO-C3), patientoutcomes (PRO-C6) and fibrolysis (CTX-III). All, previously shown to be modulated by interventions in MASH clinical trials. **Methods:** Serum biomarkers of fibrogenesis nordicPRO-C3™ (N-terminal pro-peptide of type III collagen) and for patient outcome nordicPRO-C6™ (endotrophin; type VI collagen formation) aa well as fibrosis resolution nordicCTX-III™ (MMP degraded fragment of cross-linked type III collagen) were measured in a cross-sectional cohort of 450 biopsy-proven F0-F4 ALD patients. The biomarkers were investigated as single markers to understand disease mechanisms in relation to disease severity and prognosis of outcomes (mortality, liver related events and non-liver related outcomes) over a median 5-yr follow-up. **Results:** ALD patients with advanced fibrosis (F3-F4) and cirrhosis exhibited increased fibrogenesis as observed from higher serum PRO-C3 and PRO-C6 ($p < 0.001$) as well as higher fibrolysis as shown by higher serum levels of CTX-III ($p < 0.001$) in comparison to patients with mild-moderate fibrosis (F0-F2). Kaplan-Meier curves showed that all three biomarkers provided good prognostic value to stratify ALD patients at risk of all-cause mortality and decompensation (PRO-C3 cut off 12.6, hazard ratio for mortality (HRm) of 4.7 and decompensation (HRd) of 10.6; CTX-III cutoff 15.6, HRm of 2.2 and HRd of 2.4; PRO-C6 cut off 11.0, HRm of 3.4 and HRd of 4.8). **Conclusion:** The "FIB-NIT" biomarker panel may be utilized for evaluating fibrosis remodelling and risk of patient outcomes in ALD. This panel may offer insights into the underlying mechanisms of fibrosis progression and help understanding the mode of action of novel therapies in ALD as well as other chronic liver diseases.

1541 | RACIAL DISPARITIES IN CIRRHOSIS RISK AND CLINICAL OUTCOMES AMONG PATIENTS WITH ALCOHOL USE: A PROPENSITY-MATCHED COHORT STUDY

sabtain saroya[1] mathew deleary[1] Noah Wheaton[1] soha mohammed[1] Marek Harris[1] Armando Ugarte[1] mudasir rashid[2] miriam michael[3], [1]howard university college of medicine, [2]Howard University Hospital Cancer Center, [3]Howard University Hospital

Background: Alcohol use is a leading cause of cirrhosis; however, the risk and progression of cirrhosis may differ across racial groups. Prior studies suggest that racial disparities may influence liver disease outcomes, but large-scale comparative analyses remain limited. This study evaluates cirrhosis incidence and time-to-event outcomes among Black and White patients with alcohol use, matched by age and sex. **Methods:** We conducted a retrospective cohort analysis of 205,450 patients (102,725 Black and 102,725 White) with documented alcohol use. Patients were propensity-matched 1:1 by age and sex. We calculated cirrhosis risk, odds ratios (OR), risk ratios (RR), and hazard ratios (HR). Cirrhosis-free survival was assessed using Kaplan-Meier curves and log-rank testing. **Results:** Cirrhosis developed in 0.9% of Black patients and 2.3% of White patients (Risk Difference: -1.4%; 95% CI: -1.5% to -1.3%; $p < 0.001$). The risk ratio was 0.39, and the odds ratio was 0.39, both indicating a significantly lower risk in Black patients. Kaplan-Meier analysis demonstrated higher cirrhosis-free survival in Black patients (95.99%) compared to White patients (92.98%), with a significant log-rank result ($\chi^2 = 728.4$; $p < 0.001$). The hazard ratio for cirrhosis in Black versus White patients was 0.37 (95% CI: 0.34–0.40; $p < 0.001$). **Conclusion:** Among patients with documented alcohol use, Black individuals demonstrated significantly lower risk and slower progression to cirrhosis compared to White individuals in an age- and sex-matched cohort. These findings underscore the presence of racial disparities in alcohol-associated liver disease outcomes and highlight the need for further investigation into underlying biological, behavioral, and systemic determinants. Understanding these differences is essential to developing targeted, equitable approaches to liver disease screening, prevention, and management.

1542 | IMPACT OF ALCOHOL CONSUMPTION ON FIBROSIS PROGRESSION AND CARDIOVASCULAR EVENTS IN PATIENTS WITH MASLD AND METALD: A RETROSPECTIVE COHORT STUDY

Ares Villagrasa[1] Anna Aguilar[2] Alba Jimenez[3] Juan Manuel Pericàs[3] Meritxell Cots[3], [1]Hospital Universitari Vall Hebron, [2]Liver Unit, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Spain, [3]Liver Unit, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Alcohol-related liver disease (ArLD) is a major public health issue, where abstinence is essential to prevent progression. The combination of metabolic dysfunction and alcohol intake worsens prognosis, leading to the classification of steatotic liver disease (SLD) into MASLD and MetALD. MetALD involves at least one cardiometabolic risk factor and moderate alcohol use (20–50 g/day for women, 30–60 g/day for men), with a prevalence of 2.2–2.7% in SLD populations. Recent studies show that even low to moderate alcohol use increases fibrosis risk in MASLD, particularly with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cardiometabolic comorbidities, and that MetALD is linked to higher mortality, especially in advanced fibrosis. This study aims to assess the prevalence of MetALD in a cohort of outpatients and to investigate the influence of alcohol consumption and abstinence at the end of follow-up on fibrosis progression and cardiovascular events in patients with MASLD and MetALD. **Methods:** A retrospective cohort study was conducted in outpatients with steatotic liver disease (SLD), diagnosed via imaging or CAP $\geq$275 dB/m. Patients were classified by alcohol intake (VLD, LD, MD) and reclassified as MetALD or ALD. Liver fibrosis was assessed non-invasively, and data on abstinence and cardiovascular events were collected during follow-up **Results:** Of 692 patients reviewed, 574 were analysed: 74.2% were very low-risk drinkers (VLD), 6.7% low-risk (LD), 8.1% moderate (MD), 8.9% MetALD, and 2.1% ALD. Median follow-up was 64.1 months. Women represented 50.6% of the cohort (mean age 59.4 years). Significant sex differences were observed between groups ($p < 0.0001$), while cardiometabolic risk factors were similar at baseline. Liver stiffness (LSF) differed significantly at baseline ($p = 0.0001$) and at follow-up ($p = 0.004$), with MD showing the highest LSF at follow-up (39.1 kPa; $p = 0.023$ vs VLD). Despite differences in alcohol abstinence, only age (OR = 1.00006, $p = 0.005$) and male sex (OR = 0.65, $p = 0.017$) were independently associated with fibrosis progression (> 2 kPa). No differences in overall survival or cardiovascular events were observed. Baseline LSF was borderline associated with CV risk (HR = 1.03, $p = 0.057$). Liver-related event risk differed by group ($p = 0.009$), with MetALD showing the highest estimated mortality. Only fibrosis progression was independently associated with liver-related mortality (HR = 9.53, $p = 0.040$). **Conclusion:** MetALD prevalence in our cohort is consistent with recent studies. Although MetALD patients showed greater fibrosis, only age and sex independently predicted its progression. Fibrosis change, not baseline stiffness, was the sole independent predictor of liver-related events. Monitoring fibrosis and promoting abstinence remain key to improving outcomes in patients with metabolic dysfunction and moderate alcohol use

1543 | NATIONWIDE TRENDS OF SIX MEDICATIONS FOR ALCOHOL USE DISORDER PRESCRIPTIONS POST-DISCHARGE IN PATIENTS HOSPITALIZED WITH ALCOHOL-ASSOCIATED LIVER DISEASE BETWEEN 2015 TO 2024

Emily Shu-Yen Chan[1] Yee Hui Yeo[2] Natchaya Polpichai[3] Pojsakorn Danpanichkul[4] Peng-Sheng Ting[5], [1]Department of Internal Medicine, Weiss Memorial Hospital, Chicago, IL, [2]Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Los Angeles, California, [3]Department of Gastroenterology, Medical College of Georgia, Augusta University, Augusta, Georgia, [4]Texas Tech University Health Sciences Center, [5]Division of Gastroenterology and Hepatology, Tulane University School of Medicine, New Orleans, LA

Background: Alcohol-associated liver disease (ALD) has high hospitalization and relapse risk, yet post-discharge medications for alcohol use disorder (MAUD) are not uniformly prescribed. MAUD prescriptions have been associated with reduced recidivism and hepatic decompensations. However, real-world data on trends and percentage of MAUD use in patients with ALD are limited. We examined ten-year national trends in six MAUD prescriptions, both FDA approved and off label, after hospitalization for ALD. **Methods:** This population-level cohort study analyzed de-identified longitudinal electronic health records from TriNetX to identify insured and uninsured patients aged $\geq$ 21 hospitalized for ALD (including hepatitis and cirrhosis) between 1/1/2015 and 12/31/2024, via ICD-10 codes. Primary outcomes were prevalence (%), incidence rate (cases per 1,000 person-years) and incidence proportion (%) of post-discharge MAUD for FDA-approved medications (disulfiram, acamprosate, naltrexone) and off-label medications (topiramate, baclofen, gabapentin). Subgroup analyses were stratified by cirrhosis status and sex. Ten-year incidence trends were examined using piecewise log-linear Joinpoint regression (version 5.2.0.0), calculating annual percentage change (APC) and average annual percentage change (AAPC) with 95% confidence intervals. Advanced analyses of non-parallel AAPC comparisons between subgroups employed permutation tests and parametric methods. **Results:** Among 113 million patients in this database, ALD-related hospitalizations rose 2.4-fold from 14,616 in 2015 to 36,294 in 2024. The prevalence of patients with ALD receiving FDA

approved MAUD at discharge increased from 4.7% in 2015 to 18.0 % in 2024, with a greater increase between 2015 and 2021 (APC: 18.5%) than from 2021 to 2025 (APC: 11.9%). Use of off label MAUD rose to 42.0 % by 2024 and grew at AAPC of 5.7 %, a significantly slower pace than that of FDA approved agents (AAPC difference: 10.6%, $p < 0.001$). In 2024, gabapentin (38.8%) and naltrexone (23.1%) were most prescribed. New prescriptions of disulfiram declined from 6.6 to 5.5 cases per 1000 person years, while the other five medications rose significantly for the past decade. Acamprosate showed the largest increase (AAPC: 20.4%; 95%CI:18.5-22.2), followed by naltrexone (AAPC: 17.8%; 95%CI:16.2-19.5). Subgroup analysis revealed that patients with cirrhosis had lower baseline prescription rates but had greater relative increases in FDA approved MAUD compared to off-label MAUD (AAPC difference: 5.1%, $p < 0.001$). **Conclusion:** In our study, FDA-approved and off-label post-discharge MAUD prescriptions for hospitalized ALD patients increased significantly over the past decade. Yet by 2024, under 20% of ALD patients received FDA-approved abstinence medications. Targeted interventions are urgently needed to expand access and improve long-term alcohol cessation in this high-risk population.

1544 | HOUSING STATUS AND ITS ASSOCIATION WITH COMPLICATIONS AND HOSPITAL OUTCOMES IN ALCOHOL-ASSOCIATED LIVER DISEASE

Ki Jung Lee[1] Gregory Fan[1] Anderson Huang[1] Raffi Karagozian[1] Mohammad Almeqdadi[1], [1]Tufts Medical Center

Background: Amongst unhoused individuals, alcohol use significantly contributes to the burden of liver disease. This study examines the effects of being unhoused on hospital outcomes and associated psychiatric conditions with alcohol-associated liver disease (ALD). **Methods:** Patients hospitalized with ALD from 2020 to 2024 at a tertiary care center were retrospectively reviewed. The cohort was stratified into housed (reference) and unhoused (exposure) cohorts. Exposure and reference cohorts were 1:1 propensity-score matched. Primary endpoints were length of stay (LOS), number of hospital admissions, and hepatic complications. Multivariate logistic regression and negative binomial regression models were used to evaluate categorical and discrete outcomes, respectively. **Results:** The analysis included 3,523 patients: 330 unhoused and 3,193 housed. Unhoused patients were younger, more likely to be male, and had lower BMI ($p < 0.001$). Over the 4 years of the study, Unhoused patients experienced a greater number of hospital visits (3.65 $\pm$ 0.23 vs 2.46 $\pm$ 0.06, aIRR 1.62 95% CI 1.46-1.79, $p < 0.001$), total days spent in hospital (22.35 $\pm$ 1.62 vs 15.91 $\pm$ 0.51, aIRR 1.60, 95% CI 1.42-1.82, $p < 0.001$), and higher numbers of emergency room visits (10.11 $\pm$ 0.70 vs 2.21 $\pm$ 0.07, aIRR 4.89, 95%CI 4.18-5.74, $p < 0.001$) and ICU visits (0.23 $\pm$ 0.03 vs 0.13 $\pm$ 0.01, aIRR 1.62, 95%CI 1.22-2.12, $p < 0.001$). The matched analysis showed unhoused patients having a greater number of hospital visits (aIRR 1.80, 95% CI 1.53-2.13, $p < 0.001$), longer total length of stays (aIRR 1.58, 95% CI 1.32-1.88, $p < 0.001$), more frequent emergency visits (aIRR 6.28, 95% CI 5.11-7.74, $p < 0.001$) and ICU visits (aIRR 2.04, 95% CI 1.34-3.15, $p = 0.001$). Both the unmatched and matched analyses showed that unhoused patients have an increased prevalence of substance abuse disorders, including opioid, cocaine, and fentanyl abuse, as well as psychiatric comorbidities, including anxiety, depression, and post-traumatic stress disorder. **Conclusion:** Unhoused patients with ALD experienced longer hospital lengths of stay, more frequent hospitalizations, and higher rates of hepatic complications, compounded by substance use and psychiatric comorbidities. These findings highlight the need for comprehensive care approaches to address the multifaceted challenges faced by this vulnerable population.

1545 | INCIDENCE AND CLINICAL IMPLICATIONS OF ABSTINENCE-INDUCED HEPATIC RECOMPENSATION IN DECOMPENSATED ALCOHOL-RELATED CIRRHOSIS: A BAVENO MULTICENTRE STUDY

Benedikt Hofer[1] Marta Tonon[2] Laura Buttler[3] Joana Camões Neves[4] Queralt Herms[5] Enrico Pompili[6] Mina Ignat[7] Sophie Métivier[8] Susana Gomes Rodrigues[9] Daniel Gutmann[10] Jesús Donate[11] Jimmy Lai[12] Ana Clemente-Sánchez[13] Aina Marti Carretero[14] Josune Cabello[15] Charlotte Bouzbib[16] Henrik Karbannek[17] Jan Embacher[1] Lukas Parandian[1] Antonio Accetta[2] Roberta Gagliardi[2] Marie Griemsmann[3] Jordi Gratacós-Ginès[5] Mattias Mandorfer[1] Guadalupe Garcia-Tsao[18] Georg Semmler[1] Alexander Zipprich[17] Marika Rudler[16] Jonel Trebicka[15] Joan Genescà[14] Rafael Bañares[13] Terry Yip[12] Luis Téllez[11] Emmanouil Tsochatzis[10] Annalisa Berzigotti[9] Hélène Larrue[8] Horia Stefanescu[7] Paolo Caraceni[6] Elisa Pose[5] Dalila Costa[4] Benjamin Maasoumy[3] Salvatore Piano[2] Thomas Reiberger[1], [1]Department of Medicine III, Medical University of Vienna, Vienna, Austria, [2]Department of Medicine, University of Padova, Padova, Italy, [3]Hannover Medical School, Hannover, Germany, [4]Gastroenterology Department, Braga Hospital, Sete Fontes - São Victor, Braga, Portugal, [5]Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain, [6]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy, [7]Hepatology Unit, Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Romania, [8]Department of Hepatology, University Hospital and Toulouse III - Paul Sabatier University, France, [9]Inselspital, Bern University Hospital, Bern, Switzerland, [10]Royal Free London NHS Foundation Trust, London, United Kingdom, [11]Hospital Universitario Ramón y Cajal, Universidad de Alcalá, Madrid, Spain, [12]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, [13]University Gregorio Marañón Hospital, IiSGM, CIBERehd. Facultad de Medicina, UCM, Madrid, Spain, [14]Hospital Universitari Vall d'Hebrón, Universitat Autònoma de Barcelona, Barcelona, Spain, [15]Department of Internal Medicine B, University of Münster, Munster, Germany, [16]Sorbonne University, UPMC University Paris 06, AP-HP, Pitié-Salpêtrière Hospital, Paris, France, [17]Jena University Hospital, Friedrich Schiller University, Jena, Germany, [18]Yale University, New Haven, USA; VA-CT Healthcare System, West Haven, USA

Background: Alcohol abstinence can facilitate hepatic recompensation in decompensated alcohol-related cirrhosis (ALD). This study aimed to investigate the incidence, predictors, and clinical impact of abstinence-induced recompensation in ALD. **Methods:** In this multicentre Baveno-endorsed study, patients with decompensated ALD were included at time of abstinence until December 2022. Recompensation was defined per Baveno VII as (i) resolution of ascites and encephalopathy without ongoing treatment, (ii) absence of variceal bleeding for 12 months, and (iii) restoration of hepatic function (Child-Pugh A or MELD <10). Alcohol relapse led to censoring. **Results:** 633 patients from 17 centres were included (71.7% male; median age: 55 years; median MELD: 19 [IQR: 13-24]). The median interval between index decompensation and abstinence was 0.2 (IQR: 0.0-7.6) months. Alcohol-associated hepatitis (AH) on top of cirrhosis was present in 40.8% of patients and 47.2% had progressed to further decompensation (excluding jaundice). Over a median follow-up of 36.3 (IQR: 19.2-63.2) months, 197 patients achieved recompensation, with a cumulative incidence of 12.3% at 1 year, 23.4% at 2 years and 33.8% at 5 years. Early abstinence within 1 month of decompensation doubled the likelihood of recompensation (adjusted subdistribution hazard ratio [aSHR]:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

2.042, $p < 0.001$), while being further decompensated at abstinence significantly reduced it (aSHR: 0.650, $p = 0.013$) (see Table). During the study, 123 patients died, including 69 (56.1%) liver-related deaths. None of the recompensated patients who remained abstinent died of liver-related causes during a median observation period of 24.2 (IQR: 11.2-53.0) months after recompensation. In contrast, the incidence of liver-related death in non-recompensated patients was 9.0% at 1 year, 12.8% at 2 years and 16.9% at 5 years. Recompensation (included as time-varying covariate) was also independently associated with a lower risk of all-cause mortality (5.1% vs. 25.9% in non-recompensated; aHR: 0.255 [95%CI: 0.111-0.583], $p = 0.001$). Hepatocellular carcinoma (HCC) was diagnosed in 16 patients, yet did not occur in any of the recompensated patients. **Conclusion:** Recompensation is achieved in a relevant proportion of patients with decompensated ALD, particularly with early abstinence and in the absence of further decompensation. Achieving recompensation confers a favourable prognosis, with a negligible residual risk of liver-related death or HCC.

1546 | CHARACTERISTICS OF PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS RECORDED IN A CLAIMS DATABASE FROM 2016 TO 2024

Jayashri Desai[1] Scott Bunner[2] Marty Masek[2] Dannielle Lebovitch[2] Thomas Capozza[1] Amon Asgharpour[3], [1]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA, [2]Genesis Research Group, Hoboken, New Jersey, USA, [3]Virginia Commonwealth University, Richmond, Virginia, USA

Background: Alcohol-associated hepatitis (AAH) is a rapidly progressive and life-threatening form of alcohol-associated liver disease (ALD) that is associated with high morbidity and mortality. Despite its clinical severity, real-world data quantifying the clinical burden of AAH remains limited. This study aimed to characterize the demographics, clinical characteristics, pharmacological treatments, procedures, and mortality of patients with AAH. **Methods:** This retrospective cohort study assessed claims data using the Optum Clinformatics® Data Mart Database and included adult patients with ≥ 2 inpatient claims for alcoholic hepatitis (AH; ICD-10-CM codes K70.10 and K70.11) identified between January 1, 2017, and October 30, 2024. Patients were required to have continuous medical and pharmacy enrollment for ≥ 12 months pre-index and ≥ 1 day post-index, with the index date defined as the date of first claim with an AH diagnosis. Patients with a diagnosis of AH, liver transplantation, metastatic disease, or pregnancy during the baseline (pre-index) period were excluded. Patients were followed until the end of the study period, disenrollment, or death, whichever came first. Demographics, clinical characteristics, pharmacological treatments, procedures, and mortality were assessed descriptively. **Results:** Of the 5382 patients identified, 2415 met study criteria. Most (64.8%) patients were men, with a mean (SD) age of 53.9

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(12.9) years (Table 1). The median (IQR) follow-up time was 13.2 (4.7–29.5) months. Evidence of hepatic and systemic complications representative of AAH increased substantially from baseline to follow-up (ascites, 13.2% to 62.0%; cirrhosis, 20.3% to 68.7%; hepatic failure, 7.7% to 56.7%; and acute kidney failure, 10.7% to 59.9%). Use of pharmacological treatments for alcohol use disorder (AUD) during follow-up was generally low. Key follow-up procedures included paracentesis (38.1%), hemodialysis (15.6%), liver biopsy (5.9%), and liver transplantation (5.9%). Overall, 780 (32.3%) patients died during follow-up. **Conclusion:** This large, claims-based study highlights the substantial hepatic and systemic disease burden among patients with AAH. The high prevalence of liver and renal complications, low rates of pharmacological treatments for AUD, and a mortality rate $>30\%$ during follow-up underscore the urgent, unmet need for earlier diagnosis and targeted therapies. Real-world data are critical in quantifying the disease burden and informing future research and policy decisions in AAH/ALD.

Table 1. Demographics, clinical characteristics, pharmacological treatments, procedures, and mortality in patients with alcohol-associated hepatitis (n=2415)

	Baseline	Follow-up

1547 | TRENDS IN LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED LIVER DISEASE IN THE US FROM 2018 TO 2024: A DESCRIPTIVE ANALYSIS OF UNOS DATA

Jayashri Desai[1] Scott Bunner[2] Marty Masek[2] Dannielle Lebovitch[2] Thomas Capozza[1], [1]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA, [2]Genesis Research Group, Hoboken, New Jersey, USA

Background: Alcohol-associated liver disease (ALD) has emerged as a leading indication for liver transplantation (LT) in the US, reflecting evolving practices in candidacy evaluation amid rising cases of ALD. While earlier studies characterized ALD-related LT trends through 2019, little is known about post–pandemic patterns, regional variability, and demographic shifts through 2024. **Methods:** We conducted a retrospective descriptive analysis of the United Network for Organ Sharing (UNOS) database from 2018 to 2024. LT recipients with diagnoses related to ALD—including alcohol-associated hepatitis, alcoholic cirrhosis, metabolic dysfunction and ALD (metALD), and acute hepatic necrosis with unknown etiology—were included. Annual LT trends for adults (aged ≥ 18 years) were stratified by gender and age group (18–34, 35–49, 50–64, and ≥ 65 years). Annual LT trends for all ages were stratified by region (Organ Procurement and Transplantation Network [OPTN]-defined) and waitlist status (at the time of LT). Chi-square testing assessed distributional differences across strata. **Results:** LTs overall and ALD-related LTs in the US rose steadily between 2018 and 2024, with the proportion of ALD-related LTs increasing from 23.77% (2018) to 37.12% (2024; Figure). Among ALD-related LT recipients, male patients predominated annually, but the gender gap narrowed as the absolute number of female patients tripled from 2018 (530) to 2024 (1440). The 35–49-year age group showed a notable increase in ALD-related LTs, while proportions declined in the 50–64-year age group. Significant variation in ALD-related LTs occurred across OPTN regions, with the highest proportions over time being in region 5 (AZ, CA, NV, NM, UT) and region 3 (AL, AR, FL, GA, LA, MS, PR; $P < .001$). Significant variation was observed by waitlist status and Model for End-Stage Liver Disease/Pediatric End-Stage Liver Disease score. **Conclusion:** From 2018 to 2024, ALD-related LTs increased (count and proportion of overall) across most demographic and geographic subgroups, reflecting broader clinical acceptance and shifting transplant policy. ALD-related LTs occurred more frequently over time in younger adults and women, although male predominance remains. Regional variability, despite the 2020 implementation of acuity circles, highlights the potential need for standardized selection criteria and enhanced upstream interventions for alcohol use disorder. Further studies are warranted to evaluate long-term post-LT outcomes and ensure equity in LT access.

1548 | ACUTE PHASE RESPONSE ACTIVATION IN HEPATOCYTES PROMOTES LIVER NICHE REMODELING REQUIRED FOR FIBROSIS RESOLUTION AFTER ALCOHOL CESSATION

Michael Schonfeld[1] Kruti Nataraj[1] Samson Mah[1] Steven Weinman[1] Irina Tikhanovich[1], [1]University of Kansas Medical Center

Background: Abstinence is beneficial for patients with Alcohol-associated liver disease (ALD). However, disease resolution after alcohol cessation is not uniform. We aimed to study the mechanism of fibrosis resolution in ALD following alcohol cessation to uncover potential therapeutic targets. **Methods:** Mice were fed western diet with 20% alcohol in the drinking water for 20 weeks to induce liver fibrosis, mice were then put on chow diet with plain water for 4 weeks. Livers were analyzed by scATAC-seq, 1000 plex CosMx spatial transcriptomics (Nanostrings) and RNA-seq analysis. To assess the role of Serum amyloid A, mice were treated with recombinant SAA or SAA-rich HDL. Fibrosis resolution was assessed by Sirius Red staining and COL1A1 immunohistochemistry. To evaluate relevance of SAA in human ALD niche remodeling, liver sections from Donors (N = 7), ASH (N = 8) and ALD cirrhosis (N = 5) were analyzed by spatial transcriptomics using 5k Xenium panel (10x Genomics). The role of lipid metabolites in functional niche changes was assessed with spatial metabolomics. **Results:** We identified a unique hepatocyte cluster expressing several acute phase response genes (*Saa1, Saa2, Crp*) enriched in fibrolytic niche of mouse livers after alcohol cessation. Serum amyloid A, SAA, was the top upregulated acute phase protein in these hepatocytes. We found that SAA gene and protein expression associated with fibrolytic niches in mice and humans. *In vitro* analysis confirmed that *Saa1/2* expressing hepatocytes promoted fibrolytic function in liver macrophages; moreover, *Saa1* overexpression stimulated, while SAA antibody-mediated depletion blocked pro-fibrolytic change in macrophages. *In vivo* recombinant SAA supplementation promoted fibrosis resolution after alcohol cessation in mice. In addition, we found that SAA function depended on its association with HDL. SAA-enriched HDL showed potent pro-fibrolytic properties *in vitro* and *in vivo* by promoting pro-resolving macrophage phenotype, liver niche composition change and collagen degradation. Supporting the role of lipid mediators in fibrosis resolution we identified spatially distinct lipid metabolite changes in ALD resolution livers that correlated with fibrosis persistence or resolution. **Conclusion:** Acute phase response activation after alcohol cessation triggers intrahepatic cell-cell communication changes that stimulate niche remodeling for efficient fibrosis resolution in ALD.

1549 | REAL-WORLD IMPACT OF ALCOHOL USE DISORDER PHARMACOTHERAPY ON HEALTHCARE UTILIZATION, COSTS, AND COST-EFFECTIVENESS IN THE U.S.

Chi Mai Nguyen[1] Hanna Blaney[2] Samer Gawrieh[3] Shihui Jiang[1] Wanzhu Tu[1] Suthat Liangpunsakul[3], [1]Richard M. Fairbanks School of Public Health, Indiana University, Indianapolis, IN, [2]Georgetown University, [3]Division of Gastroenterology and Hepatology, Indiana University, Indianapolis, IN

Background: Alcohol Use Disorder (AUD) is a leading preventable cause of death and a major driver of healthcare utilization and costs in the U.S. It also significantly contributes to the burden of alcohol-associated liver disease (ALD). Although several pharmacological treatments for AUD are effective, they remain underutilized, and their real-world impact on healthcare use and costs is not well established. The goal of this study is to assess the impact of pharmacological treatment for AUD on alcohol-related healthcare utilization and costs, and to evaluate its cost-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

effectiveness using national claims data. **Methods:** We conducted a retrospective cohort study using deidentified claims data from Optum's Clinformatics® Data Mart, including adults with an AUD diagnosis between January 1, 2017, and December 31, 2023. Patients with continuous insurance for ≥ 1 year were included. Those initiating AUD medications within one year of diagnosis were defined as treated and matched 1:1 to untreated controls using inverse propensity score weighting and exact matching on demographics and comorbidities. Alcohol-related outpatient (OP), emergency department (ED), and inpatient (IP) charges were analyzed using Wilcoxon signed-rank tests. All costs were inflation-adjusted to 2023 U.S. dollars. Incremental cost-effectiveness ratio (ICER) was also calculated. **Results:** The cohort included 579,018 adults with AUD; 148,551 received pharmacotherapy (gabapentin, ondansetron, naltrexone, baclofen, topiramate, varenicline, acamprosate, or disulfiram) and were matched to untreated individuals. Mean age was 57.5 years ($\pm$15.7); 58.1% were male and 63.3% white. Gabapentin (52.3%), ondansetron (19.3%), and naltrexone (12.0%) were most commonly prescribed. Within one year, alcohol-related ED visits occurred in 16.6% of treated vs. 21.1% of untreated patients, and IP admissions in 26.1% vs. 41.4%, respectively. Average alcohol-related charges were significantly lower in the treated group ($41,105 vs. $51,905; $P < 0.001$), largely due to reduced inpatient costs ($33,102 vs. $44,891; $P < 0.001$). ED charges were modestly lower ($2,586 vs. $2,764; $P < 0.001$), while OP charges were higher among treated individuals ($5,417 vs. $4,250; $P < 0.001$), possibly reflecting increased engagement with ambulatory care (Table 1). Medication costs averaged $602, with an ICER of –0.01, indicating every $1 saved in medical costs required only $0.01 in treatment spending.
Conclusion: Pharmacotherapy for AUD is associated with significantly lower alcohol-related ED visits, hospitalizations, and overall healthcare costs. These findings support broader adoption of AUD medications as a cost-effective strategy to reduce alcohol-related healthcare burden and potentially mitigate the progression of alcohol-associated liver disease.

Table 1: Comparison of Alcohol-Related Healthcare Charges by Treatment Status and Care Setting

	Untreated group	Treated group	P
Alcohol-related medical charges ($2023)			
Mean (SD)	$51,905 (146724.5)	$41,105 (136889.2)	<0.001
Alcohol-related charges by care-settings ($2023)			
Alcohol-related OP charges, Mean (SD)	$4,250 (17299.7)	$5,417 (22807.9)	<0.001
Alcohol-related ED charges, Mean (SD)	$2,764 (10200.3)	$2,586 (11155)	<0.001
Alcohol-related IP charges, Mean (SD)	$44,891 (144241.6)	$33,102 (131616.3)	<0.001

1550 | LOSS OF HEPATIC PEROXIN 3 AGGRAVATES ALCOHOL-INDUCED LIVER INJURY VIA BILE ACID INTERMEDIATE ACCUMULATION IN MICE

Yantao Zhao[1] Weiran Wang[1] Carolina Hogerty[1] Steven Weinman[1] Zhanxiang Zhou[2] Wei Zhong[1], [1]University of Kansas Medical Center, [2]University of North Carolina at Greensboro

Background: Alcohol-associated liver disease (ALD) remains a leading cause of chronic liver injury worldwide, yet the contribution of hepatic peroxisomal dysfunction to its progression is not well understood. This study aimed to investigate the mechanisms by which impaired hepatic peroxisomal function contributes to ALD pathogenesis. **Methods:** Peroxisomal biogenesis factors were analyzed in liver tissues from both ALD patients and alcohol-fed mice. Liver-specific *Pex3* knockout mice were generated and examined for metabolic alterations. Bile acid intermediates that accumulated due to peroxisomal dysfunction were administered to wild-type mice and cultured hepatocytes to assess their direct effects. Additionally, *Pex3*-deficient mice were subjected to alcohol feeding to evaluate their susceptibility to liver injury. **Results:** Liver tissues from ALD patients and alcohol-fed mice showed a marked reduction in peroxin 3 (PEX3), a key regulator of peroxisomal biogenesis, along with decreased expression of the peroxisomal membrane protein PMP70. Liver-specific *Pex3* knockout mice exhibited impaired hepatic metabolism and accumulation of bile acid intermediates, indicating disrupted bile acid biosynthesis. Notably, these intermediates were also elevated in the livers of ALD patients and alcohol-fed mice. Administration of 3α,7α,12α-trihydroxy-5β-cholestanoic acid (THCA), a representative bile acid intermediate, at 50 mg/kg for five consecutive days induced significant liver injury in wild-type mice, as evidenced by elevated serum ALT and AST levels and increased hepatic inflammation. Bulk RNA sequencing of livers from THCA-treated mice revealed transcriptional signatures indicative of mitochondrial dysfunction, endoplasmic reticulum (ER) stress, and impaired antimicrobial defense. *In vitro* treatment of Hepa1c1c7 cells with THCA led to dose-dependent cell death and upregulation of pro-inflammatory cytokines such as *Cxcl1* and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Lcn2, along with protein markers of mitochondrial and ER damage. Furthermore, liver-specific *Pex3*-deficient mice demonstrated heightened sensitivity to alcohol-induced liver injury, suggesting a synergistic effect between peroxisomal dysfunction and alcohol exposure. **Conclusion:** These findings establish hepatic peroxisomal impairment as a crucial driver of bile acid dysregulation and alcohol-related liver injury, offering new insights into the molecular mechanisms underlying ALD and highlighting peroxisomal maintenance as a potential therapeutic target.

1551 | ZONE-SPECIFIC HEPATIC GENE DYSREGULATION IN ALCOHOL-ASSOCIATED LIVER DISEASE: EVIDENCE FROM SCRNA-SEQ AND HUMAN VALIDATION

Yanchao Jiang[1] Nazmul Huda[1] THEMIS THOUDAM[1] Hui Gao[1] Ge Zeng[1] Jing Ma[1] Xinshou Ouyang[2] Suthat Liangpunsakul[1] Zhihong Yang[1], [1]Indiana University, [2]Yale University

Background: Recent advances in single-cell RNA sequencing (scRNA-seq) have enabled to study gene expression in individual cell level, offering an unbiased and comprehensive view of cellular states and spatial organization within the liver. Alcohol use can damage the liver's structure and function, leading to alcohol-associated liver disease (ALD). However, it is still unclear how alcohol affects liver zonation—the specific patterns of gene expression in different regions of the liver, which is the objective of current study. **Methods:** C57BL/6 mice were fed using the NIAAA ethanol-plus-binge model, and their livers were collected 9 hours post gavage. Liver tissues were processed for immunohistochemistry (IHC). ScRNA-seq data from the GEO database were reanalyzed in R, Python and Matlab. Liver samples from patients with alcohol-associated cirrhosis (AC) were obtained from the Liver Tissue Procurement and Distribution System (Minneapolis, MN). **Results:** Alcohol exposure significantly disrupted the normal pattern of gene expression across liver zones. Immunohistochemistry (IHC) showed altered expression of zonation markers, and analysis of scRNA-seq data revealed increased expression of pericentral (PC, zone 3) genes such as Cyp2e1, Cyp4a14 and Glul, while periportal (PP, zone 1) genes like Mup21, Saa2, Cyp2f2, and Gls2 were reduced. Pathway analysis showed that upregulated genes were linked to cell death and immune responses, while downregulated genes were involved in lipid, cholesterol, and sterol metabolism. Zonation analysis identified 152 genes with consistent zonal patterns in both control and alcohol-fed mouse livers. However, 808 genes lost their zonation pattern, and 1,050 genes gained new zonal expression after alcohol exposure. Genes uniquely zonated in alcohol-fed livers were enriched in pathways related to RNA binding and transferase activity. In liver samples from patients with AC, IHC confirmed high expression of pericentral markers such as GS and CYP2E1, and reduced expression of periportal markers like E-CAD and CYP2F2. **Conclusion:** These findings show that alcohol consumption causes major changes in the spatial organization of gene expression in the liver, with increased activity of pericentral genes involved in alcohol metabolism and stress response. This underscores the importance of spatial gene regulation in liver function and suggests that therapies targeting specific liver zones may offer new precision treatment options for ALD.

Background: Alcohol-associated liver disease (ALD) is now the most common indication for liver transplantation (LT) in the United States. This rise is largely attributed to increasing alcohol use nationwide and the broader adoption of early transplantation for alcohol-associated hepatitis. The decline in hepatitis C virus (HCV)-related transplants following the widespread use of curative antiviral therapies has further contributed to ALD's prominence. As ALD continues to reshape the liver transplant landscape, understanding these trends is critical for guiding resource allocation, optimizing patient care, and integrating evidence-based management of alcohol use disorder throughout the transplant process. **Methods:** We used data from the United Network for Organ Sharing (UNOS) database, which includes information on all liver transplants in the United States. Adult patients (aged 18 years or older) who underwent a first-time liver transplant between 2013 and 2022 were included in the analysis. Alcohol-associated liver disease (ALD) was identified using diagnosis codes for alcohol-associated cirrhosis and alcohol-associated hepatitis (AAH). We examined how the number of ALD-related transplants changed over time and looked at trends in patient age, sex, and transplant outcomes. **Results:** From 2012 to 2023, a total of 27,075 liver transplants were performed in the United States for alcohol-associated liver disease (ALD), including 25,211 for alcohol-associated cirrhosis and 1,864 for alcohol-associated hepatitis. • During this time, ALD-related transplants increased from 976 in 2012 to 4,163 in 2023. By 2016, ALD had surpassed hepatitis C virus (HCV) as the most common reason adults were added to the liver transplant waitlist. Alcohol-associated hepatitis (AAH)—a more severe form of ALD—grew even faster, from just 5 cases in 2012 to 658 in 2023, a 13,060% increase and a 56% annual growth rate. • Alcohol-associated cirrhosis (AC) transplants increased from 971 in 2012 to 3,505 in 2023, a 261% rise, with an average growth rate of 12.4% per year. • When combined, ALD-related transplants rose from 976 in 2012 to 4,163 in 2023, a 326% increase, with an annual growth rate of 14.1%. Over the same period, total liver transplants for all causes increased from 5,731 to 10,406, meaning ALD now accounts for 41% of all adult liver transplants, compared to just 17% in 2012. **Conclusion:** Alcohol-associated liver disease (ALD) has emerged as the leading indication for liver transplantation in the United States, accounting for over 40% of all adult liver transplants by 2023. The rapid growth in AAH transplants, younger recipient age, and rising representation of women reflect important demographic and clinical changes in the transplant population. These findings highlight the critical need for transplant centers to implement comprehensive, evidence-based strategies for alcohol use disorder treatment before and after transplantation.

1553 | COMPARATIVE EFFECTIVENESS OF BARIATRIC SURGERY VERSUS GLP-1 RECEPTOR AGONISTS IN PATIENTS WITH METABOLIC DYSFUNCTION–ASSOCIATED ALCOHOL-RELATED LIVER DISEASE

Amir Hossein Gougol[1] Paul Kwo[2] Seyedbabak Mirminachi[3] Willian Pike[4] Mehdi Farokhnia[5], [1]Stanford, [2]Stanford University Medical Center, [3]University of Pittsburgh Medical Center, [4]Atropos Health, [5]NIH

Background: Alcohol use disorder (AUD) and metabolic dysfunction (MetD) frequently co-occur in patients with steatotic liver disease (SLD). According to new nomenclature, these patienst are classified as Metabolic Dysfunction–Associated Alcohol-Related Liver Disease (MetALD) and alcohol-related liver disease (ALD), relative to degree of alcohol intake. While both bariatric surgery and glucagon-like peptide-1 receptor agonists (GLP-1RA) are effective in managing MetD, their impact on AUD and liver-related outcomes in patients with MetALD and ALD with metD remain unclear. In this study, we aim to compare clinical outcomes between bariatric surgery and GLP-1RA therapy in patients with MetALD and ALD with MetD. **Methods:** This was a retrospective observational cohort study of patients with MetALD and ALD with MetD. MetD was defined as the presence of obesity [body mass index (BMI) >35 kg/m^2], diabetes mellitus (DM), or both. Patients were grouped based on exposure to either bariatric surgery or GLP-1RA therapy for at least six months. Outcomes included changes in weight, BMI, and hemoglobin A1c (HbA1c) over two years from the index intervention. Longitudinal outcomes included cardiovascular events, liver-related complications, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hospitalizations. Propensity score matching was employed to reduce effects of confounding factors. **Results:** A total of 127 patients underwent bariatric surgery and 450 received GLP-1RA therapy. Bariatric surgery patients were younger (47 vs. 53 years), more often female (59% vs. 47%), had a higher baseline BMI (43.4 vs. 38.1), and a lower prevalence of DM (47% vs. 84%), compared to the GLP-1RA group. Mean follow-up duration was 5.2 years. Bariatric surgery was associated with greater reductions in weight and HbA1c. Additionally, the bariatric group had a lower incidence of cardiovascular adverse outcomes. However, no significant differences were observed between groups in the incidence of decompensated cirrhosis or its components. Rates of hospital readmission and infections were also comparable. **Conclusion:** Although bariatric surgery achieved superior metabolic outcomes compared to GLP-1RA therapy, it did not confer additional benefit in reducing liver decompensation in patients with MetALD and ALD with MetD. Further research is warranted to elucidate the effects of bariatric surgery and GLP-1RA on alcohol consumption which may explain dissociation between metabolic improvement and hepatic outcomes.

1554 | BRUTON'S TYROSINE KINASE INHIBITION AS A NOVEL MULTIMODAL THERAPY FOR ALCOHOL-ASSOCIATED HEPATITIS

Prashanth Thevkar Nagesh[1] Marti Ortega Ribera[2] Arman Patel[3] Veronika Brezani[2] Viliam Brezani[2] Aditi Ashish Datta[2] Yuan Zhuang[4] Scott Minchenberg[4] Deepika Deepika[2] Bruna Santos[2] Radhika Joshi[2] Stephen Varghese Samuel[2] Yeshaswini Katkoori[2] Gyongyi Szabo[4], [1]Beth Israel Medical Center, Harvard Medical School, [2]BIDMC - Harvard Medical School, [3]Beth Israel Deaconess Medical Centre, [4]Beth Israel Deaconess Medical Center

Background: Alcohol-associated hepatitis (AH) is a severe and life-threatening form of alcohol-associated liver disease with poor clinical outcomes. AH pathogenesis involves hepatic steatosis, neutrophil infiltration, neutrophil extracellular traps (NETs) formation, and NLRP3 inflammasome activation in macrophages. Identifying a therapeutic target common to these cellular pathways remains challenging. We recently identified Bruton's tyrosine kinase (BTK) as a critical mediator of neutrophil-driven liver injury in AH. Our findings suggest a broader multicellular role for BTK in AH that remains unexplored. We hypothesized that alcohol induces BTK phosphorylation (pBTK), and that pharmacological BTK inhibition could attenuate AH. **Methods:** Female C57BL/6J mice (12 weeks; wild-type [WT], global BTK-/-, myeloid-BTK-/-, hepatocyte-BTK-/-) received Lieber-DeCarli alcohol diet for 11 days followed by a binge (AH model) or a calorie-matched control diet. WT mice received daily oral gavage of evobrutinib (BTK inhibitor; BTKi, 5mg/kg) or DMSO (vehicle control) for 11 days. Serum ALT and cytokines were measured by ELISA. pBTK was assessed in human and mouse livers via Western blot. Hepatic steatosis markers were analyzed by qPCR and liver triglyceride content. NET markers (citrullinated histone H3, neutrophil elastase) were measured in liver lysates. Circulating and liver monocytes, neutrophils, and ASC specks were evaluated via flow cytometry. BTK-NLRP3 interaction was examined in mouse bone marrow-derived macrophages (BMDMs) via co-immunoprecipitation. **Results:** In vitro, alcohol rapidly induced pBTK in primary human/mouse hepatocytes, neutrophils, and monocytes. AH patient and mouse livers showed increased pBTK vs. controls. Alcohol-induced increases in serum ALT, cytokines (IL-1β, TNF-α, MCP-1), steatosis (triglycerides, Fasn, Fatp5, Pparα), and immune cell infiltration were all reduced in BTK-/-, myeloidBTK-/-, and hepatocyteBTK-/- mice. Mechanistically, alcohol-induced pBTK (Y223) acted upstream of pSTAT3 (Y705), regulating steatosis. Co-immunoprecipitation showed pBTK interaction with NLRP3, promoting inflammasome activation. Genetic deletion of BTK (all 3 models) reduced ASC specks and NET formation, in vivo. In the AH model, BTKi significantly attenuated steatosis, inflammation, and NETs, mimicking the effects observed in global BTK-/- mice. **Conclusion:** Alcohol-induced BTK activation occurs in parenchymal and immune cells in the liver and drives steatosis, inflammation, NLRP3 inflammasome activation, and NET formation in AH involving hepatocytes and immune

1555 | THE EFFECT OF MEDICAL ASSISTED THERAPY ON LIVER-RELATED OUTCOMES IN PATIENTS WITH ALCOHOL USE DISORDER AFTER TRANSPLANTATION

Ami Patel[1] Anita Krishnarao[2], [1]Univeristy of Massachusetts, [2]University of Massachusetts

Background: Alcohol-associated liver disease (ALD) remains the leading cause of cirrhosis and indication for liver transplantation (LT) in the United States. Despite controversy regarding the 6 months of mandated sobriety in patients with ALD pre-LT, post-LT alcohol relapse remains high, ranging from 15-50%. Minimal data exists on the effect of post-LT medical assisted therapy (MAT) for patients with alcohol use disorder (AUD). This study aims to evaluate early post-LT outcomes in patients using MAT for AUD. **Methods:** This analysis was completed using a TriNetX query of the United States Collaborative Network- a network of 70 healthcare organizations. Patients with ALD cirrhosis, AUD and LT between 2010-2022 were identified using ICD-10 codes. The study cohort included patients who were prescribed MAT within 90 days of LT and the control group included those without a history of MAT use pre-or post-LT. Propensity score matching (PSM) was used to balance cohorts by age, sex, and ethnicity. Outcomes included graft rejection, mortality, readmissions, need for Endoscopic Retrograde Cholangiopancreatography (ERCP) and liver biopsy. The probability of each outcome was compared using Chi-squared test and Kaplan-Meier analyses. Data was analyzed using TriNetX and statistical significance was evaluated at $p < 0.05$. **Results:** A total of 546 patients were included. Patients precribed MAT were more likely to be older (57 years old $\pm$ 9.55 vs. 55 $\pm$ 10.2, $p < 0.01$) and female (31% vs. 22%, $p < 0.01$).After PSM patients using MAT were found to have a lower risk of graft rejection (OR 0.43, 95% CI 0.23-0.61, $p < 0.01$) and liver biopsy (OR 0.50, 95% 0.25-0.99, $p = 0.04$) compared to those not on MAT after 1 year. There was no significant difference in mortality or readmission after 1 year. Furthermore, after 3 years patients on MAT had a lower risk of graft rejection (OR 0.43, 95% CI 0.28-0.66, $p < 0.01$), liver biopsy (OR 0.48, 95% CI 0.26-0.90, $p = 0.02$), and ERCP (OR 0.5, 95% CI 0.27-0.92, $p = 0.03$). Additionally, MAT was associated with an increased risk of 3-year (OR 1.77 95% CI 1.10-2.85, $p = 0.02$) and 5-year mortality (OR 1.75, 95% CI 1.17-2.53, $p < 0.01$). **Conclusion:** MAT use post-LT in patients with AUD may reduce the risk of graft rejection and need for procedures such as liver biopsy and ERCP, likely due increased abstinence from alcohol

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and reduced liver injury. Despite the high rates of alcohol relapse post-LT MAT is underutilized. The increased risk of mortality seen in the MAT group is more likely a consequence of the group's higher propensity for alcohol relapse, rather than an effect of MAT itself. This study further highlights the need for better management of AUD with MAT in patients post-LT, especially given possible improved graft outcomes.

