Background: Various combinations of agonists of the glucagon receptor (GCGR), glucose-dependent insulinotropic polypeptide receptor (GIPR), and glucagon-like peptide-1 receptor (GLP-1R) are in clinical trials for the treatment of metabolic dysfunction-associated liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH). We explored how US healthcare professionals (HCPs) treating people with MASLD/MASH perceive these investigational agents. **Methods:** Between November 2024 and January 2025, an online survey was completed by US hepatologists/gastroenterologists (HEP/GASTRO, n = 179), endocrinologists (ENDO, n = 172), primary care physicians (PCP, n = 177) and advanced practice providers (APP, n = 232) currently treating people with MASLD/MASH to assess their knowledge of GCGR, GIPR, and GLP-1R agonists. **Results:** Respondent HCPs reported managing a mean of 13–25 patients per week having MASLD/MASH. Ultrasound was the most common imaging technique to initially diagnose MASH across specialty (ENDO, 64.0%; PCP, 75.7%; APP, 74.0%), with the exception of HEP/GASTRO where vibration-controlled transient elastography (FibroScan®) was most common (77.7%). Liver enzymes (79.7%) and FIB-4 (55.8%) were the most frequently ordered biomarker tests for diagnosing MASH. Significant barriers to treatment reported were cost, paucity of FDA-approved treatments, and delayed diagnosis due to the asymptomatic nature of the disease. Only 30.2% and 53.9% of HCPs were "very" or "extremely familiar" with GCGR and GIPR, respectively, but most (76.8%) HCPs were "very" or "extremely familiar" with GLP-1R (Figure 1A). HCPs were also less familiar with the therapeutic effects associated with activation of GCGR and GIPR compared with GLP-1R. A total of 87.0%, 75.9% and 90.3% of respondents expected GCGR, GIPR, and GLP-1R agonists, respectively, to benefit people with MASH. Most HCPs expected dual GCGR/GLP-1R agonists to be better than GLP-1R mono-agonists for control of many cardiometabolic conditions including MASLD (88.3%), MASH (89.3%), obesity (90.1%), and type 2 diabetes (88.8%) (Figure 1B). **Conclusion:** HCPs report substantial barriers to treating people with MASH, including costs and lack of approved medications. HCPs were generally more familiar with GLP-1R, and the therapeutic effects of its activation, than with GCGR and GIPR. HCPs anticipate that dual GCGR/GLP-1R agonists will have meaningful clinical benefits for MASLD/MASH and many other cardiometabolic conditions.

Figure 1A: Familiarity with GCGR, GIPR, and GLP-1R among total respondents

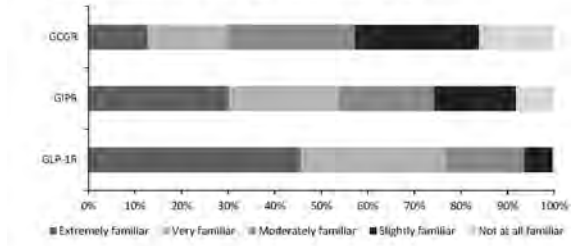

Figure 1B: Perceived benefits of GCGR agonists, GLP-1R agonists, and GCGR/GLP-1R dual agonists

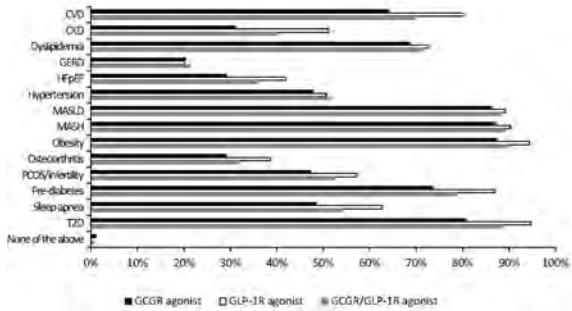

CKD, chronic kidney disease; CVD, cardiovascular disease; GCGR, glucagon receptor; GERD, gastroesophageal reflux disease; GIPR, glucose-dependent insulinotropic polypeptide receptor; GLP-1R, glucagon-like peptide-1 receptor; HFpEF, heart failure with preserved ejection fraction; MASH, metabolic dysfunction-associated steatohepatitis; MASLD, metabolic dysfunction-associated liver disease; PCOS, polycystic ovary syndrome; T2D, type 2 diabetes.

4088 | EFFECTS OF ORAL SEMAGLUTIDE ON FIB-4 SCORE IN ADULTS WITH TYPE 2 DIABETES IN REAL-WORLD CLINICAL PRACTICE: AN INDIAN OBSERVATION STUDY

Ramakrishnan Santosh[1], [1]Magna Centres for Obesity, Diabetes and Endocrinology

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an important common comorbidity in subjects with type 2 diabetes, and liver fibrosis is a factor directly related to its prognosis. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are useful treatment options for MASLD; however, the efficacy of oral semaglutide in treating liver steatosis/fibrosis has not been fully evaluated. **Methods:** This was a single-arm, multicentre, retrospective study of 6 months oral semaglutide treatment for T2DM in patients with MASLD. Among 309 consecutive patients with MASLD and T2DM who newly received oral semaglutide, 121 patients had data necessary for FIB-4 calculation at baseline and 6 months and were included in the analysis. Dose adjustments of oral semaglutide were determined by the treating endocrinologist while monitoring efficacy and adverse events. **Results:** The mean age of the participants was 44.04 ± 11.37 years. 72 (59.5%) were males. Significant improvements in fibrosis score, body weight, BMI, liver enzymes, creatinine, and glycaemic control (HbA1c) were found at 6 months compared with baseline values (Table 1). Changes in alanine aminotransferase ($r = 0.32$, $p < 0.01$), aspartate aminotransferase ($r = 0.36$, $p < 0.01$) and fibrosis score ($r = 0.43$, $p < 0.01$) were significantly correlated with changes in body weight. No serious adverse events were reported. **Conclusion:** Oral semaglutide might be a useful treatment option for adults with type 2 diabetes at high risk for liver fibrosis, even when switching from conventional medications for diabetes.

Table 1:

Parameter	Baseline	Follow-up	p-value
Fib-4 Score, Median (IQR)	1.81 (1.32-2.39)	1.16 (0.81-1.51)	<0.001
ALT (U/L), Mean ± SD	58.45 ± 25.33	47.02 ± 20.75	<0.001
AST (U/L), Mean ± SD	64.95 ± 30.87	46.41 ± 21.91	<0.001
HbA1c (%), Mean ± SD	7.73 ± 1.05	6.95 ± 0.63	<0.001
Systolic BP, Mean ± SD	126.7 ± 17.93	123.42 ± 18.17	0.181 (NS)
Diastolic BP, Mean ± SD	84.30 ± 11.31	83.73 ± 10.41	0.715 (NS)
Weight (kg), Mean ± SD	90.46 ± 12.03	87.39 ± 11.13	<0.001
BMI (kg/m²), Mean ± SD	32.25 ± 4.36	31.41 ± 4.19	0.001
Creatinine (mg/dL), Mean ± SD	0.79 ± 0.16	0.72 ± 0.16	0.019

p<0.05 considered as statistically significant

4089 | REAL-WORLD EXPERIENCE WITH RESMETIROM TO TREAT MASH IN A UNIVERSITY HOSPITAL SYSTEM

Arthi Thirumalai[1] Erin Cleveland[1] Meredith Pearson[1] Philip Vutien[1] Meagan Alvarado[1] Muyi Li[1] Lei Yu[1] Rotonya Carr[2] Paula Cox-North[2] John Scott[3] Nicole Kim[1], [1]University of Washington, [2]University of Washington Medical Center, [3]Harborview Medical Center

Background: Resmetirom, a THR-b agonist, is the first drug approved for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) with moderate to advanced liver fibrosis. We developed and implemented a protocol to standardize resmetirom use within our health system. **Methods:** Patients were prescribed resmetirom for suspected MASH with F2-F3 fibrosis based on liver biopsy, FibroScan (FS), MR-elastography, and/or Enhanced Liver Fibrosis score. We recommended use of a GLP-1 receptor agonist prior to resmetirom initiation in patients with diabetes. We monitored labs at baseline and at months 1, 3, 6, and 12. Wilcoxon signed rank test was used to assess for changes in median liver test values over time. **Results:** Since July 2024, 21 patients (median age 57 yrs [IQR 49-63], 52.4% male, 47.6% female, 52.4% White, 33.3% Asian/Pacific Islander, 14.3% Hispanic, 52.4% commercial insurance, 38.1% Medicaid, 19.1% Medicare) initiated resmetirom in our health system. Fibrosis stage was F2 in 33.3% and F3 in 66.7% of patients. Metabolic comorbidities were common (33.3% diabetes, 66.7% hypertension, 52.4% hyperlipidemia, 76.2% obesity, median BMI 35.3 kg/m^2) and 9.5% had thyroid disease. By May 2025, 20, 13, and 10 patients had completed 1, 3, and 6 months of therapy, respectively. Baseline tests included median (IQR): AST 40 (24-50), ALT 52 (32-93), bilirubin 0.7 (0.5-0.8), alkaline phosphatase (ALP) 79 (68-102), FIB-4 1.37 (1.08-1.60), SAFE 72 (46-158), LSM 10.9 kPa (10-12.8), and CAP score 314 dB/m (288-333). Median AST increased to 41 (IQR 27-87) then declined to 35.5 (25-53) and 25 (24-28) at months 1, 3, and 6 respectively ($p = 0.03$ month 3 vs. 6). Median ALT increased to 67 (31-140) then declined to 61 (31.5-88.5) and 38 (26-48) at months 1, 3, and 6 respectively ($p = 0.047$ month 1 vs. 6; $p = 0.02$ month 3 vs. 6). There were no significant changes in bilirubin or ALP levels over time. Common side effects included 33.3% elevated liver tests, 19.0% diarrhea, 14.2% upset stomach, 9.5% nausea, and 9.5% pruritus, with 1 patient discontinuing resmetirom due to diarrhea. **Conclusion:** In this real-world cohort of

patients with MASH and F2-F3 fibrosis treated with resmetirom, AST and ALT levels increased at month 1, then declined thereafter, suggestive of subsequent improvement in liver inflammation. The medication was well-tolerated by most patients. Long-term monitoring of liver tests and correlation with changes in fibrosis stage will be needed to assess treatment response.

4090 | NEW SUBMISSION

DEMOGRAPHIC VARIABLES AND CO-MORBID CONDITIONS PREDICT PRESCRIBING OF GLP-1 RECEPTOR AGONISTS FOR INDIVIDUALS WITH METABOLIC DYSFUNCTION

Emily Currier[1] Xinyuan Zhang[2] Michelle Lai[1]

[1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School

Background: While metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent liver disease nationwide, it remains notoriously underdiagnosed despite aDecting over 67% of people with Type II Diabetes (T2DM) or obesity. While GLP-1 receptor agonists (GLP-1RAs) are not FDA approved for treatment of MASLD, there is data showing that GLP1RAs resolve steatohepatitis and delay the progression of liver fibrosis. They are currently used oD-label in the treatment of MASH. Access to these medications is often limited by multiple social determinants of health. Little data exists on predictors of GLP-1RA access. The aim of this research is to evaluate if patient demographics aDect GLP-1 RA prescribing and access in those with diagnosed MASLD and those at high risk for underlying MASLD/MASH (T2DM or obesity or metabolic syndrome), while controlling for disease severity and comorbid conditions. **Methods:** An IRB approved retrospective chart review was conducted at a diverse, academic hospital system and medical records were screened to identify patients with T2DM, obesity, metabolic syndrome, or documented MASLD/MASH as defined by ICD-10 codes from January 2020 to December 2024. Over 16,000 subjects were included in the study. Variables collected included demographic data (age, sex, race, zip code, language spoken), history of HTN/HLD, BMI, A1c, LFTs, and history of GLP-1 prescriptions. FIB-4 scores were able to be calculated on 8,084 patients. Logistic regression was performed to assessforpredictorsof GLP-1RAuseanddi-DerencesinFIB-4datawasanalyzedusing multivariable adjusted linear regression. **Results:** Individuals of young age, female sex, history of hyperlipidemia, and elevated BMI were more likely to receive GLP-1 RAs (all $p < 0.001$). Factors associated with decreased rate of GLP-1 use included Black or Asian self-identified race, primary language as non- English, history of hypertension (all $p < 0.01$). Factors with no significant impact included A1c prior to GLP-1RA, prior documented liver disease, and patient income. Analysis of FIB- 4 data indicated that individuals of GLP-1 had significantly lower FIB-4 scores than those not (beta = -0.12, $p < 0.001$). 2,000 subjects in the study had ICD-10 corresponding to diagnosed MASLD/MASH. **Conclusion:** Patient demographic and co-morbid conditions are predictive of GLP-1RA prescribing in patients at risk of having underlying MASLD/MASH. Interestingly, patient typically at higher risk for MASLD based upon race, age, etc, are less likely to receive a GLP- 1, which is important given those on GLP-1 had lower fibrosis scores than their counterparts. Secondarily, this highlights ongoing underdiagnosis of MASLD given that only 2,000 of the patients included in the study have formal diagnosis of liver dysfunction in contrast to the approximately 10,000 individuals who likely have MASLD/MASH.

4091 | COMPARATIVE ANALYSIS OF RESMETIROM AND TIRZEPATIDE IN THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: INSIGHTS FROM A LARGE DATABASE

Liza Bagashvili Nino Gudushauri[1] Irakli Tskhakaia[1] Zurab Azmaiparashvili[2], [1]Jefferson Einstein Hospital Philadelphia, [2]Jefferson Einstein Philadelphia Hospital

Background: The emergence of glucagon-like peptide-1 (GLP-1) receptor agonists has significantly advanced the management of metabolic syndrome. Among the related conditions, metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) remain frequently underdiagnosed and undertreated. This analysis aimed to compare clinical outcomes associated with resmetirom and tirzepatide in the management of MASLD/MASH. **Methods:** A retrospective observational analysis was conducted using the TriNetX research network to evaluate treatment outcomes. The study population included 75,899 patients diagnosed with MASLD/MASH who received tirzepatide and 914 patients who received resmetirom. Following propensity score matching, 896 patients in each group were identified. Clinical and demographic variables were analyzed both before and after matching. The primary outcomes assessed were the incidence of cirrhosis and all-cause mortality. **Results:** Before propensity score matching, patients receiving tirzepatide exhibited an absolute risk reduction (ARR) of 7.86% in the development of cirrhosis compared to those receiving resmetirom ($p < 0.0001$). To control for potential confounding factors, patients were matched based on key clinical and demographic characteristics, including age, race, and body mass index (BMI), as well as laboratory parameters such as platelet count, aspartate aminotransferase (AST), and bilirubin levels. After matching, the lower risk of cirrhosis in the tirzepatide group persisted, with an ARR of 7.93% ($p < 0.0001$). However, data on all-cause mortality were insufficient for meaningful comparison at this time. **Conclusion:** Treatment with GLP-1 receptor agonists such as tirzepatide may be associated with a reduced risk of cirrhosis in patients with MASLD/MASH. Broader implementation of these therapies could potentially lower the incidence of cirrhosis linked to these conditions.

4092 | LONG-TERM REAL-LIFE EXPERIENCE OF SEMAGLUTIDE IN A MONOCENTRIC METABOLIC DYSFUCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) DIABETIC COHORT

Giovanni Petralli[1] Antonio Salvati[2] Simone Cappelli[1] Lidia Surace[2] Laura De Rosa[3] Maurizia Brunetto[4], [1]Università di Pisa, [2]Hepatology Unit, University Hospital Pisa, Italy, [3]Institute of Clinical Physiology, National Research Council, Pisa, Italy, [4]University of Pisa

Background: MASLD is the liver specific manifestation of a multifaceted affection with high global prevalence and a strong association with type 2 diabetes (T2D). Subcutaneous semaglutide, largely effective in T2D treatment, was recently shown to induce steatohepatitis resolution although at dosage of 2.4 mg weekly. **Methods:** We longitudinally evaluated 90 diabetic patients (pts.) [60.7 ± 9.9 yrs old, 38% female, 5 (1-8) yrs diabetes duration] after 1 mg weekly semaglutide introduction for diabetes management optimization to evaluate its long-term effect on liver disease activity and its correlation with metabolic variables improvement. Patients were non-invasively evaluated with anthropometry, biochemistry, and transient elastography by Fibroscanâ at t1 [6 (5-8) months, in all cohort] and t2 [24 (21-31) months, in a 67pts sub cohort]. ALT, controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) variations (D) were used as proxies of liver disease burden. PNPLA3 I148M polymorphism was determined too. **Results:** BMI (baseline 32.6 ± 5.7, D t1 -2.0, D t2 -2.2 kg/m^2, $p < 0.001$), glycated haemoglobin (HbA1c, baseline 53 ± 13 D t1 -10, D t2 -8 mmol/mol, $p < 0.001$), ALT [baseline 35 (22-54), D t1 -18, D t2 -20 U/L, $p < 0.001$], CAP [baseline 339 (288-372), D t1 -22, D t2 -31 dB/m, $p < 0.01$], and LSM [baseline 8.2 (5.5-11.0), Dt1 -1.6, Dt2 -1.7 kPa, $p < 0.001$] reductions were observed. At t1 60% and 22% of the cohort showed a BMI reduction of 5% and 10%, respectively, while a 30% reduction of CAP and LSM was observed in 14% and 39%, respectively; a -17 U/L reduction of ALT was shown in 36%. At t2 65% and 22% of cohort showed a BMI reduction of 5% and 10%; a 30% reduction of CAP and LSM was observed in 13% and 35%, respectively; a -17 U/L reduction of ALT was shown in 33%. ALT, CAP, and LSM variations were not influenced by PNPLA3 polymorphisms, nor with baseline BMI or HbA1c. ALT and CAP's reduction correlated with D BMI at t1 ($r = 0.351$ $p = 0.004$, $r = 0.441$ $p < 0.001$, respectively). Only D ALT was associated with D HbA1c both at t1 ($r = 0.296$, $p = 0.016$) and at t2 ($r = 0.397$, $p = 0.008$). **Conclusion:** Semaglutide is effective in reducing both steatotic and fibro-inflammatory liver involvement with persistency of the early response at 6 months. Whilst baseline anthropometry/glycemic compensation, as PNPLA3 polymorphism, do not influence semaglutide effect on liver disease, their variations in time are relevant for MASLD improvement.

4093 | ANALYSIS OF MAESTRO-NASH, RESMETIROM RELATIVE TO PLACEBO PATIENTS, ON PRIMARY AND SECONDARY LIVER BIOPSY ENDPOINTS BASED ON ALIGNED BIOPSY ENDPOINTS AND STATISTICAL METHODS: FROM MASH CLINICAL TRIALS

Rohit Loomba[1] Rebecca Taub[2] Dominic Labriola[2] Naim Alkhouri[3] Mazen Noureddin[4], [1]University of California, San Diego, [2]Madrigal Pharmaceuticals, [3]Summit Clinical Research, [4]Houston Methodist Hospital

Background: MAESTRO-NASH (MN) (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo (PBO)-controlled Phase 3 trial evaluating the efficacy of RES in patients with MASH. 917 patients with biopsy (bx)-confirmed F2F3 MASH were randomized 1:1:1 to RES 80mg, RES 100mg, or PBO once daily. Dual primary endpoints at Week 52 were achieved at both doses: NASH resolution (ballooning 0, inflammation 0,1) with no worsening of fibrosis (NR) with at least 2-point reduction in NAFLD Activity Score (NAS) or ≥1-stage improvement in fibrosis with no worsening of NAS (FI) (N Engl J Med 2024;390:497-509). Several NASH clinical trials utilized slightly different biopsy endpoints and PBO response imputation as the primary statistical methodology, including ESSENCE (ESS). Given the similarity in design and size to MN, ESS a Phase 3 trial evaluating SEMA (SEMA) (2.4 mg weekly) was used as the primary comparator (DOI: 10.1056/NEJMoa2413258). A comparison was made using aligned biopsy endpoints and statistical methods. **Methods:** Bx eligibility in MN and other NASH trials required F2/F3 stage fibrosis and NAS ≥4 with all 3 NAS components. Statistical analyses were conducted according to the statistical plan and subsequent analyses were conducted (MN) to use the assumption (PBO response multiple imputation for missing data in the PBO and RES groups) for the primary endpoints. NR without the requirement for a 2-pt reduction in NAS was analyzed. **Results:** Baseline characteristics of the F2/F3 populations were similar across MASH trials. Using a PBO-based imputation for missing data, RES 100 mg showed a ~2.4-fold odds ratio (OR) and 14.6% increment relative to PBO of FI comparable to a ~2-fold OR and a 14.4% FI with SEMA. Comparison of NR versus NR with ≥ 2 pt reduction in NAS showed that 83% of patients in MN had ≥ 2 pt improvement in NASH components to achieve NR, 17% had <2-pt reduction. In ESS 31% of the SEMA with NR and 45% of the PBO with NR had <2 pt reduction in MASH components, decreasing the rate of NR from 62.9% to 43.5% and 34.3% to 18.8% in the SEMA and PBO arms, respectively. Approximately equal numbers of drug treated and PBO patients in each study had ≥ 2-pt reduction in NAS. Ballooning reduction by RES was achieved in (66%) of RES treated patients with a difference from PBO (35%) compared with SEMA (61%, difference from PBO, 21%). **Conclusion:** Both RES and SEMA achieved both liver biopsy endpoints, improving NASH and liver fibrosis in the MN and ESS Phase 3 studies. Using an aligned statistical method, RES and SEMA showed 14-15% improvement of drug treatment relative to PBO in ≥1 stage fibrosis improvement at 1 and 1.5 years, respectively. RES and SEMA difference from PBO were 21% (3-fold relative to PBO) and 25% (2-fold relative to placebo), respectively, for NR requiring ≥2-pt NAS reduction. When evaluated for a 2-pt reduction in NAS, PBOs in MN and ESS had a similar response suggesting that PBOs responded comparably in the two studies.

4094 | IMPACT OF ENDOSCOPIC GASTRIC REMODELLING IN METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Yusuf Kagzi[1] Abuzar Asif[2] Srinivas Puli[2], [1]University of Illinois College of Medicine Peoria, [2]OSF St. Francis Medical Center

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD), a leading cause of chronic liver disease in the United States, is linked to obesity and insulin resistance. Endoscopic gastric remodelling (EGR) has proven to be safe, effective, and less invasive than bariatric surgery in the management of obesity. It includes two primary approaches, mainly endoscopic sleeve gastroplasty, endoscopic gastric plication, and primary obesity surgery endoluminal. Our meta-analysis aims to evaluate MAFLD and other metabolic parameters post-EGR. **Methods:** We performed a comprehensive, systematic search of multiple

electronic databases, including conference proceedings, from inception through November 2024 to identify studies that evaluated MAFLD and other metabolic parameters post EGR. Weighted mean differences and pooled proportions were calculated using both Mantel-Haenszel method (fixed effects model) and Der Simonian Laird method (random effects model). The heterogeneity among studies was tested using Cochran's Q test based upon inverse variance weights. The primary outcomes were improvement in non-alcoholic fatty liver disease (NAFLD) fibrosis score, hepatic steatosis index (HSI) score, and alanine aminotransferase (ALT). The secondary outcomes were improvement in fibrosis-4 score (FIB4), % excess weight loss (%EWL), % total weight loss (%TWL), body mass index (BMI), and glycated hemoglobin (HbA1c). **Results:** A total of 6 studies met our inclusion criteria and comprised 220 patients that underwent EGR. The pooled analysis showed a reduction of 0.65 in NAFLD fibrosis score (95% CI = -0.89 to -0.42), 0.07 in FIB4 score (95% CI = -0.22 to 0.07), 14.39 U/L in ALT (95% CI = -18.93 to -9.84), 6.30 kg/m2 in BMI (95% CI = -7.30 to -5.30), and 0.32% in HbA1c (95% CI = -0.43 to -0.21). The weighted mean HSI reduced from 50.36 +/- 3.00 to 42.66 +/- 2.38 post EGR. The pooled %EWL was 47.80% (95% CI = 41.03 to 54.57), and %TWL was 16.24% (95% CI = 14.98 to 17.50). The Begg-Mazumdar indicator gave Kendall's tau b value of -0.33 (p = 0.33), suggesting no publication bias. **Conclusion:** EGR provides weight loss and improvement in liver parameters. It is a safe and effective treatment strategy for MAFLD in obese patients.

4095 | EXERCISE PARTLY PROTECTS AGAINST SEMAGLUTIDE-INDUCED MUSCLE LOSS IN OBESE LDLR$^{-/-}$.LEIDEN MICE

Eveline Gart[1] Jose Inia[1] Jessica Snabel[1] Simone Droog[1] Anita van Nieuwkoop[1] Simon Folkertsma[1] Aswin Menke[1] J Wouter Jukema[2] Hans Princen[1] Anita van den Hoek[1], [1]TNO Metabolic Health Research, [2]LUMC

Background: Semaglutide, a glucagon-like peptide-1 receptor agonist, is an antidiabetic medication that has recently been approved for treatment of obesity as well. While the benefits of semaglutide for weight management are encouraging, concomitant muscle loss can be a potential drawback. Here, we evaluated the metabolic effects of semaglutide, exercise and the combination thereof in a translational model of obesity and associated complications. **Methods:** Ldlr$^{-/-}$.Leiden mice received a high fat diet (HFD) for 20 weeks to induce obesity, insulin resistance and hyperlipidemia. Mice were subsequently left untreated (control) or were treated for 14 weeks with semaglutide, exercise (running-wheel) or the combination thereof. Body weight, lean body mass (EchoMRI) and plasma parameters were evaluated during the study and liver, muscles, adipose tissue depots, hearts and brain were collected at end-point for histological analysis and future transcriptomics. **Results:** Already after 2 weeks of treatment, semaglutide either alone (-21%), or in combination with exercise (-23%) significantly decreased body weight, while exercise monotreatment tended to slightly reduce body weight (with -3%, p = 0.056). Semaglutide monotreatment significantly reduced both fat mass (-43%) and lean body mass (-11%), while in combination with exercise fat mass was significantly decreased (-50%), but loss of lean body mass could be prevented.

At the end of the study, lean body mass and muscle mass were decreased with semaglutide monotreatment but also when combined with exercise, although to a lesser extent. Absolute grip strength was significantly increased as compared to the HFD control group in combination treatment only. Semaglutide treatment either alone, or in combination with exercise significantly improved blood glucose, plasma insulin, cholesterol and triglyceride levels. Liver steatosis and inflammation in liver and adipose tissue improved with all interventions, while hepatic fibrosis was not significantly affected. Significant additional effects for the combined semaglutide/exercise intervention vs. semaglutide monotreatment were observed for plasma insulin, grip strength and macrovesicular steatosis.

Transcriptomics analyses are currently still ongoing and will be used to further evaluate the underlying pathways

and organ cross-talk. **Conclusion:** Using a translational model of obesity and the Metabolic Syndrome, we demonstrated that semaglutide has broad beneficial effects on plasma, adipose and liver parameters, but decreased lean body mass and muscle mass. Adding exercise to semaglutide intervention further improved plasma insulin, muscle strength and liver steatosis.

4096 | LEVERAGING GLUCAGON ACTIVITY TO TARGET HEPATIC STEATOSIS, FIBROSIS, AND INFLAMMATION

Sarah Anissa Hannou[1] David Bouslov[1] Sean Ferrano[1] Danielle Leander[1] Donald Wothe[1] Marshall Paisley[1] Alex Chen[1] David D'Alessio,[1] Phillip White[1] Jonathan Campbell[1], [1]Duke Molecular Physiology Institute, Duke University, Durham, North Carolina, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and steatohepatitis (MASH) have limited effective therapeutic treatments. Incretin-based therapies have revolutionized the treatment of diabetes and obesity, with emerging evidence supporting their use in liver disease. Semaglutide, a glucagon-like peptide-1 receptor (GLP-1R) agonist, reduces liver fat with limited improvements of fibrosis or inflammation. Moreover, the GLP-1R is not expressed in hepatocytes and it remains unclear whether the effects of semaglutide are independent of weight loss. The glucagon receptor (GCGR) is expressed in hepatocytes and agonism increases catabolic metabolism including lipid oxidation. GCGR:GLP-1R co-agonism is being pursued for the treatment of both obesity and MASH, however, there are gaps in our understanding of how GCGR agonism can impact features of MASH including fibrosis and inflammation. Moreover, patients with MASH may display hepatic GCGR resistance, which could limit the use of GCGR agonism. **Methods:** We hypothesized that chronic GCGR agonism would improve hepatic steatosis, fibrosis and inflammation in a mouse model of MASH. To test this, we fed mice housed at thermoneutrality a MASH inducing diet (GAN; Gubra-Amylin NASH) for 23 weeks to produce hepatic steatosis, inflammation, and fibrosis. **Results:** Hepatic GCGR signaling, assessed through the quantification of canonical signaling pathways following an acute bolus of a GCGR agonist (IUB288, 10 nmol/kg), was significantly reduced in mice fed a GAN diet compared to controls, indicating GCGR resistance. Next, we chronically treated groups of mice with PBS (control), semaglutide (3 nmol/kg), IUB288 (10 nmol/kg) or the combination of both daily for three weeks. Compared to control, all groups lost weight (semaglutide - 12%; IUB288 -18%, combination -21%). Histological and biochemical analysis of liver samples after three weeks showed reductions in steatosis and fibrosis in the IUB288 and combinations groups only. Interestingly, markers of immune cells (MAC-2) did not change in any of the treatment groups relative to control. **Conclusion:** Collectively, our data indicate that GCGR agonism can effectively reduce steatosis and fibrosis, despite the observed GCGR resistance. Moreover, semaglutide alone did not reduce either steatosis or fibrosis, however, did add to the effects of GCGR agonism. These findings provide support for GCGR agonism as a therapeutic means for improving features of MASH.

4097 | APPLYING CLINICAL TRIAL RESULTS: TO INDIVIDUAL PATIENT CARE: A GUIDE FOR CLINICIANS

Shobha Joshi[1] Jerry Gardner[2], [1]Ochsner Clinic Foundation, [2]Stanford; Science for Organizations, Inc

Background: Clinicians are often challenged in translating the results of clinical trials into treatment decisions for individual patients. We demonstrate how clinical trial information can be used to estimate an individual patient's likelihood of responding to treatment. **Methods:** Resmetirom, recently approved by the FDA for the treatment of metabolic dysfunction-associated steatohepatitis (MASH), was used as an example based on

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

data from a placebo-controlled clinical trial (N Engl J Med 2024;390:492–509). Two concepts were applied:
Prediction Interval estimates the range within which the response rate for an individual patient is likely to fall. It is derived by expanding the trial's confidence interval slightly to account for individual variability and uncertainty due to sample size.
Probability of Therapeutic Benefit estimates the likelihood that a positive treatment response in an individual is actually due to the treatment, rather than to chance or placebo effect. It is calculated by comparing the treatment and placebo response rates—specifically, by expressing the difference between them as a percentage of the total treatment response rate. **Results:** The figure accompanying this summary illustrates the calculated prediction intervals and probabilities of therapeutic benefit for subjects receiving 100 mg of Resmetirom: Prediction Interval indicates that an individual patient's likelihood of responding to Resmetirom is at least 62% for NASH resolution and 40% for improvement in fibrosis. Therapeutic Benefit Estimate indicates that among patients who respond to Resmetirom, the probability that their improvement is directly attributable to the drug—rather than to a placebo effect—is at least 20% for NASH resolution and 16% for fibrosis improvement.
Importantly, the prediction intervals are broader and higher than the therapeutic benefit estimates because they reflect the overall likelihood of a response, regardless of its cause, while the therapeutic benefit estimates isolate the effect of the treatment itself. **Conclusion:** Data from clinical trials can be used to personalize treatment decisions. The prediction interval provides an estimate of the chance that an individual will show a clinical response to therapy, while the probability of therapeutic benefit evaluates whether a positive outcome is likely due to the treatment. Both measures help clinicians make more informed decisions when applying group-level trial data to individual patients.

4098 | SAFETY AND EFFICACY OF DUAL INCRETIN RECEPTOR AGONISTS FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Najwaa Kirmani[1] Bezalel Hakkeem[2] Abdullah Alharran[3] Imran Reshi[4] Ali Artam Alajmi[5] Amal Alsubaiei[6] Dhruvi Joshi[7] Eliabe Abreu[8], [1]Dow Medical College, Karachi, Pakistan, [2]Jubilee Mission Medical College and Research Institute, Thrissur, India, [3]Arabian Gulf University, Manama, Kingdom of Bahrain., [4]Government Medical College, Srinagar, India, [5]Kuwait Institute for Medical Specializations, Al-Andalus, Kuwait., [6]Arabian Gulf University, Manama, Kingdom of Bahrain, [7]Narendra Modi Medical College, Ahmedabad, India., [8]Mayo Clinic Rochester

Background: The role of dual incretin receptor agonists in metabolic dysfunction-associated steatotic liver disease (MASLD) remains debated but may offer added benefits due to the liver's lack of GLP-1 receptor expression. Given the emerging interest in incretin co-agonists, we performed a meta-analysis to evaluate their efficacy and safety in MASLD. **Methods:** We systematically searched PubMed, Embase, and Cochrane for studies comparing incretin co-agonists to placebo in patients with MASLD, with or without fibrosis. Primary outcomes included the absolute reduction in hepatic fat fraction (HFF), resolution of metabolic dysfunction-associated steatohepatitis (MASH) without worsening of fibrosis, and regression of fibrosis without worsening of MASH. Secondary outcomes included liver transaminases, weight changes, and gastrointestinal (GI) side effects. Statistical analysis was performed using Review Manager 5.4, with doses stratified into three categories: low, medium, and high. **Results:** A total of 651 patients across four randomized controlled trials were included in the analysis. Incretin co-agonists were administered to 73.9% (n = 481) of participants: 34.9% (n = 168) received low-dose, 29.5% (n = 142) received medium-dose, and 35.6% (n = 171) received high-dose. Significant reductions in absolute HFF were observed at all dosage levels, with the most pronounced reduction seen at the medium dose: (Mean Difference [MD] –10.50%; 95% CI –15.78 to –5.21; $p < 0.0001$). Fibrosis regression without worsening of MASH was significantly better in the incretin co-agonists group at all doses, and, in patients with F2/F3 fibrosis, significant improvements in fibrosis by at least one stage were observed across all doses, with the highest significance at the high dose group (RR

1.80; 95% CI 1.22 to 2.66; p = 0.003). Reductions in ALT (MD -23.53 U/L; 95% CI -37.94 to -9.12; p = 0.001) and AST (MD -23.70 U/L; 95% CI -31.27 to -16.12; p < 0.00001) were greater at high doses. Additionally, weight loss was dose-dependent (MD -6.63%; 95% CI -12.44% to -0.82%; p = 0.03), as well as GI side effects. **Conclusion:** Incretin co-agonists were associated with improvements in liver fibrosis, fat content, and inflammation in patients with MASLD/MASH compared to placebo. Notably, their effect appears to be dose-dependent.

Table 1. Summary of Key Outcomes

Outcomes	Low Dose	Medium Dose	High Dose
Absolute Reduction in HFF (MD, %)	-6.43 (95% CI -10.17 to -2.69; p=0.0007)	-10.50 (95% CI -13.79 to -5.21; p<0.0001)	-8.51 (95% CI -11.26 to -5.76; p<0.00001)
MASH resolution without worsening of fibrosis (RR)	3.02 (95% CI 2.31 to 6.66; p<0.00001)	5.13 (95% CI 3.07 to 8.58; p<0.00001)	4.29 (95% CI 2.53 to 7.28; p<0.00001)
Fibrosis regression without worsening of MASH (RR)	1.72 (95% CI 1.18 to 2.51; p=0.005)	1.70 (95% CI 1.16 to 2.49; p=0.007)	1.69 (95% CI 1.15 to 2.47; p=0.007)
F2/F3 liver fibrosis improvement by ≥ 1 stage (RR)	1.71 (95% CI 1.15 to 2.53; p=0.008)	1.59 (95% CI 1.06 to 2.37; p=0.02)	1.69 (95% CI 1.22 to 2.66; p=0.003)
ALT Reduction (MD, U/L)	-21.29 (95% CI -36.13 to -6.44; p=0.005)	-23.53 (95% CI -40.69 to -6.37; p=0.007)	-23.53 (95% CI -37.94 to -9.12; p=0.001)
AST Reduction (MD, U/L)	-20.37 (95% CI -28.70 to -12.03; p<0.00001)	-23.21 (95% CI -29.24 to -17.18; p<0.00001)	-23.70 (95% CI -31.27 to -16.12; p<0.00001)
Weight Loss (MD, %)	-4.18 (95% CI -8.37 to 0.01; p=0.05)	-5.52 (95% CI -7.11 to -3.93; p<0.00001)	-6.63 (95% CI -12.44 to -0.82; p=0.03)
Diarrhea (RR)	1.57 (95% CI 1.08 to 2.29; p=0.02)	2.00 (95% CI 1.40 to 2.86; p=0.0002)	1.54 (95% CI 0.75 to 3.13; p=0.24)
Appetite suppression (RR)	3.07 (95% CI 1.50 to 6.28; p=0.002)	2.44 (95% CI 1.10 to 5.38; p=0.03)	3.80 (95% CI 1.12 to 10.35; p=0.03)
Vomiting (RR)	7.18 (95% CI 2.88 to 17.91; p<0.0001)	8.19 (95% CI 3.14 to 21.37; p<0.0001)	9.25 (95% CI 3.77 to 22.68; p<0.00001)

4099 | GSK4532990 PHARMACOKINETIC–PHARMACODYNAMIC (PK–PD) MODELING SUPPORTS QUARTERLY AND MONTHLY SIRNA DOSING FOR MASH IN THE HORIZON PHASE 2B STUDY

Itziar Irurzun-Arana[1] Hardik Chandasana[2] Nieves Lopez-Barrera[3] Nikhil Vergis[4] Diogo Ferrinho[2] Sumanta Mukherjee[2] Mindy Magee[2] Stuart Kendrick[5] Brandon Swift[6], [1]GSK, Madrid, Spain, [2]GSK, Collegeville, PA, USA, [3]GSK, San Francisco, CA, USA, [4]GSK, London, UK, [5]GSK, Stevenage, UK, [6]GSK, Durham, NC, USA

Background: Loss-of-function (LOF) mutations in the *hydroxysteroid 17-β-dehydrogenase-13 (HSD17B13)* gene are associated with a reduced risk of alcohol- and non-alcohol-related liver disease, including metabolic dysfunction-associated steatohepatitis (MASH). GSK4532990 is a GalNAc-siRNA-based therapeutic, that selectively targets *HSD17B13* in hepatocytes, and is being evaluated for the treatment of MASH in the Phase 2b HORIZON study (NCT05583344). Our objective was to select GSK4532990 doses with maximum reduction in hepatic HSD17B13 protein and a prolonged PD effect to allow for infrequent dosing (e.g. quarterly) to test the hypothesis that this will translate to a similar protective effect on the liver as *HSD17B13* LOF mutations. This analysis used PK–PD modeling to support Phase 2b dose selection. **Methods:** A population PK–PD model was built using GSK4532990 plasma concentrations and serum alanine aminotransferase (ALT) levels from the Phase 1/2a study in healthy volunteers (N = 16) and participants (N = 18) with clinically suspected MASH (NCT04202354). An additional PK–PD model of target engagement was developed using the hepatic HSD17B13 protein levels from the suspected MASH participants (N = 15). Standard evaluation techniques were used to assess model adequacy and robustness. **Results:** The PK–PD models accurately described the observed time course and magnitude of ALT reduction and HSD17B13 protein knockdown. The models were able to describe the interindividual variability on the PK and PD response across a wide range of doses. Consistent with other GalNAc-siRNAs, average plasma half-life of GSK4532990 was very short (8 hours or less) due to rapid hepatocyte uptake. However, the PD effect was predicted to be far longer and potentially maintained for up to 3 months, enabling infrequent dosing. Reductions in hepatic HSD17B13 protein were less variable with increasing doses and were high (> 80% on average) at 100 and 200mg, demonstrating a robust on-target pharmacologic response in the liver. **Conclusion:** PK–PD modeling of hepatic HSD17B13 protein and ALT predicted that doses of 100mg every 4 weeks and 200mg every 3 months have the potential to maintain robust HSD17B13 and ALT reduction over the respective dosing intervals despite the rapid elimination of GSK4532990 from the systemic circulation. These data support the once-quarterly or once-monthly dosing strategy in the ongoing HORIZON Phase 2b study.

4100 | TURNING THE TIDE ON FATTY LIVER: EFFICACY AND SAFETY OF GLP-1 RECEPTOR AGONISTS IN THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND STEATOHEPATITIS – A SYSTEMATIC REVIEW

Harika Dadigiri[1] Hriday Shah[1] Komal Arora[1] Pramil Cheriyath[1], [1]NYMC Saint Clare's and Saint Mary's General hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: MASH and MASLD are linked to obesity and metabolic syndrome, but there are currently no effective pharmacological treatments for these conditions. Targeting liver pathology and related metabolic risk factors has shown promise for GLP-1 RAs, which were initially created to treat type 2 diabetes and obesity. In patients with MASLD/MASH, this systematic review investigates the safety and effectiveness of GLP-1 RAs. **Methods:** A comprehensive literature search was conducted according to PRISMA guidelines across major databases from inception to January 2025. Randomized controlled trials and Observational studies investigating GLP-1 RA in adults with MASLD or MASH were included. The primary outcomes assessed were hepatic fat reduction, resolution of MASH, and improvement in fibrosis stage. Secondary outcomes included changes in body weight, glycemic control, liver enzymes, cardiovascular risk, and quality of life. Data extraction and quality assessment were independently performed by two reviewers. **Results:** Eight studies with MASLD/MASH patients and treatment durations ranging from 24 to 72 weeks were included. Semaglutide was primarily studied. Semaglutide 0.4 mg achieved MASH resolution in 59% of patients, compared to 17% with a placebo ($p < 0.001$) in patients with F1–F3 fibrosis. GLP-1 RAs consistently decreased the amount of fat in the liver. However, patients with compensated cirrhosis did not show a significant improvement in their fibrosis. Body weight, liver enzyme levels, and glycemic control (HbA1c reduction of 1.0–1.5%) were all significantly improved by all GLP-1 RAs. Additionally, semaglutide improved physical health and pain scores and significantly decreased cardiovascular events. Cotadutide produced greater weight loss than liraglutide. Although they were usually mild and temporary, gastrointestinal side effects (diarrhea, nausea) were the most frequent, occurring in 42–46% of patients. Discontinuation rates were low similar to those of a placebo. **Conclusion:** GLP-1 receptor agonists, particularly semaglutide, offer significant benefits in reducing hepatic fat, resolving MASH, and improving cardiometabolic parameters in MASLD/MASH patients, especially those with early-stage fibrosis. Their safety profile is favorable, with manageable gastrointestinal side effects. While benefits in advanced fibrosis are limited, GLP-1 RAs are poised to become a cornerstone in the management of MASLD/MASH, especially for patients with metabolic comorbidities. Further research is warranted to define their role in advanced liver disease and in combination regimens.

Table 1: Efficacy of GLP-1 receptor agonists in MASLD/MASH

Study (Year)	Intervention	Patient Population	Duration	Primary Outcome	Results
Armstrong et al. (2025)	Semaglutide	MASLD/MASH (with and without T2DM)	48-72 wks	Hepatic fat and weight loss	Significant hepatic fat and weight reduction
Liu et al. (2025)	Dulaglutide	T2DM, NAFLD	26 wks	Hepatic fat reduction	Significant hepatic fat reduction and glycemic control
Newsome et al. (2021)	Semaglutide 0.4 mg	NASH, F1–3 fibrosis	72 wks	NASH resolution, fibrosis	NASH resolution significant (59% vs. 17%), no fibrosis difference
Loomba et al. (2023)	Semaglutide 2.4 mg weekly	NASH, compensated cirrhosis	48 wks	Fibrosis, NASH resolution	No significant fibrosis or NASH resolution; improved liver enzymes, liver fat, cardiometabolic parameters
Romero-Gómez et al. (2023)	Semaglutide (various doses)	NASH, F1–3 fibrosis	72 wks	Health-related quality of life	Improved physical HRQoL; no mental HRQoL improvement
Harreiter et al. (2021)	Exenatide + Dapagliflozin vs. Placebo + Dapagliflozin	T2DM, MASLD	24 wks	Reduction of hepatocellular lipids (HCL)	Significant HCL reduction in both groups, no additional benefit from Exenatide
Zhang et al. (2020)	Liraglutide vs. Pioglitazone	T2DM, NAFLD	24 wks	Hepatic fat, fetuin-A	Liraglutide significantly restored hepatic fat, fetuin-A more than Pioglitazone
Nahra et al. (2021)	Cotadutide vs. Liraglutide	T2DM, overweight/obesity	54 wks	Metabolic, hepatic parameters	Cotadutide superior in metabolic parameters, liver biomarkers, and weight loss

★ 4101 | EFFECTIVENESS OF SEMAGLUTIDE IN NON-ALCOHOLIC STEATOHEPATITIS RESOLUTION A META-ANALYSIS AND SYSTEMATIC REVIEW

Claudine Feliciano[1], [1]Skyline Hospital and Medical Center, Philippines

Background: Non-alcohol related fatty liver disease (NAFLD) is characterized by steatosis resulting from factors unrelated to excessive alcohol consumption. It frequently coexists with other metabolic disorders such as high cholesterol, obesity, and diabetes. NAFLD can lead to complications such as fibrosis, cirrhosis, and an elevated risk of hepatocellular carcinoma, cardiovascular disease, chronic kidney disease, and mortality.
The use of glucagon-like peptide-1 (GLP-1) analogues is currently being studied as a possible treatment option in NAFLD. GLP-1 receptor agonists have pleiotropic effects on several aspects of metabolic syndrome relevant to treatment of NASH, including body weight, inflammation, and glucose and lipid metabolism. **Methods:** A comprehensive literature search showed 4 randomized controlled trials (N = 604) comparing Semaglutide (0.4mg/day or 2.4mg/week) with placebo. Two reviewers independently selected studies, assessed quality, and extracted and pooled outcomes

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

including liver histology, aspartate transaminase (AST), alanine transaminase (ALT), Triglyceride, Hba1c levels and body weight . All selected studies were found to be of low risk of bias based on Cochrane risk of bias assessment tool for randomized trials. **Results:** 4 RCTs (604 patients) were analyzed, improvement of NASH as compared to those receiving placebo was noted (WMD = 0.23 95%CI: 0.12; 0.46) with a p-value of 0.0001; I2 = 66%, fibrosis stage (WMD = 2.21 95%CI: 1.04; 4.52) with a p-value of 0.03; I2 = 0%, serum ALT activity (WMD = -0.19; 95% CI: -1.73; 1.34) with a p-value of 0.36 ; I2 = 0% (low heterogeneity) and AST activity (WMD = -0.23 95% CI: -1.90; 1.43) with a p-value of 0.33; I2 = 0%, body weight (WMD = -1.05 95%CI: -1.81; -0.29) with a p-value of 0.02; I2 = 83%, Hba1c (WMD = 0.39 95% CI: -0.84; 0.06) with a p-value of 0.07; I2 = 59%, Triglycerides (WMD = -0.28 95%CI: -0.17; 0.17) with a p-value of 0.12; I2 = 30%. **Conclusion:** Our meta-analysis of randomized controlled trials reveals that semaglutide did not significantly improve liver fibrosis, stiffness and steatosis but offers notable liver enzyme, and cardiometabolic benefits for patients with non-alcoholic fatty liver disease, while demonstrating a favorable safety profile. Currently, Semaglutide is available in the Philippines as a once-weekly subcutaneous injection, with price ranging from 7,000 to 8,000 pesos per pen which may be a deciding factor in patients considering this type of medication.

4102 | MITOCHONIC ACID-5, A NOVEL MITOCHONDRIAL CRISTAE-STABILIZING AGENT, RESTORES MITOCHONDRIAL FUNCTION AND AMELIORATES MASH PROGRESSION IN DIETARY MURINE MODELS

Masaaki Mino[1] Eiji Kakazu[1] Taiji Yamazoe[1] Michitaka Matsuda[1] Tatsuya Kanto[1], [1]Japan Institute for Health Security, National Institute of Global Health and Medicine

Background: Mitochondrial dysfunction drives hepatic lipotoxicity, oxidative stress and fibrosis in metabolic dysfunction–associated steatohepatitis (MASH), yet no approved agent directly targets these defects. Mitochonic Acid-5 (MA-5), an indole-derived compound, binds to the mitochondrial inner membrane protein mitofilin, stabilizes cristae and enhances ATP synthesis. A phase II trial in patients with primary mitochondrial disease is currently recruiting in Japan. We examined whether MA-5 can rescue hepatocyte mitochondrial dysfunction and attenuate MASH progression in diet-induced murine models. **Methods:** Fifty-week-old male C57BL/6 mice were fed for 25 weeks with a normal chow (NC), a high-fat, high-fructose, high-cholesterol diet (FFC), or an FFC + MA-5 (0.012 % w/w) (n = 7 per group). Serum biochemistry and body weight (BW) were assessed at 15 and 25 weeks. Steatohepatitis was graded by NAFLD Activity Score (NAS) and progression of fibrosis (Masson-Trichrome staining). Mitochondrial ultrastructure (TEM) and hepatic metabolomics (CE-TOFMS) were assessed at 25 weeks. External validation used a high-fat, methionine-restricted, and tyrosine-deficient diet (HF-MRTD) (Hepatology, 2021), treated with MA-5 for 22 weeks. In vitro, PXB® human hepatocytes were exposed to palmitic acid with or without MA-5. Mitochondrial morphology and reactive oxygen species (ROS) were evaluated by fluorescence imaging. Data are presented as mean ± SD. **Results:** The FFC-fed mice developed significant liver injury compared to the NC group by 15 weeks, which persisted at week 25 (ALT 455 ± 40 U/L). MA-5 treatment reduced ALT by 48% (ALT 218 ± 27 U/L, $p < 0.01$) and significantly improved NAS (5.8 ± 0.8 vs 3.2 ± 0.4, $p < 0.01$) and fibrosis scores (2.2 ± 0.4 vs 1.0 ± 0.0, $p < 0.01$). BW did not differ significantly between FFC and FFC + MA-5 (53.5 ± 7.6 vs 51.7 ± 5.2 g, $p = 0.68$), indicating that liver benefits were independent of weight loss. Electron microscopy revealed that the swollen, cristae-depleted mitochondria observed in the FFC group were restored to elongated mitochondria with dense cristae and a normalized endoplasmic reticulum in the MA-5 group. Metabolomic analysis revealed recovery of hepatic amino acids, including TCA-cycle substrates, and a 20% increase in hepatic ATP ($p < 0.01$). In the HF-MRTD mice, MA-5 similarly reduced ALT (227 ± 106 vs 94 ± 36, $p < 0.05$), NAS (4.6 ± 1.1 vs 2.0 ± 1.4, $p < 0.05$), and abolished fibrosis (1.6 ± 0.5 vs 0 ± 0, $p < 0.05$). In hepatocyte cultures, MA-5 ameliorated palmitic-acid–induced mitochondrial fragmentation and ROS generation. **Conclusion:** MA-5 rescues mitochondrial function in hepatocytes and mitigates biochemical, histologic, and metabolic progression of MASH in two independent murine models. These findings support the therapeutic potential of MA-5 as a mitochondria-targeted treatment for patients with MASH.

4103 | FAT, FIBROSIS, AND FIX: TRANSFORMING CIRRHOTIC OUTCOMES VIA MULTI-MODALITY WEIGHT LOSS APPROACHES

Yashowardhan Taparia[1] Gowri Priya Nair[1] Arathi Venu[1] Sudheer OV[1] Rajesh G[1] Arun Valsan[2], [1]Amrita Institute of Medical Sciences, [2]Amrita Institute of Medical Sciences, Kochi

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of end-stage liver disease and exhibits increased rates of both overall and specific mortality. Most often decompensated cirrhosis is considered irreversible without timely liver transplant. We highlight three cases of obese MASLD cirrhosis who have recompensated with multimodality management aimed at weight reduction. **Methods:** Case 1: 42M MASLD decompensated cirrhosis, BMI 41kg/m^2, on continuous BiPAP, presented with grade II ascites, moderate hepatic hydrothorax and hepatorenal syndrome, was listed for transplant. He was initially managed with initial optimization followed by oral semaglutide, followed by injectable tirzepatide (once commercially available in India), and has now resumed normal activities of daily living. He currently has been recompensated and has only mild lymphedema of right lower limb and is off BiPAP.

Case 2: 53M with MASLD decompensated cirrhosis (Child B9, MELD Na-18) and morbid obesity (BMI 48kg/m^2) with decompensations of encephalopathy and grade III ascites, was initially controlled on diuretics and salt restriction, followed by oral semaglutide for 3 months followed by Endoscopic (Spatz) balloon insertion, achieved around 94 kg weight loss over 1.5 years and has recompensated.

Case 3: 44M, MASLD compensated cirrhosis (CAP-341, LSM-18.1kpa), BMI 44kg/m^2, severe sleep apneoa on domiciliary nocturnal oxygen therapy. Following initial optimization, he was managed by elective laparoscopic sleeve gastrectomy, achieving weight loss of 31 kgs. He no longer requires oxygen, and has significantly reduced non-invasive fibrosis scores (4.6kpa). **Results:** All three patients are traditionally thought to be unfit for any significant clinical interventions other than LT. We demonstrate that with significant control of ascites and other decompensations, a wide array of therapeutic interventions are still possible that may help in downstaging or even recompensating, obviating the need for early LT. All cases have been on a median follow-up of one year and continue to remain recompensated, with adequate diabetic control, improvement in quality of life and improved physical performance. **Conclusion:** Targeted weight loss—pharmacologic, endoscopic or minimally invasive surgical—can reverse liver dysfunction and decompensation in carefully selected patients. These cases show the importance of integrating metabolic therapy into advanced liver care as an option that has to be continually evaluated and offered at specialized centres.

◆ 4104 | LIVER-TARGETED DELIVERY OF HUMAN PLATELET LYSATE-DERIVED HYDROGELS PROMOTE HEPATOCYTE PROLIFERATION, ANGIOGENESIS AND SURVIVAL IN POST-HEPATECTOMY LIVER FAILURE

Ashwini Vasudevan[1] DEEPIKA JAKHAR[1] Doyel Ghoshal[2] Anupama Parasar[1] Simran Sharma[1] Aarti Sharma[1] Dinesh Mani Tripathi[1] Shiv Kumar Sarin[1] Dr. Ashish Maheshwari[3] Sachin Kumar B[2] Savneet Kaur[1], [1]Department of Molecular and Cellular Medicine, Institute of Liver and Biliary Sciences, India, [2]Centre for Biomedical Engineering, Indian Institute of Technology, New Delhi, India, [3]Department of Transfusion Medicine, Institute of Liver and Biliary Sciences, India

Background: Post-hepatectomy liver failure (PHLF) and small for size syndrome (SFSS) are critical complications presenting after liver resection or transplantation. These complications arise due to significant hepatocyte loss and sinusoidal damage. Thus, therapies for PHLF need to address both these challenges simultaneously. Platelet Lysate (PL) has pro-regenerative and angiogenic properties, however its clinical utility

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

is limited due to rapid diffusion and poor retention. Here, we developed injectable human PL hydrogel (PLH) and studied its efficacy in rat models of PHLF. **Methods:** PL prepared from human platelet-rich plasma, was enzymatically cross-linked with thrombin and calcium to form PLH. Proteomics and biophysical properties of PLH were studied. In vitro, effect of PLH on primary hepatocytes (PH) and endothelial cells (EC) was assessed by flow cytometry and tube formation assay. PLH was injected in 80% extended hepatectomy (eHx) rats in liver sub-capsular region. eHX rats given hydrogel without PL served as vehicle (veh). FITC-PL and FITC-PLH were used in control rats for biodistribution studies by in vivo imaging. Thrombogenicity, survival, hepatic regeneration and angiogenesis were analysed at 72h post injection. **Results:** PLH showed gelation within 20 sec with shape retention properties. LC/MS analysis revealed 1809 and 1812 proteins in PL and PLH respectively with 99.6% common proteins. An abundant expression of albumin, PDGF, IGF-2, and stem cell/ hepatocyte nuclear growth factors was recorded in both PL and PLH. In vitro, compared to control, PLH enhanced proliferation of PH (Ki67+ cells: 12.5 vs 63.5%, $P < 0.05$) and tube length in EC culture ($P < 0.05$). In vivo, FITC-PLH but not FITC-PL was observed at 72h post-injection. No thrombosis was seen in PLH treated rats. Survival improved from 60 to 100% ($P < 0.005$ vs veh) and liver to body weight ratio increased by 60% ($P < 0.005$ vs veh) in PLH treated eHx rats. As compared to that seen in veh, PLH treated rats had increased PCNA+ mitotic hepatocytes (4-fold, $P < 0.001$) and CD31+ sinusoids (2-fold, $P < 0.05$) along with higher serum albumin levels (2-fold, $P < 0.05$). **Conclusion:** Following eHx, liver-targeted delivery of human PLH enables its site-specific retention. PLH enhances both vascular reconstitution and hepatocyte proliferation improving survival after major liver resection. Human PLH has potential as a therapeutic strategy for PHLF and SFSS.

◆ 4105 | EXPANDABLE, FUNCTIONAL HEPATOCYTES DERIVED FROM PRIMARY CELLS ENABLE LIVER THERAPEUTICS

Sophie Cazanave[1] Sunil Mallana[1] Soujanya Karanth[1] Joseph Marturano[1] Abhijith Kudva[1] Marcus Lehmann[1] Julie Morse[1] Morgan Jamiel[1] Timothy Norman[1] Christopher Wilson[1] Fabiola Munarin[1] David Broderick[1] Maxwell Van Buskirk[1] Esha Uddin[1] Michael Ret[1] Christopher Steele[1] Mehar Cheema[1] Justin Black[1] Eric Vanderploeg[1] Christopher Chen[2] Sangeeta Bhatia[3] Alireza Rezania[1] Thomas Lowery[1] Arnav Chhabra[1], [1]Satellite Bio, [2]Department of Biomedical Engineering, Boston University, Boston, MA 02215, USA, [3]David H. Koch Institute for Integrative Cancer Research, MIT, Cambridge, MA 02139, USA

Background: Cell therapy is a promising approach for end-stage liver disease, yet limited by the lack of a scalable source of functional hepatocytes and poor engraftment. To address these gaps, we hypothesized that combining expanded human hepatocytes (EHHs) with stromal support cells into 3D multicellular aggregates or "seeds," would enhance functional stability across metabolic and detoxification pathways, and improve engraftment at ectopic sites in rodents. **Methods:** EHHs were generated from multiple Primary Human Hepatocyte (PHH) donors using Satellite Bio's proprietary expansion process. To form seeds, EHHs were combined with stromal cells in suspension bioreactors. Seeds were cryopreserved, then evaluated post-thaw for viability, structural integrity, and function across protein synthesis, drug metabolism, and ammonia detoxification axes. Seeds were transplanted into NSG mice and assessed for engraftment via plasma biomarkers, immunohistochemistry of explanted tissue and Alu-based real-time PCR method. Variables such as stromal cell type, cell ratio, and immune modulation with dexamethasone (DEX) were tested across multiple extrahepatic sites (kidney capsule, spleen, fat pad) to optimize engraftment. **Results:** The expansion protocol enabled robust hepatocyte expansion across 13 donors, with 46% achieving >20-fold expansion at passage 0 and a mean fold expansion >4,000 by passage 1 for the three highest expanding donors. Aggregation of EHHs with normal human dermal fibroblasts (NHDFs) into seeds improved function, with *in vitro* albumin and A1AT secretion levels comparable to or exceeding those from PHH seeds. CYP3A4 activity in EHH seeds showed a 5.5-fold induction following rifampin treatment. Cryopreserved seeds demonstrated high stability, with 90% post-thaw recovery, preserved size distribution, and comparable viability (85.0% vs. 86.3% for PHH seeds, p

= 0.43). *In vivo*, NHDF-seeded constructs exhibited significantly higher engraftment than MSC-seeded or fibroblast-free counterparts (human albumin AUC: 258 μg·day/mL vs. 48 μg·day/mL for MSC, p < 1E-4). DEX treatment further enhanced engraftment in the spleen (AUC: 175 μg·day/mL vs. 132 μg·day/mL, p < 0.01). Stable engraftment across extrahepatic sites was confirmed by sustained human albumin levels and positive staining for OTC and CPS1. **Conclusion:** This work demonstrates that scalable expansion and stromal-supported aggregation can overcome key limitations of hepatocyte-based therapies, offering a clinically viable platform for advancing regenerative treatments in liver disease.

◆ 4106 | LIPOPOLYSACCHARIDE BINDING PROTEIN AS A POTENTIAL PREDICTIVE BIOMARKER FOR ACUTE KIDNEY INJURY ONSET IN CIRRHOSIS

Tadashi Namisaki[1] NORIHISA NISHIMURA[2] Shinya Sato[2] Kosuke Kaji[2] Hitoshi Yoshiji[1], [1]Nara Medical University, [2]奈良医大　消化器代謝・内科

Background: Hepato-renal syndrome (HRS) is a type of acute kidney injury (AKI) in patients with liver cirrhosis (LC). The International Club of Ascites (ICA-AKI) has proposed new diagnostic criteria based on changes in serum creatinine (sCr) levels, as even minor increases are associated with high short-term mortality. Most patients with AKI have no AKI-related clinical symptoms. Nonetheless, assessing renal function through sCr in cirrhotic patients is limited due to factors such as sarcopenia and gender-based differences in muscle mass. Endotoxin is a component of gram negative bacterial cell walls, and is a potent trigger of AKI in sepsis. Therefore, there is an urgent need for reliable biomarkers that can predict AKI onset and improve patient outcomes. We aimed to identify a potential biomarker for the outcomes of AKI in LC. **Methods:** This retrospective cross-sectional study included patients with LC who developed AKI (AKI group: n = 91) and patients with LC who did not develop AKI [non-AKI (NAKI) group, n = 91] as a control group. Plasma levels of lipopolysaccharide binding protein (LBP), soluble CD163 (sCD163) and soluble mannose receptor (sMR) were measured in patients with AKI or NAKI. Moreover, risk factors for onset of AKI, AKI-associated 90-day mortality, and poor AKI treatment response were investigated.All parameters were measured from 6 months to onset of AKI onset. **Results:** The AKI group had a significantly higher angiotensin 2, renin, LBP, sCD163, sMR than the NAKI group. In multivariate analysis, values of LBP ≥2550ng/ml were identified as a risk factor for AKI onset in patients with LC (odds ratio [OR], 4.3; 95% CI, 1.82–10.2; p < 0.001). Among patients with AKI, sMR was significantly higher in patients who died within 90days from AKI onset than those who survived over 90days from AKI onset. Values of sMR ≥ 1595 (ng/ml) were identified as risk factors for 90-day mortality (OR 5.98; 95% CI, 1.70– 21.1; p = 0.0054). Cumulative survival was significantly lower in those with high group (sMR ≥1595 ng/ml) than in those with low group (sMR < 1595 ng/ml). Furthermore, among patients with AKI, sMR was significantly higher in patients whose AKI improved than those whose AKI did not improve. Values of sMR ≥1460 (ng/ml) were identified as risk factor for poor treatment response (OR 3.52; 95% CI, 1.09–11.3; p = 0.035). The treatment response rates were significantly higher in those with low (sMR <1460 ng/ml) group than in those with high (sMR ≥1460 ng/ml) group. **Conclusion:** LBP potentially predicts the AKI onset, and sMR predicts survival, and treatment response of AKI in patients with LC.

◆ 4107 | TREM2 DEFICIENCY EXACERBATES ACUTE LIVER FAILURE BY IMPAIRING MACROPHAGE EFFEROCYTOSIS VIA DISRUPTION OF S100A4-MEDIATED GLYCOLYSIS

SIDUO XU[1] lingzhu zhao[1] SHOUHAN YAO[1] Jingkang Zhang[1] Guohua Lou[1] YANNING LIU[1] Min Zheng[1], [1]The first affiliated hospital of zhejiang university

Background: Acute liver failure (ALF) is a clinical syndrome characterized by rapid deterioration of liver function and high mortality. The clearance of dead cells

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by macrophages (Efferocytosis) is crucial for maintaining liver homeostasis, promoting liver injury repair, and improving the prognosis of ALF. Triggering receptor expressed on myeloid cells 2 (TREM2) is known to regulate macrophage efferocytosis, but its specific mechanism and potential role in ALF remain to be fully elucidated. **Methods:** To investigate the impact of TREM2 deficiency on ALF, wild-type and TREM2 knockout mice were treated with Lipopolysaccharide and D-galactosamine (LPS/D-GalN) to induced ALF model. Bone marrow-derived macrophages (BMDM) were isolated from both genotypes of mice for efferocytosis assay and transcriptome sequencing. Western blotting, real-time quantitative polymerase chain reaction, flow cytometry, and immunofluorescence assays were utilized to explore the potential molecular mechanisms by which TREM2 regulated macrophage efferocytosis. **Results:** TREM2 knockout exacerbated liver injury in mice with ALF and attenuated macrophage efferocytosis both in vivo and in vitro. Transcriptome sequencing and assays found that TREM2 knockout impaired macrophage efferocytosis by attenuating S100A4-mediated glycolysis. Mechanistically, TREM2 knockout inhibited the nuclear translocation of β-Catenin, thus reducing the expression of S100A4. The rescue assay showed that β-Catenin agonist could restore macrophage efferocytosis impaired by TREM2 deficiency and alleviated liver injury in TREM2 knockout mice with ALF. **Conclusion:** The TREM2-β-Catenin-S100A4 axis regulated macrophage efferocytosis, suggesting that TREM2 could be a potential therapeutic target for ALF.

4108 | CLINICAL PROFILE, PROGNOSTIC FACTORS AND OUTCOMES IN ACUTE LIVER INJURY DUE TO YELLOW PHOSPHORUS/ METAL PHOSPHIDE POISONING: A LARGE REAL-WORLD COHORT ANALYSIS

Arun Valsan[1] Zubair Mohamed[1] Arathi Venu[1] Nipun Verma[2] Sudhindran Surendran[1] Dinesh Balakrishnan[1] Nimitha Mohan[3] G Unnikrishnan[1] ST Binoj[1] Shwetha Mallick[1] Krishnanunni Nair[1] Gowri Priya Nair[1] Menon Ramachandran[1] Nair Priya[1] Kartha Anandajith[1] Raja Rajat[1] Christi Titus Varghese[1] Zachariah Paul Polachirakal[1] Anoop K Koshy[1] Dr George Eapen Puthusseril[1] Guhan Venkatakrishnan[1] Saraswathy Sivaprasadan[1] KN Anila[1] Haritha Rajakrishnan[1] Smitha Krishnamoorthy[1] Kumar Dhruv[1] Ajay Duseja[2] Rohit Loomba[4], [1]Amrita Institute of Medical Sciences, Kochi, [2]Postgraduate Institute of Medical Education and Research, Chandigarh, [3]Aster Medcity, [4]University of California, San Diego

Background: Yellow phosphorus/Metal phosphide (YPMP) poisoning is a leading cause of toxin-induced acute liver injury (ALI) and acute liver failure (ALF) in India and other developing nations. YPMP, commonly found in rodenticides, induces hepatocellular necrosis and has been responsible for a growing number of ALF cases in tertiary care centers across India. Despite its growing prevalence, the clinical trajectory and outcome predictors in YPMP-induced ALI/ALF are not fully understood. **Methods:** We conducted a retrospective cohort study at a tertiary liver care center between 2005 and 2023. ALF was defined based on the evidence of coagulopathy (INR $>$ 1.5), any degree of hepatic encephalopathy, and an illness of less than 26 weeks' duration. ALI defined as liver injury with INR $>$ 1.5 without encephalopathy. All adults $>$ 18 years with clinically and/ or toxicologically confirmed ALI/ALF were included. Patients were followed up for a minimum of 28 days or until death or liver transplantation (LT). Laboratory and clinical variables were compared across outcome groups and prognostic models evaluated using AUROC analysis to identify predictors of transplant-free survival. **Results:** The median age of the cohort was 24years(IQR:19–30), with M~F. At baseline, 46% had ALF, which was significantly higher among non-survivors (59.5% vs 32.4%, $p = 0.002$). Overall LT-free survival at 90 days was 37.2%, with 51% experiencing death and 16.6% undergoing LT. Cumulative survival was further low in those who had ALF or progressed to ALF on follow up vs those that did not (29.8% vs. 51%, $p = 0.019$). On multivariate analysis, ALF and vasopressor use ($p < 0.05$, M1), HE-grade-III/IV and INR ($p < 0.05$, M2), HE-any grade, INR $>$ 6.0 ($p < 0.039$ and 0.150, M3) were significantly associated with mortality and need for LT. ALFED and MELD models had good prognostic discrimination (AUROC for ALFED = 0.819; MELD = 0.689) for predicting 90-day LT-free survival. Use of mechanical ventilation, vasopressors, RRT, combined CRRT and PLEX was significantly associated with poor prognosis ($p <$ 0.001). 30 did not undergo LT due to financial constraints and 4 due to acuity of organ. **Conclusion:** In this largest real-world cohort of YPMP-induced liver injury, ALF was present in half, and was strongly associated with poor transplant-free survival. These findings underscore the need for early identification of high-risk patients and timely referral for liver transplant evaluation, especially in resource-limited settings. Significant proportion of patients who met LT criteria but could be transplanted due to lack of insurance coverage/ financial constraints. Public health strategies focusing on poison control and improved access to specialized care are warranted.

4109 | NOVEL PREDICTORS OF 30-DAY MORTALITY IN ACUTE LIVER FAILURE: A MULTI-CENTER ACUTE LIVER FAILURE STUDY GROUP (ALFSG) COHORT ANALYSIS

Taranika Sarkar Das[1] Kimberly Ho[2] Xucong Meng[1] Madhavi Reddy[3] Nikki Duong[4], [1]NYU Langone Health, [2]Brown University, [3]The Brooklyn Hospital Center, [4]Stanford Health Care

Background: Traditional prognostic models for acute liver failure (ALF), such as MELD and King's College Criteria, often fall short in accurately capturing the dynamic physiologic decline in these patients who have high short-term mortality. Using the Acute Liver Failure Study Group (ALFSG) registry, this study evaluates novel predictors of 30-day mortality using both established and emerging physiologic markers to enhance risk stratification. **Methods:** We retrospectively analyzed 1,601 adult patients with ALF enrolled in the ALFSG database. Predictor variables included demographics (age, sex), laboratory data (WBC count, bilirubin, creatinine), SOFA sub-scores (renal, hepatic, coagulation, neurologic, respiratory using PaO_2/FiO_2), CLIF-C organ failure (OF) score, liver transplant status, and ALF etiology. Logistic regression models were used to identify predictors of 30-day mortality. **Results:** In univariate analysis, factors associated with increased 30-day mortality included older age (OR 1.02 per year, $p < 0.001$), elevated white blood cell count (OR 1.04 per 1,000/mm³, $p = 0.002$), higher renal SOFA score (OR 1.42, $p < 0.001$), hepatic SOFA score (OR 1.34, $p = 0.001$), and neurologic SOFA (Glasgow Coma Scale) score (OR 1.34, $p < 0.001$). A higher CLIF-C OF score was also associated with increased mortality (OR 1.06 per point, $p < 0.001$), as were "other" etiologies of acute liver failure (ALF) (OR 4.02, $p < 0.001$). Liver transplantation was strongly protective (OR 0.13, $p < 0.001$). On multivariate analysis, etiologies associated with significantly higher 30-day mortality compared to acetaminophen-induced ALF included autoimmune hepatitis, Budd-Chiari syndrome, drug-induced liver injury (DILI), viral hepatitis, idiopathic ALF, mushroom poisoning, and other causes (OR 3.25, $p < 0.001$). A higher CLIF-C OF score remained an independent predictor of 30-day mortality (OR 1.15 per point, $p < 0.001$). **Conclusion:** To our knowledge, this is the first multi-center cohort analysis identifying several novel predictors of short-term mortality in ALF. This underscores the prognostic importance of CLIF-C OF scores,

disaggregated SOFA subcomponents, WBC count, and detailed subtypes of ALF. These findings highlight the limitations of traditional scoring systems and support the need for refined prognostic models that integrate systemic inflammation and organ failure metrics to guide timely therapeutic interventions.

4110 | TREATMENT OF ALCOHOLIC LIVER DISEASE AND LIVER FAILURE USING A NOVEL 3D-PRINTED PLG-BASED IMPLANTABLE THERAPY

Regeant Panday[1] Caitie Chismarich[1] Andrew Golin[1] Xin Li[1] Kirstin Kebo[1] Matthew Remy[1] Jon Burke[1] Ramille Shah[1] Rafal Witek[1], [1]Dimension Bio

Background: Alcoholic liver disease (ALD) is a leading cause of liver failure-related mortality worldwide. Severe forms, such as alcohol-associated hepatitis (AH) and severe alcohol-associated hepatitis (SAH), carry a high mortality rate of up to 50% at 28 days for AH and up to 70% at six months for SAH. Current treatments offer limited benefit, with liver transplantation remaining the only curative option. Alternatively, ectopic implants delivering functional hepatocytes could provide immediate and sustained liver support, serving as a bridge to transplantation or recovery. In this study, we investigated the use of 3D-printed, poly(lactide-co-glycolide) (PLG) scaffolds for subcutaneous delivery of high-density, functional hepatocytes as a novel, minimally invasive treatment for liver failure. **Methods:** 3D-printed PLG scaffolds were seeded with primary hepatocytes. In vitro, cell-loaded scaffolds were cultured for 2+ weeks and evaluated for cell viability, albumin and urea synthesis, and CYP3A4 activity. In vivo, scaffolds were implanted subcutaneously in healthy NOD SCID mice and C57BL/6 mice with CCl_4-induced liver failure. Circulating human albumin (hALB) levels and survival rates were monitored. Explanted scaffolds were analyzed histologically and immunohistochemically for tissue integration and vascularization. **Results:** In vitro, hepatocyte-laden scaffolds maintained stable albumin and urea production with preserved metabolic activity for 2+ weeks. In vivo, sustained hALB levels were detected up to 8 weeks post-implantation. Histological analysis revealed dense vascular networks and healthy connective tissue formation within the explanted scaffolds. In contrast, hepatocyte-loaded hydrogel controls exhibited minimal tissue integration and vascularization in the same period. Kaplan–Meier analysis in liver failure rescue models implanted with syngeneic mouse hepatocytes and xenogeneic human hepatocytes under immunosuppression, exhibited survival improvements of $>70\%$ (Fig. 1) and $>50\%$, respectively, relative to the controls. **Conclusion:** Dimension Bio's 3D-printed scaffolds represent a promising platform for ectopic liver implantation as demonstrated by efficient hepatocyte delivery and sustained functional phenotype (synthetic and metabolic), supported by robust vascularization and integration. Future studies will evaluate the efficacy of using PLG scaffolds to deliver hepatocytes to treat rapid loss of hepatic function, such as in liver failure.

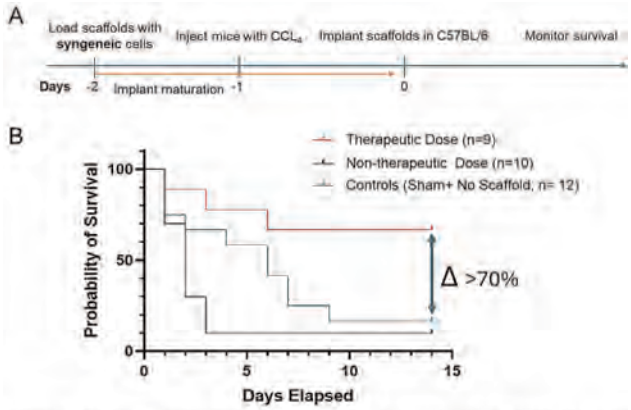

Figure 1. Syngeneic transplantation of primary mouse hepatocytes in Dimension Bio's 3D-printed scaffolds allows for significant rescue of liver failure in CCl_4-treated C57BL/6 mice. (**A**) Study timeline (**B**) CCl_4-treated mice implanted with a therapeutic dose of syngeneic hepatocytes in the scaffolds exhibited >70% improvement in survival compared to the controls.

4111 | ENHANCEMENT OF LIVER REGENERATION IN MICE THROUGH DDX3X-CD36 PATHWAY-MEDIATED PROMOTION OF HEPATIC LIPID ACCUMULATION

Ling Xu[1] Zhenzhen Pan[1] Zihao Fan[1] Feng Ren[1], [1]Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University, China

Background: The liver possesses a unique regenerative capacity, which is indispensable for the recovery process following liver resection and the management of various liver diseases. Accumulation of lipids in hepatocytes has been recognized as a pivotal factor during liver regeneration, yet the intricate mechanisms underlying this process remain elusive. This study endeavors to elucidate the mechanism through which DDX3X mediates lipid accumulation during liver regeneration. **Methods:** We collected serum samples from patients at various time points post-hepatectomy. A liver regeneration model in C57BL/6 mice was established by performing a two-thirds partial hepatectomy (PH). Hepatocyte-specific DDX3X knockout (DDX3XΔhep) mice were generated using CRISPR/Cas9/Cre-LoxP technology to investigate the pivotal role of DDX3X in liver regeneration. High-throughput RNA sequencing was conducted to dissect the downstream signaling pathways in DDX3XΔhep mice during liver regeneration. Oil Red O staining was utilized to visualize liver lipid accumulation. qPCR and Western blotting were employed to assess the expression levels of target genes and proteins, respectively. **Results:** Patients undergoing PH exhibited a progressive decrease in serum DDX3X levels. In the mouse liver regeneration model, hepatic DDX3X expression initially surged (0-12 hours) and subsequently declined (24-96 hours). Following two-thirds PH, DDX3XΔhep mice demonstrated a significantly augmented regenerative capacity compared to controls, accompanied by a marked increase in liver lipid levels. RNA sequencing revealed enhanced fatty acid uptake in DDX3XΔhep mice during liver regeneration. Notably, knockdown of the key fatty acid receptor CD36 significantly reduced hepatocyte lipid accumulation and impeded liver regeneration in DDX3XΔhep mice. **Conclusion:** During liver regeneration, hepatocyte DDX3X deficiency promotes hepatocyte proliferation by augmenting liver lipid accumulation through CD36 regulation. Our findings offer novel insights into the mechanisms underlying liver regeneration and identify potential targets for accelerating post-surgical recovery in patients.

4112 | TARGETING RAC1 AS A NOVEL STRATEGY TO REDUCE INFLAMMATION AND LIVER DAMAGE IN ACUTE LIVER FAILURE

Barbara Bueloni[1] Esteban Fiore[2] María Jose Cantero[2] Lucia Lameroli Mauriz[2] Catalina Atorrasagasti[2] Matias Ciarlantini[3] Andrea Barquero[4] Lucia Gandolfi Donadio[3] Francisco Orozco[5] Martin Fauda[6] MARIA JULIETA Comin[3] Ali Canbay[7] Juan Bayo[2] Guillermo Mazzolini[2], [1]IIMT-Universidad Austral, CONICET, [2]IIMT-Universidad Austral, CONICET, [3]Departamento de Ingredientes Activos y Biorrefinerías, Instituto Nacional de Tecnología Industrial, [4]IQUIBICEN- Universidad de Buenos Aires, CONICET, [5]Hepatobiliary Surgery and Liver Transplant Unit, Hospital Universitario Austral, [6]Hepatobiliary Surgery and Liver Transplant Unit, Hospital Universitario Austral., [7]Universitätsklinikum Knappschaftskrankenhaus Bochum

Background: Acute liver failure (ALF) is a life-threatening condition with high mortality and limited therapeutic options. There is a critical need to identify novel molecular targets to improve clinical outcomes. RAC1, a Rho GTPase, regulates inflammation and oxidative stress, two critical drivers of ALF pathogenesis. Our goal was to explore the therapeutic potential of RAC1 inhibition as a strategy to mitigate ALF progression. **Methods:** RAC1 activation in human ALF (HBV- and APAP-related) was assessed through Ingenuity Pathway Analysis and immune cell deconvolution. Three murine ALF models (ConA, APAP, D-Gal/LPS) were used to evaluate the therapeutic potential of the RAC1 inhibitor 1D-142. RNA-seq of murine livers was integrated with human datasets to identify RAC1-modulated transcriptional programs. Immune cell infiltration and reactive oxygen species were measured by flow cytometry. Cytokine profiling, NF-κB activation and apoptosis were assessed by qPCR, immunofluorescence and caspase activity assay. Liver explants from patients with liver injury were treated ex vivo with 1D-142 to assess transaminase release and cytokine expression. **Results:** Bioinformatic analyses identified RAC1 as a pivotal upstream regulator in human ALF, associated with genes involved in inflammation, oxidative stress, and cell death. In murine models, 1D-142 treatment reduced liver damage (ALT and AST), even when administered in advanced ALF. Mechanistically, 1D-142 reduced ROS production in hepatocytes, decreased cytokine release, and limited immune cell infiltration into the liver. It also reprogrammed macrophages to an anti-inflammatory phenotype and limited their migration and viability, while directly protecting hepatocytes from apoptosis. RNA-seq confirmed that 1D-142 modulates RAC1-driven transcriptional programs dysregulated in human ALF, while restoring hepatocyte metabolic pathways. In human explants,

1D-142 reduced transaminase release and modulated cytokine expression, underscoring its translational potential. **Conclusion:** This study identifies RAC1 as a central regulator of sterile inflammation and oxidative stress in ALF. Pharmacological inhibition of RAC1 with 1D-142 confers robust hepatoprotection across multiple preclinical models and in human liver explants, highlighting RAC1 as a promising and translationally relevant therapeutic target for ALF treatment.

4113 | INDICATIONS AND OUTCOMES FOR PATIENTS DELISTED FOR EMERGENCY LIVER TRANSPLANT IN ACUTE LIVER FAILURE – A SINGLE CENTRE REVIEW OVER 30 YEARS

Lily Scourfield[1] Tasneem Pirani[2] Robert Loveridge[2] Marc Zentar[2] Julia Wendon[3] William Bernal[4] Sameer Patel[2], [1]King's College Hospital, [2]Liver Intensive Care Unit, Institute of Liver Studies, King's College Hospital NHS Foundation Trust, [3]King's College London, [4]Liver Intensive Care Unit, Institute of Liver Studies, King's College Hospital NHS Foundation Trust,

Background: Acute Liver Failure (ALF) is a rare but severe condition which can rapidly progress to multi-organ failure, with high mortality without emergency liver transplantation (ELT). Tools such as the King's College Criteria are widely used to identify patients who are unlikely to survive without ELT. However, there is a lack of evidence to support the clinical decision to remove a patient from the emergency waiting list (WL) due to either clinical deterioration, as ELT will not result in patient survival, or more rarely, improvement on the WL such that ELT is not thought to improve patients outcome. We sought to address this evidence gap. **Methods:** Retrospective, single centre cohort study of 205 ALF patients listed for ELT from January 1990-December 2019. Patients were excluded if they were not transplanted from ICU, received extracorporeal membrane oxygenation (ECMO) peri-ELT, or whose notes had been destroyed. Demographics, admission characteristics, and delta organ failure scores reflecting change in physiology from listing to delisting or listing to transplant were captured. Subgroup univariate logistical regression analysis of those delisted for improvement vs deterioration compared to a transplanted ALF cohort was performed. **Results:** Fifty three patients were included: 28 were delisted for being 'too sick' (deterioration), 23 for improvement, and 2 for psychosocial reasons. Median age was 37 years, 67% female, paracetamol overdose the most common cause of ALF (44%) and time from listing to delisting 3 days. Fewer complications (refractory raised ICP, vasoplegic shock) and increasing ICU survival (18% in 1990s vs 74% in 2010s, $p < 0.01$) were observed over time. Compared to those proceeding to ELT, the delisted 'too sick' group had a deterioration in median cardiovascular (delta VIS 50, $p < 0.01$), respiratory (delta Murray 1 $p < 0.01$, delta P/F -87 mmHg $p < 0.01$), neurological (refractory raised ICP in 10 vs 6, $p < 0.01$) and ICU organ failure scores (delta SOFA 4, $p < 0.01$) on the WL. Those delisted for improvement experienced improvement in liver (delta MELD -Na -2, IQR -6-0, $p < 0.01$), and cardiovascular (delta VIS -19 IQR -41-0, $p < 0.01$) scores compared to transplanted patients, but did not show a difference in change in SOFA scores (delta SOFA 0 IQR -2-2 $p = 0.09$). ICU mortality was 96% ($n = 27$) in the delisted 'too sick' group vs 4% in transplanted ($n = 3$) and 4% ($n = 1$) delisted for improvement groups. **Conclusion:** Changes in physiological scores of organ dysfunction from listing to delisting for ELT mirror the reasons for delisting, are closely related to transplant-free survival (TFS) and may support clinical decision making.

4114 | TARGETING ALBUMIN BINDING FUNCTION TO DESCRIBE REMOVAL OF PROTEIN-BOUND TOXINS IN PERSONALIZED EXTRACORPOREAL THERAPIES

Stine Koball[1] Adrian Dominik[2] Sebastian Koball[2] Jan Stange[3], [1]ProMedTec Germany GmbH, [2]Universität Rostock, [3]University of Rostock

Background: Liver failure is a critical clinical condition marked by impaired liver function and accumulation of metabolic byproducts, often transported by albumin. Extracorporeal therapies aiming at detoxifying patient's toxin-overloaded albumin are available, but demand improved diagnostic tools. This work introduces a novel dansylsarcosine-based kinetic modeling method for serum albumin binding to enhance therapeutic decision-making in hepatic failure, aiming to provide insights into albumin's dynamic interactions and offering a more comprehensive assessment of albumin overload or damages that both affect binding function. **Methods:** We employed a titration approach to measure albumin binding function under varying concentrations of dansylsarcosine, thereby analyzing the binding kinetics of albumin's Sudlow II binding site.

The data is analyzed using a modified Michaelis-Menten model, which accounts for quenching, and intrinsic absorbance and allows to calculate Bmax (maximum number of binding sites) and Kd (ligand concentration at half-saturation). This new indicator was evaluated in a database of patients treated with OPAL or MARS extracorporeal liver support systems to test for correlations with clinical scores and evaluate therapeutic effects between startpoints (S) and endpoints (E) of treatments. **Results:** The method demonstrated significant correlations with established biomarkers, clinical scores, and therapeutic effects. Analysis of patient samples from the database revealed that Bmax and Kd were strongly associated with existing albumin biomarkers. Further subgroup analysis indicated that these kinetic parameters had meaningful correlations with clinical scores such as GCS, SOFA, MELD, ACLF, CLIF-OF, and ABiC, underscoring their clinical significance. Evaluation of therapeutic effects using the OPALESCE database showed that Bmax and Kd were effective in describing therapy outcomes. Notable differences in Bmax and Kd were observed between the beginning and end of the first treatment session for MARS and OPAL respectively. These values aligned with established parameters like ABiC and the CLIF-OF Score, highlighting their potential as reliable markers for assessing the impact of liver support interventions. **Conclusion:** This study enhances understanding of albumin binding dynamics in hepatic failure, offering a valuable tool for guiding treatment decisions. The parameters Bmax and Kd reflect treatment impact and correlate with established clinical scores, adding to a more accurate assessment of patient condition. Importantly, Bmax can detect irreversible albumin damage, helping to identify cases where alternative therapies, like plasma exchange, may be more effective if standard extracorporeal methods fall short. This biomarker thus supports a more personalized approach to managing hepatic failure, with the goal of achieving better patient outcomes.

4115 | DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF PEDIATRIC DRUG-INDUCED ACUTE LIVER FAILURE: A NATIONAL INPATIENT ANALYSIS

Janvi Bhavsar[1] Vivian Tang[2] Raj Shah[3], [1]Maimonides Medical Center, [2]The Children's Hospital of Philadelphia, [3]KU School of Medicine-Wichita

Background: Acute liver failure in pediatric populations is a rare but life-threatening condition with diverse etiologies, ranging from infectious and metabolic disorders to drug-induced injury. Among the pharmacological causes, acetaminophen and non-steroidal anti-inflammatory drugs (NSAIDs), including salicylates and aspirin, are recognized as significant contributors to acute hepatic dysfunction in children and adolescents. Understanding the demographic and clinical characteristics associated with drug-induced liver failure is essential for improving early recognition, intervention, and outcomes in affected patients. **Methods:** We conducted a retrospective analysis using the 2022 National Inpatient Sample (NIS) database, identifying pediatric patients (ages 1–18) with acute liver failure via ICD-10 codes. Two primary cohorts were established: one comprising cases of acetaminophen-induced liver failure, and another including cases attributed to salicylates, aspirin, and other non-steroidal anti-inflammatory drugs (NSAIDs). Demographic and clinical variables—including race, gender, age, median household income, mean length of hospitalization, cost of hospitalization, and mortality rate—were extracted and analyzed using logistic regression with STATA BE 18.0. These drug-induced liver failure cohorts were then compared to a cohort representing all other causes of pediatric acute liver failure. **Results:** Among 4,470 pediatric patients with acute liver failure, 505 cases

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were attributed to acetaminophen and 45 to salicylates/NSAIDs/aspirin. Notably, 77% of acetaminophen-induced and 100% of salicylate/NSAID/aspirin-induced cases occurred in females, compared to 46% in the non-drug-induced cohort. The mean age for the drug-induced cohort was 14 years, significantly higher than the mean age of 5 years in the other causes cohort. Mortality was substantially lower in the drug-induced group (3%) compared to the non-drug-induced group (26%). More details in the tables attached. **Conclusion:** Common drug-induced liver failure in pediatric patients disproportionately affects females, particularly adolescent girls (mean age 14). These findings highlight the need for targeted interventions and heightened clinical vigilance in this demographic to facilitate early diagnosis and treatment.

Variables	Acetaminophen toxicity causing liver failure	Salicylates+NSAID's+aspirin causing liver failure
Age	14.13 (sd+/- 0.31)	14.3 (sd+/- 0.34)
Race- White	55%	62%
Hispanic	18%	25%
Black	13%	0%
Other	14%	13%
Gender-male	27%	0%
Female	77%	100%
Zip quartile of median household income	Lowest-28th percentile, highest -21st percentile	Lowest 33rd percentile, highest -11th percentile
mortality	15 patients	0 patients
Mean length of stay	7 days	4.5 days
Total hospitalization charge	$110383	$37000
Variables	Drugs (acetaminophen and NSAIDs/Salicylates/Aspirin) causing liver failure	All other causes of liver failure
Age	14 years	5.8 years
Gender: Female	77%	46%
Male	27%	54%

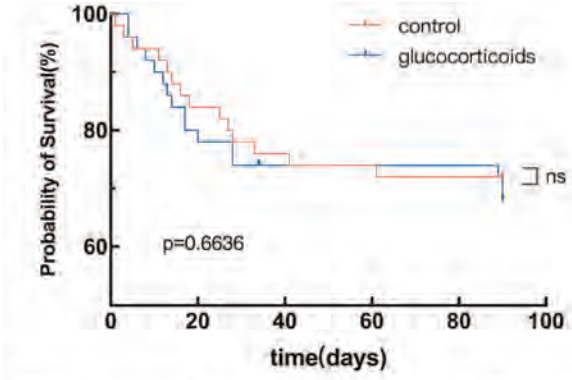
4116 | COMBINATION WITH GLUCOCORTICOIDS DURING ARTIFICIAL LIVER SUPPORT SYSTEM TREATMENT DOES NOT IMPROVE THE SURVIVAL RATE OF ACUTE-ON-CHRONIC LIVER FAILURE PATIENTS: A RETROSPECTIVE COHORT STUDY

Fu-Xia Ta[1], [1]HuaShan Hospital, FUDAN University

Background: To investigate retrospectively the efficacy of glucocorticoids in acute-on-chronic liver failure (ACLF) patients receiving artificial liver support system (ALSS) therapy. **Methods:** ACLF patients treated with ALSS were categorized into glucocorticoids-treated group and control group based on whether they receive glucocorticoids treatment. Propensity score matching (PSM) was utilized in a 1:1 ratio to balance baseline characteristics. Subgroups were stratified by the Model for End-Stage Liver Disease (MELD) scores and Chinese Group on the Study of Severe Hepatitis B ACLF 2.0 (COSSH-ACLF 2.0) scores. Survival outcomes were analyzed by using Kaplan-Meier curves and log-rank tests. Univariate and multivariate analyses identified predictors of 90-day transplant-free survival (TFS). **Results:** From 2014 to 2025, a total of 124 ACLF patients treated with ALSS were include and 100 patients (control: n = 50; glucocorticoids: n = 50) were matched by PSM. The glucocorticoids group received dexamethasone at an average dose of 5 mg/d before each ALSS procedure. At 90 days, overall survival was comparable between control and glucocorticoids groups (72.0% vs. 67.8%, p = 0.6636), with TFS rates of 58.1% versus 67.8% (p = 0.3553). Patients with MELD scores > 24 or COSSH-ACLF 2.0 scores > 7.3 exhibited significantly lower 90-day TFS (both p < 0.0001). Glucocorticoids treatment failed to show a survival benefit in any subgroup. Overall infections show no statistically significant between control group and glucocorticoids group (36% vs 30%, p = 0.3912). In the univariate analysis, neutrophil count, serum creatinine, blood urea nitrogen (BUN), INR, PT, APTT, ALSS procedures, baseline MELD scores > 24 and COSSH-ACLF 2.0 scores > 7.3 were 90-day mortality predictors. Multivariate analysis confirmed that BUN (HR = 1.19, 95% CI = 1.04–1.37, p = 0.013), ammonia (HR = 1.02, 95% CI = 1.01–1.03, p = 0.005), ALSS procedures (HR = 0.51, 95% CI = 0.32–0.80, p = 0.003), and new infections (HR = 3.99, 95% CI = 1.16–13.74, p = 0.028) as independent 90-day mortality determinants. **Conclusion:** Glucocorticoids therapy did not improve transplant-free survival in ACLF patients undergoing ALSS. Key prognostic factors included BUN, ammonia levels, and new infections.



Characteristic	28-day	60-day	90-day	p-value[1]
Overall	76.0% (68.1%, 84.8%)	74.0% (65.9%, 83.1%)	69.9% (61.5%, 79.5%)	
Group				0.7
Control	78.0% (67.3%, 90.4%)	74.0% (62.8%, 87.2%)	72.0% (60.6%, 85.6%)	
Glucocorticoids	74.0% (62.8%, 87.2%)	74.0% (62.8%, 87.2%)	67.8% (56.0%, 82.2%)

4117 | THE COMBINED ENGINEERING OF HLA GENE DISRUPTION AND BCL2 AUGMENTATION FOR HUMAN LIVER ORGANOID-BASED EXTRACORPOREAL SUPPORT SYSTEM IN TREATING LIVER FAILURE

Kentaro Ichimura[1] Yosuke Yoneyama[2] Hitomi Yamaguchi[1] Kanae Otsu[1] Akinobu Taketomi[3] Takanori Takebe[4], [1]Institute of Science Tokyo, [2]The University of Osaka, [3]Hokkaido University Graduate School of Medicine, [4]Children's Hospital Medical Center

Background: There is an urgent need for bridging therapies to support patients waiting for liver transplantation. Bioartificial liver (BAL) supporting systems are promising alternatives that incorporates extracorporeal bioreactors containing hepatocytes facilitate liver regeneration. Recent advances in human stem cell-derived organoid technology has evolved to dictate arrays of hepatic functions such as biosynthesis and detoxification, positioning these organoids as a potential cellular source for BAL systems. However, clinical translation remains challenged by alloimmunogenicity and poor tolerance to inflammatory and toxic insults present in patient blood. **Methods:** We established an extracorporeal circuit with HLA-A, HLA-B, and CIITA triple knockout human induced pluripotent stem cell (hiPSC)-derived liver organoids (HLO). We further edited the organoids by lentiviral transduction of a *B-cell lymphoma 2 (BCL2)* gene expressed under a doxycycline-inducible promoter. The efficacy was tested after direct blood exposure of the alginate-encapsulated organoids through venous flow in an hepatectomized rat model. In rats subjected to 80% hepatectomy followed by whole-blood BAL perfusion, acute liver failure ensued, as evidenced by elevated serum liver injury markers, coagulopathy, and hyperammonemia. We histologically assessed post-operative injury and regeneration of the remnant rat liver. **Results:** After whole blood perfusion by the BAL in the hepatectomized rats, HLOs retrieved from these circuits exhibited widespread apoptosis, with the majority staining positive for cleaved caspase-3. RNA-seq analysis confirmed concomitant downregulation of mitochondrial genes, a potent inducer of apoptosis. Regulation against apoptosis is mainly exerted by the BCL-2 protein family's anti-apoptotic members, which serve to preserve cell survival by inhibiting pro-apoptotic mechanisms. Therefore, we induced BCL2 expression in HLO, resulting in a significant protection of apoptosis without compromising the gene expression of hepatic metabolism including ammonia detoxification or bilirubin conjugation. The BAL treatment with BCL2-engineered HLO demonstrated the mortality benefit in rats post hepatectomy, accompanied by improved steatosis, nuclear condensation, and sinusoidal damage. In the remnant liver, the treatment with the engineered HLO reduced the number of pericentral hepatocytes positive for p21, a key protein arresting cell cycle. **Conclusion:** The BCL2 engineering of liver organoids provides a significant improvement for the duration of hepatic support in the BAL, and offered the protection from the recipient liver damage in a post-hepatectomy liver failure rat model. Understanding the hepato-protective mechanism against acute liver failure is crucial to accelerate the development of whole blood extracorporeal system with genetically-augmented organoids.

4118 | FACTORS CONTRIBUTING TO TECHNICAL SUCCESS AND ITS PREDICTORS IN TRANSJUGULAR LIVER BIOPSY

NAOHIRO WADA[1] Takashi Kobayashi[1] Asako Nogami[1] Michihiro Iwaki[1] Satoru Saito[2] Atsushi Nakajima[3] Masato Yoneda[1], [1]Yokohama City University, [2]Sanno Hospital, [3]International University of Health and Welfare, Atami Hospital

Background: Transjugular liver biopsy (TJLB) is a valuable diagnostic alternative to percutaneous liver biopsy, particularly in patients with ascites or coagulopathy. However, procedural failure occasionally occurs, and the factors and predictors of technical failure in TJLB have not been fully elucidated. This study aimed to identify the factors and predictors of technical failure in TJLB. **Methods:** We conducted a retrospective analysis of 100 TJLB procedures between November 2014 and May 2024 at a single tertiary center. We collected and analyzed patient characteristics and imaging data. The anatomical relationship between the hepatic vein and inferior vena cava (IVC) was measured on CT or MRI. The predictors of technical failure in TJLB were assessed using univariate and multivariate analyses. **Results:** TJLB was successful in 87 of 100 cases. Complications occurred in 6% of cases. No procedure-related mortality was observed. The primary reason for failure was the inability to advance the catheter into the hepatic vein (77% of failed cases). The patients of successful TJLB group were significantly younger (54.0 $\pm$ 15.0 vs. 64.5 $\pm$ 11.0 years; $p = 0.007$) and taller (162.1 $\pm$ 8.1 cm vs. 157.4 $\pm$ 9.3 cm; $p = 0.048$) than those who did not. There were significant differences with respect to gender; males were unsuccessful in 2 of 43 cases,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

while females were unsuccessful in 11 of 57 cases ($p = 0.037$). The confluence angle between the hepatic vein and IVC was significantly smaller in the successful group than in the unsuccessful group (43.8 ± 11.1° vs. 60.0 ± 11.8°; $p = 0.001$). Regarding the confluence angle, a ROC curve analysis was performed, and the optimal cutoff value of 57° for predicting TJLB failure was determined using the Youden Index. We conducted multivariate analysis, adjusted for age, height, sex and the angle. When the angle between the hepatic vein and IVC was ≥ 57°, the odds ratio for failure was 84.3, and the result was statistically significant ($p = 0.001$). In contrast, no significant differences were observed for age, height, or sex after adjustment. **Conclusion:** The most significant predictor of technical failure in TJLB was identified as a larger confluence angle between the hepatic vein and IVC, particularly when the angle exceeded 57°. The confluence angle may need to be assessed before performing TJLB, and the indications for TJLB may be reconsidered when it exceeds 57°.

4119 | ACTIVATION OF A TUMOR SUPPRESSOR P53 DRIVES ACUTE LIVER FAILURE VIA UPREGULATION OF LEUKEMIA INHIBITORY FACTOR (LIF)

Jihyun Sung[1] Yuki Makino[1] Seiya Kato[1] Yasuharu Kawamoto[1] Yoichi Sasaki[1] Kenji Fukumoto[1] Yuta Myojin[1] Kazuhiro Murai[1] Yoshinobu Saito[2] Takahiro Kodama[3] Hayato Hikita[2], [1]Department of Gastroenterology and Hepatology, University of Osaka Graduate School of Medicine, [2]Osaka University Graduate School of Medicine, [3]Osaka University

Background: Acute liver failure (ALF) is characterized by massive hepatocyte death, with no effective treatment except liver transplantation. We previously reported that constitutive activation of p53 in hepatocytes promotes chronic liver diseases. However, its impact on ALF remains unknown. This work aims to study the roles of p53 in ALF. **Methods:** We used genetically modified mice including hepatocyte-specific Mdm2-deficient mice (Alb-CreER $Mdm2^{fl/fl}$ + Tamoxifen: Mdm2ΔHep mice), Mdm2 and p53 double-deficient mice (Alb-CreER $Mdm2^{fl/fl}$ $p53^{fl/fl}$ + Tamoxifen), and LIF-deficient mice (LIF+/-). Serum and liver samples were obtained from ALF patients and healthy controls. Hepatocyte cell lines (HepG2, CL2), a hepatic stellate cell line (LX-2), and a liver sinusoidal endothelial cell line (TMNK-1) were used for in vitro experiments. **Results:** In the publicly available human ALF datasets (GDS4387), hepatic p21, a representative target of p53, was upregulated in ALF patients compared with the normal liver. acetaminophen (APAP) or concanavalin A (ConA)-induced ALF in wild type mice showed upregulation of p21 mRNA and p53 protein in the liver, indicating the activation of the p53 pathway. Loss of hepatocyte Mdm2, a negative regulator of p53, induced p53 activation, resulting in extensive hepatocyte death resembling ALF, and ultimately caused 100% mortality. Further deletion of hepatocyte p53 completely negated these ALF phenotypes. scRNA-seq and multiplex cytokine assay showed elevation of multiple inflammatory cytokines in hepatocytes, hepatic non-parenchymal cells and serum in Mdm2ΔHep mice. Among them, LIF was the most elevated inflammatory cytokine predominantly upregulated in hepatocytes. LIF upregulation was also observed in APAP and ConA models. Compared with the healthy control, hepatic LIF expression and serum LIF levels were elevated in ALF patients. In HepG2 and CL2 cells, treatment with a Mdm2 inhibitor Nutlin-3 increased LIF expression, while p53 knockdown suppressed it, indicating that LIF is

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

regulated downstream of p53 in hepatocytes. In LIF+/− mice subjected to APAP-induced ALF, serum ALT levels were decreased and survival was improved. Histologically, hepatic necrosis and the infiltration of CD11b-positive cells were drastically reduced in LIF-deficient mice. scRNA-seq revealed that the infiltrating CD11b-positive cells, consisting of macrophages and neutrophils, abundantly express proinflammatory cytokines and chemokines that can exacerbate liver injury and inflammation. Mechanistically, LIF accelerated the production of inflammatory cytokines and chemokines by hepatic stellate cells and liver sinusoidal endothelial cells, which in turn can promote the infiltration of CD11b-positive cells. **Conclusion:** p53 activation in hepatocytes drives ALF via LIF-mediated liver injury. Targeting p53-LIF axis may offer a novel therapeutic approach for ALF.

4120 | EFFICACY, SAFETY AND PROGNOSTIC FACTORS OF DUAL PLASMA MOLECULAR ADSORPTION SYSTEM COMBINED WITH PLASMA EXCHANGE ON ACUTE-ON-CHRONIC LIVER FAILURE:A SINGLE-CENTER RETROSPECTIVE COHORT STUDY

Wen-Juan Shi[1], [1]The Second People's Hospital of LanZhou

Background: To investigate retrospectively the efficacy and safety of dual plasma molecular absorption system (DPMAS) combined with plasma exchange (PE) in patients with acute-on-chronic liver failure (ACLF). **Methods:** A single-center retrospective study included 51 ACLF patients receiving DPMAS+PE from 2014 to 2025. Clinical characteristics, 28/90-day overall survival (OS), infection rates and complications were analyzed. Subgroups were classified by the model for end-stage liver disease (MELD) score. Survival analyses was performed by Kaplan–Meier method and compared by the log-rank test. Cox regression identified survival predictors for 90-day OS. **Results:** This study included 51 patients (mean age 49 ± 12 years; 74.5% male), predominantly with liver cirrhosis (76.5%) and ascites (68.6%). Laboratory profiles demonstrated elevated liver enzymes (ALT 573 ± 505 U/L, AST 569 ± 450 U/L), hyperbilirubinemia (total bilirubin 416 ± 122 μmol/L), and prolonged coagulation (PT 23.5 ± 4.8 s; INR 1.99 ± 0.43). The mean MELD score was 22.5 ± 3.3. Survival rates were 74.5% at 28 days and 66.4% at 90 days. Patients with MELD scores > 24 exhibited significantly lower 90-day OS (p = 0.0133). New infections occurred in 39.2% (pulmonary 23.5%, intra-abdominal 9.8%) with 3.9% thromboembolic complications. In multivariate analysis, prolonged APTT (HR 1.09; 95% CI, 1.02–1.17; p = 0.009), ammonia (HR 1.02; 95% CI, 1.00–1.03; p = 0.021), fewer artificial liver support system procedures (HR 0.50; 95% CI, 0.26–0.95; p = 0.034) and MELD scores > 24 (HR 8.49; 95% CI, 1.49–48.31; p = 0.016) were independent predictors of 90-day mortality. **Conclusion:** DPMAS combined with PE demonstrates clinically efficacy in ACLF. MELD scores >24, prolonged APTT, hyperammonemia independently predict mortality.

4121 | BEYOND ACETAMINOPHEN: AN UMBRELLA REVIEW OF N-ACETYLCYSTEINE IN NON- ACETAMINOPHEN-INDUCED LIVER FAILURE

Raja Chandra Chakinala[1] Abdullah Sultany[1] Adishwar Rao[1] Vikash Kumar Karmani[2] Rahul Chikatimalla[3] Chaitanya K Chandrala[1], [1]Guthrie Robert Packer Hospital, [2]Jinnah Sindh Medical University, [3]Kamineni Institute of Medical Sciences

Background: N-acetylcysteine (NAC), widely recognized for its role in treating acetaminophen toxicity, has gained attention for its potential benefits in non-acetaminophen-induced acute liver failure (NAI-ALF). This umbrella review synthesizes evidence from meta-analyses to evaluate the efficacy and safety of NAC in improving outcomes among patients with NAI-ALF. **Methods:** In adherence to the PRIOR guidelines, PubMed, Google Scholar, Web of Science, and Scopus were searched from database inception to April 2025 to identify articles related to NAI-ALF. The outcomes of interest included mortality rate,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

length of hospital stay, and transplant-free survival. Various effect measures, such as risk ratios, odds ratios, and mean differences, were compared across the studies. A corrected covered area (CCA) assessment was performed to evaluate the degree of overlap among the included reviews. The quality and methodological rigor of each review were assessed using the AMSTAR-2 tool. **Results:** From the 6,743 articles identified, five meta-analyses were included, showing a significant overlap with a corrected covered area of 45.8%. Two reviews reported mortality: Shrestha et al. (2021) found a significant reduction with NAC (OR 0.47, 0.29 to 0.75), while Amjad et al. (2022) showed a non-significant trend toward reduction (RR 0.73, 0.48 to 1.09). Four reviews assessed transplant-free survival with mixed results: Amjad et al. (2022) reported improved survival (RR 0.56, 0.33 to 0.94), whereas Jawaid et al. (2021) (RR 1.54, 1.19 to 1.98), Hu et al. (2015) (OR 1.61, 1.11 to 2.34) and Walayat et al (2021) (OR 2.85, 2.11 to 3.85) indicated worse outcomes. Length of hospital stay was reduced in all three reviews reporting this outcome: Shrestha et al. (2021) (MD –6.52 days, –12.91 to –0.13), Amjad et al. (2022) (SMD –1.62, –1.84 to –1.40), and Jawaid et al. (2021) (SMD –0.405, –1.44 to –0.63).

Refer to Table 1 for a summary of key findings from each meta-analysis. **Conclusion:** N-acetylcysteine appears to reduce mortality and shorten hospital stays in patients with non-acetaminophen-induced acute liver failure. However, evidence regarding its effect on transplant-free survival is inconsistent, with some studies suggesting benefits and others indicating potential harm. Further high-quality research is needed to clarify the role of NAC in improving transplant-free survival outcomes in this population.

Table 1. Summary of Meta-Analyses Evaluating N-Acetylcysteine in Non-Acetaminophen- Induced Acute Liver Failure

Study and Year	Metric of Measure	Effect Size [95% CI]
Mortality rate		
Shrestha et al 2021	OR	0.47(0.29 to 0.75)
Amjad et al. 2022	RR	0.73 (0.48 to 1.09)
Transplant-Free Survival		
Amjad et al. 2022	RR	0.56 (0.33 to 0.94)
Jawaid et al. 2021	RR	1.54 (1.19 to 1.98)
Hu et al. 2015	OR	1.61 (1.11 to 2.34)
Walayat et al. 2021	OR	2.85 (2.11 to 3.85)
Length of Stay in Hospital		
Shrestha et al. 2021	MD	-6.52 (- 12.91 to -0.13)
Amjad et al. 2022	SMD	-1.62 (-1.84 to -1.40)
Jawaid et al. 2021	SMD	–0.405 (–1.44 to -0.63)

4122 | SPATIOTEMPORAL-OMICS REVEALS THE ROLE OF MLXIPL$^+$ HEPATOCYTES IN LIVER REPAIR IN ACUTE LIVER INJURY MICE

Jun Li[1] Binggi Li[1] Heng Yao[1] Jing Jiang[1] Jiaojiao Xin[1] Xi Liang[1] Dongyan Shi[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: The liver possesses a remarkable regenerative capacity, restoring the structure and function following acute liver injury (ALI). Although hepatic mesenchymal stromal cells (MSCs) are known to be rapidly activated during ALI, the regulatory mechanisms of the liver injury microenvironment in repair remain unclear. This study aims to uncover the precise mechanism through which endogenous MSCs orchestrate Mlxipl$^+$ hepatocytes to promote liver tissue regeneration. **Methods:** The ALI mouse model was established by intraperitoneal injection of the anti-CD95 antibody JO2 into a SCID mouse. Liver tissues and blood samples were collected at Day 0, 1, 3 and 7 post-injury. Single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics (ST) of liver tissues were conducted to explore the mechanism driving self-repair. scRNA-seq data were clustered using dimensionality reduction, followed by cell annotation and spatial mapping via deconvolution. Cell–cell interactions, particularly between hepatocytes and MSCs, were analyzed to identify and validate key signaling pathways involved in liver repair. **Results:** The ALI mouse model was successfully established, with regional necrosis of liver tissue and elevated liver function. By integrating scRNA-seq and ST data, a spatiotemporal atlas of liver injury and repair was constructed. Eleven major liver cell types were annotated, and the ratio of hepatocytes, endothelial cells, MSCs, and cholangiocytes significantly decreased during the acute injury phase and gradually recovered during repair. Notable ligand–receptor interactions were observed between these four cell types, especially between hepatocytes, endothelial cells and MSCs. Interestingly, the similarity in cell communication patterns at Day 3 and Day 7 indicated that the process of liver repair stabilized on Day 3. Sub-clustering further revealed strong interactions between hepatic stellate cells and both classical hepatocytes and Mlxipl$^+$ hepatocytes through the regulation of extracellular matrix. **Conclusion:** The spatiotemporal dynamics of liver injury and repair in ALI mice was delineated. The decline and rebound of hepatic MSCs and hepatocytes during injury and recovery. The prominent interaction between hepatic stellate cells and MLXIPL$^+$ hepatocytes suggests that Mlxipl$^+$ hepatocytes are crucial in liver regeneration and represent a potential therapeutic target for liver injury.

◆ 4123 | IL-37 COMBINED WITH IL-22 COULD SERVE AS A THERAPEUTIC STRATEGY FOR ACLF WITH THE EFFECT OF BOTH INHIBITING SYSTEMIC INFLAMMATION AND PROMOTING LIVER REGENERATION

Dabao Shang[1] Xiaogang Xiang[2] Jinming Zhang[2] Yifan Xu[2] Zihan Zhou[2] Jingting Liu[2], [1]Ruijin Hospital, Shanghai Jiao Tong University School of Med, [2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) is a critical clinical syndrome in patients characterized by an acute intrahepatic or extrahepatic insult and subsequent rapid deterioration of liver function on the basis of chronic liver diseases resulting in high short-term mortality. Systemic inflammation is a driving force in developing ACLF, however, treatments targeted systemic inflammation are lacking till now. Interleukin 37 (IL-37), a newly identified member of the IL-1 family, functions as an inherent immunosuppressant capable of concurrently modulating both adaptive and innate immune responses. The specific role of IL-37 in the pathogenesis of ACLF is not fully elucidated. **Methods:** ACLF patients were enrolled and serums were collected. Transgenic mice with liver-specific expression of human IL-37 (IL-37-Hep-TG) were constructed. ACLF mouse model was developed {three steps: chronic liver injury (injection of carbon tetrachloride [CCl4] for 8 weeks), acute hepatic insult (injection of a double dose CCl4), and bacterial infection (intraperitoneal injection of Klebsiella pneumoniae)}. Recombinant human IL-37 (rhIL-37) was used. IL-22, a cytokine that could promote liver regeneration, was also used. **Results:** Serum levels of IL-37 were markedly elevated in ACLF patients comparing to healthy controls (HC), chronic hepatitis B patients (CHB) and hepatocellular carcinoma patients (HCC). Intravenous injection of IL-37 in ACLF mice showed ameliorative ALT and AST levels, as well as the levels of TNF-α, IL-6 and IFN-γ. However, the mortality in IL-37 group was higher than control group. Notably, BrdU staining indicated that liver regeneration was inhibited in IL-37 group. In IL-37-Hep-TG and wild type (WT) mice, IL-22 injection showed the highest survival rate among all the groups. **Conclusion:** Serum IL-37 expression is elevated in ACLF patients. Intravenous injection of IL-37 in ACLF mice could down-regulate systemic inflammation but liver regeneration is inhibited at the same time. IL-37 combined with IL-22 might serve as a potential therapeutic strategy for ACLF with systemic inflammation inhibited and liver regeneration promoted synergistically.

◆ 4124 | GUT MICROBIAL SUCCESSION AND ESCALATING ANTIBIOTIC RESISTANCE FROM CHRONIC HEPATITIS B TO ACUTE-ON-CHRONIC LIVER FAILURE: A METAGENOMIC STUDY

Jiyang Chen[1] Xianbin Xu[1] Sisi Yang[1] Zelu Meng[1] Xia Yu[1] Ying Nie[1] Yani Zhou[1] Yining Zhang[1] Siqi Sun[1] Huilan Tu[1] Yingfeng Lu[1] Jiangshan Lian[1] Hongyu Jia[1] Yu Shi[1] Yida Yang[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Disruption of the gut microbiota is increasingly recognized as a pivotal driver of chronic liver disease progression, promoting systemic inflammation, immune dysregulation, and bacterial translocation. We performed a comprehensive metagenomic analysis to characterize the ecological and functional shifts in the gut microbiota across patients with chronic hepatitis B (CHB), acute decompensation (AD), and acute-on-chronic liver failure (ACLF). **Methods:** Fecal samples (n = 90) collected from patients with CHB, AD, and ACLF were subjected to whole-genome shotgun metagenomic sequencing. Microbial diversity was assessed using alpha and beta diversity metrics, principal coordinate analysis (PCoA), and non-metric multidimensional scaling (NMDS). Differential taxa were identified using linear discriminant analysis effect size (LEfSe). Functional annotation of antibiotic resistance

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

genes (ARGs) and virulence factors (VFs) was performed using the Comprehensive Antibiotic Resistance Database (CARD) and the Virulence Factors Database (VFDB). **Results:** Alpha diversity decreased progressively from CHB to ACLF, while beta diversity demonstrated significant group-wise separation (Kruskal-Wallis test, $p < 1 \times 10^{-100}$). Symbiotic genera, including Blautia, Ruminococcus, and Coprococcus, were enriched in AD, whereas pathobionts such as Escherichia coli and Enterococcus faecium dominated in ACLF. ARG profiling revealed a substantial increase in resistance burden in ACLF, characterized by the enrichment of β-lactamases, efflux pumps, and multidrug resistance elements (e.g., ARO:3005041, ARO:3000833). VFDB analysis showed upregulation of virulence determinants including type III secretion systems, lipopolysaccharides (LPS), and β-hemolysins. Functional analysis indicated a shift from a commensal-driven resistance profile in CHB and AD to a pathogen-dominated profile in ACLF, largely mediated by Enterococcus, Klebsiella, and Streptococcus species. **Conclusion:** Progression from CHB to ACLF is associated with a stepwise ecological succession of the gut microbiota, culminating in pathogen-driven dysbiosis and heightened antimicrobial resistance. These findings highlight the gut microbiota as a potential biomarker for disease staging and a target for microbiota-directed therapeutic interventions in advanced liver disease.

◆ 4125 | SECONDARY SBP PROPHYLAXIS WORSENS SURVIVAL WITHOUT AFFECTING LIVER TRANSPLANT RATES IN VETERANS WITH CIRRHOSIS FOLLOWED AFTER THEIR FIRST DECOMPENSATION

Shari Rogal[1] Jasmohan Bajaj[2] Scott Silvey[3] Nilang Patel[4] Jacqueline O'Leary[5] Timothy Morgan[6] John Markley[7] Sofia Jakab[8] Heather Patton[9], [1]University of Pittsburgh, [2]Virginia Commonwealth University, [3]VCU, [4]Richmond VA, [5]Dallas VA, [6]VA Long Beach Healthcare System, [7]Richmond VAMC, [8]West Haven VA, [9]VA San Diego Healthcare

Background: After index decompensation, the impact of SBP occurrence, recurrence & secondary SBP prophylaxis (SecSBPPr) on mortality & liver transplant (LT) remains unclear. Aim: Define the interaction between SecSBPPr on SBP recurrence, mortality and LT . **Methods:** Using the Veterans Affairs Corporate Data Warehouse (VA-CDW), cirrhosis pts with index decompensation (HE, ascites, VB) between 2009-2023 and were followed untill Jan 2024. Demographics, labs, cirrhosis details & medications were collected. Outcomes: SBP episodes (0, 1, or ≥2), SecSBPPr initiation (continuous ciprofloxacin/Bactrim usage with ≥2 refills in 120-days post-SBP), death & LT were evaluated. Primary analysis was time-to-death & time-to-LT using Cox proportional hazards models of each cause-specific hazard separately to account for competing risks. In survival analysis, SBP groups (0, 1 or ≥2 episodes), SecSBPPr, and other predictors (i.e., MELD 3.0, medications, etc.) were analyzed as time-varying covariates to account for immortal time bias. Adjusted models were fit, controlling different covariates between SBP groups. Finally, we fit an interactive effect between SecSBPPr & SBP groups for death & LT. **Results:** 52,526 Veterans with index cirrhosis decompensation were included, of which 20.0% developed one SBP episode & 2.4% ≥2 SBP episodes (Fig A). Overall mortality was 78.1% & 2.4% received LT. After the first SBP episode, 4439 (42.2%) were put on SecSBPPr. Pts with SBP recurrence were younger, more likely to have alcohol etiology & have more advanced disease (Fig B).
Outcomes: 1st SBP was linked to 1.74×risk of death ([1.69-1.79], $p < 0.001$), while ≥2 episodes was linked with 2.31×risk of death ([2.16-2.46], $p < 0.001$). Having

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

one episode of SBP was also linked to 2.79×risk of LT ([2.40-3.24], $p < 0.001$), while ≥2 episodes was linked with 4.95× risk of LT ([3.79-6.45], $p < 0.001$). After covariate adjustment, these results remained consistent. When incorporating SecSBPPr into the model, we found a positive interaction (adj. HR for interaction: 1.63 [1.39-1.92], $p < 0.001$) – implying that patients taking SecSBPPr prior to their recurrent SBP episode were more likely to die (Fig. C). There was no interactive effect observed for LT, indicating that patients with SBP recurrence had similar rates of LT regardless of SecSBPPr ($p = 0.13$). **Conclusion:** In a national cohort of Veterans after index decompensation, SBP occurrence & recurrence was associate with a greater risk of mortality & receiving a LT in multivariable analysis controlling for MELD3.0 and other factors. Secondary SBP prophylaxis was started in <50% of patients after index SBP, increased mortality but did not impact LT risk. In Veterans with decompensated cirrhosis & prior SBP, withholding SecSBPPr improved survival & did not affect their chance of LT.

◆ 4126 | NUTRITIONAL SUPPORT INTERVENTION IN PATIENTS WITH HEPATITIS B VIRUS-RELATED ACUTE-ON-CHRONIC LIVER FAILURE AT NUTRITIONAL RISK: A RANDOMIZED CONTROLLED CLINICAL TRIAL

Zhipeng Li[1] Jia Chen[1] Yeqiong Zhang[1] Xiyao Chen[1] Wenxiong Xu[1] Liang Peng[1], [1]Third Affiliated Hospital of Sun Yat-sen University

Background: Malnutrition, a prevalent but often underrecognized complication in acute-on-chronic liver failure (ACLF), is linked to reduced quality of life, hepatic decompensation, and increased mortality. This study evaluates the safety and efficacy of individualized nutritional support in hepatitis B virus-related ACLF (HBV-ACLF) patients at nutritional risk. **Methods:** In this open-label, randomized controlled trial, 60 HBV-ACLF patients with a nutritional risk score (NRS 2002 ≥ 3) were randomized 1:1 to receive either individualized nutritional support (targeting 1.2 times resting energy expenditure [REE] per day and 1.2 g/kg/day protein, n = 30) or a standard diet (1600 kcal/day, 70 g protein, n = 30) for 10 days. The primary outcome was non-liver transplant mortality at 30 and 90 days. Secondary outcomes included the incidence of adverse clinical events (ascites, gastrointestinal bleeding, infection, hepatic encephalopathy, hepatorenal syndrome, rehospitalization, ICU admission) and changes in nutritional status (mid-arm circumference [MAC], mid-arm muscle circumference [MAMC]), muscle strength (grip strength), physical function (Short Physical Performance Battery [SPPB]), and quality of life (EQ-5D scale) at 30 and 90 days. **Results:** Of 60 enrolled patients, 58 were analyzed (intervention: 29, control: 29; mean age: 42.3 ± 7.9 years; 93.1% male; BMI: 23.9 ± 2.63; MELD score: 20.9 ± 3.82; COSSH score: 6.77 ± 0.58). Non-liver transplant mortality was lower in the intervention group at 30 days (3.4% vs. 17.2%, p = 0.196) and 90 days (20.7% vs. 31%, p = 0.782), but differences were not statistically significant. The intervention group had significantly fewer adverse clinical events at 30 days (29.4% vs. 65.4%, p = 0.036) and 90 days (37.9% vs. 79.3%, p = 0.001). At 30 days, the intervention group showed significant improvements in MAC (Δ0.02 ± 1.32 vs. Δ-1.77 ± 1.21, p = 0.001), MAMC (Δ0.44 ± 1.41 vs. Δ-1.14 ± 1.39, p = 0.001), grip strength (Δ4.54 ± 4.93 vs. Δ-1.82 ± 6.32, p = 0.007), and EQ-5D scores (Δ20.4 ± 17.2 vs. Δ1.83 ± 29.2, p = 0.021). These improvements persisted at 90 days for MAC (Δ0.68 ± 1.56 vs. Δ-1.85 ± 0.82, p = 0.002), grip strength (Δ7.93 ± 4.5 vs. Δ0.2 ± 8.82, p = 0.007), and SPPB scores (Δ2.77 ± 0.83 vs. Δ1.5 ± 0.83, p = 0.021). The intervention was well-tolerated with no serious adverse events. **Conclusion:** Individualized nutritional

support is safe and effective in reducing adverse clinical events and improving nutritional status and quality of life in HBV-ACLF patients at nutritional risk. However, larger trials are needed to confirm potential survival benefits.

Figure1. The flowchart of the study.

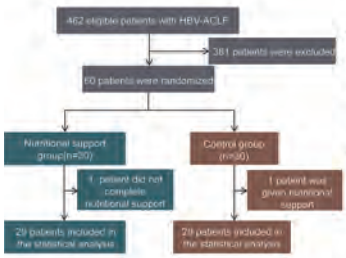

Table1.The outcomes of the study.

	Intervention group(n=29)	Control group(n=29)	P value
The primary outcome			
Non-liver transplant mortality at 30 days	3.4%(1/29)	17.2%(5/29)	0.196
Non-liver transplant mortality at 90 days	20.7%(6/29)	31.0%(10/29)	0.782
The secondary outcome			
Incidence of adverse clinical events within 30 days	29.4%	65.4%	0.036
Incidence of adverse clinical events within 90 days	37.9%	79.3%	0.001

◆ 4127 | SYSTEMIC CHALLENGES IN MANAGING ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) IN THE U.S.: DIAGNOSTIC DELAYS, REFERRAL BARRIERS, AND FRAGMENTED POST-DISCHARGE CARE

Constantine Karvellas[1] Jasmohan Bajaj[2] Armaghan Dabbagh[3] Dean Hum[3] Pierbruno Ricci[3] Katharina Staufer[3] Richard Moreau[4] Arun Sanyal[2], [1]University of Alberta, [2]Virginia Commonwealth University, [3]GENFIT S.A., [4]European Foundation for the Study of Chronic Liver Failure (EF CLIF)

Background: Acute-on-chronic liver failure (ACLF) is a high-mortality syndrome requiring prompt, specialized care. However, systemic inefficiencies across the healthcare continuum hinder optimal care, and management of patients with ACLF remains fragmented. The lack of a unified definition, an ICD code, as well as suboptimal referral and outpatient care may contribute to adverse patient outcomes. This study aimed to explore multidisciplinary challenges in ACLF care and to identify priority areas for improvement across the care continuum. **Methods:** 15 physicians were recruited for this qualitative study using purposive sampling. Data was collected via 60-minute phone interviews. Participants included 5 transplant hepatologists, 4 hepatologists, 5 hospital internists, and 2 emergency physicians from 11 U.S. states. Participants worked at 5 secondary, 7 tertiary, and 3 quaternary centers. The interview guide included over 100 open-ended and semi-structured questions across four themes: hospital admission, ACLF diagnosis, treatment, and follow-up. An inductive thematic analysis was used to identify and interpret key patterns and themes across the dataset. **Results:** In total, 4 physicians were fully familiar with the condition of ACLF, while 11 had partial familiarity. The participants estimated that ~20% of patients with ACLF are referred too late to a liver specialist, while ~10% were not referred at all. Among liver specialists, ~25% of ACLF cases are reportedly misdiagnosed, while those correctly identified are classified using varying definitions (60% EASL-CLIF, 40% NACSELD) and rely on clinical judgment rather than fixed criteria. All participants emphasized the urgent need for a unified definition and noted that the absence of a dedicated ICD code hampers systematic patient tracking and complicates reimbursement. Participants reported that about one in three patients with ACLF are readmitted within 30 days of discharge. Commonly reported barriers to effective post-discharge management included limited access to hepatologists, geographical distance from care centers, and patient non-adherence to follow-up consultations. **Conclusion:** Management of ACLF is challenging due to delayed referrals, diagnostic inconsistency, and poor post-discharge support. Findings highlight the need for a globally unified definition of ACLF, ICD coding, and improved patient follow-up post discharge. Integrated, multidisciplinary care across specialties and institutions is essential to improve outcomes and ensure timely, specialized care.

◆ 4128 | IDENTIFICATION AND VALIDATION OF RECEPTOR-INTERACTING PROTEIN KINASE 3 AS A PROGNOSTIC BIOMARKER TO GUIDE PERSONALIZED THERAPY IN ACUTELY DECOMPENSATED CIRRHOSIS: A MULTICOHORT VALIDATION STUDY

Pratibha Garg[1] Nipun Verma[2] Parminder Kaur[2] Saloni Munjal[2] Dr. Ashwin Vinod[2] Arun Valsan[3] Fausto Andreola[4] Arka De[2] Madhumita Premkumar[1] Sunil Taneja[2] Rajeshwar Mookerjee[4] Ajay Duseja[1] Rajiv Jalan[4], [1]Postgraduate Institute of Medical Education & Research, [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India, [3]Amrita Institute of Medical Sciences, Kochi, [4]University College London Medical School

Background: Identifying predominant mode of cell death and their temporal patterns in acutely decompensated cirrhosis (AD) and acute-on-chronic liver failure (ACLF) may inform personalised therapeutic strategies. We investigated the prognostic value of circulating cell death markers in relation to organ dysfunction, disease trajectory, and outcomes in AD/ACLF. **Methods:** A total of 556 patients with acutely decompensated cirrhosis were enrolled across four cohorts. A derivation cohort of 200 AD patients (47 without and 153 with ACLF) was assessed for baseline and day-7 plasma levels of Cytokeratin-18 (M30, M65), Gasdermin-D (pyroptosis), Mixed-Lineage Kinase-Like Protein (MLKL: necroptosis), and Receptor-Interacting Protein Kinase 3 (RIPK3). For standardization, expression levels were interpreted relative to the upper limit of normal defined using expression in healthy control population. A RIPK3-integrated mortality prediction model was developed and validated in two external cohorts (n = 106, 150), with temporal validation in a third cohort (n = 100). **Results:** All cell death markers correlated with disease severity, while RIPK3 showed the strongest association with ACLF grade and extra-hepatic organ failures, especially renal and hepatic ($p < 0.05$). Elevated baseline RIPK3 independently predicted worsening clinical course [adjusted OR: 4.85 (95% CI: 2.36–9.94), $p < 0.001$] and 30-day mortality [adjusted OR: 4.74 (95% CI: 2.38–9.44), $p < 0.001$]. Higher baseline RIPK3 was independently associated with worsening disease course [adjusted OR: 4.85 (95%CI: 2.36-9.94), $p < 0.001$] and mortality [adjusted OR: 4.74; (95%CI: 2.38-9.44), $p < 0.001$]. RIPK3 levels increased over time with worsening course and in non-survivors but declined in those who improved and survived ($p < 0.001$). A model including RIPK3-ULN > 2.261, CLIF-C OF, and leucocytosis/leucopoenia showed strong predictive accuracy (AUC: 0.839), validated across cohorts (AUC: 0.752, 0.794), and confirmed using longitudinal data (AUC: 0.796). **Conclusion:** RIPK3-linked necroptosis is a key contributor to organ failure and mortality in AD/ACLF. Incorporating RIPK3 into prognostic models improves risk stratification and may guide selection of patients for future personalised therapies targeting necroptotic pathways.

◆ 4129 | EMPIRIC VERSUS PRE-EMPTIVE ANTIFUNGAL IN ACUTE-ON-CHRONIC LIVER FAILURE WITH SUSPECTED INVASIVE FUNGAL INFECTIONS: A PRAGMATIC RANDOMIZED CONTROLLED TRIAL WITH MACHINE LEARNING

Nipun Verma[1] Arun Valsan[2] Pratibha Garg[3] Shreeja Sarabu[4] Parminder Kaur[4] Nimitha Mohan[5] Arka De[4] Madhumita Premkumar[3] Sunil Taneja[4] Shankar Prinja[4] Arunaloke Chakrabarti[4] Nusrat Shafiq[4] Ajay Duseja[3], [1]Postgraduate Institute of Medical Education and Research, [2]Amrita Institute of Medical Sciences, Kochi, [3]Postgraduate Institute of Medical Education & Research, [4]PGIMER Chandigarh, [5]Aster Medicity Kochi

Background: The optimal timing of antifungal therapy in acute-on-chronic liver failure (ACLF) patients with suspected invasive fungal infections (IFIs) remains uncertain. We conducted a pragmatic, randomized controlled trial to compare the efficacy, safety, and cost-effectiveness of empirical versus pre-emptive antifungal therapy in this high-risk population. **Methods:** This investigator-initiated, unblinded, parallel-group randomized trial with blinded endpoint adjudication (NCT04157465) enrolled 216 hospitalized ACLF patients with predefined host and clinical risk factors for IFI at a large tertiary-care center between 2019 and 2024. Participants were randomized 1:1 to receive either empirical antifungal therapy at enrollment or pre-emptive therapy upon laboratory, radiological, or mycological confirmation of IFI, with stewardship-based early stopping rules guided by fungal cultures and biomarkers. The primary endpoint was 28-day overall survival. Secondary outcomes included incidence of IFI, in-hospital mortality, changes in MELD-Na and CLIF-C OF scores, ventilation-free survival, adverse events, and cost-effectiveness. Treatment effect heterogeneity was explored using decision tree-based causal inference. **Results:** Baseline characteristics were balanced between groups. Empirical antifungal therapy significantly improved 28-day survival (hazard ratio: 0.64, 95% CI: 0.47–0.88; $p = 0.005$), with a relative risk reduction of 25.5% and number needed to treat of 4.5 (Fig.1A). Ventilation-free survival (35.2% vs. 13.0%; $p < 0.001$) and treatment success (37.4% vs. 16.9%; $p = 0.002$) were higher in the empirical group. In-hospital mortality was lower, with fewer adverse events. No differences were noted in new-onset IFI, fungal spontaneous bacterial peritonitis, urinary tract infections, or hospital length of stay. The empirical approach was cost-effective, yielding higher quality-adjusted life years (QALYs) (29.9 vs. 10.1) and an incremental cost-effectiveness ratio (ICER) of INR 1,42,737 per QALY gained. Decision tree analysis identified patients aged ≥ 40 years with cardiovascular failure and no respiratory failure as deriving the greatest benefit (Fig.1B). **Conclusion:** Empirical antifungal therapy, guided by clinical suspicion and risk stratification, improves short-term survival and key outcomes in ACLF patients with suspected IFI. This approach is safe, clinically effective, and cost-effective. Machine learning-based subgroup identification offers promising avenues for individualized antifungal strategies in ACLF.

Background: Drug-induced liver injury (DILI) leading to ACLF or drug-induced ACLF (DI-ACLF) inherits the dual challenges of DILI and ACLF. Impact of drugs on individual etiology of chronic liver disease (CLD) is unknown. This study aimed to evaluate the association of MAFLD as an underlying CLD, and impact of drug induced liver injury leading to ACLF. **Methods:** Data from prospectively collected 10,994 patients from the AARC registry were analyzed. The diagnosis of DI-ACLF was defined as acute hepatic insult from DILI as a precipitating event. The patients were then divided into the MAFLD-ACLF and non-MAFLD-ACLF groups. MAFLD-ACLF was diagnosed when the etiology of the underlying CLD was MAFLD. The primary outcome was the 30-day mortality. **Results:** A total of 10,994 patients, enrolled in the AARC between April 2009 and April 2024, and 661 (6%) were diagnosed with DI ACLF. In the DI-ACLF group, 5% were MAFLD-related DI-ACLF. Complementary alternative medicine (CAM) and Herbal

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Dietary Supplements (HDS) constituted 16 % of the DI-ACLF cases, with anti-tuberculosis therapy (ATT), antiretroviral, antimicrobials, and antiepileptics accounting 6% of the cases. The most common underlying liver disease etiology was alcohol (63.4%), followed by viral (21.3%), autoimmune hepatitis and cholestatic etiology (6.8%). The overall 30-day mortality rate was greater in MAFLD-related DI-ACLF patients than in non-MAFLD-related DI-ACLF patients (48.5% vs. 31.8%, $p = 0.047$). Patients with MAFLD-related DI-ACLF had higher baseline respiratory failure, baseline hepatic encephalopathy, and > 2 organ failures on day 7 (6.1% vs.0.6%, $p = 0.032$; 21.2% vs. 8.1%, $p = 0.019$; and 69.7% vs. 44.9%, $p = 0.005$, respectively). AARC Score Grade 3 at day 0 (HR: 5.52 95% CI 3.14-9.71, $p < 0.001$), and age (HR: 1.01 95% CI 1.00-1.03, $p = 0.013$) were independent predictors of 30-day mortality in DI-ACLF patients. **Conclusion:** Drugs are an important identifiable cause of ACLF, and MAFLD is increasingly becoming the underlying cause of liver disease globally. The 30-day mortality was higher in MAFLD-related DI-ACLF patients and AARC Score of day 0 was the strongest predictor of mortality in DI-ACLF patients.

and had a significant impact on disease course. We aimed to build a machine learning (ML) model for precise prediction of renal failure among hospitalised ACLF patients. **Methods:** We analysed data from the AARC registry, including clinical information-laboratory parameters and organ failure. After data pre-processing and random splitting (80:20) into derivation-and validation-sets, machine learning models (XGBoost, Random Forest, K-Nearest Neighbours, Decision Trees, Gradient boosting, Logistic Regression, Support Vector Machine (SVM), Gaussian Naive Bayes) were developed on the derivation-set. Model performance was evaluated using area under the curve (AUC), accuracy, precision, and recall/sensitivity to predict renal failure development by day 4 in initially non-affected patients. **Results:** Among 9929 patients (51.6 ± 11.8 years, 87% male), 31.5% (3132) had renal failure at presentation and another 20.8% develop new onset by 4days of hospitalization. Presence of renal failure increases mortality by 31% at 90 days. After data preparation, 46 features used to train eight ML models, and the top 13 features made the best-performing model. The XGBoost model performed best (AUC: 0.98; sensitivity: 0.92; specificity: 0.94). The top predictive variables were baseline total bilirubin, leukocyte and platelet count and 4th day PT-INR, and serum sodium. A decision tree was made with baseline bilirubin of > 32 mg/dL and INR > 3.3 and age > 58 years to predict the risk of renal failure as low risk (15%), moderate risk (30-33%) and high risk (65%) for developing renal failure with the precision, recall, and F1 score of 0.80, 0.91, and 0.85, respectively. **Conclusion:** Renal failure is the common extra-hepatic renal failure with one third at presentation and additional one fourth develop by 4 days, leading to increased mortality. The ML-based model significantly improves prediction of renal failure and simple parameters like age, serum bilirubin and PT-INR can stratify the at-risk group. This tool may enable predictions, timely interventions to improve survival outcome.

4132 | LIVER FRAILTY INDEX IS ASSOCIATED WITH DECREASED RECOVERY IN EGFR AFTER LIVER TRANSPLANTATION

Ahmed Aboseria[1] Jade Pace[1] Justin Lin[1] Michael Attanasi[1] Anwesha Satapathy[1] William Han[1] Bheesham Dayal[1] Sanjaya Satapathy[1], [1]Northwell Health

Background: Frailty has emerged as a significant predictor of adverse outcomes in patients with cirrhosis. While its role in pre-transplant evaluation is well recognized, the association between the Liver Frailty Index (LFI) and post-transplant renal recovery remains unclear. This study investigates the relationship between pre-transplant frailty and changes in renal function, as measured by estimated glomerular filtration rate (eGFR), following liver transplantation. **Methods:** We conducted a retrospective analysis of adult liver transplant recipients from December 2019 to November 2024 at a single center. eGFR was calculated using the CKD-EPI 2021 equation on post-transplant days 0, 1, 7, 14, 28, and 90. LFI was determined prior to transplantation using grip strength, chair stands, and balance testing, and categorized as robust (<3.2), pre-frail (3.2–4.4), or frail (≥ 4.5). Multivariable logistic regression was used to assess the association between LFI and renal recovery, defined as any increase in eGFR compared to baseline (Day 0), after adjusting for age, sex, BMI, MELD, diabetes, pre-transplant hospitalization, and intraoperative blood product usage. **Results:** Among 288 transplant recipients, 227 had available LFI data (mean LFI 4.55, range 2.43–7.04). Higher LFI was significantly associated with reduced odds of eGFR recovery at post-transplant days 7 (OR 0.605, 95% CI 0.416–0.881, $p = 0.009$), 14 (OR 0.617, 95% CI 0.429–0.888, $p < 0.01$), 28 (OR 0.425, 95% CI 0.285–0.633, $p < 0.001$), and 90 (OR 0.611, 95% CI 0.423–0.882, $p < 0.01$). No significant association was observed on postoperative day 1. **Conclusion:** Pre-transplant frailty, as assessed by the Liver Frailty Index, is independently associated with diminished renal recovery following liver transplantation. These findings suggest that frailty may play a critical role in post-transplant kidney function and highlight the need for frailty-targeted interventions and prospective multicenter studies to optimize outcomes in this high-risk population.

Table 1. Association Between Liver Frailty Index (LFI) and Post-Transplant eGFR Recovery

Time Point	LFI OR (95% CI)	p-value
POD 1	0.747 (0.520–1.073)	0.114
POD 7	★ 0.605 (0.416–0.881)	0.009
POD 14	★ 0.617 (0.429–0.888)	0.008
POD 28	★ 0.425 (0.285–0.633)	<0.001
POD 90	★ 0.611 (0.423–0.882)	0.009

Footnotes:

- eGFR recovery was defined as any increase in eGFR compared to post-transplant Day 0.
- Odds ratios (ORs) reflect the effect of pre-transplant Liver Frailty Index (LFI) on the odds of eGFR improvement at each postoperative time point.
- ★ Statistically significant ($p < 0.05$).
- Models adjusted for age, sex, BMI, MELD score, diabetes, pre-OLT hospital length of stay, and intraoperative blood product usage.

Background: Acute-on-chronic liver failure (ACLF) is characterised by multiorgan failure and high short-term mortality. The A-TANGO consortium is conducting a clinical trial of a novel drug to reverse ACLF (www.a-tango.eu). Given the variability in the diagnosis of ACLF using the CLIF OF score, the consortium developed the A-TANGO organ failure (OF) score to improve accuracy. This study evaluated whether the dynamic change in the A-TANGO score at day-7 can define 28-day mortality and allow it to be used as an early surrogate biomarker of response to therapy and therefore as an endpoint for clinical trials. **Methods:** *Derivation cohort:* 3896 patients with acute decompensated liver cirrhosis from the CANONIC, PREDICT and ACLARA. A-TANGO OF score was calculated at baseline, day-7 at day-28. For the analysis of disease dynamics, the final A-TANGO ACLF grade was determined within a time frame of 4-weeks, aligned with the occurrence of a clinical endpoint (death or liver transplant, at 28-days). *Validation cohort*: The Ambi-spective cohort, India (2055 patients). **Results:** The A-TANGO OF score at day-7 demonstrated improved prognostic accuracy compared to baseline, increasing from 0.793 to 0.822 (c-index) in predicting 28-day mortality. A one unit increase in the A-TANGO OF score at day-7 was associated with a hazard ratio (HR) of 1.479 and 1.369 for 28-day and 90-day mortality, which was confirmed in the validation cohort. Of 407 patients with A-TANGO ACLF at baseline, 44.9% achieved complete resolution, 33.4% remained stable, while 12.5% worsened within day-28.

Among patients without A-TANGO ACLF at baseline, 92 out of 1230 (7.5%) progressed to A-TANGO ACLF. The resolution of A-TANGO ACLF was associated with 28-day and 90-day mortality that is observed in patients with no ACLF; 3.5% and 16.7%. Reduction of A-TANGO ACLF grade corresponded to mortality rates of 7.7% and 20.4%, respectively. Worsening A-TANGO ACLF or development of new ACLF (in those without) had mortality rates of 59% and 21.8% at 28-days. These findings were consistent in the validation cohort. **Conclusion:** The results of this study show that A-TANGO ACLF is a dynamic condition, the course of which can be captured by the A-TANGO score, which responds to clinical intervention and makes it a suitable model to be used as an early surrogate marker of mortality. Improved precision helps reduce sample size and statistical errors and, strengthens the endpoint of ACLF resolution, ultimately optimizing the design and outcomes of clinical trials.

Clinical course patterns according to ATANGO organ failure score

Initial grade	Final grade				
	No ACLF (n=1321)	ACLF-1 (n=201)	ACLF-2 (n=61)	ACLF-3 (n=21)	ACLF-4 (n=33)
No ACLF (%)					
Prevalence (n=1230)	1138 (92.52)	71 (5.77)	17 (1.38)	1 (0.08)	3 (0.24)

4134 | IMPACT OF HEPATIC ENCEPHALOPATHY ON PROGNOSIS IN CIRRHOTIC PATIENTS WITH ACUTE DECOMPENSATION: THE CRUCIAL ROLE OF UNDERLYING LIVER FUNCTION AND COAGULATION FAILURE

Jung Hee Kim[1] JangHan Jung[1] Sung Eun Kim[1],
[1]Hallym university

Background: Hepatic encephalopathy (HEP) is a major complication of cirrhosis, resulting in significant impairment of the quality of life and frequent hospitalizations. HEP is considered one of the major components in the diagnosis of acute-on-chronic liver failure (ACLF), HEP is well known that it is associated with high mortality. However, there is controversial to whether HEP itself has a direct effect on the patient's prognosis and whether underlying liver function is important. This study aimed to investigate the impact of HEP on acute decompensation (AD) and adverse outcome (death or liver transplantation), utilizing real-world data. **Methods:** We analyzed prospective multicenter data collected from 31 hospitals in South Korea from 2015 to 2019. We included 1,315 patients diagnosed with liver cirrhosis who were admitted due to acute decompensation. A comparative analysis was conducted to assess the risk factors and the incidence of death or liver transplantation between patients with and without HEP. Propensity score (PS) matching was employed at a 1:3 ratio for accurate comparisons. PS were computed using the following 4 variables: age; sex; etiology of cirrhosis; and MELD score. **Results:** The mean age of the entire cohort was 54.7 years, with 74.9% being male. HE was noted in 14.7% of the cohort. Patients with HEP had positive correlations with ascites, jaundice and upper gastrointestinal bleeding. The median follow-up period was 8.0 months (range, 1.0–15.0 months), during which 332 patients (23.7%) either died or underwent liver transplantation. After adjusting for various factors, coexisting HEP did not increase the risk of death or liver transplantation for short-term and long-term. However, coagulation failure, underlying liver function such as prolonged prothrombin time, low serum albumin and elevated total bilirubin were revealed as major risk factors for short-term and long-term adverse outcomes. **Conclusion:** In patients with acute decompensation of liver cirrhosis, hepatic encephalopathy (HEP) was not an independent predictor of mortality or liver transplantation after adjusting for confounding factors. While HEP frequently coexisted with other severe complications, prognosis was more strongly influenced by underlying hepatic dysfunction, including coagulation failure, prolonged prothrombin time, hypoalbuminemia, and hyperbilirubinemia. These results highlight the prognostic importance of liver functional reserve rather than the presence of HEP alone.

4135 | NUTRITIONAL INTERVENTION FOR PATIENTS WITH LIVER FAILURE REDUCES THE RISK OF CLINICAL COMPLICATIONS

Xiong Pei[1] Wei Jiang[2] Dongbo Wu[1], [1]West China Hospital, Sichuan University, [2]Sichuan University West China Hospital

Background: Liver failure patients are at a high risk of developing various clinical complications. However, it remains unclear whether nutritional intervention can reduce the occurrence of adverse complications. **Methods:** This study included hospitalized patients diagnosed with liver failure at West China Hospital, Sichuan University. The Nutrition Risk Screening (NRS 2002) was used to assess the nutritional risk of the patients. For patients with nutritional risk, personalized additional enteral or parenteral nutrition was provided. To compare the differences between groups, the Kruskal-Wallis test was used for continuous variables, and the chi-square test was used for categorical variables. Multivariate logistic regression analyses were performed to calculate the odds ratios (OR) and 95% confidence intervals (CI) for the relationship between nutritional intervention and adverse clinical outcomes. **Results:** A total of 6097 liver failure patients were included in this study, with a median age of 53 years [interquartile range (IQR) 43, 64], and 69.2% of them were male. Hepatitis B accounted for 62.2% of the etiologies in the patients, and 1197 (19.6%) had liver cirrhosis. 555 (9.1%) were diagnosed with ascites, 191 (3.1%) with hepatorenal syndrome, 346 (5.7%) with hepatic encephalopathy, 792 (13.0%) with infection, 577 (9.46%) with coagulation disorder, 733 (12.0%) with spontaneous bacterial peritonitis. Among them, 3201 (52.5%) patients were at nutritional risk. Patients with nutritional risk were older and weighed less. Additionally, the incidence of hepatorenal syndrome, hepatic encephalopathy, infection, coagulation disorder, and all-cause mortality was significantly higher ($P < 0.01$). However, there was no change in the risk of ascites, spontaneous bacterial peritonitis. After adjusting for age, gender, height, weight, smoking, drinking, hypertension, diabetes mellitus, and education, for patients receiving nutritional intervention with nutritional risk, the OR and 95% CI of the risk of developing ascites were 0.50 (0.31-0.81), for infection were 0.70 (0.52-0.94), and for spontaneous bacterial peritonitis were 0.34 (0.24-0.49). However, there was no difference in the risk of hepatic encephalopathy, hepatorenal syndrome, and in the risk of coagulation disorder. Moreover, for patients without nutritional risk, nutritional intervention can also reduce the incidence of ascites [0.26 (0.12-0.55)], abnormal coagulation function [0.35 (0.17-0.72)], and spontaneous bacterial peritonitis [0.30 (0.17-0.54)]. **Conclusion:** Among patients with liver failure, 52.5% were found to be at nutritional risk. Personalized nutritional intervention can significantly reduce the risks of clinical complications regardless of nutritional risk.

4136 | ESTABLISHING A RANK-ORDERED HEIRARCHY OF ACLF RELATED MORTALITY RISK ASSOCIATED WITH ORGAN SUPPORT IN REAL WORLD CLINICAL PRACTICE

Kavin Parmar[1] Ana Oliveira[1] Vinay Jahagirdar[1] Ekaterina Smirnova[1] Katharina Staufer[2] Juan Pablo Arab[1] Richard Moreau[3] Jasmohan Bajaj[1] Arun Sanyal[1], [1]Virginia Commonwealth University, [2]GENFIT, [3]European Foundation for the Study of Chronic Liver Failure

Background: The number of organ failures (OF) and need for organ support are linked to mortality in ACLF. The impact of varying combinations of OFs and need for organ support on mortality in real-world clinical practice is unknown. Hypothesis: The number and type of OFs and need for organ support are differentially related to 30-day mortality in ACLF. Aims: To define (1) the impact of OFs, alone and in combination, on mortality in ACLF in real-world clinical practice and (2) within 2-4 OF combinations, the relationship of need for organ support to mortality. **Methods:** A retrospective analysis of hospitalized patients was performed using the TriNetX global collaborative network. ACLF was defined by diagnosis codes for cirrhosis with decompensation (ascites, encephalopathy or variceal hemorrhage) with one or more OFs, i.e. circulatory (hypotension, DIC etc.), brain (overt hepatic encephalopathy), renal (acute kidney injury [AKI]) and lung (respiratory failure). The use of pressors, renal replacement therapy (RRT), and ventilator support represented need for organ support. Odds ratio (OR) for 30-day mortality for those with one or combinations of OF versus controls admitted with cirrhosis decompensation without ACLF matched for age, race/ethnicity, sex, BMI, smoking status, type 2 Diabetes Mellitus, heart failure, chronic kidney disease, hypertension and chronic obstructive pulmonary disease were computed. Within combinations of OFs, the relationship between mortality and need for types of organ support was measured. **Results:** Up to 54,592 cases of ACLF with various combinations of OF were identified with matched controls. The rank-order of outcomes in single OF was: OR (95% CI): brain- 1.42 (1.3-1.6), circulatory- 1.87 (1.7-2), kidney- 3.2 (3-3.3), lung- 4 (3.7-4.3). The rank-order of outcomes for 2 OF were: circulatory-brain- 2.9 (2.5-3.4), kidney-brain- 5.2

(4.6-5.8), kidney-circulatory- 5.5 (5.1-5.8), lung-circulatory- 6.2 (5.5-6.9), lung-brain- 8.9 (7.1-11.3), lung-kidney- 11.9 (11.2-12.7). Those with 3-OF lung-kidney-brain- 18.1 (15.4-21.1) and 4-OF lung-kidney-brain-circulatory- 19.7 (18-21.5) had the highest mortality. The impact of type of organ support for each 2-4 OF combinations on mortality is shown in the Table. **Conclusion:** ACLF is heterogeneous in its outcome-profile with a hierarchy of mortality risk based on types of OF and organ support. These can inform trial design and development of hierarchical endpoints.

Background: Acute-on-chronic liver failure (ACLF) is characterised by multiorgan failure and high short-term mortality in hospitalised cirrhosis patients with acute decompensation (AD). While the EASL-CLIF criteria are widely used for its diagnosis and prognosis, evolving definitions of organ dysfunction and emerging therapies call for updated, tailored criteria to ensure accurate diagnosis, enable effective treatment assessment, and enhance applicability in clinical trials. The aims of the study were to develop and validate the new ATANGO organ failure (OF) score to enhance the diagnosis of ACLF and improve its utility for assessing treatment response and risk stratification for clinical trials. **Methods:** A retrospective analysis of prospective, observational cohort studies. Derivation cohort: 3 studies performed by the EF-CLIF consortium in Europe and Latin America (CANONIC, PREDICT, and ACLARA; n = 3896). Validation cohorts: 1 from India (Ambi-spective, n = 2055) and 1 from China (Catch-life, n = 2568). Patients were enrolled in these studies between 2011 and 2023 and last follow-up was completed in 2023. The main outcome was to redefine thresholds of organ dysfunction and failure based on 3 subscores per organ, with subscore 3 indicating $\geq$ 15% 28-day mortality and defining OF. **Results:** Compared to the CLIF-C OF score, the ATANGO OF score

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

introduced significant changes to thresholds for diagnosing OF and included an additional ACLF grade 4, addressing the wide range of mortality in the CLIF-C OF grade 3 subgroup. The ATANGO OF score identified a significantly higher number of OFs, increasing the diagnosis of ACLF from 24% to 36% and improving the net reclassification index by 16%. The ATANGO OF score exhibited non-inferior predictive accuracy for 28- and 90-day mortality. In addition, two new prognostic ACLF scores were developed (ATANGO ACLF-WBC and ACLF-CRP score), showing strong correlations with 28-day and 90-day mortality. The diagnostic and prognostic ability of the ATANGO scores were confirmed in the validation cohorts. **Conclusion:** The ATANGO OF score is a more accurate, reproducible, and comprehensive tool for diagnosing ACLF with well maintained prognostic ability, validated in large global cohorts. The ATANGO OF score offers a robust tool for clinical trials enabling more reliable diagnosis, reducing the required sample size and providing readily assessable clinical endpoints, such as ACLF resolution, to define treatment responses effectively.

Table 1. Cut-off values and outcome data of the ATANGO OF scoring system.

Organ system	Subscore 1	Subscore 2	Subscore 3[a]
Liver (n=2911)			
Cut-off value	Bilirubin <6 mg/dL	Bilirubin ≥6 and <20 mg/dL	Bilirubin ≥20 mg/dL
Amount of patients (%)	77.5 (n=2256)	18.8 (n=547)	3.7 (n=108)

[a]Individual organ failures are defined by an ATANGO subscore of 3. The definitions of ATANGO ACLF grades are as follows. **No ATANGO ACLF:** patients without liver, kidney, coagulation and respiration failure or patients with single brain or single circulatory failure without reaching for subscore 2 for the other 4 organs (n=2340, 64.2%). These patients had a 28-day mortality of 4.9% and a 90-day mortality of 14.4%. **ATANGO ACLF grade 1:** single liver, kidney, coagulation or respiration failure. Respiratory failure did not reach the 3% minimum sample size for subscore 3 but was significantly different from subscore 1, hence improving the sample size included in subscore 3. Brain failure did not meet the minimum criteria for subscore 3, so an additional organ dysfunction is required to diagnose ATANGO ACLF. For circulatory failure no improvement was achieved, meaning that the old threshold included in CLIF-OF still applies, and an additional organ dysfunction is required to diagnose ATANGO ACLF. These patients had a 28-day mortality of 19.9% and a 90-day mortality of 31.8%. **ATANGO ACLF grade 2:** patients with two organ failures (subscore 3). These patients had a 28-day mortality of 36.2% and a 90-day mortality of 47.7%. **ATANGO ACLF grade 3:** patients with three organ failures (subscore 3). These patients had a 28-day mortality of 55.5% and a 90-day mortality of 59.4%. **ATANGO ACLF grade 4:** patients with four or more organ failures to allow better prognostic discrimination. This adjustment was made because the mortality rate differed significantly between patients with three organ failures and those with four to six organ failures (28-day mortality p=0.0029, 90-day mortality p=0.0016) (eFigure. 1). Patients with ATANGO ACLF grade 4 had a 28-day mortality of 76.1% and a 90-day mortality of 80.7%.
[b]Grades are defined by the West Haven criteria; [c]Mechanical ventilation for the indication of cerebral failure; [d]Vasopressor use for the indication of circulatory failure; [e]Mechanical ventilation for the indication of respiratory failure.

4138 | MACROPHAGE POLARIZATION MEDIATED BY THE INTERACTIONS OF HYPOXIA-INDUCIBLE FACTOR 1A AND CBP/P300 INTERACTING TRANS-ACTIVATOR PLAYS AN IMPORTANT ROLE IN DISEASE PROGRESSION OF HEPATITIS B VIRUS-RELATED ACUTE-ON-CHRONIC LIVER FAILURE

Yubao Zheng[1] Yanyan Zhang[1] Yurong Gu[2] Yi Wu[1] Dandan Chen[1], [1]The Third Affiliated Hospital of Sun Yat-sen University, [2]Guangzhou First People's Hospital, South China University of Technology

Background: Acute-on-chronic liver failure (ACLF) is a deadly disease state of HBV infection that is often accompanied by immune paralysis. Our previous work has demonstrated the significant role of macrophage polarization in immune paralysis, but the specific mechanism of macrophage polarization in HBV-ACLF remains unclear. We aim to investigate the role of Hypoxia-Inducible Factor 1α (HIF-1α) and CBP/P300 interacting trans-activator with Glu/Asp-rich carboxy-terminal domain 2(CITED2) in mediating macrophage polarization during the onset and development of HBV-ACLF. **Methods:** We constructed a THP-1 macrophage model to verify the interaction of HIF-1α and CITED2 in macrophage polarization. Simultaneously, we investigated the expression levels of HIF-1α and CITED2 in peripheral blood mononuclear cells (PBMC) and monocyte-derived macrophages (MDM) from hepatitis B virus-infected patients with immune tolerance phase (n = 13), immune activation phase (n = 107), compensated cirrhosis(CC)(n = 55), decompensated cirrhosis (n = 36), HBV-ACLF (n = 54), and healthy controls (n = 30). Additionally, we conducted further tests on the expression and distribution of HIF-1α and CITED2 in normal liver tissues as well as liver tissues from patients with HBV-related liver failure. **Results:** HIF-1α and CITED2 were competitively expressed in the THP-1 macrophage polarization model(Figure-II. A-D). Pro-inflammatory macrophage M1 produced more ROS than anti-inflammatory macrophage M2, and this effect was more significant after CITED2 knockdown(Figure-III. A-E). With the progression of HBV-related liver disease, the expression of HIF-1α in peripheral blood MDM of patients showed a tendency to rise and then fall, and reached the peak at CC stage. Meanwhile, CITED2 expression showed a completely opposite trend and reached the lowest point in CC stage. Interestingly, HIF-1α expression tended to be opposite in PBMC and MDM (Figure-IV. A-D). Pro-inflammatory and anti-inflammatory factors in plasma of the ACLF group were significantly higher than those in the chronic hepatitis B group and CC group, indicating that inflammatory response increased with the progression of disease severity(Figure-V.A-E). Expression level of HIF-1α and CTIED2 were significantly increased in liver failure liver tissue compared with normal liver tissue, same as the number of Kupffer cell(Figure-I. A-C). **Conclusion:** This study showed that macrophage polarization mediated by HIF-1α and CITED2 interactions plays an important role in HBV-ACLF. And the knockdown of CITED2 can induce macrophage polarization to M1 to rescue immune paralysis of ACLF.

Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Disease, Huazhong University of Science and Technology

Background: Tenofovir amibufenamide fumarate (TMF) is a novel nucleotide reverse transcriptase inhibitor and the first-line oral drug developed originally in China for the treatment of adults with chronic hepatitis B virus (HBV) infection. However, the efficacy and safety of TMF in patients with acute-on-chronic liver failure (ACLF) has not been explored. **Methods:** A total of 196 patients with ACLF from 13 tertiary hospitals in China were divided into TMF, tenofovir alafenamide fumarate (TAF), tenofovir disoproxil fumarate (TDF), and entecavir (ETV) groups based on the antiviral drugs used. The complete blood count, liver and kidney function, coagulation function, and virological data were assessed for patients in each group at baseline and after 4 weeks of treatment. Additionally, the 28-day mortality rate was evaluated. **Results:** There were no significant statistical differences in the baseline data among the four groups of patients with ACLF, ensuring comparability and allowing for a robust analysis of the treatment effects. The 28-day survival rates for patients in the TMF, TAF, TDF, and ETV groups were 89.62%, 85.19%, 79.31%, and 82.76%, respectively, with no significantly differences ($P = 0.410$). After four weeks of antiviral therapy, patients in the TMF (Median, 5.35×105 vs. 6.37×102 IU/ml, $P < 0.001$), TAF (Median, 7.84×105 vs. 2.54×102 IU/ml, $P < 0.001$), TDF (Median, 8.84×104 vs. 8.13×102 IU/ml, $P = 0.004$), and ETV (Median, 5.89×105 vs. 1.00×102 IU/ml, $P < 0.001$) groups all experienced an obvious reduction in HBV DNA levels. Patients in the TMF group experienced significant declines in aspartate aminotransferase (AST) levels (Median, 240 vs. 59 U/L, $P < 0.001$), alanine aminotransferase (ALT) levels (Median, 304 vs. 42 U/L, $P < 0.001$), bilirubin levels (Median, 214.0 vs. 144.8 μmol/L, $P = 0.002$), and international normalized ratio (INR) levels (Median, 1.80 vs. 1.66, $P = 0.014$), and patients in the TAF group also showed similar improvements. However, in the TDF and ETV groups, only AST and ALT levels significantly reduced after 4 weeks of treatment, while bilirubin ($P = 0.840$ for TDF group, $P = 0.053$ for ETV group) and INR ($P = 0.815$ for TDF group, $P = 0.544$ for ETV group) levels remained largely unchanged. Additionally, there were no significant changes in blood cell counts, creatinine levels, and estimated glomerular filtration rate (eGFR) levels among all four groups of patients. **Conclusion:** TMF exhibits an antiviral activity in patients with HBV-related ACLF, enhances liver and coagulation functions, and without adverse effects on renal function.

4140 | DIRECT CHEMICAL REPROGRAMMING OF URINE-DERIVED STEM CELLS FROM ACLF PATIENTS INTO FUNCTIONAL HEPATOCYTE-LIKE CELLS FOR LIVER INJURY THERAPY

Jiateng Zhang[1] Pengfei Yu[1] Jiaqi Zhang[1] Huaibin Zou[1] Yu Chen[1] Zhongping Duan[1], [1]Beijing YouAn Hospital, Capital Medical University

Background: The high mortality rate of acute-on-chronic liver failure (ACLF) and the shortage of liver donors for transplantation must be urgently addressed. Urine-derived stem cells (USCs) are a highly promising source of autologous chemotaxis cells due to their simple and non-invasive acquisition, strong proliferative and immunomodulatory properties. In this study, we innovatively adopted a direct chemical reprogramming strategy to avoid the risk of genetic modification and directly transformed ACLF patient-derived USCs (LF-USCs) into chemically induced hepatocytes (CiHeps) through a combination of small molecule compounds, aiming to establish a safe, efficient, and patient-specific hepatocyte preparation system for new pathway for individualized treatment of ACLF. **Methods:** LF-USCs were isolated from urine samples of ACLF patients via centrifugation, expanded in culture, and characterized by surface marker analysis. Using a defined combination of small molecule compounds and cytokines, we directly reprogrammed LF-USCs into CiHeps without genetic modification. To evaluate hepatic functionality, CiHeps were transplanted into a Fah−/−Rag2−/−Il2rg−/− (FRG) mouse model of liver failure. **Results:** We successfully extracted LF-USCs from the urine of ACLF patients and cultured them for multiple generations. Importantly, we established a stage-specific induction protocol that enables rapid differentiation of LF-USCs into CiHeps within 15 days in vitro by using a specific chemical mixture, which consists of three stages: stereotyped endoderm (DE), hepatic progenitor cells (HPC), and hepatic differentiation and growth. The results showed that the cell morphology gradually changed from an initial “rice grain” shape to a tightly packed cube, similar to hepatocytes. After induction, most CiHeps expressed genes specific to mature hepatocytes and possessed the basic functions of hepatocytes. RNA sequencing, metabolic assays, and in vivo functional studies demonstrated that CiHeps exhibit hepatic activity and functionality comparable to

primary hepatocytes. Notably, in the Fah−/−Rag2 −/−Il2rg−/− (FRG) mouse model, CiHeps effectively contributed to liver repopulation and ameliorated liver failure in vivo. **Conclusion:** We established a safe and efficient chemical reprogramming strategy to convert patient-derived urine stem cells into functional hepatocyte-like cells. These CiHeps demonstrated comparable function to primary hepatocytes and effectively rescued liver failure in FRG mice, highlighting their potential for personalized cell therapy in ACLF.

4141 | HDL-C, CHOLESTEROL AND THE ALT/HDL-C RATIO ARE PREDICTORS OF SURVIVAL IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE

Georg Kramer[1] Vlad Taru[1] Benedikt Simbrunner[1] Benedikt Hofer[1] Nina Dominik[1] Lorenz Balcar[1] Lukas Hartl[1] Mathias Jachs[1] Michael Schwarz[1] Christian Sebesta[1] Georg Semmler[1] Paul Thoene[1] Philipp Schwabl[1] Michael Trauner[1] Mattias Mandorfer[1] Thomas Reiberger[1], [1]Medical University of Vienna

Background: Progression to cirrhosis is commonly linked to reduced high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and total cholesterol, reflecting hepatic dysfunction. As HDL-C modulates systemic inflammation, hypolipoproteinemia may impact on acute-on-chronic liver failure (ACLF). This study aimed to characterize lipid profile trajectories (HDL-C, LDL-C, total cholesterol, and triglycerides) and assess their prognostic utility in ACLF. **Methods:** We retrospectively identified patients with ACLF (EASL-CLIF criteria) at the Vienna General Hospital between 11/2003 and 11/2022. Data were collected at pre-ACLF (30-365 days before diagnosis), at diagnosis (D0), and days 7 (D7), 28 (D28), and 90 (D90) thereafter. Primary endpoints were mortality at D28 and D90. Discrimination was evaluated using area under the receiver operating characteristic curve (AUROC) compared via DeLong's test. Cox regression models – adjusted for MELD, age, sex and C-reactive protein (CRP) – were used to identify independent predictors of mortality. **Results:** The study included 164 patients with ACLF (G1: 80 (48.8%), G2: 53 (32.3%), G3: 31 (18.9%)). By D28 and D90 respectively, 60 (36.6%) and 85 (51.8%) patients died. HDL-C and total cholesterol concentrations were significantly higher pre-ACLF compared to D0 ($p < 0.001$) and recovered by D90 ($p < 0.001$ vs. D0). LDL-C showed similar dynamics (pre-ACLF vs. D0: $p = 0.022$; D0 vs. D90: $p = 0.009$), while triglyceride levels remained largely stable.
At D0, HDL-C exhibited comparable AUROCs to the CLIF-C ACLF score for D28 (0.724 vs. 0.787) and D90 (0.736 vs. 0.752) mortality. With higher alanine aminotransferase (ALT) levels in advanced ACLF (G1 vs. G3: $p < 0.001$; G2 vs. G3: $p = 0.020$), prognostic impact of the ALT/HDL-C ratio was analyzed, yielding numerically higher AUROCs for D28 (0.817) and D90 (0.816) mortality discrimination than the CLIF-C ACLF score. ALT/HDL-C independently predicted both D28 (aHR: 1.028, $p < 0.001$) and D90 (aHR: 1.030, $p < 0.001$) mortality in multivariable models. Stratification using the ALT/HDL-C ratio (< 2 vs. ≥ 2), HDL-C (< 20 vs. ≥ 20 mg/dL) and total cholesterol (< 80 vs. ≥ 80 mg/dL), proved effective (all log-rank $p < 0.01$). **Conclusion:** Reductions in HDL-C and total cholesterol are common in ACLF and reflect ACLF trajectory. The ALT/HDL-C ratio represents a robust and easily accessible prognostic ACLF biomarker score enabling bed-side risk stratification using routine laboratory parameters.

Background: Acute-on-chronic liver failure (ACLF) patients frequently have hyperbilirubinemia and hypoalbuminemia. The albumin-bilirubin (ALBI) score has been developed as an index of liver dysfunction for prognostication in hepatocellular carcinoma patients. Ithas not been evaluated in the context of ACLF patients. We studied ALBI score in determining organ failures and mortality in a large multicentric-multinational cohort of ACLF patients of alcohol etiology. **Methods:** In a prospective cohort of alcohol-related ACLF patients from AARC (n = 2427) we evaluated whether ALBI score could determine the development of extrahepatic organ failures mortality and ICU admission. **Results:** ACLF patients, aged 46.8 ± 21.3 years, 87% males, mean MELD score 30.1 < i style = 'mso-bidi-font-style:normal' > ± 7.6 < v: shapetype id = "_x0000_t75" coordsize = "21600,21600" o:spt = "75" o:preferrelative = "t" path = "m@4@5l@4@11@9@11@9@5xe" filled = "f" stroked = "f" > o:title = "" chromakey = "white"/ > , AARC 9.6 ± 2.1 and ALBI score of 1.7 ± 0.15 were assessed. At enrolment 30% had acute kidney injury, 10% had sepsis. At day 4, 19% developed kidney failure (KF), 54% circulatory failure (CF), 1.9% respiratory failure (RF) while 2.9% developed cerebral failure (CBF). A significant correlation of ALBI score was observed with the number of organ failures ($p = 0.001$, $r = 0.29$), with KF ($p < 0.001$, $r = 0.20$) and CF ($p < 0.001$, $r = 0.58$) but not with CBF ($p = 0.95$) and RF ($p = 0.90$). On multivariable binary logistic regression analysis, ALBI score (OR 2.85, 1.08-7.55), higher leucocyte counts (OR 1.03, 1.02-1.05) and lower serum bicarbonate (OR 0.87, 0.85-0.90) predicted kidney failure. The ALBI score (OR 6.9, 2.9-16.7) was an independent predictor of KF after adjusting for MELD and AARC scores but not for CF (OR 0.67, 0.38-1.19). Stratification by ALBI score Grade 1 < -1.59 (as ref), grade 2 (1.59-1.76) (HR 1.19, 1.02-1.37) and grade 3 > 1.76 (HR 1.52, 1.30-1.780) predicted mortality. The ALBI score was independently associated with ICU admission (OR 5.03, 1.42-17.77) along with higher arterial lactate (OR 1.42, 1.21-1.67), serum creatinine (OR 1.42, 1.22-1.65) and presence of systemic inflammatory response syndrome (OR 2.29, 1.62-3.24). **Conclusion:** The ALBI could be a very simple and easy screening tool which could identify alcohol-related ACLF patients at risk of kidney failure, transfer to ICU and mortality. It however, was not sensitive for cerebral failure. Stratification using a combination of ALBI and AARC could be useful for prediction of mortality. Targetting the components of ALBI using extracorporeal therapies or intravenous albumin and dynamic assessment should be evaluated for improving outcomes of ACLF patients.

