★ 0001 | CHOLESTEROL-RESPONSIVE INTERACTION OF NFE2L1-INSIG1 CONTROLS VLDL SECRETION AND ATTENUATES MASH PROGRESSION

Shijun Deng[1] Gokhan Hotamisligil[1] Isabel Graupera[2], [1]Harvard University, [2]Liver Unit Hospital Clinic, Barcelona, Spain

Background: Hepatic cholesterol overload is a central driver of metabolic dysfunction-associated steatohepatitis (MASH). While the liver exports cholesterol via very-low-density lipoprotein (VLDL) secretion to maintain homeostasis, this process is paradoxically suppressed under high cholesterol by insulin-induced gene 1 (INSIG1), which retains the sterol regulatory element-binding protein 1 (SREBP1) in the endoplasmic reticulum (ER), suppressing lipogenesis and limiting VLDL production. Despite this regulatory checkpoint, VLDL secretion persists during cholesterol overload - a critical but unresolved adaptation that prevent lipotoxicity. Here, we identify nuclear factor erythroid 2-related factor 1 (NFE2L1), an ER cholesterol sensor, as the missing link coordinating with SREBP1 activity and VLDL secretion to mitigate MASH. **Methods:** Liver-specific Nfe2l1 knockout (LKO) and wild-type (WT) mice were used to assess VLDL secretion *in vivo*. Subcellular fractionation isolated nuclear and ER compartments to quantify active (mature) SREBP1 levels. Site-directed mutagenesis generated NFE2L1 mutants, and co-immunoprecipitation (Co-IP) mapped the binding domains between NFE2L1-INSIG1. For *in vivo* rescue studies, LKO mice received hepatocyte-targeted AAV-mediated expression of NFE2L1-WT or NHB2 domain-deleted mutants (ΔNHB2). Serum and hepatic lipids were profiled via LC-MS/MS. To model human MASH, db/db mice were fed a methionine/choline-deficient (MCD) diet for 12 weeks. Liver pathology was scored blindly via immunohistochemistry (steatosis, inflammation, fibrosis). Data were analyzed by two-tailed Student's t-test or ANOVA. **Results:** NFE2L1 deficiency increased INSIG1 stability, suppressed SREBP1 activation, and impaired VLDL secretion, causing hepatic cholesterol accumulation and injury. Mechanistically, NFE2L1 binds INSIG1 via its NHB2 domain; this binding increases with free cholesterol, driving INSIG1 degradation and enabling SREBP1-driven VLDL production. In LKO mice, re-expression of NFE2L1-WT by AAV restored SREBP1 activity and VLDL secretion, while ΔNHB2 mutants failed to rescue such effects. Lipidomic profiling revealed that disrupted serum triglyceride composition in NFE2L1-LKO mice was reversed by the WT, but not by ΔNHB2 protein. Strikingly, NFE2L1 overexpression in a murine MASH model enhanced cholesterol export, and reduced liver injury, inflammation, and fibrosis via SREBP activation – without elevating atherogenic lipoproteins due to compensatory LDL receptor upregulation. **Conclusion:** We define the NFE2L1-INSIG1 axis as a cholesterol-responsive checkpoint that licenses VLDL secretion to resolve lipid toxicity and mitigate MASH. This pathway uniquely couples cholesterol sensing to lipoprotein export, offering a therapeutic strategy to combat MASH without exacerbating cardiovascular trade-offs.

★ 0002 | LIVER CD8 TISSUE-RESIDENT MEMORY T CELLS DRIVE INFLAMMATION IN ALCOHOL-ASSOCIATED HEPATITIS

Weizhe Zhong[1] Shawna Cooper[2] Fiona Xhafi[3] Benjamin Swartzwelter[1] Cao Sheng[2] Vijay Shah[2] Mengfei Liu[4], [1]Division of Digestive Disease, Internal Medicine, Yale University;Yale Liver Center, Yale University, [2]Mayo Clinic, Rochester, [3]Division of Digestive Disease, Internal Medicine, Yale University; Yale Liver Center,Yale University, [4]Division of Digestive Disease, Internal Medicine, Yale University;Yale Liver Cente,Yale University

Background: Alcohol-associated hepatitis (AH) is a severe liver disease marked by increased CD8 T cell infiltration. However, the role of CD8 T cells in AH pathogenesis remains unclear. We identified and

characterized liver CD8 tissue-resident memory T cells (TRM) as key drivers of inflammation in AH. **Methods:** A modified NIAAA chronic-binge alcohol model with LPS injection was used in mice. Single-cell RNA sequencing (scRNA-seq) was performed on immune cells isolated from liver and peripheral blood mononuclear cells (PBMCs). CD8 T cells were classified into naive/central memory T (TCM), effector memory T (TEM), and TRM subsets. The regulatory mechanisms underlying were analyzed via Ingenuity Pathway Analysis (IPA) and Gene Set Enrichment Analysis (GSEA). We performed *in silico* analysis of previously published human liver and PBMC scRNA-seq datasets that included data from patients with AH, alcohol-associated cirrhosis or health controls. TRM is found in liver sinusoids adherent to liver sinusoidal endothelial cells (LSECs) at homeostasis. We performed *in vitro* co-culture of human primary LSECs and CD8 T cells to assess the effects of co-culture on T cell activation and survival. To evaluate the function of IL15 signaling in liver TRM cells in AH, we administered an anti-IL-15 antibody in the AH mouse model and assessed liver injury. **Results:** In the murine AH model, we observed a marked increase in the proportion of CD8 T cells in alcohol/LPS-treated livers compared to controls. Liver TRM cells demonstrated greater cytokine release and cytotoxicity than blood-derived TEM cells. IPA identified IL15 to be an upstream regulator in liver TRM cells, with enrichment of the purinergic signaling pathway—previously shown to be essential for IL-15-induced TRM activation in metabolic dysfunction-associated steatohepatitis (MASH). GSEA further confirmed the upregulation of IL-15 signaling in liver TRM cells. Human AH data also identified a prominent population of TRM cells in AH liver, with higher cytotoxicity compared to blood TEM cells. CellChatDB analysis revealed enhanced cellular interactions between liver TRM cells and LSECs in alcohol/LPS-treated mice. *In vitro* co-culture of human primary LSECs with CD8 T cells enhanced activation in T cells stimulated by anti-CD3/CD28 beads or IL-15/acetate, but had no effect on unstimulated cells. Notably, LSEC co-culture increased T cell death after anti-CD3/CD28 stimulation but not with IL-15/acetate, suggesting IL-15 protects against activation-induced cell death. *In vivo*, blockade of IL-15 signaling with a neutralizing antibody significantly reduced liver injury in our murine AH model, suggesting that IL-15 signaling contributes to AH pathogenesis.
Conclusion: Our study highlights the critical role of liver TRM cells in driving liver inflammation in AH. IL-15 is a key regulator of these cells and represents a promising therapeutic target for the treatment of AH.

★ 0003 | RNA-BINDING PROTEIN ZFP36L1 CONTROLS HEPATOCYTE SENESCENCE AND SUSCEPTIBILITY TO ALCOHOLIC LIVER DISEASES

Kuo Du[1] Rajesh Dutta[2] David Umbaugh[2] Niansheng Ren[2] Seh Hoon Oh[2] Ullas Chembazi[3] Sushan Bangru[3] Auinash Kalsotra[3] Anna Mae Diehl[1], [1]Duke University, [2]Duke Universty, [3]University of Illinois

Background: Alcoholic liver diseases (ALD) progresses when liver regeneration is defective. Senescent cells lose their regenerative capacity and acquire a senescence-associated secretory phenotype (SASP) that promotes maladaptive responses in themselves and neighboring cells. The mechanisms that regulate senescent cell accumulation in ALD are poorly understood. ZFP36L1, an RNA-binding protein enriched in hepatocytes, is known to regulate mRNA stability via binding AU-rich elements in the 3′ UTRs of its targets, including key SASP factors. We hypothesized that ZFP36L1 plays a central role in controlling hepatocyte senescence and thereby modulates susceptibility to ALD. **Methods:** We

analyzed four independent human ALD transcriptomic datasets comprising 28 healthy controls, 23 patients with alcohol-related cirrhosis (AC), and 35 with alcohol-related hepatitis (AH). Senescence signatures were evaluated using bulk RNA-seq and single-nucleus RNA-seq (snRNA-seq), and validated by immunostaining. Also, we generated hepatocyte-specific Zfp36l1 knockout (Zfp36l1$^{\Delta Hep}$) mice and subjected them to mouse models of AH. Liver phenotypes were assessed via histology, biochemical injury markers, and gene profiling. Mechanistic studies included mRNA stability assays and pathway analysis to examine ZFP36L1 targets. **Results:** Transcriptomic profiling showed enriched senescence signatures in AC and AH livers, with snRNA-seq confirming senescent hepatocyte accumulation and elevated SASP scores. These findings were corroborated by increased expression of direct ZFP36l1 targets including proinflammatory cytokines and p21. Mouse models of AH showed increased TNFa and accumulation of senescent hepatocytes. Zfp36l1$^{\Delta Hep}$ mice developed a pro-inflammatory, pro-senescent phenotype even under basal conditions and worse liver injury, senescence, inflammation, and fibrosis than controls after alcohol feeding. Mechanistically, ZFP36L1 deficiency stabilized TNFa and Jag1 mRNA, activating JAG1-NOTCH signaling (which reprograms hepatocyte into bipotent progenitors) and p21 (which prevents progenitor proliferation and promotes hepatocyte senescence). **Conclusion:** Our findings identify hepatocyte senescence as a critical driver of ALD and establish ZFP36L1 as a central post-transcriptional regulator of this process. By destabilizing pro-senescent transcripts (e.g., p21) and pro-inflammatory transcripts (e.g., TNF-a), ZFP36L1 safeguards against hepatocyte dysfunction and disease progression. These results highlight a novel mechanism linking RNA-binding proteins to the control of liver regeneration and suggest that therapeutic modulation of ZFP36L1 or its downstream targets may offer new strategies for treating ALD.

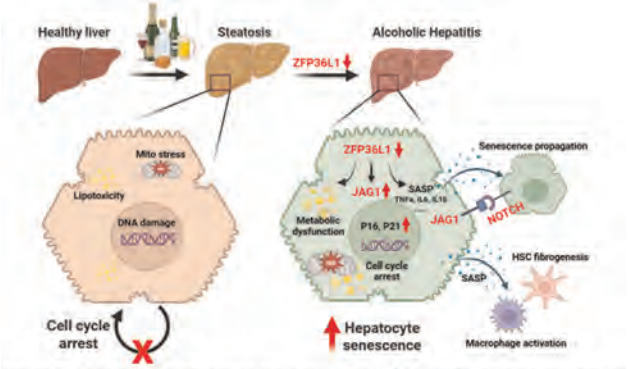

Figure 1: ZFP36L1 restricts hepatocyte senescence and fibroinflammatory crosstalk in alcoholic liver disease. Chronic alcohol exposure triggers lipotoxicity, mitochondrial stress, and DNA damage, leading to transient hepatocyte cell cycle arrest. In alcoholic hepatitis, ZFP36L1 downregulation stabilizes JAG1 mRNA and activates the JAG1–NOTCH pathway, promoting p16/p21 expression, senescence, and SASP production. This amplifies hepatocyte senescence, activates macrophages, and enhances HSC fibrogenesis, driving ALD progression.

★ 0004 | MULTI-OMICS ANALYSES IDENTIFY A NOVEL HEPATOCELLULAR CARCINOMA SUBTYPE WITH BETTER RESPONSE TO IMMUNE CHECKPOINT INHIBITOR THERAPIES

Junjie Xu[1], [1]Zhejiang University

Background: Hepatocellular carcinoma (HCC) presents persistent therapeutic challenges due to molecular heterogeneity and unpredictable immune checkpoint inhibitor (ICI) responses. **Methods:** In this study, whole transcriptome sequencing was performed on tumor and adjacent non-tumor tissues across 242 patients with hepatocellular carcinoma (HCC) and 51 patients with intrahepatic cholangiocarcinoma (ICC) and 90 prospective ICI-treated HCC patients. Whole exome sequencing was performed in selected samples (n = 61) of each cancer subtype. Single-cell RNA sequencing was performed on fresh primary tumor samples from 15 HCC patients and 8 ICC patients. **Results:** Through integrative multi-omics analyses, we identified a novel ICI-sensitive HCC subtype (IS-HCC) characterized by a pre-dysfunctional CD8+ T cell microenvironment and distinct genomic drivers (TP53, PIK3R1, OR6P1 and CHIT1). While bulk transcriptomic profiles revealed partial similarity with intrahepatic cholangiocarcinoma (ICC), single-cell resolution uncovered unique immune dynamics in IS-HCC, marked by transitional CD8+ T cells co-expressing exhaustion (PDCD1, HAVCR2) and activation (GZMB, IFNG) markers. By validation in a prospective ICI-treated HCC cohort (n = 90), this pre-dysfunctional T cell state of IS-HCC, rather than tumor mutational burden (TMB), predicted superior ICI response (OR = 4.595, 95%CI: 1.725-12.022), challenging neoantigen-centric paradigms. Moreover, glycan biosynthesis and hypoxia related immune suppression was found in IS-HCC patients, suggesting metabolic-immune crosstalk via hypoxia and glycan pathways might be actionable targets. We developed and validated a 29-gene signature across major global HCC cohorts that stratified IS-HCC patients, who exhibited aggressive baseline features but achieved favorable response to ICI therapies. **Conclusion:** Clinically, this biomarker-driven framework transcends current selection paradigms and addresses a critical unmet need by enabling precise ICI deployment

selection. Our findings redefine HCC taxonomy through immune-contextual biomarkers, offering a roadmap for biomarker-driven trials and combinatorial strategies to overcome resistance. This work bridges molecular discovery to clinical translation, with potential to double ICI efficacy rates in stratified populations and spare non-responders from futile therapies, advancing precision immuno-oncology in liver cancer.

0005 | LONG-TERM DATA OF ELAFIBRANOR IN PRIMARY SCLEROSING CHOLANGITIS: INTERIM SAFETY AND EFFICACY DATA FROM THE ONGOING OPEN-LABEL EXTENSION OF THE ELMWOOD PHASE II TRIAL

Christopher Bowlus[1] Cynthia Levy[2] George Abouda[3] Bahri Bilir[4] Isabel Campos-Varela[5] Nora Cazzagon[6] Natasha Chandok[7] Kuldeep Cheent[8] Helena Cortez-Pinto[9] Münevver Demir[10] Michael Dill[11] Bertus Eksteen[12] Jonathan Fenkel[13] Hin Hin Ko[14] Ira Jacobson[15] Yiannis Kallis[16] Kris Kowdley[17] Marcelo Kugelmas[18] Velimir Luketic[19] Alessandra Mangia[20] Aldo Montano-Loza[21] Ashis Mukhopadhya[22] Antonio Olveira[23] Bhaktasharan Patel[24] Antonello Pietrangelo[25] Faruq Pradhan[26] Magdalena Salcedo[27] Mitchell Shiffman[28] Kathrin Sprinzl[29] Rachael Swann[30] Douglas Thorburn[31] Paul Thuluvath[32] Palak Trivedi[33] Claudia Zein[34] Hugo Gomes da Silva[35] Benjamin Miller[34] Claire Milligan[36] Aude Tavenard[35] Alan Bonder[37], [1]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, CA, USA, [2]Schiff Center for Liver Diseases, University of Miami, Miami, FL, USA, [3]NHS Humber Health Partnership, Hull University Teaching Hospitals NHS Trust, Hull, UK, [4]Advent Health Transplant Institute, Denver, CO, USA, [5]Liver Unit, Hospital University Vall d'Hebron, Barcelona, Spain, [6]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy, [7]Department of Medicine, William Osler Health System, Brampton, ON, Canada, [8]Department of Hepatology, Frimley Health NHS Foundation Trust, Surrey, UK, [9]Clínica de Gastrenterologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, [10]Department of Hepatology and Gastroenterology, Charité Universitätsmedizin Berlin, Berlin, Germany, [11]Department of Gastroenterology & Hepatology, Heidelberg University Hospital, Heidelberg, Germany, [12]Aspen Woods Clinic, Calgary, AB, Canada, [13]Gastroenterology & Hepatology Division, Thomas Jefferson University Hospital, Philadelphia, PA, USA, [14]Division of Gastroenterology and Hepatology, University of British Columbia, Vancouver, BC, Canada, [15]Division of Gastroenterology and Hepatology, NYU Langone Health, New York City, NY, USA, [16]Barts Liver Centre, Blizard Institute, Queen Mary University of London, London, UK, [17]Liver Institute Northwest, Seattle, WA, USA, [18]South Denver Gastroenterology, Englewood, CO, USA, [19]VCU School of Medicine, Stravitz-Sanyal Institute for Liver Disease, Richmond, VA, USA, [20]Department of Medical Sciences, Ospedale Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [21]Division of Gastroenterology and Liver Unit, University of Alberta, Edmonton, AB, Canada, [22]Digestive Disorders Department, Aberdeen Royal Infirmary, Aberdeen, UK, [23]Department of Gastroenterology, Hospital Universitario La Paz, Madrid, Spain, [24]Department of Gastroenterology, UCHealth, Colorado Springs, CO, USA, [25]Department of Internal Medicine, University Hospital of Modena, Modena, Italy, [26]Division of Gastroenterology and Hepatology, University of Nebraska Medical Center, Omaha, NE, USA, [27]Gastroenterology and Hepatology Department, Universidad Complutense, Madrid, Spain, [28]Liver Institute of Virginia, Bon Secours Mercy Health, Richmond, VA, USA, [29]Goethe University Frankfurt, Department of Gastroenterology & Hepatology, Frankfurt/Main, Germany, [30]Queen Elizabeth University Hospital, Glasgow, UK, [31]Sheila Sherlock Liver Centre, Royal Free Hospital, London, UK, [32]Clinical Professor of Medicine, University of Maryland School of Medicine, Baltimore, MD, USA, [33]Liver Unit, University Hospitals Birmingham, Birmingham, UK, [34]Ipsen, Cambridge, MA, USA, [35]Ipsen, Paris, France, [36]Ipsen, London, UK, [37]Liver Center, Department of Gastroenterology, Harvard Medical School, Boston, MA, USA

Background: In the double-blind period (DBP) of the phase II ELMWOOD trial (NCT05627362), elafibranor (ELA) was well tolerated and improved biochemical markers of cholestasis in patients with primary sclerosing cholangitis (PSC) compared with placebo (PBO).[1] We report interim results up to 28

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

weeks of the ongoing ELMWOOD open-label extension (OLE). **Methods:** Patients completing the DBP on PBO, ELA 80 mg, or ELA 120 mg were eligible to enter the OLE and receive daily ELA 120 mg. Endpoints included treatment-emergent adverse events (TEAEs) and mean changes from DBP baseline in liver biochemistry and pruritus according to the Worst-Itch Numeric Rating Scale (WI NRS) to OLE Week 28, and in non-invasive tests (NITs) of fibrosis (enhanced liver fibrosis [ELF] and PRO-C3) to OLE Week 16. **Results:** Overall, 63/64 (98.4%) patients who completed the DBP entered the OLE; 22/22 (100%) patients continued ELA 120 mg treatment, and 20/21 (95.2%) and 21/21 (100%) crossed over having received PBO and ELA 80 mg in the DBP, respectively. At data cutoff (September 2024), TEAEs have been reported by 31/60 (51.7%) patients in the OLE; the most common TEAEs were COVID-19, nausea, pruritus, and weight increase (4/60 [6.7%] for each). TEAEs that led to treatment discontinuation have occurred in 3/60 (5.0%) patients (patient 1: diarrhea, nausea, and vomiting; patient 2: hepatocellular carcinoma; patient 3: nausea, pruritus, and agitation); all three patients had crossed over from PBO. Patients crossing over from PBO have had reductions in alkaline phosphatase (ALP) at OLE Week 4 (−36.1%) and Week 28 (−40.6%); patients initially on ELA 80 mg and 120 mg maintained ALP response or achieved further reductions to Week 28 (−35.6% and −46.3%, respectively; Table). At OLE Week 28, reductions have been seen in alanine aminotransferase, aspartate aminotransferase, total bilirubin, and γ-glutamyl transferase in patients crossing over from PBO (−21.0%, −2.5%, −10.0%, −16.9%); maintained response or further reductions have been seen in patients initially on ELA 80 mg (−33.4%, −21.7%, −26.0%, −30.0%) and ELA 120 mg (−27.5%, −6.5%, −17.0%, −37.2%). Reductions in WI NRS have been observed in all groups at OLE Week 28 (crossover PBO: −0.10; crossover ELA 80 mg: −0.90; continuous ELA 120 mg: −1.28). At OLE Week 16, patients initially on ELA 80 mg or ELA 120 mg have had further reductions in NIT of fibrosis (ELF: −0.16 and −0.15; PRO-C3: −20.6% and −14.4%); these markers have stabilized or reduced in patients initially on PBO (ELF: 0.05; PRO-C3: −9.3%). **Conclusion:** ELA 120 mg has been well tolerated in patients with PSC in the ELMWOOD OLE. All groups have had reductions in biochemical markers of cholestasis and pruritus. Patients crossing over from PBO have had stabilization or reductions in NITs of fibrosis, while patients initially on ELA have seen further reductions in NITs of fibrosis with continued ELA treatment.

0006 | LEFT VENTRICULAR MASS INDEX, A KEY METRIC FOR CIRRHOTIC CARDIOMYOPATHY, IS A BETTER PREDICTOR OF MORBIDITY AND MORTALITY THAN PELD IN PEDIATRIC CIRRHOSIS

Dalia Bashir[1] Moreshwar Desai[2] Manpreet Virk[3] Curtis Kennedy[1] N. Thao Galvan[1] Tam Doan[1] Taylor Nack[2] Anna Banc-Husu[4] Divya Sabapathy[1] Noelle Gorgis[5], [1]Texas Childrens hospital/Baylor College of Medicine, [2]Baylor College of Medicine, [3]Texas Childrens hospital/Baylor College of Medicine, [4]Baylor College of Medicine, Texas Children's Hospital, [5]Childrens Hospital of Philadelphia

Background: Cirrhotic cardiomyopathy (CCM), a rapidly emerging comorbidity in both adult and pediatric cirrhosis, is associated with adverse perioperative outcomes and death. Despite its clinical relevance, the influence of CCM on the clinical trajectory and prognosis of children with cirrhosis has not been systematically studied. We aimed to examine the impact of left ventricular hypertrophy (LVH), a key echocardiographic (ECHO) metric of pediatric chronic cholestatic liver disease (CCM), on waitlist decompensation (WLD), post-transplant (LT) composite of serious adverse events (CSAE), and overall mortality, and compare its predictive value with PELD. **Methods:** We retrospectively reviewed charts of 236

children with cirrhosis listed for liver transplantation (LT) between 2011 and 2021. LV mass (raw and indexed to height$^{2.7}$; LVMI) obtained from echo closest to LT was compared with other prognostic markers, including age at listing/LT, waitlist time, and PELD at the time of echo. Definitions: LV hypertrophy (LVH) = LVMI z score > 2; WLD = extra-hepatic organ involvement needing support pre-LT; CSAE = any post-LT life-threatening event, including graft failure; mortality = death after being listed to 1-year post-LT. Statistics: Optimal cutoff for LVMI was identified via the Youden Index. We used Fisher's exact test for categorical data and logistic regression with ROC analysis to assess the predictive ability of LVMI for WLD, CSAE, and mortality. LVMI and PELD were compared using McNemar's test ($p < 0.05$ significant). **Results:** 236 children with cirrhosis were listed for transplant, median age was 15 months [IQR: 6.6,116]; 54 females, 70 (31%) experienced WLD, 51/186 (27%) developed CSAE post-LT. Overall mortality was 11% (46% pre-LT; 54% post-LT). LVH was present in 54/236 (24%). Those with LVH had higher odds of WLD (OR 3; CI 1.6-5.7; p = 0.0012), CSAE (OR 3; CI 1.4-6; P = 0.0036), and death (OR 4.6; CI 1.9- 11; p = 0.0007). By Youden analysis, LVMI > 88 predicted WLD with 81% sensitivity and 63% specificity; LVMI > 91 predicted CSAE with 61% sensitivity and 76% specificity; and LVMI > 97 predicted mortality with 79% sensitivity and 78% specificity. LVMI performed better than PELD in predicting WLD (p = 0.02), CSAE (p = 0.044), and mortality (p = 0.02) (Figure). **Conclusion:** CCM is associated with mortality and morbidity in pediatric cirrhosis. Adding LVMI, a key metric of CCM, to PELD will vastly enhance prognostication and risk stratification in children with cirrhosis. Robust prospective multicenter studies are warranted.

0007 | EFRUXIFERMIN WAS ASSOCIATED WITH IMPROVEMENTS IN MULTIPLE NON-INVASIVE TESTS INDICATIVE OF FIBROSIS REGRESSION IN PARTICIPANTS WITH COMPENSATED CIRRHOSIS DUE TO MASH (SYMMETRY)

Vlad Ratziu[1] Arun Sanyal[2] Guy Neff[3] Doreen Chan[4] Mark Burch[4] Erik Tillman[4] Sonja Billes[4] Arian Zari[4] Dragan Mackovic[4] Brittany De Temple[4] Reshma Shringarpure[4] Meena Jain[4] Timothy Rolph[4] Andrew Cheng[4] Kitty Yale[4] Mazen Noureddin[5], [1]Service D' Hepatogastroenterologie (FR), [2]Virginia Commonwealth University, [3]Covenant Metabolic Specialist, [4]Akero Therapeutics, [5]Houston Methodist Hospital

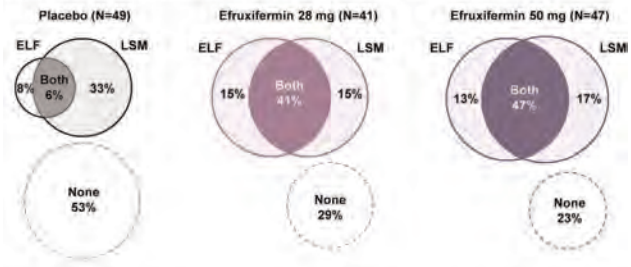
Background: Liver biopsy has limitations for measuring treatment effect in MASH trials and could be advantageously replaced by non-invasive tests (NITs). However, the optimal choice of NITs or combination thereof has been constrained by limited effect of interventions in patients with compensated MASH cirrhosis to date. We analyzed data from the phase 2b SYMMETRY efruxifermin trial (NCT05039450) that successfully demonstrated histological fibrosis regression in efruxifermin-treated participants with compensated cirrhosis due to MASH. **Methods:** Participants (N = 181) were randomly assigned (1:1:1) to once-weekly subcutaneous efruxifermin (28 or 50 mg) or placebo for 96 weeks. The primary outcome was ≥1-stage histological fibrosis improvement with no worsening of MASH (PMID:40341827). Here we analyzed data from individual participants (N = 137) for categorical improvements in imaging-based (liver stiffness measurement by vibration-controlled transient elastography [LSM]), serum (enhanced liver fibrosis [ELF] score), and composite (Agile 4) tests. **Results:** Baseline characteristics were: mean age 61 yrs, 67% female, mean BMI 36 kg/m^2, 80% T2D, mean LSM 24 kPa, ELF 11, platelets 183x10^9/L, ALT 40 U/L, AST 36 U/L. The proportion of participants with ≥1-stage fibrosis improvement and no worsening of MASH was 15% for placebo vs 29% for 28-mg (p = .131) and 39% for 50-mg efruxifermin (p = .009). The proportion of participants with ≥0.5 improvement (reduction) in ELF score was 14% in placebo vs 56% for 28-mg and 60% for 50-mg efruxifermin, while 6%, 27% and 38%, respectively, had an improvement in ELF of ≥1. The proportion of participants with an improvement in LSM (≥30% reduction) was 39% in placebo, vs 56% and 64% for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

28-mg and 50-mg efruxifermin. Evaluation of participants with a response for both ELF ($\geq$0.5 reduction) and LSM ($\geq$30% reduction) resulted in a low placebo response rate (6%) and a clearly higher response rate for 28-mg (41%) and 50-mg (47%) efruxifermin (Figure). Finally, the proportion of participants who shifted from high (Agile 4 score $\geq$0.565) to low likelihood of cirrhosis (Agile 4 score $<$0.251) at Week 96, was 4% for placebo vs 9% and 30% for 28-mg and 50-mg efruxifermin. **Conclusion:** The high level of concordance between NITs, particularly for the 50-mg dose, highlights the consistent anti-fibrotic effect of efruxifermin. The combination of LSM and ELF response provided increased confidence in the ability to effectively monitor effects of efruxifermin.

Figure. Concordance of improvements in non-invasive tests in the SYMMETRY trial



Responder definitions are based on the change from baseline to week 96: ELF score ≥0.5 improvement (decrease); LSM ≥30% improvement (decrease). None indicates the proportion of participants who did not meet the above criteria for improvement in either ELF or LSM.

0008 | ASSESSMENT OF EFFICACY AND SAFETY OUTCOMES BY LIVER FUNCTION WITH FIRST-LINE (1L) NIVOLUMAB PLUS IPILIMUMAB VS LENVATINIB OR SORAFENIB IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA (UHCC): RESULTS: FROM CHECKMATE (9DW)

Peter Galle[1] Aiwu He[2] Thomas Decaens[3] Edward Gane[4] Matthias Pinter[5] David Tai[6] Armando Santoro[7] Gonzalo Pizarro[8] Michael Schenker[9] Nan Hu[10] Maria Jesus Jimenez Exposito[10] Bruno Sangro[11] Thomas Yau[12], [1]University Medical Center, Mainz, Germany, [2]MedStar Georgetown University Hospital, Washington, DC, [3]Univ. Grenoble Alpes, CHU Grenoble Alpes, Institute for Advanced Biosciences, Grenoble, France, [4]Auckland City Hospital, Auckland, New Zealand, [5]Medical University of Vienna, Vienna, Austria, [6]National Cancer Centre, Singapore, Republic of Singapore, [7]Humanitas University, Pieve Emanuele, and IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy, [8]Bradford Hill Centro de Investigacion Clinica, Recoleta, Chile, [9]Centrul de Oncologie Sf. Nectarie, Craiova, Romania, [10]Bristol Myers Squibb, Princeton, NJ, USA, [11]Clinica Universidad de Navarra and CIBEREHD, Pamplona, Spain, [12]Center of Cancer Medicine, University Department of Medicine, The University of Hong Kong, Hong Kong

Background: In an interim analysis of the phase 3 CheckMate 9DW study (median follow-up, 35.2 months [mo]), 1L NIVO + IPI demonstrated significant overall survival (OS) benefit vs LEN/SOR (median OS [mOS]: 23.7 [95% CI, 18.8–29.4] mo vs 20.6 [95% CI, 17.5–22.5] mo; HR, 0.79 [95% CI, 0.65–0.96]; $P = 0.018$). NIVO + IPI had a higher objective response rate (ORR) vs LEN/SOR (36% vs 13%; $P < 0.0001$) and durable responses per blinded independent central review (BICR) and manageable safety in pts with uHCC. We evaluated outcomes based on liver function, longitudinal changes in albumin-bilirubin (ALBI) score during treatment, and hepatic safety in CheckMate 9DW. **Methods:** Adults with uHCC without prior systemic therapy were randomized to NIVO 1 mg/kg + IPI 3 mg/kg Q3W (up to 4 cycles), followed by NIVO 480 mg Q4W, or investigator's choice of LEN 8 mg or 12 mg QD or SOR 400 mg BID (Yau T et al. *Lancet* 2025). Liver function was assessed by ALBI scores. **Results:** Among all randomized pts (N = 668), NIVO + IPI showed clinically meaningful efficacy and manageable safety vs LEN/SOR across ALBI subgroups (Figure). In all randomized pts, ALBI scores remained relatively stable throughout the treatment period in both treatment arms, with slight improvement noted with NIVO + IPI vs LEN/SOR over time (Figure). There was an 18% reduction in the risk of liver function deterioration with NIVO + IPI vs LEN/SOR (Figure). Among 332 pts treated with NIVO + IPI, any-grade immune-mediated hepatitis occurred in 63 (19%) pts, of which 51 (15%) pts had grade 3/4 events. Median time to onset of immune-mediated hepatitis was 6.0 (range, 0.9–88.9) weeks; these resolved in 47 (14%) pts with a median duration of 10.3 (range, 0.9–129.3+) weeks. Of 332 treated pts, 56 (17%) pts received high-dose steroids for immune-mediated hepatitis management. Immune-mediated hepatitis led to treatment discontinuations in 19 (6%) pts. **Conclusion:** NIVO + IPI showed a favorable benefit-risk profile vs LEN/SOR regardless of baseline ALBI grade. Pts treated with NIVO + IPI maintained their ALBI scores during the treatment period and had a longer time to liver function deterioration vs LEN/SOR. Immune-mediated hepatitis was manageable with established algorithms and most did not lead to discontinuation. These results further support 1L NIVO + IPI as a standard of care in uHCC.

0009 | BRELOVITUG (BJT-778) MONOTHERAPY ACHIEVED 100% VIROLOGIC RESPONSE IN PATIENTS WITH CHRONIC HEPATITIS D (CHD): ON TREATMENT WEEK 48 PHASE 2 STUDY RESULTS

Kaushik Agarwal[1] Alina Jucov[2] Marta Dobryanska[3] Patrick Kennedy[4] Edward Gane[5] Man-Fung Yuen[6] Grace Lai-Hung Wong[7] Simone Strasser[8] Jacinta Holmes[9] Stuart Roberts[10] Hassan Javanbakht[11] Nancy Shulman[12] Susanna Tan[11], [1]Kings College Hospital, [2]Arensia EM, Moldova, [3]Arensia EM, Ukraine, [4]Barts and The London SMD, [5]New Zealand Clinical Research, [6]The University of Hong Kong, [7]Prince of Wales Hospital, [8]Royal Prince Alfred Hospital, [9]St. Vincent's University Hospital, [10]Alfred Hospital, [11]Bluejay Therapeutics, Inc., [12]Bluejay Therapeutics

Background: Brelovitug (BJT-778), a fully human anti-HBsAg monoclonal antibody, is currently being evaluated in an ongoing Phase 2 study, BJT-778-001, for the treatment of chronic hepatitis delta (CHD). We report interim on treatment Week 48 safety and efficacy results of brelovitug administered subcutaneously as monotherapy in patients with CHD. **Methods:** Each treatment arm enrolled up to 20 participants with quantifiable HDV RNA, HBV DNA <100 IU/ml on nucleos(t)ides, compensated liver disease, ALT ≤ 10x ULN, and PLT ≥ 100K/ul. Participants received one of the following regimens: 1) Brelovitug 300 mg SC once weekly (QW); 2) Brelovitug 600 mg SC QW for 12 weeks followed by Q2W; and 3) Brelovitug 900 mg SC every 4 weeks with a loading dose at Week 2. Endpoints include safety/tolerability and the proportion of patients achieving (i) virologic response defined as ≥ 2 log10 IU/mL reduction in HDV RNA from BL or HDV RNA below the lower limit of quantification, target not detected ($<$LLOQ, TND); (ii) ALT normalization, and (iii) composite response defined as virologic response and ALT normalization. Additional endpoints include the proportion of subjects achieving HDV RNA $<$LLOQ, and $<$LLOQ, TND. **Results:** 47 CHD patients were enrolled: 18 into Arm 1, 11 into Arm 2, and 18 into Arm 3. Overall, median age was 44 y (20-68y), 92% white, 55% male, 28% with cirrhosis, median HDV RNA of 5.3 $\log_{10}$IU/mL, and median HBsAg of 4.2 $\log_{10}$ IU/mL. Week 48 data is available on 33 subjects. 100% of participants have achieved a virologic response with responses deepening over time. At Week 48, 64%, 75%, and 82% have achieved combined virologic response and ALT normalization with 300 mg QW, 600 mg QW/Q2W, and 900 mg Q4W with a LD at W2, respectively. Interim Week 48 on-treatment results for the efficacy endpoints are listed in the table below. Across all treatment arms, brelovitug has been safe and well tolerated with no reported serious or Grade 3/4 adverse events, and no treatment discontinuations due to adverse events. Full Week 48 results will be presented. **Conclusion:** All brelovitug regimens explored achieved 100% virologic response with a combined response rate of 64%-82% at the interim Week 48 analysis. All dosing regimens have been safe and well-tolerated. Phase 3 trials are underway.

	300 mg QW (n=18)	600 mg QW/Q2W (n=10*)	900 mg Q4W (n=18)

0010 | WEIGHT-DEPENDENT AND INDEPENDENT EFFECTS OF SEMAGLUTIDE IN PARTICIPANTS WITH MASH: SECONDARY ANALYSIS OF THE PHASE 3 ESSENCE TRIAL

Philip Newsome[1] Matthew Armstrong[2] Igor Bakulin[3] Adel Belloum[4] Anna M.G. Cali[4] Anja Geerts[5] Jacob George[6] Ewa Janczewska[7] Niels Krarup[4] Chun-Jen Liu[8] Håvard Midgard[9] Kwabena Opuni[4] Vlad Ratziu[10] Mary Rinella[11] Michael Roden[12] Arun Sanyal[13] Jörn Schattenberg[14] Thea Vestergaard[4] Elisabetta Bugianesi[15], [1]Roger Williams Institute of Liver Studies and King's College Hospital, London, UK, [2]Liver Unit, Queen Elizabeth Hospital Birmingham, Birmingham, UK, [3]Central Scientific Research for Gastroenterology, St Petersburgh, Moscow, Russia, [4]Novo Nordisk A/S, Bagsværd, Denmark, [5]Department of Gastroenterology & Hepatology, University Hospital Ghent, Ghent, Belgium, [6]Storr Liver Centre, The Westmead Institute for Medical Research, Westmead Hospital, NSW, Australia, [7]Hepatology Outpatient Clinic, ID Clinic, Mysłowice, Poland, [8]Department of Internal Medicine, National Taiwan University College of Medicine, Taipei, Taiwan, [9]Department of Gastroenterology, Oslo University Hospital, Oslo, Norway, [10]Institute of Cardiometabolism and Nutrition, Sorbonne Université, Paris, France, [11]Division of Gastroenterology, Hepatology and Nutrition, University of Chicago, Chicago, IL, USA, [12]Heinrich Heine University of Düsseldorf, Düsseldorf, Germany, [13]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, Richmond, VA, USA, [14]Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany, [15]Department of Medical Sciences, University of Turin, Turin, Italy

Background: In the 72-week interim analysis of the phase 3 ESSENCE trial (NCT04822181), once-weekly subcutaneous semaglutide 2.4 mg met its primary endpoint, demonstrating superiority over placebo for histological outcomes and non-invasive tests (NITs). We aimed to determine whether its therapeutic effects are fully dependent on weight loss and to quantify the magnitude of weight-dependent and weight-independent effects. **Methods:** The first 800 randomised participants were evaluated. NITs & liver biopsies were conducted at baseline and week 72. MASH-related NIT responder endpoints included $\geq$17-unit reduction in ALT and $\geq$0.22 reduction in FAST score; fibrosis-related NIT endpoints included 30% reduction in VCTE and $\geq$0.5-unit reduction in ELF score. Histological endpoints included MASH resolution and fibrosis improvement. Logistic regression assessed total, weight loss-dependent, and weight loss-independent effects (expressed as odds ratios [OR]), with percentage weight loss as the mediator and treatment as the exposure. Analyses adjusted for baseline co-variates: T2D status, fibrosis stage and body weight. Missing data were excluded. Histological and NIT responder rates were stratified by weight reduction thresholds ($\leq$2%, $\leq$5%, $\leq$7%, $>$7%). **Results:** For MASH endpoints, the total effect of semaglutide (OR [95% CI]) for ALT reduction and MASH resolution without fibrosis worsening was 4.7 (3.3–6.6) and 3.9 (2.8–5.5) respectively (Figure 1a). The corresponding weight loss-independent effects were 3.0 (2.0–4.6) and 2.0 (1.4–3.0), whilst weight loss-dependent effects were 1.5 (1.2–2.0) and 1.9 (1.6–2.4). For fibrosis endpoints, the total effect of semaglutide for VCTE and fibrosis improvement without MASH worsening was 3.0 (2.0–4.4) and 2.1 (1.5–3.1), respectively. The corresponding weight loss-independent effects were 1.7 (1.1–2.7) and 1.5 (1.0–2.4), and weight loss-dependent effects were 1.7 (1.4–2.2) and 1.4 (1.1–1.8). Histological response increased with greater weight loss on semaglutide (Figure 1b): MASH resolution rose from 48.4% to 71.5% and fibrosis improvement from 27.2% to 41.8% across the

< 2% to > 7% weight loss range, with preservation of the estimated difference in responder proportions (EDP) versus placebo. Placebo-adjusted improvements (EDP) in ALT, FAST, VCTE and ELF with semaglutide were observed across all weight loss categories. **Conclusion:** Semaglutide confers weight-independent liver benefits, with further improvements proportionate to weight loss.

★ 0011 | A PROSPECTIVE STUDY OF PHOSPHATIDYLETHANOL (PETH) AS A DIAGNOSTIC BIOMARKER FOR IDENTIFYING ALCOHOL USE DISORDER (AUD) AMONG PARTICIPANTS AT RISK OF STEATOTIC LIVER DISEASE

Rohan Loomba[1] Luis Díaz[1] Ricki Bettencourt[1] Harris Siddiqi[1] Egbert Madamba[1] Veeral Ajmera[1], [1]University of California San Diego

Background: Alcohol intake is a leading risk factor for liver fibrosis progression in steatotic liver disease (SLD). Although alcohol use disorder (AUD) is prevalent in SLD, it has not been systematically examined. We aimed to determine the AUD prevalence in SLD and examine the performance of PEth as a biomarker of occult AUD in a large prospective cohort of participants who are at risk of steatotic liver disease in the United States. **Methods:** This prospective study included 607 (55% women) adult participants who were overweight/obese. We performed a standardized interview, physical exam, laboratory testing (including PEth), vibration-controlled transient elastography (VCTE) and magnetic resonance imaging (MRI). Hepatic steatosis was defined as MRI-proton density fat fraction (PDFF) ≥5%. Participants were classified into SLD subcategories according to the AASLD criteria. Alcohol consumption was quantified using the Lifetime Drinking History and Alcohol Use Disorders Identification Test (AUDIT). We diagnosed AUD according to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria. We examined diagnostic test performance of PEth for the AUD diagnosis using area under the receiver operating curve (AUROC). **Results:** Study participants had a mean age (+/-sd) of 51.2 ± 13.3 years, a mean body mass index (BMI) was 32.6 (± +/- 5.9) Kg/m^2 n, and 40% were Hispanics; respectively. The prevalence of SLD was 71% including 96% MASLD, 3% for MetALD, and 1% for ALD, respectively. The prevalence of AUD in the entire cohort was 5%, with no significant difference among SLD and non-SLD participants. AUD prevalence by SLD subtype was 3.6% in MASLD, 42.9% in MetALD, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

50% in ALD. PEth had a good diagnostic accuracy for AUD and yielded an AUROC of 0.80 (95% CI 0.72-0.88, p-value <0.001) with a sensitivity of 70% and specificity of 91% at the optimal cut-point of PEth $\geq$ of 43 ng/ml. We then compared Diagnostic accuracy of PEth versus other biomarkers for AUD including AST:ALT ratio, GGT and MCV and PEth remained clinically and statistically significantly superior (P-value $<$ 0.05, for all pair-wise comparisons). **Conclusion:** AUD is a common comorbidity in SLD, affecting up to half of individuals with MetALD and ALD. A PEth level $\geq$ 43 ng/mL may indicate AUD and warrant further assessment. These data have implications for changing clinical practice for which patients may benefit from AUD related interventions.

0012 | COMPARATIVE EFFECTIVENESS OF PALLIATIVE CARE DELIVERED BY TRAINED HEPATOLOGISTS VERSUS PALLIATIVE CARE SPECIALISTS: A MULTI-CENTER CLUSTER RANDOMIZED TRIAL

Manisha Verma[1] Victor Navarro[2] Andrzej Kosinski[3] Tamar Taddei[4] Michael Volk[5] Richard Kalman[1] Alfred Barritt IV[6] Sofia Jakab[7] Marina Serper[8] Eric Orman[9] Maya Balakrishnan[10] Mina Rakoski[11] Don Rockey[12] Kristel Hunt[13] Christopher Woodrell[14] Roniel Cabrera[15] Ayse Aytaman[16] Binu John[17] Brendan McGuire[18] Gyorgy Baffy[19] Elliot Tapper[20] Rohit Nathan[21] Marina Roytman[22], [1]Thomas Jefferson University, [2]Jefferson Health System, [3]Duke Clinical Research Institute, [4]Yale University, [5]Baylor Scott & White Health, [6]UNC, [7]Yale University and VA West Haven, [8]University of Pennsylvania Health System, [9]Indiana University, [10]Ben Taub General Hospital, [11]Loma Linda University, [12]MUSC, [13]VA Bronx, [14]Icahn School of Medicine at Mount Sinai, [15]University of Florida, [16]VA NY Harbor Healthcare System Brooklyn Campus, [17]University of Miami and Miami VA, [18]UAB, [19]VA Boston Healthcare System, [20]University of Michigan Medical Center, [21]Einstein Medical Center, [22]UCSF

Background: Palliative care (PC) interventions improve quality of life (QoL) for patients with serious illnesses. However, there is paucity of data examining the impact of PC in patients with end-stage liver disease (ESLD). This study aims to compare the effectiveness of PC delivered by trained hepatologists to that delivered by PC specialists in improving QoL. **Methods:** We conducted a cluster randomized controlled trial involving 19 centers randomized to one of two PC models: 1) PC delivered by PC specialists (PC-led, 8 centers), or 2) PC delivered by trained hepatologists (Hep-led, 11 centers). Hepatologists in the Hep-led arm received virtual training on PC tailored for ESLD, after randomization. The enrollment period spanned from January 2019 to March 2025. Eligible ESLD patients had decompensated cirrhosis with a complication within the past 6 months and/or hepatocellular carcinoma. Both arms followed a standardized PC intervention over 4 visits (initial, 1, 2, and 3 months) that included assessment of symptoms, distress, depression, and discussion of prognosis and goals of care. The primary outcome was change in QoL, as measured by the Functional Assessment of Cancer Therapy-Hepatobiliary (FACT-Hep) instrument at 3 months. Secondary outcomes included symptom severity [ESAS], distress [DT], depression [PHQ-9], and satisfaction with care [FAMCARE-P]. Intention-to-treat analysis was performed, excluding patients who underwent transplantation or were transferred to hospice prior to month 3. To account for the cluster-based randomization, we utilized a linear mixed model with treatment arm indicator as a covariate and site (cluster) as the random effect. We adjusted for the baseline FACT-Hep total score and randomization strata. A pre-specified non-inferiority (NI) analysis of the Hep-led model with a NI margin of -4 was planned in case the superiority p-value >0.05. **Results:** A total of 935 patients were enrolled (Table). The mean age of the overall cohort was 63 years; 70% male; 14% Hispanic; and 16% African Americans. The primary etiology of liver disease was alcohol-associated in 38%, MASH in 27%, and viral hepatitis in 24%. The FACT-Hep total score improved in both arms:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by 7.0 in the PC-led arm and 8.1 in the Hep-led arm (adjusted means, both $p < 0.01$). Pre-specified non-inferiority analyses showed that the amount of improvement in the Hep-led arm was statistically non-inferior to the PC-led arm ($p = 0.01$ for NI margin = -4). Baseline depression scores predicted change in QoL scores in the overall cohort ($p = 0.03$). Patients in both models had improvements in depression and patient satisfaction from baseline to 3 months, with better improvements in the Hep-led arm than the PC-led arm. **Conclusion:** This is the first trial demonstrating that PC intervention significantly improves QoL of patients with ESLD, with Hep-led arm as beneficial as PC-led arm. Future efforts must prioritize integration of PC into hepatology training and practice.

Table: Demographics, Clinical features and Outcomes in the Two comparative Models

Demographics	**PC Specialists led (PC-led) (N= 516)**	**Trained Hepatologists led (Hep-led) (N=419)**
Mean Age (SD) yrs	64 (10.0)	62 (10.4)
Females	24%	37%
Hispanic	12%	16%
African American	17%	14%
High School or less education	50%	48%
Charlson Comorbidity Score (mean, SD)	5.1 (2.6)	4.8 (2.1)
MELD 3.0 (mean, SD)	14.0 (4.8)	14.9 (5.5)
CTP: A/B/C	20% /62% /16%	14% /53% /33%
Hepatocellular Cancer	60%	40%
Hepatic Encephalopathy	58.7%	58.5%
***FACT-Hep subscales**	Mean raw change scores from baseline to 3-months	
Physical Well Being (PWB)	0.9 (5.4)	1.7 (5.4)
Social Well-Being (SWB)	0.5 (5.3)	0.8 (5.4)
Emotional Well-Being (EWB)	0.3 (4.6)	1.7 (4.8)
Functional Well-being (FWB)	0.8 (5.9)	1.5 (5.8)
FACT-HCS (Hepatobiliary Cancer)	2.9 (8.6)	4.1 (9.2)
FACT- G (General)	2.5 (13.8)	5.8 (14.3)
FACT-TOI (Trial Outcome Index)	4.8 (15.5)	7.3 (15.8)
FAMCARE-P (Patient Satisfaction)	1.3 (11.2)	2.8 (10.9)
***PHQ-9** (Depression)	-0.5 (5.3)	-1.5 (5.5)
***DT** (Distress Thermometer)	-0.2 (2.8)	-0.5 (3.0)
***ESAS (Edmonton Symptom Assessment Scale)**	Mean raw change scores from baseline to 3-months	
Pain	-0.2 (2.9)	-0.4 (2.7)
Tiredness	-0.5 (3.0)	-0.5 (3.0)
Well-being	-0.3 (2.8)	-0.6 (2.8)
Muscle Cramps	-0.4 (3.3)	-1.0 (3.4)
Sleep	-0.3 (3.6)	-1.1 (3.6)
Itch	-0.4 (3.4)	-1.1 (3.2)

*Decrease in ESAS, DT, and PHQ-9 is improvement in symptoms, distress and depression; while an increase in FACT-Hep scores and patient satisfaction is improvement in QoL and satisfaction with palliative care.

★ 0013 | UTILITY OF CORONARY CT ANGIOGRAPHY VERSUS DOBUTAMINE STRESS IN PREDICTING OBSTRUCTIVE CORONARY ARTERY DISEASE

Hoang Anh Richardson[1] Ashley Spann[1] Samuel Nwosu[1] Donald Sengstack[1] Benjamin French[1] Jayant Bagai[1] Alexandra Shingina[2] Jeffrey Carr[1] Manhal Izzy[1], [1]Vanderbilt University Medical Center, [2]University of Michigan Health

Background: Accurate non-invasive evaluation of obstructive coronary artery disease (CAD) in liver transplant (LT) candidates is critical for risk stratification and management. Dobutamine stress echocardiography (DSE) and coronary computed tomography angiography (CCTA) are widely used diagnostic modalities; however, reports of their success rate and predictive performance in identifying obstructive CAD are variable. **Methods:** In this retrospective cohort study, we analyzed 186 adult patients with cirrhosis who underwent both CCTA and DSE prior to invasive coronary angiography (ICA) as part of pre-transplant cardiac evaluation. Patients with heart transplantation were excluded. Obstructive CAD was defined as $\geq 70\%$ stenosis on ICA. CCTA results were grouped into low-moderate risk (CAD-RADS 0, 1, 2, 3) and high risk (CAD-RADS 4, 5). Sensitivity (SN), specificity (SP), positive predictive value (PPV), and negative predictive value (NPV) of DSE, CCTA, and CT-fractional flow reserve

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(FFR) were calculated. Receiver operating characteristic (ROC) analysis was evaluated for each testing modality with predictive performance between CCTA and DSE compared using the Delong statistical method. **Results:** Among the 61 patients who underwent ICA, preceded by CCTA and DSE, 16 had obstructive CAD confirmed by ICA. Rate of acceptable quality DSE, defined by studies with conclusive results, was 62.3% (38/61). DSE was positive for ischemia in 6.3% (1/16) of patients with obstructive CAD. 72.1% (44/61) of the obtained CCTA had definitive results. CCTA identified 56.3% (9/16) of patients with severe CAD on ICA. The SN, SP, PPV, and NPV for CCTA were 0.692 [CI 0.386, 0.909], 0.806 [95% CI 0.625, 0.925], 0.600 [95% CI 0.323, 0.837], and 0.862 [95% CI 0.683, 0.961] respectively. The SN, SP, PPV, and NPV for DSE were 0.083 [95% CI 0.002, 0.385], 0.885 [95% CI 0.698, 0.976], 0.250 [95% CI 0.006, 0.806], and 0.676 [95% CI 0.495, 0.826] respectively. 27 patients underwent FFR with CCTA. FFR was positive for a flow limiting lesion in 66.7% and negative in 33.3%. The SN, SP, PPV, and NPV for CT-FFR in diagnosing obstructive CAD were 0.636 [95% CI 0.308, 0.891], 0.267 [95% CI 0.078, 0.551], 0.389 [95% CI 0.173, 0.643], and 0.500 [95% CI 0.157, 0.843] respectively. ROC analysis demonstrated superior AUC for CCTA (AUC 0.749, $p = 0.056$) and CCTA with FFR (AUC 0.737, $p = 0.007$) compared to DSE alone (AUC 0.484) as demonstrated in Figure 1. **Conclusion:** CCTA demonstrated higher sensitivity and marginally superior predictive performance over DSE in identifying obstructive CAD in LT candidates. When combined with FFR, CCTA showed significantly improved diagnostic accuracy over DSE. These findings support the use of CCTA with FFR as a primary non-invasive modality for CAD risk stratification in transplant evaluation. Future studies are needed to validate these findings in a larger cohort.

Figure 1. ROC Analysis Comparing CCTA and CT-FFR with DSE

0014 | MELD 3.0 FAILED TO SUSTAINABLY ADDRESS SEX DISPARITIES IN US LIVER TRANSPLANT ALLOCATION

Tomohiro Tanaka[1] Dan Shane[2] Jennifer Lai[3], [1]University of Iowa School of Medicine, [2]University of Iowa College of Public Health, [3]University of California, San Francisco (UCSF)

Background: The July 2023 implementation of MELD 3.0 aimed to address longstanding sex disparities in liver transplant (LT) access. However, the causal effect of this policy change has not been formally evaluated. **Methods:** We analyzed U.S. national transplant registry data from 2/4/2020, to 9/30/2024, using a person-day structure to assess outcomes among adult ($\geq$18 years) LT candidates. Candidates with Status 1 listing or active MELD exception points were excluded. Primary outcomes included receipt of one of the top five liver organ offers and the probability of undergoing deceased donor liver transplantation. The primary exposure was the implementation of MELD 3.0. A difference-in-differences (DiD) design was used to evaluate (1) the immediate post-implementation period and (2) a secondary phase beginning three months later, capturing potential policy "burn-in" effects of the policy. DiD plot were drawn. Poisson and logistic regression models estimated offer and transplant probabilities. Mediation by height was assessed to examine residual sex disparities through a body size lens, and subgroup analyses were performed among candidates with height $<$166 cm. **Results:** We analyzed 9,952,473 person-day observations from 60,159 adult liver transplant candidates. In DiD estimates, the MELD 3.0 policy was associated with further increased organ offer rates for women at implementation (rate ratio [RR] $_{1.24}$ 1.35 $_{1.47}$) and three months later (RR $_{1.10}$ 1.15 $_{1.19}$) [Fig A]. Conversely, transplant rates for women were significantly lower than those for men before MELD 3.0 (odds ratio [OR] $_{0.84}$ 0.86 $_{0.886}$). The implimentation of MELD 3.0 conferred significantly

greater benefit to women than men (OR $_{1.13}$ 1.34 $_{1.59}$ immediately and $_{1.07}$ 1.17 $_{1.29}$ at three months), based on DiD estimates. However, by the end of the study period, the estimated effect of being female based on the fitted model was an OR of 0.81, suggesting a return to a level of disparity similar to the pre-MELD 3.0 era [Fig B]. Adjustment for height (OR $_{1.011}$ 1.012 $_{1.014}$ per 1 cm) eliminated the baseline female disadvantage in transplant rates ($_{0.99}$ 1.03 $_{1.07}$) while preserving the significant policy effect of MELD 3.0 ($p < 0.001$). Among taller candidates ($\geq$ 166 cm), the baseline sex disparity in transplant rates was attenuated (OR $_{0.892}$ 0.93 $_{0.970}$), whereas in the shorter group ($<$ 166 cm), rates were similar between sexes prior to the policy ($_{0.95}$ 1.01 $_{1.07}$). The policy benefit for women was similar in the taller group (OR $_{0.99}$ 1.13 $_{1.30}$), but more pronounced in the shorter group ($_{1.15}$ 1.47 $_{1.86}$); however, this sex-based advantage diminished over time, with the estimated OR converging to 0.98 by the end of the study period. **Conclusion:** MELD 3.0 temporarily improved transplant access for women, especially in the early post-implementation period. However, this effect diminished after the policy implementation, revealing persistent sex disparities linked to smaller body size even under MELD 3.0.

Background: While immune checkpoint inhibitors (ICIs) are increasingly used in patients with hepatocellular carcinoma (HCC), data on their use in the pre–liver transplantation (LT) setting remain limited. We aimed to identify predictors of post-LT outcomes for patients receiving LT after ICIs treatment. **Methods:** A

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

retrospective, multicenter cohort study was conducted across more than 70 centers worldwide, collecting HCC cases treated with ICIs in the context of downstaging or bridging before LT. Cox regression and Fine-Gray models were used to identify predictors of post-transplant outcomes, including recurrence-free survival (RFS), overall survival (OS), and rejection-free survival. **Results:** Among 375 patients from 12 countries, characteristics at ICI initiation were as follow: median (IQR) age: 56 (48, 62) years, 91% male, BCLC stage A in 23%, B in 36%, and C in 38%. 5.5% had metastasis and 20% had macrovascular invasion. Median tumor number and size were 3.0 (1.0, 5.0) and 4.9 cm (3.0, 7.6); 22% met Milan and 30% UCSF criteria at ICI initiation. ICI regimens included PD-1 (70%), PD-L1 (23%), PD-1/PD-L1 + CTLA-4 (3.6%), and others (2.8%). Median ICI cycles and washout were 4 (2, 10) and 72 days (37, 163), respectively. 91% received locoregional therapies. At OLT (based on pre-transplant Imaging), 38% and 43% were within Milan and UCSF criteria. Over a median follow-up of 1.6 years (95% CI 1.4-1.8), recurrence occurred in 28.0%, death in 22.2%, and rejection in 17.2% (44% mild, 54% moderate/severe; graft loss in 15% leading to retransplantation in 44% and death to 56%). One- and 4-year OS were 86% and 65%, and RFS were 73% and 55%, respectively. OS and RFS were longer among patients within Milan (vs. beyond Milan) at the time of OLT (all $p < 0.01$): 1- and 4-year OS 91% and 77%, and RFS 91% and 84% for those within Milan vs. 1- and 4-year OS 81% and 56%, and RFS 62% and 36% for those beyond Milan. AFP 100–500 vs < 20 at LT, HBV etiology, and beyond MC were associated with a higher risk of recurrence. Additionally, AFP 20–100 vs < 20 at both ICI initiation and LT, older age at LT, and female gender were associated with worse OS (Table). **Conclusion:** This represents the largest global study of pre-LT HCC patients treated with ICIs. Increased AFP and beyond MC at LT are strong predictors of HCC recurrence and shorter OS. The findings suggest that achieving Milan criteria and low AFP with ICI can lead to excellent long-term post-transplant outcomes.

Table. Cox Regression and Fine-Gray Models Evaluating Pre-Transplant Factors Associated with Allograft Rejection, HCC Recurrence, and Overall Survival in Patients Receiving Immune-Checkpoint Inhibitors Prior to Liver Transplantation

[3]Mayo Clinic Rochester, Department of Transplantation, [4]University of South Dakota Sanford School of Medicine, [5]Mayo Clinic Rochester Department of Bioethics

Background: Multi-listing (ML) has been shown to increase odds of transplantation compared to listing at a single center (SL). The February 2020 change of allocation process to acuity circles prioritized distance from the donor hospital in an attempt to decrease geographic disparities in access to transplant. This study aimed to assess the association between ML and transplantation across the acuity circle eras (ACE) and determine if the policy change impacted the frequency of ML as well as the percentage of ML patients transplanted at their primary center. **Methods:** UNOS data was queried for liver transplants (LT) between January 1, 2016 and November, 1 2024. ACE groups were based on the policy implemented on February 4, 2020. Multivariable logistic regressions were performed to assess ML's impact on transplant in each ACE. Primary transplant center was defined as the first center to be listed. Chi-square tests were performed to evaluate the difference in frequency of LT at primary centers. **Results:** There were 104,870 people listed for LT during the study period, 100,800 (96.1%) SL and 4,070 (3.9%) ML. The percentage of ML patients was higher in the pre-ACE compared to the post-ACE (4.5% vs 3.4%, $p < 0.001$). ML was associated with an increased likelihood of LT in the post-ACE (OR 1.113, 95% CI 1.009-1.228, $p = 0.033$) but not in the pre-ACE (OR 1.053, 95% CI 0.957-1.158, $p = 0.287$). Interestingly, there was no significant difference between those listed at 2 centers versus 3+ centers in either ACE (pre-ACE: OR 1.249, 95% CI 0.866-1.802; $p = 0.234$; post-ACE: OR 0.901, 95% CI 0.612-1.327, $p = 0.598$). There was a significantly higher percentage of patients transplanted at their primary center in the post-ACE (36.3% vs. 45.8%, $p < 0.001$). **Conclusion:** In the post-ACE, ML remains a significant factor in determining access to transplant. This is true despite the decreased proportion of ML patients and most ML patients being transplanted at their primary center. Our results show that the acuity circles policy change may have lessened geographic disparities (and potentially associated SES disparities as well), but this progress has not eliminated disparities in access to transplant overall. The question must be asked: has acuity circles gone far enough, or is there still an ethical imperative to make transplant access more equal, and should this include altering ML practices?

★ 0017 | DLGAP5 PROMOTES ACUTE LIVER INJURY VIA PYROPTOTIC HEPATOCYTE INFLAMMASOME-DRIVEN MACROPHAGE METABOLIC REPROGRAMMING AND M1 POLARIZATION

Xianzhi Liu[1] Zhiyuan Chen[1], [1]Xiamen University

Background: Acute liver injury (ALI) has attracted considerable attention due to its high mortality rate and complex pathogenic mechanisms, yet current therapeutic options remain limited, with a critical need for precision interventions targeting specific cell death signaling pathways. Pyroptosis is a novel programmed cell death process exists in inflammatory diseases and Methyltransferase like 3 (METTL3) is a core N6 methyladenosine (m6A) modified methyltransferase that has been shown to regulate cell fates. However, their roles in ALI are still with little information. **Methods:** METTL3 mutant and NLRP3 knockout mouse were constructed, CCl_4-induced ALI model was established and primary cells were isolated, and cell pyroptosis and m6A modification were evaluated. MeRIP-seq analysis, molecular docking and co-immunoprecipitation assay were used to explore and validate the mechanism of METTL3 promoting pyroptosis. Co culture was used to explore cell interactions. **Results:** METTL3-mediated m6A modification was significantly upregulated in hepatocytes during ALI. Inhibition of METTL3-mediated-m6A modification alleviated hepatocyte pyroptosis and ALI. Dlgap5 was determined as the target of METTL3-mediated m6A modification, which was regulated through the IGF2BP2-dependent manner. Dlgap5 can directly bind to METTL3 and NLRP3 and thereby mediating hepatocyte pyroptosis. METTL3 mutant or AT9283-meidated Dlgap5 inhibition alleviated pyroptosis and ALI. NLRP3 inflammasome releasing by the GASMD-N-dependent membrane pores from hepatocytes activated macrophages to further exacerbate ALI. NLRP3 deficiency alleviated ALI by suppressing hepatocyte pyroptosis and blocking communication between macrophages and hepatocytes. **Conclusion:** We found METTL3-induced m6A methylation plays an important role in the process of ALI by promoting hepatocyte pyroptosis and disrupting communication between hepatocytes and macrophages. Targeted -inhibition of Dlgap5 and -blocking of NLRP3 inflammation-mediated hepatocyte-macrophage interaction provide promising strategies for ALI.

0018 | DRUG-INDUCED LIVER INJURY IS MORE THAN DRUGS- THE ROLE OF METABOLIC AND VIRAL COMORBIDITIES- CASE OF TINOSPORA CORDIFOLIA (GILOY)

Sanal Madhusudana Girija[1] Sarita Gupta[1] Gulshan Kumar[2, 1]Institute of Liver and Biliary Sciences, [2]Anuvanshiki (OPC)

Background: Drug-induced liver injury (DILI) is increasingly recognized as a multifactorial syndrome. DILI frequently presents as acute-on-chronic liver failure, suggesting that underlying hepatic vulnerabilities could be key contributors to its initiation and severity. DILI from especially from herbals such as giloy, is being increasingly identified. We hypothesised that viral reactivation, particularly of latent human viruses, is a factor triggering DILI. Many viruses sense free radicals to sense host weaknesses. Phytochemicals can cause oxidative stress, which could be sensed by latent viruses, leading to their activation. Once the virus is activated, it can launch an acute immune reaction on its own. This could be relevant in the context of herbal medications like Tinospora cordifolia (Giloy), which gained popularity during the COVID-19 pandemic. The mechanisms of DILI involve both direct hepatotoxic effects (via reactive drug metabolites) and indirect immune-mediated injuries. Understanding the interplay between herbal compounds, pre-existing liver disease, and latent viral infections is critical for effective risk assessment and clinical management. **Methods:** We studied cases diagnosed as DILI and associated with Giloy in a liver specialty hospital. We performed RNASeq analysis of patient and healthy tissue samples available from the institutional biobank. We also investigated the viral signatures in patient tissue. In vitro, two liver cell lines (Huh7 and HepG2) were exposed to two Giloy preparations: P: A widely used commercial formulation not prepared according to Ayurvedic principles. K: A preparation compliant with classical Ayurvedic texts. We assessed the genotoxicity of giloy via the comet assay (cisplatin was used as a positive control) and measured Rad51 expression, a marker of oxidative DNA repair. To evaluate P450 induction, we used real-time PCR to analyse the expression of key cytochrome P450 enzymes (57 in total). **Results:** 124 DILI cases were associated with Giloy in some form. Mean age was 51 +/-14 years, 92 were men. 8 of them had liver samples stored in the institutional biobank. 87% of them had pre-existing liver disease. We found the signatures of SARS-CoV-19. Interestingly, we also found viral signatures of HCV, AAV3 (a liver-specific serotype), Thottapalayam virus (TMPV), HHV5, HHV2, and HPV, which could be pre-existing. Giloy preparations didn't cause genotoxicity. We also observed that giloy extracts could ameliorate DNA damage (although more investigations are needed to confirm these findings). However, giloy preparations had a suppressive effect on the majority of the cytochrome types. However, there were significant variations between the preparations. CYP1B was induced by the commercial preparation (P) while the authentic preparation suppressed it ($p < 0.001$). CYP2F1, CYP17A1, CYP2U1, and CYP2W1 were suppressed by both preparations. **Conclusion:** Giloy causes DILI, and pre-existing liver disease is an important determinant of DILI. It is possible that one of the giloy phytochemical metabolites caused an oxidant stress, which caused the reactivation of pre-existing virus (sleeping/latent virus), which initiated an acute immune response at least in some cases.

0019 | THERAPEUTIC PLASMA EXCHANGE IN PATIENTS WITH ACUTE LIVER FAILURE: A RANDOMIZED CONTROLLED TRIAL

Shekhar Swaroop[1] Sagnik Biswas[1] Arnav Aggarwal[1] Samagra Agarwal[1] Baibaswata Nayak[1] Poonam Coshic[1] . Shalimar[1], [1]All India Institute of Medical Sciences, New Delhi

Background: Acute liver failure (ALF) is a life-threatening condition with high short-term mortality without liver transplantation (LT). While therapeutic plasma exchange (TPE) has shown early promise, a recent large sample size study reported inconsistent survival benefits. In this randomized controlled trial, we evaluated the safety and efficacy of standard-volume TPE on the 30-day outcomes in ALF. **Methods:** In this single-center, open-label, randomized controlled trial, 40 adults with ALF were randomized 1:1 standard medical therapy (SMT) alone or SMT plus TPE. TPE was performed daily for up to five days or stopped as per the predefined criteria (improvement in hepatic encephalopathy or the development of shock or sepsis). A standard-volume (1-1.5 X plasma volume) centrifugation-based TPE was used with a 1:1 fresh frozen plasma and albumin replacement. The primary outcome was 30-day mortality; secondary outcomes included changes in biochemical parameters and adverse events. **Results:** Median age was 24 years (IQR 20-28); 23/40 (57.5%) were females and 57.5% viral hepatitis. Of 20 patients allocated to TPE, 14 received ≥ 1 session; 6 could not due to early hepatic encephalopathy improvement ($n = 3$) or refractory shock ($n = 3$). Among those treated with TPE- 1, 2, 3, 4 and 5 sessions were received by 5 (25%), 1 (5%), 2 (10%), 1 (5%) and 5 (25%) patients. TPE was discontinued primarily due to hemodynamic instability. The 30-day mortality was identical in both arms (65%; intention-to-treat, $p = 1.000$), with no difference on per-protocol analysis (TPE: 78.6% vs SMT: 65.0%, $p = 0.393$), Figure. TPE led to greater day 3 reductions in bilirubin (-2.8 vs +1.4 mg/dl, $p = 0.004$) and INR (-2.2 vs 0, $p = 0.013$), but ammonia reduction was not significant (-72 vs -5 μmol/L, $p = 0.340$), and no survival benefit was observed. Rates of infection and electrolyte disturbances were similar. TPE was not independently associated with survival (HR 0.92, 95% CI 0.43–1.99, $p = 0.83$). **Conclusion:** Standard-volume TPE, as used in this study, did not improve short-term survival in predominantly viral ALF and was frequently interrupted for clinical deterioration. Larger multicenter trials are needed to evaluate early initiation, optimized protocols, and integration with continuous renal replacement therapy.

0020 | USING ARTIFICIAL INTELLIGENCE/ MACHINE LEARNING FOR EARLY PREDICTION OF RESPONSE TO PLASMA EXCHANGE IN PEDIATRIC ACUTE LIVER FAILURE

Tamoghna Biswas[1] Varun Ramamohan[2] Tamal Majumder[3] Vikrant Sood[4] Rajeev Khanna[5] Seema Alam[1] Bikrant Biharilal Raghuvanshi[4], [1]Institute of Liver and Biliary Sciences, [2]Indian Institute of Technology Delhi, India, [3]Indian Institute of Technology, Delhi, India, [4]Institute of Liver and Biliary Sciences, New Delhi, India, [5]Institute of Liver and Biliary SCiences, New Delhi

Background: Therapeutic plasma exchange (TPE) improves survival in acute liver failure (ALF) but artificially lowers key prognostic markers like INR and bilirubin. Repeated TPE sessions cause significant fluctuations in these parameters, complicating decisions about proceeding with liver transplantation (LT) when a donor is available. Early prediction of response to TPE is thus critical to decide the need and timing of LT. This study aimed to develop and validate a machine learning (ML) model for early prediction of TPE response in ALF and to create a user-friendly, web-based tool to support clinical decision-making. **Methods:** All children (2-18 years) with ALF who received at least 1 session of TPE were included. TPE was offered to children with ALF who had a corrected INR $\geq$ 2.5 with an increasing INR and/or worsening grade of hepatic encephalopathy (HE) 6-12 hours thereafter. The number of sessions was guided by patients' clinical condition and 1.5 to 2 times the plasma volume was exchanged at each session. For response prediction, clinical and biochemical parameters at time points (T0 to T6) were collected (T0: Baseline; T1: 0-6 hours after 1st TPE; T2: 12-18 hours after 1st TPE; T3: 0-6 hours after 2nd TPE; T4: 12-18 hours after 4th TPE; T5: 0-6 hours after 3rd TPE; T6: 12-18 hours after 3rd TPE). Recursive feature elimination with cross-validation was used. The following classifiers were used for the ML-based prediction model:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Random Forest Classifier, Logistic Regression, Gradient Boosting Classifier, XG Boost, and Support Vector Machine (SVM). Finally, the study's significant variables were incorporated into a web-based application. **Results:** Data of 448 patients with pediatric ALF managed at the centre till January 2025 were scanned, and 87 patients who received TPE as a therapeutic modality were included. Fourteen, 28, 35, and 10 patients received one, two, three, and more than 3 sessions of TPE, respectively. Thirty-one patients (35.6%) survived with their native liver, 13 (14.9%) received LT, and 43 (49.4%) died. On ML-based analysis, the following variables were selected after feature selection: INR at T0 and T2, ammonia at T2, jaundice-to-HE interval for time-point T2 analysis;age, use of concomitant continuous renal replacement therapy, jaundice-to-HE interval, INR at T0, T2, T4, and ammonia at T2 and T4 for time-point T4 analysis. Based on these variables, the model correctly predicted the outcomes with accuracy ranging from 0.73 (logistic regression) to 0.816 (SVM) at T2 and accuracy ranging from 0.698 (logistic regression) to 0.759 (XGBoost) at time-point T4. The models were then incorporated into an online web-based tool to be hosted after communication. **Conclusion:** ML models based on SVM, XGBoost, and Logistic Regression can reliably predict the response to TPE as early as after the first and second sessions of TPE in pediatric ALF. They can serve as an easy bedside tool to predict response to TPE and decide the need and timing of LT in pediatric ALF.

Table: Area under receiver operating characteristic curve for different machine learning algorithms, their sensitivity and positive predictive value for predicting outcomes in children with acute liver failure undergoing therapeutic plasma exchange (TPE) at different time-points (T2: 12-18 hours after first session of TPE; T4: 12-18 hours after second session of TPE)

★ 0022 | A PHASE I CLINICAL TRIAL OF THE HEPACURE BIOARTIFICIAL LIVER SYSTEM FOR ACUTE-ON-CHRONIC LIVER FAILURE

Jingyi Hu[1] Huaibin Zou[2] Hongbo Shi[2] Li Zhou[3] Pengfei Yu[2] Shaoli You[4] Hongling Liu[4] Guoyu Pan[5] Lijian Hui[6] Yu Chen[2], [1]Institute of Molecular Medicine, College of Future Technology, Peking University, Beijing, [2]Fourth Department of Liver Disease, Beijing You An Hospital, Capital Medical University, Beijing, [3]Beijing YouAn Hospital of Capital Medical University, [4]The Fifth Medical Center of Chinese People's Liberation Army General hospital, [5]Shanghai Hexaell biotech Co., Ltd. Shanghai, 201203, China, [6]School of Life Science and Technology, ShanghaiTech University

Background: Acute-on-chronic liver failure (ACLF) is one of the leading causes of mortality among patients with chronic liver disease. The HepaCure bioartificial liver system based on human induced functional hepatocytes (hiHep) was developed to provide transient liver support to restore liver function. This Phase I trial evaluated its safety and preliminary efficacy. **Methods:** This multi-center, open-label Phase I trial aimed to assess the safety of HepaCure as the primary endpoint, with secondary endpoints including treatment success rate, device performance, and changes in hepatic function. Totally 12 ACLF patients were allocated to a single arm (6h or 9h) or multiple arm (2–3 treatments) and received standard medical therapy combined with HepaCure treatment. **Results:** The study included 12 patients with ACLF: 7 with hepatitis B virus (HBV) infection, 1 with drug-induced hepatitis, 2 with alcoholic hepatitis, and 2 with fatty liver disease. Patients were equally distributed between the single-dose ($n = 6$) and multiple-dose ($n = 6$) groups. In the multiple-dose cohort, 4 patients received 2 treatments, while 2 received 3 treatments. The HepaCure was well tolerated by all patients. A total of 147 adverse events were reported by day 14, including 136 that were mild (CTCAE Grade < 3). Of these,145 were treatment-emergent adverse events with similar incidence between the 6-hour and 9-hour treatment groups; most were determined to be unrelated to the device. Three serious adverse events occurred, all assessed as unrelated to the treatment. By day 14, statistically significant improvements ($p < 0.05$) were observed in liver function parameters: AST decreased from 163.25 ± 86.76 to 97.77 ± 71.45 U/L, ALT from 99.58 ± 70.08 to 59.15 ± 49.82 U/L, total bilirubin from 323.92 ± 156.59 to 235.85 ± 118.24 μmol/L, while

albumin increased from 29.92 ± 3.36 to 35.64 ± 4.44 g/L and PTA improved from 33.13 ± 6.47% to 39.86 ± 18.30%. Mortality was observed in one case (infection-related death at Day 36 after the first treatment), with all other patients surviving. **Conclusion:** The HepaCure system exhibited a favorable safety profile and was well tolerated, with significant improvements in hepatic function. These results suggest it is a promising treatment for ACLF, warranting further validation in large-scale Phase 2 clinical trials.

0023 | HEPATIC DYSFUNCTION AND HEPATIC FAILURE CUTOFFS IN CIRRHOSIS PATIENTS WITH ACLF

Chanyanuch Nakapakorn[1] Lauren Hall[1] Gerald Ogola[1] Jasmohan Bajaj[2] Jacqueline O'Leary[3] Patrick Kamath[4] Sumeet Asrani[5], [1]Baylor University Medical Center, [2]Virginia Commonwealth University, [3]UT Southwestern Medical Center, [4]Mayo Clinic, Rochester, [5]Liver Consultants of Texas

Background: Presence of hepatic dysfunction is central to defining acute-on-chronic liver failure (ACLF), though thresholds that define hepatic dysfunction and failure are not established. Though leading liver societies support importance of hepatic dysfunction in ACLF pathophysiology, they provide various suggested cutoffs and definitions. Recently, a global consensus (Bajaj Gastro 2025) defined hepatic dysfunction and failure based on bilirubin and INR with dysfunction (Total serum bilirubin ≥ 3 mg/dL but < 7.5 mg/dL and INR ≥ 1.3 and < 1.5) and failure (Total serum bilirubin ≥ 7.5 mg/dL and INR ≥ 1.5). However, mortality may be different given underlying kidney dysfunction as well as admission to the ICU. We sought to validate cutoffs in critically ill patients with cirrhosis and examine associated mortality in the hospital and ICU setting. **Methods:** We examined all patients with cirrhosis presenting to a large integrated healthcare system (26 hospitals, 2019-2022) with decompensation. We collected data on all hospitalized patients as well as critically ill patients with cirrhosis and followed inpatient course until inpatient mortality or death at 30 days. We created splines to assess the correlation of bilirubin, INR and creatinine after adjusting for the other two variables. We created a heatmap to assess the relations between the cutoffs. **Results:** There were 9,399 patients with cirrhosis and of these 3,913 were admitted to the ICU. Mean age was 61.2 (12.9) years, 40% females, 17.7% non-White and 21.3% Hispanic. Mortality within 30 days were 14.5% (all hospitalized) and 24.4% (ICU cohort). ICU cohort: Mortality progressively increased linearly for a given lab value, but plateaued around 2.5 (INR), 3mg/dL (creatinine) and around 7.5mg/dL (bilirubin). (Figure 1). Heatmaps assessed relationship between the three variables for relevant cutoffs with mortality range between 15-45%. (Figure 2). For an INR of 1.5, baseline mortality in the ICU was 15%, increased to 22% in presence of 7.5mg/dL and further to 33% in presence of kidney dysfunction (creatinine 2.5mg/dL). For an INR of 2.5, mortality risk increased by 10% to 23%, 33% and 45% respectively. **Conclusion:** Mortality in ACLF remains high. In critically ill patients with cirrhosis with ACLF with hepatic failure (INR 1.5 and Bilirubin 7.5), mortality within 30 days is 22%. Mortality risk is dynamic and contingent on the interaction of various factors. This data provides baseline mortality risk estimates that may be useful for further studies in ACLF using short term mortality as a relevant outcome.

0024 | FRAILTY IS ASSOCIATED WITH THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH END-STAGE LIVER DISEASE

Avesh Thuluvath[1] Fawzy Barry[2] Brendan Blackburn[3] Reeti Gulati[4] Angel Wilson[5] Grace Johnson[6] Avery Longdon[6] Caroline Yu[6] Anjana Rajan[7] Yuan Zhang[8] Robert Rahimi[5] Andres Duarte-Rojo[6] Matthew Kappus[4] Jennifer Lai[2] Elizabeth Verna[1], [1]Division of Digestive and Liver Disease, Columbia University Irving Medical Center, New York, NY, [2]Division of Gastroenterology and Hepatology, University of California, San Francisco, CA, [3]Division of Digestive and Liver Disease, Columbia University Irving Medical Center, New York, NY., [4]Division of Gastroenterology and Hepatology, Duke University Hospital, Durham, NC, [5]Annette C. and Harold C. Simmons Transplant Institute, Baylor University Medical Center, Dallas, TX, [6]Division of Gastroenterology and Hepatology, Northwestern University FSOM, Chicago, IL, [7]Division of Gastroenterology and Hepatology, Northwestern University FSOM, Chicago, IL., [8]Mailman School of Public Health, Columbia University, New York, NY.

Background: Acute-on-chronic liver failure (ACLF) is associated with significant short-term mortality in patients with end-stage liver disease (ESLD). The relationship between ACLF and frailty is unclear. The purpose of this study was to investigate the association between frailty measured in an ambulatory setting and the risk of ACLF. **Methods:** We performed a retrospective chart review of adult patients enrolled in the prospective FrAILT study, who were waitlisted for liver transplantation (LT) in an ambulatory setting at five LT centers between 1/1/2019-12/31/2022. Frailty was measured with the Liver Frailty Index (LFI: grip, chair stands, balance testing). ACLF was defined using the European Association for the Study of the Liver Chronic Liver Failure Consortium (EASL-CLIF) criteria. The primary outcome was the development of ≥ grade 1 ACLF within 1 year of LFI assessment. A time-to-event analysis was performed to evaluate the association between LFI and ACLF, with death or LT as competing risks. **Results:** 460 patients were included; 62% were male and the mean age was 56.3 (± 6.9) years. Alcohol-associated liver disease (32%) and metabolic-dysfunction associated steatotic liver disease (26%) were the most common etiologies of ESLD. Mean MELD was 16.3 (± 6.4). Mean LFI was 3.90 (± 0.74), with 19% classified as frail, 64% pre-frail and 17% robust (using previously established LFI cut-offs). 87 (19%) patients developed ACLF during the 1-year follow-up period, 271 underwent LT and 13 died. On multivariable analysis adjusted for age, sex and MELD, LFI was associated with the development of ACLF (HR 1.40, 95% CI 1.06-1.86, p = 0.02, per 1.0 LFI). When categorized by frailty status, robust patients were less likely to develop ACLF compared to frail patients on univariable analysis (HR 0.45, 95% CI 0.22-0.95, p = 0.04) (Figure). However, on multivariable analysis, robust status was no longer inversely associated with the development of ACLF (HR 0.44, 95% CI 0.18-1.03, p = 0.06). **Conclusion:** In this multi-center study, frailty measured by LFI was associated with the development of ACLF by EASL-CLIF criteria. Our findings suggest that frailty's known effect on mortality in ESLD could be in part due to an increased risk of ACLF in deconditioned patients.

[2]Department of Medicine, Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [3]Department of Medicine, Tufts Medical Center, Boston, Massachusetts, [4]Division of Gastroenterology and Hepatology, Mayo Clinic Jacksonville, Florida, [5]Department of Gastroenterology, Riverside Regional Medical Center, Newport News, VA, USA

Background: Current evidence on the safety of transjugular intrahepatic portosystemic shunt (TIPS) in elderly patients is limited to retrospective observational studies, as randomized clinical trials have excluded patients with advanced age. Given the uncertainty surrounding the outcomes of TIPS in elderly patients, this study evaluates the comparative risks and outcomes following TIPS placement in elderly vs. non-elderly patients with cirrhosis. **Methods:** A retrospective cohort study was conducted using large, population-based data from TriNetX. Patients with any form of cirrhosis who underwent TIPS were identified and stratified by age into two groups: those ≥ 65 years and those < 65 years. The cohorts were matched 1:1 using propensity score matching based on gender, demographics, comorbidities, and medications. Outcomes assessed included all-cause mortality, hepatic decompensation, major adverse liver outcomes (MALO), and portal vein thrombosis (PVT). These outcomes were analyzed at 30 and 90 days following the index event. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated to evaluate associations between variables. **Results:** A total of 10,258 adult patients with cirrhosis who underwent TIPS were included, of whom 4,977 were aged greater than 65 years. After matching, 3,685 elderly patients (mean age 65.0 years, 35.5% female) were compared with 3,685 non-elderly patients (mean age 49.7 years, 34.4% female). Elderly patients had significantly higher risk of 30-day all cause mortality (HR:1.24, 95%CI: 1.07-1.45), hepatic decompensation (HR:1.11, 95%CI: 1.04-1.18), MALO (HR:1.11, 95%CI: 1.04-1.18), ascites (HR:1.14, 95%CI: 1.06-1.23), hepatic encephalopathy (HR:1.19, 95%CI: 1.10-1.29). No differences were observed in variceal bleeding, SBP, and PVT. Similar Results: were observed at 90 days. **Conclusion: Discussion:** TIPS represents an innovative and life-extending procedure for patients with decompensated cirrhosis and clinically significant portal hypertension. However, this study underscores heightened risks in elderly patients compared to younger cohorts. Rather than discouraging TIPS use, this study's findings highlight the importance of increasing awareness of frequent outpatient follow-up in this vulnerable population.

0026 | TEMPORAL TRENDS IN OUTCOMES AND BURDEN OF ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) AMONG PATIENTS WITH CIRRHOSIS IN THE UNITED STATES: A NATIONWIDE ANALYSIS

Aalam Sohal[1] Carol Singh[2] Rahul Chikatimalla[3] Joanne Lin[4] Ruchir Paladiya[5] Bipneet Singh[6] Sunny Sandhu[3] Marina Roytman[7], [1]Liver Institute Northwest, [2]Dayanand Medical College and Hospital, [3]University of Miami Miller School of Medicine, [4]University of California San Francisco, [5]University of Connecticut, [6]Henry Ford Allegiance, Jackson, Michigan, [7]University of California San Francisco Fresno

Background: Acute-on-chronic liver failure (ACLF) is a distinct clinical syndrome in individuals with chronic liver disease, marked by acute systemic inflammation, multi-organ dysfunction, and a high short-term mortality. National trends in its epidemiology and clinical outcomes remain inadequately defined. This study examines the U.S. national trends in ACLF hospitalizations, focusing on etiology, inpatient

mortality, and resource utilization. **Methods:** The National Inpatient Sample (NIS) Database was used to identify adult hospitalizations with ACLF from 2016 to 2022. ACLF was defined as the presence of two organ dysfunctions (renal failure, cardiogenic shock, hepatic coma, and pulmonary dysfunction) using the NACSELD criteria. Data were collected on patient demographics, liver disease etiology, decompensations, comorbidity burden, interventions, and clinical outcomes. Outcomes assessed were in-hospital mortality, non-home discharges, and ACLF. **Results:** Out of 5.1 million hospitalizations with cirrhosis, 560,765 (11.1%) patients met the criteria for ACLF. The proportion of ACLF cases among patients with cirrhosis increased from 9.8% to 12.3% between 2016-2022 ($p < 0.001$) (Table 1)(Figure 1). The most common organ failure was renal failure (87.4%), followed by cerebellar dysfunction (56.5%) and respiratory dysfunction (48.9%). An increase in the rates of ACLF attributed to MASLD was noted between 2016 (29.5%) and 2022 (38.4%) ($p < 0.001$). The proportion of patients with alcohol-associated liver disease as an etiology decreased from 51.2% (2016) to 48% (2022) ($p < 0.001$). The rate of hepatitis C and hepatitis B declined from 22.6% (2016) to 10.5% (2022), and from 2.3% (2016) to 1.8% (2022), respectively ($p < 0.001$). Decline in rates of hepatocellular carcinoma-associated ACLF was also noted (5.3% in 2016 to 4.5% in 2022) ($p < 0.001$). The mortality among patients with ACLF remained stable between 2016 and 2022 (33.8% and 34.6%, respectively). The total hospitalization charges increased from $155,300.8 in 2016 to $195,678 in 2022 ($p < 0.001$) and the length of stay remained stable (11.14 and 11.6 days, respectively). **Conclusion:** Our findings suggest that rates of ACLF hospitalizations among patients with cirrhosis have increased. Although ALD remains the most frequent etiology rates of MASLD continue to increase progressively. Despite growing recognition and management of MASLD and cirrhosis, the rates of ACLF, as well as total hospitalization charges, have been increasing. Further interventions are needed to improve the outcomes.

0027 | IMPACT OF PRE-PROCEDURAL COAGULOPATHY REVERSAL ON CLINICAL OUTCOMES FOLLOWING PARACENTESIS OR EGD IN PATIENTS WITH CIRRHOSIS AND INR > 3: A PROPENSITY SCORE-MATCHED STUDY

Fatima Elmustafa[1] Ali Osman[2] Mohammad Adam[3] Abdelhaleem Sideeg[4] Ashwani Singal[5], [1]Henry Ford Health System, [2]Washington University School of Medicine, [3]University of Missouri - Kansas City School of Medicine, [4]Virginia Mason Medical Center, [5]University of Louisville

Background: Correction of coagulopathy prior to low-risk procedures such as paracentesis and upper endoscopy remains common practice, largely driven by persistent concerns about bleeding risk—despite potential harms associated with transfusions, including volume overload, exacerbation of portal hypertension, and transfusion-related complications. Using real-world data, we aimed to investigate the clinical impact of pre-procedural coagulopathy reversal with fresh frozen plasma (FFP) or cryoprecipitate in patients with cirrhosis and INR > 3 undergoing paracentesis or esophagogastroduodenoscopy (EGD). **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network to compare outcomes in adult patients with cirrhosis and INR > 3 undergoing paracentesis or EGD, with or without pre-procedural FFP or cryoprecipitate. Propensity score matching was performed based on age, race, gender, diabetes mellitus, acute kidney injury, chronic kidney disease, esophageal varices, severe sepsis, and anticoagulant use. Primary outcomes included 30-day and 90-day mortality. Secondary outcomes were acute kidney injury (AKI), respiratory failure, need for dialysis, blood transfusion, transfusion-related acute lung injury (TRALI), and transfusion-associated circulatory overload (TACO), all assessed within the first 30 days. **Results:** The initial cohorts included 194,227 patients who did not receive coagulopathy reversal and 1,864 who did; 1,843 patients were successfully matched from each group for

comparison. Among patients undergoing paracentesis, pre-procedural coagulopathy reversal was associated with significantly higher 30-day and 90-day mortality, as well as increased risk of respiratory failure and need for blood transfusion. There was no significant difference in the risk of AKI, TACO or TRALI (Fiqure 1). Similarly, among patients undergoing EGD, coagulopathy reversal was associated with worse outcomes, including elevated mortality at 30 and 90 days, higher risk of AKI, respiratory failure and need for blood transfusion, with no significant differences in TACO or TRALI (Fiqure 2). **Conclusion:** In patients with cirrhosis and INR > 3 undergoing paracentesis or EGD, pre-procedural reversal of coagulopathy with FFP or cryoprecipitate is associated with significantly worse clinical outcomes. These findings support existing recommendations against routine coagulation correction in this population and highlight the need for judicious use of blood products.

0028 | A LONGITUDINAL ANALYSIS OF CLINICAL TRAJECTORIES AND PROGNOSTIC OUTCOMES IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE (ACLF)

Wenling Wang[1] Manman Xu[1] Huaibin Zou[1] Shaoli You[2] Tao Han[3] Yu Chen[1], [1]Beijing Youan Hospital, Capital Medical University, [2]The Fifth Medical Center of Chinese PLA General Hospital, Beijing, [3]Tianjin Union Medical Center affiliated to Nankai University

Background: Acute-on-chronic liver failure (ACLF) is a clinical syndrome marked by a highly dynamic course and significant prognostic heterogeneity, necessitating ongoing assessment. This study aims to perform longitudinal monitoring of clinical indicators at multiple time points, characterize disease trajectories across distinct clinical outcomes, and identify critical intervention windows. These findings will inform new strategies for precise dynamic management of ACLF. **Methods:** Using COSSH-ACLF criteria, we prospectively recruited a nationwide multicenter cohort of ACLF patients (derivation: n = 485; validation: n = 151). Serial measurements of dynamic parameters were obtained at baseline (day 0) and key time points (days 3,7,14,21,28). Longitudinal trajectories of clinical indicators across three outcomes—death/liver transplantation, recovery, and persistent ACLF—were analyzed using mixed-effects models and generalized additive models (GAM). Differentially evolving parameters were identified for prognostic score development. **Results:** In the derivation cohort at 90 days, outcomes included death/liver transplantation (41.6%), persistent ACLF (12.6%), and recovery (45.8%). Trajectory analysis identified days 3-7 as a critical window. The death/LT group maintained sustained abnormalities (TBil > 450 μmol/L, INR > 2.5, PLT < 60×10⁹/L), while recovered patients achieved near-normalization by day 28 (TBil < 200 μmol/L, INR < 1.5, PLT > 100×10⁹/L). Persistent ACLF patients showed intermediate improvement at day 28 (TBil 200-350 μmol/L, INR 2.0-2.5, PLT 60-80×10/L. Significant heterogeneity in temporal trends was observed across all three groups (P < 0.01). Based on these parameters, we developed the simplified TIP scoring system incorporating three variables: TBil(μmol/L) scoring as ≥ 450 (3 points), 350-449 (2), 200-349 (1), or < 200 (0); INR scoring as ≥ 2.5 (3), 2.0-2.49 (2), 1.5-1.99 (1), or < 1.5 (0); and PLT(×10/L) scoring as < 60 (3), 60-79 (2), 80-99 (1), or ≥ 100 (0).Total scores (0-9) stratified patients into low- (0-2), intermediate- (3-5), and high-risk (6-9) groups. For mortality prediction, TIP achieved 28/90-day AUROCs of 0.75/0.74, performing comparably to MELD-Na (0.73/0.68), MELD (0.73/0.69), COSSH-ACLF II (0.76/0.75) and CLIF-C ACLF (0.70/0.70) (all P > 0.05) with greater simplicity. For recovery prediction, AUROCs were 0.71/0.73 - comparable to COSSH-ACLF II (P > 0.05) and superior to others (P < 0.05). External validation confirmed robustness through calibration, decision curve analysis, and risk stratification. Conclusion: This study identifies TB, INR, and PLT as critical prognostic determinants in ACLF. The 3–7 day window represents a critical intervention period. Our novel TIP scoring system—incorporating these three biomarkers—enables real-time prognostication and personalized clinical decision-making.

0029 | PRELIMINARY RESULTS: FROM THE SIMPLIFYING HEPATITIS B CARE IN PREGNANCY BY COMBINING BIRTH-DOSE VACCINE AND TENOFOVIR: THE COMBAT HBV FEASIBILITY TRIAL

Nefer Batsuli[1] Patrick Ngimbi[2] Linda James[3] Jusline Pani[2] Myriam Bonze[2] Elysée Bayayana[2] Gaetan Bondo[2] Bienvenu Tukebana[2] Jeansy Mavinga[2] Martine Tabala[4] Charles MBENDI[5] Nana Mbonze[6] Gavin Cloherty[7] Mark Anderson[8] Melchior Kashamuka[4] Camille Morgan[9] Alix Boisson-Walsh[10] Marcel Yotebieng[11] Sylvia Becker-Dreps[12] Ernest Sumaili KISWAYA[2] Feng-Chang Lin[13] Jonathan Parr[14] Samuel Mampunza[2] Peyton Thompson[15], [1]University of North Carolina at Chapel Hill, [2]Protestant University in Congo, Kinshasa, Democratic Republic of Congo, [3]Institute for Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, USA, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of Congo, [5]University of Kinshasa, Kinshasa, Democratic Republic of Congo, [6]International Training and Education for Health (I-TECH), University of Washington, Seattle, Wa, [7]Abbott, [8]Abbott Laboratories, Abbott Park, Illinois, USA, [9]School of Medicine, University of North Carolina, Chapel Hill, USA, [10]Center for Emerging Pathogens, Infectious Diseases, Rutgers, New Jersey, USA, [11]Division of Epidemiology, Albert Einstein College of Medicine, New York, USA, [12]Department of Family Medicine, University of North Carolina, Chapel Hill, USA, [13]Department of Biostatistics, Gillings School of Global Public Health, University of North Carolina, [14]Department of Medicine, Division of Infectious Diseases, University of North Carolina, Chapel Hill, [15]Department of Pediatrics, Division of Infectious Diseases, University of North Carolina, Chapel Hill

Background: Hepatitis B virus (HBV) is endemic across sub-Saharan Africa, where vertical transmission persists in resource-constrained settings such as the Democratic Republic of Congo (DRC). HBV viral load and other testing remains inaccessible in DRC, limiting implementation of evidence-based prevention. This placebo-controlled RCT aims to determine the effectiveness, safety, acceptability, and feasibility of a prophylaxis-for-all approach to prevention of vertical transmission of HBV in DRC and is among the first to evaluate this approach compared to placebo or birth-dose vaccine alone. **Methods:** Alongside existing HIV antenatal care, we introduced rapid HBV surface antigen (HBsAg) testing to screen pregnant women presenting for their first antenatal visit at three maternity centers in Kinshasa, DRC between August 2023 and January 2025. HBsAg+ women ≥ 18 years with normal creatinine (< 1.3 mg/dL) were eligible for enrollment at 28-32 weeks' gestation. Participants were randomized to receive tenofovir disoproxil fumarate or placebo upon enrollment through 4 weeks' postpartum. Infants received a birth-dose vaccine, ideally within 24 hours. Participants scored acceptability of lab draws and medication at exit visits. Safety was measured through monitoring of side effects and adverse events, and maternal alanine aminotransferase levels [ALT] through 6 months' postpartum. To determine effectiveness, infants underwent HBsAg testing at 6 months. **Results:** Of 14,027 women screened, 307(2.19%) were HBsAg-positive, and 164 eligible mothers have been enrolled and randomized to date. Most (89%) of participants deemed study activities acceptable. A third of mothers (n = 54, 32.9%) have completed follow-up through 6 months, 74 (45.4%) are being followed, 17 (10.4%) were lost to follow-up, 15 (9.2%) voluntarily withdrew, 2 (1.2%) seroconverted, and 1 (.6%) died. One quarter of participants reported mild-to-moderate side effects, 1 severe (eclampsia), and 1 death (respiratory failure). No ALT elevations (≥ 5x upper limit of normal) were observed. Of 143 infants born to date, 6 were stillborn and 4 died shortly after birth. Of live infants, 120 (83.9%) received birth-dose vaccine, 67 (55.8%) of

which were within 24 hours. No infants have tested HBsAg-positive at 6 months. **Conclusion:** Prior to unblinding, this study preliminarily demonstrates the effectiveness, safety, acceptability, and feasibility of a prophylaxis-for-all approach to prevent vertical transmission of HBV in Kinshasa, DRC. This simplified approach strengthens overall HBV prevention, and its national adoption would be an important step toward eliminating HBV in DRC and throughout sub-Saharan Africa.

Table 1. Characteristics of mothers enrolled in the COMBAT study (blinded)

	Total (N=164)
Age, years	
Mean (SD)	30.5 (6.10)
Study facility	
Barumbu	31 (18.9%)
Binza	61 (37.2%)
Kingasani	72 (43.9%)
Gestational age at enrollment, weeks	
Mean (SD)	29.3 (1.40)
Gravidity	
Mean (SD)	3.13 (1.86)
Marital status	
Married or cohabiting	154 (93.9%)
Divorced, separated, widowed	2 (1.2%)
Never married	8 (4.9%)
Highest schooling	
Primary	7 (4.3%)
Secondary	118 (72.0%)
Higher Education	39 (23.8%)
ALT at baseline (IU/L)	
Median [Min, Max]	13.0 [5.00, 59.0]
ALT 6 weeks post-delivery (IU/L)	
Median [Min, Max]	18.0 [8.00, 99.0]
ALT 6 months post-delivery (IU/L)	
Median [Min, Max]	18.0 [9.00, 83.0]

Characteristics of infants enrolled in the COMBAT study

	Total* (N=131)
Mode of delivery	
Vaginal	112 (85.5%)
C-Section	19 (14.5%)
Gestational age at birth - in weeks	
Median [Min, Max]	39.0 [30.0, 42.0]
Birth term category**	
Full term (>=37 weeks)	86 (65.6%)
Moderate to late preterm (32-36 weeks)	44 (33.6%)
Very preterm (28-31 weeks)	1 (0.8%)
Weight - in grams	
Mean (SD)	3230 (587)
Length - in cm	
Mean (SD)	49.4 (3.05)
Head circumference - in cm	
Median [Min, Max]	34.0 [30.0, 48.0]
APGAR score at 1 min	
Median [Min, Max]	8.00 [5.00, 10.0]
APGAR score at 5 min	
Median [Min, Max]	10.0 [6.00, 10.0]
HBsAg test at 6 months	
Positive	0 (0%)
Negative	57 (43.5%)
Not tested†	21 (16.0%)
6-month visit not yet reached	53 (40.5%)

	Total* (N=131)
Birth-dose vaccine	
Yes	119 (90.8%)
0–24 hours (timely)	67 (56.3%)
25–48 hours	25 (21%)
49–72 hours	6 (5%)
>72 hours	21 (17.6%)
Never given	12 (9.2%)
Congenital abnormalities	
Yes	0 (0%)
No	131 (100%)

* Of the 143 infants born to date with complete delivery visit data, 131 were included in this table. Twelve infants were excluded: six were stillborn, four died shortly after birth, and two were voluntarily withdrawn from the study by their mothers prior to completing delivery visits.

** Preterm categorizations are based on the World Health Organization's recognized sub-categories of preterm births for gestational age. No infants were classified as extremely preterm (<28 weeks).

† Infants not tested for HBsAg at six months were either lost to follow-up, voluntarily withdrawn by their mothers, or deceased.

Background: Bulevirtide (BLV) has been approved in Italy in May 2023 for patients with chronic hepatitis Delta (CHD), but no studies have addressed their responses to treatment and the differences in responses among patients with and without cirrhosis yet. **Methods:** CHD patients starting BLV 2 mg/day as monotherapy were included in a multicenter prospective real-life Italian study (D-SHIELD). Patients' features and treatment responses were assessed at baseline and trimonthly afterwards. The primary endpoint was the achievement of a virological response (>2 LogIU/mL HDV-RNA decline *vs.* baseline or HDV RNA undetectable) in patients with and without cirrhosis. **Results:** 459 patients from 42 centers were enrolled, 341 (74%) with cirrhosis. At baseline, ALT were 75 (49-124) *vs.* 75 (44-108) U/L ($p=0.61$), 54% *vs.* 52% men ($p=0.52$), 97% *vs.* 92% on NA therapy ($p=0.056$), 96% *vs.* 93% European origin ($p=0.20$). Conversely, baseline HDV RNA levels were 5.2 (3.9-6.0) *vs.* 5.6 (4.5-6.4) LogIU/ml ($p=0.007$), age 56 (47-62) *vs.* 51 (43-57) ($p=0.03$). Among cirrhotics, 43% had varices, 9% previous HCC, 10% previous ascites, 3% history of varices hemorrhage, 5% were decompensated. ALT declined in both groups at wk24 (35 *vs.* 35 U/L, $p=0.58$), wk48 (31 *vs.* 33 U/L, $p=0.23$) and wk72 (33 *vs.* 32 $p=0.35$). HDV RNA decline was similar in patients with and without cirrhosis at wk24 (3.5 *vs.* 3.7 LogIU/mL $p=0.29$), wk48 (3.0 *vs.* 3.3 $p=0.10$) and wk72 (3.0 *vs.* 3.3 $p=0.18$). Virological, biochemical, and combined responses were achieved by 47% *vs.* 44% ($p=0.81$), 64% *vs.* 71% ($p=0.40$), and 34% *vs.* 32% ($p=0.71$) of patients at wk24; 68% *vs.* 65% ($p=1.00$), 75% *vs.* 63% ($p=0.05$), and 59% *vs.* 45% ($p=0.047$) at wk48, and by 65% *vs.* 50% ($p=0.30$), 72% *vs.* 75% ($p=1.00$), and 55% *vs.* 33% ($p=0.13$), at wk72 in patients with and without cirrhosis, respectively. HDV RNA undetectability at wk48 and 72 was similar in patients with and without cirrhosis (27% *vs.* 23%; 29% *vs.* 17%). Among non-virological responders at wk24, a partial virological response (HDV RNA decline >1 but <2 LogIU/mL *vs.* baseline) was achieved by 18% *vs.* 29% ($p=0.48$), and 15% *vs.* 0% ($p=$ns) of patients with and without cirrhosis, at wk48 and 72, respectively, and a virological response by 21% *vs.* 24 % ($p=$ns) and 70% *vs.* 0 % ($p=$ns), respectively. **Conclusion:** D-SHIELD is the largest single country study on BLV treatment for CHD. Virological, biochemical and combined responses up to wk72 were overall similar between patients with and without cirrhosis.

0031 | COMPARING THE EFFICACY OF BULEVERTIDE, INTERFERONS, AND NUCLEOSIDE ANALOGS IN THE MANAGEMENT OF CHRONIC HEPATITIS DELTA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Rohan Karkra[1] Mahinaz Mohsen[1] Joshua Pagán-Busigó[1] Michael Bebawy[1] Imran Qureshi[2] Paul Gaglio[1], [1]Rutgers New Jersey Medical School, [2]RUTGERS THE STATE UNIVERSITY OF NEW JERSEY

Background: The Hepatitis D Virus (HDV) affects about 10-20 million people globally. Patients with Chronic Hepatitis Delta (CHD) are at an increased risk of hepatic fibrosis, cancer, and mortality, with an estimated 50,000 deaths every year. Several therapies such as Lamivudine, Tenofovir, Interferons, and newer drugs like Lonafarnib, Bulevirtide have been tried with variable success. This Network Meta-Analysis compares several such therapies. **Methods:** We did a comprehensive search of PubMed, Embase, and Cochrane up till March 2025, to identify all studies that investigated the efficacy of a drug for chronic Hepatitis D. The studies were reviewed for the inclusion criteria, and 3 authors extracted the data. The studied end points included complete HDV RNA suppression, ALT normalization, and combined treatment response ($\geq$2 log decrease in HDV RNA or undetectable RNA, with ALT normalization), at end of treatment ($\geq$6 months) and at follow-up ($\geq$6 months). A network meta-analysis was conducted using a random effects model, and Odds Ratios (OR) were calculated. **Results:** A total of 14 studies were included, comprising 934 patients across 10 treatment arms (Bulevirtide, interferon alpha, peginterferon alpha, Nucleos(t)ide Analogs [NAs], and their combinations). No therapy demonstrated a statistically significant biochemical response (ALT normalization) at the end of treatment compared to control. However, compared to Bulevirtide, peginterferon alpha and NAs had lower odds of normalizing ALT (OR = 0.34 and OR = 0.14, respectively; $p < 0.05$). Bulevirtide, both as monotherapy (OR = 38.63; $p < 0.05$) and in combination with NA (OR = 1.86; $p < 0.05$) or peginterferon alpha (OR = 2.29; $p < 0.05$), significantly suppressed HDV RNA to undetectable levels, compared to controls. Interferons and peginterferons also suppressed RNA, both alone and when combined with NA, whereas NA alone did not achieve this. Bulevirtide and peginterferon alpha combination demonstrated significantly greater RNA suppression (OR = 6.73; $p < 0.05$) than Bulevirtide alone. Additionally, Bulevirtide monotherapy (OR = 37.73; $p < 0.05$), Bulevirtide with NA (OR = 18.54; $p < 0.05$), and peginterferon alpha both in combination (OR = 112.69; $p < 0.05$) and alone (OR = 15.89; $p < 0.05$) had significant combined responses at the end of treatment. However, no agent was superior to Bulevirtide. Histological response was assessed infrequently, and no arm performed better than the control. At follow-up, Bulevirtide and peginterferon alpha combination was associated with higher odds of sustained biochemical (OR = 3.02; $p < 0.05$) and virological (OR = 4.12; $p < 0.05$) response. **Conclusion:** Bulevirtide in combination with Pegylated interferon alpha may be the most promising therapy for chronic Hepatitis D, while monotherapy with HBV-directed NAs are not as effective. The side effects of interferon therapy also cannot be overstated. Larger RCTs with Bulevirtide + Peginterferon alpha should be conducted.

0032 | HIGH BURDEN OF LIVER FIBROSIS IN 4,809 PEOPLE WITH HIV MONOINFECTION UNDERGOING SCREENING FOR STEATOTIC LIVER DISEASE

Felice Cinque[1] Francesca Farina[1] Bertrand Lebouche[1] Aurgho Datta[1] Jovana Milic[2] Giovanni Guaraldi[2] Giada Sebastiani[1], [1]McGill University Health Centre, Montreal, Canada, [2]University of Modena and Reggio Emilia, Modena, Italy

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common liver disease in people with HIV (PWH). Current guidelines recommend screening for liver fibrosis in the presence of metabolic comorbidities or elevated transaminases, but the true prevalence and key risk factors remain unclear. We aimed to assess the prevalence and predictors of liver fibrosis in a large, multi-national liver screening program in PWH without viral hepatitis coinfection or alcohol abuse. **Methods:** Between 2019 and 2024, we conducted a multicenter screening study of consecutive PWH from Canada and Italy. Liver fibrosis and steatosis were assessed using transient elastography. Liver fibrosis and steatosis were defined as liver stiffness measurement $\geq$8 kPa and controlled attenuation parameter $\geq$275 dB/m, respectively. The primary outcome was the overall prevalence of significant liver fibrosis. Secondary outcomes included fibrosis prevalence of fibrosis by metabolic risk profile (diabetes, obesity, metabolic syndrome), alcohol use, and steatotic liver disease, accounting for sex, ethnicity and HIV-related factors. **Results:** A total of 4,809 PWH were included (mean age 47 years, 69% men, mean BMI 25; all on antiretroviral therapy). Metabolic risk factors were common: overweight/obesity (33%/13%), dyslipidemia (39%), hypertension (15%), and diabetes (10%). Hepatic steatosis was present in 22% of patients (15% MASLD, 7% MetALD). The overall prevalence of significant fibrosis was 12%, and increased among those with diabetes, obesity, steatosis, Hispanic ethnicity or elevated ALT (Figure). Among PWH without steatosis or metabolic comorbidities, fibrosis prevalence remained notable at 9%. In multivariate analysis, independent predictors of liver fibrosis included hepatic steatosis (adjusted odds ratio [aOR] 2.66, 95% CI 2.06-3.44), Hispanic ethnicity (aOR 2.15, 95% CI 1.19-3.87) and obesity (aOR 1.39, 95% 1.01-1.90), after adjustments (Figure). Notably, 9% of patients with FIB-4 $<$ 1.30 had liver fibrosis on transient elastography, indicating that FIB-4 alone may miss at-risk PWH. **Conclusion:** This large-scale screening study reveals a high burden of liver fibrosis in PWH, largely driven by MASLD and metabolic risk factors. Fibrosis screening may need to extend beyond classical markers of dysmetabolism. Reliance on FIB-4 alone may underestimate disease burden in this population, underscoring the need for more sensitive screening approaches.

0033 | IMPACT OF MASLD ON THE DEVELOPMENT OF HEPATOCELLULAR CARCINOMA AFTER HCV CURE IN PATIENTS WITH CHRONIC HEPATITIS C: A LARGE-SCALE, MULTICENTER COHORT STUDY

Eiichi Ogawa[1] Akira Kawano[2] Motoyuki Kohjima[3] Toshimasa Koyanagi[4] Kazufumi Dohmen[5] Aritsune Ooho[6] Takeaki Satoh[7] Kazuhiro Takahashi[8] Norihiro Furusyo[9] Eiji Kajiwara[10] Koichi Azuma[11] Yasunori Ichiki[12] Rie Sugimoto[13] Hiromasa Amagase[14] Takeshi Senju[15] Masatake Tanaka[16] Makoto Nakamuta[3] Hideyuki Nomura[17] Jun Hayashi[18], [1]Kyushu University Hospital, [2]Kitakyushu Municipal Medical Center, [3]NHO Kyushu Medical Center, [4]Fukuoka City Hospital, [5]Chihaya Hospital, [6]Steel Memorial Yawata Hospital, [7]NHO Kokura Medical Center, [8]Hamanomachi Hospital, [9]Taihaku Avenue Clinic, [10]Kajiwara Clinic, [11]Kyushu Central Hospital, [12]JCHO Kyushu Hospital, [13]NHO Kyushu Cancer Center, [14]Amagase Clinic, [15]Kyushu Rosai Hospital, [16]Graduate School of Medical Sciences, Kyushu University, [17]Haradoi Hospital, [18]Kyushu University

Background: Although HCV cure can be achieved with direct-acting antiviral (DAA) therapy, advanced age and severe fibrosis remain well-established risk factors for hepatocellular carcinoma (HCC), warranting long-term surveillance. In contrast, the impact of metabolic dysfunction-associated steatotic liver disease (MASLD) on HCC development following HCV elimination is not fully elucidated. This study aimed to assess the association between MASLD and HCC incidence after HCV cure, stratified by fibrosis severity. **Methods:** We analyzed 2,689 Japanese patients with HCV cure and no prior history of HCC, enrolled in a multicenter database between 2014 and 2025. Fibrosis status was assessed using the FIB-4 index and categorized into three groups: FIB-4 <1.45, 1.45–3.25, and >3.25. Within each group, the association between MASLD and HCC development was evaluated. Cumulative HCC incidence was estimated using the Kaplan-Meier method, and independent risk factors were identified via Cox proportional hazards analysis. **Results:** In the FIB-4 <1.45 group ($n=480$), no cases of HCC were observed during follow-up. In the FIB-4 1.45–3.25 group ($n=1,132$; MASLD: 386, non-MASLD: 746), the 5- and 8-year cumulative HCC incidence rates were significantly higher in the MASLD group (4.3% and 5.9%) than in the non-MASLD group (1.4% and 2.0%) (Log-rank $P<0.001$). Multivariate analysis identified age ($P=0.026$), serum albumin level ($P<0.001$), and MASLD (hazard ratio [HR]: 3.93, $P<0.001$) as independent predictors of HCC. In the FIB-4 >3.25 group ($n=1,060$; MASLD: 395, non-MASLD: 664), the 5- and 8-year cumulative HCC incidence rates were also significantly higher in the MASLD group (14.7% and 18.6%) compared to the non-MASLD group (9.5% and 10.9%) (Log-rank $P=0.003$). Multivariate analysis similarly identified age ($P=0.040$), serum albumin level ($P=0.002$), and MASLD (HR: 1.91, $P<0.001$) as significant risk factors for HCC. **Conclusion:** MASLD was significantly associated with increased HCC incidence in patients who achieved HCV cure through DAA therapy, regardless of fibrosis stage. These findings underscore the importance of incorporating MASLD into post-cure risk stratification and highlight the need for tailored surveillance and management strategies.

0034 | CHRONIC HEPATITIS DELTA INFECTION DISPLAYS INFLAMMATORY AND ONCOGENIC GENE SIGNATURES ALONG WITH DEFECTIVE ANTIVIRAL RESPONSE

Arshi Khanam[1] Ameer Abutaleb[2] Furkan KAYSİN[3] Cihan Yurdaydin[3] Shyam Kottilil[1], [1]Institute of Human Virology, University of Maryland School of Medicine, [2]GW School of Medicine and Health Sciences, Washington DC, USA, [3]Koc University School of Medicine, Istanbul, Turkey

Background: Background: and Aims: Hepatitis delta virus (HDV) infection causes the most severe form of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

chronic viral hepatitis due to rapid progression towards end-stage liver disease including cirrhosis and hepatocellular carcinoma (HCC) leading to high mortality. Factors driving disease acceleration need to be investigated to prevent advanced disease progression. We aimed to identify molecular signatures predicting the rapid onset of severe hepatic ailment in chronic hepatitis delta (CHD) infected patients. Methods: We investigated peripheral blood transcriptomic profiles in chronic HBV and HDV coinfected (CHB/CHD-coinfection) patients and compare them with CHB-monoinfection to recognize gene signatures associated with CHD-induced disease progression. Multiplex cytokine bead array and flow cytometry assays were performed to validate RNAseq and examine the markers of inflammation, fibrosis and immune exhaustion. Results: Transcriptomic profile revealed significant upregulation of genes related to inflammation, oncogenesis, tumor growth, invasion, metastasis and inhibition of anti-tumor response such as CXCL2, 3, 8, TNFSF9, IFITM1, IL-17, IGHA2, AREG, SEMA3F, CSF1R, TREML4, ANGPTL4 and LILRB2 in CHB/CHD-coinfection than CHB-monoinfection. Interestingly, none of the CHB/CHD-coinfected patients we analyzed had cirrhosis or HCC, yet these patients experienced significant elevation of inflammatory and oncogenic genes, indicating HDV triggers these genes much before the onset of cirrhosis or HCC that contributes to rapid disease progression/acceleration towards end-stage disease. Analysis of the top canonical pathways further proved the association of these differentially expressed genes in severe inflammatory response and oncogenic process. Results from ELISA further confirmed induction of inflammatory and fibrogenic cytokines (IL-17, CXCL2, CXCL13 and TGF-β) in the plasma of CHB/CHD-coinfection. Additionally, patients with CHB/CHD-coinfection experienced severe immune exhaustion in effector CD4 and CD8 T cell compartment by displaying higher inhibitory receptors PD-1 and TIGIT, which then resulted in poor antiviral response in terms of IFN-gamma, TNF-alpha, perforin and granzyme B secretion against HBV and HDV than CHB-monoinfection alone. Polyfunctional responses among CD4/CD8 T cells coproducing IFN-gamma, TNF-alpha, along with perforin and granzyme B were reduced in CHB/CHD-coinfection. Conclusion: HDV coinfection leads to a dichotomous immune response, whereby suppressing antiviral (HBV and HDV-specific) T cell immunity, while having exaggerated inflammatory and oncogenic responses resulting in accelerated liver disease progression, cirrhosis and HCC.

★ 0035 | REAL-WORLD INSIGHTS INTO PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS: FIRST UPDATE FROM THE PROSPECTIVE TREATFIC REGISTRY

Alise de Groot[1] Mark Nomden[1] Pedro Miranda Afonso[2] Emmanuel Gonzales[3] Verena Keitel-Anselmino[4] Ekkehard Sturm[5] Richard Thompson[6] Tassos Grammatikopoulos[6] Bethany Tucker[6] Henrik Arnell[7] Björn Fischler[7] Irena Jankowska[8] Lorenzo D'Antiga[9] Angelo Di Giorgio[10] Giuseppe Indolfi[11] Nathalie Rock[12] Georg Friedrich Vogel[13] Eyal Shteyer[14] Antal Dezsofi-Gottl[15] Mara Cananzi[16] Winita Hardikar[17] Madeleine Aumar[18] Jian-She Wang[19] Denitza Kofinova[20] Arti Pawaria[21] Aglaia Zellos[22] Bettina Hansen[2] Paola Mian[23] Henkjan Verkade[1], [1]Pediatric Gastroenterology-Hepatology, University Medical Center Groningen, Groningen, Netherlands, [2]Erasmus MC Rotterdam, Rotterdam, Netherlands, [3]Hopital Bicetre, Orsay, France, [4]Otto-von-Guericke University Hospital Magdeburg, Magdeburg, Germany, [5]Universitats Klinikum Tubingen, Tubingen, Germany, [6]King's College Hospital, London, United Kingdom, [7]Karolinska University Hospital, Stockholm, Sweden, [8]Children's Memorial Health Institute, Warsaw, Poland, [9]Hospital Papa Giovanni XXIII, Bergamo, Italy, [10]Department of Medicine, University of Udine, Udine, Italy, [11]Meyer Children's Hospital, IRCCS, Florence, Italy, [12]University Hospital Geneva, Geneva, Switzerland, [13]Department of Paediatrics I, Medical University of Innsbruck, Innsbruck, Austria, [14]Shaare Zedek Medical Center, Jerusalem, Israel, [15]Pediatric Center, Semmelweis University, Budapest, Hungary, [16]University of Padova, Padova, Italy, [17]Royal Children's Hospital, University of Melbourne, Australia, [18]CHU Lille, Lille, France, [19]Children's Hospital of Fudan University, Shanghai, China, [20]University Multiprofile Hospital for Active Treatment and Emergency, Sofia, Bulgaria, [21]Institute of Liver and Biliary Sciences, New Delhi, India, [22]Mitera Children's Hospital, Athens, Greece, [23]Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands

Background: Progressive familial intrahepatic cholestasis (PFIC) is a group of rare pediatric cholestatic liver diseases, characterized by impaired bile flow. Previous retrospective analysis through the "NAtural Course and Prognosis of PFIC and Effect of Biliary Diversion" registry allowed us to identify genotype-phenotype relationships for FIC1- and BSEP-deficiency. Recently, more PFIC subtypes have been characterized and in addition, ileal bile acid transporter inhibitors (IBATi) are increasingly used for treatment. Therefore, we initiated a prospective analysis of the treatment of PFIC, TreatFIC, in 2023. The objective of TreatFIC is to determine the natural history of all PFIC subtypes and collect real-world

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

data on the efficacy and safety of current treatments, including IBATi. Here, we provide the first update on TreatFIC. **Methods:** This multicenter prospective registry includes genetic and clinical data from individuals with genetically confirmed PFIC subtypes. Demographic and clinical data were collected retrospectively and after prospectively every six months via REDCap after TreatFIC enrollment. The data cut-off was May 20, 2025. **Results:** Upon starting in January 2023, legal procedures with 50 centers worldwide have started, of which 26 centers have full IRB approval and data transfer agreements as of May 2024. We included 113 individuals from 18 centers world-wide, with different subtypes of PFIC (Figure). At data-cut off, 14 patients have a surgical biliary diversion (SBD) (median age at SBD 2.8 (0.42-9.7) years) and 27 patients had undergone liver transplantation (LtX) (median age at LtX 5.7 (0.5-30.5) years) of which 4 first had SBD before liver transplantation. Forty-six individuals are using odevixibat, 8 individuals used odevixibat in the past, 11 individuals are using maralixibat, 2 individuals used maralixibat in the past and 48 individuals are not treated with an IBATi. **Conclusion:** TreatFIC is rapidly expanding and provides prospective data on the treatments of individuals with PFIC and their efficacy. The number of included individuals has grown rapidly since its initiation in 2023. TreatFIC will allow to assess real-world data on the current treatments for PFIC diseases. To further increase the impact of the registry, centers that treat children or adults with PFIC are invited to participate (pfic@bkk.umcg.nl).

★ 0038 | TITLE: IMPROVING ACCESS TO ALCOHOL USE DISORDER PHARMACOTHERAPY IN HEPATOLOGY: A QUALITY IMPROVEMENT INITIATIVE

Summer Collier[1], [1]*University of California, San Diego*

Background: Alcohol-associated liver disease (ALD) is the leading cause of liver-related morbidity and mortality in North America. Despite strong evidence supporting pharmacologic treatment for alcohol use disorder (AUD), pharmacotherapy remains significantly underutilized in hepatology settings. Identified barriers include provider unfamiliarity, safety concerns in cirrhosis, and system-level workflow limitations. **Aim:** To increase prescription rates of AUD pharmacotherapy in a high-volume hepatology clinic through targeted, scalable quality improvement (QI) interventions integrated into existing workflows. **Methods:** This single-center, quasi-experimental QI study compared two cohorts of adults with ALD and alcohol use seen in a hepatology clinic: pre-intervention (January–March 2023; $n = 143$) and post-intervention (January–March 2025; $n = 175$). Interventions included provider education, standardized alcohol screening, integration of decision-support tools (including a prescribing algorithm and documentation templates), and clinic access to long-acting injectable naltrexone. Outcomes were assessed via retrospective chart review. Multivariable logistic regression using backward stepwise elimination was performed to identify predictors of AUD pharmacotherapy initiation. **Results:** AUD pharmacotherapy prescribing increased from 10% pre-intervention to 43% post-intervention ($p < 0.00001$), in a high risk ALD population; 86% with cirrhosis. Documented

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

discussions of pharmacotherapy rose from 33% to 80% ($p < 0.00001$), while deferral to psychiatry or primary care decreased from 7% to 1% ($p = 0.006$). Among those prescribed treatment, use of first-line agents such as oral naltrexone and acamprosate increased, and long-acting naltrexone was newly adopted. Regression analysis (AUC = 0.77) identified three independent predictors of pharmacotherapy initiation: post-intervention year (OR = 6.03, 95% CI [3.20–11.34], $p < 0.001$), recent positive PEth (phosphatidylethanol) test (OR = 2.44 vs. no PEth, 95% CI [1.28–4.64], $p = 0.007$), and a trend toward lower Child Pugh scores (OR = 0.87, 95% CI [0.75–1.00], $p = 0.057$). Model deviance R^2 was 16.2%, reflecting moderate fit likely influenced by unmeasured variables such as patient readiness to engage in behavior change. **Conclusion:** Embedded, interdisciplinary QI interventions can increase AUD pharmacotherapy rates in hepatology without requiring structural clinic overhauls. This approach enhanced provider autonomy, reduced unnecessary deferrals, and optimized the use of clinical tools such as PEth testing and a prescribing algorithm. Findings support broader implementation of pragmatic, evidence-based strategies to improve AUD care for patients with ALD in specialty settings.

★ 0039 | ALCOHOL, CARDIOMETABOLIC RISK FACTORS, AND CIRRHOSIS: TEN-YEAR RISK ESTIMATES FROM A NATIONWIDE DANISH COHORT

Jonas Rønn[1] Gro Askgaard[1] Lone Madsen[1] Peter Jepsen[2] Hamish Innes[3] Jessica Mellinger[4] Marie Eliasen[5], [1]Department of Hepatology and Gastroenterology, Zealand University Hospital, Køge, Denmark, [2]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, [3]School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK, [4]Henry Ford Health- Michigan State University, [5]Center for Clinical Research and Prevention, Bispebjerg and Frederiksberg Hospital, Denmark

Background: Alcohol consumption and cardiometabolic risk factors increase the risk of cirrhosis, and their combined effects have gained recognition with the introduction of the MetALD term. We estimated 10-year risks of cirrhosis according to alcohol consumption and cardiometabolic risk factors. **Methods:** We included participants from the population-based Danish National Health Surveys 2010-2017 and followed them in registries through 2022 for an incident hospital diagnosis of cirrhosis, linking data on alcohol consumption, smoking status, height and weight from questionnaires with data on diabetes and redeemed hypertension- and dyslipidemia prescriptions from health registries. A drink was defined as 12 grams of alcohol. We computed the 10-year risk of cirrhosis, accounting for death as a competing event and used inverse probability weights to adjust for the differences in age between participants across the strata of risk factors for cirrhosis. **Results:** The study included 304,023 participants with a median age of 52 years (IQR 43-61); 54 % were female, 3% consumed more than 28 drinks per week, 17% had a BMI greater than 30, and 4.5% had diabetes. During 2,905,528 person-years of follow-up, 1010 participants were diagnosed with cirrhosis. The level of alcohol consumption had a powerful influence on the 10-year risk of cirrhosis with an 11-fold higher risk for 29-41 drinks/week of 2.29% and 30-fold higher risk of 5.2% for those consuming more than 42 drinks/week compared to 0.2% for those drinking 1-14 drinks/week (Table 1). The largest number of cirrhosis cases occurred among participants consuming fewer than 29 drinks per week, where diabetes increased the 10-year risk of cirrhosis by fourfold, and other cardiometabolic risk factors (BMI over 30, hypertension, dyslipidemia, and smoking) increased the risk by two- to threefold. Among participants drinking more than 28 drinks/week, the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

influence of cardiometabolic risk factors on the 10-year cirrhosis risk weakened; however, notably, the highest 10-year risks of cirrhosis were found in participants drinking more than 28 drinks/week who also had diabetes or hypertension. A high BMI did not significantly affect the risk of cirrhosis in drinkers of 28-42 drinks/week, with 10-year risks of 1.9% vs. 1.8% for BMI of 18.5-25 vs. BMI > = 30. **Conclusion:** The level of alcohol consumption has a substantial impact on the absolute 10-year risk of cirrhosis. The impact of cardiometabolic risk factors on the 10-year risk of cirrhosis is markedly weaker than alcohol, especially among those who consume more than 28 drinks/week. However, most cases of cirrhosis develop in the large population segment who drink small or moderate amounts of alcohol, indicating that preventive efforts should not be restricted to those who consume the most alcohol.

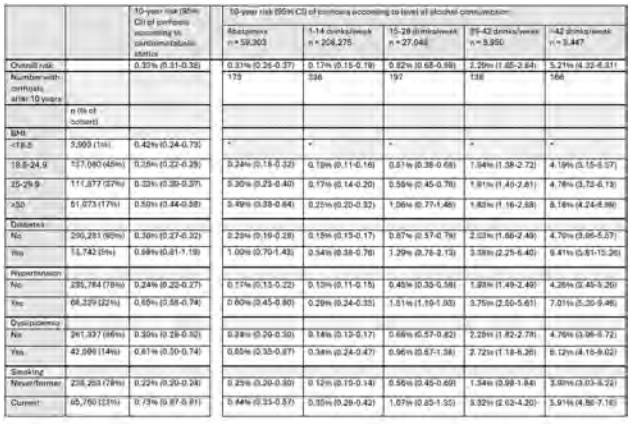

Table 1. Absolute 10-year risk with 95% confidence intervals of incident cirrhosis according to cardiometabolic risk factors for different levels of alcohol consumption for participants in the Danish National Health Surveys 2010 - 2017. A drink was defined as 12 grams of alcohol. We used inverse probability weights to adjust for the differences in age between patients with different risk factors for cirrhosis.

* Subgroup analyses on BMI <18.5 omitted due to low number of cases.

0040 | INCREASED ALCOHOL USE AFTER BARIATRIC SURGERY PREDICTS FIBROSIS PROGRESSION IN MASLD: WOMEN AT HIGHEST RISK

Brittany Bromfield[1] Kathleen Corey[2] Jay Luther[2] Wei Zhang[2] Russell Goodman[2] Esperance Schaefer[1], [1]Brigham and Women's Hospital, [2]Massachusetts General Hospital

Background: Bariatric surgery improves metabolic dysfunction-associated steatotic liver disease (MASLD) through weight loss and metabolic changes but has been associated with hazardous drinking. Many patients experience sustained improvement in MASLD, but up to 20% of patients paradoxically develop progressive fibrosis. We aimed to identify independent and modifiable predictors of fibrosis progression after bariatric surgery. **Methods:** We analyzed a cohort of 455 adults with biopsy-confirmed MASLD who underwent sleeve gastrectomy (SG) or Roux-en-Y gastric bypass (RYGB) (median 7.5-year follow-up). Fibrosis progression was defined as advancement to a higher FIB-4 risk category (<1.3 to ≥ 1.3 or ≥ 2.67). Change in alcohol use (ΔAUDIT-C) was assessed using validated screening and was analyzed as a continuous, categorical, and threshold-based variable. Cox proportional hazards regression evaluated time to progression, adjusting for age, sex, change in BMI (ΔBMI) and baseline FIB-4. **Results:** Eighty-four (18.4%) patients progressed to a higher FIB-4 category. In a multivariable analysis, three independent predictors emerged: older age increased risk (HR 1.06, 95% CI 1.03-1.09, $p<0.001$), BMI loss was protective (HR 0.95, 95% CI 0.93-0.98, $p=0.0009$), and each 1-point increase in ΔAUDIT-C conferred 19% higher risk (HR 1.19, 95% CI 1.09-1.29, $p<0.001$).The alcohol effect showed striking sex differences: women demonstrated 24% increased risk per ΔAUDIT-C point (HR 1.24, 95% CI 1.12-1.38, $p<0.001$) while men showed no significant association (HR 1.07, 95% CI 0.92-1.25, $p=0.35$). This association did not differ by surgery type (p_interaction = 0.57) or GLP-1 RA use (p_interaction = 0.39). Categorical analysis revealed dose-response patterns by sex. Among women, hazard ratios increased progressively: 1.29 for 1-point increases, 2.15 for 2-point increases, and 3.61 for ≥ 3-point increases ($p=0.005$). Men showed no elevated risk until ≥ 3-point increases (HR 2.76, $p=0.010$). Maximal rank analysis identified a ≥ 1-point increase in ΔAUDIT-C as the optimal cutoff for discriminating fibrosis risk (HR 1.95, 95% CI 1.22–3.12, p = 0.005). Female RYGB patients had the highest increase in alcohol use (ΔAUDIT-C +0.82 vs. +0.38 for SG, p = 0.02) and at-risk drinking conversion (23% vs. 8%, p = 0.01). **Conclusion:** Post-operative increases in alcohol use are an independent predictor of fibrosis progression after bariatric surgery, with effects most pronounced in women. Women show significant risk at modest alcohol increases (≥ 1-point ΔAUDIT-C), while men require larger increases (≥ 3-points) before risk emerges. A ≥ 1-point increase in AUDIT-C elevated risk, supporting its use as a clinical threshold for intervention. These findings support the need for routine longitudinal alcohol monitoring after weight loss surgery and highlight the importance of sex-specific counseling and early intervention to prevent alcohol-related liver injury.

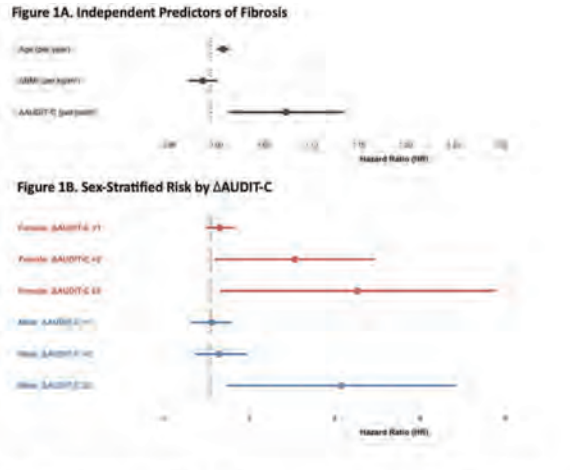

Figure 1. Independent predictors of fibrosis progression and sex-stratified risk by alcohol consumption changes. (A) Forest plot showing hazard ratios (HR) and 95% confidence intervals for independent predictors of fibrosis progression. Age per year, change in body mass index (ΔBMI) per kg/m², and change in AUDIT-C score (ΔAUDIT-C) per point were analyzed using multivariable Cox regression. The vertical dashed line represents HR = 1.0 (no effect). (B) Sex-stratified analysis of fibrosis progression risk by ΔAUDIT-C category. Hazard ratios and 95% confidence intervals are shown for males (blue) and females (red) across different levels of alcohol consumption change: +1 point, +2 points, and ≥3 points increase in AUDIT-C score. The vertical dashed line represents HR = 1.0 (no effect).

★ 0041 | INCRETIN-BASED THERAPIES AND POST-BARIATRIC ALCOHOL USE DISORDER: A PROPENSITY-MATCHED COHORT STUDY

Butros Fakhoury[1] Leandro Sierra[2] Vinay Jahagirdar[1] Luis Díaz[3] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Cleveland Clinic Foundation, [3]University of California San Diego

Background: Post-bariatric surgery (BS) patients are at an increased risk for developing alcohol use disorder (AUD). Incretin-based therapies (IBTs) are commonly utilized as adjunctive weight loss therapy in post-BS patients with inadequate weight loss or weight regain . Emerging evidence suggests that IBTs may modulate reward pathways and reduce alcohol consumption. However, their impact on the incident AUD compared to other anti-obesity medications (AOMs) remains unclear. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network. Adults who received either an IBT (semaglutide, liraglutide, tirzepatide) or a non-IBT AOM (e.g., orlistat, phentermine) following BS between January 1, 2010, and January 1, 2024, were included. Patients with prior AUD were excluded. Propensity score matching was performed using demographics, medical and psychiatric comorbidities, and substance use. Outcomes included new-onset AUD and initiation of AUD medications between 1 month and 2 years post–AOM initiation. Incidence rates, Kaplan–Meier curves, and hazard ratios (HRs) were calculated. **Results:** After matching, 4,024 patients were included in each group with a median follow-up of 2 years. The proportion undergoing Roux-en-Y gastric bypass was comparable between groups (IBT 35.8% vs. non-IBT 36.2%). Semaglutide and phentermine were the most commonly prescribed agents in the IBT and non-IBT groups, respectively. IBT use was associated with significantly lower risk of new-onset AUD (HR 0.46; 95% CI 0.26–0.84; $P = 0.009$) and initiation of medications for AUD (HR 0.48; 95% CI 0.37–0.63; $P < 0.001$). **Conclusion:** In this large, multi-institutional cohort of post-BS patients, IBT use was associated with a significantly reduced risk of developing AUD and initiating pharmacologic treatment for AUD compared to non-IBT AOMs. These associations were consistent across multiple sensitivity analyses, highlighting a potential dual benefit of IBTs in both weight management and AUD risk mitigation in this high-risk population.

0042 | CLINICAL FEATURES AND OUTCOMES OF LEAN METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE WITH INCREASED ALCOHOL INTAKE (LEAN METALD)

Binu John[1] Samuel Soon[2] Ashwani Singal[3] Suthat Liangpunsakul[4] Naim Alkhouri[5] Robert Wong[6] Ponni Perumalswami[7] Basile Njei[8] Mazen Noureddin[9] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth university, [3]University of Louisville, [4]Indiana University School of Medicine, [5]Arizona Liver Health, [6]VA Palo Alto Healthcare System, [7]University of Michigan Medical Center, [8]Yale University, [9]Houston Methodist Hospital

Background: MetALD (Metabolic Dysfunction-Associated Steatotic Liver Disease [MASLD] with increased alcohol consumption) is a distinct subtype of steatotic liver disease characterized by hepatic steatosis, cardiometabolic risk factors (CMRF), and alcohol use. The primary objective of this study was to evaluate the incidence of major adverse liver outcomes (MALO), including hepatocellular carcinoma, hepatic decompensation, liver transplantation, liver-related death, and all-cause mortality, in patients with lean MetALD versus those with non-lean MetALD. **Methods:** This was a retrospective cohort study using data from the Veterans Health Administration between January 1, 2013, and December 31, 2022, with follow-up through May 31, 2023. Lean MetALD was defined as MetALD with a BMI <25 kg/m² (<23 kg/m² for Asians). The baseline was defined as the first documentation of steatosis. We used a multivariable time-updated Fine and Gray competing risk model, treating non–liver-related death as a competing risk. All-cause mortality was analyzed using a multivariable Cox proportional hazard model, with liver transplantation treated as a censoring event. Both models were adjusted for age, sex, race/ethnicity, baseline cirrhosis, diabetes, tobacco use, AST, ALT, and platelet count. **Results:** We identified 98,932 patients who met criteria for MetALD, including 12,802 with lean MetALD. Compared to those with non-lean MetALD, patients with lean MetALD were older (mean age 63.5 vs. 58.3 years), more likely to have cirrhosis at baseline (7.5% vs. 5.4%), to be current or former smokers (87.4% vs. 77.5%), and had slightly higher peak AUDIT-C scores over the prior five years. In contrast, patients with non-lean MetALD were more likely to have type 2 diabetes (14.1% vs. 7.1%) and each of the five CMRFs. Patients with lean MetALD had a AST:ALT ratio >1 (43.0 vs. 38.3), while the opposite was true for non-lean MetALD (38.3 vs. 49.2). Additionally, lean MetALD patients had higher MCV (93.6 vs. 91.1), and lower platelet counts (208.3 vs. 210.7 $\times 10^9$/L). Patients with lean MetALD had higher adjusted incidence rates per 1,000 person-years for decompensation (25.05 vs. 20.12, $p<0.0001$), liver-related death (2.15 vs. 1.67, $p=0.02$), MALO (27.38 vs. 22.13, $p<0.0001$), and all-cause mortality (29.78 vs. 19.04, $p<0.0001$). On multivariable analysis, lean MetALD was independently associated with a 14% increased hazard of MALO compared to non-lean MetALD (adjusted Hazard Ratio [aHR] 1.14, 1.05–1.24) and a 51% higher hazard of all-cause mortality (aHR 1.51, 1.44–1.59). Conclusion: Within the spectrum of MetALD, patients with lean MetALD tend to behave more like ALD, whereas those with non-lean MetALD exhibit clinical features similar to MASLD. Patients with lean MetALD was associated with a higher risk of liver-related outcomes and all-cause mortality compared to non-lean MetALD.

0043 | METABOLOMIC ANALYSIS OF FEMALE AND MALE PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS

Mansoor Jalal Zai[1] Wajahat Mehal[2] Sherry McKee[1] Bubu Banini[2], [1]Yale School of Medicine, [2]Yale University

Background: Acute alcohol-associated hepatitis (AH) is clinically more severe in females, however sex differences in alcohol associated liver disease (ALD) especially AH remain poorly characterized. Metabolomic profiling may uncover novel pathways related to AH, especially in females. **Methods:** Serum metabolomic profiles from female (F) and male (M) patients with AH and heavy drinking controls (HD) were analyzed using ultra-performance liquid chromatography–tandem mass spectrometry (UPLC-MS/MS). Metabolites with Variable Importance in Projection > 1.5, log2 fold change > 2.0, and $p < 0.05$ in pairwise comparisons were considered significant. Analysis was performed by Creative Proteomics. **Results:** In total, 7,321 metabolites were detected in positive ion mode and 14,330 in negative ion mode. Enrichment analysis identified commonly affected pathways in both sexes with AH compared to their HD controls, including glycerolipid metabolism, steroid biosynthesis, arachidonic acid metabolism, linoleic acid metabolism, primary bile acid biosynthesis, glycerophospholipid metabolism, inositol phosphate metabolism, among others. In both sexes, glycine-conjugated bile acids such as glycocholate and glycochenodeoxycholate were increased. However, taurocholate was decreased only in females with AH; similarly taurine and hypotaurine metabolism were significantly enriched only in the females with AH compared to HD (enrichment ratio = 30; p = 2.29E-12), suggesting sex-specific alterations in bile acid metabolism. **Conclusion:** Comprehensive metabolomic analysis of female and male adults with AH demonstrates sex-independent perturbation in various pathways. In addition, sex-specific changes in taurocholate and taurine metabolism were seen. Further analyses are expected to reveal key insights into disease mechanisms and help explain the greater susceptibility of females to ALD.

Background: Metabolic dysfunction-associated steatotic liver disease (MetALD) and alcohol-associated liver disease (ALD) progress faster to advanced fibrosis, yet data on the performance of noninvasive clinical algorithms are limited. We aimed to (1) quantify the false-negative rate of standard algorithms combining Fibrosis-4 index (FIB-4) and vibration-controlled transient elastography (VCTE) for detecting advanced fibrosis in MetALD and ALD, and (2) evaluate the diagnostic accuracy of FIB-4 for advanced fibrosis in MetALD. **Methods:** In this retrospective cohort, we included 764 well-characterized adults with MetALD (n = 334, 43.7%) or ALD (n = 430, 56.3%) from 14 countries between 2003 and 2025 according to the 2023 criteria; other concomitant liver diseases were excluded. All underwent VCTE (> 8 kPa considered elevated); 244 (31.9%) also had liver biopsy. FIB-4 was categorized using standard thresholds: low risk < 1.3, indeterminate 1.3–2.67 (2.0–2.67 if ≥ 65 years), and high risk > 2.67. The primary outcome was the

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

proportion of patients with biopsy-proven ≥F3 fibrosis missed when both FIB-4 and VCTE were interpreted as low risk. In MetALD, we further assessed FIB-4 performance by area under the receiver-operating characteristic curve (AUROC) analysis. **Results:** Mean age was 49.5 years (IQR 41–59); 73.1% were male; mean BMI 28.0 kg/m² (IQR 24.1–31.6); 32.2% had diabetes. Ethnic distribution was 43.0% Asian, 38.5% Hispanic, and 17.8% non-Hispanic White. Median FIB-4 was 1.57 (IQR 0.92–3.29); median LSM 8.6 kPa (IQR 5.9–22.3). Among those biopsied (n = 244), 14.3% had F3 and 11.9% had cirrhosis (F4). Overall, 43.7% were low risk by FIB-4, 25.1% indeterminate, and 31.2% high risk. Of the low FIB-4 group, 28.1% had elevated VCTE (32.0% MetALD; 24.9% ALD). Sixteen participants classified as low-risk by both FIB-4 and LSM had ≥F3 fibrosis on biopsy—false-negative rate 6.6% overall (5.7% MetALD; 7.4% ALD)(Figure). In MetALD, FIB-4 yielded an AUROC of 0.736 (95%CI 0.610–0.863) for ≥F3 fibrosis; the optimal cut-point was ≥1.65 (sensitivity 74%, specificity 73%). Applying ≥1.65 to participants over 65 years with MetALD reduced the false-negative rate to 2.0%, while the referral rate rose only from 30.3% to 33.6%. **Conclusion:** Standard noninvasive pathways combining FIB-4 and VCTE had low false-negative rates for advanced fibrosis in MetALD and ALD. In patients with MetALD aged over 65 years, lowering the FIB-4 threshold to ≥1.65 may improve early detection of advanced fibrosis in MetALD.

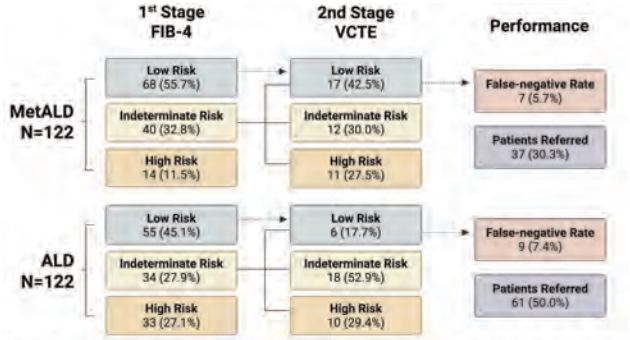

Figure: Performance of the clinical algorithms using the Fibrosis-4 index (FIB-4) and vibration-controlled transient elastography (VCTE) to detect advanced fibrosis in metabolic dysfunction–associated steatotic liver disease (MetALD) and alcohol-associated liver disease (ALD).

0045 | SIMILAR LONG-TERM INCIDENCE OF HEPATOCELLULAR CARCINOMA (HCC) IN CHRONIC HEPATITIS B PATIENTS WHO INITIATED ENTECAVIR (ETV) VERSUS TENOFOVIR ALAFENAMIDE (TAF): A REAL-B STUDY

Haruki Uojima[1] Rui Huang[1] Mindie Nguyen[1] Huy Trinh[2] Akito Nozaki[3] Philip Vutien[4] Hidenori Toyoda[5] Takashi Honda[6] Hiroshi Abe[7] Masanori Atsukawa[8] Tsunamasa Watanabe[9] Toru Ishikawa[10] Masaru Enomoto[11] Yasuhito Tanaka[12] Koichi Takaguchi[13] Pei-Chien Tsai[4] Mayumi Maeda[1] Ramsey Cheung[1] Takanori Ito[6] Manabu Morimoto[3] Ming-Lung Yu[14] Chung-Feng Huang[4] Wan Long Chuang[4] Chia-Yen Dai[4] Ming-Lun Yeh[4] Chao Wu[15] Tomonori Senoh[13] Jee-Fu Huang[4], [1]Stanford University Medical Center, [2]San Jose Gastroenterology, [3]Yokohama City University Medical Center, [4]Kaohsiung Medical University, [5]Ogaki Municipal Hospital, [6]Nagoya University Graduate School of Medicine, [7]Shinmatsudo Central General Hospital, [8]Nippon Medical School, [9]St. Marianna University School of Medicine, [10]Saiseikai Niigata Hospital, [11]Osaka Metropolitan University, [12]Kumamoto University, Kumamoto, [13]Kagawa Prefectural Central Hospital, [14]Kaohsiung Medical University/ Kaohsiung Medical University Hospital, [15]Nanjing University

Background: CHB remains a major global health burden, and long-term antiviral therapy can reduce HCC risk. ETV and TAF are both first-line therapies with potent viral suppression and favorable safety profiles. Previous comparisons between ETV and TDF yielded conflicting results regarding HCC prevention, with data with adequate adjustment for differences in treatment eras and patient characteristics showing no significant differences, but comparative data for ETV vs. TAF are limited. We aimed to investigate the long-term risk HCC with ETV vs. TAF in the same era following TAF approval in 2016. **Methods:** We enrolled previously treatment-naïve CHB patients from 24 centers across 7 countries from the REAL-B consortium who initiated either ETV or TAF between 2016 and 2023 who had no viral co-infections or prior malignancy. The primary study outcome was HCC incidence via Fine and Gray competing risk models. To balance patient background characteristics, we used inverse probability of treatment weighting (IPTW) and, as a sensitivity analysis, propensity score matching (PSM) with both matched for age, sex, race, alcohol use, cirrhosis, hepatic steatosis, HBsAg, HBV DNA, platelet, AST, ALT, and albumin. **Results:** The study included 1,437 patients (710 ETV, 727 TAF) with similar mean follow-up (48.5 ± 25.0 vs. 48.7 ± 22.5, respectively, P = 0.84). Prior to matching, ETV patients were significantly older, more likely male or had cirrhosis. After IPTW, the ETV and TAF groups had balanced characteristics (all standardized difference < 0.1). During follow-up, HCC occurred in 12 ETV patients and 14 TAF patients, corresponding to incidence rates of 0.10 and 0.18 per 100 person-years, respectively (P = 0.19). There was no statistically significant difference in the HCC risk of ETV vs. TAF patients (SHR: 2.17; 95% CI: 0.68–6.85; P = 0.19), with consistent findings across subgroups by age, sex, presence of cirrhosis, hepatic steatosis, HBeAg, ALT and HBV DNA levels and in sensitivity analyses using PSM. **Conclusion:** In this real-world multinational study of previously treatment-naïve CHB patients who initiated treatment during the same era, HCC incidence did not differ significantly between those who initiated ETV or TAF, with consistent findings across multiple analytic methods and patient subgroups. These results suggest that both agents provide comparable HCC prevention benefits, and therapeutic selection should be based on cost and other patient factors.

0046 | HBV RNA AND QUANTITATIVE HBSAG DIFFERENTIATE PARTIAL CURE FROM INACTIVE CARRIERS WITH HBEAG NEGATIVE CHRONIC HEPATITIS B

Matthew Kim[1] Gavin Nee[1] Sungyoung Auh[1] Tiffany Fortney[2] Mark Anderson[2] Gavin Cloherty[2] Marc Ghany[1], [1]National Institutes of Health, [2]Abbott Laboratories

Background: Functional cure (hepatitis B surface antigen (HBsAg) loss and HBV DNA negative) is the primary therapeutic endpoint of chronic hepatitis B (CHB). HBsAg can be derived from both cccDNA and integrated HBV DNA (iDNA). Thus, there may be persons who fail to achieve functional cure due to HBsAg derived from integrated HBV DNA i.e. partial cure (PC). We hypothesize that HBV RNA, a marker of cccDNA activity, may be used to identify such subjects. This study aimed to examine virological profiles of subjects in different phases of HBeAg(-)CHB to differentiate PC patients from inactive carriers (IC) and those with HBV DNA <2000 IU/ml with elevated ALT levels (grey zone 1 (GZ1)). **Methods:** Untreated subjects with HBeAg(-)CHB were classified based on HBV DNA and ALT levels at the time of sera collection into 7 groups: HBsAg loss, partial cure (PC) (HBV DNA <10 IU/mL and normal ALT), inactive carrier (IC) (HBV DNA <2000 IU/mL and normal ALT), grey zone 1 (GZ1) (HBV DNA <2000 IU/mL with elevated ALT), grey zone 2 (GZ2) (HBV DNA >2000 IU/mL with normal ALT), grey zone 3 (GZ3) (HBV DNA >2000 IU/mL with ALT $>$ ULN-$<$ 2X ULN), and immune active (IA) (HBV DNA >2000 and ALT >2xULN). Stored sera were tested for qHBsAg (negative samples were further tested with ultrasensitive HBsAg Next assay), HBsAg isoforms (large, middle and small), HBV RNA, and phosphorylated and non-phosphorylated HBcAg (Abbott Diagnostics research use only). Multiple logistic regression identified predictors of HBV RNA negativity. **Results:** 180 samples were tested: 30 HBsAg loss, 30 PC, 30 IC, 20 GZ1, 20 GZ2, 20 GZ3, and 30 IA. Subject demographics and results of virological testing are shown in Table 1. Subjects with HBsAg loss were older compared to other groups. The proportion testing HBV RNA negative was 73% in the HBsAg loss group, 43% PC, 17% IC, 5% GZ 1, 0% GZ 2, 10% GZ 3 and 0% IA. Interestingly, 4/30 (13%) HBsAg loss subjects tested HBsAg positive by qHBsAg assay and 10/30 were positive using the HBsAg Next assay. The proportion with qHBsAg levels <100 IU/mL was 97% in the HBsAg group, 43% PC, 30% IC, 15% GZ1, 5% GZ 2, 15% GZ 3. and 0% IA. A virological profile of HBV RNA negative and qHBsAg <100 was observed in 33% PC, 10% IC, 5% GZ1, and 5% GZ3 compared to the 73% HBsAg group could differentiate the PC group from the IA and GZ1

groups. On multiple logistic regression, low log_{10}HBV DNA ($p = 0.007$) and log_{10}qHBsAg ($p = .02$) were significantly associated with negative HBV RNA levels. **Conclusion:** Negative HBV DNA and HBV RNA results together with a qHBsAg level < 100 IU/mL are useful in differentiating PC from IA and GZ1. Up to one third of untreated subjects in the PC phase of CHB have virological profiles similar to those with HBsAg loss and may be functionally cured.

0047 | OUTCOMES FOLLOWING ANTIVIRAL THERAPY DISCONTINUATION IN HBEAG-NEGATIVE, NON-CIRRHOTIC CHRONIC HEPATITIS B PATIENTS WITH LOW BASELINE HBSAG TITERS: THE ADAPT TRIAL

Jonggi Choi[1] Won-Mook Choi[2] NEUNG HWA PARK[3] Gi-Ae Kim[4] Ji Hoon Kim[5] YOUNG-SUK LIM[2], [1]University of Ulsan, Asan Medical Center, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea, [4]Kyung Hee University Hospital, Kyung Hee University, Seoul, Republic of Korea, [5]Korea University Guro Hospital, Korea University, Seoul, Republic of Korea

Background: The benefits and risks of antiviral therapy discontinuation, including sustained virologic response and HBsAg seroclearance, remain controversial in chronic hepatitis B (CHB) patients. **Methods:** This multicenter, single-arm discontinuation trial (ADAPT trial, NCT04782375) enrolled HBeAg-negative, non-cirrhotic CHB patients from four centers in Korea who discontinued antiviral therapy (tenofovir disoproxil fumarate [TDF], tenofovir alafenamide [TAF], entecavir [ETV], or others) between September 2021 and June 2023. Eligible patients had received antiviral treatment for at least 2 years, had undetectable HBV DNA (< 20 IU/mL), serum HBsAg titers $< 3{,}000$ IU/mL, and alanine aminotransferase (ALT) levels < 40 U/L at the time of discontinuation. Follow-up visits occurred every 4 weeks until week 24, and less frequently until week 48. The primary endpoint was viral rebound (HBV DNA $\geq 2{,}000$ IU/mL) at week 24. Secondary endpoints included HBsAg seroclearance and retreatment rates at week 48. **Results:** Of 140 patients (mean age 52.6 years, 73.6% male), the antiviral treatment at discontinuation included TDF (58.6%), TAF (7.1%), ETV (29.3%), and others (5.0%). Median baseline HBsAg titer was 439 IU/mL (IQR 100–839), mean ALT was 22 U/L. Nine patients withdrew, 131 completed 24-week follow-up. At week 24, viral rebound occurred in 84 (60.0%) patients, of whom 83 resumed antiviral therapy. Among 56 patients without viral rebound, 14 (25.0%) resumed therapy based on pre-defined criteria. Consequently, by week 24, 97 patients (69.3%) resumed antiviral therapy, while 34 patients (24.3%) remained off-treatment. By week 48, HBsAg seroclearance occurred in 7 patients (5.0%), all with baseline HBsAg titers < 300 IU/mL. At week 48, 104 patients (74.3%) resumed antiviral therapy, and 27 patients (19.3%) remained off-treatment. 3 patients experienced ALT flares (ALT ≥ 5 times the upper limit of normal) without hepatic decompensation. **Conclusion:** In this multicenter trial of 140 non-cirrhotic, HBeAg-negative CHB patients with baseline HBsAg titers $< 3{,}000$ IU/mL, 74.3% required retreatment by week 48 due primarily to viral rebound. Only 5.0% achieved HBsAg seroclearance, exclusively among patients with baseline HBsAg titers < 300 IU/mL. These findings do not support universal discontinuation of antiviral therapy for most CHB patients.

0048 | PARTIAL CURE AFTER FINITE HBV THERAPY IS ASSOCIATED WITH EXCELLENT LONG-TERM OUTCOMES – RESULTS: FROM A POOLED ANALYSIS OF THE RETRACT-B AND CREATE DATASETS

Edo Dongelmans[1] Apichat Kaewdech[2] Grishma Hirode[3] Florian van Bömmel[4] Rachel Wen-Juei Jeng[5] Rong-Nan Chien[5] Chien Hung Chen[6] Mai Kilany[3] Tung-Hung Su[7] Jia-Horng Kao[7] Wai-Kay Seto[8] Lilian Yan Liang[9] Dag Henrik Reikvam[10] Marte Holmberg[11] Arno Furquim d'Almeida[12] Margarita Papatheodoridi[13] Benjamin Maasoumy[14] Kosh Agarwal[15] Ivana Carey[15] Maurizia Brunetto[16] Piero Colombatto[16] Teerha Piratvisuth[2] George N. Dalekos[17] Sang Hoon Ahn[18] Junyong Park[18] Yasuhito Tanaka[19] Bettina Hansen[1] Anna Pocurull[20] Norah Terrault[21] Marc Ghany[22] Asgeir Johannessen[11] Anna Lok[23] Thomas Vanwolleghem[12] Sabela Lens[20] Markus Cornberg[14] Man-Fung Yuen[8] Grace Lai-Hung Wong[9] George Papatheodoridis[13] Thomas Berg[4] Yao-Chun Hsu[24] Jordan Feld[3] Harry Janssen[1] Milan Sonneveld[1], [1]Erasmus University Medical Center, [2]Prince of Songkla University, [3]Toronto General Hospital/University of Toronto, [4]Leipzig University Medical Center, [5]Chang Gung Memorial Hospital, Linkou Medical Center, [6]Kaohsiung Chang Gung Memorial Hospital, [7]National Taiwan University Hospital, [8]The University of Hong Kong, [9]The Chinese University of Hong Kong, [10]Oslo University Hospital, [11]University of Oslo, [12]Antwerp University Hospital, [13]Medical School of Athens University, [14]Hannover Medical School, [15]King's College Hospital, [16]University Hospital of Pisa, [17]General University Hospital of Larissa, [18]Yonsei University College of Medicine, [19]Nagoya City University Graduate School of Medical Sciences, [20]University of Barcelona, [21]University of Southern California, [22]NIH/NIDDK, [23]University of Michigan Medical Center, [24]E-Da Hospital/I-Shou University

Background: Partial cure (HBsAg <100 IU/mL with undetectable HBV DNA at 6 months after withdrawal of antiviral therapy) has been introduced as an alternate surrogate endpoint for HBV trials. We aimed to assess long-term virological outcomes in patients with partial cure. **Methods:** Data from patients who met criteria for partial cure at 6 months after nucleos(t)ide analogue (NA) withdrawal were collected from 2 global cohorts of patients who underwent finite NA therapy (RETRACT-B and CREATE). Criteria for NA cessation were based on international guidelines (*e.g.,* HBsAg positive, HBeAg negative, and virally suppressed at end of therapy [EOT]). The primary outcome was the HBsAg loss rate at 5 years after NA withdrawal. Secondary outcome was clinical relapse (HBV DNA ≥ 2000 IU/mL and ALT ≥ 2 xULN). Outcomes in patients with partial cure were compared with patients from RETRACT-B who did not achieve partial cure, and who were HBsAg positive and free from clinical relapse or retreatment at 6 months after NA cessation. Aalen Johansen estimators with Grey's test were used for statistical comparison, considering retreatment and HBsAg loss as competing events. **Results:** We identified 100 patients with partial cure. At 6 months after EOT, median age was 54 [44-61] years, 76% were male, 70% Asian, 27% White, median HBsAg was 0.82 [0.05-1.60] log10 IU, 45% was previously treated with TDF/TAF (43% ETV) and 1% had a history of cirrhosis. Median follow up after achievement of partial cure was 3.8 [1.7-6.3] years. At 5 years after NA cessation, 62% of patients with partial cure achieved HBsAg loss compared to 7% in those without partial cure ($p < 0.001$). And only 5% of patients with partial cure developed clinical relapse (vs. 38%, $p < 0.001$). Achievement of partial cure was associated with superior 5 year HBsAg loss rates when compared to patients without partial cure, both in patients with EOT HBsAg <100 IU/mL (66% vs. 28%, $p < 0.001$) and in those with EOT HBsAg >100 IU/mL (53% vs. 4%, $p < 0.001$). Among patients with partial cure, those with HBsAg <10 IU/mL ($n = 56/100$) had higher HBsAg loss rates (81% vs. 32%, $p < 0.001$) and less clinical relapse (0% vs. 14%, $p = 0.012$) at 5 years after EOT, compared to patients with levels between 10 - 100 IU/mL. **Conclusion:** Patients with partial cure after finite NA therapy have excellent long-term outcomes, especially if HBsAg is <10 IU/mL, supporting further exploration of partial cure as a surrogate endpoint in HBV cure trials.

★ 0049 | SECRETORY ECM1A RESTORES HBV-SPECIFIC CD8˚ T CELL RESPONSE VIA INTEGRIN β1 BLOCKADE TO PROMOTE HBSAG LOSS IN CHRONIC HBV INFECTION

Zheyu Dong[1] Peng Chen[1] Yuxin Zhou[1] Qiuyue Ye[1] Yuqing Shao[1] Junling Chen[1] Yadong Wang[1] Libo Tang[1] Jinlin Hou[1] Bing Sun[2] yongyin li[1], [1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, [2]Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences, Shanghai, China

Background: Antigen-specific CD8+T cells are crucial effectors for hepatitis B virus (HBV) clearance but become functionally impaired in chronic infection. Extracellular matrix protein 1 (ECM1), an extracellular matrix component essential for hepatic environmental homeostasis, is involved in regulating the immune response. This study aims to investigate the role of ECM1 in HBsAg clearance and its underlying mechanism in anti-HBV immune responses. **Methods:** Blood and liver samples were obtained from 147 chronic HBV-infected individuals and 76 healthy controls. Multi-omics approaches including single-cell RNA sequencing (scRNA-seq), co-immunoprecipitation (Co-IP), mass spectrometry, and *in vitro* stimulation assays were employed to assess ECM1's impact on anti-HBV CD8+T cell response. HBV mouse mode with hepatic stellate cell (HSC)-specific ECM1 knockout were established for *in vivo* validation. **Results:** Screening identified six upregulated extracellular matrix components (MMP2/7, ECM1, VCAN, COL5A1/15A1) in HBV-infected livers from GEO databases. Notably, serum ECM1 was the only component correlating with disease status in our cohort, showing significantly higher levels in patients achieving HBsAg clearance versus those with persistent infection. The assays of clinical liver specimens and HBV mouse models revealed that the elevated ECM1 originates from hepatic stellate cells (HSCs). Functionally, the secretory isoform ECM1a, but not the non-secretory isoform ECM1b, enhanced HBsAg-specific cytotoxic T cell (CTL) responses, leading to HBsAg clearance. Moreover, HSC-specific ECM1 knockdown delayed HBV clearance in mice. Mechanistically, the P300-H314 domain unique to ECM1a (deficient in ECM1b) competitively bound integrin β1, thereby neutralizing the suppression of CD8˚ T cell function of integrin 1 and restoring anti-HBV immunity. Meanwhile, scRNA-seq revealed that the reduction of integrin 1 on peripheral and intrahepatic CD8˚T cells from chronic HBV-infected patients correlated with functional cure and favorable response to pegylated interferon- therapy. Consistent with this finding, pharmacological inhibition of integrin 1 signaling with ATN-161 accelerated viral clearance in HBV mouse models. Conclusion: The secretory isoform ECM1a facilitates HBV clearance by antagonizing integrin 1-mediated CD8+T cell exhaustion, enhancing cytotoxic cytokine production and HBsAg loss. Our findings unveil a novel extracellular matrix-immunity crosstalk mechanism and identify ECM1 as a potential therapeutic target for chronic HBV infection.

0050 | LOW HBSAG LEVELS BUT LESS HBSAG DECLINES REPRESENTS THE HIGH RISK OF HCC AND THE RARITY OF HBSAG LOSS IN NUC-TREATED PATIENTS WITH BASELINE HBEAG-POSITIVITY

Tetsuya Hosaka[1] Fumitaka Suzuki[1] Mariko Kobayashi[1] Yasue Takeuchi[1] Hitomi Sezaki[1] Norio Akuta[1] Yoshiyuki Suzuki[1] Satoshi Saitoh[1] Yasuji Arase[1] Kenji Ikeda[1] Hiromitsu Kumada[1], [1]Toranomon Hospital

Background: Some chronic hepatitis B (CHB) patients developed hepatocellular carcinoma (HCC) despite long-term nucleos(t)ide analogue (NUC)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

treatment. The recent paper showed that low hepatitis B surface antigen (HBsAg) associated with HCC risk in patients with hepatitis B e antigen (HBeAg) positive immune-tolerant phase. In this study, we evaluated the association between HBsAg levels and HCC development in NUC-treated patients with baseline HBeAg positivity. **Methods:** This study enrolled consecutive 947 CHB patients with baseline HBeAg-positivity who received NUC treatment for at least 1 year and whose baseline and on-treatment HBsAg levels could be measured by commercial assay. The subjects were classified into the following 3 groups based on baseline HBsAg levels: < 1,000 IU/mL, 1,000-9,999 and ≥ 10,000. Regarding on-treatment HBsAg, we evaluated the changes in HBsAg from baseline to year 1. The outcomes we evaluated were HCC incidences and HBsAg loss (< 0.05 IU/mL) according to baseline and on-treatment HBsAg kinetics. **Results:** (1) Baseline median (IQR) HBsAg levels were 5,885 (2,138-21,000) IU/mL. In the entire cohort, 129 patients (13.6%) were categorized into < 1,000 IU/mL, 442 (46.7%) into 1,000-9,999 and 376 (39.7%) into ≥ 10,000. The number of patients who achieved ≥ 0.3 log IU/mL declines (= 50% declines) in HBsAg from baseline to year 1 was 323 (34.1%). (2) Annual incidence rates of HCC were 1.3, 10.5, and 12.7 per 1,000 person-years in patients with < 1,000 IU/mL, 1,000-9,999 and ≥ 10,000 of baseline HBsAg, respectively, with higher incidences of HCC in < 1,000 IU/mL and 1,000-9,999 than those of ≥ 10,000 (P < 0.001) (Fig A). Moreover, patients who achieved ≥ 0.3 log declines in HBsAg in the first year were significantly less likely to develop HCC than those without it (P < 0.001). Multivariable Cox regression, adjusted for age, sex, cirrhotic status, platelet counts, ALT and baseline viral loads, showed that baseline low HBsAg levels were associated with high risk of HCC with their hazard ratios for HCC in < 1,000 IU/mL and 1,000-9,999 of 3.44 and 2.77, respectively. Also, the decline in HBsAg ≥ 0.3 log in the first year was associated with low risk of HCC with its hazard ratio of 0.31. Baseline higher ALT levels were associated with the decline in HBsAg ≥ 0.3 log. (3) We categorized the cohort into the following 3 groups, baseline HBsAg <10,000 & less declines in HBsAg in the first year, baseline HBsAg <10,000 & ≥ 0.3 log declines in HBsAg and baseline HBsAg ≥ 10,000. Cumulative HCC incidences were higher in patients with HBsAg <10,000 & less declines in HBsAg than those in the other two groups (P<0.001) (Fig B). However, Cumulative HBsAg seroclearance rates were lower in patients with HBsAg <10,000 & less declines in HBsAg (P = 0.003). **Conclusion:** Baseline low HBsAg levels but less HBsAg declines seem to be an unfavorable status which represents the high risk of HCC and the rarity of HBsAg loss, in NUC-treated patients with baseline HBeAg-positivity.

★ 0052 | HEPATIC STELLATE CELL NOTCH CONTRIBUTES TO LIVER FIBROSIS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Meng Li[1] Junjie Yu[1] Domenick Raphael[1] Brent Mayfield[1] Changyu Zhu[1] Robert Schwabe[1] Utpal Pajvani[1], [1]Columbia University Irving Medical Center

Background: Hepatic stellate cells (HSCs) are key drivers of fibrosis in metabolic dysfunction-associated steatohepatitis (MASH). Our previous research has demonstrated that inter-hepatocyte Jagged1 (Jag1)/Notch signaling is necessary for MASH-induced liver fibrosis in mice. We observed high HSC Notch activity in mice and patients with MASH and hypothesized that increased hepatocyte Jag1 exacerbates liver fibrosis through direct HSC Notch activation. **Methods:** We generated HSC-specific Notch loss-of-function (LOF) and gain-of-function (GOF) mice and fed them with a MASH-inducing diet rich in fructose, palmitate, and cholesterol (FPC) or with normal chow diet. We over-expressed hepatocyte Jag1 in the livers of HSC-specific Notch LOF mice by hydrodynamic injection of a Jag1-encoding plasmid. We knocked down hepatocyte Jag1 by injection of GalNAc–modified siJag1 in FPC-fed wildtype mice. We sorted HSCs from FPC-fed HSC-specific Notch LOF mice for RNA sequencing and analysis, and conducted tethered ligand assays to evaluate direct effects of Jag1 on HSC activity. **Results:** HSC-specific Notch LOF ameliorated FPC diet-associated liver fibrosis, likely due to reduced HSC proliferation. Conversely, HSC-specific Notch GOF exacerbated FPC-induced liver fibrosis in both male

and female mice, but forced activation of Notch in HSCs was insufficient to induce liver fibrosis in chow diet-fed mice. Mechanistically, we observed that knockdown of hepatocyte Jag1 significantly decreased HSC Notch activity in FPC-fed mice, and conversely, forced hepatocyte Jag1 increased HSC Notch activity, which partially accounted for Jag1-induced liver fibrosis. Similarly, Jag1-induced Notch signaling drove HSC activity in primary mouse HSCs and a human HSC cell line. **Conclusion:** These data illustrate the pathological role and therapeutic potential of the HSC Notch in MASH-associated liver fibrosis. Furthermore, as these effects appear synergistic with effects of hepatocyte Notch activity to augment liver fibrosis, our findings highlight the therapeutic potential of blocking hepatocyte Jag1 to simultaneously impact multiple arms of MASH pathogenesis.

0053 | DEVELOPMENT OF A YAP PROTAC WITH ANTI-FIBROTIC POTENTIAL

Liya Pi[1] tian tian[2], [1]Tulane University School of Medicine, [2]Depratment of Pathology, Tulane University

Background: The transcriptional coactivator Yes-associated protein (YAP) is a driver for hepatic stellate cell (HSC) activation and liver fibrosis, but historically challenging to target due to its intrinsically disordered nature. We have developed a YAP degrader (designated YZ-6) based on Proteolysis-Targeting Chimera (PROTAC) technology [*Zhou et al., Exploring Degradation of Intrinsically Disordered Protein Yes-Associated Protein Induced by Proteolysis TArgeting Chimeras. J Med Chem. 2024 Sep 12;67(17):15168-15198*]. This study aims to test whether YZ-6 can degrade YAP in HSC and have inhibitory effects on development of liver fibrosis in mice. **Methods:** YZ-6 was linked to a known YAP binder NSC682769 with VHL ligand 2 or pomalidomide via diverse linkers. Effects of YZ-6 on YAP degradation and transcriptional activities were examined by Western Analysis and luciferase under the control of 8xGTIIC promoter in human HSC LX2 cells. Cell cycle and apoptosis were analyzed in flow cytometry based on staining with propidium with or without Annexin V antibody. In addition, biliary fibrosis and ductular reaction were induced and analyzed after the feeding of 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) followed by intraperitoneal injection of YZ-6 (35 mg/kg body weight, twice a week for 14 days). **Results:** YZ-6 recruited the E3 ligase VHL for the rapid and sustained degradation of YAP. It also effectively inhibited its nuclear localization, curtailing YAP/TEAD-mediated transcription in LX2 and rat progenitor WB-F344 cells. Moreover, YZ-6 induced 43.2% and 40.6% apoptosis in LX2 and WB-F344 cells whereas mock controls only caused 3.4% and 2.9% apoptotic cells in Annexin V staining. Increased cells in G1 phase were also observed, indicating that YZ-6 promoted cell cycle arrest. Additionally, YZ-6 administration caused low levels of YAP content and attenuated biliary fibrosis as evidenced by reduced levels of connective tissue growth factor, alpha smooth muscle actin, and collagen type I after DDC-induced liver injury. These changes were associated with decreased proliferation of bile ductular epithelial cells based on staining with Ki67 and cytokeratin 19 antibodies. **Conclusion:** YZ-6 can inhibit HSC activation and reduce DDC-induced liver fibrosis and DR. These results underscore the potential of PROTAC-mediated YAP degradation as a strategy for treating fibrosis during chronic liver injury.