Figure 1. A greater proportion of patients on MAT post-LT had rejection free survival compared to no MAT after 3 years.

1556 | FACTORS ASSOCIATED WITH INCREASED LIVER FIBROSIS IN ADULTS WITH METALD: DATA FROM US NHANES 2017 - 2023

Alex Chang[1] Joao Filipe Monteiro[1] Adam Burton[1] Andrew Petrou[1] Neha Wadhavkar[1] Kittichai Promrat[1], [1]Warren Alpert School of Medicine of Brown University

Background: MetALD is recent nomenclature describing steatotic liver disease (SLD) patients with cardiometabolic risk factors (CMRFs) and concurrent alcohol use. Limited literature exists on the major factors predicting advanced fibrosis in this recently labeled MetALD population. Additionally, since alcohol use is a risk factor for CMRFs, studies have questioned whether diagnosing MetALD should require more than one CMRF. The current study looks at patients with MetALD from the US NHANES 2017 - 2023 cohorts and identifies the major risk factors associated with increased fibrosis in these patients. **Methods:** The NHANES 2017-2020 and 2021-2023 datasets, comprising of 17,843 adult participants, was utilized. Participants without a complete transient elastography (TE) examination, with past history of viral or autoimmune hepatitis, or without evidence of steatosis on TE (CAP $<$ 285) were excluded. Participants who had at least one CMRF and for men, consumed between 210 and 420g of alcohol weekly and for women, consumed between 140 - 350 g of alcohol weekly were included in the study as patients with MetALD. Clinically-significant fibrosis (CSF) was defined as LSM $\geq$ 8 kPa on TE while advanced fibrosis (AF) was defined as LSM $\geq$ 12 kPa. The number of CMRFs was determined in accordance to AASLD guidelines and includes diabetes, obesity (BMI), obesity (waist circumference), hyperlipidemia, and hypertension. Multivariable logistic regression models, accounting for relevant covariates, were used to identify independent associations with fibrosis outcomes. All statistical tests were performed using SAS version 9.4 **Results:** 192 participants met MetALD criteria. CSF affected 24.0% while AF affected 8.9% (Table 1). Individuals with four or five comorbidities had significantly higher odds (OR 2.16; 95% CI: 1.06–4.03) for CSF compared to those with fewer comorbidities (Figure 1). Diabetes was associated with increased odds of CSF (OR 1.76; 95% CI: 0.82–3.74), though this was not significant. For AF, the presence of four or five comorbidities was again significantly associated with increased risk (OR 3.02; 95% CI: 1.05–8.87). Diabetes was also significantly associated with increased risk of AF (OR 2.96; 95% CI: 1.02–8.61), while hypertension and obesity had no clear association with fibrosis. For individuals with one or two comorbidities, the odds of AF were not significantly associated. **Conclusion:** Patients who meet criteria for MetALD have risk factors for steatosis related to both alcohol consumption and cardiometabolic disease. The current study would support that diabetes is associated with highest risk of developing AF in patients with MetALD. Additionally, risk of fibrosis is increased in patients with 4 or 5 compounded CMRFs as opposed to 1 or 2 CMRFs. Future studies should continue to delineate differences in risk factors for fibrosis between patients with MASLD, MetALD, and ALD to better inform clinical practices.

1557 | OMEGA-5 FATTY ACID AS AN ADJUVANT REDUCES INFLAMMA-OXIDATION IN PATIENTS WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS NEW SUBMISSION

Gabriela Gutierrez-Reyes[1] Moises Martinez-Castillo[1] Abigail Hernandez-Barragan[1] Marisela Hernandez-Santillan[1] Froylan Martinez-Sanchez[2] Daniel Santana-Vargas[3] Erik Bojorges-Valdez[4] Adrian Flores-Sanchez[1] Danna Mercado-Herrera[1] Jacqueline Cordova-Gallardo[2], [1]Universidad Nacional Autonoma de México, [2]Hospital General Dr. Manuel Gea Gonzalez, [3]Hospital General de Mexico "Dr. Eduardo Liceaga", [4]Universidad Iberoamericana

Background: Severe alcohol-associated hepatitis (SAAH) is associated with high mortality, particularly in patients who are unresponsive to corticosteroid therapy. That is also characterized by antioxidant deficiencies and heightened inflammation, both of which contribute to the progression and severity of liver injury. Omega-5 fatty acid (nano) has been shown antioxidant and anti-inflammatory properties, offering a potential new therapy. Aim: To evaluate the efficacy of Omega-5 fatty acid (nano) as an adjuvant to prednisone in modulating oxidative and inflammatory parameters in SAAH patients. **Methods:** This randomized, double-blind, placebo-controlled clinical trial (NCT 03732586) was conducted at a single center in Mexico between 2018 and 2020. Patients with confirmed SAAH (MDF ≥ 32) were randomly assigned to Group P (prednisone 40 mg/day + placebo) or Group T (prednisone 40 mg/day + Omega-5 at 1.28 g/day). Both regimens were administered for 28 days. Biochemical markers of liver function, nutritional evaluation, malondialdehyde (MDA), protein carbonyls (PC), reduced glutathione (GSH), oxidized glutathione (GSSG), and the GSH/GSSG ratio in blood were assessed. Additionally, cytokines (IL-1a, IL-10, IL-6, TNF-alpha, IFN-gamma, IL-1b, IL-1RA), chemokines MCP-1, CXCL-8 and 10) and growth factors (IGFBP-1 to 7), were measured at baseline (day 0) and on days 7, 14, and 28. **Results:** Baseline characteristics included nutritional parameters were similar between groups. Both groups exhibited similar steroid responses with no significant difference in Lille scores (Group P: 0.46 $\pm$ 0.33; Group T: 0.36 $\pm$ 0.28). Liver function tests revealed improved ALT, AST, and bilirubin levels in Group T by day 28 ($p < 0.05$). Analysis for oxidative markers showed that lipid peroxidation (MDA) was improved ($p = 0.001$) at 28 days in group T vs group P. The GSH/GSSG ratio also showed differences with the use of Omega-5. IL-10 levels (pg/mL) significantly increased in Group T, while MCP-1, CXCL-8 and CXCL10 levels (pg/mL) showed marked reduction by day 28 vs day 0. Additionally, IGFBP 1, 2,3 and 7 levels (ng/mL) in Group T were significantly reduced. **Conclusion:** Addition to Omega-5 fatty acid (nano) to prednisone strongly showed a beneficial effect, promoting the reduction of oxidative stress, while modulating cytokine /chemokines profiles and IGFBP levels. These findings support the potential of Omega-5 as an effective adjuvant therapy in SAAH. A phase 3 clinical trial is performed to further elucidate its molecular mechanisms and explore the correct dosing regimens.

1558 | INTEGRATED SPATIAL ANALYSIS REVEALS HEPATOCELLULAR CHANGES AS A PATHOGENIC HALLMARK OF ALCOHOL-ASSOCIATED HEPATITIS

Susmita Bhattarai[1] Sizhe Wan[1] Sehrish Naz[2] Sofia Izunza Barba[2] Hua Xu[2] Zhengsheng Zhang[2] Chi Chan[2] Shuli Luo[2] Prashanth Nagesh[2] Sizun Jiang[2] Zhenghui Jiang[2], [1]BIDMC/ Harvard Medical School, [2]BIDMC/ Harvard Medical School

Background: Alcohol-associated hepatitis (AH) remains a severe subacute liver failure associated with high mortality. Medical treatment for AH is limited due to the lack of proper understanding of disease pathogenesis. Although AH and alcohol-associated cirrhosis (AC) can co-exist, AH can also differ from AC by the presence of hepatomegaly rather than liver atrophy, faster progression to decompensation, higher rate of mortality, and potential reversibility. The spatial profiling of liver tissue can provide deep insights in disease pathogenesis and ultimately offer novel therapeutic strategies. Specifically, interrogating hepatocellular changes in AH could provide better mechanistic understanding of the molecular traits of AH that is distinct from AC. **Methods:** Human liver tissues from patients with AH, AC and healthy controls were identified for this study. We used RT-PCR and Basescope to assess the expression of critical genes in hepatocytes that shape the hepatocellular phenotype. CosMx Spatial Molecular Imager platform and CosMx™ Human Universal Cell Characterization Panel (RNA, 1000 Plex) was used for cell typing and gene detection. Spatial transcriptomics were employed to identify the AH transcriptomic

signature in comparison to AC. **Results:** RT-PCR analysis and Basescope analysis in human tissues show reduced expression of essential liver genes associated with hepatocellular phenotype such as HNF4α, HNF1α, ALB, HNF4α-AS1 and OTC in AH tissues. However, HNF1α, OTC and ALB were not significantly altered in cirrhosis samples compared to healthy controls. Basescope and immunohistological analysis revealed that HNF4α-P1, a transcription factor critical for the maintenance of mature hepatocyte phenotype was significantly reduced in AH samples. With CosMx Spatial imaging, AH liver tissue demonstrates a profoundly altered cellular landscape compared to AC and healthy liver tissues. Furthermore, AH hepatocytes exhibit remarkable transcriptomic changes in comparison to hepatocytes in AC and healthy liver. Specifically, HNF4α dysregulation was associated with hepatocellular dysfunction in AH. Fig:1 Spatial transcriptomics reveals disease-specific and cell-specific transcriptomic profiles. UMAP representation of the cell types in the human liver tissues and different diseased states. **Conclusion:** Altered hepatocellular transcriptome is a hallmark of AH, suggesting that a viable therapeutic strategy could target mechanisms that drive hepatocellular regeneration and differentiation.

1559 | AQUAPORINS FACILITATE HEPATIC ACETALDEHYDE TRANSPORT AND MODULATE ALCOHOL-ASSOCIATED LIVER DISEASE

Cheng Chen[1] Yuhong Lin[1] Dechun Feng[1] Yaojie Fu[1] Yukun Guan[1] Yang Wang[1] Luca Maccioni[1] Deniz Seyhan[1] Shoupeng Wei[1] Tiantian Yao[1] Li Zhang[1] George Kunos[2], [1]NIH/NIAAA, [2]National Institute on Alcohol Abuse and Alcoholism (NIAAA)

Background: Our previous study revealed that biliary acetaldehyde (AcH) levels are significantly higher than those in serum, suggesting that bile excretion plays a key role in AcH clearance within the enterohepatic circulation. This uneven distribution implies the existence of a specific AcH transporter; however, none have been identified to date. Aquaporins (AQPs) are known to facilitate the transport of water and small solutes. Among them, AQP8 and AQP9 are predominantly localized on the canalicular and basolateral membranes of hepatocytes, respectively. Given that AcH is a water-soluble metabolite and highly carcinogenic, we hypothesized that AQP8 and AQP9 may mediate AcH transport and thereby contribute to hepatic AcH clearance, which may affect the pathogenesis of alcohol-associated liver disease (ALD). **Methods:** 1. *In situ* liver perfusion with 25% ethanol (EtOH) and 100 mg/kg AcH i.p. injection were performed in *Aqp8*$^{-/-}$ and *Aqp9*$^{-/-}$ mice, followed by measurement of AcH and EtOH levels in the liver, bile, and blood. 2. Primary hepatocytes isolated from *Aqp8*$^{-/-}$ and *Aqp9*$^{-/-}$ mice were incubated with EtOH or AcH, and intra- and extracellular AcH levels were quantified. 3. Dynamic bile flow and biliary AcH concentrations were assessed via gallbladder cannulation in *Aqp8*$^{-/-}$ mice, with or without EtOH exposure. 4. *Aqp8*$^{-/-}$ and *Aqp9*$^{-/-}$ mice were subjected to an ALD model, and liver injury markers were evaluated. Meanwhile, their expressions were evaluated in the severe alcoholic hepatitis (sAH) patients' liver. **Results:** 1. *Aqp8* deletion significantly reduced biliary and extracellular AcH levels following EtOH perfusion in the liver and EtOH incubation with isolated hepatocytes, despite comparable intrahepatic AcH accumulation. These findings suggest that AQP8 drives hepatic AcH efflux. 2. *Aqp9* deletion markedly decreased liver and intracellular AcH levels following AcH i.p. injection *in vivo* and AcH incubation with isolated hepatocytes, suggesting that AQP9 facilitates AcH influx to hepatocytes. 3. *Aqp8*$^{-/-}$ mice exhibited markedly reduced bile volume and biliary AcH concentrations, indicating impaired AcH clearance and altered bile secretion. 4. *Aqp8*$^{-/-}$ mice demonstrated significantly reduced serum ALT levels and liver damage compared to WT controls in the ALD model. AQP9 was identified as being specifically suppressed in the liver of sAH patients, suggesting that AQP8 and AQP9 are involved in the progression of different stages of ALD. **Conclusion:** This study identifies hepatic AQP8 and 9 as novel AcH transporters facilitating AcH efflux and influx in the liver, which may contribute to the progression of different stages of ALD.

1560 | MORTALITY TRENDS AND RISK FACTORS IN ALCOHOL-ASSOCIATED HEPATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Francisco Idalsoaga[1] Mushfiqur R. Siddique[2] Muzzafar Haque[3] Luis Antonio Diaz[4] Gene Im[5] Ashwani K. Singal[6] Stephen Hoang[7] Mohammad Qasim Khan[8] Juan Pablo Arab[7], [1]Pontificia Universidad Católica de Chile, Western University, [2]Jamaica Hospital Medical Center, New York, USA, [3]College of Medicine, University of Saskatchewan, Saskatchewan, Canada., [4]Pontificia Universidad Católica de Chile, University of California San Diego, La Jolla, California., [5]Columbia University, Vagelos College of Physicians and Surgeons, New York, NY, USA., [6]University of Louisville School of Medicine and University of Louisville Alcohol Research Center, [7]Virginia Commonwealth University School of Medicine, Richmond, Virginia, USA., [8]Western University, London, Ontario, Canada

Background: Severe alcohol-associated hepatitis (sAH) is a life-threatening condition. Despite advances in clinical management, prognosis remains poor and the long-term effectiveness of available therapies is uncertain. We conducted a systematic review and meta-analysis to evaluate mortality trends in sAH over the past five decades. **Methods:** We searched PubMed, EMBASE, and Scopus from inception to February 2024 for studies reporting 28-, 60-, and 90-day mortality in patients with sAH. Pooled mortality estimates were calculated using a mixed-effects model. We assessed heterogeneity using the I^2 statistic and explored sources of heterogeneity through subgroup and meta-regression analyses. Bayesian mixed-effects meta-analyses estimated the posterior distribution of mortality probability across studies. **Results:** Forty-five studies, including 5,632 patients with sAH were analyzed. Pooled mortality rates were 28.3% (95% CI: 22.5–34.8%) at 28 days, 38.3% (95% CI: 31.5–45.5%) at 60 days, and 48.7% (95% CI: 39.2–58.3%) at 90 days. Substantial heterogeneity was observed ($I^2 > 80\%$). Although Bayesian analyses showed a decline in 28-day mortality from over 50% in the 1970s to approximately 25% after 2000, no significant overall improvement in short-term mortality was detected. No consistent associations were found between mortality and mDF, HRS, age, sex ratio, or publication year. However, higher MELD scores were significantly associated with increased mortality ($\beta = +0.20$ per point; 95% CI: +0.01 to +0.39; $p = 0.037$). The reported use of corticosteroids, NAC, or G-CSF did not result in meaningful differences in log-odds of mortality across studies. **Conclusion:** Short-term mortality in sAH remains high and has not improved in recent decades. Our findings highlight the urgent need for effective therapies and may improve candidate assessment for early liver transplantation in sAH.

1561 | INTESTINAL INFLAMMATION (II) MEASURED BY FECAL CALPROTECTIN (FC) IN DECOMPENSATED ADVANCED CHRONIC LIVER DISEASE (DACLD) INPATIENTS IS HIGHER WHEN TRIGGERED BY ALCOHOL-ASSOCIATED HEPATITIS (AH), BUT: DO II/FC INDEPENDENTLY ASSOCIATE WITH ADVERSE OUTCOME?

Lubomir Skladaný[1] Tomas Koller[2] Petra Vrbova[3] Daniela Zilincanova[4] Svetlana Adamcova Selcanova[4] Daniel Jan Havaj[4] Juan Pablo Arab[5], [1]Faculty Hospital FD Roosevelt, [2]Dept Internal Medicine V, Komensky University Faculty of Medicine, University Hospital Bratislava, [3]Dept Internal Medicine V, Komensky University Faculty of Medicine, University Hospital Bratislava Ru, [4]Dept Int Medicine 2, Slovak Medical University Faculty of Medicine, F.D.Roosevelt Hosp, B. Bystrica, [5]Virginia Commonwealth University

Background: Gut-liver axis (GLA) when deranged by dysbiosis, intestinal inflammation (II) and barrier disruption plays a critical role in the pathogenesis of ACLD. GLA involvement seems to be especially pronounced in alcohol-associated liver disease (ALD) and AH-triggered dACLD. Fecal calprotectin (FC) is an established marker of II; our group has recently reported elevated levels of FC in dACLD with independent, dose-dependent, and phenotype-specific prognostic significance. However, FC has not been fully investigated against various etiologies and triggers of dACLD, especially ALD and AH. Therefore, we aimed to assess how FC relates to the severity and prognosis of dACLD triggered by AH in comparison to other causes of decompensation. **Methods:** RH7 cirrhosis registry prospectively records data from consecutive hospitalized cases with ACLD at the tertiary liver & transplant unit for more than 10 years (NCT04767945). FC has been added to RH in 2021. Here, we included ACLD cases with FC and a follow-up of at least 6 months or predefined adverse outcome (liver transplantation or death of any cause). We compared FC values and their predictive power for transplant-free survival between AH and other causes of decompensation of ACLD. **Results:** From August 2021 to March 2025 we enrolled 518 patients, with M/F ratio 325/193, a median age 57.4 years, MELD-Na score 20, Child-Pugh-Turcotte (CPTS) score 9, with refractory ascites in 117 (22.8%) and median FC of 236 ug/g (4.7 times the upper limit of normal of 50 ug/g). One hundred and thirteen cases (21,8%) had AH as a trigger of dACLD: AH patients were significantly younger (median age 48.8 vs. 59.2), had higher MELD-Na (28.0 vs. 18.0), CPTS (10 vs. 8), CRP (29.7 vs. 10.4) mg/l, with no gender difference (35% vs. 38%); patients with AH had higher FC 310.2 (IQR 120-914) vs. 200.3 (IQR 57.8-593 ug/g, $P < 0.001$). Seventy-seven (14.9%) patients had evidence of severe intestinal inflammation with FC > 1000 ug/g, 23% in the AH, and 12,6% in the non-AH group ($P = 0.006$). The Cox model for the entire cohort showed that age, MELD-Na, CRP, CTPS, and FC > 1000, but not AH, were independent risk factors of adverse outcome. In the log-rank test, patients with FC > 1000 had a significantly higher risk of adverse outcomes in both AH and non-AH groups, respectively (HR = 2.01; 95% CI 1.02-3.98 vs. 2.11; 1.24-3.56). AH cases having FC > 1000 compared to those with FC < = 1000 had significantly higher MELD-Na (30 vs. 26), and lower sodium (130 vs. 132). **Conclusion:** Patients with dACLD triggered by AH have evidence of a more pronounced intestinal inflammation reflected by *i)*significantly higher FC and *ii)*significantly higher proportion of patients with "severe intenstinal inflammation" (Graph). However, FC has not came out as an independent predictor of bad outcome and prognosis appears to be associated with the severity of the liver injury rather than a specific AH → II pathogenesis.

1562 | HIGH-SALT DIET EXACERBATES ALCOHOL-RELATED LIVER DISEASE BY RESHAPING THE GUT MICROBIOTA AND UPREGULATING SIK1 EXPRESSION IN LSECS

Hua Wang[1] Haiyuan Shen[2] Li Zuo[1], [1]Anhui Medical University, [2]the First Affiliated Hospital of Anhui Medical University

Background: Alcohol-related Liver Disease (ALD) is a form of hepatic pathology primarily induced by chronic excessive alcohol consumption, ranking as one of the foremost causes of liver-related mortality globally. Compounded by pervasive risk factors such as suboptimal dietary patterns, the global outlook for ALD

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

remains concerning. This study aims to investigate the impact of a high-salt diet on ALD and explore its molecular regulatory mechanism, as well as identify potential therapeutic targets. **Methods:** C57BL/6 mice were employed as experimental subjects, utilizing the Gao-binge alcoholic liver model. Mice were subjected to high or normal salt diets. The extent of alcohol-induced liver damage, steatosis, and inflammation was assessed across different groups. To elucidate the regulatory pathways, comprehensive analyses were conducted using microbial community amplicon sequencing, metabolomics, proteomics, and genetic engineering techniques. **Results:** High-salt diet reduced the abundance of beneficial bacteria such as *Akkermansia muciniphila* and *Lactobacillus rhamnosus* while promoting the growth of harmful bacteria like *Enterococcus faecalis*. The disruption of the intestinal barrier allowed pathogen-associated molecular patterns to translocate into the liver, thereby exacerbating hepatic inflammation. Additionally, high-salt diet reshaped the immune landscape within the liver by promoting neutrophil migration into liver while exacerbating alcohol-induced liver damage in mice. Mechanistically, a high-salt diet induces the upregulation of salt-inducible kinase 1 (Sik1) expression in liver sinusoidal endothelial cells (LSECs), leading to the release of selectin and intercellular adhesion molecule-1 (ICAM-1). **Conclusion:** High-salt intake exacerbates ALD progression by altering the gut microbiome composition. While high-salt diet facilitates neutrophil infiltration into the liver by promoting selectin and ICAM-1 expression in LSECs, thereby causing tissue damage through inflammation. These findings elucidate novel molecular mechanisms underlying alcoholic liver injury and suggest potential therapeutic strategies for ALD involving dietary modifications and probiotic interventions. Additionally, this research underscores the critical importance of maintaining a balanced diet for overall health.

1563 | STAT5 AND REV-ERBA COOPERATIVELY REGULATE CYP4A EXPRESSION DURING THE PROGRESSION OF ALCOHOL-ASSOCIATED LIVER DISEASE.

Haibo Dong[1] Wei Zhong[1] Wei Guo[1] Xinguo Sun[1] Zhanxiang Zhou[1], [1]University of North Carolina at Greensboro

Background: Members of the cytochrome P450 4A (CYP4A) subfamily play key roles in the metabolism of long-chain fatty acids and have been linked to the development of alcohol-associated liver disease (ALD). However, how CYP4A expression changes over the course of ALD and what regulates these changes remain poorly understood. This study aimed to characterize the stage-specific expression patterns of CYP4A and to explore the underlying transcriptional mechanisms. **Methods:** To model early-stage ALD, mice were fed ethanol chronically for 8 weeks. For advanced disease, liver samples from patients with alcohol-associated cirrhosis (AC) and severe alcohol-associated hepatitis (sAH) were analyzed. Liver histology was used to evaluate disease severity. CYP4A expression and related metabolic pathways were assessed using RNA-seq, RT-qPCR, and Western blotting. A hepatocyte-specific STAT5 knockout mouse model and luciferase reporter assays were used to investigate transcriptional regulation. **Results:** RNA-seq analysis of liver tissues from chronic alcohol-fed (AF) mice and alcohol-associated hepatitis (AH) patients revealed that genes of the CYP4A family are enriched in long-chain fatty acid metabolism, including arachidonic acid and linoleic acid pathways. Furthermore, analysis of CYP4A isoforms showed that chronic alcohol feeding increased the expression of Cyp4a10 and Cyp4a14, but decreased Cyp4a12a/b in mice with early-stage ALD. However, In contrast, in human liver samples from advanced ALD, CYP4A11 (the human homolog of Cyp4a10/14) was downregulated in both AC and sAH, while CYP4A22 (homologous to Cyp4a12a/b) was upregulated in AC but decreased in sAH. Mechanistic studies revealed that the dynamic changes in Cyp4a expression may depend on the coordinated actions of the transcription factors STAT5 and REV-ERBα. **Conclusion:** In early ALD, REV-ERBα appears to be the primary regulator, whereas in later stages, STAT5 takes on a more dominant role. Moreover, STAT5 was found to repress REV-ERBα expression.

1564 | DISRUPTION OF HUR AGGRAVATES ALCOHOL-INDUCED LIVER INFLAMMATION THROUGH ALTERED BILE ACID SIGNALING AND H19 UPREGULATION

NAN WU[1] Yun-Ling Tai[1] Derrick Zhao[1] Hui Li[1] Grayson Way[1] Meiyi Song[1] Sareh Bayatpour[1] Lianyong Su[1] Xuan Wang[1] Emily Gurley[1] Phillip Hylemon[1] Arun Sanyal[1] Huiping Zhou[1], [1]Virginia Commonwealth University

Background: Alcohol-associated liver disease (ALD) involves hepatic steatosis, inflammation, and disrupted bile acid homeostasis, processes partly regulated post-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transcriptionally. HuR (ELAVL1), an RNA-binding protein, stabilizes transcripts involved in metabolic and inflammatory pathways. Prior studies show that HuR suppresses *H19* expression, reducing ER stress and lipotoxicity. Metabolic stress suppresses HuR expression. However, HuR's role in ALD pathogenesis remains poorly defined and is the focus of this study. **Methods:** Twenty-four-week-old male HuR floxed and liver-specific HuR knockout (LKO) mice were fed a Lieber-DeCarli ethanol or control diet for 10 days, followed by a single ethanol binge or isocaloric maltose dextrin gavage. HuR deletion was confirmed by IHC and Western blot. Hepatic lipid accumulation was evaluated by H&E staining. Hepatic gene expression was profiled using the NanoString nCounter® Metabolic Pathways Panel with ROSALIND® analysis. *H19* expression was measured by qPCR. Hepatic bile acid composition was assessed via LC-MS and liver inflammation was evaluated via F4/80 IHC. **Results:** Following ethanol exposure, LKO mice exhibited increased F4/80$^+$ macrophage infiltration, indicating enhanced hepatic inflammation. NanoString analysis revealed upregulation of genes linked to stress responses, immune activation, and profibrogenesis—including *c-Myc*, Runt-related transcription factor 1, and protein tyrosine kinase 2—suggesting activation of stress signaling pathways and promotion of inflammatory and fibrotic remodeling. LC-MS analysis demonstrated altered bile acid composition in ethanol-fed LKO mice, with significant elevations in GCA, GβMCA, and TβMCA. However, LKO mice displayed reduced hepatic steatosis and lower serum triglyceride levels, potentially due to downregulation of *Fasn* and *Scd1*, which may impair lipid droplet formation and monounsaturated fatty acid synthesis. **Conclusion:** Liver-specific HuR deletion reprograms hepatic gene expression, alters bile acid composition, and modulates lipid metabolism in response to ethanol exposure. Although steatosis is attenuated, increased *H19* expression and activation of pro-inflammatory pathways indicate a pathological shift from lipid accumulation to inflammation-driven liver injury. Additionally, elevated levels of GCA and TβMCA may exacerbate hepatic inflammation by activating sphingosine-1-phosphate receptor 2 and antagonizing farnesoid X receptor signaling, respectively.

1565 | A SUPEROXIDE DISMUTASE-MIMETIC (BMX-001) MITIGATES LIPID PEROXIDATION IN A MOUSE MODEL OF ALCOHOL-ASSOCIATED LIVER DISEASE.

Delia Omar[1] Micah Schott[1] Nourhan Mostafa[1] Rebecca Deegan[1], [1]University of Nebraska Medical Center

Background: Alcohol-associated liver disease (ALD) is a growing public health concern. Hepatic steatosis represents the earliest stage of ALD and is marked by extreme accumulation of lipid droplets (LDs) within hepatocytes that are central to ALD progression. Additionally, hepatocytes accumulate reactive oxygen species (ROS) following ethanol (EtOH) metabolism, which then reacts with polyunsaturated fatty acids (PUFA), leading to increased lipid peroxidation. However, it is unclear whether ROS can be targeted therapeutically to decrease lipid peroxidation and improve ALD. A promising antioxidant therapy uses the superoxide dismutase SOD-mimetic (BMX-001), a lipophilic manganese porphyrin that scavenges excess intracellular ROS and is currently in Phase 2 clinical trials as a radioprotector in cancer patients. Pharmacokinetics data showed that BMX-001 stably accumulates within mouse livers in a dose dependent manner. However, its efficacy to mitigate ROS-driven hepatocyte damage in ALD has not been explored. **Methods:** C57BL6 mice were subjected to a diet enriched in PUFA with a chronic 10-day EtOH feeding followed by a single binge of EtOH or an isocaloric control-PUFA rich diet with a single binge of maltose dextrin. Mice were randomly assigned to four groups: Control + PBS, Control + BMX-001, EtOH + PBS, EtOH + BMX-001,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and the drug was administered by intraperitoneal injection four times. At 7 hours post binge, mice were euthanized, liver tissues and blood serum were collected for analysis. **Results:** Findings demonstrated a remarkable increase in the liver / body weight ratio (P-value < 0.05), and a significant elevation in the hepatic triglyceride level (P-value < 0.0001) in EtOH-fed mice compared with controls (P-value < 0.0001). Serum alanine aminotransferase, and cholesterol levels didn't reveal significant differences between groups. Liver tissue immunofluorescence (IF) staining with LD marker perilipin-2 (PLIN2) revealed a remarkable increase in the mean fluorescence intensity (MFI) in EtOH-fed mice compared with controls. IF staining for lipid peroxidation using 4-Hydroxynonenal (4HNE) antibody showed a significant reduction in the MFI by BMX-001 (P-value < 0.05) compared with PBS in EtOH-fed mice. Interestingly, 4HNE staining was observed around LDs and was strongly colocalized with PLIN2. We also observed sex variability in 4HNE staining, where male mice showed elevated lipid peroxidation compared with female mice. Lipid peroxidation measurements were complemented by malondialdehyde (MDA) immunofluorescence, which confirmed the reduction by BMX-001 in EtOH-fed mice compared to PBS-EtOH. **Conclusion:** Our data suggests that LDs may serve as central organelles for the storage and trafficking of lipid peroxides in ALD, and that BMX-001 therapy mitigates lipid peroxidation in hepatocytes. Furthermore, sex-specific differences exist with respect to EtOH-induced lipid peroxidation in male and female mice.

1566 | PATTERNS OF PRE-ALCOHOL-ASSOCIATED HEPATITIS HEALTHCARE UTILIZATION AND OUTCOMES AMONG ADOLESCENTS AND YOUNG ADULTS IN ONTARIO

Gabrielle Jutras[1] Maya Djerboua[2] Jennifer Lai[3] Norah Terrault[4] Oyedeji Ayonrinde[5] Jennifer Flemming[6], [1]University of California, San Francisco, [2]ICES, Queen's University, Kingston, Ontario, Canada, [3]Division of Gastroenterology and Hepatology, Department of Medicine, UCSF, [4]University of Southern California, [5]Department of Psychiatry, Queen's University, [6]Queen's University Cancer Research Institute

Background: Rates of alcohol-associated hepatitis (AH) in adolescents and young adults (AYAs) have tripled, with >20% dying in 5-years. Early identification and treatment of high-risk alcohol use and alcohol use disorder (AUD) may prevent AH. We examined pre-AH healthcare use among AYAs ultimately diagnosed with AH and described liver-related outcomes and mortality. **Methods:** Using Ontario administrative data (2000-2023), we identified AYAs (13-39 years) with a first AH presentation. Hierarchical agglomerative cluster analysis was used based on healthcare utilization in the 2-years preceding AH (emergency department [ED], hospitalizations, outpatient, etc.) to identify distinct patterns of usage. We described each cluster and evaluated 5-year outcomes post-AH (liver-related events, overall mortality) using cumulative incidence (CI) function estimates from competing risks analysis. **Results:** We included 3,340 AYAs with AH (median age 33, 36% female) and identified five distinct healthcare utilization clusters. In the two-years prior to AH, overall, 40% had alcohol-related ED visits (range between clusters: 27-80%) and 17% had alcohol-related admissions (6-65%). As outpatients, 86% saw a primary care provider (PCP) (81-97%), 19% saw a psychiatrist (1-84%), and 9% saw a gastroenterologist (GI)/hepatologist (0-89%). Five-year overall CI of mortality post-AH ranged from 15% to 31% ($p < .001$; Figure A). Liver-related events beyond six months post-AH ranged from 16% to 30% ($p < .001$; Figure B). The highest-mortality cluster (31%; cluster 5) included 40% females, 38% in the lowest income quintile, and 95% with mental illness. This cluster had the highest alcohol-related healthcare usage pre-AH (ED [80%], hospitalization [65%], outpatient [66%]), but only 10% received AUD pharmacotherapy and 14% saw GI/hepatology pre-AH. The cluster with the highest liver-related events (30%; cluster 4), 31% were female, 31% living in low-income areas and 63% had mental illness. Few had a GI/Hepatology visit pre-AH (23%), 3% received AUD pharmacotherapy, with 47% having an alcohol-related admission. **Conclusion:** Distinct patterns of healthcare use precede AH among AYAs. Despite extensive alcohol-related healthcare contact, many AYAs still present with AH, suggesting missed opportunities or limited effectiveness of current interventions on harmful alcohol use. These results can inform development of early identification and interdisciplinary intervention strategies to prevent AH.

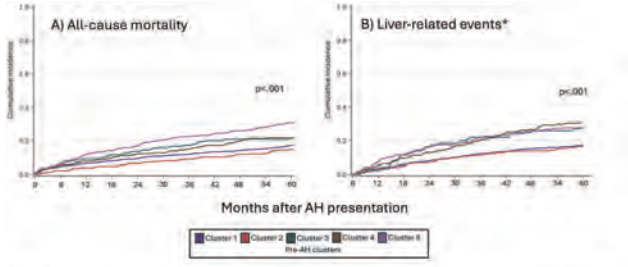

Figure: Cumulative incidence of a) mortality (competing event = liver transplant) and b) liver related events (competing event = non-liver related mortality) among adolescents and young adults with AH. *Liver events include cirrhosis, decompensation, liver transplant, hepatocellular carcinoma, liver-related death; AH: alcohol-associated hepatitis.

1567 | CLINICAL OUTCOMES BETWEEN ALCOHOL-ASSOCIATED LIVER DISEASE AND CHRONIC VIRAL HEPATITIS IN TAIWAN

Chun-Ming Hong[1] Tung-Hung Su[1] Shih-Jer Hsu[1] Tai-Chung Tseng[1] Chen-Hua Liu[1] Hung-Chih Yang[1] Shang-Chin Huang[2] Jia-Horng Kao[1] Chun-Jen Liu[1] Pei-Jer Chen[1], [1]National Taiwan University Hospital, [2]National Taiwan University Hospital Bei-Hu Branch

Background: Alcohol-associated liver disease (ALD) is becoming increasingly important after effective control of viral hepatitis. This issue has become even more serious after the COVID-19 pandemic. However, studies of ALD are not easily conducted in Taiwan because of lack of effective therapies and of stigma. On the contrary, managements towards viral hepatitis have been improving over the decades. Our study tried to investigate the difference between ALD and viral hepatitis and hence to improve managements towards ALD. **Methods:** We conducted a retrospective study by looking into Integrative Medical Database in National Taiwan University Hospital (NTUH-iMD) from 2009 to 2021. ICD-9 (International Classification of Diseases, ninth edition) and ICD-10 were used for disease coding. The inclusion criteria are patients whose diagnosis was made once at outpatient or inpatient and over 20 years old, while the exclusion criteria are those who had hepatocellular carcinoma (HCC), liver transplantation, or death before the index date. The index date was the first time when the patient was diagnosed inpatient or outpatient. **Results:** From 2009 to 2021, 63256 patients were enrolled. Among them, 3966 were ALD patients, 58853 had chronic viral hepatitis, and 437 had both ALD and chronic viral hepatitis. We further divided chronic viral hepatitis patients into several groups and each with/without antiviral therapy: chronic HBV/HCV co-infection, chronic hepatitis B, and chronic hepatitis C. As shown in Figure 1 and 2, patients with both ALD and chronic viral hepatitis had highest incidence of HCC and ALD patients had highest mortality. In addition, patients with both ALD and chronic viral hepatitis had highest incidence of liver transplantation. **Conclusion:** Our retrospective study presents a preliminary understanding of ALD versus chronic viral hepatitis in Taiwan. Compared to chronic viral hepatitis, ALD caused less HCC. However, ALD patients had the highest mortality indicating the cause of death in ALD patients was related to non-HCC mostly. Many unmet needs towards ALD warrant further studies.

1568 | SAFETY AND EFFECTIVENESS OF PHENOBARBITAL VS. BENZODIAZEPINES FOR SEVERE ALCOHOL WITHDRAWAL IN ALCOHOL-ASSOCIATED LIVER DISEASE

Rajalakshmi Govalan[1] Shengchen Hao[1] Michael Kenes[1] Jakob McSparron[1] Elliot Tapper[2], [1]University of Michigan, [2]University of Michigan Medical Center

Background: Severe alcohol withdrawal syndrome (SAWS) in patients with alcohol-associated liver disease (ALD) presents unique management challenges due to altered drug metabolism and increased drug-related toxicity. While benzodiazepines (BZDs) remain

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

standard treatment, concerns about over-sedation, hepatic encephalopathy, and respiratory depression have prompted interest in phenobarbital as an alternative. **Methods:** This retrospective cohort study utilized the MIMIC-IV database (2008–2019) to compare the safety and efficacy of phenobarbital versus BZDs in ICU patients with ALD and SAWS. Patients receiving either drug as initial treatment were identified. To reduce confounding, inverse probability of treatment weighting (IPTW) was applied based on propensity scores derived from logistic regression using all baseline variables. The model demonstrated good discrimination with an area under the curve (AUC) of 0.7636. Primary outcomes included in-hospital mortality, need for mechanical ventilation, ICU length of stay, and overall hospital stay. Weighted logistic regression was used for binary outcomes, and weighted linear regression models were used for continuous outcomes. **Results:** Among 763 phenobarbital-treated and 2,863 BZD-treated patients, in-hospital mortality was slightly lower for the phenobarbital group (OR 0.80; 95% CI: 0.63–1.01). Phenobarbital was associated with a reduced need for mechanical ventilation (34.7% vs. 39.3%; OR 0.82; 95% CI: 0.74–0.91), shorter duration of ventilation (3.0 vs. 3.8 days; $p = 0.0005$), ICU length of stay (3.6 vs. 4.2 days; $p < 0.0001$), and a trend towards slightly shorter hospital stay (9.3 vs. 9.8 days; $p = 0.05$). Among patients with decompensated cirrhosis and those with severe liver disease (MELD > 14), phenobarbital remained associated with improved ICU and ventilatory outcomes without significant difference in in-hospital mortality compared to benzodiazepines. **Conclusion:** In this large cohort study, the first to examine patients with severe liver disease, phenobarbital was associated with better respiratory and ICU outcomes than BZDs in ALD patients with SAWS, without increased mortality. These findings support phenobarbital as a promising alternative; prospective studies are warranted to confirm these results and guide clinical management.

1569 | HEPATIC SIRT7 PROMOTES PMN-MDSCS DIFFERENTIATION AND ALCOHOL RELATED LIVER INJURY VIA FXR-DEPENDENT BILE ACID METABOLISM

ZHUAN LI[1], [1]Hunan Normal University Healthy Science Center

Background: As the most recently identified subpopulation of neutrophil, polymorphonuclear myeloid derived suppressor cells (PMN-MDSCs) are crucial in regulating cancer progression via immunosuppression. Clinical evidence has suggested PMN-MDSCs involves in alcohol related liver disease (ALD) but the precise mechanisms remain elusive. The aim of the current study was to investigate mechanisms underly PMN-MDSCs differentiation and their role in ALD. **Methods:** $SIRT7^{flox/flox}$ mice were crossed with Alb-Cre mice to generate liver-specific SIRT7 gene knockout mice (Alb-$SIRT7^{-/-}$). Mice were fed with *Liber DeCarlie* diet for 4 week and the liver injury were assessed by ALT levels and histological evaluation. Unbiased metabolomics was used to identified changes in bile acid synthesis and metabolism. Western blot and qRT-PCR were utilized to evaluate protein and mRNA expression while Co-IP was employed to assess protein-protein interaction. Primary hepatic cells were isolated and evaluated and in vitro co-culture system was utilized to evaluate cell-cell communications. **Results:** Knockdown of SIRT7 in hepatocyte significantly impaired expression of genes that responsible for bile acid synthesis including *CYP27A1* and *CYP7A1*. Through unbiased metabolomics, we revealed that components of bile acid were significantly changed and secretion of deoxycholic acid (DCA) were decreased in Alb-$SIRT7^{-/-}$ mice. After 4 weeks of *Liber DeCarlie* alcohol feeding, Alb-$SIRT7^{-/-}$ mice exhibited significantly ameliorated alcohol induced liver injury and inflammation, which was associated with decreased expression of CD300ld, a recently identified PMN-MDSCs surface marker. Primary neutrophile isolated from mice after alcohol confirmed that PMN-MDSCs activation were significantly repressed in Alb-$SIRT7^{-/-}$ mice. Most importantly, we found that DCA was sufficient to promote PMN-MDSCs differentiation and activation *in vitro*. At molecular level, we demonstrated that SIRT7 interacted with and induced FXR deacetylation which was critical in regulating of bile acid synthesis via suppression of *CYP27A*, *CYP8B1* and *NTCP* gene expression. Finally,

we found that expression of CD300ld were significantly elevated in clinical samples from ALD patients. **Conclusion:** Our data thus uncovered previously unidentified role of hepatic SIRT7 in promoting PMN-MDSCs differentiation and ALD progression via FXR deacetylation and bile acid metabolism. Targeting SIRT7 mediated FXR modulation and bile acid metabolism might offer therapeutic options against ALD.