4143 | DYNAMIC CHANGES IN SPLEEN STIFFNESS PREDICTS OUTCOME OF ACLF PATIENTS BY DAY-7 - A PROSPECTIVE STUDY [NCT06069284]

Sudhir Verma[1] Chitranshu Vashishtha[1] Manoj Kumar Sharma[2] Rakhi Maiwall[2] Saggere Muralikrishna Shasthry[2] Rajan Vijaraghvan[2] VINOD ARORA[2] Harsh Vardhan Tevethia[2] Satender Pal Singh[2] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, New Delhi, [2]ILBS, New Delhi

Background: Early identification of acute on chronic liver failure (ACLF) patients with high risk of mortality is important to prioritize the need for ICU monitoring and liver transplantation (LT). In ACLF, inflammation and acute rise in portal pressure drives the outcome and can raise liver (LSM) and spleen stiffness (SSM). Compared to liver cirrhosis, studies evaluating dynamic changes in LSM and SSM assessing outcomes in ACLF are lacking. We prospectively evaluated whether acute changes in LSM and SSM on day 7 and 14 from baseline predicts day-90 outcome in ACLF patients. **Methods:** Patients of ACLF (APASL criteria) between 18 to 70 years of age were included. The primary objective was to assess predictive accuracy of dynamic LSM and SSM changes on day 7 from day 0 for transplant-free survival at day-90. The secondary objective was to compare LSM and SSM on day-14 from day-0 between those with or without transplant free survival at day-90. **Results:** Study included 117 patients{mean age 40.9 $\pm$8.6 yrs, males 88.9.%, alcohol associated 83.76 %} with ACLF. At day-90, 80 (68.4%) patients had LT free survival, with 32 (27.35%) deaths and 5 (4.27%) LT. Mean baseline AARC score among survivors and non-survivors was 7.68 $\pm$ 1.37 and 10.14 $\pm$ 1.25 respectively ($p < 0.001$). Baseline SSM among survivors and non-survivors was 77.4 $\pm$ 20.8 and 86.3 $\pm$ 16.3 kPa respectively ($p = 0.034$). Mean change in SSM(Δ SSM) at day-7 among survivors and non-survivors was-2.14 $\pm$ 1.22(-2.76%) and +4.83 $\pm$ 2.16(+5.5%) respectively ($p = 0.004$). Δ SSM at day-14 from day-0 among survivors and non-survivors was-10.12 $\pm$ 1.67(-13.07%) and + 6.40 $\pm$ 2.71(+7.41%) respectively ($p < 0.001$). Baseline LSM among survivors and non-survivors were 70.95 $\pm$ 9.13 and 73.56 $\pm$ 4.63 kPa respectively($p = 0.11$). Mean change in LSM among survivors and non-survivors at day 7 { -0.69 $\pm$ 0.63(0.95%) and -0.11 $\pm$ 0.85(0,15%) ($p = 0.6$)} and day14 {-1.83 $\pm$ 0.95 and -0.08 $\pm$ 0.75 kPa respectively ($p = 0.15$)} were not different. Other predictors of LT free survival on day-7 were delta AARC score (OR 1.79, 95% CI: 1.17-2.77, $p = 0.008$), delta TNF a (OR 1.09, 95% CI:1.03-1.15, $p = 0.003$), delta CRP (OR 1.03, 95% CI: 0.99-1.06, $p = 0.07$) and baseline SSM (OR1.03, 95% CI:1.01-1.05, $p = 0.03$). **Conclusion:** Baseline SSM and serial changes in SSM on day 7 and 14 are reliable and a promising tool for predicting 90-days outcome in ACLF patients. A lower SSM, with further reduction favors survival, while an increase of 5.5% in SSM at day 7 indicate non-survival.

4144 | HIGH RISK READMISSION FOLLOWING DISCHARGE HOME FROM EXPEDITED LIVER TRANSPLANT EVALUATION

Katherine Cooper Kathy Nguyen[1] Mary Flynn[1] Navine Nasser-Ghodsi[1], [1]UMass Chan Medical School

Background: An expedited, inpatient liver transplant evaluation (eLTe) is necessary for some critically ill patients with chronic liver disease (CLD) and acute on chronic liver failure (ACLF) but is associated with poor outpatient, transplant-free survival. We assessed risk factors for readmission following discharge to home from eLTe, with a focus on advanced care planning (ACP) initiatives. **Methods:** This is a single center, retrospective study of patients with CLD/ACLF who underwent eLTe from 2019-2021. The primary outcome was readmission within 30 days of home-discharge, referred to as high-risk home discharge (HR-HDC).We fit multivariable logistic regression models to identify the strongest predictors of HR-DC using backward elimination. The final model was developed using stepwise addition of clinically relevant covariates to maximize model discrimination via area under the receiver operating curve (AUROC). Significance was evaluated at $p < 0.05$ and $p < 0.15$ was considered a trend. A risk calculator was created, which is housed in NetLify, and accessible publically via QR code (Figure 1). **Results:** Among 165 patients with eLTe, 24.8% underwent LT (n = 42), 16.4% died or transitioned to hospice (n = 27), 13.2% discharged to a facility (n = 22), and 46.1% discharged home (n = 74), following eLTe. Among those discharged (n = 96), 45.8% were remitted, without differences by discharged location (p = 0.31). Among those discharged home, 36 patients (48.6%) were HR-DC. HR-DC patients had higher rates of ACP documentation (14% vs. 3%, p = 0.09), goals of care conversations (17% vs. 3%, p = 0.05) and palliative care (PC) consult during eLTe (17% vs. 5%, p = 0.14); they were also less likely to be evaluated for alcohol associated hepatitis (8.3% vs. 23.7%, p = 0.05). There were no differences by gender (p = 0.61), age (p = 0.68), MELD-Na (p = 0.37), or hospital length of stay (p = 0.84, LOS). A similar proportion of listed and non-listed patients were readmitted as well (p = 0.80). On backward regression, education less than high school (OR 3.3, 95% CI 0.9-12.5) and PC consult (OR 5.3, 0.8-34.4, p = 0.08) were risk factors and activated medical decision maker (OR 0.10, 95% CI 0.01-1.10, p = 0.06) and discharge from the hepatology versus hospital medicine service (OR 0.35, 95% CI 0.12-1.01, p = 0.05) were protective factors against HR-HDC. A final model with inclusion age, LOS > 14 days, CLD etiology, relationship status, and albumin level at admission had significantly higher discrimination than significant predictors alone (AUROC 0.80 vs. 0.72, p = 0.05) (Figure 1). **Conclusion:** Many patients with eLTe experience short-term readmission, independent of listing decision. Contrary to our hypotheses, ACP endpoints conferred higher risk of early readmission. This may reflect providers' ability to risk stratify patients, rather than the potential effect of a PC consult or ACP. Further research is needed to explore the role of ACP in this high-risk group.

High Risk Readmission Following Discharge Home from Expedited Liver Transplant Evaluation

Variable in Final Model	OR	95% CI	p
Palliative care consult*	10.73	1.1-102	0.039
Did not graduate HS*	2.58	0.6-11.1	0.203
MDM activated*	0.17	0.0-2.1	0.170
Hepatology attending at d/c*	0.33	0.1-1.0	0.054
Age>50 years	0.40	0.1-2.0	0.267
LOS< 14 days	1.67	0.3-8.1	0.525
Albumin <2.5 mg/dl	2.07	0.5-8.6	0.317
Listed or pending decision at d/c	0.70	0.2-2.3	0.554
Early sobriety/AH	0.09	0.0-0.8	0.032
Stable partner/relationship	0.79	0.2-2.5	0.691

4145 | WINDOW FOR PLASMA EXCHANGE (PLEX) IN ALCOHOL-RELATED ACLF (KYOTO CONSENSUS): PSM ANALYSIS OF 1-YEAR SURVIVAL WITH PLEX (WITH LOW DOSE STEROID) VS STANDARD MEDICAL TREATMENT

Santhosh Kumar[1] Lakshmi Nivedana[1] Gayathiri Chellaiya[1] Dolly Daniel[1] Uday Zachariah[1] Ashish Goel[1] Ashwani Singal[2] C Eapen[1], [1]Christian Medical College, Vellore, India, [2]University of Louisville

Background: Plasma exchange for Alcohol-related Acute on Chronic Liver Failure (A-ACLF) has shown survival benefit. The optimal patient for PLEX in this group is not known. We compared survival in A-ACLF patients treated with centrifugal PLEX (cPLEX) (with low-dose steroid) versus standard medical treatment (SMT). **Methods:** We included consecutive A-ACLF patients treated from a single centre between 2018 to 2024. We excluded patients with active infection and hypotension. Patients with A-ACLF were classified as ACLF A (implies APASL ACLF) or ACLF B (implies EASL ACLF) as per the Kyoto consensus definition. PLEX-treated patients received centrifugal low-volume (0.5 x plasma volume per session) and low-dose steroids (during the peri-PLEX period). SMT patients received supportive care without steroids. The primary outcome was 1-year transplant-free survival. Propensity score matching was done using the nearest neighbour technique with a match tolerance (calliper) of 0.03 adjusting for differences in MELD and CLIF-SOFA. Survival analysis was done using the log-rank test. **Results:** Of 300 patients with A-ACLF in the study period, 124 patients received PLEX and 176 received SMT. Following PSM there were 124 patients in each group. Baseline liver severity parameters were similar between PLEX vs SMT for MELD 30.2 (±6.6) vs 30.8 (±7.3), CLIF SOFA 9.5 (±1.3) vs 9.5(±1.5)] and significantly different for bilirubin 22.3 (±7.5) mg/dl vs 19.2 (±9.1) mg/dl, creatinine 1.1 (0.7-1.6) mg/dl vs 1.2 (0.8-2.2) mg/dl and DF 104 (77-138) vs 88 (68-111) respectively. No patient was intubated or on vaso-pressors before initiation of PLEX. Three and 13 patients each were lost to follow-up in PLEX and SMT groups respectively. ACLF A classification into sub-groups (A1, A2, A3) was possible for only 96 patients (due to missing serum lactate). On follow-up [73 (16-365) days,median (IQR)] of PSM matched groups (121 PLEX vs. 111 SMT), there was no difference in patient survival, HR 0.8 (0.57-1.1), p-0.2. Survival among ACLF A1, A2, A3, no EASL ACLF, B1, B2 and B3 are shown in the Figure below. Survival was significantly better with PLEX compared to SMT in ACLF A3 and ACLF B2 subgroups. Limitations of the study include retrospective cohorts and small sample in certain subgroups. **Conclusion:** ACLF A3 and ACLF B2 sub-groups of A-ACLF patients (with no infection/shock) have better one-year transplant-free survival when treated with PLEX and low-dose steroids compared to SMT. Our study findings may help in selecting A-ACLF patients for PLEX therapy.

4146 | INFECTION RATHER THAN BILE ACID LEVELS PREDICT MORTALITY IN ALCOHOL ASSOCIATED ACUTE ON CHRONIC LIVER FAILURE

Jaifrin Daniel[1] Shiv Kumar Sarin[2] Ankur Jindal[2] Ashok Kumar Choudhury[2] VINOD ARORA[2] Omkar Rudra[2] Guresh Kumar[2], [1]Institute of Liver And Biliary Sciences, New Delhi, [2]Institute of Liver & Biliary Sciences, New Delhi

Background: Acute on chronic liver failure due to severe alcoholic hepatitis is associated with high 28-day mortality. Ethanol is the primary hepatotoxic insult. Bile acids which are traditionally considered injurious in cholestatic liver diseases may have a role in ACLF pathophysiology. Bile acids are increasingly recognized not only for their cytotoxic potential but also for their regulatory functions in inflammation and metabolism. In this study, we aimed to explore the prognostic significance of serum bile acid levels and other inflammatory markers in patients with ACLF due to SAH. **Methods:** It is a retrospective study of patients admitted with ACLF due to severe alcoholic hepatitis and had serum bile acids at baseline. The study period was from January 2015 to April 2025. Electronic medical records were assessed to get the relevant information and were analysed. **Results:** There was total 225 patients in our study. There was male predominance noted, among non survivors all individuals were male. Mortality was seen in 74 (32.8%) individuals. We did univariate analysis to assess the predictors of mortality, WBC count: 19.6 +/- 10.3 vs 15.2 +/- 7.7, p:0.002, S. Creatinine: 2.3 +/- 1.5 vs 1.5 +/- 1.2, p:0.019, Procalcitonin: 1.02 (0.6-2.2) vs 0.63 (.42-1.1), p:0.02 were elevated among the non survivors. Serum Bile acid was 128.6 +/- 62.1 vs 150.7 +/-53.1, p:0.01 among non-survivors and survivors respectively. Baseline MELD, CTP and AARC score was higher among the non survivors as compared to survivors. Inflammatory markers (C- Reactive protein and TNF alpha) were statistically non-significant between the two groups. Multivariate analysis was done to predict the factors associated with mortality, it showed that serum Procalcitonin with HR of 1.066 (CI: 1.039 - 1.094, p:0.000) was associated with increased mortality while serum bile acid with HR of 0.992 (CI: 0.987 - 0.997, p:0.002 was associated with reduced mortality. **Conclusion:** In our study baseline procalcitonin and bile acids were the predictors of mortality in acute on chronic liver failure due to severe alcoholic hepatitis. Elevated procalcitonin reflects systemic inflammatory burden and is associated with poor prognosis, while higher serum bile acids may provide a survival advantage. This highlights the need for further research in the role of bile acids in ACLF.

4147 | DEVELOPMENT AND VALIDATION OF AN EXPLAINABLE MACHINE LEARNING MODEL FOR PREDICTING INVASIVE FUNGAL INFECTION IN ACUTE-ON-CHRONIC LIVER FAILURE WITHIN 28 DAYS

Ronghua Jin[1] Feixiang Xiong[1] Xuejie Zhang[1] Yang Zhou[1] Xiaomin Ji[1] Yixin Hou[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Acute-on-chronic liver failure (ACLF) is associated with significantly higher short-term mortality, and the presence of invasive fungal infection (IFI) further increases this risk. This study aims to develop an ML model that predicts the risk of IFI in ACLF patients. **Methods:** This study included 1,112 patients divided into a training set and a validation set, with another 188 patients serving as an external validation cohort. The Recursive Feature Elimination (RFE) method was used to select the most significant variables for model development. Four machine learning algorithms were compared to identify the optimal model. The models were evaluated and compared using C-index, time-dependent ROC curves, decision curve analysis (DCA), and calibration curves. The LIME (Local Interpretable Model-Agnostic Explanations) method was used to identify the high-risk populations utilized by the model. **Results:** 778 patients were included in the training set, 334 in the internal validation set, and 188 in the external validation set. The study found that Random Forest (RF) was the best-performing ML algorithm. In the training set, the RF model achieved an AUROC of 0.922 (0.911-0.933), significantly higher than MELD (0.854, 0.835-0.873, $P < 0.001$), CLIF-C OF (0.753, 0.724-0.783, $P < 0.001$), and CLIF-C ACLF (0.879, 0.863-0.896, $P = 0.020$). The same trend was observed in both the internal and external validation sets. The time-dependent ROC curve showed that the RF model outperformed the other scores for predicting the risk of IFI in 28 days. DCA and calibration curves also demonstrated superior clinical benefits for the RF model across all datasets. LIME revealed bacteria infection (BI), Na < 136 mmol/L, CRP (C-reactive protein) > 20.1 g/L, and TBIL(Total Bilirubin) > 196.7 μmol/L as the high-risk groups. **Conclusion:** The RF model effectively predicts the risk of IFI in ACLF patients. The application of LIME enables the identification of high-risk populations, providing clinical value for patient management.

4148 | PERFORMANCE OF THE CHINA-CLIF FRAMEWORK IN ACUTE-ON-CHRONIC LIVER FAILURE: A MULTI-COHORT STUDY ACROSS ALL AETIOLOGIES

Jun Li[1] Jinjin Luo[1] Meiqian Hu[1] Tingting Feng[2] Liyuan Zhang[3] Yan Huang[4] Yuxian Huang[5] Feng Ye[6] Jiang Li[7] Ferran Aguilar[8] Cristina Sánchez-Garrido[8] Eva Maria Uson Raposo[8] Paolo Angeli[9] Rajiv Jalan[10] Bingliang Lin[11] Yu Chen[12] Shaoli You[13] Xin Chen[14] Alberto Queiroz Farias[15] Jonel Trebicka[16] Jing Jiang[1] Richard Moreau[8], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, [2]The First Affiliated Hospital of Suzhou University, [3]The Second Affiliated Hospital of Hainan Medical University, [4]Xiangya Hospital, Central South University, [5]Huashan Hospital, Fudan University, [6]The First Affiliated Hospital of Xi'an Jiaotong University, [7]The First Affiliated Hospital of Anhui Medical University, [8]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [9]University of Padova, [10]University College London Medical School, [11]The Third Affiliated Hospital of Sun Yat-sen University, [12]Beijing Youan Hospital, Capital Medical University, [13]The Fifth Medical Center of Chinese PLA General Hospital, [14]Zhejiang University School of Medicine, [15]Hospital das Clínicas, University of São Paulo School of Medicine, [16]Department of Internal Medicine B University Clinic Münster

Background: Acute-on-chronic liver failure (ACLF) of various aetiologies is a complex syndrome with high short-term mortality and significant global burden. This study aimed to explore easily applicable diagnostic criteria and an accurate prognostic score for ACLF. **Methods:** Clinical data from 5288 patients (after exclusions from 7388 screened) with acute deterioration of chronic liver disease across various aetiologies were used to evaluate the performance of European Chronic Liver Failure (CLIF) and Chinese Group on the Study of Severe Hepatitis B (COSSH) criteria. Three non-Asian cohorts were performed to validate the results. **Results:** CLIF criteria categorised 844 patients as ACLF (28-/90-day liver transplantation (LT)-free mortality: 40.7%/57.0%; 321 with non-hepatitis B virus (HBV) aetiology, 523 with HBV aetiology), while COSSH criteria categorised 2038 patients as ACLF (28-/90-day LT-free mortality: 27.3%/41.0%; 602 with non-HBV aetiology, 1436 with HBV aetiology). COSSH criteria identified 22.6% (1194/5288) more patients (28-/90-day LT-free mortality: 19.1%/31.4%) compared to CLIF criteria, including 14.2% non-HBV patients (28-/90-day LT-free mortality: 15.9%/33.3%). COSSH criteria produced a

more reasonable epidemiological pyramid-like distribution across severity grades (Grade 1–3: 63.4%/27.5%/9.1% vs. CLIF's Grade 1–3: 25.8%/56.3%/17.9%). COSSH-ACLF II score showed the highest predictive values for 28-/90-day LT-free mortality in both cirrhotic and all ACLF patients with various aetiologies, outperforming the CLIF-C ACLF and other scores. A mimic validation, using a matching analysis of the frequency of six organ failures observed in the CANONIC cohort, further confirmed the high discriminatory ability of COSSH-ACLF II score in non-HBV patients. The comparable performance of China-CLIF score (renamed from COSSH-ACLF score) was validated in three non-Asian cohorts. **Conclusion:** This study evaluated the broader applicability of the China-CLIF framework across diverse aetiologies and varying severity levels of ACLF. These findings may provide a valuable foundation for harmonizing ACLF diagnostic and prognostic system.

4149 | A HDL-BASED CIRRHOSIS RISK SCORE IMPROVES THE PREDICTION OF SHORT-TERM MORTALITY IN ACUTELY DECOMPENSATED CIRRHOSIS

Rudolf Stauber[1] Eva Uson[2] Georg Kramer[3] Florian Rainer[1] Vanessa Stadlbauer[1] Hubert Scharnagl[1] Lorenz Balcar[3] Vlad Taru[3] CRISTINA SANCHEZ GARRIDO[4] Salvatore Piano[5] carlo alessandria[6] Paolo Caraceni[7] Wim Laleman[8] Mattias Mandorfer[3] Thomas Reiberger[3] Gunther Marsche[1] Joan Claria[9] Jonel Trebicka[10] Richard Moreau[2], [1]Medical University of Graz, Austria, [2]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [3]Medical University of Vienna, Austria, [4]European Foundation for the Study of Chronic Liver Failure (EF-CLIF), [5]University of Padova, Italy, [6]University of Turin, Italy, [7]University of Bologna, Italy, [8]KU Leuven, Belgium, [9]Fundacio de Recerca Clinic Barcelona-IDIBAPS, [10]University of Muenster, Germany

Background: Cirrhosis is associated with multiple lipidomic alterations including markedly reduced high-density lipoprotein cholesterol (HDL-C) levels. We previously demonstrated that HDL-C levels have excellent prognostic value comparable to that of MELD. In the present study we aimed to develop a new prognostic model containing HDL-C and other readily available biomarkers for prediction of 90-day mortality in patients with acutely decompensated (AD) cirrhosis without acute-on-chronic liver failure (ACLF). **Methods:** We studied a subset of the European multicentre CANONIC and PREDICT cohorts in whom HDL-C was retrospectively measured in stored plasma samples. Multivariable competing risk analysis was performed with death as the event of interest and liver transplantation as a competing risk. Cox proportional hazards regression was used to construct a new prognostic model and its performance was evaluated using Harrell's concordance index (c-index) and compared that of MELDNa, MELD 3.0 and CLIF-C AD score by the Integrated Discriminating Improvement (IDI) statistics test. The new model was validated externally in a combined AD/ACLF cohort recruited from the Vienna General Hospital. **Results:** We analyzed 823 patients with AD (median age 59 years; 69% male; etiology alcohol 58%; 90-day mortality 15%). Multivariable analysis identified 6 independent prognostic variables associated with 90-day mortality, i.e. age, HDL-C, creatinine, sodium, WBC and INR, that were incorporated in the new prognostic model termed integrated MELD (iMELD)-HDL. The new model yielded superior discrimination ability for prediction of mortality as compared to other prognostic scores (Table). In the external validation cohort including 185 patients with AD/ACLF (median age 57 years; 62% male; ACLF at inclusion 48%; etiology alcohol 55%; 90-day mortality 32%), the new model showed numerically better performance for prediction of 90-day mortality by c-index (95% CI): iMELD-HDL 0.78 (0.70-0.85), MELDNa 0.75 (0.68-0.83; p = 0.170 vs. iMELD-HDL), MELD 3.0 0.75 (0.68-0.83; p = 0.175 vs. iMELD-HDL). **Conclusion:** A new prognostic iMELD-HDL model yielded superior accuracy for prediction of short-term mortality as compared to other prognostic scores. Further external validation in larger cohorts of patients with AD cirrhosis is warranted.

	iMELD-HDL	MELD-Na	MELD3.0	CLIF-C AD score
	C-index (95% CI)

4150 | ANTI-MICROBIAL RESISTANCE PATTERNS IN ACUTE-ON-CHRONIC LIVER FAILURE AND ITS IMPACT ON CLINICAL OUTCOME

Yaduvir Singh[1], [1]SNMC, Jodhpur, India

Background: Acute-on-chronic liver failure is a distinct clinical entity characterized by acute hepatic decompensation in patients with pre-existing chronic liver disease (diagnosed or undiagnosed), leading to multiorgan failure and high short-term mortality. Infections not only act as a common trigger for ACLF but also complicate its clinical course, further worsening prognosis. **Methods:** A total of 274 patients diagnosed with Acute-on-Chronic Liver Failure, as defined by CLIF-C criteria, and with proven infections were included in the study. Of these, 78 patients underwent testing with the BioFire® Respiratory + Pneumonia Panel to detect pathogenic organisms and resistance genes. Antibiotic escalation or de-escalation was guided accordingly based on the results. **Results:** A total of 39 patients were diagnosed with multidrug-resistant (MDR) infections, 12 patients with extensively drug-resistant (XDR) infections, and 4 patients with pandrug-resistant (PDR) infections, underscoring a substantial burden of antimicrobial resistance within the cohort. Genotypic analysis identified key molecular mechanisms underlying resistance. Among *Klebsiella* isolates, 50% harbored the NDM gene (indicative of metallo-β-lactamase production), 33.3% carried VIM, and 16.7% were positive for OXA-48. All *Acinetobacter* isolates carried OXA-48, with 66.7% also harboring NDM and 50% carrying VIM. *E. coli* isolates displayed a comparable resistance pattern: 80% co-expressed NDM and OXA-48, and 40% harbored mecA, mecA/C, and MREJ. *Proteus* isolates were uniformly positive (100%) for OXA-48. *Pseudomonas* isolates exhibited universal expression of all tested resistance genes (mecA, mecA/C, MREJ, NDM, OXA-48, and VIM), consistent with an extensively drug-resistant phenotype.
Infections caused by drug-resistant organisms—including carbapenem-resistant Gram-negative bacilli (GNRs) and MRSA—were associated with significantly higher 30-day mortality in ACLF patients compared to infections caused by susceptible organisms (48.3% vs. 19.2%, $p < 0.001$). **Conclusion:** The high prevalence of MDR pathogens in ACLF patients demands stringent infection control measures, early pathogen identification, and personalized antimicrobial therapy. Rapid diagnostic tools like the BioFire panel, demonstrated in this study, significantly enhance timely detection of pathogens and resistance genes, enabling targeted treatment. Early initiation of appropriate antibiotics guided by local antibiograms, along with regular reassessment, is crucial to curbing the progression of infection-driven organ failure.

Institute of Medical Sciences (KIMS), Bhubaneshwar, India, [76]Government Medical College, Thiruvananthapuram, [77]Amrita Institute of Medical Sciences, Kochi, [78]University of Kelaniya, Ragama, Srilanka, [79]Pandit Bhagwat Dayal Sharma Post Graduate Institute of Medical Sciences, Rohtak, India, [80]All India Institute of Medical Sciences, New Delhi, India, [81]APASL ACLF Working Party

Background: Acute-on-Chronic Liver Failure (ACLF) is a rapidly progressive condition characterized by acute hepatic decompensation with or without extra-hepatic organ failure leading to a high short-term mortality. Often the infection and sepsis are the major cause of deterioration. Liver transplantation (LT) and therapeutic plasma exchange (TPE) have emerged as potential rescue strategies in this context. However, their comparative efficacy in infected versus non-infected ACLF patients is underexplored, particularly in large, real-world cohorts. This study aims to study the LT and TPE feasibility and 90-day survival outcome among patients of ACLF with or without infection. **Methods:** The prospectively collected AARC registry data of 3478 patients, having information on infection at baseline in the first weeks, were analyzed. The data was grouped for those with or without infection, and a matching cohort was done with adjustments for age, gender, etiology of CLD, and disease severity scores (MELD, SOFA, AARC). A comparison of both groups in relation to 90-day survival, organ failure, ICU need, TPE, and LT was made. Infection was defined as those with any positive culture, consolidation in chest imaging, or SBP in ascitic fluid analysis. **Results:** 1824 patients with complete data were included in the study. The mean age of patients was 48.6 $\pm$ 10.4 years, and the gender ratio (male:female) was 3.5:1 (approximately 78% male, 22% female). Mortality was highest in bloodstream infections (64.35%, 148/230), followed by urine (63.11%, 65/103) and ascitic fluid infections (60.53%, 161/266). At 90 days, infected patients had higher rates of renal (50.8% vs. 41.2%), respiratory (52.4% vs. 42.1%), cerebral (37.6% vs. 33.0%), circulatory (51.3% vs. 38.8%), coagulopathy (40.0% vs. 32.0%), and liver failure (54.3% vs. 44.6%) (all $P < 0.05$). LT reduced mortality from 64.7% to 28.6% in infected (n = 78) and from 56.5% to 21.4% in non-infected (n = 76) patients ($P < 0.001$). Mean ICU stay post-LT was 5.4 days in both groups. TPE (n = 312) improved bilirubin (infected: 18.5→13.3 mg/dL; non-infected: 17.2→12.5 mg/dL), INR (2.4→1.8 vs. 2.3→1.7), and creatinine (2.3→1.9 vs. 2.1→1.8 mg/dL) ($P < 0.05$). Infected TPE recipients had lower renal failure progression (26.7% vs. 38.3%) and improved cerebral recovery (34.4% vs. 26.1%) vs. controls ($P < 0.05$). MELD, SOFA, and AARC scores improved significantly in both groups, with greater gains in non-infected patients ($P < 0.05$). **Conclusion:** Infection significantly worsens ACLF outcomes, but both LT and TPE provide substantial mortality and clinical benefit across infected and non-infected patients. These findings support early consideration of LT and TPE irrespective of infection status.

4152 | SYSTEMIC AND MULTI-ORGAN INFLAMMATION PATTERNS ACROSS THE SPECTRUM OF EXPERIMENTAL AND HUMAN CIRRHOSIS AND ACUTE-ON-CHRONIC LIVER FAILURE

Vlad Taru[1] Georg Kramer[1] Thomas Sorz-Nechay[1] Katharina Bonitz[1] Henriette Horstmeier[1] Katja Sommer[1] Lorenz Balcar[1] Benedikt Silvester Hofer[1] Nina Dominik[1] Nicholaus Michalitsch[1] Kerstin Zinober[1] Bogdan Procopet[2] Michael Trauner[1] Philipp Schwabl[1] Thomas Reiberger[1] Benedikt Simbrunner[1], [1]Medical University of Vienna, [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Romania

Background: Decompensated cirrhosis is a fragile state, with some patients rapidly progressing to multi-organ failures (i.e. acute-on-chronic liver failure, ACLF), while others remain stable. This study analyzed systemic inflammation (SI) in different stages of decompensation in humans and dissemination of inflammation on a multi-organ level in experimental ACLF. **Methods:** Patients with decompensated cirrhosis were prospectively enrolled in the Vienna Cirrhosis Study (VICIS) between 2017 and 2021 and classified according to their 3-months follow-up as: stable decompensation (SDC; without subsequent admission); unstable decompensation (UDC; non-elective admission but without ACLF); pre-ACLF (admission with ACLF); and ACLF at baseline. Plasma biomarkers (IL-6, TIMP1) were measured by ELISA.

In two murine cirrhosis models (carbon tetrachloride, CCl4; DDC diet), ACLF was induced by a single LPS injection (i.p.,1x 200 μL/kg), followed by follow-up examination including portal pressure readings after 24h. Gene expression was quantified by qPCR and plasma biomarkers by Luminex multiplex immunoassay. **Results:** In the clinical study, 372 patients (median age: 57 years; 64.2% male; 57.8% alcohol-related liver disease) were included: 299 (80.4%) SDC, 27 (7.3%) UDC, 25 (6.7%) pre-ACLF and 21 (5.6%) ACLF. Median MELD was significantly higher in ACLF but similar between the other groups (SDC vs. UDC vs. preACLF vs. ACLF: 13 [7] vs. 17 [11] vs. 14 [8] vs. 29 [9], $p < 0.001$). IL-6 showed a significant stepwise increase across groups (SDC vs. UDC vs. pre-ACLF vs. ACLF: 12.3 [19.8] vs. 20.6 [29.2] vs. 25.5 [31.9] vs. 41.8 [59.9] pg/mL; $p < 0.001$). Enhanced Liver Fibrosis test (ELF) and TIMP1 showed a strong correlation to IL-6 (Spreaman's rho ELF: 0.51 and TIMP1: 0.63, both $p < 0.001$).

In the murine ACLF models, hepatic *Timp1* and hepatic, renal and pulmonary *Ccl2, Cxcl1, Il6, Il1b, Tnf* gene expression as well as plasma chemokines (G-CSF, CCL4, CCL5) were increased as compared to experimental cirrhosis (without ACLF) groups in both models.

Conclusion: Systemic inflammation significantly increases across the spectrum of decompensated cirrhosis and ACLF in humans and is linked to biomarkers reflecting hepatic fibrogenesis. Experimental ACLF models corroborate this mechanistic link and indicate that systemic inflammation quickly disseminates on a multi-organ level, affecting both the liver and extrahepatic organs.

4154 | ROLE OF AGE AND FRAILTY IN MORTALITY AMONG PATIENTS WITH CIRRHOSIS: A 5-YEAR POPULATION-BASED ANALYSIS

Daniela Ladner[1] Salva Balbale[2] Mohsen Mohammadi[3] Suyanpeng Zhang[3] Sijia Wei[2] Saad Hussain[2] Oriana Dentici[2] Therese Banea[2] Al'ona Furmachuk[4] Lisa VanWagner[5] Andres Duarte-Rojo[6] Nikhilesh Mazumder[7] Lihui Zhao[2] Sanjay Mehrotra[3] CAPriCORN Consortium[8], [1]Northwestern University, [2]Feinberg School of Medicine, Northwestern University, [3]McCormick School of Engineering and Applied Science, Northwestern University, [4]Feinberg School of Medicine, [5]Department of Medicine, University of Texas Southwestern Medical Center, [6]Northwestern Medicine, [7]University of Michigan Hospitals and Health Centers, [8]Chicago Area Patient Centered outcomes Research Network (CAPriCORN)

Background: Up to a third of patients with cirrhosis live with frailty. Comorbid cirrhosis and frailty mark the intersection of two broad population health problems that are further influenced by aging. **Methods:** We conducted a retrospective, longitudinal cohort study from 1/1/2016-12/31/2021 using the Chicago Area Patient-Centered Outcomes Research Network (CAPriCORN), a clinical research repository across seven healthcare systems in the metropolitan area of Chicago, IL. Our outcome of interest was mortality, ascertained from the Veritas Data Research fact-of-death records. Covariates included sex, race/ethnicity, decompensation status, and cirrhosis etiology. We estimated frailty using the validated High Frailty Risk Score (HFRS), categorizing patients into low/mild (HFRS < 5), intermediate (HFRS 5-15), and high/severe (HFRS > 15) frailty levels. We conducted a multivariable Cox regression to investigate risk factors for mortality. **Results:** The cohort included 16,341 patients with cirrhosis. Median age of the cohort was 61 years with a mean follow-up time of 1.2 years. There were 7,443 (45.6%) female patients in the cohort, and 2,774 patients (17.0%) died during the study period. Overall, 9,310 (57.0%) were decompensated. Regarding frailty, 9,168 (56.1%) patients were classified as having low frailty; 4,462 (27.3%) had intermediate frailty; and 2,711 (16.6%) had severe frailty. Mortality risk increased approximately 30% with every 10 years of chronological age gained. In adjusted analyses, 10 years of age was equal to the risk of mortality associated with intermediate frailty. Severe frailty was associated with nearly 100% increased risk of mortality, irrespective of age. **Conclusion:** Mortality risk in this cirrhosis cohort increased by approximately 30% with every 10 years of chronological age gained, the same as intermediate versus low frailty.

4156 | TITLE- TO STUDY THE EFFICACY OF INTRAVENOUS NEOSTIGMINE IN RESOLUTION OF ACUTE GI PARALYSIS IN CRITICALLY ILL CIRRHOSIS- PROSPECTIVE OBSERVATIONAL STUDY (NCT- 06462872)

NEW SUBMISSION, *Ibrar Ahmed Khan[1] Rajan Vijayaraghavan[2] Rakhi Maiwall[3] Babu Lal Meena[4] Harsh Vardhan[3] Prashant Aggarwal[3] shalini thapar[3] Manoj Sharma[4] Shiv Kumar Sarin[3]*

[1]ILBS NEW DELHI,Deemed university, [2]Institute of liver and biliary science,new delhi, [3]ILBS,NEW DELHI, [4]Institute of Liver and Biliary Sciences

Background: Gastrointestinal failure (GIF) is a common morbidity in liver ICU leading to interruption of feeding, raised intra-abdominal pressures, infections and increased mortality. Treatment options are limited, and symptoms may persist even after correction of precipitating factors. IV neostigmine has shown efficacy in cirrhosis patients with hepatic encephalopathy but its role in Critically Ill Cirrhosis (CIC) is not known. We aimed to determine the efficacy of IV neostigmine in the resolution of acute GI paralysis in patients with CIC. **Methods:** All consecutive patients of CIC admitted in liver ICU were prospectively screened and assessed for development of new onset GI failure, defined as the presence of 3 of 5 variables- absence of bowel sounds, gastric residual volume $\geq$ 500 ml, vomiting, diarrhoea and bowel distension on either abdominal x-ray or CT scan. Primary objective was proportion of patients reinitiated on enteral nutrition within 24 hours of after radiological improvement and secondary objectives were time to passage of stool, changes in intra-abdominal pressure (IAP), serial change in GRV, recurrence of GIF and 7-day survival. **Results:** Total of 32 patients of CIC were enrolled with ACLF (n = 19, 59.4%) and decompensated cirrhosis (n = 13, 40.6%). Mean age was 43.2 ± 10.9 yrs. Median ICU stay prior to GIF was 7 (4-10) days and ventilatory days was 4.4 days. The spectrum of GIF includes, all patients with new onset abdominal distension (n = 32), dilated bowel loops in x-ray (n = 24, 75%) and GRV > 500ml seen in 68.7% patients (n = 22). These patients were sicker {MELD = 30.6 ± 10.6, SOFA = 11.2 ± 3, and AARC score = 11 (9.75-13)}and had organ failures at the time of development of GIF (shock-78.1%, RRT-56.3% and mechanical ventilation- 71.8%). Within 24-hours of IV neostigmine, 78% (n = 25) patients had reinitiation of enteral nutrition with mean time of reinitiation = 11.04 ± 4.90 hrs. and time to passage of first stool = 7.5 ± 3.7 hrs. Recurrence after 24-hours was seen in 18.8 % (n = 6) patients and failure of treatment in 15.6% (n = 5) patients. Significant reduction was seen in GRV with maximum reduction within 72-hours ($p < 0.001$). IAP reduction was significant (15.4 ± 1.77 to 13.9 ± 1.87 mmHg, $p = 0.001$) in responders. Non-responder patients had need for 2nd vasopressor (71.4% vs. 28%, $p = 0.038$) and prolonged ventilatory days (7.29 ± 4.3 vs 3.3 ± 1.8 days). KM analysis shows better 7-day survival in responders ($p = 0.001$) (Fig. 1). **Conclusion:** GI failure is common in liver ICU and have worse clinical outcomes. Early detection and treatment initiation may improve survival and prevent clinical deterioration.

4157 | DISPARITIES IN LIVER TRANSPLANT EVALUATION FOR ACUTE-ON-CHRONIC LIVER FAILURE: THE IMPACT OF RACE AND SEX

Kelly Bowen[1] Alaina Miller[2] Wesam Aleyadeh[3] William Carey[2] Aanchal Kapoor[2] Omar Sims[2] Christina Lindenmeyer[2], [1]Cleveland Clinic Lerner College of Medicine, [2]Cleveland Clinic, [3]Cleveland Clinic Akron General

Background: Liver transplantation (LT) is the only definitive treatment for acute-on-chronic live failure (ACLF), yet disparities in access to LT persist based on sociodemographic factors. ACLF is associated with rapid clinical deterioration and high mortality; timely LT evaluation is critical. Studies have highlighted racial and sex-based inequities in LT access, but few have examined how these disparities manifest among critically ill patients with ACLF. We aimed to investigate whether race and sex were associated with LT evaluation status among patients admitted to a quaternary care center medical intensive liver unit (MILU) with ACLF. **Methods:** Data were collected from a prospective registry of patients admitted to the MILU between 2018 and 2023 and analyzed retrospectively. Patients were included in the analysis if they met EASL-CLIF criteria for ACLF on day one of their first MILU admission. LT evaluation status was categorized as: (1) not evaluated, (2) evaluation started in the MILU, or (3) already in evaluation on admission. A multinomial logistic regression model was constructed using "not evaluated" as the reference outcome. Covariates in the multivariate model included age, sex, race (collapsed to white and non-white), MELD-Na, ACLF grade, liver disease etiology, and Area Deprivation Index as a proxy for neighborhood-level socioeconomic disadvantage. A secondary model evaluated predictors of LT listing using the same covariates. **Results:** 428 patients were included in the analysis. After adjusting for clinical and sociodemographic covariates, non-white race was associated with lower odds of being in LT evaluation upon MILU admission compared to white race (OR 0.34, 95% CI 0.16-0.72) (Table 1). However, there were no major racial or sex-based differences in the odds of *starting* LT evaluation during the MILU stay. In the adjusted listing model, non-white race was associated with lower odds of LT listing (OR 0.42, 95% 0.20-0.84). No significant differences in LT evaluation or listing were observed by sex. **Conclusion:** Racial disparities in access to LT evaluation and listing exist among critically ill patients with ACLF, particularly in the likelihood of already being in evaluation upon ICU admission. These findings underscore the need for early outreach and structural interventions to promote equitable access to LT evaluation, especially prior to ICU-level deterioration. Sex-based differences were minimal in this cohort. Importantly, a subspecialty ICU like the MILU, staffed with teams educated and focused on bridging critically ill patients to transplant, may help mitigate disparities by standardizing evaluation pathways. Future work should explore upstream referral patterns and system-level contributors to delayed evaluation.

4158 | FROM COLONIZATION TO INFECTION: CLINICAL CONSEQUENCES OF MULTIDRUG-RESISTANT ORGANISMS IN CIRRHOSIS IN THE ICU

Iva Kosuta[1] Jaksa Babel[1] Frano Susak[1] Laura Peretin[2] Viktor Domislovic[2] Radovan Radonic[2] Anna Mrzljak[2], [1]University Hospital Centre Zagreb, Zagreb, Croatia, [2]University Hospital Center Zagreb, Zagreb, Croatia

Background: Bacterial infections are a major complication in cirrhosis, often triggering organ failure. The rise in multidrug-resistant organisms (MDROs) complicates treatment and worsens prognosis. Critically ill cirrhotic patients frequently harbor MDROs at ICU admission, and colonization may precede infection. Understanding colonization patterns could help optimize empirical therapy and improve outcomes. The primary aim of this study was to assess concordance between colonizing and infecting strains. Secondary aims included colonization and infection epidemiology, outcomes, and differences between patients with acute decompensation (AD) and acute-on-chronic liver failure (ACLF). **Methods:** This retrospective cohort study included cirrhotic patients admitted to the ICU at University Hospital Centre Zagreb, Croatia (2018–2024). Colonization was assessed by nasal, pharyngeal, and rectal swabs at admission and within five days. Clinical, laboratory, and severity scores (MELD, SOFA, CLIF-ACLF) were collected and analyzed. **Results:** Among 107 ICU admissions, 29.9% were colonized with MDROs. Colonization was more common in ACLF than AD patients (34.5% vs. 10.0%, $p = 0.033$). Colonization was not independently associated with MDRO infection (OR: 2.18; $p = 0.383$) or 28-day transplant-free mortality (OR: 1.14; $p = 0.813$), but strain concordance between colonizing and infecting organisms was high (82%). MDRO infection was significantly associated with worse outcomes, including increased need for mechanical ventilation (59.3% vs. 18.8%, $p = 0.005$), vasopressors (53.8% vs. 18.8%, $p = 0.013$), longer ICU stay (median 9.0 vs. 5.0 days, $p = 0.003$), and lower hospital survival (37.4% vs. 68.8%, $p = 0.038$). ACLF patients had significantly worse clinical outcomes than AD patients, including lower 28-day survival (39.1% vs. 75.0%, $p = 0.008$), ICU survival (43.7% vs. 85.0%, $p = 0.001$), and hospital survival (34.5% vs. 75.0%, $p = 0.002$). **Conclusion:** MDRO colonization at ICU admission was common, particularly in ACLF, but did not independently predict infection or mortality. However, the high concordance between colonizing and infecting strains supports the use of colonization data to guide early empirical therapy. Infection—not colonization—was strongly linked to worse outcomes, emphasizing the need for early recognition and intervention in this high-risk group. **Disclosures:** Iva Kosuta: Nothing to Disclose, Jaksa Babel: Fresenius Kabi: Speaking and Teaching, Frano Susak: Nothing to Disclose, Laura Peretin: Nothing to Disclose, Viktor Domislovic: Nothing to Disclose, Radovan Radonic: Nothing to Disclose, Anna Mrzljak: Nothing to Disclose

4159 | COMBINATION OF NOVEL PLASMA METABOLITES AND WEARABLE-DERIVED PHYSIOLOGIC PARAMETERS PROVIDE HIGH PROGNOSTIC VALUE FOR RISK OF HOSPITALIZATION FOR PATIENTS WITH CIRRHOSIS

Gautham Pranesh[1] Nikhil Zachariah[2] Sachin Subramanian[3] Alisha Chaubal[4] HARDIK SHAH[4] Ameet Mandot[5] AMRIK SHAH[6] Shyam Kottilil[7] Mani Subramanian[8] SAMIR SHAH[4], [1]SensEarly, [2]Mitopower Inc, [3]UC Davis, [4]Nanavati Max Super Speciality Hospital, [5]Gleneagles Hospital, [6]Sensearly Inc, [7]University of Maryland, [8]TLC

Background: The clinical course of patients with decompensated cirrhosis varies considerably and early identification of patients who progress to decompensation or Acute on Chronic Liver Failure (ACLF) is a major unmet need. Our aim is to identify biomarkers that will improve risk stratification of patients with cirrhosis and further enhance early detection of acute hepatic decompensation. **Methods:** The "Prospective Observational Study to Evaluate Biomarkers of Metabolic Dysfunction Among Patients with Liver Failure" (CTRI/2022/09/045668) was a 24-week prospective observational study conducted at a tertiary liver center in western India. Quantitative profiling of plasma acylcarnitines and plasma aminoacids, was performed using standard LC-MS techniques. Patients were monitored using the Garmin Vivosmart 5 wearable, capturing continuous data on heart rate, heart rate variability, actigraphy, respiration, SpO_2, and sleep over 6 months. Clinical outcomes were hospitalization for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

liver decompensation events, mortality, and liver transplantation during the period of observation. Associations between plasma biomarker levels and MELD scores were assessed using Spearman rank correlation. Unsupervised clustering methods (hierarchical and k-means) were applied to identify phenotypic subgroups based on biomarker profiles. Clinical events leading to hospitalization or mortality were examined across these phenotypes. **Results:** Fifty-six patients with cirrhosis were enrolled (mean age: 52 years; 84% male; 52% alcohol-related). 62.5% had Child-Pugh B/C cirrhosis and 48.2% had MELD >15. A panel of plasma metabolites and aminoacids associated with mitochondrial dysfunction showed strong correlations with MELD. These included 4-hydroxyproline ($r=0.781$, $p<0.001$), threonine ($r=0.613$, $p<0.001$), methionine ($r=0.578$, $p<0.001$), alpha-amino-n-butyric acid ($r=0.502$, $p<0.001$), hexadecenoylcarnitine ($r=0.612$, $p<0.001$), malonylcarnitine/3OH butyryl carnitine ($r=0.594$, $p<0.001$), acetylcarnitine ($r=0.585$, $p<0.001$), and octadecenoylcarnitine ($r=0.541$, $p<0.001$). Unsupervised clustering using a novel metabolite panel at baseline, identified three distinct phenotype with low to high risk of future hospitalization, with a median time to hospitalization of 24 days and a 100% hospitalization rate in the high-risk group (Figure 1). Wearable-derived physiological parameters monitored over a 6-month period including 24-hour average heart rate (AUC 0.90; 95% CI, 0.88–0.92), beat-to-beat interval (AUC 0.88; 95% CI, 0.86–0.90), and daily step count (AUC 0.70; 95% CI, 0.67–0.72) were significantly associated with subsequent clinical events. **Conclusion:** For patients with decompensated cirrhosis, the novel metabolite panel representative of mitochondrial dysfunction enables improved risk stratification, and the wearable derived signature enables early detection of patients at high risk of hospitalization.

4160 | THE LINOLEIC ACID-DERIVED LEUKOTOXIN 9,10-DIHOME DRIVES IMMUNOSUPPRESSION IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE

Bryan Contreras[1] Berta Romero-Grimaldo[1] Mireia Casulleras[1] Marta Duran Güell[1] María Belén Sánchez-Rodríguez[1] Maria Papp[2] Jonel Trebicka[3] Richard Moreau[4] MICROB-PREDICT Consortium[5] Cristina López-Vicario[1] Joan Claria[1], [1]Biochemistry and Molecular Genetics Service, Hospital Clínic–IDIBAPS, CIBERehd, Barcelona, Spain, [2]University of Debrecen, Faculty of Medicine, Department of Gastroenterology, Debrecen, Hungary, [3]Department of Internal Medicine B, University of Münster, Münster, Germany, [4]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [5]MICROB-PREDICT Consortium

Background: Patients with acutely decompensated (AD) cirrhosis present persistent immunosuppression rendering them at increased risk of recurrent bacterial infections and developing acute-on-chronic liver failure (ACLF). Here, we investigated the profile of immunomodulatory lipid mediators in patients with AD cirrhosis and their effects on leukocyte host defense mechanisms. **Methods:** Targeted lipidomics of 101 well-annotated lipid mediators was performed by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) in 308 samples of plasma from 93 AD patients with and without ACLF at hospital admission and during 90-day follow up. For comparison, 31 healthy donors were also included. Immune responses were assessed in vitro in polymorphonuclear (PMN) and mononuclear leukocytes. In vivo studies were performed in peritoneal and liver macrophages from mice with CCl_4-induced cirrhosis. **Results:** LC-MS/MS

analysis identified the linoleic acid-derived 9,10-dihydroxy-12-octadecenoic acid (9,10-DiHOME), also known as leukotoxin, as the only lipid mediator specifically elevated in ACLF patients in comparison to those without. Moreover, follow-up analysis revealed that 9,10-DiHOME levels followed the severity course of the disease and were significantly higher at the time patients developed an active infection and at ACLF presentation. Consistent with these findings, leukocytes from AD patients showed increased expression of soluble epoxyde hydrolase (sEH), the enzyme responsible for 9,10-DiHOME biosynthesis. In *in vitro* assays, 9,10-DiHOME impaired PMN degranulation, phagocytosis, and respiratory burst capacities. In addition, in mononuclear leukocytes, 9,10-DiHOME induced the expression of the immunosuppressive marker MerTK, distorted required mechanisms for the adequate host defense response against pathogens including the ability to produce cytokines in response to LPS and impaired mitochondrial dynamics and autophagic responses. In *in vivo* studies, inhibition of sEH in mice with CCl_4-induced cirrhosis impeded immunosuppressive responses in peritoneal macrophages and significantly attenuated MerTK expression in liver macrophages. **Conclusion:** Taken together, these findings indicate that increased circulating levels of the leukotoxin 9,10-DiHOME weakens immune-cell defensive responses, thus enhancing the susceptibility of AD patients to bacterial infection and precipitating ACLF. These data also position sEH as an actionable drug target in this condition.

4161 | DOSE-DEPENDENT RISK OF HEPATIC ENCEPHALOPATHY WITH CHRONIC PPI USE IN CIRRHOSIS: A MULTICENTER COHORT ANALYSIS

Ahmed Salem[1] Mohammed Abusuliman[2] Hazem Abosheaishaa[3] Mohamed Eldesouki[4] Sherif Elhanafi[5] Aaron Tokayer[1], [1]Maimonides Medical Center, [2]Henry Ford Hospital, [3]Mount Sinai Queens, [4]New York Medical College at Saint Michael Medical Center, [5]Texas Tech University Elpaso

Background: Despite widespread use, proton pump inhibitors (PPIs) have been implicated as a potential modifiable risk factor for hepatic encephalopathy (HE) in patients with cirrhosis. However, real-world data delineating this relationship remain limited, especially regarding dose and duration effects.

Aim: To investigate the association between PPI use and risk of incident hepatic encephalopathy among cirrhotic patients, accounting for exposure duration and dose intensity. **Methods:** We conducted a retrospective multicenter cohort study using TriNetX, aggregating EHRs from 90+ U.S. health systems. Adults ($\geq$18 years) with cirrhosis (ICD-10: K70.3, K74.6, K76.9) from Jan 1, 2015–Dec 31, 2023 were included. Exclusions: prior HE, HCC, TIPS, or recent sepsis.

Patients were stratified into:

- Non-users (no PPI exposure)
- Low-dose users ($\leq$20 mg omeprazole-equivalent/day)
- High-dose users ($\geq$40 mg/day)

Index date was first PPI prescription or matched pseudo-date. All had $\geq$12 months follow-up. Propensity score matching (1:1:1) used age, sex, MELD-lab equivalents (bilirubin, INR, albumin, creatinine), comorbidities (diabetes, CKD, alcohol use, varices, ascites), and medications (lactulose, rifaximin, diuretics, NSAIDs, beta-blockers).

The primary outcome was incident HE within 12 months, defined via ICD-10 codes and initiation of lactulose or rifaximin. Cox models provided adjusted hazard ratios (aHRs), with Kaplan-Meier curves illustrating incidence.

Results: 18,991 patients met criteria (6,423 per group). Baseline variables were balanced (SMD $<$ 0.1). Median follow-up: 11.2 months.

HE incidence:

- High-dose: 18.1%
- Low-dose: 13.6%
- Non-users: 9.8% (log-rank $p <$ 0.001)

Risk comparisons:

- High-dose vs non-users: aHR 1.62 (95% CI: 1.39–1.87), $p <$ 0.001
- High-dose vs low-dose: aHR 1.27 (95% CI: 1.10–1.47), $p = 0.002$
- Low-dose vs non-users: aHR 1.31 (95% CI: 1.14–1.50), $p <$ 0.001

Findings were consistent across subgroups (alcoholic vs non-alcoholic cirrhosis, sex, MELD strata). Sensitivity analyses controlling for lactulose, rifaximin, and diuretic

use confirmed robustness. KM curves showed early divergence by month 3. **Conclusion:** In cirrhotic patients, chronic PPI use—especially high-dose—was independently linked to increased HE risk. These real-world data support cautious PPI use, favoring dose reduction or discontinuation when appropriate. Prospective studies are needed to validate causality and mechanisms.

4162 | EFFECT OF VS-01 ON SYSTEMIC INFLAMMATION AND LIVER INJURY IN A RAT MODEL OF ENDOTOXEMIA

Marie Bobowski-Gerard[1] Philippe Delataille[1] Valérie Daix[1] Zouher Majd[1] Bart Staels[2] Dean Hum[1] Katharina Staufer[3] Jonel Trebicka[4] Sakina Sayah Jeanne[1], [1]Genfit SA, Loos, France, [2]Univ. Lille, Institut Pasteur de Lille, CHU Lille, Inserm U1011, Lille, France, [3]Versantis AG (GENFIT group), Zurich, Switzerland, [4]Hospital of the Goethe University Frankfurt, University Hospital Münster, Germany

Background: Systemic inflammation, triggered by bacteria or Pathogen-Associated Molecular Patterns (PAMPs), is a primary driver of acute-on-chronic liver failure (ACLF), a severe syndrome affecting patients with acutely decompensated cirrhosis. VS-01 is an intraperitoneal pH-gradient investigational liposomal drug under development for the treatment of ACLF by enhancing the clearance of ammonia and other toxins. We previously demonstrated that VS-01 counteracts lipopolysaccharide (LPS)-induced inflammatory response in a cellular model, on top of its ability to bind hydrophobic bile acids *in vitro* (Bobowski-Gerard *et al.*, Hep, 2024). The aim of this study was to assess the effect of VS-01 on ACLF-related toxins using a rat model of endotoxemia. **Methods:** Endotoxemia was induced in healthy Sprague Dawley rats by intravenous injection of 1 mg/kg LPS (E.Coli). VS-01 or a control dialysis solution (Physioneal 35, glucose 1.36%) was administered at 60 mL/kg, one hour before LPS administration. Serum was collected at 3h and at 5h post-LPS for measurement of cytokines and hepatic function and injury markers. The efficacy of VS-01 on ammonia capture was verified through ammonia measurement in the peritoneal fluid. **Results:** Intravenous administration of LPS in rats induced an increase in serum circulating cytokines levels. As an example, TNF-alpha concentrations (not detectable in healthy rats) were 4235 pg/mL and 746 pg/mL at 3h and 5h post-LPS, respectively. VS-01 reduced LPS-induced TNF-alpha levels by 65% at 3h ($p < 0.001$, Figure) and 35% at 5h ($p = 0.02$); when compared to the control dialysis group. IL-10 and IFN-gamma also decreased upon VS-01 treatment (-43%, $p = 0.02$ at 3h and -35%, $p < 0.001$ at 5h, respectively). This anti-inflammatory effect was associated with a reduction of LPS-induced ALT (-56%, $p = 0.001$, Figure) and urea (-23%, $p = 0.003$) at 5h, when compared to the control group. **Conclusion:** A single administration of VS-01 in rats with endotoxemia decreases systemic inflammation and improves liver function, supporting the ability of VS-01 to counteract the activity of ACLF-related toxins in an animal model. These studies further support the development of VS-01 in ACLF (Phase 2a study UNVEIL-IT™ NCT05900050, status: recruiting).

4163 | LONGITUDINAL SINGLE-CELL MULTIMODAL ANALYSIS REVEALS THE DYNAMIC IMMUNE MECHANISMS UNDERLYING HBV-ACLF PROGRESSION

Jun Li[1] Xi Liang[1] Jinjin Luo[1] Qian Zhou[1] Jiaojiao Xin[1] Jiaqi Li[2] Xin Chen[3] Dongyan Shi[1], *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, [2]People's Hospital Affiliated of Hangzhou Medical College, [3]Zhejiang University School of Medicine*

Background: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome involving dysfunction of multiple immune cell types. This study aimed to comprehensively depict the dynamic trajectory of immune responses throughout the disease course of hepatitis B virus-related ACLF (HBV-ACLF). **Methods:** Single-cell RNA sequencing (scRNA-seq) and single-cell proteomics were performed on the peripheral blood mononuclear cells (PBMCs) of 45 samples from 17 hospitalized patients (progressive/stable/recovering course of HBV-ACLF, 6/5/6) and 15 control subjects (liver cirrhosis, chronic hepatitis B and healthy controls, 5/5/5). Functional and mechanistic experiments were validated in vivo and in vitro. **Results:** Single-cell multiomics analysis revealed specific changes in the peripheral immune response in ACLF. VCAN+CD14 +-monocytes with activated interferon-stimulated genes and enhanced inflammatory functions, stimulated by HBV relapse and expanded in ACLF-1, contributing to early inflammatory storm. The subsequent apoptotic hepatocytes predominantly induce hyperinflammatory CXCR2+-neutrophils and M2 macrophage-like CD163 +-monocytes, which were prevalent in progressive ACLF patients, serving as significant markers of disease deterioration. Cytotoxic T-cells were functionally impaired and significantly decreased in progressive patients. CXCR2+-neutrophils were found to exhibit immunosuppressive activity and induce the exhaustion of cytotoxic T-cells. Inhibition of CXCR2 significantly reduced neutrophils infiltration, restored cytotoxic T-cells and showed therapeutic effect in ACLF mice. Six immune patterns were established to stratify patients, with CM2 and CM6 showing good predictive ability for disease outcomes and highlighting CM3 as an early therapeutic window. **Conclusion:** Our longitudinal multiomics study revealed the dynamic evolution of the immune response in HBV-ACLF and characterized diverse immune patterns for the precise management and therapeutic intervention.

4164 | IDENTIFICATION OF PLASMA EXTRACELLULAR VESICLE MICRORNA PROFILES AS DIAGNOSTIC AND PROGNOSTIC BIOMARKERS FOR HBV-ASSOCIATED ACUTE-ON-CHRONIC LIVER FAILURE

Wanying Tan[1] Xia Zhu[1] Yanfang Zhang[1] Ming Wang[1] Lingyao Du[1] Huan Liu[1] Min He[1] Hong Tang[1], *[1]Center of Infectious Diseases, West China Hospital of Sichuan University*

Background: Chronic hepatitis B virus (CHB) infection can lead to hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF), a condition characterized by high mortality. Currently, there is a lack of biomarkers with high sensitivity and specificity for diagnosing HBV-ACLF. Extracellular vesicles (EVs) are bilayer lipid vesicles containing RNA.This study aims to elucidate alterations in plasma EVs miRNAs associated with HBV-ACLF, thereby developing diagnostic and prognostic scoring systems for HBV-ACLF. **Methods:** To explore the feasibility of early HBV-ACLF diagnosis, EVs were isolated from plasma of HBV-ACLF patients and CHB patients, followed by characterization of particle size and protein markers. EV-derived miRNAs specific to HBV-ACLF were identified via miRNA microarray analysis. Candidate miRNAs were further validated in a large cohort (67 HBV-ACLF patients, 57 CHB patients) to screen potential biomarkers. For early diagnosis, machine learning models (EMR6-RF, EMR6-SVM, EMR6-LR) were developed using combinations of 6 EV miRNAs. For mortality risk assessment, a multivariate Cox proportional hazards model (EMR3I) was established by integrating EV miRNAs with clinical parameters. **Results:** Microarray analysis identified 33 differentially expressed miRNAs between HBV-ACLF and CHB patients. Six EV miRNAs (hsa-miR-548aq-3p, hsa-miR-545j-5p, hsa-miR-185-3p, hsa-miR-1455-5p, hsa-miR-6731-3p, hsa-miR-320e) showed strong diagnostic power. The EMR6 machine learning models achieved high accuracy in distinguishing CHB and HBV-ACLF: EMR6-RF: AUC 0.85 (95% CI: 0.71–0.95), EMR6-SVM: AUC 0.75 (95% CI: 0.59–0.90) and EMR6-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

LR: AUC 0.83 (95% CI: 0.68–0.95), outperforming the MELD score (AUC:0.76;95%CI:0.60-0.92). The prognostic model EMR3I (integrating hsa-miR-548aq-3p, hsa-miR-545j-5p, hsa-miR-320e, and INR) robustly predicted survival: 30 days AUC: 0.82 (95% CI: 0.74–0.90) and 90 days AUC: 0.83 (95% CI: 0.76–0.90). And the EMR3I scoring system stratifies HBV-ACLF patients into risk subgroups, with significant differences in 30 days and 90 days mortality between high- and low-risk groups. **Conclusion:** Plasma EV-derived miRNAs serve as diagnostic and prognostic biomarkers for HBV-ACLF. The EMR6 scoring model enhances early diagnosis, while the EMR3I scoring model improves risk stratification capabilities.

4165 | EFFICACY OF NITAZOXANIDE (NTZ) ON SYSTEMIC INFLAMMATION AND ORGAN FUNCTION IN DISEASE MODELS OF ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) WHEN ADMINISTERED POST-ACLF TRIGGER

Marie Bobowski-Gerard[1] Philippe Delataille[1] Simon Debaecker[1] Camille Vanbésien[1] Dean Hum[1] Vanessa Legry[1] Bart Staels[2] Jonel Trebicka[3] Sakina Sayah Jeanne[1], [1]Genfit SA, Loos, France, [2]Univ. Lille, Institut Pasteur de Lille, CHU Lille, Inserm U1011, Lille, France, [3]Hospital of the Goethe University Frankfurt, University Hospital Münster, Germany

Background: Systemic inflammation is a primary driver of acute-on-chronic liver failure (ACLF), a severe syndrome affecting patients with acutely decompensated cirrhosis. In rodent disease models, we previously demonstrated the beneficial effect of the anti-parasitic drug nitazoxanide (NTZ) on systemic inflammation and organ damage when added concomitantly or before the precipitating trigger of ACLF. The aim of this study was to better assess the activity of NTZ on preexisting inflammation, by investigating NTZ efficacy when administered after the pathological stimulus in preclinical models of inflammation and ACLF. **Methods:** TZ (the active metabolite of NTZ) was added to human PBMCs concomitantly or 30 min after the trigger (LPS) to assess its effect on cytokine secretion. *In vivo*, endotoxemia was induced in healthy rats by intraperitoneal (i.p.) injection of 1 mg/kg lipopolysaccharide (LPS). A single oral dose of NTZ pro-drug (300 mg/kg) was administered concomitantly or 15 min after LPS. Serum was collected 3 and 5h after LPS. ACLF was triggered by injecting LPS (1μg/kg, i.p.) in rats with bile duct ligation (BDL)-induced cirrhosis. A single oral dose of NTZ (300 mg/kg) or vehicle was orally administered 15 min after LPS injection. Serum was collected 3h post LPS. **Results:** In human PBMCs, TZ blunted LPS-induced IL-6 secretion with similar efficacy when added after or concomitant to LPS challenge: IC50 = 5μM and Emax = 93% vs IC50 = 7.6μM and Emax = 92%, respectively.

In rats with endotoxemia, NTZ lowered LPS-induced serum IL-6 levels at 3h: -34% ($p = 0.01$) in the post-trigger condition and -38% ($p = 0.01$) in the co-trigger condition. Hepatic marker levels were also reduced in both post-trigger and co-trigger groups: -78% ($p = 0.03$) and -86% ($p = 0.01$) of ALT, -98% ($p < 0.001$) and -100% ($p = 0.001$) of total bile acids at 5h, respectively.

In ACLF rats, NTZ administered after LPS decreased the LPS-induced increase of pro-inflammatory cytokines IL-6 by -65% ($p = 0.07$) and TNF-alpha by -58% ($p = 0.08$). NTZ also resolved liver injury as shown by a decrease of ALT by -97% ($p = 0.02$). Moreover, the levels of renal function markers were reduced upon NTZ treatment: -39% ($p = 0.04$) for cystatin C and -78% ($p = 0.08$) for creatinine. **Conclusion:** TZ lowered cytokine secretion post-LPS challenge *in vitro*. This rapid anti-inflammatory effect was also observed *in vivo*, as a single dose of NTZ reduced systemic inflammation and restored organ functions in an ACLF model. These findings further support the development of NTZ (G1090N) as a new therapeutic approach for ACLF.

4166 | AARC SCORE PREDICTS SURVIVAL OUTCOMES BETTER THAN OTHER SCORES IN PATIENTS WITH ACUTE ON CHRONIC LIVER FAILURE PATIENTS HAVING HISTOPATHOLOGICALLY-PROVEN MILD LIVER FIBROSIS

Rohit Wagh[1] Archana Rastogi[2] VINOD ARORA[3] Shiv Kumar Sarin[3], [1]LTMGH, Sion, [2]ILBS, New Delhi, [3]ILBS

Background: and aims: ACLF in chronic liver disease (CLD) patients is not well understood. The severity of the illness and the mortality do not often correlate well with the histological picture. Unlike cirrhosis, ACLF is associated with property of reversibility if appropriate interventions are taken in the golden window period. We aimed to see the survival outcomes in ACLF patients having mild fibrosis in liver biopsy using different liver disease severity indices such as AARC score with MELD-lactate. **Methods:** This was a retrospective cohort study from the data records of the hospitalised ACLF patients in Institute of liver and biliary Sciences, New Delhi who underwent liver biopsy between period from 2013 to 2025. The patients who were proven as having mild fibrosis ($<$F2) on liver biopsy were assessed for their outcomes. Patient's demographic details, clinical history, blood investigations were recorded along with outcomes. **Results:** A total of 1277 ACLF patients (males-928) who underwent liver biopsy were assessed. Altogether, 237 (males-139), mean age 43 ± 12.5 years were found to have mild fibrosis on the liver biopsy. Their baseline investigations were recorded along with the natural outcomes of the disease progression (survival, deaths, repeat hospitalisations, liver transplantations, bridge therapies) either from the hospital records or telephonic conversations or by a follow up OPD visit. Overall, only 12 patients underwent live donor liver transplantation.Irrespective of the treatment, the 3-month mortality was 26.26% while 6-month and 12-month mortality rates were similar (32.32%). On univariate analysis, clinical parameters like higher grade of ascites, presence of spontaneous bacterial peritonitis, hepatic encephalopathy, acute kidney injury and variceal bleeding were associated with poorer survival outcomes. On multivariate analysis, the higher baseline serum total bilirubin (OR 1.063, CI:1.008-1.121, $p=0.024$), serum creatinine (OR 1.862, CI:1.049-3.305, $p=0.034$), INR (OR 2.211, CI: 1.191-4.107, $p=0.012$) as well as arterial lactate (OR 3.377, CI:1.460-7.810, $p=0.004$), which already are components of AARC and MELD-lactate scores predicted poorer outcomes in these group of patients. The ROC analysis showed that the AARC score (which additionally has the component of grade of hepatic encephalopathy), had larger AUC (0.876, CI:0.823-0.930) than the MELD-lactate score (AUC = 0.850, CI:0.784-0.916), MELD score (AUC = 0.786, CI:0.710-0.863), MELD-Na score (AUC = 0.778, CI:0.702-0.855) and CTP (AUC = 0.755, CI:0.679-0.831) score. **Conclusion:** Baseline AARC scores and MELD-lactate scores predict poor survival outcomes better than other scores in patients with ACLF patients with mild fibrosis.

4167 | TREATMENT OF HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY (HRS-AKI) WITH TITRATABLE NOREPINEPHRINE OUTSIDE OF INTENSIVE CARE UNIT (ICU): A SINGLE CENTER EXPERIENCE

Kyle Schneider[1] Alicia Reeve[2] Mahintha Karthik[2] Kinnari Modi[3] Jeevin Sandhu[1] Jeffrey Weinstein[2] Parvez Mantry[3], [1]Methodist Dallas Medical Center,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Internal Medicine, [2]Methodist Dallas Medical Center, [3]Methodist Dallas Medical Center, Gastroenterology and Hepatology

Background: HRS-AKI is a significant, late-stage complication of liver cirrhosis that presents as renal impairment. It is difficult to treat and often requires ICU admission. A mainstay of treatment is splanchnic vasoconstriction to maintain a mean arterial pressure (MAP) to sustain and improve kidney perfusion[BA1] . However, vasoconstrictors, such a norepinephrine, are often only available in the ICU, thereby limiting access and increasing healthcare associated costs. Here, we present a cohort of patient who underwent treatment with norepinephrine in a step-down unit with telemetry using a well-vetted administration protocol. **Methods:** We retrospectively analyzed 23 patients with HRS-AKI who were treated in a step-down unit between November 2023 and February 2025 in a single center using our norepinephrine protocol (Table 1). The guidelines from 2021 International Club of Ascites were used to define response to treatment. A partial response to therapy was defined as a decrease in serum creatinine (SCr) by more than 0.3mg/dL from initiation of norepinephrine, complete response was a return to within 0.3 mg/dL of baseline, and all other responses as failure of therapy. **Results:** 23 patients total (16 male, 69.6%, 7 female, 30.4%) with a median age at start of treatment of 55 years (IQR 46-64). Etiologies for liver disease were alcoholic cirrhosis (18, 78.3%), MASLD (3, 13.1%), PBC (1, 4.3%), and HCV (1, 4.3%). Median serum creatinine at time of admission was 1.0 (0.7, 1.8). Characteristics are outline in Table 2. 9 patients (39.1%) required transfer to ICU. 8 patients (34.8%) received liver transplant during hospitalization, with one of them (1, 4.3%) also receiving a kidney transplant. 7 patients (30.4%) were complete responders, 10 patients (43.5%) were partial responders, and 6 patients (26.1%) were non-responders. There were no reported cardiovascular events reported while on norepinephrine. At 1 month, 14 (82.3%) of the responders and partial responders and 5 (83.3%) of the non-responders survived. Characteristics summarized in Table 2. **Conclusion:** Use of titratable norepinephrine outside of the ICU is a viable, safe and effective method to treat HRS-AKI. It can be used to help decrease overall cost of treatment as well as provide a viable platform for sustaining adequate MAP's to ensure renal perfusion in a majority of patients. Larger and perhaps multicenter studies are needed to validate this benefit and applicability.

- Initiate infusion at 2.5 mcg/min. Increase or decrease by 1 mcg/min every 1 hour to maintain MAP between *** and *** mmHg. Do not exceed 10 mcg/min.
- MAP goals are customizable, and determined by provider, to ideally target 10-15 mmHg above baseline MAP.

4168 | PRESENCE OF SEPSIS IS ASSOCIATED WITH INCREASED RISK OF ACUTE VARICEAL BLEEDING AND INCREASED MORATLITY IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE: A PROPENSITY-MATCHED MULTINATIONAL COHORT OF THE APASL ACLF RESEARCH CONSORTIUM (AARC)

Madhumita Premkumar[1] Anand Kulkarni[2] C Eapen[3] Ashok Kumar Choudhury[4] Sunil Taneja[5] Tarana Gupta[6] Ashish Goel[3] Akash Roy[7] Akash Shukla[8] Harsh Tevethia[9] Nipun Verma[5] Sahaj Rathi[10] Dibyalochan Praharaj[11] Suprabhat Giri[11] Radha Dhiman[12] Yogesh Chawla[13] VINOD ARORA[4] Shiv Kumar Sarin[4],
[1]Postgraduate Institute of Medical Education & Research, [2]Asian Institute of Gastroenterology, [3]CMC Vellore, [4]ILBS, [5]PGIMER, [6]PGIMER Rohtak, [7]Apollo Multispeciality Hospital, Kolkata, [8]Seth GS Medical College & KEM Hospital, [9]INSTITUTE OF LIVER AND BILIARY SCIENCES(ILBS),NEW DELHI, [10]Virginia Commonwealth University, [11]KIMS, [12]SGPGIMS, [13]Postgraduate Institute of Medical Education

Background: Acute variceal bleeding (AVB) is associated with poor survival in patients with acute-on-chronic liver failure (ACLF), especially in regard to coagulation dysfunction and sepsis. We evaluated the predictors and outcomes of AVB in patients with ACLF in a propensity-matched multinational cohort of the APASL ACLF Research Consortium (AARC). **Methods:** We assessed the predictors of AVB within 90 days of presentation with AARC-ACLF. Then, the sites, risk factors and outcomes of AVB (ACLF-AVB) within 90 days of presentation were assessed as compared with a propensity score matched (PSM) cohort of ACLF matched for severity of liver disease (Age, gender, and baseline MELD) without AVB (ACLF without AVB). **Results:** Of the 3380 patients with ACLF (mean age 44.5 ± 11.9years, 83.8% men, 70.6% alcohol-associated ACLF, mean MELD-Na 34.7 ± 7.4), the mortality in ACLF-AVB ($n = 140$) [mean age—44.6 ± 11 years, 83.8% men, 63.1 % with alcohol-associated disease, AARC score: 10.5 ± 2.1, MELD -Na score: 35.5 ± 5.6] were worse as compared to those without AVB despite similar age, MELD-Na, and AARC score (66.7% vs 60.7%, P = 0.043). On multivariable binary logistic regression, predictors of AVB included Platelet count (aOR 0.994, 95%CI 0.992-0.997,P < 0.001) and sepsis in the first 7 days (aOR 1.2, 95%CI 1.1-2.1, P = 0.003). The long-term transplant-free mortality was compared in patients with and without AVB in a PSM cohort selected in a ratio of 1:2 ($n = 120$: 240) Despite propensity matching for age,gender, etiology and MELD-Na, ACLF patients with AVB had a higher 90-day mortality than those without AVB. (63.3% vs% and 43.8%, respectively ($P = 0.001$). On multivariable binary logistic regression, predictors of mortality were the AARC score at admission (aOR 1.13, 95%CI 1.06-1.22, P = 0.001), and presence of sepsis (aOR 1.1, 95% CI 1.1-1.3, P = 0.010).
Table1: Disease severity, site of bleeding, and outcomes in patients with ACLF and the subset with acute variceal bleeding in the total cohort and after propensity matching. **Conclusion:** Development of AVB confers poor outcomes in patients with ACLF with a high 90-day mortality. Presence of sepsis at baseline represents a potential risk factor for future AVB and mortality in ACLF.

4169 | TIMING MATTERS: DELAYED ANTIBIOTIC THERAPY INCREASES MORTALITY IN PATIENTS WITH ACLF. A SINGLE-CENTER RETROSPECTIVE STUDY

German Barrientos - Cabrera[1] Jacqueline Cordova Gallardo[2] Mercedes Elena Rodriguez - Garcia[1] Daniela Diaz De la Vega Broissin[3] Froylan David Martinez-Sanchez[1] Samantha Melanie Armendariz Pineda[1] Andres Manuel Vargas Beltran[1], [1]Hospital General Dr. Manuel Gea Gonzalez, [2]Hospital General Dr Manuel Gea González, [3]Hospital General Dr. Manuel Gea González

Background: Acute-on-chronic liver failure (ACLF) is a life-threatening clinical condition that occurs in patients with cirrhosis who develop acute decompensation, severe systemic inflammation and multiple organ failures. Bacterial infections are the most frequent precipitating factor for ACLF.

Current guidelines from the American Association for the Study of Liver Diseases (AASLD) recommend initiating antibiotic therapy in the emergency room; given the relationship between delayed treatment and increased mortality. However, these recommendations are based on expert opinion, as no prior studies have examined the relationship between antibiotic timing and mortality in ACLF. **Methods:** A retrospective study was conducted at a single hospital in Mexico City including adults diagnosed with ACLF between 2018 and 2024 to determine the association between delayed antibiotic therapy initiation and mortality in patients with ACLF. Data were collected from medical records. The primary outcome was in-hospital mortality. **Results:** A total of 178 patients were included, mean age was 55.2 $\pm$13.1 years, 63% were women. The overall mortality rate was 52%. The mean Meld 3.0 score among deceased patients was 19 $\pm$19.9. Alcoholic liver disease (ALD) was the most common etiology (47%), followed by metabolic dysfunction–associated steatotic liver disease (13%) and hepatitis C virus infection (6.5%). The most frequent types of infection were urinary tract infection (48%), pneumonia (25%) and spontaneous bacterial peritonitis (14%).

The identification of a multidrug-resistant pathogen as the etiology of the infection was associated with an OR of mortality of 11.12 (5.24–24.94; $p < 0.001$). Delayed antibiotic initiation was significantly associated with higher mortality. For every hour of delay, the OR of death increased (OR 1.014; 95% CI: 1.004–1.024; $p = 0.005$). Antibiotic initiation $\geq$12 hours and $\geq$ 24 hours

after admission were associated with ORs for mortality of 13.12 (6.38–26.94; $p < 0.001$) and 9.79 (4.08–23.15; $p < 0.001$), respectively.
When multivariate analysis was adjusted for age, sex, MELD 3.0 score, and ACLF grade, each hour of delay had an OR for mortality of 1.012 (1.001–1.024; $p = 0.03$). For delays of ≥ 12 hours and ≥ 24 hours, the ORs were 14.4 (5.52–37.5; $p < 0.001$) and 13.1 (3.63–47.5), respectively. **Conclusion:** Delayed initiation of antibiotic therapy is significantly associated with increased mortality in patients with ACLF.
This research represents the first study to directly evaluate one of the primary recommendations from current ACLF management guidelines regarding the importance of early antibiotic initiation. The present study provides evidence supporting the critical role of early antibiotic administration in patients with ACLF.

4170 | ELEVATED FIBRIN DEGRADATION PRODUCT LEVEL PREDICT POOR OUTCOMES IN HEPATITIS B VIRUS-RELATED ACUTE-ON-CHRONIC LIVER FAILURE PATIENTS TREATED WITH ARTIFICIAL LIVER SUPPORT SYSTEM THERAPY

Xiaoqi Zhou[1] Xu Yang[1] Shiying Li[1], [1]The Second Affiliated Hospital of Chongqing Medical University

Background: Acute-on-chronic liver failure (ACLF) is a very severe clinical syndrome, often accompanied by systemic inflammation, coagulation dysfunction and fibrinolysis abnormalities. Fibrin degradation product (FDP) is a product of fibrinolysis, reflecting the state of fibrinolysis. Our aim is to explore the relationship between FDP levels and the 28-day mortality rate of patients with ACLF. **Methods:** We retrospectively enrolled 520 HBV-ACLF patients treated with artificial liver support system therapy and collected data prior to their first therapy. Restricted cubic splines (RCS) and COX regression were used to analyze the relationship between FDP and the 28-day mortality rate of HBV-ACLF patients, while receiver operating characteristic (ROC) curves were utilized to assess the predictive value of FDP. **Results:** Among the 520 eligible patients, the 28-day mortality rate was 20.2%. The FDP levels in surviving patients were significantly lower than those in deceased patients [6.15 (3.23-10.97) vs 16.98 (9.58-28.93), $P < 0.001$]. Multivariate Cox proportional hazards analysis, after adjusting for confounding factors, showed that FDP levels were significantly associated with an increased risk of 28-day mortality [HR = 1.014 (95% CI: 1.006–1.022), $P = 0.001$]. Patients with high FDP levels (≥ 11.1 μg/ml) had a significantly higher risk of death compared to those with low levels [HR = 3.114 (95% CI: 1.921-5.049), $P < 0.001$]. The restricted cubic spline (RCS) model further revealed a non-linear relationship between FDP and 28-day mortality. Among the prognostic scores, the COSSH ACLF score had the largest AUROC, comparable to FDP ($P = 0.891$), and the predictive performance of FDP was superior to that of FIB and D-dimer. Additionally, in patients who received three or more artificial liver support system therapy, the 28-day mortality risk was significantly reduced in those with high FDP levels. **Conclusion:** Elevated FDP levels are associated with the 28-day prognosis of HBV-ACLF patients, and multiple sessions of artificial liver treatment can significantly improve the prognosis of patients with high FDP levels (≥ 11.1 μg/ml).

4171 | ASK1 INHIBITOR SRT-015 REDUCES SYSTEMIC INFLAMMATION WHILE PROMOTING IMMUNE DEFENSE MECHANISMS IN PRECLINICAL IN VITRO AND IN VIVO MODELS RELATED TO ACLF

Vanessa Legry[1] Berta Romero-Grimaldo[2] Cristina López-Vicario[2] Bryan Contreras[2] María Belén Sánchez-Rodríguez[2] Alba Diaz[3] Carla Montironi[3] Richard Moreau[4] Dean Hum[5] Bart Staels[6] Sakina Sayah Jeanne[7] Joan Claria[8], [1]GENFIT SA, [2]Hospital Clinic-IDIBAPS, CIBEREHD, EF CLIF, Barcelona, Spain, [3]Hospital Clinic-IDIBAPS, CIBEREHD, Barcelona,

Spain, [4]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [5]GENFIT CORP, [6]University Lille 2, [7]Genfit, [8]Fundacio de Recerca Clinic Barcelona-IDIBAPS

Background: Acute-on-chronic liver failure (ACLF) is characterized by multiple organ failures and high short-term mortality. ACLF is closely associated with the presence of intense systemic inflammation, impaired immune defense responses against pathogens (i.e. decreased neutrophil degranulation and phagocytosis) and oxidative stress. Apoptosis-signal-regulating kinase 1 (ASK1) is a key mediator of the inflammatory response, activated by ROS produced after recognition of PAMPs. Its phosphorylation results in activation of JNK and p38 that regulate cell death and cytokine production. The aim of this study was to investigate the effects of SRT-015, a new investigational drug inhibiting ASK1, on systemic inflammation in a new model of ACLF (Flores-Costa, Hepatol Commun 2025) that recapitulates the human condition, as well as on human leukocyte functions *in vitro*. **Methods:** ACLF was induced by acute induction of polymicrobial peritonitis secondary to the ligation and puncture of the cecum (CLP) in mice with CCl_4-induced cirrhosis. CCl_4+CLP mice received oral SRT-015 (20 mg/kg) administrations 19h and 0.5h before CLP, and 20h after CLP, and samples were collected 24h post-CLP for analyses. Polymorphonuclear leukocytes (PMNs) isolated from healthy subjects were incubated with SRT-015 (2 and 10 μM) for 1.5-2h and degranulation and phagocytic capacities assessed by myeloperoxidase (MPO) release/activity and internalization of fluorescent-labeled *Escherichia coli,* respectively. The effects of SRT-015 on cytokine release were tested on mononuclear leukocytes. **Results:** CCl_4+CLP mice had elevated circulating cytokines and liver, kidney, brain, coagulation, circulation and respiratory impairments, as expected. SRT-015 administration to CCl_4+CLP mice significantly reduced circulating TNFα (25.7 vs. 70.4 pg/ml, $p = 0.02$), MCP-1 (224 vs. 921 pg/ml, $p = 0.04$), MIP-1β (147 vs. 183 pg/ml, $p = 0.02$), CXCL10 (233 vs 504 pg/ml, $p = 0.0005$) and IL-17 (3.18 vs. 5.94 pg/ml, $p = 0.03$) levels, compared to placebo. *In vitro* experiments confirmed the inhibitory effects of SRT-015 on cytokine release. While SRT-015 had no effect on MPO levels, it significantly increased PMN phagocytosis in a concentration-dependent manner. **Conclusion:** These data confirm the beneficial effect of SRT-015 on systemic inflammation in a preclinical model of ACLF and uncover its ability to improve anti-bacterial function. These results support the development of the investigational drug SRT-015 for the treatment of patients with ACLF.

4172 | NONCANONICAL INFLAMMASOME-TRIGGERED PYROPTOSIS EXACERBATES COAGULOPATHY IN ACUTE-ON-CHRONIC LIVER FAILURE VIA RELEASING HISTONE H3 AND ENHANCING TISSUE FACTOR ACTIVITY

Xueyun Zhang[1] Qiankun Hu[2] yuxian huang[3], [1]Huashan Hospital Fudan University Department of Infectious D, [2]Shanghai public health clinical center, [3]Huashan Hospital, Fudan University

Background: Coagulation failure is one of the most key independent prognostic risk factors in acute-on-chronic liver failure (ACLF) patients. We aim to study the potential role of pyroptosis in coagulopathy and pathogenesis of ACLF. **Methods:** We examined the activation of inflammasome-pyroptosis pathway as well as coagulation-related indexes in ACLF patients and mice. Also, we investigated the effect of inflammatory caspase-GSDMD activation on coagulation and prognosis in ACLF mice using *Casp11* and *Gsdmd* knockout mice. We induced pyroptosis in the THP-1 cell line, and performed thrombin production assay with cell supernatant to explore the specific mechanism by which pyroptosis affects thrombin production. **Results:** Inflammatory caspase-4 were activated in the liver macrophage of HBV-ACLF patients, and the plasma LPS, IL-1β and IL-18 were also elevated, indicating that noncanonical inflammasome-pyroptosis axis was activated in HBV-ACLF patients. Noncanonical inflammasome activity positively correlated with coagulation disorder. To figure out the underlying mechnism we established a non-canonical pyroptosis model by electroporating LPS (2 μg/ml) into THP-1 cells, and found that the pyroptosis cell supernatant promoted thrombin production. The coagulation process is mediated by the tissue factor (TF)-activated coagulation cascade, and pyroptosis mediate coagulation disorders in mice by enhancing

TF activity. However, blocking TF fails to fully restore the increased thrombin production induced by pyroptosis in our experiments, suggesting that pyroptosis may affect the coagulation system through other pathways. Histone is an important DAMP molecule released during cell death, and it is also an important way to activate the coagulation system in addition to the TF-coagulation cascade, and we speculate that pyroptosis may affect coagulation activation by releasing histones. Further experiments showed histone H3 was significantly elevated the supernatant of pyroptosis cells. Recombinant histone H3 directly promotes thrombin production, and neutralizing histone by mCBS leads to a significant decrease in pyroptosis-induced thrombin production. Knockout of *Casp11 and Gsdmd* in ACLF mice also reduced the serum histone H3 levels, mameliorated coagulation and renal injury, alleviated liver inflammation, and improved survival. **Conclusion:** Caspase 4/11-GSDMD participates in aggravating coagulation disorders in ACLF patients and mice by releasing histone H3 and increasing TF activity and thereby activating the coagulation system.

4173 | SINGLE-NUCLEUS TRANSCRIPTOMICS IDENTIFIES A CD44⁺ REGENERATIVE HEPATOCYTE SUBPOPULATION IN HEPATITIS B VIRUS-RELATED ACUTE-ON-CHRONIC LIVER FAILURE

Xiaohan Qian[1] Xiayao Li[1] Yangfan Shen[1] Diwenxin Zhou[1] Lingxiao Zhu[1] Keting He[1] Shangci Chen[1] Ke Zhou[1] Zhangya Pu[1] Zhongyang Xie[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) arises from acute exacerbation of chronic liver diseases, and is characterized by multi-organ failure and high short-term mortality. Liver regeneration is a key determinant of clinical outcomes in patients with severe liver injury, yet remains poorly understood in ACLF. Besides, there is no definite therapy specifically targeting on it. Here, we use a single-nucleus RNA sequencing (snRNA-seq) approach to explore the heterogeneity of hepatocytes and cholangiocytes and to identify potential regenerative subsets in patients with hepatitis B virus (HBV)-related ACLF. **Methods:** We performed snRNA-seq on explanted liver tissues from five patients with HBV-ACLF who underwent liver transplantation at the First Affiliated Hospital of Zhejiang University between January 1 2023 and December 31 2024. Public snRNA-seq dataset of healthy human livers were integrated as controls using Harmony. Following quality control and normalization, hepatocytes and cholangiocytes were extracted and re-clustered. Pathway enrichment was assessed using AddModuleScore, developmental trajectories were inferred by Monocle, and intercellular communication was analyzed by CellChat. **Results:** After analyzing 47,822 hepatocytes and cholangiocytes, we identified 7 hepatocyte and 3 cholangiocyte subpopulations. Compared to healthy controls, HBV-ACLF livers exhibited a marked depletion of hepatocytes but a significant expansion of cholangiocytes. Notably, we identified an ACLF-specific hepatocyte subpopulation (Hep_CD44), present in all ACLF samples, characterized by high expression of CD44, KRT23, and other progenitor-associated genes, suggesting a regenerative phenotype. This subset was enriched for pathways related to cell migration and PI3K-Akt signaling. In a trajectory analysis, Hep_CD44 cells located at the branch between mature hepatocytes and cholangiocytes, indicating bipotent lineage potential. Cell-cell interaction analysis revealed enhanced interactions between CD44 + hepatocytes and liver endothelial cells via the LIF-LIFR axis. **Conclusion:** We identified a CD44⁺ hepatocyte subset with progenitor-like features that expands in HBV-ACLF livers. The regenerative hepatocyte

subset represents a promising target for hepatocyte-based cell therapies in ACLF.

4174 | EVALUATION OF THE VALIDITY AND RELIABILITY OF THE GLIM CRITERIA IN DIAGNOSING MALNUTRITION AMONG OUTPATIENTS WITH LIVER CIRRHOSIS

Araceli López Nepomuceno[1] Alondra Rosales Padrón[1] MARTÍN PACHECO SERRANO[1] Fatima Manzo Santana[1] Tania del Socorro Grimaldo Galeana[1] Ignacio Garcia-uarez[2] Jorge Hernández Calleros[1] María Luisa Peralta-Pedrero[3] Lucía Méndez Sánchez[4], [1]National Institute of Medical Sciences and Nutrition Salvador Zubirán, [2]The National Institute of Medical Science and Nutrition, [3]Centro Dermatológico "Dr. Ladislao de la Pascua", [4]Cochrane México UNAM, Sistema Bibliotecario Facultad de Medicina. UNAM Mexico City.

Background: Liver cirrhosis is a global health issue and a leading cause of mortality. Its clinical progression often leads to malnutrition; a factor associated with morbidity and mortality. However, diagnosing malnutrition is challenging due to the disease's complications. The Global Leadership Initiative on Malnutrition (GLIM) criteria have been proposed for nutritional assessment, yet evidence their validity is limited. This study aimed to evaluate the validity and reliability of the GLIM criteria for diagnosing malnutrition in adult outpatients with liver cirrhosis. **Methods:** This cross-sectional study included 71 outpatients with liver cirrhosis recruited in Mexico City. Clinical, biochemical, and anthropometric parameters were recorded alongside the Child-Pugh and MELD scores. Malnutrition according to GLIM criteria was defined by the presence of at least one phenotypic criterion (weight loss $>5\%$ within 6 months or $>10\%$ beyond 6 months; BMI <20 kg/m² for patients <70 years or <22 kg/m² for ≥ 70 years; or reduced muscle mass assessed via skeletal muscle index [SMI] using CT) and one etiologic criterion (reduced energy intake $<50\%$ of requirements for ≥ 1 week, or inflammation indicated by a neutrophil-lymphocyte ratio >5). The Subjective Global Assessment (SGA) was used as the reference standard to evaluate validity, calculating sensitivity, specificity, PPV, NPV and AUC. Reliability was assessed using Kappa for inter-observer agreement and Cronbach's α for internal consistency. **Results:** Among the 71 patients, 26 had compensated cirrhosis, and 45 had decompensated cirrhosis. The prevalence of malnutrition was 45.1% according to SGA and 38.0% by GLIM criteria. Patients with malnutrition showed lower mid-arm circumference ($p<0.001$), calf circumference ($p<0.001$), BMI ($p<0.001$), and SMI ($p=0.002$), as well as greater weight loss over the past 6 months ($p=0.016$) and beyond 6 months ($p=0.006$). The GLIM criteria limited diagnostic validity (0.53 sensitivity, 0.74 specificity, 0.63 PPV, 0.65 NPV, 0.66 AUC) and good inter-observer agreement (0.669 Kappa). However, internal consistency was low (0.189 Cronbach's α). **Conclusion:** The GLIM criteria showed limited validity and internal consistency for diagnosing malnutrition in outpatients with liver cirrhosis, despite acceptable inter-observer agreement. Further studies with larger populations are warranted to refine items, cutoff points, and validate these criteria in this clinical setting.

4175 | USING MACHINE LEARNING TO ACCURATELY PREDICT THE 90 DAY PROGNOSIS OF ACUTE-ON-CHRONIC LIVER FAILURE BASED ON LIVER RESERVE FUNCTION AND CLINICAL FEATURES

Xia Zhu[1] Hong Tang[1] Yuanji Ma[1] Libo Yan[1] Jianhao Li[1] Ming Wang[1], [1]West China Hospital of Sichuan University

Background: Acute-on-chronic liver failure (ACLF) presents a substantial risk of short-term mortality, emphasizing the critical need for early and accurate prognosis to enhance patient care. Research has shown that liver reserve function is a key determinant of patient outcomes. This research utilizes advanced machine learning techniques to combine liver reserve parameters with clinical data, with the goal of creating a more precise prognostic model for ACLF. **Methods:** We retrospectively collected baseline demographics, clinical features, laboratory results, and 90-day survival follow-up data from 497 HBV-ACLF patients (HX cohort) and 52 patients (GZ cohort). Differential analysis and univariate logistic regression were used to pinpoint potential factors influencing prognosis in HBV-ACLF. A total of 12 machine learning algorithms were systematically tested to establish the most effective prognostic model, and ROC curve analyses were performed to evaluate predictive accuracy. The XGBoost algorithm was applied to identify critical clinical factors impacting HBV-ACLF prognosis, and an interactive web tool was developed using the Shiny R package to enhance usability in clinical practice. **Results:** We initially screened 21 potential clinical risk factors for predicting ACLF prognosis. Subsequently, using the LASSO-RF model, 15 key variables were selected for model construction: effective hepatic blood flow (EHBF), liver failure (LF) stage, Model for End-Stage Liver Disease (MELD) score, indocyanine green retention rate at 15 minutes (ICG-R15), age, hepatic encephalopathy (HE) stage, ascites score, hepatorenal syndrome (HRS), absolute neutrophil count, total bilirubin (TBIL), international normalized ratio (INR), prothrombin activity (PTA), sodium (Na), ammonia (NH3), and Child-Turcotte-Pugh (CTP) score. The final LASSO-RF model achieved an AUC of 0.99 in the training cohort and 0.98 in the validation cohort for predicting 90-day survival, outperforming conventional scoring systems such as MELD and CTP. To facilitate clinical application, an online tool (https://syx123.shinyapps.io/deploy_shiny/) was developed to provide real-time risk scores and 90-day survival predictions for individual patients. **Conclusion:** Liver reserve function indicators, especially EHBF and ICG-R15, are crucial for predicting 90-day survival in HBV-ACLF. Combining liver reserve assessment with clinical parameters via machine learning enables more accurate and individualized prognostic evaluation, supporting optimized clinical management.

4176 | COMBINATION OF MELD SCORE WITH NEUTROPHIL-TO-LYMPHOCYTE RATIO PREDICTS IN-HOSPITAL MORTALITY IN ACUTE-ON-CHRONIC LIVER FAILURE

Vasilis Papastergiou[1] Panagiotis Kanellopoulos[1] Dimitra Kozompoli[1] Konstantinos Mousourakis[1] Georgios Kalogiros[1] Dimitra Provi[1] Vasilis Karampatsos[1] Konstantinos Fiagkousakis[1] Alexandra Agorogianni[1] Maria Mela[1] Nikos Viazis[2], [1]Evangelismos General Hospital, [2]Gastroenterology Department, Evangelismos Hospital

Background: Introduction: Prediction of early mortality is crucial in patients with Acute on Chronic Liver Failure (ACLF), a highly fatal syndrome characterized by intense systemic inflammation and organ failure. Performance of the Model of End-stage Liver Disease (MELD) appears to be suboptimal in ACLF, although the prognostic potential of combining MELD with inflammatory indexes remains uncertain.
Aims: To evaluate a combination of MELD with neutrophil-to-lymphocyte ratio (NLR) for in-hospital mortality prediction in patients with ACLF. **Methods:** Retrospective cohort study evaluating consecutive ACLF patients followed till hospital discharge. The predictive ability and optimal cut-points of MELD and NLR calculated on admission were determined by ROC analyses. Four prognostic groups, determined by score combinations below or above the optimal cut-points, were analyzed with respect to in-hospital mortality. **Results:** A total of 122 patients (50.8% males, mean age 61.8 ± 12.1) were hospitalized with ACLF between April 2021 and February 2023. The etiology of pre-existing liver disease was alcoholic in 44.3% and in-hospital mortality was 31.1%. The areas under ROC were 0.79 for MELD and 0.68 for NLR, with optimal cut-off points 20 (sensitivity/specificity: 0.89/0.57) and 5.1 (sensitivity/specificity: 0.84/0.60), respectively. Compared to patients with low MELD and NLR scores, patients with high scores displayed significantly higher in-hospital mortality (73.7% vs 6.7%; adjusted OR = 13.96, $p = 0.007$), whereas those with a single elevated score did not (high-MELD/low-NLR: 15.4%; adjusted OR = 1.98, $p = 0.49$; low-MELD/high NLR: 14.2%; adjusted OR = 1.30, $p = 0.79$). **Conclusion:** In patients hospitalized with ACLF, a combination of high baseline MELD and NLR appears to delineate poor prognosis, correlating with a high risk of in-hospital death.

4177 | IMPACT OF FRAILTY AND OBESITY ON HOSPITAL LENGTH OF STAY AFTER LIVER TRANSPLANTATION

Ahmed Aboseria[1] Jade Pace[1] Michael Attanasi[1] Justin Lin[1] Anwesha Satapathy[1] William Han[1] Bheesham Dayal[1] Sanjaya Satapathy[1], [1]Northwell Health

Background: Frailty and obesity are independent predictors of adverse outcomes after liver transplantation (LT), but their combined impact on hospital length of stay (LOS) remains understudied. **Methods:** We analyzed data from 227 adult LT recipients categorized into four frailty-obesity phenotypes: Frail-Obese, Frail-NonObese, NonFrail-Obese, and NonFrail-NonObese. Total LOS was compared across groups using generalized linear modeling (GLM) and survival analysis with the Kaplan-Meier method and log-rank tests. Covariates included age at transplant, sex, and BMI. Interactions between frailty-obesity group and sex were also examined. **Results:** The study cohort ($n = 227$) was predominantly male (66%), with 32% of patients classified as obese and 43% as frail. Mean hospital length of stay (LOS) varied significantly among the frailty-obesity groups ($p = 0.0041$); the Frail-Obese group experienced the longest mean LOS (31.7 ± 14.2 days), while the NonFrail-Obese group had the shortest (21.3 ± 11.7 days). In adjusted generalized linear modeling, both Frail-Obese ($\beta = 10.76$, $p = 0.0024$) and Frail-NonObese ($\beta = 8.61$, $p = 0.0020$) patients had significantly longer LOS compared to the NonFrail-Obese group. The Liver Frailty Index showed a positive association with LOS ($\beta = 4.25$, $p < 0.0001$), whereas age at transplant was inversely associated with LOS ($\beta = -0.19$, $p = 0.0285$). No significant interaction was found between the frailty-obesity group and sex. Kaplan-Meier curves further demonstrated a clear separation in LOS by group (log-rank $p = 0.0087$). **Conclusion:** Frailty is a key determinant of prolonged hospital LOS post-LT, regardless of obesity status. Non-frail obese patients had the shortest stays, suggesting potential protective effects of obesity in non-frail individuals. Pre-transplant frailty screening may improve post-transplant planning and recovery.

4178 | TRANSCRIPTION AND TRANSLATION OF HUMAN ENDOGENOUS RETROVIRUS (HERV)-DERIVED ELEMENTS DEFINES POST-TRANSPLANT ALLOIMMUNE HEPATITIS

Kumar Subramanian[1] Nada Yazigi[1] Khalid Khan[1] Carolina Rumbo[1] Gabriel Gondolesi[1] Alexander Kroemer[1] Thomas Fishbein[1] Udeme Ekong[1], [1]Medstar Georgetown Transplant Institute, Medstar Georgetown University Hospital, 3800 Reservoir Rd,

Background: HERVs are inherited genetic germline elements derived from exogenous retroviral infections throughout the evolution of the human genome. Epigenetic mechanisms serve to transcriptionally silence HERV-derived elements through DNA methylation and/or repressive histone modifications. We and others have reported HERV reactivation and elevated HERV expression in a variety of autoimmune disorders, including post-transplant alloimmune hepatitis and autoimmune hepatitis (AIH). We sought to determine, using an independent patient cohort, if upregulation of HERV transcripts and protein in liver tissue, and HERV antigenemia in plasma, represent linked molecular signatures of post-transplant alloimmune hepatitis, and potential biomarkers for early detection of disease risk. **Methods:** Using an independent cohort for validation, we assessed HERV-T levels by qRT-PCR and Western Blot in livers with post-transplant alloimmune hepatitis and AIH ($n = 3$) and normal livers procured and subsequently transplanted in recipients ($n = 15$). Circulating HERV1-env transcript and protein was measured in plasma by qRT-PCR and ELISA in liver transplanted children with: post-transplant alloimmune hepatitis ($n = 8$), acute rejection (AR) ($n = 13$), normal graft function (LTC) ($n = 41$); and in non-transplanted children with: AIH ($n = 14$), and healthy children (HC, $n = 30$). Statistical analyses were performed using GraphPad Prism. Mann Whitney test was used for non-parametric measurements. **Results:** ***HERV-T*** was upregulated in livers with alloimmune and AIH ($p = 0.02$). Of the 15 normal livers that were procured and subsequently transplanted, ***HERV-T*** upregulation was present in three. Elevated ***HERV1*** transcript and antigenemia were seen in the plasma of children with alloimmune and AIH ($p = 0.01$; $p = 0.001$, respectively). Two children with normal graft function also had HERV1 antigenemia. None of the transplanted children are on DNA-demethylating therapy, neither were the deceased donors of

the procured livers. These **Results:** from a validation cohort confirm our previous published observation of HERV reactivation in post-transplant alloimmune hepatitis. **Conclusion:** Our results confirm enhanced transcription and translation of HERVs in children with alloimmune hepatitis. Understanding T cell recognition of HERVs in patients with alloimmune hepatitis and autoimmune hepatitis could lead to improved future immunotherapeutic strategies.

4179 | LIVER CIRRHOSIS IS ASSOCIATED WITH INCREASED PREVALENCE OF INTESTINAL POLYPS IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE ANALYSIS

Anwar Uddin[1] Madia Ahad[1] Narinderjeet Kaur[1] Selome Yewedalsew[1] Savanna Thor[1], [1]Suny Downstate Medical center

Background: Rheumatoid arthritis (RA) and liver cirrhosis (LC) are chronic systemic diseases that independently increase the risk of gastrointestinal (GI) complications, including bleeding, ulcers, bacterial overgrowth, portal hypertensive enteropathy, and increased malignancy risk. In RA, GI injury may result from chronic inflammation, NSAID use, and immunosuppressive therapy. LC contributes through portal hypertension and immune dysfunction, leading to varices, intestinal edema, and mucosal changes. Intestinal polyps, frequently found on colonoscopy and known precursors to colorectal cancer, may be more common in this high-risk population. However, their prevalence and clinical predictors have not been studied in patients with both RA and LC. This study aims to evaluate the national prevalence and predictors of intestinal polyp diagnosis among hospitalized RA patients, comparing those with and without LC. **Methods:** We performed a retrospective cross-sectional analysis using the 2016–2020 HCUP Nationwide Inpatient Sample (NIS). Adult hospitalizations with RA were identified via ICD-10-CM codes and stratified by the presence of LC. Intestinal polyps were identified using ICD-10-CM codes. Survey-weighted multivariable logistic regression assessed the independent association between LC and polyp detection, adjusting for age, sex, race, insurance, CCI, hospital bed size, region, and teaching status. **Results:** Total of 2,734,274 RA-related hospitalizations, 63,325 (2.3%) had LC. Intestinal polyps were more prevalent in RA patients with LC than without (1.3% vs. 0.6%). LC was independently associated with higher odds of polyp diagnosis (adjusted OR 2.35, 95% CI 1.99–2.78, $p < 0.001$). Among RA patients with LC, increased odds were linked to older age (OR 1.02/year, 95% CI 1.01–1.02, $p < 0.001$), male gender (female OR 0.84, 95% CI 0.78–0.91, $p < 0.001$), Black race (OR 1.27, 95% CI 1.14–1.40, $p < 0.001$), and Hispanic ethnicity (OR 1.15, 95% CI 1.01–1.31, $p = 0.036$). Private insurance was associated with higher odds (OR 1.13, 95% CI 1.02–1.25, $p = 0.020$), while Medicaid and other non-Medicare payers had lower odds. Medium (OR 1.12, 95% CI 1.01–1.24, $p = 0.034$) and large hospitals (OR 1.10, 95% CI 1.00–1.21, $p = 0.050$) had higher detection rates than small hospitals; urban non-teaching hospitals showed lower odds (OR 0.69, 95% CI 0.60–0.80, $p < 0.001$). **Conclusion:** RA patients with liver cirrhosis are more than twice as likely to be diagnosed with intestinal polyps compared to those without cirrhosis. Male patients and those of Black or Hispanic race were at particularly elevated risk. Although RA patients with liver cirrhosis had more than twice the odds of being diagnosed with intestinal polyps, the absolute prevalence remained low at 1.3%, compared to 0.6% in those without cirrhosis. This suggests that while the relative risk is increased, the overall likelihood of polyp detection is still low.

Background: Hepatic fibrosis is characterized by excessive accumulation of the extracellular matrix that occurs during most types of chronic liver diseases. Oxidative stress induced heat shock proteins (HSPs) maintain cellular proteostasis by acting as chaperones and promoting cell survival. Our previous studies show that HSP90AA1, a stress inducible chaperone, is increased in alcohol associated cirrhosis and in murine liver fibrosis. We hypothesize that HSP90AA1 plays an important role in hepatic stellate cell activation and contributes to fibrosis. **Methods:** C57BL/6 mice were injected i.p. with 0.5 μl/g BW CCl4 for 6 weeks. 17-DMAG, specific HSP90AA1 inhibitor, was administered i.p. at 5.0 mg/kg twice a week for the last 4 weeks (preventive regimen) or 50 mg/kg BW twice during the last week (treatment regimen). Serum ALT, pro-inflammatory, pro-fibrotic cytokines were measured. Effect of 17-DMAG on hepatic stellate cell activation was assessed using human primary hepatic stellate cells and stellate cell line LX-2 cells. **Results:** Stress-inducible HSP90AA1 but not HSP90AB1 is elevated in human cirrhotic livers and murine fibrotic livers induced by CCl4.17-DMAG administration in preventive and treatment regimens reduced serum ALT ($p < 0.01$), αSMA at mRNA and protein levels as well as Col1A1 mRNA levels, confirmed by Sirius red staining. Bioavailability of HSP90AA1 inhibition in vivo was confirmed by HSP70 expression. HSP90 inhibition reduced pro-fibrotic genes HSP47 and TIMP1, pro-inflammatory cytokine IL-1β and monocyte markers CD11b and Ly6C after 17-DMAG administration. Moreover, HSP90 inhibition induced GATA4, a marker of inactive quiescent like HSCs. 17-DMAG administration significantly reduced glycolytic genes such as HK2, PKM2 in liver fibrosis. The effect of HSP90AA1 inhibition on HSC activation was investigated in vitro using human primary hepatic stellate cells and LX-2 cell line. 17-DMAG treatment reduced its TGFβ mediated Col1A1 expression in both primary and LX-2 stellate cells. To understand whether HSP70 induction contributes to decreased Col1A1 expression, we transfectedHSP70 siRNA in LX-2 cells. and found that the inhibition of HSP70 did not affect 17-DMAG mediated reduction in Col1A1 expression, emphasizing a direct role for HSP90AA1 in stellate cell activation. **Conclusion:** HSP90AA1 plays an important role in hepatic stellate cell activation and pro-fibrogenic responses suggesting its potential as a therapeutic target in liver fibrosis.

4181 | REAL-WORLD DATA ON ACUTE-ON-CHRONIC LIVER FAILURE: IMPLICATIONS FOR CLINICAL MANAGEMENT AND POLICY

Hidehiro Kamezaki[1] Arisa Kato[2] Takaaki Ikegami[2] Nana Yamada[2] Terunao Iwanaga[2] Takafumi Sakuma[2] Koji Takahashi[2] Junichi Senoo[2], [1]Department of Gastroenterology, Eastern Chiba Medical Center, [2]Eastern Chiba Medical Center

Background: Acute-on-chronic liver failure (ACLF) is a rapid decline in liver function in patients with chronic liver disease, causing high morbidity and mortality. We aimed to evaluate real-world data on the incidence, characteristics, outcomes, and prognostic factors of ACLF. **Methods:** We retrospectively analyzed 363 patients with cirrhosis hospitalized between April 2014 and December 2022. Data on demographics, clinical characteristics, treatments, and outcomes were collected. ACLF was diagnosed based on the following criteria in Japan: patients with cirrhosis (Child-Pugh score of 5–9) who develop severe liver dysfunction within 28 days due to triggers such as alcohol consumption, infections, gastrointestinal bleeding, or exacerbation of the primary disease. The two ACLF categories were confirmed ACLF (prothrombin time-international normalized ratio (PT-INR) ≧1.5 or PT≦40%, and total bilirubin (T-Bil) ≧5.0 mg/dL) and extended ACLF (PT-INR≧1.5, PT≦40%, or T-Bil≧5.0 mg/dL). Statistical analyses included descriptive statistics, logistic regression, and sensitivity analysis. **Results:** Among the 363 patients (mean age, 64.4 years), 10 (2.8%) had confirmed ACLF, and 30 (8.3%) had extended ACLF. Exacerbating factors included gastrointestinal bleeding in 17 (42.5%), alcohol consumption in 15 (37.5%), and infections in 13 (32.5%) with some overlap. The mean Model for End-Stage Liver Disease Sodium (MELD-Na) score was 20.7. The 90-day and 5-year cumulative survival rates were 69.5% and 40.9%, respectively. Older age ($\geq$66 years) and a higher MELD-Na score ($\geq$21) predicted poor outcomes(P values for multivariate analysis were <0.01 and 0.01, respectively). **Conclusion:** ACLF in hospitalized patients with cirrhosis has high incidence and mortality rates. Age, MELD-Na score, gastrointestinal bleeding, alcohol use, and infection were key factors. These findings highlight the need for early risk identification and effective management.

4182 | PROGNOSTIC MODELS AND INFECTION-RELATED MORTALITY IN ACLF: A PROSPECTIVE MEXICAN COHORT STUDY

Emilio Sandoval-Gonzalez[1] Francisco Bosques-Padilla[2] Miguel Escobedo-Belloc[3] Jorge Zuñiga-Hernandez[3] Hannia Zumaya-Flores[4] Wendy Ruiz-Gallegos[4] Lilia Chavez-García[4] Leonel Castillo-Peña[4] Andres Zapata-Navarro[4], [1]Hospital Universitario Dr. Jose Eleuterio Gonzalez Universidad Autónoma de Nuevo León,Mx, [2]Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Mx, [3]Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Monterrey,Mx, [4]Facultad de Medicina, Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background: Acute-on-chronic liver failure (ACLF) is characterized by acute decompensation (AD), systemic inflammation, and multi-organ failure, associated with high short-term mortality. Although several prognostic models exist, their comparative performance and stage-based utility remain underexplored in Latin American populations. **Methods:** A prospective cohort of 140 adults with AD cirrhosis admitted to an academic referral hospital in Mexico was evaluated. Baseline clinical and laboratory data, including liver severity scores, were collected at admission. ACLF was defined and graded according to AASLD–EASL criteria using the CLIF-C OF score. All patients were assessed using Child-Pugh, MELD, MELD-Na, and MELD-Lactate. In patients meeting ACLF criteria (n = 55), CLIF-C ACLF and AARC scores were additionally applied. The primary outcome was in-hospital mortality. Predictive performance was assessed via ROC analysis; logistic regression identified clinical precipitants. **Results:** The cohort had a mean age of 54.8 ± 10.4 years, with 77.1% male. Alcohol-associated liver disease was the most frequent etiology (81.3%). In-hospital mortality was 18.6% (n = 26). Infections (OR: 6.55; 95% CI: 1.61–28.4; p = 0.008) and spontaneous bacterial peritonitis (OR: 4.16; 95% CI: 1.44–11.78; p = 0.007) were independently associated with death. Patients who did not survive had significantly elevated WBC (14.1 ± 6.9 vs. 10.0 ± 5.8; p < 0.01) and CRP (8.9 ± 6.5 vs 3.9 ± 4.9 mg/L; p = 0.0028).
In the full cohort, CLIF-C OF showed the highest prognostic accuracy (AUC 0.855, specificity 92%, accuracy 86%), followed by MELD-Na (AUC 0.765). MELD, MELD-Lactate, and Child-Pugh had moderate performance.
Within the ACLF subgroup, CLIF-C ACLF demonstrated the strongest discriminative ability (AUC 0.929, sensitivity 100%, specificity 80%, accuracy 94%), while AARC provided high sensitivity (AUC 0.803, sensitivity 88%, NPV 96%). **Conclusion:** In this prospective Latin American cohort, CLIF-C OF and CLIF-C ACLF demonstrated the strongest prognostic performance for mortality prediction in ACLF, supporting their use in clinical triage and decision-making. AARC and MELD-Na provided complementary value in earlier stages of decompensation. These findings underscore the need for stage-adapted, context-sensitive prognostic tools in cirrhotic populations, particularly in underrepresented regions such as Latin America.

◆ 4183 | OGA INDUCES NEURONAL NECROPTOSIS VIA EXTRACELLULAR VESICLES DRIVING PERINEURAL INVASION IN GALLBLADDER CANCER

Jingwei Zhao[1] Danyang Shen[2] Wei Gong[1], [1]Xinhua Hospital, Affiliated to Shanghai Jiao Tong University, [2]The First Affiliated Hospital of Soochow University

Background: Peripheral nerve invasion (PNI) is a critical early event in the progression of gallbladder cancer (GBC) and significantly influences the prognosis of patients undergoing surgery at advanced stages. Despite its importance, the precise mechanisms underlying GBC's invasion of perineural spaces remain poorly understood. **Methods:** Laser microdissection and proteomic profiling was used to construct molecular maps of the neural microenvironment for patients with PNI-positive and PNI-negative GBC. Clinical cohort analyses were conducted to assess the correlation between neuronal O-linked N-acetylglucosamine (OGA) expression, PNI severity, and overall survival. A non-contact co-culture system (including three-dimensional dorsal root ganglion explant cultures) and untargeted metabolomics were employed to investigate how GBC cells influence neuronal OGA expression. A mouse sciatic nerve invasion model was used to test the role of EV-associated OGA in promoting perineural invasion in vivo. Metabolic drug library screening and Real-time Cell Death Kinetics Assays were used to explore the functional role of OGA in neurons. Further mechanical studies focused on identifying specific sites involved in OGA-mediated regulation, and functional assays evaluated the therapeutic potential of RAGE inhibition. **Results:** We found that OGA expression was abnormally elevated in neurons following GBC invasion. Increased neuronal OGA expression correlated with greater PNI severity and poorer OS in GBC patients. GBC cells were shown to upregulate neuronal OGA expression through extracellular vesicle-mediated communication. Elevated OGA promoted neuronal necroptosis by inhibiting RIPK1 glycosylation and enhancing RIPK1 phosphorylation and activation via the RIPK1/RIPK3/MLKL pathway. RIPK1 S440 was identified as a critical site for OGA-mediated regulation. Neuronal necroptosis resulted in the release of HMGB1, which activated RAGE receptors on GBC cells, enhancing their neurotropic invasiveness. Treatment with the RAGE inhibitor FPS-ZM1, especially in combination with gemcitabine, significantly improved anticancer efficacy in experimental models. **Conclusion:** Our study reveals a novel mechanism by which GBC-derived extracellular vesicles induce neuronal necroptosis to promote PNI. OGA-mediated modulation of RIPK1 glycosylation and the subsequent release of HMGB1 play central roles in this process. Targeting the HMGB1-RAGE signaling axis offers a promising therapeutic strategy for combating PNI in GBC.

◆ 4184 | LIVER-SPECIFIC S1PR2 DELETION REDUCES HEPATIC INJURY AND FIBROSIS IN A MOUSE MODEL OF PRIMARY SCLEROSING CHOLANGITIS

Meiyi Song[1] Derrick Zhao[1] Hui Li[1] Sayed Obaidullah Aseem[2] Grayson Way[2] NAN WU[1] Yunling Tai[1] Sareh Bayatpour[1] Lianyong Su[1] Xuan Wang[1] Emily Gurley[1] Phillip Hylemon[1] Arun Sanyal[2] Huiping Zhou[2], [1]School of Medicine, Virginia Commonwealth University and Richmond Veterans Affairs Medical Center, [2]Virginia Commonwealth University

Background: Sphingosine-1-phosphate receptor 2 (S1PR2) is a GPCR. Our previous studies showed that conjugated primary bile acids (CBAs) activate S1PR2 in hepatocytes and cholangiocytes, triggering ERK1/2 and AKT signaling pathways and contributing to hepatic injury and fibrosis in bile duct ligation (BDL) and Mdr2$^{-/-}$ mice. In addition, S1PR2 is highly expressed in macrophages, where its activation by CBAs promotes inflammation, contributing to biliary injury. Global knockout of S1PR2 significantly reduced biliary fibrosis in the BDL mouse model. These findings underscore S1PR2 as a critical mediator of cholestatic liver pathology. The current study aims to define the liver-specific role of S1PR2 in cholestatic liver disease. **Methods:** Publicly available GEO datasets (GSE179993 & 268905) were analyzed. Liver-specific *S1pr2* knockout mice (S1PR2^{LKO}) were generated by crossbreeding S1pr2$^{fl/fl}$ with Alb-Cre) and further crossed with Mdr2$^{-/-}$ mice to generate Mdr2$^{-/-}$S1pr2^{LKO} double knockout mice (DKO) on a C57BL/6J background. DKO and Mdr2$^{-/-}$ (male and female, 26-week old) were used. Liver samples were processed for H&E and Picrosirius red staining. Serum lipids and liver functional enzymes were measured using the Alfa Wassermann Vet ACE Axcel System. The expression levels of the key genes involved in cholestatic liver fibrosis were measured by qPCR and Western blot analysis. **Results:** Hepatic *S1pr2* expression is upregulated in cholestatic mouse models, including Mdr2$^{-/-}$ mice. Liver-specific deletion of *S1pr2* in Mdr2$^{-/-}$ mice led to a marked reduction of inflammation and fibrosis. Biochemically, ALP levels were significantly decreased, and ALT and AST levels were modestly reduced, supporting reduced liver injury. *Ck19, Col1a1, and Col3a1* expression was downregulated, indicating a reduction of ductular reaction and fibrogenesis. Liver-specific deletion of *S1pr2* had a more prominent protective effect on liver fibrosis in male mice than in female mice, suggesting a sex-specific difference in cholestatic disease mechanisms of S1PR2 signaling. **Conclusion:** Liver-specific deletion of *S1pr2* significantly reduced biliary fibrosis, ductular reaction, and cholestatic liver injury in Mdr2$^{-/-}$ mice. Together with our previous findings that S1PR2 promotes cholangiocyte proliferation and inflammatory signaling, these results support S1PR2 as a pathogenic mediator and potential therapeutic target in cholestatic liver diseases such as PSC.

◆ 4185 | SPLEEN TYROSINE KINASE IS A POTENTIAL THERAPEUTIC TARGET FOR DUCTULAR REACTION AND SUBSEQUENT TUMOR FORMATION

Hengdong Qu[1] Di Zhang[1] Ping Tao[1] Pengqing Sun[1] Kexin Zeng[2] Zhiwei Chen[3] Zijian Xu[2] Zhibo Zhuang[2] Tingzhen Wu[1] Jian Hong[1] Nan Yao[1], [1]State Key Laboratory of Bioactive Molecules and Druggability Assessment, Jinan University, [2]Jinan University, [3]The First Affiliated Hospital of Jinan University

Background: Ductular reaction has been recognized as a critical pathogenic factor for primary sclerosing cholangitis (PSC) and cholangiocarcinoma (CCA) carcinogenesis. We previously reported that

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

pharmacological inhibition of spleen tyrosine kinase (SYK) effectively ameliorated liver fibrosis [Hepatology 2018;68(3):1125], concomitant with reduced ductular reaction. This study aims to explore the role and therapeutic potential of SYK in ductular reaction and subsequent tumor formation. **Methods:** Expression patterns and clinical relevance of SYK were assessed in murine PSC tissues and further confirmed in human livers using multiplex immunofluorescence. Pharmacological efficacy of SYK inhibitor on ductular reaction and tumor formation were determined in three distinct murine models, ranging from bile duct ligation (BDL) and 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC) diet-induced cholangitis models to *Mdr2* knockout-induced carcinogenesis model, respectively. Additionally, the therapeutic potential of a liver-specific cholesterol-conjugated heteroduplex oligonucleotides (Cho-HDO) targeting SYK on ductular reaction was evaluated. **Results:** By analysis of murine PSC livers, we found that SYK expression was dynamically upregulated in non-parenchymal cells, especially in cholangiocytes of reactive bile ducts as PSC progress. In patients with PSC ($n = 18$), we confirmed that SYK expression was markedly enhanced in ductular reactive cholangiocytes, which positively correlated with ductular reaction severity. Importantly, R788 (Fostamatinib), an FDA-approved SYK inhibitor, effectively attenuated BDL- and DDC diet-induced ductular reaction, accompanied by reduced hepatic inflammation and liver fibrosis. Moreover, R788 greatly inhibited ductular reaction and tumor formation in *Mdr2* knockout mice (both $P < 0.001$). Functional studies demonstrated that SYK promotes cholangiocyte proliferation and ductular reaction via the Hippo signaling pathway. Furthermore, pharmacological or genetic inhibition of SYK suppressed chemokine (e.g., CXCL2) released by cholangiocytes, and thereby ameliorating ductular reaction-associated neutrophils infiltration and disease progression. Clinically, tyrosine kinase inhibitors often lead to severe kidney injuries in the context of anti-tumor therapy. To improve the delivery efficacy and minimize the potential side effects, we administered liver-specific Cho-HDO. Interestingly, single administration of SYK-targeting Cho-HDO efficiently ameliorates ductular reactions, biliary fibrosis and even tumor formation in *Mdr2* knockout mice without observable hepatic and renal toxicity. **Conclusion:** Targeting SYK represents a promising therapeutic strategy for ductular reaction and carcinogenesis in PSC. Liver-specific Cho-HDO delivery may further enhance the translational potential of SYK-targeted therapy for patients with PSC.

◆ 4186 | THE CLINICAL EFFICACY OF A PPARA AGONIST ON MURINE PRIMARY BILIARY CHOLANGITIS

Masahiro Umemura[1] アキラ ホンダ [2] Yuya Ida[1] Maho Yamashita[1] Takeshi Chida[3] Hidenao Noritake[1] Teruo Miyazaki[2] Mayuko Ichimura[4] Koichi Tsuneyama[4] Patrick Leung[5] M Gershwin[5] Kazuhito Kawata[6], [1]Hamamatsu University School of Medicine, [2]Tokyo Medical University Ibaraki Medical Center, [3]Hamamatsu University School of Medicine, Japan, [4]Tokushima University Graduate School, [5]University of California, Davis, [6]Hamamatsu University

Background: Peroxisome Proliferator-Activated Receptor (PPAR) agonists, such as bezafibrate, elafibranor, and seladelpar, are recognized as one of the second-line treatments for primary biliary cholangitis (PBC). However, the underlying mechanisms of PPAR agonists remain unclear. This study aimed to investigate the impact of PPARα agonists on a well-defined murine model of PBC. **Methods:** We took advantage of our previously published murine PBC model that includes hepatic fibrosis: the Cyp2c70/Cyp2a12 double knockout mouse, which have a human-like bile acid (BA) composition and develop progressive cholangitis following immunization with a PDC-E2 mimic, 2-octynoic acid. Mice were fed either a normal/control diet ($n = 8$) or a diet containing low (0.01 mg/100 g, $n = 6$) or high (0.03 mg/100 g, $n = 6$) doses of pemafibrate (PEM), a selective PPARα modulator, for 8 weeks. We evaluated liver histology and expression of inflammatory cytokines and chemokines, hepatic fibrosis markers, nuclear receptor-related genes, and BA compositions in serum, liver, and bile. **Results:** PEM treatment significantly ameliorated portal inflammation, bile duct damage, and hepatic fibrosis in a dose-dependent manner. Similarly, the hepatic mRNA expressions of *Il-1b*, *Il-6*, *Cx3cl1*, *Col1a1*, and *Mmp2* were significantly suppressed. Additionally, *Ostb* mRNA expression was downregulated, whereas mRNA expressions of *Ntcp* and *Cyp7a1* were upregulated. PEM-treated mice exhibited decreased total BA concentrations in serum and liver, with a trend toward increased biliary BA concentrations, suggesting attenuation of cholestasis. Moreover, the ratio of chenodeoxycholic acid-derived BAs to cholic acid-derived BAs was decreased. High-dose PEM also significantly suppressed hepatic *Nfkb, Ikba* and *Nlrp3* mRNA expression. **Conclusion:** Our findings suggest that PPARα agonist exerts anti-inflammatory and anti-fibrotic effects in PBC through FXR suppression and improved BA composition. These effects collectively contribute to the

◆ 4187 | PREDICTING TRANSPLANT-FREE SURVIVAL IN PRIMARY BILIARY CIRRHOSIS USING RANDOM SURVIVAL FORESTS AND SERIAL CLINICAL MEASUREMENTS

Sri Harsha Boppana[1] Manaswitha Thota[2] Gautam Maddineni MD[3] Sachin Sravan Kumar Komati MS[4] Sai Lakshmi Prasanna Komati[5] C. David Mintz MD PhD[6], [1]Nassau University Medical Center / Johns Hopkins University, [2]Virginia Commonwealth University, [3]Creighton university school of medicine, [4]Florida International University, [5]Government Medical College, Ongole, [6]Johns Hopkins University

Background: The course of primary biliary cirrhosis often defies prediction, complicating decisions about the timing of advanced therapies. To address this, we built and tested a random survival forest model that forecasts transplant-free survival and uncovers the most influential prognostic variables in a cohort of 418 patients. **Methods:** We identified 418 individuals diagnosed with primary biliary cirrhosis and compiled repeated measures of serum bilirubin, albumin, copper, prothrombin time and 13 additional clinical parameters. Continuous gaps were imputed with the cohort mean and categorical gaps with the most common category. All continuous variables were scaled to a mean of zero and a standard deviation of one, and categorical factors were converted into binary indicators. The composite endpoint included death, liver transplantation or censoring at last follow-up. The data were randomly split into 80 percent for model training and 20 percent for validation. We fitted a random survival forest of 1 000 decision trees and evaluated its discrimination using the concordance index. To rank the predictors, we applied a permutation importance analysis. **Results:** The model achieved a concordance index of 0.94 in the training sample and 0.88 in the test sample. Permutation importance identified baseline bilirubin and albumin as the top two predictors, with prothrombin time and serum copper also contributing substantially. We calculated individual risk scores and divided patients into low-risk (n = 82), intermediate-risk (n = 134) and high-risk (n = 202) groups. The average scores were 20.1, 31.8 and 93.9 in the low-, intermediate- and high-risk strata, respectively. Kaplan-Meier survival curves displayed clear separation among all three risk categories. **Conclusion:** This machine-learning approach delivered strong prognostic discrimination and sorted patients into distinct risk tiers, with bilirubin and albumin emerging as the principal markers. These findings support further validation of such models to guide personalized management in primary biliary cirrhosis.

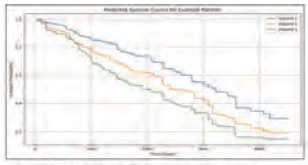

Figure 1: Survival Curves for Representative Patients

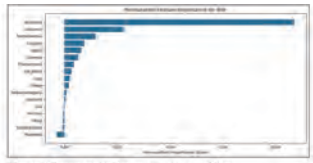

Figure 2: Permutation Feature Importance Plot

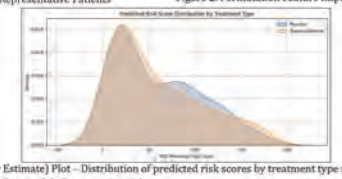

Figure 3: KDE (Kernel Density Estimate) Plot – Distribution of predicted risk scores by treatment type shows a heavier right-skew in placebo patients, indicating higher modeled progression risk.

Background: Primary Sclerosing Cholangitis (PSC) is a life-threatening disease without approved pharmacotherapy in need of innovative pathogenic insights and new druggable targets. We reported that DNA hypomethylation, cholangiocyte senescence and associated inflammatory secretome characterize PSC. Here, we provide evidence supporting the novel concept that PSC is a disease in which cholangiocytes, in response to aberrantly expressed human endogenous retroviruses (HERVs), display features of viral infection in the absence of virus (viral mimicry), driving sterile fibroinflammation. **Methods:** We used normal human cholangiocytes (NHC), induced senescent (sen)NHC, PSC patient-derived cholangiocyte organoids, PSC patient liver tissue, and PSC mouse models (DDC-fed and Mdr2$^{-/-}$). For gene expression analyses, we used methylome and RNAseq data, and quantitative PCR (qPCR). We assessed chromatin modification by chromatin immunoprecipitation (ChIP)-qPCR and analyzed RNA: protein interactions by RNA IP (RIP)-qPCR, and protein: protein interactions by co-IP and proximity ligation assay (PLA). **Results:** Pathway analyses of senNHC RNAseq showed a Type I interferon (IFN) response. Methylome data revealed hypomethylation at HERV loci in PSC patient cholangiocytes, including the HERV, MLT1F. qPCR showed upregulation of MLT1F (~9-fold), senescence markers p16 and p21 (~5-fold), the dsRNA receptor Retinoic acid inducible gene I (RIG-I, ~10-fold), and interferon response genes (IRGs; 3-6 – fold) in senNHC and PSC patient-derived cholangiocyte organoids. ChIP-qPCR revealed increased histone acetyltransferase p300 (15-fold), the chromatin mark, H3K27ac (28-fold), the epigenetic reader BRD2 (7-fold) and the transcription factor ETS1 (10-fold) at the MLT1F locus in senNHC. RIP-PCR showed MLT1F: RIG-I interaction in senNHC (10-fold increase). IP and PLA demonstrated that RIG-I interacted with mitochondrial antiviral signaling protein (MAVS, a mediator of RIG-I signaling), in senNHC, PSC mouse models, and PSC patient tissue. Deletion of MAVS in senNHC by Crispr decreased mRNA of IRGs (~40%) and fibroinflammatory cytokines (~50%). **Conclusion:** These results implicate aberrant cholangiocyte HERV expression, resultant viral mimicry, and a RIG-I/MAVS mediated IFN-response as drivers of fibroinflammation in PSC. Our data uniquely inform on PSC pathogenesis and identify novel therapeutic targets including DNA hypomethylation, HERV transcription, and the RIG/MAVS anti-viral signaling cascade.

4189 | 3A,12B-DIHYDROXYCHOLANOIC ACID-INDUCED GPAT4 PHOSPHORYLATION ELEVATES LPA LEVELS AND EXACERBATES LIVER FIBROSIS AND INFLAMMATION

yuhao zhu[1] Xingyang Luo[2] Wenhu Li[2] Linxinag Zhou[2] Jintao Xiao[2] Xiaomei Zhang[2] Xiaowei Liu[2] Haiyue He[2], [1]Xiangya Hospital, Central South University, [2]Department of Gastroenterology, Xiangya Hospital, Central South University, Changsha 410008, Hunan,

Background: Disrupted bile acid metabolism represents a central characteristic of cholestatic liver disease (CLD), resulting from obstruction of bile flow through intra or extrahepatic bile ducts. Lysophosphatidic acid (LPA) signaling has been linked to bile acid metabolism, and elevated LPA levels have been detected in cholestatic patients. The glycerophosphate acyltransferase (GPAT1-4) family catalyzes the first step in triglyceride synthesis by converting G-3-P to LPA. Among these four isoforms, GPAT4 is highly expressed in the liver and serves as the principal source of LPA production in the liver. However, the role of the GPAT4-LPA axis in CLD remains unknown. **Methods:** Gpat4-deficient (Gpat4$^{-/-}$) and wild-type control mice were subjected to bile duct ligation (BDL) or fed a 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC) Diet to construct CLD mouse models. Conditioned medium (CM) was collected from primary hepatocytes transfected with either Gpat4-overexpressed (CM-Gpat4-OE) or control (CM-Control) plasmid. Bone marrow-derived macrophages (BMDMs) were treated with LPS for 12 h prior to 1-hour exposure to a conditioned medium. Primary hepatocytes isolated from wild-type mice were treated with 36 distinct bile acid species or vehicle control. Co-immunoprecipitation (Co-IP) products from 3α,12β-DHCA-treated hepatocytes were analyzed by proteomics. Computational virtual screening was employed to discover small-molecule compounds with selective inhibitory activity against GPAT4. **Results:** We observed increased GPAT4 protein levels in both CLD patients and mouse models. Deletion of Gpat4 in liver alleviated BDL/DDC-induced hepatic inflammation and fibrosis, evidenced by decreases in plasma ALT and AST levels, collagen deposition and α-SMA protein levels. In vitro, after LPS stimulation, mRNA levels of inflammatory factors were increased in BMDMs treated with CM-Gpat4-OE, compared to CM-control. Among 36 distinct bile acids, only 3α,12β-DHCA treatment increased the p-Tyr-Gpat4 /Gpat4 ratios and total Gpat4 protein in primary hepatocytes. We also observed enhanced collagen deposition and inflammation in C57BL/6J mice intraperitoneal injected with 3α,12β-DHCA. Proteomics identified APPL2 as the top differentially expressed protein after 3α,12β-DHCA treatment. APPL2 konckdown

increased p-Tyr-GPAT4 and total GPAT4 protein levels. We also found several Gpat4 inhibitors by Computational virtual screening and verified by detecting the GPAT activity using a commercial kit. **Conclusion:** GPAT4 protein levels are significantly upregulated in CLD patients and mouse models. Deletion of GPAT4 alleviates hepatic injury and fibrosis by reducing LPA accumulation in CLD mouse models. Bile acid, particularly 3α,12β-DHCA, aggravates liver injury and fibrosis by suppressing the APPL2 expression, which upregulates GPAT4 protein levels through tyrosine phosphorylation-mediated mechanisms.

4190 | THE H19–CIRCAFF3–HUR AXIS: A NOVEL REGULATORY CIRCUIT IN CHOLESTATIC LIVER FIBROSIS

Hui Li[1] Grayson Way[1] Yun-Ling Tai[1] Nan Wu[1] Meiyi Song[1] Sareh Bayatpour[1] Derrick Zhao[1] Sayed Obaidullah Aseem[1] Lianyong Su[1] Xuan Wang[1] Emily Gurley[1] Phillip Hylemon[1] Saul Karpen[1] Arun Sanyal[1] Huiping Zhou[1], [1]Virginia Commonwealth University

Background: Cholestatic liver fibrosis is a progressive disease with limited treatment options. Prior work identified the long noncoding RNA (lncRNA) H19 as a key pro-fibrotic driver in Mdr2$^{-/-}$ mice, a model of cholestatic liver disease, yet the downstream mechanisms remain poorly defined. Circular RNAs (circRNAs), a class of covalently closed noncoding RNAs, have recently emerged as important regulators in liver pathology. This study investigates the role of H19-regulated circRNAs in cholestatic fibrosis and explores their molecular mechanisms. **Methods:** Livers from wild-type, Mdr2$^{-/-}$, and Mdr2$^{-/-}$/H19$^{-/-}$ (DKO) mice (C57BL/6, males, 10–12 weeks, n = 3) were analyzed by circRNA microarray. Candidate circRNAs were validated by qRT-PCR in primary hepatic cells and human PSC liver tissues. Functional assays in mouse large cholangiocytes (MLE) and cholangiocyte-derived organoids assessed effects on proliferation. RNA pull-down, RNA Immunoprecipitation (RIP), and public bioinformatics tools identified RNA-binding proteins (RBPs). Subcellular fractionation, confocal microscopy and FISH determined intracellular localization. **Results:** Among six circRNAs upregulated in Mdr2$^{-/-}$ and suppressed in DKO mice, circAFF3 showed the highest enrichment in primary cholangiocytes. Both H19 and circAFF3 were predominantly nuclear in MLE cells. Bioinformatic and RIP analyses indicated that H19 binds the splicing factor muscleblind-like splicing regulator 1 (MBNL1) to promote circAFF3 biogenesis. Overexpression of circAFF3 increased proliferation in MLE cells and organoids. Mechanistically, circAFF3 served as a scaffold to enhance interaction between RBP HuR and ANP32A, a nuclear export co-factor involved in Exportin 1 (CRM1)-dependent pathways. This interaction promoted HuR export to the cytoplasm, leading to stabilization of pro-inflammatory mRNAs, including IL6, CXCL1, CCL2, and VCAM1, which were upregulated 1.5- to 3.4-fold as measured by qRT-PCR ($n = 3$, $P < 0.001$). **Conclusion:** This study identifies a novel H19–circAFF3–HuR signaling axis in cholestatic liver fibrosis. H19 promotes circAFF3 expression through MBNL1, while circAFF3 facilitates HuR nuclear export by modulating ANP32A, stabilizing pro-inflammatory mRNAs. These events contribute to cholangiocyte proliferation and fibrosis. Our findings highlight circAFF3 and its associated proteins as potential therapeutic targets in cholangiopathies such as primary sclerosing cholangitis (PSC).

4191 | CHOLANGIOCYTE RUNX1 ORCHESTRATES FIBROGENIC AND INFLAMMATORY SIGNALING TO DRIVE BILIARY FIBROSIS

Sayed Obaidullah Aseem[1] Jing Wang[1] Grayson Way[1] Yunling Tai[1] Derrick Zhao[1] Xuan Wang[1] Emily Gurley[1] Nidhi Jalan-Sakrikar[2] Robert Huebert[2] Phillip Hylemon[1] Saul Karpen[3] Arun Sanyal[1] Huiping Zhou[1], [1]Virginia Commonwealth University, [2]Mayo Clinic Rochester, [3]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health

Background: Biliary fibrosis and inflammation are key drivers of cholangiopathies such as primary sclerosing cholangitis (PSC). We previously identified RUNX1 as overexpressed in PSC and a mediator of inflammatory signaling in transforming growth factor-β (TGFβ)-stimulated cholangiocytes and multidrug resistance 2 knockout (Mdr2$^{-/-}$) mice. However, the mechanistic role of RUNX1 in targeted modulation of cholangiocyte function to drive biliary inflammation and fibrosis remains ill-defined. **Methods:** PSC-derived cholangiocytes (PSC-C) and mouse large biliary epithelial cell line (MLEs) were treated with RUNX inhibitors (Ro5-3335, AI-10-104) or siRNA. Cytokines in PSC-C conditioned media were analyzed using Luminex xMAP multiplexing. Chromatin immunoprecipitation (ChIP), ChIP-seq and mass spectrometry (MS) of nuclear RUNX1 immunoprecipitant were performed on MLEs. Cholangiocyte-selective *Runx1* knockout mice (CK19-Cre) were fed 3,5-diethoxycarboncyl-1,4-dihydrocollidine (DDC) diet, and hepatic fibrosis was assessed by qPCR, Picrosirius red staining and hydroxyproline measurement by MS. **Results:** RUNX1 knockdown in PSC-C reduced secretion of cytokines, including interleukin (IL)-6, -4 and -11, tumor necrosis factor (TNF)-α/β, and granulocyte-macrophage colony-stimulating factor. TGFβ increased RUNX1 binding of *Il6* promoter in MLEs (>2-fold, $p<0.05$). ChIP-seq identified 729 differential RUNX1 binding sites (FDR < 0.05); Ingenuity Pathway Analysis (IPA) of associated genes revealing enrichment in hepatic fibrosis and inflammation pathways. Predicted upstream regulators included TGFB1, TNF, and lipopolysaccharide (LPS). RUNX1 inhibitors suppressed *Il6* expression in TGFβ- or LPS-stimulated MLEs. MS of nuclear immunoprecipitant showed RUNX1 interactions with transcriptional and epigenetic regulators; TGFβ promoted RUNX1 interaction with SMAD2 and transcription factor 7-like 2 (TCF7L2), also predicted by IPA. *In vivo*, cholangiocyte-selective *Runx1* deletion reduced hepatic *Acta2* (α-smooth muscle actin) expression, Picrosirius red staining, and hydroxyproline content in DDC-fed mice ($N=9$/group, $p<0.05$). Similarly, Ro5-3335 reduced these fibrosis markers in Mdr2$^{-/-}$ mice (~45%, $N=8$/group, $p<0.05$), consistent with attenuated biliary fibrosis. **Conclusion:** RUNX1 functions as a key transcriptional co-regulator in cholangiocytes, integrating fibrogenic and inflammatory signals. Its inhibition attenuates biliary fibrosis in cholestatic mouse models, positioning RUNX1 as a potential therapeutic target in fibroinflammatory cholangiopathies.

4192 | LOSS OF B-CATENIN IN CHOLANGIOCYTES PROMOTES ANGIOGENESIS AND HEPATOCYTE REPROGRAMMING DURING MURINE CHOLESTASIS

Matthew Carson[1] Jamie Fornsaglio[2] Laura Molina[1] Pamela Cornuet[1] Jia-jun Liu[1] Silvia Liu[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh, [2]Seton Hull University

Background: Primary sclerosing cholangitis (PSC) is a chronic liver condition with unknown etiology characterized by inflammation, fibrosis, and biliary strictures. We have previously shown that hepatocyte b-catenin plays a pleiotropic role in cholestatic injury. However, the role of cholangiocyte b-catenin during cholestasis remains unclear. The purpose of this study was to define the role of cholangiocyte b-catenin on hepatobiliary injury responses in mice with cholestasis. **Methods:** Inducible-Osteopontin (OPN)-Cre-β-catenin-floxed C57BL/6 mice were used in two cholestasis models. Mdr2 KO-β-catenin-floxed:OPN-Cre (DKO) mice were administered tamoxifen to delete β-catenin from cholangiocytes. Wild-type and cholangiocyte β-catenin KO mice were also administered a 5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet for four weeks. Serum was collected to evaluate liver enzymes. qRT-PCR and immunohistochemistry were performed on whole livers to assess injury, angiogenesis, and hepatocyte reprogramming. RNA-seq analysis was performed on isolated cholangiocytes. Cholangiocytes were treated with β-catenin siRNA *in vitro* to determine changes in angiogenic factors. Conditioned media from cholangiocytes were used to evaluate endothelial cell expansion *in vitro*. **Results:** Animals lacking cholangiocyte β-catenin have similar levels of hepatobiliary injury compared to controls. Notably, cholangiocyte β-catenin KOs had fibrotic hepatic arteries and increased periportal angiogenesis compared to controls. Isolated β-catenin KO cholangiocytes showed increased expression of angiogenesis pathways and genes that were associated with NF-kB activation. Paralleling RNA-seq findings, *in vitro* silencing of cholangiocyte β-catenin increased the expression of *Vegfa* and *Pdgfb*. Stimulated cholangiocyte media from these cells promoted endothelial cell proliferation, recapitulating the angiogenic phenotype found *in vivo*. Immunofluorescent staining showed β-catenin KO mice had an increased number of hepatocytes expressing cholangiocyte markers and ductular cells expressing β-catenin, indicating hepatocyte reprogramming. **Conclusion:** This work reveals a novel role of cholangiocyte β-catenin in regulating vasculature and hepatocyte reprogramming during cholestasis, which highlights cholangiocyte β-catenin as a potential target for therapeutic interventions.

4193 | LOSS OF DNMT1 DISRUPTS LIVER REGENERATIVE PATHWAYS AND PROGENITOR CELL ACTIVATION IN CHOLESTATIC LIVER DISEASE

Juliana Marques Affonso[1] Jovana Castven[1] Lina Jegodzinsk[1] Carolin Zimpel[1] Martha Kirstein[1] Diana Becker[2] Benjamin Heckelmann[1] Rüdiger Braun[1] Darko Castven[1] Jens Marquardt[1], [1]University of Lübeck, [2]University Medical Center of the Johannes Gutenberg University

Background: DNA methylation, a key epigenetic mechanism, plays a crucial role in regulating gene expression during development and maintainance of tissue and stem cell homeostasis in response to both acute and chronic injury. DNA methyltransferase 1 (DNMT1) is central to this process, as it preserves postmitotic DNA methylation patterns. Although DNMT1's function during development is well established, its role in the activation of stem and progenitor cells during tissue regeneration is less well explored. This project aims to explore the impact of hepatocyte-

specific DNMT1 loss on liver progenitor cell-induced regeneration. **Methods:** Cholestatic liver injury was induced using the 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) model, wherein 8-week-old liver-specific Dnmt1 knockout (Dnmt1-KO) and wild-type (WT) control mice were administered a diet containing 0.1% DDC for up to 4 weeks. Animals from each group (n = 5) were sacrificed at 1, 2, and 4 weeks post-treatment, and liver tissues were collected for further analysis. Liver injury was assessed by histopathology and the spatial distribution of CK19, a marker of biliary/progenitor cell, was evaluated. Global transcriptomic alterations were investigated using RNA sequencing. **Results:** Macroscopically, livers from both groups exhibited a pronounced dark discoloration due to cholestatic liver damage. No significant differences in macroscopic nodule count were observed. Histological examination revealed significantly more pronounced liver injury, progressive structural abnormalities, and a higher degree of infiltrating immune cells in Dnmt1-KO animals in comparison to WT. Additionally, Dnmt1-KO animals had a reduced liver/body weight ratio, reflecting impaired regenerative capacity. Supporting this, expansion of CK19-positive cells was significantly reduced in Dnmt1-KO animals, indicating impaired activation of progenitor cells . Distinct gene clustering and enrichment analysis highlight that DNMT1 deletion significantly impacts expression of pathways associated with liver homeostasis and regeneration. Specifically, DNA replication and repair, cell cycle progression, and maintenance of immune regulatory and memory-like phenotypes were notably suppressed in Dnmt1-KO animals. Notably, FOXP3-regulated immune targets were downregulated, suggesting impaired Treg function and a disrupted pro-regenerative immune microenvironment. **Conclusion:** Our findings highlight a critical role for DNMT1 in preserving liver homeostasis by sustaining key cellular programs during injury. Loss of postmitotic DNA methylation due to DNMT1 deficiency disrupts pathways essential for cell cycle progression, DNA repair and immune regulation, thereby impairing stem cell activation and effective liver regeneration in the context of cholestatic damage.

4194 | THERAPEUTIC TARGETING OF THBS1-AS1, A FIBROSIS-ASSOCIATED LNCRNA IN BILIARY DISEASE

Purnima Tyagi[1] Abid Anwar[2] Usman Yaqoob[3] Papawee Sutthirat[4] Sofia Jerez[3] Maleeha Farheen Kalaiger[2] Moira Hilscher[2] Nidhi Jalan-Sakrikar[4] Vijay Shah[4] Robert Huebert[4], [1]Mayoclinic Rochester, [2]Mayo Clinic, [3]Mayoclinic, [4]Mayo Clinic Rochester

Background: Biliary diseases like primary sclerosing cholangitis (PSC) involve progressive fibrosis and inflammation, with no curative treatments available. Emerging evidence implicates long non-coding RNAs (lncRNAs) as epigenetic regulators of cholangiocyte function, though their role in pro-fibrotic signaling remains unclear. This study explores the function of a novel lncRNA, THBS1-AS1, in driving cholangiocyte fibrogenic responses. **Methods:** Transcriptomic analysis was conducted using RNA sequencing of TGF-β treated human cholangiocytes and cholangiocytes isolated from 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) and Mdr2$^{-/-}$ mice, murine models of PSC. Differential lncRNA expression was profiled using the UClncR pipeline. Candidate lncRNAs were validated via RNA in situ hybridization (RNA-ISH), RT-PCR, and digital droplet PCR (ddPCR). Nuclear localization was assessed by cell fractionation. RNA immunoprecipitation (RIP) was performed to determine lncRNA-protein interactions. Functional studies utilized antisense oligonucleotide (ASO) mediated knockdown of lncRNA *in vitro* and *in vivo*. Epigenetic silencing was performed using guide RNAs in organoids isolated from genetically modified mice. Protein expression was assessed by western blot and immunofluorescence. **Results:** UClncR analysis identified 267 upregulated lncRNAs in TGF-β-treated cholangiocytes and 553 in DDC and Mdr2$^{-/-}$ cholangiocytes, with THBS1-AS1 emerging as the most upregulated lncRNA in both human and mouse datasets. ddPCR showed a ~10-fold increase in THBS1-AS1 expression in diseased cholangiocytes, while RT-PCR further validated its elevated levels in Mdr2$^{-/-}$ (2.2-fold, $p < 0.05$) and PSC patient livers (3-fold, $p < 0.05$). Nuclear fractionation and RNA-ISH confirmed predominant nuclear localization of THBS1-AS1, with strong expression in bile ducts of PSC patient livers and Mdr2$^{-/-}$ mice. RIP revealed that THBS1-AS1 interacts with the epigenetic silencer, EZH2, following TGF-β stimulation (2-fold, $p < 0.01$). ASO-mediated silencing of THBS1-AS1 significantly reduced TGFβ-mediated expression of key fibrogenic genes: FN1 (4-fold, $p < 0.01$), Serpine1 (4.2-fold, $p < 0.01$), CTGF (2.5-fold, $p < 0.05$) and THBS1 (2.2-fold, $p < 0.05$) confirmed at the RT-PCR level, protein level by western blotting and immunofluorescence. Administration of ASO via the tail vein resulted in decreased

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

liver injury markers in Mdr2$^{-/-}$ mice. Concurrently, epigenetic silencing of THBS1-AS1 using guide RNAs in biliary organoids from DDC-treated mice led to a 3-fold reduction in Serpine1 and a 1.7-fold reduction in FN1 ($p < 0.05$). **Conclusion:** THBS1-AS1 is a TGF-β-responsive lncRNA that is selectively upregulated in cholangiocytes and interact with epigenetic regulator EZH2. Its silencing reduces TGF-β-induced fibrogenic gene expression, likely by excluding EZH2 from chromatin, highlighting its potential as a therapeutic target in biliary fibrosis.

4195 | GENE EDITED IPSC-DERIVED BILIARY ORGANOIDS REVEAL CFTR MUTATION-SPECIFIC IMPACTS ON CHOLANGIOCYTE FUNCTION AND PROVIDES PATHOPHYSIOLOGICAL INSIGHTS RELEVANT FOR TREATMENT OF CF-RELATED LIVER DISEASE

Shakila Afroz Taleb[1] Camilla Venturin[1] Santo Diprima[1] Mario Strazzabosco[2] Romina Fiorotto[2], [1]Yale School of Medicine, [2]Yale University

Background: Cystic Fibrosis-associated liver disease (CFLD) causes significant morbidity and mortality in patients with CF. Using CF animal models and human induced pluripotent stem cells (iPSC)-derived cholangiocytes bearing the DF508 mutation, we showed that CFTR-defective biliary cells have altered secretion, polarity and innate immune responses. However, how different CFTR mutations affect CFLD phenotype and response to therapies remains unclear. In this study, we generated human cholangiocyte carrying different CFTR mutations using gene editing of iPSC and studied the effects on biliary cell physiology. **Methods:** Isogenic iPSC lines carrying W1282X (class I), ΔF508 (class II), and G551D (class III) mutations were generated via CRISPR/Cas9 from a control line. iPSC lines were differentiated to cholangiocytes and used to generate biliary organoids. Cholangiocyte specification was verified by RT-PCR and immunohistochemistry. Bulk RNA-sequencing was performed in monolayers. Forskolin-induced swelling (FIS) was used to test response to CFTR modulators. Immunofluorescence was performed for ZO1, b-catenin and F-actin. **Results:** iPSC-derived biliary organoids maintained morphological and functional properties of mature biliary epithelium. iPSC organoids with different CFTR mutations had no or minimal response to FIS. CFTR modulators (elexacaftor/tezacaftor/ivacaftor) improved FIS in ΔF508 and G551D but not W1282X organoids. β-catenin and ZO-1 staining showed disarrangement of cellular polarity in all CF lines while F-actin distribution was altered in W1282X and ΔF508 but not G551D organoids. Transcriptome analysis identified 11 differentially expressed genes (DEGs) shared across mutations. Enrichment of genes related to cytoskeletal components was observed in all mutated lines. Treatment with an Src-inhibitor (PP2) improved the effect of CFTR modulators in ΔF508 organoids. Gene and protein expression of NLRP2, a relatively uncharacterized component of the inflammasome and a negative regulator of TNF-mediated NF-kB signaling, were consistently low in all the CF lines, and possibly mechanistically linked to the pro-inflammatory phenotype described in CF cholangiocytes. **Conclusion:** Gene edited iPSC-derived cholangiocytes and organoids reveal mutation-specific

effects on morphology, transcriptome, secretory function and response to modulators. This iPSC-based platform enables mechanistic insights and will be useful to identify new therapeutics for CFLD.

4196 | TGFβ2 UPREGULATION ON REACTIVE CHOLANGIOCYTES LIMITS THE THERAPEUTIC EFFICACY OF TGFβ TRAP RAP-1332 IN MOUSE MODELS OF CHRONIC BILIARY INJURY AND FIBROSIS

Pinzhu Huang[1] Monica Shipman[1] Zaur Abilov[1] Maram Alenzi[1] Zhensheng Zhang[1] Richard (Xiwu) Chen[2] Rajasekhar Suragani[3] Patrick Andre[3] Chandra sekar Shankar[1] Yury Popov[1], [1]BIDMC Harvard Medical School, [2]Merck & Co., Inc; Acceleron Pharma Inc, [3]Acceleron Pharma Inc

Background: We report therapeutic effect of RAP-1332 (a ligand trap for TGFβ1 and TGFβ3) in comparison with pan-TGFβ signaling inhibitor (ALK5i), in mouse models of primary sclerosing cholangitis (PSC)-like biliary injury. **Methods:** RAP-1332 (1, 3 and 10 mg/kg twice a week) or TGFb/ALK5 inhibitor (SB-525334, 30 mg/kg/day) was tested in a BALBc.Mdr2$^{-/-}$ mice starting at 4 weeks (early therapy) or 6 weeks (delayed therapy) of age for the following 4-6 weeks, respectively. Portal venous pressure (PVP), serum liver function tests and histologic analyses were assessed. A second sclerosing cholangitis model due to 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) feeding model of PSC was for validation. Inn vitro experiments were conducted in immature murine ductular cell line 603B. **Results:** Alk5 inhibitor led to readily detectable improvement of liver injury and fibrosis parameters in both Mdr2$^{-/-}$ and DDC models. In contrast, both early and delayed administration of RAP-1332 into Mdr2$^{-/-}$ mice did not ameliorate liver injury and liver fibrosis, and led to paradoxical worsening of disease at the high dose. In delayed therapy arm, ALT and AST were increased by 53.50% and 44.14%, respectively at 10 mg/kg dose RAP-1332. Exacerbated ductular reaction and worsened periductular fibrosis was observed in mice receiving high dose of RAP-1332, with 2-fold increase of collagen compared to placebo. Likewise, high dose of RAP-1332 in DDC model led to similar exacerbation of biliary injury and fibrosis. Realtime PCR and *in situ* hybridization showed remarkable upregulation of TGFβ2 expression on actively proliferating reactive cholangiocytes. This was accompanied by adjacent expansion of α-SMA+ hepatic stellate cell and exacerbated inflammation (CD45+ and CD68+ cells). In vitro, TGFβ1/3 trapping by RAP-13323 directly promoted proliferation of immature ductular cells 603B. **Conclusion:** Our results suggest that selective blocking TGFβ1 and TGFβ3 in chronic biliary fibrosing disease is inefficient due to compensatory upregulation of TGFβ2 isoform on reactive cholangiocytes. This should be taken into account in rational design of TGFb inhibitors for cholangiopathies and liver diseases associated with ductular reaction.

4197 | IMPAIRING BILE DUCT FORMATION DISRUPTS HEPATIC ARTERY FORMATION IN A MOUSE MODEL OF GENETIC CHOLESTASIS

Laura Molina[1] Tyler Yasaka[1] Mara Sullivan[1] Akshita Piedy[1] Shuchang Liu[1] Lori Schmitt[2] Catherine Gestrich[2] Kari Nejak-Bowen[1], [1]University of Pittsburgh, [2]Children's Hospital of Pittsburgh

Background: We previously showed that loss of Yes-associated protein 1 (YAP) in early liver development (Foxa3-Cre YAP KO) leads to an Alagille syndrome-like phenotype, with failure of intrahepatic bile duct development and severe cholestasis. Given the close relationship between the bile ducts and hepatic arteries, we questioned whether these mice showed defects in hepatic artery formation as well. **Methods:** We deleted *Yap1* during early liver development using the *Foxa3* promoter to drive Cre expression. We evaluated the vasculature of these mice using light microscopy, transmission electron microscopy (TEM), and RNA-sequencing. **Results:** We examined WT and YAP KO liver tissue with immunohistochemistry for CD31 (general vasculature), alpha-smooth muscle actin (a-SMA; marks pericytes particularly thick around hepatic arteries), and Lyve1 (lymphatic vessels and some sinusoids). We found that most portal tracts in YAP KO mice lacked hepatic arteries and instead had visible lymphatic vessels which seemed to be dilated in contrast to those in WT mice. We also found that the expression of CD31 and Lyve1 was decreased in the midzonal and pericentral liver sinusoids in YAP KO mice relative to WT, suggesting potential capillarization. The liver vasculature plays a significant role in regulating zonation, and indeed we found that YAP KO mice showed an expansion of periportal (Cyp2f2) and midzonal (Ccnd1) areas, while no change was found

in the pericentral area (GS, Cyp2e1). We next asked if there was a change to the ultrastructure of the liver vasculature, but TEM analysis showed there was no significant change in the fenestrations of the sinusoids and their relationship with the hepatocyte brush border. We examined RNA-sequencing data and did not find a significant enrichment in hypoxia-related genes in YAP KO liver relative to WT liver. Next, we are examining the hepatic vasculature in early biopsies from patients with pediatric cholestasis from the Children's Hospital of Pittsburgh to determine whether our murine findings show relevance in conditions like Alagille syndrome (bile duct paucity) and congenital hepatic fibrosis with Caroli syndrome (bile duct overgrowth), in contrast to hepatocyte-driven cholestasis like PFIC1 and alpha-1-antitrypsin deficiency (no direct genetic damage to bile duct formation). **Conclusion:** We show that in our YAP KO mice, hepatic artery formation is developmentally dependent on bile duct formation. These mice show altered hepatic zonation and vascular marker expression but retain sinusoidal fenestration. Further is ongoing to address the functional implications of this change as well as to query whether abnormalities in hepatic artery formation can be found in patient specimens of pediatric cholestasis.

4198 | DOES CHOLANGIOCYTE FERROPTOSIS PROMOTE A PRO-FIBROGENIC MACROPHAGE PHENOTYPE IN CHOLESTASIS?

Maria Eugenia Guicciardi[1] Anuradha Krishnan[1] Kirsta Olson[1] Alexander Wixom[1] Nidhi Jalan-Sakrikar[1] Gregory Gores[1], [1]Mayo Clinic Rochester

Background: Cholangiopathies, i.e., primary sclerosing cholangitis (PSC), are characterized by oxidative stress, increased serum levels of IL-17A, periductal infiltration of Th17 cells and macrophages, and fibrosis. To date, a parsimonious mechanism to explain these disparate observations has not been proposed. Herein, we explore the concept that cholangiocyte ferroptosis, a lytic form of cell death characterized by phospholipid peroxidation, may unify these observations. Our approach was as follows: 1) Can cholangiocyte oxidative damage be identified in liver specimens? 2) Does IL-17A sensitize cholangiocytes to ferroptosis *in vitro*? and, 3) Do oxidized phospholipids skew macrophage polarization into a profibrogenic phenotype?. **Methods:** The presence of oxidized phospholipids in liver tissue was examined by immunofluorescence for 4-hydroxynonenal (4-HNE) and hyperoxidized peroxiredoxin-3 (PRDX3). Lipidomics analysis for oxidized phospholipids was performed on murine bile using mass spectrometry. Ferroptosis was induced *in vitro* in normal human cholangiocyte cell lines (NHC, H69) by RSL3 (potent inducer of ferroptosis) and measured by propidium iodide uptake and flow cytometry using the fluorescent sensor for lipid peroxidation BODIPY C11. Bone marrow-derived macrophages (BMDM) were isolated from wild type mice and treated with a mixture of oxidized phospholipids (OxPAPC; 25μg/ml). **Results:** Cholangiocyte oxidative damage was identified in bile ducts from liver tissue of PSC patients and mouse models of cholestatic injury (*Mdr2*$^{-/-}$ and DDC-fed mice). Fourteen oxidized phospholipids were detected in the bile of DDC-fed mice, but not in chow-fed mice, and decreased in mice simultaneously receiving the ferroptosis inhibitor liproxstatin 1 (Lip-1). *In vitro*, NHC and H69 cells demonstrated sensitivity to RSL3-induced ferroptosis, which was further enhanced in the presence of IL-17A. BMDM significantly upregulated *Tgfβ* and *Pdgfb* following exposure to OxPAPC, supporting a profibrotic macrophage response. Consistent with a role for ferroptosis in the cholestasis-associated fibrosis, *Mdr2*$^{-/-}$ mice injected with Lip-1 displayed reduced peribiliary macrophage accumulation and fibroblast activation. **Conclusion:** Our data identify cholangiocyte ferroptosis as a potential contributor to the fibroinflammatory biliary injury in human and murine cholestasis by releasing oxidized lipid mediators of macrophage profibrotic polarization.

4199 | SPATIOTEMPORAL RELATIONSHIP BETWEEN WNT/β-CATENIN AND YAP SIGNALING PATHWAYS IN A CHOLESTATIC MOUSE MODEL

Veronica Lee[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh

Background: Treatments for cholestatic liver disease remain limited. Often, patients develop cirrhosis and liver failure requiring a liver transplant. Therefore, it is important to study regenerative pathways to halt disease progression. Both the Wnt/β-catenin and Yap signaling pathways are involved in liver injury responses such as hepatocyte-to-cholangiocyte trans-differentiation; however, the interaction between these two pathways is unknown. The purpose of this study was to define the spatiotemporal relationship between the Wnt/β-catenin and Yap pathways in cholestatic injury. **Methods:** Wildtype (WT) mice and S45D transgenic (TG) mice, expressing a non-degradable form of β-catenin, were bred to have dual reporters for Wnt and Yap activity. These mice were placed on 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet to induce cholestasis and were sacrificed after 30 and 60 days of treatment. Livers were harvested and ductular reaction, inflammation and fibrosis were analyzed using immunohistochemistry (IHC). Wnt and Yap activity were evaluated by dual immuno-fluorescence (IF) staining. **Results:** TG mice with non-degradable β-catenin had increased ductular reaction and inflammation after 30 days of DDC diet. This corresponded to decreased fibrosis in these mice following prolonged (60 day) DDC. On the other hand, ductular reaction and inflammation did not increase in WT mice until 60 days after DDC. Notably, fibrosis was also significantly higher in WT mice than in TG at this time point. TG mice showed enhanced Wnt activation after 30 days, while in WT, levels of Wnt activation did not increase until after 60 days of DDC. Wnt activation was predominantly present in the nuclei of pericentral hepatocytes while Yap activation was seen in the cytoplasm of periportal cholangiocytes. Yap activity was equivalent in both WT and TG at both time points, indicating no contribution of Wnt signaling to Yap activation. Further, we did not observe co-localization of Wnt or Yap activity. **Conclusion:** Findings from this study suggest early compensatory responses to injury in TG mice may attenuate disease progression, which is likely due to early Wnt activation and subsequent Yap activity. Separation of Wnt and Yap expression in different cell types suggest that these two pathways may function independently or through paracrine mechanisms. Further research is necessary to elucidate the indirect and direct cross-talk between Wnt and Yap signaling in cholestatic injury.

4200 | PHARMACOLOGICAL MANIPULATION OF MYC PHOSPHORYLATION IN PSC ANIMALS MODELS DRIVES CHOLANGIOCYTE CELL FATE

Patrick Splinter[1] Steven O'Hara[1] Antonia Felzen[2] Carys Turner[1] Olivia Morgenthaler[1] Gregory Gores[1] Nicholas LaRusso[1], [1]Mayo Clinic, [2]University of Groningen

Background: Using in vitro systems, we showed that stress-induced MYC phosphorylation promotes either cholangiocyte proliferation (pS62 via p38) or senescence (pT58 via GSK3B) and proposed both phenotypes influence PSC pathogenesis. Our in vitro studies also revealed that pharmacologic inhibition of MYC [with MYCi975 (MYCi)] promoted cholangiocyte senescence while inhibition of GSK3 [with CHIR99021 (CHIR)] drove cholangiocyte proliferation, results identifying dual kinase mediators of cholangiocyte cell fate. Here, we further tested this hypothesis in PSC animal models using drugs to selectively modify MYC phosphorylation. **Methods:** We used two accepted animal models of PSC, *Mdr2*$^{-/-}$ and DDC-fed mice. DDC-fed and *Mdr2*$^{-/-}$ mice were treated by intraperitoneal injection of MYCi (50 mg/kg) or CHIR (10 mg/kg) 3 times per week for 3 weeks. Mice were sacrificed and measurements made on serum (liver function tests) and liver including H&E, Sirius red staining, IF for MYC, Keratin 7 (KRT7) and proliferating cell nuclear antigen (PCNA) and qRT-PCR for *Krt7*, *Pcna*, and the senescence marker, *p16*. **Results:** MYCi inhibition of MYC reduced fibrosis in DDC-fed mice (>70%) and in *Mdr2*$^{-/-}$ mice (~30%) versus respective vehicle controls. MYCi treatment improved serum biochemistries (20-50%) in DDC-fed mice, and improved TBILI (~60%) in *Mdr2*$^{-/-}$ mice. Immunofluorescence revealed that total KRT7 and percent PCNA-positive cholangiocytes were decreased in both DDC (25% and 40%, respectively) and *Mdr2*$^{-/-}$ mice (25% and 50%, respectively) following MYCi treatment. MYCi also reduced total liver *Krt7* (>30%) and *Pcna* (>40%) mRNA and increased *p16* mRNA (~50%) in both mouse models. GSK3 inhibition with CHIR increased fibrosis (~1.5-fold) in DDC-fed mice and *Mdr2*$^{-/-}$ mice (1.2-fold) versus respective vehicle controls. Immunofluorescence revealed that CHIR increased total KRT7 and percent PCNA-positive cholangiocytes in both DDC-fed (1.5- and 1.2-fold, respectively) and *Mdr2*$^{-/-}$ mice (1.2- and 1.5-fold, respectively) particularly in parenchymal areas (ductular reaction) and increased total liver *Krt7* (1.7-fold) and *Pcna* (1.25-fold) mRNA and decreased *p16* (>50%) mRNA in both mouse models. **Conclusion:** The data

demonstrate that MYC is a driver of cholangiocyte proliferation in PSC animal models and identify the kinase mediators that determines cholangiocyte cell fate. Together, the results support the notion that MYC is a "molecular switch" in that determines cholangiocyte responses to stress.