0054 | HOT AND COLD LIVER FIBROSIS REFLECT OPPOSING HEPATOCELLULAR CARCINOMA TRAJECTORIES IN EXPERIMENTAL METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Bruno Cogliati[1] Chittampalli Yashaswini[2] Alessandro Marins-Dos-Santos[3] Joana Almeida[1] Fanglin Ma[1] Kenneth Li[1] Li Chen[4] Dipankar Bhattacharya[1] Shuang Wang[1] Scott Friedman[2], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS), [3]Icahn School of Medicine at Mount Sinai Dean's Flow Cytometry Core, [4]PharmaNest Inc.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a rising cause of hepatocellular carcinoma (HCC) that emerges within a fibrotic niche. The composition of fibrotic tissue, classified as "hot" (immune-infiltrated) or "cold" (immune-depleted), plays a critical role in the pathogenesis of cardiac fibrosis (10.1016/j.cels.2025.101198), but it is uncertain whether these fibrosis immunophenotypes occur in liver disease and HCC. Here, we model hot versus cold fibrosis in murine MASH to investigate their links to HCC progression. **Methods:** The 'FAT-MASH' protocol (10.1016/j.jhep.2018.03.011) was administered for 40 weeks to induce advanced fibrosis and HCC. Following this 40 weeks of injury, all dietary and chemical insults were withdrawn, and mice were monitored at 2, 8, 16, and 24 weeks post-intervention

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

to evaluate fibrosis remodeling and HCC progression. Serum and liver tissues were collected for biochemical, histological, immunohistochemical, flow cytometry, and transcriptomic analyses to characterize the macrophage-myofibroblast circuit and the fibrotic immune landscape. **Results:** At 40 weeks of MASH, mice exhibited marked steatosis, fibrosis, and large HCCs, along with elevated serum levels of ALT, AST, and lipids. Following cessation of injury, mice displayed distinct regression dynamics: between weeks 2-24 of regression, steatosis and tumor burden declined significantly, while fibrosis persisted. Interestingly, tumor size increased again at 24 wks. By FACS of fibrotic tissue there was an early decline in total leukocytes, macrophages, and T cells, followed by immune reconstitution by weeks 16-24. Transcriptomic profiling revealed initial upregulation of metabolic pathways and suppression of inflammatory pathways, which reversed at later time points. Macrophage infiltration decreased during weeks 2-8, whereas hepatic stellate cell (HSC) numbers peaked during injury and remained stable throughout regression. **Conclusion:** Persistent collagen deposition and sustained HSC activation indicate a "point of no return" for fibrosis regression in this model. The immune profile of persistent fibrosis critically influences HCC behavior in experimental MASH. The evolving immune landscape of fibrosis, from a transient "cold" phase (2-8 weeks) to a "hot" phase (16-24 weeks), correlates with an initial decrease and subsequent rebound of tumor size. These findings underscore the importance of fibrosis immune contexture in dictating tumor fate and suggest a new therapeutic paradigm that targets fibrotic immunophenotypes in MASH-related HCC.

0055 | INHIBITION OF MITOCHONDRIAL FUMARASE (FH1) RESULTS: IN RELEASE OF MITOCHONDRIAL DNA AND HSC ACTIVATION

Suyavaran Arumugam[1] Xinshou Ouyang[2] Wajahat Mehal[2], [1]Yale University, [2]Section for Digestive diseases, Yale School of Medicine

Background: Ethanol is known to activate hepatic stellate cells (HSC) but the mechanism is poorly understood. Here we examined the ability of ethanol, via acetaldehyde, to activate HSC. We further examined the mechanism underlying ethanol-induced functional changes. **Methods:** Primary human HSC were isolated by liver perfusion and optiprep-GBSS density gradient centrifugation. HSC were exposed to 50mM ethanol for 16 h and assayed for transcriptional and metabolic changes. In parallel blockers of ethanol metabolic enzymes were tested in the LX-2 HSC cell line prior to ethanol stimulus. Mitochondrial proteins from LX-2 cells were analyzed via LCMS/MS LTQ-Orbitrap technique to identify changes in phosphorylation. Inhibitors such as VBIT4 10μM (VDAC inhibitor), STING inhibitor (IFM-4490 at 20μM) were used as per experimental target. We screened the TCA cycle enzymes via siRNA to identify possible targets for ethanol induced alterations. Single amino acid mutants of target TCA cycle enzymes were screened in HSC to delineate the ethanol mediated mitochondrial DNA (mtDNA) release and STING activation. **Results:** Ethanol resulted in mtDNA release and activation of primary mouse and human HSC at 50mM, and enhanced TGF-b (2.5ng/ml) mediated activation at 10mM concentrations. Alcohol dehydrogenase 5 (ADH5) knockdown or 4 methyl pyrazole pretreatments in LX-2 blocked ethanol mediated mtDNA release ($P < 0.0001$). Exposure to acetaldehyde (200μM) induce changes undistinguishable from ethanol. Upon ethanol stimulation STING colocalized to the Golgi-complex. STING inhibitor significantly suppressed ethanol induced ACTA2 transcription. Moreover, the mitochondrial phospho-proteome data showed SLC25A6 (ANT3), VDAC1 and SAM50 as the top significant modified proteins indicating the activation of mitochondrial permeability transition pore in ethanol treated LX-2 cells. TCA cycle siRNA screening showed that fumarase (FH1) knockdown activated HSC. Ethanol was observed to significantly suppress FH1 enzyme activity, leading to elevated mitochondrial fumarate and mitochondrial DNA damage as a source for STING activation. We further confirmed ethanol suppresses FH1 activity via acetylation of lysine residues K80 and K230 in the active site and block fumarate binding. In vivo FH1 inhibition worsened fibrosis in mouse model on alcohol for 5 weeks, which was blocked by STING inhibitor. **Conclusion:** Ethanol metabolism to acetaldehyde in HSC results in inhibition of FH1, mtDNA release, with activation the c-GAS-STING-IRF3 pathway. We identified that acetaldehyde mediates lysine acetylation in mitochondrial FH1 leading to its inhibition and fumarate accumulation. Increased mitochondrial fumarate induces mtDNA damage resulting in HSC activation and fibrosis progression. These findings provide novel insights into ethanol metabolite mediated fibrogenic activation of HSCs and potential therapeutic targets for hepatic fibrosis in ALD.

0056 | ACTIVATED HEPATIC STELLATE CELLS (AHSCS) ARE ESSENTIAL FOR THE PROLIFERATION OF ZONE 3 HEPATOCYTES DURING RECOVERY FROM TOXIC LIVER INJURY IN MICE

Sadatsugu Sakane[1] Hiroaki Fuji[2] Rabi Murad[3] Animesh Singh[1] Charlene Miciano[4] Hyun Young Kim[1] Mojgan Hosseini[1] Kanani Hokutan[1] Vivian Zhang[5] Raquel Weber[6] Wonseok Lee[1] Souradipta Ganguly[7] Karin Diggle[8] Xiao Liu[1] Debanjan Dhar[3] Linda Burkly[9] Allen Wang[1] David Brenner[3] Tatiana Kisseleva[1], [1]University of California, San Diego, [2]Hyogo College of Medicine, [3]Sanford Burnham Prebys Medical Discovery Institute, [4]University of California San Deigo, [5]Universtity of California, San Diego, [6]University of California San Diego, [7]Sanford Burnham Prebys, [8]University of Californania, San Diego, [9]Editas Medicine Inc.

Background: Activated Hepatic Stellate Cells (aHSCs) are the major source of fibrogenic myofibroblasts in the liver. We investigated the role of aHSCs in the development and recovery from carbon tetrachloride (CCl_4)-induced liver injury. For this purpose, human Diphtheria Toxin Receptor was overexpressed in Collagen Type I and Lrat expressing activated HSCs, so that administration of Diphtheria Toxin-α (DTA) to CCl_4-injured mice induced cellular death of $DTR^+Col1a1^+Lrat^+$ aHSCs. **Methods:** $Col1a1^{fl\text{-}stop\text{-}fl\text{-}DTR}$ mice, in which a floxP-stop-floxP-DTR cassette was knocked into the *col1a1* genetic locus, were crossed with $Lrat^{Cre}$ mice, which express Cre in HSCs in the liver, to generate $Lrat^{Col1a1\text{-}DTR}$ mice. $Lrat^{Col1a1\text{-}DTR}$ mice were subjected to CCl_4 (25 μl every other day for one week by oral gavage) liver injury. Upon cessation of liver injury, $Lrat^{Col1a1\text{-}DTR}$ mice were treated with a single dose of DTA (50ng/g) or PBS (+DTA or vehicle, n≧10 per group) to induce aHSC ablation. Mice were sacrificed at day 1, 3, 7, and 28. **Results:** CCl_4-treated vehicle and +DTA mice developed hepatocyte injury, inflammation, and mild fibrosis. Upon CCl_4 cessation, livers of vehicle mice contained areas of hepatocyte necrosis as well as marked hepatocyte proliferation at day 1, and fully recovered from injury by day 3. In turn, CCl_4-injured +DTA mice exhibited severe liver necrosis and inflammation on day 1, which remained on day 3 centered on Zone 3. At day 7, mice exhibited the loss of body weight (»20%) and liver weight (»50%). Half of CCl_4-injured +DTA mice died within 2 weeks after aHSC ablation, the surviving mice showed gradual weight gain and histological improvement. The loss of liver mass in recovering CCl_4-injured +DTA mice was attributed to the marked shrinkage of hepatocyte cytoplasm and decrease of Zone 3 due to impaired hepatocyte proliferation in the absence of HSCs. At day 28, the liver volume and architecture returned to normal due to increased hepatocyte proliferation, and this effect was associated with restoration of HSC numbers in the livers of CCl_4-injured +DTA mice. RNA-seq revealed that CCl_4-injured DTA^+ mice showed loss of metabolic function, increased Zone 1 markers and decreased Zone 3 markers on days 3 and 7, along with decreased levels of many aHSC-derived growth factors, which were normalized by day 28. **Conclusion:** Activated HSCs are essential for the proliferation of Zone 3 hepatocytes during recovery from CCl_4-induced acute liver injury. Ablation of aHSCs cannot be used for anti-fibrotic therapy.

Background: Beta-arrestin-2 (ARRB2) is a regulator of the G-protein-coupled receptors, such as the profibrotic Angiotensin II type 1 receptor (AGTR1), redirecting signalling to G-protein-independent pathways. Their role in liver fibrosis is not fully understood and was investigated in this study. **Methods:** Fibrosis was induced in Arrb2-deficient and wildtype (Wt) mice using bile duct ligation (BDL) or carbon tetrachloride (CCl4). AGTR1 was stimulated either G protein-dependent by angiotensin II administration or by the modified peptide [Ser(1), Ile(4), Ile(8)]-angiotensin II to selectively activate ARRB2 downstream of AGTR1. Fibrosis and HSC activation were investigated by gene and protein expression/histological staining. Crosstalk between primary murine hepatic stellate cells (HSC) and hepatocytes was analysed in vitro. Gene array analyses identified mediators of ARRB2-dependent signalling in primary human HSC. Findings in experimental liver fibrosis were confirmed in human tissue and hepatic cells (hepatocytes, HSC). **Results:** ARRB2 is increased in liver cirrhosis, mainly in activated HSC and injured hepatocytes. In turn, ARRB2 deficiency decreases fibrosis and HSC activation in vivo. Interestingly, ARRB2-loaded extracellular vesicles (EV) released from injured Wt hepatocytes can activate ARRB2-deficient HSC, while ARRB2-deficient EV had no effect in Wt HSC. Transcriptome analysis of human primary HSC revealed that ARRB2 induces retinoic acid receptor responder 1 (RARRES1). RARRES1 correlates with profibrotic factors, such as collagen 1, alpha-smooth muscle actin and transforming growth factor beta expression. **Conclusion:** Chronic liver injury leads to the release of ARRB2-loaded EV by hepatocytes. These EVs are taken up by HSC and induce fibrosis. ARRB2 regulates RARRES1 and may induce pre-malignant transformation.

0058 | TARGETING LRH-1 IN MICE PROMOTES LIVER HOMEOSTASIS AND INFLAMMATORY ATTENUATING TRANSCRIPTIONAL PROFILES TO AMELORIATE TYPEII DIABETES

Eric Ortlund

Background: Obesity is a significant global health challenge, which exacerbates metabolic dysfunction and leads to insulin resistance and liver disease. Liver receptor homolog-1 (LRH-1) is a key metabolic regulator in the liver, alleviates insulin resistance when activated, and represses inflammation in digestive tissues. However, targeting LRH-1 with synthetic ligands in vivo is challenging due to poor pharmacokinetic properties of current agonists. Moreover, mouse LRH-1 inaccurately reflects ligand binding and activation of human LRH-1 due to several variations in the ligand binding pocket. **Methods:** We use a combination of synthetic chemistry, structural biology, biochemistry, pharmacokinetic

studies and cellular assays to develop ME610. We use CRISPR gene editing to humanize the mouse Lrh-1 gene and a range of pre-clinical studies to evaluate target engagement and efficacy in a HFD model of TypeII diabetes. **Results:** We design and synthesize an LRH-1 agonist (ME610), with improved pharmacokinetic properties and developed a novel "humanized" LRH-1 mouse model to more accurately assess human-like target engagement *in vivo*. ME610 improves glucose and insulin tolerance in diet-induced diabetic mice and drastically reduces intrahepatic fat. ME610 reduces liver weights compared to vehicle treated males but not females. Although, ME610 reduces fatty depot weights compared to vehicle treated controls for both male and female mice. Tissue slices and oil red o staining indicate ME610 reduces intrahepatic fat deposition and partially restores tissue architecture for both male and female mice. We show a significant reduction in liver di- and triglycerides by lipidomics. Using RNAseq, we observed activation of a transcriptional profile consistent with reduced free fatty acid import into the liver and enhanced β-oxidation. We also observe elevation of direct LRH-1 targets in the acute phase response, indicating resolution of ER damage, and upregulation of other liver homeostatic regulators HNF4α and TLE3 (PPARγ activator). ME610 upregulates acute phase and inflammatory genes within hours; however, prolonged treatment with ME610 in the context of HFD results in a hepatic gene expression profile that restores homeostasis and reduces inflammation. Our findings suggest that LRH-1 restores metabolic function by balancing an inflammatory response with promotion of liver homeostasis. **Conclusion:** We improved the solubility and metabolic stability of an LRH-1 modulator. We show that humanized LRH-1 (hmLRH-1) mice are phenotypically normal and develop T2DM when fed a high fat diet (HFD). Therefore, hmLRH-1 mice are suitable for studying LRH-1 agonism *in vivo*. We report that LRH-1 agonism ameliorates insulin resistance in overweight mice and significantly reduces intrahepatic fat. We define the transcriptional and lipidomics profiles associated with LRH-1 activation in healthy and T2DM mice.

0059 | PPAR GAMMA REGULATES PNPLA3 IN A TISSUE SPECIFIC MANNER IN OBESE PEOPLE AND MICE WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Emmanuel Dixon[1] thierry claudel[1] Ursula White[2] Robert Zimmermann[3] Guenter Haemmerle[3] Martin Wabitsch[4] Claudia Fuchs[1] Veronica Mlitz[1] Michael Trauner[1], [1]Medical University of Vienna, [2]Pennington Biomedical Research Center, [3]University of Graz, [4]University Ulm Medical Centre

Background: The patatin-like phospholipase domain-containing protein 3 (PNPLA3) I148M variant is associated with the development of metabolic dysfunction-associated steatotic liver disease, but its metabolic function is not fully understood yet. Hence, there is a growing interest in understanding the role of PNPLA3 in adipose tissue and the liver as key determinants of metabolic flexibility. **Methods:** We analysed white adipose tissue (WAT) from 41 obese women on pioglitazone (30 mg/day for 16 weeks) and a diabetic and hyperlipidaemic mouse model (STAM) receiving HFD supplemented with 0.01% pioglitazone for 2 weeks. We reanalysed published NGS data obtained from Gene Expression Omnibus from inducible adipocyte-specific Pparg knockout mice, hepatocyte-specific Pparg knockout mice, and human adipose stem cell-derived adipose tissues treated with rosiglitazone to validate our *in vitro* data. Mechanistically, we used *in silico* analysis, gene expression analysis, luciferase reporter, and gel shift assay systems to demonstrate the interaction between PNPLA3 and PPARG. **Results:** We observed increased *PNPLA3* mRNA transcripts in the subcutaneous femoral fat but not in the visceral fat of obese women who received pioglitazone. In the STAM mouse, pioglitazone treatment markedly increased expression of *Pnpla3* (+31%) and *Pparg2* (+50%)mRNA and its downstream target genes such as *Fabp4* and *Pgc1a* in the gonadal WAT. In the liver (with lower *PNPLA3* expression compared to WAT), however, pioglitazone treatment did not significantly increase *Pnpla3* and *Pparg* expressions. RNA-seq data analysis from the inducible adipocyte-specific Pparg knockout mice revealed that ablating Pparg reduced *Pnpla3* expression. Interestingly, the PPARG agonist did not affect *Pnpla3* expression in the liver. Mechanistically, rosiglitazone induced *PNPLA3* in human stem cell-derived adipocytes and differentiating SGBS adipocytes (+88%) and significantly increased the luciferase activity in PPARG-PNPLA3 co-transfected Cos 7 cells (+50%), demonstrating PPARG-mediated induction of *PNPLA3* promoter activity. Interestingly, two PPREs at positions -713/-707 (+92%) and -790/-780 (+93%) were bound by the PPARG nuclear protein in the differentiating adipocytes, while mutations of these reduced PPARg binding activity by sites 40% and 60%, respectively. **Conclusion:** PPARG regulates PNPLA3 and this transcriptional regulation is tissue-specific, with profound differences between white adipose tissues and

the liver. Pharmacological agonists for PPARG (glitazones) thereby modulate PNPLA3 expression in a tissue-specific manner.

0060 | MULTIOMICS ANALYSIS REVEALS MYD88-DEPENDENT INHIBITION OF MITOCHONDRIAL OXIDATIVE FUNCTION DURING HYPERAMMONEMIC STRESS CAUSES SARCOPENIA OF CIRRHOSIS

Nicole Welch[1] Srinivasan Dasarathy[1] Amy Attaway[1] Saurabh Mishra[1] Annette Bellar[1] Pugazhendhi Kannan[1] Seshu Pothabathula[1] Jasmin Cunningham[1] Ramesh Rodda[1], [1]Cleveland Clinic

Background: Myeloid differentiation primary response-88 (MyD88) is an adaptor protein that activates NFκB signaling during hyperammonemic stress response (HASR) by direct interaction with the membrane ammonia transceptor, RhBG to cause sarcopenia of cirrhosis. During HASR, skeletal muscle oxidative dysfunction with impaired electron transport chain function with oxidative stress and post-mitotic senescence have been reported. The mechanism(s) of impaired mitochondrial oxidative function and upstream regulators are unknown. We dissected the mechanistic link between MYD88 and mitochondrial oxidative function during HASR and sarcopenia of cirrhosis. **Methods:** Untargeted data (RNAseq, proteomics, metabolomics) were performed in differentiated murine myotubes and muslce tissue. Differentially expressed genes/proteins (DEG/DEPs) in WT or MyD88 knock out (KO) C2C12 myotubes and in muscle from male and female mice with MyD88 muscle specific deletion (msd) or parental controls with/without HASR were determined (n = 8 in each group). MitoCarta3.0, a database containing mitochondrial-targeted proteins was compared against the list of DEG/DEPs and mitochondrial proteins identified. Volcano plots, upset plots, and hierarchical scatter plots were used to visualize DEG/DEPs. Untargeted metabolomics data were analyzed using HILIC (positive/negative modes), with pathway enrichment assessed via KEGG and BioCyc. Validation was performed via immunoblotting for critical proteins in the electron transport chain complexes (OXPHOS) and ACLY phosphorylation. TCA cycle intermediates were measured using GC-MS in myotubes. **Results:** Heatmaps of RNAseq and proteomics data revealed increased expression of OXPHOS components, especially complex I, in MyD88KO during HASR. TCA cycle enzymes (IDH2, ACLY, SHDA) were higher in MyD88KO vs WT myotubes. MyD88^{msd} skeletal muscle showed higher OXPHOS and TCA cycle components (notably ACLY,

MDH2). No sex differences were observed. KEGG analysis identified pyruvate metabolism, fatty acid synthesis, and lipoic acid biosynthesis as enriched pathways (Fig 1A). Volcano plots confirmed higher expression of mitochondrial membrane and OXPHOS proteins in MyD88^{msd} compared to controls with hyperammonemia (Fig 1B). Immunoblots showed lower expression of OXPHOS and phosphorylated ACLY during HASR that were reversed by MyD88 deletion in myotubes and mouse muscle. Impaired Complex I during HASR was significantly ($p < 0.05$) reversed by MyD88 deletion. TCA intermediates (α-KG, citrate, fumarate, malate) were lower with HASR and were restored ($p < 0.05$) with MyD88 deletion. **Conclusion:** Activation of MyD88 during HASR causes mitochondrial oxidative dysfunction and contributes to sarcopenia and contractile dysfunction (frailty) in cirrhosis. Targeting MYD88 is a therapeutic option to reverse mitochondrial dysfunction during HASR and reverse sarcopenia/frailty in cirrhosis.

0061 | SPATIAL ORGANELLOMICS: A NEW WINDOW INTO HEPATOCYTE SUBTYPES, ZONAL DIVERSITY, AND DISEASE PROGRESSION

Daniel Feliciano[1] Raghabendra Adhikari[1], [1]Janelia Research Campus/HHMI

Background: Hepatocyte heterogeneity underlies the liver's capacity to perform diverse metabolic functions and adapt to nutritional and environmental challenges. While this heterogeneity is often characterized at the transcriptional level, organelle architecture—driven by both gene expression and protein-level regulation—may serve as a more direct proxy for functional cell states. However, existing tools have lacked the resolution to connect tissue organization with organelle structure. Here, we introduce Spatial Organellomics (sOrganellomics), a new pipeline combining 3D imaging of hepatic acini, deep-learning-based segmentation, and machine learning to map organelle features in hepatocytes at single-cell resolution. **Methods:** We applied sOrganellomics to mouse liver samples labeled to visualize mitochondria, peroxisomes, and lipid droplets, across three nutritional conditions: control diet, western diet, and control diet plus fasting. Using our pipeline, we segmented individual cells, organelles, and organelle-organelle contacts in 3D and extracted hundreds of organelle metrics per hepatocyte. Machine learning was used to define hepatocyte categories, analyze spatial distributions, and predict nutritional and pathophysiological states. **Results:** Our analysis revealed that hepatocytes display diverse subcellular architectures not only across classical liver zones (portal, mid-lobular, central) but also within each zone, where multiple hepatocyte categories coexist in distinct proportions—highlighting a previously underappreciated intra-zonal heterogeneity. Nutritional perturbations led to a marked reduction in this intra-zonal diversity, indicating constrained cellular plasticity under metabolic stress. Unsupervised clustering identified 11 hepatocyte subtypes based on organelle organization alone, among all three nutritional conditions. These signatures were sufficient for machine learning models to accurately classify hepatocyte categories, dietary states, and early stages of metabolic-associated steatotic liver disease (MASLD) in a mouse model. **Conclusion:** sOrganellomics reveals that organelle architecture serves as a powerful marker of hepatocyte identity and metabolic adaptation. By uncovering intra-zonal heterogeneity and its modulation by diet, our findings offer new insights into liver plasticity and disease progression. This high-resolution strategy may help establish imaging-based biomarkers for MASLD and other liver conditions.

0062 | TRANSCRIPTIONAL REGULATION OF THE HEPATIC ACETYLOME BY NRF2 IN AUTOPHAGY-IMPAIRED LIVER

Kamal Baral[1] Kapil Thapa[2] Leah Spade[1] Ramsey Rohner[1] Ghaidaa Majari[1] Yuhua Xue[1] Gang Liu[1] Krzysztof Moroz[1] Xiao-Ming Yin[1] Bilon Khambu[1], [1]Tulane University School of Medicine, [2]Tulane University School of Science and Engineering

Background: The hepatic acetylome, governed by protein acetylation, plays a critical role in regulating metabolic pathways, epigenetic modifications, signal

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transduction, cell proliferation, and apoptosis. Despite its importance, the mechanisms maintaining acetylome homeostasis in the liver remain poorly understood. This study demonstrates that autophagy is essential for preserving hepatic acetylome integrity through a non-degradative, transcriptional mechanism. **Methods:** We utilized a range of genetically engineered mouse models, including hepatocyte-specific Atg7- and Atg5-deficient mice (hepAtg7$^{-/-}$, hepAtg5$^{-/-}$), inducible Atg7 knockout mice (Atg7$^{Hep\text{-}ERT2}$), and double knockout mice lacking both Atg7 and Nrf2. Pharmacological inhibition of autophagy was achieved using chloroquine and leupeptin, while autophagy activation was induced via fasting and in Becn1$^{F121A/F121A}$ mice. Liver tissues were analyzed for global protein acetylation, acetyl-CoA levels, histone acetylation, and expression of acetyl-CoA biosynthesis enzymes. Promoter analysis was conducted using Benchling to identify Nrf2-ARE binding motifs. Rescue experiments involved intraperitoneal administration of acetyl-CoA. Human liver autopsy samples from normal and cirrhotic patients were evaluated for autophagy markers, acetylation status, and expression of acetyl-CoA biosynthesis enzymes. **Results:** Autophagy-deficient livers exhibited a marked reduction in global protein acetylation across nuclear, cytosolic, mitochondrial, and membrane compartments, despite upregulation of other post-translational modifications such as ubiquitination, SUMOylation, and phosphorylation. Conversely, autophagy activation enhanced hepatic acetylation levels. Mechanistically, autophagy maintained hepatic acetyl-CoA levels by suppressing the expression of key biosynthetic enzymes (Acly, Acss1/2, Mlycd, Pdha1). Replenishment of acetyl-CoA in autophagy-deficient mice restored acetylation levels and mitigated liver injury. Transcriptional profiling identified Nrf2 as a key regulator of these enzymes. Notably, Nrf2 deletion in autophagy-deficient mice restored acetyl-CoA biosynthesis enzyme expression and normalized the hepatic acetylome. These findings were corroborated in human cirrhotic liver samples, which showed reduced autophagy, acetyl-CoA biosynthesis enzyme expression, and protein acetylation. **Conclusion:** Autophagy sustains hepatic acetylome homeostasis through transcriptional regulation of acetyl-CoA biosynthesis enzymes, mediated by Nrf2. This non-degradative role of autophagy reveals a novel regulatory axis with implications for liver metabolism and chronic liver disease.

★ 0063 | OUTCOMES OF ENDOSCOPIC ULTRASOUND-GUIDED SHUNT MODULATION FOR RECURRENT HEPATIC ENCEPHALOPATHY: PUSHING BOUNDRIES OF ENDOHEPATOLOGY

Sahaj Rathi[1] Arpit Shastri[2] Amrita Kalantri[2] Nipun Verma[2] Madhumita Premkumar[3] Sunil Taneja[2] Ajay Duseja[3], [1]Virginia Commonwealth University, [2]Post Graduate Institute of Medical Education and Research, [3]Postgraduate Institute of Medical Education & Research

Background: Spontaneous portosystemic shunts (SPSS) may lead to recurrent/refractory hepatic encephalopathy (rHE) due to shunting of gut-derived toxins from mesenteric to systemic circulation bypassing the liver. Occlusion of SPSS, usually via interventional radiology(IR) transvenous techniques, is known to improve outcomes. Endoscopic ultrasound (EUS) guided transgastric shunt obliteration (ETSO) has recently been described as an effective alternative modality, being considerably versatile and less resource intensive. In patients with rHE and poor liver reserves, shunt obliteration can increase in portal pressures and precipitate decompensation. The novel technique of EUS guided porto-splenic split (EPSS) involves occluding the splenic vein to terminate shunting without increasing portal pressure. It redirects mesenteric flow to the portal vein and splenic outflow to renal vein via the splenorenal shunt. We describe the clinical outcomes of EUS guided shunt modulation procedures, ETSO and EPSS, in rHE. **Methods:** In our retrospective review of prospectively maintained data, patients with recurrent or refractory hepatic encephalopathy despite optimal medical management were evaluated for the presence of a large SPSS($>$ 8mm). Patients who failed prior IR procedures or were not candidates for IR due to technical or financial reasons were offered EUS guided shunt modulation. The procedure was performed by cyanoacrylate glue $\pm$ coil embolization of the shunt(ETSO) or the splenic vein (EPSS) via a transgastric approach. Choice of procedure was based on liver reserves and shunt anatomy. **Results:** EUS guided shunt modulation was performed in 19 patients(ETSO, n = 15 or EPSS,n = 4) ETSO Resolution of OHE was seen in 14 of the 15 patients. Complete obliteration of shunt at index procedure was done for 10 cases. None developed overt HE over median followup of 493(range 7-906) days. Deliberate partial obliteration was performed in 5 cases to reduce risk of decompensation. Recurrence of symptoms necessitated a second session for residual shunt in 3 cases after 2, 12 and 16 months of index procedure. Four patients expired after 7, 50, 110 and 172 days, due to complications unrelated to procedure. EPSS 4

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients underwent EPSS based on poor liver reserves and suitable anatomy(shunt arising close to splenic hilum). All achieved resolution of rHE. Over a median followup of 303(range 209-624) days, only one had an episode of overt HE, precipitated by urinary tract infection, which resolved and did not recur subsequently. One patient expired after 303 days presumably due to renal failure after diarrhea. None of the patients developed procedure related serious adverse events. No significant change in MELD scores was noted at 3, 6, and 12 months of follow up. **Conclusion:** EUS-guided shunt modulation procedures can achieve effecrive and durable resolution of rHE, especially in patients poor liver reserves and who are not candidates for IR procedures.

0064 | STENT DIAMETER AND MEDICATIONS ARE NOT ASSOCIATED WITH REDUCED ODDS OF HEPATIC ENCEPHALOPATHY AFTER TIPS: A CONTEMPORARY MULTICENTER COHORT STUDY FROM THE ALTA STUDY GROUP

Yael Nobel[1] Bartley Thornburg[2] Lisa VanWagner[3] Justin Boike[2] Michael Fallon[4] Pallav Kolli[5] Adnan Said[6] Carrie Frenette[7] Aparna Goel[8] Jennifer Lai[5] Sumeet Asrani[9] Giuseppe Joseph Morelli[10] Nicholas Lim[11] Arun Jesudian[12] Adam Deising[13] Sonali Paul[14] Doug Simonetto[15] Erin Spengler[16] Mehnush Hameie[2] Cynthia Padilla[2] Dyanna Gregory[3] Elizabeth Verna[1], [1]Columbia University Irving Medical Center, [2]Northwestern University, [3]UT Southwestern, [4]Banner Health, [5]UCSF, [6]University of Wisconsin, [7]Gilead, [8]Stanford University, [9]Baylor Scott & White Health, [10]Tulane University, [11]University of Rochester, [12]Cornell University Medical Center, [13]Scripps Health, [14]University of Chicago, [15]Mayo Clinic, [16]VA UT Health

Background: A feared complication after transjugular intrahepatic portosystemic shunt (TIPS) is the development of severe hepatic encephalopathy (HE). Current strategies for preventing HE include patient selection, small stent diameter, and use of prophylactic medications (lactulose or rifaximin). Contemporary incidence and predictors of severe HE after TIPS, and whether current preventive strategies are effective, are unknown. **Methods:** This is a study from the Advancing Liver Therapeutic Approaches in Portal Hypertension (ALTA), a multi-center prospective cohort study across 13 U.S. centers of adults ($\geq$18 years) who were scheduled for TIPS between 7/2019-1/2025 and completed up to 5 years of follow-up. Patients who successfully underwent TIPS and had post-TIPS hospitalization data available were included in the current study. Severe HE after TIPS was defined as either repeated ($>=2$) hospitalizations or TIPS revision for the primary indication of HE during the study period. Predictors of severe HE were evaluated using multivariable logistic regression. **Results:** 702 TIPS recipients with a median of 306 days (IQR 101-658) of follow-up were included. Overall, 201 subjects required at least one post-TIPS re-hospitalization, 97 required repeated re-hospitalizations, and 26 required TIPS revision for a primary indication of HE. Subjects who developed severe HE after TIPS ($n=105$; 15% of cohort) were older (median 61 vs. 58 years, $p<0.01$), more likely to have diagnosis of HE before TIPS (49% vs. 38%, $p=0.06$), more likely to have TIPS indication of volume overload (ascites or hepatic hydrothorax) as opposed to other indications (67% vs. 49%, $p<0.01$), and more likely to be on renal replacement therapy at time of TIPS (4% vs. 1%, $p=0.02$). Following TIPS, 52% and 39% of patients were prescribed lactulose and rifaximin, respectively. MELD-Na at TIPS, final internal stent diameter, and prescription of preventive medications did not differ significantly between subjects who did or did not develop severe HE. When adjusting for covariates, TIPS recipient-related factors (age, TIPS indication, renal failure) were significant predictors of severe HE, while stent diameter and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

medications did not reduce odds of severe HE (Table). **Conclusion:** In this contemporary, multicenter cohort with prospectively-assessed clinical and procedural factors, advanced age and clinical decompensation (volume overload, renal dysfunction) were the main drivers of severe HE after TIPS, while other factors commonly considered for HE prevention (MELD-based selection criteria, small stent diameter, and preventive medications) did not affect odds of severe HE.

Table. Multivariable logistic regression of adjusted odds of severe HE after TIPS.

	Odds Ratio (95% CI) of Severe HE after TIPS	P-value
Final TIPS stent diameter		
Stent diameter <=8mm	1.0 (Ref)	-
Larger stent diameter	0.8 (0.5-1.4)	0.54
Rifaximin or Lactulose Prescribed at TIPS	1.3 (0.8-2.3)	0.34

0065 | BEACON: AT-HOME, SELF-ADMINISTRATION OF A TEST FOR CRITICAL FLICKER FREQUENCY AS A SCREENING TEST FOR MINIMAL HEPATIC ENCEPHALOPATHY

Philip Vutien[1] Richard Li[2] Ravi Karkar[3] James Fogarty[2] Sean Munson[2] Sabrina Omer[2] Michael Yacoub[4] George Ioannou[1], [1]University of Washington Medical Center, [2]University of Washington, [3]University of Massachusetts Amherst, [4]Pacific Northwest University of Health Sciences

Background: Critical flicker frequency (CFF) is the maximum frequency at which an observer perceives a light source as flickering instead of a steady continuous light. CFF is a validated, objective screening test for hepatic encephalopathy, which causes a reduction in CFF. We previously developed "Beacon" (Figure 1), a portable device that enables self-administration of accurate CFF measurement. This study aimed to assess the feasibility and reliability of at-home, repeated CFF testing in patients with cirrhosis. **Methods:** We recruited 21 patients with cirrhosis, after excluding those with recent alcohol use, color blindness, or severe vision impairment. Each participant received a Beacon device and a smartphone with pre-installed software to measure CFF using two different protocols: 1) method of limits-descending (MOL-D) and 2) forced choice. Participants were instructed to complete ≥ 5 tests (using both MOL-D and forced choice protocols) per week for the first 2 weeks, then 1 test per week for at least 4 weeks thereafter. Outcome measures include testing protocol adherence, CFF stability over time, and duration to complete the tests. **Results:** Among the 21 patients, 76% were male and 76% were Caucasian. Most patients had alcohol-related liver disease (43%), chronic hepatitis C (19%), or metabolic dysfunction-associated steatohepatitis (19%) as the etiology for their liver disease. Mean MELD score at study enrollment was 13.5 and eight (38%) had a prior history of HE. 18 participants (86%) completed the full six-week testing schedule (Figure 2), including both daily and weekly measurements. 3 participants (ID# 9, #18, #20) dropped out after completing only daily testing. Median CFF values ranged, across all patients, from 35.7-50.6 Hz (median 42.7 Hz) for descending only and 37.5-53.3 Hz (median 43.7 Hz) for forced choice. Overall, CFF measurements were stable over time: median within-patient IQR was 1.67 Hz (MOL-D) and 2.34 Hz (forced choice). The forced choice protocol required significantly more time to complete (median 4.91 min, IQR 3.75) compared to MOL-D (median 2.73 min, IQR 1.25). **Conclusion:** Beacon is a novel, portable, self-administered device for at-home CFF testing in patients with cirrhosis. This device demonstrated high

patient adherence and stable measurements over time. Future studies should assess the role of longitudinal CFF self-monitoring in predicting overt HE and related outcomes.

Figure 1: Beacon light source and paired smartphone application which controls the light source.

Figure 2: At-home testing results for patients: daily CFF testing with MOL-D and forced choice methods for 2 weeks, then weekly.

0066 | DIFFERENTIAL EFFECTS OF VASOPRESSIN AND TERLIPRESSIN AS ADJUNCT VASOPRESSORS ON HEMODYNAMIC PARAMETERS IN PATIENTS WITH CIRRHOSIS AND SEPTIC SHOCK: FINAL RESULTS: FROM THE VITEL-C RANDOMIZED CONTROLLED TRIAL [NCT05315557]

Rakhi Maiwall[1] Vishnu Girish[1] Harsh Tevethia[1] Mohit Prajapati[1] Fagun Sharma[1] Prashant Agarwal[1] Satender Pal Singh[1] Rajan Vijayaraghavan[1] sumegh talwalkar[1] Ayush Jain[1] Bindiya Arora[1] Priyanka Sharma[1] Charvi Nayyar[1] Sherin Thomas[1] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences (ILBS), New Delhi

Background: Critically ill patients with cirrhosis and septic shock (CIC) carry a substantial risk of multiorgan dysfunction. Although norepinephrine is first-line, adjunctive vasopressors—vasopressin (VASO) and terlipressin (TERLI)—may differentially influence hemodynamics, cardiorenal biomarkers, and endothelial function. **Methods:** In this open-label randomized trial, 120 adult CIC were assigned 1:1 to VASO (0.03 U/min; n = 60) or TERLI (1 mg/24 h; n = 60) alongside norepinephrine (NE), after they were unresponsive to NE. **Results:** One hundred and twenty CIC patients (mean age 46.8 ± 10.4 years; 97% male; 41% alcohol-related liver disease) were equally randomised to receive vasopressin (VASO; n = 60) or terlipressin (TERLI; n = 60). Baseline parameters—including mean arterial pressure (MAP; 68.24 ± 10.15 vs. 67.01 ± 9.82 mmHg), arterial lactate (3.12 ± 1.27 vs. 2.89 ± 1.31 mmol/L), MELD score (28.4 ± 5.89 vs. 29.9 ± 8.96) and KDIGO stage distribution (stage 0: 34% vs. 38%; stage 1: 34% vs. 22%; stage 2: 16% vs. 20%; stage 3: 16% vs. 20%)—were comparable (all $p > 0.05$). Shock reversal at 6 h (58% vs. 48%; $p = 0.32$) and 72 h (34% vs. 50%; $p = 0.11$) did not differ; however, at 3 h, TERLI showed significant shock reversal(23% vs 6%, $p = 0.02$). Urine output was significantly greater with TERLI at 6 h (53.1 ± 22.22 vs. 41.8 ± 21.62 mL/h; $p = 0.006$) and 12 h (48.19 ± 24.61 vs. 39.75 ± 20.15 mL/kg; $p = 0.044$), while KDIGO stage at 72 h remained similar ($p = 0.4$). Hemodynamic assessment demonstrated higher systemic vascular resistance (SVR) with VASO at 12 h (1250 ± 300 vs. 1050 ± 250 dynes/cm^5 $p < 0.05$) and 24 h (1300 ± 320 vs. 1100 ± 280 dynes/cm^5; $p < 0.05$), and greater lactate clearance with VASO at 6 h (–2.81 ± 16.5% vs. –10.65 ± 18.3%; $p = 0.02$) and 24 h (–0.07 ± 17.5% vs. –14.8 ± 21.7%; $p < 0.001$). Biomarker profiling revealed greater reductions in angiopoietin-1 (ANG-1; 239.9 ± 45.8 → 206.3 ± 35.2 pg/mL) and urinary neutrophil gelatinase-associated lipocalin (uNGAL; 1155.8 ± 170.6 → 1025.7 ± 155.7 ng/mL) with VASO versus TERLI (224.9 ± 102.2 → 218.3 ± 60.4 pg/mL; 1 134.7 ± 183.6 → 999.98 ± 107.4 ng/mL), whereas N-terminal pro–B-type natriuretic peptide (NT-proBNP) decreased with VASO (2.51 ± 3.69 → 2.21 ± 2.12 pg/mL) but increased with TERLI (1.34 ± 0.73 → 1.49 ± 0.48 pg/mL). Other secondary outcomes—including duration of mechanical ventilation and renal-replacement therapy—did not differ. Adverse events (34% vs. 8%; $p = 0.001$) and rebound hypotension (44.1% vs. 21.2%; $p = 0.046$) were significantly more frequent with TERLI. **Conclusion:** In CIC with septic shock, vasopressin is comparable to terlipressin as an adjunct to norepinephrine in reversing shock. While terlipressin led to a faster reversal of shock, it was associated with a higher incidence of adverse events and rebound hypotension. A distinct biomarker profile was noted with vasopressin conferring greater reductions in ANG-1 and NGAL, whereas terlipressin increased NT-proBNP.

0067 | THE USE OF TERLIPRESSIN IS ASSOCIATED WITH LOWER MORTALITY AND LIVER-RELATED COMPLICATION EVENTS COMPARED TO THE USE OF NOREPINEPHRINE IN PATIENTS WITH DECOMPENSATED CIRRHOSIS: A MULTINATIONAL ANALYSIS

Christina Lee[1] Donghyun Ko[2] Do Han Kim[3] Paul Kroner[4] Raffi Karagozian[1], [1]Tufts Medical Center, [2]Yale New Haven Health/Bridgeport Hospital, [3]Mount Sinai Morningside & West Hospital, [4]Riverside Health System

Background: Terlipressin improves and reduces hepatorenal syndrome (HRS) more than norepinephrine (NE) in patients with decompensated cirrhosis, by vasoconstricting the splanchnic circulation, lowering portal hypertension, and thus improving renal blood flow. There is also data suggesting that the use of terlipressin reduces ascites and variceal bleeding in patients with decompensated cirrhosis, but data on other complications remain contradictory. Thus, we aim to investigate the impact terlipressin has on various complications of decompensated cirrhosis when compared with NE in a global patient population setting. **Methods:** In this retrospective cohort study, a total of 958 patients with decompensated cirrhosis were investigated. The TriNetX, a global network database, was utilized for this study. A total of 479 patients on terlipressin and 479 patients on NE were matched based on the following characteristics: age, gender, race/ethnicity, comorbidities (such as, but not limited to, esophageal/gastric varices, chronic hepatic failure, HRS, hepatopulmonary syndrome, ascites, spontaneous bacterial peritonitis, liver transplant status, HTN, DMII, CKD), medications (carvedilol), MELD labs. After matching the demographics and clinical characteristics of patients with decompensated cirrhosis in the groups receiving terlipressin vs. NE, the following clinical primary outcomes were analyzed for both 30 and 90 days interval: all cause-mortality, hepatic decompensation, major adverse liver outcomes (MALO), ascites, hepatic encephalopathy (HE), variceal bleeding, spontaneous bacterial peritonitis (SBP), liver transplantation, paracentesis (Table 1). The Cox proportional hazard model was used to calculate the hazard ratio (HR) between the terlipressin and NE group. **Results:** Within both 30 and 90 days of receiving terlipressin, patients with decompensated cirrhosis had a statistically significant reduction in all-cause mortality [HR: 0.531, 0.589], HE [HR: 0.594, 0.721], and paracentesis [HR:0.527, 0.545], respectively. The use of terlipressin led to a reduction in ascites in both 30 and 90 days interval [0.920, 0.934] respectively; however, the values were not stastistically significant. **Conclusion:** Our retrospective study demonstrated improvement in complications of decompensated cirrhosis with the use of terlipressin, confirmed with the significant reduction in all cause mortality, HE, and the frequency of needed paracentesis. Additionally, the reduction in the frequency of paracentesis may correlate with the reduction in ascites. Overall, terlipressin reduced the majority of complications related to decompensated cirrhosis, favoring the use of terlipressin over norepinephrine in patients with decompensated cirrhosis.

Table 1. Clinical Outcomes of Patients With Decompensated Cirrhosis using Terlipressin vs Norepinephrine

Outcomes	Terlipressin Included	Terlipressin Events	Norepinephrine Included	Norepinephrine Events	HR (95% CI)
30 days					
All-cause mortality	400	159	416	242	**0.531 (0.434, 0.649)**
Hepatic decompensation	479	147	479	154	0.834 (0.665, 1.047)
MALO	479	189	479	180	0.945 (0.770, 1.159)
Ascites	479	86	479	83	0.920 (0.680, 1.245)

Background: Terlipressin became the first FDA-approved therapy for HRS-AKI in September 2022. We present its initial experience at 16 U.S. academic medical centers. **Methods:** Consecutive patients with HRS-AKI treated with terlipressin from approval through May 2024 were followed longitudinally for 90 days after drug initiation. Patients were categorized as meeting Standard Criteria (conforming to FDA labeling guidance) or Extended Criteria (acute on chronic liver failure [ACLF] grade 3, serum creatinine [sCr] >5 mg/dL, or hypoxia at initiation). Primary outcomes were HRS Reversal (sCr <1.5 mg/dL plus reduction ≥ 0.3 mg/dL at end of treatment) and Overall Response (Complete and Partial Response, defined by the 2015 International Club of Ascites). Fine and Gray competing risks models [with liver transplant (LT) as a competing event] were used to assess 90-day mortality. **Results:** 243 patients were analyzed: median age 58 years, 59.7% male, 55.6% alcohol-associated cirrhosis, initiation sCr 2.79 [IQR 2.27, 3.57] mg/dL, MELD 3.0 31 [26, 37]. 40.5% died and 28.4% received LT by 90 days. Patients received 200 [125, 350] g albumin prior to initiation and 62.5 [0, 125] g while on terlipressin. HRS Reversal occurred in 30.9%, Overall Response in 55.1% (29.6% Complete Response, 25.5% Partial Response). SCr at initiation was inversely associated with both HRS Reversal ($p<0.001$) and Overall Response ($p=0.03$, Figure). 49% patients met Standard Criteria while 51% met Extended Criteria, most commonly due to ACLF grade 3 (44.9%). Standard Criteria was associated with higher rates of Overall Response (62.9% vs. 47.1%; $p=0.019$), HRS Reversal (35.5% vs. 26.1%; $p=0.146$), and fewer adverse events leading to terlipressin discontinuation (12.1% vs. 22.7%; $p=0.044$), including respiratory failure/new oxygen requirement (5.6% vs. 13.4%; $p=0.063$). In adjusted analysis, HRS Reversal was not associated with reduced mortality (aHR 0.70 [95% CI 0.38, 1.28]; $p=0.25$) but Overall Response was (aHR 0.57 [0.38, 0.85]; $p=0.006$). **Conclusion:** Terlipressin was more effective and safer when adhering to FDA labeling for patient selection, which reinforces the importance of this guidance. Overall Response appears to be a relevant clinical endpoint for future studies.

★ 0069 | GENERATION OF MACRO-SCALE FUNCTIONAL BILIARY TREES WITH PRIMARY CILIA AND ENHANCED INJURY RESISTANCE

Jun Li[1] Shiwen Ma[1] Jiaxian Chen[1] Meiqian Hu[1] Jiaojiao Xin[1] Jing Jiang[1] Dongyan Shi[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: The reconstruction of functional biliary trees (FBT) is crucial in the development of bioengineered liver. However, the decellularized liver scaffolds (DLS) as the scaffold of FBT exhibit mechanical instability that leads to luminal collapse and subsequent hypoxic stress, severely compromising FBT functions. Furthermore, existing engineered biliary structures lack sufficient injury resistance to withstand the pathological microenvironment of end-stage liver disease. **Methods:** This work aimed to construct macro-scale FBT with enhanced injury resistance using rat DLS optimized by genipin and mouse primary cholangiocytes. The newly developed FBTs were systematically evaluated through functional assays, transcriptomic analysis, and hepatotoxic drug-induced injury testing to validate their structural stability and injury resistance. **Results:** The FBT generated with genipin-crosslinked DLS demonstrated enhanced structural stability and fluid mechanical properties, which significantly improved cholangiocyte adhesion and attenuated hypoxia response as evidenced by transcriptomic profiling. Morphological evaluation revealed that the bioengineered FBT recapitulated the hierarchical branching architecture of native biliary networks, with well-organized luminal structures and proper apical-basal polarity. Scanning electron microscopy identified elongated, upright primary cilia projecting from the luminal cholangiocytes, while JC-1 staining confirmed preserved mitochondrial membrane potential—indicative of cellular health. Functionally, the FBT exhibited enhanced bile acid transport, marked by the upregulation of *Slc51a/Slc51b* (encoding OST-α/OST-β) and *Abcc3* (encoding MRP3), along with enhanced retinoic acid (RA) synthesis capacity. Notably, such FBT exhibited unique injury resistance, maintaining cellular homeostasis and bile acid transport function after hepatotoxic drug exposure. Transcriptomic analysis confirmed that the newly developed FBT maintained anti-injury signatures and RA synthesis capacity compared to non-crosslinked controls. **Conclusion:** Our macro-scale FBT, with primary ciliary architecture and enhanced injury resistance, provides a promising strategy for bioengineered liver construction and clinical translation.

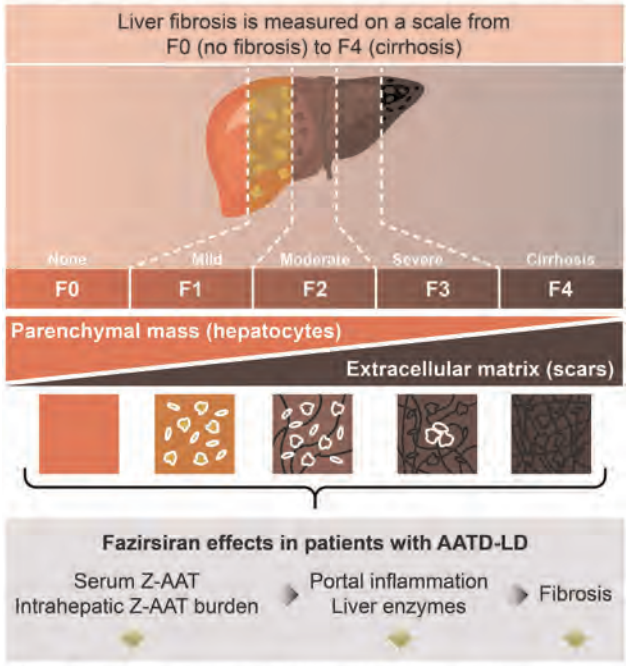
of Florida, Gainesville, FL, USA, [4]University Hospital RWTH Aachen, Aachen, Germany

Background: Fazirsiran, a GalNAc siRNA targeting misfolded alpha-1 antitrypsin (Z-AAT; coded by *SERPINA1*) in the liver, is in phase 3 development for AAT deficiency-associated liver disease (AATD-LD). Fazirsiran selectively enters hepatocytes via the asialoglycoprotein receptor (ASGPR; coded by *ASGR1*). It is unclear whether *ASGR1* expression is altered in advanced fibrosis or if dense extracellular matrix in fibrotic tissue may restrict fazirsiran delivery to hepatocytes. Here we assessed *ASGR1* and *SERPINA1* expression across fibrosis stages and evaluated the impact of fibrosis on fazirsiran uptake and activity. **Methods:** Liver tissue bulk transcriptomics and single nuclei/cell (sn/sc) RNAseq were used to identify genes dynamically modulated in advanced fibrosis from 10 studies of several fibrotic liver diseases. Overall *ASGR1* and *SERPINA1* expression was assessed in samples from: AATD-LD with Pi*ZZ vs healthy controls with a Pi*MM genotype; PSC vs healthy controls; advanced MASH (F3/4) vs MASLD or healthy controls. *ASGR1* and *SERPINA1* expression in hepatocytes was evaluated using snRNAseq from patients with MASLD or MASH, and scRNAseq from other cirrhosis etiologies vs healthy controls. Analysis of fazirsiran phase 2 studies (AROAAT-2001/-2002 [NCT03945292, NCT03946449]) investigated whether fazirsiran's effects on silencing *SERPINA1*, reducing Z-AAT burden, improving liver function and reducing fibrosis were affected by baseline fibrosis status. **Results:** Across bulk transcriptomic datasets, *SERPINA1* expression was maintained while *ASGR1* expression was reduced in advanced fibrosis (F3/4). However, sn/sc RNAseq data demonstrated that expression of both *ASGR1* and *SERPINA1* in hepatocytes was sustained in advanced fibrosis, even in cirrhosis. In fazirsiran phase 2 studies, hepatic Z-AAT burden tended to be elevated in patients with AATD-LD and advanced fibrosis (median 62 and 33 nmol/g for F3/4 vs F0–2, respectively; Wilcoxon test, $p = 0.09$). Advanced baseline fibrosis (F3/4 [n = 23] vs F0–2 [n = 8]) did not impair fazirsiran's effects vs baseline on reducing: serum Z-AAT (–89 vs –90%; $p = 0.58$), hepatic Z-AAT burden (–94 vs –89%; $p = 0.28$), portal inflammation (–0.5 vs 0.0; $p = 0.86$), liver enzymes (ALT –54 vs –28%, $p = 0.02$; AST –32 vs –14%, $p = 0.09$; GGT –40 vs –13%, $p = 0.03$), and liver stiffness measured by FibroScan (–1.38 vs –1.12 kPa, $p = 0.44$). **Conclusion:** Hepatocellular *ASGR1* and *SERPINA1* expression is constant in patients with advanced fibrosis stages although loss of parenchymal cells (hepatocytes) may lead to reduced overall *ASGR1* expression. Analysis of fazirsiran phase 2 studies indicates that fazirsiran is effective in both advanced and early fibrosis. Collectively, these findings support further development of fazirsiran in patients with AATD-LD and advanced fibrosis, given that accumulation of the disease-causing Z-AAT protein remains high. Writing support provided by S Chambers, Oxford PharmaGenesis.

Figure. Advanced fibrosis does not affect *SERPINA1* or *ASGR1* expression in hepatocytes, even in cirrhosis, hence outcomes from fazirsiran treatment in patients with AATD-LD are not affected by baseline fibrosis status (F3/4 vs F0–2).



AATD-LD, alpha-1 antitrypsin deficiency-associated liver disease; Z-AAT, misfolded alpha-1 antitrypsin.

0071 | INDUCIBLE DUAL LOSS OF β- AND γ-CATENIN IN BILE DUCTS LEADS TO CHOLESTATIC INJURY AND MORTALITY OR REPAIR BASED ON THE EXTENT OF CELL JUNCTION LOSS

Vik Meadows[1] Yekaterina Krutsenko[1] Elena Provencal[1] Minakshi Poddar[1] Sucha Singh[1] Satdarshan (Paul) Monga[1], [1]University of Pittsburgh

Background: Loss of β-catenin in adherens junctions is compensated by γ-catenin, a homologous desmosomal protein. Previously, we have shown dual loss of β- and γ-catenin in liver epithelial cells leads to progressive intrahepatic cholestasis and mortality. Loss of these catenins in hepatocytes alone led to cholemia, but without notable mortality or morbidity. In this study we determine any impact of loss of both catenins from cholangiocytes on hepatic health. **Methods:** We utilized Ctnnb fl/fl; Jup fl/fl mice with Opn-iCreERT2+/- to delete both β-catenin (*Ctnnb1*) and γ-catenin (*Jup*) from cholangiocytes. Littermate control with no Opn-iCreERT2+/+ were used as controls. All mice received tamoxifen (100 mg/kg) dissolved in corn oil injected intraperitoneally. Mice were randomly assigned to two groups: DKO2 received 2 doses of tamoxifen and DKO4 received 4 doses of tamoxifen. Both male and female mice were used in this study. **Results:** DKO2 mice showed morbidity and elevated ALT, AST, and total bilirubin levels by 2 weeks but normalized by 6 weeks post-injection. In contrast, DKO4 mice exhibited severe biliary infarcts, over 20% body weight loss by 2 weeks, and 100% mortality by 5 weeks. Total bile acids increased in DKO2 (at 2 weeks) and DKO4 (all time points) compared to controls. Histological analysis indicated immune cell infiltration, stellate cell activation, and severe portal fibrosis in DKO4 mice, along with increased bile duct mass. DKO2 mice displayed trends towards increased bile duct mass, fibrosis, and inflammation that resolved at 6 weeks post-injection. Single-nucleus RNA sequencing revealed stressed hepatocytes in DKO4, suggesting mitochondrial distress and inflammation. In DKO4 cholangiocytes, RUNX3 and IL12 signaling pathways linked to fibrosis were enriched. Increased expression of myofibroblast genes in DKO4 hepatic stellate cells indicated activated fibrosis progression. DKO2 also showed an increase in Sox9-positive cells in the portal area, some being HNF4-positive, indicating biliary program activation in hepatocytes. **Conclusion:** The loss of β- and γ-catenin from cholangiocytes can cause severe intrahepatic cholestatic injury, depending on bile duct integrity and an intact cholangiocyte population. In DKO4 mice, severe bile duct loss leads to significant liver dysfunction and death, while DKO2 mice show a reparative response to cholestatic injury via increased hepatocyte-to-biliary reprogramming. Understanding the mechanisms that promote this process may help develop novel cholangiopathy therapies.

0072 ★ NEW SUBMISSION | NEW INSIGHTS INTO PATHOGENIC MECHANISMS OF LIVER FIBROSIS IN HEMOCHROMATOSIS

Xia Xiao[1] Yongtao Wang[2] Raymond Chung[2] Jodie Babitt[1], [1]Massachusetts General Hospital/Harvard Medical School, [2]Massachusetts General Hospital

Background: Hemochromatosis is a disorder that leads to excessive iron accumulation in the liver, with ~70% of patients eventually developing liver cirrhosis through mechanisms that remain unknown. Mutations in hemochromatosis genes, HFE, TFR2, and HJV, cause reduced hepatic SMAD1/5/8 signaling, which is critical not only for systemic iron regulation but also for liver fibrosis, as we showed previously. However, the specific mechanism by which defective hepatic SMAD1/5/8 signaling contributes to liver fibrosis is poorly understood. SMAD1/5/8 and SMAD2/3 signaling pathways can counter-regulate each other through a negative feedback loop, and both pathways require SMAD4 to proceed with signal transduction. Here we investigated whether excessive hepatocyte SMAD2/3 signaling, as a consequence of hepatocyte SMAD1/5/8 signaling deficiency, contributes to liver fibrosis in the context of hemochromatosis. **Methods:** To investigate SMAD2/3 pathway activity, we measured phosphorylated (p)SMAD2/3 in isolated primary hepatocytes from *Smad1/5/8* hepatocyte conditional knockout (CKO)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

mice. We then generated mice with a combined deletion of hepatocyte *Smad4* together with *Smad1/5/8* to eliminate both SMAD 2/3 and SMAD1/5/8 signals, performed RNAseq analysis and compared iron levels and liver fibrosis between *Smad1/5/8/4* CKO mice and *Smad1/5/8* CKO mice. **Results:** pSMAD2/3 levels were increased in *Smad1/5/8* KO hepatocytes compared to Cre- controls. As previously reported, Smad1/5/8 CKO mice developed iron overload, spontaneous liver injury and fibrosis, as indicated by increased liver injury markers (serum ALT, bilirubin), enhanced collagen accumulation (Sirius Red Staining), and elevated liver fibrosis markers (*Acta2* and *Col1a1*). In contrast, although *Smad1/5/8/4* CKO mice had a similar degree of iron overload, deletion of hepatocyte *Smad4* prevented the spontaneous liver injury and fibrosis, and improved liver function observed in *Smad1/5/8* CKO mice. This is evidenced by RNAseq results and reductions in all liver injury/fibrosis markers in *Smad1/5/8/4* CKO mice, bringing them in line with those in Cre- littermates. **Conclusion:** The liver injury and fibrosis in *Smad1/5/8* CKO mice is SMAD4-dependent, suggesting a potential pathogenic role of hepatocyte SMAD2/3 signaling in SMAD1/5/8 deficient hemochromatosis. This study represents the first investigation into the molecular mechanisms underlying liver fibrosis in hemochromatosis beyond the role of iron overload, paving the way for new therapeutic advances.

0073 | RAPIDLY IMPROVED CU BALANCE IN WILSON DISEASE PATIENTS ON TIOMOLYBDATE CHOLINE

Aftab Ala[1] Thomas Sandahl[2] Anna Czlonkowska[3] Chandler Robinson[4] Andrew Cittadine[4] Valentina Medici[5] Karl Heinz Weiss[6] Frederick Askari[7], [1]Kings College Hospital, [2]Aarhus University Hospital, [3]Institute of Psychiatry and Neurology, [4]Monopar Therapeutics, [5]University of California Medical Center, [6]Stadtmission Heidelberg, [7]University of Michigan Medical Center

Background: Wilson disease (WD) is a rare autosomal recessive disorder caused by copper (Cu) accumulation in the liver and brain due to mutations in the P-type ATPase Cu transporter ATP7B. Tiomolybdate choline (TMC) is an oral once daily Cu-binding agent being investigated for the treatment of WD. The current oral chelators for WD present a less than satisfactory treatment in WD patients as they can cause neurological worsening, potential debilitating side effects, and have multiple times per day dosing regimens. **Methods:** This open-label, single-arm Phase 2 trial evaluated the effect of once daily repeat-dose TMC on Cu balance, safety, and tolerability in patients with WD. To determine Cu balance, patient intake (food and drink) and output (feces and urine) were collected and analyzed for Cu content during a pre-treatment baseline period (study days -4 through -1) and two treatment periods (study days 1-8 and 25-39). In the first treatment period, patients received 15 mg/day. In the second treatment period, the dose was increased to 30 mg/day on study day 29, except in patients who experienced an elevation in alanine aminotransferase (ALT) and were reduced to 15 mg every other day. **Results:** A total of 9 WD patients were enrolled. One patient discontinued the study early on due to a protocol violation of failing to discontinue penicillamine treatment. In the 8 who completed the study, the cumulative mean daily Cu balance was statistically significantly lower compared to pre-treatment baseline during the TMC 15 mg/day period (days 1-28) and during the whole study period (days 1-39). This improvement was due to increased fecal Cu excretion with TMC treatment. No clinically significant changes were observed in laboratory parameters, vital signs, physical examinations, or ECG results. Any elevations in ALT that occurred were grade 1 or 2 and reversible with dose modulation. No serious adverse events or deaths were reported, and no treatment-emergent adverse events (TEAEs) led to TMC discontinuation. **Conclusion:** TMC treatment resulted in a rapid and persistent improvement in daily Cu balance, due to increased fecal excretions of Cu. No significant safety issues were identified, and all TEAEs were reversible. Combined with the long-term efficacy and safety data presented at EASL 2025, the results from this key Cu balance trial indicate that TMC may provide meaningful clinical benefit in WD patients and could serve as a possible future model for early-stage drug development programs in WD.

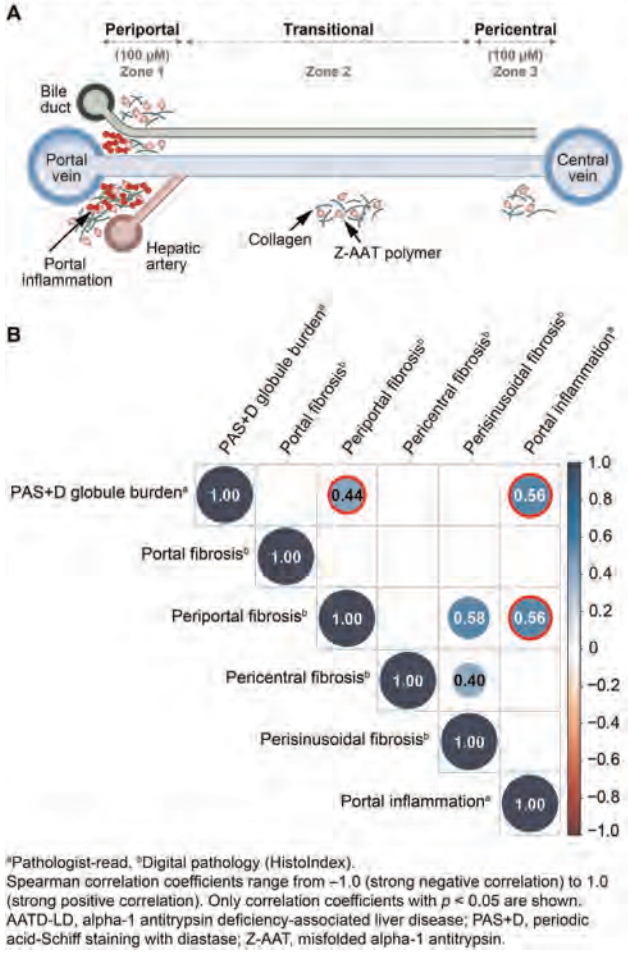
0074 | ARTIFICIAL INTELLIGENCE-BASED QFIBROSIS® ANALYSIS CORRELATES WITH CHANGES IN HISTOLOGICAL FEATURES IN ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE FOLLOWING TREATMENT WITH FAZIRSIRAN

Vandana Gupta[1] Feng Hong[1] Xinhua Hu[1] Ying-Wooi Wan[1] Jen-Chieh Chuang[1] Jie Cheng[1] William Weber[1] Natasha Darras[1] Susana Gonzalez[1] Paresh Thakker[1] Nirav Desai[1] Thomas Schluep[2] James Hamilton[2] Kutbuddin Akbary[3] Dean Tai[3] Pavel Strnad[4] Virginia Clark[5] Romil Saxena[6] Kay Washington[7] Cynthia Behling[8], [1]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [2]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [3]HistoIndex Pte Ltd, Singapore, Singapore, [4]University Hospital RWTH Aachen, Aachen, Germany, [5]University of Florida, Gainesville, FL, USA, [6]Emory School of Medicine, Atlanta, GA, USA, [7]Vanderbilt University Medical Center, Nashville, TN, USA, [8]Independent Pathologist Consultant, San Diego, CA, USA

Background: Change in liver fibrosis is considered a clinically meaningful endpoint for the evaluation of investigational therapies in liver disease; automated scoring methods that objectively evaluate histological changes in liver fibrosis over time are needed. qFibrosis® (qF) is an artificial intelligence (AI)-based fibrosis quantification method that incorporates collagen morphology and zonal distribution (Figure A). This study aimed to compare qF analyses with histological liver features in patients with alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD) treated with fazirsiran (an investigational small interfering RNA therapy) using data from phase 2 clinical trials. **Methods:** Liver biopsy samples from fazirsiran- or placebo-treated patients with AATD-LD enrolled in AROAAT-2001/-2002 trials (NCT03945292/NCT03946449) were analyzed by qF. Previously developed models were used to quantify qF as individual composite index values for a given sample (Gupta V *et al. J Hepatol* 2025;82:S719). Correlation of qF (METAVIR) stage and continuous value with intrahepatic misfolded alpha-1 antitrypsin (Z-AAT) burden assessed by periodic acid-Schiff staining with diastase (PAS+D) and histological features (portal inflammation, interface hepatitis, hepatocyte cell death) were evaluated by Spearman correlation analysis. **Results:** Overall, data from 41 patients from AROAAT-2001 (n = 25) and AROAAT-2002 (n = 16) were analyzed. When analyzed cross-sectionally (78 pre-/post-treatment visit data points), qF (METAVIR) stage and continuous value positively correlated with PAS+D globule burden, portal inflammation, interface hepatitis and hepatocyte cell death. Longitudinal analysis demonstrated that change in qF (METAVIR) stage and continuous value post-treatment with fazirsiran (29 data points) correlated with change in PAS+D globule burden, portal inflammation and interface hepatitis. After treatment with fazirsiran, change in PAS+D globule burden positively correlated with change in portal inflammation (46 data points; $\rho = 0.56$; $p < 0.0001$), specifically periportal fibrosis (37 data points; $\rho = 0.44$; $p < 0.001$; Figure B). **Conclusion:** METAVIR fibrosis assessed by digital pathology (qF analyses) positively correlated with PAS+D globule burden, portal inflammation, interface hepatitis and hepatocyte cell death in liver biopsy samples from patients with AATD-LD. This study suggests a spatial and pathobiological relationship between change in disease-driving Z-AAT globule burden and changes in portal inflammation and liver fibrosis after fazirsiran treatment. AI-based digital pathology approaches may support therapeutic development in AATD-LD but require validation in larger cohorts with longer observation periods. Writing support provided by R Tooze, Oxford PharmaGenesis.

Figure. (A) Illustration of the zonal locations of fibrosis and (B) correlation of change in PAS+D globule burden with portal-based inflammation and periportal fibrosis in patients with AATD-LD.



[a]Pathologist-read, [b]Digital pathology (HistoIndex).
Spearman correlation coefficients range from −1.0 (strong negative correlation) to 1.0 (strong positive correlation). Only correlation coefficients with $p < 0.05$ are shown.
AATD-LD, alpha-1 antitrypsin deficiency-associated liver disease; PAS+D, periodic acid-Schiff staining with diastase; Z-AAT, misfolded alpha-1 antitrypsin.

0075 | REPLACING CREATININE WITH CYSTATIN C ENHANCES MORTALITY PREDICTION IN ALL MODERN LIVER ALLOCATION SCORES

Giuseppe Cullaro[1] Manuel Rodriguez-Peralvarez[2] Ignacio Roca[3] Elizabeth Verna[4] Andrew Allegretti[5] Kavish Patidar[6] ADRIAN GADANO[7] Fernando Cairo[8] Jennifer Lai[9] Ezequiel Mauro[10], [1]Columbia University Irving Medical Center, [2]Hospital Universitario Reina Sofía, IMIBIC, [3]Hospital El Cruce de Florencio Varela, [4]Columbia University Medical Center, [5]Massachusetts General Hospital, [6]Houston Methodist Hospital, [7]Hospital Italiano de Buenos Aires, [8]HOSPITAL EL CRUCE, [9]UCSF, [10]Hospital Clinic i Provincial de Barcelona

Background: Among patients with decompensated cirrhosis, Cystatin C (CysC) more accurately captures kidney function compared to serum creatinine (sCr) and therefore should better predict mortality in liver transplant candidates. However, the impact of replacing sCr with CysC in modern liver allocation scores remains uncertain. **Methods:** We combined data from 1,301 patients with CysC measured during transplant evaluation at UCSF (USA), Hospital El Cruce, and Hospital Italiano (Argentina) between 2014-2024. CysC (mg/L) and sCr (mg/dL) were treated as interchangeable on a 1:1 scale. We compared the impact of replacing sCr with CysC in the MELD-Na, MELD 3.0, and GEMA-AI models through comparisons of AUCs and categorical net reclassification indices (NRI). Patients were stratified into 5 risk tiers (6-9, 10-19, 20-29, 30-39, 40+) to calculate NRI. We evaluated factors associated with reclassification including age, sex, hospital, Child-Pugh score (CPS), and Sarcopenia HIBA score. **Results:** We analyzed 383 patients from Hospital Italiano, 397 from Hospital El Cruce, and 521 from UCSF ($N = 1,301$). The cohort was 38.6% female, mean age 53.9 ± 11.2 years, CPS 9.0 ± 2.1, CKD-EPI eGFR 91.0 ± 28.9 mL/min/1.73m², Royal Free GFR 67.4 ± 27.7 mL/min, baseline MELD-Na 19 ± 6, MELD 3.0 15 ± 8, and GEMA-AI 18 ± 6. There were 61 90-day deaths (5.6% in Argentina, 3.3% in the US). CysC substitution increased scores by 1.9 ± 2.0 points for MELD-Na, 4.5 ± 3.1 for MELD 3.0, and 2.8 ± 2.3 for GEMA-AI. AUCs remained similar (MELD-Na: 0.78 vs 0.79, $p = 0.09$; MELD 3.0: 0.78 vs 0.79, $p = 0.58$; GEMA-AI: 0.77 vs 0.80, $p = 0.07$), but NRI analysis showed significant improvement. Overall NRI was +10.0% for MELD-Na, +13.7% for MELD 3.0, and +15.5% for GEMA-AI (all $p < 0.05$). Among 90-day deaths, 100% of reclassified patients moved to higher risk tiers: MELD-Na: 28% (18/61), MELD 3.0: 57% (35/61), GEMA-AI 39% (23/59) (Figure 1). Reclassified patients were more likely to be female (45 vs 33% for MELD 3.0, 48 vs 35% for GEMA-AI), had higher sarcopenia HIBA (-0.3 vs -0.9 for MELD-Na, -0.5 vs -1.0 for MELD 3.0, -0.1 vs -1.0 for GEMA-AI) and higher mortality (6.7% vs 4.2% for MELD-Na, 5.8% vs 3.7% for MELD 3.0, 7.3% vs 3.7% for GEMA-AI) ($p < 0.05$ for all comparisons). **Conclusion:** In a geographically diverse cohort, replacing sCr with CysC significantly improves risk stratification across MELD-Na, MELD 3.0, and GEMA-AI models, without compromising discrimination. CysC consistently identifies high-risk patients, particularly those with sarcopenia as indicated by sarcopenia HIBA score, leading to appropriate upward reclassification of all deaths. These results support incorporating CysC into liver allocation models to enhance prognostic accuracy.

0076 | LIVER VIABILITY ASSESSMENT DURING NORMOTHERMIC MACHINE PERFUSION AND NORMOTHERMIC REGIONAL PERFUSION USING INDOCYANINE GREEN CLEARANCE AND MITOCHONDRIAL BIOMARKERS: A PROSPECTIVE STUDY

Xiaojun Cai[1] Zixin Sha[1] Dana Perry[1] Burcin Taner[1] Liu Yang[1] Kristopher Croome[1], [1]Mayo Clinic Florida

Background: Ex-vivo normothermic machine perfusion (NMP) and abdominal normothermic regional perfusion(A-NRP) are emerging strategies for reconditioning and preserving marginal donor livers. However, objective and reliable biomarkers to evaluate graft viability and predict post-transplant outcomes remain limited, with current assessments relying heavily on clinical judgment. Indocyanine green (ICG), a hepatocyte-specific fluorescent dye, has been extensively utilized in liver surgery, including liver transplantation (LT). This study aimed to evaluate the utility of ICG clearance testing (IGT) and mitochondrial biomarkers—flavin mononucleotide (FMN) and mitochondrial DNA (mtDNA)—during NMP and A-NRP to assess graft quality prior to liver transplantation (LT). **Methods:** Perfusate and bile samples from human donor livers with NMP and A-NRP experience were collected at Mayo Clinic Florida. ICG kinetics, FMN levels, and mtDNA expression were analyzed. Associations between these biomarkers and clinical outcomes, including early allograft dysfunction (EAD) and primary perfusion syndrome (PRS), were evaluated. **Results:** A total of 72 donor livers were included: 63 from donation after circulatory death (DCD) and 9 from donation after brain death (DBD). No patient deaths or graft failures occurred in this cohort. The ICG retention rate at 5 minutes (ICGR5) was significantly lower in NMP compared to A-NRP ($p < 0.001$). However, ICG clearance did not differ significantly between EAD and non-EAD groups. FMN levels in the perfusate predicted EAD with a c-statistic of 0.7465 (95% CI: 0.6019–0.8912, $p = 0.0028$), and a threshold of 53.65 ng/mL was identified as optimal. Perfusate mtDNA levels were significantly lower in NMP than in A-NRP ($p < 0.05$), but mtDNA concentrations did not differ between EAD and non-EAD groups. None of the biomarkers—including ICG retention, FMN, or mtDNA—were predictive of PRS. **Conclusion:** This first prospective study demonstrates that FMN released during NMP holds promise as a predictive biomarker for EAD, potentially enhancing pre-implantation risk stratification. In our cohort, all transplanted donor livers showed effective pre-procurement ICG clearance. While there is no statistically significant difference between the EAD and PRS groups, these findings provide a strong foundation for further research, particularly in the evaluation of marginal livers.

0077 | IMPACT OF ACUITY CIRCLES POLICY ON ABO BLOOD TYPE-RELATED WAITLIST OUTCOMES IN LIVER TRANSPLANTATION

Dilara Hatipoglu[1] Anna Goebel[1] K Rajender Reddy[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: We aimed to assess the impact of Acuity Circles (AC) allocation policy on ABO blood type–related disparities in liver transplant waitlist outcomes. **Methods:** This retrospective cohort study utilized data from the United Network for Organ Sharing (UNOS).

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

The study included adult patients listed for liver transplantation between 2/2002 and 09/2023. Patients with hepatocellular carcinoma (HCC) exceptions and those listed for multi-organ transplantation were excluded. Data were stratified by pre- and post-AC reform era based on policy initiation in 2/2020. The primary exposure was recipient ABO type and the primary outcome was time to transplant in months. Median spline plots were used to visualize time to transplant by MELD score and ABO type in each era. A Fine and Gray competing risk regression analysis was performed over a one-year time horizon, adjusting for age, race, sex, BMI, etiology of liver disease, MELD score at listing, ascites category, hepatic encephalopathy grade, and U.S. region. Competing events included mortality, living donor transplant, and delisting. Cumulative incidence probabilities of transplant for each ABO type were computed relative to AB for each era. **Results:** A total of 179, 376 patients were included, of whom 34,433 were listed for transplant following AC reform. Post-AC patients were more likely to be female (41.3% vs 38.4%, $p < 0.001$), obese (39.0% vs 36.6%, $p < 0.001$), had higher median MELD score at listing (21 vs 17, $p < 0.001$), and experienced shorter median time to transplant (0.5 vs 1.9 months, $p < 0.001$). Blood type distribution showed a statistically significant ($p < 0.036$) increase in transplant rates for patients of type A (37.9% vs 37.6%), type AB (3.9% vs 3.8%), and type O (46.6% vs 46.4%), while type B decreased group (11.6% vs 12.1%). Time to transplant, stratified by ABO type and MELD score at listing, demonstrated a notable reduction in wait time, particularly for patients with lower MELD scores following AC reform compared to the pre-policy era. In competing risk models, there was a significant interaction between ABO type and policy era ($p < 0.0001$). Relative to AB, patients with blood types B and O had less reduction in cumulative probability of transplant in the post-AC era relative to pre-AC, though absolute disparities remained (Figure 1). **Conclusion:** Acuity circle policy implementation resulted in more equitable distribution in transplant outcomes by recipient ABO type, though disparities in access remain.

0078 | CONTEMPORARY PATTERNS IN OUT OF SEQUENCE ALLOCATION IN LIVER TRANSPLANTATION

Jacqueline Henson[1] Xuyang Xia[1] Ryan McDevitt[1] Norine Chan[1] Andrew Barbas[1] Lindsay King[1] Andrew Muir[1] Debra Sudan[1] Stuart Knechtle[1] Lisa McElroy[1], [1]Duke University

Background: Candidates for deceased donor organ allocation are prioritized by the match run. A deviation from this rank order is termed out-of-sequence (OOS) allocation. OOS is intended as a mechanism to expedite organ placement and improve utilization in circumstances when standard allocation is not feasible. OOS has increased in recent years, though contemporary patterns of use of OOS allocation in liver transplantation (LT) are not well characterized. We aimed to describe current OOS allocation practices in LT and evaluate their association with organ utilization. **Methods:** We conducted a retrospective cohort study using the Organ Procurement and Transplantation Network Potential Transplant Recipient dataset to examine the evolution in OOS allocation from 2019 and 2023. We examined OOS prevalence, timing, and variability across Organ Procurement Organizations (OPO) and transplant centers. OPO- and center-level characteristics were obtained from the Scientific Registry of Transplant Recipients OPO- and program-specific reports. OPO-level organ utilization was assessed using the adjusted observed/expected donor yield. Center-level offer acceptance was evaluated using the adjusted observed/expected offer acceptance ratios. Chi-square testing and correlation were used to compare groups and evaluate associations. **Results:** From 2019 to 2023, the proportion of match runs with OOS allocation rose from 4% (490/11427) to 13% (1880/14885) ($p < 0.001$). This proportion increased for nearly all OPOs (median 12% from 3%), and there was broader center participation (76% vs. 52%, $p < 0.001$). In 2023, OPO-level OOS use varied and ranged from 2-45% (2019: range 0-19%). At the center level, OOS accounted for as many as 45% of accepted offers (median 8%, interquartile range 2-16%) in 2023. The geographic distribution of OPO OOS use by quartile along with the top participating centers is shown in Figure 1. OOS events occurred earlier in the match run in 2023 (median sequence number 15 vs. 31) and sooner after initiation (median 19.8 vs. 21.2 hours). In addition, a greater proportion occurred prior to donor clamp time (67% vs. 44%, $p < 0.001$). There was no

significant correlation between OPO-level OOS use and adjusted observed/expected donor yield ($r = 0.20$, $p = 0.13$), though OOS acceptance at the center level was associated with adjusted offer acceptance ratios (overall: $r = 0.37$, $p < 0.001$; hard-to-place organs: $r = 0.43$, $p < 0.001$). **Conclusion:** OOS allocation has increased significantly in LT and is being initiated earlier in the allocation process. The highest use is concentrated among a subset of OPOs and transplant centers, often in overlapping geographic areas. OPO-level OOS use was not associated with improved organ utilization. These findings highlight the need for further evaluation and potential further standardization of OOS practices in LT.

0079 | OUTCOMES FOR PATIENTS LISTED FOR LIVER TRANSPLANTATION WITH LOW MELD-NA SCORES: HIGH FREQUENCY OF DEATH, REMOVAL FROM WAITLIST AND LIVER TRANSPLANTATION

Hamza Dahshi[1] Ahmad Anouti[2] Thomas Cotter[3] Emaree Cobb[4] Alan Hutchison[5] Michael Charlton[6] Mary Rinella[5], [1]Case Western Reserve University School of Medicine, [2]University of Texas Southwestern, [3]UT Southwestern Medical Center, [4]University of Chicago, [5]The University of Chicago, [6]Madrigal Pharmaceuticals

Background: The MELD-based score remains the cornerstone in liver transplant (LT) organ allocation, prioritizing those with higher scores guided by the 'sickest first' principle. Organ acquisition for low-MELD LT candidates (e.g. < 15, with 15 identified as a threshold for listing for LT) remains challenging, despite this subset remaining at risk of adverse outcomes, while their disease trajectory while waitlisted remains poorly characterized. This study investigates the evolution of MELD-Na among waitlisted LT candidates, and the role of liver disease etiology and disease-modulating risk factors. **Methods:** We performed a retrospective analysis of adult LT candidates patients listed between 2016 and 2022 on the UNOS database. MELD-Na trajectories were evaluated at 3, 6, 9, and 12 months post-listing. Fine & Gray subdistribution hazard regression was used to assess predictors of MELD progression, accounting for transplant and death as competing events. Survival was assessed via Kaplan–Meier. **Results:** Among 76,205 adult first-time liver transplant candidates, 37.5% had MELD-Na scores < 15 at listing. At 6 months, 17.2% of patients with MELD-Na < 15 had a ≥ 4-point increase in MELD-Na, decreasing to 11.76% by 12 months. Patients with delta MELD ≥ 4 at 3 months had a 1-year survival rate of 85.8% (95% CI: 85.1–86.6), compared to 94.6% (95% CI: 94.4–94.8) in delta MELD < 4 ($p < 0.001$). Starting from a MELD score ≥ 11, delta MELD ≥ 4 was the first point at which survival decreased below 90% and was distinct from delta MELDs 1–2. As delta MELD increased beyond 4 points (i.e., ≥ 5), 1-year survival continued to decline progressively. At 1 year, patients with MELD < 15 had a survival rate of 95.9% (95% CI: 95.6–96.1), while those with MELD ≥ 15 had a significantly lower survival of 89.1% (95% CI: 88.8–89.4, $p < 0.001$) (Figure 1). Competing risk regression identified significant predictors of MELD increase ≥ 4. Compared to alcohol-associated cirrhosis, patients with metabolic dysfunction-associated steatotic liver disease (MASLD) (HR 1.36, 95% CI: 1.28–1.44), and those with cholestatic or autoimmune liver disease (PSC, PBC, AIH) (HR 1.51, 95% CI: 1.41–1.62) had significantly higher risk of worsening MELD. In contrast, HCC (HR 0.68, 95% CI: 0.64–0.71) and Black race (HR 0.86, 95% CI: 0.82–0.90) were associated with significantly lower risk of MELD worsening (Table 1). Among patients with missing MELD at 6 months ($n = 42{,}009$), 72% had undergone transplant, 8% had died, and 20% had been removed or were lost to follow-up. **Conclusion:** A substantial proportion of patients listed with MELD-Na < 15 experience significant deterioration, with delta MELD-Na ≥ 4 as a meaningful threshold predicting death and a transition from expected variability to clinical deterioration. MASLD and cholestatic/autoimmune liver disease are associated with greater risk. These findings underscore the need to revisit referral thresholds and monitoring intensity for low MELD-Na patients.

0080 | RISK PREDICTORS FOR RECURRENT AND DE NOVO MASLD POST LIVER TRANSPLANTATION

Drew Castleberry[1] Sai Nikhila Ghanta[1] Aakash Rana[2] Mauricio Garcia Saenz de Sicilia[1] Srikanth Vallurupalli[1] Ragesh Babu Thandassery[1], [1]University of Arkansas for Medical sciences, [2]Central Arkansas Veterans Healthcare System

Background: Risk factors for recurrent metabolic dysfunction associated steatotic liver disease (R-MASLD) and de-novo MASLD (D-MASLD) post liver transplantation (LT) are not well understood. Epicardial fat thickness (EFT) is a well-established indicator of metabolic syndrome. We studied the characteristics of R-MASLD and D-MASLD in LT and its correlation with EFT and other indicators of metabolic health. **Methods:** 173 patients who underwent LT between Jan. 2015 and June 2019 at a single center were included in the study. Vibration controlled transient elastography (Fibroscan®) was performed every year post-LT, and liver stiffness measurement (>10 kPa possible cACLD, >20kPa- definite cACLD) and continued attenuation parameter ($\geq$ 275 db/m - hepatic steatosis) were calculated. Hepatic steatosis and presence of at least one cardiometabolic risk factor defined MASLD. Epicardial fat thickness (EFT) on pre-LT trans thoracic echocardiogram (TTE) was calculated. **Results:** Mean age pre-LT was 54.6 $\pm$10.7 years (89.3% Caucasians,59.2% males) with median BMI 29 (24.6-32.8). Indications for LT included 39.8% MASLD and 60.2% non-MASLD etiologies (alcohol 24.3%, chronic hepatitis C 23.4%). 82.6% were alive at 5 years post-LT, median (IQR) follow-up of 7.5 (6.6-8.9) years. At 5 years post-LT, MASLD was identified in 57.3% (D-MASLD 38.8%, R-MASLD in 18.4%). In the non-MASLD pre-LT group, 64.5% developed D-MASLD, and in MASLD pre-LT group, 53.7% developed R-MASLD. Definite cACLD developed in 4.9% and possible cACLD in 20.4%. Higher proportion of patients with D-MASLD developed possible cACLD ($p=0.04$), Table-1. None developed clinically significant portal hypertension (as

defined by Baveno VII criteria). Obesity at 1 year post-LT increased the risk of developing R-MASLD (hazard ratio (CI) 4.1(1.4-11.9), p = 0.007). Similar risk was not observed for D-MASLD. Type of immunosuppressants did not correlate with the risk of developing R-MASLD or D-MASLD. Increased EFT (≥5mm) correlated with D-MASLD (HR = 4.3, CI = 1.7-23.9, p = 0.04) and not R-MASLD. **Conclusion:** In this cohort with high pre-LT prevalence of obesity, significant proportion of patients developed MASLD at 5-year post-LT follow-up, with high rates of both recurrent and de novo MASLD. D-MASLD appears to progress faster to develop possible cACLD. Pre-LT EFT appears to correlate with D-MASLD and obesity at 1-year post-LT with R-MASLD. Emphasis on treatment of obesity and metabolic syndrome is crucial to improve outcomes post-LT.

Table 1

Comparison of recurrent and de novo MASLD post liver transplantation

	Recurrent MASLD	De novo MASLD	
Pre-LT characteristics			
Age pre-LT (SD), years	53.6 (±10.6)	56.1 (±8.4)	p=0.16
Gender (M/F), %	68.4/31.6	77.5/22.5	p=0.001
BMI pre-LT (IQR)	33.2(27.9-35.4)	29.23 (24.9-32.8)	p=0.01
HCC pre-LT, %	15.8	30	p=0.09
SLK, %	8.3	25.0	p=0.19
EFT pre-LT (IQR), mm	1.8(0.9-4.2)	2.0 (1.3-3.2)	p=0.03
Donor age (SD) , years	33.0 (19.4)	33.2(14.2)	p=0.09
Donor BMI (IQR)	26.5(22-28.8)	26(24.4-29.1)	p=0.24
Post-LT characteristics			
BMI at 1 year (IQR)	33.1 (29.2-35.8)	26.7 (24.1-30.3)	p=0.03
Metabolic syndrome at 1 year, %	63.2	50.0	p=0.34
Diabetes Mellitus at 1 year, %	52.6	42.5	p=0.04
FibroScan CAP at 5 years, dB/m	299 (294-327)	301(275-330)	p=0.001
FibroScan LSM at 5 years, kPa	7.1 (5.5-8.9)	5.8(4.5-8.0)	p=0.13
Possible cACLD at 5 years, %	28.6	52.4	p=0.04

MASLD- metabolic dysfunction associated steatotic liver disease, LT- liver transplantation, BMI- body mass index, HCC- hepatocellular carcinoma, SLK- simultaneous liver kidney transplantation, EFT- epicardial fat thickness, CAP- continued attenuation parameter, LSM- liver stiffness measurement, cACLD -compensated advanced chronic liver disease

0081 | COFFEE INTAKE, ADDITIVES, AND LIVER HEALTH: ASSOCIATIONS WITH CIRRHOSIS, HEPATOCELLULAR CARCINOMA, LIVER-RELATED MORTALITY, AND MRI IMAGING BIOMARKERS IN THE UK BIOBANK: A PROSPECTIVE STUDY

Hyunseok Kim[1] Abdelrahman Attia[1] Minsun Kwak[1] Walid Ayoub[1] Derin Celtik[1] Beza Mengistu[2] Kelsy Larios[2] David Kim[3] Alexander Kuo[1] Paul Martin[1] Hirsh Trivedi[1] Aarshi Vipaini[1] Yun Wang[1] Suthat Liangpunsakul[4] Debiao Li[1] Stephen Pandol[1] Shelly Lu[1] Ju Dong Yang[1], [1]Cedars-Sinai Medical Center, [2]UCLA, [3]Rutgers New Jersey Medical School, [4]Indiana University Medical Center

Background: Coffee intake has been linked to lower liver disease risk, but prior studies were mostly cross-sectional, retrospective, or based on small cohorts. Whether associations differ by coffee type (caffeinated vs. decaf), additives (sugar/sweeteners), or metabolic/genetic modifiers remains unclear. Data on coffee and imaging-derived liver biomarkers are also limited. We evaluated associations between coffee intake, type, and additives with incident cirrhosis, hepatocellular carcinoma (HCC), liver-related mortality, and MRI liver biomarkers, including potential effect modification by diabetes, alcohol use, and *PNPLA3* genotype. **Methods:** In UK Biobank (n = 354,957), participants without cirrhosis or HCC at baseline were followed for liver outcomes. Coffee intake, type, and additives were assessed by touchscreen questionnaire. Outcomes were identified through linked hospital and death records. Multivariable Cox models estimated adjusted hazard ratios (HRs). In a liver MRI subcohort (~10 years post-baseline; n = 76,114), coffee intake was reassessed, and cross-sectional associations with liver fat (PDFF), iron, and fibroinflammation (corrected T1 or cT1) were examined. cT1 was modeled as a binary trait using a clinical threshold of ≥800ms. **Results:** Over a median 13-year follow-up, ≥5 cups/day was associated with reduced risk of cirrhosis (HR 0.67 [95% CI 0.58-0.78]), HCC (0.53 [0.34-0.83]), and liver-related mortality (0.58 [0.45-0.74]) (Table). Protective associations were observed for both caffeinated and decaffeinated coffee, and were strongest for unsweetened coffee; sugar and artificial sweeteners modestly attenuated benefits. In the MRI subcohort, higher coffee intake was associated with lower PDFF (-0.83%, 95% CI -1.02 to -0.65) and liver iron (-0.018, 95% CI -0.029 to -0.007). Higher coffee intake was also associated with lower odds of elevated cT1: ORs were 0.76 (0.65-0.89) for low, 0.82 (0.69-0.98) for moderate, and 0.80 (0.64-0.99) for high intake-suggesting a potential plateau at moderate-to-high intake levels. Associations were attenuated among participants with diabetes but remained consistent across alcohol use categories and *PNPLA3* genotype. **Conclusion:** In this large, prospective cohort, higher coffee intake was associated with favorable liver outcomes and imaging biomarkers. Findings support coffee, especially when consumed without additives, as a potentially accessible and low-cost strategy for liver disease prevention in the general population.

0082 | TEMPORAL AND DEMOGRAPHIC TRENDS IN LIVER DISEASE AND LIVER CANCER MORTALITY ATTRIBUTABLE TO SUBSTANCE USE DISORDERS IN THE UNITED STATES, 1999–2020

Raghava Rao Alluri[1] Priyasi Monga[2] Sandeep Kotnani[3] Madhu babu Adusumilli[4] Dhrumil Sakariya[5] Nivid Patel[6] Nimrat Dhillon[7] VISHRANT AMIN[8] Hardik Desai[9], [1]Prime South GME Consortium/Harlingen Medical Center Program, [2]Wellstar Spalding Regional Hospital, Griffin, Georgia, [3]Rutgers Monmouth Medical Center, [4]HCA Ocala Florida hospital -UCF, [5]Davao Medical School Foundation Poblacion District, Davao City,Philippines, [6]American university of Barbados, [7]Sri guru Ram das institute of medical sciences and research, vallah, Amritsar, Punjab, [8]HMH JFK University Medical Center, [9]Independent Clinical and Public Health Researcher

Background: Substance use disorders (SUDs) are an emerging contributor to chronic liver disease and hepatocellular carcinoma mortality in the United States. Despite growing awareness of the opioid crisis and poly-substance misuse, the epidemiological contribution of SUDs to liver-related mortality remains insufficiently quantified across sociodemographic and geographic strata. **Methods:** We conducted a retrospective analysis of mortality data from 1999 to 2020 using the CDC WONDER database, identifying deaths due to liver disease or liver cancer in which substance use disorders were listed as a contributing cause. We calculated Annual Percentage Change (APC) to quantify temporal trends, disaggregated by substance type, region, urbanization, state, race, ethnicity, gender, and age group. **Results:** From 1999 to 2020, the absolute number of deaths due to liver disease and liver cancer associated with substance use disorders increased from 3,822 to 10,547 (APC: +2.66%). Opioid-related deaths surged from 76 to 420 (APC: +8.9%), and deaths involving psychoactive drugs rose from 58 to 293 (APC: +8.2%). In contrast, alcohol-related deaths showed a slight decline from 2,718 to 2,594 (APC: –0.23%). Regionally, the South and Midwest demonstrated the highest escalation, with deaths in the South increasing from 687 to 2,718 (APC: +4.99%) and in the South from 960 to 4,098 (APC: +3.92%). By urbanization, nonmetro areas exhibited a notable increase from 253 to 1,066 deaths (APC: +4.8%), while metropolitan areas rose from 346 to 1489 deaths (APC: +4.64%). State-level trends revealed the most significant rise in Indiana, with an (APC: +9.98%), followed by Iowa (APC: +8.07%) and Arkansas (APC: +7.29%). Racial disparities were evident, with Asian or Pacific islander populations experiencing the most accelerated rise—from 36 to 169 deaths (APC: +4.21%). Among Hispanic groups, deaths in Hispanic or Latino individuals grew from 570 to 977 (APC: +0.2%), compared to a rise from 3,223 to 9,541 (APC: +3.0%) in non-Hispanic individuals. Gender-specific analysis showed a steeper increase in females (APC: +3.23%) than males (APC: +2.46%). Age-wise, the 85+ year group exhibited the highest annual rise, with deaths increasing from 39 to 201 (APC: +8.14%), followed by the 65-74 group (APC: +5.69%). **Conclusion:** Our findings reveal a sharp rise in liver-related deaths linked to opioids and psychoactive substances, especially in rural areas, older adults, females, and Asian or Pacific Islanders—emphasizing the need for targeted, population-specific interventions.

0083 | ASSOCIATIONS OF PRIMARY BILIARY CHOLANGITIS AND PRIMARY SCLEROSIS CHOLANGITIS WITH ADVERSE PREGNANCY OUTCOMES: A PROPENSITY-SCORE MATCHED ANALYSIS OF A NATIONAL COHORT

Priyanka Gaur[1] *Tatyana Kushner*[1] *Kate Johnson*[1] *Emma Leipsner*[1], [1]*Weill Cornell Medicine*

Background: Primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) are rare, progressive cholestatic liver diseases with varying phenotypes characterized by pruritus and fibrosis. Understanding of how these diseases impact pregnancy course is limited with counseling often extrapolated from intrahepatic cholestasis of pregnancy (ICP). We sought to leverage a large national dataset to evaluate the independent influence of PBC and PSC on pregnancy outcomes. **Methods:** We performed a population-based retrospective study of pregnant persons ages 12-55 from 2005-2025 using the TriNetX research network with deidentified electronic health record data from 100 U.S. health care organizations. Cohorts were stratified by presence of PSC and PBC up to one year prior to pregnancy diagnosis. A PSC pregnant cohort was compared to a non-PSC pregnant cohort, and a PBC pregnant cohort was compared to a non-PBC pregnant cohort. Primary outcomes were ICP, preterm delivery, preeclampsia, gestational hypertension, postpartum hemorrhage, cesarean section, fetal growth restriction, and stillbirth. Propensity score matching (PSM) with replacement was performed on a 1:1 basis with the nearest neighbor method, and multivariable logistic regression was applied to balanced cohorts. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were reported. **Results:** We identified 5,070,078 pregnant participants of which 480 (0.009%) had PBC and 292 (0.006%) had PSC. There were more individuals in the PSC group who self-reported Black/African American race ($p = 0.02$) and more individuals in the PBC group who self-reported Hispanic/Latino ethnicity ($p = 0.01$). Those with PBC were more likely to have pregestational diabetes and hypertension compared to PSC, and PSC more likely to have inflammatory bowel disease ($p = 0.01$). On univariate analysis, those with PSC had increased odds of preterm delivery, postpartum hemorrhage, preeclampsia, fetal growth restriction, and ICP compared to those without PSC (all $p < 0.05$). After PSM, only ICP was significant (aOR 3.4, 95% CI 1.6-7.0) (Table 1). Compared to pregnant individuals without PBC, those with PBC were at increased odds of preterm delivery, preeclampsia, and ICP in univariate analysis (all $p < 0.05$). These outcomes were not significantly different after PSM. **Conclusion:** Pregnancy outcomes in this population are generally favorable. Pregnant individuals with PBC and PSC had similar risks of preterm delivery and preeclampsia compared to unaffected pregnancies, but those with PSC were more likely to experience ICP. After PSM, these risks

were attenuated apart from individuals with PSC who were more likely to develop ICP. These findings support the use of ursodeoxycholic acid and antenatal surveillance, given that obstetric risks appear most associated with ICP.

Table 1. Unadjusted and adjusted odds ratios for obstetric outcomes among propensity-score matched cohorts with PSC and PBC compared to pregnancy cohorts without disease status.

Pregnant PSC compared to pregnant non-PSC (n = 282 pairs)				
	OR	95% CI	aOR	95% CI
Preterm delivery	2.3	1.3, 3.9	1.4	0.6, 3.3
Preeclampsia	2.0	1.3, 2.0	1.8	0.9, 3.7
Intrahepatic cholestasis of pregnancy	62.5	43.5, 90.0	3.4	1.7, 7.0
Gestational diabetes	1.3	0.8, 2.1	1.6	0.8, 3.3
Postpartum hemorrhage	2.0	1.1, 3.4	1.4	0.62, 3.3
Cesarean section	1.5	1.0, 2.2	1.2	0.7, 2.1
Fetal growth restriction	2.0	1.3, 3.0	2.0	1.0, 4.1
Stillbirth (too low to calculate)	-	-	-	-
Pregnant PBC compared to pregnant non-PBC (n = 447 pairs)				
	OR	95% CI	aOR	95% CI
Preterm delivery	2.3	1.5, 3.7	1.2	0.60, 2.43
Preeclampsia	1.9	1.3, 2.8	1.5	0.9, 2.6
Intrahepatic cholestasis of pregnancy	14.9	7.9, 27.8	1.8	0.84, 4.0
Gestational diabetes	1.31	0.9, 1.9	1.03	0.63, 1.7
Postpartum hemorrhage	0.99	0.5, 1.9	0.58	0.26, 1.28
Cesarean section	1.33	0.96, 1.9	1.08	0.69, 1.68
Fetal growth restriction	0.89	0.53, 1.5	1.2	0.59, 2.6
Stillbirth (too low to calculate)	-	-	-	-

[1] Covariates in propensity score matching model included age, race, ethnicity, chronic hypertension, pregestational diabetes, systemic lupus erythematosus, rheumatoid arthritis, tobacco use, thyroid disease, cardiac disease, chronic kidney disease, in vitro fertilization, asthma, and obesity (BMI ≥ 30).

0084 | SOCIAL CAPITAL AS A NOVEL POPULATION-LEVEL DETERMINANT OF LIVER-RELATED MORTALITY: A NATIONWIDE COUNTY-LEVEL ANALYSIS

Tiange Zhang[1] *Jennifer Dodge*[1] *Norah Terrault*[1], [1]*University of Southern California*

Background: Social capital - the connections enabling trust and reciprocity in communities - has emerged as an important health determinant, but its association with liver-related mortality has not been examined. **Methods:** Using county-level data for adults aged ≥25 years from CDC WONDER 2010-2019 and ICD-10 coded deaths due to chronic liver diseases (including cirrhosis, hepatocellular carcinoma), liver-related age-adjusted mortality rates (AAMR) were obtained. Social capital was assessed via a validated index of 19 county-level indicators including three subtypes: bonding capital-connections within groups (e.g. similar race, age, class, language); bridging capital-connections across groups (e.g. membership in religious organizations, charities); and linking capital-connections to authorities (e.g. political participation, voter eligibility, linkage to government). Indicators were averaged by subtype (each 0 to 1) and summed for overall social capital score. Quartiles ranked counties from low (Q1) to high (Q4) capital. Linear regression estimated mortality differences by social capital adjusted for county-level covariates. **Results:** Liver-related AAMR were available for 73.3% of US counties, covering 98.7% of all liver-related deaths. Mean social capital scores were overall 1.15 (range 0.71-1.54), bonding 0.65 (0.41-0.78), bridging 0.24 (0.09-0.58), and linking 0.25 (0.11-0.55) (Fig. 1). At county-level, social capital quartiles (Q1 to Q4) showed similar proportions of female (51.5% to 52.0%), while unemployment rates declined (5.6% to 4.8%) and rural residence increased (8.9% to 29.3%) across quartiles. Mean liver-related AAMR was 20.7 (SD 0.8) deaths per 100,000, with rates of 21.7 (SD 1.3), 20.9 (SD 0.6), 20.3 (SD 0.6), and 18.0 (SD 0.6) for counties with Q1 to Q4 social capital, respectively. After adjusting for county-level covariates related to demographics (age, sex), comorbidities (diabetes, obesity, heavy alcohol use), and structural factors (rural residence, unemployment), low overall social capital was associated with 2.7 (95% CI:1.1-4.4), 1.4 (95% CI:0.7-2.0), and 1.2 (95% CI:0.5-1.9) more deaths per 100,000 in Q1-Q3 versus Q4. Bonding and bridging, but not linking, capital were associated with liver-related mortality. **Conclusion:** Lower county-level social capital – especially bonding and bridging types – are independently associated with higher liver-related mortality in a dose-response manner. These results call for greater efforts to characterize social capital and population-level strategies to strengthen social capital as a novel approach to addressing liver disease mortality.

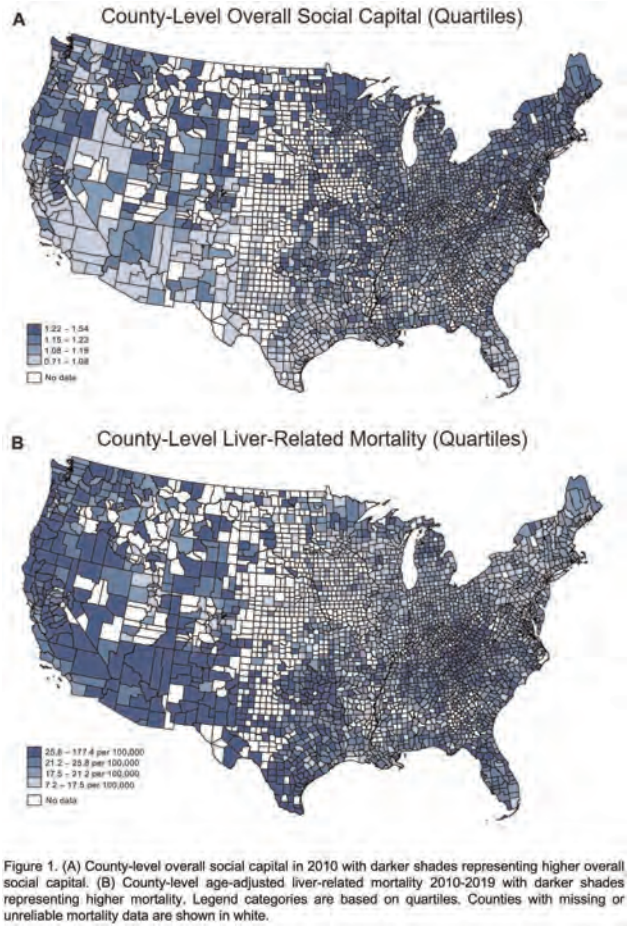

Figure 1. (A) County-level overall social capital in 2010 with darker shades representing higher overall social capital. (B) County-level age-adjusted liver-related mortality 2010-2019 with darker shades representing higher mortality. Legend categories are based on quartiles. Counties with missing or unreliable mortality data are shown in white.

0085 | PATIENT-REPORTED SYMPTOM BURDEN AS A PREDICTOR OF HOSPITALIZATIONS IN A MULTISITE COHORT OF PATIENTS WITH ADVANCED LIVER DISEASE: RESULTS: FROM THE PACE-LT CONSORTIUM

Nneka Ufere[1] Elizabeth Aby[2] Chengbo Zeng[3] Grace Bizup[1] Enya Zhu[4] Michael Kriss[5] Jon Rice[6] Thomas Leventhal[2] Deepika Devuni[7] Anita Krishnarao[7] Brett Fortune[8] Clara Tow[9] Paola Mejia[9] Lindsay King[10] Jacqueline Henson[4] Sarah Lieber[11] Alvaro Noriega Ramirez[11] Lauren Nephew[12] Patricia Jones[13] Nathaly Cortez Bazan[13] Melanie Hundt[9] Kali Zhou[14] Hyosun Han[14] Hersh Shroff[15] Krista Hunt[15] Shari Rogal[16] Alan Noll[1] Stela Celaj[17] Areej Mazhar[18] Dempsey Hughes[18] Anushka Dalvi[1] Malia Armstrong[1] Lucinda Li[19] Maria Edelen[3] Areej El-Jawahri[1], [1]Massachusetts General Hospital, [2]University of Minnesota, [3]Brigham and Women's Hospital, [4]Duke University, [5]University of Colorado School of Medicine, [6]University of Colorado, [7]University of Massachusetts, [8]Montefiore Medical Center, [9]Montefiore, [10]Duke University School of Medicine, [11]UTSW, [12]Indiana University, [13]University of Miami, [14]USC, [15]UNC Chapel Hill, [16]University of Pittsburgh, [17]UPMC, [18]Northwestern, [19]UCLA

Background: There is a growing body of literature supporting the use of patient-reported outcomes to facilitate symptom assessment in cirrhosis care. We sought to examine the association between patient-reported symptom burden and subsequent 90-day hospitalization in a multicenter cohort of adult outpatients with advanced liver disease (AdvLD). **Methods:** Data was derived from two prospective US observational cohorts: 1) 218 adult outpatients with AdvLD recruited from a single liver transplant center between 8/2018-9/2022; 2) 433 adult outpatients with AdvLD undergoing transplant evaluation recruited from 12 transplant centers between 4/2023-4/2024. Symptom burden was assessed using the validated 10-item revised Edmonton Symptom Assessment System assessing 10 common symptoms in AdvLD: pain, tiredness, drowsiness, nausea, lack of appetite, shortness of breath, depression, anxiety, poor well-being, and muscle cramps. Each individual ESAS symptom and total ESAS symptom burden (t-ESAS) was categorized as none or mild (score ranges 0-3 or 0-39, respectively), moderate (ranges 4-6 or 40-69), or severe (ranges 7-10 or 70-100). The primary outcome was a hospitalization within 90 days after completing the ESAS assessment. We calculated adjusted risk ratios of 90-day hospitalization by symptom severity using each individual ESAS symptom scores and total ESAS symptom burden scores, applying inverse-probability weighting (with death as competing risk), adjusting for age, gender, race, ethnicity, hepatic encephalopathy, ascites, and comorbidity burden. **Results:** Among the 651 patients, median age was 59 (IQR: 50-65), 57% were male, 84% were White, 17% were Hispanic, 58% had ascites, and 43% had hepatic encephalopathy. In total, 23% had a hospitalization within 90 days. In adjusted analyses, all individual ESAS symptoms were positively associated with 90-day hospitalization, with tiredness demonstrating the strongest association (aRR = 1.12 [95% CI; 1.06-1.18] per one-unit increase in the tiredness score) (Table). Compared to patients with none or mild symptom burden, those with moderate (aRR = 1.86; 95% CI: 1.38-2.50) and severe (aRR = 2.30; 95% CI: 1.40-3.77) symptom burden had a significantly higher risk of hospitalization within 90 days. **Conclusion:** We found a dose-response relationship between ESAS symptom burden scores and risk of 90-day hospitalization in a multisite cohort of outpatients with AdvLD after controlling for ascites, hepatic encephalopathy, comorbidity burden, and sociodemographic characteristics. Patient-reported symptom burden represents a modifiable risk factor and the results of our study suggest that outpatient ESAS scores may aid in risk-stratification for outpatients with AdvLD. These data provide evidence for the potential role of symptom monitoring interventions to improve healthcare utilization in cirrhosis care.

Table. Adjusted risk ratios of 90-day hospitalization by individual ESAS symptoms and total ESAS symptom burden

Individual ESAS symptom score (0-10)	aRR (95%CI)	p-value
Pain	1.06 (1.02, 1.11)	0.006
Tiredness	1.12 (1.06, 1.18)	<0.001
Drowsiness	1.09 (1.03, 1.14)	<0.001
Nausea	1.09 (1.04, 1.13)	<0.001
Lack of appetite	1.09 (1.05, 1.14)	<0.001
Shortness of breath	1.07 (1.02, 1.11)	0.002
Depression	1.05 (1.00, 1.10)	0.036
Anxiety	1.05 (1.01, 1.10)	0.023
Poor wellbeing	1.08 (1.03, 1.14)	0.002
Muscle cramps	1.06 (1.02, 1.10)	0.006
Degree of symptom burden		
Low burden (t-ESAS 0-39)	Reference	
Moderate burden (t-ESAS 40-69)	1.86 (1.38-2.50)	<0.001
Severe burden (t-ESAS 70-100)	2.30 (1.40-3.77)	<0.001

Note: We adjusted for age, gender, race, ethnicity, hepatic encephalopathy, ascites, and comorbidity burden. Results represent the risk of 90-day admission per 1-unit increase in the symptom score. t-ESAS; total ESAS symptom burden score

0086 | A RWE-BASED CHARACTERIZATION OF PATIENTS ADMITTED IN US HOSPITAL FOR AN EVENT OF ACUTE DECOMPENSATION HIGHLIGHTS DIFFERENCES IN THE MANAGEMENT OF INPATIENTS

Jonel Trebicka[1] Bérénice Alard[2] Thierry Artzner[3] William Bernal[4] Joan Claria[5] Lise Lotte Gluud[6] Jennifer Lai[7] Jacqueline O'Leary[8] Pierre-Emmanuel Rautou[9] Debbie Shawcross[10] Bart Staels[11] Florence Wong[12] CRISTINA SANCHEZ GARRIDO[13] Eva Usón-Raposo[13] Carol Addy[14] Maxime Anné[2] Stéphanie Ferreira[2] Dean Hum[14] Jérémy Magnanensi[2] Pierbruno Ricci[2] Katharina Staufer[15] Richard Moreau[16] Arun Sanyal[17] Jasmohan Bajaj[17] Javier Fernandez[18] Paolo Angeli[19], [1]University Hospital Münster, Münster, Germany, [2]GENFIT SA, [3]Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [4]King's College Hospital, [5]Fundacio de Recerca Clinic Barcelona-IDIBAPS, [6]Hvidovre Hospital, Hvidovre, Denmark, [7]University of California, San Francisco, United States, [8]University of Texas Southwestern, Dallas, United States, [9]Université Paris-Cité, INSERM, Paris, France; Hôpital Beaujon, Clichy, France, [10]Kings College London, London, United Kingdom, [11]University Lille 2, [12]University of Toronto, [13]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain, [14]GENFIT CORP, [15]Versantis AG (GENFIT Group), Zurich, Switzerland, [16]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [17]Virginia Commonwealth University, [18]Hospital Clinic, IDIBAPS and CIBEREHD, Barcelona, Spain, [19]University of Padova

Background: Acute decompensation (AD) of liver cirrhosis is defined as the acute development or worsening of ascites, gastrointestinal bleeding (GB), hepatic encephalopathy (HE), bacterial infection (BI) or any combination thereof, requiring hospitalization, and is associated with high risk of adverse liver-related outcomes. Using real-world data, we aimed to characterize the population of patients (pts) hospitalized in the US for an AD event and explore hospital care practices according to the type of AD and medical history of pts. **Methods:** All hospitalizations of pts with chronic liver disease, recorded between January 2023 and April 2025 in the Komodo's Healthcare Map US real-world database and associated with at least one AD event recorded on the date of admission, were included. For each hospitalization, the most specialized healthcare provider recorded on the first day (d) of hospitalization as well as the one seen during the entire hospital stay were extracted. The time to the first consultation with a hepatologist and/or gastroenterologist (HG) was determined, as well as the size of the hospital (small: <100 beds, medium: 100-499 beds, large: ≥ 500 beds). Hospitalizations were grouped based on either etiology of pts or type of AD recorded on the first day of hospitalization to assess potential differences in hospital care. **Results:** In total, the data from 118,457 hospitalizations in 82,741 pts (59% male, mean age at admission 54y) were analyzed. The median duration of hospitalization was 5 d. Among all pts, 52% had only 1 admission reported, 8% had ≥ 5 and 0.1% had ≥ 20 hospitalizations. 14.6% of admissions were recorded in large hospitals, 31.9% in medium-sized and 3.4% in small hospitals. Main known etiology was alcohol-associated liver disease (ALD) (38%, n = 45,033), followed by metabolic dysfunction-associated steatohepatitis (MASH, 4%, n = 4,907), and hepatitis C (3%, n = 3,180). Among admissions of pts with ALD only (n = 43,893), the main reason for hospitalization was ascites (66%) while this event was reported in 42% of admission of pts with MASH and only 18% for pts with hepatitis C. Regardless of etiology or type of event at admission, internal medicine was the main specialty involved in care (33-41% of hospitalizations). Overall, HG were consulted in only 17% of the hospitalizations, with a mean delay of 1.17 d after admission. In case of admission of pts with ALD or MASH, HG were more frequently consulted during hospital stay (20-21%) compared with pts with Hep C (9%), with the shortest

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

delay for MASH (mean: 0.71 d). Pts admitted with GB were the most likely to be seen by HG (27%, mean delay: 0.36 d), followed by ascites (19%), HE (14%), and BI (5%; mean delay of 2.15 d). **Conclusion:** Pts hospitalized for an AD event were managed differently depending on etiology and type of AD events. The majority were never seen by a hepatologist and/or gastroenterologist during their hospital stay, highlighting a key opportunity for healthcare improvement.

0087 | ULTRA-SHORT GLECAPREVIR/PIBRENTASVIR PLUS EZETIMIBE PREVENTS CHRONIC HCV IN HCV-INFECTED RECIPIENTS OF HCV-UNINFECTED NON-LIVER TRANSPLANTS: 6-YEAR OUTCOMES OF THE TORONTO PROTOCOL

Wesam Aleyadeh[1] Marcelo Cypel[2] Atul Humar[2] Ilona Bahinskaya[2] Jordan Feld[3], [1]Toronto Centre for Liver Disease, [2]University Health Network, [3]Toronto General Hospital

Background: The rise in hepatitis C virus (HCV)–positive organ donors due to the opioid crisis has expanded the transplant donor pool. However, optimal antiviral timing and duration in HCV-uninfected (D+/R−) recipients remain unclear. We previously reported that a 7-day course of glecaprevir/pibrentasvir (G/P) plus ezetimibe (E), the "Toronto Protocol", prevented chronic infection in a pilot study. Here, we present outcomes from the full cohort treated with this protocol since its adoption as standard of care. **Methods:** This retrospective cohort included all D+/R− recipients of non-liver solid organ transplants treated with the Toronto Protocol (G/P+E with 1 dose pre-transplant and 7 days post-transplant). Patients were followed until last available HCV RNA or death. The primary endpoint was chronic HCV infection, defined as detectable HCV RNA 12 weeks post-transplant or need

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

for retreatment. Secondary outcomes included patient and graft survival, treatment-related adverse events, and HCV-related complications. **Results:** Among 113 D+/R− recipients (54 kidney, 33 lung, 16 heart, 6 kidney-pancreas, 4 pancreas), all (100%) achieved undetectable HCV RNA at 12 weeks. Mean age was 55 years (range 19–82), and 65% were male. Median follow-up was 156 weeks (range 7–324). At 6 months, patient survival was 96% (108/113) and graft survival was 99% (112/113). No patients required retreatment or had any reported viremia. No treatment-related adverse events or HCV-associated complications including fibrosing cholestatic hepatitis, cryoglobulinemia, or glomerulonephritis were observed. Anti-HCV surface antibodies developed in 27 patients (24%) and persisted despite viral clearance. **Conclusion:** A 7-day course of glecaprevir/pibrentasvir plus ezetimibe achieved 100% virologic cure across 113 D+/R− recipients with no HCV-related morbidity or treatment failure. This protocol was safe, well tolerated, and feasible for pre-discharge completion. These data support the Toronto Protocol as a scalable strategy for maximizing safe donor organ utilization from HCV-positive donors.

Variable	Overall (%) (n=113)
Sex	
Male	74 (65%)
Female	39 (35%)
Mean age (range)	55 (19-82)
Median post-transplant follow-up (weeks; range)	156 (7-322)
Transplanted organ	
Kidney	54 (48%)
Lung	33 (29%)
Heart	16 (14%)
Kidney/Pancreas	6 (5%)
Pancreas	4 (4%)
Undetectable HCV RNA at 12 weeks	113 (100%)
Patient survival at 6-months	108 (96%)
Death-censored graft survival at 6-months	112 (99%)
Adverse events related to treatment	0 (0%)
HCV-related complications*	0 (0%)

*Fibrosing cholestatic hepatitis, cryoglobulinemia, and glomerulonephritis

0088 | MDL-001 AS A NEXT-GENERATION HCV THUMB-1 INHIBITOR WITH CLINICAL-STAGE SAFETY

Virgil Woods[1] Tyler Umansky[1] Sean Russell[1] Adolfo Garcia-Sastre[2] Kris White[2] William Brubaker[3] Davey Smith[4], [1]Model Medicines, San Diego, CA, USA, [2]Department of Microbiology, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [3]Farmington Pharma Development, [4]School of Medicine, University of California, San Diego, La Jolla, CA, USA

Background: The Hepatitis C virus (HCV) polymerase (NS5B) harbors a Thumb-1 subdomain that was previously a target for antiviral drug development. However, many inhibitors of this domain exhibit a limited spectrum of activity, demonstrating efficacy only against specific viral genotypes or under restricted conditions. By leveraging ChemPrint™, a machine learning model for ligand binding, in conjunction with our proprietary GALILEO™ drug discovery platform, we have identified MDL-001 as a novel Thumb-1 inhibitor for HCV. This abstract presents MDL-001's potency as evaluated in a genotype 1b replicon system, a cell-based assay employing a subgenomic replicon to simulate viral RNA replication, and it summarizes Phase I safety data indicating no serious adverse events. **Methods:** ChemPrint™ was trained on extensive thumb-pocket inhibitor data and used to screen a library of well-characterized

small molecules with established human safety records. MDL-001 emerged as a high-confidence candidate predicted to target the NS5B Thumb-1 subdomain. Antiviral efficacy against genotype 1b HCV (isolate Con1) was evaluated using the Huh-luc/neo-ET replicon system, measuring viral RNA reduction by standard readouts. Rodent safety studies assessed tolerability up to 1000 mg/kg, and archived Phase I data (collected for a prior indication) were re-examined for adverse events and preliminary pharmacokinetics. **Results:** In the Huh-luc/neo replicon (genotype 1b), MDL-001 achieved an EC_{50} of 3.28 µM with no detectable toxicity up to 10 µM (TC_{50} > 10 µM). Follow-up rodent studies confirmed high oral bioavailability and demonstrated no significant adverse findings at single doses as high as 1000 mg/kg. Past Phase I clinical trials (n ≈ 100 subjects) showed no serious adverse events, supporting the compound's favorable tolerability and once-daily dosing potential. Although primarily developed for HCV, preliminary screens suggest MDL-001's scaffold could be active against other RNA viruses with similar Thumb-1 architecture. **Conclusion:** By selectively targeting the HCV Thumb-1 subdomain, MDL-001 showed low-micromolar EC_{50} values in a genotype 1b replicon assay and an excellent safety margin in animal and early human studies. This next-generation approach to HCV therapy supports further clinical evaluation of MDL-001 as an orally available, well-tolerated antiviral that may also have broader applications against other single-stranded RNA viruses.

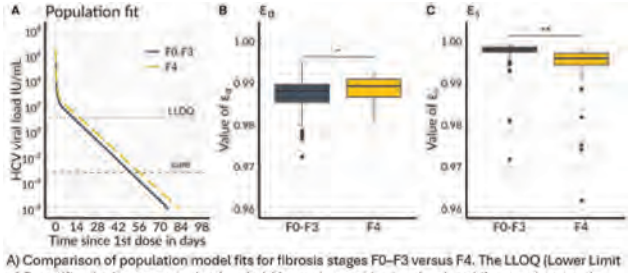
0089 | MULTISCALE MODELING OF RESULTS: FROM A PHASE 2 STUDY OF AN 8-WEEK COMBINATION REGIMEN OF BEMNIFOSBUVIR AND RUZASVIR IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

Carolin Zitzmann[1] *Ruy Ribeiro*[1] *Sergey Izmailyan*[2] *Shannan Lynch*[2] *Keith Pietropaolo*[2] *Maria Arantxa Horga*[3] *Xiao-Jian Zhou*[2] *Janet Hammond*[2] *Alan Perelson*[1], [1]*Los Alamos National Laboratory,* [2]*Atea Pharmaceuticals, Inc.,* [3]*horga.arantxa@ateapharma.com*

Background: Bemnifosbuvir (BEM) and ruzasvir (RZR) are potent, pan-genotypic HCV polymerase and NS5A inhibitors, respectively. The novel combination BEM/RZR was assessed for safety and efficacy in a phase 2 open-label study of 275 HCV-infected individuals including those with compensated cirrhosis (NCT05904470). Previously, we developed a multiscale model of HCV infection and treatment to estimate the in vivo effectiveness of antiviral therapies in blocking HCV replication and viral assembly/secretion. Here we use that model to evaluate the efficacy of the BEM/RZR combination. **Methods:** In this single arm study, a subset of 215 treatment-naïve, study drug adherent, noncirrhotic and cirrhotic individuals with chronic HCV received 550 mg BEM once daily (QD) + 180 mg RZR (QD) for 8 wks. The previously developed multiscale model was fit to the plasma viral load (VL) measured using the Roche cobas® HCV quantitative nucleic acid test with a lower limit of quantitation (LLOQ) of 15 IU/mL and the ALT data from all subjects simultaneously via population fitting. **Results:** The 215 participants were infected with GT1 (n = 151), GT2 (n = 4), GT3 (n = 58), and GT4 (n = 2) and 16% had F4 compensated cirrhosis. After treatment initiation, the VL decreased in a triphasic manner, with a very rapid first phase lasting < 12 h, followed by a slower 2nd phase and an even slower 3rd phase. The model fit both the VL and ALT data well. The population estimate of the time to reach the LLOQ was 12 days for individuals in F0-F3 and 16 days for those in F4, while the population estimate of the time to cure (VL ≤ 6.7×10^{-4} IU/mL) was 7.2 wks for F0-F3 and 8.1 wks for F4, with some variability between individuals. The population estimate of the effectiveness of the combination in blocking viral assembly/secretion was extremely high at 0.998 for F0-F3 [95% CI 0.997, 0.999] and 0.995 for F4 [95% CI, 0.991, 0.997], while the population estimate of the effectiveness in blocking viral replication was 0.988 for F0-F4 [95% CI, 0.983, 0.991]. The estimated efficacy of therapy was similar across GT1, 2, 3, and 4. **Conclusion:** BEM/RZR for 8 weeks was highly effective in blocking both viral replication and viral assembly/secretion in HCV-infected patients independent of genotype and fibrosis score. The time to cure estimates support 8 wk treatment for non-cirrhotic patients and longer treatment duration (e.g., up to 12 wks) for those with compensated cirrhosis.



A) Comparison of population model fits for fibrosis stages F0–F3 versus F4. The LLOQ (Lower Limit of Quantification) represents the threshold for undetectable virus levels, while cure denotes the viral load threshold for cure (VL ≤ 6.67×10^{-4} IU/mL).
B) Boxplots of individual parameter estimates for the drug's effectiveness, ε_a, in blocking HCV replication across fibrosis stages F0–F3 and F4.
C) Boxplots of individual parameter estimates for the drug's effectiveness, ε_s, in blocking viral assembly and secretion across fibrosis stages F0–F3 and F4.
[Significance based on t-tests; * denotes p ≤ 0.05 and ** denotes p ≤ 0.01]

0090 | A MULTI-OMIC BLOOD-BASED MODEL ACCURATELY PREDICTS LIVER RELATED EVENTS IN PATIENTS WITH CIRRHOSIS AFTER HEPATITIS C VIRUS CURE WITH DIRECT ACTING ANTIVIRALS

Cynthia Moylan[1] Emrys Yan[2] Kara Wegermann[3] Marlene Violette[4] Lucas Li[4] Rebecca Mangus[3] Mehak Bajaj[5] David Hsu[3] Matthew Foster[3] Frida Abramov[6] Keyur Patel[7] Joseph Lucas[2] Susanna Naggie[8], [1]Durham Veterans Affairs Medical Center and Duke University Medical Center, [2]Vital Statistics, [3]Duke University Medical Center, [4]Duke University School of Medicine, [5]Durham Veterans Affairs Medical Center, [6]Gilead, [7]University of Toronto, [8]Durham Veterans Affairs Medical Center and Duke Clinical Research Institute

Background: Successful eradication of chronic hepatitis C virus (HCV) infection with direct acting antivirals (DAA) significantly reduces long-term liver-related morbidity and mortality. Patients with cirrhosis remain at risk of decompensation despite sustained virologic response (SVR). Currently we lack non-invasive tools able to accurately identify patients with the greatest risk of decompensation and hepatocellular carcinoma (HCC) after SVR. Our aims were to validate and optimize a predictive biosignature of hepatic decompensation and HCC developed previously in HIV/HCV coinfected patients. **Methods:** Plasma and clinical data were obtained at entry into the Gilead SVR Registry, comprising participants with cirrhosis from registered clinical trials who achieved SVR with DAA (NCT02292706). We performed a nested case control study of participants who did (case, n = 182) and did not (control, n = 138) develop incident hepatic decompensation (ascites, varices, spontaneous bacterial peritonitis, hepatic encephalopathy, hepatorenal syndrome, and hepatic hydrothorax) or HCC during follow-up. Plasma metabolites and peptides were measured using Biocrates Q500 and Bile Acids and Quantitative Data Independent Acquisition LC-MS/MS, respectively. Logistic regression with LASSO variable selection with leave one out cross validation was used to develop the best fit model to predict liver-related events. The study was approved by the Durham Veterans Affairs Medical Center IRB and analyses were performed in Python. **Results:** Registry participants were followed for a mean of 3.7 +/- 1.5 years. The overall cohort (n = 291) was primary White race (90%) and male sex (75%). Cases were older (median 61 vs. 58.5 years), more likely to be HCV genotype 1, and had higher liver transaminases, bilirubin, FIB-4 scores, and liver stiffness than controls (all $p < 0.01$). The proteomic and metabolomic models all had a higher predictive area under the curve (AUC) compared to standard baseline clinical data alone (see Figure), with a combined model of metabolites and baseline clinical data having the greatest accuracy (AUC 0.823). Top eight proteins and metabolites are shown (see Figure) and included those involved in matrix and tissue maintenance, cell fate determination, immune regulation, and detoxification, while top metabolites included acylcarnitines, dihydroceramides, hormones and bile acids. **Conclusion:** Blood-based metabolomic and proteomic markers can predict future liver-related events in participants with cirrhosis post-SVR with higher accuracy than simple clinical parameters alone. Prospective validation in real-world cohorts is required.

Figure. Receiver operating characteristic (ROC) curves for each analyte model compared to baseline model alone.

0091 | REVERSE-ENGINEERING STRATEGY IDENTIFIED DDR1 AS HCC CHEMOPREVENTION TARGET POST HCV CURE

Courtney Katz[1] Hiroaki Kanzaki[1] Hiroyuki Suzuki[1] Naoto Fujiwara[2] Sumit Mishra[1] Subhojit Paul[1] Soumith Paritala[1] Ece Janet Dinc[1] Jingxuan Chen[1] Jeon Lee[1] Pratibha Selvakumar[1] Indu Raman[1] Prithvi Raj[1] Hayato Nakagawa[2] Amit Singal[1] Adam Yopp[1] Raymond Chung[3] Emilie Crouchet[4] Thomas Baumert[5] Yujin Hoshida[1], [1]University of Texas Southwestern Medical Center, [2]Graduate School of Medicine, Mie University, [3]Massachusetts General Hospital, [4]Institut de Recherche sur les Maladies Virales et Hépatiques, Inserm, University of Strasbourg, [5]INSERM

Background: HCC risk persists in a subset of HCV-cured patients after antiviral therapies. We previously reported a molecular signature predictive of future development of incident HCC after HCV cure (prognostic liver signature for HCV-cured patients [PLS-HCVcure]). This signature can be utilized for "reverse-engineering" exploration of chemoprevention for post-SVR HCC. **Methods:** To identify candidate chemopreventive agents, we performed in silico screening of 3,919 compounds using PLS-HCVcure and an etiology-agnostic HCC risk signature, PLS, we previously reported. In vitro validation was conducted using collagen-stimulated HepG2 cells and a PLS-inducible cell-based (cPLS) model. In vivo testing was performed in the DEN+CCl4 mouse model. Clinical relevance of the candidate compound and its target were assessed by single-nuclei and spatial transcriptomic profiling and ex vivo treatment of precision-cut liver slices (PCLS) from six HCV-cured patients. **Results:** The in silico compound screening identified a DDR1 inhibitor, 7rh, as a top candidate. In HepG2 cells cultured on collagen-coated plates, DDR1 knockdown suppressed collagen-induced PLS-HCVcure and PLS. In the cPLS model, 7rh favorably modulated PLS in a dose-dependent manner. In the DEN+CCl4 mouse model, which was identified as one of the most suitable models via a meta-analysis of diverse rodent models, treatment with 7rh significantly reduced tumor burden and favorably modulated the HCC risk signatures. Molecular pathways involved in DNA damage repair, cell cycle, apoptosis, necroptosis, TNF-alpha signaling, and RAS/ERK signaling were suppressed. Carcinogen-related DNA mutational signatures were unchanged. In the clinical SVR liver tissue, single-nuclei transcriptome profiling identified a hepatocyte subpopulation with DDR1 activation and induction of PLS-HCVcure and PLS. Spatial transcriptome profiling is ongoing to map the subpopulation on fibrotic liver tissues and identify inter-cell type interactions contributing to hepatocarcinogenesis. Four SVR PCLS tissues (67% response rate) showed improvement of PLS in response to 7rh treatment. **Conclusion:** These findings support pharmacological DDR1 inhibition as a promising chemopreventive strategy in HCV-cured patients with advanced fibrosis.

Research Institute, Lucknow, India, [7]King George's Medical University, Lucknow, India, [8]Director General of Medical Health, Uttar Pradesh, Lucknow, India, [9]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Background: Sofosbuvir and velpatasvir combination for 12 weeks is a standard treatment regimen for chronic hepatitis C virus (HCV) infection without cirrhosis. Since shorter treatment regimens are advantageous, we compared 8 weeks versus 12 weeks of treatment with this drug combination. **Methods:** Treatment-naïve, HCV viraemic (HCV RNA > 10,000 IU/mL), mono-infected adults (> 18 years), with no evidence of cirrhosis (liver stiffness > 12.5 Kpa (FibroScan®) or AST-platelet ratio index (APRI) > 2.0) were centrally randomized, using a computer-generated sequence, to receive sofosbuvir/velpatasvir for either 8 or 12 weeks. Primary outcome assessed was sustained virological response at 12 weeks after treatment completion (SVR12). HCV RNA was measured using COBAS 5800® (Roche). HCV genotyping was done using in-house Sanger sequencing of 5´-UTR and/or core regions of HCV genome. Estimated sample size for 5% non-inferiority margin, 90% power, 2.5% one-sided alpha error, and 10% data loss was 880. Data are presented as mean ± standard deviation, or proportion, as appropriate. **Results:** Data for the first 727 (82.6%) of the planned 880 participants (age 38.1 ± 12.7 years; male 47.5%; $\log_{10}$ HCV RNA 6.06 ± 1.08; genotype [n = 386] 1/3/4 proportions = 21%/77.7%/1.3% respectively; liver stiffness [n = 664] 6.6 ± 2.1 KPa; APRI [n = 63] 0.68 ± 0.34) were analyzed. Baseline characteristics were comparable between the participants in the 12- and 8-week arms (Table). Of the 727 participants, 65 (8.9%) dropped out for various reasons before SVR12 could be ascertained, 654 (90.0%) achieved SVR12 and 8 (1.1%) failed to achieve SVR12. In intention-to-treat (ITT) analysis, SVR12 was achieved in the overall cohort, 12-week, and 8-week arms in 654 (90.0%; 95% confidence interval 87.5-92.1), 325 (88.6%; 84.9-91.6), and 329 (91.4%; 88.0-94.1) participants, respectively. On per-protocol (PP) analysis, SVR12 was achieved in the overall cohort, 12-week, and 8-week arms in 654/662 (98.8%; 97.6-99.5), 325/329 (98.8%; 96.0-99.3), and 329/333 (98.8%; 97.0-99.7), respectively. The ITT and PP SVR12 rates in the 8-week group were lower by −2.8% (95% CI: -7.4% to 1.8%) and 0% (-1.7% to 1.7%), meeting the pre-specified criterion for non-inferiority. **Conclusion:** Sofosbuvir/velpatasvir for 8 weeks was non-inferior to standard 12-week treatment in chronic HCV infection without cirrhosis. Hence, in such patients, treatment duration can be reduced from 12 to 8 weeks, with advantages of lower cost and better compliance (Trial registration ID: CTRI/2022/03/041368).

Table: Comparison of baseline clinical and laboratory characteristics, and outcomes

Characteristics	12-week treatment (n=367)	8-week treatment (n=360)	p value
Age (years)	38.6 ± 12.7	37.6 ± 12.7	0.282

★ 0093 | THE ROLE OF TRAIP IN ALCOHOL-INDUCED LIVER INJURY THROUGH REGULATING Β-CATENIN UBIQUITIN DEGRADATION VIA DIRECT INTERACTION

Zhan Wu[1] Yubing Chen[2] Stephen Tomlinson[3] Sebastian Mueller[4] Songqing He[2] Guandou Yuan[2], [1]First Affiliated Hospital of Guangxi Medical University, [2]The First Affiliated Hospital of Guangxi Medical University, [3]Medical University of South Carolina, [4]Center for Alcohol Research, University Hospital Heidelberg

Background: Oxidative stress plays a critical role in the pathogenesis of alcohol-related liver disease (ALD), although the precise mechanisms involved remain unclear. Studies indicate that tumor necrosis factor receptor associated factor interacting protein (TRAIP) plays a key role in oxidative stress. We aimed to elucidate the role of TRAIP in ALD, and its mechanism of regulating liver oxidative stress. **Methods:** Different ALD models were established using mice with liver-specific overexpression (LSO) and knockout (LKO) of TRAIP to investigate its role in ALD. Chromatin immunoprecipitation and luciferase assays confirmed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the transcription factor binding site for the transcription factors associated with TRAIP. Different structural components of TRAIP and β-catenin were constructed using cloning technology, and used to determine their sites of interaction. **Results:** The expression of TRAIP was significantly upregulated in liver tissues from both human and murine ALD. In ethanol-fed TRAIP^{LSO} mice, oxidative stress and inflammation in the liver increased markedly, while fat deposition decreased. The opposite effect was detected in TRAIP^{LKO} mice. Mechanistically, ethanol induced NF-κB1 activation, and led to the transcription of TRAIP. Up-regulated TRAIP promoted β-catenin ubiquitous degradation via a direct interaction of its coiled coil domain with the Armadillo domain of β-catenin, resulting in inhibition of the downstream target gene FOXO3, which exacerbates antioxidative stress in the liver. Stablization of β-catenin by SKL20001 effectively mitigated ethanol induced liver oxidative stress damage. **Conclusion:** This study reveals that TRAIP is a key mediator in ALD by inducing oxidative stress and inflammation via promoting β-catenin degradation and inhibiting FOXO3. SKL20001 is a promising treatment for ALD.

★ 0094 | STING KNOCKDOWN ATTENUATES ALCOHOLIC LIVER DISEASE PROGRESSION VIA NLRP3-MEDIATED PYROPTOSIS SUPPRESSION

Yu xuan Song[1] Mengsi Liu[1] Mingying Zhou[1] Xueyi Ren[1] Bo Feng[1] Yandi Xie[1], [1]Peking University People's Hospital, Peking University Hepatology Institute

Background: Alcoholic liver disease (ALD) is a globally prevalent condition with limited therapeutic options. The stimulator of interferon genes (STING) pathway has been implicated in inflammatory liver diseases, but its role in ALD progression remains incompletely understood. This study aimed to investigate the mechanistic link between STING and NLRP3-mediated pyroptosis in ALD pathogenesis. **Methods:** An ALD mouse model was established using a 5% alcohol Lieber-DeCarli diet. Adenovirus-mediated STING shRNA knockdown was performed to assess its effects on liver injury, inflammation, and pyroptosis. NLRP3 inhibition (MCC950) and activation (BMS-986299) were employed to evaluate the STING-NLRP3 axis. In vitro, alcohol- and LPS/ATP-induced pyroptosis models were constructed in AML12 hepatocytes to validate the findings. **Results:** STING expression was significantly upregulated in ALD mice, correlating with worsened liver function, inflammation, fibrosis, and lipid accumulation. STING knockdown ameliorated these pathological features, reduced serum pro-inflammatory cytokines (IL-1β, TNF-α, IL-6, IL-8, LPS), and suppressed pyroptosis markers (NLRP3, GSDMD-N, caspase-1, IL-1β, p-p65). Similar protective effects were observed with NLRP3 inhibition. Mechanistically, STING knockdown attenuated hepatocyte pyroptosis by disrupting NLRP3 inflammasome activation, as evidenced by reduced co-immunoprecipitation of NLRP3. NLRP3 agonist BMS-986299 reversed the benefits of STING knockdown, confirming NLRP3 as a downstream effector. Additionally, STING silencing alleviated oxidative stress by lowering ROS, MDA, and 4-HNE while restoring GSH and SOD levels. **Conclusion:** STING knockdown mitigates ALD progression by suppressing NLRP3-dependent pyroptosis and oxidative stress, highlighting its potential as a therapeutic target for ALD.

0095 | ENVIRONMENTAL FOREVER CHEMICAL EXPOSURES MODIFY THE SEVERITY OF ALCOHOL-ASSOCIATED LIVER DISEASE

Frederick Ekuban[1] Tyler Gripshover[1] Matthew Smith[2] Jianzhu Luo[1] Vatsalya Vatsalya[1] Kushal Biswas[3] Dhimitter Bello[3] Jennifer Schlezinger[4] Hao Zheng[1] Maiying Kong[1] Jae Yeon Hwang[1] Juw Won Park[1] Dean Jones[2] Craig McClain[1] Matthew Cave[1], [1]University of Louisville, Louisville, KY, USA, [2]Emory University, Atlanta, GA, USA, [3]University of Massachusetts Lowell, Lowell, MA, USA, [4]Boston University, Boston, MA USA

Background: Per- and polyfluoroalkyl substances (PFAS) are forever chemicals that have been associated with metabolic dysfunction-associated steatohepatitis. Recent findings show PFAS have been detected in popular US beers above EPA limits (PMID: 40272161), highlighting potential exposure pathways for alcohol consumers. The potential role of PFAS in alcohol-associated steatohepatitis (ASH), therefore warrants investigation. We hypothesize that PFAS disrupt liver metabolism and exacerbate ASH. **Methods:** Exposomics and metabolomics (LC-MS^2 & GC-MS^2) were performed in archived plasmas from subjects with ASH (severe = 96, moderate = 28) and non-drinking controls (n = 11). Associations between biomarkers of PFAS exposure, ASH severity, and the metabolome were determined using linear regression models. Male C57BL/6J mice on chronic-binge ethanol feeding were co-exposed to PFOS (1 mg/kg) or vehicle control for 10 days. Comprehensive liver disease phenotyping and RNA-Seq were performed. **Results:** 691 environmental pollutants were present in the human plasmas, including six PFAS with detection rates exceeding 94%. 25.9% of subjects had high PFAS exposures ($\sum$PFAS > 20 ng/m), and PFOS accounted for half of total PFAS. PFOS and PFUnA were positively associated with the disease severity biomarkers, ABIC and MELD, respectively. PFOA and PFTrDA were increased in ASH *vs.* controls. PFOS, PFOA, and PFHxS were associated with 806, 3318 and 721 plasma metabolic features, respectively. In mice, 60% of the administered PFOS dose accumulated in the liver. PFOS upregulated ethanol-metabolizing enzymes in liver and lowered blood alcohol levels. PFAS worsened ethanol-induced hepatic steatosis and liver injury. PPARα was the top identified upstream transcriptional regulator. In both the mouse model and in the human subjects, PFOS was associated with enrichment in pathways related to linoleate, carnitine, and vitamin metabolism. **Conclusion:** A significant number of pollutants, some at high levels, were present in ASH subjects. PFAS forever chemicals were detected in 100% of them. PFAS were associated with metabolic disruption and ASH severity. Data from the reverse-translational mouse model suggest that the associations observed in human subjects may be causal. Hypothesis generating multi-omics experiments identified potential mechanisms, some of which were consistent across species. Associations between the remaining 691 identified pollutants and human ASH are currently being determined. Environmental exposures may modify the liver and systemic responses to alcohol consumption, and more research is required in these areas.

★ 0096 | GLP-1 DYSREGULATION IN ALCOHOLIC LIVER DISEASE: ELUCIDATING INTESTINAL MECHANISMS AFFECTED BY CHRONIC ALCOHOL ABUSE

Yang Wang[1] Xiaoxue Yuan[1] Xi Wang[1] Song Yang[2], [1]Beijing Ditan Hospital, Capital Medical University, [2]Center of Liver Diseases Division, Beijing Ditan Hospital, Capital Medical University

Background: Chronic alcohol abuse is a well-established cause of alcoholic liver disease (ALD). Recent evidence highlights alcohol consumption as a primary etiological factor, disrupting the intestinal microenvironment and compromising intestinal epithelial barrier integrity and gut microbiota homeostasis. Intestinal hormones, including glucagon-like peptide-1 (GLP-1) produced by intestinal L cells, play pivotal roles in the gut-liver axis, regulating blood glucose and body weight. Notably, alcohol consumption elevates GLP-1 secretion, resulting in higher circulating GLP-1 levels in ALD patients. Paradoxically, GLP-1 receptor (GLP-1R) agonists have shown promise in reducing alcohol craving and intake in individuals with alcohol use disorders. However, the mechanisms driving elevated GLP-1 expression in ALD remain unclear, as does the impact of this dysregulation on the efficacy of GLP-1-based therapies. This research elucidates the causes of elevated GLP-1 expression in ALD and evaluates its implications for GLP-1 analog and agonist efficacy. **Methods:** To analyze intestinal conditions, we used two experimental models: (1) Acute

Alcohol Exposure (single 30% ethanol gavage in C57BL/6N mice) and (2) Chronic ALD (8-week 30% ethanol gavage in C57BL/6N mice). We measured serum GLP-1 levels, quantified intestinal enteroendocrine cell (EEC) populations, and employed AlphaFold3 for de novo structural modeling of the GLP-1R-GLP-1 complex. Molecular dynamics (MD) simulations assessed the binding stability of the complex under alcohol-related conditions. Immunofluorescence staining validated in silico predictions by visualizing GLP-1 and GLP-1R co-localization in intestinal tissues. **Results:** The acute alcohol exposure model revealed a significant redistribution of endocrine cells and elevated serum GLP-1 levels. Conversely, the chronic alcohol exposure group exhibited a decline in the total population of intestinal endocrine cells and a blunted GLP-1 response. MD simulations showed that GLP-1R fluctuates more in ethanol and acetaldehyde, reducing protein structure stability. Reduced C-terminal flexibility may limit conformational adjustment of GLP-1R, decreasing its efficiency in recognizing GLP-1. Confocal results showed decreased co-localization of GLP-1 and GLP-1R in ALD mice. **Conclusion:** A single alcohol intake causes a transient increase in GLP-1 levels, while long-term excessive alcohol exposure may lead to decompensated negative feedback regulation of GLP-1. Alcohol affects the binding efficiency of GLP-1 and GLP-1R.

0097 | TARGETING GLP-1 AND GCG RECEPTORS AS POTENTIAL THERAPEUTIC APPROACHES FOR ALCOHOL-ASSOCIATED LIVER DISEASE: FOCUSING ON THE ROLE OF THE LIVER-GUT AXIS

TUO SHAO[1] Zelin Gu[1] Xiaoyi Wang[1] Chuanlong Zhu[2] Raymond Chung[3] Weifeng Zhao[1], [1]Soochow University, [2]Nanjing Medical University, [3]Massachusetts General Hospital

Background: Alcohol-associated liver disease (ALD) is a major global cause of chronic liver disease, with limited treatment options due to its complex, multifactorial pathogenesis. Given the pivotal role of the gut-liver axis in ALD, we investigated the therapeutic potential of targeting glucagon-like peptide-1 receptor (GLP-1R) and glucagon receptor (GCGR) pathways in a murine ALD model. **Methods:** C57BL/6 mice were subjected to the NIAAA model, involving 10 days of Lieber-DeCarli ethanol liquid diet followed by a single binge ethanol dose (9 hours before sacrifice). Mice received subcutaneous injections of PBS, a GLP-1R agonist (Semaglutide), a GCGR agonist (IUB288), or a GLP-1R/GCGR dual agonist on days 1, 4, 6, and 8 (0.05 mg/kg) during ethanol feeding. We assessed serum markers, liver histology, immune cell infiltration, proinflammatory cytokines, hepatic triglyceride content, intestinal single-cell RNA sequencing, transcriptomic profiles, fecal microbiota composition, microbial metabolites, and intestinal barrier integrity. **Results:** Both GLP-1R and GCGR agonists improved liver function, reduced liver/body weight ratios, and lowered serum ALT, AST, and hepatic triglyceride levels, with the dual agonist showing the strongest effects. Mechanistically, these treatments upregulated hepatic and circulating fibroblast growth factor-21 (FGF21) via PPAR-FGF21 pathway activation, reducing hepatic steatosis. In the intestine, GLP-1R and dual agonist treatments increased $CD4^+$ T cells, enterocytes, enteroendocrine cells, and Paneth cells, while decreasing B cells, $CD8^+$ T cells, and macrophages. Notably, GLP-1R agonist therapy significantly corrected alcohol-induced gut microbiota dysbiosis in both mice and ALD patients by suppressing Enterobacteriaceae and Enterococcaceae overgrowth while enriching beneficial families. Semaglutide and dual agonist also modulated key microbial metabolites (long-chain fatty acids, bile acids, indole derivatives) that reinforce intestinal barrier integrity and stimulate GLP-1 secretion. Both agents significantly reduced bacterial translocation by enhancing tight junction expression, promoting epithelial proliferation, and dampening hepatic inflammation. **Conclusion:** Targeting GLP-1R and GCGR pathways provides an effective therapeutic strategy for ALD, with the dual agonist delivering superior efficacy by comprehensively modulating the gut-liver axis, restoring intestinal and hepatic homeostasis, and attenuating alcohol-induced injury.

★ 0098 | ADIPOCYTE MIR-150 DEFICIENCY AMELIORATES ALCOHOL-INDUCED LIVER INJURY BY PROMOTING ADIPOSE TISSUE BROWNING

Jing Ma[1] THEMIS THOUDAM[1] Nazmul Huda[1] Hui Gao[1] Ge Zeng[1] Yanchao Jiang[1] Zhihong Yang[1] Suthat Liangpunsakul[1], [1]Indiana University school of medicine

Background: Alcohol-associated liver disease (ALD) is driven not only by hepatic injury but also by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

dysregulated crosstalk between adipose tissue and the liver. Adipose dysfunction contributes to hepatic steatosis and inflammation during chronic alcohol exposure. miR-150, a miRNA involved in immune and metabolic regulation, has recently emerged as a potential mediator of inter-organ communication. However, its role in adipose tissue–liver signaling in the context of ALD remains unclear. **Methods:** MiR150 levels were measured in serum (S) and liver (L) samples from healthy controls (HC, N = 15 for S, 5 for L), heavy drinkers (HD, N = 17 for S), and alcohol-associated hepatitis (AH, N = 65 for S, 5 for L) patients. Correlations between miR150 levels, MELD scores, and serum transaminases were analyzed. Global *miR150* knockout mice (*miR150*$^{-/-}$) and adipocytes cell-specific miR150 knockout mice (*miR150*-$^{Adi-/-}$) were generated to assess the function of *miR150* in a chronic plus binge alcohol feeding model. **Results:** Serum and hepatic miR-150 levels were significantly reduced in AH patients compared to healthy controls. Serum miR-150 was inversely correlated with AST levels but not with MELD scores. In ethanol-fed mice, hepatic and serum miR-150 expression was markedly decreased, while its expression in white adipose tissue (WAT) was elevated. Genetic deletion of miR-150 (miR150$^{-/-}$) attenuated ethanol-induced liver injury and steatosis, as evidenced by decreased serum ALT and hepatic triglyceride levels. miR150$^{-/-}$ mice exhibited increased hepatic expression of fatty acid β-oxidation-related proteins, including PPARα, PGC1α, UCP2, CPT1A, and hormone-sensitive lipase (HSL), along with reduced expression of fatty acid translocase (FAT), a mediator of fatty acid uptake. In WAT, miR-150 deletion led to upregulation of β-oxidation-associated genes (e.g., *Pgc1α*, *Ucp2*, *Cpt1α*) and reduced plasma free fatty acid (FFA) levels in ethanol-fed mice. Adipocyte-specific miR-150 knockout (miR150$^{Adi-/-}$) mice showed significantly reduced ethanol-induced liver injury, steatosis, and inflammation, along with decreased hepatic triglycerides, lower ALT, and reduced expression of inflammatory genes. These mice also displayed lower plasma FFA levels. Mechanistically, adipocyte-specific deletion of miR-150 promoted WAT browning, evidenced by elevated UCP1 expression, reduced adipocyte size, and increased expression of browning-related genes such as *Cycs* and *Dio2*. In vitro, miR-150-deficient adipocytes derived from preadipocytes demonstrated enhanced expression of browning-related genes (*Cpt1a*, *Cpt2*, *Cycs*, *Acadvl*, *Cox7a*, *Cox8b*, *Dio2*). **Conclusion:** Our findings identify miR-150 as a novel regulator of adipose–liver communication in ALD, linking adipocyte-derived miR-150 to the regulation of WAT browning and hepatic lipid metabolism. Targeting adipose-specific miR-150 may represent a promising therapeutic strategy to ameliorate alcohol-induced liver injury.

★ 0099 | LIVER SPECIFIC SEXUAL FUNCTION ASSESSMENT TOOL

Yooyun Chung[1] *Deepak Joshi*[1] *Niloufar Safinia*[1] *Michael Heneghan*[1], [1]*King's College London*

Background: Patients with liver disease (LD) or liver transplantation (LT) may experience sexual dysfunction (SD). The existing tools to assess SD are not specific to LD/LT and our aim was to develop a liver specific sexual function (SF) assessment tool. **Methods:** This cross-sectional study assessed SD in 822 patients with LD/LT (472 men, 350 women) at King's College Hospital. A 24-item SF assessment tool in LD/LT (SFL) for men and women were developed through a literature search, input from a multidisciplinary panel of experts and patient group feedback. The international index of erectile function (IIEF) for men, female sexual function index (FSFI) and female sexual distress scale (FSDS) for women were used as gold standard, non-liver specific SF assessment tools. Chronic liver disease questionnaire (CLDQ) was used as a liver specific quality of life (QoL) assessment tool and clinical data was gathered from patient medical records. Factor analyses (FA) were used to assess the psychometric properties of the new SFL scale. **Results:** Exploratory FA reduced the SFL to a 13-item scale with good internal consistency reliability (α = 0.96). Spearman's coefficient showed the 13-item SFL to significantly correlate with FSFI/ FSDS in women and IIEF in men (indicating criterion validity). SFL had strong correlation with the CLDQ (construct validity). The prevalence of SD were 39-46% for women and 51% for men with 23% of men having severe symptoms. A major advantage of SFL is

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

that it can be used in all gender allowing inclusivity for transgender or for whom gender identity differs from the sex assigned at birth. SFL showed that women had greater degree of SD than men (0.50 for women vs 0.23 for men, $p < 0.001$). CLDQ indicated a poorer quality of life in women compared to men ($p < 0.001$). Patients with cirrhosis had greater SD and poorer quality of life according to SFL and CLDQ respectively when compared to those without cirrhosis or following LT. For women, the FSFI and FSDS were not able to detect this difference indicating the SFL can detect disease related changes in QoL. Multiple regression analysis identified age, ALBI score, feeling anxious and depressed as predictors for SD. **Conclusion:** SD affects approximately 50% of patients with LD/LT. SFL has significant correlation with the gold standard SF assessment tools and the liver specific CLDQ. The presence of cirrhosis, ALBI score, anxiety and depression are associated with risk of SD.

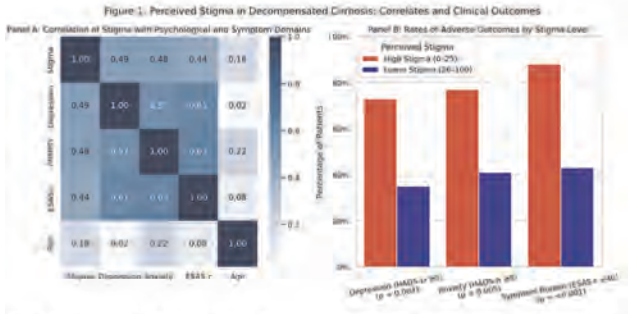
0100 | PERCEIVED STIGMA AMONG PATIENTS WITH DECOMPENSATED CIRRHOSIS AND ITS ASSOCIATION WITH PSYCHOLOGICAL DISTRESS AND SYMPTOM BURDEN

Brittany Bromfield[1] Chengbo Zeng[1] Nancy Mason[2] Michelle Diop[2] Sara Kenimer[2] Karen O'Brien[2] Kirsten Engel[2] Lucinda Li[3] John Donlan[2] Teresa Indriolo[4] Enya Zhu[5] Malia Armstrong[2] Grace Bizup[2] Anushka Dalvi[2] Cristal Brown[6] Wei Zhang[2] Nneka Ufere[2], [1]Brigham and Women's Hospital, [2]Massachusetts General Hospital, [3]UCLA, [4]Stanford University, [5]Duke University, [6]University of Texas at Austin Dell Medical School

Background: Despite its known impact in conditions like HIV and obesity, the specific burden of stigma and its association with patient-reported outcomes in decompensated cirrhosis (DC) remain under-investigated. We aimed to quantify liver-related stigma and examine its associations with psychological distress (e.g., depression and anxiety symptoms) and symptom burden in DC. **Methods:** We conducted a single-site cross-sectional study of prospectively enrolled outpatients with DC from 7/2018-9/2022. Participants completed validated instruments: the 4-item perceived stigma domain from the Short-Form Liver Disease Quality of Life questionnaire (asks the following: 1) I am embarrassed about how I look in public; 2) Some people are uncomfortable around me because of my liver disease; 3) Because of my liver disease I feel flawed and incomplete; 4) Some people avoid me because of my liver disease; score range 0–100; higher scores = lower perceived stigma), the Revised Edmonton Symptom Assessment Scale (range 0–100; scores ≥ 40: moderate-to-severe symptom burden), and the Hospital Anxiety and Depression Scale (range 0–21; scores ≥ 8: clinically significant depression/anxiety symptoms). We used multivariable linear regression adjusted for age, gender, and diagnosis of alcohol-related liver disease to examine the association of perceived stigma with psychological distress and symptom burden. **Results:** Among 218/312 (70%) patients (median age 60 [IQR 51–65]; 54% male; 89% White; 58% alcohol-related liver disease; median MELD-Na 16; 50% listed for transplant), the mean stigma score was 65.7 (SD 26.3). Stigma scores were significantly lower (i.e., greater perceived stigma) among those with more advanced liver disease (Child-Pugh A vs. B vs. C: 80.6 vs. 67.8 vs. 57.8; $p = 0.001$) and younger patients (ages 18–44: 61.4 vs. 45–64: 62.9 vs. ≥ 65: 73.8; $p = 0.019$). Patients in the highest quartile of perceived stigma (scores 0-25) were significantly more likely to report clinically significant depression (73% vs. 35%, $p = 0.004$) and anxiety (77% vs. 41%, $p = 0.005$) symptoms, and moderate-to-severe symptom burden (88% vs. 43%, $p < 0.001$) compared to those reporting lower perceived stigma (scores 26–100). In adjusted analyses, greater perceived stigma was independently associated with more severe depression symptoms (absolute $\beta = 0.08$, $p < 0.001$), anxiety symptoms (absolute $\beta = 0.08$, $p < 0.001$), and total symptom burden (absolute $\beta = 0.34$, $p < 0.001$). **Conclusion:** Stigma is a prevalent, debilitating burden in DC, particularly among younger patients and those with advanced disease, and is independently associated with psychological distress and symptom burden. Addressing stigma as a modifiable driver of distress through multilevel interventions and early psychosocial support is essential to improving health outcomes in cirrhosis care.

Figure 1. Perceived Stigma in Decompensated Cirrhosis: Correlates and Clinical Outcomes



Panel A: Heatmap displaying absolute Pearson correlation coefficients between perceived stigma and key clinical outcomes. Greater perceived stigma (lower scores on the SF-LDQOL stigma domain) was moderately correlated with depression ($r = 0.49$), anxiety ($r = 0.48$), and symptom burden (ESAS-r, $r = 0.44$), and weakly correlated with age ($r = 0.18$).

Panel B: Bar chart comparing the proportion of patients with clinically significant depression (HADS-D ≥8), anxiety (HADS-A ≥8), and symptom burden (ESAS-r ≥40) between those in the highest quartile of perceived stigma (scores 0–25) and those with lower stigma (scores 26–100). Patients with greater stigma reported substantially higher rates of depression (73% vs. 35%, $p = 0.004$), anxiety (77% vs. 41%, $p = 0.005$), and symptom burden (88% vs. 43%, $p < 0.001$).

0101 | TARGETING MENTAL HEALTH AND FATIGUE IN PBC, PSC, AND CIRRHOSIS: A SUBGROUP ANALYSIS FROM THE EMPOWER RANDOMIZED CONTROLLED TRIAL

Emily Johnson[1] Serena Isley[1] Shaina Corrick[1] Gail Wright[2] Joanne Hatchett[3] Holly Minckler[1] Alan Bonder[4] Mark Swain[5] Prasun Jalal[6] Andrew Mason[1] Mina Niazi[7] Cynthia Levy[8] Raj Vuppalanchi[9] Gideon Hirschfield[10] Christopher Bowlus[11] Jennifer Lai[12] Ben Vandermeer[1] Yinggan Zheng[1] Ashley Hyde[1] Puneeta Tandon[1],
[1]University of Alberta, [2]Canadian PBC Society, [3]PSC Partners Seeking a Cure, [4]Harvard University, [5]University of Calgary, [6]Baylor College of Medicine, [7]University of Saskatchewan, [8]University of Miami, [9]Indiana University, [10]Toronto General Hospital, [11]University of California, Davis, [12]University of California

Background: Fatigue, anxiety, and depression are common in people with chronic liver disease, yet few scalable interventions directly target these symptoms. Mind-body approaches - including psychological strategies, movement, meditation, and breathwork show potential benefit, but large randomized trial data in liver populations remain limited. **Methods:** This liver-specific subgroup analysis was embedded in the 3-arm eMPower RCT (NCT05786482), which evaluated a 12-week online mind-body wellness program combining acceptance and commitment therapy informed strategies, breathwork, meditation, mindful-movement, and disease-specific education. Adults with PBC, PSC, or cirrhosis were randomized to waitlist control (n = 85), eMPower (n = 84), or eMPower + weekly non-clinician check-ins (n = 86), with analysis comparing the two intervention groups to control. Validated measures assessed mental health (HADS), fatigue (Modified Fatigue Impact Scale (MFIS)), frailty (online Fried Frailty Phenotype, Edmonton Frail Scale (EFS)), demoralization (Demoralization-II), and quality of life (SF-12, EQ-5D-5L), and liver-specific outcomes (Chronic Liver Disease Questionnaire (CLDQ)). Analyses used ANCOVA, adjusted for baseline values, sex, and age. The primary outcome was change in HADS total score; secondary outcomes included MFIS and SF-12 scores. A nested qualitative study explored participant perspectives on symptoms and program engagement. **Results:** Among 255 liver participants (PBC 72.2%, cirrhosis 20.0%, PSC 7.8%), the mean age was 59 years ± 11.1 and 88% were female. At 12 weeks, those in the intervention arms showed greater improvements than controls in HADS total (–3.4 points; $p < 0.001$; MCID: 1.5–2.0), MFIS total (–5.9 points; $p < 0.001$; MCID: 4–8), SF-12 Mental Component Summary Score (+3.6 points; $p < 0.001$; MCID: 3–5), and Demoralization-II (–2.3 points; $p = 0.003$; MCID: 2). Physical, cognitive, and psychosocial fatigue subdomains improved alongside frailty (Fried: –1.2 points; $p = 0.001$) and EQ-5D-5L functional domains. Qualitative interviews reinforced fatigue as "cyclical," "draining," and deeply intertwined with mental health. Participants described improved self-efficacy using the program's breathwork and movement. **Conclusion:** This is the largest randomized evaluation of a digital mind-body intervention in chronic liver disease. As a subgroup analysis of a larger trial, while not powered to detect change, the eMPower program significantly improved mental health, fatigue, and quality of life in adults with PBC, PSC, and cirrhosis. Effects exceeded established MCIDs, reinforcing the clinical relevance of these changes. Findings support the use of scalable, low-intensity digital strategies to address symptom burden in hepatology care.

0102 | GETTING TO IMPLEMENTATION: A STEPPED WEDGE CLUSTER RANDOMIZED TRIAL OF A HOSPITAL-LEVEL INTERVENTION TO IMPROVE HEPATOCELLULAR CARCINOMA SURVEILLANCE

vera yakovchenko[1] Chaeryon Kang[2] Brittney Neely[1] Carolyn Lamorte[1] Heather McCurdy[3] Dawn Scott[4] Anna Nobbe[5] Gwen Robins[6] Nsikak Ekanem[7] Monica Merante[1] Sandra Gibson[1] Patrick Spoutz[8] Linda Chia[8] Rachel Gonzalez[9] matthew chinman[10] David Ross[11] Maggie Chartier[11] Lauren Beste[12] Jasmohan Bajaj[13] Tamar Taddei[14] Timothy Morgan[15] Shari Rogal[1], [1]VA Pittsburgh Healthcare System, [2]University of Pittsburgh, [3]VA Ann Arbor, [4]Central Texas Veterans Healthcare System, [5]Cincinnati VA Medical Center, [6]Martinsburg VA Medical Center, [7]VA Northern Indiana Healthcare System, [8]Veterans Integrated Service Network 20, [9]Sierra Pacific Veterans Integrated Service Network, [10]RAND Corporation, [11]Veterans Health Administration, [12]VA Puget Sound Health Care System, [13]Central Virginia VA Health Care System, [14]VA Connecticut Healthcare System, [15]VA Long Beach Healthcare System

Background: Adherence to HCC surveillance guidelines remains variable and low nationally. Implementation science offers strategies to address gaps between evidence and practice. We aimed to empirically identify and prescribe successful implementation strategies through Getting To Implementation (GTI), a manualized facilitation approach to increase HCC surveillance. **Methods:** This hybrid type III, stepped-wedge, cluster-randomized trial was conducted at 12 Veterans Health Administration (VA) hospitals between October 2020 and October 2022. GTI guided clinician teams in each hospital select, apply, and evaluate data-driven implementation strategies. HCC surveillance was monitored over time, and mixed effects models were used to assess the impact of the intervention on implementation reach (defined as The primary outcome of reach was defined as the receipt of HCC surveillance by at-risk Veterans) and sustainment (defined as reach over time). The a priori threshold for successful implementation was completion of the GTI steps by at least 80% of hospitals. **Results:** Facilitators supported hospital teams for an

average of 19 ± 5 hours over a 6-month active implementation period. Ten of 12 sites (83%) completed GTI, meeting adoption threshold. Hospitals applied a median of five strategies. HCC surveillance increased from mean 32.2% to mean 40.8% from pre- to post-intervention, and further increasing to 42.1% in the sustainment period. In unadjusted and adjusted models, odds of HCC surveillance were significantly higher during intervention (adjusted odds ratio, aOR = 1.67, 95% CI:1.59, 1.75) and 6-month sustainment (aOR = 1.68, 95% CI:1.60, 1.76), compared with baseline, with no difference between active and sustainment periods, indicating sustained improvement after facilitation ended. **Conclusion:** GTI sustainably improved HCC surveillance by approximately 10%, suggesting that data-driven implementation strategies can be "prescribed" to efficiently improve hepatology care measures.

0103 | CLINICAL OUTCOMES AND HEMIN USE OF PATIENTS WITH ACUTE HEPATIC PORPHYRIA IN THE PHASE 3 ENVISION STUDY WHO WERE NOT ATTACK-FREE AFTER 6 MONTHS OF GIVOSIRAN TREATMENT

Manish Thapar[1] Paolo Ventura[2] Encarna Guillén-Navarro[3] Bruce Wang[4] Eliane Sardh[5] Weiming Du[6] Ilaria Olivetti[6] Manisha Balwani[7], [1]Thomas Jefferson University, Philadelphia, PA, USA, [2]University of Modena and Reggio Emilia, Modena, Italy, [3]Sant Joan de Deu University Hospital, Barcelona, Spain, [4]UCSF Health, San Francisco, CA, USA, [5]Karolinska University Hospital, Stockholm, Sweden, [6]Alnylam Pharmaceuticals, Cambridge, MA, USA, [7]Icahn School of Medicine at Mount Sinai, New York, USA

Background: Acute hepatic porphyria (AHP) is a group of rare disorders with acute attacks of severe abdominal pain and neurological symptoms, increased aminolevulinic acid (ALA) and porphobilinogen (PGB) levels, chronic symptoms and long-term complications. In ENVISION, givosiran, an RNA interference therapeutic approved for AHP treatment, led to sustained reductions in annualized attack rate (AAR). **Methods:** Eligible patients with AHP, ≥ 12 years old, with ≥ 2 attacks requiring hospitalization, urgent care, or hemin at home in the 6 months (M) before enrollment, entered a 6M placebo-controlled double-blind period with 30M open-label extension (OLE) in which all patients received givosiran. This *post hoc* analysis included patients who completed the OLE. Subgroups were defined by attack frequency after the first 6M of givosiran (0 attacks, attack-free; ≥ 1 attack, not attack-free). **Results:** Of 94 randomized patients, 79 completed ENVISION; 46 (58%) were attack-free after M6 of givosiran and remained so for the OLE. Among 33 (42%) patients not attack-free at M6, the mean reduction in AAR (attacks requiring hospitalization, urgent care, or hemin at home) per 6M interval was 57% after > 6-12M of treatment and 85% after > 30-36M, relative to historical AAR (mean [SD], 12.8 [9.6]). Proportions of patients who were attack-free during 6M treatment intervals increased from 9% at > 6-12M to 79% at > 30-36M; those with no hemin use increased from 36% to 76% at the same time points. Health-related quality of life (HRQoL) improved in both groups (Table): at 6M and 36M of treatment, mean SF-12 v2 Physical Component Summary scores increased from baseline by 7.3 and 8.3 points (attack-free) and 4.1 and 9.1 points (not attack-free); EQ-VAS scores increased by 6.9 and 19.9 points (attack-free) and 2.2 and 17.5 points (not attack-free). After 6M and 36M of givosiran treatment, median ALA reductions from baseline were 88% and 93% (attack-free) and 85% and 92% (not attack-free); median PGB reductions from baseline were 88% and 97% (attack-free) and 86% and 93% (not attack-free). **Conclusion:** Both groups had fewer attacks and other treatment-related improvements with the first 6M of givosiran treatment regardless of the 6M attack status. Those who were not attack-free after the first 6M had further attack reductions and HRQoL improvements with prolonged treatment. The results suggest that the response to givosiran treatment helps with chronic symptoms as well as AHP attacks and further clinical improvement is expected over time.