1570 | AGE RELATED IMPACT OF OUTCOMES IN HOSPITALIZED PATIENTS WITH CIRRHOSIS AND ALCOHOL-ASSOCIATED LIVER DISEASE

Dhweeja Dasarathy[1], [1]*Stanford University, Department of Medicine*

Background: The prevalence and incidence of alcohol-use disorder (AUD) and alcohol-associated liver disease (ALD) continue to increase in the United States. Among patients with chronic liver disease, ALD is one of the most frequent etiologies. There is limited data on the incidence and consequences of alcohol intoxication and AUD in the hospitalized aging population, especially in those with liver disease. We investigated the impact of aging on clinical outcomes in a cohort with alcohol-associated liver injury. **Methods:** Data from 1/2017 to 12/2020 from the Nationwide Inpatient Sample were analyzed. Baseline population included patients (18–80 years old) with a clinical diagnosis of AUD (n = 523,464), without AUD (n = 238,678), alcoholic cirrhosis (n = 73,094), and ALD (n = 15,411) as defined by ICD-10 discharge codes. Primary and secondary diagnoses with ICD codes were analyzed. Clinical outcomes (length of stay, healthcare cost, mortality, sarcopenia, and frailty) were analyzed. Multivariate regression analyses were performed for each age category to identify independent associations with ALD and cirrhosis on clinical outcomes. **Results:** Among patients across all age groups with cirrhosis and ALD, healthcare utilization, social determinants of health, and comorbidities, as determined by the Elixhauser score, were significantly higher. As age increased, there was a stepwise increase in sarcopenia and frailty, with the highest prevalence in those with ALD > 70 years old (Figure 1). For all age categories, there was an independent effect of AUD associated with adverse outcomes, including sarcopenia, frailty, healthcare cost, length of stay, and discharge status. We then performed multivariate regression analyses stratified by age, and adjusted for race, sex, and comorbidities. We noted that AUD, AUD and ALD, AUD and alcoholic cirrhosis each increased risk for adverse clinical outcomes significantly. When controlling for aging, AUD, AUD and ALD, and AUD and cirrhosis also were highly associated with a diagnosis of sarcopenia, frailty, or both sarcopenia and frailty. **Conclusion:** We noted a significant association between ALD and cirrhosis on adverse clinical outcomes with increasing age including sarcopenia, frailty, and healthcare utilization. A diagnosis of sarcopenia and frailty conferred greater mortality risk than either alone in patients with ALD or cirrhosis with increasing age. Our findings highlight the need for targeted alcohol interventions in the aging population, especially in those with liver disease.

1571 | PHOSPHATIDYLETHANOL PREDICTS SHORT-TERM HEPATIC DECOMPENSATION BUT SHOWS RAPID DECLINE IN PROGNOSTIC DISCRIMINATION

Nikolaj Torp[1] Stine Johansen[1] Ellen Lyngbeck Jensen[1] Georg Semmler[1] Katrine Tholstrup Bech[1] Markus Maagaard[1] Helle Schnefeld[1] Katrine Prier Lindvig[1] Katrine Thorhauge[1] Ellen Elise Petersen[1] Johanne Kragh Hansen[1] Ida Falk Villesen[1] Peter Andersen[1] Diana Leeming[2] Morten Karsdal[2] Camilla Dalby Hansen[1] Maja Thiele[1] Mads Israelsen[1] Aleksander Krag[1], [1]Odense University Hospital, [2]Nordic Bioscience

Background: Phosphatidylethanol (PEth) reflects recent alcohol intake, while transient elastography (TE), ELF, and PRO-C3 are non-invasive tests (NITs) for liver fibrosis. The combined utility of PEth and liver fibrosis NITs for predicting hepatic decompensation and all-cause mortality, as well as the time-dependent prognostic performance of PEth, is unknown. **Methods:** We included 411 adults at risk of SLD due to a history of excessive alcohol consumption ($\geq$36 g/day men, $\geq$24 g/day women for $\geq$1 year). Known chronic liver disease and prior hepatic decompensation were key exclusion criteria. PEth, TE, ELF and ELISA PRO-C3 (Nordic-PRO-C3^{TM}) were measured at baseline. PEth was considered moderate-high if $\geq$80 ng/mL and high if $\geq$200 ng/mL. NIT cut-offs for liver fibrosis were TE $\geq$15 kPa, ELF $\geq$9.8, PRO-C3 $\geq$15.6 ng/mL. Hepatic decompensation (Baveno VII criteria) and mortality was assessed for up to 5 years. Competing risk (death prior to decompensation), Cox regression and time-dependent AUCs evaluated prognostic performance. **Results:** Median age was 58 years, 76% were male. Median PEth was 338 ng/mL, where 70% had a moderate-high PEth ($\geq$80 ng/mL) and 59% a high ($\geq$200 ng/mL). NITs suggestive of liver fibrosis were found in 22% (TE), 33% (ELF), 38% (PRO-C3). During follow-up, 60 patients died (15%) and 49 (12%) developed hepatic decompensation: ascites (n=27), encephalopathy (n=13), variceal bleed (n=9). PEth predicted hepatic decompensation (sHR=1.03, 95% CI: 1.01-1.06) and all-cause mortality (aHR=1.04, 95% CI: 1.02-1.06) independently of all NITs. A combined high PEth ($\geq$200 ng/mL) and elevated NIT (TE $\geq$15 kPa/ELF $\geq$9.8/PRO-C3 $\geq$15.6 ng/mL) identified a subgroup at high risk of decompensation within 1 year (PEth+TE: n=11/52, 21%; PEth+ELF: n=12/82, 15%; PEth+PRO-C3: 13/95, 14%). No additional decompensation episodes within 1 year were captured by using the moderate-high PEth threshold of $\geq$80 ng/mL (PEth+TE: n=11/57, 19%; PEth+ELF: n=12/92, 13%; PEth+PRO-C3: 13/105, 12%). Notably, the time-dependent AUC for hepatic decompensation declined for PEth from 0.77 at 0.5 years to 0.69 after 1 year and further to 0.62 at 2 years (Figure). At the same time, the time-dependent AUC for the liver fibrosis NITs remained stable throughout at around 0.90. **Conclusion:** PEth predicts hepatic decompensation and all-cause mortality independently of liver fibrosis NITs. Using established cut-offs for PEth and NITs identifies individuals at high short-term risk of decompensation. However, the prognostic discrimination of PEth diminish rapidly over time, underscoring the need for repeated PEth measurements to accurately risk stratify patients.

1572 | CLINICAL OUTCOMES ACROSS ORGAN SYSTEMS IN ALCOHOL-ASSOCIATED LIVER DISEASE WITH METABOLIC RISK

Pojsakorn Danpanichkul[1] Donghee Kim[2] Krittameth Rakwong[3] Peerapun Jit-are-roon[3] Phuuwadith Wattanachayakul[4] Thitiphan Srikulmontri[4] Shu-Yen Chan[5] Vincent Chen[6] Christos Mantzoros[7] Mazen Noureddin[8] Karn Wijarnpreecha[9], [1]Texas Tech University Health Sciences Center, [2]Stanford University Medical Center, [3]Chiang Mai University, [4]Jefferson University, [5]Weiss Memorial Hospital, [6]University of Michigan, [7]BIDMC, [8]Houston Methodist Hospital, [9]University of Arizona College of Medicine-Phoenix

Background: Alcohol-associated liver disease (ALD) is a major cause of liver-related morbidity and mortality. The impact of metabolic risks in ALD remains poorly understood. This study aimed to evaluate the association between metabolic risk and outcomes in patients with ALD. **Methods:** We conducted a retrospective cohort study using the TriNetX research network. Adults with ALD were stratified by the presence or absence of metabolic risk factors. Propensity score matching (1:1) balanced demographics, comorbidities, and medication use. The primary outcome was all-cause mortality; secondary outcomes included alcohol-associated hepatitis (AH), cardiovascular complications, infections, and major adverse liver outcomes (MALO). Cox proportional hazards models estimated hazard ratios (HR) and 95% confidence intervals (CI) over a 1-year follow-up. **Results:** After matching, 3,532 patients (1,766 per group) were included. No significant difference in all-cause mortality was observed between groups (HR: 1.20, 95% CI: 0.98–1.48, $p = 0.073$). However, ALD with metabolic risk was associated with higher risks of MALO (HR: 1.67, 95% CI: 1.31–2.13, $p < 0.001$), AH (HR: 2.04, 95% CI: 1.64–2.54, $p < 0.001$), major adverse cardiovascular events (HR: 2.64, 95% CI: 1.60–4.34, $p < 0.001$), and sepsis (HR: 4.07, 95% CI: 2.30–7.21, $p < 0.001$). **Conclusion:** Among patients with ALD, metabolic risk was associated with markedly higher hepatic, cardiovascular, and infectious complications. These findings highlight the need to recognize ALD with metabolic risk as a distinct high-risk subgroup requiring targeted clinical and public health strategies.

1573 | ABSTRACT WITHDRAWN

1574 | MULTICENTER VALIDATION OF PREDICTION MODELS FOR TRANSPLANT-FREE SURVIVAL IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS

Elina Stoffel[1] Olivia Blocker[2] Himel Mallick[2] Jialin Gao[2] Ziyu Liu[2] Robert Brown[2] Gene Im[3] Elizabeth Verna[1] Stephanie Rutledge[2], [1]Columbia University Medical Center, [2]Weill Cornell Medicine, [3]Center for Liver Disease and Transplantation, Division of Digestive and Liver Diseases Columbia Univ

Background: Alcohol-associated hepatitis (AH) is the fastest-growing indication for liver transplantation (LT) in the United States. Patients with severe AH (sAH), especially with acute-on-chronic liver failure (ACLF), face high short-term mortality risk. Among patients not responding to medical therapy, few qualify for early LT, and outcomes in those declined are poorly defined. A single center prediction model

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

found that adding age to MELD score or ACLF grade enhances survival prediction at the time of waitlisting decision. We aimed to validate MELD-Age and ACLF-Age models in predicting transplant-free survival (TFS) in patients with sAH evaluated for early LT. **Methods:** We conducted a retrospective cohort study of patients >18 years old hospitalized with probable or definite sAH (per NIAAA criteria, MELD >20) who underwent eLT evaluation at two centers between January 2012 and May 2025. We analyzed 180-day TFS as a composite endpoint using Cox regression. Model performance was assessed using a time-dependent area under the receiver operating characteristic curve (AUROC). **Results:** Between 2012 and 2025, 133 patients with sAH were evaluated for eLT: 82/133 (61%) were accepted, 36/133 (27%) were declined and 15/133 (11%) were deferred. Of those deferred, 3/15 (20%) were later accepted. Overall, 65/133 (48%) underwent LT. The most common reasons for denial or deferral were psychosocial factors (35/51, 69%) and medical contraindications (10/51, 20%). The mean age was 44 years (SD 10) and 37% were female. 57% of patients identified as White, 16% as Black, and 7.5% as Hispanic. 58% were treated with corticosteroids. The mean MELD 3.0 was 32.6 (8.0) and mean Maddrey's DF (MDF) was 85 (56). A total of 95/133 (71%) patients met criteria for ACLF, of whom 51/133 (37%) had grade 2 or 3. Median time from admission to listing decision was 12 days (IQR 7-19.3). Over a median follow-up of 528 days (IQR 1-1161), 27/133 (20%) patients died, with 17/27 (63%) dying during index admission. The 90- and 180-day cumulative incidence of death was 12.8% and 15%, respectively. For 180-day TFS, AUROC for MELD-Age was 0.69, and 0.61 for ACLF-Age, but MELD 3.0 performed best (AUROC of 0.74). **Conclusion:** Patients with sAH evaluated for eLT have high short-term mortality. In this cohort, MELD 3.0 performed better than ACLF in predicting 180-day transplant-free survival, perhaps because of relatively low numbers with ACLF grade 2 or 3. Interestingly, adding age to MELD 3.0 or ACLF grade worsened their predictive ability. This may be because the scores incorporating age were originally designed to evaluate the natural history of sAH in the absence of eLT and it is likely that some of this cohort who underwent eLT (probably the younger patients) would have survived to 180 days. As a subset will recover without eLT, more accurate survival prediction is needed to guide decision-making in sAH and ensure judicious use of scarce organs.

Background: The natural history of metabolic dysfunction and alcohol-associated liver disease (MetALD) remains poorly characterized. In a large global cohort, we compared the natural history of the main steatotic liver disease (SLD) subtypes in terms of liver fibrosis progression, hepatic decompensation, and incidence of hepatocellular carcinoma (HCC). **Methods:** This is a retrospective cohort study of well-characterized adult participants with SLD evaluated between 2003 and 2025, including metabolic dysfunction-associated steatotic liver disease (MASLD), MetALD, and alcohol-associated liver disease (ALD) according to the 2023 SLD criteria. Sociodemographic and clinical data, vibration-controlled transient elastography (VCTE) parameters, and liver biopsy (when available) were recorded. Patients with other causes of liver disease (including viral hepatitis) were excluded. The primary outcome was progression to cirrhosis in those without cirrhosis at baseline (defined by 1. liver biopsy, or 2. VCTE $\geq$13.6 kPa, or Fibrosis-4 [FIB-4] $>$3.25 if other techniques were missing). Secondary outcomes were incidence of hepatic decompensation (ascites, hepatic encephalopathy, variceal bleeding, or hepatorenal syndrome) and HCC. A multivariable Cox regression adjusted by age, sex, race, body mass index, diabetes, hypertension, hyperlipidemia, and smoking (for HCC) was performed. **Results:** The total cohort included 150,306 participants from 15 countries; 87.5% MASLD, 7.9% MetALD, and 4.6% ALD. Overall, the median age was 61 years [IQR 51–70]; 52.8% men, and 97.6% Asian. At baseline, 12.2% of the cohort had a liver biopsy with F4 or a VCTE/FIB-4 suggestive of cirrhosis. During a median follow-up of 2.1 years [IQR 0.6–4.7], 0.9% of participants progressed to cirrhosis, 0.4% had hepatic decompensations, and 1.3% developed HCC. Individuals with MetALD and ALD exhibited a higher risk of progression to cirrhosis (MetALD aHR 1.34, 95%CI: 1.06–1.68, $p=0.013$; ALD aHR 1.82, 95%CI: 1.41–2.35, $p<0.0001$; MASLD: reference) and of hepatic decompensation (MetALD aHR 9.33, 95%CI: 6.32–13.75, $p<0.0001$; ALD aHR 20.56, 95%CI: 13.86–30.48, $p<0.0001$) (Figure). The incidence of HCC was higher in individuals with ALD than MASLD (aHR 1.26, 95%CI: 1.02–1.55, $p=0.029$). **Conclusion:** In this multi-ethnic global cohort, MetALD and ALD were associated with more rapid cirrhosis progression and greater decompensation rates than MASLD, independent of cardiometabolic factors. These findings may support early intervention in MetALD and ALD.

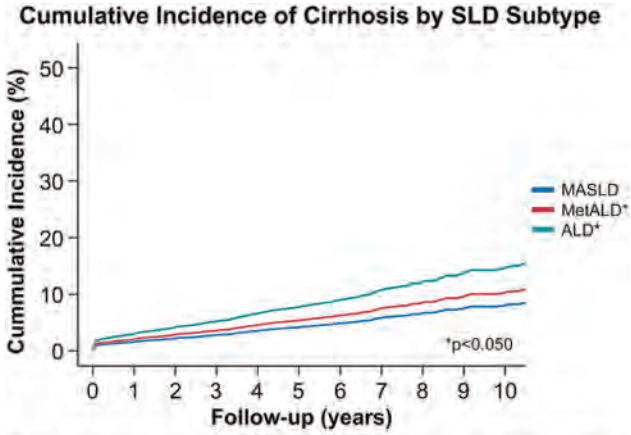

Figure. Cumulative incidence of incident cirrhosis by steatotic liver disease subtype. Participants with baseline cirrhosis—defined by (1) histologic stage F4, (2) liver stiffness ≥13.6 kPa on vibration-controlled transient elastography, or (3) Fibrosis-4 index >3.25—were excluded. Cox models were adjusted for age, sex, race, body mass index, diabetes, hypertension, and hyperlipidemia.

1576 | GREATER LIVER DISEASE–RELATED STIGMA AMONG PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE COMPARED TO NON–ALCOHOL-RELATED LIVER DISEASE

Wei Zhang[1] Kelly Hsu[2] Edward Wu[1] Ellen Zhen[1] Ana Ivkovic[1] Heidi Yeh[1] Emily Bethea[1] Sarah Wakeman[1] Russell Goodman[1] Esperance Schaefer[1] Jay Luther[1] Nneka Ufere[1] Raymond Chung[1] Annie Fox-Galalis[3], [1]Massachusetts General Hospital, [2]Tuft University School of Medicine, [3]MGH Institute of Health Professions

Background: Stigma is a critical barrier to care in patients with liver disease, particularly for those with alcohol-associated liver disease (ALD). ALD carries

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

added layers of moral judgment and blame, often rooted in perceptions of personal responsibility for illness. While prior studies have described stigma in patients with ALD, few have quantitatively assessed stigma severity across liver disease etiologies using a validated, liver-specific instrument. Understanding how stigma differs by etiology is essential to developing equitable, stigma-informed care. **Methods:** We administered the Liver Disease Stigma Scale (LDSS), a newly developed 28-item instrument assessing internalized, anticipated, and experienced stigma, to 221 adults with liver disease at a tertiary care center. The sample included 133 patients with ALD and 88 with non–alcohol-related liver disease (non-ALD). Compared to non-ALD participants, the ALD group was more likely to be male and have lower educational attainment ($p < .01$). LDSS subscale scores were compared between groups using t-tests. We also examined attitudes toward liver disease and liver disease treatment using theory-informed, pilot-tested measures designed to assess negative treatment beliefs and perceived undeservingness. **Results:** Patients with ALD reported significantly higher stigma across all LDSS subscales, including experienced stigma (mean [SD]: 1.75 [0.90] vs. 1.23 [0.46], $p < .001$), anticipated stigma (1.57 [0.77] vs. 1.24 [0.50], $p < .001$), and internalized stigma (2.34 [1.12] vs. 1.54 [0.84], $p < .001$). Differences were observed in both family- and healthcare-related stigma domains. ALD patients also endorsed more negative attitudes toward liver disease (2.11 [0.87] vs. 1.44 [0.59], $p < .001$) and liver disease treatment (1.38 [0.54] vs. 1.21 [0.39], $p = .008$). **Conclusion:** Patients with alcohol-associated liver disease experience significantly greater liver disease–related stigma than those with non–alcohol-related liver disease. These findings highlight the role of stigma as a modifiable barrier to equitable care in ALD and emphasize the need for etiology-sensitive, stigma-reducing interventions within hepatology.

Table: Comparison of liver disease stigma and treatment attitudes between patients with alcohol-associated liver disease (ALD) and non–alcohol-related liver disease (non-ALD).

Mechanism	ALL	ALD	Non-ALD	P value
LD Experienced Stigma	1.54 (0.79)	1.75 (0.90)	1.23 (0.46)	<0.001
LD Experienced Stigma-Family	1.55 (0.91)	1.79 (1.07)	1.19 (0.37)	<0.001
LD Experienced Stigma-Healthcare	1.53 (0.85)	1.71 (0.93)	1.27 (0.62)	<0.001
LD Anticipated Stigma	1.44 (0.69)	1.57 (0.77)	1.24 (0.50)	<0.001
LD Anticipated Stigma-Family	1.40 (0.74)	1.53 (0.85)	1.20 (0.46)	<0.001
LD Anticipated Stigma-Healthcare	1.48 (0.78)	1.61 (0.87)	1.28 (0.60)	0.002
LD Internalized Stigma	2.01 (1.09)	2.34 (1.12)	1.54 (0.84)	<0.001
Attitudes toward LD Treatment	1.31 (0.49)	1.38 (0.54)	1.21 (0.39)	0.008
Attitudes toward LD	1.84 (0.84)	2.11 (0.87)	1.44 (0.59)	<0.001

1577 | LOSS OF MAP3K8 IN MYELOID CELLS PROTECTS AGAINST PRECLINICAL ALD AND METALD

Alejandro H. Gutierrez[1] Sara García[1] Douglas Maya Miles[2] Javier Vaquero[3] Rafael Bañares Cañizares[3] Rocío Gallego Durán[2] Javier Ampuero Herrojo[2] Manuel Romero-Gómez[2] Yulia Nevzorova[1] Carlos Sanz-García[1] Francisco Javier Cubero[1], [1]Department of Immunology, Ophthalmology & ORL, Complutense University of Madrid, Madrid, Spain, [2]Instituto de Biomedicina de Sevilla, IBiS/Hospital Virgen del Rocío/CSIC/University Sevilla, Spain, [3]Servicio de Aparato Digestivo, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Heterogeneity of macrophages and other immune cells is a recently reported hallmark of alcohol-related liver disease (ALD) and metabolic dysfunction and alcohol-related steatotic liver disease (MetALD). MAP3K8, also known as TPL2 or COT, is a serine/threonine kinase (STK) which plays a critical role in the regulation of the immune response. Here, we investigated the cell-specific role of MAP3K8 in macrophages and myelomonocytic cells during ALD/MetALD. **Methods:** C57BL/6J mice with specific deletion of MAP3K8 in Kupffer ($\Delta^{\varnothing}$) and myeloid cells (Δ^{LysM}), and its respective controls (floxed mice, $\Delta^{f/f}$) were generated. Two experimental models of ALD (Lieber-DeCarli diet for 4 days and 25 days) and MetALD (DuAL model for 23 weeks). Samples were processed for histopathological examination and protein (IF, IHC and WB), mRNA expression was evaluated by qRT-PCR and flow citometry. The expression of MAP3K8 was analyzed in cohorts of ALD and MetALD patients. **Results:** Δ^{LysM} mice showed significantly reduction markers of liver injury (AST, ALT, LDH), liver inflammation (BW/LW ratio), cytokines and immune cell infiltration ($CD45^+$ and $CD11b^+$ cells), cell death (necrosis, TUNEL) and cell proliferation (PCNA, Ki-67), associated to pERK1/2 overexpression and downregulation of pJNK compared with $\Delta^{f/f}$ animals, both in preclinical ALD and MetALD. Moreover, collagen deposition - evaluated as Sirius red (SR) staining – and markers of hepatic fibrosis and hepatic stellate cell (HSC) activation including αSMA were significantly reduced in Δ^{LysM} mice, after 23w of DuAL diet. On the other hand, $\Delta^{\varnothing}$ mice displayed overexpression of pERK and downregulation of pJNK without variations in markers of liver injury, inflammation, cell death or fibrosis. Moreover, a significant increase in MAP3K8/pERK/pJNK expression was observed in patients with MetALD, specifically

associated with high NAS and fibrosis score, and cirrhosis. **Conclusion:** Depletion of MAP3K8 in Δ^{LysM} positive cells protected against ALD and MetALD by decreasing liver injury, inflammation, and fibrosis via activation of ERK phosphorylation, indicating that MAP3K8 could be a novel therapeutic avenue for the treatment of these liver diseases.

1578 | INFECTION AS A PREDICTOR OF MORTALITY AND DECOMPENSATION IN ALCOHOL-ASSOCIATED HEPATITIS WITH LEUKOCYTOSIS

Romelia Barba[1] Khawaja Hassam[2] Pojsakorn Danpanichkul[3] Ana Marenco-Flores[4] Natalia Rojas-Amaris[4] Denisse Rubio Cruz[4] Zeyad Elharabi[1] Gloria Erazo[1] Kanak Das[1] Hakan Akin[1], [1]Texas Tech University, [2]Lahey Hospital and Medical Center, [3]Texas Tech University Health Sciences Center, [4]Beth Israel Deaconess Medical Center

Background: Alcohol-associated hepatitis (AH) is a severe inflammatory liver condition often presenting with leukocytosis. While leukocytosis supports the diagnosis of AH, it may also signal a superimposed bacterial infection —a critical distinction, as corticosteroids, the only specific treatment for severe AH, are contraindicated in the presence of infection. Differentiating systemic inflammation from infection is clinically challenging, and misclassification may lead to inappropriate immunosuppression or delayed treatment. Despite this, limited large-scale data exist on the burden and prognostic implications of infection among AH patients with leukocytosis. We aimed to evaluate the prevalence and outcomes associated with infection in this high-risk population using a national real-world dataset. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network, a federated EHR platform comprising 67 healthcare organizations. Adults ($\geq$18 years) with AH (ICD-10 K70.10 or K70.11) and leukocytosis (WBC $\geq$12 x10³/μL) between 2016–2025 were included. Patients were stratified by the presence or absence of documented infection (e.g., sepsis, pneumonia, spontaneous bacterial peritonitis [SBP], UTI) occurring within $\pm$2 days of AH diagnosis. Outcomes included 28- and 90-day all-cause mortality (primary), major adverse liver outcomes (hepatic encephalopathy, ascites, gastrointestinal bleeding, and hepatorenal syndrome), hepatorenal syndrome (HRS), and liver transplant (secondary). Kaplan-Meier and Cox proportional hazards analyses were performed. **Results:** Among 12,329 hospitalized patients with AH and leukocytosis, 5,334 (43.3%) had a documented infection. The most common infections were sepsis (30%), followed by pneumonia (15%), UTI (11%), and SBP (8%); less frequent infections included bacteremia (6%), cellulitis (3%), and C. *difficile* (3%) (Figure 1). At 28 days, AH patients with infection had significantly higher mortality (39.81% vs. 20.59%; HR 2.18, 95% CI 2.02-2.34, $p < 0.001$), a trend that persisted at 90 days (52.16% vs. 27.51%; HR 2.25, 95% CI 2.11–2.40, $p < 0.001$). Infection was also associated with higher rates of liver-related complications (46.45% vs. 29.81%; HR 1.78, 95% CI 1.67-1.89, $p < 0.001$), and ICU admission (40.42% vs. 14.03%; HR 3.46, 95% CI 3.19-3.75, $p < 0.001$) (Figure 2). Liver transplant rates were low and similar between groups (0.6% vs. 0.3%; HR 2.12, 95% CI 1.11-4.07, $p = 0.02$). **Conclusion:** Our findings showed that infection was present in over 40% of hospitalized AH patients with leukocytosis and was associated with significantly increased mortality and complications. The early excess in mortality among those with infection was especially notable.

1579 | SIRPA$^{-/-}$ MICE DEVELOPED EXACERBATED ALCOHOL-ASSOCIATED HEPATITIS ASSOCIATED WITH EXCESSIVE INFLAMMATION

Josiah Hardesty[1] Rui Treves[1] Tyler Gripshover[1] Ashwani Singal[1], [1]University of Louisville

Background: Alcohol-associated hepatitis (AH) is a clinical manifestation of alcohol-associated liver disease (ALD) that has poor prognosis. Corticosteroids are a standard anti-inflammatory treatment used for AH patients; however, corticosteroids have limited efficacy in preventing disease progression. There is a need to

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

identify new therapeutic targets and to improve the treatment options for AH patients. Signal regulatory protein alpha (SIRPa) is an immune cell receptor that regulates efferocytosis and inflammatory responses. SIRPa is cleaved by ADAM metallopeptidase domain 10 (ADAM10) and released into the plasma in inflammatory conditions but has not yet been studied in ALD. We hypothesized that *Sirpa*$^{-/-}$ mice would develop exacerbated AH and use of an ADAM10 inhibitor would restore immunological balance. **Methods:** WT and whole body *Sirpa*$^{-/-}$ male and female experimental mice were used in an experimental model of AH. Mice were fed an 5% ethanol (EtOH) diet for 11 days and injected with galactosamine (500 mg/kg) on days 9-11 to induce parenchymal necrosis. On day 11 mice received an oral gavage of EtOH (5 g/kg) and were euthanized 9 hours later followed by tissue collection, cryopreservation, and analysis. Mouse immune cells were assayed for inflammatory endpoints. **Results:** *Sirpa*$^{-/-}$ mice developed impaired liver function (reduced albumin) and enhanced liver injury (increased ALT), and exacerbated inflammation (increased liver TNFa and IL-1b). WT bone marrow-derived macrophages (BMDMs) treated with EtOH+lipopolysaccharide (LPS) had increased SIRPa release into the supernatant and elevated ADAM10 activity. Further, Mouse peripheral blood mononuclear cells (PBMCs) from *Sirpa*$^{-/-}$ mice had increased EtOH+LPS induced TNFa production but reduced IL-4 production *ex vivo*. In mouse PBMCs pretreated with an ADAM10 inhibitor (GI254023X), there was a reduction in EtOH+LPS induced SIRPa and TNFa release, but an increase in IL-4 *ex vivo*. **Conclusion:** Mice with ablated *Sirpa* developed exacerbated AH in this experimental ALD model. Pro-inflammatory cytokine production was higher in *Sirpa*$^{-/-}$ mice and immune cells. Treatment with an ADAM10 inhibitor reduced SIRPa shedding *ex vivo* and may be a potential therapeutic option. Future studies are required to identify how cleavage or loss of SIRPa expression contributes to AH pathogenesis.

1580 | FECAL MICROBIOTA TRANSPLANT FROM SPECIFIC HUMAN DONORS REDUCE ALCOHOL PREFERENCE AND INTAKE IN CONVENTIONAL FEMALE MICE

Lauren May[1] Alexander Khoruts[2] Jennifer Wolstenholme[1] Jasmohan Bajaj[1], [1]Virginia Commonwealth University, [2]University of Minnesota

Background: Reducing alcohol consumption in patients with cirrhosis and alcohol use disorder (AUD) is critical to improve long-term prognosis. But current therapies have modest success. In a phase 1b trial, fecal microbiota transplant (FMT) from one donor reduced alcohol intake in men with cirrhosis, which was transmitted to germ-free (GF) male mice. However, we need to expand donor-recipient matching, use non-GF mice to ensure immune system integrity, and study females. Aim: Define impact of differing human FMT donors on alcohol consumption in conventional female mice. **Methods:** Adult female C57BL/6 mice (10-15 wks, n = 10-12/group) were treated with a course of antibiotics (ABX) prior to FMT administration to encourage FMT donor engraftment (Fig. A). The antibiotics were a cocktail of absorbable (ampicillin, cefoperazone & clindamycin hydrochloride) and non-absorbable (ertapenem, neomycin & vancomycin) ones that have been shown to allow engraftment in conventional mice. Three healthy human donor stools from a GMP facility were selected. These donors are in the pool for clinical human FMT studies. These stools were administered to female mice via gavage for 3 days and voluntary alcohol intake and preference were assessed for 4 weeks using the validated 2-bottle choice (2B-C) test. This test evaluates a weight-dependent (alcohol intake) and weight independent (preference) analysis of alcohol intake. Additional behavioral testing to measure locomotive and anxiety-like behaviors were also assessed using open-field test after FMT and during alcohol drinking sessions. We had 5 groups: no-ABX or control, ABX then PBS, and 3 groups of ABX followed by individual FMT donors (Donors 1, 2 or 3). **Results:** All mice tolerated ABX and subsequent FMT procedures. Following one week of FMT, alcohol intake and preference were decreased in mice following the FMT. Antibiotic treatment decreased alcohol intake and preference in all groups, however, FMT donor 1 further significantly decreased alcohol preference as compared to mice given antibiotics but no FMT. FMT donor 1 significantly reduced alcohol preference which peaked in weeks two and three, but was attenuated at the four week timepoint (Fig C/D). Alcohol intake showed a similar trend, but did not reach significance since administration of ABX slightly increased body weights in all groups (Fig B). Other behavioral tests: we report no changes in anxiety phenotypes or locomotor behavior following FMT engraftment or alcohol drinking. **Conclusion:** FMT from specific healthy humans resulted in reduced alcohol preference and intake in female conventional mice after a validated antibiotic pre-treatment protocol. This effect was restricted to stools from one donor but not the rest. The study provides a model for donor-recipient matching for human FMT studies using immunocompetent mice that include both sexes.

1581 | PRIVATE INSURANCE AND A DIAGNOSIS OF ALCOHOL-ASSOCIATED HEPATITIS ARE ASSOCIATED WITH HIGHER PARTICIPATION IN VIRTUAL GROUP-BASED POST-LIVER TRANSPLANT RELAPSE PREVENTION THERAPY

Sasha Deutsch-Link[1] Sophia Hurr[1] Heather Gallagher[1] Ellen Green[2] Christian Hendershot[3] Marie-Josee Lynch[4] Daniel Velez[1] Hersh Shroff[1], [1]UNC Chapel Hill, [2]University of North Carolina, Chapel Hill, NC, USA, [3]Keck School of Medicine at USC, [4]University of Toronto

Background: Early liver transplant (LT) for alcohol-associated hepatitis (AAH) is associated with favorable outcomes in select patients with minimal abstinence prior to LT. As a result, there is a growing trend toward transplanting patients for alcohol-associated liver disease (ALD) with more severe alcohol use disorder (AUD), including some who have received little to no formal AUD treatment before LT. These patients are particularly likely to benefit from robust post-transplant AUD treatment; however, standardized treatment protocols in this setting remain limited. In response to this need, our center implemented a monthly group-based relapse prevention therapy (RPT) program for liver transplant recipients (LTRs) transplanted for ALD. This study examines patient-level factors associated with post-LT RPT participation. **Methods:** Our transplant center's psychosocial team contacted LTRs transplanted for ALD about their interest in a monthly virtual group-based RPT program. A licensed clinical addictions specialist (LCAS) completed individual assessments of each patient at enrollment. Monthly virtual counseling sessions were conducted by a LCAS. The RPT manual was previously developed by an external organ donation agency for use in LT candidates and modified for our center's purposes (with permission). Baseline chart review variables were collected via our center's electronic health record. A joint effects multivariable logistic regression assessed patient-level factors associated with group-based RPT attendance defined as attending at least 25% of counseling sessions. **Results:** Of 46 patients contacted, 19 (41%) decided to enroll, 14 (30%) attended at least one group counseling session, and 12 (26%) attended at least 25% of counseling sessions. 28 (61%) of patients were male and 33 (72%) were transplanted for alcohol-associated cirrhosis and 13 (28%) for AAH. A joint effects multivariable logistic regression model demonstrated that private insurance (OR 6.16, 95% CI 1.02-37.32) and a diagnosis of AAH (OR 6.78, 95% CI 1.30-35.43, compared to ALD cirrhosis) were associated with increased likelihood of RPT attendance. Alcohol relapse post-LT prior to intervention enrollment was associated with reduced RPT attendance (OR 0.13, 95% CI 0.01-1.67), but this did not reach statistical significance. (Table 1). **Conclusion:** In an era of rising LT for ALD in patients with higher-risk AUD profiles, optimizing post-LT AUD treatment is imperative. Our study demonstrated that a virtual monthly group-based RPT program was more likely to be attended by patients with private insurance and a diagnosis of alcohol-associated hepatitis; post-LT alcohol relapse may reduce participation. This study highlights the need for diverse treatment paradigms to meet the needs of patients who have relapsed ato alcohol post-LT, who are on public insurance, and with a pre-LT diagnosis of ALD cirrhosis.

Table 1. Patient-Level Factors Associated with Post-Liver Transplant Virtual Group-Based Relapse Prevention Therapy Attendance

Variable	Odds Ratio	P-Value	95% CI
Final/Reduced Model			
Private insurance	6.16	0.048	1.02-37.32
Alcohol-Associated Hepatitis	6.78	0.023	1.30-35.43
Alcohol relapse prior to intervention enrollment	0.13	0.118	0.01-1.67
Full Model			
Female gender	1.30	0.790	0.19-8.98
Age ≥ 50	1.24	0.862	0.11-14.34
Private insurance	12.24	0.044	1.08-139.20
Months post-LT	0.98	0.218	0.95-1.01
Alcohol-Associated Hepatitis	8.77	0.117	0.58-132.23
MELD 3.0 at LT	1.14	0.277	0.90-1.45
Pre-LT AUD treatment	0.62	0.722	0.05-8.34
Duration of abstinence pre-LT	1.02	0.167	0.99-1.05
Alcohol relapse prior to intervention enrollment	0.12	0.144	0.01-2.05

1582 | SPATIAL AND MOLECULAR PROFILING REVEALS DISTINCT IMMUNE AND FIBROTIC SIGNATURES IN MASLD/MASH VERSUS METABOLIC ALCOHOL-ASSOCIATED LIVER DISEASE (METALD)

Omar Saldarriaga[1] Esteban Arroyave[1] Timothy Wanninger[1] Monique Ferguson[1] Daniel Bao[1] Vincent Yang[1] Michael Kueht[1] Shi Ziyu[1] Zhiyuang Song[1] Haiqing Zhao[1] Heather Stevenson-Lerner[1], [1]University of Texas Medical Branch

Background: Recent updates in liver disease nomenclature have defined metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH), along with a new classification—MetALD—for patients with MASLD who also exhibit excessive alcohol use. Despite these advances, the molecular and spatial mechanisms driving disease progression and heterogeneity in MetALD remain poorly understood. In particular, the impact of alcohol on the hepatic immune microenvironment in the setting of MASLD is underexplored. **Methods:** We performed a multi-modal analysis integrating publicly available single-cell RNA sequencing (scRNA-seq) data from controls and patients with MASH, MetALD, and ALD (total n = 46), alongside liver biopsy specimens from control individuals, patients with MASLD/MASH with minimal or advanced fibrosis, and MetALD with advanced fibrosis (total n = 44). Bulk gene expression was profiled using the NanoString nCounter PanCancer Immune panel. Spatial protein expression was assessed using multiplex immunofluorescence (CD163, CCR2, Galectin-3, Mac387, Cytoglobin, DAPI) and spectral imaging and AI-based algorithms for cell clustering and phenotypic mapping. **Results:** In MASLD/MASH, we observed enrichment of genes linked to T cell and dendritic cell recruitment and activation (e.g., CCL19, CXCL9, CCL5, ZAP70, TCF7, ITGAE, LCP1, CD74). Conversely, MetALD with advanced fibrosis showed elevated expression of genes promoting monocyte/macrophage recruitment (e.g., CCL2, CCL15, CXCL12, CXCL14), and a predominance of M2-like, anti-inflammatory, and profibrotic macrophages (e.g., NFKBIA, MSR1, F13A1, COL3A1, LGALS3, CD163). Spatial analysis confirmed regional enrichment of profibrotic immune cell populations and druggable protein targets. The public single-cell database results closely matched those obtained from liver biopsies analyzed at our institution. **Conclusion:** MASLD/MASH and MetALD are characterized by distinct immune and fibrotic molecular profiles, with MetALD shifting toward macrophage-dominant, fibrogenic responses. These findings underscore the heterogeneous nature of steatotic liver diseases and identify potential spatially resolved, druggable targets that may inform precision therapeutic strategies. Notably, findings from the public single-cell RNA-seq dataset mirrored those from liver biopsies analyzed at our institution using a smaller, cost-effective, and clinically scalable gene panel.

1583 | AREA-LEVEL DEPRIVATION STRONGLY CONTRIBUTES TO DISPARITIES IN ACCESS TO LIVER TRANSPLANTATION AND OUTCOMES AMONG PATIENTS WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS: RESULTS: FROM A PROSPECTIVE MULTICENTER STUDY

Lauren Nephew[1] Thomas Cotter[2] Ashwani Singal[3] Juan Pablo Arab[4] Jaideep Beharry[5] Qing Tang[6] Samer Gawrieh[7] Wanzhu Tu[7] Naga Chalasani[8], [1]Indiana University, [2]UT Southwestern Medical Center, [3]University of Louisville, [4]Virginia Commonwealth University, [5]University of Pittsburgh Medical Center, [6]Departmen tof Biostatitics & Health Data Science, Indiana University School of Medicine, [7]Division of Gastroenterology and Hepatology, Department of Medicine, Indiana University School of, [8]Indiana University Medical Center

Background: Severe alcohol-associated hepatitis (sAH) is a life-threatening manifestation of alcohol-related liver disease and a growing indication for liver transplantation (LT). While early LT can be life-saving, access remains inequitable. Most prior studies are retrospective and lack detailed data on social determinants of health (SDOH), which may disproportionately impact LT access in the time-sensitive context of sAH. We aimed to evaluate how clinical severity and SDOH jointly influence access to LT and short-term survival in a prospective multicenter cohort. **Methods:** We performed a secondary analysis of data from a prospective, multi-center observational study of 325 patients hospitalized with sAH (MELD ≥20) across five sites in the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Alcoholic Hepatitis Network (AlcHepNet). Demographic, clinical, and SDOH data, including the Area Deprivation Index (ADI), were collected at baseline. Outcomes included referral, waitlisting, transplant receipt, and 180-day mortality. We used generalized additive models (GAMs) with a logit link function to evaluate factors associated with each outcome and interactions between disease severity (MELD) and neighborhood disadvantage (ADI). **Results:** The study cohort had a mean age of 44.8 years, comprised 39.4% females, 9.2% Black individuals, and 12.0% Hispanic individuals, with a high disease and social burden (mean MELD 29.2; ADI 56.2). Only 37% of patients were referred for LT, with marked attrition throughout the transplant cascade. MELD scores were higher in those referred (OR 1.13, 95% CI: 1.07–1.18), waitlisted (OR 1.10, 95% CI: 1.02–1.18), and transplant recipients (OR 1.24, 95% CI: 1.07–1.44). Higher ADI was associated with lower odds of waitlisting (OR 0.98, 95% CI: 0.96–1.00, $p = 0.017$) and trended toward lower referral (OR 0.99 per point, 95% CI: 0.97–1.00, $p = 0.059$). In GAMs, MELD × ADI interactions were significant for referral ($p = 0.014$), waitlisting ($p = 0.004$), and mortality ($p = 0.01$), with the largest effects at MELD 20–30. For example, referral probability ranged from 10% at ADI > 80 to 50% at ADI < 20 (Figure 1). Overall, 180-day mortality was 25.5%; among patients with MELD < 30, predicted mortality doubled from 20% at ADI < 20 to > 40% at ADI > 80. Figure 1 Estimated probability of referral by MELD score and ADI. This contour plot shows referral probability by MELD and ADI. Warmer colors indicate higher probability; cooler colors indicate lower. Probability increases with MELD but drops with higher ADI, especially at MELD 20–30. Contour labels show estimated probabilities. **Conclusion:** Both clinical severity and social disadvantage contribute to disparities in LT access and outcomes among patients with sAH. Given a quarter of patients died within 180 days, timely referral is critical for survival. These findings suggest the need for care pathways that explicitly incorporate social determinants of health to promote equitable access to LT.

1584 | SARCOPENIA AND ALCOHOL-ASSOCIATED LIVER DISEASE: INFLUENCE ON INPATIENT OUTCOMES &MDASH; A NATIONWIDE COHORT ANALYSIS

Carla Barberan Parraga[1] Talal Bhatti[2] Kundan Jana[1] Nicole Villa[3] Leandro Sierra[4] Marwan Alsaqa[5] James Park[2] Shirley Eng[2] Sanjaya Satapathy[2], [1]Maimonides Medical Center, [2]NorthWell Health, [3]NYMC Metropolitan Hospital, [4]Cleveland Clinic Foundation, [5]BIDMC Harvard Medical School

Background: Sarcopenia, defined as the loss of skeletal muscle mass and function, is an established predictor of poor outcomes in cirrhotic patients. However, its impact among patients with alcohol-associated liver disease (ALD) without cirrhosis remains underexplored. This study aims to evaluate the influence of sarcopenia on inpatient outcomes in a nationally representative cohort of hospitalized ALD patients. **Methods:** Using the National Inpatient Sample (2016–2021), we identified adult patients (≥ 18 years) with ALD using ICD-10 codes. Patients were stratified based on the presence or absence of sarcopenia. Survey-weighted methods accounted for complex survey design. Categorical and continuous variables were analyzed using Rao–Scott chi-square and Student's t-tests, respectively. Logistic regression models (univariate and multivariate) assessed associations between sarcopenia and inpatient outcomes, adjusting for relevant covariates ($p < 0.1$ in univariate analysis). Statistical significance was defined as $p < 0.05$. Data extraction was performed in Python (v3.9.1) and statistical analysis in R (v3.6.2). **Results:** A total of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

30,860 hospitalized patients with ALD were included. Baseline characteristics were comparable between sarcopenic and non-sarcopenic patients: predominantly non-Hispanic white (62.6% vs. 65.9%), male (65.7% vs. 61.5%), under age 50 (40.0% vs. 37.4%), and Medicaid-insured (41.3% vs. 38.3%). Sarcopenic patients had significantly longer hospital stays (mean 21.3 vs. 12.5 days, $p < 0.001$) and higher hospitalization costs ($380,310 vs. $193,526, $p < 0.001$). On multivariate analysis, sarcopenia was independently associated with increased odds of vasopressor use (OR 1.02; 95% CI, 1.01–1.04; $p = 0.02$), acute kidney injury (OR 1.06; 95% CI, 1.03–1.09; $p < 0.001$), and need for hemodialysis (OR 1.07; 95% CI, 1.05–1.09; $p < 0.001$). Interestingly, sarcopenia was associated with slightly reduced in-hospital mortality (OR 0.97; 95% CI, 0.95–0.99; $p = 0.03$) and was not significantly associated with mechanical ventilation (OR 1.02; 95% CI, 0.99–1.04; $p = 0.20$). **Conclusion:** In patients hospitalized with ALD, sarcopenia is associated with significantly increased healthcare utilization, including longer length of stay, higher costs, and greater risk of inpatient complications such as vasopressor requirement, acute kidney injury, and dialysis. These findings underscore the clinical relevance of sarcopenia as a prognostic marker in ALD, even in the absence of cirrhosis, and highlight the need for early detection and targeted interventions to mitigate adverse outcomes.