4201 | THE INFLUENCE OF HYDROPHOBIC BILE ACIDS ON THE ONSET OF PRIMARY SCLEROSING CHOLANGITIS VIA CHOLEHEPATIC AND ENTEROHEPATIC CIRCULATIONS

Teruo Miyazaki[1] Hajime Ueda[1] Tadashi Ikegami[1] アキラ ホンダ[1], [1]Tokyo Medical University Ibaraki Medical Center

Background: Primary sclerosing cholangitis (PSC), caused by unknown triggers, is characterized by fibrosis around the large bile duct (onion-skin fibrosis) and frequently complicates inflammatory bowel diseases. Hydrophobic (Hbic) bile acids (BAs) circulating in the cholangio- and entero-hepatic axes are considered as the potential PSC trigger, because PSC lesion was observed in double KO mice (HuBA) of *Cyp2c70* and *Cyp2a12*, which convert a Hbic BA, chenodeoxycholic acid (CDCA), into a hydrophilic mouse-specific BA, muricholic acid, and the secondary BA, lithocholic acid (LCA), back to CDCA, respectively. This study investigated the roles of Hbic BAs on the onset of PSC in the HuBA mice, and cultured human cholangiocytes. **Methods:** Male HuBA mice (5 weeks of age) were treated with CDCA or LCA or no BAs (NT) for 15 weeks via drinking water at low dose (75 mg/L). BA profiles in the liver, serum, and feces were analyzed, along with histological examination and gene expression analysis in the liver and intestines. Serum lipopolysaccharide (LPS) level was also measured. Intestinal permeability was assessed by the FITC-dextran loading test. Highly differentiated immortalized human cholangiocyte cell line (MMNK1) was exposed to 100 μM of CDCA or LCA for 48 hours, and then, gene expression was evaluated by RNA-sequencing and RT-qPCR. **Results:** The BA composition of all examined samples in HuBA mice, which is converted to human-type BA profile, was not significantly affected by the BA administrations. The incidence rate of onion-skin fibrosis was 50-60% by CDCA and no BA treatments, but was 100% by LCA treatment with the significantly larger fibrotic area. In the LCA-treated HuBA mice, intestinal permeability and serum LPS level were significantly higher than in the others, accompanied with a low density of the large intestinal crypts. In the liver and small intestine, the gene expression of *Tnfα, Tgfβ, Tlr4,* and *Integrins-αv/β6* were significantly increased by LCA treatment. In the MMNK1 cells, *CDH1* (*E-cadherin*) gene expression was down-regulated, while *SNAI1* (*Snail*), *CDH3/10/24,* and *TLR4* genes were up-regulated, following CDCA treatment. **Conclusion:** The results support that CDCA and LCA may induce disruption of tight junctions in the cholangiocytes and enterocytes, respectively, contributing to the onset of PSC. Additionally, CDCA-induced TLR-4 expression in the cholangiocytes may promote onion-skin fibrosis and inflammation through endotoxin influx induced by LCA. Hbic BAs (CDCA and LCA) might be the principal triggers of bile duct and intestinal damages via the cholehepatic and enterohepatic circulations.

4202 | VITAMIN D SUPPLEMENTATION AMELIORATES DUCTULAR REACTION, LIVER INFLAMMATION AND FIBROSIS BY UPREGULATING TXNIP IN DUCTULAR CELLS

Jun-Yeop Song[1] Hyuk Soo Eun[1] Seok-Hwan Kim[1] Youngsuk Won[2] Hyojung Kwon[1], [1]Chungnam National University, [2]Korea Research Institute of Bioscience and Biotechnology

Background: Ductular reaction is associated with liver disease progression, but there are currently no pharmacologic drugs targeting ductular reaction. Vitamin D deficiency is common in chronic
liver diseases (CLDs) and related to disease progression, but the underlying mechanisms by which vitamin D supplementation regulates CLD progression remain unclear. **Methods:** Here, we used clinical liver samples and an experimental animal model to examine whether vitamin D supplementation ameliorates ductular reaction and subsequently reduces liver inflammation and fibrosis, and the underlying mechanisms were explored. **Results:** We found that vitamin D plasma levels were negatively correlated with the degree of ductular reaction in patients with chronic liver diseases. $1,25(OH)_2D_3$, the active form of vitamin D, reduced 3,5-diethoxycarbonyl-1,4-dihydrocollidin (DDC)-induced

ductular reaction, liver inflammation, and fibrosis in mice and upregulated the vitamin D target gene, TXNIP (encoding thioredoxin-interacting protein), in ductular cells. Cholangiocyte-specific *Txnip*-knockout mice were more susceptible to DDC-induced ductular reaction, inflammation, and fibrosis. Deletion of *Txnip* in cholangiocytes promoted proliferation and suppressed death. Furthermore, *Txnip* deficiency increased TNF-α and TGF-β secretion by cholangiocytes to stimulate Kupffer cells and hepatic stellate cells, consequently leading to inflammation and collagen deposition. Biliary *Txnip* deficiency abolished the protective effects of vitamin D, and TXNIP overexpression attenuated DDC-induced ductular reaction and hepatic inflammation and fibrosis. **Conclusion:** Collectively, our findings identify new mechanism how vitamin D ameliorates liver diseases and suggest that the vitamin D/TXNIP axis is a therapeutic target for addressing ductular reaction and liver diseases.

4203 | THE NF-Y HETEROTRIMERIC TRANSCRIPTION FACTOR COMPLEX AS A REGULATOR OF THE CHOLANGIOCYTE PROLIFERATION-ASSOCIATED PHENOTYPE IN A MODEL OF MURINE CHOLESTASIS

Kirsta Olson[1] Anuradha Krishnan[1] Patrick Splinter[1] Alexander Wixom[1] Maria Eugenia Guicciardi[1] Kevin Pavelko[1] Nidhi Jalan-Sakrikar[1] Adiba Azad[1] Nicholas LaRusso[1] Gregory Gores[1], [1]Mayo Clinic

Background: In cholestatic liver diseases, proliferating ductular reactive (DR) cells secrete chemokines promoting liver inflammation. However, the cellular processes regulating this cholangiocyte proliferation associated secretory phenotype (PASP) are incompletely understood. To provide insight into the cholangiocyte PASP, our approach was as follows: 1) first categorize a consequence of the cholangiocyte PASP, namely recruitment of a periportal macrophage subset; 2) ascertain the cholangiocyte chemokine responsible for the macrophage recruitment; and 3) identify the transcription factor(s) increasing expression of his chemokine and other components of the cholangiocyte PASP. **Methods:** Mice were fed a DDC diet for 10 days and then switched to a chow diet to permit recovery (designated as R days). **Results:** Total intrahepatic leukocytes were isolated and profiled by mass spectrometry (CyTOF), where an abundant periportal CX3CR1^{+} macrophage population was demonstrated in the DDC mice. To verify the CyTOF observations, we employed CX3CR1^{GFP} mice and noted that the CX3CR1^{GFP+} periportal macrophages increased 4-fold on the DDC diet and returned to basal values by day R10. Spatial transcriptomics identified cholangiocyte expression CX3CL1, the ligand of CX3CR1, in DR cells. To further interrogate the regulation of the cholangiocyte PASP, cholangiocytes were isolated from control, DDC, and R15 mice and RNA-seq performed. IPA Canonical pathway analysis revealed activation of the "pathogen induced cytokine storm" pathway in cholangiocytes activated from DDC fed mice, and resolution of this pathway in R15 isolated cholangiocytes. SCENIC regulon analysis identified that the NF-Y transcription factor heterotrimeric complex (A, B, and C subunits) was activated on the DDC diet and repressed at control and R15 timepoints. To examine this transactivation in human cholangiocytes, normal human cholangiocytes (NHC) were treated with an siRNA targeting the NF-YA subunit (knockdown validated by immunoblot analysis). Indeed, chemokine expression was decreased in the cells transfected with the targeting siRNA, but not the scrambled siRNA. **Conclusion:** These observations implicate the NF-Y transcription factor complex as a regulator of the cholangiocyte PASP in a model of murine cholestasis. The results also support a cholangiocyte CX3CL1/CX3CR1^{+} macrophage axis in cholestatic liver injury.

4204 | SCHISANTHERIN A, A NEW TYPE OF PPARα LIGAND ATTENUATES CHOLESTATIC LIVER INJURY IN MICE

Jiamei Chen[1] Zheng Zhang[2] En-qi Tang[3] Yue Liang[2] Wei Liu[2] Ping Liu[2], [1]Shuguang Hospital affiliated to Shanghai University of TCM, [2]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [3]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine,

Background: Schisantherin A (Sin A), the natural compound from *Schizandra chinensis (Turcz.) Baill.*, exhibits anti-hepatic fibrosis effects, but the efficacy and underlying mechanism in treating cholestatic liver injury is poorly understood. **Methods:** In this study, two mouse models, including 3,5-Diethoxycarbonyl-1,4-Dihydro-2,4,6-Collidine (DDC)-induced and *Mdr2*$^{-/-}$ spontaneous cholestatic liver injury, and the peroxisome proliferator-activated receptor alpha (Pparα) gene knockout (*Pparα*$^{-/-}$) mice were used to investigate the therapeutic effect and mechanisms of Sin A. Furthermore, proteomics and RNA-sequencing analyses, luciferase reporter assay, as well as drug affinity responsive target stability (DARTS), cellular thermal shift assay (CESTA) and surface plasmon resonance (SPR) experiments were performed. Degradation of the PPARα protein was measured after the treatment of cycloheximide (CHX) with or without Sin A at the indicated time points *in vitro*. **Results:** Treatment with Sin A significantly ameliorated the cholestasis-related disorder of bile acid metabolism, liver injury, ductular reaction (DR), inflammation and fibrosis in both DDC-induced and *Mdr2*$^{-/-}$ mice. Proteomics and RNA-sequencing analyses of both DDC-induced liver and *Mdr2*$^{-/-}$ liver samples before and after treatment with Sin A suggested that Sin A activated PPAR signaling. Further validation revealed that Sin A significantly up-regulated hepatic PPARa protein expression in these two mice models. Subsequently, luciferase reporter assay revealed that Sin A significantly activated PPARa. DARTS and CETSA experiments indicated that Sin A inhibited the PPARα degradation caused by pronase and the temperature-induced denaturation in AML12 cell lysates, thereby implying a direct interaction between herpetrione and PPARα. SPR analysis validated the interaction of Sin A with PPARα, demonstrating an equilibrium dissociation constant (KD) of 63.26 μM. The results of degradation of the PPARα protein with CHX showed that Sin A weakened PPARα degradation compared to the control group. These results revealed that Sin A bound directly to the PPARα protein to improve the stability of the PPARα protein and activate PPARa. Furthermore, PPARa deletion abolished the anti-biliary fibrotic effect of Sin A in DDC-induced mice, suggesting that Sin A alleviated cholestasis, bile acid metabolism, DR and inflammation in mice by targeting up-regulation of PPARα, thereby alleviating cholestatic liver injury. **Conclusion:** Our findings provided compelling evidence for Sin A treatment in cholestatic liver injury, as well as the broader prospects for cholestatic liver injury treatment by targeting PPARα.

4205 | UDP-GLUCURONOSYLTRANSFERASE (UGT) ENZYME POLYMORPHISMS MAY IMPACT CLINICAL VARIABLES, TREATMENT RESPONSE, AND CALCULATED RISK SCORES IN PBC AND PSC

Colleen Hayes[1] Mahesh Krishna[2] Christopher Hemme[1] Bonnie Chen[3] Scott Roberts[3] James Boyer[2] David Assis[2] Nisanne Ghonem[1], [1]University of Rhode Island, [2]Yale University, [3]Yale

Background: PBC and PSC are characterized by the accumulation of toxic bile acids. Glucuronidation is a major pathway of bile acid detoxification, conjugating glucuronic acid to the parent bile acid by UGT enzymes. Human bile acid glucuronidation is catalyzed by UGT1A1, -1A3, -1A4, -2B4, and -2B7, which are encoded by the polymorphic *UGT1A* and *-2B* genes. Single nucleotide polymorphisms (SNP) in these genes can influence glucuronidation and bile acid levels in PBC and PSC. We investigated the frequency of UGT polymorphisms in genomic data provided by the PBC and PSC cohorts in the NIH *All of Us (AoU)* database and compared those frequencies to PBC and PSC patients requiring second-line treatment with fenofibrate. We also analyzed the impact of UGT genotypes on clinical markers and risk scores in PBC and PSC. **Methods:** UGT SNP frequencies in PBC (n = 421) and PSC (n = 178) were determined from the AoU genomic database (Controlled Tier Dataset, v8). Genomic DNA was isolated from plasma samples of PBC patients on second-line therapy with UDCA + fenofibrate (n = 59), and from PSC patients with persistent cholestasis despite UDCA who received fenofibrate (n = 28), obtained from the Yale Liver Center Biorepository (New Haven, CT). Genotyping was performed for *UGT1A3* -66T > C, *UGT1A3* 31T > C, *UGT2B4* 1374A > T, and *UGT2B7* 802T > C. UGT genotypes

were correlated with clinical variables (ALP, bilirubin) and risk scores for PBC and PSC (UK, PREsTO, Mayo Risk Score (MRS)). **Results:** The *All of Us* database revealed genotype frequencies for specific UGT SNPs in PBC and PSC. Specifically, alternate genotype (heterozygote + homozygote mutant) frequencies were found for *UGT1A3* -66 T > C: 61% (PBC and PSC), *UGT1A3* 31T > C (PBC: 59%, PSC: 58%), *UGT2B4* 1374 A > T (PBC: 26%, PSC:30%), and *UGT2B7* 802 T > C (PBC: 65%, PSC: 67%). By contrast, alternate genotype frequencies in our patient cohorts requiring second-line therapy were notably different for PBC (67%, 66%, 0% ($p < 0.05$), and 34% ($p < 0.001$)) and for PSC (81% ($p = 0.08$), 82% ($p < 0.05$), 0% ($p < 0.05$), and 35% ($p < 0.01$)), respectively. Furthermore, analyses of clinical data and risk scores revealed that *UGT1A3* -66T > C, *UGT1A3* 31T > C, and *UGT2B7* 802T > C influenced ALP and bilirubin levels for PBC ($p < 0.05$), and ALP and MRS for PSC ($p = 0.09$). **Conclusion:** Our study identified UGT polymorphisms in PBC and PSC in both the AoU cohorts and our study cohorts. Our findings also revealed significant differences between the frequency of UGT SNPs in the *AoU* database and in our study cohorts. These findings raise the possibility that UGT SNPs may impact the need for second-line therapy in PBC and added anti-cholestatic therapy in PSC. Preliminary data also suggest that the *UGT1A3* -66T > C, *UGT1A3* 31T > C, and *UGT2B7* 802T > C SNPs may impact clinical variables and calculated risk scores in PBC and PSC. These findings support further investigation into UGT polymorphisms as potential factors underlying the response to anti-cholestatic therapy, and on clinical outcomes.

4206 | DISTINCT BILE MYCOBIOME SIGNATURE IDENTIFIES FUNGAL PEPTIDE PANEL PREDICTIVE FOR GALLBLADDER CARCINOMA

Sanju Yadav[1] NUPUR SHARMA[1] manisha yadav[1] neha sharma[1] gaurav tripathi[1] sushmita pandey[1] jaswinder singh Maras[2], [1]Institute of liver and biliary sciences, [2]NSTITUTE OF LIVER AND BILIARY SCIENCES

Background: Background: and **Aim:** Carcinoma of Gallbladder cancer (CAGB) has poor prognosis. While the bile microbiome and lipidome are associated with CAGB development, the contribution of fungal microbiota is unexplored. Our study aims to investigate the contribution of fungal microbiome and identify top fungal peptides to potentially stratify CAGB patients. **Methods:** Bile samples were collected from patients undergoing cholecystectomy for Gall Stone (GS) disease ($n = 10$), patients undergoing surgery for CAGB ($n = 16$) and healthy liver donors ($n = 16$) were subjected to fungal peptide-based diversity analysis and metabolomics. Results were cross-validated on the plasma samples, correlated with clinical parameters, and subjected to machine learning analysis. **Results:** Fungal peptide-based diversity analysis identified 6 Phylum and 24 Fungal Species differentially regulated in the bile samples of the study cohort. Fungal diversity (alpha and beta diversity) was significantly higher in CAGB as compared to GS or HC ($p < 0.05$). 93 fungal peptides were upregulated and 63 were downregulated in CAGB ($p < 0.05$, FC > 1.5). Linear discriminant analysis significantly segregated CAGB patients with marked increase in Aspergillus wentii (log2FC-12.21), Nosema bombycis (log2FC-11.25), Saccharomyces (log2FC-10.89), Saccharomyces cerevisiae (log2FC-10.68) and Schizosaccharomyces pombe (log2FC-10.38; $p < 0.05$)in the bile samples. Fungal-metabolite correlation analysis ($r2 > 5$, $p < 0.05$) identified Aspergillus wentii, Nosema bombycis, and others directly associated with lysine biosynthesis, taurine, and hypotaurine metabolism, fatty acid, and other in bile, and cysteine and methionine metabolism, ascorbate metabolism, purine metabolism and other in plasma. Probability of detection (POD) calculated using fungal peptides showed a diagnostic efficiency of 96% for segregation of CAGB patients. The identified top 5 fungal peptides were validated using Single reaction monitoring analysis with which it predicted early mortality > 90% accuracy/sensitivity and specificity in Machine Learning model. **Conclusion:** Bile fungal diversity correlates with CAGB development and identified fungal panel capable of segregation and early diagnosis of CAGB patients.

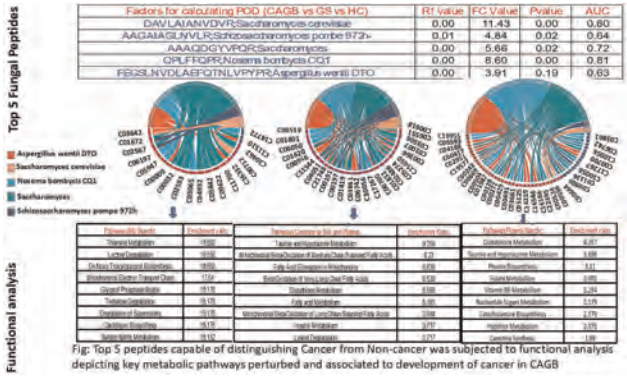

Fig: Top 5 peptides capable of distinguishing Cancer from Non-cancer was subjected to functional analysis depicting key metabolic pathways perturbed and associated to development of cancer in CAGB

4207 | MORE THAN JUST LIVER: ELUCIDATING GENETIC AND CHOLESTATIC CAUSES OF CHRONIC KIDNEY DISEASE IN A MOUSE MODEL OF BILE DUCT PAUCITY

Laura Molina[1] Jia-jun Liu[1] Akshita Piedy[1] Shuchang Liu[1] Jianhua Luo[1] Minakshi Poddar[1] Sucha Singh[1] Pamela Cornuet[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh

Background: We previously showed that loss of Yes-associated protein 1 (YAP) in early liver development (*Foxa3*-Cre YAP KO) leads to an Alagille syndrome-like phenotype, with failure of intrahepatic bile duct development and severe cholestasis. However, these mice also develop severe chronic kidney injury. Here we investigate the renal pathology and differentiate the genetic defects caused by YAP deletion from long-term exposure to severe cholestasis. **Methods:** We used microscopy, serum biochemistry, and RNA-sequencing to study *Foxa3*-Cre *Yap1*$^{fl/fl}$ mice and littermate controls, as well as *Foxa3*-Cre TdTomato healthy reporter mice. **Results:** YAP KO mice have grossly normal renal development, with no visible abnormalities at 1 month. They develop glomerular dilation and polycystic kidney disease over the first three to six months of life, accompanied by chronic inflammation and fibrosis (panels A-D). A similar phenotype was observed in a previously published mouse model of bile duct ligation (PMID37939855), although these mice were not observed past 12 weeks post-injury. However, chronic renal disease has rarely been investigated in other mouse models of cholestasis.

We next examined whether *Foxa3*-Cre may affect genitourinary tissues. Using *Foxa3*-Cre TdTomato reporter mice, we found reporter expression not just in organs derived from foregut endoderm, but also throughout the genitourinary tract, including some of the renal tubules, most urothelium, and hormone-producing cells in the testes and ovaries (panels E-F). The testosterone-producing Leydig cells and maturing spermatids in the testes were strongly positive; notably, we found that YAP KO testes lack Leydig cells and fail to produce mature sperm (panel G), demonstrating a critical role for YAP in male fertility and raising the possibility that altered testosterone levels may be affecting other organs in this model.

We next performed bulk RNA-sequencing on 3-week-old kidneys. YAP KO kidneys show changes in primary cilia-related genes, bile salt metabolism, and decreased RXR signaling. Further study is ongoing to identify mechanisms connecting YAP deficiency with polycystic kidney disease and male infertility in this model. We are also testing the effect of Vitamin A supplementation in improving renal function by activating RXR. **Conclusion:** Many genetic syndromes impact both liver and kidney function, while adults with liver injury often progress to multi-organ dysfunction. We demonstrate for the first time that the *Foxa3* promoter is active in genitourinary tissues, and consequently the YAP KO model exhibits complex multi-organ pathology. This model presents an opportunity to (1) study the combined effects of genetics and cholestasis on renal function; (2) study the impact of low testosterone on cholestatic liver injury; and (3) presents YAP as a possible disease modifier in a variety of cholestatic and renal diseases.

Ortiz[5], [1]Columbia University, [2]Albany Medical College, [3]king edward medical university, [4]George Mason University, [5]Garnet Health Medical Center

Background: Biliary atresia (BA) is a progressive fibro-obliterative cholangiopathy historically managed with portoenterostomy. However, suboptimal outcomes and long-term sequalae necessitate liver transplant (LTX) as salvage or primary therapy for most children with BA. As a result, BA is the most common indication for pediatric LTX. The impact of donor and recipient characteristics has not been well studied. We investigated the effect of sex, race and donor type on recipient outcomes. **Methods:** A retrospective analysis using the UNOS database between January 1, 2000 and September 30, 2024 was performed. 1,427 pediatric liver transplants for BA were identified. Donor, recipient and transplant characteristics were compared by sex, race and donor type using t-/Wilcoxon-Mann-Whitney, ANOVA or Chi-sq/Fishers exact tests. Graft failure and patient mortality were analyzed using Kaplan-Meier and COX regression. **Results:** BA LTX recipients had no difference in acute rejection in hospitalization ($p = 0.283$), 1 year rejection ($p = 0.457$) or graft failure at 1, 3 or 5 years ($p = 0.121$) when compared by sex. There were no differences in acute rejection in hospitalization ($p = 0.74$), rejection within 1 year ($p = 0.108$) or graft failure due to ischemic cholangiopathy ($p = 0.872$) by recipient race. However, Asian recipients experienced significantly higher rates of graft failure due to hepatic artery thrombosis ($p = 0.038$). Deceased donor LTXs with IL2 induction were at lower risk of graft failure (HR = 0.376, $p = 0.007$). Living donor LTXs with recipient age > 10 (HR = 13.02, $p = 0.037$) and prolonged total preservation time (HR = 1.338, $p = 0.032$) were at increased risk of graft failure. IL2 induction was associated with a lower risk of patient mortality (HR = 0.516, $p = 0.039$) in living donors. **Conclusion:** LTX recipients with BA experience similar rates of rejection and graft failure regardless of sex, race or donor type. Induction, age and preservation time are important considerations as feasibility and utilization of LTX continue to improve.

4209 | A NEW CLASS OF ORALLY AVAILABLE NTCP INHIBITORS DEMONSTRATES POTENT EFFICACY AGAINST HBV AND CHOLESTASIS IN HUMANIZED MICE MODELS

Stan van de Graaf[1] Hendrik Jan Thibaut[2] Philip Meuleman[3] Kaliopi Pervolaraki[4] Jean-Christoph Vanherck[4] Charlène Marcadet[4] Lieven Verhoye[3] Amse De Meyer[3] Madina Rasulova[2] Heyrhyoung Lyoo[2] Jasmine Paulissen[2] Kristof De Vos[2] Isabelle Bolt[5] Esther Vogels[5] Dagmar Tolenaars[6] Patrick Chaltin[7] Arnaud Marchand[4] Matthias Versele[4] Johan Neyts[2] Pieter Annaert[2], [1]Amsterdam UMC, [2]KU Leuven, [3]Ghent University, [4]CISTIM Leuven, [5]Amsterdam UMC, Tytgat Institute for Liver and Intestinal Research, [6]Amsterdam MC, Tytgat Institute for Liver and Intestinal Research, [7]Centre for Drug Design and Discovery, Leuven, Belgium

Background: The sodium taurocholate co-transporting polypeptide (NTCP, *SLC10A1*) is solely expressed at the basolateral membrane of hepatocytes. Here, it constitutes the main transporter of conjugated bile acids and serves as the entry receptor for the hepatitis B virus (HBV) and hepatitis delta virus (HDV). Daily injection with a Pre-S1 mimicking synthetic peptide called bulevirtide (also called Myrcludex-B) is approved in the EU for treatment of patients co-infected with HBV and HDV. We and others have previously demonstrated that pharmacological inhibition of hepatic bile salt uptake using bulevirtide ameliorates cholestatic liver injury in mice. As both treatment of viral hepatitis and cholestatic liver diseases require chronic treatment, we aimed to develop orally available small molecule NTCP inhibitors. **Methods:** Radiolabeled or fluorophore-coupled conjugated bile salts were used to identify and optimize potent and selective small-molecule inhibitors of NTCP-mediated bile acid uptake and HBV/HDV entry inhibitors with adequate *DMPK* characteristics, suitable for oral dosing. Effects of the lead candidate were assessed in a DDC-induced cholestasis mouse model transgenic for human NTCP. Urokinase-type plasminogen activator-severe combined immunodeficiency (uPA-SCID) mice engrafted with human hepatocytes were used to determine *in vivo* impact on bile acid kinetics and HBV infection. **Results:** In a comprehensive drug discovery effort we identified a novel chemical series of NTCP inhibitors with multiple compounds with single-digit nM potency for NTCP and high selectivity (> 100x) against ASBT and BSEP mediated bile salt transport. Consistently, these compounds dose-dependently reduced intracellular bile acid levels in sandwich-cultured human hepatocytes. *In vitro* infection studies demonstrated low nM HBV and HDV entry inhibition, similar to bulevirtide. A lead molecule, CIM212930, with good oral bioavailability and excellent liver distribution was prioritized. PK/PD experiments with CIM212930 in uPA/SCID mice with humanized livers illustrated dose-dependent and prolonged elevation of serum bile acid levels demonstrating both target engagement and indicative of a once-daily oral dosing regimen. Finally, CIM212930 largely reduced liver damage in DDC-induced cholestasis models and completely blocked HBV infection in a humanized liver mouse model. **Conclusion:** We describe novel and specific small-molecule orally

4210 | COMBINATION OF PHARMACOLOGICAL IBAT INHIBITION AND PPAR ACTIVATION IMPROVES LIVER HISTOPATHOLOGY OF SCLEROSING CHOLANGITIS IN MDR2$^{-/-}$ MICE

Manavi Singh[1] Pamela Sylvestre[2] Liva Pfuhler[2] Rebekah Karns[2] Annika Yang Vom Hofe[1] RAMESH KUDIRA[1] Mary Mullen[1] Priya Bariya[2] wujuan zhang[2] Kenneth Setchell[2] Jennifer Kasten[2] Cory Kostrub[3] Pamela Vig[4] Alexander Miethke[1], [1]Cincinnati Children's Hospital Medical Center, [2]CCHMC, [3]Mirum Pharmaceuticals, [4]Mirum Phamaceuticals

Background: We showed before that combination of pharmacological inhibition of intestinal bile acid uptake with IBAT inhibitors (IBATi) in combination with agonists of isoforms of peroxisome proliferator–activated receptors (PPAR) reduced serum markers of hepatocellular injury and cholestasis in the MDR2$^{-/-}$ mouse model of sclerosing cholangitis (SC). Here we examine the effects of these treatments on liver histopathology. **Methods:** 30-day-old female MDR2$^{-/-}$ FVB mice were treated for 14 days with daily orogastric gavage of either vehicle, 100 mg/kg/day Bezafibrate (pan-PPAR agonist), 100 mg/kg/day Fenofibrate (PPAR -alpha agonist), 10 mg/kg Seladelpar (PPAR-delta agonist), 0.008% SC-435 (IBATi) admixed to chow, or a combination of IBATi and PPAR agonists. End of treatment liver histopathology was assessed by a pathologist blinded to treatment groups (n = 6 per group) and by image analysis of liver sections subjected to Sirius Red (SR) staining or CK19-IHC. Hepatic bile acid (BA) composition and transcriptome were quantitated by mass-spectrometry and bulk RNA-seq, respectively. **Results:** Compared with vehicle treated MDR2$^{-/-}$ mice, reduction in Ishak stage of fibrosis was only observed in mice treated with IBATi and PPAR-delta agonist (mean ± SEM of 2.8 ± 0.4 vs 4 ± 0.3 stage, $p < 0.01$). Significant reductions in ductular reaction and periportal inflammation were observed in mice receiving IBATi alone or in combination with PPAR agonists (Fig 1A). Image analysis revealed diminished percent area fibrosis in all treatment groups containing IBATi and following monotherapy with pan-PPAR agonist; whereas, decrease in intrahepatic biliary mass was significant only in mice receiving IBATi and pan-PPAR agonist (Fig 1B). Across all treatment groups, liver concentrations of total BA, TCDCA, omega(w)-TMCA, and beta(b)-MCA, were positively correlated with serum levels of liver injury, percent area fibrosis, and intrahepatic biliary mass (Fig 1C). Principal component analysis of differentially expressed genes in bulk liver RNA-seq data revealed that mice receiving IBATi and PPAR-delta agonist more closely segregated with wild type mice compared with MDR2$^{-/-}$ vehicle and the other treatment groups. **Conclusion:** While monotherapies of PPAR agonists or IBATi improve serum biomarkers of liver injury, prevention of progression of liver fibrosis or ductular reaction requires combination therapy of IBATi and PPAR agonist. The synergistic effects may originate from specific changes in hepatic BA composition under these treatments.

4211 | EXPLORING THE ROLE OF THE WNT SIGNALING PATHWAY IN AN ALAGILLE MOUSE MODEL OF CHOLESTATIC LIVER DISEASE

Sarah Bedoyan[1] Kari Nejak-Bowen[2] Pamela Cornuet[2], [1]University of Pittsburgh Medical Center, [2]University of Pittsburgh

Background: Alagille syndrome (ALGS) is a rare, autosomal dominant systemic disease with wide variability in disease penetrance. It is caused by pathogenic variants in JAG1 which encode crucial components of the Notch signaling pathway that develop intrahepatic bile ducts. Alteration of this pathway leads to intrahepatic bile duct paucity and cholestasis. The Wnt- β -catenin signaling pathway is crucial in hepatobiliary repair, cell proliferation, apoptosis, zonation and regeneration after cholestasis-induced injury. Activators of this pathway present potentially druggable targets in cholangiopathies. Here we demonstrate the effects of augmenting this pathway in a $Jag^{+/-}$ mouse model of ALGS. **Methods:** We characterized the time course and extent of liver injury in $Jag^{+/-}$ mice, then used 2-amino-4-[3,4-(methylenedioxy) benzylamino]-6-(3-methoxyphenyl) pyrimidine (AMBMP), a small molecule Wnt agonist mixed into mouse chow at a concentration of 3.33 mg/kg. $Jag^{+/-}$ as well as WT litter mates were fed AMBMP diet starting 5 weeks after birth for a duration of 2 weeks. Liver was stained for histology and markers of cell proliferation and apoptosis. RNA was measured for expression of b-catenin, albumin, Glutamine Synthetase (GS), cyclin-D1, and biliary markers CK19, Sox9, and EpCAM. Serum biochemical markers of hepatic and biliary injury were also measured. **Results:** $Jag^{+/-}$ mice showed liver injury as early as 3 weeks post-natal age, which significant ductular reaction and fibrosis peaking at 7 weeks, before showing a visually improved phenotype at 9.5 weeks on H&E staining. $Jag^{+/-}$ mice at 9.5 weeks showed significantly more CD45 staining (a pan-leukocyte marker), indicating more inflammatory cell infiltration. Preliminary results show that when treated with AMBMP, the $Jag^{+/-}$ mouse group has higher beta-catenin and GS RNA expression by qPCR. Comparison of serum biomarkers between $Jag^{+/-}$-treated with AMBMP diet vs. regular mouse chow shows a decrease in serum alkaline phosphatase level. **Conclusion:** The Wnt-β-catenin is crucial in liver development and metabolism and augmenting its activity in models of cholestasis may reduce hepatocyte injury and help promote liver repair. $Jag^{+/-}$ mice have extensive liver injury shortly after weaning, and while studies are ongoing, treatment with AMBMP diet shows early promise in activating β -catenin and its downstream targets (GS) and reducing serum biomarkers of liver injury.

4212 | BETA-CATENIN OVEREXPRESSION DAMPENS HEPATITIS, FIBROSIS, AND DUCTULAR PROLIFERATION IN A MOUSE CHOLESTATIC LIVER DISEASE MODEL AND COINCIDES WITH INCREASED HEPATOCYTE-TO-CHOLANGIOCYTE TRANSDIFFERENTIATION

Tony (Chun-Cheng) Chiang[1] Pamela Cornuet[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh

Background: Cholestatic liver diseases are characterized by impaired bile flow and bile acid accumulation. Transdifferentiation provides a safe way to mitigate damage to the biliary epithelial cells (cholangiocytes). Our preliminary data showed that Wnt/beta-catenin signaling is increased during hepatocyte-to-cholangiocyte transdifferentiation in vitro. Knockout or inhibition of Wnt/beta-catenin reduced transdifferentiation markers and worsened biliary injury. Therefore, we hypothesize that overexpression of beta-catenin augments hepatocyte-to-cholangiocyte transdifferentiation, thus alleviating biliary injury and restoring liver functions. To test

this, we overexpressed non-degradable serine-45-aspartate mutated (S45D) beta-catenin in the mdr2 $^{-/-}$ mouse model of cholestasis and studied the impact and underlying mechanism. **Methods:** Transgenic beta-catenin S45D+ mice crossed with mdr2 knockout mice (TG/KO), mdr2 knockout alone (KO) mice, and their wildtype littermates, all carrying Rosa26-stopf/f-EYFP alleles, were injected with AAV8-TBG-Cre at 5 weeks old to label hepatocytes and then sacrificed at 12 weeks old. Biochemical markers of hepatobiliary injury were assessed. Livers were studied for histopathology and fibrosis, and ductular proliferation was quantified by CK-19 immunohistochemistry. Immunofluorescence for Sox9 and EYFP was used to trace hepatocyte-to-cholangiocyte transdifferentiation, and the number of EYFP+ cholangiocytes and Sox9+ hepatocytes was quantified for each group. **Results:** Serum biochemical studies suggested that worsening hepatitis in the injury-alone genotype (KO) can be rescued by S45D beta-catenin overexpression (TG/KO). Histopathology revealed more inflammation, fibrosis, and ductular proliferation in the KO group, which were reversed partially in the TG/KO group. Histopathology also disclosed that sex differences exist in the mice. Immunofluorescence staining showed more EYFP+ cholangiocytes and Sox9+ hepatocytes in the portal zone of the TG/KO group, indicating that more hepatocyte-to-cholangiocyte transdifferentiation occurs when beta-catenin is overexpressed in hepatocytes. **Conclusion:** S45D beta-catenin overexpression slows the progression of injury in mdr2 KO mice. Further studies are needed to separate genders to compare the effects between groups. Based on the finding of increased cellular plasticity in the S45D mice, we plan to elucidate more detailed mechanisms using both biased and unbiased approaches in the future.

4213 | IMPACT OF IGG4-RELATED DISEASE ON BILIARY OBSTRUCTION IN PRIMARY SCLEROSING CHOLANGITIS: A MULTI-CENTER RETROSPECTIVE COHORT STUDY USING TRINETX

Hazem Abosheaishaa[1] Ahmed Salem[2] Amr Dokmak[3] Mohamed Eldesouki[4] Khaled Elfert[5] Omar Abdelhalim[6] Mohamed El-Kassas[7] Mohammed Abusuliman[8] Nermin Elhossiny[9] Madhavi Reddy[3], [1]Icahn school of medicine at mount sinai, [2]Maimonides Medical Center, [3]The Brooklyn Hospital Center, [4]New York Medical College at Saint Michael Medical Center, [5]West Virginia University, [6]Queens Hospital Center, [7]Helwan University, [8]Henry Ford Hospital, [9]St Mary General hospital prime healthcare

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive inflammation and fibrosis of the bile ducts. The coexistence of IgG4-related disease (IgG4-RD) in PSC patients has been reported, yet its impact on clinical outcomes remains poorly understood. This study aimed to evaluate the differences in biliary obstruction between PSC patients with and without IgG4-RD using a large multi-center electronic health record (EHR) database. **Methods:** We conducted a retrospective cohort study utilizing the TriNetX research network, including 102 healthcare organizations. Adult patients ($\geq$ 18 years) with a diagnosis of PSC (ICD-10: K83.01) were identified and stratified into two groups: those with concurrent IgG4-RD (ICD-10: D89.84) and those without. Propensity score matching was performed 1:1 based on demographics and comorbidities, yielding 111 patients in each cohort. The primary outcome was the occurrence of biliary obstruction (ICD-10: K83.1). Secondary outcomes included survival probability and number of biliary obstruction events. Kaplan-Meier survival analysis, risk ratios, and hazard ratios were calculated. Statistical significance was set at $p < 0.05$. **Results:** After matching, the cohort included 111 PSC patients with IgG4-RD and 111 PSC patients without IgG4-RD. The risk of biliary obstruction was higher in the PSC with IgG4-RD group compared to the PSC without IgG4-RD group (45.0% vs. 29.7%; risk difference 0.153; 95% CI 0.027–0.279; $p = 0.018$). The risk ratio was 1.515 (95% CI 1.065–2.155), and the odds ratio was 1.937 (95% CI 1.115–3.367). Kaplan-Meier analysis demonstrated reduced survival in the PSC with IgG4-RD group, with a median survival of 697 days compared to non-reached median survival in the control group (Log-Rank $p = 0.043$). The hazard ratio for biliary obstruction in the IgG4-RD group was 1.570 (95% CI 1.009–2.442). The mean number of biliary obstruction episodes was higher in the IgG4-RD group (9.52 ± 15.66 vs. 6.15 ± 11.69; $p = 0.294$), though this difference was not statistically significant. **Conclusion:** PSC patients with IgG4-RD exhibit a higher risk of biliary obstruction and reduced survival compared to those without IgG4-RD. These findings underscore the importance of recognizing IgG4-RD as a potential risk factor in PSC and highlight the need for further research to guide optimal management strategies in this high-risk population.

4214 | SC435, AN INTESTINAL BILE ACID TRANSPORTER INHIBITOR (IBAT), IMPROVES LIVER FUNCTION IN CHOLESTATIC MDR2$^{-/-}$ MICE BUT NOT IN ARE-DEL$^{-/-}$ MICE

James Boyer[1] Shi-Ying Cai[1] Scott Roberts[2] David Assis[3] Ziqian Xu[4] Cory Kostrub[5] Pamala Vig[5], [1]Yale University, [2]Yale Universiiety School of Medicine, [3]Yale University School of Medicine, [4]Yale School of Medicine, [5]Mirum Pharmaceuticals

Background: Hepatic bile acid BA) accumulations in cholestatic disorders elicits a cytokine mediated inflammatory response leading to in liver injury. We postulated that decreasing BA pool size by blocking its intestinal reabsorption using an IBAT inhibitor (SC435) should reduce liver injury in cholestatic Mdr2$^{-/-}$ and ARE-Del$^{-/-}$ mice. **Methods:** 6-week-old Mdr2$^{-/-}$ male FVB mice (n = 7-8) were used as a positive control and fed a standard chow diet with or without the IBAT inhibitor for 4 weeks. ARE-del$^{-/-}$ black 6 female mice (n = 11-12) were fed the same diet for 4 weeks starting at 16 weeks of age. Blood was obtained for liver function and serum BA at start of treatment and 4 weeks later when the animals were terminated. Liver tissue and feces were obtained for fecal BA and histology. **Results:** As expected,SC435 fed Mdr2$^{-/-}$ male mice showed significant reductions in ALT (31% of the control goup, p = 0.0003), serum BA levels (41% of the control group, p = 0.017) and increased fecal BA (2.45+/-0.17 vs 1.90 +/-0.41 umole/g, p. = 0.006) with no change in ALP, compared to control mice . Significant reductions in periportal inflammatory infiltrates, bile duct proliferation but not fibrosis were also seen. Interestingly, in the ARE-Del$^{-/-}$mice that developed moderate cholestatic liver injury, the SC435 IBAT inhibitor did not substantially reduce serum levels of ALT, ALP and BA compared to the controls. Assessment of liver histology did not show significant improvements in inflammation either. Most surprisingly, fecal BA were substantially reduced rather than increased as expected (2.09+/-0.24 vs 1.73+/-0.14 umole/g, p. = 0.0003). Subsequent analysis of the bile salt export pump (Bsep) gene expression revealed a marked and significant reduction in this important bile acid transporter (mRNA WT 1.01 +/-0.19 vs KO 0.49 +/-0.29, p = 0.007), indicating that a functional Bsep is needed for IBATs to have an effect. **Conclusion:** SC435, an IBAT inhibitor, significantly improved liver function, serum BA, liver histology and fecal BA excretion in Mdr2$^{-/-}$ male mice as previously demonstrated. In contrast, it did not improve liver function in the ARE-del $^{-/-}$ mice compared to the control mice. where BA pool size was not reduced in these S435 fed animals. Because Mdr2$^{-/-}$ and ARE-Del$^{-/-}$ models pose different pathogenic mechanisms of cholestasis, this study indicates that novel approaches may be needed to restore BA homeostasis in cholestasis iver injury mediated by inflammatioin.

4215 | THE HISTONE DEACETYLASE INHIBITOR MS-275 MITIGATES HEPATOBILIARY INJURY BY MAINTAINING QUIESCENCE AND METABOLIC REPROGRAMMING IN A MURINE MODEL OF CHOLESTATIC LIVER DISEASE

Tony (Chun-Cheng) Chiang[1] Donghun Shin[1] Shuchang Liu[1] Satdarshan (Paul) Monga[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh

Background: Liver transplantation remains the sole life-extending option for patients suffering from end-

stage cholestatic liver disease; thus, a therapeutic alternative is urgently needed. Histone deacetylase (HDAC) inhibitors such as MS-275 were developed as treatments for oncologic diseases given the ability to inhibit cell growth and induce apoptosis, while their value in hepatobiliary disease is unknown. We aimed to evaluate the drug responses in mice subject to 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-induced biliary injury and understand the drug's underlying mechanism. **Methods:** Mice were given 0.1% DDC diet for 4 weeks. Starting 3 weeks after DDC, mice were given either DMSO or MS-275 along with DDC for 7 days and sacrificed 4 weeks after starting DDC. Serum and liver were collected at experiment endpoints. Real-time quantitative PCR (qPCR) was used to determine transcript levels. RNA-seq was performed to identify differential gene expression and pathways. Immunostainings were applied to validate RNA-seq results. Bile acid composition was analyzed using ultra-performance liquid chromatography-mass spectrometry. Total bile acids were measured with a colorimetric assay. AML12 mouse hepatocytes were used to confirm in vivo results. **Results:** MS-275 significantly reduced DDC-induced hepatobiliary injury, and alleviated liver pathological changes including fibrosis. Cluster analysis and differential gene expression indicated that MS-275 normalized DDC-injured livers toward baseline controls. Enrichment analysis disclosed gene expression changes in cell cycle, senescence, bile acid secretion, oxidative phosphorylation, and immune cell activation pathways between DDC alone and MS-275 groups. MS-275 decreased not only G1/S cyclins but also proliferative marker Ki-67 and senescence marker p21. This finding was reproduced in a mouse hepatocyte cell line. MS-275 preserved liver functions by increasing expression of metabolic enzymes, transporters, and autophagy proteins compared to injury alone. Though bile acid composition did not differ between DDC alone and MS-275 groups, total bile acid levels were significantly reduced after MS-275 treatment. **Conclusion:** MS-275 exerts hepatoprotective effects against DDC-induced injury in mice by restoring quiescence. Additionally, MS-275 rescues metabolic enzymes and proteins suppressed by DDC injury. Further epigenetic studies are needed to dissect a more detailed mechanism and correlate with RNA-seq findings.

◆ ★ 4216 | LIPID–IMMUNE CROSSTALK IN HCC: FXR DISRUPTS SPHINGOSINE-1-PHOSPHATE SIGNALING TO LIMIT TREG TRAFFICKING

Yasmeen Attia[1] Rasha Tawfiq[1] Aya Ali[2] Olfat Hammam[3] Mohamed Elmazar[1], [1]Department of Pharmacology, Faculty of Pharmacy, the British University in Egypt, [2]Health Research Center of Excellence, The British University in Egypt, [3]Department of Pathology, Theodor Bilharz Research Institute

Background: The paradigm of the liver as an immune graveyard—where T cells met deletion, not direction—has given way to a more dynamic view of its immunological function. Nowhere is this shift more apparent than in hepatocellular carcinoma (HCC), where the liver actively sculpts an immunosuppressive niche, with regulatory T cells (Tregs) densely infiltrating the tumor and reinforcing its "cold" immune phenotype. Beyond classical cytokine circuits, recent data suggest that Treg recruitment is shaped by lipid cues—particularly sphingosine-1-phosphate (S1P), which guides immune cell migration *via* its receptor, S1PR1. The upstream control of this axis remains incompletely defined. Farnesoid X receptor (FXR), a metabolic sentinel in the liver, has emerged as a regulator of sphingolipid pathways. This study investigates whether pharmacologic activation of FXR *via* obeticholic acid (OCA) can disrupt S1P–S1PR1–mediated Treg trafficking and help reprogram the immune architecture of HCC. **Methods:** HCC was induced in 3-week-old Swiss albino male mice using diethylnitrosamine (DEN; 1 mg/kg, i.p.) followed by carbon tetrachloride (CCl_4; 0.2 mL/kg, i.p., twice weekly). At week 20, mice received obeticholic acid (OCA; 10 mg/kg/day, p.o.) for 12 weeks. Liver tissue was assessed histologically and by immunohistochemistry for alpha-fetoprotein (AFP). FXR activation was evaluated by ELISA quantification of hepatic FXR and its downstream target, CYP7A1. Treg polarization was assessed by qRT-PCR of *Foxp3* and *Il2ra*, while sphingolipid signaling was probed by measuring *S1pr1* gene expression and S1P levels by ELISA. Hepatic concentrations of TGF-β1, IL-10, and p-SMAD2/3 were also determined by ELISA. **Results:** Histological analysis confirmed HCC in DEN +CCl_4-treated mice with OCA attenuating tumor burden. AFP immunostaining was markedly reduced in the OCA group, along with hepatic CYP7A1 levels, supporting effective FXR activation. DEN+CCl_4 exposure increased the hepatic expression of Treg markers *Foxp3* and *Il2ra*, consistent with an immunosuppressive tumor milieu. OCA treatment led to their downregulation, suggesting a suppression of Treg polarization. These changes paralelled reductions in TGF-β1, p-SMAD2/3, and IL-10 levels. Also, both hepatic S1P and *S1pr1* expression were elevated in HCC-bearing mice and diminished following FXR activation, pointing to a potential link between

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

sphingolipid signaling and Treg trafficking. **Conclusion:** These findings reveal a previously unrecognized role for FXR in modulating the sphingolipid axis that governs Treg recruitment in HCC. By disrupting S1P–S1PR1 signaling, FXR activation might attenuate the cues that sustain immune tolerance in the tumor microenvironment. This lipid–immune intersection offers a mechanistically distinct pathway for reprogramming hepatic immunosuppression and may inform future strategies for converting "cold" tumors into immunologically responsive ones.

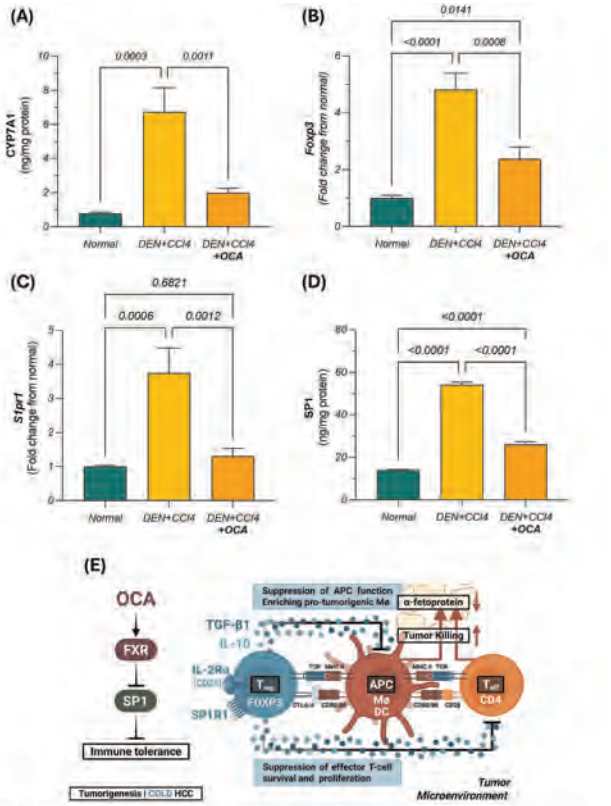

Figure 1. FXR activation modulates Treg markers and sphingolipid signaling in HCC.
(A) Hepatic CYP7A1 protein levels. **(B)** *Foxp3* and **(C)** *S1pr1* gene expression, and **(D)** S1P concentrations in DEN+CCl_4–and OCA-treated mice. Data are presented as mean ± SD. Statistical significance was assessed using one-way ANOVA followed by Tukey's post hoc test. **(E)** Schematic illustration of FXR-mediated regulation of the sphingolipid-S1P-S1PR1 axis and its influence on Treg polarization.

◆ 4217 | A CHAMELEON LIKE ROLE OF DIABETES GENE HNF4A IN REGULATING HEPATIC GENE REGULATION UPON NUCLEAR RECEPTOR ACTIVATION

Fathima Nafrisha Cassim Bawa[1] Mohit Midha[1] Abigail Holland[1] Mitchell Lazar[1], [1]Perelman School of Medicine, University of Pennsylvania

Background: The nuclear receptor Hepatocyte Nuclear Factor alpha (HNF4α) is a well-established as lineage determining factor in the liver during development that regulates lipid, glucose, and xenobiotic metabolism in the adult. Here we report that in addition to this general lineage-specific function, HNF4α genomic binding and gene regulation are also coupled to specific signals that canonically activate other nuclear receptors (NR) in the liver. Thereby HNF4α plays a role in regulating hepatic transcriptome in response to specific NR activation. **Methods:** We utilized wildtype mice with C57BL/6J background to study the changes in the HNF4α and respective NR cistromes and associated transcriptomes in response to NR activation by treating mice with specific NR agonists. We studied the effects of NR agonists on HNF4α genomic binding and related gene expression to elucidate the functional importance of non-canonical HNF4α binding regulating NR dependent drug response and associated metabolic pathways in the liver. **Results:** Our data show that lipid lowering drug fenofibrate regulates HNF4α binding and HNF4α-dependent gene regulation at specific genomic loci in a manner that is dependent upon fibrate receptor PPARα even in the absence of nearby binding by PPARα. In a similar manner, HNF4α is required for regulation of genes controlled by the glucocorticoid receptor and its cognate ligands, thyroid hormone receptor and thyroid hormones, and the oxysterol-regulated nuclear receptor LXR and its pharmacological ligands. Motif analysis at these signal-regulated sites of HNF4α binding and gene expression identified the canonical HNF4α binding motif and mostly in the intronic and intergenic regions. Remarkably, despite the known role of HNF4α to open chromatin and allow signal-dependent factors to bind, the sites where HNF4α is recruited to the genome in a signal-dependent manner are already open in the absence of signaling ligand. Our data shows that the non-canonical binding of HNF4α upon activation of NR is specific for NR being activated and the genes are specific for the function of the specific NRs. **Conclusion:** The dependence of HNF4α binding on promiscuous signals of NR activation is also reflected in the signal-dependent transcription of these gene targets. The data thus suggest a dual function of HNF4α, whereby in addition to its lineage-specific role in transcriptional regulation it has additional gene-specific regulatory functions in response to specific signals with pleotropic phenotypic repercussions that determines the downstream effects on liver metabolism by NR activation.

◆ 4218 | CHARACTERIZATION OF THE FAK-CTGF AXIS FOR THERAPEUTIC EXPLOITATION IN HCC

Claudia Rose Keating[1] Kyle Boedeker[1] Ruisong Ye[1] Zoe Pointer[1] Yucel Yankol[2] Oswaldo Aguirre[2] Xianzhong Ding[2] Scott Cotler[2] Wei Qiu[2], [1]Loyola University Chicago, [2]Loyola University Health System

Background: There is a pressing need to better understand the pathogenesis of HCC to identify novel therapeutic targets. Focal adhesion kinase (FAK) is as a driver of HCC, where patients with high FAK have decreased overall survival. FAK targeting therapies have been studied in clinical trials for decades, however these agents have been ineffective when applied broadly. We hypothesize that patients specifically with high tumoral FAK will have better responses to these treatments, but at this time, noninvasive markers for FAK remain unknown. **Methods:** We used a proteolysis-targeting chimera (FP) to degrade FAK. RNA-seq and mass spec were used for unbiased screening. We used qPCR, western blot, CUT&RUN, ELISA, and CCK-8 for analyses. For *in vivo* experiments, we used subcutaneous and orthotopic xenografts, DEN/CCl_4 model, and oncogene-driven models. We collected a new cohort of matched HCC tumor and serum samples from patients undergoing liver transplantation for HCC to assess protein levels. **Results:** HCC cell lines with high FAK showed significant growth inhibition following FP treatment. RNA-seq of FP-treated cells showed connective tissue growth factor (CTGF) was significantly downregulated. CTGF is secreted and can be detected in serum, making it a suitable serum marker candidate. RNA-seq results were confirmed *in vitro*, with FP treatment significantly decreasing CTGF mRNA, intracellular protein, and secreted protein in both a dose- and time-dependent manner. Conversely, overexpression of FAK led to an increase in intracellular and secreted CTGF protein. Next, we found FAK regulates CTGF expression through HIF1a and showed direct HIF1a binding to the *CTGF* promoter driven by FAK. We found that the addition of recombinant CTGF rescued growth after FP treatment *in vitro*; CTGF expression can compensate for FAK loss in the MET/CAT model; and CTGF can replace FAK in the FAK/CAT model to induce tumors. We found that shCTGF significantly inhibited cell growth *in vitro* and *in vivo*. Similarly, treatment with a CTGF neutralizing antibody inhibited cell growth. RNA-seq of shCTGF cells showed an increase in SKP2 and a decrease in p27. Using the DEN/CCl_4 model, serum CTGF increased during tumor formation and progression in WT mice, whereas serum CTGF was dramatically reduced in FAK KO mice. Finally, FP treatment inhibited FAK/CAT-driven tumorigenesis *in vivo*. In primary HCC patient samples, we observed a strong correlation in tumoral protein expression as well as colocalization between FAK and CTGF in tissue samples, and we observed a strong correlation in FAK intratumoral protein levels and serum CTGF levels. **Conclusion:** Overall, FAK promotes the expression and secretion of CTGF, which promotes HCC, and there is a significant positive correlation between tumor FAK expression and serum CTGF. FAK is a promising therapeutic target in HCC, and identification of CTGF as a downstream target of FAK suggests CTGF as a treatment-indicating marker for FAK in HCC.

◆ 4219 | HYPOXIA-INDUCIBLE FACTOR SIGNALING IN ENDOTHELIAL CELLS IS REQUIRED TO MAINTAIN NORMAL LIVER HOMEOSTASIS AND FOR REGENERATION AFTER PARTIAL HEPATECTOMY

Chang Kyung (Joanna) Kim[1] Prerna Chakkingal[2] Minakshi Poddar[2] Sucha Singh[2] Satdarshan (Paul) Monga[2], [1]UPMC, [2]University of Pittsburgh

Background: To maximize functional efficiency, the liver ascribes it's metabolic functions to three zones, based on location along the porto-central blood flow and oxygen gradient, a phenomenon termed as zonation. Zone 1 (periportal) receives the highest oxygen supply from oxygen-rich blood entering through the portal vein and hepatic artery, while Zone 3 (pericentral) receives the lowest oxygen levels due to progressive oxygen consumption along the sinusoid. Hypoxia-inducible factor (HIF) signaling is critical for cellular adaptation

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to hypoxic conditions and is predominantly active in Zone 3, where it regulates a range of metabolic processes. What remains unclear is the role of HIF signaling in endothelial cells, which are in contact with blood and a source of angiocrine factors with wide-ranging effects on hepatic cells. **Methods:** To investigate the function of HIF signaling in endothelial cells, we generated *Lyve1-Cre; Arnt$^{f/f}$* (*Lyve1$^{\Delta Arnt}$*) mice to delete *Arnt* (Hif-1β) from central vein and sinusoidal endothelial cells (SECs). Partial hepatectomy (PHx) was performed on 10–12-week-old mice for assessing proliferation at 40 hour post-PHx. **Results:** *Arnt* deletion in *Lyve1^{+}* endothelial cells in mice resulted in 80% embryonic lethality and surviving 20% mice were female in gender. At baseline, *Arnt* deletion resulted in significant histological changes with abnormal vasculature, areas of necrosis, immune cell infiltration, ductular reaction, and increased periportal collagen accumulation. Liver zonation was significantly altered in *Lyve1$^{\Delta Arnt}$* mice. There was a significantly contracted Zone 3 based on decreased radius of CYP1A2 staining. Additionally, unlike controls which showed uniform 1-2 layers of glutamine synthetase (GS)$^{+}$ hepatocytes around central vein, *Lyve1$^{\Delta Arnt}$* mice showed random dropout of GS^{+} hepatocytes around the central vein. On the contrary, the expression pattern of IGFBP2 (Zone 2 marker) shifted towards the central vein, and the expression of CYP2F2 (Zone 1 marker) also remarkably expanded towards the central vein. Furthermore, several factors associated with hypoxia were upregulated in *Lyve1$^{\Delta Arnt}$* mice at baseline, including *Epo, Pdgfb, Tgfb1,* and *Tnfa,* indicating endothelial HIF signaling is required for maintaining homeostasis under physiological hypoxia. Additionally, in *Lyve1$^{\Delta Arnt}$* mice, there was significantly decreased Ki-67^{+} hepatocytes at 40 hours post-PHx, as compared to control mice, which showed peak proliferation at this time, indicating HIF signaling in endothelial cells is critical to normal tissue regeneration. **Conclusion:** Taken together, our results suggest that endothelial HIF signaling is required for maintenance of liver zonation, homeostasis under physiological hypoxia, and regeneration post-Phx.

◆ 4220 | SORGANELLOMICS REVEALS NUTRIENT-DEPENDENT HEPATOCYTE HETEROGENEITY THROUGH ORGANELLE ARCHITECTURE AT SINGLE-CELL RESOLUTION

Raghabendra Adhikari[1] Alexander Hillsley[1] Alana Johnson[2] Isabel Espinosa-Medina[1] Jan Funke[1] Daniel Feliciano[1], [1]Howard Hughes Medical Institute Janelia Research Campus, [2]Janelia-Meyerhoff Undergraduate Scholars Program 2024

Background: Hepatic functions—and many liver diseases—are spatially zonated, with hepatocyte heterogeneity driven by gradients of nutrients, oxygen, and signaling molecules across the liver lobule. These gradients induce hepatocytes to adapt via changes in gene expression, protein abundance, and subcellular organization. While organelle remodeling has been extensively characterized in cultured cells, how organelle architecture is spatially distributed in intact tissue—and whether it can define hepatocyte heterogeneity in situ—remains unclear. Furthermore, although hepatocyte physiology shifts with nutritional perturbations, whether organelle architecture reflects these changes remains unknown. **Methods:** To address these questions, we developed sOrganellomics, a spatial analysis pipeline that quantifies organelle features at single-cell resolution. Using confocal fluorescence microscopy, we imaged mitochondria, peroxisomes, and lipid droplets in mouse liver tissue. We then applied custom Cellpose-based models to segment cells and organelles, extracting over 100 quantitative organelle features while preserving spatial coordinates along the portal–central axis. Liver samples from control, fasted, and Western diet-fed mice were analyzed. Organelle features were used to classify hepatocyte subtypes and train machine learning to predict physiological states. **Results:** sOrganellomics revealed spatially zonated organelle architectures across liver acini, enabling classification of hepatocytes into five distinct classes. Although central vein-adjacent regions were enriched in a specific class, all zones contained a mixture of classes with zone-specific proportions. Nutritional perturbations reduced this heterogeneity: fasted livers showed four hepatocyte classes, while Western diet livers showed only two. Machine learning models (MLPs) trained on organelle features predicted hepatocyte class and nutritional status with $>80\%$ accuracy. Interestingly, our approach also detected progressive subcellular remodeling during hepatic steatosis in a diet-induced mouse model of early MASLD, enabling quantitative assessment of disease progression following up to two months of

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

Western diet feeding. **Conclusion:** sOrganellomics enables spatially resolved, quantitative analysis of organelle architecture in liver tissue. Our findings suggest that organelle features can serve as functional signatures of hepatocyte identity and reveal altered hepatic organization under nutritional stress, offering a feasible alternative to transcriptomic profiling.

◆ 4221 | DISTINCT MORPHOLOGICAL AND FUNCTIONAL CHARACTERISTICS OF PERIDROPLET AND CYTOPLASMIC MITOCHONDRIA IN HUMAN LIVER BIOPSIES

Norihiro Imai[1] Hanna Kawecka[2] Yuki Ohsaki[3] Jinglei Cheng[4] Shinya Yokoyama[4] Kenta Yamamoto[4] Takanori Ito[4] Yoji Isihzu[4] Takashi Honda[4] Tetsuya Ishikawa[4] Michał Woźniak[2] Hiroaki Wake[4] Hiroki Kawashima[4],
[1]Nagoya University Graduate School of Medicine,
[2]Medical University of Gdańsk, Gdańsk, Poland,
[3]Department of Anatomy, Sapporo Medical University School of Medicine, Sapporo, Hokkaido, Japan,
[4]Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan

Background: Mitochondrial dysfunction and lipid droplet accumulation contribute to the pathogenesis of several liver diseases. Mitochondria located adjacent to lipid droplets, known as peridroplet mitochondria (PDM), form a distinct subpopulation with unique metabolic functions, proteomes, bioenergetics, and dynamics compared to cytoplasmic mitochondria (CM). Although the close interplay between mitochondria and lipid droplets suggests the potential for analyzing the mitochondrial cytoarchitecture in the context of liver pathology, the morphology of PDM has not been characterized in *in vivo* human liver studies. This study aimed to investigate the morphological differences between PDM and CM in human liver biopsy specimens and evaluate their association with clinical parameters. **Methods:** In total, 3,079 transmission electron microscopy (TEM) images of liver samples from 145 patients were analyzed to identify PDM. The mitochondria were automatically segmented using a deep learning model trained on a diverse dataset for rapid detection and visualization. Based on the extracted outlines, the morphological parameters related to the size and shape were quantified for each PDM and CM. Clinical data including lipid profiles, liver enzyme levels, and degree of steatosis were collected from the enrolled patients. **Results:** In total, 263 PDM and 3,016 CM were identified from the human liver biopsy TEM dataset. Morphologically, the hepatic CM were significantly smaller and more spherical and solid, whereas the PDM were larger and more elongated. PDM exhibited a more uniform morphology, whereas CM displayed morphological variations specific to liver disease. Analysis of the patients' blood test results revealed an association between CM and liver enzyme levels, suggesting sensitivity to liver damage. In contrast, PDM were associated with serum triglyceride levels, indicating their role in lipid metabolism. Additionally, a positive correlation was observed between the numbers of PDM and lipid droplets, reinforcing the close functional interactions between these organelles. **Conclusion:** PDM and CM represent distinct mitochondrial subpopulations with unique morphologies, and are associated with different pathophysiological pathways. This study highlights the significance of mitochondrial interactions with lipid droplets, which contribute to the heterogeneity of human liver mitochondria. These findings provide insight for future research and diagnostic applications.

◆ 4222 | MECHANISMS OF GENE TRANSCRIPTION REGULATION BY NUCLEAR LIPID DROPLETS IN LIVER DISEASES

Norihiro Imai[1] Yuki Ohsaki[2] Jinglei Cheng[3] Hanna Kawecka[4] Shinya Yokoyama[3] Kenta Yamamoto[3] Takanori Ito[3] Yoji Ishizu[3] Takashi Honda[3] Tetsuya Ishikawa[3] Michał Woźniak[4] Hiroaki Wake[3] Hiroki Kawashima[3], [1]Nagoya University Graduate School of Medicine, [2]Sapporo Medical University, [3]Nagoya University, [4]Medical University of Gdańsk

Background: Lipid droplets are organelles found in adipocytes and other cell types throughout the body. Recently, lipid droplets have been identified within the nuclei of hepatocytes, and their formation and function have attracted increasing attention. This study aimed to explore the pathophysiological role of nuclear lipid droplets in liver diseases. **Methods:** In total, 152 patients (79 men and 73 women; mean age, 58 years) who underwent liver biopsy between 2020 and 2024 were included in this study. Portions of the biopsy specimens were double-fixed for electron microscopy and examined by transmission electron microscopy after embedding and sectioning. The presence of intranuclear lipid droplets in hepatocytes was assessed independently of the clinical data. Additionally, RNA sequencing was performed on liver biopsy samples with electron microscopic observations, along with adjacent tissues, to conduct comprehensive genetic analysis. **Results:** Intranuclear lipid droplets were detected in the hepatocyte nuclei of 63% of the biopsy samples, with an average occurrence rate of 3.7%. These droplets were most frequently observed in cases of metabolic dysfunction-associated steatotic liver disease, drug-induced liver injury, and autoimmune hepatitis. No significant correlation was observed between the frequency of nuclear lipid droplets and the degree of hepatic steatosis, suggesting that their formation is not a direct reflection of cytoplasmic lipid accumulation. However, the frequency of intranuclear lipid droplets was significantly positively correlated with serum AST and ALT levels, indicating that their formation may be a stress response to liver injury. RNA sequencing identified 1,526 and 537 genes that were positively and negatively correlated, respectively, with the frequency of nuclear lipid droplets. Pathway analysis revealed that nuclear lipid droplets were associated with the upregulation of nucleoside-triphosphatase activity and downregulation of glutathione transferase and antioxidant activity. Analysis of DNA-binding motifs in the promoter regions showed a positive correlation with p53, a key tumor suppressor involved in DNA repair, and a negative correlation with FOXI1, a factor involved in chromatin remodeling. **Conclusion:** Intranuclear lipid droplets, which are characteristic of hepatocytes, appear to form in response to liver injury and may help maintain cellular homeostasis by regulating gene transcription.

◆ 4223 | NUCLEAR RECEPTOR CAR AS A REGULATOR OF LIPID METABOLISM IN HEPATOCELLULAR CARCINOMA

Bingning Dong[1], [1]Baylor College of Medicine

Background: Lipid metabolic reprogramming is a hallmark of hepatocellular carcinoma (HCC), supporting tumor growth, immune evasion, and therapy resistance. However, efforts to inhibit lipid biosynthesis clinically have been limited by systemic toxicity. The constitutive androstane receptor (CAR, NR1I3) is a nuclear receptor enriched in hepatocytes, known for xenobiotic metabolism but not previously studied for its role in HCC lipid remodeling or immune modulation. Here, we identify CAR as a tumor-intrinsic driver of lipogenesis and immune suppression, and demonstrate that targeting CAR with a selective inverse agonist (CAR-IA) suppresses HCC progression in preclinical models without systemic toxicity. **Methods:** We used two HCC mouse models (DEN and HDTVi-AKT/N-Ras) to evaluate CAR-IA treatment. Tumor burden, toxicity, and gene expression were assessed. RNA-seq and lipidomics analyzed lipid pathway activity; ChIP-seq and ChIP-qPCR determined CAR binding to lipid gene promoters. Rescue experiments included high-fat diet feeding and Srebf1 overexpression. Single-nucleus RNA-seq profiled CAR-high tumors, and immune–tumor cell interactions were inferred using CellChat analysis. **Results:** CAR-IA significantly reduced tumor burden in both models without toxicity. It suppressed key lipid biosynthetic genes (e.g., Srebf1 and Fasn) and decreased tumor lipid content. Lipid restoration via diet or Srebf1 overexpression reversed CAR-IA's antitumor effect, confirming CAR's role in driving lipogenesis. CAR-high tumors were identified as a poor-prognosis subtype with elevated lipid metabolism but low proliferation. These

tumors showed increased interactions with T cells, and CAR-IA induced T cell exhaustion markers and inflammatory gene signatures, suggesting CAR-mediated immune suppression. **Conclusion:** CAR is a liver-specific regulator of lipid metabolism and immune remodeling in HCC. Its inhibition reduces tumor growth by blocking lipogenesis and altering the immune microenvironment without affecting normal physiology. CAR-high tumors represent a lipid-metabolic, immune-suppressive HCC subtype with poor prognosis. These findings support a tissue-selective therapeutic strategy targeting CAR and offer a framework for repurposing CAR inhibitors, such as meclizine, for HCC treatment

◆ 4224 | IMMUNOSUPPRESSIVE TUMOR MICROENVIRONMENT IN HEPATOCELLULAR CARCINOMA ORCHESTRATED BY CD90-POSITIVE CANCER STEM CELLS

Kouki Nio[1] Hikari Okada[1] Taro Yamashita[1], [1]Kanazawa University

Background: Since the clinical application of cancer immunotherapy for hepatocellular carcinoma (HCC), there has been increasing research aimed at identifying factors that determine its therapeutic efficacy. Previously, we reported that laminin γ2 monomer (LG2m) is highly expressed in CD90-positive HCC, which harbors mesenchymal stem cell-like properties, and that serum LG2m levels are associated with poor prognosis, distant metastatic recurrence, and future liver carcinogenesis in HCC patients. In this study, we aimed to investigate the impact of CD90-positive HCC cells on the immunosuppressive tumor microenvironment (TME). **Methods:** To analyze the expression of CD90-positive HCC cells and their cell–cell interactions with stromal cells within the TME, single-cell spatial analysis of resected HCC specimens was performed. We also examined whether serum LG2m levels could serve to stratify therapeutic responses to cancer immunotherapy in HCC patients. **Results:** Single-cell spatial analysis using PhenoCycler™ was conducted on HCC specimens with varying LG2m expression levels. In LG2m-high HCCs, the tumor–non-tumor boundary regions were infiltrated by a large number of CD90-positive cells and CD206-positive macrophages, while infiltration of Ki67-positive activated $CD4^+$ and $CD8^+$ T cells was limited. Cellular neighborhood analysis revealed that CD90-positive cells were densely located at the tumor boundary in LG2m-high HCC, with relatively little proximity to Ki67-positive activated T cells. To further investigate the impact of LG2m on the efficacy of cancer immunotherapy, we measured serum LG2m levels in HCC patients undergoing immunotherapy and compared them with the therapeutic response to sorafenib treatment. Among patients with low LG2m levels, treatment with atezolizumab plus bevacizumab resulted in a significantly prolonged progression-free survival (PFS) compared to sorafenib (HR 0.33, $P < 0.001$). In contrast, no significant PFS benefit was observed in patients with high LG2m levels (HR 0.65, $P = 0.15$). **Conclusion:** These findings suggest that CD90-positive liver cancer stem cells with high LG2m expression contribute to the development of an immunosuppressive TME. Moreover, LG2m may serve as a potential biomarker for predicting the efficacy of cancer immunotherapy in HCC.

◆ 4225 | IDENTIFICATION OF A SIGNALING MICRODOMAIN IN THE HEPATOCYTE NUCLEUS THAT REGULATES CELL PROLIFERATION AND BECOMES DISRUPTED IN CHRONIC LIVER DISEASE

Jittima Weerachayaphorn[1] Mateus Guerra[1] Emma Kruglov[1] Kathy Harry[1] Vitoon Saengsirisuwan[2] Michele Rodrigues[1] Michael Nathanson[1], [1]Yale University, [2]Mahidol University

Background: A billion people worldwide have chronic liver disease. Despite diverse etiologies, a unifying feature is the liver's impaired ability to regenerate, which may relate to progression to cirrhosis. We investigated whether and how calcium (Ca^{2+}) signals in the hepatocyte nucleus become impaired in chronic liver disease, because growth factors selectively increase Ca^{2+} in the nucleus, and cell proliferation depends on these Ca^{2+} signals. **Methods:** Mouse hepatocytes (provided in part by R24AA012885) and HepG2 cells were used as model systems. Intra-nuclear binding partners of the type 2 inositol trisphosphate receptor (ITPR2), the principal calcium channel in hepatocytes, were identified by mass spectrometry (MS), and interactions were confirmed by co-IP, proximity ligation assay (PLA), and super-resolution imaging. Ca^{2+}

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

signaling was detected by time-lapse confocal microscopy, and protein expression was examined in mouse models and liver biopsies from patients with various chronic liver diseases. **Results:** Subcellular fractionation and immunoblot showed that ITPR2 is expressed in the hepatocyte nucleus, and super-resolution microscopy localized ITPR2 to the inner nuclear membrane. Nuclear Ca^{2+} signals in the hepatocytes were entirely generated by this ITPR2 pool, and MS identified, and co-IP and PLA confirmed that nucleoporin 62 (Nup62) localizes ITPR2 to the nucleus. ITPR2 and Nup62 both were lost from the hepatocytes of patients with MASLD, alcohol-associated liver disease (ALD), chronic hepatitis B and hepatitis C infections, and cirrhosis, and the loss of ITPR2 and Nup62 were highly correlated ($R^2 = 0.95$, $p < 0.001$). Similar results were observed in mouse models of MASH and ALD. Translocation of ß-catenin to the nucleus was reduced by buffering Ca^{2+} in the nucleus but not the cytosol, and Ca^{2+} signaling in the nucleus and nuclear pore permeability both were diminished in Nup62-KO cells. **Conclusion:**: Nup62 anchors ITPR2 in the nucleus of hepatocytes, which is necessary for nuclear Ca^{2+} signals and entry of ß-catenin into the nucleus. Nup62 is lost from the hepatocyte nucleus in patients with chronic liver disease and related mouse models, suggesting this contributes to impaired liver regeneration. This previously unrecognized signaling microdomain in the hepatocyte nucleus may provide a potential therapeutic avenue to preserve liver regeneration in chronic liver disease.

◆ 4226 | DFNA5-DEPENDENT HEPATOCYTE DEATH PROMOTES TNF PRODUCTION IN KUPFFER CELLS AND CONTRIBUTES TO HEPATOCARCINOGENESIS

Yoshinobu Saito[1] Tomoya Hamabe[1] Yoichi Sasaki[1] Hayato Hikita[1] Yuta Myojin[1] Kazuhiro Murai[1] Yuki Makino[1] Yuki Tahata[1] Takahiro Kodama[1] Hayato Hikita[1], [1]The University of Osaka Graduate School of Medicine

Background: Hepatocyte death is a key driver of chronic liver disease (CLD) progression. We previously demonstrated that persistent hepatocyte apoptosis promotes hepatocarcinogenesis, while non-apoptotic cell death contributes to metabolic dysfunction-associated steatotic liver disease (MASLD). Dfna5 (Gasdermin E), a pore-forming protein activated by caspase cleavage, induces membrane rupture and the release of pro-inflammatory contents. Although Dfna5 is implicated in inflammation and pyroptosis-like processes, its role in hepatocyte death and hepatocellular carcinoma (HCC) remains unclear. This study aimed to investigate the role of Dfna5-mediated hepatocyte death in liver injury and inflammation-associated hepatocarcinogenesis. **Methods:** DFNA5 was silenced using siRNA in Huh7 and AML12 cells, and intrinsic apoptosis was induced with ABT-737, a Bcl-xL inhibitor. Caspase activity and LDH release were assessed. Hepatocyte-specific Dfna5 knockout (Dfna5 L-KO) mice were generated by AAV8-TBG-Cre injection into Dfna5 fl/fl mice and treated with Fas ligand (FasL) to induce extrinsic apoptosis. Alb-Cre Mcl-1 fl/fl (Mcl-1 L-KO) mice, which develop spontaneous hepatocyte apoptosis and HCC, were crossed with Dfna5 fl/fl mice to generate Mcl-1/Dfna5 L-KO mice. To examine the role of TNFα, Alb-Cre Mcl-1 fl/fl mice were also crossed with Tnf −/− mice to create Mcl-1/Tnf double knockout (DKO) mice. Kupffer cells were depleted using clodronate liposomes to assess their contribution to cytokine production. The clinical relevance of DFNA5 was evaluated using TCGA-LIHC survival data. **Results:** ABT-737 increased caspase-3/7 activity and Dfna5 cleavage in vitro. DFNA5 knockdown reduced LDH release without affecting caspase activity, indicating suppression of secondary necrosis. Dfna5 L-KO mice showed no baseline abnormalities but had significantly lower serum ALT levels after FasL challenge. In Mcl-1 L-KO mice, Dfna5 deletion markedly reduced hepatic Tnfa mRNA without altering ALT or caspase activity. Kupffer cell depletion abolished Tnfa expression, confirming them as the main TNFα source. HCC developed in 100% (17/17) of Mcl-1 L-KO mice by 18 months, but only in 47.8% (11/23) of Mcl-1/Tnf DKO mice ($p = 0.0008$), despite comparable liver injury and apoptosis at 6 weeks. High DFNA5 expression in TCGA-LIHC was associated with worse survival (HR = 1.72, $p = 0.002$). **Conclusion:** Dfna5 promotes secondary necrosis and Kupffer cell-mediated TNFα production, fueling inflammation and hepatocarcinogenesis. Targeting the Dfna5–TNFα axis may represent a novel therapeutic strategy for CLD-associated liver cancer.

◆ 4227 | TRAINED HUMAN BONE MARROW MESENCHYMAL STEM CELLS RESTORE TISSUE IMMUNO-MICROENVIRONMENT IN FULMINANT HEPATIC FAILURE MICE

Jun Li[1] Bingqi Li[1] Xiaofei Zeng[2] Jing Jiang[1] Jiaojiao Xin[1] Xi Liang[1] Dongyan Shi[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, [2]Zunyi Medical University of Medicine

Background: Trained immunity with human bone marrow mesenchymal stem cells (hBMSC) is a promising approach to liver regeneration. This study aimed to clarify the trained-hBMSC (T-hBMSC) in restoring tissue immuno-microenvironment in fulminant hepatic failure (FHF) mice. **Methods:** hBMSC trained with tumor necrosis factor-α and interferon-γ were phenotypically characterized in vitro. FHF mouse models were established in male Balb/c mice via tail vein injection of concanavalin A. The therapeutic potential of T-hBMSC was evaluated through transplantation into FHF mice. Transcriptomic analysis was performed to elucidate the mechanism of liver regeneration post-transplantation of T-hBMSC. **Results:** T-hBMSC with the characteristics of trilineage differentiation potential showed that pro-inflammatory (IL1β, IL8, both $p < 0.0001$) and immunoregulatory genes (PDL1, IDO1, both $p < 0.0001$) were significantly upregulated compared to untrained-hBMSC (UT-hBMSC). Time-trajectory analysis revealed downregulation of pro-inflammatory genes (IL6, IL8, and CXCL9) and upregulation of immunomodulatory genes (IDO1) in T-hBMSC upon mimic-stimulation, characterized with distinct transcriptional programs. The liver function (ALT, AST) and inflammatory cytokines (IL6, MCP1, both $p < 0.01$) levels were significantly improved in T-hBMSC treatment mice. The survival status of the T-hBMSC group was superior to UT-hBMSC group, although there was no statistical significance. Histological analysis confirmed reduced necrosis and fewer infiltrating $CD45^+$ immune cells in T-hBMSC treatment mice. Significant downregulation of immune response (TNF&IL-17 signaling pathways, and neutrophil chemotaxis) and upregulation of metabolic pathways were observed in T-hBMSC group, associated with enhanced liver regeneration. The proportion of anti-inflammatory $F4/80^+CD163^+$ macrophages was increased in the liver of T-hBMSC group. **Conclusion:** T-hBMSC exhibited enhanced immunomodulation, effectively rescuing liver failure and reducing inflammation via restoring the immune-microenvironment. These findings highlighted the potential of trained immunity as a novel strategy to treatment for liver failure.

4228 | MUTATIONS IN THE ER-PHAGY RECEPTOR FAM134B REDUCE ER-CENTRIC LIPOPHAGY OF NASCENT LDS LEADING TO HEPATIC STEATOSIS

Mark McNiven[1] Hong Cao[2] Shaun Weller[3] Jing Chen[2] Eugene Krueger[2] Micah Schott[4], [1]Mayo Foundation for Medical, [2]Mayo Clinic Rochester, [3]Mayo Clinic, [4]University of Nebraska Medical Center

Background: Hepatic steatosis is a central feature of MASLD that is driven by an aberrant accumulation of cytoplasmic lipid droplets (LDs) within hepatocytes. We have observed that lipophagic catabolism of LDs in hepatocytes can occur at the surface of the endoplasmic reticulum (ER) where lysosomes act to degrade nascent LDs as they form. From this finding, the CENTRAL GOAL of this study was to define the hepatocellular machinery that supports this novel lipophagic process and test if this is altered in patients with MASLD. **Methods:** To this end, we conducted an siRNA screen in AML12 cells and primary mouse hepatocytes (PMHs) to test the role of 6 known Selective Autophagic Receptors (SARs) that might regulate lipophagy of nascent ER-associated LDs. Cellular lipid levels were measured using biochemical assays, while LD numbers and area were quantitated using confocal microscopy and ImageJ software. **Results:** We find that reducing the levels of the ER-phagy receptor/adapter protein FAM134B leads to a 6-8

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

fold increase in LD content while overexpression of wt-FAM134B in these cells reduces LD number by over 80%. This adapter is well known to mediate selective degradation of the ER by autophagy during cellular stress, while a putative role in catabolizing nascent LDs forming at the ER surface is unreported. In support of this finding, IHC of human liver tissue revealed a marked reduction of FAM134B levels in patients with MASLD. Based on this, we sought to define the role of FAM134B in an inducible, liver-specific KO mouse model. Using FAM134B$^{flox/flox}$ mice injected with AAV8-Cre, we were encouraged to find FAM134 KO in liver exhibited a 5-7-fold increase in LD number compared to control mice in a fasting/refeeding model. Importantly, these mice had reduced glucose tolerance as assessed by GTT blood glucose assays. Finally, we examined the genomes of 9,000 Mayo patients with MASLD to identify variants in FAM134B and observed 300 patients possessing 2 predominant variations that resided within the transmembrane domains. Significantly, expression of these variants into cultured cells leads to increased LD content. **Conclusion:** These findings provide mechanistic insights into a newly identified ER-phagy centric lipophagic process that plays a key role in the regulation of hepatic lipid stores with direct relevance to MASLD patients. Supported by DK44650 to MAM.

4229 | DISCOVERY OF PORCINE GREATER OMENTUM-DERIVED STEM CELL AND ITS THERAPEUTIC POTENTIAL FOR LIVER REGENERATION

Min-Gyeong Seo[1] *Jinsun Jeong*[1] *Il-Hwa Hong*[1],
[1]*Gyeongsang National University*

Background: Mesenchymal cells derived from adipose tissue are the most widely utilized stem cells (SCs) due to their accessibility and multipotent differentiation capacity. However, conventional sources of adipose tissue for SC isolation typically require invasive procedures, such as liposuction or laparotomy, and are unsuitable for large-scale SC production. For a more sustainable and abundant SC production, we investigated the porcine greater omentum (pGO), an adipose-rich tissue discarded during slaughter. This study is the first to isolate SCs from pGO, along with evaluation of their biological characteristics and therapeutic potential for liver regeneration. **Methods:** Porcine greater omentum-derived stem cells (pGOSCs) were isolated following standard SC protocols. Expression of surface markers for mesenchymal cells was analyzed by flow cytometry. Differentiation of pGOSCs to hepatocytes, osteocytes, chondrocytes and adipocytes was analyzed by histological examination and qRT-PCR. For conditioned medium (CM), pGOSCs were cultured in serum-free conditions, and growth factors were analyzed by western blot and ELISA. The viability of AML12 cells treated with CM was evaluated using CCK assay. Exosomes isolated from CM were analyzed by LC-MS/MS. **Results:** pGOSCs were confirmed to express mesenchymal stromal markers and successfully differentiate into hepatocytes, osteocytes, chondrocytes, and adipocytes, *in vitro*. Various growth factors, including hepatocyte growth factor (HGF), epidermal growth factor, vascular endothelial growth factor, and platelet-derived growth factor were identified in the CM, with HGF especially abundant. The viability of AML12 cells treated with CM was significantly increased up to 1.5-fold, compared to non-CM control. Proteomic analysis of exosomes identified 3,288 proteins enriched in biological processes related to cell adhesion, migration, and proliferation, with the highest fold enrichment in oxidant detoxification. **Conclusion:** The present study demonstrates that pGO contains multipotent mesenchymal stem cells, capable of producing CM enriched with growth factors, especially HGF, and exosomes possessing regenerative and antioxidative properties, which consequently promote hepatocyte proliferation. Given the genetic and immunological similarities between pigs and humans, pGOSCs and their secretomes may serve as promising candidates for the development of cell-based or cell-free therapeutic agents for liver regeneration in humans.

4230 | PORCINE GREATER OMENTUM-EXTRACTS PROMOTE LIVER REGENERATION BY STIMULATING CELL CYCLE PROGRESSION IN MICE AFTER PARTIAL HEPATECTOMY

Min-Gyeong Seo[1] *Jinsun Jeong*[1] *Il-Hwa Hong*[1],
[1]*Gyeongsang National University*

Background: The greater omentum (GO) has been occasionally utilized for tissue regeneration, such as bone fracture and cardiac injury. Based on a few reports of clinical trials, we hypothesize that GO may contain regenerative components which also contribute to liver regeneration. To prove this hypothesis, we employed the greater omentum from domestic pigs (pGO), which is easily available as it is routinely discarded during slaughter. This study aims to extract aqueous

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

components from pGO and evaluate their biological characteristics as well as liver regenerative effects. **Methods:** Aqueous porcine greater omentum-extract (pGOEs) were extracted via DPBS, followed by filtration, pasteurization, and lyophilization. Growth factors and antioxidant activity were analyzed by western blot, ELISA, and DPPH assay. Proteins and exosomes were identified by 2D-electrophoresis and LC-MS/MS. *In vitro*, the viability of AML12 cells treated with pGOEs was evaluated by CCK assay. *In vivo*, pGOEs were administered intraperitoneally to mice after 70% partial hepatectomy (PHx). Livers were collected at 0-96h for histology and western blot. **Results:** *In vitro*, various growth factors, including HGF, EGF, VEGF, PDGF, and IGF-1, were confirmed in pGOEs, with HGF, EGF, and IGF-1 being particularly abundant. Proteomic analysis of pGOEs revealed a large number of protein spots, among which antioxidant-related proteins, such as superoxide dismutase, peroxiredoxin, and hemopexin, were predominantly detected. Proteomic analysis of exosomes identified 729 proteins enriched in biological processes related to cell migration and oxidant detoxification. The viability of AML12 cells treated with pGOEs was significantly increased compared to non-treated controls. In PHx mice treated with pGOEs, liver regeneration rates were enhanced, with notably higher mitotic activity than vehicle-treated mice. Interestingly, expression of cell cycle proteins and phosphorylation of growth factor-related receptors was upregulated in pGOE-treated mice. **Conclusion:** The present study demonstrates that pGOEs, enriched with various growth factors and antioxidant proteins, promote hepatocyte proliferation *in vitro* and enhance liver regeneration *in vivo*. Our findings suggest that pGOEs possess therapeutic potential for liver regeneration and may be applicable for various liver injuries.

4231 | SPATIALLY RESOLVED IMMUNO-ENDOTHELIAL INTERACTOME ACROSS LIVER NICHES IN END-STAGE ALCOHOL-RELATED LIVER DISEASE

Oleksandr Petrenko[1] Thomas Sorz-Nechay[1] Martin Bilban[1] Sophia Derdak[1] Lukas Van Melkebeke[2] Wenxin Huang[2] Jef Verbeek[2] Schalk van der Merwe[2] Benedikt Hofer[1] Benedikt Simbrunner[1] Thomas Reiberger[1] Tim Hendrikx[1], [1]Medical University of Vienna, [2]KU Leuven

Background: Alcohol-related liver disease (ALD) remains a major healthcare burden yet lacks high-resolution spatial characterization. We applied ultra-high resolution spatial transcriptomics (2 μm spots) to delineate cellular interactions across tissue niches in end-stage ALD. **Methods:** We obtained a cirrhotic caudate-lobe sample during liver transplantation in the Vienna General Hospital (ethical approval 2318/2019). Picrosirius red and α-SMA areas were quantified in HALO. 5 μm H&E sections were subjected to the 10x Visium HD workflow and sequenced (NextSeq 2000, paired-end). Cells were segmented from H&E nuclei with bin2cell algorithm (on sequenced 2 μm spots), with QC and downstream analysis in Scanpy. Cells were annotated with canonical markers and refined by the pre-trained CellTypist model. QuPath was used to annotate 50x50 px niches: vascular (n = 6), fibrotic (n = 11), and parenchymal (n = 5). We computed median pairwise Euclidean distance matrices to profile cell–type-specific niche relationships. We generated directed interaction graphs per niche using LIANA +-inferred ligand-receptor interactions; hub nodes were identified as those in the top decile by combined standardized degree and betweenness (NetworkX). **Results:** Histomorphometry revealed 33.4% collagen and 28.2% α-SMA-positive areas. Post-QC, 265 573 cells were annotated (e.g., vascular endothelial cells, EC: *VWF*, *CD34*; liver sinusoidal endothelial cells, LSEC: *STAB2*, *CLEC4G*). We found that proximity patterns varied in tissue niches: in perivascular zones, EC co-localized with T cells; in perifibrotic niches, LSEC–fibroblast proximity predominated. EC in fibrotic zones were more active in overall ligand-receptor expression than LSEC; in vascular zones, LSEC had prevailing ligand expression. Reciprocal interaction analysis uncovered LSEC–stellate and LSEC–fibroblast signaling in perivascular and fibrotic contexts, and EC–immune cell crosstalk in the vascular niches. Hub network analysis highlighted SPARC-ENG signaling among EC, CD4+ T cells, and fibroblasts in fibrotic niches and CXCL12–CXCR4 interactions between EC, T cells, macrophages, and monocytes in vascular niches. The ligand-receptor pairs prioritized through the network analysis also demonstrated significant co-localization patterns. **Conclusion:** Ultra-high resolution (on 2 μm spots) spatial transcriptomics in end-stage ALD revealed niche-specific EC-immune interactomes, uncovering spatially resolved signaling networks for candidate biomarkers and therapeutic targets investigation.

4232 | ZONE-SPECIFIC Β-CATENIN EXPRESSION IS REQUIRED FOR MAINTENANCE OF LIVER ZONATION AND REGENERATION AFTER PARTIAL HEPATECTOMY

Chang Kyung (Joanna) Kim[1] Prerna Chakkingal[1] Vik Meadows[2] Tyler Yasaka[1] Minakshi Poddar[1] Sucha Singh[1] Satdarshan (Paul) Monga[2], [1]UPMC, [2]University of Pittsburgh

Background: The adult liver carries out diverse set of vital functions including metabolism (fat, protein, carbohydrate, xenobiotic), synthesis (bile, protein, vitamins) and detoxification. Liver zonation defines the spatial division of functions based on location of cells along the porto-central blood flow and largely divides into three zones: zone 1 (periportal), zone 2 (midlobular), and zone 3 (pericentral). Under various disease conditions, specific zones exhibit differential vulnerabilities, ultimately leading to a disruption of normal liver zonation. Despite recent progress elucidating Wnt/β-catenin signaling as the master regulator of liver zonation, particularly in maintaining zone 3 hepatocyte identity and function, significant gaps remain with respect to the zone-specific functions of β-catenin at baseline and after partial hepatectomy (PHx), since its upstream effectors Wnt2 and Wnt9b in endothelial cells are expressed in a decreasing gradient from zone 3 to zone 1. **Methods:** To investigate the zone-specific function of β-catenin, we generated *Igfbp2-Cre^{ERT2};Ctnnb1$^{fl/fl}$* (*Igfbp2$^{\Delta Ctnnb1}$*) and *Cyp1a2-Cre^{ERT2};Ctnnb1$^{fl/fl}$* (*Cyp1a2$^{\Delta Ctnnb1}$*) mice to delete β-catenin in zone 2 and 3, respectively. Deletion was induced by tamoxifen injection and livers were harvested after 12 days of washout period. Partial hepatectomy (Phx) was performed on 10–12-week-old mice for assessing proliferation at 40 hour post-Phx. **Results:** β-catenin deletion in zone 2 hepatocytes in *Igfbp2$^{\Delta Ctnnb1}$*mice at baseline showed a spatial shift in expression of midzonal markers IGFBP2 and Cyclin-D1 toward zone 3, with reciprocal contraction of CYP2E1 (zone 3 marker) expression. Interestingly, the expression pattern of CYP2F2 (zone 1 marker) did not expand but rather showed a trend toward contraction. β-Catenin deletion in zone 3 hepatocytes in *Cyp1a2$^{\Delta Ctnnb1}$* mice resulted in loss of glutamine synthetase (GS) and CYP2E1 expression in the 1-3 cell layers around the central vein and gain of ectopic expressions of zone 1 markers E-cadherin and CYP2F2 in these cells. No significant changes were seen in the expression of midzone markers IGFBP2 and HAMP1/2. Previous studies have suggested that midzone hepatocytes initiate proliferation during liver regeneration after PHx. At 40 hour post-PHx, at the peak of mitotic activity, loss of β-catenin in zone 3 in *Cyp1a2$^{\Delta Ctnnb1}$* mice resulted in increased proliferation of zone 1 and 2 hepatocytes compared to control mice as indicated by higher % of Ki-67^{+} expression in cell layers 2-5. On the contrary, β-catenin deletion in zone 2 hepatocytes in *Igfbp2$^{\Delta Ctnnb1}$*mice resulted in decreased proliferation across the lobule. **Conclusion:** Taken together these data suggest that β-catenin is required for zone 2 and 3 hepatocytes to maintain part of their zonal identity. These results also confirm that midzone hepatocytes are the main drivers of liver regeneration after PHx, and that β-catenin is critical to this process.

4233 | ENGINEERING BIOACTIVE MICROCAPSULES FOR HEPATIC DIFFERENTIATION OF PLURIPOTENT STEM CELLS

Kianna Nguyen[1] Quang Tuan Che[1] Youngmin Hwang[1] Kihak Gwon[2] Gulnaz Stybayeva[1] Quinn Peterson[1] Alexander Revzin[1], [1]Mayo Clinic, [2]Kyungpook National University

Background: Stem cell-derived liver organoids have many promising applications from drug discovery to cellular therapies. There remains a need for scalable hepatic differentiation protocols. Core-shell microcapsules promote cell spheroid formation and may be used to establish high-density suspension cultures. Incorporation of heparin into the shell promotes capsule retention of growth factors to enable local and continuous delivery of inductive cues to cells. As the next step in evolution of this capsule technology, Matrigel, an extracellular matrix that is commonly used for differentiation studies, has been incorporated into the core of microcapsules. We demonstrate that Matrigel retains integrity in microcapsules over the course of differentiation and that its presence is associated with improved in-capsule hepatic differentiation outcomes. **Methods:** Pluripotent stem cells and Matrigel are encapsulated using a co-axial flow focusing microfluidic device to generate aqueous core-shell droplets in oil. Eight-arm-polyethylene-glycol-maleimide and methacrylated heparin in the shell are then crosslinked to form microcapsules with an aqueous core, allowing for spheroid formation, and a hydrogel shell. Liver organoid differentiation, as adapted from Takebe et al, is then carried out in capsules. Differentiation efficiency was evaluated via gene expression, functional assays, and protein expression. **Results:** Microcapsules retained mechanical integrity for at least 28 days of culture in a stirred bioreactor. Matrigel incorporation into the core of the microcapsules was characterized with fluorescence labeling and immunohistochemical staining, demonstrating retention of Matrigel for at least 28 days. With confirmed mechanical stability and composition of microcapsules, pluripotent stem cells were encapsulated and differentiated with a multi-stage liver organoid differentiation protocol. Encapsulated spheroids produced high levels of albumin and were composed of cells from both epithelial and mesenchymal origins. Hepatic function and cellular composition of encapsulated differentiated liver organoids was comparable to standard Matrigel dome control cultures. **Conclusion:** We have engineered microcapsules with synthetic hydrogel shells and Matrigel cores, offering a scalable and tunable stem cell differentiation platform. Encapsulated pluripotent stem cells were differentiated into well characterized liver organoids within these capsules. We envision that after completing hepatic differentiation, microcapsules may be transplanted and will offer immunoisolation in vivo.

4234 | MYOSTATIN ACTIVATES AMPK DURING HYPERAMMONEMIC STRESS RESPONSE TO CAUSE SARCOPENIA OF CIRRHOSIS VIA TRANSFORMING GROWTH FACTOR BETA RECEPTOR-1, ACTIVIN LIKE KINASE 5 (ALK5)

Muaz Alsabbagh Alchirazi[1] Saurabh Mishra[1] Seshu Pothabathula[1] Pugazhendhi Kannan[1] Annette Bellar[1] Amy Attaway[1] Nicole Welch[1] Srinivasan Dasarathy[1], [1]Cleveland Clinic

Background: Sarcopenia in cirrhosis is caused by increased myostatin (MSTN) expression during hyperammonemic stress response (HASR). Canonical myostatin signaling is mediated via TGF beta receptor-1 kinases (ALK4/5) that phosphorylate the smad2/3 transcription factor(s) with nuclear translocation and expression of genes that regulate muscle mass. However, during HASR, dysregulated protein homeostasis and sarcopenic phenotype are medaited via myostatin-dependent phosphorylatoin and activation of AMPKa2 in skeletal muscle. The kinase for AMPK phosphorylation activated by myostatin during HASR were investigated. **Methods:** Skeletal muscle from mice with muscle-specific knockout of AMPK and MSTN knockout, portacaval anastamosis and sham-operated rats, human induced pluripotent stem cell (hiPSC)-derived myotubes, and diferentiated murine C2C12 myotubes with knockdown (KD) of MSTN, AMPK, ALK4, ALK5, and double KD of ALK4/5 using shRNA wwere studied. HASR was induced with 10mM ammonium acetate (AmAc) for 24h in myotubes and 2.5mmol $AmAc.kg^{-1}.d^{-1}$ or saline for 28 days infused subcutaneously via a miniosmotic pump in mice. Protein synthesis was assessed by puromycin incorporation. Phosphorylation/activation of AMPK,

mTORC1, and functional responses were quantified by immunoblots. Protein-protein interactions were studied by co-immunoprecipitation/live cell imaging. **Results:** During HASR, in skeletal muscle from a comprehensive array of models (patients with cirrhosis, mice, rats, and murine/hiPSC myotubes), expression of myostatin, ALK4,and ALK5 were increased with greater phosphorylation of AMPKa2 compared to controls. Consequences of phosphorylation/activation of AMPKa2 during HASR include impaired mTORC1 signaling, lower protein synthesis, increased autophagy markers, and a sarcopenic phenotype in myotubes and muscle tissue. Molecular and phenotype responses to HASR were reversed by myostatin and AMPKa2 depletion in mouse muscle tissue and myotubes. Co-immunoprecipitation and live cell imaing showed direct interaction between ALK5 and AMPK. ALK5 KD but not ALK4 KD reduced phosphorylation AMPK and restored mTORC1 signaling, protein synthesis with reversal of sarcopenic phenotype during HASR. In contrast, double KD of ALK4+5 also reversed AMPK phosphorylation confirming ALK5 as the primary functional TGFB receptor mediating MSTN-induced AMPK activation. **Conclusion:** Sarcopenia in cirrhosis is due to HASR-dependent upregulation of MSTN and activation of AMPKa2 via ALK5. Downstream signaling responses to AMPKa2 activation include impaired mTORC1 signaling with dysregulated protein homeostasis and a sarcopenic phenotype that were reversed by sequential depletion of MSTN, AMPKa2, and ALK5 (but not ALK4) in skeletal muscle in preclinical models. These data provide the rationale for targeting ALK5 using currently available pharmacologic agents to target sarcopenia of cirrhosis.

4235 | DEVELOPMENT OF AN INTRAHEPATIC CHOLANGIOCYTE-DERIVED CHOLANGIOCARCINOMA MOUSE MODEL

Bin Wang[1] Jiale Wang[1] Liu Yang[1] Gordon He[1] Yasmin Jahan-mihan[1] Muhammad Faheem[1] Jie Hu[1] Yuxi Wang[1] Zhu Zhu[1] Bi Yan[1] Baoan Ji[1], [1]Mayo Clinic

Background: Intrahepatic cholangiocarcinoma (iCCA) is a highly aggressive liver cancer with a poor prognosis and limited response to chemotherapy. Intrahepatic cholangiocytes are believed to be the cell of origin of iCCA. Genetically engineered iCCA mouse models derived from intrahepatic cholangiocytes are essential for studying pathogenesis and testing preclinical therapies. Currently, most existing iCCA models rely on a single recombination strategy (e.g., Cre/loxP) driven by Cytokeratin 19 (CK19) or Albumin (Alb) promoters to activate oncogenes or inactivate tumor suppressors. However, Alb promoter targets all liver parenchymal cells including hepatocytes as well as cholangiocytes. CK19 promotor targets intrahepatic cholangiocytes in the liver. Yet, CK19 is also positive in many ductal cells of other organs throughout the body. Therefore, these models may not recapitulate the features of human iCCA. An iCCA animal model derived from intrahepatic cholangiocytes is lacking because there is no known gene promoter specifically targets intrahepatic cholangiocytes. To overcome this limitation, we aimed to develop an iCCA model uniquely derived from intrahepatic cholangiocytes. **Methods:** We developed a dual-recombinase system (DRS)-based mouse model using a combination of CK19 and Alb promoters. The Alb promoter, which is active in cholangiocytes, hepatocytes, and hepatic progenitor cells (HPCs) during embryogenesis, was used to express Flp recombinase (Alb-Flpo). The CK19 promoter, which is specific in duct cells of many organs including the liver, was used to drive CreERT expression but only after Flp-mediated recombination (CK19-FSF-CreERT). By crossing these two mouse lines, we expected that CreERT would be expressed only in intrahepatic cholangiocytes. **Results:** To examine Cre recombination specificity, Alb-Flpo/CK19-FSF-CreERT double transgenic mice were crossed with LacZ reporter mice. After tamoxifen (TM) induction, positive X-gal staining was only observed in intrahepatic cholangiocytes, but not in the epithelial cells of other organs. To generate the iCCA model, we further crossed Alb-Flpo/CK19-FSF-CreERT mice with $PTEN^{L/L}$, $P53^{L/L}$, and LSL-$Kras^{G12D}$ mice for conditional oncogenic Kras expression and tumor suppressor gene PTEN and P53 deletion. Upon TM induction, iCCA were developed in these compound mice. Lineage tracing showed that the iCCA cells originated from cholangiocytes. In contrast, liver tumors developed from Alb promoter-driven recombination developed a mixture of iCCA and hepatocyte carcinoma (HCC). **Conclusion:** We developed a novel genetic iCCA mouse model that uniquely originates from intrahepatic cholangiocytes.

4236 | ABAT INHIBITS VEGFA-DRIVEN HEPATOCELLULAR CARCINOMA PROGRESSION BY PROMOTING SERRS2 NUCLEAR TRANSLOCATION

Baojia Zou[1] Peiping Li[1] Yihua Dai[1] Shanglin Cai[1] Decheng Li[1] Jianzhong He[1] Jiali Zhao[1] En Lin[1] Bailiang He[1] Genglong Zhu[1] Jian Li[1], [1]the Fifth Affiliated Hospital of Sun Yat-sen University

Background: 4-Aminobutyrate aminotransferase (ABAT), a mitochondrial enzyme in the GABA metabolic pathway, has been implicated in various cancers beyond its canonical metabolic functions. However, its role in hepatocellular carcinoma (HCC) remains unclear. This study explores the function of ABAT in modulating HCC progression and its regulatory link to VEGFA expression. **Methods:** ABAT expression was analyzed in HCC patient samples and public datasets (TCGA, Human Protein Atlas). Functional assays, including gain- and loss-of-function studies in multiple HCC cell lines, evaluated its role in proliferation, migration, invasion, and cisplatin sensitivity. In vivo validation was performed using subcutaneous xenografts in nude mice and metastasis models in zebrafish. Mechanistic investigations involved co-immunoprecipitation, Alphafold3 prediction and simulation for protein-protein interaction, nuclear-cytoplasmic fractionation, RNA sequencing, and ELISA. Clinical associations were assessed by immunodetection of ABAT, SerRS2, and VEGFA in HCC specimens. **Results:** Low ABAT Expression Predicts Poor Prognosis in HCC: Transcriptomic and clinical sample analysis revealed significantly decreased ABAT in HCC, correlating with poor overall and disease-free survival, especially post-TACE.

1. ABAT Suppresses EMT and Metastatic Traits: ABAT overexpression inhibited EMT markers and reduced invasion and migration; zebrafish models confirmed anti-metastatic effects.
2. ABAT Enhances Chemosensitivity: Functional studies showed reduced colony formation and increased cisplatin sensitivity with ABAT overexpression. Knockdown promoted proliferation and resistance in vitro and in vivo.
3. ABAT Facilitates Nuclear Translocation of SerRS2: Proteomic and biochemical assays identified ABAT–SerRS2 interaction, as validated in Alphafold 2/3 prediction and simulation; ABAT promoted nuclear localization of SerRS2.
4. ABAT Loss Activates VEGFA: ABAT depletion caused cytoplasmic retention of SerRS2 and upregulated VEGFA expression and secretion. Blocking VEGFA or SerRS2 knockdown reversed this phenotype. **Conclusion:** ABAT functions as a suppressor of HCC progression by facilitating the nuclear translocation of SerRS2 and limiting VEGFA expression. These findings suggest that ABAT-SerRS2-VEGFA axis may serve as both a prognostic biomarker and a novel target in managing advanced or chemoresistant HCC.

4237 | DEVELOPMENT AND CHARACTERIZATION OF A NOVEL LONG-TERM CULTURE SYSTEM FOR HUMAN IPSC-DERIVED HEPATIC ORGANOIDS

Taro Shimizu[1] Masato Miyoshi[1] Sei Kakinuma[1] Jun Tsuchiya[1] Daisuke Yamane[2] Tomohiro Mochida[1] Kento Inada[1] Kaho Yamada[1] Kotomi Shinozaki[2] Shun Kaneko[1] Fukiko Kawai-Kitahata[1] Miyako Murakawa[1] Sayuri Nitta[1] Mina Nakagawa[1] Yasuhiro Asahina[1] Ryuichi Okamoto[1], [1]Institute of Science Tokyo, [2]Tokyo Metropolitan Institute of Medical Science

Background: Recent advances in human induced pluripotent stem cell (iPSC) culture have enabled the generation of 3D liver organoids. However, the long-term expansion of iPSC-derived hepatocytes with preserved hepatocyte function remains a major challenge, limiting the utility of these organoids as chronic liver disease models. We have established a novel iPSC-derived hepatic organoid (iHO) culture system capable of long-term maintenance and passaging. Here, we further characterized iHOs and evaluated

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

their potential as models of chronic liver diseases, including viral hepatitis. **Methods:** Human iPSCs were differentiated into hepatocyte-like cells under 2D conditions (2D-iPS-Hep), followed by embedding in hydrogel for 3D culture using our iHO medium containing bile acids. We compared gene expression and albumin production among iHOs, 2D-iPS-Heps, and cryopreserved primary human hepatocytes (Cryo-Hep). Bulk and single-cell RNA sequence analyses were performed to determine the transcriptomic profiles of iHOs in comparison with 2D-iPS-Heps, Cryo-Heps, and publicly available datasets of human liver tissues and other iPSC-derived hepatic organoids. To assess the potential for a disease model, iHOs were infected with genotype 1a hepatitis C virus (HCV), and viral replication in iHOs was compared to that in other iPSC-derived organoids. **Results:** iHOs continuously expressed hepatocyte-related genes, including albumin, and could be passaged for over three months across different iPSC lines. Albumin production by iHOs was more than 15-fold higher than that of 2D-iPS-Heps ($p = 0.0145$; mean $\pm$ SEM: iHOs = 4.921 $\pm$ 1.318 μg/10,000 cells/48 h, 2D-iPS-Heps = 0.311 $\pm$ 0.101 μg/10,000 cells/48 h), and was almost equal to that of Cryo-Heps. Morphologically, iHOs formed "grape-like" clusters and exhibited bile canaliculi-like structures, confirmed by microscopy and dye secretion assays. Bulk RNA-seq analysis showed that iHOs resembled fetal hepatocytes, whereas 2D-iPS-Heps and other iPSC-derived organoids were closer to cholangiocytes or intestinal cells. Single-cell RNA-seq showed that over 90% of cells in passaged iHOs displayed hepatocyte-like gene expression profiles, including a proliferative subpopulation without cholangiocyte-like signature. Furthermore, iHOs supported robust HCV infection, with viral replication exceeding that of DAA-treated controls by more than 40-fold, demonstrating their strong potential for modeling viral hepatitis. **Conclusion:** Building on our previously established culture system, this study provides detailed molecular and functional characterization of iHOs and confirms their utility as a robust in vitro platform for chronic liver disease research.

4238 | AUTOPHAGY ZONATION AND ITS ROLE IN LIVER METABOLISM

Kamal Baral[1] Arya Chandrasheker[1] Leah Spade[1] Ramsey Rohner[1] Xiao-Ming Yin[1] Bilon Khambu[2], [1]School of Medicine, Tulane University, [2]Tulane University School of Medicine

Background: Autophagy is a conserved lysosomal pathway essential for metabolic homeostasis. Its deficiency contributes to chronic liver diseases (CLD) such as hepatitis, cirrhosis, and cancer. Hepatic metabolic homeostasis relies on liver zonation, where hepatocytes in pericentral (PC) and periportal (PP) zones perform specific metabolic functions. The role of autophagy in liver zonation and its impact on metabolic homeostasis remain unclear, but both processes are disrupted in liver disease development and progression. **Methods:** Wild-type mouse livers were analyzed for autophagy-related protein and gene expression to determine zonation. The Human Protein Atlas (HPA) database was screened for upstream autophagy transcriptional regulators. Various mouse models of autophagy deficiency and activation were used to investigate autophagy's role in hepatic zonation. Liver sections were immunostained for zonal markers, and qPCR and immunoblot analyses assessed zonal expression of autophagy and drug metabolism-related genes. Autophagy rescue experiments were performed using the AAV8-TBG-Atg7 system in autophagy-deficient mice. Drug metabolites were analyzed using LC/MS to evaluate autophagy's impact on hepatic drug metabolism. Normal and CLD preclinical liver samples, along with human liver sections, were examined for autophagy zonation and drug metabolism enzyme expression. **Results:** Autophagy gene expression in normal livers was zonated, with higher expression in the pericentral (PC) zone compared to the periportal (PP) zone. This zonal expression of autophagy genes was consistent with the zonal expression of autophagy proteins. Human Protein Atlas (HPA) screening revealed that transcriptional regulators of autophagy, including FOXO1, GATA4, NF-kB1, SMAD2, and SREBP2, were pericentrally zonated. Genetic deletion of core autophagy genes, such as Atg7 and Atg5, led to downregulation of Wnt/β-catenin signaling, a key regulator of liver zonation, causing disturbed liver zonation. Additionally, autophagy deficiency reduced the expression of phase I Cyps, major drug-metabolizing enzymes (DMEs), resulting in altered drug metabolite profiles. Similar disruptions in autophagy, liver zonation, and phase I Cyp expression were observed in human non-alcoholic fatty liver disease (NAFLD) autopsy samples and in mice fed a high-fat diet, underscoring the clinical significance of these findings. **Conclusion:** Hepatic autophagy function is

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

predominantly zonated in the pericentral (PC) zone and plays a crucial role in drug metabolism.

4239 | REVERSAL OF HYPERAMMONEMIC STRESS RESPONSE PERTURBATIONS-INDUCED SARCOPENIA OF CIRRHOSIS BY VOLUNTARY WHEEL RUNNING: AN INTEGRATED MULTIOMICS-EXPERIMENTAL VALIDATION APPROACH

Srinivasan Dasarathy Takhar Kasumov[1] Lopa Mishra[2] Annette Bellar[3] Nicole Welch[3] saurabh mishra[3] Muaz Alsabbagh Alchirazi[3] Amy Attaway[3] Ryan Musich[3] Pugazhendhi Kannan[3] Seshu Vardhan Pothabathula[3], [1]NEOMED, [2]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory, [3]Cleveland Clinic

Background: Hyperammonemia, a common complication of liver dysfunction, impairs skeletal muscle protein homeostasis by suppressing mTORC1 signaling, reducing protein synthesis, and enhancing catabolic AMPK and eIF2α phosphorylation. While exercise induces muscle ammoniagenesis, its impact on ammonia-induced signaling disruptions remains unclear. This study aimed to determine whether voluntary wheel running (VWR) reverses hyperammonemia-mediated impairments in muscle protein synthesis and signaling. via AMPK and eIF2α phosphorylation. We determined if voluntary wheel running (VWR) reverses hyperammonemia-mediated impairments in muscle protein synthesis and signaling pathways. **Methods:** Hyperammonemic mice, an established model of cirrhotic sarcopenia were compared with control mice. Miniosmotic pumps were implanted in wild type, male C57BL6 mice aged 8-9 weeks to deliver 2.5mM ammonium acetate (AmAc) or phosphate buffered saline (PBS) as vehicle for 6 weeks. After 2 weeks recovery from implantation surgery, mice were randomized to either voluntary wheel running (VWR) or usual activity (UA) for 4 weeks. Protein synthesis in gastrocnemius muscle was measured via puromycin incorporation. Phosphorylation of mTORC1 signaling pathway proteins (p-mTOR^{Ser248}, p-S6$^{Ser240/244}$, p-4EBP1$^{Thr37/45}$), AMPK (p-AMPK^{Thr172}), eIF2α (p-eIF2α^{Ser51}), and myostatin (MSTN) expression were quantified by immunoblots. Multi-omics analysis (RNAseq and proteomics) was performed to integrate autophagy, mTOR, and eIF2α pathway gene and protein expression. Integrated multiomics analyses of untargeted data (tissue RNAseq, proteomics, metabolomics) and plasma (proteomics, metabolomics) were performed. **Results:** AmAc-UA mice had less muscle protein synthesis vs. PBS-UA ($p < 0.05$). VWR increased synthesis in both PBS ($p < 0.01$) and AmAc groups ($p < 0.001$), as compared to their respective UA groups (Fig. 1). VWR elevated p-mTOR^{Ser248} ($p < 0.01$) and reversed AmAc-associated reductions in p-S6$^{Ser240/244}$ ($p < 0.05$). MSTN expression was increased in AmAc-UA and decreased with VWR ($p < 0.001$). p-AMPK^{Thr172} was increased by both AmAc and VWR ($p < 0.05$). Integrarted multiomics analysis revealed hyperammonemia-induced upregulation of autophagy-related genes (e.g., *Sqstm1, Rubcn, Ddit3*), decreased mTOR effectors (e.g., *Pdk1, Gsk3b, Immt*), and increased *Eif2ak1/4* expression which were reversed with VWR. **Conclusion:** VWR restores skeletal muscle protein synthesis during HASR of cirrhosis by increased mTORC1 signaling, less MSTN expression, and reversing transcriptomic/proteomic changes in autophagy and mTOR related pathways. These findings support exercise as a non-pharmacologic strategy to counteract sarcopenia in chronic liver disease.

4240 | THE XBP1 ACTIVATOR IXA4 REGULATES HUMAN BILE ACID AND FATTY ACID SYNTHESIS GENES IN IPSC-HEPATOCYTES

Moloud Aflaki Sooreshjani[1] Xiaoying Liu[2] Ekta Minocha[3] John G Purdy[3] Jason A Wertheim[3] Richard Green[1], [1]Northwestern University, [2]Northwestern University Feinberg School of Medicine, [3]Arizona University

Background: Metabolic dysfunction-associated fatty liver diseases are the most common cause of abnormal liver function tests in the United States and are a major

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cause of cirrhosis and hepatocellular carcinoma. Human induced pluripotent stem cells (iPSCs) and iPSC-hepatocytes provide valuable models for studying the mechanisms of liver disease. Using murine models, we have previously shown that the X-box binding protein 1 (XBP1) pathway of unfolded protein response (UPR) regulates fatty acid and bile acid metabolism. We used the human iPSC-hepatocytes to investigate the role of pharmacologic XBP1 activation on the gene expression of bile acid and fatty acid metabolism. **Methods:** Normal human pluripotent stem cells were differentiated into iPSC-hepatocytes over 21 days. During differentiation, cells were treated with either 10 μM of IXA4, a selective IRE1/XBP1 activator, or vehicle control for the last 1, 3, 5, or 10 days of differentiation. iPSC-hepatocytes were harvested on day 21 and gene expression was analyzed for XBP1 activation, bile acid synthesis genes, and fatty acid synthesis genes using qPCR. iPSC-hepatocytes were similarly treated with 50 μM of tauroursodeoxycholic acid (TUDCA) for 5 days and gene expression was analyzed. **Results:** Following IXA4 treatment, gene expression of the XBP1 downstream target *ERdj4* increased by 1.4- to 1.7-fold at all time points compared to vehicle controls ($p < 0.05$), confirming drug effectiveness. Gene expression of the major bile acid synthesis gene *CYP7A1* was decreased 40-90% at 3, 5, and 10 da*ys* ($p < 0.001$). In addition, the bile acid synthesis gene *CYP8B1* was also decreased 32-74% at these time points ($p < 0.05$) with the greatest reduction of both genes occurring at 3 days. In contrast, *CYP27A1* was unchanged. The fatty acid synthesis gene *SCD-1* was increased by 2- to 4.2-fold at 3 and 5 days ($p < 0.01$), with similar increase in *LCAD* expression ($p < 0.002$). There was a strong trend of 2- to 2.4-fold increase in *FASN* gene expression ($p < 0.08$). In contrast, the lipid regulatory gene *SREBP-1a* was unchanged. We subsequently treated iPSC-hepatocytes with 50 μM of TUDCA for 5 days, and KEGG pathway analysis demonstrated an increase in the bile acid secretion pathway (padj = 0.006). **Conclusion:** Treating human iPSC-hepatocytes with the pharmacologic XBP1 activator IXA4 profoundly suppressed the bile acid synthesis genes *CYP7A1* and *CYP8B1*. *SHP* expression did not increase and therefore cannot account for these changes in gene expression. In contrast, XBP1 activation increased the expression of several lipid synthesis genes. TUDCA treatment also increased the bile acid synthesis pathway. We speculate that the XBP1 pathway regulates bile acid and fatty acid metabolism in both mice and humans.

4241 | ETIOLOGY-SPECIFIC CHROMOSOME 8Q24 AMPLIFICATION ASSOCIATED WITH HUMAN INTRAHEPATIC CHOLANGIO- AND HEPATOCELLULAR CARCINOMAS PREDICTS MYC/ZEB1/MIZ1 TRANSCRIPTIONAL REGULATION AND POOR PROGNOSIS

Saniya Davis[1] Joeffrey Chahine[2] Pamela Tuma[1], [1]The Catholic University of America, [2]Medstar Georgetown University Hospital

Background: Genomic instability, in particular chromosome 8q24 amplification, is highly associated with late stage hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (iCCA) and epithelial mesenchymal transition (EMT). Limited HCC patient studies suggest that 8q24 amplification may also be etiology-dependent. On this amplified region, is the known oncogene, *c-myc*. Not only does MYC overexpression activate targets that promote cell proliferation, it also activates ZEB1 which drives EMT. Further reinforcing EMT, overexpressed MYC also represses tumor suppressors that antagonize EMT, including MIZ1. The connection between *c-myc* amplification and the corresponding changes in ZEB1 and MIZ1 have been reported, but not all three together. Nor have these relationships been characterized in the context of HCC or iCCA across grades or with respect to etiologies. **Methods:** We confirmed 8q24 amplification using FISH and established the temporal expression patterns of MYC, ZEB1 and MIZ1 in human HCC (n = 147) and iCCA (n = 114) patient resections using immunohistochemistry and retrospectively compared them to patient histories. To directly test MYC/ZEB1/MIZ1 transcriptional regulation, we examined EMT in human HCC-derived Hep3B or iCCA-derived HUCCT1 cells with amplified *c-myc*. **Results:** We found that chromosome 8 duplication and focal *c-myc* 8q24 amplification occurs only in grade III/IV HCC and grade III iCCA which correlates with increased MYC and ZEB1 nuclear expression. In contrast, MIZ1 cytosolic expression was lost and only nuclear expression retained. We found that of the high grade cancer patients that exhibited amplified *c-myc*, high MYC and ZEB1 expression and only nuclear MIZ1 expression were all associated with metastasis and poorer prognosis. Additionally, although majority of the cohort had a history of viral hepatitis, only those that also had a history of alcohol consumption exhibited this transcriptional regulation. Analysis performed in Hep3B or HUCCT1 cells revealed that alterations in MYC expression led to the predicted changes in ZEB1 and MIZ1 expression/distribution and in EMT further confirming MYC/ZEB1/MIZ1 transcriptional regulation drives EMT. **Conclusion:** Based on expression profiles of these markers, the clinician will be better able to grade a patient's HCC or iCCA, better predict its drug resistance and better decide what treatment

4242 | NUCLEAR RECEPTOR EXPRESSION IS DYSREGULATED IN ADIPOSE TISSUE IN CIRRHOSIS

Sanal Madhusudana Girija[1] Sarita Gupta[1] Kumaraswamy P[2] RAHUL SAHA[1] Archana Rastogi[1] Viniyendra Pamecha[1] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, [2]AIG Hospital, Hyderabad

Background: Cirrhosis is a multisystem disease that predominantly affects the kidneys, lungs, heart, muscles, and brain. However, its impact on adipose tissue—the body's largest endocrine organ—remains poorly understood. Our previous research demonstrated that adipose tissue in cirrhosis exhibits a proangiogenic state, characterized by elevated expression of various angiogenic factors due to oxidative inactivation of protein phosphatases (PTPs). Nuclear receptors are critical in the development and homeostasis of adipose tissue. In this study, we investigated the differential expression of 46 nuclear receptors (NRs) and 3 developmentally important transcription factors in adipose tissue from cirrhosis patients. **Methods:** Adipose tissue samples were collected from 25 liver cirrhosis patients undergoing Living Donor Liver Transplantation (LDLT) and 15 healthy donors. Patients with acute or acute-on-chronic liver failure, non-cirrhotic portal hypertension, or those who did not provide consent were excluded. Real-time PCR was employed to identify differentially expressed transcripts, while Western blot analysis was conducted to evaluate protein levels. **Results:** Mean age: Healthy vs. cirrhosis –33 ± 10 vs. 46 ± 8 years; mean BMI: Healthy vs. cirrhosis –25 ± 3 kg/m² vs. 25 ± 5 kg/m²; sex distribution: 92% of cirrhosis patients and 87% of healthy controls were men; mean MELD score: 23 ± 6 (for cirrhosis patients); mean fasting blood sugar: Controls vs. patients vs. 79 ± 12 mg/dL vs. 115 ± 34 mg/dL; diabetes prevalence: 28% of cirrhosis patients were diabetic. Controls: All biochemical and imaging parameters in healthy donors were within normal limits. Gene Expression Analysis: Real-time PCR analysis revealed upregulation of VDR, NOR, SHP, SF1, PNR, ER1, RORC, RARB, LRH1, GR, TR4, NURR1, PPARG, PPARA, PPARD, RARA, PR, DEX1, RXRA, LXRA, LXRB, V-ERB-A, RXRB, FXR, HNF4G, and FOX1 in cirrhosis patients compared to healthy controls. Conversely, the transcripts of HNF1A, TR2, PXR, HNF4A, AR, GCNF, RXRG, MR, COUPTF1, REVERBA and B, ESR2, RORB, CAR, RORA, RARB, HNF3B, ESSRA, and ESSRG were less abundant in cirrhosis patients. **Conclusion:** This is the first comprehensive study screening all nuclear receptor transcripts in adipose tissue from cirrhosis patients. Being critical regulators of metabolism, targeting nuclear receptor modulation could offer potential therapeutic strategies for lifestyle-associated diseases such as diabetes, obesity, dyslipidaemia, and fatty liver disease.

4243 | MZB1 ORCHESTRATES HEPATIC REGENERATION: ESSENTIAL ROLE IN CELL CYCLE PROGRESSION FOLLOWING LIVER INJURY

Jiang Li[1] Noriko Kitano[1] Sudrishti Chaudhary[1] Samuel Taborski[1] Juliane Beier[1] Oliver Eickelberg[1] Marta Bueno[1] Gavin Arteel[1], [1]University of Pittsburgh

Background: Marginal Zone B and B1 Cell-Specific Protein (MZB1) is a B-cell-specific protein in the endoplasmic reticulum involved in B cell function, cellular proliferation, and inflammation. Deep proteome profiling shows MZB1-positive plasma B cells in human lung and skin fibrosis, with MZB1 knockout (KO) mice

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

protected from bleomycin-induced fibrosis in these organs. This study investigated MZB1's role in liver fibrosis and regeneration, a function previously unexplored. **Methods:** Human fibrotic liver specimens from alcohol-related hepatitis, alcohol-related liver disease, MASLD, and primary biliary cholangitis were immunostained for MZB1. For mechanistic studies, two MZB1 knockout mouse models (whole-body and inducible conditional) were utilized. Mice were administered CCl_4 for acute (1 day) or chronic (28 days) exposure to induce liver injury and fibrosis. To assess regenerative capacity, mice underwent 70% partial hepatectomy with 24-hour recovery. Liver tissues were analyzed through histology, biochemical analyses, and gene expression profiling. **Results:** Immunofluorescence analysis revealed elevated MZB1 expression in all examined fibrotic liver diseases, with MZB1 signal colocalizing with fibrotic septae. MZB1 KO mice developed more severe liver injury and fibrosis following CCl_4 treatment compared to controls. Importantly, these mice exhibited impaired regenerative capacity in the CCl_4 model, prompting further investigation using partial hepatectomy. Following hepatectomy, MZB1 deficiency dramatically impaired liver regeneration, with hepatocytes blocked at the G0-G1 cell cycle transition due to downregulation of CDK6 and cyclin D1. Transcriptomic analysis revealed fundamental alterations in gene expression profiles governing cell cycle progression and growth factor signaling, with dysregulation of HGF/c-Met signaling, STAT3 activation, and mTOR pathway components. **Conclusion:** MZB1 plays a critical role in hepatocyte proliferation and liver regeneration, despite its presence in fibrotic areas of human liver disease. The exacerbated liver injury in MZB1 KO mice reflects its role in supporting hepatocyte proliferation rather than a direct antifibrotic effect, contrasting with its apparent profibrotic function in lung and skin. Mechanistically, MZB1 loss disrupts the crosstalk between cell cycle proteins and growth factor signaling. These findings identify MZB1 as a potential target for enhancing liver regeneration in clinical settings.

4244 | SINGLE CELL TRANSCRIPTOMIC PROFILE REVEALS PRIMARY TUMOR ORIGIN DEFINES THE IMMUNE MICROENVIRONMENT IN LIVER METASTASIS FROM COLORECTAL AND PANCREATIC CANCER

So Yeon Kim[1] Jieun Kim[1] Ekihiro Seki[1], [1]Cedars-Sinai Medical Center

Background: Liver metastasis is a common and lethal outcome of advanced malignancies, with colorectal cancer (CRC) and pancreatic ductal adenocarcinoma (PDAC). While the liver provides a shared metastatic site, the immune microenvironment within liver metastases may differ substantially depending on the primary tumor origin, but underlying mechanisms are still unclear. Understanding these differences is essential for immunotherapeutic strategies and improving treatment outcomes. **Methods:** We performed single-cell RNA sequencing on tumor-infiltrating immune cells isolated from mouse liver metastases originating from CRC and PDAC. Immune cells were enriched via CD45+ sorting from freshly extracted metastatic liver tumor tissues. Transcriptomic profiles were analyzed using Seurat, with clustering, dimensionality reduction (UMAP), and cell type annotation guided by canonical markers and reference datasets. Differential gene expression and gene enrichment analysis were performed. Cell-cell interactions were inferred using CellChat. **Results:** We identified distinct immune cell composition patterns between CRC- and PDAC-derived liver metastases by scRNAseq. CRC metastases were enriched in monocytes and macrophages, suggesting a more phagocytic and antigen-processing microenvironment. Notably, Ms4a7+ macrophages, a population marked by their distinct metabolic reprogramming and immune response, were enriched. This may lead to M1/M2 polarization and contribute to tumor progression. In contrast, liver metastases from PDAC showed a higher proportion of Mmp9+ neutrophils and Xcr1+ dendritic cells, along with a slightly increased abundance of CD8 T cells and B cells. These Mmp9+ neutrophils play a critical role in promoting tumor progression along with infiltration and invasion. Additionally, cell-cell interaction analysis suggested enhanced chemokine signaling in PDAC-derived liver metastases, potentially driving neutrophil recruitment. **Conclusion:** Our findings demonstrate that the primary tumor origin significantly influences the immune architecture of liver metastasis. The predominance of monocyte/macrophage populations in CRC and neutrophil/DC populations in PDAC metastases may reflect

underlying differences in immune evasion strategies and therapeutic vulnerabilities. These insights support that PDAC-derived hepatic metastasis leads to more severe outcomes, and this emphasizes the necessity of developing immunotherapies that account for the primary cancer type.

4245 | RAPID AND VERSATILE MULTIPLEX LIVER GENE EDITING IN MICE USING ADENO-ASSOCIATED VIRAL 8 OR LIPID NANOPARTICLES

Dandan Wu[1] Isabelle Bolt[1] Dagmar Tolenaars[1] Wietse In het Panhuis[1] Coen Paulusma[1] Roy van der Meel[2] Stan van de Graaf[1], [1]Tytgat Institute for Liver and Intestinal Research, [2]Institute for Complex Molecular Systems

Background: Somatic liver knockout (SLiK) is an advanced technique for rapidly knocking out multiple genes in the adult mouse liver. However, the original SLiK protocol relies on hydrodynamic tail vein injection (HTVI), which carries a risk of cardiac failure in mice. This limitation hinders its application in regions with strict animal welfare regulations, such as the European Union. To address this challenge, we replaced HTVI with adeno-associated virus serotype 8 (AAV8) and lipid nanoparticles (LNPs) to test whether these alternative delivery systems could effectively support SLiK gene editing. **Methods:** Our system leverages selective pressure from tyrosine metabolism to achieve rapid gene editing. Fumarylacetoacetate hydrolase (Fah) deficiency has a lethal phenotype, which can be rescued by disrupting upstream enzyme 4-hydroxyphenylpyruvate dioxygenase (Hpd). Mice lacking both *Fah* and *Hpd* are without phenotype. In this study, we generated $Fah^{-/-}$/spCas9Tg mice that constitutively express the spCas9 recombinase. These mice were injected with two AAV8 vectors, each containing two gRNAs targeting an intron of Hpd and an exon of a gene of interest (GOI). The Hpd-edited hepatocytes gain a survival advantage, enabling highly efficient deletion of two GOIs. Each AAV8 vector also contains a CMV promotor flanked by a multiple cloning site, allowing overexpression of any desired genes as long as it can be packed in AAV8 vector. This system theoretically allows for 2 knockouts and 2 overexpression within same hepatocytes. Additionally, LNPs were tested to deliver individual gRNAs. **Results:** Complete Hpd knockout was achieved in murine liver within two months in both systems, without significant changes in body weight or liver enzymes. With the AAV8 approach, we successfully generated humanized NTCP and AGXT mice by simultaneously deleting endogenous murine gene and overexpressing the human gene within 1-3 months. Additionally, attempts to knock out two genes (*Cyp2c70* and *mAgxt*) and overexpress another gene (*hAGXT)* led to severe biliary injury in mice, requiring euthanasia 6 weeks post-injection. At this time point, knockdown of *Cyp2c70* was confirmed at the mRNA level only. **Conclusion:** Both AAV8 and LNP are practical alternatives for HTVI to achieve rapid and multiplex gene editing in SLiK system. The successful generation of humanized NTCP and AGXT mice demonstrates the potential of this platform for creating advanced humanized mouse models. However, further studies are needed to further explore the system's capacity.

4246 | SENSING OF PHOSPHATIDIC ACID BY MTORC1 IN LIVER AND DEVELOPMENT OF MASLD

Chandrima Gain[1] Henrietta Bains[2] Debajyoti Das[3] Rajat Singh[3], [1]University of California, Los Angeles, [2]Albert Einstein College of Medicine, Bronx, NY, USA, [3]Comprehensive Liver Research Center at the David Geffen School of Medicine, University of California

Background: mTOR is a serine/threonine kinase that senses nutrients to stimulate growth and proliferation. There is a strong association of mTOR hyperactivation with metabolic dysfunction-associated steatotic liver disease (MASLD) and its progression to poorly differentiated hepatocellular carcinoma. While amino acid-mediated mTOR activation is well-studied, lipid-driven mTOR activation and its relevance to MASLD remain understudied. Here, we examined the mechanism of mTOR activation by a physiologically relevant lipid, phosphatidic acid (PA), and we determined if increased PA production drives hepatic mTOR hyperactivation during obesity. **Methods:** We used mice (injected with liver-specific AAV8 vectors) or Cas9-cultured AML12 hepatocytes (exposed to specific sgRNAs) to knock-out *Raptor*, or *Lipin1*, which encodes for a phosphatidic acid phosphohydrolase that dephosphorylates PA to yield diacylglycerol, to determine if and how PA activates mTORC1 signaling. Liver homogenates and cell lysates were immunoblotted for markers of mTORC1 signaling. HEPG2-cells transfected with Flag-mTOR or Flag-empty were treated with PA, and immunoprecipitated mTOR (via Flag beads) was digested in S-trap columns,

and peptides (of binding partners) analyzed by nLC-MS/MS. Statistical analyses were performed using unpaired Student's t-test or one or two-way ANOVAs followed by appropriate post-hoc testing. **Results:** We have found that exposure of cultured AML12 hepatocytes to PA leads to activation of mTORC1 signaling. PA-driven mTORC1 activation is marked induced in AML12 hepatocytes KO for *Lipin1*, indicating that PA accumulation upon loss of *Lipin1* leads to greater mTORC1 activity. This mTORC1 hyperactivation upon loss of *Lipin1* is Raptor-dependent since deletion of Raptor dampens mTORC1 signaling. Proteomic analyses of mTOR pulldowns has revealed a number of potential mTOR binding partners, which we are screening to determine their role in PA-driven mTORC1 activation. mTORC1 suppresses autophagy, which plays an important hepatoprotective role. Consistently, loss of *Lipin1* in livers leads to mTORC1 activation, autophagy blockage, and a MASLD phenotype. **Conclusion:** This study enhances our understanding of whether PA is sensed by mTORC1 in livers, and whether this PA-mediated mTORC1 activation has relevance to the pathophysiology of MASLD. These studies will reveal new approaches to dampen lipid-driven mTORC1 hyperactivation and delay the onset of metabolic diseases of the liver.

4247 | DISCOVERY OF A NOVEL DNA APTAMER TO FACILITATE IN VIVO TARGETED GENE THERAPY IN CHOLANGIOCARCINOMA

Enis Hikmet Ozmert[1] Ayano Kabashima[1] Brandon Wilbanks[1] Julia Driscoll[2] Irene Yan[2] Jack Sample[1] Danielle Carlson[3] Hidemi Nishi[1] Brooke Kimball[4] Jayla Millender[5] Caroline Doherty[6] Jim Maher[6] Gregory Gores[3] Tushar Patel[7] Rory Smoot[8], [1]Department of Surgery, Mayo Clinic, Rochester, MN, [2]Department of Transplantation, Mayo Clinic, Jacksonville, Florida, [3]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, [4]Division of Hematology, Mayo Clinic, Rochester, MN, [5]Division of Oncology, Mayo Clinic, Rochester, MN, [6]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, [7]Mayo Clinic Florida, [8]Mayo Clinic Rochester

Background: Cholangiocarcinoma (CCA) is an aggressive hepatobiliary malignancy with limited treatment options. Current standard-of-care therapies cause significant adverse effects, while personalized medicine approaches offer only modest survival benefits. We previously demonstrated that milk-derived nanovesicles (MNVs) show therapeutic potential against CCA. Aptamers —oligonucleotides with unique 3D structures— can be used to direct MNVs to a certain target. This study aims to discover a CCA-specific aptamer and to demonstrate that aptamer-MNV constructs effectively deliver RNA therapeutics in murine CCA models. **Methods:** We employed a Systematic Evolution of Ligands by Exponential Enrichment (SELEX) strategy to identify a CCA specific aptamer by toggling a library of 2 trillion random oligonucleotides between target (CCA) and non-target (hepatocyte/cholangiocyte) cells. Cell binding efficacies of enriched aptamers were quantified using Incucyte SX5 and validated by qPCR. The biodistribution of the lead candidate, 'Aptamer 1', was assessed in an orthotopic SB1 model of CCA. For therapeutic evaluation, mice bearing SB1 tumors received intravenous injections of Aptamer 1-MNV loaded with siRNAs targeting *Yap/Wwtr1/Lck* (siTriple) alongside appropriate controls. **Results:** After 10 selection rounds, deep sequencing revealed 'Aptamer 1' was exponentially enriched in the library. This aptamer demonstrated specificity toward various human and murine CCA cell lines with minimal binding to normal hepatocytes, confirmed by *ex vivo* staining and confocal imaging. Biodistribution analysis revealed preferential accumulation of Aptamer 1 in tumor tissue without significant off-target binding. We successfully incorporated Aptamer 1 into MNVs via 3' cholesterol modification and confirmed incorporation efficiency using ImageStream X Mk II Flow Cytometer. In vitro evaluation demonstrated that Aptamer 1-MNV loaded with siTriple effectively knocked down target genes. In the murine orthotopic CCA model, intravenous delivery of Aptamer 1-siTriple (7 doses over 14 days) achieved significant target gene and protein knockdown in CCA cells without affecting adjacent liver tissue. In conjunction with the roles *Yap/Wwtr1/Lck* play in CCA pathobiology, immunohistochemical analysis showed significantly decreased Ki-67 and increased cleaved caspase-3 staining in the Aptamer 1-siTriple group, indicating reduced proliferation and enhanced apoptosis. **Conclusion:** We identified 'Aptamer 1' as a highly specific CCA-targeting aptamer and successfully integrated it with MNVs to create a platform for precise delivery of therapeutic RNA payloads to tumors in live animals. This study establishes proof-of-concept for aptamer-guided nanovesicle delivery in CCA as a viable and generalizable approach for targeted RNA therapeutics, potentially extending beyond siRNAs to other therapeutic modalities.

4248 | PGC1 ALPHA HYPERACETYLATION DURING HYPERAMMONEMIC STRESS OF CIRRHOSIS WITH SARCOPENIA/ FRAILTY IS MEDIATED VIA PROTEIN STABILIATION OF LYSINE ACETYLTRANSFERASE 2A (GCN5)

Saurabh Mishra[1] Pugazhendhi Kannan[1] Volha Mezhnina[1] Seshu Pothabathula[1] Dhanachandra Khuraijam[1] Annette Bellar[1] Muaz Alsabbagh Alchirazi[1] Vandana Aggarwal[1] Jasmin Cunningham[1] Amy Attaway[1] Sadashiva Karnik[1] Yuxin Wang[1] Sathyamangla Prasad[1] Nicole Welch[1] Srinivasan Dasarathy[1], [1]Cleveland Clinic

Background: Hyperammonemic stress response (HASR) causes sarcopenia/frailty in cirrhosis via mitochondrial oxidative dysfunction. PGC1a is a critical positive regulator of mitochondrial function. We therefore investigated the molecular mechanisms, functional consequences, and designer peptide-based approaches targeting PGC1a-dependent mitochondrial regulation including post-translational modifications of PGC1a during HASR via lysine acetyltransferase 2A (KAT2A/GCN5). **Methods:** Mouse muscle and differentiated murine C2C12 myotubes were studied. GCN5 knockout (KO) was acchieved by CRISPR/Cas9. GCN5 mRNA levels were quantified by qPCR. Protein interactions were assessed by immunoprecipitation of GCN5 and immunoblots for STAGA complex subunits (TAF10, DR1, SUPT7L, ADA2B, SGF29)/PGC-1α. Protein stability of GCN5 was determined through cycloheximide (CHX) pulse-chase analysis. Ubiquitination of GCN5 was assessed using the TUBE (Tandem Ubiquitin Binding Entities) assay. Molecular docking-dynamics (MDD) of 3D structures of GCN5/KAT2A (Q9JHD2) and PGC-1α (O70343) were used to assess binding energies and interaction conformations followed by degron motif(s) identification (DEGRONOPEDIA). Linear (RPADSGDRETFA) and cyclic (CGKIRPDTRC) peptides (10–12 residues) were designed using PyMOL and optimized through energy minimization. Peptide incubation with lysates from myotubes without/with HASR followed by pulldown assays were done to evaluate PGC-1α-GCN5 interaction. **Results:** GCN5 protein expression was higher (due to protein sabilization) with unaltered mRNA during HASR. GCN5 interacted with and acetylates PGC-1α during HASR as part of the STAGA complex (ADA2B, SUPT7L, SGF29, TAF10), while interaction with DR1 (inhibitory transcription factor) was reduced. Ubiquitinylation-dependent activation of GCN5 was identified at 6 and 24 hours of HASR. GCN5 knockout reversed acetylation of PGC-1α during HASR. PGC-1α acetulation. Consistently, decreased expression of downstream targets, NRF1 and TFAM as well as critical components of the electron transport chain (OXPHOS) during HASR were reversed by GCN5 KO. MDD analyses showed GCN5–PGC-1α binding with a minimum energy of −82 kcal/mol. Key interactions were identified at Ser738–Lys253 (buried) and Asn408–Lys412 (exposed), contributing to acetylation and complex stabilization. Electrostatic interactions (Glu773–Arg695, Lys769–Asp694) supported catalytic intermediate stability. The linear peptide showed optimal blocking while the icircular peptide was only partially effective in disrupting GCN5-PGC1a complex. **Conclusion:** GCN5 impairs PGC-1α via acetylation with mitochondrial dysfunction during HASR by interacting with and activating components of the STAGA complex t. Our novel designer peptide-based competitive inhibitor(s) targeting GCN5-PGC1a interaction is a promising novel approach to treat sarcopenia of cirrhosis.

4249 | TRANSCEPTOR RHBG-DEPENDENT ACTIVATION OF INOSITOL REQUIRING ENZYME-1 ALPHA (IRE1A) AND X-BOX BINDING PROTEIN-1 (XBP1) SPLICING IN SKELETAL MUSCLE DURING HYPERAMMONEMIC STRESS RESPONSE CAUSES SARCOPENIA OF LIVER DISEASE

Pugazhendhi Kannan[1] Nicole Welch[1] saurabh mishra[1] Annette Bellar[1] Shashi Shekhar Singh[2] Amy Attaway[1] Muaz Alsabbagh Alchirazi[1] Seshu Vardhan Pothabathula[1] Vandana Agrawal[1] Jasmin Cunningham[1] Maria Hatzoglou[2] Srinivasan Dasarathy[1], [1]Cleveland Clinic, [2]Case Western Reserve University

Background: Sarcopenia in cirrhosis is caused by an hyperammonemic stress response (HASR) in skeletal muscle. HASR shares properties of general amino acid deficiency response (GCN2 activation) and unfolded protein response (UPR) with other characteristics distinct from the integrated stress response (PMID 27318325). The membrane transceptor (transporter/receptor), Rhesus blood group-associated B glycoprotein (RhBG) initiates molecular, metabolic, and functional consequences of HASR with sarcopenia. Given activation of some components of ISR during HASR, we evaluated if canonical IRE1a-dependent spliced XBP1 (XBP1s) mediates RhBG-dependent HASR with sarcopenia of cirrhosis. **Methods:** Studies were done in differentiated C2C12 myotubes, and muscle from inducible XBP1 and RhBG muscle specific knockout/parental control mice. HASR was induced by 10 mM ammonium acetate (myotubes) and 2.5 mmol. $kg^{-1}.d^{-1}$/saline infusion by a miniosmptic pump for 28 days in mice. Integrated multiomics analyses were done in myotubes/muscle tissue. Expression of signaling/regulatory proteins (mTORC1 signaling, autophagy markers) and measures of post-mitotic senescence were quantified by immunoblots . Binding partners for RhBG were determined by ascorbic acid peroxidase (APEXII) assay followed by liquid chromatography-mass spectrometry. Mitochondrial oxidative function was determined by high-sensitivity respirofluorometry and immunoblots for expression of proteins in the electron transport chain. **Results:** During HASR, XBP1 splicing efficiency and XBP1s protein expression were increased. Multiomics analyses showed mTORC1, oxidative phosphorylation, and senescence pathways were enriched during HASR with reversal of these changes with RhBG KO and XBP1 KO in myotubes and muscle tissue. Experimentally, XBP1 KO in myotubes and muscle tissue reversed HASR induced impaired mTORC1 signaling, protein synthesis, electron transport chain Complex I expression, mitochondrial oxidative dysfunction, and diminished global protein synthesis. Increased autophagy flux and post-mitotic senescence in muscle HASR were also reversed by XBP1 KO in myotubes and mouse muscle. Consistent with canonical IRE1a mediated XBP1 splicing, phosphorylatoin of IRE1a was higher during HASR, and IRE1a inhibitor (4u8C) reversed IREa phosphorylation, increased XBP1s, and impaired mTORC1 signaling. Activation of IRE1a was mediated by RhBG dependent Bip binding that released IRE1a for autophosphorylation and downstream XBP1s and functional consequences with molecular phenotype of sarcopenia of HASR. **Conclusion:** Transceptor RhBG initiates IRE1a-dependent XBP1s by binding to BIP1 and initiates a multicomponent response (mitochondrial oxidative dysfunction, accelerated post-mitotic senescence, and sarcopenic phenotype). Targeting RhBG-dependant XBP1s during HASR is a potential approach to treat sarcopenia in cirrhosis.

4250 | ASSESSING THE UTILITY OF SERUM CTGF AS A CLINICAL MARKER FOR HCC TUMOR FORMATION

Claudia Rose Keating[1] Irene Helenowski[1] Kyle Boedeker[1] Wei Qiu[2] Scott Cotler[2], [1]Loyola University Chicago, [2]Loyola University Health System

Background: There is a critical need for serum biomarkers to identify patients with cirrhosis who are at increased risk of developing hepatocellular carcinoma (HCC). Focal adhesion kinase (FAK) is overexpressed in more than 40% of HCC specimens and preliminary data indicate that FAK promotes the expression of connective tissue growth factor (CTGF), which is a secreted protein. Serum CTGF levels were correlated with a high degree of tumor angiogenesis, advanced staging, metastasis, and ultimately poor prognosis in HCC patients. The aim of this study was to assess serum CTGF as a clinical marker for HCC formation in patients with cirrhosis. **Methods:** In this cohort study, we used prospectively banked serum samples from 29 patients with cirrhosis who had routine surveillance and eventually progressed to HCC development. Each of these patients had between 2 and 9 serum samples collected prior to their HCC diagnosis, with a median first sample collection 1.2 years prior to diagnosis and at least one sample collected within one year of their diagnosis. Serum CTGF levels were quantified by ELISA, and a spline regression was used to determine the change in CTGF over time for each individual patient. **Results:** Using the serum CTGF measurement for each patient closest to the time of their HCC diagnosis, there was no significant difference in serum CTGF levels by sex or age at diagnosis. When patients were grouped by cirrhosis etiology, there was a trend toward higher serum CTGF levels in patients with alcohol-associated liver disease compared to metabolic dysfunction-associated steatotic liver disease, hepatitis C virus, and autoimmune etiologies (Figure). The spline regression showed that serum CTGF levels increased significantly in a subset of patients prior to their diagnosis of HCC (Figure). Additionally, the model showed a significant decline in serum CTGF levels following loco-regional therapy for HCC. **Conclusion:** Serum CTGF levels increased in a subset of patients prior to the diagnosis of HCC. We hypothesize that these individuals had high tumoral levels of FAK, driving this increase in serum CTGF. The findings suggest that CTGF merits further study as a potential circulating biomarker for HCC.

4251 | IDENTIFICATION AND VALIDATION OF BIOMARKERS FOR QUALITY CONTROL OF IN VITRO CULTURED HUMAN HEPATOCYTES

Masashi Okawa[1] Yein Woo[1] Garnik Arustamyan[1] Daniel Pinski[1] Meng Li[2] Takeshi Saito[1], [1]Keck School of Medicine, University of Southern California, [2]USC Libraries Bioinformatics Service, University of Southern California

Background: Hepatocyte heterogeneity and plasticity are essential for fulfilling the diverse liver functions and its robust regenerative and trans-differentiation capacities, respectively. These properties are disregarded when cultured in vitro, wherein cells are presumed to represent a homogeneous population, discounting their substantial propensity to deteriorate their functional and phenotypic characteristics. In vitro cultured human hepatocytes (HHs) display density-dependent variations in morphology and function; lower densities lead to loss of authentic hepatocyte characteristics, while higher densities support their identity preservation. Nevertheless, the optimal seeding density to maintain genuine characteristics of hepatocytes has yet to be elucidated. **Methods:** HHs, either primary or derived from humanized liver chimeric mice, seeded at varying densities as 2D monolayer were maintained for 7 days. Microscopic analysis was performed to evaluate cellular morphology and dimensions. Bulk and single-cell

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

mRNA sequencing analyses were performed to decipher seeding density-dependent changes at the level of the whole population and individual cells. Transcriptomic profiles were also compared against a reference panel of representative hepatocyte marker genes to determine the optimal seeding density. scRNA-seq data were further utilized to identify threshold seeding densities permitting the emergence of cell populations lacking hepatocyte marker genes, and characterize their transcriptomic divergence, and identify biomarkers. The utility of these biomarkers was assessed via functional analyses of hepatocytes. **Results:** Density-dependent heterogeneity in cell size was observed, with a higher proportion of cells exceeding physiological size ranges at lower seeding densities. This correlated with a loss of hepatocyte identity as determined by bulk RNA-seq analysis. scRNA-seq identified up to 16 distinct biomarkers representing hepatocyte populations that had lost their identity. Notably, the proportion of cells expressing these biomarkers increased as seeding density decreased. Validation studies demonstrated that HH populations with more than 5% of cells expressing at least one of these biomarkers, as determined by IHC staining, exhibit compromised overall hepatic functions, including detoxification capacity, nutrient metabolism, and bile secretion machinery. **Conclusion:** This work established an IHC-based quality assessment of in vitro cultured HHs through the detection of biomarkers representing suboptimal hepatocyte populations. This approach could be exploitable as a standardized quality control protocol to enhance the scientific integrity and translational relevance of studies utilizing primary human hepatocyte culture systems.

4252 | AGING TRIGGERS ALCOHOL-INDUCED ENDOTOXIN TOLERANCE BY REPROGRAMMING MONOCYTE RESPONSES IN A NICHE-SPECIFIC MANNER

Marti Ortega Ribera[1] Radhika Joshi[1] Sergi Guixe-Muntet[2] Veronika Brezani[1] Prashanth Thevkar Nagesh[3] Viliam Brezani[1] Arman Patel[1] Mrigya Babuta[1] Yuan Zhuang[4] Jordi Gracia-Sancho[5] Gyongyi Szabo[4], *[1]BIDMC - Harvard Medical School, [2]IDIBAPS, [3]Beth Israel Medical Center, [4]Beth Israel Deaconess Medical Center, [5]IDIBAPS - Hospital Clínic Barcelona*

Background: Bacterial infections are the leading cause of mortality in patients with alcohol-associated hepatitis (AH), and this risk is further elevated with aging. We previously showed that acute alcohol exposure suppresses immune functions. Specifically, monocyte (MO) responses to lipopolysaccharide (LPS) are blunted following acute alcohol exposure, contributing to a state of endotoxin tolerance (ET) and increased susceptibility to infections. Given the baseline inflammation state associated with aging ("inflammaging"), we hypothesized that aging would modulate alcohol-induced ET and alter MO responses during an inflammatory insult in a niche-specific fashion. **Methods:** Young (3 months) and aged (20–24 months) female C57BL/6N mice received 10 alcohol binges (3.5 g/kg) or water every other day. Twelve hours after the final binge, mice were randomized to receive LPS (1 mg/kg i.p.) or saline to mimic sepsis. Tissues were harvested 18 hours post-alcohol exposure. Three MO populations were isolated and RNA-sequenced using SMART-Seq (n = 4–6/group): 1-Liver MO, 2-microglia & 3-bone marrow MO (BM-MO). **Results:** LPS induced a robust pro-inflammatory transcriptomic response in both young and aged groups. Notably, aged liver MO and microglia exhibited exaggerated LPS responses, while aged BM-MO showed reduced responsiveness (lower number of differentially expressed genes [DEG]), indicating niche-specific reprogramming. Compared to LPS alone, alcohol pretreatment significantly reduced LPS-induced DEGs in all MO populations consistent with alcohol-induced ET. Importantly, this was exclusively observed in the aged population. This was corroborated by reduced circulating cytokines (IL-13, IL-6, MIP-2) in the aged ethanol-LPS group.

Mechanistically, aged liver MOs showed downregulation of Pattern Recognition Receptors (PRRs) including *Tlr1/2/4/6/7/8/13*, *Nlrp3* and its key signaling mediators (*Ticam2*, *CD300a*, *CD86*, *Trem1/2*), suggesting impaired pathogen sensing and response. Microglia isolated from aged mice receiving alcohol exhibited upregulation of epigenetic regulators (*Uhrf1, Wdhd1, Xist*), anti-inflammatory genes (*Igf1, Apoe, Ptpn2*), and tolerance markers (*Pdcd1, Lilrb4a/b*), confirming the establishment of an ET phenotype. Finally, BM-MO transcriptomes revealed coordinated engagement of epigenetic mechanisms and downregulation of PRR-related pathways, further supporting systemic tolerance programming. **Conclusion:** This study uncovers previously unrecognized mechanisms by which alcohol and aging synergistically impair MO phenotype, offering critical insights into the heightened susceptibility to infection in elders with alcohol misuse.

4253 | COMPREHENSIVE ANALYSIS OF THE ROLE OF TUMOR-ASSOCIATED ANTIGEN TBC1D13 IN HEPATOCELLULAR CARCINOMA

Wei Hou[1], [1]Translational Medicine Research Center, School of Clinical Medicine, Qilu Medical University, CHINA

Background: The TBC1D13 gene is a member of the TBC (Tre-2/Bub2/Cdc16) domain family, encoding proteins with GTPase-activating protein (GAP) activity specific to certain RAB GTPases. This gene has garnered attention for its critical role in cellular processes, particularly regarding insulin signaling and glucose transport. Recent studies have highlighted the multifaceted functions of TBC1D13, indicating its implications in conditions such as obesity and diabetes through the regulation of GLUT4 trafficking in adipocytes. Moreover, TBC1D13 has been identified as an important tumor-associated antigen (TAA) and plays a significant role in the development of hepatocellular carcinoma (HCC). However, detailed information regarding the regulatory mechanisms of HCC progression and the clinically aggressive phenotypes associated with tumor-associated antibodies (TAAbs) remains limited. This study aims to conduct a comprehensive analysis of the role of tumor-associated anti- TBC1D13 autoantibodies in HCC. **Methods:** Study cases were acquired from multiple databases, including GEO (GSE144269, GSE14520, GSE22058, GSE25097, GSE36376), ICGC, and TCGA_GTEx. Proteomic data were obtained from PDC000198 in the CPTAC data portal and PXD008373 from the ProteomeXchange Datasets. We utilized the R package and the online tool hccTAAb to perform gene and protein expression analysis, survival analysis, immune infiltration analysis, and similarity analysis. **Results:** The expression of TBC1D13 in cancer tissues compared to normal tissues showed a significant increase across seven transcriptomic datasets. Additionally, proteomic data from PDC000198 and PXD008373 corroborated the elevated expression of TBC1D13 in HCC cases compared to healthy controls. Survival analysis indicated that higher TBC1D13 expression is associated with poor prognosis. Log-rank tests revealed significant differences in survival outcomes between high- and low-expression groups. Cox regression analysis yielded a hazard ratio (HR) of 1.44 (95% CI: 1.11−1.87, $P < 0.0001$) for the TCGA-LIHC dataset and HR = 1.68 (95% CI: 0.98−2.86, $P < 0.0001$) for the ICGC-LIRI dataset. Immune infiltration analysis using ssGSEA and CIBERSORT demonstrated significant differences in natural killer (NK) cells between the high- and low-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

expression groups (adjusted P = 0.018). Furthermore, TBC1D13 exhibited significant correlations with six immune cell types, including NK cells. Similarity analysis identified the top 10 genes (MED22, NELFB, REXO4, TMEM250, WDR5, CIZ1, ZER1, URM1, GTF3C5, PYGO2) that exhibited positive correlations, while genes such as TAT, SLC10A1, PCK1, SERPING1, CYP2A6, SDS, HP, RIDA, AKR7A3, and SLC27A5 demonstrated negative correlations. **Conclusion:** Our findings underscore the role of tumor-associated antigen TBC1D13 and its prognostic significance in HCC. These studies warrant further molecular assays to elucidate the potential role of TBC1D13 in tumorigenesis and provide important insights into the underlying mechanisms and potential therapeutic targets related to TBC1D13 in HCC.

4254 | CHARACTERIZING SECRETED MIRNAS FROM HEPATIC SPHEROID MODELS FOR MASLD BIOMARKER DISCOVERY

Amila Iriskic Atic[1] Alexander Munk[2] Louise Torp Dalgaard[1] Helene Lykkegaard[2] Mugdha Joglekar[3] Anandwardhan Hardikar[3] Andrea De Pieri[2], [1]Roskilde University, [2]Novo Nordisk, [3]Western Sydney University

Background: Metabolism-associated liver steatotic disease (MASLD) is a spectrum of disease ranging from simple hepatic steatosis (to metabolism-associated steatohepatitis (MASH) which may progress to cirrhosis and liver cancer. MASLD is rapidly becoming a global health challenge, and there is a need for improved diagnostic- and prognostic tools and for effective pharmacotherapies to treat MASH.
In MASLD circulating extracellular vesicles (EVs) can affect hepatic cells and are involved in intercellular signaling, tissue injury and repair, and matrix remodeling. Specific cargo molecules carried by EVs are utilized for intercellular signal transduction. Among these molecules, small non-coding microRNA (miRs)s have important epigenetic functions, post-transcriptionally regulating gene expression, indicating their importance as biomarker candidates for diagnosing, monitoring and prognosis in MASH. **Methods:** Primary human hepatocytes, stellate and Kupffer cells were obtained from Fibscore 0/1 donors and cultivated as both mono- and coculture spheroids in low-attachment plates using established protocols. A -MASH model was induced after two days in the coculture system by switching to a high free fatty acid (FFA) culture media (180μM oleic acid, 125 μM palmitic acid). To increase secretion of EVs, cells were treated with 250μM palmitic acid (PA) for 6 hours. EVs were prepared from the culture supernatant using ultracentrifugation, and Cellular RNA and EV RNA was purified using Trizol and submitted for miR analysis using ThermoFisher OpenArrays. Group t-test or nonparametric test were used for comparison between groups. Statistical significance was set at $p < 0.05$. **Results:** Nine microRNAs (miRs)—*hsa-miR-572, hsa-miR-21, hsa-miR-223, hsa-miR-221, hsa-miR-665, hsa-miR-206, hsa-miR-147b*, and *hsa-miR-449b*—were significantly downregulated in RNA from hepatocyte monocultures by PA treatment. In hepatic stellate cells, three miRNAs, *hsa-miR-125a-3p, hsa-miR-432,* and *hsa-miR-192*, were also significantly downregulated by PA treatment. A comparison of cellular and EV-miRNA profiles revealed that seven miRs were selectively secreted via EVs from hepatocytes, while four miRs were secreted from hepatic stellate cells. In the co-culture model, EVs carried both hepatocyte- and stellate cell–specific miRs; however, these were not regulated by short PA treatment. **Conclusion:** These findings suggest that distinct subsets of miRs are differentially expressed by hepatocytes and hepatic stellate cells, with limited impact from short term PA exposure. Moreover, certain miRs appear to be selectively packaged into EVs, indicating potential cell-type-specific patterns of miR secretion. While most miRNAs remain intracellular, the observed EV-associated signatures may reflect underlying cell communication or regulatory mechanisms. Further studies are warranted to explore these dynamics in more detail.

4255 | ALBUMIN RESCUES ENDOTHELIAL CELL MITOCHONDRIAL MORPHOLOGY IN PATIENTS WITH DECOMPENSATED CIRRHOSIS

Susan Fischer[1] Rudmer Postma[1] Roel Bijkerk[1] Annarein Kerbert[1] Anton Jan Van Zonneveld[1] Minneke Coenraad[1], [1]Leiden University Medical Center

Background: Endothelial cell (EC) activation is a critical driver of disease progression in patients with liver cirrhosis, contributing to acute decompensation (AD) and acute-on-chronic liver failure (ACLF). The administration of human albumin in cirrhotic patients with hypoalbuminemia has been shown to improve EC function. However, the direct effects of albumin on ECs in cirrhosis are unknown. Furthermore, it is unknown which specific patient category might benefit from albumin treatment. This study investigates *ex vivo* the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

impact of human albumin administration on EC morphology, exposed to plasma derived from patients with different stages of cirrhosis aiming to explore the mechanisms underlying its protective effects and therapeutic response. **Methods:** A high-throughput *in vitro* EC model was used to observe EC responses to patient-derived plasma with or without albumin administration. Cultured human umbilical vein ECs were exposed to plasma from patients with decompensated cirrhosis and hypoalbuminemia (serum albumin < 30g/L, $n = 20$), patients with compensated cirrhosis (serum albumin > 30 g/L, $n = 20$), or healthy controls ($n = 20$). Albumin was administered to the plasma samples of patients with decompensated cirrhosis and healthy controls, aiming at physiological levels (~40 g/L) in patients with decompensated cirrhosis and similar doses to samples of healthy controls resulting in supraphysiological levels. The modulatory effects of albumin on EC activation were tested for well-described circulating factors involved in EC dysfunction (lipopolysaccharide (LPS), TNFα and bilirubin). Multiple cellular components were investigated using high-content imaging and multivariate analysis. **Results:** Factor analysis identified mitochondrial morphology as a key feature responsible for the discrimination between patients with decompensated cirrhosis from those with compensated cirrhosis and healthy controls. Multivariate analysis revealed that albumin administration shifted EC morphology in plasma of decompensated cirrhosis toward a healthier phenotype, resembling the plasma of patients with compensated cirrhosis and healthy controls. No significant shifts in morphology were observed upon titration of albumin to ECs stimulated by LPS, TNFα or bilirubin. **Conclusion:** Plasma from patients with decompensated cirrhosis and hypoalbuminemia induces important morphological changes to ECs, of which changes in mitochondrial morphology are most discriminative. Albumin administration reduces EC activation and dysfunction induced by plasma from patients with decompensated cirrhosis and hypoalbuminemia. These data underline the crucial role of albumin in EC function and point towards a potential therapeutic role of albumin in reducing vascular dysregulation and liver disease progression. Further research is required to explore the potential of this assay in predicting therapeutic responses to albumin.

4256 | CHARACTERIZATION OF HUMAN LIVER SPHEROIDS USING STABLE ISOTOPE TRACING

Kanani Hokutan[1] Hyun Young Kim[2] Samuel Kerk[3] Wonseok Lee[2] Sadatsugu Sakane[2] Karin Diggle[1] Tatiana Kisseleva[2] Christian Metallo[3] David Brenner[4], [1]University of California San Diego, [2]University of California, San Diego, [3]Salk, [4]Sanford Burnham Prebys

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) progresses from simple steatosis to metabolic dysfunction-associated steatohepatitis (MASH) and liver fibrosis. Dysregulation of lipid and glucose metabolism is a major factor in MASH development. However, progress in target discovery and drug development for MASH is limited by available methodologies to mimic metabolically injured human livers. Here we generate human 3D liver spheroids to study 'liver in a dish' and induce metabolic liver injury using a MASH-cocktail containing glucose, palmitate, and oleate. We identified significant lipid accumulation in MASH spheroids, leading to investigate the source of lipids. **Methods:** Spheroids were generated using cryopreserved primary human liver cells containing 60% hepatocytes and 40% non-parenchymal cells (NPCs) including Hepatic Stellate Cells (HSCs). Upon formation, spheroids were incubated with media supplemented isotope-labeled MASH cocktail components that can be a source for intracellular lipid synthesis; U-^{13}C-glucose, $^{13}C_2$-acetate, or $^{13}C_{18}$-BSA-oleate. Spheroids and supernatant were collected after two days and analyzed for isotope enrichment using gas chromatography-mass spectrometry and liquid chromatography with tandem mass spectrometry. Next, spheroids were generated using freshly isolated steatotic hepatocytes and NPCs, and cryopreserved HSCs, and cultured in MASH cocktail. Upon spheroid formation, culture medium was changed to MASH cocktail containing U-^{13}C-glucose. Two days later spheroids and supernatant were collected and analyzed. **Results:** Isotope-labeled glucose, acetate, and oleate are catabolized in the TCA cycle of human liver spheroids. We found that $^{13}C_{18}$-BSA-oleate is incorporated into DGs, TGs, PEs, and PCs. Spheroids produced M+3 glycerol-3P that was incorporated into lipid head groups. Minor $^{13}C_2$-acetate was incorporated into DGs, TGs, PEs, and PCs, indicating our conditions facilitate uptake of exogenous oleate, but do not undergo *de novo* lipogenesis (DNL). In MASH spheroids generated using freshly isolated steatotic hepatocytes, we found decreased glucose carbon utilization and an increased lactate/pyruvate ratio. We also observed reduced DNL from glucose in MASH; however intracellular levels are

4257 | SUGGESTED IMPORTANCE OF THE MICROENVIRONMENT SURROUNDING CANCER CELLS IN THE PROGRESSION OF HEPATOCELLULAR CARCINOMA

Hirayuki Enomoto[1] Yukihisa Yuri[1] Nobuhiro Aizawa[1] Tomoyuki Takashima[1] Naoto Ikeda[1] Ryota Nakano[1] Hideyuki Shiomi[1] Shinya Fukunishi[1] Takashi Nishimura[1] Hiroko Iijima[1] Shinichiro Shinzaki[1], [1]Hyogo Medical University

Background: The xenograft model is frequently used to examine antitumor effects in vivo by transplanting human-derived cancer cells into immunosuppressed mice. This experimental system is an extremely useful model to verify the effects of drugs in vivo, but tumors are formed from human-derived cancer cells and mouse-derived tumor stromal cells. Although tumors are formed from human-derived cancer cells and mouse-derived tumor stromal cells, few studies have discussed on this point. In this study, we focused on the fact that interferon (IFN) is a highly species-specific bioactive substance. We compared the antitumor effects of human interferon (h-IFN) and murine interferon (m-IFN) in the xenograft model. **Methods:** We compared the expression of human and mouse type I IFN receptors in the human hepatocellular carcinoma cell line Hep3B. Hep3B cells were cultured and the inhibitory effects of m-IFN and h-IFN on cell proliferation were compared in vitro. In the xenograft model in which Hep3B cells are transplanted subcutaneously into SCID mice (tumor cells are of human origin and stromal cells are of mouse origin), 5 weeks after transplantation, h-IFN or m-IFN were administered (peri-tumor injection) for 2 weeks, and in vivo anti-tumor effects were compared. **Results:** (1) Hep3B cells strongly expressed h-IFN-bound IFN receptors, but the expression level of m-IFN-bound receptors was quite low (approximately one-tenth). (2) In vitro proliferation of Hep3B cells was inhibited by the h-IFN treatment, but not by the m-IFN treatment. (3) In the in vivo model, h-IFN treatment inhibited the proliferation of Hep3B-derived cancer cells, while m-IFN did not influence the proliferation of cancer cells. However, m-IFN treatment suppressed the angiogenesis in the tumor stromal tissue, which were shown by the decreased number of the CD34-positive cells, and caused the antitumor effect comparable to that of h-IFN in vivo. **Conclusion:** In the xenograft model, h-IFN mainly act on the cancer cells of human origin, whereas m-IFN mainly affects stromal cells of mouse origin. Since cancer cells and stromal cells in the xenograft model are derived from different species, it is possible to examine the roles of cancer cells and stromal cells separately. The significant antitumor effects of m-IFN suggest the important role of the microenvironment surrounding cancer cells in the progression of the hepatocellular carcinoma.

4258 | POLYENYLPHOSPHATIDYLCHOLINE (PPC) ATTENUATES OXIDATIVE STRESS-INDUCED LIVER INJURY BY STABILIZING LYSOSOMAL MEMBRANE INTEGRITY

yongzhi li[1] Jie Lin[1] Dan Zhang[1] jiyao sheng[1], [1]The Second Hospital of Jilin University

Background: Oxidative stress, a core mechanism of liver injury, disrupts redox homeostasis, impairing organelle function. Lysosomes are key targets of ROS, and their membrane instability worsens ROS accumulation, creating a vicious cycle that accelerates hepatocyte damage. Thus, stabilizing lysosomal membranes and blocking oxidative stress are vital for liver function. Polyenylphosphatidylcholine (PPC), a clinical hepatoprotectant, is known to repair hepatocyte membranes, but its role in lysosomal protection remains unclear. This study explores PPC's novel mechanism in preserving lysosomal integrity, offering new therapeutic strategies for liver diseases. **Methods:** In vitro, H_2O_2-induced oxidative stress models in L02 and THLE-2 hepatocytes were used to assess PPC's cytoprotective effects. Cell viability (CCK-8), ROS levels (DCFH-DA flow cytometry), and apoptosis (Annexin V-FITC/PI) were measured. Lysosomal function was evaluated via Cathepsin B/D expression (Western blot), cholesterol

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

content (Filipin staining/confocal microscopy), and membrane integrity (galectin-3 puncta assay). Lysosomal dynamics (Lysotracker Red/confocal), ultrastructure (TEM), and repair protein localization were analyzed. In vivo, a CCl4-induced liver injury model assessed serum ALT/AST, histopathology (HE/Masson staining), and lysosomal markers (immunofluorescence). RNA-seq and bioinformatics identified key pathways, while molecular docking predicted PPC-lysosomal protein interactions, elucidating PPC's hepatoprotective role via lysosomal cholesterol homeostasis and PITT-mediated repair. **Results:** PPC treatment protected against oxidative liver injury both in vitro and in vivo. In H_2O_2-treated hepatocytes, PPC enhanced cell viability, reduced ROS levels, and inhibited apoptosis. Filipin staining and galectin-3 puncta assays showed PPC increased lysosomal cholesterol content, improving membrane stability and reducing permeabilization. Confocal microscopy revealed PPC activated the PITT repair pathway to restore damaged lysosomes, while TEM confirmed preserved lysosomal ultrastructure. In CCl4-treated mice, PPC decreased serum ALT/AST, attenuated histopathological damage, and upregulated lysosomal markers. Transcriptomics indicated PPC maintains lysosomal integrity through cholesterol homeostasis and membrane repair mechanisms. **Conclusion:** This study demonstrates that PPC protects against oxidative liver injury by maintaining lysosomal membrane integrity through cholesterol enrichment and PITT-mediated repair, offering new therapeutic strategies for oxidative stress-related liver diseases.