0104 | HEPATOLOGY-LED EDUCATION ON ALCOHOL-RELATED LIVER DISEASE DURING CHEMICAL DEPENDENCY TREATMENT: IMPACT ON RETURN TO DRINKING AND CLINICAL OUTCOMES

Mary Thomson[1] Lisa Vollmer[1] Alexander Hubbell[1] Elizabeth Aby[1], [1]*University of Minnesota*

Background: Chemical dependency programing for alcohol use disorder (AUD) traditionally focuses on treatment of the underlying use disorder with a limited focus on medical complications of alcohol use. To address this gap, we introduced a group-based educational session led by a hepatology provider for adults undergoing inpatient alcohol treatment. This is a retrospective study looking at effect of this educational intervention on return to alcohol use and downstream healthcare utilization. **Methods:** Adult patients attending treatment were divided into cohorts before and after implementation of this program (historical control 10/2021-9/2022, educational intervention 1/2023-12/2023). Patient demographics, ICD codes for AUD/ARLD, laboratory results, and return to drinking were abstracted. **Results:** 569 patients were included (n = 275 historical control, n = 294 educational intervention). The majority were white (70.5%) males (65.0%). The mean age at the start of treatment was 40.6 years old. Follow up was longer for the historical control as expected (Table 1). Prior to the start of treatment 55.5% had a previous inpatient diagnosis code for AUD, and 17.1% and 5.8% had any coding for compensated or decompensated ARLD, respectively. There were no baseline differences in terms of liver disease severity (Table 1). Just under a third (31.8%) returned to alcohol use after treatment, which was higher in historical controls (38.2%) compared to the educational intervention (25.9%, p = 0.002). The average return to drinking was 223.1 days, which was not different between the cohorts (222.3 v. 224.3, p = 0.18). The proportion of adults returning to drinking was higher in the historical control at 90 days (12.4% v. 5.4%, p = 0.005), 180 days (22.9% v. 12.2%, p = 0.001), and 365 days (30.9% v 20.8%, p 0.007) post treatment. Outcomes were measured after completing treatment (Table 1). Fib-4 was minimally higher in historical controls, but otherwise there were no cohort differences in coding for inpatient AUD or different stages of ARLD. In people who returned to drinking, regardless of cohort, there were higher rates of coding for inpatient AUD and compensated ARLD with higher Fib-4 scores during follow up. **Conclusion:** Return to alcohol use after treatment occurs in a significant minority of patients. We found that integrating a hepatology provider into treatment to educate patients about ARLD was associated with reduced return to drinking, potentially by increasing disease awareness and motivation for abstinence. Although the intervention was not associated with a reduction in adverse outcomes, individuals who maintained abstinence exhibited less severe liver disease and lower healthcare utilization related to AUD. This highly scalable approach represents a shift toward upstream, preventive hepatology care for ARLD and holds significant potential to improve outcomes for AUD.

★ 0105 | COMBINATION OF RIFAXIMIN, PLASMA EXCHANGE, AND GRANULOCYTE COLONY STIMULATING FACTOR WITH STANDARD MEDICAL THERAPY VERSUS STANDARD MEDICAL THERAPY ALONE IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS: RESULTS: FROM THE GRACE-AH RANDOMIZED CONTROLLED TRIAL

Dr. Ashwin Vinod[1] Nipun Verma[1] Pratibha Garg[1] Malavika Sanal[1] Parminder Kaur[1] Jayant Agarwal[1] Sahaj Rathi[1] Arka De[1] Divjot Lamba[1] Rekha Hans[1] Ashish Kakkar[1] Abhishek Ghosh[1] Sunil Taneja[1] Ratti Ram Sharma[1] Ajay Duseja[1], [1]PGIMER Chandigarh

Background: Severe alcohol associated hepatitis (SAH) is a prototypical multi-axial disease characterized by bacterial translocation, immune dysregulation, and impaired hepatic regeneration, contributing to high short-term mortality. Monotherapies have shown limited efficacy due to this complex pathobiology. There is a pressing need for combinatorial therapies that address these interlinked mechanisms. This study evaluated the efficacy of a novel multimodal approach—targeting gut-liver axis (rifaximin), endothelial and immune modulation (therapeutic plasma exchange, TPE), and hepatic regeneration or modulation of cell death (granulocyte-colony stimulating factor, G-CSF)—in addition to standard medical therapy (SMT), compared to SMT alone in SAH non-responders. **Methods:** In this single center randomized controlled trial conducted from April 2023 to April 2024, 70 patients with SAH non-responsive to SMT were randomized to receive either combinatorial therapy (intervention arm) (n = 35) or SMT alone (control arm) (n = 35). Patients were followed for 90 days. The primary endpoint was overall survival; secondary outcomes included transplant-free survival, organ dysfunction scores, infection rates, stem cell mobilization, bacterial translocation, endothelial injury, cell death, and safety. Linear mixed effects models were used to evaluate the change over time of the biomarkers between the groups (fixed effect) after adjusting for individual patient trajectories (random effect). **Results:** Thirty, Sixty, and Ninety-day survival were significantly higher in the intervention arm (Figure 1) (90-day survival- 85.7% vs. 60%; $p = 0.013$). Hazard ratio for mortality at 90 days was 0.29 (95% CI: 0.11–0.82; $p = 0.019$). The intervention also led to reductions in MELD, CLIF-C-OF, and mDF scores, lower infection rates (40% vs. 68.6%; $p = 0.031$), and improved stem cell mobilization (CD34+; $p < 0.001$). Improvements in biomarkers of translocation (LPS) [beta (95% CI) = -32.36 (-38.8 to -25.91)], endothelial injury (vWF) [beta (95% CI) = -29.9 (-37.1 to -22.65)], and necroptosis (RIPK3) [beta (95% CI) = -4.071 (-5.125 to -3.017)] were also noted. **Conclusion:** This first-in-human proof-of-concept trial demonstrates a significant survival benefit with multi-axial modulation of bacterial translocation (rifaximin), endothelial dysfunction (TPE), and cell death (G-CSF) in SAH. Future studies should explore patient enrichment strategies to further optimize outcomes in this high-risk population.

Figure 1- Overall survival in the study population

0106 | AIF-1 GENETIC UPREGULATION IS A RISK FACTOR FOR ALCOHOL-ASSOCIATED LIVER DISEASE PROGRESSION

Priscila Correa Antonello[1] Colin Hodgkinson[1] Cheryl Marietta[1] Dechun Feng[1] Baskar Mohana Krishnan[1] Maria Parra[2] Zhaoli Sun[2] Bin Gao[1] David Goldman[1] Michelle Antoine[1], [1]National Institutes of Health, [2]Johns Hopkins University School of Medicine

Background: Prolonged heavy alcohol comsumption associated with alcohol use disorder (AUD) often results in various hepatic injuries, beginning with fatty liver and potentially progressing to more serious conditions of alcohol-associated liver disease (ALD), such as hepatitis, cirrhosis, or liver cancer. Chronic inflammation, driven

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

by the persistent activation of immune cells such as macrophages and neutrophils, is thought to contribute significantly to the progression of liver damage. The Allograft Inflammatory Factor 1 (*AIF-1/IBA1*) gene, encodes a calcium-binding protein critical for immune functions, including cell proliferation, migration and activation. In this work we investigated whether the rs3132451 single-nucleotide polymorphism (SNP) in the promoter region of *AIF-1* influences its expression and affects immune and liver injury profiles in chronic alcohol use. **Methods:** A total of 868 individuals were analyzed and classified by AUD status based on DSM-IV/V criteria. Using a comprehensive serum panel, we assessed liver function and immune profiles of patients with and without AUD. Participants were genotyped for the *AIF-1* SNP (rs3132451), and classified into *C/C* (control/reference), *C/G* (heterozygous), or *G/G* (homozygous/risk) genotypes. A second cohort diagnosed with alcohol-associated hepatitis was evaluated to study the SNP's relationship with more advanced liver disease. A third group of abstinent individuals with a history of AUD was included to assess whether immune changes persisted after alcohol use cessation. **Results:** Individuals with the *G/G* genotype showed higher levels of *AIF-1* expression in liver tissue and immune cells. Chronic alcohol consumption, regardless of genotype, was linked to increased numbers of monocytes and neutrophils, along with elevated liver enzymes (aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT)). However, those with both the *G/G* genotype and chronic alcohol use were more likely to exceed clinical thresholds for neutrophilia and iron overload. In patients with alcohol-associated hepatitis, the *G/G* genotype was associated with increased neutrophil infiltration in liver tissue and higher Model for End-Stage Liver Disease (MELD) scores, indicating more severe liver dysfunction. In abstinent individuals with prior AUD, elevated immune cell levels—especially neutrophils and monocytes—persisted over time, with the *G/G* genotype (particularly in males) linked to prolonged immune activation. **Conclusion:** The rs3132451 *G/G* variant of the *AIF-1* gene appears to worsen alcohol-related immune and liver disturbances, particularly through its role in promoting neutrophil activity. These findings suggest that genetic variation in *AIF-1* may influence the severity and progression of alcohol-induced liver injury, and that some immune disruptions may persist even after alcohol use stops.

0107 | LONG-TERM OUTCOMES FOLLOWING HOSPITALIZATION FOR ACUTE ALCOHOL-ASSOCIATED HEPATITIS

Sara Hatoum[1] Don Rockey[2], [1]Medical University of South Carolina, [2]MUSC

Background: Alcohol-associated hepatitis (AAH) is an acute form of liver injury resulting from excessive alcohol use. Due to limited treatment options and rising rates of harmful drinking, AAH is becoming an increasingly common indication for liver transplant. Unfortunately, liver transplant is not an option for many patients due to strict eligibility criteria and limited organ availability. Here, we aimed to identify clinical predictors and examine the rates of in-hospital and long-term mortality, as well as liver transplantation, in patients hospitalized for acute AAH. **Methods:** In this cohort analysis, we examined consecutive patients with definite AAH, based on NIAAA Alcoholic Hepatitis Consortia criteria, who were admitted to an academic medical center between 2012 and 2022 and underwent transjugular liver biopsy with hepatic venous pressure gradient (HVPG) measurement. Clinical and laboratory data was obtained for each patient to determine clinical and biochemical outcomes. Baseline MELD and HVPG were calculated at the time of biopsy. Patients were considered to have resolution of their portal hypertensive complications if they had resolution of ascites (off diuretics), encephalopathy (off lactulose/rifaximin), and no variceal hemorrhage. **Results:** The cohort included 154 patients with acute AAH with a mean MELD score of 27 and HVPG of 17. 147/154 patients had ascites, 49/154 had hepatic encephalopathy, and 8/154 had variceal hemorrhage. During hospitalization, 15 patients (10%) died, 5 (3%) were discharged to hospice, and 9 (6%) underwent orthotopic liver transplantation (OLT). After discharge, 22 patients (14%) were lost to follow-up, while 103 (67%) were followed for a mean of 1.8 years. Among these 103 patients, 46 died and 5 underwent OLT. The mean baseline MELD score of patients who died during follow-up was significantly higher than those who were alive at the end of follow-up (28 ± 7 vs 24 ± 6, $p = 0.01$), but there was no significant difference in the mean baseline HVPG (17 ± 6 vs 17 ± 7, $p = 0.8$) or rate of biopsy proven cirrhosis (54% vs 53%, $p > 0.9$) between the two groups (Table 1). 68/103 patients remained abstinent, while 35/103 resumed alcohol use. Patients who remained abstinent had a significantly lower mortality rate than those who resumed alcohol (29% vs 74%, $p < 0.0001$). Additionally, 17/68 (25%) of abstinent patients had complete resolution of their portal hypertensive complications despite a mean baseline HVPG of 19. **Conclusion:** Patients hospitalized for acute AAH experience high rates of in-hospital and long-term mortality, particularly those with elevated MELD scores. Sustained alcohol abstinence following discharge was strongly

associated with improved survival, and in some patients, resolution of portal hypertension and recompensation. Biopsy proven cirrhosis did not have a significant impact on survival rates following hospital discharge.

Table 1: Characteristics of patients followed up after hospital discharge

Indicator	Died during follow-up (n=46)	Alive at the end of follow-up (n=57)	P value
Age	45±11	44±12	0.8
Male (%)	46	51	0.7
Baseline MELD	28±7	24±6	0.01
Baseline HVPG	17±6	17±7	0.8
Biopsy proven cirrhosis (%)	54	53	>0.9
Abstinent (%)	44	84	<0.0001

0108 | REVERSE TRANSCRIPTASE INHIBITORS ARE ASSOCIATED WITH REDUCED LIVER-RELATED COMPLICATIONS IN AUD: ESTABLISHING A PATHOGENIC ROLE OF ENDOGENOUS RETROVIRUSES IN AH AND ALD

Maddie Kubiliun[1] Ashutosh Shukla[1] Tomas Rodriguez[1] Musa Ali Rizvi[2] Samuel Piaker[1] Mujeeb Basit[2] Zhaoli Sun[3] Andrew Cameron[3] Mack Mitchell[1] Ronac Mamtani[4] Jay Luther[5] Suraj Patel[1], [1]University of Texas Southwestern Medical Center, [2]UT Southwestern Medical Center, [3]Johns Hopkins University, [4]University of Pennsylvania, [5]Massachusetts General Hospital

Background: Endogenous retroviruses (ERVs) make up ~8% of the human genome. Typically silenced, ERVs can be reactivated by inflammatory stimuli such as alcohol, triggering innate immune responses and worsening liver injury. Our preclinical mouse data show that blocking ERV reverse transcription with FDA-approved reverse transcriptase inhibitors (RTIs) attenuates alcohol-induced liver injury and inflammation. In two complementary studies, we aimed to (1) evaluate hepatic ERV expression in patients with alcoholic hepatitis (AH) and cirrhosis (AC), and (2) assess whether RTI use is associated with reduced liver-related complications in individuals with alcohol use disorder (AUD). **Methods:** Liver RNA-seq from 25 patients with alcoholic hepatitis (AH) or cirrhosis (AC) was analyzed using a custom pipeline to quantify full-length human ERV (hERV) expression, with a focus on the evolutionary young hERV-K family. hERV-K reverse transcriptase protein levels were measured in matched liver biopsies. To assess the clinical impact of RTIs, we performed a retrospective cohort study using the nationwide Epic Cosmos database. Patients with AUD and prior RTI exposure were matched 1:1 to unexposed AUD patients using propensity scores accounting for demographic, metabolic, and psychiatric covariates. Individuals with pre-existing liver disease or CD4 < 200 were excluded. Liver-related outcomes were identified by SNOMED CTs and ICD-10 codes, and associations with RTI exposure were evaluated using multivariable logistic regression. Landmark analyses were used to adjust for immortal time bias. **Results:** RNA-seq revealed significant upregulation of hERV expression in AH (FC 8.6, $p = 0.03$) and AC samples (FC 2.5, $p = 0.006$) compared to controls. Furthermore, hERV expression linearly correlated with AH severity. hERV-K reverse transcriptase protein levels were increased in liver biopsies from AH and AC patients. In the retrospective study, we identified 13,921 AUD patients with prior RTI exposure and 13,921 propensity-matched AUD patients without RTI exposure; both groups had similar follow-up durations. RTI-exposed AUD patients had reduced odds of cirrhosis (OR 0.77, $p = 2.1e\text{-}5$), MALOs (OR 0.81, $p = 1.2e\text{-}3$), AH (OR 0.74, $p = 5.4e\text{-}6$), HCC (OR 0.67, $p = 6.3e\text{-}3$), and all-cause mortality (OR 0.84, $p = 1.3e\text{-}3$). **Conclusion:** Hepatic hERV expression is increased in AH and AC, and correlates with disease severity. RTI exposure is associated with reduced liver-related outcomes, including AH, AC and mortality in AUD. These findings support a pathogenic role for ERVs in ALD and highlight RTIs as a potential therapeutic strategy.

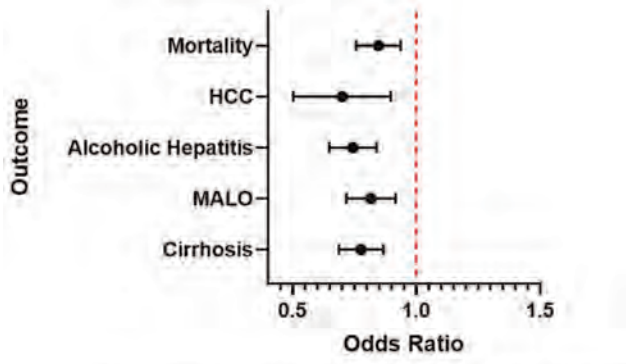

Fig 1: Odds of liver-related outcomes among RTI users vs non-RTI users with AUD

0109 | TEN-YEAR POST-TRANSPLANT SURVIVAL OUTCOMES AFTER EARLY LIVER TRANSPLANT FOR SEVERE ALCOHOL-ASSOCIATED HEPATITIS: AN ACCELERATE-AH STUDY

Matthew Dukewich[1] Christine Hsu[2] Neha Jakhete[3] George Therapondos[4] Sheila Eswaran[5] Ethan Weinberg[6] Mohamed Shoreibah[7] Manotri Chaubal[8] Adam Khalaf[8] Amol Rangnekar[9] Kirti Shetty[10] Cerise Kleb[3] Sevda Aghayeva[6] Ruona Ebiai[4] Sameera Shuaibi[4] Chandler Shapiro[5] John Rice[11] Jessica Musto[11] R. Mark Ghobrial[12] Ashton Connor[13] Michael Lucey[11] Norah Terrault[14] Brian Lee[15], [1]University of Southern California- Keck Medicine, [2]National Institute of Diabetes and Digestive and Kidney Diseases, [3]University of Maryland, [4]Ochsner Medical Center, [5]Rush University Medical Center, [6]University of Pennsylvania, [7]University of Alabama at Birmingham, [8]Georgetown University, [9]Georgetown University Hospital, [10]University of Maryland, Baltimore, [11]University of Wisconsin, [12]Houston Methodist JC Walter Transplant Center, [13]Houston Methodist, [14]University of Southern California, [15]Keck School of Medicine

Background: Early (<6 months of sobriety) liver transplant (LT) for severe alcohol-associated hepatitis (AH) is the fastest growing indication for LT in the US and Europe. Studies in this population have been limited to short-term (1- and 3-year) post-LT outcomes. Leveraging the ACCELERATE consortium, herein we investigate long-term (>3 year) post-LT alcohol use and survival outcomes and patient factors associated with early (<3 years) vs. late (>3 years) return to alcohol use and mortality. **Methods:** In this retrospective cohort of 9 US LT centers, we included LT recipients for clinically diagnosed severe AH between 2006-2021. Kaplan-Meier survival analysis estimated survival rates post-LT. Alcohol use was captured at first detection during post-LT follow-up by clinical interview and biomarkers (e.g. ethyl glucuronide or phosphatidylethanol) (early use < 3 years post-LT, late use > 3 years post-LT). Multinomial logistic and multivariable Cox regression were used to compare the relative risk ratios (aRRR) and hazard ratios (aHR) of pre-LT clinical, demographic, and psychosocial factors associated with early or late return to alcohol use (vs no alcohol use) and early or late mortality. **Results:** Among 316 included LT recipients (67% male, median age 43 years, median MELD-Na at LT of 37), median post-LT follow-up was 4.4 (IQR 1.5-7.0) years. Early return to any alcohol use occurred in 79 (risk 25.9% [95%CI 12.0-23.5%]) while late return to any alcohol use occurred in 19 (risk by 7 years post-LT 10.4%, [6.3-16.9%]) with an overall median of 273 days (IQR 91-730 days) to first post-LT drink. Older age (aRRR 0.97 [0.95-0.99] per year) and male sex (aRRR 0.50, 95%CI 0.32-0.80) were associated with lower risk for early return to alcohol use (vs. no return to use), while Medicaid (vs. private) insurance was associated with greater risk for late return to alcohol use (aRRR 3.74, 95%CI 1.28-11.0) in age, sex, and MELD adjusted analysis. There were a total of 66 deaths (21.0%) during post-LT follow-up, at a median of 1.9 years (IQR 0.8-8.0 years) post-LT. Post-LT survival was 80.8% (75.3-85.2%) at 5-years, 75.2% (68.3-80.7%) at 7-years, and 67.6% (58.6-75.0%) at 10-years. Demographics associated with psychosocial risk, peri-operative vascular complications, and return to alcohol use were associated with early post-LT mortality; need for dialysis at LT, biliary complications, and return to alcohol use were associated with late post-LT mortality (Table). **Conclusion:** In this first report of 10-year post-LT outcomes among early LT for severe AH recipients, long-term post-LT survival is better or on par with other indications for LT. More than 25% of ELT recipients returned to alcohol use in the first 3-years post-LT, while an additional 10% returned to alcohol use by 7-years post-LT. We identified different risk factors for early vs. late post-LT outcomes, which informs candidate selection and longitudinal post-LT interventions to improve outcomes.

Table. Association of Pre-LT Factors with Post-LT Return to Alcohol Use and Post-LT Survival

0110 | THE IMPACT OF CANNABINOIDS ON THE RISK OF ALCOHOL-ASSOCIATED LIVER DISEASE

Butros Fakhoury[1] Vinay Jahagirdar[1] Kaanthi Rama[1] David Hudson[2] Wei Wang[1] Luis Díaz[3] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Western University & London Health Sciences Centre, [3]University of California San Diego

Background: Alcohol-associated liver disease (ALD) is a major cause of liver-related morbidity and mortality, yet effective therapeutic options remain limited. Preclinical data suggest that modulation of the hepatic endocannabinoid system, particularly via cannabidiol (CBD), may reduce alcohol-induced liver injury. Due to CBD's limited clinical use, we sought to evaluate the association between cannabis use and ALD risk among patients with alcohol use disorder (AUD). **Methods:** Using the TriNetX US Collaborative Network, we identified adult patients with AUD from 2010 to 2022, excluding those with preexisting liver disease. Patients were stratified into three cohorts: cannabis use disorder (CUD), cannabis users without CUD (CU), and non-cannabis users (non-CU). Propensity score matching was performed based on cardiometabolic risk factors, liver function, psychiatric comorbidities, and other substance use. Outcomes included ALD, hepatic decompensation, and all-cause mortality over 3 years. Kaplan–Meier curves and Cox regression were used to estimate hazard ratios (HRs). **Results:** After matching, 32,125 patients were included in each of the CUD and non-CU groups; 11,114 in each of the CUD vs. CU comparison; and 11,231 in the CU vs. non-CU comparison. Compared to non-CU, CUD was associated with reduced risks of ALD (HR 0.61; 95% CI 0.54–0.69; $p < 0.001$), hepatic decompensation (HR 0.78; 95% CI 0.68–0.89; $p < 0.001$), and all-cause mortality (HR 0.86; 95% CI 0.79–0.94; $p < 0.001$). CU was associated with reduced ALD risk (HR 0.80; $p = 0.015$), but not decompensation or mortality. Compared to CU, CUD was also associated with lower ALD risk (HR 0.75; $p = 0.007$). Sensitivity analyses excluding patients with obesity, diabetes, or other substance use disorders yielded consistent results. As a positive control, CUD was associated with increased schizophrenia risk (HR 1.20; $p < 0.001$), but not cerebrovascular disease (HR 0.94; $p = 0.122$), supporting the internal validity of the cohort. **Conclusion:** In this large, propensity-matched cohort of AUD patients, cannabis use was associated with a reduced risk of ALD, with the greatest risk reduction seen in patients with CUD compared to CU and non-CU. Given the established risks of cannabis and the emerging evidence supporting CBD's hepatoprotective potential, further clinical studies evaluating CBD's role in ALD prevention and treatment are warranted.

Table 1. Outcomes by Cannabis Use Status at 3-Year Follow-Up

Cohort	Outcome	Incidence rate (1000PY)	HR (95% CI)	P-value
CUD vs non-CU	ALD	CUD: 3.90 vs Non-CU: 6.81	0.61 (0.54–0.69)	<0.001
	Hepatic decompensation	CUD: 4.86 vs Non-CU: 6.31	0.78 (0.68–0.89)	<0.001
	All-cause mortality	CUD: 13.39 vs Non-CU: 15.59	0.86 (0.79–0.94)	<0.001
CU vs non-CU	ALD	CU: 8.26 vs Non-CU: 10.13	0.80 (0.67–0.96)	0.015
	Hepatic decompensation	CU: 7.86 vs Non-CU: 8.44	0.92 (0.76–1.11)	0.376
	All-cause mortality	CU: 17.47 vs Non-CU: 19.36	0.89 (0.79–1.02)	0.083
CUD vs CU	ALD	CUD: 6.07 vs CU: 8.21	0.75 (0.61–0.92)	0.007
	Hepatic decompensation	CUD: 6.30 vs CU: 7.80	0.82 (0.67–1.01)	0.059
	All-cause mortality	CUD: 17.14 vs CU: 17.28	1.01 (0.88–1.15)	0.934

Abbreviations: ALD, alcohol-related liver disease; CUD, cannabis use disorder; CU, cannabis users; non-CU, non-cannabis user; PY, person-years.

Table 2. Sensitivity Analyses and Control Outcomes.

Sensitivity Analysis				
Cohort	Outcome	Incidence rate (1000PY)	HR (95% CI)	P-value
CUD vs non-CU, excluding BMI≥30 and HBA1C≥6	ALD	CUD: 6.96 vs Non-CU: 13.04	0.55 (0.42–0.67)	<0.001
	Hepatic decompensation	CUD: 7.44 vs Non-CU: 9.62	0.77 (0.61–0.98)	0.029
	All-cause mortality	CUD: 16.72 vs Non-CU: 20.31	0.82 (0.70–0.96)	0.014
CUD vs non-CU, positive control outcome	Schizophrenia	CUD: 42.94 vs Non-CU: 35.81	1.22 (1.16–1.28)	<0.001
CUD vs non-CU, negative control outcome	Cerebrovascular Diseases	CUD: 18.45 vs Non-CU: 19.63	0.94 (0.88–1.02)	0.122

Abbreviations: ALD, alcohol-related liver disease; BMI, body mass index; CUD, cannabis use disorder; HBA1C , hemoglobin A1c; non-CU, non-cannabis user; PY, person-years.

0111 | A BLUEPRINT FOR MULTIDISCIPLINARY CARE FOR ALCOHOL-ASSOCIATED LIVER DISEASE ACROSS TRANSPLANT PATHWAY: STRUCTURE, MAUD UTILIZATION, AND EARLY OUTCOMES

Jonathan Nahas[1] Bellinda Accime[1] Therese Bittermann[1] Christina Cerra[1] Arpita Goswami Banerjee[1] Kimberley Johnson[1] Renee Maggiaro[1] Emily Patrick[1] Ethan Weinberg[1] Robert Weinrieb[1] Marina Serper[1], [1]University of Pennsylvania

Background: Multidisciplinary care models to address both alcohol-associated liver disease (ALD) and alcohol use disorder (AUD) allow patients to receive coordinated care for their liver disease and substance use. Limited data exist regarding the design of these clinics and their effect on objective biomarkers of alcohol consumption among patients in the liver transplant (LT) pathway. **Methods:** We report on our center's multidisciplinary ALD/AUD clinic, ILEARN (Integrated Liver transplant Engagement And Recovery Network), from its inception in 7/2023 through 5/2025. The clinic serves patients with high-risk ALD in any phase of the transplant pathway. The clinic schedules sequential, co-located visits with hepatology and psychiatry with asynchronous integration of social work and AUD counseling. Clinic workflow and indications are shown in the Figure. **Results:** Our ILEARN cohort included 60 patients, equally distributed between pre- and post-LT at the time of their initial clinic visit (50% post-LT, 43% in evaluation, 7% listed). The cohort was 53% male, 87% White, and with mean age 50 years. At LT evaluation, mean SIPAT was 28. Among those transplanted, mean MELD 3.0 was 31. Three-quarters were enrolled in a tailored, virtual intensive outpatient program (IOP). The most recent phosphatidylethanol (PEth) was negative in 87%. Only 7% had a PEth above 200 ng/mL. Of those with a positive PEth, 25% were below 25 ng/mL, and PEth value was downtrending while receiving ILEARN care in 80%. Medications for AUD (MAUD) were prescribed in 40% of ILEARN patients, with naltrexone and gabapentin being the most common. Nearly 2/3 of the patients receiving naltrexone were newly started while in ILEARN. Only 1/60 patients had evidence of graft dysfunction attributed to alcohol. Five patients (8%) seen in the clinic died. Two were due to sepsis while in LT evaluation. Of the 3 post-LT mortalities, 2 were attributed to neurologic complications and 1 to early graft failure. No deaths were related to alcohol. **Conclusion:** Our center experience demonstrates that a multidisciplinary ALD/AUD clinic across the LT pathway is associated with a reduction in objective biomarkers of alcohol use, and our MAUD rates of 40% are well above published rates < 10%. Future studies will compare outcomes among patients with ALD that did not go through the clinic as well as provide longer term longitudinal data.

Figure. ILEARN clinic workflow

0112 | EVOLVING RISK FACTORS FOR EARLY ALLOGRAFT DYSFUNCTION IN DCD LIVER TRANSPLANTATION IN THE ERA OF MACHINE PERFUSION

ATSUSHI NISHIMAGI[1] Rikako Oki[1] Luckshi Rajendran[1] Emily Kerby[1] Adhnan Mohamed[1] Ahmed Nassar[1]

Abbas Al-Kurd[1] Atsushi Yoshida[1] Marwan Abouljoud[1] Shunji Nagai[1], [1]Division of Transplant and Hepatobiliary Surgery, Henry Ford Hospital

Background: Early allograft dysfunction (EAD) remains a known risk factor for poor graft survival (GS) in LT from DCD. This study aimed to investigate how the risk factors for EAD have changed with the advent of NMP. **Methods:** Adult LT alone from DCD donor which were performed from 2015-2024 were evaluated. Patients were divided into two groups based on the use of NMP, and logistic regression analysis was performed to identify risk factors associated with the development of EAD in each group. Additionally, the impact of EAD on 1-year GS was assessed using Kaplan-Meier analysis. All NMPs were initiated at donor hospitals (on-site NMP). **Results:** This study included 201 adult DCD liver transplant patients, in which LT was performed using NMP in 100 patients and non-NMP- in 101 patients. Donor age was significantly higher in the NMP group compared to the non-NMP group (46 years vs 38 years; $p = 0.007$). There was no significant difference in recipient age between the NMP group and the non-NMP group (60 years vs 58 years; $p = 0.803$). Multivariable logistic regression model for EAD is shown in Table 1. In the non-NMP group, donor age, donor gender(male), recipient gender (male) were identified as a significant risk factor for EAD. (OR 1.074, 95% CI 1.03-1.12, $p < 0.001$, OR 3.155, 95% CI 1.15-8.63, $p = 0.03$, OR 2.72, 95% CI 1.01-7.33, $p = 0.047$) In contrast, in the NMP group, donor age and recipient gender were no longer a significant risk factor for EAD. Donor gender(male) and donor BMI were also identified as a significant risk factor for EAD. (OR 4.94, 95% CI 1.17-20.9, $p = 0.03$, OR 1.137, 95% CI 1.05-1.23, $p = 0.002$, OR 1.14). Kaplan-Meier analysis revealed no significant difference in 1-year GS between patients with and without EAD in the non-NMP group ($p = 0.423$). In the NMP group, EAD was significantly associated with poorer 1-year GS. ($p = 0.009$). **Conclusion:** With NMP use, DCD donor age became significantly older. While donor age was considered a risk factor for EAD in non-NMP DCD LT, donor age was not a risk factor for EAD in NMP DCD LT, indicating that NMP mitigates age-related risk and contributes to expanding the donor pool without compromising post-transplant outcomes. However, the donor gender (male) is a risk factor for EAD regardless of the NMP, and the donor BMI is a risk factor for EAD in NMP. Therefore, these risk factors may need to be considered in DCD donor selection.

0113 | SIMILAR LONG-TERM LIVER RELATED AND MORTALITY OUTCOMES FOR LIVING LIVER DONORS COMPARED TO THE GENERAL POPULATION

Jennifer Flemming[1] Maya Djerboua[2] Nazia Selzner[3], [1]Queen's University Cancer Research Institute, [2]ICES-Queen's, [3]University of Toronto

Background: Understanding the long-term outcomes after living liver donation (LLD) is important to support LLD programs and for informed consent. Data from Korea have suggested survival after LLD maybe worse compared to the general population. No long-term outcomes have been described for LLD cohorts in North America. The aim of this study was to describe health-related outcomes and mortality of LLDs compared to a matched general population. **Methods:** Individuals in Ontario, Canada who were LLDs from 2004-2022 were identified using a validated algorithm in administrative healthcare data (sensitivity 99%, specificity 100%) and followed to the end of 2023. Each LLD was matched 30-days post donation to five healthy individuals in the general population based on birth year, sex, income quintile and census division. Baseline characteristics between groups were compared and liver-related outcomes (viral hepatitis, cirrhosis/decompensation, hepatocellular carcinoma, transplant), psychiatric outcomes, and overall mortality were identified using linked databases. Overall survival was

compared using the Kaplan-Meier method and the association between being an LLD and mortality was evaluated using Cox regression with the robust variance estimator to account for the matched design. Small cells <6 were supressed due to privacy policies. **Results:** A total of 949 LLDs were identified and matched to 4,745 from the general population (median age 35 [IQR 28-44], 57% female). After a median follow-up of 9 years (IQR 4-14), $<1\%$ of LLDs and matched controls had any liver-related event ($p=.654$). Mortality was also similar between groups with 13 (1.4%) of LLDs and 59 (1.3%) dying during the study period ($p=.846$; Figure). Using Cox regression, there was no association between LLD and mortality (HR 1.06, 95% CI 0.58-1.92; $p=.845$). LLDs did however have a higher rate of psychiatric encounters during follow-up (17% vs. 9%, $p<.001$) which were driven by a higher proportion of encounters for mood and anxiety disorders and adjustment/trauma/reaction disorders. No differences were observed in psychotic disorders or substance use disorders. **Conclusion:** Long-term liver-related and mortality outcomes are similar for LLDs compared to the general population. Psychiatric encounters for mood and adjustment disorders are more frequent for LLDs. These results can be used to support the use of LLD in North America and for informed consent for potential donors.

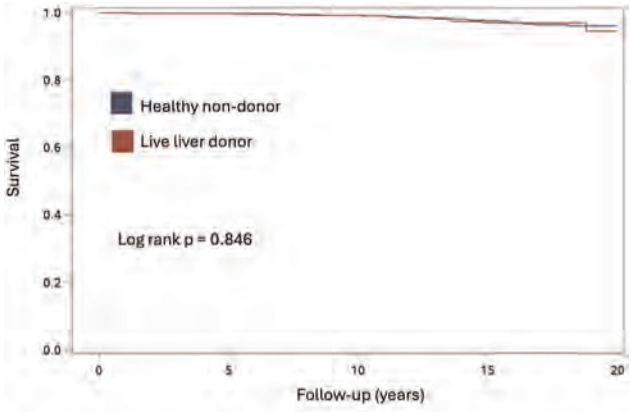

Figure: Long-term overall survival of living liver donors compared to the general population.

★ 0114 | DOSE-ESCALATION STUDIES OF MESENCHYMAL STROMAL CELL THERAPY FOR DECOMPENSATED LIVER CIRRHOSIS: PHASE IA/IB RESULTS: AND IMMUNE MODULATION INSIGHTS

Lei Shi[1] Ziying Zhang[1] Ze-Rui Wang[2] Song Mei[3] Weiqi Yao[4] Mengqi Yuan[1] Zhe Xu[1] Lei Huang[1] Yu Zhang[5] Peng Zhang[6] Yonggang Li[1] Fu-Sheng Wang[1], [1]Senior Department of Infectious Diseases, The Fifth Medical Center of Chinese PLA General Hospital, [2]Senior Department of Gastroenterology, the First Medical Center of Chinese PLA General Hospital, [3]Beijing Children's Hospital; Shanghai Jiao Tong University School of Medicine, [4]School of Life and Health Sciences, Hubei University of Technology, [5]Wuhan Optics Valley Zhongyuan Pharmaceutical Co., Ltd., [6]Rare Disease Center, Beijing Children's Hospital, Capital Medical University

Background: Decompensated liver cirrhosis (DLC) is characterized by severe liver dysfunction and immune dysregulation, posing significant treatment challenges. Mesenchymal stromal cells (MSCs) therapy has shown promise in DLC treatment, but the optimal dosing strategies and dose-dependent therapeutic mechanisms in humans remain unclear, limiting its clinical application. **Methods:** We conducted sequential Phase Ia/Ib trials using a single-arm, dose-escalation design to evaluate the safety and tolerability of MSCs therapy in DLC patients while also exploring its immunomodulatory effects and gathering preliminary therapeutic signals. In Phase Ia, four dose cohorts received a single dose of MSCs: 5.0×10^7, 1.0×10^8, 1.5×10^8, and 2.0×10^8 cells. Patients were followed up on Days 3, 7, 14, and 28. Multi-omics analyses, including single-cell RNA sequencing and cytometry by time of flight, were conducted to investigate immune cell dynamics and dose-dependent responses. Building on these findings, Phase Ib included two dose cohorts, each of whom received three doses of MSCs administered one week apart: 1.0×10^8 and 2.0×10^8 cells per dose. Patients were followed up on Days 7, 14, 21, and 28 to further evaluate the safety and feasibility of multiple-dose regimens. The trials were registered at ClinicalTrials.gov (NCT05227846 and NCT05984303). **Results:** MSCs therapy demonstrated good safety and tolerability in both Phase Ia and Phase Ib trials, with no severe adverse events, dose-limiting toxicities, or serious unexpected adverse reactions observed up to Day 28. Multi-omics analyses revealed that higher MSC doses elicited stronger immunomodulatory effects, particularly by modulating monocyte subsets. In particular, myxovirus resistance 1 positive (MX1+) monocytes, a key monocyte population, exhibited dose-dependent changes and was identified as a mediator of MSC-induced immunomodulation. These effects were sustained for up to seven days post-treatment but diminished by Day 14. Preliminary clinical signals included improvements in Child–Pugh scores, Model for End-Stage Liver Disease scores, liver function markers, and quality-of-life metrics, particularly in the higher-dose and multiple-dose groups. **Conclusion:** This study demonstrates the safety and tolerability of MSCs therapy in patients with DLC and provides the first human-based evidence on the dose-effect relationship

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and optimal administration regimens. The identification of MX1+ monocytes as a critical mediator highlights the potential of MSCs therapy to modulate immune dysfunction in DLC. These findings offer valuable insights for optimizing MSCs therapy and inform the design of future efficacy-focused clinical trials.

0115 | INTEGRATING PROTEOMICS AND TRANSCRIPTOMICS TO STUDY LIVER TRANSPLANT ACUTE REJECTION

Xiaoying Liu[1] Connor Lantz[1] Richard Green[1],
[1]Northwestern University Feinberg School of Medicine

Background: Acute rejection (AR) is a common complication that can lead to graft failure after liver transplantation. Most prior serum and liver biopsy biomarker studies have utilized gene expression-based methods, but few have examined concomitant protein expression. This investigation combines transcriptomics and proteomics approaches to uncover potential liver biomarkers for AR and to better understand its molecular pathogenesis. **Methods:** Clinically-indicated post-transplant liver biopsies (n = 27) were used for gene and protein expression analysis. Samples were classified as: (1) AR with abnormal LFT (n = 11); and (2) control with normal LFT (n = 16). RNAseq was used for transcriptomics study and mass spectrometry-based label-free quantitative proteomics was performed to assess protein expression. **Results:** Transcriptomic analysis reveals that 1179 genes are significantly upregulated and 229 genes are downregulated in the AR group compared to control (Padj < 0.05). The top 5 differentially expressed genes include *TNFRSF9*, *SERPINA12*, *CXCL10*, *DLGAP5* and *PLK1*. Pathway enrichment analysis shows that multiple metabolic process pathways including hepatic lipid and protein metabolic processes, and mitochondrial translation are downregulated in AR ($P < 0.05$). As expected, several signaling pathways related to allograft rejection and inflammatory response are upregulated in AR. Proteomics study identified a total of 3455 proteins, with 267 proteins upregulated and 67 proteins downregulated in AR compared to control ($P < 0.05$). Consistent with the results from the transcriptomics study, metabolic and biosynthetic processes are downregulated in AR, and proteins related to immune response and antigen processing and presentation are upregulated in AR. Top differentially expressed proteins include APOL3, CD74, LSP1, HIST1H1D, HLA-DRA and FABP5. Among the 334 differentially expressed proteins, 281 of them do not have significant changes in gene expression, including proteins involved in the metabolic processes, actin cytoskeleton and focal adhesion. **Conclusion:** Genes and proteins that are related to hepatic metabolic processes are downregulated in liver biopsies from patients with AR compared to control. As expected, immunologic response related pathways are upregulated in AR. Most differentially expressed proteins detected with proteomics do not have similar changes in gene expression, indicating potential post-transcription regulation and/or modulation of protein stability. These data demonstrate the importance of proteomic, and not simply transcriptomic studies in accurately identifying biomarkers for AR.

0116 | TACROLIMUS-RESISTANT, TCR-DEFICIENT, GPC3-SPECIFIC CAR T CELLS FOR SAFE AND EFFECTIVE TREATMENT OF HEPATOCELLULAR CARCINOMA AFTER LIVER TRANSPLANTATION

Lorenz Kocheise[1] Mohamed Reda Benmebarek[1] Gabriel Bacil[1] Dan Li[1] Xiao Bin Zhu[1] Patrick Huang[1] Yuta Myojin[1] Kylynda Bauer[1] Chi Ma[1] Rajiv Trehan[1] Firouzeh Korangy[1] Mitchell Ho[1] Tim F Greten[1],
[1]National Cancer Institute

Background: Liver transplantation is a curative treatment for early-stage hepatocellular carcinoma (HCC), while immunotherapy remains the first-line therapy for advanced disease. However, managing recurrent HCC after liver transplantation poses a significant therapeutic challenge, as immune checkpoint inhibitors are contraindicated due to the high risk of allograft rejection. Tumor-specific chimeric antigen receptor (CAR) T cells

targeting glypican-3 (GPC3) offer a promising alternative strategy. Here, we describe a CAR T cell platform designed for post-transplant application, featuring CRISPR/Cas9-mediated knockout of the *FK506-binding protein 12* (*FKBP12*) locus to confer tacrolimus-resistance and maintain CAR T cell function under continuous immunosuppression. Concurrent disruption of the *TRAC* locus eliminates T cell receptor (TCR) expression, reducing the risk of allograft rejection mediated by the endogenous TCR of these tacrolimus resistant CAR T cells. **Methods:** Resting human T cells were electroporated with a ribonucleoprotein (RNP) complex composed of a 1:1 mixture of single-guide RNAs targeting *FKBP12* and *TRAC*, pre-incubated with recombinant high-fidelity Cas9 protein. Following electroporation, cells were expanded in culture with CD3/CD28 beads and supplemented with IL-2, IL-7, and IL-15 and transduced with a second-generation anti-GPC3-CAR. Engineered T cells were validated and analyzed by genomic sequencing, flow cytometry, cytotoxicity assays using HCC cell lines, and antigen-specific stimulation assays. **Results:** Knockout efficiencies for *TRAC* and *FKBP12* following electroporation ranged from 70-90%, as determined by flow cytometry and genomic sequencing, respectively. TCR-negative CAR T cells were enriched to high purity ($>$ 99%) using conventional Magnetic-Activated Cell Sorting for CD3-negative cells. Upon GPC3-specific antigen stimulation, tacrolimus significantly inhibited interferon-gamma (IFN-g) production in wildtype (WT) CAR T cells, but not in *FKBP12* knockout (KO) cells (169.6 pg/ml vs. 9903 pg/ml, $p = 0.0035$). The cytotoxic activity of WT CAR T cells co-cultured with Hep3B (1.49% vs. 54.03%, $p < 0.0001$) and HepG2 (23.35% vs. 92.30%, $p < 0.0001$) tumor cells was markedly reduced in the presence of tacrolimus, whereas KO CAR T cells maintained a robust killing capacity under the same conditions. **Conclusion:** This dual-edited CAR T cell platform offers a safe and effective approach for the development of cellular immunotherapy for recurrent HCC in the post-transplant setting while continuing tacrolimus-based immunosuppression.

0117 | SINGLE-NUCLEI RNA SEQUENCING OF HUMAN LIVER IDENTIFIES CELL TYPE SIGNATURES THAT DISTINGUISH AUTOIMMUNE HEPATITIS FROM DISEASE CONTROLS

Marc Sherman[1] Daniel Schafer[1] Molly Thomas[2] George Lauer[1] Alexandra-Chloe Villani[1] Wolfram Goessling[1], [1]Massachusetts General Hospital, [2]Oregon Health Sciences University

Background: Autoimmune hepatitis (AIH) is a progressive liver disease diagnosed syndromically by abnormal liver tests, characteristic autoantibody profiles, suggestive histopathology, and steroid responsiveness. Single-nucleus RNA sequencing (snRNA-Seq) offers an opportunity to uncover cellular and molecular features that discriminate AIH from other hepatic disorders and reveal underlying disease pathogenesis. **Methods:** Liver biopsies from individuals undergoing evaluation for suspected AIH were prospectively collected under an IRB-approved protocol at Massachusetts General Hospital. Control tissue was obtained from hepatic resections in patients without underlying liver disease. Nuclei were isolated and profiled via snRNA-Seq using the 10x Genomics platform, and data were processed using SCANPY. Following cell-type annotation, each sample's cell type frequency was represented as a "cell type abundance phenotype" (CTAP), and spectral and agglomerative clustering were applied to CTAPs without reference to clinical diagnosis. **Results:** We analyzed 32 liver samples from patients ultimately diagnosed—after 2+ years of clinical follow-up—with AIH (n = 6), metabolic dysfunction-associated steatohepatitis (MASH, n = 10), simple steatosis (n = 2), AIH overlap syndromes (n = 3), other hepatic conditions (n = 5), or no liver disease (n = 6). Across these samples, 487,140 nuclei passed quality control and included all major liver cell types including hepatocytes, lymphoid and myeloid lineages. Naïve clustering of CTAPs revealed four patient groups. One cluster (CTAP-1) encompassed 6 of 6 AIH, both AIH-PBC overlap cases, and an AIH-MASH case. Other clusters corresponded to MASH and disease

controls. T-resident memory cells and mucosal invariant T-cells (MAIT) were found to be unbiased drivers of clustering, while plasma cells were only modestly important for distinguishing AIH from disease controls, and the plasma-to-B cell ratio remained stable across conditions. **Conclusion:** Cell type composition derived from snRNA-Seq data enables disease classification in liver tissue independent of clinical labels. Unexpectedly, tissue-resident memory T-cell and MAIT cell abundances were more critical for discerning AIH than plasma cell abundance. This approach holds promise for improving our diagnosis of AIH and may facilitate stratification of AIH subtypes in future large-scale studies.

★ 0118 | SPATIALLY RESOLVED SINGLE-CELL ANALYSIS OF PSC LIVER EXPLANTS REVEALS NICHE-SPECIFIC DISEASE EFFECTS

Jake Herb[1] Jiayu Zhang[1] Jane Stevens[1] Christopher Tastad[1] Ksenija Sabic[1] Maria Isabel Fiel[2] Alexandros Polydorides[1] Jawad Ahmad[2] Thomas Schiano[1] Joseph DiNorcia[1] Jang Moon[2] Chiara Rocha[1] Antonios Arvelakis[2] Marcelo Facciuto[1] Parissa Tabrizian[2] Sander Florman[1] Judy Cho[1], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Primary sclerosing cholangitis (PSC) is an immune-mediated biliary disease characterized by concentric rings of fibrosis around bile ducts (periductal fibrosis). This study aims to resolve niche-specific disease effects in the PSC liver and define drivers of periductal fibrosis using spatial transcriptomics and snRNA-seq. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) liver tissue was collected from 71 patients (37 PSC, 34 controls) undergoing liver transplant or resection between 2015 and 2024. The control group comprised 16 patients with MASH and 18 patients with metastatic colorectal cancer (metCRC, with tissue collected from the tumor-free margin). snRNA-seq was performed using the 10X Genomics Fixed-RNA Profiling workflow. Differential gene expression analysis (DEGA) was performed on pseudobulked data using edgeR. Spatial transcriptomics was performed on adjacent sections from 24 patients (16 PSC, 8 controls) using the Xenium Analyzer and a custom 480-gene panel. Cell segmentation and annotation were performed using Cellpose and Tangram. NOVAE, a graph-based model, was used to identify distinct spatial domains within the Xenium data and to identify spatially variable genes. **Results:** Using snRNA-seq, we measured 399,401 high-quality nuclei (257,250 nuclei from PSC patients and 142,151 nuclei from controls). We identified three distinct populations of cholangiocytes (BEC.A, BEC.B, and BEC.C) and, using spatial transcriptomics, showed that BEC.B cells are associated with the ductular reaction, while BEC.C cells are restricted to large bile ducts. DEGA revealed that BEC.B cells express high levels of TGFB1 and TGFB2, whereas BEC.C cells show enriched expression of PSC GWAS genes, including CCDC88B, GPR35, and SOCS1. We identified five unique populations of fibroblasts (FIB.A, FIB.B, FIB.C, FIB.D, and FIB.E) and, using spatial transcriptomics and DEGA, demonstrated that FIB.D cells are specific for periductal fibrotic lesions and sharply upregulate the negative Wnt regulators SFRP2 and SFRP4 ($p \leq 6.43E-39$). We identified four unique macrophage populations, including a pro-inflammatory subset that showed increased expression of NFKB2,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

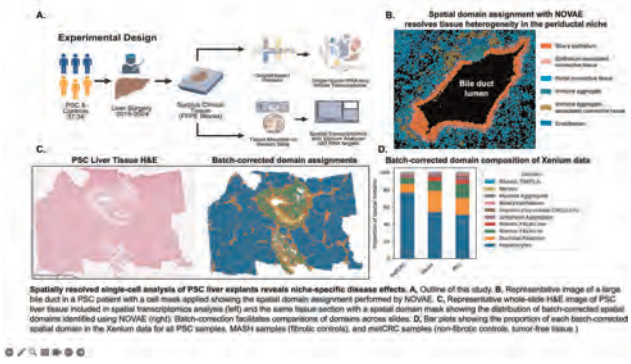
CXCL2, and ITGAX, in PSC samples. Spatial transcriptomics revealed the presence of myeloid aggregates adjacent to areas of ulceration in the biliary epithelium that showed high ITGAX expression. **Conclusion:** Using a spatially-resolved single-cell approach, we are able to map cell subsets identified using snRNA-seq to distinct niches in the PSC liver. We show that periductal fibrotic lesions are enriched for cholangiocytes expressing a module of PSC GWAS genes and fibroblasts expressing negative Wnt regulators. We show that a minority subset of pro-inflammatory macrophages displays higher level of activation in PSC and expresses marker genes found in myeloid aggregates adjacent to areas of bile duct ulceration.



Spatially resolved single-cell analysis of PSC liver explants reveals niche-specific disease effects. A, Outline of this study. **B,** Representative image of a large bile duct in a PSC patient with a cell mask applied showing the spatial domain assignment performed by NOVAE. **C,** Representative whole-slide H&E image of PSC liver tissue included in spatial transcriptomics analysis (left) and the same tissue section with a spatial domain mask showing the distribution of batch-corrected spatial domains identified using NOVAE (right). Batch-correction facilitates comparisons of domains across slides. **D,** Bar plots showing the proportion of each batch-corrected spatial domain in the Xenium data for all PSC samples. MASH samples (fibrotic controls), and metCRC samples (non-fibrotic controls, tumor-free tissue.)

★ 0119 | ROLE OF THE AUTOPHAGY INHIBITOR RUBICON IN A PSC MOUSE MODEL

Lukas Michael Gulden[1] Leonie Katz[1] Lena Voško[1] Peter Fickert[1] Katrin Panzitt[1] Martin Wagner[1], [1]Medical University Graz

Background: Autophagy is a fundamental self-digestion process required for cell homeostasis. We have previously shown that hepatic autophagy is impaired in patients with chronic cholestasis including primary sclerosing cholangitis (PSC). On a molecular level, bile acids induce Rubicon in a FXR dependent manner. Rubicon is an inhibitor of the autophagosome to lysosome fusion and therefore the induction of Rubicon prevents proper execution of autophagic processing. Since patients which chronic cholestasis and PSC have substantially increased hepatic Rubicon levels, we hypothesized that inhibition of Rubicon in cholestasis may improve impaired autophagy and consequently reduce cholestatic liver injury in a mouse model for PSC. **Methods:** We crossbred full body Rubicon- and MDR2-knockout mice over 3 generations to yield male and female Rubicon+/+/MDR2+/+ (wildtype), Rubicon+/+/MDR2-/- (MDR2-knockout) and Rubicon-/-/MDR2-/- (double-knockout) mice. Animals of both sexes were harvested at an earlier (8-10 weeks) and an older age (25-27 weeks). Markers of liver injury, inflammation, fibrosis and ductular reaction were analyzed on histologic, serum, mRNA and protein levels. In addition, we tested the effects of Rubicon deletion on bile flow under normal and choleretic (pretreatment with UDCA) conditions. **Results:** Deletion of Rubicon does not affect bile flow. Compared to MDR2-knockout mice Rubicon-MDR2-double-knockout mice show reduced liver injury (ALT, AST, AP, serum bile acids), inflammatory markers (TNFa, Icam) and less fibrosis (col1a1, desmin, hydroxyproline). While the effect in the early age group is only significant in female mice, a significant improvement can be observed in both sexes at older age. However, ductular reaction (CK19 IHC) and onion-skin-like fibrosis (Sirius Red staining) remains almost unchanged in double-knockout mice. **Conclusion:** Rubicon-knockout alleviates hepatocellular damage in the MDR2- knockout PSC-mouse-model but does not affect bile duct injury. Thus, inhibition of Rubicon may probably not diminish the initial bile duct injury but may ameliorate the detrimental hepatocellular consequences of the ascending pathophysiology of cholestatic liver diseases. We therefore believe that Rubicon may be a future distinct molecular target for chronic cholangiopathies including PSC.

0120 | IDENTIFICATION OF BST2, IL18R1, IL4R, AND KCNJ11 AS ASSOCIATED WITH PRURITUS RESPONSE TO ELAFIBRANOR IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: PROTEOMIC RESULTS: FROM THE ELATIVE® TRIAL

Mark Swain[1] Maria del Pilar Schneider[2] Pascale Plas[2] Jacquie Maignel[2] Aurélie Martin[2] Lola Lecru[2] Nuno Antunes[3] George Harb[3] Marwan Sleiman[2] Hugo Gomes da Silva[2] Andrew Mason[4], [1]Liver Unit, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]Ipsen, Paris, France, [3]Ipsen, Cambridge, MA, USA, [4]CEGIIR, University of Alberta, Edmonton, AB, Canada

Background: Pruritus is a common symptom in patients (pts) with primary biliary cholangitis (PBC). Elafibranor (ELA), a peroxisome proliferator-activated receptor (PPAR) agonist exerting effects on PPARα and PPARδ, is approved for second-line treatment of PBC and has shown clinically meaningful improvements in pruritus, as assessed by pt-reported outcome (PRO) measures. Previously, proteins associated with pruritus pathways, including BST2, IL18R1, IL4R, and KCNJ11, were identified to be downregulated in pts with PBC treated with ELA; IL31 has also been associated with pruritus in PBC. We examine the relationship between the expression of these proteins and pruritus response to ELA. **Methods:** Serum samples were collected from pts in the phase III ELATIVE® trial (NCT04526665) at baseline (BL) and Week (Wk) 52, and analysed using the Olink® Explore HT proteomic panel. Spearman correlations were evaluated between PRO measures of pruritus (Worst Itch Numeric Rating Score [WI-NRS], 5-D Itch, and PBC-40 Itch) and pruritus-associated protein expression (BST2, IL18R1, IL31, IL4R, and KCNJ11). Analyses were conducted in the overall population and in pts with moderate-to-severe pruritus (WI-NRS ≥ 4) at BL. Proteins are reported by the names of their encoding genes. **Results:** Of 161 pts in ELATIVE®, serum samples were included from 119; 50 pts had moderate-to-severe pruritus at BL, 37 of whom received ELA. At BL in the overall population, BST2, IL18R1, and IL4R expression levels were significantly correlated with each other ($r \geq 0.66$; $p < 0.05$). In ELA-treated pts with moderate-to-severe pruritus at BL, expression changes from BL (CfB) to Wk 52 between these proteins were also significantly correlated ($r \geq 0.55$; $p < 0.05$). At BL in the overall population, significant correlations were observed between IL18R and IL4R expression and WI-NRS and PBC-40 Itch ($r = 0.20–0.25$; $p < 0.05$), and between BST2 expression and PBC-40 Itch ($r = 0.23$; $p < 0.05$). Similar relationships were seen in pts with moderate-to-severe pruritus at BL, although not all were significant. In ELA-treated pts with moderate-to-severe pruritus at BL, a significant correlation was observed between CfB to Wk 52 in BST2 expression and WI-NRS ($r = 0.37$; $p < 0.05$). Although not significant, correlations between CfB to Wk 52 in IL18R1 and KCNJ11 expression and pruritus were also seen in these pts ($r = 0.32$; $p = 0.06$). No significant correlations were seen between CfB to Wk 52 in IL31 expression and pruritus in these pts. **Conclusion:** Significant correlations were observed between BST2, IL18R1, and IL4R and pruritus at BL. In ELA-treated pts with moderate-to-severe pruritus at BL, CfB to Wk 52 in BST2 and pruritus were also significantly correlated. These data suggest a potential role for these proteins in the pathophysiology of pruritus in PBC, and strong correlations between BST2, IL18R1, and IL4R suggest a complex interplay associated with pruritus and treatment response.

0121 | IDENTIFICATION OF ANTI-DOK2 ANTIBODIES IN PATIENTS WITH AUTOIMMUNE HEPATITIS VIA A HUMAN PROTEIN MICROARRAY

Kazumichi Abe[1] Jun Wada[2] Manabu Hayashi[2] Tatsuro Sugaya[2] Naoto Abe[2] Yosuke Takahata[2] Masashi Fujita[2] Hiromasa Ohira[2], [1]Fukushima Medical University School of Medicine, [2]Fukushima Medical University

Background: Autoantibodies such as antinuclear antibodies (ANAs) and anti-smooth muscle antibodies (ASMAs), which are detected in many cases of autoimmune hepatitis (AIH), are not disease-specific, so they have limited value in disease diagnosis. In this study, we aimed to identify disease-specific autoantibodies related to AIH diagnosis or pathogenesis. **Methods:** We comprehensively analysed human protein microarrays (containing more than 16,000 human proteins, including membrane, cytoplasmic, and nuclear proteins, synthesized in a wheat germ cell-free system using cDNA). To identify AIH-specific autoantibodies, we performed a cross-sectional study of AIH patients ($n = 67$) and matched healthy controls (HCs) ($n = 25$) via ELISA. An independent cohort of 123 AIH patients and 75 HCs was analysed for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

validation. All patient data were collected before corticosteroid therapy. We also evaluated the associations between candidate protein antigen expression and clinical findings in AIH patients. Candidate protein antigen expression in liver tissues was confirmed by immunohistochemistry. **Results:** According to comprehensive human protein microarray analysis, docking protein 2 (DOK2) was selected from six antigens significantly upregulated in AIH patients. The mean serum anti-DOK2 level was significantly higher in AIH patients (36.1-37.4 AU) than in those with other liver diseases (2.6-9.2) or HCs (1.0-4.5 AU) in the exploration and validation cohorts (P value/AUROC, vs HCs, <0.0001/0.87-0.90). Serum anti-DOK2 levels were positively correlated with serum IgG levels and liver histological activity. The serum IgG level was an independent factor for increasing of anti-DOK2 antibody levels in patients with AIH. Immunostaining revealed DOK2 positive cells were found in the hepatic lobules in patients with AIH. While immunohistochemical staining was performed using CD68, a surface marker for macrophages, CD68-positive cells were visually localized in the hepatic lobule in agreement with DOK2-positive cells. **Conclusion:** We demonstrated the first evidence that serum anti-DOK2 antibody levels were associated with the diagnosis and disease activity of AIH patients.

0122 | CANDIDA ALBICANS CONTRIBUTES TO LIVER FIBROSIS IN PRIMARY SCLEROSING CHOLANGITIS

Burcin Ozdirik[1] Phillipp Hartmann[2] Punnag Saha[1] Eliane Münte[1] KHURANA AMIT[1] Fernanda Raya Tonetti[1] Henriette Kreimeyer[1] Cristina Llorente[2] Xinlian Zhang[1] Frank Tacke[3] Derrick Fouts[4] Bernd Schnabl[2], [1]University of California San Diego, [2]University of California, San Diego, [3]Charité - Berlin, [4]J. Craig Venter Institute

Background: Primary sclerosing cholangitis (PSC) is a rare, immune-mediated liver disease with no treatment options other than liver transplantation. Emerging evidence highlights the gut-liver axis as a key contributor to PSC pathogenesis. However, the role of intestinal fungi remains unclear. Our aim was to characterize the fecal mycobiome in patients with PSC and explore whether fungal dysbiosis and IL-17-mediated immune activation could represent a potential therapeutic target in preclinical models. **Methods:** Fecal samples from 92 patients with PSC, 94 patients with inflammatory bowel disease (IBD), and 57 healthy controls were analyzed using ITS2 sequencing to profile the gut mycobiome. Stool samples were cultured on YPD agar plates, and colonies were tested for the presence of *Candida (C.) albicans* using qPCR with specific primers. We induced fibrotic cholangiopathy in wild-type C57BL/6 mice by feeding 0.05% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) for two weeks, along with oral gavage of *C. albicans* or PBS to assess microbial impact on disease progression. In a follow-up experiment, mice receiving *C. albicans* and DDC diet were treated with an IL-17 blocking antibody. **Results:** ITS2 sequencing analysis revealed a significant increase in the fecal abundance of *Candida* species (spp.) in patients with PSC compared with healthy controls or patients with IBD respectively ($p = 0.009$; $p = 0.026$). Notably, patients with PSC and concurrent IBD showed a higher abundance of *Candida* spp. compared with healthy controls ($p = 0.022$). Further, a higher percentage of patients with PSC demonstrated the presence of *C. albicans* in fecal samples compared with healthy controls ($p = 0.013$). Our *in vivo* models revealed significantly higher liver fibrosis in mice gavaged with *C. albicans* as quantified by Sirius Red staining (6.45% vs. 10.03%; $p = 0.043$) and fibrogenic gene expression. This increase in disease progression was significantly reduced by treatment with an IL-17 blocking antibody per Sirius Red (14.65% vs. 9.85%; $p = 0.006$) and fibrogenic gene expression. **Conclusion:** *Candida spp.,* in particular *C. albicans*, are enriched in the gut of patients with PSC. IL-17 blockade *in vivo* reduced fibrosis, implicating fungal dysbiosis-driven immune activation in PSC progression. Antifungal or IL-17-targeted therapies could be explored as therapy for patients with PSC.

Bader[3] Ian McGilvray[2] Sonya MacParland[1], [1]University of Toronto, Toronto, ON; University Health Network, Toronto, ON, [2]University Health Network, Toronto, ON, [3]University of Toronto, Toronto, ON, [4]Memorial University of Newfoundland, St. John's, NL

Background: Despite the use of immune checkpoint inhibitors (ICI) targeting well-characterized immune exhaustion pathways, the ICI response rate in chronic hepatitis B (CHB)-induced HCC remains below 40%. This may be attributed to a limited cell level understanding of the HCC niche. To address this, we employed the woodchuck hepatitis virus (WHV)-induced HCC model to characterize the immunological niche within the HCC ecosystem to identify targetable cell-cell interactions that drive the HCC-related T cell dysfunction. **Methods:** Single-cell RNA sequencing was performed on peripheral blood mononuclear cells (PBMCs) and liver biopsies from healthy (n = 8) and WHV-induced HCC woodchucks (n = 9). Spatial sampling from 9 HCC animals included matched non-malignant liver tissue (n = 8), tumor margins (n = 20), and multiple intratumoral regions (n = 23). The transcriptomic analysis was coupled with histology to visualize changes in liver morphology. **Results:** Our map of 326,847 cells from 74 samples captured 5 major immune lineages, 2 epithelial lineages, and 2 mesenchymal lineages. Gene set enrichment analysis (GSEA) based on human HCC transcriptomic data suggested that woodchuck HCC tumors transcriptionally resemble the less differentiated, most-aggressive human HCC subtype. T cell profiling revealed an increase in the ratio of exhausted CD8+ T to effector CD8+ T cells in HCC animals compared to healthy controls (p = 8.9e-05). Quantification of the CD8+ T cell exhaustion score using 69 exhaustion-related markers (e.g., TOX, CTLA4, PDCD1) showed a higher exhaustion level in CD8+ T cells in all sites of the HCC-bearing liver (p < 2.2e-16). Notably, a spatial gradient of exhaustion in three CD8+ T cell populations (CD8LoTOX+, TOX +CD8+, TOX+CTLA4+CD8+) was observed from tumor-distal to tumor regions. Pseudotime trajectory analysis using Slingshot suggested that exhausted CD8 + T cells diverged along a developmental path distinct from that of terminally differentiated KLRG1+ effector CD8+ T cells. Hematoxylin and eosin (H&E) staining confirmed tumor morphologies similar to those seen in human HCC, including nuclei-enlarged hepatocytes, pseudoglandular structures, and enriched vascularization. **Conclusion:** Our single-cell characterization of WHV-induced woodchuck HCC demonstrated a transcriptionally and morphologically proliferative tumor subtype, and revealed an immune-exhausted tumor landscape that mirrors human HCC. Future longitudinal studies using woodchucks could track the emergence of the CD8+ T cell population that gives rise to the exhausted CD8+ T cells with hepatitis progression, as they might represent a more therapeutically targetable group.

0124 | DEVELOPMENT OF GENE-EDITED T CELL THERAPY TARGETING TERT IN HEPATOCELLULAR CARCINOMA

Hidetoshi Nakagawa[1] Yuta Tamaru[1] Eishiro Mizukoshi[1] Taro Yamashita[1], [1]Kanazawa University Hospital

Background: Hepatocellular carcinoma (HCC) is characterized by recurrent genetic alterations, notably mutations in the promoter region of the telomerase reverse transcriptase (TERT) gene. While recent advancements in tyrosine kinase inhibitors and immune checkpoint blockade have expanded therapeutic options, TERT remains refractory to direct pharmacological targeting. Given the high frequency and early occurrence of TERT promoter mutations in HCC pathogenesis, TERT represents a compelling molecular vulnerability warranting further investigation as a therapeutic target. **Methods:** Immune reactivity against the HLA-A*24:02-restricted telomerase reverse transcriptase (TERT)-derived peptide (VYGFVRACL) was evaluated in lymphocytes from hepatocellular carcinoma (HCC) patients

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

using interferon-gamma (IFN-γ) ELISpot assays. The TERT peptide vaccine was administered as an adjuvant therapy in conjunction with radiofrequency ablation (RFA). Antigen-specific T cell populations were characterized by single-cell RNA sequencing coupled with T cell receptor (TCR) repertoire analysis. Functional assessment of TCR-engineered T cells was performed through both in vitro cytotoxicity assays and in vivo tumor models. **Results:** Comprehensive genomic analysis of 59 hepatocellular carcinoma (HCC) patients revealed TERT promoter mutations in 57% (34/59) of cases. Antigen-specific immune responses to the HLA-A*24:02-restricted TERT peptide were detected in 3 of 31 (10%) HCC patients, while no reactivity was observed in healthy donors (0/11) or individuals with chronic hepatitis (0/29). In a separate cohort, the TERT peptide elicited robust immune responses in 8 of 14 cases (57%). TERT-specific T cells exhibited a memory-like phenotype characterized by expression of *IL7R* and *NOSIP* contributing to prolonged survivals. Notably, the TERT-reactive TCR clone A12.78 mediated antigen-specific recognition and cytolytic activity against TERT-expressing HepG2 cells in vitro, and significantly suppressed tumor progression in HepG2-engrafted NSG mice in vivo. **Conclusion:** TERT-directed immunotherapeutic strategies represent a promising avenue for the treatment of hepatocellular carcinoma.

0125 | LIVER ZONATION BREAKDOWN FUELS HEPATOCELLULAR CARCINOMA IN CHRONIC LIVER DISEASE

SUE YANG[1] Federico Tullio[1] Joana Almeida[1] Sai Ma[1] Bruno Cogliati[1] Guo-cheng Yuan[1] Shamsa Rohan[1] Azra Krek[1] Lida Yang[1] Charlotte Ng[2] Jan Tchorz[3] Tianliang Sun[1], [1]Icahn School of Medicine at Mount Sinai, [2]Humanitas University, [3]Novartis Institutes for BioMedical Research

Background: Hepatocytes exhibit remarkable heterogeneity and plasticity, essential for sustaining liver regeneration and zonated metabolic function. Disruption of liver metabolic zonation is a hallmark of chronic liver disease (CLD) and is increasingly linked to hepatocellular carcinoma (HCC), yet how shifts in zonation contribute to tumor initiation remains unclear. ZNRF3 and RNF43, negative regulators of WNT/β-Catenin signaling, maintain the pericentral-to-periportal zonation and constrain hepatocyte proliferation. This study investigates whether loss of ZNRF3/RNF43 induced zone-1–to–zone-3 reprogramming promotes tumorigenesis in the context of CLD. **Methods:** Single-nucleus RNA-seq, spatial transcriptomics, mRNA FISH, and histological staining were applied to human CLDs samples (HCV, HBV, MASH) and MASH mouse models to characterize zonation disruption. Spatial transcriptome comparisons between MASH mice and ZNRF3/RNF43-deficient livers under homeostasis revealed overlapping patterns of zone-3 expansion. To trace hepatocyte fate, *ZNRF3/RNF43$^{fl/fl}$; LSL-EGFP* mice subjected to low-dose AAV8-TBG-Cre for clonal tracing or high-dose for bulk RNA-seq. GFP+ hepatocytes were monitored over 1–11 months with histology (CYP2E1, Ki-67, GS), spatial transcriptomics, bulk RNA-seq, and EdU labeling to assess proliferation, metabolic reprogramming, and tumor formation. **Results:** Zone-3 signature extension into zone-1 was consistently observed across human CLDs and mouse models. This pattern strongly overlapped with spatial β-Catenin activity in ZNRF3/RNF43-deficient livers, supporting its utility as a model of zone-1 to zone-3 reprogramming. Clonal tracing revealed increased proliferation, expanded clone sizes, and tumor formation localized primarily to zone-1, as confirmed using *Axin2CreER; ZNRF3/RNF43; LSLGFP* mice. Spatial transcriptomics revealed enhanced detoxification pathways and mTOR signaling. Rapamycin treatment reduced clone expansion in zone-1, indicating mTORC1 dependency. By 9 months, dysplastic lesions and HCCs emerged, marked by a lipid metabolism–enriched signature distinct from classical β-Catenin-mutant HCCs but matching a subset of human HCCs. **Conclusion:** ZNRF3/RNF43 deletion induced zone-1–to–zone-3 hepatocyte reprogramming, clonal expansion, and metabolic rewiring, accompanied by mTORC1 activation and early HCC development. This model highlights the pivotal role of spatial identity in CLD-associated tumorigenesis and provides a platform for developing spatially targeted therapies.

0126 | PHOTOTHERMALLY MODULATED LIPOSOME ENABLING EFFICIENT RELEASE OF 2-DEOXY-D-GLUCOSE SAFELY DISPLAYS VIGOROUS ANTITUMOR EFFECT AGAINST LIVER CANCER

Keisuke Hino[1] Satoshi Arai[2] KYO SASAKI[3] Kazuma Daikoh[3] Sohji Nishina[3], [1]Shunan Memorial Hospital, [2]Kanazawa University, [3]Kawasaki Medical School

Background: A glucose derivative, 2-deoxy-D-glucose (2DG), exerts cytotoxic effects against several cancers through suppression of Warburg effect. However, the clinical application of 2DG is not recognized because of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

adverse events due to high dose administration. We developed a novel drug delivery system (DDS) which delivers and releases 2DG efficiently into cancer cells, using thermodynamic cell engineering. The aim of this study was to assess antitumor effect and safety of this DDS against liver cancer. **Methods:** Liposomes, where 2DG was encapsulated and a photothermal agent (a near-infrared [NIR] absorbing dye) was embedded in the lipid bilayers, were engineered, with their surface modified with cancer-targeting cyclic peptide (iRGD) (iRGD-2DG-nanoheater [iRGD-2DG-NanoHT]). The antitumor effect of iRGD-2DG-NanoHT was assessed in murine HCC models. **Results:** Results:: NIR absorbing dye was more accumulated in liver tumors in mice treated with iRGD-2DG-NanoHT than those with 2DG-NanoHT (without iRGD). A fluorescent dye, calcein that was encapsulated in LNPs was more vigorously released above 37° through phase transitions after NIR irradiation. Thus, modification with iRGD and incorporation of NIR absorbing dye enabled iRGD-2DG-NanoHT to be more specifically delivered to tumor cells and to release 2DG more vigorously in tumor tissue. The body surface temperature rose above 37° in the area around liver but remained below 37° in the area apart from the liver 5 minutes after NIR irradiation in mice treated with iRGD-2DG-NanoHT or iRGD-NanoHT. Mice treated with iRGD-2DG-NanoHT showed significantly reduced tumor volume with more necrotic tumor cells and increased mononuclear cell infiltration than those treated with 2DG alone or iRGD-NanoHT. Mechanistically, treatment with iRGD-2DG-NanoHT displayed cytotoxicity based on both ER stress-induced apoptosis via AMPK phosphorylation and ferroptosis via reduction of GSH/GPX4 axis, and induced HMGB-1 (damage-associated molecular patterns, DAMPs)-mediated antitumor immunity in addition to increase in chemokine production. Finally, Mice treated with iRGD-2DG-NanoHT did not show obvious adverse effects compared to control mice. **Conclusion:** iRGD-2DG-NanoHT has potential as a new therapeutic treatment for liver cancer based on its cancer-specific DDS.

0127 | PD-L1(+) MACROPHAGES ACTIVATED BY TUMOR-DERIVED GM-CSF INDUCE CD8(+) T CELL EXHAUSTION IN HEPATOCELLULAR CARCINOMA

Takuto Nosaka[1] Masahiro Ohtani[1] Junki Yamashita[1] Yosuke Murata[1] Yu Akazawa[1] Tomoko Tanaka[1] Tatsushi Naito[1] Kazuto Takahashi[1] Yasunari Nakamoto[1], [1]University of Fukui

Background: The efficacy of immune checkpoint inhibitors (ICI)-based treatment is limited in patients with hepatocellular carcinoma (HCC). In tumor microenvironment, tumor-associated macrophages (TAMs) critically influence cancer progression and ICI treatment response through immunosuppression. We have reported TAMs promote the proliferative potential of HCC cells (J Immunol. 2018, Biomed phar. 2023). Granulocyte macrophage (GM)-CSF is one of the key mediators for activation of TAMs. In this study, we aimed to clarify the spatial interactions between PD-L1 (+) TAMs activated by GM-CSF and CD8(+) T cells in resected HCC tissues. **Methods:** Multiplex immunohistochemistry (mIHC) (OPAL: CD8, CD68, CD163, CD11c, PD-L1, and DAPI) was performed on 113 resected HCC specimens. Cell distribution and spatial location in the tumor center, tumor border, non-tumor border, and non-tumor area were determined using inForm (Akoya). Intercellular distances were measured using Phenoptr, and the interaction variable (proportion of target cells within 25 μm) was calculated. The mouse HCC cell line, BNL, transfected with GM-CSF vector was intraportally injected into BALB/c mice. Anti-GM-CSF antibody and/or anti-PD-L1 were injected intraperitoneally into the mice. **Results:** Spatial analysis of HCC tissue showed that higher interaction variable of PD-L1(+) TAMs and CD8T cells in the tumor center had significantly worse in recurrence and survival rates. Multivariate analysis revealed that vascular invasion, fibrosis, and interaction variable; PD-L1(+) TAM with CD8(+) T cells (T area) were independent factors for postoperative recurrence after HCC resection. The interaction variable correlated positively with the number of GM-CSF(+) tumor cells, but not with M-CSF. *In vitro*, GM-CSF upregulated PD-L1 expression and chemokines, such as CXCL9, 10, 11, in macrophages and impaired CD8(+) T cell antitumor activity. In an HCC mouse model, GM-CSF enhanced spatial interactions of PD-L1(+) TAMs and CD8(+) T cell, promoting tumor growth through immunosuppression. Anti-GM-CSF therapy disrupted PD-L1(+) TAMs and CD8(+) T cell interaction, and its combination with anti-PD-L1 synergistically boosted antitumor immunity ($p < 0.05$). **Conclusion:** The spatial analysis of PD-L1(+) TAMs and CD8(+) T cells in resected HCC revealed that a higher interaction variable was associated with increased recurrence and elevated tumor cell-derived GM-CSF expression. Targeting GM-CSF may reprogram the TAM-driven immunosuppressive niche, enhancing antitumor immunity and offering a promising therapeutic strategy for patients with HCC.

0128 | SIRPA KNOCKOUT IN T CELLS INHABITS IMMUNE EVASION OF HEPATOCELLULAR CARCINOMA

Xue Zhang[1] Hongsong Chen[2] Dongbo Chen[2], [1]Peking University People's Hospital, [2]Peking University People's Hospital

Background: Immune checkpoint inhibitors, such as anti-PD-1/PD-L1 antibodies, have shown significant antitumor activity in a subset of advanced patients, current evidence indicates that this therapeutic strategy elicits responses in only approximately 20% of advanced HCC . This limited efficacy highlights the potential involvement of alternative immune checkpoints in facilitating tumor immune evasion. A critical aspect of this process is T cell apoptosis. In this study, we discovered that SIRPα is associated with T cell apoptosis in HCC, diverging from the classical role of SIRPα as an inhibitory immune receptor on macrophages. **Methods:** By screening key genes associated with apoptosis in T cells through CRISPR libraries and identifying differentially expressed genes before and after high-concentration IL-2 culture of TILs from HCC patients, we intersected the genes identified by both methods with critical immune checkpoint-related genes. This analysis revealed that the SIRPα is correlated with T cell apoptosis in HCC tissues. In vitro studies utilized PBMCs or murine T cells to evaluate the role of SIRPα in apoptosis. In vivo experiments involved SIRPα$^{-/-}$mice to assess the impact of SIRPα on tumor growth, followed by flow cytometric analysis of T cell function. We investigated T cells in SIRPα$^{-/-}$ mice bearing subcutaneous tumors after depleting macrophage populations. We evaluated T cell functionality in mice treated with a SIRPα inhibitor. CD3^{+} T cells isolated from SIRPα$^{-/-}$ mice were adoptively transferred intravenously into tumor-bearing nude mice to determine their therapeutic effects on tumor growth. **Results:** Analyzing sequencing data, we identified a significant association between SIRPα and T cell apoptosis in HCC. In vitro, SIRPa deficiency inhibited apoptosis of T cells from PBMC and SIRPα$^{-/-}$ mice, while overexpression of SIRPα promoted T cell apoptosis. In vivo,SIRPα deficiency significantly inhibited tumor growth. SIRPα$^{-/-}$ mice exhibited markedly increased proportions of CD4^{+} and CD8+ T cells both in peripheral blood and tumor tissues, accompanied by elevated levels of GZMB. Following macrophage depletion in SIRPα$^{-/-}$ mice, WT mice displayed larger tumor volumes compared to SIRPα$^{-/-}$ mice. Importantly, even after macrophage depletion, the SIRPα$^{-/-}$ mice maintained higher proportions of CD4^{+} and CD8^{+} T cells in both peripheral blood and tumor tissues, along with sustained elevated GZMB levels and reduced PD-1 expression. In adoptive cell theropy experiment, tumors in mice receiving SIRPα$^{-/-}$ CD3^{+} T cell showed significant growth suppression. **Conclusion:** These findings demonstrate that SIRPa deficiency enhances T cell anti-apoptotic capacity and cytotoxic activity, suppressing HCC progression. The results suggest that SIRPa drives tumor immune evasion in HCC by mediating T cell apoptosis, thereby providing novel therapeutic strategies and potential targets for HCC immunotherapy.

0129 | METABOLIC REPROGRAMMING OF GLUTAMINE–GLUTAMATE AXIS IN FONTAN-ASSOCIATED LIVER DISEASE (FALD)

Eiji Kakazu[1] Taiji Yamazoe[1] Masaaki Mino[1] Michitaka Matsuda[1] Shinji Kondo[1] Tatsuya Kanto[1], [1]Japan Institute for Health Security

Background: Fontan-associated liver disease (FALD) results from chronic hypoxia and hepatic congestion after the Fontan procedure and may progress to cirrhosis or hepatocellular carcinoma over time. Conventional biomarkers are insufficiently sensitive to detect disease progression. Since hepatic amino acid metabolism plays a central role in systemic homeostasis, we hypothesized that serum free amino acids (FAAs) may reflect pathophysiologic changes in FALD. **Methods:** Human experiments: Serum levels of 20 free amino acids (FAAs) were measured by HPLC in patients with FALD (n = 40; 4 cirrhosis, no HCC), healthy controls (HC; n = 17), and patients with hepatitis C virus (HCV; n = 64). Serum FAAs, AST and ALT activity, and glutamine synthetase (GS), which is expressed in pericentral hepatocytes affected by congestion, were compared among these groups and analyzed for correlation. Spatial transcriptomics (VISIUM) was performed on representative FALD liver tissue. Mice experiments: A murine FALD model (pIVCL; Hepatology 2022) was used to compare serum FAAs, AST, ALT, GS, hepatic GS, GPT, GOT2 expression at 6, 19 and 54 weeks. Liver RNA-seq profiles with those of sham mice at 6 week. Cell experiments: To investigate the effects of hypoxia observed in FALD, hepatocytes (PXB or immortalized mouse hepatocytes) were cultured in portal blood-mimicking medium (PBM; Hepatology 2021) under normoxia or hypoxia (1% O_2). FAAs in culture supernatant and oxidative stress were assessed. **Results:** FALD patients showed significantly increased serum glutamate

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(Glu) and decreased glutamine (Gln) compared to HC and HCV, while total FAA level remained unchanged. Serum GS levels positively correlated with Glu and negatively with Gln. VISIUM revealed upregulated *GLUL* (GS) in hepatocytes within congested and inflamed areas in FALD liver, but the expression of *GOT* and *GPT* showed a diffuse expression pattern. In pIVCL mice, Glu levels were elevated in both serum and liver up to 54 weeks. Consistent with these findings, serum GS levels increased, whereas hepatic GS expressions decreased; however, the expression of hepatic GOT2 and GPT remained unchanged. RNA-seq-based pathway analysis indicated involvement of amino acid metabolism and oxidative stress pathways in the liver of pIVCL. *in vitro*, hypoxia induced ROS in hepatocytes and suppressed FAAs consumption, except for Gln, and induced glycolysis, reflected in elevated glucose consumption and lactate production. Consistent with these findings, Glu level was significantly increased in the culture supernatant. **Conclusion:** Glutamine–glutamate imbalance and altered GS expression under hypoxia and congestion characterize FALD and may serve as potential metabolic biomarkers.

0130 | YAP CONTRIBUTES TO LIVER FIBROSIS THROUGH MEDIATING CAPILLARIZATION OF LIVER SINUSOIDAL ENDOTHELIAL CELLS VIA GATA6/ENOS SIGNALING

俊俊 王[1] *Zhenyang Shen[2] Guangwen Chen[2] Yufei Yang[2] Yuecheng Guo[2] Hanjing Zhangdi[2] Qingqing Zhang[2] Qichao Ge[2] Hui Dong[2] Lungen Lu[2] Xiaobo Cai[2], [1]Shanghai General Hospital, Shanghai Jiao Tong University Sch, [2]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Capillarization of liver sinusoidal endothelial cell (LSEC) is a central event in response to liver fibrosis. In this study, we investigated the role of YAP in LSEC capillarization and liver injury. **Methods:** YAP expression was assessed in liver samples from mice injured by CCl_4 injection and DDC diet. EC-specific *Yap1* conditional knockout mice (*Yap1*$^{\Delta end}$) were generated by breeding the *Yap1*$^{fl/fl}$ mice with the *Cdh5*-Cre^{ERT2} mice. HA-PEI/si*Yap1* nanoparticles were applied to specifically inhibit YAP expression in LSEC. **Results:** YAP was primarily expressed in LSEC and its expression was elevated during liver fibrosis. EC-specific *Yap1* deficiency significantly increased the fenestrae in LSEC and mitigated hepatocyte death and liver fibrosis. Overexpression of YAP in EC aggravated capillarization, hepatocyte death and liver fibrosis. Mechanistically, YAP inhibited *Gata6* transcription via binding to its promoter and thus resulted in LSEC capillarization. Overexpression of GATA6 in EC alleviated capillarization and liver fibrosis by activating *Nos3* transcription. Moreover, specifical delivery of HA-PEI-*siYap1* nanoparticles to LSEC alleviated liver fibrosis in mice. **Conclusion:** The YAP-GATA6/eNOS signaling is essential in LSEC capillarization and subsequent liver fibrosis. Interventions targeting YAP in LSEC offers a promising strategy for the treatment of liver fibrosis.

Joseph Dearani[2] Hartzell Schaff[2] Patrick Kamath[2] Moira Hilscher[2], [1]MAYO CLINIC, ROCHESTER, MN, [2]MAYO CLINIC ROCHESTER

Background: We determined: 1. Impact of pre-operative cirrhosis, steatotic liver disease (SLD), and congestive hepatopathy (CH) on mortality post cardiac surgery, and 2. Post-operative predictors of 30-day and 1-year mortality. **Methods:** A total of 10,418 patients (> 18 years old) who underwent cardiac surgery from 2013 through 2023 were categorized as: controls (n = 8,820, no liver disease and normal liver biochemistry), cirrhosis (n = 244, diagnosed by imaging, histology, laboratory, or portal hypertension), CH (n = 995, diagnosed by laboratory and hepatic vein dilation with no other causes of liver disease), or SLD (n = 359, identified on imaging). Post-operative liver injury was graded according to the model for end stage liver disease (MELD) score, Food and Drug's Administration (FDA's) drug-induced liver injury severity index, and liver failure [LF: bilirubin > 7.5mg/dL and International Normalized Ratio (INR) ≥ 1.5]. Logistic and Cox regression analysis identified factors associated with 30-day and 1-year mortality. **Results:** Mortality at 30 days (controls 0.1%; CH 7.7%, cirrhosis 7%, and SLD 3.8%, $P < 0.001$) and 1-year (controls 2.3%; CH 17.2%, cirrhosis 17.6%, and SLD 6.7%, $P < 0.001$) were higher in patients with liver disease. 30-day mortality (Table 1) was associated with a) pre-operative grade 2 or 4 liver injury severity, serum albumin ≤ 3mg/dL and MELD ≥ 10, and b) post-operative grade ≥ 2, transaminases > 20X with shock, LF, and day 7 MELD ≥ 15. 1-year mortality (Table 1) was associated with a) postoperative transaminases > 20X, liver failure, day 7 MELD ≥ 10, and day 30 MELD ≥ 15. Patients with CH were at higher risk of postoperative shock and grade 4 liver injury. Day 7 predictors of very low 30-day mortality (< 3%) were no shock, transaminases < 20X and MELD < 10; high 30-day mortality (29%) were transaminases > 20X and MELD ≥ 15; and very high 30-day mortality (61.5%) were LF with hepatic encephalopathy and MELD ≥ 15. Day 7 predictors of very low 1-year mortality (< 3%) were MELD < 10; high 1-year mortality (37.5%) were transaminases > 20X with shock and MELD 10-15; and very high 1-year mortality (43.8%) were LF with infection and MELD > 20. **Conclusion:** CH and SLD are associated with increased 30-day and 1-year mortality post cardiac surgery, especially with pre-operative MELD ≥ 10. Day 7 grade 4 liver injury and MELD score ≥ 10 were associated with 30-day and 1-year mortality. These results inform risk stratification of patients with liver disease considered for cardiac surgery.

Table 1. Patterns of Pre- and Post-operative Liver Injury as well as MELD Score Categories and Mortality Risk

Pre-operative Liver parameters, n (%)	8-30-Day Mortality OR (95% CI)	P Value	1-12-Month Mortality HR (95% CI)	P Value

0132 | ROLE FOR ENDOKYNE-1 IN LSEC–HSC COMMUNICATION AND ITS ASSOCIATION WITH ADVANCED CHRONIC LIVER DISEASE

Ana Martínez-Alcocer[1] Alejandro H. Gutierrez[2] Laia Abad Jordà[1] Peio Aristu[1] María Andrés-Rozas[1] Francisco Javier Cubero[2] Jordi Gracia-Sancho[3] Anabel Fernandez-Iglesias[1], [1]Liver Vascular Biology Lab, IDIBAPS - Hospital Clínic de Barcelona - CIBEREHD, [2]Complutense University Madrid - CIBEREHD, [3]Liver Vascular Biology, IDIBAPS - Hospital Clínic de Barcelona - CIBEREHD

Background: Liver sinusoidal endothelial cells (LSECs) play a central role in regulating hepatic microcirculation and paracrine signaling. In chronic liver disease (CLD), LSECs undergo capillarization, losing their specialized phenotype and contributing to fibrosis and cirrhosis. Prior transcriptomic analyses identified *Endokyne-1* (EK1) as one of the most upregulated cytokines in LSECs from cirrhotic livers. This study aims to characterize the role of EK1 and its receptor EK1R in CLD progression. **Methods:** Human liver samples (healthy and cirrhotic) from internal and external cohorts were used for transcriptomic and protein analyses. EK1 expression was assessed in five independent human CLD transcriptomic datasets, as well as in serum and tissue samples (n = 61 CLD vs n = 52 healthy livers; n = 40 CLD vs n = 12 controls for serum). In vivo, EK1 was studied in a rat model of progressive liver injury induced by CCl_4 inhalation (2 weeks, 6 weeks, 12 weeks, n = 6/time-point), and in a conditional knockout mouse model lacking EK1R in hepatic stellate cells ($EK1R^{\Delta HSC}$), with CCl_4-induced fibrosis (n = 10). In vitro, primary rat LSECs and quiescent HSCs (qHSCs) were used in gain- and loss-of-function studies to examine EK1-mediated paracrine signaling. **Results:** Meta-analysis of five public human liver transcriptomic cohorts revealed consistent upregulation of *EK1* in advanced CLD. This was validated in our internal cohort at both mRNA and protein levels in liver tissue and serum. In animal models, EK1 was markedly increased in cirrhotic livers (fold change: mRNA 16.2x, protein 8x vs healthy), with LSECs identified as the primary source. EK1 was detected in LSEC-conditioned media, indicating active secretion. Functionally, recombinant EK1 activated qHSCs, increasing *ACTA2* and *COL1A1* expression. Conversely, EK1-silenced cirrhotic LSECs failed to induce HSC activation. In vivo, $EK1R^{\Delta HSC}$ mice showed improved liver function (−33% ALT), reduced fibrotic gene expression (−25% collagen) and decreased αSMA expression (−25%). **Conclusion:** LSEC-derived EK1 is a disease-induced cytokine that promotes hepatic stellate cell activation through the EK1–EK1R axis in advanced CLD. Disruption of this signaling pathway attenuates fibrogenesis and improves liver function, highlighting EK1–EK1R as a potential therapeutic target. Further studies will explore the utility of EK1 as a biomarker of advanced liver disease.

0133 | OUTCOMES AND PATENCY OF TIPS FOR PORTAL VEIN THROMBOSIS FROM THE ALTA STUDY GROUP

Justin Boike[1] K. Pallav Kolli[2] Lisa VanWagner[3] Elizabeth Verna[4] Mike Fallon[5] Adnan Said[6] Catherine Frenette[7] Aparna Goel[8] Jennifer Lai[2] Sumeet Asrani[9] Consuelo Soldevila-Pico[10] Mary Thomson[11] Brett Fortune[12] Adam Deising[13] Sonali Paul[14] Douglas Simonetto[15] Margarita German[16] Mehnush Hameie[17] Cynthia Padilla[17] Dyanna Gregory[18] Bartley Thornburg[17], [1]Northwestern Memorial Hospital/ Northwestern University, [2]University of California San Francisco, [3]University of Texas Southwestern Medical Center, [4]Columbia University Medical Center, [5]University of Arizona, [6]University of Wisconsin School of Medicine and Public Health, [7]Gilead Sciences, Inc., [8]Stanford University Medical Center, [9]Liver Consultants of Texas, [10]University of Florida, [11]University of Minnesota, [12]Montefiore Medical Center, [13]Scripps Clinic, [14]University of Chicago Medical Center, [15]Mayo Clinic Rochester, [16]University of Wisconsin, [17]Northwestern University, [18]University of Texas Southwestern

Background: TIPS creation is a recently established treatment for acute and chronic portal vein thrombosis (PVT) and related portal hypertension (pHTN) complications. Prior studies have been limited to single center experience raising questions about long-term patency of TIPS in PVT and associated complications. **Methods:** Advancing Liver Therapeutic Approaches in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Portal Hypertension (ALTA-TIPS) is a prospective, multicenter observational cohort conducted at 13 U.S. centers, enrolling adults ($\geq$18 years) who underwent TIPS creation between 6/2019–12/2024 with $\geq$6 months follow-up. Collected data included procedural details, patency, transplant/survival status, and complications such as hepatic encephalopathy (HE).

Results: Of 852 enrolled subjects, 123 (14%) underwent TIPS creation for management of acute or chronic PVT. 71 participant (58%) were cirrhotic (cPVT) and 52 (49%) were non-cirrhotic (ncPVT). A defined hypercoagulable state was more common in non-cirrhotic PVT subjects (19 vs. 6, $p < 0.001$). TIPS creation in non-cirrhotic subjects was primarily for chronic PVT management (40, 77%), while cirrhotic PVT indications included ascites (18, 25%), bleeding (11, 16%), transplant facilitation (12, 17%), or a combination of pHTN complications (30, 42%). Revision of the TIPS either with angioplasty or restenting for complete occlusion or TIPS dysfunction was more common among ncPVT (n = 36, 70%) compared to cPVT (n = 28, 39%), $p = 0.001$. Overall patency after subsequent revisions for subjects with at least 1 year of follow up was no different in ncPVT compared to cPVT, $p = 0.676$ (Figure). The overall permanent occlusion rate for both ncPVT and cPVT was significantly higher (19% vs 5.6%, $p < 0.0001$) compared to non-PVT TIPS recipients No pre-TIPS clinical factors predicted occlusion. Post-TIPS HE hospitalizations were less frequent in the ncPVT (7, 14%) compared to cPVT group (22, 31%), $p = 0.0294$.

Conclusion: TIPS creation for management of PVT was common among all TIPS recipients in a large multicenter cohort. Non-cirrhotic PVT was associated with hypercoagulability and higher reintervention rates. Despite frequent revisions in both groups, overall patency remained acceptable.

0134 | CLINICAL CHARACTERISTICS AND INFLUENTIAL FACTORS OF PORTO-SINUSOIDAL VASCULAR DISEASE WITH PORTAL HYPERTENSION

Weihua Cao[1] Yao Xie[1] Minghui Li[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Porto-sinusoidal vascular disease (PSVD) remains underdiagnosed. This study aimed to investigate the clinical characteristics, influencing factors, and clinical outcomes of PSVD. **Methods:** This was a prospective observational study. Patients diagnosed with PSVD via liver biopsy were enrolled. Demographic and clinical data were collected. Patients were stratified into portal hypertension (PH) group and non-PH group based on the presence of PH (Figure 1). Clinical and histopathological features were evaluated according to the latest PSVD diagnostic criteria. Additionally, influencing factors for PSVD with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

PH and clinical outcomes of PSVD patients were investigated. **Results:** 282 PSVD patients were enrolled, 113 with PH and 169 without PH. The most common initial presentation was abnormal liver function (69.15%) in Table 1. Additionally, 39 patients (13.83%) presented with splenomegaly detected during routine examinations, 8 (2.84%) with gastrointestinal bleeding, and 22 (7.80%) with thrombocytopenia in Table 1. Disease duration prior to biopsy ranged from 1 month to 5 years in Table 1. PSVD predominantly affected middle-aged women (56.38%), with a mean age of 44.82 ± 14.56 years. PH group patients had significantly lower white blood cell (WBC, $p = 0.020$) and platelet (PLT, $p < 0.001$) counts, reduced albumin ($p = 0.019$) and prothrombin activity (PTA, $p < 0.001$), elevated INR ($p < 0.001$), and higher liver stiffness measurement (LSM, $p < 0.001$). Non-PH group exhibited lower total bilirubin (TBIL, $p = 0.006$) and direct bilirubin (DBIL, $p < 0.001$), but higher γ-glutamyl transferase (GGT, $p = 0.019$). Histopathological analysis revealed obliterative portal venopathy (OPV, 86.17%) as the most characteristic feature, while portal tract abnormalities (93.26%) and perisinusoidal fibrosis (59.57%) were common nonspecific findings. PH group showed higher prevalence of OPV ($p = 0.048$) and incomplete septal cirrhosis (ISC, $p = 0.040$). Non-PH group had more portal tract abnormalities ($p = 0.033$), whereas architectural disturbance ($p < 0.001$) and non-zonal sinusoidal dilation ($p = 0.001$) predominated in PH group. Multivariate logistic regression identified PLT ($p = 0.001$) and LSM ($p < 0.001$) as independent risk factors for PSVD patients with PH. During a median follow-up of 18.5 months, 5.56% of patients with compensated liver experienced variceal bleeding. Non-PH patients did not progress to PH. **Conclusion:** PSVD may present as either PH or liver enzyme abnormalities, with significant differences in histopathological features among patients exhibiting distinct clinical manifestations. PLT and LSM are independent risk factors for PSVD with PH. In contrast, PSVD patients without PH exhibit slower disease progression, with elevated GGT levels being a predominant clinical feature.

★ 0135 | PATIENT REPORTED OUTCOME MEASUREMENT IS FEASIBLE DURING AMBULATORY LIVER CARE AND REQUIRES PROVIDER SUPPORT VIA CARE DELIVERY INNOVATION

Nadia Blessing[1] Miranda Stovall[1] Suhani Lodha[1] Christine Abeysekera[1] Carla Kettler[1] Marwan Ghabril[1] Naga Chalasani[2] Eric Orman[1] Archita Desai[1], [1]Indiana University, [2]Indiana University Medical Center

Background: Individuals with chronic liver disease (CLD) and cirrhosis face high symptom burden, poor health-related quality of life (HRQOL), and significant unmet health-related social needs (HRSN). However, few studies assess patient-reported outcome measurements (PROMs) in routine care or provider comfort in addressing the results. This study evaluated the feasibility of PROM collection during routine care, the burden of unmet needs in ambulatory CLD/cirrhosis patients, and provider comfort in addressing them. **Methods:** We performed a prospective study of adults seen for routine non-transplant hepatology care at an academic health center from 7/2024 to 5/2025. Participants were recruited by phone 1-2 weeks prior to their scheduled visit to complete PROMs measuring HRQOL (PROMIS-29 v2.0), HRSN (Accountable Health Communities Screening Tool, Social Network Index), and informational needs (Brief Health Literacy Scale, MyCirrhosisCoach, PROMIS Informational Support). Scores were interpreted using validated cutoffs. Hepatology providers ($n = 18$) were also surveyed to determine their comfort and training level (5-point scale) with managing each domain. Baseline characteristics and survey responses were summarized using means and compared by cirrhosis status. **Results:** From 829 adults who were approached, response rate was 31% ($n = 386$). Consent rate was 52% of those responding and 24% of all approached ($n = 202$). Lack of interest in study was low (16%, $n = 63$). The majority (78%, $n = 158$) completed study assessments and are described in the Table. Half had cirrhosis and were similar to those with CLD except lower household income and cause of liver disease. PROM score categories and needs identified were similar between those with and without cirrhosis ($p > 0.05$, Figure). Rates of poor PROs and needs by cirrhosis status are shown in the Figure alongside provider comfort in their management. Poor HRQOL was reported by 24%-71% depending on the domain measure with over 50% of providers reporting discomfort in responding to pain

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

interference or social participation. The most common HRSN was financial needs (28%). Provider discomfort rates were high in all HRSNs domains (range 53-74%). Social isolation was noted by 20% and loneliness by 70%, with 80% of providers expressing discomfort in addressing these PROs. Informational needs were also common including low health literacy (27%), obstacles to medication adherence (36%) and lack of informational support (56%), with provider discomfort noted by 32-44% of providers. **Conclusion:** Routine measurement of PROs is feasible in ambulatory liver care and reveals significant burden of unmet needs, regardless of cirrhosis status. In parallel, provider discomfort in managing these domains is striking. Taken together, routine PROMs in liver care, paired with innovative care pathways to enhance providers' comfort and capability may improve patient-centered outcomes in this high-need population.

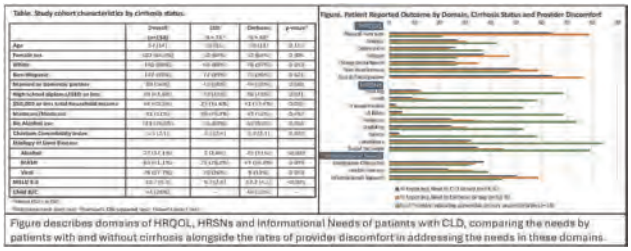

Figure describes domains of HRQOL, HRSNs and Informational Needs of patients with CLD, comparing the needs by patients with and without cirrhosis alongside the rates of provider discomfort in addressing the needs in these domains.

★ 0136 | PREDICTORS OF TIME TO TRANSPLANT IN PATIENTS WITH HEPATOCELLULAR CARCINOMA: A NATIONWIDE ANALYSIS

Imran Qureshi[1] Muhammad Ali Ibrahim Kazi[2] Ritik Mahaveer Goyal[3] Muhammad Hassaan Arif Maan[4] Wajiha Khan[4] Rohan Karkra[4] Siddharth Verma[5] Ahmed Al-Khazraji[4] Paul Gaglio[4], [1]RUTGERS THE STATE UNIVERSITY OF NEW JERSEY, [2]Luminis Health Anne Arundel Medical Centre, Annapolis, Maryland, United States, [3]Rutgers New Jersey Medical School, [4]Rutgers New Jersey Medical School, Newark, New Jersey, United States, [5]Veterans Affairs Medical Center, East Orange, New Jersey, United States

Background: Hepatocellular carcinoma(HCC) is on the rise globally and is the third most common cause of cancer-related death. Liver transplant(LT) is a potentially curative treatment modality in select patients with HCC, with potentially better outcomes than alternative treatments. Herein, we evaluate factors associated with delay in LT. **Methods:** Using the National Cancer Database, we identified 16,893 patients with HCC who received LT between 2004 and 2022. We conducted multivariate linear regression using sociodemographic factors as well as neoadjuvant therapy, liver fibrosis, and AFP levels as predictors of time to LT. We reported coefficients in days to transplant from diagnosis of HCC, along with their 95% confidence intervals(CI) and p-values. **Results:** Our analysis (Figure 1) showed that compared to Whites, Blacks(20.94 days, 95% CI:7.86 to 34.03, $p < 0.01$) and Asians(49.98 days, 95% CI:34.19 to 65.76, $p < 0.01$) had longer time to LT. Hispanics experienced more delays than non-Hispanics (16.26 days, 95% CI:4.77 to 27.75, $p < 0.01$). Areas with 9.1–15.2% high school non-graduates(12.91 days, 95% CI:0.64 to 25.18, $p = 0.04$) and $\geq 15.3\%$ high school non-graduates(22.99 days, 95% CI:8.84 to 37.14, $p < 0.01$) were associated with longer delays to LT. In contrast, residing in lower-income areas were surprisingly associated with shorter time to treatment: $< \$46,277$(–30.91 days, 95% CI:–44.59 to –17.23, $p < 0.01$), \$46,277–57,856(–27.05 days, 95% CI:–38.73 to –15.37, $p < 0.01$), and \$57,857–74,062(–16.56 days, 95% CI:–26.88 to –6.24, $p < 0.01$). Patients with a Charlson-Deyo Comorbidity score of ≥ 3 had shorter time to LT(–30.82 days, 95% CI:–39.76 to –21.87, $p < 0.01$). Treatment at a community hospital vs. academic hospital was associated with increased delays(10.68 days, 95% CI:0.98 to 20.38, $p = 0.03$). Compared to the Northeast, the South(–21.78 days, 95% CI:–32.07 to –11.48, $p < 0.01$) and Midwest(–14.03 days, 95% CI:–25.57 to –2.49, $p = 0.02$) had shorter LT wait times, whereas the West had longer delays(51.32 days, 95% CI:38.62 to 64.01, $p < 0.01$). HCC before age 50 was associated with earlier LT(–40.13 days, 95% CI:–52.91 to –27.35, $p < 0.01$). Receipt of neoadjuvant therapy(164.08 days, 95% CI:152.44 to 175.72, $p < 0.01$), cirrhosis/severe fibrosis(21.54 days, 95% CI:3.18 to 39.90, $p = 0.02$) and elevated AFP(20.89 days, 95% CI:9.58 to 32.20, $p < 0.01$) were also associated with delayed LT. Sex, insurance, or setting did not significantly influence time to LT. **Conclusion:** Our study demonstrates that race, ethnicity, education, income, comorbidity burden, type of hospital, and region influence time to LT in patients with HCC. Multiple other factors, such as techniques of tumor downstaging, locoregional therapy, or receipt of immunotherapy, may influence the time to transplant. This shows that there are significant socioeconomic disparities in time to LT, raising the need for targeted public health interventions to address these.

0137 | PATIENT PERSPECTIVES AND PERCEIVED BARRIERS TO LIVER TRANSPLANTATION IN A SAFETY-NET HOSPITAL SYSTEM

Andrea Amaro[1] Kali Zhou[1] Saroja Bangaru[1], [1]University of Southern California-Los Angeles General Medical Center

Background: Safety-net hospital (SNH) systems shoulder a disproportionate burden of cirrhosis, yet only a minority are referred for and successfully complete liver transplantation (LT). A previous study of SNH providers across the country found that patient-related factors, including insurance, finances, and psychosocial aspects, are frequently perceived as barriers to LT referral. There is limited investigation into and understanding of the safety-net patient perspective on LT. **Methods:** This ongoing anonymous survey study is being conducted among patients with cirrhosis at a large urban SNH hepatology clinic, starting in February 2025. The 49-item survey assesses knowledge of, perceptions about, and desired resources for care related to cirrhosis and LT. Surveys are being distributed to pre-screened patients in the waiting room in English or Spanish and completed independently or with family members. No identifying information is collected. **Results:** 147 patients have participated in the survey to date. Mean age was 56 (45-67) years. Respondents were 59% male, 82% foreign-born, and 92% Hispanic ethnicity. 56% of surveys were completed in Spanish. 40% had an annual household income of $10,000 or less, and 71% were insured by Medicaid. Most common etiologies of cirrhosis included alcohol (46%), metabolic-dysfunction associated steatotic liver disease (25%), and viral hepatitis (11%). 50% of patients had a prior paracentesis, 35% had hematemesis, and 35% had liver-related confusion. 54% reported having previously discussed LT with a physician, including 16% who had already been evaluated at an LT center. Regarding knowledge of LT, there was notable uncertainty: 37% were unsure whether cirrhosis is an indication for LT, 35% unsure if LT can cure cirrhosis symptoms, 76% unsure or did think all hospitals provide LT, and 75% unsure if insurance covers LT. Regarding potential barriers to LT, interestingly, 60-63% either agreed or strongly agreed they had adequate caregiver support, adequate transportation, and the ability to take off work to attend appointments, but 37% felt LT would be too much for their family and 51% were concerned about post-LT finances. Over two-thirds of patients felt the following resources would be extremely useful: a video about cirrhosis (70%); a video about liver transplantation (69%); a detailed explanation of costs of LT (74%); assistance with transportation to appointments (68%). **Conclusion:** Knowledge of benefits and availability of LT could be improved among SNH patients with cirrhosis. Caregiver support, transportation, and work obligations are reported barriers, though finances were the most prevalent source of concern. Educational interventions and detailed financial counseling may facilitate LT referral and completion of evaluation for low-income populations.

0138 | BARRIERS BEYOND BIOLOGY: THE IMPACT OF PSYCHOSOCIAL VARIABLES ON LISTING FOR EARLY LIVER TRANSPLANTATION IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS

Olivia Blocker[1] Elina Stoffel[2] Himel Mallick[1] Jialin Gao[1] Eric Liu[1] Morgan Lozano[1] Virgina Parker[1] Robert Brown[1] Gene Im[2] Elizabeth Verna[2] Stephanie Rutledge[1], [1]Weill Cornell Medicine, [2]Columbia Medical Center

Background: Severe alcohol-associated hepatitis (AH) is an acute manifestation on the spectrum of alcohol-associated liver disease with high short-term mortality. An increasing number of transplant centers are considering patients with AH for early liver transplantation (eLT) without 6 months of abstinence. Instead of a fixed period of abstinence, the evaluation includes a detailed psychosocial assessment that could disadvantage individuals with social vulnerabilities. Our aim was to define how psychosocial variables and social determinants of health (SDOH) affect the likelihood of being listed for LT. **Methods:** We conducted a retrospective cohort study of patients > 18 years old hospitalized with probable or definite severe AH (per NIAAA criteria, MELD > 20) who underwent evaluation for eLT at two academic centers in New York City between January 2012 and May 2025. Patients were defined as "declined" if they were initially either declined or deferred for LT, as we could not account for changes in variables over time among those later accepted. Variables were manually extracted from social work documentation. A univariate logistic regression model was used to assess the association between psychosocial variables and acceptance for LT. The model was adjusted for MELD 3.0; age and sex were not associated with the outcome of interest and were not adjusted for. We did not adjust for all covariates as some covariates may function as mediators or colliders rather than true confounders, and we wanted to avoid overfitting. **Results:** Between 2012 and 2025, 133 patients with severe AH were evaluated for eLT: 82/133 (61%) were accepted, 36/133 (27%) were declined, 15/133 (11%) were deferred; of those deferred, 3/15 (20%) were later accepted. The majority (35/51, 69%) were deferred or denied for psychosocial factors. The mean age was 44 years (SD: 10) and 37% were female; 57% identified as White, 16% Black, 8% Hispanic, 5% Asian, and the remainder as other or were unknown. We analyzed 30 variables in a univariate logistic regression model. We found that having good insight/judgement – specifically regarding their diagnosis and understanding of the transplant process – had the highest odds ratio (OR) for LT acceptance (3.96, 95% CI: 1.57–9.96). Other significant variables included having a caregiver plan (OR = 2.05, 95% CI: 1.01-4.16). Speaking a non-English primary language (OR = 0.28, 95% CI: 0.09-0.91) and a history of abuse (OR = 0.38, 95% CI: 0.15-0.98) predicted lower likelihood of listing. **Conclusion:** The decision regarding early LT in severe AH is crucial, given that 6-month survival is ~30% without LT versus ~90% with LT. Many are not candidates for early LT due to psychosocial factors and relapse risk; thus, it is important to define the most influential decision-making factors. We need to be cognizant of factors that influence listing for LT but may not correlate with relapse risk or outcomes, which exacerbate healthcare inequities.

0140 | HEALTH LITERACY IS AN IMPORTANT DETERMINANT OF HEALTH OUTCOMES: IDENTIFYING RISK FACTORS FOR POOR HEALTH LITERACY IN CHRONIC LIVER DISEASE

Hannah Lee[1] Alana Saddic[1] Priyam Das[2] Niki Wadhwa[1] Mary Kate Lantzy[1] Grant Chin[1] Jessica Mittler[1] Deborah DiazGranados[1] Eshban Serosh[1] Richard Sterling[1], [1]Virginia Commonwealth University, [2]Virginia Commonwealth Univeresity

Background: A multidimensional concept, health literacy (HL) is defined as the ability to access, understand, appraise, and apply health information to manage one's health. HL is a central determinant of health and a priority in addressing chronic disease management. Little is known about the HL status in chronic liver disease (CLD) patients and their outcomes. **Methods:** A prospective study of CLD patients using the Health Literacy Questionnaire (HLQ) was performed. The HLQ measures the full construct of HL assessing 9 aspects to uncover mechanisms of health inequities to inform intervention development. Cohort characteristics, HLQ scores, and interaction between demographic/ clinical variables, health-related behaviors, number of admissions and their HL scores were assessed. **Results:** 84 patients were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

included (mean age: 56, MELD 12, females 57%, White 81%, Black 10%, Other 10%, ALD 31%, MASLD 49%, MetALD 7%, HCV 10%, cirrhosis 68% (CTP 66% A, 24% B, 11% C), and Education: 47% high school or less, 39% college, 14% > college. For HLQ part 1 (response scale 1-4), scores for "Feeling understood and well supported by healthcare providers" (mean,SD) (3.5,0.50) were the highest and "Appraisal of health information" (3.0,0.61) were the lowest. For part 2 of the HLQ (response scale 1-5), scores for "Ability to actively engage with health care providers" (4.15,0.65) were the highest and "Ability to find good health information" (3.82,0.64) were the lowest. Alcohol liver disease (ALD) had lower HL scores in 3 of the 9 domains (Table). High Patient Health Questionnaire (PHQ-9) had lower HL scores in 8 of the 9 domains. High General Anxiety disorder (GAD- 7) had lower HL scores in all 9 domains. High Edmonton Symptoms Assessment (ESAS) scores had lower HL scores in 7 out of the 9 domains. History of drug/ alcohol use was associated with higher PHQ/ GAD $p < .01$, ESAS $p < .01$ scores, and lower HLQ scores in 4 of the 9 domains. Higher number of admissions were associated with ALD $p < .01$, history of drug/alcohol use $p < .05$, mental health disorder $p < .01$, and high GAD $p < .01$/ ESAS $p < .001$ scores. **Conclusion:** Lower HL was associated with ALD, anxiety/ depression, history of drug/ alcohol use, and poorer QOL. History of drug/ alcohol use, ALD, mental health disorder, anxiety, and poorer QOL were associated with higher number of admissions. Our novel data provides opportunities for interventions to address poor HL to improve patient QOL and reduce health care utilization such as optimization of behavioral health and palliative/ symptom-based care.

0141 | DEVELOPMENT AND INTERNAL VALIDATION OF THE LABORATORY-BASED LIVER FRAILTY INDEX (LAB-LFI)&MDASH; A PREDICTION MODEL BASED ON CIRCULATING BIOMARKERS FOR FRAILTY IN PATIENTS WITH CIRRHOSIS

Michael Li[1] Nghiem Ha[1] Srilakshmi Seetharaman[1] Chiung-Yu Huang[1] Catherine Lee[1] Jennifer Lai[1], [1]University of California, San Francisco

Background: Frailty, as measured by the Liver Frailty Index (LFI), is a well-established predictor of outcomes in cirrhosis patients. However, the LFI consists of grip, chair stands, and balance testing, limiting frailty testing to in-person encounters. We sought to develop an index correlated with frailty from hypothesis-driven, biologically relevant blood-based biomarkers. **Methods:** Based on prior work screening candidate frailty biomarkers, 7 serum/plasma analytes (myostatin, IL-6, growth differentiation factor-15 [GDF-15], testosterone, leucine-rich alpha-2 glycoprotein [LRG1], fetuin-A, and IGF-1) were measured by ELISA in 520 ambulatory cirrhosis patients and log2-transformed for analyses. "Frail" was defined as LFI $\geq$ 4.4. The study cohort was split randomly in half; LASSO regression was employed to develop the prediction model in the training set and internally validated in the test set. Other machine learning methods (generalized additive model [GAM], Random Forest, and XGBOOST) were utilized to construct models to compare discrimination for frailty. **Results:** Of 520 ambulatory cirrhosis patients (median age 59, median MELD 14), 111 (21%) were frail. All 7 log2-transformed biomarkers were significantly associated with frailty on univariable testing, and all but myostatin and LRG1 remained significantly associated with frailty after using logistic regression to adjust for age, sex, liver disease etiology, and MELD (Fig A). Lab-LFI was derived from the training set using LASSO regression, with the following formula for log odds of frailty: *-1.61 - 0.24*(log2[myostatin]) + 0.35*(log2[IL-6]) + 0.23*(log2[GDF-15]) - 0.52*(log2[testosterone]) + 0.05*(log2[LRG1]) - 0.61*(log2[Fetuin-A]) – 0.27*(log2[IGF-1])*. In the test set, Lab-LFI had a c-statistic of 0.80 (95% CI 0.74-0.87) for predicting frailty. Lab-LFI also had good calibration (Hosmer-Lemeshow $p = 0.740$). The GAM, random forest, and XGBOOST approaches produced models with similar performance (c-statistics 0.79-0.82; Fig B); as such, the LASSO model was chosen for maximum interpretability. Addition of clinical variables to the LASSO model, including MELD labs, sex, and liver disease etiology, did not improve discrimination (c-statistic 0.78, 95% CI 0.72-0.85). **Conclusion:** We developed and internally validated the Lab-LFI, a frailty prediction model consisting of 7

laboratory-based biomarkers with excellent discrimination. Lab-LFI enables assessment of *physical* function, as MELD does with *liver* function. Furthermore, several Lab-LFI biomarkers can be altered through supplementation (testosterone) or biologics (inhibition of IL-6 and GDF-15), raising the exciting possibility for therapeutic targets to modify frailty.

0142 | INTEGRATING WEARABLE, RADIOLOGIC, LABORATORY, AND METABOLOMIC BIOMARKERS TO CHARACTERIZE FRAILTY IN CIRRHOSIS: INSIGHTS FROM A PROSPECTIVE OBSERVATIONAL STUDY

Gautham Pranesh[1] Hiteshi Dhami- Shah[2] Nikhil Zachariah[3] Shyam Kottilil[4] Mani Subramanian[5] SAMIR SHAH[2], [1]SensEarly, [2]Max Nanavati Hospital, [3]Mitopower, [4]University of Maryland, [5]TLC

Background: Frailty is an independent predictor of mortality in cirrhosis, reflecting multisystem physiological decline. Current tools such as the Liver Frailty Index (LFI) rely on clinic-based assessments and may not capture early or evolving changes. This study evaluated wearable-derived, imaging, laboratory, and metabolomic markers as objective indicators of frailty in cirrhosis. **Methods:** This single-center prospective study (CTRI/2022/09/045668) enrolled adults with cirrhosis. Frailty was assessed using the LFI at baseline. Four domains were evaluated: (1) Wearables: Patients wore Garmin Vivosmart 5 for up to two weeks to record daily step count and physiological activity; (2) Imaging: CT-derived skeletal muscle index and MRI-based psoas area were measured; (3) Laboratory: Routine clinical parameters including serum phosphorus, total protein, and lymphocyte differential were analyzed; (4) Metabolomics: Targeted LC-MS quantified plasma amino acids and acylcarnitines. Spearman correlations were used to assess associations with LFI. **Results:** Forty-eight patients were included (15 compensated, 21 decompensated, 10 ACLF 0–1, 2 ACLF 2–3); 57% were pre-frail and 43% frail by LFI. Daily step count showed a significant inverse correlation with frailty ($r = –0.472$, $p < 0.001$). Skeletal muscle area was also inversely associated with frailty ($r = –0.496$, $p < 0.001$). Lower serum phosphorus ($r = –0.508$, $p < 0.001$) and total protein ($r = –0.444$, $p < 0.001$) were significantly associated with frailty. Metabolomic analysis showed positive correlations of LFI with free carnitine ($r = 0.447$, $p = 0.002$), acetylcarnitine ($r = 0.427$, $p = 0.003$), 4-hydroxyproline ($r = 0.500$, $p < 0.001$), methionine ($r = 0.428$, $p = 0.003$), and lysine ($r = 0.407$, $p = 0.005$). **Conclusion:** Frailty in cirrhosis is associated with objective alterations across wearable, radiologic, laboratory, and metabolomic domains. Integration of wearable technology with molecular and imaging markers may enable scalable, continuous frailty monitoring and serve as a framework for evaluating targeted interventions in liver disease.

0143 | FRAILTY, COGNITIVE IMPAIRMENT AND COMORBID CONDITIONS ADD TO CIRRHOSIS SEVERITY IN PREDICTION OF 12-MONTH HOSPITALIZATIONS IN A MULTI-CENTER OUTPATIENT CIRRHOSIS COHORT

Jasmohan Bajaj[1] Jennifer Lai[2] Puneeta Tandon[3] Jacqueline O'Leary[4] Florence Wong[5] Guadalupe Garcia-Tsao[6] Hugo Vargas[7] Philip Vutien[8] Scott Biggins[9] Kaitlyn Wethey[10] Tahira Shaikh[11] Stephanie Tsai[12] Jawaid Shaw[13] Andrew Fagan[14] Patrick Kamath[15] Leroy Thacker[13] K Rajender Reddy[16], [1]Virginia Commonwealth University, [2]UCSF, [3]University of Alberta, [4]Dallas VAMC, [5]University of Toronto, [6]Yale University, [7]Mayo Clinic Arizona, [8]University of Washington, [9]U Washington, [10]U Penn, [11]U Alberta, [12]UTSW, [13]VCU, [14]Richmond VA, [15]Mayo Rochester, [16]University of Pennsylvania

Background: Cirrhosis etiology control & changing demographics require re-evaluation of prediction models for outcomes such as hospitalizations. An integrated multi-site approach with cirrhosis-related factors, comorbidities, cognitive function, and frailty metrics is needed. Aim: To determine the integrated impact of cirrhosis-related & unrelated factors in 12-month hospitalization

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

prediction in outpatients with cirrhosis. **Methods:** NAC-SELD-3 (North American Consortium for the Study of End-Stage Liver Disease) is a cohort of outpatients with compensated & decompensated cirrhosis recruited from 10 centers across North America (Fig A). We enrolled pts able to consent, those with eradicated HCV, & without HIV/illicit drug use or alcohol misuse. Demographics, cirrhosis severity/history, comorbidities using Charlson comorbidity index (CCI), & medications were recorded. Liver frailty index instruments (LFI, high = worse), EncephalApp Stroop (High time = worse), SF-36 (low = worse), Mini-mental status (MMSE) & animal naming tests (ANT) both low = worse, were administered. Patients were systematically followed for 12 months using in-person visits every 6 months and phone calls every 3 months in between. Logistic regression analyses for hospitalizations was performed using baseline variables that were significantly different at $p < 0.10$. **Results:** 981 patients (61 yrs, 70% men, 76% White, 6% Latinx) who were able to complete EncephalApp Stroop and LFI were included. Median CCI was 5 (3-6) which denotes a moderate comorbidity burden. Cirrhosis details: 39% were compensated; major etiologies were alcohol (47%), MASLD (26%), & eradicated HCV (17%). Median MELD-Na was 11, 35% had prior HE & 19% difficult to control ascites. Hospitalizations: 334 (34%) required admissions at 12M; >85% were liver related. Pts who needed hospitalization were younger, had higher CCI, cirrhosis severity/medications, worse EncephalApp Stroop, ANT, SF-36 and LFI (Fig B). Regression (Fig C): Variables associated with greater 12M hospitalizations were cirrhosis-related (baseline diuretic use, higher MELD-Na), cognitive (higher with longer EncephalApp Stroop time), frailty (worse with higher LFI) and higher CCI. Age and greater SF-36 score (better quality of life) were associated with lower 12M hospitalizations. **Conclusion:** In this multi-center experience of nearly 1000 outpatients with compensated and decompensated cirrhosis with controlled etiologies, frailty, covert HE, patient-reported outcomes and comorbidity burden add to cirrhosis-related factors for the prediction of hospitalizations at 12 months. A holistic, integrative approach to outpatients with cirrhosis is needed to improve prognostication and potentiall reduce this burden.

Background: The spectrum of steatotic liver disease (SLD) includes patients with metabolic dysfunction-associated liver disease (MASLD), alcohol-related liver disease (ALD), and a mixed phenotype (MetALD). Granular data on the impact of SLD-subtypes on the natural history of compensated advanced chronic liver disease (cACLD), as well as the prognostic role of clinically significant portal hypertension (CSPH) and non-invasive tests (NITs), are needed. **Methods:** We included 696 SLD patients with cACLD from 17 European centers undergoing hepatic venous pressure gradient (HVPG) and NIT assessment until December 2023. The underlying etiology was MASLD in 58%, MetALD in 20% and ALD in 22%. The primary outcome of interest was first hepatic decompensation. **Results:** Most patients had Child-Pugh A (89%) with a median MELD of 8 [7-10]. CSPH (HVPG $\geq$ 10 mmHg) was present in 60% (MASLD: 56%/ MetALD: 57%/ ALD: 74%), with a high diagnostic accuracy of ANTICIPATE $\pm$ NASH across the SLD spectrum (AUROC in MASLD: 0.828/ MetALD: 0.882/ ALD: 0.856). The median follow-up was 45.0 months, with a 1- and 2-year cumulative incidence of first decompensation of 7.1% and 13.6%, respectively. Liver stiffness measurement (Harrell's C: 0.69), ANTICIPATE $\pm$ NASH (C: 0.73) and albumin (C: 0.72) provided good prognostic accuracy for hepatic decompensation during follow-up and were comparable to HVPG (C: 0.76) when combining ANTICIPAT E $\pm$ NASH with albumin (C: 0.77). In a multivariable model including MELD and albumin, both the presence of CSPH (hazard ratio [HR]: 3.97; $p < 0.001$) and ANTICIPATE $\pm$ NASH $\geq$ 60% (HR: 2.79; $p < 0.001$) were linked to a significantly higher risk of decompensation (see Figure). With regard to etiology-specific differences, the 1- and 2-year cumulative decompensation incidences were 5.0%/9.9% in MASLD, 6.1%/14.6% in MetALD and 13.7%23.1% in ALD. After adjusting for age, sex, MELD, albumin and HVPG, the risk of hepatic decompensation did not differ significantly across SLD subcategories. HVPG showed the highest predictive accuracy regarding the 2-year decompensation risk in MASLD (0.79, Brier-score: 0.071) and MetALD (0.80, Brier: 0.076) vs. ALD (0.69, Brier: 0.082). **Conclusion:** The higher decompensation risk in ALD and MetALD is primarily explained by more severe liver disease at presentation, as differences diminished after adjusting for these factors. NITs show excellent diagnostic performance for CSPH across the SLD spectrum and achieve similar prognostic accuracy as HVPG.

0145 | BELAPECTIN REDUCES LIVER STIFFNESS PROGRESSION AND PREVENTS VARICES AT 18 MONTHS IN MASH CIRRHOSIS: RESULTS: FROM THE NAVIGATE TRIAL

Raj Vuppalanchi[1] Naim Alkhouri[2] Mazen Noureddin[3] Khurram Jamil[4] Seth Zuckerman[5] Naga Chalasani[6], [1]Indiana University School of Medicine, Indianapolis, IN, [2]Summit Clinical Research, [3]Houston Methodist Hospital, [4]Galectin Therapeutics, [5]Galectin Therapeutics., [6]Indiana University Medical Center

Background: MASH cirrhosis is associated with portal hypertension, clinical decompensation, and development of esophageal varices (EV). Currently, there are no approved therapies for MASH cirrhosis. Belapectin, a galectin-3 inhibitor, is being evaluated in NAVIGATE (NCT04365868), a Phase 2b/3 randomized, placebo-controlled trial aimed at preventing variceal development in patients with compensated MASH cirrhosis and portal hypertension without baseline EV. **Methods:** NAVIGATE enrolled 355 subjects with compensated MASH cirrhosis and portal hypertension without baseline varices. Of these, 287 completed 18 months of blinded therapy, and 272 had evaluable FibroScan® data and endoscopy at both baseline and 18 months. Liver stiffness measurement (LSM) was analyzed using two predefined worsening thresholds: $\geq$30% relative increase and $\geq$10 kPa absolute increase from baseline. These thresholds were selected based on prior studies indicating clinically meaningful change. The incidence of new EV at 18 months was evaluated in relation to LSM progression. Statistical comparisons were conducted using the chi-square test. **Results:** Among 272 subjects, $\geq$30% worsening in LSM was observed in 21 of 89 subjects (23.6%) in the placebo group compared to 11 of 94 (11.7%, P = 0.03) in the belapectin 2 mg group, and 14 of 89 (15.7%) in the 4 mg group. For $\geq$10 kPa worsening, 12 of 89 subjects (13.5%) in the placebo group worsened, compared to 4 of 94 (4.3%, P = 0.02) in the 2 mg group and 9 of 89 (10.1%, P = NS) in the 4 mg group. Subjects who experienced worsening in LSM were more likely to develop new EV. Among those with a $\geq$30% LSM increase, 23.8% had EV at 18 months compared to 15.7% in those without worsening (P = 0.1951). Similarly, 14.3% of subjects with a $\geq$10 kPa increase developed EV compared to 8.3% without worsening (P = 0.2141). Although not statistically significant, likely due to sample size, these trends support the relationship between LSM progression and variceal development. **Conclusion:** Belapectin 2 mg/kg was associated with significantly less worsening of LSM at 18 months compared to placebo, using both $\geq$30% and $\geq$10 kPa thresholds. Furthermore, less worsening in LSM was linked to a lower incidence of new varices, reinforcing the clinical relevance of LSM progression as a surrogate marker. These findings suggest a potential beneficial effect of belapectin on disease progression in MASH cirrhosis and warrant further investigation in future studies.

★ 0146 | DAPAGLIFLOZIN CAN REDUCE THE INCIDENCE OF CHRONIC KIDNEY DISEASE IN METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE ASSOCIATED CIRRHOSIS PATIENTS WITH MODERATE ASCITES. A RANDOMIZED CONTROLLED TRIAL (DAPA-CLD)

Ayush Jain[1] Rakhi Maiwall[2] Harsh Vardhan Tevethia[3] Omkar Rudra[3] Shiv Kumar Sarin[3], [1]Institute of liver and biliary sciences, New Delhi, [2]Institute of Liver and Biliary Sciences, [3]ILBS, New Delhi

Background: Non-alcoholic fatty liver disease (NAFLD)-associated cirrhosis is often complicated by renal dysfunction, yet early strategies to prevent chronic kidney disease (CKD) in these patients are limited. Dapagliflozin, a sodium-glucose co-transporter-2 (SGLT2) inhibitor, has demonstrated renoprotective effects in patients without cirrhosis, metabolic benefits, and potential to aid in resolution of ascites in patients with cirrhosis; however, its role in cirrhosis remains insufficiently studied. **Methods:** Patients with MASLD associated cirrhosis with moderate ascites on diuretics were randomized in a 1:1 open label block randomization to receive either dapagliflozin, initiated at 5mg and subsequently increased to 10mg, plus standard of care (SOC) (Group 1) or SOC alone (Group 2). The primary endpoint of the study was proportion of patients developing CKD, defined as sustained eGFR < 60 mL/min/1.73 m² over ≥ 3 months, at 1 year. The secondary endpoints included development of CKD at interim time points, incidence of acute kidney disease, ascites resolution, changes in metabolic parameters, and drug-related adverse events. Analysis was performed as intention-to-treat. **Results:** Baseline parameters including age (57.08 ± 7.79 vs 57.52 ± 7.01; $p = 0.77$), duration of cirrhosis (35.82 ± 30.5 vs 35.54 ± 31.27; $p = 0.96$), incidence of diabetes (78% vs 76%; $p = 0.48$), baseline eGFR (97.8 ± 29.73 vs 95.6 ± 28.6; $p = 0.30$), MELD score (11.1 ± 2.36 vs 10.78 ± 2.61; $p = 0.66$) were similar. At 12 months, CKD developed more frequently in group 2 [13 (26%) vs. 4 (8%); $p = 0.02$; HR of 0.31 (95% CI: 0.10–0.95). A higher proportion of patients had resolution of ascites (80% vs 68%; $p = 0.01$), with higher proportion requiring discontinuation of diuretics (60% vs 28.6%; $p = 0.0048$], with lower median dose of frusemide (2.88 ± 5.73 vs 8.78 ± 10.76; $p = 0.008$) and spironolactone (7.19 ± 12.89 vs 15.54 ± 17.34; $p = 0.02$) at 12 months in group 1. Metabolic parameters, including triglycerides (84.03 ± 20.13 vs 98 ± 31.40 mg/dL; $p = 0.41$), HDL (40.15 ± 13.11 vs 40.62 ± 9.70 mg/dL; $p = 0.92$), BMI (28.35 ± 5.53vs24.66 ± 7.39 kg/m²; $p = 0.18$), and waist circumference (101 ± 10.97 vs. 98.81 ± 12.69 cm; $p = 0.66$), were comparable. HbA1c was significantly lower in group1 ($5.21 \pm 0.81\%$ vs. $6.26 \pm 1.28\%$; $p = 0.03$) and glycemic control was similar in the two groups (79.4% vs 75%; $p = 0.23$). At 12 months, the incidence of AKD was significantly higher in group 2 (3% vs 19.5%; $p = 0.03$) and mean eGFR at 12 months was higher in group 1 (112.8 ± 32.45 vs. 86.93 ± 28.97 mL/min/1.73 m²; $p = 0.04$). Most common adverse event was genitourinary infections seen in 3(6%) patients, of which 2 required drug discontinuation while no liver related complications were seen. **Conclusion:** Dapagliflozin significantly reduced the incidence of CKD and improved ascites control in patients with MASLD-associated cirrhosis without major adverse effects.

0147 | IMPROVEMENTS IN NON-INVASIVE BIOMARKERS AND BIOPSY RESPONSES WITH THE GLUCAGON RECEPTOR/GLUCAGON-LIKE PEPTIDE-1 RECEPTOR DUAL AGONIST SURVODUTIDE: CONCORDANCE ANALYSIS FROM A PHASE 2 TRIAL IN PEOPLE WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOHEPATITIS AND FIBROSIS

Quentin Anstee[1] Naim Alkhouri[2] Luiza Borowska[3] Corinna Schoelch[4] Mandy Fraessdorf[3] Renee Marshall[5] Daniel Mazo[3] Arun Sanyal[6] Jörn Schattenberg[7] Vincent Wong[8] Ramy Younes[3] Mazen Noureddin[9], [1]Newcastle University, UK, [2]Summit Clinical Research, [3]Boehringer Ingelheim International GmbH, [4]Boehringer Ingelheim Pharma GmbH & Co KG, [5]Boehringer Ingelheim Pharmaceuticals Inc., [6]Virginia Commonwealth University, [7]University Medical Center Homburg, [8]The Chinese University of Hong Kong, [9]Houston Methodist Hospital

Background: The combination of elastography and blood biomarker non-invasive tests (NITs) have been proposed to replace histology-based efficacy endpoints. This post-hoc analysis assessed NIT-based efficacy endpoints, and examined if the observed changes in histology were corroborated by NITs following treatment with survodutide, a GCGR/GLP-1R dual agonist, in a phase 2 trial in participants with biopsy-confirmed MASH and F1–F3 fibrosis. **Methods:** Among 295 people aged 18–80 years randomized to once-weekly s.c. survodutide 2.4, 4.8, or 6.0 mg, or placebo (PBO) for 48 weeks, 170 participants had F2–F3 fibrosis stage at baseline, and paired biopsy results were included in this analysis. We evaluated the concordance among participants of ≥0.5 absolute reduction in enhanced liver fibrosis (ELF™) score and ≥30% reduction in liver stiffness measurement (LSM; by vibration-controlled transient elastography [FibroScan®]) with histological improvement in fibrosis with no worsening of MASH, as well as ≥30% reduction in liver fat content (LFC) (magnetic resonance imaging proton density fat fraction assessed) and ≥17 U/L reduction in alanine aminotransferase (ALT) with histological resolution of MASH with no worsening of fibrosis. **Results:** A ≥0.5 reduction in ELF™ score and ≥30% reduction in LSM was observed in 38.9 vs 4.1% of participants treated with survodutide vs PBO, respectively; improvement in fibrosis with no worsening of MASH was observed in 52.8 vs 24.5%, respectively. A reduction in ELF™, LSM, and improvement in fibrosis with no worsening of MASH was observed in 18.5 vs 2.0% of participants treated with survodutide vs PBO, respectively ($p < 0.05$ for all doses). A ≥30% reduction in LFC and ≥17 U/L reduction in ALT was observed in 58.8 vs 5.6% of participants treated with survodutide vs PBO, respectively; resolution of MASH with no worsening of fibrosis was observed in 62.3 vs 13.0%, respectively. A reduction in LFC, ALT, and resolution of MASH with no worsening of fibrosis was observed in 38.6 vs 1.9% of participants treated with survodutide vs PBO, respectively ($p < 0.001$ for all doses) (Table). **Conclusion:** The concordance of multiple NITs and biopsy results provides clear evidence of a robust effect from survodutide (over and above the PBO response) in the improvement of fibrosis (reduction of ELF™ and LSM) and resolving steatohepatitis (reduction of LFC and ALT) across all doses after 48 weeks.

Table. Number of responders at Week 48

	2.4 mg survodutide	4.8 mg survodutide	6.0 mg survodutide	Total survodutide	Placebo
N	38	40	30	108	49
Improvement in fibrosis with no worsening of MASH	22 (57.9%)	16 (40.0%)	19 (63.3%)	57 (52.8%)	12 (24.5%)

0148 | A RANDOMIZED, PLACEBO-CONTROLLED, PHASE 2 STUDY OF THE SAFETY AND EFFICACY OF COMBINATION TREATMENT WITH SEMAGLUTIDE, CILOFEXOR AND FIRSOCOSTAT IN PATIENTS WITH COMPENSATED CIRRHOSIS DUE TO METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (WAYFIND)

Naim Alkhouri[1] Kris Kowdley[2] Eric Lawitz[3] Arun Sanyal[4] Raj Vuppalanchi[5] Antoine Jakiche[6] Edward Mena[7] Humberto Aguilar[8] Michael Ryan[9] Michael Williams[10] Mousab Tabbaa[11] William Lee[12] Anita Kohli[1] Juan Pericàs[13] Magdy Elkhashab[14] Laura Stinton[15] Stephen Pianko[16] Vincent Leroy[17] Yoshiyuki Ueno[18] Michael Lund[19] Kwabena Opuni[20] Lulu Wang[21] SHAHLA BOLBOLAN[22] Andrew Billin[22] Tim Watkins[22] Daria Crittenden[22] Mazen Noureddin[23] Rohit Loomba[24], [1]Arizona Liver Health, [2]Liver Institute Northwest, [3]Texas Liver Institute, [4]Virginia Commonwealth University, [5]Indiana University School of Medicine, [6]Southwest Gastroenterology Associates, [7]California Liver Research Institute, [8]Gastrointestinal Specialists, [9]Capital Digestive Care, [10]Gastrointestinal Associates, [11]North Shore Gastroenterology & Endoscopy Center, [12]University of Texas Southwestern Medical Center, [13]Vall d'Hebron University Hospital, [14]Toronto Liver Centre, [15]University of Calgary, [16]Monash Health, [17]Assistance publique-Hopitaux de Paris, [18]Yamagata University, [19]Novo Nordisk Inc., [20]Novo Nordisk, Inc, [21]Gilead Sciences, Inc, [22]Gilead Sciences, Inc., [23]Houston Methodist Hospital, [24]MASLD Research Center

Background: We assessed the efficacy and safety of semaglutide (SEMA; glucagon-like peptide-1 receptor agonist) alone and in fixed-dose combination with cilofexor (CILO; farnesoid X receptor agonist) and firsocostat (FIR; liver-targeted acetyl-CoA carboxylase inhibitor) in patients (pts) with compensated cirrhosis (F4C) due to metabolic dysfunction-associated steatohepatitis (MASH; NCT04971785). **Methods:** In a multicenter, double-blind, phase 2b study, adults with biopsy-proven F4C due to MASH were randomized (3:3:3:2) to receive SEMA 2.4 mg/week + CILO 30 mg/FIR 20 mg/day, SEMA 2.4 mg/week, CILO 30 mg/FIR 20 mg/day, or placebo (PBO) for 72 weeks. The primary endpoint was the proportion of pts with fibrosis improvement without MASH worsening at week 72 with SEMA +CILO/FIR vs. PBO. Secondary (with prespecified testing hierarchy; Table) and exploratory efficacy endpoints and safety were also assessed. All P values are nominal. Liver biopsies were read by central pathologists (primary endpoint) and by AIM-MASH AI Assist from PathAI (exploratory). **Results:** 457 pts were randomized; 453 had ≥ 1 study drug dose (mean age: 62 yrs; T2D: 68.2%; mean platelets: 191×10^9/L). There was no significant difference in the proportions of pts with fibrosis improvement without MASH worsening at week 72 with SEMA +CILO/FIR vs PBO (13.7% vs. 8.3%; $P = 0.2289$). However, fibrosis improvement was seen with CILO/FIR vs PBO (20.3% vs. 8.3%; $P = 0.0174$). A difference was observed with PathAI analysis with SEMA+CILO/FIR vs. PBO (21.0% vs. 6.0%; $P = 0.0011$). MASH resolution was greater with SEMA+CILO/FIR vs. CILO/FIR or PBO and with SEMA vs. PBO in both pathologist (Table) and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

PathAI analyses (data not shown). The most frequent (≥15% of pts) adverse events (AEs) occurring more often with SEMA+CILO/FIR vs. PBO were nausea (47.6% vs. 22.6%), diarrhea (27.4% vs. 17.9%), constipation (24.2% vs. 8.3%), vomiting (21.8% vs. 7.1%), and decreased appetite (15.3% vs. 6.0%). Serious AEs and AEs leading to study discontinuation were similar across all groups. One death occurred in each of the SEMA and CILO/FIR groups. **Conclusion:** SEMA+CILO/FIR did not achieve the primary endpoint of fibrosis improvement compared with PBO based on pathologist review. However, SEMA-containing regimens achieved MASH resolution and CILO/FIR achieved fibrosis improvement compared with PBO. Interestingly, PathAI showed clinical benefit with SEMA+CILO/FIR, suggesting that combination therapies should be explored for MASH.

Table. Primary (solid line), secondary (dashed line), and exploratory efficacy endpoint results (non-responder imputation) from the WAYFIND study

	SEMA+CILO/FIR (n=126)	SEMA (n=128)	CILO/FIR (n=123)	Placebo (n=60)
Proportion of patients with fibrosis improvement (≥1 stage) without MASH worsening (≥1-pt increase in hepatocellular ballooning/lobular inflammation)[a]				
n (%)	17 (13.7)	19 (15.6)	25 (20.3)	7 (8.3)
Differences in proportion, % (95% CI)				
vs Placebo	5.7 (−3.6, 14.9) P=0.2289	7.7 (−1.7, 17.1) P=0.1080	11.9 (2.1, 21.7) **P=0.0174**	–
vs CILO/FIR	−6.5 (−16.2, 3.2) P=0.1908	–	–	–
vs SEMA	−1.8 (−11.1, 7.4) P=0.6959	–	–	–
Proportion of patients with MASH resolution (lobular inflammation = 0 or 1; hepatocellular ballooning = 0) without fibrosis worsening[a]				
Evaluable patients[b], n	82	81	88	49
n (%)	47 (57.3)	40 (49.4)	28 (31.8)	11 (22.4)
Differences in proportion, % (95% CI)				
vs Placebo	35.7 (18.8, 52.6) **P<0.0001**	27.1 (10.4, 43.8) **P=0.0014**	9.2 (−6.8, 25.2) P=0.2620	–
vs CILO/FIR	26.1 (11.3, 40.9) **P=0.0006**	–	–	–
vs SEMA	9.8 (−5.8, 25.3) P=0.2190	–	–	–

A stratified Mantel–Haenszel test was used to compare the difference in proportions of patients based on baseline re-read and week 72 biopsies, with baseline diabetes status and ELF score category as stratification factors. Owing to the sequence of hierarchical testing, statistical comparisons of secondary and exploratory endpoints are considered descriptive in nature.

[a]Based on evaluation of liver biopsies by central pathologists.

[b]Evaluable patients had both hepatocellular ballooning and lobular inflammation of grades ≥1 at baseline re-read.

CILO, cilofexor; ELF, enhanced liver fibrosis; FIR, firsocostat; MASH, metabolic dysfunction-associated steatohepatitis; SEMA, semaglutide.

Background: Cotadutide, a dual GLP-1 and glucagon receptor agonist has previously demonstrated improvements in non-invasive liver markers of inflammation, steatosis and fibrosis in biopsy-proven MASH with fibrosis. **Methods:** PROXYMO-ADVANCE was a Phase IIb (Part A) / III (Part B), double-blind, placebo-controlled study to evaluate the safety and efficacy of cotadutide vs. placebo, in adults with non-cirrhotic MASH with fibrosis. Due to strategic reasons, recruitment was stopped early, and only a portion of Part A was conducted as a proof-of-concept study. Primary objectives included safety, and all efficacy objectives (histology-based at week 48) were exploratory. 54 adults with biopsy-proven MASH with fibrosis stage 2/3 (on-study/historical biopsy) were randomized to receive cotadutide 300 µg or 600 µg, or matching-placebo as a daily subcutaneous injection via a multi-dose pen for 48 weeks (included a 12-week titration for 300 µg and 24-week titration for 600 µg). Analyses involved the full-analysis set (FAS) comprising those receiving at least one dose of investigational product and per-protocol subset with evaluable post-baseline biopsy after at least 36 weeks on treatment. **Results:** Mean treatment duration was similar across the groups. Adverse events (AEs) were more frequent in the cotadutide group (94.3%) vs. placebo (68.4%), with nausea (40%), vomiting (31.4%), and decreased appetite (20%) as the most common AEs. 75.9% completed the study; 66.7% underwent post-baseline biopsy. MASH resolution without worsening of liver fibrosis was observed in 35.3%, 44.4%, and 26.3%, in the cotadutide 300 µg, cotadutide 600 µg, and placebo groups, respectively. Cotadutide 600 µg showed an 18.1% treatment-response difference (95% CI -13.0, 46.4, $p = 0.257$, FAS) compared to the placebo group. Liver fibrosis improvement by at least one stage, without MASH worsening, occurred in 5.9%, 61.1%, and 21.1% for the cotadutide 300 µg, cotadutide 600 µg, and placebo groups, respectively. Cotadutide 600 µg showed a 40.1% response difference (95% CI 8.1, 64.8, $p = 0.022$, FAS) compared to the placebo group. **Conclusion:** Cotadutide 300 µg and 600 µg showed safety and tolerability consistent with its known profile in adults with non-cirrhotic MASH with fibrosis. Numerical improvements in MASH resolution were observed without worsening of liver fibrosis. Compared to placebo, a higher proportion in the Cotadutide 600 µg group experienced liver fibrosis improvement without MASH deterioration.

0150 | EFRUXIFERMIN IMPROVED MARKERS OF PORTAL HYPERTENSION AS EVALUATED BY BAVENO VII CRITERIA IN COMPENSATED CIRRHOSIS DUE TO MASH: RESULTS: FROM A 96-WEEK, PLACEBO-CONTROLLED, PHASE 2B TRIAL (SYMMETRY)

Mazen Noureddin[1] Naga Chalasani[2] Mary Rinella[3] Doreen Chan[4] Mark Burch[4] Erik Tillman[4] Sonja Billes[4] Arian Zari[4] Dragan Mackovic[4] Brittany De Temple[4] Reshma Shringarpure[5] Meena Jain[4] Timothy Rolph[4] Andrew Cheng[4] Kitty Yale[4], [1]Houston Methodist Hospital, [2]Indiana University Medical Center, [3]The University of Chicago, [4]Akero Therapeutics, [5]Akero Therapeutics, Inc

Background: In the SYMMETRY trial, efruxifermin, a bivalent FGF21 analog, improved fibrosis by histology in participants with compensated cirrhosis due to MASH (NCT05039450). The presence of clinically significant portal hypertension (CSPH) in this population is associated with a high risk of hepatic decompensation. In this secondary analysis, non-invasive tests commonly deployed in clinical practice were used to assess the impact of efruxifermin treatment on presence of CSPH and risk of hepatic decompensation. **Methods:** SYMMETRY was a phase 2b, randomized, placebo-

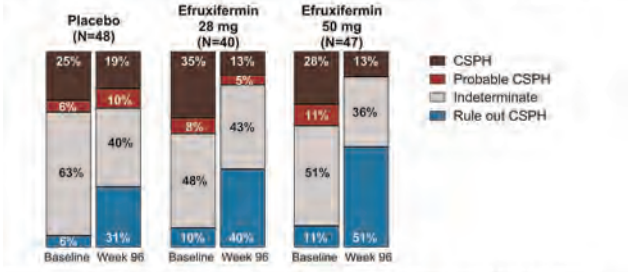
controlled, double-blind trial that enrolled 181 participants with biopsy-confirmed compensated cirrhosis (PMID:40341827). Participants were randomly assigned (1:1:1) to once-weekly efruxifermin (28 or 50 mg) or placebo for 96 weeks. Individual participants were analyzed at baseline and week 96 for: (1) presence of CSPH based on Baveno VII criteria incorporating liver stiffness measurement (LSM) by transient elastography (FibroScan) and platelet count; and (2) risk of liver-related events based on the published criterion of $>20\%$ decrease in Agile 4 (PMID:38512249). **Results:** Baseline characteristics were: 61 yrs, 67% female, BMI 36 kg/m^2, 80% T2D, LSM 24 kPa, ELF 11, platelets 183x10^9/L, ALT 40 U/L, AST 36 U/L. At baseline, 37% of participants overall had CSPH/probable CSPH, and CSPH could be ruled out in only 9%. In those with CSPH/probable CSPH, other markers were also indicative of more advanced disease. At week 96, fewer participants in the 28-mg (18%, $p=.20$) and 50-mg (13%, $p<.05$) efruxifermin groups were in the CSPH/probable CSPH category versus placebo (29%) (Figure). Compared to placebo (31%), there was a higher proportion of participants for whom CSPH could be ruled out in the 28-mg (40%, $p=.39$) and 50-mg (51%, $p<.05$) efruxifermin groups. Finally, the proportion of participants with a $>20\%$ decrease in Agile 4 score was 42% for placebo vs 58% and 64% for 28-mg and 50-mg efruxifermin. **Conclusion:** Fibrosis improvement with efruxifermin after 96 weeks of treatment was associated with reduced presence of CSPH and lower risk of hepatic decompensation. Accordingly, reversal of fibrosis by efruxifermin in patients with compensated cirrhosis may prevent progression to decompensation and liver-related outcomes. These endpoints are being evaluated in phase 3 trials.

Figure. Presence of CSPH assessed by Baveno VII criteria in the SYMMETRY trial



Data are for participants with paired baseline and week 96 data. Baveno VII criteria for CSPH: LSM ≥25; Probable CPSH: LSM ≥20 and platelet count <150 or LSM 15-20 and platelet count <110; Rule out CSPH: LSM ≤15 and platelet count ≥150. Indeterminate includes all other participants.

0151 | SAROGLITAZAR IMPROVES HEPATIC STEATOSIS IN WOMEN WITH PCOS AND MASLD: RESULTS: OF EVIDENCES VII RANDOMIZED CONTROL STUDY

Niharika Samala[1] Monika Sarkar[2] SREEMALA Murthy[3] Taufik Momin[4] Sukanya Krishnan[5] Farheen Shaikh[5] Naga Chalasani[6], [1]Indiana University, [2]University of California, San Francisco, [3]IUSchool of Medicine, [4]Zydus Life, [5]Zydus, [6]Indiana University Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is common in polycystic ovary syndrome (PCOS) and associated with more severe histology. Therapies specifically focusing on MASLD in PCOS patients are lacking. We therefore investigated the efficacy and safety of saroglitazar 4 mg/day in women with PCOS and MASLD. **Methods:** EVIDENCES VII (NCT03617263) is a multicenter, randomized, double-blind, placebo-controlled trial of saroglitazar 4mg/day for 24 weeks in women with PCOS and MASLD. The primary end point was a change in MRI-PDFF from baseline to 24 weeks in the per-protocol population (PPP) which included individuals who had an evaluable MRI PDFF at both baseline and at end of treatment. Prespecified secondary and exploratory efficacy, safety, and tolerability end points were evaluated. **Results:** 155 women with PCOS and suspected MASLD were assessed for eligibility. After applying eligibility criteria, 60 women were randomized to receive either 4 mg saroglitazar (n = 30) or placebo (n = 30). The PPP consisted of 25 saroglitazar and 23 placebo-controlled participants with baseline MRI-PDFF (mean ± SD) of 22.02% ± 8.24% and 22.66% ± 9.47%, respectively. Two groups were well matched except for higher HgA1c in the saroglitazar group (5.9% vs 5.5%, p = 0.035). MRI-PDFF absolute change from baseline (CFB) to 24 weeks was -3.13 ± 5.35 with saroglitazar vs -0.40 ± 4.98 with placebo (p = 0.061). The % CFB of MRI-PDFF at 24 weeks

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

was -14.67 ± 27.77 with saroglitazar vs 1.89 ± 27.47 with placebo ($p = 0.041$). The effect of saroglitazar were more pronounced after adjusting for HbA1c, demonstrating significant improvement based on both absolute CFB ($p = 0.002$) and %CFB ($p < 0.001$) in MRI-PDFF. The proportion with ≥30% reduction in MRI-PDFF was significantly higher with saroglitazar than placebo (36% vs 8.7%, $p = 0.024$) and mean %CFB favored saroglitazar for ALT (-37% vs 4.8%, $p = 0.007$), AlkP (-28% vs -2.1%, $p < 0.001$), triglyceride (-16% vs 18%, $p = 0.009$), Total-Cholesterol (-13% vs -1.5%, $p < 0.001$) and sdLDL-C (-21% vs 1.4%, $p = 0.027$). There were no significant changes by treatment for HOMA-IR, sex hormone binding globulin, free androgen index, or other sex hormones. Saroglitazar was well tolerated with no differences in body weight, waist circumference or adverse events between the treatment groups. **Conclusion:** In patients with PCOS and MASLD, saroglitazar 4mg/day significantly improved hepatic steatosis and dyslipidemia.

0152 | IMPROVEMENT IN LIVER FAT CONTENT AND MASH BIOMARKERS WITH ONCE WEEKLY UTREGLUTIDE (GL0034), A GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST IN SUBJECTS WITH MAFLD: A PHASE 1A/2B STUDY

Rajamannar Thennati[1] Vinod Burade[1] Muthukumaran Natarajan[1] Pradeep Shahi[1] Ravishankara Nagaraja[1] Bernard Thorens[2] Tina Vilsboll[3] Richard Pratley[4] John Olynyk[5] Rohit Loomba[6], [1]High Impact Innovations–Sustainable Health Solutions (HISHS), Sun Pharmaceutical Industries Limited, [2]Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland, [3]Clinical Research, Steno Diabetes Center Copenhagen, Herlev, University of Copenhagen, CPH, Denmark, [4]AdventHealth Translational Research Institute, Orlando, USA, [5]Professor, Curtin Medical Res. Institute, Curtin Univ. and Fiona Stanley Hospital, West Australia, [6]Chief, Division of Gastroenterol. & Hepatol., Prof. of Med., Univ. of California at San Diego, USA

Background: Utreglutide (GL0034, UTG), a novel, once weekly glucagon-like peptide-1 receptor agonist, demonstrated safety in phase 1 study along with clinically relevant reduction in body weight among healthy subjects and individuals with overweight and obesity. Improvements in lipid and metabolic biomarkers were also evident. This phase 1b/2a study evaluated the efficacy, safety, tolerability and pharmacokinetics of utreglutide in the treatment of MAFLD. **Methods:** In this randomized, double-blind, placebo-controlled, parallel group, multicenter study 48 participants, both male and females, aged 18 to 70 years with a body mass index (BMI) ≥30 kg/m^2 and liver fat content ≥10% as assessed by MRI-proton density fat fraction (PDFF) were randomized (3:1) to subcutaneous UTG doses with dose titration period (2×0.4, 4×0.8, 4×1.6 mg) of 10 weeks and fixed dose period (2.4 mg) of 3 weeks; or placebo once weekly for 13 weeks. Safety, tolerability, and key efficacy along with exploratory biomarkers were assessed at baseline and week 14. The biomarkers presented here include body weight (BW), waist circumference (WC), liver fat content by MRI-PDFF, plasma Pro-C3 (N-terminal type III collagen propeptide), controlled attenuated parameter (CAP) mean as assessed by FibroScan@, cytokeratin 18 fragment M30 (CK-18/M30) levels, liver enzymes [alanine aminotransferase (ALT) and aspartate aminotransferase (AST)], leptin, lipid panel [triglycerides (TG), total cholesterol (TC), and ApoB] and urate levels. **Results:** Utreglutide was well-tolerated and related adverse effects were mainly gastrointestinal including nausea and vomiting. The BW reduction at week 14 from baseline (BL) was 7.6 kg ($P < 0.001$) and accompanied by 9.3 cm reduction in WC ($P < 0.001$). The percent change in relative liver fat content as assessed by MRI-PDFF from BL to week 14 was 25.4 ($P < 0.001$). The non-invasive fibrosis marker, Pro-C3 levels significantly decreased by 13.2% ($P < 0.001$) and followed by reduction in CAP mean by 12.8% ($P < 0.001$) along with a 3.7% reduction in CK18/M30 fragment levels ($P < 0.05$). The liver enzyme reductions were also noted with 5.2% in ALT ($P < 0.05$) and 3.9% in AST. Improvement in lipid panel was observed together with significant reduction in leptin and urate levels by 14.0% ($P < 0.01$) and 9.8% ($P < 0.001$) respectively (Table). **Conclusion:** Once weekly utreglutide dosing for 13 weeks in subjects with MAFLD was well tolerated and demonstrated marked reductions of body weight, liver fat, non-invasive fibrosis markers, liver enzymes, lipids along with leptin and urate.

★ 0153 | LARGE-SCALE MULTI-TRAIT GWAS LINKS OPA1 GENE TO LIVER FIBROSIS AND MASLD

Xinting Yu[1] Shisong Rong[2] Yury Popov[3], [1]University of South Florida, [2]Harvard Medical School, [3]BIDMC Harvard Medical School

Background: Liver fibrosis is highly related to the mortality of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). Previous studies found mitochondrial dysfunction plays an important role in the development of liver fibrosis from MASLD. We have recently demonstrated that release of mitochondria-derived damage-associated molecular patterns (mito-DAMPs) from injured hepatocytes directly activate hepatic stellate cells and promote fibrosis independent of inflammation. However, the specific genetic and molecular mechanisms underlying relevant mitochondrial dysfunction in fibrosis remains underexplored. This study aims to broadly investigate the genetic architecture of liver fibrosis and MASLD with a specific focus on genes involved in mitochondrial turnover (e.g. mitophagy and mitochondrial fusion) in relation to liver fibrosis from MASLD. **Methods:** We integrated genome-wide association study (GWAS) summary statistics datasets focused on liver fibrosis/MASLD-related traits, exhaustively sourced from the UK Biobank (UKBB), FinnGen, GWAS Catalog, and extensive literature review. Genetic correlation analysis among these datasets was performed using linkage disequilibrium score regression (LDSC). We then employed Multi-Trait Analysis of GWAS (MTAG) on genetically aligned/integrated datasets to identify strong genome-wide association signals pertinent to fibrosis/MASLD. Validation of MTAG results was conducted through comparisons with a comprehensive meta-analysis of MASLD GWASs. We mapped genes and pathways related to mitophagy and mitochondrial fusion using MitoCarta3.0 and extensive literature review, and their associations with fibrosis/MASLD were analyzed using Multi-marker Analysis of GenoMic Annotation (MAGMA) within our MTAG GWAS framework. **Results:** Among 12 identified GWAS datasets relevant to liver fibrosis and MASLD, six of these correlated GWAS datasets, covering 6,944,270 individuals, were successfully integrated in the downstream MTAG analyses. The results from the MTAG GWAS were highly concordant with known gene loci identified previously in the meta-analysis of GWASs for MASLD ($P < 0.05$, $R^2 = 0.94$). Among 22 genes related to mitochondrial mitophagy and fusion (*BCL2L13, FKBP8, FUNDC1, NIPSNAP1, PARK7, PARL, PGAM5, PINK1, TOMM7, USP30, VPS13D, CALCOCO2, PARK2, NIPSNAP1, ARL2, MFN1, MFN2, MTCH2, OMA1, OPA1, PHB2, PLD6*), a single gene Optic Atrophy 1 (*OPA1*), with a known function in mitochondrial fusion and cristae shaping but not previously implicated in MASLD, was strongly associated with all fibrosis/MASLD MTAG GWASs ($P < 0.00208$). **Conclusion:** We identified for the first time a significant association of a mitochondrial fusion gene *OPA1* with liver fibrosis and MASLD. Further investigations are warranted to elucidate the precise biological role of *OPA1* and its variants in relation to MASLD progression and associated fibrosis.

0154 | DIAGNOSTIC AND CLINICAL IMPLICATIONS OF HIGH SPLEEN-TO-LIVER STIFFNESS RATIO IN MASLD – A PROSPECTIVE, COMPARATIVE STUDY

Christian Sebesta[1] Mathias Jachs[1] Lukas Hartl[1] Michael Schwarz[1] Lorenz Balcar[1] Benedikt Hofer[1] Nina Dominik[1] Georg Kramer[1] Bernhard Scheiner[1] Albert Friedrich Stattermayer[1] Benedikt Simbrunner[1] Till Schöchtner[1] Nicolas Balutsch[1] Paul Thoene[1] Friedrich Haimberger[1] Michael Trauner[1] Mattias Mandorfer[1] Thomas Reiberger[1] David Bauer[1], [1]Medical University of Vienna

Background: Liver stiffness measurement (LSM) and spleen stiffness measurement (SSM) are established surrogate parameters for portal hypertension (PH), exhibiting strong correlation with the hepatic venous pressure gradient (HVPG). However, SSM may overcome the limitations of HVPG and LSM lacking capability of capturing presinusoidal PH. We investigated the SSM/LSM ratio and its association with HVPG, as well as splenomegaly as a PH marker across different chronic liver disease etiologies. **Methods:** In this prospective study 399 patients with compensated liver disease undergoing HVPG measurements and 2D-SWE-based LSM and SSM were enrolled. A dataset containing demographic, biochemical, and imaging-based parameters was used for correlative and multivariate analyses. **Results:** Patients with alcohol-associated liver disease (ALD; n = 200) exhibited higher LSM (median: 45.5 kPa) and HVPG (median: 15.0 mmHg) than patients with metabolic dysfunction-associated steatotic liver disease (MASLD; n = 49; LSM: 20.9 kPa; HVPG: 12.0 mmHg). Conversely, SSM did not differ significantly between the cohorts (ALD: 58.8 kPa vs. MASLD: 52.8 kPa; p = 0.868). This resulted in a higher SSM/LSM ratio in MASLD (1.66) compared to ALD (1.28). Highest SSM/LSM values were observed in patients with porto-sinusoidal vascular liver disease (PSVD; 3.19). Importantly, upon adjustment for HVPG, MASLD retained significantly larger spleen diameters. Mathematical modeling revealed consistently higher SSM in MASLD than in ALD at any given HVPG. **Conclusion:** The SSM/LSM ratio shows significant etiological differences. The SSM/LSM ratio remained higher in MASLD than in ALD after adjustment for PH severity and – together with larger spleen size - supports the hypothesis of a presinusoidal PH component in MASLD.

0155 | DISTINGUISHING MASLD AND METALD/ALD USING PHOSPHATIDYLETHANOL AND NON-INVASIVE TESTS: A MULTICENTER COHORT ANALYSIS

Mazen Noureddin[1] Jörn Schattenberg[2] Rashmee Patil[3] Elizabeth Brombosz[4] Gražina Binkauskiene[4] Michelle Mazuranic[4] ALMA LAURA LADRON DE GUEVARA[5] Marcelo Kugelmas[6] Aasim Sheikh[7] John Poulos[8] Naim Alkhouri[4] Brian Lee[9] Juan Pablo Arab[10], [1]Houston Methodist Hospital, [2]Saarland University Medical Center, University of the Saarland, Homburg, Germany, [3]Pinnacle Clinical Research, [4]Summit Clinical Research, [5]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [6]South Denver Gastroenterology, [7]Gastrointestinal Specialists of Georgia, [8]Coastal Research Institute, [9]Keck School of Medicine, [10]Virginia Commonwealth University

Background: Accurately quantifying ethanol consumption is of utmost importance for MASLD and MetALD clinical trials. Due to the potential for underreporting in alcohol use surveys, phosphatidylethanol (PEth) is increasingly utilized in clinical trials to rule in MASLD or rule out MetALD or ALD. Therefore, it is important to understand the prevalence of exclusionary PEth levels to estimate potential enrollment for these trials. The aims of the study are to examine whether PEth can accurately identify patients with more MASLD-like or MetALD/ALD-like liver disease in the clinical trial setting and to assess the performance of non-invasive tests (NITs) in those with elevated PEth. **Methods:** A multicenter database of patients enrolled in clinical trials for MASLD pharmacologic therapies was reviewed, from which patients with PEth test results were identified. Patients were further stratified by PEth results indicating high alcohol intake ($\geq$20 ng/mL). NIT performance to detect F3/F4 fibrosis on biopsy was also quantified. Statistical analysis was performed using SAS software with $p < 0.05$ considered statistically significant. **Results:** Among 1811 patients with baseline PEth data, 202 (11%) had PEth $\geq$20 (86, 40-229; median, IQR) and 154 (9%) had PEth $\geq$40 (129, 68-318). Patients with PEth $\geq$20 were more likely to be male (69% vs 40%; $p < 0.001$) and non-diabetic (66% vs 48%; $p < 0.001$; Table 1). Fibrosis stage was similar among groups ($p = 0.20$). Having PEth $\geq$20 was associated with higher AST, ALT, GGT, and FIB-4, and lower HbA1c and LSM (all $p < 0.05$). LSM had higher performance in identifying F3/F4 fibrosis in patients with PEth $\geq$20 (AUC, 95% CI; 0.76, 0.66-0.87) vs $<$20 (0.66, 0.62-0.70). Conversely, FIB-4 ($\geq$20: 0.68, 0.56-0.80; $<$20: 0.70, 0.66-0.74) and AST/ALT ratio ($\geq$20: 0.56, 0.44-0.69; $<$20: 0.61, 0.57-0.66) had superior performance in patients with PEth $<$20. **Conclusion:** In this prospective multicenter cohort of participants enrolled in MASLD clinical trials, 11% had PEth $\geq$20, indicating possible misclassification by MetALD/ALD. In this cohort, PEth $\geq$20 ng/mL identified clinical characteristics associated with excessive alcohol consumption (elevated GGT, AST, and FIB-4), suggesting an appropriate cutoff to distinguish MASLD-like vs. MetALD/ALD-like phenotypes, which lends support to utilizing this cutoff in clinical trial inclusion/exclusion criteria. LSM may be superior to FIB-4 or AST/ALT for determining the presence of F3/F4 fibrosis in the MetALD/ALD population. Our findings highlight the value of PEth and LSM to improve clinical trial design across the spectrum of steatotic liver disease.

0156 | SCREENING PATHWAYS USING NON-INVASIVE TESTS OF LIVER FIBROSIS IN STEATOTIC LIVER DISEASES: IS IT TIME TO UPDATE THE GUIDELINES?

Jérôme Boursier[1] Jeanne Fichez[2] Odile Blanchet[2] Isabelle Fouchard[2] Adrien Iannes[2] Marine Roux[1] frederic oberti[2], [1]Angers University, [2]Angers University Hospital

Background: Vibration-Controlled Transient Elastography (VCTE) is a reference for the non-invasive evaluation of liver fibrosis. Due to the high prevalence of liver risk factors but low prevalence of advanced liver fibrosis, patients must be accurately selected before referral for VCTE. SAFE, MAF-5, eLIFT, and Liver Risk Score (LRS) are new simple blood fibrosis tests recently developed to identify at-risk patients. We aimed to evaluate screening pathways using these new tests. **Methods:** We included all consecutive patients with suspected steatotic liver disease who were referred for a non-invasive evaluation at the Liver Screening Center of a tertiary care center between 09/2019 and 12/2024. Patients underwent complete phenotyping, including VCTE and blood sampling. Five simple blood fibrosis tests were calculated: FIB4 (published thresholds $<1.30/>2.67$), SAFE ($<0/>100$), MAF-5 ($<0/\geq 1$), eLIFT (≥ 8), and LRS ($<8/>12$); as well as two specialized blood tests: ELF (≥ 9.5) and FibroMeter^{V2G} (FM; ≥ 0.45). Ten sequential algorithms (first-line simple blood test, then second-line specialized blood test if first-line result in the grey zone) were thus evaluated. The following objectives were considered for a screening pathway: 1/ at least two-thirds of VCTE ≥ 8 kPa detected (sensitivity, Se $\geq 67\%$), 2/ more than half of patients with VCTE ≥ 8 kPa among those referred (positive predictive value, PPV $\geq 50\%$), 3/ at least 80% Se for VCTE ≥ 12 kPa, and 4/ according to objectives #1 and #2 (Se 67% and PPV 50%), an expected rate of referral at 44% in our population. **Results:** 1,457 patients were referred to the Liver Screening Center (MASLD: n = 1,183; MetALD/ALD: n = 274), of whom 481 (33%) had VCTE ≥ 8 kPa. AUROCs for VCTE ≥ 8 kPa were: FIB4: 0.718 ± 0.04, SAFE: 0.782 ± 0.013, MAF-5: 0.749 ± 0.014, eLIFT: 0.767 ± 0.013, LRS: 0.771 ± 0.013, ELF: 0.746 ± 0.014, FM: 0.779 ± 0.013. Used with the published thresholds, the recommended sequential FIB4-ELF algorithm reached the objectives: 64% Se and 57% PPV for VCTE ≥ 8 kPa, 77% Se for VCTE ≥ 12 kPa, 37% referral, 39% second-line test. Similar results were obtained with the FIB4-FM algorithm. The algorithms using SAFE or MAF-5 provided excellent sensitivity (84-88%) but high referral rate (56-69%). Conversely, the algorithms using LRS had low referral rate (22%) but poor sensitivity (48%). The thresholds of the five simple blood tests were refined to target VCTE ≥ 8 kPa (80% sensitivity/95% specificity):

FIB4: $<1.20/>2.90$; SAFE: $<80/>220$, MAF-5: $<1.4/>5.1$, LRS: $<6.5/>10.6$, and eLIFT: $<7/>11$. With these thresholds, all the ten sequential algorithms evaluated showed similar accuracy and reached the objectives: 65-68% Se and 55-60% PPV for VCTE ≥ 8 kPa, 78-80% Se for VCTE ≥ 12 kPa, 36-39% referral rate, 39-47% second-line test. **Conclusion:** The recommended screening pathways for steatotic liver diseases should be updated and include the blood fibrosis tests recently developed for the case finding of at-risk patients. **Disclosures:** Jérôme Boursier: Novo Nordisk: Consultant, Lilly: Consultant, Madrigal: Advisor, Abbvie: Speaking and Teaching, Gilead: Speaking and Teaching, Sanofi: Speaking and Teaching, Echosens: Grant/Research Support, Gilead: Grant/Research Support, Intercept: Grant/Research Support, Inventiva: Grant/Research Support, Ipsen: Grant/Research Support, Siemens: Grant/Research Support, Diafir: Grant/Research Support, Jeanne Fichez: Nothing to Disclose, Odile Blanchet: Nothing to Disclose, Isabelle Fouchard: Nothing to Disclose, Adrien Iannes: Nothing to Disclose, Marine Roux: Nothing to Disclose, frederic oberti: Nothing to Disclose

0157 | UTILITY OF FIB-4, AGILE 4, AND PLATELET COUNT TO RULE OUT CIRRHOSIS ON BIOPSY IN PATIENTS WITH LSM BETWEEN 15-25 KPA: A MULTI-CENTER COHORT STUDY

Naim Alkhouri[1] Jörn Schattenberg[2] Rashmee Patil[3] Elizabeth Brombosz[1] Gražina Binkauskiene[1] Michelle Mazuranic[1] ALMA LAURA LADRON DE GUEVARA[4] Marcelo Kugelmas[5] Dimple Desai[6] Aasim Sheikh[7] John Poulos[8] Joseph Galati[9] Vlad Ratziu[10] Mazen Noureddin[11], [1]Summit Clinical Research, [2]Saarland University Medical Center, University of the Saarland, [3]Pinnacle Clinical Research, [4]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [5]South Denver Gastroenterology, [6]South Texas Research Institute, [7]Gastrointestinal Specialists of Georgia, [8]Coastal Research Institute, [9]Liver Specialists of Texas, [10]Service D' Hepatogastroenterologie (FR), [11]Houston Methodist Hospital

Background: Recent expert panel recommendations and AASLD guidance update recommended against the use of at-risk MASH pharmacologic treatment in patients with VCTE liver stiffness measurement (LSM) ≥ 20 kPa and consider treatment with caution in those with LSM 15-19.9 kPa due to the risk of having MASH cirrhosis. However, given known issues with the positive predictive value of LSM in MASH patients, it is of utmost importance for the field to be able to identify patients with LSM 15-25 kPa that have F2/F3 fibrosis and would possibly benefit from pharmacologic treatment. The aim of this study was to examine the performance of non-invasive tests (NITs) in identifying F2/F3 or F4 fibrosis in patients with LSM 15-25 kPa in a large multicenter database of patients with biopsy-proven MASH. **Methods:** An institutional database of patients screened for inclusion in MASH from multi-center pharmacotherapeutic trials with ≥ 2 metabolic risk factors was used for this analysis. Patients with LSM 15-20 kPa or LSM 20-25 kPa were identified for further analysis. Comparisons were made between those found to have F2/F3 on biopsy vs F4. NIT performance was compared to biopsy results. SAS software was used to perform statistical analyses with $p<0.05$ considered statistically significant. **Results:** Of 18402 patients reviewed, 4326 had baseline liver biopsy and LSM results, 882 of whom had LSM between 15 and 25. Among patients with LSM between 15-20 kPa ($n=586$, 66%; 354 F2/F3 and 232 F4) and 20-25 kPa (296, 34%; 141 F2/F3 and 155 F4), patients with F4 fibrosis were significantly older (both $p<0.001$), more likely to be White (both $p<0.001$), and had lower BMI (both $p<0.001$). In patients with LSM 15-20 kPa, model performance was highest using Agile 4 (AUC, 95% CI: 0.76, 0.69-0.83), followed by platelet count (0.71, 0.66-0.76) and FIB-4 (0.69, 0.64-0.75; Table 1). Among the LSM 20-25 kPa group, platelet count had superior performance (0.75, 0.69-0.82), followed by FIB-4 (0.73, 0.66-0.80), and Agile 4 (0.70, 0.60-0.79). Combining all tests resulted in an AUC of 0.76 (0.69-0.82) in the 15-20 kPa group and 0.75 (0.66-0.84) in the 20-25 kPa group. To reach $\geq 90\%$ sensitivity, for the Agile 4 score, a cutoff value of 0.104 was needed in the 15-20 kPa group and 0.099 in the 20-25 kPa group. **Conclusion:** This study highlights the interaction between NIT performance and liver stiffness in a large, multicenter cohort, where combined scores outperformed single NITs.