Table 1. Comparison of Inpatient Characteristics and Outcomes in Alcohol-Associated Liver Disease (ALD) Patients With and Without Sarcopenia

Variable	Sarcopenia	No Sarcopenia	OR (95% CI)	p-value
Demographics				
Non-Hispanic White (%)	62.6	65.9	—	NS
Male (%)	65.7	61.5	—	NS
Age < 50 years (%)	40.0	37.4	—	NS
Medicaid Insurance (%)	41.3	38.3	—	NS
Inpatient Outcomes				
Mean Length of Stay (days)	21.3	12.5	—	<0.001
Mean Hospitalization Cost ($)	$380,310.90	$193,526.05	—	<0.001
Vasopressor Use (%)	Higher	Reference	1.02 (1.01–1.04)	0.02
Acute Kidney Injury (%)	Higher	Reference	1.06 (1.03–1.09)	<0.001
Hemodialysis Requirement (%)	Higher	Reference	1.07 (1.05–1.09)	<0.001
In-hospital Mortality (%)	Lower	Reference	0.97 (0.95–0.99)	0.03
Mechanical Ventilation (%)	No difference	Reference	1.02 (0.99–1.04)	0.20

1585 | CALPAIN INHIBITION ATTENUATES EXPERIMENTAL ALCOHOL-INDUCED LIVER INJURY THROUGH REGULATION OF CHOLESTEROL METABOLISM

Noriko Kitano[1] Jiang Li[1] Charis-Marie Vanderpuye[1] Pooja Muddasani[1] Yekaterina Krutsenko[1] Hamda Siddiqui[1] Samuel Taborski[1] Juliane Beier[1] Gavin Arteel[1], [1]University of Pittsburgh

Background: Alcohol-related liver disease (ALD) represents a significant global health burden with limited therapeutic options. Ethanol consumption disrupts hepatic homeostasis, resulting in fatty liver development in most ALD patients. Recent evidence suggests that calpain, a calcium-dependent protease family, plays a critical role in liver inflammation and fibrosis. Calpain activity is primarily controlled by its essential modulatory subunit, calpain-4 (Capn4), which stabilizes and governs catalytic isoforms calpain-1 and calpain-2. **Methods:** To investigate calpain's influence on ethanol-induced liver injury, six-week-old male C57Bl6/J mice were injected with rAAV8 vectors encoding either Capn4-specific shRNA or control vectors, with transgene expression driven by the hepatocyte-specific TBG promoter. After four weeks, mice underwent a 10-day chronic-plus-binge ethanol feeding protocol with a single ethanol gavage on day 11. Liver tissues and blood samples were analyzed for histological, biochemical, and gene expression changes. **Results:** Capn4 knockdown significantly ameliorated ethanol-induced microvesicular steatosis. While triglyceride and free fatty acid levels showed no significant alterations, cholesterol levels were markedly reduced in ethanol-exposed mice with Capn4 knockdown. Mechanistically, Capn4 silencing upregulated expression of NR1H3 (encoding LXRα), ABCA1, ABCG1, and CPT1, suggesting enhanced cholesterol efflux and fatty acid oxidation. Western blot analysis revealed an increased ratio of cleaved-HMGCR to pro-HMGCR in Capn4 knockdown mice, indicating reduced HMG-CoA reductase activity and suppressed cholesterol biosynthesis. While ethanol exposure primarily increased cytoplasmic NR1H3 expression, Capn4 knockdown promoted its nuclear relocalization, consistent with functional LXRα activation. **Conclusion:** This study identifies a previously unrecognized link between calpain activity and cholesterol metabolism in ALD pathogenesis. Calpain inhibition mitigates ethanol-induced lipid accumulation primarily through modulation of cholesterol metabolism

rather than effects on triglycerides or free fatty acids. The beneficial effects involve LXRα activation, enhanced cholesterol efflux, and reduced de novo cholesterol synthesis. These findings provide a mechanistic rationale for exploring calpain inhibitors as a therapeutic approach for alcohol-related hepatitis.

1586 | THE USE OF WEARABLE ALCOHOL MEASUREMENT DEVICES INCREASES PRECISION OF ALCOHOL INTAKE ACCESSMENT IN PATIENTS WITH ALCOHOL-ASSOCIATED HEPATATIS

Ekaterina Smirnova[1] Albert Arias[1] Juan Pablo Arab Verdugo[1] Amon Asgharpour[1] Sara O'Connor[1] Frederick Moeller[1] Arun Sanyal[1], [1]Virginia Commonwealth University

Background: Alcohol-associated liver disease (AALD) has risen sharply in the last decades and became the leading cause of liver-related morbidity and mortality. Alcohol intake is one of the major factors leading to progression of AALD. However, accurate assessment of the amount, duration and time of alcohol intake is challenging due to unreliable self-reports and inability to frequently administer alcohol biomarkers in the everyday living environment. AIMS: (1) To establish validity of real-time alcohol measurement using wrist-worn alcohol detection devices in AALD patients; (2) To improve the detection of drinking episodes over the self-reported ecological momentary assessment (EMA). **Methods:** The study consisted of n = 13 patients with AALD followed daily over a period of 60 days. The alcohol intake was monitored using BACtrack Skyn Transdermal Alcohol Concentration (TAC) wrist-worn biosensor that measures alcohol concentration in the skin. Self-reported alcohol intake was assessed by EMA using phone app daily questions. Drinking episodes were detected using TAC peak values > 15mg of alcohol per liter (mg/L) in the 30-min centered average smoothed TAC data. **Results:** Among n = 13 participants, 11 had at least 1 day of alcohol sensor data, and 5 had matching dates of alcohol sensor and EMA data. Among 5 participants with complete alcohol sensor and EMA data, 3 self-reported at least one drinking episode. Among a total of 32 self-reported drinking days in these 3 participants, 21 were detected by the alcohol sensor. Additionally, n = 26 days of alcohol consumption were detected by the sensor out of n = 31 days when these participants did not self-report drinking episodes. **Conclusion:** Wearable alcohol biosensor was able to detect more than 65 % of reported episodes and additional unreported drinking episodes. These data support further validation efforts to further refine its performance as a tool to be used in clinical trials and in the management of alcohol related disorders.

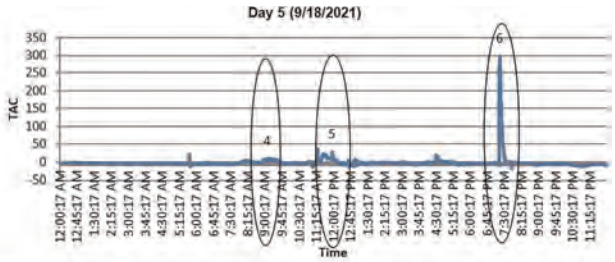

Figure 1. Alcohol intake episodes detected by the alcohol biosensor over one day (Day 5 in the study) for one study participant. Three peak values of Transdermal Alcohol Concentration (TAC) concentration (y-axis) annotated by the 3 ovals are indicate 3 drinking episodes for this day.

1587 | FATAL CONSEQUENCES OF ALCOHOL: 25-YEAR TRENDS IN ALCOHOLIC LIVER DISEASE AND ESOPHAGEAL VARICES MORTALITY AMONG UNITED STATES ADULTS

Simran Joshi[1] Muhammad Faizan[2] Husnain Ahmad[3] Sushrut Ingawale[4] Muhammad Khan[5] Jeevin Sandhu[6] Matthew Manoj[7] Marquise Soto[8] Muhammad Usman Arshad[3] Muhammad Shees Hunain[3] Corinne Caissie[1] Akshay Sharma[9] Salman Attari[10] Saman Javaid[11] Sherif Eltawansy[12] Charitha Karanam Ramapathy[13] Cheng-Hung Tai[14] Mohammad Islam[1], [1]Yale New Haven Health/Yale University School of Medicine, [2]Jinnah Postgraduate Medical Center, [3]Shalamar medical and dental college, [4]Quinnipiac University - Frank H Netter MD School of Medicine, [5]Bacha Khan Medical College, [6]Methodist Dallas Medical Center, [7]Beth Israel Deaconess Medical Center/Harvard Medical School, [8]Massachusetts General Hospital/Harvard Medical School, [9]Luminis Health/Anne Arundel Medical Center, [10]Asian Institute of Medical Sciences, [11]CMH Kharian Medical College, [12]Jersey Shore University Medical Center, [13]UAB Montgomery program/ Heersink school of Medicine, [14]Yale New Haven Health/Yale School of Medicine

Background: Alcoholic liver disease (ALD) and esophageal varices (EV) frequently coexist as complications of progressive liver dysfunction, yet national trends in comorbid ALD–EV mortality remain poorly defined. This study evaluates 25-year mortality patterns among U.S. adults with coexisting ALD and EV, highlighting demographic and regional disparities to inform targeted public health interventions. **Methods:** Mortality data from the CDC WONDER database (1999–2023) were analyzed using Joinpoint regression to assess ALD and EV-related deaths among U.S. adults aged 25 and older. Age-adjusted mortality rates (AAMRs) per hundred thousand were calculated, along with the average annual percent change (AAPC) and corresponding 95% confidence intervals (CI). **Results:** ALD among individuals with EV accounted for 28,871 deaths over 25 years. Between 1999 and 2023, the overall AAMR surged from 0.39 to 0.83, indicating a percent increase of 112.8%, with a staggering AAPC of 3.82 (95% CI: 2.80–5.97, $p < 0.000001$). Males consistently exhibited higher mortality rates than females (AAMR: 0.83 vs. 0.22); however, the trajectory of increase was steeper in females (AAPC: 5.40, 95% CI: 4.16–8.28, $p < 0.000001$) compared to males (AAPC: 3.08, 95% CI: 2.35–4.75, $p < 0.000001$). Among racial groups, Hispanics had the highest AAMR (0.90) followed by Non-Hispanic (NH) Whites (0.49) and NH Blacks (0.37). NH White individuals experienced the sharpest rise (AAPC: 4.56, 95% CI: 3.58–6.37, $p < 0.000001$), followed by Hispanic or Latino populations (AAPC: 1.43, 95% CI: 0.42–3.22, $p = 0.007998$). The highest AAMR was documented in the West (0.83), followed by the Midwest (0.45) and the South (0.42). However, the Northeast saw the most pronounced increase (AAPC: 5.41, 95% CI: 4.45–6.57, $p < 0.000001$), followed by the Midwest (AAPC: 4.98, 95% CI: 3.71–7.20, $p < 0.000001$), where the states with the highest AAMRs were South Dakota (0.98), North Dakota (0.70), and the Nebraska (0.60). Rural areas exhibited slightly higher AAMRs than urban areas (0.52 vs. 0.46), and the mortality trajectory was also steeper in rural populations (AAPC: 4.07, 95% CI: 2.74–6.32, $p < 0.000001$) compared to urban areas (AAPC: 2.85, 95% CI: 1.77–4.35, $p < 0.000001$). Age-stratified analysis revealed that individuals aged ≥ 65 years bore the highest mortality burden, with an AAPC of 4.86 (95% CI: 3.77–6.46, $p < 0.000001$), significantly outpacing the rise observed in the 45-64 years (AAPC: 4.64, 95% CI: 4.07–5.43, $p < 0.000001$) and 25-44 years (AAPC: 3.45, 95% CI: 2.17-5.82, $p < 0.000001$). **Conclusion:** ALD and EV-related mortality has escalated over the past 25 years, with the most notable increases seen in females, individuals aged ≥ 65 years, NH Whites, rural areas, and the Northeast region.These disparities emphasize the urgent need for targeted interventions to address the growing mortality burden, especially among vulnerable populations.

1588 | TRENDS IN PHOSPHATIDYLETHANOL TESTING FOR LIVER TRANSPLANT EVALUATION

Natalia Salinas Parra[1] Marina Serper[2] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania, [2]University of Pennsylvania Health System

Background: Phosphatidyethanol (PEth) is a highly sensitive direct serum biomarker for quantifying and assessing alcohol use in patients. Accurate identification of alcohol use is valuable in liver transplant evaluation and especially useful in situations where self-reported alcohol use can be unreliable. We aimed to evaluate trends in PEth monitoring at our institution over time surrounding initial liver transplant evaluation. **Methods:** This retrospective cohort study identified adult patients evaluated for liver transplant at the Hospital of the University of Pennsylvania between 1/2016 and 12/2022. Data was extracted on whether PEth testing was performed within +/- 90 days of the transplant evaluation date. Linear regression analysis was performed to assess temporal trends in the proportion of patients checked for PEth levels each evaluation year. **Results:** A total of 3,330 patients underwent liver transplant evaluations during the study time period. Of these patients, 896 (26.9%) had PEth testing checked, with 195 (21.8%) resulting in positive tests. In this cohort, the median PEth level was 214 ng/mL (IQR: 26, 239; Figure panel A), corresponding with heavy alcohol consumption. Over this period, there was a significant increase in the proportion of patients with PEth testing per year ($\beta = 0.054$, 95% CI 0.003-0.104, $p = 0.04$). The proportion of PEth positive patients also showed a significant upward trend over time ($\beta = 0.038$, 95% CI 0.008-0.059, $p = 0.02$; Figure panel B). **Conclusion:** At our large transplant center, descriptive data show rising rates of PEth checks over time. Notably, there is a rising rate of positive PEths around the time of evaluation, with almost a quarter of patients testing positive. This may suggest that PEth checks should be employed even more routinely as they may detect surreptitious alcohol use that could significantly impact transplant candidacy.

1589 | MORTALITY AND HEPATIC OUTCOMES OF SGLT2 INHIBITORS IN PATIENTS WITH ALCOHOLIC CIRRHOSIS, OBESITY, AND DIABETES: A GLOBAL COHORT STUDY

Mohamad Mahdi Osman[1] Mohamad-Noor Abu-Hammour[1] Walid Hazem[2] Leandro Sierra[1] Omar Sims[1] Dian Chiang[3], [1]Cleveland Clinic Foundation, [2]University Hospitals, [3]Cleveland Clinic

Background: Sodium-glucose co-transporter 2 inhibitors (SGLT2-i) are guideline-recommended therapies for patients with type 2 diabetes mellitus (T2DM) and obesity, with emerging benefits in cardiorenal protection. However, their safety and efficacy in patients with advanced liver disease—particularly alcoholic cirrhosis—remain poorly defined. Given the growing burden of metabolic comorbidities in this population, we aimed to evaluate the impact of SGLT2-i use on clinical outcomes in patients with alcoholic cirrhosis, coexisting T2DM, and obesity. **Methods:** Using the TriNetX research network, we identified adult patients with alcoholic cirrhosis, T2DM, and obesity who were prescribed SGLT2-i. Patients were divided into two cohorts: those prescribed SGLT2-i and those with no SGLT2-i use. Propensity score matching (1:1) was performed based on demographics, liver function tests, MELD components, and cardiometabolic comorbidities. Clinical outcomes were assessed using time-to-event analysis. The primary outcome was all-cause mortality. Secondary outcomes included all-cause hospitalizations, spontaneous bacterial peritonitis (SBP), ascites, and variceal bleeding. **Results:** After matching, SGLT2-i use was associated with a significantly lower risk of all-cause mortality [HR 0.769; 95% CI 0.719–0.823; $p < 0.0001$], all-cause hospitalizations [HR 0.937; 95% CI 0.900–0.976; $p < 0.0001$], incidence of ascites [HR

0.755; CI 0.716–0.795; p < 0.0001, and incidence of SBP [HR 0.728; 95% CI 0.636–0.833; p = 0.0008] (Figure 1). There was an associated reduction in variceal bleeding, though it did not show statistical significance. **Conclusion:** In this large real-world cohort, SGLT2-i use was associated with improved survival and lower hospitalization rates in patients with alcoholic cirrhosis, T2DM, and obesity. Additionally, SGLT2-i use correlated with significantly reduced risk of SBP and ascites and a favorable trend toward fewer variceal bleeding events. These findings support the potential utility of SGLT2-i in this high-risk population and warrant prospective evaluation to confirm safety and long-term benefit in cirrhosis management.

1590 | A DEADLY COMBINATION? EXPLORING THE BURDEN OF SEPTICEMIA IN PATIENTS WITH ALCOHOLIC LIVER DISEASE IN THE UNITED STATES (1999–2023)

Simran Joshi[1] Muhammad Ali[2] Matthew Manoj[3] Husnain Ahmad[4] Susan Feldman[5] MANJEET GOYAL[6] Muhammad Khan[7] Muhammad Hermain Amin[4] Jeevin Singh[8] Corinne Caissie[1] Muhammad Abdullah[4] Salman Attari[9] Saman Javaid[10] Sherif Eltawansy[11] Susan Feldman[5] Mohammad Islam[1] Cheng-Hung Tai[1], [1]Yale New Haven Health/Yale University School of Medicine, [2]Jinnah Postgraduate Medical Center, [3]Beth Israel Deaconess Medical Center/Harvard Medical School, [4]Shalamar Medical and Dental College, [5]University of South Carolina/Prisma Health, [6]Cleveland Clinic/Akron, [7]Bacha Khan Medical College, [8]Methodist Dallas Medical Center, [9]Asian Institue of Medical Sciences, [10]CMH Kharian Medical College, [11]Jersey Shore University Medical Center

Background: Alcoholic liver disease (ALD), a consequence of chronic alcohol consumption, compromises hepatic immune function, rendering patients more vulnerable to systemic infections. Among these, septicemia stands out as a critical cause of acute deterioration and death. The impaired host defense in ALD may predispose individuals to sepsis at a higher rate than the general population, yet national trends exploring this intersection remain under-investigated. In this study, we analyze mortality trends from 1999 to 2023 to assess whether adults with ALD are experiencing a disproportionate burden of septicemia-related deaths, while also exploring demographic and regional disparities across the United States. **Methods:** Mortality data from CDC WONDER (1999–2023) were analyzed using Joinpoint regression to evaluate ALD- and septicemia-related deaths in U.S. adults aged 25+. Age-adjusted mortality rates (AAMRs) per 100,000 and average annual percent change (AAPC) with 95% confidence intervals were calculated. **Results:** Sepsis among individuals with ALD accounted for 58,728 deaths over 25 years. Between 1999 and 2023, the overall AAMR surged from 0.49 to 1.75 per hundred thousand, with a staggering AAPC of 6.67 (95% CI: 5.97–8.45, $p < 0.000001$). Males consistently exhibited higher mortality rates than females (AAMR: 1.42 vs. 0.66); however, the trajectory of increase was steeper in females (AAPC: 7.83, 95% CI: 7.33–8.78) compared to males (AAPC: 5.82, 95% CI: 5.22–7.21,), both with $p < 0.000001$. Among racial groups, Hispanics had the highest AAMR (1.61) followed by Non-Hispanic (NH) Whites (0.97) and NH Blacks (0.83). NH White individuals experienced the sharpest rise (AAPC: 6.10, 95% CI: 5.39–7.39, $p < 0.000001$), followed by Hispanic or Latino populations (AAPC: 4.43, 95% CI: 3.91–5.24, $p < 0.000001$). The West saw the most pronounced increase (AAPC: 6.72, 95% CI: 5.85–7.93, $p < 0.000001$), followed by the Midwest (AAPC: 6.37, 95% CI: 5.52–7.87, $p < 0.000001$), where the states with the highest AAMRs were South Dakota (5.26), North Dakota (2.98), and Minnesota (1.85). Urban areas exhibited slightly higher AAMRs than rural areas (0.96 vs. 0.93), but the mortality trajectory was steeper in rural populations (AAPC: 7.91, 95% CI: 6.93–9.19, $p < 0.000001$) compared to urban areas (AAPC: 6.87, 95% CI: 6.24–7.84,$p < 0.000001$). Individuals aged ≥ 65 years bore the highest mortality burden, with an AAPC of 4.86 (95% CI: 3.77–6.46, $p <$ 0.000001), significantly outpacing the rise observed in the 45-64 years (AAPC: 4.64, 95% CI: 4.07–5.43) and 25-44 years (AAPC: 3.45, 95% CI: 2.17-5.82). **Conclusion:** ALD and sepsis-related mortality has escalated over the past 25 years, with the most notable increases seen in females, NH Whites, the West, rural areas and

1591 | ONE FIFTH OF INDIVIDUALS HAVING ALCOHOL USE DISORDER ARE SARCOPENIC

Chittaranjan Panda[1] Sananda Kumar Sethi[2] Rakesh Mohanty[2] Prajna Anirvan[2], [1]S. C. B. Medical College, Cuttack, Odisha, India, [2]S.C.B. Medical College, Cuttack, Odisha, India

Background: Sarcopenia in patients with Alcohol Use Disorder (AUD) without cirrhosis of liver or other risk factors is often underdiagnosed. Given the limited literature on this subject both globally and within India, we conducted this study to determine the prevalence of sarcopenia in individuals with AUD, identify associated risk factors, and evaluate the diagnostic accuracy of various assessment modalities for sarcopenia in this population. **Methods:** 200 consecutive patients diagnosed with AUD without liver cirrhois or other risk factors for sarcopenia were enrolled. The assessment of sarcopenia was carried out using the EWGSOP2 criteria. Initial screening was performed using the SARC-F questionnaire. Muscle strength, muscle mass and physical performance were measured by handgrip strength (HGS), CT-Skeletal Muscle Index (SMI) and gait speed of a 4-meter walk test (4MWT). Emerging modality like B-mode ultrasound measurement of rectus femoris muscle thickness (USG-MTRF) using the LOGIQ e device, was also employed and recorded in centimeters. **Results:** Sarcopenia was observed in 41 patients (20.5%), while severe sarcopenia was identified in 13 patients (6.5%). Significant association was found between sarcopenia and severity of AUD ($p = 0.02$); prevalence of sarcopenia increased with AUD severity; 7.92% (8/101) in mild AUD, 19.64% (11/56) in moderate AUD, 48.83% (21/43) in severe AUD. No significant association was observed between sarcopenia and gender, age, type of alcohol consumed. Sarcopenic patients had significantly higher mean alcohol intake (452.01 $\pm$ 101.47 g/wk vs 346.29 $\pm$ 68.90 g/wk,non-sarcopenic patients, $p = 0.05$). Mean daily caloric intake (1943.90 $\pm$ 545.45 kcal vs. 2215.1 $\pm$ 668.85 kcal;$p = 0.01$) and daily protein intake (33.29 $\pm$ 5.65 g vs. 36.03 $\pm$ 7.62 g, $p = 0.03$) were significantly lower. Significant negative correlation was noted between amount of alcohol consumption and SMI and HGS(-0.382 and -0.389, respectively;$p \leq 0.05$). No significant correlation was found between alcohol intake and physical performance (4MWT). SMI demonstrated the highest accuracy (sensitivity-95.12%, specificity-89.31%).USGMTRF had a sensitivity of 82.93% and specificity of 70.44%. Mid-arm circumference (MAC) also showed a sensitivity of 65.85% and specificity of 82.39%. SARC-F questionnaire was found to have a sensitivity of 90.24% sensitivity and specificity of 71.07%. Low physical activity level increased the risk of sarcopenia by 10.37 times, higher alcohol intake (> 210 g/week) increased this risk by 1.1 times and severe AUD increased this risk by 11.56 times in regression analysis. **Conclusion:** Sarcopenia among individuals with AUD was even higher than already reported general adult population (10.1%) and even the elderly population (14.2%–15.2%) in India. Its occurence increases with the severity of AUD. Skeletal muscle ultrasound was observed to be a simple and effective tool for quantifying muscle mass in this population.

1592 | TARGETING PDK4-MEDIATED SEPT2 PHOSPHORYLATION TO COMBAT MITOCHONDRIAL DYSFUNCTION IN ALCOHOL-ASSOCIATED LIVER DISEASE

THEMIS THOUDAM[1] Hui Gao[1] Ge Zeng[1] Nazmul Huda[1] Yanchao Jiang[1] Jing Ma[1] Zhihong Yang[1] Suthat Liangpunsakul[1], [1]Indiana University

Background: Alcohol-associated liver disease (ALD) remains a global health challenge, yet the molecular mechanisms driving its progression are not fully elucidated. Mitochondrial dysfunction, marked by excessive fragmentation and heightened production of reactive oxygen species (ROS), plays a pivotal role in ALD pathogenesis. Our prior research identified pyruvate dehydrogenase kinase 4 (PDK4) as a key regulator of mitochondrial fragmentation, acting through direct phosphorylation of Septin 2 (SEPT2) at serine 218 (S218). This modification enhances SEPT2's interaction with Dynamin-related protein 1 (DRP1), facilitating mitochondrial fission. However, the detailed role of PDK4-mediated SEPT2 phosphorylation in mitochondrial dysfunction within ALD remains poorly understood. This study investigates the role of PDK4-mediated phosphorylation of SEPT2 in promoting mitochondrial dysfunction during ALD progression. **Methods:** We utilized a combination of ethanol-fed mice, liver samples from ALD patients, and ethanol-treated hepatocyte cultures to assess mitochondrial dynamics. Mechanistic insights were explored through the use of SEPT2 phosphorylation-deficient and phospho-mimetic mutants. **Results:** In a mouse model of ALD, transmission electron microscopy revealed a reduced mitochondrial perimeter in ethanol-fed mice, indicating enhanced mitochondrial fragmentation. Ethanol exposure led to increased PDK4 expression, heightened SEPT2 phosphorylation, and augmented mitochondrial localization of DRP1, supporting a PDK4-driven SEPT2–DRP1 signaling axis. Elevated PDK4 and phosphorylated SEPT2 were also detected in liver biopsies from patients with alcohol-related cirrhosis, confirming the clinical relevance of this pathway. In vitro, ethanol treatment of AML12 hepatocytes promoted SEPT2 phosphorylation, which facilitated its interaction with DRP1, resulting in mitochondrial fragmentation—a process that was reversed by a phosphorylation-deficient SEPT2 mutant. Additionally, ethanol exposure in primary hepatocytes resulted in mitochondrial fragmentation, increased ROS production, and diminished mitochondrial respiration. However, Pdk4 knockout hepatocytes were protected from these detrimental effects. Finally, hepatocyte-specific Pdk4 knockout mice exhibited reduced serum transaminases and mitigated hepatic steatosis. **Conclusion:** Our findings uncover a novel molecular mechanism driving mitochondrial dysfunction and ALD progression through PDK4-mediated SEPT2 phosphorylation. Targeting this pathway could offer a promising therapeutic strategy for managing ALD.

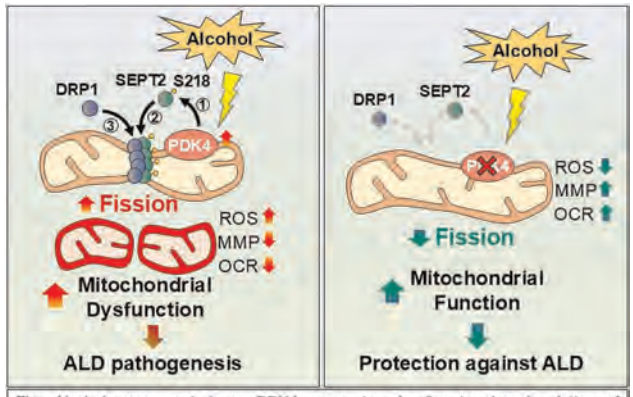

Fig. Alcohol exposure induces PDK4 expression, leading to phosphorylation of SEPT2 at serine 218. This modification promotes DRP1 recruitment to mitochondria, enhancing mitochondrial fission and dysfunction in ALD models. Genetic deletion of Pdk4 or expression of a non-phosphorylatable SEPT2 mutant mitigates these effects and preserves mitochondrial function, supporting the PDK4–SEPT2–DRP1 axis as a key mediator of alcohol-induced mitochondrial damage in ALD pathogenesis.

1593 | IN VIVO PROTEIN HALF-LIFE ANALYSIS UNVEILS THE ROLE OF THE SREBF1-SLC27A5 AXIS IN ALLEVIATING ALCOHOL-INDUCED LIVER DAMAGE

NUPUR SHARMA[1] Sadam Bhat[1] Shweta Choudhary[2] Babu Mathew[1] sushmita pandey[1] Sanju Yadav[1] manisha yadav[1] Vasundhra Bindal[1] gaurav tripathi[1] neha sharma[1] Vipul Sharma[1] Ranjan Nanda[2] Ranjan Nanda[2] Anupama Parasar[1] Shvetank Sharma[1] jaswinder singh Maras[3], [1]Institute of Liver and Biliary Sciences, [2]International Centre for Genetic Engineering and Biotechnology, [3]NSTITUTE OF LIVER AND BILIARY SCIENCES

Background: Alcohol-related associated liver disease (ALD) is a leading cause of liver dysfunction and is is characterized by inflammation, steatosis, and fibrosis. Abstinence reverses liver damage, but its effects on protein half-lives in the liver, plasma, and intestine are unclear. This study investigates site-specific protein half-life changes, its transcription regulation, and its their roles in ALD pathophysiology and damage reversal upon alcohol abstinence. **Methods:** Long-Evans rats were fed control or ethanol Lieber De Carli diets for 24 weeks to develop ALD. A separate group of ALD rats was switched to a control diet for 7 days to induce abstinence. Protein half-life was measured using

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

stable isotope labellinglabeling with deuterium oxide usingand, D2ome software. Protein half-life analysisomic analyses were was complemented with the pathway enrichment of important pathways and and transcription factors (TF) analyses. Expression of The iIdentified transcription regulator and linked associated genes were validated in rat model of ALD, human biopsy of ALD and rats under alcohol abstinence in rat model of ALD followed by, validation on human biopsy of ALD. **Results:** Liver histology showed increased steatosis (28%) and fibrosis (15%) in ALD rats, both reduced with abstinence ($<20\%$, $<12\%$, $p<0.05$). Liver function and lipid profiles improved, while alcohol-metabolizing and inflammatory markers were decreased (>1.5-fold, $p<0.05$) following abstinence. Site-specific protein half-life analysis in ALD rats revealedALD induced change in protein half-life specific to liver (82↑, 54↓), intestine (26↑, 30↓), and plasma (11↑, 17↓). Abstinence modulated; liver (64↑, 62↓), intestine (13↑, 25↓), and plasma (10↑, 12↓; FC >1.5, $p<0.05$). Notably, abstinence reversed protein half-lives linked to lipid metabolism and protein localization in the liver, neurodegeneration and and cell death in the intestine, and NET formation in plasma ($p < 0.05$). Abstinence restored protein half-lives of Cyp2d10, Ugt1a1, Slc27a5, and Hsp90b1, regulated by Srebf1. Proteomic validation confirmed increased Acat1, Ugt1a1, and Slc27a5 in ALD, linked to steatosis and inflammation, which decreased with abstinence. Further validation on liver biopsy of Severe alcoholic hepatitis patients also documented that abstinence work on modulating protein turnover under the Srebf1-Slc27a5 axis and thereby ameliorate liver damage. **Conclusion:** Alcohol consumption causes site-specific changes in protein half-life, some of which are reversed by abstinence. Targeting the transcriptional regulation of SREBF1-Slc27a5 axis a key regulator of protein stability linked to inflammation, hepato-steatosis, and antioxidant response offers potential for treating alcohol-induced liver damage.

1594 | CLINICAL UTILITY OF PHOSPHATIDYLETHANOL AS AN OBJECTIVE BIOMARKER FOR QUANTIFYING ALCOHOL USE IN STEATOTIC LIVER DISEASE: EVIDENCE FROM THE SAN DIEGO LIVER STUDY

Federica Tavaglione[1] Luis Díaz[2] Veeral Ajmera[1] Egbert Madamba[1] Seema Singh[1] Ricki Bettencourt[1] Lisa Richards[1] Rohit Loomba[1], [1]University of California San Diego, [2]Pontificia Universidad Católica de Chile

Background: The 2023 subclassification of steatotic liver disease (SLD) relies on self-reported alcohol use, which lacks diagnostic precision in routine clinical practice. Phosphatidylethanol (PEth) is a quantitative, objective alcohol biomarker with high sensitivity and specificity. In this study, we aimed to estimate the prevalence of underreported alcohol use, identify its independent predictors, and enhance SLD subclassification using PEth in a large, population-based cohort of individuals with overweight/obesity and SLD in the United States. **Methods:** This is a cross-sectional analysis of a prospective study including 391 community-dwelling adults with overweight/obesity and SLD, as defined by MRI-PDFF $\geq$ 5%, residing in Southern California. Participants underwent a standardized clinical research visit, including PEth testing and advanced liver imaging using MRI-PDFF and MRE. Participants were subclassified as having metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction and alcohol-related liver disease (MetALD) or alcohol-related liver disease (ALD) in accordance with the new AASLD–EASL–ALEH nomenclature guidance. Underreported alcohol use was defined as individuals originally classified as MASLD with PEth $\geq$ 25 ng/mL or individuals originally classified as MetALD with PEth $\geq$ 200 ng/mL. Sensitivity analyses were performed using PEth cut-points of 20 ng/mL and 35 ng/mL to differentiate between no/light and moderate drinking. **Results:** The mean (SD) age and body mass index (BMI) were 51 (13) years and 33 (6) kg/m^2, respectively. 15.9% (95% CI: 12.2%–19.5%) of individuals with SLD underreported their alcohol consumption

(Table). Male gender (OR 2.39, 95% CI: 1.31–4.51; p = 0.006), White race (OR 1.83, 95% CI: 1.02–3.32; p = 0.044), and the absence of type 2 diabetes (OR 3.30, 95% CI: 1.58–7.59; p = 0.003) were the strongest independent factors associated with alcohol underreporting. The use of PEth in addition to self-reported alcohol use resulted in a 4-fold and 3-fold increase in MetALD and ALD diagnoses, respectively. PEth and self-reported alcohol use showed a moderate positive correlation ($\rho = 0.52$, 95% CI: 0.45–0.59; $p < 0.001$), while the agreement was low ($\kappa = 0.22$, 95% CI: 0.09–0.35; $p < 0.001$). When stratified by gender, PEth and self-reported alcohol use remained similarly correlated in men ($\rho = 0.49$, 95% CI: 0.37–0.59; $p < 0.001$) and women ($\rho = 0.48$, 95% CI: 0.37–0.58; $p < 0.001$), but agreement was higher in women ($\kappa = 0.47$, 95% CI: 0.29–0.65; $p < 0.001$) compared to men ($\kappa = 0.10$, 95% CI: -0.05–0.26; p = 0.10). Sensitivity analyses yielded results substantially similar to those of the main analysis. **Conclusion:** PEth may objectively quantify alcohol use and help identify SLD subcategories alongside clinical history, mitigating diagnostic misclassification.

Table: Distribution of PEth-defined categories of alcohol use across SLD subcategories.

PEth, ng/mL	MASLD	MetALD	ALD	Total
<25: no/light drinking	312 (84%)	4 (29%)	4 (57.1%)	320
≥25-80: moderate drinking, lower range	34 (9%)	3 (21%)	1 (14.3%)	38
≥80-200: moderate drinking, upper range	14 (4%)	3 (21%)	1 (14.3%)	18
≥200: heavy drinking	10 (3%)	4 (29%)	1 (14.3%)	15
Total	370	14	7	391

Outlined boxes indicate agreement between PEth levels and self-reported alcohol consumption.
Gray-shaded boxes indicate underreporting of alcohol consumption compared to PEth levels.
Unshaded boxes indicate overreporting of alcohol consumption compared to PEth levels.
Abbreviations: ALD, alcohol-related liver disease; MASLD, metabolic dysfunction-associated steatotic liver disease; MetALD, metabolic dysfunction and alcohol-related liver disease; PEth, phosphatidylethanol.

1595 | MULTIDISCIPLINARY MANAGEMENT OF ALD: IMPROVED PATIENT OUTCOMES AND REDUCED HEALTHCARE UTILIZATION

Nabeeha Mohy-ud-din[1] Mark Guy[2] Gursimran Kochhar[1], [1]Division of Gastroenterology, Hepatology and Nutrition, Allegheny Health Network, Pittsburgh, PA, [2]Allegheny Health Netowrk Center for Inclusion Health, Pittsburgh, PA

Background: Alcohol associated liver disease (ALD) is a leading cause of liver-related mortality, with approximately half of the cirrhosis related hospitalizations occurring due to alcohol use with an annualized cost per decompensated patient of $36,384. ALD has traditionally fallen under the purview of hepatologists, however, there is increasing evidence to show that patients with ALD treated in multi-disciplinary settings have superior outcomes when alcohol use disorder (AUD) is concurrently managed. We established a multi-disciplinary clinic in conjunction with addiction medicine, at our tertiary care center with the aim of improving care for patients with ALD and decreasing health care utilization. **Methods:** Data was collected retrospectively for patients with ALD seen in a multi-disciplinary clinic (by transplant hepatology and addiction medicine) over a 6-month period (October 2024 - March 2025). Demographics, management data (including medications for AUD and behavioral interventions), outcomes data (downstream healthcare utilization), and patient satisfaction questionnaires were collected. **Results:** A total of 32 patients were seen in our multi-disciplinary ALD clinic. The average age was 50, 75% (n = 24) were men and 78% (n = 25) Caucasians. 87.5% (n = 28) patients had liver cirrhosis with a mean MELD of 17 (range 9-28). 84% (n = 27) patients had an average of 3 ER visits in the 12-month period prior to being seen in our clinic, and 60% (n = 19) were hospitalized within the 30 days prior to the clinic visit. 69% (n = 22) patients were prescribed medications for AUD, 85% (n = 27) patients reported no or decreased alcohol use at the 6-month follow-up. Only 2 patients required

hospitalization during the follow-up period. 90% (n = 29) of patients reported increased likelihood of positive lifestyle changes and improved symptom management after being seen in clinic. **Conclusion:** Patients with ALD managed in a multi-disciplinary setting with co-located hepatology/addiction medicine have increased sobriety and high patient satisfaction. Our multidisciplinary clinic reduced hospitalizations by 89% during our follow-up period, thereby reducing health care costs.

1596 | EVALUATING SERUM BIOMARKERS FOR ADVANCED LIVER FIBROSIS SCREENING AND DISEASE PROGRESSION IN ACTIVELY DRINKING HOSPITALIZED PATIENTS WITH ALCOHOL USE DISORDER

Michael Butler[1] Chantelle Marshall[2] Prasanna Challa[1] Rachael Mahle[1] Wei Zhang[1] Russell Goodman[2] Esperance Schaefer[3] Jay Luther[2], [1]MGH, [2]Massachusetts General Hospital, [3]Brigham and Women's Hospital

Background: Hospitalized patients with heavy alcohol consumption constitute a high-risk group for advanced liver disease, with an estimated prevalence of undiagnosed advanced fibrosis or cirrhosis in approximately 20%. Despite this, there is a lack of accurate and clinically available screening tools to guide targeted assessment in this patient population, especially in those with active alcohol use. We evaluated the performance of commonly used non-invasive tests for advanced fibrosis in a cohort of actively drinking, hospitalized patients with alcohol use disorder (AUD). **Methods:** We conducted a prospective study (2019-2023) of 6 liver fibrosis markers—APRI, FIB-4, FibroTest, Forns Score, GAPRI, and MELD-Na—in hospitalized AUD patients with no known history of liver disease and reported ongoing alcohol consumption. Biomarkers were obtained on the day of admission. All participants underwent liver elastography. Elastography results served as the reference standard for the presence of advanced fibrosis, defined as $\geq$11 kPa on FibroScan or $\geq$1.7 m/s on US elastography. These thresholds were validated using liver biopsy results from 20 patients who underwent both elastography and biopsy, demonstrating concordant detection of advanced fibrosis. We calculated AUROC, sensitivity, specificity, predictive values, and likelihood ratios at established literature-based cutoff values. Calibration of each test was evaluated using the Brier score. To assess the prognostic utility for future hepatic decompensation events, we calculated a Harrell's C-index for each test. **Results:** 455 patients were studied, 27.1% who were found to have advanced fibrosis as determined by elastography. There were no differences in clinical demographics—age, sex, ethnicity, BMI, diabetes mellitus, viral hepatitis, or hyperlipidemia—between patients with and without advanced fibrosis (all $P > 0.05$). Among the evaluated serum biomarkers, GAPRI demonstrated the highest sensitivity as a screening tool, with a sensitivity of 98.1% (95% CI: 94.5–100.0), a NPV of 96.6% (95% CI: 89.9–100.0), and a negative LR of 0.10. No biomarker reliably predicted the presence of advanced fibrosis. FibroTest exhibited the best overall diagnostic performance in this regard, with an area AUROC of 0.756 (95% CI: 0.684–0.823) and a Brier score of 0.183. During the follow-up period, 61 patients experienced a major hepatic decompensation event. These patients had lower ALT and higher bilirubin comparitively. None of the fibrosis biomarkers demonstrated adequate predictive accuracy for these events, with the MELD-Na score yielding the highest prognostic discrimination (Harrell's C-index = 0.685). **Conclusion:** GAPRI at the time of hospital admission is a readily available and effective screening tool to rule out advanced hepatic fibrosis in the highly prevalent group of high-risk, actively drinking hospitalized AUD patients. The need for predictive biomarkers remains.

1597 | COMPARATIVE OUTCOMES IN ALCOHOL-RELATED LIVER DISEASE VERSUS NAFLD: A RETROSPECTIVE COHORT STUDY

Abdallah Hussein[1] Islam Rajab[2] Ahmed Salem[3] Nyan Latt[4] Mohamed Eldesouki[5] Abdallatif Hussein[6], [1]Virtua health Inc, [2]St Joseph University Medical Center, [3]Maimonides Medical Center, [4]Virtua Health, [5]New York Medical College at Saint Michael Medical Center, [6]Al-Najah University

Background: Non-alcoholic fatty liver disease (NAFLD) and alcohol-related liver disease (ALD) are leading causes of hepatic fibrosis, cirrhosis, and subsequent decompensation. We sought to compare rates of cirrhosis progression, acute hepatic failure, liver transplantation, and mortality between these two etiologies. **Methods:** Using the TriNetX database, we identified adults ($\geq$18 years) who had both a diagnosis of NAFLD (ICD-10 K76.0, K75.81) or alcohol-related liver disease (ICD-10 F10.x, K70.x). To ensure two mutually exclusive cohorts, patients in the NAFLD arm were required to have no alcohol-related codes, and those in the alcohol-related arm were required to have no NAFLD codes. The index date was defined as the first cirrhosis diagnosis following the NAFLD or alcohol-related code. We then performed 1:1 propensity-score matching on age, sex, race/ethnicity, and key comorbidities, yielding 81,925 patients in each cohort. Patients were followed for 12 months from index; outcomes assessed included cirrhosis-related complications, acute hepatic failure, need for liver transplantation, and all-cause mortality. Risk ratios (RRs), 95% confidence intervals (CIs), and p-values were calculated for each outcome. **Results:** Risk of progression to liver cirrhosis over one year was lower in ALD, 41.34% versus 47.97% in NAFLD (RR 0.862; 95% CI 0.853-0.871; $p < 0.0001$), and association with hepatic failure occurred in 21.40%, versus 6.98% respectively (RR 3.03; 95% CI 2.978,3.151; $p < 0.0001$). ALD patients also had higher mortality (5.11% vs 17.07%; RR 3.33; 95% CI 3.228-3.45; $p < 0.0001$) and increased need for liver transplantation (1.79% vs 0.87% ; RR 2.045; 95% CI 1.871-2.235; $p < 0.0001$). **Conclusion:** Although NAFLD patients were more likely to develop cirrhosis over one year, they experienced significantly lower risks of acute hepatic failure, liver transplantation, and death compared with matched ALD patients.