4259 | AGING DISRUPTS HEPATOCYTE ZONATION HOMEOSTASIS IN MICE AND HUMANS

Erika Hissong[1] Robert Schwartz[1] Jason Sethiadi[1] Silvia Hanna[1] Duc Nguyen[1] Tuo Zhang[1] Qazi Ali[1] Saloni Sinha[1], [1]Weill Cornell Medicine

Background: Background and Aims: The mammalian liver performs vital physiological functions and maintains whole-body homeostasis. Thanks to its remarkable regenerative ability, age-related declines in liver function occur more slowly than in most organs. Liver aging is driven by genomic and epigenomic changes and is characterized by reduced volume and blood flow, impaired metabolism, delayed regeneration, hepatocyte polyploidy, increased numbers of hepatic stellate cells (HSCs), liver sinusoidal endothelial cells, and Kupffer cells, along with heightened inflammation and senescence. Aging-induced degenerative changes in the liver are not inherently pathologic but pose an increased risk for liver diseases. However, the molecular mechanisms underlying aging-induced hepatic dyshomeostasis remain incompletely characterized. **Methods:** Approach and **Results:** Histological analyses of aged (>24-month-old) wild-type mouse livers showed no fibrosis, but a uniform cellular enlargement compared to young (2-month-old) mouse livers was noted. For an unbiased characterization of aging-driven changes, we used single-nucleus RNA sequencing and found that aged livers had altered cell-cell interactions and hepatocyte zonation with zone-specific transcriptomic changes. Immunostaining confirmed aging-induced expansion of ASS1+, CYP2E1+ and GS+ hepatocytes, and an aberrant expression of ASS1+-GS+ "bi-zonal" hepatocytes, causing collapse of zonation. To investigate translational value, we assessed young (<25YO) and aged (>60YO) human liver biopsies and identified similar phenotypes. **Results:** See Above. **Conclusion:** In this study, we present a detailed analysis of the liver's cell type-specific transcriptome across aging, uncovering significant changes in cellular composition, gene expression, and zonation contributing to the age-related decline in structure and function. Our analyses identify profound transcriptional changes within major liver cell types, including hepatocytes, HSCs, and LSECs, and offer insights into the disruption of hepatic functions and intercellular communication. Aging causes a loss of distinct hepatic zonation, marked by an expansion and blurring of zonal boundaries. The emergence of "bi-zonal" hepatocytes near the central vein, co-expressing markers from both periportal (ASS1) and pericentral (GS) zones—mutually exclusive in young livers—

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

indicates aging significantly modifies the liver microenvironment. Parallels between aged mouse and human livers strongly evidence that mechanisms driving zonation dysregulation and bi-zonal hepatocyte emergence are conserved across species. Future research aimed at restoring hepatocyte zonal integrity, balancing intercellular communication, and targeting key transcriptional regulators could mitigate age-associated liver dysfunction and disease.

4260 | ZINC FINGER TRANSCRIPTION FACTOR FANIN IS THE UPSTREAM REGULATOR OF PIONEER FACTORS FOXA1 AND FOXA2 IN THE LIVER

Joseph Schinderle[1] Anqi Wu[1] Riya Shah[1] Irina Bochkis[1], [1]University of Pittsburgh

Background: Transcription factors regulate gene expression that orchestrates many processes, including development and physiology. Winged-helix (*forkhead*) factor paralogs Foxa1 and Foxa2, originally named HNF3α and HNF3β, are called pioneer factors for their ability to independently bind closed chromatin and change chromatin accessibility allowing other factors to bind. Foxa1 and Foxa2 are essential to liver function, both in development and differentiated tissue. Based on computational analysis, we have identified the upstream regulator of Foxa1 and Foxa2 we named FANIN. **Methods:** We performed ChIP-Seq to identify FANIN binding, and ATAC-Seq & RNA-Seq in FANIN liver-specific mutants to assess chromatin accessibility and differential gene expression. Functional analysis of genomic data was completed to identify the role of FANIN in the liver. **Results:** Deletion of FANIN leads to loss of Foxa1 and Foxa2 expression in the liver. Since Foxa1 and Foxa2 are pioneer factors, we assessed whether deletion of FANIN affects chromatin accessibility. Indeed, ATAC-Seq signal is reduced in both male and female FANIN mutants, in contrast to Foxa2 mutants in control condition. Pathway analysis of FANIN ChIP targets in males identified targets regulating collagen synthesis and ECM proteins, and we confirmed presence of collagen in male FANIN mutants. Pathway analysis of FANIN ChIP targets in females identified targets associated with liver inflammation, injury and proliferation and was confirmed by H&E and Ki67 staining. **Conclusion:** FANIN is likely a pioneer factor regulating 2 established pioneer factors, which is unprecedented. Mechanisms of regulation of ECM targets by FANIN are crucial to understanding, treating, and reversing liver fibrosis. Understanding how FANIN modulates liver injury and inflammation is critical to treatment of chronic and end-stage liver disease.

4261 | EXOSOME-DEPENDENT MECHANISM OF LIVER REGENERATION AFTER PARTIAL HEPATECTOMY

Mina McGinn[1] Christopher Rabender[1] Ross Mikkelsen[1] Vasily Yakovlev[1], [1]Virginia Commonwealth University/ Massey Cancer Center

Background: The liver is known for its remarkable ability to regenerate precisely after massive tissue loss or injury. Liver regeneration is studied by performing the partial hepatectomy (PHx) to remove 2/3 of the liver mass in rodents. Following regeneration, the liver grows back precisely to its original mass without exceeding it. Different studies have shown that loss of liver mass affects putative tissue-specific mitogenic inhibitors in the blood, which, in turn, regulate the proliferation of remaining hepatocytes and liver regeneration. Although well-documented in numerous publications, the inhibitory substances or 'sensor molecules' that control the regeneration mechanisms remain unknown. Approximately 80 years ago, a series of now classic studies suggested that within any cell line, functionally active differentiated cells may signal their existence to the mitotically active precursor cells through a tissue-

specific or cell-line-specific inhibitory substance. Exosomes are small (30–150 nm) vesicles containing unique RNA and protein cargo, secreted by all cell types in culture and in vivo. Their proposed role is stable intercellular carriers of proteins and RNAs, mostly microRNA, from secreted to recipient cells. Exosomes taken up by the recipient cells can significantly modulate their biological functions. **Methods:** Hepatocyte-derived exosomes (HD-Exos) were selectively labeled, analyzed, and isolated from mouse plasma. HD-Exos and non-HD-Exos RNA content from mouse plasma was also analyzed by Nanostring and RT-PCR methods. Using in vivo and in vitro models, we assessed the role of HD-Exos and the RNA they contain in regulating hepatocyte proliferation and liver regeneration. **Results:** We demonstrated that after PHx, the concentration of HD-Exos in the blood of animals changes in proportion to the total mass of the liver. At the same time, exosomes secreted by liver hepatocytes into the blood actively block hepatocyte proliferation in vitro and liver regeneration after PHx in vivo. We also demonstrated that miRNA-26a, miRNA-30a, and miRNA-33 carried by HD-Exos play an active part in the downregulation of hepatocyte proliferation. Thus, HD-Exos released into the bloodstream are a key element of the negative feedback mechanism regulating liver proliferation. **Conclusion:** This work opens up a completely new and unexplored area of liver biology regarding the role of liver-derived exosomes and their cargo in the regulation of liver regeneration and homeostasis.

4262 | THE CALORIC RESTRICTION MIMETIC, HYDROXYCITRATE, IS A PROMISING SUPPLEMENTAL DIETARY THERAPY TO PREVENT ALCOHOL-INDUCED LIVER INJURY

Oluwaseyi Okesooto[1] Erik Tweten[1] Pamela Tuma[1], [1]The Catholic University of America

Background: Caloric restriction has emerged as a promising therapeutic strategy for mitigating metabolic diseases, including alcohol-associated liver disease. This study investigates the potential of hydroxycitrate, a caloric restriction mimetic, as a novel therapeutic intervention. This mimetic is a competitive inhibitor of ATP citrate lyase, an enzyme that converts citrate to oxaloacetate and acetyl-CoA. Because acetyltransferases transfer the acetyl group from acetyl-CoA to the ε -amino group of lysines, ATP citrate lyase inhibition is predicted to decrease cellular acetyl-CoA levels, promoting global protein deacetylation by reducing the substrate availability for acetyltransferases. Decreased acetyl-coA levels have also been linked to decreased lipid biosynthesis such that hydroxycitrate also has the potential to prevent alcohol-induced steatosis. **Methods:** For these studies we used polarized, hepatic WIF-B cells. Importantly, these cells exhibit endogenous alcohol metabolism as observed in liver *in situ.* Cells were treated with hydroxycitrate in the absence or presence of alcohol to determine its capacity to prevent selected alcohol-induced hepatic cellular alterations. **Results:** We determined that hydroxycitrate treatment prevented alcohol-induced tubulin acetylation in a dose-dependent manner, consistent with its proposed function in global protein deacetylation. It also prevented alcohol-induced peroxisome proliferation and alcohol-induced oxidative stress (as observed by decreased ROS accumulation), suggesting it might additionally function as an anti-antioxidant. Furthermore, when alcohol-treated WIF-B cells were additionally treated with oleic acid (to mimic the Western diet), the addition of hydroxycitrate ameliorated lipid accumulation as observed by decreased numbers of lipid droplets of reduced size, consistent with its proposed function in reducing body fat. We further determined that hydroxycitrate addition prevented known alcohol-induced defects in microtubule plus-end and minus-end directed protein trafficking due to tubulin acetylation. Finally, live cell imaging revealed that hydroxycitrate prevented alcohol-induced defects in microtubule-based organelle motility. **Conclusion:** Together, these results suggest that hydroxycitrate, used alone or with aldehyde scavengers, could be a potential dietary supplement with therapeutic effects in preventing and/or attenuating alcohol-induced liver injury progression.

4263 | INCREASING MATRIX HETEROGENEITY PROMOTES CELL-MATRIX INTERACTIONS AND THE AGGRESSIVENESS OF LIVER CANCER CELLS

Alexander Hayn[1] Madlen Matz-Soja[1] Thomas Berg[1] Florian van Bömmel[1], [1]University Hospital Leipzig, Division of Hepatology

Background: Remodeling of the extracellular matrix (ECM) is a key feature of tumor development in the liver, particularly in cases of hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCC). A stiffened and heterogeneous ECM promotes the proliferation, migration and invasion of tumor cells.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Fibronectin (FN) is an important ECM glycoprotein that facilitates cell adhesion, migration, and proliferation within the ECM. The way in which HCC/iCC cells interact with heterogeneous ECMs is not well understood.
The aim is to analyze cell-matrix interactions with collagen and collagen-FN-based networks, and to identify the resulting cell-specific factors in the context of increasing ECM heterogeneity. **Methods:** ECM stiffness and structural parameters were combined to define ECM heterogeneity. HCC and iCC cell lines, represented by Huh7 and KKU-213 cells respectively, were analyzed in contact with the ECM model system. Stiffness was measured using atomic force microscopy, invasiveness using 3D invasion assays, and the mechanotransductive interaction of the cells with the network structures as a function of increasing ECM heterogeneity using 3D fiber displacement analyses. **Results:** An increase in ECM heterogeneity from low to high resulted in a 2.3-fold decrease in HCC cell stiffness and a 3.0-fold decrease in iCC cell stiffness. Analysis of invasiveness with increasing ECM heterogeneity revealed cell-specific effects. The invasiveness of the HCC cell line under FN-influence increased from 26% ± 4% in low-heterogeneous ECM to 38% ± 6% in increased-heterogeneous ECM and 51% ± 3% in highly-heterogeneous ECM, compared to 32% ± 9% in increased-heterogeneous ECM and 46% ± 9% in highly-heterogeneous ECM without FN. In addition, the highly invasive behavior of all examined cells was evident in highly heterogeneous ECM. The invasiveness of iCC cells increased independently of FN, rising from 24% ± 2% in low- to 62% ± 8% in highly heterogeneous ECM. 3D fiber displacement analyses investigated the interaction of invasive cells with ECM structural changes. **Conclusion:** The HCC and iCC cell lines examined exhibited decreased stiffness and increased invasiveness in the presence of increased ECM heterogeneity. The role of ECM heterogeneity as a risk factor for the spread of intrahepatic tumors and cell dedifferentiation needs to be investigated in vivo.

4264 | LOSS OF APOE IN CCL19^{+} STROMAL CELLS EXACERBATES LIVER DAMAGE IN EXPERIMENTAL LUPUS HEPATITIS

Yekaterina Krutsenko[1] Jiang Li[1] Sudrishti Chaudhary[1] Juliane Beier[1] Gavin Arteel[1] Catherine Poholek[1],
[1]University of Pittsburgh

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease affecting multiple organs. Hepatic manifestations affect up to 30% of SLE patients and include elevated liver enzymes, MASLD, autoimmune/lupus hepatitis, and cirrhosis, but underlying mechanisms remain poorly understood. Emerging evidence suggests that immune-stromal interactions in secondary lymphoid organs contribute to systemic inflammation in SLE. CCL19-producing lymph node stromal cells (LNSCs) regulate T cell activation and are increased in secondary lymphoid organs and inflamed tissues in lupus models. Here we show that production of apolipoprotein E (apoE), a lipid transport protein with immunomodulatory roles, regulates CCL19^{+} LNSC function, and examine how apoE loss in CCL19^{+} LNSCs affects hepatic pathology in murine lupus. **Methods:** We induced lupus in 20-week-old female mice with targeted deletion of *Apoe* in CCL19^{+} LNSCs (CCL19^{Cre}Apoe$^{fl/fl}$ (CCL19$^{\Delta apoE}$)) and control mice (CCL19^{WT}Apoe$^{fl/fl}$ (CCL19^{Ctrl})) using chronic topical application of the TLR7 agonist imiquimod (3 times weekly to ear skin for 5 weeks), then assessed liver pathology by histology and qRT-PCR. **Results:** Imiquimod induced periportal lymphocytic and plasma cell infiltration with interface inflammation and occasional necrotic foci, characteristic of lupus hepatitis, with more severe changes in CCL19$^{\Delta apoE}$ mice compared to CCL19^{Ctrl} mice. RT-qPCR revealed no differences in macrophage populations (F4/80, CD68), but immunohistochemical analysis showed mildly increased MPO-positive neutrophil infiltration and NET formation in CCL19$^{\Delta apoE}$ animals, as demonstrated by citrullinated histone H3 staining. Polarized light imaging revealed "chicken-wire" fibrotic changes that were exacerbated in CCL19$^{\Delta apoE}$ mice despite similar TGFβ1, Col1a1, and α-SMA fibrosis marker expression. CCL19$^{\Delta apoE}$ mice, but not controls, showed increased hepatic plasminogen activator inhibitor-1 (PAI-1) expression but paradoxically decreased fibrinogen deposition. **Conclusion:** ApoE deficiency in CCL19-expressing cells exacerbated imiquimod-induced hepatic manifestations that mimic features of lupus hepatitis. The paradoxical finding of elevated PAI-1 with reduced fibrinogen deposition suggests complex compensatory ECM remodeling pathways mediated by LNSC apoE. These results highlight apoE's role in LNSCs for modulating hepatic immune and fibrotic responses during systemic autoimmunity and provide insights into LNSC contributions to organ-specific lupus pathology.

4265 | ASSOCIATION OF LIVER-SPECIFIC MIR-122 EXPRESSION WITH COVID-19 SEVERITY

Nicoleta Mihai[1] Catalin Tiliscan[1] Iulia Iancu[2] Oana-Alexandra Ganea[1] Aida-Isabela Adamescu[1] Violeta Molagic[1] Anca Saran[1] Isabela Staicu[1] Adrian Marinescu[1] Sorin Arama[1] Andreea Arsene[1] Simona Ruta[1] Victoria Arama[1], [1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]"Stefan S. Nicolau" Institute of Virology, Bucharest, Romania

Background: miR-122 is a liver-specific microRNA that has been extensively studied in hepatitis C virus infection, hepatocellular carcinoma, and drug-induced liver injury. Compared to aminotransferases, miR-122 is a more sensitive and specific biomarker of liver involvement. In this study, we aimed to determine the expression of miR-122 in COVID-19 patients. **Methods:** We conducted a prospective cohort study in which we included adult patients confirmed with COVID-19 who presented in a tertiary hospital in Bucharest, Romania, between March 2022 and May 2023. Patients who had previously received antiviral treatment for SARS-CoV-2, who had liver disease and/or chronic kidney disease were excluded. Total RNA was extracted from plasma samples using a commercial kit and following the manufacturer's protocol. Circulating miR-122 levels were measured using quantitative polymerase chain reaction. Expression levels of miR-122 were normalized to U6 small nuclear RNA, which served as an endogenous control. Results were expressed as $\log_{10}2^{-\Delta CT}$ (the logarithmic transformation of relative gene expression changes). Statistical analysis of patient data was performed using SPSS version 23. $P < 0.05$ was set for statistical significance. **Results:** We enrolled 35 patients with a median (range) age of 48 (26-72) years and a female-to-male ratio of 1.9. Median BMI was 24 (17-39) kg/m2. Most patients (27, 77.1%) had a mild form of COVID-19, while 8 (22.9%) had a moderate form. Only 5 (14.3%) patients had elevated aminotransferase levels. Approximately 63% of patients had associated comorbidities. The most common were cardiovascular diseases (11, 31.4%) and dyslipidemia (8, 22.9%). Seventeen (48.6%) patients had chronic treatment, of which 6 (17.1%) had statin. In bivariate analysis, the relative expression of miR-122 was directly correlated with COVID-19 severity (Spearman coefficient [SC] = 0.397, p = 0.018) and inversely correlated with BMI (SC = −0.402, p = 0.017). In addition, we found an association of miR-122 expression with statin treatment (p = 0.021). After multivariate analysis, the correlation of miR-122 with COVID-19 severity was maintained (p = 0.04). Aminotransferase levels were not correlated with either miR-122 expression or COVID-19 severity. **Conclusion:** In our study, the relative expression of miR-122 was significantly and positively correlated with COVID-19 severity.

4266 | NUCLEAR LOCALIZATION OF ACOT12 SUGGESTS TRANSCRIPTIONAL ROLES IN SUPPRESSING HEPATOCARCINOGENESIS

Logan Carr[1] Xu Xu[2] Susan Hagen[2] Eric Ortlund[3] David Cohen[1] Mariana Acuna[1], [1]Brigham and Women's Hospital, Harvard Medical School, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, [3]Emory University

Background: Acot12 is the primary enzyme that hydrolyzes acetyl-CoA into acetate in liver cytosol. Acot12 is strongly upregulated by PPARalpha under fasting conditions. We and others have demonstrated that Acot12 modulates histone H3 acetylation, leading to suppression of hepatocarcinogenesis and metastasis. Suggestive of Acot12 activity within the nucleus, amino acid sequence analysis has identified a putative nuclear localization signal (NLS) in Acot12. A conformational change in response to metabolic stimuli or protein interactions that exposes the NLS would raise the potential for stimulus-coupled nuclear translocation. The aim of this study was to garner direct evidence for nuclear localization of Acot12.

Methods: Alpha mouse liver (AML) 12 cells were transfected for 24 h with an Acot12-GFP expression vector, using GFP as control. Acot12 localization was assessed by live cell microscopy. Cells were pretreated with leptomycin B for 2 h to inhibit nuclear efflux and then exposed to a broad spectrum of metabolic stimuli including serum depletion, forskolin, phorbol 12-myristate 12-acetate, acetate, glucagon, and fatty acids. Acot12-interacting proteins were identified using a GFP-trap approach to immunoprecipitate interacting proteins together with Acot12-GFP, using GFP as a control. Proteins were identified by mass spectrometry, and AlphaFold 3 (DeepMind) was used to predict direct Acot12-protein interactions.

Results: Of the metabolic stimuli tested, only oleic acid promoted the nuclear translocation of Acot12. We identified 43 proteins that were immunoprecipitated by Acot12-GFP but not GFP. Of these proteins, 47% were nuclear, 26% were cytosolic, 16% were mitochondrial

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and 12% were from other organelles or membranes. AlphaFold 3 predicted that 46% interacted directly with Acot12, 50% of which were nuclear proteins. **Conclusion:** Our findings reveal evidence for fatty acid-induced nuclear translocation of Acot12, where it interacts with a number of nuclear proteins. Because fatty acid uptake into liver is maximal under fasting conditions, we speculate that Acot12 participates in the transcriptional response to nutrient deprivation including suppression of cellular proliferation, thereby rationalizing its function in inhibiting hepatocarcinogenic and metastatic activities.

4267 | HEPATIC STELLATE CELL-DERIVED HB-EGF SUPPRESSED HEPATOCYTE APOPTOSIS IN ACUTE LIVER INJURY

Yoichi Sasaki[1] Yoshinobu Saito[1] Jihyun Sung[1] Seiya Kato[1] Kenji Fukumoto[1] Yuta Myojin[1] Kazuhiro Murai[1] Yuki Makino[1] Hayato Hikita[1], [1]The University of Osaka Graduate School of Medicine

Background: Hepatocyte apoptosis is a key pathological feature in liver injury. In chronic liver injury, it drives liver fibrosis, primarily through hepatic stellate cells (HSCs), which exhibit both progressive and protective roles. However, the function of HSCs in acute liver injury, especially regarding hepatocyte apoptosis, remains unclear. This study aimed to investigate the impact of HSCs on hepatocyte apoptosis during acute liver injury. **Methods:** We utilized Lrat-Cre iDTR mice expressing diphtheria toxin receptor (DTR) specifically in HSCs, followed by diphtheria toxin (DT) administration to deplete HSCs. Liver injury was induced using lipopolysaccharide (LPS) and ABT-737, a Bcl-xL inhibitor. Single-cell RNA sequencing (scRNA-seq) of wild-type mice treated with ABT-737 was conducted to analyze HSC-hepatocyte interactions to identify soluble factors regulating hepatocyte apoptosis. HepG2 cells were cultured with LX-2-conditioned media or with HepG2-conditioned media containing ABT-737 to examine the effect of HSC-derived factors. Cell viability, supernatant Caspase-3/7 activity, and Annexin V-positive area were evaluated. **Results:** DT-treated Lrat-Cre iDTR mice exhibited reduced expression of Lrat and Gfap gene expression from day 4 to one week post-DT administration, along with a decrease in Desmin-positive cells in liver tissues. The number of F4/80-positive cells in liver tissues did not significantly differ between Lrat-Cre iDTR and control mice following combined DT and LPS either ABT-737 treatment. However, the number of TUNEL-positive hepatocytes, serum ALT levels, and Caspase-3/7 activity were significantly elevated in the Lrat-Cre iDTR group, indicating increased hepatocyte apoptosis. scRNA-seq–based interaction analysis between HSCs and hepatocytes identified five candidate secreted proteins upregulated in HSCs of ABT-737–treated mice, including HB-EGF.

Under ABT737 treatment, both LX-2–conditioned media and recombinant HB-EGF reduced HepG2 cell death markers—including Annexin V-positive area and caspase-3/7 activity—and improved cell viability compared to HepG2–conditioned media; these effects were abrogated by co-treatment with a HB-EGF neutralizing agent (CRM197). **Conclusion:** Depletion of HSCs exacerbates hepatocyte apoptosis during acute liver injury. Our findings suggest that HSC-derived HB-EGF plays a protective role by mitigating hepatocyte apoptosis and liver damage.

4268 | A NOVEL MICROFLUIDIC CELL SORTING APPROACH FOR ISOLATING VIABLE PRIMARY HEPATOCYTES

Crystal Montoya[1] Hannah Johannsen[1] Nadine Chelius[1] Carsten Poggel[1] Timo Adams[1], [1]Miltenyi Biotec

Background: Hepatocytes are crucial for understanding liver function and regeneration. However, their large size, complex morphology, and high metabolic activity make them particularly vulnerable to sorter-induced cellular stress (SICS). Conventional cell sorters often cause cellular damage and reduced-cell viability; yet that is not an issue with the MACSQuant® Tyto® Cell Sorter (Miltenyi Biotec). Utilizing microchip-based, low-pressure, and fully closed sterile technology; it minimizes cellular stress and prevents contamination. The poster describes a workflow for sorting primary mouse hepatocytes using gentleMACS™ Perfusion Technology and the MACSQuant Tyto Cartridge LC, optimized for sorting larger cells. **Methods:** Mouse hepatocytes were dissociated from the liver utilizing the Liver Perfusion Kit and GentleMACS Octo Dissociator with Heaters (Miltenyi Biotec). The primary hepatocytes were stained with APC-conjugated REAfinity® CD95

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(FAS) Antibody and isolated utilizing the MACSQuant Tyto cell Sorter and MACSQuant Tyto Cartridge LC. Hepatocytes were then cultured to confirm cell survivability. **Results:** The MACSQuant Tyto sorter enriched the target antigen-specific CD95+ hepatocyte cells from 63.9% to 96.2% with cell viability was statistically comparable to non-sorted cells (above 77% viability). The survivability of hepatocytes was confirmed after 24 hours of cell culture, with cell attachment, hexagonal cell shape, and nuclei duplication visible with brightfield imaging. **Conclusion:** The isolated hepatocytes showed robust post-sorting plating capacity and exhibited typical morphological features, including hexagonal shape and nuclei duplication. These findings demonstrate that the sorting process effectively preserved both the viability and phenotypic properties of the primary hepatocytes in culture.

4269 | TARGETING FTO DEMETHYLASE ACTIVITY IMPROVES METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE IN PRECLINICAL MODELS

Sunita Giri[1] Vijay Kumar[1], [1]Institute of liver and biliary sciences

Background: NAFLD is a chronic liver disease characterized by the buildup of excess fat in the liver. Elevated expression of FTO has been implicated in steatosis and NAFLD development. There is no standard treatment for NAFLD. To address this, we investigated the therapeutic potential of entacapone - a pharmacological inhibitor of FTO - in preclinical models. **Methods:** A NAFLD mouse model was developed by feeding animals a high-fat and high-carbohydrate diet. Mice were given a daily intraperitoneal dose of 10 or 30 mg of entacapone up to 12 weeks. Changes in obesity, lipid accumulation, and liver fibrosis were monitored. Biomarkers of hepatic and metabolic functions were measured by a bioanalyzer. The mRNA levels of FTO and metabolic genes were quantified by RT-qPCR whereas N6-methyladenosine levels were measured by ELISA. The hepatic expression of FTO protein in preclinical and clinical (NAFLD, NASH, and cirrhosis) samples was visualized by immunohistochemical staining. FTO gene regulation was investigated in cell culture. **Results:** Treatment with entacapone led to a significant reduction in obesity, hepatic fat build-up, normalization of NAS score, and metabolic functions in mice. m6A levels in gene transcripts were high, coinciding with reduced expression of FTO, lipogenic, and inflammatory genes. FTO-1, FTO-5 and FTO-12 were expressed at high levels in NAFLD patients, whereas FTO-5 and FTO-12 were at basal levels in NASH and cirrhosis. Entacapone could downregulate FTO in immortalized hepatocytes. **Conclusion:** Pharmacological inhibition of FTO by entacapone normalized hepatic functions and ameliorated NAFLD in the mouse model, highlighting its therapeutic potential.

4270 | HEPATIC MITOCHONDRIAL METABOLISM ASSESSED IN VIVO BY HYPERPOLARIZED [1-^{13}C]- AND [2-^{13}C]PYRUVATE WITH EX VIVO ISOTOPOMER ANALYSIS

Baljeet Seniwal[1] Andrew Cho[1] Zohreh Erfani[1] Blanka Kucejova[1] Sasanka Wathukara Dewage[1] Sung-Han Lin[1] Shawn Burgess[1] Jae Mo Park[1], [1]UT Southwestern Medical Center

Background: ^{13}C NMR with hyperpolarized (HP) [^{13}C] pyruvate enabled *in vivo* assessment of enzyme activities, including pyruvate dehydrogenase (PDH), pyruvate carboxylase (PC), and phosphoenolpyruvate carboxykinase (PEPCK), which regulate pyruvate metabolism towards oxidative phosphorylation and gluconeogenesis. Due to the complexity of these metabolic processes and limited ^{13}C-labeling in HP products, interpretation of *in vivo* HP results has been challenging. This study compares the capabilities of HP [1-^{13}C]pyruvate and [2-^{13}C]pyruvate in describing hepatic mitochondrial metabolism and provides an

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

analytical framework for interpreting the HP data. **Methods:** Five fed and five fasted male rats were studied *in vivo* using a Bruker 3T MRI and a $^{13}C/^{1}H$ surface RF coil. Each rat received two injections of HP pyruvate ([1-^{13}C]pyruvate and [2-^{13}C]pyruvate), and time-resolved ^{13}C spectra were acquired from the liver following each injection. In parallel, five fed and five fasted rats were injected a bolus of thermal [U-$^{13}C_3$] pyruvate, and their livers were harvested 90 sec later for isotopomer analysis using NMR and GC-MS. **Results:** [^{13}C]Bicarbonate, an indicator of decarboxylation of HP [1-^{13}C]pyruvate via either PDH or PC-PEPCK, was detected under both fed and fasted conditions, although it was higher in fed condition. PC-specific [^{13}C]aspartate and [^{13}C]malate were often difficult to resolve from the crowded ^{13}C resonances at 175 – 178 ppm. In contrast, HP [2-^{13}C]pyruvate distinguished gluconeogenic (PC-PEPCK) and oxidative (PDH-TCA) pathways via [2-^{13}C] PEP and [5-^{13}C]glutamate, respectively. [1-^{13}C]Acetyl-L-carnitine (ALCAR) appeared only in fed livers, serving as a PDH-specific biomarker. GC-MS and ^{13}C NMR analyses of liver extracts confirmed that fasting reduced fractional PDH flux in the liver. MS analysis also calculated labeling fractions of ~50% for pyruvate, lactate, and alanine, 25-40% for TCA intermediates, and 20-30% of glutamate and PEP. Following fasting, ^{13}C-labeling increased across all measured metabolites. **Conclusion:** HP [2-^{13}C]pyruvate could monitor mitochondrial metabolic shifts in the liver by resolving HP products specific to gluconeogenic and oxidative pathways, whereas HP [1-^{13}C]pyruvate could not distinguish these individual routes. The *ex vivo* isotopomer analysis confirmed the sensitivity of these approaches to nutritional state, demonstrating reduced PDH flux and enhanced redistribution of ^{13}C through the TCA cycle and gluconeogenesis during fasting.

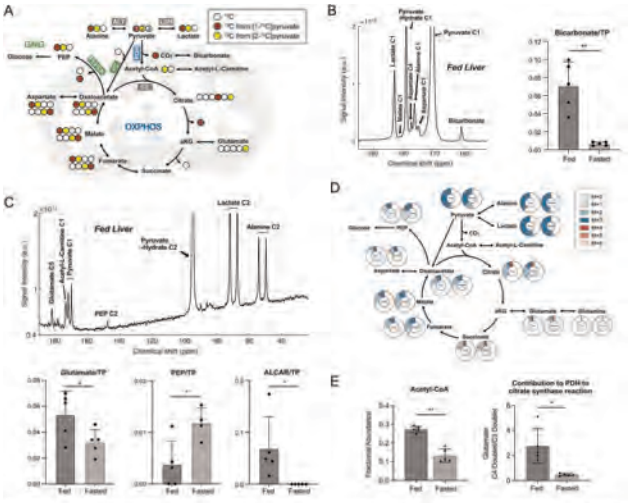

Figure 1. (A) Metabolic pathways of labeled carbon (^{13}C) in [1-^{13}C]pyruvate (red circle) and [2-^{13}C]pyruvate (yellow circle). Representative ^{13}C spectra acquired using **(B)** HP [1-^{13}C]pyruvate and **(C)** HP [2-^{13}C]pyruvate. Mitochondrial HP products were normalized to total HP product [TP]. **(D)** Fractional ^{13}C-labeling in metabolites measured by GC-MS and **(E)** fractional PDH flux measured by ^{13}C NMR *ex vivo* using non-HP [U-$^{13}C_3$]pyruvate. *: P < 0.05, **: P < 0.01

4271 | MRP1-MEDIATED AUTOPHAGY STAGNATION DRIVES HCC DEVELOPMENT AFTER SVR FOR HEPATITIS C

Katsuya Nagaoka[1] Masaya Onishi[2] Atsushi Tanaka[3] Satoshi Narahara[1] Sotaro Kurano[1] Kentaro Tanaka[1] Hiroki Inada[1] Etsuko Iio[1] Yoko Yoshimaru[1] Takehisa Watanabe[1] Hiroko Setoyama[1] Yutaka Suzuki[2] Yasuhito Tanaka[1], [1]Graduate School of Life Sciences, Kumamoto University, [2]Graduate School of Frontier Sciences, The University of Tokyo, [3]Department of Medicine, Yamagata University

Background: Despite the increase in sustained virological response (SVR) after direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) infection, the risk of hepatocellular carcinoma (HCC) remains high. This study aimed to elucidate the mechanisms of HCC development after SVR by analyzing gene expression changes in non-cancerous liver tissue from patients who developed HCC post-SVR. **Methods:** RNA sequencing (RNA-seq) was performed on non-cancerous liver tissues from 13 patients who developed HCC after SVR (SVR-HCC group) and 9 patients who did not (SVR-non HCC group). The obtained data were integrated with existing RNA-seq datasets from 65 patients with chronic HCV-HCC, 65 patients with non-B/non-C HCC, and 12 normal liver tissues. Additionally, in vitro experiments using HCV infection models and a Tet-On expression system were conducted to investigate functional mechanisms. **Results:** Gene expression analysis of adjacent non-cancerous tissues revealed prominent mitochondrial dysfunction and significantly increased expression of MRP1, a protein involved in mitochondrial fission, in the SVR-HCC group. In vitro validation showed that MRP1 gene expression tended to gradually increase after HCV clearance in HCV-infected cells. Overexpression of MRP1 in cells induced mitochondrial fragmentation, increased reactive oxygen species (ROS), and caused autophagy pathway arrest, which collectively promoted carcinogenesis. Furthermore, RNA-seq analysis comparing cancerous and adjacent non-cancerous tissues revealed the activation of mTORC1 signaling, an autophagy inhibitory factor, in the SVR-HCC group. These findings suggest that MRP1-mediated mitochondrial dysfunction and mTORC1-mediated autophagy inhibition contribute to

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

HCC development through enhanced oxidative stress and impaired cellular quality control. **Conclusion:** Elevated MRP1 expression was specifically observed in SVR-HCC patients, suggesting its potential as a biomarker for increased HCC risk. MRP1-mediated mitochondrial dysfunction is implicated in HCC development after SVR, positioning MRP1 as a potential novel therapeutic target and surveillance marker.

4272 | LOSS OF BRCA2 SENSITIZES HEPATOCELLULAR CARCINOMA TO PARP INHIBITION

Salah Adlat[1] Chunmiao Cai[2] Dingzi Yin[2] Markcus Lee[2] Kirk Wangensteen[2], [1]Mayo Clinic, Rochester, [2]Mayo Clinic

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality and still lacks effective targeted therapies. In many cancers, loss of DNA damage repair (DDR) pathways, particularly homologous recombination (HR), renders tumors sensitive to poly(ADP-ribose) polymerase inhibitors (PARPi). Although loss of HR genes is a recognized risk factor for the development of breast and ovarian cancers, loss of one copy of *BRCA2*, *FANCA*, *FANCM*, *FANCD2*, *CHEK2*, or *BRIP1* is reported only rarely in HCC, and its therapeutic relevance remains unknown. We therefore tested the hypothesis that HR genes loss promotes HCC progression and creates a therapeutic vulnerability to PARPi. **Methods:** To identify HR-DDR genes that drive HCC, we performed an *in vivo* CRISPR knockout (KO) screen targeting six HR-DDR genes (*Fanca, Fancm, Fancd2, Chek2, Brip1, Brca2*) including *Trp53* as a positive control. A pool of plasmids containing a gRNA targeting each gene or non-targeting control gRNAs, plus *Myc/Nras^{G12V}* oncogenes, was delivered to the liver hepatocytes of Cas9-expressing mice via hydrodynamic tail-vein injection (HTVI). Tumor burden was assessed 40–41 days post-injection, and the gRNA sequences present in tumors were quantified by sequencing. In validation experiments, *Brca2* was targeted in mice *in vivo* using HTVI, and mice received PARPi olaparib or vehicle control.

For *in vitro* studies, BRCA2 was disrupted in Hep3B, HepG2, and HuH7 cells using CRISPR or siRNA. Cell viability, colony formation, migration, apoptosis (Annexin V), DNA damage (γ-H2AX), and cell cycle were assessed ± olaparib. **Results:** In a pooled CRISPR screen of HR genes driving HCC *in vivo*, there was significant enrichment of gRNAs targeting *Brca2* relative to the other HR genes and non-targeting controls. Additional assays *in vivo* indicated that targeting *Brca2* in HCCs led to sensitivity to PARPi therapy, which otherwise has no effect on HCC progression. Targeting *BRCA2 in vitro* in human HCC cell lines impaired viability, and this effect was further enhanced by adding olaparib. Mechanistically, *BRCA2* depletion induced apoptosis, elevated γ-H2AX foci, and caused G2/M arrest. Critically, the addition of olaparib to *BRCA2*-depleted cells significantly potentiated these effects, leading to a further increase in apoptosis compared to *BRCA2* depletion alone. This highlights the synthetic-lethal interaction between *BRCA2* deficiency and PARP inhibition in HCC. **Conclusion:** *BRCA2* loss is a key HCC vulnerability. *In vivo*, *Brca2* loss does not impair tumor growth, whereas cells grown *in vitro* are sensitive to BRCA2 loss. Functional studies showed a critical vulnerability to PARPi therapy in the absence of *BRCA2*. These findings provide support for PARPi therapy in the rare HCCs with *BRCA2* loss.

◆ 4273 | ECTOPIC ACTIVATION OF THE WNT/β-CATENIN/CYCLIN-D1 AXIS DURING EARLY LIVER REGENERATION

Tyler Yasaka[1] Brandon Lehrich[1] Shuchang Liu[1] Satdarshan (Paul) Monga[1], [1]University of Pittsburgh

Background: The hepatic lobule displays functional polarity along the portal-central axis, a phenomenon known as metabolic zonation (MZ), in which hepatocytes engage in distinct metabolic roles from the portal vein (zone 1; Z1) to the central vein (zone 3; Z3), with zone 2 (Z2) residing in the middle. During homeostasis, Wnt/β-catenin signaling maintains Z3 identity by promoting Z3 gene expression. Further, we have shown that ablation of hepatocyte β-catenin abrogates Z2 Cyclin-D1 expression both at baseline and following partial hepatectomy (PH), where loss of β-catenin results in delayed liver regeneration (LR). In wild-type livers, Cyclin-D1 expands across the entire lobule from 24 hours (24h)-96h post-PH, enabling the rapid proliferative response. Despite its established role in homeostasis and proliferation, the function of Wnt/β-catenin signaling during the acute regenerative response, particularly in relation to the proliferative "wave" across the lobule, remains poorly understood. **Methods:** Immunohistochemistry (IHC) was used to observe protein expression of key zonation markers at 1-, 3-, 6-, and 10-hours post-PH in both wild type and AAV8-Cre/CTNNB1-Floxed (CTNNB1-KO) murine models. Immunofluorescence (IF) staining for β-galactosidase in Axin2-LacZ reporter mice was used to assess β-catenin activity during early LR. Single cell spatial transcriptomics (SCST) was leveraged to investigate the spatiotemporal changes in expression of 100 zonated genes at these time points. **Results:** IHC revealed Z2 Cyclin-D1 expansion as early as 10h post-PH, which was abrogated in CTNNB1-KO mice. Further, IF of β-galactosidase in Axin2-LacZ reporter mice demonstrated ectopic expression extending towards the portal vein at 10h, indicating panzonal β-catenin activation at this time point. Unbiased clustering of SCST data captured spatiotemporal trends, delineating distinct sets of zonated cell populations at baseline, from 1-6h, and at 10h post-PH. We observed panzonal expansion of β-catenin targets such as *Axin2* and *Glul* along with ectopic expression of the Z3 genes *Wnt2* and *Wnt9b* in Z2 and Z1 endothelial cells. **Conclusion:** Our study identifies dramatic transcriptional changes during early LR from 1-10h post-PH. These include panzonal upregulation of endothelial cell Wnt2 and Wnt9b and hepatocyte β-catenin targets. We further demonstrate ectopic β-catenin activation during early LR occurring in tandem with β-catenin-dependent expansion of Cyclin-D1 in Z2, elucidating a Wnt/β-catenin/Cyclin-D1 axis which is transiently upregulated across the lobule to enable cell cycle entry for rapid proliferation from 40-96h post-PH, thereby serving a central role in LR.

◆ 4274 | CANCER-ASSOCIATED FIBROBLAST (CAF) ATLAS IN HCC AND ASSOCIATION WITH IMMUNOTHERAPY RESPONSE

Guillem Cano Segarra[1] Ana Hernández de Sande[1] Anna Vila[1] Albert Gris-Oliver[1] Marta Piqué-Gili[1] David Camell-Raventos[2] Ezequiel Mauro[1] Agavni Mesropian[1] Ugne Balaseviciute[1] Marcus Zeitlhoefler[3] Sarah Cappuyns[4] Yulei Wang[5] Jeroen Dekervel[6] Daniela Sia[3] Roser Pinyol[1] Josep M Llovet[1], [1]Liver Cancer Translational Research Laboratory, IDIBAPS, Hospital Clínic, Universitat de Barcelona, [2]Liver Cancer Translational Research Laboratory, Hospital Clínic, Universitat de Barcelona, [3]Mount Sinai Liver Cancer Program, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, [4]Digestive Oncology, Department of Gastroenterology, University Hospitals Leuven, [5]Translational Medicine Oncology Genentech, Inc, [6]Laboratory of Clinical Digestive Oncology, Department of Oncology, KU Leuven

Background: The combination of atezolizumab+bevacizumab (atezo+bev) is a first-line therapy for advanced-stage hepatocellular carcinoma (HCC). Cancer-associated fibroblasts (CAF) support survival of cancer cells by promoting immunosuppression. This study aims to characterize CAF subtypes in HCC and evaluate their impact on immunotherapy responses. **Methods:** CAF subtypes were identified by integrating a single-cell atlas from 7 HCC cohorts (192 patients; 446,075 cells). Stromal fractions were defined using Louvain clustering and established signatures. CAF

proportions in early and late HCC (n = 171 & 247 patients) were inferred using RNAseq datasets by applying 4 single cell-derived CAF signatures with BayesPrism. Differential Expression and LASSO analyses applied to atezo+bev scRNAseq HCC data (20 patients; 40,598 cells) allowed defining a non-response CAF gene signature (NR-CAF) which was tested and validated in bulk RNAseq (386 atezo+bev cases; 33% responders, 67% non-responders). **Results:** CAFs represented ~10% of the cells identified by the single-cell HCC atlas (5% and 15% in early and advanced HCCs, respectively). We identified 6 CAF clusters, each with a unique transcriptional profile. Four CAF subtypes presented with high specificity to be used in deconvoluting RNAseq data. The most abundant CAF cluster (myofibroblastic CAFs; iMyoCAFs) was present in early (38%) and advanced (81%) HCC, displayed both inflammatory and extracellular matrix remodeling features and was enriched in the molecular proliferative class (S1, 42%-51% vs others subtypes; $p < 0.001$). Further, inflamed HCCs were significantly enriched with endothelial-like CAFs (eCAFs; 80%-83%) and iMyoCAFs (75%-94%), being the latter specifically enriched in immune exhausted tumors (41%-76% vs others; $p < 0.001$). None of the CAF clusters was associated with atezo+bev response. Conversely, the NR-CAF signature accurately segregated non-responders (242/258, 94%) in the IMbrave150 cohort (AUCs 0.77; CI 0.71-0.83) and in-house cohort (AUC 0.73; CI 0.63-0.83); and was enriched in non-inflammed tumors. **Conclusion:** CAFs represent 10% of the HCC tumor microenvironment cells. iMyoCAF - the most abundant subtype, particularly in advanced HCC- is characterized by proliferative features and an immune-exhausted phenotype. The NR-CAF signature demonstrated high accuracy in identifying non-responders to immunotherapy, thus providing insights on its potential clinical utility.

◆ 4275 | TRANSCRIPTOMIC AND CELLULAR TRAITS OF LIVER FIBROSIS REGRESSION IN ON-TREATMENT CHRONIC HEPATITIS B PATIENTS

Wei Chen[1] Shuyan Chen[2] Yameng Sun[2] Wen Zhang[2] Hong Li[2] Wenyue Wu[2] Ruoyu Gao[2] xiaoning wu[2] Xuzhen Yan[2] Aiting Yang[2] Natalia Nieto[3] Hong You[4], [1]Capital Medical University, China, [2]Beijing Friendship Hospital, Capital Medical University, [3]University of Illinois at Chicago, [4]Capital Medical University

Background: Antiviral therapy (AVT) fails to consistently induce liver fibrosis remission in chronic hepatitis B (CHB) patients. This study aimed to elucidate transcriptomic and cellular signatures underlying fibrosis regression in CHB patients receiving AVT. **Methods:** We longitudinally analyzed 68 liver biopsy (LBx) specimens from 42 CHB patients with liver fibrosis undergoing AVT. Bulk or single-cell RNA sequencing analysis, deconvolution analysis, and multiplex immunofluorescence were performed. **Results:** Transcriptomic profiling of serial LBx samples collected at baseline, 78 weeks, and 260 weeks post-AVT revealed that fibrosis regressors exhibited rapid transcriptomic and functional reprogramming throughout treatment. Baseline characterization identified a triad of features in regressors: (1) an activated immune microenvironment, (2) suppressed metabolic signaling pathways, and (3) upregulated cell cycle (CC)-related gene expression. Stratification of CHB patients into CClow and CChigh subgroups based on baseline CC gene expression demonstrated that CChigh status predicted fibrosis regression during AVT across two independent cohorts. Integrated single-cell RNA sequencing, deconvolution analysis, and multiplex immunofluorescence identified a novel CD8+ T-cell subset—proliferative T (Tpro) cells—as the primary cellular driver of CC-associated transcriptional changes. Tpro cells were functionally characterized by (1) heightened proliferative potential, (2) tissue-resident memory features, and (3) enhanced cytotoxic activity. Patients with baseline Tpro cell enrichment exhibited superior control of low-level viremia and increased odds of fibrosis regression during long-term AVT. **Conclusion:** This study defines three

critical attributes of CHB fibrosis regressors: (1) rapid initiation of transcriptomic and functional reprogramming post-AVT, (2) baseline CChigh transcriptional signatures, and (3) pre-treatment enrichment of cytotoxic Tpro cells. These findings provide novel insights for risk stratification, therapeutic monitoring, and personalized management of on-treatment CHB patients with liver fibrosis.

◆ 4276 | THE TEXAS HISPANIC HCC COLLABORATIVE: FIRST RESULTS: OF AN EXOME-WIDE RARE, DELETERIOUS VARIANT ANALYSIS OF HEPATOCELLULAR CARCINOMA IN HISPANIC AMERICAN INDIVIDUALS

Aaron Thrift[1] Xiangnan Li[1] Spiridon Tsavachidis[1] Sumeet Asrani[2] Amit Singal[3] Hashem El-Serag[1] Yanhong Liu[1], [1]Baylor College of Medicine, [2]Baylor University Medical Center, [3]University of Texas Southwestern Medical Center

Background: Hispanic Americans in Texas have the highest incidence rate of hepatocellular carcinoma (HCC) in the United States. Differential genetic predisposition could influence racial/ethnic differences in HCC risk. In particular, rare and low frequency variants may play an essential role in the etiology of HCC. Thus, we conducted the first exome-wide rare, deleterious (or pathogenic, damaging, or functional important) variant analysis of HCC in Hispanic American individuals to identify potential novel predisposition genes and pathways for HCC in this population. **Methods:** We performed whole-exome sequencing on constitutional DNA extracted from blood of 455 Hispanic HCC cases and 264 Hispanic controls. Variants were prioritized and filtered based on minor allele frequencies $<5\%$ in gnomAD global population, enrichment of rare and potential deleterious variants in cases (risk alleles) or controls (protective alleles), and a high pathogenicity prediction (CADD score ≥ 15). Allelic association analyses of single-variant and gene-based burden tests of multiple variants were performed. **Results:** We identified 38 rare variants with deleterious effects. Among the top 10 candidates were three in *PABPC3* (Polyadenylate-binding protein 3): p.G574R (OR = 6.9), p.M579I (OR = 6.9), and p.L588V (OR = 4.3); and two in *PDCD7* (Programmed cell death protein 7): p.R222W (OR = 20) and p.P685L (OR = 9.8). The most significant variant was p.V678M (OR = 20) in *CILP* (Cartilage Intermediate Layer Protein 1). Other notable findings included a pathogenic *ClinVar*-reported p.R119W (OR = 13) in *RTN4R* (Reticulon-4 receptor), p.R429C (OR = 8.5) in *CGN* (Cingulin), and a stop-gain truncating variant p.E6X (OR = 5.3) in *HMGA2* (High Mobility Group A2). There 18 potentially novel variants that require follow up. **Conclusion:** Our results extend the catalogue of regions associated with HCC and highlight the importance of germline rare coding variants in HCC susceptibility. These analyses are ongoing and will contribute to knowledge about the genetic architecture of HCC.

◆ 4277 | A LIVER-TARGETING LNCRNA MOTIF FOR DURABLE GLUCOSE AND LIPID LOWERING: GULF AS A FIRST-IN-CLASS THERAPEUTIC AGENT

Haiming Cao[1], [1]National Institutes of Health

Background: RNA-based therapeutics have gained significant momentum with the success of mRNA vaccines and siRNA/antisense oligonucleotide (ASO) drugs. However, no FDA-approved therapies currently target long non-coding RNAs (lncRNAs)—the most abundant and largely untapped class of human transcripts. We identified a liver-enriched human lncRNA, GULL (GlUcose and Lipid Lowering), with potent metabolic regulatory activity and therapeutic promise. **Methods:** Expression quantitative trait locus (eQTL) analyses were performed to link hepatic GULL expression to improved metabolic traits in humans. Functional characterization involved adenoviral and AAV-mediated overexpression of GULL in mouse liver. RNA pulldown assays identified CRTC2 as a key GULL-binding partner. To identify a druggable element, we mapped the minimal CRTC2-binding region on GULL—termed GULF—and synthesized GalNAc-conjugated GULF

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

oligonucleotides for targeted liver delivery. **Results:** GULL overexpression in mice rapidly reduced circulating and hepatic triglyceride levels and significantly enhanced glucose tolerance within one week. Prolonged expression further improved insulin sensitivity (HOMA-IR), reduced HbA1c, and decreased body weight. Mechanistically, GULL interacts with CRTC2, thereby modulating gluconeogenesis through CREB and lipogenesis via SREBP1. A single dose of GalNAc-GULF led to marked improvements in glucose and lipid metabolism in obese mice, with effects sustained for over one month—surpassing the duration of standard treatments like metformin. The GULF motif (~30 nucleotides) is comparable in size to clinically approved siRNA and ASO drugs, enabling compatibility with established RNA delivery platforms. **Conclusion:** GULF represents the first-in-class lncRNA-derived RNA therapeutic motif for metabolic disease, demonstrating robust, long-lasting metabolic benefits through liver-targeted delivery. These findings establish a new therapeutic paradigm leveraging lncRNA biology to expand the scope of RNA-based drug development.

4278 | INFERRING SPATIAL SUBTYPE SIGNATURES OF HEPATOCELLULAR CARCINOMA FROM HISTOLOGIC IMAGES: A COMPUTATIONAL PATHOLOGY APPROACH

Tyler Yasaka[1] Po-Yuan Chen[1] Rebekah Dadey[1] Riyue Bao[1] Satdarshan (Paul) Monga[1] Yu-Chiao Chiu[1],
[1]University of Pittsburgh

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality. The Hoshida system stratifies HCC into 3 subtypes (S1, S2, and S3) with distinct pathomolecular features. With the advancement of clinical trials for targeted therapies, tissue biopsies are being increasingly utilized. Thus, there is an emerging opportunity to pioneer the use of computational pathology approaches to advance precision medicine for HCC. **Methods:** We accessed publicly available spatial transcriptomics data, paired with corresponding hematoxylin and eosin (H&E) images, from 12 HCC slides. Moran's I was used to characterize the spatial correlations between S1, S2, and S3 subtypes, and spatial deconvolution was performed to estimate the cell type composition of sequenced spots and assess their relationship with subtype signatures. The H&E images were partitioned into tiles corresponding to the spatial transcriptomic spots. Building on a deep learning foundation model, neural networks were trained to predict each signature (S1, S2, and S3) from the H&E tiles and were evaluated using leave-one-out cross-validation. External validation was performed on a second spatial transcriptomic dataset of 2 HCC samples. Trained models were then applied to H&E whole-slide images from HCC patients in The Cancer Genome Atlas (TCGA; $n = 350$) and from an in-house cohort ($n = 11$). Tile-level predictions were averaged to obtain a patient-level histologic score for each signature (HIST_S1, HIST_S2, and HIST_S3). We assessed the correlation between the histologic scores available for each patient H&E and (1) their *TP53* and *CTNNB1* mutation status, (2) immune phenotype, and (3) overall survival (OS). **Results:** Spatial analysis revealed strong spatial autocorrelation (0.79-0.92; $p < 0.001$) of S1, S2, and S3 signatures. The S1 signature was associated with non-parenchymal cells, while S2 and S3 signatures were associated with hepatocytes. Our models achieved AUROCs of 0.65, 0.68, and 0.678 for S1, S2, and S3, respectively. Histologic sores positively correlated with their respective bulk RNA signatures ($p = 0.03$; $p < 0.001$; $p < 0.001$). While HIST_S1 and HIST_S2 were associated with *TP53* mutation ($p = 0.019$; $p < 0.001$), HIST_S3 was associated with *CTNNB1* mutation ($p < 0.001$). HIST_S1 and HIST_S2 were elevated in T cell-inflamed tumors ($p = 0.102$; $p = 0.024$), while HIST_S3 was increased in immune non-T cell-inflamed tumors ($p = 0.074$). Finally, all models were prognostic, with HIST_S1 and HIST_S2 portending lower OS ($p = 0.005$; $p < 0.001$) and HIST_S3 predicting improved OS ($p < 0.001$). **Conclusion:** Our results demonstrate the use of deep learning models to extract histologic biomarkers from H&E images. These signatures recapitulate established paradigms in HCC, inform immune phenotype, and provide improved prognostic value compared to bulk RNA-based signatures alone. This highlights a promising role for computational pathology in HCC precision medicine.

4279 | AI ASSISTED IMAGING ANALYSIS IMPROVING RISK PROGNOSTICATION OF HEPATOCELLULAR CARCINOMA IN VETERANS WITH CHRONIC LIVER DISEASE

Peng Zhang[1] Patrick Belancourt[2] Sven Holcombe[1] Sameer Saini[1] Grace Su[3], [1]University of Michigan, [2]VA Ann Arbor Healthcare System, [3]University of Michigan Medical Center

Background: Hepatocellular carcinoma (HCC) is a leading cause of death in patients with chronic liver disease (CLD) due to late diagnosis. Surveillance guidelines from the AASLD recommend identification of high-risk patients, particularly those with cirrhosis. But cirrhosis is underdiagnosed, and surveillance rates remain unacceptably low. Of the alternative strategies to identify high risk individuals, FIB 4 is one of the most predictive but may fail to capture nuanced disease characteristics. This study evaluates an automated computed tomography (CT) imaging analysis pipeline to predict 5-year HCC risk in Veterans with CLD, integrating high-dimensional radiomic and clinical features to improve accuracy over FIB-4. **Methods:** We developed and utilized a fully automated deep learning pipeline to extract high-dimensional radiomic features from liver and spleen regions on CT images, transforming unstructured imaging data into quantitative metrics, including textural, morphological, and intensity-based characteristics. These features were combined with clinical variables to create a comprehensive dataset. Competing risk analysis was conducted using gradient boosting models to predict 5-year HCC risk, accounting for competing events including non-HCC mortality and hepatic decompensation. The predictive performance of the combined model was compared to the standard FIB-4 model using the area under the receiver operating characteristic curve (AUROC). Statistical comparison was conducted through DeLong's test with 5-fold cross-validation to ensure robust model evaluation and prevent overfitting. **Results:** We analyzed a regional cohort of 4,615 [GS1] Veterans with CLD who had an incidental clinical CT scan at the time of CLD diagnosis between 01/2008 to 12/2014. The combined model, integrating clinical and radiomic features, achieved an AUROC of 0.84 (95% CI: 0.80–0.88) for 5-year HCC risk prediction, significantly outperforming the FIB-4 model, which yielded an AUROC of 0.80 (95% CI: 0.75–0.84). The performance difference was statistically significant ($p = 0.038$), highlighting the added predictive value of radiomic features extracted from liver and spleen CT images. **Conclusion:** An automated CT imaging analysis pipeline, combining high-dimensional radiomic features with clinical data, modestly improves 5-year HCC risk prediction in patients with CLD. Future work should focus on validation in diverse cohorts, integration with other imaging modalities, and clinical utility.

4280 | TARGETED RESEQUENCING IDENTIFIES PREDISPOSING GENETIC CORRELATES IN LEAN AND OBESE MASH SUBTYPES: FINDING THE MISSING HERITABILITY IN INDIAN POPULATION

Pramod Gautam[1] Nisha Choudhary[2] Vipin Singh[2] Mamta Maurya[2] Nikita Yadav[2] Ankit Bhardwaj[2] Rajan Vijayaraghavan[2] Chhagan Bihari[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, [2]ILBS

Background: Lean metabolic dysfunction-associated steatohepatitis (MASH) is part of the MASLD spectrum. The metabolic dysfunction in lean-MASH among other things can be genetically precipitated. We undertook to investigate the genetic markers of this subtype of MASLD. **Methods:** We sequenced 68 genes related to MASH/MASLD pathology in 1827 patients (from Feb 23-April 25), who were stratified into Lean and Obese-MASH (BMI < 23 or > 25). We further categorized the cohort into two subgroups following their fibroscan CAP parameter (CAP $<$ 250 or $\geq$ 250) and looked for variants predisposing towards clinical phenotypes of fibrosis, Lean vs Obese-MASH, serum ALT, serum triglycerides and FIB-4 score. Following standard QC measures, the clinical impact of selected mutations was assessed by multiple professional and public databases for pathogenicity/functional effects. **Results:** From a total of 13275 genotyped non-synonymous SNPs, we filtered only those having literature supported pathogenicity assigned to them. Further we only focussed on top 10 most frequent missense variants. We found multiple genotypes to be associated with clinical phenotype and showed sex-wise variability adjusted by age (Figure 1). The significant findings includes:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

PNPLA3 and GCKR mutations irrespective of CAP parameter and sex associates with high serum ALT levels while SOD2.Ala16Val is significantly associated with high ALT levels only in patients with normal CAP values (Fig1a). Mutation in UCP2 increases the odds of Obese-MASH phenotype in Normal-CAP cohort (Fig1b). Although GCKR and PCSK9 mutations together known for hypertriglyceridemia, but we report effect size to be prominent in Normal-CAP group.

PNPLA3.Ile148Met consistently increases the LSM-based fibrosis and provides a valid lead to be a genetic marker for advanced fibrosis staging(Fig1d). Interestingly, PNPLA3.Ile148Met increases the FIB-4 score in both CAP categories with prominent variability by patient's sex(Fig1e). It is to be noted that the mutation in MBOAT7 well-studied in Caucasian populations is not found to be informative in Indian population. **Conclusion:** The present study for the first time not only aims to fill the gap in genetic propensities for lean vs obese-MASH in a large Indian cohort. The study also holds a promise in further probing into genetic correlates in sex-differences for Lean-MASH. Further it paves the way to develop a multi-SNP scoring to prognosticate liver diseases to better equip researchers and clinicians alike.

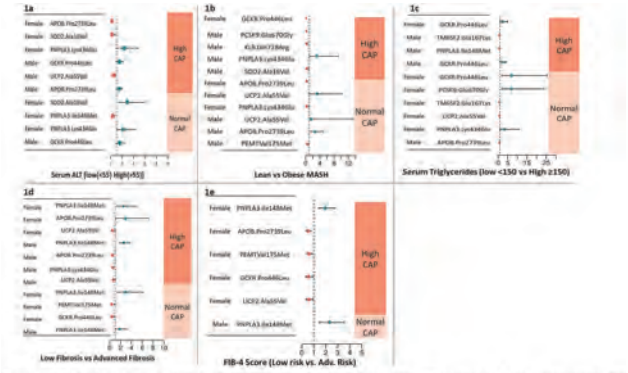

Figure1- SNP association and odds ratio for serum triglycerides, Lean- and Obese-MASH, serum ALT and fibrosis grades and FIB-4 Score. Models with lowest AIC (Akaike information) only are shown. All Odds ratio depicted are statistically significant.

4281 | CLONAL HEMATOPOIESIS OF INDETERMINATE POTENTIAL IS ASSOCIATED WITH AN INCREASED RISK OF HCC IN PATIENTS WITH MASLD

Gopanandan Parthasarathy[1] Renumathy Dhanasekaran[1] Christopher Maximilian Arends[1] Brian Sharber[2] Yash Pershad[3] Siddhartha Jaiswal[1] Alexander Bick[2], [1]Stanford University, [2]Vanderbilt University Medical Center, [3]Vanderbilt University

Background: Clonal Hematopoiesis of Indeterminate Potential (CHIP) refers to an age-associated accumulation of somatic mutations in myeloid neoplasm driver genes in hematopoietic stem cells without an overt hematological disorder. These mutations lead to dysregulated inflammatory responses in bone marrow derived macrophages and are associated with an increased risk of chronic inflammatory conditions including progression of chronic liver disease (CLD). Given that an inflammatory immune milieu in CLD is associated with hepatocellular carcinoma (HCC), we hypothesized that the presence of CHIP is associated with an increased risk of HCC among patients with metabolic dysfunction–associated steatotic liver disease (MASLD). **Methods:** We leveraged the National Institute of Health's All of Us Research program which is an ongoing US-based observational cohort study, with linked genetic and electronic health record data. CHIP has previously been ascertained using read-level whole genome sequencing data in a cohort of 98,560 participants that was released in June 2022, with an overall prevalence of CHIP of 4.8%. Individuals were enrolled between 2018 and 2021, with a median age at enrolment of 53 years (interquartile range, 37-65). Standard SNOMED codes for MASLD, MASH (metabolic dysfunction–associated steatohepatitis), MASH cirrhosis and HCC were used to identify patients with these diagnoses and those with alcohol related liver disease were excluded. According to All of Us Statistics Dissemination Policy, patient counts have been coarsened when between 1 and 20. **Results:** Among patients with any stage of MASLD (N = 6098), any HCC (N = 162), and MASLD-HCC (N = 92), CHIP was present in 361 (5.9%), < 20 (< 10%), and < 20 (< 15%) individuals respectively. The prevalence of CHIP in MASLD-HCC was greater among those without cirrhosis (15.4%), compared to with cirrhosis (7.5%). Among patients with MASLD, presence of CHIP was associated with an increased risk of developing HCC (OR = 1.96, 95% CI [1.01-3.82], $P < .05$). In a multiple logistic regression model, presence of CHIP in MASLD patients was independently associated with an increased risk of HCC, after adjusting for age, sex, and presence of cirrhosis (OR = 1.62, $P < .01$). There were no specific associations between risk of HCC and type or number of gene mutations, or the variant allele frequency. **Conclusion:** Presence of CHIP as an independent risk factor for HCC among patients with MASLD represents a potentially fibrosis-independent risk factor for HCC. This offers a clinically relevant, precision medicine-based approach to risk stratify patients with MASH and cirrhosis. Further analyses to understand the relationship between CHIP and HCC prognosis as well as treatment responses, including in the UK biobank are ongoing.

4282 | TWO DISTINCT GENETIC SUBTYPES DEFINE NON-CIRRHOTIC HCC CHARACTERIZED BY INACTIVATION OF TUMOR SUPPRESSORS (TP53, RB1, ARID1A) AND ACTIVATION OF TERT-DRIVEN ONCOGENIC PATHWAY

Khushboo Agrawal[1] Archana Rastogi[1] pramod Gautam[1] Vaishali Yadav[2] Rishab Shrama[1] Vanya Garg[1] Deepti Sharma[1] Nirupma Trehanipati[1] Shiv Kumar Sarin[1], [1]institute of liver and biliary sciences, [2]institute of liver nad biliary sciences

Background: There is an increase recognition of non-cirrhotic hepatocellular carcinoma (NC-HCC) in patients with MASLD and Hepatitis B. We employed targeted molecular profiling to examine the genetic landscape of NC-HCC aiming to uncover major oncodrivers and their impact on survival. **Methods:** 33 Formalin fixed NC-HCC cases were analysed using a 40 gene somatic mutation panel. DNA libraries were sequenced by NGS, aligned to hg38 (BWA), and variants called using FreeBayes. Filtering used depth and Phred score. COSMIC database was used to identify identified SBS signatures and pathogenic variants were classified via ClinVar. Digital PCR was used to validate TERT C228T hotspot. **Results:** NASH was the predominant (18/33; 57.5%) followed by HBV (12/33; 36.3%), HCV (1/33), and cryptogenic (2/33). Most patients were male (28M:5F). COSMIC mutational signature analysis revealed SBS25 (chemotherapy related, 39.4%), SBS40 (35%, C > T due to deamidation) SBS3 (DNA repair; 12.1%), SBS5 (clock-like; 9%), and SBS4 (tobacco-related; 21.2%).

Frequent gene mutations included RB1 (18/33; 54.5%), TP53 (18/33, 54.5%), TERT (14/33; 42.4%), BAP1 (9/33;27.3%), ARID1A (6/33;18.2%), and CTNNB1 (4/33;12.1%). TERT mutations were mutually exclusive with BAP1 ($P < 0.05$) and TP53 ($P < 0.1$). Co-occurring mutations of TP53 and RB1 were seen in 36.3% of cases. All TERT-mutated cases carried the hotspot C228T variant. TP53 variants included R249S linked to aflatoxin exposure. Common RB1 variants were Q846* and R7Q. p53 mutation was major driver of HBV, while TERT was prominent in NASH although not statically significant (χ^2, $P = 0.437$)

Germline variants included MBOAT7 rs641738 (78%), TERT rs2853669 (63%), and TP53 rs1042522 (42%). Rare actionable mutations included RET C611Y, KIT W557, TP53 Y220*, and a non-V600E BRAF mutation. Co-occurrence of TP53 and TERT mutations was associated with poor survival, indicating a worse prognosis (Log Rank, $P = 0.328$). BAP1 mutations showed better outcomes, though not statistically significant due to small sample size.

TERT C228T was validated by ddPCR in all 14 NGS (+ve) cases, with copy numbers ranging from 26 to 23,800/20 μL. 3 additional NGS(-ve) cases were detected at low abundance, highlighting higher sensitivity with ddPCR. **Conclusion:** NC-HCC exhibits distinct molecular subclasses: one with tumor suppressor disruption (TP53/RB1, BAP1, ARID1A), and another with oncogenic activation via TERT. BAP1 appeared as a novel signature of non-cirrhotic HCC. TERT C228T is a promising biomarker for molecular screening of HCC using sensitive ddPCR platform.

4283 | KIF12 DEFICIENCY UNRAVELED IN CHOLESTATIC LIVER DISEASE: LINKING ORGANELLE MISPOSITIONING TO HEPATIC PATHOLOGY

Anubha Seth[1] Joseph Brancale[1] Nina Dashti-Gibson[2] Chigoziri Konkwo[3] Silvia Vilarinho[1], [1]Yale University, [2]Virginia Commonwealth University, [3]Icahn School of Medicine at Mount Sinai

Background: Cholestasis is a major cause of pediatric liver transplantation, yet effective treatments for its underlying causes remain scarce, pointing to a critical

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

unmet medical need. Recent studies, including ours, uncovered that biallelic rare loss-of-function mutations in KIF12 cause pediatric high-GGT cholestasis, fibrosis, ductular reaction, and bile duct loss. Despite the discovery of kinesins over 40 years ago, their roles in the liver are poorly understood. While KIF12 has been putatively identified as a microtubule-associated motor protein, our understanding of its precise functionality and role in cholestasis pathogenesis remains elusive. **Methods:** Human liver single-cell atlas showed that KIF12 is predominantly expressed in cholangiocytes. To model the patient variant, we introduced homozygous Arg219* in iPSCs using CRISPR-Cas9. WT and Arg219 * iPSCs were then differentiated into cholangiocyte-like cells (iCCs) and 3D biliary organoids. Confocal microscopy is used to examine protein and organelle localization. Bulk RNAseq identified transcriptomic changes. A lentiviral overexpression approach was used to evaluate potential rescue effects. **Results:** WT and Arg219* iPSCs were differentiated into iCCs and validated. Arg219* iCCs showed elevated GGT activity, consistent with patient phenotype. Single-molecule TIRF microscopy showed that WT KIF12 moves along microtubules at 1.17 $\mu m^2/s$, confirming its motor protein function. RNAseq analysis identified downregulation of ARMCX1—a gene associated with mitochondria trafficking in neurons, in both Arg219* hepatic endoderm (iHE) and iCCs, relative to WT. In Arg219* iCCs, there was a striking disruption in organelle distribution, with both mitochondria and lysosomes showing a perinuclear localization. These findings were corroborated through immunostaining with organelle-specific markers. Seahorse assay also revealed a significant decrease in maximal respiration, indicating impaired mitochondrial function. Cilia were also mislocalized, as reported by immunostaining and cilia-specific assay, revealing a fourfold increase in bent cilia and intracellular cilia compared to WT. The organoid model further validated cilia's altered position in Arg219*, independent of membrane polarization. Importantly, over-expressing WT KIF12 in Arg219* rescues organelle mislocalization, including cilia defects seen in Arg219* iCCs. **Conclusion:** The KIF12-Arg219* variant leads to elevated GGT levels and transcriptional alterations with pronounced organelle mislocalization, suggesting impaired organelle trafficking. This evidence provides novel insights into the cellular and molecular mechanisms driving the pathogenesis of human cholestatic liver disease. The successful rescue of ciliary defects through KIF12 overexpression not only highlights the essential role of KIF12 but and identifies it as a promising target for therapeutic intervention.

4284 | PLASMA CELL-FREE DNA FRAGMENTOMICS AND METHYLOMICS ANALYSIS OF INDIVIDUALS WITH GALLSTONES AND GALLBLADDER CANCER FROM THE SHANGHAI BILIARY TRACT CANCER CASE-CONTROL STUDY

Michael Daniels[1] R. Taylor Sundby[2] Ling Su[3] Xiaolin Wu[3] Bin Zhu[4] Jonathan Hernandez[5] Ann Hsing[6] Yu-Tang Gao[7] Jill Koshiol[1], [1]National Cancer Institute, [2]National Cancer Institute, Center for Cancer Research, Pediatric Oncology Branch, [3]National Cancer Institute, Center for Cancer Research, Genomics Technology Laboratory, [4]National Cancer Institute, Division of Cancer Epidemiology and Genetics, Biostatistics Branch, [5]National Cancer Institute, Center for Cancer Research, Surgical Oncology Program, [6]Stanford Cancer Center, Stanford University, [7]Shanghai Cancer Institute, Department of Epidemiology

Background: Gallstones (GS) are a key risk factor for gallbladder cancer (GBC), which is often diagnosed in advanced stages due to non-specific symptomology, inadequate screening options, and lack of sensitive and specific noninvasive biomarkers. Enzymatic methylation sequencing of circulating cell-free DNA (cfDNA) aims to noninvasively detect cancer signals through assessing fragmentomics and methylomics features, which have been minimally studied in gallbladder disease. The purpose of this project was to evaluate whether individuals with GBC display aberrant cancer-related cfDNA alterations compared to a GS control group. **Methods:** Low-coverage enzymatic methylation sequencing of cfDNA from plasma samples derived from individuals with GS ($N = 100$), and individuals with GBC ($N = 100$) from the Shanghai Biliary Tract Cancer Case-Control Study was conducted. Data were processed using a Bismark pipeline. Copy number alterations (CNAs) were determined using ichorCNA (size selected and low tumor fraction settings) with paired cfDNA samples and whole exome sequencing data from gallbladder tumor samples. Transcription factor binding site (TFBS) accessibility was determined using Griffin and end motif analyses/motif diversity score by FinaleToolkit. Differentially methylated regions (DMRs) and related features were generated using DMRichR. **Results:** Compared to GS controls, GBC cases displayed enriched shorter (90-150bp) cfDNA fragment percentages (Fig. A). CNAs were detected in 55% of GBC cases with higher detection in late-stage cancers. In GBC cases with estimated tumor fractions $> 3\%$, detected CNAs mirrored what was observed in paired

tumor tissue (Fig. C) and positively associated with worse survival (adjusted HR of 2.08; 95% CI:1.27, 3.41) (Fig. E). Increased TFBS accessibility in GBC cases was observed for AP-1 related genes (FOS, FOSL1, FOSL2, JUNB, JUND), and NFKB1 (Fig. B). Likewise, 4-mer end motifs were profoundly altered in GBC cases, as was the motif diversity score (Fig. D). Lastly, GBC cases displayed significant reductions in global average CpG methylation; hypomethylated DMRs predominantly occurred within intron and intergenic regions, whereas hypermethylated DMRs were found in promoter regions (Fig. F). **Conclusion:** Comprehensive fragmentomics and methylomics profiling of plasma cfDNA uncovered distinct cancer-associated signatures in GBC cases relative to GS controls. These noninvasive biomarkers warrant further evaluation to help identify early detection and risk stratification strategies.

4285 | HIGH-RESOLUTION SPATIAL TRANSCRIPTOMICS OF HCC IDENTIFIES DISTINCT IMMUNE CELL ARCHITECTURES LINKED TO RESPONSE AND RESISTANCE TO ATEZOLIZUMAB–BEVACIZUMAB THERAPY

Anna Vila[1] Marta Piqué-Gili[1] Marta Casado-Pelaez[2] Roser Pinyol[1] Ana Hernández de Sande[1] Veronica Davalos[2] Albert Gris-Oliver[1] Carla Montironi[3] Judit Peix[1] Eduard Porta[4] Daniela Grases[4] Sarah Cappuyns[5] Ezequiel Mauro[1] Guillem Cano-Segarra[1] Igor Figueiredo[6] Giorgio Ioannou[6] Edgar Gonzalez-Kozlova[6] Tim Meyer[7] Anja Lachenmayer[8] Jens Marquardt[9] Helen Reeves[10] Julien Edeline[11] Fabian Finkelmeier[12] Jörg Trojan[12] Jean-Frederic Blanc[13] Richard Hubner[14] Matthias Pinter[15] Tom Luedde[16] Arndt Vogel[17] Sacha Gnjatic[6] Daniela Sia[18] Vincenzo Mazzaferro[19] Jeroen Dekervel[20] Manel Esteller[4] Josep Llovet[21], [1]Liver Cancer Translational Research Group, Institut d'Investigacions Biomèdiques August Pi i Sunyer, [2]Cancer Epigenetics Group, Josep Carreras Leukaemia Research Institute (IJC), [3]Pathology Department and Molecular Biology Core, Hospital Clínic of Barcelona, Barcelona, Spain, [4]Josep Carreras Leukemia Research Institute (IJC), [5]Digestive Oncology, Department of Gastroenterology, University Hospitals Leuven, [6]Department of Immunology and Immunotherapy, Icahn School of Medicine at Mount Sinai, [7]Research Department of Oncology, UCL Cancer Institute, University College London, [8]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, [9]University of Lübeck, [10]The Newcastle University Centre for Cancer, Newcastle University, [11]. Background: HCC patients at advanced stage receive atezolizumab + bevacizumab (atezo+bev) as first-line treatment, eliciting objective responses in ~30% of patients. $CD8^+$ T exhausted cells (CD8_Tex) and $CXCL10^+$ macrophages (Macro_CXCL10) are associated with treatment efficacy, whereas the presence of $CD14^+$ monocytes (Mono_CD14) and immunosuppressive $TREM2^+$ macrophages (Macro_TREM2) alongside these populations was a trait of resistant tumors. Our hypothesis is that the spatial location and the distance among these immune populations fundamentally influence treatment response. **Methods:** Spatial transcriptomics analysis with the Xenium Prime 5000-gene panel customized with 100 additional target genes (10x Genomics) was used to profile 14 HCC samples: 11 inflamed tumors (5 responders and 6 non-responders to atezo+bev) and 3 non-inflamed resistant tumors, all obtained prior to atezo+bev therapy. The distance between cell types was calculated using the frNN function ("dbscan" R package). Specifically, we

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

defined a 300-μm search radius around each target cell and computed the distance to the nearest-neighboring cell type of interest. The spatial location of Macro_CXCL10 was validated by multiplexed immunohistochemistry (IHC) of $CD68^{pos}$ $PDL1^{pos}$ $TREM2^{neg}$. **Results:** A total of 2.4 million cells were profiled from the 14 samples by spatial transcriptomics. Within inflamed tumors, the CD8_Tex and Macro_CXCL10 distribution differed between atezo+bev responders and non-responders. Particularly, Macro_CXCL10 and CD8_Tex laid significantly closer to malignant cells (median distances of 80.2μm and 82.0μm, respectively) in responders compared to resistant tumors (median distance of 117.4μm and 135.8μm, respectively; $p = 0.04$ and $p = 0.1$). In addition, resistant tumors exhibited both an accumulation of Macro_CXCL10 at the tumor margins -validated by multiplexed IHC- and an increased proportion of Mono_CD14 (5.2% *vs* 1.3% of all immune cells; $p = 0.02$), with a shorter median distance to Macro_TREM2 (82 μm *vs.* 118 μm in responders; $p = 0.02$) and CD8_Tex (80.5μm *vs* 131μm in responders; $p = 0.02$). **Conclusion:** Single-cell spatial transcriptomics of HCC tumors from atezo +bev-treated patients revealed that response was associated with Macro_CXCL10 and CD8_Tex being located closer to malignant cells, while Macro_CXCL10 was confined to the tumor periphery in resistant tumors. The presence of immunosuppressive niches composed of Mono_CD14 and Macro_TREM2 cells was a characteristic trait of resistance.

4286 | CARDIOMETABOLIC COMORBIDITIES ARE CAUSAL FOR HEPATIC STEATOSIS: MENDELIAN RANDOMIZATION ANALYSIS

Blake Czapla[1] Stephan Buch[2] Eric Trepo[3] Vincent Chen[4], [1]University of Michigan, [2]Uniklinikum Dresden, [3]Université libre de Bruxelles, [4]University of Michigan Medical Center

Background: Metabolic-associated steatosis liver disease (MASLD) and metabolic alcohol-related liver disease (MetALD) are characterized by hepatic steatosis and cardiometabolic risk factors (CMRF), with or without alcohol intake. However, whether all CMRF are causal for hepatic steatosis is unclear. We used genetic cause inference analysis using Mendelian randomization to investigate causality of CMRF on steatosis. **Methods:** We conducted two-sample Mendelian randomization to assess CMRF effects (exposures) on liver outcomes, using data from genetic variants associated at $p < 5x10^{-8}$ in GWAS in European populations. The primary analysis utilized inverse variance weighting (IVW) and a sensitivity analysis used Egger which can identify horizontal pleiotropy. Effects were reported as number of standard deviation (SD) unit change in the outcome per SD change in the predictor. Exposures were alcohol intake (27 instruments, 274,424 participants); BMI (1,082 instruments, 456,426 participants); Systolic blood pressure (SBP)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(18 instruments, 220,501 participants); type 2 diabetes (425 instruments, 1,042,540 participants); HDL (379 instruments, 1,244,544 participants); and triglycerides (TGs) (388 instruments, 1,253,236 participants). The effect of these instruments on exposures were from published studies on ALT (222,603 participants), cirrhosis (1,580,010 and 69,589 participants), and MASLD (228,992). **Results:** Mendelian randomization revealed BMI was positively associated with ALT (β = 0.062 [0.049, 0.076], p = 3.1e-19), cirrhosis (β = 0.416 [0.314, 0.519], p < 1.5e-15), and MASLD (β = 0.778 [0.487, 1.068], p = 1.6e-07). Diabetes was positively associated with ALT (β = 0.023 [0.015, 0.032], p = 2.4e-07) and MASLD (β = 0.310 [0.154, 0.466], p = 9.6e-05). Conversely, higher HDL was associated with reduced ALT (β = -0.026 [-0.045, -0.007], p = 0.0078) and cirrhosis (β = -0.225 [-0.388, -0.062], p = 0.0068). SBP was linked to cirrhosis (β = 0.061 [0.023, 0.099], p = 0.0018) and ALT (β = 0.010 [0.002, 0.018], p = 0.0096). Alcohol intake was associated with higher cirrhosis risk (β = 0.372 [0.129, 0.615], p = 0.0027). TGs showed no causal effects. **Conclusion:** Genetically-predicted CMRFs are causal for ALT, cirrhosis, and MASLD. These effects are strongest for BMI, diabetes, and HDL, with SBP having weaker effects and TGs having none. Future MASLD nomenclature updates should reflect the disparate effects of different CMRF on risk of hepatic steatosis.

4287 | EXTERNAL VALIDATION ON AN HCC RISK STRATIFICATION SCORE, PAAM, IN PATIENTS WITH CHRONIC LIVER DISEASE OF VARYING SEVERITY

Christine Hsu[1] Ece Janet Dinc[2] Hiroaki Kanzaki[2] Naoto Fujiwara[3] Christopher Sollenberger[1] Hiroyuki Suzuki[2] Courtney Katz[2] Pratibha Selvakumar[2] Indu Raman[2] Prithvi Raj[2] Jonathan Lim[1] Jake Liang[1] Yujin Hoshida[2], [1]National Institute of Diabetes and Digestive and Kidney Diseases, [2]University of Texas Southwestern Medical Center, [3]Graduate School of Medicine, Mie University

Background: HCC risk stratification is an unmet medical need for patients with chronic liver disease. We previously reported an HCC risk score, PAaM, integrating clinical variables and a serum proteome biomarker, which was validated in patients with cirrhosis (Gastro 168;556,2025). The clinical utility of this score in a broader patient population, including non-cirrhotic subjects, has yet to be explored. In this study, we conducted an external validation of PAaM in patients with chronic liver diseases, including non-cirrhotics. **Methods:** We analyzed archived serum samples from a retrospective cohort of patients with chronic liver disease who were followed up at the U.S. National Institute of Health (NIH) Clinical Center between 1980 and 2023. Patients with follow-up time shorter than 6 months or an HCC diagnosis within 6 months of the initial visit were excluded. The serum proteome biomarker assay (PLSec) and PAaM score calculation were performed, and the patients were classified as having high-, intermediate-, or low-risk of incident HCC development as previously reported. The association of the risk prediction and time to incident HCC was assessed by uni- and multivariable Cox and Fine-Gray regression. **Results:** We included 295 patients in the analysis, among which 33 patients developed incident HCC during a median follow-up of 7.8 years (IQR 3.2 – 12.3 years). There were 147 (49.8%) non-Hispanic white, 59 (20%) black, 57 (19.3%) Asian, and 26 (8.8%) Hispanic patients. Median age was 50 years (IQR 41 - 57 years). 180 (61%) patients were male. Major etiology was HCV (55.3%; active/cured infection 15%/85%) followed by HBV (16.6%), MASLD (10.5%), ALD (2.7%). Annual HCC incidence rate was 3.04%. The PAaM score categorized 63 (21.4%), 74 (25.1%), and 158 (53.6%) patients as having high-, intermediate-, and low-risk, with annual HCC incidence rates of 3.0%, 1.9%, and 0.4%, respectively. Hazard ratios for the high- and intermediate-risk groups were 3.67 (95% CI 1.58 – 8.5) and 2.23 (95% CI 0.95 – 5.25), respectively,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

compared to the low-risk group. Exploratory subgroup analysis is planned using clinical variables relevant to the risk of HCC development. **Conclusion:** The PAaM score was successfully validated in a multi-ethnic cohort of patients with chronic liver diseases of mixed etiologies at a tertiary center in the U.S.

4288 | CHARTING SINGLE-CELL METABOLISM CO-EVOLUTION DURING METASTASIS

Yingcheng Wu[1] Qiang Gao[2], [1]Fudan University, [2]Fudan University Zhongshan Hospital

Background: Metastasis, the leading cause of cancer death, exhibits a highly heterogeneous and suppressive cancer microenvironment. **Methods:** Here, we sequenced 97 matched samples by using single-cell RNA sequencing and spatial transcriptomics of colorectal cancer liver metastasis. **Results:** Strikingly, the metastatic microenvironment underwent remarkable spatial reprogramming of immunosuppressive cells such as MRC1+ CCL18+ M2-like macrophages. We further developed *scMetabolism*, a computational pipeline for quantifying single-cell metabolism, and observed that those macrophages harbored enhanced amino acid metabolic activity. Interestingly, neoadjuvant chemotherapy could block this status and restore the antitumor immune balance in responsive patients, whereas the nonresponsive patients deteriorated into a more suppressive one. In parallel, metastatic cancer cells displayed the metabolic switch from OXPHOS to glycolysis, which is dependent on the metabolic master regulator LY6E. **Conclusion:** Our work described the metabolism co-evolution of both immune and cancer cells during metastasis and uncovered the black box of how tumors respond to neoadjuvant chemotherapy.

4289 | IN SITU ANALYSIS OF THE HBV-ASSOCIATED HEPATOCELLULAR CARCINOMA MICROENVIRONMENT USING IMAGING-BASED SINGLE-CELL RESOLUTION XENIUM SPATIAL TRANSCRIPTOMICS

Wei Hou[1], [1]Translational Medicine Research Center, School of Clinical Medicine, Qilu Medical University, CHINA

Background: Hepatitis B virus (HBV)-associated hepatocellular carcinoma (HCC) presents a complex tumor microenvironment (TME) that contributes to oncogenesis and treatment resistance. **Methods:** Utilizing the Xenium platform's imaging-based spatial transcriptomics at single-cell resolution, we systematically characterized the spatial architecture and molecular interactions within HBV-HCC tissues. Our multi-omics approach integrated spatial transcriptomic profiling with single-cell RNA sequencing to delineate the spatial distributions of tumor cells, immune subsets, and stromal components across tumor core, paracancerous, and normal liver regions. **Results:** Employing the Xenium platform's high-resolution spatial transcriptomics workflow, we analyzed 5,000 cancer-relevant genes across 605,057 cells (with a median of 194 transcripts per cell). Cell segmentation through Xenium Explorer revealed distinct spatial compartmentalization of hepatocyte subpopulations, immune cell infiltrates (including PD-1+CD8+ T cells and SPP1+ macrophages), endothelial networks, and activated fibroblasts. Subsequent dimensionality reduction using Seurat identified five principal cellular communities with unique spatial patterns: malignant hepatocytes clustered within tumor nests, immunosuppressive myeloid cells forming peri-tumoral barriers, endothelial networks delineating angiogenic hotspots, and activated fibroblasts establishing stromal partitions. Differential gene expression analysis highlighted tumor-specific upregulation of oncogenic driver PEG10 (log2FC = 4.567, P. **Conclusion:** This study establishes a spatial atlas of HBV-associated HCC at single-cell resolution, identifying key therapeutic opportunities targeting PEG10/ IGF2 signaling and ferroptosis pathways. Our findings provide a spatial framework for the development of microenvironment-targeted strategies aimed at overcoming immunotherapy resistance in virally-driven HCC.

4290 | THE GENOMIC MUTATION OF HEPATOCELLULAR CARCINOMA IN FONTAN-ASSOCIATED LIVER DISEASES CHARACTERIZED BY CHROMOSOMAL REARRANGEMENTS

Taiji Yamazoe[1] Eiji Kakazu[1] Masaaki Mino[1] Michitaka Matsuda[1] Tatsuya Kanto[1], [1]Japan Institute for Health Security

Background: The Fontan-associated liver disease (FALD) is a congestive hepatopathy growing the number of patient and develops liver cirrhosis and hepatocellular carcinoma (HCC) after 15-20 years of the Fontan procedure. The prognosis of FALD-HCC patients is significantly worse compered to non-HCC FALD patients, thus indicating the importance of the understanding of genomic signature of FALD hepatocarcinogenesis. To this aim, we utilized the whole genome sequences (WGS). **Methods:** We performed WGS analyses of the surgically resected tissues from five FALD HCC patients, two post non-Fontan congenital heart surgery (CHS) HCC patients, and one FALD focal nodular hyperplasia (FNH) patient, respectively. To infer mutation mechanisms of FALD HCC, we utilized COSMIC signature analysis with comparison of the publicly available viral and non-viral HCC cohorts. To check the progression of liver injury, we used pIVC mouse model and examined reactive oxygen species (ROS) and the time course of phosphorylation of histone H2Ax (γH2Ax). **Results:** Eight tumors, including FALD HCCs, FALD FNH and non-Fontan CHS HCCs had relatively higher tumor mutational burden than HCCs in the databases. Based on the COSMIC v3.3, we identified the signatures related to the homologous recombination deficiency, the ROS DNA injury and the repair of DNA double-strand breaks (DSB) by non-homologous DNA end-joining mechanisms across eight tumors. The study on short variants shown that FALD HCC did not have the commonly observed mutations of HCCs in the public databases, such as *CTNNB1*, *TP53*, or *TERT*. The study on structural variants (SVs) shown that FALD HCC had significantly higher amount of <1Mb deletion and translocation than that of HCCs in the database. The unbiased clustering based on the copy number alterations (CNAs) and SVs classified FALD and non-Fontan CHS HCC as an HCC subclass characterized by the gain of chromosome 1q and a loss of 16q. On the other hand, FALD FNH had few CNAs and SVs and had been classified no chromosomal rearrangement subclass. The subclass of HCC with 1q gain and 16q loss in the database shows poor progression-free interval.

In the mouse model, we confirmed ROS production and the γH2Ax positivity were gradually increased after pIVC ligations. The γH2Ax positive hepatocytes preferentially localized in the peripheral area of the liver. **Conclusion:** Our WGS study identified distinctive genomic mutational characteristics of FALD HCCs from HCCs in the public databases. These findings would have implications for the establishment of FALD specific patient management and HCC therapy.

4291 | CLINICO-RADIOMIC FEATURES CAN STRATIFY CLINICALLY SIGNIFICANT PORTAL HYPERTENSION (CSPH) IN PATIENTS OF CIRRHOSIS NON-INVASIVELY

Ashok Kumar Choudhury[1] Tranjit Kaur[2] Garima Singhal[3] shalini thapar[4] Tapan Gandhi[5] Shiv Kumar Sarin[6], [1]Institute of Liver and Biliary Sciences, [2]Indian Institute Technology, Jodhpur. India, [3]Institute of Liver and Billiary Sciences, New Delhi India, [4]Institute of Liver and Biliary Sciences, New Delhi. India., [5]Indian Institute of Technology, Delhi, [6]Institute of Liver and Billiary Sciences

Background: Clinically significant portal hypertension, defined by a hepatic venous pressure gradient (HVPG) of >10mmHg, is associated with increased risk of decompensation and poor survival. Non-invasive measurement of portal pressure by radiomics and clinical parameters is an unmet need. We aimed to assess CSPH from CT images (radiomics) and clinical parameters as non-invasive surrogates of HVPG. **Methods:** We retrospectively analyzed EMRs of compensated cirrhosis patients, incorporating clinical, contrast CT scan images and HVPG measured within past 3 months. Patients were grouped as CSPH (HVPG >10mmHg) or no CSPH. Liver segmentation was performed on the venous phase images using a U-Net deep learning model; and 1,606 radiomic features were extracted using 3D Slicer software. These imaging-derived features, clinical parameters, were compiled for each patient to train four supervised machine learning models —Logistic Regression, Random Forest, K-Nearest Neighbors (KNN), and XGBoost—to classify as CSPH or no-CSPH. Stratified 5-fold cross-validation done for preserve class distribution and model performance was assessed using ROC curves to compare classifier performance. **Results:** Total of 50 patients (median age: 58.9+11.2 years; 76% male), mean HVPG 17.5 ± 3.8 mm Hg, were grouped as no CSPH ($n=20$) and CSPH ($n=30$). They were comparable in all parameters except HVPG (18.5 ± 4.7 versus 5.3 ± 1.7 mm Hg). Liver segmentation using the U-Net model achieved a Dice Similarity Coefficient of 96.5. Using only radiomic features, logistic regression emerged as

the best-performing model with an AUC of 0.733, sensitivity of 0.70, and specificity of 0.60 in distinguishing the two groups. Upon inclusion of clinical parameters (age, serum bilirubin, albumin, urea, AST, ALT and INR) the model performance improved, with the XGBoost classifier achieving the highest AUC of 0.80, sensitivity of 0.80, specificity of 0.60, PPV -74%, NPV-77% and F1-75% for identifying those with CSPH. **Conclusion:** Radiomic features extracted from CT images and simple laboratory parameters (clinico-radiomics) together can effectively stratify patients of cirrhosis with CSPH. Virtual measurement of HVPG (vHVPG) may be accepted for clinical practice in future, pending analysis of larger data.

4292 | SINGLE-CELL AND SINGLE-NUCLEI TRANSCRIPTOMICS REVEAL HEPATOBLASTOMA TUMOR SIGNATURES FOR PRECISION ONCOLOGY

Abhishek Murti[1] Elise Lelou[1] Simon Bucher[1] Saphia Nguyen[1] Matthew Choi[1] Soo-Jin Cho[1] Amar Nijagal[1] Bruce Wang[1], [1]University of California, San Francisco

Background: Pediatric hepatoblastoma (HB) is the most common primary liver cancer in infants and children. While early diagnosis and treatment can lead to a 70% five-year survival rate, prognosis remains poor for patients with unresectable or metastatic tumors. HB tumors exhibit marked heterogeneity, and current clinical risk stratification relies on imaging and histology, with serum alpha-fetoprotein as the only molecular biomarker. Therefore, there is an urgent need for improved molecular characterization to enable more accurate patient risk stratification. Single-cell RNA sequencing (scRNA-seq) enables the dissection of tumor complexity and identification of cell-type–specific expression programs. In our prior work, we used scRNA-seq to profile resected HB tumors and discovered five distinct tumor signatures predictive of treatment response in patient-derived spheroids. We now expand this analysis to include freshly resected and frozen biobanked HB specimens using single-cell and single-nuclei RNA sequencing (snRNA-seq), respectively. **Methods:** Fresh tumors were processed using Seq-Well for scRNA-seq, and frozen samples were profiled via snRNA-seq using the 10x Genomics Chromium platform. Libraries were sequenced on an Illumina NovaSeqX. Data preprocessing and downstream analysis were conducted using Scanpy. Quality control included filtering based on gene counts, mitochondrial content, doublet removal, and ambient RNA correction. Datasets were integrated using scvi-tools; clustering and differential gene expression was performed to define tumor signatures. Correlation analyses assessed cross-platform concordance. **Results:** Our expanded single cell dataset confirms the presence and reproducibility of previously identified tumor signatures, including a signature enriched in aggressive, high-risk tumors. Strong concordance between matched scRNA-seq and snRNA-seq profiles confirms the reproducibility of tumor signatures across platforms. These findings highlight the utility of snRNA-seq for profiling archived HB samples and expand our understanding of tumor heterogeneity diversity. **Conclusion:** This study demonstrates that both scRNA-seq and snRNA-seq can effectively resolve hepatoblastoma heterogeneity and identify biologically and clinically meaningful tumor signatures. The ability to analyze fresh and frozen tumors expands the utility of transcriptomic profiling, especially for rare or high-risk cases. These insights lay the foundation for a precision oncology framework in HB, enabling molecular stratification and personalized treatment strategies tailored to each patient's tumor biology.

4293 | PHENOTYPE-GUIDED EXOME-BASED GENE PANEL TESTING IMPROVES DIAGNOSTIC YIELD FOR RARE GENETIC CHOLESTATIC LIVER DISEASE

Akihiro Asai[1] Wenying Zhang[1] Chunyue Yin[1] Emily Vincent[1] William Balistreri[1], [1]Cincinnati Children's Hospital Medical Center

Background: Cholestatic jaundice affects one in 2,500 full-term infants; inherited conditions account for 25–50% of the cases. Identifying a genetic etiology enables early diagnosis and targeted management, improving patient outcomes. However, ~30% of patients with isolated/primary cholestasis lack mutations in known cholestasis-associated genes, limiting personalized care. Whole-exome (WES) and whole-genome sequencing (WGS) often detect numerous variants in genes with uncertain relevance. This ambiguity hinders interpretation and reduces diagnostic yield. **Methods:** We developed the Cincinnati Undiagnosed and Rare Liver (CURL) Disease Panel, a phenotype-guided test leveraging exome sequencing and targeting 1,445 genes curated for relevance to liver biology. The gene list is continuously refined by clinicians, liver researchers, and geneticists. From over 50 patients screened, we prioritized those with unknown chronic cholestasis where a genetic diagnosis could inform care. Test results were interpreted through multidisciplinary review. **Results:** The CURL panel was piloted in eight patients (seven pediatric, one adult), six with trio-based testing. All had undergone prior clinical genetic testing, including the 72-liver gene panel at CCHMC and, in two cases, commercial WGS. The CURL panel confirmed previously reported variants in three patients: Patient 1 (neonatal cholestasis) had compound heterozygous missense variants in *ABCB11* (p.Ile611Thr; p.Met185Ile); Patient 2 (bile duct paucity) had a heterozygous missense variant in *NOTCH2* (p.Gly700Val); and Patient 3 (intrahepatic cholestasis of pregnancy) had a heterozygous in-frame deletion in *ABCB4* (p.Lys620del). In three additional patients, the CURL panel identified novel variants consistent with clinical phenotypes: Patient 4 (high-GGT neonatal cholestasis) had compound heterozygous missense variants in *LARS1* (p.Asn1148Ser; p.Glu124Lys); Patient 5 (cholestasis and pancreatic insufficiency) had a hemizygous missense variant in *ATP6AP1* (p.Leu148Pro); and Patient 6 (severe lobular cholestasis) had a heterozygous missense variant in *PLEC* (p.Leu2380Pro). **Conclusion:** The CURL panel enables collaborative review and focused interpretation of the most up-to-date liver-relevant genes using a phenotype-guided exome approach. Early data indicate improved diagnostic yield over standard gene panels, WES, and WGS in patients with undefined cholestatic liver diseases.

4294 | PNPLA3-I148M HOMOZYGOSITY PROMOTES VISCERAL FAT ACCUMULATION AND REDUCES SUBCUTANEOUS FAT INDEPENDENT OF BMI

Eleonora Scorletti[1] David Zhang[1] Marijana Vujkovic[1] Kyong-Mi Chang[1] Garret FitzGerald[1] Daniel Rader[1], [1]University of Pennsylvania

Background: The *PNPLA3*-I148M genetic variant is strongly associated with hepatic fat accumulation and liver disease risk, yet its effects on adipose tissue distribution and function remain incompletely characterized. Given the critical role of adipose tissue in systemic metabolism and inflammation, understanding *PNPLA3*-I148M's influence on adiposity may illuminate novel pathways linking adipose biology to hepatic and metabolic disorders. Our preliminary data indicate that adipose tissue of *PNPLA3*-I148M carriers accumulates polyunsaturated fatty acids (PUFAs) with aging, suggesting an age-dependent metabolic impact. Here, we aimed to evaluate how *PNPLA3*-I148M homozygosity affects abdominal adipose distribution. **Methods:** We analyzed abdominal computed tomography (CT)-derived adiposity metrics from 2,109 homozygous PNPLA3-I148M (MM) carriers and 25,782 wild-type (WT) individuals enrolled in the Penn Medicine Biobank (PMBB). Primary outcomes included adipose tissue thickness (distance from skin to fascia), subcutaneous fat pixel volume, and visceral fat pixel volume. Associations between genotype (MM vs. WT) and adiposity measures were assessed using linear regression models, adjusted for age, sex, and BMI. **Results:** We found that MM carriers had lower BMI (mean 29.0, SD $\pm$6.0 kg/m²) compared to WT controls (mean 29.7, SD $\pm$6.5 kg/m², $p < 0.001$). Adjusting for age, sex, and BMI, adipose thickness did not significantly differ between groups ($\beta = +0.0036$ mm; 95% CI –0.046 to +0.054; $p = 0.89$). However, subcutaneous fat volume was significantly lower in MM carriers ($\beta = –73{,}610$ pixels; 95% CI –118,800 to –28,420; $p = 1.4\times10^{-3}$), whereas visceral fat volume was significantly higher ($\beta = +74{,}350$ pixels; 95% CI +40,811 to +107,890; $p = 1.4\times10^{-5}$). We are currently replicating these

findings in the Million Veteran Program (MVP) cohort and will present additional adipose tissue data on PUFA-derived eicosanoids at The Liver Meeting. **Conclusion:** Our study is the first to explore the effect of PNPLA3-I148M on adipose tissue distribution. Homozygosity for *PNPLA3*-I148M distinctly alters adipose tissue distribution, characterized by reduced subcutaneous fat and increased visceral fat independent of BMI, age, and sex. These findings highlight the potential role of altered adipose tissue partitioning in driving the metabolic and hepatic complications associated with the *PNPLA3*-I148M variant.

4295 | MOLECULAR RELATIONSHIP BETWEEN STEATOHEPATITIS AND ADVANCED FIBROSIS IN HUMAN MASLD: AN INVESTIGATION BASED ON MULTIPLE HUMAN RNASEQ DATASETS

Tae-Hwi Schwantes-An[1] Marco Abreu[1] Callie Zaborenko[1] Jingyi Tan[2] Xiuqing Guo[2] Jerome Rotter[2] Brent Neuschwander-Tetri[3] Arun Sanyal[4] Naga Chalasani[5], [1]Indiana University School of Medicine, [2]Lundquist Institute, [3]Saint Louis University, [4]Virginia Commonwealth University, [5]Indiana University Medical Center

Background: The molecular basis for steatohepatitis and advanced fibrosis and their sequential relationships in human MASLD are not fully understood. We sought to identify differentially expressed genes in the liver tissue in patients with MASLD which stratify risk for higher disease activity or fibrosis stages and understand their relationships. **Methods:** Differential gene expression (DGE) analyses were conducted for advanced fibrosis ($F \geq 3$) and NAFLD Activity Score (NAS) ≥ 4 from the bulk RNAseq from NASH-CRN liver samples performed by the Regeneron Genetics Center. We adjusted for age, sex, race, ethnicity, fibrosis (for NAS outcome), and NAS (for fibrosis outcome). The significant DGEs (padj < 0.05 and up/down expressed ≥ 2-folds) were used with gene set variation analysis to compute gene enrichment scores in two independent bulk RNA-seq data of patients with MASLD. In total 4 scores; 1) fibrosis, 2) NAS, 3) fibrosis adjusting for NAS, and 4) NAS adjusting for fibrosis were generated. We then assessed the performance of the scores in stratifying risks for NAS $\geq$ 4 and advanced fibrosis. **Results:** In total, 499 NASH-CRN adult participants were included in DGE analysis. There were 309 DGE associated with advanced fibrosis, after adjusting for age, sex, race/ethnicity (RNA-Fib score) and 229 DGE after also adjusting for NAS. For NAS ≥ 4, there were 268 DGE with significant association after adjusting for age, sex, race/ethnicity (RNA-NAS score), and 79 after also adjusting for fibrosis stage. Using these genes, four enrichment scores were computed in GSE135251 (Anstee et al., N = 216) and GSE225740 (Chalasani et al., N = 93).

In GSE135251, we observed that RNA-NAS score not only predicted risk for NAS ≥ 4 (OR = 18.7, $p = 2.8 \times 10^{-14}$, Rsq = 23.4%), but also fibrosis (OR = 11.9, $p = 3.9 \times 10^{-28}$, Rsq = 43.0%). After adjusting for fibrosis, the RNA-NAS score still predicted both NAS and fibrosis (Table). RNA-Fib score was associated with both fibrosis (OR = 8.7, $p = 5.9 \times 10^{-21}$, Rsq = 34%) and NAS (OR = 4.9, $p = 6.6 \times 10^{-05}$, Rsq = 6.8%). However, after adjusting for NAS, RNA-Fib score was no longer associated with NAS (p = 0.2) and showed reduced performance for fibrosis (OR = 6.3, $p = 4.7 \times 10^{-11}$, Rsq = 18%). We observed similar patterns of association in GSE225740 (data not shown). **Conclusion:** Our finding shows the genes that drive steatohepatitis also drive fibrosis while the genes that drive fibrosis do not drive NAS. These molecular data highlight the importance of steatohepatitis in driving advanced fibrosis.

Enrichment Scores	Outcomes	OR (95%C.I.)	Pvalue	Rsq	Comments/Interpretation
RNA-Fib score	Fibrosis	8.73 (5.82-13.10)	5.93E-21	33.5%	The fibrosis score is highly associated with risk for advanced fibrosis
RNA-Fib score adjusted for NAS	Fibrosis	6.30 (3.74-10.59)	4.71E-11	18.0%	The fibrosis score is still associated with the risk, however there is a decrease in performance
RNA-Fib score	NAS	4.93 (2.29-10.64)	6.61E-05	6.8%	The fibrosis score explains some variance in NAS but not as much as it does for fibrosis
RNA-Fib score adjusted for NAS	NAS	1.83 (0.73-4.57)	1.98E-01	0.3%	The fibrosis score after adjusting for NAS does not predict NAS
RNA-NAS score	NAS	18.68 (9.25-37.73)	2.78E-14	23.4%	The RNA-NAS score is highly associated with risk for higher NAS
RNA-NAS score adjusted for fibrosis	NAS	22.88 (11.62-45.03)	8.36E-17	27.4%	The RNA-NAS score shows improved performance for NAS after adjusting for fibrosis
RNA-NAS score	Fibrosis	11.85 (8.11-17.32)	3.86E-28	43.0%	The RNA-NAS score is also highly associated with risk for advanced fibrosis
RNA-NAS score adjusted for fibrosis	Fibrosis	7.15 (4.68-10.91)	5.96E-17	27.6%	The RNA-NAS score still is highly associated with advanced fibrosis after adjusting for fibrosis

4296 | TOWARDS A HUMAN-LIKE BILE ACID POOL IN MICE: DISSECTING THE ROLE OF CYP2C70 AND AGXT IN BILE ACID COMPOSITION AND CONJUGATION

Dandan Wu[1] Isabelle Bolt[1] Dagmar Tolenaars[1] Wietse In het Panhuis[1] Coen Paulusma[1] Stan van de Graaf[1], [1]Tytgat Institute for Liver and Intestinal Research

Background: Bile acids (BAs) are key regulators of lipid and glucose metabolism, as well as immune homeostasis. Alterations in BA metabolism are critically involved in cardiometabolic, inflammatory, and neoplastic diseases. While mouse models remain indispensable in studying these processes, significant species differences in BA composition and downstream signaling hinder translational relevance. Cytochrome P450 2C70 (*Cyp2c70*) converts chenodeoxycholic acid (CDCA) into muricholic acids (MCAs), hydrophilic bile acids unique to rodents. In contrast, humans lack MCAs and exhibit a CDCA-enriched BA pool. Alanine-glyoxylate aminotransferase (*Agxt*) catalyzes glycine production. Species differences in glycine synthesis, potentially linked to distinct subcellular localization of *Agxt*, have been proposed to explain the predominance of glycine-conjugated bile acids in humans versus taurine conjugation in mice. However, this hypothesis remains untested. In this study, we aimed to humanize the murine bile acid profile by targeting both *Cyp2c70* and *Agxt* in mouse hepatocytes. **Methods:** Using AAV8-mediated somatic liver knockout, we generated the following mouse models: a. *Cyp2c70* knockout (*Cyp2c70* ^{KO}); b. Murine *AGXT (mAgxt)* knockout combined with human AGXT (*hAGXT*) overexpression (*mAgxt* ^{KO}/*hAGXT* ^{OE}); c. Triple-modified mice with *Cyp2c70* and *Agxt* knockout plus hAGXT overexpression (*Cyp2c70* ^{KO}/*mAGXT* ^{KO}/*hAGXT* ^{OE}). AAV8 vectors were administered at a dose of $1*10^{13}$ vg/kg via tail vein injection to adult mice. Knockout and overexpression were confirmed via qPCR and western blot. Bile acid composition and liver function were assessed 6, 9, and 12 weeks after AAV injection. **Results:** *Cyp2c70* ^{KO} mice exhibited a marked reduction in MCAs and a significant increase in CDCA within 9 weeks. In *mAgxt* ^{KO}/*hAGXT* ^{OE} mice, total BA levels increased, while the proportion of glycine-conjugated BAs remained comparable to controls, suggesting maintained conjugation function. No significant liver injury was observed in *Cyp2c70* ^{KO} or *mAgxt* ^{KO}/*hAGXT* ^{OE} mice after 12 weeks. However, *Cyp2c70* ^{KO}/*mAGXT* ^{KO}/*hAGXT* ^{OE} mice developed severe biliary injury, necessitating euthanasia 6 weeks post-injection. **Conclusion:** Hepatocyte-specific Cyp2c70 deletion leads to a more human-like BA profile, whereas Agxt manipulation alone failed to humanize bile acid conjugation in mice, indicating that additional factors govern species-specific conjugation.

4297 | HEPATOCELLULAR CARCINOMA MICROENVIRONMENT ANALYSIS USING SINGLE-CELL RNA-SEQ TO EXPLORE NOVEL THERAPEUTIC TARGETS

Ryo Takahashi[1] Takahiro Kodama[1] Takeru Hirao[1] Yu Sato[1] Yuta Myojin[1] Satoshi Shigeno[1] Kazuhiro Murai[1] Yuki Tahata[1] Yoshinobu Saito[1] Hayato Hikita[1] Tetsuo Takehara[2], [1]The University of Osaka, [2]Kansai Rosai Hospital

Background: Angiogenesis inhibitors and immune checkpoint inhibitors targeting the tumor microenvironment (TME) have recently become the mainstay of treatment for hepatocellular carcinoma (HCC), but response rates remain unsatisfactory. Therefore, we performed TME analysis by single-cell RNA-seq to explore novel therapeutic targets in HCC. **Methods:** Flex scRNA-seq analysis was performed using 81 frozen tissue samples (63 HCC samples undergoing hepatectomy, 10 noncancerous liver tissue samples, and 8 donor liver tissue samples) to examine the association between cell type frequency, gene expression, cell-cell interactions, and clinical characteristics. We also performed TME classification by hierarchical clustering based on the cell type frequency of noncancerous cells and cancer cell classification based on the Chiang molecular classification, and examined the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

association with clinical characteristics. **Results:** The 63 cases consisted of 69.8% males, 49.2% MASLD, Stage (I/II/III/IV: 46%/31.7%/19%/3.2%), and 31.7% positive for portal vein invasion (VP). The approximately 60,000 noncancerous cells were classified into four major clusters (lymphocytes, myelocytes, vascular endothelial cells, and hepatic stellate cell) and further subdivided into 29 cell types. VP-positive cases showed a significantly higher frequency of TREM2+ macrophages and increased expression of PD-1, TIM-3, LAG-3 and TIGIT in CD8-positive T cells, and anti-tumor immunity was suppressed in TME. The 63 cases were stratified into 4 groups according to TME classification, with about 30% of the group rich in Lymphoid, which is considered Immune Hot, and the group characterized by tumor-associated endothelial cells (VECs) and tumor-associated fibroblasts (CAFs), which had a shorter PFS. In the classification of approximately 250,000 cancer cells, the CTNNB1 group was mostly consistent with the TME classification characterized by VECs, while the PROLIFERAION group was largely divided into two groups: the Lymphoid-rich TME group and the CAF-rich TME group. **Conclusion:** Our results suggest that scRNA-seq analysis may enable a detailed TME classification of HCC and identify subtypes that may be associated with the efficacy of immunotherapy. **Disclosures:** Ryo Takahashi: Nothing to Disclose, Takahiro Kodama: Nothing to Disclose, Takeru Hirao: Nothing to Disclose, Yu Sato: Nothing to Disclose, Yuta Myojin: Nothing to Disclose, Satoshi Shigeno: Nothing to Disclose, Kazuhiro Murai: Nothing to Disclose, Yuki Tahata: Nothing to Disclose, Yoshinobu Saito: Nothing to Disclose, Hayato Hikita: Nothing to Disclose, Tetsuo Takehara: Nothing to Disclose

4298 | IDENTIFICATION OF LIVER CANCER NEOANTIGENS FROM RARE TUMOR CELLS IN MALIGNANT ASCITES

Dongbo Chen[1] Hongsong Chen[1], [1]Peking University People's Hospital, Peking University Hepatology Institute

Background: In liver cancer immunotherapy, neoantigen-based immunotherapies have demonstrated remarkable clinical efficacy in patients due to their strong immunogenicity. Studies have confirmed that pre-existing neoantigen-specific T cells in tumor patients are the targets of immune checkpoint blockade (ICB) therapy and serve as the core driver of clinical benefits in immunotherapy. Therefore, neoantigen-based therapeutic vaccines represent a promising breakthrough in tumor immunotherapy.

Liver cancer is often insidious in onset, with more than half of patients diagnosed at intermediate or advanced stages, missing the optimal window for surgical intervention. This makes it difficult to obtain neoantigen profiles from surgical samples. In contrast, malignant ascites, as a key component of liquid biopsy, contains metastatic tumor cells and provides a convenient source for detecting neoantigen profiles in cancer patients. The primary objective of this study is to establish a comprehensive strategy for identifying neoantigens from malignant ascites samples of advanced liver cancer patients. **Methods:** First, ascites samples were collected from patients with liver cirrhosis and advanced liver cancer. Using flow cytometry (FCM), we isolated the 7-AAD$^-$ CD45$^-$ CD326$^+$ tumor cell subpopulation (P7 population) from malignant ascites of advanced liver cancer. For P7 populations containing fewer than 2,000 cells, RNA and DNA were separately extracted and amplified using Smart-seq2 and Discover-sc Single Cell WGA Kit technologies, respectively. The samples were then subjected to transcriptome sequencing and whole-exome sequencing, followed by comprehensive bioinformatics analysis to characterize genetic variations and expression profiles. Simultaneously, the Variant Effect Predictor (VEP) algorithm was employed to predict mutant proteins from somatic mutations and subsequently process these proteins to derive potential mutant peptides. Binding affinity between mutant peptides and patient HLA molecules was calculated using the NetMHCpan-4.1 algorithm. Potential neoantigens were predicted by applying the following criteria: mutated peptide affinity (MutAff $\leq$ 200 nM) or a ratio of referenced (wild-type) peptide affinity to mutated peptide affinity (RefAff/MutAff $\geq$ 10), while excluding duplicates and cases of HLA loss-of-heterozygosity. Finally, tetramer staining was performed to detect neoantigen-specific T cells in malignant ascites. **Results:** In this study, we developed an integrated approach combining flow cytometry (FCM) with next-generation sequencing to isolate and characterize rare tumor cells (CSCs) from malignant ascites. Our results demonstrated that liver cancer patients exhibited significantly higher numbers of P7 tumor cell subpopulations in their ascites compared to both matched peripheral blood samples and ascites from cirrhosis patients. Single-cell sequencing analysis revealed partial overlap in mutational profiles between individual tumor cells in ascites and those from primary and metastatic lesions. Whole-exome and transcriptome sequencing of P7 cells from 8 HCC cases identified C > T/G > A transitions as the predominant substitution pattern, with mutational signatures 1, 3, 12, 15 and 30 being most prominent. Using NetMHCpan-4.1 algorithm, we successfully predicted potential neoantigens derived from these ascites P7 cells, including mutant peptides from TOP3A, TUBB6, NUTM2G, FGD2, NFKBIZ and CLDND1. Importantly, we detected neoantigen-specific T cells in HCC malignant ascites, which showed characteristic high expression of CD39.

4299 | ELECTROPORATION IN HEPATOCYTES TO EVALUATE A CELL-BASED GENE EDITING STRATEGY FOR TREATING HOMOZYGOUS FAMILIAL HYPERCHOLESTEROLEMIA

Callie Clark[1] Menam Pokhrel[1] Benjamin Arthur[1] Pramita Suresh[1] Ilayda Ates[1] Justin Gibson[1] Abishek Dhungana[1] Ryan Mehlem[1] Andrew Boysia[1] Mugdha Padalkar[2] Jing Echesabal-Chen[1] Anne Vonada[3] Alexis Stamatikos[1] Olga Savinova[2] Markus Grompe[3] Renee Cottle[1], [1]Clemson University, [2]New York Institute of Technology College of Osteopathic Medicine, [3]Oregon Health & Science University

Background: We previously showed that LNP-mediated delivery of cytochrome P450 oxidoreductase (*Cypor*)-Cas9 ribonucleoproteins (RNP) combined with transient APAP treatment enables selective liver repopulation and phenotypic rescue in a phenylketonuria mouse model. Separately, we demonstrated that electroporation of CRISPR-Cas9 mRNA and RNPs corrects hereditary tyrosinemia type I. Here, we apply electroporation of Cypor-targeting Cas9 RNPs into wild-type hepatocytes, followed by APAP-driven selection, as a potential cell therapy for homozygous familial hypercholesterolemia (*Ldlr*$^{-/-}$). **Methods:** Hepatocytes from C57BL/6J mice were electroporated with *Cypor*-Cas9 RNPs and transplanted into 6-week-old male *Ldlr*$^{-/-}$ mice. At 12 days post-transplantation, recipients were randomized to receive biweekly APAP injections (n = 8) or no treatment (n = 8). After 10 days of APAP selection, half of each group (n = 4) was switched to a Western diet. Blood was collected after a 5-hour fast at baseline, post-APAP selection, and after 5 weeks on the Western diet for lipid profiling (total cholesterol, LDL-C, TG). At study endpoints (post-APAP or 12-week Western diet), livers and hearts were collected for indel analysis, atherosclerosis quantification (Oil Red O staining), and assessment of liver and kidney function markers in serum. **Results:** We observed up to 13% engraftment of electroporated Cypor-deficient hepatocytes with indels in the livers of *Ldlr*$^{-/-}$ mice following APAP administration, while negligible engraftment was observed in no-APAP controls (mean 9% and 2%, respectively, p = 0.0121). Engraftment of Cypor-deficient Ldlr-expressing hepatocytes reduced total cholesterol (5%), LDL-C (18%), and TG (52%) levels relative to untransplanted *Ldlr*$^{-/-}$ mice on the 5-week Western diet, but did not mitigate aortic atherosclerosis or steatosis. While biochemical markers for liver damage normalized post-APAP, we observed lipid accumulation in Cypor-deficient hepatocytes of *Ldlr*$^{-/-}$ grafted mice maintained on a regular chow diet, likely due to impaired cholesterol metabolism and clearance resulting from *Cypor* disruption. **Conclusion:** In contrast to findings from phenylketonuria mouse model studies, the disruption of Cypor function in recipient *Ldlr*$^{-/-}$ mice could not be compensated by unedited native hepatocytes, suggesting that a one-size-fits-all gene editing cell-based therapy approach may not be viable for inherited metabolic liver diseases. In ongoing studies, we will evaluate the use of CRISPR-Cas9-mediated gene editing to disrupt Cyp enzymes required for APAP metabolism, specifically Cyp2E1, with and without simultaneous disruption of Cyp1A2. In contrast to Cypor knockdown, the simultaneous knockdown of Cyp2E1 and Cyp1A2 is predicted to clear lipids more efficiently from the liver.

4300 | NEXT GENERATION WHOLE EXOME SEQUENCING OF LIVER TISSUES IN INDIAN HEPATOCELLULAR CARCINOMA PATIENTS TO IDENTIFY THE ACTIONABLE MUTATIONS

Baibaswata Nayak[1] SONU KUMAR[1] Neeti Nadda[1] Dibyabhabha Pradhan[1] Shivanand Gamanagatti[1] Nihar Dash[1] . Shalimar[1], [1]All India Institute of Medical Sciences, New Delhi, India

Background: Hepatocellular carcinoma (HCC) is a primary malignancy of the liver and third leading causes of cancer-mortality worldwide. HCC occurs mostly in the background chronic liver disease (CLD) either due to viral (HBV and HCV) and non-viral (alcohol, Fatty liver) etiology. Hepatocarcinogenesis usually initiated from chronic necro-inflammation of liver resulting inflammation mediated DNA damage, somatic mutations, virus induced molecular alterations in cancer hallmark genes. HCC often diagnosed at an advanced stage and not

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

found suitable for curative surgical options and mostly managed by locoregional therapy (LRT) and systemic chemotherapy using multikinase inhibitor (MTKI), combination therapy of immune check-point inhibitor and VEGF inhibitor. Next Generation Sequencing (NGS) of liver tissue can reveal HCC tumor heterogeneity and molecular profile. It can identify actionable somatic mutations those can influence treatment decisions and selection of targeted therapies or immunotherapies. **Methods:** Trans-jugular liver biopsies (TJLB) samples were obtained from 20 HCC cases by interventional radiologist and surgically resected normal liver tissues from 10 disease control were taken by GI surgeon. The genomic DNA from liver tissues were isolated using the QIAamp mini genomic DNA isolation kit (Qiagen). Twist Human comprehensive exome kit was used for library preparation. Sequencing was performed on a NovaSeq 6000 platform 550 (Illumina, San Diego, USA) following the manufacture's instructions. Quality checks and analysis was performed using the GATK pipeline. Pathogenic/likely pathogenic exonic variants were annotated. Kyoto Encyclopaedia of Genes and Genomes (KEGG) and Gene ontology analysis was done for pathogenic / likely pathogenic variants and functional annotation was done using DAVID tool. **Results:** The HCC patients recruited (n = 20) are of both viral (75%) and nonviral (25%) etiology. The disease control (n = 10) included patients of periampullary carcinoma, carcinoma of gallbladder, oesophagus and pancreas. In whole exome sequencing, we observed pathogenic/ likely pathogenic mutations in 35 genes of HCC patients and 14 genes for disease control, of which 8 genes were common in both HCC and disease control. The somatic mutationswere observed in 27 genes were unique to HCC patients. Actionable mutations are functionally annotated to PD-L1/ PD-1 checkpoint pathway, VEGF, B and T cell receptor signalling pathway, chemical carcinogenesis, stem cells pluripotency signalling pathways and hepatocarcinogensis. The prevalent somatic mutations which could be considered as actionable mutation are KRAS (p.Q61H), PI3KCA (p.H1047R), PRKCQ (p.P330L, 30%), HSP27 (p.Q190H), NQO1 (p.P115S), CTNNB1 (p.D32G) and BCL10 (p.I46X). **Conclusion:** We have identified actionable mutations in HCC tissue which may contribute to clinical selection and modulate treatment response.

4301 | B-ARRESTIN2 FACILITATES LIVER REGENERATION IN CIRRHOSIS BY INHIBITING BECLIN1-MEDIATED FERRITINOPHAGY-DEPENDENT FERROPTOSIS

WenFeng Zhu[1] xijing yan[2] Genshu Wang[3] 小峰 蒋[4], [1]Second Affiliated Hospital of Guangzhou Medical University, [2]The third Affiliated Hospital of Sun Yat-sen University, [3]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangdong Provincial Hos, [4]The Second Affiliated Hospital of Guangzhou Medical University

Background: The presence of cirrhosis is a critical factor contributing to inadequate regeneration following partial hepatectomy (PHx), significantly impacting postoperative recovery and patient prognosis. Currently, the underlying mechanisms responsible for inadequate liver regeneration in the context of cirrhosis remain poorly understood, and effective clinical interventions to address regenerative deficits post-hepatectomy in cirrhotic patients are lacking. **Methods:** Initially, we conducted RNA sequencing on liver specimens obtained from both cirrhotic patients and healthy controls undergoing Associating Liver Partition and Portal Vein Ligation for Staged Hepatectomy (ALPPS) to elucidate the relationship between ferritinophagy-dependent ferroptosis and liver regeneration in the context of cirrhosis. Subsequently, employing mass spectrometry analysis on liver specimens from both cirrhotic and normal mice pre- and post-70% hepatectomy, alongside database predictions and investigations in β-arrestin2 (ARRB2) knockout mice and their wild-type counterparts, we elucidated the regulatory function of the ARRB2 protein in ferritinophagy within a cirrhotic environment. Furthermore, utilizing mass spectrometry analysis, molecular docking, and co-immunoprecipitation (Co-IP), we identified the potential mechanism through which ARRB2 modulates ferritinophagy. Ultimately, we explored the impact of the ARRB2 agonist carvedilol on enhancing liver regeneration in cirrhotic conditions. **Results:** Ferritinophagy was found excessively activated in cirrhotic liver, and inhibiting ferritinophagy could mitigate ferroptosis in the liver and enhance PHx regeneration in murine models of liver fibrosis. Subsequent investigations demonstrated a significant upregulation of ARRB2 expression during liver regeneration in mice with liver fibrosis, and ARRB2 facilitates liver regeneration by modulating ferritinophagy-dependent ferroptosis. Further mechanistic exploration revealed that ARRB2 can competitively bind with Beclin1 against Atg14. Preclinical validation indicated that carvedilol, an ARRB2 agonist, effectively inhibited ferritinophagy and promoted liver regeneration following PHx in fibrotic liver models.

4302 | MAPPING THE UNKNOWNS IN TUMOR EVOLUTION: SPATIAL TRANSCRIPTOMIC INSIGHTS INTO GENE EXPRESSION HETEROGENEITY AT THE HCC–DYSPLASTIC NODULE INTERFACE

Nigar Khurram[1], [1]University of Pittsburgh

Background: A comprehensive understanding of molecular, cellular, and tissue-level changes—and the dynamic interactions among diverse cell types—is essential for elucidating cancer development and progression. This is particularly crucial for characterizing the poorly understood transition from premalignant lesions to invasive carcinomas. At the hepatocellular dysplasia–carcinoma interface (HCC-DN), spatial transcriptomics (ST) enables high-resolution mapping of cellular composition and heterogeneity, offering insights into tumor initiation and progression, and identifying novel gene signatures that may guide personalized therapy and targeted treatments in HCC.We used GeoMx platform by Nansotring to further elucidiate HCC-DN interface areas. **Methods:** Slides were prepared according to the manufacturer's protocol without modification (Manual 10150-04, nanoString, Seattle, WA). FFPE samples were sectioned at 5 μm onto positively charged slides, dried overnight at 37° C, and stored at 4°C in sealed containers with desiccant (Drierite, Fisher Scientific) until use.
Antigen retrieval was performed using IHC Antigen Retrieval Solution (Invitrogen), followed by proteinase K digestion (Invitrogen) to expose mRNA. Whole transcriptome profiling was performed via in situ hybridization using HuWTA DNA oligonucleotide probes (nanoString), which contain UV-photocleavable linkers and unique molecular identifiers (UMIs) for downstream sequencing. SYTO13 nuclear stain was used for morphological reference.
Slides were imaged using the GeoMx Digital Spatial Profiler (nanoString) to generate whole-slide images at single-cell resolution. Circular regions of interest (ROIs; 600 × 785 μm) were selected based on SYTO13 staining and anatomical landmarks. UV light was used to photocleave bound oligonucleotides, which were aspirated from each ROI into individual wells of a 96-well plate.
Collected probes were processed and sequenced on an Illumina NextSeq 1000/2000. Sequencing depth was calculated from the total ROI area per sample. FASTQ files were decoded and processed into count matrices using the GeoMx NGS Pipeline (v2.0.21) in Illumina BaseSpace. Final count files were reuploaded and indexed to matched slide scans for spatially resolved transcriptomic analysis in the GeoMx DSP platform. **Results:** Spatial transcriptomioc analysis with GeoMx profiling showed HCC-DN interface with high SPP1 and ASPH (tumor markers) with extensive tumoral heterogeneity (see attached graphs for detailed analysis (word limit- full data presentedat conference). **Conclusion:** By leveraging spatial transcriptomics, we identified distinct gene expression profiles differentiating dysplastic tissue from invasive carcinoma, revealing a gradient of transcriptional and microenvironmental changes across this critical transition zone which serve as early biomarkers of malignant transformation for preventive intervention.

4303 | IDENTIFICATION OF KEY PROTEINS IN CIRRHOSIS PROGRESSION VIA A BIOLOGICAL NETWORK (RICH-CLUB) ANALYSIS APPROACH

Paola Barrios[1] Indira Pla[2] Praneet Polineni[1] Aniel Sanchez[2] Michael Caldwell[2] Therese Banea[1] Neil Kelleher[2] Carl Atkinson[1] Daniela Ladner[3], [1]Northwestern University Comprehensive Transplant Center, [2]Northwestern University, Proteomics Center of Excellence, [3]Northwestern Memorial Hospital

Background: Cirrhosis affects millions, with 5-7% annually progressing to decompensation, yet current diagnostics cannot reliably predict this transition and no therapies to halt progression are currently available, creating an urgent need for novel approaches to identify key drivers. **Methods:** Plasma samples from 30 cirrhosis patients at 3 stages (compensated, portal hypertension (pHTN), decompensated) were analyzed. Protein interaction networks were constructed using correlation analysis ($r > 0.7$) on top-down proteomics data previously published by our group. Rich-club (RC) analysis measured non-random interconnectivity among hub proteins. Raw (φ; fraction of possible

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

connections) and normalized RC coefficients (ρ; connectivity compared to 1,000 random networks) were calculated to identify and compare regulatory proteins (hubs) across stages. **Results:** Characterizing protein network: We analyzed 44 proteins across compensated, pHTN, decompensated cirrhosis. Connections per protein decreased from compensated (12.9) to pHTN (11.4) to decompensated (6.5), as did network density (0.6, 0.52, 0.48), revealing decreasing network complexity with disease progression (Fig 1A). Normalized network coefficients at $\rho > 1$ confirmed meaningful, non-random, biologically relevant networks (Fig 1B). Identifying significant proteins: Compensated cirrhosis exhibited RC structure at degree threshold $k = 6$ ($\varphi = 0.6$; $\rho = 1.44$) with 28 proteins having > 6 connections. Portal hypertension showed tighter RC at $k = 9$ ($\varphi = 0.8$; $\rho = 1.49$) with 23 proteins having > 9 connections. Decompensated cirrhosis showed RC at $k = 5$ ($\varphi = 0.7$; $\rho = 1.54$) with 18 proteins having > 5 connections, demonstrating network reorganization with fewer central hubs in decompensated cirrhosis. Identifying unique proteins: Apolipoprotein A-II (apoA-II) emerged as the sole unique hub protein in decompensated cirrhosis, and there were no unique hub proteins in pHTN. **Conclusion:** Protein networks show distinct Rich-Club organization across cirrhosis stages. pHTN exhibits highest raw RC coefficient and no unique hub proteins, suggesting tightly regulated adaptation of a compensated state. Decompensated cirrhosis shows breakdown of the protein network. ApoA-II emerged as a unique hub in decompensation, representing a potential biomarker to detect imminent decompensation before clinical signs appear.

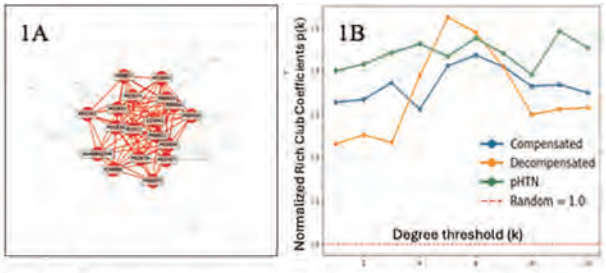

Fig 1A. Protein interaction network in decompensated cirrhosis.
Fig 1B. Normalized rich club coefficients (ρ) across different degree thresholds (k) for cirrhosis stages. Above the red dashed line (ρ>1.0) statistically significant rich club organization.

4304 | ESTABLISHMENT OF ASSAY LIMITS FOR DIFFERENTIAL GENE EXPRESSION AND DNA METHYLATION TO CHARACTERIZE SPECIFICITY OF EPIGENETIC EDITING

Erica Hildebrand[1] Amber DiPiazza[1] Ava Zhai[1] Alaina Villarreal[1] Parthu Koppana[1] Sameer Abraham[1] Xiaoyun Guo[1] Yasamun Rezvani[1] Jhon Medina[1] Yesseinia Anglero-Rodriguez[1] Melissa Bonner[1] Ricardo Ramirez[1], [1]nChroma Bio

Background: Epigenetic editing is a novel therapeutic modality that leverages DNA methylation with the intention to durably silence target genes at the level of transcription without cutting or nicking the DNA. Quantification of intended and unintended modifications of DNA methylation and gene expression are important for understanding the potential for therapeutic benefit and safety implications, respectively. A novel and comprehensive analytical approach was used to establish robust metrics for epigenetic specificity assessment. **Methods:** Control RNA and DNA experiments were utilized to determine the assay limits and data quality requirements for RNA-seq and both targeted and genome-wide (WGMS) DNA methylation assays. Appropriate thresholds and parameters for nominating differentially expressed genes (DEG) and differentially methylated regions (DMR) were established using a tool PCSK9 epigenetic editor (PCSK9-EE) in vitro in the Hep3B cell line, paired with an in silico mixing strategy. Finally, these data quality requirements and analysis parameters were applied to epigenetically edited primary cells. **Results:** To ensure robust detection of unique genes and coverage of CpGs, minimum sequencing depth requirements were determined for total RNA-seq libraries (> 50M read-pairs), targeted methylation sequencing (> 120M read-pairs), and WGMS (> 1B read-pairs). With these requirements, the LLOQ of the total RNA-seq assay was determined to be 585.94 attomoles/1 μg total RNA, which corresponds to 3.5 TPM. Analysis thresholds and parameters to nominate a DEG or DMR for confirmatory assays were determined by balancing detection of false positives with the detection of true positives using an in silico mixing strategy and parameter sweep for RNA-seq, targeted hybrid capture, and WGMS. Application of these data quality requirements and DEG/DMR specificity parameters demonstrate no substantial unintended increases in methylation with associated decreases in gene expression in an epigenetically edited primary cell experiment. **Conclusion:** We have established a robust standard for quantification of intended and unintended methylation and gene expression changes induced by epigenetic editors, a key component in the assessment of potential therapeutic

4305 | MACHINE LEARNING–BASED FRAMEWORK FOR EARLY DETECTION, SEVERITY STRATIFICATION, AND PROGNOSTIC MODELING OF LIVER DISEASE IN AN INDIAN PATIENT COHORT

Sri Harsha Boppana[1] Manaswitha Thota[2] Gautam Maddineni[3] Sachin Sravan Kumar Komati[4] Sai Lakshmi Prasanna Komati[5] C. David Mintz MD PhD[6], [1]Nassau University Medical Center / Johns Hopkins University, [2]Virginia Commonwealth University, [3]Creighton university school of medicine, [4]Florida International University, [5]Government Medical College, Ongole, [6]Johns Hopkins University

Background: Chronic liver conditions frequently remain asymptomatic until reaching advanced stages, posing a significant burden worldwide. We employed a combination of supervised and unsupervised machine learning methods—including random forest classification, k-means clustering, and long short-term memory (LSTM) networks. Our objectives were to improve early identification of liver disease, derive severity stages without predefined labels, and predict future bilirubin values and disease progression. **Methods:** Data were drawn from the Indian Liver Patient Dataset (583 records) containing demographic information (age, gender) and biochemical markers (total and direct bilirubin, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, total protein, albumin, albumin–globulin ratio). We imputed missing albumin–globulin ratios using the mean, encoded gender as a binary variable, and engineered interaction features (age × total bilirubin; gender × alkaline phosphatase). Continuous variables were standardized, and the cohort was split into 80% training and 20% testing sets. A random forest classifier distinguished diseased from non-diseased cases. To infer disease severity in an unsupervised manner, we applied k-means clustering (k = 3) on the normalized features and labeled clusters as mild, moderate, or severe based on their biochemical profiles. A second random forest was then trained on these inferred labels to predict severity in new patients. Finally, we generated synthetic longitudinal data by simulating five visits at 30-day intervals with added Gaussian noise. We trained LSTM networks to forecast next-visit bilirubin levels and severity stages using the previous three visits' data. **Results:** On the held-out test set, the disease classifier achieved 81.2% accuracy, with precision and recall both exceeding 0.80 for the positive class. Clustering produced three subgroups of roughly equal size, each characterized by distinct biochemical signatures. The severity classifier attained 99.1% accuracy in assigning mild, moderate, or severe labels. The bilirubin-forecasting LSTM yielded a mean absolute error of 1.07 mg/dL, while the severity-forecasting LSTM reached 96% overall accuracy and achieved an F1-score of 0.92 for the severe category. These outcomes demonstrate that a multi-modal machine learning pipeline can accurately detect liver disease, stratify its severity, and anticipate biomarker and stage trajectories. (Figure1). **Conclusion:** Our integrative approach—combining classification, clustering, and sequence modeling—delivered robust performance across key tasks: disease detection, severity stratification, bilirubin prediction (MAE = 1.07 mg/dL), and stage forecasting (96% accuracy). This framework shows promise for enabling earlier diagnosis, personalized risk assessment, and proactive management in liver disease care.

4306 | SHARED GENETIC VARIANTS BETWEEN LONG COVID AND VIRAL HEPATITIS B AND C INDIVIDUALS: ASSOCIATION WITH POLYMORPH IN THE PLXNA4 AND DPP9 GENES

Lucas da Silva[1] Douglas Maya-Miles[2] Juliana Maul[3] Iolanda Paulo[3] Lia Lewis[3] Vanessa de Paula[4] LIVIA VILLAR[5] Manuel Romero-Gomez[6], [1]Oswaldo Cruz Foundation, FIOCRUZ, Viral Hepatitis Laboratory, [2]SeLiver Group, Institute of Biomedicine of Seville, University of Seville, Seville, Spain., [3]National Reference Laboratory for Viral Hepatitis, Institute Oswaldo Cruz, Fiocruz, Rio de Janeiro, [4]Molecular Virology and Parasitology Laboratory, Institute Oswaldo Cruz, Oswaldo Cruz Foundation, [5]FIOCRUZ, [6]SeLiver Group, Institute of Biomedicine of Seville, University of Seville, Seville, Spain

Background: Long COVID is defined by symptoms lasting over 90 days after SARS-CoV-2 infection. It may share molecular and immune features with chronic infections like hepatitis B and C. Genetic factors, particularly single nucleotide polymorphisms (SNPs), influence susceptibility and disease progression. Studying SNPs in these conditions may uncover shared mechanisms. This study aims to investigate associations between specific SNPs and the presence of viral hepatitis B or C and Long COVID, exploring potential shared genetic signatures. **Methods:** 96 individuals were recruited from the Viral Hepatitis Outpatient Clinic, Fiocruz, Rio de Janeiro, Brazil. For analysis, participants were grouped as Hepatitis B and C carriers ($n = 49$) vs. non-carriers ($n = 47$), and Long COVID carriers ($n = 49$) vs. non-carriers ($n = 47$). Peripheral blood was collected for genomic DNA extraction (Qiagen). Eighteen SNPs were selected from literature related to COVID-19 and viral hepatitis. SNP genotyping was performed by real-time PCR (ThermoFisher) at the Institute of Biomedicine of Seville at the University of Seville, Spain, in collaboration with the SeLiver Group. Statistical analysis utilized the SNPStats tool. **Results:** Hepatitis carriers were significantly more probable to have the A allele of SNP rs1424597 G > A (*PLXNA4* gene, linked to a higher risk of long COVID-19), with 47.8% carrying this variant. This corresponded to a risk of more than double among this group (OR = 2.36; 95% CI: 1.01-5.49; $p < 0.05$). For Long COVID individuals, SNP rs12610495 A > G (*DPP9* gene, associated with clinical worsening and increased risk of developing Long COVID) was identified in codominant model as a risk factor in Long COVID individuals (OR = 2.41; 95% CI: 1.01–5.73). The A/G genotype was present in most Long COVID individuals (49%). Confirmed in the overdominant model, comparing A/G to homozygotes (OR: 2.44; CI 95%: 1.04–5.71). **Conclusion:** Genetic variants previously associated with long COVID have been identified as risk factors in individuals with hepatitis or long COVID, suggesting possible shared genetic pathways that contribute to chronicity in both conditions.

4307 | N-LOREM FOUNDATION: A NON-PROFIT BIOTECH IS TRANSFORMING THE LANDSCAPE OF PERSONALIZED MEDICINES IN GENETIC LIVER DISEASES

Konstantina Skourti Stathaki[1] Craig McIntosh[2] Lesley Saldana[2] Wei Zhang[2] Anthony Vu[2] Emily Miyoshi[2], [1]n-Lorem Foundation, [2]N-Lorem Foundation -

Background: The n-Lorem Foundation is pioneering a new paradigm in the development of individualized medicines for patients with ultra-rare genetic diseases. As a unique non-profit biotech, n-Lorem provides *free, lifetime treatment* to patients with liver genetic diseases who would otherwise be invisible to traditional drug development pathways- those with mutations found in one or a few individuals worldwide. **Methods:** In this presentation, we will share how we are building a scalable and sustainable model to treat liver diseases today that challenges the conventions of therapeutic development. Since our inception, we have received over 330 applications, launched more than 160 patient-directed drug discovery programs, submitted 25+ INDs, and treating 27 patients today. Our approach is deeply rooted in our over 35-year of experience in RNA-targeted therapies, especially antisense oligonucleotides (ASOs), offering precision tools that match the urgency and specificity of each patient's liver mutation and condition. **Results:** We will provide an overview of our mission and model, outline our end-to-end discovery and development process for two liver targets that we are developing ASOs for—one for a 9-month-old infant and another for a 13-year-old child—and discuss the scientific considerations that shape our work. We will also highlight how our close working relationship with the FDA, our unwavering focus on individual patients, and our deep scientific and clinical expertise are allowing us to deliver highly personalized RNA-targeted treatments for liver diseases where no other options exist. **Conclusion:** The n-Lorem Foundation is redefining what is possible in the treatment of ultra-rare liver genetic diseases by advancing a patient-first, mutation-specific approach to RNA-targeted drug development. Our model demonstrates that individualized, lifelong treatment can be both scientifically rigorous and operationally scalable. As we continue to expand our programs, we aim to set a precedent for how the rarest patients - those traditionally left behind - can be meaningfully and sustainably served. Our work offers

◆ 4308 | PARALLELIZED IN VIVO SCREENING IN A NON-HUMAN PRIMATE MODEL PREDICTS PHENOTYPIC EFFECTS OF GWAS VARIANTS AND CLINICAL OUTCOMES

Joanne Hsieh Jingshu Chen[1] Linda Chio[1] Christopher Carrico[1] Daniel Fuentes[1] Arnav Gupta[1] Shengping Wang[1] Vinay Kartha[1] Hikaru Miyazaki[1] Dimitry Popov[1] Chris Towne[1] Martin Borch Jensen[1] Francisco LePort[1], [1]Gordian Biotechnology

Background: Murine hepatic metabolism differs from humans in multiple pathways, including lipoprotein handling, bile acid production, and xenobiotic metabolism. Knocking out genes that were identified in human GWAS to be associated with MASLD, such as *Pnpla3* and *Hsd17b13*, showed very mild phenotypes in mouse models. One locus, *ADH1B*, is primate-specific. Modeling the functional effects of these human genetic associations may require a more translatable species. **Methods:** A male African Green Monkey (*Chlorocebus aethiops sabaeus*) was fed a high fat, cholesterol, and fructose diet for 82 weeks to induce MASH. A cocktail of barcoded AAV8 interventions was administered intravenously at a dose that transduced about 2% of hepatocytes to minimize crosstalk between perturbed cells. The left lobe was resected 6 weeks later. Individual hepatocyte transcriptomic responses to these interventions was profiled by single nucleus RNA-Sequencing. **Results:** The AAV8 cocktail induced transient hepatic inflammation that largely resolved within 6 weeks. The NHP recovered well post-partial hepatectomy, with continued weight gain for at least 6 months. Overexpression of *PNPLA3* I148M increased expression of inflammasome and senescence genes and reduced hepatocyte support for micronutrient delivery. Overexpression of the *HSD17B13* transcript isoform D reduced genes in the complement and coagulation pathways. *ADH1B* overexpression, mimicking the protective *ADH1B*2* allele, enhanced NAD generation, mitochondrial oxidation, and anaplerotic pathways. Ectopic hepatocyte expression of a GLP-1 analogue reduced expression of genes involved in cholesterol, glycosphingolipid, and sphingomyelin synthesis. These changes were unexpected, as hepatocytes lack GLP-1R, implying a paracrine mechanism driven by GLP-1R agonism in neighboring cells. C57Bl/6N mice fed an obesogenic MASH diet and treated daily with semaglutide lost weight rapidly during the first 2 weeks. Thereafter, semaglutide-treated animals resumed weight gain at rates similar to vehicle-treated animals, yet ALT remained suppressed. **Conclusion:** Our target discovery platform enables multiple hepatocyte-directed interventions to be queried in a single NHP without euthanizing the animal. We were able to detect changes induced by a GLP-1 analogue at the hepatocyte level through second-order transcriptomic effects. Some beneficial effects of GLP-1 on hepatocytes therefore appear to occur through paracrine interactions and independent of weight loss.

◆ 4309 | FECAL MICROBIOTA TRANSPLANTATION IMPROVES GUT MICROBIAL DIVERSITY AND REDUCES ANTIMICROBIAL RESISTANCE IN CIRRHOSIS: RESULTS: FROM A RANDOMIZED CONTROLLED TRIAL

Ankit Agarwal[1] Samagra Agarwal[1] Daizee Talukdar[2] Sagnik Biswas[1] Bhabatosh Das[2] . Shalimar[1], [1]All India Institute of Medical Sciences, New Delhi, [2]Microbial Research Centre, BRIC-THSTI, Faridabad, Haryana

Background: Fecal microbiota transplantation (FMT) has demonstrated clinical benefits in conditions such as *Clostridioides difficile* infection and inflammatory bowel disease. Emerging evidence also suggests that FMT may reduce hepatic encephalopathy recurrence rates. In this randomized trial, we evaluated whether two infusions of FMT could enhance the resolution of minimal hepatic encephalopathy (MHE) and modulate gut microbiota composition and antimicrobial resistance (AMR), compared to standard daily lactulose therapy. **Methods:** In this randomized trial, 130 patients with cirrhosis and MHE (1:1) received either two sessions of FMT (one-month apart) or daily oral lactulose for 3 months. The primary outcome was MHE resolution at 3 months (PHES $>$ -5). Gut microbiome composition was analyzed using targeted metagenomic sequencing via next-generation sequencing (NGS). To

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

assess the antimicrobial resistance (AMR) gene profile, fecal samples were screened with gene-specific oligonucleotide probes targeting 16 distinct resistance genes. **Results:** Of 122 patients analyzed (FMT: 60; lactulose: 62; age: 44.3 ± 8.9 years; 96.7% male; Child A/B/C: 32.1% / 53.3% / 14.6%; median MELD: 13), 3-months MHE resolution was similar between FMT and lactulose group (68.3% vs 66.1%; p = 0.80). A total of 172 fecal samples were analyzed, including paired samples from FMT arm: 37/60 (61.7%) and lactulose arm: 46/62 (74.2%). FMT resulted in a modest, non-significant increase in microbial richness, as assessed by the Observed and Chao1 indices. At the taxonomic level, *Bifidobacterium* was significantly enriched in the MHE responders (3 months post-treatment) compared to the non-responders within the FMT cohort (p = 0.02), a difference not observed in the Lactulose group (p = 0.69). Conversely, *Escherichia* (p = 0.20) and *Enterococcus* (p = 0.37) showed lower mean relative abundances in the MHE responders after FMT at 3 months. Functional pathway analysis identified upregulation of creatinine degradation in the MHE responders (Figure). Notably, AMR gene prevalence was higher in the MHE non-responders across both treatment arms. **Conclusion:** While both FMT and lactulose demonstrated comparable efficacy in improving MHE, FMT offered additional benefits, including enhanced gut microbial diversity and a reduction in AMR. Larger, multicenter studies with longer follow-up are required to validate our findings and optimise FMT protocols for clinical use.

◆ 4310 | AN INNOVATIVE DREAM (DISTAL RECIRCULATION OF ENTERAL CONTENTS AUGMENTED MECHANICALLY) PROTECTS AGAINST LIVER INJURY AND PROMOTES INTESTINAL ADAPTATION

Shaurya Mehta Kento Kurashima[1] chandrashekhara manithody[1] Ashlesha Bagwe[1] Marzena Swiderska-Syn[1] Austin Sims[1] Sree Kolli[1] Aditya Jain[2] Miguel Guzman[1] Sherri Besmer[1] Sonali Jain[1] Paula Buchanan[1] Keith Pereira[1] Chien-Jung Lin[1] John Long[1] Matthew McHale[1] Chelsea Hutchinson[1] Ajay Jain[1], [1]Saint Louis University, [2]Johns Hopkins University

Background: Short bowel syndrome (SBS) prevents sustenance of nutritional needs via regular enteral nutrition (EN) and requires parenteral nutrition, resulting in detrimental side effects. Intestinal adaptation (IA), which is driven by EN remains a major goal. We have developed a revolutionary DREAM system (Distal Recirculation of Enteral contents Augmented Mechanically, US patent 63/413,988), Fig 1-1, which allows full EN despite SBS and tested its impact on SBS related complications. **Methods:** 20 neonatal pigs were randomly allocated to EN, SBS (75% bowel resection) or DREAM. Weight gain, serum chemistries, cytokines, intestinal morphology, tight junction integrity, hepatic histology, and gene expression were analyzed. **Results:** DREAM animals demonstrated significant attenuation of liver and intestinal injury compared to SBS. DREAM reduced serum bilirubin (0.11 mg/dL vs. SBS 5.14 mg/dL, $p = 0.0008$), GGT (23.2 IU/L vs. SBS 114.6 IU/L, $p < 0.0001$), and total bile acids (9.7 μmol/L vs. SBS 39 μmol/L, $p = 0.0026$), Fig 1-2. DREAM also normalized inflammatory cytokines (e.g., IFN-γ, $p = 0.0296$; IL-1β, $p = 0.0349$; IL-6, $p = 0.0189$) and decreased LPS levels ($p = 0.0130$) versus SBS, Fig 1-3. DREAM preserved hepatic expression of BSEP and Cyp7A1 ($p = 0.0034$ vs. SBS), restored intestinal EGF and TGR5 signaling ($p < 0.01$), and reduced hepatic cholestasis scores ($p = 0.0012$ vs. SBS), Fig 1-4. IA markers, including linear gut density (proximal: 0.237 g/cm vs. SBS 0.121, $p = 0.0042$), villus-to-crypt ratio ($p = 0.0026$), Fig 1-5, and tight junction protein

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

expression (e.g., Occludin, $p < 0.0001$; E-cadherin, $p = 0.0002$) mirrored EN animals and significantly improved with DREAM, Fig 1-6. DREAM reduced transcriptional dysregulation, Fig 1-7 and reactivated key functional pathways, resulting in a gene expression profile more similar to EN, Fig 1-8. Macronutrient absorption from recirculated enteral feeds was rapid and sustained, with >80% absorption of protein and fat by 6 hours ($p < 0.0001$), Fig 1-9. **Conclusion:** DREAM enables full EN despite SBS to restore nutrient absorption and gut derived signaling, mitigating intestinal and hepatic injury. This innovative, translation system highlights a major advancement in SBS management bringing a paradigm shift to life saving strategies for SBS patients.

◆ 4311 | TARGETING THE GUT–LIVER AXIS: GRAPHENE OXIDE NANOPARTICLES RESTORE BARRIER FUNCTION, REBALANCE MICROBIOTA, AND SUPPRESS MIR-203A–TLR4 PATHWAY IN ALCOHOL ASSOCIATED LIVER DISEASE

Hiral Aghara[1] Manali Patel[2] Prashsti Chadha[2] Palash Mandal[2], [1]Department of Biological sciences, [2]P D Patel Institute of Applied Sciences

Background: Alcohol-induced liver disease (ALD) remains a major global health concern, driven in part by chronic gut barrier dysfunction, microbial imbalance (dysbiosis), and inflammation. Excessive alcohol consumption disrupts intestinal tight junctions, increasing gut permeability and allowing toxic microbial metabolites to translocate to the liver via the portal vein. This promotes liver inflammation through the activation of the TLR4 signalling pathway, a process exacerbated by the upregulation of miR-203a. Graphene oxide nanoparticles (GONPs) have shown potential as anti-inflammatory and antioxidant agents. In this study, we explored whether GONPs could protect against ALD by restoring gut barrier integrity, rebalancing gut microbiota, and modulating inflammatory responses. **Methods:** Male Wistar rats (n = 6 per group) were allocated into five groups: Control, Diseased (ethanol-fed), Pair-fed,

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

GONPs alone, and Treatment (ethanol + GONPs). Control and GONPs groups received standard chow diet, while the Diseased, Pair-fed, and Treatment groups were fed Lieber-DeCarli liquid diets. The Pair-fed group received an isocaloric maltodextrin substitute, while Diseased and Treatment groups received 5% ethanol continuously for 28 days, with binge doses of 30.5% ethanol administered for 2 consecutive days every 10 days. GONPs were administered orally five times during the study at 5-6 day intervals. Fecal samples underwent 16S rRNA gene sequencing for microbial analysis. Colon and liver tissues were evaluated histologically by hematoxylin and eosin staining. RT-qPCR assessed expression of tight junction genes and miR-203a. **Results:** GONPs treatment led to notable changes in the gut microbial community, including an increase in short-chain fatty acid producing bacteria associated with intestinal health. Histological analysis revealed improved colonic architecture and tight junction preservation in GONP and ethanol treated rats compared to the ethanol-only group. Gene expression analysis showed enhanced expression of tight junction markers (Zona occludin-1, Occludin and Claudin) of colon and reduced levels of miR-203a of liver tissue. These molecular changes were accompanied by decreased activation of the TLR4 pathway and reduced liver inflammation like TNF-α. **Conclusion:** Our findings suggest that GONPs offer protective effects against alcohol-induced liver injury by strengthening the gut barrier, restoring microbial balance, and down-regulating the miR-203a–TLR4 inflammatory axis. This study highlights the promise of GONPs as a novel nanotherapeutic strategy for managing ALD by targeting the gut–liver axis.

◆ 4312 | EXTENT OF BILIARY β- AND γ-CATENIN LOSS REGULATES INTESTINAL INFLAMMATION AND MICROBIOME DYSBIOSIS IN CHOLESTATIC MICE

Vik Meadows[1] Chang Kyung (Joanna) Kim[1] Elena Provencal[1] Minakshi Poddar[1] Satdarshan (Paul) Monga[1], [1]University of Pittsburgh

Background: Loss of β- and γ-catenin in cholangiocytes disrupts bile duct structure, leading to impaired bile flow and subsequent bile leakage. The expression of cholangiocyte markers in hepatocytes suggests that hepatocyte transdifferentiation may aid in repairing β- and γ-catenin-deficient bile duct loss over time. The response of the intestinal and gut microbiome to bile duct loss or hepatocyte transdifferentiation has not been studied. In this study, we characterize gut pathology and microbiome composition in models of acute and reparative cholestasis through the deletion of β- and γ-catenins from the biliary epithelium. **Methods:** We utilized Ctnnb fl/fl; Jup fl/fl mice with Opn-iCreERT2+/- to delete both β-catenin (Ctnnb1) and γ-catenin (Jup) from cholangiocytes. Littermate control with no Opn-iCreERT2+/+ were used as controls. All mice received tamoxifen (100 mg/kg) dissolved in corn oil injected intraperitoneally. Mice were randomly assigned to two groups: DKO2 received 2 doses of tamoxifen and DKO4 received 4 doses of tamoxifen. Male and female mice were used in this study. Plasma, liver, ileum, colon, feces, and cecum content were collected from all mice. **Results:** DKO4 mice exhibited increased morbidity with over 20% body weight loss, along with elevated serum levels of ALT, AST, and total bilirubin compared to DKO2 and control mice. DKO4 mice show reduced fecal TBA levels and circulating secondary bile acids compared to DKO2 and control mice. DKO2 mice display decreased fecal TBA two weeks after tamoxifen injection, which is restored by six weeks post-injection. DKO4 mice demonstrate significant inflammation, an increased number of goblet cells per crypt/villi unit, a rise in lysozyme-positive cells in the ileal villi, and heightened fecal lipocalin 2 levels compared to DKO2 and control mice. Additionally, microbial sequencing indicates that DKO4 mice have an increase in pathogenic bacterial genera, such as Prevotella, compared to WT mice, suggesting a favorable environment for pathobiont expansion due to decreased bile acid

circulation. **Conclusion:** Dual loss of β- and γ-catenin from cholangiocytes causes severe intrahepatic cholestatic injury in mice which disrupts ileal epithelial cell populations. Severe bile duct loss in DKO4 mice results in decreased colonic mucin production and increased colonic inflammation, suggesting that bile duct health may influence gut function and bacterial clearance. Understanding the role of cholangiocytes in the gut-liver axis may assist in patient stratification based on fecal biomarkers and microbial signatures.

◆ 4313 | INDOLE-3-LACTIC ACID DERIVED FROM LACTOBACILLUS SALIVARIUS ENHANCES NK CELL FUNCTION VIA THE MAPK PATHWAY TO SUPPRESS HEPATOCELLULAR CARCINOMA PROGRESSION

Zhewen Zhou[1] Xuefeng Huang[1] Yipeng Wang[1] Huichun Xing[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Lactobacillus species, as dominant beneficial members of the gut microbiota, have been increasingly supported by evidence indicating their antitumor activity through immune modulation. Our previous studies demonstrated that Lactobacillus salivarius alleviated alcoholic hepatitis in murine models; however, its mechanistic involvement in hepatocellular carcinoma (HCC) has yet to be elucidated. Natural killer (NK) cells are critical effectors in tumor immune surveillance. This study aimed to evaluate the therapeutic potential of L. salivarius and its metabolite indole-3-lactic acid (ILA) in HCC and to explore the potential mechanisms underlying the antitumor effects of ILA. **Methods:** A subcutaneous Hepa1-6 tumor model was established in C57BL/6 mice. Metabolomic profiling of L. salivarius culture supernatant was performed using liquid chromatography–mass spectrometry (LC-MS). The effects of L. salivarius and ILA on Hepa1-6 tumors and HepG2 cells were assessed. NK cell infiltration and function in tumors and spleens, as well as in vitro NK activity, were analyzed by flow cytometry. Integrated multi-omics analyses, including RNA-seq, ChIP-seq, and ATAC-seq, were conducted to elucidate the molecular mechanisms regulated by ILA. **Results:** Oral administration of L. salivarius significantly inhibited Hepa1-6 tumor growth in vivo, enhanced NK cell infiltration and functional activation in the tumor microenvironment, and increased splenic NK cytotoxicity. In parallel, its culture supernatant inhibited HepG2 cell proliferation and migration and induced apoptosis, with metabolomic analysis identifying ILA as the principal active compound. In vivo experiments confirmed that ILA alone also suppressed tumor growth and enhanced NK cell function. In vitro, ILA markedly promoted the tumor-killing capacity of NK cell lines. Mechanistically, ILA induced chromatin remodeling and upregulated MAP3K8, thereby activating the MAPK signaling pathway and enhancing NK cell activation and cytotoxic function. **Conclusion:** L. salivarius and its metabolite ILA exhibit inhibitory effects against HCC. Epigenetic upregulation of MAP3K8 and activation of the MAPK pathway, resulting in enhanced NK cell–mediated antitumor immunity, may represent one of the key mechanisms underlying the antitumor action of ILA. This study provides a basis for developing microbiota-derived immunotherapeutic strategies targeting HCC.

◆ 4314 | ENTEROCYTES REGULATE HEPATIC BILE ACID SYNTHESIS IN CO-CULTURED GUT AND LIVER ORGANOIDS WITH INTERRUPTION UPON SIRNA TRANSFECTION

Shaurya Mehta[1] Ashlesha Bagwe[1] chandrashekhara manithody[1] Kento Kurashima[1] Sree Kolli[1] Miguel Guzman[1] Uthayashanker Ezekiel[1] Ajay Jain[1], [1]Saint Louis University

Background: Intestinal failure-associated liver disease (IFALD) is driven by bile acid dysmetabolism, yet the mechanisms underlying gut-liver signaling remain incompletely understood. The enterohepatic circulation plays a crucial role in bile acid homeostasis, with enterocyte-derived fibroblast growth factor 19 (FGF19) regulating hepatic bile acid synthesis via CYP7A1 suppression. To evaluate this complex interaction, we developed a physiologically relevant human enteroid–liver organoid co-culture transwell system to assess hepatic responses to enterocytes exposed to FXR ligands. **Methods:** We developed a human protocol for matrigel-based 3D culture systems to generated enteroids from the small bowel biopsies from humans. Human enteroids and liver organoids were co-cultured in a transwell system to assess bile acid–induced gut-liver crosstalk. RNA strands for Dicer-substrate siRNAs (DsiRNAs) were synthesized as single-strand RNAs (ssRNAs) by Integrated DNA Technologies and resuspended in an RNase-free buffer. DsiRNA targeted Sus scrofa, FXR gene (KF597010.1). Porcine enteroids were cultured and transfected with FXR-specific siRNA and control siRNA using Lipofectamine RNAiMAX reagent. Enteroids were treated with escalating CDCA concentrations (25μM to 50μM) for 24 and 48 hrs. Real-time PCR and functional assays were performed to assess changes in bile acid uptake and efflux following transfection. **Results:** 50 μM CDCA treatment of human enteroids led to increased 2-fold increase in FXR expression, with inhibition of hepatic CYP7A1 in co-cultured liver organoids, confirming a regulatory gut-liver signaling axis. To test mechanisms, we used our established porcine enteroids. Data from 3 separate experiments of intestinal crypts showed similar results in enhanced FXR expression with CDCA against control ($p < 0.01$). CDCA resulted in a dose-dependent increase in FXR mRNA expression, reaching peak levels after 48 hours of exposure (2.8X increase) with enhanced nuclear localization. Functionally, CDCA-treated enteroids displayed increased bile acid uptake and reduced efflux, validating FXR's role in mediating bile acid driven enterohepatic circulation. There was a 68% reduction in FXR expression against scramble. FXR silencing led to decreased bile acid uptake and increased efflux. No significant effects were observed in enteroids transfected with control siRNA. **Conclusion:** The human enteroid–liver organoid co-culture system provides an ex vivo model for studying enterohepatic circulation and shows hepatic bile acid metabolism is regulated by enterocytes in IFALD. By mimicking the cellular architecture and function of the gut-liver axis, this human system enables studies of interorgan signaling pathways and holds significant promise for identifying therapeutic targets for IFALD and other bile acid–related disorders.

4315 | EARLY SHIFT IN GUT MYCOBIOME EXACERBATES ALCOHOLIC LIVER DISEASE PROGRESSION

Satya Priya Sharma[1] Ki Tae Suk[1], [1]Institute for Liver and Digestive Diseases, Hallym University, Chuncheon, Republic of Korea

Background: Despite its minor but crucial representation in gut, the role of gut fungal community remains underexplored particularly in alcohol-associated liver disease (ALD). Here, we meticulously assessed the pathophysiological role of gut mycobiome, in ALD severity progression. **Methods:** Feces collected from 68 ALD and 21 healthy individuals for Internal Transcribed Spacer 2 (ITS2) based comparative mycobiome assessment, followed a by gut fungal and bacterial suppressed NIAAA alcoholic mice model to explain the role of gut fungus in ALD. **Results:** MELD score-based classification showed a decisive MELD score severity-associated shift in fecal fungal ecology in ALD, while target read counts followed the MELD score severity pattern, but no changes were observed in operational taxonomic units (OTUs) or in alpha diversity indexes. Significant alterations occurred in phylum's (Basidiomycota, Plantae_p, and Mucoromycota) and in genus (*Saccharomyces*, *Kazachstania*, *Geotrichum*, and *Trichosporon*). Among 105 common fungal species, 3 (*S. cerevisiae*, *S. kudriavzevii*, and *A. penicillioides*) exhibited ALD-associated rises. Fungus species including *A. penicillioides* (AUC: 0.82) and *P. polonicum* (AUC: 0.80) served as biomarkers, and their combined ability improved the AUC upto 0.87. Interestingly, alcohol-producing fungal species showed significant increments in ALD patients, with their highest abundance observed at the early stage of ALD, and inversely correlated with MELD scores. Furthermore, antibiotic treatment (ABX),

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in NIAAA murine model showed significantly higher mortality, decreased body weight and liver weight compared to the alcoholic control and antifungal treatment groups, ABX also presented elevated serum AST, cholesterol, and total bilirubin levels, and upregulated the expression of alcohol dehydrogenase (***ADH1***) and Cytochrome P450 IIE1 (***CYP2E1***) genes involved in oxidative alcohol metabolism in the liver. Total fecal fungal load increased significantly in ABX treatment group compared to other groups. Relative expression of liver fibrotic markers genes such ***TGF-β***, ***TNF-α***, ***Col1a1*** and ***ACTA2*** showed significant increment in ABX group. **Conclusion:** Chronic alcohol abuse significantly altered the gut fungal composition at early stage of the ALD and potentially exacerbating ALD severity.

4316 | "BACTEROIDETES ENRICHMENT INFLUENCES HEPATOCELLULAR CARCINOMA PROGRESSION AND RESPONSE TO IMMUNOTHERAPY"

Marina Barcena Varela[1] Joan Shang[2] Ilaria Mogno[2] Anthony Lozano[3] Jeremiah Faith[2] Amaia Lujambio[3],

[1]Instituto de investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain, [2]The Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, USA., [3]Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, USA.

Background: The gut microbiome plays a critical role in cancer progression and response to immunotherapy, but its impact on hepatocellular carcinoma (HCC) remains poorly understood. **Methods:** We analyzed 81 stool samples from 10 responders and 40 non-responders with HCC treated with immune-checkpoint blockade (ICB). To investigate the role of gut microbiome in HCC, we used mouse models of HCC driven by MYC and CTNNB1 mutations, incorporating a luciferase reporter fused to model tumor-associated antigens (TAAs). We manipulated the gut microbiome composition *in vivo* by antibiotic-induced dysbiosis and fecal microbiome transplants (FMT) from patient´s stools. We also colonized mice with specific bacteria (*Bacteroidetes* species) isolated from patient's samples. **Results:** We identified an enrichment of the *Bacteroidetes* phylum in non-responders HCC patients to ICB. We found that antibiotic-induced dysbiosis accelerated tumor growth in TAA-expressing tumors, accompanied by enrichment of *Parabacteroides distasonis*. Colonization with this strain alone promoted tumorigenesis *in vivo*. Transferring human microbiota from a high-*Bacteroidetes* non-responder donor also enhanced tumor growth compared to microbiota from a responder with low-*Bacteroidetes*. A cocktail of six *Bacteroidetes* strains, isolated from the same non-responder donor, replicated the protumoral effect in colonized mice. Importantly, these microbiome-driven effects depended on TAA expression; tumors lacking immunogenic TAAs were unaffected in any of the tested conditions. **Conclusion:** Our findings highlight *Bacteroidetes* enrichment as a potential biomarker of ICB resistance in HCC and show that microbiome composition can modulate HCC progression in an antigen-dependent manner.

4317 | MUCOSAL MICROBIOTA ALTERATION IN PRIMARY SCLEROSIS CHOLANGITIS PERSISTS AFTER LIVER TRANSPLANTATION AND IS ASSOCIATED WITH CLINICAL FEATURES INDEPENDENTLY OF GEOGRAPHY

Lukas Bajer[1] Petra Polakovicova[1] Marie Heczkova[1] Kristian Holm[2] Mikal Jacob Hole[2] Mojmir Hlavaty[1] Alena Bohdanecka[1] Pavel Drastich[1] Filip Tichanek[1] Malin Meyer-Myklestad[3] Asle Medhus[4] Dag Reikvam[4] Kristin Kaasen Jørgensen[2] Jan Brezina[1] Peter Macinga[1] Pavel Wohl[1] Johannes Hov[5] Monika Cahova[1], [1]Institute for Clinical and Experimental Medicine, Prague, [2]Norwegian PSC Research Center, Oslo, [3]Oslo University Hospital, Oslo, [4]Institute of Clinical Medicine, University of Oslo, Oslo, [5]University of Oslo

Background: Primary sclerosing cholangitis (PSC) is a chronical progressive liver disease with multi-factorial pathogenesis involving gut microbiota. Majority of PSC patients develop inflammatory bowel disease (IBD). In previous studies, PSC and PSC-IBD were associated with specific gut microbiota alterations. However, there is a lack of data on microbiota alteration in context of liver transplantation (LTx) for PSC. In this multicentric cross-sectional study, we aimed to explore the disease-specific mucosal microbial pattern independent of regional conditions with respect to LTx, gut inflammation, and PSC recurrence (rPSC). **Methods:** Sequencing of the 16S ribosomal RNA gene (V3–V4) isolated from ileocolonic biopsies was performed on 115 PSC patients (pre_LTx), 159 patients after liver transplant for PSC (post_LTx) and 96 healthy controls (HC) from the Czech Republic and Norway. For the purpose of statistical correlation, clinical data and laboratory results were obtained at the time of sampling. Sequencing data were processed with QIIME 2 and all statistical analyses were conducted using R v4.3.1. **Results:** Alpha diversity was lower in all PSC groups compared with HC. Elastic Net model discriminated well both pre_LTx (avg_AUC ileum 0.97; colon 0.93) and post_LTx PSC patients (avg_AUC ileum 0.97; colon 0.97) from HC, while the separation between pre_LTx and post_LTx (avg_AUC ileum 0.83; colon 0.83) was less precise. The model's performance on merged and cohort-specific datasets was comparable. The shared cohort-independent PSC microbiota was dominated by *Enterococcus*, *Pseudomonas*, *Veillonella*, *Klebsiella*, and *Streptococcus*, while some common commensals were underrepresented. Microbial Dysbiosis Index negatively correlated with alpha diversity and serum albumin, while a positive correlation was observed with markers of cholestatic disease (ALP, GGT) and liver fibrosis (APRI). Although no rPSC microbiota signature reached statistical significance, several genera deregulated in pre_LTx PSC (*Klebsiella*, *Bilophila*, *Coprococcus*, *Odoribacter*) showed similar trend in rPSC. Microbial composition analysis revealed no significant differences in alpha diversity, beta diversity, or the relative abundance of any bacterial taxa between PSC patients with and without IBD. **Conclusion:** This international cross-sectional study represents the largest sample-size up-to-date in patients after liver transplant for PSC and it provides a novel insight to mucosa-associated dysbiosis in patients with PSC. The results demonstrated a distinct mucosal microbiota composition associated with PSC persisting after LTx which correlates with serological and clinical features of advanced liver disease. The results suggest a microbial shift driven by rPSC which will be studied in a subsequent prospective cohort.