Table 1. Performance of non-invasive tests to detect MASH fibrosis (F2/F3) or cirrhosis (F4).

	AUC (95% CI)	Sensitivity	Specificity	PPV	NPV	Accuracy
LSM 15-20 kPa						
Agile 4[a]	0.76 (0.69-0.83)	90%	46%	34%	94%	56%
FIB-4[b]	0.69 (0.64-0.75)	91%	37%	38%	90%	53%
Platelets[c]	0.71 (0.66-0.76)	90%	34%	38%	88%	51%
Combined[d]	0.76 (0.69-0.82)					
LSM 20-25 kPa						
Agile 4[e]	0.70 (0.60-0.79)	89%	22%	42%	76%	48%
FIB-4[f]	0.73 (0.66-0.80)	91%	37%	53%	84%	60%
Platelets[g]	0.75 (0.69-0.82)	93%	28%	53%	82%	58%
Combined[h]	0.75 (0.66-0.84)					

[a]Using cutoff of 0.104
[b]Using cutoff of 1.15
[c]Using a cutoff of 266,000 platelets/µl
[d]Combined Agile 4, FIB-4, and platelets
[e]Using cutoff of 0.099
[f]Using cutoff of 1.20

0158 | DEVELOPMENT, VALIDATION, AND PROGNOSTIC EVALUATION OF LIVERHEALTH SCORE FOR THE PREDICTION OF LIVER FIBROSIS AND LIVER-RELATED EVENTS IN THE GENERAL POPULATION: A PROSPECTIVE, MULTICOHORT STUDY

Shanghao Liu[1] Bicheng Ye[1] Hui Shi[2] Xibin Liu[3] Zhenyu Dai[4] Yijun Tang[5] Puqiang Liu[6] Xiao Liang[7] Huizhen Fan[8] Qing He[9] Yilin Zhang[1] Yong Pan[10] JianSong Ji[11] Manguo Zhao[12] Hui Yang[13] Yang Bo[14] Shuli Hao[15] Tongqin Han[16] Yongyi Zeng[17] Guo Zhang[18] Qiang Yan[19] Rong Hu[2] Haiying Feng[3] Pinglei Pan[4] Zhongji Meng[5] Jianping Zhang[6] Yongfen Zhu[20] Jianwen Sheng[8] Fengjuan Chen[9] Ruyu Liu[10] Yanru Xie[11] Lingxiao Wang[12] Junhong Yang[12] Yan Yang[12] Yajuan Zhao[13] Jing Wang[14] Youfang Gao[15] Yuxia Qi[16] Wenjuan Wang[18] Zhaowei Tong[19] Gao-Jun Teng[1] Xiaolong Qi[1], [1]Zhongda Hospital, Medical School, Southeast University, [2]The First People's Hospital of Lian yungang, [3]Huanghua People's Hospital, [4]Affiliated Yancheng Hospital, School of Medicine, Southeast University, [5]Taihe Hospital, Hubei University of Medicine, [6]Puxian People's Hospital, [7]Sir Run-Run Shaw Hospital, Zhejiang University, [8]Yichun People's Hospital, [9]Shenzhen third People's Hospital, [10]Beijing Ditan Hospital, Xuzhou Hospital, Capital Medical University, [11]Lishui Central Hospital, The Fifth Affiliated Hospital of Wenzhou Medical University, [12]Baiyin Central Hospital, [13]The Second Affiliated Hospital of Guangzhou Medical University, [14]General Hospital of Ningxia Medical University, [15]Bozhou People's Hospital, [16]Qingdao Public Health Clinical Center, [17]Mengchao Hepatobiliary Hospital of Fujian Medical University, [18]Guangxi Hospital Division of The First Affiliated Hospital, Sun Yat-sen University, [19]Huzhou Central Hospital, [20]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine

Background: Non-invasive tools for identifying liver fibrosis in the general population remain limited in accuracy and generalizability. This study aimed to develop and validate a novel score to predict liver fibrosis and liver-related events in the general population. **Methods:** The LiverHealth project is a large, ongoing, prospective, community-based cohort study conducted in China among individuals aged 18 years and older, in which all participants underwent liver stiffness measurement (LSM) using transient elastography (Fibroscan). Participants from the first two sites (Haizhou District and Yandu District), enrolled between September and November 2024, were included in the derivation cohort (n = 4050). Participants from subsequent sites (Maojian District, Huanghua City, Yiyang New District, and Qiantang District), enrolled between December 2024 and April 2025, formed the first external validation cohort 1 (n = 5042). The second external validation cohort (n = 6301) comprised individuals from the NHANES 2017–2020. The UK Biobank population (n = 355949) was used as the prognosis cohort, among whom 8585 individuals underwent a second assessment between 2012 and 2013 (median interval: 4.5 years), forming the dynamic cohort. Diagnostic accuracy was assessed using the AUC and compared with 12 established non-invasive scores across different liver stiffness measurement (LSM) thresholds ($\geq$6, $\geq$8, $\geq$10, $\geq$12, and $\geq$15 kPa) and at-risk MASH (FAST score > 0.35). **Results:** The LiverHealth score incorporated waist circumference, aspartate aminotransferase, gamma-glutamyltransferase, platelet count, and glycated hemoglobin. LiverHealth score showed superior performance in predicting LSM $\geq$8 kPa in the derivation cohort (AUC = 0.82 [0.79-0.85]), validation cohort 1 (AUC = 0.80 [0.76-0.83]), and validation cohort 2 (AUC = 0.82 [0.80-0.84]), outperforming existing 12 scores. LiverHealth score consistently outperformed or equaled other scores in predicting LSM $\geq$6, $\geq$10, $\geq$12, and $\geq$15 kPa and at-risk MASH across all cohorts (Figure 1A-1C). Furthermore, participants were stratified into low-, medium-, and high-risk groups using cutoffs of 2.517 and 2.830, achieving > 80% sensitivity and > 90% specificity in all cohorts. Compared with low-risk group, the medium- and high-risk groups had significantly higher incidence of liver-related events (LREs, Figure 1D). The hazard ratio in the high-risk group was 18.05 for liver-related death, 23.86 for cirrhosis, and 8.92 for liver cancer, compared with low-risk group. Furthermore, in the dynamic cohort, 60.8% of individuals remained in the high-risk group. Compared to those who consistently stayed in the low-risk group, participants who progressed to a higher risk group exhibited a significantly increased incidence of LREs (Figure 1F-1D). **Conclusion:** The LiverHealth score, based on simple parameters, accurately predicted liver fibrosis and liver-related events in the general population.

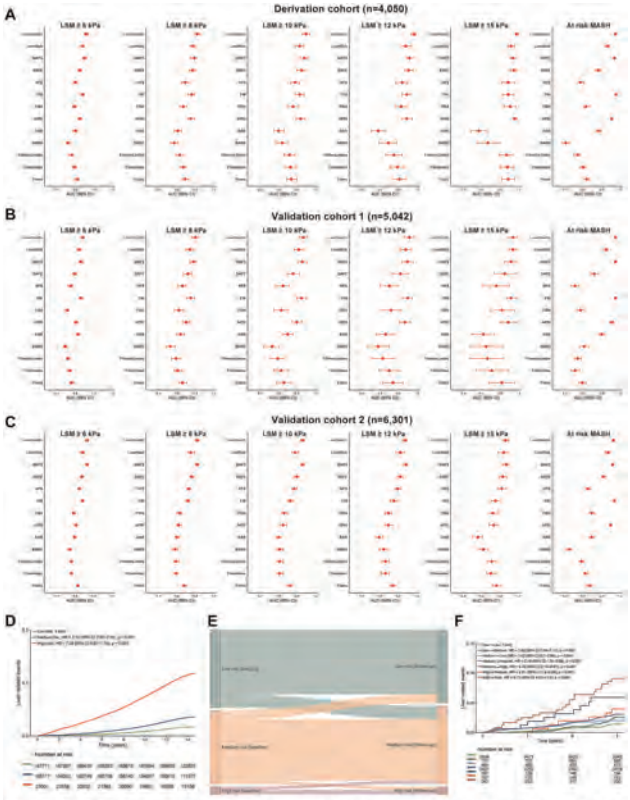

Figure 1. Discriminatory accuracy of different scores in the prediction of the degree of liver stiffness in the derivation cohort (A), validation cohort 1 (B), and validation cohort 2 (C); Cumulative incidence of liver-related events by LiverHealth score groups (D); Longitudinal changes in LiverHealth score risk groups from baseline (2006-2010) to follow-up (2012-2013) in the dynamic cohort (E); Cumulative incidence of liver-related events according to longitudinal LiverHealth score risk groups in the dynamic cohort (F).

The presence of liver fibrosis was defined as liver stiffness measurement (LSM) ≥ 6 kPa. Clinically significant liver fibrosis was defined as LSM ≥ 8 kPa. Suggestive Compensated advanced chronic liver disease (cACLD) was defined as LSM ≥ 10 kPa, advanced fibrosis as LSM ≥ 12 kPa, highly suggestive cACLD as LSM ≥ 15 kPa, and at-risk MASH (FibroScan AST [FAST] score >0.35)

★ 0159 | A RANDOMIZED CONTROLLED TRIAL IN SILICO FOR RISK STRATIFICATION IN POPULATION SCREENING FOR FIBROTIC MASH

Joseph Ahn[1] Mingzhao Hu[1] Yung-Kyun Noh[2] Alina Allen[3] W. Ray Kim[4], [1]Mayo Clinic, [2]Hanyang University, [3]Mayo Clinic Rochester, [4]Mayo Clinic Arizona

Background: Coordinated efforts needed to mitigate the accelerating epidemic of MASLD include early diagnosis of fibrotic MASH and linkage to care for effective interventions. For detection of fibrotic MASH, there is consensus for a two-step process, starting with a risk stratification score followed by liver stiffness measurement (LSM). The Steatosis-Associated Fibrosis Estimator (SAFE) score was developed for this purpose, improving upon the FIB-4 score by incorporating metabolic variables known to correlate with MASH fibrosis. In this work, we applied a novel digital twin-based trial emulation framework using synthetic data and compare the outcome of stratification using SAFE versus FIB4 in MASH screening in the community. **Methods:** We trained tabular diffusion models on a US population-based data set (NHANES 2017-2020, N = 5,076) for synthetic data generation. Synthetic data fidelity was assessed using Wasserstein distance and multivariate correlation (R^2) to verify preservation of critical multivariate relationships. The sample size of 50,000 subjects, randomly assigned 1:1 to SAFE or FIB-4 arms, based on power considerations from prior NHANES analysis. Subjects 40 years or older with cardiometabolic risk factors and a high stratification score (SAFE $\geq$ 100 or FIB4 $\geq$ 1.3) underwent LSM by transient elastography (VCTE). The primary outcome was the proportion of subjects detected with fibrotic MASH (defined as LSM 8-12 kPa and CAP $\geq$ 274 dB/m or LSM $\geq$ 12 kPa regardless of CAP). Secondary end points included the number of VCTEs performed, the diagnostic yield of VCTE and the number needed to screen to detect a case of fibrotic MASH. **Results:** The synthetic data achieved satisfactory fidelity with mean Wasserstein distance 0.003 and $R^2 = 0.998$. Table 1 compares the two arms. For the primary end point in the simulated trial, SAFE detected more fibrotic MASH than FIB4 (6.0% vs 5.4%). It did so with a higher efficiency - requiring 42% fewer VCTEs (22.4% vs 38.8%) and yielding a 90% higher diagnostic rate, among those undergoing VCTE, with SAFE (26.7% vs 14.0%). SAFE required only 3.8 VCTEs per case detected compared to 7.1 for FIB4, representing 47% fewer procedures per diagnosis. Among subjects with diabetes, SAFE demonstrated an even larger difference (detection rate 16.8% vs 10.9%). **Conclusion:** This in silico analysis suggests that SAFE may outperform FIB-4

in detecting fibrotic MASHwhile reducing resource deployment and potential harms of unnecessary diagnostic testing. This work utilizing diffusion-generated synthetic data and digital twin methodology provides a framework for informing trial designs and testing multiple scenarios, potentially accelerating the development of evidence-based screening programs.

Characteristic	Original Data	Synthetic FIB-4 Arm	Synthetic SAFE Arm
Total participants, n	5,076	25,000	25,000

0160 | ONE-YEAR CHANGES IN ALT AND LSM, BUT NOT IN CAP, PREDICT LONG-TERM LIVER OUTCOMES IN PATIENTS WITH MASLD

Grazia Pennisi[1] Giuseppe Infantino[2] Gabriele Di Maria[2] Emmanuel Tsochatzis[3] Elisabetta Bugianesi[4] Masado Yoneda[5] Ming-Hua Zheng[6] Hannes Hagström[7] Jerome Boursier[8] Jose Luis Calleja[9] Boon Bee George Goh[10] Wah-Kheong Chan[11] Rocio Gallego-Durán[9] Arun Sanyal[12] Victor de Ledinghen[13] Philip N Newsome[14] Jian-Gao Fan[15] Laurent Castéra[16] Michelle Lai[17] Celine Fournier[13] Grace Lai-Hung Wong[18] Angelo Armandi[4] Atsushi Nakajima[5] Wen Liu[19] Ying Shang[7] Marc De Saint Loup[20] Elba Llop[9] Kevin Kim Jun Teh[21] Carmen Lara Romero[22] Amon Asgharpour[23] Sara Mahgoub[24] Mandy Chan[13] Manuel Romero-Gómez[25] Huapeng LIN[26] Seung Up Kim[27] Terry Cheuk-Fung Yip[28] Adele Tulone[2] Jimmy Che-To Lai[28] Boyu Yang[28] Hye Won Lie[29] Abraham Aregay Desta[30] Giacinta Ciancimino[2] Marco Enea[2] Calogero Camma[2] Vincent Wong[28] Salvatore Petta[2], [1]Section of Gastroenterology and Hepatology, Dipartimento Di, [2]University of Palermo, [3]University of London, [4]University of Turin, [5]Yokohama City University Graduate School of Medicine, [6]University of Wenzhou, [7]University of Stockholm, [8]Angers University, [9]University of Madrid, [10]University of Singapore, [11]University of Malaya, [12]University of Richmond, [13]Echosens, [14]University of Birmingam, [15]University of Shanghai, [16]Service d'Hépatologie, Hôpital Beaujon, [17]Beth Israel Deaconess Medical Center, [18]University of Hong Kong, [19]Wenzhou Medical University, [20]Angers University Hospital, [21]Singapore General Hospital, [22]University of Sevilla, [23]VCU School of Medicine, Richmond, [24]University of Birmingham, [25]University od Sevilla, [26]Shanghai Jiaotong University School of Medicine, [27]Yonsei University College of Medicine, Seoul, [28]The Chinese University of Hong Kong, [29]Yonsei University College of Medicine, [30]University of Florence

Background: The availability of new drugs for the treatment of patients with metabolic dysfunction-associated steatotic liver disease (MASLD) underlines the need of early predictors of response to such therapies. This study evaluated the impact of 1-year changes in liver stiffness measurement by Vibration-Controlled Transient Elastography (LSM by VCTE), controlled attenuation parameters (CAP), and serum alanine aminotransferase (ALT) on liver outcomes in patients with MASLD. **Methods:** A large multicenter cohort of MASLD patients with LSM ≥ 8kPa and prospective follow-up was enrolled. Liver-related events (LRE), including hepatocellular carcinoma (HCC) and liver decompensation (LD), were evaluated during follow-up. LSM, CAP, and ALT were assessed at baseline and at 1-year follow-up. Cumulative incidence functions and cause-specific Cox regression analyses were performed to correlate 1-year reduction in LSM, CAP, and ALT with the risk of developing LRE, LD and HCC. **Results:** In 2443 patients with MASLD and LSM ≥ 8 kPa, a 1-year reduction in ALT of 17 IU/L (HR 0.62; 95% CI 0.41-0.95; p = 0.02) and a 20% reduction in LSM (HR 0.44; 95% CI 0.29-0.67; p < 0.001) were both

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

independently associated with a lower risk of LRE (Figure 1). Similarly, in 1412 patients with MASLD and LSM ≥ 10kPa, a 1-year reduction in ALT of at least 17 IU/L (HR 0.62; 95% CI 0.39-0.98; p = 0.04) and a 20% reduction in LSM (HR 0.42; 95% CI 0.27-0.66; p < 0.001) were independently associated with a decreased risk of LRE (Figure 2). Comparable results were observed when considering LD separately, but not for HCC. One-year changes in CAP did not predict liver outcomes. When combining 1-year reduction in ALT of 17 IU/L and a 1-year 20% reduction in LSM, the 5-year probabilities of LRE ranged from 2.1% in the best profile to 5% in the worst profile in patients with LSM ≥ 8kPa (Figure 3), and from 3.3% to 8.1% in those with LSM ≥ 10kPa (Figure 4). **Conclusion:** One-year reductions in ALT of 17 IU/L and in LSM by 20%, but not changes in CAP, reduce long-term liver outcomes in patients with MASLD, providing suggestion on monitoring therapy effectiveness.

0161 | PERFORMANCE OF EXPERT PANEL CRITERIA IN PREDICTING AT-RISK AND NOT-AT-RISK MASH: DATA FROM A LARGE MULTI-CENTER COHORT

Rashmee Patil[1] Jörn Schattenberg[2] Elizabeth Brombosz[3] Gražina Binkauskiene[3] Michelle Mazuranic[3] ALMA LAURA LADRON DE GUEVARA[4] Marcelo Kugelmas[5] Dimple Desai[6] Aasim Sheikh[7] John Poulos[8] Edward Mena[9] Mazen Noureddin[10] Naim Alkhouri[3], [1]Pinnacle Clinical Research, [2]Saarland University Medical Center, University of the Saarland, [3]Summit Clinical Research, [4]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [5]South Denver Gastroenterology, [6]South Texas Research Institute, [7]Gastrointestinal Specialists of Georgia, [8]Coastal Research Institute, [9]California Liver Reasearch Instituite, [10]Houston Methodist Hospital

Background: As the incidence of MASLD and MASH rises, it is increasingly important to identify patients who are at risk of liver-related morbidity from those who are not using non-invasive tests (NITs). Consequently, a 2024 expert panel summary (PMID 39038768) and an AASLD practice guidance update recommended algorithms of NITs to identify patients with at-risk MASH who might benefit from pharmacologic treatment based on liver enzymes, VCTE CAP for steatosis, and LSM for fibrosis. The purpose of this study is to investigate the efficacy of these algorithms in identifying patients with at-risk vs not-at-risk MASH. **Methods:** A large database of patients evaluated for inclusion in MASH pharmacotherapeutic trials with biopsy results available was reviewed. Patients were stratified into at-risk vs not-at-risk MASH based on biopsy results (NAS ≥ 4 and F2 or F3 fibrosis), and biopsy findings were used to determine performance of the most utilized NITs. Statistical analysis and NIT performance assessment were done with SAS software with $p < 0.05$ considered statistically significant. **Results:** Of 2647 patients identified, 1408 (53%) had at-risk MASH. Demographically, patients with at-risk MASH were more likely to be female ($p = 0.001$), non-White ($p < 0.001$), and Hispanic ($p < 0.001$). The performance of single NITs in identifying at-risk MASH ranged between sensitivity of 14-97% and specificity of 7-89% (Table 1). When multiple NITs were utilized, as recommended by expert guidelines, sensitivity was highest for CAP >280 dB/m, LSM 8-15 kPa, and AST >17 IU/L in females or >20 in males (60%). In combined models, specificity was highest for CAP, LSM 15.1-20 kPa, and AST >17 IU/L females/ >20 males (93%). Combined CAP, LSM 10-15 kPa, and high AST (>30 IU/L) yielded the highest AUC of all models considered (0.61), as well as the highest % correctly classified as at-risk (60%). The proportion of patients correctly identified as having at-risk MASH was highest (55%) using CAP alone, followed by AST alone (53%). **Conclusion:** These results suggest that the algorithms recommended by the experts can adequately identify high-risk patients via non-invasive tests, but that additional confirmatory tests (e.g., MRI-PDFF, MRE, or combination scores such as MAST) might be needed to definitively distinguish patients who will benefit from pharmacologic therapy for at-risk MASH.

Table 1. Performance of non-invasive tests in predicting at-risk MASH (F2/F3).

Test	Sensitivity	Specificity	PPV	NPV
AST[a]	97.1%	7.0%	54.3%	68.0%
LSM				
10-15 kPa	42.9%	71.0%	62.7%	52.3%
15.1-20 kPa	14.4%	88.5%	58.8%	47.7%
CAP[b]	93.8%	22.9%	57.8%	74.2%
CAP[b] + LSM 8-15 kPa + AST[a]	60.3%	57.4%	61.7%	56.0%
CAP[b] + LSM 10-15 kPa + AST[a]	38.9%	78.7%	67.5%	53.1%
CAP[b] + LSM 15.1-20 kPa + AST[a]	13.1%	93.0%	68.0%	48.5%
CAP[b] + LSM 10-15 kPa + AST >30	31.4%	90.8%	79.5%	53.8%

[a] AST: >17 IU/L if F; >20 IU/L if M
[b] CAP: >280 dB/m
AST, aspartate transferase; CAP, controlled attenuation parameter; CI, confidence interval; LSM, liver stiffness measurement; NPV; negative predictive value; PPV, positive predictive value

0162 | MISSED LIVER FIBROSIS RISK STRATIFICATION OPPORTUNITIES IN THE ALL OF US COHORT IN THE UNITED STATES

Kyle Sellers[1] Trenton White[2] Meena Bansal[3] Nicolai Brachowicz[2] Hannes Hagström[4] Paul Brennan[5] Luis Antonio Diaz[6] Pojsakorn Danpanichkul[7] Melina Manolas[8] Xiaotao Zhang[9] Jeffrey Lazarus[10], [1]City University of New York Graduate School of Public Health and Health Policy (CUNY SPH), New York, [2]Barcelona Institute for Global Health (ISGlobal), [3]Icahn School of Medicine at Mount Sinai (ISMMS), [4]Karolinska University Hospital, Karolinska Institute, [5]University of Dundee, School of Medicine, [6]University of California San Diego, [7]Texas Tech University Health Sciences Center, [8]Weill Cornell, [9]Icahn School of Medicine at Mount Sinai, [10]City University of New York Graduate School of Public Health & Health Policy (CUNY SPH)

Background: Liver fibrosis is a progressive pathological condition with substantial public health implications, associated with increased liver-related and cardiovascular mortality, as well as being a major contributor to global health and economic burdens. Non-invasive tests (NITs) for fibrosis assessment, such as the Fibrosis-4 (FIB-4) Index, offer inexpensive, scalable risk stratification, though adoption remains low, and sensitivity and specificity varies across age and comorbidity groups. The study aimed to examine variation in liver fibrosis risk and to assess the utilization of FIB-4 scoring in electronic health records (EHRs) in the United States. **Methods:** This study evaluated the prevalence of liver fibrosis in the "All of Us" database (N = 623,464) using FIB-4 scores derived from laboratory data. We analyzed 181,306 participants with complete FIB-4 inputs (AST, ALT, platelet count, age). In addition to computing FIB-4 scores using available data, we also identified participants with FIB-4 scores already recorded in their EHRs. Risk groups were: low (< 1.30), indeterminate (1.30–2.67, or 2.00–2.67 for adults 65+), and high risk (> 2.67). Liver fibrosis among three risk groups are also reported. **Results:** Of the 181,306 participants with complete analyte data, 2,082 (1.2%) had a previously calculated FIB-4 score in their EHR. After calculating FIB-4 scores in the remaining 179,224 participants, 72.99% were low risk, 18.56% indeterminate, and 8.43% high risk. Of the 15,286 participants classified as high risk, 269 (1.76%) had a previously calculated FIB-4 score in their EHR (see Figure). 14,574 (28.82%) of those with type 2 diabetes and 17,287 (22.96%) with BMI ≥ 30 kg/m2 had intermediate or high-risk scores. **Conclusion:** Despite the availability of routine liver biochemistry, liver fibrosis risk using the FIB–4 index was rarely assessed among the participants, even among those later determined in our calculations to be at high risk. Integrating automated FIB-4 calculation and structured reflex testing follow-up pathways into clinical workflows could address this gap and enable timely fibrosis assessment.

0163 | FACTORS ASSOCIATED WITH BALLOONING VS. NO BALLOONING IN PATIENTS WITH F2/F3 FIBROSIS: DATA FROM MULTICENTER MASH RANDOMIZED CLINICAL TRIALS

Mazen Noureddin[1] Jörn Schattenberg[2] Rashmee Patil[3] Elizabeth Brombosz[4] Gražina Binkauskiene[4] Michelle Mazuranic[4] ALMA LAURA LADRON DE GUEVARA[5] Marcelo Kugelmas[6] Rohit Puskoor[3] Aasim Sheikh[7] John Poulos[8] Vlad Ratziu[9] Naim Alkhouri[4], [1]Houston

Methodist Hospital, [2]Saarland University Medical Center, University of the Saarland, [3]Pinnacle Clinical Research, [4]Summit Clinical Research, [5]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [6]South Denver Gastroenterology, [7]Gastrointestinal Specialists of Georgia, [8]Coastal Research Institute, [9]Service D' Hepatogastroenterologie (FR)

Background: Phase 2 and 3 clinical trials for therapies targeting MASH fibrosis require hepatocyte ballooning to be present on biopsy. Screen failures due to the absence of ballooning, despite having significant fibrosis, are relatively common, which can reduce enrollment and inflate duration and costs. Identifying patients unlikely to qualify can reduce study burden from patients ultimately ineligible for enrollment and avoid biopsy-related risks in patients unlikely to have ballooning. We assessed characteristics and non-invasive biomarkers associated with F2/F3 fibrosis and absence of ballooning on biopsy to reduce screen failures in clinical trials. **Methods:** A multicenter database of patients screened for enrollment in MASH pharmacotherapeutic studies was investigated. Patients identified as having F2 or F3 fibrosis on biopsy were further stratified by the presence of hepatocyte ballooning on biopsy. Statistical analysis was performed using SAS software with $p < 0.05$ considered statistically significant. **Results:** Of the 2833 patients with F2/F3 fibrosis, 1103 (39%) were not eligible for inclusion in clinical trials because hepatocyte ballooning was not noted on biopsy. Patients with no ballooning were more likely to be male (54% vs 38%), White (74% vs 65%), and non-Hispanic/Latino (33% vs 37%; all $p < 0.001$). They were also less likely to have diabetes (31% vs 59%), AST > 30 IU/L (46% vs 23%), and HbA1c $\geq 6.5\%$ (28% vs 39%; all $p < 0.001$). LSM and CAP measurements and FAST and FIB-4 scores were significantly lower in patients without ballooning (all $p < 0.001$). MRI-PDFF was similar between groups (17 [12-22] vs 17 [13-23]%; $p = 0.09$). Among non-invasive tests (NITs) to identify patients with F2/F3 fibrosis and NAS ≥ 4 with ballooning (Table 1), combined AST ≥ 30 IU/L + CAP ≥ 280 dB/m and AST + CAP + LSM ≥ 8.5 kPa had the highest AUC (both 0.63). CAP alone had the highest sensitivity (93.5%), negative predictive value (58.3%), and % correctly classified (61.6%). Combining all 4 NITs resulted in the highest specificity (89.0%) and positive predictive value (92.9%). LSM alone, CAP alone, and combined CAP + LSM all exceeded 80% sensitivity. **Conclusion:** The results of this study suggest AST, HbA1c, LSM, and CAP may be helpful in pre-screening patients for formal screening in MASH clinical trials. Limiting screening efforts to patients with these risk factors may reduce the proportion of screen failures and ultimately improve efficiency in these studies.

Table 1. Performance of non-invasive tests for detecting patients with F2/F3 liver fibrosis and with a NAFLD activity score (NAS) ≥4 and hepatocyte ballooning on biopsy.

Test	AUC (95% CI)	Sensitivity	Specificity	PPV	NPV	Accuracy	% Correctly Classified
AST	0.62 (0.60–0.64)	76.8%	46.8%	69.1%	56.7%	65.1%	57.2%
LSM	0.54 (0.52–0.55)	87.6%	19.7%	64.3%	49.1%	62.0%	59.0%
CAP	0.54 (0.53–0.56)	93.5%	14.8%	64.3%	58.3%	63.7%	61.6%
HbA1c	0.59 (0.55–0.60)	43.8%	71.6%	81.2%	31.3%	51.1%	39.8%
AST + LSM	0.62 (0.60–0.65)	68.5%	56.5%	71.9%	52.5%	63.9%	54.0%
AST + CAP	0.63 (0.61–0.65)	71.7%	53.9%	71.5%	54.2%	64.9%	55.8%
AST + HbA1c	0.59 (0.57–0.61)	31.8%	86.5%	86.9%	31.1%	46.2%	30.4%
HbA1c + CAP	0.59 (0.56–0.63)	44.2%	74.5%	89.8%	21.0%	49.2%	42.1%
HbA1c + LSM	0.58 (0.55–0.62)	40.6%	76.1%	89.0%	21.1%	46.8%	38.7%
CAP + LSM	0.56 (0.54–0.58)	82.6%	29.6%	65.8%	51.0%	62.6%	57.8%
AST + CAP + LSM	0.63 (0.61–0.65)	64.4%	61.6%	73.0%	51.8%	63.3%	52.0%
AST + HbA1c + LSM	0.58 (0.56–0.61)	28.9%	88.0%	92.0%	20.6%	39.2%	28.2%
AST + HbA1c + CAP	0.59 (0.57–0.62)	31.2%	87.8%	92.8%	20.1%	40.5%	30.4%
HbA1c + CAP + LSM	0.59 (0.56–0.63)	40.3%	78.2%	90.3%	20.6%	46.5%	38.6%
AST + HbA1c + LSM + CAP	0.59 (0.56–0.62)	28.5%	89.0%	92.9%	19.7%	38.5%	27.9%

Cutoff values: AST ≥30 IU/L, LSM ≥8.5 kPa, CAP ≥280 dB/m, HbA1c ≥6.5%

Schnefeld[1] Katrine Thorhauge[1] Ida Villesen[1] Mette Andersen[1] Markus Maagaard[1] Peter Andersen[1] Katrine Lindvig[1] Camilla Hansen[1] Pere Ginés[2] Aleksander Krag[1] Maja Thiele[1] Mads Israelsen[1], [1]Centre for Liver Research, Odense University Hospital, [2]Liver Unit, Hospital Clinic of Barcelona, Barcelona, Spain

Background: AASLD and EASL recommend fibrosis screening in individuals with obesity due to its strong association with steatotic liver disease. As BMI does not directly reflect body composition or fat distribution, new clinical obesity criteria have been proposed by a Lancet Commission. We evaluated which metric best identified patients at risk for advanced fibrosis and the clinical consequences if applied as index criterion for fibrosis screening. **Methods:** We conducted a population-based fibrosis screening study evaluating obesity, defined by BMI ($\geq$30 kg/m²) and three alternative anthropometric indices: waist circumference ($\geq$102 cm for men, $\geq$88 cm for women), waist-to-hip ratio ($\geq$0.90 for men, $\geq$0.85 for women), and waist-to-height ratio ($\geq$0.50). Each was assessed as an index criterion for fibrosis screening, both alone and in combination with FIB-4 $<$1.3 as a rule-out step before liver stiffness measurement (LSM). LSM was assessed using vibration-controlled transient elastography (VCTE), with $\geq$8 kPa indicating risk of advanced fibrosis and confirmed using ELF $\geq$9.8. **Results:** We included 6,819 participants (mean age 57 years; 51% men), 7% had VCTE $\geq$8 kPa and 3% had both VCTE $\geq$8 kPa and ELF $\geq$9.8. Obesity was present in 36% as assessed by BMI, 58% by waist circumference, 70% by waist-to-hip ratio, and 78% by waist-to-height ratio. For discrimination of VCTE $\geq$8 kPa, AUCs were 0.70 (BMI), 0.76 (waist circumference), 0.74 (waist-to-hip ratio) and 0.73 (waist-to-height ratio). For the combined endpoint (VCTE $\geq$8 kPa and ELF $\geq$9.8), AUCs were 0.62 (BMI), 0.65 (waist circumference), 0.63 (waist-to-hip ratio), and 0.59 (waist-to-height ratio). Waist circumference demonstrated significantly better discriminatory ability than the other measures ($p<0.05$). Using obesity as index criterion for fibrosis screening (Figure), BMI resulted in the lowest proportion of individuals requiring further evaluation but missed 39% cases of VCTE $\geq$8 kPa. In comparison, waist circumference missed 17%; waist-to-hip ratio 10% cases, and waist-to-height ratio 6%. Finally, we applied FIB-4 $<$1.3 to rule out liver fibrosis, BMI + FIB-4 classified 10% of the cohort needing further evaluation but missed 70% cases with VCTE $\geq$8 kPa. Corresponding proportions were 18%/57% for waist circumference, 24%/52% for waist-to-hip ratio, and 26%/51% for waist-to-height ratio. **Conclusion:** Waist circumference outperforms BMI for identifying obesity-related fibrosis risk. BMI above 30 kg/m^2 is not suited for pre-test selection of patients at risk of fibrosis due to a substantial false-negative rate. Measures of waist circumference combined with FIB-4 improve the accuracy of reliably ruling out liver fibrosis.

Figure: Illustration of the consequences of using each of the four obesity measures as the index criterion for fibrosis screening in a population of 100 individuals of which 7 have TE ≥8 kPa

0165 | COMPARATIVE EFFECTIVENESS OF BARIATRIC SURGERY, GLP-1 RA, AND SGLT2I ON COMPOSITE LIVER EVENTS IN MASLD PATIENTS: A MULTICENTER RETROSPECTIVE COHORT STUDY

Diwanshu Soni[1] Leith Ghani[1] Majd Aboona[1] Pooja Rangan[1] Derek Scholes[1] Chih-Hua Chung[2] Mark Wong[2] Karn Wijarnpreecha[3] Rohit Nathan[1] Moises Ruben[1] Michael Fallon[1] Farah Husain[1] Ma Ai Thanda Han[4],
[1]University of Arizona College of Medicine - Phoenix, [2]University of Arizona College of Medicine - Phoenix, Phoenix, [3]University of Arizona College of Medicine-Phoenix, [4]University of Arizona College of Medicine Phoenix

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of chronic liver disease globally, can progress to ascites, hepatic encephalopathy, esophageal varices, hepatocellular carcinoma (HCC), and liver transplant. While bariatric surgery, GLP-1 receptor agonists (GLP-1 RA), and SGLT2 inhibitors (SGLT2i) have shown to reduce disease progression, no studies have compared their effectiveness. This study aims to compare how different interventions effect the incidence of composite liver events in MASLD patients. **Methods:** This multicenter retrospective cohort study at Banner Health evaluated the effect of specific interventions on MASLD patients, who were identified based on ICD codes and metabolic criteria. The cohort received bariatric surgery, GLP-1 RA, SGLT2i, or combination therapy and was followed for at least 12 months. Composite liver events included: LREs (ascites, hepatic encephalopathy, or esophageal varices), liver transplant and hepatocellular carcinoma (HCC) 12 months post intervention. Medication use was verified, and bariatric procedures were confirmed via ICD codes and were only included if performed by a bariatric surgeon. Competing risk analysis was performed to assess composite liver event incidence among treatment groups with bariatric surgery as the reference group while adjusting for confounding variables. A Kaplan-Meier survival curve was generated to illustrate composite liver event free survival. **Results:** The cohort included 14,589 patients: 4.6% underwent bariatric surgery, 45.4% received GLP-1 RA, 27.2% SGLT2i and 22.8% combination therapy. Univariate and multivariate analysis show that bariatric surgery treatment group had statistically significant lower rates of composite liver events —LREs, liver transplant, and hepatocellular carcinoma — 12 months post treatment compared to the GLP1-RA and SGLT2i treatment groups. However, multivariate analysis does not show statistically significant difference compared to the combination therapy treatment group (Table 1). Kaplan-Meier survival analysis demonstrated superior liver event free survival in the bariatric surgery group (Figure 1). **Conclusion:** Bariatric surgery is more effective than GLP1-RA and SGLT2i in lowering liver events in MASLD patients 12 months post intervention even when adjusting for confounding factors. Further studies can assess comparative intervention effects on MASLD patient subgroups with and without cirrhosis at the time of intervention. Furthermore, future prospective studies are necessary to validate these findings and comprehensively evaluate the long-term impact of these interventions on liver events in MASLD patients.

Table 1

Intervention	Composite Liver Events in MASLD Patients			
	HR (95% CI)	p-value	aHR (95% CI)	p-value
Bariatric Surgery	Reference			
Glucagon-Like Peptide-1 Agonist (GLP-1 RA)	2.44 (1.60 – 3.72)	0.000	1.61 (1.04 – 2.48)	0.032
Sodium-Glucose Cotransporter 2 Inhibitor (SGLT2i)	2.53 (1.64 – 3.91)	0.000	1.67 (1.05 – 2.65)	0.031
Combination Therapy	1.89 (1.24 – 2.88)	0.003	1.34 (0.86 – 2.07)	0.198

HR: Hazard Ratio
aHR: Adjusted Hazard Ratio for tobacco use, age, BMI, sex, race, HTN, HLD, DM
CI: Confidence Interval

0166 | GLP-1 RECEPTOR AGONISTS ARE SUPERIOR TO BARIATRIC SURGERY FOR PREVENTION OF ALL CAUSE MORTALITY AND MAJOR ADVERSE LIVER OUTCOMES IN TYPE 2 DIABETES MELLITUS AND OBESITY IN REAL WORLD CLINICAL PRACTICE

Ana Oliveira[1] Kavin Parmar[1] Vinay Jahagirdar[1] Arun Sanyal[1], [1]Virginia Commonwealth University

Background: Bariatric surgery (Ba) and GLP1 receptor agonists (GLP1 RA) improve multiple outcomes in type 2 diabetes mellitus (T2DM) and obesity, the key risk factors for metabolic dysfunction associated steatotic liver disease (MASLD). The real-world comparative effectiveness of GLP-1 RA vs Ba for major adverse liver- (MALO) and cardio-renal-metabolic (CRM)-outcomes in these populations are unknown. Aims: (1) To define the effectiveness of GLP-1 RA (inclusive of the GLP-1/GIP dual agonist Tirzepatide) vs Ba alone for MALO and CRM, (2) to compare the effectiveness of GLP-1 RA vs Ba on these outcomes. **Methods:** A retrospective analysis of hospitalized patients was performed using the TriNetX global collaborative network. Those with obesity+T2DM who received either GLP-1 RA or Ba with follow up to 4 years were included and compared to controls matched for age, race/ethnicity, sex, BMI, smoking status, use of statins and outcome-specific confounders. For MALO, groups were matched for AST, ALT, platelets and bilirubin in addition to the above-noted parameters. Similar matching was done for the comparison of GLP-1 RA vs Ba. Exclusion criteria included those who did not get a GLP-1 RA for 4 years or having the outcome prior to the start date. Odds ratio (O.R.) with 95% CI are reported. **Results:** A total of 16.7M individuals with obesity and T2DM were identified; of these 74361 received a GLP-1 RA and 11255 received Ba. Effectiveness of GLP-1 RA vs controls: In T2DM +obesity, the impact of GLP-1 RA (vs controls) was (O.R. 95% CI): Mortality (0.22, 0.2-0.24), MALO (0.45, 0.4-0.5), MACE (0.49, 0.46-0.52), obesity-related cancer (0.58, 0.51-0.65), chronic kidney disease (CKD) (0.7, 0.65-0.74). Effectiveness of Ba vs controls: The Odds ratio for outcomes were: Mortality (0.31, 0.26-0.38), MALO (0.99, 0.8-1.2), MACE (0.48, 0.41-0.56), obesity-related cancer (0.67, 0.5-0.9), CKD (0.37, 0.3-0.44). Comparative effectiveness of GLP-1 RA vs Ba: The distribution of BMI at the end of follow up period was left-shifted in Ba vs GLP-1 RA. The O.R. for outcomes were: Mortality (0.64, 0.49-0.83), MALO (0.41, 0.31-0.55), MACE (0.94, 0.8-1.1), obesity-related cancer (0.92, 0.67-1.3), CKD (1.5, 1.25-1.84). In those who also had MASLD, the impact of GLP-1 RA and Ba on outcomes are shown in the Table. **Conclusion:** Both Ba and GLP-1 RA improved outcomes in T2DM + obesity. GLP-1 RA were superior with respect to mortality and MALO, especially in those with MASLD, while Ba was superior for CKD prevention.

Population: MASLD + T2DM + obesity	Mortality O.R., 95% CI	MALO O.R., 95% CI	Ascites O.R., 95% CI	Encephalopathy O.R., 95% CI
GLP-1 RA vs control	0.14, 0.1-0.17	0.35, 0.3-0.42	0.27, 0.21-0.35	0.92, 0.6-1.4
Ba vs control	0.27, 0.19-0.4	0.49, 0.34-0.69	0.45, 0.28-0.69	0.99, 0.4-2.8
GLP-1 RA vs Ba	0.57, 0.3-1	0.73, 0.45-1.2	0.5, 0.24-1.14	1, 0.41-2.4

0167 | TWO-YEAR TIME COURSE OF BIOMARKER AND IMAGING RESPONSES IN WELL-COMPENSATED MASH CIRRHOSIS PATIENTS TREATED WITH RESMETIROM

Naim Alkhouri[1] Rebecca Taub[2] Xiaomin Lu[2] Michael Charlton[2] Jörn Schattenberg[3] Anita Kohli[4] Sam Moussa[5] Mazen Noureddin[6], [1]Summit Clinical Research, [2]Madrigal pharmaceuticals, [3]Universitätsklinikum des Saarlandes, [4]Arizona Liver Health, [5]Arizona Medical, [6]Houston Methodist Hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Resmetirom (RES), a selective thyroid hormone receptor beta agonist, is an approved therapy for metabolic dysfunction-associated steatohepatitis (MASH) with moderate to advanced liver fibrosis based on improvement in both NASH and fibrosis. We evaluated two years data in 122 compensated MASH cirrhosis patients treated with RES to assess durability of responses, and the impact of a treatment interruption that occurred between year 1 and 2. **Methods:** A total of 122 patients with Child Pugh A MASH cirrhosis (based on MASH F4 on historic biopsy $>66\%$ or clinical diagnosis) were treated with 80 mg resmetirom for up to 2 years (MAETRO-NAFLD-1 (NCT04197479) year 1; open-label extension trial (NCT04951219) year 2. Patients experienced a mean gap of 77 (58) days in RES treatment between years 1 and 2. Non-invasive biomarkers and imaging were analysed at baseline and out to 2 years. Results are presented as mean change or % change from baseline. **Results:** Baseline characteristics included mean age 61.3 (9.1), female 56%, Hispanic 27%, BMI 35.3 (7.6)kg/m^2, T2D 70%. Median (Q1,Q3): VCTE 20.1 (17.1,31.3)kPa; ELF 10.7 (10.0,11.5); MRI-PDFF 8.6% (6.0%,11.5%). Agile3$^+$, 0.96(.89,.99); Agile 4, 0.69(0.35,0.84). CSPH or probable CSPH was predicted in 49%, 93% with platelets(PLT) <100k; 35%, PLT ≥ 100K. Spleen volume in patients with platelet (PLT) count <100k (n = 30) and ≥ 100k (n = 92) were 867 (319) and 487 (220), respectively. Treatment interruption after year 1 resulted in loss of RES biomarker effects including lipids, MRI-PDFF, VCTE, adiponectin and spleen volume (figure). Treatment with RES restored year 1 biomarker effects except in some with baseline PLT <100K. Five of total 6 decompensation events were in patients with PLT <100K and elevated spleen volume. RES effects at year 2: mean (95% CI) change from baseline in <100K, ≥ 100k, respectively: VCTE -7.9 (-14.1,-1.8), -6.4 (-8.7,-4.0) kPa; mean (95% CI) % change from baseline, ALT 6%(-11%, 23%), -25%(-32%, -19%); AST 31% (8%, 54%), -18% (-25%, -11%); GGT -19% (-39%, 0), -40% (-47%, -33%) (baseline ALT $\geq$ 30 IU/L); LDL -9% (-19%, 1%), -17% (-23%, -12%); ApoB -12% (-19%, -6%), -22% (-25%,-18%); TGs -13% (-35%, 9%), -20% (-27%, -14%); Adiponectin 63% (31%, 94%), 36% (26%, 46%); Spleen volume 5% (1%, 9%) and -6% (-9%, -2%). High Agile shifted to lower Agile (35%); CSPH shifted to a lower CSPH risk score in 65%. Discontinuation rate was 8%. Mild gastrointestinal disorders were the most common adverse events. **Conclusion:** Resmetirom treatment for 2 years showed statistically significant improvement in multiple imaging and biomarker parameters. Temporary interruption of RES treatment between year 1 and 2 led to temporary attenuation of beneficial effects that generally reversed with treatment restoration. These findings highlight the potential of resmetirom to demonstrate clinical benefit in MAESTRO-NASH OUTCOMES, an ongoing 845 MASH cirrhosis patient clinical outcome study.

0168 | IMPACT OF GLP-1 RECEPTOR AGONIST TIMING ON LIVER OUTCOMES FOLLOWING ENDOSCOPIC SLEEVE GASTROPLASTY: A 36-MONTH PROSPECTIVE COHORT ANALYSIS

Kate Solpari[1] Dominique Gay[1] Ali Lahooti[1] Muhammad Usman Baig[1] Reem Sharaiha[1], [1]Weill Cornell Medical College

Background: Endoscopic sleeve gastroplasty (ESG) effectively treats obesity and metabolic dysfunction-associated steatotic liver disease (MASLD). While GLP-1 receptor agonists (GLP-1 RAs) are increasingly used with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

bariatric procedures, optimal timing remains unclear. We evaluated whether GLP-1 RA timing relative to ESG affects liver-related outcomes. **Methods:** We analyzed 417 ESG patients from a prospective registry, categorizing them by GLP-1 RA exposure through 36 months: PreESG (on GLP-1 RA before ESG, n = 37), EarlyPost (initiated 0-12m post-ESG, n = 30), LatePost (initiated 12-36m post-ESG, n = 35), and Naive (no GLP-1 RA through 36m, n = 315). Primary outcomes included changes in ALT, FIB-4, and Hepatic Steatosis Index (HSI) at 12 and 36 months. Secondary outcome was proportion achieving HSI <36 (steatosis resolution) at 36 months among those with baseline HSI ≥ 36. ANCOVA models adjusted for baseline values, percent total bodyweight loss (TBWL), age, BMI, and type 2 diabetes (T2DM). **Results:** Baseline characteristics differed significantly for age ($p = 0.007$) and T2DM prevalence ($p < 0.001$), with the PreESG group being older (median 51 vs 45 years) and having higher T2DM rates (32.4% vs 7.6% in the Naïve group). Baseline BMI, ALT, FIB-4, and HSI were similar across groups. Most groups demonstrated significant improvements in ALT and HSI at both timepoints. At 36 months, median ALT decreased from 26.0 to 21.0 (G1), 26.5 to 19.5 (G2), 25.0 to 17.5 (G3), and 24.0 to 19.5 (G4). HSI showed similar patterns with significant reductions in all groups except G1 at 36m ($p = 0.099$). FIB-4 remained stable across all groups. ANCOVA revealed no significant effect of GLP-1 RA timing on magnitude of change in ALT, FIB-4, or HSI at 12 or 36 months after adjusting for confounders (all $p > 0.05$). TBWL was the strongest predictor of improvement for all markers ($p < 0.001$). However, among patients with baseline HSI ≥ 36, those receiving GLP-1 RAs post-ESG showed higher rates of steatosis resolution at 36 months: 13.8% (EarlyPost) and 11.4% (LatePost) vs 3.9% (Naive) and 0% (PreESG), $p = 0.014$. **Conclusion:** ESG effectively improves liver biochemistry and steatosis regardless of GLP-1 RA use. While the magnitude of improvement in liver markers is primarily driven by weight loss rather than GLP-1 RA timing, post-ESG GLP-1 RA initiation may enhance steatosis resolution rates. These findings suggest that GLP-1 RAs started after ESG may provide additional metabolic benefits beyond weight loss alone.

★ 0169 | EFFECT OF ALTERNATE DAY FASTING OVER STANDARD MEDICAL MANAGEMENT ALONE TO REVERSE NON-ALCOHOLIC STEATOHEPATITIS, A RANDOMIZED CONTROLLED TRIAL. FAST TRIAL

Babu Lal Meena[1] Varsha Shasthry[1] Uma Kanal[1] PRATIBHA KALE[1] Omkar Rudra[1] Deepti Sharma[1] Manoj Sharma[1] Ibrar Ahmed Khan[1] Shiv Kumar Sarin[1] Suguna Sree Aakula[1],
[1]Institute of Liver and Biliary Sciences

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a highly prevalent liver disease with limited short-term therapeutic options. Untreated MASH progresses to cirrhosis and HCC. This randomized trial evaluated the efficacy of alternate day fasting (ADF) with standard of care (SOC) vs SOC only as a lifestyle intervention in MASH. **Methods:** The study was approved by the ethics committee and registered on clinicaltrials.gov. Ninety patients with biopsy-proven MASH were randomized to ADF(n = 45) or SOC standard care (Group 2, n = 45), and followed for six months. Biochemical resolution was defined as normalization of ALT, AST, and GGT along with improvements in controlled attenuation parameter(CAP), liver stiffness measurement(LSM), and enhanced liver fibrosis(ELF) scores. Quality of life(CLDQ NASH, SF-36) and metabolic parameters were also assessed. **Results:** The groups were comparable at baseline with a mean age of 41.9 ± 9.8 years, 56% males, and a mean BMI of 31.5 ± 2.7. Baseline LSM averaged 9.26 ± 1.75kPa, ELF score was 10.05 ± 0.38, CAP was 341.39 ± 27.66dB/m. Comorbidities were similar between groups. At 6 months, biochemical resolution was achieved in 73.3% of ADF group versus 31.1% of SOC group($p < 0.001$). Mean weight loss was greater in the ADF group(10.4 kg vs. 4.6 kg; $p < 0.001$). WHR at follow-up was significantly improved in the ADF group compared to SOC (0.91 ± 0.05 vs. 0.96 ± 0.07, $p = 0.01$. ADF group showed greater improvements in liver fat and fibrosis with CAP scores of 250 ± 3.1 vs. 297 ± 39.6 dB/m, LSM of 8.46 ± 2.0 vs. 9.2 ± 1.85kPa ($p < 0.001$), and ELF scores of 8.96 ± 0.92 vs. 9.56 ± 0.82 ($p = 0.002$). Lipid profile (TG, HDL-C, LDL-C, total cholesterol) and HbA1c showed significant improvement in the ADF group compared to SOC at follow-up (TG:165 ± 50 vs.220 ± 75; HDL-C:45 ± 8

vs.38 ± 7; LDL-C:120 ± 25 vs.135 ± 30; Cholesterol:200 ± 32 vs.215 ± 41; HbA1c:6.2 ± 1.0 vs.6.9 ± 1.3; all $p \leq 0.05$). Quality of life also improved significantly in ADF group: CLDQ NASH(5.62 ± 1.0 vs. 4.07 ± 0.3), SF-36 physical component summary (PCS)(52.5 ± 9.1 vs. 43.9 ± 7.6), and mental component summary (MCS) (54.4 ± 8.5 vs. 46.2 ± 7.8); all $p < 0.001$. Bone density at the femoral neck showed no significant differences between groups at the end of the study (T score, -0.92 ± 0.52 vs. -1.01 ± 0.59; $p = 0.454$). **Conclusion:** Alternate-day fasting significantly improved liver biochemistry, fibrosis markers, weight, and quality of life in MASH patients, supporting its use as an effective lifestyle intervention.

★ 0170 | IMPACT OF SEMAGLUTIDE ON CIRRHOSIS AND COMPLICATIONS IN PATIENTS WITH MASLD AND DIABETES: A RETROSPECTIVE COHORT STUDY

Ludovic Saba[1] Sarah Lieber[1] Dyanna Gregory[1] Indira Bhavsar-Burke[1] Maddie Kubiliun[2] Mark Pedersen[3] Thomas Kerr[3] Maria Rita Lepe-Suastegui[1] Lisa VanWagner[3], [1]UT Southwestern Medical Center, [2]UT Southwestern, [3]University of Texas Southwestern Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is linked to type 2 diabetes (T2DM), cirrhosis and increased mortality. Semaglutide, a glucagon-like peptide-1 receptor agonist (GLP-1 RA), has demonstrated histologic benefit in a recent phase-3 trial. Whether these gains translate into improved clinical outcomes in MASLD and T2DM remains unknown. We evaluated semaglutide association with cirrhosis, decompensation, and mortality in a real-world cohort. **Methods:** We used TriNetX (2015-2025), a large-scale database comprising electronic health records from 104 U.S. healthcare organizations to compare outcomes among adults ≥ 18 years with MASLD (ICD-10 K76.0 or K75.81, excluding other liver diseases) and T2DM (E11.x) by semaglutide user status, stratified by cirrhosis status. Baseline was the first encounter with both codes, and persons with any study outcome on or before baseline were excluded. Semaglutide exposure required a first prescription ≥ 90 days after baseline without prior exposure. Propensity score matching (1:1) balancing 15 demographic/metabolic covariates was used with follow-up ascertained up to 3 years. In persons without cirrhosis, outcomes included progression to cirrhosis and incident cirrhosis complications. In cirrhosis, outcomes were composite and individual cirrhosis complications, hepatocellular carcinoma, and liver transplantation. Binary outcomes were analyzed with logistic regression, and time-to-event outcomes with Cox proportional-hazards models. **Results:** Baseline characteristics and median follow-up were well balanced after matching. Mean age was 57 (SD 13.5) and 60 (SD 13.2) years, 52.7% and 59.6% women for the non-cirrhosis and cirrhosis cohorts, respectively. In persons without cirrhosis, non-semaglutide users had roughly twice the odds of incident cirrhosis and 2.4 times higher odds of decompensation. In the cirrhosis cohort, non-semaglutide use was associated with 60% higher decompensation risk. All-cause mortality was ~4-fold higher in non-users, regardless of cirrhosis status (Table 1). **Conclusion:** In this propensity-matched, real-world cohort of > 100,000 U.S. adults with MASLD and T2DM, semaglutide use was associated with significantly lower odds of cirrhosis, fewer cirrhosis-related complications, and improved survival. These findings extend the histologic efficacy observed in recent clinical trials to clinically meaningful endpoints and support semaglutide's potential role as a disease-modifying agent in MASLD.

Background: Metabolic risks and moderate alcohol consumption can promote adverse outcomes in MASLD. Our aim was to assess the impact of components of metabolic syndrome (MS) and mild-moderate alcohol use (M/F $<60/50$ g/day) on the diagnostic performance of common non-invasive tests (NITs), (FIB-4, ELF, liver stiffness measurement (LSM) by transient elastography). **Methods:** The Global MASLD (G-MASLD) project enrolled MASLD patients with liver biopsy, clinical and NIT data. Factors associated with the presence of advanced fibrosis (F3-F4) and accuracy of common NITs for predicting advanced fibrosis were assessed. **Results:** A total of 17,643 biopsy-proven MASLD patients were included: age 51 ± 13 years, 48% male, 70% with obesity, 47% type 2 diabetes (T2D), 53% hypertension, 53% hyperlipidemia, 35% advanced fibrosis. Subjects with advanced fibrosis had more components of MS, especially T2D (Figure). In a multivariate model, only obesity and T2D were independently associated with advanced fibrosis: OR (95% CI) = 1.16 (1.07-1.26) and 2.42 (2.24-2.61), respectively (both $p < 0.01$). However, higher cumulative number of MS components was associated with a greater risk of advanced fibrosis: 23% in patients with 1 MS component, 33% with 2 MS components, 32% with 3 MS components, and 43% with 4 MS components (trend $p < 0.0001$). In a subgroup with alcohol use data ($n = 8740$, 26% advanced fibrosis), the relationship of advanced fibrosis with MS remained (trend $p < 0.0001$) and was not affected by the (self-

reported) amount of alcohol use beyond very low levels (25% in subjects with 0-4 g/day, 34% in 4-9 g/day, 27% in 10-20 g/day for male or 10-13 g/day for female, 36% in subjects meeting the criteria for MetALD of $\geq$21/14 g/day for male/female). The crude AUC of FIB-4 for predicting advanced fibrosis was 0.80 (0.79-0.81), significantly lower in patients with T2D (0.76 (0.75-0.77), $p < 0.01$); however, there was no significant difference by the presence of obesity or alcohol use (all $p > 0.01$). The AUC of ELF was 0.78 (0.77-0.80), not affected by obesity, alcohol use ($p > 0.05$), lower in patients with T2D (0.74 (0.72-0.76), $p < 0.01$). The AUC of LSM was 0.84 (0.83-0.85), not affected by obesity, T2D, or alcohol use (all AUC changes ≤ 0.02, all $p > 0.01$). **Conclusion:** Metabolic risks and alcohol use synergistically increase the risk of advanced fibrosis in MASLD. Except for LSM, the diagnostic accuracy of commonly used NITs for predicting advanced fibrosis may be negatively affected by T2D.

0172 | RISK OF LIVER-RELATED EVENTS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: IMPACT OF CARDIOMETABOLIC RISK FACTOR COUNT AND ITS LONGITUDINAL CHANGES

Hanah Lee[1] Hyung Joon Kim[1] Seung Up Kim[2], [1]Chung-Ang University, [2]Yonsei University College of Medicine

Background: The risk of liver-related events (LREs) varies both across individuals and over time in patients with metabolic dysfunction–associated steatotic liver disease (MASLD). This study investigated the risk of LRE in MASLD based on cardiometabolic risk factor (CMRF) count and its longitudinal changes. **Methods:** This cohort study analyzed data from a cohort of patients with MASLD who underwent vibration-controlled transient elastography (VCTE) at 16 tertiary referral centers between February 2004 and January 2023, with prospective data collection at 14 centers. Patients were stratified based on the CMRF count. Additionally, individuals who underwent follow-up examinations at 2 years after initial VCTE were categorized according to changes in their CMRF count from baseline. LRE risk was evaluated using a multivariable-adjusted Cox proportional hazards model. **Results:** Among 16,603 patients (mean [SD] age, 52.5 [13.7] years; 9600 [57.8%] were male), 316 patients (1.9%) developed LREs during a median follow-up of 51.7 months (IQR, 25.2-85.2). The risk of LREs increased gradually with a higher baseline CMRF count (1: reference; 2: HR 1.25 [95% CI: 0.78–1.98]; 3: HR 1.79 [95% CI: 1.17–2.76]; 4: HR 1.85 [95% CI: 1.19–2.86]; 5: HR 2.69 [95% CI: 1.59–4.54]; per 1-higher: HR 1.29 [95% CI: 1.15–2.90]). Among those with follow-up data, an increase in CMRF count was associated with an higher risk of LREs (per +1 change; HR 1.21 [95% CI: 1.18–1.27]), with a greater risk in those who consistently had high CMRF counts compared to those who newly developed high CMRF counts (per +1 baseline count; HR 1.23 [95% CI: 1.21–1.35]). Conversely, a reduction in CMRF count was associated with a lower risk of LREs (per -1 change; HR 0.86 [95% CI: 0.82–0.89]). **Conclusion:** Both baseline CMRF count and its longitudinal changes were significantly associated with LRE risk in MASLD.

0173 | COMPARATIVE ANALYSIS OF SEMAGLUTIDE AND TIRZEPATIDE USE IN PERSONS WITH MASLD: IMPLICATIONS FOR PROGRESSION TO CIRRHOSIS AND COMPLICATIONS

Ludovic Saba[1] Sarah Lieber[1] Dyanna Gregory[1] Indira Bhavsar-Burke[1] Maddie Kubiliun[2] Thomas Kerr[1] Mark Pedersen[3] Rita Lepe[4] Lisa VanWagner[3], [1]UT Southwestern Medical Center, [2]UT Southwestern, [3]University of Texas Southwestern Medical Center, [4]UTSW Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of cirrhosis and mortality. Semaglutide, a glucagon-like peptide-1 receptor agonist (GLP-1 RA), has demonstrated histologic benefit in a recent phase-3 trial. Likewise, tirzepatide, a dual gastric inhibitory peptide (GIP)/GLP-1 RA, is being investigated for MASLD, yet comparative evidence on clinical outcomes is limited. **Methods:** We used TriNetX (2015-2025), a large-scale database comprising electronic health records from 104 U.S. healthcare organizations to compare outcomes among adults ≥18 years with MASLD (ICD-10 K76.0 or K75.81). Baseline was the first MASLD encounter; persons with other liver disease or any study endpoint on/before baseline were excluded. Separate analyses were conducted for those with and without cirrhosis at baseline. We created 2 cohorts: semaglutide ≥ 90d after baseline with no exposure to tirzepatide and tirzepatide ≥ 90d after baseline with no exposure to semaglutide. Propensity score matching (1:1) balanced 12 covariates. Outcomes were ascertained for up to 3 years. In persons without cirrhosis, outcomes were progression to cirrhosis and incident composite cirrhosis complications. In cirrhosis, outcomes were composite and individual cirrhosis complications (variceal bleeding, ascites, jaundice, hepatic encephalopathy), hepatocellular carcinoma (HCC), and liver transplantation. Logistic and Cox models (HR) compared semaglutide to tirzepatide (reference), as appropriate. **Results:** Baseline characteristics and median follow-up were well balanced after matching (Table 1). The odds of developing cirrhosis did not differ between persons prescribed semaglutide (0.25%) vs. tirzepatide (0.24%) (OR 1.1, 95% CI 0.7-1.7, p = 0.74). Similarly, the odds of composite cirrhosis complications did not differ between semaglutide and tirzepatide users with (OR 1.0, 95% CI 0.8-1.3, p = 1.00) or without cirrhosis (OR 0.9, 95% CI 0.7-1.3, p = 0.72). Risks of individual complications, HCC, and liver transplantation were also similar between treatment groups. Cox regression showed no survival difference between semaglutide and tirzepatide users in those with (HR 0.55, 95% CI 0.27–1.12) and without (HR 1.04, 95% CI 0.72–1.50) cirrhosis. **Conclusion:** In this large, propensity-matched real-world cohort of persons with MASLD, semaglutide and tirzepatide users had no differences in risk of cirrhosis progression, complications, or survival, suggesting potential therapeutic equivalence for hepatic outcomes. Prospective head-to-head trials are needed to guide optimal agent selection.

Table 1. Baseline characteristics and follow-up time after propensity-score matching among persons with MASLD in semaglutide versus tirzepatide users stratified by cirrhosis status, TriNetX database, 2015-2025

Stratum	Characteristic	Semaglutide N=16,962	Tirzepatide N=16,962	Std Diff

0174 | REAL-WORLD CLINICAL AND ECONOMIC OUTCOMES BY FIBROSIS STAGE IN PATIENTS WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOHEPATITIS (MASH)

Prachi Arora[1] Subash C[2] Patrick Lenehan[2] Jason Maron[2] Abdalla Aly[1] Maximilian Kurt Jara[1] Rakesh Luthra[1] Manal Abdelmalek[3], [1]Novo Nordisk, Inc., [2]nference, Inc., [3]Mayo Clinic

Background: Therapies for metabolic dysfunction-associated steatohepatitis (MASH) aim to improve clinically meaningful outcomes among patients with moderate to advanced fibrosis (fibrosis stages F2-F3). It is critical to better understand the real-world relationship between MASH with F2-F3 and major adverse cardiovascular events (MACE), major adverse liver outcomes (MALO), and healthcare resource utilization (HCRU). **Methods:** This retrospective cohort study used structured and unstructured data from electronic medical records of patients with biopsy-confirmed MASH at the Mayo Clinic (January 1, 2005-March 31, 2024) to compare MACE and MALO among patients stratified by histologically confirmed baseline fibrosis stages (F0-F4). A univariate Cox proportional hazards model estimated associations between fibrosis stage and time-to-event outcomes for 3-point MACE (nonfatal myocardial infarction, ischemic stroke and cardiovascular-related mortality) and MALO (cirrhosis [or related complications], hepatocellular carcinoma, liver transplant, or all-cause mortality). Per patient per month (PPPM) for HCRU categories were compared for patients stratified by F-stage. **Results:** Among 5,233 patients with biopsy-confirmed MASH (mean follow-up 7 years), 59% were female, with a mean age of 53 years. The most prevalent comorbidities were obesity (67%) and type 2 diabetes (46%). Among patients with F2, the risk (hazard ratio [HR]; 95% CI) of cirrhosis (1.41; 1.06-1.87) and related complications (1.58; 1.25-2.01) was significantly higher vs patients with F0-F1. Patients with F3 had a higher risk of 3-point MACE (1.50; 1.05-2.15) and multiple MALO, including cirrhosis (3.05; 2.36-3.96), cirrhosis-related complications (1.72; 1.32-2.24), liver transplantation (5.85; 1.62-21.07), and all-cause mortality (1.96; 1.43-2.68), vs patients with F0-F1 (Figure). HCRU did not significantly differ for patients with F2 or F3 vs patients with F0-F1. However, patients with F3 had significantly lower HCRU (PPPM) vs F4 (inpatient: 0.02 vs 0.06, $P = 0.0014$; outpatient: 0.35 vs 0.48, $P = 0.0001$; emergency room: 0.03 vs 0.06, $P = 0.0058$). **Conclusion:** Patients with F3 were at higher risk of MACE and MALO, and patients with F2 had an increased risk of MALO vs patients with F0-F1. HCRU in patients with F2 and F3 was similar to patients with F0-F1, but lower than patients with F4. Given that the risk of MACE, MALO, and HCRU increases with fibrosis severity, patients with MASH and F2-F3 may benefit from therapies targeting cardiometabolic risk factors.

0175 | RECOMPENSATION IN MASLD AND METALD RELATED DECOMPENSATED CIRRHOSIS

Madhumita Premkumar[1] Anchal Sandhu[2] Prerna Sharma[2] Jasvinder Nain[2] Arka De[2] Anand Kulkarni[3] Harish Bhujade[2] Pankaj Gupta[2] Nipun Verma[2] Ajay Duseja[2] Sunil Taneja[2] K Rajender Reddy[4], [1]Postgraduate Institute of Medical Education & Research, [2]PGIMER, [3]Asian Institute of Gastroenterology, [4]University of Pennsylvania

Background: Recompensation of decompensated liver disease in the spectrum of metabolic-dysfunction-associated steatotic liver disease (MASLD) and Metabolic Dysfunction-Associated Steatotic Liver Disease with Alcohol Consumption (MetALD) is largely unknown. We assessed rates of recompensation (Baveno VII criteria) and survival in such patients following one or more modifiable interventions of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

alcohol abstinence, attainment of weight loss, and amelioration of cardiometabolic risk factors. **Methods:** Between June 2021- March 2025, patients with decompensated MASLD/MetALD/ Alcohol-related cirrhosis (ALD) were evaluated with a 6-monthly follow-up for recompensation per Baveno-VII criteria, and improvement of CTP class with reduction in liver severity scores and synthetic function. Decompensation events at enrolment and at follow up were noted, with surveillance for hepatocellular carcinoma, and portal hypertension. Alcohol abstinence was confirmed by PeTH testing. **Results:** Of 403 patients with MASLD-related cirrhosis(age 53.2 ± 11.5 years,63% men, MELD-Na:16.5 ± 4.6,235 (58.3%) with any alcohol intake, 108 (26.8%) with DM-2, 79 (19.6%) with HTN, 5(1.2% with CAD, 44(10.9%) with tobacco intake. Decompensation events included ascites (294,73%), hepatic encephalopathy (138,34.2%), and variceal bleeding (182,45.2%). On follow of 30 months, 50 (12.4%) never decompensated, 130(32.3%) had further decompensation, and 66(16.4%) remained in the same CTP/MELD-Na class. *(Figure 1A-B)* Although all 235 quit alcohol consumption initially, 56(23.8%) admitted to intermittent alcohol relapse, and an additional 10(3.9%) were found to have a positive PeTH test. Recompensation occurred in 157 (39%) at a median time of 14.6(IQR-12.5-16.5) months, including 28.3%, 44.6%, 39.2% in patients with MASLD, MetALD, and ALD, respectively. ($P < 0.001$) *(Figure 1C-F)* Ascites resolved in 86% (diuretic withdrawal achieved in 39% of patients). Therapy included diet and lifestyle modification, carvedilol (307,76.2%), diuretics (347,86%), lactulose (308, 76.4%), and rifaximin (183, 45.4%). In 108 patients with DM-2, antidiabetic agents prescribed were metformin (100/108,92.6%, gliptins (47/108,43.5%), SGLT-2 inhibitors (35/108,32.4%), and insulin (22/108,20.4%). On multivariable Cox proportional hazards analysis, low bilirubin(aHR-0.8, 95% CI-0.6- 0.9,$P < 0.001$), weight loss $> 7\%$ estimated dry weight (aHR-1.6, 95% CI:1.3- 3.9, $P < 0.001$), and absence of large esophageal varices(aHR-0.4, 95% CI:0.2- 0.9, $P = 0.048$) predicted recompensation. 68(16.9%) patients died, 9(2.2%) and 12(3%) underwent liver transplant, while 6(1.5%) developed hepatocellular carcinoma. **Conclusion:** Alcohol abstinence, and sustained weight loss of $> 7\%$ estimated dry weight with supportive therapy, resulted in recompensation in 38.9% of patients over a follow-up of $>$ 2 years, with recompensation more likely in MetALD or ALD as compared with MASLD.

Chacon[3] Pere Torán[3] Sarwa Murad[1] Harry Janssen[1] Anita Arslanow[6] Aleksander Krag[7] Isabel Graupera[6] Pere Ginés[6] Maja Thiele[2] Willem Pieter Brouwer[4], *[1]Department of Gastroenterology and Hepatology, Erasmus MC, University Medical Centre, Rotterdam, [2]Odense University Hospital, [3]Institut Universitari d'Investigació en Atenció Primària Jordi Gol, Mataró, Barcelona, Spain, [4]Department of Gastroenterology and Hepatology, Erasmus MC, University Medical Centre, Rotterdam, [5]Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, [6]Liver Unit, Hospital Clínic, University of Barcelona, Barcelona, Catalonia, Spain, [7]University of Southern Denmark*

Background: Vibration-controlled transient elastography (VCTE) is widely used to screen for liver fibrosis, but the incidence and predictors of significant liver stiffness measurement (LSM) changes in the general population are unknown. **Methods:** In this prospective, multicenter cohort study from the European LiverScreen project, we analyzed longitudinal LSM data from three population-based cohorts (Barcelona, Rotterdam and Odense). Participants underwent baseline and follow-up VCTE, alongside questionnaires, anthropometric and laboratory standardized assessments. Clinically significant LSM change was defined as a $\geq$30% increase or decrease from baseline and crossing the 8 kPa threshold (incident fibrosis). Logistic regression models were adjusted for age, sex, baseline LSM, cohort, and follow-up duration. Here we report on the main longitudinal results and (dynamic) factors associated with LSM changes. **Results:** Of 7,884 participants with a valid baseline LSM, 4,536 had follow-up data (median follow-up 4.3 years, IQR 4.1–8.4 years, 24,907 person-years). The follow-up cohort had a median age of 62 years [56-68] and 52% were females. At baseline, 5.5% (251/4,536) had an LSM $\geq$8 kPa, of which 43% (110/251) experienced a clinically significant decrease during follow-up. Of those with a $<$8 kPa LSM at baseline, 2.6% (112/4,258) developed incident fibrosis with 54% (61/112) of these participants increasing to $\geq$10kPa at follow-up. Baseline obesity (aOR 2.66 95% CI: 1.38-5.12), alcohol risk consumption (aOR 1.80 95% CI: 1.07-3.03), diabetes (aOR 1.90 95% CI: 1.16-3.10), and increased ALT (aOR 2.42 95%CI: 1.50-3.89) independently predicted a clinically significant LSM increase, as did an increase in serum fasting glucose (aOR 2.94, 95% CI: 1.70-5.07) or ALT (aOR 2.49, 95% CI: 1.40-4.42) from $<$upper limit of normal (ULN) to $\geq$ULN during follow-up. Conversely, the presence diabetes was a negative predictor for significant LSM decrease (aOR 0.49, 95% CI: 1.10-1.91). **Conclusion:** In this large, prospective, population-based European study, we observed a 2.6% 4-year incidence of liver fibrosis. Baseline metabolic dysfunction and elevated ALT were independent predictors of liver stiffness progression, while type 2 diabetes significantly reduced the likelihood of improvement. These findings support targeted fibrosis screening in individuals with metabolic risk factors and alcohol overuse and suggest that a 4-year screening interval may be appropriate for the general population.

0177 | SUBTYPING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE USING ELECTRONIC HEALTH RECORD-LINKED GENOMIC COHORTS REVEALS DIVERSE ETIOLOGIES AND PROGRESSION

Shulan Tian[1] Tahmina Priya[2] Huihuang Yan[2] Kirk Wangensteen[1] Alina Allen[3] Konstantinos Lazaridis[1] Danfeng Yao[4] Eric Klee[2], [1]Mayo Clinic, [2]Mayo Clinic, Rochester, [3]Mayo Clinic Rochester, [4]Virginia Tech

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), affecting over 25% of the global population, presents challenges for pharmacotherapy due to its heterogeneity. Stratifying MASLD into reproducible, homogeneous subgroups can advance precision medicine and elucidate mechanisms underlying differential disease progression. **Methods:** Patient cohorts were derived from two population genomics studies: the Mayo Clinic Biobank and the Tapestry Study (Cohorts A and B). Cohort A (5,544 cases) was divided into development and validation sets (75:25, A1:A2), while Cohort B (4,079 cases) served as an independent validation cohort. Subgroups were identified in Cohort A1 using model-based latent class analysis (LCA) with 13 selected clinical variables and validated across other cohorts. Three methods for assigning new patients to subgroups were applied: distance-, density-, and probability-based models. Longitudinal electronic health records (EHRs) were analyzed to assess subgroup-specific disease progression and treatment response over a 10-year follow-up. **Results:** Five MASLD subgroups were identified in the cohort A1: C1 (non-obese cardiometabolic MASLD), C2 (male-predominant cardiorenal MASLD), C3 (female-predominant obese mood-disorder MASLD), C4 (idiopathic MASLD), and C5 (polygenic MASLD with high hepatitis), each defined by unique genetic, clinical, and metabolic profiles. Subgroup C4 showed a high liver transplantation rate and was enriched for HCC risk variants. Subgroup C5, characterized by high polygenic risk scores, exhibited elevated liver enzymes and increased risks of fibrosis and cirrhosis, alongside pronounced metabolic traits like obesity, T2D, and kidney disease, distinguishing it from C4. Longitudinal EHRs revealed subgroup-specific disease progression patterns, including cardiometabolic (C2), psycho-neurological (C3), and liver-specific (C5) events, highlighting MASLD's interindividual variability and the need for tailored, subgroup-specific therapeutic strategies (Figure 1). **Conclusion:** The analysis identified five MASLD subtypes with distinct clinical and genetic signatures. New patient assignment models were applied, with the distance-based approach demonstrating the highest accuracy. Longitudinal data analysis underscored the clinical value of disease subtyping, providing mechanistic insights into phenotypic heterogeneity and highlighting the need for personalized therapeutic strategies.

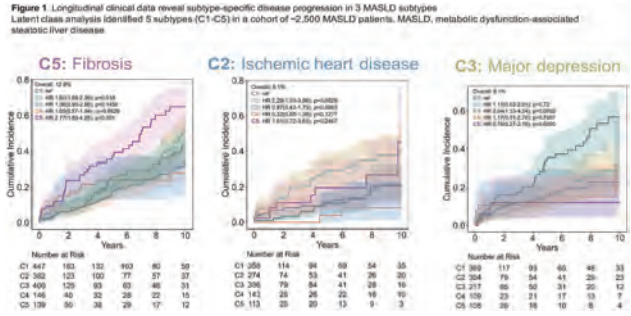

Figure 1. Longitudinal clinical data reveal subtype-specific disease progression in 3 MASLD subtypes
Latent class analysis identified 5 subtypes (C1-C5) in a cohort of ~2,500 MASLD patients. MASLD, metabolic dysfunction-associated steatotic liver disease

0178 | HSD17B13 RS72613567 VARIANT IS ASSOCIATED WITH HISTOLOGICAL PROGRESSION AND REGRESSION IN MASLD AND IT ALSO SIGNIFICANTLY MODIFIES THE EFFECT OF BMI CHANGE ON LIVER HISTOLOGY

Eduardo Vilar-Gomez[1] Katherine Yates[2] Tiebing Liang[1] Chaowapong Jarasvaraparn[1] Laura Wilson[2] David Kleiner[3] Arun Sanyal[4] Rohit Loomba[5] Naga Chalasani[6], [1]Indiana University School of Medicine, [2]Johns Hopkins University, [3]National Cancer Institute, Bethesda, [4]Virginia Commonwealth University, [5]University of California, San Diego, [6]Indiana University Medical Center

Background: *HSD17B13* rs72613567 variant has been linked to reduced inflammation and fibrosis in MASLD, however, its association with longitudinal histology changes remains unexplored. We aimed to examine relationships between *HSD17B13* rs72613567 and long-term liver histology outcomes in MASLD. **Methods:** We evaluated 671 participants (444 adults, 227 children) with biopsy-proven MASLD and ≥2 biopsies from NASH-CRN studies with a follow-up period limited to 10 years. Liver biopsies were assessed by experienced pathologists in a blinded fashion. Histology ***progression*** was defined as MASL to MASH or ≥1-point fibrosis increase; ***regression*** as MASH to MASL without fibrosis worsening or ≥1-point fibrosis decrease without MASH worsening. Interval-censored Cox models examined *HSD17B13* associations (additive model) with histological outcomes, adjusted for race/ethnicity, sex, *PNPLA3* rs738409, *TM6SF2* rs58542926, BMI, T2DM, and study design clusters. **Results:** *HSD17B13*-A allele frequency was 16%. *HSD17B13*-A allele was associated with lower MASL (aHR: 0.46) and fibrosis (aHR: 0.69) progression, and higher MASH resolution (aHR: 1.58) and fibrosis regression (aHR: 1.42) ($P < 0.05$ for all). BMI increase from baseline was associated with higher MASL (aHR: 1.06) and fibrosis (aHR: 1.06) progression, while BMI decrease was associated with higher MASH resolution (aHR: 1.17) and fibrosis regression (aHR: 1.15) ($P < 0.05$ for all) (Figure). Relationships between *HSD17B13*, BMI, and histology changes showed the same directionality among children and adults. *HSD17B13*-A allele carriage significantly modified the relationship between BMI change from baseline and histology progression and regression. Among A allele carriers, the risk of MASL (at A-allele: 1.05 vs non-A allele: 1.09, $P < 0.05$) and fibrosis (at A-allele: 1.04 vs non-A allele: 1.06, $P < 0.05$) progression due to BMI increase was significantly attenuated compared to non-A allele carriers. Similarly, among A allele carriers, the likelihood of MASH (at A-allele: 1.25 vs non-A allele: 1.03, $P < 0.05$) and fibrosis (at A-allele: 1.13 vs non-A allele: 1.08, $P < 0.05$) regression due to BMI decrease was significantly higher. **Conclusion:** *HSD17B13* rs72613567 is associated with histological progression and regression in MASLD and it also significantly modifies the effect of BMI change on liver histology, suggesting a crucial gene-environment interaction influencing disease trajectory.

Figure. Associations between *HSD17B13* rs72613567, changes in BMI from baseline, and histology outcomes.

0179 | THE USEFULNESS OF REPEATING LSM BY VCTE FOR SELECTING MASLD PATIENTS FOR PHARMACOLOGICAL TREATMENT: RESULTS: IN A LARGE REAL-WORLD COHORT OF PATIENTS

Helene Fontaine[1] Tiphaine Vidal-Trécan[2] Yelena Schwartz[2] Jean-Baptitste Julla[2] Jean-Plerre Riveline[2] Vanessa Esnault[1] Dominique Valla[1] Jean-Francois Gautier[2] Laurent Castera[1], [1]Dept of Hepatology, Hopital Beaujon, AP-HP, Clichy, France, [2]Dept of Diabetology, Hopital Lariboisière, AP-HP, Paris, France

Background: Liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) is currently recommended by AASLD guidance to select patients with MASH F2F3 for pharmacological treatment when LSM is ≥8 and ≤20 kPa. However, repeating VCTE has been suggested for these patients to reduce false positives, though data on LSM variability is scarce. We examined LSM variability over one year and tested whether repeating VCTE increases the accuracy of diagnosing fibrosis stage F2F3. **Methods:** Among a large cohort of MASLD patients from two academic centers, 1,120 patients (age 59±12 years; 42.6 % female; median BMI 30.3 (7.5) kg/m2; LSM 7.1 (5.3) kPa; CAP 299.0 (75.0) dB/m) with two valid VCTEs (≥ 10 valid measurements) within one year were selected for the study of LSM variability. A subgroup of 110 patients who underwent two VCTEs followed by a. liver biopsy (LB) within one year (median (IQR) interval between the second VCTE and LB: 3.5 (56.8) days) was also evaluated. Factors associated with LSM variability were assessed. **Results:** The within-subject coefficient of variation (wCV) for LSM was 25.6% [95% CI: 23.8-27.2] among the 1,120 patients and 26.9% [22.8-30.4] among the 110 patients with LB. Most patients remained within the same LSM value category at the second VCTE (Figure). Among the 384 patients with suspected F2F3 (LSM ≥8 and ≤20 kPa) at baseline, 157 (41%) returned to an LSM <8 kPa at the second VCTE. Meanwhile, 29 of the 77 patients (38%) with an LSM >20 kPa returned to an LSM between 8 and 20 kPa. Multivariate analysis revealed that change in LSM was associated with change in CAP and BMI, and the time interval between the two VCTEs. Of the 110 patients with a LB, the highest AUC value for diagnosing F≥2 (65%) was obtained when relying on the lowest of the two LSM values: 0.84 [0.76-0.92] vs. 0.78 [0.69-0.87] for the first VCTE and 0.79 [0.70-0.88] for the second. Of the 56 patients qualified for treatment (LSM 8-20 kPa according to the lowest LSM), 36 (72%) were classified as F2-F3 with LB. However, 21 (39%) of the 54 patients not qualifying for treatment (LSM <8 kPa or >20 kPa) were F2-F3 and would have been missed. **Conclusion:** In a large, real-world cohort of 1,120 patients with MASLD and two VCTEs, LSM variability over one year was 25.6%, which was associated with change in CAP and BMI. Repeating VCTE and using the lowest LSM value enables more accurate selection of MASLD patients with F2F3 for treatment.

Figure. Changes in LSM categories (LSM 8-20 kPa: eligible for pharmacological treatment; LSM <8 or >20 kPa: not eligible) over 1 year in 1,120 MASLD patients (Sankey diagram)

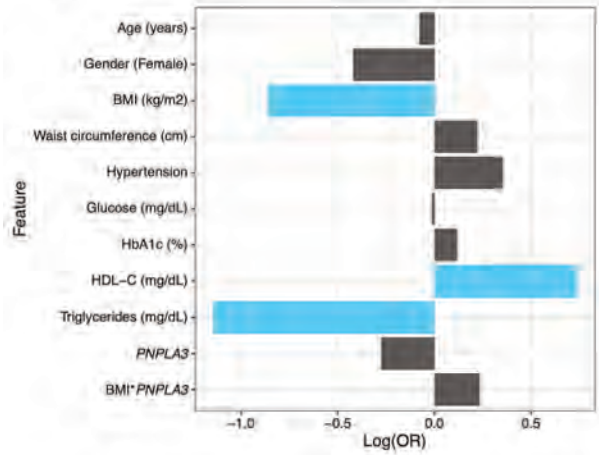
0180 | PROTECTIVE FACTORS AGAINST LIVER DISEASE DEVELOPMENT IN TYPE 2 DIABETES: A PROSPECTIVE STUDY INTEGRATING LONGITUDINAL MRI/MRE IMAGING AND STABLE ISOTOPE TRACING

Federica Tavaglione[1] Veeral Ajmera[1] Luis Díaz[2] Kelvin Li[3] Egbert Madamba[1] Ricki Bettencourt[1] Lisa Richards[1] Marc Hellerstein[3] Rohit Loomba[1], [1]University of California San Diego, [2]Pontificia Universidad Católica de Chile, [3]University of California Berkeley

Background: Type 2 diabetes is the strongest factor contributing to the development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD). Approximately two-thirds of individuals with type 2 diabetes have MASLD, and about 1 in 6 show evidence of advanced fibrosis. Within this context, encountering someone with type 2 diabetes who does not have MASLD is infrequent, even more so if they remain free of liver disease over time. Herein, we aimed to identify factors associated with hepatoprotection in a prospective cohort of individuals with type 2 diabetes and longitudinal MRI/MRE imaging. **Methods:** This prospective study included 148 individuals with type 2 diabetes who underwent a standardized clinical research visit, including MRI/MRE imaging, at baseline and 2-year follow-up. Hepatoprotection was defined as individuals not having steatosis (MRI-PDFF $< 5\%$) and significant fibrosis (MRE < 3 kPa) at both time points. Factors associated with hepatoprotection were assessed using Firth's penalized logistic regression. As complementary analyses, regularized logistic regression models were fitted using Least Absolute Shrinkage and Selection Operator (LASSO), Ridge, and Elastic Net approaches. **Results:** The mean (SD) age and body mass index (BMI) were 65 (8) years and 30.4 (4.3) kg/m^2, respectively. After a median follow-up of 2 (1.5-2.4) years, 27 (18%) individuals demonstrated hepatoprotection. These individuals had lower BMI and waist circumference, lower liver enzymes, and a more favorable lipid profile ($p < 0.05$). No hepatoprotected individuals were homozygous carriers of the *PNPLA3* I148M risk allele. Across all modeling approaches, lower BMI (OR 0.82, 95% CI 0.66–0.99; $p = 0.036$), lower circulating triglycerides (OR 0.98, 95% CI 0.97–0.99; $p = 0.002$), and higher HDL cholesterol (OR 1.06, 95% CI 1.02–1.11; $p = 0.006$) consistently emerged as the strongest predictors of hepatoprotection (Figure). To explore potential biological mechanisms, an exploratory analysis was performed in 11 individuals with type 2 diabetes and de novo lipogenesis (DNL) quantified by stable isotope tracing, revealing reduced hepatic DNL in those free from liver disease ($p < 0.05$). **Conclusion:** Managing modifiable risk factors, such as body weight and lipid profile, may be critical for preventing MASLD development and progression in individuals with type 2 diabetes.

Figure: Factors associated with protection against liver disease development in individuals with type 2 diabetes.



Log odds ratios (log[OR]) were estimated using Firth logistic regression, with hepatoprotection as the dependent variable. The bar plot displays the strength and direction of the association between each trait and the dependent variable. Positive log(OR) values indicate a direct association, whereas negative values indicate an inverse association. The magnitude of the log(OR) reflects the strength of the relationship. Predictors shown in blue were statistically significant in the model ($p<0.05$). For continuous predictors, effect sizes are presented as log(OR) for standardized variables (z-scores) to allow comparison across predictors. The corresponding odds ratios and confidence intervals from the unstandardized model are reported in the abstract text. The same significant predictors were consistently selected across all other logistic regression models (LASSO, Ridge, and Elastic Net).

0181 | IMPROVEMENT IN HEALTH-RELATED QUALITY OF LIFE AFTER TREATMENT WITH RESMETIROM IN CIRRHOTIC AND NON-CIRRHOTIC PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: DATA FROM MAESTRO-NAFLD

Zobair Younossi[1] Fatema Nader[2] Dominic Labriola[3] Rebecca Taub[4] Andrei Racila[1] Maria Stepanova[1], [1]The Global NASH Council, [2]Center for Outcomes Research in Liver Diseases, CORLD, [3]Madrigal Pharmaceutical, [4]Madrigal Pharmaceuticals

Background: Resmetirom is approved for treatment of F2-F3 metabolic dysfunction-associated steatohepatitis (MASH) in the United States. Our aim was to assess health-related quality of life (HRQL) in metabolic dysfunction steatotic liver disease (MASLD) patients with and without cirrhosis treated with resmetirom in MAESTRO-NAFLD clinical trial. **Methods:** MASLD patients with cirrhosis (CP-A) or MASLD without cirrhosis were enrolled in a 52-week, Phase 3 double-blind placebo-controlled study of resmetirom (Period 1 of MAESTRO-NAFLD) and upon treatment completion, were offered to enroll in a 52-week open-label extension study of resmetirom (Period 2). HRQL was assessed using LDQOL, CLDQ-NAFLD and WPAI throughout treatment Period 1 (baseline, week 24, week 52) and treatment Period 2 (day 1, week 12, week 28, week 52). For non-cirrhotic MASLD, PDFF response was defined as a decrease in MRI-PDFF $\geq$30% from baseline while for cirrhotic MASLD, it was defined as $\geq$20% decrease in MRI-PDFF (if baseline MRI-PDFF $>$5%). **Results:** MAESTRO NAFLD included 1307 MASLD patients (combined double-blind placebo-controlled mITT and open-label groups). Of these, 193 with cirrhosis (23% with baseline MRI-PDFF $\leq$5%) and 1114 were without cirrhosis (baseline MRI-PDFF $\geq$8%). At baseline, HRQL scores of patients with cirrhosis were significantly lower (up to -16% of score range) for all 6 domains of CLDQNAFLD, 14/17 domains of LDQOL, Activity Impairment of WPAI ($p < 0.05$). Among patients with cirrhosis, there was no significant difference in baseline HRQL scores between those with MRI-PDFF $\leq$5% and $>$5% (all $p > 0.05$). In patients with cirrhosis, by week 24 of treatment with resmetirom during Period 1, there were improvements in Worry (CLDQ-NAFLD) and Health Distress (LDQOL) up to +4% of score range which sustained by week 52 and throughout Period 2 (day 1, week 12, week 28) ($p < 0.05$). In cirrhotic subjects with MRI-PDFF $>$5%, PDFF response by Period 1 week 52, there was an improvement in Stigma score (LDQOL): mean change (+4.0 vs. -5.7, $p = 0.011$). By weeks 24 and 52 of treatment, non-cirrhotic patients receiving placebo experienced worsening of HRQL in some physical health-related domains of LDQOL (mean decrease up to -5%; $p < 0.05$) while no decreases were observed in non-cirrhotic patients treated with resmetirom. In addition, non-cirrhotic patients receiving resmetirom experienced improvement in Abdominal and Worry domains of CLDQ-NAFLD and Health Distress of LDQOL (mean increase up to +5% of score range size); no similar improvements were observed in placebo (all $p > 0.05$). Noncirrhotic patients with PDFF response experienced improvements in Abdominal and Worry scores (up to +7%) which were greater than those seen in placebo or non-responders (Figure). **Conclusion:** Patients without or with cirrhosis due to MASLD treated with resmetirom experience sustained improvement in select disease-specific HRQL scores.

0182 | RELATIONSHIP OF DIURNAL EATING BEHAVIORS AND INCIDENT MASLD AND CIRRHOSIS IN A POOLED ANALYSIS OF THREE LARGE PROSPECTIVE COHORTS

Robert Wilechansky[1] Kevin Casey[2] Andrew Chan[2] Tracey Simon[2], [1]Oregon Health & Science University, [2]Massachusetts General Hospital

Background: MASLD and cirrhosis have become pressing public health issues, and preventive efforts are critical. Prior studies have suggested benefit of certain diets and diurnal eating patterns for the prevention of diabetes and cardiovascular disease. It is known that the liver has an intrinsic circadian clock that regulates metabolism; less is certain about how diurnal variations in eating behaviors impact the development of MASLD and cirrhosis. **Methods:** We conducted a prospective study of participants without baseline liver disease enrolled in three large US cohorts: the Nurses' Health Study I and II and the Health Professionals Follow-Up Study. Participants completed validated questionnaires every 2-4 years assessing demographics, dietary habits, and medical diagnoses. In this study, participants were grouped into categories based on exposure status, including eating late at night, skipping breakfast, and the number of times eating per day. The primary outcome was physician-diagnosed incident cirrhosis, and the secondary outcome was incident MASLD; both were self-reported. Cox proportional hazard models with time-varying exposure data were used to estimate multivariable (MV)-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for incident MASLD and cirrhosis. Models were adjusted for age, cohort, BMI, daily caloric intake, diabetes mellitus, dyslipidemia, smoking, weekly physical activity, alcohol use, and adherence to the Alternate Healthy Eating Index (AHEI). **Results:** Among 199,155 participants, a total of 312 incident cirrhosis cases and 4,477 incident MASLD cases were reported over a median 16 years of follow-up. The full cohort comprised 78% women with median age 59 years, 22% with obesity (BMI > = 30), and 5% with diabetes mellitus. Baseline characteristics were well-balanced between exposure groups. In MV-adjusted models, late-night eating was associated with an increased risk of incident cirrhosis (aHR 1.28, 95% CI 1.02-1.62, p-trend = 0.036) and incident MASLD (aHR 1.31, 95% CI 1.24-1.39, p-trend < 0.001). In age-adjusted models, skipping breakfast (aHR 1.51, 95% CI 1.05-2.16, p-trend = 0.03) and eating 1-2 times per day (aHR 1.75, 95% CI 1.15-2.67, p-trend = 0.006) were associated with increased cirrhosis risk; these effects were not seen in MV-adjusted models. In age-adjusted models, eating five or more times per day (aHR 1.21, 95% CI 1.12-1.32, p-trend = < 0.001) was associated with increased MASLD risk; this effect was not seen in MV-adjusted models. Skipping breakfast was not associated with incident MASLD. Results were consistent across subgroups stratified by median AHEI score and BMI category. **Conclusion:** In a pooled analysis of three large, well-phenotyped prospective cohorts, eating late at night was associated with increased risk of incident MASLD and cirrhosis after accounting for multiple factors. Confirmatory studies may impact nutrition guidelines in chronic liver disease.

★ 0183 | HEPATOCYTE-MACROPHAGE CROSSTALK REWIRES LIVER ZONATION FEATURES IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Hanyang Liu[1] Shuai Chen[2] Dabao Shang[3] Xiaogang Xiang[3] Frank Tacke[4] Adrien Guilot[4], [1]Charité – Universitätsmedizin Berlin, [2]The Third Affiliated Hospital of Nanjing Medical University, China, [3]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [4]Charite - Universitatsmedizin Berlin

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is among the most prevalent chronic liver diseases globally, significantly contributing to liver malignancies. As is known, hepatocytes play predominant roles in liver homeostasis and diseases. The spatial heterogeneity of hepatocytes is classified into periportal (PP), midlobular (ML), and pericentral (PC) zones, each with distinct metabolic, regenerative, and inflammatory roles, a concept known as liver zonation. Simultaneously, liver macrophages (including Kupffer cells and infiltrating macrophages) act as key but multifaceted regulators in MASLD, widely participating in metabolism, inflammation, fibrosis and regeneration. Responding to steatotic (mainly lipid) stress, macrophages acquire lipid-associated phenotypes and function as disease promoters through interactions with liver cells. However, the mechanisms of hepatic zonal regulation and hepatocyte-macrophage interactions in MASLD remain unclear. **Methods:** This study implemented the transcriptomic and metabolomic analyses on MASLD patients' livers with single-cell and spatial resolution, to decipher metabolic phenotypes and cellular interactions of hepatocytes. Mouse models with MASLD (fed with choline-deficient, L-amino acid-defined, high-fat diet) and macrophage depletion (injected with clodronate-liposome) were constructed, coupled with hepatocyte-specific genetic modification (administered by adeno-associated virus). Then, the multiplex immunofluorescent staining was employed to elucidate alterations of hepatocyte-macrophage interactions and liver zonation features. Lastly, primary mouse hepatocytes and bone marrow-derived macrophages were utilized to verify specific functions and mechanisms under the interaction. **Results:** This study revealed that PC metabolic features override PP with the progression of liver steatosis. In contrast to PP and PC, ML hepatocytes exert excessive lipid and carbohydrate metabolic capacities. Exclusively in ML hepatocytes, *HNF4A* expression was upregulated with MASLD progression but downregulated with steatosis remission. Impaired hepatic HNF4A functions led to upregulation of CD36 and CCL-2, exacerbating liver steatosis and macrophage infiltration. Lipid-associated macrophages reshaped the balance of PP-PC metabolic features by regulating HNF4A functions in hepatocytes. Furthermore, enhancing hepatic *Hnf4a* expression restored metabolic features, ameliorating steatosis and macrophage-driven inflammation in the liver. **Conclusion:** This study demonstrated a novel mechanism of hepatocyte-macrophage interaction, highlighting liver zonation as a pathological factor in MASLD progression. Hepatic HNF4A emerges as a pivotal microenvironmental regulator, providing therapeutic potential in restoring liver metabolic functions and mitigating liver inflammation of MASLD.

★ 0184 | SEXUALLY DIMORPHIC PALMITOYLATION OF UTY OF LIVER SINUSOIDAL ENDOTHELIAL CELLS DRIVES ADVANCED METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) VIA PGF2Α/SPIN1 AXIS

Ruiqi Li[1] Xixuan Wang[1] Jun Guo[2] Hao Ren[1] TianHao Mao[3] Caiyun Zhang[3] Zihao Liang[4] Dawei Yang[4] Yuzheng Zhuge[5] Feng Zhang[5] Wei Chen[4] Changhua Yi[4] Qingfang Xiong[1] Shuling Chen[1] Wei Zhang[5] YongFeng Yang[1], [1]The Second Hospital of Nanjing, Medical School, Southeast University, [2]The Second Hospital of Nanjing, [3]Nanjing Key Laboratory of Hepatology, The Second Hospital of Nanjing, [4]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, [5]Nanjing Drum Tower Hospital, Medical School, Southeast University

Background: The pronounced male predominance in advanced metabolic dysfunction-associated steatohepatitis (MASH) remains mechanistically undefined beyond hormonal influences. Here, we identify a Y chromosome-encoded epigenetic circuit centered on UTY (ubiquitously transcribed tetratricopeptide repeat-containing protein Y-linked) that orchestrates sex-specific MASH through metabolic reprogramming of liver sinusoidal endothelial cells (LSECs). **Methods:** Utilizing endothelial-specific Uty knockout (Uty EC-CKO) male mice subjected to GAN diets for 20 weeks

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(MASH), we combined multi-omics profiling, chromatin topology analysis, and intercellular communication assays to delineate the UTY-mediated sexual dimorphism in MASH progression. **Results:** Male LSECs exhibited enhanced UTY demethylase activity through Cys379 palmitoylation, driving H3K27me3 erasure at the prostaglandin F synthase (PGFS) promoter. PGFS-derived PGF2α secretion from male LSECs was 2.5-fold higher than females, activating co-cultured hepatic stellate cells (HSCs) via SPIN1 stabilization. PGF2α binding to SPIN1 disrupted its MARCH9-mediated ubiquitination, enabling SPIN1-H3K4me3 complex formation at fibrogenic loci (TGFβ1, Wnt5a). PGF2α exacerbated proinflammatory cytokine release in M1 macrophages. Pharmacological inhibition of UTY palmitoylation (2-BP) or SPIN1-H3K4me3 interaction attenuated collagen deposition by 48-62% in male models, while female fibrogenesis remained unaffected. **Conclusion:** Our work unveils a Y chromosome-driven paradigm wherein palmitoylated UTY licenses male-dominant MASH through epigenetic-metabolic coupling in LSECs. The UTY-PGF2α-SPIN1 axis represents a precision therapeutic target for addressing sex disparities in MASH.

★ 0185 | NEUTROPHIL EXTRACELLULAR TRAPS DRIVE B CELL–MEDIATED FIBROGENESIS IN MASH BY SILENCING HES1 AND PROMOTING PLASMA CELL DIFFERENTIATION

Songhan Pang[1] Amelia Bergeron[1] Carolyn Tsung[1] Yiyu Zhang[1] Hongji Zhang[1], [1]University of Virginia

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe form of metabolic dysfunction-associated steatotic liver disease (MASLD) that can progress to fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). Although FDA-approved Resmetirom shows promise in reversing MASLD, its efficacy in advanced fibrosis is limited and long-term safety remains unknown. MASH-Fibrosis is difficult to treat partly due to alterations in the hepatic immune microenvironment involving multiple cell types that contribute to inflammation and fibrosis. B cells have emerged as critical contributors to the immunopathogenesis of MASH-Fibrosis, yet their mechanism remains incompletely understood. In this study, we investigated how NETs modulate B cell function to promote MASH-Fibrosis. **Methods:** Male C57BL/6 mice were fed a Western diet (WD) for 40 weeks to induce MASH-Fibrosis. NETs were inhibited via neutrophil-specific PAD4 knockout ($PAD4^{fl/fl\ LysM\text{-}Cre}$) or daily DNase I treatment. Fibrosis was assessed by Sirius Red and Masson staining; cytokines and chemokines were measured by Luminex assays. Hepatic $CD45^+$ leukocytes were analyzed by scRNA-seq and flow cytometry. Plasma B cells, HES1, and differentiation markers (CD138, Prdm1, Xbp1) were evaluated by flow cytometry and in vitro NET stimulation assays. Mature B cells were depleted in vivo using muMT mice. **Results:** Fibrosis was observed with Sirius Red and Masson staining in the WD induced MASH-Fibrosis model and was significantly ameliorated by NETs inhibition. WD-induced MASH-Fibrosis increased hepatic $CD19^+CD138^+$ plasma B cells and suppressed HES1 expression, both of which were reversed by NET inhibition in vitro. NETs suppressed HES1 and promoted plasma cell differentiation, an effect abrogated by DNase I. scRNA-seq revealed significant immune landscape changes across nine hepatic immune cell types in MASH, with B cells showing a prominent transcriptomic shift. Flow cytometry confirmed this B cell subpopulation shift, which was also reversed by NET inhibition. B cell depletion or NET inhibition significantly reduced liver fibrosis, inflammation, and cytokine levels. **Conclusion:** Our data show increased neutrophil–B cell interactions and transcriptomic shifts in hepatic B cells in a WD-induced MASH-Fibrosis model. NETs drive pro-fibrogenic plasma cell differentiation by silencing HES1 in B cells during MASH-Fibrosis progression. Targeting NET-driven B cell reprogramming may offer a therapeutic strategy to limit MASH-related inflammation and fibrosis.

★ 0186 | GENERATION OF MULTILINEAGE, HIGHLY VASCULARIZED LIVER ORGANOIDS ENABLE DISEASE MODELLING AND EXHIBIT TRANSPLANTATION POTENTIAL

Ekta Minocha[1] Ashwani Gupta[2] Jason Wertheim[2], [1]The University of Arizona, [2]College of Medicine, The University of Arizona, Tucson, Arizona

Background: Human pluripotent stem-cell (iPSC) derived organoids have emerged as novel multicellular models for studying human development and disease. However, current liver organoid models lack cellular diversity, making them less physiologically relevant compared to native tissue. Additionally, current organoid protocols rely on extracellular matrix/matrigel embedding, whose xenogeneic origin limits their suitability for clinical applications. Therefore, exploring alternatives to generate multilineage vascularized liver organoids in a matrigel-free environment remains a significant area of focus. **Methods:** De-identified human iPSCs were obtained from Cellular Dynamics International-California Institute of Regenerative Medicine (CDI-CIRM). We developed a novel method to efficiently generate highly vascularized, multicellular, functional liver organoids from human iPSCs, obviating the need for matrigel embedding. Phenotypic and functional analysis were conducted using specific markers and various functional assays. To highlight the clinical relevance of the liver organoid model, we investigated its utility in steatohepatitis disease modelling, and *in-vivo* engraftment in immuno-compromised mice. **Results:** Our protocol recapitulated *in-vivo* liver development and generated complex liver organoids that exhibited major hepatic cell types, including hepatocytes, cholangiocytes, stellate cells, sinusoidal endothelial cells, and Kupffer-like cells, confirmed by phenotypic analysis and functional assays. Liver organoids displayed functional vascular networks with perfusable lumens, as confirmed by fluorescent Ulex europaeus agglutinin I (UEAI) incubation. Upon free-fatty acid treatment, liver organoids reproduced key features of steatohepatitis, including steatosis, inflammation and fibrosis. *In-vivo* engraftment showed that all hepatic cell-types were well-maintained even after 4-weeks of engraftment, and graft-derived endothelial cells developed functional anastomoses with the mouse vasculature with evident blood flow. Moreover, the engrafted organoids stably produced human-specific albumin in the recipient mice bloodstream, thus highlighting their translational potential for *in-vivo* applications. **Conclusion:** This study presents a robust method for generating vascularized, multicellular liver organoids that may provide a versatile and valuable personalized platform for disease modeling, and regenerative therapy applications.

0187 | DELETION OF LYPLAL1 REDUCES CELLULAR UPTAKE OF FATTY ACIDS AND PROMOTES MITOCHONDRIAL B-OXIDATION TO PROTECT AGAINST METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Rawdat Hussain[1] Chinmay Raut[1] Prabhu Ponnandy[1] Akram Irshaid[2] Yue Chen[1] Lishi Yin[1] Tiffany Russell[1] Brian Halligan[3] Elizabeth Speliotes[3], [1]University of Michigan, [2]Michigan State University, [3]University of Michigan Medical Center

Background: Human genetics studies have linked single-nucleotide polymorphisms (SNPs) near LYPLAL1 with Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) but whether these SNPs act through LYPLAL1 to cause MASLD is unknown. To investigate the role of LYPLAL1 in MASLD, we analyzed rare loss-of-function (LOF) LYPLAL1 mutations using UK BioBank (UKBB) whole exome sequencing data and knocked out LYPLAL1 in human liver cells. **Methods:** We identified 100 rare missense or stop-gain LYPLAL1 variants that had AlphaMissense or GPN-MSA scores in the top 20% for causing protein disruption. We conducted burden testing in European males and females for effects on inverse normally transformed UKBB MRI Proton Density Fat Fraction (PDFF) (N = 30,050 males and 32,135 females) and UKBB ICD-based MASLD (N = 172,664 males and 208,795 females) with REGENIE. Results were meta-analyzed using fixed effects meta-analysis in METAL using sample size and direction of effect. We used CRISPR-Cas9 to knock out (KO) LYPLAL1 in a human liver cell line (HuH-7), measuring lipid levels biochemically and with imaging, fatty acid (FA) uptake by flow cytometry, and changes in *de novo* lipogenesis (DNL) and mitochondrial β-oxidation through RT-qPCR and Seahorse analysis. LYPLAL1 subcellular localization was determined by overexpressing LYPLAL1-HA tagged protein and using immunocytochemistry. **Results:** Rare loss-of-function variants were protective against MASLD in European individuals ($Z = -2.071$, $p = 0.03837$) across PDFF and ICD diagnoses and sexes. LYPLAL1 KO resulted in reduced lipid intensity and triglycerides when treated with oleic acid. Using the fluorescent FA analog NBD-stearate, we showed that LYPLAL1 KO cells had reduced FA import capability

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with decreased expression of transporters CD36 and FABP1. Expression of metabolic regulators PPARα, MLXIPL, and β-oxidation genes was higher in LYPLAL1 KO cells, with only minor changes in expression of DNL genes. These cells showed increased levels of FA oxidation in Seahorse analysis and treatment with mitochondrial β-oxidation inhibitor etomoxir restored lipid accumulation in the KO cells. We found that LYPLAL1-HA was abundantly present in mitochondria with oleic acid treatment. **Conclusion:** LYPLAL1 LOF variants had a protective effect against human MASLD and decreased intracellular lipid content in a human liver cell line. Increased levels of FA oxidation and decreased FA uptake likely protect against steatosis in LYPLAL1 KO cells.

0188 | LOSS OF DNMT1 IN HEPATOCYTES PROMOTES INFLAMMATION AND FIBROSIS DURING MASLD/MASH DEVELOPMENT IN MICE

Lina Jegodzinski[1] Darko Castven[1] Juliana Marques Affonso[1] Diana Becker[2] Dina Greinert[1] Maria Robles[3] Jenny Hetzer[4] Mohammad Rahbari[4] Suchira Gallage[4] Nisar Malek[5] Mathias Heikenwälder[6] Jens Marquardt[1], [1]Department of Medicine I, University Medical Center Schleswig-Holstein, Lübeck, [2]Department of Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, [3]Institute of Medical Psychology and Biomedical Center (BMC), Faculty of Medicine, LMU, Munich, [4]University Tübingen, Faculty of Medicine, M3-Research Center; German Cancer Research Center (DKFZ), [5]University Tübingen, Faculty of Medicine, M3-Research Center; Department Internal Medicine I, [6]University Tübingen, Faculty of Medicine, M3-Research Center, German Cancer Research Center (DKFZ)

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) constitutes an increasingly prevalent and clinically relevant spectrum of liver diseases. Key pathogenic drivers include lipotoxicity and mitochondrial dysfunction induced by excessive lipid accumulation in hepatocytes. Disruption of epigenetic regulation, particularly DNA methylation, is a major molecular hallmark of chronic inflammatory liver diseases. However, its role in MASLD pathogenesis remains unexplored. **Methods:** At 6-8 weeks of age, hepatocyte-specific *Dnmt1* knockout (KO; $Dnmt1^{flox/flox;Alb\text{-}Cre}$) and wild-type (WT; $Dnmt1^{flox/flox}$) control mice were exposed to a Western diet (WD) or a control diet (CD) for up to six months to induce MASLD/MASH. Comprehensive serum analyses and immunohistochemistry were performed. Liver samples were further subjected to RNA sequencing to assess transcriptomic changes. **Results:** *Dnmt1* KO mice exhibited reduced weight gain and attenuated hyperinsulinemia compared to WT controls. While levels of triglyceride accumulation were comparable in both genotypes, KO mice developed significantly higher intrahepatic cholesterol levels after six months of WD. Notably, serum alkaline phosphatase (ALP) levels were markedly increased in KO mice within three months of WD feeding. Histological analyses revealed increased hepatocellular senescence (p21) and enhanced inflammatory infiltration characterized by F4/80° macrophages and CD8° T cells. Strikingly, advanced hepatic fibrosis was observed exclusively in KO mice after six months of WD. Transcriptomic profiling of KO livers demonstrated enrichment of pathways associated with oxidative stress and mitochondrial dysfunction. **Conclusion:** Loss of *Dnmt1* in hepatocytes aggravates immune-cell infiltration and biliary injury during MASLD/MASH development, ultimately leading to increased liver damage and fibrosis. These findings emphasize the pathogenic role of epigenetic dysregulation, particularly through DNMT1 loss, in MASH progression and may offer novel targets for future therapeutic intervention.

0189 | GLOBAL PROGRESS TOWARD THE ELIMINATION OF HEPATITIS B: COUNTRY-LEVEL PROVISIONAL ACHIEVEMENTS OF WHO TARGETS FOR PREVENTION, CARE, AND REDUCTIONS IN MORTALITY

Jana Manning[1] John Ward[1] Lindsey Hiebert[1], [1]Coalition for Global Hepatitis Elimination

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: In 2015, the WHO set goals for the elimination of hepatitis B virus (HBV) as a global health threat. Tracking country progress towards elimination informs national planning by revealing achievements and challenges that must be overcome to eliminate HBV. **Methods:** Provisional data were systematically collected from CGHE National Hepatitis Elimination Profiles and the WHO Global Health Observatory for 166 countries and territories. Data were assessed for the number of countries provisionally meeting the 2030 HBV mortality goal of < 4 /100,000 and progress on the WHO Path to Elimination (PTE) tiers for key interventions, including timely birth dose vaccination (BD), 3-dose vaccination (3D), diagnosis (D), and treatment (T). The tiers were defined as follows: Gold (BD,3D ≥ 90%, D ≥ 80%, T ≥ 70%), Silver (BD ≥ 50%,3D ≥90, D ≥ 70%, T ≥ 60%), and Bronze (BD policy in place, 3D ≥90%, D ≥ 60%, T ≥ 50%). Data for blood safety and infection control were not included. For each country, data for the most recent year were used. Descriptive analysis, including regional cross-tabulations and distribution measures, was conducted in IBM SPSS. **Results:** The mean HBV mortality rate was 15.2 per 100,000. A total of 46 countries (28%) reported mortality rates at or below the 2030 target. In the WHO African region, 40 (86%) countries exceeded 20 deaths per 100,000; Liberia reported the highest rate (167.4). Among 103 countries reporting data, mean BD coverage was 76.8%; 62 countries reported no data or 0% coverage. A total of 164 countries reported 3D coverage with a mean of 84.8%. Of 163 countries with data, the mean diagnosis rate was 15.2% (SD = 19.1); 77 countries (47%) had coverage <10%. Average treatment coverage among persons diagnosed was 11.8% (SD = 16.2). Progress towards Path to Elimination tiers *Vaccination*: For 3D coverage, 84 countries (51%) met Gold. For BD, 103 countries (62%) met the Bronze target, 91 (55%) met Silver, and 49 (30%) met Gold. *Diagnosis*: Nineteen countries (11%) met Bronze for diagnosis coverage, 13 (8%) met Silver, and 9 (5%) achieved the Gold tier. Only Madagascar, Japan, and Iraq met the 2030 WHO target of treating at least 80% of those diagnosed. *Treatment*: Eight countries (5%) met bronze, 7 (4%) met Silver, and 6 (4%) met Gold. Overall Path to Elimination: No countries met the combined criteria for the overall Bronze, Silver, or Gold tiers. **Conclusion:** Countries have achieved progress on certain key HBV interventions, particularly hepatitis B vaccination. However, overall progress towards the WHO PTE tiers is limited. HBV diagnosis and treatment coverage is low, especially in high-burden regions such as sub-Saharan Africa. Urgent expansion of HBV screening programs, simplified models of care, and continued improvements in HepB BD vaccination are needed to accelerate progress toward hepatitis B elimination.

0190 | THE IMPACT OF CHRONIC HEPATITIS B AND ITS CLINICAL PHASES ON SIGNIFICANT LIVER FIBROSIS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Jie Li[1] Fajuan Rui[2] Jing Zhang[3] Yixuan Zhu[4] YongFeng Yang[5] Liang Xu[6] Ming-Hua Zheng[7] Qi Zheng[8] Haijun Huang[9] Chao Wu[1] Qing Xie[10] Junping Shi[11] Yuemin Nan[12], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, China, [2]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, China, [3]Beijing Youan Hospital, Capital Medical University, Beijing, China, [4]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University,China, [5]The Second Hospital of Nanjing, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China, [6]Tianjin Second People's Hospital, Tianjin, China, [7]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, Zhejiang, China, [8]The First Affiliated Hospital, Fujian Medical University, Fuzhou, Fujian, China, [9]Zhejiang Provincial People's Hospital, People's Hospital of Hangzhou Medical College,Zhejiang, China, [10]Ruijin Hospital, [11]The Affiliated Hospital and Institute of Hepatology and Metabolic Disease of Hangzhou Normal Univers, [12]Hebei Medical University Third Hospital, Shijiazhuang,Hebei, China

Background: The overlap between chronic hepatitis B (CHB) and metabolic dysfunction-associated steatotic liver disease (MASLD) has been growing. This study aimed to investigate the effect of chronic hepatitis B virus (HBV) infection on the progression of significant liver fibrosis in patients with MASLD. **Methods:** This multi-center, cross-sectional study enrolled MASLD patients who underwent liver biopsy across 16 medical centers in China between April 2004 and April 2024. Logistic regression analyses were conducted to examine the association between CHB and significant fibrosis. Propensity score matching (PSM) was used to reduce confounding factors and balance MASLD patients with and without CHB. **Results:** A total of 2,703

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

MASLD patients were included in this study (median age 40 years, 70.81% male), including 892 with MASLD only and 1,811 MASLD with CHB, among whom 930 were treatment-naïve CHB. The proportion of significant fibrosis was remarkedly higher in MASLD patients with CHB than in those with MASLD only (50.86% vs. 37.33%, $P < 0.001$). Based on the 2018 AASLD guidelines, all treatment-naïve CHB patients were categorized into five phases: immune-tolerant CHB (n = 43), inactive CHB (n = 114), HBeAg-negative immune-active CHB (n = 65), HBeAg-positive immune-active CHB (n = 127), and gray-zone CHB (n = 453). Multivariate regression analyses indicated that concurrent CHB was independently associated with higher risks of significant fibrosis (odds ratio [OR]: 2.28, 95% confidence interval [CI]: 1.81-2.89, $P < 0.001$). Both immune-active and gray-zone CHB were associated with increased risks of significant fibrosis (HBeAg-negative immune-active: OR: 2.07, 95% CI: 1.18-3.63, $P = 0.012$; HBeAg-positive immune-active: OR: 2.59, 95% CI: 1.64-4.08, $P < 0.001$; Gray-zone: OR: 2.25, 95% CI: 1.70-2.98, $P < 0.001$). After PSM, these associations remained significant, with adjusted ORs of 2.46 (95% CI: 1.18-5.11, $P = 0.016$), 2.26 (95% CI: 1.22-4.20, $P = 0.010$), and 1.97 (95% CI: 1.38–2.81, $P < 0.001$) in patients within HBeAg-negative immune-active, HBeAg-positive immune-active, and gray-zone, respectively. These findings were consistent with those when the category of CHB phases were based on the 2025 EASL guidelines. **Conclusion:** CHB independently increases the risk of fibrosis in MASLD patients, particularly in immune-active or gray-zone phases. This highlights the need for targeted screening and individualized management in high-risk groups.

0191 | GLUCOSE-LIKE PEPTIDE-1 RECEPTOR AGONISTS AND REDUCED LIVER AND NON-LIVER COMPLICATIONS IN PATIENTS WITH TYPE 2 DIABETES AND VIRAL HEPATITIS

Xinrong Zhang[1] Scott Barnet[1] Linda Henry[1] Ramsey Cheung[2], [1]Division of Gastroenterology and Hepatology, School of Medicine, Stanford University Medical Center, [2]Stanford University Medical Center

Background: Glucose-like peptide-1 receptor agonists (GLP-1RA) are a novel class of anti-diabetic drugs that can treat obesity and type 2 diabetes (T2D) and has been shown to reverse steatohepatitis and reduce cardiovascular risk. T2D and viral hepatitis frequently coexist and worsen liver and non-liver outcomes, but effective pharmacological therapies are limited. We aimed to evaluate the long-term effect of GLP-1RA on liver and non-liver complications among patients with T2D and viral hepatitis in the United States. **Methods:** Patients with T2D and viral hepatitis initiating GLP-1RA were included from 2007 to 2022 in Merative™ Marketscan® Research Databases. Primary outcomes included (1) hepatocellular carcinoma (HCC) and cirrhosis, and (2) cardiovascular disease (CVD), chronic kidney disease (CKD), and non-liver cancer. Propensity score matching (PSM) was applied to balance baseline characteristics and Cox regression models were conducted to estimate hazard ratio (HR) and 95% confidence interval (CI). **Results:** 61,164 patients with T2D and viral hepatitis were initially analyzed. Patients with and without GLP-1RA use were 1:4 matched by propensity score for their demographics, comorbidities, and background medications. A total of 9,499 patients with T2D and CHB (2,133 in GLP-1RA and 7,366 in non-GLP-1RA group; mean age 57.2 years and 41% were female at baseline) were included. Compared with non-GLP-1RA group, GLP-1RA use was associated with 34% lower risk of any liver-related outcomes (HR 0.66, 95% CI 0.53-0.81; $P < 0.001$), 50% lower risk of HCC (HR 0.50, 95% CI 0.29-0.88; $P = 0.016$), 35% lower risk of cirrhosis (HR 0.65, 95% CI 0.52-0.80; $P < 0.001$), 18% lower risk of CVD (HR 0.82, 95% CI 0.66-1.02; $P = 0.079$), 34% lower risk of CKD (HR 0.66, 95% CI 0.53-0.83; $P < 0.001$), and 28% lower risk of non-liver cancer (HR 0.72, 95% CI 0.53-0.99; $P = 0.042$) (Table 1). The association remained similar regardless of age, sex, diabetes duration, presence of diabetic complications, hypertension, hyperlipidemia, obesity and metabolic dysfunction-associated steatotic liver disease, use of antiviral treatment and background antidiabetic agents including metformin, sodium glucose co-transporter 2

inhibitors, dipeptidyl peptidase-4 inhibitors and insulin. **Conclusion:** In a nationwide cohort, GLP-1RA use was associated with a substantially lower risk of liver and non-liver complications than non-GLP-1RA group among patients with T2D and viral hepatitis. Further randomised trials are warranted.

0192 | ASSOCIATION BETWEEN STATIN USE AND THE RISK OF HEPATOCELLULAR CARCINOMA AND HEPATIC DECOMPENSATION IN CHRONIC HEPATITIS B: A NATIONWIDE COHORT STUDY

Young Chang[1] Jeong-Ju Yoo[1] Jae Young Jang[1] Tom Ryu[1] Soung Won Jeong[1] Sae Hwan Lee[1] sang gyune kim[2] Young Seok Kim[3] Hong Soo Kim[1],
[1]Soonchunhyang University, [2]Mayo Clinic Rochester, [3]Soon Chun Hyang University

Background: Statins have been suggested to provide hepatoprotective benefits beyond their lipid-lowering effects. This study aimed to evaluate whether statin use is associated with a reduced risk of hepatocellular carcinoma (HCC) and hepatic decompensation in patients with chronic hepatitis B (CHB). **Methods:** We analyzed data from the Korean National Health Insurance Service database, identifying 1,351,240 CHB patients from 2017 to 2022. After applying washout and exclusion criteria, the final cohort included 37,297 statin users with hyperlipidemia, 2,845 non-users with hyperlipidemia, and 379,985 non-users without hyperlipidemia. Incidence rate ratios (IRRs) and 95% confidence intervals (CIs) for HCC and hepatic decompensation were calculated across subgroups defined by cirrhosis and antiviral therapy status. **Results:** Statin use was significantly associated with a reduced risk of hepatocellular carcinoma in the overall population (IRR, 0.05; 95% CI, 0.04–0.06). This association remained significant in both cirrhotic (IRR, 0.06; 95% CI, 0.03–0.10) and non-cirrhotic patients (IRR, 0.04; 95% CI, 0.03–0.06), and was consistently observed regardless of antiviral therapy status. Statin use was also linked to a significantly lower risk of hepatic decompensation in the overall cohort (IRR, 0.09; 95% CI, 0.06–0.13), with particularly strong effects seen in non-cirrhotic patients (IRR, 0.09; 95% CI, 0.06–0.12). The protective association was evident in both antiviral users and non-users. In cirrhotic patients, however, the association was attenuated. **Conclusion:** Statin use was significantly associated with reduced risks of HCC and hepatic decompensation in CHB patients, independent of antiviral therapy. The effect was consistently observed across clinical subgroups, though diminished in cirrhotic patients.

0193 | HEPATOCELLULAR CARCINOMA RISK BETWEEN UNTREATED IMMUNE TOLERANT VS. TREATED IMMUNE ACTIVE CHRONIC HEPATITIS B PATIENTS: A LONGITUDINAL ANALYSIS OF NATIONAL VETERANS AFFAIRS COHORT

Robert Wong[1] Zeyuan Yang[2] Ramsey Cheung[3], [1]VA Palo Alto Healthcare System, [2]Palo Alto Veterans Institute for Research, [3]Stanford University Medical Center

Background: There have been conflicting data on the risk of hepatocellular carcinoma (HCC) between untreated immune tolerant (U-IT) vs. treated immune active (T-IA) chronic hepatitis B (CHB) patients. Some studies report significantly higher HCC risk in U-IT vs. T-IA, whereas others report no differences, but the vast majority of studies were in Asian populations. Data among predominantly non-Asian Western populations are lacking. We aim to evaluate differences in HCC risk between U-IT vs. T-IA among a large Western CHB cohort. **Methods:** Using the longitudinal national Veterans Affairs database, we identified adults with non-cirrhotic CHB that met criteria for U-IT or T-IA from 1/1/2010 to 12/31/2021 (with follow-up through 12/31/2024). Patients with concurrent HIV,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

HCV, HDV, or prior cirrhosis or HCC diagnosis were excluded. Propensity score weighting (PSW) methods were applied to balance baseline factors between U-IT and T-IA patients. Patients with at minimum 1 year of follow-up were evaluated longitudinally until development of HCC, censoring event (death or 6 months after start of antiviral therapy in U-IT), or end of the study period. HCC incidence (per 100 person-years) was compared between U-IT and T-IA, and Cox proportional hazards regression models evaluated differences in HCC risk between groups. **Results:** A total of 591 U-IT and 555 T-IA CHB patients were identified. After PSW, baseline characteristics were similar between groups, with mean age 56.4-57.5 years, 45-50% non-Hispanic white, 37-40% African American, 9-10% Asian, 25-29% with concurrent diabetes, and 35-39% with FIB-4 $>$ 3.25. Over a median follow up of 6.4 years (IQR 3.0-10.4), the incidence of HCC was significantly higher in T-IA vs. U-IT patients (0.54 [95% CI 0.41-0.72] vs. 0.28 [0.19-0.42] per 100 person-years, $p < 0.01$) (Figure). On Cox proportional hazards regression, when compared to T-IA patients, U-IT chronic HBV patients had significantly lower risk of HCC (HR 0.52, 95% CI 0.32 – 0.83, $p < 0.01$). **Conclusion:** Among a national Western cohort of predominantly non-Asian Veterans with CHB, significantly higher risk of HCC was observed in T-IA vs. U-IT patients, which differs from existing studies from Asian countries. These data continue to emphasize the importance of timely identification and prompt initiation of CHB antiviral therapy in patients who have transitioned into the IA phase.

0194 | SUMMIT: A NOVEL DEEP LEARNING MODEL USING SERIAL IMPUTATION-FREE CLINICAL DATA FOR HCC RISK PREDICTION IN CHRONIC HEPATITIS B

Tung-Hung Su[1] Yi-Hsien Hsieh[2] Shao-Wu Lee[3] Fen-Fang Chen[4] You-Hsiang Wang[2] Francis Poon[5] Wei-Yu Kao[6] Weichung Wang[7] Che Lin[2] Jia-Horng Kao[4], [1]National Taiwan University Hospital, [2]Graduate Institute of Communication Engineering, National Taiwan University, Taipei, Taiwan, [3]Department of Internal Medicine, Taichung Veterans Geneneral Hospital, Taichung, Taiwan, [4]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [5]Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, [6]Department of Internal Medicine, Taipei Medical University Hospital, Taipei, Taiwan, [7]Institute of Applied Mathematical Sciences, National Taiwan University, Taipei, Taiwan

Background: Identifying high-risk patients for hepatocellular carcinoma (HCC) among individuals with chronic hepatitis B (CHB) is crucial for timely surveillance. Although several risk scores have been developed, they often require complete data for calculation at a specific moment. We aimed to create an HCC prediction model using serial laboratory and clinical data that accommodates missing values. **Methods:** Patients with CHB who were not receiving antiviral therapy and were followed longitudinally at a tertiary medical center in Taiwan were screened. We excluded patients with prior malignancy, hepatitis C, HIV, liver transplantation, or a follow-up duration of less than five years. Laboratory data (including complete blood count, liver function tests, renal and glucose profiles, and viral markers), abdominal ultrasonographic findings, and hospital admissions within one year before the index date were summarized at three-month intervals. We applied our Scalable nUMerical eMbeddIng Transformer (SUMMIT) model to predict five-year HCC development without requiring data imputation. The performance of the SUMMIT model was compared with traditional HBV risk scores (e.g., REACH-B). An external validation was conducted using data from another tertiary medical center. Model performance was evaluated using AUROC, AUPRC, sensitivity, specificity and the C-index, where threshold-sensitive metrics were obtained with a decision threshold maximizing the Youden index on the training set. **Results:** A total of 12,455 untreated CHB patients were included, with a median age of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

49 years; 53% were male. Of these, 7060 (HCC: 261, 3.7%) were assigned to the training set, while 4708 patients (HCC: 179, 3.8%) and another 687 patients (HCC: 46, 6.7%) who could calculate the REACH-B score were assigned as two testing sets. Compared with logistic regression, support vector machine, random forest, and XGBoost models, the SUMMIT model achieved significantly higher AUROC (0.902), AUPRC (0.317; baseline: 0.023), sensitivity (0.750), specificity (0.877), and C-index (0.898) for predicting five-year HCC development. These metrics outperformed those of traditional models such as REACH-B (AUROC: 0.794), CU-HCC (AUROC: 0.868), RWS-HCC (AUROC: 0.856), and AGED (AUROC: 0.756) scores. The sensitivity of the SUMMIT model increased as the time approached HCC development. Using the external validation dataset (n = 9038), the AUROC and AUPRC were 0.792 and 0.024 (baseline: 0.007), respectively. **Conclusion:** The SUMMIT model accurately estimates HCC risk using serial laboratory and clinical data in untreated CHB patients and accommodates missing data. It outperformed other machine learning algorithms and traditional HBV risk scores and was validated externally.

Table 1. The performance of the SUMMIT model compared to other machine learning models.

	AUROC	AUPRC	Sensitivity	Specificity	C-index
LR	0.785 (0.743, 0.830)	0.128 (0.079, 0.175)	0.732 (0.651, 0.811)	0.668 (0.655, 0.681)	0.781 (0.740, 0.826)
SVM	0.826 (0.788, 0.867)	0.156 (0.094, 0.209)	0.643 (0.553, 0.729)	0.841 (0.830, 0.852)	0.823 (0.787, 0.863)
RF	0.851 (0.812, 0.893)	0.259 (0.158, 0.312)	0.455 (0.360, 0.544)	0.967 (0.963, 0.973)	0.847 (0.808, 0.889)

★ 0195 | CD4-DEPENDENT MECHANISMS DRIVE HEPLISAV-B MEDIATED HBSAG CLEARANCE AND ANTI-HBV IMMUNITY IN CHRONIC HBV CARRIER MICE

James Ahodantin[1] Jiapeng Wu[1] Masaya Funaki[2] Lydia Tang[3] Shyam Kottilil[1] Lishan Su[1], [1]University of Maryland Baltimore, [2]Kanazawa University, [3]University of Maryland, Baltimore

Background: Chronic HBV infection affects over 250 million globally, often leading to severe liver diseases. Current antiviral treatments rarely achieve functional cure, necessitating novel immunotherapeutic strategies like therapeutic vaccines to overcome immune tolerance and achieve HBV functional cure. HEPLISAV-B, an FDA-approved HBV vaccine combining HBsAg with the TLR9 agonist CpG-1018, has demonstrated superior immunogenicity clinically. This study evaluated HEPLISAV-B's therapeutic potential in a chronic HBV infection mouse model that exhibits immune tolerance to conventional HBV vaccination. **Methods:** We used an AAV-HBV carrier mouse model with chronic HBV infection and immune tolerance. Mice received two intramuscular doses of HEPLISAV-B (HBsAg/CpG: 2 ug/300 ug) four weeks apart. We monitored plasma HBV DNA, HBsAg, and HBeAg levels. Immunoblot and immunofluorescence analyses assessed liver HBsAg and HBcAg. Immune responses were evaluated by ELISA for anti-HBs IgG, ELISPOT for IFN-γ and IgG production, and flow cytometry for splenic and hepatic immune cell profiling, including CD4 and CD8 T cells, B cells, and regulatory T cells (Tregs). CD4 and CD8 T cell depletion using specific antibodies delineated their contributions. **Results:** HEPLISAV-B administration achieved HBsAg clearance and suppressed HBV production via a non-cytolytic mechanism. We observed a significant 1000-fold reduction in plasma HBV DNA and decreased HBeAg, with HBsAg becoming undetectable. Hepatic HBV DNA and RNA levels were also significantly reduced, suggesting inhibition of HBV RNA transcription and pgRNA reverse transcription. Treatment elicited robust, durable anti-HBs IgG responses ($\geq 10^4$ U/ml) and promoted Th1-biased CD4 T cell responses, characterized by enhanced IFN-g and TNF-a secretion. Immunophenotyping revealed increased splenic CD45 cells, B cells, effector memory CD8 T cells, and central memory CD4 T cells, alongside reduced Tregs and PD-1 expression on CD4 T cells. Crucially, HEPLISAV-B's therapeutic efficacy was completely abrogated by CD4 T cell depletion, while CD8 T cell depletion enhanced viral control and anti-HBs IgG responses. **Conclusion:** HEPLISAV-B effectively breaks immune tolerance in chronic HBV infection, leading to stable HBsAg clearance, suppressed viral production, and robust, durable anti-HBV humoral and cellular immunity. Our findings unequivocally demonstrate that CD4 T cells are critically essential for mediating these therapeutic effects. These results highlight HEPLISAV-B's strong potential as a promising therapeutic vaccine candidate for achieving functional cure in patients with chronic HBV infection.

0196 | HBSAG DECLINES OBSERVED WITH VRON-0200 ALONE ARE RAPIDLY ENHANCED WITH THE ADDITION OF COMBINATION ANTIVIRAL THERAPIES: RESULTS: FROM A PHASE 1B STUDY FOR FUNCTIONAL CURE IN CHRONICALLY HBV-INFECTED PATIENTS

Grace Lai-Hung Wong[1] Tien Huey Lim[2] Sue Currie[3] Andrew Luber[3] Marie Bonhomme[4] Edward Gane[5], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]NZ Liver Transplant Unit, Auckland, New Zealand, [3]Virion Therapeutics LLC, Philadelphia, USA, [4]PPD, Part of Thermo Fisher Scientific, Richmond, USA, [5]Auckland City Hospital, University of Auckland, Auckland, New Zealand

Background: HBsAg loss at EOT has been observed with some new therapies; however, sustained off-tx responses (Functional Cure), even with 24 to 48 weeks of PEG-IFN, have been very limited. VRON-0200 is an immune modulator that expresses a genetically encoded checkpoint modifier, fused with HBV core and pol (but not S) antigens, designed to enhance, broaden, and prolong CD8+ T cell responses. Here, we report safety, immunogenicity, HBsAg and HBsAb data from all patients(pts), including the combination cohort (the addition of Elebsiran and Tobevibart (E+T)). **Methods:** 34 CHB pts, NUC-suppressed with HBsAg <500IU/mL(Cohorts 1(C1) and 2(C2)), or $<1{,}000$IU/mL (Cohort 3(C3)), were randomized to receive i.m. VRON-0200 low(C1) or high dose (C2) prime on D1, w/wo VRON-0200 boost on D91; C3 receive VRON-0200 prime, followed by 6 mthly doses of E+T starting on D28, alone, or, with a VRON-0200 boost on D196. Safety, virologic, and immunologic assessments are performed. HBsAg (ELISA; LLOD:0.05IU/mL), HBsAb (detectable at >10mIU/mL), and T cell frequencies (IFN-γ ELISpot (core, pol, S antigen)), were measured. **Results:** As of May 20, 2025, 34 pts were included: 28 (82%) male, 29(85%) Asian, median age, 46.5yrs, and median BL HBsAg,178 IU/mL (range:10 – 842). In 9,937 pt safety days, 35 TRAEs were reported: 4-GR2, 31-GR1, with no tx-related SAEs or D/Cs. After a single VRON-0200 prime,10 pts(29%) had sum of core and pol IFN-γ responses above their pre-tx responses. In C1 and C2, VRON-0200 lowered HBsAg levels >0.4 log10IU/mL in 6/27(22%) and 7/26(27%) at D91 and D154, respectively; these HBsAg declines were observed at D28 and deepened over time (Figure). Boost dose did not enhance declines. In C3, at D35 (7 days post first E+T dose), HBsAg levels rapidly declined in all pts (100%; $n=6$): -3.6, -3.1, -2.6, -2.5, -2.4 and -1.3 $\log_{10}$IU/mL; all <10IU/mL (Figure); and all seroconverted from HBsAb negative to positive. Additional data to be reported. **Conclusion:** VRON-0200 alone, or in combination, had no observed safety concerns, and was well tolerated. Despite not targeting HBsAg, a single VRON-0200 dose was able to lower S-antigen in ~25% of pts. The combination of VRON-0200 with elebsiran and tobevibart rapidly and profoundly enhanced VRON-0200 HBsAg declines within 7 days in all pts, with further declines being observed with additional doses. These results suggest that broad immune restoration is possible and, coupled with VRON-0200's safety, tolerability, and ease of administration, support its potential use as the backbone therapy, in combination treatments, for HBV functional cure.

0197 | SAFETY, TOLERABILITY, IMMUNOGENICITY, AND ANTIVIRAL EFFICACY OF GS-2829 AND GS-6779, A NOVEL, ARENAVIRAL-VECTORED, THERAPEUTIC HEPATITIS B VACCINE: RESULTS: FROM A PHASE 1B STUDY IN VIRALLY SUPPRESSED PATIENTS WITH CHRONIC HEPATITIS

Edward Gane[1] Chi-Yi Chen[2] Tsung-Hui Hu[3] Ching-Chu Lo[4] Pin-Nan Cheng[5] Tung-Hung Su[6] Ming-Lung Yu[7] Frida Abramov[8] Mario Cortese[8] David Pan[8] Scott Balsitis[8] Teri Chew[8] Sarah Arterburn[8] Christopher Richards[8] Anu Osinusi[8] Wen-Juei Jeng[9] Yao-Chun Hsu[10], [1]University of Auckland, Auckland, New Zealand, [2]Ditmanson Medical Foundation Chia-Yi Christian Hospital, Chia-Yi, Taiwan, [3]Kaohsiung Chang Gung Memorial Hospital, Chang Gung University College of Medicine, Kaohsiung, Taiwan, [4]Department of Internal Medicine, St. Martin De Porres Hospital, Chiayi City, Taiwan, [5]College of Medicine, National Cheng Kung University, Tainan, Taiwan, [6]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [7]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [8]Gilead Sciences, Inc., Foster City, CA, USA, [9]Chang Gung Memorial Hospital, Linkou, Taiwan and Chang Gung University, Taoyuan, Taiwan, [10]E-Da Hospital, School of Medicine, I-Shou University, Kaohsiung, Taiwan

Background: Therapeutic vaccines, such as non-replicating arenaviral vectors GS-2829 and GS-6779, are a promising approach to achieve durable immune response and functional cure for chronic hepatitis B (CHB) infection. GS-2829 and GS-6779 were engineered to express hepatitis B surface antigen (HBsAg) and core antigen (HBcAg), and highly conserved polymerase (pol) reverse transcriptase and ribonuclease H domains. We evaluated the safety, tolerability, immunogenicity, and antiviral efficacy of GS-2829 and GS-6779 in virally suppressed patients (pts) with CHB. **Methods:** In this multicenter, randomized (4:1), blinded, placebo-controlled Phase 1b study, alternating intramuscular administrations of GS-2829 or GS-6779 every 4 weeks (ie, 1 cycle = GS-2829 at week 0; GS-6779 at week 4) were evaluated: cohort 5, 2 cycles of low doses; cohort 6, 2 cycles of high doses; cohort 7, 3 cycles of high doses. Safety and tolerability were monitored via treatment-emergent adverse events (AEs), serious AEs, and laboratory abnormalities. Viral efficacy included HBsAg, hepatitis B e antigen (HBeAg), and hepatitis B core-related antigen (HBcrAg). Immunogenicity was evaluated by interferon-gamma ELISpot analysis of hepatitis B virus (HBV)-specific T cells. **Results:** Thirty pts (n = 10 per cohort) were enrolled; median age was 51 years, 63% were male, 100% were Asian, 7% had prior interferon use, and genotype B was most common (43%). At baseline (BL), median (Q1, Q3) HBsAg levels for pts in cohorts 5–7 who received the vaccine were 1579 (480, 2901), 863 (521, 2584), and 401 (138, 925) IU/mL, respectively; 0/8, 7/8 (88%), and 4/8 (50%) pts were HBeAg positive. Among 11 HBeAg-positive pts at BL who received the vaccine, 5 (45%) achieved HBeAg loss. Quantitative declines in HBeAg and HBcrAg were observed in additional HBeAg-positive pts. In 25% (4/16) of pts in high-dose cohorts, HBsAg declined by ~0.5 $\log_{10}$ IU/mL with mild (Grade $\leq$1) alanine aminotransferase increases (Figure A). Pts on the vaccine showed induced HBV-specific T-cell responses (Figure B)—mainly against HBcAg and pol—and 94% of pts in high-dose cohorts had $\geq$3-fold increases from BL in T cells for $\geq$1 HBV antigen. All AEs were Grade $\leq$2 and nonserious; none led to discontinuation of study drugs. **Conclusion:** Alternating doses of GS-2829 and GS-6779 were safe and well tolerated in virally suppressed pts with CHB. These safety, virology, and immunogenicity data support further investigation of GS-2829 and GS-6779 as CHB treatment.

0198 | ORAL ONCE-DAILY 300 MG ALG-000184, A NOVEL CAPSID ASSEMBLY MODULATOR, DEMONSTRATED PROFOUND AND SUSTAINED SUPPRESSION OF HBV DNA TO < 10 IU/ML IN ALL TREATMENT NA&IUML;VE (TN) OR CURRENTLY-NOT-TREATED (CNT) SUBJECTS WITH CHRONIC HBV INFECTIO

Man-Fung Yuen[1] Kosh Agarwal[2] Alina Jucov[3] Alexei Haceatrean[3] Min Wu[4] Kha Le[4] Jennifer Rito[4] Lawrence Blatt[4] Sushmita Chanda[4] Tse-I Lin[4] Hardean Achneck[4] Edward Gane[5], [1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China, [2]King's College Hospital, [3]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University, [4]Aligos Therapeutics, [5]Faculty of Medicine, University of Auckland, Auckland, New Zealand

Background: Previous data from study ALG-000184-201 (NCT04536337) demonstrated favourable safety and potent antiviral effect with 300 mg ALG-000184 monotherapy for ≤ 96 weeks. Here, we present the complete 96-week monotherapy data. **Methods:** In the study Part 4 Cohort B, TN/CNT HBeAg+ and HBeAg- subjects received open-label 300 mg ALG-000184 monotherapy for 96 weeks, followed by 8 weeks of nucleos(t)ide analogues (NA) monotherapy. **Results:** 10 HBeAg+ and 11 HBeAg- subjects were enrolled. Mean baseline levels of HBV markers in HBeAg+ and HBeAg- subjects were HBV DNA 8.0 and 4.3 $\log_{10}$ IU/mL, HBV RNA 5.3 and 2.0 $\log_{10}$ copies/mL, HBsAg 4.3 and 3.5 $\log_{10}$ IU/mL, HBcrAg 8.3 and 3.1 $\log_{10}$ U/mL, respectively. The mean baseline HBeAg level in HBeAg+ subjects was 2.6 $\log_{10}$ PEI U/mL. During monotherapy, a profound and persistent antiviral effect on HBV DNA suppression was observed. At Week 48, 60% (6/10) of HBeAg+ subjects achieved HBV DNA levels < low limit of quantitation (LLOQ, 10 IU/mL, target detected [TD]), and none achieved < LLOQ (target not detected [TND], < 4.29 IU/mL). At Week 96, these rates increased to 100% (10/10) < LLOQ [TD or TND] and 50% (5/10) < LLOQ [TND]. The

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

mean reductions from baseline in HBV DNA were 6.9 and 7.0 log_{10} IU/mL at Weeks 48 and 96, respectively. All 11 HBeAg- subjects achieved HBV DNA < LLOQ [TD or TND] by Week 20 with 89% (8/9) subjects achieving HBV DNA < LLOQ [TND] at Week 96. Additionally, all subjects achieved HBV RNA < LLOQ (10 copies/mL) by Week 6 in HBeAg- or by Week 52 in HBeAg+ subjects. No viral breakthrough, as assessed by HBV DNA levels, occurred in any subject. Furthermore, multi-log reductions in HBV antigens were observed in HBeAg+ subjects along with a significant decline in HBcrAg levels in HBeAg- subjects. Treatment was well tolerated with no serious adverse events (AEs) reported and no discontinuations due to treatment-emergent AEs (TEAEs). Grade 3 TEAEs included asymptomatic ALT elevations (HBeAg+: n = 3; HBeAg-: n = 1) and cholesterol/triglycerides increase (n = 1), all resolved while dosing continued. All Grade 3 TEAEs of ALT increase accompanied a significant decline in HBV DNA, with no clinical meaningful change in synthetic/excretory liver functions. **Conclusion:** Treatment with 300 mg ALG-000184 monotherapy for 96 weeks led to maintained, profound suppression of HBV DNA in TN/CNT chronic HBV infection subjects with no viral breakthrough. These findings support the continued development of ALG-000184 as a potentially improved monotherapy regimen for chronic suppression. A head-to-head comparison of ALG-000184 vs Tenofovir monotherapy has been initiated in the Phase 2 B-SUPREME study.

0199 | EFFICACY AND SAFETY OF TOBEVIBART (VIR-3434) ALONE OR IN COMBINATION WITH ELEBSIRAN (VIR-2218) IN PARTICIPANTS WITH CHRONIC HEPATITIS DELTA VIRUS INFECTION: WEEK 48 ENDPOINT RESULTS: FROM THE PHASE 2 SOLSTICE TRIAL

Tarik Asselah[1] Anca Streinu-Cercel[2] Alina Jucov[3] Edward Gane[4] Heiner Wedemeyer[5] Pietro Lampertico[6] Michael Chattergoon[7] Brianna Bullard[7] Yimeng Lu[7] Cheng Huang[7] Rima Acosta[7] Cara Pilowa[7] Todd Correll[7] Kosh Agarwal[8], [1]Hôpital Beaujon, [2]INBIMB, Carol Davila University of Pharmacy and Medicine, [3]ARENSIA Exploratory Medicine GmbH, [4]Auckland Clinical Studies, [5]Hannover Medical School, [6]University of Milan, [7]Vir Biotechnology, Inc., [8]King's College Hospital

Background: Hepatitis delta virus (HDV) infection is the most severe form of viral hepatitis with limited treatment options. The phase 2 SOLSTICE study is investigating the antiviral activity and safety of the monoclonal antibody tobevibart alone and in combination with the small interfering RNA (siRNA) elebsiran in participants with chronic HDV infection, with or without compensated cirrhosis, on NRTI therapy (NCT05461170). **Methods:** Safety and efficacy were assessed in participants receiving either tobevibart 300 mg plus elebsiran 200 mg subcutaneously (SC) every 4 weeks (tobevibart+elebsiran Q4W *de novo*) or tobevibart 300 mg SC every 2 weeks (tobevibart Q2W) for 48 weeks. The primary endpoint was a combined endpoint (CE) defined as HDV RNA < LOD (14 IU/mL) or ≥ 2 log10 decrease compared to baseline plus ALT normalization at week 24. The proportion of participants with HDV RNA < LLOQ, target not detected (TND), otherwise referred to as HDV RNA TND, is also reported by cirrhotic and non-cirrhotic status at baseline. **Results:** At 48 weeks of therapy, declines for HDV RNA and HBsAg were greatest in participants receiving tobevibart+elebsiran Q4W

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

therapy. Higher rates of HDV RNA TND were observed in participants treated with tobevibart+elebsiran Q4W than in those receiving tobevibart Q2W, with this difference even more pronounced among cirrhotic participants. In participants receiving tobevibart+elebsiran Q4W, 56% of participants achieved CE and 38% achieved HDV RNA TND + ALT normalization at week 48. Participants receiving tobevibart+elebsiran Q4W maintained a multiple log reduction in HBsAg with HBsAg <10 IU/mL in ~90% at 48 weeks. Treatment-emergent adverse events were primarily Grade 1-2, transient in nature, with the most common being influenza-like syndrome, myalgia, headache, and chills in both treatment groups. No treatment-related serious adverse events occurred. **Conclusion:** At 48 weeks of therapy, higher rates of antiviral responses including HDV RNA TND and reductions in HBsAg were observed in participants receiving tobevibart+elebsiran Q4W; whereas lower antiviral rates were observed in participants receiving tobevibart Q2W. Adverse events were generally mild to moderate and transient, with no treatment-related SAEs observed. These results support further development of tobevibart+elebsiran Q4W, which is now being evaluated in a comprehensive registrational phase 3 ECLIPSE program in participants with chronic HDV infection.

0200 | HBV ENTRY INHIBITOR REVERSES RESISTANCE TO PEGYLATED INTERFERON IN HBEAG-POSITIVE CHRONIC HEPATITIS B PATIENTS: RESULTS: FROM A PHASE II MULTICENTER DOUBLE-BLIND RANDOMIZED TRIAL OF HEPALATIDE

Junliang Fu[1] Qing Mao[2] Qinglong Jin[3] Jia Shang[4] Hui Chen[5] Yongqian Cheng[1] Chenxin Meng[6] Jianxia Du[7] Guangming Li[8] Xiaoping Wu[9] Xiaoling Liu[10] Bei Zhong[11] Qin Zhang[12] Xiaolu Tang[13] Hanzhi Fang[13] Hongli Liu[13] Fusheng Wang[1], [1]The Fifth Medical Center of Chinese PLA General Hospital, [2]Southwest Hospital, Army Medical University, [3]The First Hospital of Jilin University, [4]Henan Provincial People's Hospital, [5]Jilin Hepatobiliary Disease Hospital, [6]The Sixth People's Hospital of Shenyang, [7]The Second Hospital of Nanjing, [8]Henan Provincial Infectious Disease Hospital, [9]The First Affiliated Hospital of Nanchang University, [10]Chizhou People's Hospital, [11]Qingyuan People's Hospital, [12]Shanghai Tongren Hospital, [13]Shanghai HEP Pharma Co. Ltd.

Background: Pegylated Interferon (PEG-IFN) remains the most established finite-duration therapy for chronic hepatitis B (CHB). IFN induces antiviral gene expression in hepatocytes and modulates immune cell activity to overcome HBV-associated immune tolerance. However, its limited efficacy in subgroups such as HBeAg-positive patients has prompted continued efforts to enhance interferon-based strategies. Although combinations of PEG-IFN with nucleos(t)ide analogues (NAs) have shown benefits in selected populations, their overall efficacy remains inconsistent. Enhancing IFN responsiveness through agents targeting other stages of the HBV life

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

cycle may offer a synergistic benefit. This phase II trial evaluated the efficacy and safety of combining hepalatide, an HBV entry inhibitor, with PEG-IFN alpha-2a in CHB patients. **Methods:** In this multicenter, randomized, double-blind trial (NCT04426968), 96 interferon-naïve CHB patients (77 HBeAg-positive, 19 HBeAg-negative) were randomly assigned in a 1:1:1:1 ratio to receive daily subcutaneous hepalatide (2.1 mg, 4.2 mg, or 6.3 mg) or placebo for 24 weeks, each combined with weekly PEG-IFN (180 μg) for 48 weeks. Virological response, defined as a ≥ 2 $\log_{10}$ IU/mL reduction in HBV DNA or HBV DNA <20 IU/mL, as well as serum HBsAg levels, were assessed at week 24. Safety profiles were also monitored throughout the study. **Results:** The combination treatment was well tolerated, with no additional adverse events attributable to hepalatide beyond those associated with PEG-IFN alone. By week 24, 5 of 6 (83.3%) HBeAg-negative patients receiving PEG-IFN monotherapy achieved HBV DNA <20 IU/mL, whereas none of the 18 HBeAg-positive patients reached this level, indicating marked resistance to PEG-IFN. However, the addition of hepalatide (4.2 mg) significantly reversed this resistance. Virological response rates at week 24 were significantly higher in HBeAg-positive patients treated with 4.2 mg hepalatide (83.3%, 95% CI: 58.6–96.4; $p<0.025$) compared to placebo (44.4%, 95% CI: 21.5–69.2). Overall, combination therapy achieved a virological response in 74.6% (44/59) of HBeAg-positive patients and resulted in greater mean HBV DNA reductions from baseline (Fig 1A). Due to higher baseline viral loads, extended treatment might be necessary for HBeAg-positive patients to achieve HBV DNA <20 IU/mL. Importantly, the proportion of HBeAg-positive patients achieving HBsAg levels <3000 IU/mL notably increased from baseline to week 24 with PEG-IFN plus hepalatide compared to placebo (Fig 1B), potentially expanding eligibility for HBsAg mRNA-targeted therapies. **Conclusion:** The addition of hepalatide to PEG-IFN therapy effectively reversed resistance in HBeAg-positive CHB patients, leading to improved antiviral efficacy. These results support further evaluation of this combination strategy to enhance long-term interferon-based treatment outcomes.

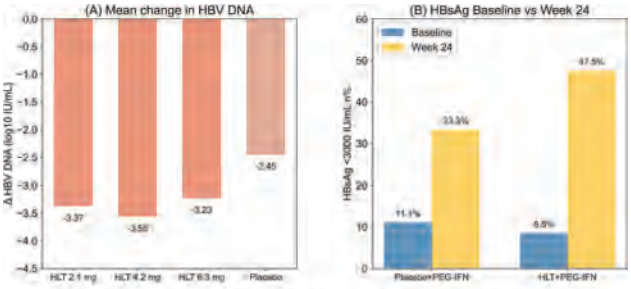

Figure 1. (A) Mean HBV DNA reduction from baseline in HBeAg-positive patients. (B) Percentage of HBeAg-positive patients with HBsAg lower than 3000 IU/mL at baseline and at 24 weeks.

0201 | HUMAN BILIARY ATRESIA EXTRAHEPATIC CHOLANGIOCYTE ORGANOIDS EXPRESS INCREASED ER AND OXIDATIVE STRESS, ALTERED DRUG METABOLISM AND CELL POLARITY CHANGES

Orith Waisbourd-Zinman[1] Adi Har-Zahav[2] Yara Hamody[2] Keren Danan[3] Ana Tobar[4] Michal Basphelchik[2] Raanan Shamir[5] Irit Gat-Viks[6], [1]Faculty of Medical and Health Sciences, Tel Aviv University, [2]Felsenstein Medical Research Center, Faculty of Medical and Health Sciences, Tel Aviv University, [3]The Shmunis School of Biomedicine and Cancer Research, George S. Wise Faculty of Life Sciences, Tel, [4]Department of Pathology, Beilenson Medical Center, Petach-Tiqva, [5]Pediatric Gastroenterology, Nutrition and Liver Diseases, Schneider Children's Medical Center, [6]The Shmunis School of Biomedicine and Cancer Research, George S. Wise Faculty of Life Sciences

Background: Biliary atresia (BA), the leading cause of liver transplantation in children, presents in neonates with jaundice and progressive extrahepatic bile duct obstruction, yet its etiology and pathogenesis remain unknown. Here, we aimed to investigate the molecular mechanisms underlying BA and the susceptibility of cholangiocytes in the extrahepatic biliary tree using patient-derived extrahepatic cholangiocyte organoids (EHCOs). **Methods:** EHCOs were derived from common bile ducts remnants of BA patients undergoing Kasai portoenterostomy and from non-BA controls at the time of liver transplantation. Transcriptomic profiling was performed via bulk RNA sequencing, and analyzed in two ways: differentially expressed pathways and perturbation analysis to predict aberrant functions. Key findings were validated through mechanistic assays, immunofluorescence staining, qPCR and transmission electron microscopy (TEM). **Results:** Transcriptomic analysis predicted significant alteration in endoplasmic reticulum (ER) stress, dysregulations of drug metabolism, alongside pronounced alterations in cellular adhesion and polarity-related genes in BA-derived EHCOs. Cell-to-cell alterations were observed with

various proteins including E-cadherin, RhoU, Sox17 and CFTR. BA EHCOs had an increased endoplasmic reticulum (ER) stress response, exemplified by elevated *PERK, BiP*, and *ATF4* along with abnormal ER on TEM. While *CHOP, ERO1A, WFS1*, and *SOD3* were decreased suggestive of abnormal ER stress response. BA EHCOs displayed increased toxicity to biliatresone-induced injury and inhibition of cytochrome P450 resulted in attenuation of the ER stress markers *PERK, BiP* and *ATF4*. Finally, liver hilum biopsies from BA patients undergoing Kasai portoenterostomy confirmed elevated PERK and PGR78(*BiP*) consistent with the EHCOs analysis. **Conclusion:** BA EHCOs exhibit disrupted polarity, ER stress, and increased susceptibility to drug toxicity. These findings highlight key pathogenic mechanisms in BA and suggest that targeting these pathways may help mitigate cholangiocyte injury in BA.

0202 | DYSPLASTIC LYMPHATIC ENDOTHELIAL NICHE SIGNALS REGULATE EPITHELIAL OUTCOMES IN BILIARY ATRESIA

Leonie Schumm[1] Robert Lorenz Chua[2] Matylda Zofia Kuzinska[1] Marie Uecker[3] Rose Behncke[1] Philip Bufler[1] Christian Conrad[2] Milad Rezvani[1], [1]Charite University Medicine Berlin, [2]Berlin Institute of Health, [3]Medizinische Hochschule Hannover

Background: Biliary Atresia (BA) is the leading cause of pediatric liver transplantation. The complex inflammatory pathophysiology of BA is extensively studied. Yet, the mechanisms by which inflammatory and morphogenic dysregulations cause biliary dedifferentiation and impaired bile drainage remain unclear. **Methods:** In our multi-modal and multi-dimensional analyses of clinically stratified liver samples from BA patients and cholestatic controls, we dissected the immune and morphogenic landscapes (Fig.1). Multiplexed immunofluorescence (mpIF), whole-mount light-sheet microscopy, single-nuclei RNA sequencing (snRNA-Seq), and spatial transcriptomics were applied. Stratified BA samples aimed at understanding intrahepatic mechanisms behind biliary outcomes after hepatoportoenterostomy: infants achieving bile drainage (successful Kasai), indicated by normalized bilirubin levels at 100 days post-Kasai, versus those needing liver transplantation (failing Kasai). Intrahepatic cholangiocyte organoids (ICOs) functionally validated inferred data. **Results:** MpIF revealed the expansion of dysplastic lymphatic endothelial cells (LECs) in the portal areas of BA patients. Whole mount light-sheet microscopy enabled detailed characterization of the abnormal LEC network morphology in BA. SnRNA-Seq and mpIF captured LEC heterogeneity and a surge of T-cell and dendritic cell-engaging chemokines in failing Kasai patients, while the same set of LEC-derived chemokines inhibited ICO growth at high doses but promoted growth in a trophic milieu. These findings indicate an inflammatory rheostat of physiological biliary growth with significant contribution of the LEC network. In addition, LECs appeared defective in Notch-signaling, underscoring that dysplastic LECs in BA may not only cause autoinflammation but also biliary dedifferentiation. **Conclusion:** In summary, we demonstrate LEC-derived regulatory effects on biliary outcomes between successful and failing Kasai patients. Targeting dysfunctional LEC signaling may be relevant for future cohort-specific treatment.

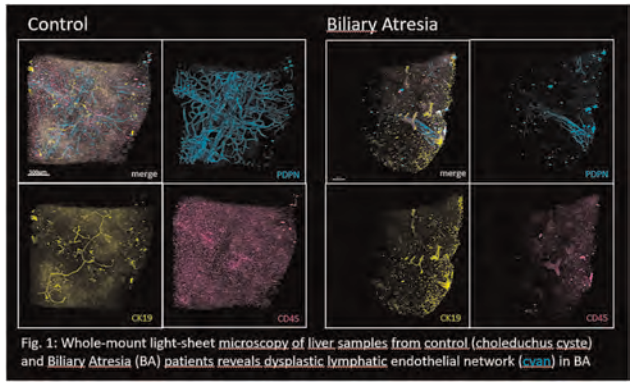

Fig. 1: Whole-mount light-sheet microscopy of liver samples from control (choledochus cyste) and Biliary Atresia (BA) patients reveals dysplastic lymphatic endothelial network (cyan) in BA

★ 0203 | DEVELOPMENT AND VALIDATION OF A RISK SCORE FOR SCREENING SIGNIFICANT LIVER FIBROSIS IN THE GENERAL PEDIATRIC POPULATION: A PROSPECTIVE COHORT STUDY

xiaoguo li[1] Bicheng Ye[1] Shanghao Liu[1] Gaojun Teng[1] Xiaolong Qi[1], [1]zhongda hospital, Southeast University, Nanjing, China.

Background: Reliable and accessible screening tools are required to screen for significant liver fibrosis in the general pediatric populations. We aimed to develop and validate a novel tool for effective screening of liver fibrosis in this population. **Methods:** This prospective cohort study comprised three independent cohorts: training, validation

and National Health and Nutrition Examination Survey (NHANES) cohorts. Nine machine learning algorithms were assessed, and the one with the highest area under the curve (AUC) was chosen to develop the PediatricLiver score. Significant liver fibrosis was defined as a liver stiffness measurement (LSM) of ≥8.0 kPa as determined by transient elastography. **Results:** In total of 1,767 participants were included, with a mean (SD) age of 14.88 (2.16) years (43.69% male; n = 772) and a mean LSM of 5.35 (2.04) kPa. The training cohort comprised 437 participants. The PediatricLiver score, developed using the K-Nearest Neighbors algorithm, incorporated age, sex, body mass index (BMI), low-density lipoprotein cholesterol, gamma-glutamyl transferase, albumin, and globulin levels. The score showed good performance with an AUC of 0.82 (95% CI: 0.74–0.89), with a sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of 0.78, 0.70, 0.13, and 0.98, respectively. A PediatricLiver score <5.53 indicates a low risk of significant liver fibrosis. The score was confirmed in the validation (n = 730) and NHANES (n = 600) cohorts and showed AUCs of 0.87 (95% CI: 0.82–0.90) and 0.79 (95% CI: 0.71–0.86), sensitivity of 0.90, specificity of 0.68, PPV of 0.17, and NPV of 0.99, and sensitivity of 0.84, specificity of 0.60, PPV of 0.10, and NPV of 0.99. The score outperformed established non-invasive fibrosis scores. In the validation cohort, it achieved an AUC of 0.87, significantly outperforming Fibrosis-4 (AUC = 0.72), AST to platelet ratio index (AUC = 0.57), and LiverRisk (AUC = 0.55). And the score demonstrated good performance in BMI-defined subgroups. In the normal-weight subgroups, AUC values ranged from 0.80 to 0.85. In the overweight/obese subgroups, AUC values ranged from 0.75 to 0.83. A free, open-access web-based calculator for the PediatricLiver score (https://pediatricliverscore.shinyapps.io/child_shiny/). **Conclusion:** The PediatricLiver score is a novel machine learning-based tool for screening significant liver fibrosis in the general pediatric population.

Background: Alagille syndrome (ALGS) is an autosomal dominant disorder associated with cholestasis and multi-system anomalies, including skeletal involvement. This study aims to describe fracture rates and patterns in ALGS. **Methods:** The Global ALagille Alliance (GALA) is an international, multicenter, retrospective study of ALGS patients. We characterized fracture rate and locations, and other clinical data in GALA. Chi-square tests, regression analyses and Wilcoxon rank-sum tests were performed. **Results:** Of 1561 patients in GALA, 182 (11.7%) patients reported at least 1fracture. 3 patients were excluded for incomplete data. Most fractures (63.7%) occurred before the age of 6 years and 25.7% were before age 2. The majority of patients had 1 fracture (62%), and the remaining had 2 fractures (14.5%), 3 (9%), and $>=4$ (14%). The mechanism of injury differed based on whether the patient had 1-2 vs. $>=3$ fractures ($p=0.006$) (Figure 1). Most fractures were in lower extremity long bones including femur (26.4%), tibia (18.3%), and fibula (6.1%), but unusual locations including skull (6.4%) and rib (3.3%) were also reported. There was no difference in platelets between those with or without fracture ($p=0.5$) nor in those with 1 fracture compared to multiple fractures ($p=0.2$). In a multivariate regression analysis, platelets were associated with age at fracture, but not sex, mechanism of injury, or history of tibia/femur fracture. Compared to the entire GALA cohort, those with fracture were more likely to have a congenital skeletal anomaly (63% vs. 51%, $p<0.002$), renal anomaly (47% vs. 35%, $p<0.001$), and been listed for liver transplant (48.9% vs. 27.6%, $p<0.001$). **Conclusion:** Fractures are a common complication in ALGS, affecting mostly young children and lower extremity long bones. Given the young age and location of fracture, these could be falsely attributed to non-accidental trauma. Reporting these fractures is important to protect caregivers of children with ALGS and to inform child abuse specialists. Cholestatic liver disease is a known risk factor for fractures, however, given the role of Notch signaling in bone development, in ALGS, patients may have intrinsic risk factors separate from cholestasis. Our

data show that fractures were more common in patients with other congenital anomalies, including skeletal and renal, and platelets did not differ based on history of fracture, suggesting that fracture risk may be impacted by more than advanced liver disease. More investigation is needed to determine if bone directed therapy may be beneficial to children with ALGS.

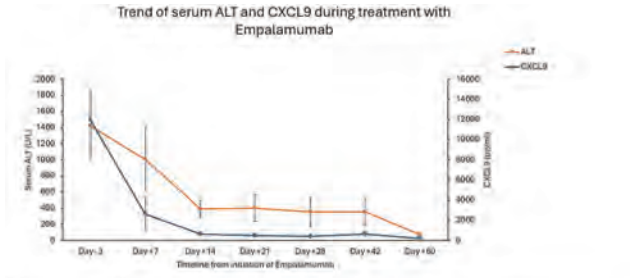
0205 | NOVEL EMAPALUMAB-CONTAINING REGIMEN FOR TREATMENT OF INDETERMINATE SEVERE HEPATITIS IN THE SETTING OF T-CELL–MEDIATED IMMUNE DYSREGULATION

Urvi Kapoor[1] Kirsty Hillier[2] Jennifer Vittorio[3] Gloria Contreras Yametti[2] Debora Kogan-Liberman[3] Dana Goldner[3] Taylor Fitch[4] Laura Youngblood[4] Amanda Cantor[5] Brenton Francisco[6] Adam Honig-Frand[7] Kelly Hayden[6] Mercedes Martinez[8] Rene Romero[9] John Bucuvalas[10] Shanmuganathan Chandrakasan[4] Prakash Satwani[1], [1]Columbia University, [2]Hassenfeld Children's Hospital at NYU Langone Health, New York, NY, [3]Hassenfeld Children's Hospital at NYU Langone Health, [4]Children's Healthcare of Atlanta, Emory University, [5]CUIMC/Morgan Stanley Children's Hospital, [6]Mount Sinai School of Medicine, New York, [7]NYU Grossman School of Medicine, New York, [8]NewYork-Presbyterian, [9]Emory University School of Medicine, [10]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Indeterminate severe hepatitis (iSH) in children is characterized by CD8˚ cytotoxic T cell infiltration and may lead to acute liver failure. Recent studies indicate that interferon-gamma (IFN-γ) plays a significant role in iSH pathogenesis. We report the largest retrospective study showing that Emapalumab (EMB), a monoclonal antibody neutralizing IFN-γ, can promote iSH resolution in a cohort of patients with steroid-refractory/dependent iSH. **Methods:** We retrospectively reviewed the medical records of 12 children diagnosed with iSH between 2019 and 2025. Liver biopsies in most patients demonstrated dense CD8˚ T-cell infiltration. Patients were classified as steroid-refractory—defined by persistent elevation or worsening of alanine transaminase (ALT) despite corticosteroid therapy, or steroid-dependent, in which ALT levels rose upon tapering steroids. Resolution of iSH was defined as normalization of ALT to <100 IU/mL. C-X-C motif chemokine ligand 9 (CXCL9), an IFN-γ chemokine, was used as a biomarker to monitor response to EMB therapy. **Results:** At presentation, patient characteristics included a median age of 56 months (22–136), ALT 2,491 U/L (1,453–4,937), total bilirubin 8.0 mg/dL (5.2–12.9), direct bilirubin 6.2 mg/dL (3.7–9.5), international normalized ratio (INR) 1.2 (1.0–1.4). Initial treatment included corticosteroids (prednisone-equivalent dose: 1–4 mg/kg/day) for a median duration of 55 days (29-78). Due to steroid refractoriness or dependence, EMB was used as a second-line agent in 8 patients and as a third- or fourth-line agent in 4 patients. EMB was initiated at a median of 37 days post-diagnosis (range: 3–104), at a starting dose ranging from 1-5 mg/kg, with a median of 11 doses (6–35). At initiation, median ALT was 1031 U/L (398-4937), total Bilirubin 3.1 mg/dl (0.4-17), direct bilirubin 2 mg/dl (0.2-10.5), INR 1.2 (0.9-1.9) and CXCL9 was 8993 pg/mL (900–33,739, normal <647 pg/mL). After four weeks of EMB therapy, CXCL9 and ALT decreased significantly, with complete normalization of ALT achieved at a median of 54 days (12-120). EMB was well tolerated, with no reported adverse events attributed to the drug. At last follow-up (median: 539 days; range: 90–1,460), all patients were alive with normal liver function, and none required liver transplantation. **Conclusion:** This study provides strong clinical evidence supporting IFN-γ blockade in iSH. EMB was associated with rapid normalization of liver function and marked reduction in CXCL9 levels, even in patients unresponsive to conventional therapies. Importantly, all patients survived without progression to liver failure or need for transplantation, and no major EMB-related adverse events were observed. These findings highlight the promising role of EMB as a targeted immunotherapy for iSH and support prospective clinical trials to define its optimal dosing, duration, and long-term efficacy in this high-risk population.



Notable reduction of ALT (levels shown on the left Y-axis in U/L, represented in the orange line) and CXCL9 (levels shown on the right Y-axis, represented in the blue line) in patients undergoing Emapalumab treatment. ALT: Alanine aminotransferase. CXCL9: Chemokine (C-X-C motif) ligand 9.

★ 0206 | INDUCTION OF EXHAUSTION PATHWAYS DEFINES THE IMMUNE MICROENVIRONMENT AND PREDICTS SURVIVAL WITH NATIVE LIVER IN PEDIATRIC ACUTE LIVER FAILURE

Jason Lee[1] Sarah Bangerth[2] Arianna Barbetta[2] Johanna Ascher Bartlett[3] Brittany Rocque[2] Carly Weaver[2] Beth Carter[4] George Yanni[5] Kambiz Etesami[5] Rohit Kohli[5] Juliet Emamaullee[2], [1]University of Southern California, [2]Keck Medical Center of USC, [3]UT Southwestern, [4]Childrens Hospital Los Angeles, [5]Children's Hospital Los Angeles

Background: Pediatric acute liver failure (PALF) is a rapidly progressive, multi-etiologic disease in otherwise healthy children. Despite its multifactorial nature, a unifying feature of PALF is a dense inflammatory infiltrate with a subset of patients distinguished by an activated T cell phenotype. Here, we look to expand our understanding of the immune microenvironment in PALF by spatial and plasma proteomics to discover features that differentiate patients who survive with native liver (SNL). **Methods:** Our single center cohort of 66 patients with PALF (24 with SNL and 34 indeterminate etiology) was compared to 33 normal liver controls (NL) (Fig. 1A). Custom immunophenotyping panels were utilized across two complementary spatial proteomic technologies to compare patients across NL vs. PALF, indeterminate vs. known cause, SNL vs. LT, and across time. Tissues results were correlated to peripheral biomarkers in a cohort of 11 PALF patients as compared to 16 healthy controls. **Results:** A total of 1.7 x 10^6 cells were identified across two spatial proteomic technologies, with enrichment of CD8+ T-cell and macrophage populations in PALF (Fig. 1B-D). Use of functional markers highlight exhaustive T cell phenotypes and damage compensatory mechanisms through parenchymal and macrophage PD-L1 upregulation and PALF exclusive proliferating monocyte subpopulations (Fig. 1C). Deep immune profiling of an indeterminate case of PALF through Phenocycler revealed significant populations of novel immunoregulatory M2 macrophage and dendritic cell populations not yet described in literature (Fig. 1D). Observation of mixed immune aggregates prompted cellular neighbourhood analysis revealing the presence of T, B, plasma, and myeloid tertiary lymphoid organs (TLO) present in PALF tissues (Fig. 1E-G). These TLOs alongside PD-L1+ hepatocyte-cholangiocyte islands associate with SNL, suggestive of spatial niches that may regulate autoimmunity (Fig. 1H). Unbiased predictive modeling of subclusters linked to outcomes reveals an enrichment of populations associated with these TLOs with robust statistical performance (Fig. 1I-J). Analysis of 1500 metabolic and immune centric peripheral plasma proteins confirms over 400 differentially expressed factors (Fig. 1K). Predictive modeling also identified 8 PALF candidate proteins that map to hepatic and immune-centric populations (Fig. 1L). **Conclusion:** Our results demonstrate that liver parenchymal and myeloid lineage subpopulations express immunoregulatory factors that reliably predict disease outcome. These subpopulations co-localize in space with adjunctive T, B, and plasma cell populations to form TLOs that may form the sites of immunoregulation to curb unmitigated hepatic damage. Furthermore, these populations can be linked to circulating proteins and can be used in conjunction as predictive biomarkers in identifying and prognosticating disease progression.