1598 | PATIENTS WITH HIGHER MELD SCORES MAY BE AT HIGHER RISK OF BEING MISCLASSIFIED AS LOW RISK FOR ALCOHOL RELAPSE BY PRE-TRANSPLANT SIPAT EVALUATION

Alex Chang[1] Aditya Sood[2] Reanay Berezovskiy[2] Christopher Dorizas[2] Nishi Joshi[2] Sanjaya Satapathy[2], [1]Warren Alpert School of Medicine of Brown University, [2]Zucker School of Medicine at Hofstra/Northwell

Background: The Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) is increasingly used to assess relapse risk in candidates undergoing liver transplantation for alcohol-associated liver disease (ALD). However, the subjective nature of SIPAT scoring —especially elements such as social support—can result in variability across institutions and evaluators. This study aimed to examine the predictive accuracy of SIPAT scores in assessing alcohol relapse post-transplant and identify pre-transplant patient characteristics associated with misclassification of relapse risk, particularly among those with high Model for End-Stage Liver Disease (MELD) scores. **Methods:** This retrospective cohort study included 60 patients who underwent liver transplantation for ALD from 2019–2023 at a single transplant center and had pre-transplant SIPAT scores. Risk categories were defined as follows: SIPAT 0–10 (low-risk), 11–20 (intermediate-risk), and >20 (high-risk). Relapse was categorized as either a slip (any alcohol use not requiring hospitalization) or harmful relapse (alcohol use resulting in hospitalization or >3 drinks/week). Misclassification was defined as follows–misclassified low-risk is a SIPAT ≤ 20 with harmful relapse or SIPAT <10 with slip or harmful relapse. Misclassified high-risk is a SIPAT >20 without any relapse. Univariate binary logistic regression was used to analyze associations between misclassification and demographic or clinical variables. **Results:** A total of 7 of 32 patients (21.9%) were misclassified low-risk. A total of 20 of 29 patients (69.0%) were misclassified high-risk. A SIPAT <10 had a negative predictive value (NPV) of 72.7% for any relapse and 90.9% for harmful relapse. SIPAT <20 had a similarly high NPV of 81.0% for harmful relapse. However, SIPAT >20 had a low positive predictive value (PPV) of 28.6% for harmful relapse. Among variables analyzed, higher MELD scores were associated with an increased likelihood of being misclassified as low-risk (mean MELD 33.6 vs 27.9, $p = 0.055$) (Figure 1). Other factors, including age, sex, race, employment, insurance, education, and abstinence duration, were not significantly associated with misclassification. **Conclusion:** While SIPAT scores <20 are effective in ruling out harmful relapse post-transplant, high SIPAT scores lack specificity in predicting relapse. Importantly, patients with higher

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

MELD scores may be at risk of being underestimated for relapse potential, potentially due to under-reporting or evaluator bias during psychosocial evaluation. These findings suggest a need for more objective and standardized assessments of relapse risk, particularly in critically ill patients.

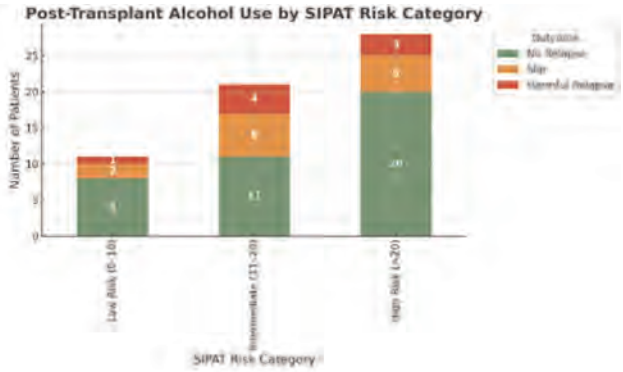

Table: Comparison of Characteristics – Misclassified vs Correctly Classified (Low-Risk Patients Only)

Variable	Misclassified (n=7)	Correctly Classified (n=24)	p-value	Odds Ratio (95% CI)
Age (mean ± SD)	51.4 ± 14.0	54.0 ± 10.4	0.592	0.979 (0.908 – 1.060)
MELD Score (mean ± SD)	33.6 ± 4.9	27.9 ± 6.3	0.055	1.22 (0.995 – 1.50)
Sex (% Male)	85.7%	75.0%	0.556	2.00 (0.199 – 20.15)
Employment (% Unemployed)	71.4%	45.8%	0.245	2.96 (0.476 – 18.34)
Education ≥ Bachelor's (%)	85.7%	54.2%	0.160	0.197 (0.020 – 1.90)
Abstinence >6 months (%)	28.6%	41.7%	–	–

1599 | EXERCISE IS A FEASIBLE MECHANISTIC INTERVENTION FOR SARCOPENIA IN ALCOHOL-RELATED LIVER DISEASE (ALD)

Nicole Welch[1] Annette Bellar[1] Amy Attaway[1] Saurabh Mishra[1] Jasmin Cunningham[1] Pugazhendhi Kannan[1] Seshu Pothabathula[1] Vandana Agrawal[1] Maxmillian Hanlon[1] Laura Nagy[2] Takhar Kasumov[3] Srinivasan Dasarathy[1], [1]Cleveland Clinic, [2]Cleveland Clinic Foundation, [3]NEOMED

Background: Sarcopenia and impaired contractile function are frequent complications in patients with alcohol related liver disease (ALD). Sarcopenia/contractile dysfunction in ALD is frequent, severe and progressive. Alcohol use disorder (AUD) is the primary causal factor for ALD with no therapies/interventions that target ALD/AUD. Exercise improves functional capacity (VO2max) and muscle mass in patients with cirrhosis. Mechanistic studies on preclinical models of exercise have been limited by concerns regarding impaired activity during ethanol treatment. Exercise also lowers alcohol consumption/cravings (alcohol use disorder) but there are no systematic studies on the effect of alcohol ingesion on physical activity in preclincal models. We studied voluntary activity and alcohol consumption in mice before and after ethanol treatment. **Methods:** Wild type C57BL/6J mice were assigned to voluntary wheel running (VWR) or usual activity (UA) and ad-lib water and chow for 28-days (n = 4 male and 4 female mice in each group). On day 28, free water was removed and 2-bottle choice: Ethanol in escalating doses every 2 days until endpoint (2% day 28-30, 4% day 30-32, 8% day 32-34) or water were provided and the bottle positions switchd daily. Total fluid and ethanol consumption, and blood alcohol concentrations were measured at the end of the study. Mean rotations, distance run, and hourly rotations/distance run were calculated over the full 24-hour period for each mouse evey day of the 6 days prior to and during the 2-bottle choice. Dark (1900-0659) and light (0700-1859) cycles were also analyzed separately in secondary analyses. Paired t-tests were used to compare activity in each individual mouse in the week pre- and post-ethanol exposure and in the light vs dark cycles. **Results:** Since there were no differences between male and female VWR (rotations,distance run) during the water only or 2-bottel choice periods of the study ($p > 0.05$) (Fig 1A). Hence, all 8 mice were analyzed together pre- and post-ethanol exposure. There was no statistically significant difference between running counts the week before ethanol and the 6 days of ethanol exposure as a 2 bottle choice ($t = 1.50$, $p = 0.178$) (Fig 1B). There were no differences in wheel running activity at different ethanol doses (2% vs 4%: $p = 0.131$, 4% vs 8%: $p = 0.944$, 2% vs 8%: $p = 0.101$) (Fig 1C). Greater wheel running during the dark vs. light cycle ($t = 8.21$, $p = 7.71 \times 10^{-5}$) is consistent with the nocturnal activity of mice. Wheel running activity also did not change between the week before and after ethanol exposure during the light cycle ($t = -0.13$, $p =$

0.899) or dark cycle (t = 1.55, p = 0.165) (Fig 1D). **Conclusion:** Ethanol exposure did not alter voluntary locomotor activity in mice when analyzed within/between groups, stratified by light/dark cycle, or increasing ethanol concentrations. VWR, a model that replicates human activity, in mice can be used to study the effects of alcohol responses in mice.

1600 | IMPLEMENTING A PARTICIPATORY PROCESS TO SUSTAIN BIO-PSYCHO-SOCIAL SUPPORT FOR AUD, METALD, AND ALD PATIENTS

Jennifer Jones[1] Neeraj Mistry[2] Suthat Liangpunsakul[3], [1]Sober Livers, [2]Fatty Liver Foundation, [3]Indiana University School of Medicine

Background: Contemporary medicine increasingly acknowledges that health outcomes are shaped not only by disease progression but also by patients' psychological and social context. Alcohol use disorder (AUD) and alcohol-associated liver disease (ALD) exemplify the bio-psycho-social complexity that demands a multifaceted approach to harm reduction, treatment, recovery, and rehabilitation. Effective interventions must be informed by scientific advances, stakeholder engagement, and the lived experiences of those affected. Given the spectrum of AUD and alcohol-associated disease severity, patient-centered and participatory models are essential to "meet patients where they are." Sober Livers is a patient-led organization supporting individuals with AUD, MetALD, and ALD, including pre- and post- liver transplant patients. The organization launched HOPE (Healing Ourselves with Peers and Education), a virtual peer community supported by the Whole Health Advisory Committee (WHAC) of scientific and clinical experts. **Methods:** HOPE and WHAC adopt a bio-psycho-social theory of change that leverages compassionate, empathic peer engagement to promote behavior change and enhance treatment outcomes. Initial data were gathered through Knowledge, Attitudes, and Practices (KAP) assessments to guide the development of a comprehensive mixed-methods evaluation framework. **Results:** Preliminary feedback and findings from the qualitative KAP assessments include: an expressed need and appreciation for peer-led AND expert-input education and information sharing; a sense of solidarity and support through the HOPE community; and support for more holistic approaches to managing AUD and ALD. More details will be presented at AASLD's The Liver Meeting (TLM) including a framework with qualitative and quantitative metrics of patient well-being; experiences of shame, stigma, and empowerment; alcohol consumption patterns; biochemical markers; and liver health. These metrics illustrate the multi-dimensional impact of peer-led engagement for behavior change and recovery outcomes. **Conclusion:** AUD/ALD care and treatment success varies, underscoring the need for holistic and personalized approaches. Supporting individuals with AUD/ALD requires a bio-psycho-social approach to address holistic patient needs. Combining peer support with medical expertise offers a strong foundation for multidisciplinary and multistakeholder engagement, enhancing the impact and reach of interventions within the patient community.

1601 | PRE-TRANSPLANT ALCOHOL-RELATED LIVER DISEASE CLINIC: A MULTIDISCIPLINARY CLINIC APPROACH TO TREATMENT OF ALCOHOL-RELATED LIVER DISEASE AND ALCOHOL USE DISORDER

Jasleen Singh[1] Eshan Walia[1] Amy Richards[1] Julio Meza[1] Akshay Shetty[1] Sammy Saab[2], [1]UCLA, [2]University of California, Los Angeles

Background: Alcohol-related liver disease (ALD) is the leading indication for liver transplantation (LT) in the United States. The underlying alcohol use disorder (AUD) is critical to address, especially when evaluating patients for LT. AUD treatment has also been shown to improve survival. A multidisciplinary clinic with hepatology and addiction medicine may further inform decision-making prior to LT, improve rates of re-compensation and may decrease risk of alcohol relapse. **Methods:** Patients with decompensated ALD and AUD referred to PAC (Pre-transplant Alcohol-related liver disease Clinic) were included in this study. In addition to sociodemographic and clinical variables, AUD treatment, TIPS, receipt of LT and mortality were collected. Re-compensation, defined as the resolution of portal hypertensive complications and normalization of liver function, was also included. Descriptive statistics were used. **Results:** From March 2024 to January 2025, 62 patients were evaluated in PAC at University of California-Los Angeles, with a mean follow up time of 236 (± 90.4) days. Most patients were male (59.7%), Caucasian (46.8%), with private PPO insurance (43.5%) and were English-speaking (85.5%). Mean MELD of patients at initial visit was 18.3 (± 8.0). Twenty patients were on naltrexone, acamprosate or a combination of both. Of those on medication, 4 discontinued treatment during the study period. Of the 62 patients, 24 patients re-compensated and 37.5% of those patients were on AUD therapy. A quarter of patients relapsed after the initial visit in PAC, and 10 (62.5%) of those 16 patients who relapsed were prescribed AUD treatment. Ultimately 39 patients were evaluated for LT and 20 were listed for LT. Five of the 20 listed patients received LT through January 2025. The full characteristics of the cohort are described in the table. **Conclusion:** In this multidisciplinary clinic with hepatology and addiction medicine, we describe a cohort of patients with ALD and AUD. While most of the patients were ultimately evaluated for liver transplant, many patients also re-compensated in this time period. Concurrent treatment of ALD and AUD may benefit this patient population, improve LT candidacy and potentially promote re-compensation, obviating the need for LT. Longer term follow up with a larger cohort is necessary to explore associations amongst these variables.

Characteristics of Patients Referred to PAC from March 2024-January 2025.

Characteristic	n (%)	Mean (SD)
Age (years)		48.4 (11.9)
Sex		
Male	37 (59.7%)	
Female	25 (40.3%)	
Race		
Caucasian	29 (46.8%)	
Other	25 (40.3%)	
African American	3 (4.8%)	
Multiracial	2 (3.2%)	
Asian	1 (1.6%)

1602 | PREDICTING ALCOHOL RELAPSE IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE AFTER TRANSPLANT EVALUATION

Mohamad Ali Ibrahim Nagham Ramadan[1] Sherry Fares[1] Caroline Ankoma-Sey[1] Megha Bhongade[1] Mazen Elsheikh[1] Sohm Manzoori[1] Islam Mohamed[2] Youseph Karouni[1] Karim Adhem[1] Ximena Ramirez-Morales[1] Manal Hassan[3] Prasun Jalal[1], [1]Baylor College of Medicine, [2]The Cleveland Clinic Foundation-Fairview hospital, [3]The University of Texas MD Anderson Cancer Center

Background: Alcohol-associated liver disease (ALD) is the leading indication for liver transplantation (LT) in the United States. However, alcohol relapse (AR) after LT remains a major concern, associated with poor graft outcomes and reduced survival. Existing predictive models focus on the post-LT period and are limited in clinical applicability. This study aims to identify predictors of AR in ALD and MetALD patients undergoing LT evaluation. **Methods:** We conducted a retrospective cohort study of 181 patients with ALD or MetALD referred for LT evaluation at Baylor College of Medicine between October 2021 and August 2023. AR was defined as a positive phosphatidylethanol (PEth) test >20 ng/mL after evaluation. Baseline clinical, psychosocial, and alcohol history data were collected. Multivariable logistic regression was used to identify independent predictors of AR. Subgroup analysis included only patients listed or transplanted, excluding patients declined for listing. **Results:** Among 181 patients (mean age 53 $\pm$ 11 years, 43% female), 30 (16%) experienced AR after evaluation. Of these, 23% relapsed while listed, 37% after LT, and 40% after being declined. The AR group was more likely to have a positive PEth at evaluation (55% vs. 21%, $p<0.001$), earlier age of alcohol initiation (17 vs. 22 years, $p=0.029$), and history of alcohol-related legal issues (40% vs. 20%, $p=0.016$). In multivariable analysis, the strongest predictors of AR were positive PEth (OR 7.34, $p=0.002$), earlier alcohol initiation (OR 0.88, $p=0.039$), and alcohol-related legal issues (OR 3.58, $p=0.046$). LT listing, receipt, and recompensation rates were similar between patients who relapsed and those who didn't. In the subgroup excluding non-listed patients, active substance abuse (OR 12.46, $p=0.013$) and alcohol-related legal issues (OR 4.54, $p=0.010$) remained significant predictors. We developed two scores to estimate AR in our patients. In the overall cohort, the model included PEth positivity, age at alcohol initiation, and legal history (AUC = 0.819). In the waitlisted/transplanted subgroup, it included active substance use and legal history (AUC = 0.729). **Conclusion:** Factors including positive PEth, early age of alcohol initiation, alcohol-related legal issues, and active substance abuse on LT evaluation are strong predictors of alcohol relapse after LT evaluation. These findings support early identification of high-risk patients during LT evaluation and highlight the need for targeted interventions prior to listing and LT.

1603 | OUTCOMES IN METABOLIC DYSFUNCTION AND ALCOHOL-RELATED LIVER DISEASE COMPARED TO ALCOHOL-ASSOCIATED LIVER DISEASE IN PATIENTS REFERRED FOR LIVER TRANSPLANT EVALUATION

Mohamad Ali Ibrahim[1] Nagham Ramadan[1] Islam Mohamed[2] Caroline Ankoma-Sey[1] Sherry Fares[1] Eric Nguyen[1] Mazen Elsheikh[1] Megha Bhongade[1] Youseph Karouni[1] Ximena Ramirez-Morales[1] Karim Adhem[1] Manal Hassan[3] Prasun Jalal[1], [1]Baylor College of Medicine, [2]The Cleveland Clinic Foundation-Fairview hospital, [3]The University of Texas MD Anderson Cancer Center

Background: Metabolic dysfunction and alcohol-related liver disease (MetALD) is a recently defined entity combining metabolic syndrome and moderate-to-high alcohol consumption (140-350g/week for females and 210-420g/week for males). Its distinction from alcohol-associated liver disease (ALD) remains underexplored, particularly regarding liver transplant (LT) evaluation outcomes. **Methods:** We conducted a retrospective cohort study of 194 patients referred for LT evaluation between October 2021 and August 2023 at a single U.S. transplant center. Patients were categorized as ALD or MetALD per Delphi consensus definitions. The primary outcomes were liver recompensation (LR) within 12 months (defined as MELD-Na <15 and absence of ascites, hepatic encephalopathy, cirrhosis-related gastrointestinal bleeding, and jaundice), LT and mortality rates. Predictors were analyzed using multivariable Cox regression. **Results:** Of the 194 patients, 135 (70%) had ALD and 59 (30%) MetALD. Baseline characteristics showed significantly higher BMI (31 vs. 28 kg/m², $p=0.001$), chronic kidney disease (32% vs. 17%, $p=0.025$), and lower Karnofsky scores

(51 vs. 62, p = 0.014) in the MetALD group. While no statistical difference was found in listing and LT rates between groups, LR occurred significantly less often in MetALD compared to ALD (3% vs.18%, p = 0.006). On multivariable analysis, MetALD independently predicted lower LR (HR 0.21, 95% CI: 0.05–0.91). Hypertension (HR 0.38, 95% CI: 0.16–0.89) and increasing BMI (HR 0.91, 95% CI: 0.84–0.99) were also significantly associated with lower LR. While overall mortality was higher in the MetALD group (42% vs. 26%, p = 0.029), MetALD was not an independent mortality predictor after adjustment. Higher MELD-Na score and older age were associated with increased mortality, while LT was protective. **Conclusion:** Compared to ALD, MetALD is associated with significantly lower LR and higher unadjusted mortality following LT evaluation. These findings emphasize the prognostic impact of metabolic comorbidities and support the need for tailored strategies in this emerging high-risk liver disease phenotype. **Disclosures:** Mohamad Ali Ibrahim: Nothing to Disclose, Nagham Ramadan: Nothing to Disclose, Islam Mohamed: Nothing to Disclose, Caroline Ankoma-Sey: Nothing to Disclose, Sherry Fares: Nothing to Disclose, Eric Nguyen: Nothing to Disclose, Mazen Elsheikh: Nothing to Disclose, Megha Bhongade: Nothing to Disclose, Youseph Karouni: Nothing to Disclose, Ximena Ramirez-Morales: Nothing to Disclose, Karim Adhem: Nothing to Disclose, Manal Hassan: Nothing to Disclose, Prasun Jalal: Nothing to Disclose

1604 | HEPATOCYTE CEBPA-ORM1 AXIS RESTRICTS ALCOHOL-ASSOCIATED LIVER DISEASE

Tingting Yan[1] Nana Yan[2] Yangliu Xia[3] Haiping Hao[1] Frank Gonzalez[3], [1]China Pharmaceutical University, [2]China Pharmaceutical University; National Cancer Institute, [3]National Cancer Institute

Background: Alcohol-associated liver disease (ALD) represents a major global health burden with limited therapeutic options. Although hepatocyte CCAAT/enhancer-binding protein α (CEBPA) critically regulates hepatocyte maturation, differentiation, glycogen metabolism, and liver fibrosis progression, its contribution to ALD pathogenesis remains undefined. **Methods:** The role of the hepatocyte CEBPA-ORM1 axis in ALD was investigated using hepatocyte-specific constitutive/inducible Cebpa-knockout mice, adeno-associated virus serotype 8 (AAV8)-mediated overexpression or knockdown, and preclinical ALD models. Mechanistic insights into CEBPA-ORM1 signaling were elucidated using chromatin immunoprecipitation (ChIP) and luciferase reporter assays, complemented by translational analyses of human ALD serum and liver specimens to establish its clinical and pathophysiological relevance. **Results:** Hepatic CEBPA expression was found to be decreased during ALD progression in human patient cohorts. Hepatocyte-specific *Cebpa*-knockout (*Cebpa*$^{\Delta Hep}$) mice exhibited exacerbated alcohol-associated steatosis in both acute and chronic ALD models. Inducible ablation of CEBPA in hepatocytes during late-stage ALD accelerated disease progression, demonstrating its persistent protective function. Mechanistically, CEBPA directly activates orosomucoid 1 (*Orm1*) transcription by binding to CEBP response elements within the *Orm1* promoter. Loss of CEBPA suppressed ORM1, a hepatokine whose hepatic production and circulating levels are inversely correlated with ALD severity in patients. Loss of hepatocyte ORM1 worsened ALD in mice, whereas restoring CEBPA or ORM1—via AAV8-mediated gene delivery or recombinant protein administration—rescued hepatic lipid metabolism and reduced disease progression. **Conclusion:** Hepatocyte CEBPA-ORM1 axis acts as a critical suppressor of ALD, which provides a compelling therapeutic target for ALD treatment and nominates serum ORM1 as a potential biomarker for staging ALD severity.

1605 | METABOLIC AND ALCOHOL-ASSOCIATED (METALD) LIVER DISEASE RELATED CIRRHOSIS HAS WORSE DISEASE SEVERITY AND HIGHER MORTALITY THAN OTHER ETIOLOGIES

Nicole Welch[1] Ana Ostojic[1] Annette Bellar[1] Amy Attaway[1] Lars Deutz[1] Ryan Musich[1] John McMichael[1] Lopa Mishra[2] Srinivasan Dasarathy[1], [1]Cleveland Clinic, [2]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory

Background: We evaluated if etiology of cirrhosis impacts adverse cliinical outcomes including

decompensation and hepatocellular carcinoma (HCC). **Methods:** 29,999 patients with cirrhosis rom January 2000-December 2024 were evaluated at a large transplant center were evaluated from their electronic medical records (EMR). Etiologies were identified by ICD9 and ICD10 codes. To standardize the cohort, patients were included if they had compensated cirrhosis or decompensated cirrhosis without recompensation (identified by bleeding, encephalopathy, and ascites). The cohort was further stratified by etiology into metabolic associated steatotic liver disease (MASLD), alcohol associated (ALD), metabolic and alcohol-associated (MetALD, had a diagnosis code for both MASLD and ALD), viral hepatitis-associated (VLD), and other liver disease. HCC was determined by biopsy, imaging, or physician documentation with corroborative evidence. A random sample of subject data were verified by investigator evaluation of the EMR. **Results:** The majority of patients in the cohort had cirrhosis from MASLD (n = 13560; 45.2%), ALD (n = 8533, 28.4%), VLD (n = 3049;10.2%), Other (n = 2764; 9.2%), MetALD(n = 2093,7.0%). Of the steatotic disease etiologies, MetALD cirrhosis patients were more likely (21.1 MetALD, 16 ALD, and 12.6% MASLD) to be on dialysis and to report abstinence from alcohol (66.8% MetALD; 61.4% MASLD; 54.9% ALD). Patients with ALD (n = 2986/8533; 35.0%) were more likely ($p < 0.001$) to report active drinking than either those with MASLD (n = 2973, 21.9%) or MetALD (n = 554/2093,26.5%). Ascites was the most frequent cause of initial decompenstation in all etiologies. Patients with ALD and MetALD were more likely to have decompensated disease (ALD:5150/8533, 60.4%; MetALD:1459/2093, 69.7%) while patients with MASLD, VLD, and other etiologies were more likely to have compensated disease (MASLD:8342/13560, 61.5%; VLD:2044/3049, 67.0%; Other: 1965/2764, 71.1%). Of the patients with HCC (n = 2489), patients with MASLD, ALD, and MetALD were more likely to have decompensated HCC while patients with VLD and other etiologies were more likely to have compensated HCC (Table 1). Of those patients who had fibroscans, patients with ALD and MetALD were more likely ($p < 0.001$) to have KPA scores $\geq$ 15 compared to patients with other etiologies of liver disease. At the end of follow-up, mortality rate was highest ($p < 0.001$) in those with MetALD (47%) compared to that in the other etiologies (ALD:46.5, MASLD:46.6, VLD:40.4, and Other:29.5%). **Conclusion:** In this large single center cohort of patients evaluated over a 24-year period, patients with MetALD cirrhosis had higher rates of alcohol use, decompensation, dialysis dependence, stiffness scores on fibroscan, and higher rates of HCC. MetALD was associated with the highest overall mortality, suggesting the need for improved clinical recognition and management strategies, especially for alcohol cessation.

Table 1. Disease and hepatocellular carcinoma (HCC) status

Etiology of cirrhosis	MASLD	ALD	MetALD	VLD	Other	Totals
No HCC compensated (%)	7881 (58.1)	3181 (37.3)	573 (27.4)	1791 (58.7)	1901 (68.8)	15327 (51)
No HCC decompensated (%)	4892 (34.6)	4703 (55.1)	1262 (60.3)	774 (25.4)	751 (27.2)	12182(41)
HCC compensated (%)	461 (3.4)	201 (2.4)	61 (2.9)	253 (8.3)	64 (2.3)	1040(3)
HCC decompensated (%)	526 (3.9)	448 (5.3)	197 (9.4)	231 (7.6)	48 (1.7)	1450(5)
Total	13560 (45.2)	8533 (28.4)	2093 (69.8)	3049 (10.2)	2764 (9.2)	29999

1606 | PROTOCOL FOR INITIATION OF MEDICATIONS FOR ALCOHOL USE DISORDER (MAUD) AT INDEX HOSPITALIZATION FOR LIVER TRANSPLANTATION IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE

Rachel Zuzul[1] Andrew Muir[1] Stephanie Garbarino[1], [1]Duke University

Background: There has been a shift in the attitude on prolonged alcohol abstinence prior to transplant for patients with alcohol-associated liver disease (ALD) over the recent years with a focus on earlier liver transplantation (LT) in this population. However, patients with ALD who experience relapse have worse outcomes. Addressing underlying alcohol use disorder (AUD) using a multi-modal approach like pharmacotherapy, has been shown to be effective. Identifying patients at high risk for relapse post-LT and initiating medications for alcohol use disorder (MAUD) is feasible and safe and may reduce rates of relapse and improve post-transplant outcomes. The aim of this study was to evaluate the feasibility of a post-LT MAUD protocol. **Methods:** This was a single center, retrospective analysis. An internal protocol was implemented in January 2024 where all patients with ALD who were deemed high risk for relapse by prespecified criteria determined by a multi disciplinary psychosocial team at the time of listing were started on post-LT MAUD at the index hospitalization (Figure 1). Choice of MAUD agent was determined primarily by renal function with the first line agent being acamprosate. Patients were continued on MAUD for at least one year post-transplant. The primary endpoint was relapse after transplant. Phosphatidyl ethanol (PEth) levels were collected every 3 months for the two years post-LT to detect alcohol relapse, definited as a PEth > 20. **Results:** Sixty-three patients underwent LT for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ALD between January 1, 2024 and April 14, 2025. Forty-two patients (67%) met the protocol indications for MAUD, and 42/42 (100%) initiated MAUD. Treatment regimens were acamprosate for 23 (55%) patients, gabapentin for 18 (43%), and naltrexone for one. Zero patients received baclofen. The median follow-up time for this patient cohort was 9 months (range 1-15 months). At the time of this analysis, 1/42 (2.4%) experienced relapse, and that patient prematurely discontinued their MAUD after 2 months of therapy due to reported lack of alcohol cravings. Of the patients who did not meet the protocol criteria for MAUD, 2/21 (9.5%) experienced relapse. **Conclusion:** Data on the use of MAUD in the post-transplant setting is limited, and this study found that implementation of a post-transplant MAUD protocol for patients undergoing LT with ALD that are deemed high risk for relapse was feasible. Early outcome data suggests low relapse rates for post-LT patients undergoing MAUD treatment. Two of the three patients with relapse were not on MAUD, suggesting there could be expansion of the eligibility criteria for MAUD in the protocol. Limitations include that this is a single-center, retrospective analysis and the limited follow-up time. Further research is needed to refine the criteria for MAUD therapy after LT and to understand the long-term outcomes of LT for AUD with MAUD.

Figure 1: Protocol for choice of MAUD agent for liver transplant in patients with ALD

1607 | DIETARY QUERCETIN SUPPLEMENTATION ATTENUATES ALCOHOL INDUCED HEPATIC ER STRESS AND APOPTOSIS BY DECREASING KYNURENINE LEVELS

Leila Gobejishvili[1] Walter Rodriguez[2] Yali Wang[2] JingWen Zhang[2] Shirish Barve[2] Craig McClain[2],
[1]University of Louisville, [2]School of Medicine, University of Louisville, Louisville, KY, USA.

Background: Alcohol mediated production of hepatic kynurenine (KYN) has been shown to contribute to dysregulated lipid metabolism in a mouse model of alcohol-associated liver disease (ALD). This effect was mediated by activation of hepatic aryl hydrocarbon receptor (Ahr) by KYN. Hepatocyte specific Ahr deletion prevented alcohol induced lipid accumulation in the liver. The dietary flavonol, quercetin has been shown to alleviate alcohol induced steatosis, however the exact underlying molecular mechanisms are not known. Hence, the present work was performed to investigate quercetin mediated protection of alcohol induced steatosis and injury involving pathogenic hepatic KYN/Ahr signaling. **Methods:** C57Bl/6 mice were used in a chronic plus binge of ALD (10 plus one, NIAAA model). Mice were fed control and alcohol diet with and without quercetin, which was dissolved in the diet. Daily quercetin dose was calculated based on the amount of food consumed (100 mg/kg body weight daily). At the end of experiment plasma and liver tissues were collected. Plasma was used to analyze liver injury markers; liver tissue was used for metabolomic and gene expression analyses. Formalin fixed liver tissues were evaluated for hepatocyte apoptosis using terminal deoxynucleotidyl transferase dUTP nick end labeling ((TUNEL). Statistical analysis was carried out using one-way ANOVA. **Results:** Metabolomic analysis of liver tissues revealed that alcohol markedly increased kynurenine and decreased quercetin levels. Notably, quercetin supplementation decreased liver kynurenine levels and activation of Ahr as demonstrated by decreased the Ahr target gene, *Cyp1a1*. Pearson correlation analysis showed that high liver KYN levels significantly correlated with the liver injury marker, alanine transaminase (ALT) ($r = 0.66$, $P = 0.0002$) and negatively correlated with liver quercetin levels ($r = -0.55$, $P = 002$). Notably high liver quercetin levels were associated with lower ALT ($r = -0.525$, $P = 0.004$). Alcohol increased the liver to body weight ratio, which was prevented by quercetin. Alcohol induced liver endoplasmic reticulum (ER) stress was decreased by quercetin as demonstrated by significantly lower mRNA levels of ER stress markers *Chop, Atf3, Gadd45a,* and *Gadd45b*. Alcohol induced hepatocyte apoptosis was also markedly attenuated by quercetin supplementation. **Conclusion:** Alcohol induced liver injury in mice is

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

associated with decreased hepatic quercetin levels and increased production of kynurenine. Dietary quercetin supplementation decreases the levels and pathogenic signaling of kynurenine caused by alcohol.

1608 | PNPLA3 RS738409 RISK VARIANT OUTPERFORMS MBOAT7 RS641738 POLYMORPHISM IN PREDICTING ALCOHOL RELATED LIVER DISEASE (ALD) AND SHORT LEUKOCYTE TELOMERE LENGTH IS ASSOCIATED WITH HIGH FIB4 SCORE

Vaishali Yadav[1] Saggere Muralikrishna Shasthry[2] Kanica Kaushal[2] Mohit Varshney[2] Satender Singh[2] GURESH KUMAR[2] Rishabh Sharma[2] Nirupama Chatterjee[3] Nirupma Trehanpati[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, [2]Institute of Liver and Biliary Sciences New Delhi, India, [3]Artemis Education & Research Artemis Hospital, Gurugram, India

Background: Alcohol related liver disease (ALD) is the leading cause of cirrhosis globally and in India. Despite heavy drinking, only ~30% develop steatohepatitis, suggesting a strong genetic influence. This study evaluated *PNPLA3* rs738409 (148M) and *MBOAT7* rs641738 risk variants as predictors of ALD and assessed whether combining them with clinical markers and leukocyte telomere length improves prediction. **Methods:** Patients with ALD (N = 183) and alcohol use disorder (AUD) without liver disease (N = 55) were enrolled. *PNPAL3* was genotyped by PCR-Sanger sequencing and TaqMan Assay was used for *MBOAT7*. Leukocyte telomere length was measured by qPCR and expressed as the T/S ratio. **Results:** Amongst the various clinical parameters AST (IU/L) (Aspartate Aminotransferase) levels were significantly high in patients with ALD compared to those with AUD with [108 (23.7–1179) vs. 30.7 (23–44), $p < 0.001$]. Interestingly, individuals with AUD had higher overall alcohol intake, both in quantity (155.6 ± 63.13 g vs. 120.6 ± 61.9 g, $p = 0.0004$) and duration (17.21 ± 10.07 years vs. 13.88 ± 5.99 years, $p = 0.0029$). The PNPLA3 rs738409 risk variant (CG/GG) was more prevalent in ALD than AUD (G = 0.355 vs. G = 0.214, $p < 0.01$). Similarly, MBOAT7 rs641738 risk variants (TC/CC) were also more frequent in ALD (C = 0.495 vs. C = 0.391, $p < 0.01$). AUC for PNPLA3 and MBOAT7 to predict ALD was 0.616 (95% CI: 0.92–3.45) and 0.566 (95% CI: 1.04–7.9), respectively. Combining both variants together offered little benefit and only PNPLA3 remained significant. Hence, PNPLA3-based models were tested for ALD: Model 1 (adjusted for AST) PNPLA3 GG genotype had OR 11.11 (CI: 1.4–87.9), AUC = 0.82. Model 2 (adjusted for alcohol amount): OR = 6.9 (CI: 1.48–32.23), AUC = 0.736. Model 3 (adjusted for duration): OR = 5.53 (CI: 1.24–24.69), AUC = 0.641. Model 4 (adjusted for both): OR = 5.56 (CI: 1.2–25.79), AUC = 0.757. A negative coefficient for alcohol usage in Models 2–4 suggests PNPLA3 adds genetic susceptibility to liver disease even at lower alcohol levels. Leukocyte telomere length (T/S ratio) was significantly shorter in ALD than AUD (8.545 ± 1.002 vs. 8.943 ± 0.9832, $p = 0.0193$), and inversely correlated with fibrosis severity (FIB-4: r = –0.64, $p < 0.001$). **Conclusion:** *PNPLA3* rs738409 is an independent ALD predictor, with *MBOAT7* showing weaker association. Combining *PNPLA3* with AST or alcohol intake improves risk prediction. And risk GG genotype of PNPALA3 increases ALD risk even at lower alcohol exposure.

	p value	Odds Ratio	95% CI	AUC
PNPLA3 GG	0.013	8.51	1.48 - 28.69	61.6
MBOAT 7 CC	0.042	2.87	1.04 - 7.9	56.6

Stärkel[6] AlcHepNet Investigators[7] Bernd Schnabl[3], [1]University of California San Diego, [2]UCSD, [3]University of California, San Diego, [4]Leibniz Institute for Natural Product Research and Infection Biology, Jena; Germany, [5]University of Zurich, University of Exeter, [6]Cliniques universitaires Saint-Luc, Brussels, [7]Indiana University School of Medicine

Background: Transitioning from yeast to hyphal morphology enables *Candida albicans* to secrete the exotoxin candidalysin, invade the intestinal mucosa, and translocate to the bloodstream. Patients with alcohol-associated hepatitis have an increased abundance of *C. albicans* in the intestinal microbiome, and fecal presence of the gene encoding candidalysin is associated with reduced survival. Paneth cell-derived peptide YY (PC-PYY) inhibits hyphal growth of *C. albicans*. In this study, we evaluated the potential of different *C. albicans* strains isolated from patients with alcohol-associated hepatitis to induce cytotoxicity and explored the therapeutic potential of PC-PYY in a mouse model of ethanol-induced liver disease. **Methods:** *C. albicans* strains isolated from fecal samples of patients with alcohol-associated hepatitis were co-cultured with intestinal epithelial Caco-2 cells to assess in vitro cytotoxicity. Caco-2 cells and primary mouse hepatocytes were incubated with *C. albicans* and PC-PYY. Mice were subjected to chronic plus binge ethanol feeding. **Results:** *C. albicans* strains isolated from stool of patients with alcohol-associated hepatitis induced significant cytotoxicity in Caco-2 cells, and high cytotoxicity was associated with worse 30-day survival (Fig. A). This functional cytotoxicity is primarily associated with the hyphal form, largely driven by candidalysin. *C. albicans* strains which expressed candidalysin induced higher cytotoxicity in primary mouse hepatocytes compared with strains expressing no candidalysin. PC-PYY significantly reduced *C. albicans*-induced cytotoxicity in Caco-2 cells and primary mouse hepatocytes compared with a scrambled peptide as a control by inhibiting hyphal morphology. Peptide YY to chromogranin A ratio in intestinal crypts was significantly elevated in ethanol-fed mice compared with both isocaloric and antifungal-treated controls indicating that fungal overgrowth in ethanol-fed mice stimulates PC-PYY release. Immunofluorescence showed that in ethanol-fed mice, PC-PYY is increased compared with isocaloric controls. In mice subjected to the chronic plus binge ethanol feeding model, PC-PYY administration attenuated liver injury and steatosis, and reduced hyphae formation in the feces (Fig. B-C). **Conclusion:** PYY inhibits filamentous growth of *C. albicans* in vitro and alleviates ethanol-induced liver disease in mice, highlighting its potential as a therapy for patients with alcohol-associated liver disease.

1610 | LIVER SINUSOIDAL ENDOTHELIAL CELLS EXHIBIT TRAINED IMMUNITY FEATURES FOLLOWING POLY I:C EXPOSURE

Weizhe Zhong[1] Benjamin Swartzwelter[1] Fiona Xhafi[1] Mengfei Liu[2], [1]Division of Digestive Disease, Internal Medicine, Yale University; Yale Liver Cente, Yale University, [2]Division of Digestive Disease, Internal Medicine, Yale University;Yale Liver Center, Yale University

Background: Trained immunity refers to the long-term functional reprogramming of innate immune cells, resulting in an altered response upon secondary stimulation. This concept was first described in myeloid cells, where prior exposure to microbial stimuli leads to epigenetic and metabolic changes that influence secondary responses to pathogen challenge. Liver sinusoidal endothelial cells (LSECs) form the primary barrier between circulating blood and hepatic parenchymal cells. Beyond their structural role, LSECs possesses multiple innate-like immune functions by secreting

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

inflammatory cytokines and interacting with immune cells. However, whether and how LSECs undergo trained immunity remains unknown. This study aims to determine whether LSECs can acquire a trained immunity–like phenotype in response to microbial stimuli. **Methods:** We established an *ex vivo* model to assess innate immune memory in LSECs. Mice were intraperitoneally injected with either PBS (control), 1 mg of β-glucan, or 200 μg of Poly I:C. After a 7-day resting period, mice were sacrificed and livers harvested. Liver tissues were processed by perfusion and enzymatic digestion. LSECs were enriched using magnetic bead-based selection for CD146-positive cells. Purified LSECs were restimulated with IFNγ, IFN-β, LPS, or TNF-α, and immune gene expression was assessed by PCR. In parallel, bone marrow cells were isolated from the femurs and tibias of treated mice and differentiated into bone marrow–derived macrophages (BMDMs) using colony-stimulating factor (CSF). Inflammatory cytokine expression in BMDMs was similarly analyzed by PCR. **Results:** Poly I:C priming induced a pronounced proinflammatory response in LSECs upon secondary stimulation, characterized by significantly elevated expression of inflammatory mediators (*Cxcl9* and *Il6*). This enhancement was particularly evident following IFN-β and LPS challenges. In addition, increased expression of *Ccl2*, *Cxcl1*, and *Vcam1* was observed across multiple stimuli in Poly I:C–primed LSECs, supporting the acquisition of a trained immunity phenotype. A comparable effect was observed in BMDMs, where LPS stimulation led to a marked upregulation of *Il6* mRNA expression in cells primed with either β-glucan or Poly I:C, relative to PBS-treated controls. These data are consistent with the induction of trained immunity in both endothelial and myeloid compartments following exposure to stimuli. **Conclusion:** Our findings provide the first evidence that LSECs are capable of developing innate immune memory in the form of trained immunity. This observation expands our understanding of the potential roles of liver structural cells in innate immune responses of the liver.

1611 | FIRST IN LINE: A SUCCESSFUL EARLY LIVER TRANSPLANT FOR CATASTROPHIC SEVERE ALCOHOL-ASSOCIATED HEPATITIS USING THE ELFSAH PROTOCOL AT A TERTIARY CENTER

Rachel Patel[1] Caty Davenport[1] Daniel Logatto[1] Asuwin Anandaram[1] Fahad Khan[1] Samir Patel[1] George Rofaiel[1] Shahid Malik[1], [1]Lehigh Valley Health Network

Background: Severe alcohol-associated hepatitis (SAH), defined by a MELD-Na ≥20 or Maddrey's DF ≥32, is associated with high short-term mortality. In catastrophic SAH (MELD-Na ≥35 or DF ≥100), outcomes are especially poor. Corticosteroids, once the mainstay of treatment, show limited efficacy in this subgroup and may delay transplant. The Expedited Liver Transplantation as First-Line Therapy for Severe Alcohol-Associated Hepatitis (ELFSAH) protocol recommends deferring steroids and prioritizing transplant in these patients. We describe the first successful application of the ELFSAH protocol at a large tertiary center. **Methods:** A 31-year-old woman with alcohol use disorder presented with jaundice, abdominal pain, and acute decompensation. Imaging revealed cirrhosis, steatosis, ascites, and pleural effusions. Labs showed bilirubin 20 mg/dL, INR 5.5, creatinine >4 mg/dL, MELD-Na >40, and DF 120—consistent with catastrophic SAH. She developed multi-organ failure requiring ICU care and renal replacement therapy. In accordance with ELFSAH, corticosteroids were deferred and transplant evaluation was initiated. **Results:** The patient was evaluated by transplant hepatology, surgery, psychiatry, and social work. She had strong psychosocial support and commitment to abstinence. She was listed and successfully transplanted within 3 days. Explant pathology confirmed cirrhosis with superimposed SAH. Postoperatively, she recovered well, was discharged in one week, and remains abstinent with normal liver function on outpatient follow-up. Her management includes behavioral therapy, acamprosate, and serial PETH testing. **Conclusion:** The application of the ELFSAH protocol in this case of catastrophic SAH resulted in a successful liver transplant and recovery for a patient who would likely not have survived under traditional management. As liver transplant programs increasingly adopt early transplantation strategies for SAH, this case serves as

a powerful example of how evidence-based, patient-centered care can redefine outcomes in one of the most challenging areas of transplant hepatology.

1612 | NON-INVASIVE TESTS FOR PROGNOSTICATION IN STEATOTIC LIVER DISEASES: RESULTS: FROM A LONG TERM FOLLOW-UP COHORT OF 3,442 PATIENTS

Jérôme Boursier Marc De Saint Loup[1] Marine Roux[2] Marc Fadel[1] Jean-Marie Chrétien[1] Valerie MOAL[1] LANNES ADRIEN[1] Isabelle Fouchard[1] Pierre Celea[1] Sandra Girre[1] Audrey Morisset[1] Andrea Klingberg[1] Nathanaelle Cornet[1] Jeanne Fichez[1] Anita Paisant[2] Sophie Michalak[1] Christophe Aube[2] frederic oberti[1] Paul Cales[2], [1]Angers University Hospital, [2]Angers University

Background: Cross-sectional studies in steatotic liver diseases (SLD) have shown that elastography and specialized blood tests are more accurate than simple blood tests for diagnosing liver fibrosis, and that combination of biology with elastography offers the highest accuracy. We aimed to evaluate how this ranking of diagnostic tests translates into prognostic accuracy in a large cohort with long-term follow-up. **Methods:** 3,442 patients with SLD (MASLD or alcohol) who underwent non-invasive testing in the Hepatology department of a tertiary care center between 06/2004 and 12/2022 were included. All patients had vibration-controlled transient elastography (VCTE) and four blood tests: the simple blood test FIB4, the specialized blood tests FibroMeter^{V3G} (FM, for advanced fibrosis) and CirrhoMeter^{V3G} (CM, for cirrhosis), and the FibroMeter^{VCTE} (FMVCTE, combination of VCTE with biology for advanced fibrosis). Clinical events during the follow-up were retrieved using CIM10 codes. Liver-related event (LRE) was defined as cirrhosis complication or hepatocellular carcinoma. **Results:** Median age was 59.4 years, 72% of patients were male, and median VCTE result was 9.5 kPa (IQR: 6.1-19.6). 1,440 patients (42%) had MASLD and 2,002 (58%) had excessive alcohol consumption (MetALD/ALD). 733 LRE occurred during the median 5.0 years follow-up (IQR: 2.2-9.0). AUC(t) for predicting LRE at 3 years was 0.82 ± 0.02 for FIB4, FM: 0.81 ± 0.02, CM: 0.82 ± 0.02, VCTE: 0.86 ± 0.03, and FMVCTE: 0.86 ± 0.02. AUC(t) for 5-year prediction was 0.82 ± 0.02 for FIB4, FM: 0.82 ± 0.03, CM: 0.83 ± 0.02, VCTE: 0.86 ± 0.03, FMVCTE: 0.86 ± 0.02. AUC(t) for 10-year prediction was 0.80 ± 0.02 for FIB4, FM: 0.81 ± 0.02, CM: 0.81 ± 0.02 VCTE: 0.84 ± 0.02, FMVCTE: 0.85 ± 0.02. There was no significant difference in AUC(t) between the three blood tests (FIB4, FM, CM) at each time horizon. VCTE and FMVCTE had significantly higher AUC(t) than the three blood tests, with no significant difference between VCTE vs FMVCTE. VCTE, prothrombin time, α2macroglobulin, gammaGT and etiology (MASLD vs alcohol) were independent predictors of LRE. A score combining these five parameters provided the highest AUC(t) (3-year prediction: 0.88 ± 0.02, 5-year: 0.88 ± 0.02, 10-year: 0.87 ± 0.02), with significant difference compared to the five non-invasive tests evaluated (all p values ≤ 0.010). Sensitivity analysis yielded similar results in MASLD and alcohol groups. At fixed results of non-invasive tests, hazard ratio for LRE was higher in patients with excessive alcohol consumption, confirming that alcoholic liver disease has a more aggressive course than MASLD. **Conclusion:** Non-invasive diagnostic tests have very good prognostic accuracy in SLD, with elastography being more accurate than blood tests. However, a specific risk score outperforms diagnostic tests for prognostication. Efforts should be made to develop new risk scores calibrated on events rather than liver lesions to stratify the disease risk.