4318 | A GUT METAGENOMIC PROFILE DISTINGUISHES COMPENSATED CIRRHOSIS FROM HEALTHY CONTROLS ACROSS MULTIPLE COUNTRY COHORTS

Darja Nikitina[1] Aldo Torre[2] Ki Tae Suk[3] Ramazan Idilman[4] Mario Alvares-da-Silva[5] Mette Lauridsen[6] Satya Priya Sharma[7] Edita Kiudeliene[1] Elise Jonasson[8] Andrew Fagan[9] Alexander Khoruts[10] Jurgita Skieceviciene[11] Masoumeh Sikaroodi[12] Juozas Kupcinskas[13] Patrick Gillevet[12] Jasmohan Bajaj[14], [1]LSMU, Lithuania, [2]Nutricion Mexico City, [3]Hallym University, Korea, [4]Ankara University, Turkiye, [5]Hospital de Clínicas de Porto Alegre, [6]University of Ejsberg, Denmark, [7]Hallym University, [8]University of Ejsberg, [9]Richmond VAMC, [10]University of Minnesota, [11]LSMU, [12]GMU, [13]LSMU Lithuania, [14]Virginia Commonwealth University

Background: Cirrhosis is increasing in prevalence but is hard to diagnose in the compensated stage. Gut microbiota are altered in cirrhosis, but studies find greatest differences centered on the easily diagnosable decompensated cirrhosis. Also there are major country-level variations. **Aim:** determine a gut metagenomic signature separating compensated cirrhosis from healthy controls across a global cohort. **Methods:** Compensated cirrhosis (comp) patients & healthy controls were recruited from seven countries. Clinical data, including demographics, cirrhosis severity (MELD, complications, medications), & dietary were collected. Stool samples underwent deep metagenomic sequencing & analysis using MetaPhlAn & MaAsLin2.
Model evaluation was performed using repeated stratified 3-fold cross-validation with SMOTE applied within each training fold to address class imbalance. Models were trained on 70% of the full dataset & internally validated on the remaining 30%. Random forest (RF) model performance was assessed on the held-out test folds only. The final model was also tested separately in each country cohort. **Results:** We enrolled 618 participants (Comp = 299; controls = 319) from 7 countries (USA n = 109, Türkiye n = 95, South Korea n = 99, Denmark n = 66, Lithuania n = 72, Brazil n = 101, & Mexico n = 85) . Comp pts were older (59 ± 9 vs 50 ± 16, $p < 0.001$) & more likely to be men (57 vs 42%, $p < 0.001$) consistently across countries. Major etiologies were alcohol 25%, HCV 24%, MASH 21% & HBV 16%.
Microbiome analysis: Shannon diversity & richness (FigA) were lower in comp in all countries except Türkiye & Denmark (where only richness showed a significant decrease). β-diversity adjusting for demographics showed significant differences in microbial community structure between comp & controls.
Microbial differences: In the entire cohort, 381 species were significantly different between controls and comp. 6 species were significantly different in five of seven countries. A set of 182 bacteria, significantly different in ≥ 2 countries, was selected as input features for RF model development. The final RF model, consisting of 40 species (*Erysipelatoclostridium ramosum, Streptococcus anginosus, Veillonella parvula, Rothia mucilaginosa, Eubacterium rectale, Coprococcus catus, Bifidobacterium dentium,* & *Parabacteroides goldsteinii* among others), achieved an AUC of 80.6% with an NPV of 83.2% (Fig B). Country-specific testing of the globally trained model demonstrated consistently strong within-cohort performance across all seven countries (Fig C). **Conclusion:** Gut metagenomic profiles effectively distinguish compensated cirrhosis from healthy controls across diverse geographic populations with granular metadata. Despite inter-country variability, a shared subset of bacterial features enabled robust and consistent model performance. These findings support the potential of microbiome-based tools for early detection of cirrhosis.

4319 | MODIFIED FORMS OF SECONDARY BILE ACID LEVELS COULD BE BIOMARKERS OF HEPATOCELLULAR CARCINOMA PATHOGENESIS IN STEATOTIC LIVER DISEASE PATIENTS

Yoshimi Yukawa-Muto[1] Hideki Fujii[1] Tomonori Kamiya[1] Norifumi Kawada[1] Naoko Ohtani[1], [1]Osaka Metropolitan University

Background: Gram-positive gut microbial metabolite deoxycholic acid (DCA) has been reported to promote MASLD-associated hepatocellular carcinoma (HCC) development in mice (*Nature*, 2013). Recent studies also suggest that specific bile acids accumulate in HCC and suppress anti-tumor immunity (*Science*, 2025). Given the recent redefinition of fatty liver disease under the term steatotic liver disease (SLD), we analyzed serum bile acid profiles in HCC patients with MASLD, MetALD, and ALD to identify novel pathophysiological mechanisms involved in hepatocarcinogenesis. **Methods:** The study includes 30 healthy controls (HC), 50 MASLD patients (35 non-HCC and 15 HCC), and Alcohol-Associated group (MetALD and ALD) patients (10 non-HCC and 12 HCC). The comparative analyses were conducted measuring a series of serum bile acid levels as follows: a) a comparative analysis between two subgroups among 15 HCC patients: 6 patients with ursodeoxycholic acid (UDCA) treatment and 9 patients without UDCA treatment. b) a comparative analysis across three groups of HC, MASLD-non-HCC and MASLD-HCC. c) a comparative analysis across three groups of HC, Alcohol-Associated-non-HCC and Alcohol-Associated-HCC. These comparisons were performed excluding patients taking UDCA. **Results:** a) In the UDCA-treated group, levels of UDCA and its glycine and taurine conjugates were significantly higher than in the untreated group. However, no significant differences were detected in other bile acid levels. b) In the HCC group, glycine and taurine conjugated DCA levels were higher than in the HC groups. Moreover, levels of lithocholic acid (LCA) and 3-oxo-LCA were significantly higher than in the non-HCC group. c) Taurine-conjugated DCA levels were markedly elevated in the HCC group compared to both the HC and non-HCC groups. Similar to MASLD-HCC, LCA was significantly higher in the HCC group. **Conclusion:** LCA and 3-oxo-LCA levels as well as glycine and taurine conjugated DCA levels were elevated in the HCC group. 3-oxo-LCA has been reported to suppress Th17 cell differentiation (Nature, 2022), while Th17 cells are known to promote cytotoxic T cell activation in tumor immunity (Immunity, 2009). Therefore, increased 3-oxo-LCA may reduce antitumor immune responses and contribute to HCC development. These findings suggest that altered bile acid metabolism may play a role in MASLD-HCC carcinogenesis, and further studies are needed to clarify the underlying mechanisms.

4320 | E-CADHERIN/β-CATENIN COMPLEX SUPPRESSION DRIVES BARRIER DYSFUNCTION AND IMMUNE ACTIVATION IN SHORT BOWEL SYNDROME

Shaurya Mehta chandrashekhara manithody[1] Kento Kurashima[1] Sree Kolli[1] Marzena Swiderska-Syn[1] Ashlesha Bagwe[1] Chien-Jung Lin[1] John Long[1] Ajay Jain[1], [1]Saint Louis University

Background: Short bowel syndrome (SBS) is a devastating cause of intestinal failure in children. While total parenteral nutrition (TPN) supports growth, it paradoxically induces mucosal atrophy, barrier breakdown, and gut-derived sepsis. β-Catenin, a multifunctional protein, mediates both adherens junction stability (via E-cadherin binding) and transcriptional activity through canonical Wnt signaling. We hypothesized that loss of E-cadherin disrupts the β-catenin pool, leading to impaired junctional integrity and transcriptional downregulation, thereby contributing to epithelial failure in SBS and TPN. **Methods:** Neonatal piglets were randomly assigned to three groups: enteral nutrition (EN, $n=4$), TPN-only ($n=4$), or SBS with TPN ($n=4$) for 14 days. Distal small intestine tissues were assessed by qPCR, immunohistochemistry, FITC-dextran permeability assays, cytokine profiling, and histology. Quantitative analysis was performed using GraphPad Prism (v10.1.2); statistical significance was set at $p<0.05$. **Results:** Both TPN and SBS significantly reduced E-cadherin and β-catenin expression ($p<0.001$ vs. EN), accompanied by cytoplasmic mislocalization of β-catenin. Wnt pathway effectors (LEF1, TCF, Cyclin D1) were markedly suppressed ($p<0.01$), while GSK3β, a Wnt antagonist, was upregulated. SPDEF and MUC2 expression were significantly diminished ($p<0.01$), consistent with impaired goblet cell differentiation and reduced mucus barrier integrity. Tight junction disruption was evident: Occludin and Claudins 1, 3, 4, 5, and 8 were downregulated, while Claudin-2 and Claudin-6 were upregulated ($p<0.05$),

indicating a shift to a leaky barrier phenotype. Functionally, this was corroborated by increased FITC-dextran permeability and elevated serum lipopolysaccharide (LPS). Histologic analysis showed severe villus blunting (V/C ratio: TPN = 1.67; SBS = 1.51; EN = 2.13, $p < 0.01$) and gut atrophy (distal gut density: SBS = 0.13 g/cm vs. EN = 0.34 g/cm). Proinflammatory cytokines (TNF-α, IL-6, IL-8, IL-1β, IFN-γ) were increased, while IL-10 was suppressed ($p < 0.01$), indicating a dysregulated immune response. $CD3^+$ T cell infiltration was also elevated ($p < 0.001$). **Conclusion:** TPN and SBS elicit a coordinated disruption of epithelial structure and intercellular signaling. Central to this disruption is the breakdown of the E-cadherin/β-catenin complex and suppression of Wnt signaling, which impairs junctional integrity, goblet cell maturation, and epithelial regeneration. These effects are exacerbated by cytokine-driven immune activation and permeability defects. Together, these findings provide a mechanistic framework for therapeutic strategies aimed at restoring barrier function in SBS.

4321 | ACYL-COA THIOESTERASE 12 PROTECTS AGAINST MASH BY COORDINATING INTESTINAL FATTY ACID UPTAKE AND ABSORPTION

Akiko Sugiyama[1] Susan Hagen[2] David Cohen[3], [1]Brigham and Women's Hospital, Harvard Medical School, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, [3]Brigham and Women's Hospital, Harvard Medical School

Background: Acyl-CoA thioesterase 12 (Acot12), a cytosolic enzyme that converts acetyl-CoA into acetate, is markedly induced in small intestinal epithelial cells (IECs) in response to excessive nutrition. We previously reported that intestinal Acot12 deletion promotes metabolic dysfunction-associated steatohepatitis (MASH) by increasing intestinal permeability, which is due to IEC necroptosis and anti-inflammatory gene expression. This study aimed to determine whether Acot12 may protect against lipotoxicity, which can lead to necroptotic IEC cell death, by regulating lipid absorption and trafficking. **Methods:** Male intestine-specific Acot12 knockout (*I-Acot12*$^{-/-}$) mice and littermates (controls) were fed a high-fat diet (HFD) for 12 w and then challenged with an olive oil gavage. Plasma was collected over 2 h and tissues were harvested. Plasma triglyceride (TG) concentrations were measured enzymatically, and apoB48 levels were assessed by immunoblotting. Cytosolic lipid droplets (CLDs) in IECs were visualized by oil red O staining and chylomicron secretion was quantified using negative staining/transmission electron microscopy (NS/TEM). Jejunal organoids (enteroids) were prepared from *Acot12*$^{-/-}$ mice and controls after 4 w of HFD feeding. To assess rates of fatty acid (FA) uptake, enteroids were treated with 5μM of C1-BODIPY C12 for 30 min, and intracellular accumulation was quantified by confocal microscopy. To examine FA incorporation into CLDs and chylomicron (CM) secretion, enteroids were exposed to 400 μM oleic acid for 2 h. CLDs were assessed by confocal microscopy following BODIPY staining. Secreted CMs were analyzed by NS/TEM. Gene expression was quantified by qPCR. **Results:** Indicative of impaired lipid absorption, *I-Acot12*$^{-/-}$ mice exhibited 45% and 35% reductions in plasma TG and ApoB48 concentration, respectively. This was accompanied by increased lipid accumulation and enlarged CLDs in IECs. Rates of FA uptake were increased in *Acot12*$^{-/-}$ enteroids, which also exhibited increased CLD size and abundance. Suggestive of impaired secretion of CM TGs, secreted CMs were 46% smaller than controls. Additionally, expression levels of *Pnpla2* and *Abhd5*, which mediate CLD TG hydrolysis and CM assembly, were reduced by 42% and 33%, respectively. **Conclusion:** Intestinal Acot12 coordinates luminal FA uptake with the assembly and secretion of CMs. We speculate that Acot12 activity limits lipid accumulation in IECs and thereby prevents lipotoxicity, preserving barrier integrity and protecting against MASH.

4322 | GUT MICROBIOME DERIVED SHORT CHAIN FATTY ACIDS INCREASE RISK OF HEPATOCELLULAR CARCINOMA

Sindhu Karnam[1] Wei Jia[2] Renwei Wang[3] Jennifer Adams-Haduch[3] Woon-Puay Koh[4] Jaideep Behari[5] Jian-Min Yuan[1], [1]University of Pittsburgh, UPMC Hillman Cancer Center, [2]Li Ka Shing Faculty of Medicine, The University of Hong Kong, [3]UPMC Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA, [4]Yong Loo Lin School of Medicine, National University of Singapore, [5]University of Pittsburgh - Division of Gastroenterology, Hepatology and Nutrition

Background: Hepatocellular carcinoma (HCC) makes up 80-90% of primary liver cancers and is typically detected at an advanced stage because of its silent nature of progression and a lack of effective non-invasive early detection biomarkers. Gut-derived metabolites such as short-chain fatty acids (SCFAs) may impact the progression of early non-malignant stages of liver disease to malignant transformation to HCC. Although most studies have shown that SCFAs including acetate, butyrate, and propionate have been associated with lower risk of intestinal disease, some experimental studies have shown dysregulated metabolism of SCFAs may induce proinflammatory milieu for liver disease progress. The goal of this study is to investigate whether metabolomic profiling of SCFAs in baseline serum is associated with risk of HCC development. **Methods:** We performed a nested case-control study with 100 incident HCC cases and 100 individually matched healthy controls within the Singapore Chinese Health Study, a cohort of 63,257 men and women aged 45-74 years at enrollment in 1993-1998. The incidence of HCC was annually surveilled with the nationwide Singapore Cancer Registry. Serum acetic, butyric, propionic, and valeric acids were quantified using ultra-performance liquid chromatography triple-quadrupole mass spectrometry assays. The conditional logistic regression was used to evaluate the association between SCFAs and HCC risk using odds ratios (ORs) and their 95% confidence intervals (CI). **Results:** Cases and controls were comparable by age, body mass index (BMI), alcohol consumption and smoking status distributions. Individuals with HCC were more likely to be HBsAg positive and have a history of diabetes than controls. Among controls, the summed SCFAs and total butyric acid and its metabolites were positively associated with BMI (P trend < 0.05). The summed and most individual SCFAs measured were significantly elevated in HCC compared with controls. Compared to the lowest tertile, the OR (95% CI) of HCC for the highest tertile of summed all SCFAs and total butyric acids was 3.24 (1.45-7.24) and 2.78 (1.27-6.12) after adjusting for age, sex, BMI, alcohol consumption, smoking status, type 2 diabetes, and HBsAg status (both P's for trend < 0.01). **Conclusion:** The present analysis demonstrated a statistically significant association between elevated SCFA levels and increased risk of HCC in a prospective cohort of Singaporean Chinese. These results align with increased risk of HCC within this cohort with elevations in other metabolites such as bile acids. Mapping metabolic profile changes in liver disease progression to cancer will provide clinicians with a novel biomarker for risk stratification and early detection.

4323 | HIGHER PLASMA KYNURENINE-TRYPTOPHAN RATIO PREDICTS INCIDENT HEPATIC FIBROSIS IN WOMEN WITH HIV

Maria Duarte[1] Phyllis Tien[1] Audrey French[2] Seble Kassaye[3] Deborah Gustafson[4] Robert Burk[5] Steven Wolinksy[6] Mallory Witt[7] Yue Chen[8] Chloe Thio[9] Svenja Albrecht[10] Margaret Fischl[11] Cecile Lahiri[12] Michelle Floris-Moore[13] Eric Seaberg[14] Jennifer Price[1] Yifei Ma[1] Ani Kardashian[15], [1]University of California, San Francisco, [2]Stroger Hospital of Cook County, [3]Georgetown University, [4]State University of New York Downstate Health Sciences University, [5]Albert Einstein College of Medicine, [6]Northwestern Feinberg School of Medicine, [7]Geffen School of Medicine at UCLA, [8]University of Pittsburgh, [9]Johns Hopkins University School of Medicine, [10]University of Mississippi Medical Center, [11]University of Miami Miller School of Medicine, [12]Emory University School of Medicine, [13]University of North Carolina Chapel Hill School of Medicine, [14]Johns Hopkins University Bloomberg School of Public Helath, [15]Keck School of Medicine at the University of Southern California

Background: The tryptophan kynurenine pathway is activated in chronic inflammation, gut dysbiosis and gut microbial translocation, and may contribute to liver disease pathogenesis. Linkage of the kynurenine to tryptophan ratio (KT ratio), a measure of the tryptophan catabolism pathway, to hepatic fibrosis in people with HIV are sparse. We evaluated whether elevated KT ratio is associated with incident liver fibrosis in women with HIV (WWH). **Methods:** We included 709 WWH from the MACS-WIHS Combined Cohort Study

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(MWCCS) with available plasma KT ratio measurements at baseline; baseline liver stiffness (LS) measurement <7.1 kPa; ≥ 1 follow-up vibration-controlled transient elastography (VCTE) assessment; and no evidence of chronic viral hepatitis. KT ratio values were log-transformed and standardized. Hepatic steatosis was defined as VCTE controlled attenuation parameter (CAP) score of $\geq$ 248 dB/m. Poisson regression with robust standard errors clustered by participant was used to estimate the association of KT ratio with incidence rate of new fibrosis (LS ≥ 7.1 kPa) and new advanced fibrosis (LS >9.5 kPa). Models were adjusted for age, BMI, waist circumference, alcohol use, smoking, CAP score, HIV viral load, and CD4 count, and included the log of follow-up interval as an offset to account for varying person-time between visits. Kaplan-Meier estimator examined KT ratio above vs. below median with cumulative incidence of fibrosis over a 4 year follow-up. Cox proportional hazards and log rank test were used to test for differences in the cumulative incidence. **Results:** Over follow-up (mean 24.5 months, maximum 72 months), 18.7% and 8.3% of participants developed new or advanced fibrosis, respectively. Most fibrosis (74%) was associated with hepatic steatosis. In multivariable analysis, each log unit increase in KT ratio was associated with higher incidence rate of both new fibrosis (IRR 1.34, 95% CI: 1.15–1.56) and new advanced fibrosis (IRR 1.56, 1.32–1.86). In Kaplan-Meier analysis limited to 48 months, KT ratio values above the median were associated with greater cumulative incidence of fibrosis over 4 years compared to those below the median (hazard ratio 2.1, 95% CI: 1.16—3.83 p = 0.014.) (Figure). **Conclusion:** Higher KT ratio is a strong independent predictor of new and advanced fibrosis in WWH, supporting a mechanistic link between gut microbial dysbiosis, chronic immune activation, and liver disease progression. KT ratio may serve as a non-invasive biomarker to identify WWH at-risk individuals for liver disease progression.

4324 | ASSOCIATION BETWEEN GUT MICROBIOTA AND TACROLIMUS DOSE-RESPONSE AFTER LIVER TRANSPLANT

Yael Nobel[1] Heekuk Park[2] Christopher McLaughlin[2] Dwayne Seeram[2] Alice Tillman[2] Tal Korem[2] Elizabeth Verna[2] Anne-Catrin Uhlemann[2], [1]Columbia University Irving Medical Center, [2]Columbia University Medical Center

Background: The ability to predictably achieve therapeutic tacrolimus levels after liver transplant (LT) is critical for preventing acute cellular rejection while minimizing drug toxicity. However, the tacrolimus levels resulting from a given dose vary widely across patients. Gut microbiota have been shown to alter the pharmacokinetics of multiple drugs. We investigated the association between the gut microbiota and tacrolimus levels after LT. **Methods:** This was a nested prospective cohort study of LT recipients taking tacrolimus who underwent post-transplant stool specimen collection within 2 weeks post-LT. Fecal bacterial V3-V4 16S rRNA sequencing from one stool specimen per patient was performed to identify associations between early post-transplant microbial features and dose-normalized tacrolimus level at 30 days post-LT, calculated as the ratio of tacrolimus trough level (ng/mL) to tacrolimus dose (mg) (L/D ratio). L/D ratio was evaluated as a continuous outcome and a binary outcome with levels above or below the mean. Clinical and tacrolimus data were extracted from the electronic medical record. **Results:** Among 107 LT recipients, median age was 59 (IQR 52-64) years, and 24%, 30%, and 46% were Childs Pugh Class A, B, and C at transplant, respectively. The most common LT indications were hepatitis C (31%), alcohol-associated liver disease (24%), and metabolic-associated steatotic liver disease (24%). The

average tacrolimus L/D ratio in the study was 1.9 (SD 2.1) ng/mL/mg. While alpha and beta diversity were not significantly associated with tacrolimus L/D ratio, the subjects with the highest alpha diversity (Chao1 index > 200; $n = 6$) all had a low tacrolimus L/D ratio (< 1.9 ng/mL/mg) (Fig. 1A and 1B). Using Analysis of Compositions of Microbiomes with Bias Correction (ANCOM-BC), there was significantly increased abundance of *Roseburia inulivorans* and *Clostridium perfringens* in subjects with a low tacrolimus L/D ratio (Fig. 1C). **Conclusion:** Subjects with low tacrolimus L/D ratio had enrichment of *R. inulivorans*, a short-chain fatty acid (SCFA) producer, and a trend toward increased alpha diversity. SCFAs have previously been shown to impact expression of intestinal drug efflux pumps and activity of hepatic drug metabolism enzymes. Future studies can quantify SCFA levels to determine associations with dose-normalized tacrolimus level. Gut microbiota composition, or concentration of metabolites such as SCFAs, offer future directions that may ultimately help inform personalized tacrolimus dosing after LT.

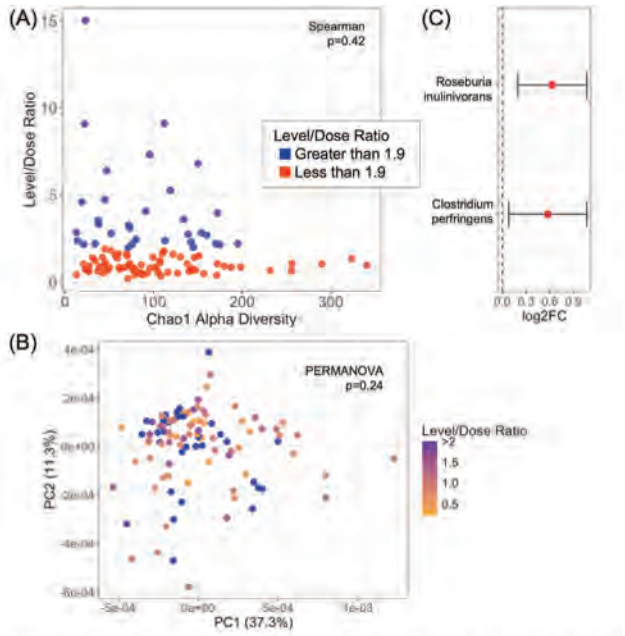

Figure 1. (A) Tacrolimus level/dose ratio according to Chao1 alpha diversity. (B) Weighted Unifrac PCoA of all samples. (C) Differentially abundant species between subjects with tacrolimus level/dose ratio above or below 1.9 ng/mL/mg ($p<0.05$ adjusting for multiple comparisons). log2FC: log2 fold change.

4325 | C-C MOTIF CHEMOKINE RECEPTOR 9 ABLATION WORSENS WHEREAS THERAPEUTIC BLOCKING PROTECTS MICE FROM WESTERN DIET-INDUCED STEATOHEPATITIS

Reben Raeman[1] Daniel Rossmiller[1] Ravi Rai[1] Vineet Mahajan[1] Michael Oertel[1], [1]University of Pittsburgh

Background: Intestinal epithelial permeability, fueled by gut microbial dysbiosis-associated mucosal inflammation, is central to metabolic dysfunction-associated steatohepatitis (MASH) pathogenesis; however, the mechanisms underlying mucosal inflammation in MASH remain incompletely understood. The gut-trophic chemokine receptor, CC chemokine receptor 9 (CCR9), regulates intestinal immune homeostasis. However, its pathogenic roles in chronic gastrointestinal diseases reveal the complex role of CCR9 on gut health. Here, we investigated the role of CCR9 in modulating intestinal mucosal inflammation in MASH. **Methods:** Male littermate $Ccr9^{+/+}$ (control) and $Ccr9^{-/-}$ mice were fed a normal diet or a Western diet (WD) consisting of 0.2% cholesterol, 20% protein, 43% carbohydrate, 23% fat (6.6% trans fat), and 2.31% fructose (TD.130885; Harlan Laboratories) for 24 weeks. C57BL/6J mice fed a WD for 24 weeks were randomized to receive subcutaneous injections of 50 mg/kg vercirnon (GSK-1605786; MedChemExpress, NJ, USA), resuspended in 5% Cremophor EL (EMD Millipore Corporation, Germany), or vehicle on alternate days for four weeks starting at week 20 of WD feeding. Liver and intestinal tissues were analyzed by histology, immunofluorescence microscopy, and quantitative reverse transcription PCR (qRT-PCR). **Results:** Our studies revealed inherent defects in the intestinal epithelial barrier (IEB) and higher intestinal mucosal inflammation in *Ccr9*$^{-/-}$ mice relative to *Ccr9*$^{+/+}$ mice. Consequently, compared to WT mice, when fed a WD, *Ccr9*$^{-/-}$ mice developed severe intestinal mucosal inflammation and IEB dysfunction. Heightened mucosal injury in WD-fed *Ccr9*$^{-/-}$ mice correlated with more severe hepatic inflammation and fibrosis relative to WT mice. In contrast, the CCR9 antagonist, vercirnon-mediated CCR9 blockade improved mucosal inflammation and restored IEB function in MASH mice. This correlated with improved biochemical, histologic, and metabolic parameters associated with MASH. **Conclusion:** Collectively, these findings emphasize the significance of CCR9 in maintaining gut health and highlight the potential of selective, intermittent CCR9 targeting as a therapeutic strategy for MASH.

4326 | BREAKING BARRIERS AND TRIGGERING DEATH: DUAL BACTERIAL MECHANISMS OF JUNCTION DAMAGE AND PARAPTOSIS IN SPONTANEOUS BACTERIAL PERITONITIS

Noah Sendtner[1] Noah Brandl[1] Martha Ernst[1] Celina Macek[1] Carina Steindl[1] Annika Scholtis[1] Philip Neubert[1] Natalie Fischer[1] Marika Haderer[1] Christoph Brochhausen[2] Arne Kandulski[1] Claudia Kunst[1] Karsten Gülow[1] Martina Müller-Schilling[1], [1]University of Regensburg, University Hospital Regensburg, Regensburg, Germany, [2]Institute of Pathology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Background: Spontaneous bacterial peritonitis (SBP) reflects a breakdown of the gut-liver axis, triggered by microbial translocation across a disrupted mucosal barrier in cirrhosis. Loss of epithelial integrity permits microbe-host interaction, inducing stress responses, junctional breakdown, and regulated cell death. Here, we investigate how bacteria isolated from the ascitic fluid of patients with SBP affect epithelial junction integrity and cell death morphology. **Methods:** Colonic biopsies from patients with liver cirrhosis and healthy controls were analyzed for mucus thickness, epithelial junction proteins, and stress signaling markers. *In vitro*, human intestinal epithelial HCT116 cells with or without specific deletion of p53 were co-cultured with *Escherichia coli (E. coli)* strains, including clinical isolates from SBP ascites. Z-VAD-fmk and Actinomycin D were used to define the cell death modality. Flow cytometry (Annexin V/DAPI) quantified cell death, while Western blotting and electron microscopy assessed protein expression and ultrastructure. **Results:** Patients with liver cirrhosis exhibited reduced mucus thickness and diminished epithelial junction protein levels. *In vitro* exposure of epithelial cells to *E. coli* resulted in rapid degradation of occludin and E-cadherin, accompanied by a form of regulated cell death consistent with paraptosis, as evidenced by vacuolization, organelle dilation, and chromatin condensation observed via electron microscopy. CRISPR/Cas9-mediated knockdown of p53 delayed the induction of bacteria-induced paraptosis, suggesting that p53 plays a regulatory role in bacteria-mediated paraptosis. Of note, Actinomycin D suppressed paraptotic features across all genetic backgrounds, indicating a transcription-dependent mechanism. **Conclusion:** Our findings identify paraptosis as a relevant form of epithelial cell death in the context of bacterial exposure during SBP. The observed disruption of epithelial junctions and associated cell death processes point to a key role of host–bacteria interaction in compromising gut barrier function within the gut-liver axis. Targeting the underlying mechanisms of epithelial destabilization may offer new therapeutic avenues to mitigate disease progression in SBP.

4327 | AN ALTERED HUMAN GUT MICROBIOME FROM HIGH FRUCTOSE INTAKE INDUCES METABOLIC RISK PHENOTYPES WHEN TRANSPLANTED INTO GERM-FREE MICE

Wontack Han[1] Jeanine Albu[1] John Hong[1] Rollie Hampton[1] Taylor Stein[1] Andrew Dorsey[1] Yanbo Zhang[2] Qibin Qi[2] Jaime Chu[3] Sarah Stanley[1] Jeremiah Faith[1] Ryan Walker[1], [1]Icahn School of Medicine at Mount Sinai, [2]Albert Einstein College of Medicine, [3]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Excess fructose (Fru) intake has adverse impacts on metabolic health, including T2D and MASLD. Malabsorbed Fru reaches the colon where it may alter the gut microbiome and its metabolites, yet causal links between the microbiome changes and metabolic risk phenotypes have not been studied. **Methods:** We enrolled 5 healthy participants in a pilot clinical dietary intervention (added Fru at 25% of total daily calories). Fecal samples were collected daily for 16s rRNA sequencing and closed reference clustering taxonomy (QIIME2). Alpha, beta diversity, and taxonomic abundance were calculated. An ex-vivo carbon tracer assay was used to analyze microbiome Fru metabolism. We used human donor samples for a fecal transplant (FMT) study in 6 C57Bl6 germ free mice in 3 groups: Control (C): chow no FMT, Fru-Baseline (F-B): 25% Fru diet + baseline FMT and Fru-Fru (F-F): 25% Fru diet + Fru FMT. Fecal samples were collected for 16s rRNA sequencing. Whole-body MRIs, plasma and tissue samples were obtained. **Results:** Human study: We observed an increase in mean alpha diversity (# unique features) from baseline to intervention (107.3 vs 109.8 ± 8.7). Beta diversity (unweighted UniFrac) showed clustering separation by intervention phase. At day 1 of Fru intervention mean abundance (CLR fold change) for *Bacteroides* decreased to -0.037 while increasing to 0.022 for *Firmicutes.* Mean abundance increased for *Blautia* (0.02) and decreased for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Ruminoccocus (-0.011) and *Prevotella* (-0.041). Mean *Firmicutes* to *Bacteroidetes* ratio (F:B) increased after Fru intervention (F:B = 3.31 vs 3.73). The microbiome showed enhanced ability to metabolize Fru compared to baseline (^{13}C $C0_2$ = 2560 vs 2100ppm).
FMT: Final alpha diversity (# unique features) was lower in the C (60.5) vs the F-F (136) group. Beta diversity (Bray Curtis) showed distinct group clustering. Comparing the F-F and F-B groups, mean *Firmicutes* abundance was higher (81.6% [8.2] vs. 60.8% [4.4]) while mean *Bacteroidetes* was lower (7.3% [3.5] vs. 28.2% [7.1]), mirroring our clinical results. The F-F group had lowest body weight, yet body fat % was double that of the C group. Plasma NEFAs and TGs differed between the F-F and C groups and IL-6 and ALT were highest in the F-F group. **Conclusion:** These results are consistent with observations that excess dietary Fru elicit acute effects on the structure and function of the gut microbiome. These alterations appear to be causally linked to metabolic risk in mice suggesting a unique contribution of Fru to metabolic disease risk.

4328 | LACTULOSE EFFICACY IS LINKED TO BIFIDOBACTERIUM AND SHORT-CHAIN FATTY ACID PRODUCTION

Patricia Bloom[1] Christine Bassis[1] Elliot Tapper[2] Krishna Rao[1] Anna Lok[2] Vincent Young[1], [1]University of Michigan, [2]University of Michigan Medical Center

Background: Lactulose is the primary treatment for hepatic encephalopathy (HE), yet it prevents only 50% of HE episodes. Data regarding the effect of lactulose on microbiome composition and function is limited – and may clarify individual differences in lactulose efficacy. **Methods:** Patients with cirrhosis and clinically significant portal hypertension were prospectively enrolled prior to initiating lactulose in clinic or as part of an open-label randomized clinical trial of lactulose. Patients had no antibiotic or alcohol use in at least the prior month. At baseline and at 4 weeks, all patients underwent the animal naming test (ANT) and fecal samples were obtained for sequencing the V4 region of the 16S rRNA gene and short-chain fatty acid (SCFA) quantification. Cognitive improvement was defined as an increase in ANT of 4 or more animals. AMOVA was used to evaluate beta diversity differences between groups and Wilcoxon or t-tests were used to compare continuous variables between groups. **Results:** Thirty patients with cirrhosis who started lactulose were enrolled: 73% female, median age 65 years, MELD 10, 60% MASLD and 20% alcohol-related. Patients reported a median daily lactulose dose of 20 g (range 2 to 56 g). Median change in ANT from baseline to week 4 was 0 (range -8 to +9) with 6 (20%) patients having increase in ANT by 4 or more animals. While the overall community structure of the microbiome did not change with lactulose administration, specific taxa did appear to respond following treatment. *Bifidobacterium* increased in abundance with lactulose ($P < 0.05$, Figure). Patients with cognitive improvement had a higher relative abundance of *Bifidobacterium* at week 4 than those without (median 7.3% vs 1.5%, $P = 0.02$, Figure).
Patients with cognitive improvement maintained the concentration of the top 3 fecal SCFA (total of butyrate, propionate, and acetate) on lactulose, while those without cognitive improvement experienced a decline in SCFA (0 [SD 10] nmol/mg vs. -31 [SD 66] nmol/mg, $P = 0.04$). Specifically, fecal butyrate concentrations were maintained in patients with cognitive improvement and dropped in those without improvement (0 [SD 2] nmol/mg vs. -4 [SD 6] nmol/mg, $P = 0.004$). **Conclusion:** An increase in *Bifidobacterium* abundance specifically was associated with cognitive improvement in patients with cirrhosis and portal hypertension on lactulose. Fecal SCFA concentrations were maintained in patients with cognitive improvement and declined in patients without cognitive improvement, possibly reflecting a dilution effect due to increased stool volume by lactulose. Therapies to augment *Bifidobacterium* might benefit patients with no cognitive improvement on lactulose.

4329 | CHARACTERIZING THE GUT MICROBIOME IN NON-CIRRHOTIC PORTAL HYPERTENSION

Jenna Oringher[1] Meital Gewirtz[1] Yue Zhang[2] Neelam Redekar[2] James Haddad[1] Rownock Afruza[1] Moumita Chakraborty[1] Julian Hercun[3] Maria Mironova[3] Anjali Rai[4] Justin Lack[2] David Kleiner[5] Michail Lionakis[2] Christopher Koh[1] Theo Heller[4], [1]NIDDK, [2]NIAID, [3]National Institutes of Health, [4]NIH/NIDDK, [5]National Cancer Institute, Bethesda

Background: Non-cirrhotic portal hypertension (NCPH) is a heterogenous group of conditions which increase the likelihood for an individual to develop portal hypertension. By studying NCPH we may better elucidate mechanisms leading to complications of PH without the confounding factor of synthetic dysfunction that occurs in cirrhosis. While it is well known that cirrhosis is associated with gut dysbiosis, the microbiome in NCPH has not been previously characterized. **Methods:** Cross-sectional analysis of 26 NCPH and 32 healthy controls (HCs) was performed via shot-gun sequencing of DNA and RNA isolated from the stool. Microbial and functional profiles were compared in NCPH vs HCs to uncover disease-specific alterations. **Results:** NCPH patients had significantly lower richness ($p = 4.3e-5$) and Shannon index ($p = 2.5e-5$) than HCs. There were also significant between-group differences in beta diversity, with NCPH having greater within-group variation. There were 89 species significantly associated with NCPH, 45 belonging to the class Clostridia. The species *F. prausnitzii*, *D. Longicatena*, and *R. gnavus*, are known to affect bile acid metabolism and have been associated with progression of gastrointestinal and liver disease. Evaluation of the functional profile revealed 111 pathways that were differentially abundant in NCPH vs HCs, all upregulated in NCPH. The pathways peptidoglycan biosynthesis and superpathway of N-acetylglucosamine (a major component of mucin) degradation were significantly upregulated in NCPH (FC: 1.99, 3.34). **Conclusion:** In NCPH there are significant microbial and functional alterations of the gut microbiome, demonstrating dysbiosis independent of cirrhosis. Alterations in several species under the class Clostridia responsible for bile acid metabolism suggests a mechanism for altered immune signaling in disease, which may influence progression of portal hypertension. Additionally, upregulation of peptidoglycan production and mucin degrading pathways in NCPH increases pathogen associated molecular patterns and may contribute to loss of barrier integrity, further activating inflammatory pathways. Overlapping microbial changes in NCPH to liver diseases of varying etiologies suggests common mechanisms of disease progression independent of the presence of cirrhosis.

4330 | CLOSTRIDIUM DIFFICILE COLONIZATION AS A PREDICTOR OF POOR OUTCOMES IN ACUTE ALCOHOLIC HEPATITIS

Isaac Swartzman[1] James Vu[1] Robert Pecha[1] Scott Crabtree[1] Vikrant Rachakonda[1], [1]University of California Davis Medical Center

Background: The gut-liver axis plays a critical role in liver disease, with gut dysbiosis and increased intestinal permeability contributing to disease progression. Clostridioides difficile (C. difficile) is a nosocomial pathogen associated with reduced microbial diversity, and C. Difficle colonization may serve as a surrogate marker of gut dysbiosis. Although the microbiome's role in alcohol-associated hepatitis (AH) is still emerging, early evidence links dysbiosis to increased disease severity. We evaluated C. difficile colonization as a predictor of adverse clinical outcomes in AH. **Methods:** We conducted a retrospective cohort study of patients admitted with acute AH who underwent *C. difficile* surveillance at our center from July 2017 to September 2024. *C. difficile* colonization (CDC) was defined as positive *C. difficile* rectal swab PCR without symptoms. Patients were followed from hospitalization up to 90 days after admission. Primary outcomes included infection, acute kidney injury (AKI), transplant-free survival, ICU admission, and hospital length of stay.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Results: Of 582 patients hospitalized with acute AH, 471 underwent C. difficile surveillance and 69 (14.7%) had CDC. CDC was associated with higher rates of infection [37 (53.6%) vs 126 (31.3%), $p = 0.001$], including *C. Difficile* infection (CDI) [4 (5.7%) vs 1 (0.2%), $p = 0.002$]. Patients with CDC had higher rates of ascites [54 (78.3%) vs. 225 (60.0%), $p < 0.001$], gastrointestinal bleeding [27 (39.1%) vs. 112 (27.9%), $p = 0.042$], and ICU admission [32 (46.4%) vs. 139 (34.6%), $p = 0.042$]. Serum albumin was lower [2.4 (IQR 2.0 – 3.0) vs. 2.8 (IQR 2.3 – 3.3) g/dl, $p = 0.001$] and WBC count was higher [11.0 (IQR 6.8 – 14.8) vs. 8.4 (IQR 5.9 – 13.1), $p = 0.044$] in CDC patients, but MELD 3.0 was similar between groups [28 (IQR 23 – 35) vs. 26 (IQR 21 – 31), $p = 0.065$]. No differences were observed in rates of AKI or hepatic encephalopathy between groups, and hospital length of stay was similar between patients with and without CDC. Kaplan Meier analysis demonstrated lower survival time in patients with CDC [66.7 (95% CI 58.9 – 74.4) days vs. 77.2 (95% CI 74.6 – 79.9) days, $p = 0.007$ by log rank test]. On multivariate Cox proportional hazards models, age [HR 1.039 (95% CI 1.021 – 1.057), $p < 0.001$] MELD 3.0 [HR 1.103 (95% CI 1.083 – 1.124), $p < 0.001$] and CDC [HR 1.604 (95% CI 1.014 – 2.537), $p = 0.043$] were associated with 90-day mortality. **Conclusion:** In patients with acute AH, CDC is associated with higher rates of infection, ascites, gastrointestinal bleeding, and ICU admission, and independently predicts reduced 90-day survival. Our study suggests that C. difficile colonization may serve as a surrogate marker of intestinal dysbiosis, disease severity, and infection risk in patients with AH.

4331 | LPS INDUCES TLR4 AND CYTOKINES IN A 3D PORCINE ENTEROID SYSTEM TO DRIVE MULTISYSTEM INJURY INCLUDING IFALD

Shaurya Mehta[1] Ashlesha Bagwe[1] chandrashekhara manithody[1] Sree Kolli[1] Marzena Swiderska-Syn[1] Uthayashanker Ezekiel[1] Ajay Jain[1], [1]Saint Louis University

Background: The intestinal epithelium plays a pivotal role in gut-liver axis signaling, acting as a barrier and immunological interface. Disruption of this interface as see in Total Parenteral Nutrition (TPN) dependent individuals, where enteral nutrient flow is bypasses; can potentiate hepatic injury. Lipopolysaccharide (LPS), a bacterial endotoxin, is a key driver of intestinal permeability and hepatic inflammation via Toll-like receptor 4 (TLR4) activation. We utilized a porcine 3D enteroid model to explore how LPS modulates epithelial immune signaling and barrier function, with implications for Intestinal Failure Related Liver Disease (IFALD). **Methods:** Enteroids were generated from the small intestine of neonatal Yorkshire pigs using Matrigel-based 3D culture. After 7 days, cultures were exposed to LPS (1, 2, or 5 μg/mL). Key markers of epithelial barrier integrity (ZO1) and immune signaling (TLR4, IL-8, IL-10) were assessed. Serum cytokine profiles from TPN- and enterally-fed (EN) animals were compared to explore systemic inflammatory responses relevant to hepatic outcomes. **Results:** High-dose LPS (5 μg/mL) significantly reduced ZO1 expression, indicating impaired epithelial barrier integrity. TLR4 expression was elevated in both 2 and 5 μg/mL LPS groups, peaking at 2 μg/mL. IL-8 and IL-10 levels increased in parallel, reflecting pro- and anti-inflammatory signaling. In vivo, TPN animals demonstrated higher serum IFN-γ ($p = 0.009$), IL-8 ($p = 0.011$), and circulating LPS ($p < 0.0001$) versus EN-fed controls—cytokine changes known to drive hepatic inflammation and cholestasis. **Conclusion:** Our enteroid model recapitulates intestinal epithelial responses to microbial stimuli, including barrier compromise and inflammatory activation, both of which may contribute to hepatic inflammation via gut-derived signals. These findings underscore the critical role of epithelial integrity in gut-liver communication and support the use of intestinal enteroids to dissect mechanisms underpinning TPN-associated liver disease.

4332 | NEONATAL OVERFEEDING ACCELERATES AGE-RELATED LIVER PATHOLOGIES AND METABOLIC DYSFUNCTION THROUGH GUT MICROBIOTA

Jiangao Fan[1] Cen Xie[2] Yameng Liu[2] Jingyi Xu[3], [1]Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, [3]Nanjing University of Chinese Medicine

Background: Childhood obesity increases lifelong risk of metabolic diseases, yet its direct effects on liver aging remain unknown. Although gut microbiota regulates metabolic aging, how obesity-altered microbes accelerate age-related liver pathologies requires mechanistic investigation. **Methods:** We utilized an established neonatal overfeeding model via litter size reduction to induce childhood obesity. On postnatal day 3, mouse litters were standardized to either 3-4 pups (over-nutrition group) or 8-9 pups (normal-nutrition controls) per dam. Aged male mice (24-28 months) underwent comprehensive phenotyping including: survival analysis, glucose and insulin tolerance tests, serum biochemistry, hepatic lipid quantification, muscle function assessments, and whole-body metabolic profiling. Tissue analyses included histopathology and qPCR quantification. To interrogate gut microbiota's role, we performed fecal microbiota transplantation (FMT) from aged donors (normal-nutrition [rNormal] vs. over-nutrition [rOver]) to young recipients fed a high-fat diet (HFD) for 20 weeks to induce MASLD. Microbial community analysis via 16S rRNA sequencing characterized taxonomic shifts. **Results:** Survival analysis demonstrated that neonatal caloric excess significantly decreased median lifespan in aged mice. Compared to normal-nutrition controls, aged over-nutrition mice exhibited accelerated metabolic dysfunction, including obesity, severe insulin resistance, dyslipidemia, increased hepatic injury markers, and exacerbated ectopic lipid deposition in the liver. Neonatal overfeeding further aggravated sarcopenia, resulting in greater reductions in muscle mass and function. Indirect calorimetry revealed significantly lower VO_2, VCO_2, energy expenditure, and physical activity in aged over-nutrition mice. Histologically, over-nutrition intensified age-associated hepatic inflammation, evidenced by heightened F4/80$^+$ macrophage infiltration. Molecular analyses demonstrated upregulation of senescence markers (*p16*, *p21*) and SASP factors (*IL-6*, *IL-1β*) in both hepatic and skeletal muscle tissues. FMT studies showed that rOver mice developed severe metabolic perturbations, including hepatomegaly, increased hepatic triglyceride content, impaired insulin sensitivity, and progressive MASLD. Notably, rOver mice displayed marked sarcopenic phenotypes. Taxonomic analysis revealed a significant depletion of *Akkermansia* in over-nutrition cohorts based on 16S rRNA sequencing. Strikingly, these microbial disparities were conserved in FMT recipients, with rNormal mice sustaining higher *Akkermansia* abundance than rOver mice. **Conclusion:** This study demonstrates that early-life over-nutrition reprograms systemic aging trajectories, establishing a causal role for gut microbial communities in driving concurrent hepatic metabolic dysfunction and sarcopenic progression.

4333 | ALTERATIONS IN SERUM METABOLOMIC PROFILES IN LIVER FIBROSIS MOUSE MODEL

Lei Ma[1] HUICHUN XING[1], [1]Center of Liver Diseases Division 3, Beijing Ditan Hospital, Capital Medical University

Background: Liver fibrosis is a consequence of chronic or recurrent liver injury and is a key pathological feature of progressive chronic liver disease. While many studies have shown alterations in the gut microbiota associated with liver fibrosis, research on serum metabolomic changes driven by gut microbiota dysbiosis remains limited. Yet, it may be a major contributor to the host metabolic dysfunction observed in liver fibrosis. **Methods:** Liver fibrosis was induced in C57 mice by intraperitoneal injection of carbon tetrachloride (CCl_4) for 8 weeks. Serum samples were collected at the end of the 8-week period, and non-targeted metabolomic profiling was performed using liquid chromatography–mass spectrometry (LC-MS). **Results:** Orthogonal projections to latent structures discriminant analysis (OPLS-DA) revealed distinct serum metabolic profiles between the CCl_4-treated group and the control group (Figure 1A). Based on the criteria of VIP $>$ 1, $|\log_2(FC)| > 1$, and $p < 0.05$, a total of 121 significantly altered serum metabolites were identified (Figure 1B). Among them, 81 metabolites were significantly upregulated, while 40 were downregulated in the CCl_4 group. KEGG annotation and enrichment analysis indicated that these differential metabolites were mainly enriched in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

pathways related to amino acid metabolism and lipid metabolism (Figure 1C). Further topological analysis identified four key metabolic pathways with significant biological relevance: histidine metabolism, glycerophospholipid metabolism, pyrimidine metabolism, and β-alanine metabolism (Figure 1D). **Conclusion:** Liver fibrosis in mice leads to significant alterations in serum metabolic profiles, with major changes enriched in histidine metabolism, glycerophospholipid metabolism, pyrimidine metabolism, and β-alanine metabolism pathways.

4334NEW SUBMISSION | CHARACTERISTICS OF GUT MICROBIOME IN DECOMPENSATED ALCOHOLIC LIVER DISEASE, ALCOHOL USE DISORDER, NAFLD, AND A HEALTHY POPULATION

Ajay Jain[1] Mustafa Malvi[1] Shohini Sikdar[1], [1]Shalby Hospital

Background: In recent years, gut dysbiosis has been implicated in many diseases, including Alcohol related liver disease. The present study was conducted to characterize gut microbiota of decompensated alcoholic liver disease (DALD), Metabolic syndrome associated fatty liver disease (NAFLD), Alcohol use disorder (AUD) & healthy population. **Methods:** This observational study was conducted from December 2022 to June 2024. The total sample size was 100 (25 in each group). DNA extraction from the fecal samples was performed using the Qiagen DNeasy PowerSoil Pro kit. Based on the quantitation using a 1x dsDNA HS assay on a QUBIT fluorometer, Nanodrop and gel electrophoresis-passed samples were selected for amplification of the 16S rRNA region. The amplification was performed using V1 to V9 full-length 16S barcoded universal primers from Pacific Biosciences. **Results:** The alpha diversity analyses indicated that the gut microbiota in DALD was less diverse than healthy and NAFLD across all tested indices, showing a negative effect of alcohol intake on gut microbiome diversity. The beta diversity analyses also revealed a significant difference between the gut of alcohol consumers and those who do not consume alcohol. The pairwise comparisons showed significant difference between AUD vs. healthy ($P = 0.043$), DALD vs. healthy ($P = 0.002$), NAFLD vs. AUD ($P = 0.002$), and NAFLD vs. DALD ($P = 0.002$). The difference was insignificant between NAFLD vs. healthy ($P = 0.431$) and AUD vs. DALD ($P = 0.156$). At the Genus level, Bifidobacterium was observed to have the highest abundance overall. At the family rank, Bifidobacteriaceae, Prevotellaceae, Bacteroidaceae, Lachnospiraceae, Streptococcaceae, and Lactobacillaceae were some of the most abundant identified families. While at the phylum level, some of the most abundant were Firmicutes, Bacteroidetes, Actinobacteria, Proteobacteria, and Verrucomicrobia. **Conclusion:** 1. A significant reduction in microbial diversity is seen in the DALD group. 2. Alcohol even in the absence of liver disease, has a significant detrimental effect on the composition of human gut microbiota.

4335 | GUT MICROENVIRONMENT RESTORATION AFTER HCV ERADICATION: INSIGHTS FROM MICROBIOTA AND BILE ACID DYNAMICS

Takako Inoue[1] Hisayoshi Watanabe[2] Kei Moriya[3] Hideto Kawaratani[3] Goki Suda[4] Tatsuya Ide[5] Satoru Kakizaki[6] Etsuko Iio[7] Takehisa Watanabe[7] Katsuya Nagaoka[7] Hitoshi Yoshiji[3] Yasuhito Tanaka[8], [1]Nagoya City University Hospital, [2]Tohoku Central Hospital of the Mutual Aid Association of Public School Teachers, [3]Nara Medical University, [4]Hokkaido University, [5]Kurume University Medical Center, [6]NHO Takasaki General Medical Center, [7]Kumamoto University, [8]Nagoya City University Graduate School of Medical Sciences

Background: In chronic hepatitis C (CHC), the gut microenvironment experiences progressive alterations. This study aims to compare the gut microenvironment before and after sustained virological response (SVR)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and elucidate the mechanisms responsible for gut microenvironment restoration following SVR. **Methods:** In the cross-sectional study, HCV-infected patients were categorized into chronic hepatitis (CH) group (n = 95) and cirrhosis/hepatocellular carcinoma (LC/HCC) group (n = 79). Similarly, post-SVR patients (CH, n = 29; LC/HCC, n = 46) had their gut microbiota and BA profiles compared with healthy individuals (n = 23). In the longitudinal study, stool samples from CHC patients were collected before HCV eradication and at 24 and 48 weeks after SVR. Gut microbiota and BA profiles were compared among the CH group (n = 29), LC/HCC group (n = 20), and healthy individuals (n = 23). Additionally, the expression levels of BA metabolic enzymes in HCV-infected patients (n = 65) and post-SVR CHC (n = 28) were compared with those of healthy individuals (n = 12). Ethical approval for this study was obtained from the appropriate institutional review boards. **Results:** In HCV-infected patients, expression levels of HSD3B7 and CYP8B1 were significantly lower than in healthy controls ($p < 0.0001$, $p = 0.071$) but normalized in post-SVR CH patients ($p = 1.0$, $p = 0.64$). Deoxycholic acid levels were significantly reduced during HCV infection ($p < 0.01$) but recovered following SVR ($p = 0.8$). HCV-associated increases in *Streptococcus* abundance were significantly reduced in the CH group 48 weeks after SVR ($p = 0.01$) but remained unchanged in the LC/HCC group. Improvements in FIB-4 index and ALT post-SVR correlated with increases in *Lachnospiraceae* abundance ($p < 0.0001$, $p = 0.0344$). **Conclusion:** In CHC, dysbiosis-driven alterations in BA metabolic enzyme expression and BA composition correlate with disease severity and are partially reversible with SVR, particularly in non-cirrhotic patients. Restoration of the gut microenvironment—including normalization of BA profiles and microbiota—was associated with improved liver fibrosis and function. Notably, *Lachnospiraceae* may play a key role in liver recovery after HCV eradication (Figure).

4336 | DEFICIENCY OF SENESCENCE MARKER PROTEIN 30 (SMP30) AGGRAVATES INTESTINAL PERMEABILITY DUE TO E-CADHERIN DYSFUNCTION IN VIVO AND IN VITRO

Jin-Kyu Park[1] Woo Jun Kim[1] Su-Min Baek[1] Tae-Un Kim[1] Jae-Hyuk Yim[1], [1]Kyungpook National University

Background: SMP30 is a key molecule that mediates vitamin c synthesis, antioxidant effect, and anti-apoptotic effect. However, it has not been reported that SMP30 regulates intestinal permeability. Therefore, we investigated the role of intestinal SMP30 in alcohol-induced permeability models. Meanwhile, nanoplastics (NPs) are ubiquitous pollutants that can affect both humans and the environment. Given the exposure route of NPs, the disruption of intestinal epithelium aggravates the accumulation of NPs. Therefore, we used fluorescence-dyed NPs as an indicator to analyze distribution and toxicity of NPs. **Methods:** Alcohol-induced permeability mouse model was induced by Lieber-deCarli diet, and polystyrene nanoplastics (PS-NP) was administered 5 times a week for 3 weeks. Histopathological analysis, immunofluorescence (IF), immunohistochemistry (IHC), serum biochemistry, and western blot (WB) were performed to analyze phenotypes and related pathogenesis. To elucidate the underlying mechanisms, SMP30 knockdown was performed using the human colon carcinoma cell line Caco-2 with ethanol treatment. **Results:** The SMP30 KO EtOH (KE) group exhibited more severe vacuolization in the intestinal villi compared with the WT EtOH (WE) group. The expression of junctional proteins, such as E-cadherin and F-actin, was significantly decreased in IF and WB in the KE group. Due to the disruption of junctional proteins, more NPs were observed in the lamina propria of injured villi. Moreover, NP accumulation was increased in the liver, spleen, and brain in the SMP30 KO mice. In the liver tissue, the KE group showed more severe hepatic steatosis and higher ALT level compared with WE group. These patterns were confirmed in serum TG assay and Oil Red O stain. In the cell experiments, SMP30 knockdown did not alter the protein levels of E-cadherin and β-catenin. However, si-SMP30 treated cells exhibited cytoplasmic E-cadherin redistribution in regardless of ethanol treatment. **Conclusion:** This study demonstrates that SMP30 deficiency aggravates intestinal permeability due to

E-cadherin dysfunction. The KE group showed severe intestinal damage accompanied with NP accumulation in parenchymal organs. These patterns resulted from the disruption of E-cadherin and F-actin. In Caco-2 cells, SMP30 knockdown induced cytoplasmic E-cadherin redistribution, suggesting impaired cell-cell adhesion. This study elucidates the novel function of SMP30 in intestinal epithelium, emphasizing E-cadherin mediated gut permeability.

4337 | HYPERAMMONEMIA AND VOLUNTARY WHEEL RUNNING MODULATE THE GUT MICROBIOME TO PROTECT AGAINST SARCOPENIA IN LIVER DISEASE

Annette Bellar[1] Nicole Welch[1] saurabh mishra[1] Muaz Alsabbagh Alchirazi[1] Amy Attaway[1] Pugazhendhi Kannan[1] Seshu Pothabathula[1] Takhar Kasumov[2] Lopa Mishra[3] Aaron Miller[1] Naseer Sangwan[1] Srinivasan Dasarathy, [1]Cleveland Clinic, [2]NEOMED, [3]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory,

Background: Liver disease results in and may be caused in part by alterations to the gut microbiome which can further lead to frailty and sarcopenia. Hyperammonemic stress response (HASR) is A consequence of liver disease which causes sarcopenia. Hyperammonemia and HASR may be worsened by ammoniagenesis that in turn contributes to alterations in the gut microbiome as an adaptive (ammonia removal) or maladaptive (increase ammoniagenesis) responses. Endurance exercise potentially reverses sarcopenia/frailty in cirrhosis and modulate the gut microbiome to support ammonia disposal. The effects of hyperammonemia and voluntary wheel running (VWR) on the gut microbiome were evaluated in mice. **Methods:** Male C57/BL6 mice aged 8-9 week (wk) with a subcutaneous implanted osmotic pump delivering 2.5mmol/kg/d of ammonium acetate (AmAc) or vehicle (PBS) for 6 week were randomized to either voluntary wheel running (VWR) or usual activity (UA) for 4wk. Stool samples were collected when the osmotic pump was placed (pump) 2 weeks after the osmotic pump surgery and prior to 4 weeks of UA or VWR (pre-intervention) and at the end of the 4-week intervention period (post-intervention). 16S sequencing was done and analyzed in R, generating mean ASV abundance, correlation matrices, heatmaps, and Shannon diversity metrics. Pairwise Wilcoxon tests were used to asses temporal changes. **Results:** Alpha diversity (AD) was decreased with both AmAc treatment and VWR intervention between the pre and post-intervention timepoint ($p < 0.05$). In PBS-UA mice there was a strong correlation between the timepoints (pump to pre and pre to post) suggesting a stable microbiome (r 0.68 $p < 1.4e-8$) while PBS VWR mice exhibited compositional shifts ($r = 0.385$ $p = 0.01$) in the microbiome pre to post-intervetnion. AmAc-UA mice had a significant shift in bacterial taxa between the pump and pre and pre and post ($r = 0.28$, p 0.12) timepoints suggesting large changes in the gut microbial enviroment. At the genus level we found a decrease in *Akkermansia* between the pump placement and post-intervention timepoints. ($p < 0.05$). Similar to PBS treated groups AmAc-VWR correlation at timepoints was moderate (r0.567 p4.2e-5) with an initial increases in *Bacteroides* with AmAc-treatment which returned to baseline with VWR intervention (Fig1).In both PBS groups of mice and the AmAc VWR mice the 3 most abudnant species included Bacteriodales wile in the AmAc-UA groups 3 species of Akkermansi suggesting AmAc-UA mice mean abundance is different from that of other groups. **Conclusion:** HASR and VWR alter microbial diversity. While VWR resulted in moderate changes to the microbiome of PBS-treated mice, AmAc-treatment caused overall disruption in the microbiome. Interestingly VWR resulted in greater correlation and remodeling of the microbiome in AmAc-treated mice. These findings support physical activity as a modulator of microbiome dynamics with potential metabolic and skeletal muscle benefits in cirrhosis.

4338 | GUT MICROBIOTA COMPOSITION IN LIVER TRANSPLANT CANDIDATES: A METAGENOMIC ANALYSIS FROM PUBLIC DATA USING OPEN-SOURCE TOOLS

Rosa Ragozzino[1], [1]*Catholic University of the Sacred Heart, Italy*

Background: The presence of dysbiosis—an imbalance in gut microbiota composition—has been associated with several pathological conditions, including non-alcoholic fatty liver disease, cirrhosis, and hepatocellular carcinoma. Recent advances in molecular biology, particularly 16S rRNA sequencing, have enhanced the identification of microbial taxa and their role in liver disease. In cirrhosis, a reduction in microbial diversity, depletion of Bacteroidetes, and expansion of Proteobacteria and Fusobacteria have been linked to disease progression and complications. This study aims to explore the gut microbial landscape in patients awaiting liver transplantation by analyzing publicly available metagenomic data. **Methods:** Ten paired-end fecal metagenomic samples from the PRJNA1039781 project, involving liver transplant candidates, were processed using the Galaxy platform (usegalaxy.org). Reads were quality-filtered with Trimmomatic and taxonomically classified using Kraken2 against a comprehensive database. Results were visualized via Krona and exported for statistical inspection. The analysis focused on the 59 most frequent microbial taxa identified across samples. **Results:** The most frequently detected genera included *Bacteroides*, *Faecalibacterium*, *Escherichia*, and *Prevotella*. While some profiles showed preservation of beneficial commensals such as *Faecalibacterium*, others revealed elevated levels of potentially pathogenic genera like *Enterococcus* and *Clostridium sensu stricto*. This variation may reflect different stages of dysbiosis and disease severity among patients awaiting transplantation. Notably, *Bacteroidetes* remained dominant, but the emergence of opportunistic taxa supports prior evidence of microbial imbalance in cirrhotic patients. **Conclusion:** This pilot study demonstrates the feasibility of using open-access fecal metagenomic data and open-source bioinformatics tools to investigate gut microbiota in liver transplant candidates. The findings align with known patterns of dysbiosis in cirrhosis and may serve as a basis for future research on microbiome-based prognostic indicators in hepatic disease.

4339 | DYSBIOSIS IN THE GUT-LIVER AXIS DRIVES BONE LOSS DURING CHOLESTATIC LIVER DISEASE

Matthew Carson[1] Brooke Hutchison[1] Jamie Fornsaglio[1] Kari Nejak-Bowen[1], [1]University of Pittsburgh

Background: Cholestatic liver diseases (CLDs) are characterized by disrupted bile acid homeostasis. Patients with CLD often develop metabolic bone diseases. These patients lose bone faster and have a higher incidence of fractures than healthy individuals. Despite the prevalence of metabolic bone diseases in CLD patients, the mechanisms underlying bone loss are unclear. The gut-liver axis refers to the bidirectional relationship between the gut microbiota and the liver. Gut-liver metabolites, such as bile acids, are critical regulators of gut microbiota signaling actions on bone. However, bile acids' role on skeletal function during chronic liver cholestasis is unclear. Purpose was to investigate the role of the gut-liver axis and bile acid signaling on bone loss during CLD. **Methods:** Mice were administered 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) from age 11-15 weeks. 16s rDNA sequencing was performed on colons. Liver bile acid synthesis and transporter expression were determined by qRT-PCR. Ex vivo micro-CT was performed in femur. Osteoblast and osteoclast outcomes were evaluated by histomorphometry. Bone marrow bile acids were evaluated by mass spectrometry. Osteoblasts and osteoclasts were treated with the bone marrow bile acid profile found in experimental mice to assess their effects on bone cell functions. **Results:** DDC-treated mice exhibit reduced bone mass, attributed to decreases in bone-forming osteoblasts and increases in bone-resorbing osteoclasts. DDC-treated mice show genus-level shifts in their gut microbiota that are linked to disrupted bile acid metabolism. Furthermore, hepatic bile acid efflux transporter genes are dysregulated in mice with cholestasis, indicating a disturbance in gut-liver bile acid homeostasis. Mice with chronic cholestasis have increases in conjugated bile acids in their bone marrow. In vitro stimulation with the bone marrow bile acid profile of DDC-treated mice suppressed osteoblast mineralization potential and enhanced osteoclastogenesis compared to controls. **Conclusion:** No known studies have measured the concentration of bile acids in the bone marrow and evaluated their direct effects on bone cell outcomes. This work is the first to demonstrate that bile acids are direct regulators of skeletal outcomes in the setting of cholestatic liver disease. Future research is necessary to determine whether targeting the gut-liver axis and bile acids are viable therapeutic approaches for treating CLD-induced bone loss.

4340 | THE MICROBIOME IN PATIENTS WITH CIRRHOSIS AND CLINICAL SIGNIFICANT PORTAL HYPERTENSION: A PILOT CASE-CONTROL STUDY

Giuseppe Colucci[1] Sonia Stella[2] Alberto Castagnetti[3] Luisa Di Rito[3] Marina Lucà[2] Giulia Tosetti[4] Pietro Lampertico[5], [1]IRCCS Fondazione Cà Granda-Policlinico, University of Milan, [2]IRCSS Fondazione Ca' Granda, [3]Wellmicro Srl, [4]IRCCS Ca' Granda, [5]University of Milan

Background: Alterations in the composition of the intestinal microbiome may affect the gut-liver axis and influence the status of liver cirrhosis with Clinical Significant Portal Hypertension (CSPH) a condition at risk of hepatic encephalopathy and decompensation. In the present study we investigated a representative group of patients for their microbiota and micobiota composition to identify pathological profiles amenable to treatment with antibiotics, dietary and specific probiotic supplementation. **Methods:** We performed a single center, prospective, case-control study in 25 patients wih cirrhosis and CSPH compared to healthy controls. Fecal samples were collected using SMART eNAT® with nucleic acid preservation buffer and shipped at room temperature to the Wellmicro laboratory. The hypervariable regions V3 and V4 of the 16S rRNA gene (bacterial component) and the ITS2 region (fungal component) from extracted DNA are sequenced on the MiSeq - Illumina® platform for massively parallel sequencing. Dysbiosis index returns a measurement of the overall deviation of the ARs of the sample with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

respect to the reference intervals of healthy subjects at the taxonomic level of genus. Diversity index is based on number of species, phylogenetic distance (P.D. Whole Tree) and distribution of species (Pielou Index). **Results:** Twentyfive patients with cirrhosis and CSPH were enrolled in the study and compared to healthy donors. All patients (mean age 60 years, 88% male) had compensated cirrhosis and CSPH (esophagel varices or splenomegaly), 34% were treated with NSBB and 32% with diuretics. The macrobiota composition of our patients included 5 Phyla: Firmicutes (57%), Bacteroidites (35%), Elusimicrobia (3%), Protebacteria (2.5%), and Actinobacteria (2.4%) with significant differences compared to normal controls in the proportion of Elusimicrobia (3% vs. 1%, $p < 0.001$), Protebacteria (2.5% vs 1.4, $p < 0.003$) and Verrucomicrobia (0% vs 0.34%, $p < 0.004$). As to the micobiota Malassezia R. and Candida A. were found in 70% and 30% of cases. Overall, the Dysbiosis and Diversity Indexes were significantly higher in patients than in controls (median 2.2 vs 1.3, $p < 0.01$; 2.9 vs 1.2, $p < 0.01$). **Conclusion:** The observed difference in the microbiota composition, in the Dysbiosis and Diversity indexes between patients and controls as well as the presence of bacterial and fungal pathobionts may suggest the need for antibiomicrobiol therapy and changes in the dietary habits with the supplementation of specific probiotics.

4341 | CROSS-KINGDOM SHIFTS IN THE BLOOD MICROBIOME DURING HCV-ASSOCIATED LIVER FIBROSIS AND POST-VIRAL CLEARANCE

Rownock Afruza[1] Theo Heller[2] Christopher Koh[2] Moumita Chakraborty[2] Jenna Oringher[2] Nicole Minerva[2] Rabab Ali[2] Grace Zhang[2] Elizabeth Townsend[2] Elliott Levy[2] Ohad Etzion[2] David Kleiner[2] Justin Lack[2] Neelam Redekar[2] Yue Zhang[2] Kareen Akiva[2] Lisa Scheuing[2], [1]National Institutes of Health, [2]NIH

Background: Liver disease is a major cause of global death and has been linked to gut microbiota imbalances. While bacterial changes are associated with liver disease severity and progression, the roles of fungi, viruses, and archaea in this context are still not well defined. This study investigates the portal and peripheral blood microbiome during active HCV infection and after viral clearance, focusing on fibrosis and cross-kingdom interactions, particularly involving fungi. **Methods:** Cell-free DNA was extracted from peripheral and portal blood plasma in patients before (HCVi, $n = 29$) and after (SVR, $n = 23$) DAA treatment. DNA was sequenced, filtered for human reads, and aligned to a curated microbial reference. Fibrosis was staged using the Ishak score, grouping subjects into cirrhotic and non-cirrhotic. Microbial associations were explored using SparCC. **Results:** Bacteria were the most abundant taxa, followed by fungi, viruses, and archaea. In cirrhotic patients, fungal DNA significantly increased after SVR ($p = 0.02$), while bacterial DNA decreased in portal plasma ($p = 0.02$). Microbial profiles in portal blood differed between HCVi and SVR in cirrhotics (Bray-Curtis, $p = 0.008$), with similar trends in fungal diversity. Fungal alpha diversity was lower post-SVR. Dominant bacterial phyla included *Pseudomonadota*, *Bacillota*, *Actinomycetota*, and *Bacteroidota*; fungal phyla were *Ascomycota* and *Basidiomycota*, with the latter increasing post-SVR. *Euryarchaeota* was the main archaeal phylum, and viral profiles were led by *Uroviricota* and *Cressdnaviricota*. SparCC revealed significant interkingdom correlations ($p < 0.05$), mostly between bacteria and fungi. **Conclusion:** This is the first detailed analysis of the blood microbiome in HCV-related fibrosis. Although fungal levels elevated after SVR, diversity declined, suggesting loss of richness and dominance by fewer species. Significant microbiome shifts between HCVi and SVR in cirrhotics and previously underappreciated strong cross-kingdom interactions underscore fungi's key role in blood microbiome dynamics during liver disease.

Samsung Hospital, Sungkyunkwan University School of Medicin, [4]Department of Internal Medicine, Hanyang University College of Medicine, [5]Department of Internal Medicine, Bundang Medical Center, CHA University College of Medicine, Seoul,

Background: Previous studies have primarily focused on the role of the intestinal microbiome in metabolic dysfunction-associated steatotic liver disease (MASLD). While the impact of the gut microbiome is well-documented, the role of the oral microbiome in influencing the gut microbial environment and metabolic pathways has been unveiled. We aimed to investigate the association between the oral microbiome and its potential impacts on gut microbiomes, metabolites, and metabolic risk factors. **Methods:** This study was conducted as a multicenter cross-sectional study involving 206 healthy individuals and 206 diagnosed with MASLD. The oral and stool microbiomes were analyzed using the V3–V4 hypervariable region of the 16S rRNA gene, following the Illumina 16S Metagenomic Sequencing Library Preparation protocol. Serum and stool metabolites were also analyzed using LC-MS. **Results:** There was a lower diversity of oral microbiota and distinct microbial distributions in MASLD compared to controls. Notably, prevalence of oral Neisseria sp. 0031, Veillonella sp. 0011, and Streptococcus sp. 0009 were higher in MASLD compared to non-SLD. These oral microbiomes showed positive associations with body mass index, waist circumference, and adverse lipid profiles, alongside a correlation with elevated liver enzymes. Additionally, specific gut microbes like Weissella sp.001 and Tyzzerella sp. 001 were more abundant in MASLD. Interestingly oral Neisseria sp. 0031, Veillonella sp. 0011, and Streptococcus sp. 0009 showed positive correlation with intestinal Weissella sp.001 and Tyzzerella sp. 001. Presence of Streptococcus sp. 0009 in MASLD was associated with higher levels of lysophosphatidylcholines (15:0), (17:0) and negative correlation with correlation with N-(1-Deoxy-1-fructosyl) aline, succinylcarnitine in serum. **Conclusion:** The oral microbiome, specifically Streptococcus sp. 0009, showed a positive correlation with intestinal microbiome, obethogenic metabolites as well as cardiometabolic parameters in patients with MASLD.

◆ 4343 | CARBOXYMETHYLCELLULOSE AND POLYSORBATE 80: BRIDGING ULTRAPROCESSED FOOD AND MASLD-ASSOCIATED HEPATOCARCINOGENESIS

Gabriel Bacil[1] Leticia Valente[1] Heloiza Ferreira[2] Julia Noveti[3] Keila Cavalcante[4] Diego Alonso[3] Paulo Ribolla[3] Daniel Cardoso[4] Guilherme Romualdo[3] Luis Fernando Barbisan[3], [1]Sao Paulo State University, [2]Sao Paulo State Unviersity (UNESP), [3]Sao Paulo State University (UNESP), [4]University of Sao Paulo (USP)

Background: Hepatocellular carcinoma (HCC) is the main primary liver neoplasia and the 3rd deadliest type of cancer worldwide, whereas metabolic-dysfunction associated liver disease (MASLD) has become the fastest-growing cause of liver disease. Carboxymethylcellulose (CMC) and polyssorbate 80 (P80) emulsifiers are extensively consumed as food additives by the global population and regarded as potential drivers of metabolic diseases by disrupting the gut-liver axis balance. Nevertheless, it is still uncertain whether these compounds modulate MASLD-associated liver carcinogenesis. **Methods:** Male 14-day-old C57BL/6 mice received an intraperitoneal protocol of diethylnitrosamine (DEN, 25 mg/kg of b.w., 1x/week) or saline vehicle, for 4 weeks, and were allocated into 8 experimental groups (G1-G8). From the 6th week on, mice (G2-G8) were kept for 24 weeks on a western diet (WD) protocol or regular diet (G1). Mice also received daily intragastric doses (5x/week), for 20 weeks, of CMC (370 and 740 mg/kg of b.w., G3 and G4, respectively), P80 (100 and 200 mg/Kg of b.w., G5 and G6, respectively), or their combination (370 +100 and 740 +200 mg/Kk of b.w., G7 and G8, respectively) or ultrapure water vehicle. A glucose tolerance test (GTT) was performed and obesity-related outcomes assessed. Hepatic tumoral/non-tumoral samples were collected for further histopathological and molecular analysis. Fecal samples were collected for gut microbiome profiling. Data were analyzed by one/two-way ANOVA or Kruskal-Wallis and Tukey's/Dunn's *post hoc* tests ($p \leq 0.05$). The Shannon's test was used for checking fecal samples' diversity. For the transcriptomic data, a Log2 Fold Change > 1 and padj < 0.05 were defined for the identification of differentially expressed genes. **Results:** G5/G7 had increased final body weight and adiposity index ($p < 0.0001$), while G6/G8 groups showed a higher proportion of larger tumors (> 50 mm^3, $p < 0.0001$). All WD-fed groups showed a glucose

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

intolerance state, as depicted by the GTT area under the curve ($p < 0.0001$), and no effects were observed on serum parameters (alanine aminotransferase, total cholesterol, and triglycerides). Surprisingly, G5-G7 had a pronounced MASLD activity score, featuring a mixed macro/microvesicular steatosis background ($p < 0.0001$) with clear signs of hepatocellular hypertrophy ($p < 0.0001$). G3/G7 featured profound gut microbiome changes, following Shannon's diversity test ($p = 0.0282$ and $p = 0.0472$) at phylum, classes, order, and genera levels. Our bulk RNA-seq analysis revealed a dissimilar impact of food additives on both tumor and adjacent liver, with prominent effects of P80 over inflammation-, lipid-, and microbiome-related genes. **Conclusion:** Our findings revealed that the exposure to populational-relevant doses of CMC and P80 or their combination promote MASLD-associated liver carcinogenesis through the modulation of the gut-liver axis.

◆ 4344 | LOSS OF HEPATIC VACUOLE MEMBRANE PROTEIN 1 PROTECTS AGAINST ACETAMINOPHEN-INDUCED LIVER INJURY

Hong-Min Ni[1] Khue Nguyen[1] Mengwei Niu[1] Wen-Xing Ding[2], [1]The University of Kansas Medical Center, [2]University of Kansas Medical Center

Background: Acetaminophen (APAP) is an analgesic and antipyretic drug that is commonly used worldwide. Although APAP is considered safe at therapeutic doses, APAP overdose may cause severe liver injury and acute liver failure (ALF). Metabolism of APAP results in formation of APAP protein adducts (APAP-AD) in hepatocytes and triggers mitochondrial dysfunction and necrosis. One proposed mechanism to counteract APAP-induced hepatotoxicity is autophagy, a highly conserved intracellular degradation pathway protecting the cell via the removal of APAP adducts and damaged mitochondria. Vacuole membrane protein 1 (VMP1) is an ER transmembrane protein essential for the elongation and closure of autophagosomes. Deletion of VMP1 in the liver leads to impaired autophagy. However, the role of VMP1 in APAP-induced liver injury is unknown. **Methods:** RNAseq database from human APAP ALF and mouse APAP overdose livers were analyzed. Liver-specific VMP1 knockout ($Vmp1^{LKO}$) and matched wild-type ($Vmp1^{LWT}$), and the liver tissues were collected at different time points. Liver injury and necrosis were assessed by serum ALT, hematoxylin and eosin (H&E), and TUNEL staining. APAP metabolism, autophagy, APAP adduct formation, and liver regeneration were also examined. **Results:** Increased mRNA levels of *VMP1* and autophagy genes, *LC3B* and *SQSTM1/p62* in human APAP ALF livers. Serum ALT and necrosis were increased in WT mice following APAP treatment and peaked at 6 hours with increased phosphorylated JNK in mouse livers. LC3B-II and p62 were increased and peaked at 24 hours, but VMP1 protein was decreased in WT mouse livers following APAP treatment. Liver injury was markedly decreased in $Vmp1^{LKO}$ mice compared with their WT littermates with reduced serum ALT and necrotic areas. No difference in basal levels of Cyp2E1 and GSH was found between WT and KO mouse livers. The protein level of phosphorylated JNK was reduced in $Vmp1^{LKO}$ mouse livers. Interestingly, APAP adduct formation and mitochondrial damage were similar in WT and $Vmp1^{LKO}$ mouse livers after APAP, but peroxynitrite formation was decreased in $Vmp1^{LKO}$ mouse livers. Furthermore, GSH replenishment was faster in $Vmp1^{LKO}$ mice than in WT. The number of PCNA-positive cells and hepatic protein levels of PCNA were higher in $Vmp1^{LKO}$ mouse livers. **Conclusion:** Loss of hepatic VMP1 does not affect APAP metabolism and APAP adduct formation but protects APAP-induced liver injury by reducing peroxynitrite formation and enhancing liver regeneration.

◆ 4345 | KINASE INHIBITOR INDUCED LIVER INJURY

Lily Dara[1] Aria Baktash[1] Yi-Ju Li[2] Elizabeth Phillips[3] Raj Vuppalanchi[4] Robert Fontana[5] LUCY MEUNIER[6] Jiezhun Gu[2] Andrew Delinger[2] Huiman Barnhart[2] Jay Hoofnagle[7], [1]University of Southern California, [2]Duke University, [3]Vanderbilt University, [4]Indiana University, [5]University of Michigan Hospitals and Health Centers, [6]Montpellier Hospital Medical Center, [7]NIH, NIDDK

Background: Protein Kinase Inhibitors (KIs) are important therapies for both neoplastic and serious non-neoplastic diseases. Since 2003, more than 100 KIs have been approved for use in the US. Many KIs are associated with aminotransferase elevations during therapy, but little has been reported on serious and clinically apparent KI-induced liver injury (KILI). We aimed to assess the frequency, clinical features, and genetic associations of KILI enrolled in the Drug-Induced Liver Injury Network (DILIN) retrospective and prospective studies. **Methods:** Cases of KILI enrolled in

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

DILIN between 2004 and 2024 were identified and reassessed for causality and clinical features and compared to 1520 non-KI DILI patients. HLA sequencing was performed on both cases and controls. **Results:** 33 cases of KILI scored as probable, highly likely, or definite were identified; the frequency increased from 0.6% of cases enrolled in 2004-09, 1.6% in 2010-14, 2.4% in 2015-19, and to 4.2% in 2020-24. Of the 33 cases, 10 were attributed to imatinib, 5 to pazopanib, 2 each to dabrafenib, lapatinib, and ribociclib, and 1 each to 12 other KI's. Clinical features varied. Overall, 58% were hepatocellular (HC), 18% mixed, and 24% cholestatic; half were anicteric, 33% hospitalized, 48% had liver biopsy, and only 1 fatal (palbociclib). Imatinib caused HC injury, with long latencies, median 7 mo (3 to 47 mo), with autoantibodies in 4, and corticosteroid therapy in 4 patients. In contrast, pazopanib usually caused cholestatic injury, with latencies of 1 to 2 mo, infrequent immune features, and prolonged course. Lapatinib cases were HC with somewhat long latencies (median 4 mo). Six patients were rechallenged and all had DILI again, one adapted eventually. Five patients were exposed to immune checkpoint inhibitors (ICI) within 6 mos of starting a KI. Genetic analysis of 25 KILI cases revealed a significant association with the extended haplotype HLA DQA1*02:01, DRB1*07:01, C*06:02 compared to 1520 DILIN controls ($P = 9.3x10^{-7}$). The HLA DQA1*02:01 allele frequency was 0.30 overall, 0.44 with imatinib and 0.50 with lapatinib compared to 0.12 in DILIN controls (Table 1). **Conclusion:** KILI is an increasingly recognized cause of serious liver injury, rising in incidence with the growing use of targeted and combination ICI–KI therapies. Imatinib was the KI most frequently linked to liver injury, had a distinct phenotype, and a close association with HLA DQA1*02:01, DRB1*07:01, C*06:02, alleles with links to multiple autoimmune diseases. Interestingly, five cases of KILI occurred within 150 days of ICI exposure, suggesting a heightened risk of KILI following immunotherapy.

Allele1	Allele2	Allele3	P-value	KILI Freq	DILIN Control Freq	Known Associations

◆ 4346 | ESTROGEN SIGNALING IN THE DEVELOPMENT OF TOXICANT-ASSOCIATED STEATOTIC LIVER DISEASE IN FEMALES

Banrida Wahlang[1] Yuan Hua[2] Oluwanifemi Esther Bolatimi[2] Gavin Phillips[3] Zayna Qaissi[2] Jeffrey Kim[2], [1]University of Louisville, [2]University of Louisville School of Medicine, [3]University of Louisville College of Arts and Sciences

Background: Persistent organic pollutants (POPs) such as PCB126 (formerly used as industrial chemical) and Chlordane (organochlorine pesticide) are linked to steatotic liver disease (SLD) development. Our prior work demonstrated that females were more susceptible to POP-induced steatosis and metabolic dysfunction compared to males. However, the underlying sex-specific mechanisms driving this disparity remain poorly understood with mechanistic studies in SLD development in women currently lacking. This study investigates how POPs contribute to SLD, with emphasis on female-specific hepatic responses and estrogen signaling. **Methods:** Female C57BL/6 mice underwent ovariectomy or sham surgery. Post recovery, mice were administered either the vehicle control or a mixture of environmentally relevant POPs, namely, Chlordane(20 mg/kg)+PCB126(20μg/kg) via oral gavage. After 2 weeks, mice were euthanized and samples collected for downstream analyses. **Results:** Ovariectomized (OVX) mice generally had higher body fat composition

and liver weights than sham (control) mice. However, exposure to POPs resulted in higher liver to body weight ratios in sham but not OVX mice. Histological analysis of liver sections (H&E) revealed that despite OVX mice showing higher frequency of lipid droplets (steatosis), POP exposure did not exacerbate this effect. However, POP-exposed sham mice exhibited greater steatosis and inflammatory foci infiltration than their unexposed controls. In contrast, serum triglycerides and lipoprotein levels, but not liver triglyceride levels, were down-regulated in POP-exposed sham mice, implicating dyslipidemia. A glucose tolerance test performed 10 days post exposure demonstrated that POP-exposed sham but not OVX mice showed signs of glucose intolerance vs. their unexposed counterparts. Hepatic expression of key target genes was also assessed. POPs increased liver mRNA levels of *Tnfa* only in sham mice while *Hnf4a* was decreased in this group. Further, POP exposure activated hepatic xenobiotic receptors known to negatively interact with estrogen signaling, namely the AHR (*Cyp1a1*, *Cyp1a2* induction) and CAR (*Cyp2b10*, *Cyp2c29* induction) in both groups. This was accompanied by lower liver *Esr1* expression in exposed sham mice, implicating xenobiotic receptor-sex hormone receptor interactions as drivers of POP-induced metabolic and liver dysfunction. **Conclusion:** Taken together, the findings revealed that POP exposure led to steatosis only in sham mice, thereby validating AHR/CAR activation and altered estrogen signaling as a mechanism in SLD development. POPs did not exacerbate steatosis or metabolic dysfunction in OVX mice as this mechanism was absent. Studies using estradiol supplementation in liver *Esr1* null mice will provide insights on potential sex-specific interventions in toxicant-associated SLD.

◆ 4347 | IDENTIFICATION OF NOVEL BIOMARKERS FOR CHOLESTATIC DRUG-INDUCED LIVER INJURY

Kota Tsuruya[1] Kosuke Saito[2] Keiji Tsuji[3] Yuji Kumagai[4] Ken Sato[5] Shotaro Sakisaka[6] Mitsuhiko Aiso[7] Naoya Sakamoto[8] Yusuke Mishima[1] Yoshitaka Arase[1] Shunji Hirose[1] Nami Mori[3] Reiko Tanaka[4] Toshio Uraoka[5] Kazuhide Takata[6] Koji Ogawa[8] Noriaki Arakawa[2] Ruri-Kikura Hanajiri[2] Yoshiro Saito[2] Hajime Takikawa[9] Tatehiro Kagawa[1], [1]Tokai University School of Medicine, [2]National Institute of Health Sciences, [3]Hiroshima Red Cross Hospital and Atomic-Bomb Survivors Hospital, [4]Kitasato University School of Medicine, [5]Gunma University Graduate School of Medicine, [6]Fukuoka University Faculty of Medicine, [7]Teikyo University School of Medicine, [8]Hokkaido University Faculty of Medicine and Graduate School of Medicine, [9]Teikyo University

Background: Drug-induced liver injury (DILI) remains a significant clinical challenge, contributing to over 10% of acute liver failure cases. Conventional liver biomarkers—ALT, AST, ALP, and total bilirubin—are often non-specific and may be influenced by extra-hepatic factors, limiting their utility in accurately diagnosing DILI. Thus, there is a critical need to identify novel, reliable biomarkers that can enhance diagnostic precision for DILI. **Methods:** We conducted a multi-center study involving 66 patients with DILI, 60 healthy controls, and 486 patients with other liver diseases, including viral hepatitis, autoimmune hepatitis (AIH), alcoholic liver injury, metabolic-associated fatty liver disease (MAFLD)/steatohepatitis (MASH), primary biliary cholangitis (PBC), obstructive jaundice (OJ), liver cirrhosis, and hepatocellular carcinoma (HCC). Serum samples from DILI patients (in both acute and recovery phases) and healthy individuals were analyzed using liquid chromatography-mass spectrometry (LC-MS)-based metabolomics. Candidate metabolites were identified based on significant differences (adjusted FDR < 0.01, effect size > 1.5) between acute and recovery phases, as well as between acute DILI and healthy controls. The serum levels of the candidate biomarkers were then quantified and evaluated for their diagnostic performance in distinguishing DILI from other liver diseases. **Results:** Of the 66 DILI patients (37 females, 29 males; age 20–87 years, mean 60.8), 40 had hepatocellular, 13 mixed, and 13 cholestatic injury. Three metabolites—pyroglutamylglycine (pyroGluGly), phenylalanyltryptophan (PheTrp), and phenylalanine (Phe)—emerged as strong candidate biomarkers. These metabolites demonstrated excellent discrimination between acute and recovery phases in mixed and cholestatic DILI (AUCs: 0.967 for pyroGluGly, 0.950 for PheTrp, and 0.984 for Phe in mixed DILI; 0.960 for pyroGluGly, 0.980 for PheTrp, and 1.00 for Phe in cholestatic DILI). In contrast, performance in hepatocellular DILI was modest (AUCs: 0.799 for pyroGluGly, 0.888 for PheTrp, and 0.718 for Phe). Notably, serum pyroGluGly concentrations were significantly elevated in patients with mixed/cholestatic DILI compared to those with other liver diseases. The ability of pyroGluGly to distinguish mixed/cholestatic DILI from other liver diseases was excellent, with AUCs of 0.98 for viral hepatitis, 0.97 for AIH, 0.90 for alcoholic liver injury, 0.97 for MAFLD/MASH, 0.92 for PBC, 0.98 for cirrhosis, and 0.98 for HCC. **Conclusion:** Our study identified pyroGluGly, PheTrp, and Phe as potential serum biomarkers for DILI, particularly cholestatic subtype. These metabolites

may provide a valuable tool for improving the diagnostic accuracy of DILI, facilitating earlier and more specific clinical decision-making.

◆ 4348 | DEVELOPMENT AND EVALUATION OF RETRIEVAL-AUGMENTED GENERATION-BASED LARGE LANGUAGE MODEL FOR ANSWERING CLINICAL QUESTIONS IN DRUG-INDUCED LIVER INJURY USING LIVERTOX DATA

Ashwin Rao[1] Terrence White[2] George Cholankeril[1] Avegail Flores[1] Gagan Sood[1] Fasiha Kanwal[1] Hashem El-Serag[1], [1]Baylor College of Medicine, [2]UTHealth Houston

Background: Idiosyncratic drug-induced liver injury (DILI) remains a major clinical challenge requiring accurate, real-time clinical decision support. LiverTox provides the most comprehensive DILI evidence base with over 1,300 drug monographs, yet its encyclopedic format challenges point-of-care navigation. Healthcare providers increasingly query general AI chatbots for rapid clinical answers, risking harm from hallucinations or non-medical sources (Figure 1, left). We hypothesize that retrieval-augmented generation (RAG), which constrains AI responses to LiverTox's expert-curated content, could deliver accurate, real-time DILI guidance without hallucinations (Figure 1, right). **Methods:** We systematically processed 1,343 LiverTox drug files into 8,759 semantically indexed segments using BioBERT embeddings. Our retrieval system employs drug-specific prioritization and section-aware weighting to identify the most relevant content per query. 25 standardized DILI clinical questions were used to evaluate four RAG-integrated language models: the smaller, open-source Mistral-7B and larger, proprietary Claude-3-Haiku, Claude-3-Opus, and GPT-4o. Each model's responses were restricted to retrieved LiverTox content. Three trained hepatologists, blinded to model type, evaluated responses for accuracy, completeness, and conciseness using standardized 5-point Likert scales. Statistical analyses included intraclass correlation coefficients and Friedman tests with Bonferroni-corrected post-hoc comparisons. **Results:** Inter-rater agreement was moderate (accuracy = 0.51, completeness = 0.52, conciseness = 0.55). RAG-integrated Claude-3-Haiku, Claude-3-Opus, and GPT-4o models significantly outperformed Mistral-7B in accuracy and completeness ($p < 0.005$). Claude-3-Haiku offered the fastest responses (57s) at minimal cost ($0.01) but was less concise than GPT-4o ($p = 0.004$). GPT-4o achieved the highest scores overall with reasonable efficiency (66s, $0.15). Notably, RAG eliminated hallucinations across all responses, with every answer traceable to LiverTox content. **Conclusion:** We developed and evaluated the first RAG system integrating language models with LiverTox for evidence-based DILI management. The three larger proprietary models demonstrated performance advantages, likely due to scale and training resources, with GPT-4o providing the optimal balance of performance, speed, and cost. Importantly, all LLMs produced hallucination-free responses when constrained to LiverTox content through RAG. Our LiverTox integrated RAG-LLM system provides a safe, practical alternative to commercial AI tools and enables reliable answers to drug hepatotoxicity questions at the point of care. Future work will explore supervised fine-tuning on expert-generated question-answer pairs to align responses with clinical reasoning and decision making.

Figure 1. Left: Hallucinated response from GPT-4o when queried directly without context retrieval, incorrectly identifying LiverTox Likelihood Score for phenytoin. **Right:** RAG-LLM pipeline. The system extracts and filters clinically relevant sections from LiverTox documents, segments them into chunks, and embeds them using a BioBERT model. Embeddings are indexed in a vector database for efficient retrieval. When a clinician submits a query, relevant context is retrieved and passed to a large language model (LLM), which synthesizes a response grounded in the retrieved content.

◆ 4349 | PPARA-MEDIATED HEPATIC RESPONSES TO PFOS EXPOSURE IN A HUMANIZED AND KNOCKOUT MOUSE MODEL OF ALCOHOL-ASSOCIATED LIVER DISEASE

Frederick Ekuban[1] Paxton Ames[1] Abigail Ekuban[1] Oluwanifemi Bolatimi[1] Yuan Hua[1] Jianzhu Luo[1] Josiah Hardesty[1] Tyler Gripshover[1] Collette Gorga[1] Walter Watson[1] Banrida Wahlang[1] Dhimitter Bello[2] Jennifer Schlezinger[3] Craig McClain[1] Matthew Cave[1], [1]University of Louisville, Louisville, KY, USA, [2]University of Massachusetts Lowell, Lowell, MA, [3]Boston University, Boston, MA USA

Background: Perfluorooctane sulfonate (PFOS) exposure is increasingly linked to metabolic dysfunction-associated steatotic liver disease (MASLD; PMID: 35475652), yet its role in ALD remains understudied. Our recent wild-type studies showed that PFOS worsened ALD severity via PPARα (PMID: 40347464), yet the exact role of PPARα in mediating these effects remains elusive. Given that PFOS is a strong mouse but weak human PPARα agonist, the relevance of murine models to human health risk is uncertain. Here, we sought to investigate species-specific hepatic responses to PFOS-ethanol co-exposure in humanized PPARα (hPPARα) and PPARα-knockout (KO) mice. **Methods:** Male hPPARα and PPARα-KO mice (C57BL/6J) received modified Lieber-DeCarli diet (5% EtOH vs. control) for 15 days with concurrent PFOS gavage (1 mg/kg) from day 6-15, followed by EtOH binge (5 g/kg) and sacrifice 5-6h later. Assessments included body composition, biochemistry, liver histology (H&E), and high-content imaging of primary hepatocytes. **Results:** EtOH decreased body weight with trends toward differential liver-to-body weight ratios (decrease in hPPARα, increase in PPARα-KO). Both genotypes showed ethanol-induced triglyceride and VLDL elevations, with PFOS augmenting VLDL levels. Notably, PFOS attenuated EtOH-induced ALT and AST increases in both genotypes, contrasting with wild-type studies where PFOS exacerbated hepatotoxicity (PMID: 40347464). Histological examination revealed marked genotype-dependent differences in hepatic architecture. While hPPARα mice maintained normal liver morphology in controls and developed progressive steatosis from mild (PFOS alone) to moderate (ethanol alone) to severe (PFOS+ethanol combination), PPARα-KO mice demonstrated significant baseline steatosis even in vehicle-treated controls, with persistent severe steatosis across all treatment groups. High-content imaging confirmed striking cellular differences: hPPARα hepatocytes showed 4-fold increased mitochondrial function with PFOS-ethanol, while PPARα-KO hepatocytes exhibited heightened oxidative stress and 5-fold increased lipid peroxidation, indicating compromised homeostasis. **Conclusion:** These findings reveal species-specific PPARα-mediated responses to PFOS-EtOH co-exposure. Baseline steatosis in PPARα-KO controls demonstrates PPARα's fundamental role in hepatic lipid homeostasis. Attenuation of EtOH-induced liver injury suggests varying PPARα activity levels modulate injury mechanisms differently than wild-type mice. More data are needed on species-specific nuclear receptor signaling that may vary with environmental pollutant exposure, particularly in alcohol consumers.

Background: Acute kidney injury (AKI) is a significant prognostic factor in cases of decompensated liver cirrhosis and liver transplantation. However, the literature has not specifically evaluated acute renal failure in the context of idiosyncratic drug-induced liver injury (DILI). This study aimed to assess the severity and mortality/liver transplantation rates in cases of DILI with acute kidney injury (DILI-AKI). **Methods:** A comprehensive analysis was conducted on cases of drug-induced liver injury (DILI) prospectively included in the Spanish DILI Registry and the LATINDILI Network for hepatotoxicity, from the inception of both registries until November 2024. Cases with acute kidney injury at the time of DILI diagnosis were compared with those without. The KDIGO 2012 criteria were used to define AKI at the time of hepatic event diagnosis: (1) an increase in serum creatinine of ≥ 0.3 mg/dL within 48 hours; (2) an increase in serum creatinine to ≥ 1.5 times the baseline value within the first seven days; or (3) urine output of < 0.5 ml/kg/hour for more than six hours. Patients with missing creatinine values in previous tests and at the onset of DILI were excluded. DILI severity criteria were those described by Aithal et al. in 2011: elevated total bilirubin and/or INR and/or hepatic encephalopathy/ascites. **Results:** After excluding cases for which creatinine value information was unavailable, 993 cases of drug-induced liver injury (DILI) were analysed, with 5.4% (54 cases) meeting the criteria for acute kidney injury (AKI). The pharmacological agent most frequently associated with AKI was amoxicillin-clavulanate, accounting for six cases (11%). DILI-AKI cases were characterised by a significantly older mean age (60 vs. 52 years, $p < 0.001$). These cases occurred more frequently in male patients (63% vs. 47%, $p < 0.001$) and had a higher prevalence of diabetes mellitus (20% vs. 11%, $p < 0.001$) and arterial hypertension (46% vs. 24%, $p < 0.001$). There was also a higher proportion of cholestatic injury in DILI-AKI cases (38% vs. 21%; $p = 0.014$). Biochemically, the median total bilirubin level was higher in DILI-AKI cases than in DILI without AKI (7.5 vs. 4.8, $p = 0.011$). The DILI-AKI group had a higher rate of hospitalisation, increased severity of cases and higher rates of death from hepatic and non-hepatic causes, reaching statistical significance. See Table 1. **Conclusion:** Acute kidney injury is not uncommon in patients with idiosyncratic drug-induced liver injury (DILI) and is associated with older age, male sex, and the presence of diabetes and hypertension. It is also associated with an increased risk of hospitalisation, disease severity, and ultimately, liver-related and non-liver mortality. Consequently, patients with DILI and acute renal dysfunction require more rigorous monitoring.

Background: Hyperammonemia, a common consequence of both acute and chronic liver injury, is increasingly implicated in the pathogenesis of emotional disturbances, particularly anxiety. Carbon tetrachloride (CCl_4), a well-established hepatotoxin, is widely used to model liver injury–associated anxiety in rodents. However, the underlying neurobiological mechanisms remain poorly characterized, and therapeutic strategies are limited. Recent evidence highlights the basolateral amygdala (BLA) as a key hub for anxiety regulation, enriched with serotonergic projections. Among serotonin receptors, 5-HT_7 has emerged as a critical modulator of affective behavior. Building on our prior findings in Parkinsonian models, we investigated the involvement of BLA 5-HT_7 receptors in CCl_4-induced anxiety. **Methods:** Anxiety-like behavior was induced in rats via intraperitoneal injection of CCl_4 (dissolved in olive oil); vehicle-only controls received olive oil alone. Behavioral assays included the elevated plus maze and open field tests. 5-HT_7 receptors function was modulated by intra-BLA microinjection of AS19 (agonist) or SB269970 (antagonist). Electrophysiological recordings, neurochemical profiling of monoamines in limbic and cortical regions, and immunofluorescent colocalization studies were conducted to explore underlying mechanisms. **Results:** In control rats, intra-BLA administration of AS19 induced anxiogenic effects, whereas SB269970 was anxiolytic. Remarkably, in CCl_4-treated rats, this pattern was reversed: AS19 produced anxiolytic-like effects, while SB269970 increased anxiety-like behavior. Neurochemical analyses revealed that AS19 and SB269970 respectively decreased and increased dopamine, serotonin, and noradrenaline levels across the medial prefrontal cortex, amygdala, habenula, and ventral hippocampus in both groups. Electrophysiological recordings showed that AS19 enhanced the firing rate of BLA GABAergic interneurons, whereas SB269970 suppressed it, with responses prolonged in CCl_4-treated rats. Notably, CCl_4 exposure did not alter the colocalization of 5-HT_7 receptors with GABAergic neurons. **Conclusion:** These findings reveal a state-dependent, bidirectional role for BLA 5-HT_7 receptors in the regulation of anxiety under hepatotoxic conditions. This is the first study to characterize a paradoxical shift in receptor sensitivity following liver injury. Our results offer novel insights into liver–brain communication and identify BLA 5-HT_7 signaling as a promising therapeutic target for anxiety disorders associated with hepatic dysfunction.

4352 | IMPACT OF STEROID DURATION ON OUTCOMES IN IMMUNE CHECKPOINT INHIBITOR HEPATITIS

Mohamed Nadeem[1] Shilpa Junna[2] prabhat kumar[3], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic, [3]Virginia Commonwealth University

Background: Immune checkpoint inhibitors (ICIs) can cause hepatitis, for which corticosteroids remain the mainstay of therapy, however, the optimal duration of steroid therapy remains contested. This study evaluates whether short (0–8 weeks), intermediate (8–16 weeks), or prolonged (16–24 weeks) steroid therapy affects clinical outcomes. **Methods:** Using a multicenter electronic health record network, TrinetX, we retrospectively identified adult patients with ICI hepatitis treated with corticosteroids. Patients were stratified into three groups based on total steroid exposure. Key outcomes included all-cause mortality, all-cause hospitalization, acute liver failure (ALF) and normalization of liver enzymes defined as ALT < 50 U/L, AST < 30 U/L, ALP < 150 U/L, total bilirubin < 1.2 mg/dL up to 1-year after initial exposure to steroids. Patients with viral hepatitis, autoimmune, and other forms of hepatitis were excluded. Propensity-matched analyses were conducted for each duration comparison using odds ratios (ORs), 95% confidence intervals (CIs), and p-values. **Results:** After matching, patients in the short duration cohort had significantly higher all-cause mortality compared to the intermediate duration cohort (47.5% vs 29.2%, OR 2.20 [95% CI: 1.29–3.74], $p = 0.003$). Rates of hospitalization (51.7% vs 41.7%, OR 1.50 [0.90–2.49], $p = 0.121$) and ALF (10.0% vs 8.3%, OR 1.22 [0.51–2.95], $p = 0.655$) were similar between the two groups. Normalization of ALP (< 150 U/L) at 1 year was significantly less frequent in the short-course group (57.5% vs 70.8%, OR 0.56 [0.33–0.95], $p = 0.031$), while normalization for AST, ALT, and bilirubin did not differ significantly between both groups.

Among intermediate and prolonged steroid duration groups there was no significant difference in mortality (25.0% vs 23.3%, OR 1.10 [0.48–2.53], $p = 0.831$). The intermediate group had higher rates of ALF (16.7% vs 0%, $p = 0.001$) and all-cause hospitalizations (46.7% vs 25.0%, OR 2.63 [1.21–5.69], $p = 0.013$) compared to the prolonged group.

When comparing outcomes between the short and long duration groups, all-cause mortality and all-cause hospitalization events were noted to be significantly higher in the short duration group (54.1% vs 23.0%, OR 3.95 [1.94–8.01], $p < 0.001$, 47.3% vs. 64.9%, OR 3.01 [1.48-6.11], respectively. **Conclusion:** Across all

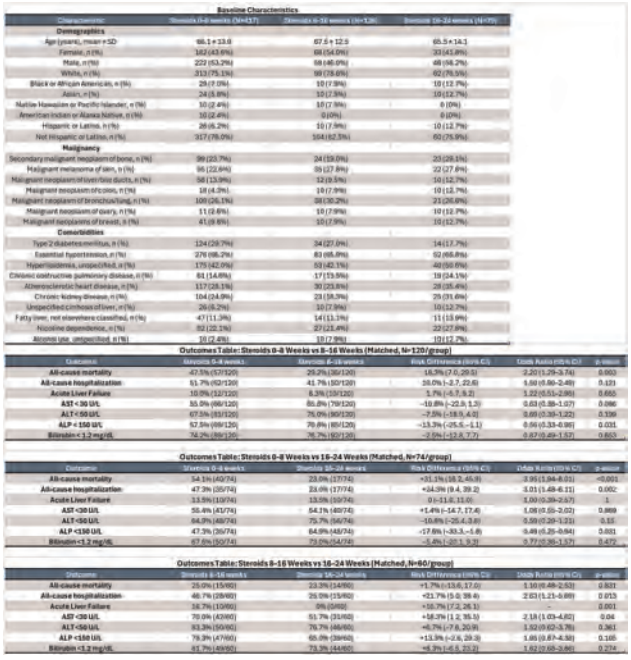
comparisons, short steroid duration (< 8 weeks) was associated with the highest mortality and hospitalization rates, supporting the use of at least 8 weeks of steroid treatment in ICI hepatitis. Intermediate steroid duration (8–16 weeks) appeared to lower mortality relative to short courses, but was associated with a higher risk of hospitalization and ALF compared to prolonged treatment. Further study is needed to determine if a longer course of steroid treatment albeit at a lower dosage may be necessary to prevent these outcomes.



Baseline Characteristics

Characteristic	Steroids 0-8 weeks (N=120)	Steroids 8-16 weeks (N=120)	Steroids 16-24 weeks (N=59)
Demographics			
Age (years), mean ± SD	66.1 ± 13.6	67.5 ± 12.5	65.5 ± 14.1

4353 | LOW DOSE ENVIRONMENTAL DIOXIN MIXTURE DISRUPTS HEPATIC HOMEOSTASIS VIA SEX- AND DIET-SPECIFIC MECHANISMS

Oluwanifemi Esther Bolatimi[1] *Yuan Hua*[1] *Gavin Philips*[1] *Frederick Ekuban*[1] *Abigail Ekuban*[1] *Paxton Ames*[1] *Banrida Wahlang*[1], [1]*University of Louisville*

Background: Persistent organic pollutants (POPs) such as “dioxins” are widely released through anthropogenic and/or natural combustion processes and exposure to these toxicants have shown causal and correlation effects in metabolic dysfunction-associated steatotic liver disease (MASLD) development. Population studies have highlighted sex-specific vulnerability to POP-induced liver damage, yet toxicological models rely on male models and the combined effects of dioxin mixtures remain poorly defined. This study addresses a critical knowledge gap by investigating sex-dependent effects from exposure to a mixture of dioxins: 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD), 2,3,4,7,8-Pentachlorodibenzofuran (PeCDF) and Polychlorinated biphenyl 126 (PCB126), in the context of hypercaloric and western diets. **Methods:** Male and female C57BL/6 mice were fed either a high-fat (HFD) or low-fat (LFD) and administered a weekly dose of TCDD(10ng/kg) +PeCDF(80ng/kg)+PCB 126(140ng/kg) or vehicle control, for 12 weeks. At euthanasia, plasma and tissue were collected for downstream analyses. **Results:** HFD-fed male mice exhibited marked micro- and macro-vesicular steatosis compared to their sex- and diet-matched controls. This was reflected in H&E staining and quantifications of hepatic triglycerides/cholesterol. Notably, LFD-fed female mice exposed to the dioxin mixture displayed reduced liver weight but elevated hepatic triglycerides alongside upregulation of the hepatic fatty acid transport gene *Cd36*. This observation was absent in the diet-matched males. Instead, dioxin exposed LFD-fed males showed suppressed expression of de novo lipogenesis regulators *Fasn* and *Scd1*. Elevated ALT and AST levels were observed in both sexes with HFD, and particularly, ALT increased significantly in dioxin-exposed LFD-fed females. Mechanistically, dioxin exposure activated the hepatic xenobiotic receptors AHR and CAR with sex- and diet-specific modulation. AHR activation was observed (*Cyp1a1* and *Cyp1a2* induction) regardless of sex or diet, although HFD decreased inducibility in males specifically. CAR activation (*Cyp2b10* and *Cyp2c29* induction) showed sex differences and were basally upregulated in females. However, dioxin exposure increased induction in LFD-fed males only, suggesting sex-specific receptor activation. **Conclusion:** Exposure to dioxin mixture resulted in sex- and diet-dependent hepatic metabolic dysregulation. Curiously, LFD-fed mice showed greater susceptibility and effects were less pronounced with HFD-feeding. Future studies will address the temporal sequence of exposure by administering the dioxin mixture prior to initiation of high-fat diet feeding, to elucidate how toxicant exposure primes and modulates sex-specific hepatic responses during the transition into a hypercaloric metabolic state.

4354 | RULE-OF-TWO AND DILISCORE FOR DRUG-INDUCED LIVER INJURY RISK ASSESSMENT ARE ASSOCIATED WITH RISK MITIGATION ACTIONS IN DRUG APPLICATIONS EVALUATED AT THE FDA

Minjun Chen[1] Edwige Chiogo Vouffo[1] Paul Hayashi[1], *[1]FDA*

Background: Predicting drug-induced liver injury (DILI) during drug development remains challenging. Developed at the National Center for Toxicological Research (NCTR), Rule-of-Two (RO2) and DILIscore are *in silico* models using drug physicochemical and pharmacological properties to predict post-market DILI risk. RO2 outputs a (+) or (-) for DILI risk while DILIscore gives a numeric value that assigns risk as mild, moderate, or high. These models are based on post-market drug labels through 2010, but their association with regulatory actions for drug candidate development since they were developed has not been assessed. **Aim:** To assess associations among RO2, DILIscore, and the presence of Hy's law cases (HL (+/-)) with DILI related risk mitigation actions (RMAs). **Methods:** We analyzed drug applications between 2021 and 2024 with NCTR RO2 and DILIscore assessments, and DILI Team assessments for HL (+/-). We assessed RO2, DILIScore, and HL (+ or -) for associations with RMAs, defined as a pause or cessation in drug development, clinical hold, or labeled box warning. Positive and negative predictive values (PPV, NPV), and sensitivities were used to further describe the associations. **Results:** Thirty-six applications (25 initial drug applications [IND]; 11 new drug applications [NDA]) had RO2, DILIscore and HL assessments from 2021 to 2024. DILIscores were indeterminable in 15; RO2 and HL (+ or -) were determined in all 36. RO2, DILIscore and HL were all statistically associated with RMA (Table). PPVs for RO2, DILIscore, and HL (+) were 68% (13 /19), 83% (10 /12), and 87% (13 of 15) respectively; while NPVs were 71% (12 of 17), 89% (8 of 9) and 76% (16 of 21), respectively. RO2 (+), a high-risk DILIscore, and HL (+) sensitivities were 72%, 91% and 72%, respectively. For HL (-) applications, having either a RO2 (+) or high-risk DILI score had a sensitivity for RMA of 80% (4 of 5) with PPV and NPV of 36% and 90%, respectively. **Conclusion:** Summary: RO2, DILIscore, and presence of HL cases were all significantly associated with RMAs ($p < 0.05$) in applications assessed by the NCTR and DILI Team. Having a high risk DILIscore had the highest sensitivity for such actions when a DILIscore could be determined. Conclusions: RO2 and DILIscore have strong associations with RMAs for DILI and may play a meaningful role in supporting regulatory decision-making during review. In silico models may be useful adjuncts for early identification of potential hepatotoxicity.

Table: RO2 results, DILIscore, presence of Hy's Law cases and risk mitigations actions in 36 drug applications evaluated by FDA NCTR and DILI Team.

Characteristic	Overall N = 36[1]	Risk mitigation actions: None N = 18[1]	Risk mitigation actions: WD/Hold/BW[3] N = 18[1]	p-value[2]
RO2[4]				0.019
Positive	19	6 (32%)	13 (68%)	
Negative	17	12 (71%)	5 (29%)	
DILIscore[5]				0.002

4355 | THE HIGH PREDICTIVE POWER OF THE MODEL OF END-STAGE LIVER DISEASE SCORE IN DRUG-INDUCED LIVER INJURY

Sabine Weber[1] Izabel Mircheva[2] Rochell Balakumar[2] Julian Allgeier[2] Didem Saka[2] Nirali Donga[2] Franziska Erhardt[2] Christian Lange[2] Alexander Gerbes[2], *[1]Department of Medicine II, LMU Klinikum, Munich, [2]Department of Medicine II, LMU Klinikum Munich*

Background: Drug-induced liver injury (DILI) can have disastrous consequences possibly leading to acute liver failure, liver transplantation or death[1]. Traditionally, Hy's law has being used to predict severe DILI, specificity however is low[2]. Thus, identifying patients at risk of an adverse outcome early in the course of disease is of outmost importance. **Methods:** We aimed to identify prognostic factors that can identify patients with high risk of a fatal outcome. To this end, the data of 273 DILI patients from our prospective study on acute liver injury with potential drug-related cause were analyzed. 479 patients with initial suspicion of DILI were enrolled, out of which 273 were diagnosed with DILI. DILI diagnosis was based on clinical, laboratory and histological features and an expert adjudication process[3]. Alternative causes of liver injury were ruled out by a thorough

hepatological work-up. The primary endpoint was an adverse outcome defined as liver transplantation (LT) or death. **Results:** 27 (10%) of patients reached the primary endpoint of having an adverse outcome. Univariate logistic regression analysis revealed that alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin, INR, the Model of End-stage Liver Disease (MELD) score and the R ratio at the time of DILI recognition as well as Hy's law positivity were significantly associated with an adverse outcome. Interestingly, the burden of comorbidity, represented by the Charlson Comorbidity Index, did not have a significant association with an adverse outcome in our DILI cohort. On multivariate logistic regression analysis only ALT (odds ratio [OR] 0.97, 95% confidence interval [CI] 0.923-0.989, $p = 0.056$), AST (OR 1.06, 95 % CI 1.02-1.10, $p = 0.005$) and MELD score (OR 1.23, 95% CI 1.13-1.34, $p < 0.001$) were independently associated with an adverser outcome. The MELD score in particular showed an extraordinarily high concordance statistic (c-statistic) of 0.93 (95% CI 0.89-0.97). At a cut-off of ≥ 20, the MELD score could predict a fatal outcome in DILI patients with a sensitivity of 89% and specificity of 82% and with this performed better than Hy's law, new Hy's law and the prognostic score published by Robles et al. in terms of prognosis[2]. **Conclusion:** The MELD score at the time of DILI recognition has a high predictive power in DILI patients. Our data shows that DILI patients with a baseline MELD score of 20 or higher are at high risk of needing high urgency liver transplantation or having a lethal outcome.

[1] Shown are the odds ratios (OR) and the 95% confidence intervals (CI) for baseline laboratory parameters with regards to adverse outcome in univariate analysis. Adverse outcome was defined as death or liver transplantation. [2] Variables considered in the multivariate logistic regression analysis were parameters with p<0.200 in univariate analysis. [3] The R-ratio is defined as (ALT/ULN)/(ALP/ULN), with R≥5 defining a hepatocellular, R≤2 a cholestatic and 2<R<5 a mixed type of injury. * indicates a statistical significance (p≤0.05).

Abbreviations: ALP: Alkaline phosphatase; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; CCI: Charlson Comorbidity Index; IgG: Immunoglobulin G; INR: International normalized ratio; MELD: Model for end-stage liver disease; TBIL: Total bilirubin; ULN: Upper limit of normal.

4356 | SINGLE-CELL RNA SEQUENCING ELUCIDATES THE PATHOGENIC ROLE OF CD74 IN ACETAMINOPHEN-INDUCED ACUTE LIVER INJURY

Pengzhan Deng[1] Qiuli Xie[1] Mingjiang Liu[1] Tingfeng Xu[1] Lijuan Liao[1] Jie Zhang[1] Songqing He[1] Wenli Xu[1], [1]First Affiliated Hospital of Guangxi Medical University

Background: Although acetaminophen (APAP) is the leading cause of drug-induced liver injury (DILI), current therapeutic strategies for this condition remain substantially limited. The inflammatory microenvironment plays a pivotal role in the progression of APAP-induced liver injury (AILI). CD74 regulates pro-inflammatory cytokine production in various hepatic pathologies and is involved in macrophage-mediated inflammatory responses and leukocyte recruitment. This study aims to elucidate the role and molecular mechanisms of CD74 in AILI, providing novel therapeutic targets for clinical management. **Methods:** In this study, wild-type (WT) and CD74-knockout ($CD74^{-/-}$) mice were intraperitoneally injected with 300 mg/kg APAP or saline. Peripheral blood and liver tissues were collected at multiple time points for single-cell RNA sequencing (scRNA-seq), biochemical, histopathological, and molecular analyses to characterize the dynamic immune landscape during the AILI progression and explore the relationship between CD74 and the immune microenvironment. **Results:** CD74 expression was upregulated in mice with AILI. Notably, a sustained accumulation of pro-inflammatory macrophages was detected in the liver post-APAP injury. In contrast, $CD74^{-/-}$ mice exhibited a phenotypically distinct subset of anti-inflammatory macrophages within hepatic tissues. Co-localization of CD74 with F4/80-positive macrophages and CXCR4 was observed in WT mice after APAP treatment. $CD74^{-/-}$ mice showed a reduction in hepatic necrotic areas and an increase in Ki-67-positive zones. These findings suggest that CD74 participates in macrophage recruitment and inflammatory cell chemotaxis during AILI. Furthermore, $CD74^{-/-}$ mice demonstrated attenuated hepatic injury accompanied by enhanced hepatocyte proliferative capacity. **Conclusion:** CD74 deficiency mitigates APAP-induced hepatotoxicity and enhances hepatocyte regeneration in mice. These findings indicate that CD74 may serve as a potential therapeutic target for AILI.

4357 | CLINICAL, LABORATORY AND GENETIC VARIANTS ASSOCIATED WITH IMMUNE MEDIATED LIVER INJURY FROM CHECKPOINT INHIBITORS VERSUS OTHER CAUSES OF LIVER INJURY

Linnea Swanson[1] Andrew Tucker[1] LaVana Greene-Higgs[1] Venkata Sai Jasty[1] Jessica Sheehan[1] Yi-Ju Li[2] Vincent Chen[3] Robert Fontana[4], [1]University of Michigan, [2]Duke, [3]University of Michigan Medical Center, [4]University of Michigan Hospitals and Health Centers

Background: Immune-mediated liver injury from checkpoint inhibitors (ILICI) arises in 5 -10% of oncology patients, often prompting early drug discontinuation and corticosteroid use. Previous studies have found genetic variants in the immune response and drug metabolism associated with ILICI. The aim of our study was to characterize the clinical features, outcomes and genetic variants in a large cohort of ILICI cases compared to those with other causes of liver injury. **Methods:** Solid tumor patients who received immune checkpoint inhibitors (ICI) from 2010-2024 and enrolled in the Michigan Genomics Initiative were analyzed. Liver injury was defined as AST or ALT $\geq$ 5x ULN, ALP $\geq$ 2x ULN, bilirubin $\geq$ 2.5, or INR $\geq$ 1.5. Causality assessment was based on the DILIN expert opinion scale [1-3 = probable ILICI, 4-5 = alternative cause (non-ILICI liver injury)] by consensus of 3 reviewers. Candidate gene associated tests for previously described single nucleotide polymorphisms (SNPs) and genome-wide association study (GWAS) was conducted using Regenie version 3.4, adjusted for age, sex, and principal components 1-2. We ran one GWAS where cases were ILICI patients and another where cases were non-ILICI patients; both use ICI-treated patients without liver injury as controls. **Results:** 979 patients received ICI therapy with 187 (19.1%) developing biochemical evidence of liver injury. Of the 187 liver injury patients, 67 (35.8%) were due to ILICI with DILIN score 1-3 and 120 were non-ILICI causes of liver injury. Mean age was 64, 62% male and 97% Caucasian (Table 1). Common malignancies were melanoma (37%), genitourinary cancers (19.5%) and non-small cell lung cancer (9.5%). Pembrolizumab (48%), ipilimumab (21%) and nivolumab (18%) were the most frequently used ICIs. Patients with ILICI were more likely to have received dual ICI therapy ($p < 0.001$), normalize their LFTs ($p < 0.001$) and receive corticosteroids ($p < 0.001$) during follow-up. Those with non-ILICI liver injury had more hepatic metastasis (33% vs 15%; $p = 0.011$) and worse cancer outcomes ($p < 0.001$) and survival in comparison to those with ILICI ($p < 0.001$). The liver injury from ILICI was more hepatocellular (*R* ratio 4.6 vs 2.5; $p < 0.001$) and less likely to result in jaundice ($p = 0.04$). A series of 17 SNPs from prior studies of DILIN were tested but not associated with a phenotype of ILICI alone or any cause of liver injury. Two and three independent variants associated with ILICI and non-ILICI liver injury, respectively, at $p < 10^{-5}$. **Conclusion:** ILICI occurred in 7% of ICI-treated patients and was associated with acute hepatocellular injury, LFT normalization, corticosteroid use, and improved survival compared to non-ILICI liver injury. Previously reported SNPs were not replicated, but novel loci were identified, meriting further investigation.

Table 1. Comparison of clinical features of ILICI versus non-ILICI liver injury

	Non ILICI N = 120[1]	ILICI N = 67[1]	p-value[2]
Age (yrs)	63 (13)	62 (14)	0.6

4358 | A LIMITED REVISED ELECTRONIC CAUSALITY ASSESSMENT METHOD (RECAM) ALGORITHM FOR DILI CASE PRIORITIZATION IN CLINICAL TRIALSSUBMISSION

Mark Gordon[1] Mark Avigan[2] Paul Hayashi[1], [1]FDA, [2]Food and Drug Adminstration

Background: Most liver injury in clinical trials is not due to drug-induced liver injury (DILI). Yet many meet criteria for detailed assessment for DILI due to the investigational products (IP). No diagnostic model can negate the need for meticulous clinical review, but we aimed to create an algorithm that identifies cases as high or low probability DILI to better prioritize case reviews. **Methods: Methods:** We retrospectively analyzed the FDA DILI Team's database from Jul 2000 to Apr 2024 for variables that predict DILI Network (DILIN) likelihood scores assigned by clinical reviewers. We excluded large protein (>40 amino acids) IPs and post-market cases. Variables, including RECAM domains, demographics, and R-values, were tested by ordinal logistic regression (OLR) to predict three outcomes: (i) at least probable; (ii) possible; or (iii) unlikely DILI assigned by the DILI Team. Data were split into training and validation sets. We used decision tree analyses to optimize predictive values for independent variables in the OLR model. **Results: Results:** There were 1330 subjects across 74 applications; 678 met inclusion criteria and had adequate data for OLR modeling. Only shorter interval (latency) between IP start and injury onset; shorter latency between IP stop and onset; and higher R value were statistically associated with at least probable DILI. Of 174 cases in the validation dataset, 69 were at least probable, 61 possible, and 44 unlikely DILI. Accuracy of modeling was 61%; kappa score 41%. For 794 cases with complete latency data, decision tree analysis found combinations of latencies after IP start and stop that identified 243 cases of which 231 (95%) were unlikely DILI and 485 cases of which 247 (51%) were at least probable DILI (Figure). **Conclusion:** Summary: Of RECAM and other variables, only shorter latencies from IP start and stop, and higher R values were predictive of probable DILI. Overall, model accuracy for predicting clinical reviewer attribution to DILI was modest, but certain long latency cut-offs had high negative predictive value for probable DILI. Conclusions: The threshold for cases with potential DILI in clinical trials requiring detailed assessment is low (e.g., peak ALT >3-5x ULN) leading to substantial work for clinical reviewers when most cases will not be DILI. No diagnostic algorithms are accurate enough to replace careful case-by-case assessment for DILI; however, combinations of long latency parameters could identify cases with low likelihood of being considered DILI.

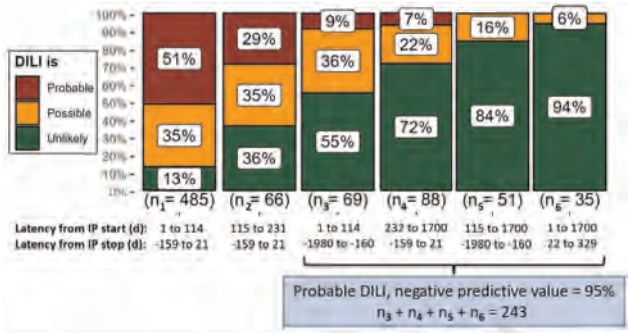

FIGURE: Bar graph proportions of liver injury cases by clinical reviewers' attribution category (at least probable, possible, unlikely DILI) and various cut-offs for latency from drug start and stop. Cut-offs determined by decision tree analyses to optimize predictive values for probable DILI. A negative Latency form IP stop value means the drug was continued for that many days after liver injury onset. A positive value means the injury onset occurred that many days after last dose. The four groups on the right yielded a negative predictive value of 95%. The content in this abstract & figure are the responsibility of the authors and do not necessarily represent the official views of the FDA.

4359 | THE EFFECT OF A FIXED AMINOTRANSFERASE UPPER LIMIT OF NORMAL ON EDISH ASSESSMENT OF LIVER INJURY RISK IN CLINICAL TRIALS

Mark Gordon[1] Ling Lan[1] Mark Avigan[1] Paul Hayashi[1] Yang Veronica Pei[1], [1]FDA

Background: Aminotransferase (AT) upper limits of normal (ULN) vary and many ULNs are higher than recommended. Evaluation for Drug Induced Severe Hepatotoxicity (eDISH) uses multiples of ULN (xULN), and it is unclear how fixed AT ULNs may affect eDISH outputs. **Aim:** To assess the use of American College of Gastroenterology (ACG) ALT ULNs of 33 U/L for males & 25 U/L for females (M33/F25) on eDISH. **Methods: Methods:** We assessed phase 2 and 3 trials having a comparator arm, enrolling ≥ 18 y-olds, and having ≥ 85% normal baseline AT & bilirubin values by trial provided ULNs (tr-ULN) submitted to the FDA in 2022. We applied M33/F25 to both ALT & AST. We compared eDISH quadrant counts using tr-ULN vs M33/F25. We also tallied subjects in Temple's Corollary quadrant (TCQ) with ALT > 5xULN. We assessed differences in proportions with 3x to 8x ULN using tr-ULN and M33/F25 stratified by sex. We determined how many active-to-comparator arm pairs did not meet Temple's Corollary (TC) using tr-ULN but met TC using M33/F25. **Results: Results:** Fifty-seven qualifying studies had

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

23141 subjects (12123 F;11018 M; 70% white, 15% Asian, 11% black, 4% other/unknown). Mean age = 54.5 y (±15.6). Female mean age was lower (52.8 vs 56.7 y). Median number of subjects for active arms was 81 (range: 11 to 1487). M33/F25 increased the number of subjects in both Hy's law and TC quadrants from 35 (0.15% of total) to 44 (0.19%), and 437 (1.9%) to 977 (4.2%), respectively. For TCQ cut-off of >5x ULN, the number increased from 154 (0.67%) to 301 (1.3%). The proportions >3x thru 8x ULN increased more for females (Figure). Of 93 active-comparator pairings, 7 (7.5%) did not meet Temple's Corollary (TC) using tr-ULNs (<1% difference between arms) but met TC using M33/F25 ULNs. Of these 7 pairings, 3 met TC by >2% difference between arms and 2 met TC by >3% difference. **Conclusion:** Summary: ACG based AT ULNs (33 U/L males; 25 U/L females) doubled the trial subjects plotting to TCQ at 3xULN and 5xULN cut-offs. Increases were higher for women. The proportion of subjects plotting to Hy's law quadrant increased by 25% but absolute numbers were small (35 to 44) considering the large number of subjects (>23000). An additional 7.5% of active-to-comparator arm pairs met TC using M33/F25. Conclusions: ACG based ULNs substantially increase the number of subjects identified as potential DILI on eDISH but may have a smaller effect on the number of subjects and trials meeting Hy's law and Temple's Corollary, respectively.

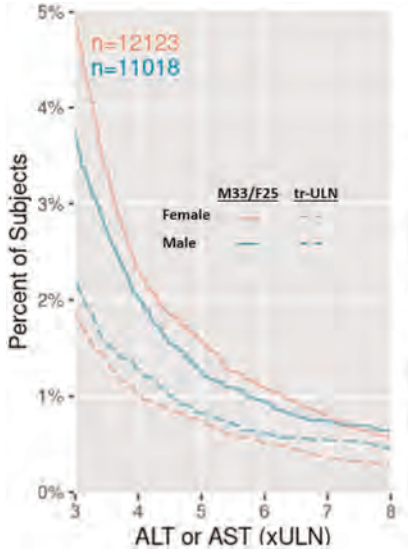

FIGURE: Percent of subjects meeting ALT or AST cut-offs of 3x ULN to 8x ULN by sex and use of trial reported ULNs (tr-ULN) versus ACG ULNs of 33 U/L and 25 U/L for males and females, respectively. The content in this figure and abstract are the responsibility of the authors and does not necessarily represent the official views of the Food and Drug Administration.

4360 | AN PHD2-TARGETED INTRABODY PROTECTS ACETAMINOPHEN-INDUCED LIVER INJURY BY IMPROVING REDOX HOMEOSTASIS AND ATTENUATING FERROPTOSIS

Ze Ren[1] Xinze Yu[1] Ying Wang[1] yanfei Liu[1] Yuchong Wei[1] cheng cheng[1] zhaoyang liu[1] jiayin Yu[1] Zijian Shi[1] Guiying Li[1], [1]School of Life Sciences, Jilin University

Background: Acetaminophen (APAP) overdose is a major cause of drug-induced acute liver failure. Although inhibiting prolyl hydroxylase 2 (PHD2)-mediated degradation of hypoxia-inducible factor-1α (HIF-1α) can alleviate APAP toxicity, the role of HIF-1α in mitigating ferroptosis during APAP toxicity remains unclear. This study developed a novel anti-PHD2 cytosolic intrabody (INP2) disrupting PHD2 and HIF-1α interaction to enhance HIF-1α protein stability and explored its protective mechanisms against APAP-induced liver injury (AILI). **Methods:** a human anti-PHD2 single-chain fragment variable (scFv) was screened from phage antibody display library and was used as template to synthesize INP2. Western blot and immunofluorescence were used to validate INP2 expression and localization in cells. The regulation of INP2 on PHD2 activity and HIF-1α level was assessed by Western blot and co-IP detection of Pro564/Pro402 hydroxylation. For APAP toxicity studies, mice received pretreatment with pINP2 or control vector and then challenged with APAP (250 mg/kg). Liver injury was evaluated through serum ALT/AST and histopathology. Antioxidant systems and lipid peroxidation markers were analyzed in liver tissue. RNA-seq of liver tissues from different groups and significantly changed pathways were validated. Finally, A liver-targeted nanoformulation (IRB@MSN@RM) was developed for INP2 delivery in vivo. **Results:** INP2 expressed in the cytoplasm specifically bound to PHD2 and disrupted PHD2 and HIF-1α interaction, effectively inhibiting HIF-1α hydroxylation and degradation. In murine models of APAP hepatotoxicity, INP2 pretreatment significantly attenuated liver injury. INP2 protects against AILI by reducing oxidative stress and lipid oxidation. Importantly, RNA-seq of liver tissues revealed that INP2 treatment led to significant changes in glutathione metabolism pathway. INP2 restored glutathione biosynthesis and anti-oxidative stress by upregulating SLC7A11 and GPX1, improving glutathione metabolism and inhibiting ferroptosis through H2O2 and 12-HPETE clearance. Finally, using the delivery system, INP2 can effectively enter cells and block intracellular PHD2 activity. By employing erythrocyte membrane camouflage, the half-life and hepatic retention time of INP2 were significantly prolonged. **Conclusion:** The PHD2-targeted intrabodies protect the liver from APAP-induced injury by upregulating the HIF-1α/GPX1 axis to improve redox

4361 | HEPATOCYTE-SPECIFIC DELETION OF BETAINE HOMOCYSTEINE METHYLTRANSFERASE PROMOTES AGE-DEPENDENT PROGRESSION OF LIVER DISEASE THROUGH ALTERING ONE-CARBON METABOLISM

Sathish kumar Perumal[1] Ramachandran Rajamanickam[1] Ramesh Bellamkonda[2] Sundararajan Mahalingam[2] Kurt Fisher[2] Natalia Osna[2] Hua Jiang[3] Kenneth Maclean[3] Benita McVicker[2] Karuna Rasineni[2] Kusum Kharbanda[1], [1]Research Service, Veterans Affairs Nebraska-Western Iowa Health Care System, Omaha, Nebraska, USA, [2]University of Nebraska Medical Center, Omaha, Nebraska, USA, [3]University of Colorado School of Medicine, Aurora, CO, USA

Background: Betaine homocysteine methyltransferase (BHMT) is an essential enzyme involved in one-carbon metabolism and liver health. Our previous research highlighted the importance of BHMT in preventing liver disease by removing harmful metabolites homocysteine and S-adenosylhomocysteine (SAH). To further understand BHMT's function in the liver, we created BHMT floxed mice and liver-specific BHMT knockout (LKO) mice. This study aimed to explore how the liver-specific deletion of BHMT impacts the development of liver disease focusing on other one-carbon metabolism enzymes and metabolites. **Methods:** One-year-old male and female C57BL/6 BHMT floxed and liver-specific BHMT knockout (BHMT LKO) mice were fed a standard chow diet and housed under ambient conditions. Liver tissues were collected for histopathological and biochemical analyses. **Results:** Compared to floxed mice, BHMT KO mice had significantly higher serum homocysteine, hepatocellular homocysteine, and SAH levels, despite a 2.5-fold compensatory increase in 5-methyltetrahydrofolate-homocysteine methyltransferase ($p < 0.01$), an alternate enzyme for homocysteine remethylation and SAH removal. Hepatic S-adenosylmethionine (SAM) levels were unchanged in LKO mice, but a seven-fold increase in SAH resulted in a significantly reduced SAM:SAH ratio ($p < 0.001$), suggesting widespread cellular methylome disturbances. Liver glutathione levels dropped significantly due to lower protein levels of cystathionine β-synthase, a key enzyme in glutathione synthesis. While compensatory increases in cystathionine γ-lyase protein levels were observed, other important enzymes remained unchanged between BHMT LKO and floxed mice. Histological and biochemical analyses showed increased steatosis, higher inflammation indices, fibrotic changes, and epigenetic alterations in the livers of BHMT LKO mice compared to age-matched floxed controls, correlating with a loss of liver methylation potential and antioxidants. **Conclusion:** The liver-specific deletion of BHMT results in increased liver injury markers in aging male and female BHMT LKO mice, reflecting significant alterations in one-carbon metabolism pathway enzymes and metabolites. This indicates that individuals with a loss-of-function BHMT polymorphism could be predisposed to developing liver disease as they age and may experience more severe liver damage with additional factors such as alcohol consumption, high-caloric intake, or viral infections.

4362 | DRUG INDUCED LIVER INJURY IN PATIENTS WITH DRUG RASH WITH EOSINOPHILIA AND SYSTEMIC SYMPTOMS (DRESS) SYNDROME

Kimberly Felipe[1] Neel Ravela[1] Elizabeth Phillips[2] Naga Chalasani[3] Sahand Rahnama[4], [1]Indiana University School of Medicine, [2]Vanderbilt University Medical Center, [3]Indiana University Medical Center, [4]Indiana University

Background: Drug induced liver injury (DILI) can occur in patients with Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) but its frequency and significance are not fully understood. We report on a cohort of patients with DRESS to better characterize hepatic involvement. **Methods:** Cases of DRESS syndrome were identified from the Indiana University Dermatology Inpatient Consult log from the years 2014 to 2017 via ICD9/ICD10 diagnoses and manual search. Eligible cases were subsequently adjudicated via RegiSCAR as a tool. Cases designated as "possible", "probable", and "definite" were used in the analysis. Demographic, laboratory, and clinical data were collected through manual chart review. DILI was defined using the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

DILIN criteria with minor modifications. **Results:** 52 patients were identified during the study period. The average age at DRESS onset was 43.5 years and 48 self-reported as White and 50 as Non-Hispanic White. 25 out of 52 patients were female. The average BMI was 28.2 kg/m2 and 18 were obese. 18/52 (35%) of our patients had pre-existing MASLD and 2 had pre-existing cirrhosis. In 23 cases, multiple agents were considered possible. In 15/52 (29%) cases of DRESS, vancomycin was either a sole culprit or considered among different agents. Beta-lactam agents were considered in 23/52 (44%) cases. Allopurinol and lamotrigine were considered in 3 cases each. No other anti-epileptic drug was a culprit in this cohort. The latency period was on average 17 days before the rash onset. The rash was "morbilliform" or "maculopapular' in 42 cases and "pustular" in 5 cases. Concomitant DILI was present in 40% of patients. The average peak ALT was 178 U/L, AST 196 U/L, peak alkaline phosphatase (ALP) was 242.9 U/L. 2 patients needed liver transplantation, and 11/52 (21%) patients died within 6 months of diagnosis. **Conclusion:** Antibiotics were most frequently implicated agents, with few anti-epileptics for causing DRESS in this experience. Concomitant liver injury was present in 40% of cases. Twenty five percent either died or needed a liver transplantation within six months after suffering from DRESS.

Table: Selected Characteristics of patients with DRESS seen at our institution over a 3-year period

Total Patients, n=52	Mean (SD) or N (%)
Age of Onset	43.5 (23.9)
BMI (kg/m2)	28.2 (9.6)
Rash latency (days)	16.7 (11.8)
Female	25 (48%)
White	48 (92%)
Not Hispanic/Latino	50 (96%)
Pre-existing Cirrhosis	2 (4%)
Pre-existing MASLD	18 (35%)
Multiple drugs possible	23 (44%)
Vancomycin possible	15 (29%)
Beta-Lactam possible	23 (44%
Allopurinol possible	3 (6%)
Lamotrigine possible	3 (6%)
Other AED possible	0 (0%)
Morbilliform rash	42 (81%)
Pustular rash	5 (10%)
Peak WBC (k/cumm)	19.4 (11.7)
Peak Eosinophil (k/cumm)	1.2 (2.5)
Peak AST (U/L)	196 (406.7)
Peak ALT (U/L)	177.9 (378.7)
Peak ALP ((U/L)	242.9 (240.8)
Peak Bilirubin (mg/dL)	2.1 (3.4)
Jaundice (Bilirubin > 2.5 mg/dL)	10 (19%)
DILI	21 (40%)
Pattern of Liver injury in DILI cases	
- Hepatocellular	4 (19%)
- Cholestatic	12 (57%)
- Mixed	5 (34%)

4363 | LIVER TEST PATTERN AND HISTOLOGIC BILE DUCT INJURY DO NOT PREDICT RESPONSE TO TREATMENT OF IMMUNOTHERAPY HEPATOTOXICITY

Benjamin Rabin[1] Michael Li[2] Jordan Sack[3] Stephen Zucker[3], [1]Brigham & Women's Hospital, [2]University of California, San Francisco, [3]Brigham and Women's Hospital

Background: Immune checkpoint-inhibitor (ICI) cholangitis is an uncommon immune-related adverse event affecting the biliary ducts that is considered distinct from ICI hepatitis. The aim of this study is to examine whether the liver injury pattern or presence of histologic bile duct damage determines response to immunosuppression. **Methods:** This multi-center retrospective cohort study includes 298 consecutive patients with cancer who received immunotherapy between 2010 and 2021 and were originally classified as grade 3 or higher ICI-related hepatitis (alanine aminotransferase (ALT) $\geq$ 200 U/L). Response to immunosuppression was stratified by pattern of liver injury (hepatocellular, cholestatic, or mixed) as defined by R-value, the presence of histologic bile duct damage, and the Drug-Induced Liver Injury Network (DILIN) severity score. The primary outcome was time to normalization of ALT ($\leq$ 40 U/L). Secondary outcomes included time to grade 1 liver injury (ALT $\leq$100 U/L), and need for additional immunosuppression. **Results:** The pattern of liver injury was hepatocellular in 60%, cholestatic in 13%, and mixed in 27%. All patients received corticosteroids as first-line therapy. There was no difference in corticosteroid dose, need for an additional immunosuppressive agent, time to normalization of ALT, or time to grade 1 liver injury between groups. Outcomes were similar among patients with or without histologic bile duct damage and between those with a DILIN severity score of 3+ versus lower score. **Conclusion:** The response of high-grade ICI hepatotoxicity to standard immunosuppression is similar regardless of the pattern of liver injury or the presence of bile duct damage.

4364 | EFFICACY OF PLASMA EXCHANGE IN SEVERE IMMUNE CHECKPOINT INHIBITOR-INDUCED HEPATITIS (CHILI): PLASMACHILI STUDY

LUCY MEUNIER Clément Monet[1] Antonio Saviano[2] Marwin Farrugia[3] François Villeret[4] Marion Khaldi[5] Olivier Moranne[6] rodolphe anty[3] Simona TRIPON[2] Mialy Randrianarisoa[2] Lina Hountondji[1] Eleonora De Martin[7], [1]CHU Montpellier, [2]CHU Strasbourg, [3]CHU Nice, [4]CHU Lyon, [5]CHU Nantes, [6]CHU Nimes, [7]CHU Paul Brousse

Background: Current management guidelines for immune checkpoint inhibitor-induced hepatitis (CHILI) recommend corticosteroids as first-line therapy, followed by immunosuppressive agents in case of non-response. In severe or refractory cases, plasma exchange (PE) may be considered as a salvage treatment, as already implemented in other ICI-related toxicities. **Methods:** All French referral centers for hepatic and ICI-related hepatotoxicity were contacted for participation. Demographic, clinical, and biological data were retrospectively collected. Ethics committee approval was obtained. **Results:** We report all French cases of PE performed for this indication between March 2021 and September 2024. Ten patients (6 females, mean age: 61.3 years) underwent PE. The ICIs involved were: nivolumab (n = 5), atezolizumab (n = 1), and pembrolizumab (n = 4), with 5 patients receiving combination therapy with anti-CTLA-4 or anti-TIGIT agents. The median interval between ICI initiation and CHILI onset was 100 days. The median MELD score at diagnosis was 14. All cases were grade 4 according to CTCAE and classified as severe per DILIN or DILI-IEGW criteria. The median peak total bilirubin was 305.5 μmol/L (range: 93–561), and the lowest median prothrombin time was 44.5% (range: 7–84). All patients received corticosteroids as first-line treatment (1 mg/kg), with dose escalation in 7 patients. Nine patients received mycophenolate mofetil (MMF) as second-line therapy, and 7 required third-line immunosuppressants (tacrolimus or MMF). Adverse events related to corticosteroids occurred in 6 patients: infections (n = 5), hyperglycemia (n = 1). PE was initiated after a median of 28.5 days (range: 13–64) from diagnosis and 9 days (range: 0–43) from the last treatment line. The number of sessions was 3 (n = 5), 5 (n = 4), and 6 (n = 1), performed via centrifugation (n = 2) or filtration (n = 8). Two PE-related adverse events were reported (hypercalcemia, hemorrhage). Median MELD score was 21 (range: 10–40) at PE initiation and 18 (range: 8–34) at the end of treatment. Median follow-up was 141 days (range: 51–842). Three patients died: one from septic shock 62 days after CHILI onset, one from tumor progression, and one from acute liver failure. In 5 patients, anticancer treatment (excluding immunotherapy) was resumed after normalization of liver tests. **Conclusion:** This first national case series, despite a limited sample size, suggests that plasma exchange may represent a therapeutic option in severe acute ICI-induced hepatitis. The optimal timing for its initiation, particularly following corticosteroid failure, remains to be clarified.

4365 | STUDY ON THE MEDIATING EFFECT OF SLEEP DISORDERS BETWEEN ANXIETY AND QUALITY OF LIFE IN PATIENTS WITH LIVER CIRRHOSIS

Guzainuer Yiliyaer[1] Zhaoxia Liu[2] Hong Yu[3] Jinhua Jing[4] Wei Sun[5] Yuyu Li[2], [1]Affiliated Hospital of Chengdu University of Traditional Chinese Medicine, [2]The Fourth Clinical Medical College of Xinjiang Medical University, [3]Xinjiang Karamay Central Hostipal, [4]Xinjiang Changji Prefecture Hospital of Traditional Chinese Medicine, [5]Affiliated Hospital of Shaanxi University of Traditional Chinese Medicine

Background: To investigate the mediating role of sleep disorders between anxiety and quality of life in patients with liver cirrhosis, providing potential intervention targets to improve patients' quality of life. **Methods:** A total of 377 patients with liver cirrhosis were enrolled. Demographic data (age, sex), clinical indicators (Child-Turcotte-Pugh [CTP] score, Model for End-Stage Liver Disease [MELD] score), Pittsburgh Sleep Quality Index (PSQI), anxiety scores, and the 36-Item Short Form Health Survey (SF-36) were collected. Correlation analysis and multiple linear regression analysis were performed using SPSS 27.0. The mediating effect was tested using Model 4 in the SPSS macro PROCESS, and the significance of the mediating pathway was verified using the Bootstrap method proposed by Hayes. **Results:** Among the 377 enrolled patients with liver cirrhosis, 195 (51.7%) were male, with a mean age of 60 $\pm$ 11.6 years. The median CTP score was 7 (5, 9), and the median MELD score was 10 (7, 13). The prevalence rates of sleep disorders and anxiety were 61.8% and 47.7%, respectively. A significant positive correlation was observed between anxiety scores and PSQI ($r = 0.534$, $P < 0.001$), while a significant negative correlation was found between anxiety scores and SF-36 total scores ($r = -0.72$, $P < 0.001$). Structural equation modeling revealed that sleep disorders partially mediated the relationship between anxiety and quality of life, accounting for 34.2% of the total effect ($\beta = -0.6$, 95% CI: -0.73 to -0.47). The total effect was -1.62 ($P < 0.001$), and the direct effect was -1.02 ($P < 0.001$). This mediating effect remained significant after adjusting for age, sex, CTP score, and MELD score. **Conclusion:** Sleep disorders serve as a significant mediator in the impact of anxiety on quality of life in patients with liver cirrhosis. Clinical interventions should prioritize sleep management to enhance overall health outcomes in this population.

4366 | CHRONIC OVERNUTRITION DEPOLARIZES MITOCHONDRIA AND DISASSEMBLES MITONEET IN MOUSE LIVERS

Yiing Lin[1] Jae-Sung Kim[2] William Chapman[1] junkyu shin[2], [1]Washington University in St. Louis, [2]Washington University School of Medicine

Background: The shortage of donor livers is a major obstacle in organ transplantation. However, steatotic donor livers are often discarded due to its hypersensitivity to ischemia/reperfusion (I/R) injury. mitoNEET (mNT) is a homo-dimeric mitochondrial outer membrane protein. We have shown that the dissociation of mNT dimers (mNTd) into mNT monomers (mNTm) contributes to autophagic and mitochondrial dysfunction after I/R in steatotic livers. How steatosis accumulates mNTm remains unknown. **Methods:** Age-matched male mice were fed either a chow diet (CD) or a high fat diet (HFD: 60 Kcal % fat) for 8 weeks. Hepatocytes were isolated either from CD- or from HFD-fed mice. To separate mNTm and oligomers (mNTo) from mNTd, we crosslinked mNTd with dithiobis (succinimidyl propionate). Changes in mNT expression, mitochondrial membrane potential (DYm) and steatosis were assessed by immunoblot and imaging analysis. Some experiments were conducted with mouse and human livers. To investigate roles of DYm in steatosis-mediated disassembly of mNTd, hepatocytes from CD mice were incubated with 500 nM of carbonyl cyanide m-chlorophenylhydrazone (CCCP), a mitochondrial

uncoupler, for up to 90 min. **Results:** The expression of mNTm and mNTo in HFD hepatocytes and livers, dysfunctional forms of mNT, was significantly greater than that of CD counterparts. Accumulation of mNTm was evident in human steatotic livers. Confocal imaging analysis of Bodipy 493/503 revealed that most hepatocytes isolated from HFD mice were microsteatotic, while some cells were non-steatotic. Fluorometry of tetramethylrhodamine methylester demonstrated that DYm of HFD hepatocytes was 28.1% of CD hepatocytes. Noticeably in HFD livers, DYm of hepatocytes with steatosis was significantly lower than that of cells without steatosis, implying the effects of steatosis on DYm. To induce mitochondrial depolarization, we conducted immunoblot and confocal analysis in lean CD hepatocytes with and without CCCP. Treatment with CCCP progressively accumulated mNTm followed by mNTo. Confocal microscopy confirmed rapid loss of DYm followed by mNTo accumulation by CCCP, suggesting the disassembly of mNTd by mitochondrial depolarization. **Conclusion:** Chronic overnutrition depolarizes mitochondria, leading to the accumulation of dysfunctional mNTm and mNTo. These pathological events contribute to enhanced oxidative stress, defective autophagy, mitochondrial dysfunction, and severe I/R injury in steatotic livers.

4367 | ACR SCORE: A NOVEL PREDICTIVE MODEL FOR DRUG-INDUCED LIVER INJURY SEVERITY ASSESSMENT

Chengjie Cui[1] Shuxian Zang[1] Jing Cui[1] Na Fu[1] Yuemin Nan[1], [1]Hebei Medical University Third Hospital

Background: Drug-induced liver injury (DILI) is caused by drugs or their metabolites, which is one of the common causes in liver injury. In severe cases, it leads to acute liver failure or even death. Due to low acceptance of liver biopsy, DILI faces challenges such as difficulties in identification and diagnosis, predicting severity and prognosis, and clinical management. **Methods:** A retrospective analysis was used to enroll 125 patients diagnosed with DILI in Hebei Medical University Third Hospital from June 2021 to October 2024 as the training set. According to the 2023 DILI guideline, 39 cases were classified as mild (grade 1) and 86 as moderate to severe ($\geq$ grade 2). Additionally, clinical data from 45 patients diagnosed with DILI in the same hospital from November 2024 to May 2025 were collected as the validation set (Fig. 1). SPSS 27.0.1 was used to analyze data and generate the ROC curve. The calibration curve, DCA curve and nomogram were created using the CNSknowall platform (https://cnsknowall.com). **Results:** In the training set, the general information of two groups was shown in Tbl. 1. Laboratory indicators with P. **Conclusion:** The predictive performance of ACR model is significantly better than that of AST, CHE and RDW. It is expected to serve as a new prediction model for evaluating the severity of DILI. However, these results need to be validated in larger, multi-center studies.

4368 | SIMULATED MILITARY BURN PIT INHALATION EXPOSURES CAUSE RAPID-ONSET HEPATIC PATHOLOGY IN A RAT MODEL

Shannon Heinig[1] Pooja Muddasani[1] Charis-Marie Vanderpuye[1] Anna Rutkowski[1] Joshlyn Mensah[1] Fodilat Ibraheem[1] hamda siddiqui[1] Donna Stolz[1] William Goldsmith[2] Anand Ranpara[2] Thomas Batchelor[2] Timothy Nurkiewicz[2] Juliane Beier[1], [1]University of Pittsburgh, [2]West Virginia University

Background: Open-air waste incineration, referred to as military "burn pits", represents a standard operational component of military installations. Since 2001, nearly 3 million U.S. service personnel have been deployed to Middle Eastern regions. Throughout these assignments, personnel encountered burn pit emissions from incineration of up to 85,000 pounds of waste, accelerated with jet fuel, daily. Veterans report chronic health complications including fatigue, gastrointestinal, cardiopulmonary, and hepatic dysfunction following these exposures. The pathophysiological mechanisms underlying liver disease remain incompletely understood. Here, the hepatic consequences of burn pit emission inhalation exposure were investigated, using a

validated model. **Methods:** A modified pellet stove combusted materials commonly disposed of in burn pits (80% wood, 10% rubber, 10% plastic, and jet fuel). The combustion emissions were delivered to an exposure chamber. Male Sprague Dawley rats underwent inhalation exposures to generated emissions (~10 mg/m^3; 5 hr/day, 2 days, 89 μg cumulative lung deposition). Hepatic tissue and plasma were analyzed for pathological changes and injury markers. Transmission electron microscopy evaluated ultrastructural alterations. **Results:** After 2 days of burn pit emission exposure, animals produced pronounced hepatic pathological changes across multiple assessment parameters. Exposed animals exhibited disrupted hepatic zonation architecture, enhanced collagen accumulation throughout the parenchyma, and robust inflammatory cell infiltration with macrophage activation. Ultrastructural examination revealed extensive smooth endoplasmic reticulum fragmentation, sinusoidal endothelial capillarization and dysfunction, and numerous autophagosomes. Notably, electron-dense particulate matter, consistent with inhaled emission components, was detected within hepatocyte and Kupffer cell autophagosomes and lipid droplets. **Conclusion:** These data provide the first evidence of acute hepatic pathology following 2 days of controlled burn pit inhalation exposure, establishing hepatotoxicity as an immediate consequence of inhalation exposures. The observed morphological and cellular alterations suggest direct mechanistic pathways linking burn pit emissions to hepatic dysfunction and metabolic perturbation. The findings support incorporating hepatic biomarkers into Veteran health screening protocols to identify novel therapeutic approaches for liver injury.

4369 | HORMONAL CONTRACEPTIVE-ASSOCIATED DRUG-INDUCED LIVER INJURY IN THE MODERN ERA: INSIGHTS FROM THE DRUG-INDUCED LIVER INJURY NETWORK

Raj Vuppalanchi[1] Alfred Barritt IV[2] Anjali Rai[3] Sherry Gu[4] Yi-Ju Li[5] Huiman Barnhardt[4] Naga Chalasani[1], [1]Indiana University School of Medicine, [2]University of North Carolina, [3]NIH/NIDDK, [4]Duke Clinical Research Institute, [5]Department of Biostatistics and Bioinformatics, Duke University School of Medicine

Background: Hormonal agents, particularly combined oral contraceptives, are widely used for both contraceptive and therapeutic purposes; however, their potential to cause DILI remains a clinical concern. This study aimed to characterize clinical and biochemical features of hormonal contraceptive-associated DILI (HC-DILI) and to explore its association with candidate genes implicated in cholestasis. **Methods:** In the DILIN study between 2004 and 2024, among 1553 high-confidence cases, 20 HC-DILI cases (1.3%) were identified after excluding 14 cases due to low causality scores or used for non-contraception purposes. Clinical presentation, laboratory parameters, and outcomes were compared with those of age- and sex-matched cases of DILI (n = 60). We examined the association between HC-DILI and candidate genetic variations associated with cholestasis, comparing it with the matched control group and a second control group comprising of other high-confidence DILI cases in women (n = 899). **Results:** The median age (15 White, 3 Black, 2 Other) was 22.1 years, with a latency of 2–12 weeks, and most presented with jaundice and pruritus. Eighteen received hormonal agents orally (combination = 14, estrogen-only = 3, and progesterone-only = 1), with one receiving it intramuscularly and one receiving it as a topical patch. The injury was mainly cholestatic or mixed, with 50% requiring liver biopsy or hospitalization. One patient who received (intravenous conjugated estrogen followed by oral estradiol) experienced prolonged jaundice with vanishing bile duct syndrome, but there were no fatalities or liver transplantation. Compared to the control group, patients with HC-DILI exhibited a cholestatic pattern, characterized by markedly lower aminotransferase levels but similar alkaline phosphatase levels (Table). There was a higher prevalence of jaundice (80% vs. 48%, P = 0.013) and pruritus (80% vs. 38%, P = 0.001), but hypersensitivity features, such as fever (0% vs. 35%, P = 0.002), were less common. Autoantibodies (ANA and SMA) were less frequent in the HC-DILI group (Table). Tight Junction Protein 2 (*TJP2*) genetic variation (rs3812536 on chr9:71869473, G > A) was significantly associated with HC-DILI compared to the matched other DILI cases (OR: 3.08,95% CI: 1.29-7.35; P = 0.01) and all other female DILI cases (n = 899) (OR: 2.75, 95% CI: 1.4-5.36; P = 0.003) with apparent minor allele frequency difference (0.68 in cases vs. 0.42 in both control groups). **Conclusion:** Hormonal agent-induced liver injury presents with a unique cholestatic phenotype, mostly lacking hypersensitivity. *TJP2* is a crucial gene in tight junction function and hepatocyte integrity, and its genetic variation has been associated with progressive familial intrahepatic cholestasis type 4. Further studies

Background: Ductopenia is a rare phenotype of drug-induced liver injury (DILI), typically manifesting after prolonged cholestasis induced by DILI. This study aimed to evaluate the clinical features, histopathological characteristics, and outcomes of drug-induced ductopenia (DID) enrolled in the Spanish and LATINDILI registries. **Methods:** From a total of 1,564 DILI cases, we identified 10 cases (0.6%) of ductopenia attributable to drugs registered within the Spanish (n = 1,037) and LATINDILI (n = 527) networks. DID was defined as vanishing interlobar ducts in more than 50% of portal tracts. Clinical data, biochemical parameters, histological findings, and clinical outcomes were analyzed and compared between groups. **Results:** The mean age of DID patients was 50 ± 19 years ; female 45%. The predominant clinical presentation was hepatocellular (40%), with cholestatic and mixed patterns accounting for 20% and 40%, respectively. The implicated medications included ciprofloxacin, amoxicillin-clavulanate, metformin, ticlopidine, stanozolol, carbamazepine, sertraline, captopril, and droxicam. The majority (90%) presented with jaundice, and 80% required hospitalization. Rash and eosinophilia were observed in 40% of cases, and autoantibodies were detected in two patients. The median time to onset was 34 days (range 21–65), with an average therapy duration of 32 days (range 8–66). Biochemical parameters revealed

elevated levels of AST (mean 4.3×ULN), ALT (8.9×ULN), ALP (2.8×ULN), GGT (10×ULN), and total bilirubin (mean 11 mg/dL). Histological examination showed varying degrees of cholestasis with inflammatory portal changes, fibrosis, ductular proliferation, and interphase hepatitis. Compared with non-ductopenic DILI patients in both registries, no significant differences were observed in the latency period or clinical pattern at presentation; however, hypersensitivity phenomena were more frequent in DID cases. While the outcomes were favourable, with no fatalities case; the bilirubin level was notably higher in DID patients. During follow-up, liver enzyme normalization occurred within a range of 2 months to 2 years (median 3,5 months). **Conclusion:** Drug-induced ductopenia is characterized by higher bilirubin levels and a greater association with hypersensitivity reactions, such as rash and eosinophilia. Unlike other series, DID exhibits an overall benign prognosis, with no reported fatalities.

4371 | SENTINEL SURVEILLANCE FOR HERBAL AND DIETARY SUPPLEMENT INDUCED LIVER INJURY IN THE UNITED STATES: A PILOT INITIATIVE IN DILIN

Victor Navarro[1] Dina Halegoua-De Marzio[2] Hoss Rostami[3] Bharathi Avula[4] Ikhlas Khan[4] Herbert Bonkovsky[5] Huiman Barnhart[3] Robert Fontana[6] Christopher Koh[7] Raj Vuppalanchi[8] Alisa Likhitsup[9] Andrew Stolz[10], [1]Jefferson Health System, [2]Thomas Jefferson University, [3]Duke Clinical Research Institute, [4]University of Mississippi, [5]Atrium Health Wake Forest Baptist, [6]University of Michigan Hospitals and Health Centers, [7]National Institutes of Health, [8]Indiana University School of Medicine, [9]University of Michigan, [10]University of Southern California

Background: The Drug-Induced Liver Injury Network (DILIN) has seen a rise in herbal and dietary supplement (HDS) cases. Our aim is to report the early results of sentinel surveillance for HDS-induced liver injury (HILI) that includes chemical analysis of suspect HDS and coordination with the Human Foods Program (HFP) of the FDA for early signal detection and outbreak management. **Methods:** De-identified information (medical history, HDS use, exam, lab data) is assembled from HILI cases enrolled as previously described (Drug safety 2009;32:55-68) at 6 DILIN sites, with available products sent for chemical analysis at the National Center for Natural Products Research using Liquid Chromatography Quadrupole Time-of-Flight Mass Spec, to verify label ingredients and detect adulterants. All information is recorded onto a case report form, and investigators (DH, AS, VN) provide a DILIN expert opinion for overall case causality score (1 = definite to 5 = unlikely). The case information with chemical analysis is sent to FDA via MedWatch to determine the presence of an injury signal and, based on other reports to the agency, if an outbreak may be occurring. It was agreed with the HFP that a 30-day turnaround time (TAT), between the date of case enrollment to MedWatch submission, would be consistent with an effective surveillance program. **Results:** Between 1/1/25 and 5/1/25, 8 suspected HILI cases were enrolled and adjudicated; 4 cases were judged to be overall highly likely, 3 possible, and one unlikely (Table) HILI. Median age was 43 years, 50% were female, 75% White, 25% Black. Six had jaundice, and all but one were hospitalized. Median ALT at onset was 706 U/L (range 65-4820), AST 718 U/L (41-4373), Alk Phos 205 U/L (120-792), and bilirubin 5.9 mg/dL (0.4-22). 15 HDS products were submitted for chemical analysis from the 8 cases. The mean TAT was 26 days (range 17-38). Chemical analyses confirmed the presence of the ingredients listed on the labels, with no adulterants. Turmeric was the most common suspected cause of HILI. **Conclusion:** Sentinel surveillance for HILI via a prospective, multicenter research network like DILIN is feasible, achieving an acceptable TAT from a regulatory standpoint. Surveillance tended to detect serious liver injury, insofar as most patients had jaundice and were hospitalized. Surveillance will support early identification of HILI safety signals that can trigger outbreak investigations, identify potentially injurious ingredients, and facilitate expedient regulatory action to enhance early warning and consumer safety.

4372 | ASSOCIATION OF GLP-1RA USE WITH LOWER SEPSIS AND URINARY TRACT INFECTION IN ALCOHOL-ASSOCIATED LIVER DISEASE

Pojsakorn Danpanichkul[1] Donghee Kim[2] Yee Hui Yeo[3] Andrew Ibrahim[4] Vincent Chen[5] Ju Dong Yang[6] Mazen Noureddin[7] Amit Singal[8] Karn Wijarnpreecha[9], [1]Texas Tech University Health Sciences Center, [2]Stanford University, [3]Cedars Sinai Hospital, [4]Texas Tech University, [5]University of Michigan Medical Center, [6]Cedars-Sinai Medical Center, [7]Houston Methodist Hospital, [8]UTSW, [9]University of Arizona College of Medicine-Phoenix

Background: Individuals with alcohol-associated liver disease (ALD) are particularly vulnerable to infections due to compromised immune function. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) offer metabolic and anti-inflammatory advantages, but their impact on infection risk among ALD patients is not well established. This study evaluated whether GLP-1RA use influences infection-related outcomes in this population. **Methods:** Using the TriNetX database, we performed a retrospective cohort study comparing adults with ALD who initiated either GLP-1RA or metformin. Propensity score matching (1:1) was applied to balance key variables including demographics, comorbidities, and concomitant medications. The primary outcome was sepsis; secondary outcomes included urinary tract infection (UTI), pneumonia, spontaneous bacterial peritonitis (SBP), and Clostridioides difficile infection (CDI). Hazard ratios (HRs) with 95% confidence intervals (CIs) were estimated using Cox proportional hazards models over a five-year follow-up. **Results:** After matching, the final cohort included 1,432 patients (716 in each group). GLP-1RA use was associated with a significantly lower risk of sepsis (HR 0.62, 95% CI 0.44–0.87) and UTI (HR 0.63, 95% CI 0.46–0.87) compared to metformin. A trend toward reduced pneumonia risk was noted (HR 0.72, 95% CI 0.51–1.02), though not statistically significant. No significant differences were observed for SBP, skin infections, or CDI. **Conclusion:** Among matched ALD patients, GLP-1RA therapy was linked to a lower risk of sepsis and UTI relative to metformin. These results suggest an added potential benefit of GLP-1RAs in this high-risk population and support further prospective investigation.

4373 | UNCOVERING TWO CLINICAL PATTERNS OF IMMUNE-RELATED LIVER INJURY: METABOLIC DYSFUNCTION AS A KEY RISK FACTOR FOR THE PERSISTENT TYPE

Sae Yumita[1] Ryo Izai[1] Sadahisa Ogasawara[1] Haruka Anzai[1] Kazuo Tsubura[1] Taro Watabe[1] Teppei Akatsuka[1] Keiichi Katayama[1] Midori Sawada[1] Takahiro Tsuchiya[1] Makoto Fujiya[1] Chihiro Miwa[1] Ryohei Yoshino[1] Takuya Yonemoto[1] Keisuke Koroki[1] Hiroaki Kanzaki[1] Masanori Inoue[1] Masato Nakamura[1] Naoya Kanogawa[1] Shingo Nakamoto[1] Jun Kato[1] Mina Komuta[2], [1]Department of Gastroenterology, Graduate School of Medicine, Chiba University, [2]Department of Pathology, International University of Health and Welfare, Narita Hospital

Background: Immune checkpoint inhibitors (ICIs) are widely used in cancer therapy, but immune-related liver injury (irLI) remains a major concern, especially in patients with preexisting liver disease. However, its

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

pathological features and risk factors are not fully understood. To better understand its clinical course and underlying mechanisms, we aimed to analyze the clinical and histological features of irLI. **Methods:** A total of 1,512 patients who received immune checkpoint inhibitors between 2014 and 2023 were retrospectively reviewed. The diagnosis of irLI was made by hepatologists through systematic exclusion of other potential causes of liver injury, including tumor progression, biliary obstruction, viral hepatitis, autoimmune liver diseases, and other drug-induced hepatotoxicity. Liver biopsy was performed prior to prednisolone administration whenever deemed feasible by the attending hepatologist based on clinical evaluation. Both clinical and histopathological findings were thoroughly examined to categorize irLI and explore potential risk factors. **Results:** A total of 71 patients (4.7%) were clinically diagnosed with irLI. Based on the R ratio, injury was classified as cholestatic (n = 35, 47.3%), mixed (n = 26, 35.1%), and hepatocellular (n = 13, 17.6%). Clinically, irLI was categorized into transient-type ($\leq$40 days, n = 39) and persistent-type ($>$40 days, n = 32), based on the time for ALT to decline by 50%. Transient-type was more common in patients $<$75 years, while persistent-type was more frequent in those $\geq$75. Multivariable Cox analysis showed that baseline ALT elevation and metabolic comorbidity independently predicted persistent, but not transient irLI. Kaplan–Meier analysis confirmed a higher incidence of persistent irLI in patients with this risk profile. Liver biopsies were performed in 21 cases, and in 9, pre-treatment specimens were available, enabling comparison before and after irLI onset. In the transient group, liver tissue often showed hepatocellular injury with centrilobular necrosis and granulomas. In contrast, the persistent group more frequently showed fibrosis, portal inflammation, and coexisting steatohepatitis. Paired biopsies (n = 9) further revealed that persistent irLI was often preceded by histological steatohepatitis, which worsened after ICI therapy, suggesting a predisposing hepatic substrate for persistence. **Conclusion:** Our findings revealed two distinct clinical patterns of irLI: transient-type and persistent-type, each characterized by different risk profiles and histopathological features. Persistent-type irLI appears to result from pre-existing steatotic hepatitis, which may predispose patients to sustained hepatitis following ICI therapy. In patients with clinical features suggestive of steatotic liver disease, pre-treatment liver biopsy may help identify those at increased risk for persistent irLI and guide risk-adapted management strategies.

4374 | RUST BELT ENVIRONMENTAL TOXICANTS TRANSFORM WESTERN DIET FROM METABOLIC CHALLENGE TO HEPATOTOXIC CRISIS IN MICE

hamda siddiqui[1] Shannon Heinig[1] Pooja Muddasani[1] Charis-Marie Vanderpuye[1] Jiang Li[1] Natalie Price[1] Zachary Zimmerman[1] Shuai Yuan[1] Sudrishti Chaudhary[1] Noriko Kitano[1] Gavin Arteel[1] Alison Sanders[1] Juliane Beier[1], [1]University of Pittsburgh

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects over 30% of Western populations with disproportionate impact on lower socioeconomic communities. While early-stage MASLD prevalence approaches 100% in at-risk individuals, progression to severe forms is not inevitable, suggesting additional risk factors drive disease severity. Environmental chemical mixtures may be such a risk factor and transform manageable dietary stress into severe liver injury. "Rust to Resilience" (R2R) chemical mixtures contain legacy toxicants (lead, cadmium, arsenic) and emerging PFAS relevant to industrialized countries and of high priority concern in southwestern Pennsylvania. This study investigated whether R2R-mixture exposure transforms Western diet-induced metabolic stress into severe hepatotoxicity. **Methods:** C57Bl/6J mice were fed Western or control diets for 12 weeks, with subgroups receiving R2R mixtures at 1× and 100× concentrations. Analysis included plasma biochemistry, histopathological assessment, and RNA-sequencing with integrated pathway analysis to determine molecular mechanisms of toxicant-diet interactions. **Results:** R2R-mixture exposure synergistically enhanced Western diet-induced liver injury, causing severe inflammation, coagulative necrosis, and portal expansion. Toxicant exposure promoted pathological lipid accumulation and hepatocyte ballooning - indicative of mitochondrial dysfunction. RNA-sequencing revealed that Western diet background amplified toxicant transcriptional responses 4.6-fold (137 vs 30 significant GO pathways) and uniquely enabled

carcinogenic pathway activation absent under control diet conditions (15 vs 0 significant KEGG pathways). Western diet transformed manageable environmental exposure into severe hepatotoxicity characterized by metabolic dysregulation and activated carcinogenesis pathways. **Conclusion:** This study reveals a critical paradigm shift: environmental toxicant exposure doesn't merely add to Western diet-induced liver injury - it fundamentally transforms the hepatic response from metabolic adaptation to pathological crisis. Western diet creates a permissive environment where otherwise manageable environmental exposures trigger severe hepatotoxicity and activate carcinogenic pathways. These findings highlight complex environmental chemical exposure as a crucial risk-modifying factor explaining interindividual variability in MASLD progression.