Background: Many cases of pediatric acute liver failure (PALF) are of unknown cause, designated indeterminate (IND-PALF). The liver injury in the majority of IND-PALF cases is characterized by hepatic CD8+ T-cell inflammation, and this phenotype has been labeled Activated T-cell PALF (TC-PALF). The Treatment for Immune Mediated Pathophysiology (TRIUMPH) trial is a multicenter double-blind, randomized, placebo-controlled trial testing the efficacy and safety of high dose methylprednisolone or antithymocyte globulin as treatment for children with PALF of unknown cause (U01DK127995). We describe the landscape of PALF during TRIUMPH enrollment to date. **Methods:** Patients aged 1-17 years admitted to a participating center hospital 2/9/2022 – 4/14/2025 who met PALF criteria were screened for TRIUMPH eligibility. Patients were not enrolled due to 1) met a study exclusion criterion, 2) improved and no longer met PALF criteria, and 3) declined to participate. TRIUMPH enrolled subjects were classified as TC-PALF if they had a liver biopsy with predominant CD8+ T-cell inflammation. **Results:** 568 PALF patients were screened by 21 study centers and 436 (77%) were ineligible for TRIUMPH. Acetaminophen toxicity (n = 189, 44%) was the most common exclusion (median age 15 years (IQR 13-16), 81% female), followed by liver injury due to ischemia (n = 83, 19%) and sepsis (n = 52, 12%). 121 patients met ≥ 2 exclusion criteria. 5 patients were excluded due to a positive adenovirus test during the outbreak in 2022 and 9 between 1/23-4/25; 15 were excluded due to SARS-CoV-2. Table 1 lists patient exclusions. 96 patients met TRIUMPH inclusion criteria but were not enrolled due to rapid improvement (n = 69) or consent decline (n = 27). Common reasons for declining to participate included risks of study medications and unknown benefits to participants. 36 subjects enrolled in TRIUMPH: median age 5 years (IQR 2-10), 50% female. 24 (67%) were classified as TC-PALF based on liver histology; the other 12 subjects remained in the IND-PALF group (n = 3 minimal CD8 staining, n = 9 no liver tissue available). **Conclusion:** In this contemporary multicenter study, acetaminophen toxicity was the most common PALF etiology identified. Among 132 eligible patients, 52% rapidly improved prior to consenting for TRIUMPH. Many IND-PALF patients can now be classified as TC-PALF and TRIUMPH trial results may shed light on optimal treatment for this group. Ongoing ancillary studies will explore more detailed characterization of patients not enrolled in TRIUMPH including those with rapid improvement.

Table 1. Reasons for exclusion for 436 patients who met at least 1 TRIUMPH exclusion criteria

Individual Reasons for Exclusion:	N	%
Acute drug- or toxin-induced liver injury	213	35.5
Acetaminophen	189	31.5
Others	24	4.0
Liver injury due to ischemia	83	13.9
Sepsis	52	8.7
Therapy with an immunosuppressive agent, including chemotherapy, within the past 6 weeks	48	8.0
History of malignant neoplasm within 5 years or current disease	32	5.3
Imminent risk of death as judged by site investigator	26	4.3
Solid organ or stem cell transplant recipient	19	3.2
History of recreational drug use within the past 4 weeks	18	3.0
Evidence of active viral infection	17	2.8
Hepatitis E	1	0.1
Herpes Simplex Virus	1	0.1
Adenovirus	14	2.3
Other/Unknown	1	0.1
Diagnosis of autoimmune hepatitis	17	2.8
Diagnosis of hemophagocytic lymphohistiocytosis	15	2.5
Positive test for SARS-CoV-2	15	2.5
Diagnosis of inborn error of metabolism	12	2.0
Other(s)	32	5.3

#Note that multiple patients met more than 1 exclusion criteria and percentages reflect contribution to 599 individual exclusion criteria entered in screening dataset

★ 0208 | BYSTANDER ACTIVATION OF CYTOTOXIC CD8 T CELLS AS A MECHANISM FOR INDETERMINATE PEDIATRIC ACUTE LIVER FAILURE

Harry Sutton[1] Manmeet Sekhon[2] Rachel Edgar[3] Jawairia Atif[2] Diana Nakib[2] Vicky Ng[1] Amanda Ricciuto[1] Blayne Amir Sayed[4] Gary Bader[2] Ian McGilvary[4] Binita Kamath[5] Sonya MacParland[4], [1]Hospital for Sick Children, [2]University of Toronto, [3]University Health Network, [4]University Health Network, Toronto, Canada, [5]Children's Hospital of Philidelphia

Background: Indeterminate Pediatric Acute Liver Failure (IPALF) is the most common etiology listed for children requiring liver transplant for PALF. IPALF is believed to be mediated by activated cytotoxic T cells and is sometimes referred to as T cell PALF (TC-PALF). A mechanistic understanding of how T cells in IPALF are activated and recruited may offer diagnostic, prognostic and/or therapeutic benefits. **Methods:** 10x Genomics 5' single-cell RNA-sequencing with VDJ sequencing, and fixed RNA profiling were used to create a single-cell RNA map of the IPALF liver. Flow cytometry, and IF staining were performed to confirm transcriptomic findings on a protein level. **Results:** Our combined 5' and fixed RNA single-cell transcriptomic map was comprised of 106,107 cells from 8 IPALF, 6 ALF, 3 Dx-PALF and 3 healthy pediatric patients. The IPALF liver map was rich in T cells, and the predominant T cell population in IPALF was cytotoxic CD8 T cells. The cytotoxic T cell population expressed markers associated with bystander activation and lacked markers associated with canonical TCR mediated activation ($NKG2D^+/CD25^-$). TCR clonality analysis indicated a polyclonal T cell population and inferred cell-ligand receptor analysis implicated CCL5:CCR5 signalling as a potential recruitment mechanism. A similar transcriptional phenotype was not seen in our three control groups. Our in-silico findings were supported by increased expression of CD8 and NKG2D in IPALF compared to healthy pediatric on IF and flow cytometry. **Conclusion:** We present an expansion of our previously reported first single-cell atlas of the liver cellular microenvironment in IPALF. We found the IPALF liver uniquely displays a transcriptional signature associated with bystander activation. These findings were supported on a protein level using IF/IHC and flow cytometry. Bystander activation of CD8 T Cells may cause IPALF in some children.

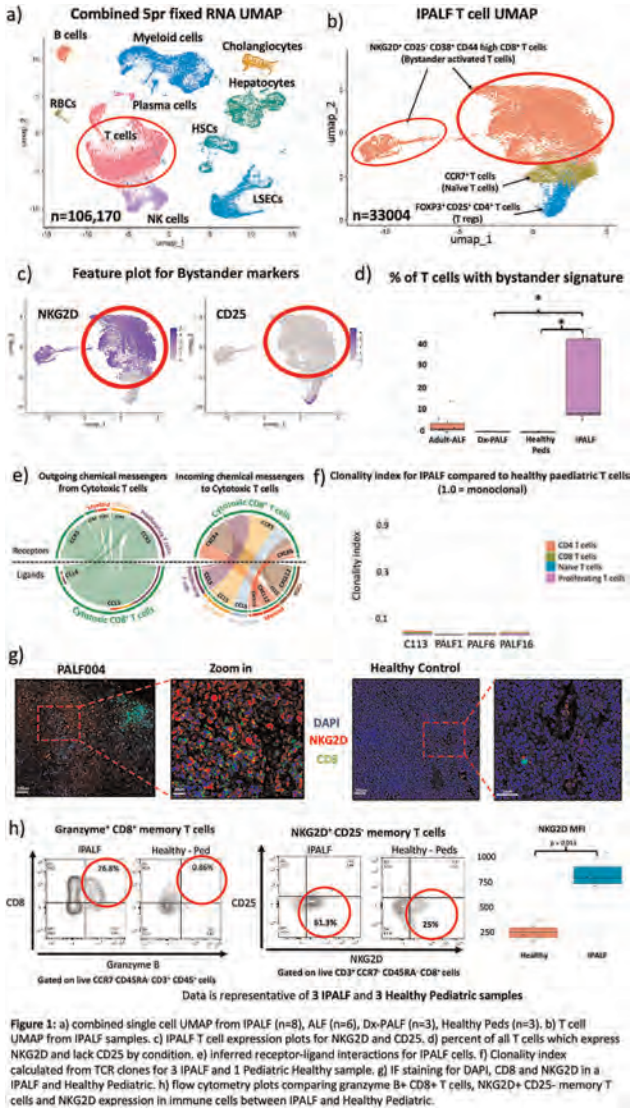

Figure 1: a) combined single cell UMAP from IPALF (n=8), ALF (n=6), Dx-PALF (n=3), Healthy Peds (n=3). b) T cell UMAP from IPALF samples. c) IPALF T cell expression plots for NKG2D and CD25. d) percent of all T cells which express NKG2D and lack CD25 by condition. e) inferred receptor-ligand interactions for IPALF cells. f) Clonality index calculated from TCR clones for 3 IPALF and 1 Pediatric Healthy sample. g) IF staining for DAPI, CD8 and NKG2D in a IPALF and Healthy Pediatric. h) flow cytometry plots comparing granzyme B+ CD8+ T cells, NKG2D+ CD25- memory T cells and NKG2D expression in immune cells between IPALF and Healthy Pediatric.

★ 0209 | EPITOPE MISMATCH SUCCESSFULLY IDENTIFIES PEDIATRIC LIVER TRANSPLANT RECIPIENTS AT RISK FOR LATE T-CELL MEDIATED REJECTION

Deepika Reddy[1] Udeme Ekong[2], [1]Georgetown University School of Medicine, [2]Georgetown University Hospital

Background: De novo anti-HLA donor specific antibodies (dnDSA) production is associated with higher mismatch (MM) load for T cell epitopes evaluated by PIRCHE-II and B cell epitopes evaluated by HLAMatchmaker. We have previously reported an association between development of dnDSA and an increased likelihood of T cell mediated rejection (TCMR) in pediatric liver transplant (LT) recipients.We therefore sought to determine if evaluation of T and B cell epitope differences in HLA-DR/DQ MM can offer a risk stratification strategy for follow- up and intervention. **Methods:** A retrospective chart review of 85 pediatric patients consecutively transplanted with an isolated LT at our center between 2019 and 2023 identified 85 patients with high resolution HLA typing and DSA measurement. Clinical data collected included demographics, transplant information, and tacrolimus levels. TCMR was biopsy proven. MM analysis was performed using PIRCHE-II and Matchmaker to derive PIRCHE, Snow, and Matchmaker scores. Statistical analysis: Descriptive statistics by dnDSA were summarized by dnDSA and comparisons between dnDSA groups were performed using two-sample t tests or Pearson's chi-squared tests. For the time to TCMR, multivariable Cox analyses using stepwise and *lasso* variable selection were performed. Landmark Cox regression was followed for the cohort after 1-year post LT. **Results:** Figure 1 shows patients included in analysis. 29 patients had dnDSA (43.9%) within 1-year post LT. Recipients with dnDSA had significantly higher median epitope MM scores ($p = 0.001$). 26 patients had TCMR (40.6%). Using a lasso model that included PIRCHE-II, Matchmaker, Snow scores, and mean tacrolimus level, the time to TCMR was shorter in recipients with high epitope MM scores vs. those with low scores [95%CI:718 (463, NA) days vs.1451 (722, NA) days $p = 0.051$]. Looking only at the cohort who developed TCMR after 1-year post LT, the time to TCMR was significantly shorter in recipients with high epitope MM scores vs. those with low scores (Figure 2; $p = 0.044$). **Conclusion:** Combined T and B cell MM load for HLA-DR/DQ is a useful tool to stratify pediatric LT recipients at risk for development of TCMR after 1-year post LT.

Background: Approaches to managing varices in children are controversial in part due to a lack of high-quality evidence regarding outcomes after pediatric first variceal hemorrhage (1VH). The International Multicenter Pediatric Portal Hypertension Registry (IMPPHR), a research collaboration of 44 centers in 18 countries on 6 continents, aims to address this knowledge gap. **Methods:** Resources and potential approaches to managing portal hypertension were assessed by querying center characteristics and clinical activity undertaken between Jan 2018 and Dec 2019. Medical records were reviewed for subjects, 0–18 years, at the centers who had 1VH between July 2012 and June 2017 with follow up to June 2020 or the first of death or liver transplant. K-means clustering was employed to cluster centers *a priori* based upon parameters in Table 1. Kaplan-Meier and multivariant Cox regression modeling were employed to assess outcomes and risk factors. 95% confidence intervals are reported [i.e. (5,95)]. **Results:** The 44 centers could be segregated into 3 clusters based upon a matrix of procedural range and volume parameters (Table). 347 subjects (129-biliary atresia [BA], 118-portal vein thrombosis [PVT], 100 other diagnoses) had 1VH at a median of 37 (13, 108) months. At 3 years post 1VH, overall survival was 87.9% (84.2,91.8), while survival with native liver (SNL) was 61.3% (56.2,66.8). Three-year survival and SNL after 1VH were significantly greater in subjects with PVT (96.4 and 95.5%) or noncirrhotic diseases (100 and 95.7%) compared to BA (85.6 and 33.9%) and other cirrhotic diseases (69.2 and 41.2%). In BA SNL after 1VH was markedly reduced in subjects whose total bilirubin did not fall below 2 mg/dL within 6 months of Kasai procedure ($p < 0.001$). Diuretic use (an indirect marker of decompensated disease) (HR 2.2 [1.5,3.2]) and employment of sclerotherapy (HR 3.2 [1.9,5.5]) were associated with significantly reduced SNL, and sclerotherapy was associated with increased mortality (HR 6.8 [2.0,22.9]). Subjects undergoing sclerotherapy ($n = 111$) were younger (median age 11 months) more likely to have biliary atresia (66%), with poor bile flow (31%) and to have ascites (50%). On multivariate analysis the impact of sclerotherapy was independent of age at 1VH as either a continuous variable or with a cut-off of 24 months. Overall 6-week mortality after 1VH was 4% (PVT 0%) and after propensity matching was significantly lower in cluster 1 compared to cluster 2 centers (cluster 1 – 0%, cluster 2 -7.7%, cluster 3 - 2.2%, $p = 0.009$). 6-week mortality for subjects undergoing sclerotherapy was 10.8%. **Conclusion:** In general early mortality following 1VH in pediatrics is low, especially for children with PVT or noncirrhotic diseases. Outcomes are worse in those with decompensated disease or those receiving sclerotherapy. Sclerotherapy appears to be employed in a specific high risk group of subjects. Center characteristics may impact short-term mortality after 1VH.

Table – Cluster Characteristics

Characteristic	Cluster 1	Cluster 2	Cluster 3
# centers	5	21	18
# hospital beds	312 [268, 378][1]	152 [60, 204]	372 [296, 477]
# ICU beds	31 [20, 60]	14 [10, 20]	48 [37, 69]
# whole liver OLT	8 [7, 9]	0 [0, 5]	18 [9, 21]
# technical variants + living donor OLT	57 [44, 91]	6 [0, 20]	10 [4, 26]
# TIPS + PSS[2]	15 [7, 15]	0 [0, 2]	1 [0, 4]
# Mesorex bypass	6 [2, 8]	0 [0, 1]	0 [0, 1]
# EVL + EST[3]	164 [18, 186]	17 [15, 30]	26 [21, 40]
% EVL/(EVL + EST)	80 [60, 84]	90 [67, 100]	92 [76, 100]

[1]median [IQR], [2] transjugular intrahepatic portosystemic + portosystemic shunt. [3] endoscopic variceal ligation + endoscopic sclerotherapy

0211 | ZETOMIPZOMIB, A FIRST-IN-CLASS SELECTIVE IMMUNOPROTEASOME INHIBITOR, DEMONSTRATES STEROID SPARING BIOCHEMICAL REMISSION IN PATIENTS WITH RELAPSED OR INSUFFICIENTLY RESPONDING AUTOIMMUNE HEPATITIS IN A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 2A STUDY

Craig Lammert[1] Neel Anand[2] David Bade[2] Theo Brandt-Sarif[2] Shraddha Desai[2] Diana Lam[2] Tony Muchamuel[2] Kiruthi Palaniswamy[3] Rachel Peterson[2] Kathryn Ray[2] Zung To[2] Jennifer Whang[2] Aparna Goel[4], [1]Richard L. Roudebush VA Medical Center, [2]Kezar Life Sciences, Inc, [3]Kezar Life Sciences, [4]Stanford University Medical Center

Background: Zetomipzomib (zeto), a selective immunoproteasome inhibitor, has shown anti-inflammatory activity in systemic lupus erythematosus. We report safety, tolerability, and efficacy of the PORTOLA study (NCT05569759), a Phase 2a, 24-week (W), randomized, double-blind, placebo-controlled trial of zeto in patients (pts) with autoimmune hepatitis (AIH) and ongoing hepatic inflammation despite standard treatments (txs). **Methods:** Eligible pts were $\geq$18 years of age with uncontrolled active disease or flare, ALT 1.25–10 $\times$ ULN, and modified HAI $\geq$5/18 on liver biopsy. Pts with decompensated cirrhosis were excluded. Pts (N = 24, intention-to-to-treat [ITT] population) were randomized (2:1) to zeto 60 mg or PBO s.c. weekly (QW) for 24 Ws in conjunction with 20 – 40 mg prednisone equivalent/day. Pts followed a suggested protocolized steroid taper. Primary efficacy endpoint was complete response (CR), defined as normalization of liver enzymes and IgG (if elevated at baseline). Secondary endpoints included the proportion of pts achieving CR with low corticosteroid (CS) dose ($\leq$5 mg prednisone equivalent/day) by W24. Samples were taken for exploratory biopsy and biomarkers. **Results:** A total of 16 AIH pts received zeto 60 mg s.c. QW for up to 24 Ws. The most common adverse events (AE) were grade 1 or 2 injection site reactions. Infectious treatment-emergent adverse events (TEAEs) were similar between zeto- and PBO-treated pts (Table 1). Three serious AEs were reported (2 zeto, 1 PBO), all unrelated. In the ITT population (N = 24), 50% (8/16) of zeto-treated pts vs. 37.5% (3/8) of PBO had CR. 31.3% (5/16) of zeto-

treated pts achieved CR with low CS dose by W24 vs. 12.5% (1/8) in the PBO arm. In a prespecified group of 21 AIH pts with CS treatment at screening, the average daily CS dose at screening was 11.4 mg/day in the PBO arm (7 pts randomized, 6 pts dosed) and 23.4 mg/d in the zeto arm. By W24, 57.1% (8/14) of zeto-treated pts achieved CR vs. 28.6% (2/7) in PBO arm. Further, 35.7% (5/14) of zeto-treated pts achieved CR with low CS dose, including 3 with complete CS withdrawal by W24 vs. no PBO arm pts. No loss of CR was observed in any zeto patient achieving CR during the 24-W period. Histological improvements, including remission, were observed after 24 Ws of zeto treatment in those with CR, with 6/8 pts achieving a ≥ 2-point improvement. **Conclusion:** Zetomipzomib treatment was associated with a favorable safety profile and showed promising efficacy in achieving steroid-sparing CR in a difficult-to-treat population of pts with AIH.

Table 1. PORTOLA Safety: Favorable Safety and Tolerability Profile with Zetomipzomib Treatment (Safety Population)

Adverse Events in Double-blind Treatment Period	Placebo n=7 n (%)	Zetomipzomib n=16 n (%)
Patient with at least 1 Treatment Emergent Adverse Event (TEAE)	7 (100.0)	16 (100.0)
Most common TEAE:		
Injection Site Reaction (ISR) – All Grade 1 or 2	4 (57.1)	15 (93.8)
Systemic Injection Reaction (SIR) – All Grade 1 or 2	1 (14.3)	12 (75.0)
TEAE leading to study drug discontinuation	0 (0)	3* (18.8)
Grade 3 TEAE^ (no Grade 4 or 5 TEAEs reported)	1 (14.3)	3 (18.8)
Serious TEAE	1† (14.3)	2‡ (12.5)
Infectious TEAE	6 (85.7)	9 (56.3)
Grade ≥3 Infectious TEAE	0 (0)	1 (6.3)
Opportunistic Infections	0 (0)	0 (0)
Death	0 (0)	0 (0)

*Grade 2 unrelated AIH flare (treatment failure per protocol), Grade 2 related hives, and Grade 1 related fatigue

^Grade 3 TEAEs were deemed unrelated

†Grade 3 unrelated variceal bleeding x2, with hematemesis and atrial fibrillation

‡Grade 3 unrelated fever (post-liver biopsy) and unrelated Grade 3 influenza B infection

★ 0212 | MACHINE LEARNING PROGNOSTIC MODEL PREDICTS ALL-CAUSE MORTALITY OR LIVER TRANSPLANT IN PATIENTS WITH AUTOIMMUNE HEPATITIS

Bishoi Aziz[1] Christina Plagiannakos[2] Jonelle Pallotta[2] Ellina Lytvyak[3] Lawrence Worobetz[4] Jennifer Flemming[5] Julian Hercun[6] Catherine Vincent[7] Angela Cheung[8] Tianyan Chen[9] Dusanka Grbic[10] Mark Swain[11] Aliya Gulamhusein[12] Bettina Hansen[13] Gideon Hirschfield[14] Andrew Mason[3] Aldo Montano-Loza[3] Karim Qumosani[1], [1]Department of Medicine, Western University, London, Canada, [2]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada, [3]Division of Gastroenterology and Hepatology, University of Alberta, Edmonton, Canada, [4]Royal University Hospital, [5]Queen's University Cancer Research Institute, [6]National Institutes of Health, [7]Liver Unit, Centre hospitalier de l'Universite de Montreal, Montreal, Canada, [8]Department of Medicine, University of Ottawa, Ottawa, Canada, [9]Department of Medicine, Division of Gastroenterology & Hepatology, McGill University Health Centre, [10]Université De Sherbrooke, Sherbrooke, Canada, [11]University of Calgary, [12]Toronto Centre for Liver Disease, University Health Network, Toronto, [13]Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, [14]Toronto General Hospital

Background: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease requiring long-term immunosuppressive therapy. Despite treatment, 50–87% relapse after withdrawal, increasing cirrhosis risk to 38% with multiple relapses. Currently, there is only one prognostic model developed, but it is trained on a small dataset and it does not include important predictors. It's built based on age, cirrhosis at diagnosis, and ethnicity. As such, it does not include labs that would reflect therapy response; a reported significant survival predictor. **Aim:** To develop a machine learning (ML)-based prognostic model for AIH. **Methods:** Data: We used the Canadian Network for Autoimmune Liver disease (CaNAL) dataset, a comprehensive multicenter longitudinal registry from 13 Canadian tertiary centers including adults (≥18 years). *Inclusion:* simplified IAIHG score. *Exclusion:* acute severe AIH, cirrhosis or transplant at baseline, death or transplant within 1 year, follow-up < 1 year, or missing key data. Outcome: A binary endpoint of all-cause mortality and/or liver transplant. Predictors: Simple blood tests including AST, ALT, ALP, GGT, IgG, total bilirubin, neutrophils, lymphocytes, platelets, albumin, INR, and hemoglobin. Model: We developed a data pipeline in Python in two stages: imputation and classification. The data was split 60/20/20 for training, validation, and testing. *a) Imputation:* We imputed the labs using machine learning. A

patient must have at least one lab in the first six months post-diagnosis to have imputation. *b) Classification:* Lab predictors were selected using univariate logistic regression ($p < 0.05$) before being fed to the ML models. We then evaluated commonly used ML models including logistic regression (LR), decision tree, random forest (RF), extreme gradient boosting (XGBoost), and support vector machine (SVM). Metrics included AUC, sensitivity, and specificity. **Results:** Out of 1799 patients (1965–2024), 323 were excluded. The mean age at diagnosis was 47.6 ± 16 years. 192 patients reached the outcome. We selected labs at a 3-month time point because it was the only time point at which AST and ALT significantly correlated with event in the univariate analysis. Significant predictors in the univariate logistic regression included ALP, INR, GGT, IgG, albumin, platelets, AST, and ALT. AUCs for LR, RF, XGBoost, decision tree, and SVM were 0.93, 0.91, 0.87, 0.86, and 0.80, respectively. **Conclusion:** ML models using standard labs at 3 months post-diagnosis can accurately predict survival in AIH. This supports early risk stratification. Moreover, both logistic regression and random forest are the best-performing models of prediction, with AUCs > 90%. Ongoing data collection aims to further improve model accuracy and build even more complex models for more robust predictions.

0213 | SELADELPAR IS ASSOCIATED WITH A SUSTAINED REDUCTION IN CHOLESTATIC MARKERS AND A CONSISTENT SAFETY PROFILE IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS TREATED UP TO 48 MONTHS IN THE ONGOING, OPEN-LABEL ASSURE STUDY

Dan Pratt[1] Eric Lawitz[2] Christopher Bowlus[3] Kyung min Kwon[4] Sarah Proehl[4] Xin Qi[4] Robert Kustra[4] Alejandra Villamil[5], [1]Autoimmune and Cholestatic Liver Center, Massachusetts General Hospital, Boston, MA, USA, [2]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, [3]Gastroenterology&Hepatology, University of California Davis School of Medicine, Sacramento, CA, USA, [4]Gilead Sciences, Inc., Foster City, CA, USA, [5]The Liver Autoimmunity Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

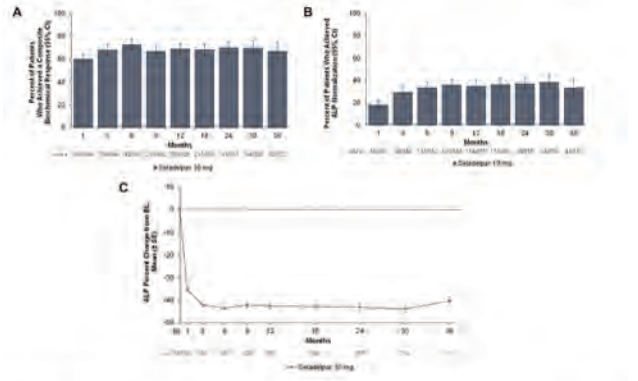
Background: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in patients (pts) intolerant to UDCA. Here, we report the latest interim, long-term biochemical efficacy and safety data in a pooled population of pts treated with SEL in ASSURE. **Methods:** The ASSURE study (NCT03301506) is an ongoing, open-label, long-term, Phase 3 trial of SEL in pts with PBC rolling over from the placebo-controlled, Phase 3 RESPONSE trial (NCT04620733) or with prior participation in legacy SEL trials. The Phase 2 and 3 parent studies for ASSURE required an inadequate response or

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

intolerance to UDCA. Using a data cutoff of 1/31/2025, pts were pooled starting with their initiation of SEL (at entry into RESPONSE for those randomized to SEL, and at entry into ASSURE for all other pts). Pts received blinded, daily oral SEL 10 mg in RESPONSE and open-label, daily oral SEL 10 mg in ASSURE. Efficacy endpoints included a composite biochemical response (CBR; ALP $< 1.67 \times$ the upper limit of normal [ULN], ALP decrease $\geq 15\%$ from baseline [BL], and total bilirubin $\leq$ ULN), ALP normalization, ALP percent change from BL, and other laboratory parameters summarized through 36 months (M). Safety was assessed by exposure-adjusted adverse events (AEs) per 100 pt-yrs of exposure through 48M. **Results:** Among 337 pts treated with open-label SEL 10 mg, 258 were treated for ≥ 2 yrs and 117 were treated for ≥ 3 yrs, with 122 pts reaching their 36M visit as of the data cutoff. At all time points, the majority of pts achieved a CBR: 69% (225/325) at 12M, 70% (181/258) at 24M, and 67% (82/122) at 36M (Figure A). ALP normalized in 35% of pts (114/325) who reached their 12M visit, with similar percentages of 37% (96/258) at 24M and 34% (41/122) at 36M (Figure B). Treatment with SEL resulted in sustained reductions in ALP, with mean percent changes from BL of −43% at 12M, −43% at 24M, and −40% at 36M (Figure C). Sustained reductions were also observed in ALT and GGT through 36M. SEL was well tolerated, with overall AEs reported in 83.2 pts per 100 pt-yrs in yr 1 and 62.3 in yr 4. **Conclusion:** SEL led to sustained reductions in biochemical markers of cholestasis with up to 36M of open-label treatment. SEL also appeared to be safe and well tolerated; no new safety signals were identified with up to 48M of follow up.

Figure. Composite Biochemical Response (A), ALP Normalization (B), and ALP Percent Change From BL (C) Through 36 Months of Open-Label Seladelpar Treatment



n/N = number of responders at each time point/total number of evaluable patients at each time point.

n = number of evaluable patients at each time point.

0214 | IMPACT OF LINERIXIBAT ON PHARMACODYNAMIC BIOMARKERS AND MEDIATORS OF CHOLESTATIC PRURITUS IN PRIMARY BILIARY CHOLANGITIS (PBC) IN THE PHASE 3 GLISTEN STUDY

Andreas Kremer[1] Christopher Bowlus[2] Janelle Lennie[3] Bishoy Hanna[3] Kerri Fuller[4] Sugato Das[5] Linda Casillas[3] Alexander Cobitz[3] Ciara Gorey[6] Jennifer Shannon[3] Philip Troke[6] Megan McLaughlin[3] Brandon Swift[7] Sumanta Mukherjee[3], [1]Dept of Gastroenterology & Hepatology, University Hospital Zurich, University of Zurich, Switzerland, [2]University of California Davis, Sacramento, CA, USA, [3]GSK, Collegeville, PA, USA, [4]GSK, Stevenage, UK, [5]GSK, Hyderabad, India, [6]GSK, London, UK, [7]GSK, Durham, NC, USA

Background: Cholestatic pruritus is common in PBC, affecting up to 89% of patients (pts) throughout the course of their disease. GLISTEN (NCT04950127), the largest investigational study for pruritus in PBC, investigated the efficacy and safety of linerixibat, a targeted ileal bile acid transporter inhibitor. This analysis evaluated the effects of linerixibat on pharmacodynamic biomarkers of bile acid synthesis and reabsorption (serum complement component 4 [C4] and fibroblast growth factor-19 [FGF-19]), as well as potential mediators of pruritus (total serum bile acids [TSBA], autotaxin [ATX] and interleukin [IL]-31). This study examined changes in biomarkers and pruritus mediators over 32 weeks, and correlations between biomarker levels, pruritus mediators and pruritus severity in pts receiving linerixibat over 24 weeks. **Methods:** GLISTEN was a Phase 3, randomized, double-blind, placebo-controlled study of 238 pts with PBC and moderate-to-severe pruritus at baseline. In the primary intervention period, pts received linerixibat 40 mg twice daily or placebo for 24 weeks; in the crossover period, pts either switched or maintained treatment for a further 8 weeks. Biomarkers were quantified at baseline and every 4 weeks through Week 32. Correlations between change from baseline (CFB) in biomarker levels versus CFB in weekly itch score (measured using a 0–10 worst itch numerical rating scale) were assessed post hoc. **Results:** Serum C4 significantly increased ($p < 0.001$), and FGF-19 significantly decreased ($p < 0.001$), with linerixibat versus placebo over 24 weeks (Table). These changes align with the pharmacology of linerixibat. Pruritus mediators were significantly reduced with linerixibat versus placebo over 24 weeks (Table: all $p < 0.001$). These reductions (TSBA, ATX, IL-31) were observed at Week 4 and maintained throughout the treatment period. Over the crossover period, pts who switched from linerixibat to placebo had decreases in C4 and increases in FGF-19, TSBA, ATX and IL-31. In the post hoc analysis, reductions in TSBA and IL-31 in linerixibat-treated pts weakly correlated with reductions in pruritus at Week 4 (TSBA: $r = 0.20$, $p = 0.04$; IL-31: $r = 0.24$, $p = 0.05$). Significant weak correlations were observed between changes in C4, FGF-19 and ATX in linerixibat-treated pts, and reductions in pruritus over time (C4: $r = -0.289$, $p < 0.0001$; FGF-19: $r = 0.205$, $p < 0.0001$; ATX: $r = 0.093$, $p = 0.028$). **Conclusion:** In pts with PBC and moderate-to-severe pruritus, linerixibat modulated C4 and FGF-19 levels, consistent with its mechanism of action. Linerixibat significantly reduced potential pruritus mediators versus placebo, which correlated with reductions in pruritus. These data support that linerixibat reduces TSBA and other potential mediators of cholestatic pruritus, supporting the biologic plausibility of its action. Furthermore, these effects were reversible upon linerixibat treatment discontinuation. Funding: GSK (212620)

Table. Summary of change from baseline in biomarkers in linerixibat versus placebo (reporting here over 24 weeks)

Biomarker	Ratio linerixibat to placebo			Sample size	
	LS mean ratio	95% CI	P-value	Linerixibat patient count	Placebo patient count
C4	2.55	(2.22, 2.93)	<0.001	119	116
FGF-19	0.58	(0.51, 0.65)	<0.001	118	116
TSBA	0.75	(0.66, 0.85)	<0.001	119	116
ATX	0.68	(0.52, 0.95)	<0.001	118	116
IL-31	0.53	(0.44, 0.65)	<0.001	65	70

ATX, autotaxin (measured as a surrogate of lysophosphatidic acid [LPA]); C4, serum complement component 4; CI, confidence interval; FGF-19, fibroblast growth factor-19; IL-31, interleukin 31; LS, least squares; TSBA, total serum bile acids.

Background: Primary biliary cholangitis (PBC) is a rare, autoimmune, cholestatic liver disease which greatly impacts overall health-related quality of life (HRQoL). Pruritus, fatigue, and sleep disturbance are frequent complaints in PBC. The burden of fatigue and sleep disturbances in patients with PBC is severe and has been difficult to adequately treat. Volixibat (VLX) is a minimally absorbed ileal bile acid transporter inhibitor which blocks the enterohepatic recirculation of bile acids. Treatment with VLX in the completed Part 1 (dose selection) of the VANTAGE study showed statistically significant and clinically relevant improvements in pruritus. Here, we explore the impact of VLX on fatigue and sleep in PBC. **Methods:** VANTAGE is a 28-week randomized, multicenter, double-blind, placebo (PBO)-controlled Phase 2b study in adults with PBC and cholestatic pruritus. The study has an adaptive design: a completed Part 1 period (1:1:1 randomization, VLX 20mg, 80mg or PBO BID) and an ongoing Part 2 confirmatory period (1:1 randomization, VLX 20mg BID or PBO BID). The primary efficacy endpoint of change in pruritus (Adult ItchRO) score from Baseline (BL) to Week 28 has been previously reported. Here we report data from Part 1 on fatigue and sleep to Week 28, assessed via two validated HRQoL tools (PBC-40 and PROMIS). VLX 20mg and 80mg arms were pooled for this analysis (VLX). Results are shown utilizing MMRM and descriptive statistics. **Results:** Thirty-one participants with moderate-to-severe pruritus were randomized (VLX = 20; PBO = 11). After VLX treatment, there was a trend towards greater improvements (LS mean [SE]) in fatigue (PBC-40: VLX -4.2 [1.7], PBO: -2.4 [2.8]; PROMIS Fatigue: VLX: -3.8 [1.9], PBO: -0.9 [3.2]) and sleep (PROMIS Sleep Disturbance: VLX: -4.3 [1.8], PBO: -0.9 [3.3]). A higher percentage of VLX-treated participants had a meaningful reduction on PROMIS-Fatigue scores (≥ 3 point reduction) compared to PBO (VLX: 47.1%; PBO: 16.7%). A higher proportion of VLX-treated participants reported normal/mild fatigue and sleep disturbances after 28 weeks of treatment compared to BL (Fatigue: BL: 8/14, W 28: 10/14; Sleep: BL: 10/14, W28: 13/14), with minimal changes in PBO-treated participants. **Conclusion:** VANTAGE Part 1 results support the hypothesis that efficacious pruritus treatment with VLX may result in improvements in sleep and fatigue in PBC. Improvements in fatigue and sleep will be further evaluated in the ongoing Part 2 period of the VANTAGE study.

Background: Liver stiffness measurements (LSM) by transient elastography is associated with advanced fibrosis and adverse clinical outcomes in PSC. We externally validated multivariable regression models using LSM to predict major clinical endpoints. **Methods:** In a retrospective PSC cohort from Toronto, we assessed the association between LSM and a composite outcome of decompensation (ascites, variceal hemorrhage, HE), liver transplant, or death. LSM was modeled as a time-dependent continuous (log-transformed) or categorical variable (<9.6, 9.6–14.4, >14.4 kPa) in multivariable Cox models adjusted for age, sex, PSC and IBD duration, and other time-dependent covariates (ALP, Tbili, plts, albumin). Final models were externally validated in 3 retrospective PSC cohorts: CALiD (13 U.S. centers), Edmonton (Canada), and Hamburg (Germany). Sensitivity analysis involved independent derivation of the logLSM model at each site, with pooled adjusted hazard ratios (aHR) via random-effects meta-analysis. **Results:** Amongst the Toronto derivation cohort, 1321 valid LSM from 2012-2023 from n = 403 (median age 34 y.o., 92% large-duct PSC, 61% male, 75% concurrent IBD, 9.5% overlap, 84 events) were evaluated. The final models incorporated LSM, age, sex, ALP and Tbili; other variables did not influence or worsened model performance (by AIC/BIC). There were 2,997 valid LSM amongst 3 external validation cohorts (CALiD: 1563 from n = 375, 64 events; Edmonton: 894 from n = 294, 95 events; Hamburg: 540 from n = 160, 37 events). LogLSM was independently associated with the composite outcome (pooled aHR 3.55, 95% CI: 2.96-4.27, Figure). Discrimination (by c-statistic) for the Toronto-derived multivariable logLSM model was 0.89, 0.84, and 0.89, with calibration slope of 1.00 (95% CI: 0.64-1.36), 0.98 (95% CI: 0.81-1.15), and 0.85 (95% CI: 0.66-1.04) for CALiD, Edmonton, and Hamburg, respectively. In the categorical LSM multivariable model, an LSM of 9.6-14.4 kPa was not significant (aHR 1.93, 95% CI: 0.86-4.32), while LSM >14.4 kPa remained prognostic (aHR 6.40, 95% CI: 3.48-11.8). Discrimination was 0.89, 0.84 and 0.86 with calibration slope of 1.00 (95% CI: 0.59-1.41), 0.98 (95% CI: 0.81-1.15), and 1.00

(95% CI: 0.77-1.24) for the CALiD, Edmonton, and Hamburg cohorts, respectively. **Conclusion:** Using data from four real-world cohorts, we externally validated multivariable models demonstrating liver stiffness measurement (LSM) as a predictor of decompensation, liver transplant, and/or death in PSC, supporting its use for longitudinal risk stratification and trial design.

Background: Hepatocellular carcinoma (HCC) is a heterogeneous disease with variable outcomes, yet existing molecular classifications lack clinical adoption. To overcome limitations in reproducibility and to account for mixed HCC/cholangiocarcinoma (CCA) tumors, we conducted a cross-lineage analysis of HCC and CCA. **Methods:** We analyzed 378 tumors from TCGA (HCC n = 345 and CCA n = 33) using multi-omic data (mutations, CNAs, mRNA/lncRNA expression, DNA methylation) and applied 4 clustering algorithms (COCA, CIMLR, iCluster, NEMO). A consensus 5-subtype classification was defined using NMF and translated into an mRNA-based classifier, which was validated in two external cohorts (ICGC-Japan, n = 240; ICGC-France, n = 161). Subtype features were compared to regulons for known transcription factors, zonation spatial signatures, immunotherapy response markers and previous HCC subtype classification. **Results:** We identified 5 distinct HCC subtypes: (1) cholangiocyte-like stem HCC (enriched in BAP1/IDH1 mutations, clustered with CCA- n = 36); (2) hepatocyte-like stem HCC (high AFP, stemness signatures, n = 78); (3) Wnt-pathway HCC (CTNNB1 mutations, n = 74); (4) focal genomic instability HCC (FIST, amplifications, TP53 mutations- n = 76); and (5) inflammatory HCC (low purity, immune infiltration- n = 70). Comparison with 6 existing classifications revealed the chol-like stem-HCC to be a distinct and aggressive subtype that was previously obscured in HCC-only analyses. Regulatory network analysis revealed proliferation-linked regulons enriched in both cholo-like and hep-like stem-like subtypes and metabolic regulons in Wnt-pathway and FIST HCCs (all $p < 0.01$). Immune profiling showed that inflammatory HCC exhibited strong anti-tumor immunity and association with signatures of ICI responsiveness, whereas chol-like stem HCC showed higher immunosuppressive infiltration, and Wnt-pathway HCC displayed T cell exclusion (all $p < 0.01$). Single-cell zonation analysis revealed a pericentral identity for Wnt-pathway HCC and periportal identity for chol-like stem HCC. Lastly, a 5-subtype ranscriptional classifier was validated it in 2 external cohorts, where it faithfully reproduced subtype distributions, molecular features (eg. CTNNB1/TP53 mut), clinical associations (eg. survival, vascular invasion) and immune signatures seen in TCGA, confirming the biological relevance of our subtypes. **Conclusion:** We present a new and refined molecular classification of HCC. By incorporating features from both HCC and CCA, we uncover an aggressive CCA-like stem HCC subtype. Immune profiling reveals striking subtype-specific differences, ranging from "cold" Wnt-pathway tumors to highly inflamed but immunosuppressive CCA-like HCC, and immunotherapy-responsive inflammatory HCCs. Lastly, we have developed a validated transcriptional classifier that provides a scalable tool for classifying tumors across diverse datasets.

★ 0218 | PER- AND POLYFLUOROALKYL SUBSTANCES, GENETIC SUSCEPTIBILITY, AND HEPATOCELLULAR CARCINOMA: A NESTED CASE CONTROL STUDY IN THE MULTIETHNIC COHORT

Jesse Goodrich[1] Hongxu Wang[1] Adelyn Paik[1] Syam Andra[2] David Conti[1] Lida Chatzi[1] Veronica Setiawan[1], [1]University of Southern California, [2]Icahn School of Medicine at Mount Sinai

Background: Per- and polyfluoroalkyl substances (PFAS) are a broad class of synthetic persistent organic pollutants with long biological half-lives that may increase the risk of Hepatocellular carcinoma (HCC), potentially by interacting with hepatic lipid metabolism associated genes. Since exposure to PFAS via food and water is ubiquitous, understanding whether PFAS exposure increases HCC risk may help identify interventions to reduce HCC incidence. We aimed to examine the associations between prediagnostic blood PFAS levels and risk of HCC, and to explore whether genetic factors associated with hepatic lipid metabolism modify these relationships. **Methods:** We analyzed 235 HCC cases and 235 controls matched on birth year, date of blood collection, sex, race/ethnicity, fasting status, and study area from the Multiethnic Cohort (MEC). Blood levels of 12 PFAS were measured from samples collected prior to diagnosis, and incident HCC cases were identified using the SEER registry. Associations between PFAS and HCC risk were evaluated using conditional logistic regression. To identify single nucleotide polymorphisms (SNPs) that may modify associations of PFAS and HCC, we used a candidate gene approach by identifying 21 SNPs from a validated polygenic risk score (PRS) on metabolic associated fatty liver disease (MASLD). Interactions between PFAS and these 21 SNPs, along with the interaction between PFAS and the MASLD PRS, were tested using conditional logistic regression. All models were adjusted for smoking, diabetes, dietary factors, weighted MASLD PRS, and genetic ancestry scores. **Results:** Two PFAS were associated with HCC risk. PFHpA was associated with 1.34 times higher odds of HCC (95% CI: 1.01-1.77; $p = 0.04$) and PFNA was associated with 1.32 times higher odds of HCC (95% CI: 1.01-1.73; $p = 0.045$). Further, the association between PFNA and HCC was modified by rs5117, an intron variant on the *APOC1* gene. In those with no risk alleles, PFNA was associated with 0.031 times lower risk of HCC (95% CI: 0.15-0.66), but in those with two risk alleles, PFNA was associated with 1.52 times higher risk of HCC (95% CI: 1.22-1.90; adjusted $p_{int} = 0.004$). No other PFAS were associated with HCC risk. **Conclusion:** PFHpA and PFNA were associated with higher risk of HCC, and the associations between PFNA and HCC appeared to be modified by genetic factors. Public health interventions to decrease exposure to these PFAS may help decrease incidence of HCC.

0219 | LONG - CHAIN ACYL - COA SYNTHETASE 4 (ACSL4): A NEWLY - IDENTIFIED DRIVER AT THE HEPATOCELLULAR CARCINOMA INVASIVE FRONT GOVERNING TUMOR INVASION, METASTASIS AND PATIENT PROGNOSIS

Yusufukadier Maimaitinijiati[1] Yuan Meng[1] Shizhong Yang[2] Zhiyu Chen[3] Jiahong Dong[2] Xiong Chen[1], [1]Hepatopancreatobiliary Center, People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China, [2]Hepatobiliary Pancreatic Center, Beijing Tsinghua Chang Gung Hospital, Beijing, China, [3]Department of Hepatobiliary Surgery, The First Hospital Affiliated to Army Medical University

Background: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide, posing a significant global health challenge. The tumor invasive front (TIF), as the most active site for tumor cell invasion, plays a pivotal role in cancer progression and metastasis. Identifying biomarkers at the TIF is crucial for

developing targeted therapies to disrupt HCC's invasive and metastatic potential. This study leverages spatial transcriptomic sequencing data from HCC clinical specimens and innovative gene screening algorithms to identify acyl-CoA synthetase long-chain family member 4 (ACSL4) as a novel TIF marker closely associated with HCC invasion, metastasis, and prognosis. **Methods:** We first applied an innovative gene screening algorithm to identify ACSL4 as a molecular biomarker of the HCC invasive front using spatial transcriptomic sequencing data. We then confirmed ACSL4's expression characteristics across various stages of HCC invasion and metastasis, including primary lesions, circulating tumor cells (CTCs), microvascular invasion (MVI), intrahepatic metastatic lesions, and extrahepatic distant metastases. The clinical value of ACSL4 was further demonstrated through a multi-center cohort study. Finally, we elucidated the functional mechanisms of ACSL4 using in vivo, in vitro experiments, and multi-omics joint analyses. **Results:** ACSL4 is specifically overexpressed in the TIF region of HCC and is involved in the entire metastatic process, from primary lesions to distant metastatic sites. The multi-center cohort study revealed that high ACSL4 expression was significantly associated with poorer overall survival and recurrence-free survival compared to low ACSL4 expression ($P < 0.05$). Furthermore, higher ACSL4 expression was more prevalent among patients who experienced recurrence than those without recurrence in both the multi-center cohort (37.19% vs. 25.62%) and the TCGA cohort (57.66% vs. 46.72%). ACSL4 expression levels were also significantly higher in tissue samples from patients with microvascular invasion (MVI) compared to those without MVI. In vivo and in vitro experiments indicated that ACSL4 promotes HCC invasion and metastasis by regulating arachidonic acid β-oxidation.
Conclusion: ACSL4 is a novel TIF biomarker that governs HCC invasion, metastasis, and patient prognosis. Our findings highlight its potential as a therapeutic target for HCC management.

0220 | SELECTED GENETIC VARIANTS RELATED TO ALTERED CHOLINE METABOLISM ARE ASSOCIATED WITH HISTOLOGICAL SEVERITY IN PATIENTS WITH MASLD

Callie Zaborenko[1] Tae-Hwi Schwantes-An[1] Marco Abreu[1] Jie Yao[2] Jingyi Tan[2] Xiuqing Guo[2] Jerome Rotter[2] Naga Chalasani[3] Brent Neuschwander-Tetri[4], [1]Indiana University School of Medicine, [2]The Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, [3]Indiana University Medical Center, [4]Saint Louis University

Background: Choline deficiency has been shown to be associated with steatotic liver disease and its severity. We investigated the association between genetic variants which may contribute to altered choline availability and metabolism and histological severity in patients with well characterized MASLD. **Methods:** Using 3,358 participants from the NASH CRN studies, we estimate logistic regressions predicting advanced fibrosis (≥ F3) and steatohepatitis (NAFLD Activity Score ≥ 4) from 23 SNPs in 11 candidate genes (*MTHFR, FMO3, MTR, CHDH, MTRR, BHMT, SLC44A1, CHKA, MTHFD1, PEMT, and RFC1*) which play role in choline metabolism. Sub-group analyses were conducted based on age, ancestry, BMI, and *PNPLA3* rs738409. Rare variant analysis was conducted among European (EUR) and Admixed American (AMR) adults. **Results:** The study cohort was 53% female, with mean age 40 years, mean BMI 34 kg/m2, 25% with advanced fibrosis, and 66% had steatohepatitis. SNPs in 4 genes, *CHDH*, *CHKA*, *FMO3*, and *PEMT,* showed strong and consistent relationships with advanced fibrosis and steatohepatitis (Table). *CHDH* rs12676 was related to higher odds of advanced fibrosis across full sample and all subgroups (full sample: OR = 1.19; 95% CI 1.04-1.36; p = 0.01). *CHKA* rs10791957 was protective against advanced fibrosis in males (OR = 0.82; 95% CI 0.68-0.99; p = 0.036). *FMO3* rs2266782 was also protective, especially in adults with two copies of *PNPLA3* rs738409, against advanced fibrosis (OR = 0.79; 95% CI 0.65-0.96; p = 0.016) and steatohepatitis (OR = 0.72; 95% CI 0.56-0.94; p = 0.018). *PEMT* rs12325817 was related to lower odds of advanced fibrosis across full sample and all subgroups (full sample: OR = 0.82; 95% CI 0.74-0.93; p = 0.001). In the rare variant analysis two genes, *MTHFD1* (Burden p = 0.03147) and *SLC44A1* (Burden p = 0.0490), were related to advanced fibrosis in EUR adults, but not AMR adults. No rare variants were associated with steatohepatitis. **Conclusion:** Both common and rare

variants related to choline metabolism are associated with advanced fibrosis in MASLD. However, the relationship with steatohepatitis is less robust. Across both outcomes, common variants in *CHDH* were consistently deleterious, whereas *CHKA*, *FMO3*, and *PEMT* were protective. Variants in these genes may provide insights into the heterogeneity of MASH pathogenesis and treatment targets.

Table: Summary of variants in four genes showing associations with advanced fibrosis and/or steatohepatitis in MASLD

Outcome	Gene	SNP	Groups	Direction	Sig count*
Advanced fibrosis (AF)	CHDH	rs12676	Everyone (full, females, not Obese, PNPLA3=1, PNPLA3=2); adults (full, males, not Obese, PNPLA3=1&2); EUR adults (full, not Obese)	Deleterious	12
AF	CHDH	rs9001	Everyone (full, females, PNPLA3=1, PNA3=2)	Deleterious	4
AF	CHKA	rs10791957	Everyone (full, males); adults (males); EUR adults (males, not Obese)	Protective	5
AF	CHKA	rs2512612	Everyone (full, males); adults (males); EUR adults (full, males, not Obese)	Protective	6
AF	CHKA	rs6591331	EUR adults (males)	Protective	1
AF	CHKA	rs7928739	EUR adults (males)	Protective	1
AF	FMO3	rs2266782	Adults (full, males)	Protective	2
AF	PEMT	rs12325817	Everyone (full, males, Obese, PNPLA3=0, PNPLA3=1); adults (full, PNPLA3=0)	Protective	7
AF	PEMT	rs3760188	Everyone (full, males, Obese, PNPLA3=0, PNPLA3=1); adults (full, PNPLA3=0)	Protective	7
AF	PEMT	rs4646343	Everyone (full, males, Obese, PNPLA3=0, PNPLA3=2)	Protective	5
NAS>4	CHDH	rs12676	Adults (PNPLA3=2)	Protective	1
NAS>4	CHDH	rs9001	Everyone (not Obese)	Deleterious	1
NAS>4	FMO3	rs2266782	Everyone (Obese, PNPLA3=2,); adults (full, males, PNPLA3=0&2); EUR adults (full, males, obese, PNPLA3=0&2)	Protective	11
NAS>4	PEMT	rs12325817	EUR adults (PNPLA3=0)	Protective	1
NAS>4	PEMT	rs3760188	EUR adults (PNPLA3=0)	Protective	1
NAS>4	PEMT	rs4646343	EUR adults (PNPLA3=0)	Protective	1

*Sig count – the number of groups which had a significant relationship between the SNP and outcome of interest. The twenty-four groups: everyone, all females, all males, obese participants, not obese participants, PNPLA3=1 participants, PNPLA3=2 participants, PNPLA3=3 participants, all adults, all adult females, all adult males, obese adults, not obese adults, PNPLA3=1 adults, PNPLA3=2 adults, PNPLA3=3 adults, EUR adults, EUR adult females, EUR adult males, obese EUR adults, not obese EUR adults, PNPLA3=1 EUR adults, PNPLA3=2 EUR adults, and PNPLA3=3 EUR adults.

★ 0221 | GENOME-WIDE CRISPR SCREEN IDENTIFIES LOSS OF FUNCTION OF DNAJC22 PROTECTS AGAINST STEATOTIC LIVER DISEASE

Aaron Hakim[1] Gavin Schnitzler[2] Michael Cho[3] Cindy Zheng[2] John Doench[2] Rajat Gupta[2], [1]Beth Israel Deaconess Medical Center, [2]Broad Institute of Harvard and MIT, [3]Channing Division of Network Medicine

Background: The accumulation of lipid droplets within hepatocytes is a causal mechanism for driving progressive liver disease. Identifying the genes which regulate lipid accumulation in hepatocytes and are associated with protection from liver disease across human biobanks may identify novel therapeutic targets. **Methods:** We performed a pooled genome-wide CRISPR-Cas9 knockout screen to systematically identify genes which regulate fatty-acid triggered neutral lipid accumulation in human hepatocytes. We integrated our CRISPR screen hits with human genome-wide association studies (GWAS) to prioritize a gene of previously unknown function, *DNAJC22*, for functional validation as a genetic mediator of steatotic liver disease. **Results:** Our CRISPR screen identified 829 hits (FDR < 0.05), including canonical lipogenesis/lipolysis genes, Mendelian lipid storage disorder genes, and multiple drug targets currently in clinical trials for steatotic liver disease. Knockout of *DNAJC22* by CRISPR-Cas9 or silencing by RNA interference dramatically decreased lipid accumulation in hepatocytes. We show that *DNAJC22* is a liver-enriched, hepatocyte-specific chaperone that interacts with VCP/p97, an inhibitor of adipose triglyceride lipase (ATGL). A rare (minor allele frequency 0.014), predicted pathogenic variant in *DNAJC22* (rs146774114, p.Ala163Thr) demonstrated significant protection against chronic liver disease across multiple human biobanks. The minor allele associated with reduced risk of cirrhosis in a multi-ancestry GWAS (n = 15,225 cases, n = 1,564,786 controls, odds ratio [OR] = 0.85, p = $7.8x10^{-03}$); reduced risk of all-cause liver disease in FinnGen (n = 15,135 cases, n = 485,213 controls, OR = 0.69, p = $1.6x10^{-04}$); reduced risk of steatotic liver disease in Million Veteran Program (n = 90,408 cases, n = 128,187 controls, OR = 0.85, p = $2.8x10^{-08}$); and reduced liver injury in UK Biobank (n = 312,672, alanine aminotransferase [ALT] p = $4.2x10^{-07}$, aspartate aminotransferase [AST] p = $4.0x10^{-05}$). We identified significant gene-environment interactions in UK Biobank between *DNAJC22* rs146774114 and body mass index in association with ALT and AST (p-interaction $1.8x10^{-06}$ and $1.5x10^{-03}$, respectively). **Conclusion:** Utilizing high-throughput genetic screens and integrating with human genetic association studies, we identified and validated *DNAJC22* as a novel therapeutic target for steatotic liver disease. Imbalances in ATGL-mediated triglyceride hydrolysis may reflect a central mechanism of steatotic liver disease.

0222 | AN EPIGENETIC ATLAS OF MASH: ULTRA-DEEP PAIRED LIVER TISSUE AND PLASMA CFDNA METHYLATION SEQUENCING ENABLES NON-INVASIVE MEASUREMENT OF PATHWAY ACTIVITY

Soheil Damangir[1] Manal Abdelmalek[2] Georgia Sofia Karachaliou[3] Cynthia Guy[3] Leila Bazargan[1] Chong Lu[1]

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Pourya Naderi[4] Hamed Amini[1] Rohit Loomba[5] Anna Mae Diehl[3], [1]Hepta Bio, Inc., [2]Mayo Clinic Rochester, [3]Duke University, [4]Beth Israel Deaconess Medical Center, Harvard Medical School, [5]University of California, San Diego

Background: Noninvasive profiling of pathways involved in MASH pathogenesis remains a challenge, hindering identification of diagnostic and therapeutic targets. Therefore, a technology that enables interrogation of liver methylome, and resultant changes in activity of pathways driving MASLD, from a simple blood draw would be transformational. The aim of this study is to present a novel technology and related data for such measurement. Using methylation sequencing of paired liver tissue and circulating cell free DNA (cfDNA) for the first time we 1) define tissue-specific differentially methylated regions (DMRs) related to MASH, 2) demonstrate their direct detectability in blood, and 3) quantify the relevant pathways that are differentially methylated. **Methods:** Plasma samples from 276 Duke MASLD Biobank subjects were analyzed with deep methylation sequencing (methyl-seq); a subset (n = 96) underwent further ultra-deep methyl-seq; and deep methyl-seq was done on paired liver tissue on a further subset (n = 50). Those 50 subjects serve as the discovery cohort; the rest as validation. High-confidence DMRs between clinically significant fibrosis (F2/3/4) vs. low fibrosis (F0/1) groups were extracted using a probabilistic model. Pathway enrichment analysis was used to identify relevant hyper- and hypomethylated pathways in tissue, i.e. discovery, and in the paired ultra-deep plasma samples, further verified in the independent validation cohort. We used the validated method on the plasma samples to discover pathways involved in MASH on a large scale. **Results:** We identified 1765 loci that were differentially methylated in liver tissue (FDR < 0.05). In the significant fibrosis group several pathways were hypermethylated (FDR < 0.05) including those related to WNT and VEGF signaling, while loci enriched in several pathways were hypomethylated (FDR < 0.05) including those associated with TGF-beta and immune cell activation. Functional analysis of tissue-specific signatures revealed enrichment of hypermethylated loci (FDR < 0.05) in distinct hepatocyte populations, while hypomethylated loci were enriched in stromal cells. DMRs in liver were differentially methylated in paired plasma cfDNA samples ($p < 0.01$) and in the validation cohort ($p < 0.05$), showing the utility of cfDNA as a measure of epigenetic changes in liver. Importantly, this enabled larger scale functional analysis using all 276 plasma samples which in addition to the abovementioned, revealed differential methylation (FDR < 0.05) in pathways implicated in MOAs of MASH therapies currently under investigation. **Conclusion:** This technology captures MASH-related changes in the liver methylome from a blood sample. This enables noninvasive measurement of differential activation of signaling pathways implicated in MASH pathogenesis, providing a novel approach to personalize diagnosis and treatment of MASH as well as monitoring changes related to the MOA of the treatment.

★ 0223 | CXCR3+ MONOCYTE-DERIVED MACROPHAGES CONTRIBUTE TO CONGESTIVE PORTAL HYPERTENSION THROUGH THE GLYCOLYSIS-DEPENDENT SYNTHESIS OF VASOACTIVE MOLECULES: INSIGHTS FROM MULTIOMICS

Papawee Sutthirat[1] Nidhi Jalan-Sakrikar[1] Sofia Jerez Ortega[1] Vijay Shah[1] Moira Hilscher[1], [1]Mayo Clinic Rochester

Background: Congestive hepatopathy (CH) and Fontan associated liver disease (FALD) can lead to portal hypertension (PHTN) which is associated with morbidity and mortality. Our prior studies show that peri-central (zone 3) liver sinusoidal endothelial cells (LSECs) express CXCL9 in CH. Treatment with an inhibitor of CXCR3, the cognate receptor for CXCL9, significantly decreases portal pressure and macrophage recruitment in a murine model of CH (partial ligation of the inferior vena cava, pIVCL). We hypothesize that CXCR3+ monocyte-derived macrophages (MoMF) drive congestive PHTN through the synthesis of vasoactive molecules. **Methods:** Integration of single-nucleus RNA sequencing (snRNA-seq) data, CosMx Spatial Molecular Imager (SMI), and imaging mass cytometry (IMC) was performed to analyze zone-specific changes in gene expression and cell-cell interactions in liver samples from patients with Fontan-associated liver disease (FALD) and healthy controls. Intra-hepatic leukocytes (IHLs) were isolated from wild-type (WT) mice 6 weeks after pIVCL or sham procedures for cytometry by time of flight (CyTOF). MoMFs were isolated from WT mice and treated with 2-deoxy-D-glucose (2-DG), an inhibitor of the rate-limiting glycolysis enzyme hexokinase-2 (HK2), or transfected with siRNA targeting HK2 (siHK2) to inhibit glycolysis. Mechanistic studies utilized RT-PCR to analyze mRNA expression and ELISA to quantify vasoactive molecule, thromboxane-A2 (TXA2). **Results:** CosMx SMI and IMC analyses revealed spatial changes in immune cell populations and gene expression patterns in FALD. While most immune cell populations were unchanged, intra-hepatic macrophages (IHMs) were significantly increased in FALD compared to controls. CyTOF performed on IHLs isolated after pIVCL identified a unique subpopulation of CXCR3+/CCR2+/CXCL4+ MoMFs recruited in CH. Spatial mapping identified enrichment of CXCR3+ [MH1] IHMs in zone 3. Pathway analysis of CosMx SMI data identified upregulation of glycolysis and arachidonic acid metabolism pathways in CXCR3+ MoMFs localized to zone 3, including the enzyme *COX-1* (log2FC 411.66, *p*-value < 0.05), which generates vasoconstrictive TXA2. We hypothesized that glycolysis fuels the COX-1-mediated synthesis of TXA2 in MoMFs in FALD. Treatment of WT MoMFs with 2-DG led to a significant decrease in COX-1 expression and TXA2 production (*p*-value < 0.05). WT MoMFs transfected with siHK2 secrete less TXA2 than siControl MoMFs (*p*-value < 0.0001). Notably, thromboxane receptor (*TBXA2R*) expression was significantly upregulated in hepatic stellate cells (HSCs) in FALD (log2FC 1.66, *p*-value < 0.03), suggesting that TXA2 signaling modifies HSC contraction. **Conclusion:** CXCR3+ MoMFs recruited to zone 3 in FALD demonstrate enhanced glycolysis and TXA2 production. We propose that TXA2 generated by MoMFs promote contraction of HSCs, leading to sinusoidal constriction and PHTN.

0224 | PRESSURE-INDUCED ENDOTHELIAL FIBULIN-7 MODULATES HSC PHENOTYPE AND LOWERS PORTAL PRESSURE IN EXPERIMENTAL CIRRHOSIS

Raül Pastó[1] Albert Gibert-Ramos[1] Peio Aristu[2] Anabel Fernández-Iglesias[2] Sergi Guixé-Muntet[1] Jordi Gracia-Sancho[1], [1]Liver Vascular Biology Lab, IDIBAPS - Hospital Clínic de Barcelona - CIBEREHD, [2]Liver Vascular Biology, IDIBAPS - Hospital Clínic de Barcelona - CIBEREHD

Background: Portal hypertension (PH) is a frequent and life-threatening complication of chronic liver disease (CLD). Beyond being a consequence of liver microvascular dysfunction and fibrosis, elevated porto-sinusoidal pressure directly alters liver sinusoidal endothelial cells (LSEC). This study aimed to identify and characterize PH-induced effectors that contribute to CLD pathophysiology. **Methods:** RNAseq was performed in primary LSEC cultured under physiological or pathological pressure using a microfluidic liver-on-a-chip device. Genes dysregulated by pressure were compared to genes dysregulated in 3 preclinical models of cirrhosis (CCl_4, TAA and BDL rats). The expression of the most promising effector, fibulin-7 (FBLN7), was validated in CCl_4-induced cirrhotic rats (qPCR and IF), and characterized in liver biopsies (WB) and in blood plasma (ELISA) from healthy and cirrhotic patients with PH ($n = 13$ CLD vs $n = 8$ controls and $n = 49$ CLD vs $n = 11$ controls, respectively). Functional studies used siRNA/adenovirus to knockdown/overexpress FBLN7 and assess its effects on LSEC phenotype and paracrine interactions. Finally, AdFBLN7 (or AdGFP control) was administered *in vivo* to cirrhotic rats and hepatic and systemic hemodynamics were measured 6 days later ($n = 9$/group). **Results:** Thirty-one genes were commonly dysregulated by pressure *in vitro* and by cirrhosis *in vivo*, being FBLN7 the most consistently upregulated. Molecular analysis confirmed a +92% protein increase in cirrhotic rats, predominantly in LSEC. FBLN7 upregulation in CLD was validated in human samples ($fc = 3$ in liver tissue and +38% in plasma). *In vitro* silencing of FBLN7 in primary LSEC mainly dysregulated cell surface and extracellular proteins, suggesting a possible paracrine effect. Interestingly, the supernatant of human endothelial cells overexpressing FBLN7 ameliorated the phenotype of primary human hepatic stellate cells (HSC), reducing *ACTA2* (-38%) and *PDGFRB* (-33%). All $p < 0.05$. *In vivo* overexpression of FBLN7 significantly improved PH (portal pressure: 10.46 +/- 0.59 mmHg in AdGFP vs 8.88 +/- 0.19 mmHg in AdFBLN7; -15%), whilst no effects in mean arterial pressure and portal blood flow were observed. Hemodynamic benefits were associated with a reduction in liver fibrosis (-26%, $p = 0.1$). **Conclusion:** FBLN7 is a pressure-induced endothelial effector that is upregulated in experimental and human CLD, modulates LSEC-HSC paracrine signaling, and improves hepatic hemodynamics when overexpressed *in vivo*. These findings identify FBLN7 as a promising therapeutic target for the management of PH.

0225 | DIRECT FXA-INHIBITOR EDOXABAN IMPROVES PORTAL HYPERTENSION IN EXPERIMENTAL TOXIC AND METABOLIC FIBROSIS MODELS

Katharina Bonitz[1] Thomas Sorz-Nechay[2] Henriette Horstmeier[2] Vlad Taru[2] Georg Kramer[2] Oleksandr Petrenko[2] Katja Sommer[2] Benedikt Simbrunner[2] Kerstin Zinober[2] Hubert Scharnagl[3] Michael Trauner[2] Philipp Schwabl[2] Thomas Reiberger[2] Benedikt Hofer[2], [1]Medical University Vienna, [2]Medical University of Vienna, [3]University Hospital Graz

Background: Protease-activated receptors (PARs) mediate activation of hepatic stellate cells and increase inflammatory cell recruitment. In this study we investigate the effects of the direct FXa (PAR agonist) inhibitor Edoxaban in experimental liver cirrhosis. **Methods:** Liver fibrosis was induced in male C57BL/6 mice by either oral gavage of carbon tetrachloride (CCl_4, 2mL/kg, 3x/week) for 12 weeks (Peak-CCl4), or choline-deficient L-Amino acid defined high fat diet (Peak-CDAHFD). Healthy controls received either olive oil or standard CHOW. Edoxaban (EDOX, 2x/day, 10mg/kg) was administered concomitantly during the last two weeks of disease induction (EDOX-CCl4 and EDOX-CDAHFD) ($n = 8$-12). To assess disease severity, we quantified portal pressure (PP), collagen proportionate area (CPA) and serum transaminases. For mechanistic understanding we performed FACS, immunohistochemistry (IHC) and whole liver transcriptomics, which was analyzed using DESeq2. **Results:** At peak disease severity, both models showed significant fibrosis and elevated PP. EDOX treatment led to a significant reduction in PP in both models (Peak-CCl4: 9.06 ± 0.89 vs. EDOX-CCl4: 7.22 ± 1.23 mmHg; Peak-CDAHFD: 7.40 ± 1.03 vs. EDOX-CDAHFD: 6.11 ± 1.11 mmHg) and liver injury markers were reduced in the CCl4 model (AST: Peak-CCl4: 5362 ± 4168 vs. EDOX-CCl4: 1374 ± 1646 U/L; ALT: Peak-CCl4: 7529 ± 5726

vs. EDOX-CCl4: 2547 ± 2636 U/L). Histologically, CPA was not affected by EDOX, yet IHC showed a reduction in aSMA with EDOX in the CDAHFD model, indicating reduced HSC activation. Furthermore, EDOX significantly reduced hepatic macrophage infiltration on F4/80 IHC in both models. This was confirmed by FACS profiling in the CDAHFD model, showing less hepatic macrophages and neutrophils with EDOX treatment. On a transcriptomic level Gene set enrichment analysis (GSEA) and transcription factor inference revealed that EDOX reduced proinflammatory gene expression in both models, with a particularly pronounced decrease of NFkB activity in the CCl4 model. EDOX also led to a restoration of metabolic activity in both models, including pathways related to fatty acid, bile acid and xenobiotic metabolism. **Conclusion:** Edoxaban treatment induced significant improvements in portal hypertension in two mouse models of liver disease progression. Mechanistically, Edoxaban acted by ameliorating the proinflammatory hepatic environment, as shown by reduced macrophage infiltration and suppressed NFkB-modulated proinflammatory pathways.

0226 | INHIBITION OF H2S PRODUCTION REDUCES PORTAL PRESSURE BY DECREASING INTRAHEPATIC RESISTANCE IN RATS WITH CIRRHOSIS

Raffaele Buono[1] Marika Crescenzi[1] Massimo Bolognesi[1] Marco Di Pascoli[1], [1]Padua University

Background: Hydrogen sulfide (H2S) is a gasotransmitter known for its vasodilatatory properties, and it is also involved in regulating oxidative stress, inflammation and fibrosis in the liver. However, its role in the development of portal hypertension and complications of cirrhosis is not clear. **Methods:** We evaluated the hemodynamic effects of *in vivo* inhibition of H2S production in a rat model of experimental cirrhosis. Eight control rats and sixteen rats with bile duct ligation-induced cirrhosis were studied. Eight cirrhotic rats were treated with propargylglycine (PAG; 30 mg/kg via intragastric gavage), a specific inhibitor of cystathionine γ-lyase (CSE), the main source of H2S in the cardiovascular system and liver. Portal and systemic pressures were measured via polyethylene-50 catheters. Small resistance mesenteric arteries were mounted on a wire myograph system, and dose-response curves to acetylcholine (ACh) and sodium hydrosulphide (NaHS), an H2S donor, were evaluated. Plasma levels of ALT, creatinine and bilirubine were assessed in cirrhotic rats. Moreover, hepatic mRNA expression of inducible nitric oxide synthase (iNOS), endotelial nitric oxide synthase (eNOS), IL-6, TGF-β, collagen I, CSE, cystathionine-β-synthase (CBS), and glutathione synthetase (GSS) was evaluated by Taqman assays Real Time PCR in cirrhotic rats. **Results:** In cirrhotic rats, PAG treatment significantly reduced portal pressure (10.4 ± 2.7 mmHg versus 16.0 ± 3.9 mmHg, $P = < 0.05$) without affecting systemic pressure. No differences were observed in mesenteric artery responses to ACh or NaHS between treated and untreated cirrhotic rats. Treated cirrhotic rats had significantly lower creatinine (24.9 ± 7.0 μmol/L versus 34.6 ± 7.9 μmol/L; $P = 0.026$) and ALT levels (23.7 ± 19.0 U/L vs 99.7 ± 21.7 U/L; $P = < 0.001$), with no significant differences in bilirubin levels. In the liver, PAG reduced the expression of CBS ($P = 0.032$) and eNOS ($P = 0.016$), and increased the expression of iNOS ($P = 0.03$), with no effect on CSE. In the liver, PAG also reduced IL-6 ($P = 0.008$), TGFβ ($P = 0.008$), and collagen I ($P = 0.008$), while increasing GSS ($P = 0.016$). **Conclusion:** In vivo inhibition of H2S synthesis in cirrhotic rats reduces portal pressure and the expression of markers of hepatic inflammation and fibrosis, without no effects on mesenteric vasodilation. These findings suggest that targeting H2S may represent an intriguing therapeutic strategy to impact on portal hypertension by acting on intrahepatic resistance.

0227 | DYSFUNCTIONAL KYNURENINE METABOLISM PROMOTES NEUROINFLAMMATION DURING HEPATIC ENCEPHALOPATHY DEVELOPMENT

Michitaka Matsuda[1] Eiji Kakazu[1] Tatsuya Kanto[1], [1]JIHS, National Institute for Global Health and Medicine

Background: Hepatic encephalopathy (HE) is a severe neurologic complication in patients with liver disease. While metabolic dysfunction and neuroinflammation underlie HE pathogenesis, what and how metabolites contribute to HE pathogenesis has not been specified. The study aims to identify the metabolites developing HE and elucidate the underlying mechanisms. **Methods:** Bile duct ligation (BDL) was conducted on C57BL/6 mice to make the HE model. The Open field test evaluated the neurobehavioral change of the mise. The Visium spatial transcriptome and CyTOF single-cell immune profiling were used to analyze the cellular dynamics in the brain during HE development. The mouse brain, liver, and blood were used for metabolomics to identify HE-associated metabolites. HE-associated metabolites, including Kynurenine, were measured in the serum of the patients with liver diseases. **Results:** The mice revealed decreased locomorbidity and anxiety-like behavior by OFT from 6 days after BDL induction. The brain spatial transcriptomics revealed that specific brain regions (e.g. cortex, striatum) upregulated neuroinflammation-associated genes, such as IL1b and Icam1. Brain immune profiling revealed an increased pro-inflammatory macrophage subpopulation that was distinguished from resident microglia, indicating the involvement of neuroinflammation in HE development. Importantly, no hyperammonemia was observed at this early stage, suggesting the contribution of non-ammonia factors to HE development. Metabolomics defined Kynurenine, which was commonly observed in the HE model mice's blood, liver, and brain and patients' serum with decompensated cirrhosis. Systemic administration of Kynurenine upregulated IL1b and Icam1 in the brain and induced abnormal behavior in the mice. IDO, which metabolizes Tryptophan into Kynurenine, was upregulated in the liver of HE model mice and cirrhosis patients. Oral administration of 1-MT, an IDO inhibitor, suppressed IL1b and Icam1 in the BDL mice. **Conclusion:** The brain immune and metabolomic profiling of the mouse model and patients delineated Kynurenine as a novel immunometabolic factor increased early in HE development. Kynurenine could be a novel biomarker and therapeutic target of HE.

0228 | CRUCIAL ROLE FOR ALBUMIN TO RESCUE IMPAIRED B CELL FUNCTION AND VIABILITY IN PATIENTS WITH ACUTELY DECOMPENSATED CIRRHOSIS

Berta Romero-Grimaldo[1] Mireia Casulleras[2] Bryan Contreras[1] Marta Duran-Güell[2] María Belén Sánchez-Rodríguez[2] Carlos Rojano Alfonso[2] Giuliana Magri[3] Javier Fernández[4] Richard Moreau[3] Cristina López-Vicario[1] Joan Claria[1], [1]Biochemistry and Molecular Genetics Service, FCRB-IDIBAPS, CIBERehd, EF CLIF, [2]Biochemistry and Molecular Genetics Service, FCRB-IDIBAPS, EF CLIF, [3]European Foundation for the Study of Chronic Liver Failure (EF CLIF), [4]Liver Unit, FCRB-IDIBAPS, CIBERehd, EF CLIF

Background: Lymphopenia is a risk factor for mortality in patients with liver cirrhosis. In this study we investigated the functional status of B lymphocytes in patients with acutely decompensated (AD) cirrhosis. In addition, since recent studies have shown that AD patients receiving albumin infusions had lower mortality and incidence of infections, we also explored the direct effects of albumin on B cells. **Methods:** B cell immunophenotyping was performed by flow cytometry in peripheral blood from 36 patients with AD cirrhosis and 18 healthy subjects. In vitro studies were performed in peripheral blood mononuclear cells (PBMCs) isolated by Ficoll and B cells isolated by magnetic-activated cell sorting. Cells were incubated with human serum albumin (15 mg/mL) or vehicle for increasing periods of time (24-72 hours) with and without T-dependent or T-independent stimuli. Gene expression was determined by qPCR and Fluidigm and cell proliferation and viability by flow cytometry. Immunoglobulin and cytokine/chemokine levels in cell supernatants were measured by ELISA and in a Milliplex magnetic bead panel, respectively. **Results:** Compared to healthy subjects, PBMCs and B cells from patients with AD cirrhosis showed reduced viability and lower capacity to produce immunoglobulins under both resting conditions and following T-dependent and T-independent stimulation. Incubation of PBMCs and B cells with albumin upregulated immunoglobulin gene expression and increased the production of IgG, specially of the IgG subclass 2, which responds to bacterial capsular polysaccharide antigens. Again, responses to albumin were observed under both resting conditions and following T-dependent and T-independent stimulation. Under resting conditions, albumin also increased the release of B cell-activating cytokines/chemokines like IL-6, IL-4 and CXCL10. Furthermore, albumin enhanced B cell viability and induced the expression of the gene coding for activation-induced cytidine deaminase (AID), an essential enzyme for the humoral adaptive immune response. **Conclusion:** These data provide evidence of the ability of albumin to boost B cell function and to expand

their viability, which are seriously compromised in patients with AD cirrhosis. **Disclosures:** Berta Romero-Grimaldo: Nothing to Disclose, Mireia Casulleras: Nothing to Disclose, Bryan Contreras: Nothing to Disclose, Marta Duran-Güell: Nothing to Disclose, María Belén Sánchez-Rodríguez: Nothing to Disclose, Carlos Rojano Alfonso: Nothing to Disclose, Giuliana Magri: Nothing to Disclose, Javier Fernández: Nothing to Disclose, Richard Moreau: Nothing to Disclose, Cristina López-Vicario: Nothing to Disclose, Joan Claria: Nothing to Disclose

★ 0229 | TEMPORAL TRENDS AND GEOGRAPHIC DISPARITIES IN NAFLD INCLUDING CIRRHOSIS ACROSS THE UNITED STATES, 1990–2021

Yashkumar Kamani[1] Mahendra Kumar[2] Sandeep Kotnani[3] Raghava Rao Alluri[4] Mahir Modi[5] Madhu babu Adusumilli[6] Jainil Parikh[7] VISHRANT AMIN[8] Hardik Desai[9], [1]BronxCare Health System, [2]Sardar Patel Medical College, Bikaner, India, [3]Rutgers Monmouth Medical Center, [4]Prime South GME Consortium/Harlingen Medical Center Program, [5]GCS Medical College Hospital and Research Centre, [6]HCA Ocala Florida hospital -UCF, [7]GMERS MEDICAL COLLEGE, GOTRI, VADODARA, [8]HMH JFK University Medical Center, [9]Independent Clinical and Public Health Researcher

Background: Nonalcoholic fatty liver disease (NAFLD), including cirrhosis, has emerged as a leading cause of chronic liver disease globally, driven by rising rates of obesity, metabolic syndrome, and sedentary lifestyles. Despite its increasing clinical and public health significance, age- and sex-specific trends in the burden of NAFLD across the United States remain under characterized, especially over long-term periods. **Methods:** We estimated the burden of NAFLD, including cirrhosis, in the United States from 1990 to 2021 utilizing standardized global burden of disease study 2021. Outcomes assessed included total prevalence, deaths, and disability-adjusted life years (DALYs), years lived with disability (YLDs) stratified by age group, sex, and state-level geography. Annual percentage change (APC) in age-standardized incidence rate (ASIR), mortality rate (ASMR), and DALY rate (ASDALR) was calculated using Joinpoint regression to quantify temporal trends over the study period. **Results:** Between 1990 and 2021, the total prevalence of NAFLD rose from 23.2 million (95% UI: 21.3–25.4) to 44.6 million (40.7–48.6), deaths increased from 2,607 (1,826–3,516) to 5,520 (3,799–7,563), and DALYs doubled from 73,608 (52,004–100,811) to 147,584 (101,373–206,069). ASIR, ASMR, and ASDALR showed APC of +0.64%, +0.58%, and +0.54%, respectively. At the subnational level, the highest APC in ASIR was observed in Tennessee (+0.81%), followed by Kentucky (+0.76%) and North Dakota (+0.70%). For ASMR, the greatest increases occurred in West Virginia (+2.11%), Oklahoma (+1.89%), Kentucky (+1.82%), and Tennessee (+1.79%). Age-specific analysis revealed the highest APC in incidence among individuals under 20 years (+0.83%), followed by those aged 20–54 years (+0.70%) and 55 years and above (+0.52%). Sex-specific trends showed a disproportionately higher burden among females, with APCs in ASIR of 0.56% (female) versus 0.70% (male), in ASMR of 0.79% (female) versus 0.32% (male), and in ASDALR where females experienced a slight increase (+0.14%) while males showed a decline (–0.3%). **Conclusion:** From 1990 to 2021, NAFLD burden in the U.S. more than doubled, with the steepest rises among youth, females, and southern states—signaling the need for early, targeted, and region-specific interventions. The shifting epidemiology toward younger age groups highlights a critical window for prevention before progression to advanced liver disease.

★ 0230 | EXPLANATORY MODELS OF WEIGHT AND LIVER DISEASE AMONG PATIENTS WITH MASLD: A QUALITATIVE STUDY

Megan Pham[1] Sriya Kakarla[1] Myriam Ibarra[1] Yarian Garcia-Alayon[1] Crystal Arguelles[1] Alexis Moreleon[1] Maya Balakrishnan[2], [1]Baylor College of Medicine, [2]Ben Taub General Hospital

Background: Effective counseling for patients with metabolic dysfunction-associated steatotic liver disease (MASLD) requires understanding how they conceptualize their weight and liver disease. Patients' beliefs about the causes of weight gain and weight loss strategies influence their motivation and engagement in behavior change. This qualitative study explored explanatory models of body

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

weight, liver disease, and weight loss among Hispanic adults with MASLD- a high-risk population in the United States. **Methods:** We conducted in-depth interviews with 51 patients with BMI $\geq$ 25 kg/m^2 and MASLD, purposively sampled and stratified by gender and acculturation status. Using framework analysis, we assessed how they conceptualized their body weight and MASLD diagnosis. **Results:** Three major themes emerged. First, there were gender differences in how patients conceptualized their weight. Men tended to attribute their weight to long-term lifestyle behaviors, while women contextualized weight in relation to life transitions, emotional stress, hormonal/medical factors, and social roles. Secondly, while men generally described a linear causal link between health behaviors, their weight, and MASLD, women more frequently offered complex explanations incorporating genetics, stress, or medication side effects into their understanding of liver disease. Third, across genders, patients perceived their excess weight as the root cause of barriers hindering their ability to lose weight. They described physical (e.g., pain, fatigue) and psychosocial (e.g., depression, fear of failure) challenges from being overweight that made it hard to initiate or sustain weight loss behaviors. **Conclusion:** To provide effective counseling that supports meaningful weight loss in patients with MASLD, it is essential to understand how patients perceive their weight and liver disease, as these beliefs strongly shape their motivation and capacity for behavior change. Our study highlights that patients often viewed their weight as a physical and psychological barrier impeding their ability to adopt and sustain lifestyle changes. These perceptions were deeply rooted in personal and social contexts shaped by gender, stress, and life experiences. Recognizing and addressing these explanatory models is key to providing culturally sensitive, gender-informed, and patient-centered care that supports long-term change.

★ 0231 | DOUBLE TROUBLE: A 25-YEAR NATIONWIDE ANALYSIS OF CHRONIC LIVER DISEASE IN THE ERA OF METABOLIC SYNDROME

Simran Joshi[1] Muhammad Ali[2] Husnain Ahmad[3] Corinne Caissie[1] Muhammad Khan[4] Sushrut Ingawale[5] Muhammad Rahim[3] Salman Attari[6] Rishi Chowdhary[7] Susan Feldman[8] Mohammad Islam[1] Marquise Soto[9] Cheng-Hung Tai[1], [1]Yale New Haven Health/Yale University School of Medicine, [2]Jinnah Postgraduate Medical Center, [3]Shalamar Medical and Dental College, [4]Bacha Khan Medical College, [5]Quinnipiac University - Frank H Netter MD School of Medicine, [6]Asian Institue of Medical Sciences, [7]Metrohealth Medical Center, [8]Susanfeldm@gmail.com, [9]Massachusetts General Hospital/Harvard Medical School

Background: Chronic liver disease (CLD) and metabolic syndrome (MetS) frequently coexist, sharing pathophysiologic mechanisms that compound morbidity and mortality. Despite their growing burden, national data on long-term mortality trends in comorbid CLD and MetS remain scarce. This study aims to evaluate 25-year mortality trends among U.S. adults with comorbid CLD and MetS, highlighting regional and demographic disparities to inform targeted public health strategies. **Methods:** Mortality data from the CDC WONDER database (1999–2023) were analyzed using Joinpoint regression to assess CLD and MetS-related deaths among U.S. adults aged 25 and older. Age-adjusted mortality rates (AAMRs) per million were calculated, along with the average annual percent change (AAPC) and corresponding 95% confidence intervals (CI). **Results:** Over the 25-year period, MetS among individuals with CLD accounted for 291,154 deaths in the United States. The overall AAMR rose markedly from 2.79 per 100,000 in 1999 to 8.59 in 2023, with a striking average annual percent change (AAPC) of 4.49% (95% CI: 4.25–4.71; $p < 0.000001$). Males consistently exhibited higher mortality than females (6.36 vs. 3.64 per 100,000), with a steeper upward trend (AAPC: 4.53% [95% CI: 4.30–4.77] vs. 4.37% [95% CI: 4.02–4.71]; both $p < 0.000001$). Among racial/ethnic groups, American Indian or Alaska Native (AI/AN) individuals had the highest AAMR (15.46), followed by Hispanic or Latino (8.25), Non-Hispanic (NH) White (4.68), NH Black (4.48), and Asian individuals (2.70). The sharpest increase in mortality was observed in AI/AN populations (AAPC: 5.31%; 95% CI: 4.66–6.02), followed by NH Whites (5.17%), NH Blacks (2.60%), Hispanics (2.30%), and Asians (1.75%), all with $p < 0.000001$ except Asians ($p = 0.0208$). Regionally, the South experienced the most pronounced rise (AAPC: 5.19%; 95% CI: 4.86–5.53), followed by the Midwest (4.56%), West (4.03%), and Northeast (2.90%). States with the highest AAMRs included New Mexico (7.99), South Dakota (7.54), and Kentucky (6.85). Rural areas had slightly higher AAMRs than urban areas (4.96 vs. 4.28) and a steeper increase over time (AAPC: 6.25% vs. 4.24%; both $p < 0.000001$). Age-stratified analysis revealed the highest mortality in adults aged 75 and older (AAMR: 14.36), followed by middle-aged (AAMR: 7.21) and younger adults (AAMR: 0.79). The greatest increase was also among the elderly (AAPC: 5.08%), followed by younger (4.74%) and middle-aged adults (4.30%), all with $p < 0.000001$. **Conclusion:** CLD and MetS-related mortality has increased substantially over the past 25 years, with the most notable increases seen in females, AI/AN, NH Whites, rural areas, the South region and individuals aged 75 and older. These

0232 | STRUCTURAL DETERMINANTS OF PREVENTABLE MASLD-RELATED PREMATURE LIVER MORTALITY ACROSS U.S. COUNTIES: A NATIONWIDE ECOLOGICAL ANALYSIS (2010–2020)

James Paik[1] Shira Zelber-Sagi[2] Annette Paik[3] Linda Henry[4] Yusuf Yilmaz[5] Mohamed El-Kassas[6] Saleh Alqahtani[7] Zobair Younossi[4], [1]Beatty Liver and Obesity Research Program, Inova Health System, Falls Church, VA, [2]Tel-Aviv Sourasky Medical Center, [3]Beatty Liver and Obesity Program, Inova Health System, Falls Church, VA, [4]The Global NASH Council, [5]Recep Tayyip Erdoğan University, [6]Helwan University, [7]Liver, Digestive, and Lifestyle Health Research Section, and Organ Transplant Center of Excellenc

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver mortality in the U.S., yet a substantial proportion of MASLD-related premature liver mortality (MASLD-PLM) may be preventable. Understanding structural and geographic drivers is critical for targeted public health interventions. **Methods:** This cross-sectional ecological study analyzed county-level data from the National Vital Statistics System and County Health Rankings & Roadmaps (2010-2020) across 3,143 U.S. counties. Preventable MASLD-PLM was defined as deaths before age 80 exceeding expected rates based on the three states with the lowest MASLD-PLM. County-level exposures encompassed socioeconomic status, rurality, food and physical environments, healthcare access, and chronic disease burden. Structural equation modeling (SEM) quantified direct and indirect pathways to proportion of preventable MASLD-PLM. **Results:** From 2010–2020, MASLD-PLM averaged 17,977 deaths annually, of which 56.1% (~10,078 deaths/year) were deemed preventable. Proportion of Preventable MASLD-PLM varied significantly by geography, with a clear rural gradient (39.2% in large central metros vs. 74.7% in noncore counties). Counties with higher proportion of preventable MASLD-PLM had lower median income, limited healthcare access, more adverse food environments, and higher rural residency. SEM revealed that higher household income was associated with lower preventable MALSD-PLM both directly (standardized $\beta = -0.14$) and indirectly ($\beta = -0.49$), largely mediated through improved education, healthcare access, and healthier environments. Rural residency ($\beta = +0.16$), food desert exposure ($\beta = +0.15$), and food swamp density ($\beta = +0.10$) had direct associations with higher preventable MASLD-PLM. Access to exercise ($\beta = -0.19$ indirect) was protective, while preventable hospitalizations ($\beta = +0.10$ indirect) and population-to-physician ratios ($\beta = +0.03$ indirect) contributed via healthcare barriers. Behavioral and metabolic risks, including smoking ($\beta = +0.10$), physical inactivity ($\beta = +0.18$), and diabetes prevalence ($\beta = +0.13$), were also directly associated with higher preventable MASLD-PLM. Figure. **Conclusion:** Over half of MASLD-related premature liver deaths in the U.S. appear preventable, with disproportionate burdens in rural and socioeconomically disadvantaged counties. Structural determinants-including income, rurality, healthcare access, and food environments-play a central role.

0233 | RACIAL/ETHNIC AND SOCIOECONOMIC DISPARITIES IN STEATOTIC LIVER DISEASE: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Heli Xu[1] Ana Diez-Roux[1] Usama Bilal[1] Brisa Sanchez[1] Kari Moore[1] Jana Hirsch[1] Matthew Budoff[2] Steven Solga[3] Xiuqing Guo[2] Jie Yao[2] Jerome Rotter[2] Stephen Dickinson[1] MARIANA LAZO[1], [1]Drexel Dornsife School of Public Health, [2]Harbor-UCLA Medical Center and The Lundquist Institute, [3]University of Pennsylvania

Background: Steatotic liver disease (SLD) is a major contributor to the increasing liver-related morbidity and mortality. It has been reported that Hispanics are disproportionately affected by SLD. However, few studies have examined the racial/ethnic disparities beyond genetic susceptibility and socioeconomic disparities in SLD. **Methods:** We conducted a cross-sectional analysis of 4968 participants (1178 non-Hispanic Black, 594 Chinese, 1174 Hispanic, and 2022 non-Hispanic White) in the Multi-Ethnic Study of Atherosclerosis study, aged 44-84 years and free of viral hepatitis and cirrhosis. Hepatic steatosis was assessed by hepatic attenuation values using computed tomography. We used standard and multilevel linear regression models, to examine the differences in hepatic steatosis associated with race/ethnicity (accounting for genetic susceptibility using a polygenic risk score [PRS]), individual-level socioeconomic status (SES) measures (education and poverty-to-income ratio), and neighborhood-level SES measure (neighborhood deprivation score). **Results:** Overall hepatic attenuation was 60 $\pm$ 11 HU among all participants. After adjusting for age, gender, and PRS, Hispanic participants showed significantly higher levels of hepatic steatosis (lower hepatic attenuation values, β = -3.00 [95% CI: -3.9, -2.2]) compared to White participants. For individual-level SES, after adjusting for age and gender, we found significant inverse associations of both income and education with hepatic steatosis. At the neighborhood level, a higher deprivation score was associated with increased hepatic steatosis levels, adjusting for age, gender, and race/ethnicity, with minimal change in estimates after additional adjustment for individual SES. (Table). **Conclusion:** This population-based study documents higher SLD burden among Hispanic participants beyond genetic susceptibility. Lower income and lower education levels are associated with higher hepatic steatosis. Residential socioeconomic environment is associated with hepatic steatosis, independent of individual-level SES. These findings highlight that SLD-related disparities exist across disadvantaged populations and call for liver-related prevention efforts focused on upstream determinants of health.

Table. Adjusted associations between individual and contextual levels of SES and hepatic steatosis (HU, lower values indicate higher hepatic steatosis)

	Beta (95% CI) *
Income-to-Poverty Ratio	
< 1	-1.43 (-2.56, -0.31)
1-1.99	-0.50 (-1.39, 0.39)
2-3.99	-0.49 (-1.22, 0.26)
≥ 4	Ref
Education	
Less than high school	-2.04 (-2.98, -1.10)
High school or some college	-1.14 (-1.82, -0.45)
College and above	Ref
Neighborhood deprivation score	**-0.53 (-0.86, -0.19)**

*adjusting for age and gender for income-to-poverty ratio and education models; adjusting for additional race/ethnicity for neighborhood deprivation score model.

México City, Mexico, [21]Marmara University, School of Medicine, Department of Gastroenterology, Istanbul, Turkey, [22]Liver, Digestive & Lifestyle Health Research Section, King Faisal Specialist Hospital Research Cente, [23]INOVA Fairfax Hospital, [24]Center for Outcomes Research in Liver Diseases, CORLD, [25]The Center for Outcomes Research in Liver Diseases, [26]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia., [27]The Global NASH Council

Background: The Impact of age on MASLD outcomes has not been fully assessed. Our aim was to assess the clinical and patient reported outcomes (PROs) of MASLD patients based on age groups. **Methods:** Patients with MASLD were prospectively enrolled into our Global NAFLD/MASLD Registry™ (GNR). Clinical and PROs (FACIT-F, CLDQ-MASH, and WPAI) data were analyzed in MASLD patients of <65 years vs. 65-74 years vs. ≥ 75 years. **Results:** 8441 MASLD patients from 18 countries were included: mean (SD) age 52 (13) years, 46% male, 65% obese, 38% type 2 diabetes (T2D), 49% hypertension, 47% hyperlipidemia, 14% with advanced fibrosis, 19% depression, 39% clinically overt fatigue and 24% sleep apnea. Of these, 83% were <65 years, 14.5% were 65-74 years, and 2.3% were ≥ 75 years old. The proportion of lean MASLD (by BMI) rose from 5% in the <65 group to 9% in the 65-74 group to 17% in the ≥ 75 group, while the prevalence of T2D was 35% in <65 vs. 50% in 65-74 vs. 49% in ≥ 75; the rates of hypertension and hyperlipidemia also increased with age (all $p < 0.0001$). In a subgroup of patients with waist circumference (63%), the proportion of lean MASLD remained higher in older patients: 10% in <65 vs. 12% in 65-74 vs. 18% in ≥ 75 ($p = 0.01$). The prevalence of advanced fibrosis (by FIB-4 or imaging or biopsy) was higher in older patients: 12% in the <65 group, 24% in the 65-74 group, and 28% in the ≥ 75 group. In multivariate logistic regression analysis, older age was independently associated with a higher risk of advanced fibrosis in MASLD (OR (95% CI) = 2.05 (1.73-2.43) for age 65-74 years, 2.83 (1.99-4.02) for age ≥ 75 years vs. reference age <65 years, $p < 0.0001$), along with obesity and T2D ($p < 0.05$); the association of fibrosis with older age was similar in lean and non-lean MASLD patients (all $p > 0.05$ for interaction). In patients of ≥ 65 years, only T2D was a predictor of advanced fibrosis (OR = 2.56 (1.94-3.38), $p < .0001$). The HRQL scores by CLDQ-MASH and FACIT-F were higher in older patients with MASLD (Figure). In multivariate analysis adjusted for confounders, older age was independently associated with higher PRO scores in emotional well-being-related domains (Emotional Health and Worry of CLDQ-MASH, Emotional well-being of FACIT-F) and lower scores in the Activity/Energy domain of CLDQ-MASH (all $p < 0.05$). In patients of ≥ 65 years, independent predictors of lower PRO scores included female sex, the presence of obesity and T2D, history of psychiatric comorbidities, clinically overt fatigue, abdominal pain, sleep apnea, and the lack of regular exercise ($p < 0.05$). **Conclusion:** Older patients with MASLD seen in tertiary care hepatology clinics have higher PRO scores despite more advanced fibrosis but lower rate of overweight/obesity.

★ 0235 | EFFICACY OF A LACTOCOCCUS LACTIS-BASED SYNBIOTIC DEVELOPED FROM A HUMAN MICROBIOTA-ASSOCIATED MICE MODEL FOR PREVENTING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Saisai Zhang[1] Zhe Zhang[1] Shing-Fung Chow[2] Hein Min Tun[3] Ning Ma[1] Hau-Tak Chau[1] Fung-Yu Huang[1] Lung-Yi Loey Mak[1] Man-Fung Yuen[1] Wai-Kay Seto[1],
[1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China, [2]Department of Pharmacology and Pharmacy, The University of Hong Kong, China, [3]The Jockey Club School of Public Health and Primary Care, The Chinese University of Hong Kong, China

Background: The gut microbiome plays a critical role in metabolic dysfunction-associated steatotic liver disease (MASLD). Specific *Lactococcus lactis* strains and microbial metabolites demonstrate therapeutic potential. A rationally designed microbial formulation may offer synergistic benefits, but its efficacy in MASLD remains unproven. **Methods:** *L. lactis* strains were isolated from feces of healthy human donors and recipient mice in a human microbiota-associated model. Species- and strain-level identification and functional analysis were performed using MALDI-TOF and PacBio whole-genome sequencing. After developing a proprietary synbiotic containing *L. lactis* strains and microbial metabolites (under patent consideration), eight-week-old male C57BL/6J mice were assigned to two experimental cohorts: (1) preventive cohort - mice were simultaneously fed a high-fat diet (HFD) and synbiotic for 12 weeks to evaluate preventive efficacy; (2) therapeutic cohort - mice were fed an HFD for 8 weeks to establish MASLD, followed by a longer, 16-week oral synbiotic treatment to assess reversal potential. **Results:** Five distinct *L. lactis* strains were identified, functionally enriched in MASLD-related pathways, with minimal antimicrobial resistance, biocide/metal tolerance, or genomic virulence. In the preventive cohort, synbiotic-treated mice, when compared to HFD-fed controls, achieved significant reductions in body weight gain (15.23 ± 0.44 g vs. 22.84 ± 1.29 g), serum triglycerides (41.95 ± 0.67 mg/dL vs. 49.67 ± 0.70 mg/dL), ALT (97.91 ± 12.15 U/L vs. 168.00 ± 9.31 U/L), AST (228.70 ± 25.01 U/L vs. 379.30 ± 16.35 U/L), liver weight (1.17 ± 0.42 g vs. 1.62 ± 0.10 g), and hepatic cholesterol (3.20 ± 0.53mg/g vs. 7.96 ± 0.61 mg/g) (all $p < 0.05$). Histological examination showed reduced NAS (steatosis grade: 0.50 ± 0.29 vs. 2.50 ± 0.29) and Oil Red O area (0.99 ± 0.50% vs. 11.95 ± 1.50%) (all $p < 0.05$). Gut barrier integrity, assessed by the FITC-dextran permeability assay, was restored (0.99 ± 0.01 vs. 1.35 ± 0.05, $p = 0.0104$). In the therapeutic cohort, synbiotic treatment led to modest, non-significant reductions in weight gain and hepatic triglycerides, but significantly improved intestinal permeability (0.97 ± 0.08 vs. 1.79 ± 0.21, $p = 0.0270$). **Conclusion:** A novel *L. lactis*-based synbiotic prevents MASLD development in mice, demonstrating the clinical potential of microbial interventions in managing MASLD. *Supported by Innovation and Technology Fund-Midstream Research Programme for Universities (ITS/046/22MS).*

0236 | MICROBIOME ROLES IN ESTROGEN HOMEOSTASIS AS REVEALED BY ESTROGEN CHALLENGE

Anushka Subrahmanian[1] Liisa Veerus[2] Anjali Patel[1] Xingnan Li[3] Adrian Franke[3] Martin Blaser[2], [1]Rutgers Robert Wood Johnson Medical School, [2]Rutgers University, [3]University of Hawai'i

Background: Increased estrogen circulation is a known consequence of cirrhosis, but little is known about the effects of an estrogen burden on the liver. The liver plays a central role in estrogen homeostasis, which requires a balance between host- and microbiome-mediated processing. In the host, the liver uses estrogen receptors to sense circulating estrogen levels and facilitates excretion via several conjugation pathways, including glucuronidation. The gut microbiome reverses host estrogen conjugation via β-glucuronidases and other enzymes, which restore the modified estrogens to active forms. These estrogens preferentially are absorbed across the intestinal wall and return to the bloodstream through the enterohepatic (portal vein) circulation, which contributes to the central role of the liver in estrogen metabolism. **Methods:** We explored the hepatic handling of estrogen by exposing 84 eight-week-old C57BL/6J mice (43 females, 41 males) to either a subcutaneous estradiol pellet (0.25mg/day for 21 days), placebo pellet, or no pellet. Hepatic tissues were harvested after sacrifice and analyzed for expression of the estrogen receptor gene *Esr1* and the estrogen conjugation genes *Ugt1a1* and *Ugt1a9*. The same analyses were then repeated in 24 formerly germ-free female C57BL/6J mice who were conventionalized in early adulthood (at seven weeks) using the cecal contents of either control (CMT-C) or estradiol-exposed (CMT-E) females from the conventional study, followed by three weeks of exposure to an estradiol pellet or not. **Results:** At the peak of estradiol treatment, there was no treatment effect on *Esr1*, *Ugt1a1*, or *Ugt1a9* expression in conventional females. However, in conventionalized ex-germ-free females, all three genes were expressed at reduced levels (Figure 1 for *Ugt1a9* as an example). Within the ex-germ-free females, transfer of the CMT-E microbiome led to a further decrease in *Esr1*, *Ugt1a1*, and *Ugt1a9* expression, while the primary estrogen exposure itself had no effect (Figure 1). **Conclusion:** These findings demonstrate that the intestinal microbiome contributes mechanistic links to hepatic estrogen metabolism, distinct from direct estrogen-mediated effects. The gut microbiome-hepatic axis thus represents a promising avenue for interventions to regulate both estrogen metabolism and the expression of hepatic genes critical to estrogen homeostasis.

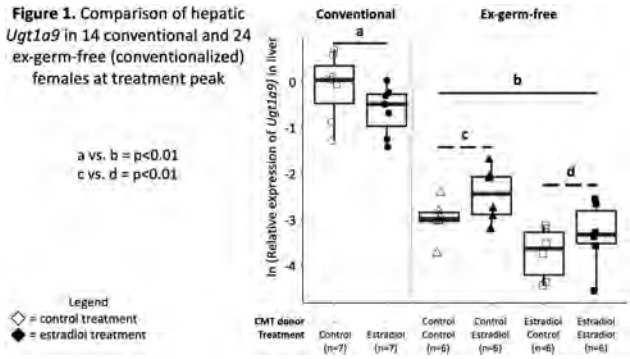

Figure 1. Comparison of hepatic *Ugt1a9* in 14 conventional and 24 ex-germ-free (conventionalized) females at treatment peak

0237 | SALIVARY MICROBIOME AND SERUM METABOLOMICS ADD TO CLINICAL BIOMARKERS TO PREDICT 6-MONTH HOSPITALIZATIONS IN A MULTI-CENTER CIRRHOSIS OUTPATIENT COHORT

Jasmohan Bajaj[1] K Rajender Reddy[2] Jennifer Lai[3] Jacqueline O'Leary[4] Puneeta Tandon[5] Florence Wong[6] Guadalupe Garcia-Tsao[7] Hugo Vargas[8] Patrick Kamath[9] Scott Biggins[10] Philip Vutien[11] Ana Limon-Moro[12] Jawaid Shaw[13] Masoumeh Sikaroodi[14] Brian Bush[15] Leroy Thacker[15] Patrick Gillevet[14], [1]Virginia Commonwealth University, [2]University of Pennsylvania, [3]UCSF, [4]Dallas VA, [5]University of Alberta, [6]University of Toronto, [7]Yale University, [8]Mayo Clinic Arizona, [9]Mayo Rochester, [10]UPMC, [11]UW Seattle, [12]U Alberta, [13]Richmond VA, [14]GMU, [15]VCU

Background: Prognosticating outcomes such as hospitalizations in cirrhosis outpatients is challenging, especially with changing etiologies and demographics. Aim: Determine impact of multi-omic strategies on outcome prediction. **Methods:** NACSELD3 (North American Consortium for the Study of End-Stage Liver Disease 3) enrolls cirrhosis outpatients with controlled and eradicated etiologies from 10 centers and follows them

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

systematically. At baseline, clinical/demographic and cirrhosis details were recorded and saliva and serum samples were collected for microbiome and metabolome analysis respectively. Multi-omic bioinformatic studies to determine interaction of microbiota and metabolites with clinical prediction of 6-month hospitalizations were performed; microbiome was analyzed using 16SrRNA sequencing with diversity & LEfSe, metabolome using LC/MS & then PLS-DA supervised. Combined: Random forest using individual & combined modalities with AUC and latent factor analysis to determine which factors were most significant were performed. **Results:** 565 patients (60.2 years, 68% men, 35% alcohol, 33% MASH, 21%, eradicated HCV with MELD3.0 12) were enrolled. 163 (29%) required 6-month hospitalizations; most (75%) were liver-related. Those hospitalized had worse cirrhosis severity, co-morbidity indices, but similar demographics and oral health variables (Fig A). Microbiome: Salivary microbiome alpha-diversity was lower (1.96 ± 0.48 versus 2.09 ± 0.45, $p = 0.018$) with greater pathobionts (*Streptococcus*, *Treponema, Enterococcaceae)* and lower commensal genera (*Veillonella, Prevotella, Haemophilus*, *Lachnospiraceae* spp) at baseline (Fig B). Serum metabolomics: showed 1729 metabolites, of which 1420 were named. Supervised analysis using PLS-DA shows major separation at the 95% CI between those who were ultimately hospitalized or not showed significant separation at baseline between hospitalized/not patients using supervised analyses with microbial-origin (phenyllactate, secondary bile acids, indoles), choline moieties, and polyamine/GABA (3-ureidopropionate/spermidine) metabolites being most prominent (Fig C). Combined: Area-under-the curve using random forest for clinical, microbial, and metabolomic variables were higher than that of these individually (Fig D-F). Latent factor analysis showed clinical variables (MELD3.0, hemoglobin and albumin) with the greatest impact followed by salivary microbiota and then serum microbiome for hospitalization prediction. **Conclusion:** In a multi-center North American outpatient cirrhosis cohort with controlled etiologies, serum metabolomics focused on microbial products and salivary microbiome add to clinical variables to prognosticate 6-month hospitalization.

0238 | HEPATOCYTE-DERIVED EXOSOMAL MIR-122 MEDIATES LIVER-TO-BRAIN CROSSTALK IN ALCOHOL-EXPOSED ALZHEIMER'S DISEASE MICE AND EXACERBATES NEUROINFLAMMATION

Veronika Brezani[1] Radhika Joshi[1] Marti Ortega-Ribera[1] Viliam Brezani[1] Mrigya Babuta[1] Bruna Santos[1] Adam Zivny[1] Gyongyi Szabo[2], [1]BIDMC & Harvard Medical School, [2]Beth Israel Deaconess Medical Center

Background: Alcohol consumption triggers inflammation in the liver and in the brain. We have previously demonstrated that alcohol increases circulating levels of exosomes enriched in miR-122, a hepatocyte-specific microRNA, in both humans and mice. Given that hepatic encephalopathy involves liver inflammation that activates microglia in the brain, we hypothesized that alcohol-induced hepatocyte-derived exosomes mediate liver-to-brain communication in Alzheimer's disease (AD) by transferring miR-122, thereby promoting neuroinflammation. **Methods:** Wild-type (WT) and APP/PS1 transgenic (AD) mice received alcohol binges (3.5 g/kg) every alternate day for a period of one month. Exosomes were isolated from serum or the supernatants of mouse hepatocytes treated with ethanol. Mouse BV-2 microglia were exposed to hepatocyte-derived exosomes prior to lipopolysaccharide (LPS) stimulation, and cytokine expression was analyzed after 24 hours. Liver and brain tissues were analyzed at mRNA and protein levels. **Results:** Alcohol significantly increased exosome biogenesis in vivo and release from primary hepatocytes in vitro. Ethanol-induced hepatocyte-derived exosomes were enriched in mature miR-122 compared to controls. Microglial uptake of hepatocyte-derived exosomes was confirmed by PKH26 staining. Exosomes from alcohol-treated hepatocytes sensitized microglia to LPS stimulation to produce significantly increased inflammatory chemokines MCP-1 and CCL3. Transfection of microglia with a miR-122 mimic recapitulated this pro-inflammatory sensitization, which was reversed after miR-122 inhibitor delivery. This supports our hypothesis that the transfer of miR-122 from ethanol-treated hepatocytes to microglia increases the pro-inflammatory responses in microglia. In APP/PS1 (AD) mice, chronic alcohol significantly increased circulating exosome numbers and miR-122 levels in the brain. Alcohol-treated AD mice showed elevated ALT, indicating liver damage, and increased inflammatory markers in the liver and inflammasome activation in the brain compared to WT mice. Importantly, ethanol-treated AD mice showed elevated amyloid β deposition in the hippocampus. This correlated with changes in ADAM10, a miR-122 target and important enzyme for cleaving amyloid precursor protein. **Conclusion:** Our findings reveal a novel alcohol-induced liver-brain crosstalk mediated by hepatocyte-derived exosomal miR-122 in AD. Alcohol-induced exosomes enhance neuroinflammatory responses via microglial sensitization and thereby exacerbate AD-related pathology. These results underscore the importance of hepatocyte-microglia communication in alcohol-associated neuroinflammation.

0239 | TARGETING NEUTROPHIL RECRUITMENT/SIGNALING ATTENUATES BILIARY DISEASE IN A MOUSE MODEL OF CAROLI DISEASE

Romina Fiorotto[1] Santo Diprima[2] Anna Palmiotti[2] syeda zehra[2] Lauren Malouin[2] Mario Strazzabosco[1], [1]Yale University, [2]Yale School of Medicine

Background: Caroli Syndrome (CS) is characterized by biliary malformations, cholangiocyte dysfunction, and portal fibrosis and recurrent bacterial cholangitis. *PKHD1*, the mutated gene, encodes fibropolycystin, a protein involved in cell polarity, matrix interaction, and differentiation. The *Pkhd1*$^{del4/del4}$ (Pkhd1-KO) mouse, an orthologous model of CS, exhibits biliary cysts, peribiliary inflammation, fibrosis, and portal hypertension. This study aimed to assess the role of the inflammatory microenvironment in disease progression in Pkhd1-KO mice. **Methods:** Liver tissues from 3-month-old Pkhd1-KO mice and wild-type littermates were analyzed. Bacteria in livers were identified by Gram staining and liver lysate cultures. Cystic area, inflammatory infiltrates, and fibrosis were quantified by immunohistochemistry (CK19, CD45, Sirius Red). The inflammatory infiltrate and cholangiocyte-immune crosstalk was profiled by single-cell RNA sequencing (scRNA-seq). Infiltrate composition was confirmed by immune mass cytometry (IMC). Pkhd1-KO mice were treated with sulfamethoxazole/trimethoprim (SMZ/TMP) or a Cxcr2 inhibitor. **Results:** Pkhd1-KO mice showed biliary infection with *Enterococcus* spp. inside the cysts. Treatment with SMZ/TMP diet significantly reduced inflammation, fibrosis, and partially cystic area in Pkhd1-KO mice. scRNA-seq and IMC revealed enrichment of neutrophils and T cells in the infiltrate. Gene expression of recruiting chemokines for neutrophils and T cells (*Cxcl1, Cxcl5, Mif, Cxcl20, Il23, Cxcl16) along with* activation of NF-κB and bacterial defense pathways were upregulated in Pkhd1 cholangiocytes and downregulated following treatment with antibiotics. Connectome analysis confirmed cholangiocyte-immune cell interactions. Immunostaining (NIMP-R14, MMP9) showed activated neutrophils in and around cysts that were reduced after antibiotics. T cell sub-clustering revealed IL-17A producing γδ T cells in Pkhd1-KO livers that were markedly reduced after antibiotics. Inhibition of Cxcr2, the receptor of Cxcl1,5 in neutrophils,significantly decreased cystic area, inflammation, and fibrosis. **Conclusion:** Biliary infection with Enterococcus spp. drives neutrophil recruitment and inflammation in Pkhd1-KO mice. Targeting neutrophil signaling, by Cxcr2 inhibition, reduces cyst growth, T-cell infiltration and fibrosis, indicating a major role of neutrophils in orchestrating the inflammatory response to biliary pathobionts.

★ 0240 | DECIPHERING HOT AND COLD FIBROTIC NICHES IN HUMAN CHRONIC LIVER DISEASE USING SPATIAL MULTIOMICS

Jacky Tam[1] Fabio Colella[1] Kexin Kong[1] Pak Kwan Qiu[2] Juliet Luft[1] George Finney[3] Ginevra Pistocchi[3] Laura Pallett[3] Prakash Ramachandran[1], [1]Institute for Regeneration and Repair, University of Edinburgh, [2]Cambridge Institute of Therapeutic Immunology and Infectious Disease, University of Cambridge, [3]Institute of Immunity and Transplantation, University College London

Background: Irrespective of etiology, the degree of fibrosis predicts worse prognosis in chronic liver diseases (CLD). However, CLD progression and responses to therapies in are highly variable, suggesting that fibrosis itself maybe heterogeneous. Recently the idea of distinct “hot” and “cold” fibrotic niches has been proposed, with different cellular compositions and treatment targets. Whilst conceptually appealing, this paradigm has not been validated in the liver. Here, we aimed to use novel spatial techniques to dissect heterogeneity in the human

liver fibrotic niche and define the nature of hot and cold fibrosis. **Methods:** We applied spatial transcriptomics (ST; Stereo-seq, n = 12 and CosMx 6K, n = 22) and proteomics (69 antibody panel on Phenocycler-Fusion [PCF], n = 60) to healthy, MASLD, PSC and ALD liver samples, encompassing biopsies and explants of differing fibrosis stages. Stereo-seq data (225μm²/spot) underwent clustering, differential abundance testing, pseudospatial trajectory inference, deconvolution and ligand-receptor analyses. CosMx and PCF data underwent cell segmentation, cell-type identification, spatial mapping and cellular neighbourhood analysis. **Results:** Unbiased ST using Stereo-seq identified transcriptional heterogeneity in the liver fibrotic niche with two distinct clusters, FN1 and FN2, mapping to the scar-edge and scar-core respectively. Differential expression and pseudospatial trajectory analyses demonstrated that FN1 was most enriched for fibrogenic gene expression (e.g. *COL1A1*, *COL3A1*). Cellular deconvolution highlighted accumulation of scar-associated macrophages (SAMacs) and myofibroblasts in FN1 indicative of hot fibrosis, whilst FN2 was more akin to cold fibrosis. The hot FN1 niche expanded in both intermediate and advanced fibrosis, while the cold FN2 niche was more prevalent in advanced disease. We confirmed these findings using single-cell resolution CosMx and PCF data, defining a hot fibrosis cellular neighbourhood containing activated hepatic stellate cells, SAMacs and bipotential epithelial cells (Fig). Hot fibrosis was enriched for CD44 interactions, suggesting this may be a means to modulate this niche. **Conclusion:** We present a new paradigm for studying liver fibrosis, using spatial multiomics to decipher the cellular and molecular features of hot and cold fibrotic niches in human liver. These findings indicate that a more nuanced approach to antifibrotic drugs is needed, individualising therapy according to the type of fibrosis present in different patients.

★ 0241 | ABSTRACT WITHDRAWN

★ 0242 | ACUTE ETHANOL-INDUCED MITOCHONDRIAL DEPOLARIZATION (MTDEPO) ENHANCES OXYGEN CONSUMPTION AND TRIGGERS PERICENTRAL MITOPHAGY IN MOUSE HEPATOCYTES

Matthew Savoca[1] Kenji Takemoto[2] Zhi Zhong[1] John Lemasters[1], [1]Medical University of South Carolina, [2]Yamaguchi University

Background: Acute and chronic ethanol (EtOH) cause hepatic mtDepo, an adaptive response that enhances overall EtOH and acetaldehyde metabolism. Here, our AIM was to characterize hepatic mtDepo relative to mitochondrial respiratory function after acute *in vivo* EtOH-treatment of mice, the subsequent activation and zonation of mitophagy. **Methods:** Male C57BL/6J and GFP-LC3 mice were gavaged with 6 g/kg EtOH or vehicle. To assess mitochondrial membrane potential ($\Delta\Psi$) in hepatocytes *in vivo*, 0.05 μmol of Mitotracker Red (MTR) was administered 1h prior to liver fixation or hepatocyte isolation at 6h after EtOH or vehicle treatment. Oxygen consumption rates (OCRs) of hepatocytes were measured with a Seahorse XFe96 Analyzer. To evaluate $\Delta\Psi$ in isolated hepatocytes, cells were loaded with 500 nM Rhodamine 123 (Rh123). For analysis of $\Delta\Psi$ and GFP-LC3 puncta forming *in vivo* in hepatocytes within the liver lobule, slices of fixed liver were prepared from GFP-LC3 mice treated with MTR for observation by confocal microscopy. **Results:** After vehicle, intracellular MTR fluorescence was mitochondrial in all liver zones, signifying mitochondrial polarization. OCRs (ATP-linked, proton leak-linked, and maximal) of sorted periportal (PP) hepatocytes were ~4 times that of pericentral (PC). After EtOH, intracellular MTR fluorescence became non-mitochondrial in the central half but not the portal half of liver lobules, signifying mtDepo. Mitophagy indicated by GFP-LC3 puncta was also only increased in the central half. After EtOH, OCRs of both PP and PC hepatocytes were ~2-times that of vehicle, but PC hepatocytes displayed greater proportional increases compared to PP. In PC hepatocytes isolated from EtOH-treated mice, basal OCR was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

inhibited by oligomycin and stimulated by uncoupler, suggesting reversal of mtDepo after isolation, which Rh123 uptake confirmed. **Conclusion:** After EtOH, mtDepo is restricted to the central half of liver lobules with a sharp midzonal demarcation from the portal half. In sorted hepatocytes without EtOH treatment, OCRs of PP hepatocytes are substantially greater than PC, but both PP and PC OCRs increase after EtOH with PC increasing proportionally more. However, mtDepo in PC hepatocytes after *in vivo* EtOH treatment reverses during isolation. Increased mitochondrial respiratory capacity in all sublobular zones likely promotes adaptive detoxifying EtOH metabolism. These findings document sharp zonal differences in hepatic metabolic responses to EtOH exposure that may help shed light on the progression to alcoholic liver disease.

0243 | THE NOVEL NON-ANTICOAGULANT SYNTHETIC HEPARAN SULFATE 18-MER REDUCES HEPATIC NON-PARENCHYMAL CELL TISSUE FACTOR INDUCTION AND INHIBITS COAGULATION ACTIVATION IN STERILE LIVER INJURY

Amish Patel[1] Katelyn Arnold[2] Gina Capece[1] James Luyendyk[3] Nigel Mackman[2] Jian Liu[2] Lauren Poole[1], [1]Rutgers Robert Wood Johnson Medical School, [2]University of North Carolina at Chapel Hill, [3]Michigan State University

Background: Strong evidence links blood coagulation to the progression of liver disease. Direct anticoagulants could be effective therapies for liver disease, but the safety and efficacy of this strategy remains unclear due to the tenuous hemostatic balance in these patients. An ideal therapy would inhibit pathological coagulation without compromising hemostasis, but the mechanisms triggering coagulation in liver disease are not known. This study tests the hypothesis that the extrinsic coagulation pathway, initiated by binding of the ligand factor VIIa to its receptor tissue factor (TF), activates the coagulation cascade in acute sterile liver injury and tests a novel pharmacologic approach to safely disable this pathway. **Methods:** Mice with whole-body TF deficiency (LowTF) or hepatocyte-selective TF deficiency ($HPC^{\Delta TF}$) and respective littermate controls were challenged with carbon tetrachloride (CCl_4, 1 ml/kg i.p.) or vehicle (corn oil). Plasma and liver tissues were collected after 24 h. In separate studies, wild-type mice were administered a novel non-anticoagulant synthetic heparan sulfate (HS 18-mer, 5 mg/kg, s.c.) or vehicle (saline) 2 h and 8 h after CCl_4. **Results:** CCl_4 challenge caused robust activation of the blood coagulation cascade, measured by plasma thrombin-antithrombin (TAT) complexes, alongside hepatic injury. Coagulation was completely blocked in CCl_4-challenged LowTF mice. Surprisingly, coagulation was not affected in $HPC^{\Delta TF}$ mice, implying that coagulation activation is not directly driven by TF activation in necrotic hepatocytes. Rather, *in situ* hybridization identified that TF (*F3*) gene expression was induced in hepatic non-parenchymal cells (NPCs) in the necrotic region of the CCl_4-challenged liver. TF gene expression can be induced in multiple cell types, e.g., leukocytes, by inflammatory stimuli. Synthetic HS 18-mer, which lacks anti-coagulant activity, has been previously shown to have anti-inflammatory activity in acetaminophen-induced acute liver injury. Interestingly, 18-mer inhibited CCl_4-induced coagulation and reduced TF expression in hepatic NPCs. **Conclusion:** These results indicate that coagulation activation in sterile liver injury is associated with induction of TF in hepatic NPCs. Hepatic NPC TF induction and coagulation activation are both blocked by anti-inflammatory 18-mer. These results point to a novel strategy to block coagulation in acute liver injury through a mechanism fully distinct from controlling hemostasis.

0244 | INTEGRIN $\alpha_4\beta_7$ PROMOTES REPAIR AND REGENERATION IN ACETAMINOPHEN-INDUCED LIVER INJURY BY RECRUITING MONOCYTES AND DRIVING THEIR PRO-REPARATIVE PROGRAMMING

Reben Raeman[1] Ravi Rai[1] PABITRA PAL[1] Daniel Rossmiller[1] Smita Iyer[1] Michael Oertel[1], [1]University of Pittsburgh

Background: Acetaminophen overdose is the leading cause of drug-induced acute liver failure (ALF) worldwide, yet effective therapies remain limited beyond the earliest stages of injury. Monocytes recruited to the liver during the early phase of APAP-induced liver injury (AILI) promote inflammation, but during the reparative phase, they adopt pro-resolving and regenerative states that support injury resolution and regeneration. Despite this recognized functional plasticity, the molecular cues driving monocyte recruitment and their transition from pathogenic to reparative states remain poorly defined. Here, we investigated how the integrin receptor $\alpha_4\beta_7$ and its ligand mucosal addressin cell adhesion

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

molecule 1(MAdCAM-1) drive monocyte recruitment to the liver and license their differentiation into reparative monocyte derived macrophages (MoMs). **Methods:** AILI was induced in 10-week-old wild-type (WT) mice by a single intraperitoneal injection of acetaminophen (APAP; 300 mg/kg). Mice were randomized to receive either an isotype IgG control or an $\alpha_4\beta_7$-blocking monoclonal antibody (mAb) 4 hours later. Liver injury, regeneration, and immune responses were assessed using histology, immunohistochemistry, qPCR, flow cytometry, and transcriptomic profiling. **Results:** During the resolution phase, 48 hours post-APAP, $\alpha_4\beta_7^{\circ}$ MoMs were selectively enriched in the liver, while $\alpha_4\beta_7^{\circ}$ T, B, and NK cells declined. A similar pattern was observed in the spleen, where $\alpha_4\beta_7^{\circ}$ monocytes and macrophages increased, but $\alpha_4\beta_7^{\circ}$ neutrophils and lymphocytes remained unchanged. These findings suggest that $\alpha_4\beta_7^{\circ}$ monocytes, but not adaptive lymphocytes, are selectively licensed for hepatic recruitment during AILI resolution. Blockade of $\alpha_4\beta_7$ impaired monocyte recruitment, disrupted hepatic immune landscape, delayed liver regeneration, and led to 40% mortality within 48 hours. Transcriptomic profiling of hepatic MoMs from $\alpha_4\beta_7$-blocked mice showed reduced expression of genes associated with tissue repair and regeneration compared to IgG controls, indicating that $\alpha_4\beta_7$/MAdCAM-1 signaling is required to program MoMs toward a reparative phenotype during the resolution phase of AILI. **Conclusion:** These findings suggest that unlike metabolic and fibrotic liver disease where $\alpha_4\beta_7$/MAdCAM-1 axis promotes inflammation and fibrosis, this axis plays a pro-reparative and pro-regenerative role in AILI. These findings redefine $\alpha_4\beta_7$ as a potential therapeutic target to enhance recovery following AILI.

0245 | HIGH-DIMENSIONAL CYTOMETRY FOR SINGLE-CELL IMMUNE PROFILING UNCOVERS IMMUNOPATHOLOGICAL MECHANISMS IN IDIOSYNCRATIC DRUG-INDUCED LIVER INJURY (DILI)

M Lucena[1] Daniel Di Zeo-Sánchez[2] Marina Villanueva[3] Irene Díaz Alberola[3] Gonzalo Matilla Cabello[3] Angela Remesal Doblado[3] Antonio Segovia Zafra[3] José María Pinazo Bandera[4] MIREN GARCIA CORTES[4] Francisco Ruiz-Cabello[5] Mercedes Robles-Diaz[6] Raul Andrade[6] Camilla Stephens[6], [1]Universidad de Malaga, [2]IBIMA-plataforma Bionand, UMA, [3]IBIMA-Bionand Platform, [4]UGC Aparato Digestivo, Servicio de Farmacología Clínica, IBIMA, [5]Instituto de Investigación Biosanitaria IBS Granada, [6]Universidad de Málaga

Background: Idiosyncratic drug-induced liver injury (DILI) involves an individual-specific adaptive immune response. However, the exact immunopathogenic mechanisms behind DILI are still not well understood. This study aimed to analyze the systemic immune response associated with DILI using high-dimensional single-cell cytometry, capturing both inflammatory and regulatory dynamics during the acute episode and recovery phase. **Methods:** Peripheral blood samples were collected from 23 DILI patients (recruited from the Spanish DILI Registry) at detection (visit 1) and during recovery (>30 days, visit 2) and from 32 healthy controls (HC). Samples were analyzed using mass cytometry (CyTOF) with a custom-designed 40-marker panel. Unsupervised clustering (FlowSOM, PhenoGraph) and dimensionality reduction (FitSNE, t-SNE-CUDA) identified different immune cell subsets within peripheral blood mononuclear cells (PBMC) and granulocytes. Differential abundance and marker expression were evaluated using Wilcoxon and Kruskal-Wallis tests with BH correction. **Results:** A total of 38 PBMC and 17 granulocyte metaclusters were identified. At DILI detection, patients exhibited increased frequencies of CD8° effector memory T cells (HLA-DR$^{\circ}$ CD38°), Th1/Th17-polarized CD4° cells, activated $\gamma\delta$ T cells, and MAIT cells compared to HC. Simultaneously, elevated expression of CD25, CD38, and TIGIT in Tregs, NK, and dendritic cells reflected a concurrent regulatory and exhaustion signature. Markers of immune migration to the liver, including gut-lymphocyte homing, were increased ($\alpha4\beta7$, CCR6, CXCR3). During recovery, most inflammatory features partially normalized, including CD38 expression in cytotoxic and non-conventional T cell subsets, such as $\gamma\delta$ and MAIT cells. However, regulatory signatures such as TIGIT$^{\circ}$ Tregs and pDC activation persisted or increased. **Conclusion:** DILI exhibits a distinct immunophenotypic profile characterized by concurrent activation of cytotoxic and unconventional T cell subsets, along with early regulatory responses. A robust inflammatory response marks the early phase of DILI and diminishes during recovery, while regulatory and exhaustion signatures remain elevated. These findings enhance the understanding of the immune-mediated mechanisms of DILI, highlighting immunophenotyping as a valuable tool for monitoring disease progression. 0246 | LACK OF HEPATIC STEAP4 IMPAIRS LIVER REGENERATION DUE TO INCREASED LYSOSOMAL IRON ACCUMULATION AND DYSFUNCTION IN ACETAMINOPHEN-INDUCED LIVER INJURY IN MICE

Peng Cao[1] Mengwei Niu[2] Hong-Min Ni[3,] [1]University of Kansas Medical center, KS, USA, and Tongji Medical College, China, [2]University of Kansas Medical Center, [3]The University of Kansas Medical Center

Background: Understanding the mechanisms behind liver repair in acetaminophen (APAP)-induced liver injury (AILI) is crucial for developing therapeutic approaches. Six-transmembrane epithelial antigen of the prostate 4 (STEAP4) is a metalloreductase involved in iron homeostasis. It is not yet known how APAP affects hepatic STEAP4 and endolysosomal iron homeostasis in regulating liver regeneration during AILI. **Methods:** Wild-type (Alb Cre- STEAP4flox/flox) and liver-specific STEAP4 knockout (Alb Cre+ STEAP4flox/flox, KO) mice were administered APAP for various durations. In some experiments, deferiprone (DFP), an iron chelator, was given either with or after APAP administration. Biochemical and histological analyses were conducted to evaluate serum, hepatic, and endolysosomal iron homeostasis, as well as liver injury and regeneration. **Results:** The expression of *STEAP4* decreased in human AILI livers. APAP treatment reduced hepatic STEAP4 expression in a time-dependent manner in mouse livers. Liver-specific STEAP4 KO mice exhibited similar hepatic necrosis and serum ALT levels during the early phase of liver injury (6–24 hours) but displayed delayed liver recovery and regeneration at 48 hours post-APAP treatment compared to APAP-treated wild-type mice. Confocal microscopy analysis indicated that STEAP4 is primarily localized on the endolysosomal membrane in hepatocytes. The loss of STEAP4 led to the accumulation of iron in endolysosomal compartments, disrupting lysosomal membrane integrity and causing the release of cathepsin B following APAP treatment. This endolysosome disruption coincided with decreased hepatic mTOR activity, mitophagy and hepatocyte proliferation 48 hours after APAP treatment. Post-treatment with the iron chelator DFP corrected mitochondrial and lysosomal dysfunction, thereby protecting against AILI. Moreover, overexpression of STEAP4 or TFEB (a master transcription factor of lysosomal biogenesis) restored lysosomal membrane integrity and promoted liver regeneration and repair in liver-specific STEAP4 KO mice. **Conclusion:** STEAP4 is not essential during the early injury phase but is crucial for liver regeneration by maintaining lysosomal iron homeostasis and lysosomal functions following APAP overdose. Targeting STEAP4 or addressing endolysosomal iron overload may offer therapeutic benefits that extend beyond the limited window of N-acetylcysteine efficacy in AILI.

0247 | REFERRALS TO TERTIARY CANCER CENTER SHOW SIGNIFICANT DIAGNOSTIC DISCREPANCIES IN HEPATOCELLULAR CARCINOMA DIAGNOSIS BY LI-RADS CRITERIA IN PATIENTS WITH CIRRHOSIS

Gabriel Lupu[1] Parsa Pazooki[2] Lauren Burke[1] A. Sidney Barritt[1] Sasha Deutsch-Link[3] Oren Fix[1] Neil Shah[1] Hersh Shroff[3] Andrew Moon[4], [1]University of North Carolina at Chapel Hill, [2]University of North Carolina at Chapel Hill School of Medicine, [3]UNC Chapel Hill, [4]University of North Carolina

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: The diagnosis of hepatocellular carcinoma (HCC) relies primarily on CT or MRI imaging using the LI-RADS classification system, introduced in 2011 and included in AASLD guidelines in 2018. The Organ Procurement and Transplantation Network (OPTN) and AASLD recommend that imaging be reviewed by a multidisciplinary tumor board and interpreted by an expert radiologist at a transplant center. With evolving liver disease etiologies and growing LI-RADS use, this study aimed to identify discrepancies in LI-RADS application between external imaging and expert reinterpretation of suspicious liver nodules. **Methods:** We performed a single-center, retrospective cohort study of adults with cirrhosis referred to an HCC clinic for liver nodules (9/30/2016–12/6/2024). Primary outcomes included the presence of LI-RADS classification and the number of LR-4/5 nodules on external reports versus transplant center reinterpretation. We collected data on demographics, liver disease etiology and severity, HCC staging, and transplant evaluation. We performed a descriptive summary of LI-RADS use and baseline patient characteristics. Wilcoxon signed-rank test was used to assess patient-level changes in LR-4/5 nodule counts. **Results:** We identified 89 patients; 76 had abdominal CT/MRI imaging and cirrhosis. Of these, 27.6% of patients were female, 35.5% lived rurally, and the most common liver disease was MASLD (40.8%; Table 1). LI-RADS was fully reported in 61.8% of external reports. Among nodules lacking LI-RADS classification on referral, 85.7% were found to be LR-4/5 on reinterpretation. Of the 62 LR-4/5 nodules present on referral, 55 retained LR-4/5 classification on reinterpretation. 26 (37.7%) patients had an increased LR-4/5 count, 6 (8.7%) had a decreased count, and 37 (53.6%) remained unchanged ($P < 0.001$). 29 (38.1%) patients were newly classified as having an LR-5 lesion. Among 15 patients eligible for United Network for Organ Sharing (UNOS) downstaging on reinterpretation, 8 had absent or incomplete LI-RADS on external imaging. **Conclusion:** LI-RADS was correctly reported in only 61.8% of external reports compared to transplant center reinterpretation. This reinforces OPTN/AASLD recommendations for expert imaging review and underscores the risk of missed referral opportunities for HCC treatment and transplantation. Accurate LI-RADS use in external imaging can improve referrals, expedite patient care, and increase access to liver transplantation and locoregional therapies.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Hepatocellular carcinoma (HCC), a leading cause of cancer-related mortality, necessitates precise interpretation of histological differentiation to guide clinical management. While artificial intelligence (AI) has shown promise in computational pathology, systematic comparisons of AI frameworks for HCC grading remain underexplored. This study evaluates multiple instance learning (MIL) strategies for aggregating patch-level features from whole slide images (WSIs) to optimize slide-level tumor grading. **Methods:** WSIs from 54 surgically resected HCC patients (n = 392 slides: 139 normal, 253 tumors [G1/well-differentiated = 9, G2/moderately-differentiated = 185, G3/poorly-differentiated = 59]) were annotated by pathologists per AJCC 8th edition criteria. Tumor differentiation was reported by a board-certified liver histopathologist with more than 10 years of experience. WSIs were segmented into 1024×1024-pixel patches, labeled by tumor differentiation if containing tumor tissue. A pretrained UNI foundation model (a large vision transformer) was fine-tuned as a patch feature extractor. Three aggregation models were compared: 1) Logistic Regression (traditional machine learning model, probability-based), 2) Attention-based MIL (the fundamental building block for most of the latest AI models), and 3) Transformer-based MIL (state-of-the-art model). The dataset was split into training (70%), validation (15%), and test (15%) sets. **Results:** UMAP visualization of UNI embeddings revealed distinct clustering between sampled normal (class 0) and tumor (grades G1–3) test patches. At the slide level, Logistic Regression achieved an AUC of 0.808 (0.660-0.920), a sensitivity of 0.600 (0.452-0.806), a specificity of 0.907 (0.852-0.950), a PPV of 0.658 (0.423-0.910), and an NPV of 0.922 (0.871-0.961). The attention MIL achieved an AUC of 0.886 (0.705-0.994), a sensitivity of 0.850 (0.725-0.951), a specificity of 0.939 (0.887-0.977), a PPV of 0.864 (0.741-0.959), and an NPV of 0.941 (0.892-0.979). The transformer MIL achieved an AUC of 0.888 (0.706-0.998), a sensitivity of 0.892 (0.784-0.976), a specificity of 0.957 (0.913-0.988), a PPV of 0.891 (0.780-0.974), and an NPV of 0.957 (0.915-0.987). All metrics were macro-averaged across multiclass predictions. The transformer's capacity to process long patch sequences enhanced diagnostic accuracy, while MIL frameworks surpassed traditional probability aggregation. **Conclusion:** Integrating MIL with pretrained foundation models significantly improves slide-level HCC differentiation grading by effectively leveraging histological patterns across WSIs. The transformer's contextual reasoning underscores its potential for complex computational pathology tasks.

0249 | APPLYING THE LI-RADS ULTRASOUND SURVEILLANCE PROTOCOL FOR HCC: EFFECTS ON DOWNSTREAM IMAGING UTILIZATION

Christopher Hernandez[1] Kexin Dong[2] Julian McDonald[1] Ali Siddiqui[1] Patrick Sullivan[1] Marcel Yibirin Wakim[1] Yamini Adusumelli[2] Soobin Song[2] Christina LeBedis[1] Arpan Mohanty[1], [1]Boston Medical Center, [2]Boston University School of Medicine

Background: The Liver Imaging Reporting and Data System (LI-RADS) Ultrasound (US) Surveillance protocol provides standardized terminology, technique, interpretation, and reporting for hepatocellular carcinoma (HCC) surveillance in at-risk patients. Despite its structured approach, it is not widely adopted in clinical practice. A key feature is the US category (US-1: negative, US-2: subthreshold, US-3: positive), which guides follow-up imaging recommendations. US-2 exams warrant repeat ultrasound in 3 to 6 months, while US-3 findings prompt further diagnostic imaging. However, the impact of implementing the LI-RADS US surveillance protocol on subsequent imaging utilization patterns remains understudied. **Methods:** In this retrospective study, we assessed how follow-up imaging patterns might differ if LI-RADS US surveillance had been applied. We reviewed 3,159 consecutive outpatient ultrasounds performed for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

HCC surveillance between January 1, 2020, and December 21, 2022, at an urban academic safety-net hospital where LI-RADS US surveillance protocol was not utilized in routine reporting. Exams not conducted for HCC surveillance or performed in patients without cirrhosis or hepatitis B were excluded. All ultrasounds were retrospectively assigned LI-RADS US categories and visualization scores. Clinical characteristics and follow-up imaging data were abstracted from medical records. **Results:** During the study period, 1,634 patients (mean age 55 years; 62% male) underwent between one and six ultrasounds for HCC surveillance. The indication for screening was cirrhosis in 1,664 (53%) exams and hepatitis B in 1,495 (47%). Visualization scores were A (no limitations) in 2,933 (92.8%) studies, B (moderate limitations) in 209 (6.6%), and C (severe limitations) in 17 (0.5%). Among the 3,142 studies with visualization scores of A or B, 3,011 (96%) were classified as US-1, 49 (1.6%) as US-2, and 82 (2.6%) as US-3. Follow-up cross-sectional imaging was ordered in 2/3,011 (0.07%) of US-1 studies (both completed), 39/49 (79.6%) of US-2 studies (completed in 32/39), and 73/82 (89.0%) of US-3 studies (completed in 64/73). HCC was diagnosed in 1 patient in the US-1 group, none in the US-2 group, and 14 in the US-3 group. The US-1 patient had an elevated AFP, which would have triggered cross-sectional imaging independent of LI-RADS classification. **Conclusion:** Adoption of the LI-RADS Ultrasound Surveillance protocol may reduce non-indicated imaging, particularly among studies categorized as US-2.

0250 | LIVER STIFFNESS AND CANCER RISK STRATIFICATION USING MR ELASTOGRAPHY

Shohei Kimura[1] Nobuharu Tamaki[1] Takuya Shima[1] Mina Taguchi[1] Yudai Yamazaki[1] Naoki Uchihara[1] Risa Seike[1] Yuki Tanaka[1] Junko Yagita[1] Ryohei Kobayashi[1] Yuka Kasano[1] Yasuyuki Komiyama[1] Kenta Takaura[1] Shohei Tanaka[1] Hitomi Takada[1] Chiaki Maeyashiki[1] Yutaka Yasui[1] Hiroyuki Nakanishi[1] KAORU TSUCHIYA[1] Namiki Izumi[1] Masayuki Kurosaki[1],
[1]Musashino Red Cross Hospital

Background: Magnetic resonance elastography (MRE) enables non-invasive assessment of liver stiffness and provides high diagnostic accuracy for liver fibrosis. However, the association between MRE-derived liver stiffness and the development of hepatocellular carcinoma (HCC) remains unclear. This study aimed to evaluate the association between liver stiffness measured by MRE and the risk of HCC development. **Methods:** We retrospectively analyzed 2,037 patients who underwent MRE between April 2015 and August 2024. Patients were regularly screened for HCC every 3–6 months using ultrasound or contrast-enhanced CT/MRI. HCC was diagnosed based on characteristic imaging findings or histology. Laboratory data within 30 days of each MRE were reviewed. **Results:** The median age was 66 years, and 46.2% were male. The median liver stiffness was 3.40 kPa; 956 patients (46.9%) had values $\geq$3.62 kPa, indicative of advanced fibrosis ($\geq$F3). During a median follow-up of 2.8 years, the overall cumulative incidences of HCC were 1.8% at 1 year and 5.3% at 3 years. The 3-year cumulative incidence of HCC was significantly higher in patients with liver stiffness $\geq$3.62 kPa than in those with lower values (8.3% vs. 2.3%, $p < 0.001$). Multivariate analysis identified age (HR: 1.06, 95% CI: 1.04–1.08, $p < 0.001$), male sex (HR: 2.69, 95% CI: 1.53–3.26, $p < 0.001$), liver stiffness by MRE (HR: 1.23 per 1kPa, 95% CI: 1.16–1.30, $p < 0.001$), platelet count (HR: 0.998 per 10^4/μL, 95% CI: 0.99–1.00, $p < 0.001$), and hypertension (HR: 1.54, 95% CI: 1.06–2.24, $p = 0.02$) as independent predictors of HCC development. **Conclusion:** Liver stiffness measured by MRE is independently associated with the development of HCC. MRE-based risk stratification may be useful for optimizing HCC surveillance strategies in patients with chronic liver disease.

0251 | CLINICAL SIGNIFICANCE OF PREOPERATIVE MRI FEATURES IN PREDICTING PROGNOSIS FOR HEPATOCELLULAR CARCINOMA TREATED WITH TACE COMBINED WITH TARGETED THERAPY AND IMMUNOTHERAPY

Xue-Gang Lu[1] Zhi-Cheng Jin[1] Fang Nie[1] Gao-Jun Teng[1], [1]Southeast University

Background: This study investigates the predictive value of preoperative MRI mosaic patterns in patients with HCC for OS following TACE combined with targeted immunotherapy. By integrating imaging features based on LI-RADS and definitions from previous literature, the study aims to identify imaging biomarkers with independent prognostic significance and validate their application value in clinical prognosis evaluation. **Methods:** A retrospective cohort of 444 HCC patients treated with TACE and targeted immunotherapy between January 2018 and December 2022 was analyzed. Enhanced three-phase MRI sequences, focusing on mosaic architecture in T2WI and arterial phase sequences, were used to assess imaging features. Univariate and multivariate Cox regression identified independent prognostic factors, and PSM balanced baseline differences. Kaplan-Meier survival curves and Log-rank tests compared survival differences before and after matching. Subgroup and sensitivity analyses were conducted to assess the robustness of results. **Results:** Univariate Cox regression identified 22 variables significantly associated with OS, with T2WI signal heterogeneity being notable (HR = 2.01, 95% CI: 1.40–2.87, $P < 0.001$). Multivariate analysis confirmed T2WI signal heterogeneity as an independent risk factor (HR = 1.84, 95% CI: 1.09–3.09, $P = 0.021$). Propensity score matching (1:1, caliper 0.05) balanced baseline characteristics and showed significant OS differences between heterogeneous and homogeneous T2WI signal groups ($P = 0.004$). Post-matching univariate Cox analysis confirmed T2WI heterogeneity as a significant OS predictor (HR = 1.90, 95% CI: 1.22–2.95, $P = 0.004$). Subgroup analyses revealed its prognostic value in males ($P = 0.012$), patients aged ≤60 years ($P = 0.009$), BCLC stage A/B ($P = 0.004$), hepatitis B ($P = 0.026$), cirrhosis ($P < 0.001$), and portal hypertension ($P = 0.006$). Sensitivity analysis confirmed stability of the results ($P < 0.05$). **Conclusion:** T2WI signal homogeneity has been identified as an independent prognostic factor for OS in patients with HCC undergoing TACE combined with systemic therapy. Heterogeneous T2WI signals are associated with poorer prognosis, highlighting their potential value as imaging biomarkers to support personalized treatment planning. Further exploration of the prognostic implications of mosaic patterns across different imaging phases may provide additional insights into their clinical utility.

0252 | ENHANCING HEPATOCELLULAR CARCINOMA SURVEILLANCE: COMPARATIVE EVALUATION OF AFP, AFP-L3, DCP, AND COMPOSITE SCORING MODELS IN A BIOBANK-BASED CASE-CONTROL STUDY

Coskun Demirtas[1] Sehnaz Akin[2] Demet Yilmaz Karadag[1] Tuba Yilmaz[3] Ugur Ciftci[3] Cavid Huseyinov[3] Tugba Tolu[3] Yasemin Kaldirim Armutcuoglu[3] Osman Cavit Ozdogan[3] Fatih Eren[1], [1]Marmara University School of Medicine, Institute of Gastroenterology, [2]Marmara University School of Medicine, Department of Internal Medicine, [3]Marmara University School of Medicine, Division of Gastroenterology and Hepatology

Background: Early detection of hepatocellular carcinoma (HCC) is critical but restricted by limiations in current surveillance tools. Biomarkers such as AFP-L3 and DCP, as well as biomarker and/or clinical parameter derived composite models (GALAD, GAAP, ASAP, aMAP, Doylestown), may improve detection in addition to AFP, yet comparative data across diverse populations remain limited. **Methods:** In this biobank-based case-control study, we evaluated 442 adults (165 HCC, 277 chronic liver disease [CLD] controls) from January 2019 to 2024. Serum AFP, AFP-L3, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

DCP levels were measured using the μTASWako i30 system. Scoring models were calculated using validated formulas. Diagnostic performance for any-stage and early-stage HCC was assessed across three thresholds: Youden-index derived optimal cut-offs, literature-established cut-offs, and cut-offs ensuring 90% specificity. ROC analysis was performed. Subgroup analyses were stratified by etiology and AFP status. **Results:** DCP was the most sensitive individual biomarker at optimal (85.5%) and 90% specificity (74.6%) cut-offs, while AFP-L3 was the most sensitive individual biomarker (61.2%) at the established cut-off. At optimal cut-offs, GALAD showed the highest sensitivity for any-stage (90.3%) and early-stage (89.1%) HCC, with 70-80% specificity. Using established cut-offs, GALAD retained the highest sensitivity for any-stage (75.8%) and early-stage (57.8%) with 93.5% specificity. At 90% specificity, GALAD exhibited the highest sensitivity for any-stage (81.2%) and early-stage (68.8%), followed by ASAP (80.0% and 66.7%, respectively). In ROC analysis, GALAD, ASAP, and GAAP achieved the highest similar AUCs for any-stage (0.931–0.932), early-stage (0.877–0.879), while GAAP showed a slightly higher AUC in AFP-negative HCCs (0.908). GALAD demonstrated the best performance in non-viral HCCs (AUC 0.872), whereas GAAP and ASAP showed similarly high AUC values in viral etiology (AUC 0.955-960). **Conclusion:** In our study, GALAD, ASAP, and GAAP significantly outperformed individual biomarkers for detecting HCC across all disease stages, AFP profiles and etiology status. GALAD offered the most consistent diagnostic accuracy across different cut-off strategies, particularly in non-viral and early-stage HCCs. These findings support the integration of composite biomarker models into tailored HCC surveillance strategies, especially in diverse global populations.

★ 0253 | ABSTRACT WITHDRAWN

0254 | IMPACT OF HEPATIC STEATOSIS AND METABOLIC DYSFUNCTION ON DISEASE SEVERITY AND TREATMENT OUTCOMES IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Ajay Duseja[1] Muhammad Uwais Ashraf[2] Priya Singh[2] Sweta Rose[2] Suvradeep Mitra[2] Arka De[2] Nipun Verma[2] Madhumita Premkumar[1] SUNIL TANEJA[2] Harish Bhujade[2] Naveen Kalra[2], [1]Postgraduate Institute of Medical Education & Research, [2]Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Severity and response in hepatocellular carcinoma (HCC) are dependent on various risk factors. This study aimed to assess the influence of hepatic steatosis and metabolic dysfunction on HCC severity and treatment response to locoregional therapy (LRT). **Methods:** In this prospective cohort study, 209 HCC patients (July 2023-December 2024), comprehensive assessment of hepatic steatosis was performed using magnetic resonance proton density fat fraction (MR-PDFF), controlled attenuation parameter (CAP), and liver biopsy (where feasible). Cardiometabolic risk factors (CMRF) were evaluated and treatment responses was assessed using LI-RADS and mRECIST criteria. **Results:** Patients were predominantly male (86.6%) with a mean age of 59.9 ± 10.4 years. Alcohol related liver disease was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the predominant etiology (32.2%), followed by metabolic dysfunction-associated steatotic liver disease (MASLD, 22.6%). CMRF prevalence was strikingly high (51.6%), with diabetes (42%), obesity (40%) and hypertension (33%) being the most common. Hepatic steatosis was present in 41.15% of all HCC patients, significantly higher than the general population prevalence ($p = 0.0378$). Using a 10% fat fraction threshold, a significant correlation between steatosis and advanced BCLC stages was observed ($p < 0.001$), with high fat fraction ($\geq 10\%$) being present in 13.6% of BCLC A, 35.7% of BCLC B, and 60.0% of BCLC C cases. Among patients undergoing locoregional therapy ($n = 58$), those with CMRF showed significantly less favorable response rates (45% vs. 65%, $p = 0.031$). In multivariate analysis, fat fraction remained an independent predictor of poor treatment response (aOR 1.06, 95% CI: 1.00-1.12, $p = 0.048$). The novel CRAFPIT score, incorporating CRP, AFP, fat fraction, PIVKA-II, insulin, and tumor size, demonstrated excellent predictive accuracy for treatment response (AUC 0.92). **Conclusion:** Hepatic steatosis and metabolic dysfunction significantly influence HCC severity and treatment outcomes across etiologies with higher risk for advanced disease at presentation and poorer treatment response. The CRAFPIT score offers potential for improved risk stratification and treatment planning.

0256 | LIVER RESECTION VERSUS TRANS-ARTERIAL CHEMOEMBOLIZATION FOR HUGE HEPATOCELLULAR CARCINOMA (>10CM): A NATIONWIDE PROPENSITY SCORE ADJUSTED ANALYSIS

Jai Young Cho[1] Boram Lee[1] Hae Won Lee[1], [1]Seoul National University Bundang Hospital

Background: The treatment of hepatocellular carcinoma (HCC) > 10 cm remains controversial. The ongoing debate regarding the treatment of patients with HCC > 10 cm is partly due to the necessity of tailoring treatment to individual patient conditions. This study aims to address the important controversy regarding the management of large HCC, focusing on providing insights into the comparative effectiveness of liver resection (LR) and Transarterial Chemoembolization (TACE). **Methods:** Patients registered in the Korean Primary Liver Cancer Registry (KPLCR) were selected. The KPLCR is a random sample consisting of approximately 15% of patients newly diagnosed with primary liver cancer registered in the Korean Central Cancer Registry (KCCR), which is a nationwide cancer registry and includes more than 95% of all cancer cases in Korea. The study design utilizes data from the KPLCR covering the years 2008 to 2017 to investigate the treatment outcomes for HCC larger than 10 cm. Starting with 15,307 cases, the study identified 9,310 HCC patients with follow-up data, excluding those with missing initial treatment data (n = 5,863) and follow-up loss (n = 132). From these, 7,662 patients with single HCC were selected, further excluding cases with multiple HCC (n = 1,394) and distant metastasis (n = 254). This refined the cohort to 504 patients with HCC tumors larger than 10 cm, who were then divided into two treatment groups: 122 patients underwent liver resection (LR), and 382 patients received TACE. **Results:** After PSM, the baseline characteristics showed no significant differences between the LR group (n = 99) and the TACE group (n = 99). Before propensity score matching (PSM), the hazard ratio (HR) for LR was 3.41 (95% CI: 2.62-4.43, $p < 0.001$), indicating a significantly better survival probability for the LR group compared to the TACE group. After PSM, the HR for LR was slightly reduced to 3.06 (95% CI: 2.18-4.29, $p < 0.001$), but the survival advantage of LR over TACE remained highly significant. Before PSM, the HR for LR was 3.29 (95% CI: 2.59-4.17, $p < 0.001$), indicating a markedly better recurrence-free survival (RFS) for the LR group compared to the TACE group. After PSM, the HR for LR increased slightly to 3.37 (95% CI: 2.43-4.68, $p < 0.001$), maintaining the significant survival advantage of LR over TACE. **Conclusion:** This study provides a comprehensive analysis of treatment outcomes for HCC > 10 cm, comparing LR and TACE using data from the KPLCR. The results indicate that LR is associated with significantly better OS and RFS compared to TACE, both before and after PSM.

0257 | LIVING DONOR LIVER TRANSPLANTATION REMAINS UNDERUTILIZED FOR CHOLANGIOCARCINOMA DESPITE COMPARABLE SURVIVAL

Farinaz Ghodrati[1] Samir Abu-Gazala[1] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania

Background: Cholangiocarcinoma (CCA) is an aggressive disease with a 5-year overall survival of less than 10%. While liver transplantation offers curative potential for select patients with CCA, it remains an uncommon and understudied indication. Limited data exist on national trends in liver transplantation for CCA and on whether post-transplant outcomes differ between deceased donor and living donor grafts. Clarifying these differences may help guide clinical decision-making and expand access to transplant options in appropriately selected patients. **Methods:** This was a retrospective cohort study using data from the United Network for Organ Sharing from 2002 to 2022. Adult patients who were waitlisted with known CCA were identified. Candidate and transplantation data were ascertained,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

including receipt of deceased donor liver transplant (DDLT) or living donor liver transplant (LDLT). Linear regression was used to evaluate trends in CCA listings and transplants were evaluated over time, which were further stratified by donor type. Among patients who received transplant, survival analysis was then performed to evaluate the association between donor type and post-transplant mortality through 5 years. Unadjusted Kaplan-Meier and multivariable Cox regression analyses (adjusted for age, sex, race/ethnicity, and BMI, MELD, ascites, and encephalopathy at transplant) were performed. **Results:** A total 1,291 waitlisted patients were included; the cohort had median age 54 years, 68.6% male, 87.7% white, with median MELD-Na at listing of 8. Over time there were significant increases in new listings for CCA (beta 4.39, 95% CI 3.29-5.50, $p < 0.001$) and absolute number of transplants for CCA (beta 2.49, 95% CI 1.81-3.17, $p < 0.001$; Figure panel A). There was an increase over time in DDLT (beta 2.27, 95% CI 1.64-2.90, $p < 0.001$) but not in LDLT ($p = 0.18$; Figure panel B). In survival analysis, there was no significant difference in post-transplant mortality through 5 years between DDLT and LDLT for CCA in either Kaplan-Meier ($p = 0.28$) or Cox regression models (HR 0.87, 0.61-1.25, $p = 0.45$; Figure panels C/D). **Conclusion:** Liver transplantation for CCA has increased over the past two decades, driven primarily by growth in deceased donor transplants. Despite stable LDLT rates, post-transplant survival was comparable between DDLT and LDLT. These findings suggest that living donor liver transplantation may be underutilized for CCA and highlight the need to optimize patient and provider awareness regarding outcomes by donor type.

Background: Advanced primary liver cancers (PLCs) — hepatocellular carcinoma (HCC), combined hepatocellular–cholangiocarcinoma (cHCC-CCA), cholangiocarcinoma (CCA), fibrolamellar carcinoma (FLC), hepatic sarcoma, and hepatic epithelioid haemangioendothelioma (HHE)—are hard to treat after first-line therapy fails. The 2025 French Genomic Medicine Initiative aimed to find actionable targets for personalized treatment based on Whole Exome/Whole Genome/RNA sequencing of the tumor. **Methods:** Patients with PLC progressing under first-line systemic therapy were enrolled across eight centers in the French Medicine Genomic Program. Tumor and blood samples were analyzed using WGS/WES/RNASeq to identify targetable genetic alterations classified using the ESCAT scale. The results of the genomic analyses and potential targeted therapies were discussed in molecular tumor board. Clinical and pathological data, radiological responses and outcomes were recorded. **Results:** 120 patients were enrolled: 80 HCC, 25 CCA,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

9 cHCC-CCA, 4 FLC, 1 hepatic angiosarcoma, and 1 HHE. Recurrent alterations included *TP53* (46%), *TERT* (44%), *CTNNB1* (20%) and *RB1* (16%) in HCC; and *TP53* (55%), *ARID1A* (20%), *BAP1* (20%) and *PIK3CA* (15%) in CCA and in cHCC-CCA, *TP53* (66.6%), *PIK3CA* (22.2%) and ARID2 (11%) In cHCC-CCA. All FLC cases harbored the *DNAJB1/PRKACA* fusion but without associated targetable alterations. Among the 103 analyzable genomic analysis, 66 patients (64%) harbored had at least one actionable alteration (59% in HCC, 80% in CCA, 78% in cHCC-CCA). Among the 66 patients with targetable genomic alterations and taking into account the highest ESCAT scale, 3 patients (4.5%) harbored ESCAT II, 49 patients (74%) ESCAT III, and 14 patients ESCAT IV (21%) genomic alterations. Thirty-one patients (22 patients with HCC, 4 with CCA, 3 with cHCC-CCA, 1 with HEE and 1 with angiosarcoma) received matched therapy (47% of patients with targetable alterations) after one line of previous systemic treatments in 10 patients, 2 lines in 9 patients and 3 lines or more in 12 patients. Two of these patients have ESCAT II mutations, 22 tiers III mutations and 7 tiers IV mutations (*ERBB2/ERBB3* amplification, *PTEN* deletion, high HRD, *TSC1/TSC2* inactivation, *CD4/CDK6* amplification, *FGFR1* amplification, *FGF19* amplification, *MET* overexpression…). Among these 31 patients, disease control (stable disease/radiological response) was achieved in 29% of these patients (23% in HCC, 50% in CCA, 67% in cHCC-CCA). Patients with disease control had a longer median PFS compared to patients without disease control (7.07 months versus 2.33 months, $P = 0.016$, Figure 1). Finally, disease control rate was observed in 38% of ESCAT II/III versus 0% of ESCAT IV alterations. **Conclusion:** Comprehensive genomic profiling of advanced primary liver cancers is feasible and was associated with disease control in a subset of heavily pretreated patients with ESCAT II/III genetic alterations.

0259 | HOW COLLABORATIVE WORKING WILL ACHIEVE THE WHO TARGET -TO ELIMINATE HEPATITIS C VIRUS (HCV) IN CHILDREN AND YOUNG PEOPLE BY 2030

Carla Lloyd[1] Tayebah Abbasi[2] Palaniswamy Karthikeyan[3] Sanjay Bansal[4] William Irving[5] Paddy McMaster[6] Alasdair Bamford[7] Caroline Foster[8] Anna Turkova[9] Dhamyanthi Thangarajah[10] Siske Struik[11] Mark Gillyon-Powell[12] Ashley Brown[8] Chayarani Kelgeri[2] Joanne Crook[13] Sarah Tizzard[14] Monica Mitcham[15] Penny North-Lewis[3] Rachel Cockayne[16] Hayley Allen[2] Stephen Corcoran[2] Clare Rayner[2] Deirdre Kelly[17]

[1]Birmingham Women's and Children's Hospital NHS FT, [2]Birmingham Women's and Children's NHS FT, [3]Leeds General Hospital, [4]King's College Hospital, [5]Nottingham University, [6]Manchester Hospital, [7]Great Ormond Street Hospital, [8]Imperial College London, [9]University College London, [10]Chelsea and Westminster Hospital, [11]Cardiff and Vale University Hospital, [12]NHS England, [13]KIng's College Hospital London, [14]St George's Hospital, London, [15]Birmingham Women's and Children's NHSFT, [16]Birmingham Women's and Children's, [17]Birmingham Women's and Children's NHFT and University of Birmingham

Background: HCV infection is a major global health problem in adults & children. Direct Acting Anti-viral therapy (DAA) with cure rates of 99% was licensed for children 3–12 years in 2020. To ensure equitable access, safe, effective & convenient supply of these medications during the Covid-19 Pandemic, we established a virtual, national treatment pathway for children & young people (CYP) aged 3-18yrs with HCV in England & evaluated its feasibility, efficacy & treatment outcomes. **Methods:** A virtual, paediatric Multidisciplinary Team Operational Delivery Network (pODN), funded by NHS England (NHSE), was established in 04/21 with relevant paediatric specialists (hepatologists, virologists, infectious disease and pharmacists) providing a single point of contact for referrals & support. A national pathway for referral & treatment protocols were agreed for DAA HCV therapy funded by NHSE at no cost to referring centres. On referral the pODN discuss & agree the most appropriate DAA therapy based on clinical presentation &patient preferences, including ability to swallow tablets. Treatment was prescribed in association with the local hepatologist, paediatrician & pharmacist, without the need for the children & families to travel to national centres. Data collected: Demographic; clinical; social; treatment; treatment outcomes; End of Treatment (EoT) Sustained Viral Response (SVR) at 12weeks & 12months in patients where reached. Feedback on feasibility & satisfaction on the pathway was sought from referrers & families. **Results:**

155 CYP referred by 14 centres, were discussed & approved for treatment, 04/21–05/25. Median (range) age yrs 8(3-17); 78F; Vertical Transmission (146/155) was the main route of transmission. Genotype 1 &3 were the most common infection; Harvoni was prescribed in 77 (48 tablets;29 granules): Epclusa in 60 (39 tablets;21granules); & Maviret in 18 (10 tablets;8 granules). 133 reached EoT; 1 child failed treatment showing an increase in viral load of EoT; treatment resistance results awaited; 132/133 cleared virus at EoT (>99% clearance); 100% 12mSVR (95/95). Referring teams found the referral process simple & clear; ODN meetings very informative: highly satisfied with overall service. Families reported DAA treatment was fully explained; staff were attentive, thoughtful providing an excellent service, with treatment closer to home(Table1). **Conclusion:** The UK National paediatric virtual network is safe, cost effective & popular with both families & referrers. Treatment success rate was >99% (132/133) in those who completed treatment with 100% confirmed SVR12m. It has enhanced access to anti-viral therapy for CYP who are treated closer to home, reducing travel time to specialist centres preventing long-term liver disease & spread of HCV & made a fundamental contribution to achieving NHSE target to eliminate HCV in children & adolescents ahead of the WHO 2030 target Acknowledgements: Referring teams; BWC; NHS England

Median (range) age in years	8.4 (3.0 – 17.8)

0260 | IMPACT OF REAL-WORLD HEPATITIS C VIRUS ANTIBODY TESTING MODALITIES ACROSS DIFFERENT COMMUNITY AND CLINICAL SETTINGS ON EFFECTIVE LINKAGE TO CARE

Grishma Hirode[1] Camelia Capraru[1] Aaron Vanderhoff[1] Andrew Mendlowitz[1] Brett Wolfson-Stofko[1] Joel Karkada[1] David Smookler[1] Mediongo-Abasi Usoro[1] Steven Friedman[2] Kathy Bates[3] Tony Mazzulli[4] Joshua Juan[5] Hemant Shah[1] Bettina Hansen[6] Harry Janssen[7] Mia Biondi[1] Jordan Feld[8], [1]Toronto Centre for Liver Disease/Viral Hepatitis Care Network (VIRCAN), University Health Network, [2]Department of Emergency Medicine, University Health Network, [3]Emergency Department, Toronto Western Hospital, University Health Network, [4]Department of Microbiology, University Health Network/Sinai Health System, [5]Toronto Western Hospital Liver Center, [6]Erasmus MC Rotterdam, [7]Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center, [8]Toronto General Hospital

Background: Optimal hepatitis C virus (HCV) screening and treatment is required to prevent transmission, and progression to advanced liver disease. Existing strategies largely focus on risk-based or population-based screening. This is a large real-world analysis comparing the effectiveness of HCV antibody (Ab) screening modalities across different community and clinical settings to understand barriers to progress through the care cascade. **Methods:** Cross-sectional study of individuals who completed HCV Ab testing at multiple centres in Ontario, Canada May 2010-June 2023. Ab testing occurred by phlebotomy-based

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

serological testing (ST), point-of-care (POC) testing, or a dried blood spot (DBS) collection card. HCV RNA testing was setting-specific and used DBS for POC and DBS Ab, and phlebotomy-based tests for ST (no reflex testing). Turnaround time was 1-2 weeks for Ab and RNA for all modalities except POC. Ab test settings included primary care/HIV pre-exposure prophylaxis clinics (PC/PrEP), emergency department/walk-in clinics (ED/walk-in), one-time screening events (SE), community outreach programs (CO), and addiction clinics (AC). **Results:** Among 61,605 tests (mean age 47 years, 51% women, 50% ST, 42% POC, 5% DBS), HCV Ab+ prevalence was 14% (n = 8,352; 50% newly identified, 32% aged 35-44 years, 63% men) and highest at AC (41%) and among DBS (26%). Overall, among HCV Ab+, 80% completed RNA testing of whom 57% were RNA+. Among RNA+, 65% attended a follow-up appointment. Among those who attended the appointment, 94% started treatment, 77% of those who started had documented treatment completion, and 60% of those who completed treatment had documented SVR12. PC/PrEP used ST (97%), ED/walk-in used both POC (38%) and DBS (62%), and SE, CO, and AC largely used POC (≥ 75%). Ab testing modality was closely related to test setting, and PC/PrEP was most effective at linkage to care (figure). After an HCV RNA+ result, treatment initiation was better in those tested by POC than DBS. **Conclusion:** Our data highlight strategies to improve progression through the cascade and linkage to care. Identifying the most effective setting-specific testing modality based on the population, staff, and available resources is crucial during the development of an HCV screening program. Receipt of an immediate response with POC likely increased patient engagement by setting up an appointment to receive the RNA result and initiate treatment if positive.

0261 | POINT-OF-CARE HCV RNA TESTING IN STREET MEDICINE: ADVANCING PATIENT ENGAGEMENT AND MEDICAID POLICY IN KENTUCKY, USA

Philip Graham[1] Morgan Cole[2] Lisa Yarber-Cambron[2] Laura Guy[2], [1]Northern Kentucky Health, [2]Solutions Health

Background: Kentucky ranks among the top 3 US states in prevalence of acute hepatitis C virus (HCV) infection. In June 2024, the FDA authorized the Cepheid Xpert® HCV VL Fingerstick (CXHVF), the first FDA-approved point-of-care (POC) HCV RNA test. Previously validated in diverse global settings, this assay offers the potential to streamline diagnosis and linkage to care. In the US, efficient diagnosis and linkage to care is a critical strategy for Medicaid beneficiaries diagnosed with HCV, among whom significant barriers persist and treatment uptake remains low. Among these barriers are KY Medicaid prior authorization (PA) requirements for quantitative HCV RNA results, limiting the utility of qualitative POC testing like CXHVF. We implemented CXHVF testing pilot in 2 organizations serving people who use drugs and assessed the acceptability, feasibility, and impact on completion of 1st appointment where AASLD pretreatment labs are drawn. **Methods:** In February 2025, the KY Department for Public Health Viral Hepatitis Program (VHP), in collaboration with the Gilead FOCUS Program, selected two partner organizations serving people who use and/or inject drugs to pilot the CXHVF. Each site implemented the system in community-based settings and systematically tracked clinical implementation challenges, patient demographics, test results, co-administered tests, completion of 1st appointment, ect. Biweekly, partner sites, VHP, and FOCUS convened to review clinical/ implementation findings. Separately, VHP regularly met with Department of Medicaid Services (DMS) to share findings. **Results:** Between February and May, 143 individuals were screened for HCV using the CXHVF. Of these, 88 (61.5%) were under age 46, 88 (61.5%) were male, 120 (83.9%) were White, and 87 (60.8%) reported IDU. Overall RNA positivity rate was 32.9%. Patient engagement was high; of those with HCV RNA-positive results, 55.3% completed their first appointment between 1 and 51 days with an average time of 8 days, and $>95\%$ screened for HCV agreed to concurrent HIV and syphilis screening. Furthermore, through VHP's sharing of patient engagement pilot findings, DMS updated the PA to accept qualitative RNA results. **Conclusion:** This real-world pilot demonstrated that the CXHVF is acceptable and feasible in community-based settings serving high-risk populations. High patient willingness to test, coupled with significant uptake of co-administered STI screening, and meaningful follow-through to the completion of the 1st appointment underscores the clinical utility of this POC platform. The pilot findings also contributed to a significant policy shift that reduces barriers Medicaid beneficiaries to treatment. These findings illustrate how implementation of innovative diagnostics can improve engagement and catalyze policy change in support of HCV elimination goals.

0262 | MOBILE HCV RNA TESTING IN ACTION: POINT-OF-CARE ENABLED DIAGNOSIS AND SVR CONFIRMATION TO DRIVE FIELD-BASED HCV ELIMINATION

Dylan Moore[1] Ann Moore[2], [1]Arizona Liver Health and Viral ElimiNation (VEN) Centers, [2]Arizona Liver Health

Background: Timely confirmation of active hepatitis C virus (HCV) infection is critical for initiating treatment, avoiding unnecessary lab draws, and conserving outreach resources. In field-based models, delays between antibody screening and RNA confirmation frequently lead to loss to follow-up, especially among individuals experiencing homelessness, substance use, or incarceration. To address this gap, VEN Centers integrated the Cepheid GeneXpert HCV RNA point-of-care (POC) platform into its mobile outreach model, enabling same-day diagnosis, treatment planning, and sustained virologic response (SVR) confirmation. This real-time strategy aims to enhance engagement, improve efficiency, and strengthen HCV elimination efforts in the field. **Methods:** Between April 1 and May 22, 2025, HCV antibody-positive individuals encountered during VEN outreach were tested using Cepheid POC RNA at the point of contact. Testing occurred in diverse non-clinical environments including home visits ($n=30$), recovery centers ($n=13$), guerrilla street outreach ($n=10$), mobile units ($n=8$), homeless services ($n=5$), syringe service programs ($n=3$), and jail ($n=1$), using units deployed in mobile vans or vehicles. Venous samples were also submitted for standard lab confirmation. Patients were categorized by HCV history and testing purpose (initial diagnosis or SVR verification). **Results:** Among 70 HCV antibody-positive individuals tested: • 32 (45.7%) were RNA positive and eligible for treatment • 26 (37.1%) were RNA negative post-treatment, confirming SVR • 8 self-reported active HCV but were RNA negative, avoiding unnecessary labs • 4 newly screened were RNA negative, indicating spontaneous clearance. Cepheid

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

results were 100% concordant with lab-based quantification. The platform provided real-time infection status, facilitated immediate treatment planning, allowed for SVR verification, and supported patient education, streamlining resources and minimizing re-engagement efforts. **Conclusion:** VEN Centers effectively implemented Cepheid GeneXpert RNA testing in a mobile, field-based HCV model, demonstrating clinical utility and operational feasibility. By embedding rapid RNA diagnostics into outreach across homes, shelters, and the streets, the approach enabled same-day clinical decisions, reduced lab burden, and improved engagement. This model offers a scalable blueprint for RNA confirmation within outreach-driven HCV elimination strategies. Additional treatment and outcome data will be presented at the conference.