1613 | MUSCLE INJURY IS CLOSELY RELATED TO HEPATIC ENCEPHALOPATHY IN MALE CHINESE PATIENTS WITH ALCOHOL - RELATED LIVER DISEASE

xiaoting Ma[1] Yu Zhang[2] Song Yang[2] Guoying Yu[3], [1]The Fourth People's Hospital of Qinghai Province, [2]Beijing Ditan Hospital of Capital Medical University, [3]The Fourth People's Hospital of Qinghai Province

Background: Alcohol-related liver disease (ALD) is a series of liver damage caused by long-term excessive alcohol consumption. Its pathological process includes alcoholic hepatitis (AH), alcohol-related cirrhosis (AC), and acute alcoholic hepatitis manifested as acute-on-chronic liver failure. In this process, hepatic encephalopathy (HE), sarcopenia, and myosteatosis are common complications, with complex interactions among them, which may affect their survival. This study aimed to evaluate the occurrence of hepatic encephalopathy and muscle damage (sarcopenia, myosteatosis) in male ALD patients in China, the association between muscle damage and hepatic encephalopathy, as well as the risk factors and prognosis of hepatic encephalopathy. It was determined by using the skeletal muscle index at the third lumbar vertebra level (L3-SMI), BMI, mean, etc. **Methods:** ALD patients hospitalized in Beijing Ditan Hospital affiliated to Capital Medical University and the Fourth People's Hospital of Qinghai Province from 2015 to 2024 were retrospectively included, and their survival status was evaluated through 6-month, 12-month, and 24-month follow-up based on the baseline time. The Cox proportional hazards regression model was used to estimate the survival factors of patients. **Results:** This study included 338 ALD patients, who were followed up for 6 months, 12 months, and 24 months respectively or until the end of the study. Among the ALD patients, 162 had sarcopenia, 241 had myosteatosis, 137 had myosteatosis combined with sarcopenia, 75 had no muscle damage, and 74 had hepatic encephalopathy. The L3-SMI of patients with hepatic encephalopathy was lower than that of patients without hepatic encephalopathy (39.68 ± 8.47cm2/m2 vs 43.65 ± 9.89cm2/m2). The prevalence of myosteatosis in patients with alcohol-related liver disease was significantly higher than that of sarcopenia and hepatic encephalopathy (71.3% vs 47.93% vs 21.89%). L3-SMI, alcoholic hepatitis, alcoholic cirrhosis, liver failure, myosteatosis, ascites, rupture and bleeding of esophagogastric varices, aspartate aminotransferase, total bilirubin, albumin, PT, INR, WBC, PLT, CR, serum sodium, hemoglobin, etc. may be related to hepatic encephalopathy. The 338 ALD patients were followed up for 6 months, 12 months, and 24 months respectively according to the baseline time (patients who did not reach the follow-up time were excluded according to the follow-up time), and the overall survival rates were 90.53% (306/338), 87.57% (296/338), and 78.31% (195/249) respectively. The mortality of patients with liver failure, sarcopenia, decreased albumin, infection, and ascites increased significantly. Multivariate Cox regression analysis showed that liver failure and infection were independent risk factors for short-term death, while liver failure and sarcopenia were independent risk factors for death at 12 and 24 months, and ascites was an independent risk factor for death at 12 months. The hazard ratios for death at 6 months (95% confidence interval) were 0.287 (0.129 - 0.639) and 1.090 (1.021 - 1.184) respectively; the hazard ratios for death at 12 months (95% confidence interval) were 0.449 (0.263 - 0.768), 0.583 (0.347 - 0.981), and 2.321 (1.222 - 4.410) respectively; the hazard ratios for death at 24 months (95% confidence interval) were 0.390 (0.211 - 0.720) and 1.849 (1.020 - 3.350) respectively. **Conclusion:** Hepatic encephalopathy is significantly associated with sarcopenia. Sarcopenia is more likely to lead to hepatic encephalopathy and is an independent risk factor for hepatic encephalopathy. Compared with sarcopenia, myosteatosis is more likely to occur in ALD patients, but there is no significant correlation between myosteatosis and hepatic encephalopathy. Sarcopenia and liver failure are independent risk factors for the onset of hepatic encephalopathy. Sarcopenia and liver failure are independent risk factors for death of patients with alcohol-related liver disease at 12 and 24 months, while sarcopenia has little impact on short-term death.

1614 | POLYENE PHOSPHATIDYLCHOLINE INJECTION REGULATES LIPID HOMEOSTASIS VIA AKT-PDE3-PKA IN MICE

Yang Hu[1] Dan Chai[1] Qiao Geng[2] Li Chen[2] Feng Zhang[2] Ping Qiu[3] Changqing Wang[2] Lungen Lu[4] Desong Kong[1], [1]Nanjing Hospital of Chinese Medicine, [2]Nanjing University of Chinese Medicine, [3]Zhejiang Chinese Medical University, [4]Shanghai General Hospital

Background: Alcoholic liver disease (ALD) is a common liver injury disorder and a growing health concern worldwide.Clinically, the prevention and treatment of alcoholic liver disease are best achieved through abstinence from alcohol, accompanied by the use of hepatoprotective drugs and nutritional support during the period of alcohol cessation.Polyene phosphatidylcholine (PPC) is commonly used as a hepatoprotective medication for a variety of liver diseases in China.The aim of the study is to investigate the mechanisms of PPC in preventing and treating ALD in mice. **Methods:** Ninety standard inbred strain C57BL/6J male mice aged 6 weeks were randomly divided into five groups, with 18 mice in each group. The groups were as follows: the control group was fed a non-alcoholic liquid diet; the alcoholic liver injury model group; the group fed an alcoholic liquid diet + PPC (50 mg/kg); the group fed analcoholic liquid diet + PPC (100 mg/kg); and the group fed an alcoholic liquid diet + PPC (200mg/kg). The feeding period lasted for 12 weeks. After the confirmation of alcoholic liver injury through blood and liver tissue slice analyses in the alcohol-administered groups, indicating the successful establishment of the alcoholic liver injury model, the corresponding concentration of drug intervention treatment was initiated. Histopathological analyses were measured by standard hematoxylin and eosin (H&E) staining、Masson's trichrome staining and Oil Red O staining. Liver damage was assessed by serum ALT, AST,ALP,γ-GGT,TBIL. Lipid metabolism levels were assessed by TG,TC,HDL-c,LDL-c. The level of oxidative stress were assessed by MDA,GSH,SOD. Serum inflammatory index were assessed by TNF-α,IL-6,IL-1β, TGF-β,LPS. RNA-seq technology was performed to search for specific differential genes and related signaling pathways. Western blotting was used to detect differentially expressed genes and related signaling pathway changes in the liver tissue. **Results:** PPC injection significantly improved the pathological damage and steatosis (Figure A), reduced the content of serum liver injury-related indexes(Figure B,C), improved lipid metabolism in serum and liver tissues, improved the levels of oxidative stress in the serum and liver tissues, reduced serum endotoxin LPS content and expression of inflammation-related factors TNF-α, IL-6, IL-1B and TGF-βin mice with alcoholic liver injury model. The three genes(Akt1, Prkaca, and Pde3b) played an important role in drug regulation for the treatment of alcoholic liver disease. **Conclusion:** The improvement in liver function by PPC injectiom was a complex, multi-pathway process. PPC injection prevented and treated ALD potentially by regulating the Akt-PDE3-PKA signaling pathway to modulate lipid homeostasis.

for Drug Research and Evaluation, Istituto Superiore di Sanità, 00161 Rome, Italy, [3]Department of Hepato-gastroenterology, St. Luc University Hospital, Université Catholique de Louvai, [4]University of California, San Diego

Background: **Background:** Alcohol-associated liver disease is a global health burden with high morbidity and mortality, and the fungal microbiome is important for its progression. In particular, *Candida albicans* and *C. albicans*-reactive T helper 17 (Th17) cells contribute to alcohol-associated liver disease. Specific *C. albicans* antigens that activate Th17 cells during this disease are unknown. The *C. albicans* 65-kDa mannoprotein (CaMp65p) is one of the most abundant and immunodominant proteins of *C. albicans*, and is capable to elicit robust T cell and interleukin (IL)-17A responses. The aim of this study was to measure levels of CaMp65p in serum of patients with alcohol use disorder and liver disease. **Methods:** **Methods:** Serum CaMp65p levels were measured in the serum of 60 patients with alcohol use disorder using an indirect competitive Enzyme-Linked Immunoabsorbent Assay (ELISA). Serum CaMp65p levels were correlated with liver disease severity. **Results:** **Results:** Serum CaMp65p levels positively correlated with several clinical and biochemical markers of liver injury and disease within the patient group with alcohol use disorder, including serum aspartate aminotransferase (AST; $R = 0.33$, $P = 0.0092$), alanine amino-transferase (ALT; $R = 0.27$, $P = 0.037$), gamma-glutamyl transferase (GGT; $R = 0.35$, $P = 0.0055$) and alkaline phosphatase ($R = 0.36$, $P = 0.0052$), and with the circulating M65 fragment of cytokeratin 18 (CK18-M65; $R = 0.51$, $P = 0.0012$), a marker of hepatocyte death. In addition, patients with alcohol use disorder in the upper quartile had significantly higher liver stiffness ($P = 0.0022$). Serum CaMp65p was significantly higher in patients with fibrosis stage F2–F4 as compared with patients with no or minimal fibrosis F0–F1 ($P = 0.0082$). The area under curve (AUC) for detecting F2–F4 fibrosis was 0.70. **Conclusion:** **Conclusion:** Elevated serum CaMp65p levels are associated not only with more severe hepatic injury, but also liver fibrosis in patients with alcohol use disorder. Therefore, CaMp65p may serve as a non-invasive biomarker for fibrosis assessment in patients with alcohol use disorder.

1616 | ENDOSCOPIC SLEEVE GASTROPLASTY IS ASSOCIATED WITH LOWER RISK OF ALCOHOL-RELATED HARM THAN SLEEVE GASTRECTOMY: A MATCHED COHORT ANALYSIS OF 608 PATIENTS

Brittany Bromfield[1] Esperance Schaefer[1] Pichamol Jirapinyo[1] Nikroo Hashemi[1], [1]Brigham and Women's Hospital

Background: Sleeve gastrectomy (SG) is the most performed bariatric surgery, which is effective for metabolic dysfunction associated liver disease but may increase alcohol use disorder (AUD) risk and risk of alcohol-related liver disease. Changes in gastric anatomy may accelerate alcohol absorption and systemic exposure. Endoscopic sleeve gastroplasty (ESG) is an anatomy-sparing, minimally invasive endoscopic bariatric procedure. We evaluated the comparative incidence of alcohol-related outcomes in matched patients undergoing ESG versus SG. **Methods:** We conducted a retrospective, 1:1 matched cohort study of patients undergoing ESG ($n = 304$) or SG ($n = 304$) from January 2013–May 2024 within a single center healthcare system. Patients were matched based on age, sex, race, and comparative health (comorbidity burden, medical visit frequency). Excluded patients with pre-existing AUD (ICD-10 codes, manual review). Primary outcome: incident AUD defined by ICD-10 diagnosis, AUD-related hospitalization, or AUDIT-C ≥ 7; Secondary: conversion from a negative baseline screen (AUDIT-C < 3 for females, < 4 for males) to at-risk drinking (AUDIT-C $\geq 3/\geq 4$). Statistical comparisons used Fisher's exact test, Kaplan-Meier analysis, and logistic regression with subgroup analyses (female, BMI < 40 or > 40, baseline non-drinkers). **Results:** A total of 608 patients with BMI ≥ 30 kg/m² were included. Cohorts comparing ESG to SG were balanced in age (mean 45.9 vs. 45.5 years), sex (90.5% vs. 92.1% female), and psychiatric comorbidity (43.4% vs. 48.7%). Mean baseline AUDIT-C scores were low and similar between groups (0.73 ± 1.0 for ESG vs. 0.86 ± 1.1 for SG). ESG patients had lower baseline BMI (38.1 ± 7.0 vs 43.0 ± 6.4 kg/m²; $p < 0.001$), consistent with real-world clinical selection. Over a median follow-up of 2.8 years (IQR 1.5–4.2), 0/304 ESG patients (0.0%) developed incident AUD compared to 23/304 SG patients (7.6%) ($p < 0.001$, exact test) (Figure 1a). Among SG patients, median time to AUD diagnosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was 1.1 years (IQR 0.8–1.7). Among 544 patients with negative baseline screens and pre/post AUDIT-C data, conversion to at-risk drinking was lower after ESG than SG (5.8% vs. 13.3%; OR 2.48, 95% CI 1.34–4.59; $p = 0.0033$), with divergence evident by 12 months (log-rank $p < 0.001$). Subgroup analysis demonstrated the protective effect of ESG was most pronounced among: Females: 6.2% ESG vs. 13.6% SG (OR 2.37, NNT = 14), baseline non-drinkers: 3.0% ESG vs. 9.9% SG (OR 3.50, NNT = 15) and BMI < 40 kg/m²: 5.0% ESG vs. 16.7% SG (OR 3.82, NNT = 9) (Figure 1b). **Conclusion:** In this first-ever study comparing alcohol-related outcomes after ESG vs. SG, ESG was associated with no incident AUD and lower risk of at-risk drinking. The protective association was consistent across key subgroups. Findings provide compelling evidence that procedural choice may influence alcohol-related harm, with ESG emerging as a safer alternative. Prospective studies are needed to validate these findings.

Figure 1A. Time to Incident Alcohol Use Disorder After ESG vs. SG.

Figure 1B. Conversion to At-Risk Drinking by Subgroup After ESG vs. SG.

Figure 1. Comparative Risk of Alcohol-Related Outcomes Following Bariatric Procedures. (A) Kaplan-Meier analysis shows probability of remaining free from alcohol use disorder (AUD) among matched patients undergoing endoscopic sleeve gastroplasty (ESG) versus sleeve gastrectomy (SG). Over a median follow-up of 2.8 years, no ESG patients developed AUD, while 7.6% of SG patients did (log-rank p = 0.00051). (B) displays rates of conversion to at-risk drinking, defined by sex-specific AUDIT-C thresholds, across key subgroups. ESG conferred significantly lower risk than SG in all strata: overall (5.8% vs. 13.3%, p = 0.003; NNT = 13), females (6.2% vs. 13.6%, p = 0.007; NNT = 14), baseline non-drinkers (3.0% vs. 9.9%, p = 0.019; NNT = 14), and patients with BMI <40 kg/m² (5.0% vs. 16.7%, p = 0.010; NNT = 9). These findings highlight the protective effect of ESG against postoperative escalation in alcohol use.

1617 | SHIFTING THE PROGNOSTIC WINDOW: DAY-4 LILLE SCORE AS A TOOL FOR EARLY CLINICAL DECISION-MAKING IN ALCOHOLIC HEPATITIS

Harisimha Godha[1] Mallikarjun Patil[1] Sunu Sara Kurien[1] Harshad Devarbhavi[2], [1]St. John's Medical College, Bengaluru, [2]St. Johns Medical College, Bengaluru

Background: Severe alcoholic hepatitis (SAH) carries high short-term mortality. Corticosteroids remain standard therapy for eligible patients, but their benefits are limited to responders. The Lille score, calculated on Day 7 of therapy, is widely used to assess steroid response. However, a 7-day wait may delay critical decisions, including therapy discontinuation and early transplant referral. Emerging evidence suggests that Day-4 Lille score may offer comparable prognostic accuracy, enabling earlier clinical intervention and reduced steroid-related complications. This study aimed to assess the prognostic performance of the Day-4 Lille score in predicting 28-day mortality and its concordance with Day-7 scores. **Methods:** In this prospective observational study conducted from March 2023 to March 2025, 154 patients with SAH were screened; 79 met inclusion criteria and were initiated on oral prednisolone (40 mg daily with 10 mg/week taper). Exclusions were due to AKI (25.5%), GI bleed (18.4%), or SBP (14.2%). Baseline and follow-up clinical data were collected, including Day-4 and Day-7 Lille scores. Responders were defined as Lille score < 0.45. Outcomes included 28-day mortality, Lille score concordance, and complication rates. **Results:** Baseline characteristics are summarized in Table 1. Mean age was 41.3 years. Baseline bilirubin was 20.5 mg/dL, decreasing to 17.1 mg/dL by Days 4 and 7. Mean MELD score was 25.7; MDF was 79.3. Among 79 patients with complete data, 84.8% were responders on Day 4 and 77.2% on Day 7. Concordance between Day-4 and Day-7 classifications was 87.3%. Pearson's $r = 0.69$ and Spearman's $\rho = 0.68$, indicating strong correlation. A total of 19 episodes of infections (24%) were recorded, with 9 (11%) occurring between days 4 and 7. **Conclusion:** The Day-4 Lille score is a reliable early predictor of steroid response and 28-day mortality in SAH. High concordance with Day-7 classification supports its use for earlier clinical decision-making. Early identification of non-responders may allow timely corticosteroid discontinuation, potentially reducing steroid-related complications. Routine use of the Day-4 Lille score may enhance risk stratification and patient safety in SAH management.

1618 | TARGETING THE LEUKOTRIENE-MEDIATED PATHWAY IMPROVES ALCOHOL-ASSOCIATED LIVER DAMAGE IN A MOUSE MODEL

Elijah Burks[1] Xiao-Ming Yin[1] Shengmin Yan[1], [1]Tulane University School of Medicine

Background: Alcoholic hepatitis (AH) is frequently accompanied by cholestasis or impairment in bile formation or flow, resulting in fatigue, pruritus, jaundice, and high levels of AST. Oxylipin profiles are altered in serum and fecal samples from patients with ALD; however, the impact of oxylipins on the pathogenesis of ALD remains unclear. **Methods:** Mice were given chronic ethanol (EtOH) feeding for 4 weeks and then subjected to a sub-toxic dose of α-naphthylisothiocyanate (ANIT) to establish alcohol-associated cholestasis and hepatitis (AlChoHep). Targeted metabolomics was applied to determine oxylipin profiles in liver samples from mice following pair-feeding, EtOH-feeding, and EtOH-feeding with ANIT. Data from mouse models were compared with previously published data from ALD patients to identify oxylipins with translational significance. Leukotrienes (LTs) are a family of pro-inflammatory mediators mainly derived from arachidonic acid. Montelukast, a leukotriene receptor antagonist (LTRi), was administered via intraperitoneal injection to inhibit the CysLT1 receptor, beginning ~16 hours before ANIT treatment and continued daily thereafter. **Results:** Hepatic levels of 57 out of 117 oxylipins were significantly altered in EtOH-fed mice, which were more dominant in EtOH-fed mice with ANIT. Levels of 16 oxylipins were also altered in patients with ALD. Interestingly, among these significantly altered oxylipins, oxylipins derived from arachidonic acid are enriched. In AlChoHep mice, LTRi treatment decreased serum levels of ALT, AST, and ALP, indicating improved liver injury. LTRi also reduced hepatic total bile acids (TBA) levels and gall bladder weight. Histologically, AlChoHep mice showed less necrosis and inflammation in the liver following LTRi treatment. **Conclusion:** Taken together, our results indicate that oxylipins are altered in ALD, and treatments targeting LT-mediated pathways can be beneficial.

1619 | TRENDS IN ALCOHOLIC HEPATITIS, LIVER CIRRHOSIS PROGRESSION, AND LIVER TRANSPLANTATION BEFORE AND AFTER THE COVID-19 PANDEMIC: A 10-YEAR RETROSPECTIVE ANALYSIS

Abdallah Hussein[1] Islam Rajab[2] Ahmed Salem[3] Nyan Latt[4] Bradley Chatterton[4] Mohammed Abu-Rumaileh[5] Mohammed Eldesouki[6] Mohammed Altammam[7], [1]Virtua Our Lady Of Lourdes Hospital, [2]St Joseph university medical center, [3]Maimonides Medical Center, [4]Virtua Our Lady Of Lourdes Hospital, [5]University Of Toledo, [6]New York Medical College at Saint Michael Medical Center, [7]Al-Njah University

Background: Alcohol-related liver disease (ALD) remains a significant public health concern, with evolving patterns potentially influenced by the COVID-19 pandemic. This study examines national trends in alcoholic hepatitis, progression to liver cirrhosis, and liver transplantation across a 10-year span, including pre- and post-COVID eras. **Methods:** We conducted a retrospective study using the TriNetX database, analyzing inpatient admissions from 2015–2024. New incidence of alcoholic hepatitis (ICD-10 K70.1), progression to cirrhosis and liver transplant were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

identified and compared pre- and post-COVID across time, sex, age, race, and ethnicity. **Results:** Out of a total cohort of 15,003,014 individuals, 100,834 cases of alcoholic hepatitis were identified between 2015 and 2024. The incidence proportion rose significantly from 0.057% (3,907 cases) in 2015 to 0.125% (7,828 cases) in 2024 ($p < 0.01$). Among males, incidence increased from 0.095% (2,593) to 0.209% (5,088), while among females, it rose from 0.032% (1,253) to 0.072% (2,647) ($p < 0.01$ for both). Hispanic or Latino individuals experienced the most notable rise, from 0.071% (420) to 0.189% (1,036) over the same period ($p < 0.01$). In the pre-COVID period (2019), the incidence was 0.091% (8,067). During the early COVID phase (2020–2021), it rose to 0.107% (9,323) and 0.11% (9,516), respectively. In the post-COVID phase (2022–2024), incidence continued to climb from 0.11% (8,813) in 2022 to 0.125% (7,828) in 2024. The progression to liver cirrhosis also showed a marked increase, from 5.664% (2,722) in 2015 to 17.8% (4,690) in 2024. Correspondingly, the need for liver transplantation rose sharply, from 0.197% (100 cases) in 2015 to 1.405% (569 cases) in 2024. **Conclusion:** The incidence of alcoholic hepatitis and its progression to cirrhosis and liver transplantation increased significantly over the past decade, with a notable acceleration during and after the COVID-19 pandemic. These findings underscore the pandemic's potential role in amplifying alcohol-related liver disease burden across demographic groups.

1620 | RECOMPENSATION AMONG PATIENTS WITH BIOPSY-PROVEN ACUTE ALCOHOL-ASSOCIATED HEPATITIS SUPERIMPOSED ON CIRRHOSIS

Beatriz Sordi Chara[1] Anahita Rabiee[1] Praveena Narayanan[2] Daniela Goyes[1] Pramod Mistry[1] Guadalupe Garcia-Tsao[1], [1]Yale University, [2]UW-Madison

Background: Previous studies have shown that up to 18% of patients with decompensated alcohol-related cirrhosis achieve recompensation with alcohol abstinence. It is uncertain whether recompensation occurs in the setting of alcohol-associated hepatitis (AH) superimposed on alcohol related cirrhosis. Therefore, we aimed to evaluate the rate and characteristics of patients with biopsy-proven AH superimposed on cirrhosis achieving recompensation. **Methods:** Patients admitted with AH to a tertiary care hospital from 2013-2022 and who had a liver biopsy during hospitalization were identified retrospectively. From this cohort, patients who presented with first decompensation (ascites, variceal hemorrhage [VH] and or encephalopathy [HE]) within 60 days of a liver biopsy confirming presence of both AH and cirrhosis were selected. Primary outcome was recompensation per Baveno VII criteria, defined as normal serum albumin and bilirubin, no ascites (off diuretics), no VH and no HE for at least a year. Patients were followed from the date of biopsy until recompensation, death, transplant, or last follow up, for a maximum of 5 years. Patients with less than 90 days of follow up and not meeting the above end points were considered lost to follow up. **Results:** A total of 138 patients with biopsy proven AH superimposed on cirrhosis presenting with first decompensation were included. Baseline characteristics are shown in the Table. Median time from admission to biopsy was 5 days. Thirteen patients (9%) were lost to follow up after discharge, 70 (51%) died (all decompensated at the time of death, except for 3 with unknown status) and 8 (6%) were transplanted. Median time from liver biopsy to death was 68 days (range 3 to 1640), and to transplant was 88 days (range 25 to 295). Among 47 transplant-free survivors (median follow up

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

3.6 years), only 10 (7.2%) achieved recompensation. The median time from the initial presentation to recompensation was 2.9 years (range 1.7 - 3.9); the median follow-up of 37 patients who did not achieve recompensation was 4 years. All recompensated patients discontinued alcohol use within 4 months of liver biopsy. Patients who recompensated were younger and had a higher AST compared to the rest of the cohort. Severity of disease based on MELD 3.0 was similar between the two groups. **Conclusion:** Our study shows that among patients with AH superimposed on cirrhosis presenting with first decompensation, recompensation is a rare event (~7%) that occurs after a long period ($\geq$ 1.5 years) of alcohol abstinence.

1621 | HEALTH CARE UTILIZATION, COSTS, AND ADVANCE CARE PLANNING IN SEVERE ALCOHOLIC HEPATITIS PATIENTS

Tanisha Ronnie[1] *Irene Helenowski*[1] *Scott Cotler*[1] *Steven Scaglione*[2], [1]*Loyola University Medical Center,* [2]*Loyola University Health System*

Background: Severe alcoholic hepatitis (sAH) is associated with high morbidity, mortality, and healthcare burden. Limited research exists evaluating the utility of palliative care (PC), cost, and advance care planning (ACP) in patients with sAH. This study aimed to assess end-of-life care (EOL), health care utilization, and ACP documentation rates in the sAH population. **Methods:** This single center, retrospective study analyzed 298 patients, admitted between 2012-2020, who met NIAAA criteria for sAH and died by 11/1/2024. We compared health care utilization, costs, and EOL care between survivors (n = 193) and decedents (n = 105) following the initial admission for sAH. Demographic and clinical variables included MELD-NA, Maddrey's discriminant function (MDF), time to death, code status, length of stay(LOS), hospitalizations, PC consultation, and ACP documentation. Statistical differences were assessed using the Wilcoxon rank-sum and Fisher's exact tests. **Results:** The median age was 48 (IQR: 39,55) years, with 37.2% male and 62.8% female. Medicaid was the primary insurance (42.3%), followed by Other (26.5%), Private (16.4%), Medicare (9.4%), and Uninsured (5.4%). Marital status was similar between survivors and decedents: 42.3% single, 37.2% married, 18.4% divorced/legally separated, and 2% widowed. The mean MELD-NA was 29 and mean MDF was 67 for both groups. Of the 298 patients, 35% died, with a mean time of 1.2 years from initial diagnosis of sAH to death. Most decedents (70%) died in-hospital, with 53% in an ICU. Of out-of-hospital deaths, 21% occurred in hospice and 8.5% occurred at home. Decedents were more likely to be DNR/DNI at discharge (74.29% vs 5.7%, $p < 0.001$) and had a higher likelihood of their code status changing from Full Code to DNR/DNI (93.3% vs 25.7%, $p < 0.001$). Among those who died, 64.4% of patients were admitted to an ICU, with a mean LOS of 7.82 days. Many underwent life sustaining procedures including intubation (10.5%), CPR (41%), dialysis (29.5%), blood transfusion (41%), vasopressors (42.9%), and arterial (42.9%), and central line placement (42.9%). Both groups had a mean of seven hospitalizations post-diagnosis, with a significant association between hospitalization frequency and survival (3(IQR: 0,11) vs 1(IQR: 0,6), $p = 0.003$). Decedents were more likely to have PC consulted (16.2% vs 2.6%, $p < 0.001$), inpatient palliative referrals (15.2% vs 2.6%, $p < 0.001$), ACP documentation (24.8% vs 15%, $p = 0.037$); higher initial admission hospitalization costs for palliative vs. non-palliative care ($16,471 vs $10,675, $p = 0.031$). The average cost of initial hospitalization was $11,000.86. **Conclusion:** Despite the high mortality in sAH patients, ACP documentation and PC consultation regarding EOL care are

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

uncommon. These patients also have substantial health care utilization and costs. Further studies should be performed to improve EOL care outcomes and reduce the health care burden for these patients.

1622 | DISPARATE REFERRAL PATTERNS FOR PATIENTS WITH ALCOHOL USE DISORDER REFERRED TO HEPATOLOGY CLINICS

Elizabeth Sun[1] Donald Sengstack[1] Jackson Resser[1] Qingxia Chen[1] Ashley Spann[1], [1]Vanderbilt University Medical Center

Background: Approximately 29.5 million individuals suffer from alcohol use disorder (AUD) in the United States, yet only 7.6% receive treatment. While treatment for AUD is increasingly available, literature on referral patterns and direct pharmacological treatment for AUD in hepatology clinics remains sparse. We aimed to evaluate AUD referral patterns for hepatology patients at a single tertiary care center. **Methods:** Retrospective data was extracted from the electronic health record for all new patient evaluations in hepatology clinics from 01/2019 – 12/2023 at a tertiary liver transplant center. Inclusion criteria were adults with current or prior documentation of alcohol use either by visit-related clinical documentation or by elevated phosphatidylethanol (PETH) levels prior to or within 30 days of initial visit. Patients without documented alcohol use or positive PETH data were excluded, along with patients with fewer than one day of survival time for the outcome of interest. The primary outcome was behavioral health referrals (BHR). The secondary outcome was prescription of medications utilized for AUD pharmacotherapy (MAUD). Cox proportional hazards ratios analysis for time to event analysis to evaluate for potential differences in referral rates/timing between subgroups of interest. **Results:** 2457 patients were seen for an initial hepatology visit during the study period. 856 (34.8%) met inclusion criteria. Of these patients, 298 (34.8%) had a diagnosis of cirrhosis at the initial visit. A total of 93 (10.9%) patients received a BHR. Hispanic patients were more likely to have BHR ordered than non-Hispanic white patients [HR = 2.99 (1.24, 7.2)], as were patients with at least one hospitalization in the year prior to the visit relative to patients with no prior hospitalizations [HR = 2.39 (1.41, 4.1)]. 164 patients (19.2%) were prescribed MAUD during this period. Female patients were more likely to be ordered a MAUD prescription than male patients [HR = 1.42 (1.04, 1.0)], as were non-Hispanic black patients relative to non-Hispanic white patients [HR = 2.01 (1.30, 3.1)] and patients with at least one prior hospitalization relative to patients with no prior hospitalizations [HR = 2.16 (1.55, 3.0)]. **Conclusion:** BHR referrals are low among eligible patients seen in hepatology clinics. MAUD initiation remains low as well with racial and gender disparities among patients with documented alcohol use attending hepatology clinics.

1623 | INTERACTION OF ALCOHOL AND DIETARY FAT INTAKE ON STEATOSIS AND FIBROSIS IN METABOLIC ALCOHOL-ASSOCIATED LIVER DISEASE (METALD): A CROSS-SECTIONAL NHANES STUDY

Katharine Tippins[1] Adnan Said[2], [1]University of Wisconsin Hospitals and Clinics, [2]University of Wisconsin School of Medicine and Public Health

Background: Metabolic alcohol-associated liver disease (MetALD) is a newly recognized phenotype of steatotic liver disease (SLD) characterized by concurrent metabolic dysfunction and moderate alcohol intake. While both alcohol and dietary fat independently contribute to liver injury, their synergistic effects - particularly within MetALD - remain poorly understood. This study examined the interaction of alcohol and dietary fat intake on hepatic steatosis and fibrosis across distinct SLD subgroups. **Methods:** We analyzed data from NHANES 2017–2020 survey information, restricting to adults ($\geq$18 years) with valid transient elastography data and hepatic steatosis (CAP $\geq$285 dB/m). Participants were classified into mutually exclusive groups: MASLD (metabolic dysfunction + low alcohol), MetALD (metabolic dysfunction + moderate alcohol), AUD (high alcohol + no metabolic dysfunction), and "Other" (i.e., viral hepatitis, hemochromatosis, cryptogenic). Alcohol intake was defined as moderate for men $>$20 - 50 g/day and women $>$10 - 30 g/day. Total dietary fat intake was derived from 24-hour recall. Survey-weighted multivariable regression models examined CAP (continuous) and significant fibrosis (LSM $\geq$8.0 kPa), testing for interaction between alcohol and fat intake. Models were adjusted for age, sex, race/ethnicity, and energy intake. Sensitivity analyses excluded "lean MASLD" (individuals with BMI $<$25 and without metabolic dysfunction) and applied stricter fibrosis thresholds. **Results:** Among 2,992 participants with CAP $\geq$285 dB/m, 663 had identifiable MASLD, 224 MetALD, and 15 AUD. The weighted mean CAP score was 332.2 dB/m (SE $\pm$2.27). In unweighted models, both alcohol and dietary fat intake were independently associated with higher CAP, with a significant alcohol $\times$ fat interaction ($p = 0.049$), primarily driven by the MetALD group. However, this interaction did not remain statistically significant in survey-weighted models ($p = 0.44$). No significant predictors or interactions were associated with fibrosis $\geq$8.0 kPa. Male sex was the only consistent predictor of fibrosis. Sensitivity analyses yielded similar findings. **Conclusion:** In this nationally representative sample of U.S. adults with steatosis, the interaction between alcohol and dietary fat intake was directionally consistent with synergy but did not reach statistical significance after applying NHANES survey weights. These findings support MetALD as a distinct clinical phenotype and underscore the importance of behavioral risk factors in liver fat accumulation. Further prospective research is needed to clarify their contribution to fibrosis progression.

1624 | PLATANOSIDES INCREASES MITOCHONDRIAL BIOGENESIS (MB) AFTER CHRONIC-BINGE ETHANOL (CBE) TREATMENT IN MICE

Devadoss Samuvel[1] Menny Benjamin[1] Cody Dickinson[1] Amir Richardson[1] John Lemasters[1] Mark Hamann[1] Zhi Zhong[1], [1]Medical University of South Carolina

Background: We showed previously that mitochondrial depolarization and mitophagy/lysosomal processing dysregulation develop after CBE. MB must occur after mitochondrial damage to restore mitochondrial homeostasis and recover mitochondrial function. In *in silico* studies, we showed that PTS isolated from American sycamore trees are good ligands for the Keap1/Nrf2 complex, which likely promotes Keap1/Nrf2 dissociation and subsequent Nrf2 pathway activation. Since Nrf2 activation reportedly increases expression of PGC1α, the master regulator of MB, we examined whether PTS treatment alters MB after CBE treatment in mice. **Methods:** Mice were fed a liquid diet containing 5% ethanol for 10 days and then gavaged once with ethanol (5 g/kg) on day 11. Liver and blood were harvested 9h later. PTS (10 mg/kg, i.p.) or vehicle were injected daily during feeding of ethanol-containing liquid diet and 30 min before gavage. **Results:** After CBE, PGC1α decreased by 55%. PGC1α regulates expression of nuclear DNA (nDNA)-encoded mitochondrial proteins as well as TFAM, a transcription factor that controls mitochondrial DNA (mtDNA) replication and transcription. TFAM decreased by about 60%, and mtDNA copy number decreased 44% after CBE. Expression of COX-IV and ND3, mitochondrial oxidative phosphorylation proteins encoded by nDNA and mtDNA, respectively, decreased by 58% and 61%, signifying suppressed MB. PTS blunted alterations of PGC1α, TFAM, mtDNA copy number, and mitochondrial oxidative phosphorylation proteins in liver tissue

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

after CBE. Mitochondria catalyze fatty acid β-oxidation. CBE decreased hepatic fatty acid oxidation (FAO) by 63% and increased hepatic triglycerides by 160%, which PTS partially reversed. By preventing mitochondrial dysfunction, PGC1α also mitigates inflammasome activation. After CBE, NLRP3 increased 280%, cleaved caspase-1 increased 188%, and interleukin-1β increased 167%, signifying inflammasome activation, which PTS blunted. Disruption of mitochondrial homeostasis can increase tissue injury and/or suppress tissue repair after damage. After CBE, serum ALT increased to ~360 U/L, which PTS decreased by 48%. Histology showed moderate hepatic steatosis, ballooning, scattered necrotic cell death, and increased leukocyte infiltration. PTS attenuated all histological alterations. **Conclusion:** MB is suppressed after CBE exposure. PTS decreases liver injury and improves liver function after CBE, at least in part, by increasing PGC1α and MB.

1625 | TRANSIENT ELASTOGRAPHY AS THERANOSTIC INTERVENTION IN ALCOHOL-ASSOCIATED LIVER DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS

Gene Im[1] Stephanie Rutledge[2] Giuseppe Cullaro[1],
[1]Center for Liver Disease and Transplantation, Columbia University, [2]Weill Cornell Medicine

Background: Several recent studies have demonstrated the potential of transient elastography (TE) as a theranostic intervention in patients with or at-risk for steatotic liver disease (SLD), particularly alcohol-associated liver disease (ALD). TE offers convenient, accurate, and actionable results about liver health in real-time that can be leveraged as an opportunistic intervention of diagnosis and therapy (theranostic) to promote alcohol harm reduction and/or abstinence. We conducted a systematic review and meta-analysis to evaluate the effect of TE on alcohol-associated outcomes in patients at-risk for ALD. **Methods:** We searched PubMed, EMBASE, Scopus, and Google Scholar from inception to 5/2025, and abstracts from AASLD, DDW, EASL in the past year using keywords for studies of alcohol and metabolic outcomes after performance of TE. The primary and secondary endpoints were self-reported abstinence from alcohol and alcohol category reduction at 6 months, respectively. MOOSE guidelines were followed for design, implementation, and reporting. The Newcastle-Ottawa Scale was used for quality assessment. Analyses of abstinence and alcohol category reduction at 6 months were calculated using common effect and random effects modeling using R version 4.5.0. Heterogeneity was assessed by the I² statistic. **Results:** Our search identified 172 citations with 13 studies meeting our inclusion criteria. Six studies (3 alcohol, 3 metabolic outcomes) were excluded for low quality (lacking controls or uniform outcomes). The remaining 7 studies included 2,591 at-risk individuals for ALD undergoing TE in mostly outpatient settings identified prospectively (5 out of 7, 71%). Six studies were included for the primary analysis, and 5 for the secondary analysis: 3 reported AUDIT-C, 1 NIAAA, and 1 WHO drinking categories. Individuals at-risk for ALD undergoing TE had significantly increased rates of abstinence at 6-months compared to controls (RR 1.54; 95% CI: 1.30-1.82, $p < 0.001$) with moderate heterogeneity ($I^2 = 63.1\%$) on common effect modeling. This represents a 54% increased likelihood of achieving abstinence compared to controls. In contrast, no significant reduction of alcohol categories after TE was seen compared to controls (RR 0.96; 95% CI: 0.85-1.09, $p = 0.54$] with very high heterogeneity ($I^2 = 92.2\%$). On sensitivity analysis with exclusion of 1 outlier study ($n = 4$), there was a significant reduction of alcohol categories after TE (RR 1.33; 95% CI: 1.13-1.56, $p = 0.001$), with low heterogeneity ($I^2 = 0\%$). On random effects modeling, there were no differences between TE and controls for abstinence (RR 1.43; 95% CI: 0.96-2.12, $p = 0.07$) and alcohol category reduction (RR 1.11; 95% CI: 0.61-2.02, $p = 0.65$). **Conclusion:** TE as a theranostic intervention is associated with improved abstinence at 6-months in individuals at-risk for ALD. These findings highlight the potential for theranostics in ALD by leveraging TE and the need for future studies.

1626 | OUTCOMES OF PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS EVALUATED FOR EARLY LIVER TRANSPLANTATION

Darine Daher[1] Hassan Azhari[2] Omar Mousa[3] Kymberly Watt[1] William Sanchez[1] Timucin Taner[3] Terry Schneekloth[1] Douglas Simonetto[3], [1]Mayo Clinic, [2]Memorial Sloan-Kettering Cancer Center, [3]Mayo Clinic Rochester

Background: The Dallas Consensus Conference set forth candidacy criteria for early liver transplantation (LT) in severe alcohol-associated hepatitis (AAH). These criteria, based on expert opinion, include first presentation of decompensated disease and rigorous psychosocial evaluation, diverging from traditional 6-month abstinence rule. This remains controversial in part because of concern for higher alcohol relapse, and for potential recovery obviating need for transplant. Our study aims to explore outcomes of those transplanted (LT-AAH) compared to those not approved for LT (Non-LT AAH). **Methods:** Consecutive patients evaluated at transplant selection committee at Mayo Clinic, Rochester, between January 1, 2018 and December 31, 2023, with a primary indication of AAH were retrospectively reviewed. Patients were divided into those who received LT and those who were deferred or denied. T-tests were used to compare the means of 2 groups when needed. **Results:** We identified 27 patients with AAH who were considered for early LT, 17 receiving LT (63%) while 10 did not (37%). Mean age at evaluation was similar in both LT-AAH and non-LT AAH groups (40.1 vs 39.1 years), with most patients being Non-Hispanic White (88% vs 80%). Among the 10 who did not receive LT, 4 were denied, 5 were deferred, and 1 was waitlisted but then de-listed due to not completing chemical dependency treatment. Reasons for deferral or denial included no insight to alcohol as cause of illness (n = 5), lack of identifiable sober system (n = 3), not first decompensating event (n = 2), unwillingness to complete alcohol use disorder treatment (n = 2), > 2 prior alcohol treatment programs with relapse (n = 2), evidence of polysubstance abuse (n = 1), not at high risk for mortality from AAH (n = 1), and presence of other life limiting conditions (n = 1) (Figure 1). Alcohol consumption was observed in 4 patients after transplant in LT-AAH group (24%), compared to 4 patients after evaluation in non-LT AAH group (40%). Mean time to first drink was 23 weeks (95CI% 3 – 42 weeks) in LT-AAH group compared to 16 weeks (95%CI 4 – 29 weeks) in non-LT AAH group (p = 0.6). There were 2 deaths in LT-AAH (12%) with 1 alcohol-related death, compared to 5 in non-LT AAH (50%) group, all of which were alcohol-related. 4 out of the 5 surviving patients in non-LT AAH group achieved recompensation with sustained alcohol abstinence. **Conclusion:** Our findings suggest that despite being deferred or denied transplant due to suspected high risk of alcohol relapse, most of these patients remain abstinent, and 40% successfully achieve recompensation. Further studies are needed to better individualize approach to early LT in patients with severe AAH.

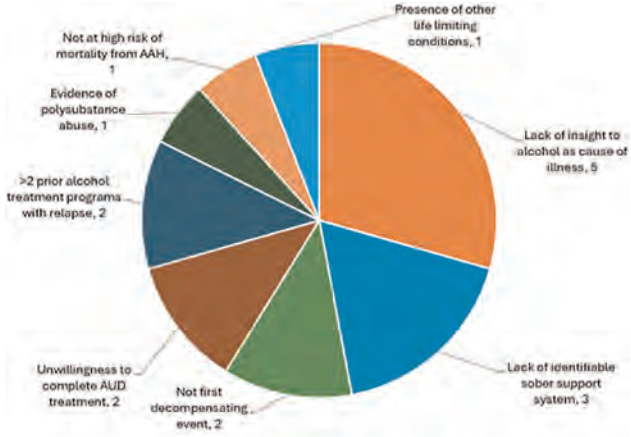

Figure 1. Reasons for early LT deferral or denial in patients with AAH.