4375 | SEX-DEPENDENT HEPATOTOXICITY OF TRICHLOROETHYLENE IN HUMANIZED PPARA MICE FED A WESTERN DIET

Abigail Ekuban[1] Paxton Ames[1] Frederick Ekuban[1] Jianzhu Luo[1] Oluwanifemi Bolatami[1] Yuan Hua[1] Megana Iyer[1] Collette Gorga[1] Josiah Hardesty[1] Banrida Wahlang[1] Jennifer Schlezinger[2] Matthew Cave[1] Walter Watson[1], [1]University of Louisville, School of Medicine, [2]Boston University School of Public Health

Background: Trichloroethylene (TCE), a commonly used industrial solvent, is linked to hepatic steatosis and metabolic dysfunction. Military personnel, their families and some civilians were exposed to TCE-contaminated drinking water at Camp Lejeune USMC Base between 1953 and 1987. TCE is known to activate peroxisome proliferator-activated receptor alpha (PPARα) in mice, but it is unclear whether human PPARα responds to TCE in the same manner. It is established that lipids activate mouse and human PPARα differently. Thus, we sought to test the hypothesis that TCE exposure exacerbates high fat diet-induced metabolic dysfunction and liver injury in a sex-dependent manner using a humanized PPARα mouse model. **Methods:** Male and female humanized PPARα C57BL/6J mice aged 9-12 weeks were placed on either a control diet (CD; 10% fat) or a Western diet (WD; 42% fat) with concurrent exposure to 0.5 mg/mL of TCE or 1% ethoxylated castor oil (used to emulsify TCE) in drinking water for 12 weeks. Body weight and water consumption were measured each week. A glucose tolerance test was performed at week 10 of exposure, and EchoMRI was performed at week 11. At week 12, blood and tissues were collected for measurement of plasma AST and ALT, tissue weights, and analysis of liver histopathology with H&E and Oil Red O. Statistical analyses were performed using two- and three-way ANOVA followed by Tukey's post hoc test, with significance set at $p \leq 0.05$. **Results:** TCE exposure combined with WD resulted in sex-specific effects. Male mice compared to females exhibited increased body weight, fat mass, white adipose tissue, and liver weight across all treatment groups. Analysis of the exact amount of TCE consumed by mice showed that females ingested significantly higher volumes across both dietary groups compared to their male counterparts. Amongst all groups, glucose tolerance was lower in response to WD in male mice only, and TCE did not affect this. Further, relative liver weight was increased by WD in males only, whilst TCE did not affect this. The only group amongst both sexes with elevated plasma AST and ALT was the male mice fed a WD and co-exposed to TCE. Histological analysis revealed enhanced steatosis in WD-fed males, regardless of TCE exposure, confirmed by H&E and Oil Red O staining. **Conclusion:** Generally, the study confirmed sex-specific differences hinging on diet and TCE exposure in humanized male and female mice. Male mice tend to be more susceptible to liver injury and toxicity but not their female counterparts.

4376 | LIVER INJURY INDUCED BY APAP IS ATTENUATED BY MESENCHYMAL STEM CELL-DERIVED SMALL EXTRACELLULAR VESICLES IN VITRO AND IN VIVO

Ana Serras[1] Sérgio Camões[1] Joana S Rodrigues[1] Joel Vej-Nielsen[2] Rui Vitorino[3] Busra Korkmaz[4] Gulcin Cakan-Akdogan[4] Joana Miranda[1], [1]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, [2]Department of Biochemistry and Molecular Biology, University of Southern Denmark, [3]LAQV/REQUIMTE, Mass Spectrometry Center; iBiMED, Universidade de Aveiro, [4]Izmir Biomedicine and Genome Center

Background: Drug-induced liver injury, including by paracetamol (APAP) overdose, is the most common cause of acute hepatic failure but current treatments present important limitations. Human neonatal mesenchymal stem cells (MSC) can constitute an alternative treatment as it has been shown that the MSC-derived secretome and small extracellular vesicles (sEV) present important immunomodulatory and regenerative effects. Physiologically, MSC adapt and respond to the microenvironment and we have previously shown that MSC primed with SOS signals from APAP-injured hepatic cells have an upregulated pro-regenerative genetic profile. As such, the aim of this study was to unravel the role of sEV derived from primed MSC on liver regeneration. **Methods:** MSC were primed with the SOS signals of APAP-injured HepG2 (pMSC) for collection of the secretome and subsequent isolation of sEV by size-exclusion chromatography. sEV were characterized by nanoparticle tracking analysis, western blot and GE-LC-MS/MS proteomics. APAP-injured hepatocyte-like cells (HLCs) were treated with sEV 1 μg/mL to assess cell viability (MTS) and gene expression (RT-qPCR). Liver reported transgenic zebrafish (2 to 5 dpf) were treated concomitantly with 5 mM of APAP and sEV 20 μg/mL and liver area was measured. **Results:** sEVs kept their physicochemical characteristics after priming with the SOS signals. The proteomic analysis showed that MSC priming promoted a higher secretion of proteins related to stress, extracellular matrix organization and metabolic process regulation. Specifically, proteins which have been functionally linked to cell proliferation, inflammation and oxidative stress regulation, *e.g.,* apolipoprotein E or apolipoprotein A, have been found to be upregulated or unique to the primed condition. Importantly, treatment of APAP-injured HLCs with sEV-pMSC led to an increase of 30% in cell viability as well as a reversion of proliferation- (*e.g., ccnd1, c-met*), oxidative stress- (*e.g., gss, cyp2e1*) and metabolism-associated genes (*e.g., fas*) to levels similar to the basal state. Most interestingly, treatment of injured zebrafish with sEV-pMSC diminished the extent of liver injury promoted by APAP. **Conclusion:** Our results indicate that priming of MSC with hepatic SOS signals resulted in a pro-regenerative enriched sEV cargo, which further promoted hepatocyte regeneration *in vitro* and decreased liver injury *in vivo*.

4377 | REAL-WORLD INCIDENCE OF LIVER ENZYME ELEVATION DUE TO MEDICATIONS IN HOSPITALIZED INDIVIDUALS: CHALLENGES AND OPPORTUNITIES OF USING BIG DATA TO STUDY HEPATOTOXICITY

Maria Mironova[1] Huiman Barnhart[2] Cynthia Moylan[2] Yaron Rotman[1], [1]National Institutes of Health, [2]Duke University

Background: Liver injury from medications poses a significant risk, especially in inpatients, where polypharmacy is common. Traditional hepatotoxicity risk assessments rely heavily on case reports or small cohorts, limiting generalizability. We aimed to leverage a large database for an unbiased assessment of medication-associated liver enzyme (LE) increases. **Methods:** We used the MIMIC-IV database, containing all admissions to BIDMC (Boston, MA) between 2008-2019. We included hospital admissions with length of stay (LOS) $\geq$ 3 days, that had $\geq$2 documented LE tests, baseline ALT $\leq$ 70 U/L, AST $\leq$ 70 U/L, ALP $\leq$ 150 U/L and total bilirubin $\leq$ 1.5 mg/dL, and no major confounding diagnoses such as chronic liver disease or shock. Primary endpoint was LE increase defined as ALT, AST or ALP increase $>$2X the patient's baseline at any time during admission. List of medications administered prior to LE increase was evaluated. Cases of LE increase were matched to controls with a 1:4 optimal pair matching on LOS and admission unit. Medication-specific incidence rates were calculated, and logistic regression identified medication associations with elevated LE. **Results:** Of 546,028 admissions, 19,729 met inclusion criteria. Most admissions were excluded due to LOS $<$3 days, or LE checked $<$2 times. 585 patients (3.0%) met the primary endpoint of LE increase. Among medications with the highest crude incidence were high-dose methotrexate (MTX), fosphenytoin, and neostigmine. After adjusting for age, sex, baseline AST & ALT, only four medications—high-dose MTX, neostigmine, phenylephrine, and fospropofol—

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were significantly associated with LE increase (FDR $q < 0.05$).(Table) In MTX, 64% of discharge notes attributed liver injury to treatment, while association with neostigmine was likely confounded by cardiac unit admissions, suggesting surgical, hemodynamic factors or a myocardial source for LE elevation rather than hepatotoxicity. **Conclusion:** Large-scale clinical data enables identification of both known and less studied potential drug-induced liver injury causes. Our unbiased approach validated known hepatotoxicity of high-dose MTX as a positive control and highlighted the importance of considering confounding factors. Despite limitations in confounding and diagnostic specificity, this method may represent an important advance in pharmacoepidemiologic research on hepatic safety. These inpatient findings may differ from outpatient patterns due to different medication exposures and populations, warranting comparative studies.

Table. Example of unadjusted and adjusted odds ratio of acute elevation of LE with 95% CI for top-3 medications with the highest incidence of LE elevation in the cohort. Results are derived from separate logistic regression models for each medication.

Medication (likelihood score of causing liver injury (LiverTox))	Crude incidence of elevated LE (%)	Univariable analysis			Multivariable analysis			
		OR	CI	p-value		OR	CI	p-value
Methotrexate, high-dose (A, high-dose)	46.8	3.69	2.34-5.80	<0.0001	Methotrexate, high-dose	3.72	2.35-5.94	<0.0001

4378 | ANALYSIS OF THE PROSPECTIVE TURKISH DRUG-INDUCED LIVER INJURY REGISTRY

Ali Rıza Caliskan[1] sezgin vatansever[2] Serkan Yaras[3] İlker Sen[4] Mujdat Zeybel[5] Dilara Turan Gokce[6] Meral Akdoğan Kayhan[7] Dinc Dincer[8] Gulsah Fidan Ozkumur[8] Elvan Isık[9] Fulya Günşar[10] Zeki Karasu[10] Coskun Ozer Demirtas[11] Tugba Tolu[11] Volkan YILMAZ[12] Emin Bodakci[12] Galip Büyükturan[13] Cemal Nuri Ercin[13] Ramazan Idılman[12], [1]Department of Gastroenterology, Faculty of Medicine, Adiyam, [2]Department of Gastroenterology, Izmir Ataturk Education and Research Hospital, Izmir, TURKEY., [3]Department of Gastroenterology, Faculty of Medicine, Mersin University, Mersin, TURKEY., [4]Department of Gastroenterology, Sisli Hamidiye Etfal Education and Research Hospital, Istanbul, TURK, [5]Department of Gastroenterology, Faculty of Medicine, Koc University, Istanbul, TURKEY., [6]Department of Gastroenterology, Sincan Training and Research Hospital, Ankara, TURKEY., [7]Department of Gastroenterology, Ankara Bilkent City Hospital, Ankara, TURKEY., [8]Department of Gastroenterology, Faculty of Medicine, Akdeniz University, Antalya, TURKEY., [9]Department of Gastroenterology, Faculty of Medicine, Ege University, Izmir, TURKEY., [10]Department of Gastroenterology, Faculty of Medicine, Ege University, Izmir, TURKEY, [11]Department of Gastroenterology, Faculty of Medicine, Marmara University, Istanbul, TURKEY., [12]Department of Gastroenterology, Faculty of Medicine, Ankara University, Ankara, TURKEY., [13]Department of Gastroenterology, Gulhane Training and Research Hospital, Ankara, TURKEY.

Background: Numerous drugs can fundamentally cause hepatotoxicity through a variety of mechanisms. The clinical spectrum of drug-induced liver injury (DILI) is different among countries. Prospective DILI registries are important sources of detailed information on DILI. In the present study, we aimed to determine patients with DILI enrolled in the Turkish DILI Registry. **Methods:** This prospective multicenter study focuses on identifying patients with DILI. Data collection and patient enrolment in this registry were conducted according to international guidelines. The data included clinical features, drug information, and disease outcomes. **Results:** A total of 131 patients who fulfilled the criteria of DILI were enrolled in this registry between January 2022 and January 2025. Sixty percent of the patients were female. The median age was 45.2 years (range:18-84 years). The predominant liver injury pattern was hepatocellular (76.3%), followed by a mixed pattern (13.0%) and a cholestatic pattern (10.7%). According to the RUCAM scale, the classification was probable in 55% of patients, highly probable in 26.7%, possible in 15.3%, and unlikely in 3.1%. Liver biopsy was performed in 24% of the patients. Acute hepatocellular liver injury was the most common histopathological feature (76.3 %).

The causative agents were mainly drugs in 111 patients (84.7%), followed by herbal and dietary supplements (13.7%). The main groups of drugs included antimicrobials (41.5%), followed by nonsteroidal anti-inflammatory drugs (19.8%), and anti-neoplastic drugs (6.1%). Amoxicillin/clavulanate was the most frequently implicated antibiotic (13.7%), followed by ornidazole (10.7%).

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Hospitalization was necessary for 101 patients (77,1%). Treatment was initiated in 79 patients, with N-Acetylcysteine being the most commonly used. Recovery was observed in 105 patients. The mean time for serum ALT values to return to normal was 61.7 days among recovered patients. Chronicity occurred in 3 three patients. Three patients underwent liver transplantation due to DILI-induced acute liver failure. Three patients died as a result of the progression of their primary diseases. Additionally, sixteen patients were lost to follow-up. **Conclusion:** DILI registry is a valuable tool for determining the causative agents, clinical features, and prognostic factors associated with disease outcomes in patients with DILI.

4379 | THE IMPACT IMMUNE-MEDIATED HEPATOTOXICITY ONSET ON LONG-TERM PROGNOSIS IN PATIENTS WITH ADVANCED CANCER WHO RECEIVED IMMUNE CHECKPOINT INHIBITORS

Yu Akazawa[1] Takuto Nosaka[1] Yosuke Murata[1] Tomoko Tanaka[1] Tatsushi Naito[1] Kazuto Takahashi[1] Masahiro Ohtani[1] Yasunari Nakamoto[1], [1]Department of Gastroenterology, Faculty of Medical Sciences, University of Fukui

Background: With the widespread use of immune checkpoint inhibitors (ICIs), the diagnosis and treatment of immune-related adverse events (irAEs) has become increasingly important. Immune-mediated hepatotoxicity (IMH) is one of the most common irAEs, and in recent years, novel diagnostic guidelines for IMH have been published in Western and Japan. However, the impact of IMH on long-term prognosis in patients with advanced cancer has varied among previous reports, and remain unclear. The aim of this study was to clarify the association between development of IMH and long-term prognosis in patients with advanced cancer who received ICIs. **Methods:** The patients with advanced cancer who received ICIs from September 2014 to December 2024 in our department were enrolled for this retrospective study. In enrolled patients, the incidence of IMH was evaluated, and long-term prognosis including overall survival compared between the two groups with IMH and non-IMH using the Kaplan-Meier method. In addition, we performed landmark analysis on three time points (3, 6, and 12 months) to control immortal-time bias. The diagnosis and grading of irAEs including IMH were defined according to CTCAE version 5.0, and adverse events of $\geq$ Grade 2 were extracted. **Results:** A total of 966 patients (691 males, 275 females; median age, 71.1 years) were enrolled in this study. Of all, 87 patients (9.0%) developed IMH: Grade 2 (G2), Grade 3, and Grade 4 in 52 (5.4%), 31 (3.2%), and 4 (0.4%) patients, respectively. The median time from the first administration of ICI to the onset of IMH was 51.0 days. The types of liver damage in IMH patients were hepatocellular, cholestatic, and mixed damage in 66.7% (58/87), 8.0% (7/87), and 25.3% (22/87), respectively. Also, the multivariate analysis revealed the onset of irAE ($\geq$G2) in other organs ($p < 0.001$) and ICI combination therapy ($p = 0.004$) were significantly independent factors associated for the onset of IMH. The median OS in the IMH onset group was significantly longer than that in non-IMH onset group (not reached vs 440 days, $p < 0.001$). Also, in the 3- ($p = 0.013$) and 6-month ($p = 0.025$) landmark analysis, patients who developed IMH had significantly better OS than those who did not, consistent with the findings of the conventional analysis. In addition, the group of patients with irAE onset in multiple organs had significantly better OS than the other groups, including the groups of patients with irAE onset in a single organ and no irAE onset ($p < 0.001$), and the results of landmark analysis (3-, 6-, and 12-month) were consistent with those of conventional analysis. **Conclusion:** The onset of IMH was closely associated with the better long-term prognosis in patients with advanced cancer who received ICIs. This finding suggests that early detection and thorough management for IMH may result in sufficient anti-tumor effects, which contribute to improve survival in patients with ICIs.

Hospital, Tianjin, China, [2]Department of Gastroenterology and Hepatology, Tianjin First Central Hospital, Tianjin, China., [3]The Second People's Hospital Affiliated to Tianjin Medical University,Tianjin, China

Background: Drug-induced liver injury (DILI) is one of the important causes of acute liver injury. Biochemical and histological injury types were classified as hepatocellular, cholestatic or mixed injury. The cholestatic DILI has longer and poor prognosis. Therefore, it is very important to identify the type of DILI as early as possible. There is still a lack of sensitive biochemical indicators in clinic. Although liver pathology is the gold standard for diagnosis, it is an invasive examination and may cause certain risks to patients, so its clinical application is limited. The Roussel Uclaf causality assessment method used the R value to distinguish cholestatic DILI. But R value was considered to have underestimated the proportion of cholestatic DILI. Therefore, this study collected biochemical indicators of patients who diagnosed as DILI by liver pathology, analyzed the characteristics of each indicators and established prediction models, trying to provid a new idea for diagnosis of cholestatic DILI. **Methods:** Patients with hepatic pathological diagnosis of DILI in Tianjin Second People's Hospital and Tianjin First Central Hospital from July 2012 to December 2024 were retrospectively analyzed. The clinical data of patients during hospitalization were collected and analyzed. The patients were divided into cholestatic group and non-cholestatic group based on the liver pathology of cholestatic drug-induced liver injury. Then we summarized the clinical characteristics of patients with cholestatic DILI, and established the cholestatic drug-induced liver injury prediction model. **Results:** A total of 480 patients with DILI were collected in this study, including 220 (41.8%) patients with cholestatic DILI and 260 (54.2%) patients with non-cholestatic DILI. According to univariate analysis, there were significant differences in peak severity, peak ALP, peak GGT, peak TBIL, peak DBIL, peak TBA, peak INR, peak PT, peak PTA, peak TG, peak ALB, peak PA and peak CHE between the two groups ($P < 0.05$). Based on the multivariate analysis and clinical recommendations, peak TBA, peak PTA, peak TG, peak ALP, peak GGT and peak CHE were incorporated into the nomogram model with high prediction accuracy and the area under ROC curve was 0.75. Using peak TBA predict cholestatic DILI, the area under ROC curve is also 0.75. The sensitivity and specificity of the nomogram model were 0.645 and 0.745. Using peak TBA predict, the sensitivity and specificity were 0.775 and 0.589. **Conclusion:** Peak TBA can predict cholestatic DILI perfectly, the sensitivity is higher and recommend it for preliminary clinical screening for cholestatic drug-induced liver injury. The nomogram model established with six variables including peak TBA, peak PTA, peak TG, peak ALP, peak GGT and peak CHE has high specificity. We recommend it for further diagnosis.

Table 1. Baseline table of patients.

Variable	All (N=480)	Non-Cholestasis (N=260)	Cholestasis (N=220)	*P* value
Gender:				0.371

4381 | IMMUNE CHECKPOINT INHIBITOR HEPATITIS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA: DIAGNOSTIC COMPLEXITY, SHORTER ONSET, AND DELAYED BIOCHEMICAL RECOVERY

Isaac Benque[1] Jordan Sack[2] Shilpa Grover[2] Jennifer Lai[1] Stephen Zucker[2] Michael Li[1], [1]University of California, San Francisco, [2]Brigham and Women's Hospital

Background: Diagnosis and management of immune checkpoint inhibitor (ICI) hepatitis are complex in patients with hepatocellular carcinoma (HCC) due to underlying liver disease and liver tumor burden. We

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

investigated diagnostic challenges and compared outcomes of ICI hepatitis in patients with HCC versus non-HCC cancers. **Methods:** In this multicenter, retrospective cohort study, all HCC patients who received corticosteroid treatment for suspected high-grade ICI hepatitis from one center were reviewed by two specialists who independently performed RUCAM causality assessments to adjudicate ICI hepatitis cases. True cases were compared to a non-HCC multicenter cohort of high-grade ICI hepatitis. The primary outcome was biochemical recovery, defined as time to ALT improvement to $\leq$100 U/L (grade 1 per CTCAE criteria) after corticosteroid initiation. **Results:** Out of 350 ICI-treated HCC patients, 25 received $\geq$0.5 mg/kg/day of prednisone for suspected ICI hepatitis. After adjudication, 18 (72%) were assessed as true cases; 6/7 false cases were attributed to cancer progression. When compared to ICI monotherapy, dual checkpoint inhibition was associated with increased hepatitis risk (RR 2.7, 95% CI 1.7-4.3, $p < 0.001$).

When compared to 298 non-HCC patients with ICI hepatitis, HCC cases had higher pre-ICI liver tests (median AST: 66 vs 21; ALT: 65 vs 19; bilirubin: 0.9 vs 0.5; alkaline phosphatase: 181 vs 76; $p < 0.001$ for all tests), though peak liver tests after developing ICI hepatitis were similar between the two groups. HCC patients had shorter time to development of high-grade ICI hepatitis (median 28 vs 70 days, log-rank $p = 0.002$; Fig A) when compared to non-HCC patients, including after multivariable adjustment (HR 1.9, 95% CI 1,1-3.1, $p = 0.017$). Fifteen (83%) HCC cases and 295 (99%) non-HCC cases reached the outcome of biochemical recovery. HCC cases had longer time to biochemical recovery (median 38 vs 20 days, log-rank $p < 0.001$; Fig B) compared to non-HCC cases, including after adjusting for ALT level at time of corticosteroid initiation, presence of liver tumors, and dual checkpoint inhibition (HR 0.3 for HCC, 95% CI 0.2-0.6, $p < 0.001$). **Conclusion:** Diagnosing ICI hepatitis in HCC patients can be challenging due to potential competing etiologies for elevated liver tests, and imaging to rule out liver tumor progression is prudent. HCC patients develop ICI hepatitis faster than non-HCC patients and experience slower biochemical recovery after steroid treatment.

4382 | ANTITUBERCULAR THERAPY INDUCED HEPATITIS IN CHILDREN: INCIDENCE, RISK FACTORS, ROLE OF CYTOKERATIN 18 AND OUTCOME

Shivani Randev[1] Aakanksha Mangotra[1] Seema Gupta[2] Pankaj Kumar[2] Vishal Guglani[2], [1]Government Medical College and Hospital, Chandigarh, [2]Government Medical College and Hospital

Background: Drug-induced liver injury (DILI) is a significant complication of antitubercular therapy (ATT) in children. Early identification of at-risk patients is crucial to prevent severe hepatotoxicity and treatment interruptions. Current monitoring relies heavily on clinical symptoms and liver function tests(LFT), which may rise only after significant liver injury has occurred, thus, highlighting need for a reliable biomarker for early detection. This study aimed to evaluate clinical and biochemical predictors of DILI in children receiving ATT, with a focus on cytokeratin18(CK18) as a potential early biomarker. **Methods:** This prospective observational cohort study included 136 children diagnosed with tuberculosis. Patients were followed clinically for up to 24 weeks after initiation of ATT. Liver function tests (LFTs) were conducted at baseline and at 2, 4, 8, and 12 weeks post-ATT initiation, and additionally if symptoms suggestive of DILI appeared. CK18 levels were measured at baseline, 2 weeks, and at the time of DILI diagnosis. **Results:** DILI developed in 26 (19.1%; 95% CI: 13.1–26.9) patients at a median of 6.5 (IQR:11.5—31) days after ATT initiation. Patients who developed DILI were less likely to have Mantoux positivity, had lower body mass index (BMI) and serum albumin and higher mean rifampicin dose ($p < 0.05$). Nine patients (34%) developed a recurrence of DILI after re-initiation of ATT. Factors significantly associated with occurrence of DILI were BMI of less than 13 Kg/m^2 BSA [OR 4.38 (1.74-11.01)], Rifampicin dose $\geq$ 13mg/kg/day [OR 4.58 (1.48-14.18)], Pyrazinamide dose $\geq$ 35mg/kg/day [OR 3.37 (1.08-10.52)]; baseline ALT $>$ 27 IU/L [OR2.70 (1.08-6.73)]; 2-week ALT $>$ 76 IU/L [OR 103.31 (23.7-450.27)]. Baseline serum CK18 level above 17892 units/L and 2-week level above 9693 units/L were seen to have a significant association with occurrence of DILI, with the area under ROC curve of 0.523 (95% CI:0.293 - 0.754) and 0.61 (95%CI:0.423 - 0.797),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

respectively ($p > 0.05$). The time taken for resolution of DILI and re-initiation of the first ATT drug was 13.71 ± 10.18 days. The total duration from DILI onset to full reintroduction of ATT ranged from 12 to 87 days, with a median duration of 27.50(IQR 16-47) days. **Conclusion:** Approximately one in five pediatric patients on ATT develop DILI. Monitoring ALT levels, especially in those with identifiable risk factors, may aid early diagnosis. Although CK18 shows promise as an early biomarker for DILI, further validation is needed.

4383 | REAL-TIME HEPATIC SURVEILLANCE IN RESIDENTS FOLLOWING THE EAST PALESTINE, OH CHEMICAL DISASTER

Olisa Okonkwo[1] Alexander Monroe[1] Kimberly Stello[1] James Fabisiak[1] Carla Ng[1] Fredrick Schumacher[2] Maureen Lichtveld[1] Juliane Beier[1], [1]University of Pittsburgh, [2]Case Western Reserve University

Background: The February 2023 train derailment in East Palestine, Ohio, released vinyl chloride and other hepatotoxic chemicals, creating urgent need for health surveillance. This study represents the first systematic liver function assessment in residents potentially exposed to these environmental toxicants, establishing critical baseline data for long-term health monitoring. **Methods:** Adults ≥18 years within 8 miles of the derailment site have been recruited since June 2024. Participants provided informed consent for blood sampling and complete questionnaires on demographics, alcohol consumption, medical history, and health status. Liver function was assessed via serum ALT and AST levels. Body mass index (BMI) was calculated from measured anthropometric data. **Results:** To date, 47 participants enrolled (mean age 65.9 years, range 32-81), representing robust community response. All participants self-identified as White. Mean BMI was 29.0 kg/m² with 25% overweight (BMI 25-29.9 kg/m²) and 56% obese (BMI ≥30 kg/m²). Alcohol consumption: 75% drank <4 times weekly, 19% abstained, and 6% consumed alcohol ≥4 times weekly. Mean liver enzyme levels remained within normal ranges: ALT 18.25 U/L (7-56 U/L) and AST 20.13 U/L (10-40 U/L). Only one participant demonstrated elevated ALT (48 U/L); this individual had BMI of 30 and abstained from alcohol, while all others exhibited normal values. No correlation was observed between enzyme levels and alcohol consumption or BMI. As recruitment remains active, these preliminary findings may evolve. **Conclusion:** This pioneering surveillance study reveals preliminary findings: despite potential vinyl chloride exposure, the vast majority demonstrate normal liver enzyme levels, though traditional biomarkers ALT and AST may not detect early hepatotoxicity. Continued vigilance remains essential, as one participant showed ALT elevation warranting monitoring. Future analyses of the bio banked samples will include CK-18, which has demonstrated superior predictive value for vinyl chloride-related liver damage. These baseline data enable longitudinal tracking of hepatic health in this uniquely exposed population. This study represents a critical model for environmental health response with implications extending beyond East Palestine to communities worldwide facing similar toxicant exposure threats.

4384 | EXPRESSION OF IL-8, IL-10, AND CXCL-14 IN LIVER TISSUES OF PATIENTS WITH DRUG-INDUCED LIVER INJURY AND THEIR ASSOCIATION WITH PATHOLOGICAL FEATURES

diandian Hao[1] Xiaoyu Wen[2] JiaLin Du[3], [1]The First Hospital of Jilin University, [2]15804301609@163.com, [3]dujl9907@163.com

Background: Drug-induced liver injury (DILI) is a clinically significant hepatic disorder with complex pathogenesis involving interactions among drug-metabolizing enzyme abnormalities, host genetic susceptibility, and immune responses. Cytokines play pivotal roles in DILI progression, yet the expression profiles of IL-8, IL-10, and CXCL-14 in liver tissues and their associations with pathological features remain unclear. This study aimed to investigate the clinical and pathological characteristics of DILI patients, quantify hepatic IL-8, IL-10, and CXCL-14 expression, and evaluate their roles in DILI pathogenesis, particularly CXCL-14's regulatory mechanisms and potential as a prognostic biomarker. **Methods:** Forty DILI patients (diagnosed via liver biopsy with confirmed drug/environmental toxin exposure) from Jilin University First Hospital (January 2023–August 2024) and 10 healthy controls were enrolled. Immunohistochemistry (IHC) was performed to quantify IL-8, IL-10, and CXCL-14 expression in liver tissues. Pathological features (inflammatory activity, fibrosis stage, clinical subtypes) were analyzed. Statistical analyses, including Spearman's correlation and logistic regression, were conducted using SPSS 27.0. **Results:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Among 40 DILI patients (90% female, mean age 50 years, BMI 22.7 kg/m²), herbal decoctions/proprietary Chinese medicines accounted for 47.5% of causative agents. Pathological subtypes exhibited distinct features: Cholestatic type: bile stasis in hepatocytes/canaliculi, intrahepatic pigment deposition, microvesicular steatosis. Hepatocellular injury type: interface hepatitis, spotty necrosis, hydropic degeneration, mixed inflammatory infiltration. Mixed type: combined features. Compared to controls, DILI patients showed significantly elevated IL-8, IL-10, and CXCL-14 expression (all $P < 0.05$) (Fig.1). IL-8 and CXCL-14 levels varied significantly across inflammatory activity grades and fibrosis stages (all $P < 0.05$). Spearman analysis revealed positive correlations between cytokine levels (IL-8, IL-10, CXCL-14) and inflammatory activity ($r = 0.53$, 0.43, 0.37; $P < 0.05$), as well as associations of IL-8 and CXCL-14 with fibrosis ($r = 0.36$, 0.38; $P < 0.05$). CXCL-14 correlated positively with AST and GGT ($r = 0.381$, 0.404; $P < 0.05$) and independently predicted poor prognosis (OR = 0.786, 95% CI: 0.633–0.975, $P = 0.028$), outperforming traditional biomarkers. **Conclusion:** DILI predominantly affects elderly females, with herbal agents as leading triggers. Early drug withdrawal and standardized treatment yield favorable outcomes in most patients.IL-8 and CXCL-14 demonstrate significant associations with inflammation and fibrosis progression, highlighting their utility in evaluating disease severity. CXCL-14 emerges as an independent prognostic risk factor, offering superior sensitivity/specificity over conventional biochemical markers.

4385 | ENABLING DILI SURVEILLANCE THROUGH AUTOMATED MEDICATION EXTRACTION FROM CLINICAL NOTES: A REAL-WORLD LLM VALIDATION STUDY

Thanathip Suenghataiphorn[1] Kanachai Boonpiraks[2] Vitchapong Prasitsumrit[3] Narathorn Kulthamrongsri[4] Pojsakorn Danpanichkul[5], [1]Yale/Griffin Hospital, [2]University of Kansas Medical Center, [3]Texas Tech Lubbock Health Science Center, [4]University of Hawaii, [5]Texas Tech University Health Sciences Center

Background: Drug-induced liver injury (DILI) presents a significant diagnostic challenge often leading to delayed detection. Unstructured clinical notes contain comprehensive medication data vital for DILI surveillance but are difficult to analyze systematically. Large language models (LLMs) show promise for automated extraction but require real-world clinical data validation to assess feasibility for clinical applications like DILI surveillance. **Methods:** We retrospectively validated an LLM system on 100 randomly sampled MIMIC-IV discharge summaries. Gold standard unique medication lists were derived via manual annotation and manual deduplication based on normalized drug names. LLM outputs underwent identical deduplication. Performance was assessed using precision, recall, and F1-score comparing deduplicated lists. MIMIC-IV DUA compliance was ensured. **Results:** Comparison yielded a precision of 0.85, recall of 1.00, and an F1-score of 0.92 for unique medication identification. The 174 false positives resulted from parsing or normalization errors; no medication hallucinations occurred. A subsequent DILI database lookup failed for approximately 6.2% of correctly identified unique medications, evaluated as a separate feasibility measure. **Conclusion:** The LLM demonstrates high accuracy and perfect recall for unique medication extraction and identification from complex clinical notes, establishing technical feasibility. This represents a feasible and possible integration of large language model towards developing automated tools for enhanced DILI surveillance and improved patient safety.

4386 | DRUG INDUCED GRANULOMATOUS HEPATITIS – A DISPROPORTIONALITY ANALYSIS USING THE FDA ADVERSE EVENT REPORTING SYSTEM (FAERS) DATABASE

Rohan Karkra[1] Mahinaz Mohsen[1] Sameer Rao[1] Ritik Mahaveer Goyal[1] Drew Fletcher[1] Ahmed Al-Khazraji[1] Paul Gaglio[1], [1]Rutgers New Jersey Medical School

Background: Granulomatous hepatitis is a form of chronic liver inflammation characterized by the presence of organized macrophages in the form of granulomas. These granulomas can result from various etiologies, including infections (e.g., tuberculosis, fungal infections), systemic diseases (e.g., sarcoidosis), drug reactions, and idiopathic causes. Clinically, it often presents with fevers, chills, night sweats, weight loss, and elevated liver enzymes, particularly alkaline phosphatase and γ-glutamyl-transferase. This is a real world pharmacovigilance study evaluating medications suspected to be associated with drug induced granulomatous hepatitis. **Methods:** The Food and Drug Administration (FDA) maintains the Adverse Event Reporting System (FAERS) database. As of December 31, 2024, the database contained 30,179,725 reported events. This database was queried to identify all reported cases of 'Granulomatous Liver Disease'. All medications implicated were identified by their generic names. The database does not report how the diagnosis was confirmed, or whether other causes were ruled out. A disproportionality analysis was conducted, wherein Reporting Odds Ratios (ROR) were calculated. An ROR >1 is considered a significant signal. **Results:** A total of 795 cases were reported to the FAERS from 1997-2024. 785 were characterized as severe, including 77 deaths (9.68%). The most common reported drugs were – Bacillus Calmette-Guerin (11.82%; ROR: 814.4 [655.43, 1011.92]; $p<0.05$), Infliximab (6.04%; ROR: 9.11 [6.8, 12.2]; $p<0.05$), Methotrexate (4.78%; ROR: 7.57 [5.46, 10.49]; $p<0.05$), Rifampin (4.03%; ROR: 69.42 [48.72, 98.9]; $p<0.05$), Allopurinol (3.52%; ROR: 43.81 [30.04, 63.9]; $p<0.05$), Isoniazid (3.14%; ROR: 92.4 [62.01, 137.67]; $p<0.05$), Etanercept (3.02%; ROR: 1.49 [0.99, 2.24]; $p<0.05$), Adalimumab (3.02%; ROR: 1.26 [0.84, 1.89]; $p<0.05$), Furosemide (2.89%; ROR: 12.79 [8.45, 19.37]; $p<0.05$), and Pyrazinamide (2.89%; ROR: 134.10 [88.51, 203.17]; $p<0.05$). **Conclusion:** Bacillus Calmette-Guerin (BCG), used in tuberculosis vaccinations and for making tuberculin extracts, was the most reported cause of drug-induced granulomatous hepatitis (11.82% of all reports), as well as the agent with the highest ROR (814) amongst the most frequently reported agents. After BCG, Isoniazid had the highest ROR (92.4). A high degree of suspicion should be employed when patients present with symptoms of chronic inflammation and elevated liver enzymes. Such patients should discontinue these medications when possible.

4387 | LIVER INJURY DUE TO MEDICATIONS FOR MENTAL HEALTH: AN ANALYSIS OF THE DRUG-INDUCED LIVER INJURY NETWORK PROSPECTIVE STUDY

Cassey Cha[1] Hersh Shroff[1] Huiman Barnhart[2] Raj Vuppalanchi[3] Alfred Barritt IV[1], [1]UNC Chapel Hill, [2]Duke University, [3]Indiana University

Background: Medications for mental health are amongst the most prescribed agents in the United States. This study characterizes drug-induced liver injury (DILI) attributed to antidepressants and antipsychotic (AP) medications. **Methods:** We queried the Drug-Induced Liver Injury Network (DILIN) prospective study (2004 to 2025) database for high-confidence causality cases of acute DILI (cases rated as definite, highly likely, or probable) due to antidepressants and APs. Agents with the same mechanisms of action (MOA) were combined for analysis. Descriptive statistics were used to describe data on demographics, clinical and laboratory characteristics, and patient

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

outcomes. **Results:** As of January 2025, among 2,678 cases in the DILIN Prospective Study database, we identified 37 cases (1.5%) of DILI ascribed to antidepressants or APs (Table 1). These included 8 selective serotonin reuptake inhibitors (SSRIs), 14 serotonin-norepinephrine reuptake inhibitors (SNRIs), and 8 atypical APs. Bupropion (6 cases) and imipramine (1 cases) were the only agents of their respective classes (aminoketone and tricyclic antidepressant). In total, 70% of subjects were women, and mean ages ranged from 30.2 (SSRIs) to 48.2 (SNRIs) years. Patterns of injury (and median R-values) were 56% hepatocellular (median R-value 11.8), 35% cholestatic (R-value 1.4), and 3% mixed (R-value 2.8). Peak mean serum aminotransferase levels across all cases ranged from 320 to 1505 U/L for AST and 425 to 2109 U/L for ALT, the highest values being among SNRI cases. Mean peak serum total bilirubin (TB) levels ranged from 4.1 to 15.0 mg/dL. Corticosteroid treatment was given to 27% of patients. Across all cases, improvement was rapid, with a mean time from peak values to $\geq$50% reduction ranging from 3 to 11 days for AST/ALT and 2 to 10.5 days for TB. Persistent elevations in liver enzymes after 6 months ("chronic DILI") were seen in 16% of cases. 11 cases met criteria for modified Hy's law (defined as initial R value $\geq$ 5 and TB $\geq$ 2.5mg/dL), with one liver-related death in a case of DILI due to bupropion. No other death nor liver transplant occurred in this cohort. **Conclusion:** Despite frequent use, the frequency of DILI cases due to antidepressants and APs in the US is low, and most cases showed rapid improvement. However, severe cases leading to chronic DILI or death rarely occur. It is important for practitioners to keep in mind the rare possibility of DILI as an adverse effect of these agents.

Table 1: Characteristics of DILI

Characteristic	SSRI* (n=8)	SNRI † (n=14)	Atypical AP^ (n=8)	Bupropion (n=6)	Imipramine (n=1)
Causality score					
Definite	2 (25)	5 (36)	0 (0)	0 (0)	-
Highly likely	4 (50)	8 (57)	5 (63)	4 (66)	1 (100)

4388 | EXPERIMENTAL STUDY ON THE REGULATION OF LY6CHI/LY6CLO MACROPHAGE BALANCE BY YIGAN XIAOJI FORMULA IN LIVER CIRRHOSIS MICE

Shihao Zheng[1] qiuyue wang[2] Xiaoke Li[2] Peng Zhang[2] Yongan Ye[2], [1]Dongzhimen Hospital, Beijing University of Chinese Medicine, [2]Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing 100700, China

Background: Liver cirrhosis (LC) is the end stage of chronic liver disease, which is a serious threat to the health of people around the globe, and nowadays there is no completely effective therapeutic drug, while in the clinical practice, traditional Chinese medicine (TCM) has shown good therapeutic effect on LC. Yigan xiaoji formula (YGXJ) is a commonly used TCM, but the specific mechanism of action in the treatment of LC is not fully understood. **Methods:** C57BL/6 mice were divided into blank, model, and herbal intervention groups (YGXJ low, medium, and high dose groups), and a mixture of 20% carbon tetrachloride and olive oil was injected intraperitoneally at 0.2 ml/100 g body weight 3 times/week for 9 weeks to induce early cirrhosis models in the mice of the model group and the herbal intervention group, and the blank group was given an equal volume (0.2 ml/100 g body weight) of olive oil The blank group was given equal volume of olive oil solution. After 5 weeks of modeling, the treatment group was given the TCM YGXJ in low, medium and high concentrations by gavage of the TCM, while the blank group and the model group were given distilled water by gavage of 0.1 ml/10 g gavage 1 time/day for a period of 4 weeks, and then at the end of the 9-week modeling period, the mice of each group were sampled. We observed the vital activities of mice and the condition of liver tissues taken from mice; we detected the levels of ALT and AST, which are the indicators of liver function, and used Masson staining to observe the pathology of liver tissues, immunohistochemistry to detect the expression of F4/80, LY6C, and α-SMA, as well as qRT-PCR to detect the TNF-α, IL1-β, MMP9 and MMP12 mRNA levels. **Results:** After 4 weeks of YGXJ intervention, compared

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with the model group, the expression of ALT and AST in each dose group had a decreasing trend, of which the medium dose group of YGXJ had the lowest content; Comparing the TCM group with the model group, after YGXJ intervention, collagen fiber deposition was significantly reduced in early cirrhotic mice, which could improve the degree of lesions, with the YGXJ medium-dose group being the most obvious; Finally, YGXJ was also able to further regulate the balance of Ly6Chi/Ly6Clo macrophages, and the number of F4/80 macrophages showed a significant downward trend after treatment, and the expression of LY6C and α-SMA was also significantly reduced; meanwhile, YGXJ was also able to down-regulate the mRNA expression of TNF-α and IL1-β, and at the same time, it up-regulated the expression of MMP9 and MMP12. **Conclusion:** YGXJ medium-dose group can improve the liver function of early cirrhotic mice; it has a role in inhibiting the structural state, hepatocyte degeneration, collagen fibers, and hepatic stellate cell activation in the liver of early cirrhotic mice; YGXJ also prevents the disease progression in the early cirrhotic mice by modulating the Ly6Chi/Ly6Clo macrophage balance.

4389 | LIVER INJURY FROM THE DEATH CAP MUSHROOM: THE PHILADELPHIA EXPERIENCE AND ROLE FOR SILIBININ

Stefanie Gallagher[1] Jonathan Fenkel[1] Rebecca Loh[1] Dina Halegoua-DeMarzio[1], [1]Thomas Jefferson University Hospital

Background: Amanita phalloides, commonly known as the death cap mushroom, is highly hepatotoxic via heat-resistant amatoxin. Native to Europe, it now grows in places like Pennsylvania, often under oaks, where its white cap is mistaken for edible mushrooms. Clinical manifestations of poisoning typically progress through stages – often initially asymptomatic followed by gastrointestinal symptoms, transient improvement and progression to liver injury. Severe cases can lead to fulminant liver failure and need for liver transplant. There are no standardized treatment protocols in the United States. Treatment focuses on limiting toxin absorption and promoting elimination, such a silibinin, a derivative of milk thistle, which inhibits amatoxin uptake. When unavailable, Penicillin G can be used. We present a case series from our health system detailing the severity to liver injury, silibinin administration, and liver transplant needs in confirmed cases. **Methods:** We retrospectively reviewed electronic medical records from our health system which includes two high-volume liver transplant centers. We investigated clinical presentation and course, laboratory values and trends, treatment initiation, need for liver transplant evaluation (LTE) and liver transplant. **Results:** We identified 10 cases of Amanita phalloides ingestion from 2016-2023. 7 cases involved a family who all ingested misidentified mushrooms after foraging, of which 5 were children. Regarding treatment, 6 patients received silibinin, through compassionate use, and 3 required LTE. 9 patients received activated charcoal, 8 patients received n-acetylcysteine, 1 patient received Penicillin G and 2 patients received penicillin-derivatives. The degree of liver injury and silibinin initiation is depicted in Figure 1. Of the patients not given silibinin, 3 had mild liver injury and 1 required a transplant. Early identification of intoxication occurred on presentation in all cases except the patient requiring a transplant. There were no fatalities. **Conclusion:** Despite exceptionally high peak liver chemistries and synthetic dysfunction, all patients who received silibinin exhibited biochemical improvement and none ultimately required liver transplantation. This case series highlights that patients with Amanita phalloides ingestion have significant risk of liver injury and should be ideally treated at a transplant center. Additionally, silibinin may be an effective treatment for toxicity compared to supportive therapy alone, though further studies are needed.

4390 | CHARACTERISATION OF LIVER INJURY INDUCED BY TRASTUZUMAB WITHIN THE FRENCH-SPEAKING NETWORK FOR THE STUDY OF HEPATOTOXICITY IN HEALTH PRODUCTS (REFHEPS)

Bénédicte Delire[1] LUCY MEUNIER[2] Magdalena Meszaros[2] Amel Zaahaf[2] Eleonora De Martin[3] François Duhoux[4] Cedric Van Marcke[4] Yves Horsmans[1] Dominique Larrey[2], [1]Department of Hepatology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [2]Liver unit, Hopital St Eloi, CHU Montpellier, France, [3]APHP, Hôpital Paul Brousse, Centre Hépato-Biliaire, Unité INSERM 1193, Villejuif, France, [4]Department Of Medical Oncology, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Background: Trastuzumab (TRA) is a targeted therapy that exists as either a monoclonal antibody or an antibody-drug conjugate: TRA-deruxtecan (T-DXd) and TRA-emtansine (T-DM1). All are used to treat breast cancer (BC) and other solid tumors and are associated with drug-induced liver injury (DILI). **Methods:** Patients assessed by the Réseau Francophone pour l'étude de l'Hépatotoxicité des Produits de Santé (REFHEPS) between January 2022 and May 2025 were evaluated. Those with TRA/T-DXd/T-DM1-induced liver toxicity were included. Hepatotoxicity was defined as ALT or AST $\geq$ 5x ULN, ALP $\geq$ 2x ULN, or total bilirubin $\geq$ 2x ULN associated with ALT $\geq$ 3x ULN or the appearance of signs of portal hypertension (PH). Causality was assessed using the CIOMS and the DILIN method and severity using the DILIN score. Approval by an ethics committee (IRB number: 198711). **Results:** Thirteen of the 322 cases collected in the REFHEPS involved TRA/T-DXd/T-DM1: 5 T-DM1, 2 T-DXd, 1 T-DM1 and nivolumab, 1 TRA, and 1 TRA+pertuzumab+tucatinib. All but one of the patients were female, median age 62 years (39–82). Eleven patients were treated for BC, 1 for ovarian tumor and 1 for bladder carcinoma. DILI phenotype was cholestatic in 5 cases, cytolytic in 3 and mixed in 1. Four patients did not meet the biological criteria for DILI but had signs of PH. When applicable, DILIN grade was probable in 8 cases and possible in 1. Same results were observed using the CIOMS method (median RUCAM score = 7 (4-8)). Hepatic damage was symptomatic in 3 cases, one had variceal haemorrhage. Six patients in the cholestatic and PH groups had liver biopsy. Histological analysis was consistent with porto-sinusoidal vascular liver disease (PSVD) in all patients whose evolution was chronic. PSVD was related to T-DM1 in 5 cases, to T-DXd in 2, to T-DM1 and nivolumab in 1 and to TRA in 1. In the cytolytic and mixted group, 2 patients had a biopsy showing an acute lobular hepatitis in one case and a cholestatic hepatitis in the other. Three patients experienced resolution of liver enzymes; one of these patients received corticosteroids, while another patient only showed improvement in hepatic tests after three months. Acute hepatitis was associated with T-DM1 in 2 cases, to T-DXd in 1 and to a combination of TRA-Pertuzumab-Tucatinib in 1. **Conclusion:** TRA, T-DXd and T-DM1 are associated with DILI, including acute hepatitis and chronic PSVD. Further data are needed to predict the development of clinical PH in patients treated with these molecules.

◆ 4391 | THE IMPACT OF CYP2E1 DELETION IN MOUSE LIVER

Kristina Stayer[1] Zaria Killingsworth[1] Madison Thornton[1] Kylie Driggers[1] Taia Mendenhall[1] Mi-Hye Lee[1] Lauren Ball[1] Kristi Helke[1] Don Rockey[1] Mindy Engevik[1] Jessica Hartman[1], [1]Medical University of South Carolina

Background: Cytochrome P450 2E1 (CYP2E1) is a mammalian enzyme present at high levels in liver that is highly conserved in mammals. Prior studies have documented the hepatotoxic effects of CYP2E1 via the production of toxic metabolites from its substrates, such as acetaldehyde from ethanol and NAPQI from acetaminophen. A global CYP2E1-knockout (KO) mouse was developed by Dr. Frank Gonzalez in the late 1990s and has no documented phenotypic abnormalities except for dramatic protection against hepatic insult from acetaminophen, ethanol, high-fat diet, Western diet, carbon tetrachloride, N,N-dimethylformamide, and many other CYP2E1-relevant challenges. CYP2E1 inhibition has been proposed as both a treatment for liver disease and a prophylactic against liver damage. **Methods:** In this study, we used 12-14 week adult mice from the 129S1/SvImJ background (WT) or 129/Sv-Cyp2e1^{tm1Gonz}/J (KO). For organoids, we embedded freshly isolated primary hepatocytes in Matrigel and used Hepatic Organoid Media from StemCell Technologies and observed organoid

formation over 6 days. For histology, we fixed liver in 10% neutral buffered formalin and embedded in paraffin before slicing and staining with H&E or antibodies against macrophages (F480 and CD68), T-cells (CD3e and CD49d), B cells (CD20), or mitochondrial HSP60 with fluorescent secondary antibodies and imaged by fluorescent microscopy. RNA and proteins were isolated from bulk liver tissue for transcriptomics (Novogene) and protein mass spectrometry (MUSC Proteomics). Mitochondria were isolated from bulk liver tissue for determination of respiratory complex activities. **Results:** We have observed that CYP2E1-KO livers from both male and female mice are impaired in forming organoids, with male livers forming significantly smaller and fewer organoids than the WT livers and female livers failing to form organoids. We also observed pathology in formalin-fixed liver tissue, including biliary hyperplasia, pericentral necrosis, and inflammatory cell infiltration in female livers. Follow-up immunofluorescent staining revealed that the infiltrating immune cell populations included macrophages and T-cells. RNA-seq and proteomic investigation of female liver tissue revealed common upregulated pathways of SREBP signaling, ER stress, and steroid metabolism and downregulated pathways of DNA damage repair, mitochondria, and anti-inflammatory response. We observed changes in mitochondrial morphology and mitochondrial respiratory complex activities in both male and female KO liver compared to WT liver. **Conclusion:** These results suggest that CYP2E1-KO has deleterious consequences that are most prevalent in female liver. In ongoing experiments, we are interrogating the endogenous activities of CYP2E1 (fatty acid hydroxylation, ketone metabolism, and ROS production) to determine the mechanism underlying these intriguing findings.

◆ 4392 | UNRAVELING THE PARADOX: CLINICAL OUTCOMES IN PRIMARY BILIARY CHOLANGITIS WITH HYPERLIPIDEMIA – A MULTINETWORK COHORT STUDY

Tinsae Tsegaye Anebo[1] Karecia Byfield[1] Laith Alomari[1] Delano Carty[1] Ghideon Ezaz[1], [1]Thomas Jefferson University

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease often associated with significant hyperlipidemia. Historically, despite elevated lipid levels, PBC patients were thought to have low atherosclerotic cardiovascular disease (ASCVD) rates, suggesting a benign lipid profile. However, recent studies have questioned this assumption, citing a rising burden of cardiovascular and metabolic comorbidities, particularly as the disease advances. This disconnect has complicated clinical management, especially decisions regarding lipid-lowering therapies. To address this gap, we conducted a multi-center, retrospective cohort study to assess the true impact of hyperlipidemia on cardiovascular and liver-related outcomes in PBC, and to evaluate the relevance of traditional lipid risk models in this population. **Methods:** Using the TriNetX US Collaborative Network, we identified adult PBC patients diagnosed between 2012 and 2024. Patients were divided into two cohorts: those with hyperlipidemia, determined via lipid panels or ICD codes, and those without. We excluded individuals with coexisting chronic liver diseases, pre-existing cardiovascular conditions, or prior statin use to minimize confounding. Propensity score matching was performed based on demographics and clinical variables. The primary outcome was the incidence of major adverse cardiovascular events (MACE). Secondary outcomes included liver-related complications. Kaplan-Meier curves assessed event-free survival, while Cox proportional hazards models evaluated associations between hyperlipidemia and clinical outcomes, adjusting for age, sex, BMI, smoking, diabetes, and hypertension. **Results:** After matching, each cohort included 7,299 patients. PBC patients with hyperlipidemia showed significantly higher rates of cardiovascular and metabolic outcomes, including ischemic heart disease, stroke/TIA, peripheral arterial disease, heart failure, hypertension, and type 2 diabetes. Interestingly, all-cause mortality was lower, while hospitalization risk was modestly higher. Liver-related complications such as ascites, hepatic encephalopathy, variceal bleeding, and spontaneous bacterial peritonitis were significantly reduced. No differences were seen in hepatocellular carcinoma or liver transplantation rates. **Conclusion:** Our findings challenge the long-standing

notion that hyperlipidemia in PBC is benign. While associated with lower mortality and fewer liver complications, hyperlipidemia in PBC confers a significantly higher burden of cardiovascular and metabolic disease. These results underscore the need for revised cardiovascular risk stratification and a personalized, proactive management approach in PBC, especially as traditional lipid metrics may underestimate true risk in this unique population.

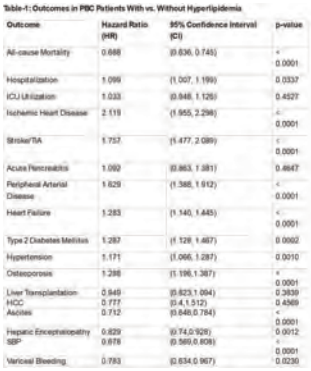

Table-1: Outcomes in PBC Patients With vs. Without Hyperlipidemia

Outcome	Hazard Ratio (HR)	95% Confidence Interval (CI)	p-value
All-cause Mortality	0.668	(0.636, 0.745)	< 0.0001
Hospitalization	1.099	(1.007, 1.199)	0.0337
ICU Utilization	1.033	(0.948, 1.126)	0.4527

◆ 4393 | REDUCTION IN INTERLEUKIN (IL)-31 WITH LINERIXIBAT IS ASSOCIATED WITH PRURITUS RESPONSE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC) AND CHOLESTATIC PRURITUS IN THE PHASE 3 GLISTEN STUDY

Christopher Bowlus[1] Andreas Kremer[2] Janelle Lennie[3] Bishoy Hanna[3] Kerri Fuller[4] Sugato Das[5] Linda Casillas[3] Alexander Cobitz[3] Ciara Gorey[6] Jennifer Shannon[7] Philip Troke[6] Megan McLaughlin[3] Sumanta Mukherjee[3] Brandon Swift[7], [1]University of California Davis, Sacramento, CA, USA, [2]University Hospital Zurich, University of Zurich, Zurich, Switzerland, [3]GSK, Collegeville, PA, USA, [4]GSK, Stevenage, UK, [5]GSK, Hyderabad, India, [6]GSK, London, UK, [7]GSK, Durham, NC, USA

Background: Cholestatic pruritus is common in PBC and negatively impacts quality of life. Several potential mediators of cholestatic pruritus have been identified, including bile acids, endogenous opioids and lysophosphatidic acid (LPA); however, the precise mechanisms leading to itch are not well understood. IL-31 has been associated with atopic dermatitis and more recently with PBC and primary sclerosing cholangitis; reductions correlate with improved itch in patients treated with a peroxisome proliferator-activated receptor agonist in PBC. Ileal bile acid transporter (IBAT) inhibition is known to impact bile acids and LPA (as measured by autotaxin), but its impact on IL-31 is unknown. Linerixibat, a minimally absorbed IBAT inhibitor, is a twice-daily oral tablet for the treatment of pruritus in PBC. Here, we report the effects of linerixibat compared with placebo on IL-31 in participants in GLISTEN (NCT04950127), the largest investigational study of pruritus in PBC. **Methods:** GLISTEN was a Phase 3, randomized, double-blind, placebo-controlled study of 238 adults with PBC and moderate-to-severe pruritus. In the primary intervention period, patients received oral linerixibat 40 mg or placebo twice daily for 24 weeks. Serum IL-31 levels were measured at baseline and Weeks 4, 8, 12, 16, 20 and 24. This analysis includes 135 patients (linerixibat $n = 65$; placebo $n = 70$) who had IL-31 measured. Correlation analyses were post hoc. Pruritus severity was assessed using a 0–10 worst itch numerical rating scale. Itch responders were defined as those achieving a ≥ 3-point improvement from baseline in weekly itch score (average of worst daily itch scores in one week) at Week 24. **Results:** Over 24 weeks, IL-31 reduction was greater in the linerixibat group compared with placebo (ratio of linerixibat to placebo change from baseline [CFB]: 0.53, 95% confidence interval [CI] 0.44, 0.65; $p < 0.001$). Change in IL-31 with linerixibat correlated with change in pruritus over time ($r = 0.21$, $p < 0.0001$). At Week 4, there was a 49.2% reduction from baseline in median IL-31 levels in the linerixibat group versus placebo, and a weak but significant correlation between CFB in IL-31 and pruritus (linerixibat $r = 0.24$, $p = 0.05$; placebo $r = 0.17$, $p = 0.17$). In itch responders, reductions from baseline in IL-31 at Week 24 were greater with linerixibat versus placebo (least squares mean ratio to baseline: linerixibat, 0.41 [95% CI 0.31, 0.54]; placebo, 0.84 [95% CI 0.65, 1.07]; Figure 1A). In linerixibat-treated patients, IL-31 levels at Week 24 were lower in itch responders than non-responders, and in comparison with placebo (Figure 1B). **Conclusion:** IL-31 reduction with linerixibat correlated with an improvement in itch at Week 24 and as early as Week 4. This reduction correlated with change in itch and was associated with treatment response. These data provide key insights into the mechanisms by which linerixibat may mediate itch reduction via IL-31 in PBC.

◆ 4394 | TOFACITINIB AS A STEROID-FREE INDUCTION THERAPY IN AUTOIMMUNE HEPATITIS: AN INITIAL EXPERIENCE

Arnav Aggarwal[1] Sarthak Saxena[1] Sagnik Biswas[1] Shekhar Swaroop[1] Ayush Agarwal[1] . Shalimar[1], [1]All India Institute of Medical Sciences, Delhi

Background: Steroids remain the cornerstone of induction therapy in autoimmune hepatitis (AIH), but long-term use is associated with significant adverse effects. Although steroid-sparing agents such as azathioprine or mycophenolate mofetil are frequently added, sustained remission often necessitates prolonged steroid use. Janus kinase inhibitors, such as tofacitinib, have emerged as potential alternatives. We report our initial real-world experience with a completely steroid-free induction regimen using tofacitinib in AIH. **Methods:** We retrospectively analysed AIH patients (simplified AIH score $>=6$) who were initiated on tofacitinib. Biochemical parameters were monitored at 1, 3 and 6 months. Liver stiffness measurement (LSM) was performed at 6 months using Fibroscan 630 Expert®. Outcomes included normalisation of serum transaminases and immunoglobulin (IgG), and adverse events. **Results:** Sixteen patients (median age: 36 years (23-44); 9 (56.2%) female) received tofacitinib 10 mg/day for 6 months. Cirrhosis was present in 13 (81.3%), and 9 (56.2%) had prior decompensation. Baseline median bilirubin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), and IgG were 1.4 (0.6-2.3) mg/dL, 84 (56-115) IU/L, 56 (34-85) IU/L and 2.4 (2.1-2.7) gm/dL. Elevated AST, ALT, and IgG were noted in 14, 11 and 15 patients, respectively, at baseline. Fourteen patients completed 6 months of treatment; 2 discontinued (one patient refused and one due to malignancy: ovarian carcinoma. At 6 months, normalisation of AST/ALT (among those with elevated AST/ALT) was seen in 7/14 (50.0%), IgG (among those with elevated IgG) in 4/15 (26.7%) and complete biochemical response (CBR) achieved in 3/16 (18.8%) (Table 1). The median change in LSM at 6 months was 0.8 (-4.6 to +5.5) kPa. Among cirrhosis patients, normalisation of AST/ALT was seen in 6/11 (54.5%), IgG in 4/13 (30.8%) and CBR in 3/13 (23.1%) patients. No major adverse events were noted. **Conclusion:** Tofacitinib appears safe and potentially effective as a steroid-free induction agent in AIH, though with a lower response rate. Low response rates observed may be explained by the high proportion of patients with cirrhosis. Prospective randomised controlled trials are needed to further explore its use in AIH as a steroid-free regimen

Table1. Response assessment withing 6 months of treatment initiation

Table 1. Response assessment within 6 months of treatment initiation

	Whole cohort (n=16)	Response in patients with abnormal baseline parameters	Response in cirrhosis patients with abnormal baseline parameters
AST Normalisation within 6 months[1]	8/16 (50%)	8/14 (57.1%)	6/11 (54.5%)
ALT Normalisation within 6 months[2]	12/16 (75%)	7/11 (63.6%)	6/8 (75.0%)
AST/ALT normalisation within 6 months	7/16 (43.8%)	7/14 (50.0%)	6/11 (54.5%)
IgG normalisation within 6 months[3]	5/16 (31.3%)	4/15 (26.7%)	4/13 (30.8%)
CBR within 6 months	3/16 (18.8%)	3/16 (18.8%)	3/13 (23.1%)

[1]Elevated AST was present in 14 patients at baseline
[2]Elevated ALT was present in 11 patients at baseline
[3]Elevated IgG was present in 15 patients at baseline

◆ 4395 | LONG-TERM BONE HEALTH IN OBETICHOLIC ACID–TREATED PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A POISE POST HOC ANALYSIS

Kimberly Brown[1] Tatyana Kushner[2] Nikeshia Dunkelly-Allen[3] Jing Li[3] Radhika Nair[3] Joseph Konen[3] Marlyn Mayo[4], [1]Henry Ford Hospital Transplant Institute, Detroit, Michigan, USA, [2]Icahn School of Medicine at Mount Sinai, New York, New York, USA, [3]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA, [4]University of Texas Southwestern, Dallas, Texas, USA

Background: Patients with primary biliary cholangitis (PBC) are at increased risk for metabolic bone disease, including osteopenia and osteoporosis. Obeticholic acid (OCA) is an approved second-line therapy for PBC, but its long-term effect on bone health is unclear. In this post hoc analysis, we evaluated bone health in OCA-treated patients from the phase 3 POISE study (NCT01473524). **Methods:** Patients with PBC who had inadequate response or intolerance to ursodeoxycholic acid were randomized to receive oral placebo ($n=73$), OCA 5–10 mg ($n=70$), or OCA 10 mg ($n=73$) daily in the 12-month double-blind phase. At the end of the double-blind phase, patients on OCA continued therapy, and patients on placebo were initiated on OCA during the 5-year open-label extension (OLE). Bone mineral density (BMD; g/cm^2) and T-scores of the femoral neck and lumbar spine were assessed at baseline and each year for up to 72 months by dual X-ray absorptiometry. Baseline measures for OCA-treated patients were recorded at the start of the double-blind phase, while baseline measures for

placebo-treated patients were recorded at the start of the OLE. Bone health data were pooled starting from the time of OCA initiation, and descriptive analyses showing trends in mean BMD and T-scores were performed. Subgroup analyses were performed in women and postmenopausal women, as well as in patients on osteoporosis medications (eg, bisphosphonates, abaloparatide, denosumab, and raloxifene) and those not on osteoporosis medications. **Results:** T-scores demonstrated a modest decline from baseline during the OLE with OCA (Figure 1A/B). Femoral neck and lumbar spine BMD (g/cm^2) remained relatively stable with OCA over 72 months (change from baseline, −0.07 and −0.06, respectively). Similar results were observed in the subgroup analyses of women and postmenopausal women, with postmenopausal women exhibiting lower T-scores at baseline and throughout the 72-month study compared with the overall patient population and women overall. OCA-treated patients on osteoporosis medication had mean femoral neck and lumbar spine T-scores in the osteopenia range (T-score between −2.5 and −1.0) at baseline. BMD and T-scores in this subgroup remained relatively stable over 72 months (Figure 1C/D). **Conclusion:** While there was a slight decline in T-scores over 72 months with OCA treatment, BMD remained relatively stable, including in high-risk subgroups and patients being treated for osteoporosis.

◆ 4396 | SAFETY AND ACTIVITY OF NEBOKITUG OVER 48 WEEKS IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: OPEN-LABEL EXTENSION RESULTS: FROM THE SPRING STUDY

Christopher Bowlus[1] Stephen Barclay[2] Deepak Joshi[3] Maria Carlota Londono[4] Parvez Mantry[5] Rifaat Safadi[6] Revital Aricha[7] Chris Cirillo[7] Matthew Frankel[7] John Lawler[7] Ilan Vaknin[8] Adi Mor[8] Douglas Thorburn[9], [1]University of California, Davis, [2]Glasgow Royal Infirmary, [3]Institute of Liver Studies, King's College Hospital, NHS Foundation Trust, [4]Hospital Clinic, [5]Methodist Dallas Medical Center, [6]Hadassah Hebrew University Hospital, [7]Chemomab Therapeutics, [8]ChemomAb Ltd., [9]Royal Free Hospital & University College of London

Background: Nebokitug is an anti-CCL24 monoclonal antibody being evaluated for the treatment of primary sclerosing cholangitis (PSC). Here we describe the safety, tolerability, and activity of nebotikug in the open-label extension (OLE) of the phase 2 SPRING study. **Methods:** Patients with large duct PSC and ALP >1.5 x ULN who had completed the 15-week double blind (DB) period of the SPRING study (NCT04595825) were eligible to enroll in the OLE to receive either nebokitug 10mg/kg or 20mg/kg every 3 weeks for 11 doses (33 weeks), for a total nebokitug treatment of up to 48 weeks. Key biomarkers including enhanced liver fibrosis (ELF) score, liver stiffness measurements (LSM) by transient elastography, and liver tests were evaluated in all patients and in a prespecified subgroup with moderate/advanced disease, defined as an ELF score $\geq$ 9.8 at baseline. **Results:** 50 of 54 patients eligible to participate enrolled in OLE. 12 patients from the placebo group received either nebokitug 10mg/kg (n = 1) or 20mg/kg (n = 11) for a total of 33 weeks of nebokitug exposure. 38 patients continued to receive nebokitug 10mg/kg (n = 11) or 20mg/kg (n = 27) for a total of 48 weeks of nebokitug exposure. Nebokitug continued to be well tolerated, and no new safety signal was observed. The most common adverse events (AEs) reported were fatigue, headache, and pruritus, which were consistent with those reported in the DB period. There were 3 serious AEs with 2 reported to be possibly related by the investigators to study drug [hospitalization due to obstructive pancreatitis (n = 1) and cholangitis (n = 1)].

Patients who received placebo in the DB and rolled over to receive nebokitug in OLE had stabilization and/or improvements in ELF score, LSM, and liver tests, consistent with observations in patients treated with nebokitug during the DB period.

For patients who received nebokitug 10 mg/kg in the DB period and continued to OLE, ELF score and its fibrotic components, proc-3, LSM, and liver tests remained stable. Patients treated with nebokitug 20mg/kg in DB period and continued to OLE, showed either a stabilization or an improvement in these biomarkers over 48 weeks, especially in patients with moderate/advanced disease. **Conclusion:** Nebokitug appears safe and well tolerated for up to 48 weeks of treatment. Sustained or continual improvements in inflammatory and fibrosis makers were observed, especially in patients with moderated/advanced disease receiving nebokitug 20mg/kg. These results support the evaluation of nebokitug 20mg/kg in a phase 3 study in patients with PSC.

Figure 1. Changes in ELF score, its components, and PROC-3 up to 48 weeks of nebokitug treatment

◆ 4397 | TREATMENT WITH ELAFIBRANOR LEADS TO STABILIZATION OF PRO-C3, A MARKER OF FIBROSIS, IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Christopher Bowlus[1] Christophe Corpechot[2] Michael Heneghan[3] Cynthia Levy[4] Marlyn Mayo[5] Jörn Schattenberg[6] Mark Swain[7] John M. Vierling[8] Nuno Antunes[9] George Harb[9] Marwan Sleiman[10] Nathan Touati[10] Kris Kowdley[11], [1]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, CA, USA, [2]Saint-Antoine Hospital & Research Center, Sorbonne University, Paris, France, [3]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, UK, [4]Schiff Center for Liver Diseases, University of Miami, Miami, FL, USA, [5]University of Texas Southwestern Medical Center, Dallas, TX, USA, [6]Saarland University Medical Center, Homburg, Germany, [7]Liver Unit, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [8]Baylor College of Medicine, Houston, TX, USA, [9]Ipsen, Cambridge, MA, USA, [10]Ipsen, Paris, France, [11]Liver Institute Northwest, Seattle, WA, USA

Background: Elafibranor (ELA) led to significant biochemical improvements in patients with primary biliary cholangitis (PBC) in the phase III ELATIVE® trial (NCT04526665), but its long-term effects on liver fibrosis are still being evaluated.[1] N-terminal type III collagen propeptide (PRO-C3) is a marker of fibrogenic activity, supplementing other non-invasive tests (NITs) for fibrosis, including enhanced liver fibrosis (ELF) and liver stiffness measurement (LSM).[2] We report data exploring changes in PRO-C3 levels with elafibranor treatment in patients with PBC. **Methods:** Patients completing the ELATIVE® double-blind period (DBP) were eligible to enter the open label extension (OLE) and receive daily ELA 80 mg. Baseline (BL) values for this analysis were set as the last value before the first ELA dose, whether that was at the start of randomization or start of OLE. Changes over time in PRO-C3, ELF, and ELF components (HA, PIINP, and TIMP-1) were assessed. Correlations between the NITs (PRO-C3, ELF, and LSM), and between the NITs and alkaline phosphatase (ALP) and total bilirubin (TB) at baseline were performed. **Results:** At data cutoff (June 2024), 153 patients had received ELA; 108 started ELA in the DBP and were followed for 156 weeks (continuous ELA), and 52 patients received placebo (PBO) for 52 weeks, 45 of whom switched to ELA in the OLE for 78 weeks (crossover ELA). Mean PRO-C3 values at DBP BL for the ELA and PBO groups, and OLE BL for the crossover ELA group were 51.4 μg/L, 46.7 μg/L, and 48.5 μg/L, respectively. There was a trend for decline in PRO-C3 among patients who received ELA in the DBP, while values increased overall in those on PBO (Figure). Patients on continuous ELA had stable values, maintained or decreased to W156. In those who switched to ELA in the OLE, there was a decrease from baseline of similar magnitude to that in patients on ELA during the DBP (mean [standard error]: continuous ELA −3.9 [1.3] μg/L vs crossover ELA −5.4 [1.8] μg/L). Similar changes were observed in ELF scores.[2] In analyses of the ELF score components, no clear trends or separation from PBO were observed. There was a moderate correlation between PRO-C3 and ELF (0.69) and LSM (0.59). There were weak-to-moderate correlations between TB and ELF (0.28), PRO-C3 (0.31), and LSM (0.38), and between ALP and ELF (0.37), PRO-C3 (0.35), and LSM (0.30). **Conclusion:** Long-term PRO-C3 data from ELATIVE® support previous findings that ELA stabilizes NITs for fibrosis in patients with PBC; the relationship between NITs and clinical outcomes will be assessed with continued data from the ongoing OLE. PRO-C3 correlates well with established NITs in PBC, therefore serving as a potentially useful marker of disease progression.

◆ 4398 | VALIDATION OF PROGNOSTIC MODELS IN HISPANIC PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: RESULTS: FROM THE ELLA-PBC COHORT

Paul Yoon[1] Adriana Shen[1] Matthew Chen[1] Tara Foroohar[1] Isai Martinez Rios[1] Sade Brown[1] Kali Zhou[1] Jeffrey Kahn[1] Saro Khemichian[2] Brian Lee[3] Jennifer Dodge[1] Lily Dara[2], [1]University of Southern California Keck School of Medicine, [2]University of Southern California, [3]Hoag Hospital

Background: Ursodeoxycholic acid (UDCA) response criteria and prognostic scoring systems are widely used to predict outcomes in primary biliary cholangitis (PBC), yet their performance in Hispanic patients remains largely unknown. In prior work, we found that Hispanic patients had 80% lower complete biochemical remission rates at 1-year compared to White patients. We aimed to evaluate the predictive accuracy of UDCA response criteria and prognostic scores for liver-related events (LE) in Hispanic patients with PBC. **Methods:** The East Los Angeles Latinx PBC (ELLA-PBC) cohort includes predominantly Hispanic patients at the University of Southern California Medical Centers (2006-2022). Patients with liver decompensation or liver transplant (LT) prior to UDCA initiation were excluded. UDCA response criteria (Barcelona, Paris I/II, Rotterdam, Toronto) and prognostic scores (GLOBE, UK-PBC) were evaluated. LE included decompensation, LT, or liver-related death. Cox proportional hazards models estimated hazard ratios (HRs), and Harrell's C-statistic assessed model discrimination. Kaplan-Meier curves were generated for risk-stratified groups. **Results:** The study included 312 patients (80 with LE) with a median follow-up of 48 months (IQR 25-74). At baseline, patients with LE were more likely to have cirrhosis ($p < 0.001$), elevated ALP ($p = 0.0016$), ALT ($p = 0.026$), AST ($p < 0.001$), bilirubin ($p < 0.001$), and lower albumin and platelets (both $p < 0.001$). The GLOBE and UK-PBC scores outperformed UDCA response criteria. Each 1 standard deviation increase in GLOBE score was associated with a near 3-fold higher risk of LE (HR 2.94, 95% CI 2.10-4.13, $p < 0.001$), with strong discrimination ($C = 0.80$). UK-PBC score also predicted LE (HR 2.21, 95% CI 1.67-2.92, $p < 0.001$, $C = 0.74$). As Hispanic patients made up 64.7% of the cohort, subgroup analysis was conducted. GLOBE (HR 2.67, 95% CI 1.86-3.83, $p < 0.001$, $C = 0.79$) and UK-PBC (HR 2.09, 95% CI 1.58-2.78, $p < 0.001$, $C = 0.77$) maintained predictive accuracy in Hispanic patients. Kaplan-Meier curves showed clear survival separation across GLOBE and UK-PBC score tertiles ($p < 0.001$ and $p = 0.0016$, respectively) in Hispanic patients. **Conclusion:** This study provides important validation of the GLOBE and UK-PBC scores in predicting LE among Hispanic patients with PBC, a population underrepresented in prognostic research. While UDCA response criteria showed variable utility, prognostic scores consistently predicted outcomes, supporting the use of GLOBE and UK-PBC scores to guide risk stratification and clinical decisions in Hispanic patients. Further studies with larger, racially diverse cohorts are needed to evaluate potential differences across racial and ethnic groups.

Predictive performance of biochemical response criteria and prognostic scores

	Overall				Hispanic

Background: Primary biliary cholangitis (PBC) is a progressive autoimmune liver disease with significant unmet needs, particularly for the 40% of patients who fail first-line UDCA therapy. Current treatments targeting bile acid metabolism do not address the underlying autoimmune pathogenesis, representing an opportunity for novel immunotherapies. To this end, CNP-104 nanoparticles encapsulating PDC-E2 antigen were designed to restore PDC-E2 tolerance, offering a mechanistically distinct approach to PBC disease-modification. Here we present the effects of CNP-104 on validated prognostic tools including the UK-PBC score (liver-related outcomes), GLOBE score (transplant-free survival), and ALBI (liver function) to risk-stratify and evaluate treatment response in PBC. **Methods:** In this randomized, placebo-controlled trial, 41 PBC patients with an incomplete biochemical response (ALP $>1.5\times$ULN) received two doses of CNP-104 or placebo one week apart. Shown here are the 4 mg/kg CNP-104 (n = 11) and placebo (n = 16) groups. The study assessed safety (reported previously) and exploratory clinical endpoints including UK-PBC 5-year risk score, GLOBE score, and ALBI score ($<$ 0.065-point increase). **Results:** CNP-104 demonstrated consistent benefit across prognostic measures. Patients treated with CNP-104 showed a between-group difference in UK-PBC 5-year risk score (Δ −3.51%) compared to placebo (p = 0.010). An exploratory analysis of the less established ALBI score, where response is defined as a change $\leq$ 0.065 /6 months favored CNP-104, with 80% (8/10) of treated patients achieving response versus 26.7% (4/15) in placebo (p = 0.0154). The more established GLOBE score also showed a between-arm difference that was worse in placebo (Δ 0.227, p = 0.0125), suggesting attenuated long-term risk. **Conclusion:** CNP-104 improved UK-PBC and GLOBE scores, indicators of long-term risk reduction, in a treatment-refractory PBC population, highlighting its potential to modify disease course in those with limited therapeutic options. Notably, these benefits were observed after two loading doses, supporting further evaluation of a chronic dosing regimen in Phase 2b trials. CNP-104 represents a multidimensional therapeutic strategy for PBC patients, warranting advancement to confirmatory studies.

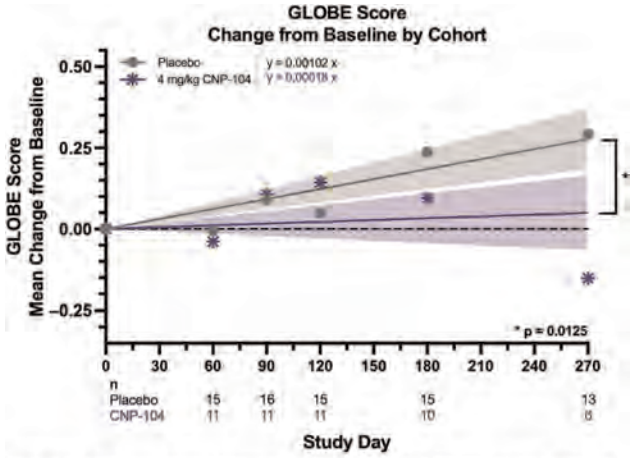

Figure 1. CNP-104 treatment suggests a separation in transplant-free survival by GLOBE Score. Plotted datapoints are representative of the mean change from baseline in GLOBE Score for each treatment group at each study timepoint. The line of best-fit displayed for each cohort is fitted by least squares regression with shading to indicate 95% confidence intervals. Statistical testing: comparison of slope via extra sum of squares F-test; * p ≤ 0.05.

◆ 4400 | NEBOKITUG TARGETS MACROPHAGE-MEDIATED MECHANISMS IN PRIMARY SCLEROSING CHOLANGITIS WITH POTENTIAL IMPACT ON DISEASE PROGRESSION

Revital Aricha[1] Tom Snir[1] John Lawler[1] Ilan Vaknin[1] Raanan Greenman[1] Adi Mor[1], [1]Chemomab Therapeutics

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive inflammatory and fibrotic injury to the biliary tree. A key element of PSC pathogenesis is sustained innate immune activation, prominently involving hepatic macrophages. Elevated levels of macrophage-associated proteins-including soluble CD14, Mannose receptor C-type 1 (MRC1), and osteopontin (SPP1) observed

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

in patients with PSC and correlate with poor clinical outcomes. Macrophage stimulating 1 (MST1), a driver of anti-inflammatory macrophage polarization, is functionally impaired by a genetic variant that is linked to PSC. Nebokitug, a monoclonal antibody against CCL24, has shown promising modulation of inflammation and fibrosis markers in the Phase 2 SPRING trial (NCT04595825) as well as modulation of macrophages activity in pre-clinical studies. Here, we evaluated its effect on macrophage-driven activity in patients with PSC by assessing changes in key macrophage related biomarkers that are known to be clinically meaningful through their association with clinical outcomes. **Methods:** SPRING study is a randomized, double-blind, placebo-controlled trial in patients with PSC receiving nebokitug 10 or 20 mg/kg IV every 3 weeks for 15 weeks or placebo. Levels of sCD14, MRC1, LBP, SPP1, and MST1 were assessed by Olink® proximity extension assay (PEA) on serum samples available from 66 patients (placebo n = 18; nebokitug 10 mg/kg n = 21 and 20 mg/kg n = 27) at baseline and week 15. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the ability of these biomarkers to predict treatment response as measured by changes in ELF score and liver stiffness measurement (LSM). **Results:** Nebokitug treatment led to dose-dependent reductions in serum macrophage-related proteins as compared to placebo treated patients, predominantly in patients with moderate/advanced disease (LSM > 8.7 Kpa at baseline), including soluble CD14 (20 mg/kg p = 0.03; 10 mg/kg p = 0.17) MRC1 (20 mg/kg p = 0.005; 10 mg/kg p = 0.2) and SPP1 (p = 0.003; 10 mg/kg p = 0.06). In addition, MST1 expression increased dose-dependently (20 mg/kg p < 0.0001; 10 mg/kg p = 0.0018). Macrophage activity is known to play a role in PSC pathophysiology and its modulation may impact disease progression. It was further shown that the changes seen in these biomarkers following treatment with nebokitug were associated with improvements seen in ELF score and LSM (AUC = 0.87). **Conclusion:** Nebokitug modulates key macrophage-related biomarkers in patients with PSC that have been shown to correlate with disease progression. These data suggest a potential role for nebokitug in modifying disease biology and support continued clinical evaluation.

◆ 4401 | TARGETING CCL24 RESTORES MST1 EXPRESSION: A MECHANISTIC INSIGHT FROM THE SPRING TRIAL

Revital Aricha[1] Tom Snir[1] John Lawler[1] Ilan Vaknin[1] Raanan Greenman[1] Adi Mor[1], [1]Chemomab Therapeutics

Background: Macrophage Stimulating 1 (MST1), acts as a negative regulator of macrophage-associated inflammation. In patients with primary sclerosing cholangitis (PSC), a disease characterized by inflammation and fibrosis of the bile ducts, MST1 function is impaired due to a disease-associated Single nucleotide polymorphism, and its expression in the liver is significantly lower in PSC compared to healthy individuals. Nebokitug, a monoclonal antibody against CCL24, has shown promising modulation of inflammation and fibrosis related markers in the Phase 2 SPRING trial (NCT04595825). Here, we evaluated the association between CCL24 blockade and MST1 as a disease relevant pharmacodynamic (PD) marker. **Methods:** SPRING phase 2 study is a randomized, double-blind, placebo-controlled study in PSC patients treated with nebokitug (10 or 20 mg/kg IV) or placebo every 3 weeks for 15 weeks. Serum MST1 levels were assessed by Olink® proteomics at baseline and week 15. Associations between MST1, CCL24 and changes in liver stiffness measurement (LSM) were evaluated. MST1 levels were also evaluated in nebokitug –treated metabolic dysfunction-associated steatohepatitis (MASH) patients (5 mg/kg SC Q2W for 16 weeks) and in two relevant preclinical models: $Mdr2^{-/-}$ and TAA-induced liver fibrosis. **Results:** Serum levels of MST1 in PSC patients were found to be reduced compared to healthy individuals. In the SPRING study, nebokitug induced a dose-dependent increase in MST1 (10 mg/kg $p = 0.0018$; 20 mg/kg $p < 0.0001$), with no change in the placebo group. A significant correlation was observed between change in MST1 and CCL24 (Pearson $R = 0.62$, $p = 3.9e{-}08$), supporting MST1 as a downstream marker of CCL24 blockade that is also relevant to liver diseases. Notably, MST1 increase was associated with a greater reduction in LSM. MASH patients treated with nebokitug showed a 1.6–1.85-fold increase in MST1 by week 16, detectable as early as week 2. In addition, in preclinical models, liver MST1 mRNA expression was increased by approximately two-fold in nebokitug treated mice compared to vehicle controls, consistent with the clinical observations. **Conclusion:** Nebokitug treatment in PSC patients leads to a significant dose-dependent increase in MST1,

correlating with CCL24 target engagement and reduction in LSM. These results from the SPRING trial suggest that MST1 may serve as a PD biomarker of nebokitug activity and further support its anti-inflammatory mechanism of action.

◆ 4402 | ESTABLISHING THE SAFETY PROFILE OF LINERIXIBAT FOR THE TREATMENT OF CHOLESTATIC PRURITUS IN PRIMARY BILIARY CHOLANGITIS: POOLED SAFETY ANALYSIS OF GLIMMER AND GLISTEN STUDIES

Gideon Hirschfield[1] Sadia Halim[2] Victoria Woodham[2] Ivana Lazic[2] Sugato Das[3] Olga Kaczmarczyk[4] Andrea Ribeiro[5] Alexander Cobitz[6] Megan McLaughlin[7] Stuart Gordon[8] Cynthia Levy[9], [1]Gastroenterology & Hepatology, University Health Network, Toronto General Hospital, Toronto, Canada, [2]GSK, London, UK, [3]GSK Hyderabad, India, [4]GSK, Warsaw, Poland, [5]GSK, Madrid, Spain, [6]GSK, Collegeville, PA, USA;, [7]GSK, Collegeville, PA, USA, [8]Henry Ford Health, Michigan State University, Detroit, MI, USA, [9]Division of Digestive Health and Liver Diseases, University of Miami, Miami, FL, USA

Background: Linerixibat is a minimally absorbed ileal bile acid transporter inhibitor in development for the treatment of cholestatic pruritus in primary biliary cholangitis (PBC). Gastrointestinal effects are anticipated adverse events (AEs) consistent with the mechanism of action of ileal bile acid transporter inhibitors. A pooled safety analysis from the Phase 2 GLIMMER study (NCT02966834) and the Phase 3 GLISTEN study (NCT04950127) was conducted to further assess the safety profile of linerixibat. **Methods:** The analysis included safety data from Part A of GLISTEN (participants received linerixibat 40 mg twice daily [BID] or matching placebo for 24 weeks) and participants concurrently randomized to the linerixibat 40 mg BID and placebo groups from the 12-week GLIMMER study. A subgroup analysis by age, race, ethnicity, sex, and cirrhosis at baseline was performed. **Results:** The analysis included 270 participants (placebo, n = 128; linerixibat, n = 142). Overall, 127 (89%) participants in the linerixibat group and 94 (73%) in the placebo group experienced ≥1 adverse event (AE) (Table); the maximum intensity experienced by most participants was mild/moderate (n = 200/221; 90%). The most common AEs in the linerixibat group were gastrointestinal (GI) events: diarrhea (n = 84; 59%) and abdominal pain (n = 24; 17%). Most participants experienced diarrhea events that were mild (n = 49/84; 58%) in intensity and occurred within 1 week of initiating treatment. Overall, 18 (13%) participants reported AEs that led to treatment discontinuation in the linerixibat group; discontinuation due to diarrhea was infrequent (n = 6; 4%). Liver-related AEs were reported more frequently in the linerixibat group (n = 22; 15%) compared with placebo (n = 10; 8%), and were mostly due to alanine aminotransferase and/or aspartate aminotransferases increases; however, these were transient and asymptomatic. There were no serious AEs (SAEs) reported in the placebo or linerixibat 40 mg BID groups in GLIMMER. In the GLISTEN study, SAEs were reported in 14 (12%) participants in the linerixibat group and 4 (3%) in the placebo group; none were fatal and were of singular frequency, with no discernible patterns. No differences were observed across all intrinsic factors in the subgroup analysis. **Conclusion:** Linerixibat was generally well-tolerated. GI events, including diarrhea and abdominal pain, were the most frequently reported AEs. There was no laboratory evidence that linerixibat causes drug-induced liver injury. These results further support the acceptable safety profile of linerixibat.

Funding: GSK (212620; 201000)

Table. Overall summary of AEs

	Pooled placebo (n=128)		Pooled linerixibat 40 mg BID (n=142)	
	n (%)	Rate/100 PY*	n (%)	Rate/100 PY*
Any AE	94 (73)	390.20	127 (89)	1049.71
AE related to study treatment	30 (23)	68.45	91 (64)	374.17
Any AEs leading to permanent discontinuation of study treatment	8 (5)	11.29	18 (13)	34.23
AEs leading to withdrawal from study	2 (2)	3.75	5 (4)	9.35

*The number of participants with occurrence of a specific event divided by the total exposure duration in years, multiplied by 100.
AE, adverse event; BID, twice daily; PY, person-years.

◆ 4403 | POSSIBLE/UNLIKELY DRUG INDUCED LIVER INJURY CASES WITH AUTOIMMUNE FEATURES ARE SIGNIFICANTLY ENRICHED WITH TRADITIONAL AIH HLA RISK ALLELES

Craig Lammert[1] Tae-Hwi Schwantes-An[1] David Kleiner[2] Yi-Ju Li[3] Huiman Barnhart[3] Elizabeth Phillips[4] Robert Fontana[5], [1]Indiana University School of Medicine, [2]National Cancer Institute, Bethesda, [3]Duke Clinical Research Institute, [4]Vanderbilt University Medical Center, [5]University of Michigan Hospitals and Health Centers

Background: Drug induced liver injury (DILI) can mimic many liver conditions and can be misdiagnosed. Discerning sporadic, autoimmune hepatitis (AIH) from idiosyncratic DILI with autoimmune features is challenging as both can have similar laboratory and histological features. Our aim was to compare clinical, histological and genetic features of suspected DILI cases enrolled into DILIN studies which were ultimately adjudicated as probable AIH to a cohort of well characterized sporadic AIH cases. **Methods:** Cohort 1: 103 patients enrolled in the Drug-Induced Liver Injury Network (DILIN) studies which were adjudicated as "possible or unlikely" by the causality committee and given an alternate diagnosis of probable AIH. Cohort 2: Sporadic AIH, 254 patients from the Genetic Repository of Autoimmune Liver Disease and Contributing Exposures (GRACE) cohort at Indiana University from 2014 to 2019. Clinical, laboratory, and histological features were compared between Cohorts 1 and 2. AIH risk alleles in both cohorts were compared to healthy controls (HC) without known liver disease from the Indiana Biobank (n = 3,016). Genetic analysis was limited to patients of European descent. **Results:** Demographic features between cohorts were similar (Table 1). Liver biochemistries were significantly higher in DILIN cases compared to sporadic AIH at diagnosis ($p = 0.001$, for all). DILIN cases were less likely than sporadic AIH cases to have positive SMA (55.7% vs 75.2%, $p = 0.004$) and increased IgG (1689 mg/dL vs 1961 mg/dL, $p = 0.007$). DILIN cases were less likely than sporadic DILIN cases to be categorized as "Definite" AIH vs DILIN cases (26.5% vs 60.8%, $p = 0.004$). Among cases with available liver biopsy (~: 85%), DILIN and sporadic AIH cases were scored relatively similarly (57.4% vs 72.3% as "likely"). Allele frequencies of *HLA-DRB1*03:01* in both DILIN cases (22.9%) and sporadic AIH (29.2%) were higher relative to HC (14.2%, $p = 2.6\times10^{-8}$ and 1.7×10^{-2}, respectively). Allele frequencies of having either *HLA DRB1*0301* or *DRB1*0401* were increased in both DILIN (34.7%) and AIH (40.6%) groups compared to HC (25%, $p = 1.6\times10^{-8}$ and 3.4×10^{-2}, respectively). **Conclusion:** AIH cases enrolled into the DILIN masquerading as suspected DILI have distinct clinical features but share HLA risk alleles. Testing for traditional AIH HLA risk alleles may facilitate the causality adjudication in selected cases of suspected DILI when it is difficult to distinguish DILI from sporadic AIH.

Table 1: Comparison of DILIN Cases ultimately adjudicated as unlikely/possible with an alternate diagnosis of probable autoimmune hepatitis and Sporadic AIH cases

	Unlikely/Possible DILIN cases (n=103)	Sporadic AIH cases from GRACE (n=254)	p-value

◆ 4404 | FACTORS ASSOCIATED WITH RECOMPENSATION AND CRITERIA FOR AETIOLOGICAL CONTROL IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Li Shen[1] Tingting Lv[1] Shuxiang Li[1] Sha Chen[1] Buer Li[1] Xin Zeng[1] Qin Xiao[1] Yuanyuan Kong[2] Yu Wang[1] Hong Ma[1] Xinyan Zhao[1] Hong You[1] Weijia Duan[1] Jidong Jia[1], [1]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, [2]Beijing Friendship Hospital, Capital Medical University, National Clinical Research Center for Diges

Background: A successful aetiological therapy may lead to hepatic recompensation in patients with decompensation cirrhosis. However, the criteria for recompensation of cirrhosis in primary biliary cholangitis (PBC) patients is not well defined. Therefore, our study aimed to explore the criteria for aetiological control and provide preliminary insights into PBC recompensation. **Methods:** In this retrospective-prospective study, we enrolled hospitalized patients with PBC from January 2014 to June 2023. Recompensation was defined according to the Baveno VII criteria. Additionally, expanded recompensation criteria were evaluated for patients on low dose diuretics and/or lactulose/rifaximin. The long-term prognosis between recompensated/expanded recompensated and compensated patients was compared. We explored whether the biochemical response to UDCA could serve as a surrogate marker for aetiological control. **Results:** A total of 305 PBC patients with follow-up data were included in the study, comprising 122 compensated cases and 183 decompensated cases. Among the 183 decompensated patients, 118 with complete data were further analyzed, with a median follow-up of 50.0 (31.0, 72.0) months. 18 (15.3%) out of 118 patients achieved hepatic recompensation. 31(26.3%) patients met the expanded recompensation criteria. The recompensated rate was highest in the variceal hemorrhage group at 52.9%, followed by the Ascites/HE group at 9.8%, and the Mixed group at 7.5%. Patients who experienced decompensation before starting UDCA therapy could achieve better biochemical response and showed a higher rate of recompensation compared with those who experienced decompensation after starting UDCA therapy for at least 12 months (23.2% *vs.* 8.1%, SHR = 2.93, $P = 0.04$). Both recompensated and expanded recompensated patients showed a similar long-term outcome with compensated patients. Achieving the response to Paris I criteria (SHR = 21.65, $P < 0.001$), Paris II criteria (SHR = 35.46, $P < 0.001$) and Momah/Lindor criteria (SHR = 33.44, $P < 0.001$) is associated with a higher incidence of recompensation. **Conclusion:** Patients with decompensated cirrhosis due to PBC may regress to recompensation stage and show a similar prognosis with compensated patients after achieving biochemical response to UDCA therapy. Paris I criteria, Paris II criteria and Momah/Lindor criteria could be used as surrogate markers for successful aetiological control of PBC.

◆ 4405 | IMMUNOMODULATION OF CYTO/CHEMOKINES AND T CELL ACTIVATION BY PPAR AGONISTS IN PBC: A COMPARATIVE ANALYSIS

Scott Roberts[1] Shi-Ying Cai[1] Ziqian Xu[1] Marina Silveira[1] Nisanne Ghonem[2] James Boyer[1] David Assis[1], [1]Yale School of Medicine, [2]University of Rhode Island

Background: Second-line treatment of PBC has been revolutionized by fibrates and more recently PPAR agonists. Their immunomodulatory effects, however, have not been characterized in PBC and it is not known if these PPAR agonists have different effects on blunting hepatocyte secretion of cyto/chemokines induced by toxic bile acids. Therefore, we studied the effect of fibrates and PPAR agonists on hepatocyte production of bile acid-induced cyto/chemokines, and on peripheral T cell activation. **Methods:** Primary human hepatocytes isolated from residual surgical specimens were plated then treated with GCDCA (100 uM) ± individual fibrates/PPAR agonists: bezafibrate, fenofibrate, seladelpar, elafibranor, or saroglitazar for 24 hrs. Hepatocytes were harvested for mRNA analysis and supernatants collected for sandwich ELISA (n = 4-6). Peripheral CD4 T cells from healthy individuals were activated with CD3/CD28 beads then treated with each of the above drugs for 48 hrs (n = 5-7) followed by flow cytometry. Peripheral CD4 T cells from PBC patients with an incomplete response to UDCA, or responding to UDCA + fenofibrate, were isolated, activated, and analyzed *ex vivo* (n = 4-5). **Results:** Stimulation with GCDCA significantly increased hepatocyte expression and secretion of inflammatory cyto/chemokines, whereas co-treatment with GCDCA and each fibrate/PPAR agonist significantly reduced gene expression of cytokines *CCL2* and *CCL15*. Secretion of CCL20 and IL-8, however, were significantly reduced only by seladelpar (mean 835 ± 404 vs. 144 ± 44 pg/mL, p = 0.02; 299 ± 135 vs. 76 ± 35 pg/mL, p = 0.07, respectively). Interestingly, treatment of activated healthy control peripheral CD4 T cells showed that seladelpar, elafibranor, and bezafibrate significantly reduced T cell activation marker CD69, while other drugs had no effect. Finally, *ex vivo* activated CD4 T cells from PBC patients, responding to UDCA + fenofibrate, expressed lower intracellular IL-17 vs. T cells from patients with incomplete response to UDCA (1.2 ± 0.5 vs. 3.7 ± 0.8%, p = 0.001). **Conclusion:** Our findings reveal heterogeneity among PPAR agonists' ability to modulate bile acid-induced cyto/chemokine secretion by hepatocytes, and to reduce peripheral T cell activation. Among the PPAR agonists tested, seladelpar was the most effective *in vitro,* while fenofibrate reduced reactivity of T cells from PBC patients *ex vivo*. Further studies comparing immunomodulatory properties of PPAR agonists in PBC patients receiving treatment are warranted.

[20]Children's Hospital of Philadelphia, Philadelphia, PA, 19104, USA, [21]University Medical Centre Groningen, University of Groningen, the Netherlands

Background: Robust long-term data demonstrate improvements in pruritus, reductions in serum bile acids (sBA), and manageable safety with odevixibat (ODX) in patients with Alagille syndrome (ALGS) across the phase III ASSERT and ASSERT-EXT studies with up to 96 weeks of treatment (NCT04674761 and NCT05035030). Here we characterize the impact of ODX on liver parameters and clinical outcomes according to sBA level at 24 weeks. **Methods:** Outcomes for patients with ALGS treated with ODX (120 μg/kg/day) in ASSERT and ASSERT-EXT were stratified by Week 24 sBA levels $\leq$102 μmol/L (versus $>$102 μmol/L); this threshold was associated with better clinical outcomes in patients with cholestatic ALGS in the GALA study (Murillo Perez, EASL 2023). Patients with sBA levels $\leq$102 μmol/L at baseline (BL) were excluded. Endpoints included: clinically meaningful pruritus response (defined as $\geq$1 point reduction in observer-reported scratching score [0−4 scale]), liver parameters, and clinical outcomes. **Results:** 52 patients with ALGS received ODX during ASSERT and ASSERT-EXT. Of these, 7 patients with BL sBA $\leq$102 μmol/L were excluded; 40 patients with available 24-week data were included in this *post-hoc* analysis. 40% (16/40) of patients achieved sBA $\leq$102 μmol/L with ODX at Week 24. Patients who achieved this threshold had lower bilirubin levels (Table) and lower mean (SD) sBA levels at BL (226.2 [91.64] vs 290.2 [125.54] μmoL/L) than patients who did not achieve sBA $>$102 μmol/L at Week 24. Pruritus responses were achieved at Weeks 21−24 in 81.3% (13/16) of patients with sBA $\leq$102 μmol/L and 69.6% (16/23) with sBA $>$102 μmol/L. At Weeks 69−72, pruritus responses were achieved in 93.3% (14/15) and 85% (17/20) patients with sBA $\leq/>$102 μmol/L, respectively. Liver parameters and platelet counts $\leq$150 x 10^9/L are reported by sBA $\leq$102/$>$102 μmol/L groups (Table). Data assessing outcomes by sBA percentage change will be presented. **Conclusion:** Patients with ALGS treated with ODX achieved clinically meaningful improvements in pruritus by Week 24 that were sustained long-term, independent of sBA level at Week 24. Higher bilirubin and sBA levels at BL, indicating more advanced disease, were seen in patients who did not achieve sBA $\leq$102 μmol/L after 24 weeks of treatment with ODX. Further study is warranted to explore sBA thresholds predictive of clinical outcomes in patients with ALGS receiving ODX.

◆ 4407 | HIGH RATE OF EARLY ALP NORMALIZATION WITH UDCA–BEZAFIBRATE COMBINATION THERAPY IN TREATMENT-NA&IUML; VE PRIMARY BILIARY CHOLANGITIS: PRELIMINARY RESULT

Juan Sorda[1] Fernando Barreyro[2] Guillermo Fernandez[3] Matias Bori[1] Esteban Gonzalez Ballerga[1], [1]Hospital de Clinicas, Universidad de Buenos Aires, [2]National University of Misiones, [3]Hospital Teodoro J. Schestakow

Background: Ursodeoxycholic acid (UDCA) is the standard first-line therapy for primary biliary cholangitis (PBC). Normalization of alkaline phosphatase (ALP) after one year of therapy is associated with improved transplant-free survival, and the one-year response can be predicted by the ALP level at six months. Bezafibrate (BZF) improves liver biochemistry in incomplete UDCA responders, but early ALP normalization with up-front UDCA + BZF has not been evaluated. We therefore assessed ALP normalization at six months with UDCA alone versus UDCA + BZF at two different doses. **Methods:** In this open-label, prospective study, anti-mitochondrial-antibody–positive, non-cirrhotic PBC patients (enrolled from January 2022) were randomized 2:2:1 to receive UDCA (13–15 mg/kg/day) alone, UDCA + BZF 400 mg, or UDCA + BZF 800 mg daily. Liver function tests, blood urea nitrogen, serum creatinine, and creatine kinase were measured monthly for six months. The primary end point was ALP $\leq 1 \times$ upper limit of normal (ULN) at month 6; secondary end points were changes in other liver enzymes, pruritus, and safety parameters. Data were analyzed with χ^2 tests, ANOVA, linear mixed-effects models, and Dunnett- or Tukey-adjusted post-hoc tests (two-sided $\alpha = 0.05$). **Results:** This interim analysis includes 52 patients who completed six months of therapy. Baseline histological stages 1/2/3 were present in 23/16/13 patients; mean age was 57 $\pm$ 11 years; 94 % were female; 38 % were symptomatic (pruritus); BMI was 25 $\pm$ 6 kg/m². Twenty-one patients received UDCA, 23 received UDCA + BZF 400 mg, and eight received UDCA + BZF 800 mg; baseline characteristics were comparable. At six months, ALP normalized in 100 % of UDCA + BZF 800 mg, 78 % of UDCA + BZF 400 mg, and 36 % of UDCA patients (χ^2 $p < 0.01$). Mean ALP ($\times$ ULN) at six months was 1.5 $\pm$ 0.7 (UDCA), 0.98 $\pm$ 0.2 (UDCA + BZF 400 mg), and 0.8 $\pm$ 0.2 (UDCA + BZF 800 mg) (ANOVA $p < 0.001$; post-hoc vs UDCA $p = 0.001$). Linear mixed-effects analysis showed significant time-dependent ALP declines in all groups; BZF intensified these monthly slopes ($\beta = -0.34$ for 400 mg and -0.44 for 800 mg vs UDCA, both Tukey-adjusted $p < 0.01$). Pruritus at six months occurred in 14 % of UDCA patients but in none of the BZF groups. Blood urea nitrogen and serum creatinine did not differ between groups at any time point. **Conclusion:** Up-front combination therapy with UDCA + BZF yields significantly higher six-month ALP normalization rates than UDCA alone and accelerates biochemical improvement in a dose-responsive manner. Notably, the 800-mg BZF combination achieved a 100 % response at six months. The clinical impact of early ALP normalization should be investigated in future studies. These preliminary results support initiating combination therapy, particularly in symptomatic patients.

4408 | THERAPEUTIC EFFECT OF PPAR AGONISTS ON PRURITUS AND QUALITY OF LIFE IN PBC: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PLACEBO-CONTROLLED TRIALS

ADRIELLY MARTINS[1] Nidah Khakoo[2] Christophe Corpechot[3] John Reynolds[4] Alexandra Rousseau[5] M Hassan Murad[6] Shahnaz Sultan[7] Andreas Kremer[8] Cynthia Levy[9], [1]Schiff Center for Liver Diseases - University of Miami, [2]Emory University, [3]Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, ERN Rare-Liver, [4]Louis Calder Memorial Library, University of Miami Miller School of Medicine, Miami, FL, USA, [5]Clinical Research Platform of East of Paris, Saint-Antoine Hospital, APHP, [6]Mayo Clinic, Rochester, [7]University of Minnesota and and Minneapolis Veterans Affairs Medical Center, [8]University of Zürich, [9]University of Miami

Background: Pruritus is a frequent and debilitating symptom in primary biliary cholangitis (PBC), with substantial impact on health-related quality of life. Peroxisome proliferator-activated receptor (PPAR) agonists have emerged as promising second-line therapies for patients inadequately controlled with ursodeoxycholic acid (UDCA). We conducted a systematic review and meta-analysis to assess the comparative effectiveness of PPAR agonists on pruritus and quality of life in PBC. **Methods:** We systematically searched for randomized controlled trials (RCTs) of PPAR agonists in PBC through April 2024. Eligible studies included patients with moderate-to-severe pruritus, defined as a

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

worst-itch numerical rating scale (WI-NRS) score ≥4 at baseline, and reported outcomes related to itch severity and quality of life, including WI-NRS, PBC-40 total score, PBC-40 itch domain, and 5-D itch score. The co-primary outcomes were mean change in WI-NRS and PBC-40 total score. Secondary outcomes included changes in the PBC-40 itch domain and 5-D itch score. Data were pooled using a random-effects model and expressed as mean differences (MD) with 95% confidence intervals (CI). **Results:** Five RCTs (n = 274 experimental, n = 162 control) met the inclusion criteria. WI-NRS improvements with PPAR agonists were observed at all assessed timepoints, including 3 months (MD −1.01; 95% CI −2.73 to 0.70), 6 months (MD −1.13; 95% CI −2.01 to −0.24), and 12 months (MD −1.73; 95% CI −2.97 to −0.48), demonstrating sustained pruritus reduction over time (Figure). PBC-40 total score and all secondary outcomes were assessed at 12 months. At that timepoint, PPAR agonists significantly improved PBC-40 total scores (MD −1.97; 95% CI −3.18 to −0.75). Significant improvements were also observed in the PBC-40 itch domain (MD −2.68; 95% CI −4.15 to −1.21) and 5-D itch score (MD −3.27; 95% CI −5.23 to −1.31). **Conclusion:** Treatment with PPAR agonists is associated with a sustained reduction in pruritus severity and improvement in health-related quality of life in patients with PBC and moderate-to-severe pruritus. These findings support their role as an effective therapeutic option in this patient population.

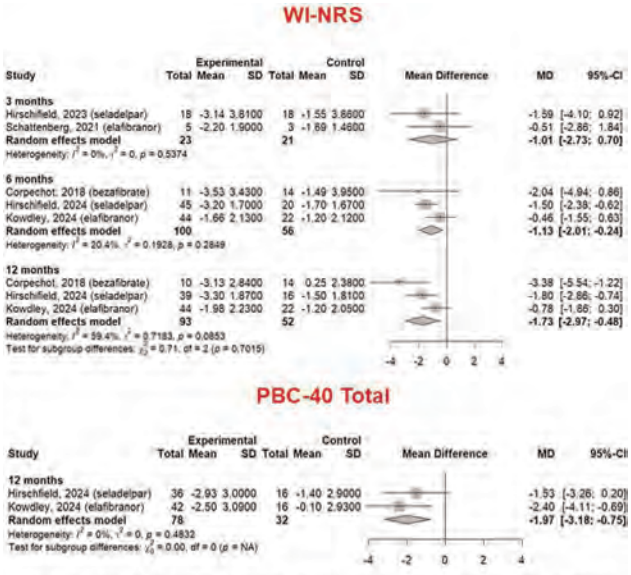

Figure. Effect of PPAR agonists on pruritus severity and quality of life in patients with PBC

[2]AIG Hospitals, [3]Apollo Hospitals, Kolkata, [4]Mahtma Gandhi Hospital, Jaipur, [5]Postgraduate Institute of Medical Education & Research, [6]University of Pennsylvania

Background: Autoimmune hepatitis (AIH) is an uncommon cause of liver disease and can have varied presentations. The rate of recompensation in those with decompensation in AIH, and survival, is not well known, and thus we aimed to address this. **Methods:** A multicenter retrospective study included patients with AIH with varying presentations between 2018 and 2025. Demographics, clinical features at presentation and during follow-up, and survival data were collected. Recompensation (defined as Baveno VII) and complete biochemical response (CBR) rates, survival, and proportion of patients achieving MELD <10 were evaluated. **Results:** 255 patients (age-46 $\pm$ 13.8 years; women-73.3%; MELD-15.7; median bilirubin 3.1 mg/dl) with AIH with a median simplified score of 6 (6-8) and a median follow-up of 18.5 (0.2-94) months were included. Twenty per cent (52/255) had concurrent PBC, and 4% (10/255) had PSC. 84.3% received corticosteroids, 69% azathioprine as an additional first-line agent and 7% received mycophenolate mofetil and 2% received tacrolimus as second-line agents. Four patients underwent living donor liver transplantation. TFS was 87.5% (223/255; 95% CI, 82.7-91.2). Of the 223 alive patients, 60% (134/223) had achieved MELD scores less than 10 by the end of follow up. Of the 255 patients, 66% (168/255) achieved CBR. Of these 168, 25.6% experienced flares after drug discontinuation/non-compliance. On Kaplan Meier analysis, TFS among those who achieved CBR was 98.8% (166/168) compared to 65.5% (57/87) among those who did not achieve CBR ($P<0.001$). The incidence of hepatocellular carcinoma was 1.5% (4/255).

Of the 149 patients with cirrhosis at diagnosis, 75.8% (113/149) had evidence of decompensations (ascites, hepatic encephalopathy, variceal bleed) at diagnosis, with 15.4% (23/149), 48.3% (72/149), and 36.2% (54/149) patients in CTP A, B and C, respectively. Among the decompensated patients, 38.1% (43/113; 95%CI, 29.1-47.7) had recompensated by 8 (0.2-58) months. The TFS rate among recompensated patients was 95.3% (41/43) compared to 60% (42/70) among those who did not ($P<0.001$). Of the 119 cirrhosis patients who were alive at the end of follow-up, 57.1% (68/119) were in CTPA, 33.6% (40/119) in CTP B and the rest in CTP C (9.2%;11/119). On multivariable stepwise cox regression analysis use of beta blocker (HR, 0.5 [95% CI, 0.3-0.8];$P=0.01$), use of azathioprine (HR, 0.37 [95%CI, 0.22-0.61];$P<0.001$) and MELD score (HR, 1.04 [95%CI, 1.007-1.07];$P=0.01$) predicted lack of recompensation. **Conclusion:** Recompensation occurs in nearly 40% of patients and more than 60% achieve CBR. Recompensation and CBR were associated with improved survival.

4410 | BRUTON'S TYROSINE KINASE REGULATES INFLAMMATION AND FIBROSIS IN PRIMARY BILIARY CHOLANGITIS

Prashanth Thevkar Nagesh[1] Marti Ortega Ribera[2] Yuan Zhuang[3] Arman Patel[2] Viliam Brezani[2] Aditi Ashish Datta[2] Scott Minchenberg[3] Bruna Santos[2] Veronika Brezani[2] Gyongyi Szabo[3], [1]Beth Israel Medical Center, [2]BIDMC - Harvard Medical School, [3]Beth Israel Deaconess Medical Center

Background: Liver fibrosis is a progressive scarring process due to chronic liver injury and remains without FDA-approved therapies. While causes like alcohol use, high-fat diet, and viral infection contribute to fibrosis, the pathogenesis of primary biliary cholangitis (PBC), an autoimmune liver disease involving inflammation and fibrosis of bile ducts, remains poorly understood. PBC progression is driven by dysregulated inflammation, hepatocyte injury, and cholangitis, which appear as promising therapeutic targets. Recently, we showed that Bruton's tyrosine kinase (BTK) is a key regulator of innate immune responses in neutrophil-driven liver injury in alcohol-associated hepatitis. BTK inhibitors are in clinical trials for autoimmune diseases, but their role in liver fibrosis, especially in PBC, is unknown. **Methods:** BTK activation (phospho-BTK Y223) was measured by ELISA in liver tissues from PBC patients and healthy controls. In mice, liver fibrosis was induced by (1) carbon tetrachloride (CCl_4; 0.6 µL/g in corn oil) injected weekly for 6 weeks or (2) bile duct ligation (BDL) in wild-type (WT) and BTK knockout ($BTK^{-/-}$) mice. Mice were euthanized 72 hours post-final CCl_4 injection or 14 days post-BDL. Liver fibrosis

was assessed via Sirius Red staining and Western blot for α-SMA and gene expression of vimentin, Timp1 and Col1a2. Serum ALT and pro-inflammatory cytokines (TNFα, IL1β, MCP1) were quantified by ELISA. Flow cytometry was used to analyze liver non-parenchymal cells. Human primary hepatocytes, stellate cells, monocytes, and neutrophils were treated with LPS, TGFβ with or without BTK inhibitor evobrutinib, and inflammatory gene expression assessed by qPCR. **Results:** Our data reveal elevated BTK expression and activation (p-Y223) in livers from human PBC patients and in mouse models of cholangitis and CCL_4-induced fibrosis. In both models, $BTK^{-/-}$ mice showed attenuated fibrosis and serum cytokines (TNFα, IL1β, MCP1) compared to WT. Further, in $BTK^{-/-}$ mice with cholangitis, liver injury markers were reduced (ALT, bilirubin) compared to WT mice. In BDL model, WT mice showed increase in $EpCam^+$ cells (Cholangiocyte proliferation), and pBTK levels in $EpCam^+$ cells which was attenuated in the $BTK^{-/-}$ mice. Notably, myeloid-specific $BTK^{-/-}$ mice also showed reduced fibrosis (α-SMA and mRNA markers). Mechanistically, LPS induced BTK phosphorylation and inflammation (TNFα, IL1β, MCP1) in hepatocytes, macrophages, neutrophils, and activated stellate cells (α-SMA), which was attenuated by BTK inhibition (evobrutinib). **Conclusion:** These findings uncover a novel role for BTK in liver fibrosis and support its potential as a therapeutic target in PBC and chronic liver diseases.

4411 | MARALIXIBAT, AN ILEAL BILE ACID TRANSPORTER INHIBITOR, REDUCES CHOLESTATIC PRURITUS IN PSC: REAL-WORLD EXPERIENCE

Jessica Hochberg[1] Robert Brown[2] David Goldberg[3] Joseph Cioffi[4] Adrielly Martins[5] Aparna Goel[6] Mercedes Martinez[7] Maria Carlota Londono[8] Taisa Kohut[9] Karan Emerick[10] Samantha Lee[11] Gloria Rothenberg[2] Cynthia Levy[3], [1]Jackson Memorial Hospital, [2]Weill Cornell Medicine, [3]University of Miami, [4]University of Miami School of Medicine, Miami, Florida, [5]Schiff Center for Liver Diseases, University of Miami Miller School of Medicine, Miami, Florida, [6]Stanford University Medical Center, [7]NewYork-Presbyterian, [8]Hospital Clinic, [9]Miller School of Medicine, University of Miami and Holtz Children's Hospital, Miami, Florida, [10]Connecticut Children's Medical Center, Hartford, Connecticut, [11]Connecticut Children's Medical Center, Hartford Connecticut

Background: Primary sclerosing cholangitis (PSC) is a progressive, autoimmune, cholestatic liver disease that may be associated with profound and debilitating pruritus. Maralixibat (MRX) is a minimally absorbed ileal bile acid transporter (IBAT) inhibitor that prevents enterohepatic bile acid recirculation. The drug is approved for the treatment of cholestatic pruritus in patients with Alagille syndrome and progressive familial intrahepatic cholestasis and led to reductions in pruritus and serum bile acids (sBA). This case series aimed to evaluate the efficacy, safety and tolerability of MRX in individuals with PSC treated through compassionate

use (CU). **Methods:** The medical records of patients with PSC and treated with MRX through a CU program were retrospectively reviewed at 7 North American tertiary referral hospitals. Pruritus was assessed with the Clinician Scratch Scale (CSS), a 0-4 scale where $\geq$1-point reduction is considered clinically meaningful. **Results:** Eight patients (50% females) were included with the median (range) age of MRX initiation being 35.5 (7.0, 44.0) years, and the initial dose ranged from 190 to 380 μg/kg QD or BID. The median duration of treatment was 7.5 (4.0, 11.0) months. All patients had large-duct PSC. At baseline (BL), CSS was 4 in three patients, 3 in two patients and 2 in three patients. Following MRX, 7/8 patients had a $>$2-point improvement, with 4 having complete resolution (CSS = 0) and 3 having minimal itch (CSS = 1). 6/7 showed reduction of median sBA from 142 (62-506) to 37 (14-106) μmol/L, while 1 patient, known to have history of chronically elevated transaminases with significant fluctuations, had an increase in sBA from 317 to 433 μmol/L; sBA levels at BL and final follow-up (FF) were missing for 1 patient. Moderate fluctuations of ALT were noted, with reductions in median BL total bilirubin (TB) levels in 5 patients and mild increases in 2 (TB at FF was missing for 1 patient). GGT levels were reduced from BL to FF (CFB: -89 U/L [-281, -56]) in the 4 patients with complete measurements. Diarrhea was reported in 2 patients, with moderate-severe diarrhea over BL levels, with dose adjustment and interruptions required in 1 patient, while the diarrhea was mild and transient in the other patient. **Conclusion:** A clinically meaningful reduction in pruritus was observed in all MRX-treated patients with PSC, and a substantial reduction in sBA levels was observed in the majority. These findings indicate a potential role for IBAT inhibitors in treating pruritus in PSC.

Table. Clinical laboratory data at baseline and last clinical follow-up, following treatment with MRX in individuals with Primary sclerosing cholangitis (PSC)

Subjects	CSS Score		sBA, μmol/L		TB, mg/dL		ALP, U/L		GGT, U/L	
	BL	FF	BL	FF	BL	FF	BL	FF	BL	FF

4412 | CLINICAL UTILITY OF COMPREHENSIVE GENETIC TESTING IN ADULT CHOLESTASIS: INSIGHTS FROM 856 PANEL TESTS

Brett Hoskins[1] Tiziano Pramparo[2] Ethan Gough[3] Amy Ponte[4] Rana Dutta[2] Jolan Terner-Rosenthal[2] Wikrom Karnsakul[5], [1]Riley Hospital for Children, Indiana University School of Medicine, Indianapolis, Indiana, [2]Mirum Pharmaceuticals, Inc., Foster City, California, [3]The Johns Hopkins University School of Medicine, Baltimore, Maryland, [4]Sanofi, Bridgewater, New Jersey, [5]Johns Hopkins University

Background: Cholestasis encompasses a broad spectrum of underlying causes, with genetic disorders being an underrepresented subset. Diagnostic evaluation is often complicated by variable clinical presentations and phenotypic overlap. The use of next-generation sequencing (NGS) panels enables more timely and comprehensive identification of genetic etiologies. This

abstract presents data from over 800 panel tests in adult patients with cholestasis, offering key insights into diagnostic yield and the utility of genetic testing in clinical practice. **Methods:** Data from a 77-gene cholestasis panel were reviewed for patients who underwent genetic testing between March 2016 and January 2022 due to a current or prior history of cholestasis without an identifiable cause or unexplained chronic liver disease. DNA sequencing was performed using custom-designed and optimized capture libraries [SureSelect by Eurofins/Emory Genetics Laboratory (2016–2021) and PGxome® by PreventionGenetics (2021–2022)]. Variants were classified according to diagnostic laboratory protocols and ACMG criteria as benign, likely benign, variant of unknown significance (VUS), likely pathogenic (LP), or pathogenic (P). A definitive diagnosis was defined as either two P or LP variants in the same gene (homozygous or compound heterozygous), or a single P or LP variant in *JAG1* or *NOTCH2*. A potential diagnosis included one P or LP variant plus one VUS in the same gene for autosomal recessive conditions. **Results:** A total of 856 samples were analyzed between March 2016 and January 2022. Ages ranged from 18 to 88 years. Among the tests, there were 261 P, 40 LP, and 1,255 VUS identified. The overall diagnostic yield was 4% and 3.5% among subjects with a definitive diagnosis (34/856) and a potential diagnosis (30/856), respectively. Definitive diagnoses were most common in genes *ABCC2* (n = 7), *ABCB11* (n = 4), *CFTR* (n = 4), *POLG* (n = 4), and *SERPINA* (n = 4). Genes with the most potential diagnoses included *ABCB4* (n = 14), *CFTR* (n = 5), and *ABCB11* (n = 4), *ABCC2* (n = 2), and *PKHD1* (n = 2). Monoallelic variants occurred most often in genes *SERPINA1* (n = 34), *CFTR* (n = 32), *ABCB4* (n = 31), *ABCB11* (n = 10), *PKHD1* (n = 8). **Conclusion:** Genetic testing using a comprehensive cholestasis panel identified a definitive or potential diagnosis in 7.5% of cases, supporting its role in the evaluation of unexplained cholestasis and chronic liver disease in adults. Definitive diagnoses were most commonly associated with *ABCC2* (Dubin-Johnson syndrome), *ABCB11* (progressive familial intrahepatic cholestasis type 2), *CFTR* (cystic fibrosis), *POLG* (mitochondrial disorders), and *SERPINA1* (alpha-1-antitrypsin deficiency). These results demonstrate the clinical utility of panel-based sequencing while also emphasizing the challenges of interpreting uncertain variants in a genetically heterogeneous population.

4413 | ASSOCIATION BETWEEN PRETREATMENT GLOBE SCORE AND HISTOLOGICAL CIRRHOSIS IN PRIMARY BILIARY CHOLANGITIS

Manabu Hayashi[1] Naoto Abe[1] Tatsuro Sugaya[1] Yosuke Takahata[1] Masashi Fujita[1] Kazumichi Abe[1] Hiromasa Ohira[1], [1]Fukushima Medical University

Background: Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease that can progress to cirrhosis and liver failure. Although liver cirrhosis diagnosed by biopsy is a robust predictor of poor prognosis, biopsy carries a risk of hemorrhage. A noninvasive test to predict liver cirrhosis and prognosis may be useful for patients with PBC. In this study, we analyzed the association between the pretreatment GLOBE score and histological cirrhosis in patients with PBC. **Methods:** In this retrospective study, we included PBC patients who underwent liver biopsy. The pretreatment GLOBE score was calculated using baseline values of age, bilirubin, alkaline phosphatase (ALP), albumin, and platelet count. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curve analysis. We also assessed the association between the pretreatment GLOBE score and transplant-free survival. **Results:** A total of 183 PBC patients were analyzed. The median age was 58 years, and 19% were male. The numbers of patients with Scheuer stage 1, 2, 3, and 4 were 76, 47, 21, and 39, respectively. The median pretreatment GLOBE score was 0.61. The pretreatment GLOBE score significantly increased with histological stage: stage 1, 0.25; stage 2, 0.53; stage 3, 0.68; and stage 4, 2.11 ($P < 0.001$). The pretreatment GLOBE score showed a higher area under the ROC curve (AUROC) compared with other noninvasive tests, including the ALBI score, FIB-4 index, FIB-3 index, AST to platelet ratio index, and the AST/ALT ratio. The optimal cutoff value of the pretreatment GLOBE score for predicting histological cirrhosis was 1.27 (AUROC: 0.868; sensitivity: 0.84; specificity: 0.84). Patients with a pretreatment GLOBE score < 1.27 had significantly longer transplant-free survival than those with a score ≥ 1.27 ($P < 0.001$). The 10-year cumulative transplant-free survival was 94.6% (95% CI: 85.1–98.1) in patients with a pretreatment GLOBE score < 1.27, compared to 45.6% (95% CI: 27.1–62.3) in untreated patients with a score ≥ 1.27. **Conclusion:** The pretreatment GLOBE score was significantly associated with baseline histological cirrhosis, and the identified cutoff value was predictive of prognosis in PBC patients. These findings suggest that the pretreatment GLOBE score may serve as a useful noninvasive test for assessing liver cirrhosis and prognosis in patients with PBC.

4414 | CORRELATION BETWEEN OPIOID LIGANDS AND RESPONSE TO OPIOID ANTAGONIST IN CHOLESTATIC PATIENTS WITH PRURITUS

Nir Barak[1] Sireesh Appajosyula[2] Randy Milby[1], [1]Tharimmune Inc, [2]Tharimmune

Background: Endogenous opioid ligands are thought to contribute to the development of pruritus in cholestatic liver disease, based on the observation that opioid antagonists can alleviate itching. However, studies have not found a consistent correlation between endogenous opioid levels and itch severity in these patients. In our recent work, we showed that nalmefene —a Mu and delta opioid receptor antagonist and kappa receptor agonist—reduced pruritus intensity in individuals with cholestatic liver disease. We have now expanded our analysis to investigate whether levels of endogenous opioids are associated with the extent of itch relief. **Methods:** This study was approved by the local IRB and competent authorities. In this study, we used TH104, a proprietary formulation of Nalmefene, 2 mg in strength formulated to a buccal film. Patients with cholestatic liver disease and a known history of persistent generalized pruritus for at least 4 weeks prior to screening were included. After an overnight fasting, subjects received one dose of 2 mg of TH104. Patients were monitored for itch severity using an 11-point NRS scale (0 – no itch, 10 – worst itch). ELISA kits (Qayeebio, China) were used to test the following ligands: Dynorphin (Kappa agonist), Beta-Endorphin (Mu agonist), Met-Enkephalin and Leu-Enkephalin (Mu and Kappa agonists). ANCOVA (D'Agostino-Pearson) test was used to assess correlation. **Results:** Nineteen patients were screened, and twelve patients were enrolled in this study. Ten subjects were male, and two were female; six were Child-Pugh class A, and six were Child-Pugh class B. A total of 2 AEs (headache) were reported in 2 subjects over the course of the study. These AEs were mild and possibly related to study drug. Mean decline in itch scores at 24-hours was 33.3% and was correlated with the pharmacokinetics of Nalmefene (Barak N et al, 2024).

Levels of all ligands were correlated with disease severity. There was no correlation between opioid ligand levels and baseline pruritus intensity, but the levels of Leu-Enkephalin correlated ($p = 0.043$) with the reduction in pruritus severity (See attached figure). **Conclusion:** Leu-Enkephalin is an endogenous opioid peptide that primarily acts on delta-opioid receptors but also interacts with mu-opioid receptors. Previous studies, such as Dull (2021), found no correlation between endogenous opioid ligand levels and pruritus severity in cholestatic liver disease. Our findings represent the first reported association between Leu-enkephalin levels and itch reduction following treatment with an opioid antagonist, and suggest a potential role for delta opioid receptors in cholestatic pruritus (Smith KM, 2023).

Background: Pruritus can be a debilitating symptom in patients with primary biliary cholangitis (PBC). While the etiology of pruritus in PBC is unknown, past research has shown an association between elevated serum bile acid (sBA), IL-31 levels, and pruritus. Volixibat (VLX) is a minimally absorbed ileal bile acid transporter inhibitor which blocks the enterohepatic recirculation of bile acids. Here, we explore the relationship between the antipruritic effect of VLX and serum levels of IL-31 and sBA in patients with PBC from the completed Part 1 (dose selection) period of the VANTAGE trial. **Methods:** VANTAGE is a 28-week randomized, multicenter, double-blind, placebo (PBO)-controlled Phase 2b study in adults with PBC and cholestatic pruritus. The study has an adaptive design: a completed Part 1 period (1:1:1 randomization, VLX 20mg, 80mg or PBO BID) and an ongoing Part 2 confirmatory period (1:1 randomization, VLX 20mg BID or PBO BID). The primary efficacy endpoint of change in pruritus (Adult ItchRO) score from Baseline (BL) to Week 28 has been previously reported. Here we report data on IL-31 and sBA levels from Part 1 to Weeks 16 (interim analysis) and 28 (final analysis). VLX 20mg and 80mg arms (VLX) were pooled for this analysis. Correlation coefficients and descriptive statistics were calculated. **Results:** Thirty-one participants with moderate-to-severe pruritus were randomized (VLX = 20; PBO = 11). At BL, sBA levels were elevated across groups, while IL-31 levels were elevated in the VLX group, but minimally in the PBO group. At BL, there was a positive correlation between IL-31 and sBA ($R = 0.63$; $p < 0.0001$). Both sBA and IL-31 levels were reduced from BL to Week 28 after VLX treatment (sBA [LS mean [SE]]: -14.2 [6.6]; IL-31: -8.2 [1.0]), whereas the PBO group observed smaller changes. There were positive correlations following VLX treatment at Week 16 between reductions from BL in both sBA and pruritus ($R = 0.27$; $p = 0.12$), as well as in IL-31 and pruritus ($R = 0.49$; $p = 0.0047$). Similar correlations between sBA and IL-31 were observed ($R = 0.65$; $p < 0.0001$). At Week 28, results were maintained albeit less pronounced, potentially reflecting increasing variability due to the small sample size. **Conclusion:** Reductions in pruritus after VLX treatment were associated with decreases in both IL-31 and sBA. These findings support the connection between sBA and IL-31 as potential mediators of pruritus in PBC.

4416 | NON-INVASIVE ASSESSMENT OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION RISK IN PATIENTS WITH COMPENSATED ADVANCED PRIMARY BILIARY CHOLANGITIS

Giulia Francesca Manfredi[1] Ilkay Ergenç[2] Maria Cristina Neglia[3] Christian Sebesta[4] Elisabetta Degasperi[5] Georg Semmler[4] Thomas Reiberger[4] Benedikt Hofer[4] Carla De Benedittis[1] Mario Pirisi[1] Vincenza Calvaruso[3] Pietro Lampertico[5] Yusuf Yilmaz[6] Michael Trauner[4] CRISTINA RIGAMONTI[1], [1]Università del Piemonte Orientale, Novara, Italy, [2]Marmara University, Istanbul, Turkey. King's College Hospital, London, UK, [3]University of Palermo, Palermo, Italy, [4]Medical University of Vienna, Vienna, Austria, [5]University of Milan, Milan, Italy, [6]Recep Tayyip Erdoğan University

Background: Primary biliary cholangitis (PBC) is a progressive cholestatic disease that may lead to clinically significant portal hypertension (CSPH). PBC patients with compensated advanced chronic liver disease (cACLD), defined according to the Baveno VI criteria based on a liver stiffness measurement (LSM) $\geq$ 10 kPa, are at risk of developing CSPH and liver decompensation (LD). Spleen stiffness measurement (SSM) is a novel tool to assist in the non-invasive estimation of CSPH, but data in PBC-related cACLD are scarce and further links with hepatic decompensation needed. **Methods:** Multicentric study including 100 cACLD patients with PBC from 5 hepatology tertiary centres (Novara, Milan, Palermo, Istanbul, Vienna) who underwent vibration-controlled transient elastography (VCTE)-based LSM and SSM. The Baveno VII-SSM single SSM cut-off ($\leq$40 kPa vs. $>$40 kPa) criterion for ruling out or ruling in CSPH was applied. Moreover, the newly proposed Non-Invasive CSPH Estimated Risk (NICER) model was applied to calculate CSPH probability. **Results:** Among the 100 PBC cACLD patients,

82% were women, median age was 62.5 (IQR 55.1-73.7) years, median BMI 25.1 (IQR 22.7-27.0) kg/m^2, median time from PBC diagnosis 2.9 (IQR 0.2-7.9) years, median ALP 1.3 (IQR 1.0-2.3) xULN, median total bilirubin 0.7 (IQR 0.5-1.1) mg/dL, median LSM 16.3 kPa (IQR 11.9-32.8), median SSM 47.4 kPa (IQR 27.8-63.2). Thirty-four (43.9%) out of the 78 patients with available esophagogastroduodenoscopy had (any size) oesophageal varices, 15 (19.2%) had high-risk oesophageal varices. Using the rule of five for LSM-based stratification, SSM differed significantly across LSM classes ($p < 0.001$). SSM >40 kPa was found in 30.4% of patients with LSM 10–14.9 kPa and 83% of those with LSM ≥ 15 kPa (85.7% in LSM 15–19.9 kPa and LSM 20-24.9 kPa; 81.8% in LSM ≥ 25 kPa). According to Baveno VII-SSM criteria, CSPH was ruled out in 47%, ruled in in 46%, and 7% remained in the grey zone. Based on the NICER model, CSPH risk distribution was: $\leq 25\%$ in 41 patients, 26-74% in 5 patients and $\geq 75\%$ in 54 patients. During a median follow-up of 17.4 months after VCTE examination, 12 patients developed LD. Two-year probability of LD was significantly higher in patients with CSPH risk by NICER $\geq 75\%$ vs those with risk $<75\%$ (19% vs 5% respectively; p 0.03). **Conclusion:** These findings support the applicability of SSM-based non-invasive risk estimation models in patients with PBC, particularly in predicting the risk of decompensation.

4417 | AUTOIMMUNE DISEASE CLUSTERING IN AUTOIMMUNE HEPATITIS: PATTERNS IN A LARGE MULTI-CENTER COHORT

Kate Solpari[1] Emma Leipsner[1] Scarlet Yang[1] Jessica Siguencia[1] Tatyana Kushner[1], [1]Weill Cornell Medical College

Background: Autoimmune hepatitis (AIH) frequently coexists with other autoimmune diseases, but the patterns of clustering remain incompletely characterized. This study investigated the co-occurrence between AIH and comorbid autoimmune conditions across race, gender, and age strata. **Methods:** We analyzed electronic health record data from patients with AIH across 99 healthcare organizations in the TriNetX research network. Prevalence of systemic lupus erythematosus (SLE), primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), Crohn's disease, ulcerative colitis, autoimmune (Hashimoto's) thyroiditis, Graves' disease, celiac disease, rheumatoid arthritis (RA), and type 1 diabetes (T1DM). were calculated for the entire cohort and stratified by gender, age groups, and race. **Results:** Among 52,992 patients with AIH, 72.7% were female with a mean age of 59 $\pm$ 19 years; they were White (62.4%), Black (13.4%), and Asian (5.94%). The most common documented autoimmune comorbidities were PBC (10.7%), Crohn's disease (10.0%), ulcerative colitis (9.1%), RA (7.7%), and SLE (7.0%) (Figure 1). Sex-stratified analysis showed that

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

SLE, PBC, and Hashimoto's thyroiditis were more common in females, while Crohn's disease, ulcerative colitis, PSC, and T1DM were more frequent in males. Age stratification revealed that SLE co-occurrence peaked in young adults (15–34 years), PBC and RA were most prevalent in middle age (35–54 years), PSC was concentrated in pediatric and adolescent patients (0–14 years), and ulcerative colitis was distributed more evenly across the lifespan. Race and ethnicity stratification showed higher SLE prevalence in Asian and Black patients, while PBC was more frequent among White individuals. Hispanic/Latino patients exhibited disproportionately high rates of PBC, PSC, and T1DM, while Native Hawaiian/Pacific Islander patients had the highest prevalence of ulcerative colitis. **Conclusion:** Autoimmune hepatitis exhibits clear, demographically patterned clustering—SLE in young adults, PBC/RA in middle-aged women, PSC/IBD in boys/men, and PBC/PSC/T1DM in Hispanic and Native Hawaiian/Pacific Islander patients—supporting age-, sex-, and race-stratified surveillance and routine multidisciplinary referral.

Figure 1. Co-occurrence of Autoimmune Conditions with AIH Stratified by Age, Race/Ethnicity, and Sex

4418 | RED CELL DISTRIBUTION WIDTH IS INDEPENDENTLY ASSOCIATED WITH FATIGUE AND COGNITION IN PRIMARY BILIARY CHOLANGITIS

Matthew Smith[1] Narmeen Umar[1] Allison Mella[1] Rahima Bhanji[1] Charmaine van Eeden[1] Mohammed Osman[1] YU JUN WONG[2] Aldo Montano-Loza[1] Andrew Mason[1], [1]University of Alberta, [2]Changi General Hospital

Background: Fatigue is the most common symptom associated with primary biliary cholangitis (PBC). The pathophysiology of fatigue and cognitive impairment is poorly understood and these symptoms are often discordant with prognostic scoring or disease severity. Red cell distribution width (RDW) is a measure of erythrocyte size variability and identified as a potential biomarker of oxidative stress and hypoxia. RDW was associated with symptom severity in other autoimmune conditions such as systemic sclerosis and lupus, but its utility in PBC has not been fully evaluated. We assessed whether RDW is independently associated with fatigue and cognitive symptoms in PBC, after adjusting for hematologic parameters, liver disease severity, and clinical decompensation. **Methods:** A multi-center retrospective analysis of 160 non-transplant patients with PBC was performed between January 2018 and January 2025 in Alberta, Canada. Fatigue and cognitive scores were collected and combined into one composite score derived from validated patient-reported PBC-40 surveys. Multiple linear regression was used to assess associations between RDW and composite PBC-40 scores with hepatic and hematologic covariates including presence of cirrhosis, cirrhosis status and GLOBE scores. **Results:** The average age of our cohort was 64 years old, the majority were female (85%) and 53 patients had cirrhosis with 20 having decompensated cirrhosis. The mean RDW was 14.5, the median GLOBE score was 0.2082, the median PBC-40 scores were 29 for fatigue, 13 for cognition, and the composite median score was 42.5. The regression model was significant ($F = 2.16$, $p = 0.041$) and explained 9.3% of the variance in the composite score (adjusted $R^2 = 0.050$). RDW was associated with higher composite scores ($B = 1.77$, 95% CI: 0.08 to 3.45, $p = 0.041$). Age, presence of cirrhosis, liver decompensation and GLOBE scores were not significantly associated with fatigue and cognitive scoring. Residuals were normally distributed, with no violations of model assumptions or evidence of multicollinearity (all VIFs < 1.7). **Conclusion:** RDW was found to be independently associated with worse

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

PBC-40 fatigue and cognitive composite scores, even after adjusting for hematologic confounders and liver disease severity. These findings suggest that RDW may reflect fatigue-related symptom burden and pathophysiology and support its potential as a low-cost, accessible biomarker for symptom stratification in PBC. Further research into potential predictive biomarkers and pathophysiology behind symptoms such as fatigue in PBC is required.

4419 | FIBROSIS AT FIRST GLANCE: CLINICAL CHARACTERISTICS AND OUTCOMES OF ADULTS WITH AUTOIMMUNE HEPATITIS WITH AND WITHOUT CIRRHOSIS AT DIAGNOSIS IN A DIVERSE U.S. COHORT

Ryan Murphy Sheng-Fang Jiang[1] Sreepriya Balasubramanian[1] Nirmala Ramalingam[1] Kavita Radhakrishnan[2], [1]Kaiser Permanente Medical Center, [2]The Permanente Medical Group

Background: Autoimmune hepatitis (AIH) is a chronic, immune-mediated liver disease that can lead to progressive hepatic injury, decompensation, and death if not diagnosed and treated in a timely manner. The clinical presentation can range from asymptomatic transaminase elevations to acute liver failure. Prior global studies indicate that up to 25% of patients have cirrhosis at AIH diagnosis, which is associated with increased liver-related complications and death. However, there are limited data on baseline characteristics and outcomes of AIH patients with cirrhosis at diagnosis in ethnically diverse U.S. populations. **Methods:** We conducted a retrospective study of adults newly diagnosed with AIH between 2010–2021 within Kaiser Permanente Northern California, a large integrated healthcare system. AIH diagnoses were identified by ICD codes (ICD-9: 571.42; ICD-10: K75.4) and confirmed with serologies and/or liver biopsy. Patients were stratified by the presence or absence of cirrhosis at the time of diagnosis. Demographic data, comorbidities, and clinical outcomes including hospitalizations, transplantation, and death were compared using chi-square and t-tests. **Results:** Among 997 patients with AIH (80% female, 17% Asian, 9% Black, 27% Hispanic, 43% White), 211 (21.2%) had cirrhosis at diagnosis. Compared to those without cirrhosis, patients with cirrhosis were older, more likely to be Hispanic, non-English-speaking, and have diabetes (all $p < 0.05$, Table 1). Those with cirrhosis also had higher prevalence of hypertension ($p = 0.02$), alcohol use disorder ($p < 0.01$), and greater comorbidity burden as reflected by the Charlson Comorbidity Index (52.1% vs. 29.0% with score ≥ 2, $p < 0.001$). Cirrhosis at diagnosis was associated with worse outcomes, including higher rates of hospitalization (28.9% vs. 13.0%, $p < 0.001$), liver transplantation (8.1% vs. 1.4%, $p < 0.001$), and death (23.7% vs. 11.8%, $p < 0.001$). There were no significant differences between groups by sex, body mass index (BMI), hyperlipidemia, or neighborhood deprivation index. **Conclusion:** In this large and diverse U.S. cohort, over 1 in 5 adults with AIH presented with cirrhosis at diagnosis. Cirrhosis at presentation was associated with worse clinical outcomes, including hospitalization, liver-related complications, and mortality. These findings underscore the importance of earlier detection and treatment of AIH, particularly among higher-risk and understudied demographic groups, to prevent disease progression and reduce adverse outcomes.

4420 | PREVALENCE OF CONCOMITANT ORAL CONTRACEPTIVE AND HORMONE REPLACEMENT THERAPY USE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: RESULTS: FROM A LARGE US CLAIMS DATABASE

Tatyana Kushner[1] Sarjita Naik[2] Nirali Kotowsky[2] Eva Flahavan[2] Catherine Frenette[2], [1]Weill Cornell Medicine, [2]Gilead Sciences, Inc.

Background: Primary biliary cholangitis (PBC) affects women predominantly and is usually diagnosed in middle age although is diagnosed in up to 25% of women during childbearing years. PBC in women has been associated with irregular menses, reduced fertility, and higher rates of osteoporosis. Treatment with estrogen-based therapies for these conditions is commonly recommended, although there is often provider hesitancy to initiate these therapies in the context of chronic liver disease. We aim to understand the background medication use of oral contraceptives (OCPs) and hormone replacement therapy (HRT) in women being treated for PBC. **Methods: Methods:**: This is a retrospective, descriptive study evaluating the prevalence of OCP and HRT among females living with PBC with a prescription claim for ursodeoxycholic acid (UDCA) alone or with second line (2L) agents, obeticholic acid (OCA) or fibrates in the Health Verity database. Health Verity covers 84 million lives and contains both medical and pharmacy insurance claims from over 150 payers, representing commercial, Medicare and Medicaid. Patients with a PBC diagnosis were identified using the ICD-10 K74.3 code between October 1, 2015 to June 30, 2024. Treatment for PBC with UDCA, OCA or fibrates was captured using National Drug Codes from prescription claims. **Results:** We identified 46,028 individuals with PBC; 40,921(89%) were on UDCA only and 5,107(11%) were on 2L treatment: 3,796(8.2%) on OCA and 1,311(2.8%) on fibrates. Baseline patient demographics for overall cohort (n = 46,028) are shown in the Table. The majority were female (89%), median age over 50, and identified as White, consistent with the known demographics of PBC. After restricting the cohort to females (n = 40,963), 18% were considered of childbearing age and the remaining were either at menopause or post-menopausal. Among patients on UDCA only, 3253(8.9%) were either on OCP or HRT compared to 651(13.9%) also on 2L therapies. **Conclusion:** The use of OCP and HRT use was numerically higher in PBC patients receiving 2L treatment versus UDCA alone. The higher

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

prevalence in women on 2L treatment may reflect those with advanced or longer duration of disease. Given the high prevalence of cardiovascular disease and osteoporosis in PBC patients, treatment with HRT is beneficial and special attention is warranted to address their need in women. With the availability of new 2L agents for PBC, patient features, which may include concomitant medications, can have implications on treatment selection.

Table. Patient demographics for overall cohort (n=46,028) during the baseline period

	Patients with UDCA only	Patients with UDCA plus OCA	Patients with UDCA plus fibrates
Number of patients	40921	3796	1311
Median age [IQR]	63.00 [55.00, 71.00]	57.00 [50.00, 64.00]	57.00 (50.00, 65.00)
Gender, n (%)			
Male	4,607 (11.3%)	317 (8.4%)	130 (9.9%)
Female	36,304 (88.7%)	3,478 (91.6%)	1,181 (90.1%)
On OCP, n (%)	581 (1.6%)	119 (3.4%)	47 (3.9%)
On HRT, n (%)	2,672 (7.4%)	375 (10.8%)	110 (9.3%)

4421 | PROTEOMIC CHARACTERIZATION OF CIRCULATING EXTRACELLULAR VESICLES REVEALS NOVEL DIAGNOSTIC AND PROGNOSTIC BIOMARKERS IN AUTOIMMUNE HEPATITIS

Swati Thangariyal[1] Chhagan Bihari[1] Ashmit Mittal[1] Sukriti Baweja[2] Shiv Kumar Sarin[1], [1]Institute Of Liver And Biliary Sciences, New-Delhi, India, [2]Institute of Liver and Biliary Sciences, New Delhi

Background: Autoimmune Hepatitis (AIH) is a chronic liver disease of unknown etiology with systemic inflammation. There is an unmet need to identify the biomarkers of diagnosis and prognosis of AIH. Emerging evidence has suggested that proteomic characterization of Extracellular vesicles (EVs) might reveal potential biomarkers for the diagnosis and prognosis of AIH. **Methods:** Pre-therapy plasma samples were collected from biopsy-proven AIH patients ($n = 20$, international simplified scoring ≥ 7, HAI score > 5, ALT 129 $\pm$ 16 U/L, AST 148 $\pm$ 16 U/L), PBC patients ($n = 4$), and age- and sex-matched healthy controls (HC) ($n = 20$). These samples were fractionated, and EVs were isolated utilizing iodixanol-sucrose density gradient ultracentrifugation. The isolated EVs were characterized by transmission electron microscopy (TEM) and nanoparticle tracking analysis (NTA). Proteomic analysis was conducted using LC-MS, and the results were interpreted with Proteome Discoverer 3.0. **Results:** Plasma EV mean levels were higher in AIH (1.2×10^8 particles/mL) and PBC (3.1×10^8 particles/mL) compared to healthy controls (7.5×10^7 particles/mL). The average diameter of EVs in AIH and PBC (157 nm) was greater than that in healthy controls (68.8 nm). EV proteomics analysis identified five proteins related to the immune response that were dysregulated among the groups. Differential expression of proteins (DEP) revealed the upregulation of immune response proteins [fold change (FC) > 2, $p = 0.005$], such as immunoglobulin gamma-1 heavy chain (IgG) and alpha-2-macroglobulin (A2M), in AIH and PBC EVs. IgG overexpression indicates liver injury, and A2M, an acute phase protein, inhibits the catabolism of matrix proteins during liver inflammation, thus causing liver fibrosis. In healthy EVs, DNA synthesis and repair-associated proteins (DNA helicase, DNA polymerase alpha) were upregulated (FC > 2, $p > 0.005$). Additionally, haptoglobin-related proteins, involved in the clearance of cell-free hemoglobin for hepatic recycling of heme iron, were upregulated in healthy EVs (FC > 2, $p > 0.005$). **Conclusion:** Our results provide the first evidence that EVs from AIH patients are enriched in immune effector proteins such as IgG and A2M, which may participate in immune complex formation and systemic inflammation. These findings propose that circulating EVs serve not only as disease reporters but also as mediators of liver injury. EV proteomics offers a promising, non-invasive tool for diagnosing and monitoring AIH and potentially for stratifying disease severity and therapeutic response.

4422 | PANORAMA OF THE HEPATIC IMMUNE MICROENVIRONMENT IN AUTOIMMUNE HEPATITIS

Han Wang[1], [1]Tongji Hospital

Background: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease with rising global prevalence. Progress in basic research is hindered by the lack of reliable animal models and comprehensive characterization of the hepatic immune microenvironment. To address this, we developed a stable AIH mouse model and provided the first panoramic view of the hepatic immune landscape in AIH. **Methods:** The novel AIH mouse model was established by transfecting the human CYP2D6 gene into the liver. Liver pathology and fibrosis were assessed using H&E and Sirius Red staining. Serum autoantibody titers were measured via ELISA. The hepatic immune microenvironment was characterized through 10× Genomics RNA sequencing, spatial transcriptomics, and flow cytometry. $CD4^+$ T cell and $CD8^+$ T depletion experiments were performed in vivo. **Results:** Liver inflammation was evident by day 14 post-injection, with chronic lymphocyte aggregation around the portal vein and detectable autoantibodies by day 28. Peak inflammation at day 35 featured hallmark AIH pathology, including interface hepatitis, rosette formation, and fibrosis, closely mirroring human AIH. 10× Genomics RNA sequencing and flow cytometry revealed significant shifts in hepatic immune cell populations, particularly $CD8^+$ T cells, NK cells, and activated Tregs. Subtype analysis highlighted changes in effector $CD8^+$ T cells and tissue-resident memory T cells (TRM). Spatial transcriptomics showed increased $CD8^+$ T cell clustering in portal areas and liver parenchyma, uncovering spatial interactions with hepatocytes that underpin AIH pathogenesis. Notably, $CD8^+$ T cell depletion significantly alleviated hepatic inflammation, whereas $CD4^+$ T cell depletion had minimal effect, underscoring the pivotal pathogenic role of CD8+ T cells in AIH. **Conclusion:** We established a mouse model of autoimmune hepatitis using the human autoantigen CYP2D6 and mapped the hepatic immune landscape. Our findings identified $CD8^+$ rather than $CD4^+$ T cells as key pathogenic drivers in AIH. This work provides a valuable experimental tool and lays a solid foundation for future mechanistic studies in AIH.

4423 | RESEARCH WITHOUT BORDERS? A CRITICAL LOOK AT GEOGRAPHIC AND TEMPORAL DISPARITIES IN PSC PUBLICATIONS

Renan Prado[1] Luma Tavares[2] Julia TIrelli Rocha[3] Melissa Lou Silva[4], [1]Cleveland Clinic Foundation, [2]Universidade Federal do Ceara, Brazil, [3]Jundiai Medical School, Brazil, [4]University of California San Diego

Background: Primary sclerosing cholangitis (PSC) is a chronic, progressive cholestatic liver disease characterized by inflammation and fibrotic stricturing of the intra- and extrahepatic bile ducts, often culminating in cirrhosis and end-stage liver disease. Although PSC is considered rare in the general population, current epidemiological data are predominantly derived from high-income regions, leading to potential biases in global understanding. The reliance on advanced imaging techniques such as magnetic resonance cholangiopancreatography (MRCP) for diagnosis may further contribute to disparities in detection and reporting. Despite increasing scientific interest, the global distribution of PSC-related research remains uneven. **Methods:** To assess global publication trends, citation patterns, and geographic disparities in PSC-related literature indexed in the Web of Science Core Collection (WoSCC), including all PSC-related articles and reviews published between 1965 and 2025. Meeting abstracts were excluded. Bibliometric indicators were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

analyzed using the *Bibliometrix* R package. Variables included publication volume, citation metrics, author affiliations, and country-level contributions. **Results:** A total of 4,565 PSC-related documents were published in 1,158 journals, with an annual growth rate of 6.87%, indicating increasing research attention. Based on first author affiliation, the top contributing countries were the United States (1,085 publications), Germany (415), the United Kingdom (352), Japan (334), and China (227). Low- and middle-income countries accounted for 853 publications (18.7%). The most productive journals were Hepatology, Journal of Hepatology, and Gastroenterology. The most cited article accrued 850 citations. Citation impact was highest in the United States, United Kingdom, and Norway. Oslo University Hospital emerged as the most frequent author affiliation—an unusual finding given the dominance typically seen by U.S.-based institutions. Among the ten most cited articles, five originated from the United States and five from Europe (Sweden, United Kingdom, Norway, and the Netherlands). International collaboration was moderate, with high-income countries disproportionately represented in multi-country publications. Developing nations remained significantly underrepresented. **Conclusion:** The global PSC research landscape is largely shaped by high-income countries, underscoring persistent disparities in scientific output and visibility. Efforts to promote international collaboration, support research infrastructure, and foster inclusion of underrepresented regions are essential for a more comprehensive and equitable understanding of PSC worldwide.

4424 | THE ROLE OF KILLER IMMUNOGLOBULIN-LIKE RECEPTOR (KIR) GENE VARIANTS IN AUTOIMMUNE HEPATITIS AND PRIMARY BILIARY CHOLANGITIS: ASSOCIATION WITH DISEASE SEVERITY AND DEEP REMISSION

mete ucdal[1] Ayse Burus[1] Ahmet Yalcinkaya[1] Basak Celtikci[1] Osman Dag[1] Yasemin Balaban[1], [1]hacettepe university

Background: Autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC) are immune-mediated liver diseases with distinct clinical phenotypes but overlapping immunopathogenic mechanisms. Killer immunoglobulin-like receptors (KIRs) regulate natural killer (NK) cell activity and contribute to autoimmunity. This study investigated the distribution of KIR variants and their association with disease severity and treatment response in AIH and PBC. **Methods:** AIH (n = 25) and PBC (n = 30) patients diagnosed per international criteria were enrolled. Peripheral blood DNA was used for KIR genotyping (activating: KIR2DS1, KIR2DS2, KIR3DS1; inhibitory: KIR2DL1, KIR3DL1; dual-function: KIR2DL4) via quantitative PCR. Disease severity was defined biochemically (AST/ALT $\geq$10×ULN in AIH; ALP/GGT $\geq$3×ULN in PBC). Treatment response was assessed after standard therapy (prednisolone/azathioprine for AIH; UDCA for PBC). Statistical analyses included Fisher's exact (a), chi-square (b), Mann–Whitney U (c), Kruskal–Wallis (d), and Bonferroni correction (e). Medians (Q1–Q3) were reported for nonparametric comparisons. **Results:** Activating KIR variants were predominant in AIH (68.0%) versus PBC (23.3%, p = 0.002[a]), notably KIR2DS2 (AIH: 32.0% vs. PBC: 3.3%, p = 0.013[a]). In contrast, inhibitory KIRs, particularly KIR3DL1, were more frequent in PBC (13.3%, p = 0.001[a]). KIR2DS2 correlated with severe AIH (p = 0.031[a]), while KIR3DS1 predicted non-response to immunosuppression (p = 0.015[b]).When examining transaminases and IgG, treatment response differed significantly across KIR genotypes ($p < 0.001$[d]). Carriers of the activating variants KIR3DS1 and KIR2DS2 exhibited markedly higher biochemical non-response than KIR2DL1 carriers (KIR3DS1, $p < 0.001$[e]; KIR2DS2, $p = 0.006$[e]). Bonferroni-corrected pairwise comparisons confirmed significant differences for KIR3DS1 vs. KIR2DL1 ($p = 0.002$[e]) and KIR2DS2 vs. KIR2DL1 ($p = 0.017$[e]). KIR genotyping effectively predicts deep remission in PBC patients in that KIR2DL1 status was a significant biomarker for 12th month treatment response according to Paris II criteria. Out of 30 PBC patients, 73% (n = 22) of them were responder. All KIR2DL1-positives (3 patients) were treatment resistant while 85.2% (23/27) of responder had other KIR genotypes (p = 0.014[a]). These patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

also had higher Globe scores compared to those with other genotypes (KIR2DL1 median 0.55 vs. 0.15–0.45 across other alleles, p = 0.0105[c]). **Conclusion:** AIH and PBC displayed distinct KIR profiles; activating KIRs were dominant in AIH, inhibitory KIRs in PBC. Certain variants correlated with disease severity and deep remission. KIR2DS2 predicted severe AIH, while KIR2DL1 negativity predicted deep remission in PBC. These KIR profiles may serve as valuable biomarkers for disease stratification and personalized treatment approaches.

4425 | CLINICAL PRACTICE PATTERNS IN THE MANAGEMENT OF PRIMARY BILIARY CHOLANGITIS IN COMMUNITY SETTINGS

Robert Gish[1] Sara Atcheson[2] Jenniffer Meza Jimenez[2] Jeffrey Carter[2] Leah Molloy[2] Laura Simone[2], [1]Robert G Gish Consultants LLC, [2]PRIME Education

Background: For patients with primary biliary cholangitis (PBC), liver disease assessment, risk stratification, and monitoring are critical for optimizing treatment plans. We sought to assess current practices in community-based clinics and identify opportunities for improving PBC care. **Methods:** From December 2024 to April 2025, surveys were conducted among clinical teams at 8 community-based gastroenterology and hepatology clinics as part of an educational initiative. Survey items focused on current practices and challenges in PBC management. **Results:** A total of 81 healthcare professionals (HCPs) completed the survey (13% gastroenterologists, 4% hepatologists, 54% NPs/PAs, 29% nurses and other clinical professions). The top challenges in assessing liver disease in PBC were difficulty interpreting tests due to comorbidities (eg, MASLD; 52%) and limited training (28%). Most HCPs (71%) reported very low to moderate confidence in using noninvasive techniques for liver disease staging in PBC and 51% reported routine use of liver biopsy in PBC. The most common strategies for risk-stratification were biochemical response to ursodeoxycholic acid (62%), FIB-4 index (49%), and elastography (49%); only 17% reported using a validated score (eg, GLOBE, UK-PBC) for risk stratification. Less than half (46%) of HCPs reported re-assessing risk of disease progression annually in all patients. Tests used to monitor treatment response included alkaline phosphatase (ALP; 88%), alanine transferase/aspartate transferase (69%), bilirubin (59%), albumin (43%), and platelets (31%). 33% of HCPs reported that more than half of their patients with PBC were currently prescribed second-line therapy. The top barriers to the use of new second-line PBC therapies were limited knowledge of clinical data (47%), uncertainty in identifying treatment candidates (44%), and lack of guideline recommendations (37%). After participation in team-based educational sessions on PBC, the top action items HCPs intended to take were use of ALP normalization as a treatment target (50%), use of non-invasive tests (44%), and earlier assessment of response to UDCA (38%; Figure). **Conclusion:** This study uncovered variation in clinical practices for the assessment and management of patients with PBC in community settings. Targeted educational and implementation initiatives are needed to more closely align PBC care with evidence-based practices.

4426 | ANALYSIS OF CIRCULATING BIOMARKERS IN THE RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PORTOLA PHASE 2A STUDY EVALUATING ZETOMIPZOMIB, A SELECTIVE IMMUNOPROTEASOME INHIBITOR, IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Janet Anderl[1] Neel Anand[1] David Bade[1] Eric Lowe[1] Kathryn Ray[1] Brian Tuch[1] Jennifer Whang[1], [1]Kezar Life Sciences

Background: Pathogenesis of autoimmune hepatitis (AIH) is still poorly understood, but involves a complex interplay of immune effector cells, including liver-invasive antigen-presenting cells, dysfunctional T cells, and autoantibody-producing plasma cells. Clinical studies in systemic lupus erythematosus (SLE) have demonstrated the ability of zetomipzomib (zeto), a selective inhibitor of the immunoproteasome, to reduce inflammatory cytokine production and modulate T and B cell gene expression and circulating populations (Fan, EULAR 2022; Furie, ACR 2024). Here we describe peripheral blood-derived biomarker changes observed following zeto administration in AIH patients from the randomized, double-blind, placebo-controlled Phase 2a PORTOLA study (NCT05569759). **Methods:** In the PORTOLA study (n = 24 patients with active AIH), zeto 60 mg was administered subcutaneously weekly for 24 weeks. Complete response (CR) was defined as normalization of ALT, AST, and IgG (if elevated at baseline) with steroid dose not higher than baseline dose. Whole blood was collected at Weeks 0, 8, 16, and 24 for transcriptomic analysis, plasma proteomics by tandem mass spectrometry, plasma cytokine immunoassay, and cryopreserved immune cell profiling by flow cytometry. **Results:** Proteomic assessment of plasma demonstrated a reduction in immunoglobulins following zeto administration, consistent with transcriptomic changes observed in SLE and despite comparable infectious adverse events between zeto and placebo in PORTOLA. In patients achieving CR, decreases in several neutrophil proteins implicated in liver inflammation, including LCN2, were observed. Plasma cytokine analysis showed an increase in BAFF associated with zeto administration, consistent with observations from studies in SLE. Elevated TGF-β1 and the macrophage chemokines, MDC and MIP-3β, correlated with CR following 6 months of treatment. Immune phenotyping following zeto administration revealed reductions in B cells and monocytes and increased Treg cells in patients achieving CR. **Conclusion:** In the PORTOLA Phase 2a study, zeto administration resulted in notable alterations in biomarker activity across both the innate and adaptive immune systems that correlated with clinically relevant biochemical responses in AIH. Circulating biomarker changes following zeto treatment were consistent with previous reports from clinical studies in patients with SLE. These findings provide intriguing starting points for further mechanistic studies and validation in the AIH population.

4427 | A DIAGNOSIS WITH LASTING IMPACT: CURRENT SEX- AND AGE-SPECIFIC EPIDEMIOLOGICAL TRENDS IN PRIMARY BILIARY CHOLANGITIS

Kristel Leung[1] Wenbin Li[2] Aliya Gulamhusein[3] Bettina Hansen[4] Abdel Aziz Shaheen[5] Jennifer Flemming[6] Gideon Hirschfield[3], [1]Queen's University; Autoimmune and Rare Liver Disease Programme; University of Toronto - IHPME, [2]ICES Queen's, [3]Autoimmune and Rare Liver Disease Programme; University Health Network, [4]Erasmus MC Rotterdam, [5]University of Calgary, [6]Queen's University, ICES Queen's

Background: Understanding sex- and age-specific epidemiology of primary biliary cholangitis (PBC) is valuable amid emerging second-line therapies, increasing multimorbidity in older adults, and a need for personalized patient counselling. **Methods:** Population-based incident and prevalent PBC cohorts in Ontario, Canada (2002–2021) were identified using health administrative data from ICES based on ICD-9/10 codes and/or anti-mitochondrial antibody positive (AMA+) status ≥1:40, with validation using a reference cohort from Toronto (total n = 18,687, with n = 913 AMA + PBC). Exclusions included viral hepatitis, genetic liver disease, acute liver failure, alcohol/toxins, drug-induced liver injury, prior liver transplant, and inflammatory

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

bowel disease. Sex- and age-specific incidence and prevalence (standardized to the 2011 Canadian population) were assessed, with trends analyzed via joinpoint regression. Outcomes until 2021 were assessed, including transplant-free survival, competing risk of transplant vs. death, and cause of death (available before 2019). **Results:** A validated prevalent PBC cohort (n = 6,152; sens. 72%, spec. 99%, PPV 85%) showed rising prevalence over time (annual percent change [APC] 4.73% from 2018–2021), particularly among adults > 50 y, while incidence plateaued (APC 0.82% from 2015–2021). In 2021, point prevalence was 31.7/100,000 person-years (PY) (95% CI: 30.7–32.7), with a female-to-male (F:M) ratio of ~6:1 (58.4 and 9.16/100,000 PY for females and males respectively). Between 2002–2021, 4,844 incident cases were identified (24% diagnosed before age 50, 76% diagnosed after age 50; 85% female). Males were older at diagnosis (median 65 y vs. 60 y for females, $p < 0.001$) and more often resided in areas with higher income quintile ($p = 0.018$) and % owned dwellings ($p = 0.0042$). Incidence was 2.28/100,000 PY overall (females: 3.77; males: 0.69), with F:M ratios ranging from 9:1 (ages 41–50 y) to 3:1 (> 70 y). Median unadjusted transplant-free survival was 19.2 y (females: 19.9 y; males: 10.6 y; $p < 0.001$), primarily driven by all-cause death. Liver-related causes accounted for ~40% of deaths in both sexes. Males had higher risks of transplant (adjusted hazard ratio [aHR] 2.62, 95% CI: 1.71–4.02) and death (aHR 1.62, 95% CI: 1.41–1.85). Older age was associated with lower transplant rates (aHR 0.96, 95% CI: 0.94–0.97) and higher mortality (aHR 1.09, 95% CI: 1.08–1.10). **Conclusion:** PBC epidemiology in Ontario reveals sex- and age-specific patterns, with males diagnosed later in life and more often residing in higher socioeconomic areas. The aging population reflects the disease's chronic course over decades. Despite higher rates of death and transplant in males, liver-related mortality remained substantial across sexes.

Figure. Cumulative Risk of (A) Transplant, and (B) Death by Cause-Specific Competing Risk Regression Analysis in Individuals Diagnosed with PBC.

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease that can lead to fibrosis and cirrhosis. While ursodeoxycholic acid (UDCA) is the first-line therapy, up to 40% of patients show an incomplete biochemical response, requiring second-line (SL) treatments. Although response criteria are well-established for UDCA, their utility in SL-treated populations is less clear. The FiOCA study aims to validate biochemical response criteria as predictors of transplant-free survival across diverse SL therapies. **Methods:** This retrospective study included 1843 patients with inadequate UDCA response from 24 international liver centers part of the Global PBC study group. After applying strict inclusion criteria—12-month follow-up, complete biochemical data, and single SL therapy—866 patients were analyzed. Data included demographics, liver histology, and biochemical markers. Transplant-free survival outcomes were assessed using Kaplan-Meier and Cox proportional hazards models. **Results:** Patients were predominantly female (87.9%) with a median age of 56 year, and a median follow-up time of 37 months. At initiation of second-line therapy, the median alkaline phosphatase (ALP) was 1.93 (IQR 1.44-2.90) xULN, 126 (23.3%) patients were cirrhotic, with 15 (2.8%) of them Child-Pugh B. In univariate Cox analyses, achieving ALP $< 1.67\times$ULN at 12 months was associated with a 43.5 % reduction in transplant-free survival (HR 0.56, 95 % CI 0.33–0.97; $p = 0.039$). After adjustment for treatment (fibrates vs OCA), this effect persisted (adjusted HR 0.52, 95 % CI 0.30–0.91; $p = 0.021$), and the ALP×treatment interaction was non-significant indicating similar prognostic value regardless of the second-line agent. An ALP decline $\geq$ 15 % at month 12 also predicted better outcome when adjusted for treatment (HR 0.49, 95 % CI 0.27–0.87; $p = 0.015$); the interaction term remained non-significant. Normalization of bilirubin yielded the strongest association, with an adjusted HR of 0.14 (95 % CI 0.08–0.25; $p < 0.001$). The composite responder definition—normal bilirubin and ALP $< 1.67\times$ULN and $\geq$ 15 % ALP decline- was associated with a 66 % risk reduction (adjusted HR 0.34, 95 % CI 0.18–0.66; $p = 0.0015$), again without a significant treatment interaction. In Kaplan–Meier analyses pooled across both treatment arms, biochemical responders had significantly higher event-free survival than non-responders for every surrogate definition at 12 months (log-rank $p = 0.037$ for ALP $< 1.67\times$ULN, $p = 0.013$ for $\geq$ 15% ALP decline, $p < 0.001$ for bilirubin normalization, and $p < 0.001$ for the composite response). **Conclusion:** We confirm that biochemical response criteria measured at 12 months reliably predict transplant-free survival in PBC patients treated with either obeticholic acid or fibrates. The composite responder definition (normal bilirubin and ALP $< 1.67\times$ULN or $\geq$ 15% ALP decline), was found to be independent of the specific second-line agent used.

4429 | IMPACT OF PRURITUS ON CLINICAL OUTCOMES IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: A PROPENSITY SCORE-MATCHED ANALYSIS

Sheena Bhushan[1] Ankit Chalia[2] Kris Kowdley[1], [1]Liver Institute Northwest, [2]WVU Medicine East, Behavioral Medicine and Psychiatry

Background: Primary sclerosing cholangitis (PSC) is a rare chronic cholestatic liver disease frequently accompanied by debilitating symptoms such as fatigue and pruritus, both of which can significantly impair patients' quality of life. Although prior studies have suggested a potential association between pruritus, fatigue and adverse mental health outcomes, large-scale comparative analyses in PSC populations are lacking. This study aims to evaluate clinical outcomes, particularly fatigue and antidepressant use, among patients with PSC, in the presence and absence of pruritus, using real world data. **Methods:** We conducted a retrospective cohort study using data from the TriNetX US Collaborative Network, which includes electronic health records from 68 healthcare organizations. Adult patients with PSC were identified using ICD-10 codes and were stratified into two cohorts: those with pruritus (n = 3,164) and those without (n = 11,160). Propensity score matching (1:1) was performed to balance 16 baseline covariates including cirrhosis, inflammatory bowel disease, mood disorders, and other comorbidites that could cause fatigue, resulting in a matched cohort of 2,988 patients in each cohort. Primary outcomes included fatigue and antidepressant use. Statistical analyses were performed using risk estim. **Results:** The prevalence of fatigue was more than double in the pruritus group (27.1% vs. 12.5%, RR 2.17, 95% CI 1.95-2.43), with earlier onset (median time to diagnosis 1,292 days vs. 3,522 days, HR 1.87, 95% CI 1.65-2.11). Antidepressant use was also higher in the pruritus

cohort (50.8% vs. 30.6%, RR 1.66, 95%CT 1,56-1.77), along with a greater number of antidepressant prescriptions on average (25.3 vs. 14.7 per patient, $p < 0.001$). All the comparisons between groups were statistically significant ($p < 0.001$) with well balanced baseline characteristics after matching balance (standardized differences < 0.1 for all variables). **Conclusion:** Patients with PSC experiencing pruritus exhibit significantly higher risks of fatigue and antidepressant use, with earlier onset and greater severity of symptoms. These findings suggest that pruritus in PSC may reflect a broader systemic disease burden rather than being a purely symptomatic manifestation. A more holistic approach to history-taking, including systematic assessment of pruritus and associated psychosocial impacts is essential for effective management.

4430 | SINGLE-CELL SPATIAL TRANSCRIPTOMICS REVEALS TNFSF SIGNALING DYNAMICS AND POTENTIAL TREATMENT TARGETS IN PEDIATRIC ONSET AUTOIMMUNE LIVER DISEASES

Yunguan Wang[1] David Adeleke[1] Michelle Damen[1] Zi Yang[1] Cyd Castro Rojas[1] Mosab Alquraish[1] Emily Miraldi[1] Pamela Sylvestre[1] Alex Miethke[1] Liva Pfuhler[1] Ramesh Kudira[1], [1]Cincinnati Children Hospital

Background: Autoimmune liver diseases (AILD) features auto inflammation and focal fibrosis surrounding interlobular bile ducts or portal tracts. Biologics blocking TNFa signaling emerge as therapy for a wide range of autoimmune conditions including IBD, commonly associated with primary sclerosing cholangitis (PSC), and autoimmune hepatitis AIH. To gain insights into the functional states of TNFSF genes in AILDs, this study presents a fine-resolution mapping of the expression levels of TNFSF ligands and receptors across diverse cell types in AIH, PSC, autoimmune sclerosing cholangitis (ASC), and healthy controls (HC). **Methods:** We performed MERSCOPE-based, single cell spatially resolved transcriptomic (scSRT) profiling using a customized 500-gene panel including 47 TNFSF ligands and receptors on archived tissue samples from diagnostic liver biopsies ($n = 8$) and explants ($n = 6$). In-house single-cell RNA-seq (scRNA-seq) data derived from patients with AILD and from livers of DDC-treated mice and liver bulk RNAseq data from patients with AILD stratified by stage of fibrosis were used for validation. **Results:** We identified major cell types involved in AILD, including macrophages (MPs), T and B cells, hepatic stellate cells (HSCs). M2-polarized MP, activated HSCs, T- and B cells were enriched in fibrotic periductal regions. Within these areas, expression levels for *LTBR, TNFRSF12A/14/19/21* were upregulated in cholangiocytes, and to a lesser extent in hepatocytes, in patients with end-stage disease from AIH, ASC, or PSC. TNFSF ligand genes, including LTB and TNFSF8/12, were primarily expressed in immune cells, sinusoidal cells, and HSCs. Consistent with scSRT, TNFSF14 and TNFRSF12A/19/21 were upregulated in bulk RNAseq data from AILD patients with established liver fibrosis compared with early disease. In mice exposed to DDC precipitating toxic bile induced liver injury, Tnfrsf12a/19/21 were upregulated in cholangiocytes during DDC challenge and recovery compared to baseline. **Conclusion:** These findings underscore the distinct, cell type–specific expression patterns of TNFSF receptors and ligands across autoimmune liver diseases. They support the involvement of TNFSF signaling in coordinating immune and epithelial responses in pediatric onset AILD. The disease-associated overexpression of TNFRSF12A/19/21 in both human AILD and the murine DDC model warrants further investigation to abrogate bile duct epithelial injury.