0263 | ILLUMINATING GAPS, IGNITING CHANGE: A DATA-POWERED APPROACH TO HCV EDUCATION IN GHANA

Zamzam Ismail Artan Ali[1] Lewis Roberts[2] Yvonne Nartey[3] Charles Adjei[4] Amoako Duah[5] Peter Fosu[6], [1]Mayo Clinic, [2]Mayo Clinic Rochester, [3]University of Cape Coast School of Medical Sciences, Ghana, [4]University of Ghana, [5]University of Ghana medical center, [6]Hepatitis Alliance of Ghana

Background: Hepatitis C virus (HCV) is one of the leading causes of liver cirrhosis and hepatocellular cancer globally. Despite existence of curative therapy, HCV-related deaths and complications remain a public health concern, especially in low- and middle-income countries. In Ghana, the national HCV seroprevalence is approximately 2.6%. However, the burden is higher in northern Ghana, ranging from 8% to 14%. Led by its National Viral Hepatitis Control Programme (NVHCP), Ghana launched the Screening and Treatment Opportunity Project for Hepatitis C (STOP HepC) in March 2023 which aims to link 50,000 Ghanaians to free HCV treatment. To increase enrolment, a nationwide education and awareness campaign on HCV was developed. This knowledge, attitude and practice survey is part of Ghana's national HCV campaign. **Methods:** A cross-sectional study in Ghana's Upper East, Central, and Ashanti regions, enrolled 1002 participants (n = 497 lay population and n = 505 healthcare workers). A questionnaire, informed by a literature review of HCV literacy and attitudes, was designed to collect sociodemographic data, HCV testing history, knowledge, attitudes, and practices using yes/no and Likert-scale formats. The instrument was piloted in the Greater Accra Region among 30 healthcare workers and lay population prior to the main study. Data collection for the main study took place from 13th June to 27th July 2024. We excluded those unable to consent, and healthcare workers in mandatory service/internship. Trained research personnel administered questionnaires in English or local languages (Buli, Fante, Twi) where relevant. Descriptive analysis of participants responses was performed, and logistic regression examined the association between factors such as hearing about HCV, knowing someone with HCV and prior HCV testing. **Results:** Demographic characteristics of study participants are shown in table 1. The mean knowledge score for the lay population is 0.294 and for healthcare providers is approximately 0.672. Despite 94% of healthcare providers hearing about HCV, only 40.8% were tested, vs 29% of the 51% of the lay population who had heard about it. Lack of awareness correlated with not testing, Individuals who had heard about HCV were 10 times more likely to have been tested for HCV compared to those who had not heard about it [OD = 10, 95% CI 5.38-21.82, $p < 0.005$] after adjusting for confounders. Furthermore, the odds of HCV testing were 7 times higher among persons who knew someone with HCV compared to those who did not [OD = 7, 95% CI 5-10.6 $p < 0.005$].We will build a predictive model to help inform the focus of the education campaign. **Conclusion:** The study revealed a significant gap in HCV knowledge. Hearing about HCV and knowing someone with the condition were strong predictors of testing. There is a need for targeted and context specific educational campaign, informed by predictive models developed from this data to enhance HCV testing and awareness in Ghana.

0264 | GLOBAL PROGRESS TOWARD HEPATITIS C ELIMINATION: MONITORING ACHIEVEMENTS OF WHO GOALS AND TARGETS FOR HEPATITIS C PREVENTION AND CARE

Zoe Ching[1] Lindsey Hiebert[2] John Ward[1], [1]Coalition for Global Hepatitis Elimination, [2]Coalition of Global Hepatitis Elimination

Background: In 2015, WHO established global goals to eliminate Hepatitis C virus (HCV) as a global health threat, defined by reductions in HCV incidence and mortality by 2030. To monitor progress toward achievement of elimination goals, WHO created the Path to Elimination (PTE) tiers (bronze, silver, gold) of coverage targets for HCV prevention, diagnosis, and treatment. **Methods:** Provisional data from WHO Global Health Observatory, Georgetown HIV Policy, UN population data, peer-reviewed literature, and CGHE National Hepatitis Elimination Profiles were analyzed for 167 countries and territories to assess progress toward the 2030 elimination goals for HCV incidence (< 5 new infections/100,000) and mortality (< 2/100,000). Three coverage targets were examined from the PTE criteria: % of HCV infected persons diagnosed (D); % of HCV diagnosed persons treated (T); and number of needle/syringes (NS) distributed per person who inject drugs per year. The tiers are defined as: Bronze ($D \geq 60\%$, $T \geq 50\%$, NS present), Silver ($D \geq 70\%$, $T \geq 60\%$, NS + opioid agonist therapy (OAT) present), Gold ($D \geq 80\%$, $T \geq 70\%$, > 150 NS). Data are presented for the most recent year available. **Results:** Progress Towards WHO Mortality and Incidence Goals A total of 25 (15%) and 24 (14%) countries are at or below the 2030 targets for HCV mortality and incidence, respectively. 10 countries (6%) meet both targets, with 6 of those countries in the Americas (Bolivia, Brazil, Chile, Ecuador, Paraguay, and Peru). Progress Towards PTE tiers For NS Coverage, 66 (39%) met Bronze, 53 (32%) met Silver, and 12 (7%) met Gold. For diagnosis coverage, 20 (12%) meet Bronze, 13 (8%) meet Silver, and 10 (6%) meet Gold. No countries in the South East Asia Region (SEARO) reached Bronze. The US diagnosis coverage (68%) meets Bronze. For treatment coverage, 29 (17%) meet Bronze, 19 (11%) meet Silver, and 10 (6%) meet Gold. Rwanda is the only African country that reached Gold. The US has 43% in HCV treatment coverage. Two other countries (Egypt and Norway) meet Gold, while three countries meet Silver (Australia, Georgia, Spain). **Conclusion:** Although achievement of PTE tiers requires validation by WHO, provisional data reveal the countries on the PTE for the 2030 targets and WHO 2030 Elimination Goals. Challenges remain for most countries. The US and other countries need to commit the resources for expanding NS services, access to HCV treatment, and policies to scale-up HCV screening to accelerate progress toward HCV elimination.

◆ 1001 | ACTIVATION OF HEPATIC USP5 AMELIORATES MASLD VIA DEUBIQUITINATING CPT-1A

Qinmei Sun[1] Jiamei Chen[2] Siting Gao[3] Xin Xin[2] Yidan Shang[2] Yaoshan Zhou[2] Ru-Tao Lin[2] Yiyang Hu[2] Ping Liu[2] qin feng[2], [1]shanghai university of traditional chinese medicine, [2]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [3]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicin

Background: The pathogenesis of Metabolic dysfunction-associated steatotic liver disease (MASLD) is complex. Deubiquitinating enzymes (DUBs) are crucial for liver pathophysiology by precisely controlling protein function, localization and degradation. This study evaluated the potential role and therapeutic value of Ubiquitin specific protease 5 (USP5) in MASLD.

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Methods: Firstly, the role of USP5 in MASLD was evaluated through liver tissues of MASLD patients, mice, and steatosis hepatocytes. Then, the hepatocyte specific USP5 knockout mice and the liver-specific USP5 overexpression mouse was constructed and feeding with a high-fat and high-sugar diet to establish MASLD. Further, chromatography-tandem mass spectrometry (CoIP-MS) analysis, co-immunoprecipitation (CoIP), and Surface Plasmon Resonance (SPR) was used to identified the interacting protein of USP5. Then, CHX, MG132 and ubiquitination assays were used to reveal the deubiquitination of USP5. Finally, a series of USP5 truncation plasmids and ubiquitin chain plasmids were constructed to clarify the mechanism of USP5 regulating downstream protein. **Results:** Both clinical samples and experimental models consistently demonstrated significantly downregulated USP5 protein expression in MASLD. Whether *in vitro* or *in vivo*, knockdown or knockout of USP5 could markedly aggravated hepatic steatosis and inflammation, whereas USP5 overexpression significantly alleviated these characteristic lesions. Subsequently, CoIP-MS identified CPT-1A, a rate-limiting enzyme in fatty acid oxidation, as a novel USP5-interacting protein. This interaction was further confirmed by endogenous co-IP and SPR, demonstrating direct binding between USP5 and CPT-1A ($Ka = 3.995E \pm 4(1/Ms)$, $Kd = 0.005009$ (1/s)). Mechanistically, the protein truncation test revealed that the 749-835 amino acid domain of USP5 could mediate this interaction. Further, CHX and MG132 treatment demonstrated that USP5 binding could stabilize CPT-1A by extending its protein half-life. And, ubiquitination assays found that USP5 deficiency enhanced CPT-1A polyubiquitination, while USP5 overexpression reduced this modification. Most importantly, the ubiquitin chain linkage mapping identified K6-linked polyubiquitination as a specific mechanism through USP5 regulating CPT-1A. **Conclusion:** This study indicates the mechanism whereby USP5 inhibits MASLD through deubiquitination-mediated stabilization of CPT-1A, suggesting that targeting USP5 is a potential therapeutic strategy for MASLD.

◆ 1002 | GENIPOSIDE ALLEVIATES MASH BY TARGETING USP15 TO ENHANCE PLIN2 UBIQUITINATION AND PROMOTE HEPATIC LIPOPHAGY

Chen Zou[1] Xin Xin[2] Xiao Xu[1] Qinmei Sun[1] Zhuoyuan Wang[1] Sheng Lyu[1] Ru-Tao Lin[1] Ziming An[1] Yiyang Hu[1] qin feng[1], [1]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [2]Shanghai University of Traditional Chinese Medicine

Background: Geniposide (GE), a natural iridoid glycoside, is known for its anti-inflammatory, antioxidant, and glucolipid metabolic regulatory effects, particularly in reducing hepatic lipid deposition and inflammation, which suggests its potential in treating metabolic dysfunction-associated steatohepatitis (MASH). This study aims to explore the therapeutic targets of GE in MASH and clarify its pharmacological mechanisms. **Methods:** In this study, MASH mouse model induced by high trans-fatty acid and high-sugar diet (HFHC) and FFAs (Free Fatty Acids)-induced AML12 cells and primary hepatocytes models were used to investigate the anti-MASH effect of GE. The potential GE-binding proteins were screened by HuProt protein chip and pull-down mass spectrometry (MS). The interaction between GE and the target protein was verified by cellular thermal shift assay (CETSA) and Drug Affinity Responsive Target Stability (DARTS). AML12 cell models with USP15 overexpression or knockout via stable transfection confirmed that USP15 is crucial for GE - regulated lipid deposition in MASH. Co-immunoprecipitation (Co-IP) MS was used to screen the downstream substrates of the binding protein. **Results:** In both in vivo and in vitro MASH models, GE treatment significantly improved MASH pathogenesis, with a notable reduction in hepatic lipid deposition. Proteomic analysis demonstrated that USP15 is a potential direct binding target of GE, which was further validated by CETSA and DARTS assays. Genetic knockout of USP15 in AML12 cells not only alleviated intracellular lipid accumulation but also attenuated the therapeutic efficacy of GE, highlighting USP15 dependency in GE-mediated lipid regulation. Mechanistically, Co-IP MS identified PLIN2, a key lipophagy regulatory protein, as a physical interactor of USP15, with their subcellular co-localization confirmed by immunofluorescence and Co-IP. GE

treatment significantly promoted PLIN2 ubiquitination, an effect reversed by USP15 overexpression. Critically, in both in vivo and in vitro, GE administration was associated with decreased PLIN2 protein expression in hepatocytes, which correlated with significantly enhanced lipophagic activity as assessed by LC3B puncta formation and autophagic flux analyses. **Conclusion:** Our research clearly demonstrated that GE can enhance hepatocyte lipophagy and reduce MASH-related hepatic lipid deposition by targeting hepatic USP15 and then up-regulating PLIN2 ubiquitination.

◆ 1004 | GENIPIN 1-GENTIOBIOSIDE TARGETING IRAK4 TO INHIBIT NLRP3 INFLAMMASOME ACTIVITY IN LIVER MACROPHAGES TO ALLEVIATE METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS INFLAMMATION

Zhuoyuan Wang[1] Beiyu Cai[2] Xin Xin[1] Qinmei Sun[3] Ziming An[1] Qian Huang[1] Sheng Lyu[1] Xiaojun Gou[4] Yiyang Hu[1] Fu-rong Qiu[1] qin feng[1], [1]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [2]Shuguang Hospital Afflicated to Shanghai University of Traditional Chinese Medicine, [3]Shanghai University of Traditional Chinese Medicine, [4]Baoshan District Hospital of Integrated Traditional Chinese and Western Medicine of Shanghai

Background: Genipin 1-gentiobioside (GG), a major active component isolated from Gardenia jasminoides, a traditional Chinese medicine for liver-related diseases, lacks defined efficacy and mechanisms against Metabolic Dysfunction-Associated Steatohepatitis (MASH). This study aims to uncover the therapeutic effects of GG on MASH and its underlying mechanisms. **Methods:** Mice were fed a high-fat high-carbohydrate diet with sugar water (HFHC) for 18 weeks to establish MASH. At the last 6 weeks, mice in the GG group received GG (50/100 mg/kg/day) by oral gavage. In vitro, free fatty acid induced primary hepatocytes and AML-12 cells were employed. Histopathological examination, biochemical examination and other methods were used to evaluate the effect of GG on MASH. Transcriptomic analysis reveals the regulatory effect of GG on hepatic inflammation in MASH mice. Dynamic molecular docking simulation, cell thermal migration analysis (CETSA) and drug affinity reaction target stability (DARTs) were used for prediction and identification. Subsequently, we evaluated the effects of GG on IRAK4 activity, NF-κB transcription, and NLRP3 inflammasome activation in both in vivo and in vitro models. The in vitro model utilized LPS+ATP to induce NLRP3 inflammasome activation in bone marrow-derived macrophages. Systemic IRAK4 knockout mice were established with wild-type mice as controls, and both in vitro and in vivo approaches were employed to investigate the impact of GG on the IRAK4/NF-κB/NLRP3 signaling pathway. **Results:** GG significantly

ameliorates MASH in both in vivo and in vitro models, through NLRP3 transcriptional regulation. In line with the suggestion of dynamic molecular docking, CETSA and DARTS assays demonstrated that GG binds to IRAK4 and stabilizes its protein structure. Critically, integrated in vivo and in vitro evidence demonstrates that GG potently suppresses IRAK4 activity in macrophages, thereby inhibiting NF-κB transcriptional activity, blunting NLRP3 inflammasome activation, and ultimately reducing pro-inflammatory mediator expression. However, when IRAK4 was knocked out, this inhibitory effect was significantly attenuated both in vivo and in vitro. **Conclusion:** GG ameliorates MASH by targeting IRAK4 to inhibit NF-κB transcriptional activity, thereby blunting NLRP3 inflammasome activation in hepatic macrophages. This mechanistic insight provides a foundation for its therapeutic translation.

◆ 1005 | LIVER SINUSOIDAL ENDOTHELIAL CELL INTERCELLULAR ADHESION MOLECULE 1 (ICAM1) PROMOTES LIVER INFLAMMATION IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Qianqian Guo[1] Nantawat Satthawiwat[1] Akitoshi Sano[1] Xin Dai[1] Chady Meroueh[1] Khaled Warasnhe[1] Alexander Washinton[1] Alex Krivonos[1] Sheng Cao[2] Enis Kostallari[2] Johan Jonker[3] Bart van de Sluis[3] Feda Hamdan[1] Samar Ibrahim[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester, [3]University Medical Center Groningen

Background: During metabolic dysfunction associated steatohepatitis (MASH), liver sinusoidal endothelial cells (LSEC) acquire a pro-inflammatory phenotype characterized by increased adhesion molecules expression and myeloid cells associated liver inflammation. We aim to uncover the pathogenic role and the transcriptional regulation of ICAM1, an upregulated LSEC adhesion molecule in MASH and lipotoxicity. **Methods:** Models of lipotoxicity and MASH employed include an in *vitro* model of primary human LSEC treated with palmitate (PA), an *ex vivo* model of cultured precision cut MASH mouse liver slices, and *in vivo* models of high fat fructose and cholesterol (FFC) diet and choline deficient high fat diet (CDHFD) induced MASH. Mice with diet-induced MASH received ICAM1 neutralizing antibody (ICAM1 Ab) or isotype control. **Results:** Analysis of GeoMx digital spatial profiling on human liver tissue (Figure1) showed enhanced outgoing extracellular matrix (ECM)-receptor signaling from endothelial cells to myeloid cells in MASH patients. The ECM- receptor signaling constitutes of profibrogenic genes contributes to the majority of communication patterns between LSECs and Myeloid cells. While cell-cell contact signaling including adhesion molecules, and secreted signaling including proinflammatory cytokines contributes mainly to the communication patterns in patients with steatosis. Differentially expressed proinflammatory and profibrogenic related genes from Von Willebrand factor (vwf)+ LSECs as well as CD68+ macrophages and (elastase) ELA2+ neutrophils showed distinct zonal distribution signatures. Furthermore, ICAM1 immunostaining is increased in human MASH and correlates with disease severity. Assay for Transposase-Accessible Chromatin with sequencing (ATAC-seq) on primary mouse LSEC revealed abundant open chromatin region at *Icam1* promoter in MASH. Chromatin immunoprecipitation (ChIP) showed enrichment for the active epigenetic mark H3K27ac and Bromodomain and Extra-Terminal motif (BET) protein member 4 (BRD4) at the *ICAM1* promoter region in PA-treated primary human LSEC. Furthermore, BET protein pan inhibitor iBET151 suppressed PA-induced upregulation of LSEC ICAM1 and proinflammatory chemokines *in vitro* and *ex vivo* models of lipotoxicity and MASH. Using loss of function paradigm, we show that GSK3β/c-Jun signaling acts as upstream regulator of lipotoxicity-induced ICAM1 upregulation. Flow-based adhesion assay shows reduced neutrophils and monocytes adhesion to PA treated LSEC in the presence of ICAM1 neutralizing antibody. ICAM1Ab-treated mice in 2 diet-induced MASH mouse models had reduced liver injury inflammation and fibrosis. **Conclusion:** LSEC ICAM1 is epigenetically upregulated during lipotoxicity via a GSK3β/c-Jun/BRD4 dependent mechanism and enhances myeloid cells adhesion. ICAM1 inhibition is salutary in murine MASH and might serve as a potential therapeutic target in human MASH.

◆ 1006 | ENDOTHELIAL GLYCOGEN SYNTHASE KINASE 3β DELETION ATTENUATES MITOCHONDRIAL DYSFUNCTION, FERROPTOSIS, AND METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS IN MURINE MASH

Akitoshi Sano[1] Qianqian Guo[1] Khaled Warasnhe[1] Nantawat Satthawiwat[1] Petra Hirsova[1] Davide Povero[1] Samar Ibrahim[1], [1]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by lipotoxicity and liver inflammation. During MASH, liver sinusoidal endothelial cells (LSECs) develop a proinflammatory phenotype known as lipotoxic endotheliopathy, leading to increased pathogenic myeloid cell hepatic infiltration. We have reported that LSEC glycogen synthase kinase 3 (GSK3β) acts as a major kinase hub in MASH. However, the molecular mechanisms and functional outcome of lipotoxicity-induced GSK3β activation in LSEC remain to be elucidated. **Methods:** Endothelial cell-specific *Gsk3β* knockout ($Gsk3\beta^{\triangle End}$) mice were generated by crossing $Gsk3\beta^{fl/fl}$ mice with mice expressing tamoxifen-inducible Cre recombinase under the regulation of the vascular endothelial cadherin promoter. Mice were fed a choline-deficient high-fat diet (CDHFD) or high fat, fructose, and cholesterol (FFC) to induce MASH. Palmitate and/or linoleate-treated primary human LSECs (hLSECs) were employed as an *in vitro* model of lipotoxicity. **Results:** The expression of Intercellular adhesion molecule-1 (ICAM1) (a marker of lipotoxic endotheliopathy), liver inflammation and injury markers were significantly reduced in the CDHFD-fed $Gsk3\beta^{\triangle End}$ mice. Immunophenotyping by flow cytometry on intrahepatic leukocytes showed reduced infiltrating monocytes and conventional type 1 dendritic cellsin CDHFD-fed $Gsk3\beta^{\triangle End}$. Similar results were replicated in mice fed the FFC diet and treated with the GSK3 inhibitor elraglusib, suggesting that LSEC GSK3β modulate dendritic cell maturation. This was further confirmed by transcriptome analysis on LSECs from chow and CDHFD-fed $Gsk3\beta^{\triangle End}$ and $Gsk3\beta^{fl/fl}$ mice showing downregulation of several pro-inflammatory and pro-fibrogenic pathways in the CDHFD-fed $Gsk3\beta^{\triangle End}$ when compared to $Gsk3\beta^{fl/fl}$. Moreover, liver fibrosis and portal pressure were reduced in CDHFD-fed $Gsk3\beta^{\triangle End}$ mice. Pathway analysis on hLSECs transcriptomic identified ferroptosis as a major pathway in LSECs under toxic lipid treatment, which was suppressed with pharamcological GSK3 inhibition. Bodipy C11 and cell viability assays showed that GSK3 inhibition rescued lipotoxicity-induced ferroptosis sensitivity in hLSECs. Moreover, GSK3 inhibition in vitro restored hLSECs mitochondrial respiration, biogenesis and improved the morphological changes induced by lipotoxicity via activation of the AMPK pathway. **Conclusion:** GSK3β inhibition in LSEC attenuates lipotoxic endotheliopathy via inhibiting ferroptosis and restoring mitochondrial function. Moreover, LSEC GSK3 inhibition attenuates proinflammatory myeloid cells hepatic infiltration likely by modulating dendritic cell maturation and reducing ICAM-1 expression. Hence, GSK3 inhibition could serve as a potential therapeutic strategy in human MASH.

Background: Liver fibrosis remains a key driver of morbidity in metabolic dysfunction-associated steatohepatitis (MASH), the progressive form of MASLD. Although highly prevalent, only a subset of patients with MASLD progress to advanced fibrosis, suggesting a loss of intrinsic hepatic resilience. Recent evidence implicates ferroptosis —a regulated form of lipid peroxidation-induced cell death —as a critical contributor to hepatocyte injury and fibrogenesis. However, upstream molecular regulators of hepatocellular ferroptosis remain largely undefined. To identify potential regulators of this loss in resilience to MASH, we reanalyzed published snRNA-seq data (GSE189600) comparing MASLD and MASH patients. Given that many genes contribute to ferroptosis, we developed a custom algorithm (FerroEnrich)[24] to calculate the ferroptosis index and identify key regulatory genes involved in the pathogenesis of metabolic liver diseases. Our analysis revealed enrichment of the ferroptosis pathway and identified GTP cyclohydrolase 1 (GCH1) as a predominant ferroptosis regulator, particularly in diseased livers. To test the hypothesis that GCH1-dependent antiferroptotic capacity acts as a resilience factor mitigating MASH progression, we investigated the molecular mechanism underlying GCH1 downregulation in MASH and demonstrated the feasibility of restoring this protective pathway. We hypothesize that inflammatory signals (e.g., TNFα) reduce RXRα acetylation, impair GCH1 transcription, and predispose hepatocytes to ferroptosis and fibrosis. We aim to define the novel RXRα-GCH1 regulatory mechanism and test whether restoring RXRα acetylation or GCH1 expression enhances hepatocellular resilience and attenuates liver injury in experimental MASH. **Methods:** We employed a multi-tiered approach combining in-silico analyses of ATAC-seq datasets (GSE162870) to assess GCH1 expression patterns in MASH liver. This revealed decreased chromatin accessibility at the RXRα/PPARα binding region within the promoter of GCH1. ChIP-qPCR further confirmed reduced binding of RXRα and PPARα to the GCH1 promoter. To elucidate why RXRα deficiency selectively impairs PPARα signaling and GCH1 expression, we revisited the role of RXRα post-translational modification in regulating its interaction with nuclear receptor partners. Using affinity purification–mass spectrometry, we identified a previously unreported acetylation site on RXRα (Ac-RXRα). To determine the physiological relevance of RXRα acetylation, we generated hepatocyte-specific RXRα knockout mice ($RXR\alpha^{hepKO}$) using Albumin-Cre and challenged them with high-fat, Western, or MASH diet. RXRα acetylation was manipulated via intravenous AAV8-TBG vectors expressing wild-type RXRα, a KQ mutant (acetylation mimic), or a KR mutant (acetylation mutant). Ferroptosis-dependent functional changes were evaluated following AAV8-mediated restoration of GCH1 expression. Liver histology (H&E, Sirius Red), fibrosis scoring, and qPCR analysis of fibrotic and inflammatory markers (Col1a1, Tnfα, Tgfβ1) were performed. Ferroptosis was assessed using LiperFluo staining, 4-HNE quantification, MDA assays, and transmission electron microscopy. RXRα acetylation was measured by IHC and western blot analysis. Data were analyzed by ANOVA or unpaired t-test ($p < 0.05$). **Results:** GCH1 expression was significantly reduced in hepatocytes from fibrotic human MASH livers. Concurrently, ATAC-seq and ChIP-qPCR results revealed decreased RXRα/PPARα binding and chromatin accessibility at the GCH1 promoter, implicating transcriptional deregulation. In $RXR\alpha^{hepKO}$ mice fed Western and MASH diets, we observed exacerbated steatosis, lobular inflammation, and fibrosis. These mice also exhibited increased expression of pro-fibrotic and ferroptosis-related genes, along with elevated levels of hepatic and circulating PCSK9, a marker of dyslipidemia and cardiovascular risk. RXRα acetylation was reduced in TNFα-treated hepatocytes and MASH mouse livers. AAV8-mediated expression of the acetylation mimic RXRα-KQ restored GCH1 transcription, suppressed lipid peroxidation (MDA, 4-HNE), and improved mitochondrial integrity, whereas the KR deacetylation mutant failed to confer these protective effects. AAV8-mediated GCH1 overexpression rescued hepatocyte ferroptosis and oxidative injury in $RXR\alpha^{hepKO}$ livers, with reduced fibrosis and improved hepatic histology, supporting GCH1 as a critical effector of RXRα-mediated protection. **Conclusion:** Our study identifies RXRα acetylation as a key regulator of hepatocellular resilience through the transcriptional activation of GCH1, a ferroptosis suppressor. Inflammatory signaling impairs RXRα acetylation, resulting in GCH1 downregulation, lipid peroxidation, mitochondrial dysfunction, and fibrogenesis. Restoration of RXRα acetylation or GCH1 expression reverses ferroptotic injury and fibrosis, establishing the RXRα–GCH1 axis as a potential dual-action therapeutic target for MASH.

disease (MASLD) using transmission electron microscopy (Journal of Gastroenterology 2025, in press). We have also demonstrated that hydroxynonenal (HNE), derived from diets rich in unsaturated fatty acids and from cellular membranes, plays a role in the progression of MASLD (Cellular and Molecular Gastroenterology and Hepatology 2022). In the present study, we report the discovery that HNE-induced damage to intracellular organelles in hepatocytes shares key morphological features with the characteristic changes observed in MASLD. **Methods:** (1) Analysis in the HNE administration model We examined optical microscopy, HNE immunostaining, and electron microscopy findings using: HepG2 human hepatocellular carcinoma cells, Liver tissue from mice administered intraperitoneal HNE three times per week for 24 weeks, Liver biopsy specimens from Japanese macaques administered intramuscular HNE once per week for 24 weeks. (2) Analysis in the MASLD model We analyzed liver tissue from: Mice fed a choline-deficient, methionine-lowered, amino acid-defined high-fat diet (CDAA) for 8 weeks, Liver biopsies from 40 patients at our institution (11 non-MASLD, 29 MASLD). All samples were evaluated using light microscopy, HNE immunostaining, and electron microscopy. **Results:** (1) In the HNE administration model, we observed mitochondrial abnormalities including loss of double membrane clarity, disrupted cristae, and the presence of highly degenerated spherical mitochondria. Glycogen granules were diminished, and the rough endoplasmic reticulum (rER) exhibited spherical expansion. These findings were consistent across HepG2 cells, HNE-treated mice, and HNE-treated macaques. (2) In CDAA-fed mice, mitochondrial double membrane blurring and cristae disruption appeared as early as week 4. By week 8, spherical degeneration of mitochondria, reduced glycogen granules, and dilated rER were observed. Similar abnormalities were noted in liver biopsies from MASLD patients. Based on previously established criteria, MASLD patients showed significantly more severe ultrastructural abnormalities compared to non-MASLD patients. The extent of these changes correlated with the NAFLD activity score and with the degree of HNE accumulation assessed via immunohistochemistry. **Conclusion:** Using transmission electron microscopy, we observed HNE-induced structural damage to intracellular organelles in hepatocytes. These findings support the involvement of HNE in the pathogenesis of MASLD and offer insights into the mechanisms underlying hepatocellular injury in this condition.

◆ 1009 | ALCOHOL RESHAPES LIVER ZONAL PLASTICITY AND IMMUNE-METABOLIC REPROGRAMMING IN METABOLIC-SYNDROME ASSOCIATED HEPATOCELLULAR CARCINOMA

tian tian[1], [1]Tulane University School of Medicine

Background: Hepatocellular carcinoma (HCC) arising from metabolic dysfunction- or alcohol-associated steatohepatitis (MASH or AH) is an escalating health challenge complicated by overlapping pathologies of metabolic dysfunction-associated alcohol-related liver disease (MetALD). β-catenin governs hepatic zonation and is mutated in 27% of human HCC; however, the tumor origin and immuno-metabolic rewiring remain elusive. **Methods:** Male mice were subcutaneously injected with 200 μg STZ at 2 days after birth (P2) in combination with the feeding of HFD starting at P30. For MetALD-tumor induction, the STAM mice were exposed to 20% alcohol in drinking water at P60. MASH and MetALD mice were euthanized at P150 by CO_2 inhalation. For the AH-HCC model, male mice were subcutaneously injected with 200 μg STZ at P2 and received ethanol containing Lieber-DeCarli diet at P60 and euthanized at P210. **Results:** Herein, we modeled MASH-associated HCC resembling the Hoshida S3-type cancer in the STAM model. These β-catenin-activated tumors originated in periportal/midlobular zones, showed defects in amino acid breakdown, and induced immunosuppressive kynurenine. Conversely, ethanol consumption triggered AH-HCC with low canonical β-catenin signaling. Unexpectedly, ethanol also mediated massive steatosis, senescence, ductular reaction, and β-catenin$^+$ MetALD-HCC of biliary/progenitor origin while decreasing kynurenine production. Compared to immune-excluded MASH-HCC, ethanol enhanced tumor sensitivity to anti-programmed-death-1 (aPD1) *immunotherapy in MetALD-HCC.* **Conclusion:** These findings reveal novel effects of ethanol on β-catenin-driven zonal plasticity and immuno-metabolic reprogramming with therapeutic implications on targeting subtype-specific HCC of steatotic liver diseases (SLD).

◆ 1010 | STARD1-DEPENDENT MITOCHONDRIAL CHOLESTEROL TRAFFICKING ACTIVATES THE NLRP3 INFLAMMASOME COMPLEX IN MASH

Hala Jaara[1] Mariana Acevedo Roldan[2] Laura Fàbrega[1] Susana Núñez[3] Vicent Ribas[3] Carmen Garcia-Ruiz[4] Jose Fernandez-Checa[4] SANDRA TORRES NUNEZ[3], [1]IIBB-CSIC-IDIBAPS-CIBEREHD-UB, [2]IIBB-CSIC-VHIR, [3]IIBB-CSIC-IDIBAPS-CIBEREHD, [4]IIBB-CSIC-IDIBAPS-CIBEREHD-USC

Background: Despite significant advances in understanding the pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH), effective pharmacological treatments for its prevention or management remain unavailable. Recent evidence suggests that the accumulation of cholesterol within mitochondria stimulates reactive oxygen species (ROS) generation, leading to mitochondrial dysfunction, inflammation, and cell death that culminate in the progression of MASH to hepatocellular carcinoma (HCC). The NLRP3 inflammasome, a protein complex activated by cellular stress, is activated by ROS, operates predominantly in macrophages, thereby linking mitochondrial damage to inflammatory liver disease. STARD1, a protein responsible for transporting cholesterol into mitochondria, is upregulated in MASH and contributes to HCC development. We hypothesize that STARD1-mediated mitochondrial ROS generation activates the NLRP3 inflammasome, likely through interactions between liver macrophages and hepatocytes. The overall goal was to explore the consequences of STARD1 induction and its impact on NLRP3 inflammasome activation and the interplay between macrophages and hepatocytes in a murine MASH dietary model. **Methods:** We generated mice with hepatocyte-specific (StARD1$^{\Delta Hep}$) and macrophage-specific (StARD1$^{\Delta Mac}$) deletion of StARD1 and were fed either a standard or a high-cholesterol/sodium cholate diet (2% cholesterol + 0.5% sodium cholate). In some groups, macrophages were depleted by intraperitoneal injection of clodronate liposomes (0.1 ml per 10 g of mouse weight). The study assessed liver injury, inflammation, steatosis, and the expression of inflammatory markers. **Results:** The findings revealed that deleting StARD1 specifically in hepatocytes led to a 50% reduction in mitochondrial cholesterol accumulation and significantly lower expression of inflammasome-associated genes (*Nlrp3, Asc, Casp1*), providing protection against diet-induced liver inflammation. Macrophage depletion in StARD1$^{f/f}$ further reduced liver inflammation with lower expression of *F4/80, Cd68* and inflammasome-associated genes, but did not provide additional benefit beyond StARD1 deletion in StARD1$^{\Delta Hep}$ mice. Similarly, deletion of StARD1 in macrophages alone also resulted in reduced inflammation, demonstrated by decreased expression of *F4/80* and inflammasome-associated genes), as well as a 50% reduction in liver damage assessed by H&E and ALT release. **Conclusion:** Overall, these results identify STARD1 as a molecular trigger of NLRP3 activation and highlight a cross-talk between hepatocytes and macrophages in cholesterol-driven liver injury and inflammation, highlighting its potential as a therapeutic target in MASLD.

◆ 1011 | HECTD3 UBIQUITINATES AND STABILIZES PRDX4 TO AMELIORATE METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Rui Jin[1] Nan Geng[1] Fajuan Rui[1] Wenjing Ni[1] Yixuan Zhu[1] Guangqi Zhu[1] Xiangyu Wu[1] Huan Zhang[1] Shengxia Yin[1] Qianwen Zhao[1] Jie Li[1], [1]Department of Infectious Disease, Nanjing Drum Tower Hospital

Background: Metabolic dysfunction-associated steatohepatitis (MASH) poses a significant global public health challenge. The pathological process of MASH is a tangled progression associated with metabolic syndrome and systemic inflammatory response syndrome. HECTD3, as an E3 ubiquitin ligase, is implicated in the regulation of multiple inflammation and fibrosis associated signaling pathways. However, its role in MASH remains inadequately clarified. This study aimed to investigate the function of HECTD3 driving the development of MASH and explore its potential downstream mechanisms. **Methods:** Hepatocellular HECTD3 were over-expressed in mice via the AAV8 system, and male C57BL/6J mice (six weeks old) were fed either a Choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for 10 weeks,or a high-fat, high-fructose diet (HFHFD) diet for 16 weeks to induce MASH. THLE-2 and AML12 cells were utilized for in vitro studies. **Results:** HECTD3 protein abundance was markedly downregulated in the livers of mice fed a CDAHFD or HFHFD and hepatocytes stimulated by PA. Hepatocyte-specific overexpression of HECTD3 alleviated the progression of MASH. Consistently, lipid accumulation were observed in HECTD3-overexpressed hepatocytes after PA stimulation. The results of co-immunoprecipitation combined with multi-dimensional mass spectrometry analysis revealed that PRDX4 is a potential binding partner of HECTD3. Further endogenous and exogenous co-IP experiments confirmed the interaction between the E3 ubiquitin ligase HECTD3 and PRDX4. Both immunofluorescence and western blot results demonstrated that hepatocyte-

specific overexpression of HECTD3 in MASH mice increased the protein expression level of PRDX4 in the liver, consistent with *in vivo* observations. *In vitro* experiments further confirmed that PRDX4 protein levels were elevated in HECTD3-overexpressed hepatocytes, accompanied by enhanced total ubiquitination of PRDX4. **Conclusion:** HECTD3 interacts with PRDX4 and stabilizes its protein expression by mediating PRDX4 ubiquitination. HECTD3 serves as a key positive regulator of PRDX4 and may represent a promising novel therapeutic target for MASH treatment.

◆ 1012 | ATRACTYLENOLIDE III CAN INHIBIT THE ACTIVATION OF NLRP3 INFLAMMASOME IN LIVER MACROPHAGES BY TARGETING RIPK3 TO TREAT METABOLIC-ASSOCIATED STEATOHEPATITIS

Ziming An[1] Xin Xin[1] Wuxing Cai[1] Zuoyuan Wang[1] Qinmei Sun[1] Yiyang Hu[1] qin feng[1], [1]Shanghai shuguang hospital

Background: Metabolic dysfunction-associated steatohepatitis (MASH) represents a critical progressive stage in metabolic dysfunction-associated steatotic liver disease (MASLD) development. Atractylenolide III (ATL III), a bioactive sesquiterpene lactone derived from Atractylodes macrocephala Koidz, demonstrates diverse pharmacological properties, including antioxidant and anti-inflammatory activities. However, its therapeutic potential and molecular mechanisms in MASH remain unexplored. **Methods:** Three experimental MASH models were employed: (1)a 26-week high-fat high-cholesterol (HFHC) diet-induced model, (2) a 24-week adeno-associated virus 9 -mediated NLRP3 knockdown MASH model, and (3) a 26-week receptor-interacting protein kinase 3 (RIPK3) knockout MASH model. Histopathological features (H&E, Oil Red O staining) and hepatic triglyceride (TG) content were analyzed. For in vitro studies, bone marrow-derived macrophages (BMDMs) isolated from wild-type and NLRP3 or RIPK3-knockout mice were stimulated with LPS+ATP. Direct binding targets of ATL III were identified using drug affinity responsive target stability (DARTS), cellular thermal shift assay (CETSA), and surface plasmon resonance (SPR). **Results:** ATL III significantly ameliorated MASH in mice, as evidenced by reduced hepatic TG accumulation, improved histopathology, and suppressed NLRP3 inflammasome activation through downregulation of NLRP3 mRNA and protein levels. NLRP3 knockdown in vivo impaired ATL III's therapeutic efficacy despite alleviating MASH phenotypes. In vivo and in vitro studies demonstrated that NLRP3 deficiency abrogated ATL III's ability to suppress inflammasome activation, confirming NLRP3 as a critical mediator of its anti-inflammatory action. DARTS/CETSA/SPR assays identified RIPK3 as a direct binding target of ATL III, with SPR confirming high-affinity interaction (KD $= 3.797 \times 10^{-7}$ M). ATL III inhibited RIPK3 phosphorylation and subsequent NF-κB activation, leading to reduced NLRP3 transcription. RIPK3 knockout mice exhibited improved liver histopathology but failed to respond to ATL III treatment. Consistently, both in vivo and vitro models revealed no suppression of NF-κB phosphorylation, NLRP3 expression, or inflammasome activation upon ATL III treatment, underscoring RIPK3's indispensable role in its mechanism. **Conclusion:** ATL III exerts robust therapeutic effects in experimental MASH by targeting RIPK3 to inhibit NF-κB-driven NLRP3 transcription and inflammasome activation in macrophages. These findings establish RIPK3 as a pivotal regulatory node and identify ATL III as a promising candidate for MASH intervention.

◆ 1013 | LIPOTOXIC ER STRESS EPIGENETICALLY UPREGULATES ALARMIN S100A11 VIA A LIPID INDUCED ENHANCER IN MASH

Hanna Erickson[1] P. Vineeth Daniel[1] Feda Hamdan[2] Amy Mauer[2] Yasuhiko Nakao[2] Daheui Choi[2] Gyanendra Puri[2] Yeriel Yoon[2] Alexander Revzin[2] Harmeet Malhi[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a multifactorial liver disease that is characterized by abnormal lipid accumulation in the liver and subsequent inflammation and fibrosis. Its incidence and progression are influenced by both genetic and environmental factors. Abnormal lipid accumulation in the liver leads to lipotoxic endoplasmic reticulum (ER) stress in hepatocytes leading to release of proinflammatory stress signals in the form of extracellular vesicles (EVs). However, whether this process is epigenetically regulated is unknown. **Methods:** We performed an unbiased proteomic screen of EVs released in response to lipotoxic ER stress. We subsequently assessed gene expression in palmitate (PA)-treated hepatocytes in the absence or presence of pharmacologic inhibitors for each of the three ER stress pathways. Using publicly available ChIP-seq data, we identified an H3K27 acetylation site near a regulated gene. To block this open chromatin region, we designed a targeting sgRNA that was introduced to dCas9-KRAB-expressing cell lines and mice. The mice were subsequently treated with 6 weeks of high fat, high fructose, high cholesterol (FFC) diet, which recapitulates human MASH, or 3 weeks of choline-deficient, L-amino acid-defined, high fat (CDAHF) diet, which is a rapid disease model of MASH. **Results:** We found increased levels of S100A11 protein, a known alarmin, in PA-induced hepatocyte-derived EVs and in serum of human MASH patients. S100A11 mRNA and protein levels were also enriched in PA-treated hepatocytes. Pharmacologic inhibition of IRE1α and not the PERK or ATF6a pathways blocked PA-induced S100A11 upregulation. We identified an H3K27 acetylation site upstream of S100A11 that was enhanced in response to PA treatment, which we named a Lipotoxic Induced Enhancer (LIE). Blocking this site with dCas9-KRAB blunted S100A11 upregulation in response to lipotoxic ER stress in the livers of mice fed FFC or CDAHF diets. This also resulted in reduced hepatic injury, steatosis, and inflammatory loci in the liver of these mice. **Conclusion:** Our study shows that lipotoxic signaling through IRE1α increases the expression of pro-inflammatory alarmin S100A11 in hepatocytes and in hepatocyte-derived EVs through H3K27 acetylation at an upstream LIE domain and that blocking this signaling results in improved inflammation and liver injury in MASH mouse models. This suggests that S100A11 may be a therapeutic target for MASH.

Tower Hospital, The Affiliated Hospital of Nanjing University Medical Schoo

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) encompasses a continuum from simple steatosis (MAFL) to metabolic dysfunction-associated steatohepatitis (MASH), a more advanced form marked by necroinflammation and fibrosis. Yet, the underlying molecular mechanisms remain incompletely understood. We aim to investigate the role of methyltransferase like 7B (METTL7B), a member of the mammalian methyltransferase-like (METTL) family, in MAFLD/MASH and explore potential mechanisms. **Methods:** We analyzed public liver transcriptome/proteome datasets to profile METTL genes in MAFLD and MASH. *Mettl7b* liver-specific knockout (*HKO*) mice on a high-fat diet and primary hepatocytes were used for functional studies. Techniques included lipid analysis, RNA-seq, qRT-PCR, IP-proteomics, IP-Western blot, and assessments of mRNA stability, protein ubiquitination, truncation mutants, and molecular docking to identify METTL7B partners and mechanisms. **Results:** METTL7B is elevated in both steatosis and steatohepatitis, with increased expression in MASH patients exhibiting fibrosis at stages F3-F4. *HKO* mice show significantly reduced liver weight compared to WT controls (liver, 1.5 $\pm$0.03 vs.1.78$\pm$0.03 g), decreased liver lipid accumulation (TC, 10$\pm$0.7 vs. 19.9$\pm$1.5 mg/g, $P<0.01$), improved liver injury (ALT, 75$\pm$1.9 vs. 88$\pm$0.5 ng/L), and improved metabolic dysfunction (fasting insulin and glucose, $P<0.01$, GTT, $P<0.01$) in western HFD induced MAFLD/MASH. Inflammation (CD11b-positive area, 1.0%$\pm$0.1 vs. 3.1%$\pm$0.18, $P<0.01$) and fibrosis (Sirus red-positive area, 1.7%$\pm$0.3 vs. 4.6%$\pm$0.5, $P<0.01$). Additionally, HKO mice exhibit specific downregulation of genes involved in the de novo lipogenesis (DNL) pathway, including *Srebf1* (*Srebf1* mRNA 39% $\pm$0.1 vs. 100% in WT). In contrast, gain-of-function studies show that METTL7B exacerbates lipid accumulation and inflammation in hepatocytes. Furthermore, GalNAc-siRNA-mediated hepatocyte-specific *Mettl7b* RNA interreference alleviates the transition from MAFL to MASH in mice (Fig.1). Mechanistically, METTL7B interacts with a group of RNA-binding proteins (RBPs) with top hit of poly(A) binding protein cytoplasmic 1 (PABPC1). Molecular docking and IP analyses identified that the RNA recognition motif 4 (RRM4) domain specifically interacts with METTL7B. Interestingly, the canonical methyltransferase domain of METTL7B does not participate in this interaction, rather, strong binding occurs through the C-terminal regions comprising amino acids 1-74 and 172-244 of METTL7B. Additionally, PABPC1 binds to *SREBF1* mRNA, protecting it from degradation, with the RRM1 domain exhibiting high affinity. **Conclusion:** METTL7B promotes MAFLD by stabilizing PABPC1, preventing SREBF1 mRNA degradation and sustaining DNL genes, establishing a pathogenic METTL7B-PABPC1-SREBF1 axis and potential therapeutic target in MASH.

◆ 1015 | HEPATIC STELLATE CELL-DERIVED WNTS CONTROL LIVER HOMEOSTASIS AND METABOLISM

Nicholas Khoo[1] Tyler Yasaka[1] Minakshi Poddar[1] Sucha Singh[1] Aaron Bell[1] Ravi Rai[1] Ian Sipula[1] Amber Vandevender[1] Xiachao Ma[1] Reben Raeman[1] Silvia Liu[1] Michael Jurczak[1] Satdarshan (Paul) Monga[1],
[1]University of Pittsburgh

Background: Hepatocytes perform essential metabolic tasks and have a remarkable capacity for regeneration following injury. These functions are spatially organized across liver lobules in a phenomenon known as liver zonation (LZ). While Wnt signaling from endothelial cells (ECs) is an established mediator of LZ, the role of hepatic stellate cells (HSCs) in this process remains largely unexplored. **Methods:** To determine the role of HSC-derived Wnts, we generated HSC-Wls-KO mice by conditionally deleting Wntless (Wls), which is essential for all Wnt secretion, through breeding Wls-floxed- with Lrat-Cre- mice. Based on baseline observations, we also fed a Western Diet (WD) to HSC-Wls-KO mice and littermate controls (Con). **Results:** HSC-Wls-KO mice exhibited decreased body weight and fat mass, increased energy expenditure, and enhanced lipid metabolism, suggesting systemic metabolic changes. Single-nucleus RNA sequencing revealed changes in hepatocyte LZ in HSC-Wls-KO livers, including a loss of periportal and expansion of pericentral gene expression programs linked to bile acid synthesis and fatty acid oxidation. These findings were confirmed by single-cell spatial transcriptomics. Immunohistochemistry validated these results, showing increased expression of pericentral markers (CYP2E1, CYP1A2) and decreased expression of periportal (CYP2F2) and even midzonal (HAMP1, HAMP2)

markers. Functionally, HSC-Wls-KO livers displayed a twofold increase in hepatic bile acid pools, shifts in bile acid composition, and increased mitochondrial respiration with a preference for lipid substrates. HSC-Wls-KO mice fed WD were resistant to weight gain and steatosis, although histological analysis revealed notable sinusoidal dilatation. Spatially resolved CellChat analysis in Con livers showed that HSC-derived Wnts appear to control Wnt2 expression in sinusoidal ECs, with HSC-Wls-KO livers showing expanded Wnt2 expression in ECs towards the periportal zone. **Conclusion:** We reveal a previously underappreciated role for HSC-derived Wnts as regulators of liver metabolism via the HSC-EC-hepatocyte signaling axis. Additional studies are ongoing to further understand the mechanistic basis of these novel observations.

◆ 1016 | LOSS OF ENDOSOMAL MICROAUTOPHAGY LEADS TO DEVELOPMENT OF HEPATIC FIBROSIS

Debajyoti Das[1] Mridul Sharma[1] Jihane Benhammou[2] Rajat Singh[1], [1]University of California Los Angeles, [2]University of California, Los Angeles

Background: Macroautophagy is a quality control (QC) pathway wherein double membrane autophagic vesicles engulf cytoplasmic organelles and proteins, which are delivered to lysosomes for degradation. Macroautophagy maintains hepatocellular QC by turning-over damaged organelles, such as mitochondria (via mitophagy) or lipid droplets (via lipophagy) in lysosomes. A large body of literature shows that loss of macroautophagy leads to development and progression of the metabolic dysfunction-associated steatotic liver disease (MASLD) spectrum. In addition to macroautophagy, a second poorly-studied form of autophagy called endosomal microautophagy (eMI) has recently been shown to also turnover organelles, e.g., mitochondria and ER, although the relationship of eMI with metabolic liver disease remains unknown. In this study, we determined the effect of liver-specific loss of eMI on the development and progression of the MASLD spectrum in mice and tested for the correlation of loss of eMI with human MASLD spectrum. **Methods:** We used C57BL6/J mice (injected with hepatocyte-specific AAV8 vectors) to selectively silence *VPS4B* (of the ESCRT pathway) that encodes for AAA-ATPase, which plays a critical role in multivesicular body (MVB) formation and late endosomal turnover of engulfed cargo. We assessed the onset and progression of MASLD to MASH and fibrosis through assessments of livers triglycerides (TGs), serum ALT/ASTs, liver H/E and Sirius Red staining. We also analyzed archived human datasets of MASLD subjects to draw correlations between loss of eMI and severity of human MASLD spectrum. **Results:** We found that loss of *VPS4B* in GAN diet-fed mice led to rapid onset of MASLD and its accelerated progression to MASH/fibrosis when compared to diet-matched controls, indicated by increased expression of inflammatory genes, elevated liver TGs, Sirius Red-positivity, and high NAS scores. Electron microscopy revealed defects in the late endosomal compartment, including the failure to form MVBs, and marked accumulation of damaged organelles. Consistently, human MASH/fibrotic livers showed significantly downregulation of *VPS4B* gene as well as other genes critically involved in the ESCRT/EMI pathway. **Conclusion:** Our study reveals the undefined role of the eMI pathway in development of MASLD and its acceleration to MASH and fibrosis, revealing a novel pathway that could be targeted to prevent the development or progression of the MASLD spectrum.

◆ 1017 | ELUCIDATING THE ROLES OF COMPLEMENT C3 IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Van-Dien Nguyen[1] Timothy Hughes[2] Birong Zhang[2] B. Paul Morgan[2] You Zhou[2], [1]103 Military Hospital, Vietnam Military Medical University & School of Medicine, Cardiff University, [2]Division of Infection and Immunity, School of Medicine, Cardiff University, Cardiff, UK.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing threat to

global public health, affecting approximately 30% of adults and becoming the leading reason for liver transplantation. Nevertheless, very limited approved specific treatment is currently available for MASLD. Accumulating evidence suggests an important role of the complement system in causation of MASLD. As the axial component of the complement system, C3 is predominantly produced in the liver, the metabolic 'engine' of the body; however, its role in metabolism remains little known. **Methods:** In this study, we have carried out a comprehensive characterisation of C3 spatial expression in normal and MASLD human liver using single cell RNA sequencing and bulk RNA sequencing data. Data were validated in free fatty acid-induced steatotic human hepatocytes and a high fat diet-induced mouse MASLD model. **Results:** We found that C3 was expressed in a zonal manner, with abundant expression in both periportal and pericentral hepatocytes. Cellular deconvolution of MASLD liver showed a disruption of hepatic zonal structure, with a depletion of pericentral hepatocytes while periportal hepatocytes were expanded. This alteration of hepatic zonal distribution was disease severity dependent with involvement of liver progenitor activation. RNA sequencing data from 408 liver biopsies confirmed significant alterations of complement C3 expression in response to MASLD development. C3 was upregulated in all forms of MASLD and positively correlated with liver fat load in patients with steatohepatitis. C3 expression was increased in steatotic human hepatocytes and hepatic C3 expression was higher in a mouse MASLD model. C3 knockout protected against high fat diet induced hepatic lipid droplet accumulation. In the hepatic response to a high fat diet, C3 knockout repressed hepatic *de novo* lipogenesis and triglyceride synthesis through downregulating liver lipogenic regulators. **Conclusion:** We demonstrate the impact of lipid accumulation on C3 expression in hepatocytes and show that C3 knockout impacts hepatic lipid handling. Overall, our study provides new insights into the role of C3 in MASLD pathogenesis and suggests its potential as a therapeutic target for the treatment of MASLD.

◆ 1018 | SUPPRESSED GPCR-DEPENDENT CALCIUM SIGNALING PROMOTES HEPATIC STEATOSIS

Paula Bartlett[1], [1]*Rutgers University - New Jersey Medical School*

Background: Hormones and catecholamines acting through G-protein coupled receptors (GPCRs) linked to inositol triphospate (IP_3) production and increases in calcium (Ca^{2+}) regulate many hepatic functions. In the liver hormones such as glucagon, catecholamines and vasopressin integrate and synergize to regulate the frequency and extent to which intracellular Ca^{2+} waves propagate across hepatic lobules to regulate metabolism. These signals oppose the anabolic effect of insulin, control blood glucose levels and regulate hepatic carbohydrate and lipid metabolism. Healthy liver is divided into functional lobules supplied by blood from the hepatic artery and portal vein which drain to the central vein. The metabolic functions of the liver are stratified into zones depending on their location on the porto-central axis, with periportal hepatocytes specialized in gluconeogenesis whereas, pericentral hepatocytes prioritize lipogensis. Dysregulation of hepatic Ca^{2+} homeostasis has been implicated in the development of MASLD, but changes in GPCR-dependent Ca^{2+} regulation of metabolism specifically in different metabolic zones has not been explored. **Methods:** We established liver specific GCaMP6f (calcium sensor) and IP_3R (calcium release channel) knockout mouse strains. Mice were fed a 45% high-fat diet (HFD) or control diet (10% fat), and the effects of HFD on GPCR-dependent Ca^{2+} signaling determined using single cell and intravital fluroscence microscopy. **Results:** We show that GPCR-dependent Ca^{2+} signals in hepatocytes are suppressed by HFD due to a decrease in IP_3. Intravital imaging revealed HFD imparied Ca^{2+} signal propagation across liver lobules. GPCRs sensitive to negative PKC regulation are impaired by HFD, indicating diet-dependent increases in DAG and PKC activity may perturb Ca^{2+} signalling. A comparison of GPCR-dependent Ca^{2+} signals in isolated periportal and pericentral hepatocytes revealed that periportal hepatoctes were most sensitive to the effects of HFD. This loss of sensitivity in periporal hepatocytes may explain why the propagation of Ca^{2+} signals across liver lobules is suppressed by HFD. Finally, IP_3R1 knockout attenuated the amplitude of hormone induced Ca^{2+} transients and lobular wave propagation rates and increased hepatic triglyceride accumulation compared to littermate controls in HFD fed mice. **Conclusion:** Propagation of GPCR-dependent Ca^{2+} signals across liver lobules regulates hepatic meabolism promoting glucnoeogenesis and glucgenolysis in the periporal zone, and inhibting lipogenesis in the pericental zone. HFD suppresses Ca^{2+} signaling and knockout of IP_3R1 increases lipid accumulation, together these results indicate that full strength Ca^{2+} signals in hepatocytes are an important inhibitor of lipogenic pathways. Suppression of hepatic Ca^{2+} signalling affects the regulation of hepatic metabolism and contributes to the etiology of MASLD.

◆ 1019 | MACROPHAGE PERILIPIN 2 ACCELERATES LIVER INFLAMMATION AND FIBROSIS IN MASH

Andrew Hakeem[1] Gavin Fredrickson[1] Patrick Fehrenbach[1] Fanta Barrow[1] Preethy Parthiban[1] Haiguang Wang[1] Xavier Revelo[1], [1]University of Minnesota

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease marked by hepatic lipid overload, persistent inflammation, and fibrotic remodeling. Macrophages are key regulators of disease progression, but the metabolic programs governing their inflammatory activity remain incompletely understood. Perilipin 2 (PLIN2) is a lipid droplet-coating protein highly expressed in macrophages that reside in lipid-rich microenvironments, but its immunometabolic role in MASH is undefined. Previous studies have shown that systemic PLIN2 deficiency reduces hepatic steatosis and inflammation, implicating PLIN2 as a pathological mediator of metabolic liver disease. Thus, we hypothesized that macrophage-intrinsic PLIN2 drives hepatic inflammation and fibrosis by constraining lipid catabolism and promoting pro-inflammatory signaling in macrophages. **Methods:** We generated CX3CR1-Cre PLIN2$^{fl/fl}$ (PLIN2$^{M\Phi\text{-}KO}$) and littermate wildtype mice and subjected them to a high-fat, high-carbohydrate (HFHC) diet for 16 weeks to induce MASH. Disease severity was assessed by histology, hepatic lipid quantification, and qPCR to assess inflammatory gene expression. Bone marrow-derived macrophages (BMDMs) from PLIN2$^{M\Phi\text{-}KO}$ and littermate controls were isolated for *in vitro* cytokine analysis following LPS exposure. **Results:** Compared with littermate controls, PLIN2$^{M\Phi\text{-}KO}$ mice exhibited reduced hepatic triglyceride accumulation, diminished lobular inflammation, and attenuated collagen deposition. Hepatic expression of pro-inflammatory genes, including *Mcp1*, *Il1b*, and *Tnfa* was significantly suppressed in PLIN2-deficient livers. In vitro, BMDMs from PLIN2$^{M\Phi\text{-}KO}$ mice secreted lower levels of tumor necrosis factor α in response to LPS, suggesting that PLIN2 promotes inflammatory cytokine production in macrophages. **Conclusion:** Here, we identified PLIN2 as a key immunometabolic regulator of hepatic macrophages, linking lipid droplet stability to inflammatory activation in MASH. These findings suggest that PLIN2 modulates macrophage function by coupling lipid storage to cytokine production. Targeting macrophage lipid droplet homeostasis may represent a novel therapeutic strategy to ameliorate inflammation and fibrosis in MASH.

◆ 1020 | MITOCHONDRIAL CHAPERONE DNAJA3 AND 3D GENOMIC INFLUENCES: INSIGHTS INTO MASH TO HCC TRANSITION

Yuto Shiode[1] Xin Wei Wang[1] Ching-Wen Chang[2], [1]Laboratory of Human Carcinogenesis Center for Cancer Research, National Cancer Institute, [2]Graduate Institute of Metabolism and Obesity Sciences, Taipei Medical University

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) is emerging as a major contributor to hepatocellular carcinoma (HCC). While MAFLD often progresses to metabolic dysfunction-associated steatohepatitis (MASH) and eventually HCC, the genetic mechanisms driving this transition remain unclear. **Methods:** We performed a genome-wide association study (GWAS) on variants related to body fat distribution in 344,369 individuals, followed by analysis of MASH and HCC associations in 1,009 NCI-UMD participants. Expression quantitative trait loci (eQTL) analyses, 3D chromatin interaction mapping, luciferase reporter assays, and RBFOX2 knockdown experiments were conducted to evaluate the regulatory impact of variant rs3747579 on DNAJA3 expression. **Results:** GWAS identified the rs3747579-TT variant as significantly associated with MASH-driven HCC. eQTL and chromatin conformation analyses revealed that this variant resides in an enhancer region with physical interaction to the mitochondrial chaperone gene DNAJA3, which showed reduced expression in TT carriers. Furthermore, only individuals with the protective CC genotype exhibited a positive

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

correlation between DNAJA3 and RAD21 expression, implicating allele-specific enhancer looping. Chromatin immunoprecipitation and knockdown experiments identified RBFOX2, a splicing regulator with chromatin-binding activity, as a key modulator. Loss of RBFOX2 led to reduced DNAJA3 expression. Luciferase assays demonstrated higher enhancer activity for the rs3747579-CC allele compared to the TT allele. **Conclusion:** Our data identify rs3747579-TT as a potential oncogenic variant that disrupts DNAJA3 expression via altered 3D enhancer interactions, contributing to the MASH to HCC transition. These findings emphasize the role of 3D genome architecture in gene regulation and suggest DNAJA3 as a novel therapeutic target for MASH-associated HCC.

◆ 1021 | GENOME-WIDE CRISPR SCREENING IDENTIFIES ACSL3 AS A KEY MEDIATOR OF LIPOTOXICITY AND ER STRESS IN MASH

Yuta Myojin[1] Takahiro Kodama[1] Hideharu Nagasawa[1] Ryo Takahashi[2] Kazuhiro Murai[1] Kosuke Yusa[3] Tomomi Hashidate-Yoshida[4] Hideo Shindou[4] Yoshinobu Saito[1] Hayato Hikita[1] Tetsuo Takehara[5], [1]Department of Gastroenterology and Hepatology, the University of Osaka, Graduate School of Medicine, [2]1Department of Gastroenterology and Hepatology, the University of Osaka, Graduate School of Medicine, [3]Stem Cell Genetics, Institute for Life and Medical Sciences, Kyoto University, [4]Department of Lipid Life Science, National Institute of Global Health and Medicine, Japan Institute, [5]Kansai Rosai Hospital

Background: The landscape of hepatocellular carcinoma (HCC) is shifting, with metabolic-associated steatohepatitis (MASH) emerging as a leading cause globally, replacing viral hepatitis. This shift parallels rising rates of obesity and metabolic syndrome. While a thyroid hormone receptor-β (THR-β) agonist was recently approved as a therapy for MASH, novel molecular targets—particularly those mediating lipotoxic hepatocyte death—are still required to address MASH progression and HCC risk. **Methods:** To identify novel regulators of lipotoxicity, we performed a genome-wide CRISPR-Cas9 knockout (KO) screen in Cas9-expressing HLF hepatocyte cells transduced with a lentiviral sgRNA library. Cells were cultured for 4 weeks under either (1) 200 μM palmitic acid (PA) to induce lipotoxic stress or (2) control medium. sgRNA representation was quantified by targeted sequencing, and gene enrichment was analyzed using MAGeCK. Top candidates were validated through gene knockout in HLF and primary human hepatocytes. Functional characterization included IncuCyte-based proliferation assays, real-time PCR, targeted lipidomics, RNA-seq, spatial transcriptomics (Visium), and analysis of public single-cell RNA-seq datasets. **Results:** The genome-wide screen identified ACSL3, INSIG1, and NF2 as significantly enriched in the PA-treated group. Among these, only ACSL3 KO conferred resistance to PA-induced cell death in both HLF cells and primary human hepatocytes. ACSL3 KO cells maintained proliferation under PA exposure, as visualized by real-time IncuCyte imaging, and exhibited minimal apoptosis, as assessed by flow cytometry. ACSL3 KO suppressed the PA-induced upregulation of GRP78, suggesting attenuation of endoplasmic reticulum (ER) stress. Targeted lipidomic profiling revealed reduced intracellular accumulation of saturated fatty acids, particularly palmitate, in ACSL3 KO cells. In parallel, quantitative PCR showed downregulation of genes involved in de novo lipogenesis. Together, these results indicate that ACSL3 promotes lipotoxic ER stress by enhancing intracellular saturated lipid accumulation. In human liver samples, bulk RNA-seq analysis demonstrated elevated ACSL3 expression in MASH livers compared to those with viral hepatitis. Visium spatial transcriptomics confirmed ACSL3 enrichment specifically in steatotic hepatocytes. Furthermore, public single-cell RNA-seq datasets revealed marked upregulation of ACSL3 in hepatocytes from patients with end-stage MASH, supporting its pathological relevance in human disease. **Conclusion:** ACSL3 drives saturated fatty acid–induced ER stress and hepatocyte death. Its consistent upregulation in advanced human MASH highlights ACSL3 as a promising therapeutic target to alleviate lipotoxicity and potentially prevent MASH-associated HCC.

Yang[4], [1]The Second Hospital of Nanjing, Southeast University, [2]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, [3]Nanjing Key Laboratory of Hepatology, The Second Hospital of Nanjing, [4]The Second Hospital of Nanjing, Medical School, Southeast University, [5]Nanjing Drum Tower Hospital, Medical School, Southeast University, [6]Xin Hua Hospital, School of Medicine, Shanghai Jiao Tong University

Background: Metabolic dysfunction-associated steatohepatitis (MASH) represents an advanced stage of metabolic dysfunction-associated steatotic liver disease (MASLD) characterized by hepatic steatosis, inflammation, and progressive fibrosis. **Methods:** Male C57BL/6J mice were fed a Gubra-Amylin NASH (GAN) diet (40% fat, 2% cholesterol, 20% fructose) for 12–32 weeks to model MASH progression. Liquid chromatography–mass spectrometry (LC-MS) and chiral-resolved LC-MS quantified D-2-hydroxyglutarate (D-2-HG) and 2-oxoglutarate (2-OG) levels in serum, urine, liver tissues, and conditioned media, validated via isotopic tracing with 13C-labeled glutamine/glucose. D2HGDH nuclear translocation was investigated via subcellular fractionation, acyl-biotin exchange (ABE) assays for palmitoylation, truncation/mutant constructs, and HDAC1 interaction analyses using co-immunoprecipitation (Co-IP) and AlphaFold-predicted structural modeling. Chromatin accessibility (ATAC-seq), histone modifications (CUT&Tag for H3K27ac/H3K4me3), and RNA m6A methylation assays were performed to assess nuclear D2HGDH-driven epigenetic reprogramming in hepatocytes and macrophages. Data were analyzed using GraphPad Prism (v9.0) with ANOVA, Tukey's post-hoc tests, and nonparametric alternatives where appropriate, ensuring reproducibility across biological replicates and clinical cohorts. **Results:** D-2-HG levels significantly increased in MASH patients and murine models, correlating with fibrosis severity and serving as a diagnostic biomarker for liver stiffness. Under lipotoxic stress, D2HGDH translocates to the nucleus via C198 palmitoylation, accumulates 2-OG, binds HDAC1, and shifts histone H3K27 modifications from methylation (H3K27me3) to acetylation (H3K27ac), activating lipogenic genes like ACC1. Hepatocyte-derived D-2-HG activates HSCs by inhibiting KDM2B-mediated H3K4me3 demethylation. D-2-HG polarizes macrophages toward a proinflammatory M1 phenotype via FTO-dependent m6A demethylation of RELA mRNA, stabilizing NF-κB transcripts and amplifying cytokine release. Pharmacological inhibition of D2HGDH palmitoylation or 2-OG supplementation reversed nuclear D2HGDH localization, suppressed lipid accumulation, and attenuated inflammation/fibrosis in vitro and in vivo. **Conclusion:** Nuclear D2HGDH and cytosolic D-2-HG create a feedforward loop—nuclear 2-OG drives epigenetic lipogenesis, while secreted D-2-HG exacerbates intercellular fibrosis and inflammation, defining a metabolite-centric mechanism in MASH pathogenesis.

◆ 1023 | HEPATOCYTE-DERIVED ARGINASE-2 PROTECTS FROM METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Jeongowoo Park[1] Hui Han[1] Xiaodong Ge[1] Sai Santosh Babu Komakula[1] Nithyananthan Subramaniyam[1] Sukanta Das[1] Chao Wang[1] Wei Chen[1] Dipti Athavale[1] Abid Anwar[1] Dan Lantvit[1] Grace Guzman[1] Natalia Nieto[1], [1]University of Illinois at Chicago

Background: Arginase-2 (ARG2), the mitochondrial isoform of arginase, primarily catalyzes the hydrolysis of L-arginine. Emerging evidence suggests it also plays a role in mitochondrial bioenergetics. We previously reported that ARG2 induction in hepatocytes mediates the protective effects of SPP1^{high} macrophages in metabolic dysfunction-associated steatohepatitis (MASH). However, the contribution of hepatocyte-specific ARG2 loss to MASH progression and its underlying mechanisms remain unclear. **Methods:** To generate hepatocyte-specific *Arg2* knockout mice, we crossed *Arg2*$^{fl/fl}$ with *Albumin*-Cre mice. Male and female mice were fed a high-fat, high-fructose, high-cholesterol (HFHC) diet for six months to induce MASH. Control mice received an isocaloric diet with calories balanced through carbohydrates. **Results:** Bone marrow transplants revealed that *Spp1*$^{KI\ Mye}$ → *Alb*.Cre mice exhibited reduced steatosis, inflammation, and hepatocyte

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

ballooning degeneration. However, no differences in MASH severity were observed between *Spp1*$^{KI\ Mye}$ → *Arg2*$^{\Delta Hep}$ and *Lyz2*.Cre → *Arg2*$^{\Delta Hep}$ mice. MASH progression was exacerbated in *Arg2*$^{\Delta Hep}$ mice, as indicated by increased hepatic steatosis, elevated liver triglycerides, serum cholesterol, and ALT levels, as well as enhanced monocyte infiltration. These mice also exhibited greater fibrosis, characterized by increased collagen type-I deposition and higher expression of *Col1a1* and *Acta2* mRNA. Metabolic dysregulation was further supported by the downregulation of key genes involved in fatty acid oxidation, including *Cpt1a*, *Cpt2*, and *Crat*. Mitochondrial dysfunction was evident, with reduced basal respiration and ATP production, accompanied by decreased expression of respiratory chain complex subunits: complex I (NADH:ubiquinone oxidoreductase), complex II (succinate dehydrogenase), and complex V (ATP synthase). Additionally, mitochondrial DNA copy number, as indicated by *Atp6*, *CoxII*, *Nd1*, and *Nd5*, was reduced. Mass spectrometry analysis revealed decreased hepatic acetyl-CoA levels and reduced concentrations of medium- to long-chain acyl-carnitines, including decanoyl-L-carnitine and oleoyl-L-carnitine. **Conclusion:** Loss of hepatocyte-specific ARG2 aggravates MASH by promoting lipid accumulation, monocyte infiltration, and fibrosis, in association with impaired mitochondrial fatty acid transport and reduced β-oxidation.

◆ 1024 | SESTRIN 3 SUPPRESSES HEPATIC STELLATE CELL ACTIVATION AND LIVER FIBROSIS

Menghao Huang[1] X Charlie Dong[2], [1]Indiana University School of Medicine, [2]Indiana University

Background: Sestrin 3 (Sesn3) is a member of a conserved protein family characterized by three unique domain structures not found in other proteins across the proteome. Despite its known involvement in metabolic regulation, the role of Sesn3 in the pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH) remains undefined. Hepatic fibrosis, a key pathological feature of MASH, arises from aberrant wound-healing responses and excessive extracellular matrix (ECM) deposition. Among the various liver cell types involved, hepatic stellate cells (HSCs) are the primary contributors to ECM accumulation. **Methods:** To investigate the role of Sesn3 in hepatic fibrosis, we generated HSC-specific Sesn3 knockout and transgenic mice and subjected them to a diet-induced MASH model. Liver phenotypes were assessed histologically and molecularly. Transcriptomic and proteomic analyses were conducted to identify pathways regulated by Sesn3. Fluorescence imaging was used to evaluate fibrogenic activity in primary HSCs and human HSC cell line LX-2 with Sesn3 deletion or overexpression. Co-immunoprecipitation assays were performed to identify Sesn3-interacting proteins. **Results:** HSC-specific deletion of Sesn3 significantly exacerbated hepatic fibrosis in response to the MASH diet, while transgenic overexpression of Sesn3 in HSCs conferred protection against fibrosis. Transcriptomic profiling revealed upregulation of ECM-related pathways, including the Yes-associated protein (YAP) and transcriptional coactivator with PDZ-binding motif (Wwtr1/TAZ) pathway. Biochemical and cell biological analyses demonstrated that Sesn3 directly modulates YAP/Wwtr1 activity through protein-protein interactions, thereby influencing fibrogenic gene expression and ECM deposition. **Conclusion:** Sesn3 serves as a critical negative regulator of hepatic fibrosis by modulating the YAP/Wwtr1 signaling pathway in HSCs. These findings suggest Sesn3 as a potential therapeutic target for preventing or treating fibrosis in MASH.

◆ 1025 | MULTI-ORGAN CROSSTALK VIA EXOSOMAL TCA CYCLE ENZYMES UNDERLIES METABOLIC BENEFITS OF EXERCISE AND DAYTIME TIME-RESTRICTED FEEDING IN MURINE MASH RESOLUTION

Xixuan Wang[1] Shuling Chen[2] Ruiqi Li[3] TianHao Mao[4] Jun Guo[2] Yang Wang[2] Zihao Liang[2] Caiyun Zhang[4] Hao Ren[1] Wei Chen[2] Changhua Yi[2] Qingfang Xiong[1] Dandan Yin[2] Dawei Yang[2] YongFeng Yang[1], [1]The Second Hospital of Nanjing, Medical School, Southeast University, [2]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, [3]The Second Hospital of Nanjing, Medical School, Southeast University, [4]Nanjing Key Laboratory of Hepatology, The Second Hospital of Nanjing

Background: Emerging evidence highlights the interplay between peripheral organs and hepatic metabolism in metabolic dysfunction-associated steatohepatitis (MASH), yet systemic mechanisms linking behavioral interventions to tissue repair remain unclear. **Methods:** We established a murine MASH model via 24-week GAN diet followed by 8-week

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

normal chow realimentation, with four intervention groups: sedentary ad libitum (SED-AL), exercise (EX), daytime time-restricted feeding (TRF), and EX +TRF. Body weight, insulin resistance, pathological staining of different organs, ultrastructure under electron microscope of different organs, and multi-omics of different organs were detected. **Results:** While both TRF and EX+TRF demonstrated superior weight loss, all active interventions ameliorated insulin resistance and hepatic steatosis. Strikingly, EX induced skeletal muscle damage and reduced adipocyte lipid droplet size, whereas TRF preferentially restored adipose morphology without myofiber injury. Ultrastructurally, EX uniquely rescued hepatic mitochondrial cristae disruption in MASH. Multi-omics integration revealed profound TCA cycle rewiring across liver, muscle, and adipose tissues, with phospho-/acetyl-/lactyl-proteomics implicating post-translational regulation of metabolic enzymes. Mechanistically, exercise triggered skeletal muscle secretion of citrate synthase (CS), IDH3, and OGDH via exosomes, which restored hepatic mitochondrial energetics and attenuated lipid peroxidation. Conversely, TRF stimulated adipose-derived exosomes enriched with phosphorylated/acylated TCA modifiers, synergistically enhancing hepatic metabolic flexibility. **Conclusion:** Our findings establish a novel paradigm of inter-organ communication through exosomal enzyme trafficking, positioning combined chrono-exercise therapy as a systems-level strategy for MASH resolution.

1026 | URIDINE HOMEOSTASIS IS IMPAIRED IN OBESITY AND MASLD AND AFFECTS FATTY ACID METABOLISM

Ozzy Ayebo[1] Montana Bilger[2] Michael Boerrigter[2] Yongbin Chen[3] Peyton Classon[3] Guillermo Delgado Aparicio[2] Rondell Graham[3] Davide Povero[3], [1]Mayo Clinic, [2]DeepSpace Biology, [3]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common chronic liver disease. Disruption of uridine level are associated with obesity and MASLD. However, how uridine regulates fatty acid metabolism remains largely unknown. Our goal is to elucidate how uridine influences fatty acid flux during obesity and MASLD development. **Methods:** Human and murine hepatocytes were treated with fatty acid mix with or without uridine. Fatty acid metabolism was assessed by lipidTOX, Seahorse Mito Stress test and immunoblotting. Male C57BL/6 mice were fed a chow or obesogenic high fat, fructose and cholesterol (FFC) diet for 8 weeks and received uridine (50 mg/kg) or vehicle for 3 weeks. Liver, adipose tissue, plasma and muscle were harvested for further analysis. Metabolic and molecular profiling were assessed by multi-omics analysis, histological, and molecular assays. **Results:** Liver uridine levels decreased with disease progression in murine MASLD ($p < 0.03$). Uridine synthesis enzyme UMPS was significantly depleted in human MASLD as compared to normal livers ($p < 0.002$). In vitro, UMPS knockdown in HepG2 cells reduced cellular uridine levels, increased accumulation of lipid droplets, and impaired mitochondrial respiration which was restored by exogenous uridine treatment. In vivo, uridine-treated FFC-fed mice (FFC +uridine) significantly increased energy expenditure, ambulatory activity, respiratory exchange and metabolic rate without affecting food and water intake, as compared to control mice. In FFC-fed mice, uridine reduced body, liver and adipose tissue weight. This was associated with a marked reduction of liver and muscle steatosis in FFC+uridine mice. Liver phospho-proteomics analysis identified large abundance of proteins involved in fatty acid catabolism and storage in FFC +uridine mice. Conditioned media of mouse adipose tissue from FFC mice with or without uridine treatment, cultured ex vivo for 24 hours, identified differential enrichment of bioactive mediators involved in adipose tissue lipolysis and obesity, such as resistin and GDF15. Lastly, treatment of mouse hepatocytes with FFC-vehicle adipose tissue conditioned media significantly impaired mitochondrial metabolism, which was restored by exposure to FFC+uridine adipose tissue conditioned media. **Conclusion:** Uridine directly or indirectly regulates anorexigenic response, energy metabolism and fatty acid storage, thus identifying novel targets for MASLD and obesity treatment.

1027 | INHIBITION OF BRUTON'S TYROSINE KINASE IN MACROPHAGE ALLEVIATES METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE BY SUPPRESSING IL-6/JAK2/STAT3/SOCS3 PATHWAY

Shiwei Chen[1] Jingkang Zhang[2] Baode Chen[1] Cheng Zhou[2] Min Zheng[3], [1]The first Affiliated Hospital, College of Medicine, Zhejiang University, [2]Zhejiang University, [3]The First Affiliated Hospital,College of Medicine, Zhejiang University

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) is the most prevalent liver disease currently characterized by hepatic steatosis and metabolic inflammation. Bruton's tyrosine kinase (BTK) is a crucial immune target for various inflammatory diseases and metabolic disorders. However, the role of BTK in MASLD still deserves further study. **Methods:** MASLD mouse model was induced by high-fat-diet (HFD). The expression and activation of BTK in the liver were compared between MASLD mouse and the control. BTK inhibitor, BTK knockout and myeloid-conditional BTK knockout mice were ultilized to observe the effect of BTK on mouse MASLD. Further, the molecular mechanism was investigated in the co-culture system composed of macrophage and hepatocyte in vitro. Flow cytometry, western blot, ELISA, qPCR, energy metabolism monitoring system were used in this research. **Results:** BTK was significantly activated (phosphorylated) in MASLD mouse liver. Both pharmacological inhibitor and gene knockout of BTK could markedly attenuate the hepatic steatosis and inflammation, increase oxygen consumption and energy consumption in MASLD mouse. Among various immune cell subsets in mouse liver, BTK in macrophage was enhanced most significantly after HFD-feeding, suggesting that BTK in macrophages plays a major role in the pathogenesis of MASLD. Thus, mouse with BTK depletion in macrophage was established and showed less hepatic steatosis and inflammation compared to the control after HFD-feeding. Mechanically, inhibition of BTK reduced the recruitment of macrophage in MASLD mouse liver, as well as skewed the polarization of macrophage toward M2 phenotype, and inhibited the release of proinflammatory cytokines (especially IL-6). In the co-culture system composed of macrophage and hepatocyte in vitro, inhibition of BTK inhibitor significantly reduced the secretion of IL-6 from macrophage, further suppressed the phosphorylation of JAK2/STAT3 and decreased the expression of SOCS3 in hepatocyte, resulting in the reduction of the lipid deposition and triglyceride (TG) content in hepatocyte. **Conclusion:** Inhibition of BTK in macrophage alleviated MASLD via reducing IL-6 secretion from macrophage and further suppressing JAK2/STAT3/SOCS3 signaling pathway in hepatocyte. Therefore, BTK in macrophage might be a valuable therapeutic target for MASLD.

1028 | HEPATIC DELETION OF THE WNT MODULATORS ZNRF3/RNF43 REVERSES METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Tianliang Sun[1] Federico Di Tullio[1] SUE YANG[2] Shamsa Roshan[2] Joana Almeida[2] Abigail Glezer[2] Jonathan Conrad[2] Siddarth Vinod Kumar[2] Shahina Saeed[2] Marina Barcena-Varela[2] Anthony Lozano[2] Lianyong Su[3] Derrick Zhao[3] Emily Bramel[2] Amaia Lujambio[2] Huiping Zhou[3] Sai Ma[2] Lida Yang[2] Bruno Cogliati[2] Scott Friedman[4], [1]Icahn School of Medicine at Mount Sanai, [2]Icahn School of Medicine at Mount Sinai, [3]Virginia Commonwealth University, [4]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Metabolic-associated steatohepatitis (MASH) is a leading cause of liver failure and hepatocellular carcinoma (HCC), yet effective therapies remain limited. MASH is marked by steatosis, inflammation, fibrosis, and impaired regeneration. The liver's remarkable regenerative capacity is compromised in MASH. Enhancing regeneration without triggering tumorigenesis could represent a novel therapeutic strategy. ZNRF3 and RNF43 are negative regulators of β-Catenin, a key mediator of liver regeneration, metabolism, inflammation, and fibrosis. However, their role in MASH regression remains unknown. **Methods:** MASH was induced using two models: the fibrosis and tumor (FAT)-MASH model (Western diet combined with low-dose CCl_4) or the Gubra Amylin (GAN) MASH diet. Hepatocyte-specific deletion of ZNRF3/RNF43 was achieved via AAV8-TBG-Cre; AAV8-TBG-GFP served as control. Phenotypic regression was assessed through histological analyses (Oil Red O, H&E, Sirius Red), immunostaining (GS, Ki-67, CYP2E1), and serum ALT. RNA-seq, qPCR, and LC-MS/MS were used to identified metabolic drivers of regression. **Results:** Short-term deletion of ZNRF3/RNF43 in hepatocytes robustly reversed key features of established MASH, including steatosis, inflammation, and fibrosis. The improved liver regeneration occurred without altering liver-to-body weight ratios, without redistributing lipid to other tissues, and were not

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

associated with increased incidence of HCC during the study period. Mechanistically, MASH regression was dependent on β-catenin activation. This activation selectively drove upregulation of the alternative bile acid synthesis pathway, specifically increasing expression of *Cyp27a1* and *Cyp7b1*, and expanding the chenodeoxycholic acid (CDCA)-derived bile acid pool. These changes were accompanied by improved bile acid and lipid transport and metabolic handling. Importantly, ZNRF3/RNF43 deletion did not increase tumor burden when compared to β-catenin gain-of-function mutants co-expressing c-Myc via hydrodynamic tail vein injection (HDTVI), nor did it promote HCC progression in the FAT-MASH-HCC model. **Conclusion:** Transient, hepatocyte-specific deletion of ZNRF3/RNF43 reverses MASH via β-catenin-dependent activation of the alternative bile acid synthesis pathway. This regenerative approach effectively reduces MASH pathology without promoting HCC, representing a promising and safe therapeutic strategy.

1029 | MUSCLE DRIVEN MSTN CONTRIBUTES TO MASLD PROGRESSION VIA HEPATOCYTE SENESCENCE

Jie Li[1], [1]*Department of Infectious Diseases, Nanjing Drum Tower Hospit*

Background: Recent studies suggest that the alterations in skeletal muscle may contribute to the pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH). Myokines, a type of bioactive peptides released by skeletal muscle, play a pivotal role in regulating peripheral tissues, especially the liver. Among them, myostatin (MSTN) has emerged as a critical regulator of muscle mass and hepatic metabolism. However, its specific role and underlying mechanisms in MASH development remain unclear. **Methods:** MASH was induced in mice using high-fat, high-fructose diet (HFHFD) and choline-deficient, amino acid-restricted, high-fat diet (CDAHFD). Muscle-specific MSTN knockdown was achieved using an adeno-associated virus 8 (AAV8) system. MSTN expression in the serum of MASH patients was assessed via Elisa. The role of MSTN in MASH progression was investigated using recombinant MSTN protein and co-cultures of C2C12 muscle cells and primary mouse hepatocytes. Additionally, RNA sequencing was employed to analyze the impact of MSTN on the hepatocyte transcriptome. **Results:** The expression of MSTN was significantly elevated in both the muscle tissue and serum of MASH patients, but showed no notable changes in the liver. Further analysis demonstrated a positive correlation between circulating MSTN levels and both hepatic inflammation and alanine aminotransferase. Skeletal muscle-specific knockdown of MSTN significantly inhibited the progression of HFHFD- and CDAHFD-induced MASH. RNA-sequencing suggested that recombinant MSTN protein may accelerate hepatocyte senescence and promote MASH progression by regulating solute carrier family 7 member 11 (SLC7A11)-mediated glutathione metabolism. Recombinant MSTN protein induced ubiquitination-dependent degradation of SLC7A11 in a dose-dependent manner. Conversely, SLC7A11 overexpression significantly alleviated MSTN-induced hepatocyte steatosis, inflammation, and senescence, accompanied by reduced reactive oxygen species (ROS) accumulation, elevated glutathione levels, and restored mitochondrial maximal respiration rate. **Conclusion:** The crosstalk between muscle and liver indicated that reducing muscular MSTN expression alleviated the severity of liver damage under the context of MASH. MSTN secreted from muscular may represent a promising therapeutic strategy for treating MASH.

1030 | BILE ACID DYSREGULATION AND LOSS OF HEPATIC POLARITY AT EARLY STAGES DRIVES MASLD PROGRESSION

*Kartik Mitra[1] Mark Muthiah[2] Yu Hanry[3] Zixuan Zhang[4] Farah Tasnim[5] Peter Low[6], [1]National university of singapore, [2]Division of Gastroenterology and Hepatology, National University Health System, Singapore., [3]Department of Physiology, Yong Loo Lin School of Medicine, National University of Singapore, [4]Department of Medicine, Yong Loo Lin school of Medicine, National University of Singapore, [5]Biomedical Sciences Industry Partnership Office (BMSIPO), A*STAR, 4 Fusionopolis Way, Kinesis #09-11, [6]Yong Loo Lin school of Medicine, National Univerisity of Singapore*

Background: Bile acid metabolism dysregulation and subtle micro-cholestatic features are often observed in patients with Metabolism dysfunction associated steatotic liver disease (MASLD). The mechanistic role of bile acid metabolism dysregulation in MASLD pathogenesis remains unclear. **Methods:** We performed a comprehensive RNA transcriptomic and lipidomic analysis on spectrum of MASLD patients (n = 140) to identify key bile acid metabolism and hepatocyte function genes that are differentially regulated across the disease spectrum. Then we leverage on bio-engineered iPSC derived 2.5D hepatic tri-culture model – HepaSin, comprising of hepatocytes (iHeps), stellate cells (iHSCs), and Kupffer cells (iKCs) to dissect the functional role of key genes in disease progression. Further, we explore strategies reinforcing hepatocellular polarity and bile acid homeostasis to ameliorate MASLD progression before irreversible liver damage occurs. **Results:** Clinical RNA transcriptomic and lipidomic analysis on MASLD patients (n = 140) revealed that bile acid dysregulation is associated with loss of hepatic polarity and function at early stages of MASLD. We show that lipid accumulation at early stages reduces the cortical tension and disrupts the tight junction E-cadherin/β-catenin complex. Failing to re-establish cortical tension and loss of E-cadherin/β-catenin complex impairs hepatocyte polarity and bile canaliculi integrity causing dysregulated bile acid transport and intracellular accumulation of bile acids (↑CYP7A1). Accumulation of 12α-hydroxylated bile acids, especially deoxycholic acid (DCA), further exacerbates MASLD progression through impaired FXR activation and increased lipoptoxicity. Restoring hepatocyte polarity at early stages improved hepatocyte function and rescued from MASLD progression in vitro. **Conclusion:** Lipid accumulation induced disruption of cortical tension causes bile metabolism dysregulation causing micro-cholestasis condition at early stages of MASLD. Elevated intracellular accumulation of bile acids and Impaired bile metabolism exacerbates MASLD progression. Restoring hepatic polarity rescues bile acid toxicity and improves MASLD progression. Thus stratergies reinforcing hepatic polarity can be explored as therapeutic stratergy to treat MASLD.

1031 | CHRONIC NANOPLASTIC EXPOSURE PROMOTES METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE PROGRESSION VIA HEDGEHOG SIGNALING

Jinsol Han[1] Hayeong Jeong[1] Youngmi Jung[1], [1]Pusan National University

Background: Nanoplastics (NPs), plastic particles less than 1 μm, are a global pollution problem. Chronically exposed NPs accumulate in various organs including kidney, adipose tissue and liver. Recently studies have reported that deposited NPs adversely affect lipid metabolism in the liver. Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common metabolic disorder featured by abnormal fat accumulation in the liver. Despite rising concerns about chronic NP exposure and MASLD, the mechanisms by which NPs contribute to the development and progression of MASLD remain poorly understood. Herein, we investigated the pathophysiological effects of NPs in MASLD and elucidated the underlying mechanism. **Methods:** To assess the effect of hepetocytes injured by NP and lipotoxicity on hepatic stellate cells (HSCs), primary HEPs (pHEPs) isolated from healthy male mice were treated with 100 μg/mL of 100nm sized-NPs and 50 μM palmitic acid (PA). Conditioned media (CM) from pHEP treated with both NPs and PA ted pHEPs was subsequently given to quiescent pHSCs. To evaluate in vivo impact of NPs in MASLD progression, mice were administered either vehicle or NPs via drinking water while being fed a choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) for 12 weeks. At the end of the treatment period, mice were sacrificed to collect blood and liver samples. **Results:** NPs exacerbated PA-induced hepatocyte damage and significantly elevated the production of Sonic Hedgehog (SHH), a ligand in the Hh pathway. pHSCs cultured in CM from NPs+PA-treated pHEPs showed increased proliferation compared to those cultured in CM from PA-treated pHEPs. In pHSCs exposed to CM from NPs+PA-given pHEPs, levels of

Smoothened (SMO), a receptor in the Hh pathway, and GLI2, a transcriptional activator, were remarkably upregulated, along with increased expression of fibrotic markers, compared to the PA group. In mice fed CDAHFD, chronic NP exposure markedly upregulated SHH and GLI2 expression in liver tissues. GLI2-positive cells were more apparent in the livers of mice treated with NPs+CDAHFD than in other groups. pHEPs from the NPs+CDAHFD group also showed significantly increased SHH expression, and pHSCs from these mice had upregulated SMO and GLI amount relative to other groups. **Conclusion:** These findings demonstrate that chronic NP exposure increases vulnerability to MASLD progression by promoting Hh signaling, suggesting that NPs are a deleterious factor contributing to the development and progression of MASLD.

1032 | REGULATORY T (TREG) CELL DEPLETION AMELIORATES HCC PROGRESSION IN MASH BY RESTORING ANTI-TUMOR INNATE AND ADAPTIVE IMMUNE RESPONSES

Joanna Picó[1] Amalia Tzoumpa[2] Yin Huang[2] Beatriz Lozano-Ruiz[2] Pedro Zapater[2] Jose Antonio Gomez-Sanchez[3] José Manuel González-Navajas[2], [1]University of Miguel Hernández (ISABIAL-IDIBE), [2]CIBER, ISABIAL, [3]ISABIAL

Background: Regulatory T cells (Tregs) promote immune tolerance and support tumor immune evasion. Despite being studied in many tumors, their role in metabolic dysfunction-associated steatohepatitis (MASH)-associated HCC remains poorly understood. With the rising incidence of MASH-HCC and limited efficacy of immune checkpoint inhibitors (ICIs) in this context, likely due to heightened immunosuppression, identifying new therapeutic targets is critical. Understanding Tregs interactions with immune cells may uncover resistance mechanisms and guide novel interventions. **Methods:** An orthotopic HCC model with underlying MASH (MASH-HCC) was established in male DTR-Foxp3 mice. To induce MASH, mice were fed a Western Diet (WD; high in fat, cholesterol, and sucrose) for 24 weeks, or maintained on a standard chow diet (CD; CD-HCC). At week 22, Hep53.4 murine cells were orthotopically injected. One week later, Tregs were selectively depleted via intraperitoneal administration of diphtheria toxin (DT; 6.25μg/Kg, twice weekly for 2 weeks), while control mice received vehicle. At week 25, tumor burden was measured, and tumor and blood samples were collected for flow cytometry and histological analysis. Treg depletion was confirmed by flow cytometry. **Results:** Treg depletion led to a significant reduction in tumor volume ($p = 0.04$) and weight ($p = 0.02$) in mice with MASH-HCC (WD+DT), but not in CD-HCC mice (CD+DT). In the tumor microenvironment, NK cells increased significantly only in WD+DT mice ($p = 0.03$), as did IFNγ expression by NK ($p = 0.02$), $CD4^+$ ($p = 0.03$), and $CD8^+$ T cells ($p = 0.001$), with no changes in CD-fed mice. Similarly, blood NK and NKT cell frequencies rose after Treg depletion in WD-fed mice ($p = 0.01$; $p = 0.004$), suggesting a stronger Treg-mediated suppression in the MASH-HCC setting. In contrast, CD-HCC tumors showed higher levels of macrophages ($p = 0.03$) and M1-like tumor-associated macrophages (TAMs) ($p = 0.03$) in the absence of Tregs, which were unaffected in the WD group. CD+DT mice also showed an increase in monocytic myeloid-derived suppressor cells (M-MDSCs) ($p = 0.047$), pointing to a potential compensatory suppressive mechanism. Finally, although total dendritic cells (DCs) remained unchanged, WD+DT mice displayed a selective rise in cDC1 ($p = 0.01$) and a reduction in cDC2 ($p = 0.02$), not observed in CD-fed counterparts. **Conclusion:** Our findings emphasize the immunosuppressive role of Tregs in MASH-HCC, impairing both innate and adaptive anti-tumor responses. These results highlight Tregs as a promising therapeutic target. Further experiments are underway to dissect their suppressive mechanisms and assess the effect of their depletion in combination with ICIs in MASH-HCC.

1033 | LACTYLATION OF FATP2 EXACERBATES THE PROGRESSION OF MASH BY INHIBITING THE PGC1A/PPAR SIGNALING PATHWAY

Jiaxin Tan[1] man Li[2] Yong He[3], [1]Shanghai University of Traditional Chinese Medicine, [2]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [3]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), defined as ectopic lipid accumulation in hepatocytes without excessive alcohol consumption and viral infections, is the most prevalent liver disease worldwide, yet few effective therapies are available. Recently, intracellular lactate is reported to drive a novel type of posttranslational modification,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

lysine lactylation (Kla); however, whether lactylation is involved in MASLD development remains unknown. **Methods:** Lactate modification proteomics is used to identify differentially expressed proteins with lactate modification sites in the MASH model mice. To validate the role of lactylation-modified FATP2 in the progression of MASH by constructing hepatocyte-specific knockout FATP2 mice. Immunoprecipitation and Western blotting were used to validate the lactylation modification site and downstream targets of FATP2 in vitro. **Results:** In this study, by using lactylation modification proteomics, we identified 128 proteins and 199 lactylation modification sites. Among these lactylation sites, we verified that lactylation at K572 in fatty acid transport protein 2 (FATP2) facilitated lipogenesis and reduced fatty acid beta-oxidation in hepatocytes. Interestingly, compared with littermate controls (*Slc27a2$^{f/f}$, Slc27a2* gene encodes FATP2), hepatocyte-specific *Slc27a2* deficient mice (*Slc27a2$^{\triangle hep}$*) mice were more resistance to metabolic dysfunction-associated steatohepatitis (MASH) diet-induced steatosis and fibrosis. Mechanistically, lactylation of FATP2 inhibited the expression of PPAR downstream target genes by downregulating PGC1α expression, thereby reducing fatty acid beta-oxidation and promoting lipid accumulation. **Conclusion:** Overall, our study reveals lactylation plays an important role in the development and progression of MASLD. Targeting FATP2 lactylation may provide a novel therapeutic target for MASH.

1034 | COMMON REGULATORY MECHANISMS FOR HEPATOCYTE STATE TRANSITIONS ARE DEFECTIVE IN ALCOHOL-RELATED AND METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Rajesh Dutta[1] Seh-Hoon Oh[1] Kuo Du[1] David Umbaugh[1] Auinash Kalsotra[2] Anna Mae Diehl[1], [1]Duke University, [2]University of Illinois

Background: Alcohol-related liver disease (ALD) and MASLD, top causes of steatotic liver disease (SLD), are progressive conditions marked by hepatocyte (Hep) lipotoxicity, inflammation and impaired regeneration, often leading to liver failure. As SLDs advance, mature Heps decline, immature Heps accumulate and liver functions deteriorate. This suggests that SLDs progress when mechanisms orchestrating state transitions in Heps are dysregulated. The Hedgehog pathway (Hh) controls Hep fate and regenerative responses. We reported that depleting Smo (an essential Hh component) in mature Heps induced iron-dependent lipid peroxidation (ferroptotic stress) that triggered Hep senescence, stalled regeneration and sensitized mice to MASLD. Here, we investigated the role of Hep Hh activity in ALD. **Methods:** We analyzed liver single nucleus RNA sequencing data from controls and patients with advanced ALD (alcohol cirrhosis, AC, or hepatitis, AH) for SMO expression, senescence, and ferroptosis signatures. Senescent Heps (ScHeps) were quantified across disease states and stratified by SMO status. Pathway analysis was done on SMO(−) Heps. Liver steatosis, injury, inflammation, and markers of immature Heps were compared in Hep-specific Smo-KO and control mice fed Lieber-DeCarli ethanol diets. **Results:** SMO-expressing Heps decreased in advanced human ALD. ScHeps increased accordingly (2.8% in controls, 34.9% in AC and 62.2% in AH). Notably, only 2.4% of ScHeps expressed SMO, while 97.6% were SMO(−). The ferroptosis marker score was also enriched in SMO(−) Heps, confirming the strong association between decreased SMO, senescence and ferroptotic stress. ScHeps promote maladaptive repair. Pathway enrichment analysis of SMO(−) Heps revealed activation of pro-inflammatory and stress response pathways; pathways involved in mitochondrial function, oxidative phosphorylation, and bile acid metabolism were downregulated. Smo-KO mice were more sensitive to ALD, exhibiting worse hepatic triglyceride accumulation, enhanced Oil Red O staining, increased Tnfα/Il1β expression, more F4/80(+) macrophages and greater accumulation of cells with immature Hep markers. **Conclusion:** Hep Hh signaling inhibits lipotoxicity and inflammatory stress responses that restrict Hep maturation and proliferative capacity. This enables regeneration during ALD. Coupled with prior MASLD data, these results indicate that SLDs progress when conserved mechanisms that control state transitions in Heps are dysregulated.

1035 | TM6SF2-DRIVEN MASH RESISTANCE TO RESMETIROM; SNP REVERSION RESTORES EFFICACY

Chih Ling Chung[1] Shahrbanoo Keshavarz-Aziziraftar[1] Mohammad Mehraban[1] Luis Jasper[1] Yuanyuan Qin[2] Elizabeth Theusch[1] Marisa Medina[2], [1]University of California San Francisco, [2]University of California, San Francisco

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and its progressive form, metabolic dysfunction-associated steatohepatitis (MASH), are rising in global prevalence, posing a

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

growing public health challenge. The 2024 FDA approval of resmetirom, a selective thyroid hormone receptor-β (THR-β) agonist, represents the first pharmacological advance for MASH. However, clinical data reveal suboptimal responses in a large majority of patients, suggesting a role for genetic variability in therapeutic outcomes. **Methods:** We established MASH models using human patient-derived induced pluripotent stem cells (iPSCs) and iPSC-derived hepatocytes (iPSC-Heps). iPSCs were differentiated to iPSC-Heps over 23 days using our published protocol. In vitro assays using oleate challenge were established and cells were stained with Nile Red, imaged and quantified. Data were analyzed by Prism with statistical analysis. **Results:** Resmetirom reduced oleic acid–induced steatosis in non-carrier iPSC-iHeps but showed dramatically diminished efficacy in TM6SF2 rs58542926 (E167K) carrier MASH-derived iPSC-Heps. TM6SF2 rs58542926 (E167K) SNP reversion restored resmetirom's intracellular lipid-lowering activity, with similar effects in double-reverted iHeps (TM6SF2 rs58542926 and SUGP1 rs10401069 both reverted to non-carrier). **Conclusion:** Our findings highlight the influence of genetic background on resmetirom response and underscore the potential for precision medicine or combinatorial therapies to optimize treatment in MASH. Our data also suggests that genotyping patients may play a strong role in therapy selection. Furthermore, carriers of TM6SF2 rs58542926 may require different theraapeutic approaches.

1036 | MIR-432-MEDIATED REGULATION OF TM6SF2 IN MASLD: A TARGETED MIR-MASK STRATEGY FOR RESTORING HEPATIC LIPID HOMEOSTASIS

Mohammad Mehraban[1] Shahrbanoo Keshavarz-Aziziraftar[1], [1]University of California San Francisco

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects ~25% of the global population and increasingly burdens healthcare systems. The TM6SF2 rs58542926 (E167K) SNP is a known genetic driver of MASLD progression to steatohepatitis (MASH), impairing TM6SF2 function and promoting hepatic lipid accumulation, inflammation, and fibrosis. Our recent findings reveal that this SNP introduces a novel binding site for miR-432, enabling miRNA-mediated degradation of TM6SF2 mRNA and reducing protein expression. **Methods:** To test novel therapeutic approaches we tested backbone stabilized oligonucleotides to either directly inhibit miR-432 or miR-mask oligonucleotides designed to interfere with microRNA recognition of the TM6SF2 rs58542926 site by miR-432 specifically. Using patient-derived iPSC-derived hepatocytes we tested the efficacy of our oligonucleotides to block binding, restore TM6SF2 RNA and protein levels. We further tested functional restoration of activity by reducing intrahepatic steatosis in unchallenged and oleate challenged iHeps. **Results:** We designed a miR-mask—an oligonucleotide that blocks the miR-432 binding site on TM6SF2 mRNA without interfering with endogenous miR-432 function. Using iPSC-derived hepatocytes (iHeps), we observed a dose-dependent increase in TM6SF2 mRNA expression, with up to a 22-fold rise upon miR-mask treatment. We also confirmed TM6SF2 protein level restoration via western-blot analysis. Functionally, miR-mask application reduced lipid accumulation in oleate-treated iHeps, indicating restored TM6SF2 activity. Importantly, overall miR-432 levels remained unchanged, preserving its effects on other targets. **Conclusion:** Unlike traditional antisense oligonucleotides (ASOs) that suppress miRNAs broadly, miR-masks offer allele-specific precision by selectively protecting target mRNAs. This minimizes off-target effects and maintains cellular homeostasis. These findings present a novel therapeutic strategy for SNP carriers by stabilizing TM6SF2 expression and improving hepatic lipid metabolism without disrupting native miRNA networks.

1037 | HETEROZYGOUS FADS2 DELETION EXACERBATES HFHC DIET–INDUCED STEATOHEPATITIS VIA ALTERATIONS IN PHOSPHOLIPID AND CERAMIDE METABOLISM

Kazuyoshi Kon[1] Heyon-Cheol Lee-Okada[2] Kumiko Arai[1] Shunsuke Ikejima[1] Kyoko Fukuhara[1] Reiko Yaginuma[1] Kei Ishizuka[1] Hiroo Fukada[1] Akira Uchiyama[1] Shunhei Yamashina[1] Takehiko Yokomizo[2] Kenichi Ikejima[1], [1]Juntendo University Graduate School of Medicine, [2]Juntendo University School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) develops due to both genetic predisposition and acquired factors such as aging, overeating, and obesity; however, the underlying mechanisms remain incompletely understood. We previously demonstrated that aged mice exhibit more severe diet-induced steatohepatitis due to decreased expression of fatty acid

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

desaturase 2 (FADS2) (Ishizuka et al., J Gastroenterol Hepatol, 2020). Here, we aimed to investigate how FADS2 downregulation affects steatohepatitis using FADS2 heterozygous knockout (FADS2$^{+/-}$) mice. **Methods:** Male FADS2$^{+/-}$ and wild-type C57BL/6 (BL6) mice were fed either a high-fat, high-cholesterol (HFHC) or control diet for 8 weeks. Hepatic mRNA/protein expression was analyzed by RT-PCR and Western blotting. Liver fibrosis was assessed via Sirius Red staining. Lipidomics was performed using LC-MS. **Results:** Under control diet, liver histology in FADS2$^{+/-}$ mice was comparable to that in BL6 mice. In contrast, HFHC-fed FADS2$^{+/-}$ mice showed marked macrovesicular steatosis and pericellular fibrosis, with serum ALT levels significantly increased to 151 $\pm$ 30 IU/L vs. 71 $\pm$ 15 IU/L in BL6 mice. Hepatic TNFα, CCL2, and CXCL10 were over 2–3-fold higher in FADS2$^{+/-}$ mice. HO-1 expression also doubled. Fibrosis markers (PDGFβ, TGFβ1, type I collagen, TIMP1) were significantly elevated in FADS2$^{+/-}$ mice. Lipidomics revealed reduced levels of PUFA-containing phospholipids (PE 16:0/20:4, 16:0/22:6, 18:0/20:4, 20:4/16:1) and lysophospholipids (LPC sn-2 20:4, sn-2 20:3). In contrast, DAGs containing 16:0, 18:1 and TAGs containing 16:0, 16:1, 18:1 were significantly increased. Ceramide d18:1/24:1 and lactosylceramide d18:1/24:1 were upregulated, whereas sphingomyelins d18:1/20:0, 22:0–24:0 were decreased. These findings indicate a shift in ceramide metabolism from sphingomyelin toward the glycosphingolipid pathway. **Conclusion:** In FADS2$^{+/-}$ mice fed an HFHC diet, reduced PUFA-containing phospholipids and elevated SFA/MUFA-rich DAGs and TAGs likely enhanced lipotoxicity. In addition, altered ceramide metabolism appears to promote macrophage and stellate cell activation. FADS2 downregulation drives hepatic lipid profiles, promoting inflammation and fibrosis in HFHC diet–induced steatohepatitis.

1038 | REGULATION OF IN VITRO FIBROGENIC PATHWAYS THROUGH CHOLECYSTOKININ RECEPTOR INHIBITION

Martha Gay[1], [1]Georgetown University

Background: Cholecystokinin (CCK) receptors, which are G-protein-coupled receptors, play crucial roles in gastrointestinal physiology; however, their overexpression in cancer and fibrosis is implicated in disease progression and therapeutic resistance. Recent evidence suggests that activation of cholecystokinin (CCK) receptors in hepatic stellate cells (HSCs) induces fibrosis-associated gene expression, contributing to liver pathology in conditions such as metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC). We have demonstrated that a diet high in saturated fat stimulates the expression of hepatic CCK-B receptors in a murine model of non-alcoholic steatohepatitis. The CCK receptor antagonist, proglumide, reversed inflammation, fibrosis, and steatosis, thereby preventing the development of HCC in the murine Metabolic dysfunction-associated steatohepatitis (MASH) model. **Methods:** Methods/murine cells: Using C57BL/6 mice, we will follow the standard protocol for the isolation of murine hematopoietic stem cells (HSC). Stellate cells will be isolated and cultured then stimulated with CCK *in vitro* (1-100nM). Another group of stellate cells will be treated with CCK and proglumide to determine if proglumide can prevent activation of fibrosis genes. Stellate cellular protein will also be extracted and subjected to Western blot analysis for fibrosis- and collagen-associated proteins. Macrophages release cytokines and chemokines that activate stellate cells. For our co-culture experiments, we will culture murine RAW264.7 macrophages with mouse HSCs to activate fibrosis genes and proteins by cytokine/chemokine activation of stellate cells. Methods/ human cells: We will use the immortalized LX-2 human HSC line to evaluate the activation of the fibrosis genes with the addition of CCK to the growth media and examine if proglumide prevents the activation of the LX-2 cells and perform independently CCK-B or CCK-A receptor CRISPR to determine if CCK-induced fibrosis activation is mediated by the CCK-B or CCK-A receptor. Clonal CRISPR CCK-receptor KO stellate cells will also be activated by co-culture and /or with spent media from our human U937 macrophages. Anticipated outcomes: When stellate cells are grown on plastic *in vitro*, they become activated. We know that the cytokines and chemokines released from macrophages will stimulate stellate cells; however, the stimulation and collagen synthesis may not be as pronounced if the stellate cells are not already in an activated state. **Results:** Cholecystokinin (CCK) receptors, particularly CCK-B receptors, have been identified in tissue fibroblasts and are implicated in the production of collagen-associated proteins that promote fibrosis and potentially impede therapeutic interventions in malignancies. However, the role of CCK receptors in liver fibrosis and hepatocellular carcinoma (HCC) remains underexplored. We hypothesize that HCC may originate from liver progenitor or stem cells, and the expression of CCK-B receptors plays a significant role in this process under inflammatory conditions. In a previous study, we evaluated the effects of CCK-B receptor expression in a liver injury model induced by a 0.1% diet of 3,5-

diethoxycarbonyl-1,4-dihydrocollidine (DDC). Cytokine expression was assessed to measure the inflammatory response and its correlation with fibrosis and hepatocellular carcinoma (HCC) progression. Cytokines, small signaling proteins secreted by immune cells, play a crucial role in immune responses and cell signaling. Dysregulation of cytokine expression has been linked to various inflammatory and immunological diseases. Our results suggest that CCK-B receptor expression in liver cells plays a pivotal role in mediating fibrosis and may contribute to the development of HCC under sustained inflammatory pressure. **Conclusion:** This investigation aims to clarify the molecular mechanisms by which CCK receptor signaling drives hepatic fibrosis and explore the therapeutic potential of proglumide in reversing fibrosis-related gene expression in liver disease

1039 | TWO PRE-CLINICAL SHORT INTERFERING RNA MOLECULES TARGETING HUMAN HSD17BETA13 FOR THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Jieun Song[1] Xuan Luong[1] Dieudonne Buh Kum[1] Lillian Adame[1] Peter Althoff[1] Sarah Stevens[1] Saul Martinez Montero[1] Christopher Novotny[2] Jerome Deval[1] Ruchika Jaisinghani[1] Erin Coyne[2] Aneerban Bhattacharya[1] Antitsa Stoycheva[1] Tilani De Costa[1] Seetha Krishnamoorthy[1] Dana Cho[1] John Cortez[1] Jacquelyn Sousa[1] Kellan Passow[1] Vivek Rajwanshi[1] Craig Parish[2] Salman Jabri[2] Shane Daguison[1] Vikrant Gohil[1] Qingling Zhang[1] Toni Williamson[2] Sushmita Chanda[1] Dinah Misner[1] Saswata Talukdar[2] David Smith[1] Julian Symons[1] Leonid Beigelman[1], [1]Aligos Therapeutics, [2]Merck

Background: The liver-enriched, hepatocyte-specific, lipid droplet-associated protein 17-beta hydroxysteroid dehydrogenase isoform 13 (HSD17beta13 or HSD) is a strong genetic risk factor for the development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD) into the more severe metabolic dysfunction-associated steatohepatitis (MASH). A loss-of-function splice variant rs72613567: TA is associated with decreased inflammation and liver injury in patients with fatty liver, indicating that HSD17beta13 is an attractive therapeutic target. The aim of our studies was to characterize short interfering RNA (siRNA) molecules that effectively silence the expression of HSD17beta13 and could be used as potential therapies for MASLD/MASH. **Methods:** An on-/off-target luciferase reporter assay in COS-7 cells and RT-qPCR assay in primary human hepatocytes (PHH) were used to screen proprietary human HSD-targeting siRNAs in vitro for effective silencing of target gene expression. Select compounds were then tested in vivo in PK/PD studies using human AAV-HSD mice, human knock-in (KI)-HSD mice, or wild type non-human primates (NHP). Endpoints included target quantification via RT-qPCR and Western blot analysis. RNA-Seq analysis of treated PHH was conducted to monitor siRNA selectivity and repeat-dose studies were conducted in rats to assess safety. **Results:** We report here two promising pre-clinical siRNAs targeting HSD17beta13, ALG-HSD #1 and ALG-HSD #2, that outperformed competitor controls in cell-based assays and in vivo studies in multiple preclinical species, providing potent target knockdown and high selectivity. The lead sequences demonstrated favorable in-vitro activity with EC_{50} values as low as 5 pM and maximal target RNA reductions of $>$ 90% and with minimal off-target activity in the luciferase reporter, PHH RT-qPCR, and PHH RNA-Seq assays. In both AAV-HSD and KI-HSD mice, selected lead siRNAs exhibited effective target gene silencing (79-92% target RNA reduction); similar robust activity that was durable up to 42 days post-single dose was observed in NHP ($>$ 90% target RNA reduction, $>$ 80% target protein reduction; Figure 1). Furthermore, the two compounds exhibited favorable safety profiles in rats with similarly strong on-target activity ($>$ 95% target RNA reduction). **Conclusion:** We discovered several potent siRNA molecules that selectively and effectively silence human *HSD17beta13* gene expression in vitro and in vivo. We implemented novel chemical modifications that worked to either increase potency without compromising selectivity or improving selectivity with conserved potency. The data generated in these studies allowed for the progression of select liver targeted GalNAc-conjugated siRNAs ALG-HSD #1 and ALG-HSD #2 into later-stage preclinical studies.

1040 | MACROPHAGE LCP1 DEFICIENCY PROMOTES LIVER FIBROSIS IN MASH

Yiwei Zhu[1] Shama Mughal[1] Xin Huang[2] Bishuang Cai[1], [1]Icahn School of Medicine at Mount Sinai, [2]Columbia University Irving Medical Center

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease posing a major global health concern. The infiltration and dysregulation of immune cells, especially macrophages, play a crucial role in the pathogenesis of MASH, contributing to inflammation, fibrosis, and potentially the progression to HCC. Lymphocyte cytosolic protein 1 (LCP1) is an actin-bundling protein that regulates actin assembly, cell adhesion, and immune cell infiltration. However, the role of LCP1 in MASH progression remain unclear. Thus, the aim of this study is to unravel the role and mechanism of LCP1 in MASH progression. **Methods:** LCP1 expression was evaluated in liver samples from MASH patients and various experimental mouse models using qPCR, western blot, and immunofluorescence (IF). *In vivo* experiments were performed using myeloid-specific LCP1 knockout (KO) mice (LysM-Cre $LCP1^{fl/fl}$) and their littermate controls in two MASH models (FAT-MASH and CDAHFD). Then, scRNA-seq, qPCR (for pro-fibrotic markers Col1a1, Col3a1, αSMA, Tgfβ, Mertk, and the macrophage marker F4/80), Sirius Red staining, and immunofluorescence (IF) staining (Col1a1, αSMA, F4/80, Mertk, Galectin-3, and Fabp5) were conducted. **Results:** LCP1 expression was increased in the liver of MASH patients compared to those of control, as assessed by western blot and qPCR. These findings were also observed in various mouse models (FAT-MASH and CDAHFD). IF staining results showed that LCP1 was mainly expressed in $F4/80^+$ macrophages in normal liver, and that $F4/80^+$ $LCP1^+$ macrophages expand in human and experimental MASH liver. Moreover, we found that myeloid-specific LCP1 KO promotes liver fibrosis in both the FAT-MASH model and CDAHFD model, as confirmed via qPCR (pro-fibrotic markers), Sirius Red staining, and IF staining (αSMA and Col1a1). In addition, the mRNA expression levels of macrophage marker F4/80 and the pro-fibrotic gene Mertk were increased in the liver of myeloid-specific LCP1 KO mice compared with their littermate controls in the FAT-MASH model. scRNA-seq data also confirmed that hepatic macrophages were increased in the myeloid-specific LCP1 KO group. Notably, our IF staining results showed that macrophages (marked by F4/80), especially pro-fibrotic $MerTK^+$ macrophages, $Galectin3^+$ macrophages, and $Fabp5^+$ macrophages, were expanded in scar areas (marked by Col1a1 or αSMA). **Conclusion:** LCP1 is highly expressed in human and experimental MASH liver. Myeloid-specific LCP1 knockout leads to an expansion of macrophages, particularly pro-fibrotic ones, within scar areas rich in activated hepatic stellate cells, thereby driving fibrosis progression in MASH. Ongoing research will focus on elucidating the mechanisms behind macrophage expansion (infiltration, proliferation, or migration from other areas) and how LCP1 regulates these processes. Additionally, the GAN diet will be used to validate the results in FAT-MASH and CDHFD models.

1041 | INOSITOL HEXAPHOSPHATE AND INOSITOL AMELIORATE METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS IN WD/CCL4 TREATMENT MICE

Zhao Chen[1] Feng Liu[1] Huiying Rao[1], [1]Peking University Hepatology Institute

Background: Inositol Hexaphosphate (IP6) and inositol (INS), primarily extracted from plants, possess antioxidative and anti-tumor effects. However, whether they can alleviate metabolic dysfunction-associated steatohepatitis (MASH)remains unclear. This study aimed to assess and compare the effects of IP6 and INS on MASH, as well as the underlying mechanisms. **Methods:** A western diet combined with low doses of CCl4 (WD/CCl4) was used to induce MASH in mice and evaluate the protective effects of IP6 and INS. Assessments of transcriptomics, metabolomics, and lipidomics analyses were conducted to explore potential molecular mechanisms. Additionally, the effects of IP6 and INS in vitro using free fatty acid (FFA)-treated HepG2 cells and activated hepatic stellate cells were investigated. **Results:** Treatment with IP6 or INS significantly reduced obesity, fibrosis and lipid accumulation, improved insulin sensitivity and glucose homeostasis, and prevented hyperglycemia in NASH mice. However, IP6 exerted more beneficial effects against inflammation and oxidative stress. IP6 and INS also alleviated FFA-induced lipid accumulation in HepG2 cells. Liver transcriptomics revealed the deleterious effects of WD/CCl4 on gene expression and their reversal by IP6 and INS. Metabolomics and lipidomics analyses indicated that IP6 and INS can effectively improve disorders in glycerophospholipid metabolism by regulating the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

expression of related genes and metabolites. Especially in the aspect of oxidative phosphorylation metabolism, IP6 is more effective than INS. **Conclusion:** Both IP6 and INS effectively improve MASH primarily by ameliorating disorders in glycerophospholipid metabolism. This finding provides a theoretical basis for the prevention and treatment of MASH in patients through the rational intake of foods containing IP6 and INS.

1042 | ESTROGEN DEFICIENCY ENHANCES AHR-DRIVEN PATHWAYS IN METABOLIC LIVER DISEASE

Jessica Cassavaugh[1] Sarah Kispert[1] Eva Csizmadia[1] Maria Serena Longhi[1] Simon Robson[1], [1]Beth Israel Deaconess Medical Center

Background: Metabolic-associated Fatty Liver Disease (MASLD) is highly associated with increased cardiovascular morbidity and mortality. Declining estrogen levels during menopause elevate the risk of MASLD and other metabolic disorders. We hypothesize that estrogen protects against MASLD by modulating aryl hydrocarbon receptor (AhR) activity. We therefore investigated mechanisms whereby estrogen lack disorders AhR transcriptional activity to exacerbate experimental MASLD. **Methods:** Liver tissue from ovariectomized (OVX) C57BL/6 mice were assessed for fat burden and reactive oxygen species (ROS), and serum cytokines. Expression of CYP1A1 and other AhR targets were measured using western blotting and q-RT-PCR. In hepatocytes, fatty acid ROS were measured along with q-RT-PCR to measure CYP1A1 and other AhR associated targets. A gene-expression profile in fatty acid treated hepatocytes was identified by means of a targeted PCR array. **Results:** A high-fat diet (HFD) combined with OVX leads to increased fatty acid deposition and reactive oxygen species (ROS), contributing to oxidative stress. Both HFD and OVX resulted in higher serum levels of proinflammatory cytokines, including TNF-α and IL-6. Protein expression of AhR and TNFa as well as gene expression of CYP1A1, a transcriptional target of AhR, was elevated in liver tissue from OVX mice. In hepatocytes, estradiol and endogenous AhR activation by unconjugated bilirubin was protective from fatty acid-induced ROS production. Conversely, exogenous AhR activation with benzo[a]pyrene and estrogen inhibition exacerbate ROS production. Gene expression of CYP1A1 was markedly increased with estrogen inhibition or exogenous activation of AhR. PCR array analysis reveals significant gene expression changes related to the AMPK, insulin resistance, and PPAR signaling pathways with exogenous AhR activation. Notably, highly regulated genes exhibit an amplified cluster of estrogen receptor alpha binding motifs, suggesting estrogen's role in modulating these pathways. **Conclusion:** Estrogen deficiency accelerates the progression of metabolic-associated fatty liver disease (MASLD) by increasing fat accumulation and inflammation, particularly when combined with a high-fat Western diet. These results may be driven by AhR-associated transcriptional changes of CYP1A1 and increases in proinflammatory signaling pathways. These findings underscore the complex interplay between diet, estrogen signaling, and liver health, highlighting potential therapeutic targets for conditions like MASLD.

1043 | MALNUTRITION-INDUCED METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE IMPAIRS PHOSPHOLIPID BIOSYNTHESIS AND TRIGLYCERIDE SECRETION IN EARLY LIFE MOUSE MODEL

Larissa Neves[1] Krishnakant Soni[1] Margaret Conner[2] Geoffrey Preidis[1], [1]Baylor College of Medicine and Texas Children's Hospital, [2]Baylor College of Medicine

Background: Globally, malnutrition is responsible for 45% of deaths of children under the age of five. Malnutrition impairs gastrointestinal and metabolic functions including dyslipidemia, nutrient

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

malabsorption, and slow gut motility. In severe malnutrition, hepatic lipid accumulation results in steatotic liver disease. Steatosis is the most prevalent form of liver disease worldwide, with nearly 10% of children affected. Currently, there is no FDA-approved drug to treat steatosis and the mechanisms by which malnutrition causes steatosis are poorly understood. Models of liver steatosis suggest that impaired phospholipid metabolism alters lipid homeostasis and secretion. Rodents fed a methionine-choline-deficient diet exhibit steatosis and altered quantities and ratios of phosphatidylcholine (PC) and phosphatidylethanolamine (PE). Disrupting PC and PE homeostasis impairs hepatic lipid secretion by very low-density lipoproteins (VLDL). Whether altered phospholipid homeostasis contributes to steatosis in protein malnutrition is unknown. Therefore, I hypothesize that protein malnutrition causes hepatic lipid accumulation by altering phospholipid biosynthesis and impairing VLDL secretion. **Methods:** Our lab models malnutrition by feeding weanling male and female C57BL/6J mice a low-protein, low-fat diet (LPLFD) until 8 weeks of life. Previously, we reported that LPLFD reduces body weight and length in male and female mice with a poorer outcome in males. To examine lipid accumulation from LPLFD and control mice, I stained flash-frozen liver sections with oil red O and quantified liver triglycerides via thin-layer chromatography. I used western blot to quantify the expression of key phospholipid biosynthesis enzymes, including phosphatidylethanolamine N-methyltransferase (PEMT), phosphatidylserine decarboxylase (PSD), choline dehydrogenase (CHDH), and betaine-homocysteine S-methyltransferase (BHMT). Additionally, I evaluated VLDL secretion via lipoprotein profiling of serum samples using high-performance liquid chromatography (HPLC). **Results:** Hepatic lipid accumulation and triglycerides were dramatically increased, and PEMT expression was markedly decreased, in malnourished male and female mice compared to controls. In contrast, expression of hepatic PSD, CHDH, and BHMT was sexually dimorphic; these proteins were reduced in malnourished males but not females. Lipoprotein profiling with HPLC revealed that LPLFD reduced serum VLDL, suggesting that impaired triglyceride secretion leads to hepatic lipid accumulation in protein malnutrition. **Conclusion:** Together, these results suggest that malnutrition induces liver steatosis by altering phospholipid biosynthesis and impairing VLDL secretion. Understanding the role that phospholipids play in LPLFD-induced steatosis allows for further exploration of therapies to ameliorate or prevent steatosis in malnourished children.

1044 | SINGLE-CELL ATLAS OF HUMAN LIVER AND BLOOD IMMUNE CELLS ACROSS FATTY LIVER DISEASE STAGES REVEALS DISTINCT SIGNATURES LINKED TO LIVER DYSFUNCTION AND FIBROGENESIS

Owen Martin[1] Michael Wallace[2] Christopher Oetheimer[2] Hailey Patel[2] Michael Butler[2] Lai Ping Wong[2] Joshua Elbaz[2] Charlotte COSTENTIN LAURENT[3] Shadi Salloum[4] Zoe Reinus[2] Adaeze Obinelo[2] Ulandt Kim[4] Stuti Shroff[2] Kathleen Corey[4] Edgar Charles[5] Ruslan Sadreyev[2] Raymond Chung[4] Nadia Alatrakchi[2], [1]Massachusetts General Hospital & Harvard Medical School, [2]Massachusetts General Hospital and Harvard Medical School, [3]Grenoble Alpes University, [4]Massachusetts General Hospital, [5]Bristol Myers Squibb

Background: Immune cells play a central yet poorly understood role in metabolic dysfunction-associated steatotic liver disease and steatohepatitis (MASLD/MASH), a global cause of liver disease with limited treatment. Limited access to human livers and lack of studies across MASLD/MASH stages thwart identification of stage-specific immunological targets. **Methods:** We studied 25 patients spanning the full MASLD/MASH spectrum (without other causes of chronic liver disease) who underwent clinical liver biopsy for diagnosis at Massachusetts General Hospital upon detection of hepatic fatty inclusions by ultrasound/CT-scan/MRI. Immune cells from paired liver fine needle aspirates and peripheral blood samples were subjected to single-cell RNA-sequencing (scRNA-seq) via the 10X Genomics platform and investigated for changes in frequency and computationally-resolved function with clinical measurements of MASLD/MASH. **Results:** Transcriptomic analysis delineated distinct immune cell signatures linked to liver dysfunction. Findings included heightened immunoregulatory programs with MASH progression, such as enriched hepatic regulatory T cells, monocytic myeloid-derived suppressor cells, *TREM2*$^{+}$*S100A9*$^{+}$ macrophages, and mature regulatory dendritic cells. Hepatic cytotoxic T-cell functions increased with inflammation but decreased with fibrosis (acquiring an exhausted signature) while natural killer cell-driven toxicity intensified. **Conclusion:** We created a human cross-compartment scRNA-seq atlas of immune cells spanning the MASLD/MASH spectrum. We uncovered contributions of immune cells to the hepatic inflammatory and profibrotic milieu and multiple types of immune regulation leading to T-cell exhaustion that can contribute to increased vulnerability to liver cancer and infections in patients with MASH. Our dataset is a valuable resource that provides a basis for a deeper understanding of immunological plasticity

1045 | GENETIC OR PHARMACOLOGICAL INHIBITION OF HEPATIC TMEM141 ATTENUATES MASH AND FIBROSIS VIA THE ROS-HNF4α SIGNALING PATHWAYNEW SUBMISSION

Jiayou Wang[1] Chwen-Lih W Chen[2] Raja Gopoju[1] Shuwei Hu[1] Yang Wang[1] Hui Wang[1] Zaid Batayneh[2] Xiaoli Pan[2] Yeong-Renn Chen[2] Jeffrey Mellott[2] Patrick Kang[2] Liya Yin[1] Yanqiao Zhang[3], [1]University of Arizona College of Medicine – Phoenix, [2]Northeast Ohio Medical University, [3]University of Arizona College of Medicine - Phoenix

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and its advanced form, metabolic dysfunction-associated steatohepatitis (MASH), have become a global epidemic due to obesity and genetic susceptibility. **Methods:** Here, we report transmembrane protein 141 (TMEM141), a protein with a largely unknown function, as a key regulator of MASH and MASH-associated fibrosis. **Results:** Hepatic TMEM141 is reduced in MASLD/MASH patients and mouse models of MASLD/MASH due to increased microRNA-149. Unexpectedly, genetic inactivation of hepatocyte TMEM141 protects against MASLD/MASH induced by a high fat/cholesterol/fructose (HFCF) diet, whereas hepatic overexpression of human TMEM141 exacerbates MASLD/MASH. We further show that TMEM141 localizes within mitochondria and interacts with mitochondrial complex I to regulate ROS production. Inactivation of TMEM141 reduces ROS production, induces hepatocyte nuclear factor 4α (HNF4α), and fails to protect against HFCF diet-induced MASH or fibrosis in the absence of hepatocyte HNF4α. Finally, pharmacological inhibition of hepatic TMEM141 by N-acetylgalactosamine (GalNAc)-siTmem141 significantly promotes the reversal of HFCF diet-induced MASH and fibrosis. **Conclusion:** These findings underscore a critical role of TMEM141 in MASH development and suggest that targeting hepatic TMEM141 may represent a novel and promising strategy for treating MASH and MASH-associated fibrosis.

1046 | ROLE OF LY6D IN HEPATIC LIPID METABOLISM AND ITS THERAPEUTIC POTENTIAL IN MASLD

Soyeon Shin[1] Yeongmin Kim[1] Moon-young Park[1] Chang-Myung Oh[1], [1]GIST

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a prevalent cause of chronic liver disease worldwide. Despite its high prevalence, the underlying mechanisms driving its progression and effective treatment options remain poorly understood. Ly6D, a membrane protein anchored to the cell surface via glycosylphosphatidylinositol and expressed in immune cells such as B-cells and T-cells, has been investigated in various diseases, including certain cancers, although its role in hepatic lipid metabolism and inflammation remains to be elucidated. This study investigates the role of Ly6D in MASLD progression and evaluates its potential as a therapeutic target for MASH, a severe progression of MASLD. **Methods:** Ly6D hepatocyte-specific knockout

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(KO) mice were generated using Alb-cre transgenic mice. Both KO and control mice were fed a high-fat diet (HFD) for 8 weeks to induce MASLD. Ly6D expression was quantified by qPCR and Western blot. Liver lipid accumulation was assessed by H&E and Oil Red O staining. To study Ly6D's role in MASH, human hepatic stellate LX-2 cells were used in vitro. Additionally, hepatic stellate cell-specific analyses were performed using Lrat-cre transgenic mice, which enable selective genetic targeting of hepatic stellate cells. **Results:** In mice fed a standard chow diet (SCD) and an HFD, liver tissues were separated into parenchymal cells (hepatocytes) and non-parenchymal cells (NPCs) for analysis. Ly6D RNA levels were significantly elevated in both cell types in the HFD group compared to SCD controls, with a notably higher upregulation observed in NPCs ($p < 0.05$). Hepatocyte-specific Ly6D KO mice generated using Alb-cre transgenic mice exhibited a significant reduction in MASLD progression compared to controls after 8 weeks of HFD feeding. Histological analysis showed significant reduction of liver steatosis in Ly6D KO mice. To further investigate Ly6D's role in MASH, Ly6D expression was silenced in human hepatic stellate LX-2 cells using siRNA. Ly6D silencing significantly attenuated the expression of activation markers such as α-SMA upon TGF-β1 stimulation ($p < 0.05$), indicating suppression of hepatic stellate cell activation. Additionally, hepatic stellate cell-specific studies were conducted in vivo using Lrat-cre transgenic mice. These findings demonstrate that Ly6D plays a critical role in both hepatic lipid metabolism and stellate cell activation, suggesting that targeting Ly6D may mitigate MASLD progression. **Conclusion:** Our findings highlight Ly6D as a significant contributor to MASLD pathogenesis, suggesting it as a potential therapeutic target. While initial results are promising, especially in reducing liver steatosis and stellate cell activation, further studies are essential to validate its role in MASH. Future research should explore the long-term effects and feasibility of Ly6D-targeted therapies to better understand their clinical application.

1047 | EXTRACELLULAR VESICLES FROM THE IPSC-DERIVED MESENCHYMAL STEM CELLS AMELIORATED LIVER FIBROSIS IN MASH-RELATED CIRRHOTIC MICE

Tsuyoshi Fujioka[1] Toshihiko Matsumoto[1], [1]Yamaguchi University Graduate School of Medicine

Background: In recent years, extracellular vesicles (EVs) derived from mesenchymal stem cells (MSCs) have shown promise in treating liver cirrhosis. However, limitations in cell proliferation make continuous use of EVs from the same donor's MSCs difficult. Therefore, we developed iPSC-derived MSCs (iMSCs) and examined the therapeutic effects of iMSC-EVs on MASH-related liver fibrosis. **Methods:** We characterized iMSCs by comparing their EV production and microRNA expression profiles in EVs to those of bone marrow-derived MSCs (BMSCs), as measured by nanoparticle tracking analysis and microRNA arrays, respectively. Next, human hepatic stellate cells (hHSCs) were activated with TGFβ and then treated with iMSC-EVs and their fibrosis-related gene expression was determined. To evaluate the effects of iMSC-EVs in vivo, a mouse model of MASH-related liver fibrosis was established by feeding Gubra-Amylin-NASH (GAN) diet and a single intraperitoneal injection of carbon tetrachloride. The mice were divided into control group and iMSC-EV group. The iMSC-EV group received intravenous injection of iMSC-EVs once a week for 4 weeks. Blood and liver samples were analyzed using biochemical tests and histological examinations. We also compared the gene expression profiles of the livers of both groups by performing a comprehensive analysis of mRNA expression profiles and using Ingenuity Pathway Analysis. **Results:** iMSCs produced more EVs than BMSCs. Thirty-nine microRNAs were extracted from the microarray data that exhibited a normalized intensity of greater than 1,000 in both iMSC- and BMSC-EVs. Five of these microRNAs had anti-fibrotic effects on hHSCs. As expected, iMSC-EVs inhibited the expression of fibrosis-related genes (COL1A1, COL1A2 and ELN) in activated hHSCs. In a murine model of MASH-related fibrosis, the iMSC-EV group showed improved liver function, reduced dyslipidemia, and elevated albumin levels compared to the control group. Histological examination revealed a significant reduction in the fibrotic areas, accompanied by a decrease in CD11c-positive M1 macrophages (Mφ) and an increase in CD163-positive M2 Mφ in the livers of iMSC-EV group. Gene expression analysis revealed suppression of extracellular matrix organization pathway and Rho

1048 | INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN 7: A PROMISING BIOMARKER FOR HEPATIC FIBROSIS AND CARDIAC DYSFUNCTION IN METABOLIC DYSFUNCTION-ASSOCIATED STEOTOTIC LIVER DISEASE

Jie Li[1] Wenjing Ni[1] Qianqian Chen[1] Yixuan Zhu[1] Fajuan Rui[1] Zhiwen Fan[1] Shengxia Yin[1] Qianwen Zhao[1], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University

Background: Individuals with metabolic dysfunction-associated steatotic liver disease (MASLD) face an elevated risk of liver-related complications and cardiovascular diseases. We have found that insulin-like growth factor binding protein 7 (Igfbp7) is a promising marker for the cross-disease communication between liver and heart. This study aimed to investigate the role of Igfbp7 in the process of liver fibrosis and its impact on cardiac dysfunction under the context of MASLD. **Methods:** Circulating Igfbp7 levels and liver tissue expression were examined in patients with liver fibrosis. Male C57BL/6J mice were fed a high-fat, high-fructose diet (HFHD) for 20 weeks to induce MASLD-associated liver fibrosis. Igfbp7 knockdown in mature myofibroblasts was achieved using Igfbp7-targeting shRNA under the Postn promoter, packaged into AAV6 (AAV-shIgfbp7). Echocardiography was performed to assess cardiac function. Liver histology was analyzed with hematoxylin-eosin (HE) staining. In vitro studies utilized TGF-β-activated human hepatic stellate cells (LX-2) to explore Igfbp7-associated mechanisms. **Results:** Reanalysis of single-cell sequencing data identified Igfbp7 as a significantly deferentially expressed gene implicated in liver fibrosis and heart failure under the context of MASLD. Circulating IGFBP7 levels correlated positively with liver stiffness measurements (LSM) in patients with liver fibrosis concurrent with heart failure. IGFBP7 expression was proportionally associated with liver fibrosis severity verified in liver samples among patients with liver fibrosis. HFHD-fed MASLD mice exhibited increased liver fibrosis and reduced cardiac function, which were alleviated by Igfbp7 knockdown. *Igfbp7* mRNA levels were elevated alongside myofibroblast markers (*Acta2, Postn, Col1a1*) in MASLD mice but decreased following Igfbp7 knockdown. Glucose tolerance test and insulin tolerance test showed an improved performance in mice with Igfbp7 knockdown (Figure 1). Consistent findings were observed in primary hepatic stellate cells (HSCs) from wild-type mice, where Igfbp7 expression increased during spontaneous activation. TGF-β-activated LX-2 cells displayed enhanced Igfbp7 expression, migration, proliferation, and contraction, and these effects were mitigated by Igfbp7 knockdown. **Conclusion:** IGFBP7 serves as a promising biomarker for assessing liver fibrosis severity and cardiac dysfunction in MASLD. Targeting IGFBP7 could offer therapeutic potential for managing liver and cardiovascular complications in MASLD patients.

Figure 1. IGFBP7 aggravated liver fibrosis and cardiac dysfunction in MASLD.

1049 | INHIBITION OF HEPATOCYTE FERROPTOSIS IN THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE BY QUSHI HUAYU DECOCTION

Yuqing Pan[1] Aojie Mao[1] Chuchu Yu[1] Huajie Tian[1] Yiyang Hu[1] Yu Zhao[1], [1]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Hepatocyte ferroptosis plays a critical role in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD). Qushi Huayu Decoction (QSHY), a traditional Chinese medicine composing five herbs, has demonstrated therapeutic potential in MASLD patients in our previous clinical trial. Hepatic R2* magnetic resonance imaging (R2*-MRI) was significant decreased in patients post-QSHY intervention. This study aimed to evaluate the anti-ferroptotic effects of QSHY in MASLD and further identify an optimized active component combination that retains the original formula's efficacy. **Methods:** A MASLD mouse model was established using a high-fat diet and high-sugar drinking water (HFHS). The chemical constituents of QSHY and its blood-incorporated components were analyzed via ultra-high-performance liquid tandem quadrupole-Q-Electrostatic Field Orbitrap High Resolution Mass Spectrometry (UHPLC-Q-Exactive Orbitrap HRMS). Mice were treated with QSHY decoction (1.733 g/kg) or a combination of ferulic acid (F) and chlorogenic acid (C) (80 mg/kg + 60 mg/kg). Mitochondrial morphology was assessed by transmission electron microscopy (TEM). Liver lipid profiles were analyzed using lipidomics, and potential drug-binding proteins were screened via drug affinity responsive target stability combined with mass spectrometry (DARTS+MS). **Results:** QSHY dose-dependently alleviated hepatocyte ferroptosis in MASLD mice. UPLC-MS identified 36 chemical components in QSHY, 22 of which were detected in the bloodstream of MASLD mice. A homogeneous design study prioritized six top-ranking liver Cmax components, leading to the identification of an optimized ferulic acid-chlorogenic acid combination (FC). Both QSHY and FC significantly decreased liver TG, serum ALT and AST levels. TEM revealed improved mitochondrial ultrastructure in treated mice. Mechanistically, QSHY and FC decreased serum and hepatic iron levels, downregulated transferrin receptor (TFR), and upregulated ferritin heavy chain 1 (FTH1), mitigating iron overload. Furthermore, they reduced malondialdehyde content, upregulated glutathione peroxidase 4 (GPX4), and downregulated key lipid peroxidation enzymes (ACSL4, LPCAT3). Hepatic lipidomics revealed that QSHY and FC reduced triglyceride and polyunsaturated fatty acid-containing phospholipids while increasing monounsaturated fatty acid-containing phospholipids. DARTS+MS analysis suggested that ferulic acid and chlorogenic acid may exert anti-ferroptotic effects by binding to ACSL3 and GPX4, respectively. **Conclusion:** QSHY and its optimized FC combination attenuate MASLD and inhibit hepatocyte ferroptosis, ferulic acid and chlorogenic acid may exert anti-ferroptotic effects by binding to ACSL3 and GPX4, respectively.

1050 | HEPATOCYTE-SPECIFIC HAF DEFICIENCY PROMOTES LIPID DYSREGULATION THROUGH MAPK PATHWAY ACTIVATION IN A MURINE MODEL OF MASH-HCC

Karen Acuna-Pilarte[1] Po-An Hu[1] Kimberley Evason[2] Ethan Reichert[1] Mei Yee Koh[1], [1]University of Utah, [2]University of California, San Francisco

Background: Progression of Metabolic dysfunction-associated steatotic liver disease (MASLD) to metabolic dysfunction-associated steatohepatitis (MASH) is marked by disruption of lipid metabolism and inflammatory pathways that can drive liver cancer development. We previously showed that conditional deletion of the hypoxia-associated factor (HAF) in mouse hepatocytes triggers NF-κB downregulation and increased apoptosis, resulting in MASH at 6 months and HCC at 18 months. HAF is downregulated in steatotic human livers, showing that loss of HAF might be key in the development of human MASH. Intriguingly, despite profound MASH, the HAF-deficient mice showed reduced overall body mass and increased lean mass, resembling human lean MASH, which is associated with a lower index of detection, resulting in later disease diagnosis. This study aims to elucidate the molecular

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

mechanisms by which HAF deficiency drives MASLD/MASH and to explore potential pathways underlying lean-MASH. **Methods:** We isolated hepatocytes from a conditional HAF knockout mouse model and assessed two major pathways within the MAPK signaling cascade: p38 mitogen-activated protein kinase (p38) and c-Jun NH2-terminal kinase (JNK). Phosphorylation of p38 and JNK, along with downstream targets and autophagy markers, was evaluated via western blotting following TNF-α stimulation. Cytokine profiling was performed on hepatocyte-conditioned media. Levels of hepatokines of interest were validated and quantified by ELISA. To assess the involvement of NF-κB in these signaling events, hepatocytes were treated with the inhibitor BAY11-7082, and subsequent p38/JNK activation was analyzed. **Results:** HAF-deficient hepatocytes exhibited elevated basal phosphorylation of p38 and JNK, independent of TNF-α stimulation. Surprisingly, upstream kinases ASK1 and MKK6 were downregulated, indicating activation of p38/JNK via a non-canonical mechanism. NF-κB inhibition did not further enhance p38/JNK activation, suggesting that JNK/p38 upregulation occurs independently of NF-κB suppression in HAF-deficient cells. Cytokine profiling revealed increased FGF21 secretion, a known p38/JNK target and autophagy regulator. Moreover, autophagy was impaired in HAF-deficient hepatocytes, as evidenced by reduced LC3A/B and elevated p62 levels. Additionally, LDLR expression was diminished, implying disrupted cholesterol homeostasis. **Conclusion:** Our findings reveal that hepatocyte-specific HAF deficiency induces non-canonical activation of p38 and JNK, contributing to lipid dysregulation through FGF21 resistance, impaired autophagy, and LDLR suppression. These mechanisms may play a role in lean-MASH pathogenesis.

1051 | ALTERNATIVELY SPLICED TISSUE FACTOR: A NOVEL CONTRIBUTOR TO MASLD PROGRESSION

Clayton Lewis[1] Kateryna Stone[1] Sabahat Ahsan[1] Josepha Sedzro[2] Lanuza Faccioli[3] Zhiping Hu[3] Rodrigo Florentino[3] Alejandro Soto-Gutierrez[3] Jiang Wang[1] James Luyendyk[4], [1]University of Cincinnati, [2]University of Michigan, [3]University of Pittsburgh, [4]Michigan State University

Background: Nearly one in three people in the United States have some degree of metabolic dysfunction associated steatotic liver disease (MASLD). 18% of these people develop a more fibrotic and severe form of disease termed metabolic dysfunction-associated steatohepatitis (MASH). Alternatively spliced tissue factor (asTF) is a soluble isoform of tissue factor (TF). In contrast to the full-length isoform of TF, which initiates the extrinsic pathway of coagulation, asTF does not trigger coagulation. Instead, asTF activates integrin-associated signaling cascades that elicit angiogenesis from endothelial cells. We have shown that patients with fibrotic liver diseases, including MASH, have significantly higher levels of circulating asTF than healthy individuals, and that these levels correlate with disease severity. Here we sought to identify the subcellular localization of asTF in normal and diseased livers, determine drivers of its expression, and examine the functional consequences of asTF signaling on non-parenchymal cells. We hypothesize that paracrine asTF signaling drives endothelial capillarization and enhanced extracellular matrix deposition by non-parenchymal cells, hallmark features of MASH. **Methods:** Immunohistochemistry was used to identify the localization of asTF in 30 human liver tissue specimens. Hepatocyte-like cell line HepaRG and primary hepatocytes were assessed for their responivness to hypoxia and nutrient deprivation, key environmental features imposed by fibrotic disease, via qPCR and western blotting. Non-parenchymal human cell lines TMNK1 and LX-2 were assessed for responsiveness to exogenous recombinant asTF via extracellular matrix (ECM) deposition and tubule formation assays. **Results:** In normal liver tissue, asTF localized to exocysts adjacent to apical membranes of pericentral hepatocytes. Polarized expression was progressively lost with increasing fibrosis; instead, high asTF levels were observed across the liver. Hypoxia stimulated asTF and flTF expression by cell line HepaRG. MASH patient hepatocytes had high asTF protein expression and minimal flTF expression. When primary hepatocytes were cultured *ex vivo*, flTF expression increased while asTF was suppressed. Hypoxia stimulated expression of both TF isoforms *in vitro*. Recombinant asTF stimulated activation of Akt in TMNK1 cells and Erk in LX-2 cells, simultaneously promoting ICAM1 and COL3A1 expression, respectively. In an ECM deposition assay, asTF promoted a 36% increase in COL3A1 deposition by LX2 cells and a 36% increase in COL1A1 by TMNK1 cells. asTF enhanced tubule formation by TMNK1 by 55%. **Conclusion:** Hypoxia and nutrient deprivation drive aberrant asTF expression by hepatocytes, and non-parenchymal cells display profibrogenic phenotypes when stimulated by asTF. Thus, asTF is likely a novel contributor to the pathological remodeling of the liver in the progression from MASLD to MASH.

1052 | INHIBITION OF OX40 IN CD4+ T CELLS ATTENUATES HEPATIC INFLAMMATION IN A HUMAN EX VIVO MODEL OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Lucia Valenzuela Perez[1] Hyun Se Kim Lee[1] Alexander Washington[1] Shravan Mishra[1] Patrick Starlinger[2] Samar Ibrahim[1] Adebowale Bamidele[1] Enis Kostallari[1] Petra Hirsova[1], [1]Mayo Clinic Rochester, [2]Mayo Clinic

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by chronic liver inflammation and fibrosis, with effector CD4+ T cells contributing to its pathogenesis. Our single-cell transcriptomics revealed a striking increase in CD4+ T cells expressing the co-stimulatory receptor OX40 in murine MASH livers. In turn, inhibition of the OX40L-OX40 axis reduced MASH severity in mice with established MASH. Here, we aimed to evaluate OX40 and OX40L protein expression and the therapeutic potential for human MASH. **Methods:** C57BL/6J mice were fed chow or a high-fat, fructose, and cholesterol (FFC) diet for 26 weeks. OX40 and OX40L protein expression was assessed in hepatic leukocytes, peripheral blood mononuclear cells (PBMCs), spleen, lamina propria (LP), and mesenteric lymph nodes (MLN) by flow cytometry. Human precision-cut liver slices (PCLS) were incubated in a MASH-inducing media (GFIPO: glucose, fructose, insulin, oleate, palmitate ± TNFα) and treated with Rocatinlimab, an antagonistic anti-OX40 monoclonal antibody. Markers of steatosis and inflammation were assessed by qPCR. **Results:** Within the murine CD45+ intrahepatic leukocytes, OX40 expression was predominantly detected in CD4+ T cells, with a significantly higher percentage in MASH livers, but was barely present in CD8+ T cells or other leukocytes. OX40+ CD4+ T cells were also increased in the spleen and PBMC, but not in MLN or LP. OX40L expression was low in normal liver leukocytes but significantly elevated in MASH livers, mainly due to increased OX40L+ monocyte-derived macrophages and a slight increase in OX40L+ dendritic cells. No changes in OX40L+ leukocytes were found in the spleen, MLN, LP, or PBMCs, indicating that OX40L upregulation is a liver-specific phenomenon. Human precision-cut liver slices incubated in GFIPO media developed steatosis alongside upregulation of genes linked to lipogenesis (e.g., FASN, DGAT2, SCD1) and inflammation, including CCL2 and OX40. Treatment of PCLS with Rocatinlimab decreased the mRNA expression of key CD4+ T cell-associated inflammatory markers, including IFNγ and CXCL10, indicating a role for OX40 signaling in MASH pathogenesis. **Conclusion:** In murine MASH, OX40 and OX40L were upregulated specifically in hepatic CD4+ T cells and monocyte-derived macrophages, respectively. Blocking OX40 in the human ex vivo MASH model reduced markers of inflammation, highlighting OX40 as a promising immunotherapeutic target to alleviate MASH.

1053 | INVESTIGATING THE ROLE OF MTARC1 RS2642438 (A165T) IN THE DEVELOPMENT AND PROGRESSION OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) USING HUMAN LIVER ORGANOIDS

Amel Ben Saad[1] Arden Weilheimer[1] Alan Mullen[1], [1]University of Massachusetts Chan Medical School

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent cause of chronic liver disease. MASLD is a progressive and multifactorial disease, starting with steatosis, which can progress to steatohepatitis, then fibrosis and can result in cirrhosis and/or liver cancer. Therapeutic options for patients with MASLD are limited. A better understanding of the pathogenesis and progression of MASLD is needed to identify more effective treatments. Different factors can regulate development, progression, and complications in MASLD, including environmental and genetic factors. Genome-wide association studies (GWAS) have identified susceptibility loci or SNPs (single nucleotide polymorphism) associated with an altered risk in developing liver disease, including the mitochondrial amidoxime reducing component 1 (*MTARC1*) *rs2642438 (A165T*) variant. In MASLD, there are strong data supporting the protective effect of the *MTARC1 rs2642438* variant in patients compared to those with the reference sequence, but little is known about the role of MTARC1 and the molecular pathways it regulates in the liver. The aim of this work is to investigate how *MTARC1 rs2642438* protects against MASLD progression using human liver organoids. **Methods:** We first edited human pluripotent stem cells (hPSCs) using prime editing to create the *MTARC1 rs2642438* variant. We then differentiated hPSCs with the *MTARC1* variant and those with the reference sequence into liver organoids and studied their phenotype and response to conditions that recapitulate MASLD in culture. **Results:** We find that liver organoids with the *MTARC1 rs2642438* variant recapitulate the protective phenotype observed in patients carrying the variant, with a reduction in steatosis and fibrosis. **Conclusion:** Understanding how MTARC1

regulates the evolution of MASLD and resulting liver injury in a human model system will help us develop new therapeutic approaches to disrupt the progression of disease.

1054 | MASLD AND PNPLA3^{I148M} ASSOCIATE WITH SKELETAL FRAGILITY VIA DELETERIOUS LIVER-BONE CROSSTALK

Galen Goldscheitter[1] Mulugeta Seneshaw[1] Faridoddin Mirshahi[1] Ronnie Li[1] Damian Genetos[2] Henry Donahue[1] Arun Sanyal[1], [1]Virginia Commonwealth University, [2]University of California - Davis

Background: MASLD associates with increased risk of fracture and greater morbidity and mortality post-fracture. The PNPLA3 I148M variant (PNPLA3^{I148M}) accounts for most MASLD heritability and accelerates steatohepatitis development in MASLD. We have previously established that MASLD, and PNPLA3^{I148M}, are independent risk factors for bone disease, but mechanisms underlying this process are unexamined. **Methods:** 8-week-old DIAMOND (S129/C57BL6) isogenic cross mice (n = 40), a validated model of MASH, were injected with AAV containing human WT PNPLA3 (PNPLA3^{WT}) or PNPLA3^{I148M}. Groups were randomized to chow diet and normal water (CDNW) or high-fat diet and sugar water (WDSW) for 36 weeks. Only mice fed WDSW develop MASH. Bone geometry was analyzed by microcomputed tomography, strength in 3-point bending, and marrow adiposity via IHC against perilipin-1. *Pnpla3* expression was measured via RT-qPCR. Liver and bone RNA were sequenced in bulk on the Illumina NovaSeq XPlus platform. RNASeq analysis yielded differential gene expression, gene set enrichment, and ligand-target inference. **Results:** (1) Compared to CDNW, PNPLA3^{WT} mice fed WDSW developed diet-induced obesity and moderate steatohepatitis with stage 2 or 3 fibrosis; and PNPLA3^{I148M} mice developed more severe steatohepatitis and stage 3 or early stage 4 fibrosis. Only PNPLA3^{WT} WDSW mice lose bone volume and strength compared to CDNW, while PNPLA3^{I148M} sensitized mice to lose bone mass independent of diet. Bone marrow adiposity is markedly higher among mice fed WDSW than CDNW especially among PNPLA3^{I148M} (*Fig. A*). *Pnpla3* was expressed in both liver and bone. (2) Inflammatory interleukin signaling and TLR4 signaling pathways are upregulated in bone, suggesting a pro-resorptive inflammatory phenotype among mice fed WDSW, exacerbated by PNPLA3^{I148M}, while down-regulation of metabolic genes and calcium channels indicates a bone formation deficit (*Fig. B*). (3) NicheNet identified *Il1rn, Ccl12, Tnf, Il1b*, *Cd209, Ihh, Rarres1, Pdgfb,* and *Areg* as hepatic ligands dysregulating skeletal transcripts (*Fig. D*). These include induction of *Tnf, Il6, Il10, Il12b, Pparg,* and *Nfkbiz* and suppression of *Tgfb2, Tnfrsf11b, Pthlh, Vegfd,* and *Mmp3* in bone (*Fig. C*). **Conclusion:** Diet-induced obesity and MASLD associate with multiple markers of bone disease which are exacerbated by PNPLA3^{I148M}. Further, these hepatic features associate with a bone inflammatory phenotype accelerating skeletal catabolism while preventing osteoanabolism. These data firmly establish deleterious liver-bone crosstalk in MASLD with PNPLA3^{I148M}, driven by inflammatory cytokines upregulated in MASLD.

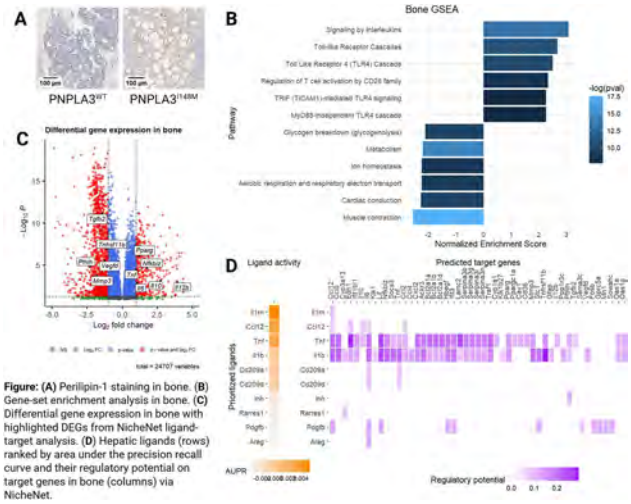

Figure: **(A)** Perilipin-1 staining in bone. **(B)** Gene-set enrichment analysis in bone. **(C)** Differential gene expression in bone with highlighted DEGs from NicheNet ligand-target analysis. **(D)** Hepatic ligands (rows) ranked by area under the precision recall curve and their regulatory potential on target genes in bone (columns) via NicheNet.

1055 | THE INNER NUCLEAR MEMBRANE PROTEIN SUN1 REGULATES CULLIN-3 NEDDYLATION TO MAINTAIN INSULIN SENSITIVITY

Kapil Upadhyay[1] Yunshu Yang[1] Aren Shah[1] Venkatesha Basrur[1] Alexey Nesvizhskii[1] Graham Brady[1], [1]University of Michigan, Ann Arbor, Michigan, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease and a growing cause of morbidity and mortality, with strong epidemiologic links to obesity and insulin resistance. We previously reported an association between the common nuclear envelope variant rs6461378 (g.842031C > T; *SUN1* H118Y) and hepatic steatosis, histologic MASLD, and related metabolic traits including insulin resistance. Here we report identification of a novel variant-specific SUN1-cullin-3 association, providing a potential mechanistic basis by which wild-type (WT) SUN1 protects against MASLD, while H118Y SUN1 drives insulin resistance and MASLD. **Methods:** To discover SUN1-interacting proteins and elucidate how H118Y SUN1 contributes to MASLD, we performed affinity purification-mass spectrometry (AP-MS) in Huh7 cells stably expressing mCherry-tagged WT or H118Y SUN1 and control Huh7 cells (n = 3 replicates each). Differential protein-protein interactions identified by AP-MS were validated by co-immunoprecipitation (co-IP) and immunoblotting. Confirmatory functional studies included siRNA-mediated gene silencing, pharmacologic blockade of protein neddylation (MLN4924), and insulin treatment followed by cell lysis, SDS-PAGE, and immunoblot. **Results:** Unbiased AP-MS revealed a novel regulatory SUN1-cullin-3 interaction, with comparative analysis showing that WT SUN1 interacted robustly with cullin-3, while cullin-3 interaction was markedly diminished with H118Y SUN1 (abundance ratio 0.01 relative to WT SUN1; $P < 10^{-15}$), which was confirmed via co-IP and immunoblot (see Figure). Silencing of endogenous *SUN1* via siRNA in Huh7 cells increased cullin-3 neddylation – a modification essential for cullin RING ligase (CRL)-mediated ubiquitination of target proteins, including insulin receptor substrate (IRS) proteins. Furthermore, H118Y SUN1-expressing Huh7 cells exhibited elevated levels of neddylated cullin-3 and reduced IRS-1 levels compared to WT SUN1-expressing cells. Finally, pharmacologic inhibition of cullin neddylation restored IRS-1 levels and insulin sensitivity in H118Y SUN1-expressing cells. **Conclusion:** Our findings support a model in which the H118Y variant of SUN1 disrupts its regulation of cullin-3, leading to enhanced cullin-3 neddylation and impaired insulin signaling. These findings provide both a potential mechanism of H118Y SUN1-driven insulin resistance and a viable therapeutic approach for its reversal.

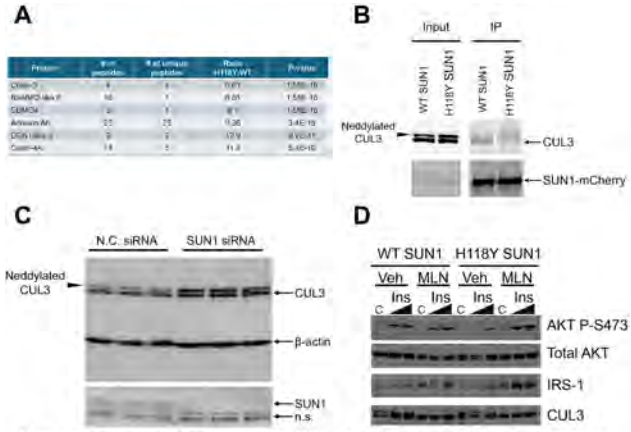

Figure Legend: Unbiased AP-MS reveals a novel SUN1-cullin-3 interaction that regulates insulin signaling. *A*, several of the top unique or preferential WT or H118Y SUN1-interacting proteins identified via AP-MS are shown. *B*, stably expressed WT SUN1 co-precipitates endogenous CUL3 (cullin-3) to a greater degree than H118Y SUN1 in Huh7 cells. Native cullin-3 is indicated by an arrow, while neddylated cullin-3 (higher band) is indicated via arrowhead. *C*, *SUN1* silencing increased cullin-3 neddylation in Huh7 cells. Cells were treated with siSUN1 oligos or a negative control (N.C.) oligo in triplicate, followed by lysis, SDS-PAGE, and immunoblot. n.s., non-specific bands present due to incomplete stripping of the membrane. *D*, a cullin neddylation inhibitor (MLN4924; MLN) restores insulin (Ins) sensitivity in H118Y SUN1-expressing Huh7 cells. Cells were treated with 1 or 10 nM human insulin for 20 min, with or without MLN4924 pre-treatment (1 μM, 16h), followed by lysis, SDS-PAGE, and immunoblot. C, control medium; Veh, vehicle (DMSO).

1056 | INTEGRATIVE FUNCTIONAL DISSECTION OF NONCODING GENETIC VARIANTS ASSOCIATED WITH METABOLIC LIVER DISEASE

Yang Xiao[1] Biying Zhu[2] Na He[2] Bin Chen[3] Chen Li[2] Yifan Liu[4] Jiayu Zhang[4] Xiao Chang[5] Fulong Yu[2] Marijana Vujkovic[4] Julie Lynch[6] Kyong-Mi Chang[4] Daniel Rader[4] Mitchell Lazar[4] Wenxiang Hu[2], [1]UNIVERSITY OF PENNSYLVANIA, [2]Department of Basic Research, Guangzhou National Laboratory, Guangzhou 510005, China, [3]Zhongshan School of Medicine, Sun Yat-Sen University, Guangdong 510080, China, [4]Institute for Diabetes, Obesity, and Metabolism, Department of Medicine, University of Pennsylvania, [5]College of Medical Information and Artificial Intelligence for Medical Sciences, Shandong, China, [6]Salt Lake City Veterans Affairs Medical Center, Salt Lake City, UT, 84112, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent and clinically heterogeneous, highlighting the needs to identify individuals at high risk. Genetic predisposition is a major contributor to MASLD. While genome-wide association studies (GWAS) have identified numerous genetic variants

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

associated with MASLD, their causality and functional roles, especially in non-coding regions, remain largely unexplored. **Methods:** To systematically investigate MASLD-associated noncoding variants from GWAS, we used a massively parallel reporter assay (MPRA) to screen for cis-regulatory activity *in vitro*. We also performed single-nucleus ATAC-seq (snATAC-seq) on human livers to map active regulatory regions *in vivo*. By integrating these two datasets, we prioritized functional variants in the form of single nucleotide polymorphisms (SNPs) likely involved in MASLD. We determined their target genes using CRISPR perturbation and base editing, and assessed clinical relevance via polygenic risk score in the Million Veteran Program (MVP) cohort. **Results:** Roughly half of MASLD-associated noncoding SNPs showed cis-regulatory activity, with 365 demonstrating allele-specific effects *in vitro*. Integrating with snATAC-seq data prioritized 87 functional variants (FrVar) in a cell type-specific context. We linked FrVar to their target genes, including rs474513, which regulates the transcription of cation transporter OCT3 and OCT3-associated lipid metabolism. The polygenic risk score built from FrVar performed comparably to the one built from 9 well-known MASLD risk variants, including PNPLA3 I148M. **Conclusion:** Our integrative approach reveals the regulatory functions of noncoding SNPs in MASLD, which were largely unknown. These variants influence key gene expression and MASLD-associated pathology, and serve as strong predictors of disease risk, offering insights into MASLD patient management and risk stratification.

1057 | THE DUAL ROLE OF APOLIPOPROTEIN C3 IN THE DEVELOPMENT OF MAFLD

Wei Zhang[1] Xiawen Yang[2] Mingming Gao[3] Xiangsha Kong[4] Lin Zhang[5] Zhengxi Wang[6] Haizhao Yan[7], [1]Peking University People's Hospital, Beijing, China, [2]Wuyi University, Jiangmen, Guangdong, China, [3]Hebei Medical University, Shijiazhuang, Hebei, China, [4]Peking University People's Hospital, Beijing, China, [5]Peking University People's Hospital, Beijing, China, [6]Capital Medical University, Beijing, China, [7]Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China

Background: Apolipoprotein C3 (APOC3) plays a pivotal role in mediating plasma triglyceride (TG) homeostasis. However, it remains controversial whether APOC3 is related to metabolic dysfunction-associated steatotic liver disease (MASLD) and its potential mechanism in the progression. The aims of our study were to clarify the histological features of the liver in APOC3-transgenic animal models, to explore its potential mechanisms and to assess the correlation of APOC3 levels to hepatic steatosis degree in MAFLD patients. **Methods:** APOC3 knockout (KO) rabbits and human APOC3 overexpressing mice with a background of Leptin deficiency (ob/ob-C3Tg) were used in the experiment. The plasma lipids, glucose and insulin were measured, and the insulin (ITT) and glucose tolerance test (GTT) were performed. The clinical data were collected and analyzed in MAFLD patients whose steatosis degree (CAP) and fibrosis stages (SLM) were evaluated using FibroScan. **Results:** After 22 weeks of the high fructose and fat diet feeding, liver histological analysis in APOC3 KO rabbits exhibited macrovesicular steatosis, but no hepatocellular ballooning (Fig1). They also showed constantly and significantly lower levels of plasma TG, TC and FFA compared with wild-type rabbits. However, higher insulin levels and no change of glucose levels were found. These results suggested that APOC3 deficiency could increase excess lipid accumulation in the hepatocytes and its role be associated with insulin resistance (IR). After 16 weeks of chow diet feeding, liver histological assessment in ob/ob- C3Tg mice indicated macrovesicular and microvesicular steatosis, inflammatory cell infiltration and hepatocellular ballooning (Fig1). They had significantly higher levels of plasma TG, TC and FFA compared with ob/ob mice. And no significant differences in results of ITT, GTT and glucose evaluation between two groups were found. As we all know, ob/ob mice do not spontaneously progress from steatosis to steatohepatitis. These results suggested that the APOC3 overexpressing could induce the incidence of steatohepatitis, and its role might not be associated with IR. In the patient cohort, no significant correlations were found between plasma APOC3 and CAP or LSM values. **Conclusion:** In this study, our findings provide new insight into the roles of APOC3 in MAFLD. APOC3 plays dual roles as an inhibition in the progress from normal to steatosis, and a promotion in the process from steatosis to steatohepatitis. The deficient and overexpression of APOC3 are paradoxically associated with insulin resistance, and further experiments are ongoing.

1058 | ERBB3 IS A NOVEL THERAPEUTIC TARGET FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Shehnaz Bano[1] Bharat Bhushan[1] George Michalopoulos[1] Anne Orr[1] John Stoops[1] Shirish Paranjpe[1] Joseph Locker[1] Alejandro Soto-Gutierrez[1] Rodrigo Florentino[1], [1]University of Pittsburgh

Background: MASLD is the most common chronic liver disorder worldwide, yet effective targeted therapies remain elusive. In our previous study, pan-ErbB inhibition showed promising efficacy in reversing steatosis and fibrosis in a preclinical MASLD model. However, the specific ErbB receptor responsible for these therapeutic effects remains undefined. Our prior work also demonstrated that hepatocyte-specific deletion of ErbB1 (EGFR) does not prevent MASLD, implicating other ErbB family members. This study investigates for the first time the role of ErbB3 (HER3), the only other ErbB receptor expressed in hepatocytes, in MASLD pathogenesis using a hepatocyte-specific knockout model. **Methods:** Hepatocyte-specific ErbB3 knockout (ErbB3-HepKO) mice were generated by administering AAV8-TBG-CRE to ErbB3$^{flox/flox}$ mice and were fed fast-food diet for up to 5 months. Complementary studies were conducted in steatotic primary human hepatocytes to validate translational relevance. **Results:** ErbB3-HepKO attenuated MASLD progression in mice, evidenced by marked reductions in hepatic steatosis and fibrosis markers along with improved insulin sensitivity. ErbB3 deletion decreased expression of major lipogenic genes while upregulating lipolytic genes. Mechanistically, ErbB3 regulated critical MASLD driving transcription factors like PPARγ and HNF4α, with increased nuclear HNF4α expression in KO livers. Further, ErbB3 deletion downregulated several pro-inflammatory and fibrotic pathways including TNFα and TGFβ. Notably, NRG1, the ErbB3 ligand, and ErbB3 signaling were elevated in both murine and human MASLD/MASH, correlating with disease severity. The protective effects of ErbB3 deletion paralleled those observed with pharmacological pan-ErbB inhibition in our previous studies. Importantly, both a clinically approved pan-ErbB inhibitor and specific ErbB3 knockdown reduced lipid accumulation in primary cultures of steatotic human hepatocytes from MASH patients, as well as in healthy hepatocytes exposed to fatty acids, further supporting the clinical relevance of targeting ErbB3. **Conclusion:** Our findings identify ErbB3 in hepatocytes as a pivotal regulator of MASLD progression, distinct from EGFR, and demonstrate that its deletion recapitulates the therapeutic benefits of pan-ErbB inhibition. This work highlights ErbB3 as a novel and promising therapeutic target for MASLD, with conserved NRG1/ErbB3 signaling pathways in human disease, paving the way for targeted interventions.

1059 | DEVELOPMENTAL EXPLORATION OF FERMENTED AMOMUM XANTHIOIDES DERIVATIVES AS NOVEL THERAPEUTIC AGENTS FOR MASLD AND METABOLIC SYNDROME

Seung-Ju Hwang[1], [1]Daejeon University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), alongside metabolic syndrome (MS), represents a growing global health burden due to its increasing prevalence and limited pharmacological treatment options. This research series was designed to evaluate the therapeutic efficacy of Amomum xanthioides (AX) and its bioenhanced forms—specifically the ethyl acetate fraction (EFAX) and fermented AX using Bacillus subtilis (BAX) or Lactobacillus casei (LAX)—in high-fat diet (HFD)-induced murine models. **Methods:** Two separate preclinical experiments were conducted using male C57BL/6J mice, fed a 60% HFD for 10 weeks. From week 4 to 10, AX-based formulations (AX, EFAX, BAX, LAX) and metformin (200 mg/kg/day) were administered orally. Experimental groups included (1) control vs. AX vs. LAX and (2) control vs. AX vs. BAX). Primary outcomes focused on hepatic steatosis (hepatic triglyceride

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and cholesterol levels) and insulin resistance (fasting glucose and serum insulin), while secondary parameters included changes in body composition, food intake, and hepatic inflammatory status. **Results:** AX and its processed forms significantly alleviated HFD-induced weight gain, adiposity, and hepatic lipid buildup. LAX, in particular, notably improved insulin resistance markers, including fasting glucose, insulin, and HOMA-IR, via enhanced expression of GLUT2/GLUT4 and insulin receptors. Both BAX and LAX exerted potent anti-inflammatory effects by lowering systemic IL-6 and downregulating hepatic pro-inflammatory mediators (TNF-α, IL-1β) and oxidative stress markers (ROS and MDA). Furthermore, LAX promoted lipid homeostasis through suppression of lipogenesis (SREBP-1 and GPAM) and activation of lipolysis-related proteins (PPAR-α and AMPK-α). Improvements in circulating lipid profiles further supported the metabolic benefits of BAX and LAX. **Conclusion:** These findings indicate that microbial fermentation significantly enhances the pharmacological actions of AX. Fermented AX products, particularly LAX and BAX, exhibit promising therapeutic potential for MASLD and MS through multifaceted metabolic and anti-inflammatory mechanisms.

1060 | HSD17B13 REGULATES HEPATIC LIPID DROPLET DYNAMICS IN A MOUSE MODEL OF MASLD

Lila Gonzalez Hodar[1] David Kleiner[2] Lalith Perera[3] Yaron Rotman[1], [1]National Institutes of Health, [2]National Cancer Institute, Bethesda, [3]National Institute of Environmental Health Sciences

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by hepatic lipid droplet (LD) accumulation. Genetic studies in MASLD identified multiple hepatic LD proteins that modulate disease severity, suggesting LD as a key organelle in disease pathogenesis. 17-beta hydroxysteroid dehydrogenase-13 (HSD17B13) is an LD-associated liver enzyme in which genetic loss-of-function variants confer protection from MASLD-associated liver injury in humans. Although anti-HSD17B13 therapies are in clinical trials, HSD17B13 function is unknown. We aimed to determine the effects of HSD17B13 on hepatic LD properties and dynamics. **Methods:** *Hsd17b13* knock-out (KO) and wildtype (WT) mice were fed high-fat diet for 8 weeks. Liver LDs were isolated by sucrose gradient and ultracentrifugation and analyzed by LC/MS/MS (lipidomics) and western blot (protein). Primary hepatocytes (PH) from WT and *Hsd17b13*-KO mice were treated with oleate:palmitate (2:1) with LD size measured by microscopy and LD fusion via live-cell imaging. **Results:** *Hsd17b13*-KO did not affect body weight, liver weight, or liver triglyceride content, as we previously published. However, *Hsd17b13*-KO livers and *Hsd17b13*-KO PH showed larger LDs. LD fusion was more frequent in *Hsd17b13*-KO PH, and CIDEC, which mediates LD fusion, was upregulated in livers from *Hsd17b13*-KO, with no change in proteins related to LD consumption (lipolysis or autophagy). Moreover, in WT PH, HSD17B13 was only found on small LDs, with no droplet >6 μm diameter showing HSD17B13. *Hsd17b13*-KO LDs had higher phosphatidylinositol (PI) concentration compared to WT. Interestingly, protein levels of two enzymes involved in the PI cycle, phosphatidylinositol 3-kinase and phosphatidylinositol 4-kinase, were increased in *Hsd17b13*-KO LDs. In a protein-lipid overlay assay, HSD17B13 directly interacted with PI and two phosphoinositides (PIPs) species. Through molecular docking, we identified regions rich in lysine and arginine residues in HSD17B13 interacting with PI/PIPs. **Conclusion:** In conclusion, HSD17B13 inhibits LD fusion and the formation of large LDs, possibly through its PI/PIPs interaction. Further experiments are needed to determine if this role underlies the protective effect of HSD17B13 loss-of-function variants.