1627 | SIGNIFICANT LIVER DISEASE AMONG INCREASED ALCOHOL CONSUMERS TRIPLED FROM 1999-2018 ALONGSIDE EVOLVING US POPULATION DEMOGRAPHICS

Kalpana Gopalkrishnan[1] Jennifer Dodge[2] Brian Lee[3], [1]Keck School of Medicine, University of Southern California, [2]Keck School of Medicine at USC, [3]Keck School of Medicine

Background: According to current teaching, 10-20% of increased alcohol consumers develop progressive liver disease in a lifetime. However, changes to U.S. population demographics may influence current risk. This study used national data to assess trends and contributors to the risk of developing alcohol associated liver disease (ALD) among increased alcohol consumers. **Methods:** The nationally-representative National Health and Nutrition Examination Survey (NHANES) was analyzed from 1999-2018. Adults aged $\geq$20 years were included and those with viral hepatitis (B or C) or unknown alcohol or Fibrosis-4 (FIB-4) score were excluded. Increased alcohol consumption was defined as $\geq$20 grams/day for women and $\geq$30 grams/day for men in the past 12 months. Demographic trends were examined from 1999-2004, 2005-2012, and 2013-2018 using survey-weighted prevalence and mean estimates. Survey-weighted prevalence of high FIB-4 (defined as $>$2.67) was estimated among those with vs. without increased alcohol consumption and stratified by demographic variables. Confidence intervals were determined using Taylor linearization. **Results:** National prevalence of high FIB-4 increased over time from 1.8% (95% CI 1.0-3.3%) in 1999-2004 to 5.6% (3.7-8.3%) in 2013-2018 among increased alcohol consumers, and from 0.1% (0.1-0.2%) to 0.2% (0.2-0.3%) among those without increased alcohol consumption. Among increased alcohol consumers, mean age increased over time, as well as the proportion of female consumers and those living in poverty. Prevalence of metabolic syndrome increased from 26.4% (23.5-29.6%) in 1999-2004 to 37.6% (32.5-43.1%) in 2013-2018 among increased alcohol consumers. Among increased alcohol consumers, mean alcohol use was similar across eras (Table 1), but prevalence of high FIB-4 increased for this group overall and among all age, sex, and ethnicity groups from 1999-2004 to 2013-2018. **Conclusion:** The national risk of significant liver fibrosis among heavy drinkers increased over 3-fold, despite *similar* alcohol use between 1999-2018. We identified increasing metabolic syndrome and changing demographics of heavy drinkers (age, women, living in poverty) as contributors to these alarming trends. These results show the importance of updated recommendations regarding screening of liver disease among increased alcohol users, and the need to address co-factors of ALD progression.

Table 1. Characteristics of US Adults with and without Increased Alcohol Consumption in NHANES between 1999-2018

	With Increased Alcohol Consumption (N=3,275)						Without Increased Alcohol Consumption (N=39,954)					
	1999-2004		2005-2012		2013-2018		1999-2004		2005-2012		2013-2018	
Characteristic	No.	Mean (n) or Prevalence (95% CI)	No.	Mean (n) or Prevalence (95% CI)	No.	Mean (n) or Prevalence (95% CI)	No.	Mean (n) or Prevalence (95% CI)	No.	Mean (n) or Prevalence (95% CI)	No.	Mean (n) or Prevalence (95% CI)

1628 | PHOSPHORYLATED UBIQUITIN CONJUGATING ENZYME 9 AS A NOVEL REGULATOR OF LIPOGENESIS IN ALCOHOL-ASSOCIATED LIVER DISEASE

Swati Chandla[1] Youngyi Lim[1] Michael Mazarei[1] Xi Yang[1] TAKASHI TSUCHIYA[1] Manisha Dagar[1] Monica Justo[1] Komal Ramani[1] Maria Lauda Tomasi[1], [1]CEDARS-SINAI MEDICAL CENTER

Background: Alcohol abuse promotes the activation of liver-resident macrophages, known as Kupffer cells (KCs), by enhancing the gut-derived endotoxins translocation into the portal circulation. Activated KCs secrete the pro-inflammatory cytokines that promote the expression of the de novo lipogenesis mediators in hepatocytes including *SrebF1* and *CEBP-β*, via an NF-κB dependant pathway. We previously reported that alcohol causes NF-κB activation in KCs through phosphorylation of ubiquitin conjugating enzyme 9

(pUBC9), the unique E2 conjugating enzyme for SUMOylation. This study aims to investigate the role of pUBC9 in modulating de novo lipogenesis in alcohol-associated liver disease (AALD). **Methods:** Primary mouse KCs and hepatocytes were used for in vitro experiments which were further validated using the NIAAA mouse model. Techniques including phosphopeptide mapping, phosphomimetic peptide treatment, Western blot, ELISA, RT-PCR, CRISPR/Cas9-mediated UBC9 Y68 editing in vivo, immunofluorescence (IF), BODIPY and H&E staining and ChIP assay were used to examine the functional role of UBC9 phosphorylation at specific residues. **Results:** Alcohol administration induced UBC9 phosphorylation at tyrosine Y68 residue (UBC9Y68) in KCs both in vitro and in vivo. The use of phosphomimetic peptide promoted the expression of pro-inflammatory cytokines, while CRISPR/Cas9-mediated UBC9 mutation of tyrosine 68 residue to phenylanine (UBC9Y68F) prevented UBC9 phosphorylation and decreased the cytokine production as well as secretion in KCs. In NIAAA model, editing of UBC9 prevented its phosphorylation that attenuated liver injury, hepatic lipid accumulation and reduced *SrebF1* and *CEBPβ* expression by lowering their promoter binding with p65, known as their main transcription factor. **Conclusion:** Phosphorylation of UBC9 at Y68 residue in KCs causes lipid accumulation promoting lipogenic genes expression. These findings identify phosphorylated UBC9 Y68 as a novel and promising therapeutic target for the treatment of AALD. **Disclosures:** Swati Chandla: Nothing to Disclose, Youngyi Lim: Nothing to Disclose, Michael Mazarei: Nothing to Disclose, Xi Yang: Nothing to Disclose, TAKASHI TSUCHIYA: Nothing to Disclose, Manisha Dagar: Nothing to Disclose, Monica Justo: Nothing to Disclose, Komal Ramani: Nothing to Disclose, Maria Lauda Tomasi: Nothing to Disclose

1629 | COMPARATIVE EFFECTIVENESS AND SAFETY OF NALTREXONE AND ACAMPROSATE IN PATIENTS WITH CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Brooke Rice[1] Prasanna Challa[1] Tracey Simon[1], [1]Massachusetts General Hospital

Background: Medications for alcohol use disorder are underutilized in patients with advanced liver disease due to a lack of data, with concerns regarding naltrexone use due to hepatic metabolism and potential hepatotoxicity. **Methods:** We identified all new initiators of naltrexone or acamprosate after diagnosis of cirrhosis within the Mass General Brigham health care system (1993 – 2024). After 1:1 propensity score matching to emulate a target trial, we estimated Cox proportional hazard ratios (HRs) and 95% CIs for the primary outcomes of death or hospitalization for liver decompensation (i.e. ascites, spontaneous bacterial peritonitis, hepatic encephalopathy, variceal hemorrhage, hepatocellular carcinoma, or hepatorenal syndrome). Subgroup analyses separately analyzed those with compensated and decompensated cirrhosis. **Results:** The PS-matched cohort included 1418 patients with cirrhosis, including 819 (57.8%) with prior decompensation. In the full population, no significant differences were found between initiator groups for the primary composite outcome (HR 0.95 [95% CI = 0.79-1.15]). However, among patients with compensated cirrhosis at baseline, initiators of acamprosate had significantly higher rates of incident major decompensation events (HR = 1.69 [95% CI = 1.07 – 2.67]) with a nonsignificant trend towards increased mortality (HR 1.46 [95% CI = 0.89 – 2.41]). In contrast, among patients with decompensated cirrhosis, no significant differences were found between exposure groups for recurrent decompensation or death. **Conclusion:** Among patients with cirrhosis, initiators of naltrexone versus acamprosate had similar hazards of decompensation and death. In patients with baseline compensated cirrhosis, acamprosate initiation was associated with higher hazard of decompensation requiring hospitalization.

1630 | EXCELLENT OUTCOMES FOLLOWING RENAL REPLACEMENT THERAPY IN YOUNG PATIENTS WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS: IS IT TIME FOR A CHANGING PARADIGM IN THE ERA OF EARLY LIVER TRANSPLANT?

Emily Harding-Theobald[1], [1]DENVER HEALTH

Background: The increasing prevalence of life-threatening alcohol-associated hepatitis (AH) among otherwise healthy young adults represents a significant challenge in modern hepatology. Patients who have very recent alcohol use are typically not considered candidates for liver transplant, and are left with no therapeutic options if anuric renal failure (ARF) develops secondary to acute tubular necrosis (ATN) or hepatorenal syndrome (HRS). Historically, renal replacement therapy (RRT) has not been offered to patients with alcohol-associated hepatitis if they are not transplant candidates, based on data suggesting dismal survival in patients with chronic decompensated cirrhosis of about 25-30% at 6 months. We describe a small case series of patients age < 50 with acute AH whose 83% survival at 6 months significantly exceeds the historic figures described for cirrhosis, suggesting that RRT as a bridge to transplant may be feasible and life-

saving in the era of early liver transplant for AH. **Methods:** We describe the experience of an integrated alcohol-associated liver disease clinic with embedded addiction medicine at a major referral center. The total cohort included 53 patients with an initial MELD score of >20 (median MELD 29) who were followed for a minimum of 6 months following an index admission for acute AH. All patients were not candidates for transplant due to recent alcohol use. 15 patients developed anuric renal failure within one month of their index admission for AH. Because of geographically remote referring hospitals, 9 patients were initiated on CRRT and transitioned to intermittent hemodialysis (iHD). 5 patients were felt by local nephrologists to have primary HRS, 4 patients were felt to have renal failure secondary to ATN. **Results:** Among 15 patients who developed ARF, 6 were not offered RRT because they were not considered transplant candidates at that time. All 6 patients died during that admission after transitioning to hospice. 9 patients were offered RRT, of whom 2 were over age 50. Both patients over age 50 died within 3 months of initiating iHD, similar to previously reported poor survival. 1 patient < 50 relapsed to alcohol use within the first 30 days and died from recurrent AH. 6 patients were offered RRT and maintained strict PETH-proven sobriety for 6 months. Of that population, 5 patients (83%) survived to 6 months. All were transitioned off iHD and now have between stage 2-3 CKD. **Conclusion:** In the era of early liver transplant for AH, the canonical teaching that RRT in AH is a 'bridge to nowhere' needs to be rigorously challenged. RRT and iHD are an unlimited resource, and increase the survival chances of young adults significantly above zero. These patients likely have different physiology than chronic decompensated cirrhotics. With the additional survival time they benefit from, many of these patients will recover well, maintain sobriety, and potentially survive to liver transplant.

1632 NEW SUBMISSION | COMPARATIVE INPATIENT OUTCOMES AND COMORBIDITY PROFILES IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE WITH AND WITHOUT METABOLIC SYNDROME: INSIGHTS FROM A NATIONALLY REPRESENTATIVE DATABASE

Talal Bhatti Carla Barberan Parraga[1] Kundan Jana[2] Sanjaya Satapathy[3] Sajid Jalil[4] Shahzad Ashraf[5] Amir Saleem[6] Madeha Irfan[7] Lubna Kamani[8] Tanveer Hussain[9] Wasim Jafri[10] Taimur Aslam[11], [1]Maimonides Medical Center, NY, [2]Maimonides medical Center NY, [3]Northwell Health, [4]Stanford University, [5]NUMS Islamabad, Pakistan, [6]SZABMU Islamabad, [7]UHS, Lahore Pakistan, [8]LNH Karachil, [9]HFH, RMU Rawalpindi, [10]AKU Karachi, [11]Northwell

Background: The intersection of metabolic syndrome and alcohol-associated liver disease (ALD) is increasingly recognized as a unique phenotype termed MetALD. However, data comparing clinical characteristics and inpatient outcomes between ALD patients with and without metabolic syndrome remain limited. **Methods:** We identified adult patients (≥18 years) hospitalized with a principal diagnosis of ALD between 2016 and 2021 using the National Inpatient Sample (NIS) and ICD-10 codes. Patients were stratified into two groups based on the presence or absence of metabolic syndrome, defined by ≥ 3 components out of obesity (BMI ≥30), diabetes, hypertension, and hyperlipidemia. Weighted analyses were performed to account for the complex survey design. Baseline characteristics were compared using Rao-Scott chi-square and Student's t-tests. Multivariate regression models were developed to assess the impact of Metabolic Syndrome associated ALD (MetS +ALD) on in-hospital outcomes, adjusting for variables with $p < 0.1$ in univariate analysis. **Results:** A total of 936,645 weighted hospitalizations were included (ALD: 759,680 [81.1%]; MetS + ALD: 6,965 [18.9%]). Met S+ ALD patients were older (57.8 vs. 52.2 years, $p < 0.001$) and more likely male (80.1% vs. 67.4%, $p < 0.001$). MetS + ALD was significantly associated with higher prevalence of diabetes (91.7% vs. 17.9%), hypertension (96.1% vs. 44.6%), hyperlipidemia (91.7% vs. 12.2%), and chronic kidney disease (25.0% vs. 10.0%; all $p < 0.001$). Despite a higher burden of comorbidities, MetS + ALD patients had lower in-hospital mortality (3.0% vs. 4.9%, $p = 0.0024$) and reduced need for mechanical ventilation (4.2% vs. 5.8%, $p = 0.0125$). No significant differences were noted in length of stay or total hospital charges. **Conclusion:** Patients with MetS + ALD represent a distinct clinical subgroup of ALD with greater metabolic comorbidity burden but paradoxically lower inpatient mortality and respiratory support needs. These findings support further investigation into the natural history and tailored management strategies for MetS + ALD.

1633 | MACROPHAGE DYSFUNCTION, NOT HEPATOCYTE OR NEUTROPHIL IMPAIRMENT, DRIVES ALCOHOL-INDUCED SUSCEPTIBILITY TO KLEBSIELLA PNEUMONIAE INFECTION

Tiantian Yao[1] Yukun Guan[1] Bryan Mackowiak[2] Luca Maccioni[1] Yang Wang[1] Yaojie Fu[1] Deniz Seyhan[1] Cheng Chen[1] Yuhong Lin[1] Dechun Feng[1] Bin Gao[1], [1]NIH, [2]National Institute on Alcohol Abuse and Alcoholism (NIAAA)

Background: Alcohol consumption increases mortality in mice infected with *Klebsiella pneumoniae* (KP), a clinically relevant pathogen. However, the mechanisms underlying this increased susceptibility remain poorly understood. While it is known that alcohol impairs various immune responses, whether alcohol compromises hepatocyte production of acute-phase proteins or neutrophil bactericidal function during KP infection remains unclear. **Methods:** We utilized a murine model of chronic-plus binge ethanol exposure followed by intraperitoneal KP infection to assess survival and immune response. Hepatic transcriptional responses were evaluated by bulk and single cell RNA sequencing. Neutrophil antibacterial function and hepatocyte acute-phase protein production were assessed using in vitro assays. The role of macrophages and Kupffer cells in alcohol promotion of KP infection was tested by cell depletion and ablation. **Results:** Chronic plus binge alcohol challenge significantly increased the mortality in mice following KP infection. Singl cell RNA seq analysis identified hepatocytes are the major sources to produce acute phase proteins, which play a key role in controlling bacterial infection. Alcohol feeding did not impair hepatocyte synthesis of key acute-phase proteins (APPs). Neutrophils are known to play important roles in controlling bacterial infection, alcohol consumption upregulated hepatic CXCL1, a key chemokine to induce neutrophil migration, and neutrophil NCF1, a key factor to promote neutrophil ROS production. Neither hepatic specific Cxcl1 deletion nor neutrophil specific Ncf1 deletion affected alcohol promotion of KP infection-induced mortality. Macrophages and Kupffer cells play an important role in controlling bacterial infection. Interestingly, we found that alcohol exposure markedly reduced macrophages in the liver and lung. Depletion of all macrophages using clodronate liposomes markedly increased the mortality in mice following KP infection, while depletion of Kupffer cells did not increase the mortality induced by KP infection. **Conclusion:** Our findings suggest that macrophage dysfunction is a key driver of alcohol-induced susceptibility to bacterial infection, rather than impaired hepatocyte or neutrophil responses. These results highlight the central role of macrophages in the innate immune defense against KP

1634 | SERUM IMMUNOGLOBULIN A LEVELS: A CORRELATE OF SEVERITY AND POTENTIAL STRATIFICATION TOOL IN ALCOHOL-ASSOCIATED CIRRHOSIS

Yanxu Hao[1] Yuxuan Song[2] Jiarui Zheng[2] Bo Feng[2] Yandi Xie[2], [1]Beijing Jingmei Group General Hospital, Beijing, [2]Peking University People's Hospital, Peking University Hepatology Institute

Background: To investigate the relationship between serum immunoglobulin A (IgA) levels and alcohol-associated cirrhosis (AC) severity, and to evaluate IgA's potential for stratifying AC severity. **Methods:** This retrospective study included 379 individuals with AC admitted to our hospital between January 2012 and December 2023. Patients were stratified into groups based on Child-Pugh score (CPs). Baseline characteristics, liver function indicators, and immunoglobulin levels were compared across groups to assess IgA's role in AC severity. Spearman correlation analysis was performed to examine the relationship between IgA levels and established severity indices (ALBI score, MELD score, CPs). Additionally, correlations between IgA and relevant serological indicators were analyzed. Finally, we evaluated the utility of combining IgA with specific serological markers for stratifying AC severity. **Results:** The 379 AC patients were divided into CPs-A, CPs-B, and CPs-C groups. Serum IgA levels were significantly higher in the CPs-C group [6.9 (5.74, 9.56)] compared to both the CPs-A [3.95 (2.63, 5.94); $p < 0.001$] and CPs-B groups [5.35 (3.63, 6.76); $p < 0.001$]. Spearman analysis revealed significant positive correlations between IgA levels and CPs, ALBI score, and MELD score. Heatmap analysis indicated that IgA correlated significantly with all other serological indicators showing statistically significant differences among the AC severity groups. Notably, the combination of IgA and albumin (ALB) demonstrated superior diagnostic ability compared to other tested indices in distinguishing between compensated and decompensated AC subgroups. **Conclusion:** Serum IgA levels correlate significantly with the severity of alcohol-associated cirrhosis and hold significant value for the stratified diagnosis of AC, particularly when combined with albumin.

1635 | LOWER HANDGRIP STRENGTH SCORES AND LIVER INJURY SEVERITY IN ALCOHOL-ASSOCIATED HEPATITIS

Harsh Tiwari[1] Henry Shay[1] Mack Mitchell[2] Gyongyi Szabo[3] Srinivasan Dasarathy[4] Bruce Barton[5] Laura Nagy[4] Maiying Kong[1] Vatsalya Vatsalya[1] Craig McClain[1], [1]University of Louisville, [2]University of Texas Southwestern Medical Center, [3]Beth Israel Deaconess Medical Center, [4]Cleveland Clinic Foundation, [5]University of Massachusetts

Background: Reduced handgrip strength (HS) is frequently observed in patients with liver disease, though its characterization in alcohol-associated hepatitis (AH) remains limited. There has yet to be an established relationship between HS and severity of liver injury or mortality in AH. This study aims to characterize HS in patients with AH and investigates the correlation between diminished HS and worsened liver injury or increased mortality. **Methods:** A total of 55 adult subjects (male and female, aged 21-67 years) were enrolled in this study. Subjects were categorized as healthy controls (HC; $n = 11$) or classified according to severity of AH using the Model for End Stage Liver Disease (MELD) score as either moderate AH (mAH, MELD ≤ 19; $n = 10$) or severe AH (sAH, MELD ≥ 20; $n = 34$). Clinical measures and laboratory data collected at a single point in time in this cross-sectional clinical investigation included demographics, alcohol consumption metrics (Alcohol Use Disorders Identification Test [AUDIT], Lifetime Drinking History [LTDH]), Controlling Nutritional Status (CONUT) scores, comprehensive metabolic panel (CMP), complete blood count (CBC), coagulation profile (PT/INR), and MELD scores. HS was measured three times for each subject. HS scores were assessed in relation to clinical parameters, biomarkers of liver injury and disease severity, and 90-day survival/mortality risk. **Results:** On average, patients with AH were in their 40s and overweight. All patients with AH reported 20+ years of drinking. Their AUDIT scores were > 20 (indicative of alcohol dependence and need for intervention) (Table 1). HS scores demonstrated a statistically significant 2-fold drop in patients with AH compared to the HC group. There was no significant difference in HS scores between the mAH and sAH groups. Average HS and ABIC scores correlated significantly ($p = 0.043$) in patients with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

sAH. There was a statistically significant correlation between 90-day survival and first handgrip scores with a good performance level of model fit (AUC = 0.708 ± 0.093 [SE], 95% CI [0.527, 0.890]; p = 0.025). There was a significant association between average HS and albumin levels (p = 0.043) among all patients with AH. In the mAH group, there was a significant association between average HS and MELD scores (adjusted $R^2 = 0.529$, p = 0.010). In the sAH group, female patients demonstrated a statistically significant reduction in average HS (>40%, 95% CI [-34.59, -4.21]; p = 0.014) compared to their male counterparts. **Conclusion:** HS decreases significantly in patients with AH. HS serves as a significant constituent phenotype in the clinical presentation of AH and correlates closely with 90-day survival/mortality risk. Reduced HS score can suggest functional deficits as noted by the correlation between HS scores and albumin levels. Sex differences in HS scores were observed in patients with sAH, highlighting a vulnerability among females.

Table 1. Demographic, drinking, and hand grip data of healthy controls and moderate and severe alcohol-associated hepatitis (AH) groups.

Variables	Healthy Controls (M = 5; F = 0)	Moderate AH (M = 5; F = 5)	Severe AH (M = 25; F = 9)
Age (yrs.) [a b]	32.50 ± 10.7	45.96 ± 9.3	46.10 ± 8.8
Weight (Lbs.) [a]	159.57 ± 26.5	236.86 ± 85.8	194.56 ± 54.6
LTDH (yrs.)	12.82 ± 11.7	22.10 ± 11.8	21.38 ± 13.8
AUDIT (Unit Score) [a b]	3.82 ± 4.9	23.50 ± 8.1	23.88 ± 7.5
1st Handgrip test [a b](/100 unit)	75.52 ± 29.6	35.73 ± 23.9	38.65 ± 19.6

Commonwealth University School of Medicine, Richmond, VA, USA.

Background: Severe alcohol-associated hepatitis (sAH) is an acute condition with high mortality. Recent studies suggest that therapeutic plasma exchange (TPE) may improve 30- and 90-day survival in patients with ACLF; however, there is no evidence of the TPE efficacy in sAH. This pilot study aimed to evaluate the effect of TPE on BA profiles and clinical outcomes. **Methods:** We conducted a retrospective study of patients with sAH who underwent TP (five sessions), collecting clinical and laboratory data. Serum levels of total, conjugated, and unconjugated bile acids (BA) were measured in serum samples before plasmapheresis and in the post-procedure effluent using high-performance liquid chromatography-tandem mass spectrometry. **Results:** We included a total of 11 patients with sAH from a single center in Banská Bystrica, Slovakia. The median age was 48.7 years [IQR: 40–60], with two patients (18%) being women. The median MELD before and after TPE was 34.3 [32–39] and 24.6 [21–29], respectively. The mean time from admission to the start of TPE was 10.1 ± 7.9 days. Overall, five patients (45.5%) died. We identified significant differences on the ursodeoxycholic acid (UDCA) (Median 399.6 [202.6 - 541.9] vs. 669.4 [520-3412.5] ng/mL; $p = 0.04$) concentrations between serum and effluent. BA composition seems to be similar ($p = 0.689$). Before TPE, participants who died had significantly higher serum levels of total BA (Median 75213.03 [72478.1 - 77677.6] vs. 44736.3 [35823.4 - 53761.8] ng/mL; $p = 0.026$), glycine-conjugated BA (Median 49769.4 [49246.7 - 52276.7] vs. 28350.1 [20241.5 - 33597.5] ng/mL; $p = 0.0132$), total conjugated BA (glycine + taurine; Median: 73836.7 [71764-77112.7] vs. 43881.4 [35100.8 - 53290.8]ng/mL; $p = 0.026$), Glycoursodeoxycholic acid (G-UDCA) (Median 19038.1 [17669.9-19872.3] vs. 7819.2 [3659.4-11428.3] ng/mL; $p = 0.021$), lithocholic acid (LCA) (Median 6.34 [5-8-6.37] vs. 4.62 [3.62-5.41]ng/mL; $p = 0.0476$), and Glycochenodeoxycholic acid (G-CDCA) (Median 21132.1[19249.2-21307] vs. 11370 [9173.9- 14514,9] ng/mL; $p = 0.012$) than in those alive at the end of follow-up. After TPE, deceased participants also showed higher levels of total unconjugated BA (Median 3512.4 [3206.7-3909.5] vs. 871.3 [631.9-911.6] ng/mL; $p = 0.0324$), UDCA (Median 3352.8 [2425.9-3472.3] vs. 520.01 [243.2-636.6]ng/mL; $p = 0.026$), and DCA (Median 25.9[22.6-31.2] vs. 17.49 [14.5-20.7] ng/mL; $p = 0.047$) on the effluent. **Conclusion:** TPE may induce changes in serum bile acid composition in patients with sAH. Patients who died showed a distinct bile acid profile both before TPE and in the effluent. Further research should explore post-TPE BA changes and their clinical significance.

1637 | DOES A DIAGNOSIS OF ALCOHOL-ASSOCIATED LIVER DISEASE INCREASE PRESCRIPTION OF ALCOHOL USE DISORDER MEDICATION? DANISH AND ENGLISH COHORT STUDIES

Gro Askgaard[1] Adina Olaru[2] Peter Jepsen[3] Colin Crooks[2], [1]Zealand University Hospital, [2]University of Nottingham, [3]Aarhus University Hospital

Background: Alcohol abstinence is key to survival in alcohol-associated liver disease (ALD) and medications to treat alcohol use disorder may help towards this goal. We investigated the pattern of prescriptions of alcohol use disorder medications before and after the time of diagnosis of ALD in Denmark and England. **Methods:** Patients with newly diagnosed ALD and their prescriptions to treat alcohol use disorder (acamprosate, naltrexone, nalmefene and disulfiram) were identified from population-based health registries of the nationwide Danish registers (2011-2024) and UK Clinical Practice Research Datalink (2011-2018). We calculated the percentage of patients being covered with a prescription every day in the two years before and after ALD diagnosis, censoring patients at death or emigration. We used a poisson regression model to evaluate predictors of any alcohol use disorder prescription one

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

year after ALD diagnosis. **Results:** Cirrhosis was present in 69% of 17,657 Danish and in 43% of 56,240 English newly diagnosed patients with ALD. In both countries, the percentage of patients covered with prescriptions to treat alcohol use disorder increased at ALD diagnosis (Figure 1 shows Danish data, n = 17,657): the percentage of patients covered each day was 2.4% one year before diagnosis, it peaked at 6.1% shortly after diagnosis, and then decreased to 3.5% one year after diagnosis. For England, the percentages were 2.1%, 4.0% and 2.5% for patients being covered by a prescription to treat alcohol use disorder 1 year before, shortly after diagnosis and 1 year after ALD diagnosis. Disulfiram was the most prescribed drug in Denmark whereas it was acamprosate in England. Naltrexone and nalmefen were prescribed in less than 0.5% of ALD patients in Denmark and England during the 2-year observation period. The predictors for being prescribed a medication to treat alcohol use disorder were younger age, female sex, lower socioeconomic position, and non-cirrhotic state of ALD. **Conclusion:** Diagnosis of ALD increases the likelihood of prescription of alcohol use disorder medications. Still, few patients are prescribed these medications indicating missed opportunities to support abstinence.

1638 | NUTRITIONAL MANAGEMENT IN PATIENTS WITH ALCOHOL RELATED HEPATITIS- A QUALITY IMPROVEMENT PROJECT

Tyler Wark[1] Chandler Patton[2] She-Yan Wong[2] Cristina Angelo[2], [1]Lehigh Valley Health Network, [2]Lehigh Valley Health

Background: Alcohol related hepatitis (AH) is a type of alcohol related liver disease associated with significant morbidity and mortality. Treatment options are limited and steroids are the mainstay of therapy. Patients with AH are often malnourished; therefore, nutrition therapy is an important part of treatment. Studies show that meeting certain calorie/protein goals was noninferior to steroids in regard to mortality in patients with acute severe AH. We aimed to increase the number of hospitalized patients with AH who received a high calorie, high protein diet. **Methods:** This quality improvement study was conducted at Lehigh Valley Hospital (LVH) in Allentown, PA with data collected between 1/2018 and 2/2025. In conjunction with the nutrition team, a new diet order was created and implemented in the electronic medical record under GI/Hepatology as "hi calorie/hi protein diet" on 7/2024, after which all data collected was considered post intervention data including the number of patients on the new diet order, demographics, and 30-day mortality. Education on the diet and its indication was provided via a PowerPoint presentation to internal medicine residents and faculty attendings on 08/2024. Adults hospitalized with AH were identified with ICD 10 codes K70.9, K70.10, and K70.11 and diet order data were collected at two LVH campuses. **Results:** A total of 108 patients were admitted with AH during our data collection period. The patient cohort was 61% male, 90% white, and average age was 50 years old. Only 2/91 (2%) patients were on a high protein/calorie diet pre- intervention, compared to 7/15 (46%) patients post-intervention. At baseline, 22/91 (24%) patients were readmitted within 30 days compared to 1/17 (5%) following intervention. 30-day mortality was 11% (10/91) and 6% (1/17) pre and post-interventions, respectively. At the conclusion of the project, a QI forum with hospitalists and other departments associated with research was held to provide updates on the project. **Conclusion:** Though nutrition therapy is one of the few known treatments of AH, this study highlights that it is underutilized. Through creation of a liver specific diet order and increasing awareness, we increased the number of patients hospitalized with AH who received standard of care nutrition requirement, and 30 day readmission rates and mortality were improved. With ongoing education, nutrition assessments, and placing inpatients on standard of care diets, we hope to improve overall outcomes in this patient population.

Lee[5] Norah Terrault[6] George Therapondos[7] Mohamed Shoreibah[8] R. Mark Ghobrial[9] Christine Hsu[10] Amol Rangnekar[11] Ethan Weinberg[12] Kirti Shetty[13] Neha Jakhete[14] Michael Lucey[2], [1]Rush University Medical Center, [2]University of Wisconsin, [3]University of Pennsylvania Health System, [4]Tufts Medical Center, [5]Keck School of Medicine, [6]University of Southern California, [7]Ochsner Medical Center, [8]University of Alabama at Birmingham, [9]Houston Methodist JC Walter Transplant Center, [10]National Institute of Diabetes, Digestive, [11]Georgetown University Hospital, [12]University of Pennsylvania, [13]University of Maryland, Baltimore, [14]University of Maryland

Background: There is currently no consensus for monitoring or treatment of alcohol use disorder (AUD) after LT in patients with ALD. Our study evaluates institutional variability in guidance documents from 8 LT centers in the ACCELERATE consortium. **Methods:** Based on the principles qualitative document analysis, using inductive content analysis, we reviewed all internal protocols related to alcohol use after LT from 8 geographically diverse US LT centers. The protocols had been updated between 2019-2025. **Results:** Our review highlights the following themes: psychosocial team engagement, alcohol testing, AUD counseling, and AUD treatment with pharmacotherapy. Elements of the documents were characterized as "vague", "specific" or "no guidance" (Table1). Five centers outlined preemptive psychosocial team engagement post-LT, among which 2 had guidelines for follow up by the psychosocial team at specific time intervals and 3 centers proposed psychosocial team follow up on an *as needed* basis (advice that we characterized as 'vague'). No guidance on engagement by psychosocial services was prescribed at 3 centers. Seven centers required surveillance for alcohol use post-LT: monthly whole blood Phosphatidylethanol (PEth) testing for one year in 4 centers, PEth testing every 3 months at 2 centers, while 1 center did not specify type or frequency of testing. One center did not have guidance on the requirement of any alcohol testing. Five centers described AUD counseling post-LT: preemptive in 3 and reactive after evidence of drinking in 2. Four centers outlined in detail the location, frequency, and duration of AUD counseling. Pharmacotherapy for AUD post-LT was addressed in documents from 2 centers only. Two centers had patient facing documents vaguely outlining the monitoring or treatment of AUD post-LT. **Conclusion:** Our study shows inter-institutional variability in post-LT guidance for patients transplanted with ALD regarding testing for alcohol use, and approaches to prevent or respond to episodes of return to drinking. This variance may contribute to disparate patient experiences and center outcomes. Further study is needed to determine the relative effectiveness of different protocols for management of AUD post-LT, which can inform efforts to standardize best practices in LT for ALD care.

Table 1: Summary of Post-LT Documents from 8 centers

	Center 1	Center 2	Center 3	Center 4	Center 5	Center 6	Center 7	Center 8
Post-LT Psychosocial Team Engagement	Specific	Specific	Vague	No Guidance	Vague	Vague	No Guidance	No Guidance
Post-LT Alcohol Testing	Specific	Specific	Specific	Specific	Vague	Specific	Specific	No Guidance
Post-LT AUD Counseling	Specific	Specific	Specific	Specific	Vague	No Guidance	No Guidance	No Guidance
Post-LT AUD Pharmacotherapy	Vague	No Guidance	No Guidance	No Guidance	No Guidance	No Guidance	No Guidance	Specific
Post-LT AUD Patient Facing Documents	No Guidance	No Guidance	Vague	No Guidance	Vague	No Guidance	No Guidance	No Guidance

Blaney[3], [1]MedStar Health-Georgetown/Washington Hospital Center, [2]Georgetown University School of Medicine, [3]Georgetown University Hospital

Background: Alcohol-associated hepatitis (AH) is the most severe presentation of alcohol-associated liver disease and is increasingly recognized as an indication for liver transplantation (LT). A substantial proportion of patients with AH have coexisting cirrhosis, with literature estimating prevalence rates of 50–70%. Clinical overlap between AH and cirrhosis complicates accurate diagnosis without histologic confirmation. Improved recognition of cirrhosis in this setting has implications for prognostication and long-term management. This study aimed to assess the prevalence of cirrhosis in patients with AH undergoing LT and to identify clinical features distinguishing patients with AH alone from those with AH and underlying cirrhosis. **Methods:** We conducted a retrospective review of patients who underwent LT for AH at a single center. Patients were stratified based on the presence or absence of histologic cirrhosis on explant pathology. Demographic, clinical, and laboratory variables at the time of transplant were compared between groups. Statistical significance was defined as $p < 0.05$. **Results:** Of 71 patients who received LT for AH, 68 (95.8%) had histologically confirmed cirrhosis, with only 3 (4.2%) without underlying cirrhosis. Compared to patients without cirrhosis, those with cirrhosis had significantly lower neutrophil percentages (34.59% ± 38.97 vs. 85.10% ± 8.51, $p = 0.029$), lower platelet counts (153 ± 97 vs. 313 ± 139 x10³/μL, $p = 0.021$), and were significantly less likely to have histologic evidence of inflammation on explant (41% vs. 100%, $p = 0.007$). MELD 3.0 scores were similar between groups (mean 36.0 ± 4.36 in patients without cirrhosis vs. 38.57 ± 10.18 in patients with cirrhosis, $p = 0.558$ using Welch's t-test). No statistically significant differences were observed in age, time from last drink, white blood cell count, ferritin, or albumin levels. On imaging, patients with cirrhosis were significantly more likely to have radiographic evidence of cirrhosis (90% vs. 0%, $p = 0.002$), while no significant differences were observed in rates of hepatomegaly (43% vs. 67%, $p = 0.580$), splenomegaly (79% vs. 33%, $p = 0.129$), or hepatic steatosis (79% vs. 67%, $p = 0.515$). **Conclusion:** Our findings demonstrate that the vast majority of patients undergoing LT for AH have underlying cirrhosis, which is often under-recognized in clinical assessment. These results suggest a much higher prevalence of cirrhosis in the AH LT population than previously reported. This likely reflects more advanced disease in those who receive LT. Features such as thrombocytopenia, reduced neutrophil percentage, and imaging may offer subtle clues to the presence of underlying cirrhosis.

Category	Variable	Cirrhosis Absent (n=3)	Cirrhosis Present (n=68)	p-value

1641 | ALCOHOL-RELATED LIVER CIRRHOSIS MORTALITY TRENDS IN OLDER ADULTS IN THE UNITED STATES (1990–2021): AGE, SEX AND SOCIODEMOGRAPHIC INDEX STRATIFIED INSIGHTS

MOHAMED A ELNAGGAR[1] Ayah Obeid[2] Ismail Elkhattib[1] Mohamad Elgozair[3] Omar Abbas[4] Mohamed Abd El Aziz[5] Raffi Karagozian[6], [1]Hartford Healthcare, [2]Saint Luke's University Health Network, [3]Danbury Hospital/Yale New Heaven, [4]Al-Azhar University, School of Medicine, [5]Deaconess health system, Henderson, KY, [6]Tufts University School of Medicine

Background: The burden of alcohol-related liver cirrhosis is increasing worldwide, but mortality trends in older adults remain underexplored. We analyzed trends in alcohol-related cirrhosis deaths among U.S. adults aged ≥70 years between 1990 and 2021, with stratification by age group, sex, and Socio-demographic Index (SDI) level. **Methods:** We used data from the Global Burden of Disease (GBD) 2019 study to examine mortality trends from 1990 to 2021. Analyses were stratified by age group (70–74, 75–79, 80–84, 85–89, 90–94, and ≥95 years), sex, and global SDI level. We calculated Average Annual Percent Change (AAPC) using log-linear regression models and visualized

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

results with 95% uncertainty intervals (UIs). **Results:** In 2021, the highest alcohol-related cirrhosis mortality was observed among U.S. males aged 70–74 years (2,135 deaths; 95% UI: 1,681–2,607). A consistent upward trend was observed across all age groups and both sexes, with AAPC ranging from 2.15% to 3.19%. Globally, the Middle SDI group experienced the highest AAPC for both sexes (male: 3.18%, female: 3.22%). High SDI countries like the U.S. showed lower AAPC values but high absolute mortality. **Conclusion:** Alcohol-related cirrhosis mortality has risen significantly in U.S. adults ≥70 years, with the most rapid increases seen in the oldest age groups and in middle-SDI countries globally. These findings highlight an urgent need for targeted preventive strategies in aging populations. Keywords: Alcohol-related cirrhosis; Global Burden of Disease; older adults; mortality trends; SDI; liver disease

1642 | LONG-TERM MAJOR ADVERSE LIVER OUTCOMES IN LEAN AND NON-LEAN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE

Pojsakorn Danpanichkul[1] Yanfang Pang[2] Vincent Chen[3] Donghee Kim[4] Karn Wijarnpreecha[5], [1]Texas Tech University Health Sciences Center, [2]Chiang Mai University, [3]University of Michigan Medical Center, [4]Stanford University, [5]University of Arizona College of Medicine-Phoenix

Background: Although differences in liver outcomes among lean and non-lean individuals with MASLD are well established, the major adverse liver outcomes (MALO) in patients with lean and non-lean ALD remain unexplored. This study leverages a large-scale federated database to investigate these differences. **Methods:** We conducted a retrospective cohort study utilizing anonymized electronic health records from the TriNetX network. Two cohorts were identified: individuals with ALD who were lean (body mass index [BMI] < 25 kg/m2) and those who were non-lean (BMI ≥ 25 kg/m2). The study focused on individuals without a prior history of liver decompensation, with a follow-up duration of median 5 years. The primary outcomes included MALO and its subcategories. To minimize confounding, 1:1 propensity score matching was performed, accounting for baseline demographics, socioeconomic factors, substance use disorder, mental health conditions, medication use, and laboratory values. **Results:** The study included 90,712 individuals with ALD, evenly distributed between the lean (n = 45,356) and non-lean patients with ALD (n = 45,356), post propensity score matching. Compared to the non-lean group, the lean ALD group was associated with a lower risk of hepatic encephalopathy (hazard ratio [HR]: 0.93, 95% confidence interval [CI] 0.87 to 1.00), variceal bleeding (HR: 0.90, 95% CI 0.82 to 0.99), hepatorenal syndrome (HR: 0.84, 95% CI 0.78 to 0.90), and portal hypertension (HR 0.91, 95% CI 0.87 to 0.94). However, the lean ALD group was associated with a higher risk of ascites (HR: 1.10, 95% CI 1.06 to 1.14) and spontaneous bacterial peritonitis (HR: 1.10, 95% CI 1.10, 95% CI 1.02 to 1.19). However, there is no difference between overall MALO in the two groups (HR: 0.97, 95% CI 0.94 to 1.01). **Conclusion:** In **Conclusion:**, this multicenter study offers preliminary evidence suggesting that lean patients with ALD have different MALO than non-lean ALD patients.

Table 1 Major Adverse Liver Outcomes different between lean and non-lean patients with alcohol-associated liver disease

Outcome	Hazard Ratio (95% CI)	p-value
Major Adverse Liver Outcomes	0.97 (0.94–1.01)	0.127
Ascites	1.10 (1.06–1.14)	**<0.001**
Hepatic Encephalopathy	0.93 (0.87–1.00)	**0.049**
Variceal Bleeding	0.90 (0.82–0.99)	**0.027**
Hepatorenal Syndrome	0.84 (0.78–0.90)	**<0.001**
Portal Hypertension	0.91 (0.87–0.94)	**<0.001**
Spontaneous Bacterial Peritonitis	1.10 (1.02–1.19)	**0.016**

1643 | INTEGRATED LIVER TRANSPLANT ENGAGEMENT & RECOVERY NETWORK: A PERSON-CENTERED APPROACH TO ALCOHOL-ASSOCIATED LIVER DISEASE

Luis Seija[1] Shimrit Keddem[1] Allison Schachter[1] Vinayak Ahluwalia[1] James Guevara[2] Jonathan Nahas[1] Marina Serper[3] Marilyn Schapira[1] Tamar Klaiman[1] Ethan Weinberg[1] Robert Weinrieb[1] Arpita Goswami Banerjee[1] Therese Bittermann[4], [1]University of Pennsylvania, [2]Children's Hospital of Philadelphia, [3]University of Pennsylvania Health System, [4]Perelman School of Medicine

Background: Alcohol-associated liver disease (ALD) is the leading indication for liver transplantation in the U.S. Patients with ALD often have co-occurring alcohol use disorder (AUD), psychiatric co-morbidities, complex psychosocial needs, and systemic barriers to care, frequently without access to coordinated, multidisciplinary treatment. While integrated care models offer a promising approach, there is limited information on how patients experience these interventions. The Integrated Transplant Engagement & Recovery Network (ILEARN), a person-centered, team-based clinic, was developed to strengthen relational continuity, improve care coordination, and enhance quality of care for patients with ALD and AUD pre- and post-transplant. This qualitative study explores how patients perceive and engage with the ILEARN model to inform future program design, implementation strategies, and opportunities to embed equity throughout the transplant pathway. **Methods:** We conducted a single-center qualitative study utilizing modified grounded theory. Between February and May 2025, we purposively sampled both pre- and post-transplant patients with documented ILEARN visits. In-depth, semi-structured interviews explored five domains: illness and transplant experience, perceptions of integrated care, barriers and facilitators to treatment engagement, and caregiver roles. Interviews continued until thematic saturation. Data were analyzed thematically. Sociodemographic information, clinical characteristics, and self-reported health data were also collected. The study followed COREQ guidelines. **Results:** Seventeen patient interviews yielded four major themes: Lived Experience of Illness & Recovery, Navigating Systems of Care, Perceptions of Multidisciplinary Care, and Relational Context & Family Systems. ILEARN was perceived as more supportive, coordinated, and behaviorally inclusive than prior care, offering a sense of stability during a time of emotional and identity disruption. Barriers included insurance obstacles, difficulty navigating transplant processes, emotional fatigue, and lack of clarity around clinic structure and AUD pharmacotherapy. Relational support, provider trust and communication, and personalized care emerged as powerful facilitators. Findings informed a patient-derived integrated care framework and key clinician-facing implementation considerations. **Conclusion:** To our knowledge, this is the first study to center the patient voice in evaluation of a multidisciplinary ALD clinic. Findings underscore the potential of integrated, person-centered models like ILEARN while revealing structural gaps and opportunities for practice change. Patient narratives offer actionable insights to inform future implementation and reshape transplant care around the lived experiences of those it aims to serve.