4431 | CNP-104 INDUCES ANTIGEN-SPECIFIC IMMUNE TOLERANCE IN PBC VIA PATHOGENIC CYTOKINE REDUCTION AND TOLEROGENIC T CELL EXPANSION

Molly Frey Adam Elhofy[1] Christopher Bowlus[2] Derrick McCarthy[1] Erik Wambre[3] Stephen Caldwell[4] Roberto Firpi-Morell[5] Brett Fortune[6] Michael Galambos[7] Stuart Gordon[8] Denise Harnois[9] Tarek Hassanein[10] Matthew Kappus[11] Eric Lawitz[12] Scott McHenry[13] Bhaktasharan Patel[14] Raymond Phillips[15] Daniel Pratt[16] Jatinder Pruthi[17] Govarthanan Rajendiran[18] K. Gautham Reddy[19] Manuel Rodriguez[20] Marina Silveira[21] Xaralambos Zervos[22] Paul Peloso[23] M Gershwin[2], [1]COUR Pharmaceuticals, [2]University of California, Davis, [3]Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, [4]University of Virginia, [5]University of Florida, [6]Montefiore Medical Center, [7]Digestive Healthcare of Georgia, [8]Henry Ford Health System, [9]Mayo Clinic Florida, [10]Southern California Research Center, [11]Duke University, [12]Texas Liver Institute, [13]Washington University in St. Louis, [14]Peak Gastroenterology Associates, [15]GI Pros Research, [16]Massachusetts General Hospital, [17]Om Research, [18]Sanford Medical Center, [19]University of Chicago, [20]Florida Research Institute/ Florida Digestive Health Specialists, [21]Yale University, [22]Cleveland Clinic Florida, [23]COUR

Background: Primary biliary cholangitis (PBC) is an archetypical autoimmune disease driven by loss of tolerance to the mitochondrial autoantigen PDC-E2, leading to immune-mediated progressive bile duct injury and fibrosis. Emerging evidence highlights Th17 cells and type 3 cytokines as drivers of biliary inflammation. Currently approved PBC therapeutics target downstream processes such as bile acid metabolism without addressing the underlying autoimmune process. CNP-104, a first-in-class tolerogenic nanoparticle encapsulating PDC-E2, aims to restore immune tolerance. We leverage antigen-specific immune biomarkers to assess the therapeutic mechanisms of CNP-104 in a Phase 2a trial in PBC. **Methods:** In this randomized, placebo-controlled trial, 41 PBC patients with an incomplete biochemical response (ALP $>1.5\times$ULN) received two doses of CNP-104 or placebo one week apart. Shown here are the 4 mg/kg CNP-104 (n = 11) and placebo (n = 16) groups. Immune profiling included antigen-specific Th17 and CD8+ TIGIT + T cells by flow cytometry and serum IL-17 by Olink. Liver stiffness via FibroScan was assessed as translational clinical endpoint. **Results:** CNP-104-treated subjects exhibited a reduction in the percentage of PDC-E2-specific Th17 T cells (-27.3%) compared to placebo (+2.5%, p = 0.034), consistent with diminished autoreactive T cell activity. Concurrently, the responder rate of PDC-E2-specific CD8+ TIGIT+ cell counts (change from baseline $\leq$ 0) was larger in CNP-104 (66.7%) compared to placebo (22.2%, p = 0.136), suggesting expansion of regulatory T cell populations. Cytokine analyses demonstrated a decrease in IL-17 levels in participants treated with CNP-104 compared to placebo, further supporting attenuation of pro-inflammatory pathways. Clinically, participants classified as Th17 responders (change from baseline $\leq$ 0) correlated to lower liver stiffness measurements compared to non-responders, suggesting a direct link between immunomodulation and reduced fibrosis progression (Figure 1). **Conclusion:** CNP-104 modulates PBC-relevant immune pathways by reducing pathogenic PDC-E2-specific Th17 cells and IL-17 while expanding tolerogenic TIGIT+ CD8 + T cells, demonstrating dual immune modulation toward tolerance. Furthermore, Th17 responders had a corresponding slowed progression of liver stiffness, suggesting a mechanism to explain CNP-104's anti-fibrotic effects. These findings support CNP-104 as a disease-modifying therapy that targets core immune dysfunction in PBC, with potential to improve outcomes beyond current standard of care.

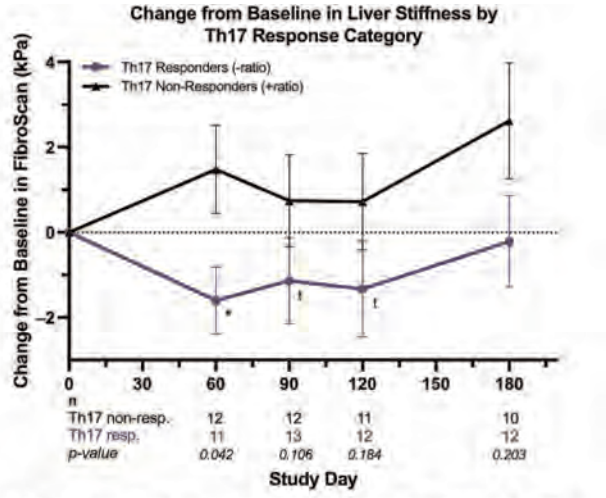

Figure 1. Antigen-specific Th17 T cell activity correlates with changes in liver stiffness. PBMCs were isolated, stimulated with DMSO (control) or PDC-E2 peptide, and enriched for antigen-specific CD4 T cells. Cells were analyzed by flow cytometry, and event counts were normalized to pre-enrich samples. Th17 CD4 T cells were gated as effector memory > CD154+CCR6+. The percentage was calculated by subtracting the normalized percent of parent in the DMSO negative control condition from the PDC-E2 stimulation condition. A Th17 responder was defined as having a Th17 ratio equal to or less than the baseline value. Liver stiffness was measured by FibroScan and had to meet validity criteria of having an IQR/median less than 30%. Mean ± SEM is shown for each timepoint. Statistical testing: Wilcoxon Rank Sum test for the median change from baseline between treatment groups; * $p \leq 0.05$; † $p \leq 0.20$.

4432 | SERUM IGM LEVELS AS A PROGNOSTIC INDICATOR OF LIVER-RELATED EVENTS IN PRIMARY BILIARY CHOLANGITIS

Taiki Okumura[1] Takanobu Iwadare[1] Shun-Ichi Wakabayashi[1] Hiroyuki Kobayashi[1] Yuki Yamashita[1] Takefumi Kimura[1], [1]Shinshu university school of medicine

Background: Elevated serum IgM levels are frequently observed in patients with primary biliary cholangitis (PBC), but few studies have examined the association between IgM and prognosis. This study aimed to investigate whether serum IgM levels could serve as a predictor of liver-related events (LREs) in PBC. **Methods:** A total of 427 patients diagnosed with PBC between at four institutions in Japan were retrospectively analyzed (273 with liver biopsy, 154 without). We assessed the association between serum IgM levels and the occurrence of LREs alongside other clinicopathological parameters. Due to sex differences in normal IgM levels, the IgM/upper limit of normal (ULN; male: 183 mg/dL, female: 269 mg/dL) ratio was used as a variable. LREs were defined as the occurrence of ascites, gastroesophageal varices, hepatic encephalopathy, or hepatocellular carcinoma. **Results:** The median age at diagnosis was 58 years, and the cohort included 70 males and 357 females. Clinical stage by Nakanuma classification was 1/2/3/4/NA in 105/126/36/6/154 patients, and ALBI grades were 1/2/3 in 325/90/12 patients. The median observation period was 9.0 years. The cumulative incidence of LREs at 20 years was 22.7%, with 39 LREs observed during the entire study period. In multivariate Cox proportional hazards analysis excluding histological factors, low serum albumin (hazard ratio [HR] 0.18, $p < 0.001$) and high IgM levels (HR 1.53, $p < 0.001$) were independently associated with LREs. Patients with IgM/ULN ≥ 1 ($n = 224$) had a significantly higher incidence of LREs than those with IgM/ULN < 1 ($n = 203$) (18.4% vs. 13.2% at 20 years, $p = 0.03$).
Further analyses in clinically earlu cases (ALBI grade 1, $n = 325$) showed that patients with IgM/ULN ≥ 1 ($n = 162$) had a significantly higher LRE incidence than those with IgM/ULN < 1 ($n = 163$) (25.3% vs. 6.1% at 20 years, $p = 0.01$). Similarly, among pathologically early cases (Nakanuma stages 1 and 2, $n = 231$), the IgM/ULN ≥ 1 group ($n = 106$) had a significantly higher incidence than the IgM/ULN < 1 group ($n = 125$) (11.4% vs. 0.8% at 20 years, $p = 0.03$). **Conclusion:** Our findings suggest that serum IgM levels are an independent predictor of LREs in PBC, even in patients with clinical and pathological early stage.

4433 | PROTOCOLLED THIOPURINE METABOLITE MONITORING LEADS TO BETTER QUALITY CARE OUTCOMES IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Cindy Ho[1] Ed Reece Ansaar[2] Joshua Abasszade[3] Ruyi Tan[1] Atul Shrestha[1] Tobie Abrahams[4] Teagan Wanigaratne[2] Suzannah Henshaw[2] Dilip Ratnam[5] Marcus Robertson[3], [1]Monash Health, Clayton, Victoria, Australia, [2]Peninsula Health, Frankston, Victoria, Australia, [3]Monash Health, Clayton, Victoria, Australia and Peninsula Health, Frankston, Victoria, Australia, [4]Alfred Health, Melbourne, Victoria, Australia, [5]Monash Health, Clayton, Victoria, Australia and Monash University, Clayton, Victoria, Australia

Background: Autoimmune hepatitis (AIH) is an immune-mediated inflammatory hepatopathy characterised by hypergammaglobulinemia, specific autoantibodies and interface hepatitis which carries a

significant risk of cirrhosis in the absence of timely and effective therapy. Initial treatment traditionally comprises glucocorticoids and a thiopurine (TP) with a view to maintaining steroid-free remission on TP monotherapy. Although well established in the inflammatory bowel disease population, the role of routine TP metabolite (TM) testing in AIH remains uncertain. We aimed to evaluate the utility of routine TM testing in TP dose-optimisation and disease remission. **Methods:** We conducted a prospective observational study of adult patients with newly diagnosed AIH who were commenced on a TP as the first steroid-sparing agent at a metropolitan tertiary health network between 2014 and 2023. International AIH Group simplified diagnostic criteria were used to standardise diagnosis of AIH. Baseline demographic, biochemical, serologic and histologic data were recorded along with TP dosing regimens and TM levels. The primary outcomes were: i) biochemical remission (alanine transaminase (ALT) <40 U/L within 12-months of diagnosis) and, ii) the frequency of TP dose adjustment following TM testing. The secondary outcome was identification of TP non-compliance and shunting. **Results:** In total, 41 patients with a male predominance (63.4%) and median age of 59 years (IQR 42-67) were included, with a median follow up time of 2.9 (IQR 1-5.4) years. At the time of diagnosis, 6 (14.6%) patients were cirrhotic, and median ALT was 1112 U/L (IQR 565-1262). Biochemical remission was achieved in 24 (58.5%) patients at 6-months and 36 (87.8%) at 12-months. Azathioprine (AZA) was commenced in 92.7% patients (median dose 100 mg daily (IQR 50-100)); the remaining 7.3% patients were commenced on 6-mercaptopurine. Median 6-thioguanine nucleotide and 6-methyl mercaptopurine levels were 220 pmol/8x10^8 RBC (IQR 129-372) and 527 pmol/8x10^8 RBC (IQR 229-1249) respectively. There was no significant difference in metabolite levels between patients who achieved biochemical remission at 12 months and those that did not. During the study period, 195 TM tests were performed, with a median of 4 (IQR 3-6) per patient. TP dose adjustment occurred following 68.6% of TM measurements. Non-compliance was identified in 29.3% patients and shunting in six patients necessitating allopurinol treatment. Six patients (14.6%) ceased TP due to side effects. One patient with identified TP shunting had a self-limiting AZA-induced liver injury. **Conclusion:** In patients with AIH treated with a TP, protocolled TM measurements optimised TPMT metabolites with high biochemical remission rates of 87.8% at 12-months. TM measurement led to TP dose alteration in 68.6% of cases and identified both medication non-compliance and metabolite shunting.

4434 | SUSTAINED EFFICACY AND SAFETY OF SELADELPAR FOR UP TO 36 MONTHS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS FROM THE PLACEBO-CONTROLLED RESPONSE STUDY TO THE OPEN-LABEL ASSURE STUDY

Cynthia Levy[1] Gideon Hirschfield[2] Eric Lawitz[3] Palak Trivedi[4] Kris Kowdley[5] Christopher Bowlus[6] Alejandra Villamil[7] Kyung min Kwon[8] Sarah Proehl[8] Xin Qi[8] Daria Crittenden[8] Stuart Gordon[9], [1]Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, FL, USA, [2]The Autoimmune and Rare Liver Disease Programme, Toronto General Hospital, Toronto, ON, Canada, [3]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, [4]University of Birmingham and University Hospitals Birmingham Queen Elizabeth, Birmingham, UK, [5]Liver Institute Northwest, Seattle, WA, USA, [6]Gastroenterology&Hepatology, University of California Davis School of Medicine, Sacramento, CA, USA, [7]The Liver Autoimmunity Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [8]Gilead Sciences, Inc., Foster City, CA, USA, [9]Wayne State University School of Medicine and Michigan State University College of Medicine, MI, USA

Background: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) combined with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in patients (pts) intolerant to UDCA. In the Phase 3, randomized, placebo (PBO)-controlled RESPONSE study (NCT04620733), SEL significantly reduced biochemical markers of cholestasis and pruritus. After completing RESPONSE, pts were eligible to enroll in ASSURE (NCT03301506), an ongoing, open-label, Phase 3 trial. Here, we report interim, long-term efficacy and safety data for pts enrolled in RESPONSE and upon rollover to ASSURE with up to 3 yrs of data. **Methods:** Data were analyzed from RESPONSE and ASSURE up to 1/31/2025. Pts with PBC with an inadequate response or intolerance to UDCA and ALP $\geq 1.67 \times$ the upper limit of normal (ULN) received blinded, daily oral SEL 10 mg or PBO in RESPONSE; pts who enrolled in ASSURE received open-label, daily oral SEL 10 mg. Pts were analyzed based on receipt of SEL (continuous SEL) or PBO (crossover SEL) in RESPONSE. Efficacy endpoints included a composite

biochemical response (CBR; ALP $<1.67 \times$ ULN, ALP decrease $\geq 15\%$, and total bilirubin $\leq$ ULN), ALP normalization, ALT normalization (among pts with ALT $>$ ULN at baseline [BL]), and ALP percent change from BL. Exposure-adjusted adverse events (AEs) were analyzed. **Results:** Of 193 pts enrolled in RESPONSE (SEL, n = 128; PBO, n = 65), 158 pts (SEL, n = 104; PBO, n = 54) enrolled in ASSURE. As of the cutoff date, 94% of continuous SEL pts (98/104) received SEL for ≥ 2 yrs and 27% (28/104) received SEL for ≥ 3 yrs; 24% of crossover SEL pts (13/54) received SEL for ≥ 2 yrs. Among continuous SEL pts, the CBR, ALP normalization, and ALT normalization rates were 69% (20/29), 24% (7/29), and 56% (10/18) through 36 months (M). Among crossover SEL pts, the CBR rate at 6M was 74% (40/54) and remained similar through 24M (85% [11/13]). Among crossover SEL pts, ALP normalized in 26% of pts (14/54) at 6M and 54% of pts (7/13) at 24M; ALP percent change from BL was also assessed (Figure). 71% (20/28) achieved ALT normalization at 6M and 75% (3/4) at 24M. Exposure-adjusted pt incidence of AEs was 90.9 per 100 pt-yrs for SEL vs 91.4 for PBO in RESPONSE; rates were generally similar or lower in yrs 2 and 3 of SEL exposure in ASSURE. **Conclusion:** Biochemical efficacy and safety with SEL in the pivotal RESPONSE study was sustained up to 36M in the open-label ASSURE study.

4435 | SEX DISPARITIES IN CLINICAL OUTCOMES AND HEALTH RESOURCE UTILIZATION IN PRIMARY BILIARY CHOLANGITIS IN THE UNITED STATES: A RETROSPECTIVE COHORT STUDY

Nisreen Shamseddine[1] Hongbo Yang[2] Su Zhang[2] Dongni Ye[2] Sherry Shi[2] Anyu Zhu[2] Julius Wilder[3], [1]Ipsen, Cambridge, MA, USA, [2]Analysis Group Inc., Boston, MA, USA, [3]Duke University School of Medicine, Durham, NC, USA

Background: Primary biliary cholangitis (PBC) is a chronic liver disease with adverse outcomes including cirrhosis and end-stage liver disease. Early diagnosis and treatments can help prevent or delay progression. While sex differences in PBC prevalence have been documented, data on PBC care by sex in the United States (US) are limited. This retrospective cohort study assessed differences in PBC treatment rates, clinical outcomes, and healthcare resource use (HRU) between males and females with PBC in the US. **Methods:** Adult patients with PBC were identified in the Komodo Research Database (01/2016–09/2023). Baseline data were assessed for 12 months before PBC diagnosis date (pre-diagnosis). Treatment rates were assessed at baseline as proportions and at follow-up (post-diagnosis; PBC diagnosis to the earliest of death, end of continuous enrollment, or end of data-cut) as time to event using Cox models comparing males and females. HRU (reported as per patient per year [PPPY]) was assessed at baseline and compared between males and females at follow-up using generalized linear models. Time to selected adverse health outcomes at follow-up were compared between males and females using Cox models (Table). All analyses at follow-up were adjusted for key baseline characteristics. **Results:** The study included 9,308 females and 2,283 males; median follow-up was 24.1 and 19.2 months, respectively. Mean age at diagnosis was comparable between males and females (57.9 versus [vs] 58.6 years; $p = 0.054$). Males, compared to females, had a significantly higher comorbidity burden (mean Charlson Comorbidity Index: 4.0 vs 2.6; $p < 0.001$) and significantly higher rates of PBC-related complications pre-diagnosis. Treatment rate was significantly lower in males pre-diagnosis (36.3% vs 42.2%; $p < 0.001$) and post-diagnosis (HR: 0.73; $p < 0.001$). Males had significantly higher risks of developing all selected adverse clinical outcomes post-diagnosis (Table). Inpatient admission number (incidence rate ratio [IRR]: 1.45; $p < 0.001$) and length of stay (IRR: 1.56; $p < 0.001$) PPPY were significantly higher in males than females post-diagnosis. **Conclusion:** This study highlights sex differences in PBC care in the US. Males had more advanced disease and a higher comorbidity burden but

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were less likely to receive treatment. Males were also more likely to have adverse outcomes related to PBC and higher HRU. These findings suggest that sex may influence both the care and clinical outcomes of PBC and should be considered in disease management.

Table. Summary of hazard ratios (95% CIs) based on adjusted Cox models comparing males vs. females, probabilities of event-free over time, and median time to event (95% CI) for adverse clinical outcomes during the post-diagnosis period

	HR (95% CI) of males vs. females	Cohort	Probability of event-free					Median time to event (95% CI) (months)
			Year 1	Year 2	Year 3	Year 4	Year 5	
Cirrhosis	1.25 (1.09, 1.38)	Male:	81.1%	75.1%	69.8%	63.4%	59.5%	Not reached
		Female:	87.1%	81.0%	76.1%	72.6%	69.0%	Not reached

4436 | A QUANTITATIVE SYSTEMS PHARMACOLOGY (QSP) MODEL TO INTERROGATE THE UNDERLYING MECHANISMS OF CHOLESTATIC PRURITUS (ITCH) IN PRIMARY BILIARY CHOLANGITIS (PBC) AND THE IMPACT OF LINERIXIBAT TREATMENT

Mario Giorgi[1] Matthias Hanke[2] Perrine Masson[2] Eulalie Courcelles[2] Janelle Lennie[3] Bishoy Hanna[3] Linda Casillas[3] Abdul-Azim Hassan[1] Sumanta Mukherjee[3] Mindy Magee[3] Megan McLaughlin[3] Jim Bosley[2] Simon Arsene[2] Hippolyte Darre[2] Anna Sher[4] Andreas Kremer[5] Brandon Swift[6], [1]GSK, Stevenage, UK, [2]Nova In Silico SA, Lyon, France, [3]GSK, Collegeville, PA, USA, [4]GSK, Waltham, MA, USA, [5]University Hospital Zurich, University of Zurich, Zurich, Switzerland, [6]GSK, Durham, NC, USA

Background: PBC is marked by impaired bile secretion in the liver, resulting in hepatic inflammation and pruritogen release into the blood. Cholestatic pruritus (itch) strongly affects patients' (pts) quality of life, yet the underlying pathophysiological mechanisms remain poorly understood. A QSP model was developed to explore these mechanisms in PBC and how they are impacted during treatment with linerixibat (IBAT inhibitor) alone or with seladelpar (peroxisome proliferator-activated receptor agonist). **Methods:** The QSP model comprises 3 modules: PBC disease, itch and treatment. The disease module describes the concentrations of known itch mediators in PBC (i.e. bile acids, bilirubin, lysophosphatidic acid [LPA; as assessed by the surrogate autotaxin] and IL-31) based on publications, the linerixibat GLISTEN study (NCT04950127) and the seladelpar ENHANCE study (NCT03602560). These biomarkers trigger an itch signal via an individual pt data-calibrated activation function of the LPAR5, MRGPRX4 and IL-31 nerve receptors in the skin to predict a WI-NRS score. The treatment module affects the PBC disease model variables, shifting the system's equilibrium after administration of linerixibat and/or

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

seladelpar. The model was calibrated using a subset of pts in GLISTEN who took both placebo and linerixibat for whom IL-31 was measured; seladelpar biomarkers and WI-NRS data were calibrated using ENHANCE data. Calibration steps allowed reproduction of pruritogen concentrations and itch scores before and after treatment, yielding digital twins for each real pt. An *in silico* clinical trial was performed; each digital twin received placebo or linerixibat (thereby acting as its own control) to investigate the characteristics of the best responders. **Results:** The model accurately captured baseline, change in biomarkers and WI-NRS scores after linerixibat, placebo or seladelpar administration. The effect of treatment on itch was quantified as mechanistic (due to changes in pruritogens; ~50%) or contextual (caused by other non-mechanistic factors e.g. placebo effect; ~50%) (Fig A). Model analysis found high heterogeneity of itch signal strengths, with 24% and 16% of pts having itch driven by bile acids and LPA, respectively, and the remaining 60% driven by an IL-31 sensitization mechanism modulated by farnesoid X receptor signaling (Fig B). In the digital twin analysis, virtual pts with high baseline IL-31 (Fig C) or a 50% IL-31 decrease after treatment were most likely to have the best itch response to linerixibat. Simulation of virtual pts receiving linerixibat or linerixibat with seladelpar revealed an additive effect in reducing itch. **Conclusion:** The QSP model highlights the heterogeneous nature of itch in pts with PBC, with IL-31 signaling an important contributor to itch and putative marker of linerixibat efficacy. Simulations also predict further itch reduction when combining linerixibat with seladelpar.

Funding: GSK (212620)

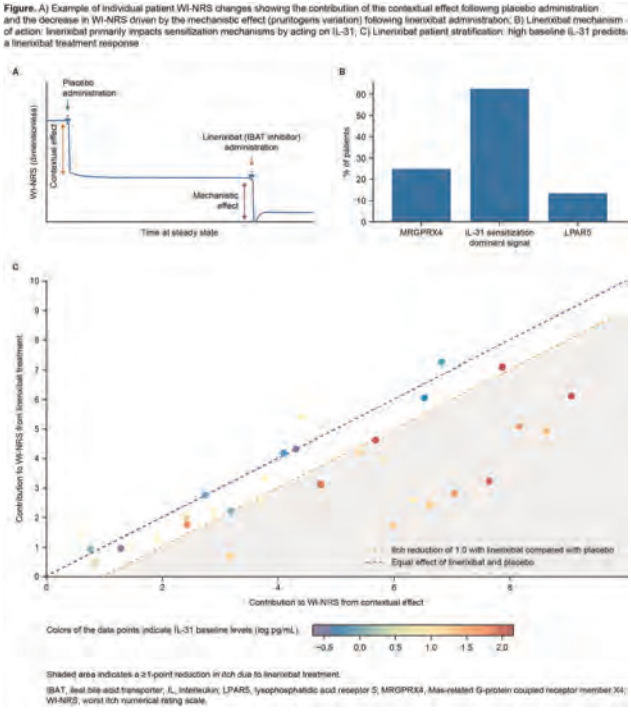

Figure. A) Example of individual patient WI-NRS changes showing the contribution of the contextual effect following placebo administration and the decrease in WI-NRS driven by the mechanistic effect (pruritogens variation) following linerixibat administration; B) Linerixibat mechanism of action: linerixibat primarily impacts sensitization mechanisms by acting on IL-31; C) Linerixibat patient stratification: high baseline IL-31 predicts a linerixibat treatment response

Background: Primary Sclerosing Cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive bile duct inflammation and fibrosis. Neutrophil infiltration and cholangiocyte activation are central features of PSC, but the spatial and molecular mechanisms underlying their interaction remain poorly defined. We aimed to elucidate the cholangiocyte–neutrophil communication axis to better understand neutrophil-mediated pathogenesis in PSC. **Methods:** GeoMx Digital Spatial Profiling on PSC and normal human liver tissues (stained for cholangiocytes [CK19] and neutrophils [neutrophil elastase, NE]) was interrogated with pathway, cell-scoring, CellChat, and Euclidean distance analysis. Single-cell, single-nucleus RNA sequencing (scRNA-seq, snRNA-seq), and bulk RNA-seq datasets from human PSC livers were integrated with our spatial data. Mechanistic studies in primary murine and human cholangiocytes were performed using RNA-seq, RT-PCR, western blot, immunohistochemistry (IHC), and immunofluorescence (IF). **Results:** Spatial transcriptomic profiling revealed a marked increase in neutrophil degranulation and neutrophil extracellular traps (NETs) formation pathway activity in the periportal regions of PSC livers compared to healthy controls. Quantitative inflammatory cell scores, reflecting the relative abundance and activation of cholangiocytes and neutrophils, were significantly elevated in PSC tissues (cholangiocyte score: mean 1.4 vs. 0.4, $p < 0.05$; neutrophil score: mean 2.0 vs. 1.4, $p < 0.05$).Cell-cell communication analysis using CellChat identified the Macrophage Migration Inhibitory Factor (MIF)–CD74 axis as the predominant signaling axis for neutrophils and cholangiocytes. Spatial proximity analysis confirmed that cholangiocytes and neutrophils expressing MIF and CD74, respectively, exhibited higher density at a shorter Euclidean distance among the analyzed ligand-receptor pairs, suggesting spatially confined signaling. Integrated transcriptomic analysis further revealed significantly increased MIF expression (3-fold, $p < 0.05$) in PSC-associated neutrophils. RNA-seq of primary mouse cholangiocytes from a cholestatic model showed 7-fold upregulation of Cd74 ($p < 0.0001$), while human cholangiocytes stimulated with TNFα exhibited an 8-fold increase in CD74 expression ($p < 0.01$). Concordantly, IHC and IF confirmed elevated MIF and CD74 protein expression in periportal neutrophils and cholangiocytes in PSC liver tissue. **Conclusion:** Our multimodal analysis uncovers a novel, spatially localized neutrophil–cholangiocyte communication axis in PSC livers mediated by the MIF–CD74 signaling pathway. This pathway likely drives NET formation, cholangiocyte activation, and sustained inflammation in the periportal niche, offering new insights into disease pathogenesis and potential therapeutic targets.

4438 | EFFICACY AND SAFETY OF SELADELPAR VS. ELAFIBRANOR IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A MATCHING-ADJUSTED INDIRECT COMPARISON

David Jones[1] Robert Gish[2] Cynthia Levy[3] Howard Thom[4] Gianluca Baio[5] Marvin Rock[6] Chong Hoon Kim[6] Mirko von Hein[7] Oskar Eklund[8] Ryan Thaliffdeen[6] Barinder Singh[9] Akanksha Sharma[9] DILIP MAKHIJA[6] Gideon Hirschfield[10], [1]Institute of Cellular Medicine & NIHR Newcastle Biomedical Research Centre, Newcastle University, UK, [2]Robert G. Gish Consultants, LLC, San Diego, CA, USA and Hepatitis B Foundation, Doylestown, PA, USA, [3]University Of Miami Miller School Of Medicine, Miami, Florida, USA, [4]Bristol Medical School, University of Bristol, UK, [5]University College London, London, UK, [6]Gilead Sciences, Inc., Foster City, CA, USA, [7]Gilead Sciences, UK, [8]Gilead Sciences Sweden AB, Solna, Sweden, [9]Pharmacoevidence, SAS Nagar Mohali, India, [10]The Autoimmune and Rare Liver Disease Programme, Toronto General Hospital, Toronto, Canada

Background: Seladelpar and elafibranor are recently approved second-line treatments for primary biliary cholangitis (PBC), both improving alkaline phosphatase (ALP) levels. However, only seladelpar significantly improves pruritus. We conducted an indirect treatment comparison (ITC) of their biochemical efficacy and safety in adult PBC patients using data from the RESPONSE and ELATIVE trials. **Methods:** Due to significant heterogeneity in effect modifiers, biochemical response thresholds, and placebo responses among trials, an anchored matching-adjusted indirect comparison (MAIC) was performed in accordance with UK NICE TSD 18 guidance. Individual-level data from RESPONSE were adjusted for age, ALP, bilirubin, and cirrhosis rates to match ELATIVE baseline characteristics. Binary biochemical efficacy endpoints of ALP normalization ($\leq$1 upper limit of normal [ULN]) and the composite biochemical response (ALP $<$ 1.67$\times$ULN, $\geq$15% ALP decrease from baseline, and total bilirubin $\leq$1.0$\times$ULN) were recalculated to account for differences in ULN thresholds for ALP and total bilirubin for a robust ITC. Additional efficacy comparison involved ALP change from baseline (CFB), which is not sensitive to normal range differences. Safety was compared based on the incidence of overall treatment emergent adverse events (TEAEs), pruritus as TEAE, and all-cause discontinuations. Several sensitivity analyses were conducted, including an unanchored MAIC for the composite response outcome, which adjusts for population imbalances between treatments without relying on a common comparator. **Results:** Seladelpar showed numerically better results for ALP normalization and ALP CFB, while a numerically lower effect was observed for the composite biochemical endpoint; none of the results were statistically significant (Table 1). In the unanchored MAIC, seladelpar was associated with a numerically better composite response. Seladelpar was also associated with lower odds of overall TEAEs, pruritus as TEAE, and all-cause discontinuations. Sensitivity analyses results were aligned with the base case. **Conclusion:** Using a robust MAIC approach to address heterogeneity, seladelpar demonstrated overall numerically better biochemical efficacy and improved safety compared to elafibranor; however, statistical significance was not achieved.

Table 1: MAIC results for comparison between seladelpar 10 mg vs. elafibranor 80 mg at 12 months

ALP normalization	Composite response	ALP change from baseline	Pruritus as TEAE*	Any TEAE*	All-cause discontinuations
RR (95% CI)		MD (95% CI)	OR (95%CI)		
1.66 (0.03, 85.54)	0.70 (0.13, 3.78) 1.02 (0.76,1.36)†	-30.43 (-97.84, 36.99)	0.35 (0.06, 2.10)	0.37 (0.06, 2.24)	0.46 (0.11, 4.06)

ALP: Alkaline Phosphatase; CI: Confidence Interval; MD: Mean Difference; OR: Odds Ratio; RR: Risk Ratio; TEAEs: Treatment-emergent adverse events; *At least one event recorded for any TEAE and pruritus as TEAE, which were reported over a longer follow-up in the ELATIVE trial (data in the 48 EPOCH); †Unanchored MAIC results using four effect modifiers

4439 | REAL-WORLD ADHERENCE TO PRIMARY BILIARY CHOLANGITIS CARE GUIDELINES: A U.S. SINGLE-CENTER COHORT STUDY

Ana Marenco-Flores[1] Natalia Rojas-Amaris[1] Romelia Barba[2] Daniela Goyes[3] Tamara Kahan[1] Denisse Rubio Cruz[1] Esli Medina Morales[4] Behnam Saberi[5] Vilas Patwardhan[1] Alan Bonder[5], [1]Beth Israel Deaconess Medical Center, [2]Texas Tech University, [3]Yale School of Medicine, [4]Rutgers New Jersey Medical School, [5]Beth Israel Deaconess Medical Center, Harvard Medical School

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease that, without early diagnosis and appropriate treatment, can progress to cirrhosis and liver failure. Although international guidelines provide clear recommendations for biochemical monitoring, ursodeoxycholic acid (UDCA) dosing, symptom assessment, and escalation to second-line therapy, gaps in care delivery remain common in clinical practice. The 90:90 PBC care initiative sets an aspirational standard, aiming for 90 percent of patients to receive 90 percent of the recommended care, with a focus on timely intervention, individualized treatment, and comprehensive disease management. This study aims to evaluate the alignment of real-world PBC care at a single U.S. tertiary center with the targets set by the 90:90 initiative. **Methods:** We conducted a prospective cohort study of 150 patients with PBC at a U.S. tertiary care center to assess adherence to guideline-based care at 6- and 12-month follow-up. Evaluated components included UDCA dosing, biochemical response, symptom assessment, risk stratification, and treatment escalation, using the 90:90 PBC Care Initiative benchmarks. Statistical analyses included t-tests, Mann–Whitney U, Kruskal–Wallis, and chi-square tests, with significance set at $P < 0.05$. **Results:** We evaluated 150 patients with PBC, predominantly female (91%) and White (77%), with a mean age at diagnosis of 55 years. The majority received ursodeoxycholic acid (UDCA) (79%; mean dose 13.4 mg/kg), and median follow-up was 13.4 months. Autoimmune overlap (AIH or PSC) was present in 38%, and 11% had cirrhosis at diagnosis. Compared to the UK-PBC audit and 90:90 targets, our center met or exceeded benchmarks for UDCA initiation (93% at 6 months, 95% at 12 months), second-line therapy escalation (74%, 76%), and cirrhosis surveillance (96%, 89%). However, optimal UDCA dosing (65% and 72%) and symptom assessment (79% and 59%) fell short. Bone health evaluation reached only 50% by 12 months. Fibrosis staging (86%) and variceal screening (91%) also exceeded UK-PBC rates and targets. **Conclusion:** Structured PBC care pathways met 90:90 benchmarks for UDCA initiation, therapy escalation, and cirrhosis surveillance but fell short on dosing and symptom monitoring. Embedding UDCA dose protocols and standardized patient assessments into care bundles is necessary for closing these gaps and improving outcomes.

4440 | TREATMENT OUTCOMES AND UNDERUTILIZATION OF SECOND-LINE THERAPIES FOR PRIMARY BILIARY CHOLANGITIS IN LATIN AMERICA: A CALL TO BRIDGE THE GAP

Claudia Couto[1] Guilherme Cancado[2] Maria Lucia Ferraz[3] Debora Terrabuio[4] Alejandra Villamil[5] Lorena Castro Solari[6] Graciela Elia Castro Narro[7] Ezequiel Ridruejo[8] Cristiane Villela-Nogueira[9] Marlen Fernandez[10] Daniela Chiodi[11] Carla Enrique[11] Paulo Bittencourt[12] Gustavo Pereira[13] Fernando Bessone[14] Eira Cerda[15] Rodrigo Zapata[16] Hugo Cheiquer[17] Manuel Mendizabal[18] Liliana Mendes[19] Alvaro Urzua[20] Pablo Murillo[21] Janaina Narciso-Schiavon[22] Rafaela Lynch[23] Raimundo Gama[3] Ana Cristina Amaral[3] Mario Pessoa[4] Sarah Rufino[4] Eduardo Cançado[4] Andreina Fragenas[5] Vinicius Alcanter[2] Natalia Sobenko[5] Fernanda Gelape[2] Franco Vuskovic[6] Gabriel Puentes[6] Mirta Peralta[8] Harlim Rodriguez[10] Vivian Rotman[9] Federico Orozco[24] Nelia Hernandez[11], [1]Federal University of Minas Gerais, [2]Universidade Federal de Minas Gerais, Brasil, [3]Universidade Federal de São Paulo, Brasil, [4]Hospital das Clínicas da Universidade de São Paulo, Brasil, [5]Hospital Italiano de Buenos Aires, Argentina, [6]Clínica Universidad de los Andes, Chile, [7]Instituto Nacional de Ciencias Medicas y Nutrición " Salvador Zubirán" Ciudad de Mexico, Mexico, [8]Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC", Buenos Aires, Argenti, [9]Universidade Federal do Rio de Janeiro, Brasil, [10]Instituto de Gastroenterología de Cuba, [11]Unidad Académica Gastroenterologia, Hospital de Clinicas, Uruguay, [12]Hospital Português, Salvador, Bahia, [13]Hospital Federal Bonsucesso, Brasil, [14]Hospital Provincia del Centenario (Facultad de Medicina de Rosario), [15]Hospital Central Militar do Mexico, [16]Clínica Alemana de Santiago, Chile, [17]Hospital de Clínicas de Porto Alegre, Brasil, [18]Hospital Universitário Austral Pilar, Argentina, [19]Hospital de Base do Distrito Federal, Brasil, [20]Hospital Clínico Universidad de Chile, [21]Hospital Dr. Rafael Ángel Calderón Guardia, Costa Rica, [22]Universidade Federal de Santa Catarina, Brasil, [23]Faculdade de Medicina Universidade Estácio de Sá (IDOMED), [24]Hospital Alemán, Buenos Aires

Background: Approximately 40% of patients with primary biliary cholangitis (PBC) exhibit an incomplete biochemical response to ursodeoxycholic acid (UDCA) and require add-on therapy. Data on treatment outcomes and clinical practice in Latin America remain scarce. This study aims to evaluate the treatment outcomes of PBC patients from Latin America. **Methods:** This is an ongoing, retrospective, international multicenter cohort study (ALLATIN) sponsored by ALEH, enrolling PBC patients from several Latin American countries. **Results:** Data from 1,204 PBC patients (92.3% female; mean age at diagnosis 53 $\pm$ 13 years) from the ALLATIN database were reviewed to assess treatment outcomes. Median follow-up was 80 months (IQR 30–133). Cirrhosis was present at diagnosis in 22.2%, and 30.2% developed advanced liver disease during follow-up. Patients with overlap syndrome with autoimmune hepatitis (AIH) (N = 164) were excluded from the treatment analysis. UDCA was prescribed to 975 patients (95.2%). At 12 months, 27.7% normalized alkaline phosphatase (ALP), 60.8% and 46.6% met Toronto and POISE criteria, respectively. Deep response (normalized ALP with bilirubin $<$ 0.6 $\times$ ULN) was obtained in 15.3%. Fibrates (bezafibrate, fenofibrate or ciprofibrate) were used in 28.8%, mostly for incomplete response (67.4%) and pruritus (15.4%). Only 31-41% of those with incomplete UDCA response received second-line therapies. Liver transplantation was performed in 5.5%, while 8.6% died. The combined endpoint (liver transplantation or death) occurred at a median follow-up of 67 months (IQR 28–116) and were independently associated with cirrhosis at diagnosis (OR = 7.12, 95%CI: 4.4-11.6; p $<$ 0.001) and UDCA response by POISE criteria (OR = 0.39; 95%CI: 0.2-0.7); 1- and 5-year transplant-free survival were 84.5 $\pm$ 0.4% and 52.4 $\pm$ 0.5%, respectively. **Conclusion:** Response to UDCA as first line PBC therapy was lower than expected. Second-line therapies remain underused in Latin America, highlighting a critical gap evidence-based recommendations and real-world clinical practice in the region. Addressing this gap requires urgent action from healthcare systems, prioritizing physician awareness, the implementation of targeted educational initiatives, and expanded access to second-line therapies to improve patient outcomes.

4441 | PRIMARY BILIARY CHOLANGITIS: ANALYSIS OF GENDER DIFFERENCES IN DISEASE PROGRESSION AND TIME TO HEPATIC DECOMPENSATION

Jade Pace[1] Michael Attanasi[1] Maham Ghani[1] Brittany Kwait[1] Christopher Dorizas[1] Bryana Belin[2] Shahidul Islam[1] Sanjaya Satapathy[1], [1]Zucker School of Medicine at Hofstra/Northwell, [2]Zucker School of Medicine at Hofstra

Background: Primary biliary cholangitis (PBC) is an autoimmune disease leading to the destruction of small bile ducts. Although initial studies favored PBC as a female-dominant condition, more recent research suggests a female-male ratio closer to 4-6:1. Additionally, males may present with more severe disease, but such data is sparse and limited by underdiagnosis. We conducted a retrospective cohort study to investigate if the male gender is associated with more severe disease and poorer outcomes. **Methods:** All patients above 18 years of age with an ICD-10 code diagnosis of PBC and positive anti-mitochondrial antibody titer $\geq$1:40 were identified over the past 10 years at 23 Northwell Care sites. The primary outcome of interest was the development of cirrhosis. A multiple logistic regression model was utilized to assess odds of cirrhosis. A subgroup analysis was performed of cirrhotic patients within this population that were followed for at least 90 days. Categorical variables were compared using Chi-squared tests. The log-rank test was used to compare Kaplan-Meier survival curves between male and female groups for time to decompensation, defined as a composite of first occurrence of ascites, bilirubin >3.0, encephalopathy, or esophageal GI bleed. **Results:** Of 378 patients with PBC, 47 (12%) were male, the median age was 71 years, and 67% were non-Hispanic White. Of 93 cirrhotic patients followed for at least 90 days, 17 (18%) were male, the median age was 72 years, and 61% were non-Hispanic White. Demographics and clinical characteristics were generally similar between male and female patients, with the exception of alcohol use disorder, which was more prevalent in males (14% vs 0%, $p=0.047$). Overall, there was an adjusted odds ratio of 1.98 (95% Confidence Interval [CI] [1.01-3.89], $p=0.048$) of males versus females in the development of cirrhosis. Among cirrhotic patients, no significant difference in time to decompensation was observed between males and females (Hazard Ratio [HR] 1.11, 95% CI [0.52-2.38], $p=0.788$). Mortality rates showed a trend toward being higher in males (41% vs 18%, $p=0.056$), though this did not reach statistical significance. **Conclusion:** Overall, male gender was found to be an independent predictor of cirrhosis in patients with PBC. Despite some baseline differences in alcohol use disorder history, time to decompensation was similar between male and female cirrhotic patients. Further research with larger sample sizes is needed to better understand gender-specific factors affecting disease progression in cirrhosis.

Table 1. Key Characteristics and Outcomes by Gender in Cirrhotic Patients with Primary Biliary Cirrhosis with ≥ 90 Day Follow-Up

	Female (n=76)	Male (n=17)	P-value
Characteristic			
Age, median (IQR)	71 (61, 78)	73 (57, 79)	0.800
Non-Hispanic White, n (%)	46 (61%)	11 (65%)	0.749
MELD 3.0, median (IQR)	15.0 (10.0, 20.0)	15.0 (13.5, 18.0)	0.657
Clinical Event			
Decompensation Events*	HR 1.11 (95% CI [0.52-2.38])	Reference	0.788
Mortality, n (%)	14 (18%)	7 (41%)	0.056
Treatment			
Ursodiol Use, n (%)	46 (61%)	11 (65%)	0.749
Steroid Use, n (%)	18 (24%)	8 (47%)	0.073

*Decompensation defined as first occurrence of esophageal GI bleed, ascites, encephalopathy, or bilirubin >3.0.

IQR = Interquartile Range; HR = Hazard Ratio; CI = Confidence Interval

4442 | SYMPTOM BURDEN AND TREATMENT PATTERNS IN PRIMARY BILIARY CHOLANGITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hon Lam CHUNG[1] Jarell Jie-Rae TAN[2] Roe Xin Jacqueline YAP[1] Jing Hong LOO[3] Wei Xuan TAY[3] Corrine Lee SINGH[2] Shi Jie ONG[2] Aidan Yuan Jie LOW[2] Yikun LIN[1] Ellina Lytvyak[4] Andrew Mason[4] Aldo J Montano-Loza[4] YU JUN WONG[5], [1]Duke-NUS Medical School, [2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [3]Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, Singapore, [4]Division of Gastroenterology & Hepatology, University of Alberta, Edmonton, Canada, [5]Duke-NUS Medical School, Singapore

Background: Patients with primary biliary cholangitis (PBC) often suffer debilitating symptoms, yet the overall symptom burden has not been systematically quantified. This study aims to systematically review the prevalence and severity of the symptom burden in PBC patients. **Methods:** We conducted a systematic search of three electronic databases from inception to 24th May 2025, including studies that reported the prevalence and severity of PBC symptoms. Subgroup analyses were performed based on study type, publication year, risk of bias, geographical region, gender, and latitude.

Results: A total of 25 studies involving 13,178 patients were included. The most commonly used symptom evaluation tool was the PBC-40 questionnaire, employed in 64% of the studies (16 out of 25). Fatigue was the commonest symptom, affecting 51% of patients PBC(51%, 95%CI: 42%-60%, $I^2 = 96\%$, 13 studies), followed by pruritus at 34% (95%CI: 29%-40%, $I^2 = 92\%$, 13 studies). Severe fatigue and severe pruritus were reported in 23% (95%CI: 16%-30%, $I^2 = 95\%$, 9 studies) and 10% of patients (95%CI: 4%-18%, $I^2 = 94\%$, 5 studies), respectively. The prevalence of fatigue was significantly higher in more recent studies ($p < 0.01$), those with smaller sample sizes($p = 0.0009$), and studies published as abstracts($p = 0.03$). Fatigue was significantly greater in female patients compared to males (standard mean difference = 3.3, 95% CI: 1.5-5.1; $p < 0.01$, 4 studies). Severe fatigue was more prevalent among Caucasian patients than in non-Caucasians (26% vs 8%, $p = 0.0005$), and in studies with a higher proportion of cirrhotic patients (28% vs 8%, $p = 0.0005$). Despite the high burden, only 38% of PBC patients with pruritus received antipruritic treatment (95% CI: 20%-59%, $I^2 = 92\%$, 7studies), with antihistamines being the most frequently prescribed medication, being used in 22% of patients (95%CI: 10%–50%, $I^2 = 95\%$, 4 studies). **Conclusion:** Nearly half of PBC patients experience significant symptom burden, with significant ethnic disparities. There remains an unmet need for standardized assessment, consistent reporting, and improved management strategies for PBC-related symptoms in future research.

4443 | PREDICTING URSODEOXYCHOLIC ACID TREATMENT RESPONSE IN PRIMARY BILIARY CHOLANGITIS USING MULTIMODAL DEEP LEARNING FRAMEWORK

Ii liu[1] Mujun Liu[2] Dong Zhao[1] Liangjun Zhang[1] Jin Chai[1], [1]Southwest Hospital, Third Military Medical University, [2]School of Biomedical Engineering and Medical Imaging,Third Military Medical University

Background: Ursodeoxycholic acid (UDCA) remains the sole first-line therapy for primary biliary cholangitis (PBC), yet 40% of patients exhibit a suboptimal response. Current predictive models based on single-modal parameters (clinical, histopathology or microbiome) show limited discriminative power due to incomplete characterization of pathobiological heterogeneity. We developed Prognostic Cross-Attention Multi-Modal (ProCAMM), a transformer-based multimodal framework integrating pretreatment histopathology, serum proteomics, and clinical parameters to address this critical unmet need. **Methods:** From a retrospective PBC cohort (ChiCTR2400086289), 168 treatment-naïve patients with complete histopathology (H&E whole-slide images), serum proteomics, and clinical data were analyzed. UDCA response was assessed by Paris II criteria after $\geq$6-month therapy. ProCAMM architecture comprises: 1) UNI-derived N x 1024-dimensional histopathological embeddings from 20x whole-slide images; 2) Self-normalizing networks processing 2707-protein panel and 40 clinical parameters; 3)Cross-modal attention mechanism enabling dynamic interaction among three models' feature

spaces; 4) Kronecker product-based tensor fusion with gated attention. Model performance was evaluated against unimodal and early-fusion baselines using five-fold cross-validation bu calculating mean area under the receiver operating characteristic curve (AUROC). **Results:** ProCAMM achieved superior discriminative performance (mean AUROC 0.721 ± 0.10) versus histopathology (0.557 ± 0.06), proteomics (0.621 ± 0.15), clinical (0.650 ± 0.09) and early-fusion models (0.579 ± 0.06). SHAP analysis identified ALP and total bilirubin as top clinical predictors. Key proteomic drivers included EH domain-binding protein 1, cathepsin B, G protein α-14, Chromosome 2 Open Reading Frame 88, and Cell Death-Inducing DFFA-Like Effector B. Histopathological attention mapping localized predictive features to interlobular bile ducts. **Conclusion:** As the first multimodal artificial intelligence framework for PBC prognosis, ProCAMM integrates histomorphometric and molecular signatures to enable clinically actionable UDCA response prediction. Biologically interpretable features highlight bile-duct-centric pathomechanisms and metabolic regulators, supporting risk stratification and combination therapy design. Future studies will validate the correlation between therapeutic targets and diseases progression, potentially guiding FXR agonist-based therapies.

Background: Primary biliary cholangitis (PBC) may manifest differently based on factors such as ethnicity and genetic background. Latin America is characterized by a highly admixed population with unique genetic diversity compared to other regions, yet data on PBC in this region remain scarce. This study aims to characterize the epidemiological profile of PBC in Latin America using data from the ALLATIN cohort. **Methods:** This is an ongoing, retrospective, international multicenter cohort study sponsored by ALEH, enrolling PBC patients from several Latin American countries. **Results:** Data were collected from 1,204 patients across Latin America: Brazil (48.3%), Argentina (23.4%), Chile (10.8%), Mexico (7.4%), Cuba (3.7%), Uruguay (3.3%), Costa Rica (1.1%), and others. Most patients were female (92.3%), with a mean age at diagnosis of 53 ± 13 years. Cirrhosis was present at baseline in 22.2%. The median follow-up was 80 months (IQR 30–133). An overlap with autoimmune hepatitis was identified in 13.6% of cases, while MASLD was present in 4.2%. At diagnosis, 78.8% of patients were symptomatic, most commonly with pruritus (41.5%) and fatigue (28.9%). Anti-mitochondrial antibodies (AMA) were positive in 76.8%, antinuclear antibodies (ANA) in 71.6%, and the anticentromere pattern was found in 6.0%. Among patients tested, anti-gp210 was positive in 9.1% (n = 318) and anti-sp100 in 8.8% (n = 317). The most frequent associated extrahepatic autoimmune diseases were Hashimoto's thyroiditis (13.6%) and Sjögren's syndrome (8.5%). Other comorbidities at diagnosis were type II diabetes (11%), systemic arterial hypertension (24%), dyslipidemia (22%), obesity (8%)

and 13% osteopenia/osteoporosis. Liver biopsy at diagnosis was performed in 601 patients (58.7%), with fibrosis stages distributed as follows: F1 (18.6%), F2 (18.6%), F3 (14.8%), and F4 (13.3%). **Conclusion:** This is the largest cohort to date describing the epidemiology of PBC in LA. The findings reveal notably lower rates of AMA positivity compared to other regions, which may have contributed to higher rates of liver biopsy at baseline, as well as a predominance of symptomatic presentation at diagnosis. These insights underscore the need for increased disease awareness, earlier detection strategies, and improved diagnostic techniques across the region. The data provide a critical foundation for future region-specific approaches to the diagnosis, management, and research of PBC.

4445 | CHARACTERIZATION OF PRODROMAL EVENTS PRECEDING THE DIAGNOSIS OF PEDIATRIC AUTOIMMUNE HEPATITIS- A RETROSPECTIVE STUDY

Forum Patel[1] Liyun Zhang[1] Ke Yan[1] Bernadette Vitola[2] Cara Mack[1], [1]Medical College of Wisconsin, [2]Children's Hospital of Wisconsin - Milwaukee, WI

Background: Pediatric autoimmune hepatitis (AIH) is a chronic, immune-mediated liver disease that can progress to liver failure if untreated. Early diagnosis is challenging due to nonspecific presenting symptoms. Identifying prodromal symptoms may enable earlier recognition and improve outcomes. **Methods:** A retrospective chart review of patients < 18 years diagnosed with AIH between 2009–2024 was conducted at a tertiary pediatric center. Patients with other chronic liver diseases (Wilson disease, hepatitis B/C, alpha-1 antitrypsin deficiency, hereditary hemochromatosis) or post-transplant AIH were excluded. Data collected included demographics, presenting symptoms, lab values, liver histology, and immunosuppressive therapies. Prodromal symptoms within four weeks of AIH evaluation were categorized as gastrointestinal (GI), systemic, or upper respiratory (URI). Data were analyzed using descriptive and comparative statistics ($p < 0.05$). **Results:** A total of 95 patients were identified: mean age at presentation 12.5 $\pm$ 4 years, median time from presentation to diagnosis 35 days, 64% female, 75% White, 77% non-Hispanic, 82% AIH type 1. At least one prodromal symptom was identified in 61% ($n = 58$) of patients. No significant differences in age, sex, race/ethnicity, or insurance status were observed between cohorts with or without prodromal symptoms. Among symptomatic patients, GI symptoms (abdominal pain, vomiting, diarrhea) were most common (48%), followed by systemic symptoms (fatigue, fever) (23%) and URI symptoms (congestion, cough, rhinorrhea) (16%). All patients received steroids; 73% received azathioprine. At 6 months, 36% achieved biochemical remission, which was more likely in those with prodromal symptoms (50% vs. 21%, $p = 0.005$). Jaundice was present in 25%, and 95% of these jaundiced patients had prodromal symptoms ($p < 0.0001$). Patients with jaundice had shorter time to steroid initiation ($p = 0.001$). **Conclusion:** Prodromal symptoms occurred in the majority of pediatric AIH patients and were associated with higher remission rates and shorter time to treatment. GI symptoms were most common and, when present with jaundice, appeared to expedite diagnosis. Early recognition of

4446 | BISPHOSPHONATE TREATMENT IS NOT ASSOCIATED WITH DECREASED FRACTURE RISK IN PRIMARY BILIARY CHOLANGITIS PATIENTS WITH OSTEOPOROSIS

Leandro Sierra[1] Hussam Kawas[1] Rachel McNulty[2] Juan Armijos[3] Xaralambos Zervos[3] Omar Sims[1] Dian Chiang[1], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic Akron, [3]Cleveland Clinic Florida

Background: Bisphosphonates (BP) improves bone mineral density (BMD) and are recommended for patients with osteoporosis. However, its benefit on fracture prevention remains unclear in Primary Biliary Cholangitis (PBC) patients with osteoporosis. We aimed to assess the relationship between BP use and fracture risk in PBC patients with osteoporosis. **Methods:** We retrospectively (2005-2025) studied women with diagnosis of PBC based on AASLD guideline and age-matched post-menopausal controls at two U.S. tertiary centers. Groups were stratified by BP exposure. BP exposure was defined as $\geq$6 months of continuous BP therapy. Baseline covariates and the main outcome of incidental fracture were calculated. Before modeling, coarsened-exact matching (CEM) on lowest T-score and lumbar BMD was conducted. CEM-weighted mixed-effects logistic regression modeled fracture odds by PBC status, BP use, follow-up time, and PBC $\times$ BP-time interaction. Mixed-effects model predicted yearly fracture BP-exposure risk. **Results:** Among 598 women $\geq$ 65 years old (289 PBC, 339 controls), fractures were more frequent in PBC (83 %) vs controls (40 %) among BP users and 43 % vs 35 % among non-users ($p < 0.001$). Mean fracture burden mirrored this excess (0.72 vs 0.50 fractures per patient in BP users and 1.69 vs 0.74 in non-users; $p < 0.001$). Notably, 50 % of PBC fractures occurred despite BP initiation, compared with 21% in BP-treated controls ($p < 0.001$). CEM-weighted regression found no independent PBC effect ($\beta = 0.99 \pm 0.74$, $p = 0.18$) and no PBC $\times$ time interaction ($\beta = 0.18 \pm 0.12$, $p = 0.13$). Nonetheless, mixed-effects estimates showed 10-year fracture probability rising from 76 % to 87 % in PBC but falling from 53 % to 28 % in controls. **Conclusion:** BP therapy is protective against fracture in post menopause women with osteoporosis but not protective against age-matched women with PBC, with rising 10-year fracture risk despite BP exposure. These findings suggest continued progression of metabolic bone disease and fracture risk unique to PBC population and underscores the need for additional therapeutic approach in this population.

4447 | IMMUNE PROFILING IN AUTOIMMUNE HEPATITIS IDENTIFIES DISTINCT HHV-6 ANTIGENS AND AUTOREACTIVITY TO THE RELAXIN FAMILY PEPTIDE RECEPTOR 1

Arielle Klepper[1] James Asaki[1] Andrew Kung[1] Sara Vazquez[1] Aaron Bodansky[1] Anthea Mitchell[1] Sabrina Mann[1] Kelsey Zorn[1] Isaac Avila-Vargas[1] Swathi Kari[1] Melawit Tekeste[1] Javier Castro[1] Briton Lee[1] Maria Duarte[2] Mandana Khalili[1] Monica Yang[2] Paul Wolters[1] Jennifer Price[1] Emily Perito[1] Sandy Feng[1] Jacquelyn Maher[1] Jennifer Lai[1] Christina Weiler-Normann[1] Ansgar Lohse[3] Joseph DeRisi[1] Michele Tana[1], [1]University of California, San Francisco, [2]britonlee88@gmail.com, [3]University Medical Centre Hamburg-Eppendorf

Background: Autoimmune hepatitis (AIH) is a severe disease characterized by elevated immunoglobulin levels. However, the role of autoantibodies in the pathophysiology of AIH remains uncertain. **Methods:** Phage Immunoprecipitation-Sequencing (PhIP-seq) was employed to identify autoantibodies in the serum of patients with AIH (n = 115), compared to patients with other liver diseases (metabolic associated steatotic liver disease (MASH) n = 178, primary biliary cholangitis (PBC), n = 26, or healthy controls, n = 94). **Results:** Logistic regression using PhIP-seq enriched peptides as inputs yielded a classification AUC of 0.81, indicating the presence of a predictive humoral immune signature for AIH. Embedded within this signature were disease relevant targets, including SLA/LP, the target of

a well-recognized autoantibody in AIH, disco interacting protein 2 homolog A (DIP2A), and the relaxin family peptide receptor 1 (RXFP1). The autoreactive fragment of DIP2A was a 9-amino acid stretch nearly identical to the U27 protein of human herpes virus 6 (HHV-6). Fine mapping of this epitope suggests the HHV-6 U27 sequence is preferentially enriched relative to the corresponding DIP2A sequence. Antibodies against RXFP1, a receptor involved in anti-fibrotic signaling, were also highly specific to AIH. The enriched peptides are within a motif adjacent to the receptor binding domain, required for signaling and serum from AIH patients positive for anti-RFXP1 antibody was able to significantly inhibit relaxin-2 singling. Depletion of IgG from anti-RXFP1 positive serum abrogated this effect. **Conclusion:** Conclusions: These data provide evidence for a novel serological profile in AIH, including a possible functional role for anti-RXFP1, and antibodies that cross react with HHV6 U27 protein.

Impact and implications: Our work has uncovered new aspects of antibody-mediated pathogenesis in AIH and opened new avenues for mechanistic studies on the role of herpesviruses, in particular HHV6, in the development of AIH.

4448 | INCREASED FRACTURE BURDEN IN PRIMARY BILIARY CHOLANGITIS COMPARED TO POST-MENOPAUSAL CONTROLS: A RETROSPECTIVE MULTICENTER STUDY

Leandro Sierra[1] Hussam Kawas[1] Rachel McNulty[2] Juan Armijos[3] Sara Valencia[1] Xaralambos Zervos[3] Omar Sims[1] Dian Chiang[1], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic Akron, [3]Cleveland Clinic Florida

Background: Primary biliary cholangitis (PBC) is associated with increased risk of metabolic bone disease. The risk of osteoporosis and fracture increases with progression to cirrhosis. However, the risk and burden of bone fracture in PBC cohort compared to age-matched post-menopause population remains unclear. **Methods:** We performed a retrospective cohort study (2005–2025) across two tertiary centers, including women ≥65 years with diagnosis of PBC based on AASLD guideline and age-matched post-menopausal controls without liver disease. Exclusion criteria included liver transplant, cirrhosis, or other liver disease. Age was balanced using coarsened exact matching. Primary outcome was incident fracture; secondary outcomes

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

included time-to-fracture and fracture count. Cox models adjusted for T-score, BMI, comorbidities, and osteoporosis therapy. Kaplan-Meier analysis evaluated time-to-fracture. **Results:** The study included 289 women with PBC and 339 controls (mean age 77.6 ± 4.8 years). Rates of osteopenia (50.7% vs 48.7%) and osteoporosis (29.7% vs 25.6%) were similar ($p = 0.43$). At the time of fracture, 83% of PBC patients were on ursodiol (mean disease duration: 86.9 ± 55.0 months). Fracture incidence was higher in the PBC group (47.4% vs 36.0%, $p = 0.004$), with more fractures per patient (0.82 vs 0.55, $p = 0.003$) and earlier fracture onset post-age 65 (109 vs 137 months, $p = 0.03$; log-rank $p = 0.02$). Use of osteoporosis-related medications (33.3% vs 30.6%), bisphosphonates, denosumab, and hormonal therapies was similar. Vitamin D supplementation (82.1% vs 74.9%, $p = 0.11$) and baseline vitamin D levels (30.7 vs 34.6 ng/mL, $p = 0.41$) were also comparable. PBC patients had significantly higher ALP levels (248 vs 88 U/L, $p < 0.001$). In multivariable analysis, PBC remained independently associated with increased fracture risk (HR 1.64, 95% CI 1.01–2.25, $p = 0.05$). **Conclusion:** PBC is associated with a significantly higher and earlier fracture burden than age-matched post-menopausal controls, independent of bone density, T-scores and current medical therapy. These findings suggest increased risk and burden of bone fracture in PBC compared to age matched post-menopause controls. Further study to identify risk factors of metabolic bone disease progression is needed to reduce fracture burden in PBC population.

4449 | ANTI-IL-23P19 AUTOANTIBODY: A HIGH-SENSITIVITY DIAGNOSTIC BIOMARKER FOR ANTIMITOCHONDRIAL ANTIBODY-NEGATIVE PRIMARY BILIARY CHOLANGITIS

Jia Zhou[1] jingyuan zhou[1] Hongqin Xu[1] Yanhang Gao[1], *[1]The First Hospital of Jilin University*

Background: Antimitochondrial antibody (AMA) serves as a pivotal diagnostic marker for primary biliary cholangitis (PBC). However, a subset of PBC patients test negative for AMA, classified as AMA-negative PBC. For these patients, non-invasive diagnosis remains challenging. Given that PBC arises from abnormal activation of the hepatic immune system, leading to attacks on bile duct epithelial cells, we focused on investigating levels of autoantibodies closely associated with immunity in PBC patients, including immune checkpoint antibodies and anti-cytokine autoantibodies (ACAAs). The objective of this study was to explore novel diagnostic biomarkers for AMA-negative PBC, with the goal of identifying more sensitive biomarkers to enable early diagnosis. **Methods:** In the initial phase of autoantibody discovery, serum samples from 9 AMA-negative PBC patients and 31 healthy controls (HC) were analyzed for 30 immune-related autoantibodies. Subsequently, an expanded cohort comprising 36 AMA-negative PBC patients, 29 disease control group members (autoimmune hepatitis), and 117 HC was was used to validate the diagnostic performance of the screened candidate antibodies, specifically IL-23P19 antibodies. The eukaryotic cell-expressed target protein antigens, including IL-23P19, IL-17A, IFN-γ, IL-6, TGF-β, CD4, IL-6Rα, IL-6Rβ, IFN-α, IL-1α, IL-3Rα, IL-4, IL-10, LAG-3, IL-22, IL-37, IL-8, CTLA-4, BAFF, CD3, TIM-3, TSLP, PD-1, FcRn, OX40L, ICOS, CD8, PD-L1, TNF-α, and CD20, were utilized to bind with specific antibodies in the samples. The antigen-antibody complexes were detected via protein tag-based chromogenic reactions. The optical signal intensity was measured using a microplate reader and expressed as relative light units (RLU). All samples were analyzed in duplicate. **Results:** The serum levels of anti-IL-23p19 antibodies in AMA-negative PBC patients are significantly higher than those in HC and disease controls ($p < .001$). Compared to other antibodies, the anti-IL-23p19 antibody assay demonstrated higher sensitivity (ranging from 83.3% to 94.4%) and specificity (ranging from

62.1% to 84.6%) in diagnosing AMA-negative PBC, with areas under the curve (AUC) of 0.937 and 0.794 for distinguishing AMA-negative PBC from healthy individuals and disease controls, respectively. At a cutoff value of 76,530 RLU, sensitivity declined to 83.3% compared to healthy populations, while specificity improved to 91.5%. When compared to AIH, sensitivity also decreased to 83.3%, but specificity markedly increased to 62.1%, reducing the misdiagnosis risk by approximately 30%. Although the diagnostic sensitivity decreased by an absolute 11.1% at the 76,530 RLU cutoff, specificity for healthy populations and AIH improved by 6.9% and 30.8%, respectively, significantly optimizing clinical differential diagnostic performance. Therefore, to balance the risks of missed diagnosis and misdiagnosis, a cutoff value of 76,530 RLU is recommended for diagnostics.Furthermore, the positivity rate of anti-IL-23p19 antibodies (83.3%) was markedly higher than that of anti-sp100 (27.8%) and anti-gp210 (30.6%) antibodies in AMA-negative PBC patients. When this novel biomarker was combined, the diagnostic sensitivity of gp210/sp100 antibodies increased from 47.2% to 88.9%. **Conclusion:** The incorporation of IL-23p19 antibody testing into AMA and ANA serological assays significantly enhances the clinical diagnostic efficacy for PBC, particularly in AMA-negative subjects. Building upon established evidence of constitutive IL-23/Th17 axis overactivation in PBC, future multicenter studies should expand cohorts to systematically collect paired serum and liver biopsy specimens from AMA-negative PBC patients. Integrated analysis of serological autoantibody profiles, tissue-specific antibody localization, and ductal injury phenotypes will elucidate the mechanistic contributions of IL-23p19 antibodies to disease pathogenesis.

4450 | THE PSC-DM: DEVELOPMENT AND VALIDATION OF A CLINICAL DIAGNOSTIC MODEL TO AID THE DIAGNOSIS OF PRIMARY VS. SECONDARY SCLEROSING CHOLANGITIS IN CLINICAL PRACTICE

Miki Scaravaglio[1] Rodrigo Motta[2] Laura Cristoferi[3] Cesare Maino[3] Alberto Marini[4] Eugenia Nofit[3] Eugenia Pesatori[5] Camilla Gallo[6] Francesca Bolis[4] Daphne D'Amato[7] Armando Curto[8] Alessio Gerussi[9] Raffaella Viganò[6] Mauro Viganò[5] Stephen Rossi[10] Kris Kowdley[11] Pietro Invernizzi[9] Alessandra Nardi[12] Marco Carbone[13] Emma Culver[14], [1]University of Milano-Bicocca, University of Cambridge, [2]John Radcliffe Hospital, and Nuffield Department of Medicine, University of Oxford, [3]Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, [4]University of Milano-Bicocca, [5]Hepatology Unit, ASST Papa Giovanni XXIII, Bergamo, Italy, [6]ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy, [7]University of Turin, [8]University of Florence, [9]Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, University of Milano-Bicocca, [10]PSC Partners Seeking a Cure, Greenwood Village, Colorado, USA, [11]Liver Institute Northwest and Elson S. Floyd College of Medicine, Washington State University, [12]Department of Mathematics, University of Rome Tor Vergata, Rome, Italy, [13]ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy, University of Milano-Bicocca, [14]John Radcliffe Hospital, and Nuffield Department of Medicine, University of Oxford, NIHR Oxford BRC

Background: Sclerosing cholangitis are a spectrum of chronic cholestatic diseases, marked by progressive fibro-inflammatory destruction of the biliary tree leading to biliary cirrhosis. It can be primary (immune-mediated) or secondary to various identifiable insults. Diagnostic uncertainty between the aetiologies is common and may affect patient management and patient selection in clinical trials. This study aimed to develop and validate a clinical diagnostic tool to differentiate primary sclerosing cholangitis (PSC) from secondary sclerosing cholangitis (SSC). **Methods:** We conducted a multicentre analysis of adult cases of sclerosing cholangitis from three tertiary liver centres in Italy. Patients were classified as PSC or SSC according to international guidelines. We performed a multivariate logistic regression analysis in the derivation cohort to identify predictors of PSC diagnosis and validated it in the external cohort. **Results:** Among 234 patients in the derivation cohort (155 PSC and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

79 SSC), six baseline variables were independently associated with PSC: younger age at diagnosis ($p < 0.0001$), presence of IBD ($p < 0.0001$), absence of prior abdominal surgery ($p < 0.0001$), presence of autoimmune comorbidities ($p = 0.0038$), family history of autoimmune diseases ($p = 0.0086$), and absence of pancreatic abnormalities ($p = 0.0338$). These variables were used to develop a predictive model for PSC diagnosis (PSC-DM) with an area under the receiver operating characteristic curve (AUROC) of 0.989 (95% confidence interval (CI) 0.980-0.998). External validation in 144 patients (99 PSC and 45 SSC), confirmed high discrimination ability (AUROC 0.945, 95% CI 0.907-0.983) (Figure 1). **Conclusion:** We derived and externally validated a model based on routinely available clinical parameters that accurately differentiates PSC from SSC, with the potential to streamline patient referral, guide personalised treatment strategies, and enhance clinical trial selection.

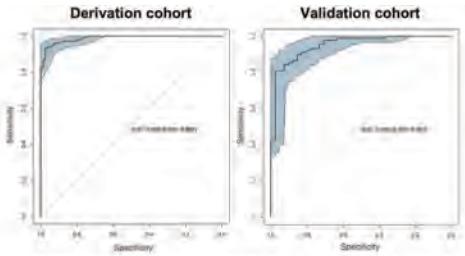

Figure 1: AUROC for the prediction of PSC diagnosis calculated by the PSC-DM in the derivation and validation cohort.

4451 | MACHINE LEARNING PREDICTS RESPONSE TO OBETICHOLIC ACID THERAPY AND IDENTIFIES PROGNOSTIC PATHWAYS LINKED WITH PRIMARY BILIARY CHOLANGITIS

Hussain Syed[1] Ning Sun[2] Doaa Waly[2] Varinder Verma[2] Matthew Smith[1] Mohamad Osman[1] Mary Erickson[3] Katherine Siminovitch[4] Andrew Mason[1] David Shapiro[5], [1]University of Alberta, [2]Mason Lab - University of Alberta, [3]Intercept Pharma, [4]Sinai Health, [5]Integrated Quality Resources

Background: Biomarkers associated with disease progression in PBC are not well characterized. To address this, we applied machine learning to whole-blood transcriptomic data from PBC patients in the POISE clinical trial, where treatment response was classified by POISE criteria, and from a prospective clinical cohort, where disease progression was defined by clinical outcomes or estimated using the GLOBE score. **Methods:** Transcriptomic data from POISE study patients and the prospectively collected cohort was analyzed to identify genes and pathways with prognostic significance. Support vector machine was used to identify 1200 candidate prognostic genes in both cohorts which were analyzed using Ingenuity Pathway Analysis (IPA). A genetic algorithm then selected an optimal 105 gene-panel which was trained on POISE end-of-treatment ($n = 53$), tested on POISE baseline ($n = 88$) and validated on the prospective cohort ($n = 63$). Transcriptomic profiles of biliary epithelial cells (BECs) from PBC patients ($n = 4$) and non-cholestatic controls ($n = 5$) were compared to assess overlap using gene set enrichment analysis (GSEA) to identify prognostic pathways. **Results:** Our model achieved an AUROC of 0.83 in the test baseline POISE and 0.88 in the validation prospective cohort, outperforming alkaline phosphatase (test: 0.80 and validation: 0.73) and bilirubin (test: 0.64 and validation: 0.81). IPA of ML derived prognostic genes highlighted pathways associated with poor outcomes. These included autoimmune inflammation (similar to complement activation in rheumatoid arthritis and multiple sclerosis), immune regulation (loss in CD155 expression linked with CD8 and NK cell activation), epithelial-to-mesenchymal transition (MMP and KRT associated tissue remodelling), integrated stress response (upregulated PTGER1 and RLN3 involved in oxidative stress) and altered metabolism (diminished ADORA1 indicating impaired mitochondrial function). To assess whether these prognostic pathways provide a distinct transcriptomic signature in PBC peripheral blood, we performed GSEA on BEC RNA-seq comparing PBC vs. non-cholestatic liver disease cholangiocytes. We observed a comparable dysregulation in the biliary epithelium potentially linking the systemic transcriptomic signature with tissue specific pathogenesis. **Conclusion:** The machine learning approach identified transcriptional changes associated with PBC progression previously observed in PBC, such as complement activation in autoimmune disorders, epithelial-to-mesenchymal transition and abnormal mitochondrial signalling. The dysregulated gene expression supports the hypothesis that PBC is a systemic disease sharing a similar pathology in whole blood and biliary epithelium that warrants further investigation.

4452 | TREATING ITCH IN PRIMARY BILIARY CHOLANGITIS – WHAT IS A CLINICALLY MEANINGFUL CHANGE IN THE WORST ITCH NUMERICAL RATING SCALE?

Brooke Currie[1] Katelyn Cutts[2] Yipin Han[3] Ren Yu[2] Marlyn Mayo[4] David Jones[5] Megan McLaughlin[1] Heather Gelhorn[3], [1]GSK, Collegeville, PA, USA, [2]Evidera, Bethesda, MD, USA, [3]Evidera|PPD, Wilmington, NC, USA, [4]University of Texas Southwestern Medical Center, Dallas, TX, USA, [5]Newcastle University, Newcastle, UK

Background: Cholestatic pruritus is common in primary biliary cholangitis (PBC), affecting up to 89% of patients. A statistically significant reduction in pruritus was seen with linerixibat in the pivotal Phase 3 study (GLISTEN; NCT04950127). The Worst Itch Numerical Rating Scale (WI-NRS; range: 0–10) was the patient-reported outcome (PRO) item underlying the primary and several key secondary endpoints in GLISTEN, which included responder analyses. Understanding what amount of change in the WI-NRS represents meaningful improvement for patients is critical when assessing clinical relevance of antipruritic treatment. Analyses were conducted to determine the meaningful change threshold (MCT) for the WI-NRS. Exploratory MCT analyses were also conducted for the Sleep Interference NRS (SI-NRS), a single PRO item designed to assess itch-related sleep interference. **Methods:** Analyses were performed on interim blinded GLISTEN data (July 2024). Anchor-based methods were used with the Patient Global Impression of Severity (PGI-S) and Change (PGI-C) as primary and supportive anchor items, respectively. Correlations between WI-NRS/SI-NRS change scores and PGI scores were assessed to determine appropriateness of the anchors. Data from patients with a 1-point PGI-S improvement from baseline and those who responded "moderately improved" on PGI-C at Week 24 were prioritized when determining the MCTs, given that a majority of these patients also reported having "meaningful" improvement in itch based on their response to a meaningful change question (yes/no). Distribution-based methods examining standard deviation (SD) and standard error of measurement (SEM) values were used as supporting evidence. **Results:** WI-NRS and PGI-S data at both baseline and Week 24 were recorded in 137 participants; 140 participants had baseline and Week 24 WI-NRS and Week 24 PGI-C data. Change in WI-NRS correlated strongly with change in PGI-S ($r = 0.68$) and PGI-C ($r = 0.64$); both $p < 0.001$. Among patients reporting meaningful improvement in itch at Week 24, mean change (SD) in WI-NRS was –3.1 (1.7) for the 1-point PGI-S group and –3.2 (2.1) for the "moderately improved" PGI-C group. Distribution -based estimates for change in WI-NRS were 0.42 (0.25 SD), 0.84 (0.5 SD), and 0.71 (SEM). Cumulative distribution function plots (Figure 1) illustrate change in WI-NRS scores by anchor response. Slightly lower estimates of meaningful change were observed for SI-NRS (mean change [SD] of –2.8 [2.1] and –2.7 [2.2] for key PGI groups). **Conclusion:** A 3-point reduction in WI-NRS was identified as an appropriate MCT for patients with PBC and moderate to severe itch, as this improvement was meaningful to most GLISTEN participants. Although a preliminary MCT of 2.8 for SI-NRS was identified, further validation is warranted using concept-specific anchors. MCTs are critical for interpretation of PRO measures and help facilitate responder endpoint analyses.

Funding: GSK (212755).

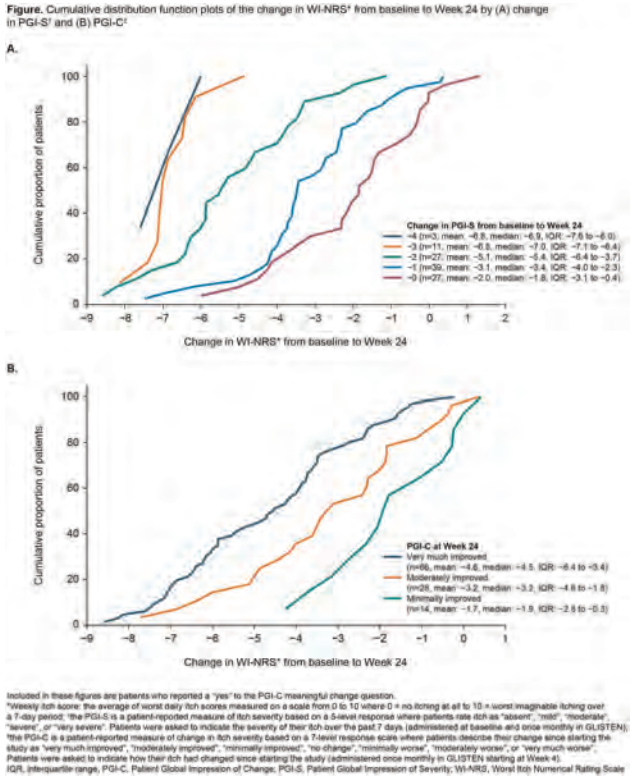

Figure. Cumulative distribution function plots of the change in WI-NRS* from baseline to Week 24 by (A) change in PGI-S† and (B) PGI-C‡

Included in these figures are patients who reported a "yes" to the PGI-C meaningful change question.
*Weekly itch score: the average of worst daily itch scores measured on a scale from 0 to 10 where 0 = no itching at all to 10 = worst imaginable itching over a 7-day period; †the PGI-S is a patient-reported measure of itch severity based on a 5-level response where patients rate itch as "absent", "mild", "moderate", "severe", or "very severe". Patients were asked to indicate the severity of their itch over the past 7 days (administered at baseline and once monthly in GLISTEN); ‡the PGI-C is a patient-reported measure of change in itch severity based on a 7-level response scale where patients describe their change since starting the study as "very much improved", "moderately improved", "minimally improved", "no change", "minimally worse", "moderately worse", or "very much worse". Patients were asked to indicate how their itch had changed since starting the study (administered once monthly in GLISTEN starting at Week 4).

4453 | CLINICAL AND PATHOLOGICAL CHARACTERISTICS OF ACUTE-ONSET AND CHRONIC AUTOIMMUNE HEPATITIS AND THE SIGNIFICANCE OF ANTI-PD-1 AUTOANTIBODIES

Takashi Oda[1] Akinobu Takaki[1] Kenichi Harada[2] Teruko Arinaga-Hino[3] Masanori Abe[4] Takeshi Matsui[5] Atsushi Takahashi[6] Yoshiyuki Suzuki[7] Nobuhiro Nakamoto[8] Hiromasa Ohira[6] Atsushi Tanaka[9] Kazuyuki Matsumoto[1] Nozomi Miyake[1] Masahiko Sue[1] YASUTO TAKEUCHI[1] Hideki Onishi[1] Motoyuki Otsuka[1], [1]Okayama University, [2]Kanazawa University Graduate School of Medical Sciences, [3]Kurume University School of Medicine, [4]Ehime University Graduate School of Medicine, [5]Teine-Keijinkai Hospital, [6]Fukushima Medical University School of Medicine, [7]Toranomon Hospital, [8]Keio University, [9]Teikyo University School of Medicine

Background: Acute-onset autoimmune hepatitis (A-AIH) often presents diagnostic challenges due to the frequent absence of autoantibodies or low IgG levels. Since autoimmune hepatitis is characterized by various autoantibodies, an immunosuppressive molecule PD-1 may also be a potential target of autoantibody. To evaluate the clinical and pathological significance of circulating anti-PD-1 autoantibodies, we investigated their association with both clinical and histological characteristics of A-AIH and chronic AIH (C-AIH). **Methods:** Serum samples from 73 cases of A-AIH and 45 cases of C-AIH were analyzed. Anti-PD-1 antibody levels were measured using an ELISA assay and evaluated based on absolute values. Furthermore, in 51 cases that underwent liver biopsy (A-AIH: 15, C-AIH: 36), the relationship between histological findings and anti-PD-1 antibody levels was evaluated. **Results:** The median age was 59 years (A-AIH [A]: 56, C-AIH [C]: 63). Median peak AST, ALT, and total bilirubin levels were 404 U/L (A: 674, C: 155), 467 U/L (A: 766, C: 180), and 2.3 mg/dL (A: 7.9, C: 1.25), respectively. The median of the lowest PT-INR was 1.09 (A: 1.16, C: 1.035), and high-titer ($\geq$80x) ANA positivity was observed in 55% of cases (A: 53%, C: 57%). Compared to C-AIH, A-AIH patients were significantly younger and had higher AST, ALT, ALP, and γ-GTP levels, along with lower PT-INR. Anti-PD-1 antibody levels were significantly higher in A-AIH than in C-AIH, with median levels of 0.0705 μg/mL (A: 0.0915, C: 0.0564). Logistic regression analysis of significant parameters identified AST, PT-INR, and anti-PD-1 antibody levels as significant factors to discriminate A and C.

Pathologically, high antibody levels were observed in cases with marked lobular necrosis/inflammation and dense plasma cell infiltration in the hepatic parenchyma, although no differences were found in relation to the presence or absence of centrilobular necrosis (CN). In the portal area, high antibody levels were associated with marked inflammatory and plasma cell infiltration, interface hepatitis, and emperipolesis. In A-AIH cases, no correlation was observed between histological findings and antibody levels. However, in C-AIH, higher levels were seen in cases with intense lobular inflammation and interface hepatitis. **Conclusion:** Serum anti-PD-1 antibody levels were significantly higher in A-AIH compared to C-AIH. As these levels were not associated with CN, which is influenced by hemodynamic factors, the antibody appears to reflect immune activity. Therefore, anti-PD-1 autoantibody may serve as a useful marker of immune-mediated inflammation.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease historically diagnosed with lab testing and liver biopsy. As anti-mitochondrial antibody (AMA) testing has demonstrated high specificity (95%) and sensitivity (92%) for PBC, guidelines do not require histologic confirmation of concurrent elevated alkaline phosphatase (ALP). However, studies with small cohorts suggest that AMA may be falsely positive in steatotic liver disease (SLD), autoimmune hepatitis (AIH), and cirrhosis, leading to the potential misdiagnosis of PBC. To address the limitations of this knowledge gap, our study assessed the diagnostic accuracy of AMA among patients with liver biopsy in a large multi-ethnic cohort. **Methods:** 1736 AMA-positive tests were identified among Kaiser Permanente Northern California patients $\geq$18 years-old from 2005-2018. 616 (36%) had a liver biopsy within 12 months of the AMA result. Liver biopsy reports were reviewed by a hepatopathologist and clinical hepatologist and deemed consistent with PBC (including overlap with AIH or SLD) or demonstrating non-PBC alternate diagnoses such as SLD, AIH, or viral hepatitis. Baseline demographics, comorbidities and lab tests were compared between AMA-positive patients with liver biopsy demonstrating PBC versus alternative diagnosis. Lastly, patients were grouped by ALP levels – elevated versus normal – to see how this correlated with biopsy findings. **Results:** Among the 616 AMA-positive patients with liver biopsy, 38% had alternative histologic diagnoses: SLD (13%), AIH (4%), Hepatitis C (2%), and nondiagnostic (17%). Patients with PBC on liver biopsy were older ($p = 0.003$), female ($p < 0.001$), and had higher ALP ($p < 0.001$), ALT ($p = 0.05$) and AMA level/titer ($p < 0.001$) (Table1). Those with PBC had a higher prevalence of hyperlipidemia ($p < 0.01$) and lower rates of type 2 diabetes and hypertension (Table 1). When grouping by ALP levels, 71% had elevated ALP level, of whom 26% had biopsy with non-PBC diagnosis. In those with normal ALP levels, 34% had histological findings that correlated with PBC. **Conclusion:** Elevated AMA levels, while classically thought to be pathognomonic for PBC, were not always diagnostic for PBC, even in patients with elevated ALP. Despite meeting laboratory criteria for PBC, 26% of patients had histological findings of an alternate diagnosis, largely SLD. In the subset of AMA-positive patients with elevated ALP levels, those with PBC on biopsy had ALP (median 235) over two times and AMA levels (median 103) over five times the upper limit of normal and higher AMA titers (median 320). Our findings suggest that a subset of AMA-positive patients may benefit from a liver biopsy for an accurate diagnosis.

Background: To increase our confidence in alkaline phosphatase (ALP) as a potential surrogate marker in patients with primary biliary cholangitis (PBC), it is important to substantiate the prognostic relevance of ALP within the context of second line therapy. We evaluated ALP changes following off-label bezafibrate (BZF) therapy, and examined the on-treatment ALP levels in relation to clinical outcome in a real world setting. **Methods:** All consecutive patients initiating fibrates in the Dutch PBC Cohort Study – a retrospective nationwide cohort study – were included. Biochemical changes (expressed in upper limits of normal) during the first year of treatment were assessed. Survival analyses were used to assess cumulative discontinuation rates and rates of clinical disease progression, defined as occurrence of either liver decompensation, liver transplantation or death. Considering the early and profound biochemical response to BZF, time 0 was defined as the date of the first on-treatment ALP measurement after 90 days. A (mean)age-adjusted cubic spline function was applied to visualize the relation between ALP and the estimated hazard of clinical disease progression. **Results:** In total, 317 individuals (290 [92%] females) initiated fibrate therapy (98% BZF). At baseline, median age was 55.3 (IQR 48.4-64.4) year, median ALP was 2.30 (IQR 1.52–3.36) and TB was 0.58 (IQR 0.41–0.92). Total median follow-up was 30.4 (IQR 18.0-50.4) months, 241(76%) individuals were treated for at least 9 months at time of last data collection. At 12 months, the cumulative BZF cessation rate was 24.6% (95%CI 19.7–29.5). The overall on-treatment median ΔALP and ΔTB at 12 months were -1.00xULN (IQR -1.50 to -0.49) and -0.06xULN (IQR -0.20 to 0.05), respectively. Higher logALP levels during fibrate therapy were associated with a higher risk of clinical disease progression (age-adjusted HR 3.29 [per ULN], 95%CI 1.76-6.16, $p < 0.001$) (Fig.), as were higher logTB levels (age-adjusted HR 7.82, 95%CI 3.99-15.32, $p < 0.001$). Sensitivity analysis showed stable results: the aHR of logALP was 3.11 (95%CI 1.67–5.79) if further adjusted for cirrhosis, and 6.17 (95%CI 2.23-16.2, $p < 0.001$) if time 0 was set as the on-treatment ALP levels around one year of BZF therapy. **Conclusion:** In this nationwide cohort study, ALP levels declined following the initiation of BZF therapy, but a quarter of patients stopped within the first year in this real-world setting. Lower ALP levels during BZF therapy were associated with a lower risk of solid clinical endpoints. Confirming this in the setting of second-line therapy further strengthens the case for ALP as a relevant endpoint in PBC drug development.

4456 | WOMEN WITH AUTOIMMUNE HEPATITIS ON AZATHIOPRINE HAVE SIMILAR OBSTETRIC OUTCOMES COMPARED TO THOSE NOT ON AZATHIOPRINE: A GLOBAL RETROSPECTIVE COHORT STUDY

Mikaela Nikkola Jara-Tantoco[1] Justin Riley Lam[1] Urvya Iyer[1] FNU Deepali[1] Maria Lagarde Mussa[2], [1]Jefferson Einstein Philadelphia Hospital, [2]Jefferson Einstein Hospital

Background: Women with autoimmune hepatitis (AIH) have often been treated with azathioprine through their pregnancy. There remains a theoretical risk of increased teratogenicity with these agents although previous studies have not seen this.[1,2] A meta-analysis looked at the effects of 6-mercaptopurine and azathioprine on pregnancy outcomes in individuals with inflammatory bowel disease.[2] However, there have only been smaller studies looking at this therapeutic agent in women with AIH.[3]

Our study aims to look at the pregnancy outcomes of women diagnosed with AIH on azathioprine (+AZ), comparing them to women diagnosed with AIH who are not on the medication (-AZ). **Methods:** TriNetX, a global health research network, with deidentified data was queried on May 21-27, 2025. Women aged 18 to 50 years old who had AIH (International Classification of Diseases [ICD-10] K75.4) were included. Comparison groups were AZ+ compared to AZ-. The index event considered was the diagnosis of AIH. Outcomes studied included pregnancy, premature birth, abortion, preeclampsia, eclampsia, gestational diabetes, and suspected teratogenicity with exclusion of those who had these outcomes prior to the index event. Statistical analyses performed were hazard ratio (HR), 95% confidence interval (CI), mean, standard deviation (SD), and p values <0.05 were considered as significant. Propensity score matching was performed for traditional risk factors that lead to high-risk pregnancy, medications, and laboratory values (Table 1). **Results:** Prior to propensity score matching, there were 3,296 AZ+ patients and 11,860 AZ- patients. After propensity score matching, there were 2,900 AZ+ and AZ- patients. There was a mean follow-up of 1510 ± 1291 days and 1040 ± 1141 days for AZ+ and AZ- patients, respectively. There were no differences in pregnancy (HR 0.977 [95% CI 0.722, 1.323]), preterm pregnancy (HR 1.199 [95% CI 0.934, 1.539]), abortion (HR 1.071 [95% CI 0.646, 1.776]), preeclampsia (HR 1.801 [95% CI 0.330, 9.836]), eclampsia (HR 2.616 [95% CI 0.271, 25.201]), gestational diabetes (RR 0.535 [95% CI 0.280, 1.019]), and visits for suspected teratogenicity (RR 1.105 [95% CI 0.723, 1.689]) between groups (all $p > 0.05$).

Dissimilar to previous findings, the use of azathioprine in our study does not increase the risk of preterm pregnancy.[1,2] With addressing traditional risk factors that lead to worse obstetric outcomes, there was no difference between groups. Ensuring that the disease process in AIH with or without the use of azathioprine leads to similar outcomes in pregnant patients.

This study is limited due to it being a database review and is dependent on accuracy of ICD coding. Determining outcomes of birth could not be ascertained as this was de-identified data with restriction of congenital outcomes. Only visits for suspected teratogenicity could be included. **Conclusion:** Women with AIH on azathioprine have similar obstetric outcomes as women with AIH not on azathioprine.

TABLE 1: Comparing characteristics before and after propensity matching.

	Before matching			After matching		
Characteristic	Azathioprine (n=3,269)	No azathioprine (n=12,567)	p value	Azathioprine (n=2,922)	No azathioprine (n=2,922)	p value†

4457 | PERFORMANCE OF THE GLOBE SCORE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS TREATED WITH SECOND-LINE THERAPY

Esmée Eikelenboom[1] Ellen Werner[1] Vincenzo Ronca[2] Gideon Hirschfield[3] Hin Hin Ko[4] George Dalekos[5] Gemma Weijsters[1] Nora Cazzagon[6] Christophe Corpechot[7] Atsushi Tanaka[8] Ellina Lytvyak[9] Aldo Montano-Loza[9] Ana Lleo[10] Pietro Invernizzi[11] Palak Trivedi[12] Umberto Vespasiani-Gentilucci[13] Henriette Ytting[14] Leandro Sierra[15] Romelia Barba[15] Alan Bonder[15] Emma Culver[16] Antonio De Vincentis[13] Laura Cristoferi[2] Alessio Gerussi[11] Miki Scaravaglio[11] Mauro Viganò[17] Marco Carbone[11] Alejandra Villamil[18] Xavier Verhelst[19] Cynthia Levy[20] Frederik Nevens[21] Ehud Zigmond[22] Vincenza Calvaruso[23] Nadir Abbas[12] María-Carlota Londoño[24] Nikolaos Gatselis[5] Adriaan van der Meer[25] Bettina Hansen[26], [1]Erasmus MC, [2]University of Milan-Bicocca, [3]Toronto General Hospital, [4]Pacific Gastroenterology Associates, [5]University of Thessaly, [6]University of Padova (Padua), [7]Hôpital Saint-Antoine, APHP, [8]Teikyo University School of Medicine, [9]University of Alberta, [10]Humanitas University, [11]University of Milano-Bicocca, [12]University of Birmingham, [13]Policlinico Universitario Campus Bio-Medico di Roma, [14]Rigshospitalet / Amager-Hvidovre University Hospital, [15]Beth Israel Deaconess Medical Center, Harvard Medical School, [16]John Radcliffe Hospital, [17]ASST Papa Giovanni XXIII, [18]Hospital Italiano de Buenos Aires, [19]Ghent University Hospital, [20]University of Miami, [21]University Hospitals KU Leuven, [22]Sheba Medical Center, [23]University of Palermo, [24]Hospital Clinic Barcelona, [25]Erasmus University Medical Center, [26]Erasmus MC Rotterdam

Background: The GLOBE score is a continuous prognostic model for liver transplant–free survival in primary biliary cholangitis (PBC), based on UDCA-treated patients from 1990 to 2012. The performance of the GLOBE score in patients diagnosed more recently and treated with UDCA or in combination with second-line therapies is unknown. This study aims to assess the prognostic performance of the GLOBE score in more recently diagnosed patients treated with UDCA or UDCA in combination with second-line therapy. **Methods:** An international multicenter cohort study was conducted using data from four different centers within the Global PBC study group. Patients with an available GLOBE score one year after the start of first- and/or second-line therapy were included. An event was defined as liver transplantation (LT) or death. The discriminative ability of the GLOBE score at one year after start of UDCA and one year after start of add-on second-line therapy for liver transplantation or death was evaluated using Harrell's C-index. Predictive accuracy was assessed with calibration plots. **Results:** A total of 1,070 patients (1,014, 94.8% females) were included, of which 286 (26.7%) were diagnosed after 2014. The median age was 52.7 years (IQR 43.1–62.0). After one year of UDCA, the median total bilirubin was 0.6 x ULN (IQR 0.4–0.8) and the median ALP level was 1.0 x ULN (IQR 0.7–1.6). During a median follow-up of 6.5 years (IQR 2.9–11.8), 152 patients underwent LT or died. A total of 166 patients (15.5%) were treated with second line therapy (fibrates n = 88, OCA n = 78), with a median follow-up of 3.2 years (IQR 1.7–3.7) thereafter (12 events). The C-index of the GLOBE score was 0.86 (95% CI 0.85–0.88) for the overall cohort, 0.94 (95% CI 0.89–0.98) for the subgroup diagnosed after 2014, and 0.91 (95% CI 0.87–0.96) among second line therapy users. Calibration appeared reasonable in those using second-line therapy (figure 1), though the model tended to overestimate liver transplant-free survival in high-risk groups. This pattern was observed in those diagnosed after 2014 and in the overall cohort as well. **Conclusion:** The GLOBE score maintains a high discriminative ability in a recent PBC population, including those treated with second-line therapy. Further studies with longer follow-up are needed to assess if calibration is sufficient for clinical decision making or whether recalibration of the model is required.

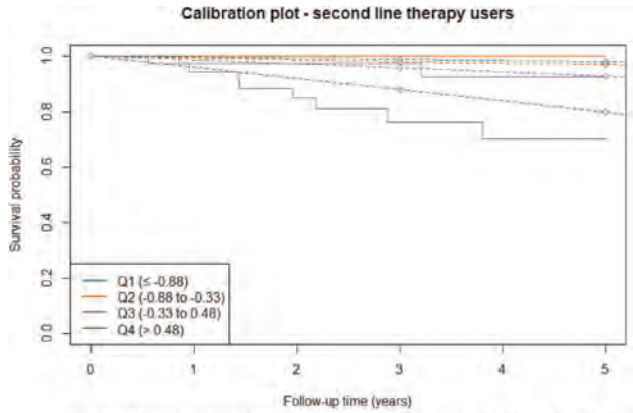

Figure 1: Dashed and straight lines represent the predicted and observed survival, respectively

4458 | MECHANISTIC INSIGHTS INTO THE PROTECTIVE EFFECTS OF FAECALIBACTERIUM PRAUSNITZII AND ITS METABOLITE SHORT CHAIN FATTY ACIDS ON BILIARY INJURY IN PRIMARY BILIARY CHOLANGITIS

Ronghua Jin[1] Qi Wang[1] Xiaoxue Yuan[1] Song Yang[1] Xi Wang[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease that primarily affects middle-aged women. Studies suggest that alterations in the gut microbiome are closely associated with the pathogenesis and treatment of PBC, but the underlying mechanisms remain unclear. **Methods:** This study first conducted gut microbiota analysis of fecal samples from PBC patients and healthy controls using metagenomic sequencing, with LEfSe and other methods employed to identify differential microbial taxa. Subsequently, a bile duct ligation (BDL) mouse model was established and treated with *F. prausnitzii* (1×10^9 CFU/day), while ductular reaction and liver fibrosis were evaluated through histopathological staining. For in vitro experiments, a GCDC-induced injury model using human primary biliary epithelial cells (HiBECs) was developed, followed by treatment with varying concentrations of short-chain fatty acids (SCFAs). Furthermore, ChIP assays were performed to detect H3K27ac modification levels, elucidating the specific mechanism by which SCFAs exert their effects through epigenetic regulation of the ELF3/PI3K-Akt pathway. All data were statistically analyzed using two-tailed t-tests/ANOVA with FDR correction ($P < 0.05$ considered statistically

significant). **Results:** We found that *F. prausnitzii* was significantly reduced in the gut microbiota of PBC patients. Supplementation with *F.prausnitzii* markedly ameliorating BDL-induced biliary injury, including cholangitis, bile duct hyperplasia, and liver fibrosis, while also restoring gut microbial balance and intestinal barrier function. These beneficial effects were linked to SCFAs produced by *F. prausnitzii*. Further studies revealed that *F. prausnitzii*-derived SCFAs enhanced histone H3K27 acetylation, upregulating the transcription factor ELF3 and subsequently activating the PI3K-Akt signaling pathway to promote bile duct cell repair. **Conclusion:** This study demonstrates that *F. prausnitzii* exerts protective effects in PBC. Its depletion in PBC patients and its therapeutic potential in alleviating cholangitis and liver fibrosis, along with restoring gut function, highlight its promising clinical application for PBC treatment.

4459 | EFFICACY AND SAFETY OF SELADELPAR IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS AND ELEVATED BILIRUBIN AT BASELINE IN THE PHASE 3 PLACEBO-CONTROLLED RESPONSE TRIAL

Sonal Kumar[1] Christophe Corpechot[2] Alejandra Villamil[3] Christopher Bowlus[4] Cynthia Levy[5] Daniel Pratt[6] Pietro Andreone[7] Victor Vargas[8] Catherine Frenette[9] Jie Liu[9] Susheela Carroll[9] Kyung min Kwon[9] Robert Kustra[9] Daria Crittenden[9] Andreas Kremer[10], [1]Gastroenterology and Hepatology, Weill Cornell Medical College, New York, NY, USA, [2]Saint-Antoine Hospital and Research Center, Assistance Publique-Hôpitaux de Paris, Paris, France, [3]The Liver Autoimmunity Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Gastroenterology&Hepatology, University of California Davis School of Medicine, Sacramento, CA, USA, [5]Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, FL, USA, [6]Autoimmune and Cholestatic Liver Center, Massachusetts General Hospital, Boston, MA, USA, [7]Nuovo Ospedale Civile S. Agostino-Estense di Baggiovara, Baggiovara, Italy, [8]Liver Unit, Hospital Vall d'Hebron, Universitat Autònoma Barcelona, Barcelona, Spain, [9]Gilead Sciences, Inc., Foster City, CA, USA, [10]Gastroenterology & Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland

Background: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) combined with ursodeoxycholic acid (UDCA) in adults with inadequate response to UDCA or as monotherapy in patients (pts) intolerant to UDCA. In the Phase 3, placebo (PBO)-controlled RESPONSE trial (NCT04620733), SEL significantly improved biomarkers of cholestasis and pruritus vs PBO in pts with PBC over 12 months (M). Here, we report efficacy and safety in prespecified subgroups of pts with total bilirubin (TB) >1 or $\leq 1\times$ the upper limit of normal (ULN) at baseline (BL) in RESPONSE. **Methods:** Pts with PBC with an inadequate response or intolerance to UDCA, ALP $\geq 1.67\times$ ULN, and TB $\leq 2\times$ ULN (ULN = 1.10 mg/dL) received daily, oral SEL 10 mg or PBO (2:1 randomization) for 12M. Prespecified subgroups of pts with TB >1 or $\leq 1\times$ ULN at BL were analyzed post hoc for the composite endpoint (ALP $<1.67\times$ ULN, ALP decrease $\geq 15\%$, and TB $\leq$ ULN), along with additional

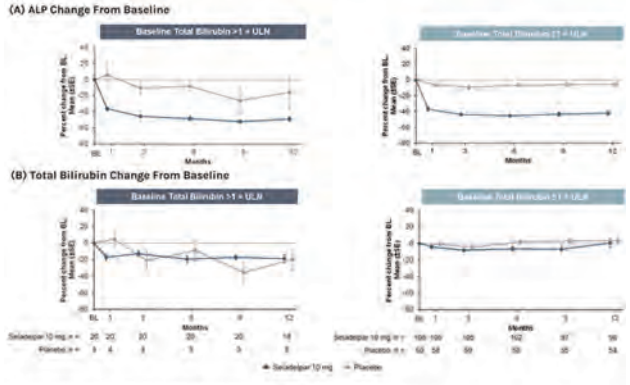
biochemical endpoints and safety. **Results:** Of 193 enrolled pts, 25 pts (13%; 20 SEL, 5 PBO) had TB $>1\times$ ULN at BL (mean TB: SEL, 1.4 mg/dL; PBO, 1.5 mg/dL). Pts with TB $>1\times$ ULN at BL had higher mean ALP (SEL, 384 U/L; PBO, 399 U/L) and higher rates of cirrhosis (SEL, 35% [7/20]; PBO, 40% [2/5]) at BL compared with pts with TB $\leq 1\times$ ULN at BL (ALP: SEL, 302 U/L; PBO, 307 U/L; cirrhosis: SEL, 10%; PBO, 12%). At 12M, 50% (10/20) of SEL pts with TB $>1\times$ ULN at BL achieved the composite endpoint compared with 20% (1/5) of PBO pts; 64% of SEL pts with TB $\leq 1\times$ ULN at BL achieved the composite endpoint compared with 20% of PBO pts. In total, 70% (14/20) of SEL pts with TB $>1\times$ ULN at BL achieved TB normalization at 12M compared with 40% (2/5) of PBO pts. ALP change from BL was similarly reduced with SEL vs PBO in pts with TB >1 or $\leq 1\times$ ULN at BL (Fig A). TB changes from BL were similar between SEL and PBO in both BL TB groups (Fig B). Greater decreases in GGT and ALT were observed with SEL vs PBO regardless of BL TB level. Adverse events (AEs) were reported in 95% and 85% of pts with TB >1 vs $\leq 1\times$ ULN at BL, respectively, with similar proportions across SEL and PBO. No treatment-related serious AEs or deaths were reported. **Conclusion:** In this small-sized, subgroup analysis of the RESPONSE trial, SEL reduced biomarkers of cholestasis and liver injury in pts with PBC who had elevated TB at BL and normalized TB in 70% (14/20) of pts by 12M. SEL was overall safe and well tolerated regardless of BL TB level.

Figure: ALP Change From Baseline Over Time (A) and Total Bilirubin Change From Baseline Over Time (B)



n = number of evaluable patients at each time point.
ALP, alkaline phosphatase; BL, baseline; ULN, upper limit of normal.

4460 | LONG-TERM SAFETY OF COMBINATION OBETICHOLIC ACID AND BEZAFIBRATE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: INTERIM DATA FROM TWO PHASE 2 TRIALS

Cynthia Levy[1] David Jones[2] Frederik Nevens[3] Meha Ballard[4] Julia O'Brien[4] Sangeeta Sawhney[4] Alan Bonder[5], [1]University of Miami, Miami, Florida, USA, [2]Newcastle University, Newcastle upon Tyne, UK, [3]University Hospital KU Leuven, Leuven, Belgium, [4]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA, [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Massachusetts, USA

Background: Obeticholic acid (OCA), a farnesoid X receptor agonist, and bezafibrate (BZF), a pan-peroxisome proliferator–activated receptor agonist, have both demonstrated improvements in hepatic serum biomarkers in primary biliary cholangitis (PBC). Here, we present long-term safety data from 2 phase 2 trials evaluating OCA and BZF combination therapy in patients (pts) with PBC who had inadequate response or intolerance to ursodeoxycholic acid. **Methods:** In Study 213 (NCT04594694), pts were randomized in a 1:1:1:1 ratio to receive once-daily oral BZF 200 mg immediate release (IR), OCA 5 mg titrated to 10 mg at week 4 + BZF 200 mg IR, BZF 400 mg sustained release (SR), or OCA 5 mg titrated to 10 mg at week 4 + BZF 400 mg SR during a 12-week, double-blind (DB) treatment period. Pts then entered a DB follow-up period before transitioning to OCA 5 mg + BZF 400 mg SR during a 96-week, open-label, long-term safety extension (LTSE). In Study 214 (NCT05239468), pts were randomized 1:1:1:1 to receive once-daily oral BZF 100 mg IR, OCA 5 mg (without titration) + BZF 100 mg IR, BZF 400 mg IR, or OCA 5 mg (without titration) + BZF 400 mg IR during a 12-week DB period. Pts then transitioned directly to OCA 5 mg + BZF 400 mg IR during a 144-week, open-label LTSE. Here, we present interim LTSE safety data from both studies as of a March 2025 data cut ($\geq$72 weeks of follow-up for each study). Safety was assessed descriptively using adverse events (AEs), with treatment assignment based on the treatment actually received. Potential events of liver injury, an AE of special interest, were reviewed by an external, blinded Hepatic Safety Adjudication Committee (HSAC). **Results:** In Studies 213 and 214, 75 and 72 pts were randomized, with 66 and 67 pts continuing to the LTSE, respectively. Among all cohorts, 11 and 7 serious AEs were reported in Studies 213 and 214, respectively (Table 1). No deaths or liver transplants were reported in either study. Eight cases of elevated liver enzymes were adjudicated by the HSAC. Of these, 5 were adjudicated as mild severity. All cases were reversible with drug interruption. No cases progressed to advanced chronic liver disease in either study, and no cases of rhabdomyolysis or renal failure were reported. **Conclusion:** OCA + BZF combination therapy was generally well tolerated across both studies, with no deaths or liver transplants and few serious AEs. The safety profile supports continued phase 3 development of fixed-dose combination therapy for pts with PBC.

Table 1. Summary of safety data from Studies 213 and 214

Number of	Study 213 (n=75)	Study 214 (n=72)
Serious AEs	11	7
Deaths	0	0
Liver transplants	0	0
Cases sent for HSAC adjudication	5	3
Cases with no evidence of liver injury	1	2
Cases with evidence of liver injury	4*	1*

Abbreviations: AE, adverse event; HSAC, Hepatic Safety Adjudication Committee.
*All cases were deemed to be mild in severity and resolved.

4461 | CHANGES IN FATIGUE AND PRURITUS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS TREATED WITH ELAFIBRANOR ARE LARGELY INDEPENDENT FROM IMPROVEMENTS IN SERUM BIOMARKERS

David Jones[1] Andreas Kremer[2] Cynthia Levy[3] Nuno Antunes[4] Hugo Gomes da Silva[5] Mickael Lothgren[6] Marwan Sleiman[5] Nathan Touati[5] Mark Swain[7],
[1]Institute of Cellular Medicine & NIHR Newcastle Biomedical Research Center, Newcastle University, UK, [2]Department of Gastroenterology and Hepatology, University Hospital Zurich, Zurich, Switzerland, [3]Schiff Center for Liver Diseases, University of Miami, FL, USA, [4]Ipsen, Cambridge, MA, USA, [5]Ipsen, Paris, France, [6]Ipsen, Zug, Switzerland, [7]Liver Unit, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

Background: Fatigue and pruritus are common debilitating symptoms in primary biliary cholangitis (PBC). Elafibranor (ELA), approved for PBC, significantly improved biomarkers of cholestasis in the phase III ELATIVE® trial (NCT04526665). Here, the association between improvements in symptoms and cholestatic biomarkers is assessed, as well time to and durability of changes in fatigue and pruritus. **Methods:** Patients (pts) with PBC were randomized 2:1 to ELA 80 mg or placebo (PBO). Fatigue was assessed via the Patient-Reported Outcome (PRO) Measurement Information System (PROMIS) Fatigue Short Form 7a (PFSF 7a) and PBC-40 Fatigue domain; pruritus was assessed via the PBC-40 Itch domain, 5-D Itch, and Worst-Itch Numeric Rating Scale (WI NRS). Data are reported for pts with moderate-to-severe (mod−sev) fatigue (PFSF 7a $\geq$60; PBC-40 Fatigue $\geq$29) and mod−sev pruritus (WI NRS $\geq$4) at baseline (BL). Mean change from BL (CfB) in PRO scores and achievement of minimal clinically important differences for fatigue (PFSF 7a: $\geq$3.0; PBC-40 Fatigue: $\geq$5.0) and clinically meaningful thresholds for pruritus (PBC-40 Itch: $\geq$2.0; 5-D Itch: $\geq$4.5; WI NRS: $\geq$1.8) are reported to Week (Wk) 52. Spearman's rank correlation coefficients were calculated between fatigue/pruritus scores and alkaline phosphatase (ALP)/total bilirubin (TB) levels at BL and in CfB to Wk 52. **Results:** At BL, fatigue and pruritus PRO scores and ALP/TB levels had weak correlations in all pts (r = 0.03–0.14). Similarly, CfB to Wk 52 in PRO scores and ALP/TB levels had weak correlations in pts receiving ELA (r = −0.06–0.22). Similar results were seen for PBO (Table). At BL, 46/108 and 58/108 pts receiving ELA and 20/53 and 30/53 receiving PBO had mod−sev fatigue according to PFSF 7a and PBC-40 Fatigue scores, respectively. Improvements in PFSF 7a scores were seen within 4 wks with ELA compared with PBO (mean [SE] CfB: −3.7 [0.9] vs −0.7 [0.9]), with further improvements to Wk 52 (mean [standard error; SE] CfB: −6.5 [1.2] vs −2.6 [1.6]). Changes in PBC-40 Fatigue scores with ELA were similar to PBO at Wk 4 (mean [SE] CfB: −2.7 [0.7] vs −2.6 [1.1]) but improved to Wk 52 (mean [SE] CfB: −3.6 [1.0] vs −2.1 [1.0]). At BL, 44/108 pts receiving ELA and 22/108 receiving PBO had mod−sev pruritus. PBC-40 Itch and 5-D Itch improved within 4 wks with ELA versus PBO (mean [SE] CfB: −1.4 [0.5], −2.9 [0.7] vs −0.6 [0.4], −1.7 [0.8]) and continued to Wk 52 (mean [SE] CfB: −2.5 [0.5], −4.3 [0.7] vs −0.2 [0.7], −1.7 [1.0]). Reductions in WI NRS at Wks 4 and 52 were similar with ELA and PBO. The proportions of pts achieving clinically meaningful improvements in fatigue and pruritus PROs were mostly greater with ELA vs PBO at all evaluated timepoints. **Conclusion:** Weak correlations between improvements in cholestatic biomarkers and fatigue/pruritus PROs suggest that ELA may improve biochemistry and symptoms independently. Some improvements in these symptoms may be seen within four weeks of ELA treatment, continued over one year.

4462 | THERAPEUTIC SILENCING OF AN UNDISCLOSED TARGET WITH A GALNAC SIRNA REVERSES LIVER INJURY AND FIBROSIS IN A HUMANIZED MOUSE MODEL OF CHOLESTATIC LIVER DISEASE

Jian Liang Xu[1] Zhi Wei Tan[2] Christine Meng Fan Goh[1] Walter Hunziker[3], [1]Institute of Molecular and Cell Biology, Agency for Sience, Technology and Research, Singapore, [2]Institute of Molecular and Cell Biology, Agency for Sience Technology and Research, SingaporeTan Zhi, [3]Agency for Science, Technology and Research Singapore

Background: Progressive familial intrahepatic cholestasis type 3 (PFIC3) is a severe autosomal recessive liver disorder caused by mutations in the *ABCB4* gene, leading to impaired biliary phosphatidylcholine secretion, bile acid toxicity, and progressive liver fibrosis. Despite recent advances, no currently approved therapy effectively reduces the bile acid toxicity or halts fibrotic progression—highlighting a significant unmet medical need for improved disease-modifying treatments. **Methods:** We evaluated the therapeutic efficacy of a GalNAc-conjugated, chemically modified small interfering RNA (GalNAc siRNA#5) targeting an undisclosed gene in *Abcb4*-deficient (KO) mice—a validated model of PFIC3. To better mimic the human pathophysiology, particularly the hydrophobicity of human bile, mice were fed a cholic acid (CA)–enriched diet, which exacerbates bile acid–mediated liver injury and fibrosis. A single subcutaneous dose (5 mg/kg) of the investigational siRNA was administered. A week later, mice were transferred to the CA supplemented diet. for two weeks, sacrificed and blood biochemistry and liver necrosis and fibrosis were analyzed. **Results:** Treated mice exhibited significant reductions in serum liver injury markers (ALT, AST, ALP, bilirubin and plasma bile acids) alongside histological evidence of fibrosis prevention. These findings demonstrate that transient silencing of the target gene is beneficial in this humanized cholestasis model. **Conclusion:** Our results support the therapeutic potential of siRNA-based approaches for cholestatic liver diseases like PFIC3

4463 | ANTICHOLESTATIC EFFECTS OF OBETICHOLIC ACID AND BEZAFIBRATE IN COMBINATION COMPARED WITH ELAFIBRANOR AND SELADELPAR IN A HUMAN HEPATOCYTE MODEL OF CHOLESTASIS

Daniela Passeri[1] Francesca De Franco[1] Sanjay Kansra[2] Luciano Adorini[2] Mary Erickson[2] Roberto Pellicciari[1], [1]Tes Pharma S.r.l, Perugia, Italy, [2]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA

Background: The combination of obeticholic acid (OCA) + bezafibrate (BZF) has been shown to induce biochemical remission in primary biliary cholangitis. We used a bile acid–overloaded hepatocyte model of cholestasis to explore the mechanism of OCA + BZF and compare its effects with the peroxisome proliferator–activated receptor (PPAR) agonists elafibranor (ELA) and seladelpar (SEL). **Methods:** To mimic bile acid–induced liver injury and assess therapeutic efficacy, primary human hepatocytes were initially cultured in Williams' Medium E with a hepatocyte plating supplement pack. Cells were then incubated for 24 hours in Willams' Medium E containing a hepatocyte maintenance supplement pack, glycochenodeoxycholic acid (250 μM), and glycocholic acid (250 μM), with or without test compounds. The expression of genes regulating hepatic bile acid synthesis, transport, and metabolism (*CYP7A1*, *FGF19*, *MDR3*, *OSTß*, and *BSEP*), as well as bilirubin metabolism and secretion (*UGT1A1*), were measured by quantitative polymerase chain reaction. Bilirubin conjugation was assessed using high-performance liquid chromatography/mass spectrometry. Statistical significance was assessed by one-way analysis of variance with Dunnett's test. **Results:** While OCA (10 μM) and BZF (30 μM) independently suppressed *CYP7A1* expression, OCA + BZF had an additive effect. At 10 μM, OCA and SEL suppressed *CYP7A1* expression more than ELA or BZF but less than OCA + BZF. Hepatic *FGF19* expression was significantly induced by OCA, but not by BZF, ELA, or SEL. Notably, BZF potentiated OCA-induced *FGF19* expression. OCA and OCA + BZF also significantly induced the expression of *MDR3*, *OSTß*, and *BSEP*, whereas ELA and SEL only induced *MDR3* and *OSTß* expression, and BZF only induced *MDR3* expression. While OCA, ELA, and SEL independently induced *UGT1A1* expression, OCA + BZF more than doubled *UGT1A1* expression compared with the individual treatments. When hepatocytes were exposed to high concentrations of bilirubin (25 μg/ml [42μM]), both OCA and BZF independently increased the amount of conjugated bilirubin in the cell culture supernatant. OCA + BZF demonstrated a further increase in secreted conjugated bilirubin. **Conclusion:** The combination of OCA + BZF was more efficacious than either drug alone or the recently approved PPAR agonists, ELA and SEL, in regulating genes involved in cholestasis, resulting in enhanced suppression of bile acid synthesis, increased bile acid secretion, and increased bilirubin metabolism. **Disclosures:** Daniela Passeri: Nothing to Disclose, Francesca De Franco: Nothing to Disclose, Sanjay Kansra: Intercept Pharmaceuticals: Employee, Luciano Adorini: Nothing to Disclose, Mary Erickson: Nothing to Disclose, Roberto Pellicciari: Nothing to Disclose

4464 | SERUM ANTI-INTEGRIN AVB6 AUTOANTIBODIES AS NON-INVASIVE BIOMARKERS FOR THE DIAGNOSIS OF PRIMARY SCLEROSING CHOLANGITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Stavros Papadakos[1] Stamatina Vogli[2] Alexandra Argyrou[1] Antonios Chatzigeorgiou[3] Andreas Koutsoumpas[1] Jiannis Vlachogiannakos[4] George Papatheodoridis[1], [1]First Department of Gastroenterology, NKUA, General Hospital of Athens "Laiko", [2]Department of Gastroenterology, "Metaxa" Cancer Hospital, Piraeus, Greece, [3]Laboratory of Physiology, Medical School of National and Kapodistrian University of Athens, Greece, [4]First Department of Gastroenterology, NKUA, General Hospital of Athens

Background: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease with no approved non-invasive diagnostic biomarker. Serum anti-integrin αvβ6 autoantibodies have emerged as potential diagnostic tools, but their accuracy remains incompletely defined, particularly in the context of inflammatory bowel disease (IBD). **Methods:** We performed a systematic review and meta-analysis of studies evaluating serum anti-αvβ6 autoantibodies for PSC diagnosis. Databases searched included PubMed, Embase, Web of Science, and Cochrane through April 2025. Pooled sensitivity, specificity, diagnostic odds ratio (DOR), and area under the summary receiver operating characteristic curve (AUC) were calculated using a bivariate random-effects model. Subgroup analyses were performed by IBD status and by comparison with other cholestatic diseases. **Results:** Four studies comprising 1294 subjects (398 PSC patients, 896 controls) met inclusion criteria. Pooled sensitivity and specificity for PSC diagnosis were 62.3% and 87.3%, respectively (AUC: 0.76). In patients without IBD, specificity rose to 96% and AUC to 0.86; in those with IBD, specificity fell to 71% and AUC to 0.67. For differentiation from other cholestatic diseases, pooled sensitivity was 81%, specificity 95%, and AUC 0.90. Sensitivity analysis showed moderate variability, with specificity consistently high across subgroups. **Conclusion:** Serum anti-αvβ6 autoantibodies demonstrate high specificity and moderate sensitivity for PSC, particularly useful in patients without IBD and in distinguishing PSC from other cholestatic conditions. These findings support their clinical utility as promising non-invasive biomarkers warranting further validation.

4465 | SINGLE-CELL RESOLUTION SPATIAL TRANSCRIPTOMIC ATLAS REVEALS DISTINCT PATHOGENIC LANDSCAPES IN AUTOIMMUNE HEPATITIS AND AIH-PBC OVERLAP SYNDROME

Shu Li[1] Chen-Yi Liu[1] Shi-Wen Wu[1] Jia-Wen Chen[1] Chao Cai[1] Bang-Guo Zhou[2] Ming-Qin Lu[1], [1]The First Affiliated Hospital of Wenzhou Medical University, [2]The First Affiliated Hospital of Zhejiang University

Background: Autoimmune hepatitis (AIH) and AIH-primary biliary cholangitis (PBC) overlap syndrome (OS) are complex autoimmune liver diseases with poorly understood pathogenesis. While AIH targets hepatocytes and PBC affects bile ducts, AIH-PBC OS combines features of both, leading to accelerated fibrosis and poor prognosis. Current therapies remain controversial due to limited mechanistic insights. This study leverages 10X Visium HD spatial transcriptomics and single-cell RNA sequencing to resolve spatial and cellular heterogeneity in these diseases. **Methods:** Liver biopsies from 5 patients (3 AIH, 2 AIH-PBC OS) were analyzed.Spatial transcriptomics (Visium HD) and single-cell sequencing were performed. Histopathological regions (hepatocytes, inflammatory zones) were mapped by pathologists.Data integration, clustering, and pseudotime trajectory analysis identified cell-type dynamics. CellChat and SCENIC explored intercellular interactions and regulatory networks. **Results:** Distinct Cellular Landscapes: AIH-PBC OS showed severe hepatocyte impairment (*Hepatocyte_impaired* clusters) and plasma cell infiltration (37% vs. 12% in AIH), while AIH exhibited higher hepatocyte (48% vs. 22%) and Kupffer cell proportions.

Active Inflammatory Signaling: AIH inflammatory zones displayed elevated *COLLAGEN* signaling and stronger cell-cell interactions. In contrast, AIH-PBC OS showed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

diffuse HSC distribution and fibrotic gene upregulation (*TNF*, *NF-κB* pathways).
XBP1 as a Key Regulator: Pseudotime analysis revealed progressive hepatocyte dysfunction in AIH-PBC OS, with *XBP1* regulons driving inflammatory/fibrotic modules. SCENIC identified XBP1 as a top transcription factor in hepatocyte subsets.
HSC and Plasma Cell Dynamics: HSCs in AIH localized to portal tracts with pro-inflammatory activity, while AIH-PBC OS HSCs exhibited panlobular fibrosis. Plasma cell subtypes(Plasma-c01) dominated OS but showed muted interactions. **Conclusion:** This study provides the first single-cell resolution spatial atlas of AIH and AIH-PBC OS, highlighting distinct inflammatory microenvironments and XBP1's role in disease progression. AIH-PBC OS exhibits severe hepatocyte injury and fibrosis, while AIH demonstrates active collagen signaling. Findings implicate XBP1 as a therapeutic target and underscore the utility of spatial transcriptomics in unraveling autoimmune liver disease mechanisms.

4466 | EVALUATION OF RESPONSE TO SECOND LINE THERAPY IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC) AND INADEQUATE RESPONSE TO UDCA: A PILOT STUDY OF LIVER BIOPSIES FOLLOW UP

Alejandra Villamil[1] Daniela De la Viña[2] Eduardo Mullen[3] Ignacio Lucero[4] Juan Bandi[4], [1]Unidad de Autoinmunidad Hepatica Hospital Italiano de Bs As, [2]Unidad de Autoinmunidad Hepatica. Hospital Italiano de Buenos Aires, [3]Servicio de Anatomia Patologica. Hospital Italiano de Bs As, [4]Hospital Italiano de Buenos Aires

Background: Response to second-line therapy in PBC is commonly defined by improvement in cholestatic markers (ALP $<1.67\times$ULN, bilirubin <1 mg/dL) and prevention of fibrosis and liver-related events. This study aimed to assess 12-month response to OCA and/or PPAR agonists and identify clinical and histological factors associated with treatment outcomes. **Methods:** Among 614 patients with PBC (Jan 2016-Dec 2023), 279 showed incomplete biochemical response to UDCA. Of these, 107 (38.3%) met eligibility criteria for second-line trials (ALP $>1.67\times$ULN, bilirubin <2 mg/dL, absence of significant portal hypertension). Fifty patients completed 12 months of therapy with obeticholic acid (n = 12), PPAR agonists (n = 29), or both (n = 9), and underwent liver biopsy at baseline and at Month 12 ± 3 months as per local practice. Histological analysis included H&E, PAS, Masson's trichrome, reticulin, and rhodanine stains. Bile duct loss was assessed with cytokeratin 7 and 19. Fibrosis was staged using the modified Scheuer system. Elastography was performed at baseline and 12 months. Statistical analysis included t-tests and one-way ANOVA. **Results:** Mean age 53.6 ± 10.6 years; 84% were female. Baseline ALP was 388.8 ± 166.6, GGT 458.8 ± 400.2, ALT 71.3 ± 40.6, and bilirubin 0.9 ± 0.4. Ten patients (20%) had cirrhosis at baseline. POISE response was achieved in 30% (n = 15); ALP normalization occurred in 14% (n = 7). Male sex ($p = 0.04$), mod/severe ductopenia ($p = 0.01$), elevated ALT (82 vs 46, $p = 0.003$), bilirubin (1.07 vs 0.7, $p = 0.02$), and baseline cirrhosis ($p = 0.02$) were associated with nonresponse. Moderate to severe portal inflammation with interface activity was observed in 56% and correlated with fibrosis progression. None of the patients with severe inflammation responded (n = 5); and only 21% with moderate inflammation showed improvement (n = 5). Response was associated with histological improvement in 11 patients. Mild ductopenia did not affect response. No biochemical marker predicted fibrosis or inflammation. Cirrhosis persisted and was associated with liver-related events (5 patients: 1 death, 3 transplants). Elastography values correlated with cirrhosis and liver events (10.4 vs 22.9 kPa, $p < 0.001$), but not with inflammation or ductopenia: no significant differences were observed among responders between baseline and Month 12. **Conclusion:** Only 30% responded by POISE criteria and 14% normalized ALP. Nonresponse was associated with male sex, cirrhosis, elevated transaminases, GGT, and bilirubin, but not ALP levels. Mod/severe inflammation and ductopenia were negative predictors. Cirrhosis and elastography values were linked to liver events. Histological findings may support early second-line intervention.

4467 | THE PREDICTIVE ROLE OF SMOKING IN ACHIEVING BIOCHEMICAL REMISSION IN AUTOIMMUNE HEPATITIS: A U.S. SINGLE CENTER STUDY

Natalia Rojas-Amaris[1] Ana Marenco-Flores[1] Romelia Barba[2] Daniela Goyes[3] John Esli Medina Morales[4] Leandro Sierra[5] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Texas Tech University, [3]Yale School of Medicine, [4]Rutgers New Jersey Medical School, [5]Cleveland Clinic Foundation

Background: Autoimmune hepatitis (AIH) is a chronic condition with a fluctuating course that can either progress to a severe disease state or enter remission, sometimes allowing patients to discontinue medication. We aimed to explore potential predictors of complete biochemical response (CBR) among patients with AIH. **Methods:** A cross-sectional analysis within a prospective cohort study was conducted using data from a single visit of AIH patients enrolled between January 2018 and December 2024 in the Autoimmune Liver Diseases Registry at Beth Israel Deaconess Medical Center (Boston, MA, USA). Patients with overlap syndromes involving primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC), or those who had undergone liver transplantation, were excluded. CBR was defined as normalization of aminotransferases and immunoglobulin G (IgG) levels. A logistic regression model was created to evaluate predictors of CBR. **Results:** 100 patients with AIH were included in this analysis, 75% of whom were women. CBR was achieved in 55% of patients, and 13% of them were no longer receiving immunosuppressive therapy. No significant differences in demographic characteristics were observed between patients who exhibited CBR and those who did not. Smoking was significantly associated with lower odds of achieving CBR (OR: 0.24; 95% CI: 0.07–0.80; p = 0.021), according to the multivariate logistic regression analysis adjusted for confounders such as ALT levels, albumin, platelet count, and prednisone dose. **Conclusion:** Patients with a current or former smoking history had 76% lower odds of achieving biochemical remission compared to non-smokers. Assessing smoking habits in AIH patients and implementing cessation strategies for smokers with AIH could positively influence the course of the disease.

Table 1. Baseline clinical characteristics (n=100)

Variable	CBR (n=55)	No CBR (n=45)	P Value

4468 | AUTOIMMUNE HEPATIC INVOLVEMENT IN SYSTEMIC SCLEROSIS- SYSTEMATIC REVIEW AND META ANALYSIS

Bipneet Singh[1] Jahnavi Ethakota[1] Palak Grover[1] Gurleen Kaur[2] Karanbir Singh[2], [1]Henry Ford Allegiance, [2]GMC Amritsar

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Systemic sclerosis (SSc) is a heterogeneous, multisystem autoimmune disease characterized by fibrosis in genetically predisposed individuals. It can involve multiple organ systems, but hepatic involvement is rare. In this study, we aim to find the correlation of liver disease, especially primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH), in the population with SSc. Further, the correlation of anti-mitochondrial antibody (AMA) and other autoantibodies was done. **Methods:** PubMed, Cochrane, Google Scholar, and Embase were searched for liver disease in SSc, and 11 studies were selected for analysis. Cochrane risk of bias tools and meta-analysis online were used. Controls were taken from the prevalence in the respective countries around the same time. **Results:** Among 11 studies including 2,797 patients with systemic sclerosis (SSc), 190 (6.7%) had liver disease, with 157 (5.6%) attributed to autoimmune causes. Primary biliary cholangitis (PBC) was the most common (5%), followed by autoimmune hepatitis (AIH) at 1.2%. PSC was only seen in 1 patient across the studies. There was a significant association in prevalence compared to the general population (Figure 1). Anti-mitochondrial antibodies (AMA) were positive in 10.87%, and anti-sp100 in 3.1%. **Conclusion:** The increased prevalence of autoimmune hepatobiliary conditions, such as primary biliary cholangitis (PBC), in systemic sclerosis (SSc) patients is likely due to overlapping immunopathogenic features, including shared regulatory T cell abnormalities and common genetic variants (e.g., STAT4, IRF5, NF-κB, IRF8). PBC was observed in approximately 5.6% of SSc patients—significantly higher than the general population prevalence of 0.02% to 0.04%—highlighting a strong association. This link is further supported by the presence of antimitochondrial antibodies (AMA) in 10.87% of patients, suggesting a high rate of subclinical or evolving PBC in this population.

4469 | DISTINCT PROGNOSTIC PATTERNS OF THE HEPATIC TRANSAMINASES IN PRIMARY BILIARY CHOLANGITIS: AST IS THE STRONGER PREDICTOR OF OUTCOME

Gemma Weijsters[1] Ellen Werner[1] Maria van Hooff[1] Rozanne de Veer[1] Ulrich Beuers[2] Joost Drenth[2] Frans Cuperus[3] Remco van Dijk[4] Bart Veldt[5] Michael Klemt-Kropp[6] Suzanne van Meer[7] Robert Verdonk[8] Hajo Flink[9] Jan Vrolijk[10] Tom Gevers[11] Cyriel Ponsioen[2] Robert Roomer[12] Ulrike de Wit[13] Johan Kuyvenhoven[14] Jerome Sint Nicolaas[15] Philip Friederich[16] Merel Tielemans[17] Marleen de Vree[18] Huseyin Aktas[19] Sunje Abraham[20] Mariëlle Meijnen[21] Janne van Rooij[22] Edith Kuiper[23] Stephan Schmittgens[24] Yasser Alderlieste[25] Pieter ter Borg[26] Harry Janssen[1] Nicole Erler[7] Pedro Miranda-Afonso[1] Bettina Hansen[1] Adriaan van der Meer[1], [1]Erasmus University Medical Center, [2]Amsterdam University Medical Center, [3]University Medical Center Groningen, [4]Leiden University Medical Center, [5]Reinier de Graaf Gasthuis, [6]Noordwest Ziekenhuisgroep, [7]University Medical Center Utrecht, [8]St. Antonius Hospital, [9]Catharina Hospital, [10]Rijnstate, [11]Maastricht University Medical Center, [12]Franciscus Gasthuis & Vlietland, [13]Elisabeth – Tweesteden Hospital (ETZ), [14]Spaarne Gasthuis Hospital, [15]Amphia Hospital, [16]Meander Medical Center, [17]Bravis Hospital, [18]Treant Hospital, [19]Hospital Group Twente (ZGT), [20]Alrijne Hospital, [21]St Jansdal Hospital, [22]Tjongerschans Hospital, [23]Maasstad Hospital, [24]Nij Smellinghe Hospital, [25]Beatrix Hospital, [26]Ikazia

Background: The prognostic value of alanine aminotransferase (ALT) versus aspartate aminotransferase (AST) in patients with primary biliary cholangitis (PBC) is unclear. This study aimed to evaluate how ALT and AST levels during ursodeoxycholic acid (UDCA) therapy are associated with clinical outcomes in PBC. **Methods:** The retrospective Dutch PBC Cohort Study includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 hospitals. Patients with autoimmune hepatitis, additional therapy (second-line/immunosuppressants) within the first year, or with less than 1 year of follow-up after start UDCA were excluded. Where feasible, laboratory values (presented in upper limit of normal (ULN)) were imputed using joint model multiple imputation. The Pearson correlation coefficient was calculated. Cox models were used to study the association between AST and ALT and two endpoints: liver transplant (LT)-free survival and liver-related events (decompensation, LT, or liver-related death). To study the association between ALT and AST and outcome, natural cubic splines were used. **Results:** A total of 3,139 UDCA-treated PBC patients were

included. At baseline, median age was 58.0 years (IQR 49.7–67.2), 2745 (87.4%) were female and 203 (6.5%) had cirrhosis. During a median follow-up of 8.0 years (IQR 3.8–13.3), 295 patients developed decompensated cirrhosis, 78 patients underwent LT, and 584 patients died (152 [26%] liver-related; 115 [20%] of unknown cause). At 1 year of UDCA, AST (median 0.9, IQR 0.6–1.2) and ALT (median 0.8, IQR 0.5–1.2) were strongly correlated ($r = 0.78$, 95%CI 0.77–0.80, $p < 0.001$). In univariable analysis for LT or death, AST levels $\geq$ 1xULN showed a positive association (Fig. 1A). In contrast, ALT showed a U-shaped risk curve, with a higher risk in those with lowest ALT levels as well. This may be explained by a skewed age distribution; the median age was 64.2 years (IQR 55.3–71.8) in the lowest ALT quartile versus 51.7 years (IQR 44.1–59.1) in the highest quartile ($p < 0.001$). A rather stable increase in the risk of liver-related events for ALT and AST $\geq$ 1xULN was observed (Fig. 1B). For both endpoints, the risk curve of AST was steeper than that of ALT. The associations of the transaminases with each endpoint remained in multivariable analyses. **Conclusion:** Both AST and ALT levels after one year of UDCA were associated with LT-free survival and liver-related events in patients with PBC. Despite their strong correlation, AST and ALT demonstrated distinct prognostic patterns. For both endpoints, AST showed a stronger association. When assessing prognosis in PBC, these results indicate that the transaminases should be interpreted separately, and per endpoint of interest.

4470 | SINGLE CELL TRANSCRIPTOMIC ATLAS OF STIMULATED PERIPHERAL T-CELL RESPONSE IN PATIENTS WITH PSC

Daniel Pratt[1] Henry Pratt[2] Taylan Erdogan[3],
[1]Massachusetts General Hospital, [2]Yale University, [3]MGH

Background: Primary sclerosing cholangitis (PSC) is heritable, but the mechanisms by which genetic associations confer risk are unknown. PSC risk variants are enriched in non-coding regulatory elements which regulate gene expression in peripheral CD4+ helper T cells, particularly in response to stimulation with antigens and IL-2. We hypothesize that PSC patient T cells are predisposed to polarize toward pro-inflammatory phenotypes and away from anti-inflammatory T-reg states after stimulation. **Methods:** We performed single cell transcriptomic profiling of perturbed peripheral T cells in PSC patients and controls. We isolated peripheral blood mononuclear cells from two patients with PSC and two healthy age and sex-matched controls and used FACS to purify CD3+ CD4+ helper T cells. For each individual, half of the cells underwent stimulation using antigenic beads against the T cell receptor and IL-2 whereas the other half were left unstimulated. The cells were then inputted to CITE-seq for profiling of surface markers and gene expression. We then trained a neural network using the scGNN framework to identify T cell phenotypes and differentially-expressed genes specific to PSC patient samples as compared with controls. **Results:** Using scGNN we were able to match most cells from all samples to

known phenotypes, including naive, memory, and regulatory T cells, based on expression of key marker transcription factors and surface markers. Even prior to stimulation, we observe that naive PSC patient T cells express a constellation of genes involved in IL-2 response, suggesting they are more primed for antigenic response than control T cells at baseline. After stimulation, we observe differential prevalence of several T cell phenotypes between patients and controls; most notably, patients have fewer T-regs after stimulation, suggesting PSC patients are deficient in mounting negative feedback during the antigenic response. We identify hundreds of genes which are differentially expressed in various cell lineages which may drive this differential immune response. **Conclusion:** To our knowledge, this is the first single cell-resolution profile of the peripheral immune response in PSC patients compared with healthy controls. Our results suggest that genetic risk for PSC influences T cells both before and after antigenic stimulation, priming naive cells for a rapid immune response and predisposing them toward pro-inflammatory phenotypes after stimulation. Using an AI-based approach we identified marker genes to aid in prioritizing translational research. We further anticipate the trained scGNN model will be extensible in the future both to predict clinical variables, such as response to particular therapies, and to identify biomarkers for PSC risk and progression from peripheral cells.

4471 | IMPROVEMENTS IN PATIENT-REPORTED GENERAL HEALTH AND WELL-BEING IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS TREATED WITH SELADELPAR IN THE RESPONSE TRIAL

Sonal Kumar[1] Andreas Kremer[2] Maria Carlota Londono[3] Anne Skalicky[4] Milena Anatchkova[4] Barinder Singh[5] Caroline Burk[6] Grace Chee[6] Catherine Frenette[6] Denise Globe[6] Marlyn Mayo[7],
[1]Gastroenterology and Hepatology, Weill Cornell Medical College, New York, NY, USA, [2]Gastroenterology & Hepatology, University Hospital Zürich, University of Zürich, Zürich, Switzerland, [3]Liver Unit, Hospital Clínic Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain, [4]Evidera, Thermo Fisher Scientific, Wilmington, NC, USA, [5]Pharmacoevidence, London, UK, [6]Gilead Sciences, Inc., Foster City, CA, USA, [7]Division of Digestive and Liver Diseases, University of Texas Southwestern, Dallas, TX, USA

Background: Primary biliary cholangitis (PBC) is a chronic, progressive, autoimmune, cholestatic liver disease that can be debilitating and substantially impair health-related quality of life (HRQoL). In the Phase 3 RESPONSE trial (NCT04620733), seladelpar (SEL), a first-in-class delpar (selective PPAR-delta agonist), led to significant improvements in biochemical markers of cholestasis and pruritus vs placebo (PBO). Here, we report the general health status of patients (pts) in RESPONSE based on the PBC-40, a PBC-specific, pt-reported outcome measure of symptoms and HRQoL. **Methods:** In RESPONSE, pts with PBC who had an inadequate response or intolerance to ursodeoxycholic acid, alkaline phosphatase $\geq 1.67 \times$ upper limit of normal (ULN), and total bilirubin $\leq 2 \times$ ULN received daily, oral SEL 10 mg or PBO (2:1 randomization) for 12 months. A post hoc analysis of responses to 3 PBC-40 questions on general health status (A, current general health; B, general health pre-diagnosis of PBC; C, general health now vs 12 months ago) was conducted in the overall population and in pts with moderate to severe pruritus (MSP) at baseline (pruritus numerical rating scale [NRS] score of ≥ 4). A 5-point response scale for A and B ranged from “poor” to “excellent”; C ranged from “much worse” to “much better”. Responses were scored separately. **Results:** Of the 193 pts enrolled in RESPONSE (SEL, n = 128; PBO, n = 65), 72 pts were in the MSP group (SEL, n = 49; PBO, n = 23). At baseline, mean (SD) durations of PBC in the overall population and in the MSP group were 8.3 (6.6) and 7.5 (5.9) years, respectively. In the overall population, 14% and 37% of pts reported their general health pre-diagnosis (B) as “excellent” and “very good” vs 2% and 12% at baseline in RESPONSE (A). In the MSP group, 7% and 42% of pts reported their general health pre-diagnosis (B) as “excellent” or “very good” vs 1% and 5% at baseline in RESPONSE (A). In the overall population, 29% of SEL pts vs 9% of PBO pts reported that their general health was “much better” at month 12 when compared with baseline in the RESPONSE trial (C). Likewise, in the MSP group, 39% of SEL pts vs 13% of PBO pts reported that their general health was “much better” at month 12 compared with baseline in RESPONSE (C). **Conclusion:** More pts reported poorer general health and well-being than prior to PBC diagnosis. Pts who received SEL reported greater improvements in their general health and well-being after 12 months compared with those who received PBO.

4472 | REAL WORLD ASSESSMENT OF CURRENT PBC TREATMENT, KEY GOALS, AND LEVEL OF TREATMENT SATISFACTION ACCORDING TO HEALTHCARE PROFESSIONALS ACROSS FRANCE, ITALY, GERMANY, SPAIN, UNITED KINGDOM, AND THE UNITED STATES

William Johnson[1] Hayley Wallinger[1] Caroline Burk[2] Marvin Rock[2] Chong Kim[2] Lena Amari[1] Robert Gish[3] David Jones[4] Gideon Hirschfield[5] Ira Jacobson[6], [1]Adelphi Real World, Bollington, United Kingdom, [2]Gilead Sciences, Inc., Foster City, CA, USA, [3]Robert G Gish Consultants LLC, [4]Newcastle University, UK, [5]Toronto General Hospital, [6]NYU Hepatology Associates

Background: To describe healthcare professionals (HCPs) treatment patterns, key treatment goals and level of satisfaction with current treatment for their patients with primary biliary cholangitis (PBC). **Methods:** Data were drawn from the Adelphi Real World PBC Disease Specific Programme™, a cross-sectional survey across EUR (France, Italy, Spain, Germany, the United Kingdom (UK)) and the United States (US), from November 2024 to May 2025. Analyses focused on HCPs reported treatment for PBC, including treatment goals and level of satisfaction. Importance of PBC treatment goals were rated from 1 to 5 (where 1 = Not at all important, 5 = Extremely important). **Results:** Data from 181 physicians (EUR; 141 and US; 40) were included. Physicians reported at the time of data collection that almost all patients were prescribed treatment for PBC (EUR; 97%, US: 98%) with ursodeoxycholic acid (UDCA) the most frequently prescribed (EUR; 83%, US; 62%). Other treatments included antihistamines, fibrates, bile acid sequestrants, obeticholic acid (OCA), corticosteroids, antibiotics, SSRIs, opioids and dual PPARs. Most important goals of treatment for US and EUR HCPs included inhibiting disease progression, reducing the risk of advanced fibrosis/liver cirrhosis, slowing down damage to the liver and delaying need for a liver transplant. In terms of ability to slow down damage to the liver, very few physicians reported being 'completely satisfied' with current treatment, with 46%, EUR and 60%, US reporting they were 'not satisfied'. The main reasons for dissatisfaction in US were due to lack of efficacy and associated treatment side effects while in EUR HCPs reasons were mainly around the inability of current treatments to manage itch and fatigue. The majority of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

US and EUR HCPs reported that they "somewhat" and "strongly" agreed that there is an urgent need for more PBC-approved drug therapy options (EUR; 88%, US; 90%). In addition, US and EUR HCPs reported that their ideal treatment for PBC would address both the underlying cause of the disease in addition to effective itch reduction, improved sleep, convenient dosing and good tolerability (EUR; 95%, US; 95%). **Conclusion:** The majority of physicians reported dissatisfaction with currently available treatment options for PBC. These findings highlight the need for novel treatments that not only address the underlying cause of PBC but also improve PBC related symptoms such as pruritus and fatigue.

	EUR	US
All physicians	**181**	**40**
Percentage of patients receiving prescribed treatment for PBC		
% on treatment for PBC	97%	98%
Percentage of patients receiving each of the following treatment classes for their PBC		
Ursodeoxycholic acid (UDCA)	83%	62%
Antihistamines	18%	20%
Fibrates	18%	18%
Bile acid sequestrants	18%	19%

4473 | CLINICAL CHARACTERISTICS, DISEASE STATUS AND SYMPTOMATOLOGY OF PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN EUROPE AND THE UNITED STATES OF AMERICA: ANALYSIS OF A REAL-WORLD DATASET

William Johnson[1] Hayley Wallinger[1] Dean Taylor[1] Caroline Burk[2] Marvin Rock[2] Chong Kim[2] Robert Gish[3] Ira Jacobson[4] Gideon Hirschfield[5] David Jones[6], [1]Adelphi Real World, Bollington, United Kingdom, [2]Gilead Sciences, Inc., Foster City, CA, USA, [3]Robert G Gish Consultants LLC, [4]NYU Hepatology Associates, [5]Toronto General Hospital, [6]Newcastle University, UK

Background: To describe demographics, clinical characteristics, diagnostic tests, disease status and symptomatology of patients with primary biliary cholangitis (PBC) in EUR (France, Germany, Italy, Spain, the United Kingdom (UK)) and the United States (US). **Methods:** Data were drawn from the Adelphi Real World PBC Disease Specific Programme™, a cross-sectional survey, with retrospective data collection in EUR and US between November 2024 to May 2025. Physicians completed patient record forms for their patients with PBC including demographics, disease status, symptoms and diagnosis tests. Analyses performed were descriptive. **Results:** Overall, 181 physicians (EUR; 141, US; 40) reported data for 582 patients with PBC (EUR; 483, US; 99), majority of patients were female (EUR; 87%, US: 73%) and white (EUR 95%, US: 81%). Mean age was 55.0, EUR [SD: 11.75] and 47.5 [SD: 11.94], US. Most common tests/assessments to diagnose PBC were clinical examination, medical history, presence of pruritus, presence of fatigue, family history, total bilirubin, alkaline phosphatase (ALP), antimitochondrial antibodies (AMA), and alanine transaminase (ALT). Liver biopsy was used in around a quarter of patients. Most patients had a physician reported disease state of PBC stage 1 or 2 (EUR; 74%, US; 71%) at diagnosis and at time of data collection (EUR; 68%, US; 65%). Physicians reported that most common symptoms experienced by patients at time of data collection were fatigue (EUR; 51%, US;

35%) and pruritus (EUR; 43%, US; 68%). Severity of pruritus at time of data collection was reported as moderate to severe by around half of physicians in EUR and US (EUR; 46%, US; 58%). Similarly, fatigue severity was reported as moderate to severe by just over half of physicians in EUR and US (both 54%). Majority of patients were receiving prescribed core treatment for their PBC at data collection (EUR; 92%, US; 68%), of which most received Ursodeoxycholic acid (UDCA) (EUR; 95%, US; 79%). Other treatments included Obeticholic acid (OCA), fibrates and Budesonide with a small proportion receiving the newer PPAR agonists Elafibranor and Seladelpar. **Conclusion:** Across EUR and US, many patients are experiencing fatigue and pruritus despite ongoing treatment. This highlights the need for more effective therapies that can address both the underlying disease and associated symptoms. Possible differences in treatment patterns between Europe and US warrant further investigation.

All patients: n	EUR (n=423)	US (n=99)
Age, years, mean [SD]	55.0 [11.75]	47.5 [11.94]

4474 | PREDICTORS OF RESPONSE TO RITUXIMAB IN REFRACTORY AUTOIMMUNE HEPATITIS AND VARIANT SYNDROMES

Juliette Labelle[1] Julian Hercun[2] Pascal Lapierre[3] Marc Bilodeau[4] Catherine Vincent[4] YouRan Zhao[1],
[1]University of Montreal, Montreal University Hospital Center, [2]National Institutes of Health, [3]Morphocell Technologies, [4]Division of Hepatology, Montreal University Hospital Center

Background: Autoimmune hepatitis (AIH) is a chronic autoimmune condition responding to immunosuppressive therapy. Rituximab (RTX) has been used off-label in AIH patients who are otherwise unresponsive or intolerant to other therapies. While recent data yield encouraging results in different stages of AIH, including cirrhosis, very few data are available regarding AIH variant syndromes. **Methods:** We conducted a single-center retrospective analysis of patients with AIH or its variant forms (overlap AIH-primary biliary cholangitis or AIH-primary sclerosing cholangitis) treated with RTX from February 2016 to September 2024 and included in our institutional biobank. Complete biochemical response (CBR) was defined as normal ALT, AST and IgG levels at 12 months. Our study aimed to evaluate predictive factors of treatment response and to assess safety of RTX. **Results:** In this 7-patient cohort (mean age 48, 71% female), four (57%) had variant forms of AIH. Two (29%) had compensated cirrhosis (F4) at diagnosis; the remainder had F0–F1 fibrosis stage. Median ALT at diagnosis was 475 IU/mL (IQR 296–1106), AST 259 IU/mL (IQR 189–526), and IgG 14.3 g/L (IQR 10.5–36.2). On average, patients had trials of 3 (and up to 5) immunosuppressants prior to

RTX; and 57% received UDCA. None achieved CBR prior to RTX. Median time from diagnosis to RTX initiation was 120 months (IQR 24–180). Overall, 5 out of 7 patients (71%) achieved CBR with RTX: 100% in pure AIH vs 50% in variant forms ($p = 0.43$). No difference in CBR was found according to the presence of cirrhosis. Higher pre-RTX ALT (489 vs 361 IU/mL, $p = 0.38$) trended towards CBR, and this finding was found more commonly in patients with classical AIH (median 1106 vs 361 IU/mL for variant forms; $p = 0.057$). Higher ALP, seen predominantly in variant forms (median 305 vs 65 IU/mL, $p = 0.057$), was more frequent in non-CBR cases (393 vs 92 IU/mL, $p = 0.19$). Three patients (42%) experienced side-effects: serum sickness-like reaction, viral infection, and alopecia. Over a mean follow-up of 59 months (SD 29; range 25–101), no patient required liver transplant or developed hepatic decompensation while on RTX. **Conclusion:** RTX allowed patients with refractory AIH disease to achieve CBR in a majority of cases, while still maintaining an encouraging safety profile. In this small cohort, AIH patients, without features of variant forms, tend to have higher levels of transaminases, and seem to respond better to RTX.

4475 | TEMPORAL TRENDS IN THE EPIDEMIOLOGY OF PRIMARY BILIARY CHOLANGITIS IN THE PUBLIC HEALTHCARE SYSTEM OF BRAZIL: PRELIMINARY DATA FROM A LARGE POPULATION-BASED STUDY

Guilherme Cancado[1] Claudia Couto[2] Luciana Faria[1] Paulo Bittencourt[3] Cristiane Villela-Nogueira[4] Vivian Rotman[4] Débora Terrabuio[5] Eduardo Cançado[5] Maria Lucia Ferraz[6], [1]Universidade Federal de Minas Gerais, [2]Federal University of Minas Gerais, [3]Hospital Português, [4]Universidade Federal do Rio de Janeiro, [5]Universidade de São Paulo, [6]Universidade Federal de São Paulo

Background: Population-based data on the epidemiology of primary biliary cholangitis (PBC) in Latin America are lacking. This study aimed to describe national trends in the incidence and prevalence of PBC in Brazil using comprehensive administrative healthcare data. **Methods:** We performed a population-based study using data from the Brazilian Ministry of Health (DATASUS), accessed via the TT Disease Explorer artificial intelligence platform. The dataset includes records for approximately 230 million individuals covered by Brazil's public universal healthcare system (SUS). All adult patients receiving ursodeoxycholic acid with the ICD-10 code for PBC between January 2021 and December 2024 were included. National population estimates were obtained from the Brazilian Institute of Geography and Statistics (IBGE), and age-standardized rates were calculated using the World Health Organization standard population. Incidence, prevalence, and average annual percentage change (AAPC) were assessed. Exploratory analyses examined regional clustering and correlation with mean Human Development Index (HDI) by region (2021). **Results:** A total of 10,124 PBC patients were identified. Age-standardized incidence declined from 1.11 per 100,000 in 2021 to 0.86 per 100,000 in 2024 [AAPC: –7.76% (95% CI: –10.95% to –4.46%); $p = 0.046$], while prevalence increased from 2.95 to 5.16 per 100,000 during the same period [AAPC: +20.3% (95% CI: 14.4% to 26.5%); $p = 0.019$]. Women had significantly higher incidence rate than men [IRR: 3.56 (95% CI: 3.36–3.77); $p < 0.001$]. Age-stratified analyses showed increasing incidence and prevalence with age, peaking at ages 56–60 [IRR: 3.82 (95% CI: 3.11–4.70); PRR: 3.90 (95% CI: 3.24–4.38, both relative to the 16-20 year-old group], followed by a gradual decline in older age groups. A south-to-north gradient in PBC prevalence was evident in 2021 and was strongly correlated with regional HDI ($r = 0.95$; $p = 0.015$). **Conclusion:** This is the first population-based study of PBC in Latin America. We identified a declining incidence but rising prevalence in Brazil, with marked sex and age disparities and regional variation linked to socioeconomic development. These findings underscore the need for improved disease awareness, timely diagnosis, and equitable access to care across regions.

4476 | IDENTIFYING GAPS IN PSC PATIENT EDUCATION AND UNDERSTANDING OF CHOLANGIOCARCINOMA SCREENING AND SURVEILLANCE PRACTICES: RESULTS: OF A MULTINATIONAL PATIENT SURVEY

Brian Thorsen[1] Martine Walmsley[2] Susan O'Dell[1] Rachel Gomel[1] Mark Chatterley[2] Mary Vyas[3] Stephen Rossi[1], [1]PSC Partners Seeking a Cure, [2]PSC Support, [3]PSC Partners Seeking a Cure Canada

Background: People with primary sclerosing cholangitis (PSC) have up to a 20% lifetime risk of cholangiocarcinoma (CCA). CCA surveillance is challenged by the poor performance of current screening methods. We report results of a multinational patient survey to assess knowledge of CCA surveillance and patient-provider communication on CCA risk and surveillance results. The primary goal was to identify gaps in knowledge and communication in anticipation of new CCA screening tests. **Methods:** A survey for adults with PSC was developed by PSC Partners and PSC Support patient organizations. Patients reported relevant medical history, CCA surveillance tests performed (MRCP, CA 19-9, ERCP), risk and results discussion, and CCA education. The data was analyzed to compare rates of proactive CCA discussion from providers by patient characteristics, region, and provider type. **Results:** A total of 623 responses met screening criteria, primarily from the US (45%) and UK (31%). 31 patients reported a biliary tract cancer diagnosis (25 CCA, 6 GBC). Only 51% of patients reported proactive discussions by their provider of CCA risks and surveillance. Among patients who had a proactive CCA discussion, 56% reported having sufficient information regarding CCA, versus only 15% among those without proactive discussion ($p < 0.001$). Patients in North America reported a higher rate of proactive discussion than Europe (58.2% / 36.9%, $p < 0.001$), and rates were higher for hepatologists than gastroenterologists (55.0% / 38.3%, $p < 0.001$). Discussion rates were not significantly different across patient gender, age, and time since PSC diagnosis.

Annual MRCP surveillance was reported by 68% of patients, with significant differences by region and provider type. Proactive CCA discussion was strongly associated with more frequent use of annual MRCP. Regular CA 19-9 testing was reported by 36% of respondents. MRCP and CA 19-9 testing results for CCA surveillance were discussed with 27% and 72% of patients who had those tests, respectively.

Only 36% of patients felt they had adequate CCA information; the majority seeking information from online search, followed by patient organizations and their care team. Patients consistently reported significant anxiety and fear regarding CCA risk and the need for a reliable, non-invasive screening test. **Conclusion:** The results show high variability in discussion of CCA risk and test results and CCA surveillance practice in a population burdened with anxiety and fear around CCA. These results are influenced by differences in regional guidelines, healthcare systems, and the lack of highly predictive non-invasive diagnostic and prognostic tools. Promising novel biomarkers to detect early CCA and risk will impact the current routine surveillance practices and patient education needs. Appropriate global patient/provider education and communication programs should be implemented to support the use and delivery of such tests.

4477 | PROTEOME-WIDE AUTOANTIBODY DISCOVERY USING PHAGE IMMUNOPRECIPITATION SEQUENCING IDENTIFIES A DISTINCT AUTOANTIBODY SIGNATURE OF PRIMARY SCLEROSING CHOLANGITIS

Arielle Klepper[1] Isaac Benque[1] Fawzy Barry[1] Julian Hou[1] Michele Tana[1] MIchael Kattah[1] Jennifer Lai[1] Joseph DeRisi[1] Michael Li[1], [1]University of California, San Francisco

Background: Primary sclerosing cholangitis (PSC) is unique among immune-mediated liver diseases in that there are currently no autoantibodies recommended for use in establishing a diagnosis. We conducted proteome-wide autoantibody discovery using phage immunoprecipitation sequencing (PhIP-seq) to identify novel targets of autoreactivity in PSC. **Methods:** PhIP-seq was performed using serum samples from 65 PSC patients, 146 healthy controls, and 60 patients with inflammatory bowel disease (IBD) who did not have PSC. Serum samples were incubated with a phage library displaying >700,000 overlapping short (49-mer) peptides encompassing the human proteome. Autoantibodies bound to phage were captured via immunoprecipitation, and the peptide-encoding phage DNA sequences were extracted and subjected to next-generation sequencing, revealing the identities of the corresponding autoantigens. Logistic regression and recursive feature elimination analysis were performed using the scikit-learn package in Python on quality

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

filtered data (at least 1 read per thousand and differentially enriched relative to healthy controls). Per peptide enrichment and Z-scores were calculated comparing PSC to control patients (IBD and healthy controls). **Results:** Of the PSC cohort, 43 (66%) were male, 46 (71%) had concurrent IBD and 40 (62%) had cirrhosis. We applied recursive feature elimination to quality filtered data; using this approach we were able to identify 8 features that could be used to effectively differentiate patients with PSC from patients with IBD in a logistic regression model (mean c-statistic on five-fold cross-validation 0.89 +/- 0.02). Additional highly specific (> 96%) hits with plausible biological relevance include melanocyte inducing transcription factor, expressed in Kupffer cells, and carbonic anhydrase 9 precursor, expressed in biliary epithelial cells; the former is dysregulated in cholangiocarcinoma and the latter is a known cholangiocarcinoma prognostic marker. **Conclusion:** Using proteome-wide immune profiling, we were able to identify 8 autoreactive targets that can be used to effectively discriminate patients with PSC from those with IBD. External validation of the antibody-based predictive model is in progress. Furthermore, certain top autoantigen hits may provide insight into PSC pathogenesis, though further studies are needed to orthogonally validate these hits and to investigate potential biological disease relevance.

4478 | COMPARATIVE EFFECTIVENESS OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR AGONISTS AS SECOND-LINE THERAPIES FOR PRIMARY BILIARY CHOLANGITIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

ADRIELLY MARTINS[1] Nidah Khakoo[2] Anish Reddy[3] John Reynolds[4] Christophe Corpechot[5] Alexandra Rousseau[5] M. Hassan Murad[6] Shahnaz Sultan[7] Cynthia Levy[3], [1]Schiff Center for Liver Diseases - University of Miami, [2]Emory University, [3]University of Miami, [4]Louis Calder Memorial Library, University of Miami Miller School of Medicine, [5]Saint-Antoine Hospital, Assistance Publique - Hôpitaux de Paris, [6]Mayo Clinic Rochester, [7]University of Minnesota and Minneapolis Veterans Affairs Medical Center

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease that may progress to cirrhosis and liver failure. For patients with inadequate response or intolerance to ursodeoxycholic acid (UDCA), peroxisome proliferator-activated receptor (PPAR) agonists have emerged as promising second-line therapies. **Methods:** We conducted a systematic review and frequentist network meta-analysis (NMA) of randomized controlled trials (RCTs) evaluating combination of UDCA + PPAR agonists versus placebo, UDCA, or both. The primary outcome was the achievement of a predefined biochemical response after 1 year of treatment (POISE); secondary outcomes included normalization of alkaline phosphatase (ALP), percentage changes in ALP and total bilirubin, and adverse events leading to treatment discontinuation. Subgroup analyses explored ALP responses across baseline ALP levels. A sensitivity analysis for the primary outcome including obeticholic acid (OCA) was also performed. **Results:** Eight RCTs comprising 727 participants and four PPAR agonists (bezafibrate, seladelpar, elafibranor and saroglitazar) were included. All agents outperformed placebo in achieving biochemical response and ALP normalization. Bezafibrate ranked highest for biochemical response; both bezafibrate and seladelpar ranked highest for ALP normalization. No significant differences were found in ALP reduction across baseline strata. Total bilirubin changes were not statistically significant. Discontinuations due to adverse events were infrequent. The sensitivity analysis including OCA confirmed the robustness of primary outcome (Figure). **Conclusion:** Add-on PPAR agonists are effective second-line therapies in PBC, bridging an important treatment gap. Treatment ranking variability may reflect heterogeneity in patient populations and drug mechanisms. In the absence of head-to-head trials, NMA provides valuable comparative insights; however, long-term safety data and patient-centered outcomes remain priorities for future studies.

Figure. Forest rank plot for biochemical response according to POISE criteria including the pivotal trials for second-line therapies in PBC

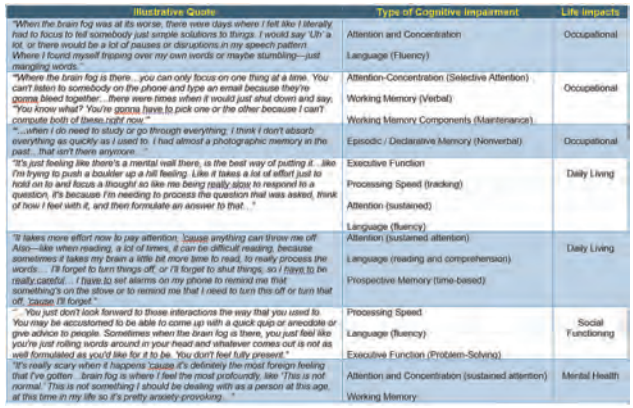
4479 | "THIS IS NOT NORMAL&RDQUO;: UNDERSTANDING COGNITIVE IMPAIRMENT THROUGH QUALITATIVE INTERVIEWS WITH ADULTS WITH PSC TO INFORM MEASURE DEVELOPMENT

Donna Evon[1] Kaya Merkler[1] Laura Mkumba[2] Lauren Wright[2] Nicole Lucas[2] Ricky Safer[3] Joanne Hatchett[3] Rachel Gomel[3] Stephen Rossi[3] Patrick Smith[1] Mark Swain[4] Sasha Deutsch-Link[1] Bryce Reeve[2], [1]UNC Chapel Hill, [2]Duke, [3]PSC Partners Seeking a Cure, [4]University of Calgary

Background: Understanding cognitive impairment experiences for adults living with PSC is essential for the development of PSC-specific, patient-reported outcome (PRO) measures that accurately reflect their real-world impact. Cognitive impairment ("brain fog") in PSC is under-recognized yet can be frequent and debilitating, and is differentiated from hepatic encephalopathy. **Methods:** Adults were recruited through the PSC Partners Patient Registry and PSC hepatologists in the U.S and screened for a range of PSC-related symptoms. Purposeful sampling was used to select 17 participants for in-depth, individual interviews focused on key symptoms, including cognitive impairment. Interviews were conducted virtually, audio-recorded, transcribed, and analyzed using NVivo software. **Results:** Eleven out of 17 participants were interviewed regarding their experience with cognitive impairment. Participants were on average 43 years old (range: 27-65), 55% male, 27% Black, 64% White, and 55% had inflammatory bowel disease. The Table below provides participants' illustrative quotes aligned with cognitive domains and life impacts. Severity ranged from mild to debilitating, with a few participants reporting inability to drive, cook independently, work full-time, or engage socially. Participants primarily characterized their cognitive impairments as occurring in the areas of working memory, verbal fluency, sustained attention, and processing speed. Others described a mental "wall" preventing them from absorbing and processing information. Half of participants endorsed experiencing some type of cognitive impairment on a daily basis, while others experienced it "a few days" a week or month. A "domino effect" can occur that begins with cognitive impairment reducing work productivity, which cuts into social time, and in turn, worsens mental health. Cognitive impairment. often accompanied fatigue, but reportedly can also occur alone. Most participants were able to differentiate PSC-related cognitive impairment from other causes based on association with severe fatigue, improvements with ERCPs and lactulose, and worsening during cholangitis attacks. **Conclusion:** PSC cognitive impairment is multi-faceted and impacts daily, work-related, and social activities among symptomatic adults with PSC. These findings will inform the customization of a PSC-specific PROMIS® Cognitive Function measure with strong content validity, enhancing its relevance for future clinical research and treatment evaluation.



Illustrative Quote	Type of Cognitive Impairment	Life Impacts
"When the brain fog was at its worse, there were days where I felt like I literally had to focus to tell somebody just simple solutions to things. I would say 'Uh' a lot, or there would be a lot of pauses or disruptions in my speech pattern. Where I found myself tripping over my own words or maybe stumbling—just mangling words."	Attention and Concentration Language (Fluency)	Occupational
"Where the brain fog is there…you can only focus on one thing at a time. You can't listen to somebody on the phone and type an email because they're gonna bleed together…there were times when it would just shut down and say, 'You know what? You're gonna have to pick one or the other because I can't compute both of these right now.'"	Attention-Concentration (Selective Attention) Working Memory (Verbal) Working Memory Components (Maintenance)	Occupational
"…when I do need to study or go through everything, I think I don't absorb everything as quickly as I used to. I had almost a photographic memory in the past…that isn't there anymore."	Episodic / Declarative Memory (Nonverbal)	Occupational
"It's just feeling like there's a mental wall there, is the best way of putting it…like I'm trying to push a boulder up a hill feeling. Like it takes a lot of effort just to hold on to and focus a thought so like me being really slow to respond to a question, it's because I'm needing to process the question that was asked, think of how I feel with it, and then formulate an answer to that…"	Executive Function Processing Speed (tracking) Attention (sustained) Language (fluency)	Daily Living
"It takes more effort now to pay attention 'cause anything can throw me off. Also—like when reading, a lot of times, it can be difficult reading, because sometimes it takes my brain a little bit more time to read, to really process the words… I'll forget to turn things off, or I'll forget to shut things, so I have to be really careful… I have to set alarms on my phone to remind me that something's on the stove or to remind me that I need to turn this off or turn that off, 'cause I'll forget."	Attention (sustained attention) Language (reading and comprehension) Prospective Memory (time-based)	Daily Living
"…You just don't look forward to those interactions the way that you used to. You may be accustomed to be able to come up with a quick quip or anecdote or give advice to people. Sometimes when the brain fog is there, you just feel like you're just rolling words around in your head and whatever comes out is not as well formulated as you'd like for it to be. You don't feel fully present."	Processing Speed Language (fluency) Executive Function (Problem-Solving)	Social Functioning
"It's really scary when it happens 'cause it's definitely the most foreign feeling that I've gotten…brain fog is where I feel the most profoundly, like 'This is not normal.' This is not something I should be dealing with as a person at this age, at this time in my life so it's pretty anxiety-provoking…"	Attention and Concentration (sustained attention) Working Memory	Mental Health

4480 | MACROPHAGE PKM2 ORCHESTRATES SPP1-MEDIATED HEPATIC PROGENITOR DIFFERENTIATION TO EXACERBATE DUCTULAR REACTION IN PRIMARY SCLEROSING CHOLANGITIS

Ping Tao[1] Di Zhang[1] Bo Hu[1] Haoxian Chen[1] Jiamin Wang[1] Zhongyan Du[1] Shan Zhang[1] Yiming Cui[1] Yuchen Lin[1] Hengdong Qu[1] Nan Yao[1] jian Hong[1], [1]Jinan University

Background: Periductal macrophages are implicated in ductular reactions during primary sclerosing cholangitis (PSC), yet the underlying mechanism of macrophage-ductular crosstalk remain undefined. This study aimed to explore the role of pyruvate kinase M2 (PKM2)-dependent macrophage reprogramming in PSC progression. **Methods:** Spatial transcriptomics and single-cell RNA sequencing (scRNA-seq) datasets from human (n = 18) and murine (n = 7) PSC livers were integrated to map macrophage niche landscape, validated by multiplex immunofluorescence. Three PSC models (DDC diet, bile duct ligation, and *Mdr2*$^{-/-}$) were employed in macrophage-specific *Pkm2* knockout mice (*Pkm2*$^{\triangle Mac}$). Mechanistic insights into PKM2-driven macrophage-ductular crosstalk were then elucidated through spatial transcriptomic profiling from *Pkm2*$^{\triangle Mac}$ models, chromatin immunoprecipitation sequencing, and human cholangiocyte organoids. Therapeutic interventions included pharmacological PKM2 inhibition (TEPP-46) and genetic knockdown (AAV8-F4/80-shPKM2) were administrated. **Results:** Integrated analyses of spatial transcriptomics and scRNA-seq revealed PKM2^{+} monocyte-derived macrophages were spatially enriched around reactive bile ducts, correlating with ductular reaction severity in human (R = 0.599, p = 0.040) and murine (R = 0.736, $p < 0.001$) PSC. *Pkm2*$^{\triangle Mac}$ mice showed reduced ductular reaction across three mouse models (DDC: -40.23 ± 0.04%; BDL: -60.12 ± 0.15%; *Mdr2*$^{-/-}$: -52.78 ± 0.20%; all $p < 0.001$ *vs.* controls), accompanied by decreased hepatic fibrosis. Our spatial transcriptomic analysis further demonstrated that periductal PKM2^{+} macrophages underwent functional reprogramming to promote differentiation of adjacent hepatic progenitor cells (HPCs) into cholangiocytes through integrin signaling. PKM2 bound the G-quadruplex in SPP1 promoter to enhance its translation and secretion in macrophages, thereby activating HPCs differentiation to exacerbate ductular reaction. Both pharmacological and genetic PKM2 inhibition effectively suppressed macrophage-driven ductular reaction and PSC progression, with corresponding reductions in hepatic SPP1/integrin signaling. **Conclusion:** PKM2 orchestrated macrophage reprogramming to aggravate ductular reaction in PSC progression via SPP1-mediated HPCs differentiation. Targeting macrophage PKM2 provides a promising therapeutic strategy for PSC.