1061 | MINCLE—THE IMMUNE ALARM AMPLIFYING METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Farhin Patel[1] Colin Varnet[1] Adam Kim[1], [1]UConn Health

Background: In the U.S., the prevalence of MASH has increased radically, currently affecting 5% of the adult population. MASH is a progressive liver disease that is linked to obesity and metabolic syndrome, where excessive accumulation of fat in the liver leads to inflammation and fibrosis. Patients with MASH have an increased risk for severe infections, likely due to dysfunctional immune responses. Mincle is a pattern recognition receptor in the C-type lectin receptor family that is involved in MASH through recognition of damage-associated molecular patterns (DAMPs), which leads to infiltrating immune cells and increased injury in liver and adipose tissue. Mincle knockout (MKO) mice are protected from liver injury caused by a high-fat diet, making Mincle a potential therapeutic target. But our group has found that MKO mice have worse adipose tissue inflammation in response to acute stimulation with bacterial lipopolysaccharides (LPS). We hypothesize that Mincle is an essential immune regulator in the liver and adipose tissue during MASH and in response to infection.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Methods: To model MASH, 5-week-old C57BL/6 and MKO mice were fed with a fat-, fructose, and cholesterol-rich (FFC) diet or standard rodent chow for 12 weeks. Mice were administered LPS (0.7 mg/kg) or saline intraperitoneally 24 hr before euthanizing as a model of acute bacterial infection during MASH. At the end of the experiment, the animals were monitored in the Comprehensive Lab Animal Monitoring System (CLAMS) for total metabolic activity. **Results:** MKO-FFC-LPS mice depicted reduced liver weight, liver-to-body weight ratio, and triglyceride levels compared to the WT-FFC-LPS group. Both liver and adipose tissue had reduced inflammatory markers in the MKO FFC-LPS group compared to the WT-FFC-LPS. In adipose tissue, the MKO-FFC-LPS fed group markedly inhibited the Ly6G levels compared to the WT-FFC-LPS fed group. Similarly, adipokines like leptin and resistin transcript levels were down-regulated, while adiponectin was up-regulated in the MKO-FFC-LPS fed group compared to the WT-FFC-LPS fed group. CLAMS data show that MKO mice ate less FFC diet than WT mice, but similar levels of energy expenditure. In response to LPS, MKO-FFC-LPS mice ate much more food than WT-FFC-LPS mice, suggesting a better overall response to infection. **Conclusion:** Targeting Mincle could be a strategic preventative approach for attenuating inflammation in MASH.

1062 | XIAYUXUE DECOCTION ALLEVIATES MASH BY RESHAPING GUT MICROBIOTA AND REGULATING ARACHIDONIC ACID AND BILE ACID METABOLISM VIA ACTIVATING FXR-SHP1/2 PATHWAY AND AFFECTING M6A TRANSCRIPTIONAL MODIFICATIONON

Yang Cheng[1], [1]Shuguang Hospital affiliated to Shanghai University of TCM

Background: Metabolic dysfunction-associated steatohepatitis (MASH) has emerged as a major global health challenge. Xiayuxue decoction, composed of Rheum palmatum L., Prunus persica (L.) Batsch, and Eupolyphaga sinensis Walker, is widely utilized in managing MASH in China. However, its precise therapeutic mechanisms remain elusive. This study aimed to elucidate the therapeutic mechanisms of Xiayuxue decoction in MASH by investigating its roles in gut microbiota remodeling, bile acid and arachidonic acid metabolism regulation, and m6A transcriptional modification. **Methods:** The chemical composition of Xiayuxue decoction was characterized using UHPLC-Exactive Orbitrap HRMS. A methionine-choline-deficient (MCD) diet-induced MASH model was established in male C57BL/6J mice for 5 weeks. Serum samples were collected for biochemical analysis of alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (TBIL), and total bile acids (TBA). Hepatic histopathology was assessed through hematoxylin-eosin (H&E) and Sirius red staining, while intrahepatic lipid accumulation was quantified via triglyceride (TG) assay kit and Oil Red O staining. Gut microbiota composition was analyzed by 16S rRNA gene sequencing. Liver, serum, and fecal metabolites, particularly arachidonic acid derivatives, were profiled using LC-MS/MS system. Real-time quantitative PCR, Western blotting, and dot blot analyses were performed to evaluate mRNA and protein expression patterns associated with bile acid metabolism, lipid homeostasis, inflammatory response, and m6A modification machinery. In vitro, RAW264.7 macrophages were treated with deoxycholic acid (DCA) or Xiayuxue decoction to assess their effects on inflammatory cytokine production and m6A dynamics. **Results:** 16S rRNA sequencing revealed that Xiayuxue decoction ameliorated intestinal dysbiosis in MASH mice. Compared with the MCD group, the decoction significantly restored α diversity and β diversity ($P < 0.01$). **Conclusion:** Xiayuxue decoction alleviates MASH by reshaping gut microbiota and regulating arachidonic acid and bile acid metabolism via activating FXR-SHP1/2 pathway and affecting m6A transcriptional modification.

Disease (MASLD), which is characterized by hepatic steatosis, liver injury, inflammation, and fibrosis. These changes exacerbate liver injury and alter drug metabolism. Acetaminophen (APAP) overdose remains the leading cause of drug-induced liver injury (DILI), and sex differences are known to influence susceptibility and severity. However, the interplay between obesity-driven MASLD and APAP hepatotoxicity, particularly regarding sex disparities, is not well understood. **Methods:** Male and female C57BL/6J mice were fed either a standard or high-fat high-cholesterol (60% calories from fat and 0,5% added cholesterol; HFHC) diet for 3 months. Male and female mice were administered a single APAP dose (300 mg/kg) and sacrificed 4 hours later. Biochemical, histological, and molecular responses were assessed to evaluate the synergistic damage between diet and APAP. **Results:** Feeding HFHC diet robustly increased body weight, liver mass, and hepatic lipid accumulation in both sexes, with males exhibiting more pronounced macrosteatosis and higher cholesterol, triglycerides, and free cholesterol levels than females. Histology analyses confirmed severe macrosteatosis in males and relative protection in females. HFHC feeding downregulated fatty acid oxidation genes (*Cpt1*, *Vlcad*, *Pgc1a*, *Pparα*) and upregulated lipogenic genes (*Srebf1*, *Pparγ*), with changes being more predominant in male than female mice. APAP further impaired these pathways, especially when combined with HFHC.

Markers of liver injury (ALT, AST) and autophagy impairment (p62 accumulation) increased with HFHC and APAP, being male mice more affected than female mice. HFHC diet and APAP treatment induced Inflammatory infiltration (F4/80 macrophages, MPO+ neutrophils), with males showing a pro-inflammatory profile (increased expression of *Il-1β, Il-6* and *Spp1*) and females an anti-inflammatory response (*Il-10, TGF-β, Arg1*), linked to higher estrogen receptor α expression and miRNA34a levels in females. HFHC and APAP induced stress markers, including Stard1, Sab, and p-JNK, particularly in males, indicating greater mitochondrial and ER stress. Gene expression analyses revealed sex-specific differences in ER stress (Ddit3, Xbp1s/u, Hspa5) and cytochrome P450 enzymes (Cyp7a1, Cyp27a1), with males more susceptible to stress and lipid dysregulation. **Conclusion:** Male mice exhibit greater vulnerability to diet- and APAP-induced hepatic steatosis, oxidative and ER stress, inflammation, and injury, driven by heightened metabolic and inflammatory pathway activation, suggesting that females are protected due to estrogen pathway activation. These findings highlight a sex-dependent MASH sensitization to APAP hepatotoxicity and underscore the need for sex-tailored interventions in MASLD and DILI.

1064 | SYNERGISTIC EFFECTS OF ECC4703, A LIVER-TARGETING THRB FULL AGONIST, IN COMBINATION WITH ECC0509, A SELECTIVE SSAO INHIBITOR, OR SEMAGLUTIDE IN A MASH ANIMAL MODEL

Jianfeng Xu[1] Xuefeng Sun[1] Jingye Zhou[2], [1]Eccogene (Shanghai) Co., Ltd., [2]Eccogene Inc.

Background: Metabolic dysfunction-associated steatohepatitis (MASH, previously known as nonalcoholic steatohepatitis [NASH]) is a chronic, serious, life-threatening, inflammatory liver disease characterized by increased liver fat content, hepatocellular injury, inflammation, and progressive fibrosis. In view of the complexity of manifestation and serious nature of the disease, employing a combination of orthogonal mechanisms may be necessary to achieve optimal efficacy for the treatment of MASH. Eccogene is developing ECC4703, a selective THRβ full agonist, and ECC0509, a mechanism-based inhibitor of semicarbazide sensitive amine oxidase (SSAO). Both molecules have demonstrated favorable safety and tolerability profiles, PK and PD profiles supporting once daily dose, and clear target engagement in phase I clinical trials. Additionally, GLP-1 analogues are being widely used for the treatment of diabetes and obesity which are common co-morbidities of MASH. **Methods:** The mouse MASH model was established by high fat diet feeding and CCL4 induction, followed by 28-days treatment of Vehicle (G1), Semaglutide 10 nmol/kg (G2), ECC4703 3 mg/kg (G3), ECC0509 20 mg/kg (G4), ECC4703 3mg/kg and Semaglutide 10 nmol/kg (G5) and ECC4703 3 mg/kg and ECC0509 20 mg/kg (G6), respectively. At the end of the study, the liver tissue was dissected for histology evaluation of NAFLD Activity Score (NAS) and fibrosis. Liver enzymes, liver cholesterol and triglyceride (TG), plasma cholesterol and TG, fasting glucose and insulin were also measured. **Results:** THRβ agonist ECC4703 is effective to decrease liver NAS and fibrosis along with other metabolic benefits in this MASH model. The combination of ECC4703 with other mechanisms, i.e., Semaglutide or ECC0509, resulted in greater improvement compared to mono-agent treatment in fibrosis score and other metabolic and liver related endpoints. **Conclusion:** ECC4703 has the potential to be the corner stone for combination with other mechanisms to treat MASH in humans.

1065 | TOX3 PROMOTES MASH PROGRESSION BY REGULATING HEPATIC A-LINOLENIC ACID METABOLISM VIA THE PI3K/AKT SIGNALING PATHWAY

Shaoping She[1] Liying Ren[1] Xue Zhang[1] Dongbo Chen[1] Ran Fei[1] Feng Liu[1] Huiying Rao[1] Hongsong Chen[1], [1]Peking University People's Hospital, Peking University Hepatology Institute

Background: The escalating global burden of metabolic dysfunction-associated steatohepatitis (MASH), now a predominant etiology of chronic liver disease, underscores an urgent need for mechanistically informed therapies. Thymocyte selection-associated high mobility group box factor 3 (TOX3) is a member of an evolutionarily conserved DNA-binding protein family. While our prior work identified TOX3 as a driver of hepatocellular carcinoma (HCC) through lipid metabolic reprogramming, its functional role in MASH pathogenesis remains unexplored. This study aims to delineate the mechanistic contributions of TOX3 to MASH progression and evaluate its therapeutic potential. **Methods:** TOX3 expression was profiled in liver biopsies from MASH patients and validated in two mechanistically distinct murine MASH models: Western diet with carbon tetrachloride injection (WD + CCl_4) and high-fat methionine-choline deficient diet (HFMCD). The role of TOX3 was evaluated in systemic Tox3 gene knockout (*Tox3*$^{-/-}$) mice and hepatocyte-specific Tox3 knockout (*Tox3*^{Hep}) mice in vivo. In vitro studies involved treating THLE-2 (normal hepatocytes) and HepG2 cells with free fatty acids (FFA) and lipopolysaccharide (LPS), as well as manipulating TOX3 expression via small interfering RNA (siRNA) and overexpression plasmids. Multi-omics integration of single-cell RNA sequencing and serum metabolomics were used to explore the molecular mechanism of TOX3 regulation of MASH progression. **Results:** In this study, we found that TOX3 expression was significantly downregulated in both MASH patients and WD+CCl_4 or HFMCD-induced mouse MASH models. TOX3 deficiency resulted in a marked amelioration of MASH pathological phenotypes in mice, including hepatic steatosis, inflammation, and fibrosis. In vitro studies demonstrated that TOX3 overexpression significantly promoted lipid droplet formation and upregulated pro-inflammatory cytokines (e.g., TNF-α, IL-6, IL-1β) expression in THLE-2 cells under combined FFA/LPS stimulation, whereas TOX3 silencing in HepG2 cells reversed these phenotypes. Mechanistically, our multi-omics analyses revealed that TOX3 activates the PI3K/Akt signaling pathway to drive α-linolenic acid (ALA) metabolic reprogramming in hepatocytes. This process synergistically enhances lipogenesis (via the SREBP-1c/FASN axis) and secretion of pro-inflammatory cytokines (e.g., TNF-α and IL-6), ultimately accelerating the pathological progression of MASH. **Conclusion:** Collectively, our findings established TOX3 as a critical regulator of MASH pathogenesis through PI3K/Akt-mediated coupling of lipid metabolism and inflammatory cascades. Targeting TOX3-mediated crosstalk between metabolic and inflammatory pathways may offer novel therapeutic strategies for MASH and its complications.

1066 | LEVERAGING MULTI-OMIC APPROACHES TO INTERROGATE DYSREGULATION IN MASH LIVER DISEASE

APOORVA MOHAN[1] Divya Ravichandar[1] Anjali Rao[1] Edith Vaquero[1] SANGEETHA MAHADEVAN[2] David Lopez[1] GRANT BUDAS[2] Anna Zagorska[1] Lauri Diehl[1] Hsiu-Chun Chuang[1], [1]GILEAD SCIENCES, [2]GILEAD SCIENCES, INC.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a chronic liver disease marked by involvement of different cell types and widespread dysregulation of key cellular pathways. Single cell RNAseq approaches provide insight into transcriptionally altered cellular populations and, when combined with spatial transcriptomic (ST) approaches, enable the dissection and localization of these aberrant populations in disease specific niches. The experimental execution and analyses of these large datasets are currently poorly standardized. In this study, we have streamlined the experimental and analytical steps to generate a high-quality, robust multi-omic dataset and to facilitate an unbiased characterization of parenchymal and fibrotic niches in MASH. **Methods:** Formalin fixed paraffin embedded (FFPE) liver surgical resection samples from 6 healthy, 6 MASH F3 and 7 MASH F4 patients were processed through the 10X Genomics Visium ST workflow using semi-automated workflows to improve the staining differentiation of histological features. Matched snRNASeq datasets were generated using the 10X genomics Chromium FLEX workflow for FFPE samples. We performed Transmission Electron Microscopy on the snRNAseq-FFPE preparations to verify the sample type recovered from the FFPE-FLEX workflow. A systematic quality control and filtering process, including ambient RNA correction, was implemented to eliminate contaminant populations and generate a high-quality single-nuclei atlas for MASH. **Results:** Transmission electron

microscopy confirmed the presence of intact nuclei in the dissociations performed through the 10x Chromium FLEX workflow from MASH liver FFPE samples. We generated a single nuclei atlas from Healthy and MASH F3, F4 FFPE samples containing 42,901 nuclei after performing ambient RNA correction and removal of contaminant nuclei populations. We observed robust recovery of expected cell types as well as cell types such as neutrophils and certain fibroblast subtypes which are frequently underrepresented in standard single cell data sets from frozen samples. The use of semi-automated approaches for tissue staining in Visium ST reduced the staining variability between samples. This enabled accurate annotation of distinct histological features for downstream analysis. Integrated clustering of spots from the MASH F4 samples enabled spatial mapping of transcriptional identities onto histologically distinct regions driving unbiased characterization of these features for downstream analytical approaches. **Conclusion:** This study streamlined and standardized experimental and analytical workflows to generate a robust multi-omic dataset for characterizing parenchymal and fibrotic niches in MASH. The high-quality single nuclei atlas obtained from paired samples is best suited for deconvolution of the spatial transcriptomic data and to examine the perturbations in the disease-relevant niches. **Disclosures:** APOORVA MOHAN: Gilead Sciences: Employee, Divya Ravichandar: Nothing to Disclose, Anjali Rao: Nothing to Disclose, Edith Vaquero: Nothing to Disclose, SANGEETHA MAHADEVAN: Nothing to Disclose, David Lopez: Nothing to Disclose, GRANT BUDAS: Nothing to Disclose, Anna Zagorska: Nothing to Disclose, Lauri Diehl: Nothing to Disclose, Hsiu-Chun Chuang: Nothing to Disclose

1067 | THE ROLE AND MECHANISM OF CD146 IN REGULATING MITOCHONDRIAL FUNCTION IN MASLD

Yixue Shu[1] Yulin Yan[1] Ruirui Li[1] Bingqing Yang[2] Quan Sun[1] Qi Wang[2], [1]Capital Medical University, Beijing, China., [2]Beijing Ditan Hospital, Capital Medical University, Beijing, China.

Background: The incidence of metabolic dysfunction-associated steatohepatitis (MASLD) has surged due to changes in lifestyle and diet, becoming the most common chronic liver disease globally. Its pathogenesis is primarily based on the "multiple-hit" hypothesis, in which mitochondrial dysfunction is a core influencing factor. CD146, a multifunctional cell adhesion molecule, shows increased expression in the liver with the worsening of chronic liver disease, this suggests that CD146 plays an important role in the occurrence and development of MASLD, but whether this role is related to mitochondrial dysfunction remains unclear. **Methods:** This study generated hepatocyte-specific ($CD146^{Alb\text{-}Cre}$) and adipocyte-specific ($CD146^{Fabp4\text{-}Cre}$) CD146 knockout mouse models, with $CD146^{flox/flox}$ mice serving as controls. The mice were subjected to a high-fat, high-fructose diet for 25 weeks to induce MASLD. The pathological and physiological effects of CD146 deficiency were systematically evaluated using histopathological examination, flow cytometry, transmission electron microscopy (TEM) ultrastructural assessment, and omics characterization, as well as in vitro experiments. **Results:** In the HFHF-induced MASLD mouse model, CD146 expression was significantly upregulated in the liver. CD146-deficient (CD146-CKO) mice exhibited attenuated body weight gain, reduced serum ALT levels, and marked improvement in hepatic steatosis and adipose tissue accumulation. Immunophenotypic analysis revealed significantly reduced infiltration of pro-inflammatory immune cells in the livers of CD146-CKO mice, along with increased polarization of macrophages towards the anti-inflammatory M2 phenotype. TEM observations showed increased mitochondrial number and improved structure in hepatocytes of CD146-CKO mice. Proteomics and lipidomics analyses indicated upregulated expression of key molecules in pyruvate metabolism, downregulated lipogenic genes (Srebp1 and Acacb), increased membrane phospholipid content, and reduced pro-inflammatory triglyceride subspecies in CD146-CKO mice. In vitro experiments confirmed that CD146 knockdown in the AML12 hepatocyte cell line significantly decreased lipid accumulation and reactive oxygen species (ROS) production induced by oleic acid and palmitic acid. **Conclusion:** CD146 likely plays a crucial role in the pathophysiology of MASLD by modulating mitochondrial function. Its deficiency improves hepatic lipid deposition and systemic metabolic disorders, offering a new potential therapeutic target for MASLD treatment.

1068 | DIFFERENTIAL EFFECTS OF HEPATOCYTE ADENOSINE KINASE OVEREXPRESSION AND AGING ON ADIPOSITY AND DIET-INDUCED MASH ASPECTS IN MICE

HONGGUI LI[1], XIAOXIAO WANG[1], XIAOJING LI[1], AND CHAODONG WU[1], Honggui Li[1] Xiaoxiao Wang[1] Xiaojing Li[1], [1]Texas A&M University

Background: Adenosine kinase (ADK), an enzyme expressed at its highest levels in hepatocytes, was recently shown to promote excessive fat deposition and stimulate liver inflammation. However, how ADK influences metabolic dysfunction-associated steatohepatitis (MASH) with consideration of aging as a biological variable remains unknown. **Methods:** The present study aimed to determine the effect of hepatocyte ADK overexpression (Hep-ADK^{Tg}), along with aging, on altering adiposity and MASH aspects in mice on a fat-enriched methionine- and choline-deficient diet (fMCD). **Results:** When at young adulthood, both fMCD-fed Hep-ADK^{Tg} mice and fMCD-fed Hep-ADK^{WT} mice displayed overt MASH phenotype while the severity of fMCD-induced MASH in Hep-ADK^{Tg} was greater. In an *in vitro* system, ADK overexpression brought about an increase in palmitate-induced fat deposition in hepatocytes incubated with MCD-mimicking media. In response to aging, Hep-ADK^{WT} mice displayed significantly increased severities of fMCD-induced hepatic steatosis and liver inflammation and showed slight decreases in body weight adiposity whereas Hep-ADK^{Tg} mice revealed increased severity of fMCD-induced hepatic steatosis and marginal changes in liver inflammation, as well as body weight and adiposity. At the level of liver RNA transcriptome, the effect of aging on promoting fMCD-induced liver inflammation in Hep-ADK^{WT} mice was attributable to activation of various proinflammatory signaling events (e.g., STING1 and NFkB) that were indicated by aging-driven up-regulation of differentially expressed genes (DEGs). Consistent with increased hepatic steatosis that was largely due to decreased fatty oxidation, down-regulation of liver DEGs indicated inhibition of liver AMPK signaling and PPARa/RXRa activation, as well as PPARd in aged Hep-ADK^{WT} mice relative to young Hep-ADK^{WT} mice. However, under aged conditions, Hep-ADK^{Tg} mice sustained body weight and adiposity whereas Hep-ADKWT revealed a significant weight loss in response to fMCD. Moreover, in response to fMCD feeding for 8 weeks, aged Hep-ADK^{Tg} mice did not reveal a significant increase in liver inflammation although showing an increase in the severity of hepatic steatosis relative to Hep-ADK^{WT} mice. In addition, liver RNA transcriptomes only revealed a small number of DEGs, three of which were increased and might be associated with MASH. **Conclusion:** Collectively, these results demonstrate that ADK overexpression in hepatocytes and aging differentially influenced the outcomes of adiposity and fMCD-induced MASH aspects. As such, there is a need to consider aging as a biological variable while ADK is a viable target for managing MASH.

1069 | ENVIRONMENTAL EXPOSURE TO BISPHENOL A MODULATES TRAINED IMMUNITY-RELATED PATHWAYS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD), CONTRIBUTING TO DISEASE PROGRESSION. A PRELIMINARY ANALYSIS

Mario Romeo[1] Fiammetta Di Nardo[1] Annachiara Coppola[1] Alessia Silvestrin[1] Giusy Senese[1] Carmine Napolitano[1] Paolo Vaia[1] Marco Niosi[1] Marcello Dallio[1] Alessandro Federico[1], [1]University of Campania Luigi Vanvitelli

Background: Trained Immunity (TI) represents a novel concept of the immunological response involving the innate immune cells, triggered by a second antigenic contact, gaining a long-term, reversible pro-inflammatory phenotype. Dysregulation of innate immunity, leading to low-grade chronic inflammation, promotes the progression of Metabolic dysfunction-associated steatohepatitis (MASH). Bisphenol A (BPA) is a well-known endocrine-disrupting compound (EDC), widely produced worldwide and potentially accumulable in human tissues, including the liver. Our group recently identified BPA as an alternative antigen capable of activating TI in healthy individuals, suggesting potential implications in immunometabolic shifts and altered immune reactivity. However, the impact of EDC exposure on TI pathways in MASH patients remains unexplored. **Methods:** We recruited 26 healthy individuals and 30 patients with histological confirmation of MASH. A 10 mL serum sample was collected to extract and quantify BPA and isolate and stimulate monocytes following a predefined TI protocol. Specifically, BPA was extracted from serum using a liquid-liquid extraction with methanol (1:1, v/v), followed by solid-phase extraction for purification and concentration. BPA quantification was performed using a high-performance liquid chromatography (HPLC) system coupled with a triple quadrupole mass spectrometer. Monocytes from healthy individuals and MASH patients were isolated via density gradient centrifugation and then stimulated with BPA for 24 hours (at concentrations of 1 nM, 10 nM, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

20 nM) and lipopolysaccharide (LPS) (10 ng/mL) for 24 hours (on days 0 and 6, respectively). **Results:** Serum BPA levels were significantly higher in MASH patients compared to healthy individuals (7.79 ± 2.34 vs 0.139 ± 0.049 ng/mL, $p < 0.0001$). BPA-induced TI (1 nM, 10 nM, and 20 nM) was more pronounced in MASH patients than in healthy individuals, with increased levels of pro-inflammatory cytokines (TNF-alpha and IL-6) observed for each BPA concentration tested (all $p < 0.05$). Furthermore, MASH patients exhibited elevated IL-10 levels in response to BPA exposure ($p < 0.05$), possibly as a compensatory mechanism (Figure). **Conclusion:** BPA acts as a potent stimulator of innate immune training in MASH patients, fueling a pro-inflammatory phenotype that may contribute to the initiation, progression, and persistence of the disease.

1070 | WESTERN DIET EXACERBATES C–MYC–INDUCED HEPATOCARCINOGENESIS IN DIAMOND MICE

Yun-Ling Tai[1] NAN WU[2] Derrick Zhao[2] Grayson Way[2] Meiyi Song[2] Hui Li[2] Sareh Bayatpour[2] Lianyong Su[2] Xuan Wang[2] Emily Gurley[2] Phillip Hylemon[3] Arun Sanyal[2] Huiping Zhou[2], [1], Virginia Commonwealth University, [2]Virginia Commonwealth University, [3]Virginia Commonwealth University and Richmond Veterans Affairs Medical Center

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide. Increasing evidence implicates metabolic risk factors—particularly dietary influences—as critical drivers of HCC pathogenesis. The Western diet supplemented with sugar water (WDSW) promotes hepatic steatosis, inflammation, and tumorigenesis, yet the mechanistic crosstalk between diet-induced metabolic stress and hepatocarcinogenesis remains incompletely defined. In this study, we employed a hydrodynamic tail vein injection (HTVI)-based murine model of HCC to investigate the impact of WDSW on tumor development and molecular signaling. **Methods:** Both male and female mice with a mixed background of C57Bl/6J and 129S1/SvImJ (B6/129) were subjected to HTVI with a Sleeping Beauty (SB) transposon system encoding the oncogene, c-Myc, to induce HCC. Following injection, mice were randomized to receive either a WDSW or a normal chow diet (ND) for six weeks. Tumor burden and liver pathology were assessed by hematoxylin and eosin (H&E) staining. *c-Myc* expression was confirmed via Western blotting and qPCR. Gene expression profiling was performed using the NanoString nCounter Mouse PanCancer Pathways Panel. **Results:** HTVI effectively delivered *c-Myc* to the liver, as confirmed by Western blot and qPCR. WDSW feeding significantly enhanced *c-Myc*-driven tumorigenesis compared to ND. Serum chemistry revealed elevated ALT, AST, and ALP in *c-Myc*-injected mice, with further increases observed in the WDSW group. Metabolic profiling showed increased levels of total bilirubin, cholesterol, triglycerides, and VLDL, alongside reduced glucose levels—indicating a dysmetabolic state induced by WDSW. NanoString profiling identified significant upregulation of pathways related to growth factor signaling (e.g., *FGF1, FGF21, VEGFA, HGF, IGF1, ERBB3*), Wnt/β-catenin signaling (*Wnt2, Wnt5a, Wnt5b, Axin1, Fzd8*), inflammation (*STAT1, IL1α, NF-κB, SOCS2, JAK1*), cell cycle and DNA damage response (*Ccnd1, Ccnd2, Bcl2l1, Casp7, Casp8*), and metabolic stress. Notably, *Hspa8* and *Gpc3* expression were markedly elevated in the WDSW + *c-Myc* group. **Conclusion:** Our findings demonstrate that WDSW significantly exacerbates *c-Myc*-driven hepatocarcinogenesis. The combination of *c-Myc* overexpression and diet-induced lipotoxicity accelerates metabolic dysfunction, inflammation, and tumor-promoting molecular changes, providing mechanistic insights into the diet-oncogene interplay in MASH-associated HCC.

1071 | HEPATIC LIPIDOMIC PROFILING ASSOCIATED WITH HEPATOCYTE PPARG EXPRESSION AND ACTIVATION IN MICE WITH DIET-INDUCED MASH

Sara Osorio-Valencia[1] Samuel Lee[1] Izabela Hawro[1] Gregory Norris[1], [1]University of Illinois at Chicago

Background: Hepatocyte peroxisome proliferator-activated receptor gamma (*Pparg*) contributes to the progression of metabolic dysfunction-associated steatohepatitis (MASH). Specifically, we have reported that hepatocyte-specific *Pparg* knockout ($Pparg^{\Delta Hep}$) male mice have reduced MASH progression when they are fed a high-fat, cholesterol, and fructose diet (HFCF). However, the hepatic benefits mediated by $Pparg^{\Delta Hep}$ are not only explained by reduced level of steatosis. Here, we have profiled hepatic lipid species in two groups of control and $Pparg^{\Delta Hep}$ male mice that were fed a HFCF for 24 or 34 weeks. **Methods:** Previously, we generated control or $Pparg^{\Delta Hep}$ mice by injecting *Pparg* floxed male mice with AAV8-TBG-Null or AAV8-TBG-Cre, respectively, before feeding them a HFCF diet for 24 weeks (Group 1), or after feeding male *Pparg* floxed mice a HFCF diet for 24 weeks (Group 2). In the group 2, a subset of control or $Pparg^{\Delta Hep}$ mice were then treated with Rosiglitazone (PPARg agonist) for 8 weeks. In this study, we used LC/MS to identify glycerophospholipids, sphingolipids, and neutral lipids, or GC/MS to quantify the total amount of fatty acids in livers. **Results:** The LC/MS workflow identified up to 316 lipid species. The HFCF diet significantly reduced 106 and 57 lipid species in Groups 1 and 2, respectively. Of note, 45 lipid species were commonly reduced in both groups—primarily glycerophospholipids containing polyunsaturated fatty acids (PUFAs) and free PUFAs. Moreover, the activation of hepatocyte PPARg with Rosiglitazone in control mice, but not in $Pparg^{\Delta Hep}$ mice, reduced the levels of 33 lipids, including phosphatidylcholine PC(38:4, 40:6, and 42:10), phosphatidylethanolamine PE(38:6), Lyso-PC and Lyso-PE(20:4, 22:6), cardiolipin CL(74:9), and FA(24:4, 22:6). These were also reduced by HFCF diet. Furthermore, using GC/MS we confirmed a Pparg-dependent negative effect of HFCF diet on total PUFA levels, particularly FA(20:4) and FA(22:4). Surprisingly, in group 1 and 2, $Pparg^{\Delta Hep}$ increased the levels of 31 and 10 lipid species, respectively. Of note, $Pparg^{\Delta Hep}$ increased the levels of PC(40:6) and PC (42:10) in both HFCF-fed groups. Supporting the hepatocyte *Pparg*-dependent effect on the hepatic lipid profile, our publicly available RNA-seq datasets of group 1 and 2 (GSE162249 and GSE162276) revealed that key genes involved in hepatic PC and PE biosynthesis (*Pemt*, *Etnk2*), as well as fatty acid elongation (*Elovl2*), were downregulated by HFCF diet and rosiglitazone in control mice, but this effect was reversed in $Pparg^{\Delta Hep}$ mice. **Conclusion:** Our comprehensive lipidomic analysis in a diet-induced MASH model reveals a hepatocyte *Pparg*-dependent negative regulation of specific PUFA-containing PC species. Reduced expression of hepatic *Elovl2*, *Etnk2*, and *Pemt* might account for the reduced levels of these lipid species, and contribute to the progression of MASH.

1072 | ROLE OF EXTRACELLULAR ATP (ATPE) AND ASSOCIATED PATHWAYS IN INFLAMMATION RELATED TO METABOLIC DYSFUNCTION – ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PROGRESSION

Vanessa Garcia-Fernandez[1] Antonio Gil-Gómez[1] Rocío Muñoz Hernández[2] Sheila Gato-Zambrano[1] Angela Rojas[1] Isabel Fernandez[1] RAQUEL MILLÁN DOMÍNGUEZ[1] Rocio Gallego-Duran[3] Douglas Maya-Miles[1] Paloma Carrillo-Fernandez[1] Javier Ampuero Herrojo[1] Manuel Romero-Gómez[1], [1]SeLiver Group. Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocí, [2]Centro de Investigación Biomédica en Red, [3]Ibis- Biomedicine Institute of Sevilla

Background: Extracellular ATP (eATP) is a damage-associated molecule that triggers the inflammatory response, inducing immune cell infiltration and cytokine release. ENTPD1 is an ectonucleotidase that hydrolyzes ATP, reducing eATP levels and modulating inflammation. P2RX7 is an ATP receptor which triggers de NLRP3 inflammasome pathway. The aim of this study was to determine the role of eATP and its associated pathways in the progression of MASLD. **Methods:** Preliminary studies involved of thirty-six male C57BL/6J mice with High Fat High Carbohydrate and Cholesterol (HFHCC) diet (n = 29) or chow (n = 7) for 52 weeks and thirty male C5BL/6J mice were fed a CDACHFD diet (n = 20) or chow (n = 10) diet for 8 weeks. A new study with forty male C57BL/6J mice fed a HFHCC diet (n = 20) or chow (n = 20) was performed. *Entpd1, P2rx7* and *Nlrp3* genes and Entpd1

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and P2rx7 protein expression were assessed by PCR and IHC assays. Moreover, serum ENTPD1 levels were measured by ELISA in one-hundred three biopsy proven MASLD patients classified as bland steatosis (n = 42) or MASH (n = 61) using SAF and NAS Score. **Results:** In mice fed HFHCC for 52 weeks, Entpd1 gene expression was 5 times higher than controls ($p < 0.0001$), while CDACHFD-fed mice showed a 4-fold increase. In the recent study, *Entpd1* was increased in the diet group (fold change 1 ± 0.83 vs 1.97 ± 0.75; $p = 0.0005$). *P2rx7* (fold change 1 ± 0.62 vs 2.24 ± 0.58; $p < 0.0001$) and *Nlrp3* (fold change 1 ± 0.41 vs 2.28 ± 0.71; $p < 0.0001$) were increased in the mice fed with HFHCC diet. The IHC assay showed an Entpd1 protein expression around the central vein in the control group, while no expression around the portal vein. However, in both HFHCC and CDACHFD diet mice, the expression showed a shift towards the portal vein, with a heightened expression in that region and a decline in the central vein region. Regarding P2rx7 expression, there is an elevated number of positive cells per area in mice fed HFHCC diet (272.4 ± 79.82 *vs.* 391.8 ± 121.8; $p = 0.0035$). Patients with MASH (1368 ± 1094pg/ml) had increased ENTPD1 levels compared to bland steatosis patients (925 ± 474pg/ml) ($p = 0.006$). Based on inflammation, an increase in ENTPD1 serum levels were observed as inflammation increased [none (n = 19), 879 ± 484 pg/ml; mild (n = 56), 1164 ± 757 pg/ml; moderate (n = 28), 1444 ± 1312 pg/ml; $p = 0.112$]. A correlation between ENTPD1 levels and SAF Score's activity was found ($p = 0.03$). **Conclusion:** The gene expression of *Entpd1*, *P2rx7* and *Nlrp3* and protein levels of Entpd1 and P2rx7 were increased along with the progression of the disease, suggesting that eATP related pathways play an important role in the progression of MASLD.

1073 | TSG-6 IMPROVES HYPERLIPIDEMIA BY SUPPRESSING ASGR1–PCSK9 AXIS BUT AGGRAVATES HEPATIC STEATOSIS IN DIET-INDUCED HYPERLIPIDEMIA

Hayeong Jeong[1] Jinsol Han[1] Youngmi Jung[1], [1]Pusan National University

Background: The liver plays a central role in lipid metabolism by regulating lipid uptake, synthesis, storage, and export. Dysregulation of hepatic lipid metabolism not only contributes to the development of hepatic steatosis but also leads to systemic hyperlipidemia. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is an essential regulator controlling LDL cholesterol levels by degrading hepatic lipid transporters such as low-density lipoprotein receptor (LDLR) and cluster of differentiation 36 (CD36), on hepatocytes, which ultimately lowers the clearance of LDL cholesterol. Hence, inhibiting PCSK9 has emerged as a promising therapeutic approach treating hyperlipidemia. However, given the strong association between hyperlipidemia and fatty liver, PCSK9 suppression may inadvertently promote hepatic lipid accumulation by enhancing lipid uptake into hepatocytes. Therefore, it is necessary to clarify the effect of impact of PCSK9-targeted interventions on hepatic lipid metabolism and liver function. Tumor necrosis factor-α-stimulated gene 6 protein (TSG-6), an anti-inflammatory cytokine secreted by mesenchymal stem cells, has recently been reported to influence hepatic lipid metabolism. Therefore, we investigated the effects of TSG-6 on hyperlipidemia and liver function, with a particular focus on its regulatory role in PCSK9 expression. **Methods:** Mice were fed a chow diet or a high-fat, high-fructose, high-cholesterol diet (HFHFrHC) for 12 weeks. TSG-6 (1.5 μg/kg, every other day) or PBS (vehicle) was injected intraperitoneally with feeding diet for 4 additional weeks. **Results:** Mice in the HFHFrHC groups developed enlarged, pale livers with increased lipid accumulation and severe liver damage compared to chow-fed controls. TSG-6 did not have any effects in chow-fed mice. However, in the HFHFrHC-fed groups, TSG-6-treated mice exhibited larger hepatic lipid droplets compared to vehicle-treated mice. The liver-to-body weight ratio also tended to be higher in TSG-6–treated mice than in vehicle-treated controls. Immunoprecipitation of TSG-6 followed by LC-MS/MS analysis identified asialoglycoprotein receptor 1 (ASGR1)- a receptor known to interact with PCSK9- as a binding partner of TSG-6 in hepatocytes. TSG-6 treatment down-regulated hepatic ASGR1 and PCSK9 levels while upregulating CD36 and LDLR expression. These changes were associated with a reduction in serum triglyceride (TG) levels, but an increase in hepatic TG accumulation in the HFHFrHC groups. **Conclusion:** These findings demonstrate that ASGR1 suppression by TSG-6 blocks PCSK9, and enhances hepatic lipid thereby facilitating clearance of circulating lipids. These results indicate that although TSG-

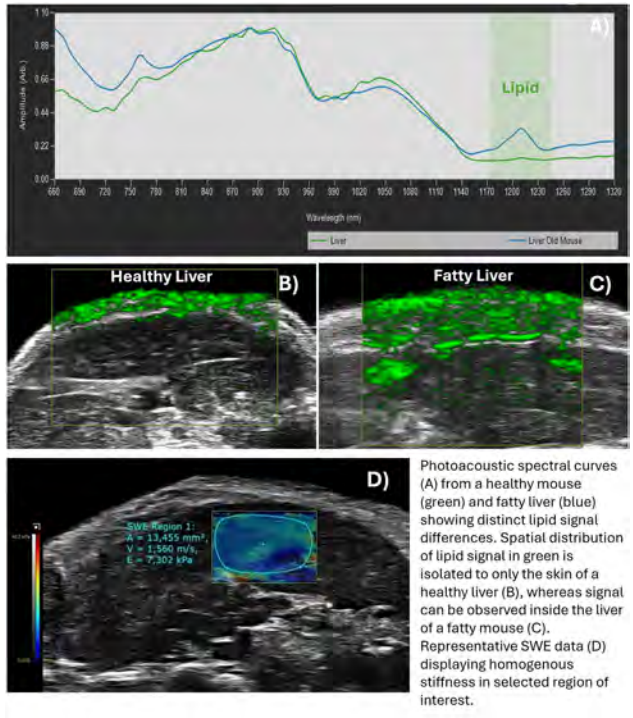
1074 | HIGH RESOLUTION MULTIMODAL APPROACH FOR COMPREHENSIVE NON-INVASIVE PRECLINICAL ASSESSMENT OF THE LIVER

Melissa Yin[1] Kristiina Aasa[1] Cassidy Rose[1] Ross Williams[1] Peter Kesa[1] Caroline O'Riordan[1] Philippe Trochet[1] Dieter Fuchs[1], [1]FUJIFILM VisualSonics Inc

Background: Early diagnosis is paramount in the treatment and management of liver disease in the clinical setting. This also translates to preclinical research, where proper staging of liver damage plays an instrumental role in the development and evaluation of novel treatments. Here, we present a multimodal approach for non-invasive assessment of the liver, combining high-frequency ultrasound with photoacoustic imaging (HFUS-PA). This approach provides anatomical, functional, and mechanical (stiffness changes relating to fibrosis development via shear wave elastography) information. As well as molecular details in the form of lipid detection relating to steatosis development. Combined, this multi-faceted approach supports the characterization of dynamic changes related to liver disease progression. **Methods:** Multi-modal liver assessments were performed in healthy and diet-induced MASLD C57Bl/6J mice using the Vevo® F2 LAZR-X20 HFUS-PA imaging system (FUJIFILM VisualSonics). Liver capillary function was assessed by injecting 50 μL of MicroMarker® contrast agents. Liver oxygenation was evaluated via an oxygen challenge assay where isoflurane anesthetized animals were subjected to varying concentrations of O_2—98% O_2, 5% O_2, 98% O_2. Shear wave elastography (SWE) stiffness measurements were obtained both in vivo and on phantoms for validation. **Results:** On liver fibrosis phantoms, all SWE measurements were within 1-2 standard deviations, or less than a 10% difference from the supplier-certified values. In vivo characterization of healthy mouse liver revealed reproducible values for stiffness (6.986 ± 1.263 kPa) and capillary perfusion (time-to-peak of 3.2 ± 0.4 sec) in the median lobe. The average liver oxygenation showed an sO_2 of 79.6 ± 11.5% which dropped to 34.7 ± 2.6% at 5% O_2, then swiftly recovered to baseline after returning to 98% O_2. In MASLD mice, increased stiffness ($p < 0.05$) was seen as early as 4 weeks after diet-commencement. Furthermore, when comparing lipid-specific PA signal in normal vs fatty liver, increased lipid signal intensity was observed in the fatty liver. **Conclusion:** Multimodal imaging using a HFUS-PA system allowed for detailed liver characterization in mice, offering novel means to detect and investigate liver disease. Using high resolution SWE, we report clinically relevant measurements of stiffness related to fibrosis development. Molecular imaging using PA showed differences in lipid accumulation in the liver—a potential method for detecting steatosis development prior to fibrosis formation. This, along with additional anatomical and functional measurements, will provide a comprehensive assessment of liver changes related to disease progression, all on one platform.



Photoacoustic spectral curves (A) from a healthy mouse (green) and fatty liver (blue) showing distinct lipid signal differences. Spatial distribution of lipid signal in green is isolated to only the skin of a healthy liver (B), whereas signal can be observed inside the liver of a fatty mouse (C). Representative SWE data (D) displaying homogenous stiffness in selected region of interest.

1075 | HISTONE DEACETYLASE 3 CONTROLS HEPATIC LIPID METABOLISM VIA NON-ENZYMATIC MECHANISMS

Nischay Rege[1] Amy Hauck[2] Mohit Midha[1] Kristina Heliodoro[1] Kun Zhu[1] Mitchell Lazar[1], [1]University of Pennsylvania, [2]University of Minnesota

Background: Nuclear receptors (NRs) are transcription factors that can activate or repress the transcription of target genes. Ligands affect the transcriptional activity of many NRs making them attractive candidates for pharmacological therapy. In fact, therapeutic agents targeting NRs have cleared phase 2 clinical trials for the treatment of liver diseases including the FDA-approved resmetirom, which targets thyroid hormone receptor β, elafibranor, which targets

PPARα/δ, and seladelpar, which targets PPARδ. NRs canonically repress gene transcription through the activity of histone deacetylase 3 (HDAC3), an enzyme that deacetylates histones at gene enhancers. HDAC3 is a class I histone deacetylase that uniquely requires complexation with the deacetylase-activation domain (DAD) of Nuclear Receptor Corepressors 1 and 2 (respectively NCOR-1 and NCOR-2, also known as SMRT) to achieve deacetylase activity. Knockout of HDAC3 in the murine liver causes steatosis through derepression of lipogenic genes. The canonical view of HDAC3-mediated transcriptional repression was challenged by the rescue of hepatic steatosis by the introduction of an enzymatically inactive HDAC3 mutant (termed Y298F) into HDAC3 knockout livers. We hypothesize HDAC3 acts as a scaffolding protein at NR-associated genomic binding sites, recruiting key transcription factors that are responsible for repressing rescued genes. **Methods:** We have developed a chimeric molecule comprising HDAC1 with two helices substituted by analogous motifs from HDAC3 termed HDAC1-D3. This molecule is expected to bind NCOR upon transduction into an HDAC3-depleted mouse liver but fail to rescue hepatosteatosis because of its inability to recruit the putative transcription factor responsible for repressing lipogenic genes due to its variant surface topography. We have utilized RNA-seq to characterize the transcriptional effects of epitope-tagged HDAC molecules transduced into HDAC3-depleted mouse livers and assessed their genomic occupancy using ChIP-seq. IP-mass spectrometry was used to characterize the interactomes of HDAC3 and mutant proteins. characterize the interactomes of HDAC3 and mutant proteins. **Results:** Whereas the catalytically inert Y298F mutant displayed native-like genomic occupancy and repressed a subset of genes that were upregulated in hepatic HDAC3 knockout, leading to a near-complete rescue of the hepatosteatosis, HDAC1-D3 failed to rescue hepatic steatosis and to repress lipogenic HDAC3 target genes despite engaging NCOR. **Conclusion:** The failure of HDAC1-D3 to rescue the HDAC3 knockout phenotype despite its similar three-dimensional structure suggests surface residues of HDAC3 that are not present in the chimeric molecule are critical to the non-enzymatic function of HDAC3. We are now comparing the interactomes of HDAC3 and HDAC1-D3 to identify transcription factors that interact with these residues and repress target genes.

1076 | REDUCED ZMPSTE24 EXPRESSION LEADS TO PRELAMIN ACCUMULATION AND DEVELOPMENT OF STEATOSIS IN MASLD PATIENTS

Joseph Schinderle[1] Irina Bochkis[1], [1]University of Pittsburgh

Background: Metabolic-associated steatotic liver disease (MASLD, formerly NAFLD) is highly prevalent in type 2 diabetes mellitus (T2D) and its incidence has increased rapidly with the obesity epidemic. Mutations of nuclear lamina-associated genes including *LMNA* have been associated with fatty liver. We previously described a mechanism relating changes at the nuclear lamina that lead to opening of previously repressed chromatin and upregulation of lipid synthesis and storage pathways to development of steatosis in MASLD. **Methods:** We performed RNA-Seq, Foxa2 and Lamin B1 ChIP-Seq and protein analysis for expression of ZMPSTE24 in livers of MASLD patients with varying degrees of steatosis. **Results:** Here we report that the changes at the nuclear envelope in MASLD patients are caused by downregulation of ZMPSTE24, an enzyme that processes prelamin to mature lamin A, leading to accumulation of prelamin. In addition, Zmpste24 mutant mice develop hepatic steatosis and Zmpste24 deficiency is linked to upregulation of p53 target genes. Functional analysis determined p53 as a regulator in genes differentially expressed and bound by FOXA2 in both male and female MASLD patients, corresponding to observations in Zmpste24 knockout animals. ZMPSTE24 expression is repressed by mir-141-3p in male MASLD patients. **Conclusion:** Downregulation of ZMPSTE24 leads to the nuclear lamina changes responsible to development of MASLD we had previously reported. Hence, MASLD should be considered as a type of laminopathy and approaches to restore ZMPSTE24 expression and nuclear lamina function should be tested for treatment of the disease.

1077 | PROTEOMIC PROFILING OF A STEATOTIC MONKEY LIVER ORGANOID MODEL FOR MASLD

Bowen Gao[1] Li Wang[2] Yun Ma[1] Wayel Jassem[3], [1]King's College London, [2]Suzhou Jiyan Biopharmaceutical Technology, [3]King's College London/King's College Hospital

Background: Although several methods for inducing liver steatosis have been well demonstrated in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

rodents, the variability between species limits the extrapolation of these results to humans. Human liver studies are constrained by limited samples availability and strict ethical regulations. Liver organoids derived from monkey tissue offer a genetic background closer to humans, making them a promising compromise for modelling Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD). This research aims to establish and characterize a reliable monkey-derived model for future drugs evaluation in MASLD. **Methods:** Liver organoids were constructed from monkey liver tissue. After 5 days differentiation, 250μM palmitic acid (PA) and oleic acid (OA) were added into the culture system for 24 hours to induce steatosis in the organoids. Lipid accumulation was evaluated by Oil Red O staining and total cholesterol (TC) quantification. Organoids were harvested before and after treatment with free fatty acid for DIA based LC-MS/MS proteomics profiling. Statistical significance was defined as $q < 0.05$ (Benjamini-Hochberg FDR correction) for enrichment analysis and $p < 0.05$ for individual proteins. **Results:** Oil Red O staining and TC detection confirmed lipid accumulation and secretion in the liver organoids ($p < 0.05$). Proteomic profiling identified 8643 proteins with 834 proteins showing differential expression between steatotic and control group, 634 upregulated and 200 downregulated. GO enrichment analysis revealed a downregulation of DNA replication initiation (enrichment ratio = 45.05, $q = 0.026$), suggesting a suppression in cell proliferation and DNA repair induced by oxidative stress from lipotoxic conditions, rather than a developmental immaturity. Conversely, pathways related to collagen trimer complex formation were upregulated (enrichment ratio = 23.15, $q = 0.0018$), indicating a remodeling of extracellular matrix (ECM) and increased risk for fibrosis. Additionally, triglyceride lipase activity was upregulated (enrichment ratio = 14.9, $q = 0.023$), involving key lipases such as hepatic lipase (LIPC) and phospholipase A1 member A (PLA1A), which might reflect an adaptive response and metabolic reprogramming. Noteworthy, TGF-β1 was upregulated significantly (Fold change = 16.37104, $p = 6.26 \times 10^{-167}$), indicating a robust activation. **Conclusion:** Free fatty acid-treated monkey liver organoids showed significant features of cell cycle abnormalities, inflammation, metabolic disorders and ECM remodeling. Preliminary findings suggest that monkey liver organoids are a promising and reliable model for MASLD research and have the potential to recapitulate liver fibrosis. This model will be used in future studies to evaluate anti-steatosis compounds as part of preclinical testing.

1078 | INTESTINAL LIPASE INHIBITION PREVENTS OBESITY BUT EXACERBATES MASH

Alvin Chan[1] Tomek Czernuszewicz[2] Kelsey Jarrett[1] Rochelle Lai[1] Andrew Lau[1] Angela Cheng[1] Zeinab Mamouei[2] Jessica Pesner[2] Christopher Hamad[1] Samuel French[1] Clara Magyar[1] Kevin Francis[1] Elizabeth Tarling[1] Thomas Vallim[3], [1]UCLA, [2]Revvity, inc., [3]University of California, Los Angeles

Background: Excessive dietary fat intake contributes to the development of metabolic dysfunction-associated steatohepatitis (MASH), but emerging evidence suggests that the type of fat (saturated vs unsaturated fat) plays a critical role in shaping disease progression. Our previous work demonstrates that polyunsaturated fatty acids (PUFAs) are preferentially absorbed over saturated fats to maintain metabolic homeostasis. However, orlistat, a lipase inhibitor used for weight loss, disrupts this selective uptake on a Western-style diet, leading to hepatic PUFA depletion. **Methods:** Here, we examined orlistat's effects in a MASH model using the Gubra-Amylin NASH (GAN) diet—a high-fat diet rich in palmitic acid (C16:0) and linoleic acid (C18:2, n-6)—to determine how dietary fat composition influences orlistat's impact on MASH. Mice were fed the GAN diet with or without orlistat for 32 weeks to induce MASH. Disease progression was monitored longitudinally using whole-body MRI and *in vivo* 3D shear wave elastography with the Vega® imager (Revvity) to assess liver size, stiffness, and echogenicity. These noninvasive imaging measures correlated with lipidomic and histologic assessments of steatosis and fibrosis. **Results:** Orlistat-treated mice were protected from obesity but not MASH, with comparable levels of steatosis and fibrosis to untreated controls. Notably, orlistat exacerbated liver transaminases and inflammatory cell infiltration, indicating increased hepatic inflammation. Mechanistically, orlistat non-selectively inhibits lipases and broadly blocks the absorption of all fatty acids. Given the abundance of linoleic acid in the GAN diet, essential PUFAs were disproportionately reduced. Since PUFAs are known to suppress *de novo* lipogenesis, their depletion likely promotes hepatic lipid accumulation and inflammatory signaling, accelerating MASH progression. Ongoing studies will elucidate the mechanisms by which impaired fatty acid absorption by orlistat triggers liver inflammation. **Conclusion:** Overall, these findings suggest that orlistat, despite its anti-obesity effects, aggravates liver injury in the context of MASH. Importantly, its therapeutic potential and risk appear to depend on the fat content of the diet, underscoring the significance of dietary fat composition in strategies that target lipid absorption.

1079 | INHIBITION OF SEROTONIN SIGNALING THROUGH HTR2A MITIGATES MASLD AND LIVER FIBROSIS

WON-IL CHOI[1] Won Hee Lee[2] Jung Eun Nam[2] Yerim Seong[2] Byung-Kwan Jeong[2] Jun Yong Park[3] Jin Hee Ahn[4] Hail Kim[2], [1]Jeonbuk National University Medical School, [2]Korea Advanced Institute of Science and Technology, [3]Yonsei University College of Medicine, [4]Gwangju Institute of Science and Technology

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease, characterized by hepatic steatosis (MASL), inflammation (MASH), fibrosis, and hepatocellular carcinoma (HCC). We previously demonstrated that gut-derived serotonin promotes hepatic lipid accumulation via the gut–liver axis, and that hepatocyte-specific knockout (KO) of the serotonin receptor HTR2A protects against MASLD development. However, a major limitation in studying the full spectrum of MASLD pathophysiology has been the lack of a preclinical model that faithfully recapitulates its progression. In this study, we established a novel MASLD mouse model and investigated the impact of HTR2A inhibition on disease progression. **Methods:** MASLD was induced using a combination of low-dose streptozotocin and high-fat diet (STZHFD), which successfully reproduced the full MASLD spectrum. Hepatic fibrosis was further modeled using chronic carbon tetrachloride (CCl_4) administration or bile duct ligation (BDL). To investigate the role of serotonin signaling in MASLD progression, we employed gut-specific *Tph1* KO, hepatocyte-specific *Htr2a* KO, and hepatic stellate cell (HSC)-specific *Htr2a* KO mice. **Results:** STZHFD mice progressively developed steatosis (MASL), steatohepatitis (MASH), fibrosis, and HCC within the context of metabolic dysfunction. Both gut-specific *Tph1* KO and hepatocyte-specific *Htr2a* KO mice exhibited significant improvements in MASL, MASH, and fibrosis. In contrast, HSC-specific *Htr2a* KO mice showed reduced hepatic fibrosis without improvements in MASL or MASH, indicating a direct profibrogenic role of HTR2A in HSCs. In vitro, *Htr2a* expression was upregulated during HSC activation, and Htr2a-deficient HSCs failed to activate in response to profibrotic stimuli. **Conclusion:** These findings underscore the pivotal role of serotonin–HTR2A signaling in MASLD progression. Targeted genetic or pharmacologic inhibition of HTR2A effectively ameliorates MASL, MASH, and fibrosis, identifying HTR2A as a promising intrahepatic therapeutic target for MASLD.

1080 | DOMINANT-INHIBITION OF RXRA PREVENTS HIGH-FAT DIET-INDUCED OBESITY AND LIVER STEATOSIS IN MICE BY REGULATING FOOD INTAKE AND ENERGY EXPENDITURE

Hiroyasu Sakai[1] Yohei Shirakami[2] Masahito Shimizu[2], [1]Gifu University Graduate School of Medicine, [2]Gifu University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by liver steatosis linked to obesity and metabolic disorders, and its prevalence is rising in tandem with the increasing number of obesity cases. Retinoid X Receptor-α (RXRα) is a retinoid nuclear receptor that forms heterodimers with other nuclear receptors, thereby regulating downstream gene expression and influencing various physiological functions. While some studies have explored the relationship between RXRα and MASLD, its specific role in the disease remains unclear. Therefore, we investigated the role of RXRα in MASLD development using RXRα transgenic (RXRα-TG) mice, in which a dominant-negative form of RXRα can be induced through doxycycline administration. **Methods:** Male RXRα-TG and their control counterparts, aged nine to ten weeks, were administered either a normal diet (ND) or a 60% high-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

fat diet (HFD) that induces obesity and hyperinsulinemia resembling MASLD, along with 0.2% doxycycline, and were sacrificed ten weeks after the experiment begun. **Results:** RXRα-TG mice exhibited significantly lower body weight at the time of sacrifice across both dietary conditions compared to control mice. These mice also showed a significant reduction in food intake. Specifically, in HFD-treated RXRα-TG mice, the weight of epididymal adipose tissue was significantly lower compared to their control counterparts. Serum analyses revealed that while triglyceride levels were significantly elevated in HFD-treated RXRα-TG mice, total cholesterol, free fatty acids, and insulin levels were markedly decreased. Interestingly, while the administration of HFD led to liver steatosis in control mice, this condition was ameliorated in HFD-treated RXRα-TG mice, where fat droplet accumulation was reduced. Correspondingly, liver triglyceride and total cholesterol levels were significantly lower in HFD-treated RXRα-TG mice. Furthermore, adipocyte size was significantly smaller in these mice compared to controls. Additionally, the expression levels of thermogenesis-related genes, *Ucp2* and *Adrb3*, were significantly higher in the livers of HFD-treated RXRα-TG mice when compared to control mice. In the epididymal adipose tissue, the expression of *Ucp1* (thermogenesis), *Acox1*, *Ehhadh*, and *Pparα* (fatty acid oxidation) genes was also significantly increased in HFD-treated RXRα-TG mice. This enhanced expression correlates with a significant rise in rectal temperature in those mice, indicating an increased energy expenditure. **Conclusion:** Dominant-inhibition of RXRα prevents high-fat diet-induced obesity and liver steatosis in mice by reducing food intake and increasing energy expenditure. These results suggest that RXRα could be a possible therapeutic target for obesity and MASLD.

1082 | THE EFFECT OF HYDROXYNONENAL ON HEPATIC MACROPHAGES IN THE PATHOGENESIS OF MASH

Masahiro Yanagi[1] Eishiro Mizukoshi[1] Hidenori Kido[1] Taro Yamashita[1], [1]Kanazawa University

Background: Oxidative stress is an important factor in the pathogenesis of MASH, and we have previously reported the effect of hydroxynonenal (HNE), a lipid peroxide, on hepatocytes in the pathogenesis of MASH. On the other hand, hepatic macrophages have been reported to play an important role in the development of liver fibrosis in MASH by producing inflammatory cytokines and fibrosis-promoting factors. In this study, we analyzed the effects of HNE on hepatic macrophages in the development of MASH. **Methods:** (1) We evaluated CD68, F4/80, and HNE staining of liver tissues from MASH patients and MASH model mice fed choline-deficient methionine-lowered, L-amino acid-defined (CDAA) diet and atherogenic high fat (AHF) diet. (2) HNE and CD68 staining were performed in 60 MAFLD patients, and the association between the degree of HNE deposition (scored in 3 levels: HNE0-2) and the number of hepatic macrophage aggregates (HMA) was analyzed. (3) Normally fed mice were divided into HNE-treated and non-treated groups, and HNE (10 mg/kg body weight) was administered intraperitoneally daily to the treated group. F4/80 and Sirius red staining of liver tissue at 8 weeks was performed to evaluate the presence of HMA and the degree of liver fibrosis. (4) CDAA mice were divided into Alda-1 (ALDH2 agonist) treated and non-treated groups, and Alda-1 (20 mg/kg body weight) was administered to the treated group three times a week. F4/80 and Sirius red staining of liver tissue from both groups of mice at 8 weeks was performed to analyze the effects of HNE detoxification on HMA formation and liver fibrosis. **Results:** (1) Numerous HMAs were observed in the liver tissues of MASH patients and CDAA and AHF mice, and strong HNE deposition was observed on the HMAs. (2) Liver tissues with higher HNE scores showed significantly more HMA (HNE0/HNE1/HNE2: 0.22/0.92/1.99 /mm2, $p < 0.0001$) and significantly more advanced liver fibrosis. (3) The liver tissues of the HNE-treated group showed the formation of HMAs, and the degree of liver fibrosis was significantly higher than that of the non-treated group. (4) The liver tissues of the Alda-1-treated group showed a significant reduction in HMA counts (treated/non-treated group: 191/119 /field, $p = 0.0159$) and a significant improvement in liver fibrosis compared to the non-treated group. **Conclusion:** In the pathogenesis of MASH, HNE may be involved in the formation of HMA and the development of liver fibrosis.

1083 | HEPATIC HOMEOSTASIS OF INTERLEUKIN-10 VIA REGULATION OF LIPOTOXICITY CONTRIBUTES TO THE IMPROVEMENT OF METABOLISM-ASSOCIATED STEATOTIC LIVER DISEASE PROGRESSION

Akira Kado[1] Kazuya Okushin[1] Takeya Tsutsumi[1] Toshiyuki Kishida[1] Kazuhiko Ikeuchi[1] Kyoji Moriya[2] Hiroshi Yotsuyanagi[3] Kazuhiko Koike[4] Mitsuhiro Fujishiro[1], [1]The University of Tokyo, [2]Tokyo Health Care

University, [3]The Institute of Medical Science, The University of Tokyo, [4]Kanto central hospital

Background: Metabolism-associated steatotic liver disease (MASLD) is characterized by hepatic lipotoxicity, which disrupts fatty acid and glucose metabolism and induces oxidative stress (OS) and apoptosis. Effective regulation of hepatic lipotoxicity is clinically needed. Interleukin (IL)-10, an endogenous anti-inflammatory cytokine, has been reported to be upregulated in liver tissue and immune cells of MASLD patients (*J Gastroenterol.* 2019), suggesting a potential compensatory role in maintaining intracellular homeostasis. This study aimed to investigate the homeostatic effects of IL-10 against lipotoxicity using *in vitro* and *in vivo* models that recapitulate MASLD pathology. **Methods:** Normal human hepatocytes were treated with palmitic acid (PA) and various concentrations of IL-10. Gene expression related to fatty acid and glucose metabolism, OS, and apoptosis was assessed, with partial validation in HepG2 cells. In vivo, six-week-old male C57BL/6J mice were fed a high-fat diet (HFD) for 12 weeks and treated with or without IL-10 (50 μg/kg) every other day for the final 6 weeks. Biochemical, histological, and gene expression analyses were performed. **Results:** In PA-treated hepatocytes, IL-10 significantly reduced intracellular lipid accumulation by downregulating fatty acid synthase (FAS) and enhancing β-oxidation (CPT1/2). IL-10 also promoted hepatic glucose storage by upregulating genes involved in glucose metabolism (GLUT2, GK, GS, PCK1). Additionally, IL-10 suppressed OS by increasing antioxidant gene expression (SOD1, CAT, GPX1) and reduced apoptosis by downregulating caspase8 and caspase3/7 activity. In HFD-fed mice, IL-10 treatment mirrored these effects: hepatic lipid droplet-containing cells were significantly reduced ($11.9 \pm 2.5\%$ vs. $32.8 \pm 3.7\%$, $p < 0.01$), and glucose uptake/glycolysis (GLUT2, GK) and gluconeogenesis (PCK1) were enhanced, resulting in lower fasting blood glucose levels (98.3 ± 5.7 vs. 178.3 ± 31.6 mg/dL, $p < 0.01$). Similar changes were observed in the antioxidant system, with a significant suppression of OS (2.4 ± 0.3 vs. $34.0 \pm 0.6\%$, $p < 0.01$), and apoptosis was significantly suppressed (0.5 ± 0.1 vs. $11.1 \pm 0.6\%$, $p < 0.01$). **Conclusion:** IL-10 exerts a protective, homeostatic effect in MASLD by attenuating lipotoxicity-induced hepatic dysfunction. It reduces lipid accumulation, OS, and apoptosis while enhancing glucose storage and glycolysis (energy metabolic activity). These findings, which bridge immunology, metabolism, and hepatology, indicate that enhancing endogenous IL-10 activity may offer a novel therapeutic strategy for MASLD.

1084 | NOVEL HAF-DRIVEN MECHANISMS CONTRIBUTING TO METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE AND HEPATOCELLULAR CARCINOMA

Po-An Hu[1] Karen Acuna-Pilarte[1], [1]University of Utah

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), which affects over 30% of the U.S. population, can advance to metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC). Hypoxia-associated factor (HAF, SART1) has been known to be involved in NF-κB pathway regulation and apoptosis inhibition, and is significantly increased in human HCC, where it is associated with poor prognosis. Thus, identifying the potential mechanisms by which HAF contributes to MASH-HCC development will provide new insights and therapeutic targets for the early detection and treatment of MASH-HCC. **Methods:** To determine whether HAF promotes tumorigenesis in vivo, we used hydrodynamic tail-vein injection (HDTVi) of EV/SART1 into C57BL6 mice to induce hepatocyte-specific HAF overexpression. These mice were fed the GAN diet to simulate MASLD. To investigate the effect of HAF on tumor growth in vivo, we used HAF overexpressing HEPG2 xenografts grown in nude mice. Additionally, primary hepatocytes from HDTVi EV/SART1 mice were isolated three weeks after HDTVi and subjected to Seahorse metabolic analysis, mRNA sequencing, and western blotting after BSA/palmitate treatment. To complement these studies, the

human HCC cell lines HEPG2 or PLC/PRF/5 were transfected with EV/SART1 to generate HAF-overexpressing cells. HEPG2 cells were subjected to 13C-palmitate tracing to investigate the impact of HAF on FA metabolism in vitro, whereas the impact of HAF on levels of proteins involved in mitochondrial function or metabolic regulation was determined using PLC/PRF/5 cells as well as the isolated HDTVi-HAF hepatocytes. **Results:** We observed a trend of improved glucose tolerance in the HDTVi-HAF mice, whereas HAF overexpression was associated with significantly increased xenograft growth. The mRNA sequencing of HDTVi-HAF hepatocytes showed increased levels of genes involved in fatty acid metabolism and glycolysis. However, western blotting revealed that levels of PPARγ and COX-IV were downregulated, whereas levels of CD36, CPT-I/II, GLUT4, and PDK2 were upregulated, suggesting reduced mitochondrial biogenesis and increased FA uptake, β-oxidation, and anerobic glycolysis, which may increase oxidative stress and promote a tumor-permissive environment. Indeed, Seahorse analysis studies confirmed that HAF-overexpressing hepatocytes have impaired mitochondrial function, including defective β-oxidation. Palmitate tracing experiments revealed elevated levels of lipotoxic ceramides and acylcarnitines in HAF-overexpressing HEPG2 cells. **Conclusion:** Our data suggest that increasing HAF levels may promote tumor progression, in part by promoting a metabolic shift from mitochondrial β-oxidation to increased anerobic glycolysis and lipotoxic lipid accumulation. This may promote hepatocyte stress and generate a tumor-permissive environment that could potentiate progression to HCC.

1085 | INCREASED SEVERITY OF DIET-INDUCED MASLD IN MALE MICE WAS ACCOMPANIED BY LIVER TRANSCRIPTOME INDICATING DECREASED SIGNALING EVENTS OF FATTY ACID OXIDATION AND INCREASED STING1 SIGNALING

XIAOJING LI[1], HONGGUI LI[1], XIAOXIAO WANG[1], AND CHAODONG WU[1], Xiaojing Li[1] Honggui Li[1] Xiaoxiao Wang[1], [1]Texas A&M University

Background: Sex-specific differences in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD) have been widely reported, with males exhibiting more severe disease phenotypes than females in both animal models and clinical studies. Although the hepatic transcriptome in diet-induced MASLD has been studied, the findings remain inconsistent and highly variable. Further investigation is needed to elucidate how transcriptomic data can enhance our understanding of sex-specific mechanisms underlying MASLD pathogenesis. **Methods:** In the present study, male and female C57BL/6J mice were fed a low-fat diet (LFD) or a high-fat diet (HFD). General phenotypic parameters, including hepatic histopathology, glucose metabolism, and liver inflammation, and liver transcriptomic profiling were assessed. **Results:** After 12 weeks of HFD feeding, both male and female mice developed MASLD phenotype compared to their respective LFD controls. However, male-HFD mice exhibited a greater increase in body weight gain and severer hepatic pathology, characterized by extensive ballooning degeneration. Hepatic inflammation levels were also significantly higher in male-HFD mice compared to female-HFD mice, indicated by increased macrophage filtration and phosphorylation states of p65 and p46. Furthermore, male-HFD mice displayed more pronounced glucose intolerance and insulin resistance. Transcriptomic analysis revealed a total of 756 significantly differentially expressed genes (DEGs), with 337 upregulated and 428 downregulated in male-HFD mice compared to female-HFD. Pathway enrichment analysis based on all DEGs indicated a significant downregulation of AMP-activated protein kinase (AMPK) signaling. Further analysis revealed that the upregulated DEGs were predominantly enriched in inflammatory pathways, particularly cGAS–STING signaling and interleukin-1 family signaling. Notably, upstream regulator analysis based on Ingenuity Pathway Analysis identified *Sting1* as a central upstream regulator, suggesting its pivotal role in driving inflammatory gene expression. In contrast, the downregulated DEGs were mainly associated with suppressed fatty acid oxidation pathways, such as PPARα/RXRα activation, along with decreased expression of key metabolic regulators including *Ppara* and *Ppargc1b*. **Conclusion:** These findings highlight

an increased severity of diet-induced MASLD in male mice, associated with distinct transcriptomic alterations characterized by increased STING1 signaling and decreased signaling events of fatty acid oxidation. The identification of *Sting1* as a central regulatory node suggests it may serve as a potential therapeutic target for sex-specific interventions in MASLD.

1086 | THERAPEUTIC EFFICACY AND PHARMACOLOGICAL MECHANISMS OF JIANPI HUOXUE FORMULA IN TREATING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Pingping Yao[1] Zhen Tu[1] Yuqing Pan[1] Aojie Mao[1] Yiyang Hu[1] Yu Zhao[1], [1]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a global health concern. Traditional Chinese medicine (TCM) has shown broad clinical application, but evidence-based efficacy evaluations remain limited. Jianpi Huoxue Formula (JPHX), an empirically validated TCM prescription for MASLD, lacks clear mechanistic understanding. This study aimed to assess its clinical efficacy for MASLD and explore its therapeutic mechanisms to support broader clinical application. **Methods:** MASLD patients were randomized into an intervention group (n = 41, JPHX granules) or a placebo control group (n = 41). The primary efficacy endpoint was the change in liver fat content measured by MRI-proton density fat fraction (MRI-PDFF) after 24 weeks, with secondary endpoints including liver function, blood lipids, and glucose metabolism. Safety was also evaluated. LC-Q-TOF/MS was used to qualitatively analyze JPHX's chemical components and their blood/liver distribution. A MASLD mouse model was established using a high-fat diet and sugar water (55% fructose + 45% sucrose, 42 g/L) for 12 weeks. Mice were treated with JPHX (2.1 g/kg, clinically equivalent dose) for 4 weeks, alongside normal-diet controls. Liver and serum biomarkers were assessed, and liver transcriptome sequencing was performed. Network pharmacology was employed to identify JPHX component targets and disease-associated pathways, followed by functional enrichment analysis and cross-validation with KEGG enrichment results from transcriptomic data to predict therapeutic mechanisms. **Results:** Among 102 screened MASLD patients, 82 were enrolled, with 81 included in the full analysis set (FAS). After 24 weeks, the JPHX group showed a significant reduction in MRI-PDFF (LSmean: 3.11%, SE: 1.31, P = 0.021) compared to placebo. Notably, 20% of JPHX-treated patients (vs. 4.9% in placebo) achieved MRI-PDFF < 5% (P = 0.021). In the per-protocol set (PPS), JPHX significantly lowered serum AST (LSmean: -8.59 U/L, P = 0.04). Safety profiles were comparable (P > 0.05), with no severe adverse events. LC-Q-TOF/MS identified 61 components in JPHX, 37 in blood, and 29 in liver tissue. In mice, JPHX alleviated hepatic steatosis, reduced NAS scores, and decreased liver TG, serum ALT, AST, and fasting glucose. It also improved glucose/insulin tolerance and increased energy expenditure/oxygen consumption. Transcriptomics and network pharmacology jointly highlighted the PPAR and MAPK signaling pathways. Key bioactive compounds (genistein, alisol A, calycosin, hesperidin) were predicted to modulate PPAR signaling, warranting further validation. **Conclusion:** JPHX significantly reduces liver fat content and improves liver injury in MASLD patients over 24 weeks, demonstrating good safety. Components like genistein, alisol A, calycosin, and hesperidin may mediate therapeutic effects via PPAR signaling pathway regulation.

1087 | AI IN THE HISTOPATHOLOGY WORKFLOW: DETECTING HEPATOCELLULAR BALLOONING TO SUPPORT SCORING OF STEATOTIC LIVER DISEASE

Jack Breen[1] Dylan Windell[1] Philip Wakefield[1] Reema Kainth[1] Paul Aljabar[1] Caitlin Langford[1] Kenneth Fleming[2] Eve Fryer[3] Timothy Kendall[4] Rob Goldin[5], [1]Perspectum Ltd, [2]University of Oxford, [3]John Radcliffe Hospital, [4]University of Edinburgh, [5]Imperial College London

Background: Hepatocyte Ballooning (HB) is a key pathological feature used to diagnose metabolic dysfunction-associated steatohepatitis, but manual scoring is

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

inconsistent, with low agreement on which cells are ballooned and on the overall severity of ballooning across a biopsy. The molecular and cellular mechanisms of ballooning are unknown, however, identifying progressive disease markers (such as non-classic HB) may allow the detection of changes in clinical trials. Artificial intelligence (AI) models can objectively detect and quantify ballooning and improve diagnostic consistency. In this study, we present a ballooning detection model and demonstrate its application in scoring liver biopsy whole slide images (WSIs) as a decision support tool for pathologists. **Methods:** Ballooning scores (0-2) were determined by a pathologist in 601 haematoxylin and eosin (H&E)-stained WSIs from three mixed liver disease cohorts. HB was annotated in 40 WSIs from two trials for model training, using human-in-the-loop relabelling after the first WSI. The third trial was reserved for external validation. Several WSI-level features were derived from the sizes and densities of AI detections. Associations between automated metrics and manual labels were assessed using Kendall's Tau correlation. Agreement between three pathologists was measured based on classifying AI outputs as classic HB, non-classic HB, or false positives in a random sample of 216 detections across 54 WSIs. **Results:** Automated metrics were found to be significantly associated (p-value < 0.05) with manual scores, including the density of large detections (Tau 0.39-0.58, Figure 1), the largest detection size (Tau 0.38-0.55), and the average size (Tau 0.37-0.49). When classifying AI outputs, pathologists exhibited only 31%, 46% and 49% pairwise agreement, consistent with previous studies. Overall, 82% of detections were labelled as HB by at least one pathologist. However, each individual pathologist labelled 31-67% of detections as HB, of which 16-71% were labelled as classic balloons. **Conclusion:** Our findings indicate that automated approaches can detect both classic and non-classic ballooned hepatocytes, and derived features correlate with manual scoring. Inter-rater agreement on ballooning severity remains low in clinical trials, however, these automated models may be used as an assistive tool for pathologists to improve the consistency of reader alignment and efficiency of liver disease diagnosis.

A)

	Trial 1 (n = 279)	Trial 2 (n = 130)	Trial 3 (n = 152)

1088 | ESTABLISHMENT OF A MURINE MODEL OF MICROVESICULAR STEATOSIS ASSOCIATED WITH ANOREXIA NERVOSA AND ITS PATHOPHYSIOLOGICAL CHARACTERIZATION

Michiko Ishii[1] Kyoko Hoshikawa[2] Yuiko Takeda[1] Fumiya Suzuki[1] Keita Maki[1] Tomohiro Katsumi[1] Taketo Nishina[1] Hiroaki Haga[1] Yoshiyuki Ueno[1], [1]Yamagata University Faculty of Medicine, [2]Yamagata University

Background: Anorexia nervosa (AN), a condition frequently affecting young women, is often associated with microvesicular hepatic steatosis. Although it is hypothesized that hypoalbuminemia and impaired synthesis of lipid-transporting proteins underlie lipid accumulation in the liver, the precise molecular mechanisms remain elusive. Furthermore, the distinction between hepatic lipid metabolism in AN and that observed in simple starvation has not been clearly defined. This study aimed to establish a murine model of AN-associated microvesicular steatosis and to compare it with models of simple caloric restriction and diet-induced obesity, thereby elucidating the unique pathogenesis of fatty liver in AN. **Methods:** Female C57BL/6 mice (5 weeks old) were divided into four groups ($n = 8$ each): (1) food-restricted (FR), (2) anorexia nervosa-like (AN), (3) high-fat diet (HFD), and (4) control (Ctr). After 7 days of acclimatization, FR and AN mice underwent progressive time-restricted feeding (6 h/day on Day 6 to 3 h/day from Day 9 onward). HFD and Ctr groups received ad libitum feeding from Day 6. On Day 17, animals were euthanized; serum and liver tissues were collected. Serum was analyzed for ALT, total cholesterol (T-CHO), and triglycerides (TG). Liver pathology was assessed by H&E and EM staining, Oil Red O staining, and immunohistochemistry for Adipophilin (Perilipin 2). Transcriptomic profiling was conducted by RNA sequencing (RNA-seq). **Results:** Two mice in the HFD group died during the protocol. Significant weight

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

loss was observed in FR (71.3%) and AN (68.5%) groups compared to controls ($p < 0.01$). Histologically, HFD mice exhibited macrovesicular steatosis, whereas no overt lipid droplets were observed in FR and AN groups by H&E. However, Oil Red O staining revealed microvesicular lipid accumulation in 37.5% of AN mice ($p = 0.054$ vs. FR). Adipophilin immunostaining demonstrated a significantly increased positive area in both AN and HFD groups compared to controls ($p < 0.05$). Serum TG levels were significantly lower in FR and AN groups ($p < 0.05$). No single biochemical marker predicted the histological accumulation of fat droplets alone. Interestingly, within the AN group, mice exhibiting hepatic steatosis had significantly less weight loss than those without steatosis (75% vs. 64%). RNA-seq clustering showed that AN and FR mice grouped similarly, with distinct gene expression profiles from both HFD and Ctr groups. **Conclusion:** We successfully established a murine model of AN-associated microvesicular steatosis. Our findings suggest that conventional serum biochemical markers are insufficient to evaluate the degree of hepatic lipid accumulation in AN. Future studies are warranted to explore the involvement of hepatic autonomic signaling in the unique pathogenesis of fatty liver in AN.

1089 | FUNCTION AND REGULATION OF NONSENSE-MEDIATED MRNA DECAY IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Marcos Jaso Vera[1] Shohei Takaoka[1] Xiangbo Ruan[1], *[1]Johns Hopkins University School of Medicine*

Background: MASH is a severe liver disease that affects 6% of the US adults. There is currently only one FDA-approved medicine for treating MASH with limited effectiveness, indicating a critical need for further understanding of MASH pathology. Nonsense-Mediated mRNA Decay (NMD) plays a crucial role in mammalian development and physiology. In addition to degrading mRNAs with premature termination codons, NMD targets ~10% of physiological mRNAs to promote an appropriate cellular response to environmental changes. Previous studies showed that liver-specific knockout of Upf2, a core component of NMD, leads to disrupted hepatic metabolism and liver damage. However, it is still unknown if and how NMD deficiency contributes to MASH. By analyzing previously existing RNA-seq databases, our lab reported an association between a loss of NMD and changes in mRNA levels during mild fatty liver disease in mice. Additionally, we analyzed a published RNA-seq dataset of human liver patients and found that established NMD targets, including ATF4, PDRG1, and DDIT3, were upregulated in MASH patients. We hypothesize that NMD plays a significant role in the development of fatty liver disease. **Methods:** UPF2 was knocked down in human hepatic stellate cells by using siRNA and lipofectamine as indicated by the supplier. Upf2 fl/fl mice were used for *in vivo* studies by getting hepatocyte-specific knock-outs using a specific adenovirus carrying the Cre gene under the control of a human thyroxine binding globulin (TBG) promoter. RNA-seq databases were analyzed by using an in-house pipeline. qPCR and Western Blot was performed using SYBR-Green and IR dyes, respectively. **Results:** The depletion of UPF2 resulted in upregulation of fibrosis marker genes, including an increase in α-SMA expression. By overlapping genes that are simultaneously upregulated in Upf2Hep-KO mice, MASH diet-fed humanized-liver mice, and MASH patients, we identified a group of hepatic NMD targets, including TNFRSF12A, CXCL10, and PDGFA, that may promote liver damage due to a failure in NMD. Furthermore, we found an increase in RIP3K expression in Upf2Hep-KO mice liver, suggesting a potential pathway for cell death. As we know that protein levels of RIP3K are low in hepatocytes, this mechanism could involve non-parenchymal cells stimulated by the Upf2 absence in the hepatocyte. We aim to find how NMD deficiency contributes to MASH development. Additionally, we will test the therapeutic potential of restoring NMD in mouse and human MASH models. **Conclusion:** NMD is showing to be an essential player in MASH development by tightly regulating the transcript levels of important genes involved in liver fibrosis, like TNFRSF12A, CXCL10 and PDGFA.

1090 | LIVER REGENERATION AND ASSOCIATED METABOLIC BENEFITS FOLLOWING VERTICAL SLEEVE GASTRECTOMY/PARTIAL HEPATECTOMY IN DIET-INDUCED OBESE MICE

Andriy Myronovych[1] Alfor Lewis[1] Mouhamadoul Toure[1] Sabrina Morrison[1] Jacob Abbott[1] Nadejda Bozadjieva-Kramer[1] Randy Seeley[1], *[1]University of Michigan*

Background: Obesity has reached epidemic levels and is associated with severe comorbidities, such as

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

MAFLD and its manifestation MASH. Fatty liver regeneration is impaired in obese mice and humans, and while bariatric surgery is effective in treating severe obesity and its comorbidities (including MASH) its impact on liver regeneration remains unclear. Therefore, we evaluated the effect of vertical sleeve gastrectomy (VSG) on hepatic regeneration and associated metabolic parameters in obese mice. **Methods:** Diet-induced obese mice underwent concomitant VSG and 70% partial hepatectomy (VSG-PH) – a single-event, novel murine surgical model. Other mice underwent Sham, 70% PH or VSG surgeries as stand-alone procedures. Survival rate, body weight and composition dynamics, food intake and glucose regulation were monitored. Plasma samples were collected at 2-week intervals after surgery. Mice were euthanized at 48 hours post-surgery to assess liver regeneration and at 2 months to evaluate metabolic effects. Hepatic steatosis, triglyceride and cholesterol content, and liver regeneration were evaluated after sacrifice. **Results:** VSG-PH mice exhibited a satisfactory survival rate after surgery with comparable metabolic benefits to the VSG group. They consumed less food, lost a significant amount of body weight, reduced body fat mass and improved glucose metabolism compared to Sham and PH groups. Plasma triglyceride levels were improved in the early post-surgery period, while plasma cholesterol levels were consistently low in the VSG-PH group throughout the study (changes not observed in the PH group). Liver injury was significantly reduced in VSG-PH mice compared to Sham and PH mice (as evidenced by the liver injury markers ALT and AST) at early and late post-surgery time points. Hepatic steatosis (NAS Score), liver cholesterol and triglyceride contents were greatly decreased in VSG-PH mice, being similar to VSG but not PH mice. Conversely, successful liver regeneration in the VSG-PH group was comparable with the PH group, as evidenced by liver weight/body weight ratios. However, PH mice did not exhibit any metabolic benefits and regenerated livers with the signs of steatosis. **Conclusion:** Experimental surgery of VSG-PH leads to significantly improved metabolic parameters and culminates in regeneration of a fully functional and healthy residual liver. Overall, our data suggest that weight management therapy is essential for proper morphology and function of regenerated livers in the setting of obesity.

1091 | HEPATOCYTE HEDGEHOG SIGNALING CONTROLS FERROPTOSIS TO PREVENT AGING-RELATED MULTI-ORGAN DYSFUNCTION

Ji Hye Jun[1] Soon-Woo Cho[2] Alan Yao[2] Rajesh Dutta[2] Seh-Hoon Oh[2] Zhi Li[3] Kuo Du[2] David Umbaugh[2] Nanchao Wang3[2] Yirui Xu[2] Jingting Li[2] Lingyan Shi[3] Jen-Tsan Ashley Chi[2] Junjie Yao[2] Anna Mae Diehl[2], [1]Gyeongsang National University 52828, 501 Jinjudaero, Jinju-si, Gyeongnam, Republic of Korea, [2]Duke University, [3]Shu Chien-Gene Lay Department of Bioengineering, University of California, San Diego, California,

Background: Aging increases vulnerability to metabolic dysfunction-associated steatotic liver disease (MASLD) and chronic kidney disease (CKD), yet mechanisms linking liver aging to multi-organ decline are unclear. Hedgehog (Hh) signaling regulates hepatic regenerative capacity and metabolic flexibility. Previously, we reported that aging suppresses the Hh pathway in hepatocytes (Heps). By deleting Smo (a critical Hh pathway component), we proved that disrupting Hh signaling in Heps induced Hep senescence and MASLD. Importantly, in human livers with MASLD, Hep Smo expression decreased as the liver burden of senescent Heps and MASLD severity increased, justifying further research to determine how Smo controls liver aging. **Methods:** We used multi-omics profiling (bulk/single-cell RNA-seq), lipid peroxidation assays, and histopathology to evaluate livers and kidneys of Hep-specific Smo knockout (Smo-KO) mice under chow or choline-deficient high-fat diet (CDAHFD) conditions. Liver perfusion was measured using non-invasive ultrasound localization microscopy (ULM), and lipid unsaturation ratio was quantified using stimulated Raman Scattering (SRS) ratiometric imaging. Iron-dependent lipid peroxidation (ferroptosis) was inhibited using ferrostatin-1 (Fer-1). Findings in mice were validated by analysis of liver RNA seq and plasma O-link proteomic data from MASLD patients. **Results:** Hep-specific Smo deletion induced ferroptotic stress, lipid peroxidation and senescence in young mouse livers. It also disrupted liver and systemic iron homeostasis. More specifically, zone 2 Hep expression of iron regulatory genes was altered and zone 2 Hep expression of the potent vasoconstrictor and renin substrate, angiotensinogen, was increased while Lyve1, a fenestrated liver sinusoidal marker, was decreased in zone 2 liver. These zonally-localized changes were accompanied by decreased liver and renal perfusion and induction of fibrotic steatohepatitis and kidney damage/dysfunction. Treating Smo-KO mice with Fer1 reversed all of this pathology. Analysis of human MASLD cohort data confirmed dysregulation of iron regulatory genes/proteins and revealed increased plasma renin levels in MASLD patients with F3-4 fibrosis. **Conclusion:** Our study reveals a previously unrecognized inter-

1092 | THE EXPRESSION OF FMNL1 IN MONOCYTE-DERIVED MACROPHAGES PROMOTES HEPATIC INFLAMMATION IN MASLD

Zilong Wang[1] Xiaoxiao Wang[1] Huiying Rao[1] Rui Huang[1] Feng Liu[1] Xin AI[1] Ran Fei[1], [1]Peking University Hepatology Institute

Background: Metabolic dysfunction - associated steatotic liver disease (MASLD) is characterized by hepatic steatosis and inflammation, involving the activation of immune cells, particularly macrophages. Fmnl1, a member of the Formin protein family, is implicated in cytoskeletal remodeling and cell migration. This study aimed to explore the role of Fmnl1 in the pathogenesis of MASLD, focusing on its expression in macrophages and its potential regulatory mechanisms. **Methods:** We utilized immunohistochemistry to assess Fmnl1 expression in liver tissues from MASLD patients and a mouse model induced by a methionine-choline deficient (MCD) diet. Multi-color fluorescence immunostaining was employed to identify FMNL1 localization in livers. THP-1 and RAW 264.7 cell lines were treated with oleic acid (OA)/ palmitic acid (PA) and lipopolysaccharide (LPS) to simulate a fatty inflammatory environment. Fmnl1 expression was manipulated using lentiviral-mediated gene knockdown, and F-actin staining with phalloidin was performed to evaluate changes in the cytoskeleton. Transwell assays assessed cell migration capabilities. RNA sequencing and pathway enrichment analysis were conducted on FMNL1 knockdown cells. Additionally, mass spectrometry and co-immunoprecipitation (Co-IP) were performed to explore interactions involving Fmnl1 and Cdc42. A GTP-bound Cdc42 pulldown assay was performed to determine Cdc42 activity by measuring GTP- Cdc42. **Results:** Immunohistochemical analysis revealed increased Fmnl1 expression in MASLD patient liver tissues and MCD mouse models, primarily localized in monocyte-derived macrophages. In THP-1 and RAW 264.7 cells, OA/PA and LPS treatment significantly upregulated Fmnl1 expression. Knockdown of Fmnl1 resulted in decreased actin polymerization, as evidenced by reduced F-actin staining. Transwell assays demonstrated impaired migratory capacity of Fmnl1-deficient macrophages. RNA sequencing revealed enriched pathways related to GTPase activity, and subsequent analysis identified Cdc42 as a regulator of Fmnl1 expression. Cdc42 activity increased in a time-dependent manner following OA/PA and LPS stimulation, correlating with enhanced migratory capabilities in macrophages upon Cdc42 activation. **Conclusion:** Our findings indicate that Fmnl1 plays a crucial role in the pathogenesis of MASLD by promoting the migration of monocyte-derived macrophages into the liver, thereby enhancing inflammation. This process is regulated by Cdc42, linking GTPase activity to FMNL1 expression in response to inflammatory stimulation. Therefore, it is possible that the Fmnl1 signaling pathway is a potential therapeutic target for MASLD.

1093 | ZONAL DYNAMICS OF FIBROSIS PROGRESSION AND REGRESSION IN A MURINE MASLD-HCC MODEL USING AI-BASED COLLAGEN AND STEATOSIS ANALYSIS

Yuyun Song[1] Ke Yin[1] Cong Xu[1] Fei Ran[1] Baiyi Liu[1] Zilong Wang[1] Xin AI[1] Minjun Liao[1] Yayun Ren[2] Kutbuddin Akbary[2] Xiao Teng[2] Wei Wang[3] Qiang Yang[3] Huiying Rao[1] Xiaoxiao Wang[1] Feng Liu[1], [1]Peking University People's Hospital, [2]HistoIndex Pte Ltd., Singapore 117674, Singapore, [3]Hangzhou Choutu Technology Co., Ltd., HangZhou 310052, China

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), including its inflammatory form MASH, can progress to cirrhosis and hepatocellular carcinoma (HCC). Rodent models, particularly those induced by Western diets (WD), are widely used for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

studying MASLD, yet detailed characterization of fibrosis dynamics remains limited. This study leverages Second Harmonic Generation/Two Photon Excitation (SHG/TPE) imaging and artificial intelligence (AI)-based analysis to characterize regional fibrosis progression and regression in a murine MASLD-HCC model. **Methods:** MASLD-associated HCC was induced in mice using a combination of Western diet with fructose (WDF) and intraperitoneal CCl_4 (WD-CCl_4) over 28 weeks, followed by a diet switch to normal diet for 12 weeks. Liver tissues were collected at weeks 0, 8, 16, 28, and 40. Histological evaluation (H&E and picrosirius red staining) and SHG/TPE imaging (Genesis, HistoIndex Pte Ltd, Singapore) were performed. AI-based image analysis quantified steatosis and fibrosis. Statistical comparisons were conducted using one-way ANOVA with Dunnett's post hoc tests, with $p < 0.05$ considered statistically significant. **Results:** By week 28, tumor formation was observed, with 49.59% steatosis area as early as week 8 and remaining at 54.72% in non-tumor tissue at week 28. Collagen deposition progressively increased during induction. Upon diet withdrawal, steatosis rapidly regressed to 13.27% by week 40. However, overall collagen content did not decline significantly; instead, selective regression was observed in fibrous septa and in collagen co-localized to macrosteatotic regions, particularly within lobular and portal areas, suggesting early fibrosis regression occurs preferentially around resolving steatosis. **Conclusion:** SHG/TPE imaging with AI-analysis enables detailed zonal analysis of fibrosis and steatosis dynamics in MASLD murine models. This approach reveals spatial patterns of fibrosis regression and supports optimized selection of in vivo models for preclinical drug development.

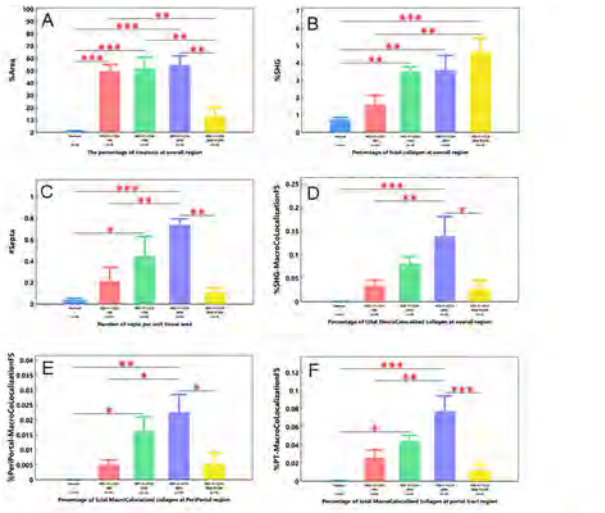

Figure 1: Temporal changes in steatosis and fibrosis in non-tumor regions of the WD-CCl_4 mouse model. Steatosis(A) peaks by week 8 and regresses after diet switch, while overall collagen(B) remains elevated. Notably, fibrosis in septa(C) and areas surrounding macrosteatosis(D,E,F) shows selective regression.

1094 | MESENCHYMAL-DERIVED EXTRACELLULAR VESICLES AS AN EMERGING TOOL FOR THE TREATMENT OF METABOLIC-ASSOCIATED FATTY LIVER DISEASE (MASLD)

Rocío Muñoz Hernández[1] Antonio Gil-Gómez[2] Vanessa Garcia-Fernandez[1] Sheila Gato[1] Angela Rojas[1] Javier De la Peña[3] Patricia Bernal[1] José Borrero de Acuña[3] Rocio Gallego-Duran[1] Isabel Fernandez[1] Douglas Maya-Miles[1] Paloma Carrillo[1] Sara Romero-Otero[1] Javier Ampuero[1] Manuel Romero-Gómez[1], [1]Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universi, [2]nstituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad, [3]Department of Microbiology, University of Seville, Seville, Spain

Background: The burden of MASLD is increasing worldwide and represents a major health concern due to its high prevalence, complexity, heterogeneity, and dynamics, requiring a multitarget therapy apporach. MASLD is characterized by progression to liver cirrhosis, end-stage liver disease, and acute-on-chronic liver failure, with liver transplantation remaining the gold standard of care. We aimed to investigate the therapeutic potential of Mesenchymal-derived extracellular vesicles (MSC-EVs) in MASLD. **Methods:** The MSC-derived EVs were obtained from the supernatant of bone marrow-derived MSC cultures and concentrated using a peristaltic pump and a specialized cassette for extracellular vesicle separation (Pellicon XL Cassette, Biomax 100 kDa). Thereafter, the concentrated sample was subjected to size exclusion chromatography using a column (qEV2, IZON), allowing for the separation of unwanted proteins from the extracellular vesicles, thereby yielding a significantly purer sample. Nano particle tracking analysis (NTA) was used to quantify and determine the EVs diameter. We have conducted a pilot study in an animal model of MASLD (n = 4) (High fat, high carbohydrates, and cholesterol (HFHCC-42% fat, high sucrose, 1.25% cholesterol + glucose/fructose in the drinking water) for 16 weeks and treated with 10^8 EVs in 100µl PBS injected thorough the tail vein, twice a week for 4 weeks. Five animals were included in the control treated with HFHCC for 16 weeks and a control group with chow diet was also included.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Results: As shown in figure A, after MSC-cells culture EVs were extracted and quantify with NTA, $4x10^9$ particles/ml with an average size of 154nm were obtained. Anthropometric data are shown in figure B; no significant changes were observed in absolute body weight, BMI and neither in liver weight, thus demonstrating that the beneficial effects of EVs- treatment could be independent of changes in anthropometric data. After 4 weeks treatment with MSC-EVs, we demonstrated a decrease in fat liver tissue compared to HFHCC mice (Fig 3C). Finally, a significant decrease in TNF-α levels after treatment with EVs was observed after comparing HFHCC group and control group (D). **Conclusion:** EV therapy appears to target hepatic inflammation as its primary mechanism of action, as evidenced by improvements in liver tissue and reductions in systemic inflammation, without significant changes in anthropometric measures.

1095 | HUMAN-SPECIFIC SUPPRESSION OF HEPATIC FATTY ACID CATABOLISM BY RNA-BINDING PROTEIN HUR

Shohei Takaoka[1] Marcos Jaso Vera[1] Xiangbo Ruan[1], [1]Institute for Fundamental Biomedical Research, Johns Hopkins All Children's Hospital

Background: RNA-binding proteins (RBPs) play essential roles in all major steps of RNA processing. Genetic studies in humans and mouse models support that many RBPs are crucial for maintaining homeostasis in key tissues/organs. However, the extent to which the function of RBPs is conserved between humans and mice remains unclear, as RBPs typically bind to non-coding regions of RNA, which are less conserved than coding regions. HuR, an RBP, was recently found to regulate fatty acid catabolism genes in a species-specific manner. **Methods:** We re-analyzed our RNA-seq data from the HuR-knockdown humanized liver mouse model. We performed GO term analysis to assess the impact on gene expression, particularly those involved in fatty acid catabolism. To explore the potential mechanism of species-specific HuR-mediated suppression of fatty acid catabolism-related genes, co-overexpression of HuR and PPARα was performed in cultured human and mouse cells. HMGCS2 was used as a model gene to study mechanisms of regulation. To understand the pathophysiological significance of our findings, published RNA-seq data from human patients with fatty liver disease and diet-induced obesity (DIO) mouse models were re-analyzed. We applied the intron-exon combined RNA-seq analysis pipeline to draw coverage plots of the HMGCS2 gene body and inspect pre-mRNA expression and mature mRNA expression. **Results:** Knockdown of human HuR in human hepatocytes led to broad upregulation of fatty acid catabolism genes, an effect not seen with mouse HuR. HuR suppressed PPARα-induced expression of fatty acid catabolism genes in human cells but not in mouse cells. This suppression was independent of PPARα's expression or localization and unrelated to mRNA stability or promoter activity. Instead, HuR inhibited pre-mRNA processing of genes like HMGCS2, leading to intron accumulation. Overexpression of HuR blocked, while knockdown sensitized, the response to PPARα agonists. Analysis of RNA-seq data revealed impaired HMGCS2 pre-mRNA processing in human patients with fatty liver disease, but not in DIO mouse models. **Conclusion:** HuR suppresses fatty acid catabolism gene expression in a human-specific manner by inhibiting pre-mRNA processing. This may help explain the reduced efficacy of PPARα agonists in treating human fatty liver disease compared to mouse models, highlighting the importance of considering species-specific regulatory mechanisms in translational research.

1096 | MECHANISTIC ROLE OF LATERAL HABENULAR NUCLEUS 5-HT_7 RECEPTORS IN LIVER–BRAIN CROSSTALK UNDERLYING NAFLD-ASSOCIATED DEPRESSION

Yuming Zhang[1] Jinyao Su[1] SongYan Guo[1], [1]Shaanxi Provincial People's Hospital

Background: Depression is increasingly recognized as a common yet underexplored comorbidity in individuals with non-alcoholic fatty liver disease (NAFLD). While the liver–brain axis has been implicated, the precise neurocircuitry

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

remains poorly defined. The lateral habenular nucleus (LHb), an epithalamic structure critical for processing aversive and reward-related signals, is hyperactive in depression and densely innervated by serotonergic projections. Among serotonin receptors, 5-HT_7 plays a pivotal role in mood regulation. Building on our previous work in Parkinsonian models implicating LHb 5-HT_7 receptors signaling in emotional dysregulation, we examined its involvement in NAFLD-associated depressive phenotypes. **Methods:** A NAFLD model was induced in male Sprague–Dawley rats through an 8-week high-fat diet (60% fat, 25.9% carbohydrate, 14.1% protein). Animals underwent behavioral testing (sucrose preference and forced swim tests), followed by targeted intra-LHb microinjection of the 5-HT_7 receptors agonist AS19 or antagonist SB269970. In vivo electrophysiological recordings, monoamine assays across key limbic regions (medial prefrontal cortex, amygdala, habenula, ventral hippocampus), and immunofluorescence imaging were used to dissect underlying mechanisms. **Results:** NAFLD rats showed clear anhedonia and behavioral despair. Activation of LHb 5-HT_7 receptors by AS19 aggravated depressive-like behaviors, whereas blockade with SB269970 produced robust antidepressant effects in both NAFLD and control rats. Neurochemical analyses revealed significant alterations in dopamine and noradrenaline levels across limbic circuits, in a drug- and disease-dependent manner. Electrophysiological recordings demonstrated that AS19 enhanced the firing rate of LHb glutamatergic neurons, while SB269970 suppressed neuronal activity. Notably, both effects were more sustained in NAFLD rats. Interestingly, 5-HT_7 receptor expression and colocalization with LHb glutamatergic neurons remained unchanged. **Conclusion:** Our findings identify a novel mechanism by which NAFLD sensitizes LHb 5-HT_7 receptors signaling, enhancing glutamatergic excitability and disrupting monoaminergic tone in mood-related brain regions. These results underscore the LHb 5-HT_7 receptors as a promising therapeutic target for metabolic syndrome–associated depression, bridging hepatic dysfunction and central affective regulation.

1097 | HEPATIC EXTRACELLULAR VESICLES SUPPRESS MACROPHAGE IMMUNE RESPONSE IN AN OLEATE- AND CERS6-DEPENDENT MANNER

Joseph Dempsey[1] Carole Smith[1] Julia Harkin[1] Samira Abdirahim[1] Rotonya Carr[2], [1]University of Washington, [2]University of Washington Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) can progress from steatosis to metabolic dysfunction-associated steatohepatitis (MASH)—the more lipotoxic, inflammatory phenotype. The drivers of this transition remain incompletely understood. Ceramide synthase 6 (CERS6) is a ceramide synthetic enzyme that produces long-chain ceramides (primarily C16:0) which we and others have linked to lipotoxicity and inflammation. C16:0 ceramides are increased in MASLD patients and are present in hepatocyte-derived extracellular vesicles (EVs) in murine and human MASLD. We hypothesize that hepatocellular accumulation of CERS6-derived C16:0 ceramides promotes the steatosis to MASH transition through C16:0-endowed hepatocyte EVs and subsequent activation of hepatic macrophages. **Methods:** Wild-type (WT) and CERS6 knockout (KO) HepG2 cells were exposed to EV-free media with oleate (0 or 1 mM) for 48 hours (WT-control, WT-oleate, KO-control, and KO-oleate). Lipid droplets were quantified by in-cell western using immunofluorescent LipidSpot488. HepG2-derived EVs were isolated using the ExoQuick-TC kit, and EV particle concentration and size was evaluated by NanoSight. For EV-induced immune response, PMA-differentiated THP-1 cells were exposed to EVs for 6 hours. THP-1 and HepG2 cells were isolated in Qiazol for RNA expression by RT-qPCR and protein expression by western blot. **Results:** WT and CERS6-KO cells exposed to oleate had more lipid droplets and higher perilipin 2 protein expression versus normal media. The mean number of EV particles isolated from the media of oleate-exposed WT and KO cells increased 1.8 and 1.5 times, respectively, versus controls. Mean particle size of KO-control EVs increased from 134.5 nm to 148 nm compared to WT-control EVs. Particle size distribution was right-skewed in an oleate- and CERS6-dependent manner, with KO-oleate EVs having a mean size of 170.5 nm. Differentiated THP-1 cells exposed to EVs from WT-oleate, KO-control, or KO-oleate showed decreased RNA expression of the macrophage inflammatory markers CXCL1, IL6, IL1β, and IL2β compared to cells exposed to WT-control EVs. **Conclusion:** EVs from CERS6-deficient cells and WT cells incubated in oleate elicited a reduced inflammatory response in macrophages, highlighting a potential therapeutic target in MASLD progression. This study suggests that CERS6 contributes to the progression from steatosis to MASH by modulating the size and inflammatory potential of hepatocyte-derived EVs.

1098 | NOVEL HUMANIZED IMMUNE SYSTEM MOUSE MODELS FOR LIVER FIBROSIS AND MASH

Dan Georgess[1] Clothilde Philouze[1] Omayra Martin-Rodriguez[1] Anaïs Meynet-Cordonnier[1] Sebastien Tabruyn[1], [1]Transcure Bioservices

Background: The development of predictive preclinical models that recapitulate human-relevant, targetable biology is critical to accelerating drug discovery. Here, we present two distinct humanized mouse models for liver fibrosis and MASH, designed to evaluate therapeutics targeting the human immune drivers of liver fibrosis, inflammation, and steatosis. **Methods:** CD34+ HSC-humanized NCG mice (HIS-NCG) were subjected to one of two disease induction protocols: (1) a 23-day course of carbon tetrachloride (CCl_4) treatment, or (2) a 14-day high-fat methionine- and choline-deficient (HFMCD) diet. **Results:** Both protocols induced rapid (within 2 weeks) health deterioration and significant liver injury, evidenced by elevated ALT levels compared to controls. However, the resultant liver phenotypes differed substantially. CCl_4 treatment induced severe fibrosis (88% of mice with either bridging F3 fibrosis or cirrhosis) without accompanying steatosis or notable macrophage infiltration. In contrast, the HFMCD diet led to a more comprehensive MASH phenotype, including a NAFLD activity score (NAS) of 6, advanced steatosis, F1 fibrosis, marked infiltration of human $CD68^+$ macrophages, and elevated circulating LGALS3BP further confirming liver injury, fibrosis, and inflammation. **Conclusion:** In summary, we describe two robust and reproducible humanized mouse models tailored for the rapid evaluation of human immune-targeting or cross-reactive therapeutic candidates: the HFMCD HIS-NCG model for MASH and the CCl_4 HIS-NCG model for advanced fibrosis. Furthermore, dual-humanized models (human immune system and liver) are also available to support studies of combination therapies targeting both immunity and metabolism. These next-generation mouse models hold significant promise for transforming the therapeutic landscape in MASH and infectious hepatitis.

1099 | SALIDROSIDE ALLEVIATES MASH THROUGH PPARΓ-MEDIATED INFLAMMATORY SIGNALING PATHWAY

Jun Zhang[1], [1]Ningbo No.2 Hospital

Background: Metabolic dysfunction-associated steatohepatitis (MASH), a progressive stage of metabolic associated fatty liver disease (MAFLD), lacks effective therapies. Salidroside, a bioactive compound from Rhodiola rosea, exhibits anti-inflammatory and metabolic regulatory properties, but its mechanism in MASH remains unclear. **Methods:** A choline-deficient L-amino acid-defined high-fat diet (CDAHFD)-induced MASH mouse model was used. Mice received salidroside (25 or 50 mg/kg) or pioglitazone (10 mg/kg) for four weeks. PPARγ inhibitor GW9662 was co-administered to validate pathway specificity. Multi-omics analyses (transcriptomics, metabolomics) identified key pathways. Network pharmacology, molecular docking, and Western blotting were employed to explore targets and mechanisms. **Results:** Salidroside reduced hepatic lipid deposition, serum ALT/AST levels, and inflammatory cytokines (IL-1β, IL-6, TNFα) in MASH mice. Transcriptomics and metabolomics revealed PPAR signaling as the most enriched pathway. Salidroside activated PPARγ, suppressed NF-κB phosphorylation, and downregulated pro-inflammatory factors. Co-treatment with GW9662 abolished these effects, confirming PPARγ dependency. Molecular docking showed strong binding affinity between salidroside and PPARγ. **Conclusion:** Salidroside ameliorates MASH by activating PPARγ, thereby inhibiting NF-κB-mediated inflammation and hepatic lipid accumulation. This study highlights PPARγ/NF-κB signaling as a critical target for salidroside, offering a foundation for developing natural therapies against MASH.

1100 | COMBINED EFFECT OF ATORVASTATIN AND AMBRISENTAN ON THE HEMODYNAMIC ALTERATIONS AND LIVER FIBROSIS IN A TRANSLATIONAL RAT MODEL OF MASLD WITH ADVANCED FIBROSIS

Maria de la Serra Cusidó Sabidó[1] Imma Raurell[2] Núria Juan Benítez[1] María Martínez Gómez[3] Sophia Christina Parks[4] Juan M Pericàs[5] Maria Martell[5] Joan Genescà[5], [1]Liver Disease Group, VHIR; UAB, [2]Liver Disease Group, VHIR; Liver Unit, VHUH; CIBERehd, [3]Liver Disease Group, VHIR; UAB; CIBERehd, [4]Liver Disease Group, VHIR, [5]Liver Disease Group, VHIR; Liver Unit, VHUH; CIBERehd; UAB

Background: Metabolic-dysfunction Associated Steatotic Liver Disease (MASLD) is characterized by hepatic steatosis, which can progress to inflammation, fibrosis, and portal hypertension (PH). Despite its increasing clinical burden, therapeutic options remain limited due to the lack of translational animal models that fully recapitulate the human disease spectrum. Previous work from our group developed a non-fibrotic NASH model, which, when

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

treated with Atorvastatin (Ato) and Ambrisentan (Amb) reduced steatohepatitis and PH. Considering the results in the NASH model, in this study we evaluate the combined effect of Ato and Amb on liver fibrosis, endothelial dysfunction, and hemodynamic alterations in a recently developed translational model of MASLD with advanced fibrosis. **Methods:** At the end of the model, liver hemodynamic was assessed. The samples were used for histological evaluation (H&E and Sirius Red), and gene and protein analysis for fibrosis, insulin signaling and endothelial function (Fig. 1). **Results:** MASLD rats exhibited increased AST/ALT, PH, insulin resistance, steatohepatitis and advanced fibrosis, corresponding to our known model features. Neither Ato nor Amb alone or combined reduced body weight or reverted insulin resistance. Endothelial dysfunction was partially reversed by AtoAmb, P-Enos and KLF2 were restored, yet P-AKT remained suppressed, indicating limited sinusoidal recovery. Markedly, AtoAmb led to fibrosis regression, evidenced by 1) decreased histological fibrosis stage, 2) reduced collagen deposition (Fig. 1), 3) downregulation of Col1a1, αSMA to near-control levels, and 4) lower levels of metalloprotease inhibitor TIMP1. However, severe steatosis and PH remained largely unaffected. Correlation analyses showed poor association between portal pressure and fibrosis, but a stronger correlation between portal pressure and steatosis severity, suggesting steatosis as the main driver to sinusoidal compression and so PH. **Conclusion:** The combination of Ato and Amb demonstrated a synergistic effect reversing liver fibrosis in a translational rat model of MASLD but failed to reduce PH, likely due to persistent severe steatosis and sinusoidal compression. These findings highlight the dissociation between fibrosis and portal pressure in advanced MASLD and emphasize the need for multi-targeted strategies addressing both lipid accumulation and fibrosis for effective PH management.

1101 | EFFECTS OF DIETARY PATTERNS ON METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A STUDY IN MORBIDLY OBESE RATS UNDERGOING BARIATRIC SURGERY

Wei-Yu Kao[1] Chin-Ying Wu[2] Chen-Yu Liao[3] Weu Wang[4] Ching-Wen Chang[3] Chi-Long Chen[5] Chun-Chao Chang[6] Shih-Yi Huang[3], [1]Taipei Medical University Hospital, [2]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan, [3]Graduate Institute of Metabolism and Obesity Sciences, Taipei Medical University, Taipei, Taiwan, [4]Division of Digestive Surgery, Department of Surgery, Taipei Medical University Hospital, Taipei, [5]Department of Pathology, Taipei Medical University Hospital, Taipei, Taiwan, [6]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Taipei Medical Univ

Background: The global rise in metabolic syndrome, obesity, and diabetes has contributed to the increased prevalence of non-alcoholic fatty liver disease (NAFLD). Obesity, characterized by excessive fat accumulation, significantly contributes to NAFLD, posing a major public health concern due to its adverse effects on overall health. Treatment strategies for obesity include lifestyle modification of diets and exercise, pharmacotherapy, and bariatric surgery, with surgery being particularly effective for long-term weight control in morbidly obese patients. This study aims to model NAFLD in morbidly obese rats and evaluate the effects of bariatric surgery, dietary changes, and exercise on liver pathology and lipid metabolism. **Methods:** A total of 102 male Wistar rats (8 weeks old) with morbid obesity and fatty liver were used. After 14 weeks of diet induction, the rats underwent sleeve gastrectomy. Following surgery, they were subjected to 18 weeks of calorie-restricted diets (CRD), non-ketogenic low-carbohydrate diets (LCD). Blood and liver samples were collected every 6 week period for analysis, including biochemical values and inflammation-related blood factors. **Results:** At 18 weeks post-surgery, body weight in the high-fat diet (HFD) group continued to increase and remained significantly higher than in all other groups. The CRD group showed significantly lower body weight compared to the LCD group. After a 14-week diet induction for morbid obesity and fatty liver, liver weight, perirenal fat weight, and epididymal fat weight were significantly higher in the HFD group compared to the control group ($p < 0.05$ for all). At

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

18 weeks post-gastrectomy, no significant differences in liver weight were observed between the groups. In terms of blood biochemistry, after 14 weeks of diet induction, serum SGOT and SGPT levels were significantly higher in the HFD group compared to the control group ($p < 0.05$ for both). At 18 weeks post-surgery, SGOT, SGPT, and triglyceride (TG) levels in the HFD group were significantly lower than those at week 0 post-surgery ($p < 0.05$ for all). Histopathological liver analysis revealed that the HFD induced hepatic lipid accumulation and resulted in a significantly higher NAFLD score than the control group. Sleeve gastrectomy and dietary interventions reduced both lipid accumulation and NAFLD scores. **Conclusion:** Sleeve gastrectomy improved liver fat and NAFLD-related biochemical markers in rat models. Among the dietary interventions, the calorie-restricted diet was more effective in reducing body weight and visceral fat compared to the non-ketogenic low-carbohydrate diet.

1102 | MACROPHAGE RECEPTOR LRP1 MEDIATES NECROPTOTIC HEPATOCYTE ENGULFMENT AND SUPPRESSES A PRO-FIBROTIC PATHWAY INVOLVING HEPATOCYTE TAZ DOWNREGULATION IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Hongxue Shi[1] Ira Tabas[2] Xiaobo Wang[1] Eui Jung Jung[1] Saheli Chowdhury[1], [1]Columbia University Irving Medical Center, [2]Columbia University

Background: MASH is an advanced stage of fatty liver disease and the leading cause of human chronic liver disease. Necroptosis in hepatocytes is a key feature during MASH progression, and improving necroptotic hepatocyte (necHC) engulfment by liver macrophage dampens MASH progression. However, the receptor in liver macrophage for recognizing and binding necHCs and the mechanism underlying the suppressed hepatic stellate cell activation by efferocytic macrophage is unknown. This study is focused on investigating the crucial role of the liver macrophage receptor LRP1 in the clearance of necHCs-mediated lowering hepatocyte TAZ expression during MASH progression. **Methods:** LRP1 expression was assayed in liver tissue sections obtained from humans and mice with normal and MASH. The necHC uptake by using siRNA-LRP1 in liver macrophage was assayed. For mouse MASH experimental mode, male C57BL/6J mice were fed either a high-fat choline-deficient L-amino-defined (HF-CDAA) diet for 8 weeks or a fructose-palmitate-cholesterol (FPC) diet for 16 weeks. For all mouse models, causation was tested by liver macrophage-Lrp1knockout mice, and hepatocyte TAZ knockout mice, followed by assessment of necHC uptake by liver macrophages, TAZ expression, and MASH fibrosis. For ex vivo studies, the engulfment of mouse necHCs by mouse liver macrophages and hepatic stellate cell activation from conditioned media transfer experiment were assayed. **Results:** We have shown improved necHC clearance by deleting macrophage Sirpα expression, associated with decreased liver pro-fibrotic factor TAZ expression in the HF-CDAA diet-fed MASH mice. Furthermore, down-regulation of liver TAZ expression was found in anti-CD47 or anti-SIRPα neutralization antibody-treated FPC diet-fed MASH mice. The conditioned media from necHCs efferoytotic macrophages decreased TAZ expression in AML12 cells ex vivo. Most importantly, liver hepatocyte TAZ deficiency did not further lower TAZ expression and hepatic fibrosis when administration of anti-SIRPα neutralization antibody in the HF-CDAA diet-fed MASH mice. Increased liver macrophage LRP1 expression was shown in human and mouse MASH liver. Treated with scramble RNA did not affect necHC uptake, while siRNA-Lrp1 treatment decreased necHC engulfment in the presence of anti- SIRPα by liver macrophage ex vivo. The improved necHC engulfment by liver macrophage was reversed in anti-SIRPα treated HF-CDAA diet-fed MASH mice, associated with increased liver fibrosis. **Conclusion:** Increased liver macrophage LRP1 expression is a compensatory mechanism for facilitating necHC engulfment when do-not-eat-me molecules exist. Down-regulation of hepatocyte TAZ expression contributes to the lower liver fibrosis effects when improving necHC clearance by liver macrophage in MASH diet-fed mice. These findings define a new mechanism contributing to MASH progression with potential therapeutic implications.

1103 | FORMATION AND REGULATION OF A HEPATIC LIPOGENIC METABOLON

Xiaotong Zhu[1] Chaiwan Kim[1] Jay Horton[1], [1]UT Southwestern Medical Center

Background: Elevated rates of *de novo* hepatic lipogenesis (DNL), which converts acetyl-CoA into fatty acids (FAs), significantly contributes to hepatic

triglyceride (TG) accumulation in metabolic dysfunction-associated fatty liver disease (MAFLD). Inhibitors of FA synthesis are in various stages of clinical development for the treatment of MAFLD. Here, we further investigate a post-transcriptional mechanism that regulates FA synthesis and that might contribute to the development of MASLD. **Methods:** Immunofluorescence, electron microscopy (EM), and cellular fractionation were used to localize proteins that synthesize FAs and TGs: ATP-citrate lyase (ACL), acyl-CoA synthetase short-chain family member 2 (ACSS2), (acetyl-CoA carboxylase 1) ACC1, fatty acid synthase (FAS), MIG12, Spot 14 (S14), and glycerol-3-phosphate acyltransferase 1 (GPAM). Protein–protein interactions were assessed via ACC1 immunoprecipitation (IP) and sucrose gradient ultracentrifugation. Blue native PAGE evaluated ACC1 polymerization of primary hepatocytes. Enzymatic assays using liver lysates and recombinant proteins were used to measure lipid synthesis under different metabolic states. **Results:** Under anabolic conditions, such as refeeding or insulin treatment, immunoprecipitation of ACC1 co-immunoprecipitates the additional key enzymes to synthesize FAs and TGs (ACL, ACSS2, FAS, MIG12, S14, and GPAM). The individual enzymatic activities of these lipogenic proteins are also enhanced under these conditions as is overall FA and TG synthesis. Immunofluorescence and electron microscopy reveal that this metabolon localizes around lipid droplets (LDs) and at the mitochondria-LD interface in the anabolic state, facilitating efficient substrate channeling through the lipid synthesis pathway. **Conclusion:** Our findings support the existence of a lipogenic metabolon that assembles under anabolic states to coordinate FA and TG synthesis. This spatially organized, post-translational mechanism enhances metabolic efficiency and may serve as a novel therapeutic target in MAFLD.

1104 | NEUTROPHIL EXTRACELLULAR TRAPS DRIVE KUPFFER CELL-MEDIATED FIBROGENESIS IN MASH BY REPRESSING IRG1

Yiyu Zhang[1] Songhan Pang[1] Amelia Bergeron[1] Hongji Zhang[1] Allan Tsung[1], [1]University of Virginia

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a severe form of metabolic dysfunction-associated steatotic liver disease (MASLD) marked by immune activation and fibrosis, with the potential to progress to cirrhosis and hepatocellular carcinoma. While Resmetirom was recently approved for MASLD, its efficacy in patients with liver fibrosis remains limited and perioperative risks often delay surgical interventions in MASH-fibrosis, underscoring the need for new therapeutic strategies. Neutrophil extracellular traps (NETs)—web-like chromatin structures released by neutrophils—exacerbate liver inflammation and fibrosis, while we have shown that NETs regulate the inflammatory microenvironment to drive MASH-fibrosis, the underlying mechanism remains unclear. Kupffer cells (KCs), as liver-resident macrophages, are central to immune responses and fibrogenesis in MASH, yet their mechanism remains incompletely understood. This study investigates how NETs modulate KC function to drive fibrosis in MASH. **Methods:** MASH was induced in C57BL/6 mice by Western diet (WD) feeding for 40 weeks. NET was inhibited using neutrophil-specific Pad4 knockout (Pad4$^{fl/fl}$ MRP8-Cre) or DNase I treatment (10 mg/kg I.P. 5x/week). Liver fibrosis was assessed via Sirius Red and Masson's trichrome staining. Hepatic CD45+ leukocytes were analyzed by single-cell RNA sequencing (scRNA-seq). KC-specific IRG1 expression was validated via western blot. **Results:** WD-fed mice developed significant hepatic fibrosis, which was markedly reduced by NET inhibition. scRNA-seq revealed broad immune remodeling in MASH liver, with KC displaying one of the most prominent transcriptional changes, characterized by pro-inflammatory and pro-fibrogenic gene expression. Neutrophil-Kupffer cell interactions were significantly elevated compared to other immune cell types. Expression of immune-responsive gene 1 protein (IRG1), a key regulator of KC metabolic reprogramming, was suppressed in KCs during MASH-fibrosis but restored upon NET inhibition. **Conclusion:** NETs promote pro-fibrogenic reprogramming of Kupffer cells in MASH by downregulating IRG1 expression. Targeting NET-KC interactions may represent a

1105 | KAHWEOL ATTENUATES WESTERN DIET-INDUCED HEPATIC STEATOSIS BY SUPPRESSING FATTY ACID SYNTHASE

Byoung Kuk Jang[1] Hye Young Seo[1] Ji Yeon Park[1] Jaeseok Hwang[2] Mi Kyung Kim[1], [1]Keimyung University School of Medicine, [2]Keimyung university

Background: Hepatic steatosis is a key feature of metabolic dysfunction-associated steatotic liver disease (MASLD) and is exacerbated by a Western diet (WD), leading to metabolic dysregulation, inflammation, and fibrosis. Our previous research demonstrated that kahweol, a diterpene found in unfiltered coffee, exhibits protective effects against liver inflammation, fibrosis, and hepatocellular carcinoma (HCC). This study investigates the potential role of kahweol in attenuating WD-induced hepatic steatosis and its underlying mechanisms. **Methods:** C57BL/6 mice were fed a chow diet, WD, or WD supplemented with kahweol (40 mg/kg) for 16 weeks. Metabolic parameters, including body weight, liver function markers, lipid profile, and glucose metabolism, were assessed. Hepatic steatosis, inflammation and fibrosis were evaluated using histological and molecular analyses, including real-time RT-PCR and Western blotting. RNA sequencing was performed to identify differentially expressed genes and enriched signaling pathways in response to kahweol treatment. **Results:** WD significantly increased body weight, impaired glucose tolerance, and elevated serum AST and ALT levels, indicating liver damage. Kahweol treatment ameliorated these effects by improving glucose tolerance and reducing liver enzyme levels. In addition, WD upregulated the expression of lipogenic genes (FASN, SREBP-1c, PPARγ), inflammatory markers (F4/80, TNFα, IL-1β, and IL-6), and fibrosis markers (collagen, α-SMA, and PAI-1) in the liver, whereas Kahweol treatment significantly downregulated these genes. These results were consistent with the RNA-seq analysis, which further confirmed that Kahweol inhibited lipogenesis by suppressing the expression of key lipogenic genes, including FASN and PPARγ. **Conclusion:** These results suggest that Kahweol alleviates WD-induced hepatic lipid accumulation, inflammation, and fibrosis by suppressing adipogenic genes such as FASN and modulating PPAR signaling. This study provides new insights into the potential use of Kahweol as a therapeutic candidate for MASLD.

1106 | MODELING METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS IN HUMAN LIVER MICROPHYSIOGICAL SYSTEMS FOR CLINICAL PREDICTION

Rachelle Baun[1] Nathan Sorensen[1] Dennis McDuffie[1] Crystal Yuri Oh[1] Dan Sazer[1] Hani Jouihan[2] Damien Demozay[2] Emma Henriksson Kraft[2] Helena Lykkegaard[2] Sara Toftegaard Hjuler[2], [1]Novo Nordisk, [2]Novo Nordisk, Inc.

Background: Metabolic Dysfunction-Associated Steatohepatitis (MASH) is an advanced form of Metabolic dysfunction-Associated steatotic Liver Disease (MASLD) and is strongly linked to obesity and the metabolic syndrome [Dufour et al., 2022]. There are currently no approved treatments for MASH due to the lack of efficacy in the clinical trials which can be attributed to the complexity of disease, which involves lipo-toxicity, insulin resistance, inflammation, and fibrosis. Furthermore, the lack of relevant non-invasive biomarkers makes the approval path difficult. Animal models of MASH, such as high-fat diet and ob/ob mouse models, develop metabolic syndrome and steatosis but lack certain human inflammatory hallmarks as well as advanced fibrosis progression characteristic of MASH in the human. Thus, the aim of this research is to recreate a human MASH model using a liver micro physiological system for clinical prediction of compound efficacy and biomarker discovery and validation. **Methods:** Using the CN Bio Liver Chip platform [Kostrzewski et al., 2017], we are able to create a human, 3D model of MASH, incorporating human hepatocytes, Kupffer and stellate cells from healthy donors. Culture conditions for healthy and MASH (elevated glucose, insulin, fatty acids, and +/- TGFb) were identified for culture medium, stellate cell propagation, and seeding methods. Endpoints consisted of general liver function (albumin production, CYP3A activity, glucose output, intracellular triglyceride formation and secretion), cytokine expression (pro-inflammatory markers associated with liver fibrosis), and collagen secretion (indicative of fibrosis). Tool compounds, such as Activin receptor-like kinase 5 inhibitor (ALK5i), were used to test against MASH culture conditions. Transcriptomics analysis was performed to understand pathways affected by MASH culture conditions and effects of tool compound perturbations. **Results:** Liver

Chips cultured in MASH medium had 2-3 fold lower CYP3A activity compared to those treated with ALK5i. Evaluation of mRNA expression revealed that fibrotic makers, aSMA and collagen 1 were significantly down regulated with ALK5i treatment; and more so in the TGFß treated MASH conditions. It was confirmed via western that ALK5i treatment significantly decreased aSMA. Alk5i was able to inhibit pro-collagen 1 secretion in both +/- TGFß MASH conditions. For recapitulation of inflammatory cytokine release, Kupffer cell response was indicated by high expression of IL-6, IL-1ß, and IL-10 at earlier culture times. **Conclusion:** MASH can be modelled in vitro with relevant liver cell types to help us recapitulate the disease progression over time and to understand the roles of the different cell types in this disease progression.

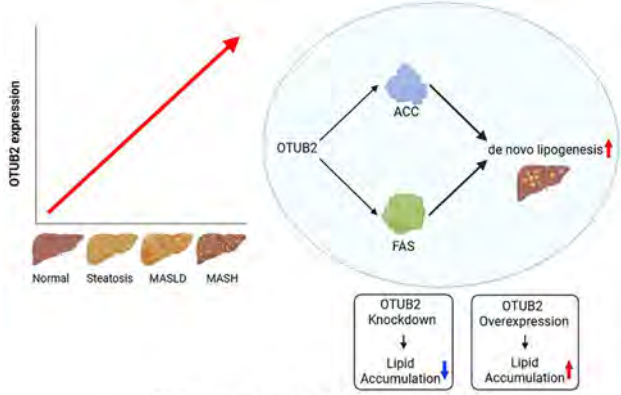
1107 | ROLE OF OTUB2 IN REGULATING HEPATIC LIPID METABOLISM DURING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PROGRESSION

Yeongmin Kim[1] Soyeon Shin[1] Chahyeon Yun[1] Chang-Myung Oh[1], [1]Gwangju Institute of Science and Technology(GIST)

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an advanced chronic liver disease characterized by excessive hepatic lipid accumulation and metabolic imbalance. Increasing evidence suggests that disruptions in proteostasis, particularly involving deubiquitinase activity, play a critical role in the progression of metabolic liver diseases. Among deubiquitinases, Otub2 has emerged as a key regulator of cellular processes including protein stability, signal transduction, and metabolic regulation. Although Otub2's functions have been studied in cancer and immune responses, its role in hepatic lipid metabolism and MASLD progression remains largely unknown. Elucidating Otub2's involvement could provide valuable insights into molecular mechanisms driving MASLD and reveal new therapeutic targets. **Methods:** Published RNA-seq datasets from MASLD patients were analyzed to evaluate changes in Otub2 expression during disease progression. The association between Otub2 expression and liver steatosis was examined using H&E-stained human liver histology from the GTEx project. To explore cell-type–specific changes in Otub2, mice were fed a high-fat diet for 16 weeks, after which hepatic parenchymal and non-parenchymal cells were isolated for expression analysis. Functional studies in hepatocytes involved siRNA-mediated knockdown and overexpression of Otub2. Lipid accumulation and expression of enzymes related to de novo lipogenesis (FAS, ACC) were assessed by Oil Red O staining and Western blot analysis. **Results:** Otub2 expression showed a progressive and significant increase correlating closely with MASLD stages. Histological examination of liver tissues from GTEx patients with elevated Otub2 revealed pronounced hepatic steatosis characterized by extensive lipid droplet accumulation in H&E-stained sections. In a murine high-fat diet model, Otub2 was broadly upregulated in both hepatic parenchymal and non-parenchymal cells. Functional experiments showed that siRNA-mediated knockdown of Otub2 in hepatocytes substantially attenuated palmitic acid–induced lipid accumulation, accompanied by marked downregulation of key lipogenic enzymes, fatty acid synthase (FAS) and acetyl-CoA carboxylase (ACC). Concurrently, genes involved in fatty acid oxidation (FAO) pathways were significantly upregulated, suggesting a metabolic shift favoring lipid catabolism. In contrast, overexpression of Otub2 led to enhanced lipid accumulation, increased expression of lipogenic enzymes, and decreased expression of FAO-related genes. **Conclusion:** Otub2 is pivotal in maintaining hepatic lipid homeostasis during MASLD by coordinately regulating lipid synthesis and oxidation. Targeting Otub2 may offer a promising therapeutic approach for MASLD, and further investigation of its regulatory network could advance understanding of metabolic liver disease pathogenesis.



OTUB2 promotes hepatic lipid accumulation by upregulating ACC and FAS during MASLD progression

1108 | BENEFICIAL EFFECTS OF MILK-DERIVED EXTRACELLULAR VESICLES ON LIVER FIBROSIS PROGRESSION BY RESTORING INTESTINAL BARRIER INTEGRITY

Shinya Sato[1] NORIHISA NISHIMURA[1] Kosuke Kaji[1] Tadashi Namisaki[1] Hitoshi Yoshiji[1], [1]Nara Medical University

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) has emerged as the most prevalent chronic liver disease, leading to metabolic dysfunction associated steatohepatitis (MASH), cirrhosis, and hepatocellular carcinoma (HCC). However, no treatment for MASH-related fibrosis is available for clinical use. Extracellular vehicles (EVs) are bilayer membrane vesicles released from various cells into the extracellular space, participating in multiple life processes. Recent studies have indicated that bovine milk-derived EVs (B-mEVs) suppress inflammation, have anti-tumor effects, and protect the intestinal barrier in an *in vivo* model. Whether EVs from bovine milk exert a beneficial effect against MASH is worth investigating. We explored the effect of B-mEVs on MASH-related liver fibrosis by modulating the gut barrier function. **Methods:** MASH-related liver fibrosis was induced in female C57BL/6J mice by feeding them a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for eight weeks. B-mEVs (1.2 mg/kg) were orally administered every two days for four weeks. Seven-week-old female C57BL/6J mice were randomly divided into four groups and treated for 12 weeks as follows, n = 5 for each; i)normal chow with vehicle; ii) normal chow with B-mEVs; iii)CDAHFD diet with vehicle; iv) CDAHFD diet with B-mEVs. The mice were then sacrificed for histological analyses to assess the effect of B-mEVs on steatohepatitis and fibrosis. Intestinal barrier integrity was also evaluated by the intestinal permeability using FITC-dextran and immunohistochemistry of tight junction proteins (TJPs). The effect of B-mEVs on the Caco-2 cell line barrier function was similarly evaluated *in vitro* using the permeability assay. **Results:** B-mEVs significantly suppressed macrophage expansion, proinflammatory responses, and liver fibrosis in CDAHFD-fed mice by blocking hepatic translocation of lipopolysaccharide (LPS) and activating toll-like receptor (TLR) 4 signaling. Moreover, B-mEVs improved intestinal permeability by restoring TJPs like ZO-1, Occludin, and Claudin-2. B-mEVs also directly suppressed LPS-induced barrier dysfunction and TJP depletion in Caco-2 cells. **Conclusion:** B-mEVs reduced MASH-related fibrosis by inhibiting lipid accumulation and macrophage expansion and suppressing LPS/TLR4/NF-κB-mediated inflammatory responses by restoring intestinal barrier function.

1109 | LOBEGLITAZONE COMBINED WITH HGF ALLEVIATES FFAS-INDUCED INTRACELLULAR LIPID ACCUMULATION BY MODULATING MITOCHONDRIAL METABOLISM IN HEPG2 CELLS

Jeayeon Park[1] Yun Bin Lee[1], [1]Seoul National University Hospital

Background: Lobeglitazone, a thiazolidinedione antidiabetic agent, predominantly activates peroxisome proliferator-activated receptor gamma (PPARγ) and has shown efficacy in improving insulin resistance and hepatic steatosis. Hepatocyte growth factor (HGF) plays roles in liver regeneration and inflammation; however, its involvement in hepatic steatosis is not well understood. In this study, we investigated the effects of lobeglitazone and HGF on free fatty acids (FFAs)-induced hepatic steatosis in HepG2 cells and explored the underlying mechanisms. **Methods:** HepG2 cells were treated with FFAs to induce intracellular lipid accumulation, followed by treatment with lobeglitazone, HGF, or their combination. Intracellular lipid accumulation was assessed by Oil Red O (ORO) staining. Mitochondrial function was evaluated using MitoTracker fluorescence staining, while the expression of mitochondrial function-related genes and proteins was analyzed by real-time reverse transcription quantitative polymerase chain reaction (RT-qPCR) and Western blotting. Oxidative stress markers were quantified by enzyme-linked immunosorbent assay (ELISA). **Results:** Lobeglitazone alone reduced intracellular lipid accumulation in FFAs-treated HepG2 cells, and this effect was further enhanced by co-treatment with HGF, as demonstrated by ORO staining (Figure 1A). Co-treatment markedly restored mitochondrial function impaired by FFAs, indicated by elevated MitoTracker signal (Figure 1B). RT-qPCR and Western blotting showed that PPARα expression, which had been suppressed by FFAs treatment, was partially restored by lobeglitazone and more effectively restored by the combination with HGF. PPARγ expression, which had been upregulated under the same conditions, was more completely normalized by co-treatment compared to lobeglitazone alone. In addition, the co-treatment of lobeglitazone and HGF more strongly upregulated mitochondrial metabolism-related proteins, including peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1α) and carnitine palmitoyltransferase 1A (CPT1A) (Figure 1C, 1D). By reducing

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

reactive oxygen species (ROS) production and restoring superoxide dismutase (SOD) activity, the co-treatment effectively mitigated FFAs-induced oxidative stress, as demonstrated by ELISA (Figure 1E). **Conclusion:** Lobeglitazone alone attenuated FFAs-induced intracellular lipid accumulation and favorably modulated PPARα/γ expression and mitochondrial metabolism-related markers, while co-treatment with HGF led to more pronounced effects across these parameters.

1110 | DIETARY FRUCTOSE-INDUCED METABOLIC REPROGRAMMING DETERMINES INTESTINAL STEM CELL FATE AND PROMOTES MASLD DEVELOPMENT THROUGH ENHANCED LIPID ABSORPTIO

Madison Taylor[1] Bradford Hill[1] Robert Mitchell[1] Elizabeth Hudson[1] Craig McClain[1] Ming Song[1], [1]University of Louisville

Background: Dietary fructose is primarily metabolized by Ketohexokinase (KHK) in the small intestine and plays a critical role in facilitating lipid absorption. Given that dietary fructose is an important risk factor in MASLD, the aim of this study is to determine the metabolic effect of fructose on small intestine stem cells (ISCs) and the implications in lipid absorption and the pathogenesis of MASLD. **Methods:** Small intestinal organoids were derived from crypts isolated from the proximal small intestine of adult male *Khk*$^{-/-}$ mice and WT littermates and were cultured and passaged with IntestiCult™ organoid growth medium. Mitochondrial stress tests were performed in organoids by Seahorse XF96 Analyzer. Lipid absorption test was performed in *Khk*$^{-/-}$ mice and their WT littermates. Male *Khk*$^{-/-}$ mice and WT littermates were subjected to STAM/MASH model and the metabolic phenotypes were profiled. **Results:** Fructose inhibits ISC self-renewal and proliferation compared to glucose. Conversely, KHK deficiency promotes ISC self-renewal and proliferation, suggesting the metabolic effect of fructose promotes ISC differentiation to enterocytes. Mitochondrial stress test showed that fructose markedly increases mitochondrial respiration compared to glucose as shown by oxygen consumption rate (OCR), and that was inhibited by inhibitors of glutaminolysis pathway (compound 968, AOA and R162) but not by mitochondrial pyruvate carrier (MPC) inhibitor UK-5099, suggesting fructose induced oxidative phosphorylation is glutamine-dependent and pyruvate-independent. Mechanistically, fructose aberrantly stabilizes HIF-1 through fructose 1-phosphate (F1P)/pyruvate kinase M2 (PKM2) axis, and that inhibits pyruvate dehydrogenase (PDH) via activation of pyruvate dehydrogenase kinase 1 (PDK1), therefore preventing pyruvate from entering TCA cycle. In support of this, KHK deficiency significantly reduces lipid absorption. Additionally, fecal fatty acids (NEFA) levels were significantly increased in *Khk*$^{-/-}$ mice compared to WT littermates in a chronic high-fat high-fructose (HFHFr) feeding model. Moreover, *Khk*$^{-/-}$ mice are protected from hepatic steatosis in a STAM/MASH model. **Conclusion:** Our data provide evidence that fructose-induced metabolic reprograming toward oxidative phosphorylation inhibits ISC proliferation and promotes differentiation to enterocytes, and that in turn, facilitates lipid absorption and contributes to MASLD development.

Toftegaard Hjuler[2] *Tomasz Kostrzewski*[1], [1]*CN Bio,* [2]*Novo Nordisk*

Background: Primary human hepatocytes (PHHs) remain the gold standard for *in vitro* liver research and drug development, with widespread use across the industry. One key benefit of PHH use in research is the ability to explore the role of patient variability. However, differences in tissue quality and PHH isolation can contribute to data variance and a lack of reproducibility. In this study we aimed to characterise a broad range of PHH donors in both 2D and 3D platforms to identify high quality PHH sources, for use in translational microphysiological systems (MPS). This research would explore whether 2D cell culture can predict PHH performance in MPS, with a particular focus on insulin sensitivity, a key feature for metabolic disease modelling. **Methods:** PHHs isolated from 23 human donors (from four commercial vendors) were assessed for ability to culture in both 2D, and in a 3D liver MPS platform. Two key parameters were assessed: hepatocyte functionality, through biomarkers albumin and cytochrome P450; and hepatocyte insulin sensitivity, a key marker for metabolic disease modelling. PHHs were assayed after 4 days in 2D culture, and 8 days in Liver MPS for their response to 3 nM insulin challenge, with the production of glucose and phospho-Akt measured. **Results:** Of the 23 donors tested, 44% were found to successfully culture in the liver MPS platform with >10 μg/day/million cells of albumin at Day 8; and high levels (>0.5 pmol/min/million cells) of CYP3A4 activity at Day 8. 48% of PHH donors showed insulin sensitivity in the 3D Liver MPS, but importantly the same donors that were insulin sensitive in 2D were not sensitive in the liver MPS, with 2 donors found to be non-responsive to insulin challenge in 2D but significantly responsive in the 3D MPS platform. Additionally, the dynamic range of responses to insulin challenge was significantly greater between the donors in the MPS compared with the cells in 2D. **Conclusion:** This work demonstrates that detailed qualification and testing of primary cells is critical in understanding how *in vitro* studies will perform, allowing establishment of robust disease models such as MASLD/MASH or viral hepatitis. Given the observed differences in results, with regards to PHH donor validation, between 2D culture and 3D Liver MPS, it is important to assay key cellular functions in the context in which they will be used, as PHH that perform well in 2D may not always perform equivalently in 3D.

1112 | KISSPEPTIN RECEPTOR SIGNALING ALLEVIATES HEPATIC DE NOVO LIPOGENESIS (DNL) AND FIBROSIS: NEW THERAPEUTIC TARGET TO TREAT MASLD

Moshmi Bhattacharya[1] *Kimberly Izarraras*[1], [1]*Rutgers Robert Wood Johnson Medical School*

Background: Kisspeptin (KP) is a circulating peptide hormone that signals via the G protein-coupled receptor, KISS1R. The central roles of KP/KISS1R signaling in regulation of energy balance and metabolism are well known. Peripherally, the liver produces kisspeptin; however, the role of KP/KISS1R signaling in the liver is largely undefined. Our previous work demonstrated that administration of KP in mouse models of MASLD decreases hepatic steatosis by activating the master energy sensor, AMPK, and increasing the b-oxidation of hepatic fats. However, whether KP directly regulates hepatic de novo lipogenesis (DNL), and fibrogenesis is not known. The objective of this study is to determine 1) whether KP attenuates hepatic DNL and 2) the impact of kisspeptin on fibrogenesis. We hypothesize that KP treatment decreases hepatic DNL and fibrogenesis. **Methods:** DNL was assessed using metabolic tracing with ^2H_2O-enriched water followed by mass spectrometry, using DIAMOND mice (a mouse model of MASLD), upon administration of KP. In another cohort of DIAMOND mice, hepatic *Kiss1r* was overexpressed using AAV8-TBG-viruses, and the effect of hepatic steatosis was evaluated. To evaluate a role for KP in regulating fibrogenesis, human precision cut liver slices (hPCLS) from fibrotic livers and human hepatic stellate cells (LX-2) were treated with KP and the expression of fibrogeneic and inflammatory markers were evaluated. **Results:** Metabolic tracing of KP-treated steatotic livers demonstrated a decrease in DNL. Transcriptomic profiling of KP-treated livers identified disruption of key metabolic pathways, the most prominent being a decrease in fatty acid metabolism, and the downregulation of *Cidea,* a key regulator of lipid droplet formation. Mechanistically, we found that KP decreased levels of transcription factor SREBP-1c, a crucial regulator of genes involved in DNL, including *Cidea*. To evaluate a role of KP in regulating fibrogenesis, hPCLS and LX-2 cells were treated with KP resulting in a decrease in fibrogenic and inflammatory markers. Mechanistically, KISS1R signaling downregulated TGFβ signaling and SNAIL expression, via activation of protein-phosphatases PP2A, a binding partner of KISS1R. **Conclusion:** Enhancement of KISS1R

1113 | INTEGRATED ANALYSIS OF WGCNA AND MACHINE LEARNING REVEALS MACROPINOCYTOSIS-RELATED BIOMARKERS IN METABOLIC-ASSOCIATED STEATOHEPATITIS

Xin Wang[1] Feng Liu[1] Huiying Rao[1], [1]Peking University People's Hospital

Background: Metabolic-associated steatohepatitis (MASH), the progressive stage of metabolic-associated fatty liver disease (MAFLD), has emerged as a major public health concern due to its strong association with liver cirrhosis, hepatic failure, and rising global prevalence linked to metabolic syndrome and obesity epidemics, while current therapeutic strategies remain limited. Macropinocytosis, a large-scale fluid-phase endocytosis process dependent on actin cytoskeleton reorganization, represents a critical adaptive mechanism through which cells respond to metabolic stress. This process maintains energy homeostasis by internalizing extracellular proteins and lipids. This study aims to explore the potential role of macropinocytosis-related genes in the pathogenesis of MASH. **Methods:** Gene expression profiles were obtained from MASH-related bulk RNA-seq datasets (GSE126848 and GSE89632) and a single-cell RNA sequencing (scRNA-seq) dataset (GSE216836). Key candidate genes were first identified using the limma R package and the WGCNA algorithm, followed by an intersection with macropinocytosis-related genes retrieved from GeneCards, yielding 26 overlapping genes. Three distinct machine learning algorithms were employed to screen two hub genes. Subsequent analyses included immune cell infiltration profiling, Gene Set Enrichment Analysis (GSEA), nomogram construction, ROC curve evaluation, and scRNA-seq trajectory analysis to investigate the associations of hub genes with co-expressed networks, specific cell subpopulations, and MASH progression. Finally, functional validation of CDH5 and CAPG in MASH pathogenesis was performed using *in vitro* cell models and *in vivo* models. **Results:** Through bioinformatics analysis, we identified 26 macropinocytosis-associated genes in MASH. Subsequent integration of machine learning, external validation, and experimental assays selected CAPG and CDH5 as hub genes, demonstrating their robust association with macropinocytosis dysregulation in MASH pathogenesis. **Conclusion:** This study identified potential hub genes that may serve as diagnostic and therapeutic targets for MASH, offering novel perspectives for the clinical management of MASH patients.

1114 | DIRECT EFFECTS OF GLP-1/GLUCAGON DUAL AGONIST SURVODUTIDE ON HEPATIC STELLATE CELLS AND LIVER CANCER CELL LINES

Toru Nakamura[1] Yasuko Imamura[1] Atsutaka Masuda[1] Hironori Koga[1] Takumi Kawaguchi[1], [1]Kurume University School of Medicine

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is associated with a high risk of progression to liver fibrosis and hepatocellular carcinoma (HCC), and elucidating the disease-modifying effects of new agents is an urgent need. Survodutide, a dual GLP-1/glucagon receptor agonist, has shown promising effects on weight loss and hepatic steatosis in clinical studies. However, its direct effects on hepatic stellate cells (HSCs) and HCC cells remain unclear. This study aimed to evaluate the direct impact of survodutide on cell proliferation and fibrogenic gene expression in human hepatic stellate and liver cancer cell lines. **Methods:** Seven liver cancer cell lines (HepG2, Hep3B, HuH7, HAK1A, HAK1B, HLF, HAK5), one normal hepatocyte cell line (OUMS29), and an HSC line (LX-2) were analyzed for GLP1R and GCGR expression by RT-PCR and Western blotting. Cell proliferation was assessed using an MTT assays with or without palmitic acid (PA) treatment. LX-2 cells were treated with survodutide under TGF-β-stimulated and unstimulated conditions, and mRNA expression of fibrogenic genes (TGFβ1, COL1a1, Acta2, Timp1) was quantified by qPCR. **Results:** GLP1R expression was undetectable in all cell lines, whereas GCGR was consistently expressed, with HuH7 showing the highest mRNA levels. Survodutide modestly promoted the proliferation in Hep3B and HuH7 cells at select concentrations under PA-free conditions but significantly inhibited the proliferation in all liver cancer cell lines at 1000 nM under PA-loaded conditions ($p < 0.05$). In LX-2 cells, survodutide enhanced the proliferation at low concentrations (10 nM)

without TGF-β, but suppressed it in a dose-dependent manner under TGF-β stimulation, with significant inhibition at ≥100 nM ($p < 0.05$). Survodutide did not alter the expression of fibrogenic genes regardless of TGF-β stimulation. **Conclusion:** Survodutide directly suppressed the proliferation of human HCC cells under lipotoxic stress. Survodutide also inhibited activated human HSC proliferation under profibrotic conditions, without affecting fibrogenic gene expression. These findings suggest a potential direct anti-tumor and anti-fibrotic effect of survodutide in the context of MASH progression.

1115 | EFFECTS OF THE FGF21 ANALOGUE EFRUXIFERMIN ON CELL PROLIFERATION AND FIBROGENIC GENE EXPRESSION IN HEPATIC STELLATE CELLS AND LIVER CANCER CELL LINES

Toru Nakamura[1] Yasuko Imamura[2] Atsutaka Masuda[2] Hironori Koga[2] Takumi Kawaguchi[2], [1]Kurume University, [2]Kurume University School of Medicine

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease that leads to fibrosis and hepatocarcinogenesis. Efruxifermin, an FGF21 analogue, is known to improve lipid and glucose metabolism, but its direct effects on hepatic stellate cells (HSCs) and hepatocellular carcinoma (HCC) cells remain unclear. This study aimed to evaluate the effects of efruxifermin on cell proliferation and fibrogenic gene expression in human HSC and liver cancer cell lines. **Methods:** Seven liver cancer cell lines (HepG2, Hep3B, HuH7, HAK1A, HAK1B, HLF, HAK5), one normal hepatocyte cell line (OUMS29), and an HSC line (LX-2) were analyzed for FGFR1 and βKlotho expression using RT-PCR and Western blotting. Cell proliferation was assessed using an MTT assays with or without palmitic acid (PA) treatment. LX-2 cells were treated with efruxifermin under TGF-β-stimulated and unstimulated conditions, and mRNA expression of fibrogenic genes (TGFβ1, COL1a1, Acta2, Timp1) was quantified by qPCR. Smad signaling (Smad2/3/4 phosphorylation) was evaluated by Western blotting. **Results:** FGFR1 was expressed in all cell lines and was highly expressed in HepG2, HAK5, and LX-2. βKlotho was highly expressed in HepG2, Hep3B, and HuH7, but undetectable in LX-2 and some liver cancer cell lines. Under PA-free conditions, efruxifermin promoted the proliferation in HuH7, HAK1B, and HAK5, while inhibiting HLF cell growth at concentrations ≥10 nM ($p < 0.05$). Under PA treatment, HuH7, Hep3B, HAK1B, and HAK5 showed dose-dependent growth inhibition from 1 nM ($p < 0.05$). In LX-2 cells, efruxifermin promoted the proliferation at low doses under TGF-β-free conditions, but significantly inhibited the proliferation at 100 nM under TGF-β stimulation ($p < 0.05$). Fibrogenic gene expression remained unchanged following efruxifermin treatment, regardless of TGF-β stimulation. However, phosphorylation of Smad2 (p-Smad2) was decreased, while the levels of p-Smad3 and Smad4 were unaffected. **Conclusion:** Efruxifermin directly suppressed the proliferation of human HCC cells under lipotoxic conditions. Efruxifermin also directly inhibited growth of human HSCs under profibrotic stimulation, suggesting a context-dependent antiproliferative effect. Although fibrogenic gene expression was not significantly altered, selective suppression of p-Smad2 suggests partial modulation of TGF-β signaling. These findings offer mechanistic insights into the potential of efruxifermin to modulate fibrosis progression and hepatocarcinogenesis in MASH.

1116 | REGULATION OF AMINO ACID CATABOLISM BY A HUMAN-SPECIFIC INCRNA IN NONALCOHOLIC FATTY LIVER DISEASE

Xiangbo Ruan[1], [1]Johns Hopkins All Children's Hospital

Background: Impaired amino acid (AA) metabolism in the liver has recently emerged as a hallmark of NAFLD in humans. Decreased expression of genes in the AA catabolism and urea cycle pathways can result in the accumulation of AAs and of ammonia, which in turn may lead to increased oxidative stress, hepatocyte death, and activation of hepatic stellate cells. These key

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

events may drive a range of presentations of NAFLD, from simple steatosis to the advanced form of NAFLD, steatohepatitis (NASH). While clinical and experimental observations support a potential causal role of impaired AA catabolism in NAFLD, we do not yet know which molecular mechanisms drive these dysregulated processes. **Methods:** Recent studies in animal models support the hypothesis that long non-coding RNA (lncRNA) genes regulate vital metabolic pathways. As most human lncRNAs are non-conserved, we recently employed a novel *humanized liver mouse model* to study lncRNAs expressed in human livers. We identified a human hepatocyte-specific lncRNA, hLMR1 (human lncRNA metabolic regulator 1), that promotes hepatic cholesterol synthesis. Our promising follow-up studies demonstrated that hLMR1 represses an array of genes in the AA catabolism and ureagenesis pathways, suggesting hLMR1 could be a key factor contributing to impaired hepatic AA catabolism and ureagenesis in NAFLD patients. **Results:** We found that: (1) hLMR1 is upregulated in NAFLD patients; (2) knocking down of hLMR1 in a humanized liver mouse model results in robust upregulation of genes in the AA catabolism and ureagenesis pathways; (3) hLMR1 overexpression in primary human hepatocytes suppresses AA catabolism and ureagenesis; (4) hLMR1 is nuclear-enriched and extensively interacts with pre-mRNAs of amino acid catabolism genes to suppress their expression. **Conclusion:** Upregulation of hLMR1, leading to suppressed AA catabolism and ureagenesis in the liver and, ultimately, progression of NAFLD.

1117 | VISCERAL ADIPOSE TISSUE FROM MORBID OBESITY PATIENTS PROMOTES THE PROLIFERATION OF HEPATOCELLULAR CARCINOMA CELLS

Byoung Kuk Jang[1] Ji Yeon Park[1] Hye-Young Seo[1] Jae Seok Hwang[1] Mi Kyung Kim[1], [1]Keimyung University School of Medicine

Background: Obesity is a major risk factor for metabolic dysfunction-associated steatotic liver disease (MASLD) and hepatocellular carcinoma (HCC). Recent studies suggest that visceral adipose tissue (VAT) plays a more significant role than subcutaneous adipose tissue (SAT) in cancer progression. However, although VAT is involved in cancer progression, its specific role and underlying molecular mechanisms in HCC remain poorly understood. **Methods:** To investigate the role of VAT in HCC, RNA sequencing (RNA-seq) was performed on VAT and SAT samples obtained from male and female obese patients. KEGG pathway analysis was conducted to identify differentially activated signaling pathways. In addition, conditioned media (CM) from VAT (VAT-CM) and SAT (SAT-CM) from male obese patients were applied to Hep3B (hepatocellular carcinoma cell line), and cell proliferation was assessed using the CCK-8 assay. Furthermore, RNA-seq analysis was conducted on Hep3B cells treated with VAT-CM and SAT-CM to identify transcriptional changes related to HCC progression. **Results:** KEGG pathway analysis revealed that multiple oncogenic pathways, including WNT signaling, IGF signaling, and inflammatory response pathways, were significantly upregulated in VAT compared to SAT. These pathways are known to be strongly associated with HCC development and progression. Furthermore, Hep3B cells treated with VAT-CM exhibited significantly enhanced proliferation compared to those treated with SAT-CM, suggesting that VAT-derived factors may contribute to HCC growth. Furthermore, RNA-seq analysis of Hep3B cells treated with VAT-CM showed activation of oncogenic and inflammatory signaling pathways, suggesting that VAT-derived inflammatory factors may play an important role in promoting hepatocellular carcinoma (HCC) progression. **Conclusion:** These findings suggest that VAT, particularly in male obese patients, promotes hepatocellular carcinoma (HCC) progression by enhancing cancer cell proliferation and activating tumor-promoting pathways. This study highlights the importance of VAT-derived factors in obesity-associated HCC and suggests that targeting VAT-related inflammatory and metabolic pathways may provide potential therapeutic strategies.

◆ 1118 | PRECLINICAL PHARMACOLOGY AND SAFETY OF CRMA-1001, A NOVEL EPIGENETIC EDITOR FOR CHRONIC HEPATITIS B THAT DEMONSTRATES HBV SURFACE ANTIGEN LOSS IN ANIMAL MODELS VIA PRECISE HBV DNA METHYLATION

Sarah Voytek[1] Yesseinia Anglero-Rodriguez[1] John Xiong[1] Glen Acosta[1] Rayman Choo-Wing[1] Ricardo Ramirez[1] Erica Hildebrand[1] Amber DiPiazza[1] Sameer Abraham[1] Ava Zhai[1] Lenka Hoffman[1] Arogya Khadka[1] Jhon Medina[1] Caroline Mugambwa[1] Chloe Pantano[1] Yasaman Rezvani[1] Kayla Hudson[1] Shefal Parikh[1] Padma Malyala[1] Melissa Bonner[1] Jennifer Marlowe[1], [1]nChroma Bio

Background: A major challenge in achieving functional cure for chronic hepatitis B virus (HBV) infection is the ability to permanently silence the production of viral antigens from both covalently closed circular DNA (cccDNA) and integrated HBV DNA (intDNA) and

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

preventing viral replication. Genomic medicines for HBV aim to overcome these challenges. CRMA-1001 is an investigational epigenetic editor consisting of an mRNA and guide RNA packaged in a lipid nanoparticle. CRMA-1001 methylates both forms of HBV DNA, without creating cuts or nicks, resulting in HBV DNA suppression and induction of HBV surface antigen (HBsAg) loss. **Methods:** The pharmacologic effect of a single or repeat administration of CRMA-1001 was evaluated for up to 6 months in AAV-HBV (episomal DNA) and transgenic (Tg)-HBV (intDNA) mouse models. To evaluate specificity and on-target methylation, host gene expression and host and HBV DNA methylation were analyzed in multiple cell types using RNA-seq and methylation sequencing. To evaluate potency in non-human primates (NHPs), CRMA-1001's effector construct was assessed using the endogenous *PCSK9* target gene. The safety and biodistribution profile of CRMA-1001 was also assessed in NHPs. **Results:** A single dose of CRMA-1001 resulted in durable, dose-dependent decreases in circulating HBsAg, with 70% of AAV-HBV mice achieving loss of HBsAg and 90% achieving loss of HBV DNA at the highest dose tested. Repeat dosing improved the reduction of circulating HBsAg versus a single dose. In vitro, on-target methylation of cccDNA and intDNA was observed. No clinically meaningful unintended effects on human genes, defined as increased methylation associated with altered expression, were seen in primary human hepatocytes. The pharmacokinetic, biodistribution, and toxicology profile of CRMA-1001 in NHPs supported further development. Assessment of the same epigenetic editing construct directed at *PCSK9* in NHPs demonstrated saturating silencing of circulating PCSK9 protein for >1 year with a single dose and suggested best-in-class potency. **Conclusion:** CRMA-1001 demonstrated robust silencing of HBsAg expression from both cccDNA and intDNA in mouse models that persisted through the follow-up period, with the same construct silencing PCSK9 expression for >1 year in NHPs. CRMA-1001 achieved HBsAg loss with an acceptable safety and specificity profile. These results support the initiation of clinical trials with CRMA-1001 with the goal of functional cure with a single course of treatment.

◆ 1119 | TRIPLE-TARGETING IMMUNOMODULATOR C3 TREATMENT PROMOTES HBV CLEARANCE THROUGH FUNCTIONAL RECONSTITUTION OF HOST IMMUNITY IN HBV-CARRIER MOUSE MODELS

Yu Wu[1] Xin Liu[1] Ting Zhang[1] Xiangmei Chen[1] Fengmin Lu[1], [1]Peking University Health Science Center

Background: Chronic hepatitis B (CHB) is still a major global health problem. Although achieving functional cure could substantially improve clinical outcomes, current first-line therapies demonstrate suboptimal efficacy in attaining this goal. Restoration of HBV specific immune responses is fundamental for achieving functional cure but immunomodulator monotherapy often yields unsatisfactory outcomes. Consequently, the development of multi-target immunotherapies has become a hot topic in the pursuit of CHB functional cure. **Methods:** In this study, a novel aptamer-based triple-targeting immunomodulator C3 was used to explore its potential for CHB functional cure *in vitro* and *in vivo*. Dually humanized mice engrafted with human liver and immune system, rAAV8-1.3X HBV mice, and hydrodynamic injection mice were employed to validate the therapeutic efficacy and safety of C3 against CHB through intravenous injection. Virological clearance was assessed through Southern blot, ELISA and immunohistochemistry. Single-cell RNA sequencing (scRNA-seq) and flow cytometry were employed to delineate C3-induced immune activation profiles. Besides, the combinatorial antiviral efficacy and response maintenance after withdraw of bepirovirsen or siRNA (si1260/1848) with C3 was systematically evaluated in rAAV8-1.3X HBV mouse models. **Results:** Across multiple HBV-carrier mouse models, C3 treatment demonstrated rapid clearance of serum HBV DNA, HBsAg, and HBeAg, with a subset of animals achieving undetectable HBV DNA levels and HBsAg seroconversion, accompanied by significantly reduced intrahepatic HBV DNA and RNA. Consistantly, few HBcAg- and HBsAg-positive hepatocytes in murine liver tissues were observed. Additionally, no significant adverse effects or toxicities were observed in C3 treatment groups. Notably, combination therapies demonstrated that C3 significantly accelarate the seroclearance of HBsAg and ameliorated the viral rebound, which was typically observed after RNAi therapy cessation. Mechanistically, C3 promotes immune cell infiltration into

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the liver, and significantly enhances the function of antigen-presenting cells (APCs) and T cells. **Conclusion:** The triple-targeting immunomodulator C3 could eliminate HBV infection and ameliorate the viral rebound via host immune system activation, representing C3 a promising CHB therapeutic candidate.

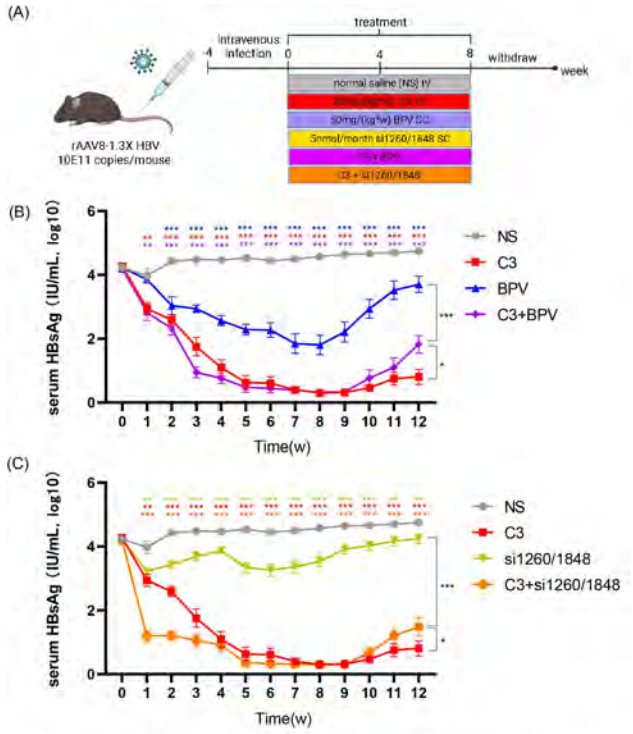

Fig. 1 C3 accelarate the seroclearance of HBsAg and ameliorated the viral rebound. (A)Flowchart of combination therapies. (B) Serum HBsAg levels in mice following C3, BPV, or combination therapy (n = 9-10 per group);(C) Serum HBsAg levels in mice following C3, BPV, or combination therapy (n =10 per group); Statistical analyses between the treated groups and the untreated group were done by one-way ANOVA. *p<0.05; **p<0.01; ***p<0.001. ◆ 1120 | TREATMENT OF TENOFOVIR AMIBUFENAMIDE VERSUS TENOFOVIR ALAFENAMIDE IN PATIENTS WITH CHRONIC HEPATITIS B-RELATED CIRRHOSIS: EVIDENCE FROM A MULTICENTER REAL-WORLD STUDY

Jun Chen[1] Zebing Huang[2] Yan Huang[2], [1]Xiangya Hospital Central South University, [2]Xiangya Hospital, Central South University

Background: Chronic hepatitis B (CHB)-related cirrhosis remains a significant global health challenge, and effective antiviral therapies are essential for long-term management. Tenofovir amibufenamide (TMF) has shown potent antiviral efficacy in randomized clinical studies for patients with CHB. However, Real-world data on TMF in cirrhotic population remain scarce. This study aimed to assess the effectiveness and safety of TMF in the real world and compared its outcomes with those of tenofovir alafenamide (TAF). **Methods:** In this multicenter, real-world cohort study, 606 patients with CHB-related cirrhosis were recruited from 11 hospitals. After adjusting for confounding factors using the propensity score matching method, patients were divided intoa TMF treatment group (TMF 25 mg, n = 304) and a TAF treatment group (TAF 25 mg, n = 302). Additionally, TMF-treated patients with hepatitis B cirrhosis were divided into treatment-naive (TN) and treatment experienced (TE) groups with low-level viremia. Safety and efficacy were thoroughly evaluated, with a focus on the virologic response (VR) rate, alanine transaminase (ALT) normalization rate, liver stiffness measurement (LSM), renal function, and changes in the lipid profile after 48 weeks of treatment. The fibrosis 4 score was also calculated in both groups. **Results:** In all subgroups (overall population, low-level viremia, HBeAg-positive, and HBeAg-negative), the primary efficacy endpoint (HBV DNA **Conclusion:** TMF was non-inferior to TAF in terms of anti-HBV efficacy and showed blood lipid and renal safety in compensated chronic hepatitis B related cirrhosis in 48 weeks.

◆ 1121 | PHASE 3 TRIAL OF HYDRONIDONE FOR LIVER FIBROSIS IN CHRONIC HEPATITIS B

Xiaobo Cai[1] Yin Qu[1] Yanbin Wang[2] Wen Xie[2] Mengyu Zhao[3] Ling Zhang[3] Ying Luo[3] Ping Yin[4] Jun Cheng[2] Lungen Lu[1], [1]Shanghai General Hospital, Shanghai Jiaotong University School of Medicine, [2]Beijing Ditan Hospital, Capital Medical University, [3]Continent Pharmaceuticals, [4]Tongji Medical College, Huazhong University of Science and Technology

Background: Currently, no potential direct anti-fibrotic drugs are available for patients with chronic hepatitis B (CHB). Hydronidone is a novel anti-fibrotic agent that inhibits TGF-β,hepatic stellate cellactivation and promotes HSC apoptosis. Our previous phase 2 trial demonstrated that hydronidone significantly improved liver fibrosis regression in CHB patients. To further evaluate its efficacy and safety, we conducted this phase 3 multicenter trial in CHB patients with liver fibrosis, administering hydronidone at a dose of 270 mg/day. **Methods:** In this 52-week, randomized, double-blind, placebo-controlled phase 3 trial, CHB patients with biopsy-confirmed significant liver fibrosis (Ishak score ≥3) were assigned (1:1) to receive either hydronidone (270 mg/day) or placebo, both combined with

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

entecavir as the basic antiviral treatment. The primary endpoint was fibrosis reversal, defined as a ≥1-point reduction in Ishak stage after 52 weeks of treatment compared to baseline. **Results:** Between January 16, 2022, and October 22, 2024, a total of 453 participants were screened for eligibility, and 247 randomized participants (hydronidone: n = 123; placebo: n = 124) were eventually included across 39 hospitals in China. The demographic and clinical characteristics of the participants at baseline were well balanced between the trial and placebo groups. For the primary end point, hydronidone demonstrated significantly greater efficacy in achieving fibrosis reversal. The fibrosis reversal was achieved in 65 (52.85%) participants in the hydronidone group versus 37 (29.84%) participants in the placebo group, with an absolute difference of 23.01% (P = 0.0002). Despite antiviral therapy with entecavir, 25.81% of placebo-treated patients experienced fibrosis progression, compared to only 8.94% in the hydronidone group. A key secondary endpoint of improvement in liver inflammation (≥1-grade reduction) without fibrosis progression was met by 49.57% of hydronidone-treated patients versus 34.82% in the placebo group (P = 0.0246). Both groups showed comparable rates of HBV DNA undetectability (81.74% vs. 85.47%) and ALT normalization (80% vs. 88.89%). Adverse event profiles were similar between groups. Serious adverse events occurred in 4.88% with hydronidone and 6.45% with placebo of participants and no discontinuations due to adverse events. **Conclusion:** Hydronidone was superior to placebo in promoting fibrosis regression and demonstrated a favorable safety profile in CHB patients. (NCT05115942)

◆ 1122 | GLOBAL, REGIONAL, AND AGE-STRATIFIED TEMPORAL TREND OF CHRONIC HEPATITIS B AND LIVER CANCER BURDEN: A SECONDARY ANALYSIS BASED ON THE GLOBAL BURDEN OF DISEASE STUDY

Kimberly Ho[1] Yunhao Li[2] Wai Keung Leung[2], [1]Brown University, [2]University of Hong Kong

Background: Despite global advances in hepatitis B (HBV) vaccination and antiviral therapy, the impact of declining HBV incidence on hepatocellular carcinoma (HCC) trends remains unclear. Given HCC's long latency period, its relationship with HBV likely varies by age, geography, and sociodemographic index (SDI). Prior studies examined HBV and HCC trends, but few have assessed their correlation globally with age stratification. We conducted an age-stratified analysis to examine the global trends between chronic HBV (CHB) infection and HCC incidence. **Methods:** We extracted cross-sectional data from the Global Burden of Diseases to analyze acute hepatitis B (AHB), CHB, and HCC burden from 1990–2021 globally, nationally, and by age group (<50 vs ≥50 years). Joinpoint regression showed significant temporal shifts. Linear regression assessed correlations between the Average Annual Percentage Change (AAPC) in CHB and HCC incidence by age group. **Results:** CHB incidence declined globally and steeply in China (middle SDI; AAPC -4.32), followed by the US (high SDI; AAPC -3.62) and India (low-middle SDI; AAPC -2.30) from 1990 to 2021 (all $p < 0.001$). AHB incidence also declined globally, particularly in China (AAPC -2.88) and the US (AAPC -2.38), with sharpest reductions in 2019–2021. India had modest decline in 1990-2021 (AAPC -1.16; all $p < 0.001$). Trends between CHB and HCC also showed age-specific patterns (Figure 1). There was a weak but significant negative correlation in the group <50 years ($r = -0.18$, $p = 0.0109$). China and the US did not show a negative change in HCC despite decline in CHB. India had lower CHB decline without corresponding reduction in HCC. No significant correlation between CHB and HCC was seen in those ≥50 years ($r = -0.12$, $p = 0.0849$). China had strong, significant negative correlation between CHB and HCC with a decline in both. India was an outlier with rising HCC despite CHB decline. The US showed no clear association between trends in CHB and HCC. **Conclusion:** Younger individuals showed significant inverse correlation between CHB and HCC, likely reflecting benefits of vaccination efforts such as China's 1992 neonatal program. Countries with lower SDI like India may lag due to a high HBV burden and limited public health infrastructure. Other HCC drivers like HCV and MASLD may predominate in other regions. This age-stratified analysis highlights greater overall global decline in HCC in younger populations and persistent disparities in prevention and HBV control.

◆ 1123 | SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF MULTIPLE DOSES OF AB-101, A SMALL-MOLECULE PD-L1 INHIBITOR, IN CHRONIC HEPATITIS B PATIENTS

Edward Gane[1] Man-Fung Yuen[2] Oana Sandulescu[3] Rajneesh Kumar[4] Alina Jucov[5] Pietro Lampertico[6] Stefano Fagiuoli[7] Grace Lai-Hung Wong[8] Marta Dobrayanska[9] Emily Thi[10] Timothy Eley[10] Sharie Ganchua[10] Christine Espiritu[10] Varun Sharma[10] Joanne Brown[10] Ganapati Reddy Pamulapati[10] Karen Sims[10] Tilly Varughese[10], [1]University of Auckland and New Zealand Clinical Research, [2]The University of Hong Kong, [3]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Carol Davila University of Medici, [4]Department of Gastroenterology and Hepatology, Singapore General Hospital, [5]Arensia Exploratory Medicine GmbH, [6]University of Milan, [7]Gastroenterology, Hepatology and Transplantation, ASST Papa Giovanni XXIII, [8]The Chinese University of Hong Kong, Prince of Wales Hospital, [9]Arensia Exploratory Medicine, Ukraine, [10]Arbutus Biopharma

Background: Programmed death 1 (PD-1)/ programmed death-ligand 1 (PD-L1) inhibition using immune checkpoint inhibitor antibodies has been associated with HBsAg loss and seroconversion in some patients with chronic hepatitis B (CHB). AB-101 is an investigational oral small-molecule PD-L1 inhibitor being developed for the treatment of CHB in combination with other agents. A Phase 1a/1b study is ongoing to assess the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of AB-101 in healthy subjects (HS) and patients with CHB suppressed on nucleos(t)ide analogue (NA) therapy. Preliminary results from HS and the first CHB cohort have been reported previously. Here we report follow-up data from the first CHB cohort and data from the second, higher dose CHB cohort. **Methods:** AB-101-001 is an ongoing randomized, double-blind, placebo-controlled 3-part study evaluating the safety, tolerability, PK and PD of AB-101 in HS and NA-suppressed CHB patients. In Part 3, patients with CHB were randomized 10:2 and administered AB-101 at 10 mg (Cohort 3A) or 30 mg (Cohort 3B) or placebo daily (QD) for 28 days. Safety was monitored via adverse event (AE) and immune related AE (irAE) reporting, vital signs, physical examination, ECGs, and laboratory assessments up to 6 months after dosing. Blood samples for single and repeat dose PK and PD were collected. PD was assessed via measurement of PD-L1 levels from peripheral cells (receptor occupancy [RO]). **Results:** AB-101 was well tolerated in CHB patients with no related serious adverse events, irAEs, or related Grade 3 or 4 treatment emergent adverse events (TEAEs). Cohorts 3A and 3B were predominantly male (92%, 75%) with mean ages of 42.8 and 45 years, respectively. Follow-up is complete for Cohort 3A. A total of 6 TEAEs (3 related to AB-101) and no irAEs were observed through follow-up. Dosing and follow-up are ongoing for Cohort 3B. No clinically significant laboratory, vital sign, or ECG abnormalities were reported in either cohort. Concentrations of AB-101 were largely comparable to healthy subjects. Mean maximal RO was 39% and 83% for 10 mg (N = 6) and 30 mg (N = 6) QD respectively, through 7-28 days of dosing. **Conclusion:** Oral doses of AB-101 up to 30 mg QD for 28 days were generally well tolerated in NA-suppressed CHB patients. Preliminary interim PD data indicate dose-related increases in RO, with 83% mean maximal RO at the 30 mg dose. Cohort 3B is ongoing and all available data, including safety, PK, RO and HBV biomarkers, will be presented.