Theme	Theme Description	Illustrative Quote(s)
Lived Experience of Illness & Recovery	Emotional, functional, and identity-related experiences of living with ALD and/or AUD, offering narrative insight into how patients understand and adapt to illness and recovery	*"Being sober now is like a second chance, I'm finally living."* *"I was functioning just fine on the outside. No one knew I had a problem until it was too late."* *"Doctors told me if this transplant hadn't happened, I had maybe two weeks to live."*
Navigating Systems of Care	Describes patients' structural and interpersonal experiences with healthcare systems, highlighting feasibility, accessibility, and system-level barriers or facilitators	*"MyChart has been amazing because my nurse practitioner is so responsive, even with questions about vitamins. I trust the information she gives me."* *"I had no liver specialist nearby. Local doctors just weren't equipped for this."* *"Insurance slowed everything down, I didn't even know what I was eligible for."*
Perceptions of Multidisciplinary & Integrated Care	Reflects how patients interpret and emotionally respond to team-based models like ILEARN with implications of care acceptability and future implementation	*"You're not just seeing a doctor; you're seeing a whole care team."* *"They treated me with dignity, not pity. That changed everything."* *"They workshopped my case together - it was about me, not just the disease."* *"Everything I know about this process came from them. I'd be lost without my team."*
Relational Context & Family Systems	Highlights the role of caregivers, family dynamics, and social context in shaping patient experiences and engagement throughout the transplant journey	*"My partner carried the whole thing. He was the one coordinating and holding it all together."* *"Telling my family was the hardest part. But it kept me accountable."* *"My mom was saying goodbye over dinner the night before surgery. I just didn't know it yet."*

1644 | EVALUATING THE IMPACT OF VARENICLINE ON MAJOR ADVERSE LIVER OUTCOMES IN ALCOHOL-ASSOCIATED LIVER DISEASE

Pojsakorn Danpanichkul[1] Yanfang Pang[2] Donghee Kim[3] Andrew Ibrahim[4] Benjamin Nah[5] Mazen Noureddin[6] Karn Wijarnpreecha[7] Suthat Liangpunsakul[8], [1]Texas Tech University Health Sciences Center, [2]Chiang Mai University, [3]Stanford University Medical Center, [4]Texas Tech University, [5]National University of Singapore, [6]Houston Methodist Hospital, [7]University of Arizona College of Medicine-Phoenix, [8]Indiana University

Background: Varenicline, an FDA-approved medication for smoking cessation, has shown promise in supporting alcohol abstinence. However, its impact on mortality and major adverse liver outcomes (MALO) among individuals with alcohol use disorder (AUD) and alcohol-associated liver disease (ALD) remains uncertain. This study utilizes a large federated database to assess varenicline's association with long-term outcomes in this population. **Methods:** A retrospective cohort study was conducted using anonymized electronic health records from the TriNetX network. Two cohorts were established, including individuals with ALD and AUD. The index event was initiation of either FDA-approved AUD pharmacotherapies (naltrexone or acamprosate) or varenicline. Outcomes were evaluated in patients without prior liver decompensation over a follow-up period of up to 10 years. The primary outcomes were MALO and all-cause mortality. To minimize confounding, propensity score matching (1:1) was applied, accounting for demographics, socioeconomic factors, substance use disorder, mental health conditions, medication use, and laboratory values. **Results:** The study included 2,272 individuals with ALD and AUD, equally divided between the FDA-approved pharmacotherapy group (n = 1,136) and the varenicline group (n = 1,136). Varenicline use was associated with a lower risk of mortality (HR: 0.76, 95% CI: 0.62–0.94, p = 0.009), MALO (HR: 0.74, 95% CI: 0.59–0.94, p = 0.012), and portal hypertension (HR: 0.70, 95% CI: 0.53–0.92, p = 0.011) compared to FDA-approved pharmacotherapy. **Conclusion:** These findings suggest that varenicline may provide clinical benefits for individuals with ALD and AUD, potentially reducing mortality and serious liver complications relative to FDA-approved AUD pharmacotherapies.

1645 | IMPACT OF ALCOHOL-RELATED HEPATITIS ON PATIENTS WITH ALCOHOL INDUCED PANCREATITIS; A NATIONWIDE ANALYSIS

Adham Obeidat[1] Hareesh Gundlapalli[2] Jawairia Memon[2] Gicel Jacklin Aguilar[2] Ahmad Abou Yassine[2] Christopher Chang[2], [1]Presbyterian Medical Group, [2]University of New Mexico

Background: Acute pancreatitis (AP) is caused by the destruction of exocrine cells due to the infiltration of inflammatory cells. Alcohol consumption is responsible for 17% to 25% of acute pancreatitis cases globally, making it the second most common cause of AP after gallstones. Additionally, excessive alcohol intake can result in steatosis, alcohol-related hepatitis (AH), and cirrhosis. This retrospective study aims to assess the potential impact of concurrent AH in patients hospitalized with alcohol-induced AP. **Methods:** The United States Nationwide Inpatient Sample (NIS) database was utilized to extract hospitalization data for patients admitted between 2019 and 2021. Using ICD-10 revision codes, we identified adults diagnosed with alcohol-induced AP and concurrent alcohol-related hepatitis (AH). The control group consisted of AP patients without AH. The primary outcome was in-hospital mortality. Secondary outcomes included sepsis, encephalopathy, pulmonary edema, respiratory failure (RF), acute kidney injury (AKI), pulmonary embolism (PE), cardiac arrest, malnutrition and length of stay (LOS). Multivariate logistic regression was used to adjust for relevant variables. **Results:** 74,756 patients were admitted with alcohol induced AP. Of these, 11,366 patients had a concurrent diagnosis of AH. In the AH group, the mean age was 43.31 years. 34.38% were females and 65.3% were Caucasians. In the AH group, 9.06% were malnourished and 11.4% were obese. 2.6% of AP patients with AH died during hospitalization compared to 1.3% in those without AH. Further, total hospital charges were more in the AH group (62,464.99$ vs 53,132.45$.). When adjusted to other relevant variables, AH was associated with increased in-hospital mortality in AP patients (OR 2.21; P-value $<$ 0.001). Congestive heart failure, malnutrition, age, male gender and Caucasian race were also associated with increased in-hospital mortality. On univariate and multi-variate analysis, AH was associated with an increased chance of developing sepsis, encephalopathy, AKI, malnutrition, pulmonary edema, RF, cardiac arrest and prolonged LOS. Interestingly, patients with AH had a lower chance for PE (see Table 1). **Conclusion:** The mortality rate in patients with alcohol-induced AP is approximately 36 times higher than in the general population, with nearly 50% of these patients dying within 20 years of diagnosis. The prevalence of concurrent alcohol-related liver disease, including AH, in patients with alcohol-induced AP varies significantly, ranging from 1.4% to 70%. In this study, we observed increased in-hospital mortality, additional complications, and a higher financial burden for patients with both alcohol-induced AP and concurrent AH. As a result, we recommend that clinicians closely monitor patients with these coexisting conditions and consider more aggressive treatment early in their hospitalization.

Complication	Univariate	P-Value	Multivariate	P-Value
Sepsis	1.29	< 0.001	1.36	< 0.001
AKI	1.34	< 0.001	1.58	< 0.001
Pulmonary edema	1.53	< 0.001	1.56	< 0.001
Respiratory Failure	1.43	< 0.001	1.67	< 0.001
Hepatic Encephalopathy	1.87	< 0.001	2.1	< 0.001
Cardiac arrest	1.47	< 0.001	1.63	< 0.001
Pulmonary embolism	0.61	< 0.001	0.68	< 0.001
Malnutrition	1.14	< 0.001	1.29	< 0.001
LOS	1.67	< 0.001	1.76	< 0.001

1646 | A NOVEL PROGRAM FOR MANAGEMENT OF ALCOHOL USE DISORDER IN A LIVER TRANSPLANT PROGRAM

Lynda Coraluzzi[1] Kevin Robinson[2] Victor Navarro[3], [1]Jefferson Health Transplant Institute, [2]Department of Medicine Jefferson Einstein, [3]Jefferson Health System

Background: There is no universally agreed upon approach to alcohol use disorder (AUD) for patients with end stage alcohol-related liver disease (ARLD) who require liver transplant (LT), and data indicates relapse rates post-LT of up to 50%.1 Involvement of an addiction specialist (AS) as a part of a multidisciplinary team reduces relapse rates when there is continuity of treatment pre- and post-LT. 2 A major challenge faced by this patient population is the inability to attend in-person outpatient AUD treatment sessions. Consequently, only about 10% of these patients receive adequate AUD treatment. 3. The HEAL (Hope, Empowerment, Acceptance, Life) program was designed to reduce relapse rates in ARLD patients post-LT. **Methods:** The AS assessed 250 patients from a single LT center for eligibility between April 2023 and October 2024. 187 were excluded due to lack of insurance or social support, or poor insight into their AUD and refusal of AUD treatment. 63 eligible patients, both pre- and post-LT, were invited to enroll in the HEAL program, which consisted of 12 weeks of virtual group and individual counseling sessions totaling 3.5 hours weekly. The curriculum was based on cognitive behavioral therapy (CBT) and psychoeducation, with the aim of increasing insight, educating on AUD, and motivating change. Monitoring for relapse was performed via self-reporting and monthly phosphatidyl ethanol (PEth) testing. Post-LT graft loss and patient deaths were recorded. **Results:** Of the 63 patients enrolled, 50 (79%) completed the HEAL program. 23 patients enrolled pre-LT and 27 enrolled post-LT. Among the 23 who enrolled pre-LT, 8 underwent LT and 15 did not require LT due to clinical improvement. One patient expired among the LT recipients who enrolled pre-LT, but there were no instances of graft loss in this group. Among the 27 who enrolled post-LT, 3 relapsed. This represents 6% relapse, 0% graft loss, and 2% death rate among all participants who enrolled both pre-LT and post-LT and completed HEAL. Among the 13 who did not complete HEAL, 6 relapsed-one of whom eventually suffered graft loss and subsequently expired. This represents 46% relapse, 7% graft loss, and 8% death rate among non-completers. **Conclusion:** This study demonstrates the benefit of LT centers investing in programs such as HEAL for patients with AUD. Results showed a favorable outcome among participants who completed the HEAL program, evidenced by a lower rate of recurrence of alcohol use and graft loss compared to participants who did not complete the program.

1647 | CARDIOVASCULAR MORTALITY IN ALCOHOL-RELATED LIVER DISEASE: NATIONAL TRENDS ANALYSIS

Pojsakorn Danpanichkul[1] Donghee Kim[2] Thanida Auttapracha[3] Luis Antonio Diaz[4] Juan Pablo Arab[5] Karn Wijarnpreecha[6] Amit Singal[7] Ju Dong Yang[8] Suthat Liangpunsakul[9], [1]Texas Tech University Health Sciences Center, [2]Stanford University, [3]Chiang Mai University, [4]UCSD, [5]VCU, [6]University of Arizona, [7]UTSW, [8]CSHS, [9]Indiana University

Background: People with alcohol-associated liver disease (ALD) are at heightened risk for cardiovascular disease (CVD)-related deaths, yet comprehensive data on this association remain scarce. This study aimed to evaluate national trends in CVD-related mortality among U.S. adults with ALD. **Methods:** We utilized mortality data from the US Census and the National Center for Health Statistics mortality records database spanning 1999 to 2020 to investigate CVD-related deaths in adults diagnosed with ALD. Age-adjusted mortality rates (AAMRs) per 100,000 population and annual percent change (APC) were calculated to assess temporal trends. **Results:** In 2020, a total of 1,840 CVD-related deaths were recorded among individuals with ALD in the United States—marking a 240% rise compared to 1999. While CVD mortality declined in the general population (APC: -2.20%, 95% CI: -2.73 to -1.73%), it significantly increased in the ALD cohort (APC: 4.19%, 95% CI: 0.65 to 7.85%). Although males exhibited higher AAMRs than females, the rate of increase was steeper among females (APC: 6.57%, 95% CI: 4.98 to 8.18%) than males (APC: 0.74%, 95% CI: 0.70 to 0.78%). American Indian and Alaska Native populations bore the highest AAMRs across racial/ethnic groups. The predominant causes of CVD-related deaths among ALD patients were ischemic heart disease (38%), hypertensive disorders (19%), and cerebrovascular conditions (15%). **Conclusion:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Contrary to the downward trend in cardiovascular mortality within the general U.S. population, individuals with ALD are experiencing a significant rise in CVD-related deaths—particularly women. These findings underscore the urgent need for sex- and population-specific strategies to mitigate cardiovascular risk in this at-risk group.

1648 | INTEGRATIVE TRANSCRIPTOME META-ANALYSIS IDENTIFIES UPSTREAM REGULATORY TARGETS IN ALCOHOLIC HEPATITIS ACROSS LIVER AND BLOOD

Seul Ki Han[1] Moon Young Kim[1] Soon Koo Baik[1],
[1]Yonsei wonju severance christian hospital

Background: Alcoholic liver disease is recognized as a complex condition caused by alcohol abuse, encompassing a wide range of liver disorders. Severe alcoholic hepatitis (SAH) is a major disease that causes liver damage and inflammation, highlighting the need for effective treatment development. Therefore, to identify therapeutic targets and validate selected genes through meta-analysis, genes that play a critical role in the onset and progression of SAH were selected, and their therapeutic potential was evaluated in an SAH animal model. **Methods:** Using bioinformatics data, we collected gene expression information related to SAH and analyzed genetic data and biological pathways from multiple databases. Changes in gene expression, selected through meta-analysis, were confirmed in liver tissues of SAH animal models using molecular biological techniques, including qPCR and western blot. **Results:** Meta-analysis results showed that specific genes cause significant changes in SAH and are promising candidates as therapeutic targets. First, it was confirmed that the expression of TNF-α and iNOS, genes related to inflammation, increased in the liver tissue of the animal model, creating an animal model that reflects SAH well. In addition, among the 10 genes that showed an increase in the AH genes selected by the meta-analysis, TGF-b1, LYN, TLR2, HDAC9, MAPK3, and AFP showed a significant increase in expression, and among the 18 genes that showed a decrease, GSTP1, SREBF2, CBS, PCBP2, PPARA, AGT, MAPK8, MET, LPIN1, DNAJB1, NR3C1, and LIPC showed a significant decrease in expression. **Conclusion:** These results not only provide important basic data for the development of diagnostic and therapeutic strategies for SAH, but also show the possibility of suggesting new therapeutic approaches in future studies. This study provides an important step toward discovering new targets for SAH treatment and demonstrates the usefulness of bioinformatic analysis.

1650 | HYALURONAN 35 PREVENTS ENDOTOXIN MEDIATED DYSREGULATED SKELETAL MUSCLE PROTEOSTASIS IN ALCOHOL RELATED LIVER DISEASE

Nicole Welch[1] Annette Bellar[1] Pugazhendhi Kannan[1] Elif Ertugral[2] Amy Attaway[1] Saurabh Mishra[1] Seshu Pothabathula[1] Carol de la Motte[1] Laura Nagy[3] Chandrasekhar Kothapalli[2] Srinivasan Dasarathy[1],
[1]Cleveland Clinic, [2]Cleveland State University, [3]Cleveland Clinic Foundation

Background: Despite pre-clinical and human data in alcohol related liver disease (ALD) that a number of signaling and functional perturbations contribute to sarcopenia, there are no effective treatments. Hyaluronans are glycosaminoglycan polymers with size specific homeostatic and signal regulatory functions. Hyaluronans with ~35 Kd molecular weight (HA35) are beneficial in hepatic and macrophage functions in ALD and modulate responses to TLR4, a lipopolysaccharide (LPS) receptor and CD44, an HA receptor. Whether low grade endotoxemis contributes to and if HA35 reverses sarcopenia of ALD were studied. **Methods:** Based on concentration and time course of ethanol/LPS treatment that replicate the phenotype,molecular, metabolic, and functional responses of skeletal muscle in human ALD,

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

responses to ethanol, LPS, and HA35 were studied in differentiated murine C2C12 and human induced pluripotent stem cell derived myotubes trearted with 100mM ethanol for 6h. In vivo studies were done in mouse models of ALD (mALD). Signaling responses and measures of protein homeostasis (proteostasis) were quantified by immunoblots, and mitochondrial oxidative function determined by high-sensitivity respirofluorometry. Membrane elasticity with ethanol treatment in myotubes was determined by atomic force microscopy (AFM), and contractile responses in skeletal muscle from mALD were determined. Integrated multiomics of untargeted data and image analyses were also performed. **Results:** Ethanol caused a sarcopenic phenotype in myotubes at 100mM for 6h and in mALD (lower myotube/myofiber diameter, muscle mass, protein synthesis, impaired mTORC1 signaling, and higher autophagy markers) without altering membrane elasticity and no membrane tethering on AFM at the dose/duration of ethanol treatment (Fig 1, A-C). Expression of LPS (TLR2, TLR4) and HA (CD44) receptors were upregulated by ethanol. In myotubes and muscle tissue from mALD, LPS caused a sarcopenic phenotype with impaired proteostasis signaling. Sarcopenic molecular/phenotype responses were observed at lower concentrations of ethanol/LPS treatment in myotubes showing increased LPS sensitivity in ALD. Treatment of myotubes and mALD with HA35 reversed proteostasis and prevented ethanol/LPS-induced lower protein synthesis, increased phosphorylation of p65-NFkB and myostatin expression, and impaired mTORC1 signaling (Fig 1, D-E). Consistently, HA35 treatment reversed the sarcopenic phenotype/signaling and functional perturbation in mALD without changes in ethanol-induced perturbations in muscle HA concentrations. **Conclusion:** Sarcopenic phenotype with signaling/molecular/functionalperturbation in ALD are worsened by lower concentrations of LPS and reversed by HA35. Safety of HA35 in humans (PMID 31121841) and sarcopenia reverasl in preclinical models provide the rationale for clinical translation (clinicaltrials.gov. NCT05018481).

1651 | OUTCOMES OF EARLY AND LATE ALCOHOL RELAPSE IN LIVER TRANSPLANT RECIPIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE

Garren Montgomery[1] Ayato Obana[1] Antonio Alvarez Castaneda[1] Benjamin Davies[2] Sylvester Black[1] Khalid Mumtaz[1], [1]Ohio State University Medical Center, [2]Ohio State University School of Medicine

Background: Alcohol-associated liver disease (ALD) is among the most common indications for liver transplantation (LT) in the United States. Candidacy for LT is influenced by the risk of alcohol relapse (AR) in LT recipients (LTRs). Early AR among LTRs for alcoholic hepatitis (AH) has been associated with poorer survival compared to late AR. However, the impact of early AR on LTR outcomes in the overall ALD transplant population is less clear. Therefore, we sought to study the impact of early and late AR on the outcomes of overall survival, graft survival, and risk of rejection among LTRs for ALD. **Methods:** We performed a retrospective study of LTRs for ALD at a single large LT center between 1/1/2016 and 11/30/2023. LTRs with AR were divided into early relapse (ER, defined as alcohol relapse within the first 12 months after LT) and late relapse (LR, alcohol relapse >12 months after LT). Cumulative risk of T cell-mediated rejection (TCMR), graft survival, and the overall survival were compared between ER, LR, and no relapse using the log-rank test. Cox proportional hazards regression analysis adjusting for age, male gender, MELD score, and type of deceased donor (donation after brain death; DBD vs donation after cardiac death; DCD) was also performed. **Results:** Out of 383 LTRs, 80 experienced AR - twenty-eight (35%) LTRs had ER while 52 (65%) LTRs had LR. The cumulative risk of TCMR was significantly higher among LTRs with ER compared to no relapse (log-rank $p=0.01$). On multivariate analysis (Table 1), using LTRs with no relapse as the reference, those with ER had a higher risk of TCMR (HR: 2.11; 95% CI: 1.03-4.32; $p=0.04$) adjusting for age (HR: 0.96; $p<0.005$), male sex (HR: 0.60; $p=0.04$), MELD score ($p=0.3$), and DCD graft type ($p=0.65$). LR was not associated with TCMR (HR: 1.19; 95% CI: 0.65-2.18; $p=0.58$).

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Neither ER nor LR were associated with an increased risk of death (ER, HR: 1.47, p = 0.47; LR, HR: 0.53, p = 0.15) or graft loss (ER, HR: 1.37, p = 0.55; LR, HR: 0.72, p = 0.39). Potential limitations to statistical power in this study included the small sample size of the ER group. **Conclusion:** Early relapse, but not late relapse, is an independent risk factor for TCMR in LTRs for ALD. However, neither ER nor LR was associated with a higher risk of graft loss or death. These observations suggest that early intervention for alcohol use disorder among LTRs with ALD is an important component of preventing TCMR in these patients.

Table 1: Multivariable Cox Regression Analyses to Determine Association of Early and Late Relapse with Rejection, Overall Survival, and Graft Survival

	Rejection		Overall Survival		Graft Survival	
Variable	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value
Early Relapse	2.11 (1.03-4.32)	0.04	1.47 (0.52-4.15	0.47	1.37 (0.48-3.85)	0.55
Late Relapse	1.19 (0.65-2.18)	0.58	0.53 (0.22-1.25)	0.15	0.72 (0.34-1.52)	0.39
No Relapse	Ref		Ref		Ref	
Age	0.96 (0.94-0.99)	<0.005	1.02 (0.99-1.05)	0.15	1.03 (1.0-1.06)	0.06
Male Sex	0.6 (0.37-0.97)	0.04	0.98 (0.5-1.84)	0.90	0.99 (0.53-1.85)	0.98
MELD Score at LT	0.99 (0.96-1.01)	0.30	0.99 (0.96-1.03)	0.69	1.0 (0.97-1.03)	0.93
DCD graft type (vs DBD)	1.13 (0.67-1.89)	0.65	1.05 (0.56-1.96)	0.87	0.91 (0.49-1.69)	0.77

1652 | BLACK PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE IS ASSOCIATED GREATER INCIDENCE OF COMPLICATIONS AND HOSPITAL-RELATED OUTCOMES

Ki Jung Lee[1], [1]*Tufts Medical Center*

Background: Alcohol-associated liver disease (ALD) is one of the leading causes of advanced liver disease in the United States and the world. Given the scarcity of race-specific data, this study examines the effects of race, specifically Black patients, on hospital outcomes and associated psychiatric conditions with ALD to assess for the racial disparities. **Methods:** Patients hospitalized with ALD from 2020 to 2024 at a tertiary care center were retrospectively reviewed. The cohort was stratified into White (reference group) and Black (exposure group). Primary endpoints included lengths of stay (LOS), number of readmissions, psychiatric comorbidities, and hepatic complications. Multivariate regression models were used for categorical outcomes, while negative binomial regression models assessed discrete outcomes. Exposure and reference cohorts were 1:1 propensity-score matched for age, race, gender, as well as the presence of chronic kidney disease, hypertension, hepatitis C. **Results:** The analysis included 3,179 patients: 239 Black (8.20%) and 2,674 White (91.80%). Black patients were younger and had lower BMI (p = 0.002). They consumed less alcohol per week than White patients (aOR 0.63, 95% CI 0.45-0.90, p = 0.008). Black population experienced longer average LOS compared to White population (aOR 1.17, 95%CI 1.00-1.37, p = 0. In the matched analysis, Black patients exhibited a significantly longer total LOS (aOR 1.49, 95% CI 1.15-1.92, p = 0.002) and more frequent hospital encounters (aOR 1.46, 95% CI 1.16-1.84, p = 0.001). Compared to White patients, Black patients had notably fewer drinks per week (aOR 0.51, 95% CI 0.31-0.86, p = 0.007) and a lower incidence of cirrhosis (aOR 0.36, 95% CI 0.22-0.67, p < 0.001). Regarding psychiatric comorbidities, Black patients had lower anxiety rates (aOR 0.63, 95% CI 0.41-0.98, p = 0.04) but higher schizophrenia rates (aOR 4.79, 95% CI 1.20-31.90, p = 0.05). Cocaine use (aOR 3.73, 95% CI 1.18-14.64, p = 0.04) and multiple substance use disorders (aOR 2.61, 95% CI 1.59-4.37, p < 0.001) were more prevalent among Black patients **Conclusion:** Black patients with ALD encountered longer hospital LOS, more frequent hospitalizations, and higher rates of sepsis, despite lower alcohol consumption and fewer substance use comorbidities. However, they had higher rates of psychiatric comorbidities such as schizophrenia and cocaine use. These disparities highlight the need for multidisciplinary, tailored care approaches to address the unique challenges faced by this vulnerable population.

1653 | ROLE OF SHEAR WAVE VISCOSITY (SWV) AS AN IMAGING BIOMARKER FOR EVALUATION OF ALCOHOLIC HEPATITIS NEW SUBMISSION

Carmen Fierbinteanu Braticevici[1] Vlad-Teodor Enciu[2] Priscila Madalina Ologeanu[2] Alexandru Constantin Moldoveanu[2], [1]University Hospital Bucharest, "Carol Davila" University of Medicine and Pharmacy, [2]University Hospital Bucharest, "Carol Davila" University of Medicine and Pharmacy

Background: Acute hepatitis is an acute and potentially life-threatening liver disease associated with high morbidity and mortality. One of the more common types of acute hepatitis is alcoholic hepatitis, which is of varying degrees of severity. Accurate assessment of the severity of the inflammation can help guide treatment choice in these patients. Shear Wave Viscosity (SWV), a novel ultrasound technique, quantifies liver tissue viscosity and may serve as an imaging biomarker for inflammation. Objective: To investigate the accuracy of liver viscosity as measured by SWV in predicting the severity of liver inflammation in alcoholic hepatitis. **Methods:** We conducted a prospective study including patients with alcoholic hepatitis. All patients underwent liver ultrasound using Shear Touch Viscosity (Resona A20 – Mindray). The machine has a module, a multi-parametric combined analysis tool, that enables real-time same-screen of attenuation, viscosity and stiffness. Laboratory evaluation included markers that are typically increased in alcoholic hepatitis: leukocyte count, C reactive protein (CRP), erythrocyte sedimentation rate (ESR), transaminases, total bilirubin, prothrombin time (PT) and international normalized ratio (INR), gamma glutamyl transpeptidase (GGT), alkaline phosphatase. The Maddrey Discriminant Function (DF) was calculated using the standard formula. The viscosity results were compared to the laboratory results, and analyzed using python. **Results:** Thirty-nine patients were included in the study. The viscosity measurements in our patients were included between 1.6 - 5 Pa.s.There was a significant correlation between liver viscosity and biological markers in univariate analysis (CRP – $p < 0.001$; ESR $p = 0.021$; AST $p < 0.001$; PT $p < 0.001$; INR $p < 0.001$; DF $p < 0.001$). Bivariate analysis shows strong positive correlations between liver viscosity and laboratory results: CRP 0.66; AST 0.80; PT 0.70; INR 0.69; DF 0.68. A ROC analysis was performed for the prediction of severe disease (DF > 32), with an AUROC of 0.95 [95% CI 0.87 – 1.00]. Using a cutoff value of 2.6, we obtain a sensitivity of 100% and a specificity of 90%. **Conclusion:** Liver viscosity correlates significantly with hepatic inflammatory activity and clinical severity in alcoholic hepatitis and may be an accurate marker of liver inflammation. Further studies are required to asses accuracy in other acute liver pathologies.

1654 | GLUTAMATE RELEASE FROM VGLUT3 GRANULES EXACERBATES ASH BY ACTIVATING MGLUR5 ON KUPFFER CELLS VIA METABOLIC SYNAPSE

Kwang Woo LEE[1] Keungmo Yang[2] Kyurae KIM[1] Sung Eun Choi[3] Min Jeong Kim[1] Katherine Po Sin Chung[3] Eunmi Lee[1] Jihyo Byun[1] Jaewoo Oh[1] Seungryong Choo[1] WON-IL JEONG[1], [1]KAIST, [2]College of Medicine, The Catholic University of Korea, [3]Korea Advanced Institute of Science and Technology

Background: Glutamate, an essential component in amino acid metabolism, has been relatively unexplored in the development of alcohol-associated steatohepatitis (ASH). This study investigates the underlying mechanism by which hepatic glutamate induces reactive oxygen species (ROS) production in Kupffer cells (KCs) and leads liver injury through bidirectional interactions via pseudosynapse formation following alcohol consumption. **Methods:** ASH was induced in mice via 2-week ethanol feeding plus a binge. Hepatic immune cells were analyzed using flow cytometry analysis and immunostaining. Public and bulk RNA-seq data were used to assess glutamate synthesis and transporter expression. Glutamate-related proteins and vesicle formation were visualized via immunostaining and tissue expansion. Intravital imaging tracked calcium changes, and electron microscopy revealed hepatocyte–KC proximity. For in vivo and in vitro experiments, KC-specific metabotropic glutamate receptor 5 (mGluR5) or NADPH oxidase 2 (NOX2)-deficient mice and isolated primary Kupffer cells were used. **Results:** 2-week alcohol consumption induces the formation of hepatic glutamate vesicles, driven by the aryl hydrocarbon receptor-mediated expression of vesicular glutamate transporter 3 (VGLUT3). Simultaneously, alcohol-induced changes, including perivenous hepatocyte ballooning, microvilli loss, and mitochondrial Ca^{2+} accumulation, bring KCs into close contact with ballooned hepatocytes. Additional binge drinking alters intracellular Ca^{2+} levels, triggering the exocytosis of glutamate from VGLUT3 vesicles. This, in turn, activates NOX2 through mGluR5 in KCs, leading to ROS production and the promotion of ASH. Accordingly, genetic or pharmacological interference of mGluR5 and NOX2 in KCs attenuates ASH. In patients, plasma glutamate and VGLUT3 vesicles correlate with ASH development. **Conclusion:** Our findings suggest that hepatocytes and KCs

form a pseudosynapse, allowing glutamatergic signaling to potentially exacerbate the development of ASH.

1655 | SINGLE-CENTER COMPARATIVE ANALYSIS OF HOSPITAL ADMISSIONS FOR ALCOHOL-RELATED LIVER DISEASE AND ITS OUTCOMES: PRE- AND POST-COVID-19 PANDEMIC

Vivek Govardhanam[1] Valerie Lavigne[1] Kyle Tong[1] Mayan Alqahtani[1] Laila Shirzad[2] Fernanda Onofrio[3], [1]University of Ottawa, [2]The Ottawal Hospital, [3]University of Toronto

Background: Alcohol-Related Liver Disease (ALD) represents a significant public health concern worldwide, contributing to substantial morbidity, mortality, and healthcare costs. ALD is uniquely characterized by its association with modifiable risk factors, including alcohol consumption patterns, nutrition, and socioeconomic determinants of health. While studies from other regions have shed light on the COVID-19 pandemic's short-term impact on ALD, knowledge gaps persist in understanding its long-term effects on disease progression and healthcare utilization patterns. This retrospective study aims to analyze hospitalizations for ALD at The Ottawa Hospital (TOH) over a five-year period spanning the Pre-COVID, COVID, and Post-COVID eras. **Methods:** This single-center retrospective study examined all hospital admissions for ALD at TOH from March 1, 2018, to March 31, 2023. The inclusion criteria were as follows: admission to TOH during the specified study period, primary or contributing diagnosis of ALD, including alcoholic hepatitis, alcohol-related cirrhosis, or acute liver failure due to alcohol use disorder. The primary outcomes of interest were to compare hospital admissions, disease severity (MELD, Maddrey, and Child-Pugh scores), and mortality (in-hospital mortality rates and causes of death) across the three eras. **Results:** The total number of admissions was highest during the COVID era (429), followed closely by the Pre-COVID era (341), and was lowest in the Post-COVID era (217), ($p = 0.264$). Mean Maddrey scores were not statistically different between the 3 eras ($p = 0.695$). The highest mean MELD score was observed during the COVID era (34.5, $SD = 4.43$), without statistically difference between the eras ($p = 0.172$). The mortality rate was highest in the Pre-COVID era (28.7%), followed by the COVID era (25.4%), and the Post-COVID era (19.8%), ($p = 0.061$). The main cause of death in all eras was acute liver failure (80/250 deaths). COVID-19 was the main cause of death in only 2 patients. **Conclusion:** This study demonstrates the impact of the COVID-19 pandemic on ALD care and its outcomes, with implications for public health and healthcare systems. While there was not statistically significant difference in hospital admissions for ALD between the 3 eras, a modest increase in hospital utilization during the COVID era was seen. The high mortality seen among this population of severe liver disease patients may reflect the delay in seeking medical attention in all eras. These results highlight the need for proactive strategies to support ALD patients, continuously ensuring equitable access to care to reduce mortality.

1656 | LOW BLOOD UREA NITROGEN DURING ALCOHOL-ASSOCIATED ADMISSION PREDICTS CIRRHOSIS IN PATIENTS WITHOUT PRE-EXISTING LIVER DISEASE: RESULTS: FROM A LARGE NATIONWIDE VETERANS AFFAIRS DATABASE

Rahul Karna[1] Anders Westanmo[2] Amy Gravely[2] Khalid Ishani[3] Natalie Wilson[4] Mohammad Bilal[5] Tessa Steel[6] Robert Wong[7] Thad Abrams[8] Prowpanga Udompap[9], [1]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, Minneapolis, MN, [2]Research Service, Minneapolis Veteran Affairs Medical Center, Minneapolis, MN, [3]University of Minnesota Medical School, Minneapolis, MN, [4]Department of Medicine, University of Minnesota, Minneapolis, MN, [5]Division of Gastroenterology & Hepatology, University of Colorado, Aurora, CO, [6]Division of Pulmonary, Critical Care and Sleep Medicine, University of Washington, Seattle, WA, [7]VA Palo Alto Healthcare System, [8]Department of Internal Medicine, University of Iowa, Iowa City, IA, [9]Minneapolis VA Medical Center, Minneapolis, MN

Background: Low Blood urea nitrogen (BUN) levels are common in individuals with alcohol use disorder (AUD) due to inadequate protein intake and impaired nutrient absorption which leads to reduced synthesis of urea in the liver. Protein metabolism may be

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

impaired further among those with chronic liver disease due to the liver's reduced ability to synthesize urea which can result in low BUN. We hypothesize that the lower BUN in patients with AUD without pre-existing liver disease is associated with more severe AUD and likely alcohol-related liver disease. We therefore aim to determine whether low BUN during a hospitalization for AUD in patients without pre-existing liver disease is associated with an increased future risk of developing cirrhosis. **Methods:** This is a retrospective cohort study of adults hospitalized for AUD between 10/1/2015 to 12/31/2019. Data was obtained from the Veterans Health Administration Corporate Data Warehouse. The normal range for BUN at Veterans Affairs labs is 8–26 mg/dL for male and 6-21 mg/dL for females. Index cohort was classified into 3 groups, adjusted by sex based on the lowest BUN during hospitalization: Very Low (BUN <5), Low (BUN 5-8) and Not Low (BUN >8). Cirrhosis development was evaluated at 1, 3, and 5 years after hospital discharge, using ICD-9/10 codes. Patients with history of cirrhosis prior to the hospitalization, new diagnosis of cirrhosis within 6 months of discharge or any pre-existing liver diseases were excluded. A multivariate regression analysis was performed to explore the association of BUN and cirrhosis, controlling for the following variables: age, sex, race, ethnicity, BMI, eGFR, and Charlson comorbidity index. **Results:** Among a total of 15,093 patients with AUD and no pre-existing liver diseases included in the analysis, 22.16% had BUN $<$ 5 mg/dL (Very Low BUN), 29.37% had BUN 5-8 mg/dl (Low BUN) and 48.45% had BUN >8 mg/dL (Not Low). Interestingly, 7.1% developed cirrhosis in Very Low BUN cohort while, 5.6% had cirrhosis in Low BUN and 3.8% in Not Low BUN cohort at 5 years (Table 1). Multivariate regression analysis showed that Low BUN cohort (OR: 1.55, 95% CI:1.28-1.87) and Very Low BUN cohort (OR: 2.14; 95% CI: 1.77-2.58) had significantly high odds of developing cirrhosis than Not Low BUN cohort. Male sex (OR:1.5; 95% CI:1.03-2.26), hypertension (OR:1.5; 95% CI:1.22-1.84) and high FIB-4 score ($>=$ 2.67) (OR: 95% 1.25; 95% CI:1.04-1.49) were also associated with higher risk of cirrhosis development. The sensitivity analysis excluding the patients with baseline high FIB-4 score was also completed and showed that a strong association between very low BUN, low BUN and cirrhosis development remained unchanged. **Conclusion:** Our large database study suggests that Low BUN during the alcohol-related admission is associated with cirrhosis development in patients with AUD. The study could pave way for prognostication and risk stratification of patients with AUD with higher risk of cirrhosis development.

Table 1: Demographic data and cirrhosis development in patients with AUD stratified by lowest BUN during hospitalization

◆ 2001 | VALIDATION AND PERFORMANCE OF A LIVER PDFF MEASUREMENT METHOD USING ARTIFICIAL INTELLIGENCE

Wenjie Pang[1], [1]*Resonance Health*

Background: Fatty liver related diseases can be closely associated to metabolic syndrome and increased risk of cardiovascular diseases in both adults and children. Magnetic Resonance Imaging (MRI) methods for hepatic steatosis measurement become the new gold standard with more benefits than liver biopsy and other non-invasive methods. The aim of this study is to validate and evaluate the performances of a Convolutional Neural Network (CNN) trained MRI-data processing method automatically quantifying multiple metrics related to hepatic steatosis in near real-time. **Methods:** 300 fully quarantined datasets previously processed within 5-year period by an FDA-cleared HepaFatScan manual method with the data scanned by different MRI makes, models and field strengths (1.5T and 3T) were recruited as a reference standard for validation of an FDA-cleared CNN (HepaFatSmart) method to simultaneously measure proton density fat fraction (PDFF), volumetric liver fat fraction (VLFF) and steatosis grade. Among them, 281 datasets passed

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

both the input quality control algorithms defined by both methods were successfully analysed. Additional 41 subjects with repeated scans were analysed by the AI method for evaluation of repeatability and comparison with manual HepaFatScan analysis. **Results:** CNN PDFF (HepaFatSmart) returned almost the same analysis results as the reference standard HepaFatScan. A small bias of 0.22% found in the validation dataset is very small and unlikely has any clinical relevance although it is statistically significant due to small standard deviation, indicating reliable and accurate measurement of liver fat by the AI device compared with the reference standard of HepaFatScan. In addition, HepaFatSmart repeatability coefficients showed a narrow range of -2.0% – 1.7% with a small bias of 0.17%, indicated robustness regarding not only reliable and consistent analysis outcomes but also slightly better repeatability than the manual HepaFatScan, which does not suggest yet the AI method is better than the manual method rather than due to historical reason when small ROIs were used in the past for the reference standard (Figure). An anomaly assessment mechanism can also automatically detect excessive liver iron level, evaluate the impact and determine when to stop as a safety measure. **Conclusion:** The accuracy and precision of the CNN PDFF method are comparable with the reference standard and the results are interchangeable. Using the ANN eliminates the need for image analysis or other technical expertise and speeds up reporting to an extent that point-of-care screening could be performed and costs associated with analysis greatly reduced. As an important measure within the quantitative MRI data analytics realm, the result is fully transparent and visible to the user to mitigate any potential residual risks of an AI method.

◆ 2002 | COMPARATIVE PERFORMANCE OF THE TWO-STEP CLINICAL CARE PATHWAY FOR DETECTING ADVANCED LIVER FIBROSIS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS: A PROSPECTIVE MULTICENTER BIOPSY-BASED STUDY

Yuping Chen[1] Bingtian Dong[2] Airong Hu[3] Xiao Liang[4] Yiling Li[5] Wei Gou[6] Qing-Lei Zeng[7] Chuan Liu[1] Minghua Zheng[8] Xiaolong Qi[1], [1]Zhongda Hospital, Southeast University, [2]The First Affiliated Hospital of Anhui Medical University, [3]Ningbo Institute of Liver Diseases, Ningbo No. 2 Hospital, [4]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, [5]The First Hospital of China Medical University, [6]Qingdao Public Health Clinical Center, [7]The First Affiliated Hospital of Zhengzhou University, [8]The First Affiliated Hospital of Wenzhou Medical University

Background: Current clinical guidelines recommend screening for advanced liver fibrosis (AF) due to metabolic dysfunction-associated steatotic liver disease (MASLD) in patients with type 2 diabetes mellitus (T2DM), using a two-step approach: initial risk stratification with the Fibrosis-4 index (FIB-4), followed by liver stiffness measurement (LSM) via vibration-controlled transient elastography or other second-line noninvasive tests (NITs). This study aimed to evaluate the performance of the two-step clinical care pathway and compare different NIT-based strategies for identifying AF in patients with T2DM. **Methods:** We prospectively enrolled 321 biopsy-proven MASLD patients with T2DM from five hospitals in China between 2017 and 2024. The diagnostic accuracy of various NITs, including LSM, FIB-4, Agile 3+ score, metabolic dysfunction-associated fibrosis-5 (MAF-5) score, LiverRisk score, FibroScan-AST (FAST) score, and NAFLD fibrosis score (NFS), were evaluated using their respective established dual cut-off values. We further evaluated the performance of novel two-step algorithms combining FIB-4 with second-line NITs and explored alternative algorithms replacing FIB-4 with NFS, MAF-5 or LiverRisk score in the first step. **Results:** The median age of participants was 49.0 ± 12.8 years, median body mass index was 27.3 ± 3.9 kg/m^2, and 52.6% were male. The prevalence of AF (≥F3) was 21.8%. For detecting AF, the area under the ROC curve values were: Agile 3+ (0.795 [95% CI: 0.747-0.838]), LSM (0.783 [0.734-0.827]), FIB-4 (0.752 [0.701-0.798]), MAF-5 (0.719 [0.652-0.779]), FAST (0.717 [0.665-0.766]), NFS (0.704

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

[0.651-0.753]), and LiverRisk (0.669[0.610-0.725]). Using predefined dual thresholds (Agile 3+: 0.451/0.679; LSM: 8/12 kPa), Agile 3+ achieved a higher correct classification rate than LSM (76.6% vs. 72.1%) and a lower indeterminate rate (18.4% vs. 26.2%). Moreover, when used as a second step following FIB-4 ($\geq$1.3 or $\geq$2.0 if age $\geq$65), Agile 3+ achieved the highest correct classification rate (74.3%) and the fewest indeterminate results (12.5%) among all tested combinations (See Figure 1 for more details). **Conclusion:** The two-step algorithm using FIB-4 followed by Agile 3+ outperformed other NIT-based strategies for AF risk stratification in T2DM patients, offering superior diagnostic accuracy and minimizing indeterminate classifications. This supports its clinical utility as an efficient noninvasive care pathway for AF screening in this high-risk population.

◆ 2003 | CROSS-NATIONAL VALIDATION OF FIBRO-SCOPE FOR LIVER FIBROSIS IN MASLD: INSIGHTS FROM JAPAN AND THE US

yuya seko[1] Georgia Sofia Karachaliou[2] Ayako Suzuki[2] Manal Abdelmalek[3] Kanji Yamaguchi[1] Toshihide Shima[4] Yoshito Itoh[1] Anna Mae Diehl[5] Takeshi Okanoue[6], [1]Kyoto Prefectural University of Medicine, [2]Division of Gastroenterology, Duke University Medical Center, Durham, NC, USA, [3]Mayo Clinic Rochester, [4]Saiseikai Suita Hospital, [5]Duke University, [6]Osaka Saiseikai Suita Hospital

Background: Fibro-Scope is an artificial intelligence-based neural network system generated non-invasive test designed to assess liver fibrosis in patients with metabolic dysfunction associated steatotic liver disease (MASLD) using 11 clinical parameters. In Japanese cohort of patients with MASLD, Fibroscope showed high specificity to diagnose advanced fibrosis among patients who were classified as intermediate risk by FIB-4 index of 1.3–2.67. This study aims to validate and compare the diagnostic performance of FibroScope in a US cohort of patients with biopsy-proven MASLD with Japanese cohorts. **Methods:** 229 U.S. patients and 796 Japanese with biopsy-proven MASLD were evaluated. The diagnostic accuracy of the FIB-4 index and Fibro-Scope was evaluated using the area under the receiver operating characteristic curve (AUROC). Cohort-specific Fibro-Scope cutoff values were adopted based on previous studies. **Results:** The U.S. cohort had significantly higher BMI and platelet counts, and lower levels of ALT, GGT, total cholesterol, and triglycerides compared to the Japanese cohort. Additionally, the Japanese cohort was significantly older than the U.S. cohort. The prevalence of advanced fibrosis (F3–F4) was 26.2% in the U.S. cohort and 18.1% in the Japanese cohort ($p = 0.008$). The AUROCs of the FIB-4 index and Fibro-Scope for detecting advanced fibrosis were 0.784 and 0.854 in the U.S. cohort, and 0.883 and 0.907 in the Japanese cohort, respectively. The prevalence of "intermediate zone" was significantly smaller in Fibro-Scope (4.8%) than FIB-4 index (32.6%). The sensitivity and specificity for F3-4 of Fibro-Scope were 71.7% and 87.6% in the U.S. cohort, and 76.4% and 86.3% in the Japanese cohort. The sensitivity of Fibro-Scope outperformed the FIB-4 index cutoff of $\geq$ 2.67 (advanced hepatic fibrosis) in both cohorts. Among patients aged $\geq$65 years, the sensitivity and specificity of Fibro-Scope were 78.6% and 83.3% in the U.S. cohort, and 90.0% and 72.4% in the Japanese cohort. **Conclusion:** Fibro-Scope demonstrated robust diagnostic performance for detecting advanced fibrosis in both US and Japanese MASLD cohorts with few intermediate ranges when using race-specific cutoff values.