4481 | THE IMPACT OF THE MELD EXCEPTION POINT POLICY CHANGE ON APPLICATION APPROVAL AND WAITLIST OUTCOMES FOR PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

Isaac Benque[1] Melinda Wang[1] Jennifer Lai[1] Michael Li[1], [1]University of California, San Francisco

Background: Patients with primary sclerosing cholangitis (PSC) may be at higher risk of adverse outcomes than is reflected by the MELD score due to bacterial cholangitis. Current Organ Procurement and Transplantation Network guidelines allow centers to apply for exception points if certain sepsis-based criteria are met. In July 2021, these guidelines were modified to be less stringent. We sought to characterize the effect of the policy change on application acceptance and waitlist outcomes. **Methods:** Using the October 2024 Standard Transplant Analysis and Research (STAR) files, adult PSC patients were split into equal 38-month periods pre and post the July 2021 policy change. MELD exception applications for sepsis/cholangitis were defined as those classified as “Other” per the STAR data dictionary. Patients with exception applications for other reasons such as cholangiocarcinoma or hepatocellular

carcinoma were excluded. If appeals were present, applications were collapsed to reflect the final decision. Logistic regression was used to assess application acceptance in the pre- vs post-policy periods. Competing risks analysis was used to investigate a composite outcome of waitlist dropout (delisting for being too sick) or mortality, with transplant as a competing risk. **Results:** Among 1778 PSC patients listed pre-policy change, 234 (13%) applied for MELD exception points while 173 (10%) patients applied out of the 1685 listed post-policy change. Out of all applications, 135 (58%) were accepted pre and 88 (51%) were accepted post (Fig A). There was no association between the post-policy period and application acceptance (OR 0.78, 95%CI 0.50-1.23, p = 0.3; Fig B). Competing risks regression demonstrated a decreased risk of waitlist dropout or mortality for patients with exception applications submitted post-policy change (HR 0.3, 95% CI 0.11-0.78, p = 0.01) compared to patients with applications submitted pre-policy change. However, the reduced risk of waitlist dropout or mortality post-policy change was re-demonstrated amongst the broader PSC population (HR 0.56, 95%CI 0.45-0.71, p < 0.001). **Conclusion:** The MELD exception policy change for PSC has not increased application submissions or lowered the threshold for application acceptance. Although there were improved pre-transplant outcomes for applicants in the post-policy period, this effect was present amongst all PSC patients. This suggests that time-based effects, such as improved organ availability due to allocation optimization and organ preservation advances, are responsible for the improved outcomes rather than the policy change.

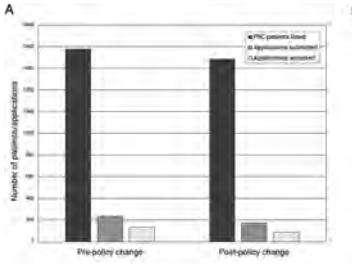

Figure 1. (A) Bar graph with number primary sclerosing cholangitis (PSC) patients listed pre vs post with the corresponding number of MELD exception points applications and number of accepted applications. (B) Multivariable logistic regression analysis of the association between time period and MELD exception point application acceptance.

4482 | EPIDEMIOLOGY, TREATMENT RESPONSE, AND GENETIC CHARACTERISTICS OF AUTOIMMUNE LIVER DISEASES: A RETROSPECTIVE AND PROSPECTIVE COHORT STUDY

Young Chang[1], [1]Soonchunhyang University

Background: Autoimmune liver diseases, including autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC), exhibit diverse clinical presentations and treatment responses. This study aimed to establish retrospective and prospective cohorts to analyze epidemiology, treatment response, and genetic differences associated with disease severity. **Methods:** A retrospective cohort included patients diagnosed with AIH or PBC between January 2005 and December 2023, while a prospective cohort was established from January 2021. Clinical characteristics, serological markers, liver biopsy findings, and treatment responses were analyzed. RNA sequencing was performed on blood samples to evaluate gene expression differences based on fibrosis stage and disease activity. **Results:** The retrospective cohort comprised 266 AIH and 40 PBC patients. AIH patients had a mean diagnosis age of 57 years, while PBC patients were diagnosed at 58.5 years, with over 80% female prevalence in both groups. AIH showed significantly higher IgG levels (1758 mg/dL) compared to PBC (1506.5 mg/dL). Antinuclear antibody positivity exceeded 90% in both groups, while anti-mitochondrial antibody was positive in 81.6% of PBC cases. After 12 months, biochemical indicators improved significantly in both groups. Steroid treatment in AIH significantly reduced immunoglobulin G, prothrombin time, and alkaline phosphatase levels. RNA sequencing revealed significant gene expression differences in AIH patients based on fibrosis severity, particularly in pathways related to cellular detoxification, response to toxic substances, steroid hormone signaling, and inflammatory regulation. In PBC, disease activity stage was associated with alterations in immune effector regulation, particularly in pathways related to natural killer cell-mediated immunity. **Conclusion:** This study highlights distinct clinical and genetic characteristics in AIH and PBC. Host factors, particularly immune-related pathways, play a crucial role in disease progression, emphasizing the need for individualized treatment approaches.

4483 | CLINICAL CHARACTERISTICS, TREATMENT PATTERNS, AND OUTCOMES AMONG AUTOIMMUNE HEPATITIS PATIENTS WITH LATER HOSPITALIZATIONS

Chandni Kapoor[1] Sheng-Fang Jiang[2] Nirmala Ramalingam[1] Sreepriya Balasubramanian[3] Kavita Radhakrishnan[4], [1]Kaiser Permanente Oakland Medical Center, [2]Kaiser Permanente Northern California Division of Research, [3]Kaiser Permanente Roseville Medical Center, [4]The Permanente Medical Group

Background: There are limited data on risk factors and outcomes for autoimmune hepatitis (AIH) hospitalizations. We recently observed that nearly 20% of adults with AIH had a liver-related hospitalization initially or later during follow-up. Among those with liver-related hospitalization, 43% were initially diagnosed outpatient and later had hospitalization >3 months after diagnosis. Those with later hospitalization were a higher-risk subgroup more likely to present with cirrhosis at AIH diagnosis and experience higher mortality. To identify potential areas for improving clinical outcomes, this study aims to characterize the indications for later hospitalization as well as both pre-hospitalization treatment patterns and post-hospitalization treatment modifications in this high-risk population. **Methods:** Adults aged ≥18 years in an integrated healthcare system with newly diagnosed AIH between 2010-2021 were identified via ICD codes (ICD-9: 571.42; ICD-10: K75.4) and confirmed with lab data and/or liver biopsy. Hospitalizations for AIH or liver decompensation (primary discharge diagnosis) were included if the hospitalization occurred >3 months after diagnosis. Admission indication and AIH treatment prior to hospitalization and at discharge were collected using electronic health record data. **Results:** Of 997 AIH patients, 169 (20%) underwent liver-related hospitalizations of whom 72 (43%) had late hospitalizations (median 866 days from AIH diagnosis). Among the 72 patients (median age 55 years), 81% were female, 14% Asian, 8% Black, 36% Hispanic, 35% White, and 21% were non-English speaking. 21% had overlap with PBC or PSC and 53% had cirrhosis at AIH diagnosis. The most common admission indications were abnormal liver labs, altered mental status, and other decompensated liver disease (ascites, bleeding). Prior to hospitalization, 46% were not on AIH treatment. Of the 39 on treatment, 21% were on steroid monotherapy and 79% were on maintenance +/- steroid therapy. Most patients (71%) had no changes to their AIH treatment regimen. Of those with treatment modification (n=21), 67% had additive modifications primarily addition or increased dosing of steroids while 33% had medications decreased. Long-term, 38% were readmitted, 20% transplanted, and 42% died. **Conclusion:** AIH patients with late hospitalizations are a high-risk subgroup with high rates of cirrhosis at diagnosis and death. These hospitalizations are largely due to liver decompensation. Nearly half of patients were not on AIH therapy prior to hospitalization and three-quarters had no changes made, suggesting their liver disease was deemed too advanced to benefit from therapy. These findings indicate a need for earlier diagnosis in this high-risk subgroup, with the goal of treatment initiation prior to development of cirrhosis to improve outcomes.

Table: AIH Patient Characteristics with Later Hospitalizations

	Later Hospitalizations N=72

Wyszomirska[1] Piotr Milkiewicz[1] Anneli Andersson[3] Piotr Socha[4], [1]Medical University of Warsaw, [2]The Children's Memorial Health Institute, [3]Perspectum Ltd, [4]The Children's Memorial Health Institute

Background: Signs of portal inflammation and fibrosis are hallmarks of autoimmune hepatitis (AIH), and a heterogeneity in disease activity across the parenchyma has been observed by imaging. The main objective of this study was to assess the heterogeneity of fibro-inflammation in AIH by non-invasive multiparametric magnetic resonance imaging (mpMRI) and its link with treatment response. **Methods:** Adults with AIH diagnosed in paediatric service were prospectively enrolled and underwent routine blood test, abdominal MRI and liver stiffness measurement (LSM, by Fibroscan, Echosens) at baseline during the transition of care. MRI was processed by LiverMultiScan (Perspectum Ltd, Oxford) to generate corrected T1 (cT1) maps of the liver using a semiautomatic method. Heterogeneity was measured as the interquartile range (IQR) of the pixels in the cT1 map. Patients were followed up over 18 months as part of the standard of care. Complete biochemical response (CBR) was defined as AST, ALT and immunoglobulin G (IgG) within normal limits, and active disease was defined as absence of CBR. **Results:** Seventy-one young adults with AIH (55% female; median age 21 ± 4 years), 44% with CBR at baseline, were included. The median age of diagnosis was 14.1 ± 4 years, and 28% presented as AIH with primary sclerosing cholangitis (AIH-PSC) and were excluded from this analysis. cT1 IQR correlated with LSM ($Rs = 0.47$, $p < 0.05$) and platelets ($Rs = -0.31$, $p < 0.05$), but not with other biochemical markers. Patients with CBR at baseline had lower cT1 IQR (103ms ± 25ms) than those in active disease (cT1 IQR: 121ms ± 32ms; $p < 0.05$). For cT1 IQR to distinguish active disease from CBR, the AUC was 0.72 (0.55-0.88, 95% CI) with sensitivity 0.80 at 104ms. cT1 IQR was lower (100ms ± 24ms) in those with CBR throughout the study, compared to active disease throughout (125ms ± 35ms; $p < 0.05$, Figure 1) and to those transitioning into active disease during follow-up, although not significantly (126ms; $p = 0.079$). cT1 IQR was lower in those who transitioned into CBR at 6 or 18 months follow-up (not significant at 12 months), than in those who remained active ($p < 0.05$). **Conclusion:** The heterogeneity in fibro-inflammation across the liver parenchyma (cT1 IQR) is associated with biochemical disease activity in young adults with AIH, and could be an early signal of transitions of disease activity. The mpMRI-derived metric show promise for utility in AIH monitoring and patient management.

4485 | SYSTEMIC METABOLIC REMODELING AND ABNORMAL MITOCHONDRIAL SIGNALING IN PRIMARY BILIARY CHOLANGITIS

Ning Sun[1] Hussain Syed[1] Filip wysokinski[2] Gopinath Sutendra[1] Evangelos Michelakis[1] Andrew Mason[1], [1]University of Alberta, [2]University of Calgary

Background: Patients with primary biliary cholangitis (PBC) produce anti-mitochondrial antibodies (AMA) targeting pyruvate dehydrogenase complex-E2 subunit (PDC-E2) that is overexpressed on the cell surface of cholangiocytes and in perihepatic lymph nodes. A hypothesis of mitochondrial dysfunction in PBC is supported by an increased number of dysmorphic mitochondria in cholangiocytes, elevated serum levels of mitochondrial Mn-superoxide dismutase, and reduced recovery from exercise with elevated lactate in muscles. We aimed to investigate the presence of metabolic remodelling and mitochondrial signalling in cholangiocytes and peripheral blood from patients with PBC. **Methods:** Oxidative phosphorylation (OXPHOS) was assessed in PBC and relevant control primary cholangiocytes in culture and peripheral blood mononuclear cells using isotopic glucose tracing and the seahorse assay. Proteomics and RNA-seq were used to profile changes in metabolic pathways, the TMRM mitochondrial dye was used to study mitochondrial membrane potential ($D\psi_m$), and qPCR was used to quantify mitochondrial DNA. **Results:** PBC cholangiocytes expressing increased PDC-E2 were found to preferentially use aerobic glycolysis as confirmed by proteomic/transcriptomic profiling, immunochemistry,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and functional studies demonstrating increased lactate production. PBC cholangiocytes expressed hyperpolarized mitochondria with increased $D\psi_m$, as well as an elevated mitochondrial DNA copy number consistent with compensatory mitochondrial biogenesis. Confocal microscopy of paraffin embedded liver samples revealed PBC cholangiocytes with activation of nuclear HIF1alpha signaling as a potential proximal factor in metabolic remodelling. Analysis of PBC whole blood revealed downregulated nuclear-encoded OXPHOS gene expression versus healthy subjects, whereas mitochondrial-encoded transcripts were increased. An increased frequency of PBC peripheral blood mononuclear cells expressed overexpression of the mitochondrial autoantigen PDC-E2, hyperpolarized mitochondria with increased $D\psi_m$, and elevated mitochondrial DNA suggesting mitochondrial biogenesis. **Conclusion:** Cholangiocytes and PBMC from PBC patients exhibited abnormal mitochondrial signalling linked with aberrant PDC-E2 expression. These findings support the hypothesis that AMA production may result from metabolic remodelling that is systemic in nature as previously reported with the overexpression of mitochondrial autoantigens in PBC lymph nodes. Further studies are merited to better understand how the metabolic remodelling impacts the development of delayed recovery from exercise, fatigue and cognitive changes in PBC.

4486 | EFFICACY AND SAFETY OUTCOMES IN PLACEBO-TREATED PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Harsimran Kalsi[1] Nikita Shah[1] Nihal Khan[2] Aalam Sohal[3] Kris Kowdley[3], [1]University of Central Florida, [2]Advent Health Orlando, [3]Liver Institute Northwest

Background: Primary sclerosing cholangitis (PSC) is a rare, progressive cholestatic liver disease with no approved medical therapies, leaving liver transplantation as the only definitive treatment. Clinical trials for PSC face challenges due to the disease's heterogeneity, small patient populations, and variable outcome measures, often complicated by placebo effects influencing subjective and biochemical endpoints. Additionally, understanding safety profiles in placebo arms is critical to distinguish disease-related complications from treatment effects. This meta-analysis aims to evaluate the magnitude of the placebo effect and safety outcomes in patients with PSC randomized clinical trials (RCTs). **Methods:** A systematic search of PubMed, Ovid, Cochrane, and clinicaltrials.gov was conducted to identify RCTs that included placebo arms in adult patients with PSC. Data were extracted for demographics, Alkaline Phosphatase (ALP) reduction, and adverse events. Pooled outcomes were calculated using a random-effects model. Heterogeneity was assessed using the I^2 statistic. **Results:** A total of 22 RCTs (N = 707) were included in the analysis. The mean age across studies was 44.6 years. Gender was reported in 21 studies, with 317 of 539 participants (58.8%) being male. Inflammatory bowel disease (IBD) was present in 345 of 497 patients (69.4%). Follow-up durations ranged from 4 to 260 weeks. UDCA was administered to 201 patients in the placebo group, representing 36.8% of participants. The pooled rate of ALP reduction $\geq$20% among placebo-treated patients was 8.1% [95% CI: 2.1 - 17.5]. In terms of safety, treatment-emergent adverse events occurred in 37.4% [95% CI: 13.9 - 64.6], and serious adverse events in 4.4% [95% CI: 1.7 - 8.2]. (Figure 1) Treatment discontinuation due to adverse events was reported in 3.1% [95% CI: 1.2-5.7] of patients. **Conclusion:** In placebo-treated patients with PSC, spontaneous ALP reduction $\geq$20% was uncommon, while a large majority experienced treatment-emergent adverse events. These findings establish important baseline benchmarks for interpreting efficacy and safety outcomes in future therapeutic trials for PSC.

4487 | CHARACTERIZATION OF YOUNG ADULTS WITH AUTOIMMUNE HEPATITIS AND FEATURES OF PRIMARY SCLEROSING CHOLANGITIS USING MULTIPARAMETRIC MRI

Maciej Janik[1] Magdalena Jaroszek[1] Kamil Janowski[2] CARLOS FERREIRA[3] Sylwia Chełstowska[2] Paulina Chodnicka[2] Elzbieta Jurkiewicz[2] Joanna Raszeja-Wyszomirska[1] Piotr Milkiewicz[1] Anneli Andersson[4] Piotr Socha[5], [1]Medical University of Warsaw, [2]The Children's Memorial Health Institute, [3]Perspectum Ltd, [4]Perspectum Ltd, [5]The Children's Memorial Health Institute

Background: Young adults with autoimmune hepatits (AIH), despite typical features in serology and histology, sometimes present with signs of primary sclerosing cholangitis (PSC) in cholangiography-MRI (MRCP). The main objective of this study was to assess the heterogeneity of fibro-inflammation by multiparametric magnetic resonance imaging (mpMRI) and quantitative MRCP to assess biliary abnormalities in patients with AIH at the transition to adult service. **Methods:** Adults with AIH diagnosed in paediatric service were prospectively enrolled and underwent routine blood test, abdominal MRI and liver stiffness measurement (LSM, by Fibroscan, Echosens) at baseline during the transition of care. MRI was processed by LiverMultiScan (Perspectum Ltd, Oxford) to generate corrected T1 (cT1) maps of the liver using a semiautomatic method. Heterogeneity was measured as the interquartile range (IQR) of the pixels in the cT1 map. Quantitative MRCP was generated by MRCP+ (Perspectum Ltd, Oxford). Patients were followed up over 18 months as part of the standard of care. Complete biochemical remission (CBR) was defined as AST, ALT and immunoglobulin G (IgG) within normal limits. **Results:** Seventy-one young adults with AIH (55% female; median age 21 ± 4 years), 44% of them in CBR at baseline, were included. The median age of diagnosis was 14.1 ± 4 years, and 28% of patients presented AIH-PSC variant. Patients with AIH-PSC had higher cT1 IQR, ALT, AST, GGTP and ALP, and lower platelets ($132ms \pm 44$, $95IU/L \pm 93$, $67IU/L \pm 50$, $249IU/L \pm 292$ and $245IU/L \pm 229$, respectively) than AIH patients ($112ms \pm 30$,$54IU/L \pm 85$, $41IU/L \pm 40$, $56IU/L \pm 74$ and $101IU/L \pm 73$) (all $p < 0.05$). Quantitative biliary metrics showed a larger tree in AIH-PSC patients compared to pure AIH (biliary tree volume $9ml \pm 5$ vs. $6ml \pm 5$ and number of ducts 62 ± 34 vs. 45 ± 38, Figure 1). In the pure AIH, cT1 IQR correlated with LSM ($Rs = 0.47$, $p < 0.05$) and platelets ($Rs = -0.31$, $p < 0.05$), but not with other biochemical markers. LSM correlated with inflammatory markers ALT ($Rs = 0.65$), AST ($Rs = 0.62$) and IgG ($Rs = 0.47$). In the AIH-PSC, cT1 IQR correlated with platelets ($Rs = -0.23$), FIB4 ($Rs = -0.31$) and number of dilatations ($Rs = 0.27$, all $p < 0.05$). **Conclusion:** Heterogeneity in fibro-inflammation across the liver parenchyma (cT1 IQR), elevated biliary tree volume and number of ducts are associated with AIH-PSC phenotype. The mpMRI-derived metrics of the parenchyma and biliary tree show promise for utility in AIH disease differentiation and patient management.

4488 | CORTICOSTEROID USE AND METABOLIC COMPLICATIONS IN AUTOIMMUNE HEPATITIS: INSIGHTS FROM A MULTINATIONAL PATIENT SURVEY

Libby Bell[1] Kelsey Green[1] Nadia Blessing[1] Craig Lammert[1], [1]Indiana University School of Medicine

Background: Although corticosteroid (CS)-sparing agents are the standard treatment for autoimmune hepatitis (AIH), CS use is commonly observed in clinical practice. Chronic CS therapy, even at low doses, is associated with significant adverse effects. This study assessed CS use patterns and related complications in a diverse multinational AIH cohort. **Methods:** Over a two-week period, members of the Autoimmune Hepatitis Association completed a 17-item online questionnaire regarding CS use throughout their disease course. Eligibility criteria included age ≥ 18 years and physician-confirmed AIH diagnosis. Significant CS use was defined as daily doses of ≥ 5 mg prednis(ol)one or ≥ 3 mg budesonide. Long-term CS use was defined as significant CS use exceeding 90 days per year, based on prior literature. **Results:** A total of 592 AIH patients participated (mean age 55.5 $\pm$ 15.8 years; mean disease duration 6.5 $\pm$ 4 years). The cohort was predominantly female (89.2%) and White (90.4%). At time of survey completion, 36.9% were receiving CS

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

treatment (mean daily doses: prednis(ol)one 8.8 ± 7.6 mg; budesonide 4.6 ± 2.9 mg). Among 557 patients treated with CS at diagnosis, 81.4% received prednis(ol)one (mean starting dose 38.3 ± 19 mg) and 10.8% budesonide (mean 4.8 ± 2.8 mg). Within six months of diagnosis, 47.9% reported at least one new metabolic complication: weight gain >5% (40.6%), hypertension (8.6%), dyslipidemia (7%), and diabetes mellitus (4.8%). No significant differences in complications were observed between CS medication type.

Long-term CS use was reported by 68.5% of patients with at least one year of disease. Those with long-term CS use were diagnosed at a younger age (47.6 ± 17.2 vs. 52.9 ± 15.6 years, $p < 0.001$) and had increased frequency of osteoporosis, type 2 diabetes, hypertension, and significant weight gain (all $p \leq 0.05$) compared to patients without long-term CS exposure. Multivariable logistic regression adjusting for sex, race, and age at diagnosis showed long-term CS use was associated with increased odds of osteoporosis (OR 2.1; 95% CI 1.3–3.3; $p = 0.007$) and hypertension (OR 2.8; 95% CI 1.3–6.4; $p = 0.01$). **Conclusion:** Metabolic complications related to CS use are common among AIH patients both near diagnosis and during long-term follow-up. Despite the availability of steroid-sparing therapies, chronic CS use remains widespread across disease durations, highlighting an urgent need for improved steroid-sparing treatments.

Table 1: Demographic and Medical Comorbidities according to Long-Term CS Use in AIH Patients

	Long-Term CS Use (n=151)	Never Long-Term CS Use (n=389)	p-value
Age at diagnosis, mean (SD) (yrs)	47.6 (17.2)	52.9 (15.6)	**<0.001**
Duration of follow-up, mean (SD) (yrs)	7.6 (7.5)	5.8 (8.6)	**0.02**
White, %	93.7%	92.2%	0.31
Non-Hispanic, %	81.4%	77.1%	0.71
Female, %	88.7%	92.4%	0.19
Osteoporosis, %	29.2%	21.2%	**0.05**
DM2, %	10%	4.1%	**0.02**
HTN, %	19.2%	10.6%	**0.01**
Dyslipidemia, %	16.8%	17.7%	0.8
Cataracts, %	17.3%	16.5%	0.82
Weight gain >5%, %	45.7%	28.2%	**<0.001**

SD: standard deviation, yrs: years, DM2: diabetes mellitus type 2, HTN: hypertension

4489 | PREDICTORS OF DEATH IN PATIENTS WITH SARCOIDOSIS AND ELEVATED LIVER ENZYMES

Neil Garg[1] Muhammad Saad Faisal[2] Syed-Mohammed Jafri[2], [1]Wayne State University School of Medicine, [2]Henry Ford Health System

Background: Sarcoidosis is a multisystem granulomatous disease that can involve the liver. While hepatic sarcoidosis is often subclinical, cholestatic liver pattern may be the first indication of hepatic involvement. However, the prognostic significance of elevated liver enzymes in patients with sarcoidosis remains poorly defined. This study aimed to evaluate the incidence and predictors of mortality in patients with sarcoidosis and elevated liver enzymes. **Methods:** We conducted a retrospective cohort study of patients with sarcoidosis daignosed between 1990 and 2025. Inclusion criteria were age 18 years or older and elevated liver enzymes (AST or ALT > 60 IU/L). Patients with a history of solid organ transplantation were excluded. They were followed up to death or May 10, 2025. Kaplan Meier survival analysis was performed to assess the cumulative probability of survival. We used logistic regression backward selection to assess the odds of being alive or dead at the end of follow up. The model was adjusted for cirrhosis, peak alkaline phosphate (ALP), peak total bilirubin, lowest albumin, and treatment for sarcoidosis. **Results:** Inclusion criteria were met by 101 patients. The median age was 61 years (Q1:51, Q3: 69), 61% were males, 67% were Black, 33% were White, 67.3% had multiorgan sarcoidosis involvement and 10% had biopsy proven hepatic sarcoidosis. While 27% were never treated, 31% were and 42% were on treatment at last follow-up. Nineteen percent of patients had cirrhosis, 18% had alcohol use disorder, and only 26% were seen by hepatology. Higher proportion of patients with cirrhosis were seen by hepatology compared to those who did not have cirrhosis (63.2% vs. 21.3%, $p < 0.001$). The median peak ALP and total bilirubin was 123.5 IU/L (Q1:86, Q3: 277) and 1.4 mg/dL (Q1: 0.9, Q3:2.2) respectively, and the median lowest albumin was 3.3 g/dL (Q1:2.7, Q3: 2.6). There were 18 deaths during the study period. The unadjusted 1, 3, 5-year survival rate was 92.8%, 90.4% and 88.8% (Figure 1). Total bilirubin and serum albumin were associated with increased odds of death after adjusting for cirrhosis, peak ALP, and treatment for sarcoidosis. Every unit increase in total bilirubin was associated with 45% lower odds of survival (OR = 0.55[0.35-0.85], $p = 0.0070$). Every unit increase of albumin was associated with 2.9 folds higher odds of survival (OR = 2.9 [1.10-7.68], $p = 0.03$). The model correctly identified no death in 74 out of 76 (97.4%) with an overall prediction accuracy of 86.2%. **Conclusion:** The survival in patients with sarcoidosis and elevated liver enzymes is favorable. Only 19% of the patients with sarcoidosis and elevated liver enzymes had cirrhosis. High total bilirubin and low albumin predicted mortality independent of the presence of cirrhosis. Early hepatology consultation and use of these factors to prognosticate survival may improve outcomes in patients with sarcoidosis.

4490 | COMPARATIVE ANALYSIS OF BIOCHEMICAL RESPONSE CRITERIA IN PREDICTING CLINICAL OUTCOMES IN PRIMARY BILIARY CHOLANGITIS PATIENTS WITH CIRRHOSIS

Christopher Dorizas[1] Maham Ghani[1] Michael Attanasi[1] Jade Pace[1] Bryana Belin[1] Islam Shahidul[1] Sanjaya Satapathy[1], [1]Zucker School of Medicine at Hofstra/ Northwell

Background: Primary biliary cholangitis (PBC) patients are typically treated with ursodeoxycholic acid (UDCA), with treatment response evaluated using various biochemical response (BR) criteria. This study aimed to compare the predictive performance of four BR criteria (Barcelona, Paris I, Paris II, and Rotterdam) for hepatic decompensation events in PBC patients with cirrhosis. **Methods:** In this retrospective study of 84 cirrhotic PBC patients on UDCA therapy, biochemical parameters were tracked over 12 months to determine BR using all four criteria. Hepatic decompensation events were monitored for the subsequent 12 months. The predictive performance of each criterion was analyzed using sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). **Results:** Paris I criteria showed the highest overall accuracy (72.4%) with good sensitivity (74.6%) and PPV (90.4%) (OR 4.70, 95% CI: 1.41–15.60; p = 0.037). Paris II demonstrated excellent specificity (84.6%) and PPV (94.6%) (OR: 6.88, 95% CI: 1.31-36.17, p = 0.013). Rotterdam criteria, though limited to 33 evaluable cases, showed perfect specificity and PPV (100%) (OR: 25.07, 95% CI: 1.37-458.23, p = 0.002). Barcelona criteria performed poorly with non-significant results. All criteria demonstrated poor NPVs (17.8-44.4%). **Conclusion:** Paris I and Paris II criteria showed complementary strengths in predicting clinical outcomes, while Rotterdam criteria, despite promising statistics, had limited practical applicability. These findings suggest that a combined application of Paris I and Paris II criteria may be optimal for clinical practice, with Rotterdam criteria considered when applicable.

Table 1: Comparative Analysis of Biochemical Response Criteria for Predicting Decompensation in Primary Biliary Cholangitis with Cirrhosis

Criteria (n)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)	Odds Ratio	95% CI	p-value
Barcelona (67)	33.9	72.7	86.4	17.8	40.3	1.37	0.32–5.92	0.722
Paris I (76)	74.6	61.5	90.4	33.3	72.4	4.70	1.41–15.60	0.037
Paris II (76)	55.6	84.6	94.6	28.2	60.5	6.88	1.31–36.17	0.013
Rotterdam (33)	60.0	100.0	100.0	44.4	69.7	25.07	1.37–458.23	0.002

4491 | ORAL VANCOMYCIN IN ADOLESCENTS AND ADULTS WITH PSC-IBD: A SINGLE-CENTER STUDY DEMONSTRATING SAFETY AND CLINICAL BENEFIT

Judah Kupferman[1] Kathryn Czepiel[2] Abhishek Dimopoulos-Verma[1] Chiraag Kulkarni[1] Sidhartha Sinha[1] Leina Alrabadi[2] Aparna Goel[1], [1]Stanford University Medical Center, [2]Stanford/Lucile Packard Childrens Hospital

Background: Nearly 70-80% of people with primary sclerosing cholangitis (PSC) have inflammatory bowel disease (IBD). The pathophysiology of PSC involves immune dysregulation and gut dysbiosis. Oral vancomycin therapy (OVT) has demonstrated efficacy in inducing IBD remission and improving liver biochemistries in PSC-IBD. We aimed to evaluate the safety and effectiveness of OVT in the management of PSC-IBD. **Methods:** This is a single-center, retrospective study of patients 12 years and older with PSC-IBD who were treated with OVT for at least

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

3 months from 2010-2024. Inclusion criteria were age 12 or older at time of PSC diagnosis. Patients were followed for up to 24 months from start of OVT or until discontinuation of therapy, whichever came first. Patients who received liver transplantation were excluded. Changes in alkaline phosphatase (ALP), gamma glutamyl transferase (GGT), Mayo PSC Risk Score, fecal calprotectin, and Mayo Endoscopic Score (MES) were evaluated during the study period. **Results:** Of 24 patients included, 54.2% were men and 9 (37.5%) were on ursodeoxycholic acid. Most patients (54.7%) were aged 12-17 years, 9 (37.5%) were 18-39 years, and 2 (8.3%) were 40+ years. Fourteen (58.3%) received OVT for >2 years, 9 have ongoing treatment for <2 years, and 1 discontinued OVT after 6 months due to lack of improvement in liver biochemistries. Sixteen (66.7%) had ulcerative colitis, 5 (20.8%) had Crohn's disease, and 3 (12.5%) had indeterminate IBD. While on OVT, 33.3% received treatment with mesalamine, 16.7% with biologics, 20.8% with steroids, and 4.2% with small molecules. Median OVT dosage was 1500 mg/day. After 12 months of OVT in 23 patients, median change in ALP was -86 U/L (IQR 272 U/L), GGT -128 U/L (IQR 207 U/L), and Mayo PSC Risk Score -0.35 (IQR 0.69). Total bilirubin and albumin remained stable during the study period. Median fecal calprotectin reduced by 343 mg/kg (IQR 350 mg/kg) after 24 months. Of 11 patients with follow-up colonoscopy at 1-2 years, 9 showed stable or improved MES on OVT and no additional IBD treatment was initiated. None developed infections with vancomycin-resistant organisms. **Conclusion:** In a single-center experience spanning adolescents and adults with PSC-IBD, 23 patients (95.8%) demonstrated improved liver biochemistries, Mayo PSC Risk score, and fecal calprotectin while receiving OVT. There were no vancomycin-resistant infections during the study period. This study emphasizes the potential of OVT as a treatment for PSC-IBD and highlights the importance of investigating its underlying mechanisms and long-term efficacy. Future research will involve comparing colonic and hepatic outcomes between a larger cohort of PSC-IBD patients and a control group.

4492 | EPIDEMIOLOGY AND OUTCOMES OF PRIMARY SCLEROSING CHOLANGITIS IN AN INTEGRATED HEALTHCARE SYSTEM

Ryan Murphy[1] Mehrnaz Siavoshi[2] Nirmala Ramalingam[2] Benjamin Hassid[2], [1]Kaiser Permanente Oakland Medical Center, [2]Kaiser Permanente Medical Center

Background: Primary Sclerosing Cholangitis (PSC) is a chronic, progressive liver disease characterized by inflammation and fibrosis of the bile ducts, leading to cirrhosis, liver failure, and increased cancer risk. Despite its rarity, PSC presents clinical challenges due to its association with inflammatory bowel disease (IBD), limited treatment options, and variable progression. In the US, data on PSC prevalence are limited, and demographic variations are poorly understood. This study examines the prevalence, demographic, and clinical characteristics of adults with PSC in Kaiser Permanente Northern California (KPNC). **Methods:** We conducted a retrospective study of KPNC members aged ≥ 18 years with PSC diagnosis during 2010-2024 in electronic health records using internal diagnosis codes and ICD-10 K83.01 (available since 2018); PSC cases were confirmed by chart review. Demographic data, body mass index, and smoking were extracted at diagnosis. Outcomes included IBD, cirrhosis, liver transplant, mortality, and PSC-related cancers. PSC diagnoses were ascertained from 2010-2024 and represented as an annual diagnosis capture rate using population denominators (Figure 1). Prevalence was estimated based on adults with PSC who were members in 2019 (and 2019 population denominators), with age-sex-adjusted prevalence by race and ethnicity derived from logistic regression. Statistical comparisons were made using Kruskal-Wallis and Wald Chi-Square tests. **Results:** We identified 469 adults with PSC (average age 49.6 years, 57.6% male and 58.8% non-Hispanic White, 9.4% Black, 12.8% Hispanic, 14.3% Asian and 4.6% other/unknown race). One-fifth had obesity (21.6%) and 4.1% and 20.7% were current or

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

former smokers, respectively. Annual diagnoses of PSC increased from 0.65–0.75 per 100,000 before 2018 to 1.65–1.67 from 2018–2019, coinciding with the new ICD-10 code for PSC. The prevalence of PSC was 10.5 per 100,000. Adjusted for age and sex, PSC prevalence was higher among White (14.0 per 100,000) and Black (14.3) adults and lower among Asian/Pacific Islander (7.8) and Hispanic (7.5) adults ($p < 0.01$ vs White). IBD was present in 61.2% of PSC patients, with 46.3% having ulcerative colitis and 13.0% having Crohn's disease. Cirrhosis occurred in 39.7% of patients and 14.9% underwent liver transplant. Overall, 13.9% of patients experienced at least one PSC-related cancer, and 12.6% experienced mortality from any cause. **Conclusion:** In this large and diverse healthcare system, we found a substantial burden of IBD, cirrhosis, malignancy, and mortality associated with PSC. The increase in PSC diagnoses beginning in 2018 likely reflects enhanced detection through ICD-10 coding. PSC prevalence was highest among White and Black adults and lower among Asian and Hispanic adults. Understanding these disparities is crucial for early diagnosis, healthcare planning, and development of targeted management strategies for PSC.

4493 | 6-MERCAPTOPURINE AND MYCOPHENOLATE MOFETIL IN PATIENTS WITH AUTOIMMUNE HEPATITIS AND AZATHIOPRINE INTOLERANCE: A COMPARATIVE MULTICENTER RETROSPECTIVE STUDY

Ludwig Jesse Horst[1] Bernardo Canhão[2] Alexander Fierenz[1] Cumali Efe[3] Álvaro Díaz-González[4] Johannes Hartl[1] Sina Hübener[1] Patricia Julianna Kovats[5] Rodrigo Liberal[6] Ansgar Lohse[1] María-Carlota Londoño[7] Ellina Lytvyak[8] Guilherme Macedo[6] João Madaleno[2] Beatriz Mateos Muñoz[9] Aldo Montano-Loza[8] Sean Morris[10] Dante Pio Pallotta[11] Maria Papp[5] Marcial Sebode[1] Palak Trivedi[10] Ye Htun Oo[12] Christoph Schramm[1], [1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Hospitais da Universidade de Coimbra, Unidade Local de Saúde de Coimbra, Coimbra, Portugal, [3]Harran University Hospital, Şanliurfa, Turkey, [4]Marqués de Valdecilla University Hospital, Santander, Spain, [5]Faculty of Medicine, University of Debrecen, Debrecen, Hungary, [6]Centro Hospitalar Sao Joao, Alameda Prof. Hernani Monteiro, Porto, Portugal, [7]Hospital Clínic Barcelona, Barcelona, Spain, [8]University of Alberta, Edmonton, Alberta, Canada, [9]Hospital Universitario Ramón y Cajal, Madrid, Spain, [10]University Hospitals Birmingham, Birmingham, UK, [11]University of Bologna, Bologna, Italy, [12]University Hospitals Birmingham, Birmingham UK

Background: Azathioprine (AZA) and corticosteroids are the recommended standard therapy for autoimmune hepatitis (AIH); however, around one-fourth of patients discontinue AZA due to intolerance. Although guidelines propose 6-mercaptopurine (6-MP) and mycophenolate mofetil (MMF) as alternatives, there is a lack of data on 6-MP and no comparative studies in AIH. This study aims to perform a comparative assessment of the efficacy and safety of 6-MP and MMF as second-line therapies for AIH patients who were intolerant to AZA. **Methods:** This multicenter retrospective cohort study involved AIH patients from eleven tertiary care centers across Europe and Canada who were intolerant to AZA and subsequently switched to either 6-MP or MMF as second-line interventions. Data on biochemical response, adverse effects, and treatment duration of second-line therapies were collected and analyzed, incorporating propensity score matching to validate the biochemical response. **Results:** We included 211 AIH patients, predominantly female (81%), with a median age of 54 years (IQR: 39–63 years). The median follow-up time was 60 months (IQR: 31–105 months). In AIH patients with prior intolerance to AZA, MMF was better tolerated than 6-MP (89% vs 67%; $p < 0.001$). Among patients who continued second-line treatment, both 6-MP and MMF exhibited comparable efficacy, achieving complete biochemical response in 61% and 66% of individuals, respectively, at the last follow-up (Figure 1). **Conclusion:** Both 6-MP and MMF are equally effective for maintaining biochemical response in AIH patients intolerant to AZA. While MMF is generally better tolerated, 6-MP may present a safer and effective treatment option in women of reproductive age. In addition, therapy with 6-MP enables clinicians to monitor drug metabolite levels, titrate dosages, and monitor adherence.

4494 | METABOLOMIC MACHINE LEARNING PREDICTOR FOR ADEQUATE AND DEEP RESPONSE TO UDCA IN NON-CIRRHOTIC PBC

Fan Yang[1] Jin Lin[1] Xiaoli Fan[1] Li Yang[1], [1]West China Hospital of Sichuan University

Background: Primary biliary cholangitis (PBC) patients exhibit heterogeneous responses to ursodeoxycholic acid (UDCA), with partial responders remaining at significant risk of disease progression. Current prognostic tools lack metabolic insights necessary for personalized management. This study aimed to elucidate the metabolic landscape of UDCA response and develop precision prediction models integrating clinical and metabolomic features. **Methods:** A total of 347 non-cirrhotic PBC patients were classified as complete responders (n = 214, Paris-II criteria) or non-responders (n = 133). Complete responders were further subdivided into deep responders (DR; ALP normalization) and adequate responders (AR; ALP 1.0–1.5× ULN). Plasma metabolomics was performed using LC/MS, identifying differential metabolites with VIP > 1, |log2FC| > 1, and $p < 0.05$. Machine learning models (LASSO/Random Forest) integrated clinical and metabolomic features. Prognostic risk was assessed using the UK-PBC and GLOBE scores. **Results:** Metabolomic profiling revealed suppressed bile acid biosynthesis (taurochenodeoxycholate, log2FC = -1.29) and enhanced glutathione metabolism in responders. AR patients exhibited a higher risk of disease decompensation ($p < 0.001$), associated with upregulated sphingolipid signaling and phospholipase D activity. Key metabolic predictors included the environmental plasticizer BBP and the anti-inflammatory agent Meloxicam. Prognostic scoring demonstrated significant differences in 15-year outcomes (UK-PBC: DR 0.041 vs. AR 0.055, p = 0.01). The integrated prediction model achieved superior performance in UDCA response classification (AUC = 0.91) and DR stratification (AUC = 0.87), outperforming clinical-only models. **Conclusion:** This study establishes a metabolically informed framework for PBC management, identifying modifiable pathways (PPARγ activation, sphingolipid inhibition) and validating clinical-metabolic prediction models. By redefining therapeutic success as metabolic restoration, these findings facilitate patient stratification and support precision diagnosis and treatment in PBC.

4495 | NK CELL PLASTICITY IN AUTOIMMUNE HEPATITIS: ACQUISITION OF GAMMA-DELTA–LIKE TRAITS

Kiandokht Bashiri[1] Atoosa Rabiee[2] Jessica Davis[2] Mark Mattar[3], [1]MedStar Washington Hospital Center, [2]Washington DC VA Medical Center, [3]Georgetown University Hospital

Background: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease driven primarily by T cells. The role of innate-like lymphocytes, such as natural killer (NK) cells and gamma-delta (γδ) T cells, remains underexplored. We investigated NK cell functional adaptations in AIH to elucidate their contribution to disease pathogenesis. **Methods:** We analyzed single-cell RNA-sequencing data (GSE216064) from peripheral blood mononuclear cells of 4 AIH patients and 4 healthy controls (Abe et al, 2024). After quality control, clustering, and annotation, we identified 14 immune cell types, including NK cells (AIH: 331; HC: 159) and γδ T cells (AIH: 14; HC: 57). Curated pathway scoring and Mann-Whitney U testing with Benjamini-Hochberg correction were applied to assess differential expression. **Results:** NK cells in AIH patients showed significantly elevated scores for γδ T cell activation pathways (Δ = +0.27, padj = 1.2×10^{-10}), T cell cytotoxicity (Δ = +0.32), chemokine signaling (Δ = +0.36), and Th1 differentiation (Δ = +0.25), indicating functional reprogramming. Conversely, γδ T cells exhibited mild upregulation of exhaustion markers (e.g., PDCD1, EOMES). Overall, 28 cell type–pathway interactions were significantly altered in AIH as shown in the dotplot, underscoring widespread immune dysregulation. **Conclusion:** While NK cell plasticity has been observed in autoimmune and neoplastic conditions, the adoption of γδ T cell–like features by NK cells in AIH represents a novel finding. This hybrid phenotype likely reflects immune adaptation to chronic liver inflammation, potentially compensating for impaired γδ T cell function. However, it may also exacerbate liver injury through heightened cytotoxic and pro-inflammatory activity. Future functional studies are needed to assess the stability, reversibility, and therapeutic modulation of this NK–γδ–like state within the hepatic microenvironment.

4496 | AUTOIMMUNE HEPATITIS PATIENTS WITH VARIABLE LEVELS OF BIOCHEMICAL RESPONSE HAVE DISTINCT DIFFERENCES IN PROTEOMIC PROFILES

Craig Lammert[1] Matthew Hamang[2] Thomas Daly[2] Christoph Preuss[2], [1]Indiana University School of Medicine, [2]Lilly Research Laboratories, Eli Lilly and Company

Background: Autoimmune hepatitis (AIH) is a prototypical auto-inflammatory liver disease that can result in liver failure and hepatic fibrosis. Normalization of liver tests (LTs) with immunosuppressive therapies have been associated with improved transplant-free survival. Treatment impact on proteins associated with immunoinflammatory response remains unknown, but clarity may provide insight into key mechanistic disease drivers. We aimed to describe proteomic differences between AIH patients at diagnosis and with varying levels of biochemical response according to LTs. **Methods:** Using a well-described AIH cohort, we utilized stored serum from distinct AIH groups and healthy controls (HC) for comparison. Group 1 (n = 9) included newly diagnosed AIH patients not currently on treatment; Group 2 (n = 24): AIH patients with normal LTs on stable treatment for at least 6 months; Group 3 (n = 26): AIH patients with abnormal liver tests despite treatment and diagnosis more than 1 year; Group 4 (n = 15): HC without known liver disease. Groups were compared using the OLINK explore platform, of which1,431 serum protein markers were assessed after QC. Proteins with log2FC changes +/- 2 were considered significant. Pathway analysis was performed using the curated KEGG pathway dataset. **Results:** 59 AIH patients satisfying the simplified criteria (69.5% female, mean age = 54 years (standard deviation (SD) = 15.2) were included in the study. Principal components analysis showed distinct clustering between Group 1 and HC which included many markers associated with inflammation and viral response (Table 1). Compared to HC, a majority of these markers remained similarly elevated in Group 3 as in Group 1, but were corrected with optimal control of inflammation (Group 2). A few markers remained elevated in Group 2 compared to Group 1 despite normalization of liver tests with ongoing treatment. While the majority of the residual markers were consistent with steroid use, KEGG pathway analysis also identified consistent PI3K-AKT-mTOR signaling in AIH patients after treatment. **Conclusion:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

These data suggest that while treatment corrects the majority of proteomic and biochemical abnormalities in AIH patients, abnormal immune activity can persist even in patients meeting treatment goal with ALT normalization. Persistent inflammatory perturbations could contribute to risk of ongoing disease progression.

Background: While absolute alkaline phosphatase (ALP) levels during ursodeoxycholic acid (UDCA) therapy have been associated with prognosis in patients with primary biliary cholangitis (PBC), treatment efficacy may be better evaluated by the change in ALP. The aim of this study was to assess how the reduction of ALP after start of ursodeoxycholic acid (UDCA) relates to clinical outcome in a nationwide cohort of patients with PBC. **Methods:** The retrospective Dutch PBC Cohort Study (DPCS) includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019-2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Where feasible, imputation was performed using joint model multiple imputation. Patients were included in case of at least one year of follow-up after start of UDCA. Laboratory values are presented in upper limits of normal (ULN). Patients were categorized according to their percentual reduction in ALP at one year after start of UDCA. The association with liver transplant (LT) and death was evaluated using Cox models. **Results:** In total, 3566 patients were included with a median age of 57.6 years (IQR 49.5–66.9) of whom 3131 (87.8%) were female. The median follow-up was 8.0 years (IQR 3.9–13.3) during which 622 patients died and 95 patients underwent LT. At one year after start of UDCA, 3054/3479 (87.8%) patients showed any ALP reduction, of whom 599 (19.6%) had a reduction of $\geq$60%. Table 1 shows that patients with greater one-year ALP reduction had higher baseline ALP levels; those without ALP reduction had a median baseline ALP of 1.09 x ULN (IQR 0.78-1.40) which was 3.84 x ULN (IQR 2.77-5.37) in the group with $\geq$60% reduction ($p < 0.001$). Adjusted for the absolute level of baseline ALP (and other prognostic parameters), the aHR was 0.93 (95% 0.90-0.96, $p < 0.001$) per 10% ALP decline. Across the subgroups based on percentage ALP reduction, the absolute ALP levels at one year were rather similar; median

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ALP at one year ranged between 1.13 x ULN (IQR 0.85-1.51) and 1.28 x ULN (IQR 0.94-1.72) ($p < 0.001$). Adjusted for the absolute level of ALP at one year of UDCA (and other prognostic parameters), the percentage reduction in ALP was no longer associated with LT or death (aHR 0.99 per 10% ALP decline, 95%CI 0.97-1.02, $p = 0.59$). **Conclusion:** The larger the percentage decline in ALP after start of UDCA therapy, the greater the reduction of the relative risk for LT or death. This substantiates that ALP can serve as surrogate endpoint to evaluate the efficacy of therapy for PBC. However, for the purpose of prognosis assessment, the percentage decline in ALP from baseline is not of additional value over the absolute ALP level at one year after start of UDCA.

ALP x ULN at start of UDCA	% reduction of ALP 1 year after start of UDCA	N	ALP x ULN 1 year after start of UDCA
1.09 (IQR 0.78 – 1.40)	No reduction	425	1.28 (IQR 0.94 – 1.72)
1.32 (IQR 1.03 – 1.72)	0%-10%	238	1.27 (IQR 0.97 – 1.66)
1.35 (IQR 1.09 – 1.82)	10%-20%	310	1.14 (IQR 0.94 – 1.52)
1.53 (IQR 1.18 – 2.01)	20%-30%	386	1.16 (IQR 0.89 – 1.51)
1.73 (IQR 1.33 – 2.49)	30%-40%	451	1.13 (IQR 0.87 – 1.60)
2.16 (IQR 1.62 – 3.23)	40%-50%	529	1.19 (IQR 0.89 – 1.77)
2.62 (IQR 1.99 – 4.13)	50%-60%	541	1.17 (IQR 0.89 – 1.81)
3.84 (IQR 2.77 – 5.37)	>=60%	599	1.13 (IQR 0.85 – 1.51)

Table 1. shows the median ALP levels of patients with PBC categorized based on their percentual reduction in ALP at one year after start of UDCA.

Erler[7] Adriaan van der Meer[1], [1]Erasmus University Medical Center, [2]Amsterdam University Medical Center, [3]University Medical Center Groningen, [4]Leiden University Medical Center, [5]Reinier de Graaf Gasthuis, [6]Noordwest Ziekenhuisgroep, [7]University Medical Center Utrecht, [8]St.Antonius Hospital, [9]Catharina Hospital, [10]Rijnstate, [11]Maastricht University Medical Center, [12]Gelre Hospitals, [13]Jeroen Bosch Hospital, [14]Albert Schweitzer Hospital, [15]Onze Lieve Vrouwe Gasthuis, [16]Diakonessenhuis, [17]Medical Center Leeuwarden, [18]Hospital De Gelderse Vallei, [19]Tergooi Hospital, [20]VieCuri, [21]Canisius/Wilhemina Hospital, [22]Bernhoven, [23]Medical Center Haaglanden, [24]Deventer Hospital, [25]Isala Hospital, [26]St. Anna Hospital

Background: Alkaline phosphatase (ALP), total bilirubin (TB) and gamma-glutamyl transferase (GGT) are associated with clinical outcome in patients with primary biliary cholangitis (PBC) treated with ursodeoxycholic acid (UDCA). A clear understanding of the evolution of these parameters is relevant for the discussion on the timing of response evaluation. We aimed to map the course of the cholestatic parameters following UDCA initiation in a nationwide cohort of patients with PBC. **Methods:** The Dutch PBC Cohort Study (DPCS) includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019-2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Laboratory values are expressed as upper limits of normal (ULN). The biochemical course after start of UDCA was explored and visualized using linear mixed-effects models with natural cubic splines, applied to the full dataset regardless of length of follow-up. Follow-up was censored at the initiation of second-line therapy and/or immunosuppressants. Effect plots were generated to show the expected biochemical values (back-transformed to their original scale) with corresponding 95% confidence intervals over 10 years. **Results:** A total of 4095 patients (3608 [88.1%] female) from the DPCS could be included. The median year UDCA was started was 2011 (IQR 2010 - 2014). At baseline, median age was 57.5 (IQR

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

49.3-67.0) years, 292 (7.1%) patients had cirrhosis, median ALP, GGT and TB were 1.9 x ULN (IQR 1.3 - 3.2), 6.5 x ULN (IQR 3.6-11.4) and 0.5 x ULN (IQR 0.4-0.9). During a median follow-up of 8.3 (IQR 3.4 – 14.0) years, the median number of ALP measurements per patient was 11 (IQR 7-17) with a median interval of 8.3 (IQR 5.6-10.7) months. This was 11 (IQR 6-17) with a median interval of 8.4 (5.8 – 10.9) months for GGT and 10 (IQR 5 - 15) for TB with a median interval of 9.1 (IQR 6.0-12.5) months. Overall, a steep decline in ALP, GGT and TB was primarily evident during the first year after start of UDCA. A more gradual second phase decline up to three years for ALP and GGT was observed in those with higher baseline levels (Fig. 1A-C). The course of the cholestatic parameters did not differ in subgroups based on age or sex. During long-term follow-up, the levels of the cholestatic parameters were generally stable except for TB in patients with cirrhosis at baseline (Fig.1D-F). **Conclusion:** In patients with PBC, ALP, GGT and TB primarily decline during the first year after start of UDCA. In some patients, the second phase decline in ALP may be considered when deciding on the timing of UDCA response evaluation. During long-term UDCA, the cholestatic parameters were stable. The increase in TB levels in patients with cirrhosis suggests disease progression over time.

4499 | ACHIEVING BIOCHEMICAL RESPONSE IN AUTOIMMUNE HEPATITIS: A COMPARATIVE STUDY BETWEEN KOREAN AND AMERICAN COHORTS

Kwang Il Seo[1] Laura Lavette[2] Mary McGrath[2] Sahil Khanna[2] Brian Wentworth[3], [1]Kosin University College of Medicine, [2]University of Virginia School of Medicine, [3]University of Virginia

Background: Autoimmune hepatitis (AIH) can affect patients of all ages, sex, and ethnicity. However, current standards of care are derived from research involving predominantly Western populations and less is known about AIH in East Asian populations. To address this deficiency, we conducted an international, multicenter study to assess patient profiles and time to biochemical response (BR) in Korean and American cohorts. **Methods:** We retrospectively reviewed the electronic medical records of patients with newly diagnosed AIH by compatible clinical features and liver biopsy at tertiary care centers [University of Virginia (UVA) and Kosin University Gospel Hospital (KUGH)] in the United States and Korea from January 2011 through December 2023. Normalization of transaminases within institutional laboratory reference range defined BR. Chi-square, Fisher exact, Mann-Whitney U, and two-sided t-tests were performed as appropriate for comparative univariate analysis. Time to BR between groups at 6- and 12-month intervals was assessed with the Kaplan-Meier method and log-rank test. Independent predictors of BR were analyzed via multivariate Cox proportional hazard (CPH) model. **Results:** A total of 175 patients (UVA: 140; KUGH: 35) were included. UVA patients were younger (mean 51.5 vs. 56.7, $p = 0.019$), more likely to be male (22.9% vs. 5.7%, $p = 0.022$), had higher baseline ALT (median 452 vs. 111 U/L, $p < 0.001$) and INR (median 1.2 vs. 1.1, $p = 0.021$), lower ANA positivity (60.4% vs. 77.1%, $p = 0.067$), and higher SMA positivity (47.7% vs. 15.6%, $p = 0.001$). There was no difference in mean IgG level, presence of acute severe-AIH, or degree of fibrosis between groups. Biochemical response rates were similar

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

in UVA and KUGH at 6 months (65.9% vs. 65.7%, $p = 0.980$) and 12 months (65.9% vs. 65.6%, $p = 0.976$). However, KUGH patients achieved BR faster at 6 months (log-rank, $p = 0.020$) and 12 months (log-rank, $p = 0.010$). METAVIR stage 4 (cirrhosis) predicted failure to achieve BR at 6 months (OR 0.211, 95% CI 0.064–0.701, $p = 0.011$); older age predicted BR at 12 months (OR 1.034, 95% CI 1.010–1.059, $p = 0.006$). **Conclusion:** Autoimmune hepatitis patient profiles were different between representative Western and East Asian populations. While Korean patients achieved BR faster, American patients achieved comparable rates of BR by 6 months, the current treatment standard. Further research is needed to understand if guideline-suggested immunosuppression regimens should account for ethnic differences.

4500 | MONITORING AZATHIOPRINE METABOLITES IN AUTOIMMUNE HEPATITIS AND IMPACT ON DISEASE OUTCOME

Anna HADJISOTERIOU[1] Laurenda Obeng[1] Fiona Rees[1] Yazan Haddadin[1] Ala Abu Layla[1] Emily Kerr[1] adele mourad[1] Lucy Ryan[1] Anthony To[1] Sumita Verma[2], [1]University Hospitals Sussex NHS Foundation Trust, [2]Brighton and Sussex Medical School

Background: Autoimmune hepatitis (AIH) is a chronic inflammatory condition of unknown aetiology. Azathioprine is usually the first line treatment for long term management of AIH. Our aim was to assess impact of monitoring of azathioprine metabolites (6TGN) on disease outcome. **Methods:** This was a single centre retrospective cohort study (2005 and 2021), last follow up being May 31st, 2024. Patients with AIH were identified from the histopathology database. From 2020, a dedicated gastroenterology pharmacist was involved in monitoring of azathioprine metabolites. Poor outcome was defined as one or more of the following: development of cirrhosis and or cirrhosis complications, failure to achieve remission, need for liver transplant and all-cause mortality. Data are presented as mean +/- SD or median (IQR). Multiple logistic regression analysis was performed. **Results:** A total of n = 112 patients were identified, females n = 88 (79%), mean age being 55.7 + 17 years. Pre-treatment n = 59 (53%) had definite and 43 (38%) probable AIH (IAIHG criteria). At presentation, n = 83 (74%) were symptomatic, n = 15 (13%) having acute severe AIH. Mean serum bilirubin (µmol/L) and ALT (iu/L) at presentation were 46 (13-148) and 525 (180-1325) respectively. Overall, 40 (36%) had cirrhosis at presentation and 14 (13%) developed it during follow up. Forty-nine (44%) had been assessed by a dedicated pharmacist. Sixty-one (54%) had results of azathioprine metabolite available and mean 6TGN levels (closest to remission) and at last follow up were 260 +/- 17 and 254 +/- 15 respectively (therapeutic range being 235-450 pm/8x10e8c).Azathioprine metabolite levels stayed relatively stable throughout follow-up. Overall n = 46 (41%) had poor outcome. On univariate analysis, predictors of poor outcome were pharmacist involvement (OR 0.29, 95% CI 0.12-0.67, p = 0.004), any 6TGN monitoring (OR 0.15, 95% CI 0.06-0.39, p < 0.001) and 6TGN levels in therapeutic range at last follow up (OR 0.11, 95% CI 0.01-0.91, p = 0.04). On multivariate analysis, the only predictor of poor outcome was any 6TGN monitoring (OR 0.17, 95% CI 0.05-0.62, p = 0.008). Of those with TGN monitoring 25% (n = 15) had a poor outcome vs 66% (= 29) without TGN monitoring (p < 0.001). Liver histology at presentation including fibrosis stage did not predict outcome. Mean total follow up duration was 119 +/- 70 months. **Conclusion:** This retrospective cohort study shows that monitoring of azathioprine metabolites and addition of a dedicated pharmacist could improve outcomes in patients with AIH. Our results however need to be corroborated by future prospective studies. Nonetheless, based on our findings, and to optimise outcomes in our patients with AIH, all newly diagnosed patients with AIH are now also monitored by a gastroenterology pharmacist including a helpline. We have also set up a combined hepatology-pharmacy clinic.

4501 | HEPATITIS B–DERIVED P-I-R CLASSIFICATION IS APPLICABLE TO ANTIBODY-POSITIVE PBC: EVIDENCE FROM REPEAT LIVER BIOPSIES

Hongli Liu[1] Xing Liu[2] Yi-Fan Hu[2] Sha-Sha Li[3] Miao-Yang Chen[4] Xi-Xuan Wang[1] Shu-Ling Chen[4] Yi-Jun Bao[4] Yu Zhang[4] Si-Wei Zheng[5] Li Wang[4] Zhi-Xiang Du[4] Qing-Fang Xiong[4] Yan-Dan Zhong[4] Du-Xian Liu[4] Cai-Yun Zhang[4] Kai Zhang[4] Yong-Feng Yang[1], [1]The Second Hospital of Nanjing, Teaching Hospital of Southeast University, [2]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, [3]The Second Hospital of Nanjing, Clinical Teaching Hospital of Medical School, Nanjing University, [4]The Second Hospital of Nanjing, Nanjing University of Chinese Medicine, [5]The Second Hospital of Nanjing, Clinical Teaching Hospital of Medical School, Nanjing University

Background: The P-I-R classification system (Progressive–Indeterminate–Regressive) was originally developed for assessing repeat liver biopsies in hepatitis B. Primary biliary cholangitis (PBC) is a chronic, progressive cholestatic liver disease. Traditional histological staging systems such as Ludwig and Nakanuma are limited in evaluating dynamic histological changes after treatment. Given that both hepatitis B and PBC primarily involve portal inflammation, this study aimed to explore the value of applying the P-I-R classification system in repeat liver biopsies of PBC patients. **Methods:** A retrospective analysis was conducted on the clinical and pathological data of 30 antibody-positive PBC patients who underwent two liver biopsies between December 2017 and December 2021 at Nanjing Second Hospital. The P-I-R classification was determined based on fibrous septa morphology and inflammatory activity. These results were compared with traditional histological staging systems (Ludwig, G, S, Nakanuma) and analyzed for correlations with biochemical indicators, symptom changes, and histological improvement. **Results:** The distribution of P-I-R types was equal (10 cases each for P, I, and R types). After treatment, patients classified as R-type showed significantly higher rates of histological improvement in Ludwig, S, and Nakanuma staging (all $p < 0.05$) compared to P-type, along with the greatest improvement in fatigue and pruritus symptoms (70% and 60%, respectively). Although ALP, AST, and GGT levels declined significantly ($p < 0.05$), their changes were not statistically associated with P-I-R classification ($p > 0.3$), suggesting that P-I-R provides independent histological assessment value. **Conclusion:** The P-I-R classification system effectively identifies directional histological changes in PBC patients. Compared to traditional static staging systems, it demonstrates higher sensitivity in detecting histological regression and aligns well with clinical symptom improvement. Therefore, it can serve as a valuable supplementary tool in evaluating treatment efficacy.

assess efficacy and safety of telitacicept, a novel BLyS/APRIL dual inhibitor, as a third-line therapy in AIH patients. **Methods:** This retrospective single-center study included 3 AIH patients diagnosed by the 2008 simplified criteria, with steroid dependence or refractory AIH. Telitacicept was initially given at 160mg weekly subcutaneously, then reduced to 160mg every two weeks in two patients. **Results:** Case 1
A 13-year-old female presented with jaundice and elevated transaminases (ALT 798U/L). Immunological tests showed positive ANA (1:100), SMA (1:100), and IgG (25.5g/L). Liver biopsy showed severe interface hepatitis (G3S3-4). Prednisolone 25mg/d improved liver function, but reducing to 15mg/d caused a flare. Subsequent combination therapies with MMF, or MMF and CsA, or tacrolimus, or sirolimus failed to achieve complete biochemical response (CBR). Steroid dose reduction always led to flares. Two months after adding telitacicept, ALT and IgG began to decline. At the end of follow-up, ALT was 56U/L and IgG 9.97g/L, with steroid doses tapered to 10mg/d. Side effects were injection site reactions and upper respiratory infection (Fig.1A).
Case 2
A 53-year-old woman with a 6-year history of recurrent liver dysfunction was diagnosed with AIH based on the liver biopsy, positive ANA (1:320), elevated ALT (152U/L) and IgG levels (19.3 g/L). She failed to achieve CBR with prednisolone and MMF. Steroids were stopped due to side effects, with MMF 0.75g/d as a maintenance therapy. After a flare, prednisolone was restarted but failed again. Switching MMF to tacrolimus provided only transient improvement. Telitacicept 160mg/week normalized IgG and reduced transaminases within 2 months. The dose was then reduced to 160mg every two weeks, keeping IgG below ULN, though transaminases were elevated. No side effects occurred (Fig.1B).
Case 3
A 48-year-old male with SLE presented with elevated transaminases (ALT 599U/L), IgG levels (20g/L) and positive ANA (1:1000). The liver biopsy showed moderate interface hepatitis (G3S3). Budesonide monotherapy or prednisolone combined with MMF could induce CBR but not prevent flares during steroid tapering. Adding telitacicept 160mg/week induced CBR and allowed steroid dose reduction. A flare occurred when tapering doses of MMF and telitacicept. Reinstituting prednisolone 20mg/d induced CBR again. Prednisolone and telitacicept doses were successfully tapered to 5mg/d and 160mg every two weeks respectively, with no side effects (Fig.1C). **Conclusion:** Our study demonstrates the potential of telitacicept in refractory AIH, marked by its ability to reduce transaminases and IgG, and decrease steroid doses. It was well-tolerated and safe.

Background: Autoimmune hepatitis (AIH) is a rare, chronic, immune-mediated liver disease, with rising incidence and prevalence worldwide. Non-White ethnicity has been associated with worse clinical outcomes in AIH. However, data from Latin America remain scarce, limiting the understanding of ethnic and regional variations in disease presentation, management, and prognosis. **Methods:** Retrospective, ongoing, observational, multicenter cohort study (ALLATIN) including 515 patients with autoimmune hepatitis from eight Latin American countries: Brazil, Argentina, Chile, Ecuador, Cuba, Mexico, Costa Rica, and Peru. **Results:** Most patients were female (82.5%), mean age at diagnosis 42.8 ± 19.2 years, and diagnosed with type 1 AIH (90.9%). Type 2 AIH accounted for 2.8% of cases, while 6.4% had no detectable autoantibodies. Disease presentation was asymptomatic in 42%, with isolated liver enzyme elevation. Among those presenting acutely, 2.2% had fulminant hepatitis [defined by jaundice, coagulopathy (INR $\geq$ 1.5), and encephalopathy], 8.7% had severe acute hepatitis [jaundice and coagulopathy (INR $\geq$ 1.5) without encephalopathy], and 28.4% had acute icteric hepatitis [jaundice without coagulopathy (INR $<$ 1.5) or encephalopathy]. At diagnosis, 42.9% of patients had advanced fibrosis (F3–F4) on liver biopsy, 35.0% were cirrhotic on ultrasound, and 26.6% had clinically significant portal hypertension. Overlap with autoimmune cholangiopathies was identified in 11.0% of patients (8.6% with primary biliary cholangitis and 2.4% with primary sclerosing cholangitis). Concomitant metabolic dysfunction-associated steatotic liver disease (MASLD) was present in 4.8%. First-line therapy included prednisone in 96.5% and azathioprine in 91.9% of patients. Second-line treatment was required in 9.2%, with mycophenolate mofetil being the most frequently used (63.6%), followed by tacrolimus (13.6%), cyclosporine (13.6%), chloroquine (6.8%), and rituximab (2.3%). Data on biochemical outcomes in 6 months were available for 71.1 % of the patients and in 63.9% in 12 months. Complete biochemical response was achieved in 68.4% at 6 months and 55.7% at 12 months. Incidence of hepatocellular carcinoma was low (1.1%). Liver transplantation was required in 3.9% of patients, and all-cause mortality was 3.1% in a mean follow up of 6.72 ± 6.0 years. **Conclusion:** This is the largest cohort of AIH reported from Latin America to date. Despite the predominance of type 1 AIH and the widespread use of standard first-line therapies, a substantial proportion of patients presented with advanced liver disease at diagnosis. Biochemical response was similar to European cohorts. These findings highlight the need for increased awareness, earlier detection, and region-specific strategies to improve outcomes in underrepresented populations.

Background: Biliary atresia is a rare, life-threatening, highly complex, progressive obstructive cholangiopathy. There are no approved pharmacologic treatments, and a Kasai hepatoportoenterostomy (HPE) is essential to restore bile flow and help prevent progression to liver failure. Patients can have elevated serum bile acids (sBA) and experience ongoing liver disease despite restoration of bile flow; 50–75% of patients will eventually require a liver transplant within 20 years of a Kasai HPE.[1] By reducing intrahepatic retention of bile acids and diverting them to the intestine, the ileal bile acid transporter (IBAT) inhibitor odevixibat could augment and sustain the native liver protective effects of Kasai HPE. BOLD is the first and only phase III clinical program investigating the disease-modifying potential of odevixibat in biliary atresia post-Kasai HPE. **Methods:** BOLD (NCT04336722) is a placebo-controlled phase III study evaluating odevixibat over 104 weeks in infants who have undergone Kasai HPE at $\leq$90 days old. Primary endpoint: time from date of first dose of study treatment to the first occurrence of liver transplant or death; secondary endpoints include time to onset of first sentinel event, total bilirubin levels, sBA levels, and time to pediatric end-stage liver disease score $>$15. BOLD-EXT (NCT05426733) is an open-label extension study to evaluate the long-term efficacy and safety of

odevixibat in eligible patients with biliary atresia who completed the BOLD study. Patients receive oral odevixibat 120 μg/kg/day once daily for 104 weeks (with an optional extension period), followed by a 4-week safety follow-up. Study endpoints are shown in the Figure. **Results:** BOLD initiated in July 2020 across 66 sites in North America, Europe, the Middle East, and Asia-Pacific (N = 254) with an estimated completion in mid-2026. BOLD-EXT initiated in 2022 (target enrollment, N = 180) and is currently running in 17 countries and is estimated to be completed in 2028. **Conclusion:** BOLD and BOLD-EXT will provide the first data on the use of odevixibat to target disease pathogenesis of biliary atresia in infants and children post-Kasai HPE. Results from BOLD-EXT will help to determine whether odevixibat is efficacious and protects the native liver in the long term.

Background: Pruritus is a common symptom of primary biliary cholangitis (PBC), affecting up to 80% of patients (pts). PBC-associated pruritus may cause substantial disability, including disruptions in sleep and impacts on everyday life. Pruritus can affect any body part of a pt with PBC but is often reported on the head, lower legs, back, palms, and soles. In the Phase 3 RESPONSE trial (NCT04620733), seladelpar, a first-in-class delpar (selective peroxisome proliferator–activated receptor delta [PPARδ] agonist), significantly decreased pruritus in pts with PBC with moderate to severe pruritus (numerical rating scale [NRS] ≥ 4) at baseline vs placebo. A greater reduction in itch was also observed with seladelpar vs placebo as measured by the 5-D Itch and PBC-40 scales in RESPONSE. Here, we further evaluate patient-reported disability and distribution of itch from the 5-D Itch scale in RESPONSE. **Methods:** Pts with PBC who had an inadequate response or intolerance to ursodeoxycholic acid, with alkaline phosphatase $\geq 1.67 \times$ the upper limit of normal (ULN) and total bilirubin $\leq 2 \times$ ULN, were randomized 2:1 to receive daily oral seladelpar 10 mg or placebo for 12 months. Within the 5-D Itch Disability domain, trends in the leisure/social, housework/errands, and work/school items were assessed in the overall population and in pts with NRS ≥ 4 at baseline. Changes in the 5-D Itch Distribution domain across different body regions were also analyzed in pts with NRS ≥ 4 at baseline. **Results:** Of the 193 pts in RESPONSE, 128 received seladelpar and 65 received placebo; 49 pts receiving seladelpar and 23 pts receiving placebo had NRS ≥ 4 at baseline. Scores for individual questions within the 5-D Itch Disability and Distribution domains were similar between seladelpar and placebo groups at baseline. At month 12, pts with NRS ≥ 4 at baseline who received seladelpar showed greater improvements vs placebo in the impact of itching on leisure/social (mean change from baseline −1.2 vs −0.2, $P < .005$), housework/errands (−1.1 vs −0.2, $P < .005$), and work/school (−1.2 vs −0.5, $P < .05$). Greater improvements in these questions were also seen with seladelpar vs placebo in the overall population regardless of baseline itch level. Among pts with NRS ≥ 4 at baseline, fewer seladelpar-treated pts reported itching across different body regions, including on the head, back, and other regions, vs placebo at month 12. **Conclusion:** Treatment with seladelpar improved itch-related disability and decreased bodily distribution of itch vs placebo.

4506 | CHARACTERIZATION OF A COHORT OF PATIENTS WITH ALAGILLE SYNDROME (ALGS) FROM TWO US HEALTH SYSTEMS IDENTIFIED LEVERAGING NATURAL LANGUAGE PROCESSING

Seema Meloni[1] Ravikumar Patel[1] Praveen Kumar-M[2] Sivaprakasm G[2] Gopinath Ashokkumar[2] Fatine Elaraki[3] Marie-Cecile Fournier[3] Danielle Dray[1] Sara Hassan[4], [1]Ipsen, Cambridge, MA, US, [2]nference, Cambridge, MA, US, [3]Ipsen, Boulogne-Billancourt, France, [4]University of Texas Southwestern, Children's Medical Center, Dallas, TX, US

Background: Alagille syndrome (ALGS) is a rare, genetically inherited disease that primarily presents in early childhood. Though this syndrome follows an autosomal dominant inheritance pattern, its variable penetrance can lead to challenges with diagnosis. For that reason, having more published data on characteristics and profiles of diagnosed patients can aid in future identification of yet undiagnosed patients. This study aimed to identify and characterize individuals diagnosed with ALGS from electronic health record (EHR) data from two major medical health systems in the United States (US) to add to the knowledge base regarding presentation of this disease. **Methods:** This is a non-interventional study leveraging de-identified data ranging from January 1, 2005 to November 15, 2024 from Mayo Clinic and Duke Health Systems. Patients were identified using both structured and unstructured data, where natural language processing (NLP) was utilized to review unstructured data. Patients were included if they had at least one relevant ICD code (ICD 9: 759.89, ICD 10: Q44.71), unstructured instance of diagnosis, or presence of any genetic mutations reported in structured or unstructured data at any time. All records of identified patients underwent manual review to confirm diagnosis. **Results:** In total, 141 patients (Mayo Clinic = 74; Duke Health = 67) were confirmed to have evidence of ALGS. Within the combined cohort, the majority were male (53.2%), White (67.4%), and not Hispanic/Latino (82.3%). The

median age at first available record with mention of ALGS was 3 years in the Mayo cohort and 2 years in the Duke cohort. Hepatic abnormalities were common and included jaundice (27.7%), pruritus (22%), cholestasis (22%), cirrhosis (12.1%), and end-stage liver disease (8.5%) (Table 1). Cardiac abnormalities were the second most common reported clinical feature, with hypertension (22%) and congenital heart disease (9.9%) being prevalent. Reports of skeletal, ophthalmologic, facial, and renal abnormalities were less frequent than other known common characteristics seen in ALGS patients for the identified cohort. **Conclusion:** To our knowledge, this is the first study to leverage EHR from two large medical institutions to identify and characterize a cohort of patients diagnosed with ALGS. These data will be valuable in furthering the understanding of the disease and potentially aid in faster diagnosis of yet undiagnosed patients.

Table 1: Baseline and Clinical Characteristics of Patients Diagnosed with ALGS

Variable	Mayo Clinic (n=74)	Duke Health (n=67)	Combined (N=141)
Age (years) at first available record, median (IQR)	3 (0.0 - 19.0)	2.0 (1.0 - 7.0)	N/A

4507 | EVALUATION OF CLINICAL EVENTS AND HEPATIC BIOMARKERS IN OBETICHOLIC ACID-TREATED PATIENTS ALIGNED TO 2021 US PRESCRIBING INFORMATION CRITERIA FROM THE HEROES STUDY

David Jones[1] Bettina Hansen[2] Thomas Capozza[3] Yutong Liu[4] Joanna McEwan[4] Brad Lasley[3] Jing Li[5] Joseph Konen[5] Gideon Hirschfield[6], [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Erasmus MC, Rotterdam, Netherlands; IHPME University of Toronto, Ontario, Canada, [3]Intercept Pharmaceuticals, Inc., Morristown, New Jersey, USA, [4]Genesis Research Group, Hoboken, New Jersey, USA, [5]Intercept Pharmaceuticals, Morristown, New Jersey, USA, [6]Division of Gastroenterology and Hepatology, Toronto General Hospital, Toronto, Canada

Background: Obeticholic acid (OCA) is indicated as second-line treatment for primary biliary cholangitis (PBC) in patients (pts) with intolerance or inadequate response to ursodeoxycholic acid (UDCA). In 2021, the OCA US Prescribing Information (USPI) was updated, contraindicating use in pts with decompensated cirrhosis, a prior decompensation event, or with compensated cirrhosis who have evidence of portal hypertension (PHTN). We evaluated clinical events and trends in hepatic biomarkers in OCA-treated vs non–OCA-treated pts who were aligned to OCA 2021 USPI criteria from HEROES, a fully real-world trial emulation (NCT05292872). **Methods:** HEROES analyzed pts with PBC from Komodo's Healthcare Map who experienced failure of UDCA and were either treated with OCA or eligible for but not treated with OCA from 2016 to 2021. Non–OCA-treated pts were followed from the visit date (control index) until the first occurrence of a clinical event, end of follow-up, or initiation of OCA; OCA-treated pts were followed from the date of first OCA dose (OCA index) until the first occurrence of a clinical event, end of follow-up, or OCA termination. Patients were allowed to contribute multiple control indexes. Standardized morbidity ratio weights were calculated to standardize the treatment arms. The USPI-aligned population excluded all pts with hepatic decompensation and/or presence of cirrhosis with clinical evidence of PHTN. Events of liver transplantation or death, as well as trends in total bilirubin (TB), alanine aminotransferase (ALT), aspartate aminotransferase (AST), platelets, and albumin, were assessed over 60 months. **Results:** In the weighted USPI-aligned population, 308 OCA-treated pts contributed OCA indexes, and 3252 non–OCA-treated pts contributed 310.4 control indexes. Liver transplants and deaths were less frequent among OCA-treated indexes (0 and 1 [0.32%], respectively) compared with non–

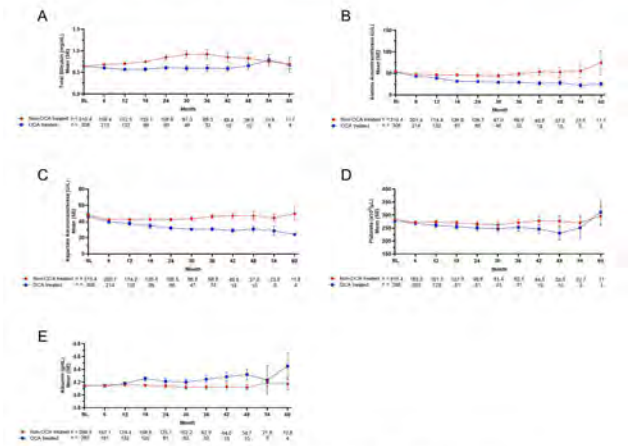
OCA-treated indexes (0.56 [0.18%] and 5.33 [1.72%], respectively). Compared with the non–OCA-treated arm, mean TB, ALT, and AST levels were consistently lower over time in the OCA-treated arm (Figure). Platelet and albumin levels generally remained the same through month 60 in the OCA-treated arm. **Conclusion:** In the real-world setting, no liver transplants were observed in the OCA-treated arm aligned to the USPI criteria, and fewer deaths occurred in the OCA-treated arm compared with the non–OCA-treated arm. Serum albumin, TB, and platelets remained stable, while ALT/AST improved over 60 months with OCA treatment.

Figure. Trends in total bilirubin (**A**), ALT (**B**), AST (**C**), platelet count (**D**), and albumin (**E**) from baseline to month 60 in the OCA-treated and non–OCA-treated arms



Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; OCA, obeticholic acid.

4508 | RATE OF LIVER EVENTS AND RELATED COMPLICATIONS IN A PREVALENT PRIMARY BILIARY CHOLANGITIS POPULATION: A US CLAIMS DATABASE ANALYSIS

Kaitlin Hagan[1] Sadia Halim[2] Lina Titievsky[1] Veronica Earley-Valovic[2] Alexander Cobitz[1] Megan McLaughlin[1] Walid Ayoub[3] Stuart Gordon[4], [1]GSK, Collegeville, PA, USA, [2]GSK, London, UK, [3]Cedars-Sinai Medical Center, Los Angeles, CA, USA, [4]Henry Ford Health, Michigan State University, Detroit, MI, USA

Background: Primary biliary cholangitis (PBC) is a chronic, progressive, immune-mediated, cholestatic liver disease. Liver-related complications include portal hypertension, varices, hepatic decompensation, and hepatocellular carcinoma. Patients with PBC may also experience other complications related to liver disease, including osteoporosis leading to fractures, and fat-soluble vitamin malabsorption due to reduced bile salts in the intestinal lumen. Limited population-based data exist on incidence rates (IRs) of these events among patients with PBC. These data are needed to contextualize clinical program findings and distinguish potential drug effects from those of the underlying disease. In this study, two cohorts—an overall PBC cohort and a trial-like cohort—were defined to generate relevant data for such contextualization. **Methods:** This was a retrospective cohort study of patients with prevalent PBC using 2016–2023 administrative claims data from Merative MarketScan Commercial and Medicare Supplemental Database. Patients with PBC were identified based on $\geq$2 ICD-10 diagnosis codes for PBC on separate inpatient or outpatient visits within a 1-year period. IRs of liver events and related complications (defined using ICD-10 codes) were estimated for the overall PBC population and a trial-like cohort meeting key inclusion/exclusion criteria of the Phase 3 Global Linerixibat Itch STudy of Efficacy and Safety iN PBC (GLISTEN) trial (NCT04950127). **Results:** Overall, 7160 patients with PBC were identified (mean age: 58.2 years, 86.7% female) of whom 2796 were included in the trial-like cohort (mean age: 56.1 years, 90.5% female). The median follow-up time was 1.4 years (interquartile range [IQR]: 0.6–2.7) for each cohort. In the overall PBC cohort, the IRs of liver-related events ranged from 0 events per 1000 person-years (PYs) for vitamin K deficiency to 200.5 per 1000 PYs for cirrhosis (95% confidence interval [CI]: 191.7, 209.6) (Table). Other liver-related events and related complications with the greatest IRs were ascites (IR: 41.2 per 1000 PYs, 95% CI: 37.8, 44.9), esophageal varices (IR: 48.9 per 1000 PYs, 95% CI: 45.1, 53.0), portal hypertension (IR: 43.9 per 1000 PYs, 95% CI: 40.3, 47.8), and fracture (IR: 48.1 per 1000 PYs, 95% CI: 44.3, 52.1). IRs were consistently higher in the overall PBC cohort

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

compared with the trial-like cohort. **Conclusion:** In the overall PBC cohort, cirrhosis, ascites, esophageal varices, portal hypertension, and fracture had the highest IR and cumulative occurrence. The same trend was seen in the trial-like cohort, with the exception of ascites. Overall, many of these events are common in the natural course of PBC. The higher IRs in the overall PBC cohort compared with the trial-like cohort likely reflect the trial exclusion criteria. These results provide important information to aid in contextualizing safety findings from PBC clinical trials.

Funding: GSK (222317)

Table. Incidence rates of liver events and related complications in the overall PBC cohort and trial-like cohort in Merative MarketScan Commercial and Medicare Supplemental Database 2016–2023

	Overall PBC cohort			Trial-like cohort*		
	Events, n	PY	IR per 1000 PY (95% CI)	Events, n	PY	IR per 1000 PY (95% CI)
Spontaneous bacterial peritonitis	89	13,564.2	5.1 (4.0, 6.4)	5	5186.4	1.0 (0.3, 2.3)
Ascites	530	12,858.3	41.2 (37.8, 44.9)	53	5118.0	10.4 (7.8, 13.6)
Cirrhosis	1942	9686.6	200.5 (191.7, 209.6)	478	4111.3	116.3 (106.1, 127.2)
Esophageal varices	608	12,424.0	48.9 (45.1, 53.0)	99	4986.0	19.9 (16.1, 24.2)
Varices other than esophagus	231	13,130.8	17.6 (15.4, 20.0)	67	5060.7	13.2 (10.3, 16.6)
Variceal bleeding	139	13,377.9	10.4 (8.7, 12.3)	19	5167.8	3.7 (2.2, 5.7)
Portal hypertension	551	12,543.1	43.9 (40.3, 47.6)	92	5002.5	18.4 (14.8, 22.6)
Hepatic encephalopathy	46	13,561.0	3.4 (2.5, 4.5)	0	5191.7	0

4509 | BIOPSYCHOSOCIAL APPROACH TO FATIGUE IN PRIMARY SCLEROSING CHOLANGITIS: IDENTIFYING TREATMENT TARGETS IN THE PROSPECTIVE SOMA.LIV STUDY

Anne Toussaint[1] Laura Buck[1] Bernd Loewe[1] Katharina Stahlmann[1] Jan Philipp Weltzsch[2] Ansgar W Lohse[3] Christoph Schramm[2] Johannes Hartl[4], [1]Department of Psychosomatic Medicine and Psychotherapy, University Medical Center Hamburg-Eppendorf, [2]Medical Center, University Medical Centre Hamburg-Eppendorf (UKE), Hamburg, Germany, [3]Medical Center, University Medical Centre Hamburg-Eppendorf (UKE), [4]Fist Medcical Center, University Hospital Hamburg-Eppendorf

Background: Fatigue is a debilitating symptom in autoimmune liver diseases, yet research in Primary Sclerosing Cholangitis (PSC) is scarce. This study aimed to estimate the prevalence of fatigue in PSC, investigate its biopsychosocial correlates, and identify predictors of fatigue severity to inform future treatment strategies. **Methods:** In this prospective study, 226 patients with PSC were enrolled. Fatigue severity was assessed using the fatigue domain of the PBC-40 questionnaire at baseline and again after six months. Potential predictors—including biomedical, psychological, and social variables—were assessed via clinical records, laboratory tests, and self-reported measures. **Results:** At baseline, 19% of patients exhibited clinically significant fatigue, defined as a PBC-40 fatigue score >33. Compared to those without significant fatigue, these patients reported greater psychosocial burden and showed worse disease-related biomarkers, including higher bilirubin and increased liver stiffness. However, multivariate regression analysis revealed that only elevated C-reactive protein (CRP) levels ($p = 0.02$)—not markers of cholestasis or liver disease stage—were significantly associated with fatigue severity at baseline. Psychological and social factors significantly associated with greater fatigue included maternal migration status ($p < 0.001$), fear-avoidance beliefs ($p < 0.001$), depression ($p < 0.001$), and antidepressant use ($p < 0.001$). Interestingly, higher anxiety severity was negatively associated with fatigue ($p < 0.001$). Over the six-month follow-up, fatigue levels remained relatively stable: 92% of patients without significant fatigue at baseline remained below the threshold, while fatigue persisted in 79% of those initially affected. Notably, higher baseline fatigue predicted greater fatigue reduction over time ($p < 0.001$), whereas elevated IL-6 levels ($p = 0.04$) and fear-avoidance beliefs ($p < 0.001$) were associated with worsening fatigue. **Conclusion:** Fatigue is a common and persistent symptom in PSC, shaped by both biological and psychological factors. Findings highlight the need for further research into the roles of systemic inflammation, as well psychosocial factors such as depression, and maladaptive coping behaviors. Interventions targeting these domains—particularly through promoting adaptive coping strategies—may offer promising avenues for treatment.

4510 | MODELING THE CLINICAL CONSEQUENCES OF GAPS AND DELAYS IN INITIATING SECOND-LINE THERAPIES IN PRIMARY BILIARY CHOLANGITIS PATIENTS WHO HAVE INADEQUATE RESPONSE TO URSODEOXYCHOLIC ACID

Robert Wong[1] Robert Gish[2] Alex van Doornewaard[3] Sasha Vidisheva[3] Nathaniel Smith[3] Ira Jacobson[4] Marvin Rock[5] Maria Agapova[5] Chong Hoon Kim[5], [1]VA Palo Alto Healthcare System, [2]Robert G Gish Consultants LLC, [3]Maple Health Group, LLC, [4]NYU Langone Health, [5]Gilead Sciences, Inc.

Background: In primary biliary cholangitis (PBC), inadequate biochemical control is associated with greater risk of progression to advanced liver disease and, in turn, transplant, and death. Approximately 40% of patients respond inadequately to first-line (1L) ursodeoxycholic acid (UDCA), while up to 5% are intolerant to UDCA. For these patients, timely initiation of effective second-line (2L) therapies is critical to avoid disease progression. This study aimed to evaluate the impact of gaps and delays in initiation of 2L therapies in PBC patients who have not achieved adequate response to 1L UCDA. **Methods:** A Markov model was developed to simulate clinical outcomes for patients with PBC over a 20-year time horizon. The model included health states for PBC, defined by alkaline phosphatase (ALP) and bilirubin elevation and compensated cirrhosis status, and advanced liver disease, including decompensated cirrhosis, hepatocellular carcinoma and transplant. For a cohort of 1,000 patients, timely 2L (i.e., immediate treatment) was compared with a gaps and delays scenario considering a range of 2L delay times (1-5 years) and never 2L (10-50%) estimates; in the base case, the mean delay was 1.25 years and 25% of patients never received 2L. Transition probabilities were derived from published literature and clinical trials. UDCA-intolerant patients were not considered as this subgroup (~5-10% of PBC patients) are not well characterized and likely have a different disease trajectory. Outcomes were assessed in terms of biochemical status and advanced liver disease outcomes, namely liver transplant-free survival (LTFS). **Results:** In the base case, timely 2L resulted in more patients achieving normalization of ALP after 1 (284/1,000 vs. 0/1,000) and 3 years (271 vs. 188). Alongside, more patients had ALP $\leq$ 1.67x the upper limit of normal: 659 vs. 0; 657 vs. 464. These differences translated to higher 10- and 20-year LTFS for timely 2L: 839 patients were alive and transplant-free at 10-years vs. 767 in the gaps and delays scenario; at 20-years, 630 vs. 516 patients, respectively. Outcomes were worse for longer delays and higher percentage never 2L estimates (Table 1). **Conclusion:** Gaps and delays in initiation of 2L therapies among PBC patients with inadequate response to 1L UCDA resulted in notably lower LTFS. Therefore, timely identification of inadequate responders to 1L UDCA and prompt linkage to 2L treatment is crucial for avoiding adverse clinical consequences of PBC.

4511 | PHYSICIAN REPORTED ASSESSMENT OF PRURITUS AMONGST PATIENTS WITH PSC: RESULTS: FROM A REAL-WORLD SURVEY IN FRANCE, GERMANY, ITALY AND THE UNITED STATES

Marlyn Mayo[1] Marco Carbone[2] William Johnson[3] Lena Amari[3] Guy Lacey[4] Lucia Quadrado[4] Jolan Terner-Rosenthal[4] Robin Howard[4] Verena Keitel-Anselmino[5], [1]University of Texas Southwestern Medical Center, [2]University of Milano-Bicocca, Milan, Italy, [3]Adelphi Real World, Bollington, United Kingdom, [4]Mirum Pharmaceuticals, Inc., Foster City, California, [5]University Hospital Magdeburg, Magdeburg, Germany

Background: Primary sclerosing cholangitis (PSC) is a chronic, progressive liver disease characterized by damage to intra- and extrahepatic bile ducts. Approximately 70% of patients with PSC indicate that they experience pruritus, but it is unclear if that frequency is also observed by the treating physicians and how often pruritus is discussed during office visits. The purpose of the current study is to describe physician reported frequency and assessment of pruritus amongst patients with PSC. **Methods:** Data were extracted from the

Adelphi Real World PSC Disease Specific Programme™, a cross-sectional survey with retrospective data collection of physicians and their patients with PSC in France, Germany, Italy, and the United States from November 2024 to April 2025. Elements of the retrospective data collection utilized physicians' EMRs which will be presented at a later date. The current presentation is focused on physicians' perceptions and attitudes around their management of PSC. Analyses used descriptive statistics. **Results:** Overall, results from 132 physicians were included in this analysis. The mean (SD) number of patients with PSC managed by each physician was 33 (42). Physicians stated that 41% (24) of their patients with PSC had pruritus and almost all (93%) believe that pruritus has a profound impact on a patient's quality of life (QoL). The majority (81%) of physicians indicated that clinically significant pruritus may be unidentified in many patients so pruritus is proactively assessed during routine visits. The most common ways physicians assess their patients' pruritus is through visual assessment of the patient's skin (77%), and questions focused on sleep (69%) and QoL (67%). Assessment of pruritus severity (62%) and frequency of episodes (64%) is also common. Importantly, 71% of physicians agree that a standard, easy to use pruritus assessment tool is needed to determine the severity of pruritus and impact on patients' QoL. While most physicians proactively discuss pruritus with their patients with PSC, common reasons for not assessing at every visit include: discussed in previous consultations (45%), patient has not complained of pruritus (41%), lack of effective antipruritic medications (30%), and limited visit time (29%). **Conclusion:** While most physicians report that they assess the presence of pruritus in their patients with PSC, there is a lack of uniformity in how it is ascertained. Perceived barriers include lack of time and effective treatment.

4512 | THE ROLE OF CHOLESTATIC GENETIC TESTING IN THE EVALAUTION OF PATIENTS WITH UNEXPLAINED CHOLESTASIS

Mitchell Shiffman[1] Jennifer Miller[1] Kimberly Taylor[1] Marilou Cicero[1] Sarah Hubbard[1] April Ashworth[2] Rebecca Rathburn[1] Staci Harpster[1] Karla Pray[1] Philip Alexander[1], [1]Bon Secours Mercy Health, [2]Bon Secours Liver Institute

Background: Genetic cholestatic disorders (GCD) are considered a rare form of cholestatic liver disease. These disorders are due to defective bile salt and/or phospholipid secretion into bile, the intrahepatic accumulation of toxic bile acids, liver injury, progressive fibrosis, cirrhosis, and liver failure. The most well recognized forms of GCD include Progressive Familial Intrahepatic Cholestasis (PFIC) and Alagille syndrome. These disorders typically present in infancy and early childhood and lead to the need for liver transplant at an early age. More recently, milder forms of GCD have been recognized in adults. This has been facilitated by the development of genetic panels for GCD which are now available for clinical use. Many adults have cholestasis of undefined etiology despite a thorough evaluation which would typically include serology, MRI/MRCP and liver biopsy. We hypothesized that the majority of these patients (pts) have a GCD. **Methods:** A total of 42 pts with cholestasis of undefined etiology underwent genetic testing. The criteria for genetic testing included an elevation in ALP that could not be explained by serologic testing, MRI/MRCP and/or liver histology; and either an elevation in serum bile acids, or unexplained itching. Pts were excluded if they had a defined etiology for cholestasis including PBC, PSC, sarcoidosis, amyloidosis, choledocholithiasis. **Results:** The mean age of the cohort was 56 years (16-81), 26% male, 50% Caucasian, 36% African American, 12% Hispanic. The mean ALP was 281 (61-1839), GGT 278 (17-1248), AST 54 (14-275), ALT 66 (10-488), TBILI 1.2 (0.2-24.0). Mean LS by Fibroscan was 7.2 kPa (3.2-17.3). 28/42 pts underwent liver biopsy. The most common histologic finding was mild non-specific portal inflammation with no fibrosis. 17% of pts had cirrhosis. Itching was present in 26%. Mutations in various genes associated with cholestasis were identified in 73% of pts. A total of 24 genes were affected in the 42 pts. 6 pts had 1 affected gene, 7 pts had 2 affected genes, 13 pts had 3 or more affected genes. The most commonly affected genes were: UGT1A1, CFTR, AKRIC4, ADAR. Mutations in ABCB4, a gene associated with PFIC-3 and MYO5B, a gene associated with PFIC-6, were identified in 3 and 1 pts respectively. Of the 7 pts with cirrhosis 75% had a mutation in at least one cholestatic gene. There was no relationship between which genes were affected and either the serum level of ALP, GGT, the presence of itching or cirrhosis. **Conclusion:** We conclude that mutations in genes associated with cholestasis are

common in adults with cholestasis of undefined etiology. The majority of pts with a GCD have affected genes that are not currenly known to be associated with PFIC or Alegille syndrome. Although the natural history of GCD in adults remains undefined and the majority of these pts appear to have mild histologic findings, 17% of pts had cirrhosis. Testing for GCD appears to be useful in adults with cholestsis of undefined etiology.

4513 | DISTINCT MOLECULAR MECHANISMS UNDERLYING PPAR-Δ–MEDIATED ALLEVIATION OF HEPATOCYTE INJURY IN PRIMARY BILIARY CHOLANGITIS

Garnik Arustamyan[1] Masashi Okawa[1] Yein Woo[1] Daniel Pinski[1] Ju Won Kim[1] Meng Li[2] Takeshi Saito[1], [1]Keck School of Medicine, University of Southern California, [2]USC Libraries Bioinformatics Service, University of Southern California

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease characterized by immune-mediated destruction of intrahepatic bile ducts, resulting in cholestasis and secondary bile acid-induced hepatocyte injury. Ursodeoxycholic acid (UDCA), the first-line therapy, achieves remission in only approximately 30% of patients, leaving the majority at risk of progressing to end-stage liver disease. Recently approved second-line treatments, PPAR-δ agonists, have demonstrated favorable clinical outcomes; however, the mechanisms through which PPAR-δ activation mitigates bile acid toxicity in hepatocytes remain poorly defined. This study, therefore, aims to delineate the molecular and biochemical effects of PPAR-δ activation in human hepatocytes (HHs) and elucidate whether these effects contribute to potential synergistic benefits with other PBC therapeutics. **Methods:** HHs were cultured in vitro and treated with PPAR-δ agonists (seladelpar or elafibranor) either as monotherapy or in combination with other PBC therapeutics, including FXR agonists (UDCA, obeticholic acid) and a PPAR-α agonist (fenofibrate). mRNA-seq-based transcriptomic profiling, followed by bioinformatics analyses, was performed to decipher hepatocellular responses unique to PPAR-δ agonism and shared pathways with other therapeutics to identify mechanisms regulating bile acid homeostasis. Additionally, the impact of PPAR-δ agonists on bile acid dynamics in HHs was evaluated using a fluorescently labeled bile acid trafficking assay and LC-MS–based bile acid profiling. Lastly, the therapeutic efficacy of PPAR-δ agonists, alone or in combination with other agents, was assessed in an in vitro cholestatic HH model through evaluation of cell death pathway activation status. **Results:** Transcriptomic analysis identified differentially expressed genes (DEGs) uniquely regulated via the PPAR-δ pathway, notably those involved in bile acid metabolism and trafficking. Comparative bioinformatics analysis indicated that gene expression changes driven by PPAR-δ were distinct, showing minimal overlap with patterns induced by FXR agonists or fenofibrate. Activation of PPAR-δ in HHs significantly decreased intracellular bile acid abundance. Quantitative LC-MS–based profiling further confirmed this reduction, particularly for highly toxic bile acid species, establishing a molecular basis for improved bile acid homeostasis via PPAR-δ activation. **Conclusion:** This study demonstrates that PPAR-δ activation restores hepatocellular bile acid homeostasis through molecular mechanisms distinct from those of other PBC therapeutics. Our findings highlight the therapeutic potential of PPAR-δ agonists for alleviating hepatocyte injury in PBC and suggest the utility of combination therapies with complemental mechanisms to enhance clinical outcomes.

4514 | HIGHER CIRRHOSIS BURDEN AMONG MINORITY PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A HEALTH DISPARITIES STUDY

Jade Pace[1] Maham Ghani[1] Michael Attanasi[1] Brittany Kwait[1] Christopher Dorizas[1] Bryana Belin[1] Shahidul Islam[1] Sanjaya Satapathy[1], [1]Zucker School of Medicine at Hofstra/Northwell

Background: Primary biliary cholangitis (PBC) outcomes may be influenced by racial disparities and social determinants of health, but this relationship remains understudied. **Methods:** We conducted a retrospective analysis of non-Hispanic White and minority patients with PBC to examine racial disparities and predictors of cirrhosis. Inclusion criteria consisted of patients at least 18 years of age with an ICD-10 code diagnosis of PBC and positive anti-mitochondrial antibody titer $\geq$1:40 that were admitted over the past 10 years at any of 23 Northwell Care sites. Demographic and clinical characteristics were compared between groups using the Chi-square or Fisher's exact test for categorical variables and Wilcoxon rank sum-test for continuous variables. Multiple logistic regression analysis was performed to identify independent predictors of cirrhosis, adjusting for relevant covariates including the Social Deprivation Index (SDI). **Results:** We identified 378 patients that met inclusion criteria (254 non-Hispanic White and 124 minority). Minority patients were younger (66 vs 73 years, $p < 0.001$), had lower BMI (24 vs 27, $p = 0.001$), and had higher SDI scores (59 vs 23, $p < 0.001$) compared to non-Hispanic Whites. They were more likely to be on Medicaid (22% vs 3.3%, $p < 0.001$) and undergo liver biopsy (9.7% vs 4.3%, $p = 0.041$). Minority patients had higher rates of cirrhosis (51% vs 37%, $p = 0.014$) and longer ICU stays (124 vs 72 hours, $p = 0.03$), but received less ursodiol treatment (44% vs 65%, $p < 0.001$). In the adjusted analysis, minority status remained an independent predictor of cirrhosis (Odds Ratio 1.95, 95% Confidence Interval [1.18-3.24], $p = 0.01$). **Conclusion:** Significant racial disparities exist in PBC care and outcomes, with minority patients having higher rates of cirrhosis despite younger age. These findings highlight the need for targeted interventions to address healthcare disparities in PBC management.

Table 1. Key Characteristics and Outcomes by Racial Groups in Patients with PBC

	Minority (n=124)	Non-Hispanic White (n=254)	P-value
Demographics			
Age, median (IQR)	66 (55, 75)	73 (63, 80)	<0.001
BMI, median (IQR)	24 (22, 28)	27 (23, 31)	0.001
SDI score, median (IQR)	59 (28, 83)	23 (8, 46)	<0.001
Medicaid Insurance, n (%)	18 (22)	7 (3.3)	<0.001
Clinical Outcomes			
Cirrhosis, n (%)	58 (51)	77 (37)	0.014
ICU Length of Stay, hours, median (IQR) *	124 (71, 277)	72 (44, 129)	0.030
Liver Biopsy, n (%)	12 (9.7)	11 (4.3)	0.041
Ursodiol Treatment, n (%)	54 (44)	165 (65)	<0.001

progressive bile duct damage and can progress to end-stage liver disease. While often asymptomatic at diagnosis, many patients later develop fatigue and pruritus, impacting health-related quality of life (HRQoL). The growing emphasis on HRQoL in liver disease highlights the need for patient-centered care. This study examines HRQoL in a U.S. PBC cohort by correlating clinical markers with patient-reported outcomes (PROs). **Methods:** We conducted a prospective, single-center study to assess HRQoL in U.S. PBC patients by examining associations between PROs and clinical data. Participants completed the PBC-40 and consented to medical record review. Exclusion criteria included age <18, missing data for score assessment, early ursodeoxycholic acid (UDCA) discontinuation, or missing PROs after 12 months. Clinical variables included demographics, liver biochemistry, cirrhosis status, and treatment response per Paris II criteria. GLOBE scores stratified prognostic risk, and standard cutoffs defined liver stiffness categories. Categorical variables are reported as frequencies (%), with comparisons via χ^2, Mann–Whitney U, or Kruskal–Wallis tests. Pairwise Pearson correlations assessed relationships between PBC-40 domains, GLOBE score, and liver stiffness ($p < 0.05$). **Results:** A total of 121 U.S. patients with PBC were included, with a mean age at diagnosis of 54 years; 89% were female. UDCA response was observed in 59% of patients, while only 3% were high risk by GLOBE score. Despite biochemical response, Paris II responders reported worse social, emotional, and total PBC-40 scores ($p = 0.017$, 0.015, 0.021), while the GLOBE score showed no association with HRQoL. In contrast, liver stiffness–based risk correlated with worse social, cognitive, and emotional scores ($p = 0.017$, 0.020, 0.041), with a trend toward higher total scores ($p = 0.052$). PBC-40 domains showed no significant correlations with GLOBE score or liver stiffness. GLOBE score correlated modestly with liver stiffness ($r = 0.28$, $p = 0.002$). **Conclusion:** PROs in PBC often diverged from objective disease measures, suggesting that traditional clinical parameters may not fully capture the patient experience. These discrepancies underscore the importance of a personalized approach to care, incorporating both baseline risk and PROs. Treatment should focus not only on slowing disease progression and improving liver tests but also on recognizing and addressing quality of life.

4516 | AUTOIMMUNE-RELATED CIRRHOSIS IS ASSOCIATED WITH AN INITIAL LOWER RISK OF DECOMPENSATION AND HEALTHCARE UTILIZATION: A POPULATION-BASED ANALYSIS

Raj Vuppalanchi[1] Craig Lammert[1] LaKeisha Boyd[2] Yang Li[2] Lauren Nephew[1] Marwan Ghabril[1] Naga Chalasani[1] Eric Orman[1] Archita Desai[1], [1]Indiana University School of Medicine, [2]Indiana University School of Medicine and Richard M. Fairbanks School of Public Health

Background: Cirrhosis due to autoimmune etiologies (Autoimmune-related cirrhosis, ARC) has a distinct clinical phenotype with unique patterns in natural history. The current study aims to characterize patients with ARC and compare their outcomes with those of patients with other common etiologies of cirrhosis.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Methods: The Indiana Digital Cirrhosis Cohort comprises 13,264 adults diagnosed with cirrhosis between 2018 and 2020. Participants were stratified into two groups based on cirrhosis etiology: (1) ARC (AIH/PBC/PSC) and (2) other etiologies (non-ARC). We compared baseline demographics, clinical characteristics, and healthcare utilization (HCU) between the two groups. Outcomes included time to first decompensation, liver transplant (LT), and death. Multivariable Cox regression models examined the time from diagnosis to these outcomes between the two groups, adjusting for age, gender, race, insurance, marital status, and MELD3.0 score. Multivariable logistic regression was used to identify predictors of initial decompensation and LT/death. **Results:** The prevalence of ARC was 11% (n = 1454), and differed from those with non-ARC in sociodemographic, clinical, and HCU features [more female (75% vs. 44%, $p < 0.0001$), White (91% vs. 87%, $p < 0.0001$), commercially insured (34% vs. 26%, $p < 0.0001$), married (57% vs. 43%, $p < 0.0001$)]. The ARC group had significantly lower prevalence of alcohol use disorder (3% vs. 20%), type 2 diabetes (22% vs. 33%), coronary artery disease (11% vs. 17%), and substance use disorder (1% vs. 8%) [all $p < 0.0001$]. They also had higher albumin (3.8 vs. 3.6 g/dL), higher platelet count (173 vs. 136 $\times 10^9$/L), and lower MELD3.0 scores (13.1 vs. 15.2, $p < 0.0001$). At baseline, 87% (n = 1267) of the ARC group and 77% of the non-ARC group were compensated. The frequency of HCU and decompensating events is reported in Table 1. A greater proportion of ARC patients remained compensated over time, with a lower risk of decompensation compared to the non-ARC group (HR: 0.58; 95% CI: 0.52-0.65). Significant predictors of decompensation for the ARC group included lower age, male gender, White race, and a MELD score of 15 or higher. After initial decompensation, the transplant-free survival rates were similar between the two groups (HR 0.997; 95% CI: 0.867-1.147). **Conclusion:** Patients with ARC have a better early prognosis with fewer comorbidities, fewer hepatic decompensations, and lower HCU. However, after the initial decompensation event, survival in the ARC group is similar to that of cirrhosis from other etiologies.

Variables	Autoimmune-related Cirrhosis (N=1454)	Cirrhosis of Other Etiology (N=11,810)	p-value
Healthcare Utilization in the prior 12 months **(N, %)**			
Patients with at least one Emergency Department visit	497 (34.2)	5435 (46.0)	<0.0001
Patients with at least one Hospitalization	349 (24.0)	4655 (39.4)	<0.0001
Cirrhosis Complications, Prevalence (N, %)

4517 | ASSOCIATION BETWEEN INSOMNIA AND DISEASE SEVERITY IN PRIMARY BILIARY CHOLANGITIS: A PROPENSITY-MATCHED COHORT STUDY

Sameer Rao[1] Ritik Mahaveer Goyal[1] Manas Gunani[2] Rohan Karkra[1] Anjul Verma[3] Menna-Allah Elaskandrany[4] Paul Gaglio[1] Nikki Duong[5], [1]Rutgers New Jersey Medical School, [2]Allegheny General Hospital, [3]Texas Tech University of Health Science Center, [4]Lenox Hill Hospital, [5]Stanford University

Background: Primary biliary cholangitis (PBC) is a chronic, progressive autoimmune cholestatic liver disease characterized by immune-mediated destruction of the intrahepatic bile ducts, resulting in cholestasis, inflammation, fibrosis, and potentially cirrhosis. Recent studies have shown that patients with PBC are at increased risk for poor sleep quality, and among these patients, those with more severe sleep impairment may experience worse biochemical and clinical outcomes. Therefore, we aimed to conduct a population-level study to evaluate the impact of insomnia on outcomes in patients with PBC. **Methods:** We conducted a retrospective cohort study using the TriNetX database and International Classification of Diseases-10 codes to compare outcomes in patients with PBC with comorbid insomnia and those with PBC alone. Patients with coexisting liver diseases such fatty liver, alcoholic liver disease, viral hepatitis, primary sclerosing cholangitis, and other chronic liver conditions were excluded. Primary outcomes were major adverse liver outcomes (MALOs). Other outcomes included major cardiovascular events, biochemical parameters, and all-cause mortality. Propensity score matching (1:1) was performed to adjust for demographics, pruritus, chronic medical and psychiatric conditions, and use of hepatotoxic or psychotropic medications. Relative risks (RRs)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and 95% confidence intervals (CIs) were calculated, with a P-value $<.05$ considered statistically significant. **Results:** We included 1,202 PBC patients with comorbid insomnia (mean age 70.3 $\pm$ 13.9 years; 85.8% female) and 15,952 without insomnia (mean age 68.0 $\pm$ 14.9 years; 82.9% female). After propensity score matching, 1,137 patients per group were followed for a mean of 3.6 $\pm$ 3.3 years. Insomnia was not associated with increased risk of MALOs, including ascites (RR 0.85; 95% CI 0.65–1.12; P = 0.25), hepatic failure (1.11; 0.82–1.51; P = 0.49), hepatic failure with coma (1.11; 0.68–1.83; P = 0.67), portal hypertension (1.00; 0.75–1.32; P = 0.98), esophageal varices (0.93; 0.67–1.31; P = 0.69), spontaneous bacterial peritonitis (0.96; 0.51–1.79; P = 0.90), hepatorenal syndrome (1.06; 0.57–1.94; P = 0.86), and liver transplantation (1.62; 0.74–3.54; P = 0.23). While rates of acute myocardial infarction (1.44; 1.00–2.08; P = 0.05) and mortality (1.16; 0.98–1.38; P = 0.09) were higher in the insomnia group, they were not statistically significant. Biochemical parameters were also comparable, including alkaline phosphatase (168.26 vs 177.47 U/L; P = 0.25), total bilirubin (1.37 vs 1.51 mg/dL; P = 0.43), albumin (3.67 vs 3.65 g/dL; P = 0.50), international normalized ratio (1.24 vs 1.33; P = 0.10), and platelet count (216.72 vs 218.28 $\times 10^9$/L; P = 0.75). **Conclusion:** PBC patients with insomnia do not appear to have worse MALOs when compared to patients without insomnia. The clinical significance of this association remains unclear and warrants further investigation.

Table – Comparison of clinical and biochemical outcomes in primary biliary cholangitis with and without insomnia

Clinical outcomes after propensity matching	N (1,137)	%	Relative Risk	Confidence interval	P-value
Acute myocardial infarction	66	6.05	1.44	(0.998,2.079)	.0500
	46	4.20

4518 | STATINS ARE SAFE AND BENEFICIAL IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Mark Pedersen[1] Prajwal Gowda[1] Meena Tadros[1] Saiabhiroop Govindu[1] Marlyn Mayo[1], [1]University of Texas Southwestern Medical Center

Background: Statins may potentially improve portal pressure, risk of decompensation, and survival in patients with chronic liver disease. We examine the effect of statins on alkaline phosphatase, decompensation, and liver events in patients with PBC. **Methods:** A retrospective cohort study was composed of all patients with PBC who were seen at either the private university hospital system or the public hospital system in Dallas, TX between 2002 and 2023. The primary outcome was a composite of major liver events (MLE), including decompensation (defined as variceal bleeding, hepatic encephalopathy, or ascites requiring diuretics or paracentesis), liver transplantation, hepatocellular carcinoma, and liver-related death. The secondary outcome was decompensation. Categorical variables compared with chi square, continuous variables with T test. **Results:** Patients with a MLE were less likely to be on a statin (34.2% vs 48.2%, p = 0.05), more likely to have cirrhosis at their baseline visit (70.8% vs 36.0%, p < 0.001), had a higher alkaline phosphatase (336 vs. 197 IU/L, p = 0.01), higher total bilirubin (3.9 vs. 0.8 mg/dL, p = 0.03), and a lower albumin (3.6 vs 4.1 mg/dL, p = 0.01). Over 96% of patients were taking UDCA. On multivariable cox regression analysis (table 1), statins protected against MLE (aHR 0.146, p < 0.001) and decompensation (aHR 0.128, p < 0.001) when controlling for alkaline phosphatase at 1 year, total bilirubin at 1 year, platelets at 1 year, diagnosis of cirrhosis at baseline, and concurrent MASH. Propensity matched (based on cirrhosis, alkaline phosphatase at 1 year, bilirubin at 1 year, platelets at 1 year) Kaplan Meier curves revealed improved decompensation-free survival (p < 0.001) and trend toward improved MLE-free survival (p = 0.06). Patients who received a statin and those who did not had similar alkaline phosphatase levels at baseline (258 vs 204 IU/L, p = 0.37). After one year on statin therapy, alkaline phosphatase decreased in the statin group (-17.0% [-44 IU/L] vs +17.3% [+35 IU/L] p = 0.05). Statins were used for an average of

6.25 years. 2 patients stopped the statins due to muscle aches; there were no cases of elevated LFTs or rhabdomyolysis. **Conclusion:** In a study of two Dallas hospital systems, statins were beneficial in patients with PBC, protecting against decompensation and liver events. Statins were associated with an improvement in alkaline phosphatase and were not associated with significant adverse events. This should be further examined in a large, diverse population of patients with PBC.

Variable	MLE Endpoints	Decompensation
	aHR (95% CI) p =	aHR (95% CI) p =
Statin	0.163 (0.0530.501) p = 0.002	0.128 (0.039-0.421) p < 0.001
Alk Phos at 1 year	1.006 (1.003-1.009) p < 0.001	1.004 (1.002-1.007) p < 0.001
Total bilirubin at 1 year	1.168 (1.061-1.285) p = 0.002	1.146 (1.023-1.284) p = 0.018
Platelets at 1 year	0.996 (0.993-0.998) p = 0.002	0.997 (0.994-1.000) p = 0.029
Cirrhosis at baseline	2.414 (0.953-0.6110) p = 0.06	3.328 (1.311-8.445) p = 0.011
Concurrent MASH (biopsy proven)	4.901 (1.125-21.350) p = 0.03	4.409 (1.013-19.189) p = 0.048

4519 | FIBROSIS IN FAST-FORWARD: MASLD DRIVES FIBROSIS IN PSC WITHOUT AFFECTING MORTALITY

Sushrut Ingawale[1] Shefali Mody[2] Simran Joshi[3] Pujitha Vallivedu Chennakesavulu[4] Akshay Sharma[5] Suprabhat Giri[6], [1]Quinnipiac University / St. Vincent's Medical Center, [2]SUNY Upstate Medical University, [3]Bridgeport Hospital, [4]Quinnipiac University / St. Vincent's Medical Center, [5]Luminis Health Anne Arundel Medical Center, [6]Kalinga Institute of Medical Sciences

Background: The influence of Metabolic Associated Steatotic Liver Disease (MASLD) on the clinical trajectory of Primary Sclerosing Cholangitis (PSC) remains incompletely characterized. Given the rising prevalence of MASLD and its known fibrogenic potential, we aimed to evaluate the association of MASLD with fibrosis progression, hepatocellular carcinoma (HCC), liver transplantation, and all-cause mortality among patients with PSC. **Methods:** A retrospective cohort analysis was performed using the TriNetX Global Collaborative Network. Adults (≥ 18 years) diagnosed with PSC between 5–20 years ago were identified and divided into two cohorts: PSC with MASLD ($n = 506$) and PSC without MASLD ($n = 4{,}183$), excluding patients with viral hepatitis, autoimmune liver diseases, or alcohol-related liver disease. The primary outcome was fibrosis progression; secondary outcomes included HCC, liver transplantation, and all-cause mortality. Patients with outcomes prior to the index date were excluded. Kaplan-Meier survival analyses and risk comparisons were conducted. **Results:** Mean follow-up was comparable between cohorts (PSC+MASLD: 2062 days vs. PSC-only: 1882 days). The incidence of fibrosis progression was significantly higher in the PSC+MASLD group (2.0%) compared to PSC-only (0.2%), yielding a risk ratio (RR) of 8.31 (95% CI: 3.48–19.87, $p < 0.001$). There were no statistically significant differences in the risk of HCC (2.2% vs. 2.6%, $RR = 0.85$, $p = 0.603$), liver transplantation (4.3% vs. 4.9%, $RR = 0.89$, $p = 0.590$), or all-cause mortality (14.5% vs. 15.1%, $RR = 0.96$, $p = 0.717$). Kaplan-Meier analysis demonstrated a significantly reduced fibrosis-free survival in the PSC +MASLD group (log-rank $p = 0.229$), with no significant differences observed for other outcomes. **Conclusion:** MASLD is associated with an eightfold increased risk of fibrosis progression in PSC, suggesting synergistic liver injury when both conditions coexist. Incorporating routine metabolic risk assessment, lifestyle modification, and non-invasive fibrosis monitoring may help mitigate liver disease progression in this subgroup. Further prospective studies using metabolic phenotyping are warranted to clarify causality and guide management strategies.

4520 | NON-RESPONSE TO OBETICHOIC ACID IS ASSOCIATED WITH HEIGHTENED RISKS OF DEVELOPING CLINICAL EVENTS IN PRIMARY BILIARY CHOLANGITIS

Palak Trivedi[1] Rachel Smith[2] Nadir Abbas[1] Ellina Lytvyak[3] Miki Scraravaglio[4] Neil Halliday[5] Nadia Eden[5]

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Diane Lloyd-Madden[6] Sanchit Sharma[6] James Ferguson[7] Jessica Dyson[8] Douglas Thorburn[5] David Jones[8] Aldo Montano-Loza[3] Marco Carbone[9] Pietro Invernizzi[9] George Mells[10] Emma Culver[11], [1]University of Birmingham, [2]Addenbrookes Hospital, Cambridge, [3]University of Alberta, [4]University of Cambridge, [5]Royal Free Hospital, London, [6]University Hospitals Birmingham, UK, [7]University of Birmingham, UK, [8]Newcastle University, UK, [9]University of Milano-Bicocca, [10]University of Newcastle, [11]John Radcliffe Hospital

Background: Biochemical non-response to ursodeoxycholic acid (UDCA), as a first-line therapy, is associated with a heightened risk of clinical events in primary biliary cholangitis (PBC). Herein, we determine whether biochemical non-response to obeticholic acid (OCA) is also predictive of long-term event-free survival. A further, exploratory objective was to evaluate whether responses differ between combination OCA + fibric acid derivative therapy compared to switching from OCA to bezafibrate/fenofibrate. **Methods:** Data were collected from patients (pts) initiating OCA at high-volume centres in the UK, Italy and Canada between Aug. 2017 and 2019, with follow-up continuing until Jun. 2024. Biochemical non-response was defined by POISE criteria. Clinical events were defined as decompensation, referral for transplantation, hepatocellular carcinoma or death. **Results:** Our cohort consisted of 336 pts of whom n = 150 (45%) discontinued OCA over 48 months. Over 851-pt-years of OCA use, without addition of another PBC therapy, n = 230, n = 192, n = 158 and n = 150 pts completed 12-, 24-, 36- and 48-months follow-up, respectively. Of this cohort, 37%, 48%, 63% and 55% attained biochemical response (Fig A), with 7%, 14%, 25% and 19% normalising ALP ($P < 0.01$; all comparisons vs. baseline). Over four years, 64 pts experienced a clinical event. Twelve-month biochemical non-response associated with a heightened risk of clinical events (Fig B; hazard ratio [HR]:4.50; 95% CI:1.74-20.23), as did cirrhosis (HR:20.24, 10.15-40.32), hyperbilirubinaemia (HR:2.55, 1/71-3.76), hypoalbuminaemia (HR:0.92, 0.90-0.96) and thrombocytopenia (HR:0.99, 0.98-0.99). The prognostic utility of biochemical non-response (HR:3.29, 1.72-14.96) and cirrhosis (HR:19.67, 5.09-76.08) persisted on multivariable analyses. Next, in exploratory sub-analysis on the UK group initiating fibric acid derivatives during follow-up, we compared biochemical changes in those who initiated treatment alongside OCA (combination) to those who discontinued OCA and switched to bezafibrate or fenofibrate (switch group). Of 240 UK pts treated with OCA initially, 44 initiated a fibric acid derivative in the combination group (n = 40 bezafibrate, 4 fenofibrate), of whom 31 were also taking UDCA. In turn, 74 pts switched from OCA to bezafibrate (n = 57) or fenofibrate (n = 17), with 61 also taking UDCA. Follow-up at 1, 2, 3, and 4 years was completed by 29, 25, 21 and 22 pts in the combination group and by 57, 47, 38 and 37 pts in the switch group. Biochemical response was met in 31%, 44%, 86% and 91% of pts at 1, 2, 3, and 4 yrs., respectively, in the combination therapy group. This compared to 16%, 34%, 42% and 43% in the switch group. **Conclusion:** Biochemical response stratifies risk of clinical events under OCA treatment. Whilst response rates increase over time, discontinuation rates underscore need for newer treatment paradigms, including combination therapy with fibric acid derivatives.

4521 | INCIDENCE, CAUSES AND PATTERNS OF ELEVATED LIVER ENZYMES AFTER HEART OR LUNG TRANSPLANT FOR SARCOIDOSIS

Neil Garg[1] Muhammad Saad Faisal[2] Jennifer Cowger[2] Patrick Bradley[2] Syed-Mohammed Jafri[2], [1]Wayne State University School of Medicine, [2]Henry Ford Health System

Background: Sarcoidosis commonly affects the lungs and heart. The true burden of clinical or subclinical

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

hepatic sarcoid disease is unclear, as guidelines for monitoring or diagnosis are lacking. We examined the incidence and causes of elevated liver enzymes (LE) in recipients of non-liver solid organ transplants (Tx) with sarcoidosis. **Methods:** Data on recipients of non-liver solid organ Tx, age $>/=18$ years, due to sarcoidosis between 2018 and 2025 was collected. Patients were followed from Tx to death or the most recent follow-up. The outcomes of interest were causes of elevated liver enzymes defined as ALT or AST $>$ 60 IU/L, death and hepatology consultation. The elevated LE were defined as early (between 0-28 days after Tx) or late (>180 days after Tx). Causes of elevated liver enzymes and death were manually collected from the chart. **Results:** The study included 25 patients: 5 bilateral lung Tx, 16 heart Tx, 1 heart-lung Tx, and 3 heart-kidney Tx. The median age was 59 years (range: 29–70). Nineteen (76%) were male, and 6 (24%) were female. Nine (36%) were Caucasian, and 16 (64%) were Black. Nine patients (36%) had multisystem sarcoidosis including the heart, lungs, skin, eyes, lymphatics, and liver. Two patients had a liver biopsy showing noncaseating granulomas consistent with sarcoid prior to transplant but lacked hepatology follow-up. Median time from diagnosis to Tx was 15.1 months, and from Tx to last follow-up was 26.9 months. Twenty-one patients (81%) met the definition of elevated LE post-Tx (median peak ALT: 104 IU/L, AST: 136 IU/L, ALP: 127 IU/L, total bilirubin: 1.9 mg/dL). Eighteen (85%) had early (0-28 days), and 3 (14%) had late post-Tx elevated LE (>180 days). Causes of early post-Tx elevated LE in 18 patients were congestive hepatopathy (6; 33%), shock liver (5; 28%), post-Tx transaminitis (3; 17%), drug-induced liver injury (2; 11%), and unknown (2; 11%). Causes of late elevated LE in 3 patients were CMV viremia (1; 33%) and post-Tx transaminitis (2; 66%). These 3 had alcohol use disorder in remission. Only 7 (27%) of the 21 with elevated LE had a hepatology consult. No liver biopsies or elastography were performed to evaluate elevated LE post-Tx. However, elevated LE normalized in all 21 patients by the latest follow-up. Twenty-three (92%) were alive at the last follow-up. Two deaths occurred at 17 days (multi-organ failure) and 824 days (Nocardia infection) post-Tx. **Conclusion:** Elevated liver enzymes are commonly seen after heart, lung, and combined organ Tx for sarcoidosis in the early post-Tx period. These are transient, secondary to congestive hepatopathy and shock liver, not related to hepatic sarcoid, and generally self-limiting. However, late elevated liver enzymes is likely liver-related. Given the high prevalence of elevated LE, hepatology consultation may be considered, especially in cases of persistent elevations.

Summary of Post-Transplant Sarcoidosis Patient Data

Category	Details
Total Patients	25
Transplant Types	5 Bilateral Lung, 16 Heart, 1 Heart-Lung, 3 Heart-Kidney
Median Age (Range)	59 years (29–70)
Sex Distribution	19 Male (76%), 6 Female (24%)
Race	9 Caucasian (36%), 16 Black (64%)
Multisystem Sarcoidosis	9 patients (36%)
Pre-Tx Liver Biopsy with Sarcoid	2 patients (no hepatology follow-up)
Median Time from Diagnosis to Tx	15.1 months
Median Time from Tx to Last Follow-up	26.9 months
Elevated Liver Enzymes Post-Tx	21 patients (81%)
Median Peak Liver Enzymes (Post-Tx)	ALT: 104 IU/L, AST: 136 IU/L, ALP: 127 IU/L, Total Bilirubin: 1.9 mg/dL
Timing of Elevated LE Post-Tx	Early (0–28 days): 18 patients; Late (>180 days): 3 patients
Causes of Early Elevated LE (n=18)	Congestive Hepatopathy: 6 (33%) Shock Liver: 5 (28%) Post-Tx Transaminitis: 3 (17%) Drug-Induced Liver Injury: 2 (11%) Unknown: 2 (11%)
Causes of Late Elevated LE (n=3)	CMV Viremia: 1 (33%) Post-Tx Transaminitis: 2 (66%)
Alcohol Use Disorder (Late LE Group)	3 patients (in remission)
Hepatology Consult Post-Tx	7 patients (27%)
Liver Biopsy/Elastography Post-Tx	None performed
Liver Enzyme Normalization	All 21 patients with elevated LE normalized
Survival at Last Follow-up	23 patients (92%) alive
Deaths	2 patients (17 days – multi-organ failure; 824 days – Nocardia infection)

4522 | THE EFFICACY OF ELAFIBRANOR IS NOT AFFECTED BY BODY MASS INDEX IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Andreas Kremer[1] Cynthia Levy[2] Christopher Bowlus[3] Marco Carbone[4] Marwan Sleiman[5] Nuno Antunes[6] Marion Dehez[5] Hugo Gomes da Silva[5] Vincent Leroy[7], [1]Department of Gastroenterology and Hepatology, University Hospital Zurich, Zurich, Switzerland, [2]Schiff Center for Liver Diseases, University of Miami, Miami, Florida, USA, [3]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, California, US, [4]University of Milano-Bicocca, Milan, Italy and The Niguarda Liver Transplant Centre, Milan, Italy, [5]Ipsen, Paris, France, [6]Ipsen, Cambridge, MA,

Background: Elafibranor is a peroxisome proliferator-activated receptor (PPAR) α and δ agonist approved for treatment of adults with primary biliary cholangitis (PBC). In the phase 3 ELATIVE® study, elafibranor significantly improved biochemical response rate and markers of disease progression compared with placebo in patients with PBC. We investigated the effect of body mass index (BMI) on elafibranor pharmacokinetics using population modelling, and on efficacy in healthy, overweight and obese subgroups of ELATIVE®. **Methods:** Population pharmacokinetic models for elafibranor and its active metabolite GFT1007 were developed using data from 17 phase 1–3 clinical studies (including ELATIVE and a phase 2 trial in patients with PBC). In ELATIVE, patients with PBC and an inadequate response to or intolerable side effects with ursodeoxycholic acid were randomized 2:1 to receive elafibranor 80 mg daily or placebo for 52 weeks. The primary endpoint was biochemical response at week 52 (alkaline phosphatase [ALP] $<1.67\times$ upper limit of normal [ULN] with $\geq 15\%$ reduction from baseline and total bilirubin $\leq$ ULN). Change in ALP levels from baseline to week 52 was a secondary efficacy endpoint. Randomized patients were classified *post hoc* into subgroups of healthy weight (BMI ≥ 18.5 to <25 kg/m^2), overweight (BMI ≥ 25 to <30 kg/m^2) or obese (BMI ≥ 30 kg/m^2); those with BMI <18.5 kg/m^2 (n = 5) were not included. Statistical tests were *post hoc* and non-inferential; *p* values were nominal. **Results:** In the pharmacokinetic models, BMI had no clinically relevant effect on exposure to elafibranor or GFT1007 in patients with PBC (Table). In ELATIVE, 161 patients were randomised to elafibranor (n = 108) or placebo (n = 53). In the elafibranor arm, biochemical response rates at week 52 were 56.3%, 46.4% and 44.8% in the healthy weight, overweight and obese subgroups, respectively (Table). Mean changes in ALP levels from baseline to week 52 in the elafibranor arm were –41.5%, –41.8% and –32.3% for elafibranor in the healthy weight, overweight and obese subgroups respectively (Table). **Conclusion:** The pharmacokinetics of elafibranor are not clinically meaningfully affected by BMI in patients with PBC. The efficacy of the clinical dose of elafibranor is stable in patients with PBC, regardless of baseline BMI or weight changes during the course of treatment.

Population PK analysis	**BMI 21.338 kg/m²**		**BMI 25.93 kg/m²**		**BMI 33.73 kg/m²**

4523 | SYMPTOM PROFILES AMONG ADULTS WITH PRIMARY SCLEROSING CHOLANGITIS IDENTIFIES LOW, MODERATE AND HIGH BURDENED GROUPS

Donna Evon[1] Kaya Merkler[1] Chelsea Anderson[1] Joanne Hatchett[2] Ricky Safer[2] Rachel Gomel[2] Sasha Deutsch-Link[1] Christopher Bowlus[3] Bryce Reeve[4], [1]UNC Chapel Hill, [2]PSC Partners Seeking a Cure, [3]University of California, Davis, [4]Duke

Background: Patient-reported symptoms of PSC are not well documented. The study's aim was to understand the prevalence of PSC symptoms and identify distinct symptom profiles and their association with demographic and clinical characteristics among symptomatic adults. **Methods:** Adults were recruited through the PSC Partners Patient Registry and PSC hepatologists in the U.S. Individuals were eligible if they were 18 or older, symptomatic in the last year, and not waitlisted or a transplant recipient. Individuals engaged in a phone survey that screened for the presence (yes/no) of 13 PSC-associated symptoms in the last month. Sociodemographic and medical history were self-reported. Latent class analysis (LCA) was used to identify symptom-based participant profiles based on symptom presence and participants were assigned to one symptom class. Multinomial logistic regression models were used to evaluate demographic or clinical factors associated with profile membership. **Results:** Participants (n = 126) were on average 47 years old (range:20-81), 60% female, 88% white, 8% black and 3% asian, 59% had inflammatory bowel disease (IBD), 39% reported cirrhosis, 75% were taking ursodiol (UCDA), and 57% had a history of cholangitis attacks. The most prevalent symptoms in the last month included fatigue (83%), daytime drowsiness (73%), and liver pain, cognitive impairment, anxiety, sleep disturbance and itch (all 62-63%). The LCA and clinical interpretation suggested a 4-symptom profile solution: (1) "Low Symptom" class (22% of sample), (2) "Moderate Symptom" class (21%), (3) "Moderate+Distressed" class (39% of sample), and a "High Symptom" class (18%). In unadjusted models, compared to the Low Symptom class, females were more likely than males to be in the High Symptom class (OR = 4.36; 95% CI: 1.31-14.51), participants taking UCDA were less likely to be in the High Symptom class (OR = 0.25; 95% CI: 0.08-0.80) and those with a history of cholangitis attacks were less likely to be in the Moderate Symptom class (OR = 0.22; 95% CI: 0.07-0.70). In the multvariable model, only a history of cholangitis attacks ($p = 0.03$) was statistically associated with class membership. A statistically significant worsening trend

was observed in PROMIS® Global Physical and Mental Health T-scores from the Low to the High Symptom classes. **Conclusion:** Among symptomatic adults with PSC, over 60% report fatigue, daytime drowsiness, liver pain, cognitive impairment, anxiety, sleep disturbance and itch in the past month. The four-symptom profiles ranging from low to high burden needs validation in larger cohorts as they have clinically meaningful implications for patients' health status and care of symptomatic individuals.

Figure. Four Symptom Profiles for Presence of Symptoms in Last Month

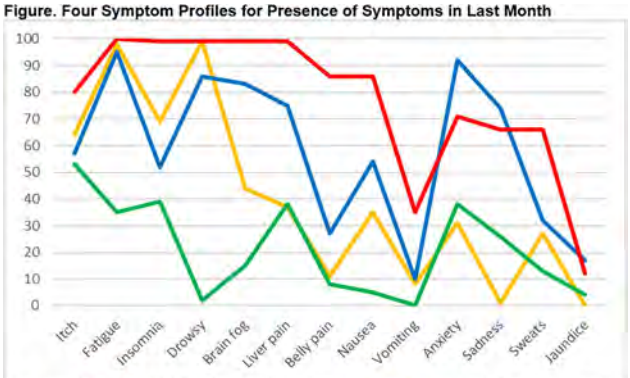

Figure Legend: Red line = High Symptom class (18% of sample); Yellow line = Moderate Symptom class (21% of sample); Blue line = Moderate+Distressed" class (39% of sample) and Green line = Low Symptom class (22% of sample)

4524 | EFFICACY OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR AGONISTS IN THE TREATMENT OF PRIMARY BILIARY CHOLANGITIS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

sabtain saroya[1] andrew canakis[2] Umme Ferdaush[3] Nuha Mohammed[1] Emily Gorman[4] Zurabi Lominadze[5] Kirti Shetty[5], [1]Howard University College of Medicine, [2]The University of North Carolina Divison of Gastroenterology and Hepatology, [3]TidalHealth Internal Medicine Department, [4]University of Maryland School of Medicine, [5]University of Maryland Department of Gastroenterology and Hepatology

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease marked by progressive bile duct destruction. While ursodeoxycholic acid (UDCA) is first-line therapy, approximately 40% of patients show an incomplete response. Peroxisome proliferator-activated receptor (PPAR) agonists have emerged as promising agents due to their anti-inflammatory and metabolic effects. This meta-analysis evaluates the efficacy of PPAR agonists in improving liver biochemical markers in PBC. **Methods:** A systematic search of MEDLINE, Embase, and Scopus was performed to identify randomized controlled trials (RCTs) comparing PPAR agonists to placebo in patients with PBC. Eligible studies (1) were placebo-controlled RCTs, (2) included patients with PBC regardless of disease stage or PPAR agonist dose, and (3) reported pre- and post-treatment values for alkaline phosphatase (ALP), bilirubin, and gamma-glutamyl transferase (GGT). Exclusion criteria included studies without a placebo or control group, non-human studies, trials with no relevant outcomes, and trials with incomplete or withdrawn data. Six trials met these criteria. Follow-up durations ranged from 3 to 24 months. To account for variability in treatment effect due to time,

we used post-minus-pre-treatment mean differences and a random-effects model. Standard errors were derived using an assumed correlation coefficient (r = 0.7) between paired values. Pooled estimates were weighted by inverse variance and calculated separately for each biomarker. **Results:** PPAR agonists were associated with significant reductions in liver biomarkers compared to placebo. ALP decreased by –87.14 U/L (95% CI: –90.20, –84.08). Bilirubin declined by –1.04 mg/dL (95% CI: –1.37, –0.71). GGT was reduced by –46.90 U/L (95% CI: –51.64, –42.16). All reductions were statistically significant. **Conclusion:** In placebo-controlled trials, PPAR agonists significantly improved ALP, bilirubin, and GGT levels in patients with PBC. These findings support their potential role as effective adjunctive therapy, particularly for patients with inadequate response to UDCA.

Table 1: Pooled Treatment Effects of Biomarkers

Biomarker	Pooled Effect	Std. Error	95% Confidence Interval
Alkaline Phosphatase (ALP)	-87.14	1.56	(-90.20, -84.08)
Bilirubin	-1.04	0.17	(-1.37, -0.71)
Gamma-Glutamyl Transferase (GGT)	-46.90	2.42	(-51.64, -42.16)

4525 | ASSESING OUTCOMES IN AUTOIMMUNE HEPATITIS PRESENTING AS ACUTE ON CHRONIC LIVER FAILURE, WITH AND WITHOUT EXTRAHEPATIC ORGAN DSFUNCTION

Souveek Mitra[1] Abhijit Chowdhury[2] Ranajoy Ghosh[1] Dipankar Mondal[1] Srijan Mazumdar[1] Kishalaya.[1], [1]Indian Institute of Liver and Digestive Sciences, [2]Indian Institute of Liver & Digestive Sciences,

Background: Autoimmune Hepatitis (AIH), presenting as Acute on Chronic liver failure (ACLF), is a challenging clinical entity, with limited clinical data regarding its management, prognosis and response to immunosuppressants. ACLF is a distinct clinical entity, with increased propensity for infection, extrahepatic organ failure and high mortality. Data is also ver limited regarding the role of steroids in AIH-ACLF populatoion. In light of these background knowledge, this study aimed to evaluate the outcomes in AIH -ACLF having both hepatic and extrahepatic organ failure, along with steroid responsiveness. **Methods:** Single centre retrospective study from a tertiary care centre where AIH subjects presenting as ACLF from January 2019 till December 2024 were included. Clinical, laboratory and histological parameteres were assessed at baseline. Various prognostic scores like model for end stage liver disease (MELD), Child Turcotte Pugh score (CTP), Asia pacific association for study of liver disease ACLF score (AARC ACLF score), Chronic Liver failure -consortium organ failure score (CLIF -OF score) were computed at baseline and also were periodically monitored during follow up. Primary outcome were 90 day and 180 day transplant free survival. Follow up clinical parameters, infections were assessed and predictors of end points were identified. **Results:** 47 subjects presenting as AIH-ACLF were included in the study. Median follow up 212 days. Two (2) subjects underwent liver transplantation (4.26%), 12 deaths (25.56%). Infections were present at baseline in 11 subjects (23.40%) and further new onset infections developed in 14 subjects (38.89%). Most common acute precipitants were flare of underling AIH (46.81%) along with sepsis (17.02%), followed by acute viral hepatitis HAV related (12.77%). All the subjects underwent liver biopsy. Underlying advanced fibrosis(F3or F4) was found in 87.23%. Of the 36 subjects started on steroids, 18 subjects required discontinuation in the follow up. Most common cause for steroid discontinuation was new onset infection. The 90 and 180 day transplant free survival rates were 73.33% (95% CI 55.2- 91.2) and 68.74 % (95% CI 48.61- 80.1). Baseline AARC- ACLF score < 11 (sensitivity 74.2%, specificity 92.78%), MELD score < 22 (sensitivity 81.3%, specificity 87%) and baseline serum creatinine < 2 mg/dl (Sensitivity 67.89%,specificity 89.12%) were the best predictors for survival. **Conclusion:** Patients of AIH presenting with ACLF have a morbid clinical course, carrying a high mortality rate. Baseline infection is often present in these group. Subjects having extrahepatic organ failure, particularly renal carry a worse prognosis. Steroids can be administered in select subgroups having a good prognostic score at baseline and no evidence of infection. Although strong vigilance is warranted for development of new onset infection and changes in prognostic scores.

Wendy van der Woerd[6] Mary Tessier[7] Henkjan Verkade[8] Nathan Touati[9] Virginie Jacquemin[9] Fatine Elaraki[9] Praneeta Nagraj[10] Terese Wallefors[11] Richard Thompson[12], [1]Hôpital Bicêtre, AP-HP, Université Paris-Saclay, Hépatinov, Inserm U 1193, Paris, France, [2]King Faisal Specialist Hospital and Research Centre, Al Mathar Ash Shamali, Riyadh, Saudi Arabia, [3]Université Catholique de Louvain, Cliniques St Luc, Brussels, Belgium, [4]King's College Hospital NHS Trust, London, UK, [5]Hacettepe University Faculty of Medicine, Ankara, Turkey, [6]Wilhelmina Children's Hospital and University Medical Center, Utrecht, the Netherlands, [7]Baylor College of Medicine/Texas Children's Hospital, Houston, TX, USA, [8]Beatrix Children's Hospital/ University Medical Center Groningen, Groningen, the Netherlands, [9]Ipsen, Boulogne-Billancourt, France, [10]Ipsen, Cambridge, MA, USA, [11]Ipsen, Gothenburg, Sweden, [12]Institute of Liver Studies, King's College London, London, UK

Background: Long-term data demonstrate improvements in pruritus, reductions in serum bile acids (sBA), and manageable safety with odevixibat (ODX) across progressive familial intrahepatic cholestasis types in the phase III PEDFIC 1 and PEDFIC 2 open-label extension studies (NCT03659916 and NCT03566238). Multidrug resistance protein-3 (MDR3) deficiency, caused by *ABCB4* variants, leads to chronic cholangitis and secondary cholestasis. Here we analyze efficacy, liver parameters, and clinical events for patients with MDR3 deficiency treated with odevixibat in the PEDFIC 2 study. **Methods:** Patients with MDR3 deficiency treated with ODX (120 μg/kg/day) were included in the *post-hoc* analysis (data cutoff: Feb 15, 2024). Type and effect of pathologic variants were determined by ClinVar and gnomAD databases. Responses vs baseline (BL) were defined at Week 24 as ≥70% reduction in fasting sBA or sBA ≤70 μmol/L, or a pruritus response of ≥1-point reduction in observer-reported scratching score (0–4 scale). **Results:** 7 patients with MDR3 deficiency, mean (SD) age 7.61 (4.59) years, were enrolled. 6 patients had homozygous variants: missense (n = 2); nonsense (n = 1); intronic variants predicted to disrupt splicing (n = 3). 1 patient had a heterozygous missense and splice variant. At BL: 5 patients were receiving ursodeoxycholic acid (UDCA), and 1 rifampicin, 3 patients had cirrhosis; all patients had abnormal liver tests. Mean (SD) sBA level was 197.14 (99.90) μmol/L; platelet count was 188 (97) x 10^9/L (3 patients had < 150 x 10^9/L, indicating cirrhosis); bilirubin was 27.51 (11.37) μmol/L; gamma-glutamyl transferase (GGT) was 215.57 (129.58) U/L. Mean (SD) ODX duration was 110.94 (51.81) weeks. ODX initiation rapidly reduced sBA levels and improved pruritus in most patients (Figure). At Week 24, 3 patients achieved an sBA response, 4 a pruritus response, and 2 had a dual response. Treatment with ODX did not appear to impact transaminases, GGT, or bilirubin. 5 patients discontinued ODX over time, 3 due to adverse events (AEs) unrelated to ODX, and 2 due to liver transplantation (LT). 1 patient with an AE unrelated to ODX later underwent LT for an AE of disease progression; all 3 patients with LT had BL thrombocytopenia indicating portal hypertension and cirrhosis. **Conclusion:** These data suggest ODX, in addition to UDCA, may have clinical benefit, providing symptomatic relief in patients with MDR3 deficiency; further investigation is warranted.

Figure: Scratching score (A) and sBA levels (B) up to 72 weeks in patients with MDR3 deficiency treated with ODX

4527 | LONGITUDINAL DESCRIPTION OF LIVER BIOCHEMISTRY AMONG PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN THE UNITED STATES

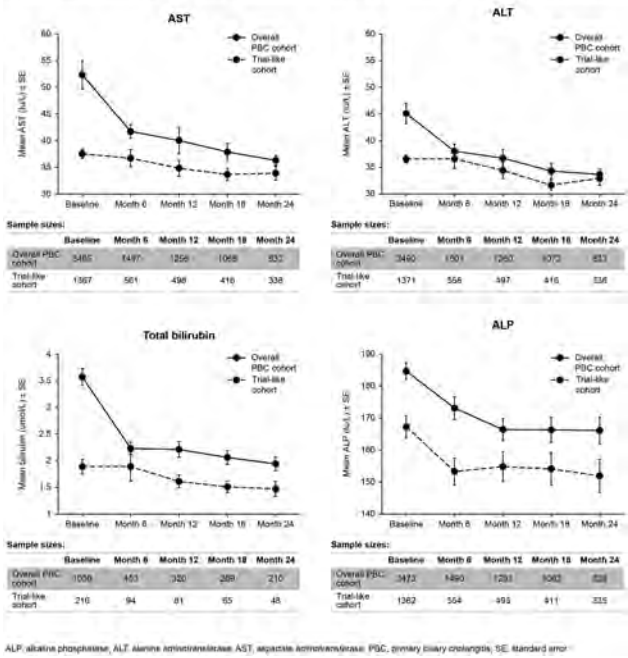
Kaitlin Hagan[1] Sadia Halim[2] Lina Titievsky[1] Veronika Earley-Valovic[2] Megan McLaughlin[1] Alexander Cobitz[1] Kris Kowdley[3] Robert Gish[4], [1]GSK, Collegeville, PA, USA, [2]GSK, London, UK, [3]Liver Institute Northwest, Seattle, WA, USA, [4]Hepatitis B Foundation, Doylestown, PA, USA

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Primary biliary cholangitis (PBC) is a chronic, progressive, immune-mediated cholestatic liver disease. Patients with PBC have abnormal liver tests, including elevations of alkaline phosphatase (ALP) and gamma-glutamyl transpeptidase, frequently with elevations of alanine aminotransferase (ALT) and aspartate aminotransferase (AST). However, there are limited data describing how liver biochemistry measures evolve over time in a population-based setting, which can inform clinical program findings and help differentiate the potential effect of the drug from that of the underlying disease. In this study, two cohorts—an overall PBC cohort and a trial-like cohort—were defined to generate relevant data for such contextualization. **Methods:** This was a retrospective cohort study of patients with prevalent PBC using 2016–2020 Optum Electronic Health Record data. Patients with PBC were identified based on ≥2 diagnosis codes on separate days within a 1-year period. Changes in liver biochemistry measures of interest (i.e., ALT, AST, ALP, total bilirubin), including stopping criteria in a Phase 3 clinical trial, were described over up to 2 years of follow-up. **Results:** Overall, 3510 patients with PBC were identified (mean age: 62.9 years, 82.7% female); 70% were receiving UDCA. Of these, 1376 met the inclusion/exclusion criteria for the trial-like cohort. Compared with the overall PBC cohort, the trial-like cohort had a similar mean age at baseline (63.0 years), a greater proportion of female patients (90.8%), and a lower comorbidity burden. In the overall cohort, at baseline, 38.6% of patients had ALT > upper limit of normal (ULN), 47.3% had AST > ULN, 69.0% had ALP > ULN, 33.1% had ALP ≥ 1.67×ULN, and 1.9% had total bilirubin > ULN (median total bilirubin [2 µmol/L] was within the normal range). In the trial-like cohort, 38.1% of patients had ALT > ULN, 40.0% had AST > ULN, 66.4% had ALP > ULN, and 29.7% had ALP ≥ 1.67×ULN. There was a general trend of decreasing mean lab values over the follow-up period for both cohorts, but it was less pronounced in the trial-like cohort compared with the overall cohort (Figure). Additionally, the changes were not as pronounced when examining change in lab values as medians compared to means. A proportion of patients had liver enzyme elevations meeting clinical trial increased monitoring and/or stopping criteria. **Conclusion:** This study leveraged data from a large dataset of electronic health records to describe how liver biochemistry parameters evolve in an overall PBC cohort and a trial-like cohort. While there was a general trend of decreasing lab values over follow-up, a proportion of patients had liver enzyme elevations over the follow-up period that would correspond to monitoring or stopping criteria in a clinical trial context. These data offer valuable insights into contextualizing liver biochemistry changes over time in PBC clinical trials. Funding: GSK (218576).

Figure. Baseline and follow-up liver laboratory measures in the real-world PBC cohort (overall PBC cohort) and the trial-like cohort



ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; PBC, primary biliary cholangitis; SE, standard error

4528 | ESTIMATING THE PREVALENCE OF PRIMARY BILIARY CHOLANGITIS AMONG A NATIONAL COHORT OF VETERANS IN THE UNITED STATES

Zeyuan Yang[1] Ramsey Cheung[2] Robert Wong[3], [1]Palo Alto Veterans Institute for Research, [2]Stanford University Medical Center, [3]VA Palo Alto Healthcare System

Background: The prevalence of primary biliary cholangitis (PBC) in the U.S. has been estimated at approximately 40 per 100,000 persons based on administrative claims data. However, awareness of PBC is sub-optimal among patients and providers, and the aforementioned reported prevalence that is based solely on ICD-9/10 likely underestimates the true burden of PBC. We aim to provide estimates of PBC prevalence among a national cohort of Veterans using both ICD-9/10 and supporting laboratory data. **Methods:** Using the national Veterans Affairs database from 1/1/2010 to 4/30/2025, adults with PBC were identified

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

using a combination of ICD-9/10 diagnosis codes (571.6, K74.3, K74.5) and positive anti-mitochondrial antibody (AMA) laboratory testing. PBC prevalence was calculated by dividing the number of individuals meeting aforementioned criteria with a denominator of individuals who had at least 1 health encounter each year of the study period. PBC prevalence (per 100,000 persons) was stratified by sex, age groups, and race/ethnicity and compared between groups using the z-statistic. **Results:** Overall, when using ICD-9/10 diagnosis codes, 5,736 adults with PBC were identified (86.4% men, 13.6% women, 74.5% age >60y, 71.0% non-Hispanic white, 13.7% African American, 7.3% Hispanic). PBC prevalence ranged from 111.7 per 100,000 (based on ICD-9/10) to 446.1 per 100,000 based on positive AMA. PBC prevalence was significantly higher in women vs. men when using ICD-9/10 codes (157.9 vs. 106.8 per 100,000, $p < 0.01$) or positive AMA (469.1 vs. 443.6 per 100,000, $p < 0.05$). When stratified by age groups, the highest prevalence of PBC was observed among those age ≥60y when using ICD-9/10 codes (160.4 vs. 82.9 per 100,000 in age 40-59y, $p < 0.01$) and highest among age 40-59y when using positive AMA (557.0 vs. 422.8 per 100,000 in age ≥60y, $p < 0.01$). When stratified by race/ethnicity, the highest prevalence of PBC was observed among Hispanics when using either ICD-9/10 or positive AMA criteria. **Conclusion:** Among a national cohort of Veterans in the U.S., the prevalence of PBC ranged from ~112 to 446 per 100,000 persons when using ICD-9/10 diagnostic codes or positive AMA results, respectively. PBC prevalence was significantly higher in women vs. men and was observed to be highest among Hispanic Veterans. Greater awareness among patients and providers can help improve timely diagnosis of PBC, which will improve our understanding of disease prevalence and epidemiology.

4529 | 2ND LINE THERAPY FOR PRIMARY BILIARY CHOLANGITIS (PBC) IS UNDERUTILIZED IN PATIENTS WITH SUBOPTIMAL RESPONSE TO URSODEOXYCHOLIC ACID (UDCA) AND ADVANCED FIBROSIS

Nancy Reau[1] Krishan Puri[2] Ana Maria Davila Morales[3] Zoe Post[3], [1]Rush University Medical Center, [2]University of Illinois, [3]Rush

Background: PBC is a chronic progressive liver disease characterized by the destruction of small bile ducts within the liver. PBC primarily affects older women and is diagnosed by elevated alkaline phosphatase (ALP) levels and positive antimitochondrial autoantibodies (AMA). Prognosis is worse in those that cannot achieve biochemical remission (BR) defined by ALP and bilirubin. 2nd line therapy (2LT) should be used in those that are not in BR but may be underutilized in those with advanced disease. This study aims to compare treatment outcome in those with fibrosis scores F0-F2, to those with advanced fibrosis (F3+). Utilization of 2LT will also be assessed. **Methods:** *Retrospective analysis of PBC patients followed in an off-site location from 01/01/19 to 01/01/25. Data included baseline demographics, ALP before UDCA initiation, and UDCA response. A positive UDCA response is defined as deep remission [DR] ALP < 105, normal ALP [NL] (ALP 106-120), Biochemical remission [BR] (ALP < 1.67 x ULN: 121 to 175) and not in remission [NR] (ALP > 1.67 x ULN or ALP > 175). For those without biochemical remission, initiation of second-line therapy with OCA, fibrate, or PPAR was recorded.* **Results:** *65 patients with PBC were identified after excluding those lost to follow-up (2), incomplete data (6), and death (2). Average age 65 years, 92% female, 93% white, 5% black, and 2% other. 37 (57%) were F0 to F2, and 28 (43%) had advanced fibrosis (F3-4). 17 (26%) were in DR, 7 (11%) were NL, 23 (35%) were BR, and 18 (28%) were NR. Only 6 (33%) NR patients received 2LT of these 6 patients, 4 were F0-F2 and 2 were F3-F4. F0-2 patients: nine (24%) were NR whereas 5 NL, 13 BR, and 10 DR. Compared to the 28 patients with advanced fibrosis, nine (32%) were NR whereas 2 NL, 10 BR, and 7 DR (Table1). Three F0-F2 were on no therapy and 25 received one therapy. 24% required 2LT with 6 on two therapies and 3 on three agents. Compared to patients with advanced fibrosis, four were on no therapy, 19 on one therapy. 18% received 2LT with 3 on two therapies and 2 on three therapies. There were 9 NR patients with advanced fibrosis: 2 received 2LT. However, 7 were not optimized. 2 (29%) had decompensated cirrhosis, and 5 (71%) were undertreated.* **Conclusion:** *Conclusion: Patients with PBC and advanced fibrosis (F3-4) who do not*

4530 | EPIDEMIOLOGY OF PRIMARY SCLEROSING CHOLANGITIS: INSIGHTS FROM ALLATIN COHORT

Guilherme Cancado[1] Paulo Bittencourt[2] Maria Lucia Ferraz[3] Lorena Solari[4] Margarita Anders[5] Nicolas Ortiz[6] Raimundo Gama[3] Liana Codes[2] Simone Cunha[2] Janaina Narciso-Schiavon[7] Claudia Couto[8], [1]Universidade Federal de Minas Gerais, Brasil, [2]Hospital Português, Salvador, Bahia, [3]Universidade Federal de São Paulo, Brasil, [4]Clínica Universidad de los Andes, Chile, [5]Hospital Alemán, Buenos Aires, [6]Hospital Clínico Universidad de Chile, [7]Universidade Federal de Santa Catarina, Brasil, [8]Federal University of Minas Gerais

Background: Primary sclerosing cholangitis (PSC) is an immune-mediated cholestatic liver diseaswith variable presentation across populations. Latin America, characterized by high admixture and unique genetic diversity, is underrepresented in PSC research. This study describes the clinical and epidemiological profile of PSC in Latin America. **Methods:** Ongoing, retrospective, international multicenter cohort (ALLATIN) study sponsored by ALEH, enrolling PSC patients from different Latin American countries. **Results:** Data from 146 patients were analyzed: Brazil (76.7%), Chile (13.0%), Costa Rica (3.4%), Argentina (2.7%), Ecuador (2.1%), and Cuba (1.4%). Most were male (56.5%), mean age at diagnosis 35 ± 17.7 years, mean follow up time 92.1 ± 193 months. The majority had large-duct PSC (79.3%), 27.3% (36/132) cirrhotic at diagnosis. Overlap with autoimmune hepatitis was reported in 11.4%. Inflammatory bowel disease was present in 56.7% (80/141): 76% ulcerative colitis, 18.7% Crohn's disease. MRCP was the primary diagnostic tool in 93.6%. Still, liver biopsy was performed in 51.1% (70/137). UDCA was prescribed in 90.1% (118/131) and fibrates in 13.6% (18/132). During follow-up, 28.6% (36/126) developed cirrhosis, 10.4% (13/125) had recurrent cholangitis, 3.9% (5/127) hepatocellular carcinoma, 7.0% (9/129) cholangiocarcinoma, and 0.69% (1/144) colorectal cancer; no gallbladder cancers were reported. Liver transplantation was performed in 19.7% (25/127), and mortality reached 15.6% (20/128), with 65% liver-related. **Conclusion:** This is the first multinational study of PSC in Latin America. Differences in IBD prevalence, sex distribution, diagnostic and treatment approaches reflect regional heterogeneity and a broader global lack of consensus on optimal PSC management, emphasizing the need for prospective, multicenter studies.

4531 | PREVALENCE AND OUTCOMES OF EXTRAHEPATIC AUTOIMMUNE DISEASES IN U.S. PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A REAL-WORLD EHR STUDY

Romelia Barba[1] Ana Marenco-Flores[2] Khawaja Hassam[3] Rubab Rizwan[4] Natalia Rojas-Amaris[2] Daniela Goyes[5] Iman Waheed Khan[6] Kanak Das[1] Hakan Akin[1] Vilas Patwardhan[2] Alan Bonder[2], [1]Texas Tech University, [2]Beth Israel Deaconess Medical Center, [3]Lahey Hospital and Medical Center, [4]Vassar Brothers Medical Center, [5]Yale University School of Medicine, [6]Reading Hospital, Tower Health

Background: Primary biliary cholangitis (PBC) often coexists with extrahepatic autoimmune diseases (EHAIDs), but U.S. real-world data on their prevalence and clinical impact are limited. Prior European and inpatient U.S. studies were constrained by small cohorts or a lack of long-term follow-up. We used a national EHR network to evaluate EHAID prevalence and outcomes in PBC. **Aim:** To assess the prevalence of EHAIDs and their association with transplant-free survival, hepatorenal syndrome (HRS), and hepatic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

encephalopathy in a real-world cohort of PBC patients. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network. Adults ($\geq$18 years) with PBC (ICD-10 K74.3) from 2010–2025 were included. Patients with autoimmune hepatitis or primary sclerosing cholangitis were excluded. Of 36,362 PBC patients, 8,304 (22.8%) had $\geq$1 EHAID diagnosis before or after PBC, while 20,536 (56.5%) had none. The remaining 7,522 had insufficient structured data to classify EHAID status and were excluded from subgroup comparisons. Outcomes included death, liver transplant, HRS, and hepatic encephalopathy over 10 years. Kaplan-Meier and risk analyses were used. Competing risks and site-level data were not available. **Results:** The most common EHAIDs were Sjögren's syndrome (5.4%), ulcerative colitis (4.9%), rheumatoid arthritis (4.4%), systemic sclerosis (3.1%), and systemic lupus erythematosus (2.8%). Compared to patients without EHAID, those with EHAID had higher risks of death (20.1% vs. 14.0%; OR 1.54, 95% CI 1.44–1.65, $p < 0.001$), HRS (2.9% vs. 2.4%; OR 1.22, $p = 0.013$), and encephalopathy (5.6% vs. 5.0%; OR 1.13, $p = 0.040$). Transplant rates were slightly higher (2.4% vs. 2.1%, $p = 0.087$). Ten-year survival was lower in the EHAID group (61.4% vs. 71.7%; HR 1.41, 95% CI 1.32–1.49, $p < 0.001$). **Conclusion:** In this large, national cohort, over one in five PBC patients had coexisting EHAIDs. Their presence was associated with higher mortality and hepatic decompensation. Unlike prior inpatient-only studies, this analysis includes outpatient and long-term data, offering a more complete view of EHAID burden in PBC.

4532 | IMPACT OF MARALIXIBAT ON CAREGIVER BURDEN FOR PATIENTS WITH ALAGILLE SYNDROME AND PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS: BASELINE AND 6-MONTH FOLLOW-UP

Natasha Dilwali[1] Fiona Coll[2] Yushan Kim[3] Robin Howard[4] Rachel Hallum-Montes[2] Douglas Mogul[3] Wikrom Karnsakul[5], [1]Johns Hopkins University, Baltimore, Maryland, [2]Motivo Insights, Colorado Springs, Colorado, [3]Mirum Pharmaceuticals, Inc., Foster City, California, [4]Mirum Pharmaceuticals, Inc., [5]Johns Hopkins University

Background: Alagille syndrome (ALGS) and progressive familial intrahepatic cholestasis (PFIC) are rare conditions leading to end-stage liver disease. As a result of cholestasis, patients experience pruritus, which impacts quality of life, sleep, and is a leading cause of transplant. Maralixibat (MRX) is approved to treat cholestatic pruritus in ALGS/PFIC, with trials showing improvements in pruritus are linked to better patient sleep and quality of life. This study evaluates the impact of MRX on caregiver burden before and 6 months after starting treatment. **Methods:** All MRX prescriptions in the US are dispensed through one pharmacy. Beginning in March 2024, caregivers of newly prescribed MRX for ALGS/PFIC were invited to complete a survey assessing caregiver burden. Questions addressed sleep, pruritus, financial strain, and included the Hospital Anxiety and Depression Scale (HADS) and Zarit Burden Interview (ZBI-12). Follow-up surveys were completed after six months. Data analysis included descriptive statistics, medians, standard deviations, and proportions. **Results:** A total of 21 baseline and 10 6-month follow-up surveys were completed. Most respondents were parents of children with ALGS, identified as Caucasian, and aged 30–39. Among the 10 caregivers with paired surveys, sleep metrics improved over time. On a 1–10 Likert scale (10 = extreme impact), the median sleep impact score decreased from 8 (range 1–10) at baseline to 5.5 (0–10) at 6 months (32% improvement). Similarly, at baseline, 100% reported caregiving impacted their sleep, decreasing to 60% at 6 months. Reports of fair/poor sleep dropped from 90% to 70%. Average nightly sleep increased from 5.6 to 6.3 hours (12.5% increase). ZBI-12 scores showed 6 caregivers had no/mild burden at baseline, 3 had mild/moderate, and 1 had high burden. At 6-month follow-up, 7 had no/mild burden, 1 had mild/moderate, and 2 had high burden. On the HADS, two caregivers had abnormal depression scores at baseline, decreasing to one at follow-up; three had abnormal anxiety scores

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

at baseline, which remained unchanged at follow-up. **Conclusion:** These results suggest 6 months of MRX treatment may reduce caregiver sleep disruption and burden, likely due to improved pruritus in patients. ZBI-12 trends support reduced burden, though HADS results were mixed. While encouraging, these findings are preliminary. Longer-term follow-up is needed to fully understand the broader caregiver benefits of MRX therapy.

4533 | BILE ACID-MEDIATED TISSUE FACTOR ACTIVATION IN HEPATOCYTES

Alex Nartey[1] Sandra Preinstorfer[1] Katrin Panzitt[1] Marion Mussbacher[2] Martin Wagner[1] Axel Schlagenhauf[1], [1]Medical University of Graz, [2]University of Graz

Background: Cholestasis is a hepatobiliary disorder associated with decreased hepatic secretion of bile, causing long-term exposure of hepatocytes to bile acids (BAs) and subsequent liver damage. Intrahepatic coagulation activation during cholestasis can lead to microscopic thrombi that may obstruct hepatic blood flow. Anticoagulant therapy, one of the few available treatments, is often contraindicated when hepatic synthetic dysfunction has already impaired coagulation. Previously, our group showed that in hepatic cell lines, BAs induce the activity of the membrane protein tissue factor (TF, initiator of coagulation), which coincided with activation of farnesoid X receptor (FXR) signalling. Thus, we hypothesise that in cholestasis, prolonged BA exposure induces TF activation through FXR overstimulation, triggering coagulation and stress pathways ultimately leading to hepatocellular decline and thrombus formation. **Methods:** We studied the effects of 24h BA and tunicamycin (ER stress inducer) treatment on cultured hepatocytes, analysed hepatic tissue from liver surgery patients, and examined FXR-deficient mice with bile duct ligation as well as tunicamycin-treated mice. **Results:** We found an expression-independent TF activity increase coupled with FXR activation in hepatocytes treated with unconjugated BAs. Tunicamycin induced ER stress together with an increase in TF activity and early activation of FXR signalling. Both treatments resulted in a rapid viability decline accompanied by an increase in apoptosis/necroptosis that played a key role in TF activity.

Patients with high bilirubin serum levels (indicating cholestatic diseases) exhibited FXR activation with signs of enhanced coagulation.

Lastly, FXR activity and hepatic thrombin levels were elevated in mice after bile duct ligation, with a reduction in the FXR-deficient cohort. Tunicamycin-treated mice showed a similar early activation of FXR signalling. **Conclusion:** Our results suggest that prolonged exposure of hepatocytes to BAs post-translationally increases TF activity coinciding with continuous intracellular FXR activation, a similar phenotype observed after early ER stress elicited by tunicamycin. Both conditions triggered rapid hepatocellular decline, mediated at least partially by apoptosis/necroptosis-dependent pathways. We thus conclude that FXR overstimulation (via BAs) and ER stress (via tunicamycin) triggers downstream pathways like apoptosis/necroptosis and other key mechanisms regulating BA-mediated activation of the membrane protein TF. Our findings provide valuable insights into the largely elusive molecular mechanisms underlying intrahepatic coagulation activation during cholestasis.

4534 | YOUR GUIDE TO LIVING WELL WITH PRIMARY BILIARY CHOLANGITIS: CO-CREATION OF AN EVIDENCE-BASED RESOURCE FOR SYMPTOM MANAGEMENT AND DISEASE UNDERSTANDING

Victoria Barghout[1] Laura Medina[1] Sophie Griswold[1] Gail Wright[2] Carol Roberts[3] Robert Mitchel-Thain[4] Mo Christie[4] Kerin Stevens[5] ANNIE SON[5] Jamie Zagorski[5], [1]Viver Health LLC, Morristown, NJ, USA, [2]Canada PBC Society, Toronto, Canada, [3]PBCers Organization, Rochester, NY, USA, [4]PBC Foundation, Edinburgh, UK, [5]Gilead Sciences, Inc.

Background: Primary biliary cholangitis (PBC) is a chronic, inflammatory autoimmune liver disease characterized by progressive cholestasis and high symptom burden, including pruritus, fatigue, and cognitive dysfunction. While treatments may slow disease progression, patients often experience persistent symptom burden. Patients frequently report gaps in disease education and lack tools to manage symptoms, improve quality of life (QoL), and engage in shared decision-making with healthcare providers (HCPs). **Methods:** We used a qualitative, stakeholder-informed approach with literature review and iterative resource creation. A literature review and structured interviews with a

geographically and demographically diverse group of individuals with PBC, advocates, and HCPs identified key gaps in patient education, symptom management, and shared decision-making in PBC. Findings informed creation of Your Guide to Living Well with PBC. The same participants reviewed the Guide for clarity, usability, and relevance. Medical experts conducted a clinical review to ensure guideline alignment. Throughout development, three leading PBC advocacy groups provided input, health literacy review, and endorsement. An online survey was created to assess usage, satisfaction, behavior change, and reach. **Results:** A need was identified for a user-friendly evidence-based resource to support symptom self-management and facilitate informed discussions with HCPs. The resulting resource, Your Guide to Living Well with PBC, is an accordion, four-fold printed Guide, backed by 202 references. It covers whole-person disease management and lifestyle adaptations like stress management, nutrition, and movement, which may improve QoL. Emphasis is given to integrative approaches for managing fatigue, pruritus, and cognitive symptoms. Patients stated that "[they] would have loved this when first diagnosed." HCPs noted it "fills an unmet need" and "allows patients to take control." Early survey feedback showed greater confidence in understanding disease mechanisms, symptom management, and shared decision-making. Patients rated use likelihood as extremely likely (9.89/10). **Conclusion:** Your Guide to Living Well with PBC addresses key gaps in patient education, symptom self-management, and shared decision-making. By combining evidence-based content with patient and provider insights, the Guide offers a practical tool to support whole-person care. Ongoing metrics will guide development and dissemination.

4535 | DIET QUALITY IS POSITIVELY ASSOCIATED WITH QUALITY OF LIFE IN ADULT FEMALES WITH PRIMARY BILIARY CHOLANGITIS

Audrey-Anne Lavoie[1] Mélanie Verreault[2] Jacob Lessard-Lord[1] Roxanne Rochon[3] Valérie Guay[4] Laurence Constantin[1] Mandana Salkhi[1] Catherine Vincent[3] Jean-Philippe Drouin-Chartier[1] Olivier Barbier[1], [1]Université Laval, Faculty of Pharmacy, Quebec, Canada, [2]CHU De Québec Research Center, Quebec, Canada, [3]University of Montreal Health Centre (CHUM), Quebec, Canada, [4]Institute of Nutrition and Functional Foods, Université Laval, Quebec, Canada

Background: Primary biliary cholangitis (PBC) is a rare hepatobiliary disease characterized by the destruction of the bile ducts, which leads to cholestasis, fibrosis, cirrhosis and liver failure. Although pharmacological options are effective in slowing disease progression, they offer limited relief from symptoms such as fatigue and pruritus. Diet could slow disease progression and offer an additional strategy to improve symptom burden. However, the relationship between diet and PBC remains poorly understood. *Thus, this study aimed to evaluate the association between diet, symptom management and liver-related outcomes in patients with PBC.* **Methods:** Adult female with PBC ($n = 48$) were recruited at the Department of Hepatology of the CHU de Montréal, Quebec, Canada. Liver enzymes, fibrosis, steatosis levels (CAP score) and cirrhosis were measured through blood tests or Fibroscan. Symptoms burden and diet quality were evaluated using the PBC-40 questionnaire and the Alternative Healthy Eating Index (AHEI) upon completion of 1 or more web-based 24h diet recalls. **Results:** Participants had a mean age of 63.9 ± 8.1 years and most exhibited hepatic steatosis and/or fibrosis (CAP score: 249.7 ± 52.8dB/m; fibrosis score: 5.9 ± 2.0kPa). While diet quality was suboptimal (AHEI score: 50.7 ± 11.0), better dietary habits was associated with improved liver outcomes. Each 10-points increase in the AHEI score corresponded to reductions of -1.8dB/m [95% CI: -3.2, -0.5; $P = 0.009$] in CAP score and -0.09kPa [-0.1, -0.03; $P = 0.003$] in fibrosis score. Higher polyunsaturated fatty acids (PUFA) intake was also associated with -3.9% decreased odds of developing cirrhosis [-0.09, 0.006, $P = 0.09$]. Whole vegetable intake was inversely associated with total bilirubin levels (-0.7µmol/L [-1.3, -0.1; $P = 0.02$] per 1-point increase in the $AHEI_{vegetable}$ subscore). Diet quality also aligned with improved quality of life: higher fruit intake was associated with a reduced itch score of -0.5 [-1.1, 0.04; $P = 0.07$] per 1-point increase in the $AHEI_{fruits}$ subscore, while higher PUFA intake with lower emotional and social scores of -0.5 [-0.8, -0.2; $P = 0.004$] and -1.5 [-2.8, -0.2; $P = 0.03$] per 1-point increase in the $AHEI_{PUFA}$ subscore. Higher total protein intake was associated with lower fatigue score of -0.2 [-0.5, 0.004; $P = 0.09$] per 1g increase of protein. **Conclusion:** Healthy food consumption could provide an alternative option to improve quality of life and reduce pathological parameters in patients with PBC.