◆ 1124 | SEX DISPARITIES IN VIRAL HEPATITIS: CLINICAL AND EPIDEMIOLOGICAL EVIDENCE FROM THE ITALIAN PITER COHORTS

Loreta Kondili[1] Samantha Hall[2] Maria Giovanna Quaranta[3] Luigina Ferrigno[3] Homie Razavi[4], [1]Istituto Superior Di Sanita (ISS), [2]Center for Disease Analysis, [3]Istituto Superiore Di Sanita (ISS), [4]Center for Disease Analysis Foundation

Background: The influence of sex on long-term disease progression, treatment adherence, and therapeutic response remains underexplored in chronic viral hepatitis, particularly in hepatitis B and D virus (HBV and HDV) infections. To address this gap, we analyzed sex-based clinical and epidemiological differences in HBV and HDV populations enrolled in the national PITER cohorts. **Methods:** We analyzed baseline clinical and virological data from the PITER HBV and HDV cohorts. Sex-based associations with antiviral treatment status, treatment duration, disease severity (as measured by FIB-4), and virological response were evaluated using chi-square tests and multivariate regression models. **Results:** Epidemiological and clinical data on chronic HBV and HDV infection by gender are summarized in Table 1. In the HBV cohort, females were more frequently PCR-positive and had a higher median viral load at enrollment. Nevertheless, males were significantly more likely to receive treatment (odds ratio: 1.79; $p < 0.001$), independent of age and place of birth. Overall, HBV treatment coverage was high, with 73.1% of HBsAg-positive males and 60.3% of females undergoing antiviral therapy. The median treatment duration was 6.1 years and did not significantly differ between sexes, except in the 60–79 age group, where males had a longer duration. Liver fibrosis at treatment initiation, measured by the FIB-4 score, increased with age and was consistently higher in males, suggesting more advanced liver disease at baseline. In the HDV cohort, no significant sex-based differences were observed. The median age was 60 years, and 33% of infections occurred in migrants. HDV viremia rates ranged from 71% to 74.8%, with first-year treatment uptake nearly identical between sexes:62.9% in males and 62.8% in females. The proportion of individuals initiating HDV treatment increased with age in both groups. **Conclusion:** The clinical and virological profiles of HBV differ by sex, with treatment initiation appearing to be influenced more by disease severity than by HBV DNA positivity alone. In contrast, HDV infection shows minimal sex-based differences in clinical characteristics and treatment uptake. These baseline, real-world data on HBV and HDV, stratified by sex, provide a valuable foundation for future studies aiming to forecast the burden of chronic liver disease and to explore potential sex-related differences in the long-term impact of treatment on disease progression. The young age of non-Italian females affected by chronic HBV and HDV infections in our cohorts highlights the importance of sex-sensitive approaches in the clinical management of viral hepatitis. Even in countries with successful HBV vaccination programs, additional public health measures remain necessary to curb the burden of viral hepatitis,particularly among unvaccinated migrant populations.

◆ 1125 | TRACKING A DECADE OF HEPATITIS B OUTCOMES IN THE UK: INSIGHTS FROM NATURAL LANGUAGE PROCESSING DRIVEN EHR ANALYSIS

Mahd Siddiqi[1] Saima Ajaz[1] Mohammad Al-Agil[1] Kosh Agarwal[1], [1]Kings College Hospital, London, United Kingdom

Background: Hepatitis B virus (HBV) infection is a persistent global health issue, with over 296 million people chronically infected worldwide. Individuals are at risk of adverse complications such as hepatocellular carcinoma (HCC) and cirrhosis. In the UK, recent public health strategies have emphasised early detection, long-term monitoring, and expanded access to antivirals. However, real-world evidence on the impact of these efforts on HBV-related outcomes is limited. This study aimed to evaluate trends in HBV diagnoses, treatment uptake, and complications over the past decade using natural language processing (NLP) of electronic health records (EHRs). **Methods:** Our study retrospectively analysed the past decade (2013 to 2023) of HBsAg-positive patients' EHRs at King's College Hospital, London. Data were extracted and collated using CogStack, an NLP platform to process clinical text. Key variables included yearly HBsAg-positive diagnoses, antiviral therapy (tenofovir, entecavir), liver-related complications (HCC, cirrhosis, liver transplantation), and all-cause mortality. Demographic information was assessed, and trends were examined across diagnoses and major clinical endpoints. **Results:** A total of 7,158 HBsAg-positive patients were identified through CogStack. The cohort had a male predominance (55.7% male and 44.4% female) and was ethnically diverse: Black (35.8%), Unknown (25.7%), White (19.0%), Asian (13.9%), Other (5.5%), and Mixed (0.3%). Across the cohort, 1,501 patients (21.2%) had cirrhosis, 2,224 (31.4%) had HCC, and 106 (1.5%) underwent liver transplantation. Between 2013 and 2023, annual HBsAg-positive diagnoses significantly decreased from 2,382 to 394, representing an 83.5% reduction (compound annual decline: 16.5%). Over the same period, cirrhosis cases decreased from 283 to 209 (-26.1%; -3.0% annually) and HCC diagnoses dropped from 395 to 195 (-50.6%; -6.8% annually). Liver transplant numbers fluctuated annually (range: 7 to 17), returning to 9 in 2023, the same level as 2013. Statistical analysis (Mann-Kendall test) confirmed a significant monotonic decline in new diagnoses (τ = -0.67, p = 0.003). However, trends for cirrhosis (τ = 0.27, p = 0.283), HCC (τ = 0.20, p = 0.445), and liver transplantation (τ = 0.06, p = 0.813) were not statistically significant. **Conclusion:** The integration of advanced NLP tools shows potential for improvement in the identification of HBV patients and assessing the effectiveness of screening and treatment initiatives. To build on this progress, we must enhance our digital-health infrastructure, deepen targeted outreach, and streamline linkage to care and adherence support.

◆ 1126 | DIVERGENT EFFECTS OF GLYCEMIC BURDEN ON HBEAG SEROCLEARANCE AND HCC RISKS IN HBEAG-POSITIVE CHB: A LARGE MULTICENTER COHORT STUDY

Shang-Chin Huang[1] Rex Wan-Hin Hui[2] Tai-Chung Tseng[1] Karen Cheuk Ying Ho[2] Lung Yi Mak[2] Chun-Jen Liu[1] Wai-Kay Seto[2] Tung-Hung Su[1] Man-Fung Yuen[2] Jia-Horng Kao[1], [1]National Taiwan University Hospital, [2]The University of Hong Kong

Background: HBeAg seroclearance marks a critical milestone in the natural course of chronic hepatitis B (CHB). With the rising prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic comorbidities, their impact on HBeAg-positive CHB remains poorly understood, particularly regarding viral clearance and long-term oncologic outcomes. **Methods:** HBeAg-positive CHB patients with serial HBeAg measurements were consecutively enrolled from the National Taiwan University Hospital (NTUH, internal cohort). Steatotic liver disease (SLD) and cardiometabolic risk factors were defined per international guidelines. Cumulative incidences of HBeAg seroclearance and hepatocellular carcinoma (HCC) were compared after adjustment for confounding factors. External validation was conducted in an independent cohort from The University of Hong Kong (HKU, external cohort). **Results:** This study included 2,531 HBeAg-positive patients in the internal cohort and 866 in the external cohort, with a median follow-up of 8.2 and 14.4 years, respectively. At baseline, the median age was 38.8 and 39.2 years, and the proportion of males was 57.8% and 61.0%, respectively. Nucleos(t)ide analogue therapy had been initiated in 30.6% and 36.6% of patients, while diabetes mellitus (DM) was present in 5.3% and 4.5%. In both cohorts, SLD was not associated with HBeAg seroclearance. Conversely, DM significantly increased the likelihood of HBeAg seroclearance (internal cohort: adjusted hazard ratio [aHR]: 1.38, 95% confidence interval [CI]: 1.07 – 1.77; external cohort: aHR 1.61, 95% CI 1.02 – 2.55; both $p < 0.05$). The glycemic burden consistently demonstrated a dose-dependent association with HBeAg seroclearance (aHR: 1.41 and 1.17 for HbA1c $\geq$6.5% and

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

5.9 – 6.4% vs. ≤5.8%; p for trend = 0.006). HbA1c ≥ 6.5% was also independently associated with an increased HCC risk (internal cohort: aHR: 1.92, 95% CI: 1.17 – 3.16; external cohort: aHR 6.58, 95% CI 1.75 – 27.42; both $p < 0.05$). The sensitivity analyses, including propensity score matching, multiple imputation for missing data, and time-dependent covariate analysis for antiviral therapy, confirmed the robustness of results. **Conclusion:** The glycemic burden exerts a diverse and paradoxical impact on HBeAg-positive CHB, enhancing HBeAg seroclearance while increasing HCC risks. These findings underscore the importance of routine glycemic monitoring and metabolic control in this special population. The mechanisms behind the virus-host metabolic interplay represent a novel area for future research.

◆ 1127 | FACTORS ASSOCIATED WITH HEPATITIS B INFECTION IN SUB-SAHARAN AFRICA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Nkengeh Tazinkeng[1] Sonia Yonta Kenne[2] Jan René Nkeck[3] Monela Ntonifor[4] Fatima Elmustafa[5] Ryan Tanjoh[6] Ephesians Anutebeh[1] Yasmin Osman Ali[7] Adedeji Adenusi[8] David Makanga[1] Lydia Lantum Dzeenyuy[9] Cameg-Brenda Meriki[10] Emmanuel Agyemang[1] Noon Altijani[11] Valirie Ndip Agbor[12], [1]Rutgers/Newark Beth Israel Medical Center, New Jersey, USA, [2]Centre Hospitalier de l'Estran, Pontorson, France, [3]Faculty of Medicine and Biomedical Sciences, University of Yaoundé I, Yaoundé, Cameroon, [4]North Carolina Agricultural and Technical State University, North Carolina, USA, [5]Henry Ford Hospital System, Michigan, USA, [6]South Liverpool & Birkenhead GP training program, Mersey and West Lancashire Hospitals NHS Trust, UK, [7]Hennepin Healthcare, Minnesota, USA, [8]One Brooklyn Health-Interfaith Medical Center, New York, USA, [9]Faculty of Health Sciences, University of Buea, Cameroon, [10]Faculty of Health Sciences, University of Bamenda, Cameroon, [11]Postgraduate Team, Education Centre, Liverpool University Hospitals NHS Foundation Trust, UK, [12]Department of Clinical Sciences, Global Health Trials Unit, Liverpool School of Tropical Medicine,UK

Background: Hepatitis B virus (HBV) is the main cause of liver disease in the WHO Africa region, where despite the availability of effective vaccines, the burden of new infections surpasses that of all other regions combined. Progress towards HBV elimination is hampered by insufficient domestic funding. Previous evidence on the determinants of HBV in sub-Saharan Africa (SSA) has been limited by small sample sizes. This systematic review and meta-analysis investigated the factors associated with HBV infection in SSA. **Methods:** Following the PRISMA guidelines, we conducted a comprehensive search on MEDLINE, Embase, Global Health Library, and Africa-specific databases (AFROLIB, African Index Medicus, and African Journals Online) for articles published from inception of the databases to 27 October 2024. Random-effects meta-analytic models were used to calculate pooled log-transformed odds ratios (ORs) and their variances to evaluate the determinants of HBV infection. Heterogeneity across studies was assessed using the I² statistic and Cochran's Q test. **Results:** We screened 3838 studies for eligibility and included 137, comprising 1,784,317 participants. Most were cross-sectional studies (126/137), published between 2011 and 2020 (85/137). East (n = 66) and West Africa (47) had the most publications, with Ethiopia (n = 41), Nigeria (13), and Ghana (12) contributing the most publications. The following factors were significantly associated with higher rates of HBV infection: Male gender (OR 1.4, 95% confidence interval: 1.2–1.6), being unemployed (1.6, 1.2–1.9), living with a person infected with HBV (2.9, 2.1–4.0), sharing razors (2.6, 1.3–5.0), history of blood transfusion (2.1, 1.4–3.1), history of surgery (1.8, 1.3–2.4), dental procedures (1.6, 1.1–2.4), tattoos (2.1, 1.6–2.8), history of traditional operation and scarification (1.5, 1.3–1.8), history of abortion (2.2, 1.4–3.4), history of STI (2.4, 1.7–3.5), HIV infection (1.4, 1.2–1.7), and multiple sexual partners (3.0, 2.1–4.4). **Conclusion:** This study

suggests that household and healthcare exposures, and sexual behavior are the most emerging drivers of HBV transmission in SSA. These insights can guide targeted public health interventions such as education, improved infection control policies, and vaccination programs.

◆ 1128 | 4-1BB COSTIMULATION RESTORE TFH1 FUNCTION TO AUGMENT HBV-SPECIFIC HUMORAL IMMUNITY IN CHRONIC INFECTION

yongyin li[1] Yanchen Ma[1] Xiaoyi Liu[1] Haonan Lou[1] Hui Zhang[1] Jinyan Jiang[1] Weiying He[1] Libo Tang[1] Yunfei Gao[1] Jinlin Hou[2] ZHIHUA LIU[2], [1]NanFang Hospital, Southern Medical University, [2]Nanfang Hospital, Southern Medical University

Background: Chronic HBV infection is closely associated with dysregulated humoral immunity. Although our study demonstrated that Mother-to-child transmission (MTCT) could be dramatically reduced by the comprehensive interventions among HBV-infected pregnant women (Nature Medicine,2024), how intrauterine HBV antigen exposure shapes host humoral immunity remains incompletely understood. Here, we investigated the humoral immune profile in cord blood from neonates born to HBV-infected mothers to identify potential therapeutic targets and validate whether targeting these pathways could restore HBV-specific humoral immunity through clinical cohorts with persistent chronic infection. **Methods:** We analyzed cord blood samples from 73 neonates born to HBsAg-positive mothers and 24 counterpart controls (HBsAg-negative mothers) within our previously reported clinical cohort (NCT05172453). B cell and CD4$^+$ T cell phenotypes and transcriptomes were analyzed by flow cytometry and RNA-seq. HBV-specific B cells were quantified via ELISPOT and ELISA. Additionally, peripheral blood from 85 untreated chronic HBV patients (aged 1–65 years) were evaluated by full-spectrum flow cytometry to determine Tfh1-cell functional dominance and age-related distribution. **Results:** Cord blood from HBV antigen-exposed neonates exhibited enhanced HBV-specific B cell responses along with significantly elevated frequencies of type 1 follicular T helper cells (Tfh1) compared to controls. HBsAg could induced naïve CD4$^+$ T cells to differentiate into Tfh1 cells, but not the other T helper cells (Th1/Th2/Th17) or alternative follicular T helper cells (Tfh2/Tfh17) subsets. These Tfh1 cells secrete both IFN-γ and IL-21, which synergistically enhanced HBsAb production by B cells via the activation of mTORC1-STAT1/STAT3 pathway. These data demonstrate that primary HBV antigen exposure preferentially induces a Tfh1-polarized immune response that initiates HBV-specific humoral immunity. To assess Tfh1 dynamics in chronic infection, we performed full-spectrum flow cytometry on a clinical HBV cohort, revealing an age-dependent decline in both Tfh1 frequency and 4-1BB expression, which positively correlated with HBsAb-secreting B cell counts. Strikingly, 4-1BB stimulation in vitro restored Tfh1 function, rescuing IFN-γ and IL-21 production and enhancing B cell help. **Conclusion:** Tfh1-derived IFN-γ and IL-21 potentiate HBsAb production by activating mTORC1-STAT1/STAT3 signaling in B cells. The age-dependent decline in Tfh1 frequency and 4-1BB expression suggests progressive immune dysfunction in chronic HBV infection. Targeting 4-1BB may rejuvenate Tfh1 activity, offering a novel strategy to restore HBV-specific humoral immunity.

◆ ★ 1129 | TENOFOVIR ALAFENAMIDE, TENOFOVIR DISOPROXIL FUMARATE, AND ENTECAVIR ON HCC RECURRENCE AND DEATH AFTER CURATIVE TREATMENT: A KOREAN NATIONWIDE REAL-WORLD STUDY

Ji Eun Han[1] Gi Hyeon Seo[2] Yoon Je Cho[1] Hyo Jung Cho[1] jaeyoun cheong[1] Soon Sun Kim[1], [1]Ajou University School of Medicine, [2]VUNO Inc. Seoul, Korea

Background: Chronic hepatitis B (CHB) can lead to hepatocellular carcinoma (HCC) due to persistent covalently closed circular DNA and integrated HBV DNA, even after curative HCC treatment. Hepatitis B viral load is a prognostic factor for HCC recurrence, underscoring the importance of effective antiviral therapy. Entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide (TAF) are first-line nucleot(s)ide analogs for CHB. TAF, approved in Korea in 2017, has shown favorable safety, but long-term real-world data on HCC recurrence and mortality remain limited. This study aimed to compare the effects of ETV, TDF, and TAF on HCC recurrence or death after curative treatment in Korea. **Methods:** This retrospective cohort study used data from the Korean Health Insurance Review and Assessment Service and included 11,763 CHB patients (aged 19–99) who received ETV, TDF, or TAF for $\geq$3months and underwent curative HCC treatment (surgical resection or local ablation, including radiofrequency ablation, percutaneous ethanol injection therapy, cryoablation, or microwave ablation) between November 1, 2017, and July 31, 2023. Patients who switched to TAF for $\geq$90 days were assigned to the TAF group. The primary outcome was HCC recurrence or death. Inverse probability of treatment weighting (IPTW) was applied to adjust for age, sex, comorbidities, and treatment modality. Kaplan-Meier survival curves and Cox proportional hazards regression were used to compare outcomes among the groups. **Results:** A total of 11,763 patients (TAF: 1,024, TDF: 5,533, ETV: 5,206) were analyzed, with a median follow-up of 29.4 months. The incidence rates of HCC recurrence or death per 100 person-years were 16.66 in the TAF group, 15.20 in the TDF group, and 16.57 in the ETV group. In IPTW-adjusted analysis, TAF was not associated with a significantly different risk of recurrence or death compared to ETV (HR: 0.88, 95% CI: 0.76–1.02, p = 0.098) or TDF (HR: 0.93, 95% CI: 0.80–1.07, p = 0.307). Multivariate Cox regression analysis identified male sex, older age, diabetes, liver cirrhosis, and local ablation therapy as independent risk factors for HCC recurrence or death (all $p < 0.05$). Kaplan-Meier analysis showed no significant difference among the groups. **Conclusion:** In patients with CHB-related HCC who received curative treatment, the risk of HCC recurrence or death did not differ significantly among patients treated with TAF, TDF, or ETV.

◆ 1130 | A NOVEL MRNA-BASED IMMUNOTHERAPY INDUCES STRONG HBV-SPECIFIC CD8+ T CELL RESPONSES IN VITRO AND IN VIVO

Yuchun Nie[1] Gongxin He[2] Ren Zhu[2] (Zoe) Jia Meng[2] Wenyuan Fan[2] Jialin Chen[2] Xiaowu Chen[2], [1]Shanghai CureGene Pharmaceutical, [2]Shanghai CureGene Pharmaceutical Co.

Background: Chronic hepatitis B (CHB) virus infection is a major health burden. Currently long-term treatment with nucleoside drugs suppresses HBV replication, but rarely results in functional cure (HBV DNA and HBsAg level undetectable for $>$6 months). Recent researches indicate that reactivation of HBV-specific immunity is the key for functional cure of CHB. We discovered novel mRNA-based immunomodulators (IMs) encoding various HBV RNA fragments, capable of eliciting strong HBV-specific immune

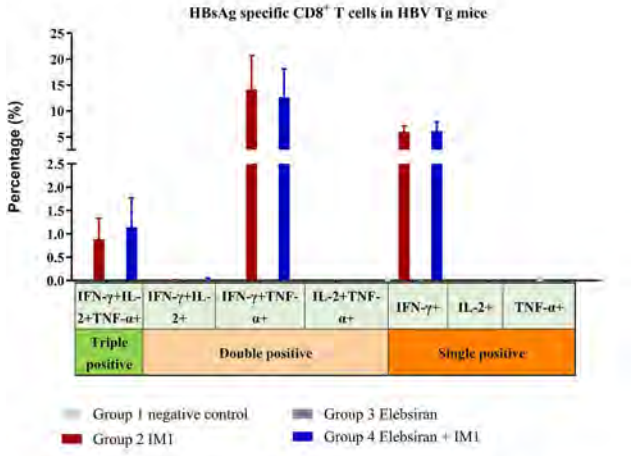
responses in vitro and in vivo and complete eliminating HBV from mouse model. **Methods:** IMs were injected at 1~10 μg/mouse in wild-type and HBV mice models, including AAV-HBV or HBV transgenic (tg) mice. Mice sera were collected for biochemical and viral biomarker analysis. The splenocytes were harvested for cellular immune responses analysis. To further test immune activation of IMs in human immune cells, an in vitro immune stimulation system was assembled with human PBMCs. **Results:** Here we report the results of IM1 which induced strong HBV-specific immune response. After three dosages, extreme high anti-HBsAb (> 100,000 IU/mL) was elicited in Balb/c mice. Meanwhile, a significant amount of HBV-specific IFN-γ+ T cells were induced. Next, we accessed their ability to induce both anti-viral & immune responses in AAV-HBV mice. The IM1 monotherapy resulted in 1.4 log IU/mL reduction of HBsAg, which maintained at a low level for at least 60 days post treatment. Strikingly, the combination of siRNA and IM1 lead to a reduction of HBsAg to undetectable level (> 3 log IU/mL) without relapse. At the same time, we observed extensive HBV-specific CD8+ T cell populations in those IM1 treated mice; the HBV-specific CD8 + T cell responses were more pronounced when IM1 was combined with siRNA. In addition, HBV tg mice were treated with IM1 and siRNA, their HBsAg level was sustained at undetectable level 70 days post treatment. Simultaneously, vigorous HBV specific polyfunctional CD8+ T cells were induced (Figure 1). In order to understand whether IM1 could stimulate human CD8+ T cells, the primary human T cells were cocultured with IM1 transfected mDC. Significant high amount of HBV specific CD8+ T cells were induced successfully. **Conclusion:** We developed a novel mRNA-based immunotherapy, which can clear HBV in various mice models (see another poster from CureGene), likely through eliciting strong, polyfunctional and long-lasting HBV-specific immune responses.

Figure 1



HBV-specific T cells were evaluated by intracellular cytokines staining in spleen from HBV tg mice 70 days post-treatment.

◆ 1131 | A FUNCTIONAL CURE AFTER NUCLEOS(T)IDE ANALOGUE DISCONTINUATION IN NON-CIRRHOTIC PATIENTS WITH HBEAG-NEGATIVE CHRONIC HEPATITIS B

Zeynep Melekoglu Ellik[1] Özge Koç[1] Fatma Tuğçe Şah Ünal[1] Emin Bodakci[2] Mesut Gumussoy[1] Abdullah Mubin Ozercan[3] Volkan YILMAZ[1] ramazan erdem er[1] Hale Gokcan[1] Atilla Halil Elhan[1] Ramazan Idilman[1], [1]Ankara University School of Medicine, [2]Gaziantep City Hospital, [3]Fırat University School of Medicine

Background: Discontinuation of long-term nucleos(t)ide analog (NA) treatment can induce functional cure in patients with chronic hepatitis B (CHB); however, data are scarce. This study aimed to evaluate HBsAg loss after NA treatment discontinuation in non-cirrhotic patients with HBeAg-negative CHB and to determine virological outcomes after NA discontinuation. **Methods:** This single-center cohort study included 146 non-cirrhotic, HBeAg-negative CHB patients who achieved long-term viral suppression under NAs treatment. Seventy-three patients discontinued NA therapy after more than 5 years of treatment and at least the last 3 years of virological suppression (consolidation period). The historical age- and sex-matched control group comprised 73 patients who continued NA therapy for a 60-month observational period. HBV reactivation was defined as HBV DNA > 2000 IU/mL with serum ALT levels exceeding two times the upper limit of normal. The primary endpoint was sustained HBsAg loss for at least 6 months, while the secondary outcome was virological and biochemical response at month 60 after NA cessation. **Results:** Patients' characteristics were similar in both groups. HBsAg loss occurred in eight patients (11%) in the discontinuation group, while none were observed in the treatment-continued group (p = 0.004). The cumulative probability of HBsAg loss was 13% at month 120. Multivariate Cox regression analysis revealed that a younger age at NA cessation (< 50 years), (Odds ratio [OR]: 6.71, 95%CI: 1.166-38.603, p = 0.033) and abnormal baseline serum AST level (≥ 40 U/L) (OR: 7.394, 95%CI: 1.249-43.783, p = 0.027) were independent predictors of HBsAg loss. Anti-HBs seroconversion was observed in six patients with HBsAg loss. Forty-four patients (60%) experienced sustained remission. HBV reactivation occurred in 29 patients, primarily (72%) within the first three months

after treatment discontinuation. Patients' characteristics were not associated with HBV reactivation. However, HBV reactivation was slightly higher in patients with HBsAg titer of > 1000 IU/mL at NA discontinuation than in those patients with < 1000 IU/mL (p = 0.097). NA retreatment was initiated in all relapsed patients, resulting in a virological and biochemical response upon re-initiation of therapy. No serious adverse events or hepatic decompensation were observed. **Conclusion:** NA discontinuation in non-cirrhotic patients with HBeAg-negative CHB was associated with a functional cure. Younger age and abnormal aminotransferase levels at baseline may predict a higher likelihood of achieving this outcome. NA discontinuation is safe and tolerable in selected patients with CHB.

◆ 1132 | INTERFERON-α ENHANCES HBSAG-SPECIFIC B CELL RESPONSES VIA MONOCYTE-TFH-B CELL AXIS TO FACILITATE FUNCTIONAL CURE OF HEPATITIS B

yongyin li[1] Shihong Zhong[1] Yang Zhou[1] Libo Tang[1] Xiaofang Li[2] Jinlin Hou[1] Jianhua Li[2] Xiaoyong Zhang[1], [1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, [2]Key Laboratory of Medical Molecular Virology (MOE/NHC/CAMS), Department of Pathogen Biology, School

Background: Achieving a functional cure for chronic HBV infection remains an unmet challenge. Our recent clinical trial demonstrated the combination of siRNA with peg-IFNα resulted in a higher rate of functional cure compared to siRNA monotherapy (New Engl J Med. 2024). This finding substantiates an important role of IFNα in mediating functional cure, however, its underlying immune mechanisms remain poorly defined, particularly in how IFNα shaping antiviral humoral immunity. Herein, we aimed to elucidate how IFNα regulates B cell immunity to facilitate functional cure. **Methods:** We longitudinally followed CHB patients receiving Peg-IFNα therapy and stratified them based on virological outcomes at week 72: HBeAg-non-seroconversion (eAg-NSC, n = 11), HBeAg-seroconversion (eAg-SC, n = 7), and HBsAg seroconversion (sAg-SC, n = 6). In addition, 3 CHB patients who achieved HBsAg seroconversion after five years of nucleos(t)ide analogues therapy (NAs-sAg-SC) were enrolled for comparison. Peripheral blood was collected at baseline and week 12 for scRNA-seq and flow cytometry. The effects of IFNα on immune subsets and HBV-specific B cell responses were further examined through in vitro cytokine stimulation assays and in vivo validation using *Il6*$^{-/-}$, *Il21r*$^{-/-}$, *Ccr2*$^{-/-}$ chimeric, and *Cxcl13*$^{-/-}$ HBV mouse models treated with IFNα plasmid. **Results:** scRNA-seq and flow cytometry revealed that Peg-IFNα selectively expanded Tfh and plasma cells specifically in sAg-SC patients. However, in vitro stimulation of purified CD19^{+}B cells with IFNα showed minimal effects indicating the involvement of intermediary cells. Given the robust upregulation of IL6–related gene programs in monocytes, we further investigated IFNα's effects on these cells and confirmed that IFNα enhanced humoral immunity by augmenting monocyte-derived IL6 secretion. Intriguingly, while IL-6 failed to directly activate B cells, subsequent analyses revealed that IFNα enhanced IL6–mediated Tfh cell interactions and promoted IL6ST-high Tfh subsets with elevated IL21 expression in sAg-SC patients. In vitro IL6 stimulation increased IL21 production in CXCR5^{+}CD4^{+} T cells, whereas IL21 induction was abolished in *Il6−/−* or monocyte-deficient mice. Transcriptomic profiling of IL21–stimulated B cells showed significant enrichment of humoral response. scRNA-seq further revealed elevated IL21–IL21R signaling between Tfh and GC-like/plasma B cells exclusively in IFNα–treated sAg-SC patients. Finally, spatial analysis demonstrated that IFNα promoted GC formation via CXCL13-CXCR5 signaling. Notably, GC development was abrogated in *Il6*$^{-/-}$, *Ccr2*$^{-/-}$ chimeric, and *Cxcl13*$^{-/-}$ mice. **Conclusion:** IFNα promotes anti-HBV humoral immunity via a monocyte-Tfh-B cell axis, strategically bridging innate and adaptive immunity to facilitate HBV cure. These findings provide mechanistic insights and identify potential targets to optimize IFNα-based therapeutic strategies.

◆ 1133 | REAL-WORLD IMPACT OF EVOLVING CHINESE CHRONIC HEPATITIS B GUIDELINES ON ANTIVIRAL TREATMENT UPTAKE: A 5-YEAR LONGITUDINAL ANALYSIS

Wei Ye[1], [1]Nanjing Second Hospital

Background: The Chinese Society of Hepatology has progressively refined chronic hepatitis B (CHB) management guidelines, expanding treatment eligibility criteria. This study evaluates the temporal association between guideline updates and real-world antiviral treatment rates in a large clinical cohort. **Methods:** We conducted a retrospective analysis of HBV DNA-positive adults at Nanjing Second Hospital (2019-2024). Annual treatment rates were calculated as the proportion of eligible patients receiving nucleos(t)ide analogs or interferon. Three guideline epochs were examined: 2015 version, 2019 version, and 2022 version. **Results:** The Chinese guidelines for CHB management have undergone three major revisions: the 3rd edition in December 2015, the 4th edition in December 2019, and the 5th edition in December 2022. Our data demonstrate the following treatment patterns according to respective guideline versions. In 2019, when following the 2015 guideline criteria, 2,430 of 4,489 HBV DNA-positive patients (54%) received antiviral therapy. After implementation of the 2019 guidelines, treatment rates increased to 59% (2,239/3,782) in 2020, 57.9% (2,268/3,913) in 2021, and 61.6% (2,246/3,645) in 2022. Following adoption of the 2022 guidelines, the treatment rate rose to 65% (2,204/3,343) in 2023. Current data through 2024 show further improvement to 74% (1,374/1,878), demonstrating a consistent upward trend. **Conclusion:** This longitudinal analysis demonstrates the significant clinical impact of Chinese CHB guideline evolution, with each iteration contributing to progressive improvements in treatment rates. These findings underscore the importance of regular, evidence-based guideline updates and systematic implementation strategies in optimizing CHB management.

◆ 1134 | LONGITUDINAL PATTERNS OF QUANTITATIVE HBSAG DECLINE IN A LARGE REAL-WORLD COHORT OF TREATED CHRONIC HEPATITIS B PATIENTS

Sanam Tabataba Vakili[1] Leila Amiri[1] Aaron Vanderhoff[2] Andrew Mendlowitz[1] Grishma Hirode[1] Harry Janssen[3] Adam Gehring[4] Scott Fung[4] Jordan Feld[5], [1]Toronto Centre for Liver Disease, University Health Network, Toronto, Ontario, Canada, [2]Toronto Centre for Liver Disease; Viral Hepatitis Care Network (VIRCAN), University Health Network, [3]Toronto Centre for Liver Disease, University Health Network; Erasmus University Medical Centre, Rott, [4]University Health Network, [5]Toronto General Hospital

Background: Quantitative hepatitis B surface antigen (qHBsAg) levels reflect virologic activity and host immune control in chronic hepatitis B (CHB). Characterizing the kinetics of qHBsAg over time can inform prognosis and response prediction to emerging cure-directed therapies. **Methods:** We conducted a retrospective analysis of adult CHB patients with ≥ 1 qHBsAg measurement and ≥ 1 year of follow-up from April 2010 to May 2022 at a tertiary liver center in Canada. qHBsAg values were log-transformed and changes in qHBsAg (ΔqHBsAg) were standardized by subtracting each patient's baseline level, anchoring all trajectories at 0. Individual linear regression models estimated the slope of Δ(qHBsAg) over time for each patient. Slope distributions were analyzed overall and stratified by baseline qHBsAg levels. Model-predicted and observed group trends were compared to validate fit. **Results:** Among 7,677 CHB patients (56.6% male; mean age 49.8 years), median follow-up was 5.04 years. The median baseline qHBsAg level was 1,110 IU/mL, ranging from 0.05 to 124,925 IU/mL. Overall, 69.6% had qHBsAg <3000 IU/mL, including 84.1% of those over age 50. The mean slope of Δlog(qHBsAg) was –0.210 log IU/mL/year, indicating an overall decline. Patients with low baseline levels (0.05–10 IU/mL) showed the most consistent trajectories, while those $>10{,}000$ IU/mL had steeper declines (–0.437 log/year) but with greater variability. LOESS-smoothed plots revealed uniform reductions in lower qHBsAg categories and erratic trends in those with higher values. Factors associated with rapid qHBsAg decline (>0.25 log IU/mL/year) were identified using multivariable logistic regression; this threshold was selected because it is above the median slope, providing greater sensitivity for detecting covariate associations. Lower baseline qHBsAg (OR = 0.96 per log increase), higher ALT (OR = 1.32), treatment (OR = 1.23), and cirrhosis (OR = 1.23) were independently associated with greater odds of qHBsAg decline >0.25 logIU/year. Age was not a significant predictor in the overall model and sex had a modest effect (Male sex OR = 1.17). In models stratified by baseline qHBsAg level, treatment and baseline

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ALT remained strong predictors of more rapid qHBsAg decline in those with baseline levels > 3,000 IU/mL but were also associated with Δlog(qHBsAg) in those with lower baseline qHBsAg levels. **Conclusion:** In this large real-world cohort, qHBsAg levels declined over time in most CHB patients. The rate and consistency of decline were influenced by baseline qHBsAg levels, ALT, treatment, and cirrhosis. Lower baseline levels showed consistent trajectories, while higher levels exhibited variable but deeper declines. These patterns may help guide individualized monitoring and treatment strategies.

◆ 1135 | PROTEOMIC CHARACTERISTICS AND DIAGNOSTIC BIOMARKER IDENTIFICATION IN THE PROGRESSION OF HBV-RELATED LIVER DISEASE

Mengqi Li[1] Wenhao Shi[2] Yiying Zhu[2] Wen Xie[1], [1]Center of Liver Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing, China, [2]Analysis Center, Chemistry Department, Tsinghua University, Beijing, China

Background: Hepatitis B virus (HBV) infection is a major global public health challenge. HBV-related liver diseases progress through multiple stages, from chronic hepatitis B to cirrhosis and hepatocellular carcinoma (HCC). The changes in plasma protein expression across different disease stages have not been fully explored. This study aims to identify the proteomic characteristics of plasma proteins at different stages of HBV-related liver diseases and explore potential biomarkers for HCC. **Methods:** This study employed data-independent acquisition mass spectrometry, combined with trend clustering and enrichment analysis, to explore changes in plasma protein levels across different disease stages and their biological

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

significance. The Least Absolute Shrinkage and Selection Operator regression was used for variable selection, and three machine learning algorithms, including Random Forest (RF), Decision Tree, and Extreme Gradient Boosting, were employed to develop a diagnostic model for HCC. **Results:** Proteomic analysis was conducted on plasma samples from 30 healthy controls, 30 chronic hepatitis B patients, 30 HBV-related cirrhosis patients, and 30 HBV-related HCC patients. The analysis identified four major protein clusters: Cluster I, elevated in chronic hepatitis B, enriched in hemostasis and immune response pathways; Cluster II, elevated in both HBV-related cirrhosis and HCC, enriched in extracellular matrix pathways; Cluster III, showing decreased expression from chronic hepatitis B to cirrhosis and HCC, enriched in hemostasis, metabolism, and immune response pathways; and Cluster IV, upregulated in HCC, enriched in cellular stress response, cell cycle regulation, immune response, and extracellular matrix pathways. The study identified five potential biomarkers for HCC: Transketolase (TKT), Polyadenylate-binding protein 1 (PABPC1), Alpha-1-antichymotrypsin (SERPINA3), Chitinase-3-like protein 1 (CHI3L1), and Papilin (PAPLN). The RF-based diagnostic model (P5) demonstrated optimal performance (AUROC = 0.983, Figure 1), outperforming traditional alpha-fetoprotein testing (AUROC = 0.839). **Conclusion:** This study revealed the proteomic characteristics of plasma proteins at different stages of HBV-related liver disease and developed a diagnostic model for HCC with high diagnostic performance. The identified plasma proteins offer new insights into the mechanisms of disease progression and provide new biomarkers for HCC diagnosis.

◆ 1136 | SPATIAL COMPARTMENTALIZATION OF HBV AND HDV IN COINFECTED LIVER TISSUE MEDIATED BY HDV-INDUCED SUPPRESSION OF HBSAG NEW SUBMISSION

Soichi Takeda[1] Anirudh Krishnan[1] Davide De Battista[1] Neelam Redekar[2] Hanh Nguyen[1] Sandra Kendra[1] Quan Yu[1] Rana Eltahan[3] David McGivern[3], [1]Hepatic Pathogenesis Section, Laboratory of Infectious Diseases, NIAID, NIH, Bethesda, USA, [2]Integrated Data Science Section, Research Technologies Branch, NIAID, NIH, Bethesda, USA, [3]Office of Blood Research and Review, Center for Biologics Evaluation and Research, FDA

Background: As HDV is a defective virus, which requires HBsAg for virion assembly and propagation, it remains unclear whether hepatocellular carcinoma (HCC) arises from the underlying cirrhosis, direct oncogenic effects of HDV, or a combined effect of HBV and HDV. We investigated the spatial distribution of viral antigens and transcriptional differences in HDV/HBV coinfected vs. HBV-monoinfected patients with HCC. **Methods:** RNAsequencing was performed on paired tumor and nontumorous liver tissues from patients with HDV-associated HCC (n = 4), non-HCC HDV cirrhosis (n = 7), and HBV-associated HCC (n = 11). All HBV HCC patients received nucleos(t)ide analogue antiviral therapy prior to surgery or liver transplantation. *In vivo* molecular findings were complemented by *in vitro* studies. Immunohistochemistry was used to localize viral markers (HDAg, HBsAg, HBcAg, and HDV RNA by *in situ* hybridization). Triple immunostaining with anti-HBsAg and two in-house antibodies generated against HDAg and large HDAg (L-HDAg) was conducted on 46 HDV liver specimens, including 10 HDV HCC (paired tumor and nontumorous tissue) and 26 specimens from the right and left lobes of 8 non-HCC HDV cirrhosis obtained at the time of liver transplantation. **Results:** Confocal microscopy showed variable HDAg expression across patients and tissues, with a predominance of small HDAg (S-HDAg) both within and outside tumors. HBcAg was absent in all tumor and nontumorous tissues from HDV-infected livers, except in one patient with HDV cirrhosis. Among HBV-related HCC cases, HBcAg was detected in a few cells in only one nontumorous sample. *In situ* HDV RNA correlated with the expression of HDAg. Contrary to expectations, HDAg and HBsAg rarely colocalized, suggesting compartmentalization of HDV and HBV within the hepatic microenvironment. Transcriptomic analysis showed distinct molecular signatures with upregulation of genes involved in cell cycle and DNA repair in HDV HCC and metabolism switch-off in HBV HCC. Notably, HDV HCC was characterized by

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

upregulation of host genes previously reported to inhibit HBsAg expression (Hyrina et al.2019) in both tumor and nontumor tissue, compared to HBV HCC. To elucidate the molecular basis for HBsAg suppression in HDAg-infected cells, we interrogated *in vitro* transcriptomic data and found that transfection with an HDV plasmid [pSVL(D3)], in the absence of HBV, into Huh7 cells induced upregulation of host genes involved in HBsAg suppression. **Conclusion:** Our study demonstrates spatial compartmentalization of HDV and HBV within coinfected livers, with minimal colocalization of HDAg and HBsAg at the single-cell level. *In vivo* and *in vitro* analyses reveal that HDV suppresses HBsAg expression through host gene modulation. These findings uncover a mechanism underlying the mutual exclusion of HDV and HBV antigen expression in coinfected hepatocytes and provide new insights into HDV biology and pathogenesis.

◆ 1137 | HEC191834, A HIGHLY SELECTIVE AND POTENT HTLR8 AGONIST, EXHIBITS SYNERGISTIC ANTIVIRAL ACTIVITY WITH SIRNA IN AN AAV-HBV MOUSE MODEL

Pu Wang[1] Guanghua Yan[2] YingLin Zuo[2] Baohua Gu[2] Jing Li[2] Yunfu Chen[2], [1]Sunshine Lake Pharma Co., Ltd., Dongguan 523871, PR China, [2]Sunshine Lake Pharma Co., Ltd., Dongguan

Background: Achieving a functional cure for chronic hepatitis B (CHB) requires reducing hepatitis B surface antigen (HBsAg) and restoring immune responses. HBsAg rebound after small interfering RNA (siRNA) or antisense oligonucleotide therapy highlights the need for immune stimulators. HEC191834, a novel human Toll-like receptor 8 (hTLR8) agonist, was evaluated for its selectivity, immune-modulatory effects, and synergistic antiviral activity with siRNA in preclinical models. **Methods:** HEC191834 selectivity was assessed in hTLR7 and hTLR8 reporter cells. Immune-stimulatory effects were evaluated in hPBMCs and cynomolgus monkeys, and antiviral activity was tested in primary human hepatocytes (PHH) and an AAV-HBV-transduced, hTLR8-humanized mouse model. Mice received 4-week treatments: 1) HEC191834 orally (10 or 30 mg/kg weekly), 2) HECN30227 (HBV-X-targeting siRNA) subcutaneously (3 mg/kg biweekly), or 3) their combination. Viral parameters, ALT, IL-12p40, and TNF-α were measured. IFN-γ^+ T cells were analyzed by intracellular cytokine staining post-HBsAg peptide stimulation. Liver RNA sequencing (RNAseq) assessed gene expression. **Results:** HEC191834 exhibited potent hTLR8 agonism (EC_{50} = 16 nM) with >6250-fold selectivity over hTLR7. It induced IL-12p40, IFN-γ, IL-8 and TNFα in hPBMCs, and the conditioned medium showed inhibitory activity against HBV in PHH. The EC_{50} of HBV DNA, HBV RNA, and HBsAg were 10.6 nM, 8.8 nM, and 127.6 nM, respectively. In cynomolgus monkeys, HEC191834 dose-dependently increased IL-12p40 (0.3–10 mg/kg). In the AAV-HBV mouse model, HEC191834, but not HECN30227, induced IL-12p40, TNF-α, anti-HBs antibodies, and HBV-specific IFN-γ^+ $CD4^+$/$CD8^+$ T cells. Both 30 mg/kg HEC191834 and 3 mg/kg HECN30227 significantly reduced serum HBV DNA and HBsAg compared to controls. Notably, the combination synergistically enhanced anti-HBs and HBV-specific IFN-γ^+ T cells. Serum ALT levels remained unchanged across groups. RNAseq analysis of liver tissue revealed comprehensive effects of HBV infection and drug treatment on antiviral and immune-regulatory pathways. **Conclusion:** HEC191834 is a novel, potent, and selective hTLR8 agonist with synergistic antiviral activity when combined with an HBV-targeting siRNA. These findings support further clinical studies to evaluate its potential for achieving a functional HBV cure.

Background: Close to half of patients with chronic hepatitis B (CHB) fall into the indeterminate phase with a higher risk of hepatocellular carcinoma (HCC) than the untreated patients with inactive phase as well as the treated patients with active phase. However, the HCC risk varied significantly among diverse subgroups of indeterminate CHB patients. We developed and validated the risk score to stratify the HCC risk in a large consortium of untreated CHB with indeterminate phase to help inform treatment decision of indeterminate patients. **Methods:** We conducted a retrospective multinational REAL-B cohort study which included 2,075 adult CHB patients with indeterminate phase based on the AASLD guidance from 23 sites of 9 countries/regions. Patients were randomly divided into a derivation dataset (n = 1,384) and a validation dataset (n = 691) with a ratio of 2:1. An HCC risk score was developed based on multivariable Cox regression models and scores system for simplification. Harrell's c-index was used as discrimination. **Results:** A total of 38 (1.8%) patients developed HCC during a median follow-up of 6.54 (IQR: 2.6-12.5) years. The 15-year cumulative HCC incidence rates were 3.58% (95% CI: 2.28%-5.61%) and 3.67% (95%CI: 2.02%-6.63%) in the derivation dataset and validation dataset, respectively. In the derivation dataset, age, platelets, HBeAg status, albumin, total bilirubin and the presence of diabetes were independently associated with HCC development. The indeterminate REAL-B (iREAL-B) score was developed for the prediction of HCC based on those six predictors with good predictability of HCC (Harrell's C-index = 0.84) in the derivation dataset. The predictability of iREAL-B score was similar (Harrell's C-index = 0.77) in the validation dataset. Patients with low (0-3), intermediate (4-6) and high (≥ 7) iREAL-B scores had 15-year cumulative HCC incidence rates of 1.91% (95%CI: 0.07%-5.11%), 6.07% (95%CI: 3.10%-11.7%), 41.94% (95%CI: 18.42%-76.59%) in the derivation dataset and 2.23% (95%CI: 0.67%-7.31%), 5.44% (2.01%-14.30%), 21.3% (4.88%-68.22%) in the validation dataset, respectively (Figure). **Conclusion:** iREAL-B, which is based on 6 simple readily available clinical parameters (age, platelets, HBeAg status, albumin, total bilirubin and the presence of diabetes) can help risk stratify indeterminate patients to inform shared decision making between patients and care providers regarding antiviral treatment.

Figure. Construction and predictive performance of iREAL-B score for prediction of HCC development.

◆ 1139 | PROTEOMIC PROFILING IN PREFILLED SYRINGE STUDY DEMONSTRATES BEPIROVIRSEN'S IMMUNE STIMULATORY EFFECT

Jennifer Singh[1] Scott Van Buren[1] Cheng Zhu[2] Johannes Freudenberg[1] Kristen Consalvo[1] Luca Pagliaroli[1] Sohil Joshi[1] Puneet Dhawan[1] Amir Youssef[1] Poonam Shah[3] Jill Walker[4], [1]GSK, Collegeville, PA, USA, [2]GSK, Waltham, MA, USA, [3]GSK, Stevenage, UK, [4]GSK, San Francisco, CA, USA

Background: Bepirovirsen is an investigational antisense oligonucleotide that impacts hepatitis B virus (HBV) infection in three ways by: (1) reducing hepatitis B surface antigen, (2) suppressing viral DNA, and (3) stimulating immune activity. A Phase 1 randomized trial evaluated the relative bioavailability of subcutaneous bepirovirsen when delivered from a vial or a ready-to-use prefilled syringe (PFS) fitted with a safety syringe device (SSD) in healthy participants. Here, serum protein changes at early time points following bepirovirsen administration were evaluated to further elucidate the mechanism of action of bepirovirsen and its role in immune stimulation. **Methods:** This Phase 1, open-label, parallel group study (NCT06058390) randomized (3:3:2:2) 160 healthy adult participants to receive a single 300 mg dose of bepirovirsen from a vial administered by a healthcare professional (HCP; Arm 1), from the PFS SSD administered by an HCP (Arm 2), self-administered using the PFS SSD with training from an HCP (Arm 3), or self-administered using the PFS SSD without training (Arm 4). Proteomics data were generated from participants' serum samples (collected at baseline, 2, 4, 8, 12, 24, and 48 hours post-treatment) using the Olink Explore 1536 Panel (consisting of cardiometabolic, inflammation, neurology, and oncology 384 panels). Linear modeling using the Limma method was applied to investigate immune protein changes across different subgroups. Comparisons were made between each time point versus baseline and across treatment arms, sex, and injection sites (upper arm, abdomen, or thigh [Arm 1, 2] and abdomen or thigh [Arm 3, 4]). Results from this study were then compared with those from an earlier Phase 2a study in patients with chronic HBV infection (NCT02981602). **Results:** Across multiple immune pathways, the majority of proteins downstream of Toll-like receptors (TLR) and select immune protein signatures showed significant induction, with peak induction observed at 24–48 hours post-treatment (Table). Profiling of selected proteins downstream of TLRs showed strong innate immune responses as early as 2 hours post-dose. No systematic differences were observed across treatment arms, but some immune protein profiles differed by sex or injection site. Activated immune proteins identified from the Phase 2a study showed similar stimulation patterns to those identified in this study. **Conclusion:** These data demonstrate that bepirovirsen mediates a strong innate immune response, with the highest activity observed at 24–48 hours, suggesting a sustained immune response that lasts at least 48 hours. The similar immune protein profile changes observed in patients with chronic HBV infection and in healthy volunteers in this study suggests that this immune response is stimulated by bepirovirsen treatment regardless of the presence of HBV. Funding: GSK (219239)

Table. Number of differentially expressed innate immune proteins in serum compared to baseline

Time point, hours	Number of upregulated proteins	Number of downregulated proteins	Total number of differentially expressed proteins
2	5	0	5
4	10	0	10
8	15	0	15
12	19	0	19
24	22	1	23
48	15	1	16

◆ 1140 | MBOAT2–ESCRT AXIS LIMITS THE ANTIVIRAL EFFECT OF TENOFOVIR ALAFENAMIDE PLUS INTERFERON-A IN CHRONIC HEPATITIS B

Bei Jiang[1] Zhiqaing Liu[2] Yixuan Wang[2] Mu Qiao[2] Yue Hu[3], [1]Tianjin Second People's Hospital, [2]Shandong Cancer Hospital and Institute, Shandong First Medical University, [3]Tianjin Second People's Hospital Department of Gastroenterology

Background: Pegylated interferon-α (PEG-IFNα) combined with nucleos(t)ide analogues (NAs) such as tenofovir alafenamide (TAF) is widely used to treat chronic hepatitis B virus (HBV) infection, yet ≥70 % of patients fail to achieve functional cure, defined as hepatitis B surface antigen (HBsAg) seroclearance. The contribution of host metabolic genes to this limited response remains poorly understood. **Methods:** A genome-scale CRISPR/Cas9 single-guide RNA library targeting 2,981 human metabolic genes was applied to HBV-infected hepatocytes exposed to tenofovir alafenamide (TAF) plus IFNα to identify regulators of HBsAg clearance. Findings were validated through: (i) time-course mRNA/protein analyses in cell lines and HBV mouse models; (ii) targeted and untargeted lipidomics; (iii) pharmacological or siRNA manipulation of sphingolipid synthesis and MBOAT2 expression; (iv) co-immunoprecipitation and mutagenesis to map MBOAT2 interactions with ESCRT components; and (v) histological and biochemical assessment of liver biopsies from chronically infected patients before and after TAF + PEG-IFNα therapy. **Results:** Treatment with TAF + IFNα progressively elevated intracellular sphingomyelin, which in turn up-regulated MBOAT2 expression in vitro, in AAV mouse models, and in CHB patient biopsies. MBOAT2 emerged as the top hit whose deletion enhanced HBsAg loss under antiviral pressure. MBOAT2 levels remained high even when serum HBsAg declined clinically. Sphingomyelin-driven MBOAT2 bound ESCRT proteins CHMP4C promoted itsacylation-dependent activation, attenuated TAF + IFNα–induced endoplasmic-reticulum stress (diminished IRE1α phosphorylation, reduced BiP, and less ER vacuolization). This process facilitated endoplasmic reticulum membrane repair and fluidity, thereby sustaining HBV-DNA replication and HBsAg secretion. Pharmacologic blockade of sphingomyelin synthesis or genetic silencing of MBOAT2 restored ER-stress signaling and markedly potentiated the antiviral efficacy of TAF + IFNα. **Conclusion:** We delineate a previously unrecognized sphingomyelin–MBOAT2–ESCRT axis that shields HBV from TAF + PEG-IFNα-mediated suppression by dampening ER stress and sustaining HBsAg production. Targeting MBOAT2 or sphingomyelin biosynthesis offers a promising strategy to enhance functional cure rates in chronic HBV infection.

◆ 1141 | THE PROFILE OF HEPATITIS D VIRUS (HDV)-INFECTED PATIENTS RECEIVING A LIVER TRANSPLANT IN THE UNITED STATES AND EUROPE OVER THE PAST TWO DECADES

Zobair Younossi[1] Giacomo Germani[2] Robert Wong[3] Maria Stepanova[1] Fatema Nader[4] Vincent Karam[5] Maria Buti[6] George Papatheodoridis[7] Pietro Lampertico[8] Saleh Alqahtani[9] Linda Henry[1] Patrizia Burra[10], [1]The Global NASH Council, [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy, [3]VA Palo Alto Healthcare System, [4]Center for Outcomes Research in Liver Diseases, CORLD, [5]The European Society for Organ Transplantation, Amsterdam, the Netherlands, [6]Hospital Valle Hebron, [7]First Academic Department of Gastroenterology, Medical School of National and Kapodistrian Univer, [8]University of Milan, [9]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King, [10]3. Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy

Background: Hepatitis D virus (HDV) coinfection with hepatitis B virus (HBV) is a relatively uncommon but an important indication for liver transplantation. The aim was to

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

compare clinical presentation and outcomes between patients transplanted with HDV and those who were transplanted for HBV only. **Methods:** Adult liver transplant recipients with HBV from the European Liver Transplant Registry (ELTR) and the U.S. Scientific Registry of Transplant Recipients (SRTR) were included (years 2000-2022). Common clinical parameters and post-transplant mortality were collected and summarized by the presence of HDV coinfection (as determined by the respective listing diagnosis). **Results:** Of 13,093 HBV-infected patients, 2,327 (18%) had HDV coinfection (HDV group) and 10,766 (82%) had HBV mono-infection (HBV group). Overall, a significantly higher number of HDV transplants were reported from European centers than US (24% of all HBV-infected patients from ELTR had HDV vs. 2.6% of all HBV-infected patients from SRTR). In both registries, the proportions of HDV patients among LT recipients with HBV infection remained stable over time in the last 20 years (both trend $p > 0.05$). As compared to the HBV group, HDV liver transplant recipients were significantly younger (mean ± SD age: 48 ± 10 years vs. 54 ± 10 years), had lower BMI (25.4 ± 4.0 vs. 26.3 ± 4.7), and less likely to be male (68% vs. 83%) (all $p < 0.0001$). In addition, fewer HDV patients were listed for liver transplantation with a secondary diagnosis of HCC (27% vs. 44%, $p < 0.0001$), and their MELD scores at the time of transplantation were higher (17.6 ± 7.4 vs. 17.0 ± 9.3, $p < 0.0001$). In this context, ascites was more frequent in HDV (66% vs. 55%, $p < 0.0001$) while the rates of hepatic encephalopathy were similar ($p > 0.05$). Post-transplant mortality was lower in HDV patients: cumulative 15% vs. 27% over median (IQR) of 5.2 (1.3-11.7) years, 1-year 8% vs. 12%, 3-year 14% vs. 20%, 5-year 19% vs. 26%, 10-year 32% vs. 39% (all $p < 0.01$). Similar trends were also observed in the subpopulation of HDV vs. HBV patients without HCC (1-year mortality 8% vs. 14%, 3-year 13% vs. 21%, 5-year 17% vs. 25%, 10-year 29% vs. 38%; all $p < 0.01$) while mortality rates in patients with HCC were similar between HDV and HBV groups (1-year 10% vs. 10%, 3-year 19% vs. 20%, 5-year 25% vs. 28%, 10-year 40% vs. 41%; all $p > 0.05$). **Conclusion:** Compared to HBV mono-infection patients, HDV patients were more often listed for decompensated liver disease and at younger age suggesting the need of effective therapies to suppress HDV replication. Nevertheless, the HDV group appears to have similar or more favorable post-transplant outcomes in comparison to patients transplanted with HBV alone.

◆ 1142 | A NOVEL MRNA-BASED IMMUNOTHERAPY ACHIEVES COMPLETE ELIMINATION OF HUMAN HEPATITIS B VIRUS IN CHRONIC HBV MOUSE MODELS

Gongxin He[1] Zoe Jia Meng[1] Wenyuan Fan[1] Jialin Chen[1] Xiaowu Chen[2] Ren Zhu[1] Yuchun Nie[1],
[1]Shanghai CureGene Pharmaceutical Co, Ltd,
[2]Shanghai CureGene Pharmaceutical Co

Background: Chronic hepatitis B (CHB) remains a formidable global public health challenge, with ~250 million patients and more than 1.2 million new infections each year. Despite recent advances in antiviral treatments-including siRNA and antisense oligonucleotide (ASO) therapies in clinical trials, achieving functional cure remains elusive. Current consensus underscores the necessity of combining immunomodulatory strategies with direct-acting antivirals to substantially improve functional cure rates. **Methods:** We developed two mRNA-based immunomodulators (IMs) and evaluated their therapeutic potential in combination with entecavir and either a siRNA (Elebsiran) or an ASO (Bepirovirsen) in two distinct chronic HBV mouse models for elimination of HBV both in the periphery and intrahepatic compartment. **Results:** Combination therapies containing one of the IMs led to a rapid and profound decline in HBsAg and HBV DNA, whereas prophylactic HBV vaccine (Engerix) had minimum impact on these viral markers. Remarkably, these antiviral effects persisted for at least 10 weeks after treatment discontinuation, with no viral rebound observed (Figure 1). Further, HBcAg immunostaining in the liver sections at two timepoints (post last dosing and 10 weeks later) clearly demonstrated durable intrahepatic viral control. Consistent antiviral effects were demonstrated in both AAV-HBV and transgenic mouse models. Combinations with either siRNA or ASO yielded similar results. Treatments with siRNA or

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

ASO alone showed rapid viral rebound after treatment discontinuation. Notably, seroconversion was also observed in animals receiving combination therapies. **Conclusion:** Our study demonstrated that either novel IMs, when used in combination with direct antivirals, achieved a rapid, robust, and sustained suppression of HBV infection in chronic mouse models. We observed rapid and sustained declines in HBsAg and HBV DNA in plasma and HBcAg in the liver. Unlike treatments lacking the IMs, which only induced a rapid yet transient HBsAg and HBV DNA decline followed by a rapid rebound of these viral markers once the treatments were discontinued, our approach clearly promotes durable viral control and clearance of HBV from the mouse models mediated by HBV-specific immune responses (see the other poster from CureGene). These findings highlight the transformative potential of mRNA-based immunotherapy to significantly improve functional cure rates in chronic hepatitis B patients.

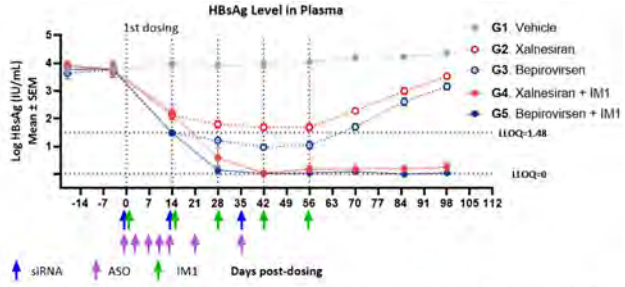

Fig 1. HBsAg levels in the AAV-HBV mouse model after treatment with G1 (vehicle), G2 (Xalnesiran), G3 (Bepirovirsen), G4 (Xalnesiran and IM1) or G5 (Bepirovirsen and IM1). Arrows indicate days of dosing with either siRNA/ASO (blue) or IM1 (green). LLOQ, lower limit of quantification.

◆ 1143 | THE SAFETY AND EFFICACY PROFILE OF CANOCAPAVIR IN A PHASE 2 TRIAL: A CAPSID ASSEMBLY MODULATOR FOR LOW-LEVEL VIREMIA TREATMENT

Yanhang Gao[1] Ge Yu[1] Baini Li[2] Bin He[2] Fei Kong[1] Zhihong Lu[2] Huanming Chen[2] Man-Fung Yuen[3] Junqi Niu[1], [1]The First Hospital of Jilin Uiversity, [2]Shanghai Zhimeng Biopharma Inc., [3]The University of Hong Kong

Background: Canocapavir is a hepatitis B virus (HBV) capsid assembly modulator with a novel pyrazole chemical structure. It showed a desired pharmacokinetics and safety profile in Phase 1 studies. The Phase 2 study of Canocapavir (NCT05484466) was conducted to evaluate its safety, tolerability, and efficacy in low-level viremia (LLV) patients with Entecavir (ETV)-treated chronic hepatitis B (CHB) patients. **Methods:** Non-cirrhotic, ETV-treated CHB patients with HBV DNA levels $< 2{,}000$ IU/mL but ≥ 50 IU/mL were randomized to 50 mg or 100 mg Canocapavir once daily or matching placebo. Treatment was stratified by hepatitis B e antigen (HBeAg) status. After 48 weeks of treatment, all subjects are set to continue taking ETV as monotherapy for a 12-week follow-up. The efficacy endpoints included the percentage of subjects who achieved a complete virologic response (CVR), as defined by a serum HBV DNA level of ≤ 10 IU/mL, at the end of the 24/48-week, and the time to achieve CVR in each group. **Results:** A total of 83 subjects were randomized, with one subject excluded from full analysis set (FAS) due to the absence of valid post-dose efficacy data. The demographic characteristics of 82 subjects (FAS) were mean age 40.6 years; male 64.6 %; HBeAg positive 79.3%. The percentage of subjects reported at least one TEAEs was similar among three treatment groups and the majority of TEAEs were mild or moderate (CTAE 5.0 Grade 1 or 2) in severity. There were 6 SAEs, 2 from the 100 mg cohort and 4 from the placebo, and all SAEs were considered to be not related or unlikely related. No case of ALT flare was observed. At week 24, the percentages of patients who achieved CVR were 14.3%, 46.2%, and 82.1% in the placebo, 50 mg, and 100 mg cohorts, respectively. At week 48, the percentages were 10.7%, 53.8%, and 78.6%, respectively. The 100 mg cohort exhibited the most rapid decline in HBV DNA, attaining CVR with a median of 3.07 weeks. **Conclusion:** Current results indicate that adjunctive treatment of Canocapavir with ETV was generally well tolerated and effective for LLV patients with reduced HBV DNA to less than 10 IU/mL and maintained. Canocapavir enhanced viral suppression when combined with ETV. These findings support the further development of Canocapavir for the treatment of CHB.

◆ 1144 | HEPATITIS B SURFACE ANTIGEN LOSS IS ASSOCIATED WITH REVERSAL OF SYSTEMIC AND INTRAHEPATIC B-CELL DYSREGULATION IN CHRONIC HEPATITIS B

Nour NASSER[1] Stéphanie Narguet[2] Samira Laouirem[3] Margaux BOSSIS[4] Adel HAMMOUTENE[1] Miguel ALBUQUERQUE[1] Issam TOUT[1] Nathalie BOYER[5] Gregory GAUTIER[1] Dahbia DJAROUN[1] Valerie Paradis[6] Patrick Kennedy[7] Safi DOKMAK[8] Abdellah Mansouri[3] Pierre Tonnerre[9] Tarik Asselah[10], [1]INSERM UMR1149, Paris, France, [2]Hôpital Beaujon, AP-HP, Clichy, France., [3]INSERM UMR1149, Paris, France.,

Background: Hepatitis B virus (HBV) infection remains a major global health issue and can lead to chronic hepatitis B (CHB). Hepatitis B surface antigen (HBsAg) seroclearance is associated with improved clinical outcomes and is considered a functional cure. This study investigates B-cell phenotype, function, and dynamics in patients with CHB, focusing on their potential contribution to HBsAg loss. **Methods:** Patients and Methods: In this prospective and longitudinal study, 114 individuals were included: 21 patients who achieved HBsAg loss (HBsAg-), 50 untreated CHB patients, 20 nucleos(t)ide analogs-treated CHB patients, and 23 healthy controls. Plasma cytokines and markers of B-cell exhaustion were quantified using ELISA and Meso Scale Discovery assays. B-cell subsets were assessed using flow cytometry. Additionally, immunohistochemistry staining and digital image analysis was performed on liver tissue to examine the hepatic immune microenvironment. **Results:** Untreated CHB patients displayed elevated plasma levels of TNFα, IL-10, soluble BAFF, and G-CSF, which normalized in HBsAg- individuals. Phenotypically, CHB patients had reduced frequencies of $CD19^+$ $CD27^+CD38$^hi plasma B cells and increased $CD19^+$ $CD10^+$ $CD27^-$ $CD21^-$ atypical memory B cells compared to both controls and HBsAg- individuals. HBsAg-specific B-cell analyses further confirmed a higher frequency of atypical B cells in CHB patients relative to treated and healthy individuals. Longitudinal analyses revealed a progressive increase in atypical B cells in untreated CHB patients, while HBsAg- individuals showed a reduction in atypical B cells alongside with an increase in plasma B cells. In liver tissue, CHB patients exhibited increased infiltration of B cells and formation of tertiary lymphoid structures all of which were normalized in HBsAg-. **Conclusion:** These findings indicate systemic and intrahepatic B-cell dysregulation in CHB, with functional and phenotypic restoration in patients who cleared HBsAg. These insights may support future therapies aiming to enhance immune control of HBV.

1145 | GAPS IN HEPATITIS B TREATMENT AMONG U.S. VETERANS: A RETROSPECTIVE ANALYSIS WITHIN THE VETERANS HEALTH ADMINISTRATION

Phillip Chen[1] Steven-Huy Han[1], [1]UCLA

Background: Chronic hepatitis B (HBV) continues to be a leading cause of liver disease morbidity and mortality. Despite effective antiviral therapies, linkage to care and treatment adherence continues to be suboptimal nationally. Veterans are a unique cohort with access to integrated care through the Veterans Health Association (VHA). Treatment gaps of the VHA in accordance to societal guidelines remain unclear. **Methods:** Veterans with HBsAg positivity, elevated ALT, and HBV viremia were identified. Patients were stratified based on cirrhosis status via ICD 10 codes or calculated Fibrosis-4 scores, and other comorbidities. Treatment eligibility was assessed per AASLD guidelines. Subgroup analyses examined disparities by race/ethnicity, mental health comorbidities, and rural vs. urban residence. **Results:** Of 57,403 veterans with a positive HBV sAg, 3,366 had both an elevated ALT and HBV PCR level (5.8%), and 7,867 had Hepatocellular Carcinoma (HCC) or Cirrhosis (13.7%). In total, there were 9,715 veterans treatment eligible (16.92%) per AASLD guidelines. Among these, 4,017 were treated (41%). Veterans with cirrhosis were less likely to be treated (35%, $P < 0.001$). Non-hispanic white veterans (65%) and Hispanic or Latino veterans (65%) were less likely to be treated ($P < 0.0001$) compared to Asian veterans (67%). Veterans residing in rural areas as indicated by geospatial codes were less likely to be treated (67%) compared to urban (55%) residing veterans ($P < 0.0001$). Patients with AUD as identified by AUDIT-C were less likely to be treated (62%, $P < 0.0001$). And when comparing AUD with other mental health related comorbidities (i.e. depression, anxiety, and etc) or substance use disorder, veterans with AUD was also less likely to be treated for HBV (39%, $P < 0.0001$). Patients with HIV were more likely to be treated (44%, $P < .0001$), whereas veterans who were treated for HCV were less likely to be treated for HBV (28%, $P < .0001$). There was no detectable association between treatment for those with comorbid metabolic associated steatitic liver disease ($P = 0.69$). **Conclusion:** Despite centralized care within the VHA, major treatment gaps persist for HBV-infected veterans. Racial, geographic, and psychosocial disparities potentially impact treatment uptake. Targeted strategies are needed to address these inequities and improve HBV outcomes within the VHA.

1146 | MITOCHONDRIAL RESPIRATORY CHAIN REGULATES HBV AUTOPHAGIC DEGRADATION THROUGH DUAL MODULATION OF LYSOSOMAL ACIDIFICATION

Zhiqiang Wei[1] Xueyu Wang[1] Yanying Yan[1] Minwei Li[1] Zhengyun Xiao[1] Guohua Lou[1] Zhenggang Yang[1] Min Zheng[1], [1]Zhejiang University

Background: Mitochondria are crucial organelle involved in cellular homeostasis in both health and a wide range of diseases. Mitochondrial abnormalities have been observed in the hepatocytes of CHB patients. Given that mitochondria serve as the central hub of cellular signaling pathways, mitochondrial dysfunction inevitably results in significant alterations. However, the role of mitochondrial dysfunction in the persistence of viral replication remains unclear. **Methods:** We tested the role of mitochondrial dysfunction in viral replication in vivo and in vitro. **Results:** Both mitochondria and lysosomes were dysfunctional in HBV-replicating cells. Moreover, HBV replication inhibited mitochondrial respiratory chain both *in vitro* and *in vivo*. Inhibition of mitochondrial respiratory complex I activity using rotenone (Rot) increased HBV replication and decreased autophagic degradation capacity *in vitro* and *in vivo*. Mechanistically, elevated mitochondrial reactive oxygen species (mtROS) levels by Rot treatment or SOD2 knockdown led to deteriorated lysosomal membrane permeabilization, which elevated lysosomal pH and promoted HBV replication. While scavenging mtROS with mitoquinone (mitoQ) and mitoTEMPO (mitoT) had the opposite effect. Additionally, mitochondrial dysfunction reduced mitochondrial ATP production and diminished mitochondria-lysosome contacts. Obstructing mitochondrial ATP synthesis with Oligomycin A treatment or disruption of mitochondria-lysosome contacts with vacuolar protein sorting 13 A (VPS13A) knockdown resulted in lysosomal alkalinization and increased HBV replication by inhibiting vacuolar (H+)-adenosine triphosphatase (v-ATPase) assembly in an mtROS-independent manner. Ultimately, inhibition of mitochondrial complex I facilitated HBV secretion by promoting endosomal trafficking of HBV components. **Conclusion:** Mitochondrial function plays a crucial role in HBV autophagic degradation. HBV impairs mitochondrial function, leading to a reduction in the lysosomal degradation capacity, which may hinder effective clearance of the virus.

1147 | INTEGRATED CARE PATHWAYS FOR HEPATITIS B: A HOLISTIC CO-DESIGNED SERVICE FOR PEOPLE LIVING WITH HEPATITIS B IN ENGLAND

Stuart Flanagan[1] Daniel Forton[2] Doug Macdonald[3] Binta Sultan[1] Jessica Carter[4] David Leeman[5] Ruth Simmons[5] Kosh Agarwal[6] Bo Wang[7] Patrick Kennedy[8] Ashley Brown[9] Douglas Thorburn[3] Sital Shah[6] Helen Boothman[10] Julian Surey[11] Kabir Sandhu[12] Nina Van Syl[13] Alice Ward[7] Amy Bowkett[14] Katherine McNaughton[15] Gary Dark[14] Stephen Hindle[16] Carrie Gardner[16] Ian Jackson[16] Rachel Hill-Tout[16] Simon Barton[16] Denis Onyango[17] Rachel Halford[18] Vanessa Hebditch[19] Supa Chantschool[20] Claire Martin[20] Joy Ko[1], [1]Central & North West London NHS Foundation Trust, [2]St George's Hospital, [3]Royal Free Hospital NHS Trust, [4]Clerkenwell Medical Practice, London, [5]UK Health Security Agency, [6]Kings' College Hospital NHS Trust, [7]Guys & St Thomas' NHS Trust, [8]Barts and The London

SMD, [9]Imperial College Hospital NHS Trust, [10]St George's University Hospitals NHS Foundation trust, [11]University College Hospital NHS Trust, [12]West Hampstead Medical Practice, London, [13]Guys and St Thomas' NHS Trust, [14]North East London Integrated Care Board, [15]North Central London Integrated Care Board, [16]NHS England, [17]Africa Advocacy Foundation, [18]World Hepatitis Alliance, [19]British Liver Trust, [20]Hep B Companion

Background: The success of the Emergency Department opt-out Blood Borne Virus testing programme in England has led to >4800 people being newly diagnosed with Hepatitis B Virus (HBV), and >1100 identified as 'not in care'. This represents merely one facet of the undiagnosed HBV population. Currently viral hepatitis services are significantly challenged with increasing HBV diagnoses. There is an urgent need to develop a service specification for specialised adult outpatient HBV services providing a template clinical pathway as well as supporting individuals to stay well, remain engaged in care whilst ensuring equitable access. **Methods:** In 2024, NHS London established the HBV Pathway Development Task & Finish Group to develop holistic pathways and services for people living with this disease. More than 50 stakeholders were consulted, including people with lived experience, British Liver Trust, World Hepatitis Alliance, clinicians, allied healthcare professionals, General Practitioners, UKHSA and Integrated Care Board members. Representatives from each stakeholder group contributed to the Task & Finish outputs. Six areas were identified as being under resourced: 1. Presence of the patient voice in decision making. 2. Placement of specialised HBV care within Integrated Care Systems. 3. Agreed Standards of Equitable Care. 4. Data Management & Cohort Management Tools. 5. Engagement Support. 6. Role of Primary care and community-based care. **Results:** The Task & Finish Group developed: 1. A co-designed HBV template service model to provide care for patients from diagnosis to assessment, treatment, monitoring, community based integrated care and the vaccination of contacts. 2. A template digital solution for a patient cohort management tool and patient registry to provide oversight of all individuals identified as HBV SAg positive within the ICS, to ensure engagement can be supported and case cascade outcomes collated from a plurality of providers. 3. A workforce solution to include specialist expertise, people with lived experience, and administrative support. **Conclusion:** The NHS London Pathways group co-designed a care model (figure 1) to ensure quality of life and wellbeing outcomes for people living with HBV are maximised and that negative outcomes (cirrhosis, hepatocellular carcinoma, transplantation, death) are minimised. This model enshrines that people with HBV are central to decisions about their health and social care and that information must be culturally and language competent (in recognition of the diverse backgrounds of those living with HBV). To achieve WHO HBV elimination targets, co-designed models of care must be priority for Integrated Care Systems and resourced appropriately.

1148 | ESTIMATING POSTPARTUM TREATMENT-ELIGIBLE POPULATION IN HIGHLY VIREMIC HBV-INFECTED WOMEN UNDER UPDATED GUIDELINES

Wan-Hsin Wen[1] Yu-Chun Chen[2] Chun Jen Liu[3] Mei-Hwei Chang[3] Huey-Ling Chen[3], [1]Cardinal Tien Hospital, [2]National Taiwan University Hospital, [3]National Taiwan University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Short-term antiviral therapy during pregnancy is now a standard strategy to prevent mother-to-child transmission among highly viremic hepatitis B virus (HBV)-infected women. Postpartum alanine aminotransferase (ALT) elevations or flares are commonly observed in these women, regardless of whether they received antiviral therapy during pregnancy. Recently updated guidelines have lowered the HBV DNA and ALT thresholds for initiating treatment. This study aims to estimate the postpartum treatment-eligible population under the expanded treatment eligibility criteria. **Methods:** A cohort of 351 HBV-infected mothers with high viral loads was followed for up to one year postpartum. Of these, 248 received tenofovir disoproxil fumarate (TDF) or tenofovir alafenamide (TAF) from 30-32 gestational weeks until 2-4 weeks postpartum. The remaining 103 women did not receive any antiviral therapy during pregnancy. Serum ALT levels and HBV viral loads were measured at 6 and 12 months postpartum. During postpartum follow-up, these women received standard care for chronic hepatitis B and antiviral treatment was initiated or re-initiated according to Taiwan's National Health Insurance treatment criteria, which largely aligns with the APASL guidelines. The proportion of women meeting treatment eligibility was estimated based on the AASLD guidelines and the expanded criteria introduced in the 2024 WHO guidelines. **Results:** At six months postpartum, 12.3% (43/351) of women met the AASLD treatment criteria, while 69.2% (243/351) met the WHO criteria. There were no significant differences in eligibility rates between women who received antiviral therapy during pregnancy and those who did not. At 12 months postpartum, 9.1% met the AASLD criteria and 51.5% met the WHO criteria. Among women who received antiviral therapy during pregnancy, the proportions meeting either criterion did not differ between those treated with TDF and those treated with TAF. At one year postpartum, 11.9% of women were receiving antiviral treatment under standard care, closely aligning with the proportion meeting the AASLD criteria. **Conclusion:** Under the expanded treatment eligibility criteria, the proportion of highly viremic mothers eligible for postpartum antiviral treatment increased from 9-12% to 51-69% at 6-12 months postpartum. Enhanced monitoring and increased awareness among both patients and healthcare providers are essential for optimizing postpartum care in women with chronic hepatitis B and advancing global HBV elimination efforts.

1149 | SERIAL INCREASES OF ALPHA-FETOPROTEIN LEVELS PREDICT THE RISK OF CHRONIC HEPATITIS B-RELATED HEPATOCELLULAR CARCINOMA

Tung-Hung Su[1] Yun-Chun Wu[2] Shang-Chin Huang[3] Chun-Ming Hong[3] Shih-Jer Hsu[4] Tai-Chung Tseng[1] Chen-Hua Liu[4] Hung-Chih Yang[4] Chun Jen Liu[4] Pei-Jer Chen[1] Jia-Horng Kao[4], [1]National Taiwan University Hospital, [2]Roche Products Ltd, Taipei, Taiwan, [3]National Taiwan University, [4]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Background: Alpha-fetoprotein (AFP) has been used as a diagnostic and prognostic marker for hepatocellular carcinoma (HCC). However, the low sensitivity limits its usefulness for HCC surveillance. In this study, we aimed to evaluate the serial changes of AFP as a predictive marker for HCC and whether it could perform better than a single AFP measurement. **Methods:** We conducted a retrospective cohort study to screen eligible patients with chronic hepatitis B followed in a tertiary medical center in Taiwan from 2006 to 2021. They received regular HCC surveillance with abdominal ultrasonography and AFP biannually. Those with prior liver malignancies, follow-up less than 1 year, and pregnant women were excluded. Several time-varying AFP parameters were generated from longitudinal AFP measurements. These include the last recorded values, average values, and slope of change over various time windows. The slope would be assigned as zero if there is only a single AFP measurement. A Cox proportional hazards model with time-dependent AFP parameter was built to identify the risk predictors of HCC incidence. Statistical analysis was performed using the R statistical software. **Results:** Overall, 42,552 patients with chronic hepatitis B were screened, after a 10% random sampling and excluding ineligible patients, and finally, 3258 patients were included for further analyses. The median age was 50 years, and 56% were men. In this cohort, 5.7% had cirrhosis, 4.9% had HCV-coinfection, and 29.9% received anti-HBV therapy. After a median follow-up of 7.8 years, 125 patients developed HCC. Older age, male sex, cirrhosis, diabetes, a 6-month AFP increase rate, and HBV antiviral therapy were factors predictive of HCC. After adjustment for confounding factors, the 6-month AFP increase rate (HR: 1.02, $P = 0.003$) was predictive for the development of HCC with an AUROC of 0.845. It was also confirmed in a subgroup of patients with two or more AFP measurements as a sensitivity analysis. Before HCC development, the last 6-month AFP increase rate was 0.41 vs. 0.01 ng/mL in the HCC and non-HCC patients, respectively. **Conclusion:** A 6-month AFP increase rate is a significant predictor for the development of HCC in patients with chronic hepatitis B. AFP should be serially monitored and judged to improve HCC surveillance.

1150 | TEMPORAL ATTENUATION OF THE PARABOLIC ASSOCIATION BETWEEN BASELINE HBV DNA AND HCC RISK FOLLOWING ANTIVIRAL THERAPY IN CHRONIC HEPATITIS

Hyeyeon Hong[1] Won-Mook Choi[1] Gi-Ae Kim[2] Jonggi Choi[1] Gwang Hyeon Choi[3] Yun Bin Lee[4] Dong Hyun Sinn[5] YOUNG-SUK LIM[1], [1]Asan Medical Center, University of Ulsan College of Medicine, [2]Kyung Hee University School of Medicine, [3]Seoul National University Bundang Hospital, Seoul National University College of Medicine, [4]Seoul National University College of Medicine, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine

Background: A non-linear parabolic association between baseline HBV DNA levels and hepatocellular carcinoma (HCC) risk has been reported, regardless of antiviral treatment. However, it remains unclear whether this association persists over time after initiating antiviral therapy. This study aimed to evaluate the temporal evolution of the relationship between baseline HBV DNA levels and HCC risk at various landmark time points in patients with chronic hepatitis B (CHB). **Methods:** In this multicenter retrospective cohort study of 9,904 non-cirrhotic CHB patients with baseline HBV DNA levels $\geq$2,000 IU/mL (4,888 antiviral-treated and 5,016 untreated), we performed time-dependent landmark analyses at 1, 3, 5, and 7 years after cohort entry. Multivariable Cox regression was used to evaluate the association between baseline HBV DNA levels, categorized into discrete groups, and subsequent HCC risk at each time point, stratified by antiviral treatment status. **Results:** During a median follow-up of 7.4 and 8.6 years, 202 antiviral-treated (4.1%) patients and 322 untreated (6.4%) patients developed HCC, respectively. Among untreated patients, the parabolic association between baseline HBV DNA and HCC risk persisted across all landmark time points, with the highest risk observed at moderate viral loads (6.00–6.99 $\log_{10}$ IU/mL: hazard ratio [HR], 5.32; $p < 0.001$ at 1-year, HR, 5.70; $p < 0.001$ at 3-year, HR, 6.81; $p < 0.001$ at 5-year, and HR, 4.59; $p < 0.001$ at 7-year landmark), compared with HBV DNA levels $\geq$8.00 $\log_{10}$ IU/mL. In contrast, among antiviral-treated patients, the parabolic association progressively attenuated over time (HBV DNA 6.00–6.99 $\log_{10}$ IU/mL: hazard ratio [HR], 2.81; $p < 0.001$ at 1-year, HR, 2.54; $p = 0.001$ at 3-year, HR, 2.36; $p = 0.02$ at 5-year, and HR, 1.10; $p = 0.83$ at 7-year landmark). At the 7-year landmark, the relationship between baseline HBV DNA and HCC risk had flattened, indicating no significant difference in HCC risk across baseline viral load categories. **Conclusion:** The parabolic association between baseline HBV DNA levels and HCC risk persists in untreated patients but progressively flattens over time with antiviral therapy. These findings suggest that antiviral treatment mitigates HBV DNA–driven hepatocarcinogenesis, supporting earlier initiation of therapy in CHB patients.

Figure. Temporal association between baseline HBV DNA levels and HCC risk. (A) Antiviral untreated patients and (B) antiviral treated patients. HBV, hepatitis B virus; HCC, hepatocellular carcinoma.

1151 | HEPATITIS B SURFACE ANTIGEN LEVEL IDENTIFIES INACTIVE CHRONIC HEPATITIS B PATIENTS WITH HCC RISK BELOW SURVEILLANCE THRESHOLD

Tai-Chung Tseng[1] Shang-Chin Huang[1] Mei-Hung Pan[2] Chun Jen Liu[1] Chien-Jen Chen[2] Tung-Hung Su[1] Hung-Chih Yang[1] Chen-Hua Liu[1] Pei-Jer Chen[1] Hwai-I Yang[2] Jia-Horng Kao[1], [1]National Taiwan University Hospital, [2]Academia Sinica, Taipei, Taiwan

Background: Chronic hepatitis B (CHB) is a major global health concern, primarily due to hepatocellular carcinoma (HCC) development. This study aimed to identify inactive CHB patients with negligible HCC risk using hepatitis B surface antigen (HBsAg) levels, which is the key to define partial HBV cure. **Methods:** Data from 2674 inactive CHB patients (non-cirrhotic, HBeAg-negative, normal ALT, HBV DNA <2000 IU/mL) in the ERADICATE-B and REVEAL-HBV cohorts were analyzed. The primary endpoint was HCC development, with HBsAg levels used to identify patients with annual HCC risk $<0.2\%$. **Results:** Over a median follow-up of 26.3 years, 76 patients developed HCC. Among 989 inactive CHB patients with HBsAg <100 IU/mL, the annual HCC incidence was 0.08% (95% CI: 0.05%-0.13%), lower than those with HBsAg ≥ 100 IU/mL (adjusted HR: 0.35, 95% CI: 0.21-0.61). Their HCC risk was lower than the recommended threshold for HCC surveillance. Notably, even for older patients recommended for HCC surveillance, those with HBsAg levels <100 IU/mL were associated with HCC risk lower than the surveillance threshold. After 1:4 propensity-score matching, the risks of HCC and liver-related mortality were comparable to those of the NonB/NonC population. Moreover, inactive CHB patients with negligible HCC risk could be identified by combining HBsAg <100 IU/mL and normal ALT levels, without the need for HBV DNA testing, as validated in the NTUH-iMD cohort. **Conclusion:** Serum HBsAg levels <100 IU/mL effectively identify inactive CHB patients with negligible HCC risk and limited viral activity, which is important in optimizing surveillance strategies and defining partial HBV cure.

1152 | CHRONIC HEPATITIS B SURFACE ANTIGEN SEROCONVERSION IN THE COVID-19 VACCINATION ERA

Allison Carroll[1] Michael Butler[1] Vy Nguyen[1] Xuan Zhang[2] Raymond Chung[1], [1]Massachusetts General Hospital, [2]Newton Wellesley Hospital

Background: Chronic hepatitis B virus (HBV) infection affects over 250 million people despite widespread prevention efforts. Annual hepatitis B surface antigen (HBsAg) seroconversion rates in chronic HBV infection have historically been low (~1%). Coronavirus disease 2019 (COVID-19) vaccines are mRNA and protein subunit vaccines that first became available in the United States in December 2020. Receipt of COVID-19 vaccine has been associated with nonspecific immune stimulation. There has been limited data on seroconversion after COVID-19 vaccination without validation in a larger healthcare system. Here we evaluated rates of HBV seroconversion across a large, US-based academic health center before and after the COVID-19 vaccine became available. **Methods:** A large electronic health record database for the MGB healthcare system (Research Patient Data Registry) was queried for patients with at least one positive HBsAg (1979-2024), resulting in 3,025 unique patients. Chronic HBV was defined as at least two positive HBsAg at least six months apart ($n = 2,274$). We defined two study windows to evaluate HBV conversion rates before and after the introduction of COVID-19 vaccine (12/13/2016 – 12/12/2020 and 12/13/2020- 12/13/2024 respectively). Patients were included in each window if they had a positive HBsAg test before or during the window and at least one HBsAg test (positive or negative) during the window, indicating ongoing follow-up. Conversion was defined as a first negative HBsAg result within the window, and conversion rates were compared between windows using a two-proportion test. **Results:** Among patients with chronic HBV and active follow-up, the annualized clearance rate was significantly higher in the 2020-2024 window compared to the 2016-2020 window. From 2016–2020, 45 of 1,247 patients (3.6%) cleared HBsAg, corresponding to an

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

annual conversion rate of 0.72%. In the 2020–2024 window, 69 of 1,027 patients (6.7%) converted, with an annual rate of 1.34%. This difference in conversion rates was statistically significant (p = 0.0007; 95% CI, 1.26% to 4.96%; Figure 1). There was no significant difference in distribution of age, sex or number of HBsAg tests performed between groups (p = 0.48, 0.32, 0.78 respectively). **Conclusion:** HBV clearance rates were significantly higher following the introduction of the COVID-19 vaccine, suggesting a potential association between COVID-19 vaccination and increased likelihood of HBsAg seroclearance. Further study evaluating the precise relationship between HBsAg loss with receipt of COVID-19 vaccine is warranted.

Figure 1. Annualized rate of HBsAg clearance before and after COVID-19 vaccination availability

1153 | IB-001 IS A PARTIAL AGONIST OF THE TYPE I INTERFERON PATHWAY THAT EXHIBITS POTENT ANTI-HBV ACTIVITY WITH THE POTENTIAL FOR AN IMPROVED SAFETY PROFILE

Cheyne Kurokawa[1] Nathanael Sallada[1] Ruipeng Wang[1] Qingxiang Liu[1] Lynn Chen[1] Marcus Bolton[1] Eunice Cho[1] Aracely Romero[1] Madison Mann[1] Andrew Mercer[1] Yueh-Ming Loo[1] Wade Blair[1], [1]INTEGERBIO, INC.

Background: The type I interferon (IFN) system is a potent innate immune defense mechanism against viral pathogens. While IFNs have been utilized in patients as antiviral drugs, toxicity has limited widespread therapeutic use. Our goal is to develop synthetic interferons, SYNFERON™ molecules, that maintain the antiviral properties of type I IFN while reducing the inflammatory properties for an improved safety profile. SYNFERON molecules (SYN) are comprised of bispecific antibody-derived domains that bind IFN alpha receptors 1 and 2 (IFNAR1/2) and activate the IFN pathway with novel biological outcomes. **Methods:** STAT1 phosphorylation in human PBMCs was monitored by flow cytometry. Primary human hepatocytes (PHH) were infected with HBV or co-infected with HBV and hepatitis delta virus (HDV) and HBV DNA or HDV RNA was measured. FRG liver-humanized mice were infected with HBV and serum HBV DNA levels were measured. Human IFNAR1/2 knock-in mice were infected with respiratory syncytial virus (RSV) and viral load was measured in lungs 5 days after infection. Neutrophil count was also measured. **Results:** IB-001 represents a development candidate comprised of SYN1 expressed as a fusion to human serum albumin to extend half-life. We show that the IB-001 parental molecule, SYN1, activates IFNAR1/2 signaling as demonstrated by monitoring the phosphorylation of STAT transcription factors in primary cells. IB-001 exhibited antiviral activity against multiple virus families, including HBV and HDV in PHH, that was more potent than that measured for IFNα. In addition, IB-001 potently inhibited HBV replication in a mouse model of HBV infection and was more potent than Pegasys® at clinically relevant doses. IB-001 showed reduced induction of pro-inflammatory cytokines/chemokines in primary human cells and in vivo as well as reduced antiproliferative activity against bone marrow progenitor cells compared to IFNα, indicating the potential for improved safety. Furthermore, IB-001 inhibited RSV infection of mice without toxicity, while the antiviral efficacy of Peg-IFNa was linked to toxicity. Finally, our results show that IB-001 retains immune modulatory properties associated with the type I IFN pathway. **Conclusion:** Our data demonstrate that IB-001 confers potent antiviral activity against HBV and HDV in vitro and HBV in vivo with reduced inflammatory properties resulting in the potential for an improved tolerability and safety profile in the clinic.

1154 | TREATMENT ADHERENCE PATTERNS AND FOLLOW-UP CHALLENGES IN CHB PATIENTS: A COMPREHENSIVE SINGLE-CENTER ANALYSIS

Ziqun Qu[1] Wei Ye[1], [1]Nanjing Second Hospital

Background: The management of chronic hepatitis B virus (HBV) infection presents significant challenges in maintaining treatment adherence and minimizing loss to follow-up (LTFU), particularly among high-risk populations. This study aimed to comprehensively evaluate treatment initiation rates, regimen selection patterns, and LTFU dynamics among HBV DNA-positive patients, with special emphasis on clinically vulnerable subgroups including those with low-level viremia (LLV) or renal impairment. **Methods:** We conducted a retrospective analysis of data from January 1 to August 20, 2024, at Nanjing Second Hospital. The study population comprised 1,878 consecutive HBV DNA-positive patients. Primary endpoints included: (1) treatment initiation rates stratified by treatment status, (2) antiviral regimen selection in renal impairment (creatinine >104 μmol/L), (3) treatment modification rates in LLV patients, and (4) LTFU rates at 3- and 6-month intervals. Secondary analyses examined LTFU patterns in key clinical subgroups. **Results:** The overall treatment initiation rate was 73% (1,374/1,878). Among treatment-naïve patients with renal impairment ($n=113$), first-line regimen selection showed: ETV/TAF 72% (81/113), TMF 24.7% (28/113), and TDF 3.5% (4/113). Only half (50%, 138/278) of LLV patients on prior therapy received guideline-recommended regimen modifications. The cohort demonstrated alarmingly high LTFU rates: 79% (984/1,245) at 3 months declining to 10% (125/1,245) by 6 months. Subgroup analyses revealed particularly concerning 3-month LTFU rates: 72% (102/141) in LLV patients undergoing treatment modification, 56% (45/80) in treatment-naïve renal impairment patients receiving ETV/TAF, and 69% (20/29) in renal-impaired experienced patients transitioning to ETV/TAF. **Conclusion:** This study reveals a critical gap in HBV management with high early attrition at 3 months and partial re-engagement at 6 months, particularly among high-risk populations. These findings support prioritizing high genetic barrier agents to prevent resistance, enhancing early retention strategies, and selecting renal-safe regimens for prolonged unsupervised treatment.

1155 | LEAD OPTIMIZATION AND SELECTION OF A POTENTIAL BEST-IN-CLASS HBV ASO

Jin Hong[1] Vivek Rajwanshi[1] Dinah Misner[1] JIMMY LU[2] Kusum Gupta[1] Antitsa Stoycheva[1] Dana Cho[1] John Cortez[1] Min Luo[1] Hyunsoon Kang[1] Kellan Passow[1] Jacquelyn Sousa[1] Shane Daguison[1] Jieun Song[1] Lillian Adame[1] Cheng Liu[1] Sarah Stevens[1] Aneerban Bhattacharya[1] Rostom Ahmed-Belkacem[3] Susan Luong[1] Lawrence Blatt[1] Li Sun[2] David Smith[1] Leonid Beigelman[3] Julian Symons[1], [1]Aligos Therapeutics, [2]Amoytop Biotech., [3]Previously Aligos Therapeutics

Background: To achieve functional cure in chronic hepatitis B, the future treatment regimen will likely include direct antiviral and immunomodulatory drugs. Current clinical stage HBV ASOs, bepirovirsen (GSK-836) and AHB-137, are unique in their dual RNase H-mediated direct antiviral and immunomodulatory (e.g. TLR8 agonist) activities. GSK-836 as a single agent achieved a moderate functional cure rate of ~10% in a phase 2b trial, this was superior to many other modalities such as siRNA, but still suboptimal. Our aim is to develop a best-in-class HBV ASO with an improved overall therapeutic index over both clinical stage HBV ASOs. **Methods:** RNase H-mediated activity was analyzed with an HBsAg ELISA in HepG2.2.15 cells and AAV-HBV mice. To validate ASO hTLR8 activity in vivo, hTLR8 knock-in mice were dosed with ASO subcutaneously and mouse cytokine induction was monitored. Toxicity derived from ASO off-target effects was measured in a HepG2 Caspase3/7 assay and an ATP assay in InSphero 3-D liver microtissues. PXB mice with humanized livers were tested to assess the potential hepatotoxic effect of the ASOs. **Results:** Over 1300 ASOs were designed, synthesized and screened. Three optimized leads ALG-170675, ALG-171036 and ALG-171191 were selected for further investigation to identify a lead candidate. The three leads incorporated a novel ASO platform technology that reduced caspase activity in vitro when compared to clinical stage ASOs. In the HepG2.2.15 assay, ALG-171036, ALG-171191 showed enhanced in vitro RNase H-mediated activities compared to GSK-836 with EC_{50} values of 2.4, 2.8 and 8.6 nM respectively. ALG-170675 demonstrated comparable activity to GSK-836 with an EC_{50} value of 9.2 nM. In AAV-HBV mice, ALG-171191 exhibited deeper HBsAg knockdown in mouse plasma than clinical stage ASOs. ALG-171036 and ALG-170675 demonstrated superior HBsAg knockdown to GSK-836. Enhanced liver drug exposures over clinical benchmarks were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

found for all three lead ASOs. Comparable hTLR8 agonist activities in vitro and in vivo were observed for all lead ASOs and clinical benchmarks. In vitro toxicology studies showed CC_{50} values >500 μM in a 3-D human liver microtissue assay for all three leads and no human ALT elevation when dosed at 7 x 50 mg/kg in uninfected PXB mice with humanized livers. **Conclusion:** Optimized HBV ASO leads ALG-170675, ALG-171036 and ALG-171191 showed significant potential to be best-in-class HBV ASOs. Further investigations are underway.

1156 | HIGHER RISK OF POSTPARTUM PHASE TRANSITION TO IMMUNE-ACTIVE AMONG HBEAG-POSITIVE PREGNANT WOMEN WITH INDETERMINATE PHASE

Qiao Tang[1] Peng Hu[0], [1]The second affiliated hospital of Chongqing medical uni., [0] The First Affiliated Hospital of Chongqing Medical University

Background: Investigation on natural history of hepatitis B infection helps to guide the timing of initiating antiviral therapy, and which was primarily performed in non-pregnant patients. The natural history dynamics in pregnant women with chronic hepatitis B (CHB) remain unknown. **Methods:** We performed a retrospective-prospective real-world study including 352 pregnant women with CHB. Dynamics of natural history during pregnancy (including 248 HBeAg-positive and 48 HBeAg-negative participants) and the postpartum period (including 108 HBeAg-positive who received short-term antiviral intervention and 21 HBeAg-negative participants), and liver disease progression of different phases were investigated. **Results:** The proportion of immune-tolerance (IT) gradually increased, whereas the proportion of HBeAg-positive indeterminate phase (IP) and HBeAg-positive immune-active (IA) gradually decreased during pregnancy. In the third trimester of pregnancy, IT was dominant (48.7%), followed by HBeAg-positive IP (24.6%), HBeAg-positive IA (9.4%), inactive carrier (9.4%), HBeAg-negative IP (7.1%) and HBeAg-negative IA (0.9%). A numerical higher cumulative incidence of postpartum maintenance the phase and a significantly lower cumulative incidence of transition to HBeAg-positive IA in pregnant women with IT compared with pregnant women with HBeAg-negative IP. The cumulative incidence of postpartum maintenance the phase and transition to HBeAg-negative IA were comparable between pregnant women with IC and HBeAg-negative IP ($p > 0.05$). Pregnant women with different phases had similar low risk of postpartum liver disease progression. **Conclusion:** Pregnancy, short-term antiviral therapy, and delivery may have an impact on natural history of HBV infection in HBeAg-positive pregnant women, especially in those with indeterminate phase at 24-28 weeks of gestation.

1157 | A NOVEL POST-TRANSCRIPTIONAL MECHANISM OF HBSAG SUPPRESSION BY HOST FACTORS

YAN ZHAOYU[1] Takehisa Watanabe[1] Sanae Kimura Hayashi[1] Chang Wu[1] Katsuya Nagaoka[1] Yasuhito Tanaka[1], [1]Kumamoto University

Background: SAG-524 is a small-molecule compound that we previously reported to suppress HBsAg expression, at least in part by destabilizing HBV RNAs through PAPD5. However, the full post-transcriptional regulatory network downstream of SAG remains undefined. Given the importance of RNA-binding proteins (RBPs) in viral RNA fate, we sought to identify novel RBPs involved in HBsAg regulation, with the aim of uncovering alternative effector pathways mediating host-driven antiviral responses. **Methods:** Luciferase

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

assays were performed to identify 3′ untranslated regions (UTR) required for SAG-mediated suppression of HBsAg. Predicted RBPs were retrieved from "RBPDB" and subjected to siRNA knockdown in HepG2.2.15 cells, followed by quantification of HBsAg in culture supernatants. Protein–protein interaction data from "BioGRID" and the published CRISPR-Cas9 screening datasets related to HBsAg expression were used for overlap analysis. RNA-seq was conducted after the knockdown, and HBV RNA and HBsAg were quantified by qPCR and CLEIA, respectively. **Results:** Initial screening identified MARP1, an m6A reader acting in concert with other cofactors, as a protein binding to the SAG-responsive 3′UTR of HBV-RNA. "BioGRID" and the CRISPR screening datasets were used to prioritize associated RBPs, among which RBP3 was selected and followed by functional analysis. Knockdown of RBP3 in HepG2.2.15 cells significantly reduced HBsAg in the medium without altering total HBV RNA, indicating a post-transcriptional effect. RNA-seq was conducted in the RBP3 depleted HepG2.2.15 cells, and the top differentially expressed genes were compared with the CRISPR screening datasets related to HBsAg downregulation. PRG1 was identified as a common hit. Western blotting confirmed the upregulation of PRG1 protein in the RBP3 depleted cells. Further knockdown of PRG1 did not affect HBV RNA but led to a marked increase in extracellular HBsAg. **Conclusion:** This study identified a host regulatory module of HBsAg expression initiated by MARP1. RBP3 was identified as a functional cofactor of MARP1 that regulated HBsAg levels through PRG1. These findings support further investigation into host-mediated antigen control. This study suggests that the MARP1/RBP3/PRG1 pathway represents a novel molecular mechanism involved in HBsAg regulation.

1158 | SAFE BUT NOT SILENT: HBV REACTIVATION IN NON-LIVER ORGAN TRANSPLANTATION

Imran Hasanoglu[1] Melike Hallemoglu Topcu[2] Tansu Yamazhan[3] Ayse Ozlem Mete[4] Muammer Celik[5] Esra Tanyel[6] Tugba Arslan Gulen[7] Bengu Tatar[8] Elif Ates[9] Ayse Yasemin Tezer[2] Sibel Altunisik Toplu[10] Selda Sayin Kutlu[11] Erkan Olcucuoglu[2] Oguzhan Acet[3] Yelda Deligoz Bildaci[5] Melda Dilek[12] Edip Akpinar[7] Adam Uslu[8] Adem Safak[9] Fatmanur Celik Basaran[2] Turgut Piskin[10] Belda Dursun[11] Vildan Avkan Oguz[5] Hande Arslan[9], [1]Ankara Yildirim Beyazit University Bilkent City Hospital, [2]Ankara Bilkent City Hospital, [3]Ege University Faculty of Medicine, [4]Gaziantep University Faculty of Medicine, [5]Dokuz Eylul University Faculty of Medicine, [6]Ondokuz Mayıs University Faculty of Medicine, [7]Adana City Training and Research Hospital, [8]Izmir City Hospital, [9]Baskent University Faculty of Medicine, [10]Inonu University Faculty of Medicine, [11]Pamukkale University Faculty of Medicine, [12]Ondokuz Mayis University Faculty of Medicine

Background: Hepatitis B virus (HBV) reactivation remains a clinically significant but under-recognized complication in non-liver solid organ transplant recipients (SOTR). By analyzing real-world data from multiple centers, this study evaluated the risk and clinical trajectory of HBV reactivation in non-liver SOTR. **Methods:** This retrospective study, conducted across 12 transplant centers, included non-liver SOTRs with a minimum of one year of post-transplant follow-up. Patients were considered at risk for HBV reactivation if either the donor or recipient tested positive for HBsAg and/or anti-HBc IgG prior to transplantation. Data were collected on patient demographics, type of transplanted organ, immunosuppressive regimens, and the use of antiviral prophylaxis. **Results:** The study included 309 patients from 12 transplant centers, among whom 95.8% were kidney recipients, followed by lung (3.5%) and heart (0.6%) transplant recipients. The mean age was 51.4 years, and 71.5% were male. About one-third received organs from deceased donors (32.6%). Induction therapy mainly involved anti-thymocyte globulin (65.3%), while maintenance commonly included calcineurin inhibitors (97.4%), antimetabolites (94.8%), and prednisone (84.1%). HBV prophylaxis was given to 43% of patients, using tenofovir alafenamide (33.0%), lamivudine (29.3%), entecavir (27.8%), and tenofovir disoproxil fumarate (2.2%). HBV reactivation was observed in 11 patients, yielding an overall reactivation rate of 3.5% during a median follow-up period of 68.5 months (2-252 months). Patients who received antiviral prophylaxis experienced significantly fewer HBV reactivation. No HBV-related mortality was observed. Among the six seronegative recipients who received HBsAg-positive donors, none developed HBV reactivation during follow-up. Clinical characteristics and outcomes of the patients are presented in Figure 1. **Conclusion:** Although relatively uncommon, HBV reactivation in non-liver solid organ transplant recipients remains a clinically significant concern. These findings underscore the importance of thorough pre-transplant screening and individualized antiviral prevention strategies. Although the number of patients is limited, the data supports the cautious use of HBsAg-positive donors under strict prophylactic protocols, offering a potential avenue to expand the donor pool without compromising recipient safety.

1159 | MEETING HEPATITIS B ELIMINATION GOALS IN THE ALASKA NATIVE POPULATION

AUTHORS: BRIAN J MCMAHON, MARY SNOWBALL, LESLEIGH KOWALSKI, LISA TOWNSHEND-BULSON, LIVER DISEASE AND HEPATITIS PROGRAM, ALASKA NATIVE TRIBAL HEALTH CONSORTIUM, Brian McMahon[1] Lesleigh Kowalski Frank .[2] Lisa Townshend-Bulson[1] mary snowball[3], [1]Alaska Native Medical Center, [2]Liver Disease and Hepatitis Program, Alaska Native Tribal Health Consortium, [3]Alaska Native Tribal Health Consortium

Background: In the United States, hepatitis B was only endemic in western Alaska primarily among Alaska Native (AN) Peoples; Prior to 1980, the annual incidence of hepatocellular carcinoma (HCC) in children was among the highest in the world peaking at almost 3/100,000 (Figure 1). In the 1980s the Alaska Native Tribal Health Organizations screened 53,860 AN peoples for hepatitis B virus (HBV) infection, administered HBV vaccine to 43,618 HBV seronegative persons, and initiated universal newborn vaccination. Between 1962 and 1999, 1658 AN peoples were identified with chronic hepatitis B (CHB) and entered into a registry and are followed on a regular basis. In this study we examine the impact of this effort 40 years later comparing to the 2030 WHO global HBV elimination goals. **Methods:** This is a population-based outcome study. We used vaccine and electronic and State of Alaska Department of Health records to assess progress towards HBV elimination goals in the AN population by examining rates of newborn and childhood vaccination between 2015-2019. We used records from the National Cancer Institiure funeded Alaska Native Tumor Board from 1969 through 2019 to identify persons with HBV-related HCC. We also examined changes in HBV incidence rates of new hepatitis B antigen positive (HBsAg) infection in this region from 1990 through 2019, using both electronic and State of Alaska records. Finally, we calculated the incidence of HBV associated HCC in persons under 20 years of age.as well as the number of new cases of HBsAg. **Results:** In HBV endemic regions in Alaska between 2015 and 2019, approximately 90% of newborns received an HBV vaccine birth dose and over 80% of infants received a complete HBV vaccine series by 18 months of age. Over 99% of AN peoples diagnosed with CHB are in a computerized registry and labs and radiographic studies are reviewed yearly. Since 1998, annual incidence of new HBsAg-positive tests among AN peoples ranged from 1.4 to 2.6 per 100,000, down from 6.2 per 100,000 ststewide between 1993 and 1997. There have been no HBsAg-positive or HBV-related HCC cases identified in AN peoples under age 20 since 1993. **Conclusion:** Mass population-based screening for HBV seromarkers and vaccination of those seronegative coupled with continuing universal newborn immunization instituted four-decades ago have halted transmission of HBV in an endenic area in Western Alaska. The greatest impact has been on children under 20 years of age where both new cases of HBsAg-positive HBV infection which can lead to chronic HBV as well as new cases of HCC have been eliminated. This approach has sucessfully shown that the 2030 elimiation goals. HBV eliminaion goals can be successfully achieved.

1160 | IMDUSIRAN (AB-729) IS SAFE AND WELL-TOLERATED AFTER REPEAT DOSING IN CHRONIC HEPATITIS B PATIENTS: AN INTEGRATED SAFETY ANALYSIS OF PHASE 1 AND 2 IMDUSIRAN CLINICAL TRIALS

Tilly Varughese[1] Man-Fung Yuen[2] Grace Lai-Hung Wong[3] Kosh Agarwal[4] Kevin Gray[1] Deana Antoniello[1] Varun Sharma[1] Joanne Brown[1] Elina Medvedeva[1] Gaston Picchio[1] Karen Sims[1], [1]Arbutus Biopharma, [2]The University of Hong Kong, [3]The Chinese University of Hong Kong, Prince of Wales Hospital, [4]Institute of Liver Studies, Kings College Hospital

Background: Imdusiran (IDR) is a N-Acetylgalactosamine–conjugated, pan-genotypic small interfering RNA that blocks all HBV RNA transcripts, resulting in suppression of viral replication and all viral antigens. The safety and tolerability of repeat subcutaneous dosing of 60 mg or 90 mg of IDR when added to background nucleos(t)ide analogue (NA) therapy were evaluated in an integrated analysis of clinical trial results from over 150 subjects with chronic hepatitis B (CHB). **Methods:** Safety data including clinical and laboratory results was pooled (n = 151) and evaluated from a Phase 1 trial (AB-729-001; ACTRN12620000295943) and three Phase 2 combination treatment trials of IDR with immunotherapies (AB-729-201; NCT04980482, AB-729-202; ACTRN12622000317796) or a capsid assembly modulator (ABI-H0731-204; NCT04820686). Patients were divided into 4 groups by treatment regimen for the safety analysis as follows: Group 1 was IDR 60 mg x 4 doses [24 weeks (W)]+NA with 48 weeks follow up after IDR dosing from AB-729-202 Group B (n = 20); Group 2 was IDR 60 mg x 4 doses (24W)+NA lead-in from AB-729-202 Groups A and C through W26 and AB-729-201 lead-in period in all cohorts through W28 prior to the addition of immunotherapies (n = 85); Group 3 was IDR 60 mg x 6 doses (48W)+NA with 48 weeks follow up after IDR dosing from AB-729-001 Cohort F and ABI-H0731-204 Group 3 (n = 24); and Group 4 was IDR 90 mg x 6 doses (48W)+NA with 48 weeks follow up after IDR dosing from AB-729-001 Cohorts G, I and K (n = 22). **Results:** The majority of treatment emergent adverse events (TEAEs) in all 4 groups were Grades 1-2, with only 5 (3.3%) TEAEs reported as Grade 3 (only two Grade 3 TEAEs of alanine aminotransferase (ALT) elevations were deemed related to IDR). Related TEAEs that occurred most frequently among all groups were injection related events (13.9%) and ALT elevations (6.0%). The most frequent lab abnormalities observed were ALT and aspartate aminotransferase (AST) elevations (50% and 29% of subjects in all groups, respectively) with >95% of elevations being Grade 1 or 2. The only Grade 4 lab abnormalities observed were creatine kinase elevations in one patient each in Groups 1-3 that were unrelated to IDR and likely related to physical exercise. The safety profile from Group 4 (IDR 90 mg x 6 doses) was similar to the other groups. There were no deaths, Grade 4 TEAEs or SAEs related to IDR, or signs/symptoms of hepatic decompensation in any of the trial subjects. **Conclusion:** IDR therapy in patients with CHB was safe and well tolerated when administered at both 60 mg and 90 mg dose levels every 8 weeks for 4 – 6 doses (24 – 48 weeks) and through up to 48 weeks of follow up after IDR dosing.

Table 1: Treatment Emergent Adverse Events with Repeat Imdusiran Dosing Across Phase 1 and Phase 2 Clinical Trials

Number (%) [Events] of Subjects with Any	Group 1 (n=20)	Group 2 (n=85)	Group 3 (n=24)	Group 4 (n=22)	Total (N=151)
TEAE	17 (85.0) [68]	42 (49.4) [103]	17 (70.8) [83]	18 (81.8) [76]	94 (62.3) [330]
TEAE related to IDR	2 (10.0) [5]	15 (17.6) [27]	9 (37.5) [26]	9 (40.9) [12]	35 (23.2) [71]
Grade 3 TEAEs	0	3 (3.5) [3]	0	2 (9.1) [2]	5 (3.3) [5]
Grade 3 TEAEs Related to IDR	0	2 (2.4) [2]*	0	0	2 (1.3) [2]*
Grade 4 TEAEs or SAEs related to IDR	0	0	0	0	0
TEAEs Related to IDR in 2 or more subjects					
Injection related reactions	2 (10.0) [4]	5 (5.9) [12]	7 (29.2) [18]	7 (31.8) [7]	21 (13.9) [41]
ALT elevation	1 (5.0) [2]	5 (5.9) [6]	2 (8.3) [3]	1 (4.5) [1]	9 (6.0) [12]
Dizziness	0	1 (1.2) [1]	1 (4.2) [1]	0	2 (1.3) [2]
Pruritus	0	1 (1.2) [1]	1 (4.2) [1]	0	2 (1.3) [2]
Headache	0	1 (1.2) [1]	1 (4.2) [1]	0	2 (1.3) [2]
Nausea	0	1 (1.2) [1]	0	1 (4.5) [1]	2 (1.3) [2]

ALT=alanine transaminase; IDR=imdusiran; N=number; TEAE=treatment emergent adverse event; W=weeks
*The only two Grade 3 TEAEs reported related to IDR were 2 subjects with ALT elevations.
Group 1: IDR 60 mg q8W x 4 doses [24 W] + NA with follow-up up to 48 weeks after the last dose – AB-729-202 Group B
Group 2: IDR 60 mg q8W x 4 doses [24 W] + NA – AB-729-202 Groups A and C with follow up until Week 26 (2 weeks after the last dose); AB-729-201 all lead-in cohorts with follow up until Week 28 (4 weeks after the last dose)
Group 3: IDR 60 mg q8W x 6 doses [48 W] + NA with up to 48 weeks post dosing follow-up - AB-729-001 Cohort F and ABI-H0731-204 Group 3
Group 4: IDR 90 mg q8W x 6 doses [48 W] + NA with up to 48 weeks post dosing follow-up - AB-729-001 Cohorts G, I and K

1161 | HEPATITIS B CORE-RELATED ANTIGEN (HBCRAG) MEASUREMENTS CAN PREDICT THE RISK OF ALT FLARE IN PATIENTS WITH HBEAG-NEGATIVE CHRONIC HEPATITIS B INFECTION IN INACTIVE PHASE

Tetsuya Hosaka[1] Fumitaka Suzuki[1] Mariko Kobayashi[1] Hitomi Sezaki[1] Norio Akuta[1] Yoshiyuki Suzuki[1] Satoshi Saitoh[1] Yasuji Arase[1] Yasue Takeuchi[1] Kenji Ikeda[1] Hiromitsu Kumada[1], [1]Toranomon Hospital

Background: Serum hepatitis B core-related antigen (HBcrAg) has been known as surrogate markers of intrahepatic covalently closed circular DNA (cccDNA) and transcriptional activity. However, its clinical usefulness is still unclear in inactive chronic hepatitis B infection (CHB). In this study, we evaluated the risk of ALT flare in HBeAg-negative CHB using HBcrAg measurements. **Methods:** This study

enrolled 511 HBeAg-negative non-cirrhotic patients without antiviral therapy who had been followed up for at least 1 year and whose baseline HBcrAg levels could be measured by highly-sensitive HBcrAg assay (iTACT-HBcrAg). The lower limit of quantification of iTACT-HBcrAg assay is 2.1 Log U/mL. Normal ALT was defined as 35 IU/L in male and 25 in female. According to baseline HBcrAg, the entire cohort was categorized into two groups; HBcrAg $<$ 3.0 log U/mL as the low-HBcrAg group and $\geq$ 3.0 as the high-HBcrAg group. Inactive phase was defined as persistently normal ALT and low viral loads ($<$ 2,000 IU/mL) from baseline to year 1. ALT flare was defined as $>$ twice upper limit of normal (ULN). We also evaluated severe ALT flares over 100 IU/L and hepatocellular carcinoma (HCC) incidences according to baseline HBcrAg levels. We excluded the events of elevated ALT by obvious metabolic factors. **Results:** (1) In the entire cohort, median HBcrAg level was 2.2 log U/mL. 373 patients (73%) were categorized into the low-HBcrAg, and 138 (27%) into the high-HBcrAg groups. Patients in the high-HBcrAg group were significantly younger and had higher HBsAg levels than those in the low-HBcrAg group. (2) During follow-up of median 10 years, ALT flares occurred in 22 patients in the entire cohort. Annual incidence rates of ALT flares were 2.3 and 5.8 per 1,000 person-years in the low-HBcrAg and high-HBcrAg groups, respectively, with a lower incidence of ALT flares in the low-HBcrAg (P = 0.026) (Fig A). In the low-HBcrAg group, cumulative incidences of ALT flares in patients with HBcrAg $<$ 2.1 were marginally lower than those with HBcrAg 2.1-2.9 (P = 0.096). However, there were no significant differences in severe ALT flare and HCC incidences between the low-HBcrAg and high-HBcrAg groups. **Conclusion:** Patients with HBcrAg over 3.0 log U/mL in inactive HBeAg-negative CHB had the higher risk of ALT flares than those without it. HBcrAg can be a useful tool for predicting phase transition in inactive CHB.

1162 | APPLYING AASLD, EASL, AND WHO HEPATITIS B TREATMENT GUIDELINES TO A COMMUNITY-BASED HEPATITIS B REGISTRY

Zinnia Dong[1] Amy Tang[2], [1]North East Medical Services, [2]North East Medical Servies

Background: Community health centers (CHCs) are high-impact settings for hepatitis B virus (HBV) screening and retention in care. An estimated 1.6 to 2.4 million people have chronic HBV in the United States, and in 2022, Federally Qualified Health Centers (FQHCs) cared for almost 45,000 people with chronic HBV. North East Medical Services (NEMS) is an FQHC in the San Francisco Bay Area serving over 70,000 patients annually with a large HBV registry-based care management program, of which over one-third of HBV registry patients have been prescribed HBV antiviral treatment. We aimed to describe the cohort of HBV treatment-naïve NEMS patients indicated for HBV antiviral treatment based on the American Association for the Study of Liver Diseases' (AASLD) 2015 guidelines and 2018 guidance and the recently updated 2024 World Health Organization (WHO) and 2025 European Association for the Study of the Liver (EASL) guidelines. **Methods:** We performed a retrospective analysis of treatment-naïve HBV registry patients with at least one primary care medical visit at the FQHC from 10/2/23 to 5/19/25. HBV registry patients had a positive HBV surface antigen (HBsAg) or HBV DNA in the last 3 years or a chronic HBV ICD-code on their problems list. Demographic and clinical data were extracted from the FQHC's electronic health records and used for determining treatment indications. **Results:** Of the 1,850 treatment-naïve chronic HBV patients, we identified 920 (50%) patients using WHO guidelines, 270 (15%) patients using EASL guidelines, and 45 (2%) patients using AASLD guidelines who were indicated for treatment. WHO's guidelines had the lowest threshold for HBV antiviral treatment initiation with metabolic dysfunction-associated steatotic liver disease (MASLD) (63%) and diabetes mellitus (34%) contributing the largest treatment indication. Using EASL's guidelines, HBV DNA $\geq$2,000 IU/mL with a hepatocellular carcinoma (HCC) risk factor had the largest impact; and of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

these HCC risk factors, age (77%) contributed the most. AASLD's guidance was the strictest, which was influenced by higher ALT criteria and reliance on HBV "e" antigen (HBeAg) for determining treatment eligibility, as 14% of the treatment-naïve population did not have a documented HBeAg status. **Conclusion:** CHCs are crucial in the nation's viral hepatitis elimination plan as they provide longitudinal care to low-income immigrant populations. Utilizing an HBV registry, we identified 2% to 50% of treatment-naïve chronic HBV patients indicated for HBV antiviral treatment using recommendations and guidelines from AASLD, EASL, and WHO. A simplified HBV treatment guidance that distills the complexities of the various HBV antiviral treatment thresholds and is tailored to primary care providers would greatly impact and improve HBV care delivery in this primary care setting.

Table 1. Applying AASLD, WHO, and EASL HBV treatment guidelines to treatment-naive HBV registry patients (N = 1,850)

	AASLD 2015/18 n (%[1])	WHO 2024 n (%[1])	EASL 2025 n (%[1])

1163 | IN SILICO ANALYSIS OF INTRAHEPATIC NEUTROPHILS IN ON-TREATMENT CHRONIC HEPATITIS B PATIENTS WITH LIVER FIBROSIS

Wenyue Wu[1] Wen Zhang[1] Hong Li[1] Ziyan Pan[1] Haodong Ma[1] Caihong Wang[1] Yameng Sun[1] Wei Chen[1] Hong You[2], [1]Beijing Friendship Hospital, Capital Medical University, [2]Capital Medical University

Background: The dynamics of intrahepatic neutrophils and their functional heterogeneity in chronic hepatitis B (CHB) patients with liver fibrosis undergoing antiviral therapy (AVT) remain poorly defined. This study aimed to elucidate the characteristics of intrahepatic neutrophils in on-treatment CHB-associated liver fibrosis using in silico analyses based on liver transcriptomics. **Methods:** Transcriptomics of 54 serial liver biopsies obtained from 28 CHB liver fibrosis patients at baseline (0W), 78 weeks (78W), and 260 weeks (260W) post-AVT were analyzed to characterize intrahepatic neutrophil dynamics. Publicly available transcriptomics (GSE84044) from 82 AVT-naïve CHB patients with liver fibrosis were enrolled to verify intrahepatic neutrophil profiles at baseline. Additionally, publicly available single-cell RNA sequencing data (scRNA-seq; GSE186343) from 5 CHB liver fibrosis patients were utilized to map the heterogeneity of intrahepatic neutrophils. **Results:** Deconvolution analyses revealed that the fraction of neutrophils exhibited an upward trend at 78W ($P = 0.2770$), and increased significantly at 260W ($P < 0.001$) of AVT, accompanied by sustained reductions in the number of T cells, $CD8^+$ T cells, and NK cells. Additionally, patients were stratified into Neu-Low and Neu-High groups based on average neutrophil fractions. The Neu-Low group showed higher Ishak scores and elevated expression of liver fibrosis-specific matrisome genes, regardless of treatment status. Moreover, Gene Set Enrichment Analysis indicated that the KEGG pathways involved in extracellular matrix remodeling, immune response, and cell cycle regulation were significantly activated in the Neu-Low group, while metabolic pathways, including carbohydrate, lipid, and amino acid-related metabolism pathways were evidently downregulated. These baseline characteristics of intrahepatic neutrophils were validated in the AVT-naïve GSE84044 cohort. Furthermore, scRNA-seq analysis based on GSE186343 identified three distinct intrahepatic neutrophil subpopulations: NEU1 ($FCGR3B^+CXCR2^+CMTM2^+$), NEU2 ($LGALS1^+CST3^+GSTP1^+$) and NEU3 ($CCL5^+IL32^+GZMA^+$), among which the fraction of NEU2 progressively increased post-AVT by deconvolution analysis. NEU2 exhibited upregulated gene profiles associated with antigen presentation and immunosuppression, suggesting a role in maintaining immune homeostasis and preventing excessive inflammatory responses during AVT. **Conclusion:** Intrahepatic neutrophil fractions increased during antiviral therapy for HBV-related fibrosis. Lower neutrophil levels were associated with more severe fibrosis and metabolic dysfunction. Neutrophils exhibited heterogeneity, with NEU2 expanding during therapy and potentially contributing to immune homeostasis.

1164 | ASSOCIATION OF BASELINE SERUM HBV RNA AND ANTIVIRAL RESPONSE IN CHRONIC HEPATITIS B PATIENTS WITH NUCLEOS(T)IDE ANALOGUE TREATMENT

Jian Wang[1] Rui Huang[1] Chao Wu[1], [1]Nanjing Drum Tower Hospital

Background: Hepatitis B virus (HBV) RNA is a novel serological marker which can reflect the intrahepatic HBV covalently closed circular DNA (cccDNA) transcriptional activity. We investigated the association between serum HBV RNA levels and antiviral response in patients with chronic hepatitis B (CHB). **Methods:** A total of 685 CHB patients who received nucleos(t)ide analogues (NAs) treatment were included. HBV RNA was measured by cobas HBV RNA quantitative assay (RUO, Roche Molecular Systems, CA, USA), with a lower limit of detection of 10 copies/mL. Biochemical response (BR), virological response (VR), and serological response (SR) were defined as normal ALT (<40 U/L), undetectable HBV DNA levels (<20 IU/mL), and HBeAg clearance (for HBeAg positive patients), respectively. **Results:** At baseline, the median age of patients was 41.0 years with 52.7% of HBeAg-positive. The median levels of ALT, HBV RNA, HBV DNA, and HBsAg were 68.2 U/L, 4.7 Log_{10} copies/mL, 6.2 Log_{10} IU/mL, and 3.6 Log_{10} IU/mL, respectively. HBeAg-positive patients had a higher median HBV RNA level (6.3 Log_{10} copies/mL vs. 2.4 Log_{10} copies/mL, $P<0.001$) than HBeAg-negative patients. Serum HBV RNA levels were positively associated with serum HBV DNA ($r=0.82$, $P<0.001$) and HBsAg levels ($r=0.69$, $P<0.001$). After 48 weeks of NAs treatment, 73.9%, 72.5%, and 9.4% of patients achieved BR, VR, and SR, respectively. Patients with baseline HBV RNA <5 Log_{10} copies/mL had significantly higher rates of VR (92.0% vs. 50.0%, $P<0.001$) and SR (20.0% vs. 6.6%, $P<0.001$) than those with baseline HBV RNA ≥ 5 Log_{10} copies/mL. However, the BR rates (75.4% vs. 72.7%, $P=0.505$) were comparable between patients with different HBV RNA levels. Baseline HBV RNA <5 Log_{10} copies/mL was associated with higher chance of achieving VR (OR 4.0, 95% CI: 2.3-6.9, $P<0.001$) after adjusted for age, sex, ALT levels, and HBeAg status, as well as SR (OR 4.4, 95% CI: 2.0-9.6, $P<0.001$) after adjusted for age, sex, and ALT levels. **Conclusion:** Baseline HBV RNA <5 Log_{10} copies/mL was associated with higher rates of VR and SR in CHB with NAs treatment. Serum HBV RNA may serve as a promising marker for predicting treatment response in CHB patients with NA therapy.

1165 | TWO-YEAR HISTOLOGICAL EFFICACY OF TENOFOVIR ALAFENAMIDE ON LIVER FIBROSIS IN TREATMENT-NAÏVE PATIENTS WITH CHRONIC HEPATITIS B

Jialing Zhou[1] Xiaoning Wu[1] Chuanwu Zhu[2] Jiming Zhang[3] Ping Li[4] Tao Han[5] HUIGUO DING[6] Chenghai Liu[7] Wen Xie[8] Qing Xie[9] Yali Zong[10] Yameng Sun[1] Chen Shao[6] Hui Liu[6] Tongtong Meng[1] Hong You[1] Jidong Jia[1], [1]Beijing Friendship Hospital, Capital Medical University, [2]The Fifth People's Hospital of Suzhou, [3]Huashan Hospital, Shanghai Medical College, Fudan University, [4]Tianjin Second People's Hospital, [5]Tianjin Third Central Hospital, China, [6]Beijing Youan Hospital, Capital Medical University, [7]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [8]Beijing Ditan Hospital, Capital Medical University, [9]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, [10]The Ninth Hospital of Nanchang

Background: The antiviral efficacy of tenofovir alafenamide (TAF) has been well confirmed in patients with chronic hepatitis B (CHB) in both controlled trials and real-world studies. However, the histological effect of TAF on liver fibrosis remains unclear. **Methods:** This prospective study recruited treatment-naïve patients with CHB and biopsy-proven liver fibrosis or cirrhosis from 10 tertiary hospitals in China (NCT04939441). After receiving TAF monotherapy for 96 weeks, all participants received a second liver biopsy. Fibrosis regression was defined as a ≥ 1 stage decrease in fibrosis assessed by Ishak score or predominant regression as assessed by P-I-R criteria. Virological response (VR: HBV DNA <20 IU/mL) and biochemical response (ALT ≤ 40 IU/L), liver stiffness measurement (LSM) by VCTE, aspartate aminotransferase-to-platelet ratio index (APRI), and Fibrosis 4 Score (FIB-4), were also employed every 24 weeks during treatment. The Wilcoxon signed-rank test was used for non-parametric paired sample analysis. **Results:** A total of 100 treatment-naïve patients with CHB (61% HBeAg positive) were enrolled, with 82 patients completing a second liver biopsy and 80 of them provided assessable liver sections. At baseline, 10%, 39%, 30% and 21% of the participants had Ishak score 1/2, 3, 4, and 5/6, respectively; 34%, 34%,14% and 19% of them had necroinflammation activity grade (HAI) 1, 2, 3, and 4, respectively. After 96 weeks of TAF treatment, 70% (56/80) of the participants showed fibrosis regression, whereas 29% (23/80) showed no change in Ishak score. Among the 17 patients with cirrhosis at baseline, 15 achieved Ishak score decrease by ≥ 1 and 2 became predominant regression, resulting in a significantly higher regression rate than that in non-cirrhotic participants (17/17 vs 39/63, $p < 0.009$). Similarly, 52% of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the participants showed a reduction of at least one grade of necroinflammation (HAI). The median HBV DNA level declined from 5.73 log IU/ml at baseline to 0 log IU/ml at week 96, achieving VR rates of 73% at week 48 and 86% at week 96. The ALT normalization rate was 78% at week 48 and 74% at week 96. The LSM decreased from 9.7 at baseline to 6.5 kPa at week 96 ($p < 0.001$), with 51% of the participants experiencing a $>30\%$ decline. APRI and FIB-4 scores also decreased significantly from 0.55 and 1.14 at baseline to 0.31 and 0.99 at week 96, respectively (both $p < 0.001$). **Conclusion:** After 96 weeks of TAF treatment, liver fibrosis was significantly regressed, as evidenced by improvements in both histological and non-invasive measurements.

1166 | HEPATOTOXIC-LIKE CD38$^+$HLADR$^+$PD1$^+$CD8$^+$ T CELLS DEFINE A FUNCTIONALLY DISTINCT SUBSET ASSOCIATED WITH HBSAG REDUCTION AND HBV-SPECIFIC IMMUNITY IN CHB

Hsiang-Wei Huang[1] Rachel Wen-Juei Jeng[2] Chia-Wei Lin[1] Yen-Chun Liu[3] Jian He Fan[1] Thi Kim Duyen Nguyen[1] Wei-Ting Ku[1] Cheng-Heng Wu[1] Chun-Yen Lin[1], [1]Chang Gung University, [2]Chang Gung Memorial Hospital, Linkou Medical Center, [3]Chang Gung Memorial Hospital, Linkou main branch

Background: Chronic hepatitis B (CHB) is characterized dysfunctional HBV-specific CD8$^+$ T cell responses. Recent studies suggest CD38$^+$HLADR$^+$CD8$^+$ T cells with hepatotoxic, innate-like features may contribute to liver inflammation in chronic hepatitis C. However, their relationship with HBV-specific immunity remains unclear. This study aimed to characterize these T cell subsets and evaluate their association with HBV-specific immune response in CHB patients. **Methods:** A total of 43 CHB patients with ALT $\geq 2\times$ the upper limit of normal (ULN) were prospectively enrolled at a treatment-free timepoint. Peripheral CD8$^+$ T cells were analyzed using a single-cell RNA sequencing (scRNAseq) approach. Flow cytometry was subsequently performed to validate cell phenotypes . HBV-specific T cell responses (Core, polymerase, X, and S peptides) were evaluated by IFN-γ ELISPOT. Associations between T cell subsets, HBV-specific immunity, and on-treatment HBsAg reduction velocity were analyzed by linear regression analysis. **Results:** A cluster of peripheral CD8$^+$ T cells, recognized as CD38$^+$HLADR$^+$CD8$^+$ T cells with a hepatotoxic transcriptome profile (Gehring et al., J Clin Invest, 2023) was identified by a scRNAseq approach using unsupervised clustering. This cluster showed a distinct transcriptional signature enriched in NK receptor pathways and cytokine-responsive modules, and exhibited significantly higher innate-like scores compared to the other CD8$^+$ T cell clusters. This CD38$^+$HLADR$^+$CD8$^+$ T cell cluster was further subclustered into PD1$^+$ and PD1$^-$ subsets. In CHB patients with active hepatitis before treatment, the frequency of PD1$^+$CD38$^+$HLADR$^+$CD8$^+$ T cells was significantly associated with the velocity of on-treatment HBsAg reduction (estimate: 0.626, $p < 0.01$). Furthermore, this subset was significantly correlated with HBV Core- and S-specific T cell responses as measured by ELISPOT (estimates: 7.511, $p < 0.01$; 3.812, $p < 0.05$, respectively). These associations were not observed in the PD1$^-$CD38$^+$HLADR$^+$CD8$^+$ T cell subset, suggesting functional heterogeneity within this hepatotoxic CD8$^+$ T cell cluster and a potential link to the rejuvenation of HBV-specific CD8$^+$T cells. **Conclusion:** PD1$^+$CD38$^+$HLADR$^+$CD8$^+$ T cells display hepatotoxic transcriptomic features. The frequency of this subset is significantly associated with HBV Core- and S-specific T cell responses and subsequent on-treatment HBsAg reduction. Therefore, this subset may be closely related to the recovery of HBV-specific CD8$^+$ T cell responses and contribute to HBsAg seroclearance.

1167 | CORE PROTEIN MUTATIONS IN HBSAG/HBV DNA DOUBLE-NEGATIVE OCCULT HEPATITIS B INFECTION AND THEIR BIDIRECTIONAL REGULATION ON VIRAL REPLICATION

Minghui Zeng[1] Liang Xu[1] Yuqiang Mi[1] Wentao Kuai[1], [1]Tianjin City Second People's Hospital

Background: Patients with occult hepatitis B virus infection (OBI) can transmit HBV through blood transfusion or vertical mother-to-child transmission. but the formation mechanism of OBI has not been fully clarified. HBV gene mutation is considered to be one of the key factors. Previous studies have mostly focused on the

mutation characteristics of S region and X region in HBV DNA positive patients, while the exploration of core protein (CP) encoded by C region in HBsAg/HBV DNA double negative OBI population remains a blank. **Methods:** HBV DNA was extracted from the patient's serum by phenol-chloroform method, and the CP gene fragment of HBV DNA was amplified by nested PCR. The target fragment was purified and cloned into dPMD-18T vector and transformed into DH5α competent cells. Plasmid was extracted after plate coating and Sanger sequencing was used to confirm the amplified fragment sequence. Bioinformatics tools were used to predict mutant protein, and the dynamic changes of the mutant HBcAg were analyzed by molecular dynamics simulation. WT and mutant plasmids were transfected into Huh7 and HepG2 cell. Chemiluminescence microparticle immunoassay was used to detect HBsAg and HBeAg in supernatant, PCR- immunofluorescence probe method was used to quantify HBVDNA, the expression of intracellular HBcAg and HBsAg subtype (L/M/S) were analyzed by Western blot, and the levels of HBV RNA were detected by qPCR to systematically evaluate the effect of CP region mutation on HBV expression. **Results:** 1. All patients showed nucleotide mutations in CP region, with 100% mutation rates at G2137A/T and G2152T/A sites. 46.2%(6/13) of the patients had missense mutations, including A11V, V13M, A58V, E64G, S74N, S74I, L95P and L119P. Among them, two patients had double mutations, A58V +S74N and A11V+L119P respectively. 2. A58V+S74N mutation can increase the distribution area of CP in cytoplasm; E64G mutation can increase the isoelectric point of protein; The mutations of A58V+S74N, A11V +L119P and L95P cause the long helix of the protein to bend. 3. A58V+S74N mutation significantly promoted HBcAg synthesis and HBeAg expression, as well as the levels of HBV preC RNA and 3.5kb HBV RNA. 4. A11V +L119P and V13M mutations inhibited the synthesis of HBcAg, the expression of HBsAg, HBeAg and HBV DNA, and simultaneously reduce the level of 2.4 kb+2.1 kb HBV RNA. 5. E64G mutation inhibited the secretion of HBsAg, HBeAg and HBV DNA,accompanied by a decrease in the expression of 0.7 kb HBV RNA. 6. A11V +L119P and E64G Mutations significantly inhibited intracellular S/M/L-HBsAg synthesis, while V13M mainly showed the decrease of S-HBsAg synthesis. **Conclusion:** A58V+S74N mutation can promote virus transcription and protein expression, while other mutations suppress virus replication to varying degrees. Among them, A11V+L119P and V13M mutations may destroy the capsid assembly interaction between HBsAg and HBcAg, and E64G mutation may be related to X gene regulation.

1168 | SERUM HEPATITIS B CORE-RELATED ANTIGEN LEVEL STRATIFIES RISK OF IMMUNE-ACTIVE TRANSITION IN INACTIVE CHRONIC HEPATITIS B PATIENTS

Kuan-Hui Hsin[1] Tai-Chung Tseng[1] Chun-Jen Liu[1] Chun-Ming Hong[1] Tung-Hung Su[1] Hung-Chih Yang[1] Chen-Hua Liu[1] Pei-Jer Chen[1] Jia-Horng Kao[1], [1]National Taiwan University Hospital

Background: Chronic hepatitis B (CHB) affects millions of people globally, with one-third classified as inactive CHB. However, 20-30% of them progress to immune-active CHB. We aimed to explore whether hepatitis B core-related antigen (HBcrAg), reflecting the size and transcriptional activity of covalently closed circular DNA (cccDNA), predicts immune-active transition, HBV-

associated hepatitis and HCC, with the goal of refining risk stratification in this special population. **Methods:** Among 2666 treatment-naïve CHB patients from the ERADICATE-B cohort, 540 fulfilled the criteria of inactive CHB (non-cirrhotic, HBeAg-negative, persistently normal ALT at 1 year, HBV DNA < 2,000 IU/mL). Three viral biomarkers were determined retrospectively using stored serum samples. The endpoints were immune-active transition (ALT ≥ 2-fold the upper limit of normal (ULN) and HBV DNA ≥ 2,000 IU/mL), HBV-associated hepatitis (ALT ≥ 100 IU/L and HBV DNA ≥ 2,000 IU/mL) and HCC. Kaplan–Meier curves and Cox proportional hazard models were used to evaluate the long-term prognostic utility of HBcrAg. **Results:** Among the 540 inactive CHB patients, a total of 8,016.9 person-years of follow-up were accumulated (mean ± SD: 13.98 ± 5.91 years). During this period, 158 (1.97 %/y) progressed to immune-active CHB, 82 (0.96 %/y) experienced HBV-associated hepatitis, and 8 (0.09 %/y) developed HCC. Among three HBV biomarkers, HBcrAg outperformed HBsAg and HBV DNA in predicting immune-active transition, with an AUROC of 0.59 (95% CI: 0.54–0.64). Patients with HBcrAg levels ≥ 10 KU/mL (N = 172) had a higher risk of developing immune-active transition than those with levels < 10 KU/mL (N = 368), with a hazard ratio (HR) of 1.74 (95% CI: 1.27–2.39) (Table 1). In multivariable analysis including age, sex, HBcrAg, HBsAg, and HBV DNA, HBcrAg ≥ 10 KU/mL remained the only independent viral risk factor (Table 1). In addition, HBcrAg levels ≥ 10 KU/mL were also associated with increased risks of developing HBV-associated hepatitis (HR: 2.40, 95% CI: 1.55–3.71), and HCC (HR: 13.97, 95% CI: 1.72–113.54). **Conclusion:** Inactive CHB patients constitute a clinically heterogeneous population, and reliable viral markers are essential to guide clinical decision-making. Previous studies have demonstrated that serum HBsAg levels < 1000 IU/mL can effectively identify patients with low viral activity and minimal risk of HCC. In our study on 540 inactive CHB patients, baseline HBcrAg levels ≥ 10 KU/mL emerged as an independent predictor of immune-active transition, HBV-associated hepatitis and HCC. These findings underscore the clinical utility of HBcrAg, thereby supporting refinements to current management strategies.

1169 | HEPATITIS B VIRUS CCCDNA FORMATION REGULATED BY DOCK11 VIA PARP1

Hideo Takayama[1] Kouki Nio[1] Taro Yamashita[1], *[1]Kanazawa University*

Background: Hepatitis B virus (HBV) infection is one of the most important infectious diseases worldwide. Although nucleos(t)ide analogues have enabled effective suppression of HBV replication in clinical settings, eliminating covalently closed circular DNA (cccDNA) formed in the nucleus of hepatocytes remains a major challenge. Consequently, the risk of HBV reactivation and carcinogenesis persists. We recently identified Dedicator of Cytokinesis 11 (DOCK11) as a molecule involved in HBV maintenance. In this study, we aimed to investigate the role of DOCK11 in HBV cccDNA formation. **Methods:** First, we established an in vitro system for HBV cccDNA formation by incubating nuclear extracts (NEs) with HBV relaxed circular DNA (rcDNA) isolated from the supernatant of HepAD38 cells, a liver-derived cell line that inducibly expresses the HBV genome. We then prepared NEs from DOCK11-overexpressing HepG2 cells and DOCK11-knockout Huh7 cells to evaluate the effect of DOCK11 in this in vitro system. Additionally, we performed immunoprecipitation of DOCK11 from the overexpression samples, followed by liquid chromatography-mass spectrometry (LC/MS) to identify key components of the DOCK11-HBV complex. Finally, we used super-resolution microscopy to observe DOCK11-overexpressing HepG2 cells and UV-irradiated DOCK11-knockdown Huh7 cells, in order to examine the interaction between DOCK11 and the identified component. **Results:** In vitro cccDNA formation system revealed that DOCK11 overexpression promotes HBV cccDNA formation by 42% ($p < 0.005$), while DOCK11 knockout suppresses HBV cccDNA formation by 85% ($p = 0.0001$). These results suggest that DOCK11 plays a regulatory role in HBV cccDNA formation. Immunoprecipitation experiments further indicated that DOCK11 forms a complex with HBV DNA. LC/MS analysis of the DOCK11-HBV

DNA complex identified poly [ADP-ribose] polymerase 1 (PARP1), a key molecule involved in DNA repair, as a major component of the complex. Moreover, super resolution microscopy demonstrated nuclear colocalization of DOCK11 and PARP1, and revealed that the recruitment of PARP1 to DNA damage sites is abolished in DOCK11-knockout cells. These results suggest that DOCK11 is essential for the recruitment of PARP1 to DNA damage sites. **Conclusion:** This study demonstrates that DOCK11 plays a crucial role in HBV cccDNA formation by forming a complex with HBV DNA and PARP1. These findings indicate that DOCK11 may serve as promising therapeutic target for preventing HBV cccDNA formation.

1170 | DURABILITY AND OUTCOMES OF HBSAG LOSS IN CHRONIC HEPATITIS B PATIENTS TREATED BY NUCLEOS(T)IDE ANALOGUE

Minghui Li[1] Si Xie[2] Weihua Cao[1] Xinxin Li[1] Ziyu Zhang[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University

Background: Hepatitis B surface antigen (HBsAg) seroclearance, is associated with improved outcomes for chronic hepatitis B (CHB) patients. Only few patients can achieve HBsAg loss through nucleos(t)ide analogue (NA) therapy, and little is known about it. So our study investigated the durability and outcomes of HBsAg loss achieved by NA therapy, and the predictive factors of HBsAg reversion in CHB patients. **Methods:** CHB patients who achieved confirmed HBsAg loss after NA therapy were retrospectively enrolled and followed up every 3-6 months. The sustained HBsAg loss rate was evaluated. The rate and the predictive factors of HBsAg reversion, the rate of hepatitis B virus (HBV) desoxyribose nucleic acid (DNA) relapse, and the incidence of hepatitis recurrence, decompensated cirrhosis, hepatocellular carcinoma (HCC) were also investigated. **Results:** Of the 172 patients included, sustained HBsAg seroclearance was found in 96.51% patients after 105.65 (54.22, 181.65) weeks post-treatment follow-up. Six patients occurred HBsAg reversion. Only one patient developed HBV DNA relapse following HBsAg seroreversion, which was accompanied by hepatitis recurrence. One patient experienced liver decompensation and another patient developed HCC. Hepatitis B surface antibody (anti-HBs) and consolidation treatment were not associated with HBsAg seroreversion. We did not find any predictive factors of HBsAg seroreversion in this study. **Conclusion:** The HBsAg loss induced by NA is stable in most of patients after discontinuation of treatment. Anti-HBs seroconversion is not a prerequisite for discontinuation of NA. Patients with CHB exhibit improved clinical outcomes after HBsAg seroclearance.

1171 | LG2M AND AFP, WHEN COMBINED WITH PAGE-B, EFFECTIVELY RISK-STRATIFY CHB PATIENTS FOR EARLY AND LATE STAGE HCC REGARDLESS OF SLD STATUS

Michael Stec[1] Mark Anderson[1] Ming-Lung Yu[2] Chung-Feng Huang[2] Gavin Cloherty[1], [1]Abbott Laboratories, [2]Kaohsiung Medical University/ Kaohsiung Medical University Hospital

Background: Hepatocellular Carcinoma (HCC) causes both EpCAM and CD90 expressing cancer stem cells (CSCs) to form, and evidence of these CSCs can be found through the serological presence of AFP and LG2m, respectively. We highlight a risk-stratification method, PAGE-CSC, which combines PAGE-B with both LG2m and AFP immunoassays to effectively identify chronic hepatitis B (CHB) patients at risk for developing HCC within 5 years, regardless of Steatotic Liver Disease (SLD) comorbidities or HCC stage at time of diagnosis. **Methods:** AFP and research use only (RUO) LG2m immunoassays were run on the Alinity i platform (Abbott Laboratories) to analyze baseline (BL) serum collected from 1,016 CHB patients, 332 of which had SLD comorbidities. Patients were put on first-line NUC therapy and regularly monitored for over 10 years. GraphPad Prism 9 was then used to run Kaplan-Meier analyses from BL data to determine the effectiveness of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

various HCC risk-stratification methods within the cohorts. **Results:** Kaplan-Meier analyses were run on BL PAGE-B for the SLD$^+$ and SLD$^-$ cohorts to identify those who would develop HCC within 5 years, both showed significance ($p < 0.0001$, and $p = 0.0003$, respectively). Additional Kaplan-Meier Analyses were run combining PAGE-B with a 10 ng/mL AFP cutoff, PAGE-B with a novel 50 pg/mL LG2m cutoff, and PAGE-B with both LG2m and AFP cutoffs between the cohorts, all of which showed significance ($p < 0.0001$, $p = 0.0007$, and $p = 0.0003$, respectively, for the SLD$^-$ cohort and $p = 0.0037$, $p = 0.0094$, and $p = 0.0092$ respectively for the SLD$^+$ cohort). While PAGE-B was effective in identifying 68.2% of patients in the SLD- cohort and 66.7% of patients in the SLD$^+$ cohort that developed HCC within 5 years, the risk-stratification model incorporating PAGE-B, AFP, and LG2m (PAGE-CSC) had the greatest sensitivity with 95% identification in the SLD$^-$ cohort and 91.7% identification in the SLD$^+$ cohort. Unsurprisingly when this same assessment was run on the combined cohort, this combined model of PAGE-CSC had the greatest sensitivity at 94.6% with a p-value of < 0.0001. By the Barcelona Clinic Liver Cancer (BCLC) staging system PAGE-CSC also improved upon PAGE-B by 17.6%, 25.0%, 50.0%, and 44.1% for stages 0, A, B, and C, respectively. **Conclusion:** The PAGE-CSC risk stratification system that combines the PAGE-B model with indicators of both EpCAM and CD90 expressing CSCs, through serological AFP and LG2m, respectively, better accounts for the heterogeneous nature of HCC than current proposed methods. This was proven in the SLD$^+$ cohort, the SLD$^-$ cohort, and the combined SLD$^{+/-}$ cohort and regardless of the HCC stage at time of diagnosis.

1172 | ESTIMATING THE ECONOMIC BURDEN OF CHRONIC HEPATITIS B IN FRANCE USING THE FRENCH NATIONAL HEALTH DATA SYSTEM

Samuel Nilusmas[1] Clotilde Lepers[2] Paul Burgat[1] Jonathan Bellet[1] Clovis Lusivika Nzinga[1] Sylvie Deuffic-Burban[3] Fabrice Carrat[4], [1]Sorbonne Université, Inserm, iPLesp, Paris, France, [2]Université Paris Cité, Inserm, IAME, Hôpital Bichat, AP-HP Nord, Paris, France, [3]Université Paris Cité and Université Sorbonne Paris Nord, Inserm, IAME, Paris, France, [4]Sorbonne Université, Inserm, iPLesp, Hôpital Saint-Antoine, AP-HP, Paris, France

Background: Chronic hepatitis B (CHB) causes a wide spectrum of liver disease, from early-stage forms to life-threatening conditions such as decompensated cirrhosis (DC) and hepatocellular carcinoma (HCC). Disease progression places a substantial burden on healthcare systems. We conducted a national observational study to estimate monthly healthcare costs by health state (pre-cirrhosis, cirrhosis, DC, HCC, liver transplantation [LT], death) using the French National Health Data System (SNDS). **Methods:** The SNDS covers over 99% of the French population. It includes information on reimbursed outpatient care, hospital discharge diagnoses, interventions, and death. We identified all individuals with CHB residing in France between 01/01/2012, and 31/12/2022. Health states were defined using ICD-10 codes. For each health state, and separately for nucleosit(d)ic analogues (NA) treated and untreated pre-cirrhotic patients, monthly costs per patient were estimated using descriptive statistics. Additional costs for LT and death were assessed separately. Disease state classification was clinically validated in a subset of ANRS CO22 HEPATHER patients individually linked to SNDS to assess the robustness of cost estimates. **Results:** A total of 114,662 patients with CHB were identified in the SNDS. Of these, 102,756 were in a pre-cirrhotic state, 10,273 in cirrhosis, 416 in DC, 372 in HCC, and 1,972 underwent LT. In the HEPATHER-linked cohort (n = 4,627), 3,985 were in a pre-cirrhotic state, 363 in cirrhosis, 203 in DC, 186 in HCC, and 122 underwent LT. In the SNDS, median monthly costs increased with disease severity: €107 for untreated pre-cirrhosis (Q1-Q3: 44-373), €314 (132–686) for treated pre-cirrhosis (€144 (55-764) excluding NA cost), €954 (403–2,111) for cirrhosis, €1,254 (480–2,898) for DC, €1,233 (558–2,561) for HCC and €1,520 (1,045–2,304) post-LT. Additional cost for LT was €55,538 (31,555–72,823) and those for death ranged from €4,713 (221-12,955) to €11,356 (289-19,762). In the HEPATHER-linked SNDS subset, costs were slightly lower but remained within similar ranges, supporting the consistency of the estimates across sources. **Conclusion:** This study provides robust

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

stage-specific cost estimates for CHB using national administrative data. The consistency observed in the HEPATHER-linked subset supports the reliability of disease state identification and associated cost estimations in the SNDS. These estimates can inform cost-effectiveness analyses and lifetime projections using Markov models.

1173 | THE RELATIONSHIP BETWEEN THE DURABILITY OF RESPONSE TO INTERFERON THERAPY FOR HEPATITIS B VIRUS INFECTION AND THE PROPORTION/FUNCTION OF HLA-DR+CD38+CD8+ T LYMPHOCYTES

Minghui Li[1] Yao Xie[1] Yanjie Lin[2] weihua cao[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]Peking University First Hospital

Background: Interferon (IFN) exerts dual roles in anti-hepatitis B virus (HBV) therapy, including direct antiviral effects and immune modulation. Some patients exhibit an early hepatitis B surface antigen (HBsAg) response during the initial phase of IFN therapy, but HBsAg decline stagnates in later stages, and antiviral efficacy diminishes even with continued IFN treatment. The immunological mechanisms underlying this phenomenon remain unclear. Activated CD8+ T lymphocytes play a pivotal role in viral clearance, and the co-expression of CD38 and HLA-DR serves as a key marker of T cell activation. Therefore, we aimed to investigate the phenotypic and functional changes of HLA-DR+CD38+CD8+ T lymphocytes in chronic hepatitis B (CHB) patients receiving IFN therapy and their association with sustained IFN treatment response. **Methods:** CHB patients were divided into three groups: treatment-naive, nucleos(t)ide analog (NAs)-experienced, and IFN-experienced plateau groups. After baseline assessments, treatment-naive and some NAs-experienced patients received Peg-IFNα therapy. Patients in the IFN-experienced plateau group (showing stagnant HBsAg decline) discontinued IFN and resumed it after a treatment-free interval. Peripheral blood samples were collected at specified timepoints to assess clinical indicators and analyze HLA-DR+CD38+CD8+ T cell phenotypes/function via flow cytometry. **Results:** A total of 151 patients were enrolled: 53 treatment-naive, 51 NAs-experienced, and 47 IFN-experienced plateau patients. HLA-DR+CD38+CD8+ T cells were further stratified into HLA-DR+CD38dim and HLA-DR+CD38hi subsets. During IFN therapy, both treatment-naive and NAs-experienced groups showed an initial surge in HLA-DR+CD38dim subsets (all $P < 0.0001$), followed by a significant decline (all $P < 0.0001$), while HLA-DR+CD38hi subsets increased markedly (all $P < 0.0001$) (Figure 1A-B). In IFN-experienced plateau patients, after 12–24 weeks of discontinuation, HLA-DR+CD38dim subsets rebounded ($P < 0.0001$), whereas HLA-DR+CD38hi subsets decreased ($P < 0.0001$). Upon IFN retreatment for 12–24 weeks, HLA-DR+CD38dim subsets declined again ($P < 0.0001$), while HLA-DR+CD38hi subsets increased ($P < 0.001$), accompanied by significant HBsAg reduction compared to baseline ($P < 0.05$). Notably, only HLA-DR+CD38hi subsets showed sustained reduction post-retreatment ($P < 0.05$) (Figure 1C). Compared to HLA-DR+CD38dim subsets, HLA-DR+CD38hi cells exhibited lower co-stimulatory molecule expression and impaired cytotoxic effector function (Figure 2). **Conclusion:** During IFN therapy, the transition of HLA-DR+CD38dim (activated) to HLA-DR+CD38hi (cytotoxic-impaired) subsets in CD8+ T cells may explain the loss of sustained antiviral efficacy. Intermittent IFN therapy reverses this trend, overcoming the IFN plateau phase and restoring antiviral activity.

mitochondrial homeostasis. However, their relationship and underlying mechanisms remain elusive. Since lactate, a key glycolytic metabolite that can modulate immune response, we investigated its role in HBV-specific T cell dysfunction during chronic HBV infection. **Methods:** We recruited 242 patients with chronic HBV infection and 78 health controls. The metabolic characteristics of peripheral blood mononuclear cells (PBMC) were comprehensively analyzed using RNA-seq, metabonomics and scRNA-seq. Additionally, we systematically evaluated the glucose uptake, mitochondrial function, autophagy flux, and mitophagy activity of HBV-specific $CD8^+$ T cells using flow cytometry from both PBMC and liver mononuclear cells (LMC). To investigate lactate-mediated T cell exhaustion, we performed exogenous stimulations with Bay-876, lactate, Oligomycin, and Midivi-1, and assessed through multiparametric cytokine profiling and functional assays. **Results:** The glucose metabolic status in PBMC was significantly activated during HBV infection, accompanied by the accumulation of lactate. Specifically, HBV-specific $CD8^+$ T cells exhibited more dramatically increased Glut1 expression and 2-NBDG uptake than global T cells, especially in intrahepatic HBV-specific $CD8^+$ T cells. Restraining glucose uptake *via* Bay-876 improved HBV-specific T cell function, while lactate accelerated their dysfunction. Mechanistically, lactate elicited aberrant mtROS production and mitochondrial membrane potential *via* suppressing mitophagy dysfunction. Meanwhile, reversing mitochondrial dysfunction by MitoQ and MitoTempo restored the HBV-specific T cells function. However, aggravating mitophagy impairment by Midivi-1blunted the production of IFN-γ and TNF-α in HBV-specific T cell. Concurrently, dysfunctional autophagy also significantly contributed to HBV-specific T cells dysfunction, but this effect was independent of the lactate-mediated exhaustion pathway. **Conclusion:** Lactate drives HBV-specific T cell exhaustion by disrupting mitochondrial function *via* restraining mitophagy. These results highlight lactate metabolism as a potential therapeutic target for chronic HBV infection.

1175 | ELEVATED HBCRAG LEVELS ARE ASSOCIATED WITH YOUNG-ONSET HEPATOCELLULAR CARCINOMA IN HBV INFECTION

YOSHIAKI KOBAYASHI[1] Taiki Okumura[1], [1]Shinshu University School of Medicine

Background: Young-onset hepatocellular carcinoma (HCC) in patients with hepatitis B virus (HBV) infection poses a significant clinical challenge. Hepatitis B core-related antigen (HBcrAg) can reflect intrahepatic covalently closed circular DNA activity in HBV patients; however, its significance in young-onset HCC remains underexplored. The present study examined the age-dependent distribution patterns of HBcrAg and other disease markers along with their association with young-onset HCC. **Methods:** This retrospective cross-sectional investigation analyzed two cohorts from Shinshu University Hospital. Cohort 1 included 101 elderly ($\geq$65 years) HBV-infected patients without a history of HCC recruited between April 2018 and February 2022. Cohort 2 comprised 43 patients with newly diagnosed HBV-related HCC who were seen between May 2005 and June 2023 and categorized as either young-onset ($<$65 years) or elderly-onset ($\geq$65 years). HBcrAg was measured using an ultrasensitive immunoassay (iTACT technology, Fujirebio Inc., Tokyo, Japan). **Results:** In Cohort 1, 13.9% (14/101) of cases were HBcrAg positive using conventional sensitivity testing (3.0 log U/mL), suggesting an association between lower HBcrAg and decreased young-onset HCC risk. In Cohort 2, young-onset HCC patients had significantly higher alanine aminotransferase (median 39 vs. 21 U/L, $p=0.006$), HBV DNA (3.3 vs. 1.8 log IU/mL, $p=0.031$), and iTACT-HBcrAg (4.9 vs. 2.5 log U/mL, $p<0.001$) levels compared with elderly-onset patients. Hepatitis B e antigen positivity was also significantly more frequent in the young-onset group (29.4% vs. 7.7%, $p=0.049$). Multivariable analysis revealed iTACT-HBcrAg level as significantly associated with young-onset HCC (odds ratio 1.78; 95% confidence interval 1.20–2.63; $p=0.004$). Moreover, HBcrAg demonstrated superior predictive performance (area under the receiver operating characteristic curve [AUROC] 0.80) versus both hepatitis B surface antigen (AUROC 0.67) and fibrosis-4 index (AUROC 0.50) for young-onset HCC, with a calculated optimal cut-off value of 3.0 log U/mL. At this threshold, young-onset HCC patients had a significantly higher HBcrAg positivity rate compared with elderly-onset patients (88.2% vs. 34.6%, $p<0.001$).

1176 | CHARACTERISTICS AND HEALTHCARE RESOURCE UTILIZATION FOR PATIENTS EXPERIENCING HEPATITIS B SURFACE ANTIGEN LOSS AND LIVING WITH CHRONIC HEPATITIS B VIRUS IN THE UNITED STATES

Myriam Drysdale[1] Rose Chang[2] Megan Pinaire[2] Manasi Mohan[2] Rui Song[2] Shuang Wang[2] Theo Man[2] Anna Coutinho[3] Mei Sheng Duh[2] Dickens Theodore[4] Iain Gillespie[5], [1]GSK, London, UK, [2]Analysis Group, Inc., Boston, MA, USA, [3]GSK, Collegeville, PA, USA, [4]GSK, Durham, NC, USA, [5]GSK, Stevenage, UK

Background: Chronic hepatitis B virus (cHBV) infection represents a critical public health issue worldwide and in the United States (US). The loss of hepatitis B surface antigen (HBsAg) is regarded as an indicator of functional cure in cHBV infection; however, its influence on healthcare resource utilization (HCRU) within the US population is not well understood. **Methods:** A retrospective cohort study was conducted using data from the Optum® electronic health records database for patients with cHBV infection between 1 Jan 2012 and 31 Dec 2019. Exposure was HBsAg loss, defined as ≥2 consecutive negative HBsAg tests ≥6 months apart, with the second marking date of loss. Time to seroreversion up to 5 years was also evaluated using Kaplan-Meier analysis. HCRU outcomes such as hospital admissions, emergency room (ER) visits, outpatient visits, and anti-HBV prescriptions were evaluated among patients with HBsAg loss and reported as rates per person-year (PPY) in the 12 months prior to HBsAg loss and 6, 12, 24, and 60 months post-HBsAg loss. **Results:** A total of 24,694 patients were included (~11% on stable nucleos(t)ide analogue [NA] treatment), among whom 776 (3%) experienced HBsAg loss. Nine patients (1%) seroreverted within 5 years of follow-up; median time to seroreversion was not reached. Hospital admissions, days in hospital and NA prescriptions were numerically lower in the 12 months after than in the 12 months before HBsAg loss (0.4 vs 0.6 PPY; 3.1 vs 5.7 PPY; 1.3 vs 2.6 PPY, respectively). Rate of ER visits was 0.7 PPY in the 12 months before HBsAg loss, 0.6 PPY in the 12 months after loss, and 0.4 PPY in the 60 months after loss. Rate of outpatient visits was 20.4 PPY in the 12 months before HBsAg loss, 18.9 in the 12 months after loss and 17.0 in the 60 months after loss. **Conclusion:** Rates of all-cause HCRU and NA prescriptions were numerically lower after HBsAg loss than before HBsAg loss. HBsAg loss, although rare, was found to be durable, with a very small proportion of patients experiencing seroreversion within 5 years. Funding: GSK Study 217281.

Figure: All-cause and cHBV-related HCRU rates PPY in the year prior to HBsAg loss, and the 6 months, 12 months, 2 years, and 5 years after HBsAg loss

1177 | CONSTRUCTION OF A COMBINED PREDICTIVE MODEL FOR LIVER FIBROSIS STAGING IN CHRONIC HEPATITIS B PATIENTS BASED ON CAPSID-ANTIBODY-COMPLEXES

Jin Li[1] Li Zhu[2] Tingting Li[2], [1]The Affiliated Infectious Diseases Hospital of Soochow Unive, [2]The Affiliated Infectious Diseases Hospital of Soochow University

Background: Hepatitis B virus infection represents a significant public health challenge globally, as it can lead to the progressive development of liver fibrosis. There exists a significant lack of effective noninvasive predictive models for liver fibrosis staging assessment in chronic hepatitis B (CHB) patients. Our previous studies identified that circulating CACs display significant positive correlation with liver fibrosis staging. This paper aims to establish a combined predictive model for liver fibrosis staging of chronic hepatitis B patients based on circulating capsid-antibody-complexes (CACs) and to facilitate clinical implementation. **Methods:** A total of 161 treatment-native CHB patients who underwent liver biopsy were enrolled and divided into two groups: 64 individuals with no or mild fibrosis (S < 2) and 97 individuals with advanced fibrosis (S ≥ 2). The expression levels of circulating CACs were determined by enzyme-linked immunosorbent assay (ELISA) techniques. Univariate and multivariate logistic regression analysis was used to screen the key factors for liver fibrosis staging of CHB patients. Receiver operating characteristic curve (ROC) was used to evaluate the diagnostic efficiency of the combined prediction model. **Results:** The expression levels of CACs ($P = 6.19E-11$), M30 ($P = 1.60E-13$), M65 ($P = 6.79E-11$), ALT ($P = 2.20E-5$), AST ($P = 6.16E-8$), GGT ($P = 0.0009$), ALB ($P = 0.0120$), PLT ($P = 9.62E-7$), APRI ($P = 1.54E-11$) and FIB-4 ($P = 6.19E-8$) scores displayed statistically differences between the S < 2 group and the S ≥ 2 group. Importantly, circulating CACs exhibited the most significant positive correlation with liver fibrosis staging (r = 0.5253, $P = 3.3E-3$). Through univariate and multivariate logistic regression analysis, circulating CACs, M30 and PLT were identified as independent key factors for liver fibrosis staging of CHB patients. Furthermore, a combined prediction model was constructed as follows: logistic(p) = -1.976 + 3.701*CACs + 0.036*M30 - 0.014*PLT, with an area under the ROC curve (AUC) of 0.923, a sensitivity of 93.8% and a specificity of 81.2%. The performance of our combined model was superior to APRI (AUC = 0.814) and FIB-4 score (AUC = 0.752), and the differences were statistically significant between the ROC curves (P < 0.05). **Conclusion:** In our study,it was identified that circulating CACs, M30, and PLT serve as independent predictors for liver fibrosis staging of CHB patients. Based on these key biomarkers, a promising combined model for liver fibrosis staging was constructed and evaluated. This combined model based on circulaing CACs demonstrated high predictive diagnostic efficiency for liver fibrosis staging. It may contribute to achieving more accurate liver fibrosis staging assessment in clinical, thereby facilitating precise treatment and functional cure for CHB patients.

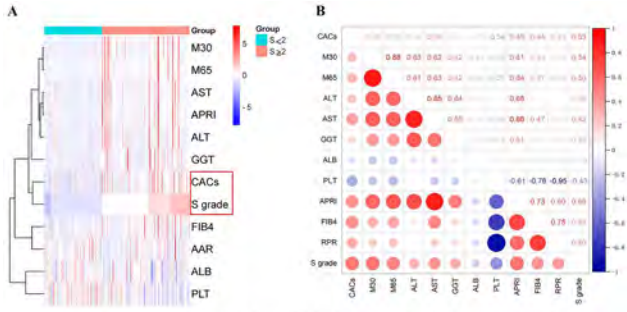

Figure 1. Cluster and correlation analysis revealed that the CACs level positively correlated with S grade.

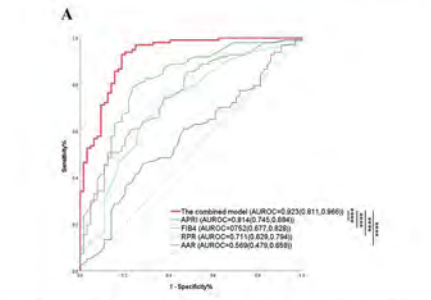

Figure 2. The area under the ROC curve of the combined model (Logit(p) = -1.908 + 3.647*CACs + 0.035*M30 - 0.014*PLT) was 0.923.

1178 | A PHASE 1 STUDY OF THE SIRNA HRS-5635 IN HEALTHY SUBJECTS AND PATIENTS WITH CHRONIC HEPATITIS B

Zhaoyi Yang[1] Yongyi Zeng[2] Xian Yu[3] Shuang Li[4] Guang-Ming Li[4] Xuebing Yan[5] Xuejia Zhai[6] Lingling Xu[7] Ying Wang[7] Huilan Zhu[7] Aizong Shen[1], [1]The First Affiliated Hospital of University of Science and Technology of China, [2]Mengchao Hepatobiliary Hospital of Fujian Medical University, [3]The Second Affiliated Hospital of Chongqing Medical University, [4]Zhengzhou Sixth People's Hospital, [5]The Affiliated Hospital of Xuzhou Medical University, [6]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, [7]Jiangsu Hengrui Pharmaceuticals

Background: HRS-5635 is a novel N-acetyl-D-galactosamine–conjugated siRNA that targets the HBV X gene, suppressing the expression of viral proteins, and thereby exerting antiviral effects. This first-in-human study aimed to assess the safety, tolerability, pharmacokinetics, and pharmacodynamics of HRS-5635 in healthy volunteers and patients with chronic hepatitis B (CHB). **Methods:** This was a multicenter, randomized, double-blind, placebo-controlled phase 1 study (ClinicalTrials.gov: NCT05808374). In the single ascending dose (SAD) part, healthy volunteers received subcutaneous HRS-5635 at 50, 100, 200, 400, and 600 mg (n = 3 for 50 mg; n = 6 each for other dose levels) or placebo (n = 10). In the multiple ascending dose (MAD) part, nucleoside analog-treated CHB patients were given 3 subcutaneous HRS-5635 at 100 mg, 200 mg, or 400 mg every 4 weeks (n = 6 per dose level) or placebo (n = 6). **Results:** HRS-5635 was safe and well tolerated in healthy and CHB participants. In the MAD, the most common treatment-emergent adverse events (TEAEs) occurring more frequently with HRS-5635 than placebo were upper respiratory tract infection, increased blood creatine phosphokinase (CK), hypercalcemia, and increased blood CK MB. No TEAEs led to treatment discontinuation. No serious TEAEs or TEAEs leading to death occurred. After single dose of HRS-5635, absorption was rapid, with a median T_{max} of 3.00 to 6.00 h; the geometric mean $t_{1/2}$ was 3.97 to 5.12 h; HRS-5635 was essentially cleared from plasma within 48 h post-dose; and its exposure increased in an approximately dose-proportional manner from 50 to 200 mg, but increased more than dose proportionally at 200 to 600 mg. No obvious differences in plasma exposure were found between healthy and CHB participants. HRS-5635 showed no apparent accumulation upon 3 doses administered every 4 weeks. The maximum reduction in hepatitis B surface antigen (HBsAg) from baseline was 1.615 to 1.886 $\log_{10}$ IU/mL after 3 doses of HRS-5635 administered every 4 weeks, compared with 0.009 $\log_{10}$ IU/mL with placebo. **Conclusion:** HRS-5635 at the tested doses were tolerated, showed favorable safety and pharmacokinetic profiles, and demonstrated preliminary evidence of antiviral activity through HBsAg reduction, supporting further clinical development of HRS-5635 for treating CHB.

1179 | HEPATIC STEATOSIS INHIBITS HEPATITIS B VIRUS REPLICATION BY PROMOTING MIR-122-5P-SOX4

Guanghui Ren[1] Sitong Yi[1] Shi Yin[1] Guiqun Huang[1] Ying Zhu[1], [1]Department of Infectious Disease, The First Affiliated Hospital of Dalian Medical University, Dalian, China

Background: Chronic hepatitis B (CHB) and metabolic dysfunction-associated fatty liver disease (MAFLD) are prevalent chronic liver diseases. The rising incidence of CHB-MAFLD comorbidity necessitates exploration of their interplay. MiR-122, a liver-specific miRNA, modulates chronic liver diseases, but its role in CHB-MAFLD remains unclear. **Methods:** Serum miR-122 levels in CHB patients with or without MAFLD were assessed via qPCR. Bioinformatics identified miR-122-5p targets linked to comorbidity. An HBV-infected steatotic cell model was used to evaluate miR-122-5p's effects on viral replication and targets. Gene knockdown/overexpression and molecular assays (qPCR, Western blot, ELISA) elucidated the roles of miR-122/SOX4 in HBV regulation. **Results:** A total of 360 patients with CHB were included, of which 66.1% received antiviral therapy. The antiviral regimens included nucleoside analogue (NAs) monotherapy as well as polyethylene glycol interferon α-2b in combination/sequence with NAs. Interferon therapy accounted for 27.8% of the cases and NAs accounted for 72.2% of the cases. CHB-MAFLD patients showed reduced HBV DNA, pgRNA, HBsAg (all $P < 0.05$), and elevated miR-122 versus CHB-only on baseline. The downstream target gene of miR-122-5p was SOX4. The comorbidity model exhibited suppressed HBV replication markers (DNA, pgRNA, HBsAg, HBcrAg) and upregulated miR-122-5p/SOX4. MiR-122-5p knockdown increased HBV replication, while overexpression suppressed it. Similarly, SOX4 knockdown enhanced HBV activity, whereas SOX4 overexpression inhibited it.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: CHB-MAFLD comorbidity may suppress HBV replication via miR-122/SOX4 upregulation, suggesting a novel regulatory axis. This highlights miR-122 as a potential therapeutic target in dual-pathology management.
